| | | |
|----------|---|-----------|
| 1 | Introduction | 3 |
| 1.1 | Notes on availability | 4 |
| 2 | Ενσωματωμένες (Built-in) Συναρτήσεις | 5 |
| 3 | Built-in Constants | 31 |
| 3.1 | Constants added by the <code>site</code> module | 32 |
| 4 | Τύποι Built-in | 33 |
| 4.1 | Έλεγχος Έγκυρης Τιμής | 33 |
| 4.2 | Λογικές (Boolean) Πράξεις — <code>and</code> , <code>or</code> , <code>not</code> | 34 |
| 4.3 | Συγκρίσεις | 34 |
| 4.4 | Αριθμητικοί Τύποι — <code>int</code> , <code>float</code> , <code>complex</code> | 35 |
| 4.4.1 | Bitwise Πράξεις σε Ακέραιους Τύπους | 37 |
| 4.4.2 | Περαιτέρω Μέθοδοι των Ακέραιων Τύπων | 38 |
| 4.4.3 | Περαιτέρω Μέθοδοι για <code>Float</code> | 39 |
| 4.4.4 | Κατακερματισμός των αριθμητικών τύπων | 40 |
| 4.5 | Τύποι <code>Iterator</code> | 42 |
| 4.5.1 | Τύποι <code>Generator</code> | 42 |
| 4.6 | Τύποι Ακολουθίας (Sequence) — <code>list</code> , <code>tuple</code> , <code>range</code> | 43 |
| 4.6.1 | Κοινές Λειτουργίες Ακολουθιών (Sequences) | 43 |
| 4.6.2 | Τύποι Αμετάβλητων Ακολουθιών (Sequences) | 45 |
| 4.6.3 | Τύποι Μεταβλητών Ακολουθιών (Sequences) | 45 |
| 4.6.4 | Λίστες | 46 |
| 4.6.5 | Πλειάδες (Tuples) | 47 |
| 4.6.6 | Εύρη (Ranges) | 48 |
| 4.7 | Τύπος Ακολουθίας (Sequence) Κειμένου — <code>str</code> | 49 |
| 4.7.1 | Μέθοδοι Συμβολοσειράς (String) | 50 |
| 4.7.2 | <code>printf</code> -style String Formatting | 60 |
| 4.8 | Τύποι δυαδικής ακολουθίας — <code>bytes</code> , <code>bytearray</code> , <code>memoryview</code> | 62 |
| 4.8.1 | Αντικείμενα <code>Bytes</code> | 62 |
| 4.8.2 | Αντικείμενα <code>Bytearray</code> | 64 |
| 4.8.3 | Λειτουργίες <code>Bytes</code> και <code>Bytearray</code> | 65 |
| 4.8.4 | Μορφοποίηση <code>Bytes</code> τύπου <code>printf</code> | 76 |
| 4.8.5 | Όψεις Μνήμης | 78 |
| 4.9 | Τύποι Συνόλου (Set) — <code>set</code> , <code>frozenset</code> | 86 |
| 4.10 | Τύποι αντιστοίχισης — <code>dict</code> | 88 |

| | | |
|----------|--|------------|
| 4.10.1 | Αντικείμενα όψης λεξικού | 92 |
| 4.11 | Τύποι Διαχείρισης Περιεχομένου | 93 |
| 4.12 | Τύπος <code>Generic Alias</code> | 94 |
| 4.12.1 | Τυπικές Γενικές Κλάσεις | 96 |
| 4.12.2 | Ειδικά Χαρακτηριστικά αντικειμένων <code>GenericAlias</code> | 98 |
| 4.13 | Άλλοι Ενσωματωμένοι (built-in) Τύποι | 99 |
| 4.13.1 | <code>Modules</code> | 99 |
| 4.13.2 | Κλάσεις και Στιγμιότυπα Κλάσης | 99 |
| 4.13.3 | Συναρτήσεις | 99 |
| 4.13.4 | Μέθοδοι | 99 |
| 4.13.5 | Αντικείμενα Κώδικα | 100 |
| 4.13.6 | Τύποι Αντικειμένων | 100 |
| 4.13.7 | Το Αντικείμενο <code>Null</code> | 100 |
| 4.13.8 | Το αντικείμενο <code>Ellipsis</code> | 101 |
| 4.13.9 | Το <code>NotImplemented</code> Αντικείμενο | 101 |
| 4.13.10 | <code>Boolean Values</code> | 101 |
| 4.13.11 | Εσωτερικά Αντικείμενα | 101 |
| 4.14 | Ειδικά Χαρακτηριστικά | 101 |
| 4.15 | Περιορισμός μήκους μετατροπής συμβολοσειράς ακέραιου αριθμού | 102 |
| 4.15.1 | Επηρεασμένα APIs | 103 |
| 4.15.2 | Διαμόρφωση ορίου | 103 |
| 4.15.3 | Προτεινόμενη διαμόρφωση | 104 |
| 5 | Built-in Exceptions | 105 |
| 5.1 | Exception context | 105 |
| 5.2 | Inheriting from built-in exceptions | 106 |
| 5.3 | Base classes | 106 |
| 5.4 | Concrete exceptions | 107 |
| 5.4.1 | OS exceptions | 112 |
| 5.5 | Warnings | 113 |
| 5.6 | Exception hierarchy | 114 |
| 6 | Text Processing Services | 117 |
| 6.1 | <code>string</code> — Common string operations | 117 |
| 6.1.1 | String constants | 117 |
| 6.1.2 | Custom String Formatting | 118 |
| 6.1.3 | Format String Syntax | 119 |
| 6.1.4 | Template strings | 126 |
| 6.1.5 | Helper functions | 128 |
| 6.2 | <code>re</code> — Regular expression operations | 128 |
| 6.2.1 | Regular Expression Syntax | 128 |
| 6.2.2 | Module Contents | 133 |
| 6.2.3 | Regular Expression Objects | 138 |
| 6.2.4 | Match Objects | 140 |
| 6.2.5 | Regular Expression Examples | 142 |
| 6.3 | <code>difflib</code> — Helpers for computing deltas | 148 |
| 6.3.1 | SequenceMatcher Objects | 152 |
| 6.3.2 | SequenceMatcher Examples | 155 |
| 6.3.3 | Differ Objects | 156 |
| 6.3.4 | Differ Example | 156 |
| 6.3.5 | A command-line interface to <code>difflib</code> | 157 |
| 6.4 | <code>textwrap</code> — Text wrapping and filling | 159 |
| 6.5 | <code>unicodedata</code> — Unicode Database | 162 |
| 6.6 | <code>stringprep</code> — Internet String Preparation | 164 |

| | | |
|----------|--|------------|
| 6.7 | <code>readline</code> — GNU readline interface | 165 |
| 6.7.1 | Init file | 166 |
| 6.7.2 | Line buffer | 166 |
| 6.7.3 | History file | 166 |
| 6.7.4 | History list | 167 |
| 6.7.5 | Startup hooks | 168 |
| 6.7.6 | Completion | 168 |
| 6.7.7 | Example | 169 |
| 6.8 | <code>rlcompleter</code> — Completion function for GNU readline | 170 |
| 6.8.1 | Completer Objects | 170 |
| 7 | Binary Data Services | 171 |
| 7.1 | <code>struct</code> — Interpret bytes as packed binary data | 171 |
| 7.1.1 | Συναρτήσεις και εξαιρέσεις | 172 |
| 7.1.2 | Συμβολοσειρές μορφοποίησης | 172 |
| 7.1.3 | Κλάσεις | 176 |
| 7.2 | <code>codecs</code> — Codec registry and base classes | 177 |
| 7.2.1 | Codec Base Classes | 180 |
| 7.2.2 | Encodings and Unicode | 186 |
| 7.2.3 | Standard Encodings | 188 |
| 7.2.4 | Python Specific Encodings | 191 |
| 7.2.5 | <code>encodings.idna</code> — Internationalized Domain Names in Applications | 193 |
| 7.2.6 | <code>encodings.mbcs</code> — Windows ANSI codepage | 193 |
| 7.2.7 | <code>encodings.utf_8_sig</code> — UTF-8 codec with BOM signature | 194 |
| 8 | Data Types | 195 |
| 8.1 | <code>datetime</code> — Basic date and time types | 195 |
| 8.1.1 | Aware and Naive Objects | 196 |
| 8.1.2 | Constants | 196 |
| 8.1.3 | Available Types | 196 |
| 8.1.4 | <code>timedelta</code> Objects | 198 |
| 8.1.5 | <code>date</code> Objects | 201 |
| 8.1.6 | <code>datetime</code> Objects | 205 |
| 8.1.7 | <code>time</code> Objects | 216 |
| 8.1.8 | <code>tzinfo</code> Objects | 220 |
| 8.1.9 | <code>timezone</code> Objects | 226 |
| 8.1.10 | <code>strptime()</code> and <code>strftime()</code> Behavior | 227 |
| 8.2 | <code>zoneinfo</code> — IANA time zone support | 231 |
| 8.2.1 | Using <code>ZoneInfo</code> | 231 |
| 8.2.2 | Data sources | 232 |
| 8.2.3 | The <code>ZoneInfo</code> class | 233 |
| 8.2.4 | Functions | 235 |
| 8.2.5 | Globals | 236 |
| 8.2.6 | Exceptions and warnings | 236 |
| 8.3 | <code>calendar</code> — General calendar-related functions | 236 |
| 8.4 | <code>collections</code> — Container datatypes | 240 |
| 8.4.1 | <code>ChainMap</code> objects | 241 |
| 8.4.2 | <code>Counter</code> objects | 243 |
| 8.4.3 | <code>deque</code> objects | 246 |
| 8.4.4 | <code>defaultdict</code> objects | 250 |
| 8.4.5 | <code>namedtuple()</code> Factory Function for Tuples with Named Fields | 251 |
| 8.4.6 | <code>OrderedDict</code> objects | 255 |
| 8.4.7 | <code>UserDict</code> objects | 256 |
| 8.4.8 | <code>UserList</code> objects | 257 |

| | | |
|----------|---|------------|
| 8.4.9 | UserString objects | 257 |
| 8.5 | collections.abc — Abstract Base Classes for Containers | 258 |
| 8.5.1 | Αφηρημένες Βασικές Κλάσεις Συλλογών | 258 |
| 8.6 | heapq — Heap queue algorithm | 262 |
| 8.6.1 | Basic Examples | 264 |
| 8.6.2 | Priority Queue Implementation Notes | 264 |
| 8.6.3 | Theory | 265 |
| 8.7 | bisect — Array bisection algorithm | 266 |
| 8.7.1 | Searching Sorted Lists | 267 |
| 8.7.2 | Other Examples | 268 |
| 8.8 | array — Efficient arrays of numeric values | 268 |
| 8.9 | weakref — Weak references | 271 |
| 8.9.1 | Weak Reference Objects | 275 |
| 8.9.2 | Example | 276 |
| 8.9.3 | Finalizer Objects | 276 |
| 8.9.4 | Comparing finalizers with <code>__del__()</code> methods | 277 |
| 8.10 | types — Dynamic type creation and names for built-in types | 279 |
| 8.10.1 | Dynamic Type Creation | 279 |
| 8.10.2 | Standard Interpreter Types | 280 |
| 8.10.3 | Additional Utility Classes and Functions | 283 |
| 8.10.4 | Coroutine Utility Functions | 284 |
| 8.11 | copy — Shallow and deep copy operations | 284 |
| 8.12 | pprint — Data pretty printer | 285 |
| 8.12.1 | PrettyPrinter Objects | 287 |
| 8.12.2 | Example | 288 |
| 8.13 | reprlib — Alternate <code>repr()</code> implementation | 291 |
| 8.13.1 | Repr Objects | 291 |
| 8.13.2 | Subclassing Repr Objects | 292 |
| 8.14 | enum — Support for enumerations | 293 |
| 8.14.1 | Module Contents | 293 |
| 8.14.2 | Creating an Enum | 293 |
| 8.14.3 | Programmatic access to enumeration members and their attributes | 295 |
| 8.14.4 | Duplicating enum members and values | 295 |
| 8.14.5 | Ensuring unique enumeration values | 296 |
| 8.14.6 | Using automatic values | 296 |
| 8.14.7 | Iteration | 297 |
| 8.14.8 | Comparisons | 298 |
| 8.14.9 | Allowed members and attributes of enumerations | 298 |
| 8.14.10 | Restricted Enum subclassing | 299 |
| 8.14.11 | Pickling | 300 |
| 8.14.12 | Functional API | 300 |
| 8.14.13 | Derived Enumerations | 301 |
| 8.14.14 | When to use <code>__new__()</code> vs. <code>__init__()</code> | 305 |
| 8.14.15 | Interesting examples | 305 |
| 8.14.16 | How are Enums different? | 309 |
| 8.15 | graphlib — Functionality to operate with graph-like structures | 312 |
| 8.15.1 | Exceptions | 315 |
| 9 | Αριθμητικά και Μαθηματικά Modules | 317 |
| 9.1 | numbers — Numeric abstract base classes | 317 |
| 9.1.1 | The numeric tower | 317 |
| 9.1.2 | Notes for type implementors | 318 |
| 9.2 | math — Mathematical functions | 320 |
| 9.2.1 | Number-theoretic and representation functions | 321 |

| | | |
|-----------|--|------------|
| 9.2.2 | Power and logarithmic functions | 324 |
| 9.2.3 | Trigonometric functions | 325 |
| 9.2.4 | Angular conversion | 326 |
| 9.2.5 | Hyperbolic functions | 326 |
| 9.2.6 | Special functions | 326 |
| 9.2.7 | Constants | 327 |
| 9.3 | <code>cmath</code> — Mathematical functions for complex numbers | 328 |
| 9.3.1 | Conversions to and from polar coordinates | 328 |
| 9.3.2 | Power and logarithmic functions | 329 |
| 9.3.3 | Trigonometric functions | 329 |
| 9.3.4 | Hyperbolic functions | 329 |
| 9.3.5 | Classification functions | 330 |
| 9.3.6 | Constants | 330 |
| 9.4 | <code>decimal</code> — Decimal fixed point and floating point arithmetic | 331 |
| 9.4.1 | Quick-start Tutorial | 332 |
| 9.4.2 | Decimal objects | 336 |
| 9.4.3 | Context objects | 342 |
| 9.4.4 | Constants | 348 |
| 9.4.5 | Rounding modes | 349 |
| 9.4.6 | Signals | 350 |
| 9.4.7 | Floating Point Notes | 351 |
| 9.4.8 | Working with threads | 353 |
| 9.4.9 | Recipes | 353 |
| 9.4.10 | Decimal FAQ | 356 |
| 9.5 | <code>fractions</code> — Rational numbers | 359 |
| 9.6 | <code>random</code> — Generate pseudo-random numbers | 361 |
| 9.6.1 | Bookkeeping functions | 362 |
| 9.6.2 | Functions for bytes | 363 |
| 9.6.3 | Functions for integers | 363 |
| 9.6.4 | Functions for sequences | 363 |
| 9.6.5 | Real-valued distributions | 364 |
| 9.6.6 | Alternative Generator | 366 |
| 9.6.7 | Notes on Reproducibility | 366 |
| 9.6.8 | Examples | 366 |
| 9.6.9 | Recipes | 369 |
| 9.7 | <code>statistics</code> — Mathematical statistics functions | 369 |
| 9.7.1 | Averages and measures of central location | 370 |
| 9.7.2 | Measures of spread | 370 |
| 9.7.3 | Function details | 370 |
| 9.7.4 | Exceptions | 376 |
| 9.7.5 | <code>NormalDist</code> objects | 376 |
| 10 | Functional Programming Modules | 381 |
| 10.1 | <code>itertools</code> — Functions creating iterators for efficient looping | 381 |
| 10.1.1 | Itertool functions | 383 |
| 10.1.2 | Itertools Recipes | 392 |
| 10.2 | <code>functools</code> — Higher-order functions and operations on callable objects | 396 |
| 10.2.1 | <code>partial</code> Objects | 405 |
| 10.3 | <code>operator</code> — Standard operators as functions | 405 |
| 10.3.1 | Mapping Operators to Functions | 410 |
| 10.3.2 | In-place Operators | 411 |
| 11 | File and Directory Access | 413 |
| 11.1 | <code>pathlib</code> — Object-oriented filesystem paths | 413 |

| | | |
|-----------|---|------------|
| 11.1.1 | Basic use | 414 |
| 11.1.2 | Pure paths | 415 |
| 11.1.3 | Concrete paths | 423 |
| 11.1.4 | Correspondence to tools in the <code>os</code> module | 431 |
| 11.2 | <code>os.path</code> — Common pathname manipulations | 431 |
| 11.3 | <code>fileinput</code> — Iterate over lines from multiple input streams | 437 |
| 11.4 | <code>stat</code> — Interpreting <code>stat()</code> results | 439 |
| 11.5 | <code>filecmp</code> — File and Directory Comparisons | 445 |
| 11.5.1 | The <code>dircmp</code> class | 445 |
| 11.6 | <code>tempfile</code> — Generate temporary files and directories | 447 |
| 11.6.1 | Examples | 450 |
| 11.6.2 | Deprecated functions and variables | 451 |
| 11.7 | <code>glob</code> — Unix style pathname pattern expansion | 451 |
| 11.8 | <code>fnmatch</code> — Unix filename pattern matching | 453 |
| 11.9 | <code>linecache</code> — Random access to text lines | 454 |
| 11.10 | <code>shutil</code> — High-level file operations | 454 |
| 11.10.1 | Directory and files operations | 455 |
| 11.10.2 | Archiving operations | 460 |
| 11.10.3 | Querying the size of the output terminal | 464 |
| 12 | Data Persistence | 465 |
| 12.1 | <code>pickle</code> — Python object serialization | 465 |
| 12.1.1 | Relationship to other Python modules | 466 |
| 12.1.2 | Data stream format | 467 |
| 12.1.3 | Module Interface | 467 |
| 12.1.4 | What can be pickled and unpickled? | 471 |
| 12.1.5 | Pickling Class Instances | 472 |
| 12.1.6 | Custom Reduction for Types, Functions, and Other Objects | 477 |
| 12.1.7 | Out-of-band Buffers | 478 |
| 12.1.8 | Restricting Globals | 480 |
| 12.1.9 | Performance | 481 |
| 12.1.10 | Examples | 481 |
| 12.2 | <code>copyreg</code> — Register <code>pickle</code> support functions | 482 |
| 12.2.1 | Example | 482 |
| 12.3 | <code>shelve</code> — Python object persistence | 483 |
| 12.3.1 | Restrictions | 484 |
| 12.3.2 | Example | 484 |
| 12.4 | <code>marshal</code> — Internal Python object serialization | 485 |
| 12.5 | <code>dbm</code> — Interfaces to Unix «databases» | 487 |
| 12.5.1 | <code>dbm.gnu</code> — GNU's reinterpretation of <code>dbm</code> | 488 |
| 12.5.2 | <code>dbm.ndbm</code> — Interface based on <code>ndbm</code> | 489 |
| 12.5.3 | <code>dbm.dumb</code> — Portable DBM implementation | 490 |
| 12.6 | <code>sqlite3</code> — DB-API 2.0 interface for SQLite databases | 491 |
| 12.6.1 | Module functions and constants | 493 |
| 12.6.2 | Connection Objects | 496 |
| 12.6.3 | Cursor Objects | 502 |
| 12.6.4 | Row Objects | 505 |
| 12.6.5 | Exceptions | 506 |
| 12.6.6 | SQLite and Python types | 507 |
| 12.6.7 | Controlling Transactions | 511 |
| 12.6.8 | Using <code>sqlite3</code> efficiently | 512 |
| 13 | Συμπίεση Δεδομένων και Αρχειοθέτηση | 515 |
| 13.1 | <code>zlib</code> — Compression compatible with <code>gzip</code> | 515 |

| | | |
|-----------|---|------------|
| 13.2 | <code>gzip</code> — Support for gzip files | 519 |
| 13.2.1 | Παραδείγματα χρήσης | 521 |
| 13.2.2 | Διεπαφή Γραμμής Εντολών | 522 |
| 13.3 | <code>bz2</code> — Support for bzip2 compression | 522 |
| 13.3.1 | (De)compression of files | 522 |
| 13.3.2 | Incremental (de)compression | 524 |
| 13.3.3 | One-shot (de)compression | 525 |
| 13.3.4 | Examples of usage | 525 |
| 13.4 | <code>lzma</code> — Compression using the LZMA algorithm | 526 |
| 13.4.1 | Reading and writing compressed files | 526 |
| 13.4.2 | Compressing and decompressing data in memory | 528 |
| 13.4.3 | Miscellaneous | 530 |
| 13.4.4 | Specifying custom filter chains | 530 |
| 13.4.5 | Examples | 531 |
| 13.5 | <code>zipfile</code> — Work with ZIP archives | 532 |
| 13.5.1 | ZipFile Objects | 533 |
| 13.5.2 | Path Objects | 537 |
| 13.5.3 | PyZipFile Objects | 538 |
| 13.5.4 | ZipInfo Objects | 539 |
| 13.5.5 | Command-Line Interface | 540 |
| 13.5.6 | Decompression pitfalls | 541 |
| 13.6 | <code>tarfile</code> — Read and write tar archive files | 542 |
| 13.6.1 | TarFile Objects | 545 |
| 13.6.2 | TarInfo Objects | 549 |
| 13.6.3 | Extraction filters | 551 |
| 13.6.4 | Command-Line Interface | 554 |
| 13.6.5 | Examples | 555 |
| 13.6.6 | Supported tar formats | 557 |
| 13.6.7 | Unicode issues | 557 |
| 14 | File Formats | 559 |
| 14.1 | <code>csv</code> — CSV File Reading and Writing | 559 |
| 14.1.1 | Module Contents | 560 |
| 14.1.2 | Dialects and Formatting Parameters | 563 |
| 14.1.3 | Reader Objects | 564 |
| 14.1.4 | Writer Objects | 564 |
| 14.1.5 | Examples | 565 |
| 14.2 | <code>configparser</code> — Configuration file parser | 566 |
| 14.2.1 | Quick Start | 566 |
| 14.2.2 | Supported Datatypes | 568 |
| 14.2.3 | Fallback Values | 568 |
| 14.2.4 | Supported INI File Structure | 569 |
| 14.2.5 | Interpolation of values | 570 |
| 14.2.6 | Mapping Protocol Access | 571 |
| 14.2.7 | Customizing Parser Behaviour | 572 |
| 14.2.8 | Legacy API Examples | 577 |
| 14.2.9 | ConfigParser Objects | 578 |
| 14.2.10 | RawConfigParser Objects | 582 |
| 14.2.11 | Exceptions | 583 |
| 14.3 | <code>netrc</code> — netrc file processing | 583 |
| 14.3.1 | netrc Objects | 584 |
| 14.4 | <code>plistlib</code> — Generate and parse Apple .plist files | 584 |
| 14.4.1 | Examples | 586 |

| | | |
|-----------|--|------------|
| 15 | Cryptographic Services | 587 |
| 15.1 | hashlib — Secure hashes and message digests | 587 |
| 15.1.1 | Hash algorithms | 587 |
| 15.1.2 | SHAKE variable length digests | 589 |
| 15.1.3 | Key derivation | 590 |
| 15.1.4 | BLAKE2 | 591 |
| 15.2 | hmac — Keyed-Hashing for Message Authentication | 598 |
| 15.3 | secrets — Generate secure random numbers for managing secrets | 599 |
| 15.3.1 | Random numbers | 600 |
| 15.3.2 | Generating tokens | 600 |
| 15.3.3 | Other functions | 601 |
| 15.3.4 | Recipes and best practices | 601 |
| 16 | Γενικές Υπηρεσίες Λειτουργικού Συστήματος | 603 |
| 16.1 | os — Miscellaneous operating system interfaces | 603 |
| 16.1.1 | File Names, Command Line Arguments, and Environment Variables | 604 |
| 16.1.2 | Process Parameters | 604 |
| 16.1.3 | File Object Creation | 610 |
| 16.1.4 | File Descriptor Operations | 610 |
| 16.1.5 | Files and Directories | 620 |
| 16.1.6 | Process Management | 641 |
| 16.1.7 | Interface to the scheduler | 653 |
| 16.1.8 | Miscellaneous System Information | 654 |
| 16.1.9 | Random numbers | 656 |
| 16.2 | io — Core tools for working with streams | 657 |
| 16.2.1 | Overview | 657 |
| 16.2.2 | High-level Module Interface | 658 |
| 16.2.3 | Class hierarchy | 659 |
| 16.2.4 | Performance | 668 |
| 16.3 | time — Time access and conversions | 669 |
| 16.3.1 | Functions | 670 |
| 16.3.2 | Clock ID Constants | 677 |
| 16.3.3 | Timezone Constants | 679 |
| 16.4 | argparse — Parser for command-line options, arguments and sub-commands | 679 |
| 16.4.1 | Example | 680 |
| 16.4.2 | ArgumentParser objects | 681 |
| 16.4.3 | The add_argument() method | 690 |
| 16.4.4 | The parse_args() method | 701 |
| 16.4.5 | Other utilities | 704 |
| 16.4.6 | Upgrading optparse code | 712 |
| 16.5 | getopt — C-style parser for command line options | 713 |
| 16.6 | logging — Logging facility for Python | 715 |
| 16.6.1 | Logger Objects | 716 |
| 16.6.2 | Logging Levels | 719 |
| 16.6.3 | Handler Objects | 720 |
| 16.6.4 | Formatter Objects | 721 |
| 16.6.5 | Filter Objects | 722 |
| 16.6.6 | LogRecord Objects | 723 |
| 16.6.7 | LogRecord attributes | 724 |
| 16.6.8 | LoggerAdapter Objects | 725 |
| 16.6.9 | Thread Safety | 726 |
| 16.6.10 | Module-Level Functions | 726 |
| 16.6.11 | Module-Level Attributes | 730 |
| 16.6.12 | Integration with the warnings module | 731 |

| | | |
|-----------|--|------------|
| 16.7 | <code>logging.config</code> — Logging configuration | 731 |
| 16.7.1 | Configuration functions | 731 |
| 16.7.2 | Security considerations | 733 |
| 16.7.3 | Configuration dictionary schema | 734 |
| 16.7.4 | Configuration file format | 739 |
| 16.8 | <code>logging.handlers</code> — Logging handlers | 742 |
| 16.8.1 | <code>StreamHandler</code> | 742 |
| 16.8.2 | <code>FileHandler</code> | 743 |
| 16.8.3 | <code>NullHandler</code> | 743 |
| 16.8.4 | <code>WatchedFileHandler</code> | 744 |
| 16.8.5 | <code>BaseRotatingHandler</code> | 744 |
| 16.8.6 | <code>RotatingFileHandler</code> | 745 |
| 16.8.7 | <code>TimedRotatingFileHandler</code> | 746 |
| 16.8.8 | <code>SocketHandler</code> | 747 |
| 16.8.9 | <code>DatagramHandler</code> | 748 |
| 16.8.10 | <code>SysLogHandler</code> | 749 |
| 16.8.11 | <code>NTEventLogHandler</code> | 751 |
| 16.8.12 | <code>SMTPHandler</code> | 751 |
| 16.8.13 | <code>MemoryHandler</code> | 752 |
| 16.8.14 | <code>HTTPHandler</code> | 753 |
| 16.8.15 | <code>QueueHandler</code> | 753 |
| 16.8.16 | <code>QueueListener</code> | 754 |
| 16.9 | <code>getpass</code> — Portable password input | 755 |
| 16.10 | <code>curses</code> — Terminal handling for character-cell displays | 756 |
| 16.10.1 | Functions | 756 |
| 16.10.2 | Window Objects | 763 |
| 16.10.3 | Constants | 769 |
| 16.11 | <code>curses.textpad</code> — Text input widget for <code>curses</code> programs | 774 |
| 16.11.1 | Textbox objects | 774 |
| 16.12 | <code>curses.ascii</code> — Utilities for ASCII characters | 775 |
| 16.13 | <code>curses.panel</code> — A panel stack extension for <code>curses</code> | 778 |
| 16.13.1 | Functions | 778 |
| 16.13.2 | Panel Objects | 778 |
| 16.14 | <code>platform</code> — Access to underlying platform's identifying data | 779 |
| 16.14.1 | Cross Platform | 779 |
| 16.14.2 | Πλατφόρμα Java | 781 |
| 16.14.3 | Πλατφόρμα Windows | 781 |
| 16.14.4 | Πλατφόρμα macOS | 782 |
| 16.14.5 | Πλατφόρμες Unix | 782 |
| 16.15 | <code>errno</code> — Standard <code>errno</code> system symbols | 782 |
| 16.16 | <code>ctypes</code> — A foreign function library for Python | 788 |
| 16.16.1 | <code>ctypes</code> tutorial | 788 |
| 16.16.2 | <code>ctypes</code> reference | 806 |
| 17 | Concurrent Execution | 823 |
| 17.1 | <code>threading</code> — Thread-based parallelism | 823 |
| 17.1.1 | Thread-Local Data | 825 |
| 17.1.2 | Thread Objects | 826 |
| 17.1.3 | Lock Objects | 828 |
| 17.1.4 | <code>RLock</code> Objects | 829 |
| 17.1.5 | Condition Objects | 830 |
| 17.1.6 | Semaphore Objects | 832 |
| 17.1.7 | Event Objects | 833 |
| 17.1.8 | Timer Objects | 834 |

| | | |
|-----------|--|------------|
| 17.1.9 | Barrier Objects | 834 |
| 17.1.10 | Using locks, conditions, and semaphores in the <code>with</code> statement | 836 |
| 17.2 | <code>multiprocessing</code> — Process-based parallelism | 836 |
| 17.2.1 | Introduction | 836 |
| 17.2.2 | Reference | 843 |
| 17.2.3 | Programming guidelines | 871 |
| 17.2.4 | Examples | 875 |
| 17.3 | <code>multiprocessing.shared_memory</code> — Provides shared memory for direct access across processes | 881 |
| 17.4 | The <code>concurrent</code> package | 885 |
| 17.5 | <code>concurrent.futures</code> — Launching parallel tasks | 885 |
| 17.5.1 | Executor Objects | 886 |
| 17.5.2 | <code>ThreadPoolExecutor</code> | 887 |
| 17.5.3 | <code>ProcessPoolExecutor</code> | 888 |
| 17.5.4 | Future Objects | 890 |
| 17.5.5 | Module Functions | 891 |
| 17.5.6 | Exception classes | 892 |
| 17.6 | <code>subprocess</code> — Subprocess management | 892 |
| 17.6.1 | Using the <code>subprocess</code> Module | 893 |
| 17.6.2 | Security Considerations | 901 |
| 17.6.3 | Popen Objects | 901 |
| 17.6.4 | Windows Popen Helpers | 903 |
| 17.6.5 | Older high-level API | 905 |
| 17.6.6 | Replacing Older Functions with the <code>subprocess</code> Module | 907 |
| 17.6.7 | Legacy Shell Invocation Functions | 910 |
| 17.6.8 | Notes | 911 |
| 17.7 | <code>sched</code> — Event scheduler | 911 |
| 17.7.1 | Scheduler Objects | 912 |
| 17.8 | <code>queue</code> — A synchronized queue class | 913 |
| 17.8.1 | Queue Objects | 914 |
| 17.8.2 | <code>SimpleQueue</code> Objects | 915 |
| 17.9 | <code>contextvars</code> — Context Variables | 916 |
| 17.9.1 | Context Variables | 916 |
| 17.9.2 | Manual Context Management | 917 |
| 17.9.3 | <code>asyncio</code> support | 919 |
| 17.10 | <code>_thread</code> — Low-level threading API | 920 |
| 18 | Networking and Interprocess Communication | 923 |
| 18.1 | <code>asyncio</code> — Asynchronous I/O | 923 |
| 18.1.1 | Coroutines and Tasks | 924 |
| 18.1.2 | Streams | 938 |
| 18.1.3 | Synchronization Primitives | 945 |
| 18.1.4 | Subprocesses | 949 |
| 18.1.5 | Ουπέξ | 954 |
| 18.1.6 | Exceptions | 957 |
| 18.1.7 | Event Loop | 957 |
| 18.1.8 | Futures | 979 |
| 18.1.9 | Transports and Protocols | 982 |
| 18.1.10 | Policies | 997 |
| 18.1.11 | Platform Support | 1000 |
| 18.1.12 | High-level API Index | 1001 |
| 18.1.13 | Low-level API Index | 1004 |
| 18.1.14 | Developing with <code>asyncio</code> | 1010 |
| 18.2 | <code>socket</code> — Low-level networking interface | 1013 |
| 18.2.1 | Socket families | 1013 |

| | | |
|-----------|---|-------------|
| 18.2.2 | Module contents | 1016 |
| 18.2.3 | Socket Objects | 1027 |
| 18.2.4 | Notes on socket timeouts | 1034 |
| 18.2.5 | Example | 1034 |
| 18.3 | ssl — TLS/SSL wrapper for socket objects | 1038 |
| 18.3.1 | Functions, Constants, and Exceptions | 1039 |
| 18.3.2 | SSL Sockets | 1051 |
| 18.3.3 | SSL Contexts | 1055 |
| 18.3.4 | Certificates | 1064 |
| 18.3.5 | Examples | 1066 |
| 18.3.6 | Notes on non-blocking sockets | 1068 |
| 18.3.7 | Memory BIO Support | 1069 |
| 18.3.8 | SSL session | 1071 |
| 18.3.9 | Security considerations | 1071 |
| 18.3.10 | TLS 1.3 | 1073 |
| 18.3.11 | LibreSSL support | 1073 |
| 18.4 | select — Waiting for I/O completion | 1074 |
| 18.4.1 | /dev/poll Polling Objects | 1076 |
| 18.4.2 | Edge and Level Trigger Polling (epoll) Objects | 1077 |
| 18.4.3 | Polling Objects | 1078 |
| 18.4.4 | Kqueue Objects | 1079 |
| 18.4.5 | Kevent Objects | 1079 |
| 18.5 | selectors — High-level I/O multiplexing | 1081 |
| 18.5.1 | Introduction | 1081 |
| 18.5.2 | Classes | 1081 |
| 18.5.3 | Examples | 1084 |
| 18.6 | signal — Set handlers for asynchronous events | 1084 |
| 18.6.1 | General rules | 1084 |
| 18.6.2 | Module contents | 1085 |
| 18.6.3 | Example | 1091 |
| 18.6.4 | Note on SIGPIPE | 1092 |
| 18.6.5 | Note on Signal Handlers and Exceptions | 1092 |
| 18.7 | mmap — Memory-mapped file support | 1093 |
| 18.7.1 | MADV_* Constants | 1097 |
| 19 | Internet Data Handling | 1099 |
| 19.1 | email — An email and MIME handling package | 1099 |
| 19.1.1 | email.message: Representing an email message | 1100 |
| 19.1.2 | email.parser: Parsing email messages | 1108 |
| 19.1.3 | email.generator: Generating MIME documents | 1112 |
| 19.1.4 | email.policy: Policy Objects | 1115 |
| 19.1.5 | email.errors: Exception and Defect classes | 1122 |
| 19.1.6 | email.headerregistry: Custom Header Objects | 1123 |
| 19.1.7 | email.contentmanager: Managing MIME Content | 1128 |
| 19.1.8 | email: Examples | 1131 |
| 19.1.9 | email.message.Message: Representing an email message using the compat32 API | 1137 |
| 19.1.10 | email.mime: Creating email and MIME objects from scratch | 1146 |
| 19.1.11 | email.header: Internationalized headers | 1148 |
| 19.1.12 | email.charset: Representing character sets | 1151 |
| 19.1.13 | email.encoders: Encoders | 1153 |
| 19.1.14 | email.utils: Miscellaneous utilities | 1154 |
| 19.1.15 | email.iterators: Iterators | 1157 |
| 19.2 | json — JSON encoder and decoder | 1158 |
| 19.2.1 | Basic Usage | 1160 |

| | | |
|-----------|--|-------------|
| 19.2.2 | Encoders and Decoders | 1162 |
| 19.2.3 | Exceptions | 1164 |
| 19.2.4 | Standard Compliance and Interoperability | 1164 |
| 19.2.5 | Command Line Interface | 1166 |
| 19.3 | mailbox — Manipulate mailboxes in various formats | 1167 |
| 19.3.1 | Mailbox objects | 1168 |
| 19.3.2 | Message objects | 1176 |
| 19.3.3 | Exceptions | 1183 |
| 19.3.4 | Examples | 1184 |
| 19.4 | mimetypes — Map filenames to MIME types | 1185 |
| 19.4.1 | MimeTypes Objects | 1187 |
| 19.5 | base64 — Base16, Base32, Base64, Base85 Data Encodings | 1188 |
| 19.6 | binhex — Encode and decode binhex4 files | 1191 |
| 19.6.1 | Notes | 1191 |
| 19.7 | binascii — Convert between binary and ASCII | 1191 |
| 19.8 | quopri — Encode and decode MIME quoted-printable data | 1194 |
| 20 | Structured Markup Processing Tools | 1195 |
| 20.1 | html — HyperText Markup Language support | 1195 |
| 20.2 | html.parser — Simple HTML and XHTML parser | 1196 |
| 20.2.1 | Example HTML Parser Application | 1196 |
| 20.2.2 | HTMLParser Methods | 1197 |
| 20.2.3 | Examples | 1198 |
| 20.3 | html.entities — Definitions of HTML general entities | 1200 |
| 20.4 | XML Processing Modules | 1201 |
| 20.4.1 | XML vulnerabilities | 1201 |
| 20.4.2 | The defusedxml Package | 1202 |
| 20.5 | xml.etree.ElementTree — The ElementTree XML API | 1203 |
| 20.5.1 | Tutorial | 1203 |
| 20.5.2 | XPath support | 1208 |
| 20.5.3 | Reference | 1210 |
| 20.5.4 | XInclude support | 1213 |
| 20.5.5 | Reference | 1214 |
| 20.6 | xml.dom — The Document Object Model API | 1222 |
| 20.6.1 | Περιεχόμενα Module | 1223 |
| 20.6.2 | Αντικείμενα στο DOM | 1224 |
| 20.6.3 | Συμμόρφωση | 1233 |
| 20.7 | xml.dom.minidom — Minimal DOM implementation | 1234 |
| 20.7.1 | DOM Objects | 1235 |
| 20.7.2 | DOM Example | 1236 |
| 20.7.3 | minidom and the DOM standard | 1238 |
| 20.8 | xml.dom.pulldom — Support for building partial DOM trees | 1238 |
| 20.8.1 | DOMEventStream Objects | 1240 |
| 20.9 | xml.sax — Support for SAX2 parsers | 1240 |
| 20.9.1 | SAXException Objects | 1242 |
| 20.10 | xml.sax.handler — Base classes for SAX handlers | 1242 |
| 20.10.1 | ContentHandler Objects | 1244 |
| 20.10.2 | DTDHandler Objects | 1246 |
| 20.10.3 | EntityResolver Objects | 1246 |
| 20.10.4 | ErrorHandler Objects | 1247 |
| 20.11 | xml.sax.saxutils — SAX Utilities | 1247 |
| 20.12 | xml.sax.xmlreader — Interface for XML parsers | 1248 |
| 20.12.1 | XMLReader Objects | 1249 |
| 20.12.2 | IncrementalParser Objects | 1250 |

| | | |
|-----------|---|-------------|
| 20.12.3 | Locator Objects | 1250 |
| 20.12.4 | InputSource Objects | 1251 |
| 20.12.5 | The <code>Attributes</code> Interface | 1251 |
| 20.12.6 | The <code>AttributesNS</code> Interface | 1252 |
| 20.13 | <code>xml.parsers.expat</code> — Fast XML parsing using Expat | 1252 |
| 20.13.1 | XMLParser Objects | 1253 |
| 20.13.2 | ExpatError Exceptions | 1258 |
| 20.13.3 | Example | 1258 |
| 20.13.4 | Content Model Descriptions | 1259 |
| 20.13.5 | Expat error constants | 1260 |
| 21 | Πρωτόκολλα Internet και Υποστήριξη | 1263 |
| 21.1 | <code>webbrowser</code> — Convenient Web-browser controller | 1263 |
| 21.1.1 | Browser Controller Objects | 1266 |
| 21.2 | <code>wsgiref</code> — WSGI Utilities and Reference Implementation | 1266 |
| 21.2.1 | <code>wsgiref.util</code> — WSGI environment utilities | 1266 |
| 21.2.2 | <code>wsgiref.headers</code> — WSGI response header tools | 1268 |
| 21.2.3 | <code>wsgiref.simple_server</code> — a simple WSGI HTTP server | 1269 |
| 21.2.4 | <code>wsgiref.validate</code> — WSGI conformance checker | 1270 |
| 21.2.5 | <code>wsgiref.handlers</code> — server/gateway base classes | 1271 |
| 21.2.6 | Examples | 1275 |
| 21.3 | <code>urllib</code> — URL handling modules | 1276 |
| 21.4 | <code>urllib.request</code> — Extensible library for opening URLs | 1276 |
| 21.4.1 | Request Objects | 1281 |
| 21.4.2 | OpenerDirector Objects | 1283 |
| 21.4.3 | BaseHandler Objects | 1284 |
| 21.4.4 | HTTPRedirectHandler Objects | 1285 |
| 21.4.5 | HTTPCookieProcessor Objects | 1286 |
| 21.4.6 | ProxyHandler Objects | 1286 |
| 21.4.7 | HTTPPasswordMgr Objects | 1286 |
| 21.4.8 | HTTPPasswordMgrWithPriorAuth Objects | 1286 |
| 21.4.9 | AbstractBasicAuthHandler Objects | 1287 |
| 21.4.10 | HTTPBasicAuthHandler Objects | 1287 |
| 21.4.11 | ProxyBasicAuthHandler Objects | 1287 |
| 21.4.12 | AbstractDigestAuthHandler Objects | 1287 |
| 21.4.13 | HTTPDigestAuthHandler Objects | 1287 |
| 21.4.14 | ProxyDigestAuthHandler Objects | 1287 |
| 21.4.15 | HTTPHandler Objects | 1287 |
| 21.4.16 | HTTPSHandler Objects | 1288 |
| 21.4.17 | FileHandler Objects | 1288 |
| 21.4.18 | DataHandler Objects | 1288 |
| 21.4.19 | FTPHandler Objects | 1288 |
| 21.4.20 | CacheFTPHandler Objects | 1288 |
| 21.4.21 | UnknownHandler Objects | 1288 |
| 21.4.22 | HTTPErrorProcessor Objects | 1289 |
| 21.4.23 | Examples | 1289 |
| 21.4.24 | Legacy interface | 1292 |
| 21.4.25 | <code>urllib.request</code> Restrictions | 1294 |
| 21.5 | <code>urllib.response</code> — Response classes used by <code>urllib</code> | 1294 |
| 21.6 | <code>urllib.parse</code> — Parse URLs into components | 1295 |
| 21.6.1 | URL Parsing | 1295 |
| 21.6.2 | URL parsing security | 1300 |
| 21.6.3 | Parsing ASCII Encoded Bytes | 1300 |
| 21.6.4 | Structured Parse Results | 1301 |

| | | |
|---------|---|------|
| 21.6.5 | URL Quoting | 1302 |
| 21.7 | <code>urllib.error</code> — Exception classes raised by <code>urllib.request</code> | 1304 |
| 21.8 | <code>urllib.robotparser</code> — Parser for <code>robots.txt</code> | 1304 |
| 21.9 | <code>http</code> — HTTP modules | 1306 |
| 21.9.1 | HTTP status codes | 1306 |
| 21.10 | <code>http.client</code> — HTTP protocol client | 1308 |
| 21.10.1 | HTTPConnection Objects | 1311 |
| 21.10.2 | HTTPResponse Objects | 1313 |
| 21.10.3 | Examples | 1314 |
| 21.10.4 | HTTPMessage Objects | 1315 |
| 21.11 | <code>ftplib</code> — FTP protocol client | 1315 |
| 21.11.1 | FTP Objects | 1317 |
| 21.11.2 | FTP_TLS Objects | 1320 |
| 21.12 | <code>poplib</code> — POP3 protocol client | 1320 |
| 21.12.1 | POP3 Objects | 1322 |
| 21.12.2 | POP3 Example | 1323 |
| 21.13 | <code>imaplib</code> — IMAP4 protocol client | 1324 |
| 21.13.1 | IMAP4 Objects | 1325 |
| 21.13.2 | IMAP4 Example | 1330 |
| 21.14 | <code>smtplib</code> — SMTP protocol client | 1330 |
| 21.14.1 | SMTP Objects | 1333 |
| 21.14.2 | SMTP Example | 1336 |
| 21.15 | <code>uuid</code> — UUID objects according to RFC 4122 | 1337 |
| 21.15.1 | Example | 1340 |
| 21.16 | <code>socketserver</code> — A framework for network servers | 1340 |
| 21.16.1 | Server Creation Notes | 1341 |
| 21.16.2 | Server Objects | 1343 |
| 21.16.3 | Request Handler Objects | 1345 |
| 21.16.4 | Examples | 1345 |
| 21.17 | <code>http.server</code> — HTTP servers | 1349 |
| 21.17.1 | Security Considerations | 1355 |
| 21.18 | <code>http.cookies</code> — HTTP state management | 1355 |
| 21.18.1 | Cookie Objects | 1356 |
| 21.18.2 | Morsel Objects | 1356 |
| 21.18.3 | Example | 1358 |
| 21.19 | <code>http.cookiejar</code> — Cookie handling for HTTP clients | 1359 |
| 21.19.1 | CookieJar and FileCookieJar Objects | 1360 |
| 21.19.2 | FileCookieJar subclasses and co-operation with web browsers | 1362 |
| 21.19.3 | CookiePolicy Objects | 1363 |
| 21.19.4 | DefaultCookiePolicy Objects | 1364 |
| 21.19.5 | Cookie Objects | 1366 |
| 21.19.6 | Examples | 1367 |
| 21.20 | <code>xmlrpc</code> — XMLRPC server and client modules | 1367 |
| 21.21 | <code>xmlrpc.client</code> — XML-RPC client access | 1368 |
| 21.21.1 | ServerProxy Objects | 1369 |
| 21.21.2 | DateTime Objects | 1370 |
| 21.21.3 | Binary Objects | 1371 |
| 21.21.4 | Fault Objects | 1372 |
| 21.21.5 | ProtocolError Objects | 1373 |
| 21.21.6 | MultiCall Objects | 1373 |
| 21.21.7 | Convenience Functions | 1374 |
| 21.21.8 | Example of Client Usage | 1375 |
| 21.21.9 | Example of Client and Server Usage | 1375 |
| 21.22 | <code>xmlrpc.server</code> — Basic XML-RPC servers | 1375 |

| | | |
|-----------|--|-------------|
| 21.22.1 | SimpleXMLRPCServer Objects | 1376 |
| 21.22.2 | CGIXMLRPCRequestHandler | 1380 |
| 21.22.3 | Documenting XMLRPC server | 1380 |
| 21.22.4 | DocXMLRPCServer Objects | 1381 |
| 21.22.5 | DocCGIXMLRPCRequestHandler | 1381 |
| 21.23 | ipaddress — IPv4/IPv6 manipulation library | 1382 |
| 21.23.1 | Convenience factory functions | 1382 |
| 21.23.2 | IP Addresses | 1383 |
| 21.23.3 | IP Network definitions | 1387 |
| 21.23.4 | Interface objects | 1393 |
| 21.23.5 | Other Module Level Functions | 1395 |
| 21.23.6 | Custom Exceptions | 1396 |
| 22 | Multimedia Services | 1397 |
| 22.1 | wave — Read and write WAV files | 1397 |
| 22.1.1 | Wave_read Objects | 1398 |
| 22.1.2 | Wave_write Objects | 1399 |
| 22.2 | colorsys — Conversions between color systems | 1400 |
| 23 | Internationalization | 1401 |
| 23.1 | gettext — Multilingual internationalization services | 1401 |
| 23.1.1 | GNU gettext API | 1401 |
| 23.1.2 | Class-based API | 1403 |
| 23.1.3 | Internationalizing your programs and modules | 1407 |
| 23.1.4 | Acknowledgements | 1410 |
| 23.2 | locale — Internationalization services | 1410 |
| 23.2.1 | Background, details, hints, tips and caveats | 1417 |
| 23.2.2 | For extension writers and programs that embed Python | 1417 |
| 23.2.3 | Access to message catalogs | 1417 |
| 24 | Program Frameworks | 1419 |
| 24.1 | turtle — Turtle graphics | 1419 |
| 24.1.1 | Introduction | 1419 |
| 24.1.2 | Overview of available Turtle and Screen methods | 1421 |
| 24.1.3 | Methods of RawTurtle/Turtle and corresponding functions | 1424 |
| 24.1.4 | Methods of TurtleScreen/Screen and corresponding functions | 1441 |
| 24.1.5 | Public classes | 1448 |
| 24.1.6 | Help and configuration | 1449 |
| 24.1.7 | turtledemo — Demo scripts | 1452 |
| 24.1.8 | Changes since Python 2.6 | 1453 |
| 24.1.9 | Changes since Python 3.0 | 1453 |
| 24.2 | cmd — Support for line-oriented command interpreters | 1453 |
| 24.2.1 | Cmd Objects | 1454 |
| 24.2.2 | Cmd Example | 1456 |
| 24.3 | shlex — Simple lexical analysis | 1458 |
| 24.3.1 | shlex Objects | 1460 |
| 24.3.2 | Parsing Rules | 1462 |
| 24.3.3 | Improved Compatibility with Shells | 1463 |
| 25 | Graphical User Interfaces with Tk | 1465 |
| 25.1 | tkinter — Python interface to Tcl/Tk | 1465 |
| 25.1.1 | Tkinter Modules | 1466 |
| 25.1.2 | Tkinter Life Preserver | 1468 |
| 25.1.3 | A (Very) Quick Look at Tcl/Tk | 1469 |
| 25.1.4 | Mapping Basic Tk into Tkinter | 1470 |

| | | |
|-----------|---|-------------|
| 25.1.5 | How Tk and Tkinter are Related | 1470 |
| 25.1.6 | Handy Reference | 1471 |
| 25.1.7 | File Handlers | 1476 |
| 25.2 | <code>tkinter.colorchooser</code> — Color choosing dialog | 1477 |
| 25.3 | <code>tkinter.font</code> — Tkinter font wrapper | 1477 |
| 25.4 | Tkinter Dialogs | 1478 |
| 25.4.1 | <code>tkinter.simpledialog</code> — Standard Tkinter input dialogs | 1478 |
| 25.4.2 | <code>tkinter.filedialog</code> — File selection dialogs | 1479 |
| 25.4.3 | <code>tkinter.commondialog</code> — Dialog window templates | 1481 |
| 25.5 | <code>tkinter.messagebox</code> — Tkinter message prompts | 1481 |
| 25.6 | <code>tkinter.scrolledtext</code> — Scrolled Text Widget | 1482 |
| 25.7 | <code>tkinter.dnd</code> — Drag and drop support | 1482 |
| 25.8 | <code>tkinter.ttk</code> — Tk themed widgets | 1483 |
| 25.8.1 | Using Tk | 1484 |
| 25.8.2 | Ttk Widgets | 1484 |
| 25.8.3 | Widget | 1485 |
| 25.8.4 | Combobox | 1487 |
| 25.8.5 | Spinbox | 1489 |
| 25.8.6 | Notebook | 1490 |
| 25.8.7 | Progressbar | 1492 |
| 25.8.8 | Separator | 1493 |
| 25.8.9 | Sizegrip | 1493 |
| 25.8.10 | Treeview | 1493 |
| 25.8.11 | Ttk Styling | 1499 |
| 25.9 | <code>tkinter.tix</code> — Extension widgets for Tk | 1502 |
| 25.9.1 | Using Tix | 1503 |
| 25.9.2 | Tix Widgets | 1503 |
| 25.9.3 | Tix Commands | 1506 |
| 25.10 | IDLE | 1507 |
| 25.10.1 | Menus | 1507 |
| 25.10.2 | Editing and navigation | 1511 |
| 25.10.3 | Startup and code execution | 1514 |
| 25.10.4 | Help and preferences | 1517 |
| 26 | Development Tools | 1519 |
| 26.1 | <code>typing</code> — Support for type hints | 1519 |
| 26.1.1 | Relevant PEPs | 1520 |
| 26.1.2 | Type aliases | 1520 |
| 26.1.3 | <code>NewType</code> | 1521 |
| 26.1.4 | Callable | 1522 |
| 26.1.5 | Generics | 1522 |
| 26.1.6 | User-defined generic types | 1523 |
| 26.1.7 | The <code>Any</code> type | 1525 |
| 26.1.8 | Nominal vs structural subtyping | 1526 |
| 26.1.9 | Module contents | 1526 |
| 26.2 | <code>pydoc</code> — Documentation generator and online help system | 1547 |
| 26.3 | Python Development Mode | 1549 |
| 26.4 | Effects of the Python Development Mode | 1549 |
| 26.5 | ResourceWarning Example | 1550 |
| 26.6 | Bad file descriptor error example | 1551 |
| 26.7 | <code>doctest</code> — Test interactive Python examples | 1552 |
| 26.7.1 | Simple Usage: Checking Examples in Docstrings | 1554 |
| 26.7.2 | Simple Usage: Checking Examples in a Text File | 1555 |
| 26.7.3 | How It Works | 1556 |

| | | |
|-----------|--|-------------|
| 26.7.4 | Basic API | 1563 |
| 26.7.5 | Unittest API | 1565 |
| 26.7.6 | Advanced API | 1567 |
| 26.7.7 | Debugging | 1571 |
| 26.7.8 | Soapbox | 1574 |
| 26.8 | unittest — Unit testing framework | 1575 |
| 26.8.1 | Basic example | 1576 |
| 26.8.2 | Command-Line Interface | 1577 |
| 26.8.3 | Test Discovery | 1578 |
| 26.8.4 | Organizing test code | 1579 |
| 26.8.5 | Re-using old test code | 1581 |
| 26.8.6 | Skipping tests and expected failures | 1582 |
| 26.8.7 | Distinguishing test iterations using subtests | 1583 |
| 26.8.8 | Classes and functions | 1584 |
| 26.8.9 | Class and Module Fixtures | 1603 |
| 26.8.10 | Signal Handling | 1605 |
| 26.9 | unittest.mock — mock object library | 1605 |
| 26.9.1 | Quick Guide | 1606 |
| 26.9.2 | The Mock Class | 1608 |
| 26.9.3 | The patchers | 1624 |
| 26.9.4 | MagicMock and magic method support | 1634 |
| 26.9.5 | Helpers | 1637 |
| 26.10 | unittest.mock — getting started | 1646 |
| 26.10.1 | Using Mock | 1646 |
| 26.10.2 | Patch Decorators | 1651 |
| 26.10.3 | Further Examples | 1653 |
| 26.11 | 2to3 - Automated Python 2 to 3 code translation | 1666 |
| 26.11.1 | Using 2to3 | 1667 |
| 26.11.2 | Fixers | 1668 |
| 26.11.3 | lib2to3 - 2to3's library | 1672 |
| 26.12 | test — Regression tests package for Python | 1672 |
| 26.12.1 | Writing Unit Tests for the test package | 1673 |
| 26.12.2 | Running tests using the command-line interface | 1674 |
| 26.13 | test.support — Utilities for the Python test suite | 1675 |
| 26.14 | test.support.socket_helper — Utilities for socket tests | 1688 |
| 26.15 | test.support.script_helper — Utilities for the Python execution tests | 1689 |
| 26.16 | test.support.bytecode_helper — Support tools for testing correct bytecode generation | 1690 |
| 27 | Debugging and Profiling | 1691 |
| 27.1 | Audit events table | 1691 |
| 27.2 | bdb — Debugger framework | 1695 |
| 27.3 | faulthandler — Dump the Python traceback | 1700 |
| 27.3.1 | Dumping the traceback | 1700 |
| 27.3.2 | Fault handler state | 1700 |
| 27.3.3 | Dumping the tracebacks after a timeout | 1701 |
| 27.3.4 | Dumping the traceback on a user signal | 1701 |
| 27.3.5 | Issue with file descriptors | 1701 |
| 27.3.6 | Example | 1701 |
| 27.4 | pdb — The Python Debugger | 1702 |
| 27.4.1 | Debugger Commands | 1704 |
| 27.5 | The Python Profilers | 1708 |
| 27.5.1 | Introduction to the profilers | 1708 |
| 27.5.2 | Instant User's Manual | 1709 |
| 27.5.3 | profile and cProfile Module Reference | 1711 |

| | | |
|-----------|--|-------------|
| 27.5.4 | The Stats Class | 1712 |
| 27.5.5 | What Is Deterministic Profiling? | 1715 |
| 27.5.6 | Limitations | 1715 |
| 27.5.7 | Calibration | 1715 |
| 27.5.8 | Using a custom timer | 1716 |
| 27.6 | timeit — Measure execution time of small code snippets | 1717 |
| 27.6.1 | Basic Examples | 1717 |
| 27.6.2 | Python Interface | 1717 |
| 27.6.3 | Command-Line Interface | 1719 |
| 27.6.4 | Examples | 1720 |
| 27.7 | trace — Trace or track Python statement execution | 1722 |
| 27.7.1 | Command-Line Usage | 1722 |
| 27.7.2 | Programmatic Interface | 1723 |
| 27.8 | tracemalloc — Trace memory allocations | 1724 |
| 27.8.1 | Examples | 1725 |
| 27.8.2 | API | 1729 |
| 28 | Software Packaging and Distribution | 1737 |
| 28.1 | distutils — Building and installing Python modules | 1737 |
| 28.2 | ensurepip — Bootstrapping the pip installer | 1738 |
| 28.2.1 | Command line interface | 1738 |
| 28.2.2 | Module API | 1739 |
| 28.3 | venv — Creation of virtual environments | 1739 |
| 28.3.1 | Creating virtual environments | 1740 |
| 28.3.2 | API | 1742 |
| 28.3.3 | An example of extending EnvBuilder | 1744 |
| 28.4 | zipapp — Manage executable Python zip archives | 1748 |
| 28.4.1 | Basic Example | 1748 |
| 28.4.2 | Command-Line Interface | 1749 |
| 28.4.3 | Python API | 1749 |
| 28.4.4 | Examples | 1750 |
| 28.4.5 | Specifying the Interpreter | 1751 |
| 28.4.6 | Creating Standalone Applications with zipapp | 1751 |
| 28.4.7 | The Python Zip Application Archive Format | 1754 |
| 29 | Υπηρεσίες χρόνου εκτέλεσης Python | 1755 |
| 29.1 | sys — System-specific parameters and functions | 1755 |
| 29.2 | sysconfig — Provide access to Python’s configuration information | 1775 |
| 29.2.1 | Configuration variables | 1775 |
| 29.2.2 | Installation paths | 1775 |
| 29.2.3 | Other functions | 1777 |
| 29.2.4 | Using sysconfig as a script | 1778 |
| 29.3 | builtins — Built-in objects | 1778 |
| 29.4 | __main__ — Top-level script environment | 1779 |
| 29.5 | warnings — Warning control | 1779 |
| 29.5.1 | Warning Categories | 1780 |
| 29.5.2 | The Warnings Filter | 1780 |
| 29.5.3 | Temporarily Suppressing Warnings | 1783 |
| 29.5.4 | Testing Warnings | 1783 |
| 29.5.5 | Updating Code For New Versions of Dependencies | 1784 |
| 29.5.6 | Available Functions | 1784 |
| 29.5.7 | Available Context Managers | 1785 |
| 29.6 | dataclasses — Data Classes | 1785 |
| 29.6.1 | Module-level decorators, classes, and functions | 1786 |

| | | |
|-----------|---|-------------|
| 29.6.2 | Post-init processing | 1791 |
| 29.6.3 | Class variables | 1792 |
| 29.6.4 | Init-only variables | 1792 |
| 29.6.5 | Frozen instances | 1792 |
| 29.6.6 | Inheritance | 1792 |
| 29.6.7 | Default factory functions | 1793 |
| 29.6.8 | Mutable default values | 1793 |
| 29.6.9 | Exceptions | 1794 |
| 29.7 | contextlib — Utilities for with-statement contexts | 1794 |
| 29.7.1 | Utilities | 1794 |
| 29.7.2 | Examples and Recipes | 1801 |
| 29.7.3 | Single use, reusable and reentrant context managers | 1805 |
| 29.8 | abc — Abstract Base Classes | 1807 |
| 29.9 | atexit — Exit handlers | 1811 |
| 29.9.1 | atexit Example | 1812 |
| 29.10 | traceback — Print or retrieve a stack traceback | 1813 |
| 29.10.1 | TracebackException Objects | 1815 |
| 29.10.2 | StackSummary Objects | 1816 |
| 29.10.3 | FrameSummary Objects | 1816 |
| 29.10.4 | Traceback Examples | 1817 |
| 29.11 | __future__ — Future statement definitions | 1819 |
| 29.12 | gc — Garbage Collector interface | 1820 |
| 29.13 | inspect — Inspect live objects | 1824 |
| 29.13.1 | Types and members | 1824 |
| 29.13.2 | Retrieving source code | 1828 |
| 29.13.3 | Introspecting callables with the Signature object | 1829 |
| 29.13.4 | Classes and functions | 1833 |
| 29.13.5 | The interpreter stack | 1836 |
| 29.13.6 | Fetching attributes statically | 1837 |
| 29.13.7 | Current State of Generators and Coroutines | 1838 |
| 29.13.8 | Code Objects Bit Flags | 1839 |
| 29.13.9 | Command Line Interface | 1839 |
| 29.14 | site — Site-specific configuration hook | 1840 |
| 29.14.1 | Readline configuration | 1841 |
| 29.14.2 | Module contents | 1841 |
| 29.14.3 | Command Line Interface | 1842 |
| 30 | Custom Python Interpreters | 1843 |
| 30.1 | code — Interpreter base classes | 1843 |
| 30.1.1 | Interactive Interpreter Objects | 1844 |
| 30.1.2 | Interactive Console Objects | 1845 |
| 30.2 | codeop — Compile Python code | 1845 |
| 31 | Importing Modules | 1847 |
| 31.1 | zipimport — Import modules from Zip archives | 1847 |
| 31.1.1 | zipimporter Objects | 1848 |
| 31.1.2 | Examples | 1849 |
| 31.2 | pkgutil — Package extension utility | 1849 |
| 31.3 | modulefinder — Find modules used by a script | 1852 |
| 31.3.1 | Example usage of ModuleFinder | 1853 |
| 31.4 | runpy — Locating and executing Python modules | 1854 |
| 31.5 | importlib — The implementation of import | 1856 |
| 31.5.1 | Introduction | 1856 |
| 31.5.2 | Functions | 1857 |

| | | |
|-----------|--|-------------|
| 31.5.3 | <code>importlib.abc</code> – Abstract base classes related to import | 1858 |
| 31.5.4 | <code>importlib.resources</code> – Resources | 1865 |
| 31.5.5 | <code>importlib.machinery</code> – Importers and path hooks | 1867 |
| 31.5.6 | <code>importlib.util</code> – Utility code for importers | 1872 |
| 31.5.7 | Examples | 1875 |
| 31.6 | Using <code>importlib.metadata</code> | 1877 |
| 31.6.1 | Overview | 1877 |
| 31.6.2 | Functional API | 1878 |
| 31.6.3 | Distributions | 1880 |
| 31.6.4 | Extending the search algorithm | 1880 |
| 32 | Python Language Services | 1883 |
| 32.1 | <code>parser</code> — Access Python parse trees | 1883 |
| 32.1.1 | Creating ST Objects | 1884 |
| 32.1.2 | Converting ST Objects | 1885 |
| 32.1.3 | Queries on ST Objects | 1885 |
| 32.1.4 | Exceptions and Error Handling | 1886 |
| 32.1.5 | ST Objects | 1886 |
| 32.1.6 | Example: Emulation of <code>compile()</code> | 1886 |
| 32.2 | <code>ast</code> — Abstract Syntax Trees | 1887 |
| 32.2.1 | Abstract Grammar | 1887 |
| 32.2.2 | Node classes | 1890 |
| 32.2.3 | <code>ast</code> Helpers | 1911 |
| 32.2.4 | Compiler Flags | 1914 |
| 32.2.5 | Command-Line Usage | 1914 |
| 32.3 | <code>symtable</code> — Access to the compiler's symbol tables | 1915 |
| 32.3.1 | Generating Symbol Tables | 1915 |
| 32.3.2 | Examining Symbol Tables | 1915 |
| 32.4 | <code>symbol</code> — Constants used with Python parse trees | 1917 |
| 32.5 | <code>token</code> — Constants used with Python parse trees | 1918 |
| 32.6 | <code>keyword</code> — Testing for Python keywords | 1921 |
| 32.7 | <code>tokenize</code> — Tokenizer for Python source | 1922 |
| 32.7.1 | Tokenizing Input | 1922 |
| 32.7.2 | Command-Line Usage | 1923 |
| 32.7.3 | Examples | 1924 |
| 32.8 | <code>tabnanny</code> — Detection of ambiguous indentation | 1926 |
| 32.9 | <code>pyclbr</code> — Python module browser support | 1926 |
| 32.9.1 | Function Objects | 1927 |
| 32.9.2 | Class Objects | 1927 |
| 32.10 | <code>py_compile</code> — Compile Python source files | 1928 |
| 32.11 | <code>compileall</code> — Byte-compile Python libraries | 1930 |
| 32.11.1 | Command-line use | 1930 |
| 32.11.2 | Public functions | 1931 |
| 32.12 | <code>dis</code> — Disassembler for Python bytecode | 1934 |
| 32.12.1 | Bytecode analysis | 1934 |
| 32.12.2 | Analysis functions | 1935 |
| 32.12.3 | Python Bytecode Instructions | 1937 |
| 32.12.4 | Opcodes collections | 1946 |
| 32.13 | <code>pickletools</code> — Tools for pickle developers | 1947 |
| 32.13.1 | Command line usage | 1947 |
| 32.13.2 | Programmatic Interface | 1948 |
| 33 | Miscellaneous Services | 1949 |
| 33.1 | <code>formatter</code> — Generic output formatting | 1949 |

| | | |
|-----------|---|-------------|
| 33.1.1 | The Formatter Interface | 1950 |
| 33.1.2 | Formatter Implementations | 1951 |
| 33.1.3 | The Writer Interface | 1952 |
| 33.1.4 | Writer Implementations | 1953 |
| 34 | MS Windows Specific Services | 1955 |
| 34.1 | msvcrt — Useful routines from the MS VC++ runtime | 1955 |
| 34.1.1 | File Operations | 1955 |
| 34.1.2 | Console I/O | 1956 |
| 34.1.3 | Other Functions | 1957 |
| 34.2 | winreg — Windows registry access | 1957 |
| 34.2.1 | Functions | 1957 |
| 34.2.2 | Constants | 1963 |
| 34.2.3 | Registry Handle Objects | 1965 |
| 34.3 | winsound — Sound-playing interface for Windows | 1966 |
| 35 | Unix Specific Services | 1969 |
| 35.1 | posix — The most common POSIX system calls | 1969 |
| 35.1.1 | Large File Support | 1969 |
| 35.1.2 | Notable Module Contents | 1970 |
| 35.2 | pwd — The password database | 1970 |
| 35.3 | grp — The group database | 1971 |
| 35.4 | termios — POSIX style tty control | 1972 |
| 35.4.1 | Example | 1973 |
| 35.5 | tty — Terminal control functions | 1973 |
| 35.6 | pty — Pseudo-terminal utilities | 1973 |
| 35.6.1 | Example | 1974 |
| 35.7 | fcntl — The fcntl and ioctl system calls | 1975 |
| 35.8 | resource — Resource usage information | 1977 |
| 35.8.1 | Resource Limits | 1977 |
| 35.8.2 | Resource Usage | 1980 |
| 35.9 | syslog — Unix syslog library routines | 1981 |
| 35.9.1 | Examples | 1983 |
| 36 | Superseded Modules | 1985 |
| 36.1 | aifc — Ανάγνωση και εγγραφή AIFF και AIFC αρχείων | 1985 |
| 36.2 | asynchat — Asynchronous socket command/response handler | 1988 |
| 36.2.1 | asynchat Example | 1989 |
| 36.3 | asyncore — Asynchronous socket handler | 1990 |
| 36.3.1 | asyncore Example basic HTTP client | 1993 |
| 36.3.2 | asyncore Example basic echo server | 1994 |
| 36.4 | audioop — Manipulate raw audio data | 1995 |
| 36.5 | cgi — Common Gateway Interface support | 1998 |
| 36.5.1 | Introduction | 1998 |
| 36.5.2 | Using the cgi module | 1999 |
| 36.5.3 | Higher Level Interface | 2000 |

| Ευρετήριο Μονάδων της Python | 2119 |
| Ευρετήριο | 2123 |

While reference-index describes the exact syntax and semantics of the Python language, this library reference manual describes the standard library that is distributed with Python. It also describes some of the optional components that are commonly included in Python distributions.

Python's standard library is very extensive, offering a wide range of facilities as indicated by the long table of contents listed below. The library contains built-in modules (written in C) that provide access to system functionality such as file I/O that would otherwise be inaccessible to Python programmers, as well as modules written in Python that provide standardized solutions for many problems that occur in everyday programming. Some of these modules are explicitly designed to encourage and enhance the portability of Python programs by abstracting away platform-specifics into platform-neutral APIs.

The Python installers for the Windows platform usually include the entire standard library and often also include many additional components. For Unix-like operating systems Python is normally provided as a collection of packages, so it may be necessary to use the packaging tools provided with the operating system to obtain some or all of the optional components.

In addition to the standard library, there is a growing collection of several thousand components (from individual programs and modules to packages and entire application development frameworks), available from the [Python Package Index](#).

The «Python library» contains several different kinds of components.

It contains data types that would normally be considered part of the «core» of a language, such as numbers and lists. For these types, the Python language core defines the form of literals and places some constraints on their semantics, but does not fully define the semantics. (On the other hand, the language core does define syntactic properties like the spelling and priorities of operators.)

The library also contains built-in functions and exceptions — objects that can be used by all Python code without the need of an `import` statement. Some of these are defined by the core language, but many are not essential for the core semantics and are only described here.

The bulk of the library, however, consists of a collection of modules. There are many ways to dissect this collection. Some modules are written in C and built in to the Python interpreter; others are written in Python and imported in source form. Some modules provide interfaces that are highly specific to Python, like printing a stack trace; some provide interfaces that are specific to particular operating systems, such as access to specific hardware; others provide interfaces that are specific to a particular application domain, like the World Wide Web. Some modules are available in all versions and ports of Python; others are only available when the underlying system supports or requires them; yet others are available only when a particular configuration option was chosen at the time when Python was compiled and installed.

This manual is organized «from the inside out:» it first describes the built-in functions, data types and exceptions, and finally the modules, grouped in chapters of related modules.

This means that if you start reading this manual from the start, and skip to the next chapter when you get bored, you will get a reasonable overview of the available modules and application areas that are supported by the Python library. Of course, you don't *have* to read it like a novel — you can also browse the table of contents (in front of the manual), or look for a specific function, module or term in the index (in the back). And finally, if you enjoy learning about random subjects, you choose a random page number (see module `random`) and read a section or two. Regardless of the order in which you read the sections of this manual, it helps to start with chapter *Ενσωματωμένες (Built-in) Συναρτήσεις*, as the remainder of the manual assumes familiarity with this material.

Let the show begin!

1.1 Notes on availability

- An «Availability: Unix» note means that this function is commonly found on Unix systems. It does not make any claims about its existence on a specific operating system.
- If not separately noted, all functions that claim «Availability: Unix» are supported on macOS, which builds on a Unix core.

Ενσωματωμένες (Built-in) Συναρτήσεις

Ο interpreter της Python έχει έναν αριθμό από συναρτήσεις και τύπους ενσωματωμένους (built-in) σε αυτόν, που είναι πάντα διαθέσιμα. Παρατίθενται εδώ με αλφαβητική σειρά.

| | | Ενσωματωμένες (Built-in) Συναρτήσεις | | |

| <code>complex()</code> | <code>hasattr()</code> | <code>max()</code> | <code>round()</code> | |

abs(x)

Return the absolute value of a number. The argument may be an integer, a floating point number, or an object implementing `__abs__()`. If the argument is a complex number, its magnitude is returned.

all(iterable)

Επιστρέφει True εάν όλα τα στοιχεία του *iterable* είναι true (ή εάν το *iterable* είναι κενό). Ισοδυναμεί με:

```
def all(iterable):
    for element in iterable:
        if not element:
            return False
    return True
```

any (*iterable*)

Επιστρέφει True εάν οποιοδήποτε στοιχείο του *iterable* είναι αληθές. Εάν το *iterable* είναι κενό, επιστρέφει False. Ισοδυναμεί με:

```
def any(iterable):
    for element in iterable:
        if element:
            return True
    return False
```

ascii (*object*)

As *repr()*, return a string containing a printable representation of an object, but escape the non-ASCII characters in the string returned by *repr()* using `\x`, `\u` or `\U` escapes. This generates a string similar to that returned by *repr()* in Python 2.

bin (*x*)

Convert an integer number to a binary string prefixed with «0b». The result is a valid Python expression. If *x* is not a Python *int* object, it has to define an `__index__()` method that returns an integer. Some examples:

```
>>> bin(3)
'0b11'
>>> bin(-10)
'-0b1010'
```

If prefix «0b» is desired or not, you can use either of the following ways.

```
>>> format(14, '#b'), format(14, 'b')
('0b1110', '1110')
>>> f'{14:#b}', f'{14:b}'
('0b1110', '1110')
```

Δείτε επίσης τη *format()* για περισσότερες πληροφορίες.

class bool (*[x]*)

Return a Boolean value, i.e. one of True or False. *x* is converted using the standard *truth testing procedure*. If *x* is false or omitted, this returns False; otherwise it returns True. The *bool* class is a subclass of *int* (see *Αριθμητικοί Τύποι — int, float, complex*). It cannot be subclassed further. Its only instances are False and True (see *Boolean Values*).

Άλλαξε στην έκδοση 3.7: *x* is now a positional-only parameter.

breakpoint (**args, **kws*)

This function drops you into the debugger at the call site. Specifically, it calls *sys.breakpointhook()*, passing *args* and *kws* straight through. By default, *sys.breakpointhook()* calls *pdb.set_trace()* expecting no arguments. In this case, it is purely a convenience function so you don't have to explicitly import *pdb* or type as much code to enter the debugger. However, *sys.breakpointhook()* can be set to some other function and *breakpoint()* will automatically call that, allowing you to drop into the debugger of choice.

Εγείρει ένα *auditing event* *builtins.breakpoint* με όρισμα *breakpointhook*.

Νέο στην έκδοση 3.7.

class bytearray (*[source[, encoding[, errors]]]*)

Επιστρέφεται ένας νέος πίνακας από bytes. Η κλάση *bytearray* είναι μια μεταβλητή ακολουθία ακεραίων στο εύρος $0 \leq x < 256$. Έχει τις περισσότερες από τις συνήθεις μεθόδους μεταβλητών ακολουθιών, που περιγράφονται στο *Τύποι Μεταβλητών Ακολουθιών (Sequences)*, καθώς και τις περισσότερες μεθόδους που έχει ο τύπος *bytes*, δείτε *Λειτουργίες Bytes και bytearray*.

Η προαιρετική παράμετρος *source* μπορεί να χρησιμοποιηθεί για την αρχικοποίηση του πίνακα με μερικούς διαφορετικούς τρόπους:

- Εάν είναι *string*, πρέπει επίσης να δώσετε τις παραμέτρους *encoding* (και προαιρετικά, *errors*)• η *bytearray()* στη συνέχεια μετατρέπει τη συμβολοσειρά σε byte χρησιμοποιώντας *str.encode()*.
- Εάν είναι *integer*, ο πίνακας θα έχει αυτό το μέγεθος και θα αρχικοποιηθεί με null bytes.
- Εάν είναι αντικείμενο που συμμορφώνεται με το buffer interface, θα χρησιμοποιηθεί μια προσωρινή μνήμη μόνο για ανάγνωση του αντικείμενου για την προετοιμασία του πίνακα με τα bytes.
- Εάν είναι *iterable*, πρέπει να είναι ένας iterable ακεραίων στο εύρος $0 \leq x < 256$, οι οποίοι χρησιμοποιούνται ως αρχικά περιεχόμενα του πίνακα.

Χωρίς όρισμα δημιουργείται ένας πίνακας μεγέθους 0.

Βλ. επίσης *Τύποι δυαδικής ακολουθίας* — *bytes*, *bytearray*, *memoryview* και *Αντικείμενα bytearray*.

class bytes ([*source* [, *encoding* [, *errors*]]])

Return a new «bytes» object, which is an immutable sequence of integers in the range $0 \leq x < 256$. *bytes* is an immutable version of *bytearray* – it has the same non-mutating methods and the same indexing and slicing behavior.

Συνεπώς, τα ορίσματα του constructor ερμηνεύονται ως *bytearray()*.

Τα αντικείμενα bytes μπορούν επίσης να δημιουργηθούν με literals, βλέπε strings.

Βλέπε επίσης *Τύποι δυαδικής ακολουθίας* — *bytes*, *bytearray*, *memoryview*, *Αντικείμενα Bytes*, και *Λειτουργίες Bytes και bytearray*.

callable (*object*)

Return *True* if the *object* argument appears callable, *False* if not. If this returns *True*, it is still possible that a call fails, but if it is *False*, calling *object* will never succeed. Note that classes are callable (calling a class returns a new instance); instances are callable if their class has a `__call__()` method.

Νέο στην έκδοση 3.2: Αυτή η συνάρτηση πρώτα αφαιρέθηκε στην Python 3.0 και στη συνέχεια επανήλθε στην Python 3.2.

chr (*i*)

Επιστρέφει τη συμβολοσειρά που αντιπροσωπεύει έναν χαρακτήρα του οποίου ο κωδικός σημείου Unicode είναι ο ακέραιος *i*. Για παράδειγμα, `chr(97)` επιστρέφει τη συμβολοσειρά 'a', ενώ το `chr(8364)` επιστρέφει τη συμβολοσειρά '€'. Αυτό είναι το αντίστροφο του *ord()*.

Το έγκυρο εύρος για το όρισμα είναι από 0 έως 1,114,111 (0x10FFFF στη βάση 16). Το *ValueError* θα γίνει raise εάν το *i* είναι εκτός αυτού του εύρους.

@classmethod

Μετατροπή μιας μεθόδου σε μέθοδο κλάσης.

A class method receives the class as implicit first argument, just like an instance method receives the instance. To declare a class method, use this idiom:

```
class C:
    @classmethod
    def f(cls, arg1, arg2): ...
```

Η φόρμα `@classmethod` είναι μια συνάρτηση *decorator* – βλέπε function για λεπτομέρειες.

Μια μέθοδος κλάσης μπορεί να κληθεί είτε στην κλάση (όπως `C.f()`) είτε σε ένα instance (όπως `C().f()`). Το instance αγνοείται εκτός από την κλάση της. Εάν μια μέθοδος κλάσης καλείται για μια παραγόμενη κλάση, το αντικείμενο παραγόμενης κλάσης μεταβιβάζεται ως το υπονοούμενο πρώτο όρισμα.

Οι μέθοδοι κλάσης διαφέρουν από τις στατικές μεθόδους C++ ή Java. Αν θέλετε, ανατρέξτε στο *staticmethod()* σε αυτήν την ενότητα. Για περισσότερες πληροφορίες σχετικά με τις μεθόδους κλάσης, ανατρέξτε στο *types*.

Άλλαξε στην έκδοση 3.9: Οι μέθοδοι κλάσης μπορούν πλέον να αναδιπλώσουν άλλους *descriptors* όπως η *property()*.

compile (*source*, *filename*, *mode*, *flags=0*, *dont_inherit=False*, *optimize=-1*)

Μεταγλωττίστε το *source* σε έναν κώδικα ή αντικείμενο AST. Τα αντικείμενα κώδικα μπορούν να εκτελεστούν από *exec()* ή *eval()*. Η *source* μπορεί να είναι είτε μια κανονική συμβολοσειρά, μια συμβολοσειρά byte ή μια συμβολοσειρά AST αντικείμενου. Ανατρέξτε στην τεκμηρίωση του module *ast* για πληροφορίες σχετικά με τον τρόπο εργασίας με αντικείμενα AST.

Το όρισμα *filename* θα πρέπει να δίνει το αρχείο από το οποίο διαβάζεται ο κώδικας· να περάσει κάποια αναγνωρίσιμη τιμή εάν δεν διαβαστεί από ένα αρχείο (χρησιμοποιείται συνήθως '<string>').

Το όρισμα *mode* καθορίζει το είδος του κώδικα που πρέπει να μεταγλωττιστεί· μπορεί να είναι 'exec' εάν η *source* αποτελείται από μια ακολουθία δηλώσεων, 'eval' εάν αποτελείται από μία μόνο έκφραση, ή 'single' εάν αποτελείται από μία μόνο διαδραστική πρόταση (στην τελευταία περίπτωση, θα εκτυπωθούν δηλώσεις έκφρασης που αξιολογούνται σε κάτι διαφορετικό από None).

Τα προαιρετικά ορίσματα *flags* και *dont_inherit* ελέγχουν ποιες *compiler options* θα πρέπει να ενεργοποιηθούν και ποιες future features θα πρέπει να επιτρέπονται. Εάν δεν υπάρχει καμία (ή και οι δύο είναι μηδέν) ο κώδικας μεταγλωττίζεται με τα ίδια flags που επηρεάζουν τον κώδικα που καλεί *compile()*. Εάν το όρισμα *flags* δίνεται και το *dont_inherit* δεν είναι (ή είναι μηδέν), τότε οι επιλογές του μεταγλωττιστή και οι μελλοντικές δηλώσεις που καθορίζονται από το όρισμα *flags* χρησιμοποιούνται ανεξάρτητα από αυτές που θα χρησιμοποιούνταν ούτως ή άλλως. Εάν το *dont_inherit* είναι ένα μη μηδενικός ακέραιος, τότε το όρισμα *flags* είναι αυτό – οι σημαίες (μελλοντικές δυνατότητες και επιλογές μεταγλωττιστή) στον περιβάλλοντα κώδικα αγνοούνται.

Οι επιλογές του μεταγλωττιστή και οι μελλοντικές εντολές καθορίζονται από bits που μπορούν να συνδυαστούν κατά bit ORed μαζί για να καθορίσουν πολλές επιλογές. Το πεδίο bit που απαιτείται για το καθορισμό ενός δεδομένου μελλοντικού χαρακτηριστικού μπορεί να βρεθεί ως το χαρακτηριστικό *compiler_flag* στο *_Feature* instance του module *__future__*. *Compiler flags* μπορούν να βρεθούν στο module *ast*, με το πρόθεμα *PyCF_*.

Το όρισμα *optimize* καθορίζει το επίπεδο βελτιστοποίησης του μεταγλωττιστή· η προεπιλεγμένη τιμή -1 επιλέγει το επίπεδο βελτιστοποίησης του διερμηνέα όπως δίνεται από τις επιλογές -O. Τα ρητά επίπεδα είναι 0 (χωρίς βελτιστοποίηση· το *__debug__* είναι αληθές), 1 (οι ισχυρισμοί καταργήθηκαν, το *__debug__* είναι ψευδές) ή 2 (οι συμβολοσειρές εγγραφών καταργήθηκαν επίσης).

Αυτή η συνάρτηση κάνει *raise SyntaxError* εάν ο μεταγλωττισμένος κώδικας είναι άκυρος, και το *ValueError* εάν ο κώδικας περιλαμβάνει null bytes.

Εάν θέλετε να αναλύσετε τον κώδικα Python στην αναπαράσταση του AST, δείτε το *ast.parse()*.

Κάνει *raise* ένα *auditing event* *compile* με ορίσματα *source* και *filename*. Αυτό το συμβάν μπορεί επίσης να προκύψει από έμμεση μεταγλώττιση.

Σημείωση: Κατά τη μεταγλώττιση μιας συμβολοσειράς με κωδικό πολλαπλών γραμμών στη λειτουργία 'single' ή 'eval', η είσοδος πρέπει να τερματίζεται με τουλάχιστον έναν χαρακτήρα νέας γραμμής. Αυτό γίνεται για να διευκολυνθεί ο εντοπισμός μη ολοκληρωμένων και ολοκληρωμένων δηλώσεων στο module *code*.

Προειδοποίηση: Είναι δυνατό να καταρρεύσει ο interpreter της Python με μια αρκετά μεγάλη/σύνθετη συμβολοσειρά κατά τη μεταγλώττιση σε ένα αντικείμενο AST λόγω περιορισμών βάρους στοίβας στον μεταγλωττιστή AST της Python.

Άλλαξε στην έκδοση 3.2: Allowed use of Windows and Mac newlines. Also input in 'exec' mode does not

have to end in a newline anymore. Added the *optimize* parameter.

Άλλαξε στην έκδοση 3.5: Προηγουμένως, το *TypeError* έγινε raise όταν null bytes συναντήθηκαν στο *source*.

Νέο στην έκδοση 3.8: `ast.PyCF_ALLOW_TOP_LEVEL_AWAIT` μπορεί τώρα να μεταβιβαστεί σε σημαίες για να ενεργοποιηθεί η υποστήριξη για `await`, `async for`, και `async with`.

class complex(*[real[, imag]]*)

Return a complex number with the value *real* + *imag**1j or convert a string or number to a complex number. If the first parameter is a string, it will be interpreted as a complex number and the function must be called without a second parameter. The second parameter can never be a string. Each argument may be any numeric type (including complex). If *imag* is omitted, it defaults to zero and the constructor serves as a numeric conversion like *int* and *float*. If both arguments are omitted, returns 0j.

For a general Python object *x*, `complex(x)` delegates to `x.__complex__()`. If `__complex__()` is not defined then it falls back to `__float__()`. If `__float__()` is not defined then it falls back to `__index__()`.

Σημείωση: When converting from a string, the string must not contain whitespace around the central + or - operator. For example, `complex('1+2j')` is fine, but `complex('1 + 2j')` raises *ValueError*.

Ο μιγαδικός τύπος περιγράφεται στο *Αριθμητικοί Τύποι — int, float, complex*.

Άλλαξε στην έκδοση 3.6: Επιτρέπεται η ομαδοποίηση ψηφίων με κάτω παύλες όπως στα literals του κώδικα.

Άλλαξε στην έκδοση 3.8: Falls back to `__index__()` if `__complex__()` and `__float__()` are not defined.

delattr(*object, name*)

This is a relative of `setattr()`. The arguments are an object and a string. The string must be the name of one of the object's attributes. The function deletes the named attribute, provided the object allows it. For example, `delattr(x, 'foobar')` is equivalent to `del x.foobar`.

class dict(***kwarg*)

class dict(*mapping, **kwarg*)

class dict(*iterable, **kwarg*)

Δημιουργεί ένα νέο λεξικό. Το αντικείμενο *dict* είναι η κλάση λεξικού. Δείτε το *dict* και το *Τύποι αντιστοίχισης — dict* για τεκμηρίωση σχετικά με αυτή την κατηγορία.

Για άλλα containers, δείτε τις ενσωματωμένες κλάσεις *list*, *set*, και *tuple*, καθώς και το module *collections*.

dir(*[object]*)

Χωρίς ορίσματα, επιστρέφει τη λίστα ονομάτων στο τρέχον τοπικό πεδίο. Με ένα όρισμα, προσπαθεί να επιστρέψει μια λίστα έγκυρων χαρακτηριστικών για αυτό το αντικείμενο.

If the object has a method named `__dir__()`, this method will be called and must return the list of attributes. This allows objects that implement a custom `__getattr__()` or `__getattribute__()` function to customize the way `dir()` reports their attributes.

If the object does not provide `__dir__()`, the function tries its best to gather information from the object's `__dict__` attribute, if defined, and from its type object. The resulting list is not necessarily complete, and may be inaccurate when the object has a custom `__getattr__()`.

Ο προεπιλεγμένος μηχανισμός `dir()` συμπεριφέρεται διαφορετικά με διαφορετικούς τύπους αντικειμένων, καθώς προσπαθεί να παράγει τις πιο σχετικές και όχι τις πιο ολοκληρωμένες πληροφορίες:

- Εάν το αντικείμενο είναι module τύπου αντικειμένου, η λίστα περιέχει τα ονόματα των χαρακτηριστικών του module.
- Εάν το αντικείμενο είναι ένας τύπος ή κλάση αντικειμένου, η λίστα περιέχει τα ονόματα των χαρακτηριστικών του, και αναδρομικά τα χαρακτηριστικά της βάσεώς του.
- Εναλλακτικά, η λίστα περιέχει τα ονόματα των χαρακτηριστικών του αντικειμένου, τα ονόματα των χαρακτηριστικών της κλάσης, και αναδρομικά τα χαρακτηριστικά της κλάσης βάσεως της κλάσης.

Η παραγόμενη λίστα είναι ταξινομημένη αλφαβητικά. Για παράδειγμα:

```
>>> import struct
>>> dir() # show the names in the module namespace
['__builtins__', '__name__', 'struct']
>>> dir(struct) # show the names in the struct module
['Struct', '__all__', '__builtins__', '__cached__', '__doc__', '__file__',
 '__initializing__', '__loader__', '__name__', '__package__',
 '__clearcache__', 'calcsiz', 'error', 'pack', 'pack_into',
 'unpack', 'unpack_from']
>>> class Shape:
...     def __dir__(self):
...         return ['area', 'perimeter', 'location']
>>> s = Shape()
>>> dir(s)
['area', 'location', 'perimeter']
```

Σημείωση: Επειδή η `dir()` παρέχεται κυρίως ως ευκολία για χρήση σε μια διαδραστική γραμμή εντολών, προσπαθεί να παρέχει ένα ενδιαφέρον σύνολο ονομάτων περισσότερα από οτιδήποτε προσπαθεί να παρέχει ένα αυστηρό ή με συνέπεια, καθορισμένο σύνολο ονομάτων, και η λεπτομερής συμπεριφορά του μπορεί να αλλάξει μεταξύ των εκδόσεων. Για παράδειγμα, τα χαρακτηριστικά μετακλάσης δεν βρίσκονται στη λίστα αποτελεσμάτων όταν το όρισμα είναι μια κλάση.

`divmod(a, b)`

Take two (non complex) numbers as arguments and return a pair of numbers consisting of their quotient and remainder when using integer division. With mixed operand types, the rules for binary arithmetic operators apply. For integers, the result is the same as $(a // b, a \% b)$. For floating point numbers the result is $(q, a \% b)$, where q is usually $\text{math.floor}(a / b)$ but may be 1 less than that. In any case $q * b + a \% b$ is very close to a , if $a \% b$ is non-zero it has the same sign as b , and $0 \leq \text{abs}(a \% b) < \text{abs}(b)$.

`enumerate(iterable, start=0)`

Επιστρέφει ένα αντικείμενο απαρίθμησης. Το *iterable* πρέπει να είναι μια ακολουθία, ένα *iterator*, ή κάποιο άλλο αντικείμενο που υποστηρίζει το iteration. Η μέθοδος `__next__()` του iterator που επιστρέφεται από το `enumerate()` επιστρέφει μια πλειάδα (tuple) που περιέχει μια καταμέτρηση (από το *start* που είναι με προεπιλογή στο 0) και τις τιμές που λαμβάνονται από την επανάληψη πάνω στο *iterable*.

```
>>> seasons = ['Spring', 'Summer', 'Fall', 'Winter']
>>> list(enumerate(seasons))
[(0, 'Spring'), (1, 'Summer'), (2, 'Fall'), (3, 'Winter')]
>>> list(enumerate(seasons, start=1))
[(1, 'Spring'), (2, 'Summer'), (3, 'Fall'), (4, 'Winter')]
```

Ισοδύναμο με:

```
def enumerate(sequence, start=0):
    n = start
    for elem in sequence:
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
yield n, elem
n += 1
```

eval (*expression* [, *globals* [, *locals*]])

The arguments are a string and optional globals and locals. If provided, *globals* must be a dictionary. If provided, *locals* can be any mapping object.

The *expression* argument is parsed and evaluated as a Python expression (technically speaking, a condition list) using the *globals* and *locals* dictionaries as global and local namespace. If the *globals* dictionary is present and does not contain a value for the key `__builtins__`, a reference to the dictionary of the built-in module *builtins* is inserted under that key before *expression* is parsed. This means that *expression* normally has full access to the standard *builtins* module and restricted environments are propagated. If the *locals* dictionary is omitted it defaults to the *globals* dictionary. If both dictionaries are omitted, the expression is executed with the *globals* and *locals* in the environment where *eval()* is called. Note, *eval()* does not have access to the *nested scopes* (non-locals) in the enclosing environment.

The return value is the result of the evaluated expression. Syntax errors are reported as exceptions. Example:

```
>>> x = 1
>>> eval('x+1')
2
```

This function can also be used to execute arbitrary code objects (such as those created by *compile()*). In this case pass a code object instead of a string. If the code object has been compiled with 'exec' as the *mode* argument, *eval()*'s return value will be None.

Hints: dynamic execution of statements is supported by the *exec()* function. The *globals()* and *locals()* functions returns the current global and local dictionary, respectively, which may be useful to pass around for use by *eval()* or *exec()*.

Βλ. τη *ast.literal_eval()* για μια συνάρτηση που μπορεί με ασφάλεια να αξιολογήσει τις συμβολοσειρές με εκφράσεις που περιέχουν μόνο literals.

Κάνει raise ένα *auditing event* *exec* με το αντικείμενο κώδικα ως όρισμα. Μπορεί επίσης να εμφανιστούν συμβάντα μεταγλώττισης κώδικα.

exec (*object* [, *globals* [, *locals*]])

Αυτή η συνάρτηση υποστηρίζει δυναμική εκτέλεση κώδικα Python. Το *object* πρέπει να είναι είτε μια συμβολοσειρά (string) είτε ένα αντικείμενο κώδικα. Εάν είναι μια συμβολοσειρά, η συμβολοσειρά αναλύεται ως μια σούιτα δηλώσεων Python που στη συνέχεια εκτελείται (εκτός εάν παρουσιαστεί σφάλμα σύνταξης).¹ Εάν πρόκειται για ένα αντικείμενο κώδικα, απλά εκτελείται. Σε όλες τις περιπτώσεις, ο κώδικας που εκτελείται αναμένεται να είναι έγκυρος ως είσοδος αρχείου (δείτε την ενότητα file-input στο Εγχειρίδιο Αναφοράς). Λάβετε υπόψη ότι οι εντολές *nonlocal*, *yield*, και *return* δεν μπορούν να χρησιμοποιηθούν εκτός των ορισμών συναρτήσεων, ακόμη και στο πλαίσιο του κώδικα που διαβιβάζεται στη *exec()*. Η επιστρεφόμενη τιμή είναι None.

In all cases, if the optional parts are omitted, the code is executed in the current scope. If only *globals* is provided, it must be a dictionary (and not a subclass of dictionary), which will be used for both the global and the local variables. If *globals* and *locals* are given, they are used for the global and local variables, respectively. If provided, *locals* can be any mapping object. Remember that at module level, *globals* and *locals* are the same dictionary. If *exec* gets two separate objects as *globals* and *locals*, the code will be executed as if it were embedded in a class definition.

Εάν το λεξικό *globals* δεν περιέχει τιμή για το κλειδί `__builtins__`, μια αναφορά στο λεξικό του ενσωματωμένου module *builtins* εισάγεται κάτω από αυτό το κλειδί. Με αυτόν τον τρόπο μπορεί να

¹ Λάβετε υπόψη ότι ο αναλυτής δέχεται μόνο τη σύμβαση τέλους γραμμής τύπου Unix. Εάν διαβάσετε τον κώδικα από ένα αρχείο βεβαιωθείτε ότι χρησιμοποιείτε την λειτουργία μετατροπής νέας γραμμής για την μετατροπή νέων γραμμών σε styl Windows ή Mac.

ελέγξετε τι ενσωματωμένα (built-ins) είναι διαθέσιμα στον εκτελέσιμο κώδικα εισάγοντας το δικό σας `__builtins__` λεξικό στο `globals` πριν το διαβάσετε στο `exec()`.

Κάνει `raise` ένα *auditing event* `exec` με το αντικείμενο κώδικα ως όρισμα. Μπορεί επίσης να εμφανιστούν συμβάντα μεταγλώττισης κώδικα.

Σημείωση: Οι ενσωματωμένες συναρτήσεις `globals()` και `locals()` επιστρέφουν το τρέχον global και local λεξικό, αντίστοιχα, που μπορεί να είναι χρήσιμο για χρήση ως δεύτερο και τρίτο όρισμα στο `exec()`.

Σημείωση: Το προεπιλεγμένο `locals` ενεργεί όπως περιγράφεται για τη συνάρτηση `locals()` παρακάτω: δεν πρέπει να επιχειρήσετε τροποποιήσεις στο προεπιλεγμένο `locals` λεξικό. Περνάει ένα ρητό `locals` λεξικό εάν θέλετε να δείτε τα αποτελέσματα του κώδικα στο `locals` με την επιστροφή της συνάρτησης `exec()`.

filter (*function, iterable*)

Construct an iterator from those elements of *iterable* for which *function* returns true. *iterable* may be either a sequence, a container which supports iteration, or an iterator. If *function* is `None`, the identity function is assumed, that is, all elements of *iterable* that are false are removed.

Λάβετε υπόψη ότι το `filter(function, iterable)` είναι ισοδύναμο με την έκφραση της γεννήτριας `(item for item in iterable if function(item))` εάν η συνάρτηση δεν είναι `None` και `(item for item in iterable if item)` εάν η συνάρτηση είναι `None`.

See `itertools.filterfalse()` for the complementary function that returns elements of *iterable* for which *function* returns false.

class float (`[x]`)

Return a floating point number constructed from a number or string *x*.

If the argument is a string, it should contain a decimal number, optionally preceded by a sign, and optionally embedded in whitespace. The optional sign may be '+' or '-'; a '+' sign has no effect on the value produced. The argument may also be a string representing a NaN (not-a-number), or a positive or negative infinity. More precisely, the input must conform to the following grammar after leading and trailing whitespace characters are removed:

```
sign          ::= "+" | "-"
infinity      ::= "Infinity" | "inf"
nan           ::= "nan"
numeric_value ::= floatnumber | infinity | nan
numeric_string ::= [sign] numeric_value
```

Here `floatnumber` is the form of a Python floating-point literal, described in `floating`. Case is not significant, so, for example, «inf», «Inf», «INFINITY» and «iNfINity» are all acceptable spellings for positive infinity.

Otherwise, if the argument is an integer or a floating point number, a floating point number with the same value (within Python's floating point precision) is returned. If the argument is outside the range of a Python float, an `OverflowError` will be raised.

For a general Python object *x*, `float(x)` delegates to `x.__float__()`. If `__float__()` is not defined then it falls back to `__index__()`.

Εάν δεν δοθεί όρισμα, επιστρέφεται το `0.0`.

Examples:

```
>>> float('+1.23')
1.23
>>> float('  -12345\n')
-12345.0
>>> float('1e-003')
0.001
>>> float('+1E6')
1000000.0
>>> float('-Infinity')
-inf
```

Ο τύπος float περιγράφεται στο *Αριθμητικοί Τύποι — int, float, complex*.

Άλλαξε στην έκδοση 3.6: Επιτρέπεται η ομαδοποίηση ψηφίων με κάτω παύλες όπως στα literals του κώδικα.

Άλλαξε στην έκδοση 3.7: *x* is now a positional-only parameter.

Άλλαξε στην έκδοση 3.8: Falls back to `__index__()` if `__float__()` is not defined.

format (*value* [, *format_spec*])

Convert a *value* to a «formatted» representation, as controlled by *format_spec*. The interpretation of *format_spec* will depend on the type of the *value* argument, however there is a standard formatting syntax that is used by most built-in types: *Format Specification Mini-Language*.

Η προεπιλεγμένη *format_spec* είναι μια κενή συμβολοσειρά που συνήθως δίνει το ίδιο αποτέλεσμα με την κλήση του `str(value)`.

A call to `format(value, format_spec)` is translated to `type(value).__format__(value, format_spec)` which bypasses the instance dictionary when searching for the value's `__format__()` method. A `TypeError` exception is raised if the method search reaches *object* and the *format_spec* is non-empty, or if either the *format_spec* or the return value are not strings.

Άλλαξε στην έκδοση 3.4: Το `object().__format__(format_spec)` κάνει raise το `TypeError` εάν το *format_spec* δεν είναι κενή συμβολοσειρά.

class frozenset ([*iterable*])

Επιστρέφει ένα νέο αντικείμενο *frozenset*, προαιρετικά με στοιχεία που λαμβάνονται από το *iterable*. Το *frozenset* είναι μια ενσωματωμένη κλάση. Δείτε το *frozenset* και το *Τύποι Συνόλου (Set) — set, frozenset* για τεκμηρίωση αυτής της κλάσης.

Για άλλα containers, ανατρέξτε στις ενσωματωμένες κλάσεις *set*, *list*, *tuple*, και *dict*, καθώς και το module *collections*.

getattr (*object*, *name* [, *default*])

Return the value of the named attribute of *object*. *name* must be a string. If the string is the name of one of the object's attributes, the result is the value of that attribute. For example, `getattr(x, 'foobar')` is equivalent to `x.foobar`. If the named attribute does not exist, *default* is returned if provided, otherwise `AttributeError` is raised.

Σημείωση: Δεδομένου ότι το private name mangling συμβαίνει κατά τη στιγμή της μεταγλώττισης, πρέπει κανείς να παραμορφώνει χειροκίνητα το όνομα ενός ιδιωτικού χαρακτηριστικού (χαρακτηριστικά με δύο κορυφαίες υπογραμμίσεις) για να ανακτήσει με `getattr()`.

globals ()

Επιστρέφει το λεξικό που υλοποιεί τον τρέχοντα χώρο ονομάτων του module. Για κώδικα εντός συναρτήσεων, αυτό ορίζεται όταν ορίζεται η συνάρτηση και παραμένει το ίδιο ανεξάρτητη από το που καλείται η συνάρτηση.

hasattr (*object*, *name*)

Τα ορίσματα είναι ένα αντικείμενο και μια συμβολοσειρά (string). Το αποτέλεσμα είναι `True` εάν η συμβολοσειρά είναι το όνομα ενός από τα χαρακτηριστικά του αντικειμένου, `False` εάν όχι. (Αυτό υλοποιείται καλώντας το `getattr(object, name)` και να δούμε αν γίνεται `raise` ένα `AttributeError` ή όχι.)

hash (*object*)

Επιστρέφει την τιμή κατακερματισμού του αντικειμένου (αν έχει). Οι τιμές κατακερματισμού είναι ακέραιοι. Χρησιμοποιούνται για τη γρήγορη σύγκριση των κλειδιών του λεξικού κατά τη διάρκεια μιας αναζήτησης λεξικού. Οι αριθμητικές τιμές που συγκρίνονται ίσες έχουν την ίδια τιμή κατακερματισμού (ακόμα και αν είναι διαφορετικοί τύποι, όπως συμβαίνει για τα 1 και 1.0).

Σημείωση: For objects with custom `__hash__()` methods, note that `hash()` truncates the return value based on the bit width of the host machine. See `__hash__()` for details.

help ([*object*])

Καλείται το ενσωματωμένο (built-in) σύστημα βοήθειας. (Αυτή η συνάρτηση προορίζεται για διαδραστική χρήση.) Εάν δεν δοθεί όρισμα, το διαδραστικό σύστημα βοήθειας ξεκινά την κονσόλα του interpreter. Εάν το όρισμα είναι μια συμβολοσειρά, τότε η συμβολοσειρά αναζητείται ως όνομα ενός module, μιας συνάρτησης, μια κλάσης μιας μεθόδου, μιας λέξης κλειδιού ή θέματος τεκμηρίωσης και μια σελίδα βοήθειας εκτυπώνεται στην κονσόλα. Εάν το όρισμα είναι οποιοδήποτε άλλο είδος αντικειμένου, δημιουργείται μια σελίδα βοήθειας στο αντικείμενο.

Note that if a slash(/) appears in the parameter list of a function, when invoking `help()`, it means that the parameters prior to the slash are positional-only. For more info, see the FAQ entry on positional-only parameters.

Αυτή η συνάρτηση προστίθεται στον ενσωματωμένο χώρο ονομάτων από το module `site`.

Άλλαξε στην έκδοση 3.4: Οι αλλαγές σε `pydoc` και `inspect` σημαίνουν ότι οι αναφερόμενες υπογραφές για callables είναι πλέον πιο ολοκληρωμένες και συνεπείς.

hex (*x*)

Convert an integer number to a lowercase hexadecimal string prefixed with «0x». If *x* is not a Python `int` object, it has to define an `__index__()` method that returns an integer. Some examples:

```
>>> hex(255)
'0xff'
>>> hex(-42)
'-0x2a'
```

Εάν θέλετε να μετατρέψετε έναν ακέραιο αριθμό σε μια κεφαλαία ή πεζή δεκαεξαδική συμβολοσειρά (string) με πρόθεμα ή όχι, μπορείτε να χρησιμοποιήσετε έναν από τους παρακάτω τρόπους:

```
>>> '%#x' % 255, '%x' % 255, '%X' % 255
('0xff', 'ff', 'FF')
>>> format(255, '#x'), format(255, 'x'), format(255, 'X')
('0xff', 'ff', 'FF')
>>> f'{255:#x}', f'{255:x}', f'{255:X}'
('0xff', 'ff', 'FF')
```

Δείτε επίσης τη `format()` για περισσότερες πληροφορίες.

Δείτε επίσης τη `int()` για τη μετατροπή μιας δεκαεξαδικής συμβολοσειράς σε ακέραιο χρησιμοποιώντας μια βάση του 16.

Σημείωση: Για να αποκτήσετε μια αναπαράσταση δεκαεξαδικής συμβολοσειράς για ένα float, χρησιμοποιήστε τη μέθοδο `float.hex()`.

id (*object*)

Επιστρέφει την «ταυτότητα» ενός αντικειμένου. Αυτό είναι ένα ακέραιος αριθμός που εγγυάται ότι είναι μοναδικός και σταθερός για αυτό το αντικείμενο κατά τη διάρκεια της ζωής του. Δύο αντικείμενα με μη επικαλυπτόμενες διάρκειες ζωής μπορεί να έχουν την ίδια τιμή `id()`.

CPython implementation detail: This is the address of the object in memory.

Εγείρει ένα [auditing event](#) `builtins.id` με όρισμα `id`.

input (*[prompt]*)

Εάν υπάρχει το όρισμα *prompt*, γράφεται στην τυπική έξοδο χωρίς μια νέα γραμμή μετάδοσης. Στη συνέχεια, η συνάρτηση διαβάζει μια γραμμή από την είσοδο, τη μετατρέπει σε μια συμβολοσειρά (με την αφαίρεση μιας νέας γραμμής) και την επιστρέφει. Όταν διαβάζεται το EOF, γίνεται `raise EOFError`. Παράδειγμα:

```
>>> s = input('--> ')
--> Monty Python's Flying Circus
>>> s
"Monty Python's Flying Circus"
```

Εάν έχει φορτωθεί το module [readline](#), τότε η `input()` θα το χρησιμοποιήσει για να παρέχει περίπλοκες λειτουργίες επεξεργασίας γραμμής και ιστορικού.

Κάνει `raise` ένα [auditing event](#) `builtins.input` με όρισμα `prompt` προτού διαβάσει την είσοδο

Raises an auditing event `builtins.input/result` with the result after successfully reading input.

class int (*[x]*)**class int** (*x*, *base=10*)

Return an integer object constructed from a number or string *x*, or return 0 if no arguments are given. If *x* defines `__int__()`, `int(x)` returns `x.__int__()`. If *x* defines `__index__()`, it returns `x.__index__()`. If *x* defines `__trunc__()`, it returns `x.__trunc__()`. For floating point numbers, this truncates towards zero.

If *x* is not a number or if *base* is given, then *x* must be a string, [bytes](#), or [bytearray](#) instance representing an integer literal in radix *base*. Optionally, the literal can be preceded by + or - (with no space in between) and surrounded by whitespace. A base-*n* literal consists of the digits 0 to *n*-1, with a to z (or A to Z) having values 10 to 35. The default *base* is 10. The allowed values are 0 and 2–36. Base-2, -8, and -16 literals can be optionally prefixed with `0b/0B`, `0o/0O`, or `0x/0X`, as with integer literals in code. Base 0 means to interpret exactly as a code literal, so that the actual base is 2, 8, 10, or 16, and so that `int('010', 0)` is not legal, while `int('010')` is, as well as `int('010', 8)`.

Ο ακέραιος τύπος περιγράφεται στο [Αριθμητικοί Τύποι — int, float, complex](#).

Αλλάξε στην έκδοση 3.4: Εάν το *base* δεν είναι ένα instance της `int` και το *base* αντικείμενο έχει μια μέθοδο `base.__index__`, αυτή η μέθοδος καλείται για να αποκτήσει τον ακέραιο της βάσης. Προηγούμενες εκδόσεις χρησιμοποιούσαν την `base.__int__` αντί της `base.__index__`.

Αλλάξε στην έκδοση 3.6: Επιτρέπεται η ομαδοποίηση ψηφίων με κάτω παύλες όπως στα literals του κώδικα.

Αλλάξε στην έκδοση 3.7: *x* is now a positional-only parameter.

Αλλάξε στην έκδοση 3.8: Falls back to `__index__()` if `__int__()` is not defined.

Αλλάξε στην έκδοση 3.9.14: `int` string inputs and string representations can be limited to help avoid denial of service attacks. A `ValueError` is raised when the limit is exceeded while converting a string *x* to an `int` or when converting an `int` into a string would exceed the limit. See the [integer string conversion length limitation](#) documentation.

isinstance (*object*, *classinfo*)

Return True if the *object* argument is an instance of the *classinfo* argument, or of a (direct, indirect or *virtual*)

subclass thereof. If *object* is not an object of the given type, the function always returns `False`. If *classinfo* is a tuple of type objects (or recursively, other such tuples), return `True` if *object* is an instance of any of the types. If *classinfo* is not a type or tuple of types and such tuples, a `TypeError` exception is raised.

issubclass (*class*, *classinfo*)

Return `True` if *class* is a subclass (direct, indirect or *virtual*) of *classinfo*. A class is considered a subclass of itself. *classinfo* may be a tuple of class objects (or recursively, other such tuples), in which case return `True` if *class* is a subclass of any entry in *classinfo*. In any other case, a `TypeError` exception is raised.

iter (*object* [, *sentinel*])

Return an *iterator* object. The first argument is interpreted very differently depending on the presence of the second argument. Without a second argument, *object* must be a collection object which supports the iteration protocol (the `__iter__()` method), or it must support the sequence protocol (the `__getitem__()` method with integer arguments starting at 0). If it does not support either of those protocols, `TypeError` is raised. If the second argument, *sentinel*, is given, then *object* must be a callable object. The iterator created in this case will call *object* with no arguments for each call to its `__next__()` method; if the value returned is equal to *sentinel*, `StopIteration` will be raised, otherwise the value will be returned.

Δείτε επίσης *Τύποι Iterator*.

Μια χρήσιμη εφαρμογή της δεύτερης μορφής του `iter()` είναι η κατασκευή ενός block-reader. Για παράδειγμα, η ανάγνωση μπλοκ σταθερού πλάτους από ένα δυαδικό αρχείο βάσης δεδομένων μέχρι να φτάσει στο τέλος του αρχείου:

```
from functools import partial
with open('mydata.db', 'rb') as f:
    for block in iter(partial(f.read, 64), b''):
```

len (*s*)

Επιστρέφει το μήκος (τον αριθμό των ειδών-περιεχομένων) ενός αντικειμένου. Το όρισμα μπορεί να είναι μια ακολουθία (όπως μια συμβολοσειρά, bytes, πλειάδα, λίστα, ή εύρος) ή μια συλλογή (όπως ένα λεξικό, ένα σετ, ή ένα παγωμένο σετ).

CPython implementation detail: Το `len` κάνει raise μια `OverflowError` σε μήκη τα οποία είναι μεγαλύτερα από `sys.maxsize`, όπως `range(2 ** 100)`.

class list ([*iterable*])

Αντί να είναι συνάρτηση, το `list` είναι στην πραγματικότητα ένας μεταβλητός τύπος ακολουθίας, όπως τεκμηριώνεται στα *Λίστες* και *Τύποι Ακολουθίας (Sequence)* — *list*, *tuple*, *range*.

locals ()

Ενημέρωση και επιστροφή ενός λεξικού που αντιπροσωπεύει τον τρέχοντα πίνακα τοπικών συμβόλων. Οι ελεύθερες μεταβλητές επιστρέφονται από `locals()` όταν καλείται σε μπλοκ συναρτήσεων, αλλά όχι σε μπλοκ κλάσεων. Σημειώστε ότι σε επίπεδο module, οι `locals()` και `globals()` είναι το ίδιο λεξικό.

Σημείωση: Τα περιεχόμενα αυτού του λεξικού δεν πρέπει να τροποποιηθούν• οι αλλαγές ενδέχεται να μην επηρεάσουν τις τιμές των τοπικών και ελεύθερων μεταβλητών που χρησιμοποιούνται από τον διερμηνέα.

map (*function*, *iterable*, ...)

Return an iterator that applies *function* to every item of *iterable*, yielding the results. If additional *iterable* arguments are passed, *function* must take that many arguments and is applied to the items from all iterables in parallel. With multiple iterables, the iterator stops when the shortest iterable is exhausted. For cases where the function inputs are already arranged into argument tuples, see `itertools.starmap()`.

max (*iterable*, *[, *key*, *default*])

max (*arg1*, *arg2*, **args*[, *key*])

Επιστρέφει το μεγαλύτερο στοιχείο σε ένα iterable ή το μεγαλύτερο από δύο ή περισσότερα ορίσματα.

Εάν παρέχεται ένα όρισμα θέσης, θα πρέπει να είναι ένα *iterable*. Επιστρέφεται το μεγαλύτερο στοιχείο στο iterable. Εάν παρέχονται δύο ή περισσότερα ορίσματα θέσης, επιστρέφεται το μεγαλύτερο από τα ορίσματα θέσης.

Υπάρχουν δύο προαιρετικά ορίσματα τύπου λέξη-κλειδί. Το όρισμα *key* καθορίζει μια συνάρτηση ταξινόμησης ενός ορίσματος όπως αυτή χρησιμοποιείται για το `list.sort()`. Το όρισμα *default* καθορίζει ένα αντικείμενο που θα επιστρέψει εάν το iterable που παρέχεται είναι κενό. Εάν το iterable είναι κενό και το *default* δεν παρέχεται, γίνεται raise μια *ValueError*.

Εάν πολλά στοιχεία είναι μέγιστα, η συνάρτηση επιστρέφει το πρώτο που συναντήθηκε. Αυτό είναι σύμφωνο με άλλα εργαλεία διατήρησης σταθερότητας ταξινόμησης όπως `sorted(iterable, key=keyfunc, reverse=True)[0]` και `heapq.nlargest(1, iterable, key=keyfunc)`.

Νέο στην έκδοση 3.4: The *default* keyword-only argument.

Άλλαξε στην έκδοση 3.8: Το *key* μπορεί να είναι None.

class memoryview (*object*)

Επιστρέφει ένα αντικείμενο «memory view» που δημιουργήθηκε από το συγκεκριμένο όρισμα. Βλέπε *Όψεις Μνήμης* για περισσότερες λεπτομέρειες.

min (*iterable*, *[, *key*, *default*])

min (*arg1*, *arg2*, **args*[, *key*])

Επιστρέφει το μικρότερο στοιχείο σε έναν iterable ή το μικρότερο από δύο ή περισσότερα ορίσματα.

Εάν παρέχεται ένα όρισμα θέσης, θα πρέπει να είναι ένα *iterable*. Επιστρέφει το μικρότερο στοιχείο στον iterable. Εάν παρέχονται δύο ή περισσότερα ορίσματα θέσης, επιστρέφεται το μικρότερο από τα ορίσματα θέσης.

Υπάρχουν δύο προαιρετικά ορίσματα τύπου λέξη-κλειδί. Το όρισμα *key* καθορίζει μια συνάρτηση ταξινόμησης ενός ορίσματος όπως αυτή χρησιμοποιείται για το `list.sort()`. Το όρισμα *default* καθορίζει ένα αντικείμενο που θα επιστρέψει εάν το iterable που παρέχεται είναι κενό. Εάν το iterable είναι κενό και το *default* δεν παρέχεται, γίνεται raise μια *ValueError*.

Εάν πολλά στοιχεία είναι ελάχιστα, η συνάρτηση επιστρέφει το πρώτο που συναντήθηκε. Αυτό είναι σύμφωνο με άλλα εργαλεία διατήρησης σταθερότητας ταξινόμησης, όπως `sorted(iterable, key=keyfunc)[0]` και `heapq.nsmallest(1, iterable, key=keyfunc)`.

Νέο στην έκδοση 3.4: The *default* keyword-only argument.

Άλλαξε στην έκδοση 3.8: Το *key* μπορεί να είναι None.

next (*iterator*[, *default*])

Retrieve the next item from the *iterator* by calling its `__next__()` method. If *default* is given, it is returned if the iterator is exhausted, otherwise *StopIteration* is raised.

class object

Return a new featureless object. *object* is a base for all classes. It has the methods that are common to all instances of Python classes. This function does not accept any arguments.

Σημείωση: *object* does not have a `__dict__`, so you can't assign arbitrary attributes to an instance of the *object* class.

oct (*x*)

Convert an integer number to an octal string prefixed with «0o». The result is a valid Python expression. If *x* is not a Python *int* object, it has to define an `__index__()` method that returns an integer. For example:

```
>>> oct(8)
'0o10'
>>> oct(-56)
'-0o70'
```

If you want to convert an integer number to octal string either with prefix «0o» or not, you can use either of the following ways.

```
>>> '%#o' % 10, '%o' % 10
('0o12', '12')
>>> format(10, '#o'), format(10, 'o')
('0o12', '12')
>>> f'{10:#o}', f'{10:o}'
('0o12', '12')
```

Δείτε επίσης τη `format()` για περισσότερες πληροφορίες.

open (*file*, *mode*='r', *buffering*=-1, *encoding*=None, *errors*=None, *newline*=None, *closefd*=True, *opener*=None)

Ανοίγει το *file* και επιστρέφει ένα αντίστοιχο *file object*. Εάν το αρχείο δεν μπορεί να ανοίξει, γίνεται *raise* μια *OSError*. Δείτε το `tut-files` για περισσότερα παραδείγματα χρήσης αυτής της συνάρτησης.

file is a *path-like object* giving the pathname (absolute or relative to the current working directory) of the file to be opened or an integer file descriptor of the file to be wrapped. (If a file descriptor is given, it is closed when the returned I/O object is closed, unless *closefd* is set to `False`.)

mode is an optional string that specifies the mode in which the file is opened. It defaults to 'r' which means open for reading in text mode. Other common values are 'w' for writing (truncating the file if it already exists), 'x' for exclusive creation and 'a' for appending (which on *some* Unix systems, means that *all* writes append to the end of the file regardless of the current seek position). In text mode, if *encoding* is not specified the encoding used is platform dependent: `locale.getpreferredencoding(False)` is called to get the current locale encoding. (For reading and writing raw bytes use binary mode and leave *encoding* unspecified.) The available modes are:

| Χαρακτήρας | Έννοια |
|------------|---|
| 'r' | άνοιγμα για ανάγνωση (default) |
| 'w' | άνοιγμα για εγγραφή, περικλύποντας πρώτα το αρχείο |
| 'x' | άνοιγμα για αποκλειστική δημιουργία, αποτυγχάνοντας εάν το αρχείο υπάρχει ήδη |
| 'a' | open for writing, appending to the end of the file if it exists |
| 'b' | δυναμική (binary) λειτουργία |
| 't' | λειτουργία κειμένου (default) |
| '+' | άνοιγμα για ενημέρωση (ανάγνωση και εγγραφή) |

The default mode is 'r' (open for reading text, synonym of 'rt'). Modes 'w+' and 'w+b' open and truncate the file. Modes 'r+' and 'r+b' open the file with no truncation.

Όπως αναφέρεται στο *Overview*, η Python κάνει διάκριση μεταξύ δυαδικού και κειμένου I/O. Τα αρχεία που ανοίγουν σε δυαδική λειτουργία (συμπεριλαμβανομένου του 'b' στο όρισμα *mode*) επιστρέφουν τα περιεχόμενα ως *bytes* αντικείμενα χωρίς αποκωδικοποίηση. Στη λειτουργία κειμένου (η προεπιλογή, ή όταν το 't' περιλαμβάνεται στο όρισμα *mode*), τα περιεχόμενα του αρχείου επιστρέφονται ως *str*, τα bytes έχουν πρώτα αποκωδικοποιηθεί χρησιμοποιώντας μια εξαρτώμενη από πλατφόρμα κωδικοποίηση ή χρήση της καθορισμένης *κωδικοποίησης* εάν δίνεται.

There is an additional mode character permitted, 'U', which no longer has any effect, and is considered deprecated. It previously enabled *universal newlines* in text mode, which became the default behaviour in Python 3.0. Refer to the documentation of the *newline* parameter for further details.

Σημείωση: Η Python δεν εξαρτάται από την έννοια των αρχείων κειμένου του υποκείμενου λειτουργικού συστήματος· όλη η επεξεργασία γίνεται από την ίδια την Python και επομένως είναι ανεξάρτητη από την πλατφόρμα.

buffering is an optional integer used to set the buffering policy. Pass 0 to switch buffering off (only allowed in binary mode), 1 to select line buffering (only usable in text mode), and an integer > 1 to indicate the size in bytes of a fixed-size chunk buffer. Note that specifying a buffer size this way applies for binary buffered I/O, but `TextIOWrapper` (i.e., files opened with `mode='r+'`) would have another buffering. To disable buffering in `TextIOWrapper`, consider using the `write_through` flag for `io.TextIOWrapper.reconfigure()`. When no *buffering* argument is given, the default buffering policy works as follows:

- Binary files are buffered in fixed-size chunks; the size of the buffer is chosen using a heuristic trying to determine the underlying device's «block size» and falling back on `io.DEFAULT_BUFFER_SIZE`. On many systems, the buffer will typically be 4096 or 8192 bytes long.
- «Interactive» αρχεία κειμένου (αρχεία για τα οποία το `isatty()` επιστρέφει `True`) χρησιμοποιούν αποθήκευση γραμμής. Άλλα αρχεία κειμένου χρησιμοποιούν την πολιτική που περιγράφεται παραπάνω για δυαδικά αρχεία.

encoding is the name of the encoding used to decode or encode the file. This should only be used in text mode. The default encoding is platform dependent (whatever `locale.getpreferredencoding()` returns), but any *text encoding* supported by Python can be used. See the `codecs` module for the list of supported encodings.

Το *errors* είναι μια προαιρετική συμβολοσειρά που καθορίζει τον τρόπο χειρισμού των σφαλμάτων κωδικοποίησης και αποκωδικοποίησης-αυτό δεν μπορεί να χρησιμοποιηθεί σε δυαδική λειτουργία. Διατίθεται μια ποικιλία τυπικών εργαλείων χειρισμού σφαλμάτων (παρατίθενται στην ενότητα [Error Handlers](#)), αν και οποιοδήποτε όνομα χειρισμού σφαλμάτων έχει καταχωρηθεί με το `codecs.register_error()` είναι επίσης έγκυρο. Τα τυπικά ονόματα περιλαμβάνουν:

- Το `'strict'` κάνει `raise` μια εξαίρεση `ValueError` εάν υπάρχει σφάλμα κωδικοποίησης. Η προεπιλεγμένη τιμή του `None` έχει το ίδιο αποτέλεσμα.
- Το `'ignore'` αγνοεί τα σφάλματα. Σημειώστε ότι η παράβλεψη σφαλμάτων κωδικοποίησης μπορεί να οδηγήσει σε απώλεια δεδομένων.
- Το `'replace'` προκαλεί την εισαγωγή ενός δείκτη αντικατάστασης (όπως `'?'`) όταν υπάρχουν δεδομένα με λανθασμένη μορφή.
- Το `'surrogateescape'` θα αντιπροσωπεύει τυχόν λανθασμένα bytes ως μονάδες χαμηλού υποκατάστατου κωδικού που κυμαίνονται από `U+DC80` έως `U+DCFF`. Αυτές οι μονάδες υποκατάστατου κωδικού θα μετατραπούν στη συνέχεια στα ίδια bytes όταν ο χειριστής σφαλμάτων `surrogateescape` χρησιμοποιείται κατά την εγγραφή δεδομένων. Αυτό είναι χρήσιμο για την επεξεργασία αρχείων σε άγνωστη κωδικοποίηση.
- `'xmlcharrefreplace'` is only supported when writing to a file. Characters not supported by the encoding are replaced with the appropriate XML character reference `&#nnn;`.
- Το `'backslashreplace'` αντικαθιστά δεδομένα με λανθασμένη μορφή από τις ακολουθίες διαφυγής με αναστροφής καθέτου Python.
- Το `'namereplace'` (υποστηρίζεται επίσης μόνο κατά τη σύνταξη) αντικαθιστά τους μη υποστηριζόμενους χαρακτήρες με ακολουθίες διαφυγής `\N{...}`.

newline controls how *universal newlines* mode works (it only applies to text mode). It can be `None`, `' '`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows:

- Κατά την ανάγνωση εισόδου από την ροή, εάν το *newline* είναι `None`, η καθολική λειτουργία νέων γραμμών είναι ενεργοποιημένη. Οι γραμμές στην είσοδο μπορούν να τελειώνουν σε `'\n'`, `'\r'`, ή

'\r\n', και αυτά μεταφράζονται σε '\n' πριν επιστραφούν στον καλούντα. Εάν είναι ' ', η καθολική λειτουργία νέων γραμμών είναι ενεργοποιημένη, αλλά οι κατάληξεις γραμμών επιστρέφονται στον καλούντα αμετάφραστα. Εάν έχει κάποια από τις άλλες νόμιμες τιμές, οι γραμμές εισόδου τερματίζονται μόνο από τη δεδομένη συμβολοσειρά και η κατάληξη γραμμής επιστρέφεται στον καλούντα αμετάφραστη.

- Κατά την εγγραφή εξόδου στη ροή, εάν το *newline* είναι *None*, τυχόν χαρακτήρες '\n' μεταφράζονται στο διαχωριστικό προεπιλεγμένων γραμμών του συστήματος, *os.linesep*. Εάν το *newline* είναι ' ' ή '\n', δεν πραγματοποιείται μετάφραση εάν το *newline* είναι οποιαδήποτε από τις άλλες νόμιμες τιμές, γράφονται οποιοιδήποτε χαρακτήρες '\n' μεταφράζονται στη δεδομένη συμβολοσειρά.

If *closefd* is *False* and a file descriptor rather than a filename was given, the underlying file descriptor will be kept open when the file is closed. If a filename is given *closefd* must be *True* (the default) otherwise an error will be raised.

Ένα προσαρμοσμένο πρόγραμμα ανοίγματος μπορεί να χρησιμοποιηθεί μεταβιβάζοντας ένα callable ως *opener*. Ο υποκείμενος περιγραφέας αρχείου για το αντικείμενο αρχείου λαμβάνεται στη συνέχεια καλώντας το *opener* με (*file*, *flags*). Το *opener* πρέπει να επιστρέψει ένα περιγραφέα ανοιχτού αρχείου (περνώντας *os.open* ως *opener* έχει ως αποτέλεσμα λειτουργικότητας παρόμοια με το να περάσουμε το *None*).

Το νέο δημιουργημένο αρχείο είναι *non-inheritable*.

Το παρακάτω παράδειγμα χρησιμοποιεί την παράμετρο *dir_fd* της συνάρτησης *os.open()* για να ανοίξει ένα αρχείο σε σχέση με έναν δεδομένο κατάλογο:

```
>>> import os
>>> dir_fd = os.open('somedir', os.O_RDONLY)
>>> def opener(path, flags):
...     return os.open(path, flags, dir_fd=dir_fd)
...
>>> with open('spamspam.txt', 'w', opener=opener) as f:
...     print('This will be written to somedir/spamspam.txt', file=f)
...
>>> os.close(dir_fd) # don't leak a file descriptor
```

Ο τύπος του *file object* που επιστρέφεται από τη συνάρτηση *open()* εξαρτάται από τη λειτουργία. Όταν το *open()* χρησιμοποιείται για το άνοιγμα ενός αρχείου σε λειτουργία κειμένου ('w', 'r', 'wt', 'rt', κ.λπ.), επιστρέφει μια υποκλάση του *io.TextIOBase* (specifically *io.TextIOWrapper*). Όταν χρησιμοποιείται για το άνοιγμα ενός αρχείου σε δυαδική λειτουργία με προσωρινή αποθήκευση, η κλάση που επιστρέφεται είναι μια υποκλάση του *io.BufferedIOBase*. Η ακριβής κλάση ποικίλλει: σε λειτουργία δυαδικής ανάγνωσης, επιστρέφει ένα *io.BufferedReader* • σε δυαδικές καταστάσεις εγγραφής και δυαδικής προσθήκης, επιστρέφει ένα *io.BufferedWriter*, και στη λειτουργία ανάγνωσης/εγγραφής, επιστρέφει ένα *io.BufferedRandom*. Όταν η προσωρινή αποθήκευση είναι απενεργοποιημένη, επιστρέφεται, η ακατέργαστη ροή, μια υποκλάση *io.RawIOBase*, *io.FileIO*.

See also the file handling modules, such as, *fileinput*, *io* (where *open()* is declared), *os*, *os.path*, *tempfile*, and *shutil*.

Raises an *auditing event* open with arguments file, mode, flags.

Τα ορίσματα *mode* και *flags* μπορεί να έχουν τροποποιηθεί ή να έχουν συναχθεί από την αρχική κλήση.

Άλλαξε στην έκδοση 3.3:

- Προστέθηκε η παράμετρος *opener*.
- Προστέθηκε η λειτουργία 'x'.
- Το *IOError* γινόταν raise παλιά, τώρα είναι ψευδώνυμο του *OSError*.

- Το `FileExistsError` γίνεται `raise` τώρα εάν το αρχείο που ανοίγει σε λειτουργία αποκλειστικής δημιουργίας ('x') υπάρχει ήδη.

Άλλαξε στην έκδοση 3.4:

- Το αρχείο είναι πλέον μη κληρονομικό.

Deprecated since version 3.4, will be removed in version 3.10: The 'U' mode.

Άλλαξε στην έκδοση 3.5:

- Εάν η κλήση συστήματος διακοπεί και ο χειριστής σήματος δεν κάνει `raise` μια εξαίρεση, η συνάρτηση επαναλαμβάνει τώρα την κλήση συστήματος αντί να κάνει `raise` μια εξαίρεση `InterruptedError` (δείτε το [PEP 475](#) για το σκεπτικό).
- Προστέθηκε το πρόγραμμα χειρισμού σφαλμάτων 'namereplace'.

Άλλαξε στην έκδοση 3.6:

- Προστέθηκε υποστήριξη για την αποδοχή αντικειμένων που υλοποιούν `os.PathLike`.
- Στα Windows, το άνοιγμα μιας προσωρινής μνήμης κονσόλας μπορεί να επιστρέψει μια υποκλάση του `io.RawIOBase` εκτός από το `io.FileIO`.

ord(c)

Δεδομένου μιας συμβολοσειράς που αντιπροσωπεύει έναν χαρακτήρα Unicode, επιστρέφει έναν ακέραιο που αντιπροσωπεύει το σημείο κωδικού Unicode αυτού του χαρακτήρα. Για παράδειγμα, το `ord('a')` επιστρέφει τον ακέραιο αριθμό 97 και `ord('€')` (σύμβολο του ευρώ) επιστρέφει 8364. Αυτό είναι το αντίστροφο του `chr()`.

pow(base, exp[, mod])

Επιστρέφει `base` στην δύναμη `exp`. Εάν υπάρχει το `*mod`, επιστρέφει `base` στην δύναμη `exp`, modulo `mod` (υπολογίζεται πιο αποτελεσματικά από το `pow(base, exp) % mod`). Η φόρμα δύο ορισμάτων `pow(base, exp)` ισοδυναμεί με τη χρήση του τελεστή δύναμης: `base**exp`.

The arguments must have numeric types. With mixed operand types, the coercion rules for binary arithmetic operators apply. For `int` operands, the result has the same type as the operands (after coercion) unless the second argument is negative; in that case, all arguments are converted to float and a float result is delivered. For example, `pow(10, 2)` returns 100, but `pow(10, -2)` returns 0.01. For a negative base of type `int` or `float` and a non-integral exponent, a complex result is delivered. For example, `pow(-9, 0.5)` returns a value close to 3j.

Για τους τελεστές της `int` `base` και `exp`, εάν υπάρχει `mod`, το `mod` πρέπει επίσης να είναι ακεραίου τύπου και το `mod` πρέπει να είναι μη μηδενικό. Εάν υπάρχει `mod` και το `exp` είναι αρνητικό, το `base` πρέπει να είναι σχετικά πρώτο στο `mod`. Σε αυτήν την περίπτωση, επιστρέφεται το `pow(inv_base, -exp, mod)`, όπου το `inv_base` είναι αντίστροφο του `base` modulo `mod`.

Ακολουθεί ένα παράδειγμα υπολογισμού ενός αντίστροφου για το 38 modulo 97:

```
>>> pow(38, -1, mod=97)
23
>>> 23 * 38 % 97 == 1
True
```

Άλλαξε στην έκδοση 3.8: Για τον τελεστή `int`, η μορφή τριών ορισμών του `pow` επιτρέπει τώρα το δεύτερο όρισμα να είναι αρνητικό, επιτρέποντας τον υπολογισμό των αρθρωτών αντίστροφων.

Άλλαξε στην έκδοση 3.8: Επιτρέπονται ορίσματα keyword. Παλαιότερα, υποστηρίζονταν μόνο ορίσματα θέσης.

print (*objects, sep=' ', end='\n', file=sys.stdout, flush=False)

Print *objects* to the text stream *file*, separated by *sep* and followed by *end*. *sep*, *end*, *file* and *flush*, if present, must be given as keyword arguments.

Όλα τα μη keyword ορίσματα μετατρέπονται σε συμβολοσειρές όπως κάνει η `str()` και γράφονται στη ροή, χωρισμένα με *sep* και ακολουθούνται από *end*. Και τα δύο *sep* και *end* πρέπει να είναι συμβολοσειρές. Μπορεί επίσης να είναι `None`, που σημαίνει ότι θα χρησιμοποιηθούν οι προεπιλεγμένες τιμές. Εάν δεν δίνονται αντικείμενα, η `print()` θα γράψει απλά *end*.

Το όρισμα *file* πρέπει να είναι αντικείμενο με μια μέθοδο `write(string)`. Εάν δεν υπάρχει ή είναι `None`, θα χρησιμοποιηθεί το `sys.stdout`. Επειδή τα τυπωμένα ορίσματα μετατρέπονται σε συμβολοσειρές κειμένου, η `print()` δεν μπορεί να χρησιμοποιηθεί με αντικείμενα αρχείου δυαδικής λειτουργίας. Για αυτά, χρησιμοποιούμε το `file.write(...)`.

Whether output is buffered is usually determined by *file*, but if the *flush* keyword argument is true, the stream is forcibly flushed.

Άλλαξε στην έκδοση 3.3: Προστέθηκε το όρισμα keyword *flush*.

class property (fget=None, fset=None, fdel=None, doc=None)

Επιστρέφει ένα χαρακτηριστικό ιδιότητας.

Το *fget* είναι μια συνάρτηση για τη λήψη μιας τιμής χαρακτηριστικού. Το *fset* είναι μια συνάρτηση για τον ορισμό μιας τιμής χαρακτηριστικού. Το *fdel* είναι μια συνάρτηση για τη διαγραφή μιας τιμής χαρακτηριστικού. Και το *doc* δημιουργεί μια συμβολοσειρά εγγράφων για το χαρακτηριστικό.

Μια τυπική χρήση είναι ο ορισμός ενός διαχειριζόμενου χαρακτηριστικού *x*:

```
class C:
    def __init__(self):
        self._x = None

    def getx(self):
        return self._x

    def setx(self, value):
        self._x = value

    def delx(self):
        del self._x

x = property(getx, setx, delx, "I'm the 'x' property.")
```

If *c* is an instance of *C*, *c.x* will invoke the getter, *c.x* = *value* will invoke the setter and *del c.x* the deleter.

Εάν δίνεται, το *doc* θα είναι το docstring του χαρακτηριστικού ιδιότητας. Διαφορετικά, η ιδιότητα θα αντιγράψει τη συμβολοσειρά του *fget* (εάν υπάρχει). Αυτό καθιστά δυνατή τη δημιουργία ιδιοτήτων μόνο για ανάγνωση, εύκολα χρησιμοποιώντας τη `property()` ως *decorator*:

```
class Parrot:
    def __init__(self):
        self._voltage = 100000

    @property
    def voltage(self):
        """Get the current voltage."""
        return self._voltage
```

The `@property` decorator turns the `voltage()` method into a «getter» for a read-only attribute with the same name, and it sets the docstring for `voltage` to «Get the current voltage.»

A property object has `getter`, `setter`, and `deleter` methods usable as decorators that create a copy of the property with the corresponding accessor function set to the decorated function. This is best explained with an example:

```
class C:
    def __init__(self):
        self._x = None

    @property
    def x(self):
        """I'm the 'x' property."""
        return self._x

    @x.setter
    def x(self, value):
        self._x = value

    @x.deleter
    def x(self):
        del self._x
```

Αυτός ο κώδικας είναι ακριβώς ισοδύναμος με το πρώτο παράδειγμα. Φροντίστε να δώσετε στις πρόσθετες συναρτήσεις το ίδιο όνομα με την αρχική ιδιότητα (`x` σε αυτήν την περίπτωση.)

Το επιστρεφόμενο αντικείμενο ιδιότητας έχει επίσης τα χαρακτηριστικά `fget`, `fset`, και `fdel` που αντιστοιχούν στα ορίσματα του κατασκευαστή.

Άλλαξε στην έκδοση 3.5: Τα *docstrings* των αντικειμένων ιδιότητας είναι πλέον εγγράψιμες.

class `range` (*stop*)

class `range` (*start*, *stop* [, *step*])

Αντί να είναι συνάρτηση, το `range` είναι στην πραγματικότητα ένας αμετάβλητος τύπος ακολουθίας, όπως τεκμηριώνεται στα *Εύρη (Ranges)* και *Τύποι Ακολουθίας (Sequence)* — *list*, *tuple*, *range*.

repr (*object*)

Return a string containing a printable representation of an object. For many types, this function makes an attempt to return a string that would yield an object with the same value when passed to `eval()`, otherwise the representation is a string enclosed in angle brackets that contains the name of the type of the object together with additional information often including the name and address of the object. A class can control what this function returns for its instances by defining a `__repr__()` method.

reversed (*seq*)

Return a reverse *iterator*. *seq* must be an object which has a `__reversed__()` method or supports the sequence protocol (the `__len__()` method and the `__getitem__()` method with integer arguments starting at 0).

round (*number* [, *ndigits*])

Επιστρέφει τον *number* στρογγυλοποιημένο σε *ndigits* ακρίβεια μετά την υποδιαστολή. Εάν το *ndigits* παραληφθεί ή είναι `None`, επιστρέφει τον πλησιέστερο ακέραιο αριθμό στην είσοδό του.

For the built-in types supporting `round()`, values are rounded to the closest multiple of 10 to the power minus *ndigits*; if two multiples are equally close, rounding is done toward the even choice (so, for example, both `round(0.5)` and `round(-0.5)` are 0, and `round(1.5)` is 2). Any integer value is valid for *ndigits* (positive, zero, or negative). The return value is an integer if *ndigits* is omitted or `None`. Otherwise the return value has the same type as *number*.

Για ένα γενικό αντικείμενο Python `number`, `round` εκχωρεί στο `number.__round__`.

Σημείωση: Η συμπεριφορά του `round()` για floats μπορεί να είναι εκπληκτική: για παράδειγμα, το `round(2.675, 2)` δίνει 2.67 αντί για το αναμενόμενο 2.68. Αυτό δεν είναι bug: είναι αποτέλεσμα του γεγονότος ότι τα περισσότερα δεκαδικά κλάσματα δεν μπορούν να αναπαρασταθούν ακριβώς ως float. Δείτε το [tut-fp-issues](#) για περισσότερες πληροφορίες.

class `set` (`[iterable]`)

Επιστρέφει ένα νέο αντικείμενο `set`, προαιρετικά με στοιχεία που λαμβάνονται από το `iterable`. Το `set` είναι μια ενσωματωμένη κλάση. Δείτε `set` και *Τύποι Συνόλου (Set)* — `set`, `frozenset` για τεκμηρίωση αυτής της κλάσης.

Για άλλα containers, δείτε τις ενσωματωμένες κλάσεις `frozenset`, `list`, `tuple`, και `dict`, καθώς και το module `collections`.

setattr (`object`, `name`, `value`)

This is the counterpart of `getattr()`. The arguments are an object, a string and an arbitrary value. The string may name an existing attribute or a new attribute. The function assigns the value to the attribute, provided the object allows it. For example, `setattr(x, 'foobar', 123)` is equivalent to `x.foobar = 123`.

Σημείωση: Δεδομένου ότι το private name mangling συμβαίνει κατά τη στιγμή της μεταγλώττισης, πρέπει κανείς να παραμορφώσει με μη αυτόματο τρόπο το όνομα ενός ιδιωτικού χαρακτηριστικού (χαρακτηριστικά με δύο προπορευόμενες κάτω παύλες) για να το ορίσει με `setattr()`.

class `slice` (`stop`)

class `slice` (`start`, `stop` [, `step`])

Return a *slice* object representing the set of indices specified by `range(start, stop, step)`. The `start` and `step` arguments default to `None`. Slice objects have read-only data attributes `start`, `stop` and `step` which merely return the argument values (or their default). They have no other explicit functionality; however they are used by NumPy and other third party packages. Slice objects are also generated when extended indexing syntax is used. For example: `a[start:stop:step]` or `a[start:stop, i]`. See `itertools.islice()` for an alternate version that returns an iterator.

sorted (`iterable`, `/`, `*`, `key=None`, `reverse=False`)

Επιστρέφει μια νέα ταξινομημένη λίστα από τα στοιχεία στο `iterable`.

Έχει δύο προαιρετικά ορίσματα που πρέπει να καθοριστούν ως ορίσματα λέξεων-κλειδιών.

Το `key` καθορίζει μια συνάρτηση ενός ορίσματος που χρησιμοποιείται για την εξαγωγή ενός κλειδιού σύγκρισης από κάθε στοιχείο στο `iterable` (για παράδειγμα, `key=str.lower`). Η προεπιλεγμένη τιμή είναι `None` (συγκρίνει τα στοιχεία απευθείας).

Το `reverse` είναι μια δυαδική τιμή. Εάν οριστεί σε `True`, τότε τα στοιχεία της λίστας ταξινομούνται σαν να είχε αντιστραφεί κάθε σύγκριση.

Χρησιμοποιήστε το `functools.cmp_to_key()` για να μετατρέψετε μια συνάρτηση `cmp` παλιού τύπου σε συνάρτηση `key`.

Η ενσωματωμένη συνάρτηση `sorted()` είναι εγγυημένη ότι είναι σταθερή. Μια ταξινόμηση είναι σταθερή εάν εγγυάται ότι δεν θα αλλάξει η σχετική σειρά των στοιχείων που συγκρίνονται ίσα — αυτό είναι χρήσιμο για ταξινόμηση σε πολλαπλά περάσματα (για παράδειγμα, ταξινόμηση ανά τμήμα, μετά ανά μισθολογικό βαθμό).

Ο αλγόριθμος ταξινόμησης χρησιμοποιεί μόνο συγκρίσεις `<` μεταξύ στοιχείων. Ενώ ο ορισμός μιας μεθόδου `__lt__()` αρκεί για την ταξινόμηση, το **PEP 8** συνιστά και τις έξι rich comparisons που θα εφαρμοστούν. Αυτό θα βοηθήσει στην αποφυγή σφαλμάτων κατά τη χρήση των ίδιων δεδομένων με άλλα εργαλεία διάταξης, όπως `max()` που βασίζονται σε διαφορετική υποκείμενη μέθοδο. Η υλοποίηση και των έξι συ-

γκρίσεων βοηθά επίσης στην αποφυγή σύγχυσης για συγκρίσεις μικτού τύπου που μπορούν να καλέσουν την ανακλώμενη μέθοδο `__gt__()`.

Για παραδείγματα ταξινόμησης και ένα σύντομο σεμινάριο ταξινόμησης, ανατρέξτε στο `sortinghowto`.

@staticmethod

Μετατροπή μιας μεθόδου σε στατική μέθοδο.

Μια στατική μέθοδος δεν λαμβάνει ένα σιωπηρό πρώτο όρισμα. Για να δηλώσετε μια στατική μέθοδο, χρησιμοποιήστε αυτό το ιδίωμα:

```
class C:
    @staticmethod
    def f(arg1, arg2, ...): ...
```

Η φόρμα `@staticmethod` είναι μια συνάρτηση *decorator* – δείτε `function` για λεπτομέρειες.

A static method can be called either on the class (such as `C.f()`) or on an instance (such as `C().f()`).

Static methods in Python are similar to those found in Java or C++. Also see `classmethod()` for a variant that is useful for creating alternate class constructors.

Όπως όλοι οι διακοσμητές, είναι επίσης δυνατό να καλέσετε την `staticmethod` ως κανονική συνάρτηση και να κάνετε κάτι με το αποτέλεσμά της. Αυτό είναι απαραίτητο σε ορισμένες περιπτώσεις όπου χρειάζεστε μια αναφορά σε μια συνάρτηση από ένα σώμα κλάσης και θέλετε να αποφύγετε την αυτόματη μετατροπή σε instance μέθοδο. Για αυτές τις περιπτώσεις, χρησιμοποιήστε αυτό το ιδίωμα:

```
class C:
    builtin_open = staticmethod(open)
```

Για περισσότερες πληροφορίες σχετικά με τις στατικές μεθόδους, δείτε το `types`.

class str (*object*="")

class str (*object*=`b''`, *encoding*=`'utf-8'`, *errors*=`'strict'`)

Επιστρέφει μια έκδοση `str` του *object*. Δείτε `str()` για λεπτομέρειες.

Το `str` είναι η ενσωματωμένη συμβολοσειρά *class*. Για γενικές πληροφορίες σχετικά με τις συμβολοσειρές, ανατρέξτε *Τύπος Ακολουθίας (Sequence) Κειμένου — str*.

sum (*iterable*, */*, *start*=0)

Αθροίζει το *start* και τα στοιχεία ενός *iterable* από αριστερά προς δεξιά και επιστρέφει το σύνολο. Τα στοιχεία του *iterable* είναι συνήθως αριθμοί και η τιμή έναρξης δεν επιτρέπεται να είναι συμβολοσειρά.

For some use cases, there are good alternatives to `sum()`. The preferred, fast way to concatenate a sequence of strings is by calling `' '.join(sequence)`. To add floating point values with extended precision, see `math.fsum()`. To concatenate a series of iterables, consider using `itertools.chain()`.

Άλλαξε στην έκδοση 3.8: Η παράμετρος *start* μπορεί να καθοριστεί ως όρισμα keyword.

super ([*type*[, *object-or-type*]])

Επιστρέφει ένα αντικείμενο διακομιστή μεσολάβησης που εκχωρεί κλήσεις μεθόδου σε μια γονική ή αδερφή κλάση *type*. Αυτό είναι χρήσιμο για την πρόσβαση σε μεταβιβασμένες μεθόδους που έχουν πα-ρακαμφθεί σε μια κλάση.

The *object-or-type* determines the *method resolution order* to be searched. The search starts from the class right after the *type*.

For example, if `__mro__` of *object-or-type* is `D -> B -> C -> A -> object` and the value of *type* is `B`, then `super()` searches `C -> A -> object`.

The `__mro__` attribute of the *object-or-type* lists the method resolution search order used by both `getattr()` and `super()`. The attribute is dynamic and can change whenever the inheritance hierarchy is updated.

Εάν το δεύτερο όρισμα παραλειφθεί, το υπεραντικείμενο που επιστράφηκε δεν είναι δεσμευμένο. Εάν το δεύτερο όρισμα είναι αντικείμενο, `isinstance(obj, type)` πρέπει να είναι αληθές. Εάν το δεύτερο όρισμα είναι ένας τύπος, το `issubclass(type2, type)` πρέπει να είναι αληθές (αυτό είναι χρήσιμο για μεθόδους κλάσης).

Υπάρχουν δύο τυπικές περιπτώσεις χρήσης για το `super`. Σε μια ιεραρχία κλάσεων με ενιαία κληρονομικότητα, το `super` μπορεί να χρησιμοποιηθεί για να αναφέρεται σε γονικές κλάσεις χωρίς να τις ονομάζει ρητά, καθιστώντας έτσι τον κώδικα πιο διατηρήσιμο. Αυτή η χρήση είναι πολύ παράλληλη με τη χρήση του `super` σε άλλες γλώσσες προγραμματισμού.

Η δεύτερη περίπτωση χρήσης είναι η υποστήριξη πολλαπλής κληρονομικότητας συνεργασίας σε ένα δυναμικό περιβάλλον εκτέλεσης. Αυτή η περίπτωση χρήσης είναι μοναδική για την Python και δεν βρίσκεται σε στατικά μεταγλωττισμένες γλώσσες ή γλώσσες που υποστηρίζουν μόνο μεμονωμένη κληρονομικότητα. Αυτό καθιστά δυνατή την υλοποίηση «διαγραμμάτων διαμαντιών» όπου πολλές βασικές κλάσεις υλοποιούν την ίδια μέθοδο. Ο καλός σχεδιασμός υπαγορεύει ότι τέτοιες υλοποιήσεις έχουν την ίδια υπογραφή κλήσης σε κάθε περίπτωση (επειδή η σειρά των κλήσεων καθορίζεται κατά τον χρόνο εκτέλεσης, επειδή αυτή η σειρά προσαρμόζεται στις αλλαγές στην ιεραρχία κλάσεων και επειδή αυτή η διάταξη μπορεί να περιλαμβάνει αδερφικές κλάσεις πριν από τον χρόνο εκτέλεσης).

Και για τις δύο περιπτώσεις χρήσης, μια τυπική κλήση υπερκλάσης μοιάζει με αυτό:

```
class C(B):
    def method(self, arg):
        super().method(arg)      # This does the same thing as:
                                # super(C, self).method(arg)
```

Εκτός από τις αναζητήσεις μεθόδων, το `super()` λειτουργεί επίσης για αναζητήσεις χαρακτηριστικών. Μια πιθανή περίπτωση χρήσης για αυτό είναι η κλήση *descriptors* σε μια κλάση γονέα ή αδελφού.

Note that `super()` is implemented as part of the binding process for explicit dotted attribute lookups such as `super().__getitem__(name)`. It does so by implementing its own `__getattribute__()` method for searching classes in a predictable order that supports cooperative multiple inheritance. Accordingly, `super()` is undefined for implicit lookups using statements or operators such as `super()[name]`.

Λάβετε επίσης υπόψη ότι, εκτός από τη μορφή μηδενικού ορίσματος, η `super()` δεν περιορίζεται στη χρήση μεθόδων εντός. Η φόρμα δύο ορισμάτων καθορίζει ακριβώς τα ορίσματα και κάνει τις κατάλληλες αναφορές. Η φόρμα μηδενικού ορίσματος λειτουργεί μόνο μέσα σε έναν ορισμό κλάσης, καθώς ο μεταγλωττιστής συμπληρώνει τις απαραίτητες λεπτομέρειες για την σωστή ανάκτηση της κλάσης που ορίζεται, καθώς και για την πρόσβαση στην τρέχουσα παρουσία για συνηθισμένες μεθόδους.

Για πρακτικές προτάσεις σχετικά με το πώς να σχεδιάσετε συνεργατικές τάξεις χρησιμοποιώντας το `super()`, ανατρέξτε οδηγός χρήσης `super()`.

class tuple (*[iterable]*)

Αντί να είναι συνάρτηση, το `tuple` είναι στην πραγματικότητα ένα αμετάβλητος τύπος ακολουθίας, όπως τεκμηριώνεται στα *Πλειάδες (Tuples)* και *Τύποι Ακολουθίας (Sequence)* — *list, tuple, range*.

class type (*object*)

class type (*name, bases, dict, **kwargs*)

With one argument, return the type of an *object*. The return value is a type object and generally the same object as returned by `object.__class__`.

Η ενσωματωμένη συνάρτηση `isinstance()` συνίσταται για τη δοκιμή του τύπου ενός αντικειμένου, επειδή λαμβάνει υπόψη τις υποκλάσεις.

With three arguments, return a new type object. This is essentially a dynamic form of the `class` statement. The *name* string is the class name and becomes the `__name__` attribute. The *bases* tuple contains the base classes and becomes the `__bases__` attribute; if empty, *object*, the ultimate base of all classes, is added.

The *dict* dictionary contains attribute and method definitions for the class body; it may be copied or wrapped before becoming the `__dict__` attribute. The following two statements create identical *type* objects:

```
>>> class X:
...     a = 1
...
>>> X = type('X', (), dict(a=1))
```

See also *Τύποι Αντικειμένων*.

Τα ορίσματα λέξεων-κλειδιών που παρέχονται στη φόρμα τριών ορισμάτων μεταβιβάζονται στον κατάλληλο μηχανισμό μετακλάσης (συνήθως `__init_subclass__()`) με τον ίδιο τρόπο που θα έκαναν οι λέξεις-κλειδιά στον ορισμό μιας κλάσης (εκτός από το *metaclass*).

Δείτε επίσης class-customization.

Άλλαξε στην έκδοση 3.6: Subclasses of *type* which don't override `type.__new__` may no longer use the one-argument form to get the type of an object.

vars ([*object*])

Return the `__dict__` attribute for a module, class, instance, or any other object with a `__dict__` attribute.

Objects such as modules and instances have an updateable `__dict__` attribute; however, other objects may have write restrictions on their `__dict__` attributes (for example, classes use a *types.MappingProxyType* to prevent direct dictionary updates).

Χωρίς ένα όρισμα, το `vars()` λειτουργεί όπως `locals()`. Σημειώστε, ότι το λεξικό των τοπικών είναι χρήσιμο μόνο για ανάγνωση, καθώς οι ενημερώσεις στο λεξικό των τοπικών αγνοούνται.

Μια εξαίρεση *TypeError* γίνεται *raise* εάν ένα αντικείμενο έχει καθοριστεί αλλά δεν έχει ένα χαρακτηριστικό `__dict__` (για παράδειγμα, εάν η κλάση του ορίζει το `__slots__` χαρακτηριστικό).

zip (**iterables*)

Make an iterator that aggregates elements from each of the iterables.

Returns an iterator of tuples, where the *i*-th tuple contains the *i*-th element from each of the argument sequences or iterables. The iterator stops when the shortest input iterable is exhausted. With a single iterable argument, it returns an iterator of 1-tuples. With no arguments, it returns an empty iterator. Equivalent to:

```
def zip(*iterables):
    # zip('ABCD', 'xy') --> Ax By
    sentinel = object()
    iterators = [iter(it) for it in iterables]
    while iterators:
        result = []
        for it in iterators:
            elem = next(it, sentinel)
            if elem is sentinel:
                return
            result.append(elem)
        yield tuple(result)
```

The left-to-right evaluation order of the iterables is guaranteed. This makes possible an idiom for clustering a data series into *n*-length groups using `zip(*[iter(s)]*n)`. This repeats the *same* iterator *n* times so that each output tuple has the result of *n* calls to the iterator. This has the effect of dividing the input into *n*-length chunks.

`zip()` should only be used with unequal length inputs when you don't care about trailing, unmatched values from the longer iterables. If those values are important, use `itertools.zip_longest()` instead.

Η `zip()` σε συνδυασμό με τον τελεστή `*` μπορεί να χρησιμοποιηθεί για την αποσυμπίεση μιας λίστας:

```
>>> x = [1, 2, 3]
>>> y = [4, 5, 6]
>>> zipped = zip(x, y)
>>> list(zipped)
[(1, 4), (2, 5), (3, 6)]
>>> x2, y2 = zip(*zip(x, y))
>>> x == list(x2) and y == list(y2)
True
```

`__import__` (*name*, *globals*=None, *locals*=None, *fromlist*=(), *level*=0)

Σημείωση: Αυτή είναι μια προηγμένη συνάρτηση που δεν χρειάζεται στον καθημερινό προγραμματισμό της Python, σε αντίθεση με το `importlib.import_module()`.

Αυτή η συνάρτηση καλείται από τη δήλωση `import`. Μπορεί να αντικατασταθεί (με εισαγωγή του module `builtins` και αντιστοίχιση σε `builtins.__import__`) προκειμένου να αλλάξει η σημασιολογία της δήλωσης `import`, αλλά αυτό αποθαρρύνεται **σθεναρά**, καθώς είναι συνήθως απλούστερο να χρησιμοποιήσετε τα άγκιστρα εισαγωγής (δείτε **PEP 302**) για την επίτευξη των ίδιων στόχων και δεν προκαλεί προβλήματα με τον κώδικα που προϋποθέτει την χρήση της προεπιλεγμένης υλοποίησης εισαγωγής. Η άμεση χρήση του `__import__()` επίσης αποθαρρύνεται υπέρ του `importlib.import_module()`.

The function imports the module *name*, potentially using the given *globals* and *locals* to determine how to interpret the name in a package context. The *fromlist* gives the names of objects or submodules that should be imported from the module given by *name*. The standard implementation does not use its *locals* argument at all, and uses its *globals* only to determine the package context of the `import` statement.

Το *level* καθορίζει εάν θα χρησιμοποιηθούν απόλυτες ή σχετικές εισαγωγές. Το 0 (η προεπιλογή) σημαίνει μόνο απόλυτες εισαγωγές. Οι θετικές τιμές για το *level* υποδεικνύουν τον αριθμό των γονικών καταλόγων προς αναζήτηση σε σχέση με τον κατάλογο του module που καλεί την `__import__()` (δείτε το **PEP 328** για λεπτομέρειες).

Όταν η μεταβλητή *name* είναι της μορφής `package.module`, κανονικά, επιστρέφεται το πακέτο ανωτάτου επιπέδου (το όνομα μέχρι την πρώτη κουκκίδα), *όχι* το module που ονομάζεται *name*. Ωστόσο, όταν δίνεται ένα μη κενό όρισμα *fromlist*, επιστρέφεται το module με το όνομα *name*.

Για παράδειγμα, η δήλωση `import spam` καταλήγει σε bytecode που μοιάζει με τον ακόλουθο κώδικα:

```
spam = __import__('spam', globals(), locals(), [], 0)
```

Η δήλωση `import spam.ham` καταλήγει σε αυτήν την κλήση:

```
spam = __import__('spam.ham', globals(), locals(), [], 0)
```

Σημειώστε πως το `__import__()` επιστρέφει το ανωτάτου επιπέδου module εδώ, επειδή αυτό είναι το αντικείμενο που συνδέεται με ένα όνομα με τη δήλωση `import`.

Από την άλλη πλευρά, η δήλωση `from spam.ham import eggs, sausage as saus` καταλήγει σε

```
_temp = __import__('spam.ham', globals(), locals(), ['eggs', 'sausage'], 0)
eggs = _temp.eggs
saus = _temp.sausage
```

Εδώ, το module `spam.ham` επιστρέφεται από τη `__import__()`. Από αυτό το αντικείμενο, τα ονόματα προς εισαγωγή ανακτώνται και εκχωρούνται στα αντίστοιχα ονόματά τους.

Εάν θέλετε απλώς να εισάγετε ένα `module` (ενδεχομένως μέσα σε ένα πακέτο) με το όνομα, χρησιμοποιήστε το `importlib.import_module()`.

Άλλαξε στην έκδοση 3.3: Αρνητικές τιμές για το `level` δεν υποστηρίζονται πλέον (το οποίο επίσης αλλάζει την προεπιλεγμένη τιμή σε 0).

Άλλαξε στην έκδοση 3.9: Όταν χρησιμοποιούνται επιλογές της γραμμής εντολών `-E` ή `-I`, τότε η μεταβλητή περιβάλλοντος `PYTHONCASEOK` δεν λαμβάνεται υπόψιν.

Υποσημειώσεις

Built-in Constants

A small number of constants live in the built-in namespace. They are:

False

The false value of the *bool* type. Assignments to `False` are illegal and raise a *SyntaxError*.

True

The true value of the *bool* type. Assignments to `True` are illegal and raise a *SyntaxError*.

None

The sole value of the type `NoneType`. `None` is frequently used to represent the absence of a value, as when default arguments are not passed to a function. Assignments to `None` are illegal and raise a *SyntaxError*.

NotImplemented

Special value which should be returned by the binary special methods (e.g. `__eq__()`, `__lt__()`, `__add__()`, `__rsub__()`, etc.) to indicate that the operation is not implemented with respect to the other type; may be returned by the in-place binary special methods (e.g. `__imul__()`, `__iand__()`, etc.) for the same purpose. It should not be evaluated in a boolean context.

Σημείωση: When a binary (or in-place) method returns `NotImplemented` the interpreter will try the reflected operation on the other type (or some other fallback, depending on the operator). If all attempts return `NotImplemented`, the interpreter will raise an appropriate exception. Incorrectly returning `NotImplemented` will result in a misleading error message or the `NotImplemented` value being returned to Python code.

See *Implementing the arithmetic operations* for examples.

Σημείωση: `NotImplementedError` and `NotImplemented` are not interchangeable, even though they have similar names and purposes. See *NotImplementedError* for details on when to use it.

Άλλαξε στην έκδοση 3.9: Evaluating `NotImplemented` in a boolean context is deprecated. While it currently evaluates as true, it will emit a *DeprecationWarning*. It will raise a *TypeError* in a future version of Python.

Ellipsis

The same as the ellipsis literal «. . .». Special value used mostly in conjunction with extended slicing syntax for user-defined container data types.

__debug__

This constant is true if Python was not started with an `-O` option. See also the `assert` statement.

Σημείωση: The names *None*, *False*, *True* and `__debug__` cannot be reassigned (assignments to them, even as an attribute name, raise *SyntaxError*), so they can be considered «true» constants.

3.1 Constants added by the `site` module

The *site* module (which is imported automatically during startup, except if the `-S` command-line option is given) adds several constants to the built-in namespace. They are useful for the interactive interpreter shell and should not be used in programs.

quit (*code=None*)

exit (*code=None*)

Objects that when printed, print a message like «Use quit() or Ctrl-D (i.e. EOF) to exit», and when called, raise *SystemExit* with the specified exit code.

copyright

credits

Objects that when printed or called, print the text of copyright or credits, respectively.

license

Object that when printed, prints the message «Type license() to see the full license text», and when called, displays the full license text in a pager-like fashion (one screen at a time).

Οι παρακάτω κατηγορίες περιγράφουν τους standard τύπους που είναι ενσωματωμένοι (built) μέσα στον interpreter.

Οι κύριοι ενσωματωμένοι (built) τύποι είναι αριθμοί, ακολουθίες, αντιστοιχίσεις (mappings), κλάσεις, instances και exceptions.

Ορισμένες collection κλάσεις είναι μεταβλητές (mutable). Οι μέθοδοι που προσθέτουν, αφαιρούν ή αναδιατάσσουν τα μέλη τους και δεν επιστρέφουν ένα συγκεκριμένο αντικείμενο, ποτέ δεν επιστρέφουν το ίδιο collection instance αλλά `None`.

Ορισμένες λειτουργίες υποστηρίζονται από διάφορους τύπους αντικειμένων· ειδικότερα, σχεδόν όλα τα αντικείμενα μπορούν να συγκριθούν ως προς την ισότητα, να ελεγχθούν για την έγκυρη τιμή και να μετατραπούν σε συμβολοσειρά (string) (με τη συνάρτηση `repr()` ή την ελαφρώς διαφορετική συνάρτηση `str()`). Η τελευταία συνάρτηση χρησιμοποιείται έμμεσα όταν ένα αντικείμενο γράφεται από τη συνάρτηση `print()`.

4.1 Έλεγχος Έγκυρης Τιμής

Οποιοδήποτε αντικείμενο μπορεί να ελεγχθεί ως προς την εγκυρότητα της τιμής του, για χρήση σε `if` ή `while` συνθήκη ή ως τελεστής των λογικών πράξεων παρακάτω.

By default, an object is considered true unless its class defines either a `__bool__()` method that returns `False` or a `__len__()` method that returns zero, when called with the object.¹ Here are most of the built-in objects considered false:

- constants defined to be false: `None` and `False`.
- μηδέν οποιουδήποτε αριθμητικού τύπου: `0`, `0.0`, `0j`, `Decimal(0)`, `Fraction(0, 1)`
- κενές ακολουθίες και collections: `''`, `()`, `[]`, `{}`, `set()`, `range(0)`

¹ Πρόσθετε πληροφορίες σχετικά με αυτές τις ειδικές μεθόδους μπορείτε να βρείτε στο Εγχειρίδιο Αναφοράς Python (customization).

Οι πράξεις και οι ενσωματωμένες (built-in) συναρτήσεις που έχουν αποτέλεσμα Boolean πάντα επιστρέφουν 0 ή False για false και 1 ή True για true, εκτός εάν δηλώνεται διαφορετικά. (Σημαντική εξαίρεση: οι λογικές (Boolean) πράξεις or και and επιστρέφουν πάντα έναν από τους τελεστές τους.)

4.2 Λογικές (Boolean) Πράξεις — and, or, not

Αυτές είναι οι λογικές (Boolean) πράξεις, ταξινομημένες βάσει προτεραιότητας:

| Πράξη | Αποτέλεσμα | Σημειώσεις |
|----------------------|---|------------|
| <code>x or y</code> | if <i>x</i> is false, then <i>y</i> , else <i>x</i> | (1) |
| <code>x and y</code> | αν το <i>x</i> είναι false, τότε <i>x</i> , αλλιώς <i>y</i> | (2) |
| <code>not x</code> | if <i>x</i> είναι false, τότε True, αλλιώς False | (3) |

Σημειώσεις:

- (1) Αυτός είναι ένας τελεστής μικρού κυκλώματος, επομένως αξιολογεί μόνο το δεύτερο όρισμα αν το πρώτο είναι false.
- (2) Αυτός είναι ένας τελεστής μικρού κυκλώματος, επομένως αξιολογεί μόνο το δεύτερο όρισμα αν το πρώτο είναι true.
- (3) Το `not` έχει χαμηλότερη προτεραιότητα από τους μη λογικούς (non-Boolean) τελεστές, οπότε το `not a == b` μεταφράζεται σαν `not (a==b)`, και το `a == not b` είναι συντακτικό σφάλμα.

4.3 Συγκρίσεις

Υπάρχουν οκτώ πράξεις σύγκρισης στην Python. Όλες έχουν την ίδια προτεραιότητα (η οποία είναι υψηλότερη από αυτή των λογικών (Boolean) πράξεων). Οι συγκρίσεις μπορεί να αλυσοδοθούν αυθαίρετα· για παράδειγμα, το `x < y <= z` ισοδυναμεί με `x < y` και `y <= z`, εκτός από το ότι το `y` αξιολογείται μόνο μία φορά (αλλά και στις δύο περιπτώσεις το `z` δεν αξιολογείται καθόλου όταν το `x < y` είναι false).

Αυτός ο πίνακας συνοψίζει τις πράξεις σύγκρισης:

| Πράξη | Έννοια |
|---------------------|---------------------------------|
| <code><</code> | αυστηρά μικρότερο από |
| <code><=</code> | μικρότερο από ή ίσο |
| <code>></code> | αυστηρά μεγαλύτερο από |
| <code>>=</code> | μεγαλύτερο από ή ίσο |
| <code>==</code> | ίσο |
| <code>!=</code> | διάφορο |
| <code>is</code> | ταυτότητα αντικειμένου |
| <code>is not</code> | αρνητική ταυτότητα αντικειμένου |

Αντικείμενα διαφορετικών τύπων, εκτός από διαφορετικούς αριθμητικούς τύπους, δεν συγκρίνονται ποτέ ως ίσα. Ο τελεστής `==` ορίζεται πάντα αλλά για ορισμένους τύπους αντικειμένων (για παράδειγμα, αντικείμενα κλάσης) ισοδυναμεί με `is`. Οι τελεστές `<`, `<=`, `>` και `>=` ορίζονται μόνο όπου έχουν νόημα· για παράδειγμα, δημιουργούν μια εξαίρεση `TypeError` όταν ένα από τα ορίσματα είναι μιγαδικός αριθμός.

Μη πανομοιότυπα instances μιας κλάσης συνήθως συγκρίνονται ως μη ίσα εκτός εάν το η κλάση ορίζει τη μέθοδο `__eq__()`.

Τα instances μιας κλάσης δεν μπορούν να ταξινομηθούν σε σχέση με άλλα instances της ίδιας κλάσης, ή άλλους τύπους του αντικειμένου, εκτός εάν η κλάση ορίζει αρκετές από τις μεθόδους `__lt__()`, `__le__()`, `__gt__()`, και `__ge__()` (γενικά, `__lt__()` και `__eq__()` είναι αρκετά, αν θέλετε τις συμβατικές έννοιες των τελεστών σύγκρισης).

Η συμπεριφορά των τελεστών `is` και `is not` δεν μπορεί να είναι προσαρμοσμένη· επίσης, μπορούν να εφαρμοστούν σε οποιαδήποτε δύο αντικείμενα και ποτέ να μην δημιουργήσουν μία εξαίρεση.

Two more operations with the same syntactic priority, `in` and `not in`, are supported by types that are *iterable* or implement the `__contains__()` method.

4.4 Αριθμητικοί Τύποι — `int`, `float`, `complex`

There are three distinct numeric types: *integers*, *floating point numbers*, and *complex numbers*. In addition, Booleans are a subtype of integers. Integers have unlimited precision. Floating point numbers are usually implemented using `double` in C; information about the precision and internal representation of floating point numbers for the machine on which your program is running is available in `sys.float_info`. Complex numbers have a real and imaginary part, which are each a floating point number. To extract these parts from a complex number `z`, use `z.real` and `z.imag`. (The standard library includes the additional numeric types `fractions.Fraction`, for rationals, and `decimal.Decimal`, for floating-point numbers with user-definable precision.)

Numbers are created by numeric literals or as the result of built-in functions and operators. Unadorned integer literals (including hex, octal and binary numbers) yield integers. Numeric literals containing a decimal point or an exponent sign yield floating point numbers. Appending `'j'` or `'J'` to a numeric literal yields an imaginary number (a complex number with a zero real part) which you can add to an integer or float to get a complex number with real and imaginary parts.

Η Python υποστηρίζει πλήρως τα μικτά αριθμητικά: όταν ένας δυαδικός αριθμητικός τελεστής έχει τελεστές διαφορετικών αριθμητικών τύπων, ο τελεστής με το «στενότερο» τύπο διευρύνεται σε αυτόν του άλλου, όπου ένας ακέραιος αριθμός είναι στενότερος από έναν με κινητή υποδιαστολή, που είναι στενότερο από ένα μιγαδικό. Η σύγκριση μεταξύ αριθμών διαφορετικών τύπων συμπεριφέρεται σαν να ήταν οι ακριβείς τιμές αυτών των αριθμών σε σύγκριση.²

Μπορούν να χρησιμοποιηθούν οι κατασκευαστές `int()`, `float()` και `complex()` για να παράγουν αριθμούς συγκεκριμένου τύπου.

Όλοι οι αριθμητικοί τύποι (εκτός των μιγαδικών) υποστηρίζουν τις ακόλουθες πράξεις (για προτεραιότητες των πράξεων, βλέπε `operator-summary`):

² Σαν συνέπεια, η λίστα `[1, 2]` θεωρείται ίση με `[1.0, 2.0]`, και ομοίως για πλειάδες (tuples).

| Πράξη | Αποτέλεσμα | Σημειώσεις | Ολόκληρη τεκμηρίωση |
|------------------------------|---|------------|------------------------|
| $x + y$ | άθροισμα του x και y | | |
| $x - y$ | διαφορά του x και y | | |
| $x * y$ | γινόμενο των x και y | | |
| x / y | πηλίκιο των x και y | | |
| $x // y$ | ακέραιο μέρος του πηλίκιου των x και y | (1) | |
| $x \% y$ | υπόλοιπο του x / y | (2) | |
| $-x$ | x αρνητικό | | |
| $+x$ | x αμετάβλητο | | |
| <code>abs(x)</code> | απόλυτη τιμή ή μέγεθος του x | | <code>abs()</code> |
| <code>int(x)</code> | μετατροπή του x σε ακέραιο | (3)(6) | <code>int()</code> |
| <code>float(x)</code> | μετατροπή του x σε κινητής υποδιαστολής | (4)(6) | <code>float()</code> |
| <code>complex(re, im)</code> | ένας μιγαδικός αριθμός με πραγματικό μέρος re , φανταστικό μέρος im . Το im μετατρέπεται αυτόματα σε μηδέν. | (6) | <code>complex()</code> |
| <code>c.conjugate()</code> | συζυγές του μιγαδικού αριθμού c | | |
| <code>divmod(x, y)</code> | το ζευγάρι $(x // y, x \% y)$ | (2) | <code>divmod()</code> |
| <code>pow(x, y)</code> | x σε δύναμη του y | (5) | <code>pow()</code> |
| $x ** y$ | x σε δύναμη του y | (5) | |

Σημειώσεις:

- (1) Also referred to as integer division. The resultant value is a whole integer, though the result's type is not necessarily `int`. The result is always rounded towards minus infinity: $1 // 2$ is 0, $(-1) // 2$ is -1, $1 // (-2)$ is -1, and $(-1) // (-2)$ is 0.
- (2) Όχι για μιγαδικούς αριθμούς. Αντίθετα μετατρέψτε σε `float` χρησιμοποιώντας `abs()` εάν είναι εφαρμόσιμο.
- (3) Conversion from floating point to integer may round or truncate as in C; see functions `math.floor()` and `math.ceil()` for well-defined conversions.
- (4) το `float` δέχεται επίσης τις συμβολοσειρές (strings) «nan» και «inf» με ένα προαιρετικό πρόθεμα «+» ή «-» για το Not a Number (NaN - Όχι αριθμός) και θετικό ή αρνητικό άπειρο.
- (5) Η Python ορίζει το `pow(0, 0)` και το $0 ** 0$ ως 1, όπως συνηθίζεται για τις γλώσσες προγραμματισμού.
- (6) Τα αριθμητικά κυριολεκτικά (numeric literals) που γίνονται δεκτά περιλαμβάνουν τα ψηφία 0 έως 9 ή οποιοδήποτε ισοδύναμο Unicode (σημεία κώδικα με την ιδιότητα Nd).

See <https://www.unicode.org/Public/13.0.0/ucd/extracted/DerivedNumericType.txt> for a complete list of code points with the Nd property.

Όλοι οι τύποι `numbers.Real` (`int` και `float`) επίσης περιλαμβάνουν τις ακόλουθες λειτουργίες:

| Πράξη | Αποτέλεσμα |
|----------------------------|---|
| <code>math.trunc(x)</code> | x μετατρέπεται σε <i>Integral</i> |
| <code>round(x[, n])</code> | x στρογγυλοποιημένο σε n ψηφία, στρογγυλοποιώντας το μισό σε ζυγό. Εάν το n παραλειφθεί, το default του είναι το 0. |
| <code>math.floor(x)</code> | το μεγαλύτερο <i>Integral</i> $\leq x$ |
| <code>math.ceil(x)</code> | το μικρότερο <i>Integral</i> $\geq x$ |

Για περαιτέρω αριθμητικές πράξεις δείτε τα modules *math* και *cmath*.

4.4.1 Bitwise Πράξεις σε Ακέραιους Τύπους

Οι πράξεις bitwise έχουν νόημα μόνο για ακέραιους αριθμούς. Το αποτέλεσμα των bitwise πράξεων υπολογίζεται σαν να εκτελείται σε συμπλήρωμα ως προς δύο με άπειρο αριθμό bits πρόσημου.

Οι προτεραιότητες των δυαδικών πράξεων bitwise είναι όλες χαμηλότερες από τις αριθμητικές πράξεις και υψηλότερες από τις συγκρίσεις· η μοναδιαία πράξη \sim έχει την ίδια προτεραιότητα με τις άλλες μοναδιαίες αριθμητικές πράξεις (+ και -).

Αυτός ο πίνακας παραθέτει όλες τις bitwise πράξεις ταξινομημένες σε αύξουσα σειρά:

| Πράξη | Αποτέλεσμα | Σημειώσεις |
|--------------|---|------------|
| $x \mid y$ | bitwise <i>or</i> των x και y | (4) |
| $x \wedge y$ | bitwise <i>exclusive or</i> των x και y | (4) |
| $x \& y$ | bitwise <i>and</i> των x και y | (4) |
| $x \ll n$ | x ολισθημένο (shifted) αριστερά κατά n bits | (1)(2) |
| $x \gg n$ | x ολισθημένο (shifted) δεξιά κατά n bits | (1)(3) |
| $\sim x$ | τα bits του x αντιστραμμένα | |

Σημειώσεις:

- (1) Οι μετρήσεις αρνητικών ολισθήσεων (negative shift) είναι άκυρες και κάνουν raise *ValueError*.
- (2) Μια αριστερή ολίσθηση (shift) κατά n bits ισοδυναμεί με πολλαπλασιασμό με `pow(2, n)`.
- (3) Μια δεξιά ολίσθηση (shift) κατά n bits ισοδυναμεί με διαίρεση πατώματος με `pow(2, n)`.
- (4) Η εκτέλεση αυτών των υπολογισμών με τουλάχιστον ένα επιπλέον bit επέκτασης πρόσημου σε μια αναπαράσταση ενός πεπερασμένου συμπληρώματος ως προς δύο (ένα ωφέλιμο bit-width `1 + max(x.bit_length(), y.bit_length())` ή περισσότερο) είναι αρκετό για να πάρει το ίδιο αποτέλεσμα σαν να υπήρχε ένας άπειρος αριθμός bits πρόσημου.

4.4.2 Περαιτέρω Μέθοδοι των Ακέραιων Τύπων

Ο τύπος `int` υλοποιεί την *numbers.Integral abstract base class*. Επιπλέον, παρέχει μερικές ακόμη μεθόδους:

`int.bit_length()`

Επιστρέφει τον αριθμό των bits που είναι απαραίτητος για να αναπαραστήσει έναν ακέραιο σε δυαδικό, αποκλείοντας το πρόσημο και τα αρχικά μηδέν:

```
>>> n = -37
>>> bin(n)
'-0b100101'
>>> n.bit_length()
6
```

Πιο συγκεκριμένα, εάν το `x` είναι μη μηδενικό, τότε το `x.bit_length()` είναι μοναδικός θετικός αριθμός `k` έτσι ώστε $2^{k-1} \leq \text{abs}(x) < 2^k$. Ισοδύναμα, όταν το `abs(x)` είναι αρκετά μικρό για να έχει ένα σωστά στρογγυλοποιημένο λογάριθμο, τότε $k = 1 + \text{int}(\log(\text{abs}(x), 2))$. Εάν το `x` είναι μηδέν, τότε το `x.bit_length()` επιστρέφει 0.

Ισοδύναμο με:

```
def bit_length(self):
    s = bin(self)          # binary representation: bin(-37) --> '-0b100101'
    s = s.lstrip('-0b')    # remove leading zeros and minus sign
    return len(s)          # len('100101') --> 6
```

Νέο στην έκδοση 3.1.

`int.to_bytes(length, byteorder, *, signed=False)`

Επιστρέφει ένα πίνακα από bytes που αναπαριστούν έναν ακέραιο.

```
>>> (1024).to_bytes(2, byteorder='big')
b'\x04\x00'
>>> (1024).to_bytes(10, byteorder='big')
b'\x00\x00\x00\x00\x00\x00\x00\x00\x04\x00'
>>> (-1024).to_bytes(10, byteorder='big', signed=True)
b'\xff\xff\xff\xff\xff\xff\xff\xff\xfc\x00'
>>> x = 1000
>>> x.to_bytes((x.bit_length() + 7) // 8, byteorder='little')
b'\xe8\x03'
```

The integer is represented using *length* bytes. An *OverflowError* is raised if the integer is not representable with the given number of bytes.

The *byteorder* argument determines the byte order used to represent the integer. If *byteorder* is "big", the most significant byte is at the beginning of the byte array. If *byteorder* is "little", the most significant byte is at the end of the byte array. To request the native byte order of the host system, use *sys.byteorder* as the byte order value.

Το όρισμα *signed* καθορίζει εάν το συμπλήρωμα ως προς δύο χρησιμοποιείται για να αντιπροσωπεύσει τον ακέραιο. Εάν το *signed* είναι *False* και έχει δοθεί ένας αρνητικός ακέραιος, γίνεται raise ένα *OverflowError*. Η προεπιλεγμένη τιμή (default) για το *signed* είναι *False*.

Νέο στην έκδοση 3.2.

classmethod `int.from_bytes(bytes, byteorder, *, signed=False)`

Επιστρέφει έναν ακέραιο που αναπαρίσταται από τον δοσμένο πίνακα των bytes.

```

>>> int.from_bytes(b'\x00\x10', byteorder='big')
16
>>> int.from_bytes(b'\x00\x10', byteorder='little')
4096
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=True)
-1024
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=False)
64512
>>> int.from_bytes([255, 0, 0], byteorder='big')
16711680

```

Το όρισμα *bytes* πρέπει είτε να είναι ένα *bytes-like object* είτε ένα iterable που παράγει bytes.

The *byteorder* argument determines the byte order used to represent the integer. If *byteorder* is "big", the most significant byte is at the beginning of the byte array. If *byteorder* is "little", the most significant byte is at the end of the byte array. To request the native byte order of the host system, use *sys.byteorder* as the byte order value.

Το όρισμα *signed* υποδεικνύει εάν το συμπλήρωμα ως προς δύο χρησιμοποιείται για να αντιπροσωπεύσει τον ακέραιο.

Νέο στην έκδοση 3.2.

`int.as_integer_ratio()`

Return a pair of integers whose ratio is exactly equal to the original integer and with a positive denominator. The integer ratio of integers (whole numbers) is always the integer as the numerator and 1 as the denominator.

Νέο στην έκδοση 3.8.

4.4.3 Περαιτέρω Μέθοδοι για Float

Ο τύπος float (κινητής υποδιαστολής) υλοποιεί την *numbers.Real abstract base class*. Ο float έχει επίσης τις ακόλουθες πρόσθετες μεθόδους.

`float.as_integer_ratio()`

Return a pair of integers whose ratio is exactly equal to the original float and with a positive denominator. Raises *OverflowError* on infinities and a *ValueError* on NaNs.

`float.is_integer()`

Επιστρέφει True εάν το float instance είναι πεπερασμένο με ακέραια τιμή και False διαφορετικά:

```

>>> (-2.0).is_integer()
True
>>> (3.2).is_integer()
False

```

Δύο μέθοδοι υποστηρίζουν τη μετατροπή από και προς δεκαεξαδικές συμβολοσειρές (strings). Αφού τα floats της Python αποθηκεύονται εσωτερικά ως δυαδικοί αριθμοί, η μετατροπή ενός float προς ή από μια δεκαδική συμβολοσειρά συνήθως περιλαμβάνει ένα μικρό σφάλμα στρογγυλοποίησης. Αντιθέτως, οι δεκαεξαδικές συμβολοσειρές επιτρέπουν ακριβή αναπαράσταση και συγκεκριμενοποίηση των αριθμών κινητής υποδιαστολής. Αυτό μπορεί να είναι χρήσιμο κατά το debugging και στην αριθμητική.

`float.hex()`

Επιστρέφει μια αναπαράσταση ενός αριθμού κινητής υποδιαστολής ως δεκαεξαδική συμβολοσειρά (string). Για πεπερασμένους αριθμούς κινητής υποδιαστολής, αυτή η αναπαράσταση θα περιλαμβάνει πάντα ένα προπορευόμενο 0x και ένα τελευταίο p και εκθέτη.

classmethod `float.fromhex(s)`

Μέθοδος κλάσης για την επιστροφή του `float` που αντιπροσωπεύεται από μια δεκαεξαδική συμβολοσειρά (string) `s`. Η συμβολοσειρά `s` μπορεί να έχει κενό διάστημα που στην αρχή ή το τέλος.

Σημειώστε ότι το `float.hex()` είναι ένα instance method, ενώ το `float.fromhex()` είναι μια μέθοδος κλάσης.

Μια δεκαεξαδική συμβολοσειρά (string) έχει τη μορφή:

```
[sign] ['0x'] integer ['.' fraction] ['p' exponent]
```

όπου το προαιρετικό `sign` μπορεί να είναι είτε `+` ή `-`, `integer` και `fraction` είναι συμβολοσειρές (strings) δεκαεξαδικών ψηφίων και ο `exponent` (εκθέτης) είναι ένας δεκαδικός ακέραιος με προαιρετικό πρόσημο. Τα πεζά ή κεφαλαία δεν είναι σημαντικά και πρέπει να υπάρχει τουλάχιστον ένα δεκαεξαδικό ψηφίο είτε στον ακέραιο είτε στο κλάσμα. Αυτή η σύνταξη είναι παρόμοια με τη σύνταξη που καθορίζεται στην ενότητα 6.4.4.2 του προτύπου C99, καθώς και στη σύνταξη που χρησιμοποιείται στην Java 1.5 και μετά. Ιδιαίτερα, η έξοδος του `float.hex()` μπορεί να χρησιμοποιηθεί ως δεκαεξαδικό Κυριολεκτική κινητής υποδιαστολής σε κώδικα C ή Java, και παράχθηκαν δεκαεξαδικές συμβολοσειρές με τον χαρακτήρα μορφής `%a` της C ή το `Double.toHexString` της Java είναι αποδεκτά από το `float.fromhex()`.

Σημειώστε ότι ο εκθέτης είναι γραμμένος με δεκαδικό και όχι δεκαεξαδικό και ότι δίνει τη δύναμη του 2 με την οποία πολλαπλασιάζεται ο συντελεστής. Για παράδειγμα, η δεκαεξαδική συμβολοσειρά (string) `0x3.a7p10` αντιπροσωπεύει τον αριθμό κινητής υποδιαστολής $(3 + 10./16 + 7./16*2) * 2, 0*10$, ή 3740, 0:

```
>>> float.fromhex('0x3.a7p10')
3740.0
```

Η εφαρμογή της αντίστροφης μετατροπής σε 3740.0 δίνει μία διαφορετική δεκαεξαδική συμβολοσειρά (string) που αντιπροσωπεύει τον ίδιο αριθμό:

```
>>> float.hex(3740.0)
'0x1.d380000000000p+11'
```

4.4.4 Κατακερματισμός των αριθμητικών τύπων

For numbers `x` and `y`, possibly of different types, it's a requirement that `hash(x) == hash(y)` whenever `x == y` (see the `__hash__()` method documentation for more details). For ease of implementation and efficiency across a variety of numeric types (including `int`, `float`, `decimal.Decimal` and `fractions.Fraction`) Python's hash for numeric types is based on a single mathematical function that's defined for any rational number, and hence applies to all instances of `int` and `fractions.Fraction`, and all finite instances of `float` and `decimal.Decimal`. Essentially, this function is given by reduction modulo `P` for a fixed prime `P`. The value of `P` is made available to Python as the `modulus` attribute of `sys.hash_info`.

CPython implementation detail: Αυτή τη στιγμή, ο πρώτος που χρησιμοποιείται είναι $P = 2^{31} - 1$ σε μηχανήματα με μήκους 32-bit C και $P = 2^{61} - 1$ σε μηχανήματα με μήκους 64-bit C.

Εδώ οι κανόνες λεπτομερώς:

- Αν το $x = m / n$ είναι ένας μη αρνητικός ρητός αριθμός και το `n` δεν διαιρείται από `P`, ορίστε το `hash(x)` ως $m * \text{invmod}(n, P) \% P$, όπου το `invmod(n, P)` μας δίνει το αντίστροφο του modulo `n P`.
- Αν το $x = m / n$ είναι ένας μη αρνητικός ρητός αριθμός και το `n` διαιρείται με το `P` (αλλά το `m` όχι) τότε το `n` δεν έχει αντίστροφο modulo `P` και ο κανόνας παραπάνω δεν ισχύει. Σε αυτήν την περίπτωση ορίστε το `hash(x)` ως σταθερή τιμή `sys.hash_info.inf`.
- Αν $x = m / n$ είναι ένας αρνητικός ρητός αριθμός τότε το `hash(x)` ορίζεται ως `-hash(-x)`. Αν το `hash` που προκύπτει είναι `-1`, αντικαθίσταται με `-2`.

- The particular values `sys.hash_info.inf`, `-sys.hash_info.inf` and `sys.hash_info.nan` are used as hash values for positive infinity, negative infinity, or nans (respectively). (All hashable nans have the same hash value.)
- Για έναν *complex* αριθμό `z`, οι τιμές κατακερματισμού των πραγματικών και φανταστικών μερών συνδυάζονται με τον υπολογισμό `hash(z.real) + sys.hash_info.imag * hash(z.imag)`, μειωμένο modulo `2**sys.hash_info.width` έτσι ώστε να βρίσκεται στο `range(-2**(sys.hash_info.width - 1), 2**(sys.hash_info.width - 1))`. Και πάλι, αν το αποτέλεσμα είναι `-1`, αντικαθίσταται με `-2`.

Για να αποσαφηνίσουμε τους παραπάνω κανόνες, εδώ είναι ένα παράδειγμα κώδικα της Python, ισοδύναμο με το built-in hash, για τον υπολογισμό του hash ενός ρητού αριθμού, *float*, ή *complex*:

```
import sys, math

def hash_fraction(m, n):
    """Compute the hash of a rational number m / n.

    Assumes m and n are integers, with n positive.
    Equivalent to hash(fractions.Fraction(m, n)).

    """
    P = sys.hash_info.modulus
    # Remove common factors of P. (Unnecessary if m and n already coprime.)
    while m % P == n % P == 0:
        m, n = m // P, n // P

    if n % P == 0:
        hash_value = sys.hash_info.inf
    else:
        # Fermat's Little Theorem: pow(n, P-1, P) is 1, so
        # pow(n, P-2, P) gives the inverse of n modulo P.
        hash_value = (abs(m) % P) * pow(n, P - 2, P) % P
    if m < 0:
        hash_value = -hash_value
    if hash_value == -1:
        hash_value = -2
    return hash_value

def hash_float(x):
    """Compute the hash of a float x."""

    if math.isnan(x):
        return sys.hash_info.nan
    elif math.isinf(x):
        return sys.hash_info.inf if x > 0 else -sys.hash_info.inf
    else:
        return hash_fraction(*x.as_integer_ratio())

def hash_complex(z):
    """Compute the hash of a complex number z."""

    hash_value = hash_float(z.real) + sys.hash_info.imag * hash_float(z.imag)
    # do a signed reduction modulo 2**sys.hash_info.width
    M = 2**(sys.hash_info.width - 1)
    hash_value = (hash_value & (M - 1)) - (hash_value & M)
    if hash_value == -1:
        hash_value = -2
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
return hash_value
```

4.5 Τύποι Iterator

Η Python υποστηρίζει την έννοια της επανάληψης σε containers. Αυτό υλοποιείται χρησιμοποιώντας δύο διαφορετικές μεθόδους· αυτές χρησιμοποιούνται για να επιτρέψουν σε κλάσεις που ορίζονται από το χρήστη να υποστηρίξουν την επανάληψη. Οι ακολουθίες (sequences), που περιγράφονται παρακάτω με περισσότερες λεπτομέρειες, πάντα υποστηρίζουν τις μεθόδους επανάληψης.

One method needs to be defined for container objects to provide iteration support:

```
container.__iter__()
```

Return an iterator object. The object is required to support the iterator protocol described below. If a container supports different types of iteration, additional methods can be provided to specifically request iterators for those iteration types. (An example of an object supporting multiple forms of iteration would be a tree structure which supports both breadth-first and depth-first traversal.) This method corresponds to the `tp_iter` slot of the type structure for Python objects in the Python/C API.

Τα ίδια τα αντικείμενα επανάληψης απαιτείται να υποστηρίζουν τις ακόλουθες δύο μεθόδους, οι οποίες από κοινού αποτελούν το *iterator protocol*:

```
iterator.__iter__()
```

Return the iterator object itself. This is required to allow both containers and iterators to be used with the `for` and `in` statements. This method corresponds to the `tp_iter` slot of the type structure for Python objects in the Python/C API.

```
iterator.__next__()
```

Return the next item from the container. If there are no further items, raise the *StopIteration* exception. This method corresponds to the `tp_iternext` slot of the type structure for Python objects in the Python/C API.

Η Python ορίζει διάφορα αντικείμενα iterator για την υποστήριξη της επανάληψης πάνω σε γενικούς και συγκεκριμένους τύπους ακολουθιών (sequences), λεξικά (dictionaries) και άλλες πιο εξειδικευμένες μορφές. Οι συγκεκριμένοι τύποι δεν είναι σημαντικοί πέρα από την υλοποίησή του iterator πρωτοκόλλου.

Μόλις η μέθοδος `__next__()` ενός iterator κάνει raise ένα *StopIteration*, πρέπει να συνεχίσει να το κάνει σε επόμενες κλήσεις. Υλοποιήσεις που δεν υπακούν σε αυτή την ιδιότητα θεωρούνται εσφαλμένες.

4.5.1 Τύποι Generator

Python's *generators* provide a convenient way to implement the iterator protocol. If a container object's `__iter__()` method is implemented as a generator, it will automatically return an iterator object (technically, a generator object) supplying the `__iter__()` and `__next__()` methods. More information about generators can be found in the documentation for the `yield` expression.

4.6 Τύποι Ακολουθίας (Sequence) — list, tuple, range

Υπάρχουν τρεις βασικοί τύποι ακολουθιών: lists (λίστες), tuples (πλειάδες) και range objects (αντικείμενα εύρους). Πρόσθετοι τύποι ακολουθίας προσαρμοσμένοι για την επεξεργασία *binary data* και *text strings* περιγράφονται σε ειδικές ενότητες.

4.6.1 Κοινές Λειτουργίες Ακολουθιών (Sequences)

Οι λειτουργίες του παρακάτω πίνακα υποστηρίζονται από τους περισσότερους τύπους ακολουθιών, τόσο μεταβλητών (mutable) όσο και αμετάβλητων (immutable). Η `collections.abc.Sequence` ABC παρέχεται για να διευκολύνει τη σωστή υλοποίηση αυτών των πράξεων σε προσαρμοσμένους τύπους ακολουθίας.

Αυτός ο πίνακας απαριθμεί τις λειτουργίες ακολουθίας ταξινομημένες κατά αύξουσα προτεραιότητα. Στον πίνακα, τα s και t είναι ακολουθίες του ίδιου τύπου, τα n , i , j και k είναι ακέραιοι αριθμοί και το x είναι ένα αυθαίρετο αντικείμενο που πληροί οποιονδήποτε τύπο και περιορισμούς τιμής που επιβάλλονται από το s .

Οι πράξεις `in` και `not in` έχουν τις ίδιες προτεραιότητες με τις πράξεις σύγκρισης. Οι πράξεις $+$ (συνένωση) και $*$ (επανάληψη) έχουν την ίδια προτεραιότητα με τις αντίστοιχες αριθμητικές πράξεις.³

| Πράξη | Αποτέλεσμα | Σημειώσεις |
|---|---|------------|
| <code>x in s</code> | True αν ένα στοιχείο του s είναι ίσο με το x , αλλιώς False | (1) |
| <code>x not in s</code> | False αν ένα στοιχείο του s είναι ίσο με το x , αλλιώς True | (1) |
| <code>s + t</code> | η συνένωση του s και t | (6)(7) |
| <code>s * n</code> ή <code>n * s</code> | ίσο με την πρόσθεση του s στον εαυτό του n φορές | (2)(7) |
| <code>s[i]</code> | ιο στοιχείο του s , αρχή το 0 | (3) |
| <code>s[i:j]</code> | slice (υποσύνολο) του s από το i μέχρι το j | (3)(4) |
| <code>s[i:j:k]</code> | slice (υποσύνολο) του s από το i μέχρι το j με βήμα k | (3)(5) |
| <code>len(s)</code> | μήκος του s | |
| <code>min(s)</code> | μικρότερο αντικείμενο του s | |
| <code>max(s)</code> | μεγαλύτερο αντικείμενο του s | |
| <code>s.index(x[, i[, j]])</code> | δείκτης της πρώτης εμφάνισης του x στο s (μετά από τον ή στον δείκτη i και πριν από το δείκτη j) | (8) |
| <code>s.count(x)</code> | συνολικές εμφανίσεις του x στο s | |

Οι ακολουθίες (sequences) του ίδιου τύπου υποστηρίζουν επίσης συγκρίσεις. Ειδικότερα, τα tuples (πλειάδες) και οι λίστες συγκρίνονται λεξικογραφικά συγκρίνοντας τα αντίστοιχα στοιχεία. Αυτό σημαίνει ότι για να συγκρίνουμε ίσα, κάθε στοιχείο πρέπει να συγκρίνεται ως ίσο με το αντίστοιχό του, οι δύο ακολουθίες πρέπει να είναι του ίδιου τύπου και να έχουν το ίδιο μήκος. (Για πλήρεις λεπτομέρειες δείτε την αναφορά `comparisons`.)

Σημειώσεις:

- (1) Ενώ οι πράξεις `in` και `not in` χρησιμοποιούνται γενικά μόνο για απλό έλεγχο containment (αν στοιχείο περιέχεται σε μια δομή), ορισμένες εξειδικευμένες ακολουθίες (όπως όπως οι `str`, `bytes` και `bytearray`) τις χρησιμοποιούν επίσης για subsequence testing (έλεγχος υποακολουθίας):

```
>>> "gg" in "eggs"
True
```

- (2) Τιμές του n μικρότερες από το 0 αντιμετωπίζονται ως 0 (που δίνει μια κενή ακολουθία του ίδιου τύπου με s). Σημειώστε ότι τα στοιχεία της ακολουθίας s δεν αντιγράφονται· αναφέρονται πολλές φορές. Αυτό συχνά στοιχειώνει τα άτομα που ξεκινούν με Python- σκεφτείτε:

³ Πρέπει να έχουν, αφού ο parser δεν μπορεί να ξεχωρίσει τον τύπο των τελεστών.

```
>>> lists = [[]] * 3
>>> lists
[[], [], []]
>>> lists[0].append(3)
>>> lists
[[3], [], []]
```

Αυτό που συνέβη είναι ότι το `[]` είναι μια λίστα ενός στοιχείου που περιέχει μία κενή λίστα, οπότε και τα τρία στοιχεία της `[] * 3` είναι αναφορές σε αυτή τη μία κενή λίστα. Η τροποποίηση οποιουδήποτε από τα στοιχεία της `lists` τροποποιεί αυτή τη μοναδική λίστα. Μπορείτε να δημιουργήσετε μια λίστα από διαφορετικές λίστες με αυτόν τον τρόπο:

```
>>> lists = [[] for i in range(3)]
>>> lists[0].append(3)
>>> lists[1].append(5)
>>> lists[2].append(7)
>>> lists
[[3], [5], [7]]
```

Περαιτέρω επεξήγηση είναι διαθέσιμη στο λήμμα FAQ `faq-multidimensional-list`.

- (3) Εάν το i ή το j είναι αρνητικό, ο δείκτης είναι σχετικός με το τέλος της ακολουθίας s : το $\text{len}(s) + i$ ή το $\text{len}(s) + j$ αντικαθίσταται. Σημειώστε όμως ότι το -0 εξακολουθεί να είναι 0 .
- (4) Το υποσύνολο (slice) του s από το i έως το j ορίζεται ως η ακολουθία στοιχείων με δείκτη k τέτοια ώστε $i \leq k < j$. Εάν το i ή το j είναι μεγαλύτερο από το $\text{len}(s)$, χρησιμοποιήστε το $\text{len}(s)$. Αν το i παραλείπεται ή είναι `None`, χρησιμοποιήστε 0 . Αν το j παραλείπεται ή είναι μηδέν, χρησιμοποιήστε το $\text{len}(s)$. Εάν το i είναι μεγαλύτερο από ή ίσο με το j , το υποσύνολο (slice) είναι κενό.
- (5) Το υποσύνολο (slice) του s από i έως j με βήμα k ορίζεται ως η ακολουθία των στοιχείων με δείκτη $x = i + n*k$ τέτοια ώστε $0 \leq n < (j-i)/k$. Με άλλα λόγια, οι δείκτες είναι $i, i+k, i+2*k, i+3*k$ και ούτω καθεξής, σταματώντας όταν φτάσουμε στο j (αλλά ποτέ δεν περιλαμβάνει το j). Όταν το k είναι θετικό, τα i και j μειώνονται σε $\text{len}(s)$ αν είναι μεγαλύτερα. Όταν το k είναι αρνητικό, τα i και j μειώνονται σε $\text{len}(s) - 1$ αν είναι μεγαλύτερα. Εάν τα i ή j παραλείπονται ή είναι `None`, γίνονται τιμές «end» (το τέλος εξαρτάται από το πρόσημο του k). Σημειώστε ότι το k δεν μπορεί να είναι μηδέν. Εάν το k είναι `None`, αντιμετωπίζεται όπως το 1 .
- (6) Η συνένωση αμετάβλητων ακολουθιών (immutable sequences) οδηγεί πάντα σε ένα νέο αντικείμενο. Αυτό σημαίνει ότι η δημιουργία μιας ακολουθίας με επαναλαμβανόμενη συνένωση θα έχει τετραγωνικό κόστος χρόνου εκτέλεσης (runtime cost) στο συνολικό μήκος της ακολουθίας. Για να πάρετε ένα γραμμικό κόστος χρόνου εκτέλεσης (runtime cost), πρέπει να μεταβείτε σε μία από τις παρακάτω εναλλακτικές λύσεις:
 - αν συνενώνεται αντικείμενα `str`, μπορείτε να δημιουργήσετε μια λίστα και να χρησιμοποιήσετε την `str.join()` στο τέλος ή αλλιώς να γράψετε σε ένα `io.StringIO` instance και ανακτήσετε την τιμή της όταν ολοκληρωθεί
 - αν συνενώνεται αντικείμενα `bytes`, μπορείτε να χρησιμοποιήσετε παρόμοια τη μέθοδο `bytes.join()` ή `io.BytesIO`, ή μπορείτε να κάνετε in-place συνένωση (concatenation) με ένα `bytearray` αντικείμενο. Τα αντικείμενα `bytearray` είναι μεταβλητά και έχουν έναν αποτελεσματικό μηχανισμό συνολικής κατανομής (overallocation)
 - αν συνενώνεται αντικείμενα `tuple`, επεκτείνετε μια `list` αντ' αυτού
 - για άλλους τύπους, ερευνήστε τη σχετική τεκμηρίωση των κλάσεων
- (7) Ορισμένοι τύποι ακολουθιών (όπως `range`) υποστηρίζουν μόνο ακολουθίες στοιχείων που ακολουθούν συγκεκριμένα μοτίβα, και ως εκ τούτου δεν υποστηρίζουν ακολουθία συνένωση ή επανάληψη.
- (8) Το `index` κάνει `raise ValueError` όταν το x δεν βρίσκεται στο s . Όχι όλες οι υλοποιήσεις υποστηρίζουν τη διαβίβαση των πρόσθετων ορίων i και j . Αυτές οι παράμετροι επιτρέπουν την αποτελεσματική αναζήτηση

υποτιμημάτων της ακολουθίας. Η διαβίβαση των πρόσθετων ορίων είναι περίπου ισοδύναμη με τη χρήση του `s[i:j].index(x)`, μόνο χωρίς να αντιγράφονται δεδομένα και με τον επιστρεφόμενο δείκτη να είναι σχετικός με την αρχή της ακολουθίας και όχι στην αρχή του υποσυνόλου (slice).

4.6.2 Τύποι Αμετάβλητων Ακολουθιών (Sequences)

Η μόνη λειτουργία που υλοποιούν οι αμετάβλητοι γενικοί τύποι ακολουθίας που δεν είναι υλοποιημένοι από μεταβλητούς τύπους ακολουθίας, είναι η υποστήριξη της `hash()` built-in.

Αυτή η υποστήριξη επιτρέπει αμετάβλητες ακολουθίες, όπως οι περιπτώσεις των `tuple`, να χρησιμοποιούνται ως κλειδιά `dict` και να αποθηκεύονται σε `set` και `frozenset` instances.

Η προσπάθεια κατακερματισμού μιας αμετάβλητης ακολουθίας που περιέχει μη κατακερματιστέες (unhashable) τιμές θα οδηγήσει σε `TypeError`.

4.6.3 Τύποι Μεταβλητών Ακολουθιών (Sequences)

Οι λειτουργίες του ακόλουθου πίνακα ορίζονται σε μεταβλητούς τύπους ακολουθίας. Η `collections.abc.MutableSequence` ABC παρέχεται για να κάνει ευκολότερη την σωστή υλοποίηση αυτών των λειτουργιών σε προσαρμοσμένους τύπους ακολουθιών.

Στον πίνακα το `s` είναι ένα instance ενός μεταβλητού τύπου ακολουθίας, το `t` είναι οποιοδήποτε iterable αντικείμενο και το `x` είναι ένα αυθαίρετο αντικείμενο που πληροί οποιονδήποτε τύπο και περιορισμούς τιμής που επιβάλλονται από το `s` (για παράδειγμα, το `bytearray` δέχεται μόνο ακέραιους που πληρούν τον περιορισμό `0 <= x <= 255`).

| Πράξη | Αποτέλεσμα | Σημειώσεις |
|--|---|------------|
| <code>s[i] = x</code> | το στοιχείο <code>i</code> του <code>s</code> αντικαθίσταται από το <code>x</code> | |
| <code>s[i:j] = t</code> | το υποσύνολο (slice) του <code>s</code> από το <code>i</code> έως το <code>j</code> αντικαθίσταται από τα περιεχόμενα του iterable <code>t</code> | |
| <code>del s[i:j]</code> | ίδιο με το <code>s[i:j] = []</code> | |
| <code>s[i:j:k] = t</code> | τα στοιχεία του <code>s[i:j:k]</code> αντικαθίστανται από εκείνα του <code>t</code> | (1) |
| <code>del s[i:j:k]</code> | αφαιρεί τα στοιχεία του <code>s[i:j:k]</code> από τη λίστα | |
| <code>s.append(x)</code> | εισάγει το <code>x</code> στο τέλος της ακολουθίας (ίδιο με <code>s[len(s):len(s)] = [x]</code>) | |
| <code>s.clear()</code> | αφαιρεί όλα τα στοιχεία από το <code>s</code> (ίδιο με το <code>del s[:]</code>) | (5) |
| <code>s.copy()</code> | δημιουργεί ένα shallow αντίγραφο του <code>s</code> (ίδιο με το <code>s[:]</code>) | (5) |
| <code>s.extend(t)</code> ή <code>s += t</code> | επεκτείνει το <code>s</code> με τα περιεχόμενα του <code>t</code> (ως επί το πλείστον το ίδιο με το <code>s[len(s):len(s)] = t</code>) | |
| <code>s *= n</code> | ενημερώνει το <code>s</code> με το περιεχόμενό του επαναλαμβανόμενο <code>n</code> φορές | (6) |
| <code>s.insert(i, x)</code> | εισάγει το <code>x</code> στο <code>s</code> στο δείκτη που δίνεται από το <code>i</code> (το ίδιο με το <code>s[i:i] = [x]</code>) | |
| <code>s.pop()</code> ή <code>s.pop(i)</code> | ανακτά το στοιχείο στο <code>i</code> και το αφαιρεί επίσης από το <code>s</code> | (2) |
| <code>s.remove(x)</code> | remove the first item from <code>s</code> where <code>s[i]</code> is equal to <code>x</code> | (3) |
| <code>s.reverse()</code> | αντιστρέφει τα στοιχεία του <code>s</code> | (4) |

Σημειώσεις:

- (1) `t` must have the same length as the slice it is replacing.
- (2) Το προαιρετικό όρισμα `i` έχει προεπιλεγμένη τιμή `-1`, έτσι ώστε από default το τελευταίο στοιχείο αφαιρείται και επιστρέφεται.

- (3) η `remove()` κάνει `raise ValueError` όταν το `x` δεν βρίσκεται στο `s`.
- (4) Η μέθοδος `reverse()` τροποποιεί την ακολουθία στη θέση της για οικονομία χώρου όταν αντιστρέφεται μια μεγάλη ακολουθία. Να υπενθυμίσουμε στους χρήστες ότι λειτουργεί με παρενέργεια, δεν επιστρέφει την αντιστραμμένη ακολουθία.
- (5) η `clear()` και η `copy()` περιλαμβάνονται για λόγους συνέπειας με τα `interfaces` των μεταβλητών `container` που δεν υποστηρίζουν λειτουργίες τμηματοποίησης (όπως τα `dict` και `set`). Η `copy()` δεν αποτελεί μέρος της `collections.abc.MutableSequence` ABC, αλλά οι περισσότερες κλάσεις μεταβλητών ακολουθιών την παρέχουν.
- Νέο στην έκδοση 3.3: μέθοδοι `clear()` και `copy()`.
- (6) Η τιμή `n` είναι ένας ακέραιος αριθμός ή ένα αντικείμενο που υλοποιεί την `__index__()`. Οι μηδενικές και αρνητικές τιμές του `n` καθαρίζουν την ακολουθία. Τα στοιχεία της ακολουθίας δεν αντιγράφονται· αναφέρονται πολλές φορές, όπως εξηγείται για το `s * n` στο *Κοινές Λειτουργίες Ακολουθιών (Sequences)*.

4.6.4 Λίστες

Οι λίστες είναι μεταβλητές ακολουθίες, που συνήθως χρησιμοποιούνται για την αποθήκευση συλλογών ομοιογενών στοιχείων (όπου ο ακριβής βαθμός ομοιότητας ποικίλλει ανάλογα με εφαρμογή).

class list (*[iterable]*)

Οι λίστες μπορούν να κατασκευαστούν με διάφορους τρόπους:

- Χρησιμοποιείτε ένα ζεύγος αγκυλών για να δηλώσετε την κενή λίστα: `[]`
- Χρησιμοποιώντας αγκύλες, διαχωρίζοντας τα στοιχεία με κόμματα: `[a], [a, b, c]`
- Χρήση ενός list comprehension: `[x for x in iterable]`
- Χρήση του κατασκευαστή τύπου (type constructor): `list()` ή `list(iterable)`

Ο κατασκευαστής (constructor) δημιουργεί μια λίστα της οποίας τα στοιχεία είναι τα ίδια και με την ίδια σειρά όπως τα στοιχεία του *iterable*. Το *iterable* μπορεί να είναι είτε μια ακολουθία, είτε ένας `container` που υποστηρίζει την επανάληψη, ή ένα αντικείμενο `iterator`. Εάν το *iterable* είναι ήδη μια λίστα, δημιουργείται ένα αντίγραφο και επιστρέφεται, παρόμοια με την `iterable[:]`. Για παράδειγμα, η `list('abc')` επιστρέφει `['a', 'b', 'c']` και η `list((1, 2, 3))` επιστρέφει `[1, 2, 3]`. Αν δεν δοθεί κανένα όρισμα, ο κατασκευαστής δημιουργεί μία νέα κενή λίστα, `[]`.

Πολλές άλλες λειτουργίες παράγουν επίσης λίστες, συμπεριλαμβανομένης της built-in `sorted()`.

Οι λίστες υλοποιούν όλες τις *common* και *mutable* λειτουργίες ακολουθίας. Οι λίστες παρέχουν επίσης την ακόλουθη πρόσθετη μέθοδο:

sort (*, *key=None*, *reverse=False*)

Αυτή η μέθοδος ταξινομεί τη λίστα, χρησιμοποιώντας μόνο συγκρίσεις `<` μεταξύ στοιχείων. Οι εξαιρέσεις δεν καταστέλλονται - αν αποτύχει κάποια πράξη σύγκρισης, ολόκληρη η λειτουργία ταξινόμησης θα αποτύχει (και η λίστα θα παραμείνει πιθανότατα σε μια μερικώς τροποποιημένη κατάσταση).

η `sort()` δέχεται δύο ορίσματα που μπορούν να περάσουν μόνο με τη λέξη-κλειδί (*keyword-only arguments*):

το *key* καθορίζει μια συνάρτηση ενός ορίσματος που χρησιμοποιείται για την εξαγωγή ενός κλειδιού σύγκρισης (comparison key) από κάθε στοιχείο της λίστας (για παράδειγμα, `key=str.lower`). Το κλειδί που αντιστοιχεί σε κάθε στοιχείο της λίστας υπολογίζεται μία φορά και στη συνέχεια χρησιμοποιείται για ολόκληρη τη διαδικασία ταξινόμησης. Η προεπιλεγμένη τιμή (default) `None` σημαίνει ότι τα στοιχεία της λίστας ταξινομούνται απευθείας χωρίς να υπολογίζεται ξεχωριστή τιμή κλειδιού.

Το utility `functools.cmp_to_key()` είναι διαθέσιμο για τη μετατροπή μια συνάρτησης `cmp` styl 2.x σε συνάρτηση *key*.

η *reverse* είναι μια λογική (boolean) τιμή. Αν τεθεί σε `True`, τότε τα στοιχεία της λίστας ταξινομούνται σαν να ήταν αντίστροφη κάθε σύγκριση.

Αυτή η μέθοδος τροποποιεί την ακολουθία για εξοικονόμηση χώρου κατά την ταξινόμηση μιας μεγάλης ακολουθίας. Να υπενθυμίσουμε στους χρήστες ότι λειτουργεί με παρενέργεια, δεν επιστρέφει την ταξινομημένη ακολουθία (χρησιμοποιήστε την `sorted()` για να ζητήσετε μια νέα περίπτωση ταξινομημένης λίστας).

Η μέθοδος `sort()` είναι εγγυημένα σταθερή. Μια ταξινόμηση είναι σταθερή αν εγγυάται ότι δεν θα αλλάξει τη σχετική σειρά των στοιχείων που συγκρίνουν ίσα — αυτό είναι χρήσιμο για την ταξινόμηση σε πολλαπλά περάσματα (για παράδειγμα, ταξινόμηση κατά τιμήμα, στη συνέχεια με βάση το μισθολογικό κλιμάκιο κτλ).

Για παραδείγματα ταξινόμησης και ένα σύντομο tutorial, δείτε [sortinghowto](#).

CPython implementation detail: Ενώ μια λίστα ταξινομείται, το αποτέλεσμα της προσπάθειας μετάλλαξης, ή ακόμα και η επιθεώρηση, της λίστας είναι απροσδιόριστη. Η υλοποίηση της Python στη C κάνει την λίστα να εμφανίζεται κενή για όλη τη διάρκεια, και κάνει `raise ValueError` αν ανιχνεύσει ότι η λίστα έχει μεταλλαχθεί κατά τη διάρκεια μιας ταξινόμησης.

4.6.5 Πλειάδες (Tuples)

Οι πλειάδες (tuples) είναι αμετάβλητες ακολουθίες, που συνήθως χρησιμοποιούνται για την αποθήκευση συλλογών ετερογενών δεδομένων (όπως οι 2-tuples που παράγονται από την built-in `enumerate()`). Τα tuples χρησιμοποιούνται επίσης για περιπτώσεις όπου μια αμετάβλητη ακολουθία ομοιογενών δεδομένων (όπως για παράδειγμα για να επιτρέπεται η αποθήκευση σε ένα `set` ή σε ένα `dict` instance).

class tuple (`[iterable]`)

Οι πλειάδες (tuples) μπορούν να κατασκευαστούν με διάφορους τρόπους:

- Χρήση ενός ζεύγους παρενθέσεων για να δηλωθεί το κενό tuple (πλειάδα): `()`
- Χρήση ενός κόμματος στο τέλος για ένα μοναδικό tuple (πλειάδα): `a,` ή `(a,)`
- Διαχωρισμός στοιχείων με κόμμα: `a, b, c` ή `(a, b, c)`
- Χρήση του ενσωματωμένου `tuple():tuple()` ή `tuple(iterable)`

Ο κατασκευαστής (constructor) δημιουργεί μια πλειάδα (tuple) του οποίου τα στοιχεία είναι τα ίδια και στην ίδια σειρά με τα στοιχεία του `iterable`. Η `iterable` μπορεί να είναι είτε μια ακολουθία, είτε έναν container που υποστηρίζει την επανάληψη, ή ένα αντικείμενο iterator. Εάν το `iterable` είναι ήδη ένα tuple, επιστρέφεται αμετάβλητο. Για παράδειγμα, το `tuple('abc')` επιστρέφει `('a', 'b', 'c')` και το `tuple([1, 2, 3])` επιστρέφει `(1, 2, 3)`. Αν δεν δοθεί κανένα όρισμα, ο κατασκευαστής δημιουργεί μια ένα κενό tuple, `()`.

Σημειώστε ότι στην πραγματικότητα το κόμμα είναι αυτό που κάνει ένα tuple (πλειάδα), όχι οι παρενθέσεις. Οι παρενθέσεις είναι προαιρετικές, εκτός από την περίπτωση κενού tuple ή όταν χρειάζονται για την αποφυγή συντακτικής ασάφειας. Για παράδειγμα, η `f(a, b, c)` είναι μια κλήση συνάρτησης με τρία ορίσματα, ενώ η `f((a, b, c))` είναι μια συνάρτηση κλήση συνάρτησης με ένα 3-tuple ως μοναδικό όρισμα.

Τα Tuples υλοποιούν όλες τις πράξεις ακολουθιών *common*.

Για ετερογενείς συλλογές δεδομένων όπου η πρόσβαση με βάση το όνομα είναι σαφέστερη από την πρόσβαση με βάση το δείκτη, το `collections.namedtuple()` μπορεί να είναι μια πιο κατάλληλη επιλογή από ένα απλό αντικείμενο tuple (πλειάδα).

4.6.6 Εύρη (Ranges)

Ο τύπος `range` αναπαριστά μια αμετάβλητη ακολουθία αριθμών και συνήθως χρησιμοποιείται για την επανάληψη ενός συγκεκριμένου αριθμού επαναλήψεων σε βρόχους `for`.

class `range` (*stop*)

class `range` (*start*, *stop* [, *step*])

Τα ορίσματα του κατασκευαστή εύρους (`range` constructor) πρέπει να είναι ακέραιοι αριθμοί (είτε της built-in `int` ή οποιοδήποτε αντικείμενο που υλοποιεί την ειδική μέθοδο `__index__()`). Εάν το όρισμα *step* παραλείπεται, το προεπιλογή (default) είναι 1. Εάν το όρισμα *start* παραλείπεται, το προεπιλογή (default) είναι 0. Εάν το *step* είναι μηδέν, γίνεται `raise` ένα `ValueError`.

Για ένα θετικό βήμα, τα περιεχόμενα του `range` (εύρους) `r` καθορίζονται από τον τύπο `r[i] = start + step*i` όπου `i >= 0` και `r[i] < stop`.

Για ένα αρνητικό βήμα, τα περιεχόμενα του εύρους (`range`) εξακολουθούν να καθορίζονται από τον τύπο `r[i] = start + step*i`, αλλά οι περιορισμοί είναι `i >= 0` και `r[i] > stop`.

Ένα αντικείμενο `range` θα είναι άδαιο εάν το `r[0]` δεν πληροί τον περιορισμό τιμής. Τα `ranges` υποστηρίζουν αρνητικούς δείκτες, αλλά αυτοί ερμηνεύονται ως δείκτες από το τέλος της ακολουθίας που καθορίζεται από τους θετικούς δείκτες.

Τα `ranges` που περιέχουν απόλυτες τιμές μεγαλύτερες από `sys.maxsize` είναι επιτρεπτά, αλλά ορισμένα χαρακτηριστικά (όπως `len()`) μπορεί να κάνουν `raise OverflowError`.

Παραδείγματα `Range`:

```
>>> list(range(10))
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> list(range(1, 11))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> list(range(0, 30, 5))
[0, 5, 10, 15, 20, 25]
>>> list(range(0, 10, 3))
[0, 3, 6, 9]
>>> list(range(0, -10, -1))
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
>>> list(range(0))
[]
>>> list(range(1, 0))
[]
```

Τα `ranges` υλοποιούν όλες τις ακολουθίες *common* εκτός από τη συνένωση και την επανάληψη (λόγω του γεγονότος ότι τα `range` αντικείμενα μπορούν να αναπαραστήσουν μόνο ακολουθίες που ακολουθούν ένα αυστηρό μοτίβο και η επανάληψη και η συνένωση συνήθως παραβιάζουν αυτό το πρότυπο).

start

Η τιμή της παραμέτρου *start* (ή 0 αν η παράμετρος δεν παρέχεται)

stop

Η τιμή της παραμέτρου *stop*

step

Η τιμή της παραμέτρου *step* (ή 1 αν η παράμετρος δεν παρέχεται)

Το πλεονέκτημα του τύπου `range` έναντι ενός κανονικού τύπου `list` ή `tuple` είναι ότι ένα αντικείμενο `range` θα παίρνει πάντα το ίδιο (μικρό) ποσό μνήμης, ανεξάρτητα από το μέγεθος του `range` που αντιπροσωπεύει (μιας και αποθηκεύει μόνο τις τιμές *start*, *stop* και *step*, υπολογίζοντας τα μεμονωμένα στοιχεία και τις υποπεριοχές όπως απαιτείται).

Τα αντικείμενα `range` υλοποιούν την `collections.abc.Sequence` ABC, και παρέχουν χαρακτηριστικά όπως δοκιμές περιορισμού, αναζήτηση δείκτη στοιχείου, τεμαχισμό και υποστήριξη αρνητικών δεικτών (βλ. *Τύποι Ακολουθίας (Sequence) — list, tuple, range*):

```
>>> r = range(0, 20, 2)
>>> r
range(0, 20, 2)
>>> 11 in r
False
>>> 10 in r
True
>>> r.index(10)
5
>>> r[5]
10
>>> r[:5]
range(0, 10, 2)
>>> r[-1]
18
```

Ο έλεγχος των αντικειμένων `range` για ισότητα με `==` και `!=` τα συγκρίνει ως ακολουθίες. Δηλαδή, δύο αντικείμενα `range` θεωρούνται ίσα αν αντιπροσωπεύουν την ίδια ακολουθία τιμών. (Σημειώστε ότι δύο αντικείμενα `range` που συγκρίνονται ως ίσα μπορεί να έχουν διαφορετικά `start`, `stop` και `step` χαρακτηριστικά, για παράδειγμα `range(0) == range(2, 1, 3)` ή `range(0, 3, 2) == range(0, 4, 2)`.)

Άλλαξε στην έκδοση 3.2: Υλοποιείστε την ακολουθία ABC. Υποστηρίξτε την τμηματοποίηση και τους αρνητικούς δείκτες. Δοκιμάστε τα `int` αντικείμενα για συμμετοχή σε σταθερό χρόνο αντί της επανάληψης σε όλα τα αντικείμενα.

Άλλαξε στην έκδοση 3.3: Ορίστε τα `==` και `!=` για να συγκρίνετε αντικείμενα `range` με βάση την ακολουθία των τιμών που ορίζουν (αντί να συγκρίνουν με βάση την ταυτότητα του αντικειμένου).

Νέο στην έκδοση 3.3: The `start`, `stop` and `step` attributes.

Δείτε επίσης:

- The [linspace recipe](#) shows how to implement a lazy version of range suitable for floating point applications.

4.7 Τύπος Ακολουθίας (Sequence) Κειμένου — `str`

Τα δεδομένα κειμένου στην Python αντιμετωπίζονται με αντικείμενα `str` ή *strings*. Τα αλφαριθμητικά (strings) είναι αμετάβλητες *sequences* των Unicode points. Τα αλφαριθμητικά γράφονται με διάφορους τρόπους:

- Απλά εισαγωγικά: `'allows embedded "double" quotes'`
- Διπλά εισαγωγικά: `"allows embedded "double" quotes"`
- Τριπλά εισαγωγικά: `'''Three single quotes'''`, `"""Three double quotes"""`

Τα αλφαριθμητικά σε τριπλά εισαγωγικά μπορούν να καλύπτουν πολλές γραμμές - όλα τα σχετικά κενά θα συμπεριληφθούν στο αλφαριθμητικό.

Τα Αλφαριθμητικά (strings) που αποτελούν μέρος μιας ενιαίας έκφρασης και έχουν μόνο κενά μεταξύ τους, θα μετατραπούν σιωπηρά σε ένα ενιαίο αλφαριθμητικό literal. Δηλαδή, `("spam " "eggs") == "spam eggs"`.

See strings for more about the various forms of string literal, including supported escape sequences, and the `r` («raw») prefix that disables most escape sequence processing.

Τα αλφαριθμητικά (strings) μπορούν επίσης να δημιουργηθούν από άλλα αντικείμενα χρησιμοποιώντας τον constructor `str`.

Εφόσον δεν υπάρχει ξεχωριστός τύπος «character», το indexing μιας συμβολοσειράς (string) παράγει συμβολοσειρές μήκους 1. Δηλαδή, για μια μη κενή συμβολοσειρά *s*, *s*[0] == *s*[0:1].

Δεν υπάρχει επίσης μεταβλητός τύπος συμβολοσειράς (string), αλλά το *str.join()* ή το *io.StringIO* μπορεί να χρησιμοποιηθεί για την αποτελεσματική κατασκευή συμβολοσειρών από πολλαπλά μέρη.

Άλλαξε στην έκδοση 3.3: Για συμβατότητα προς τα πίσω (backwards compatibility) με τη σειρά Python 2, το πρόθεμα *u* είναι επιτρεπτό και πάλι σε αλφαριθμητικά. Δεν έχει καμία επίδραση στη σημασία των αλφαριθμητικών και δεν μπορεί να συνδυαστεί με το πρόθεμα *r*.

class str (*object*="")

class str (*object*=*b*", *encoding*='utf-8', *errors*='strict')

Επιστρέφει μια έκδοση *string* του *object*. Αν το *object* δεν παρέχεται, επιστρέφει κενό αλφαριθμητικό. Διαφορετικά, η συμπεριφορά της *str()* εξαρτάται από το αν δίνεται *encoding* ή *errors*, ως εξής.

If neither *encoding* nor *errors* is given, *str(object)* returns *type(object).__str__(object)*, which is the «informal» or nicely printable string representation of *object*. For string objects, this is the string itself. If *object* does not have a *__str__()* method, then *str()* falls back to returning *repr(object)*.

Εάν δίνεται τουλάχιστον ένα από τα *encoding* ή *errors*, το *object* θα πρέπει να είναι ένα *bytes-like object* (π.χ. *bytes* ή *bytearray*). Σε αυτή την περίπτωση, αν το *object* είναι ένα αντικείμενο *bytes* (ή *bytearray*), τότε το *str(bytes, encoding, errors)* είναι ισοδύναμο με το *bytes.decode(encoding, errors)*. Διαφορετικά, το αντικείμενο *bytes* που υποκρύπτει το αντικείμενο *buffer* λαμβάνεται πριν από την κλήση του *bytes.decode()*. Δείτε *Τύποι δυαδικής ακολουθίας* — *bytes*, *bytearray*, *memoryview* και *bufferobjects* για πληροφορίες σχετικά με τα αντικείμενα *buffer*.

Πέρασμα ενός αντικειμένου *bytes* στο *str()* χωρίς το *encoding* ή το *errors* ορίσματα εμπίπτει στην πρώτη περίπτωση επιστροφής της άτυπης αναπαράστασης συμβολοσειράς (string) (δείτε επίσης την επιλογή *-b* της γραμμής εντολών για Python). Για παράδειγμα:

```
>>> str(b'Zoot!')
"b'Zoot!'"
```

Για περισσότερες πληροφορίες σχετικά με την κλάση *str* και τις μεθόδους της, δείτε *Τύπος Ακολουθίας (Sequence) Κεμένον* — *str* και την ενότητα *Μέθοδοι Συμβολοσειράς (String)* παρακάτω. Για την παραγωγή μορφοποιημένων συμβολοσειρών (string), ανατρέξτε στις ενότητες *f-strings* και *Format String Syntax*. Επιπλέον, δείτε την ενότητα *Text Processing Services*.

4.7.1 Μέθοδοι Συμβολοσειράς (String)

Οι συμβολοσειρές (string) υλοποιούν όλες τις λειτουργίες των *common* ακολουθιών, μαζί με τις πρόσθετες μεθόδους που περιγράφονται παρακάτω.

Οι συμβολοσειρές (string) υποστηρίζουν επίσης δύο στυλ μορφοποίησης συμβολοσειρών, το ένα παρέχει ένα μεγάλο βαθμό ευελιξίας και προσαρμογής (βλέπε *str.format()*, *Format String Syntax* και *Custom String Formatting*) και το άλλο βασίζεται στο στυλ μορφοποίησης *printf* της C που χειρίζεται ένα στενότερο εύρος τύπων και είναι λίγο πιο δύσκολο να χρησιμοποιηθεί σωστά, αλλά είναι συχνά ταχύτερο για τις περιπτώσεις που μπορεί να χειριστεί (*printf-style String Formatting*).

Το τμήμα *Text Processing Services* της πρότυπης βιβλιοθήκης καλύπτει έναν αριθμό από άλλες ενότητες που παρέχουν διάφορες βοηθητικές υπηρεσίες που σχετίζονται με το κείμενο (συμπεριλαμβανομένης της υποστήριξης των κανονικών εκφράσεων στην ενότητα *re*).

str.capitalize()

Επιστρέφει ένα αντίγραφο της συμβολοσειράς (string) με τον πρώτο χαρακτήρα κεφαλαίο και τα υπόλοιπα με πεζά γράμματα.

Άλλαξε στην έκδοση 3.8: Ο πρώτος χαρακτήρας τίθεται τώρα σε titlecase αντί για uppercase. Αυτό σημαίνει ότι χαρακτήρες όπως οι διγράφοι (digraphs) θα έχουν μόνο το πρώτο γράμμα τους με κεφαλαίο, αντί για όλους τους χαρακτήρες.

`str.casefold()`

Επιστρέφει ένα αντίγραφο της συμβολοσειράς (string) σε casefolded μορφή. Οι casefolded συμβολοσειρές μπορούν να χρησιμοποιηθούν για caseless matching.

Το casefolding είναι παρόμοιο με το lowercasing αλλά πιο επιθετικό επειδή έχει ως στόχο να αφαιρέσει όλες τις διακρίσεις της πεζότητας σε μια συμβολοσειρά (string). Για παράδειγμα, το γερμανικό πεζό γράμμα 'ß' ισοδυναμεί με "ss". Αφού είναι ήδη πεζό, η `lower()` δεν θα έκανε τίποτα στο 'ß'· η `casefold()` το μετατρέπει σε "ss".

The casefolding algorithm is described in section 3.13 of the Unicode Standard.

Νέο στην έκδοση 3.3.

`str.center(width[, fillchar])`

Επιστρέφει ένα κεντραρισμένο σε μια συμβολοσειρά (string) μήκους *πλάτος*. Το padding γίνεται με τη χρήση του καθορισμένου *fillchar* (το default είναι ένα κενό ASCII). Η αρχική συμβολοσειρά επιστρέφεται εάν το *width* είναι μικρότερο ή ίσο με το `len(s)`.

`str.count(sub[, start[, end]])`

Επιστρέφει τον αριθμό των μη επικαλυπτόμενων (non-overlapping) εμφανίσεων της υποομάδας *sub* στο εύρος *[start, end]*. Τα προαιρετικά ορίσματα *start* και *end* ερμηνεύονται όπως στο slice notation.

`str.encode(encoding="utf-8", errors="strict")`

Return an encoded version of the string as a bytes object. Default encoding is 'utf-8'. *errors* may be given to set a different error handling scheme. The default for *errors* is 'strict', meaning that encoding errors raise a [UnicodeError](#). Other possible values are 'ignore', 'replace', 'xmlcharrefreplace', 'backslashreplace' and any other name registered via `codecs.register_error()`, see section [Error Handlers](#). For a list of possible encodings, see section [Standard Encodings](#).

By default, the *errors* argument is not checked for best performances, but only used at the first encoding error. Enable the [Python Development Mode](#), or use a debug build to check *errors*.

Άλλαξε στην έκδοση 3.1: Support for keyword arguments added.

Άλλαξε στην έκδοση 3.9: The *errors* is now checked in development mode and in debug mode.

`str.endswith(suffix[, start[, end]])`

Επιστρέφει True αν η συμβολοσειρά (string) τελειώνει με το καθορισμένο *suffix*, αλλιώς επιστρέφει False. Το *suffix* μπορεί επίσης να είναι ένα tuple (πλειάδα) από επιθέματα που πρέπει να αναζητηθούν. Με το προαιρετικό *start*, το τεστ αρχίζει από αυτή τη θέση. Με το προαιρετικό *end*, η σύγκριση σταματά σε αυτή τη θέση.

`str.expandtabs(tabsize=8)`

Επιστρέφει ένα αντίγραφο της συμβολοσειράς (string) όπου όλοι οι χαρακτήρες tab αντικαθίστανται από έναν ή περισσότερα κενά, ανάλογα με την τρέχουσα στήλη και το δεδομένο μέγεθος των tabs. Οι θέσεις tab εμφανίζονται κάθε *tabsize* χαρακτήρες (το default είναι 8, δίνοντας tab θέσεις στις στήλες 0, 8, 16 κ.ο.κ.). Για την επέκταση της συμβολοσειράς, η τρέχουσα στήλη μηδενίζεται και η συμβολοσειρά εξετάζεται χαρακτήρας προς χαρακτήρα. Εάν ο χαρακτήρας είναι tab (\t), εισάγονται ένας ή περισσότεροι χαρακτήρες κενών στο αποτέλεσμα μέχρι η τρέχουσα στήλη να είναι ίση με την επόμενη θέση tab. (Ο ίδιος ο χαρακτήρας tab δεν αντιγράφεται.) Εάν ο χαρακτήρας είναι νέα γραμμή (\n) ή return (\r), αντιγράφεται και η τρέχουσα στήλη επαναφέρεται στο μηδέν. Οποιοσδήποτε άλλος χαρακτήρας αντιγράφεται αμετάβλητος και η τρέχουσα στήλη αυξάνεται κατά ένα, ανεξάρτητα από τον τρόπο αναπαράστασης του χαρακτήρα όταν τυπώνεται.

```
>>> '01\t012\t0123\t01234'.expandtabs()
'01      012      0123      01234'
>>> '01\t012\t0123\t01234'.expandtabs(4)
'01  012 0123    01234'
```

`str.find(sub[, start[, end]])`

Επιστρέφει τον χαμηλότερο δείκτη στη συμβολοσειρά (string) όπου η υπό-συμβολοσειρά *sub* βρίσκεται μέσα στο υποσύνολο (slice) `s[start:end]`. Τα προαιρετικά ορίσματα *start* και *end* ερμηνεύονται όπως στο notation του υποσυνόλου. Επιστρέφει `-1` αν δεν βρεθεί το *sub*.

Σημείωση: Η μέθοδος `find()` θα πρέπει να χρησιμοποιείται μόνο αν πρέπει να γνωρίζετε τη θέση του *sub*. Για να ελέγξετε αν το *sub* είναι υποσύνολο ή όχι, χρησιμοποιήστε τον τελεστή `in`:

```
>>> 'Py' in 'Python'
True
```

`str.format(*args, **kwargs)`

Εκτέλεση μιας λειτουργίας μορφοποίησης συμβολοσειράς (string formatting). Η συμβολοσειρά στην οποία αυτή η μέθοδος καλείται μπορεί να περιέχει κυριολεκτικό κείμενο ή πεδία αντικατάστασης που οριοθετούνται από αγκύλες `{ }`. Κάθε πεδίο αντικατάστασης περιέχει είτε τον αριθμητικό δείκτη ενός ορίσματος θέσης, είτε το όνομα ενός keyword ορίσματος. Επιστρέφει ένα αντίγραφο της συμβολοσειράς όπου κάθε πεδίο αντικατάστασης αντικαθίσταται με την τιμή της συμβολοσειράς του αντίστοιχου ορίσματος.

```
>>> "The sum of 1 + 2 is {0}".format(1+2)
'The sum of 1 + 2 is 3'
```

Δείτε το *Format String Syntax* για μια περιγραφή των διαφόρων επιλογών μορφοποίησης που μπορούν να καθοριστούν στην μορφοποίηση συμβολοσειρών (format strings).

Σημείωση: Κατά τη μορφοποίηση ενός αριθμού (*int*, *float*, *complex*, *decimal.Decimal* και υποκλάσεις) με τον τύπο `n` (π.χ.: `'{:n}'.format(1234)`), η συνάρτηση θέτει προσωρινά την τοποθεσία `LC_CTYPE` στην τοποθεσία `LC_NUMERIC` για την αποκωδικοποίηση των `decimal_point` και `thousands_sep` πεδίων του `localeconv()` αν είναι μη ASCII ή μεγαλύτερα από 1 byte, και το `locale LC_NUMERIC` είναι διαφορετικό από το `locale LC_CTYPE`. Αυτή η προσωρινή αλλαγή επηρεάζει και άλλα νήματα (threads).

Άλλαξε στην έκδοση 3.7: Κατά τη μορφοποίηση ενός αριθμού με τον τύπο `n`, η συνάρτηση θέτει προσωρινά το `locale LC_CTYPE` στο `locale LC_NUMERIC` σε κάποιες περιπτώσεις.

`str.format_map(mapping)`

Παρόμοιο με το `str.format(**mapping)`, εκτός από το ότι χρησιμοποιείται το `mapping` απευθείας και δεν αντιγράφεται σε μια *dict*. Αυτό είναι χρήσιμο αν για παράδειγμα το `mapping` είναι μια υποκλάση του `dict`:

```
>>> class Default(dict):
...     def __missing__(self, key):
...         return key
...
>>> '{name} was born in {country}'.format_map(Default(name='Guido'))
'Guido was born in country'
```

Νέο στην έκδοση 3.2.

`str.index(sub[, start[, end]])`

Όπως η `find()`, αλλά κάνει `raise ValueError` όταν η υπό-συμβολοσειρά (substring) δεν έχει βρεθεί.

`str.isalnum()`

Επιστρέφει `True` αν όλοι οι χαρακτήρες στη συμβολοσειρά (string) είναι αλφαριθμητικοί και υπάρχει τουλάχιστον ένας χαρακτήρας, διαφορετικά `False`. Ένας χαρακτήρας `c` είναι αλφαριθμητικό εάν ένα από τα ακόλουθα επιστρέφει `True`: `c.isalpha()`, `c.isdecimal()`, `c.isdigit()`, ή `c.isnumeric()`.

`str.isalpha()`

Return `True` if all characters in the string are alphabetic and there is at least one character, `False` otherwise. Alphabetic characters are those characters defined in the Unicode character database as «Letter», i.e., those with general category property being one of «Lm», «Lt», «Lu», «Ll», or «Lo». Note that this is different from the «Alphabetic» property defined in the Unicode Standard.

`str.isascii()`

Επιστρέφει `True` εάν η συμβολοσειρά (string) είναι κενή ή όλοι οι χαρακτήρες της συμβολοσειράς είναι ASCII, αλλιώς `False`. Οι χαρακτήρες ASCII έχουν σημεία κωδικοποίησης στην περιοχή U+0000-U+007F.

Νέο στην έκδοση 3.7.

`str.isdecimal()`

Επιστρέφει `True` αν όλοι οι χαρακτήρες στη συμβολοσειρά (string) είναι δεκαδικοί χαρακτήρες και υπάρχει τουλάχιστον ένας χαρακτήρας, διαφορετικά `False`. Οι δεκαδικοί χαρακτήρες είναι αυτοί που μπορούν να χρησιμοποιηθούν για το σχηματισμό αριθμών στη βάση 10, π.χ. U+0660, ARABIC-INDIC DIGIT ZERO. Επίσης ένας δεκαδικός χαρακτήρας είναι ένας χαρακτήρας του Unicode General Category «Nd».

`str.isdigit()`

Επιστρέφει `True` αν όλοι οι χαρακτήρες στη συμβολοσειρά είναι ψηφία και υπάρχει τουλάχιστον ένας χαρακτήρας, διαφορετικά `False`. Τα ψηφία περιλαμβάνουν δεκαδικούς χαρακτήρες και ψηφία που χρειάζονται ειδικό χειρισμό, όπως τα compatibility superscript ψηφία. Αυτό καλύπτει τα ψηφία που δεν μπορούν να χρησιμοποιηθούν για το σχηματισμό αριθμών στη βάση 10, όπως οι αριθμοί Kharosthi. Τυπικά, ένα ψηφίο είναι ένας χαρακτήρας που έχει την τιμή της ιδιότητας `Numeric_Type=Digit` ή `Numeric_Type=Decimal`.

`str.isidentifier()`

Επιστρέφει `True` αν η συμβολοσειρά είναι έγκυρο αναγνωριστικό σύμφωνα με το ορισμό της γλώσσας, ενότητα `identifiers`.

Call `keyword.iskeyword()` to test whether string `s` is a reserved identifier, such as `def` and `class`.

Παράδειγμα

```
>>> from keyword import iskeyword

>>> 'hello'.isidentifier(), iskeyword('hello')
(True, False)
>>> 'def'.isidentifier(), iskeyword('def')
(True, True)
```

`str.islower()`

Επιστρέφει `True` αν όλοι οι χαρακτήρες⁴ στο αλφαριθμητικό (string) είναι πεζοί και υπάρχει τουλάχιστον ένας `cased` χαρακτήρας, αλλιώς `False`.

`str.isnumeric()`

Επιστρέφει `True` αν όλοι οι χαρακτήρες στη συμβολοσειρά είναι αριθμητικοί (numeric) χαρακτήρες, και υπάρχει τουλάχιστον ένας χαρακτήρας, διαφορετικά `False`. Οι αριθμητικοί χαρακτήρες περιλαμβάνουν ψηφιακούς χαρακτήρες και όλους τους χαρακτήρες που έχουν την αριθμητική τιμή, π.χ. U+2155, VULGAR

⁴ Οι χαρακτήρες με πεζά είναι αυτοί με την ιδιότητα γενικής κατηγορίας να είναι ένας από τους «Lu» (Γράμμα, κεφαλαίο), «Ll» (Γράμμα, πεζό), ή «Lt» (Γράμμα, κεφαλαίο).

FRACTION ONE FIFTH. Τυπικά, οι αριθμητικοί χαρακτήρες είναι εκείνοι με την τιμή της ιδιότητας `Numeric_Type=Digit`, `Numeric_Type=Decimal` ή `Numeric_Type=Numeric`.

`str.isprintable()`

Return `True` if all characters in the string are printable or the string is empty, `False` otherwise. Nonprintable characters are those characters defined in the Unicode character database as «Other» or «Separator», excepting the ASCII space (0x20) which is considered printable. (Note that printable characters in this context are those which should not be escaped when `repr()` is invoked on a string. It has no bearing on the handling of strings written to `sys.stdout` or `sys.stderr`.)

`str.isspace()`

Επιστρέφει `True` αν υπάρχουν μόνο χαρακτήρες κενού (whitespace) στο αλφαριθμητικό (string) και υπάρχει τουλάχιστον ένας χαρακτήρας, διαφορετικά `False`.

Ένας χαρακτήρας είναι *whitespace* εάν στη βάση δεδομένων χαρακτήρων Unicode (βλέπε *unicodedata*), είτε η γενική κατηγορία του είναι `Zs` («Separator, space»), είτε η αμφίδρομη κατηγορία του είναι μία από τις κατηγορίες `WS`, `B`, ή `S`.

`str.istitle()`

Επιστρέφει `True` αν η συμβολοσειρά (string) είναι μια titlecased συμβολοσειρά και υπάρχει τουλάχιστον ένας χαρακτήρας, για παράδειγμα, οι κεφαλαίοι χαρακτήρες μπορούν να ακολουθούν μόνο τους uncased χαρακτήρες και οι πεζοί χαρακτήρες μόνο cased χαρακτήρες. Διαφορετικά, επιστρέφει `False`.

`str.isupper()`

Επιστρέφει `True` αν όλοι οι χαρακτήρες⁴ στο αλφαριθμητικό είναι κεφαλαίοι και υπάρχει τουλάχιστον ένας cased χαρακτήρας, διαφορετικά `False`.

```
>>> 'BANANA'.isupper()
True
>>> 'banana'.isupper()
False
>>> 'baNana'.isupper()
False
>>> ''.isupper()
False
```

`str.join(iterable)`

Επιστρέφει μια συμβολοσειρά (string) που είναι η συνένωση των συμβολοσειρών στο *iterable*. Ένα *TypeError* θα γίνει raise αν υπάρχουν τιμές μη συμβολοσειράς (non-string) στο *iterable*, συμπεριλαμβανομένων των αντικειμένων *bytes*. Το διαχωριστικό μεταξύ των στοιχείων είναι η συμβολοσειρά που παρέχει αυτή η μέθοδος.

`str.ljust(width[, fillchar])`

Επιστρέφει τη συμβολοσειρά (string) με αριστερή ευθυγράμμιση σε μια συμβολοσειρά μήκους *width*. Το padding γίνεται με τη χρήση του καθορισμένου *fillchar* (το default είναι ένα κενό ASCII). Η αρχική συμβολοσειρά επιστρέφεται εάν το *width* είναι μικρότερο ή ίσο με το `len(s)`.

`str.lower()`

Επιστρέφει ένα αντίγραφο της συμβολοσειράς (string) με όλους τους cased χαρακτήρες⁴ να έχουν μετατραπεί σε πεζούς.

The lowercasing algorithm used is described in section 3.13 of the Unicode Standard.

`str.lstrip([chars])`

Επιστρέφει ένα αντίγραφο της συμβολοσειράς (string) με την αφαίρεση των αρχικών χαρακτήρων. Τα *chars* είναι μια συμβολοσειρά που καθορίζει το σύνολο των χαρακτήρων που πρέπει να αφαιρεθούν. Εάν παραλειφθεί ή είναι `None`, το όρισμα *chars* έχει ως default την αφαίρεση των κενών χαρακτήρων. Το όρισμα *chars* δεν είναι ένα πρόθεμα: οπότε, όλοι οι συνδυασμοί των τιμών του αφαιρούνται:

```
>>> '   spacious   '.lstrip()
'spacious   '
>>> 'www.example.com'.lstrip('cmowz.')
'example.com'
```

Δείτε την `str.removeprefix()` για μια μέθοδο που θα αφαιρέσει ένα μόνο πρόθεμα συμβολοσειράς (string) αντί για όλο το σύνολο των χαρακτήρων. Για παράδειγμα:

```
>>> 'Arthur: three!'.lstrip('Arthur: ')
'ee!'
>>> 'Arthur: three!'.removeprefix('Arthur: ')
'three!'
```

static `str.maketrans(x[, y[, z]])`

Αυτή η στατική μέθοδος επιστρέφει έναν πίνακα μεταφράσεων που μπορεί να χρησιμοποιηθεί για το `str.translate()`.

Εάν υπάρχει μόνο ένα όρισμα, πρέπει να είναι ένα λεξικό αντιστοίχισης Unicode ordinals (ακέραιοι αριθμοί) ή χαρακτήρες (συμβολοσειρές - strings μήκους 1) σε ordinals Unicode, συμβολοσειρές (αυθαίρετου μήκους) ή None. Τα κλειδιά χαρακτήρων τότε θα μετατραπούν σε κανονικούς αριθμούς.

Εάν υπάρχουν δύο ορίσματα, πρέπει να είναι συμβολοσειρές (strings) ίσου μήκους και στο λεξικό (dictionary) που θα προκύψει, κάθε χαρακτήρας στο x θα αντιστοιχιστεί στο χαρακτήρα στην ίδια θέση στο y. Αν υπάρχει τρίτο όρισμα, πρέπει να είναι συμβολοσειρά, του οποίου οι χαρακτήρες θα αντιστοιχιστούν στο αποτέλεσμα σε None.

`str.partition(sep)`

Διαχωρίστε τη συμβολοσειρά (string) στην πρώτη εμφάνιση του `sep`, και επιστρέφει ένα 3-tuple που περιέχει το μέρος πριν από το διαχωριστικό, το ίδιο το διαχωριστικό και το μέρος μετά το διαχωριστικό. Αν ο διαχωριστής δεν βρεθεί, επιστρέφει ένα 3-σύνολο που περιέχει την ίδια τη συμβολοσειρά, ακολουθούμενη από δύο κενές συμβολοσειρές.

`str.removeprefix(prefix, /)`

Εάν η συμβολοσειρά (string) ξεκινά με το `prefix`, επιστρέφει `string[len(prefix):]`. Διαφορετικά, επιστρέφει ένα αντίγραφο της αρχικής συμβολοσειράς:

```
>>> 'TestHook'.removeprefix('Test')
'Hook'
>>> 'BaseTestCase'.removeprefix('Test')
'BaseTestCase'
```

Νέο στην έκδοση 3.9.

`str.removesuffix(suffix, /)`

Αν η συμβολοσειρά τελειώνει με το `suffix` και το `suffix` δεν είναι κενό, επιστρέφει `string[:-len(suffix)]`. Διαφορετικά, επιστρέφει ένα αντίγραφο της αρχικής συμβολοσειράς:

```
>>> 'MiscTests'.removesuffix('Tests')
'Misc'
>>> 'TmpDirMixin'.removesuffix('Tests')
'TmpDirMixin'
```

Νέο στην έκδοση 3.9.

`str.replace(old, new[, count])`

Επιστρέφει ένα αντίγραφο της συμβολοσειράς (string) με όλες τις εμφανίσεις της υπό-συμβολοσειράς `old` αντικατεστημένες από την `new`. Εάν δοθεί το προαιρετικό όρισμα `count`, μόνο οι πρώτες `count` εμφανίσεις αντικαθίστανται.

`str.rfind(sub[, start[, end]])`

Επιστρέφει το υψηλότερο index στη συμβολοσειρά (string) όπου βρίσκεται η υπό-συμβολοσειρά *sub*, έτσι ώστε το *sub* περιέχεται στο `s[start:end]`. Τα προαιρετικά ορίσματα *start* και *end* ερμηνεύονται ως slice notation. Επιστρέφει -1 σε περίπτωση αποτυχίας.

`str.rindex(sub[, start[, end]])`

Όπως η `rfind()`, αλλά κάνει raise `ValueError` όταν η υπό-συμβολοσειρά (sub-string) *sub* δεν βρέθηκε.

`str.rjust(width[, fillchar])`

Επιστρέφει τη συμβολοσειρά (string) με δεξιό προσανατολισμό σε μια συμβολοσειρά μήκους *width*. Το padding γίνεται χρησιμοποιώντας το καθορισμένο *fillchar* (η προεπιλογή είναι ένα διάστημα ASCII). Η αρχική συμβολοσειρά επιστρέφεται εάν το *width* είναι μικρότερο ή ίσο με `len(s)`.

`str.rpartition(sep)`

Διαχωρίζει τη συμβολοσειρά (string) στην τελευταία εμφάνιση του *sep* και επιστρέφει ένα 3-tuple που περιέχει το τμήμα πριν από το διαχωριστικό, το ίδιο το διαχωριστικό και το μέρος μετά το διαχωριστικό. Εάν το διαχωριστικό δεν βρεθεί, επιστρέφει ένα 3-tuple που περιέχει δύο κενές συμβολοσειρές, ακολουθούμενες από την ίδια τη συμβολοσειρά.

`str.rsplit(sep=None, maxsplit=-1)`

Επιστρέφει μια λίστα με τις λέξεις στη συμβολοσειρά (string), χρησιμοποιώντας το *sep* ως οριοθέτη. Εάν δοθεί το *maxsplit*, θα γίνουν το πολύ *maxsplit* διαχωρισμοί, ξεκινώντας από τα δεξιά. Εάν το *sep* δεν έχει καθοριστεί ή είναι None, οποιοδήποτε κενό διάστημα γίνεται διαχωριστικό. Εκτός από το διαχωρισμό από τα δεξιά, η `rsplit()` συμπεριφέρεται όπως η `split()` που περιγράφεται λεπτομερώς παρακάτω.

`str.rstrip([chars])`

Επιστρέφει ένα αντίγραφο της συμβολοσειράς (string) με τους χαρακτήρες που έχουν αφαιρεθεί. Τα όρισμα *chars* είναι μια συμβολοσειρά που καθορίζει το σύνολο των χαρακτήρων που πρέπει να αφαιρεθούν. Εάν παραληφθεί ή είναι None, το όρισμα *chars* έχει ως προεπιλογή την αφαίρεση των κενών διαστημάτων. Το όρισμα *chars* δεν είναι suffix, αλλά όλοι οι συνδυασμοί των τιμών του αφαιρούνται:

```
>>> '   spacious   '.rstrip()
'   spacious'
>>> 'mississippi'.rstrip('ipz')
'mississ'
```

Δείτε τη `str.removesuffix()` για μια μέθοδο που θα αφαιρέσει ένα απλό suffix αντί για όλο το σύνολο των χαρακτήρων. Για παράδειγμα:

```
>>> 'Monty Python'.rstrip(' Python')
'M'
>>> 'Monty Python'.removesuffix(' Python')
'Monty'
```

`str.split(sep=None, maxsplit=-1)`

Επιστρέφει μια λίστα με τις λέξεις της συμβολοσειράς (string), χρησιμοποιώντας το *sep* ως διαχωριστικό. Αν δοθεί το *maxsplit*, γίνονται το πολύ *maxsplit* διαχωρισμοί (έτσι, η λίστα θα έχει το πολύ `maxsplit+1` στοιχεία). Εάν το *maxsplit* δεν καθοριστεί ή είναι -1, τότε δεν υπάρχει όριο στον αριθμό των διαχωρισμών (γίνονται όλες οι πιθανές διασπάσεις).

If *sep* is given, consecutive delimiters are not grouped together and are deemed to delimit empty strings (for example, `'1,,2'.split(',')` returns `['1', '', '2']`). The *sep* argument may consist of multiple characters (for example, `'1<>2<>3'.split('<>')` returns `['1', '2', '3']`). Splitting an empty string with a specified separator returns `['']`.

Για παράδειγμα:

```
>>> '1,2,3'.split(',')
['1', '2', '3']
>>> '1,2,3'.split(',', maxsplit=1)
['1', '2,3']
>>> '1,2,,3'.split(',')
['1', '2', '', '3', '']
```

Αν το *sep* καθοριστεί ή είναι `None`, εφαρμόζεται ένας διαφορετικός αλγόριθμος διαχωρισμού: οι εμφανίσεις διαδοχικών κενών θεωρούνται ως ένα ενιαίο διαχωριστικό, και το αποτέλεσμα δεν θα περιέχει κενές συμβολοσειρές (strings) στην αρχή ή στο τέλος, αν η συμβολοσειρά έχει κενό διάστημα στην αρχή ή στο τέλος. Κατά συνέπεια, η διάσπαση μιας κενής συμβολοσειράς ή μιας συμβολοσειράς που αποτελείται μόνο από κενά διαστήματα με ένα `None` ως διαχωριστικό επιστρέφει `[]`.

Για παράδειγμα:

```
>>> '1 2 3'.split()
['1', '2', '3']
>>> '1 2 3'.split(maxsplit=1)
['1', '2 3']
>>> ' 1 2 3 '.split()
['1', '2', '3']
```

`str.splitlines` (*keepends=False*)

Επιστρέφει μια λίστα με τις γραμμές της συμβολοσειράς (string), διαχωρίζοντας στα όρια των γραμμών. Τα διαχωριστικά των γραμμών δεν περιλαμβάνονται στην νέα λίστα, εκτός αν δοθεί το *keepends* και είναι `true`.

Αυτή η μέθοδος διαχωρίζει στα ακόλουθα όρια γραμμών. Πιο συγκεκριμένα, τα όρια είναι ένα υπερσύνολο του *universal newlines*.

| Αναπαράσταση | Περιγραφή |
|--------------------------------------|----------------------------------|
| <code>\n</code> | Line Feed |
| <code>\r</code> | Carriage Return |
| <code>\r\n</code> | Carriage Return + Line Feed |
| <code>\v</code> or <code>\x0b</code> | Line Tabulation |
| <code>\f</code> or <code>\x0c</code> | Form Feed |
| <code>\x1c</code> | Διαχωριστής Αρχείου |
| <code>\x1d</code> | Διαχωριστής Group |
| <code>\x1e</code> | Διαχωριστής Εγγραφών |
| <code>\x85</code> | Επόμενη Γραμμή (C1 Control Code) |
| <code>\u2028</code> | Διαχωριστής Γραμμής |
| <code>\u2029</code> | Διαχωριστής Παραγράφου |

Άλλαξε στην έκδοση 3.2: Τα `\v` και `\f` προστίθενται στην λίστα ορίων των γραμμών.

Για παράδειγμα:

```
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines()
['ab c', '', 'de fg', 'kl']
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines(keepends=True)
['ab c\n', '\n', 'de fg\r', 'kl\r\n']
```

Σε αντίθεση με την `split()` όταν δίνεται μια συμβολοσειρά (string) οριοθέτησης *sep*, αυτή η μέθοδος επιστρέφει μια κενή λίστα για το κενό αλφαριθμητικό, και μια τερματικό break γραμμής δεν οδηγεί σε μια επιπλέον γραμμή:

```
>>> "".splitlines()
[]
>>> "One line\n".splitlines()
['One line']
```

Συγκριτικά, η `split('\n')` δίνει:

```
>>> ''.split('\n')
['']
>>> 'Two lines\n'.split('\n')
['Two lines', '']
```

`str.startswith(prefix[, start[, end]])`

Επιστρέφει `True` αν η συμβολοσειρά (string) αρχίζει με το *prefix*, αλλιώς επιστρέφει `False`. Το *prefix* μπορεί επίσης να είναι μια πλειάδα (tuple) *prefix* προς αναζήτηση. Με το προαιρετικό *start*, ελέγχεται το αλφαριθμητικό που αρχίζει από τη συγκεκριμένη θέση. Με το προαιρετικό *end*, σταματά η σύγκριση της συμβολοσειράς σε αυτή τη θέση.

`str.strip([chars])`

Επιστρέφει ένα αντίγραφο της συμβολοσειράς (string) με τους πρώτους και τους τελευταίους χαρακτήρες να έχουν αφαιρεθεί. Το όρισμα *chars* είναι μια συμβολοσειρά που καθορίζει το σύνολο των χαρακτήρων που πρέπει να αφαιρεθούν. Εάν παραλειφθεί ή είναι `None`, το όρισμα *chars* έχει ως default την αφαίρεση των κενών διαστημάτων. Το όρισμα *chars* δεν είναι *prefix* ή *suffix*· μάλλον, όλοι οι συνδυασμοί των τιμών του αφαιρούνται:

```
>>> '   spacious   '.strip()
'spacious'
>>> 'www.example.com'.strip('cmowz.')
'example'
```

Οι ακραίες αρχικές και τελικές τιμές του ορίσματος *chars* αφαιρούνται από τη συμβολοσειρά (string). Οι χαρακτήρες αφαιρούνται από το μπροστινό άκρο μέχρι να φτάσουν στο χαρακτήρα της συμβολοσειράς (string) που δεν περιέχεται στο σύνολο χαρακτήρων του *chars*. Μια παρόμοια ενέργεια λαμβάνει χώρα στο τέλος της ουράς. Για παράδειγμα:

```
>>> comment_string = '#..... Section 3.2.1 Issue #32 ..... '
>>> comment_string.strip('.#! ')
'Section 3.2.1 Issue #32'
```

`str.swapcase()`

Επιστρέφει ένα αντίγραφο της συμβολοσειράς (string) με κεφαλαίους χαρακτήρες που έχουν μετατραπεί σε πεζούς και αντίστροφα. Σημειώστε ότι δεν είναι απαραίτητα αληθές ότι `s.swapcase().swapcase() == s`.

`str.title()`

Επιστρέφει μια *titlecased* έκδοση της συμβολοσειράς, όπου οι λέξεις ξεκινούν με ένα κεφαλαίο χαρακτήρα και οι υπόλοιποι χαρακτήρες είναι πεζοί.

Για παράδειγμα:

```
>>> 'Hello world'.title()
'Hello World'
```

Ο αλγόριθμος χρησιμοποιεί έναν απλό, ανεξάρτητο από τη γλώσσα, ορισμό μιας λέξης ως *group* διαδοχικών γραμμικών χαρακτήρων. Ο ορισμός λειτουργεί σε πολλά contexts, αλλά σημαίνει ότι οι απόστροφες σε συναιρέσεις και κτητικές λέξεις αποτελούν όρια λέξεων, που μπορεί να μην είναι το επιθυμητό αποτέλεσμα:

```
>>> "they're bill's friends from the UK".title()
'They'Re Bill'S Friends From The UK'
```

Η συνάρτηση `string.capwords()` δεν έχει αυτό το πρόβλημα, καθώς χωρίζει τις λέξεις μόνο σε κενά.

Εναλλακτικά, μπορεί να κατασκευαστεί μια λύση για τις αποστροφές χρησιμοποιώντας κανονικές εκφράσεις:

```
>>> import re
>>> def titlecase(s):
...     return re.sub(r"[A-Za-z]+(' [A-Za-z]+)?",
...                   lambda mo: mo.group(0).capitalize(),
...                   s)
...
>>> titlecase("they're bill's friends.")
'They're Bill's Friends.'
```

`str.translate(table)`

Return a copy of the string in which each character has been mapped through the given translation table. The table must be an object that implements indexing via `__getitem__()`, typically a *mapping* or *sequence*. When indexed by a Unicode ordinal (an integer), the table object can do any of the following: return a Unicode ordinal or a string, to map the character to one or more other characters; return `None`, to delete the character from the return string; or raise a *LookupError* exception, to map the character to itself.

Μπορείτε να χρησιμοποιήσετε το `str.maketrans()` για να δημιουργήσετε ένα χάρτη μετάφρασης αντιστοίχισης από χαρακτήρα-σε-χαρακτήρα σε διαφορετικές μορφές.

Δείτε επίσης την ενότητα *codecs* για μια πιο ευέλικτη προσέγγιση σε προσαρμοσμένα mappings χαρακτήρων.

`str.upper()`

Επιστρέφει ένα αντίγραφο της συμβολοσειράς (string) με όλους τους χαρακτήρες⁴ που έχουν μετατραπεί σε κεφαλαία. Σημειώστε ότι το `s.upper().isupper()` μπορεί να είναι `False` αν το `s` περιέχει χαρακτήρες χωρίς πεζά γράμματα ή αν η κατηγορία Unicode του προκύπτοντος χαρακτήρα(ων) δεν είναι «Lu» (Γράμμα, κεφαλαίο), αλλά π.χ. «Lt» (Γράμμα, titlecase).

The uppercasing algorithm used is described in section 3.13 of the Unicode Standard.

`str.zfill(width)`

Επιστρέφει ένα αντίγραφο της συμβολοσειράς (string) που έμεινε γεμάτη με ψηφία ASCII '0' για να δημιουργήσει μία συμβολοσειρά μήκους *width*. Χειρίζεται ένα leading sign prefix ('+'/'-') εισάγοντας την συμπλήρωση μετά τον χαρακτήρα sign αντί για πριν. Η αρχική συμβολοσειρά επιστρέφεται εάν το *width* είναι μικρότερο ή ίσο με `len(s)`.

Για παράδειγμα:

```
>>> "42".zfill(5)
'00042'
>>> "-42".zfill(5)
'-0042'
```

4.7.2 printf-style String Formatting

Σημείωση: Οι λειτουργίες μορφοποίησης που περιγράφονται εδώ παρουσιάζουν μια ποικιλία ιδιορρυθμιών που οδηγούν σε έναν αριθμό κοινών σφαλμάτων (όπως η αποτυχία εμφάνισης tuple και σωστών λεξικών). Χρησιμοποιώντας τα νεότερα formatted string literals, το `str.format()` interface ή το *template strings* μπορεί να βοηθήσει στην αποφυγή αυτών των σφαλμάτων. Κάθε μία από αυτές τις εναλλακτικές παρέχει τους δικούς της συμβιβασμούς και τα οφέλη της απλότητας, ευελιξίας και/ή επεκτασιμότητας.

Τα αντικείμενα string έχουν μια μοναδική ενσωματωμένη λειτουργία: τον τελεστή % (modulo). Αυτός είναι επίσης γνωστός ως τελεστής *formatting* ή ** interpolation**. Δεδομένων των `format % values` (όπου *format* είναι μία συμβολοσειρά), % οι προδιαγραφές μετατροπής στο *format* αντικαθίστανται από μηδέν ή περισσότερα στοιχεία των *values*. Το αποτέλεσμα είναι παρόμοιο με τη χρήση του `sprintf()` στη γλώσσα C.

Εάν το *format* απαιτεί ένα μεμονωμένο όρισμα, το *values* μπορεί να είναι ένα μεμονωμένο non-tuple αντικείμενο.⁵ Διαφορετικά, τα *values* πρέπει να είναι ένα tuple με ακριβώς τον ίδιο αριθμό των στοιχείων που καθορίζονται από το format string ή ένα μεμονωμένο αντικείμενο αντιστοίχισης (για παράδειγμα, ένα λεξικό).

Ένας προσδιοριστής μετατροπής περιέχει δύο ή περισσότερους χαρακτήρες και έχει τους εξής components, οι οποίοι πρέπει να εμφανίζονται με αυτή τη σειρά:

1. Ο χαρακτήρας `'%'`, που σηματοδοτεί την αρχή του προσδιοριστή.
2. Κλειδί mapping (προαιρετικό), που αποτελείται από μια ακολουθία χαρακτήρων σε παρένθεση (για παράδειγμα, `(somename)`).
3. Δείκτες μετατροπής (προαιρετικό), που επηρεάζουν το αποτέλεσμα κάποιων τύπων μετατροπής.
4. Ελάχιστο πλάτος πεδίου (προαιρετικό). Εάν ορίζεται ως `'*'` (αστερίσκος), το πραγματικό πλάτος διαβάζεται από το επόμενο στοιχείο του tuple στα *values*, και το αντικείμενο προς μετατροπή έρχεται μετά από το ελάχιστο πλάτος πεδίου και το προαιρετικό precision.
5. Ακρίβεια (προαιρετικό), δίνεται ως `'.'` (τελεία) ακολουθούμενη από το precision. Εάν ορίζεται ως `'*'` (αστερίσκος), το πραγματικό precision διαβάζεται από το επόμενο στοιχείο του tuple στα *values*, και η τιμή προς μετατροπή έρχεται μετά το precision.
6. Μετατροπέας του length (προαιρετικό).
7. Τύπος conversion.

Όταν το σωστό όρισμα είναι ένα λεξικό (ή άλλος τύπος αντιστοίχισης), τότε οι μορφές στη συμβολοσειρά *πρέπει* να περιλαμβάνουν ένα κλειδί αντιστοίχισης σε παρένθεση σε αυτό το λεξικό που εισήχθη αμέσως μετά τον χαρακτήρα `'%'`. Το κλειδί αντιστοίχισης επιλέγει την τιμή που θα μορφοποιηθεί από την αντιστοίχιση. Για παράδειγμα:

```
>>> print('%(language)s has %(number)03d quote types.' %
...       {'language': "Python", "number": 2})
Python has 002 quote types.
```

Σε αυτήν την περίπτωση δεν μπορεί να υπάρχουν προσδιοριστές * σε μια μορφή (καθώς απαιτούν μια διαδοχική λίστα παραμέτρων).

Οι δείκτες μετατροπής είναι:

⁵ Για να μορφοποιήσετε μόνο μια πλειάδα (tuple) θα πρέπει επομένως να παρέχετε μια πλειάδα singleton της οποίας το μόνο στοιχείο είναι η πλειάδα που πρόκειται να μορφοποιηθεί.

| Flag | Έννοια |
|------|--|
| '#' | Οι μετατροπή τιμής θα χρησιμοποιήσει την «εναλλακτική φόρμα» (όπου ορίζεται παρακάτω). |
| '0' | Η μετατροπή θα έχει μηδενική συμπλήρωση για αριθμητικές τιμές. |
| '-' | Η τιμή μετατροπής αφήνεται προσαρμοσμένη (παρακάμπτει τη μετατροπή '0' εάν δίνονται και τα δύο). |
| ' ' | (ένα κενό) Πρέπει να προστεθεί ένα κενό πριν από έναν θετικό αριθμό (ή κενή συμβολοσειρά) που παράγεται από μια υπογεγραμμένη μετατροπή. |
| '+' | Ένα χαρακτήρας προσήμου ('+' ή '-') θα προηγείται της μετατροπής (παρακάμπτει ένα «κενό» δείκτη). |

Ένας τροποποιητής μήκους (h, l, or L) μπορεί να υπάρχει, αλλά αγνοείται καθώς δεν είναι απαραίτητος για την Python – οπότε π.χ. %ld είναι πανομοιότυπο σε %d.

Οι τύποι μετατροπής είναι:

| Μετα-τροπή | Έννοια | Σημειώσεις |
|------------|--|------------|
| 'd' | Υπογεγραμμένος δεκαδικός ακέραιος. | |
| 'i' | Υπογεγραμμένος δεκαδικός ακέραιος. | |
| 'o' | Υπογεγραμμένη οκταδική τιμή. | (1) |
| 'u' | Απαρχαιωμένος τύπος – είναι πανομοιότυπος με το 'd'. | (6) |
| 'x' | Υπογεγραμμένο δεκαεξαδικό (πεζά). | (2) |
| 'X' | Υπογεγραμμένο δεκαεξαδικό (κεφαλαίο). | (2) |
| 'e' | Floating point exponential format (lowercase). | (3) |
| 'E' | Floating point exponential format (uppercase). | (3) |
| 'f' | Floating point decimal format. | (3) |
| 'F' | Floating point decimal format. | (3) |
| 'g' | Floating point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise. | (4) |
| 'G' | Floating point format. Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise. | (4) |
| 'c' | Μεμονωμένος χαρακτήρας (δέχεται αέριο ή μονό χαρακτήρα συμβολοσειράς). | |
| 'r' | Συμβολοσειρά (μετατρέπει οποιοδήποτε αντικείμενο Python χρησιμοποιώντας <code>repr()</code>). | (5) |
| 's' | Συμβολοσειρά (μετατρέπει οποιοδήποτε αντικείμενο Python χρησιμοποιώντας <code>str()</code>). | (5) |
| 'a' | Συμβολοσειρά (μετατρέπει οποιοδήποτε αντικείμενο Python χρησιμοποιώντας <code>ascii()</code>). | (5) |
| '%' | Κανένα όρισμα δεν μετατρέπεται, έχει ως αποτέλεσμα έναν χαρακτήρα '%' το αποτέλεσμα. | |

Σημειώσεις:

- (1) Η εναλλακτική μορφή προκαλεί την εισαγωγή ενός πρώτου οκταδικού προσδιοριστή ('0o') πριν από το πρώτο ψηφίο.
- (2) Η εναλλακτική φόρμα προκαλεί την εισαγωγή ενός αρχικού '0x' ή '0X' (ανάλογα με το εάν χρησιμοποιήθηκε η μορφή 'x' ή 'X') πριν το πρώτο ψηφίο.
- (3) Η εναλλακτική μορφή κάνει το αποτέλεσμα να περιέχει πάντα μια υποδιαστολή, ακόμα κι αν δεν ακολουθούν ψηφία.

Η ακρίβεια καθορίζει τον αριθμό των ψηφίων μετά την υποδιαστολή και ορίζεται από προεπιλογή ως 6.

- (4) Η εναλλακτική μορφή κάνει το αποτέλεσμα να περιέχει πάντα μια υποδιαστολή και τα μηδενικά στο τέλος δεν αφαιρούνται όπως θα ήταν διαφορετικά.

Η ακρίβεια καθορίζει τον αριθμό των σημαντικών ψηφίων πριν και μετά την υποδιαστολή και ορίζει το 6.

- (5) Εάν η ακρίβεια είναι ``N``, η έξοδος περικόπτεται σε `N` χαρακτήρες.

- (6) Βλέπε [PEP 237](#).

Δεδομένου ότι οι συμβολοσειρές Python έχουν ρητό μήκος, οι `%s` μετατροπές δεν υποθέτουν ότι το `'\0'` είναι το τέλος της συμβολοσειράς.

Άλλαξε στην έκδοση 3.1: Οι μετατροπές `%f` για αριθμούς των οποίων η απόλυτη τιμή είναι μεγαλύτερη από `1e50` δεν αντικαθίστανται πλέον από μετατροπές `%g`.

4.8 Τύποι δυαδικής ακολουθίας — `bytes`, `bytearray`, `memoryview`

Οι βασικοί ενσωματωμένοι (built-in) τύποι για τον χειρισμό δυαδικών δεδομένων είναι `bytes` και `bytearray`. Υποστηρίζονται από τη `memoryview` που χρησιμοποιεί το πρωτόκολλο buffer protocol για την πρόσβαση στη μνήμη άλλων δυαδικών αντικειμένων χωρίς να χρειάζεται η δημιουργία αντιγράφου.

Το module `array` υποστηρίζει αποδοτική αποθήκευση για βασικούς τύπους δεδομένων όπως 32-bit ακέραιους και IEEE754 διπλής ακρίβειας κινητής υποδιαστολής τιμές.

4.8.1 Αντικείμενα Bytes

Τα αντικείμενα `bytes` είναι αμετάβλητες ακολουθίες μεμονωμένων `bytes`. Δεδομένου ότι πολλά κύρια δυαδικά πρωτόκολλα βασίζονται στην κωδικοποίηση κειμένου ASCII, τα αντικείμενα `bytes` προσφέρουν διάφορες μεθόδους που ισχύουν μόνο όταν εργάζονται με δεδομένα συμβατά με ASCII και σχετίζονται στενά με αντικείμενα συμβολοσειρών σε μια ποικιλία διαφόρων τρόπων.

class `bytes` (`[source[, encoding[, errors]]]`)

Πρώτον, η σύνταξη για τα `bytes` literals είναι σε μεγάλο βαθμό η ίδια με αυτή για τα `literals` συμβολοσειρών, με τη διαφορά ότι προστίθεται ένα πρόθεμα `b`:

- Μονά εισαγωγικά: `b'ακόμα επιτρέπει ενσωματωμένα "διπλά" εισαγωγικά'`
- Διπλά εισαγωγικά: `b"εξακολουθεί να επιτρέπει ενσωματωμένα 'μονά' εισαγωγικά"`
- Τριπλά εισαγωγικά: `b'''3 μονά εισαγωγικά''', b"""3 διπλά εισαγωγικά"""`

Επιτρέπονται μόνο χαρακτήρες ASCII σε `bytes` literals (ανεξάρτητα από τη δηλωμένη κωδικοποίηση του πηγαιού κώδικα). Τυχόν δυαδικές τιμές, πάνω από 127, πρέπει να εισαχθούν σε `bytes` literals χρησιμοποιώντας την κατάλληλη ακολουθία διαφυγής χαρακτήρων.

Όπως και με τα `literals` συμβολοσειρών, τα `bytes` literals μπορούν επίσης να χρησιμοποιήσουν ένα πρόθεμα `r` για να απενεργοποιήσουν την επεξεργασία των ακολουθιών διαφυγής χαρακτήρων. Βλέπε `strings` για περισσότερες πληροφορίες σχετικά με τις διάφορες μορφές `bytes literal`, συμπεριλαμβανομένων των υποστηριζόμενων ακολουθιών διαφυγής χαρακτήρων.

Ενώ τα `bytes` literals και οι αναπαραστάσεις βασίζονται σε κείμενο ASCII, τα αντικείμενα `bytes` συμπεριφέρονται στην πραγματικότητα σαν αμετάβλητες ακολουθίες ακεραίων με κάθε τιμή στην ακολουθία περιορισμένη έτσι ώστε `0 <= x < 256` (προσπάθειες παραβίασης αυτού του περιορισμού θα κάνουν `raise` την `ValueError`). Αυτό γίνεται σκόπιμα για να τονιστεί ότι, ενώ πολλές δυαδικές μορφές περιλαμβάνουν στοιχεία που βασίζονται σε ASCII και μπορούν να χρησιμοποιηθούν χρήσιμα με ορισμένους αλγορίθμους προσανατολισμένους στο κείμενο, αυτό δεν ισχύει γενικά για αυθαίρετα δυαδικά δεδομένα (τυφλή εφαρμογή αλγορίθμων επεξεργασίας κειμένου σε δυαδικές μορφές δεδομένων που δεν είναι συμβατές με ASCII συνήθως οδηγεί σε καταστροφή δεδομένων).

Εκτός από τις literal μορφές, τα αντικείμενα `bytes` μπορούν να δημιουργηθούν με πολλούς άλλους τρόπους:

- Ένα μηδενικό αντικείμενο `bytes` με καθορισμένο μήκος: `bytes(10)`
- Από ένα iterable ακεραίων αριθμών: `bytes(range(20))`
- Αντιγραφή υπαρχόντων δυαδικών δεδομένων μέσω του πρωτοκόλλου `buffer`: `bytes(obj)`

Δείτε επίσης το ενσωματωμένο `bytes`.

Δεδομένου ότι 2 δεκαεξαδικά ψηφία αντιστοιχούν ακριβώς σε ένα μόνο `byte`, οι δεκαεξαδικοί αριθμοί είναι μια συνήθως χρησιμοποιούμενη μορφή για την περιγραφή δυαδικών δεδομένων. Συνεπώς, ο τύπος `bytes` έχει μια πρόσθετη μέθοδο κλάσης για την ανάγνωση δεδομένων σε αυτήν την μορφή:

classmethod `fromhex` (*string*)

Αυτή η μέθοδος κλάσης `bytes` επιστρέφει ένα αντικείμενο `bytes`, αποκωδικοποιώντας το δεδομένο αντικείμενο συμβολοσειράς. Η συμβολοσειρά πρέπει να περιέχει δύο δεκαεξαδικά ψηφία ανά `byte`, με το κενό διάστημα ASCII να αγνοείται.

```
>>> bytes.fromhex('2Ef0 F1f2 ')
b'\xf0\xf1\xf2'
```

Άλλαξε στην έκδοση 3.7: Το `bytes.fromhex()` παρακάμπτει πλέον όλα τα κενά ASCII στη συμβολοσειρά, όχι μόνο τα κενά.

Υπάρχει μια συνάρτηση αντίστροφης μετατροπής για τη μετατροπή ενός αντικειμένου `bytes` στην δεκαεξαδική του αναπαράσταση.

hex (*[sep[, bytes_per_sep]]*)

Επιστρέφεται ένα αντικείμενο συμβολοσειράς που περιέχει δύο δεκαεξαδικά ψηφία για κάθε `byte` στο στιγμότυπο.

```
>>> b'\xf0\xf1\xf2'.hex()
'f0f1f2'
```

If you want to make the hex string easier to read, you can specify a single character separator *sep* parameter to include in the output. By default between each byte. A second optional *bytes_per_sep* parameter controls the spacing. Positive values calculate the separator position from the right, negative values from the left.

```
>>> value = b'\xf0\xf1\xf2'
>>> value.hex('-')
'f0-f1-f2'
>>> value.hex('_', 2)
'f0_f1f2'
>>> b'UDDLRLRAB'.hex(' ', -4)
'55554444 4c524c52 4142'
```

Νέο στην έκδοση 3.5.

Άλλαξε στην έκδοση 3.8: Η `bytes.hex()` υποστηρίζει πλέον προαιρετικές παραμέτρους *sep* και *bytes_per_sep* για την εισαγωγή διαχωριστικών μεταξύ των `byte` στην έξοδο δεκαεξαδικού.

Δεδομένου ότι τα αντικείμενα `bytes` είναι ακολουθίες ακεραίων αριθμών (όμοια με μια πλειάδα (tuple)), για ένα αντικείμενο `bytes` *b*, το `b[0]` θα είναι ένας ακεραίος αριθμός, ενώ το `b[0:1]` θα είναι ένα αντικείμενο `bytes` μήκους 1. (Αυτό έρχεται σε αντίθεση με τις συμβολοσειρές κειμένου, όπου τόσο η λειτουργία πρόσβασης ως ευρετήριο όσο και η λειτουργία τμηματοποίησης θα παράγουν μια συμβολοσειρά μήκους 1)

Η αναπαράσταση αντικειμένων `bytes` χρησιμοποιεί την literal μορφή (`b' . . '`), καθώς είναι συχνά πιο χρήσιμη από π.χ. `bytes([46, 46, 46])`. Μπορείτε πάντα να μετατρέψετε ένα αντικείμενο `bytes` σε μια λίστα ακεραίων αριθμών που χρησιμοποιούν `list(b)`.

4.8.2 Αντικείμενα Bytearray

Τα αντικείμενα `bytearray` είναι ένα μεταβλητό, αντίστοιχο, των αντικειμένων `bytes`.

class bytearray ([*source* [, *encoding* [, *errors*]]])

Δεν υπάρχει αποκλειστική literal σύνταξη για αντικείμενα `bytearray`, αντίθετα δημιουργούνται πάντα καλώντας τον constructor:

- Δημιουργία ενός κενού στιγμιότυπου: `bytearray()`
- Δημιουργία μηδενικού στιγμιότυπου με δεδομένο μήκος: `bytearray(10)`
- Από έναν iterable αριθμό ακεραίων: `bytearray(range(20))`
- Αντιγραφή υπαρχόντων δυαδικών δεδομένων μέσω του πρωτοκόλλου buffer: `bytearray(b'Hi!')`

Καθώς τα αντικείμενα του `bytearray` είναι μεταβλητά, υποστηρίζουν τις λειτουργίες της ακολουθίας *mutable* επιπλέον των κοινών λειτουργιών `bytes` και `bytearray` που περιγράφονται στο [Λειτουργίες Bytes και Bytearray](#).

Δείτε επίσης το ενσωματωμένο `bytearray`.

Δεδομένου ότι 2 δεκαεξαδικά ψηφία αντιστοιχούν ακριβώς σε ένα μόνο byte, οι δεκαεξαδικοί αριθμοί είναι συνήθως χρησιμοποιούμενη μορφή για την περιγραφή δυαδικών δεδομένων. Συνεπώς, ο τύπος `bytearray` έχει μια πρόσθετη μέθοδο κλάσης για την ανάγνωση δεδομένων σε αυτήν την μορφή:

classmethod fromhex (*string*)

Αυτή η μέθοδος κλάσης `bytearray` επιστρέφει αντικείμενο `bytearray`, αποκωδικοποιώντας το δεδομένο αντικείμενο συμβολοσειράς. Η συμβολοσειρά πρέπει να περιέχει δύο δεκαεξαδικά ψηφία ανά byte, με το κενό διάστημα ASCII να αγνοείται.

```
>>> bytearray.fromhex('2Ef0 F1f2 ')
bytearray(b'\xf0\xf1\xf2')
```

Αλλάξε στην έκδοση 3.7: Το `bytearray.fromhex()` παρακάμπτει τώρα όλα τα κενά ASCII στη συμβολοσειρά, όχι μόνο τα κενά.

Υπάρχει μια συνάρτηση αντίστροφης μετατροπής για να μετατρέψει ένα αντικείμενο `bytearray` στη δεκαεξαδική αναπαράσταση του.

hex ([*sep* [, *bytes_per_sep*]])

Επιστρέφεται ένα αντικείμενο συμβολοσειράς που περιέχει δύο δεκαεξαδικά ψηφία για κάθε byte στο στιγμιότυπο.

```
>>> bytearray(b'\xf0\xf1\xf2').hex()
'f0f1f2'
```

Νέο στην έκδοση 3.5.

Αλλάξε στην έκδοση 3.8: Παρόμοια με το `bytes.hex()`, το `bytearray.hex()` υποστηρίζει τώρα προαιρετικές παραμέτρους *sep* και *bytes_per_sep* για την εισαγωγή διαχωριστικών μεταξύ των byte στην δεκαεξαδική έξοδο.

Δεδομένου ότι τα αντικείμενα `bytearray` είναι ακολουθίες ακεραίων αριθμών (παρόμοια με μια λίστα), για ένα αντικείμενο `bytearray b`, το `b[0]` θα είναι ένας ακέραιος αριθμός, ενώ το `b[0:1]` θα είναι ένα αντικείμενο `bytearray` μήκους 1. (Αυτό έρχεται σε αντίθεση με τις συμβολοσειρές κειμένου, όπου τόσο το indexing και το slicing θα παράγουν μια συμβολοσειρά μήκους 1)

Η αναπαράσταση αντικειμένων `bytearray` χρησιμοποιεί τη μορφή bytes literal (`bytearray(b'...')`), καθώς είναι συχνά πιο χρήσιμη από π.χ. `bytearray([46, 46, 46])`. Μπορείτε πάντα να μετατρέψετε ένα αντικείμενο `bytearray` σε λίστα ακεραίων χρησιμοποιώντας το `list(b)`.

4.8.3 Λειτουργίες Bytes και Bytearray

Τόσο τα `byte` όσο και τα αντικείμενα του πίνακα `byte` υποστηρίζουν τις λειτουργίες της ακολουθίας *common*. Αλληλεπιδρούν όχι μόνο με τελεστές του ίδιου τύπου, αλλά και με οποιοδήποτε αντικείμενο *bytes-like object*. Λόγω αυτής της ευελιξίας, μπορούν να αναμειχθούν ελεύθερα σε λειτουργίες χωρίς να προκαλούνται σφάλματα. Ωστόσο, ο τύπος επιστροφής του αποτελέσματος μπορεί να εξαρτάται από τη σειρά των τελεστών.

Σημείωση: Οι μέθοδοι στα `bytes` και τα αντικείμενα `bytearray` δεν δέχονται συμβολοσειρές ως ορίσματά τους, όπως και οι μέθοδοι σε συμβολοσειρές δεν δέχονται `bytes` ως ορίσματα. Για παράδειγμα, πρέπει να γράψετε:

```
a = "abc"
b = a.replace("a", "f")
```

και:

```
a = b"abc"
b = a.replace(b"a", b"f")
```

Ορισμένες λειτουργίες `byte` και `bytearray` προϋποθέτουν τη χρήση δυαδικών μορφών συμβατών με ASCII και, ως εκ τούτου, θα πρέπει να αποφεύγονται όταν εργάζεστε με αυθαίρετα δυαδικά δεδομένα. Αυτοί οι περιορισμοί καλύπτονται παρακάτω.

Σημείωση: Η χρήση αυτών των λειτουργιών βασίζονται στο ASCII για τον χειρισμό δυαδικών δεδομένων που δεν είναι αποθηκευμένα σε μορφή που βασίζεται σε ASCII μπορεί να οδηγήσει σε καταστροφή δεδομένων.

Οι ακόλουθες μέθοδοι σε `byte` και αντικείμενα `bytearray` μπορούν να χρησιμοποιηθούν με αυθαίρετα δυαδικά δεδομένα.

```
bytes.count(sub[, start[, end]])
bytearray.count(sub[, start[, end]])
```

Επιστρέφει τον αριθμό των μη επικαλυπτόμενων εμφανίσεων της δευτερεύουσας ακολουθίας *sub* στο εύρος *[start, end]*. Τα προαιρετικά ορίσματα *start* και *end* ερμηνεύονται όπως στη σημειογραφία τμηματοποίησης.

Η υποακολουθία για αναζήτηση μπορεί να είναι οποιοδήποτε *bytes-like object* ή ένας ακέραιος αριθμός στην περιοχή από 0 έως 255.

Άλλαξε στην έκδοση 3.3: Επίσης αποδέχεται έναν ακέραιο αριθμό στο εύρος 0 έως 255 ως υποακολουθία.

```
bytes.removeprefix(prefix, /)
```

```
bytearray.removeprefix(prefix, /)
```

Εάν τα δυαδικά δεδομένα ξεκινούν με τη συμβολοσειρά *prefix*, επιστρέφει `bytes[len(prefix):]`. Διαφορετικά επιστρέφτε ένα αντίγραφο των αρχικών δυαδικών δεδομένων:

```
>>> b'TestHook'.removeprefix(b'Test')
b'Hook'
>>> b'BaseTestCase'.removeprefix(b'Test')
b'BaseTestCase'
```

Το *prefix* μπορεί να είναι οποιοδήποτε *bytes-like object*.

Σημείωση: Η έκδοση `bytearray` αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

Νέο στην έκδοση 3.9.

```
bytes.removeprefix(suffix, /)
bytearray.removeprefix(suffix, /)
```

Εάν τα δυαδικά δεδομένα τελειώνουν με τη συμβολοσειρά *suffix* και αυτό το *suffix* δεν είναι κενό, επιστρέφει `bytes[:-len(suffix)]`. Διαφορετικά, επιστρέφει ένα αντίγραφο των αρχικών δυαδικών δεδομένων:

```
>>> b'MiscTests'.removeprefix(b'Tests')
b'Misc'
>>> b'TmpDirMixin'.removeprefix(b'Tests')
b'TmpDirMixin'
```

Το *suffix* μπορεί να είναι οποιοδήποτε *bytes-like object*.

Σημείωση: Η έκδοση `bytearray` αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

Νέο στην έκδοση 3.9.

```
bytes.decode(encoding="utf-8", errors="strict")
bytearray.decode(encoding="utf-8", errors="strict")
```

Return a string decoded from the given bytes. Default encoding is 'utf-8'. *errors* may be given to set a different error handling scheme. The default for *errors* is 'strict', meaning that encoding errors raise a *UnicodeError*. Other possible values are 'ignore', 'replace' and any other name registered via `codecs.register_error()`, see section *Error Handlers*. For a list of possible encodings, see section *Standard Encodings*.

By default, the *errors* argument is not checked for best performances, but only used at the first decoding error. Enable the *Python Development Mode*, or use a debug build to check *errors*.

Σημείωση: Passing the *encoding* argument to *str* allows decoding any *bytes-like object* directly, without needing to make a temporary bytes or bytearray object.

Άλλαξε στην έκδοση 3.1: Επιπρόσθετη υποστήριξη για keyword ορίσματα.

Άλλαξε στην έκδοση 3.9: The *errors* is now checked in development mode and in debug mode.

```
bytes.endswith(suffix[, start[, end]])
bytearray.endswith(suffix[, start[, end]])
```

Επιστρέφει `True` εάν τα δυαδικά δεδομένα τελειώνουν με το καθορισμένο *suffix*, διαφορετικά επιστρέφει `False`. Το *suffix* μπορεί επίσης να είναι μια πλειάδα από επιθέματα που πρέπει να αναζητήσετε. Με το προαιρετικό *start*, η δοκιμή ξεκινά από αυτή τη θέση. Με το προαιρετικό *end*, σταματήστε να συγκρίνετε σε αυτή τη θέση.

Το(α) επίθεμα(τα) για αναζήτηση μπορεί να είναι οποιοδήποτε *bytes-like object*.

```
bytes.find(sub[, start[, end]])
bytearray.find(sub[, start[, end]])
```

Επιστρέφει το χαμηλότερο index στα δεδομένα όπου βρίσκεται η υποακολουθία *sub*, έτσι ώστε το *sub* να περιέχεται στο slice `s[start:end]`. Τα προαιρετικά ορίσματα *start* και *end* ερμηνεύονται ως συμβολισμός τμηματοποίησης. Επιστρέφει `-1` εάν το *sub* δεν βρεθεί.

Η υποακολουθία για αναζήτηση μπορεί να είναι οποιοδήποτε *bytes-like object* ή ένας ακέραιος αριθμός στην περιοχή από 0 έως 255.

Σημείωση: Η μέθοδος `find()` θα πρέπει να χρησιμοποιείται μόνο εάν χρειάζεται να γνωρίζετε τη θέση του *sub*. Για να ελέγξετε εάν το *sub* είναι υποσυμβολοσειρά ή όχι, χρησιμοποιήστε τον τελεστή `in`:

```
>>> b'Py' in b'Python'
True
```

Άλλαξε στην έκδοση 3.3: Επίσης αποδέχεται έναν ακέραιο αριθμό στο εύρος 0 έως 255 ως υποακολουθία.

```
bytes.index(sub[, start[, end]])
bytearray.index(sub[, start[, end]])
```

Όπως η `find()`, αλλά κάνει `raise` μια `ValueError` όταν δεν βρεθεί η δευτερεύουσα ακολουθία.

Η υποακολουθία για αναζήτηση μπορεί να είναι οποιοδήποτε *bytes-like object* ή ένας ακέραιος αριθμός στην περιοχή από 0 έως 255.

Άλλαξε στην έκδοση 3.3: Επίσης αποδέχεται έναν ακέραιο αριθμό στο εύρος 0 έως 255 ως υποακολουθία.

```
bytes.join(iterable)
bytearray.join(iterable)
```

Επιστρέφει ένα αντικείμενο `bytes` ή `bytearray` που είναι η συνένωση των δυαδικών ακολουθιών δεδομένων στο *iterable*. Μια `TypeError` θα γίνει `raise` εάν υπάρχουν τιμές στο *iterable* που δεν είναι σαν *bytes-like objects*, συμπεριλαμβανομένων των αντικειμένων `str`. Το διαχωριστικό μεταξύ των στοιχείων είναι τα περιεχόμενα των `byte` ή του αντικειμένου `bytearray` που παρέχει αυτή τη μέθοδο.

```
static bytes.maketrans(from, to)
static bytearray.maketrans(from, to)
```

Αυτή η στατική μέθοδος επιστρέφει έναν πίνακα μετάφρασης που μπορεί να χρησιμοποιηθεί για την `bytes.translate()` που θα αντιστοιχίσει κάθε χαρακτήρα στο *from* στον χαρακτήρα στην ίδια θέση στο *to*. Τα *from* και *to* πρέπει να είναι και τα δύο *bytes-like objects* και να έχουν το ίδιο μήκος.

Νέο στην έκδοση 3.1.

```
bytes.partition(sep)
bytearray.partition(sep)
```

Διαχωρίζει την ακολουθία κατά την πρώτη εμφάνιση του *sep*, και επιστρέφει μια 3-πλειάδα που περιέχει το τμήμα πριν από το διαχωριστικό ή το αντίγραφο του `bytearray` του και το τμήμα μετά το διαχωριστικό. Εάν δεν βρεθεί το διαχωριστικό, επιστρέφει μια 3-πλειάδα που περιέχει ένα αντίγραφο της αρχικής ακολουθίας, ακολουθούμενη από δύο κενά `byte` ή αντικείμενα `bytearray`.

Το διαχωριστικό για αναζήτηση μπορεί να είναι οποιοδήποτε *bytes-like object*.

```
bytes.replace(old, new[, count])
bytearray.replace(old, new[, count])
```

Επιστρέφει ένα αντίγραφο της ακολουθίας με όλες τις εμφανίσεις της δευτερεύουσας ακολουθίας *old* αντικαθιστούμενη από την *new*. Εάν δοθεί το προαιρετικό όρισμα *count*, αντικαθίστανται μόνο οι πρώτες εμφανίσεις *count*.

Η ακολουθία για αναζήτηση και αντικατάσταση της μπορεί να είναι οποιοδήποτε *bytes-like object*.

Σημείωση: Η έκδοση `bytearray` αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

```
bytes.rfind(sub[, start[, end]])
bytearray.rfind(sub[, start[, end]])
```

Επιστρέφει τον υψηλότερο δείκτη στην ακολουθία όπου βρίσκεται η υποακολουθία *sub*, έτσι ώστε το *sub* να περιέχεται στο `s[start:end]`. Τα προαιρετικά ορίσματα *start* και *end* ερμηνεύονται με συμβολισμό τμηματοποίησης. Επιστρέφει `-1` σε περίπτωση αποτυχίας.

Η υποακολουθία για αναζήτηση μπορεί να είναι οποιοδήποτε *bytes-like object* ή ένας ακέραιος αριθμός στην περιοχή από 0 έως 255.

Άλλαξε στην έκδοση 3.3: Επίσης αποδέχεται έναν ακέραιο αριθμό στο εύρος 0 έως 255 ως υποακολουθία.

```
bytes.rindex(sub[, start[, end]])
bytearray.rindex(sub[, start[, end]])
```

Όπως η `rfind()` αλλά κάνει `raise` μια `ValueError` όταν δεν βρεθεί η υποακολουθία `sub`.

Η υποακολουθία για αναζήτηση μπορεί να είναι οποιοδήποτε *bytes-like object* ή ένας ακέραιος αριθμός στην περιοχή από 0 έως 255.

Άλλαξε στην έκδοση 3.3: Επίσης αποδέχεται έναν ακέραιο αριθμό στο εύρος 0 έως 255 ως υποακολουθία.

```
bytes.rpartition(sep)
bytearray.rpartition(sep)
```

Διαχωρίζει την ακολουθία στην τελευταία εμφάνιση του `sep`, και επιστρέφει μια 3-πλειάδα που περιέχει το τμήμα πριν από το διαχωριστικό, το ίδιο το διαχωριστικό ή το αντίγραφο του `bytearray` και το τμήμα μετά το διαχωριστικό. Εάν δεν βρεθεί το διαχωριστικό επιστρέφει μια 3-πλειάδα που περιέχει δύο κενά `byte` ή αντικείμενα `bytearray`, ακολουθούμενα από ένα αντίγραφο της αρχικής ακολουθίας.

Το διαχωριστικό για αναζήτηση μπορεί να είναι οποιοδήποτε *bytes-like object*.

```
bytes.startswith(prefix[, start[, end]])
bytearray.startswith(prefix[, start[, end]])
```

Επιστρέφει `True` εάν τα δυαδικά δεδομένα ξεκινούν με το καθορισμένο `prefix`, διαφορετικά επιστρέφει `False`. Το `prefix` μπορεί επίσης να είναι μια πλειάδα από προθέματα προς αναζήτηση. Με το προαιρετικό `start`, η δοκιμή ξεκινά από αυτή τη θέση. Με το προαιρετικό `end`, σταματάει να συγκρίνει σε αυτή τη θέση.

Το(α) πρόθεμα(τα) για αναζήτηση μπορεί να είναι οποιοδήποτε *bytes-like object*.

```
bytes.translate(table, /, delete=b'')
bytearray.translate(table, /, delete=b'')
```

Επιστρέφει ένα αντίγραφο των `bytes` ή του αντικειμένου `bytearray` όπου αφαιρούνται όλα τα `byte` που εμφανίζονται στο προαιρετικό όρισμα `delete` και τα υπόλοιπα `byte` έχουν αντιστοιχιστεί μέσω του δεδομένου πίνακα μετάφρασης, ο οποίος πρέπει να είναι ένα αντικείμενο `bytes` μήκους 256.

Μπορείτε να χρησιμοποιήσετε τη μέθοδο `bytes.maketrans()` για να δημιουργήσετε έναν πίνακα μετάφρασης.

Ορίζει το όρισμα `table` σε `None` για μεταφράσεις που διαγράφουν μόνο χαρακτήρες:

```
>>> b'read this short text'.translate(None, b'aeiou')
b'rd ths shrt txt'
```

Άλλαξε στην έκδοση 3.6: Το `delete` υποστηρίζεται πλέον ως όρισμα λέξης-κλειδιού.

Οι ακόλουθες μέθοδοι σε `byte` και `bytearray` αντικείμενα έχουν προεπιλεγμένες συμπεριφορές που προϋποθέτουν τη χρήση δυαδικών μορφών συμβατών με ASCII, αλλά μπορούν να χρησιμοποιηθούν με αυθαίρετα δυαδικά δεδομένα περνώντας κατάλληλα ορίσματα. Σημειώστε ότι όλες οι μέθοδοι `bytearray` σε αυτήν την ενότητα δεν λειτουργούν στη θέση τους και όμως παράγουν νέα αντικείμενα.

```
bytes.center(width[, fillbyte])
bytearray.center(width[, fillbyte])
```

Επιστρέφει ένα αντίγραφο του αντικειμένου με κέντρο σε μια ακολουθία μήκους `width`. Η συμπλήρωση πραγματοποιείται χρησιμοποιώντας το καθορισμένο `fillbyte` (η προεπιλογή είναι ένα διάστημα ASCII). Για αντικείμενα `bytes`, η αρχική ακολουθία επιστρέφεται εάν το `*width*` είναι μικρότερο ή ίσο με `len(s)`.

Σημείωση: Η έκδοση `bytearray` αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

```
bytes.ljust (width[, fillbyte])
bytearray.ljust (width[, fillbyte])
```

Επιστρέφει ένα αντίγραφο του αντικειμένου αριστερά ευθυγραμμισμένο σε μια ακολουθία μήκους *width*. Η συμπλήρωση πραγματοποιείται χρησιμοποιώντας το καθορισμένο *fillbyte* (η προεπιλογή είναι ένα διάστημα ASCII). Για αντικείμενα *bytes*, η αρχική ακολουθία επιστρέφεται εάν το **width** είναι μικρότερο ή ίσο με `len(s)`.

Σημείωση: Η έκδοση *bytearray* αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

```
bytes.lstrip ([chars])
bytearray.lstrip ([chars])
```

Επιστρέφει ένα αντίγραφο της ακολουθίας με καθορισμένα βασικά byte που έχουν αφαιρεθεί. Το όρισμα *chars* είναι μια δυαδική ακολουθία που καθορίζει το σύνολο των τιμών byte που πρέπει να αφαιρεθούν - το όνομα αναφέρεται στο γεγονός ότι αυτή η μέθοδος χρησιμοποιείται συνήθως με χαρακτήρες ASCII. Εάν παραληφθεί ή είναι *None*, το όρισμα *chars* έχει ως προεπιλογή την αφαίρεση του κενού διαστήματος ASCII. Το όρισμα *chars* δεν είναι πρόθεμα, αλλά οι συνδυασμοί των τιμών του αφαιρούνται:

```
>>> b'   spacious   '.lstrip()
b'spacious   '
>>> b'www.example.com'.lstrip(b'cmowz.')
b'example.com'
```

Η δυαδική ακολουθία τιμών byte προς κατάργηση μπορεί να είναι οποιαδήποτε *bytes-like object*. Βλέπε *removeprefix()* για μια μέθοδο που θα αφαιρέσει μια μεμονωμένη συμβολοσειρά προθέματος αντί όλο το σύνολο χαρακτήρων. Για παράδειγμα:

```
>>> b'Arthur: three!'.lstrip(b'Arthur: ')
b'ee!'
>>> b'Arthur: three!'.removeprefix(b'Arthur: ')
b'three!'
```

Σημείωση: Η έκδοση *bytearray* αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

```
bytes.rjust (width[, fillbyte])
bytearray.rjust (width[, fillbyte])
```

Επιστρέφει ένα αντίγραφο του αντικειμένου ευθυγραμμισμένο δεξιά που δικαιολογείται σε μια ακολουθία μήκους *width*. Η συμπλήρωση πραγματοποιείται χρησιμοποιώντας το καθορισμένο *fillbyte* (η προεπιλογή είναι ένα διάστημα ASCII). Για αντικείμενα *bytes*, η αρχική ακολουθία επιστρέφεται εάν το *width* είναι μικρότερο ή ίσο με `len(s)`.

Σημείωση: Η έκδοση *bytearray* αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

```
bytes.rsplit (sep=None, maxsplit=-1)
bytearray.rsplit (sep=None, maxsplit=-1)
```

Διαχωρίζει τη δυαδική ακολουθία σε υποακολουθίες του ίδιου τύπου, χρησιμοποιώντας το *sep* ως συμβολοσειρά οριοθέτησης. Εάν δοθεί *maxsplit*, γίνονται το πολύ *maxsplit* διαχωρισμοί, οι *rightmost*. Εάν δεν καθορίζεται *sep* ή *None*, οποιαδήποτε υποακολουθία που αποτελείται αποκλειστικά από κενό διάστημα ASCII είναι διαχωριστικό, εκτός από το διαχωρισμό από τα δεξιά, η *rsplit()* συμπεριφέρεται όπως *split()* που περιγράφεται λεπτομερώς παρακάτω.

`bytes.rstrip([chars])`
`bytearray.rstrip([chars])`

Επιστρέφει ένα αντίγραφο της ακολουθίας με τα καθορισμένα δευτερεύοντα byte που έχουν αφαιρεθεί. Το όρισμα *chars* είναι μια δυαδική ακολουθία που καθορίζει το σύνολο των τιμών byte που πρέπει να αφαιρεθούν - το όνομα αναφέρεται στο γεγονός ότι αυτή η μέθοδος χρησιμοποιείται συνήθως με χαρακτήρες ASCII. Εάν παραληφθεί ή είναι `None`, το όρισμα *chars* έχει ως προεπιλογή την αφαίρεση του κενού διαστήματος ASCII. Το όρισμα *chars* δεν είναι επίθημα, αλλά αφαιρούνται όλοι οι συνδυασμοί των τιμών του:

```
>>> b'   spacious   '.rstrip()
b'   spacious'
>>> b'mississippi'.rstrip(b'ipz')
b'mississ'
```

Η δυαδική ακολουθία τιμών byte προς κατάργηση μπορεί να είναι οποιοδήποτε *bytes-like object*. Βλέπε τη `removesuffix()` για μια μέθοδο που θα αφαιρέσει μια συμβολοσειρά επιθέματος και όχι όλο το σύνολο χαρακτήρων. Για παράδειγμα:

```
>>> b'Monty Python'.rstrip(b' Python')
b'M'
>>> b'Monty Python'.removesuffix(b' Python')
b'Monty'
```

Σημείωση: Η έκδοση `bytearray` αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

`bytes.split(sep=None, maxsplit=-1)`
`bytearray.split(sep=None, maxsplit=-1)`

Διαχωρίζει την δυαδική ακολουθία σε υποακολουθίες του ίδιου τύπου, χρησιμοποιώντας το *sep* ως συμβολοσειρά οριοθέτησης. Εάν δοθεί *maxsplit* και μη αρνητικό, γίνονται το πολύ *maxsplit* διαχωρισμοί (άρα, η λίστα θα έχει το πολύ *maxsplit*+1 στοιχεία). Εάν το *maxsplit* δεν έχει καθοριστεί ή είναι `-1`, τότε δεν υπάρχει όριο στον αριθμό των διαχωρισμών (όλες οι πιθανές διασπάσεις γίνονται).

If *sep* is given, consecutive delimiters are not grouped together and are deemed to delimit empty subsequences (for example, `b'1,2'.split(b',')` returns `[b'1', b'', b'2']`). The *sep* argument may consist of a multibyte sequence (for example, `b'1<>2<>3'.split(b'<>')` returns `[b'1', b'2', b'3']`). Splitting an empty sequence with a specified separator returns `[b'']` or `[bytearray(b'')]` depending on the type of object being split. The *sep* argument may be any *bytes-like object*.

Για παράδειγμα:

```
>>> b'1,2,3'.split(b',')
[b'1', b'2', b'3']
>>> b'1,2,3'.split(b',', maxsplit=1)
[b'1', b'2,3']
>>> b'1,2,,3'.split(b',')
[b'1', b'2', b'', b'3', b'']
```

Εάν το *sep* δεν έχει καθοριστεί ή είναι `None`, εφαρμόζεται ένας διαφορετικός αλγόριθμος διαχωρισμού: οι εκτελέσεις διαδοχικών κενών διαστημάτων ASCII θεωρούνται ως ένα ενιαίο διαχωριστικό, και το αποτέλεσμα δεν θα περιέχει κενές συμβολοσειρές στην αρχή ή στο τέλος, εάν η ακολουθία έχει κενό που έπεται ή προηγείται. Κατά συνέπεια, ο διαχωρισμός μιας κενής ακολουθίας ή μιας ακολουθίας που αποτελείται αποκλειστικά από κενό διάστημα ASCII χωρίς καθορισμένο διαχωριστικό επιστρέφει το `[]`.

Για παράδειγμα:

```
>>> b'1 2 3'.split()
[b'1', b'2', b'3']
>>> b'1 2 3'.split(maxsplit=1)
[b'1', b'2 3']
>>> b'    1    2    3    '.split()
[b'1', b'2', b'3']
```

`bytes.strip([chars])`
`bytearray.strip([chars])`

Επιστρέφει ένα αντίγραφο της ακολουθίας με τα καθορισμένα bytes που προηγούνται και τα bytes που έπονται. Το όρισμα *chars* είναι μια δυαδική ακολουθία που καθορίζει το σύνολο των τιμών byte που πρέπει να αφαιρεθούν - το όνομα αναφέρεται στο γεγονός ότι αυτή η μέθοδος χρησιμοποιείται συνήθως με χαρακτήρες ASCII. Εάν παραλείπεται ή είναι `None`, το όρισμα *chars* από προεπιλογή αφαιρεί το ASCII λευκό διάστημα. Το όρισμα *chars* δεν είναι πρόθεμα ή επίθημα, αλλά αφαιρούνται όλοι οι συνδυασμοί των τιμών του:

```
>>> b'    spacious    '.strip()
b'spacious'
>>> b'www.example.com'.strip(b'cmowz.')
b'example'
```

Η δυαδική ακολουθία τιμών byte προς αφαίρεση μπορεί να είναι οποιοδήποτε *bytes-like object*.

Σημείωση: Η έκδοση `bytearray` αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

Οι ακόλουθες μέθοδοι σε `byte` και αντικείμενα `bytearray` προϋποθέτουν τη χρήση δυαδικών μορφών συμβατών με ASCII και δεν πρέπει να εφαρμόζονται σε αυθαίρετα δυαδικά δεδομένα. Σημειώστε ότι όλες οι μέθοδοι `bytearray` σε αυτήν την ενότητα δεν λειτουργούν στη θέση τους και αντ' αυτού παράγουν νέα αντικείμενα.

`bytes.capitalize()`
`bytearray.capitalize()`

Επιστρέφει ένα αντίγραφο της ακολουθίας με κάθε byte να ερμηνεύεται ως ένας χαρακτήρας ASCII, και το πρώτο byte γραμμένο με κεφαλαία και το υπόλοιπο με πεζά. Οι τιμές των byte που δεν είναι ASCII μεταβιβάζονται αμετάβλητες.

Σημείωση: Η έκδοση `bytearray` αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

`bytes.expandtabs(tabsize=8)`
`bytearray.expandtabs(tabsize=8)`

Επιστρέφει ένα αντίγραφο της ακολουθίας όπου όλοι οι `tab` χαρακτήρες ASCII αντικαθίστανται από ένα ή περισσότερα κενά ASCII, ανάλογα με την τρέχουσα στήλη και το δεδομένο μέγεθος `tab`. Οι θέσεις των `tab` εμφανίζονται κάθε `tabsize` bytes (η προεπιλογή είναι 8, δίνοντας θέσεις καρτελών στις στήλες 0, 8, 16 και ούτω καθεξής). Για την επέκταση της ακολουθίας, η τρέχουσα στήλη ορίζεται στο μηδέν και η ακολουθία εξετάζεται byte προς byte. Εάν το byte είναι `tab` χαρακτήρας ASCII (`b'\t'`), ένας ή περισσότεροι χαρακτήρες διαστήματος εισάγονται στο αποτέλεσμα έως ότου η τρέχουσα στήλη ισούται με την επόμενη θέση `tab`. (Ο ίδιος `tab` χαρακτήρας δεν αντιγράφεται.) Εάν το τρέχον byte είναι μια νέα γραμμή ASCII (`b'\n'`), αντιγράφεται και η τρέχουσα στήλη επαναφέρεται στο μηδέν. Οποιαδήποτε άλλη τιμή byte αντιγράφεται αμετάβλητη και η τρέχουσα στήλη προσαυξάνεται κατά ένα, ανεξάρτητα από το πώς αναπαρίσταται η τιμή byte όταν εκτυπώνεται:

```
>>> b'01\t012\t0123\t01234'.expandtabs()
b'01      012      0123      01234'
>>> b'01\t012\t0123\t01234'.expandtabs(4)
b'01    012 0123    01234'
```

Σημείωση: Η έκδοση bytearray αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

`bytes.isalnum()`

`bytearray.isalnum()`

Επιστρέφει True εάν όλα τα byte της ακολουθίας είναι αλφαβητικοί χαρακτήρες ASCII ή ASCII δεκαδικά ψηφία και η ακολουθία δεν είναι κενή, False διαφορετικά. Οι αλφαβητικοί χαρακτήρες ASCII είναι εκείνες οι τιμές byte στην ακολουθία `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'`. Τα δεκαδικά ψηφία ASCII είναι αυτές οι τιμές byte στην ακολουθία `b'0123456789'`.

Για παράδειγμα:

```
>>> b'ABCabc1'.isalnum()
True
>>> b'ABC abc1'.isalnum()
False
```

`bytes.isalpha()`

`bytearray.isalpha()`

Επιστρέφει True εάν όλα τα bytes της ακολουθίας είναι αλφαβητικοί χαρακτήρες ASCII και η ακολουθία δεν είναι κενή, False διαφορετικά. Οι αλφαβητικοί χαρακτήρες ASCII είναι εκείνες οι τιμές bytes στην ακολουθία `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

Για παράδειγμα:

```
>>> b'ABCabc'.isalpha()
True
>>> b'ABCabc1'.isalpha()
False
```

`bytes.isascii()`

`bytearray.isascii()`

Επιστρέφει True εάν η ακολουθία είναι κενή ή όλα τα byte της ακολουθίας είναι ASCII, False διαφορετικά. Τα bytes ASCII βρίσκονται στο εύρος 0-0x7F.

Νέο στην έκδοση 3.7.

`bytes.isdigit()`

`bytearray.isdigit()`

Επιστρέφει True εάν όλα τα bytes στην ακολουθία είναι δεκαδικά ψηφία ASCII και η ακολουθία δεν είναι κενή, False διαφορετικά. Τα δεκαδικά ψηφία ASCII είναι αυτές οι τιμές byte στην ακολουθία `b'0123456789'`.

Για παράδειγμα:

```
>>> b'1234'.isdigit()
True
>>> b'1.23'.isdigit()
False
```

`bytes.islower()``bytearray.islower()`

Επιστρέφει `True` εάν υπάρχει τουλάχιστον ένας πεζός χαρακτήρας ASCII στην ακολουθία και κανέναν κεφαλαίο χαρακτήρα ASCII, `False` διαφορετικά.

Για παράδειγμα:

```
>>> b'hello world'.islower()
True
>>> b'Hello world'.islower()
False
```

Οι πεζοί χαρακτήρες ASCII είναι αυτές οι τιμές `byte` στην ακολουθία `b'abcdefghijklmnopqrstuvwxyz'`. Οι κεφαλαίοι χαρακτήρες ASCII είναι αυτές οι τιμές `byte` στην ακολουθία `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

`bytes.isspace()``bytearray.isspace()`

Επιστρέφει `True` εάν όλα τα `byte` στην ακολουθία είναι κενά ASCII και η ακολουθία δεν είναι κενή, `False` διαφορετικά. Οι χαρακτήρες κενού διαστήματος ASCII είναι αυτές οι τιμές `byte` στην ακολουθία `b' \t \n \r \x0b \f '` (κενό, `tab`, νέα γραμμή, επιστροφή μεταφοράς, κάθετο `tab`, μορφή ροής).

`bytes.istitle()``bytearray.istitle()`

Επιστρέφει `True` εάν η ακολουθία είναι ASCII κεφαλαία τίτλου (δηλαδή τα πρώτα γράμματα των λέξεων κεφαλαία) και η ακολουθία δεν είναι κενή, `False` διαφορετικά. Δείτε `bytes.title()` για περισσότερες λεπτομέρειες σχετικά με τον ορισμό του «titlecase».

Για παράδειγμα:

```
>>> b'Hello World'.istitle()
True
>>> b'Hello world'.istitle()
False
```

`bytes.isupper()``bytearray.isupper()`

Επιστρέφει `True` εάν υπάρχει τουλάχιστον ένας κεφαλαίος αλφαβητικός χαρακτήρας ASCII στην ακολουθία και κανέναν πεζό χαρακτήρα ASCII, διαφορετικά `False`.

Για παράδειγμα:

```
>>> b'HELLO WORLD'.isupper()
True
>>> b'Hello world'.isupper()
False
```

Οι πεζοί χαρακτήρες ASCII είναι αυτές οι τιμές `byte` στην ακολουθία `b'abcdefghijklmnopqrstuvwxyz'`. Οι κεφαλαίοι χαρακτήρες ASCII είναι αυτές οι τιμές `byte` στην ακολουθία `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

`bytes.lower()``bytearray.lower()`

Επιστρέφει ένα αντίγραφο της ακολουθίας με όλους τους κεφαλαίους χαρακτήρες ASCII να έχουν μετατραπεί στα ισοδύναμα πεζά.

Για παράδειγμα:

```
>>> b'Hello World'.lower()
b'hello world'
```

Οι πεζοί χαρακτήρες ASCII είναι αυτές οι τιμές byte στην ακολουθία b'abcdefghijklmnopqrstuvwxyz'. Οι κεφαλαίοι χαρακτήρες ASCII είναι αυτές οι τιμές byte στην ακολουθία b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'.

Σημείωση: Η έκδοση bytearray αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

bytes.**splitlines** (*keepends=False*)

bytearray.**splitlines** (*keepends=False*)

Επιστρέφει μια λίστα με τις γραμμές στη δυαδική ακολουθία, σπάζοντας τα όρια γραμμής του ASCII. Αυτή η μέθοδος χρησιμοποιεί την προσέγγιση *universal newlines* για τον διαχωρισμό των γραμμών. Οι αλλαγές γραμμής δεν περιλαμβάνονται στη λίστα που προκύπτει εκτός εάν δοθεί *keepends* και είναι αληθής.

Για παράδειγμα:

```
>>> b'ab c\nnde fg\rkl\r\n'.splitlines()
[b'ab c', b'', b'de fg', b'kl']
>>> b'ab c\nnde fg\rkl\r\n'.splitlines(keepends=True)
[b'ab c\n', b'\n', b'de fg\r', b'kl\r\n']
```

Σε αντίθεση με το *split()* όταν δίνεται μια οριοθετημένη συμβολοσειρά *sep*, αυτή η μέθοδος επιστρέφει μια κενή λίστα για την κενή συμβολοσειρά και μια αλλαγή γραμμής τερματικού δεν οδηγεί σε μια επιπλέον γραμμή:

```
>>> b"".split(b'\n'), b"Two lines\n".split(b'\n')
([b''], [b'Two lines', b''])
>>> b"".splitlines(), b"One line\n".splitlines()
([], [b'One line'])
```

bytes.**swapcase** ()

bytearray.**swapcase** ()

Επιστρέφει ένα αντίγραφο της ακολουθίας με όλους τους πεζούς χαρακτήρες ASCII να έχουν μετατραπεί στο αντίστοιχο ισοδύναμο κεφαλαίο και αντίστροφα.

Για παράδειγμα:

```
>>> b'Hello World'.swapcase()
b'hELLO wORLD'
```

Οι πεζοί χαρακτήρες ASCII είναι αυτές οι τιμές byte στην ακολουθία b'abcdefghijklmnopqrstuvwxyz'. Οι κεφαλαίοι χαρακτήρες ASCII είναι αυτές οι τιμές byte στην ακολουθία b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'.

Unlike *str.swapcase()*, it is always the case that *bin.swapcase().swapcase() == bin* for the binary versions. Case conversions are symmetrical in ASCII, even though that is not generally true for arbitrary Unicode code points.

Σημείωση: Η έκδοση bytearray αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

bytes.**title** ()

`bytearray.title()`

Επιστρέφει μια έκδοση με κεφαλαία τίτλου (δηλαδή τα πρώτα γράμματα των λέξεων κεφαλαία) της δυαδικής ακολουθίας όπου οι λέξεις ξεκινούν με κεφαλαίο χαρακτήρα ASCII και οι υπόλοιποι χαρακτήρες είναι πεζοί. Οι τιμές `byte` χωρίς κεφαλαία γράμματα παραμένουν χωρίς τροποποίηση.

Για παράδειγμα:

```
>>> b'Hello world'.title()
b'Hello World'
```

Οι πεζοί χαρακτήρες ASCII είναι εκείνες οι τιμές `byte` στην ακολουθία `b'abcdefghijklmnopqrstuvwxyz'`. Οι κεφαλαίοι χαρακτήρες ASCII είναι εκείνες οι τιμές `byte` στην ακολουθία `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`. Όλες οι άλλες τιμές `byte` είναι χωρίς κεφαλαία.

Ο αλγόριθμος χρησιμοποιεί έναν απλό, ανεξάρτητο από τη γλώσσα, ορισμό μιας λέξης ως `group` διαδοχικών γραμμικών. Ο ορισμός λειτουργεί σε πολλά contexts, αλλά σημαίνει ότι οι απόστροφες σε συναιρέσεις και κτητικές λέξεις αποτελούν όρια λέξεων, που μπορεί να μην είναι το επιθυμητό αποτέλεσμα:

```
>>> b"they're bill's friends from the UK".title()
b'They'Re Bill'S Friends From The Uk'
```

Μια λύση για αποστροφους μπορεί να δημιουργηθεί χρησιμοποιώντας κανονικές εκφράσεις:

```
>>> import re
>>> def titlecase(s):
...     return re.sub(rb"[A-Za-z]+(' [A-Za-z]+)?",
...                     lambda mo: mo.group(0)[0:1].upper() +
...                               mo.group(0)[1:].lower(),
...                     s)
>>> titlecase(b"they're bill's friends.")
b'They're Bill's Friends.'
```

Σημείωση: Η έκδοση `bytearray` αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

`bytes.upper()``bytearray.upper()`

Επιστρέφει ένα αντίγραφο της ακολουθίας με όλους τους πεζούς χαρακτήρες ASCII να έχουν μετατραπεί στο αντίστοιχο ισοδύναμο κεφαλαίο.

Για παράδειγμα:

```
>>> b'Hello World'.upper()
b'HELLO WORLD'
```

Οι πεζοί χαρακτήρες ASCII είναι αυτές οι τιμές `byte` στην ακολουθία `b'abcdefghijklmnopqrstuvwxyz'`. Οι κεφαλαίοι χαρακτήρες ASCII είναι αυτές οι τιμές `byte` στην ακολουθία `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

Σημείωση: Η έκδοση `bytearray` αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

`bytes.zfill(width)`

`bytearray.zfill(width)`

Επιστρέφει ένα αντίγραφο της ακολουθίας που έχει απομείνει γεμάτο με ψηφία ASCII `b'0'` για να δημιουργήσετε μια ακολουθία μήκους *width*. Ένα πρόθεμα προπορευόμενου σήματος (`b'+' / b'-'`) αντιμετωπίζεται με την εισαγωγή της συμπλήρωσης του *after* χαρακτήρα προσήμου και όχι πριν. Για αντικείμενα *bytes*, η αρχική ακολουθία επιστρέφεται εάν το *width* είναι μικρότερο ή ίσο με `len(seq)`.

Για παράδειγμα:

```
>>> b"42".zfill(5)
b'00042'
>>> b"-42".zfill(5)
b'-0042'
```

Σημείωση: Η έκδοση `bytearray` αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα και αν δεν έγιναν αλλαγές.

4.8.4 Μορφοποίηση Bytes τύπου `printf`

Σημείωση: Οι λειτουργίες μορφοποίησης που περιγράφονται εδώ παρουσιάζουν μια ποικιλία ιδιορρυθμιών που οδηγούν σε μια σειρά από κοινά σφάλματα (όπως η αποτυχία εμφάνισης των πλειάδων και των λεξικών σωστά). Εάν η τιμή που εκτυπώνεται μπορεί να είναι πλειάδα ή λεξικό, κάντε το `wrap` σε μια πλειάδα.

Τα αντικείμενα `bytes` (`bytes/bytearray`) έχουν μια μοναδική ενσωματωμένη λειτουργία: τον τελεστή `%` (`modulo`). Αυτό είναι επίσης γνωστό ως τελεστής `bytes formatting` ή *interpolation*. Δεδομένων των `format % values` (όπου η *format* είναι αντικείμενο `bytes`), οι προδιαγραφές μετατροπής `%` σε *format* αντικαθιστά με μηδέν ή περισσότερα στοιχεία *values*. Το αποτέλεσμα είναι παρόμοιο με τη χρήση του `sprintf()` στη γλώσσα C.

Εάν το *format* απαιτεί ένα μεμονωμένο όρισμα, το *values* μπορεί να είναι ένα μεμονωμένο μη πολλαπλό αντικείμενο.⁵ Διαφορετικά, το *values* πρέπει να είναι πλειάδα με ακριβώς τον αριθμό των στοιχείων που καθορίζονται από το αντικείμενο μορφής `bytes` ή μεμονωμένο `mapping` αντικείμενο (για παράδειγμα, ένα λεξικό).

Ένας προσδιοριστής μετατροπής περιέχει δύο ή περισσότερους χαρακτήρες και έχει τους εξής `components`, οι οποίοι πρέπει να εμφανίζονται με αυτή τη σειρά:

1. Ο χαρακτήρας `'%'`, που σηματοδοτεί την αρχή του προσδιοριστή.
2. Κλειδί `mapping` (προαιρετικό), που αποτελείται από μια ακολουθία χαρακτήρων σε παρένθεση (για παράδειγμα, `(somename)`).
3. Δείκτης μετατροπής (προαιρετικό), που επηρεάζουν το αποτέλεσμα κάποιων τύπων μετατροπής.
4. Ελάχιστο πλάτος πεδίου (προαιρετικό). Εάν ορίζεται ως `'*'` (αστερίσκος), το πραγματικό πλάτος διαβάζεται από το επόμενο στοιχείο του `tuple` στα *values*, και το αντικείμενο προς μετατροπή έρχεται μετά από το ελάχιστο πλάτος πεδίου και το προαιρετικό `precision`.
5. Ακρίβεια (προαιρετικό), δίνεται ως `'.'` (τελεία) ακολουθούμενη από το `precision`. Εάν ορίζεται ως `'*'` (αστερίσκος), το πραγματικό `precision` διαβάζεται από το επόμενο στοιχείο του `tuple` στα *values*, και η τιμή προς μετατροπή έρχεται μετά το `precision`.
6. Μετατροπέας του `length` (προαιρετικό).
7. Τύπος `conversion`.

Όταν το σωστό όρισμα είναι ένα λεξικό (ή άλλος τύπος αντιστοίχισης), τότε οι μορφές στο αντικείμενο `bytes` πρέπει να περιλαμβάνουν ένα κλειδί αντιστοίχισης σε παρένθεση σε αυτό το λεξικό που έχει εισαχθεί αμέσως

μετά τον χαρακτήρα '%'. Το κλειδί αντιστοίχισης επιλέγει την τιμή που θα μορφοποιηθεί από την αντιστοίχιση. Για παράδειγμα:

```
>>> print(b'%(language)s has %(number)03d quote types.' %
...       {b'language': b'Python', b'number': 2})
b'Python has 002 quote types.'
```

Σε αυτήν την περίπτωση δεν μπορεί να υπάρχουν προσδιοριστές * σε μια μορφή (καθώς απαιτούν μια διαδοχική λίστα παραμέτρων).

Οι δείκτες μετατροπής είναι:

| Flag | Έννοια |
|------|--|
| '#' | Οι μετατροπή τιμής θα χρησιμοποιήσει την «εναλλακτική φόρμα» (όπου ορίζεται παρακάτω). |
| '0' | Η μετατροπή θα έχει μηδενική συμπλήρωση για αριθμητικές τιμές. |
| '-' | Η τιμή μετατροπής αφήνεται προσαρμοσμένη (παρακάμπτει τη μετατροπή '0' εάν δίνονται και τα δύο). |
| ' ' | (ένα κενό) Πρέπει να προστεθεί ένα κενό πριν από έναν θετικό αριθμό (ή κενή συμβολοσειρά) που παράγεται από μια υπογεγραμμένη μετατροπή. |
| '+' | Ένα χαρακτήρας προσήμου ('+' ή '-') θα προηγείται της μετατροπής (παρακάμπτει ένα «κενό» δείκτη). |

Ένας τροποποιητής μήκους (h, l, or L) μπορεί να υπάρχει, αλλά αγνοείται καθώς δεν είναι απαραίτητος για την Python – οπότε π.χ. %ld είναι πανομοιότυπο σε %d.

Οι τύποι μετατροπής είναι:

| Μετα-τροπή | Έννοια | Σημειώσεις |
|------------|--|------------|
| 'd' | Υπογεγραμμένος δεκαδικός ακέραιος. | |
| 'i' | Υπογεγραμμένος δεκαδικός ακέραιος. | |
| 'o' | Υπογεγραμμένη οκταδική τιμή. | (1) |
| 'u' | Απαρχαιωμένος τύπος – είναι πανομοιότυπος με το 'd'. | (8) |
| 'x' | Υπογεγραμμένο δεκαεξαδικό (πεζά). | (2) |
| 'X' | Υπογεγραμμένο δεκαεξαδικό (κεφαλαίο). | (2) |
| 'e' | Floating point exponential format (lowercase). | (3) |
| 'E' | Floating point exponential format (uppercase). | (3) |
| 'f' | Floating point decimal format. | (3) |
| 'F' | Floating point decimal format. | (3) |
| 'g' | Floating point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise. | (4) |
| 'G' | Floating point format. Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise. | (4) |
| 'c' | Μονό byte (δέχεται ακέραια ή μεμονωμένα byte αντικείμενα). | |
| 'b' | Bytes (any object that follows the buffer protocol or has <code>__bytes__()</code>). | (5) |
| 's' | Το 's' είναι ένα ψευδώνυμο για το 'b' και θα πρέπει να χρησιμοποιείται μόνο για κώδικα βάσει Python2/3. | (6) |
| 'a' | Bytes (μετατρέπει οποιοδήποτε αντικείμενο Python χρησιμοποιώντας <code>repr(obj).encode('ascii', 'backslashreplace')</code>). | (5) |
| 'r' | Το 'r' είναι ένα ψευδώνυμο για 'a' και θα πρέπει να χρησιμοποιείται μόνο για βάσεις κώδικα Python2/3. | (7) |
| '%' | Κανένα όρισμα δεν μετατρέπεται, έχει ως αποτέλεσμα έναν χαρακτήρα '%' το αποτέλεσμα. | |

Σημειώσεις:

- (1) Η εναλλακτική μορφή προκαλεί την εισαγωγή ενός πρώτου οκταδικού προσδιοριστή ('0o') πριν από το πρώτο ψηφίο.
- (2) Η εναλλακτική φόρμα προκαλεί την εισαγωγή ενός αρχικού '0x' ή '0X' (ανάλογα με το εάν χρησιμοποιήθηκε η μορφή 'x' ή 'X') πριν το πρώτο ψηφίο.
- (3) Η εναλλακτική μορφή κάνει το αποτέλεσμα να περιέχει πάντα μια υποδιαστολή, ακόμα κι αν δεν ακολουθούν ψηφία.
Η ακρίβεια καθορίζει τον αριθμό των ψηφίων μετά την υποδιαστολή και ορίζεται από προεπιλογή ως 6.
- (4) Η εναλλακτική μορφή κάνει το αποτέλεσμα να περιέχει πάντα μια υποδιαστολή και τα μηδενικά στο τέλος δεν αφαιρούνται όπως θα ήταν διαφορετικά.
Η ακρίβεια καθορίζει τον αριθμό των σημαντικών ψηφίων πριν και μετά την υποδιαστολή και ορίζει το 6.
- (5) Εάν η ακρίβεια είναι 'N', η έξοδος περικόπτεται σε N χαρακτήρες.
- (6) Το `b'%s'` έχει καταργηθεί, αλλά δεν θα αφαιρεθεί κατά τη διάρκεια της σειράς 3.x.
- (7) Το `b'%r'` έχει καταργηθεί, αλλά δεν θα αφαιρεθεί κατά τη διάρκεια της σειράς 3.x.
- (8) Βλέπε [PEP 237](#).

Σημείωση: Η έκδοση `bytearray` αυτής της μεθόδου δεν λειτουργεί στη θέση της - παράγει πάντα ένα νέο αντικείμενο, ακόμα κι αν δεν έγιναν αλλαγές.

[PEP 461](#) - Προσθήκη `%` για μορφοποίηση σε `bytes` και `bytearray`

Νέο στην έκδοση 3.5.

4.8.5 Όψεις Μνήμης

Τα αντικείμενα `memoryview` επιτρέπουν στον κώδικα Python να έχει πρόσβαση στα εσωτερικά δεδομένα ενός αντικειμένου που υποστηρίζει το πρωτόκολλο `buffer protocol` χωρίς αντιγραφή.

class `memoryview` (*object*)

Δημιουργεί μια `memoryview` που αναφέρεται στο *object*. Το *object* πρέπει να υποστηρίζει το πρωτόκολλο `buffer`. Τα ενσωματωμένα αντικείμενα που υποστηρίζουν το πρωτόκολλο `buffer` περιλαμβάνουν `bytes` και `bytearray`.

Μια `memoryview` έχει την έννοια ενός *στοιχείου*, το οποίο είναι η μονάδα ατομικής μνήμης που χειρίζεται το αρχικό *object*. Για πολλούς απλούς τύπους όπως `bytes` και `bytearray`, ένα στοιχείο είναι ένα μεμονωμένο `byte`, αλλά άλλοι τύποι όπως `array.array` μπορεί να έχουν μεγαλύτερα στοιχεία.

`len(view)` is equal to the length of *tolist*. If `view.ndim = 0`, the length is 1. If `view.ndim = 1`, the length is equal to the number of elements in the view. For higher dimensions, the length is equal to the length of the nested list representation of the view. The `itemsizes` attribute will give you the number of bytes in a single element.

Μια `memoryview` υποστηρίζει λειτουργίες τμηματοποίησης και πρόσβαση μέσω ευρετηρίου στα δεδομένα του. Μια μονοδιάστατη τμηματοποίηση θα έχει ως αποτέλεσμα μια δευτερεύουσα προβολή:

```
>>> v = memoryview(b'abcefg')
>>> v[1]
98
>>> v[-1]
103
>>> v[1:4]
<memory at 0x7f3ddc9f4350>
>>> bytes(v[1:4])
b'bce'
```

Εάν το *format* είναι ένας από τους προσδιοριστές εγγενούς μορφής από το module *struct*, η πρόσβαση μέσω ευρετηρίου με έναν ακέραιο ή μια πλειάδα (tuple) ακεραίων υποστηρίζεται επίσης και επιστρέφει ένα μεμονωμένο στοιχείο με το σωστό τύπο. Τα μονοδιάστατα memoryviews μπορούν να γίνουν indexed με έναν ακέραιο ή έναν ακέραιο πλειάδα (tuple). Τα πολυδιάστατα memoryviews μπορούν να γίνουν indexed με πλειάδες (tuples) ακριβώς *ndim* ακεραίων όπου *ndim* είναι ο αριθμός των διαστάσεων. Τα μηδενικών διαστάσεων memoryviews μπορούν να γίνουν indexed με την κενή πλειάδα (tuple).

Ακολουθεί ένα παράδειγμα με μη-byte μορφή:

```
>>> import array
>>> a = array.array('l', [-11111111, 22222222, -33333333, 44444444])
>>> m = memoryview(a)
>>> m[0]
-11111111
>>> m[-1]
44444444
>>> m[::2].tolist()
[-11111111, -33333333]
```

Εάν το βασικό αντικείμενο είναι εγγράψιμο, το memoryview υποστηρίζει μονοδιάστατη εκχώρηση τμηματοποίησης. Δεν επιτρέπεται η αλλαγή μεγέθους:

```
>>> data = bytearray(b'abcefg')
>>> v = memoryview(data)
>>> v.readonly
False
>>> v[0] = ord(b'z')
>>> data
bytearray(b'zbcefg')
>>> v[1:4] = b'123'
>>> data
bytearray(b'z123fg')
>>> v[2:3] = b'spam'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: memoryview assignment: lvalue and rvalue have different structures
>>> v[2:6] = b'spam'
>>> data
bytearray(b'z1spam')
```

One-dimensional memoryviews of hashable (read-only) types with formats “B”, “b” or “c” are also hashable. The hash is defined as `hash(m) == hash(m.tobytes())`:

```
>>> v = memoryview(b'abcefg')
>>> hash(v) == hash(b'abcefg')
True
>>> hash(v[2:4]) == hash(b'ce')
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
True
>>> hash(v[::-2]) == hash(b'abcefg'[::-2])
True
```

Άλλαξε στην έκδοση 3.3: One-dimensional memoryviews can now be sliced. One-dimensional memoryviews with formats “B”, “b” or “c” are now hashable.

Άλλαξε στην έκδοση 3.4: το memoryview εγγράφεται πλέον αυτόματα με `collections.abc.Sequence`

Άλλαξε στην έκδοση 3.5: τα memoryviews μπορούν τώρα να γίνουν ευρετηριοποίηση με πλειάδα (tuple) ακεραίων.

το `memoryview` έχει διάφορες μεθόδους:

`__eq__` (*exporter*)

Ένα memoryview και ένας εξαγωγέας **PEP 3118** είναι ίσοι εάν τα σχήματα τους είναι ισοδύναμα και εάν όλες οι αντίστοιχες τιμές είναι ίσες όταν οι αντίστοιχοι κωδικοί μορφής των τελεστών ερμηνεύονται χρησιμοποιώντας τη σύνταξη `struct`.

Για το υποσύνολο του `struct` οι συμβολοσειρές μορφής που υποστηρίζονται αυτή τη στιγμή από το `tolist()`, `v` και `w` είναι ίσες εάν `v.tolist() == w.tolist()`:

```
>>> import array
>>> a = array.array('I', [1, 2, 3, 4, 5])
>>> b = array.array('d', [1.0, 2.0, 3.0, 4.0, 5.0])
>>> c = array.array('b', [5, 3, 1])
>>> x = memoryview(a)
>>> y = memoryview(b)
>>> x == a == y == b
True
>>> x.tolist() == a.tolist() == y.tolist() == b.tolist()
True
>>> z = y[::-2]
>>> z == c
True
>>> z.tolist() == c.tolist()
True
```

Εάν καμία συμβολοσειρά μορφής δεν υποστηρίζεται από το module `struct`, τότε τα αντικείμενα θα συγκρίνονται πάντα ως άνισα (ακόμα και αν οι συμβολοσειρές μορφοποίησης και τα περιεχόμενα της προσωρινής μνήμης είναι πανομοιότυπα):

```
>>> from ctypes import BigEndianStructure, c_long
>>> class BEPoint(BigEndianStructure):
...     _fields_ = [("x", c_long), ("y", c_long)]
...
>>> point = BEPoint(100, 200)
>>> a = memoryview(point)
>>> b = memoryview(point)
>>> a == point
False
>>> a == b
False
```

Note that, as with floating point numbers, `v is w` does *not* imply `v == w` for memoryview objects.

Άλλαξε στην έκδοση 3.3: Οι προηγούμενες εκδόσεις συνέκριναν την ακατέργαστη μνήμη αγνοώντας τη μορφή του στοιχείου και τη δομή του λογικού πίνακα.

tobytes (*order=None*)

Επιστρέφει τα δεδομένα στο buffer ως ένα bytestring. Αυτό ισοδυναμεί με την κλήση του κατασκευαστή `bytes` στο `memoryview`.

```
>>> m = memoryview(b"abc")
>>> m.tobytes()
b'abc'
>>> bytes(m)
b'abc'
```

Για μη συνεχόμενους πίνακες, το αποτέλεσμα είναι ίσο με την αναπαράσταση της ισοπεδωμένης λίστας με όλα τα στοιχεία να μετατρέπονται σε bytes. Η `tobytes()` υποστηρίζει όλες τις συμβολοσειρές μορφής, συμπεριλαμβανομένων εκείνων που δεν είναι στη σύνταξη του module `struct`.

Νέο στην έκδοση 3.8: Το `order` μπορεί να είναι {"C", "F", "A"}. Όταν το `order` είναι "C" ή "F", τα δεδομένα του αρχικού πίνακα μετατρέπονται σε C ή σε σειρά Fortran. Για συνεχόμενες όψεις, το "A" επιστρέφει ένα ακριβές αντίγραφο της φυσικής μνήμης. Συγκεκριμένα, διατηρείται σειρά Fortran στη μνήμη. Για μη συνεχόμενες προβολές, τα δεδομένα μετατρέπονται πρώτα σε C. Το `order=None` είναι το ίδιο με το `order="C"`.

hex (*[sep[, bytes_per_sep]]*)

Επιστρέφει ένα αντικείμενο συμβολοσειράς που περιέχει δύο δεκαεξαδικά ψηφία για κάθε byte στο buffer.

```
>>> m = memoryview(b"abc")
>>> m.hex()
'616263'
```

Νέο στην έκδοση 3.5.

Άλλαξε στην έκδοση 3.8: Παρόμοιο με το `bytes.hex()`, το `memoryview.hex()` τώρα υποστηρίζει προαιρετικές παραμέτρους `sep` και `bytes_per_sep` για να εισάγετε διαχωριστικά μεταξύ των byte στην εξαγωγή δεκαεξαδικού.

tolist ()

Επιστρέφει τα δεδομένα στο buffer ως λίστα στοιχείων.

```
>>> memoryview(b'abc').tolist()
[97, 98, 99]
>>> import array
>>> a = array.array('d', [1.1, 2.2, 3.3])
>>> m = memoryview(a)
>>> m.tolist()
[1.1, 2.2, 3.3]
```

Άλλαξε στην έκδοση 3.3: Η `tolist()` υποστηρίζει πλέον όλες τις εγγενείς μορφές μεμονωμένων χαρακτήρων στη σύνταξη του `struct`, καθώς και πολυδιάστατες αναπαραστάσεις.

toreadonly ()

Επιστρέφει μια έκδοση μόνο για ανάγνωση του αντικειμένου `memoryview`. Το αρχικό αντικείμενο `memoryview` είναι αμετάβλητο.

```
>>> m = memoryview(bytearray(b'abc'))
>>> mm = m.toreadonly()
>>> mm.tolist()
[89, 98, 99]
>>> mm[0] = 42
Traceback (most recent call last):
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
File "<stdin>", line 1, in <module>
TypeError: cannot modify read-only memory
>>> m[0] = 43
>>> mm.tolist()
[43, 98, 99]
```

Νέο στην έκδοση 3.8.

release()

Απελευθερώνει το υποκείμενο buffer που εκτίθεται από το αντικείμενο `memoryview`. Πολλά αντικείμενα πραγματοποιούν ειδικές ενέργειες όταν διατηρείται μια προβολή σε αυτά (για παράδειγμα, μια `bytearray` θα απαγόρευε προσωρινά την αλλαγή μεγέθους). επομένως, η κλήση της `release()` είναι βολική για την κατάργηση αυτών των περιορισμών (και απελευθερώνει οποιουσδήποτε αιωρούμενους πόρους) το συντομότερο δυνατό.

After this method has been called, any further operation on the view raises a `ValueError` (except `release()` itself which can be called multiple times):

```
>>> m = memoryview(b'abc')
>>> m.release()
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memoryview object
```

Το πρωτόκολλο διαχείρισης περιεχομένου μπορεί να χρησιμοποιηθεί για παρόμοιο αποτέλεσμα, χρησιμοποιώντας τη δήλωση `with`:

```
>>> with memoryview(b'abc') as m:
...     m[0]
...
97
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memoryview object
```

Νέο στην έκδοση 3.2.

cast([, shape])

Μορφοποιεί ένα `memoryview` σε νέα μορφή ή σχήμα. Το `shape` είναι από προεπιλογή `[byte_length//new_itemsize]`, που σημαίνει ότι η προβολή αποτελέσματος θα είναι μονοδιάστατη. Η επιστρεφόμενη τιμή είναι ένα νέο `memoryview`, αλλά το ίδιο το buffer δεν αντιγράφεται. Οι υποστηριζόμενες μετατροπές είναι 1D -> C-contiguous και C-contiguous -> 1D.

The destination format is restricted to a single element native format in `struct` syntax. One of the formats must be a byte format ("B", "b" or "c"). The byte length of the result must be the same as the original length.

Μορφοποίηση από 1D/long σε 1D/unsigned bytes:

```
>>> import array
>>> a = array.array('l', [1, 2, 3])
>>> x = memoryview(a)
>>> x.format
'l'
>>> x.itemsize
8
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

>>> len(x)
3
>>> x.nbytes
24
>>> y = x.cast('B')
>>> y.format
'B'
>>> y.itemsize
1
>>> len(y)
24
>>> y.nbytes
24

```

Μορφοποίηση από 1D/unsigned bytes σε 1D/char:

```

>>> b = bytearray(b'zyz')
>>> x = memoryview(b)
>>> x[0] = b'a'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: memoryview: invalid value for format "B"
>>> y = x.cast('c')
>>> y[0] = b'a'
>>> b
bytearray(b'ayz')

```

Μορφοποίηση από 1D/bytes σε 3D/ints σε 1D/signed char:

```

>>> import struct
>>> buf = struct.pack("i"*12, *list(range(12)))
>>> x = memoryview(buf)
>>> y = x.cast('i', shape=[2,2,3])
>>> y.tolist()
[[[0, 1, 2], [3, 4, 5]], [[6, 7, 8], [9, 10, 11]]]
>>> y.format
'i'
>>> y.itemsize
4
>>> len(y)
2
>>> y.nbytes
48
>>> z = y.cast('b')
>>> z.format
'b'
>>> z.itemsize
1
>>> len(z)
48
>>> z.nbytes
48

```

Μορφοποίηση από 1D/unsigned long σε 2D/unsigned long:

```

>>> buf = struct.pack("L"*6, *list(range(6)))

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> x = memoryview(buf)
>>> y = x.cast('L', shape=[2,3])
>>> len(y)
2
>>> y.nbytes
48
>>> y.tolist()
[[0, 1, 2], [3, 4, 5]]
```

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.5: Η πηγαία μορφή δεν είναι πλέον περιορισμένη κατά τη μορφοποίηση σε μια όψη byte.

Υπάρχουν επίσης αρκετά διαθέσιμα χαρακτηριστικά μόνο για ανάγνωση:

obj

Το βασικό αντικείμενο του memoryview:

```
>>> b = bytearray(b'xyz')
>>> m = memoryview(b)
>>> m.obj is b
True
```

Νέο στην έκδοση 3.3.

nbytes

`nbytes == product(shape) * itemsize == len(m.tobytes())`. Αυτή είναι η ποσότητα χώρου σε byte που θα χρησιμοποιούσε ο πίνακας σε μια συνεχόμενη αναπαράσταση. Δεν ισούται απαραίτητα με `len(m)`:

```
>>> import array
>>> a = array.array('i', [1,2,3,4,5])
>>> m = memoryview(a)
>>> len(m)
5
>>> m.nbytes
20
>>> y = m[:2]
>>> len(y)
3
>>> y.nbytes
12
>>> len(y.tobytes())
12
```

Πολυδιάστατοι πίνακες:

```
>>> import struct
>>> buf = struct.pack("d"*12, *[1.5*x for x in range(12)])
>>> x = memoryview(buf)
>>> y = x.cast('d', shape=[3,4])
>>> y.tolist()
[[0.0, 1.5, 3.0, 4.5], [6.0, 7.5, 9.0, 10.5], [12.0, 13.5, 15.0, 16.5]]
>>> len(y)
3
>>> y.nbytes
96
```

Νέο στην έκδοση 3.3.

readonly

Ένα bool που υποδεικνύει εάν η μνήμη είναι μόνο για ανάγνωση.

format

Μια συμβολοσειρά που περιέχει τη μορφή (σε module style *struct*) για κάθε στοιχείο σε μια όψη. Μπορεί να δημιουργηθεί ένα `memoryview` από εξαγωγείς με συμβολοσειρές αυθαίρετης μορφής, αλλά ορισμένες μέθοδοι (π.χ. `tolist()`) είναι περιορισμένες σε εγγενείς μορφές ενός στοιχείου.

Άλλαξε στην έκδοση 3.3: η μορφή 'B' αντιμετωπίζεται πλέον σύμφωνα με τη σύνταξη ενός `struct` module. Αυτό σημαίνει ότι `memoryview(b'abc')[0] == b'abc'[0] == 97`.

itemsize

Το μέγεθος σε bytes κάθε στοιχείου στο `memoryview`:

```
>>> import array, struct
>>> m = memoryview(array.array('H', [32000, 32001, 32002]))
>>> m.itemsize
2
>>> m[0]
32000
>>> struct.calcsize('H') == m.itemsize
True
```

ndim

Ένα ακέραιος αριθμός που δείχνει πόσες διαστάσεις ενός πολυδιάστατου πίνακα αντιπροσωπεύει η μνήμη.

shape

Μια πλειάδα (tuple) ακεραίων με μήκος *ndim* δίνοντας το σχήμα της μνήμης ως πίνακα N-διαστάσεων.

Άλλαξε στην έκδοση 3.3: Μια κενή πλειάδα (tuple) αντί για `None` όταν `ndim = 0`.

strides

Μια πλειάδα ακεραίων με μήκος *ndim* που δίνει το μέγεθος σε bytes για την πρόσβαση σε κάθε στοιχείο για κάθε διάσταση του πίνακα.

Άλλαξε στην έκδοση 3.3: Μια κενή πλειάδα (tuple) αντί για `None` όταν `ndim = 0`.

suboffsets

Χρησιμοποιείται εσωτερικά για συστοιχίες τύπου PIL. Η τιμή είναι μόνο ενημερωτική.

c_contiguous

Ένα bool που υποδεικνύει εάν η μνήμη είναι C-*contiguous*.

Νέο στην έκδοση 3.3.

f_contiguous

Ένα bool που υποδεικνύει εάν η μνήμη είναι Fortran *contiguous*.

Νέο στην έκδοση 3.3.

contiguous

Ένα bool που υποδεικνύει εάν η μνήμη είναι *contiguous*.

Νέο στην έκδοση 3.3.

4.9 Τύποι Συνόλου (Set) — set, frozenset

Ένα αντικείμενο *set* είναι μια μη ταξινομημένη συλλογή από διακριτά αντικείμενα *hashable*. Οι συνήθεις χρήσεις περιλαμβάνουν τη δοκιμή ιδιότητας μέλους, την αφαίρεση διπλότυπων από μια ακολουθία και τον υπολογισμό μαθηματικών πράξεων όπως τομή, ένωση, διαφορά, και συμμετρική διαφορά. (Για άλλα containers, δείτε τις ενσωματωμένες κλάσεις *dict*, *list*, και *tuple* και το module *collections*).

Όπως και άλλες συλλογές, τα σύνολα (sets) υποστηρίζουν `x in set`, `len(set)`, και `for x in set`. Όντως μια μη ταξινομημένη συλλογή, τα σύνολα δεν καταγράφουν τη θέση του στοιχείου ή τη σειρά εισαγωγής. Συνεπώς, τα σύνολα (sets) δεν υποστηρίζουν λειτουργίες ευρετηριοποίησης, τμηματοποίησης ή άλλη συμπεριφορά ακολουθίας.

Υπάρχουν αυτή τη στιγμή δύο ενσωματωμένοι τύποι συνόλου, *set* και *frozenset*. Ο τύπος *set* είναι ευμετάβλητος — τα περιεχόμενα του μπορούν να αλλάξουν χρησιμοποιώντας μεθόδους όπως `add()` και `remove()`. Δεδομένου ότι είναι ευμετάβλητο, δεν έχει τιμή κατακερματισμού και δεν μπορεί να χρησιμοποιηθεί ούτε ως κλειδί λεξικού ούτε ως στοιχείο ενός άλλου συνόλου (set). Ο τύπος *frozenset* είναι αμετάβλητος και *hashable* — το περιεχόμενό του δεν μπορεί να αλλάξει μετά τη δημιουργία του· μπορεί επομένως να χρησιμοποιηθεί ως κλειδί λεξικού ή ως στοιχείο άλλου συνόλου (set).

Μπορούν να δημιουργηθούν μη κενά σύνολα (όχι παγωμένα σύνολα (frozensets)) τοποθετώντας μια λίστα στοιχείων διαχωρισμένων με κόμμα μέσα σε αγκύλες, για παράδειγμα: `{'jack', 'sjoerd'}`, επιπλέον με τη χρήση του constructor του *set*.

Οι constructors και για τις δύο κλάσεις λειτουργούν το ίδιο:

```
class set([iterable])
class frozenset([iterable])
```

Επιστρέφει ένα νέο σύνολο (set) ή ένα παγωμένο σύνολο (frozenset) των οποίων τα στοιχεία έχουν ληφθεί από το *iterable*. Τα στοιχεία ενός συνόλου πρέπει να είναι *hashable*. Για να αναπαραστήσουν σύνολα συνόλων, τα εσωτερικά σύνολα πρέπει να είναι *frozenset* αντικείμενα. Εάν δεν έχει καθοριστεί το *iterable*, επιστρέφεται ένα νέο κενό σύνολο.

Τα σύνολα μπορούν να δημιουργηθούν με διάφορους τρόπους:

- Χρησιμοποιώντας μια λίστα στοιχείων διαχωρισμένη με κόμματα: `{'jack', 'sjoerd'}`
- Χρησιμοποιώντας ένα set comprehension: `{c for c in 'abracadabra' if c not in 'abc'}`
- Χρησιμοποιώντας τον τύπο constructor: `set()`, `set('foobar')`, `set(['a', 'b', 'foo'])`

Τα στιγμιότυπα των *set* και *frozenset* παρέχουν τις ακόλουθες λειτουργίες:

len(s)

Επιστρέφει τον αριθμό των στοιχείων στο σύνολο *s* (πληθικότητα του *s*).

x in s

Ελέγχει αν το *x* είναι μέρος στο *s*.

x not in s

Ελέγχει αν το *x* δεν είναι μέρος στο *s*.

isdisjoint(other)

Επιστρέφει `True` εάν το σύνολο δεν έχει κοινά στοιχεία με το *other*. Τα σύνολα είναι ασύνδετα εάν και μόνο εάν η τομή τους είναι το κενό σύνολο.

issubset(other)

set <= other

Ελέγχει εάν κάθε στοιχείο στο σύνολο βρίσκεται στο *other*.

set < other

Ελέγχει εάν το σύνολο είναι σωστό υποσύνολο του *other*, δηλαδή, `set <= other` and `set != other`.

issuperset (other)**set >= other**

Ελέγχει αν κάθε στοιχείο του *other* είναι στο σύνολο.

set > other

Ελέγχει αν το σύνολο είναι σωστό υπερσύνολο του *other*, δηλαδή, `set >= other` and `set != other`.

union (*others)**set | other | ...**

Επιστρέφει ένα νέο σύνολο με στοιχεία από το σύνολο και όλα τα άλλα.

intersection (*others)**set & other & ...**

Επιστρέφει ένα νέο σύνολο με στοιχεία κοινά στο σύνολο και σε όλα τα άλλα.

difference (*others)**set - other - ...**

Επιστρέφει ένα νέο σύνολο με στοιχεία στο σύνολο που δεν υπάρχουν στα άλλα.

symmetric_difference (other)**set ^ other**

Επιστρέφει ένα νέο σύνολο με στοιχεία είτε στο σύνολο είτε στο *other* αλλά όχι και στα δύο.

copy ()

Επιστρέφει ένα ρηχό αντίγραφο του συνόλου.

Note, the non-operator versions of `union()`, `intersection()`, `difference()`, and `symmetric_difference()`, `issubset()`, and `issuperset()` methods will accept any iterable as an argument. In contrast, their operator based counterparts require their arguments to be sets. This precludes error-prone constructions like `set('abc') & 'cbs'` in favor of the more readable `set('abc').intersection('cbs')`.

Τόσο το `set` και `frozenset` υποστηρίζουν τη σύγκριση μεταξύ συνόλων. Δύο σύνολα είναι ίσα εάν και μόνο εάν κάθε στοιχείο κάθε συνόλου περιέχεται στο άλλο (το καθένα είναι υποσύνολο του άλλου). Ένα σύνολο είναι μικρότερο από ένα άλλο σύνολο εάν και μόνο αν το πρώτο σύνολο είναι σωστό υποσύνολο του δεύτερου συνόλου (είναι υποσύνολο, αλλά δεν είναι ίσο), ένα σύνολο είναι μεγαλύτερο από ένα άλλο σύνολο, αν και μόνο αν το πρώτο σύνολο είναι σωστό υπερσύνολο του δεύτερου συνόλου (είναι υπερσύνολο αλλά δεν είναι ίσο).

Τα στιγμιότυπα της `set` συγκρίνονται με τα στιγμιότυπα της `frozenset` με βάση τα μέλη τους. Για παράδειγμα, το `set('abc') == frozenset('abc')` επιστρέφει `True` και το ίδιο συμβαίνει και με το `set('abc') in set([frozenset('abc')])`.

Οι συγκρίσεις υποσυνόλου και ισότητας δεν γενικεύονται σε μια συνάρτηση ολικής ταξινόμησης. Για παράδειγμα, οποιαδήποτε δύο μη κενά συνεχή σύνολα δεν είναι ίσα και δεν είναι υποσύνολα το ένα του άλλου, επομένως όλα τα ακόλουθα επιστρέφουν `False`: `a<b`, `a==b`, or `a>b`.

Δεδομένου ότι τα σύνολα ορίζουν μόνο μερική σειρά (σχέσεις υποσυνόλων), η έξοδος της μεθόδου `list.sort()` δεν έχει οριστεί για λίστες συνόλων.

Τα στοιχεία συνόλου, όπως τα κλειδιά λεξικού, πρέπει να είναι *hashable*.

Διαδικές πράξεις που συνδυάζουν στιγμιότυπα `set` με `frozenset` επιστρέφουν τον τύπο του πρώτου τελεστή. Για παράδειγμα: `frozenset('ab') | set('bc')` επιστρέφει ένα στιγμιότυπο του `frozenset`.

Ο παρακάτω πίνακας παραθέτει λειτουργίες που είναι διαθέσιμες για `set` που δεν ισχύουν για αμετάβλητα στιγμιότυπα της `frozenset`:

update (*others)

set |= other | ...

Ενημερώνει το σύνολο (set), προσθέτοντας στοιχεία από όλα τα άλλα.

intersection_update (*others)

set &= other & ...

Ενημερώνει το σύνολο, διατηρώντας μόνο τα στοιχεία που βρίσκονται σε αυτό και όλα τα άλλα.

difference_update (*others)

set -= other | ...

Ενημερώνει το σύνολο, αφαιρώντας στοιχεία που βρίσκονται σε άλλα.

symmetric_difference_update (other)

set ^= other

Ενημερώνει το σύνολο, διατηρώντας μόνο τα στοιχεία που βρίσκονται σε κάθε σύνολο, αλλά όχι και στα δύο.

add (elem)

Προσθέτει το στοιχείο *elem* στο σύνολο.

remove (elem)

Αφαιρεί το στοιχείο *elem* από το σύνολο. Κάνει raise τη `KeyError` εάν το *elem* δεν περιέχεται στο σύνολο.

discard (elem)

Αφαιρεί το στοιχείο *elem* από το σύνολο εάν υπάρχει.

pop ()

Αφαιρεί και επιστρέφει ένα αυθαίρετο στοιχείο από το σύνολο. Κάνει raise μια `KeyError` εάν το σύνολο είναι κενό.

clear ()

Αφαιρεί όλα τα στοιχεία από το σύνολο (set).

Σημείωση, οι εκδόσεις μη-τελεστή μεθόδων `update()`, `intersection_update()`, `difference_update()`, και `symmetric_difference_update()` θα δέχονται οποιοδήποτε επαναλαμβανόμενο στοιχείο ως όρισμα.

Note, the *elem* argument to the `__contains__()`, `remove()`, and `discard()` methods may be a set. To support searching for an equivalent frozenset, a temporary one is created from *elem*.

4.10 Τύποι αντιστοίχισης — dict

Ένα αντικείμενο *mapping* αντιστοιχίζει *hashable* τιμές σε αυθαίρετα αντικείμενα. Οι αντιστοιχίσεις είναι μεταβλητά αντικείμενα. Υπάρχει επί του παρόντος μόνο ένα τυπικός τύπο αντιστοίχισης, το *dictionary*. (Για άλλα containers δείτε τις ενσωματωμένες (built-in) *list*, *set*, και *tuple* κλάσεις, και το module *collections*.)

A dictionary's keys are *almost* arbitrary values. Values that are not *hashable*, that is, values containing lists, dictionaries or other mutable types (that are compared by value rather than by object identity) may not be used as keys. Numeric types used for keys obey the normal rules for numeric comparison: if two numbers compare equal (such as 1 and 1.0) then they can be used interchangeably to index the same dictionary entry. (Note however, that since computers store floating-point numbers as approximations it is usually unwise to use them as dictionary keys.)

class dict (**kwargs)

class dict (mapping, **kwargs)

class dict (*iterable*, ***kwargs*)

Επιστρέφει ένα νέο λεξικό που έχει αρχικοποιηθεί από ένα προαιρετικό όρισμα θέσης και ένα πιθανό κενό σύνολο ορισμάτων λέξεων-κλειδιών.

Τα λεξικά μπορούν να δημιουργηθούν με διάφορους τρόπους:

- Χρησιμοποιήστε μια λίστα διαχωρισμένων με κόμματα ζευγών `key: value` μέσα σε αγκύλες: `{'jack': 4098, 'sjoerd': 4127}` or `{4098: 'jack', 4127: 'sjoerd'}`
- Χρησιμοποιήστε ένα *comprehension* λεξικού: `{x: x ** 2 for x in range(10)}`
- Χρησιμοποιήστε τον κατασκευαστή τύπου: `dict()`, `dict([('foo', 100), ('bar', 200)])`, `dict(foo=100, bar=200)`

If no positional argument is given, an empty dictionary is created. If a positional argument is given and it is a mapping object, a dictionary is created with the same key-value pairs as the mapping object. Otherwise, the positional argument must be an *iterable* object. Each item in the iterable must itself be an iterable with exactly two objects. The first object of each item becomes a key in the new dictionary, and the second object the corresponding value. If a key occurs more than once, the last value for that key becomes the corresponding value in the new dictionary.

Εάν δίνονται ορίσματα λέξης-κλειδιού, τα ορίσματα λέξης-κλειδιού και οι τιμές τους προστίθενται στο λεξικό που δημιουργήθηκε από το όρισμα θέσης. Εάν υπάρχει ήδη ένα κλειδί που προστίθεται, η τιμή από το όρισμα λέξης-κλειδιού αντικαθιστά την τιμή από το όρισμα θέσης.

Για επεξήγηση, τα ακόλουθα παραδείγματα επιστρέφουν όλα ένα λεξικό ίσο με `{"one": 1, "two": 2, "three": 3}`:

```
>>> a = dict(one=1, two=2, three=3)
>>> b = {'one': 1, 'two': 2, 'three': 3}
>>> c = dict(zip(['one', 'two', 'three'], [1, 2, 3]))
>>> d = dict([('two', 2), ('one', 1), ('three', 3)])
>>> e = dict({'three': 3, 'one': 1, 'two': 2})
>>> f = dict({'one': 1, 'three': 3}, two=2)
>>> a == b == c == d == e == f
True
```

Η παροχή ορισμάτων λέξεων-κλειδιών όπως στο πρώτο παράδειγμα λειτουργεί μόνο για κλειδιά που είναι έγκυρα αναγνωριστικά Python. Διαφορετικά, μπορούν να χρησιμοποιηθούν οποιαδήποτε έγκυρα κλειδιά.

Αυτές είναι οι λειτουργίες που υποστηρίζουν τα λεξικά (και επομένως, θα πρέπει να υποστηρίζουν και προσαρμοσμένους τύπους αντιστοίχισης επίσης):

list(d)

Επιστρέφει μια λίστα με όλα τα κλειδιά που χρησιμοποιούνται στο λεξικό *d*.

len(d)

Επιστρέφει τον αριθμό των στοιχείων στο λεξικό *d*.

d[key]

Επιστρέφει το στοιχείο του *d* με το κλειδί *key*. Κάνει *raise* μια *KeyError* εάν το *key* δεν υπάρχει για να αντιστοιχηθεί.

Εάν μια υποκλάση ενός λεξικού ορίζει μια μέθοδο `__missing__()` και το *key* δεν υπάρχει, η λειτουργία `d[key]` καλεί αυτήν την μέθοδο με το κλειδί *key* ως όρισμα. Στη συνέχεια, η λειτουργία `d[key]` επιστρέφει ή κάνει *raise* ό, τι επιστρέφεται ή γίνεται *raise* από την κλήση `__missing__(key)`. Καμία άλλη λειτουργία ή μέθοδος δεν επικαλεί την `__missing__()`. Εάν το `__missing__()` δεν έχει οριστεί, γίνεται *raise* *KeyError*. Το `__missing__()` πρέπει να είναι μέθοδος· δεν μπορεί να είναι ένα στιγμότυπο μεταβλητής:

```

>>> class Counter(dict):
...     def __missing__(self, key):
...         return 0
>>> c = Counter()
>>> c['red']
0
>>> c['red'] += 1
>>> c['red']
1

```

Το παραπάνω παράδειγμα δείχνει μέρος της υλοποίησης του `collections.Counter`. Μια διαφορετική μέθοδος `__missing__` χρησιμοποιείται από την `collections.defaultdict`.

d[key] = value

Ορίζει το `d[key]` στο `value`.

del d[key]

Αφαιρεί το `d[key]` από το `d`. Κάνει `raise` ένα `KeyError` εάν το `key` δεν υπάρχει για αντιστοίχιση.

key in d

Επιστρέφει `True` εάν το `d` έχει ένα κλειδί `key`, διαφορετικά `False`.

key not in d

Ισοδυναμεί με `not key in d`.

iter(d)

Επιστρέφει έναν iterator πάνω από τα κλειδιά του λεξικού. Αυτή είναι μια συντόμευση για `iter(d, keys())`.

clear()

Αφαιρεί όλα τα στοιχεία από το λεξικό.

copy()

Επιστρέφει ένα ρηχό αντίγραφο του λεξικού.

classmethod fromkeys(iterable[, value])

Δημιουργεί ένα νέο λεξικό με κλειδιά από το `iterable` και τιμές ως `value`.

Το `fromkeys()` είναι μια μέθοδος κλάσης που επιστρέφει ένα νέο λεξικό. Η τιμή `value` ορίζεται από προεπιλογή σε `None`. Όλες οι τιμές αναφέρονται σε ένα μόνο στιγμιότυπο, επομένως γενικά δεν έχει νόημα για το `value` να είναι μεταβλητό αντικείμενο, όπως μια κενή λίστα. Για να λάβετε διαφορετικές τιμές, χρησιμοποιήστε αντ' αυτού ένα dict comprehension.

get(key[, default])

Επιστρέφει την τιμή για το `key` εάν το `key` είναι στο λεξικό, αλλιώς `default`. Εάν το `default` δεν δίνεται, ορίζεται από προεπιλογή σε `None`, έτσι ώστε αυτή η μέθοδος να μην κάνει `raise` μια `KeyError`.

items()

Επιστρέφει μια νέα όψη των στοιχείων του λεξικού ((`key`, `value`) ζεύγη). Δείτε την *documentation of view objects*.

keys()

Επιστρέφει μια νέα όψη των κλειδιών του λεξικού. Δείτε το *documentation of view objects*.

pop(key[, default])

Εάν το `key` βρίσκεται στο λεξικό, αφαιρείται και επιστρέφει την τιμή του, διαφορετικά επιστρέφει `default`. Εάν `default` δεν δίνεται και το `key` δεν είναι στο λεξικό, γίνεται `raise` ένα `KeyError`.

popitem()

Αφαιρεί και επιστρέφει ένα ζεύγος (`key`, `value`) από το λεξικό. Τα ζεύγη επιστρέφονται με τη σειρά LIFO (last-in, first-out).

Η μέθοδος `popitem()` είναι χρήσιμη για καταστροφική επανάληψη σε ένα λεξικό, όπως χρησιμοποιείται συχνά σε αλγόριθμους συνόλου. Εάν το λεξικό είναι κενό, η κλήση της `popitem()` κάνει `raise` ένα `KeyError`.

Άλλαξε στην έκδοση 3.7: Η σειρά LIFO είναι πλέον εγγυημένη. Σε προηγούμενες εκδόσεις, η `popitem()` επιστρέφει ένα αυθαίρετο ζεύγος κλειδιού/τιμής.

reversed(d)

Επιστρέφει έναν αντίστροφο iterator πάνω από τα κλειδιά του λεξικού. Αυτή είναι μια συντόμευση για `reversed(d.keys())`.

Νέο στην έκδοση 3.8.

setdefault(key[, default])

Εάν το `key` βρίσκεται στο λεξικό, επιστρέφει την τιμή του. Εάν όχι, εισάγετε το `key` με τιμή `default` και επιστρέφει `default`. Το `default` από προεπιλογή είναι `None`.

update([other])

Ενημερώνει το λεξικό με τα ζεύγη κλειδιών/τιμών από το `other`, αντικαθιστώντας τα υπάρχοντα κλειδιά. Επιστρέφει `None`.

`update()` accepts either another dictionary object or an iterable of key/value pairs (as tuples or other iterables of length two). If keyword arguments are specified, the dictionary is then updated with those key/value pairs: `d.update(red=1, blue=2)`.

values()

Επιστρέφει μια νέα όψη των τιμών του λεξικού. Δείτε την [documentation of view objects](#).

Μια σύγκριση ισότητας μεταξύ μιας όψης `dict.values()` και μιας άλλης θα επιστρέφει πάντα `False`. Αυτό ισχύει επίσης όταν συγκρίνετε το `dict.values()` με τον εαυτό της:

```
>>> d = {'a': 1}
>>> d.values() == d.values()
False
```

d | other

Δημιουργεί ένα νέο λεξικό με τα συγχωνευμένα κλειδιά και τις τιμές των `d` και `other`, τα οποία πρέπει να είναι και τα δύο λεξικά. Οι τιμές του `other` έχουν προτεραιότητα όταν τα κλειδιά των `d` και `other` είναι κοινά.

Νέο στην έκδοση 3.9.

d |= other

Ενημερώνει το λεξικό `d` με κλειδιά και τιμές από το `other`, που μπορεί να είναι είτε *mapping* είτε *iterable* ζευγάρι κλειδιών/τιμών. Οι τιμές του `other` έχουν προτεραιότητα όταν τα κλειδιά των `d` και `other` είναι κοινά.

Νέο στην έκδοση 3.9.

Τα λεξικά συγκρίνονται ως ίσα εάν και μόνο εάν έχουν τα ίδια ζεύγη (`key`, `value`) (ανεξάρτητα από τη σειρά). Οι συγκρίσεις διάταξης ("`<`", "`<=`", "`>=`", "`>`") κάνουν `raise` την `TypeError`.

Τα λεξικά διατηρούν τη σειρά εισαγωγής. Σημειώστε ότι η ενημέρωση ενός κλειδιού δεν επηρεάζει τη σειρά. Τα κλειδιά που προστέθηκαν μετά τη διαγραφή εισάγονται στο τέλος.

```
>>> d = {"one": 1, "two": 2, "three": 3, "four": 4}
>>> d
{'one': 1, 'two': 2, 'three': 3, 'four': 4}
>>> list(d)
['one', 'two', 'three', 'four']
>>> list(d.values())
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
[1, 2, 3, 4]
>>> d["one"] = 42
>>> d
{'one': 42, 'two': 2, 'three': 3, 'four': 4}
>>> del d["two"]
>>> d["two"] = None
>>> d
{'one': 42, 'three': 3, 'four': 4, 'two': None}
```

Άλλαξε στην έκδοση 3.7: Η σειρά λεξικού είναι εγγυημένη ότι είναι η σειρά εισαγωγής. Αυτή η συμπεριφορά ήταν μια λεπτομέρεια υλοποίησης της CPython από την έκδοση 3.6.

Τα λεξικά και οι όψεις λεξικών είναι αναστρέψιμες.

```
>>> d = {"one": 1, "two": 2, "three": 3, "four": 4}
>>> d
{'one': 1, 'two': 2, 'three': 3, 'four': 4}
>>> list(reversed(d))
['four', 'three', 'two', 'one']
>>> list(reversed(d.values()))
[4, 3, 2, 1]
>>> list(reversed(d.items()))
[('four', 4), ('three', 3), ('two', 2), ('one', 1)]
```

Άλλαξε στην έκδοση 3.8: Τα λεξικά είναι πλέον αναστρέψιμα.

Δείτε επίσης:

Η `types.MappingProxyType` μπορεί να χρησιμοποιηθεί για τη δημιουργία μιας όψης μόνο για ανάγνωση μιας `dict`.

4.10.1 Αντικείμενα όψης λεξικού

Τα αντικείμενα που επιστρέφονται από τις `dict.keys()`, `dict.values()` and `dict.items()` είναι *όψεις αντικειμένων* (*view objects*). Παρέχουν μια δυναμική όψη στις εγγραφές του λεξικού, που σημαίνει ότι όταν αλλάξει το λεξικό, η όψη αντικατοπτρίζει αυτές τις αλλαγές.

Οι όψεις λεξικού μπορούν να γίνουν `iterate` για την απόδοση των αντίστοιχων δεδομένων τους και την υποστήριξη ελέγχων για το αν είναι μέρος του:

`len(dictview)`

Επιστρέφει τον αριθμό των καταχωρήσεων στο λεξικό.

`iter(dictview)`

Επιστρέφει έναν `iterator` πάνω στα κλειδιά, τις τιμές ή τα στοιχεία (που αντιπροσωπεύονται ως πλειάδες (`tuples`) του (`key`, `value`) στο λεξικό.

Τα κλειδιά και οι τιμές επαναλαμβάνονται με την σειρά εισαγωγής. Αυτό επιτρέπει τη δημιουργία ζευγών (`value`, `key`) χρησιμοποιώντας τη `zip()`: `pairs = zip(d.values(), d.keys())`. Ένας άλλος τρόπος είναι να δημιουργήσετε την ίδια λίστα είναι `pairs = [(v, k) for (k, v) in d.items()]`.

Το `iterate` όψεων κατά την προσθήκη ή τη διαγραφή καταχωρήσεων στο λεξικό μπορεί να κάνει `raise` μια `RuntimeError` ή να αποτύχει το `iterate` σε όλες τις καταχωρήσεις.

Άλλαξε στην έκδοση 3.7: Η σειρά λεξικού είναι εγγυημένη σειρά εισαγωγής.

x in dictview

Επιστρέφει True εάν το *x* βρίσκεται στα κλειδιά του λεξικού, τις τιμές ή τα στοιχεία του υποκείμενου λεξικού (στην τελευταία περίπτωση, το *x* θα πρέπει να είναι μια (key, value) πλειάδα (tuple)).

reversed(dictview)

Επιστρέφει έναν αντίστροφο iterator πάνω στα κλειδιά, τις τιμές ή τα στοιχεία του λεξικού. Η όψη θα γίνει iterate με την αντίστροφη σειρά από την εισαγωγή.

Άλλαξε στην έκδοση 3.8: Οι όψεις λεξικού είναι πλέον αναστρέψιμες.

Keys views are set-like since their entries are unique and hashable. If all values are hashable, so that (key, value) pairs are unique and hashable, then the items view is also set-like. (Values views are not treated as set-like since the entries are generally not unique.) For set-like views, all of the operations defined for the abstract base class *collections.abc.Set* are available (for example, ==, <, or ^).

Ένα παράδειγμα χρήσης όψης λεξικού:

```
>>> dishes = {'eggs': 2, 'sausage': 1, 'bacon': 1, 'spam': 500}
>>> keys = dishes.keys()
>>> values = dishes.values()

>>> # iteration
>>> n = 0
>>> for val in values:
...     n += val
>>> print(n)
504

>>> # keys and values are iterated over in the same order (insertion order)
>>> list(keys)
['eggs', 'sausage', 'bacon', 'spam']
>>> list(values)
[2, 1, 1, 500]

>>> # view objects are dynamic and reflect dict changes
>>> del dishes['eggs']
>>> del dishes['sausage']
>>> list(keys)
['bacon', 'spam']

>>> # set operations
>>> keys & {'eggs', 'bacon', 'salad'}
{'bacon'}
>>> keys ^ {'sausage', 'juice'}
{'juice', 'sausage', 'bacon', 'spam'}
```

4.11 Τύποι Διαχείρισης Περιεχομένου

Η δήλωση with της Python υποστηρίζει την έννοια ενός περιεχομένου χρόνου εκτέλεσης που ορίζεται από έναν διαχειριστή περιεχομένου. Αυτό υλοποιείται χρησιμοποιώντας ένα ζεύγος μεθόδων που επιτρέπουν σε κλάσεις που ορίζονται από το χρήστη να ορίζουν περιεχόμενο χρόνου εκτέλεσης που εισάγεται πριν από την εκτέλεση του σώματος της δήλωσης και να κάνει έξοδο όταν τερματιστεί η δήλωση:

contextmanager.__enter__()

Εισάγει το περιεχόμενο εκτέλεσης και επιστρέφει είτε αυτό το αντικείμενο είτε ένα άλλο που σχετίζεται με το περιεχόμενο χρόνου εκτέλεσης. Η τιμή που επιστρέφεται από αυτήν την μέθοδο είναι δεσμευμένη στο αναγνωριστικό στην πρόταση as των δηλώσεων with διαχείρισης περιεχομένου.

Ένα παράδειγμα ενός διαχειριστή περιεχομένου που επιστρέφει ο ίδιος είναι ένα *file object*. Τα αντικείμενα αρχείου επιστρέφουν μόνα τους από `__enter__()` για να επιτρέψουν στο `open()` να χρησιμοποιηθεί ως έκφραση περιεχομένου σε μια δήλωση `with`.

Ένα παράδειγμα διαχείρισης περιεχομένου που επιστρέφει ένα σχετικό αντικείμενο είναι αυτό που επιστρέφεται από το `decimal.localcontext()`. Αυτοί οι διαχειριστές ορίζουν το ενεργό δεκαδικό περιεχόμενο σε ένα αντίγραφο του αρχικού δεκαδικού περιεχομένου και στη συνέχεια επιστρέφουν το αντίγραφο. Αυτό επιτρέπει την πραγματοποίηση αλλαγών στο τρέχον δεκαδικό πλαίσιο στο σώμα της δήλωσης `with`, χωρίς να επηρεάζεται ο κώδικας εκτός της δήλωσης `with`.

`contextmanager.__exit__(exc_type, exc_val, exc_tb)`

Τερματίζει από το περιεχόμενο χρόνου εκτέλεσης και επιστρέφει ένα Boolean δείκτη που υποδεικνύει εάν κάποια εξαίρεση που προέκυψε θα πρέπει να καταργηθεί. Εάν προκύψει μια εξαίρεση κατά την εκτέλεση του σώματος της δήλωσης `with`, τα ορίσματα περιέχουν τον τύπο εξαίρεσης, την τιμή και τις πληροφορίες ανίχνευσης. Διαφορετικά, και τα τρία ορίσματα είναι `None`.

Η επιστροφή μιας πραγματικής τιμής από αυτήν την μέθοδο θα έχει ως αποτέλεσμα η δήλωση `with` να καταργήσει την εξαίρεση και να συνεχίσει την εκτέλεση με τη δήλωση αμέσως μετά τη δήλωση `with`. Διαφορετικά, η εξαίρεση θα συνεχίσει να διαδίδεται μετά την ολοκλήρωση αυτής της μεθόδου. Οι εξαιρέσεις που προκύπτουν κατά την εκτέλεση αυτής της μεθόδου θα αντικαταστήσουν κάθε εξαίρεση που προέκυψε στο σώμα της δήλωσης `with`.

The exception passed in should never be reraised explicitly - instead, this method should return a false value to indicate that the method completed successfully and does not want to suppress the raised exception. This allows context management code to easily detect whether or not an `__exit__()` method has actually failed.

Η Python ορίζει αρκετούς διαχειριστές περιεχομένου για να υποστηρίξουν τον εύκολο συγχρονισμό νημάτων, το άμεσο κλείσιμο αρχείων ή άλλων αντικειμένων και τον απλούστερο χειρισμό του ενεργού δεκαδικού αριθμητικού περιεχομένου. Οι συγκεκριμένοι τύποι δεν αντιμετωπίζονται ειδικά πέρα από την εφαρμογή τους πρωτοκόλλου διαχείρισης περιεχομένου. Δείτε το module `contextlib` για μερικά παραδείγματα.

Οι decorators της Python *generators* και `contextlib.contextmanager` παρέχουν έναν βολικό τρόπο υλοποίησης αυτών των πρωτοκόλλων. Εάν μια συνάρτηση γεννήτριας είναι decorated με τον `contextlib.contextmanager` decorator, θα επιστρέψει έναν διαχειριστή περιεχομένου που εφαρμόζει τις απαραίτητες μεθόδους `__enter__()` και `__exit__()`, αντί του iterator που παράγεται από μια undecorated συνάρτηση γεννήτριας.

Λάβετε υπόψη ότι δεν υπάρχει συγκεκριμένη υποδοχή για καμία από αυτές τις μεθόδους στη δομή τύπου για αντικείμενα Python στο Python/C API. Οι τύποι επεκτάσεων που θέλουν να ορίσουν αυτές τις μεθόδους πρέπει να τις παρέχουν ως μια κανονική μέθοδο προσβάσιμη στην Python. Σε σύγκριση με την επιβάρυνση της ρύθμισης στο πλαίσιο του χρόνου εκτέλεσης, η επιβάρυνση μιας απλής αναζήτησης κλάσης λεξικού είναι αμελητέα.

4.12 Τύπος Generic Alias

Τα αντικείμενα `GenericAlias` δημιουργούνται γενικά με subscripting κλάση. Χρησιμοποιούνται πιο συχνά με container classes, όπως `list` ή `dict`. Για παράδειγμα, το `list[int]` είναι ένα αντικείμενο `GenericAlias` που δημιουργήθηκε με την εγγραφή της κλάσης `list` με το όρισμα `int`. Τα αντικείμενα `GenericAlias` προορίζονται κυρίως για χρήση με *type annotations*.

Σημείωση: Γενικά είναι δυνατή η εγγραφή μιας κλάσης μόνο εάν η κλάση εφαρμόζει την ειδική μέθοδο `__class_getitem__()`.

Ένα αντικείμενο `GenericAlias` λειτουργεί ως διακομιστής μεσολάβησης (proxy) για έναν *generic type*, υλοποιώντας *parameterized generics*.

Για μια κλάση `container`, το(α) όρισμα(τα) που παρέχει σε μια `subscription` της κλάσης μπορεί να υποδεικνύει τον(ους) τύπο(ους) των στοιχείων που περιέχει ένα αντικείμενο. Για παράδειγμα, το `set[bytes]` μπορεί να χρησιμοποιηθεί σε `annotations` τύπου για να υποδηλώσει ένα `set` στο οποίο όλα τα στοιχεία είναι τύπου `bytes`.

Για μια κλάση που ορίζει `__class_getitem__()` αλλά δεν είναι `container`, τα ορίσματα που παρέχονται σε μια συνδρομή της κλάσης θα υποδεικνύουν συχνά τον τύπο ή τους τύπους επιστροφής μιας ή περισσότερων μεθόδων που ορίζονται σε ένα αντικείμενο. Για παράδειγμα, το `regular expressions` μπορούν να χρησιμοποιηθούν τόσο στον τύπο δεδομένων `str` όσο και στον τύπο δεδομένων `bytes`:

- Εάν `x = re.search('foo', 'foo')`, το `x` θα είναι ένα αντικείμενο `re.Match` όπου επιστρέφονται οι τιμές του `x.group(0)` και το `x[0]` θα είναι και τα δύο τύπου `str`. Μπορούμε να αναπαραστήσουμε αυτό το είδος αντικειμένου σε σχολιασμούς τύπου με το `GenericAlias re.Match[str]`.
- Εάν `y = re.search(b'bar', b'bar')`, (σημειώστε το `b` για `bytes`), το `y` θα είναι επίσης μια παρουσία του `re.Match`, αλλά οι επιστρεφόμενες τιμές των `y.group(0)` και `y[0]` θα είναι και οι δύο τύπου `bytes`. Στους τύπους `annotations`, θα αντιπροσωπεύαμε αυτήν την ποικιλία αντικειμένων `re.Match` με το `re.Match[bytes]`.

Τα αντικείμενα `GenericAlias` είναι στιγμότυπα της κλάσης `types.GenericAlias`, τα οποία μπορούν επίσης να χρησιμοποιηθούν για την δημιουργία αντικειμένων `GenericAlias` απευθείας.

T[X, Y, ...]

Δημιουργεί ένα `GenericAlias` που αντιπροσωπεύει έναν τύπο `T` παραμετροποιημένο από τύπους `X`, `Y`, και άλλα ανάλογα με το `T` που χρησιμοποιείται. Για παράδειγμα, μια συνάρτηση που αναμένει μια `list` που περιέχει στοιχεία της `float`:

```
def average(values: list[float]) -> float:
    return sum(values) / len(values)
```

Ένα άλλο παράδειγμα για αντικείμενα `mapping`, χρησιμοποιώντας ένα `dict`, που είναι ένας generic τύπος που αναμένει δύο παραμέτρους τύπου που αντιπροσωπεύουν τον τύπο κλειδιού και τον τύπο τιμής. Σε αυτό το παράδειγμα, η συνάρτηση αναμένει ένα `dict` με κλειδιά τύπου `str` και τιμές τύπου `int`:

```
def send_post_request(url: str, body: dict[str, int]) -> None:
    ...
```

Οι ενσωματωμένες συναρτήσεις (built-in) `isinstance()` και `issubclass()` δεν δέχονται τους τύπους `GenericAlias` για το δεύτερο όρισμά τους:

```
>>> isinstance([1, 2], list[str])
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: isinstance() argument 2 cannot be a parameterized generic
```

Ο χρόνος εκτέλεσης Python δεν επιβάλλει `type annotations`. Αυτό επεκτείνεται σε generic τύπους και στις παραμέτρους τύπου τους. Κατά τη δημιουργία ενός αντικειμένου `container` από ένα `GenericAlias`, τα στοιχεία στο `container` δεν ελέγχονται ως προς τον τύπο τους. Για παράδειγμα, ο ακόλουθος κώδικας αποθαρρύνεται, αλλά θα εκτελεστεί χωρίς σφάλματα:

```
>>> t = list[str]
>>> t([1, 2, 3])
[1, 2, 3]
```

Επιπλέον, τα παραμετροποιημένα generics διαγράφουν τις παραμέτρους τύπου κατά τη δημιουργία αντικειμένου:

```
>>> t = list[str]
>>> type(t)
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
<class 'types.GenericAlias'>

>>> l = t()
>>> type(l)
<class 'list'>
```

Η κλήση `repr()` ή `str()` σε ένα generic δείχνει τον παραμετροποιημένο τύπο:

```
>>> repr(list[int])
'list[int]'

>>> str(list[int])
'list[int]'
```

Η μέθοδος `__getitem__()` των generic containers θα κάνει raise μια εξαίρεση για την απαγόρευση λαθών όπως `dict[str][str]`:

```
>>> dict[str][str]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: There are no type variables left in dict[str]
```

Ωστόσο, τέτοιες εκφράσεις είναι έγκυρες όταν χρησιμοποιούνται μεταβλητές τύπου *type variables*. Το ευρετήριο πρέπει να έχει τόσα στοιχεία όσα και τα στοιχεία μεταβλητής τύπου στο αντικείμενο `GenericAlias` `__args__`.

```
>>> from typing import TypeVar
>>> Y = TypeVar('Y')
>>> dict[str, Y][int]
dict[str, int]
```

4.12.1 Τυπικές Γενικές Κλάσεις

Οι ακόλουθες τυπικές κλάσεις βιβλιοθήκης υποστηρίζουν γενικά παραμετροποιημένα. Αυτή η λίστα δεν είναι εξαντλητική.

- `tuple`
- `list`
- `dict`
- `set`
- `frozenset`
- `type`
- `collections.deque`
- `collections.defaultdict`
- `collections.OrderedDict`
- `collections.Counter`
- `collections.ChainMap`
- `collections.abc.Awaitable`

- `collections.abc.Coroutine`
- `collections.abc.AsyncIterable`
- `collections.abc.AsyncIterator`
- `collections.abc.AsyncGenerator`
- `collections.abc.Iterable`
- `collections.abc.Iterator`
- `collections.abc.Generator`
- `collections.abc.Reversible`
- `collections.abc.Container`
- `collections.abc.Collection`
- `collections.abc.Callable`
- `collections.abc.Set`
- `collections.abc.MutableSet`
- `collections.abc.Mapping`
- `collections.abc.MutableMapping`
- `collections.abc.Sequence`
- `collections.abc.MutableSequence`
- `collections.abc.ByteString`
- `collections.abc.MappingView`
- `collections.abc.KeysView`
- `collections.abc.ItemsView`
- `collections.abc.ValuesView`
- `contextlib.AbstractContextManager`
- `contextlib.AbstractAsyncContextManager`
- `dataclasses.Field`
- `functools.cached_property`
- `functools.partialmethod`
- `os.PathLike`
- `queue.LifoQueue`
- `queue.Queue`
- `queue.PriorityQueue`
- `queue.SimpleQueue`
- `re.Pattern`
- `re.Match`
- `shelve.BsdDbShelf`
- `shelve.DbfilenameShelf`

- `shelve.Shelf`
- `types.MappingProxyType`
- `weakref.WeakKeyDictionary`
- `weakref.WeakMethod`
- `weakref.WeakSet`
- `weakref.WeakValueDictionary`

4.12.2 Ειδικά Χαρακτηριστικά αντικειμένων `GenericAlias`

Όλα τα παραμετροποιημένα generics εφαρμόζουν ειδικά χαρακτηριστικά μόνο για ανάγνωση.

`genericalias.__origin__`

Αυτό το χαρακτηριστικό δείχνει στη μη παραμετροποιημένη γενική κλάση:

```
>>> list[int].__origin__
<class 'list'>
```

`genericalias.__args__`

Αυτό το χαρακτηριστικό είναι μια *tuple* (πιθανώς μήκους 1) generic τύπων που μεταβιβάστηκαν στο αρχικό `__class_getitem__()` της generic κλάσης:

```
>>> dict[str, list[int]].__args__
(<class 'str'>, list[int])
```

`genericalias.__parameters__`

Αυτό το χαρακτηριστικό είναι μία νωχελικά υπολογισμένη πλειάδα (*tuple*) (πιθανώς κενή) μεταβλητών μοναδικού τύπου που βρίσκονται στο `__args__`:

```
>>> from typing import TypeVar

>>> T = TypeVar('T')
>>> list[T].__parameters__
(~T,)
```

PEP 484 - Type Hints Παρουσιάζοντας το framework της Python για τύπους annotations.

PEP 585 - Τύπος Generics Συμβουλών στις Τυπικές Συλλογές Εισαγωγή της δυνατότητας εγγενούς παραμετροποίησης κλάσεων τυπικής βιβλιοθήκης, υπό την προϋπόθεση ότι εφαρμόζουν τη μέθοδο ειδικής κλάσης `__class_getitem__()`.

Τα *Generics*, *user-defined generics* και *typing.Generic* Τεκμηρίωση για τον τρόπο υλοποίησης generic κλάσεων που μπορούν να παραμετροποιηθούν κατά το χρόνο εκτέλεσης και να κατανοηθούν από στατικούς ελεγκτές τύπων.

Νέο στην έκδοση 3.9.

4.13 Άλλοι Ενσωματωμένοι (built-in) Τύποι

Ο διερμηνέας υποστηρίζει πολλά άλλα είδη αντικειμένων. Τα περισσότερα από αυτά υποστηρίζουν μόνο μία ή δύο λειτουργίες.

4.13.1 Modules

Η μόνη ειδική λειτουργία σε ένα module είναι η πρόσβαση χαρακτηριστικών: `m.name`, όπου το *m* είναι ένα module και το *name* έχει πρόσβαση σε ένα όνομα που ορίζεται στον πίνακα συμβόλων του *m*. Τα χαρακτηριστικά του module μπορούν να εκχωρηθούν. (Σημειώστε ότι η δήλωση `import` δεν είναι, αυστηρά, μια λειτουργία σε ένα αντικείμενο module· το `import foo` δεν απαιτεί να υπάρχει ένα αντικείμενο module με το όνομα *foo* αλλά απαιτεί έναν (εξωτερικό) *definition* για ένα module που ονομάζεται *foo* κάπου.)

Ένα ειδικό χαρακτηριστικό κάθε module είναι `__dict__`. Αυτό είναι το λεξικό που περιέχει τον πίνακα συμβόλων της ενότητας. Η τροποποίηση αυτού του λεξικού θα αλλάξει στην πραγματικότητα τον πίνακα συμβόλων του module, αλλά η απευθείας εκχώρηση στο χαρακτηριστικό `__dict__` δεν είναι δυνατή (μπορείτε να γράψετε `m.__dict__['a'] = 1`, που ορίζει το `m.a` να είναι 1, αλλά δεν μπορείτε να γράψετε `m.__dict__ = {}`). Δεν συνίσταται η απευθείας τροποποίηση του `__dict__`.

Τα modules που είναι ενσωματωμένες στον διερμηνέα γράφονται ως εξής: `<module 'sys' (built-in)>`. Εάν φορτωθούν από ένα αρχείο, γράφονται ως `<module 'os' from '/usr/local/lib/pythonX.Y/os.pyc'>`.

4.13.2 Κλάσεις και Στιγμιότυπα Κλάσης

Δείτε objects και class για αυτά.

4.13.3 Συναρτήσεις

Τα αντικείμενα συναρτήσεων δημιουργούνται από ορισμούς συναρτήσεων. Η μόνη λειτουργία σε ένα αντικείμενο συνάρτησης είναι να το ονομάσουμε: `func(argument-list)`.

Υπάρχουν πραγματικά δύο είδη αντικειμένων συναρτήσεων: ενσωματωμένες συναρτήσεις και συναρτήσεις που καθορίζονται από τον χρήστη. Και οι δύο υποστηρίζουν την ίδια λειτουργία (για να καλέσετε τη συνάρτηση), αλλά η υλοποίηση είναι διαφορετική, εξ ου και οι διαφορετικοί τύποι αντικειμένων.

Δείτε το function για περισσότερες πληροφορίες.

4.13.4 Μέθοδοι

Methods are functions that are called using the attribute notation. There are two flavors: built-in methods (such as `append()` on lists) and class instance methods. Built-in methods are described with the types that support them.

If you access a method (a function defined in a class namespace) through an instance, you get a special object: a *bound method* (also called *instance method*) object. When called, it will add the `self` argument to the argument list. Bound methods have two special read-only attributes: `m.__self__` is the object on which the method operates, and `m.__func__` is the function implementing the method. Calling `m(arg-1, arg-2, ..., arg-n)` is completely equivalent to calling `m.__func__(m.__self__, arg-1, arg-2, ..., arg-n)`.

Like function objects, bound method objects support getting arbitrary attributes. However, since method attributes are actually stored on the underlying function object (`meth.__func__`), setting method attributes on bound methods is disallowed. Attempting to set an attribute on a method results in an `AttributeError` being raised. In order to set a method attribute, you need to explicitly set it on the underlying function object:

```
>>> class C:
...     def method(self):
...         pass
...
>>> c = C()
>>> c.method.whoami = 'my name is method' # can't set on the method
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
AttributeError: 'method' object has no attribute 'whoami'
>>> c.method.__func__.whoami = 'my name is method'
>>> c.method.whoami
'my name is method'
```

Δείτε `types` για περισσότερες πληροφορίες.

4.13.5 Αντικείμενα Κώδικα

Code objects are used by the implementation to represent «pseudo-compiled» executable Python code such as a function body. They differ from function objects because they don't contain a reference to their global execution environment. Code objects are returned by the built-in `compile()` function and can be extracted from function objects through their `__code__` attribute. See also the `code` module.

Accessing `__code__` raises an *auditing event* object `__getattr__` with arguments `obj` and `"__code__"`.

Ένα αντικείμενο κώδικα μπορεί να εκτελεστεί ή να αξιολογηθεί περνώντας το (αντί για πηγαία συμβολοσειρά) στις ενσωματωμένες συναρτήσεις `exec()` ή `eval()`.

Δείτε `types` για περισσότερες πληροφορίες.

4.13.6 Τύποι Αντικειμένων

Τα αντικείμενα τύπου αντιπροσωπεύουν τους διάφορους τύπους αντικειμένων. Ο τύπος ενός αντικειμένου προσεγγίζεται από την ενσωματωμένη συνάρτηση `type()`. Δεν υπάρχουν ειδικές λειτουργίες στους τύπους. Το τυπικό (standard) module `types` ορίζει ονόματα για όλους τους τυπικούς ενσωματωμένους τύπους.

Οι τύποι γράφονται ως εξής: `<class 'int'>`.

4.13.7 Το Αντικείμενο Null

Αυτό το αντικείμενο επιστρέφεται από συναρτήσεις που δεν επιστρέφουν ρητά μια τιμή. Δεν υποστηρίζει ειδικές λειτουργίες. Υπάρχει ακριβώς ένα μηδενικό αντικείμενο, που ονομάζεται `None` (ένα ενσωματωμένο όνομα). Το `type(None)()` παράγει το ίδιο singleton.

Γράφεται ως `None`.

4.13.8 Το αντικείμενο Ellipsis

Αυτό το αντικείμενο χρησιμοποιείται συνήθως με λειτουργία τμηματοποίησης (δείτε *slicings*). Δεν υποστηρίζει ειδικές λειτουργίες. Υπάρχει ακριβώς ένα αντικείμενο έλλειψης, που ονομάζεται *Ellipsis* (ένα ενσωματωμένο όνομα). Το `type(Ellipsis)()` παράγει το *Ellipsis* singleton.

Γράφεται ως `Ellipsis` ή `...`.

4.13.9 Το NotImplemented Αντικείμενο

This object is returned from comparisons and binary operations when they are asked to operate on types they don't support. See comparisons for more information. There is exactly one `NotImplemented` object. `type(NotImplemented)()` produces the singleton instance.

It is written as `NotImplemented`.

4.13.10 Boolean Values

Boolean values are the two constant objects `False` and `True`. They are used to represent truth values (although other values can also be considered false or true). In numeric contexts (for example when used as the argument to an arithmetic operator), they behave like the integers 0 and 1, respectively. The built-in function `bool()` can be used to convert any value to a Boolean, if the value can be interpreted as a truth value (see section *Έλεγχος Έγκυρης Τιμής* above).

They are written as `False` and `True`, respectively.

4.13.11 Εσωτερικά Αντικείμενα

See types for this information. It describes stack frame objects, traceback objects, and slice objects.

4.14 Ειδικά Χαρακτηριστικά

Η υλοποίηση προσθέτει μερικά ειδικά χαρακτηριστικά μόνο για ανάγνωση σε διάφορους τύπους αντικειμένων, όπου είναι σχετικά. Ορισμένα από αυτά δεν αναφέρονται από την ενσωματωμένη συνάρτηση `dir()`.

`object.__dict__`

A dictionary or other mapping object used to store an object's (writable) attributes.

`instance.__class__`

The class to which a class instance belongs.

`class.__bases__`

The tuple of base classes of a class object.

`definition.__name__`

Το όνομα της κλάσης, της συνάρτησης, της μεθόδου, του descriptor ή του στιγμοτύπου generator.

`definition.__qualname__`

Το *qualified name* της κλάσης, της συνάρτησης, της μεθόδου, του descriptor, ή του στιγμοτύπου generator.

Νέο στην έκδοση 3.3.

`class.__mro__`

This attribute is a tuple of classes that are considered when looking for base classes during method resolution.

```
class.mro()
```

This method can be overridden by a metaclass to customize the method resolution order for its instances. It is called at class instantiation, and its result is stored in `__mro__`.

```
class.__subclasses__()
```

Each class keeps a list of weak references to its immediate subclasses. This method returns a list of all those references still alive. The list is in definition order. Example:

```
>>> int.__subclasses__()
[<class 'bool'>]
```

4.15 Περιορισμός μήκους μετατροπής συμβολοσειράς ακέραιου αριθμού

Η CPython έχει ένα παγκόσμιο όριο για τη μετατροπή μεταξύ `int` and `str` για τον μετριάσμό των επιθέσεων άρνησης υπηρεσίας. Αυτό το όριο ισχύει μόνο για δεκαδικές ή άλλες βάσεις αριθμών που δεν έχουν την δύναμη του δύο. Οι δεξαεξαδικές, οκταδικές, και δυαδικές μετατροπές είναι απεριόριστες. Το όριο μπορεί να διαμορφωθεί.

Ο τύπος `int` στην CPython είναι ένας αυθαίρετος αριθμός μήκους που είναι αποθηκευμένος σε δυαδική μορφή (κοινώς γνωστός ως «bignum»). Δεν υπάρχει αλγόριθμος που να μπορεί να μετατρέψει μια συμβολοσειρά σε δυαδικό ακέραιο ή δυαδικό ακέραιο σε μια συμβολοσειρά σε γραμμικό χρόνο, εκτός εάν η βάση είναι δύναμη του 2. Ακόμη και οι πιο γνωστοί αλγόριθμοι για τη βάση 10 έχουν υποτετραγωνική πολυπλοκότητα. Η μετατροπή μιας μεγάλης τιμής όπως `int('1' * 500_000)` μπορεί να διαρκέσει περισσότερο από ένα δευτερόλεπτο σε μια γρήγορη CPU.

Limiting conversion size offers a practical way to avoid [CVE-2020-10735](#).

Το όριο εφαρμόζεται στον αριθμό των ψηφιακών χαρακτήρων στη συμβολοσειρά εισόδου ή εξόδου όταν εμπλέκεται ένας μη γραμμικός αλγόριθμος μετατροπής. Τα underscores και το πρόσημο δεν υπολογίζονται στο όριο.

Όταν μια λειτουργία υπερβαίνει το όριο, γίνεται `raise` μια `ValueError`:

```
>>> import sys
>>> sys.set_int_max_str_digits(4300) # Illustrative, this is the default.
>>> _ = int('2' * 5432)
Traceback (most recent call last):
...
ValueError: Exceeds the limit (4300) for integer string conversion: value has 5432_
↳digits; use sys.set_int_max_str_digits() to increase the limit.
>>> i = int('2' * 4300)
>>> len(str(i))
4300
>>> i_squared = i*i
>>> len(str(i_squared))
Traceback (most recent call last):
...
ValueError: Exceeds the limit (4300) for integer string conversion: value has 8599_
↳digits; use sys.set_int_max_str_digits() to increase the limit.
>>> len(hex(i_squared))
7144
>>> assert int(hex(i_squared), base=16) == i*i # Hexadecimal is unlimited.
```

Το προεπιλεγμένο όριο είναι 4300 ψηφία όπως προβλέπεται στο `sys.int_info.default_max_str_digits`. Το κατώτατο όριο που μπορεί να διαμορφωθεί είναι 640 ψηφία όπως προβλέπεται στο `sys.int_info.str_digits_check_threshold`.

Επαλήθευση:

```
>>> import sys
>>> assert sys.int_info.default_max_str_digits == 4300, sys.int_info
>>> assert sys.int_info.str_digits_check_threshold == 640, sys.int_info
>>> msg = int('578966293710682886880994035146873798396722250538762761564'
...          '9252925514383915483333812743580549779436104706260696366600'
...          '571186405732').to_bytes(53, 'big')
...
...
...

```

Νέο στην έκδοση 3.9.14.

4.15.1 Επηρεασμένα APIs

Ο περιορισμός ισχύει μόνο για δυνητικά αργές μετατροπές μεταξύ *int* και *str* ή *bytes*:

- `int(string)` με default βάση το 10.
- `int(string, base)` για όλες τις βάσεις που δεν είναι δύναμη του 2.
- `str(integer)`.
- `repr(integer)`.
- οποιαδήποτε άλλη μετατροπή συμβολοσειράς στη βάση 10, για παράδειγμα `f"{integer}", "{}".format(integer)`, ή `b"%d" % integer`.

Οι περιορισμοί δεν ισχύουν για συναρτήσεις με γραμμικό αλγόριθμο:

- `int(string, base)` με βάση 2, 4, 8, 16, ή 32.
- `int.from_bytes()` και `int.to_bytes()`.
- `hex()`, `oct()`, `bin()`.
- *Format Specification Mini-Language* για δεκαεξαδικούς, οκταδικούς και δυαδικούς αριθμούς.
- *str* σε *float*.
- *str* σε *decimal.Decimal*.

4.15.2 Διαμόρφωση ορίου

Πριν από την εκκίνηση της Python, μπορείτε να χρησιμοποιήσετε μια μεταβλητή περιβάλλοντος ή ένα δείκτη γραμμής εντολών διερμηνέα για να διαμορφώσετε το όριο:

- `PYTHONINTMAXSTRDIGITS`, π.χ. `PYTHONINTMAXSTRDIGITS=640 python3` για να ορίσετε το όριο σε 640 ή `PYTHONINTMAXSTRDIGITS=0 python3` για να απενεργοποιήσετε τον περιορισμό.
- `-X int_max_str_digits`, π.χ. `python3 -X int_max_str_digits=640`
- Το `sys.flags.int_max_str_digits` περιέχει την τιμή `PYTHONINTMAXSTRDIGITS` ή `-X int_max_str_digits`. Εάν και η επιλογή `env var` και η επιλογή `-X` είναι καθορισμένη, η επιλογή `-X` έχει προτεραιότητα. Μια τιμή `-1` υποδεικνύει ότι και τα δύο δεν ορίστηκαν, επομένως χρησιμοποιήθηκε μια τιμή `sys.int_info.default_max_str_digits` κατά την προετοιμασία.

Από τον κώδικα, μπορείτε να επιθεωρήσετε το τρέχον όριο και να ορίσετε ένα νέο χρησιμοποιώντας αυτά τα *sys* APIs:

- Οι `sys.get_int_max_str_digits()` και `sys.set_int_max_str_digits()` είναι ένας getter και setter για το όριο σε όλο τον διερμηνέα. Οι δευτερεύοντες διερμηνείς έχουν το δικό τους όριο.

Information about the default and minimum can be found in `sys.int_info`:

- Το `sys.int_info.default_max_str_digits` είναι το μεταγλωττισμένο προεπιλεγμένο όριο.
- Το `sys.int_info.str_digits_check_threshold` είναι η χαμηλότερη αποδεκτή τιμή για το όριο (εκτός από το 0 που το απενεργοποιεί).

Νέο στην έκδοση 3.9.14.

Προσοχή: Ο ορισμός ενός χαμηλού ορίου *μπορεί* να οδηγήσει σε προβλήματα. Αν και σπάνιος, υπάρχει κώδικας που περιέχει ακέραιες σταθερές σε δεκαδικό αριθμό στην πηγή τους που υπερβαίνουν το ελάχιστο όριο. Συνέπεια της ρύθμισης του ορίου είναι ότι ο πηγαίος κώδικας Python που περιέχει δεκαδικούς ακέραιους αριθμούς μεγαλύτερους από το όριο θα αντιμετωπίσει σφάλμα κατά την ανάλυση, συνήθως κατά την εκκίνηση ή την ώρα της εισαγωγής ή ακόμα και κατά την εγκατάσταση - ανά πάσα στιγμή είναι ενημερωμένο `.pyc` δεν υπάρχει ήδη για τον κώδικα. Μια λύση για τον πηγαίο που περιέχει τόσο μεγάλες σταθερές είναι να τις μετατρέψετε σε δεκαεξαδική μορφή `0x` καθώς δεν έχει όριο.

Δοκιμάστε σχολαστικά την εφαρμογή σας εάν χρησιμοποιείτε χαμηλό όριο. Βεβαιωθείτε ότι οι δοκιμές σας εκτελούνται με το όριο που έχει οριστεί νωρίς μέσω του περιβάλλοντος ή του δείκτη, ώστε να ισχύει κατά την εκκίνηση και ακόμη και κατά τη διάρκεια οποιουδήποτε βήματος εγκατάστασης που μπορεί να καλέσει την Python για να μεταγλωττίσει εκ των προτέρων το `.py` πηγαίο σε αρχεία `.pyc`.

4.15.3 Προτεινόμενη διαμόρφωση

The default `sys.int_info.default_max_str_digits` is expected to be reasonable for most applications. If your application requires a different limit, set it from your main entry point using Python version agnostic code as these APIs were added in security patch releases in versions before 3.11.

Παράδειγμα:

```
>>> import sys
>>> if hasattr(sys, "set_int_max_str_digits"):
...     upper_bound = 68000
...     lower_bound = 4004
...     current_limit = sys.get_int_max_str_digits()
...     if current_limit == 0 or current_limit > upper_bound:
...         sys.set_int_max_str_digits(upper_bound)
...     elif current_limit < lower_bound:
...         sys.set_int_max_str_digits(lower_bound)
```

Εάν πρέπει να το απενεργοποιήσετε εντελώς, ορίστε το σε 0.

Υποσημειώσεις

Built-in Exceptions

In Python, all exceptions must be instances of a class that derives from `BaseException`. In a `try` statement with an `except` clause that mentions a particular class, that clause also handles any exception classes derived from that class (but not exception classes from which *it* is derived). Two exception classes that are not related via subclassing are never equivalent, even if they have the same name.

The built-in exceptions listed below can be generated by the interpreter or built-in functions. Except where mentioned, they have an «associated value» indicating the detailed cause of the error. This may be a string or a tuple of several items of information (e.g., an error code and a string explaining the code). The associated value is usually passed as arguments to the exception class's constructor.

User code can raise built-in exceptions. This can be used to test an exception handler or to report an error condition «just like» the situation in which the interpreter raises the same exception; but beware that there is nothing to prevent user code from raising an inappropriate error.

The built-in exception classes can be subclassed to define new exceptions; programmers are encouraged to derive new exceptions from the `Exception` class or one of its subclasses, and not from `BaseException`. More information on defining exceptions is available in the Python Tutorial under `tut-userexceptions`.

5.1 Exception context

When raising a new exception while another exception is already being handled, the new exception's `__context__` attribute is automatically set to the handled exception. An exception may be handled when an `except` or `finally` clause, or a `with` statement, is used.

This implicit exception context can be supplemented with an explicit cause by using `from with raise`:

```
raise new_exc from original_exc
```

The expression following `from` must be an exception or `None`. It will be set as `__cause__` on the raised exception. Setting `__cause__` also implicitly sets the `__suppress_context__` attribute to `True`, so that using `raise new_exc from None` effectively replaces the old exception with the new one for display purposes (e.g. converting `KeyError` to `AttributeError`), while leaving the old exception available in `__context__` for introspection when debugging.

The default traceback display code shows these chained exceptions in addition to the traceback for the exception itself. An explicitly chained exception in `__cause__` is always shown when present. An implicitly chained exception in `__context__` is shown only if `__cause__` is *None* and `__suppress_context__` is false.

In either case, the exception itself is always shown after any chained exceptions so that the final line of the traceback always shows the last exception that was raised.

5.2 Inheriting from built-in exceptions

User code can create subclasses that inherit from an exception type. It's recommended to only subclass one exception type at a time to avoid any possible conflicts between how the bases handle the `args` attribute, as well as due to possible memory layout incompatibilities.

CPython implementation detail: Most built-in exceptions are implemented in C for efficiency, see: [Objects/exceptions.c](#). Some have custom memory layouts which makes it impossible to create a subclass that inherits from multiple exception types. The memory layout of a type is an implementation detail and might change between Python versions, leading to new conflicts in the future. Therefore, it's recommended to avoid subclassing multiple exception types altogether.

5.3 Base classes

The following exceptions are used mostly as base classes for other exceptions.

exception **BaseException**

The base class for all built-in exceptions. It is not meant to be directly inherited by user-defined classes (for that, use *Exception*). If `str()` is called on an instance of this class, the representation of the argument(s) to the instance are returned, or the empty string when there were no arguments.

args

The tuple of arguments given to the exception constructor. Some built-in exceptions (like *OSError*) expect a certain number of arguments and assign a special meaning to the elements of this tuple, while others are usually called only with a single string giving an error message.

with_traceback (*tb*)

This method sets *tb* as the new traceback for the exception and returns the exception object. It is usually used in exception handling code like this:

```
try:
    ...
except SomeException:
    tb = sys.exc_info()[2]
    raise OtherException(...).with_traceback(tb)
```

exception **Exception**

All built-in, non-system-exiting exceptions are derived from this class. All user-defined exceptions should also be derived from this class.

exception **ArithmeticError**

The base class for those built-in exceptions that are raised for various arithmetic errors: *OverflowError*, *ZeroDivisionError*, *FloatingPointError*.

exception **BufferError**

Raised when a buffer related operation cannot be performed.

exception LookupError

The base class for the exceptions that are raised when a key or index used on a mapping or sequence is invalid: *IndexError*, *KeyError*. This can be raised directly by *codecs.lookup()*.

5.4 Concrete exceptions

The following exceptions are the exceptions that are usually raised.

exception AssertionError

Raised when an assert statement fails.

exception AttributeError

Raised when an attribute reference (see attribute-references) or assignment fails. (When an object does not support attribute references or attribute assignments at all, *TypeError* is raised.)

exception EOFError

Raised when the *input()* function hits an end-of-file condition (EOF) without reading any data. (N.B.: the *io.IOBase.read()* and *io.IOBase.readline()* methods return an empty string when they hit EOF.)

exception FloatingPointError

Not currently used.

exception GeneratorExit

Raised when a *generator* or *coroutine* is closed; see *generator.close()* and *coroutine.close()*. It directly inherits from *BaseException* instead of *Exception* since it is technically not an error.

exception ImportError

Raised when the import statement has troubles trying to load a module. Also raised when the «from list» in *from ... import* has a name that cannot be found.

The name and path attributes can be set using keyword-only arguments to the constructor. When set they represent the name of the module that was attempted to be imported and the path to any file which triggered the exception, respectively.

Άλλαξε στην έκδοση 3.3: Added the name and path attributes.

exception ModuleNotFoundError

A subclass of *ImportError* which is raised by *import* when a module could not be located. It is also raised when None is found in *sys.modules*.

Νέο στην έκδοση 3.6.

exception IndexError

Raised when a sequence subscript is out of range. (Slice indices are silently truncated to fall in the allowed range; if an index is not an integer, *TypeError* is raised.)

exception KeyError

Raised when a mapping (dictionary) key is not found in the set of existing keys.

exception KeyboardInterrupt

Raised when the user hits the interrupt key (normally Control-C or Delete). During execution, a check for interrupts is made regularly. The exception inherits from *BaseException* so as to not be accidentally caught by code that catches *Exception* and thus prevent the interpreter from exiting.

Σημείωση: Catching a *KeyboardInterrupt* requires special consideration. Because it can be raised at unpredictable points, it may, in some circumstances, leave the running program in an inconsistent state. It is

generally best to allow *KeyboardInterrupt* to end the program as quickly as possible or avoid raising it entirely. (See *Note on Signal Handlers and Exceptions*.)

exception MemoryError

Raised when an operation runs out of memory but the situation may still be rescued (by deleting some objects). The associated value is a string indicating what kind of (internal) operation ran out of memory. Note that because of the underlying memory management architecture (C's `malloc()` function), the interpreter may not always be able to completely recover from this situation; it nevertheless raises an exception so that a stack traceback can be printed, in case a run-away program was the cause.

exception NameError

Raised when a local or global name is not found. This applies only to unqualified names. The associated value is an error message that includes the name that could not be found.

exception NotImplementedError

This exception is derived from *RuntimeError*. In user defined base classes, abstract methods should raise this exception when they require derived classes to override the method, or while the class is being developed to indicate that the real implementation still needs to be added.

Σημείωση: It should not be used to indicate that an operator or method is not meant to be supported at all – in that case either leave the operator / method undefined or, if a subclass, set it to *None*.

Σημείωση: *NotImplementedError* and *NotImplemented* are not interchangeable, even though they have similar names and purposes. See *NotImplemented* for details on when to use it.

exception OSError ([arg])**exception OSError (errno, strerror[, filename[, winerror[, filename2]]])**

This exception is raised when a system function returns a system-related error, including I/O failures such as «file not found» or «disk full» (not for illegal argument types or other incidental errors).

The second form of the constructor sets the corresponding attributes, described below. The attributes default to *None* if not specified. For backwards compatibility, if three arguments are passed, the *args* attribute contains only a 2-tuple of the first two constructor arguments.

The constructor often actually returns a subclass of *OSError*, as described in *OS exceptions* below. The particular subclass depends on the final *errno* value. This behaviour only occurs when constructing *OSError* directly or via an alias, and is not inherited when subclassing.

errno

A numeric error code from the C variable `errno`.

winerror

Under Windows, this gives you the native Windows error code. The *errno* attribute is then an approximate translation, in POSIX terms, of that native error code.

Under Windows, if the *winerror* constructor argument is an integer, the *errno* attribute is determined from the Windows error code, and the *errno* argument is ignored. On other platforms, the *winerror* argument is ignored, and the *winerror* attribute does not exist.

strerror

The corresponding error message, as provided by the operating system. It is formatted by the C functions `perror()` under POSIX, and `FormatMessage()` under Windows.

filename

filename2

For exceptions that involve a file system path (such as `open()` or `os.unlink()`), `filename` is the file name passed to the function. For functions that involve two file system paths (such as `os.rename()`), `filename2` corresponds to the second file name passed to the function.

Άλλαξε στην έκδοση 3.3: `EnvironmentError`, `IOError`, `WindowsError`, `socket.error`, `select.error` and `mmap.error` have been merged into `OSError`, and the constructor may return a subclass.

Άλλαξε στην έκδοση 3.4: The `filename` attribute is now the original file name passed to the function, instead of the name encoded to or decoded from the filesystem encoding. Also, the `filename2` constructor argument and attribute was added.

exception OverflowError

Raised when the result of an arithmetic operation is too large to be represented. This cannot occur for integers (which would rather raise `MemoryError` than give up). However, for historical reasons, `OverflowError` is sometimes raised for integers that are outside a required range. Because of the lack of standardization of floating point exception handling in C, most floating point operations are not checked.

exception RecursionError

This exception is derived from `RuntimeError`. It is raised when the interpreter detects that the maximum recursion depth (see `sys.getrecursionlimit()`) is exceeded.

Νέο στην έκδοση 3.5: Previously, a plain `RuntimeError` was raised.

exception ReferenceError

This exception is raised when a weak reference proxy, created by the `weakref.proxy()` function, is used to access an attribute of the referent after it has been garbage collected. For more information on weak references, see the `weakref` module.

exception RuntimeError

Raised when an error is detected that doesn't fall in any of the other categories. The associated value is a string indicating what precisely went wrong.

exception StopIteration

Raised by built-in function `next()` and an *iterator*'s `__next__()` method to signal that there are no further items produced by the iterator.

The exception object has a single attribute `value`, which is given as an argument when constructing the exception, and defaults to `None`.

When a *generator* or *coroutine* function returns, a new `StopIteration` instance is raised, and the value returned by the function is used as the `value` parameter to the constructor of the exception.

If a generator code directly or indirectly raises `StopIteration`, it is converted into a `RuntimeError` (retaining the `StopIteration` as the new exception's cause).

Άλλαξε στην έκδοση 3.3: Added `value` attribute and the ability for generator functions to use it to return a value.

Άλλαξε στην έκδοση 3.5: Introduced the `RuntimeError` transformation via `from __future__ import generator_stop`, see [PEP 479](#).

Άλλαξε στην έκδοση 3.7: Enable [PEP 479](#) for all code by default: a `StopIteration` error raised in a generator is transformed into a `RuntimeError`.

exception StopAsyncIteration

Must be raised by `__anext__()` method of an *asynchronous iterator* object to stop the iteration.

Νέο στην έκδοση 3.5.

exception SyntaxError (*message, details*)

Raised when the parser encounters a syntax error. This may occur in an `import` statement, in a call to the

built-in functions `compile()`, `exec()`, or `eval()`, or when reading the initial script or standard input (also interactively).

The `str()` of the exception instance returns only the error message. Details is a tuple whose members are also available as separate attributes.

filename

The name of the file the syntax error occurred in.

lineno

Which line number in the file the error occurred in. This is 1-indexed: the first line in the file has a `lineno` of 1.

offset

The column in the line where the error occurred. This is 1-indexed: the first character in the line has an `offset` of 1.

text

The source code text involved in the error.

For errors in f-string fields, the message is prefixed by «f-string: » and the offsets are offsets in a text constructed from the replacement expression. For example, compiling f“Bad {a b} field” results in this `args` attribute: (“f-string: ...”, (“”, 1, 4, “(a b)n”)).

exception IndentationError

Base class for syntax errors related to incorrect indentation. This is a subclass of `SyntaxError`.

exception TabError

Raised when indentation contains an inconsistent use of tabs and spaces. This is a subclass of `IndentationError`.

exception SystemError

Raised when the interpreter finds an internal error, but the situation does not look so serious to cause it to abandon all hope. The associated value is a string indicating what went wrong (in low-level terms).

You should report this to the author or maintainer of your Python interpreter. Be sure to report the version of the Python interpreter (`sys.version`; it is also printed at the start of an interactive Python session), the exact error message (the exception’s associated value) and if possible the source of the program that triggered the error.

exception SystemExit

This exception is raised by the `sys.exit()` function. It inherits from `BaseException` instead of `Exception` so that it is not accidentally caught by code that catches `Exception`. This allows the exception to properly propagate up and cause the interpreter to exit. When it is not handled, the Python interpreter exits; no stack traceback is printed. The constructor accepts the same optional argument passed to `sys.exit()`. If the value is an integer, it specifies the system exit status (passed to C’s `exit()` function); if it is `None`, the exit status is zero; if it has another type (such as a string), the object’s value is printed and the exit status is one.

A call to `sys.exit()` is translated into an exception so that clean-up handlers (`finally` clauses of `try` statements) can be executed, and so that a debugger can execute a script without running the risk of losing control. The `os._exit()` function can be used if it is absolutely positively necessary to exit immediately (for example, in the child process after a call to `os.fork()`).

code

The exit status or error message that is passed to the constructor. (Defaults to `None`.)

exception TypeError

Raised when an operation or function is applied to an object of inappropriate type. The associated value is a string giving details about the type mismatch.

This exception may be raised by user code to indicate that an attempted operation on an object is not supported, and is not meant to be. If an object is meant to support a given operation but has not yet provided an implementation,

NotImplementedError is the proper exception to raise.

Passing arguments of the wrong type (e.g. passing a *list* when an *int* is expected) should result in a *TypeError*, but passing arguments with the wrong value (e.g. a number outside expected boundaries) should result in a *ValueError*.

exception UnboundLocalError

Raised when a reference is made to a local variable in a function or method, but no value has been bound to that variable. This is a subclass of *NameError*.

exception UnicodeError

Raised when a Unicode-related encoding or decoding error occurs. It is a subclass of *ValueError*.

UnicodeError has attributes that describe the encoding or decoding error. For example, `err.object[err.start:err.end]` gives the particular invalid input that the codec failed on.

encoding

The name of the encoding that raised the error.

reason

A string describing the specific codec error.

object

The object the codec was attempting to encode or decode.

start

The first index of invalid data in *object*.

end

The index after the last invalid data in *object*.

exception UnicodeEncodeError

Raised when a Unicode-related error occurs during encoding. It is a subclass of *UnicodeError*.

exception UnicodeDecodeError

Raised when a Unicode-related error occurs during decoding. It is a subclass of *UnicodeError*.

exception UnicodeTranslateError

Raised when a Unicode-related error occurs during translating. It is a subclass of *UnicodeError*.

exception ValueError

Raised when an operation or function receives an argument that has the right type but an inappropriate value, and the situation is not described by a more precise exception such as *IndexError*.

exception ZeroDivisionError

Raised when the second argument of a division or modulo operation is zero. The associated value is a string indicating the type of the operands and the operation.

The following exceptions are kept for compatibility with previous versions; starting from Python 3.3, they are aliases of *OSError*.

exception EnvironmentError

exception IOError

exception WindowsError

Only available on Windows.

5.4.1 OS exceptions

The following exceptions are subclasses of *OSError*, they get raised depending on the system error code.

exception BlockingIOError

Raised when an operation would block on an object (e.g. socket) set for non-blocking operation. Corresponds to errno *EAGAIN*, *EALREADY*, *EWOULDBLOCK* and *EINPROGRESS*.

In addition to those of *OSError*, *BlockingIOError* can have one more attribute:

characters_written

An integer containing the number of characters written to the stream before it blocked. This attribute is available when using the buffered I/O classes from the *io* module.

exception ChildProcessError

Raised when an operation on a child process failed. Corresponds to errno *ECHILD*.

exception ConnectionError

A base class for connection-related issues.

Subclasses are *BrokenPipeError*, *ConnectionAbortedError*, *ConnectionRefusedError* and *ConnectionResetError*.

exception BrokenPipeError

A subclass of *ConnectionError*, raised when trying to write on a pipe while the other end has been closed, or trying to write on a socket which has been shutdown for writing. Corresponds to errno *EPIPE* and *ESHUTDOWN*.

exception ConnectionAbortedError

A subclass of *ConnectionError*, raised when a connection attempt is aborted by the peer. Corresponds to errno *ECONNABORTED*.

exception ConnectionRefusedError

A subclass of *ConnectionError*, raised when a connection attempt is refused by the peer. Corresponds to errno *ECONNREFUSED*.

exception ConnectionResetError

A subclass of *ConnectionError*, raised when a connection is reset by the peer. Corresponds to errno *ECONNRESET*.

exception FileExistsError

Raised when trying to create a file or directory which already exists. Corresponds to errno *EEXIST*.

exception FileNotFoundError

Raised when a file or directory is requested but doesn't exist. Corresponds to errno *ENOENT*.

exception InterruptedError

Raised when a system call is interrupted by an incoming signal. Corresponds to errno *EINTR*.

Άλλαξε στην έκδοση 3.5: Python now retries system calls when a syscall is interrupted by a signal, except if the signal handler raises an exception (see [PEP 475](#) for the rationale), instead of raising *InterruptedError*.

exception IsADirectoryError

Raised when a file operation (such as *os.remove()*) is requested on a directory. Corresponds to errno *EISDIR*.

exception NotADirectoryError

Raised when a directory operation (such as *os.listdir()*) is requested on something which is not a directory. On most POSIX platforms, it may also be raised if an operation attempts to open or traverse a non-directory file as if it were a directory. Corresponds to errno *ENOTDIR*.

exception `PermissionError`

Raised when trying to run an operation without the adequate access rights - for example filesystem permissions. Corresponds to `errno` [EACCES](#) and [EPERM](#).

exception `ProcessLookupError`

Raised when a given process doesn't exist. Corresponds to `errno` [ESRCH](#).

exception `TimeoutError`

Raised when a system function timed out at the system level. Corresponds to `errno` [ETIMEDOUT](#).

Νέο στην έκδοση 3.3: All the above [OSError](#) subclasses were added.

PEP 3151 - Reworking the OS and IO exception hierarchy

5.5 Warnings

The following exceptions are used as warning categories; see the [Warning Categories](#) documentation for more details.

exception `Warning`

Base class for warning categories.

exception `UserWarning`

Base class for warnings generated by user code.

exception `DeprecationWarning`

Base class for warnings about deprecated features when those warnings are intended for other Python developers.

Ignored by the default warning filters, except in the `__main__` module (**PEP 565**). Enabling the [Python Development Mode](#) shows this warning.

The deprecation policy is described in **PEP 387**.

exception `PendingDeprecationWarning`

Base class for warnings about features which are obsolete and expected to be deprecated in the future, but are not deprecated at the moment.

This class is rarely used as emitting a warning about a possible upcoming deprecation is unusual, and [DeprecationWarning](#) is preferred for already active deprecations.

Ignored by the default warning filters. Enabling the [Python Development Mode](#) shows this warning.

The deprecation policy is described in **PEP 387**.

exception `SyntaxWarning`

Base class for warnings about dubious syntax.

exception `RuntimeWarning`

Base class for warnings about dubious runtime behavior.

exception `FutureWarning`

Base class for warnings about deprecated features when those warnings are intended for end users of applications that are written in Python.

exception `ImportWarning`

Base class for warnings about probable mistakes in module imports.

Ignored by the default warning filters. Enabling the [Python Development Mode](#) shows this warning.

exception `UnicodeWarning`

Base class for warnings related to Unicode.

exception BytesWarning

Base class for warnings related to *bytes* and *bytearray*.

exception ResourceWarning

Base class for warnings related to resource usage.

Ignored by the default warning filters. Enabling the *Python Development Mode* shows this warning.

Νέο στην έκδοση 3.2.

5.6 Exception hierarchy

The class hierarchy for built-in exceptions is:

```
BaseException
+-- SystemExit
+-- KeyboardInterrupt
+-- GeneratorExit
+-- Exception
    +-- StopIteration
    +-- StopAsyncIteration
    +-- ArithmeticError
        |   +-- FloatingPointError
        |   +-- OverflowError

Text Processing Services

The modules described in this chapter provide a wide range of string manipulation operations and other text processing services.

The *codecs* module described under *Binary Data Services* is also highly relevant to text processing. In addition, see the documentation for Python's built-in string type in *Τύπος Ακολουθίας (Sequence) Κειμένου — str*.

6.1 string — Common string operations

Source code: [Lib/string.py](#)

Δείτε επίσης:

Τύπος Ακολουθίας (Sequence) Κειμένου — str

Μέθοδοι Συμβολοσειράς (String)

6.1.1 String constants

The constants defined in this module are:

`string.ascii_letters`

The concatenation of the *ascii_lowercase* and *ascii_uppercase* constants described below. This value is not locale-dependent.

`string.ascii_lowercase`

The lowercase letters 'abcdefghijklmnopqrstuvwxyz'. This value is not locale-dependent and will not change.

`string.ascii_uppercase`

The uppercase letters 'ABCDEFGHIJKLMNOPQRSTUVWXYZ'. This value is not locale-dependent and will not change.

`string.digits`

The string `'0123456789'`.

`string.hexdigits`

The string `'0123456789abcdefABCDEF'`.

`string.octdigits`

The string `'01234567'`.

`string.punctuation`

String of ASCII characters which are considered punctuation characters in the C locale: `!"#$%&'()*+,-./:;<=>?@[\\]^_`{|}~.`

`string.printable`

String of ASCII characters which are considered printable. This is a combination of *digits*, *ascii_letters*, *punctuation*, and *whitespace*.

`string.whitespace`

A string containing all ASCII characters that are considered whitespace. This includes the characters space, tab, linefeed, return, formfeed, and vertical tab.

6.1.2 Custom String Formatting

The built-in string class provides the ability to do complex variable substitutions and value formatting via the `format()` method described in [PEP 3101](#). The `Formatter` class in the `string` module allows you to create and customize your own string formatting behaviors using the same implementation as the built-in `format()` method.

class `string.Formatter`

The `Formatter` class has the following public methods:

format (*format_string*, *l*, **args*, ***kwargs*)

The primary API method. It takes a format string and an arbitrary set of positional and keyword arguments. It is just a wrapper that calls `vformat()`.

Αλλάξε στην έκδοση 3.7: A format string argument is now *positional-only*.

vformat (*format_string*, *args*, *kwargs*)

This function does the actual work of formatting. It is exposed as a separate function for cases where you want to pass in a predefined dictionary of arguments, rather than unpacking and repacking the dictionary as individual arguments using the **args* and ***kwargs* syntax. `vformat()` does the work of breaking up the format string into character data and replacement fields. It calls the various methods described below.

In addition, the `Formatter` defines a number of methods that are intended to be replaced by subclasses:

parse (*format_string*)

Loop over the *format_string* and return an iterable of tuples (*literal_text*, *field_name*, *format_spec*, *conversion*). This is used by `vformat()` to break the string into either literal text, or replacement fields.

The values in the tuple conceptually represent a span of literal text followed by a single replacement field. If there is no literal text (which can happen if two replacement fields occur consecutively), then *literal_text* will be a zero-length string. If there is no replacement field, then the values of *field_name*, *format_spec* and *conversion* will be `None`.

get_field (*field_name*, *args*, *kwargs*)

Given *field_name* as returned by `parse()` (see above), convert it to an object to be formatted. Returns a tuple (*obj*, *used_key*). The default version takes strings of the form defined in [PEP 3101](#), such as `«0[name]»` or `«label.title»`. *args* and *kwargs* are as passed in to `vformat()`. The return value *used_key* has the same meaning as the *key* parameter to `get_value()`.

get_value (*key*, *args*, *kwargs*)

Retrieve a given field value. The *key* argument will be either an integer or a string. If it is an integer, it represents the index of the positional argument in *args*; if it is a string, then it represents a named argument in *kwargs*.

The *args* parameter is set to the list of positional arguments to `vformat()`, and the *kwargs* parameter is set to the dictionary of keyword arguments.

For compound field names, these functions are only called for the first component of the field name; subsequent components are handled through normal attribute and indexing operations.

So for example, the field expression “0.name” would cause `get_value()` to be called with a *key* argument of 0. The `name` attribute will be looked up after `get_value()` returns by calling the built-in `getattr()` function.

If the index or keyword refers to an item that does not exist, then an `IndexError` or `KeyError` should be raised.

check_unused_args (*used_args*, *args*, *kwargs*)

Implement checking for unused arguments if desired. The arguments to this function is the set of all argument keys that were actually referred to in the format string (integers for positional arguments, and strings for named arguments), and a reference to the *args* and *kwargs* that was passed to `vformat`. The set of unused args can be calculated from these parameters. `check_unused_args()` is assumed to raise an exception if the check fails.

format_field (*value*, *format_spec*)

`format_field()` simply calls the global `format()` built-in. The method is provided so that subclasses can override it.

convert_field (*value*, *conversion*)

Converts the value (returned by `get_field()`) given a conversion type (as in the tuple returned by the `parse()` method). The default version understands “s” (str), “r” (repr) and “a” (ascii) conversion types.

6.1.3 Format String Syntax

The `str.format()` method and the `Formatter` class share the same syntax for format strings (although in the case of `Formatter`, subclasses can define their own format string syntax). The syntax is related to that of formatted string literals, but it is less sophisticated and, in particular, does not support arbitrary expressions.

Format strings contain «replacement fields» surrounded by curly braces `{}`. Anything that is not contained in braces is considered literal text, which is copied unchanged to the output. If you need to include a brace character in the literal text, it can be escaped by doubling: `{{` and `}}`.

The grammar for a replacement field is as follows:

```
replacement_field ::= "{" [field_name] ["!" conversion] [":" format_spec] "}"
field_name        ::= arg_name ("." attribute_name | "[" element_index "]") *
arg_name          ::= [identifier | digit+]
attribute_name    ::= identifier
element_index     ::= digit+ | index_string
index_string      ::= <any source character except "]"> +
conversion        ::= "r" | "s" | "a"
format_spec       ::= <described in the next section>
```

In less formal terms, the replacement field can start with a *field_name* that specifies the object whose value is to be formatted and inserted into the output instead of the replacement field. The *field_name* is optionally followed by a

conversion field, which is preceded by an exclamation point '!', and a *format_spec*, which is preceded by a colon ':'. These specify a non-default format for the replacement value.

See also the *Format Specification Mini-Language* section.

The *field_name* itself begins with an *arg_name* that is either a number or a keyword. If it's a number, it refers to a positional argument, and if it's a keyword, it refers to a named keyword argument. If the numerical *arg_names* in a format string are 0, 1, 2, ... in sequence, they can all be omitted (not just some) and the numbers 0, 1, 2, ... will be automatically inserted in that order. Because *arg_name* is not quote-delimited, it is not possible to specify arbitrary dictionary keys (e.g., the strings '10' or ':-]') within a format string. The *arg_name* can be followed by any number of index or attribute expressions. An expression of the form '.name' selects the named attribute using *getattr()*, while an expression of the form '[index]' does an index lookup using *__getitem__()*.

Αλλάξε στην έκδοση 3.1: The positional argument specifiers can be omitted for *str.format()*, so '{ } { }'.format(a, b) is equivalent to '{0} {1}'.format(a, b).

Αλλάξε στην έκδοση 3.4: The positional argument specifiers can be omitted for *Formatter*.

Some simple format string examples:

```
"First, thou shalt count to {0}" # References first positional argument
"Bring me a {}"                 # Implicitly references the first positional_
↪argument
"From {} to {}"                 # Same as "From {0} to {1}"
"My quest is {name}"            # References keyword argument 'name'
"Weight in tons {0.weight}"     # 'weight' attribute of first positional arg
"Units destroyed: {players[0]}" # First element of keyword argument 'players'.
```

The *conversion* field causes a type coercion before formatting. Normally, the job of formatting a value is done by the *__format__()* method of the value itself. However, in some cases it is desirable to force a type to be formatted as a string, overriding its own definition of formatting. By converting the value to a string before calling *__format__()*, the normal formatting logic is bypassed.

Three conversion flags are currently supported: '!'s' which calls *str()* on the value, '!r' which calls *repr()* and '!a' which calls *ascii()*.

Some examples:

```
"Harold's a clever {0!s}"        # Calls str() on the argument first
"Bring out the holy {name!r}"    # Calls repr() on the argument first
"More {!a}"                     # Calls ascii() on the argument first
```

The *format_spec* field contains a specification of how the value should be presented, including such details as field width, alignment, padding, decimal precision and so on. Each value type can define its own «formatting mini-language» or interpretation of the *format_spec*.

Most built-in types support a common formatting mini-language, which is described in the next section.

A *format_spec* field can also include nested replacement fields within it. These nested replacement fields may contain a field name, conversion flag and format specification, but deeper nesting is not allowed. The replacement fields within the *format_spec* are substituted before the *format_spec* string is interpreted. This allows the formatting of a value to be dynamically specified.

See the *Format examples* section for some examples.

Format Specification Mini-Language

«Format specifications» are used within replacement fields contained within a format string to define how individual values are presented (see *Format String Syntax* and f-strings). They can also be passed directly to the built-in `format()` function. Each formattable type may define how the format specification is to be interpreted.

Most built-in types implement the following options for format specifications, although some of the formatting options are only supported by the numeric types.

A general convention is that an empty format specification produces the same result as if you had called `str()` on the value. A non-empty format specification typically modifies the result.

The general form of a *standard format specifier* is:

```
format_spec      ::=  [[fill]align] [sign] [#] [0] [width] [grouping_option] [.precision] [type]
```

```
fill             ::=  <any character>
```

```
align            ::=  "<" | ">" | "=" | "^"
```

```
sign            ::=  "+" | "-" | " "
```

```
width           ::=  digit+
```

```
grouping_option ::=  "_" | ","
```

```
precision       ::=  digit+
```

```
type            ::=  "b" | "c" | "d" | "e" | "E" | "f" | "F" | "g" | "G" | "n" | "o" | "s"
```

If a valid *align* value is specified, it can be preceded by a *fill* character that can be any character and defaults to a space if omitted. It is not possible to use a literal curly brace (`>{>` or `<{<`) as the *fill* character in a formatted string literal or when using the `str.format()` method. However, it is possible to insert a curly brace with a nested replacement field. This limitation doesn't affect the `format()` function.

The meaning of the various alignment options is as follows:

| Option | Meaning |
|--------|--|
| '<' | Forces the field to be left-aligned within the available space (this is the default for most objects). |
| '>' | Forces the field to be right-aligned within the available space (this is the default for numbers). |
| '= ' | Forces the padding to be placed after the sign (if any) but before the digits. This is used for printing fields in the form <code>" +000000120"</code> . This alignment option is only valid for numeric types. It becomes the default when <code>"0"</code> immediately precedes the field width. |
| '^' | Forces the field to be centered within the available space. |

Note that unless a minimum field width is defined, the field width will always be the same size as the data to fill it, so that the alignment option has no meaning in this case.

The *sign* option is only valid for number types, and can be one of the following:

| Option | Meaning |
|--------|--|
| '+' | indicates that a sign should be used for both positive as well as negative numbers. |
| '- ' | indicates that a sign should be used only for negative numbers (this is the default behavior). |
| space | indicates that a leading space should be used on positive numbers, and a minus sign on negative numbers. |

The `'#'` option causes the «alternate form» to be used for the conversion. The alternate form is defined differently for different types. This option is only valid for integer, float and complex types. For integers, when binary, octal, or hexadecimal output is used, this option adds the respective prefix `'0b'`, `'0o'`, `'0x'`, or `'0X'` to the output value. For float and complex the alternate form causes the result of the conversion to always contain a decimal-point character, even

if no digits follow it. Normally, a decimal-point character appears in the result of these conversions only if a digit follows it. In addition, for 'g' and 'G' conversions, trailing zeros are not removed from the result.

The ',' option signals the use of a comma for a thousands separator. For a locale aware separator, use the 'n' integer presentation type instead.

Άλλαξε στην έκδοση 3.1: Added the ',' option (see also [PEP 378](#)).

The '_' option signals the use of an underscore for a thousands separator for floating point presentation types and for integer presentation type 'd'. For integer presentation types 'b', 'o', 'x', and 'X', underscores will be inserted every 4 digits. For other presentation types, specifying this option is an error.

Άλλαξε στην έκδοση 3.6: Added the '_' option (see also [PEP 515](#)).

width is a decimal integer defining the minimum total field width, including any prefixes, separators, and other formatting characters. If not specified, then the field width will be determined by the content.

When no explicit alignment is given, preceding the *width* field by a zero ('0') character enables sign-aware zero-padding for numeric types. This is equivalent to a *fill* character of '0' with an *alignment* type of '='.

The *precision* is a decimal integer indicating how many digits should be displayed after the decimal point for presentation types 'f' and 'F', or before and after the decimal point for presentation types 'g' or 'G'. For string presentation types the field indicates the maximum field size - in other words, how many characters will be used from the field content. The *precision* is not allowed for integer presentation types.

Finally, the *type* determines how the data should be presented.

The available string presentation types are:

| Type | Meaning |
|------|---|
| 's' | String format. This is the default type for strings and may be omitted. |
| None | The same as 's'. |

The available integer presentation types are:

| Type | Meaning |
|------|--|
| 'b' | Binary format. Outputs the number in base 2. |
| 'c' | Character. Converts the integer to the corresponding unicode character before printing. |
| 'd' | Decimal Integer. Outputs the number in base 10. |
| 'o' | Octal format. Outputs the number in base 8. |
| 'x' | Hex format. Outputs the number in base 16, using lower-case letters for the digits above 9. |
| 'X' | Hex format. Outputs the number in base 16, using upper-case letters for the digits above 9. In case '#' is specified, the prefix '0x' will be upper-cased to '0X' as well. |
| 'n' | Number. This is the same as 'd', except that it uses the current locale setting to insert the appropriate number separator characters. |
| None | The same as 'd'. |

In addition to the above presentation types, integers can be formatted with the floating point presentation types listed below (except 'n' and None). When doing so, `float()` is used to convert the integer to a floating point number before formatting.

The available presentation types for *float* and *Decimal* values are:

| Type | Meaning |
|------|---|
| 'e' | Scientific notation. For a given precision <i>p</i> , formats the number in scientific notation with the letter “e” separating the coefficient from the exponent. The coefficient has one digit before and <i>p</i> digits after the decimal point, for a total of <i>p</i> + 1 significant digits. With no precision given, uses a precision of 6 digits after the decimal point for <i>float</i> , and shows all coefficient digits for <i>Decimal</i> . If no digits follow the decimal point, the decimal point is also removed unless the # option is used. |
| 'E' | Scientific notation. Same as 'e' except it uses an upper case “E” as the separator character. |
| 'f' | Fixed-point notation. For a given precision <i>p</i> , formats the number as a decimal number with exactly <i>p</i> digits following the decimal point. With no precision given, uses a precision of 6 digits after the decimal point for <i>float</i> , and uses a precision large enough to show all coefficient digits for <i>Decimal</i> . If no digits follow the decimal point, the decimal point is also removed unless the # option is used. |
| 'F' | Fixed-point notation. Same as 'f', but converts <i>nan</i> to <i>NAN</i> and <i>inf</i> to <i>INF</i> . |
| 'g' | General format. For a given precision <i>p</i> >= 1, this rounds the number to <i>p</i> significant digits and then formats the result in either fixed-point format or in scientific notation, depending on its magnitude. A precision of 0 is treated as equivalent to a precision of 1. The precise rules are as follows: suppose that the result formatted with presentation type 'e' and precision <i>p</i> -1 would have exponent <i>exp</i> . Then, if <i>m</i> <= <i>exp</i> < <i>p</i> , where <i>m</i> is -4 for floats and -6 for <i>Decimals</i> , the number is formatted with presentation type 'f' and precision <i>p</i> -1- <i>exp</i> . Otherwise, the number is formatted with presentation type 'e' and precision <i>p</i> -1. In both cases insignificant trailing zeros are removed from the significand, and the decimal point is also removed if there are no remaining digits following it, unless the '#' option is used. With no precision given, uses a precision of 6 significant digits for <i>float</i> . For <i>Decimal</i> , the coefficient of the result is formed from the coefficient digits of the value; scientific notation is used for values smaller than 1e-6 in absolute value and values where the place value of the least significant digit is larger than 1, and fixed-point notation is used otherwise. Positive and negative infinity, positive and negative zero, and nans, are formatted as <i>inf</i> , <i>-inf</i> , 0, <i>-0</i> and <i>nan</i> respectively, regardless of the precision. |
| 'G' | General format. Same as 'g' except switches to 'E' if the number gets too large. The representations of infinity and NaN are uppercased, too. |
| 'n' | Number. This is the same as 'g', except that it uses the current locale setting to insert the appropriate number separator characters. |
| '%' | Percentage. Multiplies the number by 100 and displays in fixed ('f') format, followed by a percent sign. |
| None | For <i>float</i> this is the same as 'g', except that when fixed-point notation is used to format the result, it always includes at least one digit past the decimal point. The precision used is as large as needed to represent the given value faithfully. For <i>Decimal</i> , this is the same as either 'g' or 'G' depending on the value of <i>context.capitals</i> for the current decimal context. The overall effect is to match the output of <i>str()</i> as altered by the other format modifiers. |

Format examples

This section contains examples of the *str.format()* syntax and comparison with the old %-formatting.

In most of the cases the syntax is similar to the old %-formatting, with the addition of the {} and with : used instead of %. For example, '%03.2f' can be translated to '{:03.2f}'.

The new format syntax also supports new and different options, shown in the following examples.

Accessing arguments by position:

```
>>> '{0}, {1}, {2}'.format('a', 'b', 'c')
'a, b, c'
>>> '{}, {}, {}'.format('a', 'b', 'c')  # 3.1+ only
'a, b, c'
>>> '{2}, {1}, {0}'.format('a', 'b', 'c')
'c, b, a'
>>> '{2}, {1}, {0}'.format(*'abc')      # unpacking argument sequence
'c, b, a'
>>> '{0}{1}{0}'.format('abra', 'cad')  # arguments' indices can be repeated
'abracadabra'
```

Accessing arguments by name:

```
>>> 'Coordinates: {latitude}, {longitude}'.format(latitude='37.24N', longitude='-115.
↳ 81W')
'Coordinates: 37.24N, -115.81W'
>>> coord = {'latitude': '37.24N', 'longitude': '-115.81W'}
>>> 'Coordinates: {latitude}, {longitude}'.format(**coord)
'Coordinates: 37.24N, -115.81W'
```

Accessing arguments' attributes:

```
>>> c = 3-5j
>>> ('The complex number {0} is formed from the real part {0.real} '
... 'and the imaginary part {0.imag}.').format(c)
'The complex number (3-5j) is formed from the real part 3.0 and the imaginary part -5.
↳ 0.'
>>> class Point:
...     def __init__(self, x, y):
...         self.x, self.y = x, y
...     def __str__(self):
...         return 'Point({self.x}, {self.y})'.format(self=self)
...
>>> str(Point(4, 2))
'Point(4, 2)'
```

Accessing arguments' items:

```
>>> coord = (3, 5)
>>> 'X: {0[0]}; Y: {0[1]}'.format(coord)
'X: 3; Y: 5'
```

Replacing %s and %r:

```
>>> "repr() shows quotes: {!r}; str() doesn't: {!s}".format('test1', 'test2')
'repr() shows quotes: 'test1'; str() doesn't: test2'
```

Aligning the text and specifying a width:

```
>>> '{:<30}'.format('left aligned')
'left aligned'
>>> '{:>30}'.format('right aligned')
'right aligned'
>>> '{:^30}'.format('centered')
'centered'
>>> '{:*^30}'.format('centered')  # use '*' as a fill char
'*****centered*****'
```

Replacing %+f, %-f, and % f and specifying a sign:

```
>>> '{:+f}; {:+f}'.format(3.14, -3.14) # show it always
'+3.140000; -3.140000'
>>> '{: f}; {: f}'.format(3.14, -3.14) # show a space for positive numbers
' 3.140000; -3.140000'
>>> '{:-f}; {: -f}'.format(3.14, -3.14) # show only the minus -- same as '{:f}; {:f}'
'3.140000; -3.140000'
```

Replacing %x and %o and converting the value to different bases:

```
>>> # format also supports binary numbers
>>> "int: {0:d}; hex: {0:x}; oct: {0:o}; bin: {0:b}".format(42)
'int: 42; hex: 2a; oct: 52; bin: 101010'
>>> # with 0x, 0o, or 0b as prefix:
>>> "int: {0:d}; hex: {0:#x}; oct: {0:#o}; bin: {0:#b}".format(42)
'int: 42; hex: 0x2a; oct: 0o52; bin: 0b101010'
```

Using the comma as a thousands separator:

```
>>> '{:,}'.format(1234567890)
'1,234,567,890'
```

Expressing a percentage:

```
>>> points = 19
>>> total = 22
>>> 'Correct answers: {:.2%}'.format(points/total)
'Correct answers: 86.36%'
```

Using type-specific formatting:

```
>>> import datetime
>>> d = datetime.datetime(2010, 7, 4, 12, 15, 58)
>>> '{:%Y-%m-%d %H:%M:%S}'.format(d)
'2010-07-04 12:15:58'
```

Nesting arguments and more complex examples:

```
>>> for align, text in zip('<^>', ['left', 'center', 'right']):
...     '{0:{fill}{align}16}'.format(text, fill=align, align=align)
...
'left<<<<<<<<<<<'
'^^^^^center^^^^^'
'>>>>>>>>>>>right'
>>>
>>> octets = [192, 168, 0, 1]
>>> '{:02X}{:02X}{:02X}{:02X}'.format(*octets)
'C0A80001'
>>> int(_, 16)
3232235521
>>>
>>> width = 5
>>> for num in range(5,12):
...     for base in 'dXob':
...         print('{0:{width}{base}}'.format(num, base=base, width=width), end=' ')
...     print()
... 
```

| 11 | B | 13 | 1011 |

6.1.4 Template strings

Template strings provide simpler string substitutions as described in [PEP 292](#). A primary use case for template strings is for internationalization (i18n) since in that context, the simpler syntax and functionality makes it easier to translate than other built-in string formatting facilities in Python. As an example of a library built on template strings for i18n, see the [flufl.i18n](#) package.

Template strings support `$`-based substitutions, using the following rules:

- `$$` is an escape; it is replaced with a single `$`.
- `$identifier` names a substitution placeholder matching a mapping key of `"identifier"`. By default, `"identifier"` is restricted to any case-insensitive ASCII alphanumeric string (including underscores) that starts with an underscore or ASCII letter. The first non-identifier character after the `$` character terminates this placeholder specification.
- `${identifier}` is equivalent to `$identifier`. It is required when valid identifier characters follow the placeholder but are not part of the placeholder, such as `"${noun}ification"`.

Any other appearance of `$` in the string will result in a `ValueError` being raised.

The `string` module provides a `Template` class that implements these rules. The methods of `Template` are:

class `string.Template` (*template*)

The constructor takes a single argument which is the template string.

substitute (*mapping*=`{}`, */*, *******kws*)

Performs the template substitution, returning a new string. *mapping* is any dictionary-like object with keys that match the placeholders in the template. Alternatively, you can provide keyword arguments, where the keywords are the placeholders. When both *mapping* and *kws* are given and there are duplicates, the placeholders from *kws* take precedence.

safe_substitute (*mapping*=`{}`, */*, *******kws*)

Like `substitute()`, except that if placeholders are missing from *mapping* and *kws*, instead of raising a `KeyError` exception, the original placeholder will appear in the resulting string intact. Also, unlike with `substitute()`, any other appearances of the `$` will simply return `$` instead of raising `ValueError`.

While other exceptions may still occur, this method is called «safe» because it always tries to return a usable string instead of raising an exception. In another sense, `safe_substitute()` may be anything other than safe, since it will silently ignore malformed templates containing dangling delimiters, unmatched braces, or placeholders that are not valid Python identifiers.

`Template` instances also provide one public data attribute:

template

This is the object passed to the constructor's *template* argument. In general, you shouldn't change it, but read-only access is not enforced.

Here is an example of how to use a `Template`:

```

>>> from string import Template
>>> s = Template('$who likes $what')
>>> s.substitute(who='tim', what='kung pao')
'tim likes kung pao'
>>> d = dict(who='tim')
>>> Template('Give $who $100').substitute(d)
Traceback (most recent call last):
...
ValueError: Invalid placeholder in string: line 1, col 11
>>> Template('$who likes $what').substitute(d)
Traceback (most recent call last):
...
KeyError: 'what'
>>> Template('$who likes $what').safe_substitute(d)
'tim likes $what'

```

Advanced usage: you can derive subclasses of *Template* to customize the placeholder syntax, delimiter character, or the entire regular expression used to parse template strings. To do this, you can override these class attributes:

- *delimiter* – This is the literal string describing a placeholder introducing delimiter. The default value is `$`. Note that this should *not* be a regular expression, as the implementation will call `re.escape()` on this string as needed. Note further that you cannot change the delimiter after class creation (i.e. a different delimiter must be set in the subclass's class namespace).
- *idpattern* – This is the regular expression describing the pattern for non-braced placeholders. The default value is the regular expression `(?a: [_a-z] [_a-z0-9] *)`. If this is given and *braceidpattern* is `None` this pattern will also apply to braced placeholders.

Σημείωση: Since default *flags* is `re.IGNORECASE`, pattern `[a-z]` can match with some non-ASCII characters. That's why we use the local `a` flag here.

Άλλαξε στην έκδοση 3.7: *braceidpattern* can be used to define separate patterns used inside and outside the braces.

- *braceidpattern* – This is like *idpattern* but describes the pattern for braced placeholders. Defaults to `None` which means to fall back to *idpattern* (i.e. the same pattern is used both inside and outside braces). If given, this allows you to define different patterns for braced and unbraced placeholders.

Νέο στην έκδοση 3.7.

- *flags* – The regular expression flags that will be applied when compiling the regular expression used for recognizing substitutions. The default value is `re.IGNORECASE`. Note that `re.VERBOSE` will always be added to the flags, so custom *idpatterns* must follow conventions for verbose regular expressions.

Νέο στην έκδοση 3.2.

Alternatively, you can provide the entire regular expression pattern by overriding the class attribute *pattern*. If you do this, the value must be a regular expression object with four named capturing groups. The capturing groups correspond to the rules given above, along with the invalid placeholder rule:

- *escaped* – This group matches the escape sequence, e.g. `$$`, in the default pattern.
- *named* – This group matches the unbraced placeholder name; it should not include the delimiter in capturing group.
- *braced* – This group matches the brace enclosed placeholder name; it should not include either the delimiter or braces in the capturing group.
- *invalid* – This group matches any other delimiter pattern (usually a single delimiter), and it should appear last in the regular expression.

6.1.5 Helper functions

`string.capitalize(s, sep=None)`

Split the argument into words using `str.split()`, capitalize each word using `str.capitalize()`, and join the capitalized words using `str.join()`. If the optional second argument `sep` is absent or `None`, runs of whitespace characters are replaced by a single space and leading and trailing whitespace are removed, otherwise `sep` is used to split and join the words.

6.2 `re` — Regular expression operations

Source code: [Lib/re.py](#)

This module provides regular expression matching operations similar to those found in Perl.

Both patterns and strings to be searched can be Unicode strings (`str`) as well as 8-bit strings (`bytes`). However, Unicode strings and 8-bit strings cannot be mixed: that is, you cannot match a Unicode string with a byte pattern or vice-versa; similarly, when asking for a substitution, the replacement string must be of the same type as both the pattern and the search string.

Regular expressions use the backslash character (`'\'`) to indicate special forms or to allow special characters to be used without invoking their special meaning. This collides with Python's usage of the same character for the same purpose in string literals; for example, to match a literal backslash, one might have to write `'\\\\'` as the pattern string, because the regular expression must be `\\`, and each backslash must be expressed as `\\` inside a regular Python string literal. Also, please note that any invalid escape sequences in Python's usage of the backslash in string literals now generate a `DeprecationWarning` and in the future this will become a `SyntaxError`. This behaviour will happen even if it is a valid escape sequence for a regular expression.

The solution is to use Python's raw string notation for regular expression patterns; backslashes are not handled in any special way in a string literal prefixed with `'r'`. So `r"\n"` is a two-character string containing `'\'` and `'n'`, while `"\n"` is a one-character string containing a newline. Usually patterns will be expressed in Python code using this raw string notation.

It is important to note that most regular expression operations are available as module-level functions and methods on *compiled regular expressions*. The functions are shortcuts that don't require you to compile a regex object first, but miss some fine-tuning parameters.

The third-party `regex` module, which has an API compatible with the standard library `re` module, but offers additional functionality and a more thorough Unicode support.

6.2.1 Regular Expression Syntax

A regular expression (or RE) specifies a set of strings that matches it; the functions in this module let you check if a particular string matches a given regular expression (or if a given regular expression matches a particular string, which comes down to the same thing).

Regular expressions can be concatenated to form new regular expressions; if *A* and *B* are both regular expressions, then *AB* is also a regular expression. In general, if a string *p* matches *A* and another string *q* matches *B*, the string *pq* will match *AB*. This holds unless *A* or *B* contain low precedence operations; boundary conditions between *A* and *B*; or have numbered group references. Thus, complex expressions can easily be constructed from simpler primitive expressions like the ones described here. For details of the theory and implementation of regular expressions, consult the Friedl book [Frie09], or almost any textbook about compiler construction.

A brief explanation of the format of regular expressions follows. For further information and a gentler presentation, consult the [regex-howto](#).

Regular expressions can contain both special and ordinary characters. Most ordinary characters, like 'A', 'a', or '0', are the simplest regular expressions; they simply match themselves. You can concatenate ordinary characters, so `last` matches the string 'last'. (In the rest of this section, we'll write RE's in this special style, usually without quotes, and strings to be matched 'in single quotes'.)

Some characters, like '| ' or '(', are special. Special characters either stand for classes of ordinary characters, or affect how the regular expressions around them are interpreted.

Repetition qualifiers (`*`, `+`, `?`, `{m, n}`, etc) cannot be directly nested. This avoids ambiguity with the non-greedy modifier suffix `?`, and with other modifiers in other implementations. To apply a second repetition to an inner repetition, parentheses may be used. For example, the expression `(?:a{6})*` matches any multiple of six 'a' characters.

The special characters are:

- `.` (Dot.) In the default mode, this matches any character except a newline. If the `DOTALL` flag has been specified, this matches any character including a newline.
- `^` (Caret.) Matches the start of the string, and in `MULTILINE` mode also matches immediately after each newline.
- `$` Matches the end of the string or just before the newline at the end of the string, and in `MULTILINE` mode also matches before a newline. `foo` matches both "foo" and "foobar", while the regular expression `foo$` matches only "foo". More interestingly, searching for `foo.$` in 'foo1\nfoo2\n' matches "foo2" normally, but "foo1" in `MULTILINE` mode; searching for a single `$` in 'foo\n' will find two (empty) matches: one just before the newline, and one at the end of the string.
- `*` Causes the resulting RE to match 0 or more repetitions of the preceding RE, as many repetitions as are possible. `ab*` will match "a", "ab", or "a" followed by any number of "b's".
- `+` Causes the resulting RE to match 1 or more repetitions of the preceding RE. `ab+` will match "a" followed by any non-zero number of "b's"; it will not match just "a".
- `?` Causes the resulting RE to match 0 or 1 repetitions of the preceding RE. `ab?` will match either "a" or "ab".
- `*?, +?, ??` The `'*'`, `'+'`, and `'?'` qualifiers are all *greedy*; they match as much text as possible. Sometimes this behaviour isn't desired; if the RE `<.*>` is matched against '`<a> b <c>`', it will match the entire string, and not just '`<a>`'. Adding `?` after the qualifier makes it perform the match in *non-greedy* or *minimal* fashion; as *few* characters as possible will be matched. Using the RE `<.*?>` will match only '`<a>`'.
- `{m}` Specifies that exactly *m* copies of the previous RE should be matched; fewer matches cause the entire RE not to match. For example, `a{6}` will match exactly six 'a' characters, but not five.
- `{m, n}` Causes the resulting RE to match from *m* to *n* repetitions of the preceding RE, attempting to match as many repetitions as possible. For example, `a{3, 5}` will match from 3 to 5 'a' characters. Omitting *m* specifies a lower bound of zero, and omitting *n* specifies an infinite upper bound. As an example, `a{4, }b` will match 'aaaab' or a thousand 'a' characters followed by a 'b', but not 'aaab'. The comma may not be omitted or the modifier would be confused with the previously described form.
- `{m, n}?` Causes the resulting RE to match from *m* to *n* repetitions of the preceding RE, attempting to match as *few* repetitions as possible. This is the non-greedy version of the previous qualifier. For example, on the 6-character string 'aaaaaa', `a{3, 5}` will match 5 'a' characters, while `a{3, 5}?` will only match 3 characters.
- `\` Either escapes special characters (permitting you to match characters like `'*'`, `'?'`, and so forth), or signals a special sequence; special sequences are discussed below.

If you're not using a raw string to express the pattern, remember that Python also uses the backslash as an escape sequence in string literals; if the escape sequence isn't recognized by Python's parser, the backslash and subsequent character are included in the resulting string. However, if Python would recognize the resulting sequence, the backslash should be repeated twice. This is complicated and hard to understand, so it's highly recommended that you use raw strings for all but the simplest expressions.

[] Used to indicate a set of characters. In a set:

- Characters can be listed individually, e.g. `[amk]` will match `'a'`, `'m'`, or `'k'`.
- Ranges of characters can be indicated by giving two characters and separating them by a `-`, for example `[a-z]` will match any lowercase ASCII letter, `[0-5][0-9]` will match all the two-digits numbers from 00 to 59, and `[0-9A-Fa-f]` will match any hexadecimal digit. If `-` is escaped (e.g. `[a\ -z]`) or if it's placed as the first or last character (e.g. `[-a]` or `[a-]`), it will match a literal `'-'`.
- Special characters lose their special meaning inside sets. For example, `[(+*)]` will match any of the literal characters `'('`, `'+'`, `'*'`, or `')'`.
- Character classes such as `\w` or `\S` (defined below) are also accepted inside a set, although the characters they match depends on whether *ASCII* or *LOCALE* mode is in force.
- Characters that are not within a range can be matched by *complementing* the set. If the first character of the set is `^`, all the characters that are *not* in the set will be matched. For example, `[^5]` will match any character except `'5'`, and `[^ ^]` will match any character except `'^'`. `^` has no special meaning if it's not the first character in the set.
- To match a literal `' '` inside a set, precede it with a backslash, or place it at the beginning of the set. For example, both `[(\] { }]` and `[] () [{ }]` will both match a parenthesis.
- Support of nested sets and set operations as in [Unicode Technical Standard #18](#) might be added in the future. This would change the syntax, so to facilitate this change a *FutureWarning* will be raised in ambiguous cases for the time being. That includes sets starting with a literal `' ['` or containing literal character sequences `'--'`, `'&&'`, `'~~'`, and `'||'`. To avoid a warning escape them with a backslash.

Άλλαξε στην έκδοση 3.7: *FutureWarning* is raised if a character set contains constructs that will change semantically in the future.

| `A|B`, where *A* and *B* can be arbitrary REs, creates a regular expression that will match either *A* or *B*. An arbitrary number of REs can be separated by the `'|'` in this way. This can be used inside groups (see below) as well. As the target string is scanned, REs separated by `'|'` are tried from left to right. When one pattern completely matches, that branch is accepted. This means that once *A* matches, *B* will not be tested further, even if it would produce a longer overall match. In other words, the `'|'` operator is never greedy. To match a literal `'|'`, use `\|`, or enclose it inside a character class, as in `[|]`.

(`...`) Matches whatever regular expression is inside the parentheses, and indicates the start and end of a group; the contents of a group can be retrieved after a match has been performed, and can be matched later in the string with the `\number` special sequence, described below. To match the literals `'('` or `')'`, use `\(` or `\)`, or enclose them inside a character class: `[()]`.

(`?...?`) This is an extension notation (a `'?'` following a `'('` is not meaningful otherwise). The first character after the `'?'` determines what the meaning and further syntax of the construct is. Extensions usually do not create a new group; (`?P<name>...`) is the only exception to this rule. Following are the currently supported extensions.

(`?aiLmsux`) (One or more letters from the set `'a', 'i', 'L', 'm', 's', 'u', 'x'`.) The group matches the empty string; the letters set the corresponding flags: *re.A* (ASCII-only matching), *re.I* (ignore case), *re.L* (locale dependent), *re.M* (multi-line), *re.S* (dot matches all), *re.U* (Unicode matching), and *re.X* (verbose), for the entire regular expression. (The flags are described in [Module Contents](#).) This is useful if you wish to include the flags as part of the regular expression, instead of passing a *flag* argument to the *re.compile()* function. Flags should be used first in the expression string.

(`?:...?`) A non-capturing version of regular parentheses. Matches whatever regular expression is inside the parentheses, but the substring matched by the group *cannot* be retrieved after performing a match or referenced later in the pattern.

(`?aiLmsux-imsx:...?`) (Zero or more letters from the set `'a', 'i', 'L', 'm', 's', 'u', 'x'`, optionally followed by `'-'` followed by one or more letters from the `'i', 'm', 's', 'x'`.) The letters set or remove the

corresponding flags: `re.A` (ASCII-only matching), `re.I` (ignore case), `re.L` (locale dependent), `re.M` (multiline), `re.S` (dot matches all), `re.U` (Unicode matching), and `re.X` (verbose), for the part of the expression. (The flags are described in [Module Contents](#).)

The letters `'a'`, `'L'` and `'u'` are mutually exclusive when used as inline flags, so they can't be combined or follow `'-'`. Instead, when one of them appears in an inline group, it overrides the matching mode in the enclosing group. In Unicode patterns `(?a: . . .)` switches to ASCII-only matching, and `(?u: . . .)` switches to Unicode matching (default). In byte pattern `(?L: . . .)` switches to locale depending matching, and `(?a: . . .)` switches to ASCII-only matching (default). This override is only in effect for the narrow inline group, and the original matching mode is restored outside of the group.

Νέο στην έκδοση 3.6.

Άλλαξε στην έκδοση 3.7: The letters `'a'`, `'L'` and `'u'` also can be used in a group.

(?P<name> . . .) Similar to regular parentheses, but the substring matched by the group is accessible via the symbolic group name *name*. Group names must be valid Python identifiers, and each group name must be defined only once within a regular expression. A symbolic group is also a numbered group, just as if the group were not named.

Named groups can be referenced in three contexts. If the pattern is `(?P<quote>['"])*?(?P=quote)` (i.e. matching a string quoted with either single or double quotes):

| Context of reference to group «quote» | Ways to reference it |
|---|---|
| in the same pattern itself | <ul style="list-style-type: none"> <code>(?P=quote)</code> (as shown) <code>\1</code> |
| when processing match object <i>m</i> | <ul style="list-style-type: none"> <code>m.group('quote')</code> <code>m.end('quote')</code> (etc.) |
| in a string passed to the <i>repl</i> argument of <code>re.sub()</code> | <ul style="list-style-type: none"> <code>\g<quote></code> <code>\g<1></code> <code>\1</code> |

(?P=name) A backreference to a named group; it matches whatever text was matched by the earlier group named *name*.

(?# . . .) A comment; the contents of the parentheses are simply ignored.

(?= . . .) Matches if *. . .* matches next, but doesn't consume any of the string. This is called a *lookahead assertion*. For example, `Isaac (?=Asimov)` will match `'Isaac '` only if it's followed by `'Asimov'`.

(?! . . .) Matches if *. . .* doesn't match next. This is a *negative lookahead assertion*. For example, `Isaac (?!Asimov)` will match `'Isaac '` only if it's *not* followed by `'Asimov'`.

(?<= . . .) Matches if the current position in the string is preceded by a match for *. . .* that ends at the current position. This is called a *positive lookbehind assertion*. `(?<=abc)def` will find a match in `'abcdef'`, since the lookbehind will back up 3 characters and check if the contained pattern matches. The contained pattern must only match strings of some fixed length, meaning that `abc` or `a|b` are allowed, but `a*` and `a{3,4}` are not. Note that patterns which start with positive lookbehind assertions will not match at the beginning of the string being searched; you will most likely want to use the `search()` function rather than the `match()` function:

```
>>> import re
>>> m = re.search('(?<=abc)def', 'abcdef')
>>> m.group(0)
'def'
```

This example looks for a word following a hyphen:

```
>>> m = re.search(r'(?<=-)\w+', 'spam-egg')
>>> m.group(0)
'egg'
```

Άλλαξε στην έκδοση 3.5: Added support for group references of fixed length.

(?<!...) Matches if the current position in the string is not preceded by a match for ... This is called a *negative lookbehind assertion*. Similar to positive lookbehind assertions, the contained pattern must only match strings of some fixed length. Patterns which start with negative lookbehind assertions may match at the beginning of the string being searched.

(?(id/name)yes-pattern|no-pattern) Will try to match with `yes-pattern` if the group with given `id` or `name` exists, and with `no-pattern` if it doesn't. `no-pattern` is optional and can be omitted. For example, `(<)?(\w+@\w+(?:\.\w+)+)(?(1)>|$)` is a poor email matching pattern, which will match with `'<user@host.com>'` as well as `'user@host.com'`, but not with `'<user@host.com'` nor `'user@host.com>'`.

The special sequences consist of `'\'` and a character from the list below. If the ordinary character is not an ASCII digit or an ASCII letter, then the resulting RE will match the second character. For example, `\$` matches the character `'$'`.

\number Matches the contents of the group of the same number. Groups are numbered starting from 1. For example, `(.+)\1` matches `'the the'` or `'55 55'`, but not `'thethe'` (note the space after the group). This special sequence can only be used to match one of the first 99 groups. If the first digit of *number* is 0, or *number* is 3 octal digits long, it will not be interpreted as a group match, but as the character with octal value *number*. Inside the `'['` and `'] '` of a character class, all numeric escapes are treated as characters.

\A Matches only at the start of the string.

\b Matches the empty string, but only at the beginning or end of a word. A word is defined as a sequence of word characters. Note that formally, `\b` is defined as the boundary between a `\w` and a `\W` character (or vice versa), or between `\w` and the beginning/end of the string. This means that `r'\bfoo\b'` matches `'foo'`, `'foo.'`, `'(foo)'`, `'bar foo baz'` but not `'foobar'` or `'foo3'`.

By default Unicode alphanumerics are the ones used in Unicode patterns, but this can be changed by using the [ASCII](#) flag. Word boundaries are determined by the current locale if the [LOCALE](#) flag is used. Inside a character range, `\b` represents the backspace character, for compatibility with Python's string literals.

\B Matches the empty string, but only when it is *not* at the beginning or end of a word. This means that `r'py\B'` matches `'python'`, `'py3'`, `'py2'`, but not `'py'`, `'py.'`, or `'py!'`. `\B` is just the opposite of `\b`, so word characters in Unicode patterns are Unicode alphanumerics or the underscore, although this can be changed by using the [ASCII](#) flag. Word boundaries are determined by the current locale if the [LOCALE](#) flag is used.

\d

For Unicode (str) patterns: Matches any Unicode decimal digit (that is, any character in Unicode character category `[Nd]`). This includes `[0-9]`, and also many other digit characters. If the [ASCII](#) flag is used only `[0-9]` is matched.

For 8-bit (bytes) patterns: Matches any decimal digit; this is equivalent to `[0-9]`.

\D Matches any character which is not a decimal digit. This is the opposite of `\d`. If the [ASCII](#) flag is used this becomes the equivalent of `[^0-9]`.

\s

For Unicode (str) patterns: Matches Unicode whitespace characters (which includes `[\t\n\r\f\v]`, and also many other characters, for example the non-breaking spaces mandated by typography rules in many languages). If the [ASCII](#) flag is used, only `[\t\n\r\f\v]` is matched.

For 8-bit (bytes) patterns: Matches characters considered whitespace in the ASCII character set; this is equivalent to `[\t\n\r\f\v]`.

\S Matches any character which is not a whitespace character. This is the opposite of `\s`. If the *ASCII* flag is used this becomes the equivalent of `[\t\n\r\f\v]`.

\w

For Unicode (str) patterns: Matches Unicode word characters; this includes most characters that can be part of a word in any language, as well as numbers and the underscore. If the *ASCII* flag is used, only `[a-zA-Z0-9_]` is matched.

For 8-bit (bytes) patterns: Matches characters considered alphanumeric in the ASCII character set; this is equivalent to `[a-zA-Z0-9_]`. If the *LOCALE* flag is used, matches characters considered alphanumeric in the current locale and the underscore.

\W Matches any character which is not a word character. This is the opposite of `\w`. If the *ASCII* flag is used this becomes the equivalent of `[\t\n\r\f\v]`. If the *LOCALE* flag is used, matches characters which are neither alphanumeric in the current locale nor the underscore.

\Z Matches only at the end of the string.

Most of the standard escapes supported by Python string literals are also accepted by the regular expression parser:

| | | | |
|-----------------|-----------------|-----------------|-----------------|
| <code>\a</code> | <code>\b</code> | <code>\f</code> | <code>\n</code> |
| <code>\N</code> | <code>\r</code> | <code>\t</code> | <code>\u</code> |
| <code>\U</code> | <code>\v</code> | <code>\x</code> | <code>\\</code> |

(Note that `\b` is used to represent word boundaries, and means «backspace» only inside character classes.)

`'\u'`, `'\U'`, and `'\N'` escape sequences are only recognized in Unicode patterns. In bytes patterns they are errors. Unknown escapes of ASCII letters are reserved for future use and treated as errors.

Octal escapes are included in a limited form. If the first digit is a 0, or if there are three octal digits, it is considered an octal escape. Otherwise, it is a group reference. As for string literals, octal escapes are always at most three digits in length.

Άλλαξε στην έκδοση 3.3: The `'\u'` and `'\U'` escape sequences have been added.

Άλλαξε στην έκδοση 3.6: Unknown escapes consisting of `'\ '` and an ASCII letter now are errors.

Άλλαξε στην έκδοση 3.8: The `'\N{name}'` escape sequence has been added. As in string literals, it expands to the named Unicode character (e.g. `'\N{EM DASH}'`).

6.2.2 Module Contents

The module defines several functions, constants, and an exception. Some of the functions are simplified versions of the full featured methods for compiled regular expressions. Most non-trivial applications always use the compiled form.

Άλλαξε στην έκδοση 3.6: Flag constants are now instances of `RegexFlag`, which is a subclass of `enum.IntFlag`.

`re.compile(pattern, flags=0)`

Compile a regular expression pattern into a *regular expression object*, which can be used for matching using its `match()`, `search()` and other methods, described below.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the following variables, combined using bitwise OR (the `|` operator).

The sequence

```
prog = re.compile(pattern)
result = prog.match(string)
```

is equivalent to

```
result = re.match(pattern, string)
```

but using `re.compile()` and saving the resulting regular expression object for reuse is more efficient when the expression will be used several times in a single program.

Σημείωση: The compiled versions of the most recent patterns passed to `re.compile()` and the module-level matching functions are cached, so programs that use only a few regular expressions at a time needn't worry about compiling regular expressions.

re.A

re.ASCII

Make `\w`, `\W`, `\b`, `\B`, `\d`, `\D`, `\s` and `\S` perform ASCII-only matching instead of full Unicode matching. This is only meaningful for Unicode patterns, and is ignored for byte patterns. Corresponds to the inline flag `(?a)`.

Note that for backward compatibility, the `re.U` flag still exists (as well as its synonym `re.UNICODE` and its embedded counterpart `(?u)`), but these are redundant in Python 3 since matches are Unicode by default for strings (and Unicode matching isn't allowed for bytes).

re.DEBUG

Display debug information about compiled expression. No corresponding inline flag.

re.I

re.IGNORECASE

Perform case-insensitive matching; expressions like `[A-Z]` will also match lowercase letters. Full Unicode matching (such as `Ü` matching `ü`) also works unless the `re.ASCII` flag is used to disable non-ASCII matches. The current locale does not change the effect of this flag unless the `re.LOCALE` flag is also used. Corresponds to the inline flag `(?i)`.

Note that when the Unicode patterns `[a-z]` or `[A-Z]` are used in combination with the `IGNORECASE` flag, they will match the 52 ASCII letters and 4 additional non-ASCII letters: “İ” (U+0130, Latin capital letter I with dot above), “ı” (U+0131, Latin small letter dotless i), “İ” (U+017F, Latin small letter long s) and “K” (U+212A, Kelvin sign). If the `ASCII` flag is used, only letters “a” to “z” and “A” to “Z” are matched.

re.L

re.LOCALE

Make `\w`, `\W`, `\b`, `\B` and case-insensitive matching dependent on the current locale. This flag can be used only with bytes patterns. The use of this flag is discouraged as the locale mechanism is very unreliable, it only handles one «culture» at a time, and it only works with 8-bit locales. Unicode matching is already enabled by default in Python 3 for Unicode (str) patterns, and it is able to handle different locales/languages. Corresponds to the inline flag `(?L)`.

Άλλαξε στην έκδοση 3.6: `re.LOCALE` can be used only with bytes patterns and is not compatible with `re.ASCII`.

Άλλαξε στην έκδοση 3.7: Compiled regular expression objects with the `re.LOCALE` flag no longer depend on the locale at compile time. Only the locale at matching time affects the result of matching.

re.M

re.MULTILINE

When specified, the pattern character `^` matches at the beginning of the string and at the beginning of each line (immediately following each newline); and the pattern character `$` matches at the end of the string and at the end of each line (immediately preceding each newline). By default, `^` matches only at the beginning of the

string, and '\$' only at the end of the string and immediately before the newline (if any) at the end of the string. Corresponds to the inline flag (`?m`).

`re.S`

`re.DOTALL`

Make the '.' special character match any character at all, including a newline; without this flag, '.' will match anything *except* a newline. Corresponds to the inline flag (`?s`).

`re.X`

`re.VERBOSE`

This flag allows you to write regular expressions that look nicer and are more readable by allowing you to visually separate logical sections of the pattern and add comments. Whitespace within the pattern is ignored, except when in a character class, or when preceded by an unescaped backslash, or within tokens like `*?`, `(?:` or `(?P<...>`. When a line contains a `#` that is not in a character class and is not preceded by an unescaped backslash, all characters from the leftmost such `#` through the end of the line are ignored.

This means that the two following regular expression objects that match a decimal number are functionally equal:

```
a = re.compile(r"""\d +   # the integral part
                \.      # the decimal point
                \d *    # some fractional digits""", re.X)
b = re.compile(r"\d+\.\d*")
```

Corresponds to the inline flag (`?x`).

`re.search(pattern, string, flags=0)`

Scan through *string* looking for the first location where the regular expression *pattern* produces a match, and return a corresponding *match object*. Return `None` if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

`re.match(pattern, string, flags=0)`

If zero or more characters at the beginning of *string* match the regular expression *pattern*, return a corresponding *match object*. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

Note that even in *MULTILINE* mode, `re.match()` will only match at the beginning of the string and not at the beginning of each line.

If you want to locate a match anywhere in *string*, use `search()` instead (see also `search()` vs. `match()`).

`re.fullmatch(pattern, string, flags=0)`

If the whole *string* matches the regular expression *pattern*, return a corresponding *match object*. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

Νέο στην έκδοση 3.4.

`re.split(pattern, string, maxsplit=0, flags=0)`

Split *string* by the occurrences of *pattern*. If capturing parentheses are used in *pattern*, then the text of all groups in the pattern are also returned as part of the resulting list. If *maxsplit* is nonzero, at most *maxsplit* splits occur, and the remainder of the string is returned as the final element of the list.

```
>>> re.split(r'\W+', 'Words, words, words.')
['Words', 'words', 'words', '']
>>> re.split(r'(\W+)', 'Words, words, words.')
['Words', '', ' ', 'words', '', ' ', 'words', '.', '']
>>> re.split(r'\W+', 'Words, words, words.', 1)
['Words', 'words, words.']
>>> re.split(r'[a-f]+', '0a3B9', flags=re.IGNORECASE)
['0', '3', '9']
```

If there are capturing groups in the separator and it matches at the start of the string, the result will start with an empty string. The same holds for the end of the string:

```
>>> re.split(r'(\W+)', '...words, words...')
['', '...', 'words', ',', ' ', 'words', '...', '']
```

That way, separator components are always found at the same relative indices within the result list.

Empty matches for the pattern split the string only when not adjacent to a previous empty match.

```
>>> re.split(r'\b', 'Words, words, words.')
['', 'Words', ',', ' ', 'words', ',', ' ', 'words', '.']
>>> re.split(r'\W*', '...words...')
['', '', 'w', 'o', 'r', 'd', 's', '', '']
>>> re.split(r'(\W*)', '...words...')
['', '...', '', '', 'w', '', 'o', '', 'r', '', 'd', '', 's', '...', '', '', '']
```

Άλλαξε στην έκδοση 3.1: Added the optional flags argument.

Άλλαξε στην έκδοση 3.7: Added support of splitting on a pattern that could match an empty string.

re.findall (*pattern*, *string*, *flags=0*)

Return all non-overlapping matches of *pattern* in *string*, as a list of strings or tuples. The *string* is scanned left-to-right, and matches are returned in the order found. Empty matches are included in the result.

The result depends on the number of capturing groups in the pattern. If there are no groups, return a list of strings matching the whole pattern. If there is exactly one group, return a list of strings matching that group. If multiple groups are present, return a list of tuples of strings matching the groups. Non-capturing groups do not affect the form of the result.

```
>>> re.findall(r'\bf[a-z]*', 'which foot or hand fell fastest')
['foot', 'fell', 'fastest']
>>> re.findall(r'(\w+)=(\d+)', 'set width=20 and height=10')
[('width', '20'), ('height', '10')]
```

Άλλαξε στην έκδοση 3.7: Non-empty matches can now start just after a previous empty match.

re.finditer (*pattern*, *string*, *flags=0*)

Return an *iterator* yielding *match objects* over all non-overlapping matches for the RE *pattern* in *string*. The *string* is scanned left-to-right, and matches are returned in the order found. Empty matches are included in the result.

Άλλαξε στην έκδοση 3.7: Non-empty matches can now start just after a previous empty match.

re.sub (*pattern*, *repl*, *string*, *count=0*, *flags=0*)

Return the string obtained by replacing the leftmost non-overlapping occurrences of *pattern* in *string* by the replacement *repl*. If the pattern isn't found, *string* is returned unchanged. *repl* can be a string or a function; if it is a string, any backslash escapes in it are processed. That is, `\n` is converted to a single newline character, `\r` is converted to a carriage return, and so forth. Unknown escapes of ASCII letters are reserved for future use and treated as errors. Other unknown escapes such as `\&` are left alone. Backreferences, such as `\6`, are replaced with the substring matched by group 6 in the pattern. For example:

```
>>> re.sub(r'def\s+([a-zA-Z_][a-zA-Z_0-9]*)\s*\(\s*\):',
...       r'static PyObject*\np_{1}(void)\n{',
...       'def myfunc():')
'static PyObject*\np_myfunc(void)\n{'
```

If *repl* is a function, it is called for every non-overlapping occurrence of *pattern*. The function takes a single *match object* argument, and returns the replacement string. For example:

```
>>> def dashrepl(matchobj):
...     if matchobj.group(0) == '-': return ' '
...     else: return '-'
>>> re.sub('-{1,2}', dashrepl, 'pro---gram-files')
'pro--gram files'
>>> re.sub(r'\sAND\s', ' & ', 'Baked Beans And Spam', flags=re.IGNORECASE)
'Baked Beans & Spam'
```

The pattern may be a string or a *pattern object*.

The optional argument *count* is the maximum number of pattern occurrences to be replaced; *count* must be a non-negative integer. If omitted or zero, all occurrences will be replaced. Empty matches for the pattern are replaced only when not adjacent to a previous empty match, so `sub('x*', '-', 'abxd')` returns `'-a-b--d-'`.

In string-type *repl* arguments, in addition to the character escapes and backreferences described above, `\g<name>` will use the substring matched by the group named *name*, as defined by the `(?P<name>...)` syntax. `\g<number>` uses the corresponding group number; `\g<2>` is therefore equivalent to `\2`, but isn't ambiguous in a replacement such as `\g<2>0`. `\20` would be interpreted as a reference to group 20, not a reference to group 2 followed by the literal character `'0'`. The backreference `\g<0>` substitutes in the entire substring matched by the RE.

Άλλαξε στην έκδοση 3.1: Added the optional flags argument.

Άλλαξε στην έκδοση 3.5: Unmatched groups are replaced with an empty string.

Άλλαξε στην έκδοση 3.6: Unknown escapes in *pattern* consisting of `'\'` and an ASCII letter now are errors.

Άλλαξε στην έκδοση 3.7: Unknown escapes in *repl* consisting of `'\'` and an ASCII letter now are errors.

Άλλαξε στην έκδοση 3.7: Empty matches for the pattern are replaced when adjacent to a previous non-empty match.

`re.subn(pattern, repl, string, count=0, flags=0)`

Perform the same operation as `sub()`, but return a tuple (*new_string*, *number_of_subs_made*).

Άλλαξε στην έκδοση 3.1: Added the optional flags argument.

Άλλαξε στην έκδοση 3.5: Unmatched groups are replaced with an empty string.

`re.escape(pattern)`

Escape special characters in *pattern*. This is useful if you want to match an arbitrary literal string that may have regular expression metacharacters in it. For example:

```
>>> print(re.escape('https://www.python.org'))
https://www\.python\.org

>>> legal_chars = string.ascii_lowercase + string.digits + "!#$%&'*+-.^_`|~:"
>>> print('[%s]+' % re.escape(legal_chars))
[abcdefghijklmnopqrstuvwxyz0123456789!#$%&'*\+\-\.^_`|\~:]+

>>> operators = ['+', '-', '*', '/', '**']
>>> print(''.join(map(re.escape, sorted(operators, reverse=True))))
/|\-|\\+|\\*\\*|\\*
```

This function must not be used for the replacement string in `sub()` and `subn()`, only backslashes should be escaped. For example:

```
>>> digits_re = r'\d+'
>>> sample = '/usr/sbin/sendmail - 0 errors, 12 warnings'
>>> print(re.sub(digits_re, digits_re.replace('\\', r'\\'), sample))
/usr/sbin/sendmail - \d+ errors, \d+ warnings
```

Άλλαξε στην έκδοση 3.3: The `'_'` character is no longer escaped.

Άλλαξε στην έκδοση 3.7: Only characters that can have special meaning in a regular expression are escaped. As a result, `'!'`, `'\"'`, `'%'`, `'\"'`, `'/'`, `':'`, `','`, `'<'`, `'='`, `'>'`, `'@'`, and `'\"'` are no longer escaped.

`re.purge()`

Clear the regular expression cache.

exception `re.error` (*msg*, *pattern=None*, *pos=None*)

Exception raised when a string passed to one of the functions here is not a valid regular expression (for example, it might contain unmatched parentheses) or when some other error occurs during compilation or matching. It is never an error if a string contains no match for a pattern. The error instance has the following additional attributes:

msg

The unformatted error message.

pattern

The regular expression pattern.

pos

The index in *pattern* where compilation failed (may be `None`).

lineno

The line corresponding to *pos* (may be `None`).

colno

The column corresponding to *pos* (may be `None`).

Άλλαξε στην έκδοση 3.5: Added additional attributes.

6.2.3 Regular Expression Objects

Compiled regular expression objects support the following methods and attributes:

`Pattern.search` (*string*[, *pos*[, *endpos*]])

Scan through *string* looking for the first location where this regular expression produces a match, and return a corresponding *match object*. Return `None` if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

The optional second parameter *pos* gives an index in the string where the search is to start; it defaults to 0. This is not completely equivalent to slicing the string; the `'^'` pattern character matches at the real beginning of the string and at positions just after a newline, but not necessarily at the index where the search is to start.

The optional parameter *endpos* limits how far the string will be searched; it will be as if the string is *endpos* characters long, so only the characters from *pos* to *endpos* - 1 will be searched for a match. If *endpos* is less than *pos*, no match will be found; otherwise, if *rx* is a compiled regular expression object, `rx.search(string, 0, 50)` is equivalent to `rx.search(string[:50], 0)`.

```
>>> pattern = re.compile("d")
>>> pattern.search("dog")          # Match at index 0
<re.Match object; span=(0, 1), match='d'>
>>> pattern.search("dog", 1)       # No match; search doesn't include the "d"
```

`Pattern.match` (*string*[, *pos*[, *endpos*]])

If zero or more characters at the *beginning* of *string* match this regular expression, return a corresponding *match object*. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

The optional *pos* and *endpos* parameters have the same meaning as for the `search()` method.

```
>>> pattern = re.compile("o")
>>> pattern.match("dog")           # No match as "o" is not at the start of "dog".
>>> pattern.match("dog", 1)        # Match as "o" is the 2nd character of "dog".
<re.Match object; span=(1, 2), match='o'>
```

If you want to locate a match anywhere in *string*, use *search()* instead (see also *search()* vs. *match()*).

Pattern.fullmatch (*string*[, *pos*[, *endpos*]])

If the whole *string* matches this regular expression, return a corresponding *match object*. Return None if the string does not match the pattern; note that this is different from a zero-length match.

The optional *pos* and *endpos* parameters have the same meaning as for the *search()* method.

```
>>> pattern = re.compile("o[gh]")
>>> pattern.fullmatch("dog")        # No match as "o" is not at the start of "dog".
>>> pattern.fullmatch("ogre")       # No match as not the full string matches.
>>> pattern.fullmatch("doggie", 1, 3) # Matches within given limits.
<re.Match object; span=(1, 3), match='og'>
```

Νέο στην έκδοση 3.4.

Pattern.split (*string*, *maxsplit*=0)

Identical to the *split()* function, using the compiled pattern.

Pattern.findall (*string*[, *pos*[, *endpos*]])

Similar to the *findall()* function, using the compiled pattern, but also accepts optional *pos* and *endpos* parameters that limit the search region like for *search()*.

Pattern.finditer (*string*[, *pos*[, *endpos*]])

Similar to the *finditer()* function, using the compiled pattern, but also accepts optional *pos* and *endpos* parameters that limit the search region like for *search()*.

Pattern.sub (*repl*, *string*, *count*=0)

Identical to the *sub()* function, using the compiled pattern.

Pattern.subn (*repl*, *string*, *count*=0)

Identical to the *subn()* function, using the compiled pattern.

Pattern.flags

The regex matching flags. This is a combination of the flags given to *compile()*, any (?. . .) inline flags in the pattern, and implicit flags such as UNICODE if the pattern is a Unicode string.

Pattern.groups

The number of capturing groups in the pattern.

Pattern.groupindex

A dictionary mapping any symbolic group names defined by (?P<id>) to group numbers. The dictionary is empty if no symbolic groups were used in the pattern.

Pattern.pattern

The pattern string from which the pattern object was compiled.

Άλλαξε στην έκδοση 3.7: Added support of *copy.copy()* and *copy.deepcopy()*. Compiled regular expression objects are considered atomic.

6.2.4 Match Objects

Match objects always have a boolean value of `True`. Since `match()` and `search()` return `None` when there is no match, you can test whether there was a match with a simple `if` statement:

```
match = re.search(pattern, string)
if match:
    process(match)
```

Match objects support the following methods and attributes:

`Match.expand(template)`

Return the string obtained by doing backslash substitution on the template string *template*, as done by the `sub()` method. Escapes such as `\n` are converted to the appropriate characters, and numeric backreferences (`\1`, `\2`) and named backreferences (`\g<1>`, `\g<name>`) are replaced by the contents of the corresponding group.

Άλλαξε στην έκδοση 3.5: Unmatched groups are replaced with an empty string.

`Match.group([group1, ...])`

Returns one or more subgroups of the match. If there is a single argument, the result is a single string; if there are multiple arguments, the result is a tuple with one item per argument. Without arguments, *group1* defaults to zero (the whole match is returned). If a *groupN* argument is zero, the corresponding return value is the entire matching string; if it is in the inclusive range `[1..99]`, it is the string matching the corresponding parenthesized group. If a group number is negative or larger than the number of groups defined in the pattern, an `IndexError` exception is raised. If a group is contained in a part of the pattern that did not match, the corresponding result is `None`. If a group is contained in a part of the pattern that matched multiple times, the last match is returned.

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m.group(0)          # The entire match
'Isaac Newton'
>>> m.group(1)          # The first parenthesized subgroup.
'Isaac'
>>> m.group(2)          # The second parenthesized subgroup.
'Newton'
>>> m.group(1, 2)       # Multiple arguments give us a tuple.
('Isaac', 'Newton')
```

If the regular expression uses the `(?P<name>...)` syntax, the *groupN* arguments may also be strings identifying groups by their group name. If a string argument is not used as a group name in the pattern, an `IndexError` exception is raised.

A moderately complicated example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.group('first_name')
'Malcolm'
>>> m.group('last_name')
'Reynolds'
```

Named groups can also be referred to by their index:

```
>>> m.group(1)
'Malcolm'
>>> m.group(2)
'Reynolds'
```

If a group matches multiple times, only the last match is accessible:

```
>>> m = re.match(r"(..)+", "a1b2c3") # Matches 3 times.
>>> m.group(1)                        # Returns only the last match.
'c3'
```

`Match.__getitem__(g)`

This is identical to `m.group(g)`. This allows easier access to an individual group from a match:

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m[0]          # The entire match
'Isaac Newton'
>>> m[1]          # The first parenthesized subgroup.
'Isaac'
>>> m[2]          # The second parenthesized subgroup.
'Newton'
```

Νέο στην έκδοση 3.6.

`Match.groups (default=None)`

Return a tuple containing all the subgroups of the match, from 1 up to however many groups are in the pattern. The *default* argument is used for groups that did not participate in the match; it defaults to `None`.

For example:

```
>>> m = re.match(r"(\d+)\.(\d+)", "24.1632")
>>> m.groups()
('24', '1632')
```

If we make the decimal place and everything after it optional, not all groups might participate in the match. These groups will default to `None` unless the *default* argument is given:

```
>>> m = re.match(r"(\d+)\.?(\d+)?", "24")
>>> m.groups()      # Second group defaults to None.
('24', None)
>>> m.groups('0')   # Now, the second group defaults to '0'.
('24', '0')
```

`Match.groupdict (default=None)`

Return a dictionary containing all the *named* subgroups of the match, keyed by the subgroup name. The *default* argument is used for groups that did not participate in the match; it defaults to `None`. For example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.groupdict()
{'first_name': 'Malcolm', 'last_name': 'Reynolds'}
```

`Match.start ([group])`

`Match.end ([group])`

Return the indices of the start and end of the substring matched by *group*; *group* defaults to zero (meaning the whole matched substring). Return `-1` if *group* exists but did not contribute to the match. For a match object *m*, and a group *g* that did contribute to the match, the substring matched by group *g* (equivalent to `m.group(g)`) is

```
m.string[m.start(g):m.end(g)]
```

Note that `m.start(group)` will equal `m.end(group)` if *group* matched a null string. For example, after `m = re.search('b(c?)', 'cba')`, `m.start(0)` is 1, `m.end(0)` is 2, `m.start(1)` and `m.end(1)` are both 2, and `m.start(2)` raises an *IndexError* exception.

An example that will remove *remove_this* from email addresses:

```
>>> email = "tony@tiremove_thisger.net"
>>> m = re.search("remove_this", email)
>>> email[:m.start()] + email[m.end():]
'tony@tiger.net'
```

Match.span([group])

For a match *m*, return the 2-tuple (m.start(group), m.end(group)). Note that if *group* did not contribute to the match, this is (-1, -1). *group* defaults to zero, the entire match.

Match.pos

The value of *pos* which was passed to the *search()* or *match()* method of a *regex object*. This is the index into the string at which the RE engine started looking for a match.

Match.endpos

The value of *endpos* which was passed to the *search()* or *match()* method of a *regex object*. This is the index into the string beyond which the RE engine will not go.

Match.lastindex

The integer index of the last matched capturing group, or None if no group was matched at all. For example, the expressions (a)b, ((a)(b)), and ((ab)) will have *lastindex* == 1 if applied to the string 'ab', while the expression (a)(b) will have *lastindex* == 2, if applied to the same string.

Match.lastgroup

The name of the last matched capturing group, or None if the group didn't have a name, or if no group was matched at all.

Match.re

The *regular expression object* whose *match()* or *search()* method produced this match instance.

Match.string

The string passed to *match()* or *search()*.

Άλλαξε στην έκδοση 3.7: Added support of *copy.copy()* and *copy.deepcopy()*. Match objects are considered atomic.

6.2.5 Regular Expression Examples

Checking for a Pair

In this example, we'll use the following helper function to display match objects a little more gracefully:

```
def displaymatch(match):
    if match is None:
        return None
    return '<Match: %r, groups=%r>' % (match.group(), match.groups())
```

Suppose you are writing a poker program where a player's hand is represented as a 5-character string with each character representing a card, «a» for ace, «k» for king, «q» for queen, «j» for jack, «t» for 10, and «2» through «9» representing the card with that value.

To see if a given string is a valid hand, one could do the following:

```
>>> valid = re.compile(r"^[a2-9tjqk]{5}$")
>>> displaymatch(valid.match("akt5q")) # Valid.
'<Match: 'akt5q', groups=()>'
>>> displaymatch(valid.match("akt5e")) # Invalid.
>>> displaymatch(valid.match("akt"))   # Invalid.
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> displaymatch(valid.match("727ak")) # Valid.
"<Match: '727ak', groups=()>"
```

That last hand, "727ak", contained a pair, or two of the same valued cards. To match this with a regular expression, one could use backreferences as such:

```
>>> pair = re.compile(r".*(.)*\1")
>>> displaymatch(pair.match("717ak")) # Pair of 7s.
"<Match: '717', groups=('7',)>"
>>> displaymatch(pair.match("718ak")) # No pairs.
>>> displaymatch(pair.match("354aa")) # Pair of aces.
"<Match: '354aa', groups=('a',)>"
```

To find out what card the pair consists of, one could use the `group()` method of the match object in the following manner:

```
>>> pair = re.compile(r".*(.)*\1")
>>> pair.match("717ak").group(1)
'7'

# Error because re.match() returns None, which doesn't have a group() method:
>>> pair.match("718ak").group(1)
Traceback (most recent call last):
  File "<pyshell#23>", line 1, in <module>
    re.match(r".*(.)*\1", "718ak").group(1)
AttributeError: 'NoneType' object has no attribute 'group'

>>> pair.match("354aa").group(1)
'a'
```

Simulating scanf()

Python does not currently have an equivalent to `scanf()`. Regular expressions are generally more powerful, though also more verbose, than `scanf()` format strings. The table below offers some more-or-less equivalent mappings between `scanf()` format tokens and regular expressions.

| scanf() Token | Regular Expression |
|----------------|--|
| %c | . |
| %5c | .{5} |
| %d | [+]? \d+ |
| %e, %E, %f, %g | [+]? (\d+ (\.\d*)? \.\d+) ([eE] [+]? \d+)? |
| %i | [+]? (0[xX] [\dA-Fa-f] + 0[0-7] * \d+) |
| %o | [+]? [0-7] + |
| %s | \S+ |
| %u | \d+ |
| %x, %X | [+]? (0[xX])? [\dA-Fa-f] + |

To extract the filename and numbers from a string like

```
/usr/sbin/sendmail - 0 errors, 4 warnings
```

you would use a `scanf()` format like

```
%s - %d errors, %d warnings
```

The equivalent regular expression would be

```
(\S+) - (\d+) errors, (\d+) warnings
```

search() vs. match()

Python offers two different primitive operations based on regular expressions: `re.match()` checks for a match only at the beginning of the string, while `re.search()` checks for a match anywhere in the string (this is what Perl does by default).

For example:

```
>>> re.match("c", "abcdef")      # No match
>>> re.search("c", "abcdef")     # Match
<re.Match object; span=(2, 3), match='c'>
```

Regular expressions beginning with '^' can be used with `search()` to restrict the match at the beginning of the string:

```
>>> re.match("c", "abcdef")      # No match
>>> re.search("^c", "abcdef")    # No match
>>> re.search("^a", "abcdef")    # Match
<re.Match object; span=(0, 1), match='a'>
```

Note however that in *MULTILINE* mode `match()` only matches at the beginning of the string, whereas using `search()` with a regular expression beginning with '^' will match at the beginning of each line.

```
>>> re.match('X', 'A\nB\nX', re.MULTILINE) # No match
>>> re.search('^X', 'A\nB\nX', re.MULTILINE) # Match
<re.Match object; span=(4, 5), match='X'>
```

Making a Phonebook

`split()` splits a string into a list delimited by the passed pattern. The method is invaluable for converting textual data into data structures that can be easily read and modified by Python as demonstrated in the following example that creates a phonebook.

First, here is the input. Normally it may come from a file, here we are using triple-quoted string syntax

```
>>> text = """Ross McFluff: 834.345.1254 155 Elm Street
...
... Ronald Heathmore: 892.345.3428 436 Finley Avenue
... Frank Burger: 925.541.7625 662 South Dogwood Way
...
... Heather Albrecht: 548.326.4584 919 Park Place"""
```

The entries are separated by one or more newlines. Now we convert the string into a list with each nonempty line having its own entry:

```
>>> entries = re.split("\n+", text)
>>> entries
['Ross McFluff: 834.345.1254 155 Elm Street',
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
'Ronald Heathmore: 892.345.3428 436 Finley Avenue',
'Frank Burger: 925.541.7625 662 South Dogwood Way',
'Heather Albrecht: 548.326.4584 919 Park Place']
```

Finally, split each entry into a list with first name, last name, telephone number, and address. We use the `maxsplit` parameter of `split()` because the address has spaces, our splitting pattern, in it:

```
>>> [re.split("?: ", entry, 3) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155 Elm Street'],
['Ronald', 'Heathmore', '892.345.3428', '436 Finley Avenue'],
['Frank', 'Burger', '925.541.7625', '662 South Dogwood Way'],
['Heather', 'Albrecht', '548.326.4584', '919 Park Place']]
```

The `?:` pattern matches the colon after the last name, so that it does not occur in the result list. With a `maxsplit` of 4, we could separate the house number from the street name:

```
>>> [re.split("?: ", entry, 4) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155', 'Elm Street'],
['Ronald', 'Heathmore', '892.345.3428', '436', 'Finley Avenue'],
['Frank', 'Burger', '925.541.7625', '662', 'South Dogwood Way'],
['Heather', 'Albrecht', '548.326.4584', '919', 'Park Place']]
```

Text Munging

`sub()` replaces every occurrence of a pattern with a string or the result of a function. This example demonstrates using `sub()` with a function to «munge» text, or randomize the order of all the characters in each word of a sentence except for the first and last characters:

```
>>> def repl(m):
...     inner_word = list(m.group(2))
...     random.shuffle(inner_word)
...     return m.group(1) + "".join(inner_word) + m.group(3)
>>> text = "Professor Abdolmalek, please report your absences promptly."
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Poefsrosr Aealmlobdk, pslaee reorpt your abnseces plmrptoy.'
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Pofsroser Aodlambelk, plasee reoprt yuor asnebces potlmrpy.'
```

Finding all Adverbs

`findall()` matches *all* occurrences of a pattern, not just the first one as `search()` does. For example, if a writer wanted to find all of the adverbs in some text, they might use `findall()` in the following manner:

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> re.findall(r"\w+ly\b", text)
['carefully', 'quickly']
```

Finding all Adverbs and their Positions

If one wants more information about all matches of a pattern than the matched text, `finditer()` is useful as it provides *match objects* instead of strings. Continuing with the previous example, if a writer wanted to find all of the adverbs *and their positions* in some text, they would use `finditer()` in the following manner:

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> for m in re.finditer(r"\w+ly\b", text):
...     print('%02d-%02d: %s' % (m.start(), m.end(), m.group(0)))
07-16: carefully
40-47: quickly
```

Raw String Notation

Raw string notation (`r"text"`) keeps regular expressions sane. Without it, every backslash (`'\'`) in a regular expression would have to be prefixed with another one to escape it. For example, the two following lines of code are functionally identical:

```
>>> re.match(r"\W(.)\1\W", " ff ")
<re.Match object; span=(0, 4), match=' ff '>
>>> re.match("\\W(.)\\1\\W", " ff ")
<re.Match object; span=(0, 4), match=' ff '>
```

When one wants to match a literal backslash, it must be escaped in the regular expression. With raw string notation, this means `r"\"`. Without raw string notation, one must use `"\\\"`, making the following lines of code functionally identical:

```
>>> re.match(r"\\", r"\\")
<re.Match object; span=(0, 1), match='\\'>
>>> re.match("\\\\", r"\\")
<re.Match object; span=(0, 1), match='\\'>
```

Writing a Tokenizer

A *tokenizer* or *scanner* analyzes a string to categorize groups of characters. This is a useful first step in writing a compiler or interpreter.

The text categories are specified with regular expressions. The technique is to combine those into a single master regular expression and to loop over successive matches:

```
from typing import NamedTuple
import re

class Token(NamedTuple):
    type: str
    value: str
    line: int
    column: int

def tokenize(code):
    keywords = {'IF', 'THEN', 'ENDIF', 'FOR', 'NEXT', 'GOSUB', 'RETURN'}
    token_specification = [
        ('NUMBER',   r'\d+(\.\d*)?'), # Integer or decimal number
        ('ASSIGN',   r':='),          # Assignment operator
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

        ('END',      r';'),          # Statement terminator
        ('ID',       r'[A-Za-z]+'),  # Identifiers
        ('OP',       r'[+\-*/]'),    # Arithmetic operators
        ('NEWLINE',  r'\n'),         # Line endings
        ('SKIP',     r'[ \t]+'),     # Skip over spaces and tabs
        ('MISMATCH', r'.'),          # Any other character
    ]
    tok_regex = '|'.join('(?P<%s>%s)' % pair for pair in token_specification)
    line_num = 1
    line_start = 0
    for mo in re.finditer(tok_regex, code):
        kind = mo.lastgroup
        value = mo.group()
        column = mo.start() - line_start
        if kind == 'NUMBER':
            value = float(value) if '.' in value else int(value)
        elif kind == 'ID' and value in keywords:
            kind = value
        elif kind == 'NEWLINE':
            line_start = mo.end()
            line_num += 1
            continue
        elif kind == 'SKIP':
            continue
        elif kind == 'MISMATCH':
            raise RuntimeError(f'{value!r} unexpected on line {line_num}')
        yield Token(kind, value, line_num, column)

statements = '''
    IF quantity THEN
        total := total + price * quantity;
        tax := price * 0.05;
    ENDIF;
'''

for token in tokenize(statements):
    print(token)

```

The tokenizer produces the following output:

```

Token(type='IF', value='IF', line=2, column=4)
Token(type='ID', value='quantity', line=2, column=7)
Token(type='THEN', value='THEN', line=2, column=16)
Token(type='ID', value='total', line=3, column=8)
Token(type='ASSIGN', value=':=', line=3, column=14)
Token(type='ID', value='total', line=3, column=17)
Token(type='OP', value='+', line=3, column=23)
Token(type='ID', value='price', line=3, column=25)
Token(type='OP', value='*', line=3, column=31)
Token(type='ID', value='quantity', line=3, column=33)
Token(type='END', value=';', line=3, column=41)
Token(type='ID', value='tax', line=4, column=8)
Token(type='ASSIGN', value=':=', line=4, column=12)
Token(type='ID', value='price', line=4, column=15)
Token(type='OP', value='*', line=4, column=21)
Token(type='NUMBER', value=0.05, line=4, column=23)

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
Token(type='END', value=';', line=4, column=27)
Token(type='ENDIF', value='ENDIF', line=5, column=4)
Token(type='END', value=';', line=5, column=9)
```

6.3 difflib — Helpers for computing deltas

Source code: [Lib/difflib.py](#)

This module provides classes and functions for comparing sequences. It can be used for example, for comparing files, and can produce information about file differences in various formats, including HTML and context and unified diffs. For comparing directories and files, see also, the *filecmp* module.

class difflib.SequenceMatcher

This is a flexible class for comparing pairs of sequences of any type, so long as the sequence elements are *hashable*. The basic algorithm predates, and is a little fancier than, an algorithm published in the late 1980's by Ratcliff and Obershelp under the hyperbolic name «gestalt pattern matching.» The idea is to find the longest contiguous matching subsequence that contains no «junk» elements; these «junk» elements are ones that are uninteresting in some sense, such as blank lines or whitespace. (Handling junk is an extension to the Ratcliff and Obershelp algorithm.) The same idea is then applied recursively to the pieces of the sequences to the left and to the right of the matching subsequence. This does not yield minimal edit sequences, but does tend to yield matches that «look right» to people.

Timing: The basic Ratcliff-Obershelp algorithm is cubic time in the worst case and quadratic time in the expected case. *SequenceMatcher* is quadratic time for the worst case and has expected-case behavior dependent in a complicated way on how many elements the sequences have in common; best case time is linear.

Automatic junk heuristic: *SequenceMatcher* supports a heuristic that automatically treats certain sequence items as junk. The heuristic counts how many times each individual item appears in the sequence. If an item's duplicates (after the first one) account for more than 1% of the sequence and the sequence is at least 200 items long, this item is marked as «popular» and is treated as junk for the purpose of sequence matching. This heuristic can be turned off by setting the *autojunk* argument to *False* when creating the *SequenceMatcher*.

Νέο στην έκδοση 3.2: The *autojunk* parameter.

class difflib.Differ

This is a class for comparing sequences of lines of text, and producing human-readable differences or deltas. Differ uses *SequenceMatcher* both to compare sequences of lines, and to compare sequences of characters within similar (near-matching) lines.

Each line of a *Differ* delta begins with a two-letter code:

| Code | Meaning |
|-------|---|
| '- ' | line unique to sequence 1 |
| '+' ' | line unique to sequence 2 |
| ' ' ' | line common to both sequences |
| '?' ' | line not present in either input sequence |

Lines beginning with “?” attempt to guide the eye to intraline differences, and were not present in either input sequence. These lines can be confusing if the sequences contain tab characters.

class difflib.HtmlDiff

This class can be used to create an HTML table (or a complete HTML file containing the table) showing a side by

side, line by line comparison of text with inter-line and intra-line change highlights. The table can be generated in either full or contextual difference mode.

The constructor for this class is:

__init__ (*tabsize=8, wrapcolumn=None, linejunk=None, charjunk=IS_CHARACTER_JUNK*)
 Initializes instance of *HtmlDiff*.

tabsize is an optional keyword argument to specify tab stop spacing and defaults to 8.

wrapcolumn is an optional keyword to specify column number where lines are broken and wrapped, defaults to None where lines are not wrapped.

linejunk and *charjunk* are optional keyword arguments passed into *ndiff()* (used by *HtmlDiff* to generate the side by side HTML differences). See *ndiff()* documentation for argument default values and descriptions.

The following methods are public:

make_file (*fromlines, tolines, fromdesc="", todesc="", context=False, numlines=5, *, charset='utf-8'*)
 Compares *fromlines* and *toline*s (lists of strings) and returns a string which is a complete HTML file containing a table showing line by line differences with inter-line and intra-line changes highlighted.

fromdesc and *todesc* are optional keyword arguments to specify from/to file column header strings (both default to an empty string).

context and *numlines* are both optional keyword arguments. Set *context* to *True* when contextual differences are to be shown, else the default is *False* to show the full files. *numlines* defaults to 5. When *context* is *True* *numlines* controls the number of context lines which surround the difference highlights. When *context* is *False* *numlines* controls the number of lines which are shown before a difference highlight when using the «next» hyperlinks (setting to zero would cause the «next» hyperlinks to place the next difference highlight at the top of the browser without any leading context).

Σημείωση: *fromdesc* and *todesc* are interpreted as unescaped HTML and should be properly escaped while receiving input from untrusted sources.

Άλλαξε στην έκδοση 3.5: *charset* keyword-only argument was added. The default charset of HTML document changed from 'ISO-8859-1' to 'utf-8'.

make_table (*fromlines, tolines, fromdesc="", todesc="", context=False, numlines=5*)
 Compares *fromlines* and *toline*s (lists of strings) and returns a string which is a complete HTML table showing line by line differences with inter-line and intra-line changes highlighted.

The arguments for this method are the same as those for the *make_file()* method.

Tools/scripts/diff.py is a command-line front-end to this class and contains a good example of its use.

difflib.context_diff (*a, b, fromfile="", tofile="", fromfiledate="", tofiledate="", n=3, lineterm='\n'*)
 Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in context diff format.

Context diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in a before/after style. The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with ***** or *---*) are created with a trailing newline. This is helpful so that inputs created from *io.IOBBase.readlines()* result in diffs that are suitable for use with *io.IOBBase.writelines()* since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to *" "* so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(context_diff(s1, s2, fromfile='before.py', tofile=
↳ 'after.py'))
*** before.py
--- after.py
*****
*** 1,4 ****
! bacon
! eggs
! ham
! guido
--- 1,4 ----
! python
! eggy
! hamster
! guido
```

See [A command-line interface to difflib](#) for a more detailed example.

difflib.get_close_matches (*word*, *possibilities*, *n*=3, *cutoff*=0.6)

Return a list of the best «good enough» matches. *word* is a sequence for which close matches are desired (typically a string), and *possibilities* is a list of sequences against which to match *word* (typically a list of strings).

Optional argument *n* (default 3) is the maximum number of close matches to return; *n* must be greater than 0.

Optional argument *cutoff* (default 0.6) is a float in the range [0, 1]. Possibilities that don't score at least that similar to *word* are ignored.

The best (no more than *n*) matches among the possibilities are returned in a list, sorted by similarity score, most similar first.

```
>>> get_close_matches('appel', ['ape', 'apple', 'peach', 'puppy'])
['apple', 'ape']
>>> import keyword
>>> get_close_matches('wheel', keyword.kwlist)
['while']
>>> get_close_matches('pineapple', keyword.kwlist)
[]
>>> get_close_matches('accept', keyword.kwlist)
['except']
```

difflib.ndiff (*a*, *b*, *linejunk*=None, *charjunk*=IS_CHARACTER_JUNK)

Compare *a* and *b* (lists of strings); return a *Differ*-style delta (a *generator* generating the delta lines).

Optional keyword parameters *linejunk* and *charjunk* are filtering functions (or None):

linejunk: A function that accepts a single string argument, and returns true if the string is junk, or false if not. The default is None. There is also a module-level function `IS_LINE_JUNK()`, which filters out lines without visible characters, except for at most one pound character ('#') – however the underlying *SequenceMatcher* class does a dynamic analysis of which lines are so frequent as to constitute noise, and this usually works better than using this function.

charjunk: A function that accepts a character (a string of length 1), and returns if the character is junk, or false if not. The default is module-level function `IS_CHARACTER_JUNK()`, which filters out whitespace characters (a blank or tab; it's a bad idea to include newline in this!).

Tools/scripts/ndiff.py is a command-line front-end to this function.

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keepends=True),
...              'ore\ntree\nemu\n'.splitlines(keepends=True))
>>> print(''.join(diff), end="")
- one
?  ^
+ ore
?  ^
- two
- three
?  -
+ tree
+ emu
```

`difflib.restore(sequence, which)`

Return one of the two sequences that generated a delta.

Given a *sequence* produced by `Differ.compare()` or `ndiff()`, extract lines originating from file 1 or 2 (parameter *which*), stripping off line prefixes.

Example:

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keepends=True),
...              'ore\ntree\nemu\n'.splitlines(keepends=True))
>>> diff = list(diff) # materialize the generated delta into a list
>>> print(''.join	restore(diff, 1)), end="")
one
two
three
>>> print(''.join	restore(diff, 2)), end="")
ore
tree
emu
```

`difflib.unified_diff(a, b, fromfile="", tofile="", fromfiledate="", tofiledate="", n=3, lineterm='\n')`

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in unified diff format.

Unified diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in an inline style (instead of separate before/after blocks). The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with ---, +++, or @@) are created with a trailing newline. This is helpful so that inputs created from `io.IOBase.readlines()` result in diffs that are suitable for use with `io.IOBase.writelines()` since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to "" so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(unified_diff(s1, s2, fromfile='before.py', tofile=
↪ 'after.py'))
--- before.py
+++ after.py
```

(συνεχίζεται από την προηγούμενη σελίδα)

```
@@ -1,4 +1,4 @@
-bacon
-eggs
-ham
+python
+eggy
+hamster
guido
```

See [A command-line interface to difflib](#) for a more detailed example.

`difflib.diff_bytes(dfunc, a, b, fromfile=b'', tofile=b'', fromfiledate=b'', tofiledate=b'', n=3, lineterm=b'\n')`

Compare *a* and *b* (lists of bytes objects) using *dfunc*; yield a sequence of delta lines (also bytes) in the format returned by *dfunc*. *dfunc* must be a callable, typically either `unified_diff()` or `context_diff()`.

Allows you to compare data with unknown or inconsistent encoding. All inputs except *n* must be bytes objects, not str. Works by losslessly converting all inputs (except *n*) to str, and calling `dfunc(a, b, fromfile, tofile, fromfiledate, tofiledate, n, lineterm)`. The output of *dfunc* is then converted back to bytes, so the delta lines that you receive have the same unknown/inconsistent encodings as *a* and *b*.

Νέο στην έκδοση 3.5.

`difflib.IS_LINE_JUNK(line)`

Return True for ignorable lines. The line *line* is ignorable if *line* is blank or contains a single '#', otherwise it is not ignorable. Used as a default for parameter *linejunk* in `ndiff()` in older versions.

`difflib.IS_CHARACTER_JUNK(ch)`

Return True for ignorable characters. The character *ch* is ignorable if *ch* is a space or tab, otherwise it is not ignorable. Used as a default for parameter *charjunk* in `ndiff()`.

Pattern Matching: The Gestalt Approach Discussion of a similar algorithm by John W. Ratcliff and D. E. Metzener. This was published in *Dr. Dobbs' Journal* in July, 1988.

6.3.1 SequenceMatcher Objects

The `SequenceMatcher` class has this constructor:

class `difflib.SequenceMatcher(isjunk=None, a='', b='', autojunk=True)`

Optional argument *isjunk* must be None (the default) or a one-argument function that takes a sequence element and returns true if and only if the element is «junk» and should be ignored. Passing None for *isjunk* is equivalent to passing `lambda x: x in " \t"`; in other words, no elements are ignored. For example, pass:

```
lambda x: x in " \t"
```

if you're comparing lines as sequences of characters, and don't want to synch up on blanks or hard tabs.

The optional arguments *a* and *b* are sequences to be compared; both default to empty strings. The elements of both sequences must be [hashable](#).

The optional argument *autojunk* can be used to disable the automatic junk heuristic.

Νέο στην έκδοση 3.2: The *autojunk* parameter.

SequenceMatcher objects get three data attributes: *bjunk* is the set of elements of *b* for which *isjunk* is True; *bpopular* is the set of non-junk elements considered popular by the heuristic (if it is not disabled); *b2j* is a dict

mapping the remaining elements of *b* to a list of positions where they occur. All three are reset whenever *b* is reset with `set_seqs()` or `set_seq2()`.

Νέο στην έκδοση 3.2: The *bjunk* and *bpopular* attributes.

`SequenceMatcher` objects have the following methods:

set_seqs (*a*, *b*)

Set the two sequences to be compared.

`SequenceMatcher` computes and caches detailed information about the second sequence, so if you want to compare one sequence against many sequences, use `set_seq2()` to set the commonly used sequence once and call `set_seq1()` repeatedly, once for each of the other sequences.

set_seq1 (*a*)

Set the first sequence to be compared. The second sequence to be compared is not changed.

set_seq2 (*b*)

Set the second sequence to be compared. The first sequence to be compared is not changed.

find_longest_match (*alo=0*, *ahi=None*, *blo=0*, *bhi=None*)

Find longest matching block in `a[alo:ahi]` and `b[blo:bhi]`.

If *isjunk* was omitted or `None`, `find_longest_match()` returns (*i*, *j*, *k*) such that `a[i:i+k]` is equal to `b[j:j+k]`, where `alo <= i <= i+k <= ahi` and `blo <= j <= j+k <= bhi`. For all (*i'*, *j'*, *k'*) meeting those conditions, the additional conditions `k >= k'`, `i <= i'`, and if `i == i'`, `j <= j'` are also met. In other words, of all maximal matching blocks, return one that starts earliest in *a*, and of all those maximal matching blocks that start earliest in *a*, return the one that starts earliest in *b*.

```
>>> s = SequenceMatcher(None, "abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=0, b=4, size=5)
```

If *isjunk* was provided, first the longest matching block is determined as above, but with the additional restriction that no junk element appears in the block. Then that block is extended as far as possible by matching (only) junk elements on both sides. So the resulting block never matches on junk except as identical junk happens to be adjacent to an interesting match.

Here's the same example as before, but considering blanks to be junk. That prevents 'abcd' from matching the 'abcd' at the tail end of the second sequence directly. Instead only the 'abcd' can match, and matches the leftmost 'abcd' in the second sequence:

```
>>> s = SequenceMatcher(lambda x: x==" ", "abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=1, b=0, size=4)
```

If no blocks match, this returns (*alo*, *blo*, 0).

This method returns a *named tuple* `Match(a, b, size)`.

Άλλαξε στην έκδοση 3.9: Added default arguments.

get_matching_blocks ()

Return list of triples describing non-overlapping matching subsequences. Each triple is of the form (*i*, *j*, *n*), and means that `a[i:i+n] == b[j:j+n]`. The triples are monotonically increasing in *i* and *j*.

The last triple is a dummy, and has the value (`len(a)`, `len(b)`, 0). It is the only triple with `n == 0`. If (*i*, *j*, *n*) and (*i'*, *j'*, *n'*) are adjacent triples in the list, and the second is not the last triple in the list, then `i+n < i'` or `j+n < j'`; in other words, adjacent triples always describe non-adjacent equal blocks.

```
>>> s = SequenceMatcher(None, "abxcd", "abcd")
>>> s.get_matching_blocks()
[Match(a=0, b=0, size=2), Match(a=3, b=2, size=2), Match(a=5, b=4, size=0)]
```

get_opcodes()

Return list of 5-tuples describing how to turn *a* into *b*. Each tuple is of the form (tag, i1, i2, j1, j2). The first tuple has i1 == j1 == 0, and remaining tuples have i1 equal to the i2 from the preceding tuple, and, likewise, j1 equal to the previous j2.

The tag values are strings, with these meanings:

| Value | Meaning |
|-----------|---|
| 'replace' | a[i1:i2] should be replaced by b[j1:j2]. |
| 'delete' | a[i1:i2] should be deleted. Note that j1 == j2 in this case. |
| 'insert' | b[j1:j2] should be inserted at a[i1:i1]. Note that i1 == i2 in this case. |
| 'equal' | a[i1:i2] == b[j1:j2] (the sub-sequences are equal). |

For example:

```
>>> a = "qabxcd"
>>> b = "abycdf"
>>> s = SequenceMatcher(None, a, b)
>>> for tag, i1, i2, j1, j2 in s.get_opcodes():
...     print('{:7}  a[{:}:{:}] --> b[{:}:{:}] {!r:>8} --> {!r}'.format(
...         tag, i1, i2, j1, j2, a[i1:i2], b[j1:j2]))
delete    a[0:1] --> b[0:0]      'q' --> ''
equal     a[1:3] --> b[0:2]      'ab' --> 'ab'
replace   a[3:4] --> b[2:3]      'x' --> 'y'
equal     a[4:6] --> b[3:5]      'cd' --> 'cd'
insert    a[6:6] --> b[5:6]      '' --> 'f'
```

get_grouped_opcodes(n=3)

Return a *generator* of groups with up to *n* lines of context.

Starting with the groups returned by `get_opcodes()`, this method splits out smaller change clusters and eliminates intervening ranges which have no changes.

The groups are returned in the same format as `get_opcodes()`.

ratio()

Return a measure of the sequences' similarity as a float in the range [0, 1].

Where T is the total number of elements in both sequences, and M is the number of matches, this is 2.0*M / T. Note that this is 1.0 if the sequences are identical, and 0.0 if they have nothing in common.

This is expensive to compute if `get_matching_blocks()` or `get_opcodes()` hasn't already been called, in which case you may want to try `quick_ratio()` or `real_quick_ratio()` first to get an upper bound.

Σημείωση: Caution: The result of a `ratio()` call may depend on the order of the arguments. For instance:

```
>>> SequenceMatcher(None, 'tide', 'diet').ratio()
0.25
>>> SequenceMatcher(None, 'diet', 'tide').ratio()
0.5
```

quick_ratio()

Return an upper bound on *ratio()* relatively quickly.

real_quick_ratio()

Return an upper bound on *ratio()* very quickly.

The three methods that return the ratio of matching to total characters can give different results due to differing levels of approximation, although *quick_ratio()* and *real_quick_ratio()* are always at least as large as *ratio()*:

```
>>> s = SequenceMatcher(None, "abcd", "bcde")
>>> s.ratio()
0.75
>>> s.quick_ratio()
0.75
>>> s.real_quick_ratio()
1.0
```

6.3.2 SequenceMatcher Examples

This example compares two strings, considering blanks to be «junk»:

```
>>> s = SequenceMatcher(lambda x: x == " ",
...                       "private Thread currentThread;",
...                       "private volatile Thread currentThread;")
```

ratio() returns a float in [0, 1], measuring the similarity of the sequences. As a rule of thumb, a *ratio()* value over 0.6 means the sequences are close matches:

```
>>> print(round(s.ratio(), 3))
0.866
```

If you're only interested in where the sequences match, *get_matching_blocks()* is handy:

```
>>> for block in s.get_matching_blocks():
...     print("a[%d] and b[%d] match for %d elements" % block)
a[0] and b[0] match for 8 elements
a[8] and b[17] match for 21 elements
a[29] and b[38] match for 0 elements
```

Note that the last tuple returned by *get_matching_blocks()* is always a dummy, (*len(a)*, *len(b)*, 0), and this is the only case in which the last tuple element (number of elements matched) is 0.

If you want to know how to change the first sequence into the second, use *get_opcodes()*:

```
>>> for opcode in s.get_opcodes():
...     print("%6s a[%d:%d] b[%d:%d]" % opcode)
equal a[0:8] b[0:8]
insert a[8:8] b[8:17]
equal a[8:29] b[17:38]
```

Δείτε επίσης:

- The *get_close_matches()* function in this module which shows how simple code building on *SequenceMatcher* can be used to do useful work.
- Simple version control recipe for a small application built with *SequenceMatcher*.

6.3.3 Differ Objects

Note that *Differ*-generated deltas make no claim to be **minimal** diffs. To the contrary, minimal diffs are often counter-intuitive, because they synch up anywhere possible, sometimes accidental matches 100 pages apart. Restricting synch points to contiguous matches preserves some notion of locality, at the occasional cost of producing a longer diff.

The *Differ* class has this constructor:

```
class difflib.Differ (linejunk=None, charjunk=None)
```

Optional keyword parameters *linejunk* and *charjunk* are for filter functions (or *None*):

linejunk: A function that accepts a single string argument, and returns true if the string is junk. The default is *None*, meaning that no line is considered junk.

charjunk: A function that accepts a single character argument (a string of length 1), and returns true if the character is junk. The default is *None*, meaning that no character is considered junk.

These junk-filtering functions speed up matching to find differences and do not cause any differing lines or characters to be ignored. Read the description of the *find_longest_match()* method's *isjunk* parameter for an explanation.

Differ objects are used (deltas generated) via a single method:

```
compare (a, b)
```

Compare two sequences of lines, and generate the delta (a sequence of lines).

Each sequence must contain individual single-line strings ending with newlines. Such sequences can be obtained from the *readlines()* method of file-like objects. The delta generated also consists of newline-terminated strings, ready to be printed as-is via the *writelines()* method of a file-like object.

6.3.4 Differ Example

This example compares two texts. First we set up the texts, sequences of individual single-line strings ending with newlines (such sequences can also be obtained from the *readlines()* method of file-like objects):

```
>>> text1 = ''' 1. Beautiful is better than ugly.
... 2. Explicit is better than implicit.
... 3. Simple is better than complex.
... 4. Complex is better than complicated.
... '''.splitlines(keepends=True)
>>> len(text1)
4
>>> text1[0][-1]
'\n'
>>> text2 = ''' 1. Beautiful is better than ugly.
... 3. Simple is better than complex.
... 4. Complicated is better than complex.
... 5. Flat is better than nested.
... '''.splitlines(keepends=True)
```

Next we instantiate a *Differ* object:

```
>>> d = Differ()
```

Note that when instantiating a *Differ* object we may pass functions to filter out line and character «junk.» See the *Differ()* constructor for details.

Finally, we compare the two:

```
>>> result = list(d.compare(text1, text2))
```

result is a list of strings, so let's pretty-print it:

```
>>> from pprint import pprint
>>> pprint(result)
['  1. Beautiful is better than ugly.\n',
'-  2. Explicit is better than implicit.\n',
'-  3. Simple is better than complex.\n',
'+  3.   Simple is better than complex.\n',
'?    ++\n',
'-  4. Complex is better than complicated.\n',
'?      ^                ---- ^\n',
'+  4. Complicated is better than complex.\n',
'?      ++++ ^                ^\n',
'+  5. Flat is better than nested.\n']
```

As a single multi-line string it looks like this:

```
>>> import sys
>>> sys.stdout.writelines(result)
 1. Beautiful is better than ugly.
- 2. Explicit is better than implicit.
- 3. Simple is better than complex.
+ 3.   Simple is better than complex.
?    ++
- 4. Complex is better than complicated.
?      ^                ---- ^
+ 4. Complicated is better than complex.
?      ++++ ^                ^
+ 5. Flat is better than nested.
```

6.3.5 A command-line interface to difflib

This example shows how to use difflib to create a diff-like utility. It is also contained in the Python source distribution, as Tools/scripts/diff.py.

```
#!/usr/bin/env python3
""" Command line interface to difflib.py providing diffs in four formats:

* ndiff:    lists every line and highlights interline changes.
* context:  highlights clusters of changes in a before/after format.
* unified:  highlights clusters of changes in an inline format.
* html:     generates side by side comparison with change highlights.

"""

import sys, os, difflib, argparse
from datetime import datetime, timezone

def file_mtime(path):
    t = datetime.fromtimestamp(os.stat(path).st_mtime,
                              timezone.utc)
    return t.astimezone().isoformat()
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

def main():

    parser = argparse.ArgumentParser()
    parser.add_argument('-c', action='store_true', default=False,
                        help='Produce a context format diff (default)')
    parser.add_argument('-u', action='store_true', default=False,
                        help='Produce a unified format diff')

→todate, n=n)

    sys.stdout.writelines(diff)

if __name__ == '__main__':
    main()

```

6.4 textwrap — Text wrapping and filling

Source code: [Lib/textwrap.py](#)

The `textwrap` module provides some convenience functions, as well as `TextWrapper`, the class that does all the work. If you're just wrapping or filling one or two text strings, the convenience functions should be good enough; otherwise, you should use an instance of `TextWrapper` for efficiency.

```
textwrap.wrap(text, width=70, *, initial_indent="", subsequent_indent="", expand_tabs=True,
               replace_whitespace=True, fix_sentence_endings=False, break_long_words=True,
               drop_whitespace=True, break_on_hyphens=True, tabsize=8, max_lines=None, placeholder='
[...]')
```

Wraps the single paragraph in `text` (a string) so every line is at most `width` characters long. Returns a list of output lines, without final newlines.

Optional keyword arguments correspond to the instance attributes of `TextWrapper`, documented below.

See the `TextWrapper.wrap()` method for additional details on how `wrap()` behaves.

```
textwrap.fill(text, width=70, *, initial_indent="", subsequent_indent="", expand_tabs=True,
               replace_whitespace=True, fix_sentence_endings=False, break_long_words=True,
               drop_whitespace=True, break_on_hyphens=True, tabsize=8, max_lines=None, placeholder='
[...]')
```

Wraps the single paragraph in `text`, and returns a single string containing the wrapped paragraph. `fill()` is shorthand for

```
"\n".join(wrap(text, ...))
```

In particular, `fill()` accepts exactly the same keyword arguments as `wrap()`.

```
textwrap.shorten(text, width, *, fix_sentence_endings=False, break_long_words=True,
                  break_on_hyphens=True, placeholder='[...]')
```

Collapse and truncate the given `text` to fit in the given `width`.

First the whitespace in `text` is collapsed (all whitespace is replaced by single spaces). If the result fits in the `width`, it is returned. Otherwise, enough words are dropped from the end so that the remaining words plus the `placeholder` fit within `width`:

```
>>> textwrap.shorten("Hello world!", width=12)
'Hello world!'
>>> textwrap.shorten("Hello world!", width=11)
'Hello [...]'
>>> textwrap.shorten("Hello world", width=10, placeholder="...")
'Hello...'
```

Optional keyword arguments correspond to the instance attributes of `TextWrapper`, documented below. Note that the whitespace is collapsed before the text is passed to the `TextWrapper.fill()` function, so changing the value of `tabsize`, `expand_tabs`, `drop_whitespace`, and `replace_whitespace` will have no effect.

Νέο στην έκδοση 3.4.

```
textwrap.dedent(text)
```

Remove any common leading whitespace from every line in `text`.

This can be used to make triple-quoted strings line up with the left edge of the display, while still presenting them in the source code in indented form.

Note that tabs and spaces are both treated as whitespace, but they are not equal: the lines `" hello"` and `"\thello"` are considered to have no common leading whitespace.

Lines containing only whitespace are ignored in the input and normalized to a single newline character in the output.

For example:

```
def test():
    # end first line with \ to avoid the empty line!
    s = '''\
hello
    world
'''
    print(repr(s))          # prints '    hello\n        world\n    '
    print(repr(dedent(s)))  # prints 'hello\n world\n'
```

`textwrap.indent(text, prefix, predicate=None)`

Add *prefix* to the beginning of selected lines in *text*.

Lines are separated by calling `text.splitlines(True)`.

By default, *prefix* is added to all lines that do not consist solely of whitespace (including any line endings).

For example:

```
>>> s = 'hello\n\n \nworld'
>>> indent(s, ' ')
' hello\n\n \n world'
```

The optional *predicate* argument can be used to control which lines are indented. For example, it is easy to add *prefix* to even empty and whitespace-only lines:

```
>>> print(indent(s, '+ ', lambda line: True))
+ hello
+
+
+ world
```

Νέο στην έκδοση 3.3.

`wrap()`, `fill()` and `shorten()` work by creating a `TextWrapper` instance and calling a single method on it. That instance is not reused, so for applications that process many text strings using `wrap()` and/or `fill()`, it may be more efficient to create your own `TextWrapper` object.

Text is preferably wrapped on whitespaces and right after the hyphens in hyphenated words; only then will long words be broken if necessary, unless `TextWrapper.break_long_words` is set to false.

class `textwrap.TextWrapper` (***kwargs*)

The `TextWrapper` constructor accepts a number of optional keyword arguments. Each keyword argument corresponds to an instance attribute, so for example

```
wrapper = TextWrapper(initial_indent="* ")
```

is the same as

```
wrapper = TextWrapper()
wrapper.initial_indent = "* "
```

You can re-use the same `TextWrapper` object many times, and you can change any of its options through direct assignment to instance attributes between uses.

The `TextWrapper` instance attributes (and keyword arguments to the constructor) are as follows:

width

(default: 70) The maximum length of wrapped lines. As long as there are no individual words in the input text longer than `width`, `TextWrapper` guarantees that no output line will be longer than `width` characters.

expand_tabs

(default: `True`) If true, then all tab characters in `text` will be expanded to spaces using the `expandtabs()` method of `text`.

tabsize

(default: 8) If `expand_tabs` is true, then all tab characters in `text` will be expanded to zero or more spaces, depending on the current column and the given tab size.

Νέο στην έκδοση 3.3.

replace_whitespace

(default: `True`) If true, after tab expansion but before wrapping, the `wrap()` method will replace each whitespace character with a single space. The whitespace characters replaced are as follows: tab, newline, vertical tab, formfeed, and carriage return (`'\t\n\v\f\r'`).

Σημείωση: If `expand_tabs` is false and `replace_whitespace` is true, each tab character will be replaced by a single space, which is *not* the same as tab expansion.

Σημείωση: If `replace_whitespace` is false, newlines may appear in the middle of a line and cause strange output. For this reason, text should be split into paragraphs (using `str.splitlines()` or similar) which are wrapped separately.

drop_whitespace

(default: `True`) If true, whitespace at the beginning and ending of every line (after wrapping but before indenting) is dropped. Whitespace at the beginning of the paragraph, however, is not dropped if non-whitespace follows it. If whitespace being dropped takes up an entire line, the whole line is dropped.

initial_indent

(default: `' '`) String that will be prepended to the first line of wrapped output. Counts towards the length of the first line. The empty string is not indented.

subsequent_indent

(default: `' '`) String that will be prepended to all lines of wrapped output except the first. Counts towards the length of each line except the first.

fix_sentence_endings

(default: `False`) If true, `TextWrapper` attempts to detect sentence endings and ensure that sentences are always separated by exactly two spaces. This is generally desired for text in a monospaced font. However, the sentence detection algorithm is imperfect: it assumes that a sentence ending consists of a lowercase letter followed by one of `'.'`, `','`, `':'`, or `'?'`, possibly followed by one of `'\"'` or `'\"'`, followed by a space. One problem with this algorithm is that it is unable to detect the difference between «Dr.» in

```
[...] Dr. Frankenstein's monster [...]
```

and «Spot.» in

```
[...] See Spot. See Spot run [...]
```

`fix_sentence_endings` is false by default.

Since the sentence detection algorithm relies on `string.lowercase` for the definition of «lowercase letter», and a convention of using two spaces after a period to separate sentences on the same line, it is

specific to English-language texts.

break_long_words

(default: `True`) If true, then words longer than *width* will be broken in order to ensure that no lines are longer than *width*. If it is false, long words will not be broken, and some lines may be longer than *width*. (Long words will be put on a line by themselves, in order to minimize the amount by which *width* is exceeded.)

break_on_hyphens

(default: `True`) If true, wrapping will occur preferably on whitespaces and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set *break_long_words* to false if you want truly insecable words. Default behaviour in previous versions was to always allow breaking hyphenated words.

max_lines

(default: `None`) If not `None`, then the output will contain at most *max_lines* lines, with *placeholder* appearing at the end of the output.

Νέο στην έκδοση 3.4.

placeholder

(default: `' [. . .] '`) String that will appear at the end of the output text if it has been truncated.

Νέο στην έκδοση 3.4.

TextWrapper also provides some public methods, analogous to the module-level convenience functions:

wrap (*text*)

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. All wrapping options are taken from instance attributes of the *TextWrapper* instance. Returns a list of output lines, without final newlines. If the wrapped output has no content, the returned list is empty.

fill (*text*)

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph.

6.5 unicodedata — Unicode Database

This module provides access to the Unicode Character Database (UCD) which defines character properties for all Unicode characters. The data contained in this database is compiled from the *UCD version 13.0.0*.

The module uses the same names and symbols as defined by Unicode Standard Annex #44, «Unicode Character Database». It defines the following functions:

unicodedata.lookup (*name*)

Look up character by name. If a character with the given name is found, return the corresponding character. If not found, *KeyError* is raised.

Άλλαξε στην έκδοση 3.3: Support for name aliases¹ and named sequences² has been added.

unicodedata.name (*chr* [, *default*])

Returns the name assigned to the character *chr* as a string. If no name is defined, *default* is returned, or, if not given, *ValueError* is raised.

unicodedata.decimal (*chr* [, *default*])

Returns the decimal value assigned to the character *chr* as integer. If no such value is defined, *default* is returned, or, if not given, *ValueError* is raised.

¹ <https://www.unicode.org/Public/13.0.0/ucd/NameAliases.txt>

² <https://www.unicode.org/Public/13.0.0/ucd/NamedSequences.txt>

`unicodedata.digit(chr[, default])`

Returns the digit value assigned to the character *chr* as integer. If no such value is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.numeric(chr[, default])`

Returns the numeric value assigned to the character *chr* as float. If no such value is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.category(chr)`

Returns the general category assigned to the character *chr* as string.

`unicodedata.bidirectional(chr)`

Returns the bidirectional class assigned to the character *chr* as string. If no such value is defined, an empty string is returned.

`unicodedata.combining(chr)`

Returns the canonical combining class assigned to the character *chr* as integer. Returns 0 if no combining class is defined.

`unicodedata.east_asian_width(chr)`

Returns the east asian width assigned to the character *chr* as string.

`unicodedata.mirrored(chr)`

Returns the mirrored property assigned to the character *chr* as integer. Returns 1 if the character has been identified as a «mirrored» character in bidirectional text, 0 otherwise.

`unicodedata.decomposition(chr)`

Returns the character decomposition mapping assigned to the character *chr* as string. An empty string is returned in case no such mapping is defined.

`unicodedata.normalize(form, unistr)`

Return the normal form *form* for the Unicode string *unistr*. Valid values for *form* are “NFC”, “NFKC”, “NFD”, and “NFKD”.

The Unicode standard defines various normalization forms of a Unicode string, based on the definition of canonical equivalence and compatibility equivalence. In Unicode, several characters can be expressed in various way. For example, the character U+00C7 (LATIN CAPITAL LETTER C WITH CEDILLA) can also be expressed as the sequence U+0043 (LATIN CAPITAL LETTER C) U+0327 (COMBINING CEDILLA).

For each character, there are two normal forms: normal form C and normal form D. Normal form D (NFD) is also known as canonical decomposition, and translates each character into its decomposed form. Normal form C (NFC) first applies a canonical decomposition, then composes pre-combined characters again.

In addition to these two forms, there are two additional normal forms based on compatibility equivalence. In Unicode, certain characters are supported which normally would be unified with other characters. For example, U+2160 (ROMAN NUMERAL ONE) is really the same thing as U+0049 (LATIN CAPITAL LETTER I). However, it is supported in Unicode for compatibility with existing character sets (e.g. gb2312).

The normal form KD (NFKD) will apply the compatibility decomposition, i.e. replace all compatibility characters with their equivalents. The normal form KC (NFKC) first applies the compatibility decomposition, followed by the canonical composition.

Even if two unicode strings are normalized and look the same to a human reader, if one has combining characters and the other doesn't, they may not compare equal.

`unicodedata.is_normalized(form, unistr)`

Return whether the Unicode string *unistr* is in the normal form *form*. Valid values for *form* are “NFC”, “NFKC”, “NFD”, and “NFKD”.

Νέο στην έκδοση 3.8.

In addition, the module exposes the following constant:

`unicodedata.unicdata_version`

The version of the Unicode database used in this module.

`unicodedata.ucd_3_2_0`

This is an object that has the same methods as the entire module, but uses the Unicode database version 3.2 instead, for applications that require this specific version of the Unicode database (such as IDNA).

Examples:

```
>>> import unicodedata
>>> unicodedata.lookup('LEFT CURLY BRACKET')
'{'
>>> unicodedata.name('/')
'SOLIDUS'
>>> unicodedata.decimal('9')
9
>>> unicodedata.decimal('a')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: not a decimal
>>> unicodedata.category('A') # 'L'etter, 'u'ppercase
'Lu'
>>> unicodedata.bidirectional('\u0660') # 'A'rabic, 'N'umber
'AN'
```

6.6 stringprep — Internet String Preparation

Source code: [Lib/stringprep.py](#)

When identifying things (such as host names) in the internet, it is often necessary to compare such identifications for «equality». Exactly how this comparison is executed may depend on the application domain, e.g. whether it should be case-insensitive or not. It may be also necessary to restrict the possible identifications, to allow only identifications consisting of «printable» characters.

RFC 3454 defines a procedure for «preparing» Unicode strings in internet protocols. Before passing strings onto the wire, they are processed with the preparation procedure, after which they have a certain normalized form. The RFC defines a set of tables, which can be combined into profiles. Each profile must define which tables it uses, and what other optional parts of the `stringprep` procedure are part of the profile. One example of a `stringprep` profile is `nameprep`, which is used for internationalized domain names.

The module `stringprep` only exposes the tables from **RFC 3454**. As these tables would be very large to represent them as dictionaries or lists, the module uses the Unicode character database internally. The module source code itself was generated using the `mkstringprep.py` utility.

As a result, these tables are exposed as functions, not as data structures. There are two kinds of tables in the RFC: sets and mappings. For a set, `stringprep` provides the «characteristic function», i.e. a function that returns `True` if the parameter is part of the set. For mappings, it provides the mapping function: given the key, it returns the associated value. Below is a list of all functions available in the module.

`stringprep.in_table_a1` (*code*)

Determine whether *code* is in tableA.1 (Unassigned code points in Unicode 3.2).

`stringprep.in_table_b1` (*code*)

Determine whether *code* is in tableB.1 (Commonly mapped to nothing).

`stringprep.map_table_b2 (code)`
 Return the mapped value for *code* according to tableB.2 (Mapping for case-folding used with NFKC).

`stringprep.map_table_b3 (code)`
 Return the mapped value for *code* according to tableB.3 (Mapping for case-folding used with no normalization).

`stringprep.in_table_c11 (code)`
 Determine whether *code* is in tableC.1.1 (ASCII space characters).

`stringprep.in_table_c12 (code)`
 Determine whether *code* is in tableC.1.2 (Non-ASCII space characters).

`stringprep.in_table_c11_c12 (code)`
 Determine whether *code* is in tableC.1 (Space characters, union of C.1.1 and C.1.2).

`stringprep.in_table_c21 (code)`
 Determine whether *code* is in tableC.2.1 (ASCII control characters).

`stringprep.in_table_c22 (code)`
 Determine whether *code* is in tableC.2.2 (Non-ASCII control characters).

`stringprep.in_table_c21_c22 (code)`
 Determine whether *code* is in tableC.2 (Control characters, union of C.2.1 and C.2.2).

`stringprep.in_table_c3 (code)`
 Determine whether *code* is in tableC.3 (Private use).

`stringprep.in_table_c4 (code)`
 Determine whether *code* is in tableC.4 (Non-character code points).

`stringprep.in_table_c5 (code)`
 Determine whether *code* is in tableC.5 (Surrogate codes).

`stringprep.in_table_c6 (code)`
 Determine whether *code* is in tableC.6 (Inappropriate for plain text).

`stringprep.in_table_c7 (code)`
 Determine whether *code* is in tableC.7 (Inappropriate for canonical representation).

`stringprep.in_table_c8 (code)`
 Determine whether *code* is in tableC.8 (Change display properties or are deprecated).

`stringprep.in_table_c9 (code)`
 Determine whether *code* is in tableC.9 (Tagging characters).

`stringprep.in_table_d1 (code)`
 Determine whether *code* is in tableD.1 (Characters with bidirectional property «R» or «AL»).

`stringprep.in_table_d2 (code)`
 Determine whether *code* is in tableD.2 (Characters with bidirectional property «L»).

6.7 readline — GNU readline interface

The `readline` module defines a number of functions to facilitate completion and reading/writing of history files from the Python interpreter. This module can be used directly, or via the `rlcompleter` module, which supports completion of Python identifiers at the interactive prompt. Settings made using this module affect the behaviour of both the interpreter's interactive prompt and the prompts offered by the built-in `input()` function.

Readline keybindings may be configured via an initialization file, typically `.inputrc` in your home directory. See [Readline Init File](#) in the GNU Readline manual for information about the format and allowable constructs of that file, and the capabilities of the Readline library in general.

Σημείωση: The underlying Readline library API may be implemented by the `libedit` library instead of GNU readline. On macOS the `readline` module detects which library is being used at run time.

The configuration file for `libedit` is different from that of GNU readline. If you programmatically load configuration strings you can check for the text «libedit» in `readline.__doc__` to differentiate between GNU readline and libedit.

If you use `editline/libedit` readline emulation on macOS, the initialization file located in your home directory is named `.editrc`. For example, the following content in `~/ .editrc` will turn ON *vi* keybindings and TAB completion:

```
python:bind -v
python:bind ^I rl_complete
```

6.7.1 Init file

The following functions relate to the init file and user configuration:

`readline.parse_and_bind(string)`
Execute the init line provided in the *string* argument. This calls `rl_parse_and_bind()` in the underlying library.

`readline.read_init_file([filename])`
Execute a readline initialization file. The default filename is the last filename used. This calls `rl_read_init_file()` in the underlying library.

6.7.2 Line buffer

The following functions operate on the line buffer:

`readline.get_line_buffer()`
Return the current contents of the line buffer (`rl_line_buffer` in the underlying library).

`readline.insert_text(string)`
Insert text into the line buffer at the cursor position. This calls `rl_insert_text()` in the underlying library, but ignores the return value.

`readline.redisplay()`
Change what's displayed on the screen to reflect the current contents of the line buffer. This calls `rl_redisplay()` in the underlying library.

6.7.3 History file

The following functions operate on a history file:

`readline.read_history_file([filename])`
Load a readline history file, and append it to the history list. The default filename is `~/ .history`. This calls `read_history()` in the underlying library.

`readline.write_history_file([filename])`
Save the history list to a readline history file, overwriting any existing file. The default filename is `~/ .history`. This calls `write_history()` in the underlying library.

`readline.append_history_file(nelements[, filename])`

Append the last *nelements* items of history to a file. The default filename is `~/.history`. The file must already exist. This calls `append_history()` in the underlying library. This function only exists if Python was compiled for a version of the library that supports it.

Νέο στην έκδοση 3.5.

`readline.get_history_length()`

`readline.set_history_length(length)`

Set or return the desired number of lines to save in the history file. The `write_history_file()` function uses this value to truncate the history file, by calling `history_truncate_file()` in the underlying library. Negative values imply unlimited history file size.

6.7.4 History list

The following functions operate on a global history list:

`readline.clear_history()`

Clear the current history. This calls `clear_history()` in the underlying library. The Python function only exists if Python was compiled for a version of the library that supports it.

`readline.get_current_history_length()`

Return the number of items currently in the history. (This is different from `get_history_length()`, which returns the maximum number of lines that will be written to a history file.)

`readline.get_history_item(index)`

Return the current contents of history item at *index*. The item index is one-based. This calls `history_get()` in the underlying library.

`readline.remove_history_item(pos)`

Remove history item specified by its position from the history. The position is zero-based. This calls `remove_history()` in the underlying library.

`readline.replace_history_item(pos, line)`

Replace history item specified by its position with *line*. The position is zero-based. This calls `replace_history_entry()` in the underlying library.

`readline.add_history(line)`

Append *line* to the history buffer, as if it was the last line typed. This calls `add_history()` in the underlying library.

`readline.set_auto_history(enabled)`

Enable or disable automatic calls to `add_history()` when reading input via `readline`. The *enabled* argument should be a Boolean value that when true, enables auto history, and that when false, disables auto history.

Νέο στην έκδοση 3.6.

CPython implementation detail: Auto history is enabled by default, and changes to this do not persist across multiple sessions.

6.7.5 Startup hooks

`readline.set_startup_hook([function])`

Set or remove the function invoked by the `rl_startup_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments just before `readline` prints the first prompt.

`readline.set_pre_input_hook([function])`

Set or remove the function invoked by the `rl_pre_input_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments after the first prompt has been printed and just before `readline` starts reading input characters. This function only exists if Python was compiled for a version of the library that supports it.

6.7.6 Completion

The following functions relate to implementing a custom word completion function. This is typically operated by the Tab key, and can suggest and automatically complete a word being typed. By default, `Readline` is set up to be used by `rlcompleter` to complete Python identifiers for the interactive interpreter. If the `readline` module is to be used with a custom completer, a different set of word delimiters should be set.

`readline.set_completer([function])`

Set or remove the completer function. If *function* is specified, it will be used as the new completer function; if omitted or `None`, any completer function already installed is removed. The completer function is called as `function(text, state)`, for *state* in 0, 1, 2, ..., until it returns a non-string value. It should return the next possible completion starting with *text*.

The installed completer function is invoked by the `entry_func` callback passed to `rl_completion_matches()` in the underlying library. The *text* string comes from the first parameter to the `rl_attempted_completion_function` callback of the underlying library.

`readline.get_completer()`

Get the completer function, or `None` if no completer function has been set.

`readline.get_completion_type()`

Get the type of completion being attempted. This returns the `rl_completion_type` variable in the underlying library as an integer.

`readline.get_begidx()`

`readline.get_endidx()`

Get the beginning or ending index of the completion scope. These indexes are the *start* and *end* arguments passed to the `rl_attempted_completion_function` callback of the underlying library.

`readline.set_completer_delims(string)`

`readline.get_completer_delims()`

Set or get the word delimiters for completion. These determine the start of the word to be considered for completion (the completion scope). These functions access the `rl_completer_word_break_characters` variable in the underlying library.

`readline.set_completion_display_matches_hook([function])`

Set or remove the completion display function. If *function* is specified, it will be used as the new completion display function; if omitted or `None`, any completion display function already installed is removed. This sets or clears the `rl_completion_display_matches_hook` callback in the underlying library. The completion display function is called as `function(substitution, [matches], longest_match_length)` once each time matches need to be displayed.

6.7.7 Example

The following example demonstrates how to use the `readline` module's history reading and writing functions to automatically load and save a history file named `.python_history` from the user's home directory. The code below would normally be executed automatically during interactive sessions from the user's `PYTHONSTARTUP` file.

```
import atexit
import os
import readline

histfile = os.path.join(os.path.expanduser("~"), ".python_history")
try:
    readline.read_history_file(histfile)
    # default history len is -1 (infinite), which may grow unruly
    readline.set_history_length(1000)
except FileNotFoundError:
    pass

atexit.register(readline.write_history_file, histfile)
```

This code is actually automatically run when Python is run in interactive mode (see [Readline configuration](#)).

The following example achieves the same goal but supports concurrent interactive sessions, by only appending the new history.

```
import atexit
import os
import readline

histfile = os.path.join(os.path.expanduser("~"), ".python_history")

try:
    readline.read_history_file(histfile)
    h_len = readline.get_current_history_length()
except FileNotFoundError:
    open(histfile, 'wb').close()
    h_len = 0

def save(prev_h_len, histfile):
    new_h_len = readline.get_current_history_length()
    readline.set_history_length(1000)
    readline.append_history_file(new_h_len - prev_h_len, histfile)
atexit.register(save, h_len, histfile)
```

The following example extends the `code.InteractiveConsole` class to support history save/restore.

```
import atexit
import code
import os
import readline

class HistoryConsole(code.InteractiveConsole):
    def __init__(self, locals=None, filename="<console>",
                 histfile=os.path.expanduser("~/console-history")):
        code.InteractiveConsole.__init__(self, locals, filename)
        self.init_history(histfile)

    def init_history(self, histfile):
        readline.parse_and_bind("tab: complete")
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

if hasattr(readline, "read_history_file"):
    try:
        readline.read_history_file(histfile)
    except FileNotFoundError:
        pass
    atexit.register(self.save_history, histfile)

def save_history(self, histfile):
    readline.set_history_length(1000)
    readline.write_history_file(histfile)

```

6.8 rlcompleter — Completion function for GNU readline

Source code: [Lib/rlcompleter.py](#)

The `rlcompleter` module defines a completion function suitable for the `readline` module by completing valid Python identifiers and keywords.

When this module is imported on a Unix platform with the `readline` module available, an instance of the `Completer` class is automatically created and its `complete()` method is set as the `readline` completer.

Example:

```

>>> import rlcompleter
>>> import readline
>>> readline.parse_and_bind("tab: complete")
>>> readline. <TAB PRESSED>
readline.__doc__          readline.get_line_buffer(  readline.read_init_file(
readline.__file__        readline.insert_text(      readline.set_completer(
readline.__name__        readline.parse_and_bind(
>>> readline.

```

The `rlcompleter` module is designed for use with Python's interactive mode. Unless Python is run with the `-S` option, the module is automatically imported and configured (see [Readline configuration](#)).

On platforms without `readline`, the `Completer` class defined by this module can still be used for custom purposes.

6.8.1 Completer Objects

Completer objects have the following method:

`Completer.complete(text, state)`

Return the *stateth* completion for *text*.

If called for *text* that doesn't include a period character (`'.'`), it will complete from names currently defined in `__main__`, `builtins` and keywords (as defined by the `keyword` module).

If called for a dotted name, it will try to evaluate anything without obvious side-effects (functions will not be evaluated, but it can generate calls to `__getattr__()` up to the last part, and find matches for the rest via the `dir()` function. Any exception raised during the evaluation of the expression is caught, silenced and `None` is returned.

Binary Data Services

The modules described in this chapter provide some basic services operations for manipulation of binary data. Other operations on binary data, specifically in relation to file formats and network protocols, are described in the relevant sections.

Some libraries described under *Text Processing Services* also work with either ASCII-compatible binary formats (for example, *re*) or all binary data (for example, *difflib*).

In addition, see the documentation for Python's built-in binary data types in *Τύποι δυαδικής ακολουθίας* — *bytes*, *bytearray*, *memoryview*.

7.1 struct — Interpret bytes as packed binary data

Πηγαίος κώδικας: `Lib/struct.py`

This module performs conversions between Python values and C structs represented as Python *bytes* objects. This can be used in handling binary data stored in files or from network connections, among other sources. It uses *Συμβολοσειρές μορφοποίησης* as compact descriptions of the layout of the C structs and the intended conversion to/from Python values.

Σημείωση: By default, the result of packing a given C struct includes pad bytes in order to maintain proper alignment for the C types involved; similarly, alignment is taken into account when unpacking. This behavior is chosen so that the bytes of a packed struct correspond exactly to the layout in memory of the corresponding C struct. To handle platform-independent data formats or omit implicit pad bytes, use `standard` size and alignment instead of `native` size and alignment: see *Διάταξη Byte, Μέγεθος και Στοιχίση* for details.

Αρκετές συναρτήσεις του *struct* (και μέθοδοι της κλάσης *Struct*) δέχονται μια παράμετρο *buffer*. Αυτή αναφέρεται σε αντικείμενα που υλοποιούν τα *bufferobjects* και παρέχουν είτε ένα αναγνώσιμο είτε έναν αναγνώσιμο-εγγράψιμο *buffer*. Οι πιο συνηθισμένοι τύποι που χρησιμοποιούνται για αυτόν τον σκοπό είναι οι *bytes* και *bytearray*, αλλά πολλοί άλλοι τύποι που μπορούν να θεωρηθούν ως πίνακες *bytes* υλοποιούν το πρωτόκολλο *buffer*, επιτρέποντας την ανάγνωση/τροφοδότηση χωρίς επιπλέον αντιγραφή από ένα αντικείμενο *bytes*.

7.1.1 Συναρτήσεις και εξαιρέσεις

Το module ορίζει την ακόλουθη εξαιρέση και συναρτήσεις:

exception `struct.error`

Εξαιρέση που γίνεται `raise` σε διάφορες περιπτώσεις· το όρισμα είναι μια συμβολοσειρά που περιγράφει το σφάλμα.

`struct.pack(format, v1, v2, ...)`

Επιστρέφει ένα αντικείμενο τύπου `bytes` που περιέχει τις τιμές `v1`, `v2`, ... πακεταρισμένες σύμφωνα με τη συμβολοσειρά μορφοποίησης `format`. Τα ορίσματα πρέπει να ταιριάζουν ακριβώς με τις απαιτούμενες τιμές της μορφοποίησης.

`struct.pack_into(format, buffer, offset, v1, v2, ...)`

Πακετάρει τις τιμές `v1`, `v2`, ... σύμφωνα με τη συμβολοσειρά μορφοποίησης `format` και γράφει τα πακεταρισμένα `bytes` στον εγγράψιμο `buffer` ξεκινώντας από τη θέση `offset`. Σημειώστε ότι το `offset` είναι υποχρεωτικό όρισμα.

`struct.unpack(format, buffer)`

Αποσυμπιέζει από τον `buffer` `buffer` (ο οποίος υποτίθεται έχει πακεταριστεί με τη μέθοδο `pack(format, ...)`) σύμφωνα με την συμβολοσειρά μορφοποίησης `format`. Το αποτέλεσμα είναι μια πλειάδα, ακόμα κι αν περιέχει μόνο ένα στοιχείο. Το μέγεθος του `buffer` σε `bytes` πρέπει να ταιριάζει με το απαιτούμενο μέγεθος σύμφωνα με τη μορφή, όπως καθορίζεται από τη συνάρτηση `calcsize()`.

`struct.unpack_from(format, /, buffer, offset=0)`

Αποσυμπιέζει από τον `buffer` ξεκινώντας από τη θέση `offset`, σύμφωνα με τη συμβολοσειρά μορφοποίησης `format`. Το αποτέλεσμα είναι μια πλειάδα, ακόμα κι αν περιέχει μόνο ένα στοιχείο. Το μέγεθος του `buffer` σε `bytes`, ξεκινώντας από τη θέση `offset`, πρέπει να είναι τουλάχιστον το μέγεθος που απαιτείται από τη μορφή, όπως καθορίζεται από τη συνάρτηση `calcsize()`.

`struct.iter_unpack(format, buffer)`

Iteratively unpack from the `buffer` `buffer` according to the format string `format`. This function returns an iterator which will read equally-sized chunks from the buffer until all its contents have been consumed. The buffer's size in bytes must be a multiple of the size required by the format, as reflected by `calcsize()`.

Κάθε επανάληψη επιστρέφει μια πλειάδα σύμφωνα με τη συμβολοσειρά μορφοποίησης.

Νέο στην έκδοση 3.4.

`struct.calcsize(format)`

Επιστρέφει το μέγεθος της δομής (και κατά συνέπεια του αντικειμένου `bytes` που παράγεται από το `pack(format, ...)`) που αντιστοιχεί στη συμβολοσειρά μορφοποίησης `format`.

7.1.2 Συμβολοσειρές μορφοποίησης

Format strings are the mechanism used to specify the expected layout when packing and unpacking data. They are built up from *Χαρακτήρες μορφής*, which specify the type of data being packed/unpacked. In addition, there are special characters for controlling the *Διάταξη Byte*, *Μέγεθος και Στοιχισή*.

Διάταξη Byte, Μέγεθος και Στοιχισι

By default, C types are represented in the machine's native format and byte order, and properly aligned by skipping pad bytes if necessary (according to the rules used by the C compiler).

Εναλλακτικά, ο πρώτος χαρακτήρας της συμβολοσειράς μορφοποίησης μπορεί να χρησιμοποιηθεί για να υποδείξει τη σειρά byte, το μέγεθος και την ευθυγράμμιση των συσκευασμένων δεδομένων, σύμφωνα με το παρακάτω πίνακα:

| Χαρακτήρας | Σειρά bytes | Μέγεθος | Στοιχισι |
|------------|-----------------------|---------|----------|
| @ | native | native | native |
| = | native | τυπικό | κανένα |
| < | little-endian | τυπικό | κανένα |
| > | big-endian | τυπικό | κανένα |
| ! | δίκτυο (= big-endian) | τυπικό | κανένα |

Αν ο πρώτος χαρακτήρας δεν είναι ένας από αυτούς, υποτίθεται ' @ '.

Native byte order is big-endian or little-endian, depending on the host system. For example, Intel x86 and AMD64 (x86-64) are little-endian; Motorola 68000 and PowerPC G5 are big-endian; ARM and Intel Itanium feature switchable endianness (bi-endian). Use `sys.byteorder` to check the endianness of your system.

Το native μέγεθος και η στοιχισι καθορίζονται χρησιμοποιώντας την έκφραση `sizeof` του μεταγλωττιστή C. Αυτό συνδυάζεται πάντα με την native σειρά byte.

Το τυπικό μέγεθος εξαρτάται μόνο από τον χαρακτήρα μορφοποίησης· δείτε τον πίνακα στην ενότητα *Χαρακτήρες μορφής*.

Σημειώστε τη διαφορά μεταξύ του ' @ ' και ' = ': και τα δύο χρησιμοποιούν τη native σειρά byte, αλλά το μέγεθος και η στοιχισι του τελευταίου είναι τυποποιημένα.

Η μορφή ' ! ' αντιπροσωπεύει τη σειρά byte του δικτύου, η οποία είναι πάντα big-endian όπως ορίζεται στο [IETF RFC 1700](#).

Δεν υπάρχει τρόπος να δηλωθεί non-native σειρά byte (να επιβληθεί εναλλαγή byte). Χρησιμοποιήστε την κατάλληλη επιλογή ' < ' ή ' > '.

Σημειώσεις:

- (1) Το συμπλήρωμα (padding) προστίθεται αυτόματα μόνο μεταξύ διαδοχικών μελών της δομής. Δεν προστίθεται συμπλήρωμα στην αρχή ή στο τέλος της κωδικοποιημένης δομής.
- (2) Δεν προστίθεται συμπλήρωμα όταν χρησιμοποιείται non-native μέγεθος και στοιχισι, π.χ. με "<", ">", "=", και "!".
- (3) Για να ευθυγραμμίσετε το τέλος μιας δομής με την απαίτηση στοιχισι ενός συγκεκριμένου τύπου, τελειώστε τη μορφή με τον κωδικό για αυτό τον τύπο με πλήθος επαναλήψεων μηδέν. Δείτε *Παραδείγματα*.

Χαρακτήρες μορφής

Οι χαρακτήρες μορφής έχουν την ακόλουθη σημασία: η μετατροπή μεταξύ τιμών C και Python είναι προφανής, δεδομένων των τύπων τους. Η στήλη "Τυπικό μέγεθος" αναφέρεται στο μέγεθος της συμπίεσμνης τιμής σε byte όταν χρησιμοποιείται τυπικό μέγεθος: δηλαδή, όταν η συμβολοσειρά μορφής ξεκινά με ένα από τα ' < ', ' > ', ' ! ' or ' = '. Όταν χρησιμοποιείται το native μέγεθος, το μέγεθος της συμπίεσμνης τιμής εξαρτάται από την πλατφόρμα.

| Μορφή | Τύπος C | Τύπος Python | Τυπικό μέγεθος | Σημειώσεις |
|-------|---------------------|----------------|----------------|------------|
| x | συμπληρωματικό byte | καμία τιμή | | |
| c | char | bytes μήκους 1 | 1 | |
| b | signed char | integer | 1 | (1), (2) |
| B | unsigned char | integer | 1 | (2) |
| ? | _Bool | bool | 1 | (1) |
| h | short | integer | 2 | (2) |
| H | unsigned short | integer | 2 | (2) |
| i | int | integer | 4 | (2) |
| I | unsigned int | integer | 4 | (2) |
| l | long | integer | 4 | (2) |
| L | unsigned long | integer | 4 | (2) |
| q | long long | integer | 8 | (2) |
| Q | unsigned long long | integer | 8 | (2) |
| n | ssize_t | integer | | (3) |
| N | size_t | integer | | (3) |
| e | (6) | float | 2 | (4) |
| f | float | float | 4 | (4) |
| d | double | float | 8 | (4) |
| s | char[] | bytes | | |
| p | char[] | bytes | | |
| P | void * | integer | | (5) |

Άλλαξε στην έκδοση 3.3: Προστέθηκε υποστήριξη για τις μορφές 'n' και 'N'.

Άλλαξε στην έκδοση 3.6: Προστέθηκε υποστήριξη για τη μορφή 'e'.

Σημειώσεις:

- (1) The ' ? ' conversion code corresponds to the `_Bool` type defined by C99. If this type is not available, it is simulated using a `char`. In standard mode, it is always represented by one byte.
- (2) When attempting to pack a non-integer using any of the integer conversion codes, if the non-integer has a `__index__()` method then that method is called to convert the argument to an integer before packing.

Άλλαξε στην έκδοση 3.2: Added use of the `__index__()` method for non-integers.

- (3) Οι κωδικοί μετατροπής 'n' και 'N' είναι διαθέσιμοι μόνο για το native μέγεθος (επιλεγμένο ως προ-επιλογή ή με τον χαρακτήρα διάταξης byte '@'). Για το τυπικό μέγεθος, μπορείτε να χρησιμοποιήσετε οποιαδήποτε από τις άλλες μορφές ακέραιων που ταιριάζουν στην εφαρμογή σας.
- (4) Για τους κωδικούς μετατροπής 'f', 'd' και 'e', η συσκευασμένη αναπαράσταση χρησιμοποιεί τη μορφή IEEE 754 binary32, binary64 ή binary16 (αντίστοιχα για 'f', 'd' ή 'e'), ανεξάρτητα από τη μορφή κινητής υποδιαστολής που χρησιμοποιεί η πλατφόρμα.
- (5) Ο χαρακτήρας μορφοποίησης 'P' είναι διαθέσιμος μόνο για τη φυσική σειρά byte (επιλεγμένη ως προ-επιλογή ή με τον χαρακτήρα σειράς byte '='). Ο χαρακτήρας σειράς byte '=' επιλέγει τη χρήση little- ή big-endian σειράς με βάση το σύστημα. Το module `struct` δεν ερμηνεύει αυτό ως native σειρά, επομένως η μορφή 'P' δεν είναι διαθέσιμη.
- (6) Ο τύπος IEEE 754 binary16 «half precision» εισήχθη στην αναθεώρηση του 2008 του προτύπου [IEEE 754 standard](#). Διαθέτει ένα bit προσήμου, έναν εκθέτη 5-bit και ακρίβεια 11-bit (με 10 bit αποθηκευμένα ρητά) και μπορεί να αναπαραστήσει αριθμούς μεταξύ περίπου $6.1e-05$ και $6.5e+04$ με πλήρη ακρίβεια. Αυτός ο τύπος δεν υποστηρίζεται ευρέως από τους μεταγλωττιστές της C: σε μια τυπική μηχανή, ένας μη προσημασμένος short μπορεί να χρησιμοποιηθεί για αποθήκευση, αλλά όχι για αριθμητικές πράξεις. Δείτε τη σελίδα της Wikipedia για τη [half-precision floating-point format](#) για περισσότερες πληροφορίες.

Ένας χαρακτήρας μορφοποίησης μπορεί να προηγείται από έναν ακέραιο αριθμό επαναλήψεων. Για παράδειγμα, η συμβολοσειρά μορφοποίησης '4h' σημαίνει ακριβώς το ίδιο με 'hhhh'.

Οι χαρακτήρες κενού μεταξύ των μορφοποιήσεων αγνοούνται· ωστόσο, ένας αριθμός και η μορφή του δεν πρέπει να περιέχουν κενά.

For the 's' format character, the count is interpreted as the length of the bytes, not a repeat count like for the other format characters; for example, '10s' means a single 10-byte string, while '10c' means 10 characters. If a count is not given, it defaults to 1. For packing, the string is truncated or padded with null bytes as appropriate to make it fit. For unpacking, the resulting bytes object always has exactly the specified number of bytes. As a special case, '0s' means a single, empty string (while '0c' means 0 characters).

Κατά το πακετάρισμα μιας τιμής x χρησιμοποιώντας μια από τις μορφές ακεραίων ('b', 'B', 'h', 'H', 'i', 'I', 'l', 'L', 'q', 'Q'), εάν το x είναι εκτός του έγκυρου εύρους για αυτήν τη μορφή, γίνεται raise μια εξαίρεση `struct.error`.

Άλλαξε στην έκδοση 3.1: Προηγουμένως, ορισμένες από τις μορφές ακεραίων περιτύλιγαν τιμές εκτός εύρους και εμφάνιζαν `DeprecationWarning` αντί για `struct.error`.

Ο χαρακτήρας μορφοποίησης 'p' κωδικοποιεί ένα «Pascal string», δηλαδή μια μικρή συμβολοσειρά μεταβλητού μήκους αποθηκευμένη σε σταθερό αριθμό byte, που καθορίζεται από τον μετρητή. Το πρώτο byte που αποθηκεύεται είναι το μήκος της συμβολοσειράς ή 255, όποιο είναι μικρότερο. Ακολουθούν τα byte της συμβολοσειράς. Εάν η συμβολοσειρά που περνά στην `pack()` είναι πολύ μεγάλη (μεγαλύτερη από τον μετρητή μείον 1), αποθηκεύονται μόνο τα πρώτα `count-1` byte της συμβολοσειράς. Εάν η συμβολοσειρά είναι μικρότερη από `count-1`, συμπληρώνεται με μηδενικά byte ώστε να χρησιμοποιηθούν ακριβώς τόσα byte όσα καθορίζει ο μετρητής. Σημειώστε ότι για τη `unpack()`, ο χαρακτήρας μορφοποίησης 'p' καταναλώνει `count` byte, αλλά η συμβολοσειρά που επιστρέφεται δεν μπορεί ποτέ να περιέχει περισσότερα από 255 byte.

Για το χαρακτήρα μορφής '?', η τιμή που επιστρέφεται είναι είτε `True` είτε `False`. Κατά την συσκευασία, χρησιμοποιείται η λογική τιμή του αντικειμένου-ορίσματος. Είτε 0 είτε 1 στη native ή τυπική αναπαράσταση του bool θα συσκευαστούν, και οποιαδήποτε μη μηδενική τιμή θα είναι `True` κατά την αποσυσκευασία.

Παραδείγματα

Σημείωση: All examples assume a native byte order, size, and alignment with a big-endian machine.

A basic example of packing/unpacking three integers:

```
>>> from struct import *
>>> pack('hhl', 1, 2, 3)
b'\x00\x01\x00\x02\x00\x00\x00\x03'
>>> unpack('hhl', b'\x00\x01\x00\x02\x00\x00\x00\x03')
(1, 2, 3)
>>> calcsiz('hhl')
8
```

Τα αποσυσκευασμένα πεδία μπορούν να ονομαστούν είτε αναθέτοντάς τα σε μεταβλητές είτε περιτυλίγοντάς τα σε μια ονομασμένη πλειάδα:

```
>>> record = b'raymond \x32\x12\x08\x01\x08'
>>> name, serialnum, school, gradelevel = unpack('<10sHHb', record)

>>> from collections import namedtuple
>>> Student = namedtuple('Student', 'name serialnum school gradelevel')
>>> Student._make(unpack('<10sHHb', record))
Student(name=b'raymond ', serialnum=4658, school=264, gradelevel=8)
```

The ordering of format characters may have an impact on size since the padding needed to satisfy alignment requirements is different:

```
>>> pack('ci', b'*', 0x12131415)
b'*\x00\x00\x00\x12\x13\x14\x15'
>>> pack('ic', 0x12131415, b'*')
b'\x12\x13\x14\x15*'
>>> calcsizes('ci')
8
>>> calcsizes('ic')
5
```

The following format 'llh01' specifies two pad bytes at the end, assuming longs are aligned on 4-byte boundaries:

```
>>> pack('llh01', 1, 2, 3)
b'\x00\x00\x00\x01\x00\x00\x00\x02\x00\x03\x00\x00'
```

This only works when native size and alignment are in effect; standard size and alignment does not enforce any alignment.

Module `array` Πακεταρισμένη δυαδική αποθήκευση ομοιογενών δεδομένων.

Module `xdrlib` Packing and unpacking of XDR data.

7.1.3 Κλάσεις

To module `struct` ορίζει επίσης τον ακόλουθο τύπο:

class `struct.Struct` (*format*)

Return a new Struct object which writes and reads binary data according to the format string *format*. Creating a Struct object once and calling its methods is more efficient than calling the `struct` functions with the same format since the format string only needs to be compiled once.

Σημείωση: The compiled versions of the most recent format strings passed to `Struct` and the module-level functions are cached, so programs that use only a few format strings needn't worry about reusing a single `Struct` instance.

Τα μεταγλωττισμένα αντικείμενα Struct υποστηρίζουν τις ακόλουθες μεθόδους και ιδιότητες:

pack (*v1*, *v2*, ...)

Ταυτόσημο με τη συνάρτηση `pack()`, χρησιμοποιώντας τη μεταγλωττισμένη μορφή. (`len(result)` θα είναι ίσο με *size*.)

pack_into (*buffer*, *offset*, *v1*, *v2*, ...)

Ταυτόσημο με τη συνάρτηση `pack_into()`, χρησιμοποιώντας τη μεταγλωττισμένη μορφή.

unpack (*buffer*)

Ταυτόσημο με τη συνάρτηση `unpack()`, χρησιμοποιώντας τη μεταγλωττισμένη μορφή. Το μέγεθος του *buffer* σε bytes πρέπει να είναι ίσο με *size*.

unpack_from (*buffer*, *offset*=0)

Ταυτόσημο με τη συνάρτηση `unpack_from()`, χρησιμοποιώντας τη μεταγλωττισμένη μορφή. Το μέγεθος του *buffer* σε bytes, ξεκινώντας από τη θέση *offset*, πρέπει να είναι τουλάχιστον *size*.

iter_unpack (*buffer*)

Ταυτόσημο με τη συνάρτηση `iter_unpack()`, χρησιμοποιώντας τη μεταγλωττισμένη μορφή. Το μέγεθος του *buffer* σε bytes πρέπει να είναι πολλαπλάσιο του *size*.

Νέο στην έκδοση 3.4.

format

Η συμβολοσειρά μορφής που χρησιμοποιήθηκε για τη δημιουργία αυτού του αντικειμένου Struct.

Άλλαξε στην έκδοση 3.7: Ο τύπος της συμβολοσειράς μορφής είναι πλέον *str* αντί για *bytes*.

size

Το υπολογισμένο μέγεθος της δομής (και κατά συνέπεια του αντικειμένου bytes που παράγεται από τη μέθοδο *pack()*) που αντιστοιχεί στη *format*.

7.2 codecs — Codec registry and base classes

Source code: [Lib/codecs.py](#)

This module defines base classes for standard Python codecs (encoders and decoders) and provides access to the internal Python codec registry, which manages the codec and error handling lookup process. Most standard codecs are *text encodings*, which encode text to bytes (and decode bytes to text), but there are also codecs provided that encode text to text, and bytes to bytes. Custom codecs may encode and decode between arbitrary types, but some module features are restricted to be used specifically with *text encodings* or with codecs that encode to *bytes*.

The module defines the following functions for encoding and decoding with any codec:

`codecs.encode(obj, encoding='utf-8', errors='strict')`

Encodes *obj* using the codec registered for *encoding*.

Errors may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that encoding errors raise *ValueError* (or a more codec specific subclass, such as *UnicodeEncodeError*). Refer to *Codec Base Classes* for more information on codec error handling.

`codecs.decode(obj, encoding='utf-8', errors='strict')`

Decodes *obj* using the codec registered for *encoding*.

Errors may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that decoding errors raise *ValueError* (or a more codec specific subclass, such as *UnicodeDecodeError*). Refer to *Codec Base Classes* for more information on codec error handling.

The full details for each codec can also be looked up directly:

`codecs.lookup(encoding)`

Looks up the codec info in the Python codec registry and returns a *CodecInfo* object as defined below.

Encodings are first looked up in the registry's cache. If not found, the list of registered search functions is scanned. If no *CodecInfo* object is found, a *LookupError* is raised. Otherwise, the *CodecInfo* object is stored in the cache and returned to the caller.

class `codecs.CodecInfo` (*encode*, *decode*, *streamreader=None*, *streamwriter=None*,
incrementalencoder=None, *incrementaldecoder=None*, *name=None*)

Codec details when looking up the codec registry. The constructor arguments are stored in attributes of the same name:

name

The name of the encoding.

encode

decode

The stateless encoding and decoding functions. These must be functions or methods which have the same interface as the *encode()* and *decode()* methods of Codec instances (see *Codec Interface*). The functions or methods are expected to work in a stateless mode.

incrementalencoder**incrementaldecoder**

Incremental encoder and decoder classes or factory functions. These have to provide the interface defined by the base classes *IncrementalEncoder* and *IncrementalDecoder*, respectively. Incremental codecs can maintain state.

streamwriter**streamreader**

Stream writer and reader classes or factory functions. These have to provide the interface defined by the base classes *StreamWriter* and *StreamReader*, respectively. Stream codecs can maintain state.

To simplify access to the various codec components, the module provides these additional functions which use *lookup()* for the codec lookup:

`codecs.getencoder(encoding)`

Look up the codec for the given encoding and return its encoder function.

Raises a *LookupError* in case the encoding cannot be found.

`codecs.getdecoder(encoding)`

Look up the codec for the given encoding and return its decoder function.

Raises a *LookupError* in case the encoding cannot be found.

`codecs.getincrementalencoder(encoding)`

Look up the codec for the given encoding and return its incremental encoder class or factory function.

Raises a *LookupError* in case the encoding cannot be found or the codec doesn't support an incremental encoder.

`codecs.getincrementaldecoder(encoding)`

Look up the codec for the given encoding and return its incremental decoder class or factory function.

Raises a *LookupError* in case the encoding cannot be found or the codec doesn't support an incremental decoder.

`codecs.getreader(encoding)`

Look up the codec for the given encoding and return its *StreamReader* class or factory function.

Raises a *LookupError* in case the encoding cannot be found.

`codecs.getwriter(encoding)`

Look up the codec for the given encoding and return its *StreamWriter* class or factory function.

Raises a *LookupError* in case the encoding cannot be found.

Custom codecs are made available by registering a suitable codec search function:

`codecs.register(search_function)`

Register a codec search function. Search functions are expected to take one argument, being the encoding name in all lower case letters with hyphens and spaces converted to underscores, and return a *CodecInfo* object. In case a search function cannot find a given encoding, it should return *None*.

Αλλαξε στην έκδοση 3.9: Hyphens and spaces are converted to underscore.

Σημείωση: Search function registration is not currently reversible, which may cause problems in some cases, such as unit testing or module reloading.

While the builtin *open()* and the associated *io* module are the recommended approach for working with encoded text files, this module provides additional utility functions and classes that allow the use of a wider range of codecs when working with binary files:

`codecs.open(filename, mode='r', encoding=None, errors='strict', buffering=-1)`

Open an encoded file using the given *mode* and return an instance of *StreamReaderWriter*, providing transparent encoding/decoding. The default file mode is 'r', meaning to open the file in read mode.

Σημείωση: Underlying encoded files are always opened in binary mode. No automatic conversion of '\n' is done on reading and writing. The *mode* argument may be any binary mode acceptable to the built-in *open()* function; the 'b' is automatically added.

encoding specifies the encoding which is to be used for the file. Any encoding that encodes to and decodes from bytes is allowed, and the data types supported by the file methods depend on the codec used.

errors may be given to define the error handling. It defaults to 'strict' which causes a *ValueError* to be raised in case an encoding error occurs.

buffering has the same meaning as for the built-in *open()* function. It defaults to -1 which means that the default buffer size will be used.

`codecs.EncodedFile(file, data_encoding, file_encoding=None, errors='strict')`

Return a *StreamRecoder* instance, a wrapped version of *file* which provides transparent transcoding. The original file is closed when the wrapped version is closed.

Data written to the wrapped file is decoded according to the given *data_encoding* and then written to the original file as bytes using *file_encoding*. Bytes read from the original file are decoded according to *file_encoding*, and the result is encoded using *data_encoding*.

If *file_encoding* is not given, it defaults to *data_encoding*.

errors may be given to define the error handling. It defaults to 'strict', which causes *ValueError* to be raised in case an encoding error occurs.

`codecs.iterencode(iterator, encoding, errors='strict', **kwargs)`

Uses an incremental encoder to iteratively encode the input provided by *iterator*. This function is a *generator*. The *errors* argument (as well as any other keyword argument) is passed through to the incremental encoder.

This function requires that the codec accept text *str* objects to encode. Therefore it does not support bytes-to-bytes encoders such as *base64_codec*.

`codecs.iterdecode(iterator, encoding, errors='strict', **kwargs)`

Uses an incremental decoder to iteratively decode the input provided by *iterator*. This function is a *generator*. The *errors* argument (as well as any other keyword argument) is passed through to the incremental decoder.

This function requires that the codec accept *bytes* objects to decode. Therefore it does not support text-to-text encoders such as *rot_13*, although *rot_13* may be used equivalently with *iterencode()*.

The module also provides the following constants which are useful for reading and writing to platform dependent files:

```
codecs.BOM
codecs.BOM_BE
codecs.BOM_LE
codecs.BOM_UTF8
codecs.BOM_UTF16
codecs.BOM_UTF16_BE
codecs.BOM_UTF16_LE
codecs.BOM_UTF32
codecs.BOM_UTF32_BE
codecs.BOM_UTF32_LE
```

These constants define various byte sequences, being Unicode byte order marks (BOMs) for several encodings. They are used in UTF-16 and UTF-32 data streams to indicate the byte order used, and in UTF-8 as a Unicode signature. *BOM_UTF16* is either *BOM_UTF16_BE* or *BOM_UTF16_LE* depending on the platform's native byte

order, *BOM* is an alias for *BOM_UTF16*, *BOM_LE* for *BOM_UTF16_LE* and *BOM_BE* for *BOM_UTF16_BE*. The others represent the BOM in UTF-8 and UTF-32 encodings.

7.2.1 Codec Base Classes

The *codecs* module defines a set of base classes which define the interfaces for working with codec objects, and can also be used as the basis for custom codec implementations.

Each codec has to define four interfaces to make it usable as codec in Python: stateless encoder, stateless decoder, stream reader and stream writer. The stream reader and writers typically reuse the stateless encoder/decoder to implement the file protocols. Codec authors also need to define how the codec will handle encoding and decoding errors.

Error Handlers

To simplify and standardize error handling, codecs may implement different error handling schemes by accepting the *errors* string argument:

```
>>> 'German β, ϣ'.encode(encoding='ascii', errors='backslashreplace')
b'German \\xdf, \\u266c'
>>> 'German β, ϣ'.encode(encoding='ascii', errors='xmlcharrefreplace')
b'German &#223;, &#9836;'
```

The following error handlers can be used with all Python *Standard Encodings* codecs:

| Value | Meaning |
|--------------------|--|
| 'strict' | Raise <i>UnicodeError</i> (or a subclass), this is the default. Implemented in <i>strict_errors()</i> . |
| 'ignore' | Ignore the malformed data and continue without further notice. Implemented in <i>ignore_errors()</i> . |
| 'replace' | Replace with a replacement marker. On encoding, use ? (ASCII character). On decoding, use ◊ (U+FFFD, the official REPLACEMENT CHARACTER). Implemented in <i>replace_errors()</i> . |
| 'backslashreplace' | Replace with backslashed escape sequences. On encoding, use hexadecimal form of Unicode code point with formats \xhh \uxxxx \Uxxxxxxxx. On decoding, use hexadecimal form of byte value with format \xhh. Implemented in <i>backslashreplace_errors()</i> . |
| 'surrogateescape' | On decoding, replace byte with individual surrogate code ranging from U+DC80 to U+DCFF. This code will then be turned back into the same byte when the 'surrogateescape' error handler is used when encoding the data. (See PEP 383 for more.) |

The following error handlers are only applicable to encoding (within *text encodings*):

| Value | Meaning |
|---------------------|--|
| 'xmlcharrefreplace' | Replace with XML/HTML numeric character reference, which is a decimal form of Unicode code point with format &#num; Implemented in <i>xmlcharrefreplace_errors()</i> . |
| 'namereplace' | Replace with \N{...} escape sequences, what appears in the braces is the Name property from Unicode Character Database. Implemented in <i>namereplace_errors()</i> . |

In addition, the following error handler is specific to the given codecs:

| Value | Codecs | Meaning |
|-------------------|---|---|
| 'surrogateescape' | utf-8, utf-16, utf-32, utf-16-be, utf-16-le, utf-32-be, utf-32-le | Allow encoding and decoding surrogate code point (U+D800 - U+DFFF) as normal code point. Otherwise these codecs treat the presence of surrogate code point in <i>str</i> as an error. |

Νέο στην έκδοση 3.1: The 'surrogateescape' and 'surrogatepass' error handlers.

Άλλαξε στην έκδοση 3.4: The 'surrogatepass' error handler now works with utf-16* and utf-32* codecs.

Νέο στην έκδοση 3.5: The 'namereplace' error handler.

Άλλαξε στην έκδοση 3.5: The 'backslashreplace' error handler now works with decoding and translating.

The set of allowed values can be extended by registering a new named error handler:

`codecs.register_error(name, error_handler)`

Register the error handling function *error_handler* under the name *name*. The *error_handler* argument will be called during encoding and decoding in case of an error, when *name* is specified as the errors parameter.

For encoding, *error_handler* will be called with a *UnicodeEncodeError* instance, which contains information about the location of the error. The error handler must either raise this or a different exception, or return a tuple with a replacement for the unencodable part of the input and a position where encoding should continue. The replacement may be either *str* or *bytes*. If the replacement is bytes, the encoder will simply copy them into the output buffer. If the replacement is a string, the encoder will encode the replacement. Encoding continues on original input at the specified position. Negative position values will be treated as being relative to the end of the input string. If the resulting position is out of bound an *IndexError* will be raised.

Decoding and translating works similarly, except *UnicodeDecodeError* or *UnicodeTranslateError* will be passed to the handler and that the replacement from the error handler will be put into the output directly.

Previously registered error handlers (including the standard error handlers) can be looked up by name:

`codecs.lookup_error(name)`

Return the error handler previously registered under the name *name*.

Raises a *LookupError* in case the handler cannot be found.

The following standard error handlers are also made available as module level functions:

`codecs.strict_errors(exception)`

Implements the 'strict' error handling.

Each encoding or decoding error raises a *UnicodeError*.

`codecs.ignore_errors(exception)`

Implements the 'ignore' error handling.

Malformed data is ignored; encoding or decoding is continued without further notice.

`codecs.replace_errors(exception)`

Implements the 'replace' error handling.

Substitutes ? (ASCII character) for encoding errors or ◈ (U+FFFD, the official REPLACEMENT CHARACTER) for decoding errors.

`codecs.backslashreplace_errors(exception)`

Implements the 'backslashreplace' error handling.

Malformed data is replaced by a backslashed escape sequence. On encoding, use the hexadecimal form of Unicode code point with formats \xhh \uxxxx \Uxxxxxxxx. On decoding, use the hexadecimal form of byte value with format \xhh.

Άλλαξε στην έκδοση 3.5: Works with decoding and translating.

`codecs.xmlcharrefreplace_errors` (*exception*)

Implements the 'xmlcharrefreplace' error handling (for encoding within *text encoding* only).

The unencodable character is replaced by an appropriate XML/HTML numeric character reference, which is a decimal form of Unicode code point with format `&#num;` .

`codecs.namereplace_errors` (*exception*)

Implements the 'namereplace' error handling (for encoding within *text encoding* only).

The unencodable character is replaced by a `\N{ . . . }` escape sequence. The set of characters that appear in the braces is the Name property from Unicode Character Database. For example, the German lowercase letter 'ß' will be converted to byte sequence `\N{LATIN SMALL LETTER SHARP S}` .

Νέο στην έκδοση 3.5.

Stateless Encoding and Decoding

The base `Codec` class defines these methods which also define the function interfaces of the stateless encoder and decoder:

`Codec.encode` (*input*, *errors*='strict')

Encodes the object *input* and returns a tuple (output object, length consumed). For instance, *text encoding* converts a string object to a bytes object using a particular character set encoding (e.g., `cp1252` or `iso-8859-1`).

The *errors* argument defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the `Codec` instance. Use *StreamWriter* for codecs which have to keep state in order to make encoding efficient.

The encoder must be able to handle zero length input and return an empty object of the output object type in this situation.

`Codec.decode` (*input*, *errors*='strict')

Decodes the object *input* and returns a tuple (output object, length consumed). For instance, for a *text encoding*, decoding converts a bytes object encoded using a particular character set encoding to a string object.

For text encodings and bytes-to-bytes codecs, *input* must be a bytes object or one which provides the read-only buffer interface – for example, buffer objects and memory mapped files.

The *errors* argument defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the `Codec` instance. Use *StreamReader* for codecs which have to keep state in order to make decoding efficient.

The decoder must be able to handle zero length input and return an empty object of the output object type in this situation.

Incremental Encoding and Decoding

The *IncrementalEncoder* and *IncrementalDecoder* classes provide the basic interface for incremental encoding and decoding. Encoding/decoding the input isn't done with one call to the stateless encoder/decoder function, but with multiple calls to the *encode()*/*decode()* method of the incremental encoder/decoder. The incremental encoder/decoder keeps track of the encoding/decoding process during method calls.

The joined output of calls to the *encode()*/*decode()* method is the same as if all the single inputs were joined into one, and this input was encoded/decoded with the stateless encoder/decoder.

IncrementalEncoder Objects

The `IncrementalEncoder` class is used for encoding an input in multiple steps. It defines the following methods which every incremental encoder must define in order to be compatible with the Python codec registry.

class `codecs.IncrementalEncoder` (*errors='strict'*)

Constructor for an `IncrementalEncoder` instance.

All incremental encoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The `IncrementalEncoder` may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for possible values.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `IncrementalEncoder` object.

encode (*object*, *final=False*)

Encodes *object* (taking the current state of the encoder into account) and returns the resulting encoded object. If this is the last call to `encode()` *final* must be true (the default is false).

reset ()

Reset the encoder to the initial state. The output is discarded: call `.encode(object, final=True)`, passing an empty byte or text string if necessary, to reset the encoder and to get the output.

getstate ()

Return the current state of the encoder which must be an integer. The implementation should make sure that 0 is the most common state. (States that are more complicated than integers can be converted into an integer by marshaling/pickling the state and encoding the bytes of the resulting string into an integer.)

setstate (*state*)

Set the state of the encoder to *state*. *state* must be an encoder state returned by `getstate()`.

IncrementalDecoder Objects

The `IncrementalDecoder` class is used for decoding an input in multiple steps. It defines the following methods which every incremental decoder must define in order to be compatible with the Python codec registry.

class `codecs.IncrementalDecoder` (*errors='strict'*)

Constructor for an `IncrementalDecoder` instance.

All incremental decoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The `IncrementalDecoder` may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for possible values.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `IncrementalDecoder` object.

decode (*object*, *final=False*)

Decodes *object* (taking the current state of the decoder into account) and returns the resulting decoded object. If this is the last call to `decode()` *final* must be true (the default is false). If *final* is true the decoder must decode the input completely and must flush all buffers. If this isn't possible (e.g. because of incomplete byte sequences at the end of the input) it must initiate error handling just like in the stateless case (which might raise an exception).

reset ()

Reset the decoder to the initial state.

getstate()

Return the current state of the decoder. This must be a tuple with two items, the first must be the buffer containing the still undecoded input. The second must be an integer and can be additional state info. (The implementation should make sure that 0 is the most common additional state info.) If this additional state info is 0 it must be possible to set the decoder to the state which has no input buffered and 0 as the additional state info, so that feeding the previously buffered input to the decoder returns it to the previous state without producing any output. (Additional state info that is more complicated than integers can be converted into an integer by marshaling/pickling the info and encoding the bytes of the resulting string into an integer.)

setstate(state)

Set the state of the decoder to *state*. *state* must be a decoder state returned by `getstate()`.

Stream Encoding and Decoding

The `StreamWriter` and `StreamReader` classes provide generic working interfaces which can be used to implement new encoding submodules very easily. See `encodings.utf_8` for an example of how this is done.

StreamWriter Objects

The `StreamWriter` class is a subclass of `Codec` and defines the following methods which every stream writer must define in order to be compatible with the Python codec registry.

class `codecs.StreamWriter` (*stream*, *errors*='strict')

Constructor for a `StreamWriter` instance.

All stream writers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for writing text or binary data, as appropriate for the specific codec.

The `StreamWriter` may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `StreamWriter` object.

write(object)

Writes the object's contents encoded to the stream.

writelines(list)

Writes the concatenated iterable of strings to the stream (possibly by reusing the `write()` method). Infinite or very large iterables are not supported. The standard bytes-to-bytes codecs do not support this method.

reset()

Resets the codec buffers used for keeping internal state.

Calling this method should ensure that the data on the output is put into a clean state that allows appending of new fresh data without having to rescan the whole stream to recover state.

In addition to the above methods, the `StreamWriter` must also inherit all other methods and attributes from the underlying stream.

StreamReader Objects

The `StreamReader` class is a subclass of `Codec` and defines the following methods which every stream reader must define in order to be compatible with the Python codec registry.

class `codecs.StreamReader` (*stream*, *errors*='strict')

Constructor for a `StreamReader` instance.

All stream readers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for reading text or binary data, as appropriate for the specific codec.

The `StreamReader` may implement different error handling schemes by providing the *errors* keyword argument. See [Error Handlers](#) for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `StreamReader` object.

The set of allowed values for the *errors* argument can be extended with `register_error()`.

read (*size*=-1, *chars*=-1, *firstline*=False)

Decodes data from the stream and returns the resulting object.

The *chars* argument indicates the number of decoded code points or bytes to return. The `read()` method will never return more data than requested, but it might return less, if there is not enough available.

The *size* argument indicates the approximate maximum number of encoded bytes or code points to read for decoding. The decoder can modify this setting as appropriate. The default value -1 indicates to read and decode as much as possible. This parameter is intended to prevent having to decode huge files in one step.

The *firstline* flag indicates that it would be sufficient to only return the first line, if there are decoding errors on later lines.

The method should use a greedy read strategy meaning that it should read as much data as is allowed within the definition of the encoding and the given size, e.g. if optional encoding endings or state markers are available on the stream, these should be read too.

readline (*size*=None, *keepends*=True)

Read one line from the input stream and return the decoded data.

size, if given, is passed as *size* argument to the stream's `read()` method.

If *keepends* is false line-endings will be stripped from the lines returned.

readlines (*sizehint*=None, *keepends*=True)

Read all lines available on the input stream and return them as a list of lines.

Line-endings are implemented using the codec's `decode()` method and are included in the list entries if *keepends* is true.

sizehint, if given, is passed as the *size* argument to the stream's `read()` method.

reset ()

Resets the codec buffers used for keeping internal state.

Note that no stream repositioning should take place. This method is primarily intended to be able to recover from decoding errors.

In addition to the above methods, the `StreamReader` must also inherit all other methods and attributes from the underlying stream.

StreamReaderWriter Objects

The *StreamReaderWriter* is a convenience class that allows wrapping streams which work in both read and write modes.

The design is such that one can use the factory functions returned by the *lookup()* function to construct the instance.

class `codecs.StreamReaderWriter` (*stream*, *Reader*, *Writer*, *errors*='strict')

Creates a *StreamReaderWriter* instance. *stream* must be a file-like object. *Reader* and *Writer* must be factory functions or classes providing the *StreamReader* and *StreamWriter* interface resp. Error handling is done in the same way as defined for the stream readers and writers.

StreamReaderWriter instances define the combined interfaces of *StreamReader* and *StreamWriter* classes. They inherit all other methods and attributes from the underlying stream.

StreamRecoder Objects

The *StreamRecoder* translates data from one encoding to another, which is sometimes useful when dealing with different encoding environments.

The design is such that one can use the factory functions returned by the *lookup()* function to construct the instance.

class `codecs.StreamRecoder` (*stream*, *encode*, *decode*, *Reader*, *Writer*, *errors*='strict')

Creates a *StreamRecoder* instance which implements a two-way conversion: *encode* and *decode* work on the frontend — the data visible to code calling *read()* and *write()*, while *Reader* and *Writer* work on the backend — the data in *stream*.

You can use these objects to do transparent transcodings, e.g., from Latin-1 to UTF-8 and back.

The *stream* argument must be a file-like object.

The *encode* and *decode* arguments must adhere to the `Codec` interface. *Reader* and *Writer* must be factory functions or classes providing objects of the *StreamReader* and *StreamWriter* interface respectively.

Error handling is done in the same way as defined for the stream readers and writers.

StreamRecoder instances define the combined interfaces of *StreamReader* and *StreamWriter* classes. They inherit all other methods and attributes from the underlying stream.

7.2.2 Encodings and Unicode

Strings are stored internally as sequences of code points in range U+0000–U+10FFFF. (See [PEP 393](#) for more details about the implementation.) Once a string object is used outside of CPU and memory, endianness and how these arrays are stored as bytes become an issue. As with other codecs, serialising a string into a sequence of bytes is known as *encoding*, and recreating the string from the sequence of bytes is known as *decoding*. There are a variety of different text serialisation codecs, which are collectively referred to as *text encodings*.

The simplest text encoding (called 'latin-1' or 'iso-8859-1') maps the code points 0–255 to the bytes 0x0–0xff, which means that a string object that contains code points above U+00FF can't be encoded with this codec. Doing so will raise a *UnicodeEncodeError* that looks like the following (although the details of the error message may differ): `UnicodeEncodeError: 'latin-1' codec can't encode character '\u1234' in position 3: ordinal not in range(256)`.

There's another group of encodings (the so called charmap encodings) that choose a different subset of all Unicode code points and how these code points are mapped to the bytes 0x0–0xff. To see how this is done simply open e.g. `encodings/cp1252.py` (which is an encoding that is used primarily on Windows). There's a string constant with 256 characters that shows you which character is mapped to which byte value.

All of these encodings can only encode 256 of the 1114112 code points defined in Unicode. A simple and straightforward way that can store each Unicode code point, is to store each code point as four consecutive bytes. There are two possibilities: store the bytes in big endian or in little endian order. These two encodings are called UTF-32-BE and UTF-32-LE respectively. Their disadvantage is that if e.g. you use UTF-32-BE on a little endian machine you will always have to swap bytes on encoding and decoding. UTF-32 avoids this problem: bytes will always be in natural endianness. When these bytes are read by a CPU with a different endianness, then bytes have to be swapped though. To be able to detect the endianness of a UTF-16 or UTF-32 byte sequence, there's the so called BOM («Byte Order Mark»). This is the Unicode character U+FEFF. This character can be prepended to every UTF-16 or UTF-32 byte sequence. The byte swapped version of this character (0xFFFE) is an illegal character that may not appear in a Unicode text. So when the first character in a UTF-16 or UTF-32 byte sequence appears to be a U+FFFE the bytes have to be swapped on decoding. Unfortunately the character U+FEFF had a second purpose as a ZERO WIDTH NO-BREAK SPACE: a character that has no width and doesn't allow a word to be split. It can e.g. be used to give hints to a ligature algorithm. With Unicode 4.0 using U+FEFF as a ZERO WIDTH NO-BREAK SPACE has been deprecated (with U+2060 (WORD JOINER) assuming this role). Nevertheless Unicode software still must be able to handle U+FEFF in both roles: as a BOM it's a device to determine the storage layout of the encoded bytes, and vanishes once the byte sequence has been decoded into a string; as a ZERO WIDTH NO-BREAK SPACE it's a normal character that will be decoded like any other.

There's another encoding that is able to encode the full range of Unicode characters: UTF-8. UTF-8 is an 8-bit encoding, which means there are no issues with byte order in UTF-8. Each byte in a UTF-8 byte sequence consists of two parts: marker bits (the most significant bits) and payload bits. The marker bits are a sequence of zero to four 1 bits followed by a 0 bit. Unicode characters are encoded like this (with x being payload bits, which when concatenated give the Unicode character):

| Range | Encoding |
|---------------------------|-------------------------------------|
| U-00000000 ... U-0000007F | 0xxxxxxx |
| U-00000080 ... U-000007FF | 110xxxxx 10xxxxxx |
| U-00000800 ... U-0000FFFF | 1110xxxx 10xxxxxx 10xxxxxx |
| U-00010000 ... U-0010FFFF | 11110xxx 10xxxxxx 10xxxxxx 10xxxxxx |

The least significant bit of the Unicode character is the rightmost x bit.

As UTF-8 is an 8-bit encoding no BOM is required and any U+FEFF character in the decoded string (even if it's the first character) is treated as a ZERO WIDTH NO-BREAK SPACE.

Without external information it's impossible to reliably determine which encoding was used for encoding a string. Each charmap encoding can decode any random byte sequence. However that's not possible with UTF-8, as UTF-8 byte sequences have a structure that doesn't allow arbitrary byte sequences. To increase the reliability with which a UTF-8 encoding can be detected, Microsoft invented a variant of UTF-8 (that Python calls "utf-8-sig") for its Notepad program: Before any of the Unicode characters is written to the file, a UTF-8 encoded BOM (which looks like this as a byte sequence: 0xef, 0xbb, 0xbf) is written. As it's rather improbable that any charmap encoded file starts with these byte values (which would e.g. map to

LATIN SMALL LETTER I WITH DIAERESIS
 RIGHT-POINTING DOUBLE ANGLE QUOTATION MARK
 INVERTED QUESTION MARK

in iso-8859-1), this increases the probability that a utf-8-sig encoding can be correctly guessed from the byte sequence. So here the BOM is not used to be able to determine the byte order used for generating the byte sequence, but as a signature that helps in guessing the encoding. On encoding the utf-8-sig codec will write 0xef, 0xbb, 0xbf as the first three bytes to the file. On decoding utf-8-sig will skip those three bytes if they appear as the first three bytes in the file. In UTF-8, the use of the BOM is discouraged and should generally be avoided.

7.2.3 Standard Encodings

Python comes with a number of codecs built-in, either implemented as C functions or with dictionaries as mapping tables. The following table lists the codecs by name, together with a few common aliases, and the languages for which the encoding is likely used. Neither the list of aliases nor the list of languages is meant to be exhaustive. Notice that spelling alternatives that only differ in case or use a hyphen instead of an underscore are also valid aliases; therefore, e.g. `'utf-8'` is a valid alias for the `'utf_8'` codec.

CPython implementation detail: Some common encodings can bypass the codecs lookup machinery to improve performance. These optimization opportunities are only recognized by CPython for a limited set of (case insensitive) aliases: `utf-8`, `utf8`, `latin-1`, `latin1`, `iso-8859-1`, `iso8859-1`, `mbcs` (Windows only), `ascii`, `us-ascii`, `utf-16`, `utf16`, `utf-32`, `utf32`, and the same using underscores instead of dashes. Using alternative aliases for these encodings may result in slower execution.

Άλλαξε στην έκδοση 3.6: Optimization opportunity recognized for `us-ascii`.

Many of the character sets support the same languages. They vary in individual characters (e.g. whether the EURO SIGN is supported or not), and in the assignment of characters to code positions. For the European languages in particular, the following variants typically exist:

- an ISO 8859 codeset
- a Microsoft Windows code page, which is typically derived from an 8859 codeset, but replaces control characters with additional graphic characters
- an IBM EBCDIC code page
- an IBM PC code page, which is ASCII compatible

| Codec | Aliases | Languages |

Άλλαξε στην έκδοση 3.4: The utf-16* and utf-32* encoders no longer allow surrogate code points (U+D800–U+DFFF) to be encoded. The utf-32* decoders no longer decode byte sequences that correspond to surrogate code points.

Άλλαξε στην έκδοση 3.8: cp65001 is now an alias to utf_8.

7.2.4 Python Specific Encodings

A number of predefined codecs are specific to Python, so their codec names have no meaning outside Python. These are listed in the tables below based on the expected input and output types (note that while text encodings are the most common use case for codecs, the underlying codec infrastructure supports arbitrary data transforms rather than just text encodings). For asymmetric codecs, the stated meaning describes the encoding direction.

Text Encodings

The following codecs provide *str* to *bytes* encoding and *bytes-like object* to *str* decoding, similar to the Unicode text encodings.

| Codec | Aliases | Meaning |
|--------------------|------------|---|
| idna | | Implement RFC 3490 , see also encodings.idna . Only <code>errors='strict'</code> is supported. |
| mbcs | ansi, dbcs | Windows only: Encode the operand according to the ANSI codepage (CP_ACP). |
| oem | | Windows only: Encode the operand according to the OEM codepage (CP_OEMCP). Νέο στην έκδοση 3.6. |
| palmos | | Encoding of PalmOS 3.5. |
| punycode | | Implement RFC 3492 . Stateful codecs are not supported. |
| raw_unicode_escape | | Latin-1 encoding with <code>\uXXXX</code> and <code>\UXXXXXXXX</code> for other code points. Existing backslashes are not escaped in any way. It is used in the Python pickle protocol. |
| undefined | | Raise an exception for all conversions, even empty strings. The error handler is ignored. |
| unicode_escape | | Encoding suitable as the contents of a Unicode literal in ASCII-encoded Python source code, except that quotes are not escaped. Decode from Latin-1 source code. Beware that Python source code actually uses UTF-8 by default. |

Άλλαξε στην έκδοση 3.8: «unicode_internal» codec is removed.

Binary Transforms

The following codecs provide binary transforms: *bytes-like object* to *bytes* mappings. They are not supported by *bytes.decode()* (which only produces *str* output).

| Codec | Aliases | Meaning | Encoder / decoder |
|---------------------------|---|---|---|
| base64_codec ¹ | base64, base_64 | Convert the operand to multiline MIME base64 (the result always includes a trailing '\n'). Άλλαξε στην έκδοση 3.4: accepts any <i>bytes-like object</i> as input for encoding and decoding | <i>base64.encodebytes()</i> / <i>base64.decodebytes()</i> |
| bz2_codec | bz2 | Compress the operand using bz2. | <i>bz2.compress()</i> / <i>bz2.decompress()</i> |
| hex_codec | hex | Convert the operand to hexadecimal representation, with two digits per byte. | <i>binascii.b2a_hex()</i> / <i>binascii.a2b_hex()</i> |
| quopri_codec | quopri, quotedprintable, quoted_printable | Convert the operand to MIME quoted printable. | <i>quopri.encode()</i> with quotetabs=True / <i>quopri.decode()</i> |
| uu_codec | uu | Convert the operand using uuencode. | <i>uu.encode()</i> / <i>uu.decode()</i> |
| zlib_codec | zip, zlib | Compress the operand using gzip. | <i>zlib.compress()</i> / <i>zlib.decompress()</i> |

Νέο στην έκδοση 3.2: Restoration of the binary transforms.

Άλλαξε στην έκδοση 3.4: Restoration of the aliases for the binary transforms.

Text Transforms

The following codec provides a text transform: a *str* to *str* mapping. It is not supported by *str.encode()* (which only produces *bytes* output).

| Codec | Aliases | Meaning |
|--------|---------|---|
| rot_13 | rot13 | Return the Caesar-cypher encryption of the operand. |

Νέο στην έκδοση 3.2: Restoration of the `rot_13` text transform.

Άλλαξε στην έκδοση 3.4: Restoration of the `rot13` alias.

¹ In addition to *bytes-like objects*, 'base64_codec' also accepts ASCII-only instances of *str* for decoding

7.2.5 `encodings.idna` — Internationalized Domain Names in Applications

This module implements [RFC 3490](#) (Internationalized Domain Names in Applications) and [RFC 3492](#) (Nameprep: A Stringprep Profile for Internationalized Domain Names (IDN)). It builds upon the `punycode` encoding and `stringprep`.

If you need the IDNA 2008 standard from [RFC 5891](#) and [RFC 5895](#), use the third-party `idna` module.

These RFCs together define a protocol to support non-ASCII characters in domain names. A domain name containing non-ASCII characters (such as `www.Alliancefrançaise.nu`) is converted into an ASCII-compatible encoding (ACE, such as `www.xn--alliancefranaise-npb.nu`). The ACE form of the domain name is then used in all places where arbitrary characters are not allowed by the protocol, such as DNS queries, HTTP *Host* fields, and so on. This conversion is carried out in the application; if possible invisible to the user: The application should transparently convert Unicode domain labels to IDNA on the wire, and convert back ACE labels to Unicode before presenting them to the user.

Python supports this conversion in several ways: the `idna` codec performs conversion between Unicode and ACE, separating an input string into labels based on the separator characters defined in [section 3.1 of RFC 3490](#) and converting each label to ACE as required, and conversely separating an input byte string into labels based on the `.` separator and converting any ACE labels found into unicode. Furthermore, the `socket` module transparently converts Unicode host names to ACE, so that applications need not be concerned about converting host names themselves when they pass them to the socket module. On top of that, modules that have host names as function parameters, such as `http.client` and `ftplib`, accept Unicode host names (`http.client` then also transparently sends an IDNA hostname in the *Host* field if it sends that field at all).

When receiving host names from the wire (such as in reverse name lookup), no automatic conversion to Unicode is performed: applications wishing to present such host names to the user should decode them to Unicode.

The module `encodings.idna` also implements the nameprep procedure, which performs certain normalizations on host names, to achieve case-insensitivity of international domain names, and to unify similar characters. The nameprep functions can be used directly if desired.

`encodings.idna.nameprep(label)`

Return the nameprepped version of *label*. The implementation currently assumes query strings, so `AllowUnassigned` is true.

`encodings.idna.ToASCII(label)`

Convert a label to ASCII, as specified in [RFC 3490](#). `UseSTD3ASCIIRules` is assumed to be false.

`encodings.idna.ToUnicode(label)`

Convert a label to Unicode, as specified in [RFC 3490](#).

7.2.6 `encodings.mbc`s — Windows ANSI codepage

This module implements the ANSI codepage (CP_ACP).

Availability: Windows only.

Άλλαξε στην έκδοση 3.3: Support any error handler.

Άλλαξε στην έκδοση 3.2: Before 3.2, the *errors* argument was ignored; 'replace' was always used to encode, and 'ignore' to decode.

7.2.7 `encodings.utf_8_sig` — UTF-8 codec with BOM signature

This module implements a variant of the UTF-8 codec. On encoding, a UTF-8 encoded BOM will be prepended to the UTF-8 encoded bytes. For the stateful encoder this is only done once (on the first write to the byte stream). On decoding, an optional UTF-8 encoded BOM at the start of the data will be skipped.

The modules described in this chapter provide a variety of specialized data types such as dates and times, fixed-type arrays, heap queues, double-ended queues, and enumerations.

Python also provides some built-in data types, in particular, *dict*, *list*, *set* and *frozenset*, and *tuple*. The *str* class is used to hold Unicode strings, and the *bytes* and *bytearray* classes are used to hold binary data.

The following modules are documented in this chapter:

8.1 *datetime* — Basic date and time types

Source code: [Lib/datetime.py](#)

The *datetime* module supplies classes for manipulating dates and times.

While date and time arithmetic is supported, the focus of the implementation is on efficient attribute extraction for output formatting and manipulation.

Δείτε επίσης:

Module *calendar* General calendar related functions.

Module *time* Time access and conversions.

Module *zoneinfo* Concrete time zones representing the IANA time zone database.

Package *dateutil* Third-party library with expanded time zone and parsing support.

8.1.1 Aware and Naive Objects

Date and time objects may be categorized as «aware» or «naive» depending on whether or not they include timezone information.

With sufficient knowledge of applicable algorithmic and political time adjustments, such as time zone and daylight saving time information, an **aware** object can locate itself relative to other aware objects. An aware object represents a specific moment in time that is not open to interpretation.¹

A **naive** object does not contain enough information to unambiguously locate itself relative to other date/time objects. Whether a naive object represents Coordinated Universal Time (UTC), local time, or time in some other timezone is purely up to the program, just like it is up to the program whether a particular number represents metres, miles, or mass. Naive objects are easy to understand and to work with, at the cost of ignoring some aspects of reality.

For applications requiring aware objects, `datetime` and `time` objects have an optional time zone information attribute, `tzinfo`, that can be set to an instance of a subclass of the abstract `tzinfo` class. These `tzinfo` objects capture information about the offset from UTC time, the time zone name, and whether daylight saving time is in effect.

Only one concrete `tzinfo` class, the `timezone` class, is supplied by the `datetime` module. The `timezone` class can represent simple timezones with fixed offsets from UTC, such as UTC itself or North American EST and EDT timezones. Supporting timezones at deeper levels of detail is up to the application. The rules for time adjustment across the world are more political than rational, change frequently, and there is no standard suitable for every application aside from UTC.

8.1.2 Constants

The `datetime` module exports the following constants:

`datetime.MINYEAR`

The smallest year number allowed in a `date` or `datetime` object. `MINYEAR` is 1.

`datetime.MAXYEAR`

The largest year number allowed in a `date` or `datetime` object. `MAXYEAR` is 9999.

8.1.3 Available Types

class `datetime.date`

An idealized naive date, assuming the current Gregorian calendar always was, and always will be, in effect. Attributes: `year`, `month`, and `day`.

class `datetime.time`

An idealized time, independent of any particular day, assuming that every day has exactly 24*60*60 seconds. (There is no notion of «leap seconds» here.) Attributes: `hour`, `minute`, `second`, `microsecond`, and `tzinfo`.

class `datetime.datetime`

A combination of a date and a time. Attributes: `year`, `month`, `day`, `hour`, `minute`, `second`, `microsecond`, and `tzinfo`.

class `datetime.timedelta`

A duration expressing the difference between two `date`, `time`, or `datetime` instances to microsecond resolution.

class `datetime.tzinfo`

An abstract base class for time zone information objects. These are used by the `datetime` and `time` classes to provide a customizable notion of time adjustment (for example, to account for time zone and/or daylight saving time).

¹ If, that is, we ignore the effects of Relativity

class `datetime.timezone`

A class that implements the `tzinfo` abstract base class as a fixed offset from the UTC.

Νέο στην έκδοση 3.2.

Objects of these types are immutable.

Subclass relationships:

```
object
  timedelta
  tzinfo
    timezone
  time
  date
    datetime
```

Common Properties

The `date`, `datetime`, `time`, and `timezone` types share these common features:

- Objects of these types are immutable.
- Objects of these types are hashable, meaning that they can be used as dictionary keys.
- Objects of these types support efficient pickling via the `pickle` module.

Determining if an Object is Aware or Naive

Objects of the `date` type are always naive.

An object of type `time` or `datetime` may be aware or naive.

A `datetime` object `d` is aware if both of the following hold:

1. `d.tzinfo` is not `None`
2. `d.tzinfo.utcoffset(d)` does not return `None`

Otherwise, `d` is naive.

A `time` object `t` is aware if both of the following hold:

1. `t.tzinfo` is not `None`
2. `t.tzinfo.utcoffset(None)` does not return `None`.

Otherwise, `t` is naive.

The distinction between aware and naive doesn't apply to `timedelta` objects.

8.1.4 `timedelta` Objects

A `timedelta` object represents a duration, the difference between two dates or times.

class `datetime.timedelta` (*days=0, seconds=0, microseconds=0, milliseconds=0, minutes=0, hours=0, weeks=0*)

All arguments are optional and default to 0. Arguments may be integers or floats, and may be positive or negative.

Only *days*, *seconds* and *microseconds* are stored internally. Arguments are converted to those units:

- A millisecond is converted to 1000 microseconds.
- A minute is converted to 60 seconds.
- An hour is converted to 3600 seconds.
- A week is converted to 7 days.

and *days*, *seconds* and *microseconds* are then normalized so that the representation is unique, with

- $0 \leq \text{microseconds} < 1000000$
- $0 \leq \text{seconds} < 3600 \times 24$ (the number of seconds in one day)
- $-999999999 \leq \text{days} \leq 999999999$

The following example illustrates how any arguments besides *days*, *seconds* and *microseconds* are «merged» and normalized into those three resulting attributes:

```
>>> from datetime import timedelta
>>> delta = timedelta(
...     days=50,
...     seconds=27,
...     microseconds=10,
...     milliseconds=29000,
...     minutes=5,
...     hours=8,
...     weeks=2
... )
>>> # Only days, seconds, and microseconds remain
>>> delta
datetime.timedelta(days=64, seconds=29156, microseconds=10)
```

If any argument is a float and there are fractional microseconds, the fractional microseconds left over from all arguments are combined and their sum is rounded to the nearest microsecond using round-half-to-even tiebreaker. If no argument is a float, the conversion and normalization processes are exact (no information is lost).

If the normalized value of *days* lies outside the indicated range, `OverflowError` is raised.

Note that normalization of negative values may be surprising at first. For example:

```
>>> from datetime import timedelta
>>> d = timedelta(microseconds=-1)
>>> (d.days, d.seconds, d.microseconds)
(-1, 86399, 999999)
```

Class attributes:

`timedelta.min`

The most negative `timedelta` object, `timedelta(-999999999)`.

`timedelta.max`

The most positive `timedelta` object, `timedelta(days=999999999, hours=23, minutes=59, seconds=59, microseconds=999999)`.

`timedelta.resolution`

The smallest possible difference between non-equal `timedelta` objects, `timedelta(microseconds=1)`.

Note that, because of normalization, `timedelta.max > -timedelta.min`. `-timedelta.max` is not representable as a `timedelta` object.

Instance attributes (read-only):

| Attribute | Value |
|---------------------------|--|
| <code>days</code> | Between -999999999 and 999999999 inclusive |
| <code>seconds</code> | Between 0 and 86399 inclusive |
| <code>microseconds</code> | Between 0 and 999999 inclusive |

Supported operations:

| Operation | Result |
|---|---|
| <code>t1 = t2 + t3</code> | Sum of <code>t2</code> and <code>t3</code> . Afterwards <code>t1-t2 == t3</code> and <code>t1-t3 == t2</code> are true. (1) |
| <code>t1 = t2 - t3</code> | Difference of <code>t2</code> and <code>t3</code> . Afterwards <code>t1 == t2 - t3</code> and <code>t2 == t1 + t3</code> are true. (1)(6) |
| <code>t1 = t2 * i</code> or <code>t1 = i * t2</code> | Delta multiplied by an integer. Afterwards <code>t1 // i == t2</code> is true, provided <code>i != 0</code> . In general, <code>t1 * i == t1 * (i-1) + t1</code> is true. (1) |
| <code>t1 = t2 * f</code> or <code>t1 = f * t2</code> | Delta multiplied by a float. The result is rounded to the nearest multiple of <code>timedelta.resolution</code> using round-half-to-even. |
| <code>f = t2 / t3</code> | Division (3) of overall duration <code>t2</code> by interval unit <code>t3</code> . Returns a <code>float</code> object. |
| <code>t1 = t2 / f</code> or <code>t1 = t2 / i</code> | Delta divided by a float or an int. The result is rounded to the nearest multiple of <code>timedelta.resolution</code> using round-half-to-even. |
| <code>t1 = t2 // i</code> or <code>t1 = t2 // t3</code> | The floor is computed and the remainder (if any) is thrown away. In the second case, an integer is returned. (3) |
| <code>t1 = t2 % t3</code> | The remainder is computed as a <code>timedelta</code> object. (3) |
| <code>q, r = divmod(t1, t2)</code> | Computes the quotient and the remainder: <code>q = t1 // t2</code> (3) and <code>r = t1 % t2</code> . <code>q</code> is an integer and <code>r</code> is a <code>timedelta</code> object. |
| <code>+t1</code> | Returns a <code>timedelta</code> object with the same value. (2) |
| <code>-t1</code> | equivalent to <code>timedelta(-t1.days, -t1.seconds, -t1.microseconds)</code> , and to <code>t1*-1</code> . (1)(4) |
| <code>abs(t)</code> | equivalent to <code>+t</code> when <code>t.days >= 0</code> , and to <code>-t</code> when <code>t.days < 0</code> . (2) |
| <code>str(t)</code> | Returns a string in the form <code>[D day[s],][H]H:MM:SS[.UUUUUU]</code> , where <code>D</code> is negative for negative <code>t</code> . (5) |
| <code>repr(t)</code> | Returns a string representation of the <code>timedelta</code> object as a constructor call with canonical attribute values. |

Notes:

- (1) This is exact but may overflow.
- (2) This is exact and cannot overflow.
- (3) Division by 0 raises `ZeroDivisionError`.
- (4) `-timedelta.max` is not representable as a `timedelta` object.
- (5) String representations of `timedelta` objects are normalized similarly to their internal representation. This leads to somewhat unusual results for negative timedeltas. For example:

```
>>> timedelta(hours=-5)
datetime.timedelta(days=-1, seconds=68400)
>>> print(_)
-1 day, 19:00:00
```

- (6) The expression `t2 - t3` will always be equal to the expression `t2 + (-t3)` except when `t3` is equal to `timedelta.max`; in that case the former will produce a result while the latter will overflow.

In addition to the operations listed above, `timedelta` objects support certain additions and subtractions with `date` and `datetime` objects (see below).

Άλλαξε στην έκδοση 3.2: Floor division and true division of a `timedelta` object by another `timedelta` object are now supported, as are remainder operations and the `divmod()` function. True division and multiplication of a `timedelta` object by a `float` object are now supported.

Comparisons of `timedelta` objects are supported, with some caveats.

The comparisons `==` or `!=` *always* return a `bool`, no matter the type of the compared object:

```
>>> from datetime import timedelta
>>> delta1 = timedelta(seconds=57)
>>> delta2 = timedelta(hours=25, seconds=2)
>>> delta2 != delta1
True
>>> delta2 == 5
False
```

For all other comparisons (such as `<` and `>`), when a `timedelta` object is compared to an object of a different type, `TypeError` is raised:

```
>>> delta2 > delta1
True
>>> delta2 > 5
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: '>' not supported between instances of 'datetime.timedelta' and 'int'
```

In Boolean contexts, a `timedelta` object is considered to be true if and only if it isn't equal to `timedelta(0)`.

Instance methods:

`timedelta.total_seconds()`

Return the total number of seconds contained in the duration. Equivalent to `td / timedelta(seconds=1)`. For interval units other than seconds, use the division form directly (e.g. `td / timedelta(microseconds=1)`).

Note that for very large time intervals (greater than 270 years on most platforms) this method will lose microsecond accuracy.

Νέο στην έκδοση 3.2.

Examples of usage: `timedelta`

An additional example of normalization:

```
>>> # Components of another_year add up to exactly 365 days
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> another_year = timedelta(weeks=40, days=84, hours=23,
...                          minutes=50, seconds=600)
>>> year == another_year
True
>>> year.total_seconds()
31536000.0
```

Examples of *timedelta* arithmetic:

```
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> ten_years = 10 * year
>>> ten_years
datetime.timedelta(days=3650)
>>> ten_years.days // 365
10
>>> nine_years = ten_years - year
>>> nine_years
datetime.timedelta(days=3285)
>>> three_years = nine_years // 3
>>> three_years, three_years.days // 365
(datetime.timedelta(days=1095), 3)
```

8.1.5 date Objects

A *date* object represents a date (year, month and day) in an idealized calendar, the current Gregorian calendar indefinitely extended in both directions.

January 1 of year 1 is called day number 1, January 2 of year 1 is called day number 2, and so on.²

class `datetime.date` (*year*, *month*, *day*)

All arguments are required. Arguments must be integers, in the following ranges:

- `MINYEAR <= year <= MAXYEAR`
- `1 <= month <= 12`
- `1 <= day <= number of days in the given month and year`

If an argument outside those ranges is given, *ValueError* is raised.

Other constructors, all class methods:

classmethod `date.today()`

Return the current local date.

This is equivalent to `date.fromtimestamp(time.time())`.

classmethod `date.fromtimestamp(timestamp)`

Return the local date corresponding to the POSIX timestamp, such as is returned by `time.time()`.

This may raise *OverflowError*, if the timestamp is out of the range of values supported by the platform C `localtime()` function, and *OSError* on `localtime()` failure. It's common for this to be restricted to years from 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`.

Αλλαξε στην έκδοση 3.3: Raise *OverflowError* instead of *ValueError* if the timestamp is out of the range of values supported by the platform C `localtime()` function. Raise *OSError* instead of *ValueError* on `localtime()` failure.

classmethod `date.fromordinal(ordinal)`

Return the date corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1.

ValueError is raised unless `1 <= ordinal <= date.max.toordinal()`. For any date *d*, `date.fromordinal(d.toordinal()) == d`.

² This matches the definition of the «proleptic Gregorian» calendar in Dershowitz and Reingold's book *Calendrical Calculations*, where it's the base calendar for all computations. See the book for algorithms for converting between proleptic Gregorian ordinals and many other calendar systems.

classmethod `date.fromisoformat(date_string)`

Return a *date* corresponding to a *date_string* given in the format YYYY-MM-DD:

```
>>> from datetime import date
>>> date.fromisoformat('2019-12-04')
datetime.date(2019, 12, 4)
```

This is the inverse of `date.isoformat()`. It only supports the format YYYY-MM-DD.

Νέο στην έκδοση 3.7.

classmethod `date.fromisocalendar(year, week, day)`

Return a *date* corresponding to the ISO calendar date specified by year, week and day. This is the inverse of the function `date.isocalendar()`.

Νέο στην έκδοση 3.8.

Class attributes:

`date.min`

The earliest representable date, `date(MINYEAR, 1, 1)`.

`date.max`

The latest representable date, `date(MAXYEAR, 12, 31)`.

`date.resolution`

The smallest possible difference between non-equal date objects, `timedelta(days=1)`.

Instance attributes (read-only):

`date.year`

Between *MINYEAR* and *MAXYEAR* inclusive.

`date.month`

Between 1 and 12 inclusive.

`date.day`

Between 1 and the number of days in the given month of the given year.

Supported operations:

| Operation | Result |
|--|--|
| <code>date2 = date1 + timedelta</code> | <i>date2</i> is <code>timedelta.days</code> days removed from <i>date1</i> . (1) |
| <code>date2 = date1 - timedelta</code> | Computes <i>date2</i> such that <code>date2 + timedelta == date1</code> . (2) |
| <code>timedelta = date1 - date2</code> | (3) |
| <code>date1 < date2</code> | <i>date1</i> is considered less than <i>date2</i> when <i>date1</i> precedes <i>date2</i> in time. (4) |

Notes:

- (1) *date2* is moved forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. Afterward `date2 - date1 == timedelta.days * timedelta.seconds` and `timedelta.microseconds` are ignored. *OverflowError* is raised if `date2.year` would be smaller than *MINYEAR* or larger than *MAXYEAR*.
- (2) `timedelta.seconds` and `timedelta.microseconds` are ignored.
- (3) This is exact, and cannot overflow. `timedelta.seconds` and `timedelta.microseconds` are 0, and `date2 + timedelta == date1` after.
- (4) In other words, `date1 < date2` if and only if `date1.toordinal() < date2.toordinal()`. Date comparison raises *TypeError* if the other comparand isn't also a *date* object. However, *NotImplemented* is returned instead if the other comparand has a `timetuple()` attribute. This hook gives other kinds of date

objects a chance at implementing mixed-type comparison. If not, when a `date` object is compared to an object of a different type, `TypeError` is raised unless the comparison is `==` or `!=`. The latter cases return `False` or `True`, respectively.

In Boolean contexts, all `date` objects are considered to be true.

Instance methods:

`date.replace(year=self.year, month=self.month, day=self.day)`

Return a date with the same value, except for those parameters given new values by whichever keyword arguments are specified.

Example:

```
>>> from datetime import date
>>> d = date(2002, 12, 31)
>>> d.replace(day=26)
datetime.date(2002, 12, 26)
```

`date.timetuple()`

Return a `time.struct_time` such as returned by `time.localtime()`.

The hours, minutes and seconds are 0, and the DST flag is -1.

`d.timetuple()` is equivalent to:

```
time.struct_time((d.year, d.month, d.day, 0, 0, 0, d.weekday(), yday, -1))
```

where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st.

`date.toordinal()`

Return the proleptic Gregorian ordinal of the date, where January 1 of year 1 has ordinal 1. For any `date` object `d`, `date.fromordinal(d.toordinal()) == d`.

`date.weekday()`

Return the day of the week as an integer, where Monday is 0 and Sunday is 6. For example, `date(2002, 12, 4).weekday() == 2`, a Wednesday. See also `isoweekday()`.

`date.isoweekday()`

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. For example, `date(2002, 12, 4).isoweekday() == 3`, a Wednesday. See also `weekday()`, `isocalendar()`.

`date.isocalendar()`

Return a *named tuple* object with three components: `year`, `week` and `weekday`.

The ISO calendar is a widely used variant of the Gregorian calendar.³

The ISO year consists of 52 or 53 full weeks, and where a week starts on a Monday and ends on a Sunday. The first week of an ISO year is the first (Gregorian) calendar week of a year containing a Thursday. This is called week number 1, and the ISO year of that Thursday is the same as its Gregorian year.

For example, 2004 begins on a Thursday, so the first week of ISO year 2004 begins on Monday, 29 Dec 2003 and ends on Sunday, 4 Jan 2004:

```
>>> from datetime import date
>>> date(2003, 12, 29).isocalendar()
datetime.IsoCalendarDate(year=2004, week=1, weekday=1)
>>> date(2004, 1, 4).isocalendar()
datetime.IsoCalendarDate(year=2004, week=1, weekday=7)
```

³ See R. H. van Gent's [guide to the mathematics of the ISO 8601 calendar](#) for a good explanation.

Άλλαξε στην έκδοση 3.9: Result changed from a tuple to a *named tuple*.

`date.isoformat()`

Return a string representing the date in ISO 8601 format, YYYY-MM-DD:

```
>>> from datetime import date
>>> date(2002, 12, 4).isoformat()
'2002-12-04'
```

This is the inverse of `date.fromisoformat()`.

`date.__str__()`

For a date *d*, `str(d)` is equivalent to `d.isoformat()`.

`date.ctime()`

Return a string representing the date:

```
>>> from datetime import date
>>> date(2002, 12, 4).ctime()
'Wed Dec 4 00:00:00 2002'
```

`d.ctime()` is equivalent to:

```
time.ctime(time.mktime(d.timetuple()))
```

on platforms where the native C `ctime()` function (which `time.ctime()` invokes, but which `date.ctime()` does not invoke) conforms to the C standard.

`date.strftime(format)`

Return a string representing the date, controlled by an explicit format string. Format codes referring to hours, minutes or seconds will see 0 values. For a complete list of formatting directives, see *strftime()* and *strptime() Behavior*.

`date.__format__(format)`

Same as `date.strftime()`. This makes it possible to specify a format string for a *date* object in formatted string literals and when using `str.format()`. For a complete list of formatting directives, see *strftime()* and *strptime() Behavior*.

Examples of Usage: date

Example of counting days to an event:

```
>>> import time
>>> from datetime import date
>>> today = date.today()
>>> today
datetime.date(2007, 12, 5)
>>> today == date.fromtimestamp(time.time())
True
>>> my_birthday = date(today.year, 6, 24)
>>> if my_birthday < today:
...     my_birthday = my_birthday.replace(year=today.year + 1)
>>> my_birthday
datetime.date(2008, 6, 24)
>>> time_to_birthday = abs(my_birthday - today)
>>> time_to_birthday.days
202
```

More examples of working with `date`:

```
>>> from datetime import date
>>> d = date.fromordinal(730920) # 730920th day after 1. 1. 0001
>>> d
datetime.date(2002, 3, 11)

>>> # Methods related to formatting string output
>>> d.isoformat()
'2002-03-11'
>>> d.strftime("%d/%m/%y")
'11/03/02'
>>> d.strftime("%A %d. %B %Y")
'Monday 11. March 2002'
>>> d.ctime()
'Mon Mar 11 00:00:00 2002'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}.'.format(d, "day", "month")
'The day is 11, the month is March.'

>>> # Methods for to extracting 'components' under different calendars
>>> t = d.timetuple()
>>> for i in t:
...     print(i)
2002          # year
3             # month
11            # day
0
0
0
0             # weekday (0 = Monday)
70            # 70th day in the year
-1

>>> ic = d.isocalendar()
>>> for i in ic:
...     print(i)
2002          # ISO year
11            # ISO week number
1             # ISO day number ( 1 = Monday )

>>> # A date object is immutable; all operations produce a new object
>>> d.replace(year=2005)
datetime.date(2005, 3, 11)
```

8.1.6 datetime Objects

A `datetime` object is a single object containing all the information from a `date` object and a `time` object.

Like a `date` object, `datetime` assumes the current Gregorian calendar extended in both directions; like a `time` object, `datetime` assumes there are exactly 3600*24 seconds in every day.

Constructor:

```
class datetime.datetime (year, month, day, hour=0, minute=0, second=0, microsecond=0, tzinfo=None,
                        *, fold=0)
```

The `year`, `month` and `day` arguments are required. `tzinfo` may be `None`, or an instance of a `tzinfo` subclass. The remaining arguments must be integers in the following ranges:

- MINYEAR <= year <= MAXYEAR,

- `1 <= month <= 12`,
- `1 <= day <= number of days in the given month and year`,
- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- fold in `[0, 1]`.

If an argument outside those ranges is given, `ValueError` is raised.

Νέο στην έκδοση 3.6: Added the `fold` argument.

Other constructors, all class methods:

classmethod `datetime.today()`

Return the current local datetime, with `tzinfo` `None`.

Equivalent to:

```
datetime.fromtimestamp(time.time())
```

See also `now()`, `fromtimestamp()`.

This method is functionally equivalent to `now()`, but without a `tz` parameter.

classmethod `datetime.now(tz=None)`

Return the current local date and time.

If optional argument `tz` is `None` or not specified, this is like `today()`, but, if possible, supplies more precision than can be gotten from going through a `time.time()` timestamp (for example, this may be possible on platforms supplying the `C gettimeofday()` function).

If `tz` is not `None`, it must be an instance of a `tzinfo` subclass, and the current date and time are converted to `tz`'s time zone.

This function is preferred over `today()` and `utcnow()`.

classmethod `datetime.utcnow()`

Return the current UTC date and time, with `tzinfo` `None`.

This is like `now()`, but returns the current UTC date and time, as a naive `datetime` object. An aware current UTC datetime can be obtained by calling `datetime.now(timezone.utc)`. See also `now()`.

Προειδοποίηση: Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC. As such, the recommended way to create an object representing the current time in UTC is by calling `datetime.now(timezone.utc)`.

classmethod `datetime.fromtimestamp(timestamp, tz=None)`

Return the local date and time corresponding to the POSIX timestamp, such as is returned by `time.time()`. If optional argument `tz` is `None` or not specified, the timestamp is converted to the platform's local date and time, and the returned `datetime` object is naive.

If `tz` is not `None`, it must be an instance of a `tzinfo` subclass, and the timestamp is converted to `tz`'s time zone.

`fromtimestamp()` may raise `OverflowError`, if the timestamp is out of the range of values supported by the platform `C localtime()` or `gmtime()` functions, and `OSError` on `localtime()` or `gmtime()` failure. It's common for this to be restricted to years in 1970 through 2038. Note that on non-POSIX systems that

include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`, and then it's possible to have two timestamps differing by a second that yield identical `datetime` objects. This method is preferred over `utcfromtimestamp()`.

Άλλαξε στην έκδοση 3.3: Raise `OverflowError` instead of `ValueError` if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions. Raise `OSErrors` instead of `ValueError` on `localtime()` or `gmtime()` failure.

Άλλαξε στην έκδοση 3.6: `fromtimestamp()` may return instances with `fold` set to 1.

classmethod `datetime.utcfromtimestamp(timestamp)`

Return the UTC `datetime` corresponding to the POSIX timestamp, with `tzinfo` `None`. (The resulting object is naive.)

This may raise `OverflowError`, if the timestamp is out of the range of values supported by the platform C `gmtime()` function, and `OSErrors` on `gmtime()` failure. It's common for this to be restricted to years in 1970 through 2038.

To get an aware `datetime` object, call `fromtimestamp()`:

```
datetime.fromtimestamp(timestamp, timezone.utc)
```

On the POSIX compliant platforms, it is equivalent to the following expression:

```
datetime(1970, 1, 1, tzinfo=timezone.utc) + timedelta(seconds=timestamp)
```

except the latter formula always supports the full years range: between `MINYEAR` and `MAXYEAR` inclusive.

Προειδοποίηση: Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC. As such, the recommended way to create an object representing a specific timestamp in UTC is by calling `datetime.fromtimestamp(timestamp, tz=timezone.utc)`.

Άλλαξε στην έκδοση 3.3: Raise `OverflowError` instead of `ValueError` if the timestamp is out of the range of values supported by the platform C `gmtime()` function. Raise `OSErrors` instead of `ValueError` on `gmtime()` failure.

classmethod `datetime.fromordinal(ordinal)`

Return the `datetime` corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1. `ValueError` is raised unless `1 <= ordinal <= datetime.max.toordinal()`. The hour, minute, second and microsecond of the result are all 0, and `tzinfo` is `None`.

classmethod `datetime.combine(date, time, tzinfo=self.tzinfo)`

Return a new `datetime` object whose date components are equal to the given `date` object's, and whose time components are equal to the given `time` object's. If the `tzinfo` argument is provided, its value is used to set the `tzinfo` attribute of the result, otherwise the `tzinfo` attribute of the `time` argument is used.

For any `datetime` object `d`, `d == datetime.combine(d.date(), d.time(), d.tzinfo)`. If `date` is a `datetime` object, its time components and `tzinfo` attributes are ignored.

Άλλαξε στην έκδοση 3.6: Added the `tzinfo` argument.

classmethod `datetime.fromisoformat(date_string)`

Return a `datetime` corresponding to a `date_string` in one of the formats emitted by `date.isoformat()` and `datetime.isoformat()`.

Specifically, this function supports strings in the format:

```
YYYY-MM-DD[*HH[:MM[:SS[.fff[fff]]]][+HH:MM[:SS[.ffffff]]]]
```

where `*` can match any single character.

Προσοχή: This does *not* support parsing arbitrary ISO 8601 strings - it is only intended as the inverse operation of `datetime.isoformat()`. A more full-featured ISO 8601 parser, `dateutil.parser.isoparse` is available in the third-party package `dateutil`.

Examples:

```
>>> from datetime import datetime
>>> datetime.fromisoformat('2011-11-04')
datetime.datetime(2011, 11, 4, 0, 0)
>>> datetime.fromisoformat('2011-11-04T00:05:23')
datetime.datetime(2011, 11, 4, 0, 5, 23)
>>> datetime.fromisoformat('2011-11-04 00:05:23.283')
datetime.datetime(2011, 11, 4, 0, 5, 23, 283000)
>>> datetime.fromisoformat('2011-11-04 00:05:23.283+00:00')
datetime.datetime(2011, 11, 4, 0, 5, 23, 283000, tzinfo=datetime.timezone.utc)
>>> datetime.fromisoformat('2011-11-04T00:05:23+04:00')
datetime.datetime(2011, 11, 4, 0, 5, 23,
tzinfo=datetime.timezone(datetime.timedelta(seconds=14400)))
```

Νέο στην έκδοση 3.7.

classmethod `datetime.fromisocalendar(year, week, day)`

Return a `datetime` corresponding to the ISO calendar date specified by year, week and day. The non-date components of the datetime are populated with their normal default values. This is the inverse of the function `datetime.isocalendar()`.

Νέο στην έκδοση 3.8.

classmethod `datetime.strptime(date_string, format)`

Return a `datetime` corresponding to `date_string`, parsed according to `format`.

This is equivalent to:

```
datetime(*(time.strptime(date_string, format)[0:6]))
```

`ValueError` is raised if the `date_string` and `format` can't be parsed by `time.strptime()` or if it returns a value which isn't a time tuple. For a complete list of formatting directives, see *strftime() and strptime() Behavior*.

Class attributes:

`datetime.min`

The earliest representable `datetime`, `datetime(MINYEAR, 1, 1, tzinfo=None)`.

`datetime.max`

The latest representable `datetime`, `datetime(MAXYEAR, 12, 31, 23, 59, 59, 999999, tzinfo=None)`.

`datetime.resolution`

The smallest possible difference between non-equal `datetime` objects, `timedelta(microseconds=1)`.

Instance attributes (read-only):

`datetime.year`

Between `MINYEAR` and `MAXYEAR` inclusive.

`datetime.month`

Between 1 and 12 inclusive.

`datetime.day`

Between 1 and the number of days in the given month of the given year.

`datetime.hour`

In range(24).

`datetime.minute`

In range(60).

`datetime.second`

In range(60).

`datetime.microsecond`

In range(1000000).

`datetime.tzinfo`

The object passed as the *tzinfo* argument to the *datetime* constructor, or None if none was passed.

`datetime.fold`

In [0, 1]. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The value 0 (1) represents the earlier (later) of the two moments with the same wall time representation.

Νέο στην έκδοση 3.6.

Supported operations:

| Operation | Result |
|--|---|
| <code>datetime2 = datetime1 + timedelta</code> | (1) |
| <code>datetime2 = datetime1 - timedelta</code> | (2) |
| <code>timedelta = datetime1 - datetime2</code> | (3) |
| <code>datetime1 < datetime2</code> | Compares <i>datetime</i> to <i>datetime</i> . (4) |

- (1) `datetime2` is a duration of `timedelta` removed from `datetime1`, moving forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. The result has the same *tzinfo* attribute as the input *datetime*, and `datetime2 - datetime1 == timedelta` after. *OverflowError* is raised if `datetime2.year` would be smaller than *MINYEAR* or larger than *MAXYEAR*. Note that no time zone adjustments are done even if the input is an aware object.
- (2) Computes the `datetime2` such that `datetime2 + timedelta == datetime1`. As for addition, the result has the same *tzinfo* attribute as the input *datetime*, and no time zone adjustments are done even if the input is aware.
- (3) Subtraction of a *datetime* from a *datetime* is defined only if both operands are naive, or if both are aware. If one is aware and the other is naive, *TypeError* is raised.

If both are naive, or both are aware and have the same *tzinfo* attribute, the *tzinfo* attributes are ignored, and the result is a *timedelta* object *t* such that `datetime2 + t == datetime1`. No time zone adjustments are done in this case.

If both are aware and have different *tzinfo* attributes, *a-b* acts as if *a* and *b* were first converted to naive UTC datetimes first. The result is `(a.replace(tzinfo=None) - a.utcoffset()) - (b.replace(tzinfo=None) - b.utcoffset())` except that the implementation never overflows.

- (4) *datetime1* is considered less than *datetime2* when *datetime1* precedes *datetime2* in time.

If one comparand is naive and the other is aware, *TypeError* is raised if an order comparison is attempted. For equality comparisons, naive instances are never equal to aware instances.

If both comparands are aware, and have the same `tzinfo` attribute, the common `tzinfo` attribute is ignored and the base datetimes are compared. If both comparands are aware and have different `tzinfo` attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`).

Άλλαξε στην έκδοση 3.3: Equality comparisons between aware and naive `datetime` instances don't raise `TypeError`.

Σημείωση: In order to stop comparison from falling back to the default scheme of comparing object addresses, `datetime` comparison normally raises `TypeError` if the other comparand isn't also a `datetime` object. However, `NotImplemented` is returned instead if the other comparand has a `timetuple()` attribute. This hook gives other kinds of date objects a chance at implementing mixed-type comparison. If not, when a `datetime` object is compared to an object of a different type, `TypeError` is raised unless the comparison is `==` or `!=`. The latter cases return `False` or `True`, respectively.

Instance methods:

`datetime.date()`

Return `date` object with same year, month and day.

`datetime.time()`

Return `time` object with same hour, minute, second, microsecond and fold. `tzinfo` is `None`. See also method `timetz()`.

Άλλαξε στην έκδοση 3.6: The fold value is copied to the returned `time` object.

`datetime.timetz()`

Return `time` object with same hour, minute, second, microsecond, fold, and `tzinfo` attributes. See also method `time()`.

Άλλαξε στην έκδοση 3.6: The fold value is copied to the returned `time` object.

`datetime.replace(year=self.year, month=self.month, day=self.day, hour=self.hour, minute=self.minute, second=self.second, microsecond=self.microsecond, tzinfo=self.tzinfo, *, fold=0)`

Return a `datetime` with the same attributes, except for those attributes given new values by whichever keyword arguments are specified. Note that `tzinfo=None` can be specified to create a naive `datetime` from an aware `datetime` with no conversion of date and time data.

Νέο στην έκδοση 3.6: Added the `fold` argument.

`datetime.astimezone(tz=None)`

Return a `datetime` object with new `tzinfo` attribute `tz`, adjusting the date and time data so the result is the same UTC time as `self`, but in `tz`'s local time.

If provided, `tz` must be an instance of a `tzinfo` subclass, and its `utcoffset()` and `dst()` methods must not return `None`. If `self` is naive, it is presumed to represent time in the system timezone.

If called without arguments (or with `tz=None`) the system local timezone is assumed for the target timezone. The `.tzinfo` attribute of the converted `datetime` instance will be set to an instance of `timezone` with the zone name and offset obtained from the OS.

If `self.tzinfo` is `tz`, `self.astimezone(tz)` is equal to `self`: no adjustment of date or time data is performed. Else the result is local time in the timezone `tz`, representing the same UTC time as `self`: after `astz = dt.astimezone(tz)`, `astz - astz.utcoffset()` will have the same date and time data as `dt - dt.utcoffset()`.

If you merely want to attach a time zone object `tz` to a `datetime` `dt` without adjustment of date and time data, use `dt.replace(tzinfo=tz)`. If you merely want to remove the time zone object from an aware `datetime` `dt` without conversion of date and time data, use `dt.replace(tzinfo=None)`.

Note that the default `tzinfo.fromutc()` method can be overridden in a `tzinfo` subclass to affect the result returned by `astimezone()`. Ignoring error cases, `astimezone()` acts like:

```
def astimezone(self, tz):
    if self.tzinfo is tz:
        return self
    # Convert self to UTC, and attach the new time zone object.
    utc = (self - self.utcoffset()).replace(tzinfo=tz)
    # Convert from UTC to tz's local time.
    return tz.fromutc(utc)
```

Άλλαξε στην έκδοση 3.3: `tz` now can be omitted.

Άλλαξε στην έκδοση 3.6: The `astimezone()` method can now be called on naive instances that are presumed to represent system local time.

`datetime.utcoffset()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.utcoffset(self)`, and raises an exception if the latter doesn't return `None` or a `timedelta` object with magnitude less than one day.

Άλλαξε στην έκδοση 3.7: The UTC offset is not restricted to a whole number of minutes.

`datetime.dst()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.dst(self)`, and raises an exception if the latter doesn't return `None` or a `timedelta` object with magnitude less than one day.

Άλλαξε στην έκδοση 3.7: The DST offset is not restricted to a whole number of minutes.

`datetime.tzname()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.tzname(self)`, raises an exception if the latter doesn't return `None` or a string object,

`datetime.timetuple()`

Return a `time.struct_time` such as returned by `time.localtime()`.

`d.timetuple()` is equivalent to:

```
time.struct_time((d.year, d.month, d.day,
                  d.hour, d.minute, d.second,
                  d.weekday(), yday, dst))
```

where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st. The `tm_isdst` flag of the result is set according to the `dst()` method: `tzinfo` is `None` or `dst()` returns `None`, `tm_isdst` is set to `-1`; else if `dst()` returns a non-zero value, `tm_isdst` is set to `1`; else `tm_isdst` is set to `0`.

`datetime.utctimetuple()`

If `datetime` instance `d` is naive, this is the same as `d.timetuple()` except that `tm_isdst` is forced to `0` regardless of what `d.dst()` returns. DST is never in effect for a UTC time.

If `d` is aware, `d` is normalized to UTC time, by subtracting `d.utcoffset()`, and a `time.struct_time` for the normalized time is returned. `tm_isdst` is forced to `0`. Note that an `OverflowError` may be raised if `d.year` was `MINYEAR` or `MAXYEAR` and UTC adjustment spills over a year boundary.

Προειδοποίηση: Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC; as a result, using `utcfromtimetuple` may give misleading results. If you have a naive `datetime` representing UTC, use `datetime.replace(tzinfo=timezone.utc)` to make it aware, at which point you can use `datetime.timetuple()`.

`datetime.toordinal()`

Return the proleptic Gregorian ordinal of the date. The same as `self.date().toordinal()`.

`datetime.timestamp()`

Return POSIX timestamp corresponding to the `datetime` instance. The return value is a *float* similar to that returned by `time.time()`.

Naive `datetime` instances are assumed to represent local time and this method relies on the platform `C mktime()` function to perform the conversion. Since `datetime` supports wider range of values than `mktime()` on many platforms, this method may raise *OverflowError* for times far in the past or far in the future.

For aware `datetime` instances, the return value is computed as:

```
(dt - datetime(1970, 1, 1, tzinfo=timezone.utc)).total_seconds()
```

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.6: The `timestamp()` method uses the *fold* attribute to disambiguate the times during a repeated interval.

Σημείωση: There is no method to obtain the POSIX timestamp directly from a naive `datetime` instance representing UTC time. If your application uses this convention and your system timezone is not set to UTC, you can obtain the POSIX timestamp by supplying `tzinfo=timezone.utc`:

```
timestamp = dt.replace(tzinfo=timezone.utc).timestamp()
```

or by calculating the timestamp directly:

```
timestamp = (dt - datetime(1970, 1, 1)) / timedelta(seconds=1)
```

`datetime.weekday()`

Return the day of the week as an integer, where Monday is 0 and Sunday is 6. The same as `self.date().weekday()`. See also *isoweekday()*.

`datetime.isoweekday()`

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. The same as `self.date().isoweekday()`. See also *weekday()*, *isocalendar()*.

`datetime.isocalendar()`

Return a *named tuple* with three components: year, week and weekday. The same as `self.date().isocalendar()`.

`datetime.isoformat(sep='T', timespec='auto')`

Return a string representing the date and time in ISO 8601 format:

- YYYY-MM-DDTHH:MM:SS.ffffff, if *microsecond* is not 0
- YYYY-MM-DDTHH:MM:SS, if *microsecond* is 0

If *utcoffset()* does not return *None*, a string is appended, giving the UTC offset:

- YYYY-MM-DDTHH:MM:SS.ffffff+HH:MM[:SS[.ffffff]], if *microsecond* is not 0
- YYYY-MM-DDTHH:MM:SS+HH:MM[:SS[.ffffff]], if *microsecond* is 0

Examples:

```
>>> from datetime import datetime, timezone
>>> datetime(2019, 5, 18, 15, 17, 8, 132263).isoformat()
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
'2019-05-18T15:17:08.132263'
>>> datetime(2019, 5, 18, 15, 17, tzinfo=timezone.utc).isoformat()
'2019-05-18T15:17:00+00:00'
```

The optional argument *sep* (default 'T') is a one-character separator, placed between the date and time portions of the result. For example:

```
>>> from datetime import tzinfo, timedelta, datetime
>>> class TZ(tzinfo):
...     """A time zone with an arbitrary, constant -06:39 offset."""
...     def utcoffset(self, dt):
...         return timedelta(hours=-6, minutes=-39)
...
>>> datetime(2002, 12, 25, tzinfo=TZ()).isoformat(' ')
'2002-12-25 00:00:00-06:39'
>>> datetime(2009, 11, 27, microsecond=100, tzinfo=TZ()).isoformat()
'2009-11-27T00:00:00.000100-06:39'
```

The optional argument *timespec* specifies the number of additional components of the time to include (the default is 'auto'). It can be one of the following:

- 'auto': Same as 'seconds' if *microsecond* is 0, same as 'microseconds' otherwise.
- 'hours': Include the *hour* in the two-digit HH format.
- 'minutes': Include *hour* and *minute* in HH:MM format.
- 'seconds': Include *hour*, *minute*, and *second* in HH:MM:SS format.
- 'milliseconds': Include full time, but truncate fractional second part to milliseconds. HH:MM:SS.sss format.
- 'microseconds': Include full time in HH:MM:SS.ffffff format.

Σημείωση: Excluded time components are truncated, not rounded.

ValueError will be raised on an invalid *timespec* argument:

```
>>> from datetime import datetime
>>> datetime.now().isoformat(timespec='minutes')
'2002-12-25T00:00'
>>> dt = datetime(2015, 1, 1, 12, 30, 59, 0)
>>> dt.isoformat(timespec='microseconds')
'2015-01-01T12:30:59.000000'
```

Νέο στην έκδοση 3.6: Added the *timespec* argument.

`datetime.__str__()`

For a *datetime* instance *d*, `str(d)` is equivalent to `d.isoformat(' ')`.

`datetime.ctime()`

Return a string representing the date and time:

```
>>> from datetime import datetime
>>> datetime(2002, 12, 4, 20, 30, 40).ctime()
'Wed Dec 4 20:30:40 2002'
```

The output string will *not* include time zone information, regardless of whether the input is aware or naive.

`d.ctime()` is equivalent to:

```
time.ctime(time.mktime(d.timetuple()))
```

on platforms where the native C `ctime()` function (which `time.ctime()` invokes, but which `datetime.ctime()` does not invoke) conforms to the C standard.

`datetime.strptime(format)`

Return a string representing the date and time, controlled by an explicit format string. For a complete list of formatting directives, see *strptime() and strptime() Behavior*.

`datetime.__format__(format)`

Same as `datetime.strptime()`. This makes it possible to specify a format string for a `datetime` object in formatted string literals and when using `str.format()`. For a complete list of formatting directives, see *strptime() and strptime() Behavior*.

Examples of Usage: datetime

Examples of working with `datetime` objects:

```
>>> from datetime import datetime, date, time, timezone

>>> # Using datetime.combine()
>>> d = date(2005, 7, 14)
>>> t = time(12, 30)
>>> datetime.combine(d, t)
datetime.datetime(2005, 7, 14, 12, 30)

>>> # Using datetime.now()
>>> datetime.now()
datetime.datetime(2007, 12, 6, 16, 29, 43, 79043)    # GMT +1
>>> datetime.now(timezone.utc)
datetime.datetime(2007, 12, 6, 15, 29, 43, 79060, tzinfo=datetime.timezone.utc)

>>> # Using datetime.strptime()
>>> dt = datetime.strptime("21/11/06 16:30", "%d/%m/%y %H:%M")
>>> dt
datetime.datetime(2006, 11, 21, 16, 30)

>>> # Using datetime.timetuple() to get tuple of all attributes
>>> tt = dt.timetuple()
>>> for it in tt:
...     print(it)
...
2006    # year
11      # month
21      # day
16      # hour
30      # minute
0       # second
1       # weekday (0 = Monday)
325     # number of days since 1st January
-1      # dst - method tzinfo.dst() returned None

>>> # Date in ISO format
>>> ic = dt.isocalendar()
>>> for it in ic:
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

...     print(it)
...
2006     # ISO year
47       # ISO week
2        # ISO weekday

>>> # Formatting a datetime
>>> dt.strftime("%A, %d. %B %Y %I:%M%p")
'Tuesday, 21. November 2006 04:30PM'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}, the {3} is {0:%I:%M%p}.'.format(dt, "day",
↪ "month", "time")
'The day is 21, the month is November, the time is 04:30PM.'
```

The example below defines a `tzinfo` subclass capturing time zone information for Kabul, Afghanistan, which used +4 UTC until 1945 and then +4:30 UTC thereafter:

```

from datetime import timedelta, datetime, tzinfo, timezone

class KabulTz(tzinfo):
    # Kabul used +4 until 1945, when they moved to +4:30
    UTC_MOVE_DATE = datetime(1944, 12, 31, 20, tzinfo=timezone.utc)

    def utcoffset(self, dt):
        if dt.year < 1945:
            return timedelta(hours=4)
        elif (1945, 1, 1, 0, 0) <= dt.timetuple()[5] < (1945, 1, 1, 0, 30):
            # An ambiguous ("imaginary") half-hour range representing
            # a 'fold' in time due to the shift from +4 to +4:30.
            # If dt falls in the imaginary range, use fold to decide how
            # to resolve. See PEP495.
            return timedelta(hours=4, minutes=(30 if dt.fold else 0))
        else:
            return timedelta(hours=4, minutes=30)

    def fromutc(self, dt):
        # Follow same validations as in datetime.tzinfo
        if not isinstance(dt, datetime):
            raise TypeError("fromutc() requires a datetime argument")
        if dt.tzinfo is not self:
            raise ValueError("dt.tzinfo is not self")

        # A custom implementation is required for fromutc as
        # the input to this function is a datetime with utc values
        # but with a tzinfo set to self.
        # See datetime.astimezone or fromtimestamp.
        if dt.replace(tzinfo=timezone.utc) >= self.UTC_MOVE_DATE:
            return dt + timedelta(hours=4, minutes=30)
        else:
            return dt + timedelta(hours=4)

    def dst(self, dt):
        # Kabul does not observe daylight saving time.
        return timedelta(0)

    def tzname(self, dt):
        if dt >= self.UTC_MOVE_DATE:
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

    return "+04:30"
return "+04"

```

Usage of `KabulTz` from above:

```

>>> tz1 = KabulTz()

>>> # Datetime before the change
>>> dt1 = datetime(1900, 11, 21, 16, 30, tzinfo=tz1)
>>> print(dt1.utcoffset())
4:00:00

>>> # Datetime after the change
>>> dt2 = datetime(2006, 6, 14, 13, 0, tzinfo=tz1)
>>> print(dt2.utcoffset())
4:30:00

>>> # Convert datetime to another time zone
>>> dt3 = dt2.astimezone(timezone.utc)
>>> dt3
datetime.datetime(2006, 6, 14, 8, 30, tzinfo=datetime.timezone.utc)
>>> dt2
datetime.datetime(2006, 6, 14, 13, 0, tzinfo=KabulTz())
>>> dt2 == dt3
True

```

8.1.7 time Objects

A *time* object represents a (local) time of day, independent of any particular day, and subject to adjustment via a *tzinfo* object.

class `datetime.time` (*hour=0, minute=0, second=0, microsecond=0, tzinfo=None, *, fold=0*)

All arguments are optional. *tzinfo* may be `None`, or an instance of a *tzinfo* subclass. The remaining arguments must be integers in the following ranges:

- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- `fold` in `[0, 1]`.

If an argument outside those ranges is given, `ValueError` is raised. All default to 0 except *tzinfo*, which defaults to `None`.

Class attributes:

`time.min`

The earliest representable *time*, `time(0, 0, 0, 0)`.

`time.max`

The latest representable *time*, `time(23, 59, 59, 999999)`.

`time.resolution`

The smallest possible difference between non-equal *time* objects, `timedelta(microseconds=1)`, although note that arithmetic on *time* objects is not supported.

Instance attributes (read-only):

`time.hour`
In range(24).

`time.minute`
In range(60).

`time.second`
In range(60).

`time.microsecond`
In range(1000000).

`time.tzinfo`
The object passed as the `tzinfo` argument to the `time` constructor, or `None` if none was passed.

`time.fold`
In [0, 1]. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The value 0 (1) represents the earlier (later) of the two moments with the same wall time representation.

Νέο στην έκδοση 3.6.

`time` objects support comparison of `time` to `time`, where *a* is considered less than *b* when *a* precedes *b* in time. If one comparand is naive and the other is aware, `TypeError` is raised if an order comparison is attempted. For equality comparisons, naive instances are never equal to aware instances.

If both comparands are aware, and have the same `tzinfo` attribute, the common `tzinfo` attribute is ignored and the base times are compared. If both comparands are aware and have different `tzinfo` attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`). In order to stop mixed-type comparisons from falling back to the default comparison by object address, when a `time` object is compared to an object of a different type, `TypeError` is raised unless the comparison is `==` or `!=`. The latter cases return `False` or `True`, respectively.

Άλλαξε στην έκδοση 3.3: Equality comparisons between aware and naive `time` instances don't raise `TypeError`.

In Boolean contexts, a `time` object is always considered to be true.

Άλλαξε στην έκδοση 3.5: Before Python 3.5, a `time` object was considered to be false if it represented midnight in UTC. This behavior was considered obscure and error-prone and has been removed in Python 3.5. See [bpo-13936](#) for full details.

Other constructor:

classmethod `time.fromisoformat(time_string)`
Return a `time` corresponding to a `time_string` in one of the formats emitted by `time.isoformat()`. Specifically, this function supports strings in the format:

```
HH[:MM[:SS[.fff[fff]]]][+HH:MM[:SS[.ffffff]]]
```

Προσοχή: This does *not* support parsing arbitrary ISO 8601 strings. It is only intended as the inverse operation of `time.isoformat()`.

Examples:

```
>>> from datetime import time
>>> time.fromisoformat('04:23:01')
datetime.time(4, 23, 1)
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> time.fromisoformat('04:23:01.000384')
datetime.time(4, 23, 1, 384)
>>> time.fromisoformat('04:23:01+04:00')
datetime.time(4, 23, 1, tzinfo=datetime.timezone(datetime.
↪timedelta(seconds=14400)))
```

Νέο στην έκδοση 3.7.

Instance methods:

`time.replace(hour=self.hour, minute=self.minute, second=self.second, microsecond=self.microsecond, tzinfo=self.tzinfo, *, fold=0)`

Return a *time* with the same value, except for those attributes given new values by whichever keyword arguments are specified. Note that `tzinfo=None` can be specified to create a naive *time* from an aware *time*, without conversion of the time data.

Νέο στην έκδοση 3.6: Added the `fold` argument.

`time.isoformat(timespec='auto')`

Return a string representing the time in ISO 8601 format, one of:

- `HH:MM:SS.ffffff`, if *microsecond* is not 0
- `HH:MM:SS`, if *microsecond* is 0
- `HH:MM:SS.ffffff+HH:MM[:SS[.ffffff]]`, if `utcoffset()` does not return `None`
- `HH:MM:SS+HH:MM[:SS[.ffffff]]`, if *microsecond* is 0 and `utcoffset()` does not return `None`

The optional argument *timespec* specifies the number of additional components of the time to include (the default is 'auto'). It can be one of the following:

- 'auto': Same as 'seconds' if *microsecond* is 0, same as 'microseconds' otherwise.
- 'hours': Include the *hour* in the two-digit HH format.
- 'minutes': Include *hour* and *minute* in HH:MM format.
- 'seconds': Include *hour*, *minute*, and *second* in HH:MM:SS format.
- 'milliseconds': Include full time, but truncate fractional second part to milliseconds. HH:MM:SS.sss format.
- 'microseconds': Include full time in HH:MM:SS.ffffff format.

Σημείωση: Excluded time components are truncated, not rounded.

ValueError will be raised on an invalid *timespec* argument.

Example:

```
>>> from datetime import time
>>> time(hour=12, minute=34, second=56, microsecond=123456).isoformat(timespec=
↪'minutes')
'12:34'
>>> dt = time(hour=12, minute=34, second=56, microsecond=0)
>>> dt.isoformat(timespec='microseconds')
'12:34:56.000000'
>>> dt.isoformat(timespec='auto')
'12:34:56'
```

Νέο στην έκδοση 3.6: Added the *timespec* argument.

`time.__str__()`

For a time *t*, `str(t)` is equivalent to `t.isoformat()`.

`time.strftime(format)`

Return a string representing the time, controlled by an explicit format string. For a complete list of formatting directives, see *strftime()* and *strptime()* Behavior.

`time.__format__(format)`

Same as `time.strftime()`. This makes it possible to specify a format string for a *time* object in formatted string literals and when using `str.format()`. For a complete list of formatting directives, see *strftime()* and *strptime()* Behavior.

`time.utcoffset()`

If *tzinfo* is None, returns None, else returns `self.tzinfo.utcoffset(None)`, and raises an exception if the latter doesn't return None or a *timedelta* object with magnitude less than one day.

Άλλαξε στην έκδοση 3.7: The UTC offset is not restricted to a whole number of minutes.

`time.dst()`

If *tzinfo* is None, returns None, else returns `self.tzinfo.dst(None)`, and raises an exception if the latter doesn't return None, or a *timedelta* object with magnitude less than one day.

Άλλαξε στην έκδοση 3.7: The DST offset is not restricted to a whole number of minutes.

`time.tzname()`

If *tzinfo* is None, returns None, else returns `self.tzinfo.tzname(None)`, or raises an exception if the latter doesn't return None or a string object.

Examples of Usage: time

Examples of working with a *time* object:

```
>>> from datetime import time, tzinfo, timedelta
>>> class TZ1(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=1)
...     def dst(self, dt):

>>> 'The {} is {:%H:%M}'.format("time", t)
'The time is 12:10.'
```

8.1.8 tzinfo Objects

`class datetime.tzinfo`

This is an abstract base class, meaning that this class should not be instantiated directly. Define a subclass of `tzinfo` to capture information about a particular time zone.

An instance of (a concrete subclass of) `tzinfo` can be passed to the constructors for `datetime` and `time` objects. The latter objects view their attributes as being in local time, and the `tzinfo` object supports methods revealing offset of local time from UTC, the name of the time zone, and DST offset, all relative to a date or time object passed to them.

You need to derive a concrete subclass, and (at least) supply implementations of the standard `tzinfo` methods needed by the `datetime` methods you use. The `datetime` module provides `timezone`, a simple concrete subclass of `tzinfo` which can represent timezones with fixed offset from UTC such as UTC itself or North American EST and EDT.

Special requirement for pickling: A `tzinfo` subclass must have an `__init__()` method that can be called with no arguments, otherwise it can be pickled but possibly not unpickled again. This is a technical requirement that may be relaxed in the future.

A concrete subclass of `tzinfo` may need to implement the following methods. Exactly which methods are needed depends on the uses made of aware `datetime` objects. If in doubt, simply implement all of them.

`tzinfo.utcoffset(dt)`

Return offset of local time from UTC, as a `timedelta` object that is positive east of UTC. If local time is west of UTC, this should be negative.

This represents the *total* offset from UTC; for example, if a `tzinfo` object represents both time zone and DST adjustments, `utcoffset()` should return their sum. If the UTC offset isn't known, return `None`. Else the value returned must be a `timedelta` object strictly between `-timedelta(hours=24)` and `timedelta(hours=24)` (the magnitude of the offset must be less than one day). Most implementations of `utcoffset()` will probably look like one of these two:

```
return CONSTANT                # fixed-offset class
return CONSTANT + self.dst(dt) # daylight-aware class
```

If `utcoffset()` does not return `None`, `dst()` should not return `None` either.

The default implementation of `utcoffset()` raises `NotImplementedError`.

Αλλάξε στην έκδοση 3.7: The UTC offset is not restricted to a whole number of minutes.

`tzinfo.dst(dt)`

Return the daylight saving time (DST) adjustment, as a `timedelta` object or `None` if DST information isn't known.

Return `timedelta(0)` if DST is not in effect. If DST is in effect, return the offset as a `timedelta` object (see `utcoffset()` for details). Note that DST offset, if applicable, has already been added to the UTC offset returned by `utcoffset()`, so there's no need to consult `dst()` unless you're interested in obtaining DST info separately. For example, `datetime.datetime.now()` calls its `tzinfo` attribute's `dst()` method to determine how the `tm_isdst` flag should be set, and `tzinfo.fromutc()` calls `dst()` to account for DST changes when crossing time zones.

An instance `tz` of a `tzinfo` subclass that models both standard and daylight times must be consistent in this sense:

```
tz.utcoffset(dt) - tz.dst(dt)
```

must return the same result for every `datetime dt` with `dt.tzinfo == tz`. For sane `tzinfo` subclasses, this expression yields the time zone's «standard offset», which should not depend on the date or the time, but only on geographic location. The implementation of `datetime.astimezone()` relies on this, but cannot detect violations; it's the programmer's responsibility to ensure it. If a `tzinfo` subclass cannot guarantee this, it may be

able to override the default implementation of `tzinfo.fromutc()` to work correctly with `astimezone()` regardless.

Most implementations of `dst()` will probably look like one of these two:

```
def dst(self, dt):
    # a fixed-offset class: doesn't account for DST
    return timedelta(0)
```

or:

```
def dst(self, dt):
    # Code to set dston and dstoff to the time zone's DST
    # transition times based on the input dt.year, and expressed
    # in standard local time.

    if dston <= dt.replace(tzinfo=None) < dstoff:
        return timedelta(hours=1)
    else:
        return timedelta(0)
```

The default implementation of `dst()` raises `NotImplementedError`.

Άλλαξε στην έκδοση 3.7: The DST offset is not restricted to a whole number of minutes.

`tzinfo.tzname(dt)`

Return the time zone name corresponding to the `datetime` object `dt`, as a string. Nothing about string names is defined by the `datetime` module, and there's no requirement that it mean anything in particular. For example, «GMT», «UTC», «-500», «-5:00», «EDT», «US/Eastern», «America/New York» are all valid replies. Return `None` if a string name isn't known. Note that this is a method rather than a fixed string primarily because some `tzinfo` subclasses will wish to return different names depending on the specific value of `dt` passed, especially if the `tzinfo` class is accounting for daylight time.

The default implementation of `tzname()` raises `NotImplementedError`.

These methods are called by a `datetime` or `time` object, in response to their methods of the same names. A `datetime` object passes itself as the argument, and a `time` object passes `None` as the argument. A `tzinfo` subclass's methods should therefore be prepared to accept a `dt` argument of `None`, or of class `datetime`.

When `None` is passed, it's up to the class designer to decide the best response. For example, returning `None` is appropriate if the class wishes to say that time objects don't participate in the `tzinfo` protocols. It may be more useful for `utcoffset(None)` to return the standard UTC offset, as there is no other convention for discovering the standard offset.

When a `datetime` object is passed in response to a `datetime` method, `dt.tzinfo` is the same object as `self`. `tzinfo` methods can rely on this, unless user code calls `tzinfo` methods directly. The intent is that the `tzinfo` methods interpret `dt` as being in local time, and not need worry about objects in other timezones.

There is one more `tzinfo` method that a subclass may wish to override:

`tzinfo.fromutc(dt)`

This is called from the default `datetime.astimezone()` implementation. When called from that, `dt.tzinfo` is `self`, and `dt`'s date and time data are to be viewed as expressing a UTC time. The purpose of `fromutc()` is to adjust the date and time data, returning an equivalent `datetime` in `self`'s local time.

Most `tzinfo` subclasses should be able to inherit the default `fromutc()` implementation without problems. It's strong enough to handle fixed-offset time zones, and time zones accounting for both standard and daylight time, and the latter even if the DST transition times differ in different years. An example of a time zone the default `fromutc()` implementation may not handle correctly in all cases is one where the standard offset (from UTC) depends on the specific date and time passed, which can happen for political reasons. The default implementations

of `astimezone()` and `fromutc()` may not produce the result you want if the result is one of the hours straddling the moment the standard offset changes.

Skipping code for error cases, the default `fromutc()` implementation acts like:

```
def fromutc(self, dt):
    # raise ValueError error if dt.tzinfo is not self
    dtoff = dt.utcoffset()
    dtdst = dt.dst()
    # raise ValueError if dtoff is None or dtdst is None
    delta = dtoff - dtdst # this is self's standard offset
    if delta:
        dt += delta # convert to standard local time
        dtdst = dt.dst()
        # raise ValueError if dtdst is None
    if dtdst:
        return dt + dtdst
    else:
        return dt
```

In the following `tzinfo_examples.py` file there are some examples of `tzinfo` classes:

```
from datetime import tzinfo, timedelta, datetime

ZERO = timedelta(0)
HOUR = timedelta(hours=1)
SECOND = timedelta(seconds=1)

# A class capturing the platform's idea of local time.
# (May result in wrong values on historical times in
# timezones where UTC offset and/or the DST rules had
# changed in the past.)
import time as _time

STDOFFSET = timedelta(seconds = -_time.timezone)
if _time.daylight:
    DSTOFFSET = timedelta(seconds = -_time.altzone)
else:
    DSTOFFSET = STDOFFSET

DSTDIFF = DSTOFFSET - STDOFFSET

class LocalTimezone(tzinfo):

    def fromutc(self, dt):
        assert dt.tzinfo is self
        stamp = (dt - datetime(1970, 1, 1, tzinfo=self)) // SECOND
        args = _time.localtime(stamp)[:6]
        dst_diff = DSTDIFF // SECOND
        # Detect fold
        fold = (args == _time.localtime(stamp - dst_diff))
        return datetime(*args, microsecond=dt.microsecond,
                        tzinfo=self, fold=fold)

    def utcoffset(self, dt):
        if self._isdst(dt):
            return DSTOFFSET
        else:
```

Eastern = USTimeZone(-5, "Eastern", "EST", "EDT")
Central = USTimeZone(-6, "Central", "CST", "CDT")
Mountain = USTimeZone(-7, "Mountain", "MST", "MDT")
Pacific = USTimeZone(-8, "Pacific", "PST", "PDT")

```

Note that there are unavoidable subtleties twice per year in a `tzinfo` subclass accounting for both standard and daylight time, at the DST transition points. For concreteness, consider US Eastern (UTC -0500), where EDT begins the minute after 1:59 (EST) on the second Sunday in March, and ends the minute after 1:59 (EDT) on the first Sunday in November:

| | | | | | | |
|-------|-------|-------|------|------|------|------|
| UTC | 3:MM | 4:MM | 5:MM | 6:MM | 7:MM | 8:MM |
| EST | 22:MM | 23:MM | 0:MM | 1:MM | 2:MM | 3:MM |
| EDT | 23:MM | 0:MM | 1:MM | 2:MM | 3:MM | 4:MM |
| start | 22:MM | 23:MM | 0:MM | 1:MM | 3:MM | 4:MM |
| end | 23:MM | 0:MM | 1:MM | 1:MM | 2:MM | 3:MM |

When DST starts (the «start» line), the local wall clock leaps from 1:59 to 3:00. A wall time of the form 2:MM doesn't really make sense on that day, so `astimezone(Eastern)` won't deliver a result with `hour == 2` on the day DST begins. For example, at the Spring forward transition of 2016, we get:

```

>>> from datetime import datetime, timezone
>>> from tzinfo_examples import HOUR, Eastern
>>> u0 = datetime(2016, 3, 13, 5, tzinfo=timezone.utc)
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)
...     print(u.time(), 'UTC =', t.time(), t.tzname())
...
05:00:00 UTC = 00:00:00 EST
06:00:00 UTC = 01:00:00 EST
07:00:00 UTC = 03:00:00 EDT
08:00:00 UTC = 04:00:00 EDT

```

When DST ends (the «end» line), there's a potentially worse problem: there's an hour that can't be spelled unambiguously in local wall time: the last hour of daylight time. In Eastern, that's times of the form 5:MM UTC on the day daylight time ends. The local wall clock leaps from 1:59 (daylight time) back to 1:00 (standard time) again. Local times of the form 1:MM are ambiguous. `astimezone()` mimics the local clock's behavior by mapping two adjacent UTC hours into the same local hour then. In the Eastern example, UTC times of the form 5:MM and 6:MM both map to 1:MM when converted to Eastern, but earlier times have the `fold` attribute set to 0 and the later times have it set to 1. For example, at the Fall back transition of 2016, we get:

```
>>> u0 = datetime(2016, 11, 6, 4, tzinfo=timezone.utc)
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)
...     print(u.time(), 'UTC =', t.time(), t.tzname(), t.fold)
...
04:00:00 UTC = 00:00:00 EDT 0
05:00:00 UTC = 01:00:00 EDT 0
06:00:00 UTC = 01:00:00 EST 1
07:00:00 UTC = 02:00:00 EST 0
```

Note that the `datetime` instances that differ only by the value of the `fold` attribute are considered equal in comparisons.

Applications that can't bear wall-time ambiguities should explicitly check the value of the `fold` attribute or avoid using hybrid `tzinfo` subclasses; there are no ambiguities when using `timezone`, or any other fixed-offset `tzinfo` subclass (such as a class representing only EST (fixed offset -5 hours), or only EDT (fixed offset -4 hours)).

Δείτε επίσης:

zoneinfo The `datetime` module has a basic `timezone` class (for handling arbitrary fixed offsets from UTC) and its `timezone.utc` attribute (a UTC timezone instance).

`zoneinfo` brings the *IANA timezone database* (also known as the Olson database) to Python, and its usage is recommended.

IANA timezone database The Time Zone Database (often called tz, tzdata or zoneinfo) contains code and data that represent the history of local time for many representative locations around the globe. It is updated periodically to reflect changes made by political bodies to time zone boundaries, UTC offsets, and daylight-saving rules.

8.1.9 timezone Objects

The `timezone` class is a subclass of `tzinfo`, each instance of which represents a timezone defined by a fixed offset from UTC.

Objects of this class cannot be used to represent timezone information in the locations where different offsets are used in different days of the year or where historical changes have been made to civil time.

class `datetime.timezone` (*offset*, *name=None*)

The *offset* argument must be specified as a `timedelta` object representing the difference between the local time and UTC. It must be strictly between `-timedelta(hours=24)` and `timedelta(hours=24)`, otherwise `ValueError` is raised.

The *name* argument is optional. If specified it must be a string that will be used as the value returned by the `datetime.tzname()` method.

Νέο στην έκδοση 3.2.

Άλλαξε στην έκδοση 3.7: The UTC offset is not restricted to a whole number of minutes.

`timezone.utcoffset` (*dt*)

Return the fixed value specified when the `timezone` instance is constructed.

The *dt* argument is ignored. The return value is a *timedelta* instance equal to the difference between the local time and UTC.

Άλλαξε στην έκδοση 3.7: The UTC offset is not restricted to a whole number of minutes.

`timezone.tzname(dt)`

Return the fixed value specified when the *timezone* instance is constructed.

If *name* is not provided in the constructor, the name returned by `tzname(dt)` is generated from the value of the *offset* as follows. If *offset* is `timedelta(0)`, the name is «UTC», otherwise it is a string in the format `UTC±HH:MM`, where \pm is the sign of *offset*, HH and MM are two digits of *offset.hours* and *offset.minutes* respectively.

Άλλαξε στην έκδοση 3.6: Name generated from `offset=timedelta(0)` is now plain “UTC”, not ‘UTC+00:00’.

`timezone.dst(dt)`

Always returns None.

`timezone.fromutc(dt)`

Return `dt + offset`. The *dt* argument must be an aware *datetime* instance, with *tzinfo* set to *self*.

Class attributes:

`timezone.utc`

The UTC timezone, `timezone(timedelta(0))`.

8.1.10 `strftime()` and `strptime()` Behavior

date, *datetime*, and *time* objects all support a `strftime(format)` method, to create a string representing the time under the control of an explicit format string.

Conversely, the `datetime.strptime()` class method creates a *datetime* object from a string representing a date and time and a corresponding format string.

The table below provides a high-level comparison of `strftime()` versus `strptime()`:

| | <code>strftime</code> | <code>strptime</code> |
|----------------|--|---|
| Usage | Convert object to a string according to a given format | Parse a string into a <i>datetime</i> object given a corresponding format |
| Type of method | Instance method | Class method |
| Method of | <i>date</i> ; <i>datetime</i> ; <i>time</i> | <i>datetime</i> |
| Signature | <code>strftime(format)</code> | <code>strptime(date_string, format)</code> |

`strftime()` and `strptime()` Format Codes

The following is a list of all the format codes that the 1989 C standard requires, and these work on all platforms with a standard C implementation.

| Directive | Meaning | Example | Notes |
|------------|--|---|-------------------------------|
| %a | Weekday as locale's abbreviated name. | Sun, Mon, ..., Sat (en_US); So, Mo, ..., Sa (de_DE) | (1) |
| %A | Weekday as locale's full name. | Sunday, Monday, ..., Saturday (en_US); Sonntag, Montag, ..., Samstag (de_DE) | (1) |
| %w | Weekday as a decimal number, where 0 is Sunday and 6 is Saturday. | 0, 1, ..., 6 | |
| %d | Day of the month as a zero-padded decimal number. | 01, 02, ..., 31 | (9) |
| %b | Month as locale's abbreviated name. | Jan, Feb, ..., Dec (en_US); Jan, Feb, ..., Dez (de_DE) | (1) |
| %B | Month as locale's full name. | January, February, ..., December (en_US); Januar, Februar, ..., Dezember (de_DE) | (1) |
| %m | Month as a zero-padded decimal number. | 01, 02, ..., 12 | (9) |
| %y | Year without century as a zero-padded decimal number. | 00, 01, ..., 99 | (9) |
| %Y | Year with century as a decimal number. | 0001, 0002, ..., 2013, 2014, ..., 9998, 9999 | (2) |
| %H | Hour (24-hour clock) as a zero-padded decimal number. | 00, 01, ..., 23 | (9) |
| %I | Hour (12-hour clock) as a zero-padded decimal number. | 01, 02, ..., 12 | (9) |
| %p | Locale's equivalent of either AM or PM. | AM, PM (en_US); am, pm (de_DE) | (1), (3) |
| %M | Minute as a zero-padded decimal number. | 00, 01, ..., 59 | (9) |
| %S | Second as a zero-padded decimal number. | 00, 01, ..., 59 | (4), (9) |
| %f | Microsecond as a decimal number, zero-padded to 6 digits. | 000000, 000001, ..., 999999 | (5) |
| 228 | | | Κεφάλαιο 8. Data Types |
| %z | UTC offset in the form ±HHMM[SS[.ffffff]] (empty string if the object has no tzinfo attribute) | (empty), +0000, -0400, +1030, +063415, - 030712.345216 | (6) |

Several additional directives not required by the C89 standard are included for convenience. These parameters all correspond to ISO 8601 date values.

| Directive | Meaning | Example | Notes |
|-----------|---|--|-------------|
| %G | ISO 8601 year with century representing the year that contains the greater part of the ISO week (%V). | 0001, 0002, ..., 2013, 2014, ..., 9998, 9999 | (8) |
| %u | ISO 8601 weekday as a decimal number where 1 is Monday. | 1, 2, ..., 7 | |
| %V | ISO 8601 week as a decimal number with Monday as the first day of the week. Week 01 is the week containing Jan 4. | 01, 02, ..., 53 | (8), (9) |

These may not be available on all platforms when used with the `strptime()` method. The ISO 8601 year and ISO 8601 week directives are not interchangeable with the year and week number directives above. Calling `strptime()` with incomplete or ambiguous ISO 8601 directives will raise a `ValueError`.

The full set of format codes supported varies across platforms, because Python calls the platform C library's `strptime()` function, and platform variations are common. To see the full set of format codes supported on your platform, consult the `strptime(3)` documentation. There are also differences between platforms in handling of unsupported format specifiers.

Νέο στην έκδοση 3.6: %G, %u and %V were added.

Technical Detail

Broadly speaking, `d.strptime(fmt)` acts like the `time` module's `time.strptime(fmt, d.timetuple())` although not all objects support a `timetuple()` method.

For the `datetime.strptime()` class method, the default value is `1900-01-01T00:00:00.000`: any components not specified in the format string will be pulled from the default value.⁴

Using `datetime.strptime(date_string, format)` is equivalent to:

```
datetime(*(time.strptime(date_string, format)[0:6]))
```

except when the format includes sub-second components or timezone offset information, which are supported in `datetime.strptime` but are discarded by `time.strptime`.

For `time` objects, the format codes for year, month, and day should not be used, as `time` objects have no such values. If they're used anyway, 1900 is substituted for the year, and 1 for the month and day.

For `date` objects, the format codes for hours, minutes, seconds, and microseconds should not be used, as `date` objects have no such values. If they're used anyway, 0 is substituted for them.

For the same reason, handling of format strings containing Unicode code points that can't be represented in the charset of the current locale is also platform-dependent. On some platforms such code points are preserved intact in the output, while on others `strptime` may raise `UnicodeError` or return an empty string instead.

Notes:

- (1) Because the format depends on the current locale, care should be taken when making assumptions about the output value. Field orderings will vary (for example, «month/day/year» versus «day/month/year»), and the output may contain Unicode characters encoded using the locale's default encoding (for example, if the current locale is `ja_JP`, the default encoding could be any one of `eucJP`, `SJIS`, or `utf-8`; use `locale.getlocale()` to determine the current locale's encoding).
- (2) The `strptime()` method can parse years in the full [1, 9999] range, but years < 1000 must be zero-filled to 4-digit width.

⁴ Passing `datetime.strptime('Feb 29', '%b %d')` will fail since 1900 is not a leap year.

Άλλαξε στην έκδοση 3.2: In previous versions, `strptime()` method was restricted to years ≥ 1900 .

Άλλαξε στην έκδοση 3.3: In version 3.2, `strptime()` method was restricted to years ≥ 1000 .

- (3) When used with the `strptime()` method, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.
- (4) Unlike the `time` module, the `datetime` module does not support leap seconds.
- (5) When used with the `strptime()` method, the `%f` directive accepts from one to six digits and zero pads on the right. `%f` is an extension to the set of format characters in the C standard (but implemented separately in `datetime` objects, and therefore always available).
- (6) For a naive object, the `%z` and `%Z` format codes are replaced by empty strings.

For an aware object:

%z `utcoffset()` is transformed into a string of the form `±HHMM[SS[.ffffff]]`, where `HH` is a 2-digit string giving the number of UTC offset hours, `MM` is a 2-digit string giving the number of UTC offset minutes, `SS` is a 2-digit string giving the number of UTC offset seconds and `ffffff` is a 6-digit string giving the number of UTC offset microseconds. The `ffffff` part is omitted when the offset is a whole number of seconds and both the `ffffff` and the `SS` part is omitted when the offset is a whole number of minutes. For example, if `utcoffset()` returns `timedelta(hours=-3, minutes=-30)`, `%z` is replaced with the string `'-0330'`.

Άλλαξε στην έκδοση 3.7: The UTC offset is not restricted to a whole number of minutes.

Άλλαξε στην έκδοση 3.7: When the `%z` directive is provided to the `strptime()` method, the UTC offsets can have a colon as a separator between hours, minutes and seconds. For example, `'+01:00:00'` will be parsed as an offset of one hour. In addition, providing `'Z'` is identical to `'+00:00'`.

%Z In `strptime()`, `%Z` is replaced by an empty string if `tzname()` returns `None`; otherwise `%Z` is replaced by the returned value, which must be a string.

`strptime()` only accepts certain values for `%Z`:

1. any value in `time.tzname` for your machine's locale
2. the hard-coded values `UTC` and `GMT`

So someone living in Japan may have `JST`, `UTC`, and `GMT` as valid values, but probably not `EST`. It will raise `ValueError` for invalid values.

Άλλαξε στην έκδοση 3.2: When the `%z` directive is provided to the `strptime()` method, an aware `datetime` object will be produced. The `tzinfo` of the result will be set to a `timezone` instance.

- (7) When used with the `strptime()` method, `%U` and `%W` are only used in calculations when the day of the week and the calendar year (`%Y`) are specified.
- (8) Similar to `%U` and `%W`, `%V` is only used in calculations when the day of the week and the ISO year (`%G`) are specified in a `strptime()` format string. Also note that `%G` and `%Y` are not interchangeable.
- (9) When used with the `strptime()` method, the leading zero is optional for formats `%d`, `%m`, `%H`, `%I`, `%M`, `%S`, `%J`, `%U`, `%W`, and `%V`. Format `%y` does require a leading zero.

8.2 zoneinfo — IANA time zone support

Νέο στην έκδοση 3.9.

The `zoneinfo` module provides a concrete time zone implementation to support the IANA time zone database as originally specified in [PEP 615](#). By default, `zoneinfo` uses the system's time zone data if available; if no system time zone data is available, the library will fall back to using the first-party `tzdata` package available on PyPI.

Δείτε επίσης:

Module: `datetime` Provides the `time` and `datetime` types with which the `ZoneInfo` class is designed to be used.

Package: `tzdata` First-party package maintained by the CPython core developers to supply time zone data via PyPI.

8.2.1 Using ZoneInfo

`ZoneInfo` is a concrete implementation of the `datetime.tzinfo` abstract base class, and is intended to be attached to `tzinfo`, either via the constructor, the `datetime.replace` method or `datetime.astimezone`:

```
>>> from zoneinfo import ZoneInfo
>>> from datetime import datetime, timedelta

>>> dt = datetime(2020, 10, 31, 12, tzinfo=ZoneInfo("America/Los_Angeles"))
>>> print(dt)
2020-10-31 12:00:00-07:00

>>> dt.tzname()
'PDT'
```

Datetimes constructed in this way are compatible with datetime arithmetic and handle daylight saving time transitions with no further intervention:

```
>>> dt_add = dt + timedelta(days=1)

>>> print(dt_add)
2020-11-01 12:00:00-08:00

>>> dt_add.tzname()
'PST'
```

These time zones also support the `fold` attribute introduced in [PEP 495](#). During offset transitions which induce ambiguous times (such as a daylight saving time to standard time transition), the offset from *before* the transition is used when `fold=0`, and the offset *after* the transition is used when `fold=1`, for example:

```
>>> dt = datetime(2020, 11, 1, 1, tzinfo=ZoneInfo("America/Los_Angeles"))
>>> print(dt)
2020-11-01 01:00:00-07:00

>>> print(dt.replace(fold=1))
2020-11-01 01:00:00-08:00
```

When converting from another time zone, the `fold` will be set to the correct value:

```
>>> from datetime import timezone
>>> LOS_ANGELES = ZoneInfo("America/Los_Angeles")
>>> dt_utc = datetime(2020, 11, 1, 8, tzinfo=timezone.utc)

>>> # Before the PDT -> PST transition
>>> print(dt_utc.astimezone(LOS_ANGELES))
2020-11-01 01:00:00-07:00

>>> # After the PDT -> PST transition
>>> print((dt_utc + timedelta(hours=1)).astimezone(LOS_ANGELES))
2020-11-01 01:00:00-08:00
```

8.2.2 Data sources

The `zoneinfo` module does not directly provide time zone data, and instead pulls time zone information from the system time zone database or the first-party PyPI package `tzdata`, if available. Some systems, including notably Windows systems, do not have an IANA database available, and so for projects targeting cross-platform compatibility that require time zone data, it is recommended to declare a dependency on `tzdata`. If neither system data nor `tzdata` are available, all calls to `ZoneInfo` will raise `ZoneInfoNotFoundError`.

Configuring the data sources

When `ZoneInfo(key)` is called, the constructor first searches the directories specified in `TZPATH` for a file matching `key`, and on failure looks for a match in the `tzdata` package. This behavior can be configured in three ways:

1. The default `TZPATH` when not otherwise specified can be configured at *compile time*.
2. `TZPATH` can be configured using *an environment variable*.
3. At *runtime*, the search path can be manipulated using the `reset_tzpath()` function.

Compile-time configuration

The default `TZPATH` includes several common deployment locations for the time zone database (except on Windows, where there are no «well-known» locations for time zone data). On POSIX systems, downstream distributors and those building Python from source who know where their system time zone data is deployed may change the default time zone path by specifying the compile-time option `TZPATH` (or, more likely, the configure flag `--with-tzpath`), which should be a string delimited by `os.pathsep`.

On all platforms, the configured value is available as the `TZPATH` key in `sysconfig.get_config_var()`.

Environment configuration

When initializing `TZPATH` (either at import time or whenever `reset_tzpath()` is called with no arguments), the `zoneinfo` module will use the environment variable `PYTHONTZPATH`, if it exists, to set the search path.

PYTHONTZPATH

This is an `os.pathsep`-separated string containing the time zone search path to use. It must consist of only absolute rather than relative paths. Relative components specified in `PYTHONTZPATH` will not be used, but otherwise the behavior when a relative path is specified is implementation-defined; CPython will raise `InvalidTZPathWarning`, but other implementations are free to silently ignore the erroneous component or raise an exception.

To set the system to ignore the system data and use the tzdata package instead, set `PYTHONTZPATH=""`.

Runtime configuration

The TZ search path can also be configured at runtime using the `reset_tzpath()` function. This is generally not an advisable operation, though it is reasonable to use it in test functions that require the use of a specific time zone path (or require disabling access to the system time zones).

8.2.3 The `ZoneInfo` class

class `zoneinfo.ZoneInfo(key)`

A concrete `datetime.tzinfo` subclass that represents an IANA time zone specified by the string `key`. Calls to the primary constructor will always return objects that compare identically; put another way, barring cache invalidation via `ZoneInfo.clear_cache()`, for all values of `key`, the following assertion will always be true:

```
a = ZoneInfo(key)
b = ZoneInfo(key)
assert a is b
```

`key` must be in the form of a relative, normalized POSIX path, with no up-level references. The constructor will raise `ValueError` if a non-conforming key is passed.

If no file matching `key` is found, the constructor will raise `ZoneInfoNotFoundError`.

The `ZoneInfo` class has two alternate constructors:

classmethod `ZoneInfo.from_file(fobj, /, key=None)`

Constructs a `ZoneInfo` object from a file-like object returning bytes (e.g. a file opened in binary mode or an `io.BytesIO` object). Unlike the primary constructor, this always constructs a new object.

The `key` parameter sets the name of the zone for the purposes of `__str__()` and `__repr__()`.

Objects created via this constructor cannot be pickled (see *pickling*).

classmethod `ZoneInfo.no_cache(key)`

An alternate constructor that bypasses the constructor's cache. It is identical to the primary constructor, but returns a new object on each call. This is most likely to be useful for testing or demonstration purposes, but it can also be used to create a system with a different cache invalidation strategy.

Objects created via this constructor will also bypass the cache of a deserializing process when unpickled.

Προσοχή: Using this constructor may change the semantics of your datetimes in surprising ways, only use it if you know that you need to.

The following class methods are also available:

classmethod `ZoneInfo.clear_cache(*, only_keys=None)`

A method for invalidating the cache on the `ZoneInfo` class. If no arguments are passed, all caches are invalidated and the next call to the primary constructor for each key will return a new instance.

If an iterable of key names is passed to the `only_keys` parameter, only the specified keys will be removed from the cache. Keys passed to `only_keys` but not found in the cache are ignored.

Προειδοποίηση: Invoking this function may change the semantics of datetimes using `ZoneInfo` in surprising ways; this modifies process-wide global state and thus may have wide-ranging effects. Only use it if you know that you need to.

The class has one attribute:

`ZoneInfo.key`

This is a read-only *attribute* that returns the value of `key` passed to the constructor, which should be a lookup key in the IANA time zone database (e.g. `America/New_York`, `Europe/Paris` or `Asia/Tokyo`).

For zones constructed from file without specifying a `key` parameter, this will be set to `None`.

Σημείωση: Although it is a somewhat common practice to expose these to end users, these values are designed to be primary keys for representing the relevant zones and not necessarily user-facing elements. Projects like CLDR (the Unicode Common Locale Data Repository) can be used to get more user-friendly strings from these keys.

String representations

The string representation returned when calling `str` on a `ZoneInfo` object defaults to using the `ZoneInfo.key` attribute (see the note on usage in the attribute documentation):

```
>>> zone = ZoneInfo("Pacific/Kwajalein")
>>> str(zone)
'Pacific/Kwajalein'

>>> dt = datetime(2020, 4, 1, 3, 15, tzinfo=zone)
>>> f"{dt.isoformat()} [{dt.tzinfo}]"
'2020-04-01T03:15:00+12:00 [Pacific/Kwajalein]'
```

For objects constructed from a file without specifying a `key` parameter, `str` falls back to calling `repr()`. `ZoneInfo`'s `repr` is implementation-defined and not necessarily stable between versions, but it is guaranteed not to be a valid `ZoneInfo` key.

Pickle serialization

Rather than serializing all transition data, `ZoneInfo` objects are serialized by key, and `ZoneInfo` objects constructed from files (even those with a value for `key` specified) cannot be pickled.

The behavior of a `ZoneInfo` file depends on how it was constructed:

1. `ZoneInfo(key)`: When constructed with the primary constructor, a `ZoneInfo` object is serialized by key, and when deserialized, the deserializing process uses the primary and thus it is expected that these are expected to be the same object as other references to the same time zone. For example, if `europe_berlin_pkl` is a string containing a pickle constructed from `ZoneInfo("Europe/Berlin")`, one would expect the following behavior:

```
>>> a = ZoneInfo("Europe/Berlin")
>>> b = pickle.loads(europe_berlin_pkl)
>>> a is b
True
```

2. `ZoneInfo.no_cache(key)`: When constructed from the cache-bypassing constructor, the `ZoneInfo` object is also serialized by key, but when deserialized, the deserializing process uses the cache bypassing

constructor. If `europe_berlin_pkl_nc` is a string containing a pickle constructed from `ZoneInfo.no_cache("Europe/Berlin")`, one would expect the following behavior:

```
>>> a = ZoneInfo("Europe/Berlin")
>>> b = pickle.loads(europe_berlin_pkl_nc)
>>> a is b
False
```

3. `ZoneInfo.from_file(fobj, /, key=None)`: When constructed from a file, the `ZoneInfo` object raises an exception on pickling. If an end user wants to pickle a `ZoneInfo` constructed from a file, it is recommended that they use a wrapper type or a custom serialization function: either serializing by key or storing the contents of the file object and serializing that.

This method of serialization requires that the time zone data for the required key be available on both the serializing and deserializing side, similar to the way that references to classes and functions are expected to exist in both the serializing and deserializing environments. It also means that no guarantees are made about the consistency of results when unpickling a `ZoneInfo` pickled in an environment with a different version of the time zone data.

8.2.4 Functions

`zoneinfo.available_timezones()`

Get a set containing all the valid keys for IANA time zones available anywhere on the time zone path. This is recalculated on every call to the function.

This function only includes canonical zone names and does not include «special» zones such as those under the `posix/` and `right/` directories, or the `posixrules` zone.

Προσοχή: This function may open a large number of files, as the best way to determine if a file on the time zone path is a valid time zone is to read the «magic string» at the beginning.

Σημείωση: These values are not designed to be exposed to end-users; for user facing elements, applications should use something like CLDR (the Unicode Common Locale Data Repository) to get more user-friendly strings. See also the cautionary note on `ZoneInfo.key`.

`zoneinfo.reset_tzpath(to=None)`

Sets or resets the time zone search path (`TZPATH`) for the module. When called with no arguments, `TZPATH` is set to the default value.

Calling `reset_tzpath` will not invalidate the `ZoneInfo` cache, and so calls to the primary `ZoneInfo` constructor will only use the new `TZPATH` in the case of a cache miss.

The `to` parameter must be a *sequence* of strings or `os.PathLike` and not a string, all of which must be absolute paths. `ValueError` will be raised if something other than an absolute path is passed.

8.2.5 Globals

`zoneinfo.TZPATH`

A read-only sequence representing the time zone search path – when constructing a `ZoneInfo` from a key, the key is joined to each entry in the `TZPATH`, and the first file found is used.

`TZPATH` may contain only absolute paths, never relative paths, regardless of how it is configured.

The object that `zoneinfo.TZPATH` points to may change in response to a call to `reset_tzpath()`, so it is recommended to use `zoneinfo.TZPATH` rather than importing `TZPATH` from `zoneinfo` or assigning a long-lived variable to `zoneinfo.TZPATH`.

For more information on configuring the time zone search path, see *Configuring the data sources*.

8.2.6 Exceptions and warnings

exception `zoneinfo.ZoneInfoNotFoundError`

Raised when construction of a `ZoneInfo` object fails because the specified key could not be found on the system. This is a subclass of `KeyError`.

exception `zoneinfo.InvalidTZPathWarning`

Raised when `PYTHONTZPATH` contains an invalid component that will be filtered out, such as a relative path.

8.3 `calendar` — General calendar-related functions

Source code: [Lib/calendar.py](#)

This module allows you to output calendars like the Unix `cal` program, and provides additional useful functions related to the calendar. By default, these calendars have Monday as the first day of the week, and Sunday as the last (the European convention). Use `setfirstweekday()` to set the first day of the week to Sunday (6) or to any other weekday. Parameters that specify dates are given as integers. For related functionality, see also the `datetime` and `time` modules.

The functions and classes defined in this module use an idealized calendar, the current Gregorian calendar extended indefinitely in both directions. This matches the definition of the «proleptic Gregorian» calendar in Dershowitz and Reingold’s book «Calendrical Calculations», where it’s the base calendar for all computations. Zero and negative years are interpreted as prescribed by the ISO 8601 standard. Year 0 is 1 BC, year -1 is 2 BC, and so on.

class `calendar.Calendar` (*firstweekday=0*)

Creates a `Calendar` object. *firstweekday* is an integer specifying the first day of the week. 0 is Monday (the default), 6 is Sunday.

A `Calendar` object provides several methods that can be used for preparing the calendar data for formatting. This class doesn’t do any formatting itself. This is the job of subclasses.

`Calendar` instances have the following methods:

iterweekdays ()

Return an iterator for the week day numbers that will be used for one week. The first value from the iterator will be the same as the value of the `firstweekday` property.

itermonthdates (*year, month*)

Return an iterator for the month *month* (1–12) in the year *year*. This iterator will return all days (as `datetime.date` objects) for the month and all days before the start of the month or after the end of the month that are required to get a complete week.

itermonthdays (*year, month*)

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`, but not restricted by the `datetime.date` range. Days returned will simply be day of the month numbers. For the days outside of the specified month, the day number is 0.

itermonthdays2 (*year, month*)

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`, but not restricted by the `datetime.date` range. Days returned will be tuples consisting of a day of the month number and a week day number.

itermonthdays3 (*year, month*)

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`, but not restricted by the `datetime.date` range. Days returned will be tuples consisting of a year, a month and a day of the month numbers.

Νέο στην έκδοση 3.7.

itermonthdays4 (*year, month*)

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`, but not restricted by the `datetime.date` range. Days returned will be tuples consisting of a year, a month, a day of the month, and a day of the week numbers.

Νέο στην έκδοση 3.7.

monthdatescalendar (*year, month*)

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven `datetime.date` objects.

monthdays2calendar (*year, month*)

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven tuples of day numbers and weekday numbers.

monthdayscalendar (*year, month*)

Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven day numbers.

yeardatescalendar (*year, width=3*)

Return the data for the specified year ready for formatting. The return value is a list of month rows. Each month row contains up to *width* months (defaulting to 3). Each month contains between 4 and 6 weeks and each week contains 1-7 days. Days are `datetime.date` objects.

yeardays2calendar (*year, width=3*)

Return the data for the specified year ready for formatting (similar to `yeardatescalendar()`). Entries in the week lists are tuples of day numbers and weekday numbers. Day numbers outside this month are zero.

yeardayscalendar (*year, width=3*)

Return the data for the specified year ready for formatting (similar to `yeardatescalendar()`). Entries in the week lists are day numbers. Day numbers outside this month are zero.

class `calendar.TextCalendar` (*firstweekday=0*)

This class can be used to generate plain text calendars.

`TextCalendar` instances have the following methods:

formatmonth (*theyear, themonth, w=0, l=0*)

Return a month's calendar in a multi-line string. If *w* is provided, it specifies the width of the date columns, which are centered. If *l* is given, it specifies the number of lines that each week will use. Depends on the first weekday as specified in the constructor or set by the `setfirstweekday()` method.

prmonth (*theyear, themonth, w=0, l=0*)

Print a month's calendar as returned by `formatmonth()`.

formatyear (*theyear*, *w*=2, *l*=1, *c*=6, *m*=3)

Return a *m*-column calendar for an entire year as a multi-line string. Optional parameters *w*, *l*, and *c* are for date column width, lines per week, and number of spaces between month columns, respectively. Depends on the first weekday as specified in the constructor or set by the `setfirstweekday()` method. The earliest year for which a calendar can be generated is platform-dependent.

pryear (*theyear*, *w*=2, *l*=1, *c*=6, *m*=3)

Print the calendar for an entire year as returned by `formatyear()`.

class `calendar.HTMLCalendar` (*firstweekday*=0)

This class can be used to generate HTML calendars.

`HTMLCalendar` instances have the following methods:

formatmonth (*theyear*, *themoth*, *withyear*=True)

Return a month's calendar as an HTML table. If *withyear* is true the year will be included in the header, otherwise just the month name will be used.

formatyear (*theyear*, *width*=3)

Return a year's calendar as an HTML table. *width* (defaulting to 3) specifies the number of months per row.

formatyearpage (*theyear*, *width*=3, *css*='calendar.css', *encoding*=None)

Return a year's calendar as a complete HTML page. *width* (defaulting to 3) specifies the number of months per row. *css* is the name for the cascading style sheet to be used. *None* can be passed if no style sheet should be used. *encoding* specifies the encoding to be used for the output (defaulting to the system default encoding).

`HTMLCalendar` has the following attributes you can override to customize the CSS classes used by the calendar:

cssclasses

A list of CSS classes used for each weekday. The default class list is:

```
cssclasses = ["mon", "tue", "wed", "thu", "fri", "sat", "sun"]
```

more styles can be added for each day:

```
cssclasses = ["mon text-bold", "tue", "wed", "thu", "fri", "sat", "sun red"]
```

Note that the length of this list must be seven items.

cssclass_noday

The CSS class for a weekday occurring in the previous or coming month.

Νέο στην έκδοση 3.7.

cssclasses_weekday_head

A list of CSS classes used for weekday names in the header row. The default is the same as `cssclasses`.

Νέο στην έκδοση 3.7.

cssclass_month_head

The month's head CSS class (used by `formatmonthname()`). The default value is "month".

Νέο στην έκδοση 3.7.

cssclass_month

The CSS class for the whole month's table (used by `formatmonth()`). The default value is "month".

Νέο στην έκδοση 3.7.

cssclass_year

The CSS class for the whole year's table of tables (used by `formatyear()`). The default value is "year".

Νέο στην έκδοση 3.7.

cssclass_year_head

The CSS class for the table head for the whole year (used by `formatyear()`). The default value is "year".

Νέο στην έκδοση 3.7.

Note that although the naming for the above described class attributes is singular (e.g. `cssclass_month` `cssclass_noday`), one can replace the single CSS class with a space separated list of CSS classes, for example:

```
"text-bold text-red"
```

Here is an example how `HTMLCalendar` can be customized:

```
class CustomHTMLCal(calendar.HTMLCalendar):
    cssclasses = [style + " text-nowrap" for style in
                  calendar.HTMLCalendar.cssclasses]
    cssclass_month_head = "text-center month-head"
    cssclass_month = "text-center month"
    cssclass_year = "text-italic lead"
```

class `calendar.LocaleTextCalendar` (*firstweekday=0, locale=None*)

This subclass of `TextCalendar` can be passed a locale name in the constructor and will return month and weekday names in the specified locale. If this locale includes an encoding all strings containing month and weekday names will be returned as unicode.

class `calendar.LocaleHTMLCalendar` (*firstweekday=0, locale=None*)

This subclass of `HTMLCalendar` can be passed a locale name in the constructor and will return month and weekday names in the specified locale. If this locale includes an encoding all strings containing month and weekday names will be returned as unicode.

Σημείωση: The `formatweekday()` and `formatmonthname()` methods of these two classes temporarily change the current locale to the given *locale*. Because the current locale is a process-wide setting, they are not thread-safe.

For simple text calendars this module provides the following functions.

`calendar.setfirstweekday` (*weekday*)

Sets the weekday (0 is Monday, 6 is Sunday) to start each week. The values `MONDAY`, `TUESDAY`, `WEDNESDAY`, `THURSDAY`, `FRIDAY`, `SATURDAY`, and `SUNDAY` are provided for convenience. For example, to set the first weekday to Sunday:

```
import calendar
calendar.setfirstweekday(calendar.SUNDAY)
```

`calendar.firstweekday` ()

Returns the current setting for the weekday to start each week.

`calendar.isleap` (*year*)

Returns *True* if *year* is a leap year, otherwise *False*.

`calendar.leapdays` (*y1, y2*)

Returns the number of leap years in the range from *y1* to *y2* (exclusive), where *y1* and *y2* are years.

This function works for ranges spanning a century change.

`calendar.weekday` (*year, month, day*)

Returns the day of the week (0 is Monday) for *year* (1970–...), *month* (1–12), *day* (1–31).

`calendar.weekheader` (*n*)

Return a header containing abbreviated weekday names. *n* specifies the width in characters for one weekday.

`calendar.monthrange(year, month)`

Returns weekday of first day of the month and number of days in month, for the specified *year* and *month*.

`calendar.monthcalendar(year, month)`

Returns a matrix representing a month's calendar. Each row represents a week; days outside of the month are represented by zeros. Each week begins with Monday unless set by `setfirstweekday()`.

`calendar.prmnth(theyear, themonth, w=0, l=0)`

Prints a month's calendar as returned by `month()`.

`calendar.month(theyear, themonth, w=0, l=0)`

Returns a month's calendar in a multi-line string using the `formatmonth()` of the `TextCalendar` class.

`calendar.prcal(year, w=0, l=0, c=6, m=3)`

Prints the calendar for an entire year as returned by `calendar()`.

`calendar.calendar(year, w=2, l=1, c=6, m=3)`

Returns a 3-column calendar for an entire year as a multi-line string using the `formatyear()` of the `TextCalendar` class.

`calendar.timegm(tuple)`

An unrelated but handy function that takes a time tuple such as returned by the `gmtime()` function in the `time` module, and returns the corresponding Unix timestamp value, assuming an epoch of 1970, and the POSIX encoding. In fact, `time.gmtime()` and `timegm()` are each others' inverse.

The `calendar` module exports the following data attributes:

`calendar.day_name`

An array that represents the days of the week in the current locale.

`calendar.day_abbr`

An array that represents the abbreviated days of the week in the current locale.

`calendar.month_name`

An array that represents the months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_name[0]` is the empty string.

`calendar.month_abbr`

An array that represents the abbreviated months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_abbr[0]` is the empty string.

8.4 collections — Container datatypes

Source code: `Lib/collections/__init__.py`

This module implements specialized container datatypes providing alternatives to Python's general purpose built-in containers, `dict`, `list`, `set`, and `tuple`.

| | |
|---------------------------|--|
| <code>namedtuple()</code> | factory function for creating tuple subclasses with named fields |
| <code>deque</code> | list-like container with fast appends and pops on either end |
| <code>ChainMap</code> | dict-like class for creating a single view of multiple mappings |
| <code>Counter</code> | dict subclass for counting hashable objects |
| <code>OrderedDict</code> | dict subclass that remembers the order entries were added |
| <code>defaultdict</code> | dict subclass that calls a factory function to supply missing values |
| <code>UserDict</code> | wrapper around dictionary objects for easier dict subclassing |
| <code>UserList</code> | wrapper around list objects for easier list subclassing |
| <code>UserString</code> | wrapper around string objects for easier string subclassing |

Deprecated since version 3.3, will be removed in version 3.10: Moved *Αφηρημένες Βασικές Κλάσεις Συλλογών* to the `collections.abc` module. For backwards compatibility, they continue to be visible in this module through Python 3.9.

8.4.1 ChainMap objects

Νέο στην έκδοση 3.3.

A `ChainMap` class is provided for quickly linking a number of mappings so they can be treated as a single unit. It is often much faster than creating a new dictionary and running multiple `update()` calls.

The class can be used to simulate nested scopes and is useful in templating.

class `collections.ChainMap(*maps)`

A `ChainMap` groups multiple dicts or other mappings together to create a single, updateable view. If no `maps` are specified, a single empty dictionary is provided so that a new chain always has at least one mapping.

The underlying mappings are stored in a list. That list is public and can be accessed or updated using the `maps` attribute. There is no other state.

Lookups search the underlying mappings successively until a key is found. In contrast, writes, updates, and deletions only operate on the first mapping.

A `ChainMap` incorporates the underlying mappings by reference. So, if one of the underlying mappings gets updated, those changes will be reflected in `ChainMap`.

All of the usual dictionary methods are supported. In addition, there is a `maps` attribute, a method for creating new subcontexts, and a property for accessing all but the first mapping:

maps

A user updateable list of mappings. The list is ordered from first-searched to last-searched. It is the only stored state and can be modified to change which mappings are searched. The list should always contain at least one mapping.

new_child(m=None)

Returns a new `ChainMap` containing a new map followed by all of the maps in the current instance. If `m` is specified, it becomes the new map at the front of the list of mappings; if not specified, an empty dict is used, so that a call to `d.new_child()` is equivalent to: `ChainMap({}, *d.maps)`. This method is used for creating subcontexts that can be updated without altering values in any of the parent mappings.

Άλλαξε στην έκδοση 3.4: The optional `m` parameter was added.

parents

Property returning a new `ChainMap` containing all of the maps in the current instance except the first one. This is useful for skipping the first map in the search. Use cases are similar to those for the `nonlocal` keyword used in *nested scopes*. The use cases also parallel those for the built-in `super()` function. A reference to `d.parents` is equivalent to: `ChainMap(*d.maps[1:])`.

Note, the iteration order of a `ChainMap()` is determined by scanning the mappings last to first:

```
>>> baseline = {'music': 'bach', 'art': 'rembrandt'}
>>> adjustments = {'art': 'van gogh', 'opera': 'carmen'}
>>> list(ChainMap(adjustments, baseline))
['music', 'art', 'opera']
```

This gives the same ordering as a series of `dict.update()` calls starting with the last mapping:

```
>>> combined = baseline.copy()
>>> combined.update(adjustments)
>>> list(combined)
['music', 'art', 'opera']
```

Άλλαξε στην έκδοση 3.9: Added support for `|` and `|=` operators, specified in [PEP 584](#).

- The [Nested Contexts recipe](#) has options to control whether writes and other mutations apply only to the first mapping or to any mapping in the chain.
- A [greatly simplified read-only version of Chainmap](#).

ChainMap Examples and Recipes

This section shows various approaches to working with chained maps.

Example of simulating Python's internal lookup chain:

```
import builtins
pylookup = ChainMap(locals(), globals(), vars(builtins))
```

Example of letting user specified command-line arguments take precedence over environment variables which in turn take precedence over default values:

```
import os, argparse

defaults = {'color': 'red', 'user': 'guest'}

parser = argparse.ArgumentParser()
parser.add_argument('-u', '--user')
parser.add_argument('-c', '--color')
namespace = parser.parse_args()
command_line_args = {k: v for k, v in vars(namespace).items() if v is not None}

combined = ChainMap(command_line_args, os.environ, defaults)
print(combined['color'])
print(combined['user'])
```

Example patterns for using the `ChainMap` class to simulate nested contexts:

```

c = ChainMap()           # Create root context
d = c.new_child()        # Create nested child context
e = c.new_child()        # Child of c, independent from d
e.maps[0]                # Current context dictionary -- like Python's locals()
e.maps[-1]               # Root context -- like Python's globals()
e.parents                # Enclosing context chain -- like Python's nonlocals

d['x'] = 1                # Set value in current context
d['x']                   # Get first key in the chain of contexts
del d['x']                # Delete from current context
list(d)                  # All nested values
k in d                   # Check all nested values
len(d)                   # Number of nested values
d.items()                # All nested items
dict(d)                  # Flatten into a regular dictionary

```

The `ChainMap` class only makes updates (writes and deletions) to the first mapping in the chain while lookups will search the full chain. However, if deep writes and deletions are desired, it is easy to make a subclass that updates keys found deeper in the chain:

```

class DeepChainMap(ChainMap):
    'Variant of ChainMap that allows direct updates to inner scopes'

    def __setitem__(self, key, value):
        for mapping in self.maps:
            if key in mapping:
                mapping[key] = value
                return
        self.maps[0][key] = value

    def __delitem__(self, key):
        for mapping in self.maps:
            if key in mapping:
                del mapping[key]
                return
        raise KeyError(key)

>>> d = DeepChainMap({'zebra': 'black'}, {'elephant': 'blue'}, {'lion': 'yellow'})
>>> d['lion'] = 'orange'           # update an existing key two levels down
>>> d['snake'] = 'red'             # new keys get added to the topmost dict
>>> del d['elephant']              # remove an existing key one level down
>>> d                             # display result
DeepChainMap({'zebra': 'black', 'snake': 'red'}, {}, {'lion': 'orange'})

```

8.4.2 Counter objects

A counter tool is provided to support convenient and rapid tallies. For example:

```

>>> # Tally occurrences of words in a list
>>> cnt = Counter()
>>> for word in ['red', 'blue', 'red', 'green', 'blue', 'blue']:
...     cnt[word] += 1
>>> cnt
Counter({'blue': 3, 'red': 2, 'green': 1})

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> # Find the ten most common words in Hamlet
>>> import re
>>> words = re.findall(r'\w+', open('hamlet.txt').read().lower())
>>> Counter(words).most_common(10)
[('the', 1143), ('and', 966), ('to', 762), ('of', 669), ('i', 631),
 ('you', 554), ('a', 546), ('my', 514), ('hamlet', 471), ('in', 451)]
```

class collections.Counter(*[iterable-or-mapping]*)

A *Counter* is a *dict* subclass for counting hashable objects. It is a collection where elements are stored as dictionary keys and their counts are stored as dictionary values. Counts are allowed to be any integer value including zero or negative counts. The *Counter* class is similar to bags or multisets in other languages.

Elements are counted from an *iterable* or initialized from another *mapping* (or counter):

```
>>> c = Counter() # a new, empty counter
>>> c = Counter('gallahad') # a new counter from an iterable
>>> c = Counter({'red': 4, 'blue': 2}) # a new counter from a mapping
>>> c = Counter(cats=4, dogs=8) # a new counter from keyword args
```

Counter objects have a dictionary interface except that they return a zero count for missing items instead of raising a *KeyError*:

```
>>> c = Counter(['eggs', 'ham'])
>>> c['bacon'] # count of a missing element is zero
0
```

Setting a count to zero does not remove an element from a counter. Use `del` to remove it entirely:

```
>>> c['sausage'] = 0 # counter entry with a zero count
>>> del c['sausage'] # del actually removes the entry
```

Νέο στην έκδοση 3.1.

Άλλαξε στην έκδοση 3.7: As a *dict* subclass, *Counter* inherited the capability to remember insertion order. Math operations on *Counter* objects also preserve order. Results are ordered according to when an element is first encountered in the left operand and then by the order encountered in the right operand.

Counter objects support additional methods beyond those available for all dictionaries:

elements()

Return an iterator over elements repeating each as many times as its count. Elements are returned in the order first encountered. If an element's count is less than one, *elements()* will ignore it.

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> sorted(c.elements())
['a', 'a', 'a', 'a', 'b', 'b']
```

most_common(*[n]*)

Return a list of the *n* most common elements and their counts from the most common to the least. If *n* is omitted or None, *most_common()* returns *all* elements in the counter. Elements with equal counts are ordered in the order first encountered:

```
>>> Counter('abracadabra').most_common(3)
[('a', 5), ('b', 2), ('r', 2)]
```

subtract(*[iterable-or-mapping]*)

Elements are subtracted from an *iterable* or from another *mapping* (or counter). Like *dict.update()* but subtracts counts instead of replacing them. Both inputs and outputs may be zero or negative.

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> d = Counter(a=1, b=2, c=3, d=4)
>>> c.subtract(d)
>>> c
Counter({'a': 3, 'b': 0, 'c': -3, 'd': -6})
```

Νέο στην έκδοση 3.2.

The usual dictionary methods are available for *Counter* objects except for two which work differently for counters.

fromkeys (*iterable*)

This class method is not implemented for *Counter* objects.

update ([*iterable-or-mapping*])

Elements are counted from an *iterable* or added-in from another *mapping* (or counter). Like *dict.update()* but adds counts instead of replacing them. Also, the *iterable* is expected to be a sequence of elements, not a sequence of (key, value) pairs.

Common patterns for working with *Counter* objects:

```
sum(c.values())           # total of all counts
c.clear()                 # reset all counts
list(c)                   # list unique elements
set(c)                    # convert to a set
dict(c)                   # convert to a regular dictionary
c.items()                 # convert to a list of (elem, cnt) pairs
Counter(dict(list_of_pairs)) # convert from a list of (elem, cnt) pairs
c.most_common()[:n-1:-1]  # n least common elements
+c                         # remove zero and negative counts
```

Several mathematical operations are provided for combining *Counter* objects to produce multisets (counters that have counts greater than zero). Addition and subtraction combine counters by adding or subtracting the counts of corresponding elements. Intersection and union return the minimum and maximum of corresponding counts. Each operation can accept inputs with signed counts, but the output will exclude results with counts of zero or less.

```
>>> c = Counter(a=3, b=1)
>>> d = Counter(a=1, b=2)
>>> c + d                      # add two counters together: c[x] + d[x]
Counter({'a': 4, 'b': 3})
>>> c - d                      # subtract (keeping only positive counts)
Counter({'a': 2})
>>> c & d                      # intersection: min(c[x], d[x])
Counter({'a': 1, 'b': 1})
>>> c | d                      # union: max(c[x], d[x])
Counter({'a': 3, 'b': 2})
```

Unary addition and subtraction are shortcuts for adding an empty counter or subtracting from an empty counter.

```
>>> c = Counter(a=2, b=-4)
>>> +c
Counter({'a': 2})
>>> -c
Counter({'b': 4})
```

Νέο στην έκδοση 3.3: Added support for unary plus, unary minus, and in-place multiset operations.

Σημείωση: Counters were primarily designed to work with positive integers to represent running counts; however, care

was taken to not unnecessarily preclude use cases needing other types or negative values. To help with those use cases, this section documents the minimum range and type restrictions.

- The `Counter` class itself is a dictionary subclass with no restrictions on its keys and values. The values are intended to be numbers representing counts, but you *could* store anything in the value field.
 - The `most_common()` method requires only that the values be orderable.
 - For in-place operations such as `c[key] += 1`, the value type need only support addition and subtraction. So fractions, floats, and decimals would work and negative values are supported. The same is also true for `update()` and `subtract()` which allow negative and zero values for both inputs and outputs.
 - The multiset methods are designed only for use cases with positive values. The inputs may be negative or zero, but only outputs with positive values are created. There are no type restrictions, but the value type needs to support addition, subtraction, and comparison.
 - The `elements()` method requires integer counts. It ignores zero and negative counts.

```
map(Counter, combinations_with_replacement('ABC', 2)) # --> AA AB AC BB BC CC
```

8.4.3 deque objects

class `collections.deque` (`[iterable[, maxlen]]`)

Returns a new deque object initialized left-to-right (using `append()`) with data from *iterable*. If *iterable* is not specified, the new deque is empty.

Deques are a generalization of stacks and queues (the name is pronounced «deck» and is short for «double-ended queue»). Deques support thread-safe, memory efficient appends and pops from either side of the deque with approximately the same $O(1)$ performance in either direction.

Though `list` objects support similar operations, they are optimized for fast fixed-length operations and incur $O(n)$ memory movement costs for `pop(0)` and `insert(0, v)` operations which change both the size and position of the underlying data representation.

If *maxlen* is not specified or is `None`, deques may grow to an arbitrary length. Otherwise, the deque is bounded to the specified maximum length. Once a bounded length deque is full, when new items are added, a corresponding number of items are discarded from the opposite end. Bounded length deques provide functionality similar to the `tail` filter in Unix. They are also useful for tracking transactions and other pools of data where only the most recent activity is of interest.

Deque objects support the following methods:

append (*x*)

Add *x* to the right side of the deque.

appendleft (*x*)

Add *x* to the left side of the deque.

clear ()

Remove all elements from the deque leaving it with length 0.

copy ()

Create a shallow copy of the deque.

Νέο στην έκδοση 3.5.

count (*x*)

Count the number of deque elements equal to *x*.

Νέο στην έκδοση 3.2.

extend (*iterable*)

Extend the right side of the deque by appending elements from the iterable argument.

extendleft (*iterable*)

Extend the left side of the deque by appending elements from *iterable*. Note, the series of left appends results in reversing the order of elements in the iterable argument.

index (*x* [, *start* [, *stop*]])

Return the position of *x* in the deque (at or after index *start* and before index *stop*). Returns the first match or raises *ValueError* if not found.

Νέο στην έκδοση 3.5.

insert (*i*, *x*)

Insert *x* into the deque at position *i*.

If the insertion would cause a bounded deque to grow beyond *maxlen*, an *IndexError* is raised.

Νέο στην έκδοση 3.5.

pop ()

Remove and return an element from the right side of the deque. If no elements are present, raises an *IndexError*.

popleft ()

Remove and return an element from the left side of the deque. If no elements are present, raises an *IndexError*.

remove (*value*)

Remove the first occurrence of *value*. If not found, raises a *ValueError*.

reverse ()

Reverse the elements of the deque in-place and then return *None*.

Νέο στην έκδοση 3.2.

rotate (*n=1*)

Rotate the deque *n* steps to the right. If *n* is negative, rotate to the left.

When the deque is not empty, rotating one step to the right is equivalent to `d.appendleft(d.pop())`, and rotating one step to the left is equivalent to `d.append(d.popleft())`.

Deque objects also provide one read-only attribute:

maxlen

Maximum size of a deque or *None* if unbounded.

Νέο στην έκδοση 3.1.

In addition to the above, deques support iteration, pickling, `len(d)`, `reversed(d)`, `copy.copy(d)`, `copy.deepcopy(d)`, membership testing with the `in` operator, and subscript references such as `d[0]` to access the first element. Indexed access is $O(1)$ at both ends but slows to $O(n)$ in the middle. For fast random access, use lists instead.

Starting in version 3.5, deques support `__add__()`, `__mul__()`, and `__imul__()`.

Example:

```
>>> from collections import deque
>>> d = deque('ghi')           # make a new deque with three items
>>> for elem in d:             # iterate over the deque's elements
...     print(elem.upper())
G
H
I

>>> d.append('j')              # add a new entry to the right side
>>> d.appendleft('f')          # add a new entry to the left side
>>> d                          # show the representation of the deque
deque(['f', 'g', 'h', 'i', 'j'])

>>> d.pop()                   # return and remove the rightmost item
'j'
>>> d.popleft()               # return and remove the leftmost item
'f'
>>> list(d)                  # list the contents of the deque
['g', 'h', 'i']
>>> d[0]                     # peek at leftmost item
'g'
>>> d[-1]                    # peek at rightmost item
'i'

>>> list(reversed(d))         # list the contents of a deque in reverse
['i', 'h', 'g']
>>> 'h' in d                  # search the deque
True
>>> d.extend('jkl')           # add multiple elements at once
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])
>>> d.rotate(1)               # right rotation
>>> d
deque(['l', 'g', 'h', 'i', 'j', 'k'])
>>> d.rotate(-1)              # left rotation
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])

>>> deque(reversed(d))        # make a new deque in reverse order
deque(['l', 'k', 'j', 'i', 'h', 'g'])
>>> d.clear()                 # empty the deque
>>> d.pop()                   # cannot pop from an empty deque
Traceback (most recent call last):
  File "<pyshell#6>", line 1, in <module>
    d.pop()
IndexError: pop from an empty deque

>>> d.extendleft('abc')       # extendleft() reverses the input order
>>> d
deque(['c', 'b', 'a'])
```

deque Recipes

This section shows various approaches to working with deques.

Bounded length deques provide functionality similar to the `tail` filter in Unix:

```
def tail(filename, n=10):
    'Return the last n lines of a file'
    with open(filename) as f:
        return deque(f, n)
```

Another approach to using deques is to maintain a sequence of recently added elements by appending to the right and popping to the left:

```
def moving_average(iterable, n=3):
    # moving_average([40, 30, 50, 46, 39, 44]) --> 40.0 42.0 45.0 43.0
    # http://en.wikipedia.org/wiki/Moving_average
    it = iter(iterable)
    d = deque(itertools.islice(it, n-1))
    d.appendleft(0)
    s = sum(d)
    for elem in it:
        s += elem - d.popleft()
        d.append(elem)
        yield s / n
```

A round-robin scheduler can be implemented with input iterators stored in a *deque*. Values are yielded from the active iterator in position zero. If that iterator is exhausted, it can be removed with *popleft()*; otherwise, it can be cycled back to the end with the *rotate()* method:

```
def roundrobin(*iterables):
    "roundrobin('ABC', 'D', 'EF') --> A D E B F C"
    iterators = deque(map(iter, iterables))
    while iterators:
        try:
            while True:
                yield next(iterators[0])
                iterators.rotate(-1)
        except StopIteration:
            # Remove an exhausted iterator.
            iterators.popleft()
```

The *rotate()* method provides a way to implement *deque* slicing and deletion. For example, a pure Python implementation of `del d[n]` relies on the *rotate()* method to position elements to be popped:

```
def delete_nth(d, n):
    d.rotate(-n)
    d.popleft()
    d.rotate(n)
```

To implement *deque* slicing, use a similar approach applying *rotate()* to bring a target element to the left side of the deque. Remove old entries with *popleft()*, add new entries with *extend()*, and then reverse the rotation. With minor variations on that approach, it is easy to implement Forth style stack manipulations such as *dup*, *drop*, *swap*, *over*, *pick*, *rot*, and *roll*.

8.4.4 defaultdict objects

class `collections.defaultdict` (*default_factory=None*, /[, ...])

Return a new dictionary-like object. `defaultdict` is a subclass of the built-in `dict` class. It overrides one method and adds one writable instance variable. The remaining functionality is the same as for the `dict` class and is not documented here.

The first argument provides the initial value for the `default_factory` attribute; it defaults to `None`. All remaining arguments are treated the same as if they were passed to the `dict` constructor, including keyword arguments.

`defaultdict` objects support the following method in addition to the standard `dict` operations:

`__missing__` (*key*)

If the `default_factory` attribute is `None`, this raises a `KeyError` exception with the *key* as argument.

If `default_factory` is not `None`, it is called without arguments to provide a default value for the given *key*, this value is inserted in the dictionary for the *key*, and returned.

If calling `default_factory` raises an exception this exception is propagated unchanged.

This method is called by the `__getitem__()` method of the `dict` class when the requested key is not found; whatever it returns or raises is then returned or raised by `__getitem__()`.

Note that `__missing__()` is *not* called for any operations besides `__getitem__()`. This means that `get()` will, like normal dictionaries, return `None` as a default rather than using `default_factory`.

`defaultdict` objects support the following instance variable:

`default_factory`

This attribute is used by the `__missing__()` method; it is initialized from the first argument to the constructor, if present, or to `None`, if absent.

Άλλαξε στην έκδοση 3.9: Added merge (`|`) and update (`|=`) operators, specified in **PEP 584**.

defaultdict Examples

Using `list` as the `default_factory`, it is easy to group a sequence of key-value pairs into a dictionary of lists:

```
>>> s = [('yellow', 1), ('blue', 2), ('yellow', 3), ('blue', 4), ('red', 1)]
>>> d = defaultdict(list)
>>> for k, v in s:
...     d[k].append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

When each key is encountered for the first time, it is not already in the mapping; so an entry is automatically created using the `default_factory` function which returns an empty `list`. The `list.append()` operation then attaches the value to the new list. When keys are encountered again, the look-up proceeds normally (returning the list for that key) and the `list.append()` operation adds another value to the list. This technique is simpler and faster than an equivalent technique using `dict.setdefault()`:

```
>>> d = {}
>>> for k, v in s:
...     d.setdefault(k, []).append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

Setting the `default_factory` to `int` makes the `defaultdict` useful for counting (like a bag or multiset in other languages):

```
>>> s = 'mississippi'
>>> d = defaultdict(int)
>>> for k in s:
...     d[k] += 1
...
>>> sorted(d.items())
[('i', 4), ('m', 1), ('p', 2), ('s', 4)]
```

When a letter is first encountered, it is missing from the mapping, so the `default_factory` function calls `int()` to supply a default count of zero. The increment operation then builds up the count for each letter.

The function `int()` which always returns zero is just a special case of constant functions. A faster and more flexible way to create constant functions is to use a lambda function which can supply any constant value (not just zero):

```
>>> def constant_factory(value):
...     return lambda: value
>>> d = defaultdict(constant_factory('<missing>'))
>>> d.update(name='John', action='ran')
>>> '%(name)s %(action)s to %(object)s' % d
'John ran to <missing>'
```

Setting the `default_factory` to `set` makes the `defaultdict` useful for building a dictionary of sets:

```
>>> s = [('red', 1), ('blue', 2), ('red', 3), ('blue', 4), ('red', 1), ('blue', 4)]
>>> d = defaultdict(set)
>>> for k, v in s:
...     d[k].add(v)
...
>>> sorted(d.items())
[('blue', {2, 4}), ('red', {1, 3})]
```

8.4.5 `namedtuple()` Factory Function for Tuples with Named Fields

Named tuples assign meaning to each position in a tuple and allow for more readable, self-documenting code. They can be used wherever regular tuples are used, and they add the ability to access fields by name instead of position index.

`collections.namedtuple` (*typename*, *field_names*, *, *rename=False*, *defaults=None*, *module=None*)

Returns a new tuple subclass named *typename*. The new subclass is used to create tuple-like objects that have fields accessible by attribute lookup as well as being indexable and iterable. Instances of the subclass also have a helpful docstring (with *typename* and *field_names*) and a helpful `__repr__()` method which lists the tuple contents in a `name=value` format.

The *field_names* are a sequence of strings such as `['x', 'y']`. Alternatively, *field_names* can be a single string with each fieldname separated by whitespace and/or commas, for example `'x y'` or `'x, y'`.

Any valid Python identifier may be used for a fieldname except for names starting with an underscore. Valid identifiers consist of letters, digits, and underscores but do not start with a digit or underscore and cannot be a *keyword* such as `class`, `for`, `return`, `global`, `pass`, or `raise`.

If *rename* is true, invalid fieldnames are automatically replaced with positional names. For example, `['abc', 'def', 'ghi', 'abc']` is converted to `['abc', '_1', 'ghi', '_3']`, eliminating the keyword `def` and the duplicate fieldname `abc`.

defaults can be `None` or an *iterable* of default values. Since fields with a default value must come after any fields without a default, the *defaults* are applied to the rightmost parameters. For example, if the fieldnames are `['x',`

'y', 'z'] and the defaults are (1, 2), then x will be a required argument, y will default to 1, and z will default to 2.

If *module* is defined, the `__module__` attribute of the named tuple is set to that value.

Named tuple instances do not have per-instance dictionaries, so they are lightweight and require no more memory than regular tuples.

To support pickling, the named tuple class should be assigned to a variable that matches *typename*.

Άλλαξε στην έκδοση 3.1: Added support for *rename*.

Άλλαξε στην έκδοση 3.6: The *verbose* and *rename* parameters became *keyword-only arguments*.

Άλλαξε στην έκδοση 3.6: Added the *module* parameter.

Άλλαξε στην έκδοση 3.7: Removed the *verbose* parameter and the `__source` attribute.

Άλλαξε στην έκδοση 3.7: Added the *defaults* parameter and the `__field_defaults` attribute.

```
>>> # Basic example
>>> Point = namedtuple('Point', ['x', 'y'])
>>> p = Point(11, y=22)      # instantiate with positional or keyword arguments
>>> p[0] + p[1]              # indexable like the plain tuple (11, 22)
33
>>> x, y = p                 # unpack like a regular tuple
>>> x, y
(11, 22)
>>> p.x + p.y                # fields also accessible by name
33
>>> p                        # readable __repr__ with a name=value style
Point(x=11, y=22)
```

Named tuples are especially useful for assigning field names to result tuples returned by the *csv* or *sqlite3* modules:

```
EmployeeRecord = namedtuple('EmployeeRecord', 'name, age, title, department, paygrade
↪')

import csv
for emp in map(EmployeeRecord._make, csv.reader(open("employees.csv", "rb"))):
    print(emp.name, emp.title)

import sqlite3
conn = sqlite3.connect('/companydata')
cursor = conn.cursor()
cursor.execute('SELECT name, age, title, department, paygrade FROM employees')
for emp in map(EmployeeRecord._make, cursor.fetchall()):
    print(emp.name, emp.title)
```

In addition to the methods inherited from tuples, named tuples support three additional methods and two attributes. To prevent conflicts with field names, the method and attribute names start with an underscore.

classmethod `somenamedtuple._make(iterable)`

Class method that makes a new instance from an existing sequence or iterable.

```
>>> t = [11, 22]
>>> Point._make(t)
Point(x=11, y=22)
```

`somenamedtuple._asdict()`

Return a new *dict* which maps field names to their corresponding values:

```
>>> p = Point(x=11, y=22)
>>> p._asdict()
{'x': 11, 'y': 22}
```

Αλλάξε στην έκδοση 3.1: Returns an *OrderedDict* instead of a regular *dict*.

Αλλάξε στην έκδοση 3.8: Returns a regular *dict* instead of an *OrderedDict*. As of Python 3.7, regular dicts are guaranteed to be ordered. If the extra features of *OrderedDict* are required, the suggested remediation is to cast the result to the desired type: `OrderedDict(nt._asdict())`.

`somenamedtuple._replace(**kwargs)`

Return a new instance of the named tuple replacing specified fields with new values:

```
>>> p = Point(x=11, y=22)
>>> p._replace(x=33)
Point(x=33, y=22)

>>> for partnum, record in inventory.items():
...     inventory[partnum] = record._replace(price=newprices[partnum],
... timestamp=time.now())
```

`somenamedtuple._fields`

Tuple of strings listing the field names. Useful for introspection and for creating new named tuple types from existing named tuples.

```
>>> p._fields           # view the field names
('x', 'y')

>>> Color = namedtuple('Color', 'red green blue')
>>> Pixel = namedtuple('Pixel', Point._fields + Color._fields)
>>> Pixel(11, 22, 128, 255, 0)
Pixel(x=11, y=22, red=128, green=255, blue=0)
```

`somenamedtuple._field_defaults`

Dictionary mapping field names to default values.

```
>>> Account = namedtuple('Account', ['type', 'balance'], defaults=[0])
>>> Account._field_defaults
{'balance': 0}
>>> Account('premium')
Account(type='premium', balance=0)
```

To retrieve a field whose name is stored in a string, use the `getattr()` function:

```
>>> getattr(p, 'x')
11
```

To convert a dictionary to a named tuple, use the double-star-operator (as described in [tut-unpacking-arguments](#)):

```
>>> d = {'x': 11, 'y': 22}
>>> Point(**d)
Point(x=11, y=22)
```

Since a named tuple is a regular Python class, it is easy to add or change functionality with a subclass. Here is how to add a calculated field and a fixed-width print format:

```
>>> class Point(namedtuple('Point', ['x', 'y'])):
...     __slots__ = ()
...     @property
...     def hypot(self):
...         return (self.x ** 2 + self.y ** 2) ** 0.5
...     def __str__(self):
...         return 'Point: x=%6.3f y=%6.3f hypot=%6.3f' % (self.x, self.y, self.
↵hypot)

>>> for p in Point(3, 4), Point(14, 5/7):
...     print(p)
Point: x= 3.000 y= 4.000 hypot= 5.000
Point: x=14.000 y= 0.714 hypot=14.018
```

The subclass shown above sets `__slots__` to an empty tuple. This helps keep memory requirements low by preventing the creation of instance dictionaries.

Subclassing is not useful for adding new, stored fields. Instead, simply create a new named tuple type from the `__fields__` attribute:

```
>>> Point3D = namedtuple('Point3D', Point.__fields__ + ('z',))
```

Docstrings can be customized by making direct assignments to the `__doc__` fields:

```
>>> Book = namedtuple('Book', ['id', 'title', 'authors'])
>>> Book.__doc__ += ': Hardcover book in active collection'
>>> Book.id.__doc__ = '13-digit ISBN'
>>> Book.title.__doc__ = 'Title of first printing'
>>> Book.authors.__doc__ = 'List of authors sorted by last name'
```

Άλλαξε στην έκδοση 3.5: Property docstrings became writeable.

Δείτε επίσης:

- See [`typing.NamedTuple`](#) for a way to add type hints for named tuples. It also provides an elegant notation using the `class` keyword:

```
class Component(NamedTuple):
    part_number: int
    weight: float
    description: Optional[str] = None
```

- See [`types.SimpleNamespace\(\)`](#) for a mutable namespace based on an underlying dictionary instead of a tuple.
- The [`dataclasses`](#) module provides a decorator and functions for automatically adding generated special methods to user-defined classes.

8.4.6 OrderedDict objects

Ordered dictionaries are just like regular dictionaries but have some extra capabilities relating to ordering operations. They have become less important now that the built-in `dict` class gained the ability to remember insertion order (this new behavior became guaranteed in Python 3.7).

Some differences from `dict` still remain:

- The regular `dict` was designed to be very good at mapping operations. Tracking insertion order was secondary.
- The `OrderedDict` was designed to be good at reordering operations. Space efficiency, iteration speed, and the performance of update operations were secondary.
- Algorithmically, `OrderedDict` can handle frequent reordering operations better than `dict`. This makes it suitable for tracking recent accesses (for example in an `LRU cache`).
- The equality operation for `OrderedDict` checks for matching order.
- The `popitem()` method of `OrderedDict` has a different signature. It accepts an optional argument to specify which item is popped.
- `OrderedDict` has a `move_to_end()` method to efficiently reposition an element to an endpoint.
- Until Python 3.8, `dict` lacked a `__reversed__()` method.

class `collections.OrderedDict` (`[items]`)

Return an instance of a `dict` subclass that has methods specialized for rearranging dictionary order.

Νέο στην έκδοση 3.1.

popitem (`last=True`)

The `popitem()` method for ordered dictionaries returns and removes a (key, value) pair. The pairs are returned in LIFO order if `last` is true or FIFO (first-in, first-out) order if false.

move_to_end (`key`, `last=True`)

Move an existing `key` to either end of an ordered dictionary. The item is moved to the right end if `last` is true (the default) or to the beginning if `last` is false. Raises `KeyError` if the `key` does not exist:

```
>>> d = OrderedDict.fromkeys('abcde')
>>> d.move_to_end('b')
>>> ''.join(d.keys())
'acdeb'
>>> d.move_to_end('b', last=False)
>>> ''.join(d.keys())
'bacde'
```

Νέο στην έκδοση 3.2.

In addition to the usual mapping methods, ordered dictionaries also support reverse iteration using `reversed()`.

Equality tests between `OrderedDict` objects are order-sensitive and are implemented as `list(od1.items()) == list(od2.items())`. Equality tests between `OrderedDict` objects and other `Mapping` objects are order-insensitive like regular dictionaries. This allows `OrderedDict` objects to be substituted anywhere a regular dictionary is used.

Άλλαξε στην έκδοση 3.5: The items, keys, and values *views* of `OrderedDict` now support reverse iteration using `reversed()`.

Άλλαξε στην έκδοση 3.6: With the acceptance of [PEP 468](#), order is retained for keyword arguments passed to the `OrderedDict` constructor and its `update()` method.

Άλλαξε στην έκδοση 3.9: Added `merge()` and `update(|=)` operators, specified in [PEP 584](#).

OrderedDict Examples and Recipes

It is straightforward to create an ordered dictionary variant that remembers the order the keys were *last* inserted. If a new entry overwrites an existing entry, the original insertion position is changed and moved to the end:

```
class LastUpdatedOrderedDict(OrderedDict):
    'Store items in the order the keys were last added'

    def __setitem__(self, key, value):
        super().__setitem__(key, value)
        self.move_to_end(key)
```

An *OrderedDict* would also be useful for implementing variants of `functools.lru_cache()`:

```
class LRU:

    def __init__(self, func, maxsize=128):
        self.func = func
        self.maxsize = maxsize
        self.cache = OrderedDict()

    def __call__(self, *args):
        if args in self.cache:
            value = self.cache[args]
            self.cache.move_to_end(args)
            return value
        value = self.func(*args)
        if len(self.cache) >= self.maxsize:
            self.cache.popitem(False)
        self.cache[args] = value
        return value
```

8.4.7 UserDict objects

The class, *UserDict* acts as a wrapper around dictionary objects. The need for this class has been partially supplanted by the ability to subclass directly from *dict*; however, this class can be easier to work with because the underlying dictionary is accessible as an attribute.

class `collections.UserDict` (`[initialdata]`)

Class that simulates a dictionary. The instance's contents are kept in a regular dictionary, which is accessible via the `data` attribute of *UserDict* instances. If `initialdata` is provided, `data` is initialized with its contents; note that a reference to `initialdata` will not be kept, allowing it to be used for other purposes.

In addition to supporting the methods and operations of mappings, *UserDict* instances provide the following attribute:

data

A real dictionary used to store the contents of the *UserDict* class.

8.4.8 `UserList` objects

This class acts as a wrapper around list objects. It is a useful base class for your own list-like classes which can inherit from them and override existing methods or add new ones. In this way, one can add new behaviors to lists.

The need for this class has been partially supplanted by the ability to subclass directly from `list`; however, this class can be easier to work with because the underlying list is accessible as an attribute.

class `collections.UserList` (`[list]`)

Class that simulates a list. The instance's contents are kept in a regular list, which is accessible via the `data` attribute of `UserList` instances. The instance's contents are initially set to a copy of `list`, defaulting to the empty list `[]`. `list` can be any iterable, for example a real Python list or a `UserList` object.

In addition to supporting the methods and operations of mutable sequences, `UserList` instances provide the following attribute:

data

A real `list` object used to store the contents of the `UserList` class.

Subclassing requirements: Subclasses of `UserList` are expected to offer a constructor which can be called with either no arguments or one argument. List operations which return a new sequence attempt to create an instance of the actual implementation class. To do so, it assumes that the constructor can be called with a single parameter, which is a sequence object used as a data source.

If a derived class does not wish to comply with this requirement, all of the special methods supported by this class will need to be overridden; please consult the sources for information about the methods which need to be provided in that case.

8.4.9 `UserString` objects

The class, `UserString` acts as a wrapper around string objects. The need for this class has been partially supplanted by the ability to subclass directly from `str`; however, this class can be easier to work with because the underlying string is accessible as an attribute.

class `collections.UserString` (`seq`)

Class that simulates a string object. The instance's content is kept in a regular string object, which is accessible via the `data` attribute of `UserString` instances. The instance's contents are initially set to a copy of `seq`. The `seq` argument can be any object which can be converted into a string using the built-in `str()` function.

In addition to supporting the methods and operations of strings, `UserString` instances provide the following attribute:

data

A real `str` object used to store the contents of the `UserString` class.

Άλλαξε στην έκδοση 3.5: New methods `__getnewargs__`, `__rmod__`, `casefold`, `format_map`, `isprintable`, and `maketrans`.

8.5 `collections.abc` — Abstract Base Classes for Containers

Νέο στην έκδοση 3.3: Παλαιότερα, αυτό το module ήταν μέρος του `collections` module.

Πηγαίος κώδικας: `Lib/_collections_abc.py`

This module provides *abstract base classes* that can be used to test whether a class provides a particular interface; for example, whether it is hashable or whether it is a mapping.

Νέο στην έκδοση 3.9: Αυτές οι αφηρημένες κλάσεις υποστηρίζουν πλέον []. Δείτε *Τύπος Generic Alias* και **PEP 585**.

8.5.1 Αφηρημένες Βασικές Κλάσεις Συλλογών

To `collections` module προσφέρει τις εξής *ABCs*:

class `collections.abc.Container`
ABC for classes that provide the `__contains__()` method.

class `collections.abc.Hashable`
ABC for classes that provide the `__hash__()` method.

class `collections.abc.Sized`

ABC for classes that provide the `__len__()` method.

class `collections.abc.Callable`

ABC for classes that provide the `__call__()` method.

class `collections.abc.Iterable`

ABC for classes that provide the `__iter__()` method.

Checking `isinstance(obj, Iterable)` detects classes that are registered as *Iterable* or that have an `__iter__()` method, but it does not detect classes that iterate with the `__getitem__()` method. The only reliable way to determine whether an object is *iterable* is to call `iter(obj)`.

class `collections.abc.Collection`

ABC για τις κλάσεις επαναλαμβανόμενων container με μέγεθος.

Νέο στην έκδοση 3.6.

class `collections.abc.Iterator`

ABC για κλάσεις που παρέχουν τις μεθόδους `__iter__()` και `__next__()`. Δείτε επίσης τον ορισμό του *iterator*.

class `collections.abc.Reversible`

ABC for iterable classes that also provide the `__reversed__()` method.

Νέο στην έκδοση 3.6.

class `collections.abc.Generator`

ABC for generator classes that implement the protocol defined in **PEP 342** that extends iterators with the `send()`, `throw()` and `close()` methods. See also the definition of *generator*.

Νέο στην έκδοση 3.5.

class `collections.abc.Sequence`

class `collections.abc.MutableSequence`

class `collections.abc.ByteString`

ABCs μόνο για ανάγνωση (read-only) και mutable *sequences*.

Implementation note: Some of the mixin methods, such as `__iter__()`, `__reversed__()` and `index()`, make repeated calls to the underlying `__getitem__()` method. Consequently, if `__getitem__()` is implemented with constant access speed, the mixin methods will have linear performance; however, if the underlying method is linear (as it would be with a linked list), the mixins will have quadratic performance and will likely need to be overridden.

Άλλαξε στην έκδοση 3.5: Η μέθοδος `index()` πρόσθεσε υποστήριξη για τα ορίσματα *stop* και *start*.

class `collections.abc.Set`

class `collections.abc.MutableSet`

ABCs for read-only and mutable sets.

class `collections.abc.Mapping`

class `collections.abc.MutableMapping`

ABCs μόνο για ανάγνωση (read-only) και mutable *mappings*.

class `collections.abc.MappingView`

class `collections.abc.ItemsView`

class `collections.abc.KeysView`

class `collections.abc.ValuesView`

ABCs για αντιστοιχίσεις, στοιχεία, κλειδιά και τιμές *views*.

class `collections.abc.Awaitable`

ABC for *awaitable* objects, which can be used in `await` expressions. Custom implementations must provide the `__await__()` method.

Τα αντικείμενα *Coroutine* και τα στιγμιότυπα της κλάσης *Coroutine* είναι όλα παραδείγματα αυτής της ABC.

Σημείωση: In CPython, generator-based coroutines (generators decorated with `types.coroutine()` or `asyncio.coroutine()`) are *awaitables*, even though they do not have an `__await__()` method. Using `isinstance(gencoro, Awaitable)` for them will return `False`. Use `inspect.isawaitable()` to detect them.

Νέο στην έκδοση 3.5.

class `collections.abc.Coroutine`

ABC for coroutine compatible classes. These implement the following methods, defined in coroutine-objects: `send()`, `throw()`, and `close()`. Custom implementations must also implement `__await__()`. All *Coroutine* instances are also instances of *Awaitable*. See also the definition of *coroutine*.

Σημείωση: In CPython, generator-based coroutines (generators decorated with `types.coroutine()` or `asyncio.coroutine()`) are *awaitables*, even though they do not have an `__await__()` method. Using `isinstance(gencoro, Coroutine)` for them will return `False`. Use `inspect.isawaitable()` to detect them.

Νέο στην έκδοση 3.5.

class `collections.abc.AsyncIterable`

ABC for classes that provide `__aiter__` method. See also the definition of *asynchronous iterable*.

Νέο στην έκδοση 3.5.

class `collections.abc.AsyncIterator`

ABC για κλάσεις που παρέχουν τις μεθόδους `__aiter__` και `__anext__`. Δείτε επίσης τον ορισμό του *asynchronous iterator*.

Νέο στην έκδοση 3.5.

class `collections.abc.AsyncGenerator`

ABC for asynchronous generator classes that implement the protocol defined in **PEP 525** and **PEP 492**.

Νέο στην έκδοση 3.6.

These ABCs allow us to ask classes or instances if they provide particular functionality, for example:

```
size = None
if isinstance(myvar, collections.abc.Sized):
    size = len(myvar)
```

Several of the ABCs are also useful as mixins that make it easier to develop classes supporting container APIs. For example, to write a class supporting the full *Set* API, it is only necessary to supply the three underlying abstract methods: `__contains__()`, `__iter__()`, and `__len__()`. The ABC supplies the remaining methods such as `__and__()` and `isdisjoint()`:

```
class ListBasedSet(collections.abc.Set):
    ''' Alternate set implementation favoring space over speed
        and not requiring the set elements to be hashable. '''
    def __init__(self, iterable):
        self.elements = lst = []
        for value in iterable:
            if value not in lst:
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

        lst.append(value)

    def __iter__(self):
        return iter(self.elements)

    def __contains__(self, value):
        return value in self.elements

    def __len__(self):
        return len(self.elements)

s1 = ListBasedSet('abcdef')
s2 = ListBasedSet('defghi')
overlap = s1 & s2          # The __and__() method is supported automatically

```

Σημειώσεις για τη χρήση των `Set` και `MutableSet` ως mixin:

- (1) Since some set operations create new sets, the default mixin methods need a way to create new instances from an iterable. The class constructor is assumed to have a signature in the form `ClassName(iterable)`. That assumption is factored-out to an internal classmethod called `_from_iterable()` which calls `cls(iterable)` to produce a new set. If the `Set` mixin is being used in a class with a different constructor signature, you will need to override `_from_iterable()` with a classmethod or regular method that can construct new instances from an iterable argument.
- (2) To override the comparisons (presumably for speed, as the semantics are fixed), redefine `__le__()` and `__ge__()`, then the other operations will automatically follow suit.
- (3) The `Set` mixin provides a `_hash()` method to compute a hash value for the set; however, `__hash__()` is not defined because not all sets are hashable or immutable. To add set hashability using mixins, inherit from both `Set()` and `Hashable()`, then define `__hash__ = Set._hash`.

8.6 `heapq` — Heap queue algorithm

Source code: [Lib/heapq.py](#)

This module provides an implementation of the heap queue algorithm, also known as the priority queue algorithm.

Heaps are binary trees for which every parent node has a value less than or equal to any of its children. This implementation uses arrays for which `heap[k] <= heap[2*k+1]` and `heap[k] <= heap[2*k+2]` for all *k*, counting elements from zero. For the sake of comparison, non-existing elements are considered to be infinite. The interesting property of a heap is that its smallest element is always the root, `heap[0]`.

The API below differs from textbook heap algorithms in two aspects: (a) We use zero-based indexing. This makes the relationship between the index for a node and the indexes for its children slightly less obvious, but is more suitable since Python uses zero-based indexing. (b) Our `pop` method returns the smallest item, not the largest (called a «min heap» in textbooks; a «max heap» is more common in texts because of its suitability for in-place sorting).

These two make it possible to view the heap as a regular Python list without surprises: `heap[0]` is the smallest item, and `heap.sort()` maintains the heap invariant!

To create a heap, use a list initialized to `[]`, or you can transform a populated list into a heap via function `heapify()`.

The following functions are provided:

`heapq.heappush(heap, item)`

Push the value *item* onto the *heap*, maintaining the heap invariant.

`heapq.heappop(heap)`

Pop and return the smallest item from the *heap*, maintaining the heap invariant. If the heap is empty, `IndexError` is raised. To access the smallest item without popping it, use `heap[0]`.

`heapq.heappushpop(heap, item)`

Push *item* on the heap, then pop and return the smallest item from the *heap*. The combined action runs more efficiently than `heappush()` followed by a separate call to `heappop()`.

`heapq.heapify(x)`

Transform list *x* into a heap, in-place, in linear time.

`heapq.heapreplace(heap, item)`

Pop and return the smallest item from the *heap*, and also push the new *item*. The heap size doesn't change. If the heap is empty, `IndexError` is raised.

This one step operation is more efficient than a `heappop()` followed by `heappush()` and can be more appropriate when using a fixed-size heap. The pop/push combination always returns an element from the heap and replaces it with *item*.

The value returned may be larger than the *item* added. If that isn't desired, consider using `heappushpop()` instead. Its push/pop combination returns the smaller of the two values, leaving the larger value on the heap.

The module also offers three general purpose functions based on heaps.

`heapq.merge(*iterables, key=None, reverse=False)`

Merge multiple sorted inputs into a single sorted output (for example, merge timestamped entries from multiple log files). Returns an *iterator* over the sorted values.

Similar to `sorted(itertools.chain(*iterables))` but returns an iterable, does not pull the data into memory all at once, and assumes that each of the input streams is already sorted (smallest to largest).

Has two optional arguments which must be specified as keyword arguments.

key specifies a *key function* of one argument that is used to extract a comparison key from each input element. The default value is `None` (compare the elements directly).

reverse is a boolean value. If set to `True`, then the input elements are merged as if each comparison were reversed. To achieve behavior similar to `sorted(itertools.chain(*iterables), reverse=True)`, all iterables must be sorted from largest to smallest.

Αλλάξε στην έκδοση 3.5: Added the optional *key* and *reverse* parameters.

`heapq.nlargest(n, iterable, key=None)`

Return a list with the *n* largest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). Equivalent to: `sorted(iterable, key=key, reverse=True)[:n]`.

`heapq.nsmallest(n, iterable, key=None)`

Return a list with the *n* smallest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). Equivalent to: `sorted(iterable, key=key)[:n]`.

The latter two functions perform best for smaller values of *n*. For larger values, it is more efficient to use the `sorted()` function. Also, when *n*=1, it is more efficient to use the built-in `min()` and `max()` functions. If repeated usage of these functions is required, consider turning the iterable into an actual heap.

8.6.1 Basic Examples

A `heapsort` can be implemented by pushing all values onto a heap and then popping off the smallest values one at a time:

```
>>> def heapsort(iterable):
...     h = []
...     for value in iterable:
...         heappush(h, value)
...     return [heappop(h) for i in range(len(h))]
...
>>> heapsort([1, 3, 5, 7, 9, 2, 4, 6, 8, 0])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

This is similar to `sorted(iterable)`, but unlike `sorted()`, this implementation is not stable.

Heap elements can be tuples. This is useful for assigning comparison values (such as task priorities) alongside the main record being tracked:

```
>>> h = []
>>> heappush(h, (5, 'write code'))
>>> heappush(h, (7, 'release product'))
>>> heappush(h, (1, 'write spec'))
>>> heappush(h, (3, 'create tests'))
>>> heappop(h)
(1, 'write spec')
```

8.6.2 Priority Queue Implementation Notes

A `priority queue` is common use for a heap, and it presents several implementation challenges:

- Sort stability: how do you get two tasks with equal priorities to be returned in the order they were originally added?
- Tuple comparison breaks for (priority, task) pairs if the priorities are equal and the tasks do not have a default comparison order.
- If the priority of a task changes, how do you move it to a new position in the heap?
- Or if a pending task needs to be deleted, how do you find it and remove it from the queue?

A solution to the first two challenges is to store entries as 3-element list including the priority, an entry count, and the task. The entry count serves as a tie-breaker so that two tasks with the same priority are returned in the order they were added. And since no two entry counts are the same, the tuple comparison will never attempt to directly compare two tasks.

Another solution to the problem of non-comparable tasks is to create a wrapper class that ignores the task item and only compares the priority field:

```
from dataclasses import dataclass, field
from typing import Any

@dataclass(order=True)
class PrioritizedItem:
    priority: int
    item: Any=field(compare=False)
```

The remaining challenges revolve around finding a pending task and making changes to its priority or removing it entirely. Finding a task can be done with a dictionary pointing to an entry in the queue.

Removing the entry or changing its priority is more difficult because it would break the heap structure invariants. So, a possible solution is to mark the entry as removed and add a new entry with the revised priority:

```

pq = []                                # list of entries arranged in a heap
entry_finder = {}                      # mapping of tasks to entries
REMOVED = '<removed-task>'             # placeholder for a removed task
counter = itertools.count()            # unique sequence count

def add_task(task, priority=0):
    'Add a new task or update the priority of an existing task'
    if task in entry_finder:
        remove_task(task)
    count = next(counter)
    entry = [priority, count, task]
    entry_finder[task] = entry
    heappush(pq, entry)

def remove_task(task):
    'Mark an existing task as REMOVED. Raise KeyError if not found.'
    entry = entry_finder.pop(task)
    entry[-1] = REMOVED

def pop_task():
    'Remove and return the lowest priority task. Raise KeyError if empty.'
    while pq:
        priority, count, task = heappop(pq)
        if task is not REMOVED:
            del entry_finder[task]
            return task
    raise KeyError('pop from an empty priority queue')

```

8.6.3 Theory

Heaps are arrays for which $a[k] \leq a[2k+1]$ and $a[k] \leq a[2k+2]$ for all k , counting elements from 0. For the sake of comparison, non-existing elements are considered to be infinite. The interesting property of a heap is that $a[0]$ is always its smallest element.

The strange invariant above is meant to be an efficient memory representation for a tournament. The numbers below are k , not $a[k]$:

In the tree above, each cell k is topping $2k+1$ and $2k+2$. In a usual binary tournament we see in sports, each cell is the winner over the two cells it tops, and we can trace the winner down the tree to see all opponents s/he had. However, in many computer applications of such tournaments, we do not need to trace the history of a winner. To be more memory efficient, when a winner is promoted, we try to replace it by something else at a lower level, and the rule becomes that a cell and the two cells it tops contain three different items, but the top cell «wins» over the two topped cells.

If this heap invariant is protected at all time, index 0 is clearly the overall winner. The simplest algorithmic way to remove it and find the «next» winner is to move some loser (let's say cell 30 in the diagram above) into the 0 position, and then

percolate this new 0 down the tree, exchanging values, until the invariant is re-established. This is clearly logarithmic on the total number of items in the tree. By iterating over all items, you get an $O(n \log n)$ sort.

A nice feature of this sort is that you can efficiently insert new items while the sort is going on, provided that the inserted items are not «better» than the last 0th element you extracted. This is especially useful in simulation contexts, where the tree holds all incoming events, and the «win» condition means the smallest scheduled time. When an event schedules other events for execution, they are scheduled into the future, so they can easily go into the heap. So, a heap is a good structure for implementing schedulers (this is what I used for my MIDI sequencer :-).

Various structures for implementing schedulers have been extensively studied, and heaps are good for this, as they are reasonably speedy, the speed is almost constant, and the worst case is not much different than the average case. However, there are other representations which are more efficient overall, yet the worst cases might be terrible.

Heaps are also very useful in big disk sorts. You most probably all know that a big sort implies producing «runs» (which are pre-sorted sequences, whose size is usually related to the amount of CPU memory), followed by a merging passes for these runs, which merging is often very cleverly organised¹. It is very important that the initial sort produces the longest runs possible. Tournaments are a good way to achieve that. If, using all the memory available to hold a tournament, you replace and percolate items that happen to fit the current run, you'll produce runs which are twice the size of the memory for random input, and much better for input fuzzily ordered.

Moreover, if you output the 0th item on disk and get an input which may not fit in the current tournament (because the value «wins» over the last output value), it cannot fit in the heap, so the size of the heap decreases. The freed memory could be cleverly reused immediately for progressively building a second heap, which grows at exactly the same rate the first heap is melting. When the first heap completely vanishes, you switch heaps and start a new run. Clever and quite effective!

In a word, heaps are useful memory structures to know. I use them in a few applications, and I think it is good to keep a «heap» module around. :-)

8.7 bisect — Array bisection algorithm

Source code: [Lib/bisect.py](#)

This module provides support for maintaining a list in sorted order without having to sort the list after each insertion. For long lists of items with expensive comparison operations, this can be an improvement over the more common approach. The module is called *bisect* because it uses a basic bisection algorithm to do its work. The source code may be most useful as a working example of the algorithm (the boundary conditions are already right!).

The following functions are provided:

`bisect.bisect_left(a, x, lo=0, hi=len(a))`

Locate the insertion point for *x* in *a* to maintain sorted order. The parameters *lo* and *hi* may be used to specify a subset of the list which should be considered; by default the entire list is used. If *x* is already present in *a*, the insertion point will be before (to the left of) any existing entries. The return value is suitable for use as the first parameter to `list.insert()` assuming that *a* is already sorted.

The returned insertion point *i* partitions the array *a* into two halves so that `all(val < x for val in a[lo:i])` for the left side and `all(val >= x for val in a[i:hi])` for the right side.

`bisect.bisect_right(a, x, lo=0, hi=len(a))`

¹ The disk balancing algorithms which are current, nowadays, are more annoying than clever, and this is a consequence of the seeking capabilities of the disks. On devices which cannot seek, like big tape drives, the story was quite different, and one had to be very clever to ensure (far in advance) that each tape movement will be the most effective possible (that is, will best participate at «progressing» the merge). Some tapes were even able to read backwards, and this was also used to avoid the rewinding time. Believe me, real good tape sorts were quite spectacular to watch! From all times, sorting has always been a Great Art! :-)

`bisect.bisect(a, x, lo=0, hi=len(a))`

Similar to `bisect_left()`, but returns an insertion point which comes after (to the right of) any existing entries of `x` in `a`.

The returned insertion point `i` partitions the array `a` into two halves so that `all(val <= x for val in a[lo:i])` for the left side and `all(val > x for val in a[i:hi])` for the right side.

`bisect.insort_left(a, x, lo=0, hi=len(a))`

Insert `x` in `a` in sorted order. This is equivalent to `a.insert(bisect.bisect_left(a, x, lo, hi), x)` assuming that `a` is already sorted. Keep in mind that the $O(\log n)$ search is dominated by the slow $O(n)$ insertion step.

`bisect.insort_right(a, x, lo=0, hi=len(a))`

`bisect.insort(a, x, lo=0, hi=len(a))`

Similar to `insort_left()`, but inserting `x` in `a` after any existing entries of `x`.

Δείτε επίσης:

`SortedCollection` recipe that uses `bisect` to build a full-featured collection class with straight-forward search methods and support for a key-function. The keys are precomputed to save unnecessary calls to the key function during searches.

8.7.1 Searching Sorted Lists

The above `bisect()` functions are useful for finding insertion points but can be tricky or awkward to use for common searching tasks. The following five functions show how to transform them into the standard lookups for sorted lists:

```
def index(a, x):
    'Locate the leftmost value exactly equal to x'
    i = bisect_left(a, x)
    if i != len(a) and a[i] == x:
        return i
    raise ValueError

def find_lt(a, x):
    'Find rightmost value less than x'
    i = bisect_left(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_le(a, x):
    'Find rightmost value less than or equal to x'
    i = bisect_right(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_gt(a, x):
    'Find leftmost value greater than x'
    i = bisect_right(a, x)
    if i != len(a):
        return a[i]
    raise ValueError

def find_ge(a, x):
    'Find leftmost item greater than or equal to x'
    i = bisect_left(a, x)
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

if i != len(a):
    return a[i]
raise ValueError

```

8.7.2 Other Examples

The `bisect()` function can be useful for numeric table lookups. This example uses `bisect()` to look up a letter grade for an exam score (say) based on a set of ordered numeric breakpoints: 90 and up is an “A”, 80 to 89 is a “B”, and so on:

```

>>> def grade(score, breakpoints=[60, 70, 80, 90], grades='FDCBA'):
...     i = bisect(breakpoints, score)
...     return grades[i]
...
>>> [grade(score) for score in [33, 99, 77, 70, 89, 90, 100]]
['F', 'A', 'C', 'C', 'B', 'A', 'A']

```

Unlike the `sorted()` function, it does not make sense for the `bisect()` functions to have `key` or `reversed` arguments because that would lead to an inefficient design (successive calls to `bisect` functions would not «remember» all of the previous key lookups).

Instead, it is better to search a list of precomputed keys to find the index of the record in question:

```

>>> data = [('red', 5), ('blue', 1), ('yellow', 8), ('black', 0)]
>>> data.sort(key=lambda r: r[1])
>>> keys = [r[1] for r in data]           # precomputed list of keys
>>> data[bisect_left(keys, 0)]
('black', 0)
>>> data[bisect_left(keys, 1)]
('blue', 1)
>>> data[bisect_left(keys, 5)]
('red', 5)
>>> data[bisect_left(keys, 8)]
('yellow', 8)

```

8.8 array — Efficient arrays of numeric values

This module defines an object type which can compactly represent an array of basic values: characters, integers, floating point numbers. Arrays are sequence types and behave very much like lists, except that the type of objects stored in them is constrained. The type is specified at object creation time by using a *type code*, which is a single character. The following type codes are defined:

| Type code | C Type | Python Type | Minimum size in bytes | Notes |
|-----------|--------------------|-------------------|-----------------------|-------|
| 'b' | signed char | int | 1 | |
| 'B' | unsigned char | int | 1 | |
| 'u' | wchar_t | Unicode character | 2 | (1) |
| 'h' | signed short | int | 2 | |
| 'H' | unsigned short | int | 2 | |
| 'i' | signed int | int | 2 | |
| 'I' | unsigned int | int | 2 | |
| 'l' | signed long | int | 4 | |
| 'L' | unsigned long | int | 4 | |
| 'q' | signed long long | int | 8 | |
| 'Q' | unsigned long long | int | 8 | |
| 'f' | float | float | 4 | |
| 'd' | double | float | 8 | |

Notes:

- (1) It can be 16 bits or 32 bits depending on the platform.

Άλλαξε στην έκδοση 3.9: `array('u')` now uses `wchar_t` as C type instead of deprecated `Py_UNICODE`. This change doesn't affect to its behavior because `Py_UNICODE` is alias of `wchar_t` since Python 3.3.

Deprecated since version 3.3, will be removed in version 4.0.

The actual representation of values is determined by the machine architecture (strictly speaking, by the C implementation). The actual size can be accessed through the `itemsize` attribute.

The module defines the following type:

class `array.array`(*typecode*[, *initializer*])

A new array whose items are restricted by *typecode*, and initialized from the optional *initializer* value, which must be a list, a *bytes-like object*, or iterable over elements of the appropriate type.

If given a list or string, the initializer is passed to the new array's `fromlist()`, `frombytes()`, or `fromunicode()` method (see below) to add initial items to the array. Otherwise, the iterable initializer is passed to the `extend()` method.

Raises an *auditing event* `array.__new__` with arguments `typecode`, `initializer`.

`array.typecodes`

A string with all available type codes.

Array objects support the ordinary sequence operations of indexing, slicing, concatenation, and multiplication. When using slice assignment, the assigned value must be an array object with the same type code; in all other cases, `TypeError` is raised. Array objects also implement the buffer interface, and may be used wherever *bytes-like objects* are supported.

The following data items and methods are also supported:

`array.typecode`

The typecode character used to create the array.

`array.itemsize`

The length in bytes of one array item in the internal representation.

`array.append`(*x*)

Append a new item with value *x* to the end of the array.

`array.buffer_info`()

Return a tuple (*address*, *length*) giving the current memory address and the length in elements of the

buffer used to hold array's contents. The size of the memory buffer in bytes can be computed as `array.buffer_info()[1] * array.itemsize`. This is occasionally useful when working with low-level (and inherently unsafe) I/O interfaces that require memory addresses, such as certain `ioctl()` operations. The returned numbers are valid as long as the array exists and no length-changing operations are applied to it.

Σημείωση: When using array objects from code written in C or C++ (the only way to effectively make use of this information), it makes more sense to use the buffer interface supported by array objects. This method is maintained for backward compatibility and should be avoided in new code. The buffer interface is documented in `bufferobjects`.

`array.byteswap()`

«Byteswap» all items of the array. This is only supported for values which are 1, 2, 4, or 8 bytes in size; for other types of values, `RuntimeError` is raised. It is useful when reading data from a file written on a machine with a different byte order.

`array.count(x)`

Return the number of occurrences of `x` in the array.

`array.extend(iterable)`

Append items from *iterable* to the end of the array. If *iterable* is another array, it must have *exactly* the same type code; if not, `TypeError` will be raised. If *iterable* is not an array, it must be iterable and its elements must be the right type to be appended to the array.

`array.frombytes(s)`

Appends items from the string, interpreting the string as an array of machine values (as if it had been read from a file using the `fromfile()` method).

Νέο στην έκδοση 3.2: `fromstring()` is renamed to `frombytes()` for clarity.

`array.fromfile(f, n)`

Read *n* items (as machine values) from the *file object* *f* and append them to the end of the array. If less than *n* items are available, `EOFError` is raised, but the items that were available are still inserted into the array.

`array.fromlist(list)`

Append items from the list. This is equivalent to `for x in list: a.append(x)` except that if there is a type error, the array is unchanged.

`array.fromunicode(s)`

Extends this array with data from the given unicode string. The array must be a type 'u' array; otherwise a `ValueError` is raised. Use `array.frombytes(unicodestring.encode(enc))` to append Unicode data to an array of some other type.

`array.index(x)`

Return the smallest *i* such that *i* is the index of the first occurrence of *x* in the array.

`array.insert(i, x)`

Insert a new item with value *x* in the array before position *i*. Negative values are treated as being relative to the end of the array.

`array.pop([i])`

Removes the item with the index *i* from the array and returns it. The optional argument defaults to `-1`, so that by default the last item is removed and returned.

`array.remove(x)`

Remove the first occurrence of *x* from the array.

`array.reverse()`

Reverse the order of the items in the array.

`array.tobytes()`

Convert the array to an array of machine values and return the bytes representation (the same sequence of bytes that would be written to a file by the `tofile()` method.)

Νέο στην έκδοση 3.2: `tostring()` is renamed to `tobytes()` for clarity.

`array.tofile(f)`

Write all items (as machine values) to the *file object* `f`.

`array.tolist()`

Convert the array to an ordinary list with the same items.

`array.tounicode()`

Convert the array to a unicode string. The array must be a type 'u' array; otherwise a `ValueError` is raised.

Use `array.tobytes().decode(enc)` to obtain a unicode string from an array of some other type.

When an array object is printed or converted to a string, it is represented as `array(typecode, initializer)`. The *initializer* is omitted if the array is empty, otherwise it is a string if the *typecode* is 'u', otherwise it is a list of numbers. The string is guaranteed to be able to be converted back to an array with the same type and value using `eval()`, so long as the `array` class has been imported using `from array import array`. Examples:

```
array('l')
array('u', 'hello \u2641')
array('l', [1, 2, 3, 4, 5])
array('d', [1.0, 2.0, 3.14])
```

8.9 weakref — Weak references

Source code: [Lib/weakref.py](#)

The `weakref` module allows the Python programmer to create *weak references* to objects.

In the following, the term *referent* means the object which is referred to by a weak reference.

A weak reference to an object is not enough to keep the object alive: when the only remaining references to a referent are weak references, *garbage collection* is free to destroy the referent and reuse its memory for something else. However, until the object is actually destroyed the weak reference may return the object even if there are no strong references to it.

A primary use for weak references is to implement caches or mappings holding large objects, where it's desired that a large object not be kept alive solely because it appears in a cache or mapping.

For example, if you have a number of large binary image objects, you may wish to associate a name with each. If you used a Python dictionary to map names to images, or images to names, the image objects would remain alive just because they appeared as values or keys in the dictionaries. The `WeakKeyDictionary` and `WeakValueDictionary` classes supplied by the `weakref` module are an alternative, using weak references to construct mappings that don't keep objects alive solely because they appear in the mapping objects. If, for example, an image object is a value in a `WeakValueDictionary`, then when the last remaining references to that image object are the weak references held by weak mappings, garbage collection can reclaim the object, and its corresponding entries in weak mappings are simply deleted.

`WeakKeyDictionary` and `WeakValueDictionary` use weak references in their implementation, setting up callback functions on the weak references that notify the weak dictionaries when a key or value has been reclaimed by garbage collection. `WeakSet` implements the `set` interface, but keeps weak references to its elements, just like a `WeakKeyDictionary` does.

`finalize` provides a straight forward way to register a cleanup function to be called when an object is garbage collected. This is simpler to use than setting up a callback function on a raw weak reference, since the module automatically ensures that the finalizer remains alive until the object is collected.

Most programs should find that using one of these weak container types or `finalize` is all they need – it's not usually necessary to create your own weak references directly. The low-level machinery is exposed by the `weakref` module for the benefit of advanced uses.

Not all objects can be weakly referenced; those objects which can include class instances, functions written in Python (but not in C), instance methods, sets, frozensets, some *file objects*, *generators*, type objects, sockets, arrays, dequeues, regular expression pattern objects, and code objects.

Άλλαξε στην έκδοση 3.2: Added support for `thread.lock`, `threading.Lock`, and code objects.

Several built-in types such as `list` and `dict` do not directly support weak references but can add support through subclassing:

```
class Dict(dict):
    pass

obj = Dict(red=1, green=2, blue=3)  # this object is weak referenceable
```

CPython implementation detail: Other built-in types such as `tuple` and `int` do not support weak references even when subclassed.

Extension types can easily be made to support weak references; see `weakref-support`.

When `__slots__` are defined for a given type, weak reference support is disabled unless a `'__weakref__'` string is also present in the sequence of strings in the `__slots__` declaration. See `__slots__` documentation for details.

class `weakref.ref(object[, callback])`

Return a weak reference to *object*. The original object can be retrieved by calling the reference object if the referent is still alive; if the referent is no longer alive, calling the reference object will cause `None` to be returned. If *callback* is provided and not `None`, and the returned weakref object is still alive, the callback will be called when the object is about to be finalized; the weak reference object will be passed as the only parameter to the callback; the referent will no longer be available.

It is allowable for many weak references to be constructed for the same object. Callbacks registered for each weak reference will be called from the most recently registered callback to the oldest registered callback.

Exceptions raised by the callback will be noted on the standard error output, but cannot be propagated; they are handled in exactly the same way as exceptions raised from an object's `__del__()` method.

Weak references are *hashable* if the *object* is hashable. They will maintain their hash value even after the *object* was deleted. If `hash()` is called the first time only after the *object* was deleted, the call will raise `TypeError`.

Weak references support tests for equality, but not ordering. If the referents are still alive, two references have the same equality relationship as their referents (regardless of the *callback*). If either referent has been deleted, the references are equal only if the reference objects are the same object.

This is a subclassable type rather than a factory function.

__callback__

This read-only attribute returns the callback currently associated to the weakref. If there is no callback or if the referent of the weakref is no longer alive then this attribute will have value `None`.

Άλλαξε στην έκδοση 3.4: Added the `__callback__` attribute.

`weakref.proxy(object[, callback])`

Return a proxy to *object* which uses a weak reference. This supports use of the proxy in most contexts instead of requiring the explicit dereferencing used with weak reference objects. The returned object will have a type of either `ProxyType` or `CallableProxyType`, depending on whether *object* is callable. Proxy objects are not *hashable* regardless of the referent; this avoids a number of problems related to their fundamentally mutable nature, and prevent their use as dictionary keys. *callback* is the same as the parameter of the same name to the `ref()` function.

Άλλαξε στην έκδοση 3.8: Extended the operator support on proxy objects to include the matrix multiplication operators `@` and `@=`.

`weakref.getweakrefcount(object)`

Return the number of weak references and proxies which refer to *object*.

`weakref.getweakrefs(object)`

Return a list of all weak reference and proxy objects which refer to *object*.

class `weakref.WeakKeyDictionary([dict])`

Mapping class that references keys weakly. Entries in the dictionary will be discarded when there is no longer a strong reference to the key. This can be used to associate additional data with an object owned by other parts of an application without adding attributes to those objects. This can be especially useful with objects that override attribute accesses.

Άλλαξε στην έκδοση 3.9: Added support for `|` and `|=` operators, specified in [PEP 584](#).

WeakKeyDictionary objects have an additional method that exposes the internal references directly. The references are not guaranteed to be «live» at the time they are used, so the result of calling the references needs to be checked before being used. This can be used to avoid creating references that will cause the garbage collector to keep the keys around longer than needed.

`WeakKeyDictionary.keyrefs()`

Return an iterable of the weak references to the keys.

class `weakref.WeakValueDictionary([dict])`

Mapping class that references values weakly. Entries in the dictionary will be discarded when no strong reference to the value exists any more.

Άλλαξε στην έκδοση 3.9: Added support for `|` and `|=` operators, as specified in [PEP 584](#).

WeakValueDictionary objects have an additional method that has the same issues as the `keyrefs()` method of *WeakKeyDictionary* objects.

`WeakValueDictionary.valuerefs()`

Return an iterable of the weak references to the values.

class `weakref.WeakSet([elements])`

Set class that keeps weak references to its elements. An element will be discarded when no strong reference to it exists any more.

class `weakref.WeakMethod(method)`

A custom *ref* subclass which simulates a weak reference to a bound method (i.e., a method defined on a class and looked up on an instance). Since a bound method is ephemeral, a standard weak reference cannot keep hold of it. *WeakMethod* has special code to recreate the bound method until either the object or the original function dies:

```
>>> class C:
...     def method(self):
...         print("method called!")
...
>>> c = C()
>>> r = weakref.ref(c.method)
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> r()
>>> r = weakref.WeakMethod(c.method)
>>> r()
<bound method C.method of <__main__.C object at 0x7fc859830220>>
>>> r() ()
method called!
>>> del c
>>> gc.collect()
0
>>> r()
>>>
```

Νέο στην έκδοση 3.4.

class `weakref.finalize(obj, func, /, *args, **kwargs)`

Return a callable finalizer object which will be called when *obj* is garbage collected. Unlike an ordinary weak reference, a finalizer will always survive until the reference object is collected, greatly simplifying lifecycle management.

A finalizer is considered *alive* until it is called (either explicitly or at garbage collection), and after that it is *dead*. Calling a live finalizer returns the result of evaluating `func(*args, **kwargs)`, whereas calling a dead finalizer returns *None*.

Exceptions raised by finalizer callbacks during garbage collection will be shown on the standard error output, but cannot be propagated. They are handled in the same way as exceptions raised from an object's `__del__()` method or a weak reference's callback.

When the program exits, each remaining live finalizer is called unless its *atexit* attribute has been set to false. They are called in reverse order of creation.

A finalizer will never invoke its callback during the later part of the *interpreter shutdown* when module globals are liable to have been replaced by *None*.

__call__()

If *self* is alive then mark it as dead and return the result of calling `func(*args, **kwargs)`. If *self* is dead then return *None*.

detach()

If *self* is alive then mark it as dead and return the tuple `(obj, func, args, kwargs)`. If *self* is dead then return *None*.

peek()

If *self* is alive then return the tuple `(obj, func, args, kwargs)`. If *self* is dead then return *None*.

alive

Property which is true if the finalizer is alive, false otherwise.

atexit

A writable boolean property which by default is true. When the program exits, it calls all remaining live finalizers for which *atexit* is true. They are called in reverse order of creation.

Σημείωση: It is important to ensure that *func*, *args* and *kwargs* do not own any references to *obj*, either directly or indirectly, since otherwise *obj* will never be garbage collected. In particular, *func* should not be a bound method of *obj*.

Νέο στην έκδοση 3.4.

`weakref.ReferenceType`

The type object for weak references objects.

`weakref.ProxyType`

The type object for proxies of objects which are not callable.

`weakref.CallableProxyType`

The type object for proxies of callable objects.

`weakref.ProxyTypes`

Sequence containing all the type objects for proxies. This can make it simpler to test if an object is a proxy without being dependent on naming both proxy types.

Δείτε επίσης:

PEP 205 - Weak References The proposal and rationale for this feature, including links to earlier implementations and information about similar features in other languages.

8.9.1 Weak Reference Objects

Weak reference objects have no methods and no attributes besides `ref.__callback__`. A weak reference object allows the referent to be obtained, if it still exists, by calling it:

```
>>> import weakref
>>> class Object:
...     pass
...
>>> o = Object()
>>> r = weakref.ref(o)
>>> o2 = r()
>>> o is o2
True
```

If the referent no longer exists, calling the reference object returns `None`:

```
>>> del o, o2
>>> print(r())
None
```

Testing that a weak reference object is still live should be done using the expression `ref() is not None`. Normally, application code that needs to use a reference object should follow this pattern:

```
# r is a weak reference object
o = r()
if o is None:
    # referent has been garbage collected
    print("Object has been deallocated; can't frobnicate.")
else:
    print("Object is still live!")
    o.do_something_useful()
```

Using a separate test for «liveness» creates race conditions in threaded applications; another thread can cause a weak reference to become invalidated before the weak reference is called; the idiom shown above is safe in threaded applications as well as single-threaded applications.

Specialized versions of `ref` objects can be created through subclassing. This is used in the implementation of the `WeakValueDictionary` to reduce the memory overhead for each entry in the mapping. This may be most useful to

associate additional information with a reference, but could also be used to insert additional processing on calls to retrieve the referent.

This example shows how a subclass of `ref` can be used to store additional information about an object and affect the value that's returned when the referent is accessed:

```
import weakref

class ExtendedRef(weakref.ref):
    def __init__(self, ob, callback=None, /, **annotations):
        super().__init__(ob, callback)
        self.__counter = 0
        for k, v in annotations.items():
            setattr(self, k, v)

    def __call__(self):
        """Return a pair containing the referent and the number of
        times the reference has been called.
        """
        ob = super().__call__()
        if ob is not None:
            self.__counter += 1
            ob = (ob, self.__counter)
        return ob
```

8.9.2 Example

This simple example shows how an application can use object IDs to retrieve objects that it has seen before. The IDs of the objects can then be used in other data structures without forcing the objects to remain alive, but the objects can still be retrieved by ID if they do.

```
import weakref

_id2obj_dict = weakref.WeakValueDictionary()

def remember(obj):
    oid = id(obj)
    _id2obj_dict[oid] = obj
    return oid

def id2obj(oid):
    return _id2obj_dict[oid]
```

8.9.3 Finalizer Objects

The main benefit of using `finalize` is that it makes it simple to register a callback without needing to preserve the returned finalizer object. For instance

```
>>> import weakref
>>> class Object:
...     pass
...
>>> kenny = Object()
>>> weakref.finalize(kenny, print, "You killed Kenny!")
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
<finalize object at ...; for 'Object' at ...>
>>> del kenny
You killed Kenny!
```

The finalizer can be called directly as well. However the finalizer will invoke the callback at most once.

```
>>> def callback(x, y, z):
...     print("CALLBACK")
...     return x + y + z
...
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> assert f.alive
>>> assert f() == 6
CALLBACK
>>> assert not f.alive
>>> f()                                # callback not called because finalizer dead
>>> del obj                            # callback not called because finalizer dead
```

You can unregister a finalizer using its `detach()` method. This kills the finalizer and returns the arguments passed to the constructor when it was created.

```
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> f.detach()
(<...Object object ...>, <function callback ...>, (1, 2), {'z': 3})
>>> newobj, func, args, kwargs = _
>>> assert not f.alive
>>> assert newobj is obj
>>> assert func(*args, **kwargs) == 6
CALLBACK
```

Unless you set the `atexit` attribute to `False`, a finalizer will be called when the program exits if it is still alive. For instance

```
>>> obj = Object()
>>> weakref.finalize(obj, print, "obj dead or exiting")
<finalize object at ...; for 'Object' at ...>
>>> exit()
obj dead or exiting
```

8.9.4 Comparing finalizers with `__del__()` methods

Suppose we want to create a class whose instances represent temporary directories. The directories should be deleted with their contents when the first of the following events occurs:

- the object is garbage collected,
- the object's `remove()` method is called, or
- the program exits.

We might try to implement the class using a `__del__()` method as follows:

```
class TempDir:
    def __init__(self):
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

        self.name = tempfile.mkdtemp()

    def remove(self):
        if self.name is not None:
            shutil.rmtree(self.name)
            self.name = None

    @property
    def removed(self):
        return self.name is None

    def __del__(self):
        self.remove()

```

Starting with Python 3.4, `__del__()` methods no longer prevent reference cycles from being garbage collected, and module globals are no longer forced to `None` during *interpreter shutdown*. So this code should work without any issues on CPython.

However, handling of `__del__()` methods is notoriously implementation specific, since it depends on internal details of the interpreter's garbage collector implementation.

A more robust alternative can be to define a finalizer which only references the specific functions and objects that it needs, rather than having access to the full state of the object:

```

class TempDir:
    def __init__(self):
        self.name = tempfile.mkdtemp()
        self._finalizer = weakref.finalize(self, shutil.rmtree, self.name)

    def remove(self):
        self._finalizer()

    @property
    def removed(self):
        return not self._finalizer.alive

```

Defined like this, our finalizer only receives a reference to the details it needs to clean up the directory appropriately. If the object never gets garbage collected the finalizer will still be called at exit.

The other advantage of weakref based finalizers is that they can be used to register finalizers for classes where the definition is controlled by a third party, such as running code when a module is unloaded:

```

import weakref, sys
def unloading_module():
    # implicit reference to the module globals from the function body
    weakref.finalize(sys.modules[__name__], unloading_module)

```

Σημείωση: If you create a finalizer object in a daemon thread just as the program exits then there is the possibility that the finalizer does not get called at exit. However, in a daemon thread `atexit.register()`, try: ... finally: ... and with: ... do not guarantee that cleanup occurs either.

8.10 `types` — Dynamic type creation and names for built-in types

Source code: [Lib/types.py](#)

This module defines utility functions to assist in dynamic creation of new types.

It also defines names for some object types that are used by the standard Python interpreter, but not exposed as builtins like `int` or `str` are.

Finally, it provides some additional type-related utility classes and functions that are not fundamental enough to be builtins.

8.10.1 Dynamic Type Creation

`types.new_class` (*name*, *bases=()*, *kwds=None*, *exec_body=None*)

Creates a class object dynamically using the appropriate metaclass.

The first three arguments are the components that make up a class definition header: the class name, the base classes (in order), the keyword arguments (such as `metaclass`).

The *exec_body* argument is a callback that is used to populate the freshly created class namespace. It should accept the class namespace as its sole argument and update the namespace directly with the class contents. If no callback is provided, it has the same effect as passing in `lambda ns: None`.

Νέο στην έκδοση 3.3.

`types.prepare_class` (*name*, *bases=()*, *kwds=None*)

Calculates the appropriate metaclass and creates the class namespace.

The arguments are the components that make up a class definition header: the class name, the base classes (in order) and the keyword arguments (such as `metaclass`).

The return value is a 3-tuple: `metaclass, namespace, kwds`

metaclass is the appropriate metaclass, *namespace* is the prepared class namespace and *kwds* is an updated copy of the passed in *kwds* argument with any 'metaclass' entry removed. If no *kwds* argument is passed in, this will be an empty dict.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.6: The default value for the *namespace* element of the returned tuple has changed. Now an insertion-order-preserving mapping is used when the metaclass does not have a `__prepare__` method.

Δείτε επίσης:

metaclasses Full details of the class creation process supported by these functions

PEP 3115 - Metaclasses in Python 3000 Introduced the `__prepare__` namespace hook

`types.resolve_bases` (*bases*)

Resolve MRO entries dynamically as specified by **PEP 560**.

This function looks for items in *bases* that are not instances of `type`, and returns a tuple where each such object that has an `__mro_entries__` method is replaced with an unpacked result of calling this method. If a *bases* item is an instance of `type`, or it doesn't have an `__mro_entries__` method, then it is included in the return tuple unchanged.

PEP 560 - Core support for typing module and generic types

8.10.2 Standard Interpreter Types

This module provides names for many of the types that are required to implement a Python interpreter. It deliberately avoids including some of the types that arise only incidentally during processing such as the `listiterator` type.

Typical use of these names is for `isinstance()` or `issubclass()` checks.

If you instantiate any of these types, note that signatures may vary between Python versions.

Standard names are defined for the following types:

`types.FunctionType`

`types.LambdaType`

The type of user-defined functions and functions created by `lambda` expressions.

Raises an *auditing event* `function.__new__` with argument `code`.

The audit event only occurs for direct instantiation of function objects, and is not raised for normal compilation.

`types.GeneratorType`

The type of *generator*-iterator objects, created by generator functions.

`types.CoroutineType`

The type of *coroutine* objects, created by `async def` functions.

Νέο στην έκδοση 3.5.

`types.AsyncGeneratorType`

The type of *asynchronous generator*-iterator objects, created by asynchronous generator functions.

Νέο στην έκδοση 3.6.

class `types.CodeType` (***kwargs*)

The type for code objects such as returned by `compile()`.

Raises an *auditing event* `code.__new__` with arguments `code`, `filename`, `name`, `argcount`, `posonlyargcount`, `kwonlyargcount`, `nlocals`, `stacksize`, `flags`.

Note that the audited arguments may not match the names or positions required by the initializer. The audit event only occurs for direct instantiation of code objects, and is not raised for normal compilation.

replace (***kwargs*)

Return a copy of the code object with new values for the specified fields.

Νέο στην έκδοση 3.8.

`types.CellType`

The type for cell objects: such objects are used as containers for a function's free variables.

Νέο στην έκδοση 3.8.

`types.MethodType`

The type of methods of user-defined class instances.

`types.BuiltinFunctionType`

`types.BuiltinMethodType`

The type of built-in functions like `len()` or `sys.exit()`, and methods of built-in classes. (Here, the term «built-in» means «written in C».)

`types WrapperDescriptorType`

The type of methods of some built-in data types and base classes such as `object.__init__()` or `object.__lt__()`.

Νέο στην έκδοση 3.7.

types.MethodWrapperType

The type of *bound* methods of some built-in data types and base classes. For example it is the type of `object()`.
`__str__`.

Νέο στην έκδοση 3.7.

types.MethodDescriptorType

The type of methods of some built-in data types such as `str.join()`.

Νέο στην έκδοση 3.7.

types.ClassMethodDescriptorType

The type of *unbound* class methods of some built-in data types such as `dict.__dict__['fromkeys']`.

Νέο στην έκδοση 3.7.

class types.ModuleType(name, doc=None)

The type of *modules*. The constructor takes the name of the module to be created and optionally its *docstring*.

Σημείωση: Use `importlib.util.module_from_spec()` to create a new module if you wish to set the various import-controlled attributes.

__doc__

The *docstring* of the module. Defaults to `None`.

__loader__

The *loader* which loaded the module. Defaults to `None`.

This attribute is to match `importlib.machinery.ModuleSpec.loader` as stored in the attr: `__spec__` object.

Σημείωση: A future version of Python may stop setting this attribute by default. To guard against this potential change, preferably read from the `__spec__` attribute instead or use `getattr(module, "__loader__", None)` if you explicitly need to use this attribute.

Άλλαξε στην έκδοση 3.4: Defaults to `None`. Previously the attribute was optional.

__name__

The name of the module. Expected to match `importlib.machinery.ModuleSpec.name`.

__package__

Which *package* a module belongs to. If the module is top-level (i.e. not a part of any specific package) then the attribute should be set to `'`, else it should be set to the name of the package (which can be `__name__` if the module is a package itself). Defaults to `None`.

This attribute is to match `importlib.machinery.ModuleSpec.parent` as stored in the attr: `__spec__` object.

Σημείωση: A future version of Python may stop setting this attribute by default. To guard against this potential change, preferably read from the `__spec__` attribute instead or use `getattr(module, "__package__", None)` if you explicitly need to use this attribute.

Άλλαξε στην έκδοση 3.4: Defaults to `None`. Previously the attribute was optional.

__spec__

A record of the module's import-system-related state. Expected to be an instance of `importlib.machinery.ModuleSpec`.

Νέο στην έκδοση 3.4.

class `types.GenericAlias` (*t_origin*, *t_args*)

The type of *parameterized generics* such as `list[int]`.

t_origin should be a non-parameterized generic class, such as `list`, `tuple` or `dict`. *t_args* should be a *tuple* (possibly of length 1) of types which parameterize *t_origin*:

```
>>> from types import GenericAlias

>>> list[int] == GenericAlias(list, (int,))
True
>>> dict[str, int] == GenericAlias(dict, (str, int))
True
```

Νέο στην έκδοση 3.9.

Άλλαξε στην έκδοση 3.9.2: This type can now be subclassed.

class `types.TracebackType` (*tb_next*, *tb_frame*, *tb_lasti*, *tb_lineno*)

The type of traceback objects such as found in `sys.exc_info()` [2].

See the language reference for details of the available attributes and operations, and guidance on creating tracebacks dynamically.

`types.FrameType`

The type of frame objects such as found in `tb.tb_frame` if *tb* is a traceback object.

See the language reference for details of the available attributes and operations.

`types.GetSetDescriptorType`

The type of objects defined in extension modules with `PyGetSetDef`, such as `FrameType.f_locals` or `array.array.typecode`. This type is used as descriptor for object attributes; it has the same purpose as the *property* type, but for classes defined in extension modules.

`types.MemberDescriptorType`

The type of objects defined in extension modules with `PyMemberDef`, such as `datetime.timedelta.days`. This type is used as descriptor for simple C data members which use standard conversion functions; it has the same purpose as the *property* type, but for classes defined in extension modules.

CPython implementation detail: In other implementations of Python, this type may be identical to `GetSetDescriptorType`.

class `types.MappingProxyType` (*mapping*)

Read-only proxy of a mapping. It provides a dynamic view on the mapping's entries, which means that when the mapping changes, the view reflects these changes.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.9: Updated to support the new union (`|`) operator from **PEP 584**, which simply delegates to the underlying mapping.

key in proxy

Return `True` if the underlying mapping has a key *key*, else `False`.

proxy[key]

Return the item of the underlying mapping with key *key*. Raises a *KeyError* if *key* is not in the underlying mapping.

iter(proxy)

Return an iterator over the keys of the underlying mapping. This is a shortcut for `iter(proxy.keys())`.

len(proxy)

Return the number of items in the underlying mapping.

copy()

Return a shallow copy of the underlying mapping.

get(key[, default])

Return the value for *key* if *key* is in the underlying mapping, else *default*. If *default* is not given, it defaults to `None`, so that this method never raises a `KeyError`.

items()

Return a new view of the underlying mapping's items ((*key*, *value*) pairs).

keys()

Return a new view of the underlying mapping's keys.

values()

Return a new view of the underlying mapping's values.

reversed(proxy)

Return a reverse iterator over the keys of the underlying mapping.

Νέο στην έκδοση 3.9.

8.10.3 Additional Utility Classes and Functions

class types.SimpleNamespace

A simple *object* subclass that provides attribute access to its namespace, as well as a meaningful repr.

Unlike *object*, with `SimpleNamespace` you can add and remove attributes. If a `SimpleNamespace` object is initialized with keyword arguments, those are directly added to the underlying namespace.

The type is roughly equivalent to the following code:

```
class SimpleNamespace:
    def __init__(self, /, **kwargs):
        self.__dict__.update(kwargs)

    def __repr__(self):
        items = (f"{k}={v!r}" for k, v in self.__dict__.items())
        return "{}({})".format(type(self).__name__, ", ".join(items))

    def __eq__(self, other):
        if isinstance(self, SimpleNamespace) and isinstance(other, SimpleNamespace):
            return self.__dict__ == other.__dict__
        return NotImplemented
```

`SimpleNamespace` may be useful as a replacement for `class NS: pass`. However, for a structured record type use `namedtuple()` instead.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.9: Attribute order in the repr changed from alphabetical to insertion (like `dict`).

types.DynamicClassAttribute(fget=None, fset=None, fdel=None, doc=None)

Route attribute access on a class to `__getattr__`.

This is a descriptor, used to define attributes that act differently when accessed through an instance and through a class. Instance access remains normal, but access to an attribute through a class will be routed to the class's `__getattr__` method; this is done by raising `AttributeError`.

This allows one to have properties active on an instance, and have virtual attributes on the class with the same name (see `enum.Enum` for an example).

Νέο στην έκδοση 3.4.

8.10.4 Coroutine Utility Functions

`types.coroutine(gen_func)`

This function transforms a *generator* function into a *coroutine function* which returns a generator-based coroutine. The generator-based coroutine is still a *generator iterator*, but is also considered to be a *coroutine* object and is *awaitable*. However, it may not necessarily implement the `__await__()` method.

If `gen_func` is a generator function, it will be modified in-place.

If `gen_func` is not a generator function, it will be wrapped. If it returns an instance of `collections.abc.Generator`, the instance will be wrapped in an *awaitable* proxy object. All other types of objects will be returned as is.

Νέο στην έκδοση 3.5.

8.11 copy — Shallow and deep copy operations

Source code: [Lib/copy.py](#)

Assignment statements in Python do not copy objects, they create bindings between a target and an object. For collections that are mutable or contain mutable items, a copy is sometimes needed so one can change one copy without changing the other. This module provides generic shallow and deep copy operations (explained below).

Interface summary:

`copy.copy(x)`

Return a shallow copy of *x*.

`copy.deepcopy(x[, memo])`

Return a deep copy of *x*.

exception `copy.Error`

Raised for module specific errors.

The difference between shallow and deep copying is only relevant for compound objects (objects that contain other objects, like lists or class instances):

- A *shallow copy* constructs a new compound object and then (to the extent possible) inserts *references* into it to the objects found in the original.
- A *deep copy* constructs a new compound object and then, recursively, inserts *copies* into it of the objects found in the original.

Two problems often exist with deep copy operations that don't exist with shallow copy operations:

- Recursive objects (compound objects that, directly or indirectly, contain a reference to themselves) may cause a recursive loop.
- Because deep copy copies everything it may copy too much, such as data which is intended to be shared between copies.

The `deepcopy()` function avoids these problems by:

- keeping a memo dictionary of objects already copied during the current copying pass; and
- letting user-defined classes override the copying operation or the set of components copied.

This module does not copy types like module, method, stack trace, stack frame, file, socket, window, or any similar types. It does «copy» functions and classes (shallow and deeply), by returning the original object unchanged; this is compatible with the way these are treated by the *pickle* module.

Shallow copies of dictionaries can be made using *dict.copy()*, and of lists by assigning a slice of the entire list, for example, *copied_list = original_list[:]*.

Classes can use the same interfaces to control copying that they use to control pickling. See the description of module *pickle* for information on these methods. In fact, the *copy* module uses the registered pickle functions from the *copyreg* module.

In order for a class to define its own copy implementation, it can define special methods *__copy__()* and *__deepcopy__()*. The former is called to implement the shallow copy operation; no additional arguments are passed. The latter is called to implement the deep copy operation; it is passed one argument, the memo dictionary. If the *__deepcopy__()* implementation needs to make a deep copy of a component, it should call the *deepcopy()* function with the component as first argument and the memo dictionary as second argument.

Module *pickle* Discussion of the special methods used to support object state retrieval and restoration.

8.12 pprint — Data pretty printer

Source code: [Lib/pprint.py](#)

The *pprint* module provides a capability to «pretty-print» arbitrary Python data structures in a form which can be used as input to the interpreter. If the formatted structures include objects which are not fundamental Python types, the representation may not be loadable. This may be the case if objects such as files, sockets or classes are included, as well as many other objects which are not representable as Python literals.

The formatted representation keeps objects on a single line if it can, and breaks them onto multiple lines if they don't fit within the allowed width. Construct *PrettyPrinter* objects explicitly if you need to adjust the width constraint.

Dictionaries are sorted by key before the display is computed.

Άλλαξε στην έκδοση 3.9: Added support for pretty-printing *types.SimpleNamespace*.

The *pprint* module defines one class:

```
class pprint.PrettyPrinter(indent=1, width=80, depth=None, stream=None, *, compact=False,
                             sort_dicts=True)
```

Construct a *PrettyPrinter* instance. This constructor understands several keyword parameters. An output stream may be set using the *stream* keyword; the only method used on the stream object is the file protocol's *write()* method. If not specified, the *PrettyPrinter* adopts *sys.stdout*. The amount of indentation added for each recursive level is specified by *indent*; the default is one. Other values can cause output to look a little odd, but can make nesting easier to spot. The number of levels which may be printed is controlled by *depth*; if the data structure being printed is too deep, the next contained level is replaced by *. . .*. By default, there is no constraint on the depth of the objects being formatted. The desired output width is constrained using the *width* parameter; the default is 80 characters. If a structure cannot be formatted within the constrained width, a best effort will be made. If *compact* is false (the default) each item of a long sequence will be formatted on a separate line. If *compact* is true, as many items as will fit within the *width* will be formatted on each output line. If *sort_dicts* is true (the default), dictionaries will be formatted with their keys sorted, otherwise they will display in insertion order.

Άλλαξε στην έκδοση 3.4: Added the *compact* parameter.

Άλλαξε στην έκδοση 3.8: Added the *sort_dicts* parameter.

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff[:])
>>> pp = pprint.PrettyPrinter(indent=4)
>>> pp.pprint(stuff)
[
    'spam',
    'eggs',
    'lumberjack',
    'knights',
    'ni'
]
>>> pp = pprint.PrettyPrinter(width=41, compact=True)
>>> pp.pprint(stuff)
[['spam', 'eggs', 'lumberjack',
  'knights', 'ni'],
 'spam', 'eggs', 'lumberjack', 'knights',
 'ni']
>>> tup = ('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead',
... ('parrot', ('fresh fruit',)))))))
>>> pp = pprint.PrettyPrinter(depth=6)
>>> pp.pprint(tup)
('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead', (...)))))))
```

The *pprint* module also provides several shortcut functions:

`pprint.pformat(object, indent=1, width=80, depth=None, *, compact=False, sort_dicts=True)`

Return the formatted representation of *object* as a string. *indent*, *width*, *depth*, *compact* and *sort_dicts* will be passed to the *PrettyPrinter* constructor as formatting parameters.

Άλλαξε στην έκδοση 3.4: Added the *compact* parameter.

Άλλαξε στην έκδοση 3.8: Added the *sort_dicts* parameter.

`pprint.pp(object, *args, sort_dicts=False, **kwargs)`

Prints the formatted representation of *object* followed by a newline. If *sort_dicts* is false (the default), dictionaries will be displayed with their keys in insertion order, otherwise the dict keys will be sorted. *args* and *kwargs* will be passed to *pprint()* as formatting parameters.

Νέο στην έκδοση 3.8.

`pprint.pprint(object, stream=None, indent=1, width=80, depth=None, *, compact=False, sort_dicts=True)`

Prints the formatted representation of *object* on *stream*, followed by a newline. If *stream* is None, `sys.stdout` is used. This may be used in the interactive interpreter instead of the *print()* function for inspecting values (you can even reassign `print = pprint.pprint` for use within a scope). *indent*, *width*, *depth*, *compact* and *sort_dicts* will be passed to the *PrettyPrinter* constructor as formatting parameters.

Άλλαξε στην έκδοση 3.4: Added the *compact* parameter.

Άλλαξε στην έκδοση 3.8: Added the *sort_dicts* parameter.

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff)
>>> pprint.pprint(stuff)
[<Recursion on list with id=...>,
 'spam',
 'eggs',
 'lumberjack',
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
'knights',
'ni']
```

`pprint.isreadable(object)`

Determine if the formatted representation of *object* is «readable», or can be used to reconstruct the value using `eval()`. This always returns `False` for recursive objects.

```
>>> pprint.isreadable(stuff)
False
```

`pprint.isrecursive(object)`

Determine if *object* requires a recursive representation.

One more support function is also defined:

`pprint.saferepr(object)`

Return a string representation of *object*, protected against recursive data structures. If the representation of *object* exposes a recursive entry, the recursive reference will be represented as `<Recursion on typename with id=number>`. The representation is not otherwise formatted.

```
>>> pprint.saferepr(stuff)
"[<Recursion on list with id=...>, 'spam', 'eggs', 'lumberjack', 'knights', 'ni']"
```

8.12.1 PrettyPrinter Objects

PrettyPrinter instances have the following methods:

`PrettyPrinter.pformat(object)`

Return the formatted representation of *object*. This takes into account the options passed to the *PrettyPrinter* constructor.

`PrettyPrinter.pprint(object)`

Print the formatted representation of *object* on the configured stream, followed by a newline.

The following methods provide the implementations for the corresponding functions of the same names. Using these methods on an instance is slightly more efficient since new *PrettyPrinter* objects don't need to be created.

`PrettyPrinter.isreadable(object)`

Determine if the formatted representation of the object is «readable,» or can be used to reconstruct the value using `eval()`. Note that this returns `False` for recursive objects. If the *depth* parameter of the *PrettyPrinter* is set and the object is deeper than allowed, this returns `False`.

`PrettyPrinter.isrecursive(object)`

Determine if the object requires a recursive representation.

This method is provided as a hook to allow subclasses to modify the way objects are converted to strings. The default implementation uses the internals of the `saferepr()` implementation.

`PrettyPrinter.format(object, context, maxlevels, level)`

Returns three values: the formatted version of *object* as a string, a flag indicating whether the result is readable, and a flag indicating whether recursion was detected. The first argument is the object to be presented. The second is a dictionary which contains the `id()` of objects that are part of the current presentation context (direct and indirect containers for *object* that are affecting the presentation) as the keys; if an object needs to be presented which is already represented in *context*, the third return value should be `True`. Recursive calls to the `format()` method should add additional entries for containers to this dictionary. The third argument, *maxlevels*, gives the requested limit to recursion; this will be 0 if there is no requested limit. This argument should be passed unmodified to

recursive calls. The fourth argument, *level*, gives the current level; recursive calls should be passed a value less than that of the current call.

8.12.2 Example

To demonstrate several uses of the `pprint()` function and its parameters, let's fetch information about a project from PyPI:

```
>>> import json
>>> import pprint
>>> from urllib.request import urlopen
>>> with urlopen('https://pypi.org/pypi/sampleproject/json') as resp:
...     project_info = json.load(resp)['info']
```

In its basic form, `pprint()` shows the whole object:

```
>>> pprint.pprint(project_info)
{'author': 'The Python Packaging Authority',
 'author_email': 'pypa-dev@googlegroups.com',

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
'summary': 'A sample Python project',
'version': '1.2.0'}
```

Additionally, maximum character *width* can be suggested. If a long object cannot be split, the specified width will be exceeded:

```
>>> pprint.pprint(project_info, depth=1, width=60)
{'author': 'The Python Packaging Authority',
 'author_email': 'pypa-dev@googlegroups.com',
 'bugtrack_url': None,
 'classifiers': [...],
 'description': 'A sample Python project\n'
               '=====\n'
               '\n'
               'This is the description file for the '
               'project.\n'
               '\n'
               'The file should use UTF-8 encoding and be '
               'written using ReStructured Text. It\n'
               'will be used to generate the project '
               'webpage on PyPI, and should be written '
               'for\n'
               'that purpose.\n'
               '\n'
               'Typical contents for this file would '
               'include an overview of the project, '
               'basic\n'
               'usage examples, etc. Generally, including '
               'the project changelog in here is not\n'
               'a good idea, although a simple "What\'s '
               'New" section for the most recent version\n'
               'may be appropriate.',

8.13 reprlib — Alternate repr () implementation

Source code: [Lib/reprlib.py](#)

The `reprlib` module provides a means for producing object representations with limits on the size of the resulting strings. This is used in the Python debugger and may be useful in other contexts as well.

This module provides a class, an instance, and a function:

`class reprlib.Repr`

Class which provides formatting services useful in implementing functions similar to the built-in `repr()`; size limits for different object types are added to avoid the generation of representations which are excessively long.

`reprlib.aRepr`

This is an instance of `Repr` which is used to provide the `repr()` function described below. Changing the attributes of this object will affect the size limits used by `repr()` and the Python debugger.

`reprlib.repr(obj)`

This is the `repr()` method of `aRepr`. It returns a string similar to that returned by the built-in function of the same name, but with limits on most sizes.

In addition to size-limiting tools, the module also provides a decorator for detecting recursive calls to `__repr__()` and substituting a placeholder string instead.

`@reprlib.recursive_repr(fillvalue="...")`

Decorator for `__repr__()` methods to detect recursive calls within the same thread. If a recursive call is made, the `fillvalue` is returned, otherwise, the usual `__repr__()` call is made. For example:

```
>>> from reprlib import recursive_repr
>>> class MyList(list):
...     @recursive_repr()
...     def __repr__(self):
...         return '<' + '|'.join(map(repr, self)) + '>'
...
>>> m = MyList('abc')
>>> m.append(m)
>>> m.append('x')
>>> print(m)
<'a'|'b'|'c'|...|'x'>
```

Νέο στην έκδοση 3.2.

8.13.1 Repr Objects

`Repr` instances provide several attributes which can be used to provide size limits for the representations of different object types, and methods which format specific object types.

`Repr.maxlevel`

Depth limit on the creation of recursive representations. The default is 6.

`Repr.maxdict`

`Repr.maxlist`

`Repr.maxtuple`

`Repr.maxset`

`Repr.maxfrozenset`

`Repr.maxdeque`

Repr.maxarray

Limits on the number of entries represented for the named object type. The default is 4 for *maxdict*, 5 for *maxarray*, and 6 for the others.

Repr.maxlong

Maximum number of characters in the representation for an integer. Digits are dropped from the middle. The default is 40.

Repr.maxstring

Limit on the number of characters in the representation of the string. Note that the «normal» representation of the string is used as the character source: if escape sequences are needed in the representation, these may be mangled when the representation is shortened. The default is 30.

Repr.maxother

This limit is used to control the size of object types for which no specific formatting method is available on the *Repr* object. It is applied in a similar manner as *maxstring*. The default is 20.

Repr.repr(obj)

The equivalent to the built-in *repr()* that uses the formatting imposed by the instance.

Repr.repr1(obj, level)

Recursive implementation used by *repr()*. This uses the type of *obj* to determine which formatting method to call, passing it *obj* and *level*. The type-specific methods should call *repr1()* to perform recursive formatting, with *level - 1* for the value of *level* in the recursive call.

Repr.repr_TYPE(obj, level)

Formatting methods for specific types are implemented as methods with a name based on the type name. In the method name, **TYPE** is replaced by `'_'.join(type(obj).__name__.split())`. Dispatch to these methods is handled by *repr1()*. Type-specific methods which need to recursively format a value should call `self.repr1(subobj, level - 1)`.

8.13.2 Subclassing Repr Objects

The use of dynamic dispatching by *Repr.repr1()* allows subclasses of *Repr* to add support for additional built-in object types or to modify the handling of types already supported. This example shows how special support for file objects could be added:

```
import reprlib
import sys

class MyRepr(reprlib.Repr):

    def repr_TextIOWrapper(self, obj, level):
        if obj.name in {'<stdin>', '<stdout>', '<stderr>'}:
            return obj.name
        return repr(obj)

aRepr = MyRepr()
print(aRepr.repr(sys.stdin))           # prints '<stdin>'
```

8.14 enum — Support for enumerations

Νέο στην έκδοση 3.4.

Source code: [Lib/enum.py](#)

An enumeration is a set of symbolic names (members) bound to unique, constant values. Within an enumeration, the members can be compared by identity, and the enumeration itself can be iterated over.

Σημείωση: Case of Enum Members

Because Enums are used to represent constants we recommend using UPPER_CASE names for enum members, and will be using that style in our examples.

8.14.1 Module Contents

This module defines four enumeration classes that can be used to define unique sets of names and values: *Enum*, *IntEnum*, *Flag*, and *IntFlag*. It also defines one decorator, *unique()*, and one helper, *auto*.

class enum.Enum

Base class for creating enumerated constants. See section *Functional API* for an alternate construction syntax.

class enum.IntEnum

Base class for creating enumerated constants that are also subclasses of *int*.

class enum.IntFlag

Base class for creating enumerated constants that can be combined using the bitwise operators without losing their *IntFlag* membership. *IntFlag* members are also subclasses of *int*.

class enum.Flag

Base class for creating enumerated constants that can be combined using the bitwise operations without losing their *Flag* membership.

enum.unique()

Enum class decorator that ensures only one name is bound to any one value.

class enum.auto

Instances are replaced with an appropriate value for Enum members. By default, the initial value starts at 1.

Νέο στην έκδοση 3.6: *Flag*, *IntFlag*, *auto*

8.14.2 Creating an Enum

Enumerations are created using the `class` syntax, which makes them easy to read and write. An alternative creation method is described in *Functional API*. To define an enumeration, subclass *Enum* as follows:

```
>>> from enum import Enum
>>> class Color(Enum):
...     RED = 1
...     GREEN = 2
...     BLUE = 3
... 
```

Σημείωση: Enum member values

Member values can be anything: `int`, `str`, etc.. If the exact value is unimportant you may use `auto` instances and an appropriate value will be chosen for you. Care must be taken if you mix `auto` with other values.

Σημείωση: Nomenclature

- The class `Color` is an *enumeration* (or *enum*)
 - The attributes `Color.RED`, `Color.GREEN`, etc., are *enumeration members* (or *enum members*) and are functionally constants.
 - The enum members have *names* and *values* (the name of `Color.RED` is `RED`, the value of `Color.BLUE` is 3, etc.)
-

Σημείωση: Even though we use the `class` syntax to create Enums, Enums are not normal Python classes. See [How are Enums different?](#) for more details.

Enumeration members have human readable string representations:

```
>>> print(Color.RED)
Color.RED
```

...while their `repr` has more information:

```
>>> print(repr(Color.RED))
<Color.RED: 1>
```

The *type* of an enumeration member is the enumeration it belongs to:

```
>>> type(Color.RED)
<enum 'Color'>
>>> isinstance(Color.GREEN, Color)
True
>>>
```

Enum members also have a property that contains just their item name:

```
>>> print(Color.RED.name)
RED
```

Enumerations support iteration, in definition order:

```
>>> class Shake(Enum):
...     VANILLA = 7
...     CHOCOLATE = 4
...     COOKIES = 9
...     MINT = 3
...
>>> for shake in Shake:
...     print(shake)
...
Shake.VANILLA
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
Shake.CHOCOLATE
Shake.COOKIES
Shake.MINT
```

Enumeration members are hashable, so they can be used in dictionaries and sets:

```
>>> apples = {}
>>> apples[Color.RED] = 'red delicious'
>>> apples[Color.GREEN] = 'granny smith'
>>> apples == {Color.RED: 'red delicious', Color.GREEN: 'granny smith'}
True
```

8.14.3 Programmatic access to enumeration members and their attributes

Sometimes it's useful to access members in enumerations programmatically (i.e. situations where `Color.RED` won't do because the exact color is not known at program-writing time). `Enum` allows such access:

```
>>> Color(1)
<Color.RED: 1>
>>> Color(3)
<Color.BLUE: 3>
```

If you want to access enum members by *name*, use item access:

```
>>> Color['RED']
<Color.RED: 1>
>>> Color['GREEN']
<Color.GREEN: 2>
```

If you have an enum member and need its name or value:

```
>>> member = Color.RED
>>> member.name
'RED'
>>> member.value
1
```

8.14.4 Duplicating enum members and values

Having two enum members with the same name is invalid:

```
>>> class Shape(Enum):
...     SQUARE = 2
...     SQUARE = 3
...
Traceback (most recent call last):
...
TypeError: Attempted to reuse key: 'SQUARE'
```

However, two enum members are allowed to have the same value. Given two members A and B with the same value (and A defined first), B is an alias to A. By-value lookup of the value of A and B will return A. By-name lookup of B will also return A:

```
>>> class Shape(Enum):
...     SQUARE = 2
...     DIAMOND = 1
...     CIRCLE = 3
...     ALIAS_FOR_SQUARE = 2
...
>>> Shape.SQUARE
<Shape.SQUARE: 2>
>>> Shape.ALIAS_FOR_SQUARE
<Shape.SQUARE: 2>
>>> Shape(2)
<Shape.SQUARE: 2>
```

Σημείωση: Attempting to create a member with the same name as an already defined attribute (another member, a method, etc.) or attempting to create an attribute with the same name as a member is not allowed.

8.14.5 Ensuring unique enumeration values

By default, enumerations allow multiple names as aliases for the same value. When this behavior isn't desired, the following decorator can be used to ensure each value is used only once in the enumeration:

`@enum.unique`

A class decorator specifically for enumerations. It searches an enumeration's `__members__` gathering any aliases it finds; if any are found `ValueError` is raised with the details:

```
>>> from enum import Enum, unique
>>> @unique
... class Mistake(Enum):
...     ONE = 1
...     TWO = 2
...     THREE = 3
...     FOUR = 3
...
Traceback (most recent call last):
...
ValueError: duplicate values found in <enum 'Mistake': FOUR -> THREE
```

8.14.6 Using automatic values

If the exact value is unimportant you can use `auto`:

```
>>> from enum import Enum, auto
>>> class Color(Enum):
...     RED = auto()
...     BLUE = auto()
...     GREEN = auto()
...
>>> list(Color)
[<Color.RED: 1>, <Color.BLUE: 2>, <Color.GREEN: 3>]
```

The values are chosen by `_generate_next_value_()`, which can be overridden:

```
>>> class AutoName(Enum):
...     def _generate_next_value_(name, start, count, last_values):
...         return name
...
>>> class Ordinal(AutoName):
...     NORTH = auto()
...     SOUTH = auto()
...     EAST = auto()
...     WEST = auto()
...
>>> list(Ordinal)
[<Ordinal.NORTH: 'NORTH'>, <Ordinal.SOUTH: 'SOUTH'>, <Ordinal.EAST: 'EAST'>, <Ordinal.
↳WEST: 'WEST'>]
```

Σημείωση: The goal of the default `_generate_next_value_()` method is to provide the next `int` in sequence with the last `int` provided, but the way it does this is an implementation detail and may change.

Σημείωση: The `_generate_next_value_()` method must be defined before any members.

8.14.7 Iteration

Iterating over the members of an enum does not provide the aliases:

```
>>> list(Shape)
[<Shape.SQUARE: 2>, <Shape.DIAMOND: 1>, <Shape.CIRCLE: 3>]
```

The special attribute `__members__` is a read-only ordered mapping of names to members. It includes all names defined in the enumeration, including the aliases:

```
>>> for name, member in Shape.__members__.items():
...     name, member
...
('SQUARE', <Shape.SQUARE: 2>)
('DIAMOND', <Shape.DIAMOND: 1>)
('CIRCLE', <Shape.CIRCLE: 3>)
('ALIAS_FOR_SQUARE', <Shape.SQUARE: 2>)
```

The `__members__` attribute can be used for detailed programmatic access to the enumeration members. For example, finding all the aliases:

```
>>> [name for name, member in Shape.__members__.items() if member.name != name]
['ALIAS_FOR_SQUARE']
```

8.14.8 Comparisons

Enumeration members are compared by identity:

```
>>> Color.RED is Color.RED
True
>>> Color.RED is Color.BLUE
False
>>> Color.RED is not Color.BLUE
True
```

Ordered comparisons between enumeration values are *not* supported. Enum members are not integers (but see [IntEnum](#) below):

```
>>> Color.RED < Color.BLUE
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: '<' not supported between instances of 'Color' and 'Color'
```

Equality comparisons are defined though:

```
>>> Color.BLUE == Color.RED
False
>>> Color.BLUE != Color.RED
True
>>> Color.BLUE == Color.BLUE
True
```

Comparisons against non-enumeration values will always compare not equal (again, [IntEnum](#) was explicitly designed to behave differently, see below):

```
>>> Color.BLUE == 2
False
```

8.14.9 Allowed members and attributes of enumerations

The examples above use integers for enumeration values. Using integers is short and handy (and provided by default by the [Functional API](#)), but not strictly enforced. In the vast majority of use-cases, one doesn't care what the actual value of an enumeration is. But if the value *is* important, enumerations can have arbitrary values.

Enumerations are Python classes, and can have methods and special methods as usual. If we have this enumeration:

```
>>> class Mood(Enum):
...     FUNKY = 1
...     HAPPY = 3
...
...     def describe(self):
...         # self is the member here
...         return self.name, self.value
...
...     def __str__(self):
...         return 'my custom str! {0}'.format(self.value)
...
...     @classmethod
...     def favorite_mood(cls):
...         # cls here is the enumeration
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
...     return cls.HAPPY
...
```

Then:

```
>>> Mood.favorite_mood()
<Mood.HAPPY: 3>
>>> Mood.HAPPY.describe()
('HAPPY', 3)
>>> str(Mood.FUNKY)
'my custom str! 1'
```

The rules for what is allowed are as follows: names that start and end with a single underscore are reserved by enum and cannot be used; all other attributes defined within an enumeration will become members of this enumeration, with the exception of special methods (`__str__()`, `__add__()`, etc.), descriptors (methods are also descriptors), and variable names listed in `__ignore__`.

Note: if your enumeration defines `__new__()` and/or `__init__()` then any value(s) given to the enum member will be passed into those methods. See [Planet](#) for an example.

8.14.10 Restricted Enum subclassing

A new [Enum](#) class must have one base Enum class, up to one concrete data type, and as many *object*-based mixin classes as needed. The order of these base classes is:

```
class EnumName([mix-in, ...,] [data-type,] base-enum):
    pass
```

Also, subclassing an enumeration is allowed only if the enumeration does not define any members. So this is forbidden:

```
>>> class MoreColor(Color):
...     PINK = 17
...
Traceback (most recent call last):
...
TypeError: Cannot extend enumerations
```

But this is allowed:

```
>>> class Foo(Enum):
...     def some_behavior(self):
...         pass
...
>>> class Bar(Foo):
...     HAPPY = 1
...     SAD = 2
...
```

Allowing subclassing of enums that define members would lead to a violation of some important invariants of types and instances. On the other hand, it makes sense to allow sharing some common behavior between a group of enumerations. (See [OrderedEnum](#) for an example.)

8.14.11 Pickling

Enumerations can be pickled and unpickled:

```
>>> from test.test_enum import Fruit
>>> from pickle import dumps, loads
>>> Fruit.TOMATO is loads(dumps(Fruit.TOMATO))
True
```

The usual restrictions for pickling apply: picklable enums must be defined in the top level of a module, since unpickling requires them to be importable from that module.

Σημείωση: With pickle protocol version 4 it is possible to easily pickle enums nested in other classes.

It is possible to modify how Enum members are pickled/unpickled by defining `__reduce_ex__()` in the enumeration class.

8.14.12 Functional API

The `Enum` class is callable, providing the following functional API:

```
>>> Animal = Enum('Animal', 'ANT BEE CAT DOG')
>>> Animal
<enum 'Animal'>
>>> Animal.ANT
<Animal.ANT: 1>
>>> Animal.ANT.value
1
>>> list(Animal)
[<Animal.ANT: 1>, <Animal.BEE: 2>, <Animal.CAT: 3>, <Animal.DOG: 4>]
```

The semantics of this API resemble *namedtuple*. The first argument of the call to `Enum` is the name of the enumeration.

The second argument is the *source* of enumeration member names. It can be a whitespace-separated string of names, a sequence of names, a sequence of 2-tuples with key/value pairs, or a mapping (e.g. dictionary) of names to values. The last two options enable assigning arbitrary values to enumerations; the others auto-assign increasing integers starting with 1 (use the `start` parameter to specify a different starting value). A new class derived from `Enum` is returned. In other words, the above assignment to `Animal` is equivalent to:

```
>>> class Animal(Enum):
...     ANT = 1
...     BEE = 2
...     CAT = 3
...     DOG = 4
... 
```

The reason for defaulting to 1 as the starting number and not 0 is that 0 is `False` in a boolean sense, but enum members all evaluate to `True`.

Pickling enums created with the functional API can be tricky as frame stack implementation details are used to try and figure out which module the enumeration is being created in (e.g. it will fail if you use a utility function in separate module, and also may not work on IronPython or Jython). The solution is to specify the module name explicitly as follows:

```
>>> Animal = Enum('Animal', 'ANT BEE CAT DOG', module=__name__)
```

Προειδοποίηση: If `module` is not supplied, and `Enum` cannot determine what it is, the new `Enum` members will not be unpicklable; to keep errors closer to the source, pickling will be disabled.

The new pickle protocol 4 also, in some circumstances, relies on `__qualname__` being set to the location where pickle will be able to find the class. For example, if the class was made available in class `SomeData` in the global scope:

```
>>> Animal = Enum('Animal', 'ANT BEE CAT DOG', qualname='SomeData.Animal')
```

The complete signature is:

```
Enum(value='NewEnumName', names=<...>, *, module='...', qualname='...', type=<mixed-
↪in class>, start=1)
```

value What the new `Enum` class will record as its name.

names The `Enum` members. This can be a whitespace or comma separated string (values will start at 1 unless otherwise specified):

```
'RED GREEN BLUE' | 'RED, GREEN, BLUE' | 'RED, GREEN, BLUE'
```

or an iterator of names:

```
['RED', 'GREEN', 'BLUE']
```

or an iterator of (name, value) pairs:

```
[('CYAN', 4), ('MAGENTA', 5), ('YELLOW', 6)]
```

or a mapping:

```
{'CHARTREUSE': 7, 'SEA_GREEN': 11, 'ROSEMARY': 42}
```

module name of module where new `Enum` class can be found.

qualname where in module new `Enum` class can be found.

type type to mix in to new `Enum` class.

start number to start counting at if only names are passed in.

Άλλαξε στην έκδοση 3.5: The `start` parameter was added.

8.14.13 Derived Enumerations

IntEnum

The first variation of `Enum` that is provided is also a subclass of `int`. Members of an `IntEnum` can be compared to integers; by extension, integer enumerations of different types can also be compared to each other:

```
>>> from enum import IntEnum
>>> class Shape(IntEnum):
...     CIRCLE = 1
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

...     SQUARE = 2
...
>>> class Request(IntEnum):
...     POST = 1
...     GET = 2
...
>>> Shape == 1
False
>>> Shape.CIRCLE == 1
True
>>> Shape.CIRCLE == Request.POST
True

```

However, they still can't be compared to standard *Enum* enumerations:

```

>>> class Shape(IntEnum):
...     CIRCLE = 1
...     SQUARE = 2
...
>>> class Color(Enum):
...     RED = 1
...     GREEN = 2
...
>>> Shape.CIRCLE == Color.RED
False

```

IntEnum values behave like integers in other ways you'd expect:

```

>>> int(Shape.CIRCLE)
1
>>> ['a', 'b', 'c'][Shape.CIRCLE]
'b'
>>> [i for i in range(Shape.SQUARE)]
[0, 1]

```

IntFlag

The next variation of *Enum* provided, *IntFlag*, is also based on *int*. The difference being *IntFlag* members can be combined using the bitwise operators (&, |, ^, ~) and the result is still an *IntFlag* member. However, as the name implies, *IntFlag* members also subclass *int* and can be used wherever an *int* is used. Any operation on an *IntFlag* member besides the bit-wise operations will lose the *IntFlag* membership.

Νέο στην έκδοση 3.6.

Sample *IntFlag* class:

```

>>> from enum import IntFlag
>>> class Perm(IntFlag):
...     R = 4
...     W = 2
...     X = 1
...
>>> Perm.R | Perm.W
<Perm.R|W: 6>
>>> Perm.R + Perm.W

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
6
>>> RW = Perm.R | Perm.W
>>> Perm.R in RW
True
```

It is also possible to name the combinations:

```
>>> class Perm(IntFlag):
...     R = 4
...     W = 2
...     X = 1
...     RWX = 7
>>> Perm.RWX
<Perm.RWX: 7>
>>> ~Perm.RWX
<Perm.-8: -8>
```

Another important difference between *IntFlag* and *Enum* is that if no flags are set (the value is 0), its boolean evaluation is *False*:

```
>>> Perm.R & Perm.X
<Perm.0: 0>
>>> bool(Perm.R & Perm.X)
False
```

Because *IntFlag* members are also subclasses of *int* they can be combined with them:

```
>>> Perm.X | 8
<Perm.8|X: 9>
```

Flag

The last variation is *Flag*. Like *IntFlag*, *Flag* members can be combined using the bitwise operators (&, |, ^, ~). Unlike *IntFlag*, they cannot be combined with, nor compared against, any other *Flag* enumeration, nor *int*. While it is possible to specify the values directly it is recommended to use *auto* as the value and let *Flag* select an appropriate value.

Νέο στην έκδοση 3.6.

Like *IntFlag*, if a combination of *Flag* members results in no flags being set, the boolean evaluation is *False*:

```
>>> from enum import Flag, auto
>>> class Color(Flag):
...     RED = auto()
...     BLUE = auto()
...     GREEN = auto()
...
>>> Color.RED & Color.GREEN
<Color.0: 0>
>>> bool(Color.RED & Color.GREEN)
False
```

Individual flags should have values that are powers of two (1, 2, 4, 8, ...), while combinations of flags won't:

```
>>> class Color(Flag):
...     RED = auto()
...     BLUE = auto()
...     GREEN = auto()
...     WHITE = RED | BLUE | GREEN
...
>>> Color.WHITE
<Color.WHITE: 7>
```

Giving a name to the «no flags set» condition does not change its boolean value:

```
>>> class Color(Flag):
...     BLACK = 0
...     RED = auto()
...     BLUE = auto()
...     GREEN = auto()
...
>>> Color.BLACK
<Color.BLACK: 0>
>>> bool(Color.BLACK)
False
```

Σημείωση: For the majority of new code, *Enum* and *Flag* are strongly recommended, since *IntEnum* and *IntFlag* break some semantic promises of an enumeration (by being comparable to integers, and thus by transitivity to other unrelated enumerations). *IntEnum* and *IntFlag* should be used only in cases where *Enum* and *Flag* will not do; for example, when integer constants are replaced with enumerations, or for interoperability with other systems.

Others

While *IntEnum* is part of the *enum* module, it would be very simple to implement independently:

```
class IntEnum(int, Enum):
    pass
```

This demonstrates how similar derived enumerations can be defined; for example a *StrEnum* that mixes in *str* instead of *int*.

Some rules:

1. When subclassing *Enum*, mix-in types must appear before *Enum* itself in the sequence of bases, as in the *IntEnum* example above.
2. While *Enum* can have members of any type, once you mix in an additional type, all the members must have values of that type, e.g. *int* above. This restriction does not apply to mix-ins which only add methods and don't specify another type.
3. When another data type is mixed in, the `value` attribute is *not the same* as the enum member itself, although it is equivalent and will compare equal.
4. %-style formatting: `%s` and `%r` call the *Enum* class's `__str__()` and `__repr__()` respectively; other codes (such as `%i` or `%h` for *IntEnum*) treat the enum member as its mixed-in type.
5. Formatted string literals, `str.format()`, and `format()` will use the mixed-in type's `__format__()` unless `__str__()` or `__format__()` is overridden in the subclass, in which case the overridden methods or *Enum* methods will be used. Use the `!s` and `!r` format codes to force usage of the *Enum* class's `__str__()` and `__repr__()` methods.

8.14.14 When to use `__new__()` vs. `__init__()`

`__new__()` must be used whenever you want to customize the actual value of the *Enum* member. Any other modifications may go in either `__new__()` or `__init__()`, with `__init__()` being preferred.

For example, if you want to pass several items to the constructor, but only want one of them to be the value:

```
>>> class Coordinate(bytes, Enum):
...     """
...     Coordinate with binary codes that can be indexed by the int code.
...     """
...     def __new__(cls, value, label, unit):
...         obj = bytes.__new__(cls, [value])
...         obj._value_ = value
...         obj.label = label
...         obj.unit = unit
...         return obj
...     PX = (0, 'P.X', 'km')
...     PY = (1, 'P.Y', 'km')
...     VX = (2, 'V.X', 'km/s')
...     VY = (3, 'V.Y', 'km/s')
...

>>> print(Coordinate['PY'])
Coordinate.PY

>>> print(Coordinate(3))
Coordinate.VY
```

8.14.15 Interesting examples

While *Enum*, *IntEnum*, *IntFlag*, and *Flag* are expected to cover the majority of use-cases, they cannot cover them all. Here are recipes for some different types of enumerations that can be used directly, or as examples for creating one's own.

Omitting values

In many use-cases one doesn't care what the actual value of an enumeration is. There are several ways to define this type of simple enumeration:

- use instances of *auto* for the value
- use instances of *object* as the value
- use a descriptive string as the value
- use a tuple as the value and a custom `__new__()` to replace the tuple with an *int* value

Using any of these methods signifies to the user that these values are not important, and also enables one to add, remove, or reorder members without having to renumber the remaining members.

Whichever method you choose, you should provide a *repr()* that also hides the (unimportant) value:

```
>>> class NoValue(Enum):
...     def __repr__(self):
...         return '<%s.%s>' % (self.__class__.__name__, self.name)
... 
```

Using `auto`

Using `auto` would look like:

```
>>> class Color(NoValue):
...     RED = auto()
...     BLUE = auto()
...     GREEN = auto()
...
>>> Color.GREEN
<Color.GREEN>
```

Using `object`

Using `object` would look like:

```
>>> class Color(NoValue):
...     RED = object()
...     GREEN = object()
...     BLUE = object()
...
>>> Color.GREEN
<Color.GREEN>
```

Using a descriptive string

Using a string as the value would look like:

```
>>> class Color(NoValue):
...     RED = 'stop'
...     GREEN = 'go'
...     BLUE = 'too fast!'
...
>>> Color.GREEN
<Color.GREEN>
>>> Color.GREEN.value
'go'
```

Using a custom `__new__()`

Using an auto-numbering `__new__()` would look like:

```
>>> class AutoNumber(NoValue):
...     def __new__(cls):
...         value = len(cls.__members__) + 1
...         obj = object.__new__(cls)
...         obj._value_ = value
...         return obj
...
>>> class Color(AutoNumber):
...     RED = ()
...     GREEN = ()
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
...      BLUE = ()
...
>>> Color.GREEN
<Color.GREEN>
>>> Color.GREEN.value
2
```

To make a more general purpose `AutoNumber`, add `*args` to the signature:

```
>>> class AutoNumber(NoValue):
...     def __new__(cls, *args):          # this is the only change from above
...         value = len(cls.__members__) + 1
...         obj = object.__new__(cls)
...         obj._value_ = value
...         return obj
... 
```

Then when you inherit from `AutoNumber` you can write your own `__init__` to handle any extra arguments:

```
>>> class Swatch(AutoNumber):
...     def __init__(self, pantone='unknown'):
...         self.pantone = pantone
...         AUBURN = '3497'
...         SEA_GREEN = '1246'
...         BLEACHED_CORAL = () # New color, no Pantone code yet!
...
>>> Swatch.SEA_GREEN
<Swatch.SEA_GREEN: 2>
>>> Swatch.SEA_GREEN.pantone
'1246'
>>> Swatch.BLEACHED_CORAL.pantone
'unknown'
```

Σημείωση: The `__new__()` method, if defined, is used during creation of the Enum members; it is then replaced by Enum's `__new__()` which is used after class creation for lookup of existing members.

OrderedEnum

An ordered enumeration that is not based on `IntEnum` and so maintains the normal `Enum` invariants (such as not being comparable to other enumerations):

```
>>> class OrderedEnum(Enum):
...     def __ge__(self, other):
...         if self.__class__ is other.__class__:
...             return self.value >= other.value
...         return NotImplemented
...     def __gt__(self, other):
...         if self.__class__ is other.__class__:
...             return self.value > other.value
...         return NotImplemented
...     def __le__(self, other):
...         if self.__class__ is other.__class__:
...             return self.value <= other.value
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

...     return NotImplemented
...     def __lt__(self, other):
...         if self.__class__ is other.__class__:
...             return self.value < other.value
...         return NotImplemented
...
>>> class Grade(OrderedEnum):
...     A = 5
...     B = 4
...     C = 3
...     D = 2
...     F = 1
...
>>> Grade.C < Grade.A
True

```

DuplicateFreeEnum

Raises an error if a duplicate member name is found instead of creating an alias:

```

>>> class DuplicateFreeEnum(Enum):
...     def __init__(self, *args):
...         cls = self.__class__
...         if any(self.value == e.value for e in cls):
...             a = self.name
...             e = cls(self.value).name
...             raise ValueError(
...                 "aliases not allowed in DuplicateFreeEnum: %r --> %r"
...                 % (a, e))
...
>>> class Color(DuplicateFreeEnum):
...     RED = 1
...     GREEN = 2
...     BLUE = 3
...     GRENE = 2
...
Traceback (most recent call last):
...
ValueError: aliases not allowed in DuplicateFreeEnum: 'GRENE' --> 'GREEN'

```

Σημείωση: This is a useful example for subclassing Enum to add or change other behaviors as well as disallowing aliases. If the only desired change is disallowing aliases, the `unique()` decorator can be used instead.

Planet

If `__new__()` or `__init__()` is defined the value of the enum member will be passed to those methods:

```
>>> class Planet(Enum):
...     MERCURY = (3.303e+23, 2.4397e6)
...     VENUS   = (4.869e+24, 6.0518e6)
...     EARTH   = (5.976e+24, 6.37814e6)
...     MARS    = (6.421e+23, 3.3972e6)
...     JUPITER = (1.9e+27, 7.1492e7)
...     SATURN  = (5.688e+26, 6.0268e7)
...     URANUS  = (8.686e+25, 2.5559e7)
...     NEPTUNE = (1.024e+26, 2.4746e7)
...     def __init__(self, mass, radius):
...         self.mass = mass          # in kilograms
...         self.radius = radius      # in meters
...     @property
...     def surface_gravity(self):
...         # universal gravitational constant (m3 kg-1 s-2)
...         G = 6.67300E-11
...         return G * self.mass / (self.radius * self.radius)
...
>>> Planet.EARTH.value
(5.976e+24, 6378140.0)
>>> Planet.EARTH.surface_gravity
9.802652743337129
```

TimePeriod

An example to show the `__ignore__` attribute in use:

```
>>> from datetime import timedelta
>>> class Period(timedelta, Enum):
...     "different lengths of time"
...     __ignore__ = 'Period i'
...     Period = vars()
...     for i in range(367):
...         Period['day_%d' % i] = i
...
>>> list(Period)[:2]
[<Period.day_0: datetime.timedelta(0)>, <Period.day_1: datetime.timedelta(days=1)>]
>>> list(Period)[-2:]
[<Period.day_365: datetime.timedelta(days=365)>, <Period.day_366: datetime.
↳timedelta(days=366)>]
```

8.14.16 How are Enums different?

Enums have a custom metaclass that affects many aspects of both derived Enum classes and their instances (members).

Enum Classes

The `EnumMeta` metaclass is responsible for providing the `__contains__()`, `__dir__()`, `__iter__()` and other methods that allow one to do things with an `Enum` class that fail on a typical class, such as `list(Color)` or `some_enum_var in Color`. `EnumMeta` is responsible for ensuring that various other methods on the final `Enum` class are correct (such as `__new__()`, `__getnewargs__()`, `__str__()` and `__repr__()`).

Enum Members (aka instances)

The most interesting thing about Enum members is that they are singletons. `EnumMeta` creates them all while it is creating the `Enum` class itself, and then puts a custom `__new__()` in place to ensure that no new ones are ever instantiated by returning only the existing member instances.

Finer Points

Supported `__dunder__` names

`__members__` is a read-only ordered mapping of `member_name:member` items. It is only available on the class.

`__new__()`, if specified, must create and return the enum members; it is also a very good idea to set the member's `_value_` appropriately. Once all the members are created it is no longer used.

Supported `_sunder_` names

- `_name_` – name of the member
- `_value_` – value of the member; can be set / modified in `__new__`
- `_missing_` – a lookup function used when a value is not found; may be overridden
- `_ignore_` – a list of names, either as a `list` or a `str`, that will not be transformed into members, and will be removed from the final class
- `_order_` – used in Python 2/3 code to ensure member order is consistent (class attribute, removed during class creation)
- `_generate_next_value_` – used by the *Functional API* and by `auto` to get an appropriate value for an enum member; may be overridden

Νέο στην έκδοση 3.6: `_missing_`, `_order_`, `_generate_next_value_`

Νέο στην έκδοση 3.7: `_ignore_`

To help keep Python 2 / Python 3 code in sync an `_order_` attribute can be provided. It will be checked against the actual order of the enumeration and raise an error if the two do not match:

```
>>> class Color(Enum):
...     _order_ = 'RED GREEN BLUE'
...     RED = 1
...     BLUE = 3
...     GREEN = 2
...
Traceback (most recent call last):
...
TypeError: member order does not match _order_
```

Σημείωση: In Python 2 code the `_order_` attribute is necessary as definition order is lost before it can be recorded.

`_Private_` names

Private names will be normal attributes in Python 3.11 instead of either an error or a member (depending on if the name ends with an underscore). Using these names in 3.9 and 3.10 will issue a *DeprecationWarning*.

Enum member type

Enum members are instances of their *Enum* class, and are normally accessed as `EnumClass.member`. Under certain circumstances they can also be accessed as `EnumClass.member.member`, but you should never do this as that lookup may fail or, worse, return something besides the *Enum* member you are looking for (this is another good reason to use all-uppercase names for members):

```
>>> class FieldTypes(Enum):
...     name = 0
...     value = 1
...     size = 2
...
>>> FieldTypes.value.size
<FieldTypes.size: 2>
>>> FieldTypes.size.value
2
```

Σημείωση: This behavior is deprecated and will be removed in 3.11.

Άλλαξε στην έκδοση 3.5.

Boolean value of *Enum* classes and members

Enum members that are mixed with non-*Enum* types (such as *int*, *str*, etc.) are evaluated according to the mixed-in type's rules; otherwise, all members evaluate as *True*. To make your own *Enum*'s boolean evaluation depend on the member's value add the following to your class:

```
def __bool__(self):
    return bool(self.value)
```

Enum classes always evaluate as *True*.

Enum classes with methods

If you give your *Enum* subclass extra methods, like the *Planet* class above, those methods will show up in a *dir()* of the member, but not of the class:

```
>>> dir(Planet)
['EARTH', 'JUPITER', 'MARS', 'MERCURY', 'NEPTUNE', 'SATURN', 'URANUS', 'VENUS', '__class__', '__doc__', '__members__', '__module__']
>>> dir(Planet.EARTH)
['__class__', '__doc__', '__module__', 'name', 'surface_gravity', 'value']
```

Combining members of Flag

If a combination of Flag members is not named, the *repr()* will include all named flags and all named combinations of flags that are in the value:

```
>>> class Color(Flag):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...     MAGENTA = RED | BLUE
...     YELLOW = RED | GREEN
...     CYAN = GREEN | BLUE
...
>>> Color(3) # named combination
<Color.YELLOW: 3>
>>> Color(7) # not named combination
<Color.CYAN|MAGENTA|BLUE|YELLOW|GREEN|RED: 7>
```

Σημείωση: In 3.11 unnamed combinations of flags will only produce the canonical flag members (aka single-value flags). So *Color(7)* would produce something like *<Color.BLUE|GREEN|RED: 7>*.

8.15 graphlib — Functionality to operate with graph-like structures

Source code: [Lib/graphlib.py](#)

class `graphlib.TopologicalSorter` (*graph=None*)

Provides functionality to topologically sort a graph of hashable nodes.

A topological order is a linear ordering of the vertices in a graph such that for every directed edge *u* -> *v* from vertex *u* to vertex *v*, vertex *u* comes before vertex *v* in the ordering. For instance, the vertices of the graph may represent tasks to be performed, and the edges may represent constraints that one task must be performed before another; in this example, a topological ordering is just a valid sequence for the tasks. A complete topological ordering is possible if and only if the graph has no directed cycles, that is, if it is a directed acyclic graph.

If the optional *graph* argument is provided it must be a dictionary representing a directed acyclic graph where the keys are nodes and the values are iterables of all predecessors of that node in the graph (the nodes that have edges that point to the value in the key). Additional nodes can be added to the graph using the *add()* method.

In the general case, the steps required to perform the sorting of a given graph are as follows:

- Create an instance of the `TopologicalSorter` with an optional initial graph.
- Add additional nodes to the graph.
- Call `prepare()` on the graph.
- While `is_active()` is True, iterate over the nodes returned by `get_ready()` and process them. Call `done()` on each node as it finishes processing.

In case just an immediate sorting of the nodes in the graph is required and no parallelism is involved, the convenience method `TopologicalSorter.static_order()` can be used directly:

```
>>> graph = {"D": {"B", "C"}, "C": {"A"}, "B": {"A"}}
>>> ts = TopologicalSorter(graph)
>>> tuple(ts.static_order())
('A', 'C', 'B', 'D')
```

The class is designed to easily support parallel processing of the nodes as they become ready. For instance:

```
topological_sorter = TopologicalSorter()

# Add nodes to 'topological_sorter'...

topological_sorter.prepare()
while topological_sorter.is_active():
    for node in topological_sorter.get_ready():
        # Worker threads or processes take nodes to work on off the
        # 'task_queue' queue.
        task_queue.put(node)

    # When the work for a node is done, workers put the node in
    # 'finalized_tasks_queue' so we can get more nodes to work on.
    # The definition of 'is_active()' guarantees that, at this point, at
    # least one node has been placed on 'task_queue' that hasn't yet
    # been passed to 'done()', so this blocking 'get()' must (eventually)
    # succeed. After calling 'done()', we loop back to call 'get_ready()'
    # again, so put newly freed nodes on 'task_queue' as soon as
    # logically possible.
    node = finalized_tasks_queue.get()
    topological_sorter.done(node)
```

add(*node*, **predecessors*)

Add a new node and its predecessors to the graph. Both the *node* and all elements in *predecessors* must be hashable.

If called multiple times with the same node argument, the set of dependencies will be the union of all dependencies passed in.

It is possible to add a node with no dependencies (*predecessors* is not provided) or to provide a dependency twice. If a node that has not been provided before is included among *predecessors* it will be automatically added to the graph with no predecessors of its own.

Raises `ValueError` if called after `prepare()`.

prepare()

Mark the graph as finished and check for cycles in the graph. If any cycle is detected, `CycleError` will be raised, but `get_ready()` can still be used to obtain as many nodes as possible until cycles block more progress. After a call to this function, the graph cannot be modified, and therefore no more nodes can be added using `add()`.

is_active()

Returns `True` if more progress can be made and `False` otherwise. Progress can be made if cycles do not block the resolution and either there are still nodes ready that haven't yet been returned by `TopologicalSorter.get_ready()` or the number of nodes marked `TopologicalSorter.done()` is less than the number that have been returned by `TopologicalSorter.get_ready()`.

The `__bool__()` method of this class defers to this function, so instead of:

```
if ts.is_active():
    ...
```

it is possible to simply do:

```
if ts:
    ...
```

Raises `ValueError` if called without calling `prepare()` previously.

done(*nodes)

Marks a set of nodes returned by `TopologicalSorter.get_ready()` as processed, unblocking any successor of each node in `nodes` for being returned in the future by a call to `TopologicalSorter.get_ready()`.

Raises `ValueError` if any node in `nodes` has already been marked as processed by a previous call to this method or if a node was not added to the graph by using `TopologicalSorter.add()`, if called without calling `prepare()` or if node has not yet been returned by `get_ready()`.

get_ready()

Returns a tuple with all the nodes that are ready. Initially it returns all nodes with no predecessors, and once those are marked as processed by calling `TopologicalSorter.done()`, further calls will return all new nodes that have all their predecessors already processed. Once no more progress can be made, empty tuples are returned.

Raises `ValueError` if called without calling `prepare()` previously.

static_order()

Returns an iterator object which will iterate over nodes in a topological order. When using this method, `prepare()` and `done()` should not be called. This method is equivalent to:

```
def static_order(self):
    self.prepare()
    while self.is_active():
        node_group = self.get_ready()
        yield from node_group
        self.done(*node_group)
```

The particular order that is returned may depend on the specific order in which the items were inserted in the graph. For example:

```
>>> ts = TopologicalSorter()
>>> ts.add(3, 2, 1)
>>> ts.add(1, 0)
>>> print(list(ts.static_order()))
[2, 0, 1, 3]

>>> ts2 = TopologicalSorter()
>>> ts2.add(1, 0)
>>> ts2.add(3, 2, 1)
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> print([*ts2.static_order()])  
[0, 2, 1, 3]
```

This is due to the fact that «0» and «2» are in the same level in the graph (they would have been returned in the same call to `get_ready()`) and the order between them is determined by the order of insertion.

If any cycle is detected, `CycleError` will be raised.

Νέο στην έκδοση 3.9.

8.15.1 Exceptions

The `graphlib` module defines the following exception classes:

exception `graphlib.CycleError`

Subclass of `ValueError` raised by `TopologicalSorter.prepare()` if cycles exist in the working graph. If multiple cycles exist, only one undefined choice among them will be reported and included in the exception.

The detected cycle can be accessed via the second element in the `args` attribute of the exception instance and consists in a list of nodes, such that each node is, in the graph, an immediate predecessor of the next node in the list. In the reported list, the first and the last node will be the same, to make it clear that it is cyclic.

Αριθμητικά και Μαθηματικά Modules

Τα modules που περιγράφονται σε αυτό το κεφάλαιο παρέχουν αριθμητικές και μαθηματικές συναρτήσεις και τύπους δεδομένων. Το πακέτο *numbers* ορίζει μια αφηρημένη ιεραρχία τύπων δεδομένων. Τα modules *math* και *cmath* περιέχουν διάφορες μαθηματικές συναρτήσεις για αριθμούς κινητής υποδιαστολής και μιγαδικούς αριθμούς. Το module *decimal* υποστηρίζει ακριβείς αναπαραστάσεις δεκαδικών αριθμών χρησιμοποιώντας αριθμητική αυθαίρετης ακρίβειας.

Τα ακόλουθα modules αναλύονται σε αυτό το κεφάλαιο

9.1 numbers — Numeric abstract base classes

Source code: [Lib/numbers.py](#)

The *numbers* module ([PEP 3141](#)) defines a hierarchy of numeric *abstract base classes* which progressively define more operations. None of the types defined in this module are intended to be instantiated.

class `numbers.Number`

The root of the numeric hierarchy. If you just want to check if an argument *x* is a number, without caring what kind, use `isinstance(x, Number)`.

9.1.1 The numeric tower

class `numbers.Complex`

Subclasses of this type describe complex numbers and include the operations that work on the built-in *complex* type. These are: conversions to *complex* and *bool*, *real*, *imag*, *+*, *-*, ***, */*, ****, *abs()*, *conjugate()*, *==*, and *!=*. All except *-* and *!=* are abstract.

real

Abstract. Retrieves the real component of this number.

imag

Abstract. Retrieves the imaginary component of this number.

abstractmethod conjugate()

Abstract. Returns the complex conjugate. For example, `(1+3j).conjugate() == (1-3j)`.

class numbers.Real

To *Complex*, *Real* adds the operations that work on real numbers.

In short, those are: a conversion to *float*, *math.trunc()*, *round()*, *math.floor()*, *math.ceil()*, *divmod()*, *//*, *%*, *<*, *<=*, *>*, and *>=*.

Real also provides defaults for *complex()*, *real*, *imag*, and *conjugate()*.

class numbers.Rational

Subtypes *Real* and adds *numerator* and *denominator* properties, which should be in lowest terms. With these, it provides a default for *float()*.

numerator

Abstract.

denominator

Abstract.

class numbers.Integral

Subtypes *Rational* and adds a conversion to *int*. Provides defaults for *float()*, *numerator*, and *denominator*. Adds abstract methods for *pow()* with modulus and bit-string operations: *<<*, *>>*, *&*, *^*, *|*, *~*.

9.1.2 Notes for type implementors

Implementors should be careful to make equal numbers equal and hash them to the same values. This may be subtle if there are two different extensions of the real numbers. For example, *fractions.Fraction* implements *hash()* as follows:

```
def __hash__(self):
    if self.denominator == 1:
        # Get integers right.
        return hash(self.numerator)
    # Expensive check, but definitely correct.
    if self == float(self):
        return hash(float(self))
    else:
        # Use tuple's hash to avoid a high collision rate on
        # simple fractions.
        return hash((self.numerator, self.denominator))
```

Adding More Numeric ABCs

There are, of course, more possible ABCs for numbers, and this would be a poor hierarchy if it precluded the possibility of adding those. You can add *MyFoo* between *Complex* and *Real* with:

```
class MyFoo(Complex): ...
MyFoo.register(Real)
```

Implementing the arithmetic operations

We want to implement the arithmetic operations so that mixed-mode operations either call an implementation whose author knew about the types of both arguments, or convert both to the nearest built in type and do the operation there. For subtypes of *Integral*, this means that `__add__()` and `__radd__()` should be defined as:

```
class MyIntegral(Integral):

    def __add__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(self, other)
        elif isinstance(other, OtherTypeIKnowAbout):
            return do_my_other_adding_stuff(self, other)
        else:
            return NotImplemented

    def __radd__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(other, self)
        elif isinstance(other, OtherTypeIKnowAbout):
            return do_my_other_adding_stuff(other, self)
        elif isinstance(other, Integral):
            return int(other) + int(self)
        elif isinstance(other, Real):
            return float(other) + float(self)
        elif isinstance(other, Complex):
            return complex(other) + complex(self)
        else:
            return NotImplemented
```

There are 5 different cases for a mixed-type operation on subclasses of *Complex*. I'll refer to all of the above code that doesn't refer to *MyIntegral* and *OtherTypeIKnowAbout* as «boilerplate». *a* will be an instance of *A*, which is a subtype of *Complex* (*a* : *A* <: *Complex*), and *b* : *B* <: *Complex*. I'll consider *a* + *b*:

1. If *A* defines an `__add__()` which accepts *b*, all is well.
2. If *A* falls back to the boilerplate code, and it were to return a value from `__add__()`, we'd miss the possibility that *B* defines a more intelligent `__radd__()`, so the boilerplate should return *NotImplemented* from `__add__()`. (Or *A* may not implement `__add__()` at all.)
3. Then *B*'s `__radd__()` gets a chance. If it accepts *a*, all is well.
4. If it falls back to the boilerplate, there are no more possible methods to try, so this is where the default implementation should live.
5. If *B* <: *A*, Python tries *B*.`__radd__` before *A*.`__add__`. This is ok, because it was implemented with knowledge of *A*, so it can handle those instances before delegating to *Complex*.

If *A* <: *Complex* and *B* <: *Real* without sharing any other knowledge, then the appropriate shared operation is the one involving the built in *complex*, and both `__radd__()`s land there, so *a*+*b* == *b*+*a*.

Because most of the operations on any given type will be very similar, it can be useful to define a helper function which generates the forward and reverse instances of any given operator. For example, *fractions.Fraction* uses:

```
def _operator_fallbacks(monomorphic_operator, fallback_operator):
    def forward(a, b):
        if isinstance(b, (int, Fraction)):
            return monomorphic_operator(a, b)
        elif isinstance(b, float):
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

        return fallback_operator(float(a), b)
    elif isinstance(b, complex):
        return fallback_operator(complex(a), b)
    else:
        return NotImplemented
forward.__name__ = '__' + fallback_operator.__name__ + '__'
forward.__doc__ = monomorphic_operator.__doc__

def reverse(b, a):
    if isinstance(a, Rational):
        # Includes ints.
        return monomorphic_operator(a, b)
    elif isinstance(a, numbers.Real):
        return fallback_operator(float(a), float(b))
    elif isinstance(a, numbers.Complex):
        return fallback_operator(complex(a), complex(b))
    else:
        return NotImplemented
reverse.__name__ = '__r' + fallback_operator.__name__ + '__'
reverse.__doc__ = monomorphic_operator.__doc__

return forward, reverse

def _add(a, b):
    """a + b"""
    return Fraction(a.numerator * b.denominator +
                    b.numerator * a.denominator,
                    a.denominator * b.denominator)

__add__, __radd__ = _operator_fallbacks(_add, operator.add)

# ...

```

9.2 math — Mathematical functions

This module provides access to the mathematical functions defined by the C standard.

These functions cannot be used with complex numbers; use the functions of the same name from the `cmath` module if you require support for complex numbers. The distinction between functions which support complex numbers and those which don't is made since most users do not want to learn quite as much mathematics as required to understand complex numbers. Receiving an exception instead of a complex result allows earlier detection of the unexpected complex number used as a parameter, so that the programmer can determine how and why it was generated in the first place.

The following functions are provided by this module. Except when explicitly noted otherwise, all return values are floats.

9.2.1 Number-theoretic and representation functions

`math.ceil(x)`

Return the ceiling of x , the smallest integer greater than or equal to x . If x is not a float, delegates to `x.__ceil__`, which should return an *Integral* value.

`math.comb(n, k)`

Return the number of ways to choose k items from n items without repetition and without order.

Evaluates to $n! / (k! * (n - k)!)$ when $k \leq n$ and evaluates to zero when $k > n$.

Also called the binomial coefficient because it is equivalent to the coefficient of k -th term in polynomial expansion of the expression $(1 + x) ** n$.

Raises *TypeError* if either of the arguments are not integers. Raises *ValueError* if either of the arguments are negative.

Νέο στην έκδοση 3.8.

`math.copysign(x, y)`

Return a float with the magnitude (absolute value) of x but the sign of y . On platforms that support signed zeros, `copysign(1.0, -0.0)` returns *-1.0*.

`math.fabs(x)`

Return the absolute value of x .

`math.factorial(x)`

Return x factorial as an integer. Raises *ValueError* if x is not integral or is negative.

Αποσύρθηκε στην έκδοση 3.9: Accepting floats with integral values (like `5.0`) is deprecated.

`math.floor(x)`

Return the floor of x , the largest integer less than or equal to x . If x is not a float, delegates to `x.__floor__`, which should return an *Integral* value.

`math.fmod(x, y)`

Return `fmod(x, y)`, as defined by the platform C library. Note that the Python expression `x % y` may not return the same result. The intent of the C standard is that `fmod(x, y)` be exactly (mathematically; to infinite precision) equal to $x - n*y$ for some integer n such that the result has the same sign as x and magnitude less than `abs(y)`. Python's `x % y` returns a result with the sign of y instead, and may not be exactly computable for float arguments. For example, `fmod(-1e-100, 1e100)` is `-1e-100`, but the result of Python's `-1e-100 % 1e100` is `1e100-1e-100`, which cannot be represented exactly as a float, and rounds to the surprising `1e100`. For this reason, function `fmod()` is generally preferred when working with floats, while Python's `x % y` is preferred when working with integers.

`math.frexp(x)`

Return the mantissa and exponent of x as the pair `(m, e)`. m is a float and e is an integer such that $x == m * 2**e$ exactly. If x is zero, returns `(0.0, 0)`, otherwise `0.5 <= abs(m) < 1`. This is used to «pick apart» the internal representation of a float in a portable way.

`math.fsum(iterable)`

Return an accurate floating point sum of values in the iterable. Avoids loss of precision by tracking multiple intermediate partial sums:

```
>>> sum([.1, .1, .1, .1, .1, .1, .1, .1, .1, .1])
0.9999999999999999
>>> fsum([.1, .1, .1, .1, .1, .1, .1, .1, .1, .1])
1.0
```

The algorithm's accuracy depends on IEEE-754 arithmetic guarantees and the typical case where the rounding mode is half-even. On some non-Windows builds, the underlying C library uses extended precision addition and may occasionally double-round an intermediate sum causing it to be off in its least significant bit.

For further discussion and two alternative approaches, see the [ASPN cookbook recipes for accurate floating point summation](#).

`math.gcd(*integers)`

Return the greatest common divisor of the specified integer arguments. If any of the arguments is nonzero, then the returned value is the largest positive integer that is a divisor of all arguments. If all arguments are zero, then the returned value is 0. `gcd()` without arguments returns 0.

Νέο στην έκδοση 3.5.

Άλλαξε στην έκδοση 3.9: Added support for an arbitrary number of arguments. Formerly, only two arguments were supported.

`math.isclose(a, b, *, rel_tol=1e-09, abs_tol=0.0)`

Return `True` if the values `a` and `b` are close to each other and `False` otherwise.

Whether or not two values are considered close is determined according to given absolute and relative tolerances.

`rel_tol` is the relative tolerance – it is the maximum allowed difference between `a` and `b`, relative to the larger absolute value of `a` or `b`. For example, to set a tolerance of 5%, pass `rel_tol=0.05`. The default tolerance is `1e-09`, which assures that the two values are the same within about 9 decimal digits. `rel_tol` must be greater than zero.

`abs_tol` is the minimum absolute tolerance – useful for comparisons near zero. `abs_tol` must be at least zero.

If no errors occur, the result will be: `abs(a-b) <= max(rel_tol * max(abs(a), abs(b)), abs_tol)`.

The IEEE 754 special values of NaN, `inf`, and `-inf` will be handled according to IEEE rules. Specifically, NaN is not considered close to any other value, including NaN. `inf` and `-inf` are only considered close to themselves.

Δείτε επίσης:

PEP 485 – A function for testing approximate equality

`math.isfinite(x)`

Return `True` if `x` is neither an infinity nor a NaN, and `False` otherwise. (Note that `0.0` is considered finite.)

Νέο στην έκδοση 3.2.

`math.isinf(x)`

Return `True` if `x` is a positive or negative infinity, and `False` otherwise.

`math.isnan(x)`

Return `True` if `x` is a NaN (not a number), and `False` otherwise.

`math.isqrt(n)`

Return the integer square root of the nonnegative integer `n`. This is the floor of the exact square root of `n`, or equivalently the greatest integer `a` such that $a^2 \leq n$.

For some applications, it may be more convenient to have the least integer `a` such that $n \leq a^2$, or in other words the ceiling of the exact square root of `n`. For positive `n`, this can be computed using `a = 1 + isqrt(n - 1)`.

Νέο στην έκδοση 3.8.

`math.lcm(*integers)`

Return the least common multiple of the specified integer arguments. If all arguments are nonzero, then the returned value is the smallest positive integer that is a multiple of all arguments. If any of the arguments is zero, then the returned value is 0. `lcm()` without arguments returns 1.

Νέο στην έκδοση 3.9.

`math.ldexp(x, i)`

Return $x * (2^{**i})$. This is essentially the inverse of function `frexp()`.

`math.modf(x)`

Return the fractional and integer parts of x . Both results carry the sign of x and are floats.

`math.nextafter(x, y)`

Return the next floating-point value after x towards y .

If x is equal to y , return y .

Examples:

- `math.nextafter(x, math.inf)` goes up: towards positive infinity.
- `math.nextafter(x, -math.inf)` goes down: towards minus infinity.
- `math.nextafter(x, 0.0)` goes towards zero.
- `math.nextafter(x, math.copysign(math.inf, x))` goes away from zero.

See also `math.ulp()`.

Νέο στην έκδοση 3.9.

`math.perm(n, k=None)`

Return the number of ways to choose k items from n items without repetition and with order.

Evaluates to $n! / (n - k)!$ when $k \leq n$ and evaluates to zero when $k > n$.

If k is not specified or is `None`, then k defaults to n and the function returns $n!$.

Raises `TypeError` if either of the arguments are not integers. Raises `ValueError` if either of the arguments are negative.

Νέο στην έκδοση 3.8.

`math.prod(iterable, *, start=1)`

Calculate the product of all the elements in the input *iterable*. The default *start* value for the product is 1.

When the iterable is empty, return the start value. This function is intended specifically for use with numeric values and may reject non-numeric types.

Νέο στην έκδοση 3.8.

`math.remainder(x, y)`

Return the IEEE 754-style remainder of x with respect to y . For finite x and finite nonzero y , this is the difference $x - n*y$, where n is the closest integer to the exact value of the quotient x / y . If x / y is exactly halfway between two consecutive integers, the nearest *even* integer is used for n . The remainder $r = \text{remainder}(x, y)$ thus always satisfies $\text{abs}(r) \leq 0.5 * \text{abs}(y)$.

Special cases follow IEEE 754: in particular, `remainder(x, math.inf)` is x for any finite x , and `remainder(x, 0)` and `remainder(math.inf, x)` raise `ValueError` for any non-NaN x . If the result of the remainder operation is zero, that zero will have the same sign as x .

On platforms using IEEE 754 binary floating-point, the result of this operation is always exactly representable: no rounding error is introduced.

Νέο στην έκδοση 3.7.

`math.trunc(x)`

Return x with the fractional part removed, leaving the integer part. This rounds toward 0: `trunc()` is equivalent to `floor()` for positive x , and equivalent to `ceil()` for negative x . If x is not a float, delegates to `x.__trunc__`, which should return an *Integral* value.

`math.ulp(x)`

Return the value of the least significant bit of the float x :

- If x is a NaN (not a number), return x .
- If x is negative, return `ulp(-x)`.
- If x is a positive infinity, return x .
- If x is equal to zero, return the smallest positive *denormalized* representable float (smaller than the minimum positive *normalized* float, `sys.float_info.min`).
- If x is equal to the largest positive representable float, return the value of the least significant bit of x , such that the first float smaller than x is $x - \text{ulp}(x)$.
- Otherwise (x is a positive finite number), return the value of the least significant bit of x , such that the first float bigger than x is $x + \text{ulp}(x)$.

ULP stands for «Unit in the Last Place».

See also `math.nextafter()` and `sys.float_info.epsilon`.

Νέο στην έκδοση 3.9.

Note that `frexp()` and `modf()` have a different call/return pattern than their C equivalents: they take a single argument and return a pair of values, rather than returning their second return value through an “output parameter” (there is no such thing in Python).

For the `ceil()`, `floor()`, and `modf()` functions, note that *all* floating-point numbers of sufficiently large magnitude are exact integers. Python floats typically carry no more than 53 bits of precision (the same as the platform C double type), in which case any float x with `abs(x) >= 2**52` necessarily has no fractional bits.

9.2.2 Power and logarithmic functions

`math.exp(x)`

Return e raised to the power x , where $e = 2.718281\dots$ is the base of natural logarithms. This is usually more accurate than `math.e ** x` or `pow(math.e, x)`.

`math.expm1(x)`

Return e raised to the power x , minus 1. Here e is the base of natural logarithms. For small floats x , the subtraction in `exp(x) - 1` can result in a *significant loss of precision*; the `expm1()` function provides a way to compute this quantity to full precision:

```
>>> from math import exp, expm1
>>> exp(1e-5) - 1 # gives result accurate to 11 places
1.0000050000069649e-05
>>> expm1(1e-5) # result accurate to full precision
1.0000050000166668e-05
```

Νέο στην έκδοση 3.2.

`math.log(x[, base])`

With one argument, return the natural logarithm of x (to base e).

With two arguments, return the logarithm of x to the given *base*, calculated as `log(x) / log(base)`.

`math.log1p(x)`

Return the natural logarithm of $1+x$ (base e). The result is calculated in a way which is accurate for x near zero.

`math.log2(x)`

Return the base-2 logarithm of x . This is usually more accurate than `log(x, 2)`.

Νέο στην έκδοση 3.3.

Δείτε επίσης:

`int.bit_length()` returns the number of bits necessary to represent an integer in binary, excluding the sign and leading zeros.

`math.log10(x)`

Return the base-10 logarithm of x . This is usually more accurate than `log(x, 10)`.

`math.pow(x, y)`

Return x raised to the power y . Exceptional cases follow Annex “F” of the C99 standard as far as possible. In particular, `pow(1.0, x)` and `pow(x, 0.0)` always return `1.0`, even when x is a zero or a NaN. If both x and y are finite, x is negative, and y is not an integer then `pow(x, y)` is undefined, and raises `ValueError`.

Unlike the built-in `**` operator, `math.pow()` converts both its arguments to type `float`. Use `**` or the built-in `pow()` function for computing exact integer powers.

`math.sqrt(x)`

Return the square root of x .

9.2.3 Trigonometric functions

`math.acos(x)`

Return the arc cosine of x , in radians. The result is between 0 and π .

`math.asin(x)`

Return the arc sine of x , in radians. The result is between $-\pi/2$ and $\pi/2$.

`math.atan(x)`

Return the arc tangent of x , in radians. The result is between $-\pi/2$ and $\pi/2$.

`math.atan2(y, x)`

Return `atan(y / x)`, in radians. The result is between $-\pi$ and π . The vector in the plane from the origin to point (x, y) makes this angle with the positive X axis. The point of `atan2()` is that the signs of both inputs are known to it, so it can compute the correct quadrant for the angle. For example, `atan(1)` and `atan2(1, 1)` are both $\pi/4$, but `atan2(-1, -1)` is $-3\pi/4$.

`math.cos(x)`

Return the cosine of x radians.

`math.dist(p, q)`

Return the Euclidean distance between two points p and q , each given as a sequence (or iterable) of coordinates. The two points must have the same dimension.

Roughly equivalent to:

```
sqrt(sum((px - qx) ** 2.0 for px, qx in zip(p, q)))
```

Νέο στην έκδοση 3.8.

`math.hypot(*coordinates)`

Return the Euclidean norm, `sqrt(sum(x**2 for x in coordinates))`. This is the length of the vector from the origin to the point given by the coordinates.

For a two dimensional point (x, y) , this is equivalent to computing the hypotenuse of a right triangle using the Pythagorean theorem, `sqrt(x*x + y*y)`.

Άλλαξε στην έκδοση 3.8: Added support for n-dimensional points. Formerly, only the two dimensional case was supported.

`math.sin(x)`

Return the sine of x radians.

`math.tan(x)`

Return the tangent of x radians.

9.2.4 Angular conversion

`math.degrees(x)`

Convert angle x from radians to degrees.

`math.radians(x)`

Convert angle x from degrees to radians.

9.2.5 Hyperbolic functions

Hyperbolic functions are analogs of trigonometric functions that are based on hyperbolas instead of circles.

`math.acosh(x)`

Return the inverse hyperbolic cosine of x .

`math.asinh(x)`

Return the inverse hyperbolic sine of x .

`math.atanh(x)`

Return the inverse hyperbolic tangent of x .

`math.cosh(x)`

Return the hyperbolic cosine of x .

`math.sinh(x)`

Return the hyperbolic sine of x .

`math.tanh(x)`

Return the hyperbolic tangent of x .

9.2.6 Special functions

`math.erf(x)`

Return the error function at x .

The `erf()` function can be used to compute traditional statistical functions such as the cumulative standard normal distribution:

```
def phi(x):  
    'Cumulative distribution function for the standard normal distribution'  
    return (1.0 + erf(x / sqrt(2.0))) / 2.0
```

Νέο στην έκδοση 3.2.

`math.erfc(x)`

Return the complementary error function at x . The complementary error function is defined as $1.0 - \text{erf}(x)$. It is used for large values of x where a subtraction from one would cause a loss of significance.

Νέο στην έκδοση 3.2.

`math.gamma(x)`
Return the [Gamma function](#) at x .
Νέο στην έκδοση 3.2.

`math.lgamma(x)`
Return the natural logarithm of the absolute value of the Gamma function at x .
Νέο στην έκδοση 3.2.

9.2.7 Constants

`math.pi`
The mathematical constant $\pi = 3.141592\dots$, to available precision.

`math.e`
The mathematical constant $e = 2.718281\dots$, to available precision.

`math.tau`
The mathematical constant $\tau = 6.283185\dots$, to available precision. Tau is a circle constant equal to 2π , the ratio of a circle's circumference to its radius. To learn more about Tau, check out Vi Hart's video [Pi is \(still\) Wrong](#), and start celebrating [Tau day](#) by eating twice as much pie!
Νέο στην έκδοση 3.6.

`math.inf`
A floating-point positive infinity. (For negative infinity, use `-math.inf`.) Equivalent to the output of `float('inf')`.
Νέο στην έκδοση 3.5.

`math.nan`
A floating-point «not a number» (NaN) value. Equivalent to the output of `float('nan')`. Due to the requirements of the [IEEE-754 standard](#), `math.nan` and `float('nan')` are not considered to equal to any other numeric value, including themselves. To check whether a number is a NaN, use the `isnan()` function to test for NaNs instead of `is` or `==`. Example:

```
>>> import math
>>> math.nan == math.nan
False
>>> float('nan') == float('nan')
False
>>> math.isnan(math.nan)
True
>>> math.isnan(float('nan'))
True
```

Νέο στην έκδοση 3.5.

CPython implementation detail: The `math` module consists mostly of thin wrappers around the platform C math library functions. Behavior in exceptional cases follows Annex F of the C99 standard where appropriate. The current implementation will raise [ValueError](#) for invalid operations like `sqrt(-1.0)` or `log(0.0)` (where C99 Annex F recommends signaling invalid operation or divide-by-zero), and [OverflowError](#) for results that overflow (for example, `exp(1000.0)`). A NaN will not be returned from any of the functions above unless one or more of the input arguments was a NaN; in that case, most functions will return a NaN, but (again following C99 Annex F) there are some exceptions to this rule, for example `pow(float('nan'), 0.0)` or `hypot(float('nan'), float('inf'))`.

Note that Python makes no effort to distinguish signaling NaNs from quiet NaNs, and behavior for signaling NaNs remains unspecified. Typical behavior is to treat all NaNs as though they were quiet.

Δείτε επίσης:

Module `cmath` Complex number versions of many of these functions.

9.3 `cmath` — Mathematical functions for complex numbers

This module provides access to mathematical functions for complex numbers. The functions in this module accept integers, floating-point numbers or complex numbers as arguments. They will also accept any Python object that has either a `__complex__()` or a `__float__()` method: these methods are used to convert the object to a complex or floating-point number, respectively, and the function is then applied to the result of the conversion.

Σημείωση: On platforms with hardware and system-level support for signed zeros, functions involving branch cuts are continuous on *both* sides of the branch cut: the sign of the zero distinguishes one side of the branch cut from the other. On platforms that do not support signed zeros the continuity is as specified below.

9.3.1 Conversions to and from polar coordinates

A Python complex number `z` is stored internally using *rectangular* or *Cartesian* coordinates. It is completely determined by its *real part* `z.real` and its *imaginary part* `z.imag`. In other words:

```
z == z.real + z.imag*1j
```

Polar coordinates give an alternative way to represent a complex number. In polar coordinates, a complex number `z` is defined by the modulus `r` and the phase angle `phi`. The modulus `r` is the distance from `z` to the origin, while the phase `phi` is the counterclockwise angle, measured in radians, from the positive `x`-axis to the line segment that joins the origin to `z`.

The following functions can be used to convert from the native rectangular coordinates to polar coordinates and back.

`cmath.phase(x)`

Return the phase of `x` (also known as the *argument* of `x`), as a float. `phase(x)` is equivalent to `math.atan2(x.imag, x.real)`. The result lies in the range $[-\pi, \pi]$, and the branch cut for this operation lies along the negative real axis, continuous from above. On systems with support for signed zeros (which includes most systems in current use), this means that the sign of the result is the same as the sign of `x.imag`, even when `x.imag` is zero:

```
>>> phase(complex(-1.0, 0.0))
3.141592653589793
>>> phase(complex(-1.0, -0.0))
-3.141592653589793
```

Σημείωση: The modulus (absolute value) of a complex number `x` can be computed using the built-in `abs()` function. There is no separate `cmath` module function for this operation.

`cmath.polar(x)`

Return the representation of `x` in polar coordinates. Returns a pair `(r, phi)` where `r` is the modulus of `x` and `phi` is the phase of `x`. `polar(x)` is equivalent to `(abs(x), phase(x))`.

`cmath.rect(r, phi)`

Return the complex number `x` with polar coordinates `r` and `phi`. Equivalent to `r * (math.cos(phi) + math.sin(phi)*1j)`.

9.3.2 Power and logarithmic functions

`cmath.exp(x)`

Return e raised to the power x , where e is the base of natural logarithms.

`cmath.log(x[, base])`

Returns the logarithm of x to the given *base*. If the *base* is not specified, returns the natural logarithm of x . There is one branch cut, from 0 along the negative real axis to $-\infty$, continuous from above.

`cmath.log10(x)`

Return the base-10 logarithm of x . This has the same branch cut as `log()`.

`cmath.sqrt(x)`

Return the square root of x . This has the same branch cut as `log()`.

9.3.3 Trigonometric functions

`cmath.acos(x)`

Return the arc cosine of x . There are two branch cuts: One extends right from 1 along the real axis to ∞ , continuous from below. The other extends left from -1 along the real axis to $-\infty$, continuous from above.

`cmath.asin(x)`

Return the arc sine of x . This has the same branch cuts as `acos()`.

`cmath.atan(x)`

Return the arc tangent of x . There are two branch cuts: One extends from $1j$ along the imaginary axis to ∞j , continuous from the right. The other extends from $-1j$ along the imaginary axis to $-\infty j$, continuous from the left.

`cmath.cos(x)`

Return the cosine of x .

`cmath.sin(x)`

Return the sine of x .

`cmath.tan(x)`

Return the tangent of x .

9.3.4 Hyperbolic functions

`cmath.acosh(x)`

Return the inverse hyperbolic cosine of x . There is one branch cut, extending left from 1 along the real axis to $-\infty$, continuous from above.

`cmath.asinh(x)`

Return the inverse hyperbolic sine of x . There are two branch cuts: One extends from $1j$ along the imaginary axis to ∞j , continuous from the right. The other extends from $-1j$ along the imaginary axis to $-\infty j$, continuous from the left.

`cmath.atanh(x)`

Return the inverse hyperbolic tangent of x . There are two branch cuts: One extends from 1 along the real axis to ∞ , continuous from below. The other extends from -1 along the real axis to $-\infty$, continuous from above.

`cmath.cosh(x)`

Return the hyperbolic cosine of x .

`cmath.sinh(x)`

Return the hyperbolic sine of x .

`cmath.tanh(x)`

Return the hyperbolic tangent of x .

9.3.5 Classification functions

`cmath.isfinite(x)`

Return `True` if both the real and imaginary parts of x are finite, and `False` otherwise.

Νέο στην έκδοση 3.2.

`cmath.isinf(x)`

Return `True` if either the real or the imaginary part of x is an infinity, and `False` otherwise.

`cmath.isnan(x)`

Return `True` if either the real or the imaginary part of x is a NaN, and `False` otherwise.

`cmath.isclose(a, b, *, rel_tol=1e-09, abs_tol=0.0)`

Return `True` if the values a and b are close to each other and `False` otherwise.

Whether or not two values are considered close is determined according to given absolute and relative tolerances.

rel_tol is the relative tolerance – it is the maximum allowed difference between a and b , relative to the larger absolute value of a or b . For example, to set a tolerance of 5%, pass *rel_tol*=0.05. The default tolerance is 1e-09, which assures that the two values are the same within about 9 decimal digits. *rel_tol* must be greater than zero.

abs_tol is the minimum absolute tolerance – useful for comparisons near zero. *abs_tol* must be at least zero.

If no errors occur, the result will be: $\text{abs}(a-b) \leq \max(\text{rel_tol} * \max(\text{abs}(a), \text{abs}(b)), \text{abs_tol})$.

The IEEE 754 special values of NaN, `inf`, and `-inf` will be handled according to IEEE rules. Specifically, NaN is not considered close to any other value, including NaN. `inf` and `-inf` are only considered close to themselves.

Complex number with zero real part and NaN imaginary part. Equivalent to `complex(0.0, float('nan'))`.

Νέο στην έκδοση 3.6.

Note that the selection of functions is similar, but not identical, to that in module `math`. The reason for having two modules is that some users aren't interested in complex numbers, and perhaps don't even know what they are. They would rather have `math.sqrt(-1)` raise an exception than return a complex number. Also note that the functions defined in `cmath` always return a complex number, even if the answer can be expressed as a real number (in which case the complex number has an imaginary part of zero).

A note on branch cuts: They are curves along which the given function fails to be continuous. They are a necessary feature of many complex functions. It is assumed that if you need to compute with complex functions, you will understand about branch cuts. Consult almost any (not too elementary) book on complex variables for enlightenment. For information of the proper choice of branch cuts for numerical purposes, a good reference should be the following:

9.4 decimal — Decimal fixed point and floating point arithmetic

Source code: [Lib/decimal.py](#)

The `decimal` module provides support for fast correctly-rounded decimal floating point arithmetic. It offers several advantages over the `float` datatype:

- Decimal «is based on a floating-point model which was designed with people in mind, and necessarily has a paramount guiding principle – computers must provide an arithmetic that works in the same way as the arithmetic that people learn at school.» – excerpt from the decimal arithmetic specification.
- Decimal numbers can be represented exactly. In contrast, numbers like 1.1 and 2.2 do not have exact representations in binary floating point. End users typically would not expect $1.1 + 2.2$ to display as 3.3000000000000003 as it does with binary floating point.
- The exactness carries over into arithmetic. In decimal floating point, $0.1 + 0.1 + 0.1 - 0.3$ is exactly equal to zero. In binary floating point, the result is $5.5511151231257827e-017$. While near to zero, the differences prevent reliable equality testing and differences can accumulate. For this reason, decimal is preferred in accounting applications which have strict equality invariants.
- The decimal module incorporates a notion of significant places so that $1.30 + 1.20$ is 2.50. The trailing zero is kept to indicate significance. This is the customary presentation for monetary applications. For multiplication, the «schoolbook» approach uses all the figures in the multiplicands. For instance, $1.3 * 1.2$ gives 1.56 while $1.30 * 1.20$ gives 1.5600.
- Unlike hardware based binary floating point, the decimal module has a user alterable precision (defaulting to 28 places) which can be as large as needed for a given problem:

```
>>> from decimal import *
>>> getcontext().prec = 6
>>> Decimal(1) / Decimal(7)
Decimal('0.142857')
>>> getcontext().prec = 28
>>> Decimal(1) / Decimal(7)
Decimal('0.1428571428571428571428571428571429')
```

- Both binary and decimal floating point are implemented in terms of published standards. While the built-in float type exposes only a modest portion of its capabilities, the decimal module exposes all required parts of the standard. When needed, the programmer has full control over rounding and signal handling. This includes an option to enforce exact arithmetic by using exceptions to block any inexact operations.
- The decimal module was designed to support «without prejudice, both exact unrounded decimal arithmetic (sometimes called fixed-point arithmetic) and rounded floating-point arithmetic.» – excerpt from the decimal arithmetic specification.

The module design is centered around three concepts: the decimal number, the context for arithmetic, and signals.

A decimal number is immutable. It has a sign, coefficient digits, and an exponent. To preserve significance, the coefficient digits do not truncate trailing zeros. Decimals also include special values such as `Infinity`, `-Infinity`, and `NaN`. The standard also differentiates `-0` from `+0`.

The context for arithmetic is an environment specifying precision, rounding rules, limits on exponents, flags indicating the results of operations, and trap enablers which determine whether signals are treated as exceptions. Rounding options include `ROUND_CEILING`, `ROUND_DOWN`, `ROUND_FLOOR`, `ROUND_HALF_DOWN`, `ROUND_HALF_EVEN`, `ROUND_HALF_UP`, `ROUND_UP`, and `ROUND_05UP`.

Signals are groups of exceptional conditions arising during the course of computation. Depending on the needs of the application, signals may be ignored, considered as informational, or treated as exceptions. The signals in the decimal module are: `Clamped`, `InvalidOperation`, `DivisionByZero`, `Inexact`, `Rounded`, `Subnormal`, `Overflow`, `Underflow` and `FloatOperation`.

For each signal there is a flag and a trap enabler. When a signal is encountered, its flag is set to one, then, if the trap enabler is set to one, an exception is raised. Flags are sticky, so the user needs to reset them before monitoring a calculation.

Δείτε επίσης:

- IBM's General Decimal Arithmetic Specification, [The General Decimal Arithmetic Specification](#).

9.4.1 Quick-start Tutorial

The usual start to using decimals is importing the module, viewing the current context with `getcontext()` and, if necessary, setting new values for precision, rounding, or enabled traps:

```
>>> from decimal import *
>>> getcontext()
Context(prec=28, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
       capitals=1, clamp=0, flags=[], traps=[Overflow, DivisionByZero,
       InvalidOperation])

>>> getcontext().prec = 7           # Set a new precision
```

Decimal instances can be constructed from integers, strings, floats, or tuples. Construction from an integer or a float performs an exact conversion of the value of that integer or float. Decimal numbers include special values such as `NaN` which stands for «Not a number», positive and negative `Infinity`, and `-0`:

```
>>> getcontext().prec = 28
>>> Decimal(10)
Decimal('10')
>>> Decimal('3.14')
Decimal('3.14')
>>> Decimal(3.14)
Decimal('3.1400000000000000124344978758017532527446746826171875')
>>> Decimal((0, (3, 1, 4), -2))
Decimal('3.14')
>>> Decimal(str(2.0 ** 0.5))
Decimal('1.4142135623730951')
>>> Decimal(2) ** Decimal('0.5')
Decimal('1.414213562373095048801688724')
>>> Decimal('NaN')
Decimal('NaN')
>>> Decimal('-Infinity')
Decimal('-Infinity')
```

If the `FloatOperation` signal is trapped, accidental mixing of decimals and floats in constructors or ordering comparisons raises an exception:

```
>>> c = getcontext()
>>> c.traps[FloatOperation] = True
>>> Decimal(3.14)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: []
>>> Decimal('3.5') < 3.7
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: []
>>> Decimal('3.5') == 3.5
True
```

Νέο στην έκδοση 3.3.

The significance of a new Decimal is determined solely by the number of digits input. Context precision and rounding only come into play during arithmetic operations.

```
>>> getcontext().prec = 6
>>> Decimal('3.0')
Decimal('3.0')
>>> Decimal('3.1415926535')
Decimal('3.1415926535')
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85987')
>>> getcontext().rounding = ROUND_UP
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85988')
```

If the internal limits of the C version are exceeded, constructing a decimal raises *InvalidOperation*:

```
>>> Decimal("1e999999999999999999")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.InvalidOperation: [
```

Άλλαξε στην έκδοση 3.3.

Decimals interact well with much of the rest of Python. Here is a small decimal floating point flying circus:

```
>>> data = list(map(Decimal, '1.34 1.87 3.45 2.35 1.00 0.03 9.25'.split()))
>>> max(data)
Decimal('9.25')
>>> min(data)
Decimal('0.03')
>>> sorted(data)
[Decimal('0.03'), Decimal('1.00'), Decimal('1.34'), Decimal('1.87'),
 Decimal('2.35'), Decimal('3.45'), Decimal('9.25')]
>>> sum(data)
Decimal('19.29')
>>> a,b,c = data[:3]
>>> str(a)
'1.34'
>>> float(a)
1.34
>>> round(a, 1)
Decimal('1.3')
>>> int(a)
1
>>> a * 5
Decimal('6.70')
>>> a * b
Decimal('2.5058')
>>> c % a
Decimal('0.77')
```

And some mathematical functions are also available to Decimal:

```
>>> getcontext().prec = 28
>>> Decimal(2).sqrt()
Decimal('1.414213562373095048801688724')
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal('10').ln()
Decimal('2.302585092994045684017991455')
>>> Decimal('10').log10()
Decimal('1')
```

The `quantize()` method rounds a number to a fixed exponent. This method is useful for monetary applications that often round results to a fixed number of places:

```
>>> Decimal('7.325').quantize(Decimal('.01'), rounding=ROUND_DOWN)
Decimal('7.32')
>>> Decimal('7.325').quantize(Decimal('1.'), rounding=ROUND_UP)
Decimal('8')
```

As shown above, the `getcontext()` function accesses the current context and allows the settings to be changed. This approach meets the needs of most applications.

For more advanced work, it may be useful to create alternate contexts using the `Context()` constructor. To make an alternate active, use the `setcontext()` function.

In accordance with the standard, the `decimal` module provides two ready to use standard contexts, `BasicContext` and `ExtendedContext`. The former is especially useful for debugging because many of the traps are enabled:

```

>>> myothercontext = Context(prec=60, rounding=ROUND_HALF_DOWN)
>>> setcontext(myothercontext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857142857142857142857142857142857142857142857142857142857')

>>> ExtendedContext
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
       capitals=1, clamp=0, flags=[], traps=[])
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857143')
>>> Decimal(42) / Decimal(0)
Decimal('Infinity')

>>> setcontext(BasicContext)
>>> Decimal(42) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#143>", line 1, in -toplevel-
    Decimal(42) / Decimal(0)
DivisionByZero: x / 0

```

Contexts also have signal flags for monitoring exceptional conditions encountered during computations. The flags remain set until explicitly cleared, so it is best to clear the flags before each set of monitored computations by using the `clear_flags()` method.

```

>>> setcontext(ExtendedContext)
>>> getcontext().clear_flags()
>>> Decimal(355) / Decimal(113)
Decimal('3.14159292')
>>> getcontext()
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
       capitals=1, clamp=0, flags=[Inexact, Rounded], traps=[])

```

The *flags* entry shows that the rational approximation to π was rounded (digits beyond the context precision were thrown away) and that the result is inexact (some of the discarded digits were non-zero).

Individual traps are set using the dictionary in the `traps` field of a context:

```

>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(0)
Decimal('Infinity')
>>> getcontext().traps[DivisionByZero] = 1
>>> Decimal(1) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#112>", line 1, in -toplevel-
    Decimal(1) / Decimal(0)
DivisionByZero: x / 0

```

Most programs adjust the current context only once, at the beginning of the program. And, in many applications, data is converted to `Decimal` with a single cast inside a loop. With context set and decimals created, the bulk of the program manipulates the data no differently than with other Python numeric types.

9.4.2 Decimal objects

class `decimal.Decimal` (*value*="0", *context*=None)

Construct a new *Decimal* object based from *value*.

value can be an integer, string, tuple, *float*, or another *Decimal* object. If no *value* is given, returns `Decimal('0')`. If *value* is a string, it should conform to the decimal numeric string syntax after leading and trailing whitespace characters, as well as underscores throughout, are removed:

```
sign          ::= '+' | '-'
digit         ::= '0' | '1' | '2' | '3' | '4' | '5' | '6' | '7' | '8' | '9'
indicator     ::= 'e' | 'E'
digits        ::= digit [digit]...
decimal-part  ::= digits '.' [digits] | ['.' ] digits
exponent-part ::= indicator [sign] digits
infinity      ::= 'Infinity' | 'Inf'
nan           ::= 'NaN' [digits] | 'sNaN' [digits]
numeric-value ::= decimal-part [exponent-part] | infinity
numeric-string ::= [sign] numeric-value | [sign] nan
```

Other Unicode decimal digits are also permitted where *digit* appears above. These include decimal digits from various other alphabets (for example, Arabic-Indic and Devanāgarī digits) along with the fullwidth digits `'\uff10'` through `'\uff19'`.

If *value* is a *tuple*, it should have three components, a sign (0 for positive or 1 for negative), a *tuple* of digits, and an integer exponent. For example, `Decimal((0, (1, 4, 1, 4), -3))` returns `Decimal('1.414')`.

If *value* is a *float*, the binary floating point value is losslessly converted to its exact decimal equivalent. This conversion can often require 53 or more digits of precision. For example, `Decimal(float('1.1'))` converts to `Decimal('1.100000000000000088817841970012523233890533447265625')`.

The *context* precision does not affect how many digits are stored. That is determined exclusively by the number of digits in *value*. For example, `Decimal('3.00000')` records all five zeros even if the context precision is only three.

The purpose of the *context* argument is determining what to do if *value* is a malformed string. If the context traps *InvalidOperation*, an exception is raised; otherwise, the constructor returns a new *Decimal* with the value of NaN.

Once constructed, *Decimal* objects are immutable.

Άλλαξε στην έκδοση 3.2: The argument to the constructor is now permitted to be a *float* instance.

Άλλαξε στην έκδοση 3.3: *float* arguments raise an exception if the *FloatOperation* trap is set. By default the trap is off.

Άλλαξε στην έκδοση 3.6: Underscores are allowed for grouping, as with integral and floating-point literals in code.

Decimal floating point objects share many properties with the other built-in numeric types such as *float* and *int*. All of the usual math operations and special methods apply. Likewise, decimal objects can be copied, pickled, printed, used as dictionary keys, used as set elements, compared, sorted, and coerced to another type (such as *float* or *int*).

There are some small differences between arithmetic on *Decimal* objects and arithmetic on integers and floats. When the remainder operator `%` is applied to *Decimal* objects, the sign of the result is the sign of the *dividend* rather than the sign of the divisor:

```
>>> (-7) % 4
1
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> Decimal(-7) % Decimal(4)
Decimal('-3')
```

The integer division operator `//` behaves analogously, returning the integer part of the true quotient (truncating towards zero) rather than its floor, so as to preserve the usual identity $x == (x // y) * y + x \% y$:

```
>>> -7 // 4
-2
>>> Decimal(-7) // Decimal(4)
Decimal('-1')
```

The `%` and `//` operators implement the remainder and divide-integer operations (respectively) as described in the specification.

Decimal objects cannot generally be combined with floats or instances of `fractions.Fraction` in arithmetic operations: an attempt to add a `Decimal` to a `float`, for example, will raise a `TypeError`. However, it is possible to use Python's comparison operators to compare a `Decimal` instance `x` with another number `y`. This avoids confusing results when doing equality comparisons between numbers of different types.

Άλλαξε στην έκδοση 3.2: Mixed-type comparisons between `Decimal` instances and other numeric types are now fully supported.

In addition to the standard numeric properties, decimal floating point objects also have a number of specialized methods:

adjusted()

Return the adjusted exponent after shifting out the coefficient's rightmost digits until only the lead digit remains: `Decimal('321e+5').adjusted()` returns seven. Used for determining the position of the most significant digit with respect to the decimal point.

as_integer_ratio()

Return a pair `(n, d)` of integers that represent the given `Decimal` instance as a fraction, in lowest terms and with a positive denominator:

```
>>> Decimal('-3.14').as_integer_ratio()
(-157, 50)
```

The conversion is exact. Raise `OverflowError` on infinities and `ValueError` on NaNs.

Νέο στην έκδοση 3.6.

as_tuple()

Return a *named tuple* representation of the number: `DecimalTuple(sign, digits, exponent)`.

canonical()

Return the canonical encoding of the argument. Currently, the encoding of a `Decimal` instance is always canonical, so this operation returns its argument unchanged.

compare(other, context=None)

Compare the values of two `Decimal` instances. `compare()` returns a `Decimal` instance, and if either operand is a NaN then the result is a NaN:

```
a or b is a NaN ==> Decimal('NaN')
a < b           ==> Decimal('-1')
a == b          ==> Decimal('0')
a > b           ==> Decimal('1')
```

compare_signal (*other*, *context=None*)

This operation is identical to the `compare()` method, except that all NaNs signal. That is, if neither operand is a signaling NaN then any quiet NaN operand is treated as though it were a signaling NaN.

compare_total (*other*, *context=None*)

Compare two operands using their abstract representation rather than their numerical value. Similar to the `compare()` method, but the result gives a total ordering on `Decimal` instances. Two `Decimal` instances with the same numeric value but different representations compare unequal in this ordering:

```
>>> Decimal('12.0').compare_total(Decimal('12'))
Decimal('-1')
```

Quiet and signaling NaNs are also included in the total ordering. The result of this function is `Decimal('0')` if both operands have the same representation, `Decimal('-1')` if the first operand is lower in the total order than the second, and `Decimal('1')` if the first operand is higher in the total order than the second operand. See the specification for details of the total order.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

compare_total_mag (*other*, *context=None*)

Compare two operands using their abstract representation rather than their value as in `compare_total()`, but ignoring the sign of each operand. `x.compare_total_mag(y)` is equivalent to `x.copy_abs().compare_total(y.copy_abs())`.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

conjugate ()

Just returns self, this method is only to comply with the Decimal Specification.

copy_abs ()

Return the absolute value of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

copy_negate ()

Return the negation of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

copy_sign (*other*, *context=None*)

Return a copy of the first operand with the sign set to be the same as the sign of the second operand. For example:

```
>>> Decimal('2.3').copy_sign(Decimal('-1.5'))
Decimal('-2.3')
```

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

exp (*context=None*)

Return the value of the (natural) exponential function e^{**x} at the given number. The result is correctly rounded using the `ROUND_HALF_EVEN` rounding mode.

```
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal(321).exp()
Decimal('2.561702493119680037517373933E+139')
```

from_float (*f*)

Classmethod that converts a float to a decimal number, exactly.

Note `Decimal.from_float(0.1)` is not the same as `Decimal("0.1")`. Since 0.1 is not exactly representable in binary floating point, the value is stored as the nearest representable value which is $0x1.999999999999ap-4$. That equivalent value in decimal is `0.1000000000000000055511151231257827021181583404541015625`.

Σημείωση: From Python 3.2 onwards, a `Decimal` instance can also be constructed directly from a `float`.

```
>>> Decimal.from_float(0.1)
Decimal('0.1000000000000000055511151231257827021181583404541015625')
>>> Decimal.from_float(float('nan'))
Decimal('NaN')
>>> Decimal.from_float(float('inf'))
Decimal('Infinity')
>>> Decimal.from_float(float('-inf'))
Decimal('-Infinity')
```

Νέο στην έκδοση 3.1.

fma (*other, third, context=None*)

Fused multiply-add. Return `self*other+third` with no rounding of the intermediate product `self*other`.

```
>>> Decimal(2).fma(3, 5)
Decimal('11')
```

is_canonical ()

Return `True` if the argument is canonical and `False` otherwise. Currently, a `Decimal` instance is always canonical, so this operation always returns `True`.

is_finite ()

Return `True` if the argument is a finite number, and `False` if the argument is an infinity or a NaN.

is_infinite ()

Return `True` if the argument is either positive or negative infinity and `False` otherwise.

is_nan ()

Return `True` if the argument is a (quiet or signaling) NaN and `False` otherwise.

is_normal (*context=None*)

Return `True` if the argument is a *normal* finite number. Return `False` if the argument is zero, subnormal, infinite or a NaN.

is_qnan ()

Return `True` if the argument is a quiet NaN, and `False` otherwise.

is_signed ()

Return `True` if the argument has a negative sign and `False` otherwise. Note that zeros and NaNs can both carry signs.

is_snan ()

Return `True` if the argument is a signaling NaN and `False` otherwise.

is_subnormal (*context=None*)

Return `True` if the argument is subnormal, and `False` otherwise.

is_zero ()

Return `True` if the argument is a (positive or negative) zero and `False` otherwise.

ln (*context=None*)

Return the natural (base e) logarithm of the operand. The result is correctly rounded using the `ROUND_HALF_EVEN` rounding mode.

log10 (*context=None*)

Return the base ten logarithm of the operand. The result is correctly rounded using the `ROUND_HALF_EVEN` rounding mode.

logb (*context=None*)

For a nonzero number, return the adjusted exponent of its operand as a `Decimal` instance. If the operand is a zero then `Decimal('-Infinity')` is returned and the `DivisionByZero` flag is raised. If the operand is an infinity then `Decimal('Infinity')` is returned.

logical_and (*other, context=None*)

`logical_and()` is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise and of the two operands.

logical_invert (*context=None*)

`logical_invert()` is a logical operation. The result is the digit-wise inversion of the operand.

logical_or (*other, context=None*)

`logical_or()` is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise or of the two operands.

logical_xor (*other, context=None*)

`logical_xor()` is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise exclusive or of the two operands.

max (*other, context=None*)

Like `max(self, other)` except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

max_mag (*other, context=None*)

Similar to the `max()` method, but the comparison is done using the absolute values of the operands.

min (*other, context=None*)

Like `min(self, other)` except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

min_mag (*other, context=None*)

Similar to the `min()` method, but the comparison is done using the absolute values of the operands.

next_minus (*context=None*)

Return the largest number representable in the given context (or in the current thread's context if no context is given) that is smaller than the given operand.

next_plus (*context=None*)

Return the smallest number representable in the given context (or in the current thread's context if no context is given) that is larger than the given operand.

next_toward (*other, context=None*)

If the two operands are unequal, return the number closest to the first operand in the direction of the second operand. If both operands are numerically equal, return a copy of the first operand with the sign set to be the same as the sign of the second operand.

normalize (*context=None*)

Normalize the number by stripping the rightmost trailing zeros and converting any result equal to `Decimal('0')` to `Decimal('0e0')`. Used for producing canonical values for attributes of an equivalence class. For example, `Decimal('32.100')` and `Decimal('0.321000e+2')` both normalize to the equivalent value `Decimal('32.1')`.

number_class (*context=None*)

Return a string describing the *class* of the operand. The returned value is one of the following ten strings.

- `"-Infinity"`, indicating that the operand is negative infinity.

- `"-Normal"`, indicating that the operand is a negative normal number.
- `"-Subnormal"`, indicating that the operand is negative and subnormal.
- `"-Zero"`, indicating that the operand is a negative zero.
- `"+Zero"`, indicating that the operand is a positive zero.
- `"+Subnormal"`, indicating that the operand is positive and subnormal.
- `"+Normal"`, indicating that the operand is a positive normal number.
- `"+Infinity"`, indicating that the operand is positive infinity.
- `"NaN"`, indicating that the operand is a quiet NaN (Not a Number).
- `"sNaN"`, indicating that the operand is a signaling NaN.

quantize (*exp*, *rounding=None*, *context=None*)

Return a value equal to the first operand after rounding and having the exponent of the second operand.

```
>>> Decimal('1.41421356').quantize(Decimal('1.000'))
Decimal('1.414')
```

Unlike other operations, if the length of the coefficient after the quantize operation would be greater than precision, then an *InvalidOperation* is signaled. This guarantees that, unless there is an error condition, the quantized exponent is always equal to that of the right-hand operand.

Also unlike other operations, quantize never signals Underflow, even if the result is subnormal and inexact.

If the exponent of the second operand is larger than that of the first then rounding may be necessary. In this case, the rounding mode is determined by the `rounding` argument if given, else by the given `context` argument; if neither argument is given the rounding mode of the current thread's context is used.

An error is returned whenever the resulting exponent is greater than `Emax` or less than `Etiny`.

radix ()

Return `Decimal(10)`, the radix (base) in which the *Decimal* class does all its arithmetic. Included for compatibility with the specification.

remainder_near (*other*, *context=None*)

Return the remainder from dividing *self* by *other*. This differs from `self % other` in that the sign of the remainder is chosen so as to minimize its absolute value. More precisely, the return value is `self - n * other` where `n` is the integer nearest to the exact value of `self / other`, and if two integers are equally near then the even one is chosen.

If the result is zero then its sign will be the sign of *self*.

```
>>> Decimal(18).remainder_near(Decimal(10))
Decimal('-2')
>>> Decimal(25).remainder_near(Decimal(10))
Decimal('5')
>>> Decimal(35).remainder_near(Decimal(10))
Decimal('-5')
```

rotate (*other*, *context=None*)

Return the result of rotating the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range `-precision` through `precision`. The absolute value of the second operand gives the number of places to rotate. If the second operand is positive then rotation is to the left; otherwise rotation is to the right. The coefficient of the first operand is padded on the left with zeros to length `precision` if necessary. The sign and exponent of the first operand are unchanged.

same_quantum (*other*, *context=None*)

Test whether self and other have the same exponent or whether both are NaN.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

scaleb (*other*, *context=None*)

Return the first operand with exponent adjusted by the second. Equivalently, return the first operand multiplied by $10^{**other}$. The second operand must be an integer.

shift (*other*, *context=None*)

Return the result of shifting the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range `-precision` through `precision`. The absolute value of the second operand gives the number of places to shift. If the second operand is positive then the shift is to the left; otherwise the shift is to the right. Digits shifted into the coefficient are zeros. The sign and exponent of the first operand are unchanged.

sqrt (*context=None*)

Return the square root of the argument to full precision.

to_eng_string (*context=None*)

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

For example, this converts `Decimal('123E+1')` to `Decimal('1.23E+3')`.

to_integral (*rounding=None*, *context=None*)

Identical to the `to_integral_value()` method. The `to_integral` name has been kept for compatibility with older versions.

to_integral_exact (*rounding=None*, *context=None*)

Round to the nearest integer, signaling *Inexact* or *Rounded* as appropriate if rounding occurs. The rounding mode is determined by the `rounding` parameter if given, else by the given `context`. If neither parameter is given then the rounding mode of the current context is used.

to_integral_value (*rounding=None*, *context=None*)

Round to the nearest integer without signaling *Inexact* or *Rounded*. If given, applies *rounding*; otherwise, uses the rounding method in either the supplied `context` or the current context.

Logical operands

The `logical_and()`, `logical_invert()`, `logical_or()`, and `logical_xor()` methods expect their arguments to be *logical operands*. A *logical operand* is a *Decimal* instance whose exponent and sign are both zero, and whose digits are all either 0 or 1.

9.4.3 Context objects

Contexts are environments for arithmetic operations. They govern precision, set rules for rounding, determine which signals are treated as exceptions, and limit the range for exponents.

Each thread has its own current context which is accessed or changed using the `getcontext()` and `setcontext()` functions:

`decimal.getcontext()`

Return the current context for the active thread.

`decimal.setcontext(c)`

Set the current context for the active thread to *c*.

You can also use the `with` statement and the `localcontext()` function to temporarily change the active context.

`decimal.localcontext(ctx=None)`

Return a context manager that will set the current context for the active thread to a copy of *ctx* on entry to the `with`-statement and restore the previous context when exiting the `with`-statement. If no context is specified, a copy of the current context is used.

For example, the following code sets the current decimal precision to 42 places, performs a calculation, and then automatically restores the previous context:

```
from decimal import localcontext

with localcontext() as ctx:
    ctx.prec = 42    # Perform a high precision calculation
    s = calculate_something()
s = +s    # Round the final result back to the default precision
```

New contexts can also be created using the `Context` constructor described below. In addition, the module provides three pre-made contexts:

class `decimal.BasicContext`

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to `ROUND_HALF_UP`. All flags are cleared. All traps are enabled (treated as exceptions) except `Inexact`, `Rounded`, and `Subnormal`.

Because many of the traps are enabled, this context is useful for debugging.

class `decimal.ExtendedContext`

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to `ROUND_HALF_EVEN`. All flags are cleared. No traps are enabled (so that exceptions are not raised during computations).

Because the traps are disabled, this context is useful for applications that prefer to have result value of NaN or Infinity instead of raising exceptions. This allows an application to complete a run in the presence of conditions that would otherwise halt the program.

class `decimal.DefaultContext`

This context is used by the `Context` constructor as a prototype for new contexts. Changing a field (such as precision) has the effect of changing the default for new contexts created by the `Context` constructor.

This context is most useful in multi-threaded environments. Changing one of the fields before threads are started has the effect of setting system-wide defaults. Changing the fields after threads have started is not recommended as it would require thread synchronization to prevent race conditions.

In single threaded environments, it is preferable to not use this context at all. Instead, simply create contexts explicitly as described below.

The default values are `prec=28`, `rounding=ROUND_HALF_EVEN`, and enabled traps for `Overflow`, `InvalidOperation`, and `DivisionByZero`.

In addition to the three supplied contexts, new contexts can be created with the `Context` constructor.

class `decimal.Context` (*prec=None, rounding=None, Emin=None, Emax=None, capitals=None, clamp=None, flags=None, traps=None*)

Creates a new context. If a field is not specified or is `None`, the default values are copied from the `DefaultContext`. If the `flags` field is not specified or is `None`, all flags are cleared.

prec is an integer in the range [1, `MAX_PREC`] that sets the precision for arithmetic operations in the context.

The *rounding* option is one of the constants listed in the section *Rounding Modes*.

The *traps* and *flags* fields list any signals to be set. Generally, new contexts should only set traps and leave the flags clear.

The *Emin* and *Emax* fields are integers specifying the outer limits allowable for exponents. *Emin* must be in the range `[MIN_EMIN, 0]`, *Emax* in the range `[0, MAX_EMAX]`.

The *capitals* field is either 0 or 1 (the default). If set to 1, exponents are printed with a capital E; otherwise, a lowercase e is used: `Decimal('6.02e+23')`.

The *clamp* field is either 0 (the default) or 1. If set to 1, the exponent *e* of a *Decimal* instance representable in this context is strictly limited to the range $E_{min} - \text{prec} + 1 \leq e \leq E_{max} - \text{prec} + 1$. If *clamp* is 0 then a weaker condition holds: the adjusted exponent of the *Decimal* instance is at most *Emax*. When *clamp* is 1, a large normal number will, where possible, have its exponent reduced and a corresponding number of zeros added to its coefficient, in order to fit the exponent constraints; this preserves the value of the number but loses information about significant trailing zeros. For example:

```
>>> Context(prec=6, Emax=999, clamp=1).create_decimal('1.23e999')
Decimal('1.23000E+999')
```

A *clamp* value of 1 allows compatibility with the fixed-width decimal interchange formats specified in IEEE 754.

The *Context* class defines several general purpose methods as well as a large number of methods for doing arithmetic directly in a given context. In addition, for each of the *Decimal* methods described above (with the exception of the *adjusted()* and *as_tuple()* methods) there is a corresponding *Context* method. For example, for a *Context* instance *C* and *Decimal* instance *x*, *C.exp(x)* is equivalent to *x.exp(context=C)*. Each *Context* method accepts a Python integer (an instance of *int*) anywhere that a *Decimal* instance is accepted.

clear_flags()

Resets all of the flags to 0.

clear_traps()

Resets all of the traps to 0.

Νέο στην έκδοση 3.3.

copy()

Return a duplicate of the context.

copy_decimal(num)

Return a copy of the *Decimal* instance *num*.

create_decimal(num)

Creates a new *Decimal* instance from *num* but using *self* as context. Unlike the *Decimal* constructor, the context precision, rounding method, flags, and traps are applied to the conversion.

This is useful because constants are often given to a greater precision than is needed by the application. Another benefit is that rounding immediately eliminates unintended effects from digits beyond the current precision. In the following example, using unrounded inputs means that adding zero to a sum can change the result:

```
>>> getcontext().prec = 3
>>> Decimal('3.4445') + Decimal('1.0023')
Decimal('4.45')
>>> Decimal('3.4445') + Decimal(0) + Decimal('1.0023')
Decimal('4.44')
```

This method implements the to-number operation of the IBM specification. If the argument is a string, no leading or trailing whitespace or underscores are permitted.

create_decimal_from_float (*f*)

Creates a new `Decimal` instance from a float *f* but rounding using *self* as the context. Unlike the `Decimal.from_float()` class method, the context precision, rounding method, flags, and traps are applied to the conversion.

```
>>> context = Context(prec=5, rounding=ROUND_DOWN)
>>> context.create_decimal_from_float(math.pi)
Decimal('3.1415')
>>> context = Context(prec=5, traps=[Inexact])
>>> context.create_decimal_from_float(math.pi)
Traceback (most recent call last):
...
decimal.Inexact: None
```

Νέο στην έκδοση 3.1.

Etiny ()

Returns a value equal to $E_{\min} - \text{prec} + 1$ which is the minimum exponent value for subnormal results. When underflow occurs, the exponent is set to *Etiny*.

Etop ()

Returns a value equal to $E_{\max} - \text{prec} + 1$.

The usual approach to working with decimals is to create `Decimal` instances and then apply arithmetic operations which take place within the current context for the active thread. An alternative approach is to use context methods for calculating within a specific context. The methods are similar to those for the `Decimal` class and are only briefly recounted here.

abs (*x*)

Returns the absolute value of *x*.

add (*x*, *y*)

Return the sum of *x* and *y*.

canonical (*x*)

Returns the same `Decimal` object *x*.

compare (*x*, *y*)

Compares *x* and *y* numerically.

compare_signal (*x*, *y*)

Compares the values of the two operands numerically.

compare_total (*x*, *y*)

Compares two operands using their abstract representation.

compare_total_mag (*x*, *y*)

Compares two operands using their abstract representation, ignoring sign.

copy_abs (*x*)

Returns a copy of *x* with the sign set to 0.

copy_negate (*x*)

Returns a copy of *x* with the sign inverted.

copy_sign (*x*, *y*)

Copies the sign from *y* to *x*.

divide (*x*, *y*)

Return *x* divided by *y*.

divide_int (*x*, *y*)
Return *x* divided by *y*, truncated to an integer.

divmod (*x*, *y*)
Divides two numbers and returns the integer part of the result.

exp (*x*)
Returns $e^{**}x$.

fma (*x*, *y*, *z*)
Returns *x* multiplied by *y*, plus *z*.

is_canonical (*x*)
Returns `True` if *x* is canonical; otherwise returns `False`.

is_finite (*x*)
Returns `True` if *x* is finite; otherwise returns `False`.

is_infinite (*x*)
Returns `True` if *x* is infinite; otherwise returns `False`.

is_nan (*x*)
Returns `True` if *x* is a qNaN or sNaN; otherwise returns `False`.

is_normal (*x*)
Returns `True` if *x* is a normal number; otherwise returns `False`.

is_qnan (*x*)
Returns `True` if *x* is a quiet NaN; otherwise returns `False`.

is_signed (*x*)
Returns `True` if *x* is negative; otherwise returns `False`.

is_snan (*x*)
Returns `True` if *x* is a signaling NaN; otherwise returns `False`.

is_subnormal (*x*)
Returns `True` if *x* is subnormal; otherwise returns `False`.

is_zero (*x*)
Returns `True` if *x* is a zero; otherwise returns `False`.

ln (*x*)
Returns the natural (base *e*) logarithm of *x*.

log10 (*x*)
Returns the base 10 logarithm of *x*.

logb (*x*)
Returns the exponent of the magnitude of the operand's MSD.

logical_and (*x*, *y*)
Applies the logical operation *and* between each operand's digits.

logical_invert (*x*)
Invert all the digits in *x*.

logical_or (*x*, *y*)
Applies the logical operation *or* between each operand's digits.

logical_xor (*x*, *y*)
Applies the logical operation *xor* between each operand's digits.

max(*x*, *y*)
Compares two values numerically and returns the maximum.

max_mag(*x*, *y*)
Compares the values numerically with their sign ignored.

min(*x*, *y*)
Compares two values numerically and returns the minimum.

min_mag(*x*, *y*)
Compares the values numerically with their sign ignored.

minus(*x*)
Minus corresponds to the unary prefix minus operator in Python.

multiply(*x*, *y*)
Return the product of *x* and *y*.

next_minus(*x*)
Returns the largest representable number smaller than *x*.

next_plus(*x*)
Returns the smallest representable number larger than *x*.

next_toward(*x*, *y*)
Returns the number closest to *x*, in direction towards *y*.

normalize(*x*)
Reduces *x* to its simplest form.

number_class(*x*)
Returns an indication of the class of *x*.

plus(*x*)
Plus corresponds to the unary prefix plus operator in Python. This operation applies the context precision and rounding, so it is *not* an identity operation.

power(*x*, *y*, *modulo=None*)
Return *x* to the power of *y*, reduced modulo *modulo* if given.

With two arguments, compute $x^{**}y$. If *x* is negative then *y* must be integral. The result will be inexact unless *y* is integral and the result is finite and can be expressed exactly in “precision” digits. The rounding mode of the context is used. Results are always correctly-rounded in the Python version.

`Decimal(0) ** Decimal(0)` results in `InvalidOperation`, and if `InvalidOperation` is not trapped, then results in `Decimal('NaN')`.

Αλλάξε στην έκδοση 3.3: The C module computes `power()` in terms of the correctly-rounded `exp()` and `ln()` functions. The result is well-defined but only «almost always correctly-rounded».

With three arguments, compute $(x^{**}y) \% modulo$. For the three argument form, the following restrictions on the arguments hold:

- all three arguments must be integral
- *y* must be nonnegative
- at least one of *x* or *y* must be nonzero
- *modulo* must be nonzero and have at most “precision” digits

The value resulting from `Context.power(x, y, modulo)` is equal to the value that would be obtained by computing $(x^{**}y) \% modulo$ with unbounded precision, but is computed more efficiently. The exponent of the result is zero, regardless of the exponents of *x*, *y* and *modulo*. The result is always exact.

quantize (*x*, *y*)

Returns a value equal to *x* (rounded), having the exponent of *y*.

radix ()

Just returns 10, as this is Decimal, :)

remainder (*x*, *y*)

Returns the remainder from integer division.

The sign of the result, if non-zero, is the same as that of the original dividend.

remainder_near (*x*, *y*)

Returns $x - y * n$, where *n* is the integer nearest the exact value of x / y (if the result is 0 then its sign will be the sign of *x*).

rotate (*x*, *y*)

Returns a rotated copy of *x*, *y* times.

same_quantum (*x*, *y*)

Returns `True` if the two operands have the same exponent.

scaleb (*x*, *y*)

Returns the first operand after adding the second value its exp.

shift (*x*, *y*)

Returns a shifted copy of *x*, *y* times.

sqrt (*x*)

Square root of a non-negative number to context precision.

subtract (*x*, *y*)

Return the difference between *x* and *y*.

to_eng_string (*x*)

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

to_integral_exact (*x*)

Rounds to an integer.

to_sci_string (*x*)

Converts a number to a string using scientific notation.

9.4.4 Constants

The constants in this section are only relevant for the C module. They are also included in the pure Python version for compatibility.

| | 32-bit | 64-bit |
|--------------------------------|------------|----------------------|
| <code>decimal.MAX_PREC</code> | 425000000 | 999999999999999999 |
| <code>decimal.MAX_EMAX</code> | 425000000 | 999999999999999999 |
| <code>decimal.MIN_EMIN</code> | -425000000 | -999999999999999999 |
| <code>decimal.MIN_ETINY</code> | -849999999 | -1999999999999999997 |

`decimal.HAVE_THREADS`

The value is `True`. Deprecated, because Python now always has threads.

Αποσύρθηκε στην έκδοση 3.9.

`decimal.HAVE_CONTEXTVAR`

The default value is `True`. If Python is compiled `--without-decimal-contextvar`, the C version uses a thread-local rather than a coroutine-local context and the value is `False`. This is slightly faster in some nested context scenarios.

Νέο στην έκδοση 3.9: backported to 3.7 and 3.8.

9.4.5 Rounding modes

`decimal.ROUND_CEILING`

Round towards Infinity.

`decimal.ROUND_DOWN`

Round towards zero.

`decimal.ROUND_FLOOR`

Round towards -Infinity.

`decimal.ROUND_HALF_DOWN`

Round to nearest with ties going towards zero.

`decimal.ROUND_HALF_EVEN`

Round to nearest with ties going to nearest even integer.

`decimal.ROUND_HALF_UP`

Round to nearest with ties going away from zero.

`decimal.ROUND_UP`

Round away from zero.

`decimal.ROUND_05UP`

Round away from zero if last digit after rounding towards zero would have been 0 or 5; otherwise round towards zero.

9.4.6 Signals

Signals represent conditions that arise during computation. Each corresponds to one context flag and one context trap enabler.

The context flag is set whenever the condition is encountered. After the computation, flags may be checked for informational purposes (for instance, to determine whether a computation was exact). After checking the flags, be sure to clear all flags before starting the next computation.

If the context's trap enabler is set for the signal, then the condition causes a Python exception to be raised. For example, if the *DivisionByZero* trap is set, then a *DivisionByZero* exception is raised upon encountering the condition.

class `decimal.Clamped`

Altered an exponent to fit representation constraints.

Typically, clamping occurs when an exponent falls outside the context's `Emin` and `Emax` limits. If possible, the exponent is reduced to fit by adding zeros to the coefficient.

class `decimal.DecimalException`

Base class for other signals and a subclass of *ArithmeticError*.

class `decimal.DivisionByZero`

Signals the division of a non-infinite number by zero.

Can occur with division, modulo division, or when raising a number to a negative power. If this signal is not trapped, returns `Infinity` or `-Infinity` with the sign determined by the inputs to the calculation.

class `decimal.Inexact`

Indicates that rounding occurred and the result is not exact.

Signals when non-zero digits were discarded during rounding. The rounded result is returned. The signal flag or trap is used to detect when results are inexact.

class `decimal.InvalidOperation`

An invalid operation was performed.

Indicates that an operation was requested that does not make sense. If not trapped, returns `NaN`. Possible causes include:

```
Infinity - Infinity
0 * Infinity
Infinity / Infinity
x % 0
Infinity % x
sqrt(-x) and x > 0
0 ** 0
x ** (non-integer)
x ** Infinity
```

class `decimal.Overflow`

Numerical overflow.

Indicates the exponent is larger than `Emax` after rounding has occurred. If not trapped, the result depends on the rounding mode, either pulling inward to the largest representable finite number or rounding outward to `Infinity`. In either case, *Inexact* and *Rounded* are also signaled.

class `decimal.Rounded`

Rounding occurred though possibly no information was lost.

Signaled whenever rounding discards digits; even if those digits are zero (such as rounding `5.00` to `5.0`). If not trapped, returns the result unchanged. This signal is used to detect loss of significant digits.

class decimal.Subnormal

Exponent was lower than Emin prior to rounding.

Occurs when an operation result is subnormal (the exponent is too small). If not trapped, returns the result unchanged.

class decimal.Underflow

Numerical underflow with result rounded to zero.

Occurs when a subnormal result is pushed to zero by rounding. *Inexact* and *Subnormal* are also signaled.

class decimal.FloatOperation

Enable stricter semantics for mixing floats and Decimals.

If the signal is not trapped (default), mixing floats and Decimals is permitted in the *Decimal* constructor, *create_decimal()* and all comparison operators. Both conversion and comparisons are exact. Any occurrence of a mixed operation is silently recorded by setting *FloatOperation* in the context flags. Explicit conversions with *from_float()* or *create_decimal_from_float()* do not set the flag.

Otherwise (the signal is trapped), only equality comparisons and explicit conversions are silent. All other mixed operations raise *FloatOperation*.

The following table summarizes the hierarchy of signals:

```
exceptions.ArithmeticError(exceptions.Exception)
    DecimalException
        Clamped
        DivisionByZero(DecimalException, exceptions.ZeroDivisionError)
        Inexact
            Overflow(Inexact, Rounded)
            Underflow(Inexact, Rounded, Subnormal)
        InvalidOperation
        Rounded
        Subnormal
        FloatOperation(DecimalException, exceptions.TypeError)
```

9.4.7 Floating Point Notes

Mitigating round-off error with increased precision

The use of decimal floating point eliminates decimal representation error (making it possible to represent 0.1 exactly); however, some operations can still incur round-off error when non-zero digits exceed the fixed precision.

The effects of round-off error can be amplified by the addition or subtraction of nearly offsetting quantities resulting in loss of significance. Knuth provides two instructive examples where rounded floating point arithmetic with insufficient precision causes the breakdown of the associative and distributive properties of addition:

```
# Examples from Seminumerical Algorithms, Section 4.2.2.
>>> from decimal import Decimal, getcontext
>>> getcontext().prec = 8

>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.5111111')
>>> u + (v + w)
Decimal('10')

>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> (u*v) + (u*w)
Decimal('0.01')
>>> u * (v+w)
Decimal('0.0060000')
```

The `decimal` module makes it possible to restore the identities by expanding the precision sufficiently to avoid loss of significance:

```
>>> getcontext().prec = 20
>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.51111111')
>>> u + (v + w)
Decimal('9.51111111')
>>>
>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.0060000')
>>> u * (v+w)
Decimal('0.0060000')
```

Special values

The number system for the `decimal` module provides special values including NaN, sNaN, -Infinity, Infinity, and two zeros, +0 and -0.

Infinities can be constructed directly with: `Decimal('Infinity')`. Also, they can arise from dividing by zero when the `DivisionByZero` signal is not trapped. Likewise, when the `Overflow` signal is not trapped, infinity can result from rounding beyond the limits of the largest representable number.

The infinities are signed (affine) and can be used in arithmetic operations where they get treated as very large, indeterminate numbers. For instance, adding a constant to infinity gives another infinite result.

Some operations are indeterminate and return NaN, or if the `InvalidOperation` signal is trapped, raise an exception. For example, `0/0` returns NaN which means «not a number». This variety of NaN is quiet and, once created, will flow through other computations always resulting in another NaN. This behavior can be useful for a series of computations that occasionally have missing inputs — it allows the calculation to proceed while flagging specific results as invalid.

A variant is sNaN which signals rather than remaining quiet after every operation. This is a useful return value when an invalid result needs to interrupt a calculation for special handling.

The behavior of Python's comparison operators can be a little surprising where a NaN is involved. A test for equality where one of the operands is a quiet or signaling NaN always returns `False` (even when doing `Decimal('NaN')==Decimal('NaN')`), while a test for inequality always returns `True`. An attempt to compare two Decimals using any of the `<`, `<=`, `>` or `>=` operators will raise the `InvalidOperation` signal if either operand is a NaN, and return `False` if this signal is not trapped. Note that the General Decimal Arithmetic specification does not specify the behavior of direct comparisons; these rules for comparisons involving a NaN were taken from the IEEE 854 standard (see Table 3 in section 5.7). To ensure strict standards-compliance, use the `compare()` and `compare-signal()` methods instead.

The signed zeros can result from calculations that underflow. They keep the sign that would have resulted if the calculation had been carried out to greater precision. Since their magnitude is zero, both positive and negative zeros are treated as equal and their sign is informational.

In addition to the two signed zeros which are distinct yet equal, there are various representations of zero with differing precisions yet equivalent in value. This takes a bit of getting used to. For an eye accustomed to normalized floating point

representations, it is not immediately obvious that the following calculation returns a value equal to zero:

```
>>> 1 / Decimal('Infinity')
Decimal('0E-1000026')
```

9.4.8 Working with threads

The `getcontext()` function accesses a different `Context` object for each thread. Having separate thread contexts means that threads may make changes (such as `getcontext().prec=10`) without interfering with other threads.

Likewise, the `setcontext()` function automatically assigns its target to the current thread.

If `setcontext()` has not been called before `getcontext()`, then `getcontext()` will automatically create a new context for use in the current thread.

The new context is copied from a prototype context called `DefaultContext`. To control the defaults so that each thread will use the same values throughout the application, directly modify the `DefaultContext` object. This should be done *before* any threads are started so that there won't be a race condition between threads calling `getcontext()`. For example:

```
# Set applicationwide defaults for all threads about to be launched
DefaultContext.prec = 12
DefaultContext.rounding = ROUND_DOWN
DefaultContext.traps = ExtendedContext.traps.copy()
DefaultContext.traps[InvalidOperation] = 1
setcontext(DefaultContext)

# Afterwards, the threads can be started
t1.start()
t2.start()
t3.start()
. . .
```

9.4.9 Recipes

Here are a few recipes that serve as utility functions and that demonstrate ways to work with the `Decimal` class:

```
def moneyfmt(value, places=2, curr='', sep=',', dp='.',
             pos='', neg='-', trailneg=''):
    """Convert Decimal to a money formatted string.

    places:  required number of places after the decimal point
    curr:    optional currency symbol before the sign (may be blank)
    sep:     optional grouping separator (comma, period, space, or blank)
    dp:      decimal point indicator (comma or period)
             only specify as blank when places is zero
    pos:     optional sign for positive numbers: '+', space or blank
    neg:     optional sign for negative numbers: '-', '(', space or blank
    trailneg: optional trailing minus indicator: '- ', ')', space or blank

    >>> d = Decimal('-1234567.8901')
    >>> moneyfmt(d, curr='$')
    '-$1,234,567.89'
    >>> moneyfmt(d, places=0, sep='.', dp='', neg='', trailneg='-')
    '1.234.568-'
    >>> moneyfmt(d, curr='$', neg='(', trailneg=')')
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

'($1,234,567.89)'
>>> moneyfmt(Decimal(123456789), sep=' ')
'123 456 789.00'
>>> moneyfmt(Decimal('-0.02'), neg='<', trailneg='>')
'<0.02>'

"""
q = Decimal(10) ** -places          # 2 places --> '0.01'
sign, digits, exp = value.quantize(q).as_tuple()
result = []
digits = list(map(str, digits))
build, next = result.append, digits.pop
if sign:
    build(trailneg)
for i in range(places):
    build(next() if digits else '0')
if places:
    build(dp)
if not digits:
    build('0')
i = 0
while digits:
    build(next())
    i += 1
    if i == 3 and digits:
        i = 0
        build(sep)
build(curr)
build(neg if sign else pos)
return ''.join(reversed(result))

def pi():
    """Compute Pi to the current precision.

    >>> print(pi())
    3.141592653589793238462643383

    """
    getcontext().prec += 2 # extra digits for intermediate steps
    three = Decimal(3)     # substitute "three=3.0" for regular floats
    lasts, t, s, n, na, d, da = 0, three, 3, 1, 0, 0, 24
    while s != lasts:
        lasts = s
        n, na = n+na, na+8
        d, da = d+da, da+32
        t = (t * n) / d
        s += t
    getcontext().prec -= 2
    return +s               # unary plus applies the new precision

def exp(x):
    """Return e raised to the power of x. Result type matches input type.

    >>> print(exp(Decimal(1)))
    2.718281828459045235360287471

getcontext().prec -= 2
return +s

```

9.4.10 Decimal FAQ

Q. It is cumbersome to type `decimal.Decimal('1234.5')`. Is there a way to minimize typing when using the interactive interpreter?

A. Some users abbreviate the constructor to just a single letter:

```

>>> D = decimal.Decimal
>>> D('1.23') + D('3.45')
Decimal('4.68')

```

Q. In a fixed-point application with two decimal places, some inputs have many places and need to be rounded. Others are not supposed to have excess digits and need to be validated. What methods should be used?

A. The `quantize()` method rounds to a fixed number of decimal places. If the *Inexact* trap is set, it is also useful for validation:

```

>>> TWOPLACES = Decimal(10) ** -2           # same as Decimal('0.01')

```

```

>>> # Round to two places
>>> Decimal('3.214').quantize(TWOPLACES)
Decimal('3.21')

```

```

>>> # Validate that a number does not exceed two places
>>> Decimal('3.21').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Decimal('3.21')

```

```

>>> Decimal('3.214').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Traceback (most recent call last):
...
Inexact: None

```

Q. Once I have valid two place inputs, how do I maintain that invariant throughout an application?

A. Some operations like addition, subtraction, and multiplication by an integer will automatically preserve fixed point. Others operations, like division and non-integer multiplication, will change the number of decimal places and need to be followed-up with a `quantize()` step:

```

>>> a = Decimal('102.72')           # Initial fixed-point values
>>> b = Decimal('3.17')

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

>>> a + b                                # Addition preserves fixed-point
Decimal('105.89')
>>> a - b
Decimal('99.55')
>>> a * 42                                # So does integer multiplication
Decimal('4314.24')
>>> (a * b).quantize(TWOPLACES)          # Must quantize non-integer multiplication
Decimal('325.62')
>>> (b / a).quantize(TWOPLACES)          # And quantize division
Decimal('0.03')

```

In developing fixed-point applications, it is convenient to define functions to handle the `quantize()` step:

```

>>> def mul(x, y, fp=TWOPLACES):
...     return (x * y).quantize(fp)
>>> def div(x, y, fp=TWOPLACES):
...     return (x / y).quantize(fp)

```

```

>>> mul(a, b)                            # Automatically preserve fixed-point
Decimal('325.62')
>>> div(b, a)
Decimal('0.03')

```

Q. There are many ways to express the same value. The numbers 200, 200.000, 2E2, and 02E+4 all have the same value at various precisions. Is there a way to transform them to a single recognizable canonical value?

A. The `normalize()` method maps all equivalent values to a single representative:

```

>>> values = map(Decimal, '200 200.000 2E2 .02E+4'.split())
>>> [v.normalize() for v in values]
[Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2')]

```

Q. Some decimal values always print with exponential notation. Is there a way to get a non-exponential representation?

A. For some values, exponential notation is the only way to express the number of significant places in the coefficient. For example, expressing 5.0E+3 as 5000 keeps the value constant but cannot show the original's two-place significance.

If an application does not care about tracking significance, it is easy to remove the exponent and trailing zeroes, losing significance, but keeping the value unchanged:

```

>>> def remove_exponent(d):
...     return d.quantize(Decimal(1)) if d == d.to_integral() else d.normalize()

```

```

>>> remove_exponent(Decimal('5E+3'))
Decimal('5000')

```

Q. Is there a way to convert a regular float to a *Decimal*?

A. Yes, any binary floating point number can be exactly expressed as a *Decimal* though an exact conversion may take more precision than intuition would suggest:

```

>>> Decimal(math.pi)
Decimal('3.141592653589793115997963468544185161590576171875')

```

Q. Within a complex calculation, how can I make sure that I haven't gotten a spurious result because of insufficient precision or rounding anomalies.

A. The decimal module makes it easy to test results. A best practice is to re-run calculations using greater precision and with various rounding modes. Widely differing results indicate insufficient precision, rounding mode issues, ill-conditioned inputs, or a numerically unstable algorithm.

Q. I noticed that context precision is applied to the results of operations but not to the inputs. Is there anything to watch out for when mixing values of different precisions?

A. Yes. The principle is that all values are considered to be exact and so is the arithmetic on those values. Only the results are rounded. The advantage for inputs is that «what you type is what you get». A disadvantage is that the results can look odd if you forget that the inputs haven't been rounded:

```
>>> getcontext().prec = 3
>>> Decimal('3.104') + Decimal('2.104')
Decimal('5.21')
>>> Decimal('3.104') + Decimal('0.000') + Decimal('2.104')
Decimal('5.20')
```

The solution is either to increase precision or to force rounding of inputs using the unary plus operation:

```
>>> getcontext().prec = 3
>>> +Decimal('1.23456789')      # unary plus triggers rounding
Decimal('1.23')
```

Alternatively, inputs can be rounded upon creation using the `Context.create_decimal()` method:

```
>>> Context(prec=5, rounding=ROUND_DOWN).create_decimal('1.2345678')
Decimal('1.2345')
```

Q. Is the CPython implementation fast for large numbers?

A. Yes. In the CPython and PyPy3 implementations, the C/CFFI versions of the decimal module integrate the high speed `libmpdec` library for arbitrary precision correctly-rounded decimal floating point arithmetic¹. `libmpdec` uses [Karatsuba multiplication](#) for medium-sized numbers and the [Number Theoretic Transform](#) for very large numbers.

The context must be adapted for exact arbitrary precision arithmetic. `Emin` and `Emax` should always be set to the maximum values, `clamp` should always be 0 (the default). Setting `prec` requires some care.

The easiest approach for trying out bignum arithmetic is to use the maximum value for `prec` as well²:

```
>>> setcontext(Context(prec=MAX_PREC, Emax=MAX_EMAX, Emin=MIN_EMIN))
>>> x = Decimal(2) ** 256
>>> x / 128
Decimal('904625697166532776746648320380374280103671755200316906558262375061821325312')
```

For inexact results, `MAX_PREC` is far too large on 64-bit platforms and the available memory will be insufficient:

```
>>> Decimal(1) / 3
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
MemoryError
```

On systems with overallocation (e.g. Linux), a more sophisticated approach is to adjust `prec` to the amount of available RAM. Suppose that you have 8GB of RAM and expect 10 simultaneous operands using a maximum of 500MB each:

¹

Νέο στην έκδοση 3.3.

²

Άλλαξε στην έκδοση 3.9: This approach now works for all exact results except for non-integer powers.

```

>>> import sys
>>>
>>> # Maximum number of digits for a single operand using 500MB in 8-byte words
>>> # with 19 digits per word (4-byte and 9 digits for the 32-bit build):
>>> maxdigits = 19 * ((500 * 1024**2) // 8)
>>>
>>> # Check that this works:
>>> c = Context(prec=maxdigits, Emax=MAX_EMAX, Emin=MIN_EMIN)
>>> c.traps[Inexact] = True
>>> setcontext(c)
>>>
>>> # Fill the available precision with nines:
>>> x = Decimal(0).logical_invert() * 9
>>> sys.getsizeof(x)
524288112
>>> x + 2
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.Inexact: [<class 'decimal.Inexact'>]

```

In general (and especially on systems without overallocation), it is recommended to estimate even tighter bounds and set the *Inexact* trap if all calculations are expected to be exact.

9.5 fractions — Rational numbers

Source code: [Lib/fractions.py](#)

The *fractions* module provides support for rational number arithmetic.

A *Fraction* instance can be constructed from a pair of integers, from another rational number, or from a string.

```

class fractions.Fraction (numerator=0, denominator=1)
class fractions.Fraction (other_fraction)
class fractions.Fraction (float)
class fractions.Fraction (decimal)
class fractions.Fraction (string)

```

The first version requires that *numerator* and *denominator* are instances of *numbers.Rational* and returns a new *Fraction* instance with value *numerator*/*denominator*. If *denominator* is 0, it raises a *ZeroDivisionError*. The second version requires that *other_fraction* is an instance of *numbers.Rational* and returns a *Fraction* instance with the same value. The next two versions accept either a *float* or a *decimal.Decimal* instance, and return a *Fraction* instance with exactly the same value. Note that due to the usual issues with binary floating-point (see *tut-fp-issues*), the argument to *Fraction*(1.1) is not exactly equal to 11/10, and so *Fraction*(1.1) does *not* return *Fraction*(11, 10) as one might expect. (But see the documentation for the *limit_denominator*() method below.) The last version of the constructor expects a string or unicode instance. The usual form for this instance is:

```
[sign] numerator ['/' denominator]
```

where the optional *sign* may be either “+” or “-” and *numerator* and *denominator* (if present) are strings of decimal digits. In addition, any string that represents a finite value and is accepted by the *float* constructor is also accepted by the *Fraction* constructor. In either form the input string may also have leading and/or trailing whitespace. Here are some examples:

```
>>> from fractions import Fraction
>>> Fraction(16, -10)
Fraction(-8, 5)
>>> Fraction(123)
Fraction(123, 1)
>>> Fraction()
Fraction(0, 1)
>>> Fraction('3/7')
Fraction(3, 7)
>>> Fraction(' -3/7 ')
Fraction(-3, 7)
>>> Fraction('1.414213 \t\n')
Fraction(1414213, 1000000)
>>> Fraction('-.125')
Fraction(-1, 8)
>>> Fraction('7e-6')
Fraction(7, 1000000)
>>> Fraction(2.25)
Fraction(9, 4)
>>> Fraction(1.1)
Fraction(2476979795053773, 2251799813685248)
>>> from decimal import Decimal
>>> Fraction(Decimal('1.1'))
Fraction(11, 10)
```

The *Fraction* class inherits from the abstract base class *numbers.Rational*, and implements all of the methods and operations from that class. *Fraction* instances are hashable, and should be treated as immutable. In addition, *Fraction* has the following properties and methods:

Άλλαξε στην έκδοση 3.2: The *Fraction* constructor now accepts *float* and *decimal.Decimal* instances.

Άλλαξε στην έκδοση 3.9: The *math.gcd()* function is now used to normalize the *numerator* and *denominator*. *math.gcd()* always return a *int* type. Previously, the GCD type depended on *numerator* and *denominator*.

numerator

Numerator of the Fraction in lowest term.

denominator

Denominator of the Fraction in lowest term.

as_integer_ratio()

Return a tuple of two integers, whose ratio is equal to the Fraction and with a positive denominator.

Νέο στην έκδοση 3.8.

from_float(*flt*)

This class method constructs a *Fraction* representing the exact value of *flt*, which must be a *float*. Beware that *Fraction.from_float(0.3)* is not the same value as *Fraction(3, 10)*.

Σημείωση: From Python 3.2 onwards, you can also construct a *Fraction* instance directly from a *float*.

from_decimal(*dec*)

This class method constructs a *Fraction* representing the exact value of *dec*, which must be a *decimal.Decimal* instance.

Σημείωση: From Python 3.2 onwards, you can also construct a *Fraction* instance directly from a

`decimal.Decimal` instance.

limit_denominator (*max_denominator=1000000*)

Finds and returns the closest *Fraction* to *self* that has denominator at most *max_denominator*. This method is useful for finding rational approximations to a given floating-point number:

```
>>> from fractions import Fraction
>>> Fraction('3.1415926535897932').limit_denominator(1000)
Fraction(355, 113)
```

or for recovering a rational number that's represented as a float:

```
>>> from math import pi, cos
>>> Fraction(cos(pi/3))
Fraction(4503599627370497, 9007199254740992)
>>> Fraction(cos(pi/3)).limit_denominator()
Fraction(1, 2)
>>> Fraction(1.1).limit_denominator()
Fraction(11, 10)
```

__floor__ ()

Returns the greatest *int* \leq *self*. This method can also be accessed through the *math.floor()* function:

```
>>> from math import floor
>>> floor(Fraction(355, 113))
3
```

__ceil__ ()

Returns the least *int* \geq *self*. This method can also be accessed through the *math.ceil()* function.

__round__ ()

__round__ (*ndigits*)

The first version returns the nearest *int* to *self*, rounding half to even. The second version rounds *self* to the nearest multiple of *Fraction(1, 10**ndigits)* (logically, if *ndigits* is negative), again rounding half toward even. This method can also be accessed through the *round()* function.

Module *numbers* The abstract base classes making up the numeric tower.

9.6 random — Generate pseudo-random numbers

Source code: [Lib/random.py](#)

This module implements pseudo-random number generators for various distributions.

For integers, there is uniform selection from a range. For sequences, there is uniform selection of a random element, a function to generate a random permutation of a list in-place, and a function for random sampling without replacement.

On the real line, there are functions to compute uniform, normal (Gaussian), lognormal, negative exponential, gamma, and beta distributions. For generating distributions of angles, the von Mises distribution is available.

Almost all module functions depend on the basic function *random()*, which generates a random float uniformly in the semi-open range [0.0, 1.0). Python uses the Mersenne Twister as the core generator. It produces 53-bit precision floats

and has a period of $2^{19937}-1$. The underlying implementation in C is both fast and threadsafe. The Mersenne Twister is one of the most extensively tested random number generators in existence. However, being completely deterministic, it is not suitable for all purposes, and is completely unsuitable for cryptographic purposes.

The functions supplied by this module are actually bound methods of a hidden instance of the `random.Random` class. You can instantiate your own instances of `Random` to get generators that don't share state.

Class `Random` can also be subclassed if you want to use a different basic generator of your own devising: in that case, override the `random()`, `seed()`, `getstate()`, and `setstate()` methods. Optionally, a new generator can supply a `getrandbits()` method — this allows `randrange()` to produce selections over an arbitrarily large range.

The `random` module also provides the `SystemRandom` class which uses the system function `os.urandom()` to generate random numbers from sources provided by the operating system.

Προειδοποίηση: The pseudo-random generators of this module should not be used for security purposes. For security or cryptographic uses, see the `secrets` module.

[Complementary-Multiply-with-Carry recipe](#) for a compatible alternative random number generator with a long period and comparatively simple update operations.

9.6.1 Bookkeeping functions

`random.seed(a=None, version=2)`

Initialize the random number generator.

If *a* is omitted or `None`, the current system time is used. If randomness sources are provided by the operating system, they are used instead of the system time (see the `os.urandom()` function for details on availability).

If *a* is an int, it is used directly.

With version 2 (the default), a `str`, `bytes`, or `bytearray` object gets converted to an `int` and all of its bits are used.

With version 1 (provided for reproducing random sequences from older versions of Python), the algorithm for `str` and `bytes` generates a narrower range of seeds.

Άλλαξε στην έκδοση 3.2: Moved to the version 2 scheme which uses all of the bits in a string seed.

Αποσύρθηκε στην έκδοση 3.9: In the future, the *seed* must be one of the following types: `NoneType`, `int`, `float`, `str`, `bytes`, or `bytearray`.

`random.getstate()`

Return an object capturing the current internal state of the generator. This object can be passed to `setstate()` to restore the state.

`random.setstate(state)`

state should have been obtained from a previous call to `getstate()`, and `setstate()` restores the internal state of the generator to what it was at the time `getstate()` was called.

9.6.2 Functions for bytes

`random.randrange(n)`
Generate n random bytes.

This method should not be used for generating security tokens. Use `secrets.token_bytes()` instead.

Νέο στην έκδοση 3.9.

9.6.3 Functions for integers

`random.randrange(stop)`

`random.randrange(start, stop[, step])`

Return a randomly selected element from `range(start, stop, step)`. This is equivalent to `choice(range(start, stop, step))`, but doesn't actually build a range object.

The positional argument pattern matches that of `range()`. Keyword arguments should not be used because the function may use them in unexpected ways.

Άλλαξε στην έκδοση 3.2: `randrange()` is more sophisticated about producing equally distributed values. Formerly it used a style like `int(random() * n)` which could produce slightly uneven distributions.

`random.randint(a, b)`

Return a random integer N such that $a \leq N \leq b$. Alias for `randrange(a, b+1)`.

`random.getrandbits(k)`

Returns a non-negative Python integer with k random bits. This method is supplied with the MersenneTwister generator and some other generators may also provide it as an optional part of the API. When available, `getrandbits()` enables `randrange()` to handle arbitrarily large ranges.

Άλλαξε στην έκδοση 3.9: This method now accepts zero for k .

9.6.4 Functions for sequences

`random.choice(seq)`

Return a random element from the non-empty sequence `seq`. If `seq` is empty, raises `IndexError`.

`random.choices(population, weights=None, *, cum_weights=None, k=1)`

Return a k sized list of elements chosen from the `population` with replacement. If the `population` is empty, raises `IndexError`.

If a `weights` sequence is specified, selections are made according to the relative weights. Alternatively, if a `cum_weights` sequence is given, the selections are made according to the cumulative weights (perhaps computed using `itertools.accumulate()`). For example, the relative weights `[10, 5, 30, 5]` are equivalent to the cumulative weights `[10, 15, 45, 50]`. Internally, the relative weights are converted to cumulative weights before making selections, so supplying the cumulative weights saves work.

If neither `weights` nor `cum_weights` are specified, selections are made with equal probability. If a `weights` sequence is supplied, it must be the same length as the `population` sequence. It is a `TypeError` to specify both `weights` and `cum_weights`.

The `weights` or `cum_weights` can use any numeric type that interoperates with the `float` values returned by `random()` (that includes integers, floats, and fractions but excludes decimals). Behavior is undefined if any weight is negative. A `ValueError` is raised if all weights are zero.

For a given seed, the `choices()` function with equal weighting typically produces a different sequence than repeated calls to `choice()`. The algorithm used by `choices()` uses floating point arithmetic for internal

consistency and speed. The algorithm used by `choice()` defaults to integer arithmetic with repeated selections to avoid small biases from round-off error.

Νέο στην έκδοση 3.6.

Άλλαξε στην έκδοση 3.9: Raises a `ValueError` if all weights are zero.

`random.shuffle(x[, random])`
Shuffle the sequence *x* in place.

The optional argument *random* is a 0-argument function returning a random float in [0.0, 1.0); by default, this is the function `random()`.

To shuffle an immutable sequence and return a new shuffled list, use `sample(x, k=len(x))` instead.

Note that even for small `len(x)`, the total number of permutations of *x* can quickly grow larger than the period of most random number generators. This implies that most permutations of a long sequence can never be generated. For example, a sequence of length 2080 is the largest that can fit within the period of the Mersenne Twister random number generator.

Deprecated since version 3.9, will be removed in version 3.11: The optional parameter *random*.

`random.sample(population, k, *, counts=None)`

Return a *k* length list of unique elements chosen from the population sequence or set. Used for random sampling without replacement.

Returns a new list containing elements from the population while leaving the original population unchanged. The resulting list is in selection order so that all sub-slices will also be valid random samples. This allows raffle winners (the sample) to be partitioned into grand prize and second place winners (the subslices).

Members of the population need not be *hashable* or unique. If the population contains repeats, then each occurrence is a possible selection in the sample.

Repeated elements can be specified one at a time or with the optional keyword-only *counts* parameter. For example, `sample(['red', 'blue'], counts=[4, 2], k=5)` is equivalent to `sample(['red', 'red', 'red', 'red', 'blue', 'blue'], k=5)`.

To choose a sample from a range of integers, use a `range()` object as an argument. This is especially fast and space efficient for sampling from a large population: `sample(range(10000000), k=60)`.

If the sample size is larger than the population size, a `ValueError` is raised.

Άλλαξε στην έκδοση 3.9: Added the *counts* parameter.

Αποσύρθηκε στην έκδοση 3.9: In the future, the *population* must be a sequence. Instances of `set` are no longer supported. The set must first be converted to a `list` or `tuple`, preferably in a deterministic order so that the sample is reproducible.

9.6.5 Real-valued distributions

The following functions generate specific real-valued distributions. Function parameters are named after the corresponding variables in the distribution's equation, as used in common mathematical practice; most of these equations can be found in any statistics text.

`random.random()`

Return the next random floating point number in the range [0.0, 1.0).

`random.uniform(a, b)`

Return a random floating point number *N* such that $a \leq N \leq b$ for $a \leq b$ and $b \leq N \leq a$ for $b < a$.

The end-point value *b* may or may not be included in the range depending on floating-point rounding in the equation $a + (b-a) * \text{random}()$.

`random.triangular` (*low*, *high*, *mode*)

Return a random floating point number *N* such that `low <= N <= high` and with the specified *mode* between those bounds. The *low* and *high* bounds default to zero and one. The *mode* argument defaults to the midpoint between the bounds, giving a symmetric distribution.

`random.betavariate` (*alpha*, *beta*)

Beta distribution. Conditions on the parameters are `alpha > 0` and `beta > 0`. Returned values range between 0 and 1.

`random.expovariate` (*lambd*)

Exponential distribution. *lambd* is 1.0 divided by the desired mean. It should be nonzero. (The parameter would be called «lambda», but that is a reserved word in Python.) Returned values range from 0 to positive infinity if *lambd* is positive, and from negative infinity to 0 if *lambd* is negative.

`random.gammavariate` (*alpha*, *beta*)

Gamma distribution. (*Not* the gamma function!) Conditions on the parameters are `alpha > 0` and `beta > 0`.

The probability distribution function is:

$$\text{pdf}(x) = \frac{x^{(\alpha - 1)} * \text{math.exp}(-x / \text{beta})}{\text{math.gamma}(\alpha) * \text{beta}^{\alpha}}$$

`random.gauss` (*mu*, *sigma*)

Gaussian distribution. *mu* is the mean, and *sigma* is the standard deviation. This is slightly faster than the `normalvariate()` function defined below.

Multithreading note: When two threads call this function simultaneously, it is possible that they will receive the same return value. This can be avoided in three ways. 1) Have each thread use a different instance of the random number generator. 2) Put locks around all calls. 3) Use the slower, but thread-safe `normalvariate()` function instead.

`random.lognormvariate` (*mu*, *sigma*)

Log normal distribution. If you take the natural logarithm of this distribution, you'll get a normal distribution with mean *mu* and standard deviation *sigma*. *mu* can have any value, and *sigma* must be greater than zero.

`random.normalvariate` (*mu*, *sigma*)

Normal distribution. *mu* is the mean, and *sigma* is the standard deviation.

`random.vonmisesvariate` (*mu*, *kappa*)

mu is the mean angle, expressed in radians between 0 and 2π , and *kappa* is the concentration parameter, which must be greater than or equal to zero. If *kappa* is equal to zero, this distribution reduces to a uniform random angle over the range 0 to 2π .

`random.paretovariate` (*alpha*)

Pareto distribution. *alpha* is the shape parameter.

`random.weibullvariate` (*alpha*, *beta*)

Weibull distribution. *alpha* is the scale parameter and *beta* is the shape parameter.

9.6.6 Alternative Generator

class `random.Random([seed])`

Class that implements the default pseudo-random number generator used by the `random` module.

Αποσύρθηκε στην έκδοση 3.9: In the future, the `seed` must be one of the following types: `NoneType`, `int`, `float`, `str`, `bytes`, or `bytearray`.

class `random.SystemRandom([seed])`

Class that uses the `os.urandom()` function for generating random numbers from sources provided by the operating system. Not available on all systems. Does not rely on software state, and sequences are not reproducible. Accordingly, the `seed()` method has no effect and is ignored. The `getstate()` and `setstate()` methods raise `NotImplementedError` if called.

9.6.7 Notes on Reproducibility

Sometimes it is useful to be able to reproduce the sequences given by a pseudo-random number generator. By re-using a seed value, the same sequence should be reproducible from run to run as long as multiple threads are not running.

Most of the random module's algorithms and seeding functions are subject to change across Python versions, but two aspects are guaranteed not to change:

- If a new seeding method is added, then a backward compatible seeder will be offered.
- The generator's `random()` method will continue to produce the same sequence when the compatible seeder is given the same seed.

9.6.8 Examples

Basic examples:

```
>>> random()                                # Random float:  0.0 <= x < 1.0
0.37444887175646646

>>> uniform(2.5, 10.0)                     # Random float:  2.5 <= x <= 10.0
3.1800146073117523

>>> expovariate(1 / 5)                      # Interval between arrivals averaging 5_
↪seconds
5.148957571865031

>>> randrange(10)                           # Integer from 0 to 9 inclusive
7

>>> randrange(0, 101, 2)                    # Even integer from 0 to 100 inclusive
26

>>> choice(['win', 'lose', 'draw'])          # Single random element from a sequence
'draw'

>>> deck = 'ace two three four'.split()
>>> shuffle(deck)                           # Shuffle a list
>>> deck
['four', 'two', 'ace', 'three']
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> sample([10, 20, 30, 40, 50], k=4)      # Four samples without replacement
[40, 10, 50, 30]
```

Simulations:

```
>>> # Six roulette wheel spins (weighted sampling with replacement)
>>> choices(['red', 'black', 'green'], [18, 18, 2], k=6)
['red', 'green', 'black', 'black', 'red', 'black']

>>> # Deal 20 cards without replacement from a deck
>>> # of 52 playing cards, and determine the proportion of cards
>>> # with a ten-value: ten, jack, queen, or king.
>>> dealt = sample(['tens', 'low cards'], counts=[16, 36], k=20)
>>> dealt.count('tens') / 20
0.15

>>> # Estimate the probability of getting 5 or more heads from 7 spins
>>> # of a biased coin that settles on heads 60% of the time.
>>> def trial():
...     return choices('HT', cum_weights=(0.60, 1.00), k=7).count('H') >= 5
...
>>> sum(trial() for i in range(10_000)) / 10_000
0.4169

>>> # Probability of the median of 5 samples being in middle two quartiles
>>> def trial():
...     return 2_500 <= sorted(choices(range(10_000), k=5))[2] < 7_500
...
>>> sum(trial() for i in range(10_000)) / 10_000
0.7958
```

Example of **statistical bootstrapping** using resampling with replacement to estimate a confidence interval for the mean of a sample:

```
# http://statistics.about.com/od/Applications/a/Example-Of-Bootstrapping.htm
from statistics import fmean as mean
from random import choices

data = [41, 50, 29, 37, 81, 30, 73, 63, 20, 35, 68, 22, 60, 31, 95]
means = sorted(mean(choices(data, k=len(data))) for i in range(100))
print(f'The sample mean of {mean(data):.1f} has a 90% confidence '
      f'interval from {means[5]:.1f} to {means[94]:.1f}')
```

Example of a **resampling permutation test** to determine the statistical significance or **p-value** of an observed difference between the effects of a drug versus a placebo:

```
# Example from "Statistics is Easy" by Dennis Shasha and Manda Wilson
from statistics import fmean as mean
from random import shuffle

drug = [54, 73, 53, 70, 73, 68, 52, 65, 65]
placebo = [54, 51, 58, 44, 55, 52, 42, 47, 58, 46]
observed_diff = mean(drug) - mean(placebo)

n = 10_000
count = 0
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

combined = drug + placebo
for i in range(n):
    shuffle(combined)
    new_diff = mean(combined[:len(drug)]) - mean(combined[len(drug):])
    count += (new_diff >= observed_diff)

print(f'{n} label reshufflings produced only {count} instances with a difference')
print(f'at least as extreme as the observed difference of {observed_diff:.1f}.')
print(f'The one-sided p-value of {count / n:.4f} leads us to reject the null')
print(f'hypothesis that there is no difference between the drug and the placebo.')

```

Simulation of arrival times and service deliveries for a multiserver queue:

```

from heapq import heapify, heapreplace
from random import expovariate, gauss
from statistics import mean, median, stdev

average_arrival_interval = 5.6
average_service_time = 15.0
stdev_service_time = 3.5
num_servers = 3

waits = []
arrival_time = 0.0
servers = [0.0] * num_servers # time when each server becomes available
heapify(servers)
for i in range(1_000_000):
    arrival_time += expovariate(1.0 / average_arrival_interval)
    next_server_available = servers[0]
    wait = max(0.0, next_server_available - arrival_time)
    waits.append(wait)
    service_duration = max(0.0, gauss(average_service_time, stdev_service_time))
    service_completed = arrival_time + wait + service_duration
    heapreplace(servers, service_completed)

print(f'Mean wait: {mean(waits):.1f}. Stdev wait: {stdev(waits):.1f}.')
print(f'Median wait: {median(waits):.1f}. Max wait: {max(waits):.1f}.')

```

[Economics Simulation](#) a simulation of a marketplace by [Peter Norvig](#) that shows effective use of many of the tools and distributions provided by this module (gauss, uniform, sample, betavariate, choice, triangular, and randrange).

[A Concrete Introduction to Probability \(using Python\)](#) a tutorial by [Peter Norvig](#) covering the basics of probability theory, how to write simulations, and how to perform data analysis using Python.

9.6.9 Recipes

The default `random()` returns multiples of 2^{-53} in the range $0.0 \leq x < 1.0$. All such numbers are evenly spaced and are exactly representable as Python floats. However, many other representable floats in that interval are not possible selections. For example, `0.05954861408025609` isn't an integer multiple of 2^{-53} .

The following recipe takes a different approach. All floats in the interval are possible selections. The mantissa comes from a uniform distribution of integers in the range $2^{52} \leq \text{mantissa} < 2^{53}$. The exponent comes from a geometric distribution where exponents smaller than -53 occur half as often as the next larger exponent.

```
from random import Random
from math import ldexp

class FullRandom(Random):

    def random(self):
        mantissa = 0x10_0000_0000_0000 | self.getrandbits(52)
        exponent = -53
        x = 0
        while not x:
            x = self.getrandbits(32)
            exponent += x.bit_length() - 32
        return ldexp(mantissa, exponent)
```

All *real valued distributions* in the class will use the new method:

```
>>> fr = FullRandom()
>>> fr.random()
0.05954861408025609
>>> fr.expovariate(0.25)
8.87925541791544
```

The recipe is conceptually equivalent to an algorithm that chooses from all the multiples of 2^{-1074} in the range $0.0 \leq x < 1.0$. All such numbers are evenly spaced, but most have to be rounded down to the nearest representable Python float. (The value 2^{-1074} is the smallest positive unnormalized float and is equal to `math.ulp(0.0)`.)

[Generating Pseudo-random Floating-Point Values](#) a paper by Allen B. Downey describing ways to generate more fine-grained floats than normally generated by `random()`.

9.7 statistics — Mathematical statistics functions

Νέο στην έκδοση 3.4.

Source code: [Lib/statistics.py](#)

This module provides functions for calculating mathematical statistics of numeric (*Real*-valued) data.

The module is not intended to be a competitor to third-party libraries such as [NumPy](#), [SciPy](#), or proprietary full-featured statistics packages aimed at professional statisticians such as Minitab, SAS and Matlab. It is aimed at the level of graphing and scientific calculators.

Unless explicitly noted, these functions support `int`, `float`, `Decimal` and `Fraction`. Behaviour with other types (whether in the numeric tower or not) is currently unsupported. Collections with a mix of types are also undefined

and implementation-dependent. If your input data consists of mixed types, you may be able to use `map()` to ensure a consistent result, for example: `map(float, input_data)`.

9.7.1 Averages and measures of central location

These functions calculate an average or typical value from a population or sample.

| | |
|-------------------------------|---|
| <code>mean()</code> | Arithmetic mean («average») of data. |
| <code>fmean()</code> | Fast, floating point arithmetic mean. |
| <code>geometric_mean()</code> | Geometric mean of data. |
| <code>harmonic_mean()</code> | Harmonic mean of data. |
| <code>median()</code> | Median (middle value) of data. |
| <code>median_low()</code> | Low median of data. |
| <code>median_high()</code> | High median of data. |
| <code>median_grouped()</code> | Median, or 50th percentile, of grouped data. |
| <code>mode()</code> | Single mode (most common value) of discrete or nominal data. |
| <code>multimode()</code> | List of modes (most common values) of discrete or nominal data. |
| <code>quantiles()</code> | Divide data into intervals with equal probability. |

9.7.2 Measures of spread

These functions calculate a measure of how much the population or sample tends to deviate from the typical or average values.

| | |
|--------------------------|--|
| <code>pstdev()</code> | Population standard deviation of data. |
| <code>pvariance()</code> | Population variance of data. |
| <code>stdev()</code> | Sample standard deviation of data. |
| <code>variance()</code> | Sample variance of data. |

9.7.3 Function details

Note: The functions do not require the data given to them to be sorted. However, for reading convenience, most of the examples show sorted sequences.

`statistics.mean(data)`

Return the sample arithmetic mean of *data* which can be a sequence or iterable.

The arithmetic mean is the sum of the data divided by the number of data points. It is commonly called «the average», although it is only one of many different mathematical averages. It is a measure of the central location of the data.

If *data* is empty, `StatisticsError` will be raised.

Some examples of use:

```
>>> mean([1, 2, 3, 4, 4])
2.8
>>> mean([-1.0, 2.5, 3.25, 5.75])
2.625

>>> from fractions import Fraction as F
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> mean([F(3, 7), F(1, 21), F(5, 3), F(1, 3)])
Fraction(13, 21)

>>> from decimal import Decimal as D
>>> mean([D("0.5"), D("0.75"), D("0.625"), D("0.375")])
Decimal('0.5625')
```

Σημείωση: The mean is strongly affected by [outliers](#) and is not necessarily a typical example of the data points. For a more robust, although less efficient, measure of [central tendency](#), see [median\(\)](#).

The sample mean gives an unbiased estimate of the true population mean, so that when taken on average over all the possible samples, `mean(sample)` converges on the true mean of the entire population. If *data* represents the entire population rather than a sample, then `mean(data)` is equivalent to calculating the true population mean μ .

`statistics.fmean(data)`

Convert *data* to floats and compute the arithmetic mean.

This runs faster than the [mean\(\)](#) function and it always returns a *float*. The *data* may be a sequence or iterable. If the input dataset is empty, raises a [StatisticsError](#).

```
>>> fmean([3.5, 4.0, 5.25])
4.25
```

Νέο στην έκδοση 3.8.

`statistics.geometric_mean(data)`

Convert *data* to floats and compute the geometric mean.

The geometric mean indicates the central tendency or typical value of the *data* using the product of the values (as opposed to the arithmetic mean which uses their sum).

Raises a [StatisticsError](#) if the input dataset is empty, if it contains a zero, or if it contains a negative value. The *data* may be a sequence or iterable.

No special efforts are made to achieve exact results. (However, this may change in the future.)

```
>>> round(geometric_mean([54, 24, 36]), 1)
36.0
```

Νέο στην έκδοση 3.8.

`statistics.harmonic_mean(data)`

Return the harmonic mean of *data*, a sequence or iterable of real-valued numbers.

The harmonic mean, sometimes called the subcontrary mean, is the reciprocal of the arithmetic [mean\(\)](#) of the reciprocals of the data. For example, the harmonic mean of three values *a*, *b* and *c* will be equivalent to $3 / (1/a + 1/b + 1/c)$. If one of the values is zero, the result will be zero.

The harmonic mean is a type of average, a measure of the central location of the data. It is often appropriate when averaging rates or ratios, for example speeds.

Suppose a car travels 10 km at 40 km/hr, then another 10 km at 60 km/hr. What is the average speed?

```
>>> harmonic_mean([40, 60])
48.0
```

Suppose an investor purchases an equal value of shares in each of three companies, with P/E (price/earning) ratios of 2.5, 3 and 10. What is the average P/E ratio for the investor's portfolio?

```
>>> harmonic_mean([2.5, 3, 10]) # For an equal investment portfolio.
3.6
```

`StatisticsError` is raised if *data* is empty, or any element is less than zero.

The current algorithm has an early-out when it encounters a zero in the input. This means that the subsequent inputs are not tested for validity. (This behavior may change in the future.)

Νέο στην έκδοση 3.6.

`statistics.median(data)`

Return the median (middle value) of numeric data, using the common «mean of middle two» method. If *data* is empty, `StatisticsError` is raised. *data* can be a sequence or iterable.

The median is a robust measure of central location and is less affected by the presence of outliers. When the number of data points is odd, the middle data point is returned:

```
>>> median([1, 3, 5])
3
```

When the number of data points is even, the median is interpolated by taking the average of the two middle values:

```
>>> median([1, 3, 5, 7])
4.0
```

This is suited for when your data is discrete, and you don't mind that the median may not be an actual data point.

If the data is ordinal (supports order operations) but not numeric (doesn't support addition), consider using `median_low()` or `median_high()` instead.

`statistics.median_low(data)`

Return the low median of numeric data. If *data* is empty, `StatisticsError` is raised. *data* can be a sequence or iterable.

The low median is always a member of the data set. When the number of data points is odd, the middle value is returned. When it is even, the smaller of the two middle values is returned.

```
>>> median_low([1, 3, 5])
3
>>> median_low([1, 3, 5, 7])
3
```

Use the low median when your data are discrete and you prefer the median to be an actual data point rather than interpolated.

`statistics.median_high(data)`

Return the high median of data. If *data* is empty, `StatisticsError` is raised. *data* can be a sequence or iterable.

The high median is always a member of the data set. When the number of data points is odd, the middle value is returned. When it is even, the larger of the two middle values is returned.

```
>>> median_high([1, 3, 5])
3
>>> median_high([1, 3, 5, 7])
5
```

Use the high median when your data are discrete and you prefer the median to be an actual data point rather than interpolated.

`statistics.median_grouped(data, interval=1)`

Return the median of grouped continuous data, calculated as the 50th percentile, using interpolation. If *data* is empty, *StatisticsError* is raised. *data* can be a sequence or iterable.

```
>>> median_grouped([52, 52, 53, 54])
52.5
```

In the following example, the data are rounded, so that each value represents the midpoint of data classes, e.g. 1 is the midpoint of the class 0.5–1.5, 2 is the midpoint of 1.5–2.5, 3 is the midpoint of 2.5–3.5, etc. With the data given, the middle value falls somewhere in the class 3.5–4.5, and interpolation is used to estimate it:

```
>>> median_grouped([1, 2, 2, 3, 4, 4, 4, 4, 4, 5])
3.7
```

Optional argument *interval* represents the class interval, and defaults to 1. Changing the class interval naturally will change the interpolation:

```
>>> median_grouped([1, 3, 3, 5, 7], interval=1)
3.25
>>> median_grouped([1, 3, 3, 5, 7], interval=2)
3.5
```

This function does not check whether the data points are at least *interval* apart.

CPython implementation detail: Under some circumstances, *median_grouped()* may coerce data points to floats. This behaviour is likely to change in the future.

Δείτε επίσης:

- «Statistics for the Behavioral Sciences», Frederick J Gravetter and Larry B Wallnau (8th Edition).
- The *SSMEDIAN* function in the Gnome Gnumeric spreadsheet, including [this discussion](#).

`statistics.mode(data)`

Return the single most common data point from discrete or nominal *data*. The mode (when it exists) is the most typical value and serves as a measure of central location.

If there are multiple modes with the same frequency, returns the first one encountered in the *data*. If the smallest or largest of those is desired instead, use `min(multimode(data))` or `max(multimode(data))`. If the input *data* is empty, *StatisticsError* is raised.

mode assumes discrete data and returns a single value. This is the standard treatment of the mode as commonly taught in schools:

```
>>> mode([1, 1, 2, 3, 3, 3, 3, 4])
3
```

The mode is unique in that it is the only statistic in this package that also applies to nominal (non-numeric) data:

```
>>> mode(["red", "blue", "blue", "red", "green", "red", "red"])
'red'
```

Άλλαξε στην έκδοση 3.8: Now handles multimodal datasets by returning the first mode encountered. Formerly, it raised *StatisticsError* when more than one mode was found.

`statistics.multimode(data)`

Return a list of the most frequently occurring values in the order they were first encountered in the *data*. Will return more than one result if there are multiple modes or an empty list if the *data* is empty:

```
>>> multimode('aabbbbccdddeeffffgg')
['b', 'd', 'f']
>>> multimode('')
[]
```

Νέο στην έκδοση 3.8.

`statistics.pstdev(data, mu=None)`

Return the population standard deviation (the square root of the population variance). See [pvariance\(\)](#) for arguments and other details.

```
>>> pstdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
0.986893273527251
```

`statistics.pvariance(data, mu=None)`

Return the population variance of *data*, a non-empty sequence or iterable of real-valued numbers. Variance, or second moment about the mean, is a measure of the variability (spread or dispersion) of data. A large variance indicates that the data is spread out; a small variance indicates it is clustered closely around the mean.

If the optional second argument *mu* is given, it is typically the mean of the *data*. It can also be used to compute the second moment around a point that is not the mean. If it is missing or `None` (the default), the arithmetic mean is automatically calculated.

Use this function to calculate the variance from the entire population. To estimate the variance from a sample, the [variance\(\)](#) function is usually a better choice.

Raises [StatisticsError](#) if *data* is empty.

Examples:

```
>>> data = [0.0, 0.25, 0.25, 1.25, 1.5, 1.75, 2.75, 3.25]
>>> pvariance(data)
1.25
```

If you have already calculated the mean of your data, you can pass it as the optional second argument *mu* to avoid recalculation:

```
>>> mu = mean(data)
>>> pvariance(data, mu)
1.25
```

Decimals and Fractions are supported:

```
>>> from decimal import Decimal as D
>>> pvariance([D("27.5"), D("30.25"), D("30.25"), D("34.5"), D("41.75")])
Decimal('24.815')

>>> from fractions import Fraction as F
>>> pvariance([F(1, 4), F(5, 4), F(1, 2)])
Fraction(13, 72)
```

Σημείωση: When called with the entire population, this gives the population variance σ^2 . When called on a sample instead, this is the biased sample variance s^2 , also known as variance with N degrees of freedom.

If you somehow know the true population mean μ , you may use this function to calculate the variance of a sample, giving the known population mean as the second argument. Provided the data points are a random sample of the population, the result will be an unbiased estimate of the population variance.

`statistics.stdev(data, xbar=None)`

Return the sample standard deviation (the square root of the sample variance). See [variance\(\)](#) for arguments and other details.

```
>>> stdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
1.0810874155219827
```

`statistics.variance(data, xbar=None)`

Return the sample variance of *data*, an iterable of at least two real-valued numbers. Variance, or second moment about the mean, is a measure of the variability (spread or dispersion) of data. A large variance indicates that the data is spread out; a small variance indicates it is clustered closely around the mean.

If the optional second argument *xbar* is given, it should be the mean of *data*. If it is missing or `None` (the default), the mean is automatically calculated.

Use this function when your data is a sample from a population. To calculate the variance from the entire population, see [pvariance\(\)](#).

Raises `StatisticsError` if *data* has fewer than two values.

Examples:

```
>>> data = [2.75, 1.75, 1.25, 0.25, 0.5, 1.25, 3.5]
>>> variance(data)
1.3720238095238095
```

If you have already calculated the mean of your data, you can pass it as the optional second argument *xbar* to avoid recalculation:

```
>>> m = mean(data)
>>> variance(data, m)
1.3720238095238095
```

This function does not attempt to verify that you have passed the actual mean as *xbar*. Using arbitrary values for *xbar* can lead to invalid or impossible results.

Decimal and Fraction values are supported:

```
>>> from decimal import Decimal as D
>>> variance([D("27.5"), D("30.25"), D("30.25"), D("34.5"), D("41.75")])
Decimal('31.01875')

>>> from fractions import Fraction as F
>>> variance([F(1, 6), F(1, 2), F(5, 3)])
Fraction(67, 108)
```

Σημείωση: This is the sample variance s^2 with Bessel's correction, also known as variance with $N-1$ degrees of freedom. Provided that the data points are representative (e.g. independent and identically distributed), the result should be an unbiased estimate of the true population variance.

If you somehow know the actual population mean μ you should pass it to the [pvariance\(\)](#) function as the *mu* parameter to get the variance of a sample.

`statistics.quantiles` (*data*, *, *n*=4, *method*='exclusive')

Divide *data* into *n* continuous intervals with equal probability. Returns a list of $n - 1$ cut points separating the intervals.

Set *n* to 4 for quartiles (the default). Set *n* to 10 for deciles. Set *n* to 100 for percentiles which gives the 99 cuts points that separate *data* into 100 equal sized groups. Raises `StatisticsError` if *n* is not least 1.

The *data* can be any iterable containing sample data. For meaningful results, the number of data points in *data* should be larger than *n*. Raises `StatisticsError` if there are not at least two data points.

The cut points are linearly interpolated from the two nearest data points. For example, if a cut point falls one-third of the distance between two sample values, 100 and 112, the cut-point will evaluate to 104.

The *method* for computing quantiles can be varied depending on whether the *data* includes or excludes the lowest and highest possible values from the population.

The default *method* is «exclusive» and is used for data sampled from a population that can have more extreme values than found in the samples. The portion of the population falling below the *i*-th of *m* sorted data points is computed as $i / (m + 1)$. Given nine sample values, the method sorts them and assigns the following percentiles: 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%.

Setting the *method* to «inclusive» is used for describing population data or for samples that are known to include the most extreme values from the population. The minimum value in *data* is treated as the 0th percentile and the maximum value is treated as the 100th percentile. The portion of the population falling below the *i*-th of *m* sorted data points is computed as $(i - 1) / (m - 1)$. Given 11 sample values, the method sorts them and assigns the following percentiles: 0%, 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 100%.

```
# Decile cut points for empirically sampled data
>>> data = [105, 129, 87, 86, 111, 111, 89, 81, 108, 92, 110,
...         100, 75, 105, 103, 109, 76, 119, 99, 91, 103, 129,
...         106, 101, 84, 111, 74, 87, 86, 103, 103, 106, 86,
...         111, 75, 87, 102, 121, 111, 88, 89, 101, 106, 95,
...         103, 107, 101, 81, 109, 104]
>>> [round(q, 1) for q in quantiles(data, n=10)]
[81.0, 86.2, 89.0, 99.4, 102.5, 103.6, 106.0, 109.8, 111.0]
```

Νέο στην έκδοση 3.8.

9.7.4 Exceptions

A single exception is defined:

exception `statistics.StatisticsError`

Subclass of `ValueError` for statistics-related exceptions.

9.7.5 NormalDist objects

`NormalDist` is a tool for creating and manipulating normal distributions of a [random variable](#). It is a class that treats the mean and standard deviation of data measurements as a single entity.

Normal distributions arise from the [Central Limit Theorem](#) and have a wide range of applications in statistics.

class `statistics.NormalDist` (*mu*=0.0, *sigma*=1.0)

Returns a new `NormalDist` object where *mu* represents the [arithmetic mean](#) and *sigma* represents the [standard deviation](#).

If *sigma* is negative, raises `StatisticsError`.

mean

A read-only property for the [arithmetic mean](#) of a normal distribution.

median

A read-only property for the [median](#) of a normal distribution.

mode

A read-only property for the [mode](#) of a normal distribution.

stdev

A read-only property for the [standard deviation](#) of a normal distribution.

variance

A read-only property for the [variance](#) of a normal distribution. Equal to the square of the standard deviation.

classmethod from_samples (*data*)

Makes a normal distribution instance with *mu* and *sigma* parameters estimated from the *data* using [fmean\(\)](#) and [stdev\(\)](#).

The *data* can be any [iterable](#) and should consist of values that can be converted to type [float](#). If *data* does not contain at least two elements, raises [StatisticsError](#) because it takes at least one point to estimate a central value and at least two points to estimate dispersion.

samples (*n*, *, *seed=None*)

Generates *n* random samples for a given mean and standard deviation. Returns a [list](#) of [float](#) values.

If *seed* is given, creates a new instance of the underlying random number generator. This is useful for creating reproducible results, even in a multi-threading context.

pdf (*x*)

Using a [probability density function](#) (pdf), compute the relative likelihood that a random variable *X* will be near the given value *x*. Mathematically, it is the limit of the ratio $P(x \leq X < x+dx) / dx$ as *dx* approaches zero.

The relative likelihood is computed as the probability of a sample occurring in a narrow range divided by the width of the range (hence the word «density»). Since the likelihood is relative to other points, its value can be greater than 1.0.

cdf (*x*)

Using a [cumulative distribution function](#) (cdf), compute the probability that a random variable *X* will be less than or equal to *x*. Mathematically, it is written $P(X \leq x)$.

inv_cdf (*p*)

Compute the inverse cumulative distribution function, also known as the [quantile function](#) or the [percent-point function](#). Mathematically, it is written $x : P(X \leq x) = p$.

Finds the value *x* of the random variable *X* such that the probability of the variable being less than or equal to that value equals the given probability *p*.

overlap (*other*)

Measures the agreement between two normal probability distributions. Returns a value between 0.0 and 1.0 giving the [overlapping area for the two probability density functions](#).

quantiles (*n=4*)

Divide the normal distribution into *n* continuous intervals with equal probability. Returns a list of (*n* - 1) cut points separating the intervals.

Set *n* to 4 for quartiles (the default). Set *n* to 10 for deciles. Set *n* to 100 for percentiles which gives the 99 cut points that separate the normal distribution into 100 equal sized groups.

zscore (*x*)

Compute the **Standard Score** describing *x* in terms of the number of standard deviations above or below the mean of the normal distribution: $(x - \text{mean}) / \text{stdev}$.

Νέο στην έκδοση 3.9.

Instances of *NormalDist* support addition, subtraction, multiplication and division by a constant. These operations are used for translation and scaling. For example:

```
>>> temperature_february = NormalDist(5, 2.5)           # Celsius
>>> temperature_february * (9/5) + 32                  # Fahrenheit
NormalDist(mu=41.0, sigma=4.5)
```

Dividing a constant by an instance of *NormalDist* is not supported because the result wouldn't be normally distributed.

Since normal distributions arise from additive effects of independent variables, it is possible to **add and subtract two independent normally distributed random variables** represented as instances of *NormalDist*. For example:

```
>>> birth_weights = NormalDist.from_samples([2.5, 3.1, 2.1, 2.4, 2.7, 3.5])
>>> drug_effects = NormalDist(0.4, 0.15)
>>> combined = birth_weights + drug_effects
>>> round(combined.mean, 1)
3.1
>>> round(combined.stdev, 1)
0.5
```

Νέο στην έκδοση 3.8.

NormalDist Examples and Recipes

NormalDist readily solves classic probability problems.

For example, given **historical data for SAT exams** showing that scores are normally distributed with a mean of 1060 and a standard deviation of 195, determine the percentage of students with test scores between 1100 and 1200, after rounding to the nearest whole number:

```
>>> sat = NormalDist(1060, 195)
>>> fraction = sat.cdf(1200 + 0.5) - sat.cdf(1100 - 0.5)
>>> round(fraction * 100.0, 1)
18.4
```

Find the **quantiles** and **deciles** for the SAT scores:

```
>>> list(map(round, sat.quantiles()))
[928, 1060, 1192]
>>> list(map(round, sat.quantiles(n=10)))
[810, 896, 958, 1011, 1060, 1109, 1162, 1224, 1310]
```

To estimate the distribution for a model than isn't easy to solve analytically, *NormalDist* can generate input samples for a **Monte Carlo simulation**:

```
>>> def model(x, y, z):
...     return (3*x + 7*x*y - 5*y) / (11 * z)
...
>>> n = 100_000
>>> X = NormalDist(10, 2.5).samples(n, seed=3652260728)
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> Y = NormalDist(15, 1.75).samples(n, seed=4582495471)
>>> Z = NormalDist(50, 1.25).samples(n, seed=6582483453)
>>> quantiles(map(model, X, Y, Z))
[1.4591308524824727, 1.8035946855390597, 2.175091447274739]
```

Normal distributions can be used to approximate [Binomial distributions](#) when the sample size is large and when the probability of a successful trial is near 50%.

For example, an open source conference has 750 attendees and two rooms with a 500 person capacity. There is a talk about Python and another about Ruby. In previous conferences, 65% of the attendees preferred to listen to Python talks. Assuming the population preferences haven't changed, what is the probability that the Python room will stay within its capacity limits?

```
>>> n = 750                # Sample size
>>> p = 0.65               # Preference for Python
>>> q = 1.0 - p           # Preference for Ruby
>>> k = 500                # Room capacity

>>> # Approximation using the cumulative normal distribution
>>> from math import sqrt
>>> round(NormalDist(mu=n*p, sigma=sqrt(n*p*q)).cdf(k + 0.5), 4)
0.8402

>>> # Solution using the cumulative binomial distribution
>>> from math import comb, fsum
>>> round(fsum(comb(n, r) * p**r * q**(n-r) for r in range(k+1)), 4)
0.8402

>>> # Approximation using a simulation
>>> from random import seed, choices
>>> seed(8675309)
>>> def trial():
...     return choices(('Python', 'Ruby'), (p, q), k=n).count('Python')
>>> mean(trial() <= k for i in range(10_000))
0.8398
```

Normal distributions commonly arise in machine learning problems.

Wikipedia has a [nice example of a Naive Bayesian Classifier](#). The challenge is to predict a person's gender from measurements of normally distributed features including height, weight, and foot size.

We're given a training dataset with measurements for eight people. The measurements are assumed to be normally distributed, so we summarize the data with *NormalDist*:

```
>>> height_male = NormalDist.from_samples([6, 5.92, 5.58, 5.92])
>>> height_female = NormalDist.from_samples([5, 5.5, 5.42, 5.75])
>>> weight_male = NormalDist.from_samples([180, 190, 170, 165])
>>> weight_female = NormalDist.from_samples([100, 150, 130, 150])
>>> foot_size_male = NormalDist.from_samples([12, 11, 12, 10])
>>> foot_size_female = NormalDist.from_samples([6, 8, 7, 9])
```

Next, we encounter a new person whose feature measurements are known but whose gender is unknown:

```
>>> ht = 6.0                # height
>>> wt = 130                # weight
>>> fs = 8                  # foot size
```

Starting with a 50% [prior probability](#) of being male or female, we compute the posterior as the prior times the product of likelihoods for the feature measurements given the gender:

```
>>> prior_male = 0.5
>>> prior_female = 0.5
>>> posterior_male = (prior_male * height_male.pdf(ht) *
...                   weight_male.pdf(wt) * foot_size_male.pdf(fs))
>>> posterior_female = (prior_female * height_female.pdf(ht) *
...                     weight_female.pdf(wt) * foot_size_female.pdf(fs))
```

The final prediction goes to the largest posterior. This is known as the [maximum a posteriori](#) or MAP:

```
>>> 'male' if posterior_male > posterior_female else 'female'
'female'
```

Functional Programming Modules

The modules described in this chapter provide functions and classes that support a functional programming style, and general operations on callables.

The following modules are documented in this chapter:

10.1 `itertools` — Functions creating iterators for efficient looping

This module implements a number of *iterator* building blocks inspired by constructs from APL, Haskell, and SML. Each has been recast in a form suitable for Python.

The module standardizes a core set of fast, memory efficient tools that are useful by themselves or in combination. Together, they form an «iterator algebra» making it possible to construct specialized tools succinctly and efficiently in pure Python.

For instance, SML provides a tabulation tool: `tabulate(f)` which produces a sequence `f(0), f(1), ...`. The same effect can be achieved in Python by combining `map()` and `count()` to form `map(f, count())`.

These tools and their built-in counterparts also work well with the high-speed functions in the *operator* module. For example, the multiplication operator can be mapped across two vectors to form an efficient dot-product: `sum(map(operator.mul, vector1, vector2))`.

Infinite iterators:

| Iterator | Arguments | Results | Example |
|-----------------------|------------------|--|---|
| <code>count()</code> | start, [step] | start, start+step, start+2*step, ... | <code>count(10) --> 10 11 12 13 14 ...</code> |
| <code>cycle()</code> | p | p0, p1, ... plast, p0, p1, ... | <code>cycle('ABCD') --> A B C D A B C D ...</code> |
| <code>repeat()</code> | elem [,n] | elem, elem, elem, ... endlessly or up to n times | <code>repeat(10, 3) --> 10 10 10</code> |

Iterators terminating on the shortest input sequence:

| Iterator | Arguments | Results | Example |
|------------------------------------|---|--|---|
| <code>accumulate()</code> | <code>p [,func]</code> | <code>p0</code> , <code>p0+p1</code> , <code>p0+p1+p2</code> , ... | <code>accumulate([1,2,3,4,5]) --> 1 3 6 10 15</code> |
| <code>chain()</code> | <code>p, q, ...</code> | <code>p0</code> , <code>p1</code> , ... <code>plast</code> , <code>q0</code> , <code>q1</code> , ... | <code>chain('ABC', 'DEF') --> A B C D E F</code> |
| <code>chain.from_iterable()</code> | iterable | <code>p0</code> , <code>p1</code> , ... <code>plast</code> , <code>q0</code> , <code>q1</code> , ... | <code>chain.from_iterable(['ABC', 'DEF']) --> A B C D E F</code> |
| <code>compress()</code> | data, selectors | (<code>d[0]</code> if <code>s[0]</code>), (<code>d[1]</code> if <code>s[1]</code>), ... | <code>compress('ABCDEF', [1,0,1,0,1,1]) --> A C E F</code> |
| <code>dropwhile()</code> | <code>pred</code> , <code>seq</code> | <code>seq[n]</code> , <code>seq[n+1]</code> , starting when <code>pred</code> fails | <code>dropwhile(lambda x: x<5, [1,4,6,4,1]) --> 6 4 1</code> |
| <code>filterfalse()</code> | <code>pred</code> , <code>seq</code> | elements of <code>seq</code> where <code>pred(elem)</code> is false | <code>filterfalse(lambda x: x%2, range(10)) --> 0 2 4 6 8</code> |
| <code>groupby()</code> | iterable[, <code>key</code>] | sub-iterators grouped by value of <code>key(v)</code> | |
| <code>islice()</code> | <code>seq</code> , [<code>start</code> ,] <code>stop</code> [, <code>step</code>] | elements from <code>seq[start:stop:step]</code> | <code>islice('ABCDEFGH', 2, None) --> C D E F G</code> |
| <code>starmap()</code> | <code>func</code> , <code>seq</code> | <code>func(*seq[0])</code> , <code>func(*seq[1])</code> , ... | <code>starmap(pow, [(2,5), (3,2), (10,3)]) --> 32 9 1000</code> |
| <code>takewhile()</code> | <code>pred</code> , <code>seq</code> | <code>seq[0]</code> , <code>seq[1]</code> , until <code>pred</code> fails | <code>takewhile(lambda x: x<5, [1,4,6,4,1]) --> 1 4</code> |
| <code>tee()</code> | <code>it</code> , <code>n</code> | <code>it1</code> , <code>it2</code> , ... <code>itn</code> splits one iterator into <code>n</code> | |
| <code>zip_longest()</code> | <code>p</code> , <code>q</code> , ... | (<code>p[0]</code> , <code>q[0]</code>), (<code>p[1]</code> , <code>q[1]</code>), ... | <code>zip_longest('ABCD', 'xy', fillvalue='-') --> Ax By C-D-</code> |

Combinatoric iterators:

| Iterator | Arguments | Results |
|--|---|---|
| <code>product()</code> | <code>p</code> , <code>q</code> , ... [<code>repeat=1</code>] | cartesian product, equivalent to a nested for-loop |
| <code>permutations()</code> | <code>p</code> [, <code>r</code>] | <code>r</code> -length tuples, all possible orderings, no repeated elements |
| <code>combinations()</code> | <code>p</code> , <code>r</code> | <code>r</code> -length tuples, in sorted order, no repeated elements |
| <code>combinations_with_replacement()</code> | <code>p</code> [, <code>r</code>] | <code>r</code> -length tuples, in sorted order, with repeated elements |

| Examples | Results |
|---|---|
| <code>product('ABCD', repeat=2)</code> | AA AB AC AD BA BB BC BD CA CB CC CD DA DB DC DD |
| <code>permutations('ABCD', 2)</code> | AB AC AD BA BC BD CA CB CD DA DB DC |
| <code>combinations('ABCD', 2)</code> | AB AC AD BC BD CD |
| <code>combinations_with_replacement('ABCD', 2)</code> | AA AB AC AD BB BC BD CC CD DD |

10.1.1 Itertool functions

The following module functions all construct and return iterators. Some provide streams of infinite length, so they should only be accessed by functions or loops that truncate the stream.

`itertools.accumulate(iterable[, func, *, initial=None])`

Make an iterator that returns accumulated sums, or accumulated results of other binary functions (specified via the optional *func* argument).

If *func* is supplied, it should be a function of two arguments. Elements of the input *iterable* may be any type that can be accepted as arguments to *func*. (For example, with the default operation of addition, elements may be any addable type including *Decimal* or *Fraction*.)

Usually, the number of elements output matches the input iterable. However, if the keyword argument *initial* is provided, the accumulation leads off with the *initial* value so that the output has one more element than the input iterable.

Roughly equivalent to:

```
def accumulate(iterable, func=operator.add, *, initial=None):
    'Return running totals'
    # accumulate([1,2,3,4,5]) --> 1 3 6 10 15
    # accumulate([1,2,3,4,5], initial=100) --> 100 101 103 106 110 115
    # accumulate([1,2,3,4,5], operator.mul) --> 1 2 6 24 120
    it = iter(iterable)
    total = initial
    if initial is None:
        try:
            total = next(it)
        except StopIteration:
            return
    yield total
    for element in it:
        total = func(total, element)
        yield total
```

There are a number of uses for the *func* argument. It can be set to *min()* for a running minimum, *max()* for a running maximum, or *operator.mul()* for a running product. Amortization tables can be built by accumulating interest and applying payments. First-order *recurrence relations* can be modeled by supplying the initial value in the iterable and using only the accumulated total in *func* argument:

```
>>> data = [3, 4, 6, 2, 1, 9, 0, 7, 5, 8]
>>> list(accumulate(data, operator.mul))          # running product
[3, 12, 72, 144, 144, 1296, 0, 0, 0, 0]
>>> list(accumulate(data, max))                  # running maximum
[3, 4, 6, 6, 6, 9, 9, 9, 9, 9]

# Amortize a 5% loan of 1000 with 4 annual payments of 90
>>> cashflows = [1000, -90, -90, -90, -90]
>>> list(accumulate(cashflows, lambda bal, pmt: bal*1.05 + pmt))
[1000, 960.0, 918.0, 873.9000000000001, 827.5950000000001]

# Chaotic recurrence relation https://en.wikipedia.org/wiki/Logistic_map
>>> logistic_map = lambda x, _: r * x * (1 - x)
>>> r = 3.8
>>> x0 = 0.4
>>> inputs = repeat(x0, 36)                      # only the initial value is used
>>> [format(x, '.2f') for x in accumulate(inputs, logistic_map)]
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
[ '0.40', '0.91', '0.30', '0.81', '0.60', '0.92', '0.29', '0.79', '0.63',
  '0.88', '0.39', '0.90', '0.33', '0.84', '0.52', '0.95', '0.18', '0.57',
  '0.93', '0.25', '0.71', '0.79', '0.63', '0.88', '0.39', '0.91', '0.32',
  '0.83', '0.54', '0.95', '0.20', '0.60', '0.91', '0.30', '0.80', '0.60']
```

See `functools.reduce()` for a similar function that returns only the final accumulated value.

Νέο στην έκδοση 3.2.

Άλλαξε στην έκδοση 3.3: Added the optional *func* parameter.

Άλλαξε στην έκδοση 3.8: Added the optional *initial* parameter.

`itertools.chain(*iterables)`

Make an iterator that returns elements from the first iterable until it is exhausted, then proceeds to the next iterable, until all of the iterables are exhausted. Used for treating consecutive sequences as a single sequence. Roughly equivalent to:

```
def chain(*iterables):
    # chain('ABC', 'DEF') --> A B C D E F
    for it in iterables:
        for element in it:
            yield element
```

`classmethod chain.from_iterable(iterable)`

Alternate constructor for `chain()`. Gets chained inputs from a single iterable argument that is evaluated lazily. Roughly equivalent to:

```
def from_iterable(iterables):
    # chain.from_iterable(['ABC', 'DEF']) --> A B C D E F
    for it in iterables:
        for element in it:
            yield element
```

`itertools.combinations(iterable, r)`

Return *r* length subsequences of elements from the input *iterable*.

The combination tuples are emitted in lexicographic ordering according to the order of the input *iterable*. So, if the input *iterable* is sorted, the combination tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. So if the input elements are unique, there will be no repeat values in each combination.

Roughly equivalent to:

```
def combinations(iterable, r):
    # combinations('ABCD', 2) --> AB AC AD BC BD CD
    # combinations(range(4), 3) --> 012 013 023 123
    pool = tuple(iterable)
    n = len(pool)
    if r > n:
        return
    indices = list(range(r))
    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != i + n - r:
                break
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

else:
    return
indices[i] += 1
for j in range(i+1, r):
    indices[j] = indices[j-1] + 1
yield tuple(pool[i] for i in indices)

```

The code for `combinations()` can be also expressed as a subsequence of `permutations()` after filtering entries where the elements are not in sorted order (according to their position in the input pool):

```

def combinations(iterable, r):
    pool = tuple(iterable)
    n = len(pool)
    for indices in permutations(range(n), r):
        if sorted(indices) == list(indices):
            yield tuple(pool[i] for i in indices)

```

The number of items returned is $n! / r! / (n-r)!$ when $0 \leq r \leq n$ or zero when $r > n$.

`itertools.combinations_with_replacement(iterable, r)`

Return r length subsequences of elements from the input *iterable* allowing individual elements to be repeated more than once.

The combination tuples are emitted in lexicographic ordering according to the order of the input *iterable*. So, if the input *iterable* is sorted, the combination tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. So if the input elements are unique, the generated combinations will also be unique.

Roughly equivalent to:

```

def combinations_with_replacement(iterable, r):
    # combinations_with_replacement('ABC', 2) --> AA AB AC BB BC CC
    pool = tuple(iterable)
    n = len(pool)
    if not n and r:
        return
    indices = [0] * r
    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != n - 1:
                break
        else:
            return
        indices[i:] = [indices[i] + 1] * (r - i)
        yield tuple(pool[i] for i in indices)

```

The code for `combinations_with_replacement()` can be also expressed as a subsequence of `product()` after filtering entries where the elements are not in sorted order (according to their position in the input pool):

```

def combinations_with_replacement(iterable, r):
    pool = tuple(iterable)
    n = len(pool)
    for indices in product(range(n), repeat=r):
        if sorted(indices) == list(indices):
            yield tuple(pool[i] for i in indices)

```

The number of items returned is $(n+r-1)! / r! / (n-1)!$ when $n > 0$.

Νέο στην έκδοση 3.1.

`itertools.compress(data, selectors)`

Make an iterator that filters elements from *data* returning only those that have a corresponding element in *selectors* that evaluates to `True`. Stops when either the *data* or *selectors* iterables has been exhausted. Roughly equivalent to:

```
def compress(data, selectors):
    # compress('ABCDEF', [1,0,1,0,1,1]) --> A C E F
    return (d for d, s in zip(data, selectors) if s)
```

Νέο στην έκδοση 3.1.

`itertools.count(start=0, step=1)`

Make an iterator that returns evenly spaced values starting with number *start*. Often used as an argument to `map()` to generate consecutive data points. Also, used with `zip()` to add sequence numbers. Roughly equivalent to:

```
def count(start=0, step=1):
    # count(10) --> 10 11 12 13 14 ...
    # count(2.5, 0.5) -> 2.5 3.0 3.5 ...
    n = start
    while True:
        yield n
        n += step
```

When counting with floating point numbers, better accuracy can sometimes be achieved by substituting multiplicative code such as: `(start + step * i for i in count())`.

Άλλαξε στην έκδοση 3.1: Added *step* argument and allowed non-integer arguments.

`itertools.cycle(iterable)`

Make an iterator returning elements from the iterable and saving a copy of each. When the iterable is exhausted, return elements from the saved copy. Repeats indefinitely. Roughly equivalent to:

```
def cycle(iterable):
    # cycle('ABCD') --> A B C D A B C D A B C D ...
    saved = []
    for element in iterable:
        yield element
        saved.append(element)
    while saved:
        for element in saved:
            yield element
```

Note, this member of the toolkit may require significant auxiliary storage (depending on the length of the iterable).

`itertools.dropwhile(predicate, iterable)`

Make an iterator that drops elements from the iterable as long as the predicate is true; afterwards, returns every element. Note, the iterator does not produce *any* output until the predicate first becomes false, so it may have a lengthy start-up time. Roughly equivalent to:

```
def dropwhile(predicate, iterable):
    # dropwhile(lambda x: x<5, [1,4,6,4,1]) --> 6 4 1
    iterable = iter(iterable)
    for x in iterable:
        if not predicate(x):
            yield x
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

        break
    for x in iterable:
        yield x

```

itertools.filterfalse (*predicate, iterable*)

Make an iterator that filters elements from *iterable* returning only those for which the predicate is False. If *predicate* is None, return the items that are false. Roughly equivalent to:

```

def filterfalse(predicate, iterable):
    # filterfalse(lambda x: x%2, range(10)) --> 0 2 4 6 8
    if predicate is None:
        predicate = bool
    for x in iterable:
        if not predicate(x):
            yield x

```

itertools.groupby (*iterable, key=None*)

Make an iterator that returns consecutive keys and groups from the *iterable*. The *key* is a function computing a key value for each element. If not specified or is None, *key* defaults to an identity function and returns the element unchanged. Generally, the *iterable* needs to already be sorted on the same key function.

The operation of *groupby()* is similar to the *uniq* filter in Unix. It generates a break or new group every time the value of the key function changes (which is why it is usually necessary to have sorted the data using the same key function). That behavior differs from SQL's GROUP BY which aggregates common elements regardless of their input order.

The returned group is itself an iterator that shares the underlying *iterable* with *groupby()*. Because the source is shared, when the *groupby()* object is advanced, the previous group is no longer visible. So, if that data is needed later, it should be stored as a list:

```

groups = []
uniquekeys = []
data = sorted(data, key=keyfunc)
for k, g in groupby(data, keyfunc):
    groups.append(list(g))      # Store group iterator as a list
    uniquekeys.append(k)

```

groupby() is roughly equivalent to:

```

class groupby:
    # [k for k, g in groupby('AAAABBBCCDAABBB')] --> A B C D A B
    # [list(g) for k, g in groupby('AAAABBBCCD')] --> AAAA BBB CC D
    def __init__(self, iterable, key=None):
        if key is None:
            key = lambda x: x
        self.keyfunc = key
        self.it = iter(iterable)
        self.tgtkey = self.currkey = self.currvalue = object()
    def __iter__(self):
        return self
    def __next__(self):
        self.id = object()
        while self.currkey == self.tgtkey:
            self.currvalue = next(self.it)      # Exit on StopIteration
            self.currkey = self.keyfunc(self.currvalue)
        self.tgtkey = self.currkey

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

    return (self.currkey, self._grouper(self.tgtkey, self.id))
def _grouper(self, tgtkey, id):
    while self.id is id and self.currkey == tgtkey:
        yield self.currvalue
        try:
            self.currvalue = next(self.it)
        except StopIteration:
            return
        self.currkey = self.keyfunc(self.currvalue)

```

`itertools.islice(iterable, stop)`

`itertools.islice(iterable, start, stop[, step])`

Make an iterator that returns selected elements from the iterable. If *start* is non-zero, then elements from the iterable are skipped until *start* is reached. Afterward, elements are returned consecutively unless *step* is set higher than one which results in items being skipped. If *stop* is `None`, then iteration continues until the iterator is exhausted, if at all; otherwise, it stops at the specified position. Unlike regular slicing, `islice()` does not support negative values for *start*, *stop*, or *step*. Can be used to extract related fields from data where the internal structure has been flattened (for example, a multi-line report may list a name field on every third line). Roughly equivalent to:

```

def islice(iterable, *args):
    # islice('ABCDEFGH', 2) --> A B
    # islice('ABCDEFGH', 2, 4) --> C D
    # islice('ABCDEFGH', 2, None) --> C D E F G
    # islice('ABCDEFGH', 0, None, 2) --> A C E G
    s = slice(*args)
    start, stop, step = s.start or 0, s.stop or sys.maxsize, s.step or 1
    it = iter(range(start, stop, step))
    try:
        nexti = next(it)
    except StopIteration:
        # Consume *iterable* up to the *start* position.
        for i, element in zip(range(start), iterable):
            pass
        return
    try:
        for i, element in enumerate(iterable):
            if i == nexti:
                yield element
                nexti = next(it)
    except StopIteration:
        # Consume to *stop*.
        for i, element in zip(range(i + 1, stop), iterable):
            pass

```

If *start* is `None`, then iteration starts at zero. If *step* is `None`, then the step defaults to one.

`itertools.permutations(iterable, r=None)`

Return successive *r* length permutations of elements in the *iterable*.

If *r* is not specified or is `None`, then *r* defaults to the length of the *iterable* and all possible full-length permutations are generated.

The permutation tuples are emitted in lexicographic ordering according to the order of the input *iterable*. So, if the input *iterable* is sorted, the combination tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. So if the input elements are unique, there will be no repeat values in each permutation.

Roughly equivalent to:

```
def permutations(iterable, r=None):
    # permutations('ABCD', 2) --> AB AC AD BA BC BD CA CB CD DA DB DC
    # permutations(range(3)) --> 012 021 102 120 201 210
    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    if r > n:
        return
    indices = list(range(n))
    cycles = list(range(n, n-r, -1))
    yield tuple(pool[i] for i in indices[:r])
    while n:
        for i in reversed(range(r)):
            cycles[i] -= 1
            if cycles[i] == 0:
                indices[i:] = indices[i+1:] + indices[i:i+1]
                cycles[i] = n - i
            else:
                j = cycles[i]
                indices[i], indices[-j] = indices[-j], indices[i]
                yield tuple(pool[i] for i in indices[:r])
                break
        else:
            return
```

The code for `permutations()` can be also expressed as a subsequence of `product()`, filtered to exclude entries with repeated elements (those from the same position in the input pool):

```
def permutations(iterable, r=None):
    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    for indices in product(range(n), repeat=r):
        if len(set(indices)) == r:
            yield tuple(pool[i] for i in indices)
```

The number of items returned is $n! / (n-r)!$ when $0 \leq r \leq n$ or zero when $r > n$.

`itertools.product(*iterables, repeat=1)`

Cartesian product of input iterables.

Roughly equivalent to nested for-loops in a generator expression. For example, `product(A, B)` returns the same as `((x,y) for x in A for y in B)`.

The nested loops cycle like an odometer with the rightmost element advancing on every iteration. This pattern creates a lexicographic ordering so that if the input's iterables are sorted, the product tuples are emitted in sorted order.

To compute the product of an iterable with itself, specify the number of repetitions with the optional `repeat` keyword argument. For example, `product(A, repeat=4)` means the same as `product(A, A, A, A)`.

This function is roughly equivalent to the following code, except that the actual implementation does not build up intermediate results in memory:

```
def product(*args, repeat=1):
    # product('ABCD', 'xy') --> Ax Ay Bx By Cx Cy Dx Dy
    # product(range(2), repeat=3) --> 000 001 010 011 100 101 110 111
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

pools = [tuple(pool) for pool in args] * repeat
result = [[]]
for pool in pools:
    result = [x+[y] for x in result for y in pool]
for prod in result:
    yield tuple(prod)

```

Before `product()` runs, it completely consumes the input iterables, keeping pools of values in memory to generate the products. Accordingly, it is only useful with finite inputs.

`itertools.repeat(object[, times])`

Make an iterator that returns *object* over and over again. Runs indefinitely unless the *times* argument is specified. Used as argument to `map()` for invariant parameters to the called function. Also used with `zip()` to create an invariant part of a tuple record.

Roughly equivalent to:

```

def repeat(object, times=None):
    # repeat(10, 3) --> 10 10 10
    if times is None:
        while True:
            yield object
    else:
        for i in range(times):
            yield object

```

A common use for `repeat` is to supply a stream of constant values to `map` or `zip`:

```

>>> list(map(pow, range(10), repeat(2)))
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]

```

`itertools.starmap(function, iterable)`

Make an iterator that computes the function using arguments obtained from the iterable. Used instead of `map()` when argument parameters are already grouped in tuples from a single iterable (the data has been «pre-zipped»). The difference between `map()` and `starmap()` parallels the distinction between `function(a,b)` and `function(*c)`. Roughly equivalent to:

```

def starmap(function, iterable):
    # starmap(pow, [(2,5), (3,2), (10,3)]) --> 32 9 1000
    for args in iterable:
        yield function(*args)

```

`itertools.takewhile(predicate, iterable)`

Make an iterator that returns elements from the iterable as long as the predicate is true. Roughly equivalent to:

```

def takewhile(predicate, iterable):
    # takewhile(lambda x: x<5, [1,4,6,4,1]) --> 1 4
    for x in iterable:
        if predicate(x):
            yield x
        else:
            break

```

`itertools.tee(iterable, n=2)`

Return *n* independent iterators from a single iterable.

The following Python code helps explain what *tee* does (although the actual implementation is more complex and uses only a single underlying FIFO queue).

Roughly equivalent to:

```
def tee(iterable, n=2):
    it = iter(iterable)
    dequeues = [collections.deque() for i in range(n)]
    def gen(mydeque):
        while True:
            if not mydeque:           # when the local deque is empty
                try:
                    newval = next(it) # fetch a new value and
                except StopIteration:
                    return
            for d in dequeues:        # load it to all the dequeues
                d.append(newval)
            yield mydeque.popleft()
    return tuple(gen(d) for d in dequeues)
```

Once *tee()* has made a split, the original *iterable* should not be used anywhere else; otherwise, the *iterable* could get advanced without the tee objects being informed.

tee iterators are not threadsafe. A *RuntimeError* may be raised when using simultaneously iterators returned by the same *tee()* call, even if the original *iterable* is threadsafe.

This *itertools* may require significant auxiliary storage (depending on how much temporary data needs to be stored). In general, if one iterator uses most or all of the data before another iterator starts, it is faster to use *list()* instead of *tee()*.

itertools.zip_longest (*iterables, fillvalue=None)

Make an iterator that aggregates elements from each of the iterables. If the iterables are of uneven length, missing values are filled-in with *fillvalue*. Iteration continues until the longest iterable is exhausted. Roughly equivalent to:

```
def zip_longest(*args, fillvalue=None):
    # zip_longest('ABCD', 'xy', fillvalue='-') --> Ax By C- D-
    iterators = [iter(it) for it in args]
    num_active = len(iterators)
    if not num_active:
        return
    while True:
        values = []
        for i, it in enumerate(iterators):
            try:
                value = next(it)
            except StopIteration:
                num_active -= 1
                if not num_active:
                    return
                iterators[i] = repeat(fillvalue)
                value = fillvalue
        values.append(value)
        yield tuple(values)
```

If one of the iterables is potentially infinite, then the *zip_longest()* function should be wrapped with something that limits the number of calls (for example *islice()* or *takewhile()*). If not specified, *fillvalue* defaults to *None*.

10.1.2 Itertools Recipes

This section shows recipes for creating an extended toolset using the existing itertools as building blocks.

Substantially all of these recipes and many, many others can be installed from the [more-itertools project](#) found on the Python Package Index:

```
pip install more-itertools
```

The extended tools offer the same high performance as the underlying toolset. The superior memory performance is kept by processing elements one at a time rather than bringing the whole iterable into memory all at once. Code volume is kept small by linking the tools together in a functional style which helps eliminate temporary variables. High speed is retained by preferring «vectorized» building blocks over the use of for-loops and *generators* which incur interpreter overhead.

```
def take(n, iterable):
    "Return first n items of the iterable as a list"
    return list(islice(iterable, n))

def prepend(value, iterator):
    "Prepend a single value in front of an iterator"

        result.append(pool[-1-n])
    return tuple(result)

```

10.2 functools — Higher-order functions and operations on callable objects

Source code: [Lib/functools.py](#)

The `functools` module is for higher-order functions: functions that act on or return other functions. In general, any callable object can be treated as a function for the purposes of this module.

The `functools` module defines the following functions:

`@functools.cache` (*user_function*)

Simple lightweight unbounded function cache. Sometimes called «memoize».

Returns the same as `lru_cache(maxsize=None)`, creating a thin wrapper around a dictionary lookup for the function arguments. Because it never needs to evict old values, this is smaller and faster than `lru_cache()` with a size limit.

For example:

```

@cache
def factorial(n):
    return n * factorial(n-1) if n else 1

>>> factorial(10)      # no previously cached result, makes 11 recursive calls
3628800
>>> factorial(5)       # just looks up cached value result
120
>>> factorial(12)      # makes two new recursive calls, the other 10 are cached
479001600

```

Νέο στην έκδοση 3.9.

`@functools.cached_property` (*func*)

Transform a method of a class into a property whose value is computed once and then cached as a normal attribute for the life of the instance. Similar to `property()`, with the addition of caching. Useful for expensive computed properties of instances that are otherwise effectively immutable.

Example:

```
class DataSet:

    def __init__(self, sequence_of_numbers):
        self._data = tuple(sequence_of_numbers)

    @cached_property
    def stdev(self):
        return statistics.stdev(self._data)
```

The mechanics of `cached_property()` are somewhat different from `property()`. A regular property blocks attribute writes unless a setter is defined. In contrast, a `cached_property` allows writes.

The `cached_property` decorator only runs on lookups and only when an attribute of the same name doesn't exist. When it does run, the `cached_property` writes to the attribute with the same name. Subsequent attribute reads and writes take precedence over the `cached_property` method and it works like a normal attribute.

The cached value can be cleared by deleting the attribute. This allows the `cached_property` method to run again.

Note, this decorator interferes with the operation of **PEP 412** key-sharing dictionaries. This means that instance dictionaries can take more space than usual.

Also, this decorator requires that the `__dict__` attribute on each instance be a mutable mapping. This means it will not work with some types, such as metaclasses (since the `__dict__` attributes on type instances are read-only proxies for the class namespace), and those that specify `__slots__` without including `__dict__` as one of the defined slots (as such classes don't provide a `__dict__` attribute at all).

If a mutable mapping is not available or if space-efficient key sharing is desired, an effect similar to `cached_property()` can be achieved by a stacking `property()` on top of `cache()`:

```
class DataSet:

    def __init__(self, sequence_of_numbers):
        self._data = sequence_of_numbers

    @property
    @cache
    def stdev(self):
        return statistics.stdev(self._data)
```

Νέο στην έκδοση 3.8.

`functools.cmp_to_key(func)`

Transform an old-style comparison function to a *key function*. Used with tools that accept key functions (such as `sorted()`, `min()`, `max()`, `heapq.nlargest()`, `heapq.nsmallest()`, `itertools.groupby()`). This function is primarily used as a transition tool for programs being converted from Python 2 which supported the use of comparison functions.

A comparison function is any callable that accept two arguments, compares them, and returns a negative number for less-than, zero for equality, or a positive number for greater-than. A key function is a callable that accepts one argument and returns another value to be used as the sort key.

Example:

```
sorted(iterable, key=cmp_to_key(locale.strcoll)) # locale-aware sort order
```

For sorting examples and a brief sorting tutorial, see `sortinghowto`.

Νέο στην έκδοση 3.2.

`@functools.lru_cache(user_function)`

`@functools.lru_cache (maxsize=128, typed=False)`

Decorator to wrap a function with a memoizing callable that saves up to the *maxsize* most recent calls. It can save time when an expensive or I/O bound function is periodically called with the same arguments.

Since a dictionary is used to cache results, the positional and keyword arguments to the function must be hashable.

Distinct argument patterns may be considered to be distinct calls with separate cache entries. For example, $f(a=1, b=2)$ and $f(b=2, a=1)$ differ in their keyword argument order and may have two separate cache entries.

If *user_function* is specified, it must be a callable. This allows the *lru_cache* decorator to be applied directly to a user function, leaving the *maxsize* at its default value of 128:

```
@lru_cache
def count_vowels(sentence):
    sentence = sentence.casefold()
    return sum(sentence.count(vowel) for vowel in 'aeiou')
```

If *maxsize* is set to None, the LRU feature is disabled and the cache can grow without bound.

If *typed* is set to true, function arguments of different types will be cached separately. For example, $f(3)$ and $f(3.0)$ will be treated as distinct calls with distinct results.

The wrapped function is instrumented with a *cache_parameters()* function that returns a new *dict* showing the values for *maxsize* and *typed*. This is for information purposes only. Mutating the values has no effect.

To help measure the effectiveness of the cache and tune the *maxsize* parameter, the wrapped function is instrumented with a *cache_info()* function that returns a *named tuple* showing *hits*, *misses*, *maxsize* and *currsize*. In a multi-threaded environment, the hits and misses are approximate.

The decorator also provides a *cache_clear()* function for clearing or invalidating the cache.

The original underlying function is accessible through the *__wrapped__* attribute. This is useful for introspection, for bypassing the cache, or for rewrapping the function with a different cache.

An LRU (least recently used) cache works best when the most recent calls are the best predictors of upcoming calls (for example, the most popular articles on a news server tend to change each day). The cache's size limit assures that the cache does not grow without bound on long-running processes such as web servers.

In general, the LRU cache should only be used when you want to reuse previously computed values. Accordingly, it doesn't make sense to cache functions with side-effects, functions that need to create distinct mutable objects on each call, or impure functions such as *time()* or *random()*.

Example of an LRU cache for static web content:

```
@lru_cache(maxsize=32)
def get_pep(num):
    'Retrieve text of a Python Enhancement Proposal'
    resource = 'https://www.python.org/dev/peps/pep-%04d/' % num
    try:
        with urllib.request.urlopen(resource) as s:
            return s.read()
    except urllib.error.HTTPError:
        return 'Not Found'

>>> for n in 8, 290, 308, 320, 8, 218, 320, 279, 289, 320, 9991:
...     pep = get_pep(n)
...     print(n, len(pep))

>>> get_pep.cache_info()
CacheInfo(hits=3, misses=8, maxsize=32, currsize=8)
```

Example of efficiently computing Fibonacci numbers using a cache to implement a dynamic programming technique:

```
@lru_cache(maxsize=None)
def fib(n):
    if n < 2:
        return n
    return fib(n-1) + fib(n-2)

>>> [fib(n) for n in range(16)]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610]

>>> fib.cache_info()
CacheInfo(hits=28, misses=16, maxsize=None, currsize=16)
```

Νέο στην έκδοση 3.2.

Άλλαξε στην έκδοση 3.3: Added the *typed* option.

Άλλαξε στην έκδοση 3.8: Added the *user_function* option.

Νέο στην έκδοση 3.9: Added the function `cache_parameters()`

@functools.total_ordering

Given a class defining one or more rich comparison ordering methods, this class decorator supplies the rest. This simplifies the effort involved in specifying all of the possible rich comparison operations:

The class must define one of `__lt__()`, `__le__()`, `__gt__()`, or `__ge__()`. In addition, the class should supply an `__eq__()` method.

For example:

```
@total_ordering
class Student:
    def _is_valid_operand(self, other):
        return (hasattr(other, "lastname") and
                hasattr(other, "firstname"))
    def __eq__(self, other):
        if not self._is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()) ==
                (other.lastname.lower(), other.firstname.lower()))
    def __lt__(self, other):
        if not self._is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()) <
                (other.lastname.lower(), other.firstname.lower()))
```

Σημείωση: While this decorator makes it easy to create well behaved totally ordered types, it *does* come at the cost of slower execution and more complex stack traces for the derived comparison methods. If performance benchmarking indicates this is a bottleneck for a given application, implementing all six rich comparison methods instead is likely to provide an easy speed boost.

Νέο στην έκδοση 3.2.

Άλλαξε στην έκδοση 3.4: Returning `NotImplemented` from the underlying comparison function for unrecognised types is now supported.

`functools.partial(func, /, *args, **keywords)`

Return a new *partial object* which when called will behave like *func* called with the positional arguments *args* and keyword arguments *keywords*. If more arguments are supplied to the call, they are appended to *args*. If additional keyword arguments are supplied, they extend and override *keywords*. Roughly equivalent to:

```
def partial(func, /, *args, **keywords):
    def newfunc(*fargs, **fkeywords):
        newkeywords = {**keywords, **fkeywords}
        return func(*args, *fargs, **newkeywords)
    newfunc.func = func
    newfunc.args = args
    newfunc.keywords = keywords
    return newfunc
```

The *partial()* is used for partial function application which «freezes» some portion of a function's arguments and/or keywords resulting in a new object with a simplified signature. For example, *partial()* can be used to create a callable that behaves like the *int()* function where the *base* argument defaults to two:

```
>>> from functools import partial
>>> basetwo = partial(int, base=2)
>>> basetwo.__doc__ = 'Convert base 2 string to an int.'
>>> basetwo('10010')
18
```

`class functools.partialmethod(func, /, *args, **keywords)`

Return a new *partialmethod* descriptor which behaves like *partial* except that it is designed to be used as a method definition rather than being directly callable.

func must be a *descriptor* or a callable (objects which are both, like normal functions, are handled as descriptors).

When *func* is a descriptor (such as a normal Python function, *classmethod()*, *staticmethod()*, *abstractmethod()* or another instance of *partialmethod*), calls to `__get__` are delegated to the underlying descriptor, and an appropriate *partial object* returned as the result.

When *func* is a non-descriptor callable, an appropriate bound method is created dynamically. This behaves like a normal Python function when used as a method: the *self* argument will be inserted as the first positional argument, even before the *args* and *keywords* supplied to the *partialmethod* constructor.

Example:

```
>>> class Cell:
...     def __init__(self):
...         self._alive = False
...     @property
...     def alive(self):
...         return self._alive
...     def set_state(self, state):
...         self._alive = bool(state)
...     set_alive = partialmethod(set_state, True)
...     set_dead = partialmethod(set_state, False)
...
>>> c = Cell()
>>> c.alive
False
>>> c.set_alive()
>>> c.alive
True
```

Νέο στην έκδοση 3.4.

`functools.reduce(function, iterable[, initializer])`

Apply *function* of two arguments cumulatively to the items of *iterable*, from left to right, so as to reduce the iterable to a single value. For example, `reduce(lambda x, y: x+y, [1, 2, 3, 4, 5])` calculates `(((1+2)+3)+4)+5`. The left argument, *x*, is the accumulated value and the right argument, *y*, is the update value from the *iterable*. If the optional *initializer* is present, it is placed before the items of the iterable in the calculation, and serves as a default when the iterable is empty. If *initializer* is not given and *iterable* contains only one item, the first item is returned.

Roughly equivalent to:

```
def reduce(function, iterable, initializer=None):
    it = iter(iterable)
    if initializer is None:
        value = next(it)
    else:
        value = initializer
    for element in it:
        value = function(value, element)
    return value
```

See `itertools.accumulate()` for an iterator that yields all intermediate values.

`@functools.singledispatch`

Transform a function into a *single-dispatch generic function*.

To define a generic function, decorate it with the `@singledispatch` decorator. When defining a function using `@singledispatch`, note that the dispatch happens on the type of the first argument:

```
>>> from functools import singledispatch
>>> @singledispatch
... def fun(arg, verbose=False):
...     if verbose:
...         print("Let me just say,", end=" ")
...     print(arg)
```

To add overloaded implementations to the function, use the `register()` attribute of the generic function, which can be used as a decorator. For functions annotated with types, the decorator will infer the type of the first argument automatically:

```
>>> @fun.register
... def _(arg: int, verbose=False):
...     if verbose:
...         print("Strength in numbers, eh?", end=" ")
...     print(arg)
...
>>> @fun.register
... def _(arg: list, verbose=False):
...     if verbose:
...         print("Enumerate this:")
...     for i, elem in enumerate(arg):
...         print(i, elem)
```

For code which doesn't use type annotations, the appropriate type argument can be passed explicitly to the decorator itself:

```
>>> @fun.register(complex)
... def _(arg, verbose=False):
...     if verbose:
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
...     print("Better than complicated.", end=" ")
...     print(arg.real, arg.imag)
...
```

To enable registering *lambdas* and pre-existing functions, the `register()` attribute can also be used in a functional form:

```
>>> def nothing(arg, verbose=False):
...     print("Nothing.")
...
>>> fun.register(type(None), nothing)
```

The `register()` attribute returns the undecorated function. This enables decorator stacking, *pickling*, and the creation of unit tests for each variant independently:

```
>>> @fun.register(float)
... @fun.register(Decimal)
... def fun_num(arg, verbose=False):
...     if verbose:
...         print("Half of your number:", end=" ")
...     print(arg / 2)
...
>>> fun_num is fun
False
```

When called, the generic function dispatches on the type of the first argument:

```
>>> fun("Hello, world.")
Hello, world.
>>> fun("test.", verbose=True)
Let me just say, test.
>>> fun(42, verbose=True)
Strength in numbers, eh? 42
>>> fun(['spam', 'spam', 'eggs', 'spam'], verbose=True)
Enumerate this:
0 spam
1 spam
2 eggs
3 spam
>>> fun(None)
Nothing.
>>> fun(1.23)
0.615
```

Where there is no registered implementation for a specific type, its method resolution order is used to find a more generic implementation. The original function decorated with `@singledispatch` is registered for the base *object* type, which means it is used if no better implementation is found.

If an implementation is registered to an *abstract base class*, virtual subclasses of the base class will be dispatched to that implementation:

```
>>> from collections.abc import Mapping
>>> @fun.register
... def _(arg: Mapping, verbose=False):
...     if verbose:
...         print("Keys & Values")
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
...     for key, value in arg.items():
...         print(key, "=>", value)
...
>>> fun({"a": "b"})
a => b
```

To check which implementation the generic function will choose for a given type, use the `dispatch()` attribute:

```
>>> fun.dispatch(float)
<function fun_num at 0x1035a2840>
>>> fun.dispatch(dict) # note: default implementation
<function fun at 0x103fe0000>
```

To access all registered implementations, use the read-only registry attribute:

```
>>> fun.registry.keys()
dict_keys([<class 'NoneType'>, <class 'int'>, <class 'object'>,
          <class 'decimal.Decimal'>, <class 'list'>,
          <class 'float'>])
>>> fun.registry[float]
<function fun_num at 0x1035a2840>
>>> fun.registry[object]
<function fun at 0x103fe0000>
```

Νέο στην έκδοση 3.4.

Άλλαξε στην έκδοση 3.7: The `register()` attribute now supports using type annotations.

class `functools.singledispatchmethod` (*func*)

Transform a method into a *single-dispatch generic function*.

To define a generic method, decorate it with the `@singledispatchmethod` decorator. When defining a function using `@singledispatchmethod`, note that the dispatch happens on the type of the first non-*self* or non-*cls* argument:

```
class Negator:
    @singledispatchmethod
    def neg(self, arg):
        raise NotImplementedError("Cannot negate a")

    @neg.register
    def _(self, arg: int):
        return -arg

    @neg.register
    def _(self, arg: bool):
        return not arg
```

`@singledispatchmethod` supports nesting with other decorators such as `@classmethod`. Note that to allow for `dispatcher.register`, `singledispatchmethod` must be the *outer most* decorator. Here is the `Negator` class with the `neg` methods bound to the class, rather than an instance of the class:

```
class Negator:
    @singledispatchmethod
    @classmethod
    def neg(cls, arg):
        raise NotImplementedError("Cannot negate a")
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

@neg.register
@classmethod
def _(cls, arg: int):
    return -arg

@neg.register
@classmethod
def _(cls, arg: bool):
    return not arg

```

The same pattern can be used for other similar decorators: `@staticmethod`, `@abstractmethod`, and others.

Νέο στην έκδοση 3.8.

`functools.update_wrapper(wrapper, wrapped, assigned=WRAPPER_ASSIGNMENTS, updated=WRAPPER_UPDATES)`

Update a *wrapper* function to look like the *wrapped* function. The optional arguments are tuples to specify which attributes of the original function are assigned directly to the matching attributes on the wrapper function and which attributes of the wrapper function are updated with the corresponding attributes from the original function. The default values for these arguments are the module level constants `WRAPPER_ASSIGNMENTS` (which assigns to the wrapper function's `__module__`, `__name__`, `__qualname__`, `__annotations__` and `__doc__`, the documentation string) and `WRAPPER_UPDATES` (which updates the wrapper function's `__dict__`, i.e. the instance dictionary).

To allow access to the original function for introspection and other purposes (e.g. bypassing a caching decorator such as `lru_cache()`), this function automatically adds a `__wrapped__` attribute to the wrapper that refers to the function being wrapped.

The main intended use for this function is in *decorator* functions which wrap the decorated function and return the wrapper. If the wrapper function is not updated, the metadata of the returned function will reflect the wrapper definition rather than the original function definition, which is typically less than helpful.

`update_wrapper()` may be used with callables other than functions. Any attributes named in *assigned* or *updated* that are missing from the object being wrapped are ignored (i.e. this function will not attempt to set them on the wrapper function). `AttributeError` is still raised if the wrapper function itself is missing any attributes named in *updated*.

Νέο στην έκδοση 3.2: Automatic addition of the `__wrapped__` attribute.

Νέο στην έκδοση 3.2: Copying of the `__annotations__` attribute by default.

Άλλαξε στην έκδοση 3.2: Missing attributes no longer trigger an `AttributeError`.

Άλλαξε στην έκδοση 3.4: The `__wrapped__` attribute now always refers to the wrapped function, even if that function defined a `__wrapped__` attribute. (see [bpo-17482](#))

`@functools.wraps(wrapped, assigned=WRAPPER_ASSIGNMENTS, updated=WRAPPER_UPDATES)`

This is a convenience function for invoking `update_wrapper()` as a function decorator when defining a wrapper function. It is equivalent to `partial(update_wrapper, wrapped=wrapped, assigned=assigned, updated=updated)`. For example:

```

>>> from functools import wraps
>>> def my_decorator(f):
...     @wraps(f)
...     def wrapper(*args, **kwargs):
...         print('Calling decorated function')
...         return f(*args, **kwargs)
...     return wrapper

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

...
>>> @my_decorator
... def example():
...     """Docstring"""
...     print('Called example function')
...
>>> example()
Calling decorated function
Called example function
>>> example.__name__
'example'
>>> example.__doc__
'Docstring'

```

Without the use of this decorator factory, the name of the example function would have been 'wrapper', and the docstring of the original `example()` would have been lost.

10.2.1 partial Objects

partial objects are callable objects created by *partial()*. They have three read-only attributes:

`partial.func`

A callable object or function. Calls to the *partial* object will be forwarded to *func* with new arguments and keywords.

`partial.args`

The leftmost positional arguments that will be prepended to the positional arguments provided to a *partial* object call.

`partial.keywords`

The keyword arguments that will be supplied when the *partial* object is called.

partial objects are like function objects in that they are callable, weak referencable, and can have attributes. There are some important differences. For instance, the `__name__` and `__doc__` attributes are not created automatically. Also, *partial* objects defined in classes behave like static methods and do not transform into bound methods during instance attribute look-up.

10.3 operator — Standard operators as functions

Source code: [Lib/operator.py](#)

The *operator* module exports a set of efficient functions corresponding to the intrinsic operators of Python. For example, `operator.add(x, y)` is equivalent to the expression `x+y`. Many function names are those used for special methods, without the double underscores. For backward compatibility, many of these have a variant with the double underscores kept. The variants without the double underscores are preferred for clarity.

The functions fall into categories that perform object comparisons, logical operations, mathematical operations and sequence operations.

The object comparison functions are useful for all objects, and are named after the rich comparison operators they support:

`operator.lt(a, b)`

```
operator.le(a, b)
operator.eq(a, b)
operator.ne(a, b)
operator.ge(a, b)
operator.gt(a, b)
operator.__lt__(a, b)
operator.__le__(a, b)
operator.__eq__(a, b)
operator.__ne__(a, b)
operator.__ge__(a, b)
operator.__gt__(a, b)
```

Perform «rich comparisons» between *a* and *b*. Specifically, `lt(a, b)` is equivalent to `a < b`, `le(a, b)` is equivalent to `a <= b`, `eq(a, b)` is equivalent to `a == b`, `ne(a, b)` is equivalent to `a != b`, `gt(a, b)` is equivalent to `a > b` and `ge(a, b)` is equivalent to `a >= b`. Note that these functions can return any value, which may or may not be interpretable as a Boolean value. See comparisons for more information about rich comparisons.

The logical operations are also generally applicable to all objects, and support truth tests, identity tests, and boolean operations:

```
operator.not_(obj)
operator.__not__(obj)
```

Return the outcome of `not obj`. (Note that there is no `__not__()` method for object instances; only the interpreter core defines this operation. The result is affected by the `__bool__()` and `__len__()` methods.)

```
operator.truth(obj)
```

Return `True` if *obj* is true, and `False` otherwise. This is equivalent to using the `bool` constructor.

```
operator.is_(a, b)
```

Return `a is b`. Tests object identity.

```
operator.is_not(a, b)
```

Return `a is not b`. Tests object identity.

The mathematical and bitwise operations are the most numerous:

```
operator.abs(obj)
operator.__abs__(obj)
Return the absolute value of obj.
```

```
operator.add(a, b)
operator.__add__(a, b)
Return a + b, for a and b numbers.
```

```
operator.and_(a, b)
operator.__and__(a, b)
Return the bitwise and of a and b.
```

```
operator.floordiv(a, b)
operator.__floordiv__(a, b)
Return a // b.
```

```
operator.index(a)
operator.__index__(a)
Return a converted to an integer. Equivalent to a.__index__().
```

```
operator.inv(obj)
operator.invert(obj)
operator.__inv__(obj)
```

`operator.__invert__ (obj)`

Return the bitwise inverse of the number *obj*. This is equivalent to `~obj`.

`operator.lshift (a, b)`

`operator.__lshift__ (a, b)`

Return *a* shifted left by *b*.

`operator.mod (a, b)`

`operator.__mod__ (a, b)`

Return *a* % *b*.

`operator.mul (a, b)`

`operator.__mul__ (a, b)`

Return *a* * *b*, for *a* and *b* numbers.

`operator.matmul (a, b)`

`operator.__matmul__ (a, b)`

Return *a* @ *b*.

Νέο στην έκδοση 3.5.

`operator.neg (obj)`

`operator.__neg__ (obj)`

Return *obj* negated (`-obj`).

`operator.or_ (a, b)`

`operator.__or__ (a, b)`

Return the bitwise or of *a* and *b*.

`operator.pos (obj)`

`operator.__pos__ (obj)`

Return *obj* positive (`+obj`).

`operator.pow (a, b)`

`operator.__pow__ (a, b)`

Return *a* ** *b*, for *a* and *b* numbers.

`operator.rshift (a, b)`

`operator.__rshift__ (a, b)`

Return *a* shifted right by *b*.

`operator.sub (a, b)`

`operator.__sub__ (a, b)`

Return *a* - *b*.

`operator.truediv (a, b)`

`operator.__truediv__ (a, b)`

Return *a* / *b* where `2/3` is `.66` rather than `0`. This is also known as «true» division.

`operator.xor (a, b)`

`operator.__xor__ (a, b)`

Return the bitwise exclusive or of *a* and *b*.

Operations which work with sequences (some of them with mappings too) include:

`operator.concat (a, b)`

`operator.__concat__ (a, b)`

Return *a* + *b* for *a* and *b* sequences.

`operator.contains (a, b)`

`operator.__contains__ (a, b)`

Return the outcome of the test `b in a`. Note the reversed operands.

`operator.countOf(a, b)`

Return the number of occurrences of *b* in *a*.

`operator.delitem(a, b)`

`operator.__delitem__(a, b)`

Remove the value of *a* at index *b*.

`operatorgetitem(a, b)`

`operator.__getitem__(a, b)`

Return the value of *a* at index *b*.

`operator.indexOf(a, b)`

Return the index of the first of occurrence of *b* in *a*.

`operator.setitem(a, b, c)`

`operator.__setitem__(a, b, c)`

Set the value of *a* at index *b* to *c*.

`operator.length_hint(obj, default=0)`

Return an estimated length for the object *o*. First try to return its actual length, then an estimate using `object.__length_hint__()`, and finally return the default value.

Νέο στην έκδοση 3.4.

The `operator` module also defines tools for generalized attribute and item lookups. These are useful for making fast field extractors as arguments for `map()`, `sorted()`, `itertools.groupby()`, or other functions that expect a function argument.

`operator.attrgetter(attr)`

`operator.attrgetter(*attrs)`

Return a callable object that fetches *attr* from its operand. If more than one attribute is requested, returns a tuple of attributes. The attribute names can also contain dots. For example:

- After `f = attrgetter('name')`, the call `f(b)` returns `b.name`.
- After `f = attrgetter('name', 'date')`, the call `f(b)` returns `(b.name, b.date)`.
- After `f = attrgetter('name.first', 'name.last')`, the call `f(b)` returns `(b.name.first, b.name.last)`.

Equivalent to:

```
def attrgetter(*items):
    if any(not isinstance(item, str) for item in items):
        raise TypeError('attribute name must be a string')
    if len(items) == 1:
        attr = items[0]
        def g(obj):
            return resolve_attr(obj, attr)
    else:
        def g(obj):
            return tuple(resolve_attr(obj, attr) for attr in items)
    return g

def resolve_attr(obj, attr):
    for name in attr.split("."):
        obj = getattr(obj, name)
    return obj
```

`operator.itemgetter(item)`

`operator.itemgetter(*items)`

Return a callable object that fetches *item* from its operand using the operand's `__getitem__()` method. If multiple items are specified, returns a tuple of lookup values. For example:

- After `f = itemgetter(2)`, the call `f(r)` returns `r[2]`.
- After `g = itemgetter(2, 5, 3)`, the call `g(r)` returns `(r[2], r[5], r[3])`.

Equivalent to:

```
def itemgetter(*items):
    if len(items) == 1:
        item = items[0]
        def g(obj):
            return obj[item]
    else:
        def g(obj):
            return tuple(obj[item] for item in items)
    return g
```

The items can be any type accepted by the operand's `__getitem__()` method. Dictionaries accept any hashable value. Lists, tuples, and strings accept an index or a slice:

```
>>> itemgetter(1)('ABCDEFGH')
'B'
>>> itemgetter(1, 3, 5)('ABCDEFGH')
('B', 'D', 'F')
>>> itemgetter(slice(2, None))('ABCDEFGH')
'CDEFGH'
>>> soldier = dict(rank='captain', name='dotterbart')
>>> itemgetter('rank')(soldier)
'captain'
```

Example of using `itemgetter()` to retrieve specific fields from a tuple record:

```
>>> inventory = [('apple', 3), ('banana', 2), ('pear', 5), ('orange', 1)]
>>> getcount = itemgetter(1)
>>> list(map(getcount, inventory))
[3, 2, 5, 1]
>>> sorted(inventory, key=getcount)
[('orange', 1), ('banana', 2), ('apple', 3), ('pear', 5)]
```

`operator.methodcaller(name, /, *args, **kwargs)`

Return a callable object that calls the method *name* on its operand. If additional arguments and/or keyword arguments are given, they will be given to the method as well. For example:

- After `f = methodcaller('name')`, the call `f(b)` returns `b.name()`.
- After `f = methodcaller('name', 'foo', bar=1)`, the call `f(b)` returns `b.name('foo', bar=1)`.

Equivalent to:

```
def methodcaller(name, /, *args, **kwargs):
    def caller(obj):
        return getattr(obj, name)(*args, **kwargs)
    return caller
```

10.3.1 Mapping Operators to Functions

This table shows how abstract operations correspond to operator symbols in the Python syntax and the functions in the `operator` module.

| Operation | Syntax | Function |
|-----------------------|--------------------------------|--|
| Addition | <code>a + b</code> | <code>add(a, b)</code> |
| Concatenation | <code>seq1 + seq2</code> | <code>concat(seq1, seq2)</code> |
| Containment Test | <code>obj in seq</code> | <code>contains(seq, obj)</code> |
| Division | <code>a / b</code> | <code>truediv(a, b)</code> |
| Division | <code>a // b</code> | <code>floordiv(a, b)</code> |
| Bitwise And | <code>a & b</code> | <code>and_(a, b)</code> |
| Bitwise Exclusive Or | <code>a ^ b</code> | <code>xor(a, b)</code> |
| Bitwise Inversion | <code>~ a</code> | <code>invert(a)</code> |
| Bitwise Or | <code>a b</code> | <code>or_(a, b)</code> |
| Exponentiation | <code>a ** b</code> | <code>pow(a, b)</code> |
| Identity | <code>a is b</code> | <code>is_(a, b)</code> |
| Identity | <code>a is not b</code> | <code>is_not(a, b)</code> |
| Indexed Assignment | <code>obj[k] = v</code> | <code>setitem(obj, k, v)</code> |
| Indexed Deletion | <code>del obj[k]</code> | <code>delitem(obj, k)</code> |
| Indexing | <code>obj[k]</code> | <code>getitem(obj, k)</code> |
| Left Shift | <code>a << b</code> | <code>lshift(a, b)</code> |
| Modulo | <code>a % b</code> | <code>mod(a, b)</code> |
| Multiplication | <code>a * b</code> | <code>mul(a, b)</code> |
| Matrix Multiplication | <code>a @ b</code> | <code>matmul(a, b)</code> |
| Negation (Arithmetic) | <code>- a</code> | <code>neg(a)</code> |
| Negation (Logical) | <code>not a</code> | <code>not_(a)</code> |
| Positive | <code>+ a</code> | <code>pos(a)</code> |
| Right Shift | <code>a >> b</code> | <code>rshift(a, b)</code> |
| Slice Assignment | <code>seq[i:j] = values</code> | <code>setitem(seq, slice(i, j), values)</code> |
| Slice Deletion | <code>del seq[i:j]</code> | <code>delitem(seq, slice(i, j))</code> |
| Slicing | <code>seq[i:j]</code> | <code>getitem(seq, slice(i, j))</code> |
| String Formatting | <code>s % obj</code> | <code>mod(s, obj)</code> |
| Subtraction | <code>a - b</code> | <code>sub(a, b)</code> |
| Truth Test | <code>obj</code> | <code>truth(obj)</code> |
| Ordering | <code>a < b</code> | <code>lt(a, b)</code> |
| Ordering | <code>a <= b</code> | <code>le(a, b)</code> |
| Equality | <code>a == b</code> | <code>eq(a, b)</code> |
| Difference | <code>a != b</code> | <code>ne(a, b)</code> |
| Ordering | <code>a >= b</code> | <code>ge(a, b)</code> |
| Ordering | <code>a > b</code> | <code>gt(a, b)</code> |

10.3.2 In-place Operators

Many operations have an «in-place» version. Listed below are functions providing a more primitive access to in-place operators than the usual syntax does; for example, the *statement* `x += y` is equivalent to `x = operator.iadd(x, y)`. Another way to put it is to say that `z = operator.iadd(x, y)` is equivalent to the compound statement `z = x; z += y`.

In those examples, note that when an in-place method is called, the computation and assignment are performed in two separate steps. The in-place functions listed below only do the first step, calling the in-place method. The second step, assignment, is not handled.

For immutable targets such as strings, numbers, and tuples, the updated value is computed, but not assigned back to the input variable:

```
>>> a = 'hello'
>>> iadd(a, ' world')
'hello world'
>>> a
'hello'
```

For mutable targets such as lists and dictionaries, the in-place method will perform the update, so no subsequent assignment is necessary:

```
>>> s = ['h', 'e', 'l', 'l', 'o']
>>> iadd(s, [' ', 'w', 'o', 'r', 'l', 'd'])
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
>>> s
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
```

```
operator.iadd(a, b)
operator.__iadd__(a, b)
    a = iadd(a, b) is equivalent to a += b.
```

```
operator.iand(a, b)
operator.__iand__(a, b)
    a = iand(a, b) is equivalent to a &= b.
```

```
operator.iconcat(a, b)
operator.__iconcat__(a, b)
    a = iconcat(a, b) is equivalent to a += b for a and b sequences.
```

```
operator.ifloordiv(a, b)
operator.__ifloordiv__(a, b)
    a = ifloordiv(a, b) is equivalent to a //= b.
```

```
operator.ilshift(a, b)
operator.__ilshift__(a, b)
    a = ilshift(a, b) is equivalent to a <<= b.
```

```
operator.imod(a, b)
operator.__imod__(a, b)
    a = imod(a, b) is equivalent to a %= b.
```

```
operator.imul(a, b)
operator.__imul__(a, b)
    a = imul(a, b) is equivalent to a *= b.
```

```
operator.imatmul(a, b)
operator.__imatmul__(a, b)
    a = imatmul(a, b) is equivalent to a @= b.
```

Νέο στην έκδοση 3.5.

`operator.ior(a, b)`

`operator.__ior__(a, b)`

`a = ior(a, b)` is equivalent to `a |= b`.

`operator.ipow(a, b)`

`operator.__ipow__(a, b)`

`a = ipow(a, b)` is equivalent to `a **= b`.

`operator.irshift(a, b)`

`operator.__irshift__(a, b)`

`a = irshift(a, b)` is equivalent to `a >>= b`.

`operator.isub(a, b)`

`operator.__isub__(a, b)`

`a = isub(a, b)` is equivalent to `a -= b`.

`operator.itruediv(a, b)`

`operator.__itruediv__(a, b)`

`a = itrueidiv(a, b)` is equivalent to `a /= b`.

`operator.ixor(a, b)`

`operator.__ixor__(a, b)`

`a = ixor(a, b)` is equivalent to `a ^= b`.

File and Directory Access

The modules described in this chapter deal with disk files and directories. For example, there are modules for reading the properties of files, manipulating paths in a portable way, and creating temporary files. The full list of modules in this chapter is:

11.1 `pathlib` — Object-oriented filesystem paths

Νέο στην έκδοση 3.4.

Source code: [Lib/pathlib.py](#)

This module offers classes representing filesystem paths with semantics appropriate for different operating systems. Path classes are divided between *pure paths*, which provide purely computational operations without I/O, and *concrete paths*, which inherit from pure paths but also provide I/O operations.

If you've never used this module before or just aren't sure which class is right for your task, `Path` is most likely what you need. It instantiates a *concrete path* for the platform the code is running on.

Pure paths are useful in some special cases; for example:

1. If you want to manipulate Windows paths on a Unix machine (or vice versa). You cannot instantiate a `WindowsPath` when running on Unix, but you can instantiate `PureWindowsPath`.
2. You want to make sure that your code only manipulates paths without actually accessing the OS. In this case, instantiating one of the pure classes may be useful since those simply don't have any OS-accessing operations.

Δείτε επίσης:

PEP 428: The pathlib module – object-oriented filesystem paths.

Δείτε επίσης:

For low-level path manipulation on strings, you can also use the `os.path` module.

11.1.1 Basic use

Importing the main class:

```
>>> from pathlib import Path
```

Listing subdirectories:

```
>>> p = Path('.')
>>> [x for x in p.iterdir() if x.is_dir()]
[PosixPath('.hg'), PosixPath('docs'), PosixPath('dist'),
 PosixPath('__pycache__'), PosixPath('build')]
```

Listing Python source files in this directory tree:

```
>>> list(p.glob('**/*.py'))
[PosixPath('test_pathlib.py'), PosixPath('setup.py'),
 PosixPath('pathlib.py'), PosixPath('docs/conf.py'),
 PosixPath('build/lib/pathlib.py')]
```

Navigating inside a directory tree:

```
>>> p = Path('/etc')
>>> q = p / 'init.d' / 'reboot'
>>> q
PosixPath('/etc/init.d/reboot')
>>> q.resolve()
PosixPath('/etc/rc.d/init.d/halt')
```

Querying path properties:

```
>>> q.exists()
True
>>> q.is_dir()
False
```

Opening a file:

```
>>> with q.open() as f: f.readline()
...
'#!/bin/bash\n'
```

11.1.2 Pure paths

Pure path objects provide path-handling operations which don't actually access a filesystem. There are three ways to access these classes, which we also call *flavours*:

class `pathlib.PurePath` (**pathsegments*)

A generic class that represents the system's path flavour (instantiating it creates either a *PurePosixPath* or a *PureWindowsPath*):

```
>>> PurePath('setup.py')           # Running on a Unix machine
PurePosixPath('setup.py')
```

Each element of *pathsegments* can be either a string representing a path segment, an object implementing the *os.PathLike* interface which returns a string, or another path object:

```
>>> PurePath('foo', 'some/path', 'bar')
PurePosixPath('foo/some/path/bar')
>>> PurePath(Path('foo'), Path('bar'))
PurePosixPath('foo/bar')
```

When *pathsegments* is empty, the current directory is assumed:

```
>>> PurePath()
PurePosixPath('.')
```

When several absolute paths are given, the last is taken as an anchor (mimicking *os.path.join()*'s behaviour):

```
>>> PurePath('/etc', '/usr', 'lib64')
PurePosixPath('/usr/lib64')
>>> PureWindowsPath('c:/Windows', 'd:bar')
PureWindowsPath('d:bar')
```

However, in a Windows path, changing the local root doesn't discard the previous drive setting:

```
>>> PureWindowsPath('c:/Windows', '/Program Files')
PureWindowsPath('c:/Program Files')
```

Spurious slashes and single dots are collapsed, but double dots ('..') are not, since this would change the meaning of a path in the face of symbolic links:

```
>>> PurePath('foo//bar')
PurePosixPath('foo/bar')
>>> PurePath('foo/./bar')
PurePosixPath('foo/bar')
>>> PurePath('foo/../bar')
PurePosixPath('foo/../bar')
```

(a naïve approach would make `PurePosixPath('foo/../bar')` equivalent to `PurePosixPath('bar')`, which is wrong if `foo` is a symbolic link to another directory)

Pure path objects implement the `os.PathLike` interface, allowing them to be used anywhere the interface is accepted.

Άλλαξε στην έκδοση 3.6: Added support for the `os.PathLike` interface.

class `pathlib.PurePosixPath(*pathsegments)`

A subclass of `PurePath`, this path flavour represents non-Windows filesystem paths:

```
>>> PurePosixPath('/etc')
PurePosixPath('/etc')
```

`pathsegments` is specified similarly to `PurePath`.

class `pathlib.PureWindowsPath(*pathsegments)`

A subclass of `PurePath`, this path flavour represents Windows filesystem paths:

```
>>> PureWindowsPath('c:/Program Files/')
PureWindowsPath('c:/Program Files')
```

`pathsegments` is specified similarly to `PurePath`.

Regardless of the system you're running on, you can instantiate all of these classes, since they don't provide any operation that does system calls.

General properties

Paths are immutable and hashable. Paths of a same flavour are comparable and orderable. These properties respect the flavour's case-folding semantics:

```
>>> PurePosixPath('foo') == PurePosixPath('FOO')
False
>>> PureWindowsPath('foo') == PureWindowsPath('FOO')
True
>>> PureWindowsPath('FOO') in { PureWindowsPath('foo') }
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
True
>>> PureWindowsPath('C:') < PureWindowsPath('d:')
True
```

Paths of a different flavour compare unequal and cannot be ordered:

```
>>> PureWindowsPath('foo') == PurePosixPath('foo')
False
>>> PureWindowsPath('foo') < PurePosixPath('foo')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: '<' not supported between instances of 'PureWindowsPath' and 'PurePosixPath'
↪
```

Operators

The slash operator helps create child paths, similarly to `os.path.join()`:

```
>>> p = PurePath('/etc')
>>> p
PurePosixPath('/etc')
>>> p / 'init.d' / 'apache2'
PurePosixPath('/etc/init.d/apache2')
>>> q = PurePath('bin')
>>> '/usr' / q
PurePosixPath('/usr/bin')
```

A path object can be used anywhere an object implementing `os.PathLike` is accepted:

```
>>> import os
>>> p = PurePath('/etc')
>>> os.fspath(p)
'/etc'
```

The string representation of a path is the raw filesystem path itself (in native form, e.g. with backslashes under Windows), which you can pass to any function taking a file path as a string:

```
>>> p = PurePath('/etc')
>>> str(p)
'/etc'
>>> p = PureWindowsPath('c:/Program Files')
>>> str(p)
'c:\\Program Files'
```

Similarly, calling `bytes` on a path gives the raw filesystem path as a bytes object, as encoded by `os.fsencode()`:

```
>>> bytes(p)
b'/etc'
```

Σημείωση: Calling `bytes` is only recommended under Unix. Under Windows, the unicode form is the canonical representation of filesystem paths.

Accessing individual parts

To access the individual «parts» (components) of a path, use the following property:

PurePath.parts

A tuple giving access to the path's various components:

```
>>> p = PurePath('/usr/bin/python3')
>>> p.parts
('/', 'usr', 'bin', 'python3')

>>> p = PureWindowsPath('c:/Program Files/PSF')
>>> p.parts
('c:\\', 'Program Files', 'PSF')
```

(note how the drive and local root are regrouped in a single part)

Methods and properties

Pure paths provide the following methods and properties:

PurePath.drive

A string representing the drive letter or name, if any:

```
>>> PureWindowsPath('c:/Program Files/').drive
'c:'
>>> PureWindowsPath('/Program Files/').drive
''
>>> PurePosixPath('/etc').drive
''
```

UNC shares are also considered drives:

```
>>> PureWindowsPath('//host/share/foo.txt').drive
'\\\\host\\share'
```

PurePath.root

A string representing the (local or global) root, if any:

```
>>> PureWindowsPath('c:/Program Files/').root
'\\'
>>> PureWindowsPath('c:Program Files/').root
''
>>> PurePosixPath('/etc').root
 '/'
```

UNC shares always have a root:

```
>>> PureWindowsPath('//host/share').root
'\\'
```

PurePath.anchor

The concatenation of the drive and root:

```
>>> PureWindowsPath('c:/Program Files/').anchor
'c:\\'
>>> PureWindowsPath('c:Program Files/').anchor
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
'c:'
>>> PurePosixPath('/etc').anchor
 '/'
>>> PureWindowsPath('//host/share').anchor
 '\\\\host\\share\\'
```

PurePath.parents

An immutable sequence providing access to the logical ancestors of the path:

```
>>> p = PureWindowsPath('c:/foo/bar/setup.py')
>>> p.parents[0]
PureWindowsPath('c:/foo/bar')
>>> p.parents[1]
PureWindowsPath('c:/foo')
>>> p.parents[2]
PureWindowsPath('c:/')
```

PurePath.parent

The logical parent of the path:

```
>>> p = PurePosixPath('/a/b/c/d')
>>> p.parent
PurePosixPath('/a/b/c')
```

You cannot go past an anchor, or empty path:

```
>>> p = PurePosixPath('/')
>>> p.parent
PurePosixPath('/')
>>> p = PurePosixPath('.')
>>> p.parent
PurePosixPath('.')
```

Σημείωση: This is a purely lexical operation, hence the following behaviour:

```
>>> p = PurePosixPath('foo/..')
>>> p.parent
PurePosixPath('foo')
```

If you want to walk an arbitrary filesystem path upwards, it is recommended to first call `Path.resolve()` so as to resolve symlinks and eliminate «..» components.**PurePath.name**

A string representing the final path component, excluding the drive and root, if any:

```
>>> PurePosixPath('my/library/setup.py').name
'setup.py'
```

UNC drive names are not considered:

```
>>> PureWindowsPath('//some/share/setup.py').name
'setup.py'
>>> PureWindowsPath('//some/share').name
''
```

`PurePath.suffix`

The file extension of the final component, if any:

```
>>> PurePosixPath('my/library/setup.py').suffix
'.py'
>>> PurePosixPath('my/library.tar.gz').suffix
'.gz'
>>> PurePosixPath('my/library').suffix
''
```

`PurePath.suffixes`

A list of the path's file extensions:

```
>>> PurePosixPath('my/library.tar.gar').suffixes
['.tar', '.gar']
>>> PurePosixPath('my/library.tar.gz').suffixes
['.tar', '.gz']
>>> PurePosixPath('my/library').suffixes
[]
```

`PurePath.stem`

The final path component, without its suffix:

```
>>> PurePosixPath('my/library.tar.gz').stem
'library.tar'
>>> PurePosixPath('my/library.tar').stem
'library'
>>> PurePosixPath('my/library').stem
'library'
```

`PurePath.as_posix()`

Return a string representation of the path with forward slashes (/):

```
>>> p = PureWindowsPath('c:\\windows')
>>> str(p)
'c:\\windows'
>>> p.as_posix()
'c:/windows'
```

`PurePath.as_uri()`

Represent the path as a file URI. *ValueError* is raised if the path isn't absolute.

```
>>> p = PurePosixPath('/etc/passwd')
>>> p.as_uri()
'file:///etc/passwd'
>>> p = PureWindowsPath('c:/Windows')
>>> p.as_uri()
'file:///c:/Windows'
```

`PurePath.is_absolute()`

Return whether the path is absolute or not. A path is considered absolute if it has both a root and (if the flavour allows) a drive:

```
>>> PurePosixPath('/a/b').is_absolute()
True
>>> PurePosixPath('a/b').is_absolute()
False
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> PureWindowsPath('c:/a/b').is_absolute()
True
>>> PureWindowsPath('/a/b').is_absolute()
False
>>> PureWindowsPath('c:').is_absolute()
False
>>> PureWindowsPath('//some/share').is_absolute()
True
```

PurePath.is_relative_to(*other)Return whether or not this path is relative to the *other* path.

```
>>> p = PurePath('/etc/passwd')
>>> p.is_relative_to('/etc')
True
>>> p.is_relative_to('/usr')
False
```

Νέο στην έκδοση 3.9.

PurePath.is_reserved()With *PureWindowsPath*, return True if the path is considered reserved under Windows, False otherwise. With *PurePosixPath*, False is always returned.

```
>>> PureWindowsPath('nul').is_reserved()
True
>>> PurePosixPath('nul').is_reserved()
False
```

File system calls on reserved paths can fail mysteriously or have unintended effects.

PurePath.joinpath(*other)Calling this method is equivalent to combining the path with each of the *other* arguments in turn:

```
>>> PurePosixPath('/etc').joinpath('passwd')
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath(PurePosixPath('passwd'))
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath('init.d', 'apache2')
PurePosixPath('/etc/init.d/apache2')
>>> PureWindowsPath('c:').joinpath('/Program Files')
PureWindowsPath('c:/Program Files')
```

PurePath.match(pattern)

Match this path against the provided glob-style pattern. Return True if matching is successful, False otherwise.

If *pattern* is relative, the path can be either relative or absolute, and matching is done from the right:

```
>>> PurePath('a/b.py').match('*.py')
True
>>> PurePath('/a/b/c.py').match('b/*.py')
True
>>> PurePath('/a/b/c.py').match('a/*.py')
False
```

If *pattern* is absolute, the path must be absolute, and the whole path must match:

```
>>> PurePath('/a.py').match('/*.py')
True
>>> PurePath('a/b.py').match('/*.py')
False
```

As with other methods, case-sensitivity follows platform defaults:

```
>>> PurePosixPath('b.py').match('*.PY')
False
>>> PureWindowsPath('b.py').match('*.PY')
True
```

`PurePath.relative_to(*other)`

Compute a version of this path relative to the path represented by *other*. If it's impossible, `ValueError` is raised:

```
>>> p = PurePosixPath('/etc/passwd')
>>> p.relative_to('/')
PurePosixPath('etc/passwd')
>>> p.relative_to('/etc')
PurePosixPath('passwd')
>>> p.relative_to('/usr')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 694, in relative_to
    .format(str(self), str(formatted)))
ValueError: '/etc/passwd' is not in the subpath of '/usr' OR one path is relative_
↳and the other absolute.
```

NOTE: This function is part of *PurePath* and works with strings. It does not check or access the underlying file structure.

`PurePath.with_name(name)`

Return a new path with the *name* changed. If the original path doesn't have a name, `ValueError` is raised:

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_name('setup.py')
PureWindowsPath('c:/Downloads/setup.py')
>>> p = PureWindowsPath('c:/')
>>> p.with_name('setup.py')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/antoine/cpython/default/Lib/pathlib.py", line 751, in with_name
    raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

`PurePath.with_stem(stem)`

Return a new path with the *stem* changed. If the original path doesn't have a name, `ValueError` is raised:

```
>>> p = PureWindowsPath('c:/Downloads/draft.txt')
>>> p.with_stem('final')
PureWindowsPath('c:/Downloads/final.txt')
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_stem('lib')
PureWindowsPath('c:/Downloads/lib.gz')
>>> p = PureWindowsPath('c:/')
>>> p.with_stem('')
Traceback (most recent call last):
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
File "<stdin>", line 1, in <module>
File "/home/antoine/cpython/default/Lib/pathlib.py", line 861, in with_stem
    return self.with_name(stem + self.suffix)
File "/home/antoine/cpython/default/Lib/pathlib.py", line 851, in with_name
    raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

Νέο στην έκδοση 3.9.

`PurePath.with_suffix(suffix)`

Return a new path with the *suffix* changed. If the original path doesn't have a suffix, the new *suffix* is appended instead. If the *suffix* is an empty string, the original suffix is removed:

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_suffix('.bz2')
PureWindowsPath('c:/Downloads/pathlib.tar.bz2')
>>> p = PureWindowsPath('README')
>>> p.with_suffix('.txt')
PureWindowsPath('README.txt')
>>> p = PureWindowsPath('README.txt')
>>> p.with_suffix('')
PureWindowsPath('README')
```

11.1.3 Concrete paths

Concrete paths are subclasses of the pure path classes. In addition to operations provided by the latter, they also provide methods to do system calls on path objects. There are three ways to instantiate concrete paths:

class `pathlib.Path(*pathsegments)`

A subclass of *PurePath*, this class represents concrete paths of the system's path flavour (instantiating it creates either a *PosixPath* or a *WindowsPath*):

```
>>> Path('setup.py')
PosixPath('setup.py')
```

pathsegments is specified similarly to *PurePath*.

class `pathlib.PosixPath(*pathsegments)`

A subclass of *Path* and *PurePosixPath*, this class represents concrete non-Windows filesystem paths:

```
>>> PosixPath('/etc')
PosixPath('/etc')
```

pathsegments is specified similarly to *PurePath*.

class `pathlib.WindowsPath(*pathsegments)`

A subclass of *Path* and *PureWindowsPath*, this class represents concrete Windows filesystem paths:

```
>>> WindowsPath('c:/Program Files/')
WindowsPath('c:/Program Files')
```

pathsegments is specified similarly to *PurePath*.

You can only instantiate the class flavour that corresponds to your system (allowing system calls on non-compatible path flavours could lead to bugs or failures in your application):

```
>>> import os
>>> os.name
'posix'
>>> Path('setup.py')
PosixPath('setup.py')
>>> PosixPath('setup.py')
PosixPath('setup.py')
>>> WindowsPath('setup.py')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 798, in __new__
    % (cls.__name__,))
NotImplementedError: cannot instantiate 'WindowsPath' on your system
```

Methods

Concrete paths provide the following methods in addition to pure paths methods. Many of these methods can raise an *OSError* if a system call fails (for example because the path doesn't exist).

Άλλαξε στην έκδοση 3.8: *exists()*, *is_dir()*, *is_file()*, *is_mount()*, *is_symlink()*, *is_block_device()*, *is_char_device()*, *is_fifo()*, *is_socket()* now return False instead of raising an exception for paths that contain characters unrepresentable at the OS level.

classmethod `Path.cwd()`

Return a new path object representing the current directory (as returned by *os.getcwd()*):

```
>>> Path.cwd()
PosixPath('/home/antoine/pathlib')
```

classmethod `Path.home()`

Return a new path object representing the user's home directory (as returned by *os.path.expanduser()* with ~ construct):

```
>>> Path.home()
PosixPath('/home/antoine')
```

Note that unlike *os.path.expanduser()*, on POSIX systems a *KeyError* or *RuntimeError* will be raised, and on Windows systems a *RuntimeError* will be raised if home directory can't be resolved.

Νέο στην έκδοση 3.5.

`Path.stat()`

Return a *os.stat_result* object containing information about this path, like *os.stat()*. The result is looked up at each call to this method.

```
>>> p = Path('setup.py')
>>> p.stat().st_size
956
>>> p.stat().st_mtime
1327883547.852554
```

`Path.chmod(mode)`

Change the file mode and permissions, like *os.chmod()*:

```
>>> p = Path('setup.py')
>>> p.stat().st_mode
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

33277
>>> p.chmod(0o444)
>>> p.stat().st_mode
33060

```

Path.exists()

Whether the path points to an existing file or directory:

```

>>> Path('.').exists()
True
>>> Path('setup.py').exists()
True
>>> Path('/etc').exists()
True
>>> Path('nonexistentfile').exists()
False

```

Σημείωση: If the path points to a symlink, *exists()* returns whether the symlink *points to* an existing file or directory.

Path.expanduser()Return a new path with expanded ~ and ~user constructs, as returned by *os.path.expanduser()*:

```

>>> p = PosixPath('~ /films/Monty Python')
>>> p.expanduser()
PosixPath('/home/eric/films/Monty Python')

```

Note that unlike *os.path.expanduser()*, on POSIX systems a *KeyError* or *RuntimeError* will be raised, and on Windows systems a *RuntimeError* will be raised if home directory can't be resolved.

Νέο στην έκδοση 3.5.

Path.glob(pattern)Glob the given relative *pattern* in the directory represented by this path, yielding all matching files (of any kind):

```

>>> sorted(Path('.').glob('*.py'))
[PosixPath('pathlib.py'), PosixPath('setup.py'), PosixPath('test_pathlib.py')]
>>> sorted(Path('.').glob('**/*.py'))
[PosixPath('docs/conf.py')]

```

The «**» pattern means «this directory and all subdirectories, recursively». In other words, it enables recursive globbing:

```

>>> sorted(Path('.').glob('**/*.py'))
[PosixPath('build/lib/pathlib.py'),
 PosixPath('docs/conf.py'),
 PosixPath('pathlib.py'),
 PosixPath('setup.py'),
 PosixPath('test_pathlib.py')]

```

Σημείωση: Using the «**» pattern in large directory trees may consume an inordinate amount of time.

Raises an *auditing event* `pathlib.Path.glob` with arguments `self, pattern`.

`Path.group()`

Return the name of the group owning the file. `KeyError` is raised if the file's gid isn't found in the system database.

`Path.is_dir()`

Return `True` if the path points to a directory (or a symbolic link pointing to a directory), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

`Path.is_file()`

Return `True` if the path points to a regular file (or a symbolic link pointing to a regular file), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

`Path.is_mount()`

Return `True` if the path is a *mount point*: a point in a file system where a different file system has been mounted. On POSIX, the function checks whether *path*'s parent, `path/..`, is on a different device than *path*, or whether `path/..` and *path* point to the same i-node on the same device — this should detect mount points for all Unix and POSIX variants. Not implemented on Windows.

Νέο στην έκδοση 3.7.

`Path.is_symlink()`

Return `True` if the path points to a symbolic link, `False` otherwise.

`False` is also returned if the path doesn't exist; other errors (such as permission errors) are propagated.

`Path.is_socket()`

Return `True` if the path points to a Unix socket (or a symbolic link pointing to a Unix socket), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

`Path.is_fifo()`

Return `True` if the path points to a FIFO (or a symbolic link pointing to a FIFO), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

`Path.is_block_device()`

Return `True` if the path points to a block device (or a symbolic link pointing to a block device), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

`Path.is_char_device()`

Return `True` if the path points to a character device (or a symbolic link pointing to a character device), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

`Path.iterdir()`

When the path points to a directory, yield path objects of the directory contents:

```
>>> p = Path('docs')
>>> for child in p.iterdir(): child
...
PosixPath('docs/conf.py')
PosixPath('docs/_templates')
PosixPath('docs/make.bat')
PosixPath('docs/index.rst')
PosixPath('docs/_build')
PosixPath('docs/_static')
PosixPath('docs/Makefile')
```

The children are yielded in arbitrary order, and the special entries `'.'` and `'..'` are not included. If a file is removed from or added to the directory after creating the iterator, whether a path object for that file be included is unspecified.

`Path.lchmod(mode)`

Like `Path.chmod()` but, if the path points to a symbolic link, the symbolic link's mode is changed rather than its target's.

`Path.lstat()`

Like `Path.stat()` but, if the path points to a symbolic link, return the symbolic link's information rather than its target's.

`Path.mkdir(mode=0o777, parents=False, exist_ok=False)`

Create a new directory at this given path. If *mode* is given, it is combined with the process' umask value to determine the file mode and access flags. If the path already exists, `FileExistsError` is raised.

If *parents* is true, any missing parents of this path are created as needed; they are created with the default permissions without taking *mode* into account (mimicking the POSIX `mkdir -p` command).

If *parents* is false (the default), a missing parent raises `FileNotFoundError`.

If *exist_ok* is false (the default), `FileExistsError` is raised if the target directory already exists.

If *exist_ok* is true, `FileExistsError` exceptions will be ignored (same behavior as the POSIX `mkdir -p` command), but only if the last path component is not an existing non-directory file.

Άλλαξε στην έκδοση 3.5: The *exist_ok* parameter was added.

`Path.open(mode='r', buffering=-1, encoding=None, errors=None, newline=None)`

Open the file pointed to by the path, like the built-in `open()` function does:

```
>>> p = Path('setup.py')
>>> with p.open() as f:
...     f.readline()
...
'#!/usr/bin/env python3\n'
```

`Path.owner()`

Return the name of the user owning the file. `KeyError` is raised if the file's uid isn't found in the system database.

`Path.read_bytes()`

Return the binary contents of the pointed-to file as a bytes object:

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

Νέο στην έκδοση 3.5.

`Path.read_text(encoding=None, errors=None)`

Return the decoded contents of the pointed-to file as a string:

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

The file is opened and then closed. The optional parameters have the same meaning as in `open()`.

Νέο στην έκδοση 3.5.

`Path.readlink()`

Return the path to which the symbolic link points (as returned by `os.readlink()`):

```
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.readlink()
PosixPath('setup.py')
```

Νέο στην έκδοση 3.9.

`Path.rename(target)`

Rename this file or directory to the given *target*, and return a new Path instance pointing to *target*. On Unix, if *target* exists and is a file, it will be replaced silently if the user has permission. *target* can be either a string or another path object:

```
>>> p = Path('foo')
>>> p.open('w').write('some text')
9
>>> target = Path('bar')
>>> p.rename(target)
PosixPath('bar')
>>> target.open().read()
'some text'
```

The target path may be absolute or relative. Relative paths are interpreted relative to the current working directory, *not* the directory of the Path object.

Άλλαξε στην έκδοση 3.8: Added return value, return the new Path instance.

`Path.replace(target)`

Rename this file or directory to the given *target*, and return a new Path instance pointing to *target*. If *target* points to an existing file or empty directory, it will be unconditionally replaced.

The target path may be absolute or relative. Relative paths are interpreted relative to the current working directory, *not* the directory of the Path object.

Άλλαξε στην έκδοση 3.8: Added return value, return the new Path instance.

`Path.resolve(strict=False)`

Make the path absolute, resolving any symlinks. A new path object is returned:

```
>>> p = Path()
>>> p
PosixPath('.')
>>> p.resolve()
PosixPath('/home/antoine/pathlib')
```

«`.`» components are also eliminated (this is the only method to do so):

```
>>> p = Path('docs/../setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
```

If the path doesn't exist and *strict* is `True`, `FileNotFoundError` is raised. If *strict* is `False`, the path is resolved as far as possible and any remainder is appended without checking whether it exists. If an infinite loop is encountered along the resolution path, `RuntimeError` is raised.

Νέο στην έκδοση 3.6: The *strict* argument (pre-3.6 behavior is strict).

`Path.rglob(pattern)`

This is like calling `Path.glob()` with «`**/`» added in front of the given relative *pattern*:

```
>>> sorted(Path().rglob("*.py"))
[PosixPath('build/lib/pathlib.py'),
 PosixPath('docs/conf.py'),
 PosixPath('pathlib.py'),
 PosixPath('setup.py'),
 PosixPath('test_pathlib.py')]
```

Raises an *auditing event* `pathlib.Path.rglob` with arguments `self, pattern`.

`Path.rmdir()`

Remove this directory. The directory must be empty.

`Path.samefile(other_path)`

Return whether this path points to the same file as *other_path*, which can be either a `Path` object, or a string. The semantics are similar to `os.path.samefile()` and `os.path.samestat()`.

An `OSError` can be raised if either file cannot be accessed for some reason.

```
>>> p = Path('spam')
>>> q = Path('eggs')
>>> p.samefile(q)
False
>>> p.samefile('spam')
True
```

Νέο στην έκδοση 3.5.

`Path.symlink_to(target, target_is_directory=False)`

Make this path a symbolic link to *target*. Under Windows, *target_is_directory* must be `true` (default `False`) if the link's target is a directory. Under POSIX, *target_is_directory*'s value is ignored.

```
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
>>> p.stat().st_size
956
>>> p.lstat().st_size
8
```

Σημείωση: The order of arguments (link, target) is the reverse of `os.symlink()`'s.

`Path.link_to(target)`

Make *target* a hard link to this path.

Προειδοποίηση: This function does not make this path a hard link to *target*, despite the implication of the function and argument names. The argument order (*target*, *link*) is the reverse of `Path.symlink_to()`, but matches that of `os.link()`.

Νέο στην έκδοση 3.8.

`Path.touch(mode=0o666, exist_ok=True)`

Create a file at this given path. If *mode* is given, it is combined with the process' umask value to determine the file mode and access flags. If the file already exists, the function succeeds if *exist_ok* is true (and its modification time is updated to the current time), otherwise `FileExistsError` is raised.

`Path.unlink(missing_ok=False)`

Remove this file or symbolic link. If the path points to a directory, use `Path.rmdir()` instead.

If *missing_ok* is false (the default), `FileNotFoundError` is raised if the path does not exist.

If *missing_ok* is true, `FileNotFoundError` exceptions will be ignored (same behavior as the POSIX `rm -f` command).

Άλλαξε στην έκδοση 3.8: The *missing_ok* parameter was added.

`Path.write_bytes(data)`

Open the file pointed to in bytes mode, write *data* to it, and close the file:

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

An existing file of the same name is overwritten.

Νέο στην έκδοση 3.5.

`Path.write_text(data, encoding=None, errors=None)`

Open the file pointed to in text mode, write *data* to it, and close the file:

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

An existing file of the same name is overwritten. The optional parameters have the same meaning as in `open()`.

Νέο στην έκδοση 3.5.

11.1.4 Correspondence to tools in the `os` module

Below is a table mapping various `os` functions to their corresponding `PurePath/Path` equivalent.

Σημείωση: Although `os.path.relpath()` and `PurePath.relative_to()` have some overlapping use-cases, their semantics differ enough to warrant not considering them equivalent.

| os and os.path | pathlib |
|---|--|
| <code>os.path.abspath()</code> | <code>Path.resolve()</code> |
| <code>os.chmod()</code> | <code>Path.chmod()</code> |
| <code>os.mkdir()</code> | <code>Path.mkdir()</code> |
| <code>os.makedirs()</code> | <code>Path.mkdir()</code> |
| <code>os.rename()</code> | <code>Path.rename()</code> |
| <code>os.replace()</code> | <code>Path.replace()</code> |
| <code>os.rmdir()</code> | <code>Path.rmdir()</code> |
| <code>os.remove()</code> , <code>os.unlink()</code> | <code>Path.unlink()</code> |
| <code>os.getcwd()</code> | <code>Path.cwd()</code> |
| <code>os.path.exists()</code> | <code>Path.exists()</code> |
| <code>os.path.expanduser()</code> | <code>Path.expanduser()</code> and <code>Path.home()</code> |
| <code>os.listdir()</code> | <code>Path.iterdir()</code> |
| <code>os.path.isdir()</code> | <code>Path.is_dir()</code> |
| <code>os.path.isfile()</code> | <code>Path.is_file()</code> |
| <code>os.path.islink()</code> | <code>Path.is_symlink()</code> |
| <code>os.link()</code> | <code>Path.link_to()</code> |
| <code>os.symlink()</code> | <code>Path.symlink_to()</code> |
| <code>os.readlink()</code> | <code>Path.readlink()</code> |
| <code>os.stat()</code> | <code>Path.stat()</code> , <code>Path.owner()</code> , <code>Path.group()</code> |

| <code>os.path.basename()</code> | <code>PurePath.name</code> |
| <code>os.path.dirname()</code> | <code>PurePath.parent</code> |
| <code>os.path.samefile()</code> | <code>Path.samefile()</code> |
| <code>os.path.splitext()</code> | <code>PurePath.suffix</code> |

11.2 `os.path` — Common pathname manipulations

Source code: `Lib/posixpath.py` (for POSIX) and `Lib/ntpath.py` (for Windows).

This module implements some useful functions on pathnames. To read or write files see `open()`, and for accessing the filesystem see the `os` module. The path parameters can be passed as strings, or bytes, or any object implementing the `os.PathLike` protocol.

Unlike a unix shell, Python does not do any *automatic* path expansions. Functions such as `expanduser()` and `expandvars()` can be invoked explicitly when an application desires shell-like path expansion. (See also the `glob` module.)

Δείτε επίσης:

The `pathlib` module offers high-level path objects.

Σημείωση: All of these functions accept either only bytes or only string objects as their parameters. The result is an object of the same type, if a path or file name is returned.

Σημείωση: Since different operating systems have different path name conventions, there are several versions of this module in the standard library. The `os.path` module is always the path module suitable for the operating system Python is running on, and therefore usable for local paths. However, you can also import and use the individual modules if you want to manipulate a path that is *always* in one of the different formats. They all have the same interface:

- `posixpath` for UNIX-style paths
 - `ntpath` for Windows paths
-

Άλλαξε στην έκδοση 3.8: `exists()`, `lexists()`, `isdir()`, `isfile()`, `islink()`, and `ismount()` now return `False` instead of raising an exception for paths that contain characters or bytes unrepresentable at the OS level.

`os.path.abspath(path)`

Return a normalized absolutized version of the pathname *path*. On most platforms, this is equivalent to calling the function `normpath()` as follows: `normpath(join(os.getcwd(), path))`.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.basename(path)`

Return the base name of pathname *path*. This is the second element of the pair returned by passing *path* to the function `split()`. Note that the result of this function is different from the Unix `basename` program; where `basename` for `'/foo/bar/'` returns `'bar'`, the `basename()` function returns an empty string (`' '`).

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.commonpath(paths)`

Return the longest common sub-path of each pathname in the sequence *paths*. Raise `ValueError` if *paths* contain both absolute and relative pathnames, the *paths* are on the different drives or if *paths* is empty. Unlike `commonprefix()`, this returns a valid path.

Availability: Unix, Windows.

Νέο στην έκδοση 3.5.

Άλλαξε στην έκδοση 3.6: Accepts a sequence of *path-like objects*.

`os.path.commonprefix(list)`

Return the longest path prefix (taken character-by-character) that is a prefix of all paths in *list*. If *list* is empty, return the empty string (`' '`).

Σημείωση: This function may return invalid paths because it works a character at a time. To obtain a valid path, see `commonpath()`.

```
>>> os.path.commonprefix(['/usr/lib', '/usr/local/lib'])
'/usr/l'

>>> os.path.commonpath(['/usr/lib', '/usr/local/lib'])
'/usr'
```

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.dirname(path)`

Return the directory name of pathname *path*. This is the first element of the pair returned by passing *path* to the function `split()`.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.exists(path)`

Return `True` if *path* refers to an existing path or an open file descriptor. Returns `False` for broken symbolic links. On some platforms, this function may return `False` if permission is not granted to execute `os.stat()` on the requested file, even if the *path* physically exists.

Άλλαξε στην έκδοση 3.3: *path* can now be an integer: `True` is returned if it is an open file descriptor, `False` otherwise.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.lexists(path)`

Return `True` if *path* refers to an existing path. Returns `True` for broken symbolic links. Equivalent to `exists()` on platforms lacking `os.lstat()`.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.expanduser(path)`

On Unix and Windows, return the argument with an initial component of `~` or `~user` replaced by that *user*'s home directory.

On Unix, an initial `~` is replaced by the environment variable `HOME` if it is set; otherwise the current user's home directory is looked up in the password directory through the built-in module `pwd`. An initial `~user` is looked up directly in the password directory.

On Windows, `USERPROFILE` will be used if set, otherwise a combination of `HOMEPATH` and `HOMEDRIVE` will be used. An initial `~user` is handled by stripping the last directory component from the created user path derived above.

If the expansion fails or if the path does not begin with a tilde, the path is returned unchanged.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

Άλλαξε στην έκδοση 3.8: No longer uses `HOME` on Windows.

`os.path.expandvars(path)`

Return the argument with environment variables expanded. Substrings of the form `$name` or `${name}` are replaced by the value of environment variable *name*. Malformed variable names and references to non-existing variables are left unchanged.

On Windows, `%name%` expansions are supported in addition to `$name` and `${name}`.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.getatime(path)`

Return the time of last access of *path*. The return value is a floating point number giving the number of seconds since the epoch (see the `time` module). Raise `OSError` if the file does not exist or is inaccessible.

`os.path.getmtime(path)`

Return the time of last modification of *path*. The return value is a floating point number giving the number of seconds since the epoch (see the `time` module). Raise `OSError` if the file does not exist or is inaccessible.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.getctime(path)`

Return the system's `ctime` which, on some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time for *path*. The return value is a number giving the number of seconds since the epoch (see the `time` module). Raise `OSError` if the file does not exist or is inaccessible.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.getsize(path)`

Return the size, in bytes, of *path*. Raise *OSError* if the file does not exist or is inaccessible.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.isabs(path)`

Return *True* if *path* is an absolute pathname. On Unix, that means it begins with a slash, on Windows that it begins with a (back)slash after chopping off a potential drive letter.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.isfile(path)`

Return *True* if *path* is an *existing* regular file. This follows symbolic links, so both *islink()* and *isfile()* can be true for the same path.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.isdir(path)`

Return *True* if *path* is an *existing* directory. This follows symbolic links, so both *islink()* and *isdir()* can be true for the same path.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.islink(path)`

Return *True* if *path* refers to an *existing* directory entry that is a symbolic link. Always *False* if symbolic links are not supported by the Python runtime.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.ismount(path)`

Return *True* if pathname *path* is a *mount point*: a point in a file system where a different file system has been mounted. On POSIX, the function checks whether *path*'s parent, *path/..*, is on a different device than *path*, or whether *path/..* and *path* point to the same i-node on the same device — this should detect mount points for all Unix and POSIX variants. It is not able to reliably detect bind mounts on the same filesystem. On Windows, a drive letter root and a share UNC are always mount points, and for any other path *GetVolumePathName* is called to see if it is different from the input path.

Νέο στην έκδοση 3.4: Support for detecting non-root mount points on Windows.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.join(path, *paths)`

Join one or more path components intelligently. The return value is the concatenation of *path* and any members of **paths* with exactly one directory separator following each non-empty part except the last, meaning that the result will only end in a separator if the last part is empty. If a component is an absolute path, all previous components are thrown away and joining continues from the absolute path component.

On Windows, the drive letter is not reset when an absolute path component (e.g., *r'\foo'*) is encountered. If a component contains a drive letter, all previous components are thrown away and the drive letter is reset. Note that since there is a current directory for each drive, *os.path.join("c:", "foo")* represents a path relative to the current directory on drive C: (*c:foo*), not *c:\foo*.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object* for *path* and *paths*.

`os.path.normcase(path)`

Normalize the case of a pathname. On Windows, convert all characters in the pathname to lowercase, and also convert forward slashes to backward slashes. On other operating systems, return the path unchanged.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.normpath(path)`

Normalize a pathname by collapsing redundant separators and up-level references so that `A//B`, `A/B/`, `A/./B` and `A/foo/./B` all become `A/B`. This string manipulation may change the meaning of a path that contains symbolic links. On Windows, it converts forward slashes to backward slashes. To normalize case, use `normcase()`.

Σημείωση:

On POSIX systems, in accordance with IEEE Std 1003.1 2013 Edition; 4.13 Pathname Resolution, if a pathname begins with exactly two slashes, the first component following the leading characters may be interpreted in an implementation-defined manner, although more than two leading characters shall be treated as a single character.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.realpath(path, *, strict=False)`

Return the canonical path of the specified filename, eliminating any symbolic links encountered in the path (if they are supported by the operating system).

By default, the path is evaluated up to the first component that does not exist, is a symlink loop, or whose evaluation raises `OSError`. All such components are appended unchanged to the existing part of the path.

Some errors that are handled this way include «access denied», «not a directory», or «bad argument to internal function». Thus, the resulting path may be missing or inaccessible, may still contain links or loops, and may traverse non-directories.

This behavior can be modified by keyword arguments:

If `strict` is `True`, the first error encountered when evaluating the path is re-raised. In particular, `FileNotFoundError` is raised if `path` does not exist, or another `OSError` if it is otherwise inaccessible.

If `strict` is `os.path.ALLOW_MISSING`, errors other than `FileNotFoundError` are re-raised (as with `strict=True`). Thus, the returned path will not contain any symbolic links, but the named file and some of its parent directories may be missing.

Σημείωση: This function emulates the operating system's procedure for making a path canonical, which differs slightly between Windows and UNIX with respect to how links and subsequent path components interact.

Operating system APIs make paths canonical as needed, so it's not normally necessary to call this function.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

Άλλαξε στην έκδοση 3.8: Symbolic links and junctions are now resolved on Windows.

Άλλαξε στην έκδοση 3.9.23: The `strict` parameter was added.

Άλλαξε στην έκδοση 3.9.24 (unreleased): The `ALLOW_MISSING` value for the `strict` parameter was added.

`os.path.ALLOW_MISSING`

Special value used for the `strict` argument in `realpath()`.

Νέο στην έκδοση 3.9.24 (unreleased).

`os.path.relpath(path, start=os.curdir)`

Return a relative filepath to `path` either from the current directory or from an optional `start` directory. This is a path computation: the filesystem is not accessed to confirm the existence or nature of `path` or `start`. On Windows, `ValueError` is raised when `path` and `start` are on different drives.

`start` defaults to `os.curdir`.

Availability: Unix, Windows.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.samefile(path1, path2)`

Return `True` if both pathname arguments refer to the same file or directory. This is determined by the device number and i-node number and raises an exception if an `os.stat()` call on either pathname fails.

Availability: Unix, Windows.

Άλλαξε στην έκδοση 3.2: Added Windows support.

Άλλαξε στην έκδοση 3.4: Windows now uses the same implementation as all other platforms.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.sameopenfile(fp1, fp2)`

Return `True` if the file descriptors `fp1` and `fp2` refer to the same file.

Availability: Unix, Windows.

Άλλαξε στην έκδοση 3.2: Added Windows support.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.samestat(stat1, stat2)`

Return `True` if the stat tuples `stat1` and `stat2` refer to the same file. These structures may have been returned by `os.fstat()`, `os.lstat()`, or `os.stat()`. This function implements the underlying comparison used by `samefile()` and `sameopenfile()`.

Availability: Unix, Windows.

Άλλαξε στην έκδοση 3.4: Added Windows support.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.split(path)`

Split the pathname `path` into a pair, (`head`, `tail`) where `tail` is the last pathname component and `head` is everything leading up to that. The `tail` part will never contain a slash; if `path` ends in a slash, `tail` will be empty. If there is no slash in `path`, `head` will be empty. If `path` is empty, both `head` and `tail` are empty. Trailing slashes are stripped from `head` unless it is the root (one or more slashes only). In all cases, `join(head, tail)` returns a path to the same location as `path` (but the strings may differ). Also see the functions `dirname()` and `basename()`.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.splitdrive(path)`

Split the pathname `path` into a pair (`drive`, `tail`) where `drive` is either a mount point or the empty string. On systems which do not use drive specifications, `drive` will always be the empty string. In all cases, `drive + tail` will be the same as `path`.

On Windows, splits a pathname into drive/UNC sharepoint and relative path.

If the path contains a drive letter, `drive` will contain everything up to and including the colon:

```
>>> splitdrive("c:/dir")
("c:", "/dir")
```

If the path contains a UNC path, `drive` will contain the host name and share, up to but not including the fourth separator:

```
>>> splitdrive("//host/computer/dir")
("//host/computer", "/dir")
```

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.splitext(path)`

Split the pathname *path* into a pair (*root*, *ext*) such that *root* + *ext* == *path*, and the extension, *ext*, is empty or begins with a period and contains at most one period.

If the path contains no extension, *ext* will be '':

```
>>> splitext('bar')
('bar', '')
```

If the path contains an extension, then *ext* will be set to this extension, including the leading period. Note that previous periods will be ignored:

```
>>> splitext('foo.bar.exe')
('foo.bar', '.exe')
>>> splitext('/foo/bar.exe')
('/foo/bar', '.exe')
```

Leading periods of the last component of the path are considered to be part of the root:

```
>>> splitext('.cshrc')
('.cshrc', '')
>>> splitext('/foo/....jpg')
('/foo/....jpg', '')
```

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.path.supports_unicode_filenames`

True if arbitrary Unicode strings can be used as file names (within limitations imposed by the file system).

11.3 fileinput — Iterate over lines from multiple input streams

Source code: [Lib/fileinput.py](#)

This module implements a helper class and functions to quickly write a loop over standard input or a list of files. If you just want to read or write one file see [open\(\)](#).

The typical use is:

```
import fileinput
for line in fileinput.input():
    process(line)
```

This iterates over the lines of all files listed in `sys.argv[1:]`, defaulting to `sys.stdin` if the list is empty. If a filename is '-', it is also replaced by `sys.stdin` and the optional arguments *mode* and *openhook* are ignored. To specify an alternative list of filenames, pass it as the first argument to [input\(\)](#). A single file name is also allowed.

All files are opened in text mode by default, but you can override this by specifying the *mode* parameter in the call to [input\(\)](#) or [FileInput](#). If an I/O error occurs during opening or reading a file, [OSError](#) is raised.

Άλλαξε στην έκδοση 3.3: [IOError](#) used to be raised; it is now an alias of [OSError](#).

If `sys.stdin` is used more than once, the second and further use will return no lines, except perhaps for interactive use, or if it has been explicitly reset (e.g. using `sys.stdin.seek(0)`).

Empty files are opened and immediately closed; the only time their presence in the list of filenames is noticeable at all is when the last file opened is empty.

Lines are returned with any newlines intact, which means that the last line in a file may not have one.

You can control how files are opened by providing an opening hook via the *openhook* parameter to *fileinput.input()* or *FileInput()*. The hook must be a function that takes two arguments, *filename* and *mode*, and returns an accordingly opened file-like object. Two useful hooks are already provided by this module.

The following function is the primary interface of this module:

`fileinput.input(files=None, inplace=False, backup='', *, mode='r', openhook=None)`

Create an instance of the *FileInput* class. The instance will be used as global state for the functions of this module, and is also returned to use during iteration. The parameters to this function will be passed along to the constructor of the *FileInput* class.

The *FileInput* instance can be used as a context manager in the `with` statement. In this example, *input* is closed after the `with` statement is exited, even if an exception occurs:

```
with fileinput.input(files=('spam.txt', 'eggs.txt')) as f:
    for line in f:
        process(line)
```

Άλλαξε στην έκδοση 3.2: Can be used as a context manager.

Άλλαξε στην έκδοση 3.8: The keyword parameters *mode* and *openhook* are now keyword-only.

The following functions use the global state created by *fileinput.input()*; if there is no active state, *RuntimeError* is raised.

`fileinput.filename()`

Return the name of the file currently being read. Before the first line has been read, returns *None*.

`fileinput.fileno()`

Return the integer «file descriptor» for the current file. When no file is opened (before the first line and between files), returns *-1*.

`fileinput.lineno()`

Return the cumulative line number of the line that has just been read. Before the first line has been read, returns *0*. After the last line of the last file has been read, returns the line number of that line.

`fileinput.filelineno()`

Return the line number in the current file. Before the first line has been read, returns *0*. After the last line of the last file has been read, returns the line number of that line within the file.

`fileinput.isfirstline()`

Return *True* if the line just read is the first line of its file, otherwise return *False*.

`fileinput.isstdin()`

Return *True* if the last line was read from `sys.stdin`, otherwise return *False*.

`fileinput.nextfile()`

Close the current file so that the next iteration will read the first line from the next file (if any); lines not read from the file will not count towards the cumulative line count. The filename is not changed until after the first line of the next file has been read. Before the first line has been read, this function has no effect; it cannot be used to skip the first file. After the last line of the last file has been read, this function has no effect.

`fileinput.close()`

Close the sequence.

The class which implements the sequence behavior provided by the module is available for subclassing as well:

`class fileinput.FileInput(files=None, inplace=False, backup='', *, mode='r', openhook=None)`

Class *FileInput* is the implementation; its methods *filename()*, *fileno()*, *lineno()*, *filelineno()*, *isfirstline()*, *isstdin()*, *nextfile()* and *close()* correspond to the

functions of the same name in the module. In addition it has a `readline()` method which returns the next input line, and a `__getitem__()` method which implements the sequence behavior. The sequence must be accessed in strictly sequential order; random access and `readline()` cannot be mixed.

With *mode* you can specify which file mode will be passed to `open()`. It must be one of `'r'`, `'rU'`, `'U'` and `'rb'`.

The *openhook*, when given, must be a function that takes two arguments, *filename* and *mode*, and returns an accordingly opened file-like object. You cannot use *inplace* and *openhook* together.

A `FileInput` instance can be used as a context manager in the `with` statement. In this example, *input* is closed after the `with` statement is exited, even if an exception occurs:

```
with FileInput(files=('spam.txt', 'eggs.txt')) as input:
    process(input)
```

Άλλαξε στην έκδοση 3.2: Can be used as a context manager.

Αποσύρθηκε στην έκδοση 3.4: The `'rU'` and `'U'` modes.

Αποσύρθηκε στην έκδοση 3.8: Support for `__getitem__()` method is deprecated.

Άλλαξε στην έκδοση 3.8: The keyword parameter *mode* and *openhook* are now keyword-only.

Optional in-place filtering: if the keyword argument `inplace=True` is passed to `fileinput.input()` or to the `FileInput` constructor, the file is moved to a backup file and standard output is directed to the input file (if a file of the same name as the backup file already exists, it will be replaced silently). This makes it possible to write a filter that rewrites its input file in place. If the *backup* parameter is given (typically as `backup='.<some extension>'`), it specifies the extension for the backup file, and the backup file remains around; by default, the extension is `'.bak'` and it is deleted when the output file is closed. In-place filtering is disabled when standard input is read.

The two following opening hooks are provided by this module:

`fileinput.hook_compressed(filename, mode)`

Transparently opens files compressed with `gzip` and `bzip2` (recognized by the extensions `'.gz'` and `'.bz2'`) using the `gzip` and `bz2` modules. If the filename extension is not `'.gz'` or `'.bz2'`, the file is opened normally (ie, using `open()` without any decompression).

Usage example: `fi = fileinput.FileInput(openhook=fileinput.hook_compressed)`

`fileinput.hook_encoded(encoding, errors=None)`

Returns a hook which opens each file with `open()`, using the given *encoding* and *errors* to read the file.

Usage example: `fi = fileinput.FileInput(openhook=fileinput.hook_encoded("utf-8", "surrogateescape"))`

Άλλαξε στην έκδοση 3.6: Added the optional *errors* parameter.

11.4 stat — Interpreting `stat()` results

Source code: `Lib/stat.py`

The `stat` module defines constants and functions for interpreting the results of `os.stat()`, `os.fstat()` and `os.lstat()` (if they exist). For complete details about the `stat()`, `fstat()` and `lstat()` calls, consult the documentation for your system.

Άλλαξε στην έκδοση 3.4: The `stat` module is backed by a C implementation.

The `stat` module defines the following functions to test for specific file types:

`stat.S_ISDIR(mode)`

Return non-zero if the mode is from a directory.

`stat.S_ISCHR(mode)`

Return non-zero if the mode is from a character special device file.

`stat.S_ISBLK(mode)`

Return non-zero if the mode is from a block special device file.

`stat.S_ISREG(mode)`

Return non-zero if the mode is from a regular file.

`stat.S_ISFIFO(mode)`

Return non-zero if the mode is from a FIFO (named pipe).

`stat.S_ISLNK(mode)`

Return non-zero if the mode is from a symbolic link.

`stat.S_ISSOCK(mode)`

Return non-zero if the mode is from a socket.

`stat.S_ISDOOR(mode)`

Return non-zero if the mode is from a door.

Νέο στην έκδοση 3.4.

`stat.S_ISPORT(mode)`

Return non-zero if the mode is from an event port.

Νέο στην έκδοση 3.4.

`stat.S_ISWHT(mode)`

Return non-zero if the mode is from a whiteout.

Νέο στην έκδοση 3.4.

Two additional functions are defined for more general manipulation of the file's mode:

`stat.S_IMODE(mode)`

Return the portion of the file's mode that can be set by `os.chmod()`—that is, the file's permission bits, plus the sticky bit, set-group-id, and set-user-id bits (on systems that support them).

`stat.S_IFMT(mode)`

Return the portion of the file's mode that describes the file type (used by the `S_IS*()` functions above).

Normally, you would use the `os.path.is*()` functions for testing the type of a file; the functions here are useful when you are doing multiple tests of the same file and wish to avoid the overhead of the `stat()` system call for each test. These are also useful when checking for information about a file that isn't handled by `os.path`, like the tests for block and character devices.

Example:

```
import os, sys
from stat import *

def walktree(top, callback):
    '''recursively descend the directory tree rooted at top,
       calling the callback function for each regular file'''

    for f in os.listdir(top):
        pathname = os.path.join(top, f)
        mode = os.lstat(pathname).st_mode
        if S_ISDIR(mode):
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

        # It's a directory, recurse into it
        walktree(pathname, callback)
    elif S_ISREG(mode):
        # It's a file, call the callback function
        callback(pathname)
    else:
        # Unknown file type, print a message
        print('Skipping %s' % pathname)

def visitfile(file):
    print('visiting', file)

if __name__ == '__main__':
    walktree(sys.argv[1], visitfile)

```

An additional utility function is provided to convert a file's mode in a human readable string:

`stat.filemode(mode)`
 Convert a file's mode to a string of the form “-rwxrwxrwx”.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.4: The function supports `S_IFDOOR`, `S_IFPORT` and `S_IFWHT`.

All the variables below are simply symbolic indexes into the 10-tuple returned by `os.stat()`, `os.fstat()` or `os.lstat()`.

`stat.ST_MODE`
 Inode protection mode.

`stat.ST_INO`
 Inode number.

`stat.ST_DEV`
 Device inode resides on.

`stat.ST_NLINK`
 Number of links to the inode.

`stat.ST_UID`
 User id of the owner.

`stat.ST_GID`
 Group id of the owner.

`stat.ST_SIZE`
 Size in bytes of a plain file; amount of data waiting on some special files.

`stat.ST_ATIME`
 Time of last access.

`stat.ST_MTIME`
 Time of last modification.

`stat.ST_CTIME`
 The «ctime» as reported by the operating system. On some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time (see platform documentation for details).

The interpretation of «file size» changes according to the file type. For plain files this is the size of the file in bytes. For FIFOs and sockets under most flavors of Unix (including Linux in particular), the «size» is the number of bytes waiting to be read at the time of the call to `os.stat()`, `os.fstat()`, or `os.lstat()`; this can sometimes be useful,

especially for polling one of these special files after a non-blocking open. The meaning of the size field for other character and block devices varies more, depending on the implementation of the underlying system call.

The variables below define the flags used in the `ST_MODE` field.

Use of the functions above is more portable than use of the first set of flags:

```
stat.S_IFSOCK
    Socket.

stat.S_IFLNK
    Symbolic link.

stat.S_IFREG
    Regular file.

stat.S_IFBLK
    Block device.

stat.S_IFDIR
    Directory.

stat.S_IFCHR
    Character device.

stat.S_IFIFO
    FIFO.

stat.S_IFDOOR
    Door.

    Νέο στην έκδοση 3.4.

stat.S_IFPORT
    Event port.

    Νέο στην έκδοση 3.4.

stat.S_IFWHT
    Whiteout.

    Νέο στην έκδοση 3.4.
```

Σημείωση: `S_IFDOOR`, `S_IFPORT` or `S_IFWHT` are defined as 0 when the platform does not have support for the file types.

The following flags can also be used in the *mode* argument of `os.chmod()`:

```
stat.S_ISUID
    Set UID bit.

stat.S_ISGID
    Set-group-ID bit. This bit has several special uses. For a directory it indicates that BSD semantics is to be used
    for that directory: files created there inherit their group ID from the directory, not from the effective group ID
    of the creating process, and directories created there will also get the S_ISGID bit set. For a file that does not
    have the group execution bit (S_IXGRP) set, the set-group-ID bit indicates mandatory file/record locking (see also
    S_ENFMT).

stat.S_ISVTX
    Sticky bit. When this bit is set on a directory it means that a file in that directory can be renamed or deleted only
    by the owner of the file, by the owner of the directory, or by a privileged process.
```

`stat.S_IRWXU`
Mask for file owner permissions.

`stat.S_IRUSR`
Owner has read permission.

`stat.S_IWUSR`
Owner has write permission.

`stat.S_IXUSR`
Owner has execute permission.

`stat.S_IRWXG`
Mask for group permissions.

`stat.S_IRGRP`
Group has read permission.

`stat.S_IWGRP`
Group has write permission.

`stat.S_IXGRP`
Group has execute permission.

`stat.S_IRWXO`
Mask for permissions for others (not in group).

`stat.S_IROTH`
Others have read permission.

`stat.S_IWOTH`
Others have write permission.

`stat.S_IXOTH`
Others have execute permission.

`stat.S_ENFMT`
System V file locking enforcement. This flag is shared with `S_ISGID`: file/record locking is enforced on files that do not have the group execution bit (`S_IXGRP`) set.

`stat.S_IREAD`
Unix V7 synonym for `S_IRUSR`.

`stat.S_IWRITE`
Unix V7 synonym for `S_IWUSR`.

`stat.S_IEXEC`
Unix V7 synonym for `S_IXUSR`.

The following flags can be used in the *flags* argument of `os.chflags()`:

`stat.UF_NODUMP`
Do not dump the file.

`stat.UF_IMMUTABLE`
The file may not be changed.

`stat.UF_APPEND`
The file may only be appended to.

`stat.UF_OPAQUE`
The directory is opaque when viewed through a union stack.

`stat.UF_NOUNLINK`
The file may not be renamed or deleted.

`stat.UF_COMPRESSED`
The file is stored compressed (macOS 10.6+).

`stat.UF_HIDDEN`
The file should not be displayed in a GUI (macOS 10.5+).

`stat.SF_ARCHIVED`
The file may be archived.

`stat.SF_IMMUTABLE`
The file may not be changed.

`stat.SF_APPEND`
The file may only be appended to.

`stat.SF_NOUNLINK`
The file may not be renamed or deleted.

`stat.SF_SNAPSHOT`
The file is a snapshot file.

See the **BSD* or macOS systems man page *chflags(2)* for more information.

On Windows, the following file attribute constants are available for use when testing bits in the `st_file_attributes` member returned by `os.stat()`. See the [Windows API documentation](#) for more detail on the meaning of these constants.

`stat.FILE_ATTRIBUTE_ARCHIVE`
`stat.FILE_ATTRIBUTE_COMPRESSED`
`stat.FILE_ATTRIBUTE_DEVICE`
`stat.FILE_ATTRIBUTE_DIRECTORY`
`stat.FILE_ATTRIBUTE_ENCRYPTED`
`stat.FILE_ATTRIBUTE_HIDDEN`
`stat.FILE_ATTRIBUTE_INTEGRITY_STREAM`
`stat.FILE_ATTRIBUTE_NORMAL`
`stat.FILE_ATTRIBUTE_NOT_CONTENT_INDEXED`
`stat.FILE_ATTRIBUTE_NO_SCRUB_DATA`
`stat.FILE_ATTRIBUTE_OFFLINE`
`stat.FILE_ATTRIBUTE_READONLY`
`stat.FILE_ATTRIBUTE_REPARSE_POINT`
`stat.FILE_ATTRIBUTE_SPARSE_FILE`
`stat.FILE_ATTRIBUTE_SYSTEM`
`stat.FILE_ATTRIBUTE_TEMPORARY`
`stat.FILE_ATTRIBUTE_VIRTUAL`
Νέο στην έκδοση 3.5.

On Windows, the following constants are available for comparing against the `st_reparse_tag` member returned by `os.lstat()`. These are well-known constants, but are not an exhaustive list.

`stat.IO_REPARSE_TAG_SYMLINK`
`stat.IO_REPARSE_TAG_MOUNT_POINT`
`stat.IO_REPARSE_TAG_APPEXECLINK`
Νέο στην έκδοση 3.8.

11.5 filecmp — File and Directory Comparisons

Source code: [Lib/filecmp.py](#)

The `filecmp` module defines functions to compare files and directories, with various optional time/correctness trade-offs. For comparing files, see also the `difflib` module.

The `filecmp` module defines the following functions:

`filecmp.cmp(f1, f2, shallow=True)`

Compare the files named *f1* and *f2*, returning `True` if they seem equal, `False` otherwise.

If *shallow* is true and the `os.stat()` signatures (file type, size, and modification time) of both files are identical, the files are taken to be equal.

Otherwise, the files are treated as different if their sizes or contents differ.

Note that no external programs are called from this function, giving it portability and efficiency.

This function uses a cache for past comparisons and the results, with cache entries invalidated if the `os.stat()` information for the file changes. The entire cache may be cleared using `clear_cache()`.

`filecmp.cmpfiles(dir1, dir2, common, shallow=True)`

Compare the files in the two directories *dir1* and *dir2* whose names are given by *common*.

Returns three lists of file names: *match*, *mismatch*, *errors*. *match* contains the list of files that match, *mismatch* contains the names of those that don't, and *errors* lists the names of files which could not be compared. Files are listed in *errors* if they don't exist in one of the directories, the user lacks permission to read them or if the comparison could not be done for some other reason.

The *shallow* parameter has the same meaning and default value as for `filecmp.cmp()`.

For example, `cmpfiles('a', 'b', ['c', 'd/e'])` will compare *a/c* with *b/c* and *a/d/e* with *b/d/e*. *'c'* and *'d/e'* will each be in one of the three returned lists.

`filecmp.clear_cache()`

Clear the filecmp cache. This may be useful if a file is compared so quickly after it is modified that it is within the mtime resolution of the underlying filesystem.

Νέο στην έκδοση 3.4.

11.5.1 The `dircmp` class

`class filecmp.dircmp(a, b, ignore=None, hide=None)`

Construct a new directory comparison object, to compare the directories *a* and *b*. *ignore* is a list of names to ignore, and defaults to `filecmp.DEFAULT_IGNORES`. *hide* is a list of names to hide, and defaults to `[os.curdir, os.pardir]`.

The `dircmp` class compares files by doing *shallow* comparisons as described for `filecmp.cmp()`.

The `dircmp` class provides the following methods:

`report()`

Print (to `sys.stdout`) a comparison between *a* and *b*.

`report_partial_closure()`

Print a comparison between *a* and *b* and common immediate subdirectories.

`report_full_closure()`

Print a comparison between *a* and *b* and common subdirectories (recursively).

The `dircmp` class offers a number of interesting attributes that may be used to get various bits of information about the directory trees being compared.

Note that via `__getattr__()` hooks, all attributes are computed lazily, so there is no speed penalty if only those attributes which are lightweight to compute are used.

left

The directory *a*.

right

The directory *b*.

left_list

Files and subdirectories in *a*, filtered by *hide* and *ignore*.

right_list

Files and subdirectories in *b*, filtered by *hide* and *ignore*.

common

Files and subdirectories in both *a* and *b*.

left_only

Files and subdirectories only in *a*.

right_only

Files and subdirectories only in *b*.

common_dirs

Subdirectories in both *a* and *b*.

common_files

Files in both *a* and *b*.

common_funny

Names in both *a* and *b*, such that the type differs between the directories, or names for which `os.stat()` reports an error.

same_files

Files which are identical in both *a* and *b*, using the class's file comparison operator.

diff_files

Files which are in both *a* and *b*, whose contents differ according to the class's file comparison operator.

funny_files

Files which are in both *a* and *b*, but could not be compared.

subdirs

A dictionary mapping names in `common_dirs` to `dircmp` objects.

filecmp.DEFAULT_IGNORES

Νέο στην έκδοση 3.4.

List of directories ignored by `dircmp` by default.

Here is a simplified example of using the `subdirs` attribute to search recursively through two directories to show common different files:

```
>>> from filecmp import dircmp
>>> def print_diff_files(dcmp):
...     for name in dcmp.diff_files:
...         print("diff_file %s found in %s and %s" % (name, dcmp.left,
...             dcmp.right))
...     for sub_dcmp in dcmp.subdirs.values():
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

...         print_diff_files(sub_dcmp)
...
>>> dcmp = dircmp('dir1', 'dir2')
>>> print_diff_files(dcmp)

```

11.6 tempfile — Generate temporary files and directories

Source code: [Lib/tempfile.py](#)

This module creates temporary files and directories. It works on all supported platforms. *TemporaryFile*, *NamedTemporaryFile*, *TemporaryDirectory*, and *SpooledTemporaryFile* are high-level interfaces which provide automatic cleanup and can be used as context managers. *mkstemp()* and *mkdtemp()* are lower-level functions which require manual cleanup.

All the user-callable functions and constructors take additional arguments which allow direct control over the location and name of temporary files and directories. Files names used by this module include a string of random characters which allows those files to be securely created in shared temporary directories. To maintain backward compatibility, the argument order is somewhat odd; it is recommended to use keyword arguments for clarity.

The module defines the following user-callable items:

`tempfile.TemporaryFile(mode='w+b', buffering=-1, encoding=None, newline=None, suffix=None, prefix=None, dir=None, *, errors=None)`

Return a *file-like object* that can be used as a temporary storage area. The file is created securely, using the same rules as *mkstemp()*. It will be destroyed as soon as it is closed (including an implicit close when the object is garbage collected). Under Unix, the directory entry for the file is either not created at all or is removed immediately after the file is created. Other platforms do not support this; your code should not rely on a temporary file created using this function having or not having a visible name in the file system.

The resulting object can be used as a context manager (see *Examples*). On completion of the context or destruction of the file object the temporary file will be removed from the filesystem.

The *mode* parameter defaults to 'w+b' so that the file created can be read and written without being closed. Binary mode is used so that it behaves consistently on all platforms without regard for the data that is stored. *buffering*, *encoding*, *errors* and *newline* are interpreted as for *open()*.

The *dir*, *prefix* and *suffix* parameters have the same meaning and defaults as with *mkstemp()*.

The returned object is a true file object on POSIX platforms. On other platforms, it is a file-like object whose *file* attribute is the underlying true file object.

The *os.O_TMPFILE* flag is used if it is available and works (Linux-specific, requires Linux kernel 3.11 or later).

On platforms that are neither Posix nor Cygwin, *TemporaryFile* is an alias for *NamedTemporaryFile*.

Raises an *auditing event* `tempfile.mkstemp` with argument `fullpath`.

Άλλαξε στην έκδοση 3.5: The *os.O_TMPFILE* flag is now used if available.

Άλλαξε στην έκδοση 3.8: Added *errors* parameter.

`tempfile.NamedTemporaryFile(mode='w+b', buffering=-1, encoding=None, newline=None, suffix=None, prefix=None, dir=None, delete=True, *, errors=None)`

This function operates exactly as *TemporaryFile()* does, except that the file is guaranteed to have a visible name in the file system (on Unix, the directory entry is not unlinked). That name can be retrieved from the *name* attribute of the returned file-like object. Whether the name can be used to open the file a second time, while the

named temporary file is still open, varies across platforms (it can be so used on Unix; it cannot on Windows). If *delete* is true (the default), the file is deleted as soon as it is closed. The returned object is always a file-like object whose *file* attribute is the underlying true file object. This file-like object can be used in a *with* statement, just like a normal file.

Raises an *auditing event* `tempfile.mkstemp` with argument `fullpath`.

Άλλαξε στην έκδοση 3.8: Added *errors* parameter.

```
tempfile.SpoiledTemporaryFile(max_size=0, mode='w+b', buffering=-1, encoding=None,
                               newline=None, suffix=None, prefix=None, dir=None, *,
                               errors=None)
```

This function operates exactly as `TemporaryFile()` does, except that data is spooled in memory until the file size exceeds *max_size*, or until the file's `fileno()` method is called, at which point the contents are written to disk and operation proceeds as with `TemporaryFile()`.

The resulting file has one additional method, `rollover()`, which causes the file to roll over to an on-disk file regardless of its size.

The returned object is a file-like object whose `_file` attribute is either an *io.BytesIO* or *io.TextIOWrapper* object (depending on whether binary or text *mode* was specified) or a true file object, depending on whether `rollover()` has been called. This file-like object can be used in a *with* statement, just like a normal file.

Άλλαξε στην έκδοση 3.3: the `truncate` method now accepts a *size* argument.

Άλλαξε στην έκδοση 3.8: Added *errors* parameter.

```
tempfile.TemporaryDirectory(suffix=None, prefix=None, dir=None)
```

This function securely creates a temporary directory using the same rules as `mkdtemp()`. The resulting object can be used as a context manager (see *Examples*). On completion of the context or destruction of the temporary directory object the newly created temporary directory and all its contents are removed from the filesystem.

The directory name can be retrieved from the `name` attribute of the returned object. When the returned object is used as a context manager, the `name` will be assigned to the target of the *as* clause in the *with* statement, if there is one.

The directory can be explicitly cleaned up by calling the `cleanup()` method.

Raises an *auditing event* `tempfile.mkdtemp` with argument `fullpath`.

Νέο στην έκδοση 3.2.

```
tempfile.mkstemp(suffix=None, prefix=None, dir=None, text=False)
```

Creates a temporary file in the most secure manner possible. There are no race conditions in the file's creation, assuming that the platform properly implements the *os.O_EXCL* flag for *os.open()*. The file is readable and writable only by the creating user ID. If the platform uses permission bits to indicate whether a file is executable, the file is executable by no one. The file descriptor is not inherited by child processes.

Unlike `TemporaryFile()`, the user of `mkstemp()` is responsible for deleting the temporary file when done with it.

If *suffix* is not *None*, the file name will end with that suffix, otherwise there will be no suffix. `mkstemp()` does not put a dot between the file name and the suffix; if you need one, put it at the beginning of *suffix*.

If *prefix* is not *None*, the file name will begin with that prefix; otherwise, a default prefix is used. The default is the return value of `gettempprefix()` or `gettempprefixb()`, as appropriate.

If *dir* is not *None*, the file will be created in that directory; otherwise, a default directory is used. The default directory is chosen from a platform-dependent list, but the user of the application can control the directory location by setting the *TMPDIR*, *TEMP* or *TMP* environment variables. There is thus no guarantee that the generated filename will have any nice properties, such as not requiring quoting when passed to external commands via *os.popen()*.

If any of *suffix*, *prefix*, and *dir* are not `None`, they must be the same type. If they are bytes, the returned name will be bytes instead of `str`. If you want to force a bytes return value with otherwise default behavior, pass `suffix=b''`.

If *text* is specified and `true`, the file is opened in text mode. Otherwise, (the default) the file is opened in binary mode.

`mkstemp()` returns a tuple containing an OS-level handle to an open file (as would be returned by `os.open()`) and the absolute pathname of that file, in that order.

Raises an *auditing event* `tempfile.mkstemp` with argument `fullpath`.

Άλλαξε στην έκδοση 3.5: *suffix*, *prefix*, and *dir* may now be supplied in bytes in order to obtain a bytes return value. Prior to this, only `str` was allowed. *suffix* and *prefix* now accept and default to `None` to cause an appropriate default value to be used.

Άλλαξε στην έκδοση 3.6: The *dir* parameter now accepts a *path-like object*.

`tempfile.mkdtemp(suffix=None, prefix=None, dir=None)`

Creates a temporary directory in the most secure manner possible. There are no race conditions in the directory's creation. The directory is readable, writable, and searchable only by the creating user ID.

The user of `mkdtemp()` is responsible for deleting the temporary directory and its contents when done with it.

The *prefix*, *suffix*, and *dir* arguments are the same as for `mkstemp()`.

`mkdtemp()` returns the absolute pathname of the new directory.

Raises an *auditing event* `tempfile.mkdtemp` with argument `fullpath`.

Άλλαξε στην έκδοση 3.5: *suffix*, *prefix*, and *dir* may now be supplied in bytes in order to obtain a bytes return value. Prior to this, only `str` was allowed. *suffix* and *prefix* now accept and default to `None` to cause an appropriate default value to be used.

Άλλαξε στην έκδοση 3.6: The *dir* parameter now accepts a *path-like object*.

`tempfile.gettempdir()`

Return the name of the directory used for temporary files. This defines the default value for the *dir* argument to all functions in this module.

Python searches a standard list of directories to find one which the calling user can create files in. The list is:

1. The directory named by the `TMPDIR` environment variable.
2. The directory named by the `TEMP` environment variable.
3. The directory named by the `TMP` environment variable.
4. A platform-specific location:
 - On Windows, the directories `C:\TEMP`, `C:\TMP`, `\TEMP`, and `\TMP`, in that order.
 - On all other platforms, the directories `/tmp`, `/var/tmp`, and `/usr/tmp`, in that order.
5. As a last resort, the current working directory.

The result of this search is cached, see the description of *tempdir* below.

`tempfile.gettempdirb()`

Same as `gettempdir()` but the return value is in bytes.

Νέο στην έκδοση 3.5.

`tempfile.gettempprefix()`

Return the filename prefix used to create temporary files. This does not contain the directory component.

`tempfile.gettempprefixb()`

Same as `gettempprefix()` but the return value is in bytes.

Νέο στην έκδοση 3.5.

The module uses a global variable to store the name of the directory used for temporary files returned by `gettempdir()`. It can be set directly to override the selection process, but this is discouraged. All functions in this module take a *dir* argument which can be used to specify the directory and this is the recommended approach.

`tempfile.tempdir`

When set to a value other than `None`, this variable defines the default value for the *dir* argument to the functions defined in this module.

If `tempdir` is `None` (the default) at any call to any of the above functions except `gettempprefix()` it is initialized following the algorithm described in `gettempdir()`.

11.6.1 Examples

Here are some examples of typical usage of the `tempfile` module:

```
>>> import tempfile

# create a temporary file and write some data to it
>>> fp = tempfile.TemporaryFile()
>>> fp.write(b'Hello world!')
# read data from file
>>> fp.seek(0)
>>> fp.read()
b'Hello world!'
# close the file, it will be removed
>>> fp.close()

# create a temporary file using a context manager
>>> with tempfile.TemporaryFile() as fp:
...     fp.write(b'Hello world!')
...     fp.seek(0)
...     fp.read()
b'Hello world!'
>>>
# file is now closed and removed

# create a temporary directory using the context manager
>>> with tempfile.TemporaryDirectory() as tmpdirname:
...     print('created temporary directory', tmpdirname)
>>>
# directory and contents have been removed
```

11.6.2 Deprecated functions and variables

A historical way to create temporary files was to first generate a file name with the `mktemp()` function and then create a file using this name. Unfortunately this is not secure, because a different process may create a file with this name in the time between the call to `mktemp()` and the subsequent attempt to create the file by the first process. The solution is to combine the two steps and create the file immediately. This approach is used by `mkstemp()` and the other functions described above.

`tempfile.mktemp(suffix='', prefix='tmp', dir=None)`

Αποσύρθηκε στην έκδοση 2.3: Use `mkstemp()` instead.

Return an absolute pathname of a file that did not exist at the time the call is made. The *prefix*, *suffix*, and *dir* arguments are similar to those of `mkstemp()`, except that bytes file names, `suffix=None` and `prefix=None` are not supported.

Προειδοποίηση: Use of this function may introduce a security hole in your program. By the time you get around to doing anything with the file name it returns, someone else may have beaten you to the punch. `mktemp()` usage can be replaced easily with `NamedTemporaryFile()`, passing it the `delete=False` parameter:

```
>>> f = NamedTemporaryFile(delete=False)
>>> f.name
'/tmp/tmpjtujjt'
>>> f.write(b"Hello World!\n")
13
>>> f.close()
>>> os.unlink(f.name)
>>> os.path.exists(f.name)
False
```

11.7 glob — Unix style pathname pattern expansion

Source code: [Lib/glob.py](#)

The `glob` module finds all the pathnames matching a specified pattern according to the rules used by the Unix shell, although results are returned in arbitrary order. No tilde expansion is done, but `*`, `?`, and character ranges expressed with `[]` will be correctly matched. This is done by using the `os.scandir()` and `fnmatch.fnmatch()` functions in concert, and not by actually invoking a subshell.

Note that files beginning with a dot (`.`) can only be matched by patterns that also start with a dot, unlike `fnmatch.fnmatch()` or `pathlib.Path.glob()`. (For tilde and shell variable expansion, use `os.path.expanduser()` and `os.path.expandvars()`.)

For a literal match, wrap the meta-characters in brackets. For example, `'[?]'` matches the character `'?'`.

Δείτε επίσης:

The `pathlib` module offers high-level path objects.

`glob.glob(pathname, *, recursive=False)`

Return a possibly-empty list of path names that match *pathname*, which must be a string containing a path specification. *pathname* can be either absolute (like `/usr/src/Python-1.5/Makefile`) or relative (like `../../Tools/*/*.gif`), and can contain shell-style wildcards. Broken symlinks are included in the results

(as in the shell). Whether or not the results are sorted depends on the file system. If a file that satisfies conditions is removed or added during the call of this function, whether a path name for that file be included is unspecified.

If *recursive* is true, the pattern «*» will match any files and zero or more directories, subdirectories and symbolic links to directories. If the pattern is followed by an *os.sep* or *os.altsep* then files will not match.

Raises an *auditing event* `glob.glob` with arguments `pathname`, `recursive`.

Σημείωση: Using the «*» pattern in large directory trees may consume an inordinate amount of time.

Άλλαξε στην έκδοση 3.5: Support for recursive globs using «*».

`glob.iglob` (*pathname*, *, *recursive=False*)

Return an *iterator* which yields the same values as *glob()* without actually storing them all simultaneously.

Raises an *auditing event* `glob.glob` with arguments `pathname`, `recursive`.

`glob.escape` (*pathname*)

Escape all special characters ('?', '*', and '['). This is useful if you want to match an arbitrary literal string that may have special characters in it. Special characters in drive/UNC sharepoints are not escaped, e.g. on Windows `escape('///?/c:/Quo vadis?.txt')` returns `'///?/c:/Quo vadis[?].txt'`.

Νέο στην έκδοση 3.4.

For example, consider a directory containing the following files: `1.gif`, `2.txt`, `card.gif` and a subdirectory `sub` which contains only the file `3.txt`. *glob()* will produce the following results. Notice how any leading components of the path are preserved.

```
>>> import glob
>>> glob.glob('./[0-9].*')
['./1.gif', './2.txt']
>>> glob.glob('*.gif')
['1.gif', 'card.gif']
>>> glob.glob('?.gif')
['1.gif']
>>> glob.glob('**/*.txt', recursive=True)
['2.txt', 'sub/3.txt']
>>> glob.glob('./**/', recursive=True)
['./', './sub/']
```

If the directory contains files starting with `.` they won't be matched by default. For example, consider a directory containing `card.gif` and `.card.gif`:

```
>>> import glob
>>> glob.glob('*.gif')
['card.gif']
>>> glob.glob('.*')
['.card.gif']
```

Δείτε επίσης:

Module *fnmatch* Shell-style filename (not path) expansion

11.8 fnmatch — Unix filename pattern matching

Source code: [Lib/fnmatch.py](#)

This module provides support for Unix shell-style wildcards, which are *not* the same as regular expressions (which are documented in the [re](#) module). The special characters used in shell-style wildcards are:

| Pattern | Meaning |
|---------|---|
| * | matches everything |
| ? | matches any single character |
| [seq] | matches any character in <i>seq</i> |
| [!seq] | matches any character not in <i>seq</i> |

For a literal match, wrap the meta-characters in brackets. For example, '[?]' matches the character '?'.
 Note that the filename separator ('/' on Unix) is *not* special to this module. See module [glob](#) for pathname expansion ([glob](#) uses [filter\(\)](#) to match pathname segments). Similarly, filenames starting with a period are not special for this module, and are matched by the * and ? patterns.

fnmatch.fnmatch(*filename*, *pattern*)

Test whether the *filename* string matches the *pattern* string, returning *True* or *False*. Both parameters are case-normalized using [os.path.normcase\(\)](#). [fnmatchcase\(\)](#) can be used to perform a case-sensitive comparison, regardless of whether that's standard for the operating system.

This example will print all file names in the current directory with the extension `.txt`:

```
import fnmatch
import os

for file in os.listdir('.'):
    if fnmatch.fnmatch(file, '*.txt'):
        print(file)
```

fnmatch.fnmatchcase(*filename*, *pattern*)

Test whether *filename* matches *pattern*, returning *True* or *False*; the comparison is case-sensitive and does not apply [os.path.normcase\(\)](#).

fnmatch.filter(*names*, *pattern*)

Construct a list from those elements of the iterable *names* that match *pattern*. It is the same as `[n for n in names if fnmatch(n, pattern)]`, but implemented more efficiently.

fnmatch.translate(*pattern*)

Return the shell-style *pattern* converted to a regular expression for using with [re.match\(\)](#).

Example:

```
>>> import fnmatch, re
>>>
>>> regex = fnmatch.translate('*.txt')
>>> regex
'(?s:.*\.\.txt)\Z'
>>> reobj = re.compile(regex)
>>> reobj.match('foobar.txt')
<re.Match object; span=(0, 10), match='foobar.txt'>
```

Δείτε επίσης:

Module *glob* Unix shell-style path expansion.

11.9 linecache — Random access to text lines

Source code: [Lib/linecache.py](#)

The *linecache* module allows one to get any line from a Python source file, while attempting to optimize internally, using a cache, the common case where many lines are read from a single file. This is used by the *traceback* module to retrieve source lines for inclusion in the formatted traceback.

The *tokenize.open()* function is used to open files. This function uses *tokenize.detect_encoding()* to get the encoding of the file; in the absence of an encoding token, the file encoding defaults to UTF-8.

The *linecache* module defines the following functions:

linecache.getline(*filename*, *lineno*, *module_globals=None*)

Get line *lineno* from file named *filename*. This function will never raise an exception — it will return ' ' on errors (the terminating newline character will be included for lines that are found).

If a file named *filename* is not found, the function first checks for a **PEP 302** *__loader__* in *module_globals*. If there is such a loader and it defines a *get_source* method, then that determines the source lines (if *get_source()* returns *None*, then ' ' is returned). Finally, if *filename* is a relative filename, it is looked up relative to the entries in the module search path, *sys.path*.

linecache.clearcache()

Clear the cache. Use this function if you no longer need lines from files previously read using *getline()*.

linecache.checkcache(*filename=None*)

Check the cache for validity. Use this function if files in the cache may have changed on disk, and you require the updated version. If *filename* is omitted, it will check all the entries in the cache.

linecache.lazycache(*filename*, *module_globals*)

Capture enough detail about a non-file-based module to permit getting its lines later via *getline()* even if *module_globals* is *None* in the later call. This avoids doing I/O until a line is actually needed, without having to carry the module globals around indefinitely.

Νέο στην έκδοση 3.5.

Example:

```
>>> import linecache
>>> linecache.getline(linecache.__file__, 8)
'import sys\n'
```

11.10 shutil — High-level file operations

Source code: [Lib/shutil.py](#)

The *shutil* module offers a number of high-level operations on files and collections of files. In particular, functions are provided which support file copying and removal. For operations on individual files, see also the *os* module.

Προειδοποίηση: Even the higher-level file copying functions (`shutil.copy()`, `shutil.copy2()`) cannot copy all file metadata.

On POSIX platforms, this means that file owner and group are lost as well as ACLs. On Mac OS, the resource fork and other metadata are not used. This means that resources will be lost and file type and creator codes will not be correct. On Windows, file owners, ACLs and alternate data streams are not copied.

11.10.1 Directory and files operations

`shutil.copyfileobj(fsrc, fdst[, length])`

Copy the contents of the file-like object *fsrc* to the file-like object *fdst*. The integer *length*, if given, is the buffer size. In particular, a negative *length* value means to copy the data without looping over the source data in chunks; by default the data is read in chunks to avoid uncontrolled memory consumption. Note that if the current file position of the *fsrc* object is not 0, only the contents from the current file position to the end of the file will be copied.

`shutil.copyfile(src, dst, *, follow_symlinks=True)`

Copy the contents (no metadata) of the file named *src* to a file named *dst* and return *dst* in the most efficient way possible. *src* and *dst* are path-like objects or path names given as strings.

dst must be the complete target file name; look at `copy()` for a copy that accepts a target directory path. If *src* and *dst* specify the same file, `SameFileError` is raised.

The destination location must be writable; otherwise, an `OSError` exception will be raised. If *dst* already exists, it will be replaced. Special files such as character or block devices and pipes cannot be copied with this function.

If *follow_symlinks* is false and *src* is a symbolic link, a new symbolic link will be created instead of copying the file *src* points to.

Raises an *auditing event* `shutil.copyfile` with arguments *src*, *dst*.

Άλλαξε στην έκδοση 3.3: `IOError` used to be raised instead of `OSError`. Added *follow_symlinks* argument. Now returns *dst*.

Άλλαξε στην έκδοση 3.4: Raise `SameFileError` instead of `Error`. Since the former is a subclass of the latter, this change is backward compatible.

Άλλαξε στην έκδοση 3.8: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

exception `shutil.SameFileError`

This exception is raised if source and destination in `copyfile()` are the same file.

Νέο στην έκδοση 3.4.

`shutil.copymode(src, dst, *, follow_symlinks=True)`

Copy the permission bits from *src* to *dst*. The file contents, owner, and group are unaffected. *src* and *dst* are path-like objects or path names given as strings. If *follow_symlinks* is false, and both *src* and *dst* are symbolic links, `copymode()` will attempt to modify the mode of *dst* itself (rather than the file it points to). This functionality is not available on every platform; please see `copystat()` for more information. If `copymode()` cannot modify symbolic links on the local platform, and it is asked to do so, it will do nothing and return.

Raises an *auditing event* `shutil.copymode` with arguments *src*, *dst*.

Άλλαξε στην έκδοση 3.3: Added *follow_symlinks* argument.

`shutil.copystat(src, dst, *, follow_symlinks=True)`

Copy the permission bits, last access time, last modification time, and flags from *src* to *dst*. On Linux, `copystat()` also copies the «extended attributes» where possible. The file contents, owner, and group are unaffected. *src* and *dst* are path-like objects or path names given as strings.

If `follow_symlinks` is false, and `src` and `dst` both refer to symbolic links, `copystat()` will operate on the symbolic links themselves rather than the files the symbolic links refer to—reading the information from the `src` symbolic link, and writing the information to the `dst` symbolic link.

Σημείωση: Not all platforms provide the ability to examine and modify symbolic links. Python itself can tell you what functionality is locally available.

- If `os.chmod` in `os.supports_follow_symlinks` is True, `copystat()` can modify the permission bits of a symbolic link.
- If `os.utime` in `os.supports_follow_symlinks` is True, `copystat()` can modify the last access and modification times of a symbolic link.
- If `os.chflags` in `os.supports_follow_symlinks` is True, `copystat()` can modify the flags of a symbolic link. (`os.chflags` is not available on all platforms.)

On platforms where some or all of this functionality is unavailable, when asked to modify a symbolic link, `copystat()` will copy everything it can. `copystat()` never returns failure.

Please see `os.supports_follow_symlinks` for more information.

Raises an *auditing event* `shutil.copystat` with arguments `src`, `dst`.

Άλλαξε στην έκδοση 3.3: Added `follow_symlinks` argument and support for Linux extended attributes.

`shutil.copy(src, dst, *, follow_symlinks=True)`

Copies the file `src` to the file or directory `dst`. `src` and `dst` should be *path-like objects* or strings. If `dst` specifies a directory, the file will be copied into `dst` using the base filename from `src`. If `dst` specifies a file that already exists, it will be replaced. Returns the path to the newly created file.

If `follow_symlinks` is false, and `src` is a symbolic link, `dst` will be created as a symbolic link. If `follow_symlinks` is true and `src` is a symbolic link, `dst` will be a copy of the file `src` refers to.

`copy()` copies the file data and the file's permission mode (see `os.chmod()`). Other metadata, like the file's creation and modification times, is not preserved. To preserve all file metadata from the original, use `copy2()` instead.

Raises an *auditing event* `shutil.copyfile` with arguments `src`, `dst`.

Raises an *auditing event* `shutil.copymode` with arguments `src`, `dst`.

Άλλαξε στην έκδοση 3.3: Added `follow_symlinks` argument. Now returns path to the newly created file.

Άλλαξε στην έκδοση 3.8: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

`shutil.copy2(src, dst, *, follow_symlinks=True)`

Identical to `copy()` except that `copy2()` also attempts to preserve file metadata.

When `follow_symlinks` is false, and `src` is a symbolic link, `copy2()` attempts to copy all metadata from the `src` symbolic link to the newly-created `dst` symbolic link. However, this functionality is not available on all platforms. On platforms where some or all of this functionality is unavailable, `copy2()` will preserve all the metadata it can; `copy2()` never raises an exception because it cannot preserve file metadata.

`copy2()` uses `copystat()` to copy the file metadata. Please see `copystat()` for more information about platform support for modifying symbolic link metadata.

Raises an *auditing event* `shutil.copyfile` with arguments `src`, `dst`.

Raises an *auditing event* `shutil.copystat` with arguments `src`, `dst`.

Άλλαξε στην έκδοση 3.3: Added *follow_symlinks* argument, try to copy extended file system attributes too (currently Linux only). Now returns path to the newly created file.

Άλλαξε στην έκδοση 3.8: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

`shutil.ignore_patterns(*patterns)`

This factory function creates a function that can be used as a callable for `copytree()`'s *ignore* argument, ignoring files and directories that match one of the glob-style *patterns* provided. See the example below.

`shutil.copytree(src, dst, symlinks=False, ignore=None, copy_function=copy2, ignore_dangling_symlinks=False, dirs_exist_ok=False)`

Recursively copy an entire directory tree rooted at *src* to a directory named *dst* and return the destination directory. All intermediate directories needed to contain *dst* will also be created by default.

Permissions and times of directories are copied with `copystat()`, individual files are copied using `copy2()`.

If *symlinks* is true, symbolic links in the source tree are represented as symbolic links in the new tree and the metadata of the original links will be copied as far as the platform allows; if false or omitted, the contents and metadata of the linked files are copied to the new tree.

When *symlinks* is false, if the file pointed by the symlink doesn't exist, an exception will be added in the list of errors raised in an *Error* exception at the end of the copy process. You can set the optional *ignore_dangling_symlinks* flag to true if you want to silence this exception. Notice that this option has no effect on platforms that don't support `os.symlink()`.

If *ignore* is given, it must be a callable that will receive as its arguments the directory being visited by `copytree()`, and a list of its contents, as returned by `os.listdir()`. Since `copytree()` is called recursively, the *ignore* callable will be called once for each directory that is copied. The callable must return a sequence of directory and file names relative to the current directory (i.e. a subset of the items in its second argument); these names will then be ignored in the copy process. `ignore_patterns()` can be used to create such a callable that ignores names based on glob-style patterns.

If exception(s) occur, an *Error* is raised with a list of reasons.

If *copy_function* is given, it must be a callable that will be used to copy each file. It will be called with the source path and the destination path as arguments. By default, `copy2()` is used, but any function that supports the same signature (like `copy()`) can be used.

If *dirs_exist_ok* is false (the default) and *dst* already exists, a *FileExistsError* is raised. If *dirs_exist_ok* is true, the copying operation will continue if it encounters existing directories, and files within the *dst* tree will be overwritten by corresponding files from the *src* tree.

Raises an *auditing event* `shutil.copytree` with arguments *src*, *dst*.

Άλλαξε στην έκδοση 3.3: Copy metadata when *symlinks* is false. Now returns *dst*.

Άλλαξε στην έκδοση 3.2: Added the *copy_function* argument to be able to provide a custom copy function. Added the *ignore_dangling_symlinks* argument to silence dangling symlinks errors when *symlinks* is false.

Άλλαξε στην έκδοση 3.8: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

Νέο στην έκδοση 3.8: The *dirs_exist_ok* parameter.

`shutil.rmtree(path, ignore_errors=False, onerror=None)`

Delete an entire directory tree; *path* must point to a directory (but not a symbolic link to a directory). If *ignore_errors* is true, errors resulting from failed removals will be ignored; if false or omitted, such errors are handled by calling a handler specified by *onerror* or, if that is omitted, they raise an exception.

Σημείωση: On platforms that support the necessary fd-based functions a symlink attack resistant version of `rmtree()` is used by default. On other platforms, the `rmtree()` implementation is susceptible to a symlink

attack: given proper timing and circumstances, attackers can manipulate symlinks on the filesystem to delete files they wouldn't be able to access otherwise. Applications can use the `rmtree.avoids_symlink_attacks` function attribute to determine which case applies.

If *onerror* is provided, it must be a callable that accepts three parameters: *function*, *path*, and *excinfo*.

The first parameter, *function*, is the function which raised the exception; it depends on the platform and implementation. The second parameter, *path*, will be the path name passed to *function*. The third parameter, *excinfo*, will be the exception information returned by `sys.exc_info()`. Exceptions raised by *onerror* will not be caught.

Raises an *auditing event* `shutil.rmtree` with argument *path*.

Άλλαξε στην έκδοση 3.3: Added a symlink attack resistant version that is used automatically if platform supports fd-based functions.

Άλλαξε στην έκδοση 3.8: On Windows, will no longer delete the contents of a directory junction before removing the junction.

`rmtree.avoids_symlink_attacks`

Indicates whether the current platform and implementation provides a symlink attack resistant version of `rmtree()`. Currently this is only true for platforms supporting fd-based directory access functions.

Νέο στην έκδοση 3.3.

`shutil.move(src, dst, copy_function=copy2)`

Recursively move a file or directory (*src*) to another location (*dst*) and return the destination.

If the destination is an existing directory, then *src* is moved inside that directory. If the destination already exists but is not a directory, it may be overwritten depending on `os.rename()` semantics.

If the destination is on the current filesystem, then `os.rename()` is used. Otherwise, *src* is copied to *dst* using *copy_function* and then removed. In case of symlinks, a new symlink pointing to the target of *src* will be created in or as *dst* and *src* will be removed.

If *copy_function* is given, it must be a callable that takes two arguments *src* and *dst*, and will be used to copy *src* to *dst* if `os.rename()` cannot be used. If the source is a directory, `copytree()` is called, passing it the *copy_function()*. The default *copy_function* is `copy2()`. Using `copy()` as the *copy_function* allows the move to succeed when it is not possible to also copy the metadata, at the expense of not copying any of the metadata.

Raises an *auditing event* `shutil.move` with arguments *src*, *dst*.

Άλλαξε στην έκδοση 3.3: Added explicit symlink handling for foreign filesystems, thus adapting it to the behavior of GNU's **mv**. Now returns *dst*.

Άλλαξε στην έκδοση 3.5: Added the *copy_function* keyword argument.

Άλλαξε στην έκδοση 3.8: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

Άλλαξε στην έκδοση 3.9: Accepts a *path-like object* for both *src* and *dst*.

`shutil.disk_usage(path)`

Return disk usage statistics about the given path as a *named tuple* with the attributes *total*, *used* and *free*, which are the amount of total, used and free space, in bytes. *path* may be a file or a directory.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.8: On Windows, *path* can now be a file or directory.

Availability: Unix, Windows.

`shutil.chown(path, user=None, group=None)`

Change owner *user* and/or *group* of the given *path*.

user can be a system user name or a uid; the same applies to *group*. At least one argument is required.

See also `os.chown()`, the underlying function.

Raises an *auditing event* `shutil.chown` with arguments *path*, *user*, *group*.

Availability: Unix.

Νέο στην έκδοση 3.3.

`shutil.which(cmd, mode=os.F_OK | os.X_OK, path=None)`

Return the path to an executable which would be run if the given *cmd* was called. If no *cmd* would be called, return `None`.

mode is a permission mask passed to `os.access()`, by default determining if the file exists and executable.

When no *path* is specified, the results of `os.environ()` are used, returning either the «PATH» value or a fallback of `os.defpath`.

On Windows, the current directory is always prepended to the *path* whether or not you use the default or provide your own, which is the behavior the command shell uses when finding executables. Additionally, when finding the *cmd* in the *path*, the `PATHEXT` environment variable is checked. For example, if you call `shutil.which("python")`, `which()` will search `PATHEXT` to know that it should look for `python.exe` within the *path* directories. For example, on Windows:

```
>>> shutil.which("python")
'C:\\Python33\\python.EXE'
```

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.8: The *bytes* type is now accepted. If *cmd* type is *bytes*, the result type is also *bytes*.

exception `shutil.Error`

This exception collects exceptions that are raised during a multi-file operation. For `copytree()`, the exception argument is a list of 3-tuples (*srcname*, *dstname*, *exception*).

Platform-dependent efficient copy operations

Starting from Python 3.8, all functions involving a file copy (`copyfile()`, `copy()`, `copy2()`, `copytree()`, and `move()`) may use platform-specific «fast-copy» syscalls in order to copy the file more efficiently (see [bpo-33671](#)). «fast-copy» means that the copying operation occurs within the kernel, avoiding the use of userspace buffers in Python as in «`outfd.write(infd.read())`».

On macOS `fcopyfile` is used to copy the file content (not metadata).

On Linux `os.sendfile()` is used.

On Windows `shutil.copyfile()` uses a bigger default buffer size (1 MiB instead of 64 KiB) and a `memoryview()`-based variant of `shutil.copyfileobj()` is used.

If the fast-copy operation fails and no data was written in the destination file then `shutil` will silently fallback on using less efficient `copyfileobj()` function internally.

Άλλαξε στην έκδοση 3.8.

copytree example

An example that uses the `ignore_patterns()` helper:

```
from shutil import copytree, ignore_patterns

copytree(source, destination, ignore=ignore_patterns('*.pyc', 'tmp*'))
```

This will copy everything except `.pyc` files and files or directories whose name starts with `tmp`.

Another example that uses the `ignore` argument to add a logging call:

```
from shutil import copytree
import logging

def _logpath(path, names):
    logging.info('Working in %s', path)
    return [] # nothing will be ignored

copytree(source, destination, ignore=_logpath)
```

rmtree example

This example shows how to remove a directory tree on Windows where some of the files have their read-only bit set. It uses the `onerror` callback to clear the readonly bit and reattempt the remove. Any subsequent failure will propagate.

```
import os, stat
import shutil

def remove_readonly(func, path, _):
    "Clear the readonly bit and reattempt the removal"
    os.chmod(path, stat.S_IWRITE)
    func(path)

shutil.rmtree(directory, onerror=remove_readonly)
```

11.10.2 Archiving operations

Νέο στην έκδοση 3.2.

Άλλαξε στην έκδοση 3.5: Added support for the *xz*tar format.

High-level utilities to create and read compressed and archived files are also provided. They rely on the *zipfile* and *tarfile* modules.

`shutil.make_archive(base_name, format[, root_dir[, base_dir[, verbose[, dry_run[, owner[, group[, logger]]]]]])`

Create an archive file (such as zip or tar) and return its name.

base_name is the name of the file to create, including the path, minus any format-specific extension. *format* is the archive format: one of «zip» (if the *zlib* module is available), «tar», «gz» (if the *zlib* module is available), «bz2» (if the *bz2* module is available), or «xz» (if the *lzma* module is available).

root_dir is a directory that will be the root directory of the archive, all paths in the archive will be relative to it; for example, we typically `chdir` into *root_dir* before creating the archive.

base_dir is the directory where we start archiving from; i.e. *base_dir* will be the common prefix of all files and directories in the archive. *base_dir* must be given relative to *root_dir*. See [Archiving example with base_dir](#) for how to use *base_dir* and *root_dir* together.

root_dir and *base_dir* both default to the current directory.

If *dry_run* is true, no archive is created, but the operations that would be executed are logged to *logger*.

owner and *group* are used when creating a tar archive. By default, uses the current owner and group.

logger must be an object compatible with [PEP 282](#), usually an instance of `logging.Logger`.

The *verbose* argument is unused and deprecated.

Raises an [auditing event](#) `shutil.make_archive` with arguments *base_name*, *format*, *root_dir*, *base_dir*.

Σημείωση: This function is not thread-safe.

Άλλαξε στην έκδοση 3.8: The modern pax (POSIX.1-2001) format is now used instead of the legacy GNU format for archives created with `format="tar"`.

`shutil.get_archive_formats()`

Return a list of supported formats for archiving. Each element of the returned sequence is a tuple (name, description).

By default *shutil* provides these formats:

- *zip*: ZIP file (if the *zlib* module is available).
- *tar*: Uncompressed tar file. Uses POSIX.1-2001 pax format for new archives.
- *gztar*: gzip'ed tar-file (if the *zlib* module is available).
- *bztar*: bzip2'ed tar-file (if the *bz2* module is available).
- *xztar*: xz'ed tar-file (if the *lzma* module is available).

You can register new formats or provide your own archiver for any existing formats, by using `register_archive_format()`.

`shutil.register_archive_format(name, function[, extra_args[, description]])`

Register an archiver for the format *name*.

function is the callable that will be used to unpack archives. The callable will receive the *base_name* of the file to create, followed by the *base_dir* (which defaults to `os.curdir`) to start archiving from. Further arguments are passed as keyword arguments: *owner*, *group*, *dry_run* and *logger* (as passed in `make_archive()`).

If given, *extra_args* is a sequence of (name, value) pairs that will be used as extra keywords arguments when the archiver callable is used.

description is used by `get_archive_formats()` which returns the list of archivers. Defaults to an empty string.

`shutil.unregister_archive_format(name)`

Remove the archive format *name* from the list of supported formats.

`shutil.unpack_archive(filename[, extract_dir[, format[, filter]]])`

Unpack an archive. *filename* is the full path of the archive.

extract_dir is the name of the target directory where the archive is unpacked. If not provided, the current working directory is used.

format is the archive format: one of «zip», «tar», «gztar», «bztar», or «xztar». Or any other format registered with `register_unpack_format()`. If not provided, `unpack_archive()` will use the archive file name extension and see if an unpacker was registered for that extension. In case none is found, a `ValueError` is raised.

The keyword-only *filter* argument, which was added in Python 3.9.17, is passed to the underlying unpacking function. For zip files, *filter* is not accepted. For tar files, it is recommended to set it to 'data', unless using features specific to tar and UNIX-like filesystems. (See [Extraction filters](#) for details.) The 'data' filter will become the default for tar files in Python 3.14.

Raises an *auditing event* `shutil.unpack_archive` with arguments `filename`, `extract_dir`, `format`.

Προειδοποίηση: Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of the path specified in the *extract_dir* argument, e.g. members that have absolute filenames starting with «/» or filenames with two dots «..».

Άλλαξε στην έκδοση 3.7: Accepts a *path-like object* for *filename* and *extract_dir*.

Άλλαξε στην έκδοση 3.9.17: Added the *filter* argument.

`shutil.register_unpack_format(name, extensions, function[, extra_args[, description]])`

Registers an unpack format. *name* is the name of the format and *extensions* is a list of extensions corresponding to the format, like `.zip` for Zip files.

function is the callable that will be used to unpack archives. The callable will receive:

- the path of the archive, as a positional argument;
- the directory the archive must be extracted to, as a positional argument;
- possibly a *filter* keyword argument, if it was given to `unpack_archive()`;
- additional keyword arguments, specified by *extra_args* as a sequence of (name, value) tuples.

description can be provided to describe the format, and will be returned by the `get_unpack_formats()` function.

`shutil.unregister_unpack_format(name)`

Unregister an unpack format. *name* is the name of the format.

`shutil.get_unpack_formats()`

Return a list of all registered formats for unpacking. Each element of the returned sequence is a tuple (name, extensions, description).

By default *shutil* provides these formats:

- *zip*: ZIP file (unpacking compressed files works only if the corresponding module is available).
- *tar*: uncompressed tar file.
- *gztar*: gzip'ed tar-file (if the *zlib* module is available).
- *bztar*: bzip2'ed tar-file (if the *bz2* module is available).
- *xztar*: xz'ed tar-file (if the *lzma* module is available).

You can register new formats or provide your own unpacker for any existing formats, by using `register_unpack_format()`.

Archiving example

In this example, we create a gzipped tar-file archive containing all files found in the `.ssh` directory of the user:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~', 'myarchive'))
>>> root_dir = os.path.expanduser(os.path.join('~', '.ssh'))
>>> make_archive(archive_name, 'gztar', root_dir)
'/Users/tarek/myarchive.tar.gz'
```

The resulting archive contains:

```
$ tar -tzvf /Users/tarek/myarchive.tar.gz
drwx----- tarek/staff      0 2010-02-01 16:23:40 ./
-rw-r--r-- tarek/staff    609 2008-06-09 13:26:54 ./authorized_keys
-rwxr-xr-x tarek/staff     65 2008-06-09 13:26:54 ./config
-rwx----- tarek/staff    668 2008-06-09 13:26:54 ./id_dsa
-rwxr-xr-x tarek/staff    609 2008-06-09 13:26:54 ./id_dsa.pub
-rw----- tarek/staff   1675 2008-06-09 13:26:54 ./id_rsa
-rw-r--r-- tarek/staff    397 2008-06-09 13:26:54 ./id_rsa.pub
-rw-r--r-- tarek/staff  37192 2010-02-06 18:23:10 ./known_hosts
```

Archiving example with *base_dir*

In this example, similar to the *one above*, we show how to use `make_archive()`, but this time with the usage of `base_dir`. We now have the following directory structure:

```
$ tree tmp
tmp
├── root
│   └── structure
│       ├── content
│           └── please_add.txt
│       └── do_not_add.txt
```

In the final archive, `please_add.txt` should be included, but `do_not_add.txt` should not. Therefore we use the following:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~', 'myarchive'))
>>> make_archive(
...     archive_name,
...     'tar',
...     root_dir='tmp/root',
...     base_dir='structure/content',
... )
'/Users/tarek/my_archive.tar'
```

Listing the files in the resulting archive gives us:

```
$ python -m tarfile -l /Users/tarek/myarchive.tar
structure/content/
structure/content/please_add.txt
```

11.10.3 Querying the size of the output terminal

`shutil.get_terminal_size (fallback=(columns, lines))`

Get the size of the terminal window.

For each of the two dimensions, the environment variable, COLUMNS and LINES respectively, is checked. If the variable is defined and the value is a positive integer, it is used.

When COLUMNS or LINES is not defined, which is the common case, the terminal connected to `sys.__stdout__` is queried by invoking `os.get_terminal_size()`.

If the terminal size cannot be successfully queried, either because the system doesn't support querying, or because we are not connected to a terminal, the value given in `fallback` parameter is used. `fallback` defaults to (80, 24) which is the default size used by many terminal emulators.

The value returned is a named tuple of type `os.terminal_size`.

See also: The Single UNIX Specification, Version 2, [Other Environment Variables](#).

Νέο στην έκδοση 3.3.

Δείτε επίσης:

Module `os` Operating system interfaces, including functions to work with files at a lower level than Python *file objects*.

Module `io` Python's built-in I/O library, including both abstract classes and some concrete classes such as file I/O.

Built-in function `open()` The standard way to open files for reading and writing with Python.

The modules described in this chapter support storing Python data in a persistent form on disk. The `pickle` and `marshal` modules can turn many Python data types into a stream of bytes and then recreate the objects from the bytes. The various DBM-related modules support a family of hash-based file formats that store a mapping of strings to other strings.

The list of modules described in this chapter is:

12.1 `pickle` — Python object serialization

Source code: [Lib/pickle.py](#)

The `pickle` module implements binary protocols for serializing and de-serializing a Python object structure. «Pickling» is the process whereby a Python object hierarchy is converted into a byte stream, and «unpickling» is the inverse operation, whereby a byte stream (from a *binary file* or *bytes-like object*) is converted back into an object hierarchy. Pickling (and unpickling) is alternatively known as «serialization», «marshalling»,¹ or «flattening»; however, to avoid confusion, the terms used here are «pickling» and «unpickling».

Προειδοποίηση: The `pickle` module **is not secure**. Only unpickle data you trust.

It is possible to construct malicious pickle data which will **execute arbitrary code during unpickling**. Never unpickle data that could have come from an untrusted source, or that could have been tampered with.

Consider signing data with `hmac` if you need to ensure that it has not been tampered with.

Safer serialization formats such as `json` may be more appropriate if you are processing untrusted data. See [Comparison with json](#).

¹ Don't confuse this with the `marshal` module

12.1.1 Relationship to other Python modules

Comparison with `marshal`

Python has a more primitive serialization module called `marshal`, but in general `pickle` should always be the preferred way to serialize Python objects. `marshal` exists primarily to support Python's `.pyc` files.

The `pickle` module differs from `marshal` in several significant ways:

- The `pickle` module keeps track of the objects it has already serialized, so that later references to the same object won't be serialized again. `marshal` doesn't do this.

This has implications both for recursive objects and object sharing. Recursive objects are objects that contain references to themselves. These are not handled by `marshal`, and in fact, attempting to marshal recursive objects will crash your Python interpreter. Object sharing happens when there are multiple references to the same object in different places in the object hierarchy being serialized. `pickle` stores such objects only once, and ensures that all other references point to the master copy. Shared objects remain shared, which can be very important for mutable objects.

- `marshal` cannot be used to serialize user-defined classes and their instances. `pickle` can save and restore class instances transparently, however the class definition must be importable and live in the same module as when the object was stored.
- The `marshal` serialization format is not guaranteed to be portable across Python versions. Because its primary job in life is to support `.pyc` files, the Python implementers reserve the right to change the serialization format in non-backwards compatible ways should the need arise. The `pickle` serialization format is guaranteed to be backwards compatible across Python releases provided a compatible pickle protocol is chosen and pickling and unpickling code deals with Python 2 to Python 3 type differences if your data is crossing that unique breaking change language boundary.

Comparison with `json`

There are fundamental differences between the pickle protocols and **JSON (JavaScript Object Notation)**:

- JSON is a text serialization format (it outputs unicode text, although most of the time it is then encoded to `utf-8`), while pickle is a binary serialization format;
- JSON is human-readable, while pickle is not;
- JSON is interoperable and widely used outside of the Python ecosystem, while pickle is Python-specific;
- JSON, by default, can only represent a subset of the Python built-in types, and no custom classes; pickle can represent an extremely large number of Python types (many of them automatically, by clever usage of Python's introspection facilities; complex cases can be tackled by implementing *specific object APIs*);
- Unlike pickle, deserializing untrusted JSON does not in itself create an arbitrary code execution vulnerability.

Δείτε επίσης:

The `json` module: a standard library module allowing JSON serialization and deserialization.

12.1.2 Data stream format

The data format used by *pickle* is Python-specific. This has the advantage that there are no restrictions imposed by external standards such as JSON or XDR (which can't represent pointer sharing); however it means that non-Python programs may not be able to reconstruct pickled Python objects.

By default, the *pickle* data format uses a relatively compact binary representation. If you need optimal size characteristics, you can efficiently *compress* pickled data.

The module *pickletools* contains tools for analyzing data streams generated by *pickle*. *pickletools* source code has extensive comments about opcodes used by pickle protocols.

There are currently 6 different protocols which can be used for pickling. The higher the protocol used, the more recent the version of Python needed to read the pickle produced.

- Protocol version 0 is the original «human-readable» protocol and is backwards compatible with earlier versions of Python.
- Protocol version 1 is an old binary format which is also compatible with earlier versions of Python.
- Protocol version 2 was introduced in Python 2.3. It provides much more efficient pickling of *new-style classes*. Refer to **PEP 307** for information about improvements brought by protocol 2.
- Protocol version 3 was added in Python 3.0. It has explicit support for *bytes* objects and cannot be unpickled by Python 2.x. This was the default protocol in Python 3.0–3.7.
- Protocol version 4 was added in Python 3.4. It adds support for very large objects, pickling more kinds of objects, and some data format optimizations. It is the default protocol starting with Python 3.8. Refer to **PEP 3154** for information about improvements brought by protocol 4.
- Protocol version 5 was added in Python 3.8. It adds support for out-of-band data and speedup for in-band data. Refer to **PEP 574** for information about improvements brought by protocol 5.

Σημείωση: Serialization is a more primitive notion than persistence; although *pickle* reads and writes file objects, it does not handle the issue of naming persistent objects, nor the (even more complicated) issue of concurrent access to persistent objects. The *pickle* module can transform a complex object into a byte stream and it can transform the byte stream into an object with the same internal structure. Perhaps the most obvious thing to do with these byte streams is to write them onto a file, but it is also conceivable to send them across a network or store them in a database. The *shelve* module provides a simple interface to pickle and unpickle objects on DBM-style database files.

12.1.3 Module Interface

To serialize an object hierarchy, you simply call the *dumps()* function. Similarly, to de-serialize a data stream, you call the *loads()* function. However, if you want more control over serialization and de-serialization, you can create a *Pickler* or an *Unpickler* object, respectively.

The *pickle* module provides the following constants:

`pickle.HIGHEST_PROTOCOL`

An integer, the highest *protocol version* available. This value can be passed as a *protocol* value to functions *dump()* and *dumps()* as well as the *Pickler* constructor.

`pickle.DEFAULT_PROTOCOL`

An integer, the default *protocol version* used for pickling. May be less than *HIGHEST_PROTOCOL*. Currently the default protocol is 4, first introduced in Python 3.4 and incompatible with previous versions.

Αλλάξε στην έκδοση 3.0: The default protocol is 3.

Άλλαξε στην έκδοση 3.8: The default protocol is 4.

The `pickle` module provides the following functions to make the pickling process more convenient:

`pickle.dump(obj, file, protocol=None, *, fix_imports=True, buffer_callback=None)`

Write the pickled representation of the object *obj* to the open *file object file*. This is equivalent to `Pickler(file, protocol).dump(obj)`.

Arguments *file*, *protocol*, *fix_imports* and *buffer_callback* have the same meaning as in the `Pickler` constructor.

Άλλαξε στην έκδοση 3.8: The *buffer_callback* argument was added.

`pickle.dumps(obj, protocol=None, *, fix_imports=True, buffer_callback=None)`

Return the pickled representation of the object *obj* as a *bytes* object, instead of writing it to a file.

Arguments *protocol*, *fix_imports* and *buffer_callback* have the same meaning as in the `Pickler` constructor.

Άλλαξε στην έκδοση 3.8: The *buffer_callback* argument was added.

`pickle.load(file, *, fix_imports=True, encoding="ASCII", errors="strict", buffers=None)`

Read the pickled representation of an object from the open *file object file* and return the reconstituted object hierarchy specified therein. This is equivalent to `Unpickler(file).load()`.

The protocol version of the pickle is detected automatically, so no protocol argument is needed. Bytes past the pickled representation of the object are ignored.

Arguments *file*, *fix_imports*, *encoding*, *errors*, *strict* and *buffers* have the same meaning as in the `Unpickler` constructor.

Άλλαξε στην έκδοση 3.8: The *buffers* argument was added.

`pickle.loads(data, /, *, fix_imports=True, encoding="ASCII", errors="strict", buffers=None)`

Return the reconstituted object hierarchy of the pickled representation *data* of an object. *data* must be a *bytes-like object*.

The protocol version of the pickle is detected automatically, so no protocol argument is needed. Bytes past the pickled representation of the object are ignored.

Arguments *fix_imports*, *encoding*, *errors*, *strict* and *buffers* have the same meaning as in the `Unpickler` constructor.

Άλλαξε στην έκδοση 3.8: The *buffers* argument was added.

The `pickle` module defines three exceptions:

exception `pickle.PickleError`

Common base class for the other pickling exceptions. It inherits `Exception`.

exception `pickle.PicklingError`

Error raised when an unpicklable object is encountered by `Pickler`. It inherits `PickleError`.

Refer to *What can be pickled and unpickled?* to learn what kinds of objects can be pickled.

exception `pickle.UnpicklingError`

Error raised when there is a problem unpickling an object, such as a data corruption or a security violation. It inherits `PickleError`.

Note that other exceptions may also be raised during unpickling, including (but not necessarily limited to) `AttributeError`, `EOFError`, `ImportError`, and `IndexError`.

The `pickle` module exports three classes, `Pickler`, `Unpickler` and `PickleBuffer`:

class `pickle.Pickler(file, protocol=None, *, fix_imports=True, buffer_callback=None)`

This takes a binary file for writing a pickle data stream.

The optional *protocol* argument, an integer, tells the pickler to use the given protocol; supported protocols are 0 to `HIGHEST_PROTOCOL`. If not specified, the default is `DEFAULT_PROTOCOL`. If a negative number is specified, `HIGHEST_PROTOCOL` is selected.

The *file* argument must have a `write()` method that accepts a single bytes argument. It can thus be an on-disk file opened for binary writing, an `io.BytesIO` instance, or any other custom object that meets this interface.

If *fix_imports* is true and *protocol* is less than 3, pickle will try to map the new Python 3 names to the old module names used in Python 2, so that the pickle data stream is readable with Python 2.

If *buffer_callback* is None (the default), buffer views are serialized into *file* as part of the pickle stream.

If *buffer_callback* is not None, then it can be called any number of times with a buffer view. If the callback returns a false value (such as None), the given buffer is *out-of-band*; otherwise the buffer is serialized in-band, i.e. inside the pickle stream.

It is an error if *buffer_callback* is not None and *protocol* is None or smaller than 5.

Άλλαξε στην έκδοση 3.8: The *buffer_callback* argument was added.

dump(obj)

Write the pickled representation of *obj* to the open file object given in the constructor.

persistent_id(obj)

Do nothing by default. This exists so a subclass can override it.

If *persistent_id()* returns None, *obj* is pickled as usual. Any other value causes *Pickler* to emit the returned value as a persistent ID for *obj*. The meaning of this persistent ID should be defined by *Unpickler.persistent_load()*. Note that the value returned by *persistent_id()* cannot itself have a persistent ID.

See *Persistence of External Objects* for details and examples of uses.

dispatch_table

A pickler object's dispatch table is a registry of *reduction functions* of the kind which can be declared using *copyreg.pickle()*. It is a mapping whose keys are classes and whose values are reduction functions. A reduction function takes a single argument of the associated class and should conform to the same interface as a *__reduce__()* method.

By default, a pickler object will not have a *dispatch_table* attribute, and it will instead use the global dispatch table managed by the *copyreg* module. However, to customize the pickling for a specific pickler object one can set the *dispatch_table* attribute to a dict-like object. Alternatively, if a subclass of *Pickler* has a *dispatch_table* attribute then this will be used as the default dispatch table for instances of that class.

See *Dispatch Tables* for usage examples.

Νέο στην έκδοση 3.3.

reducer_override(obj)

Special reducer that can be defined in *Pickler* subclasses. This method has priority over any reducer in the *dispatch_table*. It should conform to the same interface as a *__reduce__()* method, and can optionally return `NotImplemented` to fallback on *dispatch_table*-registered reducers to pickle *obj*.

For a detailed example, see *Custom Reduction for Types, Functions, and Other Objects*.

Νέο στην έκδοση 3.8.

fast

Deprecated. Enable fast mode if set to a true value. The fast mode disables the usage of memo, therefore speeding the pickling process by not generating superfluous PUT opcodes. It should not be used with self-referential objects, doing otherwise will cause *Pickler* to recurse infinitely.

Use `pickletools.optimize()` if you need more compact pickles.

class `pickle.Unpickler` (*file*, *, *fix_imports*=*True*, *encoding*="ASCII", *errors*="strict", *buffers*=*None*)

This takes a binary file for reading a pickle data stream.

The protocol version of the pickle is detected automatically, so no protocol argument is needed.

The argument *file* must have three methods, a `read()` method that takes an integer argument, a `readinto()` method that takes a buffer argument and a `readline()` method that requires no arguments, as in the `io.BufferedReader` interface. Thus *file* can be an on-disk file opened for binary reading, an `io.BytesIO` object, or any other custom object that meets this interface.

The optional arguments *fix_imports*, *encoding* and *errors* are used to control compatibility support for pickle stream generated by Python 2. If *fix_imports* is true, pickle will try to map the old Python 2 names to the new names used in Python 3. The *encoding* and *errors* tell pickle how to decode 8-bit string instances pickled by Python 2; these default to “ASCII” and “strict”, respectively. The *encoding* can be “bytes” to read these 8-bit string instances as bytes objects. Using *encoding*='latin1' is required for unpickling NumPy arrays and instances of `datetime`, `date` and `time` pickled by Python 2.

If *buffers* is *None* (the default), then all data necessary for deserialization must be contained in the pickle stream. This means that the *buffer_callback* argument was *None* when a `Pickler` was instantiated (or when `dump()` or `dumps()` was called).

If *buffers* is not *None*, it should be an iterable of buffer-enabled objects that is consumed each time the pickle stream references an *out-of-band* buffer view. Such buffers have been given in order to the *buffer_callback* of a `Pickler` object.

Άλλαξε στην έκδοση 3.8: The *buffers* argument was added.

load ()

Read the pickled representation of an object from the open file object given in the constructor, and return the reconstituted object hierarchy specified therein. Bytes past the pickled representation of the object are ignored.

persistent_load (*pid*)

Raise an `UnpicklingError` by default.

If defined, `persistent_load()` should return the object specified by the persistent ID *pid*. If an invalid persistent ID is encountered, an `UnpicklingError` should be raised.

See *Persistence of External Objects* for details and examples of uses.

find_class (*module*, *name*)

Import *module* if necessary and return the object called *name* from it, where the *module* and *name* arguments are *str* objects. Note, unlike its name suggests, `find_class()` is also used for finding functions.

Subclasses may override this to gain control over what type of objects and how they can be loaded, potentially reducing security risks. Refer to *Restricting Globals* for details.

Raises an *auditing event* `pickle.find_class` with arguments *module*, *name*.

class `pickle.PickleBuffer` (*buffer*)

A wrapper for a buffer representing picklable data. *buffer* must be a buffer-providing object, such as a *bytes-like object* or a N-dimensional array.

`PickleBuffer` is itself a buffer provider, therefore it is possible to pass it to other APIs expecting a buffer-providing object, such as *memoryview*.

`PickleBuffer` objects can only be serialized using pickle protocol 5 or higher. They are eligible for *out-of-band serialization*.

Νέο στην έκδοση 3.8.

raw()

Return a *memoryview* of the memory area underlying this buffer. The returned object is a one-dimensional, C-contiguous memoryview with format B (unsigned bytes). *BufferError* is raised if the buffer is neither C- nor Fortran-contiguous.

release()

Release the underlying buffer exposed by the *PickleBuffer* object.

12.1.4 What can be pickled and unpickled?

The following types can be pickled:

- None, True, and False;
- integers, floating-point numbers, complex numbers;
- strings, bytes, bytearrays;
- tuples, lists, sets, and dictionaries containing only picklable objects;
- functions (built-in and user-defined) defined at the top level of a module (using `def`, not `lambda`);
- classes defined at the top level of a module;
- instances of such classes whose `__dict__` or the result of calling `__getstate__()` is picklable (see section *Pickling Class Instances* for details).

Attempts to pickle unpicklable objects will raise the *PicklingError* exception; when this happens, an unspecified number of bytes may have already been written to the underlying file. Trying to pickle a highly recursive data structure may exceed the maximum recursion depth, a *RecursionError* will be raised in this case. You can carefully raise this limit with `sys.setrecursionlimit()`.

Note that functions (built-in and user-defined) are pickled by fully qualified name, not by value.² This means that only the function name is pickled, along with the name of the module the function is defined in. Neither the function's code, nor any of its function attributes are pickled. Thus the defining module must be importable in the unpickling environment, and the module must contain the named object, otherwise an exception will be raised.³

Similarly, classes are pickled by fully qualified name, so the same restrictions in the unpickling environment apply. Note that none of the class's code or data is pickled, so in the following example the class attribute `attr` is not restored in the unpickling environment:

```
class Foo:
    attr = 'A class attribute'

picklestring = pickle.dumps(Foo)
```

These restrictions are why picklable functions and classes must be defined at the top level of a module.

Similarly, when class instances are pickled, their class's code and data are not pickled along with them. Only the instance data are pickled. This is done on purpose, so you can fix bugs in a class or add methods to the class and still load objects that were created with an earlier version of the class. If you plan to have long-lived objects that will see many versions of a class, it may be worthwhile to put a version number in the objects so that suitable conversions can be made by the class's `__setstate__()` method.

² This is why `lambda` functions cannot be pickled: all `lambda` functions share the same name: `<lambda>`.

³ The exception raised will likely be an *ImportError* or an *AttributeError* but it could be something else.

12.1.5 Pickling Class Instances

In this section, we describe the general mechanisms available to you to define, customize, and control how class instances are pickled and unpickled.

In most cases, no additional code is needed to make instances picklable. By default, pickle will retrieve the class and the attributes of an instance via introspection. When a class instance is unpickled, its `__init__()` method is usually *not* invoked. The default behaviour first creates an uninitialized instance and then restores the saved attributes. The following code shows an implementation of this behaviour:

```
def save(obj):
    return (obj.__class__, obj.__dict__)

def restore(cls, attributes):
    obj = cls.__new__(cls)
    obj.__dict__.update(attributes)
    return obj
```

Classes can alter the default behaviour by providing one or several special methods:

`object.__getnewargs_ex__()`

In protocols 2 and newer, classes that implements the `__getnewargs_ex__()` method can dictate the values passed to the `__new__()` method upon unpickling. The method must return a pair `(args, kwargs)` where `args` is a tuple of positional arguments and `kwargs` a dictionary of named arguments for constructing the object. Those will be passed to the `__new__()` method upon unpickling.

You should implement this method if the `__new__()` method of your class requires keyword-only arguments. Otherwise, it is recommended for compatibility to implement `__getnewargs__()`.

Άλλαξε στην έκδοση 3.6: `__getnewargs_ex__()` is now used in protocols 2 and 3.

`object.__getnewargs__()`

This method serves a similar purpose as `__getnewargs_ex__()`, but supports only positional arguments. It must return a tuple of arguments `args` which will be passed to the `__new__()` method upon unpickling.

`__getnewargs__()` will not be called if `__getnewargs_ex__()` is defined.

Άλλαξε στην έκδοση 3.6: Before Python 3.6, `__getnewargs__()` was called instead of `__getnewargs_ex__()` in protocols 2 and 3.

`object.__getstate__()`

Classes can further influence how their instances are pickled; if the class defines the method `__getstate__()`, it is called and the returned object is pickled as the contents for the instance, instead of the contents of the instance's dictionary. If the `__getstate__()` method is absent, the instance's `__dict__` is pickled as usual.

`object.__setstate__(state)`

Upon unpickling, if the class defines `__setstate__()`, it is called with the unpickled state. In that case, there is no requirement for the state object to be a dictionary. Otherwise, the pickled state must be a dictionary and its items are assigned to the new instance's dictionary.

Σημείωση: If `__getstate__()` returns a false value, the `__setstate__()` method will not be called upon unpickling.

Refer to the section *Handling Stateful Objects* for more information about how to use the methods `__getstate__()` and `__setstate__()`.

Σημείωση: At unpickling time, some methods like `__getattr__()`, `__getattribute__()`, or `__setattr__()` may be called upon the instance. In case those methods rely on some internal invariant being

true, the type should implement `__new__()` to establish such an invariant, as `__init__()` is not called when unpickling an instance.

As we shall see, pickle does not use directly the methods described above. In fact, these methods are part of the copy protocol which implements the `__reduce__()` special method. The copy protocol provides a unified interface for retrieving the data necessary for pickling and copying objects.⁴

Although powerful, implementing `__reduce__()` directly in your classes is error prone. For this reason, class designers should use the high-level interface (i.e., `__getnewargs_ex__()`, `__getstate__()` and `__setstate__()`) whenever possible. We will show, however, cases where using `__reduce__()` is the only option or leads to more efficient pickling or both.

`object.__reduce__()`

The interface is currently defined as follows. The `__reduce__()` method takes no argument and shall return either a string or preferably a tuple (the returned object is often referred to as the «reduce value»).

If a string is returned, the string should be interpreted as the name of a global variable. It should be the object's local name relative to its module; the pickle module searches the module namespace to determine the object's module. This behaviour is typically useful for singletons.

When a tuple is returned, it must be between two and six items long. Optional items can either be omitted, or `None` can be provided as their value. The semantics of each item are in order:

- A callable object that will be called to create the initial version of the object.
- A tuple of arguments for the callable object. An empty tuple must be given if the callable does not accept any argument.
- Optionally, the object's state, which will be passed to the object's `__setstate__()` method as previously described. If the object has no such method then, the value must be a dictionary and it will be added to the object's `__dict__` attribute.
- Optionally, an iterator (and not a sequence) yielding successive items. These items will be appended to the object either using `obj.append(item)` or, in batch, using `obj.extend(list_of_items)`. This is primarily used for list subclasses, but may be used by other classes as long as they have `append()` and `extend()` methods with the appropriate signature. (Whether `append()` or `extend()` is used depends on which pickle protocol version is used as well as the number of items to append, so both must be supported.)
- Optionally, an iterator (not a sequence) yielding successive key-value pairs. These items will be stored to the object using `obj[key] = value`. This is primarily used for dictionary subclasses, but may be used by other classes as long as they implement `__setitem__()`.
- Optionally, a callable with a `(obj, state)` signature. This callable allows the user to programmatically control the state-updating behavior of a specific object, instead of using `obj's static __setstate__()` method. If not `None`, this callable will have priority over `obj's __setstate__()`.

Νέο στην έκδοση 3.8: The optional sixth tuple item, `(obj, state)`, was added.

`object.__reduce_ex__(protocol)`

Alternatively, a `__reduce_ex__()` method may be defined. The only difference is this method should take a single integer argument, the protocol version. When defined, pickle will prefer it over the `__reduce__()` method. In addition, `__reduce__()` automatically becomes a synonym for the extended version. The main use for this method is to provide backwards-compatible reduce values for older Python releases.

⁴ The `copy` module uses this protocol for shallow and deep copying operations.

Persistence of External Objects

For the benefit of object persistence, the `pickle` module supports the notion of a reference to an object outside the pickled data stream. Such objects are referenced by a persistent ID, which should be either a string of alphanumeric characters (for protocol 0)⁵ or just an arbitrary object (for any newer protocol).

The resolution of such persistent IDs is not defined by the `pickle` module; it will delegate this resolution to the user-defined methods on the pickler and unpickler, `persistent_id()` and `persistent_load()` respectively.

To pickle objects that have an external persistent ID, the pickler must have a custom `persistent_id()` method that takes an object as an argument and returns either `None` or the persistent ID for that object. When `None` is returned, the pickler simply pickles the object as normal. When a persistent ID string is returned, the pickler will pickle that object, along with a marker so that the unpickler will recognize it as a persistent ID.

To unpickle external objects, the unpickler must have a custom `persistent_load()` method that takes a persistent ID object and returns the referenced object.

Here is a comprehensive example presenting how persistent ID can be used to pickle external objects by reference.

```
# Simple example presenting how persistent ID can be used to pickle
# external objects by reference.

import pickle
import sqlite3
from collections import namedtuple

# Simple class representing a record in our database.
MemoRecord = namedtuple("MemoRecord", "key, task")

class DBPickler(pickle.Pickler):

    def persistent_id(self, obj):
        # Instead of pickling MemoRecord as a regular class instance, we emit a
        # persistent ID.
        if isinstance(obj, MemoRecord):
            # Here, our persistent ID is simply a tuple, containing a tag and a
            # key, which refers to a specific record in the database.
            return ("MemoRecord", obj.key)
        else:
            # If obj does not have a persistent ID, return None. This means obj
            # needs to be pickled as usual.
            return None

class DBUnpickler(pickle.Unpickler):

    def __init__(self, file, connection):
        super().__init__(file)
        self.connection = connection

    def persistent_load(self, pid):
        # This method is invoked whenever a persistent ID is encountered.
        # Here, pid is the tuple returned by DBPickler.
        cursor = self.connection.cursor()
        type_tag, key_id = pid
        if type_tag == "MemoRecord":
```

(συνέχεια στην επόμενη σελίδα)

⁵ The limitation on alphanumeric characters is due to the fact that persistent IDs in protocol 0 are delimited by the newline character. Therefore if any kind of newline characters occurs in persistent IDs, the resulting pickled data will become unreadable.

(συνεχίζεται από την προηγούμενη σελίδα)

```

        # Fetch the referenced record from the database and return it.
        cursor.execute("SELECT * FROM memos WHERE key=?", (str(key_id),))
        key, task = cursor.fetchone()
        return MemoRecord(key, task)
    else:
        # Always raises an error if you cannot return the correct object.
        # Otherwise, the unpickler will think None is the object referenced
        # by the persistent ID.
        raise pickle.UnpicklingError("unsupported persistent object")

def main():
    import io
    import pprint

    # Initialize and populate our database.
    conn = sqlite3.connect(":memory:")
    cursor = conn.cursor()
    cursor.execute("CREATE TABLE memos(key INTEGER PRIMARY KEY, task TEXT)")
    tasks = (
        'give food to fish',
        'prepare group meeting',
        'fight with a zebra',
    )
    for task in tasks:
        cursor.execute("INSERT INTO memos VALUES(NULL, ?)", (task,))

    # Fetch the records to be pickled.
    cursor.execute("SELECT * FROM memos")
    memos = [MemoRecord(key, task) for key, task in cursor]
    # Save the records using our custom DBPickler.
    file = io.BytesIO()
    DBPickler(file).dump(memos)

    print("Pickled records:")
    pprint.pprint(memos)

    # Update a record, just for good measure.
    cursor.execute("UPDATE memos SET task='learn italian' WHERE key=1")

    # Load the records from the pickle data stream.
    file.seek(0)
    memos = DBUnpickler(file, conn).load()

    print("Unpickled records:")
    pprint.pprint(memos)

if __name__ == '__main__':
    main()

```

Dispatch Tables

If one wants to customize pickling of some classes without disturbing any other code which depends on pickling, then one can create a pickler with a private dispatch table.

The global dispatch table managed by the `copyreg` module is available as `copyreg.dispatch_table`. Therefore, one may choose to use a modified copy of `copyreg.dispatch_table` as a private dispatch table.

For example

```
f = io.BytesIO()
p = pickle.Pickler(f)
p.dispatch_table = copyreg.dispatch_table.copy()
p.dispatch_table[SomeClass] = reduce_SomeClass
```

creates an instance of `pickle.Pickler` with a private dispatch table which handles the `SomeClass` class specially. Alternatively, the code

```
class MyPickler(pickle.Pickler):
    dispatch_table = copyreg.dispatch_table.copy()
    dispatch_table[SomeClass] = reduce_SomeClass
f = io.BytesIO()
p = MyPickler(f)
```

does the same but all instances of `MyPickler` will by default share the private dispatch table. On the other hand, the code

```
copyreg.pickle(SomeClass, reduce_SomeClass)
f = io.BytesIO()
p = pickle.Pickler(f)
```

modifies the global dispatch table shared by all users of the `copyreg` module.

Handling Stateful Objects

Here's an example that shows how to modify pickling behavior for a class. The `TextReader` class opens a text file, and returns the line number and line contents each time its `readline()` method is called. If a `TextReader` instance is pickled, all attributes *except* the file object member are saved. When the instance is unpickled, the file is reopened, and reading resumes from the last location. The `__setstate__()` and `__getstate__()` methods are used to implement this behavior.

```
class TextReader:
    """Print and number lines in a text file."""

    def __init__(self, filename):
        self.filename = filename
        self.file = open(filename)
        self.lineno = 0

    def readline(self):
        self.lineno += 1
        line = self.file.readline()
        if not line:
            return None
        if line.endswith('\n'):
            line = line[:-1]
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

    return "%i: %s" % (self.lineno, line)

    def __getstate__(self):
        # Copy the object's state from self.__dict__ which contains
        # all our instance attributes. Always use the dict.copy()
        # method to avoid modifying the original state.
        state = self.__dict__.copy()
        # Remove the unpicklable entries.
        del state['file']
        return state

    def __setstate__(self, state):
        # Restore instance attributes (i.e., filename and lineno).
        self.__dict__.update(state)
        # Restore the previously opened file's state. To do so, we need to
        # reopen it and read from it until the line count is restored.
        file = open(self.filename)
        for _ in range(self.lineno):
            file.readline()
        # Finally, save the file.
        self.file = file

```

A sample usage might be something like this:

```

>>> reader = TextReader("hello.txt")
>>> reader.readline()
'1: Hello world!'
>>> reader.readline()
'2: I am line number two.'
>>> new_reader = pickle.loads(pickle.dumps(reader))
>>> new_reader.readline()
'3: Goodbye!'

```

12.1.6 Custom Reduction for Types, Functions, and Other Objects

Νέο στην έκδοση 3.8.

Sometimes, `dispatch_table` may not be flexible enough. In particular we may want to customize pickling based on another criterion than the object's type, or we may want to customize the pickling of functions and classes.

For those cases, it is possible to subclass from the `Pickler` class and implement a `reducer_override()` method. This method can return an arbitrary reduction tuple (see `__reduce__()`). It can alternatively return `NotImplemented` to fallback to the traditional behavior.

If both the `dispatch_table` and `reducer_override()` are defined, then `reducer_override()` method takes priority.

Σημείωση: For performance reasons, `reducer_override()` may not be called for the following objects: `None`, `True`, `False`, and exact instances of `int`, `float`, `bytes`, `str`, `dict`, `set`, `frozenset`, `list` and `tuple`.

Here is a simple example where we allow pickling and reconstructing a given class:

```

import io
import pickle

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

class MyClass:
    my_attribute = 1

class MyPickler(pickle.Pickler):
    def reducer_override(self, obj):
        """Custom reducer for MyClass."""
        if getattr(obj, "__name__", None) == "MyClass":
            return type, (obj.__name__, obj.__bases__,
                          {'my_attribute': obj.my_attribute})
        else:
            # For any other object, fallback to usual reduction
            return NotImplemented

f = io.BytesIO()
p = MyPickler(f)
p.dump(MyClass)

del MyClass

unpickled_class = pickle.loads(f.getvalue())

assert isinstance(unpickled_class, type)
assert unpickled_class.__name__ == "MyClass"
assert unpickled_class.my_attribute == 1

```

12.1.7 Out-of-band Buffers

Νέο στην έκδοση 3.8.

In some contexts, the *pickle* module is used to transfer massive amounts of data. Therefore, it can be important to minimize the number of memory copies, to preserve performance and resource consumption. However, normal operation of the *pickle* module, as it transforms a graph-like structure of objects into a sequential stream of bytes, intrinsically involves copying data to and from the pickle stream.

This constraint can be eschewed if both the *provider* (the implementation of the object types to be transferred) and the *consumer* (the implementation of the communications system) support the out-of-band transfer facilities provided by pickle protocol 5 and higher.

Provider API

The large data objects to be pickled must implement a `__reduce_ex__()` method specialized for protocol 5 and higher, which returns a *PickleBuffer* instance (instead of e.g. a *bytes* object) for any large data.

A *PickleBuffer* object *signals* that the underlying buffer is eligible for out-of-band data transfer. Those objects remain compatible with normal usage of the *pickle* module. However, consumers can also opt-in to tell *pickle* that they will handle those buffers by themselves.

Consumer API

A communications system can enable custom handling of the `PickleBuffer` objects generated when serializing an object graph.

On the sending side, it needs to pass a `buffer_callback` argument to `Pickler` (or to the `dump()` or `dumps()` function), which will be called with each `PickleBuffer` generated while pickling the object graph. Buffers accumulated by the `buffer_callback` will not see their data copied into the pickle stream, only a cheap marker will be inserted.

On the receiving side, it needs to pass a `buffers` argument to `Unpickler` (or to the `load()` or `loads()` function), which is an iterable of the buffers which were passed to `buffer_callback`. That iterable should produce buffers in the same order as they were passed to `buffer_callback`. Those buffers will provide the data expected by the reconstructors of the objects whose pickling produced the original `PickleBuffer` objects.

Between the sending side and the receiving side, the communications system is free to implement its own transfer mechanism for out-of-band buffers. Potential optimizations include the use of shared memory or datatype-dependent compression.

Example

Here is a trivial example where we implement a `bytearray` subclass able to participate in out-of-band buffer pickling:

```
class ZeroCopyByteArray(bytearray):

    def __reduce_ex__(self, protocol):
        if protocol >= 5:
            return type(self)._reconstruct, (PickleBuffer(self),), None
        else:
            # PickleBuffer is forbidden with pickle protocols <= 4.
            return type(self)._reconstruct, (bytearray(self),)

    @classmethod
    def _reconstruct(cls, obj):
        with memoryview(obj) as m:
            # Get a handle over the original buffer object
            obj = m.obj
            if type(obj) is cls:
                # Original buffer object is a ZeroCopyByteArray, return it
                # as-is.
                return obj
            else:
                return cls(obj)
```

The reconstructor (the `_reconstruct` class method) returns the buffer's providing object if it has the right type. This is an easy way to simulate zero-copy behaviour on this toy example.

On the consumer side, we can pickle those objects the usual way, which when unserialized will give us a copy of the original object:

```
b = ZeroCopyByteArray(b"abc")
data = pickle.dumps(b, protocol=5)
new_b = pickle.loads(data)
print(b == new_b) # True
print(b is new_b) # False: a copy was made
```

But if we pass a `buffer_callback` and then give back the accumulated buffers when unserializing, we are able to get back the original object:

```
b = ZeroCopyByteArray(b"abc")
buffers = []
data = pickle.dumps(b, protocol=5, buffer_callback=buffers.append)
new_b = pickle.loads(data, buffers=buffers)
print(b == new_b) # True
print(b is new_b) # True: no copy was made
```

This example is limited by the fact that `bytearray` allocates its own memory: you cannot create a `bytearray` instance that is backed by another object's memory. However, third-party datatypes such as NumPy arrays do not have this limitation, and allow use of zero-copy pickling (or making as few copies as possible) when transferring between distinct processes or systems.

PEP 574 – Pickle protocol 5 with out-of-band data

12.1.8 Restricting Globals

By default, unpickling will import any class or function that it finds in the pickle data. For many applications, this behaviour is unacceptable as it permits the unpickler to import and invoke arbitrary code. Just consider what this hand-crafted pickle data stream does when loaded:

```
>>> import pickle
>>> pickle.loads(b"cos\nsystem\n(S'echo hello world'\ntr.")
hello world
0
```

In this example, the unpickler imports the `os.system()` function and then apply the string argument «echo hello world». Although this example is inoffensive, it is not difficult to imagine one that could damage your system.

For this reason, you may want to control what gets unpickled by customizing `Unpickler.find_class()`. Unlike its name suggests, `Unpickler.find_class()` is called whenever a global (i.e., a class or a function) is requested. Thus it is possible to either completely forbid globals or restrict them to a safe subset.

Here is an example of an unpickler allowing only few safe classes from the `builtins` module to be loaded:

```
import builtins
import io
import pickle

safe_builtins = {
    'range',
    'complex',
    'set',
    'frozenset',
    'slice',
}

class RestrictedUnpickler(pickle.Unpickler):

    def find_class(self, module, name):
        # Only allow safe classes from builtins.
        if module == "builtins" and name in safe_builtins:
            return getattr(builtins, name)
        # Forbid everything else.
        raise pickle.UnpicklingError("global '%s.%s' is forbidden" %
                                     (module, name))
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
def restricted_loads(s):
    """Helper function analogous to pickle.loads()."""
    return RestrictedUnpickler(io.BytesIO(s)).load()
```

A sample usage of our unpickler working as intended:

```
>>> restricted_loads(pickle.dumps([1, 2, range(15)]))
[1, 2, range(0, 15)]
>>> restricted_loads(b"cos\nsystem\n(S'echo hello world'\nR.")
Traceback (most recent call last):
...
pickle.UnpicklingError: global 'os.system' is forbidden
>>> restricted_loads(b'cbuiltins\neval\n'
...                  b'(S\'getattr(__import__("os"), "system")'
...                  b'("echo hello world")\'\nR.')
Traceback (most recent call last):
...
pickle.UnpicklingError: global 'builtins.eval' is forbidden
```

As our examples shows, you have to be careful with what you allow to be unpickled. Therefore if security is a concern, you may want to consider alternatives such as the marshalling API in *xmlrpc.client* or third-party solutions.

12.1.9 Performance

Recent versions of the pickle protocol (from protocol 2 and upwards) feature efficient binary encodings for several common features and built-in types. Also, the *pickle* module has a transparent optimizer written in C.

12.1.10 Examples

For the simplest code, use the *dump()* and *load()* functions.

```
import pickle

# An arbitrary collection of objects supported by pickle.
data = {
    'a': [1, 2.0, 3+4j],
    'b': ("character string", b"byte string"),
    'c': {None, True, False}
}

with open('data.pickle', 'wb') as f:
    # Pickle the 'data' dictionary using the highest protocol available.
    pickle.dump(data, f, pickle.HIGHEST_PROTOCOL)
```

The following example reads the resulting pickled data.

```
import pickle

with open('data.pickle', 'rb') as f:
    # The protocol version used is detected automatically, so we do not
    # have to specify it.
    data = pickle.load(f)
```

Module `copyreg` Pickle interface constructor registration for extension types.

Module `pickletools` Tools for working with and analyzing pickled data.

Module `shelve` Indexed databases of objects; uses `pickle`.

Module `copy` Shallow and deep object copying.

Module `marshal` High-performance serialization of built-in types.

12.2 copyreg — Register pickle support functions

Source code: [Lib/copyreg.py](#)

The `copyreg` module offers a way to define functions used while pickling specific objects. The `pickle` and `copy` modules use those functions when pickling/copying those objects. The module provides configuration information about object constructors which are not classes. Such constructors may be factory functions or class instances.

`copyreg.constructor(object)`

Declares *object* to be a valid constructor. If *object* is not callable (and hence not valid as a constructor), raises `TypeError`.

`copyreg.pickle(type, function, constructor=None)`

Declares that *function* should be used as a «reduction» function for objects of type *type*. *function* should return either a string or a tuple containing two or three elements.

The optional *constructor* parameter, if provided, is a callable object which can be used to reconstruct the object when called with the tuple of arguments returned by *function* at pickling time. A `TypeError` is raised if the *constructor* is not callable.

See the `pickle` module for more details on the interface expected of *function* and *constructor*. Note that the `dispatch_table` attribute of a pickler object or subclass of `pickle.Pickler` can also be used for declaring reduction functions.

12.2.1 Example

The example below would like to show how to register a pickle function and how it will be used:

```
>>> import copyreg, copy, pickle
>>> class C:
...     def __init__(self, a):
...         self.a = a
...
>>> def pickle_c(c):
...     print("pickling a C instance...")
...     return C, (c.a,)
...
>>> copyreg.pickle(C, pickle_c)
>>> c = C(1)
>>> d = copy.copy(c)
pickling a C instance...
>>> p = pickle.dumps(c)
pickling a C instance...
```

12.3 `shelve` — Python object persistence

Source code: [Lib/shelve.py](#)

A «shelf» is a persistent, dictionary-like object. The difference with «dbm» databases is that the values (not the keys!) in a shelf can be essentially arbitrary Python objects — anything that the `pickle` module can handle. This includes most class instances, recursive data types, and objects containing lots of shared sub-objects. The keys are ordinary strings.

`shelve.open(filename, flag='c', protocol=None, writeback=False)`

Open a persistent dictionary. The filename specified is the base filename for the underlying database. As a side-effect, an extension may be added to the filename and more than one file may be created. By default, the underlying database file is opened for reading and writing. The optional `flag` parameter has the same interpretation as the `flag` parameter of `dbm.open()`.

By default, version 3 pickles are used to serialize values. The version of the pickle protocol can be specified with the `protocol` parameter.

Because of Python semantics, a shelf cannot know when a mutable persistent-dictionary entry is modified. By default modified objects are written *only* when assigned to the shelf (see [Example](#)). If the optional `writeback` parameter is set to `True`, all entries accessed are also cached in memory, and written back on `sync()` and `close()`; this can make it handier to mutate mutable entries in the persistent dictionary, but, if many entries are accessed, it can consume vast amounts of memory for the cache, and it can make the close operation very slow since all accessed entries are written back (there is no way to determine which accessed entries are mutable, nor which ones were actually mutated).

Σημείωση: Do not rely on the shelf being closed automatically; always call `close()` explicitly when you don't need it any more, or use `shelve.open()` as a context manager:

```
with shelve.open('spam') as db:
    db['eggs'] = 'eggs'
```

Προειδοποίηση: Because the `shelve` module is backed by `pickle`, it is insecure to load a shelf from an untrusted source. Like with `pickle`, loading a shelf can execute arbitrary code.

Shelf objects support most of methods and operations supported by dictionaries (except copying, constructors and operators `|` and `|=`). This eases the transition from dictionary based scripts to those requiring persistent storage.

Two additional methods are supported:

`Shelf.sync()`

Write back all entries in the cache if the shelf was opened with `writeback` set to `True`. Also empty the cache and synchronize the persistent dictionary on disk, if feasible. This is called automatically when the shelf is closed with `close()`.

`Shelf.close()`

Synchronize and close the persistent `dict` object. Operations on a closed shelf will fail with a `ValueError`.

Δείτε επίσης:

[Persistent dictionary recipe](#) with widely supported storage formats and having the speed of native dictionaries.

12.3.1 Restrictions

- The choice of which database package will be used (such as `dbm.ndbm` or `dbm.gnu`) depends on which interface is available. Therefore it is not safe to open the database directly using `dbm`. The database is also (unfortunately) subject to the limitations of `dbm`, if it is used — this means that (the pickled representation of) the objects stored in the database should be fairly small, and in rare cases key collisions may cause the database to refuse updates.
- The `shelve` module does not support *concurrent* read/write access to shelved objects. (Multiple simultaneous read accesses are safe.) When a program has a shelf open for writing, no other program should have it open for reading or writing. Unix file locking can be used to solve this, but this differs across Unix versions and requires knowledge about the database implementation used.

class `shelve.Shelf` (*dict*, *protocol=None*, *writeback=False*, *keyencoding='utf-8'*)

A subclass of `collections.abc.MutableMapping` which stores pickled values in the *dict* object.

By default, version 3 pickles are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter. See the `pickle` documentation for a discussion of the pickle protocols.

If the *writeback* parameter is `True`, the object will hold a cache of all entries accessed and write them back to the *dict* at sync and close times. This allows natural operations on mutable entries, but can consume much more memory and make sync and close take a long time.

The *keyencoding* parameter is the encoding used to encode keys before they are used with the underlying dict.

A `Shelf` object can also be used as a context manager, in which case it will be automatically closed when the `with` block ends.

Άλλαξε στην έκδοση 3.2: Added the *keyencoding* parameter; previously, keys were always encoded in UTF-8.

Άλλαξε στην έκδοση 3.4: Added context manager support.

class `shelve.BsddbShelf` (*dict*, *protocol=None*, *writeback=False*, *keyencoding='utf-8'*)

A subclass of `Shelf` which exposes `first()`, `next()`, `previous()`, `last()` and `set_location()` which are available in the third-party `bsddb` module from `pybsddb` but not in other database modules. The *dict* object passed to the constructor must support those methods. This is generally accomplished by calling one of `bsddb.hashopen()`, `bsddb.btopen()` or `bsddb.rnopen()`. The optional *protocol*, *writeback*, and *keyencoding* parameters have the same interpretation as for the `Shelf` class.

class `shelve.DbfilenameShelf` (*filename*, *flag='c'*, *protocol=None*, *writeback=False*)

A subclass of `Shelf` which accepts a *filename* instead of a dict-like object. The underlying file will be opened using `dbm.open()`. By default, the file will be created and opened for both read and write. The optional *flag* parameter has the same interpretation as for the `open()` function. The optional *protocol* and *writeback* parameters have the same interpretation as for the `Shelf` class.

12.3.2 Example

To summarize the interface (key is a string, data is an arbitrary object):

```
import shelve

d = shelve.open(filename) # open -- file may get suffix added by low-level
                           # library

d[key] = data              # store data at key (overwrites old data if
                           # using an existing key)
data = d[key]              # retrieve a COPY of data at key (raise KeyError
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

                                # if no such key)
del d[key]                      # delete data stored at key (raises KeyError)
                                # if no such key)

flag = key in d                  # true if the key exists
klist = list(d.keys())          # a list of all existing keys (slow!)

# as d was opened WITHOUT writeback=True, beware:
d['xx'] = [0, 1, 2]              # this works as expected, but...
d['xx'].append(3)                # *this doesn't!* -- d['xx'] is STILL [0, 1, 2]!

# having opened d without writeback=True, you need to code carefully:
temp = d['xx']                   # extracts the copy
temp.append(5)                   # mutates the copy
d['xx'] = temp                   # stores the copy right back, to persist it

# or, d=shelve.open(filename,writeback=True) would let you just code
# d['xx'].append(5) and have it work as expected, BUT it would also
# consume more memory and make the d.close() operation slower.

d.close()                        # close it

```

Δείτε επίσης:**Module `dbm`** Generic interface to dbm-style databases.**Module `pickle`** Object serialization used by `shelve`.

12.4 `marshal` — Internal Python object serialization

This module contains functions that can read and write Python values in a binary format. The format is specific to Python, but independent of machine architecture issues (e.g., you can write a Python value to a file on a PC, transport the file to a Sun, and read it back there). Details of the format are undocumented on purpose; it may change between Python versions (although it rarely does).¹

This is not a general «persistence» module. For general persistence and transfer of Python objects through RPC calls, see the modules `pickle` and `shelve`. The `marshal` module exists mainly to support reading and writing the «pseudo-compiled» code for Python modules of `.pyc` files. Therefore, the Python maintainers reserve the right to modify the marshal format in backward incompatible ways should the need arise. If you're serializing and de-serializing Python objects, use the `pickle` module instead – the performance is comparable, version independence is guaranteed, and pickle supports a substantially wider range of objects than marshal.

Προειδοποίηση: The `marshal` module is not intended to be secure against erroneous or maliciously constructed data. Never unmarshal data received from an untrusted or unauthenticated source.

Not all Python object types are supported; in general, only objects whose value is independent from a particular invocation of Python can be written and read by this module. The following types are supported: booleans, integers, floating point numbers, complex numbers, strings, bytes, bytearrays, tuples, lists, sets, frozensets, dictionaries, and code objects, where it

¹ The name of this module stems from a bit of terminology used by the designers of Modula-3 (amongst others), who use the term «marshalling» for shipping of data around in a self-contained form. Strictly speaking, «to marshal» means to convert some data from internal to external form (in an RPC buffer for instance) and «unmarshalling» for the reverse process.

should be understood that tuples, lists, sets, frozensets and dictionaries are only supported as long as the values contained therein are themselves supported. The singletons *None*, *Ellipsis* and *StopIteration* can also be marshalled and unmarshalled. For format *version* lower than 3, recursive lists, sets and dictionaries cannot be written (see below).

There are functions that read/write files as well as functions operating on bytes-like objects.

The module defines these functions:

`marshal.dump(value, file[, version])`

Write the value on the open file. The value must be a supported type. The file must be a writeable *binary file*.

If the value has (or contains an object that has) an unsupported type, a *ValueError* exception is raised — but garbage data will also be written to the file. The object will not be properly read back by `load()`.

The *version* argument indicates the data format that dump should use (see below).

Raises an *auditing event* `marshal.dumps` with arguments `value`, `version`.

`marshal.load(file)`

Read one value from the open file and return it. If no valid value is read (e.g. because the data has a different Python version's incompatible marshal format), raise *EOFError*, *ValueError* or *TypeError*. The file must be a readable *binary file*.

Raises an *auditing event* `marshal.load` with no arguments.

Σημείωση: If an object containing an unsupported type was marshalled with `dump()`, `load()` will substitute *None* for the unmarshallable type.

Άλλαξε στην έκδοση 3.9.7: This call used to raise a `code.__new__` audit event for each code object. Now it raises a single `marshal.load` event for the entire load operation.

`marshal.dumps(value[, version])`

Return the bytes object that would be written to a file by `dump(value, file)`. The value must be a supported type. Raise a *ValueError* exception if value has (or contains an object that has) an unsupported type.

The *version* argument indicates the data format that dumps should use (see below).

Raises an *auditing event* `marshal.dumps` with arguments `value`, `version`.

`marshal.loads(bytes)`

Convert the *bytes-like object* to a value. If no valid value is found, raise *EOFError*, *ValueError* or *TypeError*. Extra bytes in the input are ignored.

Raises an *auditing event* `marshal.loads` with argument `bytes`.

Άλλαξε στην έκδοση 3.9.7: This call used to raise a `code.__new__` audit event for each code object. Now it raises a single `marshal.loads` event for the entire load operation.

In addition, the following constants are defined:

`marshal.version`

Indicates the format that the module uses. Version 0 is the historical format, version 1 shares interned strings and version 2 uses a binary format for floating point numbers. Version 3 adds support for object instancing and recursion. The current version is 4.

12.5 dbm — Interfaces to Unix «databases»

Source code: `Lib/dbm/__init__.py`

`dbm` is a generic interface to variants of the DBM database — `dbm.gnu` or `dbm.ndbm`. If none of these modules is installed, the slow-but-simple implementation in module `dbm.dumb` will be used. There is a [third party interface](#) to the Oracle Berkeley DB.

exception `dbm.error`

A tuple containing the exceptions that can be raised by each of the supported modules, with a unique exception also named `dbm.error` as the first item — the latter is used when `dbm.error` is raised.

`dbm.whichdb (filename)`

This function attempts to guess which of the several simple database modules available — `dbm.gnu`, `dbm.ndbm` or `dbm.dumb` — should be used to open a given file.

Returns one of the following values: `None` if the file can't be opened because it's unreadable or doesn't exist; the empty string (`' '`) if the file's format can't be guessed; or a string containing the required module name, such as `'dbm.ndbm'` or `'dbm.gnu'`.

`dbm.open (file, flag='r', mode=0o666)`

Open the database file `file` and return a corresponding object.

If the database file already exists, the `whichdb()` function is used to determine its type and the appropriate module is used; if it does not exist, the first module listed above that can be imported is used.

The optional `flag` argument can be:

| Value | Meaning |
|------------------|--|
| <code>'r'</code> | Open existing database for reading only (default) |
| <code>'w'</code> | Open existing database for reading and writing |
| <code>'c'</code> | Open database for reading and writing, creating it if it doesn't exist |
| <code>'n'</code> | Always create a new, empty database, open for reading and writing |

The optional `mode` argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666` (and will be modified by the prevailing `umask`).

The object returned by `open()` supports the same basic functionality as dictionaries; keys and their corresponding values can be stored, retrieved, and deleted, and the `in` operator and the `keys()` method are available, as well as `get()` and `setdefault()`.

Αλλάξε στην έκδοση 3.2: `get()` and `setdefault()` are now available in all database modules.

Αλλάξε στην έκδοση 3.8: Deleting a key from a read-only database raises database module specific error instead of `KeyError`.

Key and values are always stored as bytes. This means that when strings are used they are implicitly converted to the default encoding before being stored.

These objects also support being used in a `with` statement, which will automatically close them when done.

Αλλάξε στην έκδοση 3.4: Added native support for the context management protocol to the objects returned by `open()`.

The following example records some hostnames and a corresponding title, and then prints out the contents of the database:

```
import dbm

# Open database, creating it if necessary.
with dbm.open('cache', 'c') as db:

    # Record some values
    db[b'hello'] = b'there'
    db['www.python.org'] = 'Python Website'
    db['www.cnn.com'] = 'Cable News Network'

    # Note that the keys are considered bytes now.
    assert db[b'www.python.org'] == b'Python Website'
    # Notice how the value is now in bytes.
    assert db['www.cnn.com'] == b'Cable News Network'

    # Often-used methods of the dict interface work too.
    print(db.get('python.org', b'not present'))

    # Storing a non-string key or value will raise an exception (most
    # likely a TypeError).
    db['www.yahoo.com'] = 4

# db is automatically closed when leaving the with statement.
```

Module *shelve* Persistence module which stores non-string data.

The individual submodules are described in the following sections.

12.5.1 dbm.gnu — GNU’s reinterpretation of dbm

Source code: `Lib/dbm/gnu.py`

This module is quite similar to the *dbm* module, but uses the GNU library *gdbm* instead to provide some additional functionality. Please note that the file formats created by *dbm.gnu* and *dbm.ndbm* are incompatible.

The *dbm.gnu* module provides an interface to the GNU DBM library. `dbm.gnu.gdbm` objects behave like mappings (dictionaries), except that keys and values are always converted to bytes before storing. Printing a *gdbm* object doesn’t print the keys and values, and the `items()` and `values()` methods are not supported.

exception `dbm.gnu.error`

Raised on *dbm.gnu*-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

`dbm.gnu.open(filename[, flag[, mode]])`

Open a *gdbm* database and return a *gdbm* object. The *filename* argument is the name of the database file.

The optional *flag* argument can be:

| Value | Meaning |
|-------|--|
| 'r' | Open existing database for reading only (default) |
| 'w' | Open existing database for reading and writing |
| 'c' | Open database for reading and writing, creating it if it doesn’t exist |
| 'n' | Always create a new, empty database, open for reading and writing |

The following additional characters may be appended to the flag to control how the database is opened:

| Value | Meaning |
|-------|---|
| 'f' | Open the database in fast mode. Writes to the database will not be synchronized. |
| 's' | Synchronized mode. This will cause changes to the database to be immediately written to the file. |
| 'u' | Do not lock database. |

Not all flags are valid for all versions of `gdbm`. The module constant `open_flags` is a string of supported flag characters. The exception `error` is raised if an invalid flag is specified.

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666`.

In addition to the dictionary-like methods, `gdbm` objects have the following methods:

`gdbm.firstkey()`

It's possible to loop over every key in the database using this method and the `nextkey()` method. The traversal is ordered by `gdbm`'s internal hash values, and won't be sorted by the key values. This method returns the starting key.

`gdbm.nextkey(key)`

Returns the key that follows *key* in the traversal. The following code prints every key in the database `db`, without having to create a list in memory that contains them all:

```
k = db.firstkey()
while k is not None:
    print(k)
    k = db.nextkey(k)
```

`gdbm.reorganize()`

If you have carried out a lot of deletions and would like to shrink the space used by the `gdbm` file, this routine will reorganize the database. `gdbm` objects will not shorten the length of a database file except by using this reorganization; otherwise, deleted file space will be kept and reused as new (key, value) pairs are added.

`gdbm.sync()`

When the database has been opened in fast mode, this method forces any unwritten data to be written to the disk.

`gdbm.close()`

Close the `gdbm` database.

12.5.2 `dbm.ndbm` — Interface based on `ndbm`

Source code: [Lib/dbm/ndbm.py](#)

The `dbm.ndbm` module provides an interface to the Unix «(n)dbm» library. `Dbm` objects behave like mappings (dictionaries), except that keys and values are always stored as bytes. Printing a `dbm` object doesn't print the keys and values, and the `items()` and `values()` methods are not supported.

This module can be used with the «classic» `ndbm` interface or the GNU GDBM compatibility interface. On Unix, the `configure` script will attempt to locate the appropriate header file to simplify building this module.

exception `dbm.ndbm.error`

Raised on `dbm.ndbm`-specific errors, such as I/O errors. `KeyError` is raised for general mapping errors like specifying an incorrect key.

`dbm.ndbm.library`

Name of the `ndbm` implementation library used.

`dbm.ndbm.open(filename[, flag[, mode]])`

Open a `dbm` database and return a `ndbm` object. The *filename* argument is the name of the database file (without the `.dir` or `.pag` extensions).

The optional *flag* argument must be one of these values:

| Value | Meaning |
|-------|--|
| 'r' | Open existing database for reading only (default) |
| 'w' | Open existing database for reading and writing |
| 'c' | Open database for reading and writing, creating it if it doesn't exist |
| 'n' | Always create a new, empty database, open for reading and writing |

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666` (and will be modified by the prevailing `umask`).

In addition to the dictionary-like methods, `ndbm` objects provide the following method:

`ndbm.close()`

Close the `ndbm` database.

12.5.3 `dbm.dumb` — Portable DBM implementation

Source code: [Lib/dbm/dumb.py](#)

Σημείωση: The `dbm.dumb` module is intended as a last resort fallback for the `dbm` module when a more robust module is not available. The `dbm.dumb` module is not written for speed and is not nearly as heavily used as the other database modules.

The `dbm.dumb` module provides a persistent dictionary-like interface which is written entirely in Python. Unlike other modules such as `dbm.gnu` no external library is required. As with other persistent mappings, the keys and values are always stored as bytes.

The module defines the following:

exception `dbm.dumb.error`

Raised on `dbm.dumb`-specific errors, such as I/O errors. `KeyError` is raised for general mapping errors like specifying an incorrect key.

`dbm.dumb.open(filename[, flag[, mode]])`

Open a `dumbdbm` database and return a `dumbdbm` object. The *filename* argument is the basename of the database file (without any specific extensions). When a `dumbdbm` database is created, files with `.dat` and `.dir` extensions are created.

The optional *flag* argument can be:

| Value | Meaning |
|-------|--|
| 'r' | Open existing database for reading only (default) |
| 'w' | Open existing database for reading and writing |
| 'c' | Open database for reading and writing, creating it if it doesn't exist |
| 'n' | Always create a new, empty database, open for reading and writing |

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal 00666 (and will be modified by the prevailing umask).

Προειδοποίηση: It is possible to crash the Python interpreter when loading a database with a sufficiently large/complex entry due to stack depth limitations in Python's AST compiler.

Άλλαξε στην έκδοση 3.5: `open()` always creates a new database when the flag has the value 'n'.

Άλλαξε στην έκδοση 3.8: A database opened with flags 'r' is now read-only. Opening with flags 'r' and 'w' no longer creates a database if it does not exist.

In addition to the methods provided by the `collections.abc.MutableMapping` class, `dumbdbm` objects provide the following methods:

`dumbdbm.sync()`

Synchronize the on-disk directory and data files. This method is called by the `Shelve.sync()` method.

`dumbdbm.close()`

Close the `dumbdbm` database.

12.6 sqlite3 — DB-API 2.0 interface for SQLite databases

Source code: [Lib/sqlite3/](#)

SQLite is a C library that provides a lightweight disk-based database that doesn't require a separate server process and allows accessing the database using a nonstandard variant of the SQL query language. Some applications can use SQLite for internal data storage. It's also possible to prototype an application using SQLite and then port the code to a larger database such as PostgreSQL or Oracle.

The `sqlite3` module was written by Gerhard Häring. It provides an SQL interface compliant with the DB-API 2.0 specification described by [PEP 249](#).

To use the module, start by creating a `Connection` object that represents the database. Here the data will be stored in the `example.db` file:

```
import sqlite3
con = sqlite3.connect('example.db')
```

The special path name `:memory:` can be provided to create a temporary database in RAM.

Once a `Connection` has been established, create a `Cursor` object and call its `execute()` method to perform SQL commands:

```
cur = con.cursor()

# Create table
cur.execute('CREATE TABLE stocks
            (date text, trans text, symbol text, qty real, price real)')

# Insert a row of data
cur.execute("INSERT INTO stocks VALUES ('2006-01-05', 'BUY', 'RHAT', 100, 35.14)")

# Save (commit) the changes
con.commit()
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
# We can also close the connection if we are done with it.
# Just be sure any changes have been committed or they will be lost.
con.close()
```

The saved data is persistent: it can be reloaded in a subsequent session even after restarting the Python interpreter:

```
import sqlite3
con = sqlite3.connect('example.db')
cur = con.cursor()
```

To retrieve data after executing a SELECT statement, either treat the cursor as an *iterator*, call the cursor's *fetchone()* method to retrieve a single matching row, or call *fetchall()* to get a list of the matching rows.

This example uses the iterator form:

```
>>> for row in cur.execute('SELECT * FROM stocks ORDER BY price'):
    print(row)

('2006-01-05', 'BUY', 'RHAT', 100, 35.14)
('2006-03-28', 'BUY', 'IBM', 1000, 45.0)
('2006-04-06', 'SELL', 'IBM', 500, 53.0)
('2006-04-05', 'BUY', 'MSFT', 1000, 72.0)
```

SQL operations usually need to use values from Python variables. However, beware of using Python's string operations to assemble queries, as they are vulnerable to SQL injection attacks (see the [xkcd webcomic](#) for a humorous example of what can go wrong):

```
# Never do this -- insecure!
symbol = 'RHAT'
cur.execute("SELECT * FROM stocks WHERE symbol = '%s'" % symbol)
```

Instead, use the DB-API's parameter substitution. To insert a variable into a query string, use a placeholder in the string, and substitute the actual values into the query by providing them as a *tuple* of values to the second argument of the cursor's *execute()* method. An SQL statement may use one of two kinds of placeholders: question marks (qmark style) or named placeholders (named style). For the qmark style, parameters must be a *sequence*. For the named style, it can be either a *sequence* or *dict* instance. The length of the *sequence* must match the number of placeholders, or a *ProgrammingError* is raised. If a *dict* is given, it must contain keys for all named parameters. Any extra items are ignored. Here's an example of both styles:

```
import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table lang (name, first_appeared)")

# This is the qmark style:
cur.execute("insert into lang values (?, ?)", ("C", 1972))

# The qmark style used with executemany():
lang_list = [
    ("Fortran", 1957),
    ("Python", 1991),
    ("Go", 2009),
]
cur.executemany("insert into lang values (?, ?)", lang_list)
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
# And this is the named style:
cur.execute("select * from lang where first_appeared=:year", {"year": 1972})
print(cur.fetchall())

con.close()
```

<https://www.w3schools.com/sql/> Tutorial, reference and examples for learning SQL syntax.

PEP 249 - Database API Specification 2.0 PEP written by Marc-André Lemburg.

12.6.1 Module functions and constants**sqlite3.apilevel**

String constant stating the supported DB-API level. Required by the DB-API. Hard-coded to "2.0".

sqlite3.paramstyle

String constant stating the type of parameter marker formatting expected by the *sqlite3* module. Required by the DB-API. Hard-coded to "qmark".

Σημείωση: The *sqlite3* module supports both `qmark` and `numeric` DB-API parameter styles, because that is what the underlying SQLite library supports. However, the DB-API does not allow multiple values for the `paramstyle` attribute.

sqlite3.version

The version number of this module, as a string. This is not the version of the SQLite library.

sqlite3.version_info

The version number of this module, as a tuple of integers. This is not the version of the SQLite library.

sqlite3.sqlite_version

The version number of the run-time SQLite library, as a string.

sqlite3.sqlite_version_info

The version number of the run-time SQLite library, as a tuple of integers.

sqlite3.threadafety

Integer constant required by the DB-API, stating the level of thread safety the *sqlite3* module supports. Currently hard-coded to 1, meaning «*Threads may share the module, but not connections.*» However, this may not always be true. You can check the underlying SQLite library's compile-time threaded mode using the following query:

```
import sqlite3
con = sqlite3.connect(":memory:")
con.execute("""
    select * from pragma_compile_options
    where compile_options like 'THREADSAFE=%'
""").fetchall()
```

Note that the `SQLITE_THREADSAFE` levels do not match the DB-API 2.0 `threadafety` levels.

sqlite3.PARSE_DECLTYPES

This constant is meant to be used with the *detect_types* parameter of the *connect()* function.

Setting it makes the *sqlite3* module parse the declared type for each column it returns. It will parse out the first word of the declared type, i. e. for «integer primary key», it will parse out «integer», or for «number(10)» it will parse out «number». Then for that column, it will look into the converters dictionary and use the converter function registered for that type there.

sqlite3.PARSE_COLNAMES

This constant is meant to be used with the *detect_types* parameter of the *connect()* function.

Setting this makes the SQLite interface parse the column name for each column it returns. It will look for a string formed [mytype] in there, and then decide that “mytype” is the type of the column. It will try to find an entry of “mytype” in the converters dictionary and then use the converter function found there to return the value. The column name found in *Cursor.description* does not include the type, i. e. if you use something like 'as "Expiration date [datetime]" ' in your SQL, then we will parse out everything until the first '[' for the column name and strip the preceding space: the column name would simply be «Expiration date».

sqlite3.connect(*database*[, *timeout*, *detect_types*, *isolation_level*, *check_same_thread*, *factory*,
cached_statements, *uri*])

Opens a connection to the SQLite database file *database*. By default returns a *Connection* object, unless a custom *factory* is given.

database is a *path-like object* giving the pathname (absolute or relative to the current working directory) of the database file to be opened. You can use `":memory:"` to open a database connection to a database that resides in RAM instead of on disk.

When a database is accessed by multiple connections, and one of the processes modifies the database, the SQLite database is locked until that transaction is committed. The *timeout* parameter specifies how long the connection should wait for the lock to go away until raising an exception. The default for the timeout parameter is 5.0 (five seconds).

For the *isolation_level* parameter, please see the *isolation_level* property of *Connection* objects.

SQLite natively supports only the types TEXT, INTEGER, REAL, BLOB and NULL. If you want to use other types you must add support for them yourself. The *detect_types* parameter and the using custom **converters** registered with the module-level *register_converter()* function allow you to easily do that.

detect_types defaults to 0 (i. e. off, no type detection), you can set it to any combination of *PARSE_DECLTYPES* and *PARSE_COLNAMES* to turn type detection on. Due to SQLite behaviour, types can't be detected for generated fields (for example `max(data)`), even when *detect_types* parameter is set. In such case, the returned type is *str*.

By default, *check_same_thread* is *True* and only the creating thread may use the connection. If set *False*, the returned connection may be shared across multiple threads. When using multiple threads with the same connection writing operations should be serialized by the user to avoid data corruption.

By default, the *sqlite3* module uses its *Connection* class for the connect call. You can, however, subclass the *Connection* class and make *connect()* use your class instead by providing your class for the *factory* parameter.

Consult the section *SQLite and Python types* of this manual for details.

The *sqlite3* module internally uses a statement cache to avoid SQL parsing overhead. If you want to explicitly set the number of statements that are cached for the connection, you can set the *cached_statements* parameter. The currently implemented default is to cache 100 statements.

If *uri* is *True*, *database* is interpreted as a URI (Uniform Resource Identifier) with a file path and an optional query string. The scheme part *must* be `"file:"`. The path can be a relative or absolute file path. The query string allows us to pass parameters to SQLite. Some useful URI tricks include:

```
# Open a database in read-only mode.
con = sqlite3.connect("file:template.db?mode=ro", uri=True)

# Don't implicitly create a new database file if it does not already exist.
# Will raise sqlite3.OperationalError if unable to open a database file.
con = sqlite3.connect("file:nosuchdb.db?mode=rw", uri=True)

# Create a shared named in-memory database.
con1 = sqlite3.connect("file:mem1?mode=memory&cache=shared", uri=True)
con2 = sqlite3.connect("file:mem1?mode=memory&cache=shared", uri=True)
con1.executescript("create table t(t); insert into t values(28);")
rows = con2.execute("select * from t").fetchall()
```

More information about this feature, including a list of recognized parameters, can be found in the [SQLite URI documentation](#).

Raises an *auditing event* `sqlite3.connect` with argument `database`.

Άλλαξε στην έκδοση 3.4: Added the *uri* parameter.

Άλλαξε στην έκδοση 3.7: *database* can now also be a *path-like object*, not only a string.

`sqlite3.register_converter` (*typename*, *callable*)

Registers a callable to convert a bytestring from the database into a custom Python type. The callable will be invoked for all database values that are of the type *typename*. Confer the parameter *detect_types* of the `connect()` function for how the type detection works. Note that *typename* and the name of the type in your query are matched in case-insensitive manner.

`sqlite3.register_adapter` (*type*, *callable*)

Registers a callable to convert the custom Python type *type* into one of SQLite's supported types. The callable *callable* accepts as single parameter the Python value, and must return a value of the following types: int, float, str or bytes.

`sqlite3.complete_statement` (*sql*)

Returns *True* if the string *sql* contains one or more complete SQL statements terminated by semicolons. It does not verify that the SQL is syntactically correct, only that there are no unclosed string literals and the statement is terminated by a semicolon.

This can be used to build a shell for SQLite, as in the following example:

```
# A minimal SQLite shell for experiments

import sqlite3

con = sqlite3.connect(":memory:")
con.isolation_level = None
cur = con.cursor()

buffer = ""

print("Enter your SQL commands to execute in sqlite3.")
print("Enter a blank line to exit.")

while True:
    line = input()
    if line == "":
        break
    buffer += line
    if sqlite3.complete_statement(buffer):
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

try:
    buffer = buffer.strip()
    cur.execute(buffer)

    if buffer.lstrip().upper().startswith("SELECT"):
        print(cur.fetchall())
except sqlite3.Error as e:
    print("An error occurred:", e.args[0])
buffer = ""

con.close()

```

`sqlite3.enable_callback_tracebacks(flag)`

By default you will not get any tracebacks in user-defined functions, aggregates, converters, authorizer callbacks etc. If you want to debug them, you can call this function with *flag* set to `True`. Afterwards, you will get tracebacks from callbacks on `sys.stderr`. Use `False` to disable the feature again.

12.6.2 Connection Objects

class `sqlite3.Connection`

An SQLite database connection has the following attributes and methods:

isolation_level

Get or set the current default isolation level. `None` for autocommit mode or one of «DEFERRED», «IMMEDIATE» or «EXCLUSIVE». See section *Controlling Transactions* for a more detailed explanation.

in_transaction

`True` if a transaction is active (there are uncommitted changes), `False` otherwise. Read-only attribute.

Νέο στην έκδοση 3.2.

cursor (*factory=Cursor*)

The cursor method accepts a single optional parameter *factory*. If supplied, this must be a callable returning an instance of `Cursor` or its subclasses.

commit()

This method commits the current transaction. If you don't call this method, anything you did since the last call to `commit()` is not visible from other database connections. If you wonder why you don't see the data you've written to the database, please check you didn't forget to call this method.

rollback()

This method rolls back any changes to the database since the last call to `commit()`.

close()

This closes the database connection. Note that this does not automatically call `commit()`. If you just close your database connection without calling `commit()` first, your changes will be lost!

execute (*sql[, parameters]*)

Create a new `Cursor` object and call `execute()` on it with the given *sql* and *parameters*. Return the new cursor object.

executemany (*sql[, parameters]*)

Create a new `Cursor` object and call `executemany()` on it with the given *sql* and *parameters*. Return the new cursor object.

executescript (*sql_script*)

Create a new `Cursor` object and call `executescript()` on it with the given *sql_script*. Return the new cursor object.

create_function (*name, num_params, func, *, deterministic=False*)

Creates a user-defined function that you can later use from within SQL statements under the function name *name*. *num_params* is the number of parameters the function accepts (if *num_params* is -1, the function may take any number of arguments), and *func* is a Python callable that is called as the SQL function. If *deterministic* is true, the created function is marked as *deterministic*, which allows SQLite to perform additional optimizations. This flag is supported by SQLite 3.8.3 or higher, *NotSupportedError* will be raised if used with older versions.

The function can return any of the types supported by SQLite: bytes, str, int, float and None.

Αλλάξε στην έκδοση 3.8: The *deterministic* parameter was added.

Example:

```
import sqlite3
import hashlib

def md5sum(t):
    return hashlib.md5(t).hexdigest()

con = sqlite3.connect(":memory:")
con.create_function("md5", 1, md5sum)
cur = con.cursor()
cur.execute("select md5(?)", (b"foo",))
print(cur.fetchone()[0])

con.close()
```

create_aggregate (*name, num_params, aggregate_class*)

Creates a user-defined aggregate function.

The aggregate class must implement a *step* method, which accepts the number of parameters *num_params* (if *num_params* is -1, the function may take any number of arguments), and a *finalize* method which will return the final result of the aggregate.

The *finalize* method can return any of the types supported by SQLite: bytes, str, int, float and None.

Example:

```
import sqlite3

class MySum:
    def __init__(self):
        self.count = 0

    def step(self, value):
        self.count += value

    def finalize(self):
        return self.count

con = sqlite3.connect(":memory:")
con.create_aggregate("mysum", 1, MySum)
cur = con.cursor()
cur.execute("create table test(i)")
cur.execute("insert into test(i) values (1)")
cur.execute("insert into test(i) values (2)")
cur.execute("select mysum(i) from test")
print(cur.fetchone()[0])
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
con.close()
```

create_collation (*name*, *callable*)

Creates a collation with the specified *name* and *callable*. The callable will be passed two string arguments. It should return -1 if the first is ordered lower than the second, 0 if they are ordered equal and 1 if the first is ordered higher than the second. Note that this controls sorting (ORDER BY in SQL) so your comparisons don't affect other SQL operations.

Note that the callable will get its parameters as Python bytestrings, which will normally be encoded in UTF-8.

The following example shows a custom collation that sorts «the wrong way»:

```
import sqlite3

def collate_reverse(string1, string2):
    if string1 == string2:
        return 0
    elif string1 < string2:
        return 1
    else:
        return -1

con = sqlite3.connect(":memory:")
con.create_collation("reverse", collate_reverse)

cur = con.cursor()
cur.execute("create table test(x)")
cur.executemany("insert into test(x) values (?)", [("a",), ("b",)])
cur.execute("select x from test order by x collate reverse")
for row in cur:
    print(row)
con.close()
```

To remove a collation, call `create_collation` with `None` as callable:

```
con.create_collation("reverse", None)
```

interrupt ()

You can call this method from a different thread to abort any queries that might be executing on the connection. The query will then abort and the caller will get an exception.

set_authorizer (*authorizer_callback*)

This routine registers a callback. The callback is invoked for each attempt to access a column of a table in the database. The callback should return `SQLITE_OK` if access is allowed, `SQLITE_DENY` if the entire SQL statement should be aborted with an error and `SQLITE_IGNORE` if the column should be treated as a NULL value. These constants are available in the `sqlite3` module.

The first argument to the callback signifies what kind of operation is to be authorized. The second and third argument will be arguments or `None` depending on the first argument. The 4th argument is the name of the database («main», «temp», etc.) if applicable. The 5th argument is the name of the inner-most trigger or view that is responsible for the access attempt or `None` if this access attempt is directly from input SQL code.

Please consult the SQLite documentation about the possible values for the first argument and the meaning of the second and third argument depending on the first one. All necessary constants are available in the `sqlite3` module.

set_progress_handler (*handler*, *n*)

This routine registers a callback. The callback is invoked for every *n* instructions of the SQLite virtual machine. This is useful if you want to get called from SQLite during long-running operations, for example to update a GUI.

If you want to clear any previously installed progress handler, call the method with *None* for *handler*.

Returning a non-zero value from the handler function will terminate the currently executing query and cause it to raise an *OperationalError* exception.

set_trace_callback (*trace_callback*)

Registers *trace_callback* to be called for each SQL statement that is actually executed by the SQLite backend.

The only argument passed to the callback is the statement (as *str*) that is being executed. The return value of the callback is ignored. Note that the backend does not only run statements passed to the *Cursor.execute()* methods. Other sources include the *transaction management* of the *sqlite3* module and the execution of triggers defined in the current database.

Passing *None* as *trace_callback* will disable the trace callback.

Σημείωση: Exceptions raised in the trace callback are not propagated. As a development and debugging aid, use *enable_callback_tracebacks()* to enable printing tracebacks from exceptions raised in the trace callback.

Νέο στην έκδοση 3.3.

enable_load_extension (*enabled*)

This routine allows/disallows the SQLite engine to load SQLite extensions from shared libraries. SQLite extensions can define new functions, aggregates or whole new virtual table implementations. One well-known extension is the fulltext-search extension distributed with SQLite.

Loadable extensions are disabled by default. See¹.

Νέο στην έκδοση 3.2.

```
import sqlite3

con = sqlite3.connect(":memory:")

# enable extension loading
con.enable_load_extension(True)

# Load the fulltext search extension
con.execute("select load_extension('./fts3.so')")

# alternatively you can load the extension using an API call:
# con.load_extension("./fts3.so")

# disable extension loading again
con.enable_load_extension(False)

# example from SQLite wiki
con.execute("create virtual table recipe using fts3(name, ingredients)")
con.executescript("""
    insert into recipe (name, ingredients) values ('broccoli stew', 'broccoli
↵peppers cheese tomatoes');
```

(συνέχεια στην επόμενη σελίδα)

¹ The *sqlite3* module is not built with loadable extension support by default, because some platforms (notably macOS) have SQLite libraries which are compiled without this feature. To get loadable extension support, you must pass `--enable-loadable-sqlite-extensions` to configure.

(συνεχίζεται από την προηγούμενη σελίδα)

```

        insert into recipe (name, ingredients) values ('pumpkin stew', 'pumpkin_
↪onions garlic celery');
        insert into recipe (name, ingredients) values ('broccoli pie', 'broccoli_
↪cheese onions flour');
        insert into recipe (name, ingredients) values ('pumpkin pie', 'pumpkin_
↪sugar flour butter');
        """
    for row in con.execute("select rowid, name, ingredients from recipe where_
↪name match 'pie'"):
        print(row)

con.close()

```

load_extension (*path*)

This routine loads an SQLite extension from a shared library. You have to enable extension loading with `enable_load_extension()` before you can use this routine.

Loadable extensions are disabled by default. See¹.

Νέο στην έκδοση 3.2.

row_factory

You can change this attribute to a callable that accepts the cursor and the original row as a tuple and will return the real result row. This way, you can implement more advanced ways of returning results, such as returning an object that can also access columns by name.

Example:

```

import sqlite3

def dict_factory(cursor, row):
    d = {}
    for idx, col in enumerate(cursor.description):
        d[col[0]] = row[idx]
    return d

con = sqlite3.connect(":memory:")
con.row_factory = dict_factory
cur = con.cursor()
cur.execute("select 1 as a")
print(cur.fetchone() ["a"])

con.close()

```

If returning a tuple doesn't suffice and you want name-based access to columns, you should consider setting `row_factory` to the highly-optimized `sqlite3.Row` type. `Row` provides both index-based and case-insensitive name-based access to columns with almost no memory overhead. It will probably be better than your own custom dictionary-based approach or even a `db_row` based solution.

text_factory

Using this attribute you can control what objects are returned for the TEXT data type. By default, this attribute is set to `str` and the `sqlite3` module will return `str` objects for TEXT. If you want to return `bytes` instead, you can set it to `bytes`.

You can also set it to any other callable that accepts a single bytestring parameter and returns the resulting object.

See the following example code for illustration:

```

import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()

AUSTRIA = "Österreich"

# by default, rows are returned as str
cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert row[0] == AUSTRIA

# but we can make sqlite3 always return bytestrings ...
con.text_factory = bytes
cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert type(row[0]) is bytes
# the bytestrings will be encoded in UTF-8, unless you stored garbage in the
# database ...
assert row[0] == AUSTRIA.encode("utf-8")

# we can also implement a custom text_factory ...
# here we implement one that appends "foo" to all strings
con.text_factory = lambda x: x.decode("utf-8") + "foo"
cur.execute("select ?", ("bar",))
row = cur.fetchone()
assert row[0] == "barfoo"

con.close()

```

total_changes

Returns the total number of database rows that have been modified, inserted, or deleted since the database connection was opened.

iterdump()

Returns an iterator to dump the database in an SQL text format. Useful when saving an in-memory database for later restoration. This function provides the same capabilities as the `.dump` command in the **sqlite3** shell.

Example:

```

# Convert file existing_db.db to SQL dump file dump.sql
import sqlite3

con = sqlite3.connect('existing_db.db')
with open('dump.sql', 'w') as f:
    for line in con.iterdump():
        f.write('%s\n' % line)
con.close()

```

backup(target, *, pages=-1, progress=None, name="main", sleep=0.250)

This method makes a backup of an SQLite database even while it's being accessed by other clients, or concurrently by the same connection. The copy will be written into the mandatory argument *target*, that must be another *Connection* instance.

By default, or when *pages* is either 0 or a negative integer, the entire database is copied in a single step; otherwise the method performs a loop copying up to *pages* pages at a time.

If *progress* is specified, it must either be *None* or a callable object that will be executed at each iteration with

three integer arguments, respectively the *status* of the last iteration, the *remaining* number of pages still to be copied and the *total* number of pages.

The *name* argument specifies the database name that will be copied: it must be a string containing either "main", the default, to indicate the main database, "temp" to indicate the temporary database or the name specified after the AS keyword in an ATTACH DATABASE statement for an attached database.

The *sleep* argument specifies the number of seconds to sleep by between successive attempts to backup remaining pages, can be specified either as an integer or a floating point value.

Example 1, copy an existing database into another:

```
import sqlite3

def progress(status, remaining, total):
    print(f'Copied {total-remaining} of {total} pages...')

con = sqlite3.connect('existing_db.db')
bck = sqlite3.connect('backup.db')
with bck:
    con.backup(bck, pages=1, progress=progress)
bck.close()
con.close()
```

Example 2, copy an existing database into a transient copy:

```
import sqlite3

source = sqlite3.connect('existing_db.db')
dest = sqlite3.connect(':memory:')
source.backup(dest)
```

Availability: SQLite 3.6.11 or higher

Νέο στην έκδοση 3.7.

12.6.3 Cursor Objects

class `sqlite3.Cursor`

A *Cursor* instance has the following attributes and methods.

execute (`sql`[, `parameters`])

Executes an SQL statement. Values may be bound to the statement using *placeholders*.

`execute()` will only execute a single SQL statement. If you try to execute more than one statement with it, it will raise a *Warning*. Use `executescript()` if you want to execute multiple SQL statements with one call.

executemany (`sql`, `seq_of_parameters`)

Executes a *parameterized* SQL command against all parameter sequences or mappings found in the sequence `seq_of_parameters`. The `sqlite3` module also allows using an *iterator* yielding parameters instead of a sequence.

```
import sqlite3

class IterChars:
    def __init__(self):
        self.count = ord('a')
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

def __iter__(self):
    return self

def __next__(self):
    if self.count > ord('z'):
        raise StopIteration
    self.count += 1
    return (chr(self.count - 1),) # this is a 1-tuple

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table characters(c)")

theIter = IterChars()
cur.executemany("insert into characters(c) values (?)", theIter)

cur.execute("select c from characters")
print(cur.fetchall())

con.close()

```

Here's a shorter example using a *generator*:

```

import sqlite3
import string

def char_generator():
    for c in string.ascii_lowercase:
        yield (c,)

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table characters(c)")

cur.executemany("insert into characters(c) values (?)", char_generator())

cur.execute("select c from characters")
print(cur.fetchall())

con.close()

```

executescript (*sql_script*)

This is a nonstandard convenience method for executing multiple SQL statements at once. It issues a COMMIT statement first, then executes the SQL script it gets as a parameter. This method disregards *isolation_level*; any transaction control must be added to *sql_script*.

sql_script can be an instance of *str*.

Example:

```

import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.executescript("""
    create table person(

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

        firstname,
        lastname,
        age
    );

    create table book(
        title,
        author,
        published
    );

    insert into book(title, author, published)
    values (
        'Dirk Gently''s Holistic Detective Agency',
        'Douglas Adams',
        1987
    );
    """
con.close()

```

fetchone()

Fetches the next row of a query result set, returning a single sequence, or *None* when no more data is available.

fetchmany() (*size=cursor.arraysize*)

Fetches the next set of rows of a query result, returning a list. An empty list is returned when no more rows are available.

The number of rows to fetch per call is specified by the *size* parameter. If it is not given, the cursor's *arraysize* determines the number of rows to be fetched. The method should try to fetch as many rows as indicated by the *size* parameter. If this is not possible due to the specified number of rows not being available, fewer rows may be returned.

Note there are performance considerations involved with the *size* parameter. For optimal performance, it is usually best to use the *arraysize* attribute. If the *size* parameter is used, then it is best for it to retain the same value from one *fetchmany()* call to the next.

fetchall()

Fetches all (remaining) rows of a query result, returning a list. Note that the cursor's *arraysize* attribute can affect the performance of this operation. An empty list is returned when no rows are available.

close()

Close the cursor now (rather than whenever `__del__` is called).

The cursor will be unusable from this point forward; a *ProgrammingError* exception will be raised if any operation is attempted with the cursor.

setinputsizes() (*sizes*)

Required by the DB-API. Does nothing in *sqlite3*.

setoutputsize() (*size[, column]*)

Required by the DB-API. Does nothing in *sqlite3*.

rowcount

Although the *Cursor* class of the *sqlite3* module implements this attribute, the database engine's own support for the determination of «rows affected»/«rows selected» is quirky.

For *executemany()* statements, the number of modifications are summed up into *rowcount*.

As required by the Python DB API Spec, the *rowcount* attribute «is -1 in case no *executeXX()* has been performed on the cursor or the rowcount of the last operation is not determinable by the interface».

This includes `SELECT` statements because we cannot determine the number of rows a query produced until all rows were fetched.

With SQLite versions before 3.6.5, `rowcount` is set to 0 if you make a `DELETE FROM table` without any condition.

lastrowid

This read-only attribute provides the row id of the last inserted row. It is only updated after successful `INSERT` or `REPLACE` statements using the `execute()` method. For other statements, after `executemany()` or `executescript()`, or if the insertion failed, the value of `lastrowid` is left unchanged. The initial value of `lastrowid` is `None`.

Σημείωση: Inserts into `WITHOUT ROWID` tables are not recorded.

Άλλαξε στην έκδοση 3.6: Added support for the `REPLACE` statement.

arraysize

Read/write attribute that controls the number of rows returned by `fetchmany()`. The default value is 1 which means a single row would be fetched per call.

description

This read-only attribute provides the column names of the last query. To remain compatible with the Python DB API, it returns a 7-tuple for each column where the last six items of each tuple are `None`.

It is set for `SELECT` statements without any matching rows as well.

connection

This read-only attribute provides the SQLite database `Connection` used by the `Cursor` object. A `Cursor` object created by calling `con.cursor()` will have a `connection` attribute that refers to `con`:

```
>>> con = sqlite3.connect(":memory:")
>>> cur = con.cursor()
>>> cur.connection == con
True
```

12.6.4 Row Objects

class `sqlite3.Row`

A `Row` instance serves as a highly optimized `row_factory` for `Connection` objects. It tries to mimic a tuple in most of its features.

It supports mapping access by column name and index, iteration, representation, equality testing and `len()`.

If two `Row` objects have exactly the same columns and their members are equal, they compare equal.

keys()

This method returns a list of column names. Immediately after a query, it is the first member of each tuple in `Cursor.description`.

Άλλαξε στην έκδοση 3.5: Added support of slicing.

Let's assume we initialize a table as in the example given above:

```
con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute('create table stocks
(date text, trans text, symbol text,
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
    qty real, price real)'''
cur.execute("""insert into stocks
              values ('2006-01-05','BUY','RHAT',100,35.14) """)
con.commit()
cur.close()
```

Now we plug *Row* in:

```
>>> con.row_factory = sqlite3.Row
>>> cur = con.cursor()
>>> cur.execute('select * from stocks')
<sqlite3.Cursor object at 0x7f4e7dd8fa80>
>>> r = cur.fetchone()
>>> type(r)
<class 'sqlite3.Row'>
>>> tuple(r)
('2006-01-05', 'BUY', 'RHAT', 100.0, 35.14)
>>> len(r)
5
>>> r[2]
'RHAT'
>>> r.keys()
['date', 'trans', 'symbol', 'qty', 'price']
>>> r['qty']
100.0
>>> for member in r:
...     print(member)
...
2006-01-05
BUY
RHAT
100.0
35.14
```

12.6.5 Exceptions

exception `sqlite3.Warning`

A subclass of *Exception*.

exception `sqlite3.Error`

The base class of the other exceptions in this module. It is a subclass of *Exception*.

exception `sqlite3.DatabaseError`

Exception raised for errors that are related to the database.

exception `sqlite3.IntegrityError`

Exception raised when the relational integrity of the database is affected, e.g. a foreign key check fails. It is a subclass of *DatabaseError*.

exception `sqlite3.ProgrammingError`

Exception raised for programming errors, e.g. table not found or already exists, syntax error in the SQL statement, wrong number of parameters specified, etc. It is a subclass of *DatabaseError*.

exception `sqlite3.OperationalError`

Exception raised for errors that are related to the database's operation and not necessarily under the control of the

programmer, e.g. an unexpected disconnect occurs, the data source name is not found, a transaction could not be processed, etc. It is a subclass of *DatabaseError*.

exception `sqlite3.NotSupportedError`

Exception raised in case a method or database API was used which is not supported by the database, e.g. calling the `rollback()` method on a connection that does not support transaction or has transactions turned off. It is a subclass of *DatabaseError*.

12.6.6 SQLite and Python types

Introduction

SQLite natively supports the following types: NULL, INTEGER, REAL, TEXT, BLOB.

The following Python types can thus be sent to SQLite without any problem:

| Python type | SQLite type |
|--------------|-------------|
| <i>None</i> | NULL |
| <i>int</i> | INTEGER |
| <i>float</i> | REAL |
| <i>str</i> | TEXT |
| <i>bytes</i> | BLOB |

This is how SQLite types are converted to Python types by default:

| SQLite type | Python type |
|-------------|--|
| NULL | <i>None</i> |
| INTEGER | <i>int</i> |
| REAL | <i>float</i> |
| TEXT | depends on <i>text_factory</i> , <i>str</i> by default |
| BLOB | <i>bytes</i> |

The type system of the *sqlite3* module is extensible in two ways: you can store additional Python types in an SQLite database via object adaptation, and you can let the *sqlite3* module convert SQLite types to different Python types via converters.

Using adapters to store additional Python types in SQLite databases

As described before, SQLite supports only a limited set of types natively. To use other Python types with SQLite, you must **adapt** them to one of the *sqlite3* module's supported types for SQLite: one of `NoneType`, `int`, `float`, `str`, `bytes`.

There are two ways to enable the *sqlite3* module to adapt a custom Python type to one of the supported ones.

Letting your object adapt itself

This is a good approach if you write the class yourself. Let's suppose you have a class like this:

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y
```

Now you want to store the point in a single SQLite column. First you'll have to choose one of the supported types to be used for representing the point. Let's just use str and separate the coordinates using a semicolon. Then you need to give your class a method `__conform__(self, protocol)` which must return the converted value. The parameter *protocol* will be `PrepareProtocol`.

```
import sqlite3

class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __conform__(self, protocol):
        if protocol is sqlite3.PrepareProtocol:
            return "%f;%f" % (self.x, self.y)

con = sqlite3.connect(":memory:")
cur = con.cursor()

p = Point(4.0, -3.2)
cur.execute("select ?", (p,))
print(cur.fetchone()[0])

con.close()
```

Registering an adapter callable

The other possibility is to create a function that converts the type to the string representation and register the function with `register_adapter()`.

```
import sqlite3

class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

def adapt_point(point):
    return "%f;%f" % (point.x, point.y)

sqlite3.register_adapter(Point, adapt_point)

con = sqlite3.connect(":memory:")
cur = con.cursor()

p = Point(4.0, -3.2)
cur.execute("select ?", (p,))
print(cur.fetchone()[0])

con.close()
```

The `sqlite3` module has two default adapters for Python's built-in `datetime.date` and `datetime.datetime` types. Now let's suppose we want to store `datetime.datetime` objects not in ISO representation, but as a Unix timestamp.

```
import sqlite3
import datetime
import time

def adapt_datetime(ts):
    return time.mktime(ts.timetuple())

sqlite3.register_adapter(datetime.datetime, adapt_datetime)

con = sqlite3.connect(":memory:")
cur = con.cursor()

now = datetime.datetime.now()
cur.execute("select ?", (now,))
print(cur.fetchone()[0])

con.close()
```

Converting SQLite values to custom Python types

Writing an adapter lets you send custom Python types to SQLite. But to make it really useful we need to make the Python to SQLite to Python roundtrip work.

Enter converters.

Let's go back to the `Point` class. We stored the `x` and `y` coordinates separated via semicolons as strings in SQLite.

First, we'll define a converter function that accepts the string as a parameter and constructs a `Point` object from it.

Σημείωση: Converter functions **always** get called with a `bytes` object, no matter under which data type you sent the value to SQLite.

```
def convert_point(s):
    x, y = map(float, s.split(b";"))
    return Point(x, y)
```

Now you need to make the `sqlite3` module know that what you select from the database is actually a point. There are two ways of doing this:

- Implicitly via the declared type
- Explicitly via the column name

Both ways are described in section *Module functions and constants*, in the entries for the constants `PARSE_DECLTYPES` and `PARSE_COLNAMES`.

The following example illustrates both approaches.

```
import sqlite3

class Point:
    def __init__(self, x, y):
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

        self.x, self.y = x, y

    def __repr__(self):
        return "({f};{f})".format(self.x, self.y)

def adapt_point(point):
    return "({f};{f})".format(point.x, point.y).encode('ascii')

def convert_point(s):
    x, y = list(map(float, s.split(b";")))
    return Point(x, y)

# Register the adapter
sqlite3.register_adapter(Point, adapt_point)

# Register the converter
sqlite3.register_converter("point", convert_point)

p = Point(4.0, -3.2)

#####
# 1) Using declared types
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES)
cur = con.cursor()
cur.execute("create table test(p point)")

cur.execute("insert into test(p) values (?)", (p,))
cur.execute("select p from test")
print("with declared types:", cur.fetchone()[0])
cur.close()
con.close()

#####
# 1) Using column names
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_COLNAMES)
cur = con.cursor()
cur.execute("create table test(p)")

cur.execute("insert into test(p) values (?)", (p,))
cur.execute('select p as "p [point]" from test')
print("with column names:", cur.fetchone()[0])
cur.close()
con.close()

```

Default adapters and converters

There are default adapters for the date and datetime types in the datetime module. They will be sent as ISO dates/ISO timestamps to SQLite.

The default converters are registered under the name «date» for `datetime.date` and under the name «timestamp» for `datetime.datetime`.

This way, you can use date/timestamps from Python without any additional fiddling in most cases. The format of the adapters is also compatible with the experimental SQLite date/time functions.

The following example demonstrates this.

```

import sqlite3
import datetime

con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES|sqlite3.PARSE_
↳COLNAMES)
cur = con.cursor()
cur.execute("create table test(d date, ts timestamp)")

today = datetime.date.today()
now = datetime.datetime.now()

cur.execute("insert into test(d, ts) values (?, ?)", (today, now))
cur.execute("select d, ts from test")
row = cur.fetchone()
print(today, "=>", row[0], type(row[0]))
print(now, "=>", row[1], type(row[1]))

cur.execute('select current_date as "d [date]", current_timestamp as "ts [timestamp]"
↳')
row = cur.fetchone()
print("current_date", row[0], type(row[0]))
print("current_timestamp", row[1], type(row[1]))

con.close()

```

If a timestamp stored in SQLite has a fractional part longer than 6 numbers, its value will be truncated to microsecond precision by the timestamp converter.

Σημείωση: The default «timestamp» converter ignores UTC offsets in the database and always returns a naive `datetime.datetime` object. To preserve UTC offsets in timestamps, either leave converters disabled, or register an offset-aware converter with `register_converter()`.

12.6.7 Controlling Transactions

The underlying `sqlite3` library operates in autocommit mode by default, but the Python `sqlite3` module by default does not.

autocommit mode means that statements that modify the database take effect immediately. A `BEGIN` or `SAVEPOINT` statement disables autocommit mode, and a `COMMIT`, a `ROLLBACK`, or a `RELEASE` that ends the outermost transaction, turns autocommit mode back on.

The Python `sqlite3` module by default issues a `BEGIN` statement implicitly before a Data Modification Language (DML) statement (i.e. `INSERT/UPDATE/DELETE/REPLACE`).

You can control which kind of `BEGIN` statements `sqlite3` implicitly executes via the `isolation_level` parameter to the `connect()` call, or via the `isolation_level` property of connections. If you specify no `isolation_level`, a plain `BEGIN` is used, which is equivalent to specifying `DEFERRED`. Other possible values are `IMMEDIATE` and `EXCLUSIVE`.

You can disable the `sqlite3` module's implicit transaction management by setting `isolation_level` to `None`. This will leave the underlying `sqlite3` library operating in autocommit mode. You can then completely control the transaction state by explicitly issuing `BEGIN`, `ROLLBACK`, `SAVEPOINT`, and `RELEASE` statements in your code.

Note that `executescript()` disregards `isolation_level`; any transaction control must be added explicitly.

Αλλάξε στην έκδοση 3.6: `sqlite3` used to implicitly commit an open transaction before DDL statements. This is no longer the case.

12.6.8 Using `sqlite3` efficiently

Using shortcut methods

Using the nonstandard `execute()`, `executemany()` and `executescript()` methods of the *Connection* object, your code can be written more concisely because you don't have to create the (often superfluous) *Cursor* objects explicitly. Instead, the *Cursor* objects are created implicitly and these shortcut methods return the cursor objects. This way, you can execute a `SELECT` statement and iterate over it directly using only a single call on the *Connection* object.

```
import sqlite3

langs = [
    ("C++", 1985),
    ("Objective-C", 1984),
]

con = sqlite3.connect(":memory:")

# Create the table
con.execute("create table lang(name, first_appeared)")

# Fill the table
con.executemany("insert into lang(name, first_appeared) values (?, ?)", langs)

# Print the table contents
for row in con.execute("select name, first_appeared from lang"):
    print(row)

print("I just deleted", con.execute("delete from lang").rowcount, "rows")

# close is not a shortcut method and it's not called automatically,
# so the connection object should be closed manually
con.close()
```

Accessing columns by name instead of by index

One useful feature of the `sqlite3` module is the built-in `sqlite3.Row` class designed to be used as a row factory.

Rows wrapped with this class can be accessed both by index (like tuples) and case-insensitively by name:

```
import sqlite3

con = sqlite3.connect(":memory:")
con.row_factory = sqlite3.Row

cur = con.cursor()
cur.execute("select 'John' as name, 42 as age")
for row in cur:
    assert row[0] == row["name"]
    assert row["name"] == row["nAmE"]
    assert row[1] == row["age"]
    assert row[1] == row["AgE"]

con.close()
```

Using the connection as a context manager

Connection objects can be used as context managers that automatically commit or rollback transactions. In the event of an exception, the transaction is rolled back; otherwise, the transaction is committed:

```
import sqlite3

con = sqlite3.connect(":memory:")
con.execute("create table lang (id integer primary key, name varchar unique)")

# Successful, con.commit() is called automatically afterwards
with con:
    con.execute("insert into lang(name) values (?)", ("Python",))

# con.rollback() is called after the with block finishes with an exception, the
# exception is still raised and must be caught
try:
    with con:
        con.execute("insert into lang(name) values (?)", ("Python",))
except sqlite3.IntegrityError:
    print("couldn't add Python twice")

# Connection object used as context manager only commits or rollbacks transactions,
# so the connection object should be closed manually
con.close()
```

Συμπίεση Δεδομένων και Αρχειοθέτηση

Τα modules που περιγράφονται σε αυτό το κεφάλαιο υποστηρίζουν την συμπίεση δεδομένων με τους αλγόριθμους `zlib`, `gzip`, `bzip2` και `lzma`, καθώς και τη δημιουργία αρχείων σε μορφή ZIP- και tar-. Δείτε επίσης τις *Archiving operations* που παρέχονται από το module `shutil`.

13.1 `zlib` — Compression compatible with `gzip`

For applications that require data compression, the functions in this module allow compression and decompression, using the `zlib` library. The `zlib` library has its own home page at <https://www.zlib.net>. There are known incompatibilities between the Python module and versions of the `zlib` library earlier than 1.1.3; 1.1.3 has a *security vulnerability*, so we recommend using 1.1.4 or later.

`zlib`'s functions have many options and often need to be used in a particular order. This documentation doesn't attempt to cover all of the permutations; consult the `zlib` manual at <http://www.zlib.net/manual.html> for authoritative information.

For reading and writing `.gz` files see the `gzip` module.

The available exception and functions in this module are:

exception `zlib.error`

Exception raised on compression and decompression errors.

`zlib.adler32` (*data* [, *value*])

Computes an Adler-32 checksum of *data*. (An Adler-32 checksum is almost as reliable as a CRC32 but can be computed much more quickly.) The result is an unsigned 32-bit integer. If *value* is present, it is used as the starting value of the checksum; otherwise, a default value of 1 is used. Passing in *value* allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm.

Αλλαξε στην έκδοση 3.0: The result is always unsigned. To generate the same numeric value when using Python 2 or earlier, use `adler32(data) & 0xffffffff`.

`zlib.compress(data, /, level=-1)`

Compresses the bytes in *data*, returning a bytes object containing compressed data. *level* is an integer from 0 to 9 or -1 controlling the level of compression; 1 (Z_BEST_SPEED) is fastest and produces the least compression, 9 (Z_BEST_COMPRESSION) is slowest and produces the most. 0 (Z_NO_COMPRESSION) is no compression. The default value is -1 (Z_DEFAULT_COMPRESSION). Z_DEFAULT_COMPRESSION represents a default compromise between speed and compression (currently equivalent to level 6). Raises the `error` exception if any error occurs.

Άλλαξε στην έκδοση 3.6: *level* can now be used as a keyword parameter.

`zlib.compressobj(level=-1, method=DEFLATED, wbits=MAX_WBITS, memLevel=DEF_MEM_LEVEL, strategy=Z_DEFAULT_STRATEGY[, zdict])`

Returns a compression object, to be used for compressing data streams that won't fit into memory at once.

level is the compression level – an integer from 0 to 9 or -1. A value of 1 (Z_BEST_SPEED) is fastest and produces the least compression, while a value of 9 (Z_BEST_COMPRESSION) is slowest and produces the most. 0 (Z_NO_COMPRESSION) is no compression. The default value is -1 (Z_DEFAULT_COMPRESSION). Z_DEFAULT_COMPRESSION represents a default compromise between speed and compression (currently equivalent to level 6).

method is the compression algorithm. Currently, the only supported value is DEFLATED.

The *wbits* argument controls the size of the history buffer (or the «window size») used when compressing data, and whether a header and trailer is included in the output. It can take several ranges of values, defaulting to 15 (MAX_WBITS):

- +9 to +15: The base-two logarithm of the window size, which therefore ranges between 512 and 32768. Larger values produce better compression at the expense of greater memory usage. The resulting output will include a zlib-specific header and trailer.
- -9 to -15: Uses the absolute value of *wbits* as the window size logarithm, while producing a raw output stream with no header or trailing checksum.
- +25 to +31 = 16 + (9 to 15): Uses the low 4 bits of the value as the window size logarithm, while including a basic **gzip** header and trailing checksum in the output.

The *memLevel* argument controls the amount of memory used for the internal compression state. Valid values range from 1 to 9. Higher values use more memory, but are faster and produce smaller output.

strategy is used to tune the compression algorithm. Possible values are Z_DEFAULT_STRATEGY, Z_FILTERED, Z_HUFFMAN_ONLY, Z_RLE (zlib 1.2.0.1) and Z_FIXED (zlib 1.2.2.2).

zdict is a predefined compression dictionary. This is a sequence of bytes (such as a `bytes` object) containing subsequences that are expected to occur frequently in the data that is to be compressed. Those subsequences that are expected to be most common should come at the end of the dictionary.

Άλλαξε στην έκδοση 3.3: Added the *zdict* parameter and keyword argument support.

`zlib.crc32(data[, value])`

Computes a CRC (Cyclic Redundancy Check) checksum of *data*. The result is an unsigned 32-bit integer. If *value* is present, it is used as the starting value of the checksum; otherwise, a default value of 0 is used. Passing in *value* allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm.

Άλλαξε στην έκδοση 3.0: The result is always unsigned. To generate the same numeric value when using Python 2 or earlier, use `crc32(data) & 0xffffffff`.

`zlib.decompress(data, /, wbits=MAX_WBITS, bufsize=DEF_BUF_SIZE)`

Decompresses the bytes in *data*, returning a bytes object containing the uncompressed data. The *wbits* parameter depends on the format of *data*, and is discussed further below. If *bufsize* is given, it is used as the initial size of the output buffer. Raises the `error` exception if any error occurs.

The *wbits* parameter controls the size of the history buffer (or «window size»), and what header and trailer format is expected. It is similar to the parameter for `compressobj()`, but accepts more ranges of values:

- +8 to +15: The base-two logarithm of the window size. The input must include a zlib header and trailer.
- 0: Automatically determine the window size from the zlib header. Only supported since zlib 1.2.3.5.
- -8 to -15: Uses the absolute value of *wbits* as the window size logarithm. The input must be a raw stream with no header or trailer.
- +24 to +31 = 16 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm. The input must include a gzip header and trailer.
- +40 to +47 = 32 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm, and automatically accepts either the zlib or gzip format.

When decompressing a stream, the window size must not be smaller than the size originally used to compress the stream; using a too-small value may result in an `error` exception. The default *wbits* value corresponds to the largest window size and requires a zlib header and trailer to be included.

bufsize is the initial size of the buffer used to hold decompressed data. If more space is required, the buffer size will be increased as needed, so you don't have to get this value exactly right; tuning it will only save a few calls to `malloc()`.

Άλλαξε στην έκδοση 3.6: *wbits* and *bufsize* can be used as keyword arguments.

`zlib.decompressobj(wbits=MAX_WBITS[, zdict])`

Returns a decompression object, to be used for decompressing data streams that won't fit into memory at once.

The *wbits* parameter controls the size of the history buffer (or the «window size»), and what header and trailer format is expected. It has the same meaning as *described for decompress()*.

The *zdict* parameter specifies a predefined compression dictionary. If provided, this must be the same dictionary as was used by the compressor that produced the data that is to be decompressed.

Σημείωση: If *zdict* is a mutable object (such as a `bytearray`), you must not modify its contents between the call to `decompressobj()` and the first call to the decompressor's `decompress()` method.

Άλλαξε στην έκδοση 3.3: Added the *zdict* parameter.

Compression objects support the following methods:

`Compress.compress(data)`

Compress *data*, returning a bytes object containing compressed data for at least part of the data in *data*. This data should be concatenated to the output produced by any preceding calls to the `compress()` method. Some input may be kept in internal buffers for later processing.

`Compress.flush([mode])`

All pending input is processed, and a bytes object containing the remaining compressed output is returned. *mode* can be selected from the constants `Z_NO_FLUSH`, `Z_PARTIAL_FLUSH`, `Z_SYNC_FLUSH`, `Z_FULL_FLUSH`, `Z_BLOCK` (zlib 1.2.3.4), or `Z_FINISH`, defaulting to `Z_FINISH`. Except `Z_FINISH`, all constants allow compressing further bytestrings of data, while `Z_FINISH` finishes the compressed stream and prevents compressing any more data. After calling `flush()` with *mode* set to `Z_FINISH`, the `compress()` method cannot be called again; the only realistic action is to delete the object.

`Compress.copy()`

Returns a copy of the compression object. This can be used to efficiently compress a set of data that share a common initial prefix.

Άλλαξε στην έκδοση 3.8: Added `copy.copy()` and `copy.deepcopy()` support to compression objects.

Decompression objects support the following methods and attributes:

Decompress.unused_data

A bytes object which contains any bytes past the end of the compressed data. That is, this remains `b""` until the last byte that contains compression data is available. If the whole bytestring turned out to contain compressed data, this is `b""`, an empty bytes object.

Decompress.unconsumed_tail

A bytes object that contains any data that was not consumed by the last `decompress()` call because it exceeded the limit for the uncompressed data buffer. This data has not yet been seen by the zlib machinery, so you must feed it (possibly with further data concatenated to it) back to a subsequent `decompress()` method call in order to get correct output.

Decompress.eof

A boolean indicating whether the end of the compressed data stream has been reached.

This makes it possible to distinguish between a properly-formed compressed stream, and an incomplete or truncated one.

Νέο στην έκδοση 3.3.

Decompress.decompress(data, max_length=0)

Decompress *data*, returning a bytes object containing the uncompressed data corresponding to at least part of the data in *string*. This data should be concatenated to the output produced by any preceding calls to the `decompress()` method. Some of the input data may be preserved in internal buffers for later processing.

If the optional parameter *max_length* is non-zero then the return value will be no longer than *max_length*. This may mean that not all of the compressed input can be processed; and unconsumed data will be stored in the attribute `unconsumed_tail`. This bytestring must be passed to a subsequent call to `decompress()` if decompression is to continue. If *max_length* is zero then the whole input is decompressed, and `unconsumed_tail` is empty.

Άλλαξε στην έκδοση 3.6: *max_length* can be used as a keyword argument.

Decompress.flush([length])

All pending input is processed, and a bytes object containing the remaining uncompressed output is returned. After calling `flush()`, the `decompress()` method cannot be called again; the only realistic action is to delete the object.

The optional parameter *length* sets the initial size of the output buffer.

Decompress.copy()

Returns a copy of the decompression object. This can be used to save the state of the decompressor midway through the data stream in order to speed up random seeks into the stream at a future point.

Άλλαξε στην έκδοση 3.8: Added `copy.copy()` and `copy.deepcopy()` support to decompression objects.

Information about the version of the zlib library in use is available through the following constants:

zlib.ZLIB_VERSION

The version string of the zlib library that was used for building the module. This may be different from the zlib library actually used at runtime, which is available as `ZLIB_RUNTIME_VERSION`.

zlib.ZLIB_RUNTIME_VERSION

The version string of the zlib library actually loaded by the interpreter.

Module `gzip` Reading and writing `gzip`-format files.

<http://www.zlib.net> The zlib library home page.

<http://www.zlib.net/manual.html> The zlib manual explains the semantics and usage of the library's many functions.

13.2 gzip — Support for gzip files

Πηγαίος κώδικας: `Lib/gzip.py`

Αυτό το module παρέχει μια απλή διεπαφή για τη συμπίεση και αποσυμπίεση αρχείων όπως ακριβώς θα έκαναν τα προγράμματα της GNU **gzip** και **gunzip**.

Η συμπίεση δεδομένων παρέχεται από το `zlib` module.

Το `gzip` module παρέχει την κλάση `GzipFile`, καθώς και τις συναρτήσεις διευκόλυνσης `open()`, `compress()` και `decompress()`. Η κλάση `GzipFile` διαβάζει και γράφει αρχεία μορφής **gzip**, συμπιέζοντας ή αποσυμπιέζοντας αυτόματα τα δεδομένα, ώστε να φαίνεται σαν ένα συνηθισμένο *file object*.

Σημειώστε ότι πρόσθετες μορφές αρχείων που μπορούν να αποσυμπιεστούν από τα προγράμματα **gzip** και **gunzip**, όπως αυτές που παράγονται από τα **compress** και **pack**, δεν υποστηρίζονται από αυτό το module.

Το module ορίζει τα ακόλουθα στοιχεία:

`gzip.open(filename, mode='rb', compresslevel=9, encoding=None, errors=None, newline=None)`

Ανοίγει ένα gzip-συμπίεσμένο αρχείο σε δυαδική ή σε λειτουργία κειμένου, επιστρέφοντας ένα *file object*.

Η παράμετρος `filename` μπορεί να είναι ένα πραγματικό όνομα αρχείου (ένα αντικείμενο `str` ή `bytes`), ή ένα υπάρχον αντικείμενο αρχείου για ανάγνωση και εγγραφή.

Η παράμετρος `mode` μπορεί να είναι οποιαδήποτε από τις `'r'`, `'rb'`, `'a'`, `'ab'`, `'w'`, `'wb'`, `'x'` ή `'xb'` για δυαδική λειτουργία, ή `'rt'`, `'at'`, `'wt'` ή `'xt'` για λειτουργία κειμένου. Η προεπιλογή είναι το `'rb'`.

Η παράμετρος `compresslevel` είναι ένας ακέραιος από 0 έως 9, όπως και για τον constructor της κλάσης `GzipFile`.

Για δυαδική λειτουργία, αυτή η συνάρτηση είναι ισοδύναμη με τον constructor της κλάσης `GzipFile(filename, mode, compresslevel)`. Σε αυτή την περίπτωση, οι παράμετροι `encoding`, `errors` και `newline` δεν πρέπει να παρέχονται.

Για τη λειτουργία κειμένου, δημιουργείται ένα αντικείμενο `GzipFile` και γίνεται wrap σε ένα στιγμιότυπο της κλάσης `io.TextIOWrapper` με την καθορισμένη κωδικοποίηση, τη συμπεριφορά διαχείρισης σφαλμάτων και το(α) τέλος(η) γραμμής.

Άλλαξε στην έκδοση 3.3: Προστέθηκε υποστήριξη για την παράμετρο `filename` ως αντικείμενο αρχείου, υποστήριξη για τη λειτουργία κειμένου, καθώς και οι παράμετροι `encoding`, `errors` και `newline`.

Άλλαξε στην έκδοση 3.4: Προστέθηκε υποστήριξη για τις λειτουργίες `'x'`, `'xb'` και `'xt'`.

Άλλαξε στην έκδοση 3.6: Δέχεται ένα *path-like object*.

exception `gzip.BadGzipFile`

An exception raised for invalid gzip files. It inherits `OSError`. `EOFError` and `zlib.error` can also be raised for invalid gzip files.

Νέο στην έκδοση 3.8.

class `gzip.GzipFile(filename=None, mode=None, compresslevel=9, fileobj=None, mtime=None)`

Constructor for the `GzipFile` class, which simulates most of the methods of a *file object*, with the exception of the `truncate()` method. At least one of `fileobj` and `filename` must be given a non-trivial value.

Το νέο στιγμιότυπο της κλάσης βασίζεται στο `fileobj`, το οποίο μπορεί να είναι ένα κανονικό αρχείο, ένα αντικείμενο `io.BytesIO`, ή οποιοδήποτε άλλο αντικείμενο που προσομοιώνει αρχείο. Η προεπιλογή είναι `None`, οπότε στην περίπτωση αυτή το `filename` ανοίγεται για να παρέχει ένα αντικείμενο αρχείου.

Όταν το *fileobj* δεν είναι *None*, η παράμετρος *filename* χρησιμοποιείται μόνο για να συμπεριληφθεί στην επικεφαλίδα του αρχείου **gzip**, η οποία μπορεί να περιέχει το αρχικό όνομα του μη συμπιεσμένου αρχείου. Η προεπιλογή είναι το όνομα αρχείου του *fileobj*, αν αυτό μπορεί να προσδιοριστεί· διαφορετικά, η προεπιλογή είναι η κενή συμβολοσειρά, και σε αυτή την περίπτωση το αρχικό όνομα αρχείου δεν περιλαμβάνεται στην επικεφαλίδα.

Η παράμετρος *mode* μπορεί να είναι οποιαδήποτε από τις *'r'*, *'rb'*, *'a'*, *'ab'*, *'w'*, *'wb'*, *'x'* ή *'xb'*, ανάλογα με το αν το αρχείο θα διαβαστεί ή θα γραφτεί. Η προεπιλογή είναι η λειτουργία του *fileobj*, αν αυτό μπορεί να προσδιοριστεί· διαφορετικά, η προεπιλογή είναι *'rb'*. Σε μελλοντικές εκδόσεις της Python, η λειτουργία του *fileobj* δεν θα χρησιμοποιείται. Είναι καλύτερο να καθορίζεται πάντα η παράμετρος *mode* κατά την εγγραφή.

Σημειώστε ότι το αρχείο ανοίγει πάντα σε δυαδική λειτουργία. Για να ανοίξετε ένα συμπιεσμένο αρχείο σε λειτουργία κειμένου, χρησιμοποιήστε τη συνάρτηση *open()* (ή κάντε *wrap* το *GzipFile* με ένα *io.TextIOWrapper*).

Η παράμετρος *compresslevel* είναι ένας ακέραιος από 0 έως 9 που ελέγχει το επίπεδο συμπίεσης· το 1 είναι το ταχύτερο και παράγει τη μικρότερη συμπίεση, ενώ το 9 είναι το πιο αργό και παράγει τη μεγαλύτερη συμπίεση. Το 0 σημαίνει καθόλου συμπίεση. Η προεπιλογή είναι το 9.

Η παράμετρος *mtime* είναι ένας προαιρετικός αριθμητικός χρονικός δείκτης που γράφεται στο πεδίο τελευταίας τροποποίησης στη ροή κατά τη συμπίεση. Πρέπει να παράγεται μόνο σε λειτουργία συμπίεσης. Αν παραλειφθεί ή είναι *None*, χρησιμοποιείται η τρέχουσα χρονική στιγμή. Δείτε το χαρακτηριστικό *mtime* για περισσότερες λεπτομέρειες.

Calling a *GzipFile* object's *close()* method does not close *fileobj*, since you might wish to append more material after the compressed data. This also allows you to pass an *io.BytesIO* object opened for writing as *fileobj*, and retrieve the resulting memory buffer using the *io.BytesIO* object's *getvalue()* method.

GzipFile supports the *io.BufferedIOBase* interface, including iteration and the *with* statement. Only the *truncate()* method isn't implemented.

Η *GzipFile* παρέχει επίσης την ακόλουθη μέθοδο και ιδιότητα:

peek(*n*)

Διαβάξει *n* μη συμπιεσμένα bytes χωρίς να μετακινεί τη θέση του αρχείου. Γίνεται το πολύ μία μόνο ανάγνωση στη συμπιεσμένη ροή για να ικανοποιηθεί η κλήση. Ο αριθμός των bytes που επιστρέφονται μπορεί να είναι περισσότερα ή λιγότερα από τα ζητούμενα.

Σημείωση: Αν και η κλήση της μεθόδου *peek()* δεν αλλάζει τη θέση του αρχείου του αντικειμένου *GzipFile*, μπορεί να αλλάξει τη θέση του υποκείμενου αντικειμένου αρχείου (π.χ. αν το *GzipFile* δημιουργήθηκε με την παράμετρο *fileobj*).

Νέο στην έκδοση 3.2.

mtime

Κατά την αποσυμπίεση, η τιμή του πεδίου τελευταίας τροποποίησης στην πιο πρόσφατα αναγνωσμένη κεφαλίδα μπορεί να διαβαστεί από αυτή την ιδιότητα, ως ακέραιος αριθμός. Η αρχική τιμή πριν από την ανάγνωση οποιασδήποτε κεφαλίδας είναι *None*.

Όλες οι συμπιεσμένες ροές **gzip** απαιτείται να περιέχουν αυτό το πεδίο χρονικής σήμανσης. Ορισμένα προγράμματα, όπως το **gunzip**, χρησιμοποιούν αυτήν τη χρονική σήμανση. Η μορφή της είναι ίδια με την τιμή που επιστρέφει η συνάρτηση *time.time()* και το χαρακτηριστικό *st_mtime* του αντικειμένου που επιστρέφει η συνάρτηση *os.stat()*.

Άλλαξε στην έκδοση 3.1: Προστέθηκε η υποστήριξη για τη δήλωση *with*, μαζί με την παράμετρο *mtime* στον κατασκευαστή και την ιδιότητα *mtime*.

Άλλαξε στην έκδοση 3.2: Προστέθηκε υποστήριξη για αρχεία με μηδενική συμπλήρωση και μη αναζητήσιμα αρχεία.

Άλλαξε στην έκδοση 3.3: Η μέθοδος `io.BufferedIOBase.read1()` έχει πλέον υλοποιηθεί.

Άλλαξε στην έκδοση 3.4: Προστέθηκε υποστήριξη για τις λειτουργίες `'x'` και `'xb'`.

Άλλαξε στην έκδοση 3.5: Προστέθηκε υποστήριξη για εγγραφή αυθαίρετων *bytes-like objects*. Η μέθοδος `read()` δέχεται πλέον ένα όρισμα `None`.

Άλλαξε στην έκδοση 3.6: Δέχεται ένα *path-like object*.

Αποσύρθηκε στην έκδοση 3.9: Το άνοιγμα ενός *GzipFile* για εγγραφή χωρίς να καθοριστεί η παράμετρος *mode* έχει καταργηθεί.

`gzip.compress(data, compresslevel=9, *, mtime=None)`

Compress the *data*, returning a *bytes* object containing the compressed data. *compresslevel* and *mtime* have the same meaning as in the *GzipFile* constructor above.

Νέο στην έκδοση 3.2.

Άλλαξε στην έκδοση 3.8: Προστέθηκε η παράμετρος *mtime* για αναπαραγωγή με έξοδο.

`gzip.decompress(data)`

Decompress the *data*, returning a *bytes* object containing the uncompressed data.

Νέο στην έκδοση 3.2.

13.2.1 Παραδείγματα χρήσης

Παράδειγμα ανάγνωσης ενός συμπιεσμένου αρχείου:

```
import gzip
with gzip.open('/home/joe/file.txt.gz', 'rb') as f:
    file_content = f.read()
```

Παράδειγμα δημιουργίας ενός συμπιεσμένου αρχείου GZIP:

```
import gzip
content = b"Lots of content here"
with gzip.open('/home/joe/file.txt.gz', 'wb') as f:
    f.write(content)
```

Παράδειγμα συμπίεσης ενός υπάρχοντος αρχείου σε μορφή GZIP:

```
import gzip
import shutil
with open('/home/joe/file.txt', 'rb') as f_in:
    with gzip.open('/home/joe/file.txt.gz', 'wb') as f_out:
        shutil.copyfileobj(f_in, f_out)
```

Παράδειγμα συμπίεσης μιας δυαδικής συμβολοσειράς σε μορφή GZIP:

```
import gzip
s_in = b"Lots of content here"
s_out = gzip.compress(s_in)
```

Module *zlib* Το βασικό module συμπίεσης δεδομένων που απαιτείται για την υποστήριξη της μορφής αρχείου `gzip`.

13.2.2 Διεπαφή Γραμμής Εντολών

Το module `gzip` παρέχει μια απλή διεπαφή γραμμής εντολών για τη συμπίεση ή αποσυμπίεση αρχείων.

Μόλις εκτελεστεί, το module `gzip` διατηρεί το(α) αρχείο(α) εισόδου.

Άλλαξε στην έκδοση 3.8: Προστέθηκε νέα διεπαφή γραμμής εντολών με οδηγίες χρήσης. Από προεπιλογή, όταν εκτελείτε την CLI, το προεπιλεγμένο επίπεδο συμπίεσης είναι 6.

Επιλογές γραμμής εντολών

file

If *file* is not specified, read from `sys.stdin`.

--fast

Δηλώνει τη γρηγορότερη μέθοδο συμπίεσης (λιγότερη συμπίεση).

--best

Δηλώνει την βραδύτερη μέθοδο συμπίεσης (καλύτερη συμπίεση).

-d, --decompress

Αποσυμπιέζει το δοσμένο αρχείο.

-h, --help

Εμφανίζει το μήνυμα βοήθειας.

13.3 bz2 — Support for bzip2 compression

Source code: [Lib/bz2.py](#)

This module provides a comprehensive interface for compressing and decompressing data using the bzip2 compression algorithm.

The `bz2` module contains:

- The `open()` function and `BZ2File` class for reading and writing compressed files.
- The `BZ2Compressor` and `BZ2Decompressor` classes for incremental (de)compression.
- The `compress()` and `decompress()` functions for one-shot (de)compression.

All of the classes in this module may safely be accessed from multiple threads.

13.3.1 (De)compression of files

`bz2.open(filename, mode='rb', compresslevel=9, encoding=None, errors=None, newline=None)`

Open a bzip2-compressed file in binary or text mode, returning a *file object*.

As with the constructor for `BZ2File`, the *filename* argument can be an actual filename (a *str* or *bytes* object), or an existing file object to read from or write to.

The *mode* argument can be any of 'r', 'rb', 'w', 'wb', 'x', 'xb', 'a' or 'ab' for binary mode, or 'rt', 'wt', 'xt', or 'at' for text mode. The default is 'rb'.

The *compresslevel* argument is an integer from 1 to 9, as for the `BZ2File` constructor.

For binary mode, this function is equivalent to the `BZ2File` constructor: `BZ2File(filename, mode, compresslevel=compresslevel)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a `BZ2File` object is created, and wrapped in an `io.TextIOWrapper` instance with the specified encoding, error handling behavior, and line ending(s).

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.4: The 'x' (exclusive creation) mode was added.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

class `bz2.BZ2File` (*filename*, *mode*='r', *, *compresslevel*=9)

Open a bzip2-compressed file in binary mode.

If *filename* is a *str* or *bytes* object, open the named file directly. Otherwise, *filename* should be a *file object*, which will be used to read or write the compressed data.

The *mode* argument can be either 'r' for reading (default), 'w' for overwriting, 'x' for exclusive creation, or 'a' for appending. These can equivalently be given as 'rb', 'wb', 'xb' and 'ab' respectively.

If *filename* is a file object (rather than an actual file name), a mode of 'w' does not truncate the file, and is instead equivalent to 'a'.

If *mode* is 'w' or 'a', *compresslevel* can be an integer between 1 and 9 specifying the level of compression: 1 produces the least compression, and 9 (default) produces the most compression.

If *mode* is 'r', the input file may be the concatenation of multiple compressed streams.

`BZ2File` provides all of the members specified by the `io.BufferedIOBase`, except for `detach()` and `truncate()`. Iteration and the `with` statement are supported.

`BZ2File` also provides the following method:

peek (*[n]*)

Return buffered data without advancing the file position. At least one byte of data will be returned (unless at EOF). The exact number of bytes returned is unspecified.

Σημείωση: While calling `peek()` does not change the file position of the `BZ2File`, it may change the position of the underlying file object (e.g. if the `BZ2File` was constructed by passing a file object for *filename*).

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.1: Support for the `with` statement was added.

Άλλαξε στην έκδοση 3.3: The `fileno()`, `readable()`, `seekable()`, `writable()`, `read1()` and `readinto()` methods were added.

Άλλαξε στην έκδοση 3.3: Support was added for *filename* being a *file object* instead of an actual filename.

Άλλαξε στην έκδοση 3.3: The 'a' (append) mode was added, along with support for reading multi-stream files.

Άλλαξε στην έκδοση 3.4: The 'x' (exclusive creation) mode was added.

Άλλαξε στην έκδοση 3.5: The `read()` method now accepts an argument of `None`.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

Άλλαξε στην έκδοση 3.9: The *buffering* parameter has been removed. It was ignored and deprecated since Python 3.0. Pass an open file object to control how the file is opened.

The *compresslevel* parameter became keyword-only.

13.3.2 Incremental (de)compression

class `bz2.BZ2Compressor` (*compresslevel=9*)

Create a new compressor object. This object may be used to compress data incrementally. For one-shot compression, use the `compress()` function instead.

compresslevel, if given, must be an integer between 1 and 9. The default is 9.

compress (*data*)

Provide data to the compressor object. Returns a chunk of compressed data if possible, or an empty byte string otherwise.

When you have finished providing data to the compressor, call the `flush()` method to finish the compression process.

flush ()

Finish the compression process. Returns the compressed data left in internal buffers.

The compressor object may not be used after this method has been called.

class `bz2.BZ2Decompressor`

Create a new decompressor object. This object may be used to decompress data incrementally. For one-shot compression, use the `decompress()` function instead.

Σημείωση: This class does not transparently handle inputs containing multiple compressed streams, unlike `decompress()` and `BZ2File`. If you need to decompress a multi-stream input with `BZ2Decompressor`, you must use a new decompressor for each stream.

decompress (*data*, *max_length=-1*)

Decompress *data* (a *bytes-like object*), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to `decompress()`. The returned data should be concatenated with the output of any previous calls to `decompress()`.

If *max_length* is nonnegative, returns at most *max_length* bytes of decompressed data. If this limit is reached and further output can be produced, the `needs_input` attribute will be set to `False`. In this case, the next call to `decompress()` may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max_length* bytes, or because *max_length* was negative), the `needs_input` attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an `EOFError`. Any data found after the end of the stream is ignored and saved in the `unused_data` attribute.

Άλλαξε στην έκδοση 3.5: Added the *max_length* parameter.

eof

`True` if the end-of-stream marker has been reached.

Νέο στην έκδοση 3.3.

unused_data

Data found after the end of the compressed stream.

If this attribute is accessed before the end of the stream has been reached, its value will be `b''`.

needs_input

`False` if the `decompress()` method can provide more decompressed data before requiring new uncompressed input.

Νέο στην έκδοση 3.5.

13.3.3 One-shot (de)compression

`bz2.compress(data, compresslevel=9)`

Compress *data*, a *bytes-like object*.

compresslevel, if given, must be an integer between 1 and 9. The default is 9.

For incremental compression, use a *BZ2Compressor* instead.

`bz2.decompress(data)`

Decompress *data*, a *bytes-like object*.

If *data* is the concatenation of multiple compressed streams, decompress all of the streams.

For incremental decompression, use a *BZ2Decompressor* instead.

Άλλαξε στην έκδοση 3.3: Support for multi-stream inputs was added.

13.3.4 Examples of usage

Below are some examples of typical usage of the *bz2* module.

Using *compress()* and *decompress()* to demonstrate round-trip compression:

```
>>> import bz2
>>> data = b"""\
... Donec rhoncus quis sapien sit amet molestie. Fusce scelerisque vel augue
... nec ullamcorper. Nam rutrum pretium placerat. Aliquam vel tristique lorem,
... sit amet cursus ante. In interdum laoreet mi, sit amet ultrices purus
... pulvinar a. Nam gravida euismod magna, non varius justo tincidunt feugiat.
... Aliquam pharetra lacus non risus vehicula rutrum. Maecenas aliquam leo
... felis. Pellentesque semper nunc sit amet nibh ullamcorper, ac elementum
... dolor luctus. Curabitur lacinia mi ornare consectetur vestibulum."""
>>> c = bz2.compress(data)
>>> len(data) / len(c) # Data compression ratio
1.513595166163142
>>> d = bz2.decompress(c)
>>> data == d # Check equality to original object after round-trip
True
```

Using *BZ2Compressor* for incremental compression:

```
>>> import bz2
>>> def gen_data(chunks=10, chunksize=1000):
...     """Yield incremental blocks of chunksize bytes."""
...     for _ in range(chunks):
...         yield b"z" * chunksize
...
>>> comp = bz2.BZ2Compressor()
>>> out = b""
>>> for chunk in gen_data():
...     # Provide data to the compressor object
...     out = out + comp.compress(chunk)
...
>>> # Finish the compression process. Call this once you have
>>> # finished providing data to the compressor.
>>> out = out + comp.flush()
```

The example above uses a very «nonrandom» stream of data (a stream of *b»z»* chunks). Random data tends to compress poorly, while ordered, repetitive data usually yields a high compression ratio.

Writing and reading a *bzip2*-compressed file in binary mode:

```
>>> import bz2
>>> data = b"""\
... Donec rhoncus quis sapien sit amet molestie. Fusce scelerisque vel augue
... nec ullamcorper. Nam rutrum pretium placerat. Aliquam vel tristique lorem,
... sit amet cursus ante. In interdum laoreet mi, sit amet ultrices purus
... pulvinar a. Nam gravida euismod magna, non varius justo tincidunt feugiat.
... Aliquam pharetra lacus non risus vehicula rutrum. Maecenas aliquam leo
... felis. Pellentesque semper nunc sit amet nibh ullamcorper, ac elementum
... dolor luctus. Curabitur lacinia mi ornare consectetur vestibulum."""
>>> with bz2.open("myfile.bz2", "wb") as f:
...     # Write compressed data to file
...     unused = f.write(data)
>>> with bz2.open("myfile.bz2", "rb") as f:
...     # Decompress data from file
...     content = f.read()
>>> content == data # Check equality to original object after round-trip
True
```

13.4 lzma — Compression using the LZMA algorithm

Νέο στην έκδοση 3.3.

Source code: [Lib/lzma.py](#)

This module provides classes and convenience functions for compressing and decompressing data using the LZMA compression algorithm. Also included is a file interface supporting the *.xz* and legacy *.lzma* file formats used by the **xz** utility, as well as raw compressed streams.

The interface provided by this module is very similar to that of the *bz2* module. However, note that *LZMAFile* is *not* thread-safe, unlike *bz2.BZ2File*, so if you need to use a single *LZMAFile* instance from multiple threads, it is necessary to protect it with a lock.

exception *lzma.LZMAError*

This exception is raised when an error occurs during compression or decompression, or while initializing the compressor/decompressor state.

13.4.1 Reading and writing compressed files

lzma.open(*filename*, *mode*="rb", *, *format*=None, *check*=-1, *preset*=None, *filters*=None, *encoding*=None, *errors*=None, *newline*=None)

Open an LZMA-compressed file in binary or text mode, returning a *file object*.

The *filename* argument can be either an actual file name (given as a *str*, *bytes* or *path-like* object), in which case the named file is opened, or it can be an existing file object to read from or write to.

The *mode* argument can be any of "r", "rb", "w", "wb", "x", "xb", "a" or "ab" for binary mode, or "rt", "wt", "xt", or "at" for text mode. The default is "rb".

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for *LZMADecompressor*. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for *LZMACompressor*.

For binary mode, this function is equivalent to the *LZMAFile* constructor: `LZMAFile(filename, mode, ...)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a *LZMAFile* object is created, and wrapped in an *io.TextIOWrapper* instance with the specified encoding, error handling behavior, and line ending(s).

Άλλαξε στην έκδοση 3.4: Added support for the "x", "xb" and "xt" modes.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

class lzma.LZMAFile(*filename=None, mode="r", *, format=None, check=-1, preset=None, filters=None*)

Open an LZMA-compressed file in binary mode.

An *LZMAFile* can wrap an already-open *file object*, or operate directly on a named file. The *filename* argument specifies either the file object to wrap, or the name of the file to open (as a *str*, *bytes* or *path-like object*). When wrapping an existing file object, the wrapped file will not be closed when the *LZMAFile* is closed.

The *mode* argument can be either "r" for reading (default), "w" for overwriting, "x" for exclusive creation, or "a" for appending. These can equivalently be given as "rb", "wb", "xb" and "ab" respectively.

If *filename* is a file object (rather than an actual file name), a mode of "w" does not truncate the file, and is instead equivalent to "a".

When opening a file for reading, the input file may be the concatenation of multiple separate compressed streams. These are transparently decoded as a single logical stream.

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for *LZMADecompressor*. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for *LZMACompressor*.

LZMAFile supports all the members specified by *io.BufferedIOBase*, except for `detach()` and `truncate()`. Iteration and the `with` statement are supported.

The following method is also provided:

peek (*size=-1*)

Return buffered data without advancing the file position. At least one byte of data will be returned, unless EOF has been reached. The exact number of bytes returned is unspecified (the *size* argument is ignored).

Σημείωση: While calling *peek()* does not change the file position of the *LZMAFile*, it may change the position of the underlying file object (e.g. if the *LZMAFile* was constructed by passing a file object for *filename*).

Άλλαξε στην έκδοση 3.4: Added support for the "x" and "xb" modes.

Άλλαξε στην έκδοση 3.5: The *read()* method now accepts an argument of `None`.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

13.4.2 Compressing and decompressing data in memory

class `lzma.LZMACompressor` (*format=FORMAT_XZ, check=-1, preset=None, filters=None*)

Create a compressor object, which can be used to compress data incrementally.

For a more convenient way of compressing a single chunk of data, see `compress()`.

The *format* argument specifies what container format should be used. Possible values are:

- **FORMAT_XZ:** The **.xz container format**. This is the default format.
- **FORMAT_ALONE:** The legacy **.lzma container format**. This format is more limited than **.xz** – it does not support integrity checks or multiple filters.
- **FORMAT_RAW:** A raw data stream, not using any container format. This format specifier does not support integrity checks, and requires that you always specify a custom filter chain (for both compression and decompression). Additionally, data compressed in this manner cannot be decompressed using `FORMAT_AUTO` (see `LZMADecompressor`).

The *check* argument specifies the type of integrity check to include in the compressed data. This check is used when decompressing, to ensure that the data has not been corrupted. Possible values are:

- `CHECK_NONE`: No integrity check. This is the default (and the only acceptable value) for `FORMAT_ALONE` and `FORMAT_RAW`.
- `CHECK_CRC32`: 32-bit Cyclic Redundancy Check.
- `CHECK_CRC64`: 64-bit Cyclic Redundancy Check. This is the default for `FORMAT_XZ`.
- `CHECK_SHA256`: 256-bit Secure Hash Algorithm.

If the specified check is not supported, an `LZMAError` is raised.

The compression settings can be specified either as a preset compression level (with the *preset* argument), or in detail as a custom filter chain (with the *filters* argument).

The *preset* argument (if provided) should be an integer between 0 and 9 (inclusive), optionally OR-ed with the constant `PRESET_EXTREME`. If neither *preset* nor *filters* are given, the default behavior is to use `PRESET_DEFAULT` (preset level 6). Higher presets produce smaller output, but make the compression process slower.

Σημείωση: In addition to being more CPU-intensive, compression with higher presets also requires much more memory (and produces output that needs more memory to decompress). With preset 9 for example, the overhead for an `LZMACompressor` object can be as high as 800 MiB. For this reason, it is generally best to stick with the default preset.

The *filters* argument (if provided) should be a filter chain specifier. See *Specifying custom filter chains* for details.

compress (*data*)

Compress *data* (a `bytes` object), returning a `bytes` object containing compressed data for at least part of the input. Some of *data* may be buffered internally, for use in later calls to `compress()` and `flush()`. The returned data should be concatenated with the output of any previous calls to `compress()`.

flush ()

Finish the compression process, returning a `bytes` object containing any data stored in the compressor's internal buffers.

The compressor cannot be used after this method has been called.

class `lzma.LZMADecompressor` (*format=FORMAT_AUTO, memlimit=None, filters=None*)

Create a decompressor object, which can be used to decompress data incrementally.

For a more convenient way of decompressing an entire compressed stream at once, see `decompress()`.

The *format* argument specifies the container format that should be used. The default is `FORMAT_AUTO`, which can decompress both `.xz` and `.lzma` files. Other possible values are `FORMAT_XZ`, `FORMAT_ALONE`, and `FORMAT_RAW`.

The *memlimit* argument specifies a limit (in bytes) on the amount of memory that the decompressor can use. When this argument is used, decompression will fail with an `LZMAError` if it is not possible to decompress the input within the given memory limit.

The *filters* argument specifies the filter chain that was used to create the stream being decompressed. This argument is required if *format* is `FORMAT_RAW`, but should not be used for other formats. See *Specifying custom filter chains* for more information about filter chains.

Σημείωση: This class does not transparently handle inputs containing multiple compressed streams, unlike `decompress()` and `LZMAFile`. To decompress a multi-stream input with `LZMADecompressor`, you must create a new decompressor for each stream.

decompress (*data*, *max_length*=-1)

Decompress *data* (a *bytes-like object*), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to `decompress()`. The returned data should be concatenated with the output of any previous calls to `decompress()`.

If *max_length* is nonnegative, returns at most *max_length* bytes of decompressed data. If this limit is reached and further output can be produced, the *needs_input* attribute will be set to `False`. In this case, the next call to `decompress()` may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max_length* bytes, or because *max_length* was negative), the *needs_input* attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an `EOFError`. Any data found after the end of the stream is ignored and saved in the *unused_data* attribute.

Άλλαξε στην έκδοση 3.5: Added the *max_length* parameter.

check

The ID of the integrity check used by the input stream. This may be `CHECK_UNKNOWN` until enough of the input has been decoded to determine what integrity check it uses.

eof

`True` if the end-of-stream marker has been reached.

unused_data

Data found after the end of the compressed stream.

Before the end of the stream is reached, this will be `b''`.

needs_input

`False` if the `decompress()` method can provide more decompressed data before requiring new uncompressed input.

Νέο στην έκδοση 3.5.

`lzma.compress(data, format=FORMAT_XZ, check=-1, preset=None, filters=None)`

Compress *data* (a *bytes* object), returning the compressed data as a *bytes* object.

See `LZMACompressor` above for a description of the *format*, *check*, *preset* and *filters* arguments.

`lzma.decompress(data, format=FORMAT_AUTO, memlimit=None, filters=None)`

Decompress *data* (a *bytes* object), returning the uncompressed data as a *bytes* object.

If *data* is the concatenation of multiple distinct compressed streams, decompress all of these streams, and return the concatenation of the results.

See *LZMA**decompressor* above for a description of the *format*, *memlimit* and *filters* arguments.

13.4.3 Miscellaneous

`lzma.is_check_supported(check)`

Return `True` if the given integrity check is supported on this system.

`CHECK_NONE` and `CHECK_CRC32` are always supported. `CHECK_CRC64` and `CHECK_SHA256` may be unavailable if you are using a version of **liblzma** that was compiled with a limited feature set.

13.4.4 Specifying custom filter chains

A filter chain specifier is a sequence of dictionaries, where each dictionary contains the ID and options for a single filter. Each dictionary must contain the key `"id"`, and may contain additional keys to specify filter-dependent options. Valid filter IDs are as follows:

- **Compression filters:**
 - `FILTER_LZMA1` (for use with `FORMAT_ALONE`)
 - `FILTER_LZMA2` (for use with `FORMAT_XZ` and `FORMAT_RAW`)
- **Delta filter:**
 - `FILTER_DELTA`
- **Branch-Call-Jump (BCJ) filters:**
 - `FILTER_X86`
 - `FILTER_IA64`
 - `FILTER_ARM`
 - `FILTER_ARMTHUMB`
 - `FILTER_POWERPC`
 - `FILTER_SPARC`

A filter chain can consist of up to 4 filters, and cannot be empty. The last filter in the chain must be a compression filter, and any other filters must be delta or BCJ filters.

Compression filters support the following options (specified as additional entries in the dictionary representing the filter):

- `preset`: A compression preset to use as a source of default values for options that are not specified explicitly.
- `dict_size`: Dictionary size in bytes. This should be between 4 KiB and 1.5 GiB (inclusive).
- `lc`: Number of literal context bits.
- `lp`: Number of literal position bits. The sum `lc + lp` must be at most 4.
- `pb`: Number of position bits; must be at most 4.
- `mode`: `MODE_FAST` or `MODE_NORMAL`.
- `nice_len`: What should be considered a «nice length» for a match. This should be 273 or less.
- `mf`: What match finder to use – `MF_HC3`, `MF_HC4`, `MF_BT2`, `MF_BT3`, or `MF_BT4`.

- `depth`: Maximum search depth used by match finder. 0 (default) means to select automatically based on other filter options.

The delta filter stores the differences between bytes, producing more repetitive input for the compressor in certain circumstances. It supports one option, `dist`. This indicates the distance between bytes to be subtracted. The default is 1, i.e. take the differences between adjacent bytes.

The BCJ filters are intended to be applied to machine code. They convert relative branches, calls and jumps in the code to use absolute addressing, with the aim of increasing the redundancy that can be exploited by the compressor. These filters support one option, `start_offset`. This specifies the address that should be mapped to the beginning of the input data. The default is 0.

13.4.5 Examples

Reading in a compressed file:

```
import lzma
with lzma.open("file.xz") as f:
    file_content = f.read()
```

Creating a compressed file:

```
import lzma
data = b"Insert Data Here"
with lzma.open("file.xz", "w") as f:
    f.write(data)
```

Compressing data in memory:

```
import lzma
data_in = b"Insert Data Here"
data_out = lzma.compress(data_in)
```

Incremental compression:

```
import lzma
lzc = lzma.LZMACompressor()
out1 = lzc.compress(b"Some data\n")
out2 = lzc.compress(b"Another piece of data\n")
out3 = lzc.compress(b"Even more data\n")
out4 = lzc.flush()
# Concatenate all the partial results:
result = b"".join([out1, out2, out3, out4])
```

Writing compressed data to an already-open file:

```
import lzma
with open("file.xz", "wb") as f:
    f.write(b"This data will not be compressed\n")
    with lzma.open(f, "w") as lzf:
        lzf.write(b"This *will* be compressed\n")
    f.write(b"Not compressed\n")
```

Creating a compressed file using a custom filter chain:

```
import lzma
my_filters = [
    {"id": lzma.FILTER_DELTA, "dist": 5},
    {"id": lzma.FILTER_LZMA2, "preset": 7 | lzma.PRESET_EXTREME},
]
with lzma.open("file.xz", "w", filters=my_filters) as f:
    f.write(b"blah blah blah")
```

13.5 zipfile — Work with ZIP archives

Source code: [Lib/zipfile.py](#)

The ZIP file format is a common archive and compression standard. This module provides tools to create, read, write, append, and list a ZIP file. Any advanced use of this module will require an understanding of the format, as defined in [PKZIP Application Note](#).

This module does not currently handle multi-disk ZIP files. It can handle ZIP files that use the ZIP64 extensions (that is ZIP files that are more than 4 GiB in size). It supports decryption of encrypted files in ZIP archives, but it currently cannot create an encrypted file. Decryption is extremely slow as it is implemented in native Python rather than C.

The module defines the following items:

exception `zipfile.BadZipFile`

The error raised for bad ZIP files.

Νέο στην έκδοση 3.2.

exception `zipfile.BadZipfile`

Alias of `BadZipFile`, for compatibility with older Python versions.

Αποσύρθηκε στην έκδοση 3.2.

exception `zipfile.LargeZipFile`

The error raised when a ZIP file would require ZIP64 functionality but that has not been enabled.

class `zipfile.ZipFile`

The class for reading and writing ZIP files. See section [ZipFile Objects](#) for constructor details.

class `zipfile.Path`

A pathlib-compatible wrapper for zip files. See section [Path Objects](#) for details.

Νέο στην έκδοση 3.8.

class `zipfile.PyZipFile`

Class for creating ZIP archives containing Python libraries.

class `zipfile.ZipInfo` (*filename*='NoName', *date_time*=(1980, 1, 1, 0, 0, 0))

Class used to represent information about a member of an archive. Instances of this class are returned by the `getinfo()` and `infolist()` methods of `ZipFile` objects. Most users of the `zipfile` module will not need to create these, but only use those created by this module. *filename* should be the full name of the archive member, and *date_time* should be a tuple containing six fields which describe the time of the last modification to the file; the fields are described in section [ZipInfo Objects](#).

`zipfile.is_zipfile` (*filename*)

Returns True if *filename* is a valid ZIP file based on its magic number, otherwise returns False. *filename* may be a file or file-like object too.

Άλλαξε στην έκδοση 3.1: Support for file and file-like objects.

`zipfile.ZIP_STORED`

The numeric constant for an uncompressed archive member.

`zipfile.ZIP_DEFLATED`

The numeric constant for the usual ZIP compression method. This requires the *zlib* module.

`zipfile.ZIP_BZIP2`

The numeric constant for the BZIP2 compression method. This requires the *bz2* module.

Νέο στην έκδοση 3.3.

`zipfile.ZIP_LZMA`

The numeric constant for the LZMA compression method. This requires the *lzma* module.

Νέο στην έκδοση 3.3.

Σημείωση: The ZIP file format specification has included support for bzip2 compression since 2001, and for LZMA compression since 2006. However, some tools (including older Python releases) do not support these compression methods, and may either refuse to process the ZIP file altogether, or fail to extract individual files.

PKZIP Application Note Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

Info-ZIP Home Page Information about the Info-ZIP project's ZIP archive programs and development libraries.

13.5.1 ZipFile Objects

class `zipfile.ZipFile` (*file*, *mode*='r', *compression*=`ZIP_STORED`, *allowZip64*=*True*,
compresslevel=None, *, *strict_timestamps*=*True*)

Open a ZIP file, where *file* can be a path to a file (a string), a file-like object or a *path-like object*.

The *mode* parameter should be 'r' to read an existing file, 'w' to truncate and write a new file, 'a' to append to an existing file, or 'x' to exclusively create and write a new file. If *mode* is 'x' and *file* refers to an existing file, a *FileExistsError* will be raised. If *mode* is 'a' and *file* refers to an existing ZIP file, then additional files are added to it. If *file* does not refer to a ZIP file, then a new ZIP archive is appended to the file. This is meant for adding a ZIP archive to another file (such as `python.exe`). If *mode* is 'a' and the file does not exist at all, it is created. If *mode* is 'r' or 'a', the file should be seekable.

compression is the ZIP compression method to use when writing the archive, and should be `ZIP_STORED`, `ZIP_DEFLATED`, `ZIP_BZIP2` or `ZIP_LZMA`; unrecognized values will cause *NotImplementedError* to be raised. If `ZIP_DEFLATED`, `ZIP_BZIP2` or `ZIP_LZMA` is specified but the corresponding module (*zlib*, *bz2* or *lzma*) is not available, *RuntimeError* is raised. The default is `ZIP_STORED`.

If *allowZip64* is *True* (the default) `zipfile` will create ZIP files that use the ZIP64 extensions when the zipfile is larger than 4 GiB. If it is *false* `zipfile` will raise an exception when the ZIP file would require ZIP64 extensions.

The *compresslevel* parameter controls the compression level to use when writing files to the archive. When using `ZIP_STORED` or `ZIP_LZMA` it has no effect. When using `ZIP_DEFLATED` integers 0 through 9 are accepted (see *zlib* for more information). When using `ZIP_BZIP2` integers 1 through 9 are accepted (see *bz2* for more information).

The *strict_timestamps* argument, when set to *False*, allows to zip files older than 1980-01-01 at the cost of setting the timestamp to 1980-01-01. Similar behavior occurs with files newer than 2107-12-31, the timestamp is also set to the limit.

If the file is created with mode `'w'`, `'x'` or `'a'` and then `closed` without adding any files to the archive, the appropriate ZIP structures for an empty archive will be written to the file.

`ZipFile` is also a context manager and therefore supports the `with` statement. In the example, *myzip* is closed after the `with` statement's suite is finished—even if an exception occurs:

```
with ZipFile('spam.zip', 'w') as myzip:
    myzip.write('eggs.txt')
```

Νέο στην έκδοση 3.2: Added the ability to use `ZipFile` as a context manager.

Άλλαξε στην έκδοση 3.3: Added support for `bzip2` and `lzma` compression.

Άλλαξε στην έκδοση 3.4: ZIP64 extensions are enabled by default.

Άλλαξε στην έκδοση 3.5: Added support for writing to unseekable streams. Added support for the `'x'` mode.

Άλλαξε στην έκδοση 3.6: Previously, a plain `RuntimeError` was raised for unrecognized compression values.

Άλλαξε στην έκδοση 3.6.2: The `file` parameter accepts a *path-like object*.

Άλλαξε στην έκδοση 3.7: Add the `compresslevel` parameter.

Νέο στην έκδοση 3.8: The `strict_timestamps` keyword-only argument

`ZipFile.close()`

Close the archive file. You must call `close()` before exiting your program or essential records will not be written.

`ZipFile.getinfo(name)`

Return a `ZipInfo` object with information about the archive member *name*. Calling `getinfo()` for a name not currently contained in the archive will raise a `KeyError`.

`ZipFile.infolist()`

Return a list containing a `ZipInfo` object for each member of the archive. The objects are in the same order as their entries in the actual ZIP file on disk if an existing archive was opened.

`ZipFile.namelist()`

Return a list of archive members by name.

`ZipFile.open(name, mode='r', pwd=None, *, force_zip64=False)`

Access a member of the archive as a binary file-like object. *name* can be either the name of a file within the archive or a `ZipInfo` object. The `mode` parameter, if included, must be `'r'` (the default) or `'w'`. *pwd* is the password used to decrypt encrypted ZIP files.

`open()` is also a context manager and therefore supports the `with` statement:

```
with ZipFile('spam.zip') as myzip:
    with myzip.open('eggs.txt') as myfile:
        print(myfile.read())
```

With `mode 'r'` the file-like object (`ZipExtFile`) is read-only and provides the following methods: `read()`, `readline()`, `readlines()`, `seek()`, `tell()`, `__iter__()`, `__next__()`. These objects can operate independently of the `ZipFile`.

With `mode='w'`, a writable file handle is returned, which supports the `write()` method. While a writable file handle is open, attempting to read or write other files in the ZIP file will raise a `ValueError`.

When writing a file, if the file size is not known in advance but may exceed 2 GiB, pass `force_zip64=True` to ensure that the header format is capable of supporting large files. If the file size is known in advance, construct a `ZipInfo` object with `file_size` set, and use that as the *name* parameter.

Σημείωση: The `open()`, `read()` and `extract()` methods can take a filename or a `ZipInfo` object. You will appreciate this when trying to read a ZIP file that contains members with duplicate names.

Άλλαξε στην έκδοση 3.6: Removed support of `mode='U'`. Use `io.TextIOWrapper` for reading compressed text files in *universal newlines* mode.

Άλλαξε στην έκδοση 3.6: `ZipFile.open()` can now be used to write files into the archive with the `mode='w'` option.

Άλλαξε στην έκδοση 3.6: Calling `open()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.extract(member, path=None, pwd=None)`

Extract a member from the archive to the current working directory; *member* must be its full name or a `ZipInfo` object. Its file information is extracted as accurately as possible. *path* specifies a different directory to extract to. *member* can be a filename or a `ZipInfo` object. *pwd* is the password used for encrypted files.

Returns the normalized path created (a directory or new file).

Σημείωση: If a member filename is an absolute path, a drive/UNC sharepoint and leading (back)slashes will be stripped, e.g.: `///foo/bar` becomes `foo/bar` on Unix, and `C:\foo\bar` becomes `foo\bar` on Windows. And all `".."` components in a member filename will be removed, e.g.: `../../foo../../ba..r` becomes `foo../ba..r`. On Windows illegal characters (`:`, `<`, `>`, `|`, `"`, `?`, and `*`) replaced by underscore (`_`).

Άλλαξε στην έκδοση 3.6: Calling `extract()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

Άλλαξε στην έκδοση 3.6.2: The *path* parameter accepts a *path-like object*.

`ZipFile.extractall(path=None, members=None, pwd=None)`

Extract all members from the archive to the current working directory. *path* specifies a different directory to extract to. *members* is optional and must be a subset of the list returned by `namelist()`. *pwd* is the password used for encrypted files.

Προειδοποίηση: Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `".."`. This module attempts to prevent that. See `extract()` note.

Άλλαξε στην έκδοση 3.6: Calling `extractall()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

Άλλαξε στην έκδοση 3.6.2: The *path* parameter accepts a *path-like object*.

`ZipFile.printdir()`

Print a table of contents for the archive to `sys.stdout`.

`ZipFile.setpassword(pwd)`

Set *pwd* as default password to extract encrypted files.

`ZipFile.read(name, pwd=None)`

Return the bytes of the file *name* in the archive. *name* is the name of the file in the archive, or a `ZipInfo` object. The archive must be open for read or append. *pwd* is the password used for encrypted files and, if specified, it will override the default password set with `setpassword()`. Calling `read()` on a `ZipFile` that uses a compression method other than `ZIP_STORED`, `ZIP_DEFLATED`, `ZIP_BZIP2` or `ZIP_LZMA` will raise a `NotImplementedError`. An error will also be raised if the corresponding compression module is not available.

Άλλαξε στην έκδοση 3.6: Calling `read()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.testzip()`

Read all the files in the archive and check their CRC's and file headers. Return the name of the first bad file, or else return `None`.

Άλλαξε στην έκδοση 3.6: Calling `testzip()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.write(filename, arcname=None, compress_type=None, compresslevel=None)`

Write the file named `filename` to the archive, giving it the archive name `arcname` (by default, this will be the same as `filename`, but without a drive letter and with leading path separators removed). If given, `compress_type` overrides the value given for the `compression` parameter to the constructor for the new entry. Similarly, `compresslevel` will override the constructor if given. The archive must be open with mode `'w'`, `'x'` or `'a'`.

Σημείωση: Archive names should be relative to the archive root, that is, they should not start with a path separator.

Σημείωση: If `arcname` (or `filename`, if `arcname` is not given) contains a null byte, the name of the file in the archive will be truncated at the null byte.

Σημείωση: A leading slash in the filename may lead to the archive being impossible to open in some zip programs on Windows systems.

Άλλαξε στην έκδοση 3.6: Calling `write()` on a `ZipFile` created with mode `'r'` or a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.writestr(zinfo_or_arcname, data, compress_type=None, compresslevel=None)`

Write a file into the archive. The contents is `data`, which may be either a `str` or a `bytes` instance; if it is a `str`, it is encoded as UTF-8 first. `zinfo_or_arcname` is either the file name it will be given in the archive, or a `ZipInfo` instance. If it's an instance, at least the filename, date, and time must be given. If it's a name, the date and time is set to the current date and time. The archive must be opened with mode `'w'`, `'x'` or `'a'`.

If given, `compress_type` overrides the value given for the `compression` parameter to the constructor for the new entry, or in the `zinfo_or_arcname` (if that is a `ZipInfo` instance). Similarly, `compresslevel` will override the constructor if given.

Σημείωση: When passing a `ZipInfo` instance as the `zinfo_or_arcname` parameter, the compression method used will be that specified in the `compress_type` member of the given `ZipInfo` instance. By default, the `ZipInfo` constructor sets this member to `ZIP_STORED`.

Άλλαξε στην έκδοση 3.2: The `compress_type` argument.

Άλλαξε στην έκδοση 3.6: Calling `writestr()` on a `ZipFile` created with mode `'r'` or a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

The following data attributes are also available:

`ZipFile.filename`

Name of the ZIP file.

`ZipFile.debug`

The level of debug output to use. This may be set from 0 (the default, no output) to 3 (the most output). Debugging

information is written to `sys.stdout`.

`ZipFile.comment`

The comment associated with the ZIP file as a *bytes* object. If assigning a comment to a *ZipFile* instance created with mode `'w'`, `'x'` or `'a'`, it should be no longer than 65535 bytes. Comments longer than this will be truncated.

13.5.2 Path Objects

`class zipfile.Path(root, at=)`

Construct a Path object from a `root` zipfile (which may be a *ZipFile* instance or file suitable for passing to the *ZipFile* constructor).

`at` specifies the location of this Path within the zipfile, e.g. `"dir/file.txt"`, `"dir/"`, or `""`. Defaults to the empty string, indicating the root.

Path objects expose the following features of *pathlib.Path* objects:

Path objects are traversable using the `/` operator.

`Path.name`

The final path component.

`Path.open(mode='r', *, pwd, **)`

Invoke *ZipFile.open()* on the current path. Allows opening for read or write, text or binary through supported modes: `"r"`, `"w"`, `"rb"`, `"wb"`. Positional and keyword arguments are passed through to *io.TextIOWrapper* when opened as text and ignored otherwise. `pwd` is the `pwd` parameter to *ZipFile.open()*.

Άλλαξε στην έκδοση 3.9: Added support for text and binary modes for open. Default mode is now text.

`Path.iterdir()`

Enumerate the children of the current directory.

`Path.is_dir()`

Return `True` if the current context references a directory.

`Path.is_file()`

Return `True` if the current context references a file.

`Path.exists()`

Return `True` if the current context references a file or directory in the zip file.

`Path.read_text(*, **)`

Read the current file as unicode text. Positional and keyword arguments are passed through to *io.TextIOWrapper* (except `buffer`, which is implied by the context).

`Path.read_bytes()`

Read the current file as bytes.

13.5.3 PyZipFile Objects

The `PyZipFile` constructor takes the same parameters as the `ZipFile` constructor, and one additional parameter, `optimize`.

class `zipfile.PyZipFile` (*file*, *mode*='r', *compression*=ZIP_STORED, *allowZip64*=True, *optimize*=-1)

Νέο στην έκδοση 3.2: The `optimize` parameter.

Άλλαξε στην έκδοση 3.4: ZIP64 extensions are enabled by default.

Instances have one method in addition to those of `ZipFile` objects:

writepy (*pathname*, *basename*="", *filterfunc*=None)

Search for files `*.py` and add the corresponding file to the archive.

If the `optimize` parameter to `PyZipFile` was not given or `-1`, the corresponding file is a `*.pyc` file, compiling if necessary.

If the `optimize` parameter to `PyZipFile` was `0`, `1` or `2`, only files with that optimization level (see `compile()`) are added to the archive, compiling if necessary.

If *pathname* is a file, the filename must end with `.py`, and just the (corresponding `*.pyc`) file is added at the top level (no path information). If *pathname* is a file that does not end with `.py`, a `RuntimeError` will be raised. If it is a directory, and the directory is not a package directory, then all the files `*.pyc` are added at the top level. If the directory is a package directory, then all `*.pyc` are added under the package name as a file path, and if any subdirectories are package directories, all of these are added recursively in sorted order.

basename is intended for internal use only.

filterfunc, if given, must be a function taking a single string argument. It will be passed each path (including each individual full file path) before it is added to the archive. If *filterfunc* returns a false value, the path will not be added, and if it is a directory its contents will be ignored. For example, if our test files are all either in test directories or start with the string `test_`, we can use a *filterfunc* to exclude them:

```
>>> zf = PyZipFile('myprog.zip')
>>> def notests(s):
...     fn = os.path.basename(s)
...     return (not (fn == 'test' or fn.startswith('test_')))
>>> zf.writepy('myprog', filterfunc=notests)
```

The `writepy()` method makes archives with file names like this:

```
string.pyc           # Top level name
test/__init__.pyc    # Package directory
test/testall.pyc     # Module test.testall
test/bogus/__init__.pyc # Subpackage directory
test/bogus/myfile.pyc # Submodule test.bogus.myfile
```

Νέο στην έκδοση 3.4: The *filterfunc* parameter.

Άλλαξε στην έκδοση 3.6.2: The *pathname* parameter accepts a *path-like object*.

Άλλαξε στην έκδοση 3.7: Recursion sorts directory entries.

13.5.4 ZipInfo Objects

Instances of the `ZipInfo` class are returned by the `getinfo()` and `infolist()` methods of `ZipFile` objects. Each object stores information about a single member of the ZIP archive.

There is one classmethod to make a `ZipInfo` instance for a filesystem file:

classmethod `ZipInfo.from_file(filename, arcname=None, *, strict_timestamps=True)`

Construct a `ZipInfo` instance for a file on the filesystem, in preparation for adding it to a zip file.

filename should be the path to a file or directory on the filesystem.

If *arcname* is specified, it is used as the name within the archive. If *arcname* is not specified, the name will be the same as *filename*, but with any drive letter and leading path separators removed.

The *strict_timestamps* argument, when set to `False`, allows to zip files older than 1980-01-01 at the cost of setting the timestamp to 1980-01-01. Similar behavior occurs with files newer than 2107-12-31, the timestamp is also set to the limit.

Νέο στην έκδοση 3.6.

Άλλαξε στην έκδοση 3.6.2: The *filename* parameter accepts a *path-like object*.

Νέο στην έκδοση 3.8: The *strict_timestamps* keyword-only argument

Instances have the following methods and attributes:

`ZipInfo.is_dir()`

Return `True` if this archive member is a directory.

This uses the entry's name: directories should always end with `/`.

Νέο στην έκδοση 3.6.

`ZipInfo.filename`

Name of the file in the archive.

`ZipInfo.date_time`

The time and date of the last modification to the archive member. This is a tuple of six values:

| Index | Value |
|-------|--------------------------|
| 0 | Year (≥ 1980) |
| 1 | Month (one-based) |
| 2 | Day of month (one-based) |
| 3 | Hours (zero-based) |
| 4 | Minutes (zero-based) |
| 5 | Seconds (zero-based) |

Σημείωση: The ZIP file format does not support timestamps before 1980.

`ZipInfo.compress_type`

Type of compression for the archive member.

`ZipInfo.comment`

Comment for the individual archive member as a *bytes* object.

`ZipInfo.extra`

Expansion field data. The [PKZIP Application Note](#) contains some comments on the internal structure of the data contained in this *bytes* object.

ZipInfo.create_system
System which created ZIP archive.

ZipInfo.create_version
PKZIP version which created ZIP archive.

ZipInfo.extract_version
PKZIP version needed to extract archive.

ZipInfo.reserved
Must be zero.

ZipInfo.flag_bits
ZIP flag bits.

ZipInfo.volume
Volume number of file header.

ZipInfo.internal_attr
Internal attributes.

ZipInfo.external_attr
External file attributes.

ZipInfo.header_offset
Byte offset to the file header.

ZipInfo.CRC
CRC-32 of the uncompressed file.

ZipInfo.compress_size
Size of the compressed data.

ZipInfo.file_size
Size of the uncompressed file.

13.5.5 Command-Line Interface

The `zipfile` module provides a simple command-line interface to interact with ZIP archives.

If you want to create a new ZIP archive, specify its name after the `-c` option and then list the filename(s) that should be included:

```
$ python -m zipfile -c monty.zip spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m zipfile -c monty.zip life-of-brian_1979/
```

If you want to extract a ZIP archive into the specified directory, use the `-e` option:

```
$ python -m zipfile -e monty.zip target-dir/
```

For a list of the files in a ZIP archive, use the `-l` option:

```
$ python -m zipfile -l monty.zip
```

Command-line options

```
-l <zipfile>
--list <zipfile>
    List files in a zipfile.

-c <zipfile> <source1> ... <sourceN>
--create <zipfile> <source1> ... <sourceN>
    Create zipfile from source files.

-e <zipfile> <output_dir>
--extract <zipfile> <output_dir>
    Extract zipfile into target directory.

-t <zipfile>
--test <zipfile>
    Test whether the zipfile is valid or not.
```

13.5.6 Decompression pitfalls

The extraction in zipfile module might fail due to some pitfalls listed below.

From file itself

Decompression may fail due to incorrect password / CRC checksum / ZIP format or unsupported compression method / decryption.

File System limitations

Exceeding limitations on different file systems can cause decompression failed. Such as allowable characters in the directory entries, length of the file name, length of the pathname, size of a single file, and number of files, etc.

Resources limitations

The lack of memory or disk volume would lead to decompression failed. For example, decompression bombs (aka [ZIP bomb](#)) apply to zipfile library that can cause disk volume exhaustion.

Interruption

Interruption during the decompression, such as pressing control-C or killing the decompression process may result in incomplete decompression of the archive.

Default behaviors of extraction

Not knowing the default extraction behaviors can cause unexpected decompression results. For example, when extracting the same archive twice, it overwrites files without asking.

13.6 `tarfile` — Read and write tar archive files

Source code: [Lib/tarfile.py](#)

The `tarfile` module makes it possible to read and write tar archives, including those using `gzip`, `bz2` and `lzma` compression. Use the `zipfile` module to read or write `.zip` files, or the higher-level functions in `shutil`.

Some facts and figures:

- reads and writes `gzip`, `bz2` and `lzma` compressed archives if the respective modules are available.
- read/write support for the POSIX.1-1988 (ustar) format.
- read/write support for the GNU tar format including `longname` and `longlink` extensions, read-only support for all variants of the `sparse` extension including restoration of sparse files.
- read/write support for the POSIX.1-2001 (pax) format.
- handles directories, regular files, hardlinks, symbolic links, fifos, character devices and block devices and is able to acquire and restore file information like timestamp, access permissions and owner.

Άλλαξε στην έκδοση 3.3: Added support for `lzma` compression.

`tarfile.open` (*name=None, mode='r', fileobj=None, bufsize=10240, **kwargs*)

Return a `TarFile` object for the pathname *name*. For detailed information on `TarFile` objects and the keyword arguments that are allowed, see [TarFile Objects](#).

mode has to be a string of the form `'filemode[:compression]'`, it defaults to `'r'`. Here is a full list of mode combinations:

| mode | action |
|---------------|---|
| 'r' or 'r: *' | Open for reading with transparent compression (recommended). |
| 'r: ' | Open for reading exclusively without compression. |
| 'r: gz' | Open for reading with gzip compression. |
| 'r: bz2' | Open for reading with bzip2 compression. |
| 'r: xz' | Open for reading with lzma compression. |
| 'x' or 'x: ' | Create a tarfile exclusively without compression. Raise an <i>FileExistsError</i> exception if it already exists. |
| 'x: gz' | Create a tarfile with gzip compression. Raise an <i>FileExistsError</i> exception if it already exists. |
| 'x: bz2' | Create a tarfile with bzip2 compression. Raise an <i>FileExistsError</i> exception if it already exists. |
| 'x: xz' | Create a tarfile with lzma compression. Raise an <i>FileExistsError</i> exception if it already exists. |
| 'a' or 'a: ' | Open for appending with no compression. The file is created if it does not exist. |
| 'w' or 'w: ' | Open for uncompressed writing. |
| 'w: gz' | Open for gzip compressed writing. |
| 'w: bz2' | Open for bzip2 compressed writing. |
| 'w: xz' | Open for lzma compressed writing. |

Note that 'a:gz', 'a:bz2' or 'a:xz' is not possible. If *mode* is not suitable to open a certain (compressed) file for reading, *ReadError* is raised. Use *mode* 'r' to avoid this. If a compression method is not supported, *CompressionError* is raised.

If *fileobj* is specified, it is used as an alternative to a *file object* opened in binary mode for *name*. It is supposed to be at position 0.

For modes 'w:gz', 'r:gz', 'w:bz2', 'r:bz2', 'x:gz', 'x:bz2', *tarfile.open()* accepts the keyword argument *compresslevel* (default 9) to specify the compression level of the file.

For modes 'w:xz' and 'x:xz', *tarfile.open()* accepts the keyword argument *preset* to specify the compression level of the file.

For special purposes, there is a second format for *mode*: 'filemode|[compression]'. *tarfile.open()* will return a *TarFile* object that processes its data as a stream of blocks. No random seeking will be done on the file. If given, *fileobj* may be any object that has a *read()* or *write()* method (depending on the *mode*). *bufsize* specifies the blocksize and defaults to 20 * 512 bytes. Use this variant in combination with e.g. *sys.stdin*, a socket *file object* or a tape device. However, such a *TarFile* object is limited in that it does not allow random access, see *Examples*. The currently possible modes:

| Mode | Action |
|----------|--|
| 'r *' | Open a <i>stream</i> of tar blocks for reading with transparent compression. |
| 'r ' | Open a <i>stream</i> of uncompressed tar blocks for reading. |
| 'r gz' | Open a gzip compressed <i>stream</i> for reading. |
| 'r bz2' | Open a bzip2 compressed <i>stream</i> for reading. |
| 'r xz' | Open an lzma compressed <i>stream</i> for reading. |
| 'w ' | Open an uncompressed <i>stream</i> for writing. |
| 'w gz' | Open a gzip compressed <i>stream</i> for writing. |
| 'w bz2' | Open a bzip2 compressed <i>stream</i> for writing. |
| 'w xz' | Open an lzma compressed <i>stream</i> for writing. |

Άλλαξε στην έκδοση 3.5: The 'x' (exclusive creation) mode was added.

Άλλαξε στην έκδοση 3.6: The *name* parameter accepts a *path-like object*.

class tarfile.TarFile

Class for reading and writing tar archives. Do not use this class directly: use `tarfile.open()` instead. See *TarFile Objects*.

`tarfile.is_tarfile(name)`

Return *True* if *name* is a tar archive file, that the *tarfile* module can read. *name* may be a *str*, file, or file-like object.

Άλλαξε στην έκδοση 3.9: Support for file and file-like objects.

The *tarfile* module defines the following exceptions:

exception tarfile.TarError

Base class for all *tarfile* exceptions.

exception tarfile.ReadError

Is raised when a tar archive is opened, that either cannot be handled by the *tarfile* module or is somehow invalid.

exception tarfile.CompressionError

Is raised when a compression method is not supported or when the data cannot be decoded properly.

exception tarfile.StreamError

Is raised for the limitations that are typical for stream-like *TarFile* objects.

exception tarfile.ExtractError

Is raised for *non-fatal* errors when using *TarFile.extract()*, but only if *TarFile.errorlevel*== 2.

exception tarfile.HeaderError

Is raised by *TarInfo.frombuf()* if the buffer it gets is invalid.

exception tarfile.FilterError

Base class for members *refused* by filters.

tarinfo

Information about the member that the filter refused to extract, as *TarInfo*.

exception tarfile.AbsolutePathError

Raised to refuse extracting a member with an absolute path.

exception tarfile.OutsideDestinationError

Raised to refuse extracting a member outside the destination directory.

exception tarfile.SpecialFileError

Raised to refuse extracting a special file (e.g. a device or pipe).

exception tarfile.AbsoluteLinkError

Raised to refuse extracting a symbolic link with an absolute path.

exception tarfile.LinkOutsideDestinationError

Raised to refuse extracting a symbolic link pointing outside the destination directory.

exception tarfile.LinkFallbackError

Raised to refuse emulating a link (hard or symbolic) by extracting another archive member, when that member would be rejected by the filter location. The exception that was raised to reject the replacement member is available as `BaseException.__context__`.

Νέο στην έκδοση 3.9.24 (unreleased).

The following constants are available at the module level:

tarfile.ENCODING

The default character encoding: 'utf-8' on Windows, the value returned by `sys.getfilesystemencoding()` otherwise.

Each of the following constants defines a tar archive format that the `tarfile` module is able to create. See section *Supported tar formats* for details.

tarfile.USTAR_FORMAT

POSIX.1-1988 (ustar) format.

tarfile.GNU_FORMAT

GNU tar format.

tarfile.PAX_FORMAT

POSIX.1-2001 (pax) format.

tarfile.DEFAULT_FORMAT

The default format for creating archives. This is currently `PAX_FORMAT`.

Άλλαξε στην έκδοση 3.8: The default format for new archives was changed to `PAX_FORMAT` from `GNU_FORMAT`.

Δείτε επίσης:

Archiving operations Documentation of the higher-level archiving facilities provided by the standard `shutil` module.

GNU tar manual, Basic Tar Format Documentation for tar archive files, including GNU tar extensions.

13.6.1 TarFile Objects

The `TarFile` object provides an interface to a tar archive. A tar archive is a sequence of blocks. An archive member (a stored file) is made up of a header block followed by data blocks. It is possible to store a file in a tar archive several times. Each archive member is represented by a `TarInfo` object, see *TarInfo Objects* for details.

A `TarFile` object can be used as a context manager in a `with` statement. It will automatically be closed when the block is completed. Please note that in the event of an exception an archive opened for writing will not be finalized; only the internally used file object will be closed. See the *Examples* section for a use case.

Νέο στην έκδοση 3.2: Added support for the context management protocol.

```
class tarfile.TarFile(name=None, mode='r', fileobj=None, format=DEFAULT_FORMAT,
                      tarinfo=TarInfo, dereference=False, ignore_zeros=False, encoding=ENCODING,
                      errors='surrogateescape', pax_headers=None, debug=0, errorlevel=1)
```

All following arguments are optional and can be accessed as instance attributes as well.

`name` is the pathname of the archive. `name` may be a *path-like object*. It can be omitted if `fileobj` is given. In this case, the file object's `name` attribute is used if it exists.

`mode` is either 'r' to read from an existing archive, 'a' to append data to an existing file, 'w' to create a new file overwriting an existing one, or 'x' to create a new file only if it does not already exist.

If `fileobj` is given, it is used for reading or writing data. If it can be determined, `mode` is overridden by `fileobj`'s `mode`. `fileobj` will be used from position 0.

Σημείωση: `fileobj` is not closed, when `TarFile` is closed.

format controls the archive format for writing. It must be one of the constants `USTAR_FORMAT`, `GNU_FORMAT` or `PAX_FORMAT` that are defined at module level. When reading, format will be automatically detected, even if different formats are present in a single archive.

The *tarinfo* argument can be used to replace the default `TarInfo` class with a different one.

If *dereference* is `False`, add symbolic and hard links to the archive. If it is `True`, add the content of the target files to the archive. This has no effect on systems that do not support symbolic links.

If *ignore_zeros* is `False`, treat an empty block as the end of the archive. If it is `True`, skip empty (and invalid) blocks and try to get as many members as possible. This is only useful for reading concatenated or damaged archives.

debug can be set from 0 (no debug messages) up to 3 (all debug messages). The messages are written to `sys.stderr`.

errorlevel controls how extraction errors are handled, see the corresponding attribute.

The *encoding* and *errors* arguments define the character encoding to be used for reading or writing the archive and how conversion errors are going to be handled. The default settings will work for most users. See section [Unicode issues](#) for in-depth information.

The *pax_headers* argument is an optional dictionary of strings which will be added as a pax global header if *format* is `PAX_FORMAT`.

Άλλαξε στην έκδοση 3.2: Use 'surrogateescape' as the default for the *errors* argument.

Άλλαξε στην έκδοση 3.5: The 'x' (exclusive creation) mode was added.

Άλλαξε στην έκδοση 3.6: The *name* parameter accepts a *path-like object*.

classmethod `TarFile.open(...)`

Alternative constructor. The `tarfile.open()` function is actually a shortcut to this classmethod.

`TarFile.getmember(name)`

Return a `TarInfo` object for member *name*. If *name* can not be found in the archive, `KeyError` is raised.

Σημείωση: If a member occurs more than once in the archive, its last occurrence is assumed to be the most up-to-date version.

`TarFile.getmembers()`

Return the members of the archive as a list of `TarInfo` objects. The list has the same order as the members in the archive.

`TarFile.getnames()`

Return the members as a list of their names. It has the same order as the list returned by `getmembers()`.

`TarFile.list(verbose=True, *, members=None)`

Print a table of contents to `sys.stdout`. If *verbose* is `False`, only the names of the members are printed. If it is `True`, output similar to that of `ls -l` is produced. If optional *members* is given, it must be a subset of the list returned by `getmembers()`.

Άλλαξε στην έκδοση 3.5: Added the *members* parameter.

`TarFile.next()`

Return the next member of the archive as a `TarInfo` object, when `TarFile` is opened for reading. Return `None` if there is no more available.

`TarFile.extractall(path=".", members=None, *, numeric_owner=False, filter=None)`

Extract all members from the archive to the current working directory or directory *path*. If optional *members* is given, it must be a subset of the list returned by `getmembers()`. Directory information like owner, modification time and permissions are set after all members have been extracted. This is done to work around two problems: A

directory's modification time is reset each time a file is created in it. And, if a directory's permissions do not allow writing, extracting files to it will fail.

If *numeric_owner* is *True*, the uid and gid numbers from the tarfile are used to set the owner/group for the extracted files. Otherwise, the named values from the tarfile are used.

The *filter* argument, which was added in Python 3.9.17, specifies how *members* are modified or rejected before extraction. See [Extraction filters](#) for details. It is recommended to set this explicitly depending on which *tar* features you need to support.

Προειδοποίηση: Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with "/" or filenames with two dots ".".

Set *filter*='data' to prevent the most dangerous security issues, and read the [Extraction filters](#) section for details.

Άλλαξε στην έκδοση 3.5: Added the *numeric_owner* parameter.

Άλλαξε στην έκδοση 3.6: The *path* parameter accepts a *path-like object*.

Άλλαξε στην έκδοση 3.9.17: Added the *filter* parameter.

`TarFile.extract(member, path="", set_attrs=True, *, numeric_owner=False, filter=None)`

Extract a member from the archive to the current working directory, using its full name. Its file information is extracted as accurately as possible. *member* may be a filename or a *TarInfo* object. You can specify a different directory using *path*. *path* may be a *path-like object*. File attributes (owner, mtime, mode) are set unless *set_attrs* is false.

The *numeric_owner* and *filter* arguments are the same as for `extractall()`.

Σημείωση: The `extract()` method does not take care of several extraction issues. In most cases you should consider using the `extractall()` method.

Προειδοποίηση: See the warning for `extractall()`.

Set *filter*='data' to prevent the most dangerous security issues, and read the [Extraction filters](#) section for details.

Άλλαξε στην έκδοση 3.2: Added the *set_attrs* parameter.

Άλλαξε στην έκδοση 3.5: Added the *numeric_owner* parameter.

Άλλαξε στην έκδοση 3.6: The *path* parameter accepts a *path-like object*.

Άλλαξε στην έκδοση 3.9.17: Added the *filter* parameter.

`TarFile.extractfile(member)`

Extract a member from the archive as a file object. *member* may be a filename or a *TarInfo* object. If *member* is a regular file or a link, an *io.BufferedReader* object is returned. For all other existing members, *None* is returned. If *member* does not appear in the archive, *KeyError* is raised.

Άλλαξε στην έκδοση 3.3: Return an *io.BufferedReader* object.

`TarFile.errorlevel: int`

If *errorlevel* is 0, errors are ignored when using `TarFile.extract()` and `TarFile.extractall()`. Nevertheless, they appear as error messages in the debug output when *debug* is greater than 0. If 1 (the default),

all *fatal* errors are raised as *OSError* or *FilterError* exceptions. If 2, all *non-fatal* errors are raised as *TarError* exceptions as well.

Some exceptions, e.g. ones caused by wrong argument types or data corruption, are always raised.

Custom *extraction filters* should raise *FilterError* for *fatal* errors and *ExtractError* for *non-fatal* ones.

Note that when an exception is raised, the archive may be partially extracted. It is the user's responsibility to clean up.

`TarFile.extraction_filter`

Νέο στην έκδοση 3.9.17.

The *extraction filter* used as a default for the *filter* argument of *extract()* and *extractall()*.

The attribute may be *None* or a callable. String names are not allowed for this attribute, unlike the *filter* argument to *extract()*.

If *extraction_filter* is *None* (the default), calling an extraction method without a *filter* argument will use the *fully_trusted* filter for compatibility with previous Python versions.

In Python 3.12+, leaving *extraction_filter=None* will emit a *DeprecationWarning*.

In Python 3.14+, leaving *extraction_filter=None* will cause extraction methods to use the *data* filter by default.

The attribute may be set on instances or overridden in subclasses. It also is possible to set it on the *TarFile* class itself to set a global default, although, since it affects all uses of *tarfile*, it is best practice to only do so in top-level applications or *site configuration*. To set a global default this way, a filter function needs to be wrapped in *staticmethod()* to prevent injection of a *self* argument.

`TarFile.add(name, arcname=None, recursive=True, *, filter=None)`

Add the file *name* to the archive. *name* may be any type of file (directory, fifo, symbolic link, etc.). If given, *arcname* specifies an alternative name for the file in the archive. Directories are added recursively by default. This can be avoided by setting *recursive* to *False*. Recursion adds entries in sorted order. If *filter* is given, it should be a function that takes a *TarInfo* object argument and returns the changed *TarInfo* object. If it instead returns *None* the *TarInfo* object will be excluded from the archive. See *Examples* for an example.

Άλλαξε στην έκδοση 3.2: Added the *filter* parameter.

Άλλαξε στην έκδοση 3.7: Recursion adds entries in sorted order.

`TarFile.addfile(tarinfo, fileobj=None)`

Add the *TarInfo* object *tarinfo* to the archive. If *fileobj* is given, it should be a *binary file*, and *tarinfo.size* bytes are read from it and added to the archive. You can create *TarInfo* objects directly, or by using *gettinfo()*.

`TarFile.gettarinfo(name=None, arcname=None, fileobj=None)`

Create a *TarInfo* object from the result of *os.stat()* or equivalent on an existing file. The file is either named by *name*, or specified as a *file object fileobj* with a file descriptor. *name* may be a *path-like object*. If given, *arcname* specifies an alternative name for the file in the archive, otherwise, the name is taken from *fileobj's name* attribute, or the *name* argument. The name should be a text string.

You can modify some of the *TarInfo's* attributes before you add it using *addfile()*. If the file object is not an ordinary file object positioned at the beginning of the file, attributes such as *size* may need modifying. This is the case for objects such as *GzipFile*. The *name* may also be modified, in which case *arcname* could be a dummy string.

Άλλαξε στην έκδοση 3.6: The *name* parameter accepts a *path-like object*.

`TarFile.close()`

Close the *TarFile*. In write mode, two finishing zero blocks are appended to the archive.

`TarFile.pax_headers`

A dictionary containing key-value pairs of pax global headers.

13.6.2 TarInfo Objects

A *TarInfo* object represents one member in a *TarFile*. Aside from storing all required attributes of a file (like file type, size, time, permissions, owner etc.), it provides some useful methods to determine its type. It does *not* contain the file's data itself.

TarInfo objects are returned by *TarFile*'s methods *getmember()*, *getmembers()* and *gettinfo()*.

Modifying the objects returned by *getmember()* or *getmembers()* will affect all subsequent operations on the archive. For cases where this is unwanted, you can use *copy.copy()* or call the *replace()* method to create a modified copy in one step.

Several attributes can be set to *None* to indicate that a piece of metadata is unused or unknown. Different *TarInfo* methods handle *None* differently:

- The *extract()* or *extractall()* methods will ignore the corresponding metadata, leaving it set to a default.
- *addfile()* will fail.
- *list()* will print a placeholder string.

Άλλαξε στην έκδοση 3.9.17: Added *replace()* and handling of *None*.

class `tarfile.TarInfo` (*name=""*)

Create a *TarInfo* object.

classmethod `TarInfo.frombuf` (*buf*, *encoding*, *errors*)

Create and return a *TarInfo* object from string buffer *buf*.

Raises *HeaderError* if the buffer is invalid.

classmethod `TarInfo.fromtarfile` (*tarfile*)

Read the next member from the *TarFile* object *tarfile* and return it as a *TarInfo* object.

`TarInfo.tobuf` (*format=DEFAULT_FORMAT*, *encoding=ENCODING*, *errors='surrogateescape'*)

Create a string buffer from a *TarInfo* object. For information on the arguments see the constructor of the *TarFile* class.

Άλλαξε στην έκδοση 3.2: Use 'surrogateescape' as the default for the *errors* argument.

A *TarInfo* object has the following public data attributes:

`TarInfo.name`: **str**

Name of the archive member.

`TarInfo.size`: **int**

Size in bytes.

`TarInfo.mtime`: **int** | **float**

Time of last modification in seconds since the *epoch*, as in *os.stat_result.st_mtime*.

Άλλαξε στην έκδοση 3.9.17: Can be set to *None* for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

`TarInfo.mode`: **int**

Permission bits, as for *os.chmod()*.

Άλλαξε στην έκδοση 3.9.17: Can be set to *None* for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.type

File type. *type* is usually one of these constants: REGTYPE, AREGTYPE, LNKTYPE, SYMTYPE, DIRTYPE, FIFOTYPE, CONTTYPE, CHRTYPE, BLKTYPE, GNUTYPE_SPARSE. To determine the type of a *TarInfo* object more conveniently, use the `is*()` methods below.

TarInfo.linkname: str

Name of the target file name, which is only present in *TarInfo* objects of type LNKTYPE and SYMTYPE.

For symbolic links (SYMTYPE), the *linkname* is relative to the directory that contains the link. For hard links (LNKTYPE), the *linkname* is relative to the root of the archive.

TarInfo.uid: int

User ID of the user who originally stored this member.

Άλλαξε στην έκδοση 3.9.17: Can be set to None for `extract()` and `extractall()`, causing extraction to skip applying this attribute.

TarInfo.gid: int

Group ID of the user who originally stored this member.

Άλλαξε στην έκδοση 3.9.17: Can be set to None for `extract()` and `extractall()`, causing extraction to skip applying this attribute.

TarInfo.uname: str

User name.

Άλλαξε στην έκδοση 3.9.17: Can be set to None for `extract()` and `extractall()`, causing extraction to skip applying this attribute.

TarInfo.gname: str

Group name.

Άλλαξε στην έκδοση 3.9.17: Can be set to None for `extract()` and `extractall()`, causing extraction to skip applying this attribute.

TarInfo.pax_headers: dict

A dictionary containing key-value pairs of an associated pax extended header.

TarInfo.replace(name=..., mtime=..., mode=..., linkname=..., uid=..., gid=..., uname=..., gname=..., deep=True)

Νέο στην έκδοση 3.9.17.

Return a *new* copy of the *TarInfo* object with the given attributes changed. For example, to return a *TarInfo* with the group name set to 'staff', use:

```
new_tarinfo = old_tarinfo.replace(gname='staff')
```

By default, a deep copy is made. If *deep* is false, the copy is shallow, i.e. `pax_headers` and any custom attributes are shared with the original *TarInfo* object.

A *TarInfo* object also provides some convenient query methods:

TarInfo.isfile()

Return *True* if the *Tarinfo* object is a regular file.

TarInfo.isreg()

Same as `isfile()`.

TarInfo.isdir()

Return *True* if it is a directory.

`TarInfo.issym()`
Return *True* if it is a symbolic link.

`TarInfo.islnk()`
Return *True* if it is a hard link.

`TarInfo.ischr()`
Return *True* if it is a character device.

`TarInfo.isblk()`
Return *True* if it is a block device.

`TarInfo.isfifo()`
Return *True* if it is a FIFO.

`TarInfo.isdev()`
Return *True* if it is one of character device, block device or FIFO.

13.6.3 Extraction filters

Νέο στην έκδοση 3.9.17.

The *tar* format is designed to capture all details of a UNIX-like filesystem, which makes it very powerful. Unfortunately, the features make it easy to create tar files that have unintended – and possibly malicious – effects when extracted. For example, extracting a tar file can overwrite arbitrary files in various ways (e.g. by using absolute paths, `..` path components, or symlinks that affect later members).

In most cases, the full functionality is not needed. Therefore, *tarfile* supports extraction filters: a mechanism to limit functionality, and thus mitigate some of the security issues.

Δείτε επίσης:

PEP 706 Contains further motivation and rationale behind the design.

The *filter* argument to `TarFile.extract()` or `extractall()` can be:

- the string `'fully_trusted'`: Honor all metadata as specified in the archive. Should be used if the user trusts the archive completely, or implements their own complex verification.
- the string `'tar'`: Honor most *tar*-specific features (i.e. features of UNIX-like filesystems), but block features that are very likely to be surprising or malicious. See `tar_filter()` for details.
- the string `'data'`: Ignore or block most features specific to UNIX-like filesystems. Intended for extracting cross-platform data archives. See `data_filter()` for details.
- `None` (default): Use `TarFile.extraction_filter`.

If that is also `None` (the default), the `'fully_trusted'` filter will be used (for compatibility with earlier versions of Python).

In Python 3.12, the default will emit a `DeprecationWarning`.

In Python 3.14, the `'data'` filter will become the default instead. It's possible to switch earlier; see `TarFile.extraction_filter`.

- A callable which will be called for each extracted member with a *TarInfo* describing the member and the destination path to where the archive is extracted (i.e. the same path is used for all members):

```
filter(/, member: TarInfo, path: str) -> TarInfo | None
```

The callable is called just before each member is extracted, so it can take the current state of the disk into account. It can:

- return a `TarInfo` object which will be used instead of the metadata in the archive, or
- return `None`, in which case the member will be skipped, or
- raise an exception to abort the operation or skip the member, depending on `errorlevel`. Note that when extraction is aborted, `extractall()` may leave the archive partially extracted. It does not attempt to clean up.

Default named filters

The pre-defined, named filters are available as functions, so they can be reused in custom filters:

`tarfile.fully_trusted_filter(/, member, path)`

Return *member* unchanged.

This implements the 'fully_trusted' filter.

`tarfile.tar_filter(/, member, path)`

Implements the 'tar' filter.

- Strip leading slashes (/ and `os.sep`) from filenames.
- *Refuse* to extract files with absolute paths (in case the name is absolute even after stripping slashes, e.g. `C:/foo` on Windows). This raises `AbsolutePathError`.
- *Refuse* to extract files whose absolute path (after following symlinks) would end up outside the destination. This raises `OutsideDestinationError`.
- Clear high mode bits (setuid, setgid, sticky) and group/other write bits (`S_IWOTH`).

Return the modified `TarInfo` member.

`tarfile.data_filter(/, member, path)`

Implements the 'data' filter. In addition to what `tar_filter` does:

- Normalize link targets (`TarInfo.linkname`) using `os.path.normpath()`. Note that this removes internal `..` components, which may change the meaning of the link if the path in `TarInfo.linkname` traverses symbolic links.
- *Refuse* to extract links (hard or soft) that link to absolute paths, or ones that link outside the destination. This raises `AbsoluteLinkError` or `LinkOutsideDestinationError`.
Note that such files are refused even on platforms that do not support symbolic links.
- *Refuse* to extract device files (including pipes). This raises `SpecialFileError`.
- For regular files, including hard links:
 - Set the owner read and write permissions (`S_IWUSR`).
 - Remove the group & other executable permission (`S_IXOTH`) if the owner doesn't have it (`S_IXUSR`).
- For other files (directories), set mode to `None`, so that extraction methods skip applying permission bits.
- Set user and group info (`uid`, `gid`, `uname`, `gname`) to `None`, so that extraction methods skip setting it.

Return the modified `TarInfo` member.

Άλλαξε στην έκδοση 3.9.24 (unreleased): Link targets are now normalized.

Filter errors

When a filter refuses to extract a file, it will raise an appropriate exception, a subclass of `FilterError`. This will abort the extraction if `TarFile.errorlevel` is 1 or more. With `errorlevel=0` the error will be logged and the member will be skipped, but extraction will continue.

Hints for further verification

Even with `filter='data'`, `tarfile` is not suited for extracting untrusted files without prior inspection. Among other issues, the pre-defined filters do not prevent denial-of-service attacks. Users should do additional checks.

Here is an incomplete list of things to consider:

- Extract to a *new temporary directory* to prevent e.g. exploiting pre-existing links, and to make it easier to clean up after a failed extraction.
- Disallow symbolic links if you do not need the functionality.
- When working with untrusted data, use external (e.g. OS-level) limits on disk, memory and CPU usage.
- Check filenames against an allow-list of characters (to filter out control characters, confusables, foreign path separators, etc.).
- Check that filenames have expected extensions (discouraging files that execute when you “click on them”, or extension-less files like Windows special device names).
- Limit the number of extracted files, total size of extracted data, filename length (including symlink length), and size of individual files.
- Check for files that would be shadowed on case-insensitive filesystems.

Also note that:

- Tar files may contain multiple versions of the same file. Later ones are expected to overwrite any earlier ones. This feature is crucial to allow updating tape archives, but can be abused maliciously.
- `tarfile` does not protect against issues with “live” data, e.g. an attacker tinkering with the destination (or source) directory while extraction (or archiving) is in progress.

Supporting older Python versions

Extraction filters were added to Python 3.12, and are backported to older versions as security updates. To check whether the feature is available, use e.g. `hasattr(tarfile, 'data_filter')` rather than checking the Python version.

The following examples show how to support Python versions with and without the feature. Note that setting `extraction_filter` will affect any subsequent operations.

- Fully trusted archive:

```
my_tarfile.extraction_filter = (lambda member, path: member)
my_tarfile.extractall()
```

- Use the 'data' filter if available, but revert to Python 3.11 behavior ('fully_trusted') if this feature is not available:

```
my_tarfile.extraction_filter = getattr(tarfile, 'data_filter',
                                       (lambda member, path: member))
my_tarfile.extractall()
```

- Use the 'data' filter; *fail* if it is not available:

```
my_tarfile.extractall(filter=tarfile.data_filter)
```

or:

```
my_tarfile.extraction_filter = tarfile.data_filter
my_tarfile.extractall()
```

- Use the 'data' filter; *warn* if it is not available:

```
if hasattr(tarfile, 'data_filter'):
    my_tarfile.extractall(filter='data')
else:
    # remove this when no longer needed
    warn_the_user('Extracting may be unsafe; consider updating Python')
    my_tarfile.extractall()
```

Stateful extraction filter example

While *tarfile*'s extraction methods take a simple *filter* callable, custom filters may be more complex objects with an internal state. It may be useful to write these as context managers, to be used like this:

```
with StatefulFilter() as filter_func:
    tar.extractall(path, filter=filter_func)
```

Such a filter can be written as, for example:

```
class StatefulFilter:
    def __init__(self):
        self.file_count = 0

    def __enter__(self):
        return self

    def __call__(self, member, path):
        self.file_count += 1
        return member

    def __exit__(self, *exc_info):
        print(f'{self.file_count} files extracted')
```

13.6.4 Command-Line Interface

Νέο στην έκδοση 3.4.

The *tarfile* module provides a simple command-line interface to interact with tar archives.

If you want to create a new tar archive, specify its name after the `-c` option and then list the filename(s) that should be included:

```
$ python -m tarfile -c monty.tar spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m tarfile -c monty.tar life-of-brian_1979/
```

If you want to extract a tar archive into the current directory, use the `-e` option:

```
$ python -m tarfile -e monty.tar
```

You can also extract a tar archive into a different directory by passing the directory's name:

```
$ python -m tarfile -e monty.tar other-dir/
```

For a list of the files in a tar archive, use the `-l` option:

```
$ python -m tarfile -l monty.tar
```

Command-line options

```
-l <tarfile>
--list <tarfile>
    List files in a tarfile.

-c <tarfile> <source1> ... <sourceN>
--create <tarfile> <source1> ... <sourceN>
    Create tarfile from source files.

-e <tarfile> [<output_dir>]
--extract <tarfile> [<output_dir>]
    Extract tarfile into the current directory if output_dir is not specified.

-t <tarfile>
--test <tarfile>
    Test whether the tarfile is valid or not.

-v, --verbose
    Verbose output.

--filter <filtername>
    Specifies the filter for --extract. See Extraction filters for details. Only string names are accepted (that is,
    fully_trusted, tar, and data).

    Νέο στην έκδοση 3.9.17.
```

13.6.5 Examples

How to extract an entire tar archive to the current working directory:

```
import tarfile
tar = tarfile.open("sample.tar.gz")
tar.extractall()
tar.close()
```

How to extract a subset of a tar archive with `TarFile.extractall()` using a generator function instead of a list:

```
import os
import tarfile

def py_files(members):
    for tarinfo in members:
        if os.path.splitext(tarinfo.name)[1] == ".py":
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
        yield tarinfo

tar = tarfile.open("sample.tar.gz")
tar.extractall(members=py_files(tar))
tar.close()
```

How to create an uncompressed tar archive from a list of filenames:

```
import tarfile
tar = tarfile.open("sample.tar", "w")
for name in ["foo", "bar", "quux"]:
    tar.add(name)
tar.close()
```

The same example using the with statement:

```
import tarfile
with tarfile.open("sample.tar", "w") as tar:
    for name in ["foo", "bar", "quux"]:
        tar.add(name)
```

How to read a gzip compressed tar archive and display some member information:

```
import tarfile
tar = tarfile.open("sample.tar.gz", "r:gz")
for tarinfo in tar:
    print(tarinfo.name, "is", tarinfo.size, "bytes in size and is ", end="")
    if tarinfo.isreg():
        print("a regular file.")
    elif tarinfo.isdir():
        print("a directory.")
    else:
        print("something else.")
tar.close()
```

How to create an archive and reset the user information using the *filter* parameter in *TarFile.add()*:

```
import tarfile
def reset(tarinfo):
    tarinfo.uid = tarinfo.gid = 0
    tarinfo.uname = tarinfo.gname = "root"
    return tarinfo
tar = tarfile.open("sample.tar.gz", "w:gz")
tar.add("foo", filter=reset)
tar.close()
```

13.6.6 Supported tar formats

There are three tar formats that can be created with the `tarfile` module:

- The POSIX.1-1988 ustar format (`USTAR_FORMAT`). It supports filenames up to a length of at best 256 characters and linknames up to 100 characters. The maximum file size is 8 GiB. This is an old and limited but widely supported format.
- The GNU tar format (`GNU_FORMAT`). It supports long filenames and linknames, files bigger than 8 GiB and sparse files. It is the de facto standard on GNU/Linux systems. `tarfile` fully supports the GNU tar extensions for long names, sparse file support is read-only.
- The POSIX.1-2001 pax format (`PAX_FORMAT`). It is the most flexible format with virtually no limits. It supports long filenames and linknames, large files and stores pathnames in a portable way. Modern tar implementations, including GNU tar, bsdtar/libarchive and star, fully support extended *pax* features; some old or unmaintained libraries may not, but should treat *pax* archives as if they were in the universally-supported *ustar* format. It is the current default format for new archives.

It extends the existing *ustar* format with extra headers for information that cannot be stored otherwise. There are two flavours of pax headers: Extended headers only affect the subsequent file header, global headers are valid for the complete archive and affect all following files. All the data in a pax header is encoded in *UTF-8* for portability reasons.

There are some more variants of the tar format which can be read, but not created:

- The ancient V7 format. This is the first tar format from Unix Seventh Edition, storing only regular files and directories. Names must not be longer than 100 characters, there is no user/group name information. Some archives have miscalculated header checksums in case of fields with non-ASCII characters.
- The SunOS tar extended format. This format is a variant of the POSIX.1-2001 pax format, but is not compatible.

13.6.7 Unicode issues

The tar format was originally conceived to make backups on tape drives with the main focus on preserving file system information. Nowadays tar archives are commonly used for file distribution and exchanging archives over networks. One problem of the original format (which is the basis of all other formats) is that there is no concept of supporting different character encodings. For example, an ordinary tar archive created on a *UTF-8* system cannot be read correctly on a *Latin-1* system if it contains non-ASCII characters. Textual metadata (like filenames, linknames, user/group names) will appear damaged. Unfortunately, there is no way to autodetect the encoding of an archive. The pax format was designed to solve this problem. It stores non-ASCII metadata using the universal character encoding *UTF-8*.

The details of character conversion in `tarfile` are controlled by the *encoding* and *errors* keyword arguments of the `TarFile` class.

encoding defines the character encoding to use for the metadata in the archive. The default value is `sys.getfilesystemencoding()` or `'ascii'` as a fallback. Depending on whether the archive is read or written, the metadata must be either decoded or encoded. If *encoding* is not set appropriately, this conversion may fail.

The *errors* argument defines how characters are treated that cannot be converted. Possible values are listed in section *Error Handlers*. The default scheme is `'surrogateescape'` which Python also uses for its file system calls, see *File Names, Command Line Arguments, and Environment Variables*.

For `PAX_FORMAT` archives (the default), *encoding* is generally not needed because all the metadata is stored using *UTF-8*. *encoding* is only used in the rare cases when binary pax headers are decoded or when strings with surrogate characters are stored.

The modules described in this chapter parse various miscellaneous file formats that aren't markup languages and are not related to e-mail.

14.1 `csv` — CSV File Reading and Writing

Source code: [Lib/csv.py](#)

The so-called CSV (Comma Separated Values) format is the most common import and export format for spreadsheets and databases. CSV format was used for many years prior to attempts to describe the format in a standardized way in [RFC 4180](#). The lack of a well-defined standard means that subtle differences often exist in the data produced and consumed by different applications. These differences can make it annoying to process CSV files from multiple sources. Still, while the delimiters and quoting characters vary, the overall format is similar enough that it is possible to write a single module which can efficiently manipulate such data, hiding the details of reading and writing the data from the programmer.

The `csv` module implements classes to read and write tabular data in CSV format. It allows programmers to say, «write this data in the format preferred by Excel,» or «read data from this file which was generated by Excel,» without knowing the precise details of the CSV format used by Excel. Programmers can also describe the CSV formats understood by other applications or define their own special-purpose CSV formats.

The `csv` module's `reader` and `writer` objects read and write sequences. Programmers can also read and write data in dictionary form using the `DictReader` and `DictWriter` classes.

Δείτε επίσης:

PEP 305 - CSV File API The Python Enhancement Proposal which proposed this addition to Python.

14.1.1 Module Contents

The `csv` module defines the following functions:

`csv.reader(csvfile, dialect='excel', **fmtparams)`

Return a reader object which will iterate over lines in the given *csvfile*. *csvfile* can be any object which supports the *iterator* protocol and returns a string each time its `__next__()` method is called — *file objects* and list objects are both suitable. If *csvfile* is a file object, it should be opened with `newline=''`.¹ An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the *Dialect* class or one of the strings returned by the `list_dialects()` function. The other optional *fmtparams* keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section *Dialects and Formatting Parameters*.

Each row read from the csv file is returned as a list of strings. No automatic data type conversion is performed unless the `QUOTE_NONNUMERIC` format option is specified (in which case unquoted fields are transformed into floats).

A short usage example:

```
>>> import csv
>>> with open('eggs.csv', newline='') as csvfile:
...     spamreader = csv.reader(csvfile, delimiter=' ', quotechar='|')
...     for row in spamreader:
...         print(', '.join(row))
Spam, Spam, Spam, Spam, Spam, Baked Beans
Spam, Lovely Spam, Wonderful Spam
```

`csv.writer(csvfile, dialect='excel', **fmtparams)`

Return a writer object responsible for converting the user's data into delimited strings on the given file-like object. *csvfile* can be any object with a `write()` method. If *csvfile* is a file object, it should be opened with `newline=''`. An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the *Dialect* class or one of the strings returned by the `list_dialects()` function. The other optional *fmtparams* keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about dialects and formatting parameters, see the *Dialects and Formatting Parameters* section. To make it as easy as possible to interface with modules which implement the DB API, the value *None* is written as the empty string. While this isn't a reversible transformation, it makes it easier to dump SQL NULL data values to CSV files without preprocessing the data returned from a `cursor.fetch*` call. All other non-string data are stringified with `str()` before being written.

A short usage example:

```
import csv
with open('eggs.csv', 'w', newline='') as csvfile:
    spamwriter = csv.writer(csvfile, delimiter=' ',
                           quotechar='|', quoting=csv.QUOTE_MINIMAL)
    spamwriter.writerow(['Spam'] * 5 + ['Baked Beans'])
    spamwriter.writerow(['Spam', 'Lovely Spam', 'Wonderful Spam'])
```

`csv.register_dialect(name[, dialect[, **fmtparams]])`

Associate *dialect* with *name*. *name* must be a string. The dialect can be specified either by passing a sub-class of *Dialect*, or by *fmtparams* keyword arguments, or both, with keyword arguments overriding parameters of the dialect. For full details about dialects and formatting parameters, see section *Dialects and Formatting Parameters*.

`csv.unregister_dialect(name)`

Delete the dialect associated with *name* from the dialect registry. An *Error* is raised if *name* is not a registered

¹ If `newline=''` is not specified, newlines embedded inside quoted fields will not be interpreted correctly, and on platforms that use `\r\n` line endings on write an extra `\r` will be added. It should always be safe to specify `newline=''`, since the csv module does its own (*universal*) newline handling.

dialect name.

`csv.get_dialect(name)`

Return the dialect associated with *name*. An *Error* is raised if *name* is not a registered dialect name. This function returns an immutable *Dialect*.

`csv.list_dialects()`

Return the names of all registered dialects.

`csv.field_size_limit([new_limit])`

Returns the current maximum field size allowed by the parser. If *new_limit* is given, this becomes the new limit.

The *csv* module defines the following classes:

class `csv.DictReader(f, fieldnames=None, restkey=None, restval=None, dialect='excel', *args, **kws)`

Create an object that operates like a regular reader but maps the information in each row to a *dict* whose keys are given by the optional *fieldnames* parameter.

The *fieldnames* parameter is a *sequence*. If *fieldnames* is omitted, the values in the first row of file *f* will be used as the fieldnames. Regardless of how the fieldnames are determined, the dictionary preserves their original ordering.

If a row has more fields than fieldnames, the remaining data is put in a list and stored with the fieldname specified by *restkey* (which defaults to *None*). If a non-blank row has fewer fields than fieldnames, the missing values are filled-in with the value of *restval* (which defaults to *None*).

All other optional or keyword arguments are passed to the underlying *reader* instance.

Άλλαξε στην έκδοση 3.6: Returned rows are now of type *OrderedDict*.

Άλλαξε στην έκδοση 3.8: Returned rows are now of type *dict*.

A short usage example:

```
>>> import csv
>>> with open('names.csv', newline='') as csvfile:
...     reader = csv.DictReader(csvfile)
...     for row in reader:
...         print(row['first_name'], row['last_name'])
...
Eric Idle
John Cleese

>>> print(row)
{'first_name': 'John', 'last_name': 'Cleese'}
```

class `csv.DictWriter(f, fieldnames, restval="", extrasaction='raise', dialect='excel', *args, **kws)`

Create an object which operates like a regular writer but maps dictionaries onto output rows. The *fieldnames* parameter is a *sequence* of keys that identify the order in which values in the dictionary passed to the *writerow()* method are written to file *f*. The optional *restval* parameter specifies the value to be written if the dictionary is missing a key in *fieldnames*. If the dictionary passed to the *writerow()* method contains a key not found in *fieldnames*, the optional *extrasaction* parameter indicates what action to take. If it is set to 'raise', the default value, a *ValueError* is raised. If it is set to 'ignore', extra values in the dictionary are ignored. Any other optional or keyword arguments are passed to the underlying *writer* instance.

Note that unlike the *DictReader* class, the *fieldnames* parameter of the *DictWriter* class is not optional.

A short usage example:

```
import csv

with open('names.csv', 'w', newline='') as csvfile:
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

fieldnames = ['first_name', 'last_name']
writer = csv.DictWriter(csvfile, fieldnames=fieldnames)

writer.writeheader()
writer.writerow({'first_name': 'Baked', 'last_name': 'Beans'})
writer.writerow({'first_name': 'Lovely', 'last_name': 'Spam'})
writer.writerow({'first_name': 'Wonderful', 'last_name': 'Spam'})

```

class csv.Dialect

The *Dialect* class is a container class whose attributes contain information for how to handle doublequotes, whitespace, delimiters, etc. Due to the lack of a strict CSV specification, different applications produce subtly different CSV data. *Dialect* instances define how *reader* and *writer* instances behave.

All available *Dialect* names are returned by *list_dialects()*, and they can be registered with specific *reader* and *writer* classes through their initializer (*__init__*) functions like this:

```

import csv

with open('students.csv', 'w', newline='') as csvfile:
    writer = csv.writer(csvfile, dialect='unix')
    ^^^^^^^^^^^^^^^^^^^

```

class csv.excel

The *excel* class defines the usual properties of an Excel-generated CSV file. It is registered with the dialect name 'excel'.

class csv.excel_tab

The *excel_tab* class defines the usual properties of an Excel-generated TAB-delimited file. It is registered with the dialect name 'excel-tab'.

class csv.unix_dialect

The *unix_dialect* class defines the usual properties of a CSV file generated on UNIX systems, i.e. using '\n' as line terminator and quoting all fields. It is registered with the dialect name 'unix'.

Νέο στην έκδοση 3.2.

class csv.Sniffer

The *Sniffer* class is used to deduce the format of a CSV file.

The *Sniffer* class provides two methods:

sniff (*sample*, *delimiters=None*)

Analyze the given *sample* and return a *Dialect* subclass reflecting the parameters found. If the optional *delimiters* parameter is given, it is interpreted as a string containing possible valid delimiter characters.

has_header (*sample*)

Analyze the sample text (presumed to be in CSV format) and return *True* if the first row appears to be a series of column headers.

An example for *Sniffer* use:

```

with open('example.csv', newline='') as csvfile:
    dialect = csv.Sniffer().sniff(csvfile.read(1024))
    csvfile.seek(0)
    reader = csv.reader(csvfile, dialect)
    # ... process CSV file contents here ...

```

The *csv* module defines the following constants:

CSV.QUOTE_ALL

Instructs *writer* objects to quote all fields.

CSV.QUOTE_MINIMAL

Instructs *writer* objects to only quote those fields which contain special characters such as *delimiter*, *quotechar* or any of the characters in *lineterminator*.

CSV.QUOTE_NONNUMERIC

Instructs *writer* objects to quote all non-numeric fields.

Instructs the reader to convert all non-quoted fields to type *float*.

CSV.QUOTE_NONE

Instructs *writer* objects to never quote fields. When the current *delimiter* occurs in output data it is preceded by the current *escapechar* character. If *escapechar* is not set, the writer will raise *Error* if any characters that require escaping are encountered.

Instructs *reader* to perform no special processing of quote characters.

The *csv* module defines the following exception:

exception CSV.Error

Raised by any of the functions when an error is detected.

14.1.2 Dialects and Formatting Parameters

To make it easier to specify the format of input and output records, specific formatting parameters are grouped together into dialects. A dialect is a subclass of the *Dialect* class having a set of specific methods and a single *validate()* method. When creating *reader* or *writer* objects, the programmer can specify a string or a subclass of the *Dialect* class as the dialect parameter. In addition to, or instead of, the *dialect* parameter, the programmer can also specify individual formatting parameters, which have the same names as the attributes defined below for the *Dialect* class.

Dialects support the following attributes:

Dialect.delimiter

A one-character string used to separate fields. It defaults to *','*.

Dialect.doublequote

Controls how instances of *quotechar* appearing inside a field should themselves be quoted. When *True*, the character is doubled. When *False*, the *escapechar* is used as a prefix to the *quotechar*. It defaults to *True*.

On output, if *doublequote* is *False* and no *escapechar* is set, *Error* is raised if a *quotechar* is found in a field.

Dialect.escapechar

A one-character string used by the writer to escape the *delimiter* if *quoting* is set to *QUOTE_NONE* and the *quotechar* if *doublequote* is *False*. On reading, the *escapechar* removes any special meaning from the following character. It defaults to *None*, which disables escaping.

Dialect.lineterminator

The string used to terminate lines produced by the *writer*. It defaults to *'\\r\\n'*.

Σημείωση: The *reader* is hard-coded to recognise either *'\\r'* or *'\\n'* as end-of-line, and ignores *lineterminator*. This behavior may change in the future.

Dialect.quotechar

A one-character string used to quote fields containing special characters, such as the *delimiter* or *quotechar*, or which contain new-line characters. It defaults to *'\"'*.

Dialect.quoting

Controls when quotes should be generated by the writer and recognised by the reader. It can take on any of the `QUOTE_*` constants (see section *Module Contents*) and defaults to `QUOTE_MINIMAL`.

Dialect.skipinitialspace

When `True`, whitespace immediately following the *delimiter* is ignored. The default is `False`.

Dialect.strict

When `True`, raise exception *Error* on bad CSV input. The default is `False`.

14.1.3 Reader Objects

Reader objects (*DictReader* instances and objects returned by the *reader()* function) have the following public methods:

csvreader.__next__()

Return the next row of the reader's iterable object as a list (if the object was returned from *reader()*) or a dict (if it is a *DictReader* instance), parsed according to the current *Dialect*. Usually you should call this as `next(reader)`.

Reader objects have the following public attributes:

csvreader.dialect

A read-only description of the dialect in use by the parser.

csvreader.line_num

The number of lines read from the source iterator. This is not the same as the number of records returned, as records can span multiple lines.

DictReader objects have the following public attribute:

csvreader.fieldnames

If not passed as a parameter when creating the object, this attribute is initialized upon first access or when the first record is read from the file.

14.1.4 Writer Objects

Writer objects (*DictWriter* instances and objects returned by the *writer()* function) have the following public methods. A *row* must be an iterable of strings or numbers for *Writer* objects and a dictionary mapping fieldnames to strings or numbers (by passing them through *str()* first) for *DictWriter* objects. Note that complex numbers are written out surrounded by parens. This may cause some problems for other programs which read CSV files (assuming they support complex numbers at all).

csvwriter.writerow(row)

Write the *row* parameter to the writer's file object, formatted according to the current *Dialect*. Return the return value of the call to the *write* method of the underlying file object.

Άλλαξε στην έκδοση 3.5: Added support of arbitrary iterables.

csvwriter.writerows(rows)

Write all elements in *rows* (an iterable of *row* objects as described above) to the writer's file object, formatted according to the current dialect.

Writer objects have the following public attribute:

csvwriter.dialect

A read-only description of the dialect in use by the writer.

DictWriter objects have the following public method:

`DictWriter.writeheader()`

Write a row with the field names (as specified in the constructor) to the writer's file object, formatted according to the current dialect. Return the return value of the `csvwriter.writerow()` call used internally.

Νέο στην έκδοση 3.2.

Άλλαξε στην έκδοση 3.8: `writeheader()` now also returns the value returned by the `csvwriter.writerow()` method it uses internally.

14.1.5 Examples

The simplest example of reading a CSV file:

```
import csv
with open('some.csv', newline='') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

Reading a file with an alternate format:

```
import csv
with open('passwd', newline='') as f:
    reader = csv.reader(f, delimiter=':', quoting=csv.QUOTE_NONE)
    for row in reader:
        print(row)
```

The corresponding simplest possible writing example is:

```
import csv
with open('some.csv', 'w', newline='') as f:
    writer = csv.writer(f)
    writer.writerows(someiterable)
```

Since `open()` is used to open a CSV file for reading, the file will by default be decoded into unicode using the system default encoding (see `locale.getpreferredencoding()`). To decode a file using a different encoding, use the encoding argument of `open`:

```
import csv
with open('some.csv', newline='', encoding='utf-8') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

The same applies to writing in something other than the system default encoding: specify the encoding argument when opening the output file.

Registering a new dialect:

```
import csv
csv.register_dialect('unixpwd', delimiter=':', quoting=csv.QUOTE_NONE)
with open('passwd', newline='') as f:
    reader = csv.reader(f, 'unixpwd')
```

A slightly more advanced use of the reader — catching and reporting errors:

```
import csv, sys
filename = 'some.csv'
with open(filename, newline='') as f:
    reader = csv.reader(f)
    try:
        for row in reader:
            print(row)
    except csv.Error as e:
        sys.exit('file {}, line {}: {}'.format(filename, reader.line_num, e))
```

And while the module doesn't directly support parsing strings, it can easily be done:

```
import csv
for row in csv.reader(['one,two,three']):
    print(row)
```

14.2 configparser — Configuration file parser

Source code: [Lib/configparser.py](#)

This module provides the *ConfigParser* class which implements a basic configuration language which provides a structure similar to what's found in Microsoft Windows INI files. You can use this to write Python programs which can be customized by end users easily.

Σημείωση: This library does *not* interpret or write the value-type prefixes used in the Windows Registry extended version of INI syntax.

Δείτε επίσης:

Module *shlex* Support for creating Unix shell-like mini-languages which can be used as an alternate format for application configuration files.

Module *json* The json module implements a subset of JavaScript syntax which can also be used for this purpose.

14.2.1 Quick Start

Let's take a very basic configuration file that looks like this:

```
[DEFAULT]
ServerAliveInterval = 45
Compression = yes
CompressionLevel = 9
ForwardX11 = yes

[bitbucket.org]
User = hg

[topsecret.server.com]
Port = 50022
ForwardX11 = no
```

The structure of INI files is described *in the following section*. Essentially, the file consists of sections, each of which contains keys with values. `configparser` classes can read and write such files. Let's start by creating the above configuration file programmatically.

```
>>> import configparser
>>> config = configparser.ConfigParser()
>>> config['DEFAULT'] = {'ServerAliveInterval': '45',
...                     'Compression': 'yes',
...                     'CompressionLevel': '9'}
>>> config['bitbucket.org'] = {}
>>> config['bitbucket.org']['User'] = 'hg'
>>> config['topsecret.server.com'] = {}
>>> topsecret = config['topsecret.server.com']
>>> topsecret['Port'] = '50022'      # mutates the parser
>>> topsecret['ForwardX11'] = 'no'  # same here
>>> config['DEFAULT']['ForwardX11'] = 'yes'
>>> with open('example.ini', 'w') as configfile:
...     config.write(configfile)
...
>>>
```

As you can see, we can treat a config parser much like a dictionary. There are differences, *outlined later*, but the behavior is very close to what you would expect from a dictionary.

Now that we have created and saved a configuration file, let's read it back and explore the data it holds.

```
>>> config = configparser.ConfigParser()
>>> config.sections()
[]
>>> config.read('example.ini')
['example.ini']
>>> config.sections()
['bitbucket.org', 'topsecret.server.com']
>>> 'bitbucket.org' in config
True
>>> 'bytebong.com' in config
False
>>> config['bitbucket.org']['User']
'hg'
>>> config['DEFAULT']['Compression']
'yes'
>>> topsecret = config['topsecret.server.com']
>>> topsecret['ForwardX11']
'no'
>>> topsecret['Port']
'50022'
>>> for key in config['bitbucket.org']:
...     print(key)
user
compressionlevel
serveraliveinterval
compression
forwardx11
>>> config['bitbucket.org']['ForwardX11']
'yes'
```

As we can see above, the API is pretty straightforward. The only bit of magic involves the `DEFAULT` section which provides default values for all other sections¹. Note also that keys in sections are case-insensitive and stored in lowercase¹.

¹ Config parsers allow for heavy customization. If you are interested in changing the behaviour outlined by the footnote reference, consult the

14.2.2 Supported Datatypes

Config parsers do not guess datatypes of values in configuration files, always storing them internally as strings. This means that if you need other datatypes, you should convert on your own:

```
>>> int(topsecret['Port'])
50022
>>> float(topsecret['CompressionLevel'])
9.0
```

Since this task is so common, config parsers provide a range of handy getter methods to handle integers, floats and booleans. The last one is the most interesting because simply passing the value to `bool()` would do no good since `bool('False')` is still `True`. This is why config parsers also provide `getboolean()`. This method is case-insensitive and recognizes Boolean values from `'yes'/'no'`, `'on'/'off'`, `'true'/'false'` and `'1'/'0'`¹. For example:

```
>>> topsecret.getboolean('ForwardX11')
False
>>> config['bitbucket.org'].getboolean('ForwardX11')
True
>>> config.getboolean('bitbucket.org', 'Compression')
True
```

Apart from `getboolean()`, config parsers also provide equivalent `getint()` and `getfloat()` methods. You can register your own converters and customize the provided ones.¹

14.2.3 Fallback Values

As with a dictionary, you can use a section's `get()` method to provide fallback values:

```
>>> topsecret.get('Port')
'50022'
>>> topsecret.get('CompressionLevel')
'9'
>>> topsecret.get('Cipher')
>>> topsecret.get('Cipher', '3des-cbc')
'3des-cbc'
```

Please note that default values have precedence over fallback values. For instance, in our example the `'CompressionLevel'` key was specified only in the `'DEFAULT'` section. If we try to get it from the section `'topsecret.server.com'`, we will always get the default, even if we specify a fallback:

```
>>> topsecret.get('CompressionLevel', '3')
'9'
```

One more thing to be aware of is that the parser-level `get()` method provides a custom, more complex interface, maintained for backwards compatibility. When using this method, a fallback value can be provided via the `fallback` keyword-only argument:

```
>>> config.get('bitbucket.org', 'monster',
...           fallback='No such things as monsters')
'No such things as monsters'
```

The same fallback argument can be used with the `getint()`, `getfloat()` and `getboolean()` methods, for example:

Customizing Parser Behaviour section.

```
>>> 'BatchMode' in topsecret
False
>>> topsecret.getboolean('BatchMode', fallback=True)
True
>>> config['DEFAULT']['BatchMode'] = 'no'
>>> topsecret.getboolean('BatchMode', fallback=True)
False
```

14.2.4 Supported INI File Structure

A configuration file consists of sections, each led by a `[section]` header, followed by key/value entries separated by a specific string (= or : by default¹). By default, section names are case sensitive but keys are not¹. Leading and trailing whitespace is removed from keys and values. Values can be omitted if the parser is configured to allow it¹, in which case the key/value delimiter may also be left out. Values can also span multiple lines, as long as they are indented deeper than the first line of the value. Depending on the parser's mode, blank lines may be treated as parts of multiline values or ignored.

By default, a valid section name can be any string that does not contain “\n” or “[”. To change this, see *ConfigParser.SECTCRE*.

Configuration files may include comments, prefixed by specific characters (# and ; by default¹). Comments may appear on their own on an otherwise empty line, possibly indented.¹

For example:

```
[Simple Values]
key=value
spaces in keys=allowed
spaces in values=allowed as well
spaces around the delimiter = obviously
you can also use : to delimit keys from values

[All Values Are Strings]
values like this: 1000000
or this: 3.14159265359
are they treated as numbers? : no
integers, floats and booleans are held as: strings
can use the API to get converted values directly: true

[Multiline Values]
chorus: I'm a lumberjack, and I'm okay
      I sleep all night and I work all day

[No Values]
key_without_value
empty string value here =

[You can use comments]
# like this
; or this

# By default only in an empty line.
# Inline comments can be harmful because they prevent users
# from using the delimiting characters as parts of values.
# That being said, this can be customized.
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
[Sections Can Be Indented]
can_values_be_as_well = True
does_that_mean_anything_special = False
purpose = formatting for readability
multiline_values = are
    handled just fine as
    long as they are indented
    deeper than the first line
    of a value
# Did I mention we can indent comments, too?
```

14.2.5 Interpolation of values

On top of the core functionality, *ConfigParser* supports interpolation. This means values can be preprocessed before returning them from `get()` calls.

class `configparser.BasicInterpolation`

The default implementation used by *ConfigParser*. It enables values to contain format strings which refer to other values in the same section, or values in the special default section¹. Additional default values can be provided on initialization.

For example:

```
[Paths]
home_dir: /Users
my_dir: %(home_dir)s/lumberjack
my_pictures: %(my_dir)s/Pictures

[Escape]
# use a %% to escape the % sign (% is the only character that needs to be_
↳ escaped):
gain: 80%%
```

In the example above, *ConfigParser* with *interpolation* set to `BasicInterpolation()` would resolve `%(home_dir)s` to the value of `home_dir` (`/Users` in this case). `%(my_dir)s` in effect would resolve to `/Users/lumberjack`. All interpolations are done on demand so keys used in the chain of references do not have to be specified in any specific order in the configuration file.

With *interpolation* set to `None`, the parser would simply return `%(my_dir)s/Pictures` as the value of `my_pictures` and `%(home_dir)s/lumberjack` as the value of `my_dir`.

class `configparser.ExtendedInterpolation`

An alternative handler for interpolation which implements a more advanced syntax, used for instance in `zc.buildout`. Extended interpolation is using `${section:option}` to denote a value from a foreign section. Interpolation can span multiple levels. For convenience, if the `section:` part is omitted, interpolation defaults to the current section (and possibly the default values from the special section).

For example, the configuration specified above with basic interpolation, would look like this with extended interpolation:

```
[Paths]
home_dir: /Users
my_dir: ${home_dir}/lumberjack
my_pictures: ${my_dir}/Pictures
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
[Escape]
# use a $$ to escape the $ sign ($ is the only character that needs to be_
↪escaped):
cost: $$80
```

Values from other sections can be fetched as well:

```
[Common]
home_dir: /Users
library_dir: /Library
system_dir: /System
macports_dir: /opt/local

[Frameworks]
Python: 3.2
path: ${Common:system_dir}/Library/Frameworks/

[Arthur]
nickname: Two Sheds
last_name: Jackson
my_dir: ${Common:home_dir}/twosheds
my_pictures: ${my_dir}/Pictures
python_dir: ${Frameworks:path}/Python/Versions/${Frameworks:Python}
```

14.2.6 Mapping Protocol Access

Νέο στην έκδοση 3.2.

Mapping protocol access is a generic name for functionality that enables using custom objects as if they were dictionaries. In case of *configparser*, the mapping interface implementation is using the `parser['section']['option']` notation.

`parser['section']` in particular returns a proxy for the section's data in the parser. This means that the values are not copied but they are taken from the original parser on demand. What's even more important is that when values are changed on a section proxy, they are actually mutated in the original parser.

configparser objects behave as close to actual dictionaries as possible. The mapping interface is complete and adheres to the *MutableMapping* ABC. However, there are a few differences that should be taken into account:

- By default, all keys in sections are accessible in a case-insensitive manner¹. E.g. for `option` in `parser["section"]` yields only `optionxformed` option key names. This means lowercased keys by default. At the same time, for a section that holds the key `'a'`, both expressions return `True`:

```
"a" in parser["section"]
"A" in parser["section"]
```

- All sections include `DEFAULTSECT` values as well which means that `.clear()` on a section may not leave the section visibly empty. This is because default values cannot be deleted from the section (because technically they are not there). If they are overridden in the section, deleting causes the default value to be visible again. Trying to delete a default value causes a *KeyError*.
- `DEFAULTSECT` cannot be removed from the parser:
 - trying to delete it raises *ValueError*,
 - `parser.clear()` leaves it intact,

- `parser.popitem()` never returns it.

- `parser.get(section, option, **kwargs)` - the second argument is **not** a fallback value. Note however that the section-level `get()` methods are compatible both with the mapping protocol and the classic `configparser` API.
- `parser.items()` is compatible with the mapping protocol (returns a list of *section_name*, *section_proxy* pairs including the `DEFAULTSECT`). However, this method can also be invoked with arguments: `parser.items(section, raw, vars)`. The latter call returns a list of *option*, *value* pairs for a specified *section*, with all interpolations expanded (unless `raw=True` is provided).

The mapping protocol is implemented on top of the existing legacy API so that subclasses overriding the original interface still should have mappings working as expected.

14.2.7 Customizing Parser Behaviour

There are nearly as many INI format variants as there are applications using it. `configparser` goes a long way to provide support for the largest sensible set of INI styles available. The default functionality is mainly dictated by historical background and it's very likely that you will want to customize some of the features.

The most common way to change the way a specific config parser works is to use the `__init__()` options:

- *defaults*, default value: `None`

This option accepts a dictionary of key-value pairs which will be initially put in the `DEFAULT` section. This makes for an elegant way to support concise configuration files that don't specify values which are the same as the documented default.

Hint: if you want to specify default values for a specific section, use `read_dict()` before you read the actual file.

- *dict_type*, default value: `dict`

This option has a major impact on how the mapping protocol will behave and how the written configuration files look. With the standard dictionary, every section is stored in the order they were added to the parser. Same goes for options within sections.

An alternative dictionary type can be used for example to sort sections and options on write-back.

Please note: there are ways to add a set of key-value pairs in a single operation. When you use a regular dictionary in those operations, the order of the keys will be ordered. For example:

```
>>> parser = configparser.ConfigParser()
>>> parser.read_dict({'section1': {'key1': 'value1',
...                               'key2': 'value2',
...                               'key3': 'value3'},
...                  'section2': {'keyA': 'valueA',
...                               'keyB': 'valueB',
...                               'keyC': 'valueC'},
...                  'section3': {'foo': 'x',
...                               'bar': 'y',
...                               'baz': 'z'}})
>>> parser.sections()
['section1', 'section2', 'section3']
>>> [option for option in parser['section3']]
['foo', 'bar', 'baz']
```

- *allow_no_value*, default value: `False`

Some configuration files are known to include settings without values, but which otherwise conform to the syntax supported by `configparser`. The `allow_no_value` parameter to the constructor can be used to indicate that such values should be accepted:

```
>>> import configparser

>>> sample_config = """
... [mysqld]
...     user = mysql
...     pid-file = /var/run/mysqld/mysqld.pid
...     skip-external-locking
...     old_passwords = 1
...     skip-bdb
...     # we don't need ACID today
...     skip-innodb
... """
>>> config = configparser.ConfigParser(allow_no_value=True)
>>> config.read_string(sample_config)

>>> # Settings with values are treated as before:
>>> config["mysqld"]["user"]
'mysql'

>>> # Settings without values provide None:
>>> config["mysqld"]["skip-bdb"]

>>> # Settings which aren't specified still raise an error:
>>> config["mysqld"]["does-not-exist"]
Traceback (most recent call last):
...
KeyError: 'does-not-exist'
```

- `delimiters`, default value: `('=', ':')`

Delimiters are substrings that delimit keys from values within a section. The first occurrence of a delimiting substring on a line is considered a delimiter. This means values (but not keys) can contain the delimiters.

See also the `space_around_delimiters` argument to `ConfigParser.write()`.

- `comment_prefixes`, default value: `(' # ', ';')`
- `inline_comment_prefixes`, default value: `None`

Comment prefixes are strings that indicate the start of a valid comment within a config file. `comment_prefixes` are used only on otherwise empty lines (optionally indented) whereas `inline_comment_prefixes` can be used after every valid value (e.g. section names, options and empty lines as well). By default inline comments are disabled and `' # '` and `' ; '` are used as prefixes for whole line comments.

Αλλάξε στην έκδοση 3.2: In previous versions of `configparser` behaviour matched `comment_prefixes=(' # ', ';')` and `inline_comment_prefixes=(' ; ',)`.

Please note that config parsers don't support escaping of comment prefixes so using `inline_comment_prefixes` may prevent users from specifying option values with characters used as comment prefixes. When in doubt, avoid setting `inline_comment_prefixes`. In any circumstances, the only way of storing comment prefix characters at the beginning of a line in multiline values is to interpolate the prefix, for example:

```
>>> from configparser import ConfigParser, ExtendedInterpolation
>>> parser = ConfigParser(interpolation=ExtendedInterpolation())
>>> # the default BasicInterpolation could be used as well
>>> parser.read_string("""
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

... [DEFAULT]
... hash = #
...
... [hashes]
... shebang =
...     ${hash}#!/usr/bin/env python
...     ${hash} -*- coding: utf-8 -*-
...
... extensions =
...     enabled_extension
...     another_extension
...     #disabled_by_comment
...     yet_another_extension
...
... interpolation not necessary = if # is not at line start
... even in multiline values = line #1
...     line #2
...     line #3
...     """
>>> print(parser['hashes']['shebang'])

#!/usr/bin/env python
# -*- coding: utf-8 -*-
>>> print(parser['hashes']['extensions'])

enabled_extension
another_extension
yet_another_extension
>>> print(parser['hashes']['interpolation not necessary'])
if # is not at line start
>>> print(parser['hashes']['even in multiline values'])
line #1
line #2
line #3

```

- *strict*, default value: True

When set to True, the parser will not allow for any section or option duplicates while reading from a single source (using `read_file()`, `read_string()` or `read_dict()`). It is recommended to use strict parsers in new applications.

Αλλάξε στην έκδοση 3.2: In previous versions of *configparser* behaviour matched `strict=False`.

- *empty_lines_in_values*, default value: True

In config parsers, values can span multiple lines as long as they are indented more than the key that holds them. By default parsers also let empty lines to be parts of values. At the same time, keys can be arbitrarily indented themselves to improve readability. In consequence, when configuration files get big and complex, it is easy for the user to lose track of the file structure. Take for instance:

```

[Section]
key = multiline
    value with a gotcha

    this = is still a part of the multiline value of 'key'

```

This can be especially problematic for the user to see if she's using a proportional font to edit the file. That is why when your application does not need values with empty lines, you should consider disallowing them. This will make

empty lines split keys every time. In the example above, it would produce two keys, `key` and `this`.

- *default_section*, default value: `configparser.DEFAULTSECT` (that is: "DEFAULT")

The convention of allowing a special section of default values for other sections or interpolation purposes is a powerful concept of this library, letting users create complex declarative configurations. This section is normally called "DEFAULT" but this can be customized to point to any other valid section name. Some typical values include: "general" or "common". The name provided is used for recognizing default sections when reading from any source and is used when writing configuration back to a file. Its current value can be retrieved using the `parser_instance.default_section` attribute and may be modified at runtime (i.e. to convert files from one format to another).

- *interpolation*, default value: `configparser.BasicInterpolation`

Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. None can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the [dedicated documentation section](#). `RawConfigParser` has a default value of None.

- *converters*, default value: not set

Config parsers provide option value getters that perform type conversion. By default `getint()`, `getfloat()`, and `getboolean()` are implemented. Should other getters be desirable, users may define them in a subclass or pass a dictionary where each key is a name of the converter and each value is a callable implementing said conversion. For instance, passing `{'decimal': decimal.Decimal}` would add `getdecimal()` on both the parser object and all section proxies. In other words, it will be possible to write both `parser_instance.getdecimal('section', 'key', fallback=0)` and `parser_instance['section'].getdecimal('key', 0)`.

If the converter needs to access the state of the parser, it can be implemented as a method on a config parser subclass. If the name of this method starts with `get`, it will be available on all section proxies, in the dict-compatible form (see the `getdecimal()` example above).

More advanced customization may be achieved by overriding default values of these parser attributes. The defaults are defined on the classes, so they may be overridden by subclasses or by attribute assignment.

`ConfigParser.BOOLEAN_STATES`

By default when using `getboolean()`, config parsers consider the following values True: '1', 'yes', 'true', 'on' and the following values False: '0', 'no', 'false', 'off'. You can override this by specifying a custom dictionary of strings and their Boolean outcomes. For example:

```
>>> custom = configparser.ConfigParser()
>>> custom['section1'] = {'funky': 'nope'}
>>> custom['section1'].getboolean('funky')
Traceback (most recent call last):
...
ValueError: Not a boolean: nope
>>> custom.BOOLEAN_STATES = {'sure': True, 'nope': False}
>>> custom['section1'].getboolean('funky')
False
```

Other typical Boolean pairs include `accept/reject` or `enabled/disabled`.

`ConfigParser.optionxform(option)`

This method transforms option names on every read, get, or set operation. The default converts the name to lowercase. This also means that when a configuration file gets written, all keys will be lowercase. Override this method if that's unsuitable. For example:

```
>>> config = """
... [Section1]
... Key = Value
...
... [Section2]
... AnotherKey = Value
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> list(typical['Section1'].keys())
['key']
>>> list(typical['Section2'].keys())
['anotherkey']
>>> custom = configparser.RawConfigParser()
>>> custom.optionxform = lambda option: option
>>> custom.read_string(config)
>>> list(custom['Section1'].keys())
['Key']
>>> list(custom['Section2'].keys())
['AnotherKey']
```

Σημείωση: The optionxform function transforms option names to a canonical form. This should be an idempotent function: if the name is already in canonical form, it should be returned unchanged.

ConfigParser.SECTCRE

A compiled regular expression used to parse section headers. The default matches `[section]` to the name "section". Whitespace is considered part of the section name, thus `[larch]` will be read as a section of name " larch ". Override this attribute if that's unsuitable. For example:

```
>>> import re
>>> config = """
... [Section 1]
... option = value
...
... [ Section 2 ]
... another = val
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> typical.sections()
['Section 1', ' Section 2 ']
>>> custom = configparser.ConfigParser()
>>> custom.SECTCRE = re.compile(r"\[ *(?P<header>[^\]]+?) *\]")
>>> custom.read_string(config)
>>> custom.sections()
['Section 1', 'Section 2']
```

Σημείωση: While ConfigParser objects also use an OPTCRE attribute for recognizing option lines, it's not recommended to override it because that would interfere with constructor options *allow_no_value* and *delimiters*.

14.2.8 Legacy API Examples

Mainly because of backwards compatibility concerns, `configparser` provides also a legacy API with explicit get/set methods. While there are valid use cases for the methods outlined below, mapping protocol access is preferred for new projects. The legacy API is at times more advanced, low-level and downright counterintuitive.

An example of writing to a configuration file:

```
import configparser

config = configparser.RawConfigParser()

# Please note that using RawConfigParser's set functions, you can assign
# non-string values to keys internally, but will receive an error when
# attempting to write to a file or when you get it in non-row mode. Setting
# values using the mapping protocol or ConfigParser's set() does not allow
# such assignments to take place.
config.add_section('Section1')
config.set('Section1', 'an_int', '15')
config.set('Section1', 'a_bool', 'true')
config.set('Section1', 'a_float', '3.1415')
config.set('Section1', 'baz', 'fun')
config.set('Section1', 'bar', 'Python')
config.set('Section1', 'foo', '%(bar)s is %(baz)s!')

# Writing our configuration file to 'example.cfg'
with open('example.cfg', 'w') as configfile:
    config.write(configfile)
```

An example of reading the configuration file again:

```
import configparser

config = configparser.RawConfigParser()
config.read('example.cfg')

# getfloat() raises an exception if the value is not a float
# getint() and getboolean() also do this for their respective types
a_float = config.getfloat('Section1', 'a_float')
an_int = config.getint('Section1', 'an_int')
print(a_float + an_int)

# Notice that the next output does not interpolate '%(bar)s' or '%(baz)s'.
# This is because we are using a RawConfigParser().
if config.getboolean('Section1', 'a_bool'):
    print(config.get('Section1', 'foo'))
```

To get interpolation, use `ConfigParser`:

```
import configparser

cfg = configparser.ConfigParser()
cfg.read('example.cfg')

# Set the optional *raw* argument of get() to True if you wish to disable
# interpolation in a single get operation.
print(cfg.get('Section1', 'foo', raw=False))  # -> "Python is fun!"
print(cfg.get('Section1', 'foo', raw=True))  # -> "%(bar)s is %(baz)s!"
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
# The optional *vars* argument is a dict with members that will take
# precedence in interpolation.
print(cfg.get('Section1', 'foo', vars={'bar': 'Documentation',
                                       'baz': 'evil'}))

# The optional *fallback* argument can be used to provide a fallback value
print(cfg.get('Section1', 'foo'))
# -> "Python is fun!"

print(cfg.get('Section1', 'foo', fallback='Monty is not.'))
# -> "Python is fun!"

print(cfg.get('Section1', 'monster', fallback='No such things as monsters.'))
# -> "No such things as monsters."

# A bare print(cfg.get('Section1', 'monster')) would raise NoOptionError
# but we can also use:

print(cfg.get('Section1', 'monster', fallback=None))
# -> None
```

Default values are available in both types of ConfigParsers. They are used in interpolation if an option used is not defined elsewhere.

```
import configparser

# New instance with 'bar' and 'baz' defaulting to 'Life' and 'hard' each
config = configparser.ConfigParser({'bar': 'Life', 'baz': 'hard'})
config.read('example.cfg')

print(config.get('Section1', 'foo'))      # -> "Python is fun!"
config.remove_option('Section1', 'bar')
config.remove_option('Section1', 'baz')
print(config.get('Section1', 'foo'))      # -> "Life is hard!"
```

14.2.9 ConfigParser Objects

```
class configparser.ConfigParser (defaults=None, dict_type=dict, allow_no_value=False,
                                delimiters=('=', ':'), comment_prefixes=(';', '#'),
                                inline_comment_prefixes=None,
                                strict=True, empty_lines_in_values=True,
                                default_section=configparser.DEFAULTSECT,
                                interpolation=BasicInterpolation(), converters={})
```

The main configuration parser. When *defaults* is given, it is initialized into the dictionary of intrinsic defaults. When *dict_type* is given, it will be used to create the dictionary objects for the list of sections, for the options within a section, and for the default values.

When *delimiters* is given, it is used as the set of substrings that divide keys from values. When *comment_prefixes* is given, it will be used as the set of substrings that prefix comments in otherwise empty lines. Comments can be indented. When *inline_comment_prefixes* is given, it will be used as the set of substrings that prefix comments in non-empty lines.

When *strict* is *True* (the default), the parser won't allow for any section or option duplicates while reading from a single source (file, string or dictionary), raising *DuplicateSectionError* or *DuplicateOptionError*.

When *empty_lines_in_values* is `False` (default: `True`), each empty line marks the end of an option. Otherwise, internal empty lines of a multiline option are kept as part of the value. When *allow_no_value* is `True` (default: `False`), options without values are accepted; the value held for these is `None` and they are serialized without the trailing delimiter.

When *default_section* is given, it specifies the name for the special section holding default values for other sections and interpolation purposes (normally named "DEFAULT"). This value can be retrieved and changed on runtime using the *default_section* instance attribute.

Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. `None` can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the [dedicated documentation section](#).

All option names used in interpolation will be passed through the *optionxform()* method just like any other option name reference. For example, using the default implementation of *optionxform()* (which converts option names to lower case), the values `foo %(bar) s` and `foo %(BAR) s` are equivalent.

When *converters* is given, it should be a dictionary where each key represents the name of a type converter and each value is a callable implementing the conversion from string to the desired datatype. Every converter gets its own corresponding *get*()* method on the parser object and section proxies.

Άλλαξε στην έκδοση 3.1: The default *dict_type* is `collections.OrderedDict`.

Άλλαξε στην έκδοση 3.2: *allow_no_value*, *delimiters*, *comment_prefixes*, *strict*, *empty_lines_in_values*, *default_section* and *interpolation* were added.

Άλλαξε στην έκδοση 3.5: The *converters* argument was added.

Άλλαξε στην έκδοση 3.7: The *defaults* argument is read with *read_dict()*, providing consistent behavior across the parser: non-string keys and values are implicitly converted to strings.

Άλλαξε στην έκδοση 3.8: The default *dict_type* is `dict`, since it now preserves insertion order.

defaults()

Return a dictionary containing the instance-wide defaults.

sections()

Return a list of the sections available; the *default section* is not included in the list.

add_section(section)

Add a section named *section* to the instance. If a section by the given name already exists, `DuplicateSectionError` is raised. If the *default section* name is passed, `ValueError` is raised. The name of the section must be a string; if not, `TypeError` is raised.

Άλλαξε στην έκδοση 3.2: Non-string section names raise `TypeError`.

has_section(section)

Indicates whether the named *section* is present in the configuration. The *default section* is not acknowledged.

options(section)

Return a list of options available in the specified *section*.

has_option(section, option)

If the given *section* exists, and contains the given *option*, return `True`; otherwise return `False`. If the specified *section* is `None` or an empty string, `DEFAULT` is assumed.

read(filename, encoding=None)

Attempt to read and parse an iterable of filenames, returning a list of filenames which were successfully parsed.

If *filenames* is a string, a `bytes` object or a *path-like object*, it is treated as a single filename. If a file named in *filenames* cannot be opened, that file will be ignored. This is designed so that you can specify an iterable of

potential configuration file locations (for example, the current directory, the user's home directory, and some system-wide directory), and all existing configuration files in the iterable will be read.

If none of the named files exist, the `ConfigParser` instance will contain an empty dataset. An application which requires initial values to be loaded from a file should load the required file or files using `read_file()` before calling `read()` for any optional files:

```
import configparser, os

config = configparser.ConfigParser()
config.read_file(open('defaults.cfg'))
config.read(['site.cfg', os.path.expanduser('~/.myapp.cfg')],
            encoding='cp1250')
```

Νέο στην έκδοση 3.2: The `encoding` parameter. Previously, all files were read using the default encoding for `open()`.

Νέο στην έκδοση 3.6.1: The `filenames` parameter accepts a *path-like object*.

Νέο στην έκδοση 3.7: The `filenames` parameter accepts a *bytes* object.

read_file (*f*, *source=None*)

Read and parse configuration data from *f* which must be an iterable yielding Unicode strings (for example files opened in text mode).

Optional argument *source* specifies the name of the file being read. If not given and *f* has a `name` attribute, that is used for *source*; the default is '`<???`'.

Νέο στην έκδοση 3.2: Replaces `readfp()`.

read_string (*string*, *source=<string>*)

Parse configuration data from a string.

Optional argument *source* specifies a context-specific name of the string passed. If not given, '`<string>`' is used. This should commonly be a filesystem path or a URL.

Νέο στην έκδοση 3.2.

read_dict (*dictionary*, *source=<dict>*)

Load configuration from any object that provides a `dict-like items()` method. Keys are section names, values are dictionaries with keys and values that should be present in the section. If the used dictionary type preserves order, sections and their keys will be added in order. Values are automatically converted to strings.

Optional argument *source* specifies a context-specific name of the dictionary passed. If not given, `<dict>` is used.

This method can be used to copy state between parsers.

Νέο στην έκδοση 3.2.

get (*section*, *option*, *, *raw=False*, *vars=None* [, *fallback*])

Get an *option* value for the named *section*. If *vars* is provided, it must be a dictionary. The *option* is looked up in *vars* (if provided), *section*, and in `DEFAULTSECT` in that order. If the key is not found and *fallback* is provided, it is used as a fallback value. `None` can be provided as a *fallback* value.

All the '`%`' interpolations are expanded in the return values, unless the *raw* argument is true. Values for interpolation keys are looked up in the same manner as the *option*.

Αλλαξε στην έκδοση 3.2: Arguments *raw*, *vars* and *fallback* are keyword only to protect users from trying to use the third argument as the *fallback* fallback (especially when using the mapping protocol).

getint (*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to an integer. See [get\(\)](#) for explanation of *raw*, *vars* and *fallback*.

getfloat (*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to a floating point number. See [get\(\)](#) for explanation of *raw*, *vars* and *fallback*.

getboolean (*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to a Boolean value. Note that the accepted values for the option are '1', 'yes', 'true', and 'on', which cause this method to return True, and '0', 'no', 'false', and 'off', which cause it to return False. These string values are checked in a case-insensitive manner. Any other value will cause it to raise [ValueError](#). See [get\(\)](#) for explanation of *raw*, *vars* and *fallback*.

items (*raw=False*, *vars=None*)

items (*section*, *raw=False*, *vars=None*)

When *section* is not given, return a list of *section_name*, *section_proxy* pairs, including DEFAULTSECT.

Otherwise, return a list of *name*, *value* pairs for the options in the given *section*. Optional arguments have the same meaning as for the [get\(\)](#) method.

Αλλάξε στην έκδοση 3.8: Items present in *vars* no longer appear in the result. The previous behaviour mixed actual parser options with variables provided for interpolation.

set (*section*, *option*, *value*)

If the given section exists, set the given option to the specified value; otherwise raise [NoSectionError](#). *option* and *value* must be strings; if not, [TypeError](#) is raised.

write (*fileobject*, *space_around_delimiters=True*)

Write a representation of the configuration to the specified *file object*, which must be opened in text mode (accepting strings). This representation can be parsed by a future [read\(\)](#) call. If *space_around_delimiters* is true, delimiters between keys and values are surrounded by spaces.

Σημείωση: Comments in the original configuration file are not preserved when writing the configuration back. What is considered a comment, depends on the given values for *comment_prefix* and *inline_comment_prefix*.

remove_option (*section*, *option*)

Remove the specified *option* from the specified *section*. If the section does not exist, raise [NoSectionError](#). If the option existed to be removed, return [True](#); otherwise return [False](#).

remove_section (*section*)

Remove the specified *section* from the configuration. If the section in fact existed, return True. Otherwise return False.

optionxform (*option*)

Transforms the option name *option* as found in an input file or as passed in by client code to the form that should be used in the internal structures. The default implementation returns a lower-case version of *option*; subclasses may override this or client code can set an attribute of this name on instances to affect this behavior.

You don't need to subclass the parser to use this method, you can also set it on an instance, to a function that takes a string argument and returns a string. Setting it to `str`, for example, would make option names case sensitive:

```
cfgparser = ConfigParser()
cfgparser.optionxform = str
```

Note that when reading configuration files, whitespace around the option names is stripped before `optionxform()` is called.

readfp (*fp*, *filename=None*)

Αποσύρθηκε στην έκδοση 3.2: Use `read_file()` instead.

Άλλαξε στην έκδοση 3.2: `readfp()` now iterates on *fp* instead of calling `fp.readline()`.

For existing code calling `readfp()` with arguments which don't support iteration, the following generator may be used as a wrapper around the file-like object:

```
def readline_generator(fp):
    line = fp.readline()
    while line:
        yield line
        line = fp.readline()
```

Instead of `parser.readfp(fp)` use `parser.read_file(readline_generator(fp))`.

`configparser.MAX_INTERPOLATION_DEPTH`

The maximum depth for recursive interpolation for `get()` when the *raw* parameter is false. This is relevant only when the default *interpolation* is used.

14.2.10 RawConfigParser Objects

```
class configparser.RawConfigParser (defaults=None, dict_type=dict, allow_no_value=False,
                                     *, delimiters=('=', ':'), comment_prefixes=(';',
                                     ';'), inline_comment_prefixes=None,
                                     strict=True, empty_lines_in_values=True,
                                     default_section=configparser.DEFAULTSECT[, interpolation
                                     ])
```

Legacy variant of the `ConfigParser`. It has interpolation disabled by default and allows for non-string section names, option names, and values via its unsafe `add_section` and `set` methods, as well as the legacy `defaults=` keyword argument handling.

Άλλαξε στην έκδοση 3.8: The default *dict_type* is `dict`, since it now preserves insertion order.

Σημείωση: Consider using `ConfigParser` instead which checks types of the values to be stored internally. If you don't want interpolation, you can use `ConfigParser(interpolation=None)`.

add_section (*section*)

Add a section named *section* to the instance. If a section by the given name already exists, `DuplicateSectionError` is raised. If the *default section* name is passed, `ValueError` is raised.

Type of *section* is not checked which lets users create non-string named sections. This behaviour is unsupported and may cause internal errors.

set (*section*, *option*, *value*)

If the given section exists, set the given option to the specified value; otherwise raise `NoSectionError`. While it is possible to use `RawConfigParser` (or `ConfigParser` with *raw* parameters set to true) for *internal* storage of non-string values, full functionality (including interpolation and output to files) can only be achieved using string values.

This method lets users assign non-string values to keys internally. This behaviour is unsupported and will cause errors when attempting to write to a file or get it in non-raw mode. **Use the mapping protocol API** which does not allow such assignments to take place.

14.2.11 Exceptions

exception `configparser.Error`

Base class for all other `configparser` exceptions.

exception `configparser.NoSectionError`

Exception raised when a specified section is not found.

exception `configparser.DuplicateSectionError`

Exception raised if `add_section()` is called with the name of a section that is already present or in strict parsers when a section is found more than once in a single input file, string or dictionary.

Νέο στην έκδοση 3.2: Optional `source` and `lineno` attributes and arguments to `__init__()` were added.

exception `configparser.DuplicateOptionError`

Exception raised by strict parsers if a single option appears twice during reading from a single file, string or dictionary. This catches misspellings and case sensitivity-related errors, e.g. a dictionary may have two keys representing the same case-insensitive configuration key.

exception `configparser.NoOptionError`

Exception raised when a specified option is not found in the specified section.

exception `configparser.InterpolationError`

Base class for exceptions raised when problems occur performing string interpolation.

exception `configparser.InterpolationDepthError`

Exception raised when string interpolation cannot be completed because the number of iterations exceeds `MAX_INTERPOLATION_DEPTH`. Subclass of `InterpolationError`.

exception `configparser.InterpolationMissingOptionError`

Exception raised when an option referenced from a value does not exist. Subclass of `InterpolationError`.

exception `configparser.InterpolationSyntaxError`

Exception raised when the source text into which substitutions are made does not conform to the required syntax. Subclass of `InterpolationError`.

exception `configparser.MissingSectionHeaderError`

Exception raised when attempting to parse a file which has no section headers.

exception `configparser.ParsingError`

Exception raised when errors occur attempting to parse a file.

Άλλαξε στην έκδοση 3.2: The `filename` attribute and `__init__()` argument were renamed to `source` for consistency.

14.3 netrc — netrc file processing

Source code: [Lib/netrc.py](#)

The `netrc` class parses and encapsulates the netrc file format used by the Unix `ftp` program and other FTP clients.

class `netrc.netrc([file])`

A `netrc` instance or subclass instance encapsulates data from a netrc file. The initialization argument, if present, specifies the file to parse. If no argument is given, the file `.netrc` in the user's home directory – as determined by `os.path.expanduser()` – will be read. Otherwise, a `FileNotFoundError` exception will be raised. Parse errors will raise `NetrcParseError` with diagnostic information including the file name, line number, and terminating token. If no argument is specified on a POSIX system, the presence of passwords in the `.netrc` file

will raise a `NetrcParseError` if the file ownership or permissions are insecure (owned by a user other than the user running the process, or accessible for read or write by any other user). This implements security behavior equivalent to that of ftp and other programs that use `.netrc`.

Άλλαξε στην έκδοση 3.4: Added the POSIX permission check.

Άλλαξε στην έκδοση 3.7: `os.path.expanduser()` is used to find the location of the `.netrc` file when *file* is not passed as argument.

exception `netrc.NetrcParseError`

Exception raised by the `netrc` class when syntactical errors are encountered in source text. Instances of this exception provide three interesting attributes: `msg` is a textual explanation of the error, `filename` is the name of the source file, and `lineno` gives the line number on which the error was found.

14.3.1 netrc Objects

A `netrc` instance has the following methods:

`netrc.authenticators(host)`

Return a 3-tuple (`login`, `account`, `password`) of authenticators for *host*. If the `netrc` file did not contain an entry for the given host, return the tuple associated with the “default” entry. If neither matching host nor default entry is available, return `None`.

`netrc.__repr__()`

Dump the class data as a string in the format of a `netrc` file. (This discards comments and may reorder the entries.)

Instances of `netrc` have public instance variables:

`netrc.hosts`

Dictionary mapping host names to (`login`, `account`, `password`) tuples. The “default” entry, if any, is represented as a pseudo-host by that name.

`netrc.macros`

Dictionary mapping macro names to string lists.

Σημείωση: Passwords are limited to a subset of the ASCII character set. All ASCII punctuation is allowed in passwords, however, note that whitespace and non-printable characters are not allowed in passwords. This is a limitation of the way the `.netrc` file is parsed and may be removed in the future.

14.4 plistlib — Generate and parse Apple .plist files

Source code: `Lib/plistlib.py`

This module provides an interface for reading and writing the «property list» files used by Apple, primarily on macOS and iOS. This module supports both binary and XML plist files.

The property list (`.plist`) file format is a simple serialization supporting basic object types, like dictionaries, lists, numbers and strings. Usually the top level object is a dictionary.

To write out and to parse a plist file, use the `dump()` and `load()` functions.

To work with plist data in bytes objects, use `dumps()` and `loads()`.

Values can be strings, integers, floats, booleans, tuples, lists, dictionaries (but only with string keys), `bytes`, `bytearray` or `datetime.datetime` objects.

Άλλαξε στην έκδοση 3.4: New API, old API deprecated. Support for binary format plists added.

Άλλαξε στην έκδοση 3.8: Support added for reading and writing *UID* tokens in binary plists as used by `NSKeyedArchiver` and `NSKeyedUnarchiver`.

Άλλαξε στην έκδοση 3.9: Old API removed.

Δείτε επίσης:

PList manual page Apple's documentation of the file format.

This module defines the following functions:

`plistlib.load(fp, *, fmt=None, dict_type=dict)`

Read a plist file. *fp* should be a readable and binary file object. Return the unpacked root object (which usually is a dictionary).

The *fmt* is the format of the file and the following values are valid:

- *None*: Autodetect the file format
- *FMT_XML*: XML file format
- *FMT_BINARY*: Binary plist format

The *dict_type* is the type used for dictionaries that are read from the plist file.

XML data for the *FMT_XML* format is parsed using the Expat parser from `xml.parsers.expat` – see its documentation for possible exceptions on ill-formed XML. Unknown elements will simply be ignored by the plist parser.

The parser for the binary format raises `InvalidFileException` when the file cannot be parsed.

Νέο στην έκδοση 3.4.

`plistlib.loads(data, *, fmt=None, dict_type=dict)`

Load a plist from a bytes object. See `load()` for an explanation of the keyword arguments.

Νέο στην έκδοση 3.4.

`plistlib.dump(value, fp, *, fmt=FMT_XML, sort_keys=True, skipkeys=False)`

Write *value* to a plist file. *Fp* should be a writable, binary file object.

The *fmt* argument specifies the format of the plist file and can be one of the following values:

- *FMT_XML*: XML formatted plist file
- *FMT_BINARY*: Binary formatted plist file

When *sort_keys* is true (the default) the keys for dictionaries will be written to the plist in sorted order, otherwise they will be written in the iteration order of the dictionary.

When *skipkeys* is false (the default) the function raises `TypeError` when a key of a dictionary is not a string, otherwise such keys are skipped.

A `TypeError` will be raised if the object is of an unsupported type or a container that contains objects of unsupported types.

An `OverflowError` will be raised for integer values that cannot be represented in (binary) plist files.

Νέο στην έκδοση 3.4.

`plistlib.dumps(value, *, fmt=FMT_XML, sort_keys=True, skipkeys=False)`

Return *value* as a plist-formatted bytes object. See the documentation for `dump()` for an explanation of the keyword arguments of this function.

Νέο στην έκδοση 3.4.

The following classes are available:

class plistlib.**UID** (*data*)

Wraps an *int*. This is used when reading or writing NSKeyedArchiver encoded data, which contains UID (see PList manual).

It has one attribute, *data*, which can be used to retrieve the int value of the UID. *data* must be in the range $0 \leq \text{data} < 2^{*64}$.

Νέο στην έκδοση 3.8.

The following constants are available:

plistlib.**FMT_XML**

The XML format for plist files.

Νέο στην έκδοση 3.4.

plistlib.**FMT_BINARY**

The binary format for plist files

Νέο στην έκδοση 3.4.

14.4.1 Examples

Generating a plist:

```
pl = dict(
    aString = "Doodah",
    aList = ["A", "B", 12, 32.1, [1, 2, 3]],
    aFloat = 0.1,
    anInt = 728,
    aDict = dict(
        anotherString = "<hello & hi there!>",
        aThirdString = "M\xe4ssig, Ma\xdf",
        aTrueValue = True,
        aFalseValue = False,
    ),
    someData = b"<binary gunk>",
    someMoreData = b"<lots of binary gunk>" * 10,
    aDate = datetime.datetime.fromtimestamp(time.mktime(time.gmtime()))),
)
with open(fileName, 'wb') as fp:
    dump(pl, fp)
```

Parsing a plist:

```
with open(fileName, 'rb') as fp:
    pl = load(fp)
    print(pl["aKey"])
```

Cryptographic Services

The modules described in this chapter implement various algorithms of a cryptographic nature. They are available at the discretion of the installation. On Unix systems, the *crypt* module may also be available. Here's an overview:

15.1 *hashlib* — Secure hashes and message digests

Source code: [Lib/hashlib.py](#)

This module implements a common interface to many different secure hash and message digest algorithms. Included are the FIPS secure hash algorithms SHA1, SHA224, SHA256, SHA384, and SHA512 (defined in FIPS 180-2) as well as RSA's MD5 algorithm (defined in Internet **RFC 1321**). The terms «secure hash» and «message digest» are interchangeable. Older algorithms were called message digests. The modern term is secure hash.

Σημείωση: If you want the *adler32* or *crc32* hash functions, they are available in the *zlib* module.

| |
|---|
| Προειδοποίηση: Some algorithms have known hash collision weaknesses, refer to the «See also» section at the end. |
|---|

15.1.1 Hash algorithms

There is one constructor method named for each type of *hash*. All return a hash object with the same simple interface. For example: use `sha256()` to create a SHA-256 hash object. You can now feed this object with *bytes-like objects* (normally *bytes*) using the `update()` method. At any point you can ask it for the *digest* of the concatenation of the data fed to it so far using the `digest()` or `hexdigest()` methods.

Σημείωση: For better multithreading performance, the Python *GIL* is released for data larger than 2047 bytes at object creation or on update.

Σημείωση: Feeding string objects into `update()` is not supported, as hashes work on bytes, not on characters.

Constructors for hash algorithms that are always present in this module are `sha1()`, `sha224()`, `sha256()`, `sha384()`, `sha512()`, `blake2b()`, and `blake2s()`. `md5()` is normally available as well, though it may be missing or blocked if you are using a rare «FIPS compliant» build of Python. Additional algorithms may also be available depending upon the OpenSSL library that Python uses on your platform. On most platforms the `sha3_224()`, `sha3_256()`, `sha3_384()`, `sha3_512()`, `shake_128()`, `shake_256()` are also available.

Νέο στην έκδοση 3.6: SHA3 (Keccak) and SHAKE constructors `sha3_224()`, `sha3_256()`, `sha3_384()`, `sha3_512()`, `shake_128()`, `shake_256()`.

Νέο στην έκδοση 3.6: `blake2b()` and `blake2s()` were added. Άλλαξε στην έκδοση 3.9: All hashlib constructors take a keyword-only argument *usedforsecurity* with default value `True`. A false value allows the use of insecure and blocked hashing algorithms in restricted environments. `False` indicates that the hashing algorithm is not used in a security context, e.g. as a non-cryptographic one-way compression function.

Hashlib now uses SHA3 and SHAKE from OpenSSL 1.1.1 and newer.

For example, to obtain the digest of the byte string `b'Nobody inspects the spammish repetition'`:

```
>>> import hashlib
>>> m = hashlib.sha256()
>>> m.update(b"Nobody inspects")
>>> m.update(b" the spammish repetition")
>>> m.digest()
b'\x03\x1e\xddAe\x15\x93\xc5\xfe\\\x00o\xa5u+7\xfd\xdf\xfd\x7\xbcN\x84:\xa6\xaf\x0c\x95\
↪x0fK\x94\x06'
>>> m.digest_size
32
>>> m.block_size
64
```

More condensed:

```
>>> hashlib.sha224(b"Nobody inspects the spammish repetition").hexdigest()
'a4337bc45a8fc544c03f52dc550cd6e1e87021bc896588bd79e901e2'
```

`hashlib.new(name[, data], *, usedforsecurity=True)`

Is a generic constructor that takes the string *name* of the desired algorithm as its first parameter. It also exists to allow access to the above listed hashes as well as any other algorithms that your OpenSSL library may offer. The named constructors are much faster than `new()` and should be preferred.

Using `new()` with an algorithm provided by OpenSSL:

```
>>> h = hashlib.new('sha256')
>>> h.update(b"Nobody inspects the spammish repetition")
>>> h.hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fddff7bc4e843aa6af0c950f4b9406'
```

Hashlib provides the following constant attributes:

`hashlib.algorithms_guaranteed`

A set containing the names of the hash algorithms guaranteed to be supported by this module on all platforms.

Note that “md5” is in this list despite some upstream vendors offering an odd «FIPS compliant» Python build that excludes it.

Νέο στην έκδοση 3.2.

`hashlib.algorithms_available`

A set containing the names of the hash algorithms that are available in the running Python interpreter. These names will be recognized when passed to `new()`. `algorithms_guaranteed` will always be a subset. The same algorithm may appear multiple times in this set under different names (thanks to OpenSSL).

Νέο στην έκδοση 3.2.

The following values are provided as constant attributes of the hash objects returned by the constructors:

`hash.digest_size`

The size of the resulting hash in bytes.

`hash.block_size`

The internal block size of the hash algorithm in bytes.

A hash object has the following attributes:

`hash.name`

The canonical name of this hash, always lowercase and always suitable as a parameter to `new()` to create another hash of this type.

Άλλαξε στην έκδοση 3.4: The name attribute has been present in CPython since its inception, but until Python 3.4 was not formally specified, so may not exist on some platforms.

A hash object has the following methods:

`hash.update(data)`

Update the hash object with the *bytes-like object*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a)` ; `m.update(b)` is equivalent to `m.update(a+b)`.

Άλλαξε στην έκδοση 3.1: The Python GIL is released to allow other threads to run while hash updates on data larger than 2047 bytes is taking place when using hash algorithms supplied by OpenSSL.

`hash.digest()`

Return the digest of the data passed to the `update()` method so far. This is a bytes object of size `digest_size` which may contain bytes in the whole range from 0 to 255.

`hash.hexdigest()`

Like `digest()` except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

`hash.copy()`

Return a copy («clone») of the hash object. This can be used to efficiently compute the digests of data sharing a common initial substring.

15.1.2 SHAKE variable length digests

The `shake_128()` and `shake_256()` algorithms provide variable length digests with `length_in_bits//2` up to 128 or 256 bits of security. As such, their digest methods require a length. Maximum length is not limited by the SHAKE algorithm.

`shake.digest(length)`

Return the digest of the data passed to the `update()` method so far. This is a bytes object of size `length` which may contain bytes in the whole range from 0 to 255.

`shake.hexdigest` (*length*)

Like `digest()` except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

15.1.3 Key derivation

Key derivation and key stretching algorithms are designed for secure password hashing. Naive algorithms such as `sha1(password)` are not resistant against brute-force attacks. A good password hashing function must be tunable, slow, and include a `salt`.

`hashlib.pbkdf2_hmac` (*hash_name, password, salt, iterations, dklen=None*)

The function provides PKCS#5 password-based key derivation function 2. It uses HMAC as pseudorandom function.

The string *hash_name* is the desired name of the hash digest algorithm for HMAC, e.g. “sha1” or “sha256”. *password* and *salt* are interpreted as buffers of bytes. Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. `os.urandom()`.

The number of *iterations* should be chosen based on the hash algorithm and computing power. As of 2013, at least 100,000 iterations of SHA-256 are suggested.

dklen is the length of the derived key. If *dklen* is `None` then the digest size of the hash algorithm *hash_name* is used, e.g. 64 for SHA-512.

```
>>> import hashlib
>>> dk = hashlib.pbkdf2_hmac('sha256', b'password', b'salt', 100000)
>>> dk.hex()
'0394a2ede332c9a13eb82e9b24631604c31df978b4e2f0fbd2c549944f9d79a5'
```

Νέο στην έκδοση 3.4.

Σημείωση: A fast implementation of `pbkdf2_hmac` is available with OpenSSL. The Python implementation uses an inline version of `hmac`. It is about three times slower and doesn't release the GIL.

`hashlib.scrypt` (*password, *, salt, n, r, p, maxmem=0, dklen=64*)

The function provides scrypt password-based key derivation function as defined in **RFC 7914**.

password and *salt* must be *bytes-like objects*. Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. `os.urandom()`.

n is the CPU/Memory cost factor, *r* the block size, *p* parallelization factor and *maxmem* limits memory (OpenSSL 1.1.0 defaults to 32 MiB). *dklen* is the length of the derived key.

Availability: OpenSSL 1.1+.

Νέο στην έκδοση 3.6.

15.1.4 BLAKE2

BLAKE2 is a cryptographic hash function defined in [RFC 7693](#) that comes in two flavors:

- **BLAKE2b**, optimized for 64-bit platforms and produces digests of any size between 1 and 64 bytes,
- **BLAKE2s**, optimized for 8- to 32-bit platforms and produces digests of any size between 1 and 32 bytes.

BLAKE2 supports **keyed mode** (a faster and simpler replacement for [HMAC](#)), **salted hashing**, **personalization**, and **tree hashing**.

Hash objects from this module follow the API of standard library's *hashlib* objects.

Creating hash objects

New hash objects are created by calling constructor functions:

```
hashlib.blake2b(data=b'', *, digest_size=64, key=b'', salt=b'', person=b'', fanout=1, depth=1, leaf_size=0,
                node_offset=0, node_depth=0, inner_size=0, last_node=False, usedforsecurity=True)
```

```
hashlib.blake2s(data=b'', *, digest_size=32, key=b'', salt=b'', person=b'', fanout=1, depth=1, leaf_size=0,
                node_offset=0, node_depth=0, inner_size=0, last_node=False, usedforsecurity=True)
```

These functions return the corresponding hash objects for calculating BLAKE2b or BLAKE2s. They optionally take these general parameters:

- *data*: initial chunk of data to hash, which must be *bytes-like object*. It can be passed only as positional argument.
- *digest_size*: size of output digest in bytes.
- *key*: key for keyed hashing (up to 64 bytes for BLAKE2b, up to 32 bytes for BLAKE2s).
- *salt*: salt for randomized hashing (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).
- *person*: personalization string (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).

The following table shows limits for general parameters (in bytes):

| Hash | digest_size | len(key) | len(salt) | len(person) |
|---------|-------------|----------|-----------|-------------|
| BLAKE2b | 64 | 64 | 16 | 16 |
| BLAKE2s | 32 | 32 | 8 | 8 |

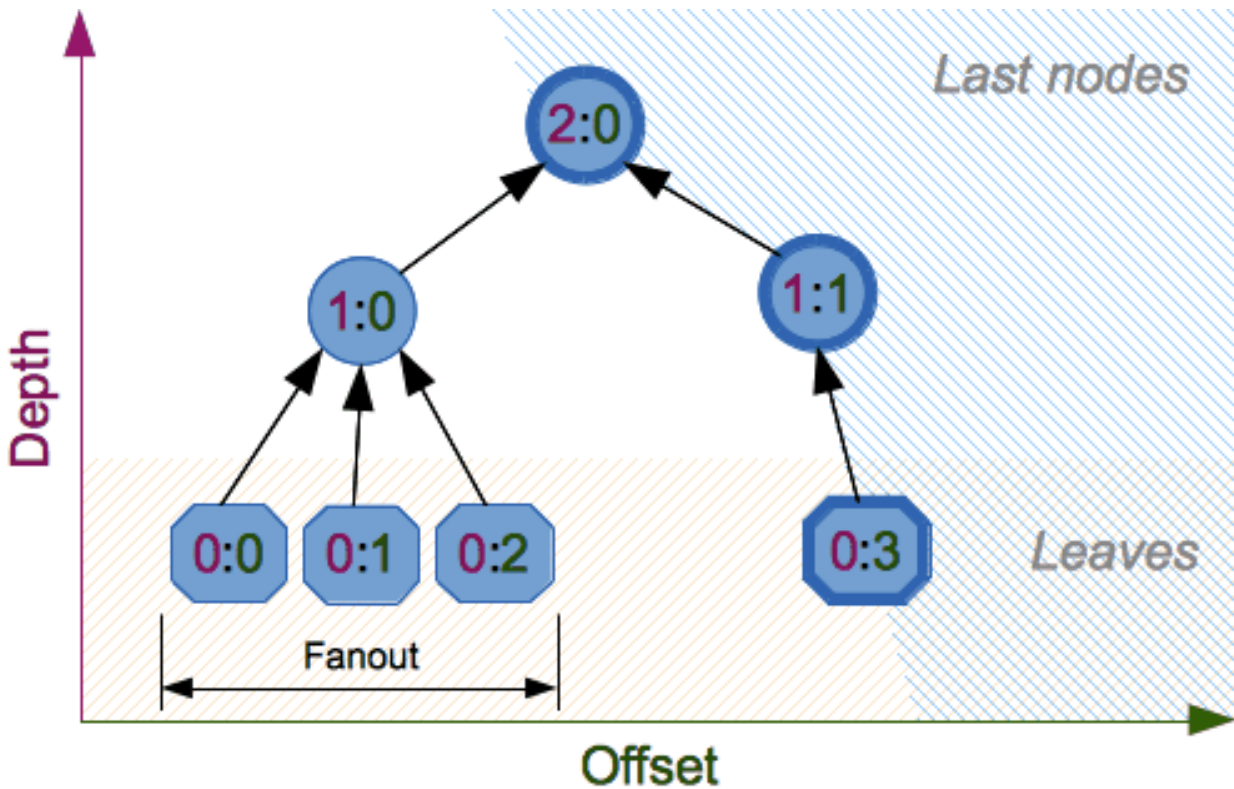

Σημείωση: BLAKE2 specification defines constant lengths for salt and personalization parameters, however, for convenience, this implementation accepts byte strings of any size up to the specified length. If the length of the parameter is less than specified, it is padded with zeros, thus, for example, `b'salt'` and `b'salt\x00'` is the same value. (This is not the case for *key*.)

These sizes are available as module *constants* described below.

Constructor functions also accept the following tree hashing parameters:

- *fanout*: fanout (0 to 255, 0 if unlimited, 1 in sequential mode).
- *depth*: maximal depth of tree (1 to 255, 255 if unlimited, 1 in sequential mode).
- *leaf_size*: maximal byte length of leaf (0 to $2^{*32}-1$, 0 if unlimited or in sequential mode).
- *node_offset*: node offset (0 to $2^{*64}-1$ for BLAKE2b, 0 to $2^{*48}-1$ for BLAKE2s, 0 for the first, leftmost, leaf, or in sequential mode).
- *node_depth*: node depth (0 to 255, 0 for leaves, or in sequential mode).

- *inner_size*: inner digest size (0 to 64 for BLAKE2b, 0 to 32 for BLAKE2s, 0 in sequential mode).
- *last_node*: boolean indicating whether the processed node is the last one (*False* for sequential mode).

See section 2.10 in [BLAKE2 specification](#) for comprehensive review of tree hashing.

Constants

`blake2b.SALT_SIZE`

`blake2s.SALT_SIZE`

Salt length (maximum length accepted by constructors).

`blake2b.PERSON_SIZE`

`blake2s.PERSON_SIZE`

Personalization string length (maximum length accepted by constructors).

`blake2b.MAX_KEY_SIZE`

`blake2s.MAX_KEY_SIZE`

Maximum key size.

`blake2b.MAX_DIGEST_SIZE`

`blake2s.MAX_DIGEST_SIZE`

Maximum digest size that the hash function can output.

Examples

Simple hashing

To calculate hash of some data, you should first construct a hash object by calling the appropriate constructor function (*blake2b()* or *blake2s()*), then update it with the data by calling *update()* on the object, and, finally, get the digest out of the object by calling *digest()* (or *hexdigest()* for hex-encoded string).

```
>>> from hashlib import blake2b
>>> h = blake2b()
>>> h.update(b'Hello world')
>>> h.hexdigest()

↪ '6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495d'
↪ '
```

As a shortcut, you can pass the first chunk of data to *update* directly to the constructor as the positional argument:

```
>>> from hashlib import blake2b
>>> blake2b(b'Hello world').hexdigest()

↪ '6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495d'
↪ '
```

You can call *hash.update()* as many times as you need to iteratively update the hash:

```
>>> from hashlib import blake2b
>>> items = [b'Hello', b' ', b'world']
>>> h = blake2b()
>>> for item in items:
...     h.update(item)
>>> h.hexdigest()

↪ '6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495d'
↪ '
```

Using different digest sizes

BLAKE2 has configurable size of digests up to 64 bytes for BLAKE2b and up to 32 bytes for BLAKE2s. For example, to replace SHA-1 with BLAKE2b without changing the size of output, we can tell BLAKE2b to produce 20-byte digests:

```
>>> from hashlib import blake2b
>>> h = blake2b(digest_size=20)
>>> h.update(b'Replacing SHA1 with the more secure function')
>>> h.hexdigest()
'd24f26cf8de66472d58d4e1b1774b4c9158b1f4c'
>>> h.digest_size
20
>>> len(h.digest())
20
```

Hash objects with different digest sizes have completely different outputs (shorter hashes are *not* prefixes of longer hashes); BLAKE2b and BLAKE2s produce different outputs even if the output length is the same:

```
>>> from hashlib import blake2b, blake2s
>>> blake2b(digest_size=10).hexdigest()
'6fa1d8fcfd719046d762'
>>> blake2b(digest_size=11).hexdigest()
'eb6ec15daf9546254f0809'
>>> blake2s(digest_size=10).hexdigest()
'1bf21a98c78a1c376ae9'
>>> blake2s(digest_size=11).hexdigest()
'567004bf96e4a25773ebf4'
```

Keyed hashing

Keyed hashing can be used for authentication as a faster and simpler replacement for [Hash-based message authentication code](#) (HMAC). BLAKE2 can be securely used in prefix-MAC mode thanks to the indistinguishability property inherited from BLAKE.

This example shows how to get a (hex-encoded) 128-bit authentication code for message `b'message data'` with key `b'pseudorandom key'`:

```
>>> from hashlib import blake2b
>>> h = blake2b(key=b'pseudorandom key', digest_size=16)
>>> h.update(b'message data')
>>> h.hexdigest()
'3d363ff7401e02026f4a4687d4863ced'
```

As a practical example, a web application can symmetrically sign cookies sent to users and later verify them to make sure they weren't tampered with:

```
>>> from hashlib import blake2b
>>> from hmac import compare_digest
>>>
>>> SECRET_KEY = b'pseudorandomly generated server secret key'
>>> AUTH_SIZE = 16
>>>
>>> def sign(cookie):
...     h = blake2b(digest_size=AUTH_SIZE, key=SECRET_KEY)
...     h.update(cookie)
...     return h.hexdigest().encode('utf-8')
>>>
>>> def verify(cookie, sig):
...     good_sig = sign(cookie)
...     return compare_digest(good_sig, sig)
>>>
>>> cookie = b'user-alice'
>>> sig = sign(cookie)
>>> print("{0},{1}".format(cookie.decode('utf-8'), sig))
user-alice,b'43b3c982cf697e0c5ab22172d1ca7421'
>>> verify(cookie, sig)
True
>>> verify(b'user-bob', sig)
False
>>> verify(cookie, b'0102030405060708090a0b0c0d0e0f00')
False
```

Even though there's a native keyed hashing mode, BLAKE2 can, of course, be used in HMAC construction with `hmac` module:

```
>>> import hmac, hashlib
>>> m = hmac.new(b'secret key', digestmod=hashlib.blake2s)
>>> m.update(b'message')
>>> m.hexdigest()
'e3c8102868d28b5ff85fc35dda07329970d1a01e273c37481326fe0c861c8142'
```

Randomized hashing

By setting *salt* parameter users can introduce randomization to the hash function. Randomized hashing is useful for protecting against collision attacks on the hash function used in digital signatures.

Randomized hashing is designed for situations where one party, the message preparer, generates all or part of a message to be signed by a second party, the message signer. If the message preparer is able to find cryptographic hash function collisions (i.e., two messages producing the same hash value), then they might prepare meaningful versions of the message that would produce the same hash value and digital signature, but with different results (e.g., transferring \$1,000,000 to an account, rather than \$10). Cryptographic hash functions have been designed with collision resistance as a major goal, but the current concentration on attacking cryptographic hash functions may result in a given cryptographic hash function providing less collision resistance than expected. Randomized hashing offers the signer additional protection by reducing the likelihood that a preparer can generate two or more messages that ultimately yield the same hash value during the digital signature generation process — even if it is practical to find collisions for the hash function. However, the use of randomized hashing may reduce the amount of security provided by a digital signature when all portions of the message are prepared by the signer.

(NIST SP-800-106 «Randomized Hashing for Digital Signatures»)

In BLAKE2 the salt is processed as a one-time input to the hash function during initialization, rather than as an input to each compression function.

Προειδοποίηση: *Salted hashing* (or just hashing) with BLAKE2 or any other general-purpose cryptographic hash function, such as SHA-256, is not suitable for hashing passwords. See [BLAKE2 FAQ](#) for more information.

```
>>> import os
>>> from hashlib import blake2b
>>> msg = b'some message'
>>> # Calculate the first hash with a random salt.
>>> salt1 = os.urandom(blake2b.SALT_SIZE)
>>> h1 = blake2b(salt=salt1)
>>> h1.update(msg)
>>> # Calculate the second hash with a different random salt.
>>> salt2 = os.urandom(blake2b.SALT_SIZE)
>>> h2 = blake2b(salt=salt2)
>>> h2.update(msg)
>>> # The digests are different.
>>> h1.digest() != h2.digest()
True
```

Personalization

Sometimes it is useful to force hash function to produce different digests for the same input for different purposes. Quoting the authors of the Skein hash function:

We recommend that all application designers seriously consider doing this; we have seen many protocols where a hash that is computed in one part of the protocol can be used in an entirely different part because two hash computations were done on similar or related data, and the attacker can force the application to make the hash inputs the same. Personalizing each hash function used in the protocol summarily stops this type of attack.

(The Skein Hash Function Family, p. 21)

BLAKE2 can be personalized by passing bytes to the *person* argument:

```
>>> from hashlib import blake2b
>>> FILES_HASH_PERSON = b'MyApp Files Hash'
>>> BLOCK_HASH_PERSON = b'MyApp Block Hash'
>>> h = blake2b(digest_size=32, person=FILES_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'20d9cd024d4fb086aae819a1432dd2466de12947831b75c5a30cf2676095d3b4'
>>> h = blake2b(digest_size=32, person=BLOCK_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'cf68fb5761b9c44e7878bfb2c4c9aea52264a80b75005e65619778de59f383a3'
```

Personalization together with the keyed mode can also be used to derive different keys from a single one.

```
>>> from hashlib import blake2s
>>> from base64 import b64decode, b64encode
>>> orig_key = b64decode(b'Rm5EPJai72qcK3RGBpW3vPNfZy5OZothY+kHY6h21KM=')
>>> enc_key = blake2s(key=orig_key, person=b'kEncrypt').digest()
>>> mac_key = blake2s(key=orig_key, person=b'kMAC').digest()
>>> print(b64encode(enc_key).decode('utf-8'))
rbPb15S/Z9t+agffno5wuhB77VbRi6F9Iv2qIxU7WHw=
>>> print(b64encode(mac_key).decode('utf-8'))
G9GtHFE1YluXY1zWP1Yk1e/nWfu0WSEb0KRcjhDeP/o=
```

Tree mode

Here's an example of hashing a minimal tree with two leaf nodes:

```
  10
 /  \
00  01
```

This example uses 64-byte internal digests, and returns the 32-byte final digest:

```
>>> from hashlib import blake2b
>>>
>>> FANOUT = 2
>>> DEPTH = 2
>>> LEAF_SIZE = 4096
>>> INNER_SIZE = 64
>>>
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

>>> buf = bytearray(6000)
>>>
>>> # Left leaf
... h00 = blake2b(buf[0:LEAF_SIZE], fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=0, node_depth=0, last_node=False)
>>> # Right leaf
... h01 = blake2b(buf[LEAF_SIZE:], fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=1, node_depth=0, last_node=True)
>>> # Root node
... h10 = blake2b(digest_size=32, fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=0, node_depth=1, last_node=True)
>>> h10.update(h00.digest())
>>> h10.update(h01.digest())
>>> h10.hexdigest()
'3ad2a9b37c6070e374c7a8c508fe20ca86b6ed54e286e93a0318e95e881db5aa'

```

Credits

BLAKE2 was designed by *Jean-Philippe Aumasson*, *Samuel Neves*, *Zooko Wilcox-O'Hearn*, and *Christian Winnerlein* based on **SHA-3** finalist **BLAKE** created by *Jean-Philippe Aumasson*, *Luca Henzen*, *Willi Meier*, and *Raphael C.-W. Phan*.

It uses core algorithm from **ChaCha** cipher designed by *Daniel J. Bernstein*.

The stdlib implementation is based on **pyblake2** module. It was written by *Dmitry Chestnykh* based on C implementation written by *Samuel Neves*. The documentation was copied from **pyblake2** and written by *Dmitry Chestnykh*.

The C code was partly rewritten for Python by *Christian Heimes*.

15.2 hmac — Keyed-Hashing for Message Authentication

Source code: [Lib/hmac.py](#)

This module implements the HMAC algorithm as described by [RFC 2104](#).

`hmac.new(key, msg=None, digestmod=)`

Return a new hmac object. *key* is a bytes or bytearray object giving the secret key. If *msg* is present, the method call `update(msg)` is made. *digestmod* is the digest name, digest constructor or module for the HMAC object to use. It may be any name suitable to [hashlib.new\(\)](#). Despite its argument position, it is required.

Άλλαξε στην έκδοση 3.4: Parameter *key* can be a bytes or bytearray object. Parameter *msg* can be of any type supported by [hashlib](#). Parameter *digestmod* can be the name of a hash algorithm.

Deprecated since version 3.4, removed in version 3.8: MD5 as implicit default digest for *digestmod* is deprecated. The *digestmod* parameter is now required. Pass it as a keyword argument to avoid awkwardness when you do not have an initial msg.

`hmac.digest(key, msg, digest)`

Return digest of *msg* for given secret *key* and *digest*. The function is equivalent to `HMAC(key, msg, digest).digest()`, but uses an optimized C or inline implementation, which is faster for messages that fit into memory. The parameters *key*, *msg*, and *digest* have the same meaning as in `new()`.

CPython implementation detail, the optimized C implementation is only used when *digest* is a string and name of a digest algorithm, which is supported by OpenSSL.

Νέο στην έκδοση 3.7.

An HMAC object has the following methods:

`HMAC.update(msg)`

Update the hmac object with *msg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a + b)`.

Άλλαξε στην έκδοση 3.4: Parameter *msg* can be of any type supported by [hashlib](#).

`HMAC.digest()`

Return the digest of the bytes passed to the `update()` method so far. This bytes object will be the same length as the *digest_size* of the digest given to the constructor. It may contain non-ASCII bytes, including NUL bytes.

Προειδοποίηση: When comparing the output of `digest()` to an externally-supplied digest during a verification routine, it is recommended to use the `compare_digest()` function instead of the `==` operator to reduce the vulnerability to timing attacks.

`HMAC.hexdigest()`

Like `digest()` except the digest is returned as a string twice the length containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

Προειδοποίηση: When comparing the output of `hexdigest()` to an externally-supplied digest during a verification routine, it is recommended to use the `compare_digest()` function instead of the `==` operator to reduce the vulnerability to timing attacks.

`HMAC.copy()`

Return a copy («clone») of the hmac object. This can be used to efficiently compute the digests of strings that share a common initial substring.

A hash object has the following attributes:

`HMAC.digest_size`

The size of the resulting HMAC digest in bytes.

`HMAC.block_size`

The internal block size of the hash algorithm in bytes.

Νέο στην έκδοση 3.4.

`HMAC.name`

The canonical name of this HMAC, always lowercase, e.g. `hmac-md5`.

Νέο στην έκδοση 3.4.

Αποσύρθηκε στην έκδοση 3.9: The undocumented attributes `HMAC.digest_cons`, `HMAC.inner`, and `HMAC.outer` are internal implementation details and will be removed in Python 3.10.

This module also provides the following helper function:

`hmac.compare_digest(a, b)`

Return `a == b`. This function uses an approach designed to prevent timing analysis by avoiding content-based short circuiting behaviour, making it appropriate for cryptography. *a* and *b* must both be of the same type: either *str* (ASCII only, as e.g. returned by `HMAC.hexdigest()`), or a *bytes-like object*.

Σημείωση: If *a* and *b* are of different lengths, or if an error occurs, a timing attack could theoretically reveal information about the types and lengths of *a* and *b*—but not their values.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.9: The function uses OpenSSL's `CRYPTO_memcmp()` internally when available.

Δείτε επίσης:

Module `hashlib` The Python module providing secure hash functions.

15.3 secrets — Generate secure random numbers for managing secrets

Νέο στην έκδοση 3.6.

Source code: `Lib/secrets.py`

The `secrets` module is used for generating cryptographically strong random numbers suitable for managing data such as passwords, account authentication, security tokens, and related secrets.

In particular, `secrets` should be used in preference to the default pseudo-random number generator in the `random` module, which is designed for modelling and simulation, not security or cryptography.

Δείτε επίσης:

PEP 506

15.3.1 Random numbers

The `secrets` module provides access to the most secure source of randomness that your operating system provides.

class `secrets.SystemRandom`

A class for generating random numbers using the highest-quality sources provided by the operating system. See `random.SystemRandom` for additional details.

`secrets.choice(sequence)`

Return a randomly-chosen element from a non-empty sequence.

`secrets.randbelow(n)`

Return a random int in the range $[0, n)$.

`secrets.randbits(k)`

Return an int with k random bits.

15.3.2 Generating tokens

The `secrets` module provides functions for generating secure tokens, suitable for applications such as password resets, hard-to-guess URLs, and similar.

`secrets.token_bytes([nbytes=None])`

Return a random byte string containing $nbytes$ number of bytes. If $nbytes$ is `None` or not supplied, a reasonable default is used.

```
>>> token_bytes(16)
b'\xebr\x17D*t\xae\xd4\xe3S\xb6\xe2\xebP1\x8b'
```

`secrets.token_hex([nbytes=None])`

Return a random text string, in hexadecimal. The string has $nbytes$ random bytes, each byte converted to two hex digits. If $nbytes$ is `None` or not supplied, a reasonable default is used.

```
>>> token_hex(16)
'f9bf78b9a18ce6d46a0cd2b0b86df9da'
```

`secrets.token_urlsafe([nbytes=None])`

Return a random URL-safe text string, containing $nbytes$ random bytes. The text is Base64 encoded, so on average each byte results in approximately 1.3 characters. If $nbytes$ is `None` or not supplied, a reasonable default is used.

```
>>> token_urlsafe(16)
'Drmhze6EPcv0fN_81Bj-nA'
```

How many bytes should tokens use?

To be secure against [brute-force attacks](#), tokens need to have sufficient randomness. Unfortunately, what is considered sufficient will necessarily increase as computers get more powerful and able to make more guesses in a shorter period. As of 2015, it is believed that 32 bytes (256 bits) of randomness is sufficient for the typical use-case expected for the `secrets` module.

For those who want to manage their own token length, you can explicitly specify how much randomness is used for tokens by giving an `int` argument to the various `token_*` functions. That argument is taken as the number of bytes of randomness to use.

Otherwise, if no argument is provided, or if the argument is `None`, the `token_*` functions will use a reasonable default instead.

Σημείωση: That default is subject to change at any time, including during maintenance releases.

15.3.3 Other functions

`secrets.compare_digest(a, b)`

Return True if strings *a* and *b* are equal, otherwise False, in such a way as to reduce the risk of [timing attacks](#). See `hmac.compare_digest()` for additional details.

15.3.4 Recipes and best practices

This section shows recipes and best practices for using `secrets` to manage a basic level of security.

Generate an eight-character alphanumeric password:

```
import string
import secrets
alphabet = string.ascii_letters + string.digits
password = ''.join(secrets.choice(alphabet) for i in range(8))
```

Σημείωση: Applications should not [store passwords in a recoverable format](#), whether plain text or encrypted. They should be salted and hashed using a cryptographically-strong one-way (irreversible) hash function.

Generate a ten-character alphanumeric password with at least one lowercase character, at least one uppercase character, and at least three digits:

```
import string
import secrets
alphabet = string.ascii_letters + string.digits
while True:
    password = ''.join(secrets.choice(alphabet) for i in range(10))
    if (any(c.islower() for c in password)
        and any(c.isupper() for c in password)
        and sum(c.isdigit() for c in password) >= 3):
        break
```

Generate an XKCD-style passphrase:

```
import secrets
# On standard Linux systems, use a convenient dictionary file.
# Other platforms may need to provide their own word-list.
with open('/usr/share/dict/words') as f:
    words = [word.strip() for word in f]
    password = ' '.join(secrets.choice(words) for i in range(4))
```

Generate a hard-to-guess temporary URL containing a security token suitable for password recovery applications:

```
import secrets
url = 'https://example.com/reset=' + secrets.token_urlsafe()
```

Γενικές Υπηρεσίες Λειτουργικού Συστήματος

Τα modules που περιγράφονται σε αυτό το κεφάλαιο παρέχουν διεπαφές για λειτουργίες του λειτουργικού συστήματος που είναι διαθέσιμες σε (σχεδόν) όλα τα λειτουργικά συστήματα, όπως τα αρχεία και το ρολόι. Οι διεπαφές είναι γενικά βασισμένες στα πρότυπα των Unix ή C, αλλά είναι διαθέσιμες και στα περισσότερα άλλα συστήματα. Ακολουθεί μια επισκόπηση:

16.1 `os` — Miscellaneous operating system interfaces

Source code: [Lib/os.py](#)

This module provides a portable way of using operating system dependent functionality. If you just want to read or write a file see [`open\(\)`](#), if you want to manipulate paths, see the [`os.path`](#) module, and if you want to read all the lines in all the files on the command line see the [`fileinput`](#) module. For creating temporary files and directories see the [`tempfile`](#) module, and for high-level file and directory handling see the [`shutil`](#) module.

Notes on the availability of these functions:

- The design of all built-in operating system dependent modules of Python is such that as long as the same functionality is available, it uses the same interface; for example, the function `os.stat(path)` returns stat information about *path* in the same format (which happens to have originated with the POSIX interface).
- Extensions peculiar to a particular operating system are also available through the `os` module, but using them is of course a threat to portability.
- All functions accepting path or file names accept both bytes and string objects, and result in an object of the same type, if a path or file name is returned.
- On VxWorks, `os.fork`, `os.execv` and `os.spawn*p*` are not supported.

Σημείωση: All functions in this module raise [`OSError`](#) (or subclasses thereof) in the case of invalid or inaccessible file names and paths, or other arguments that have the correct type, but are not accepted by the operating system.

exception `os.error`

An alias for the built-in `OSError` exception.

`os.name`

The name of the operating system dependent module imported. The following names have currently been registered: 'posix', 'nt', 'java'.

Δείτε επίσης:

`sys.platform` has a finer granularity. `os.uname()` gives system-dependent version information.

The `platform` module provides detailed checks for the system's identity.

16.1.1 File Names, Command Line Arguments, and Environment Variables

In Python, file names, command line arguments, and environment variables are represented using the string type. On some systems, decoding these strings to and from bytes is necessary before passing them to the operating system. Python uses the file system encoding to perform this conversion (see `sys.getfilesystemencoding()`).

Αλλάξε στην έκδοση 3.1: On some systems, conversion using the file system encoding may fail. In this case, Python uses the `surrogateescape encoding error handler`, which means that undecodable bytes are replaced by a Unicode character U+DCxx on decoding, and these are again translated to the original byte on encoding.

The file system encoding must guarantee to successfully decode all bytes below 128. If the file system encoding fails to provide this guarantee, API functions may raise `UnicodeErrors`.

16.1.2 Process Parameters

These functions and data items provide information and operate on the current process and user.

`os.ctermid()`

Return the filename corresponding to the controlling terminal of the process.

Availability: Unix.

`os.environ`

A *mapping* object where keys and values are strings that represent the process environment. For example, `environ['HOME']` is the pathname of your home directory (on some platforms), and is equivalent to `getenv("HOME")` in C.

This mapping is captured the first time the `os` module is imported, typically during Python startup as part of processing `site.py`. Changes to the environment made after this time are not reflected in `os.environ`, except for changes made by modifying `os.environ` directly.

This mapping may be used to modify the environment as well as query the environment. `putenv()` will be called automatically when the mapping is modified.

On Unix, keys and values use `sys.getfilesystemencoding()` and 'surrogateescape' error handler. Use `environb` if you would like to use a different encoding.

Σημείωση: Calling `putenv()` directly does not change `os.environ`, so it's better to modify `os.environ`.

Σημείωση: On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

You can delete items in this mapping to unset environment variables. `unsetenv()` will be called automatically when an item is deleted from `os.environ`, and when one of the `pop()` or `clear()` methods is called.

Άλλαξε στην έκδοση 3.9: Updated to support **PEP 584**'s merge (`|`) and update (`|=`) operators.

`os.environb`

Bytes version of `environ`: a *mapping* object where both keys and values are *bytes* objects representing the process environment. `environ` and `environb` are synchronized (modifying `environb` updates `environ`, and vice versa).

`environb` is only available if `supports_bytes_environ` is `True`.

Νέο στην έκδοση 3.2.

Άλλαξε στην έκδοση 3.9: Updated to support **PEP 584**'s merge (`|`) and update (`|=`) operators.

`os.chdir(path)`

`os.fchdir(fd)`

`os.getcwd()`

These functions are described in *Files and Directories*.

`os.fsencode(filename)`

Encode *path-like filename* to the filesystem encoding with 'surrogateescape' error handler, or 'strict' on Windows; return *bytes* unchanged.

`fsdecode()` is the reverse function.

Νέο στην έκδοση 3.2.

Άλλαξε στην έκδοση 3.6: Support added to accept objects implementing the `os.PathLike` interface.

`os.fsdecode(filename)`

Decode the *path-like filename* from the filesystem encoding with 'surrogateescape' error handler, or 'strict' on Windows; return *str* unchanged.

`fsencode()` is the reverse function.

Νέο στην έκδοση 3.2.

Άλλαξε στην έκδοση 3.6: Support added to accept objects implementing the `os.PathLike` interface.

`os.fspath(path)`

Return the file system representation of the path.

If *str* or *bytes* is passed in, it is returned unchanged. Otherwise `__fspath__()` is called and its value is returned as long as it is a *str* or *bytes* object. In all other cases, `TypeError` is raised.

Νέο στην έκδοση 3.6.

`class os.PathLike`

An *abstract base class* for objects representing a file system path, e.g. `pathlib.PurePath`.

Νέο στην έκδοση 3.6.

`abstractmethod __fspath__()`

Return the file system path representation of the object.

The method should only return a *str* or *bytes* object, with the preference being for *str*.

`os.getenv(key, default=None)`

Return the value of the environment variable *key* if it exists, or *default* if it doesn't. *key*, *default* and the result are *str*. Note that since `getenv()` uses `os.environ`, the mapping of `getenv()` is similarly also captured on import, and the function may not reflect future environment changes.

On Unix, keys and values are decoded with `sys.getfilesystemencoding()` and 'surrogateescape' error handler. Use `os.getenvb()` if you would like to use a different encoding.

Availability: most flavors of Unix, Windows.

`os.getenvb(key, default=None)`

Return the value of the environment variable *key* if it exists, or *default* if it doesn't. *key*, *default* and the result are bytes. Note that since `getenvb()` uses `os.environb`, the mapping of `getenvb()` is similarly also captured on import, and the function may not reflect future environment changes.

`getenvb()` is only available if `supports_bytes_environ` is True.

Availability: most flavors of Unix.

Νέο στην έκδοση 3.2.

`os.get_exec_path(env=None)`

Returns the list of directories that will be searched for a named executable, similar to a shell, when launching a process. *env*, when specified, should be an environment variable dictionary to lookup the PATH in. By default, when *env* is None, `environ` is used.

Νέο στην έκδοση 3.2.

`os.getegid()`

Return the effective group id of the current process. This corresponds to the «set id» bit on the file being executed in the current process.

Availability: Unix.

`os.geteuid()`

Return the current process's effective user id.

Availability: Unix.

`os.getgid()`

Return the real group id of the current process.

Availability: Unix.

`os.getgrouplist(user, group)`

Return list of group ids that *user* belongs to. If *group* is not in the list, it is included; typically, *group* is specified as the group ID field from the password record for *user*, because that group ID will otherwise be potentially omitted.

Availability: Unix.

Νέο στην έκδοση 3.3.

`os.getgroups()`

Return list of supplemental group ids associated with the current process.

Availability: Unix.

Σημείωση: On macOS, `getgroups()` behavior differs somewhat from other Unix platforms. If the Python interpreter was built with a deployment target of 10.5 or earlier, `getgroups()` returns the list of effective group ids associated with the current user process; this list is limited to a system-defined number of entries, typically 16, and may be modified by calls to `setgroups()` if suitably privileged. If built with a deployment target greater than 10.5, `getgroups()` returns the current group access list for the user associated with the effective user id of the process; the group access list may change over the lifetime of the process, it is not affected by calls to `setgroups()`, and its length is not limited to 16. The deployment target value, `MACOSX_DEPLOYMENT_TARGET`, can be obtained with `sysconfig.get_config_var()`.

os.getlogin()

Return the name of the user logged in on the controlling terminal of the process. For most purposes, it is more useful to use `getpass.getuser()` since the latter checks the environment variables `LOGNAME` or `USERNAME` to find out who the user is, and falls back to `pwd.getpwuid(os.getuid())[0]` to get the login name of the current real user id.

Availability: Unix, Windows.

os.getpgid(pid)

Return the process group id of the process with process id *pid*. If *pid* is 0, the process group id of the current process is returned.

Availability: Unix.

os.getpgrp()

Return the id of the current process group.

Availability: Unix.

os.getpid()

Return the current process id.

os.getppid()

Return the parent's process id. When the parent process has exited, on Unix the id returned is the one of the init process (1), on Windows it is still the same id, which may be already reused by another process.

Availability: Unix, Windows.

Άλλαξε στην έκδοση 3.2: Added support for Windows.

os.getpriority(which, who)

Get program scheduling priority. The value *which* is one of `PRIO_PROCESS`, `PRIO_PGRP`, or `PRIO_USER`, and *who* is interpreted relative to *which* (a process identifier for `PRIO_PROCESS`, process group identifier for `PRIO_PGRP`, and a user ID for `PRIO_USER`). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process.

Availability: Unix.

Νέο στην έκδοση 3.3.

os.PRIO_PROCESS**os.PRIO_PGRP****os.PRIO_USER**

Parameters for the `getpriority()` and `setpriority()` functions.

Availability: Unix.

Νέο στην έκδοση 3.3.

os.getresuid()

Return a tuple (ruid, euid, suid) denoting the current process's real, effective, and saved user ids.

Availability: Unix.

Νέο στην έκδοση 3.2.

os.getresgid()

Return a tuple (rgid, egid, sgid) denoting the current process's real, effective, and saved group ids.

Availability: Unix.

Νέο στην έκδοση 3.2.

`os.getuid()`

Return the current process's real user id.

Availability: Unix.

`os.initgroups(username, gid)`

Call the system `initgroups()` to initialize the group access list with all of the groups of which the specified username is a member, plus the specified group id.

Availability: Unix.

Νέο στην έκδοση 3.2.

`os.putenv(key, value)`

Set the environment variable named *key* to the string *value*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

Assignments to items in `os.environ` are automatically translated into corresponding calls to `putenv()`; however, calls to `putenv()` don't update `os.environ`, so it is actually preferable to assign to items of `os.environ`. This also applies to `getenv()` and `getenvb()`, which respectively use `os.environ` and `os.environb` in their implementations.

Σημείωση: On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

Raises an *auditing event* `os.putenv` with arguments *key*, *value*.

Άλλαξε στην έκδοση 3.9: The function is now always available.

`os.setegid(egid)`

Set the current process's effective group id.

Availability: Unix.

`os.seteuid(euid)`

Set the current process's effective user id.

Availability: Unix.

`os.setgid(gid)`

Set the current process' group id.

Availability: Unix.

`os.setgroups(groups)`

Set the list of supplemental group ids associated with the current process to *groups*. *groups* must be a sequence, and each element must be an integer identifying a group. This operation is typically available only to the superuser.

Availability: Unix.

Σημείωση: On macOS, the length of *groups* may not exceed the system-defined maximum number of effective group ids, typically 16. See the documentation for `getgroups()` for cases where it may not return the same group list set by calling `setgroups()`.

`os.setpgrp()`

Call the system call `setpgrp()` or `setpgrp(0, 0)` depending on which version is implemented (if any). See the Unix manual for the semantics.

Availability: Unix.

os.setpgid (*pid*, *grp*)

Call the system call `setpgid()` to set the process group id of the process with id *pid* to the process group with id *grp*. See the Unix manual for the semantics.

Availability: Unix.

os.setpriority (*which*, *who*, *priority*)

Set program scheduling priority. The value *which* is one of `PRIO_PROCESS`, `PRIO_PGRP`, or `PRIO_USER`, and *who* is interpreted relative to *which* (a process identifier for `PRIO_PROCESS`, process group identifier for `PRIO_PGRP`, and a user ID for `PRIO_USER`). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process. *priority* is a value in the range -20 to 19. The default priority is 0; lower priorities cause more favorable scheduling.

Availability: Unix.

Νέο στην έκδοση 3.3.

os.setregid (*rgid*, *egid*)

Set the current process's real and effective group ids.

Availability: Unix.

os.setresgid (*rgid*, *egid*, *sgid*)

Set the current process's real, effective, and saved group ids.

Availability: Unix.

Νέο στην έκδοση 3.2.

os.setresuid (*ruid*, *euid*, *suid*)

Set the current process's real, effective, and saved user ids.

Availability: Unix.

Νέο στην έκδοση 3.2.

os.setreuid (*ruid*, *euid*)

Set the current process's real and effective user ids.

Availability: Unix.

os.getsid (*pid*)

Call the system call `getsid()`. See the Unix manual for the semantics.

Availability: Unix.

os.setsid ()

Call the system call `setsid()`. See the Unix manual for the semantics.

Availability: Unix.

os.setuid (*uid*)

Set the current process's user id.

Availability: Unix.

os.strerror (*code*)

Return the error message corresponding to the error code in *code*. On platforms where `strerror()` returns NULL when given an unknown error number, `ValueError` is raised.

os.supports_bytes_environ

True if the native OS type of the environment is bytes (eg. False on Windows).

Νέο στην έκδοση 3.2.

`os.umask(mask)`

Set the current numeric umask and return the previous umask.

`os.uname()`

Returns information identifying the current operating system. The return value is an object with five attributes:

- `sysname` - operating system name
- `nodename` - name of machine on network (implementation-defined)
- `release` - operating system release
- `version` - operating system version
- `machine` - hardware identifier

For backwards compatibility, this object is also iterable, behaving like a five-tuple containing `sysname`, `nodename`, `release`, `version`, and `machine` in that order.

Some systems truncate `nodename` to 8 characters or to the leading component; a better way to get the hostname is `socket.gethostname()` or even `socket.gethostbyaddr(socket.gethostname())`.

Availability: recent flavors of Unix.

Άλλαξε στην έκδοση 3.3: Return type changed from a tuple to a tuple-like object with named attributes.

`os.unsetenv(key)`

Unset (delete) the environment variable named *key*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

Deletion of items in `os.environ` is automatically translated into a corresponding call to `unsetenv()`; however, calls to `unsetenv()` don't update `os.environ`, so it is actually preferable to delete items of `os.environ`.

Raises an *auditing event* `os.unsetenv` with argument *key*.

Άλλαξε στην έκδοση 3.9: The function is now always available and is also available on Windows.

16.1.3 File Object Creation

These functions create new *file objects*. (See also `open()` for opening file descriptors.)

`os.fdopen(fd, *args, **kwargs)`

Return an open file object connected to the file descriptor *fd*. This is an alias of the `open()` built-in function and accepts the same arguments. The only difference is that the first argument of `fdopen()` must always be an integer.

16.1.4 File Descriptor Operations

These functions operate on I/O streams referenced using file descriptors.

File descriptors are small integers corresponding to a file that has been opened by the current process. For example, standard input is usually file descriptor 0, standard output is 1, and standard error is 2. Further files opened by a process will then be assigned 3, 4, 5, and so forth. The name «file descriptor» is slightly deceptive; on Unix platforms, sockets and pipes are also referenced by file descriptors.

The `fileno()` method can be used to obtain the file descriptor associated with a *file object* when required. Note that using the file descriptor directly will bypass the file object methods, ignoring aspects such as internal buffering of data.

`os.close(fd)`
Close file descriptor *fd*.

Σημείωση: This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To close a «file object» returned by the built-in function `open()` or by `popen()` or `fdopen()`, use its `close()` method.

`os.closerange(fd_low, fd_high)`
Close all file descriptors from *fd_low* (inclusive) to *fd_high* (exclusive), ignoring errors. Equivalent to (but much faster than):

```
for fd in range(fd_low, fd_high):
    try:
        os.close(fd)
    except OSError:
        pass
```

`os.copy_file_range(src, dst, count, offset_src=None, offset_dst=None)`
Copy *count* bytes from file descriptor *src*, starting from offset *offset_src*, to file descriptor *dst*, starting from offset *offset_dst*. If *offset_src* is None, then *src* is read from the current position; respectively for *offset_dst*. The files pointed by *src* and *dst* must reside in the same filesystem, otherwise an `OSError` is raised with *errno* set to `errno.EXDEV`.

This copy is done without the additional cost of transferring data from the kernel to user space and then back into the kernel. Additionally, some filesystems could implement extra optimizations. The copy is done as if both files are opened as binary.

The return value is the amount of bytes copied. This could be less than the amount requested.

Availability: Linux kernel >= 4.5 or glibc >= 2.27.

Νέο στην έκδοση 3.8.

`os.device_encoding(fd)`
Return a string describing the encoding of the device associated with *fd* if it is connected to a terminal; else return `None`.

`os.dup(fd)`
Return a duplicate of file descriptor *fd*. The new file descriptor is *non-inheritable*.

On Windows, when duplicating a standard stream (0: stdin, 1: stdout, 2: stderr), the new file descriptor is *inheritable*.

Άλλαξε στην έκδοση 3.4: The new file descriptor is now non-inheritable.

`os.dup2(fd, fd2, inheritable=True)`
Duplicate file descriptor *fd* to *fd2*, closing the latter first if necessary. Return *fd2*. The new file descriptor is *inheritable* by default or non-inheritable if *inheritable* is `False`.

Άλλαξε στην έκδοση 3.4: Add the optional *inheritable* parameter.

Άλλαξε στην έκδοση 3.7: Return *fd2* on success. Previously, `None` was always returned.

`os.fchmod(fd, mode)`
Change the mode of the file given by *fd* to the numeric *mode*. See the docs for `chmod()` for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(fd, mode)`.

Raises an *auditing event* `os.chmod` with arguments *path*, *mode*, *dir_fd*.

Availability: Unix.

os.fchown (*fd*, *uid*, *gid*)

Change the owner and group id of the file given by *fd* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1. See [chown\(\)](#). As of Python 3.3, this is equivalent to `os.chown(fd, uid, gid)`.

Raises an [auditing event](#) `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

Availability: Unix.

os.fdatasync (*fd*)

Force write of file with filedescriptor *fd* to disk. Does not force update of metadata.

Availability: Unix.

Σημείωση: This function is not available on MacOS.

os.fpathconf (*fd*, *name*)

Return system configuration information relevant to an open file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, [ValueError](#) is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an [OSError](#) is raised with `errno.EINVAL` for the error number.

As of Python 3.3, this is equivalent to `os.pathconf(fd, name)`.

Availability: Unix.

os.fstat (*fd*)

Get the status of the file descriptor *fd*. Return a [stat_result](#) object.

As of Python 3.3, this is equivalent to `os.stat(fd)`.

Δείτε επίσης:

The [stat\(\)](#) function.

os.fstatvfs (*fd*)

Return information about the filesystem containing the file associated with file descriptor *fd*, like [statvfs\(\)](#).

As of Python 3.3, this is equivalent to `os.statvfs(fd)`.

Availability: Unix.

os.fsync (*fd*)

Force write of file with filedescriptor *fd* to disk. On Unix, this calls the native `fsync()` function; on Windows, the `MS_commit()` function.

If you're starting with a buffered Python [file object](#) *f*, first do `f.flush()`, and then do `os.fsync(f.fileno())`, to ensure that all internal buffers associated with *f* are written to disk.

Availability: Unix, Windows.

os.ftruncate (*fd*, *length*)

Truncate the file corresponding to file descriptor *fd*, so that it is at most *length* bytes in size. As of Python 3.3, this is equivalent to `os.truncate(fd, length)`.

Raises an [auditing event](#) `os.truncate` with arguments `fd`, `length`.

Availability: Unix, Windows.

Άλλαξε στην έκδοση 3.5: Added support for Windows

os.get_blocking(*fd*)

Get the blocking mode of the file descriptor: `False` if the `O_NONBLOCK` flag is set, `True` if the flag is cleared.

See also `set_blocking()` and `socket.socket.setblocking()`.

Availability: Unix.

Νέο στην έκδοση 3.5.

os.isatty(*fd*)

Return `True` if the file descriptor *fd* is open and connected to a tty(-like) device, else `False`.

os.lockf(*fd*, *cmd*, *len*)

Apply, test or remove a POSIX lock on an open file descriptor. *fd* is an open file descriptor. *cmd* specifies the command to use - one of `F_LOCK`, `F_TLOCK`, `F_ULOCK` or `F_TEST`. *len* specifies the section of the file to lock.

Raises an *auditing event* `os.lockf` with arguments *fd*, *cmd*, *len*.

Availability: Unix.

Νέο στην έκδοση 3.3.

os.F_LOCK**os.F_TLOCK****os.F_ULOCK****os.F_TEST**

Flags that specify what action `lockf()` will take.

Availability: Unix.

Νέο στην έκδοση 3.3.

os.lseek(*fd*, *pos*, *how*)

Set the current position of file descriptor *fd* to position *pos*, modified by *how*: `SEEK_SET` or 0 to set the position relative to the beginning of the file; `SEEK_CUR` or 1 to set it relative to the current position; `SEEK_END` or 2 to set it relative to the end of the file. Return the new cursor position in bytes, starting from the beginning.

os.SEEK_SET**os.SEEK_CUR****os.SEEK_END**

Parameters to the `lseek()` function. Their values are 0, 1, and 2, respectively.

Νέο στην έκδοση 3.3: Some operating systems could support additional values, like `os.SEEK_HOLE` or `os.SEEK_DATA`.

os.open(*path*, *flags*, *mode=0o777*, *, *dir_fd=None*)

Open the file *path* and set various flags according to *flags* and possibly its mode according to *mode*. When computing *mode*, the current umask value is first masked out. Return the file descriptor for the newly opened file. The new file descriptor is *non-inheritable*.

For a description of the flag and mode values, see the C run-time documentation; flag constants (like `O_RDONLY` and `O_WRONLY`) are defined in the `os` module. In particular, on Windows adding `O_BINARY` is needed to open files in binary mode.

This function can support *paths relative to directory descriptors* with the *dir_fd* parameter.

Raises an *auditing event* `open` with arguments *path*, *mode*, *flags*.

Άλλαξε στην έκδοση 3.4: The new file descriptor is now non-inheritable.

Σημείωση: This function is intended for low-level I/O. For normal usage, use the built-in function `open()`, which returns a *file object* with `read()` and `write()` methods (and many more). To wrap a file descriptor in a

file object, use `fdopen()`.

Νέο στην έκδοση 3.3: The `dir_fd` argument.

Άλλαξε στην έκδοση 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](#) for the rationale).

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

The following constants are options for the `flags` parameter to the `open()` function. They can be combined using the bitwise OR operator `|`. Some of them are not available on all platforms. For descriptions of their availability and use, consult the `open(2)` manual page on Unix or [the MSDN](#) on Windows.

```
os.O_RDONLY
os.O_WRONLY
os.O_RDWR
os.O_APPEND
os.O_CREAT
os.O_EXCL
os.O_TRUNC
```

The above constants are available on Unix and Windows.

```
os.O_DSYNC
os.O_RSYNC
os.O_SYNC
os.O_NDELAY
os.O_NONBLOCK
os.O_NOCTTY
os.O_CLOEXEC
```

The above constants are only available on Unix.

Άλλαξε στην έκδοση 3.3: Add `O_CLOEXEC` constant.

```
os.O_BINARY
os.O_NOINHERIT
os.O_SHORT_LIVED
os.O_TEMPORARY
os.O_RANDOM
os.O_SEQUENTIAL
os.O_TEXT
```

The above constants are only available on Windows.

```
os.O_ASYNC
os.O_DIRECT
os.O_DIRECTORY
os.O_NOFOLLOW
os.O_NOATIME
os.O_PATH
os.O_TMPFILE
os.O_SHLOCK
os.O_EXLOCK
```

The above constants are extensions and not present if they are not defined by the C library.

Άλλαξε στην έκδοση 3.4: Add `O_PATH` on systems that support it. Add `O_TMPFILE`, only available on Linux Kernel 3.11 or newer.

```
os.openpty()
```

Open a new pseudo-terminal pair. Return a pair of file descriptors (`master`, `slave`) for the `pty` and the `tty`, respectively. The new file descriptors are *non-inheritable*. For a (slightly) more portable approach, use the `pty` module.

Availability: some flavors of Unix.

Άλλαξε στην έκδοση 3.4: The new file descriptors are now non-inheritable.

`os.pipe()`

Create a pipe. Return a pair of file descriptors (`r`, `w`) usable for reading and writing, respectively. The new file descriptor is *non-inheritable*.

Availability: Unix, Windows.

Άλλαξε στην έκδοση 3.4: The new file descriptors are now non-inheritable.

`os.pipe2(flags)`

Create a pipe with *flags* set atomically. *flags* can be constructed by ORing together one or more of these values: `O_NONBLOCK`, `O_CLOEXEC`. Return a pair of file descriptors (`r`, `w`) usable for reading and writing, respectively.

Availability: some flavors of Unix.

Νέο στην έκδοση 3.3.

`os.posix_fallocate(fd, offset, len)`

Ensures that enough disk space is allocated for the file specified by *fd* starting from *offset* and continuing for *len* bytes.

Availability: Unix.

Νέο στην έκδοση 3.3.

`os.posix_fadvise(fd, offset, len, advice)`

Announces an intention to access data in a specific pattern thus allowing the kernel to make optimizations. The advice applies to the region of the file specified by *fd* starting at *offset* and continuing for *len* bytes. *advice* is one of `POSIX_FADV_NORMAL`, `POSIX_FADV_SEQUENTIAL`, `POSIX_FADV_RANDOM`, `POSIX_FADV_NOREUSE`, `POSIX_FADV_WILLNEED` or `POSIX_FADV_DONTNEED`.

Availability: Unix.

Νέο στην έκδοση 3.3.

`os.POSIX_FADV_NORMAL`

`os.POSIX_FADV_SEQUENTIAL`

`os.POSIX_FADV_RANDOM`

`os.POSIX_FADV_NOREUSE`

`os.POSIX_FADV_WILLNEED`

`os.POSIX_FADV_DONTNEED`

Flags that can be used in *advice* in `posix_fadvise()` that specify the access pattern that is likely to be used.

Availability: Unix.

Νέο στην έκδοση 3.3.

`os.pread(fd, n, offset)`

Read at most *n* bytes from file descriptor *fd* at a position of *offset*, leaving the file offset unchanged.

Return a bytearray containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

Availability: Unix.

Νέο στην έκδοση 3.3.

os.preadv (*fd, buffers, offset, flags=0*)

Read from a file descriptor *fd* at a position of *offset* into mutable *bytes-like objects buffers*, leaving the file offset unchanged. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

The flags argument contains a bitwise OR of zero or more of the following flags:

- *RWF_HIPRI*
- *RWF_NOWAIT*

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (*sysconf()* value 'SC_IOV_MAX') on the number of buffers that can be used.

Combine the functionality of *os.readv()* and *os.pread()*.

Availability: Linux 2.6.30 and newer, FreeBSD 6.0 and newer, OpenBSD 2.7 and newer, AIX 7.1 and newer. Using flags requires Linux 4.6 or newer.

Νέο στην έκδοση 3.7.

os.RWF_NOWAIT

Do not wait for data which is not immediately available. If this flag is specified, the system call will return instantly if it would have to read data from the backing storage or wait for a lock.

If some data was successfully read, it will return the number of bytes read. If no bytes were read, it will return `-1` and set *errno* to *errno.EAGAIN*.

Availability: Linux 4.14 and newer.

Νέο στην έκδοση 3.7.

os.RWF_HIPRI

High priority read/write. Allows block-based filesystems to use polling of the device, which provides lower latency, but may use additional resources.

Currently, on Linux, this feature is usable only on a file descriptor opened using the *O_DIRECT* flag.

Availability: Linux 4.6 and newer.

Νέο στην έκδοση 3.7.

os.pwrite (*fd, str, offset*)

Write the bytestring in *str* to file descriptor *fd* at position of *offset*, leaving the file offset unchanged.

Return the number of bytes actually written.

Availability: Unix.

Νέο στην έκδοση 3.3.

os.pwritev (*fd, buffers, offset, flags=0*)

Write the *buffers* contents to file descriptor *fd* at a offset *offset*, leaving the file offset unchanged. *buffers* must be a sequence of *bytes-like objects*. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

The flags argument contains a bitwise OR of zero or more of the following flags:

- *RWF_DSYNC*
- *RWF_SYNC*

Return the total number of bytes actually written.

The operating system may set a limit (`sysconf()` value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Combine the functionality of `os.writev()` and `os.pwrite()`.

Availability: Linux 2.6.30 and newer, FreeBSD 6.0 and newer, OpenBSD 2.7 and newer, AIX 7.1 and newer. Using flags requires Linux 4.7 or newer.

Νέο στην έκδοση 3.7.

`os.RWF_DSYNC`

Provide a per-write equivalent of the `O_DSYNC` `open(2)` flag. This flag effect applies only to the data range written by the system call.

Availability: Linux 4.7 and newer.

Νέο στην έκδοση 3.7.

`os.RWF_SYNC`

Provide a per-write equivalent of the `O_SYNC` `open(2)` flag. This flag effect applies only to the data range written by the system call.

Availability: Linux 4.7 and newer.

Νέο στην έκδοση 3.7.

`os.read(fd, n)`

Read at most *n* bytes from file descriptor *fd*.

Return a bytearray containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

Σημείωση: This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To read a «file object» returned by the built-in function `open()` or by `popen()` or `fdopen()`, or `sys.stdin`, use its `read()` or `readline()` methods.

Άλλαξε στην έκδοση 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](#) for the rationale).

`os.sendfile(out_fd, in_fd, offset, count)`

`os.sendfile(out_fd, in_fd, offset, count, headers=(), trailers=(), flags=0)`

Copy *count* bytes from file descriptor *in_fd* to file descriptor *out_fd* starting at *offset*. Return the number of bytes sent. When EOF is reached return 0.

The first function notation is supported by all platforms that define `sendfile()`.

On Linux, if *offset* is given as `None`, the bytes are read from the current position of *in_fd* and the position of *in_fd* is updated.

The second case may be used on macOS and FreeBSD where *headers* and *trailers* are arbitrary sequences of buffers that are written before and after the data from *in_fd* is written. It returns the same as the first case.

On macOS and FreeBSD, a value of 0 for *count* specifies to send until the end of *in_fd* is reached.

All platforms support sockets as *out_fd* file descriptor, and some platforms allow other types (e.g. regular file, pipe) as well.

Cross-platform applications should not use *headers*, *trailers* and *flags* arguments.

Availability: Unix.

Σημείωση: For a higher-level wrapper of `sendfile()`, see `socket.socket.sendfile()`.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.9: Parameters `out` and `in` was renamed to `out_fd` and `in_fd`.

`os.set_blocking(fd, blocking)`

Set the blocking mode of the specified file descriptor. Set the `O_NONBLOCK` flag if `blocking` is `False`, clear the flag otherwise.

See also `get_blocking()` and `socket.socket.setblocking()`.

Availability: Unix.

Νέο στην έκδοση 3.5.

`os.SF_NODISKIO`

`os.SF_MNOWAIT`

`os.SF_SYNC`

Parameters to the `sendfile()` function, if the implementation supports them.

Availability: Unix.

Νέο στην έκδοση 3.3.

`os.readv(fd, buffers)`

Read from a file descriptor `fd` into a number of mutable *bytes-like objects* `buffers`. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (`sysconf()` value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Availability: Unix.

Νέο στην έκδοση 3.3.

`os.tcgetpgrp(fd)`

Return the process group associated with the terminal given by `fd` (an open file descriptor as returned by `os.open()`).

Availability: Unix.

`os.tcsetpgrp(fd, pg)`

Set the process group associated with the terminal given by `fd` (an open file descriptor as returned by `os.open()`) to `pg`.

Availability: Unix.

`os.ttyname(fd)`

Return a string which specifies the terminal device associated with file descriptor `fd`. If `fd` is not associated with a terminal device, an exception is raised.

Availability: Unix.

`os.write(fd, str)`

Write the bytestring in `str` to file descriptor `fd`.

Return the number of bytes actually written.

Σημείωση: This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To write a «file object» returned by the built-in function `open()` or by `popen()` or `fdopen()`, or `sys.stdout` or `sys.stderr`, use its `write()` method.

Άλλαξε στην έκδοση 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](#) for the rationale).

`os.writev(fd, buffers)`

Write the contents of *buffers* to file descriptor *fd*. *buffers* must be a sequence of *bytes-like objects*. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

Returns the total number of bytes actually written.

The operating system may set a limit (`sysconf()` value 'SC_IOV_MAX') on the number of buffers that can be used.

Availability: Unix.

Νέο στην έκδοση 3.3.

Querying the size of a terminal

Νέο στην έκδοση 3.3.

`os.get_terminal_size(fd=STDOUT_FILENO)`

Return the size of the terminal window as (`columns`, `lines`), tuple of type *terminal_size*.

The optional argument *fd* (default `STDOUT_FILENO`, or standard output) specifies which file descriptor should be queried.

If the file descriptor is not connected to a terminal, an `OSError` is raised.

`shutil.get_terminal_size()` is the high-level function which should normally be used, `os.get_terminal_size` is the low-level implementation.

Availability: Unix, Windows.

class `os.terminal_size`

A subclass of tuple, holding (`columns`, `lines`) of the terminal window size.

columns

Width of the terminal window in characters.

lines

Height of the terminal window in characters.

Inheritance of File Descriptors

Νέο στην έκδοση 3.4.

A file descriptor has an «inheritable» flag which indicates if the file descriptor can be inherited by child processes. Since Python 3.4, file descriptors created by Python are non-inheritable by default.

On UNIX, non-inheritable file descriptors are closed in child processes at the execution of a new program, other file descriptors are inherited.

On Windows, non-inheritable handles and file descriptors are closed in child processes, except for standard streams (file descriptors 0, 1 and 2: `stdin`, `stdout` and `stderr`), which are always inherited. Using *spawn** functions, all inheritable

handles and all inheritable file descriptors are inherited. Using the `subprocess` module, all file descriptors except standard streams are closed, and inheritable handles are only inherited if the `close_fds` parameter is `False`.

`os.get_inheritable(fd)`

Get the «inheritable» flag of the specified file descriptor (a boolean).

`os.set_inheritable(fd, inheritable)`

Set the «inheritable» flag of the specified file descriptor.

`os.get_handle_inheritable(handle)`

Get the «inheritable» flag of the specified handle (a boolean).

Availability: Windows.

`os.set_handle_inheritable(handle, inheritable)`

Set the «inheritable» flag of the specified handle.

Availability: Windows.

16.1.5 Files and Directories

On some Unix platforms, many of these functions support one or more of these features:

- **specifying a file descriptor:** Normally the *path* argument provided to functions in the `os` module must be a string specifying a file path. However, some functions now alternatively accept an open file descriptor for their *path* argument. The function will then operate on the file referred to by the descriptor. (For POSIX systems, Python will call the variant of the function prefixed with `f` (e.g. call `fchdir` instead of `chdir`.)

You can check whether or not *path* can be specified as a file descriptor for a particular function on your platform using `os.supports_fd`. If this functionality is unavailable, using it will raise a `NotImplementedError`.

If the function also supports *dir_fd* or *follow_symlinks* arguments, it's an error to specify one of those when supplying *path* as a file descriptor.

- **paths relative to directory descriptors:** If *dir_fd* is not `None`, it should be a file descriptor referring to a directory, and the path to operate on should be relative; *path* will then be relative to that directory. If the path is absolute, *dir_fd* is ignored. (For POSIX systems, Python will call the variant of the function with an `at` suffix and possibly prefixed with `f` (e.g. call `faccessat` instead of `access`).

You can check whether or not *dir_fd* is supported for a particular function on your platform using `os.supports_dir_fd`. If it's unavailable, using it will raise a `NotImplementedError`.

- **not following symlinks:** If *follow_symlinks* is `False`, and the last element of the path to operate on is a symbolic link, the function will operate on the symbolic link itself rather than the file pointed to by the link. (For POSIX systems, Python will call the `l...` variant of the function.)

You can check whether or not *follow_symlinks* is supported for a particular function on your platform using `os.supports_follow_symlinks`. If it's unavailable, using it will raise a `NotImplementedError`.

`os.access(path, mode, *, dir_fd=None, effective_ids=False, follow_symlinks=True)`

Use the real uid/gid to test for access to *path*. Note that most operations will use the effective uid/gid, therefore this routine can be used in a `suid/sgid` environment to test if the invoking user has the specified access to *path*. *mode* should be `F_OK` to test the existence of *path*, or it can be the inclusive OR of one or more of `R_OK`, `W_OK`, and `X_OK` to test permissions. Return `True` if access is allowed, `False` if not. See the Unix man page `access(2)` for more information.

This function can support specifying *paths relative to directory descriptors* and *not following symlinks*.

If *effective_ids* is `True`, `access()` will perform its access checks using the effective uid/gid instead of the real uid/gid. *effective_ids* may not be supported on your platform; you can check whether or not it is available using `os.supports_effective_ids`. If it is unavailable, using it will raise a `NotImplementedError`.

Σημείωση: Using `access()` to check if a user is authorized to e.g. open a file before actually doing so using `open()` creates a security hole, because the user might exploit the short time interval between checking and opening the file to manipulate it. It's preferable to use *EAFP* techniques. For example:

```
if os.access("myfile", os.R_OK):
    with open("myfile") as fp:
        return fp.read()
return "some default data"
```

is better written as:

```
try:
    fp = open("myfile")
except PermissionError:
    return "some default data"
else:
    with fp:
        return fp.read()
```

Σημείωση: I/O operations may fail even when `access()` indicates that they would succeed, particularly for operations on network filesystems which may have permissions semantics beyond the usual POSIX permission-bit model.

Άλλαξε στην έκδοση 3.3: Added the `dir_fd`, `effective_ids`, and `follow_symlinks` parameters.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.F_OK`
`os.R_OK`
`os.W_OK`
`os.X_OK`

Values to pass as the *mode* parameter of `access()` to test the existence, readability, writability and executability of *path*, respectively.

`os.chdir(path)`

Change the current working directory to *path*.

This function can support *specifying a file descriptor*. The descriptor must refer to an opened directory, not an open file.

This function can raise `OSError` and subclasses such as `FileNotFoundError`, `PermissionError`, and `NotADirectoryError`.

Raises an *auditing event* `os.chdir` with argument *path*.

Νέο στην έκδοση 3.3: Added support for specifying *path* as a file descriptor on some platforms.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.chflags(path, flags, *, follow_symlinks=True)`

Set the flags of *path* to the numeric *flags*. *flags* may take a combination (bitwise OR) of the following values (as defined in the `stat` module):

- `stat.UF_NODUMP`
- `stat.UF_IMMUTABLE`
- `stat.UF_APPEND`

- `stat.UF_OPAQUE`
- `stat.UF_NOUNLINK`
- `stat.UF_COMPRESSED`
- `stat.UF_HIDDEN`
- `stat.SF_ARCHIVED`
- `stat.SF_IMMUTABLE`
- `stat.SF_APPEND`
- `stat.SF_NOUNLINK`
- `stat.SF_SNAPSHOT`

This function can support *not following symlinks*.

Raises an *auditing event* `os.chflags` with arguments `path`, `flags`.

Availability: Unix.

Νέο στην έκδοση 3.3: The *follow_symlinks* argument.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

os.**chmod** (*path*, *mode*, *, *dir_fd=None*, *follow_symlinks=True*)

Change the mode of *path* to the numeric *mode*. *mode* may take one of the following values (as defined in the *stat* module) or bitwise ORed combinations of them:

- `stat.S_ISUID`
- `stat.S_ISGID`
- `stat.S_ENFMT`
- `stat.S_ISVTX`
- `stat.S_IREAD`
- `stat.S_IWRITE`
- `stat.S_IEXEC`
- `stat.S_IRWXU`
- `stat.S_IRUSR`
- `stat.S_IWUSR`
- `stat.S_IXUSR`
- `stat.S_IRWXG`
- `stat.S_IRGRP`
- `stat.S_IWGRP`
- `stat.S_IXGRP`
- `stat.S_IRWXO`
- `stat.S_IROTH`
- `stat.S_IWOTH`
- `stat.S_IXOTH`

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

Σημείωση: Although Windows supports `chmod()`, you can only set the file's read-only flag with it (via the `stat.S_IWRITE` and `stat.S_IREAD` constants or a corresponding integer value). All other bits are ignored.

Raises an *auditing event* `os.chmod` with arguments `path`, `mode`, `dir_fd`.

Νέο στην έκδοση 3.3: Added support for specifying *path* as an open file descriptor, and the *dir_fd* and *follow_symlinks* arguments.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.chown(path, uid, gid, *, dir_fd=None, follow_symlinks=True)`

Change the owner and group id of *path* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1.

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

See `shutil.chown()` for a higher-level function that accepts names in addition to numeric ids.

Raises an *auditing event* `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

Availability: Unix.

Νέο στην έκδοση 3.3: Added support for specifying *path* as an open file descriptor, and the *dir_fd* and *follow_symlinks* arguments.

Άλλαξε στην έκδοση 3.6: Supports a *path-like object*.

`os.chroot(path)`

Change the root directory of the current process to *path*.

Availability: Unix.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.fchdir(fd)`

Change the current working directory to the directory represented by the file descriptor *fd*. The descriptor must refer to an opened directory, not an open file. As of Python 3.3, this is equivalent to `os.chdir(fd)`.

Raises an *auditing event* `os.chdir` with argument *path*.

Availability: Unix.

`os.getcwd()`

Return a string representing the current working directory.

`os.getcwdb()`

Return a bytestring representing the current working directory.

Άλλαξε στην έκδοση 3.8: The function now uses the UTF-8 encoding on Windows, rather than the ANSI code page: see [PEP 529](#) for the rationale. The function is no longer deprecated on Windows.

`os.lchflags(path, flags)`

Set the flags of *path* to the numeric *flags*, like `chflags()`, but do not follow symbolic links. As of Python 3.3, this is equivalent to `os.chflags(path, flags, follow_symlinks=False)`.

Raises an *auditing event* `os.chflags` with arguments *path*, *flags*.

Availability: Unix.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

os.lchmod (*path*, *mode*)

Change the mode of *path* to the numeric *mode*. If *path* is a symlink, this affects the symlink rather than the target. See the docs for [chmod\(\)](#) for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(path, mode, follow_symlinks=False)`.

Raises an [auditing event](#) `os.chmod` with arguments *path*, *mode*, *dir_fd*.

Availability: Unix.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

os.lchown (*path*, *uid*, *gid*)

Change the owner and group id of *path* to the numeric *uid* and *gid*. This function will not follow symbolic links. As of Python 3.3, this is equivalent to `os.chown(path, uid, gid, follow_symlinks=False)`.

Raises an [auditing event](#) `os.chown` with arguments *path*, *uid*, *gid*, *dir_fd*.

Availability: Unix.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

os.link (*src*, *dst*, *, *src_dir_fd=None*, *dst_dir_fd=None*, *follow_symlinks=True*)

Create a hard link pointing to *src* named *dst*.

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*, and *not following symlinks*.

Raises an [auditing event](#) `os.link` with arguments *src*, *dst*, *src_dir_fd*, *dst_dir_fd*.

Availability: Unix, Windows.

Άλλαξε στην έκδοση 3.2: Added Windows support.

Νέο στην έκδοση 3.3: Added the *src_dir_fd*, *dst_dir_fd*, and *follow_symlinks* arguments.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object* for *src* and *dst*.

os.listdir (*path*='.')

Return a list containing the names of the entries in the directory given by *path*. The list is in arbitrary order, and does not include the special entries `'.'` and `'..'` even if they are present in the directory. If a file is removed from or added to the directory during the call of this function, whether a name for that file be included is unspecified.

path may be a *path-like object*. If *path* is of type `bytes` (directly or indirectly through the [PathLike](#) interface), the filenames returned will also be of type `bytes`; in all other circumstances, they will be of type `str`.

This function can also support *specifying a file descriptor*; the file descriptor must refer to a directory.

Raises an [auditing event](#) `os.listdir` with argument *path*.

Σημείωση: To encode `str` filenames to `bytes`, use [fsencode\(\)](#).

Δείτε επίσης:

The [scandir\(\)](#) function returns directory entries along with file attribute information, giving better performance for many common use cases.

Άλλαξε στην έκδοση 3.2: The *path* parameter became optional.

Νέο στην έκδοση 3.3: Added support for specifying *path* as an open file descriptor.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.lstat(path, *, dir_fd=None)`

Perform the equivalent of an `lstat()` system call on the given path. Similar to `stat()`, but does not follow symbolic links. Return a `stat_result` object.

On platforms that do not support symbolic links, this is an alias for `stat()`.

As of Python 3.3, this is equivalent to `os.stat(path, dir_fd=dir_fd, follow_symlinks=False)`.

This function can also support *paths relative to directory descriptors*.

Δείτε επίσης:

The `stat()` function.

Άλλαξε στην έκδοση 3.2: Added support for Windows 6.0 (Vista) symbolic links.

Άλλαξε στην έκδοση 3.3: Added the `dir_fd` parameter.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

Άλλαξε στην έκδοση 3.8: On Windows, now opens reparse points that represent another path (name surrogates), including symbolic links and directory junctions. Other kinds of reparse points are resolved by the operating system as for `stat()`.

`os.mkdir(path, mode=0o777, *, dir_fd=None)`

Create a directory named *path* with numeric mode *mode*.

If the directory already exists, `FileExistsError` is raised. If a parent directory in the path does not exist, `FileNotFoundError` is raised.

On some systems, *mode* is ignored. Where it is used, the current umask value is first masked out. If bits other than the last 9 (i.e. the last 3 digits of the octal representation of the *mode*) are set, their meaning is platform-dependent. On some platforms, they are ignored and you should call `chmod()` explicitly to set them.

On Windows, a *mode* of `0o700` is specifically handled to apply access control to the new directory such that only the current user and administrators have access. Other values of *mode* are ignored.

This function can also support *paths relative to directory descriptors*.

It is also possible to create temporary directories; see the `tempfile` module's `tempfile.mkdtemp()` function.

Raises an *auditing event* `os.mkdir` with arguments *path*, *mode*, *dir_fd*.

Νέο στην έκδοση 3.3: The `dir_fd` argument.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

Άλλαξε στην έκδοση 3.9.20: Windows now handles a *mode* of `0o700`.

`os.makedirs(name, mode=0o777, exist_ok=False)`

Recursive directory creation function. Like `mkdir()`, but makes all intermediate-level directories needed to contain the leaf directory.

The *mode* parameter is passed to `mkdir()` for creating the leaf directory; see *the mkdir() description* for how it is interpreted. To set the file permission bits of any newly-created parent directories you can set the umask before invoking `makedirs()`. The file permission bits of existing parent directories are not changed.

If *exist_ok* is `False` (the default), an `FileExistsError` is raised if the target directory already exists.

Σημείωση: `makedirs()` will become confused if the path elements to create include *pardir* (eg. «...» on UNIX systems).

This function handles UNC paths correctly.

Raises an *auditing event* `os.mkdir` with arguments `path`, `mode`, `dir_fd`.

Νέο στην έκδοση 3.2: The `exist_ok` parameter.

Άλλαξε στην έκδοση 3.4.1: Before Python 3.4.1, if `exist_ok` was `True` and the directory existed, `makedirs()` would still raise an error if `mode` did not match the mode of the existing directory. Since this behavior was impossible to implement safely, it was removed in Python 3.4.1. See [bpo-21082](#).

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

Άλλαξε στην έκδοση 3.7: The `mode` argument no longer affects the file permission bits of newly-created intermediate-level directories.

`os.mkfifo` (*path*, *mode=0o666*, *, *dir_fd=None*)

Create a FIFO (a named pipe) named *path* with numeric mode *mode*. The current umask value is first masked out from the mode.

This function can also support *paths relative to directory descriptors*.

FIFOs are pipes that can be accessed like regular files. FIFOs exist until they are deleted (for example with `os.unlink()`). Generally, FIFOs are used as rendezvous between «client» and «server» type processes: the server opens the FIFO for reading, and the client opens it for writing. Note that `mkfifo()` doesn't open the FIFO — it just creates the rendezvous point.

Availability: Unix.

Νέο στην έκδοση 3.3: The `dir_fd` argument.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.mknod` (*path*, *mode=0o600*, *device=0*, *, *dir_fd=None*)

Create a filesystem node (file, device special file or named pipe) named *path*. *mode* specifies both the permissions to use and the type of node to be created, being combined (bitwise OR) with one of `stat.S_IFREG`, `stat.S_IFCHR`, `stat.S_IFBLK`, and `stat.S_IFIFO` (those constants are available in `stat`). For `stat.S_IFCHR` and `stat.S_IFBLK`, *device* defines the newly created device special file (probably using `os.makedev()`), otherwise it is ignored.

This function can also support *paths relative to directory descriptors*.

Availability: Unix.

Νέο στην έκδοση 3.3: The `dir_fd` argument.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.major` (*device*)

Extract the device major number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.minor` (*device*)

Extract the device minor number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.makedev` (*major*, *minor*)

Compose a raw device number from the major and minor device numbers.

`os.pathconf` (*path*, *name*)

Return system configuration information relevant to a named file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, *ValueError* is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an *OSError* is raised with `errno.EINVAL` for the error number.

This function can support *specifying a file descriptor*.

Availability: Unix.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.pathconf_names`

Dictionary mapping names accepted by `pathconf()` and `fpathconf()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

`os.readlink(path, *, dir_fd=None)`

Return a string representing the path to which the symbolic link points. The result may be either an absolute or relative pathname; if it is relative, it may be converted to an absolute pathname using `os.path.join(os.path.dirname(path), result)`.

If the *path* is a string object (directly or indirectly through a *PathLike* interface), the result will also be a string object, and the call may raise a *UnicodeDecodeError*. If the *path* is a bytes object (direct or indirectly), the result will be a bytes object.

This function can also support *paths relative to directory descriptors*.

When trying to resolve a path that may contain links, use `realpath()` to properly handle recursion and platform differences.

Availability: Unix, Windows.

Άλλαξε στην έκδοση 3.2: Added support for Windows 6.0 (Vista) symbolic links.

Νέο στην έκδοση 3.3: The *dir_fd* argument.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object* on Unix.

Άλλαξε στην έκδοση 3.8: Accepts a *path-like object* and a bytes object on Windows.

Άλλαξε στην έκδοση 3.8: Added support for directory junctions, and changed to return the substitution path (which typically includes `\\?\` prefix) rather than the optional «print name» field that was previously returned.

`os.remove(path, *, dir_fd=None)`

Remove (delete) the file *path*. If *path* is a directory, an *IsADirectoryError* is raised. Use `rmdir()` to remove directories. If the file does not exist, a *FileNotFoundError* is raised.

This function can support *paths relative to directory descriptors*.

On Windows, attempting to remove a file that is in use causes an exception to be raised; on Unix, the directory entry is removed but the storage allocated to the file is not made available until the original file is no longer in use.

This function is semantically identical to `unlink()`.

Raises an *auditing event* `os.remove` with arguments *path*, *dir_fd*.

Νέο στην έκδοση 3.3: The *dir_fd* argument.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.removedirs(name)`

Remove directories recursively. Works like `rmdir()` except that, if the leaf directory is successfully removed, `removedirs()` tries to successively remove every parent directory mentioned in *path* until an error is

raised (which is ignored, because it generally means that a parent directory is not empty). For example, `os.removedirs('foo/bar/baz')` will first remove the directory `'foo/bar/baz'`, and then remove `'foo/bar'` and `'foo'` if they are empty. Raises `OSError` if the leaf directory could not be successfully removed.

Raises an *auditing event* `os.remove` with arguments `path`, `dir_fd`.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

os.rename (*src*, *dst*, *, *src_dir_fd=None*, *dst_dir_fd=None*)

Rename the file or directory *src* to *dst*. If *dst* exists, the operation will fail with an `OSError` subclass in a number of cases:

On Windows, if *dst* exists a `FileExistsError` is always raised.

On Unix, if *src* is a file and *dst* is a directory or vice-versa, an `IsADirectoryError` or a `NotADirectoryError` will be raised respectively. If both are directories and *dst* is empty, *dst* will be silently replaced. If *dst* is a non-empty directory, an `OSError` is raised. If both are files, *dst* it will be replaced silently if the user has permission. The operation may fail on some Unix flavors if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*.

If you want cross-platform overwriting of the destination, use `replace()`.

Raises an *auditing event* `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

Νέο στην έκδοση 3.3: The *src_dir_fd* and *dst_dir_fd* arguments.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object* for *src* and *dst*.

os.rename (*old*, *new*)

Recursive directory or file renaming function. Works like `rename()`, except creation of any intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned away using `removedirs()`.

Σημείωση: This function can fail with the new directory structure made if you lack permissions needed to remove the leaf directory or file.

Raises an *auditing event* `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object* for *old* and *new*.

os.replace (*src*, *dst*, *, *src_dir_fd=None*, *dst_dir_fd=None*)

Rename the file or directory *src* to *dst*. If *dst* is a non-empty directory, `OSError` will be raised. If *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*.

Raises an *auditing event* `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object* for *src* and *dst*.

os.rmdir (*path*, *, *dir_fd=None*)

Remove (delete) the directory *path*. If the directory does not exist or is not empty, an `FileNotFoundError` or an `OSError` is raised respectively. In order to remove whole directory trees, `shutil.rmtree()` can be used.

This function can support *paths relative to directory descriptors*.

Raises an *auditing event* `os.rmdir` with arguments `path`, `dir_fd`.

Νέο στην έκδοση 3.3: The `dir_fd` parameter.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.scandir(path='.')`

Return an iterator of `os.DirEntry` objects corresponding to the entries in the directory given by *path*. The entries are yielded in arbitrary order, and the special entries `'.'` and `'..'` are not included. If a file is removed from or added to the directory after creating the iterator, whether an entry for that file be included is unspecified.

Using `scandir()` instead of `listdir()` can significantly increase the performance of code that also needs file type or file attribute information, because `os.DirEntry` objects expose this information if the operating system provides it when scanning a directory. All `os.DirEntry` methods may perform a system call, but `is_dir()` and `is_file()` usually only require a system call for symbolic links; `os.DirEntry.stat()` always requires a system call on Unix but only requires one for symbolic links on Windows.

path may be a *path-like object*. If *path* is of type `bytes` (directly or indirectly through the *PathLike* interface), the type of the *name* and *path* attributes of each `os.DirEntry` will be `bytes`; in all other circumstances, they will be of type `str`.

This function can also support *specifying a file descriptor*; the file descriptor must refer to a directory.

Raises an *auditing event* `os.scandir` with argument *path*.

The `scandir()` iterator supports the *context manager* protocol and has the following method:

`scandir.close()`

Close the iterator and free acquired resources.

This is called automatically when the iterator is exhausted or garbage collected, or when an error happens during iterating. However it is advisable to call it explicitly or use the `with` statement.

Νέο στην έκδοση 3.6.

The following example shows a simple use of `scandir()` to display all the files (excluding directories) in the given *path* that don't start with `'.'`. The `entry.is_file()` call will generally not make an additional system call:

```
with os.scandir(path) as it:
    for entry in it:
        if not entry.name.startswith('.') and entry.is_file():
            print(entry.name)
```

Σημείωση: On Unix-based systems, `scandir()` uses the system's `opendir()` and `readdir()` functions. On Windows, it uses the Win32 `FindFirstFileW` and `FindNextFileW` functions.

Νέο στην έκδοση 3.5.

Νέο στην έκδοση 3.6: Added support for the *context manager* protocol and the `close()` method. If a `scandir()` iterator is neither exhausted nor explicitly closed a *ResourceWarning* will be emitted in its destructor.

The function accepts a *path-like object*.

Άλλαξε στην έκδοση 3.7: Added support for *file descriptors* on Unix.

class `os.DirEntry`

Object yielded by `scandir()` to expose the file path and other file attributes of a directory entry.

`scandir()` will provide as much of this information as possible without making additional system calls. When a `stat()` or `lstat()` system call is made, the `os.DirEntry` object will cache the result.

`os.DirEntry` instances are not intended to be stored in long-lived data structures; if you know the file metadata has changed or if a long time has elapsed since calling `scandir()`, call `os.stat(entry.path)` to fetch up-to-date information.

Because the `os.DirEntry` methods can make operating system calls, they may also raise `OSError`. If you need very fine-grained control over errors, you can catch `OSError` when calling one of the `os.DirEntry` methods and handle as appropriate.

To be directly usable as a *path-like object*, `os.DirEntry` implements the `PathLike` interface.

Attributes and methods on a `os.DirEntry` instance are as follows:

name

The entry's base filename, relative to the `scandir()` *path* argument.

The `name` attribute will be `bytes` if the `scandir()` *path* argument is of type `bytes` and `str` otherwise. Use `fsdecode()` to decode byte filenames.

path

The entry's full path name: equivalent to `os.path.join(scandir_path, entry.name)` where `scandir_path` is the `scandir()` *path* argument. The path is only absolute if the `scandir()` *path* argument was absolute. If the `scandir()` *path* argument was a *file descriptor*, the `path` attribute is the same as the `name` attribute.

The `path` attribute will be `bytes` if the `scandir()` *path* argument is of type `bytes` and `str` otherwise. Use `fsdecode()` to decode byte filenames.

inode()

Return the inode number of the entry.

The result is cached on the `os.DirEntry` object. Use `os.stat(entry.path, follow_symlinks=False).st_ino` to fetch up-to-date information.

On the first, uncached call, a system call is required on Windows but not on Unix.

is_dir(*, follow_symlinks=True)

Return `True` if this entry is a directory or a symbolic link pointing to a directory; return `False` if the entry is or points to any other kind of file, or if it doesn't exist anymore.

If `follow_symlinks` is `False`, return `True` only if this entry is a directory (without following symlinks); return `False` if the entry is any other kind of file or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object, with a separate cache for `follow_symlinks` `True` and `False`. Call `os.stat()` along with `stat.S_ISDIR()` to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, for non-symlinks, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`. If the entry is a symlink, a system call will be required to follow the symlink unless `follow_symlinks` is `False`.

This method can raise `OSError`, such as `PermissionError`, but `FileNotFoundError` is caught and not raised.

is_file(*, follow_symlinks=True)

Return `True` if this entry is a file or a symbolic link pointing to a file; return `False` if the entry is or points to a directory or other non-file entry, or if it doesn't exist anymore.

If `follow_symlinks` is `False`, return `True` only if this entry is a file (without following symlinks); return `False` if the entry is a directory or other non-file entry, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Caching, system calls made, and exceptions raised are as per `is_dir()`.

is_symlink()

Return `True` if this entry is a symbolic link (even if broken); return `False` if the entry points to a directory or any kind of file, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Call `os.path.islink()` to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`.

This method can raise `OSError`, such as `PermissionError`, but `FileNotFoundError` is caught and not raised.

stat(*, follow_symlinks=True)

Return a `stat_result` object for this entry. This method follows symbolic links by default; to stat a symbolic link add the `follow_symlinks=False` argument.

On Unix, this method always requires a system call. On Windows, it only requires a system call if `follow_symlinks` is `True` and the entry is a reparse point (for example, a symbolic link or directory junction).

On Windows, the `st_ino`, `st_dev` and `st_nlink` attributes of the `stat_result` are always set to zero. Call `os.stat()` to get these attributes.

The result is cached on the `os.DirEntry` object, with a separate cache for `follow_symlinks` `True` and `False`. Call `os.stat()` to fetch up-to-date information.

Note that there is a nice correspondence between several attributes and methods of `os.DirEntry` and of `pathlib.Path`. In particular, the `name` attribute has the same meaning, as do the `is_dir()`, `is_file()`, `is_symlink()` and `stat()` methods.

Νέο στην έκδοση 3.5.

Άλλαξε στην έκδοση 3.6: Added support for the `PathLike` interface. Added support for `bytes` paths on Windows.

os.stat(path, *, dir_fd=None, follow_symlinks=True)

Get the status of a file or a file descriptor. Perform the equivalent of a `stat()` system call on the given path. `path` may be specified as either a string or bytes – directly or indirectly through the `PathLike` interface – or as an open file descriptor. Return a `stat_result` object.

This function normally follows symlinks; to stat a symlink add the argument `follow_symlinks=False`, or use `lstat()`.

This function can support *specifying a file descriptor* and *not following symlinks*.

On Windows, passing `follow_symlinks=False` will disable following all name-surrogate reparse points, which includes symlinks and directory junctions. Other types of reparse points that do not resemble links or that the operating system is unable to follow will be opened directly. When following a chain of multiple links, this may result in the original link being returned instead of the non-link that prevented full traversal. To obtain stat results for the final path in this case, use the `os.path.realpath()` function to resolve the path name as far as possible and call `lstat()` on the result. This does not apply to dangling symlinks or junction points, which will raise the usual exceptions.

Example:

```
>>> import os
>>> statinfo = os.stat('somefile.txt')
>>> statinfo
os.stat_result(st_mode=33188, st_ino=7876932, st_dev=234881026,
st_nlink=1, st_uid=501, st_gid=501, st_size=264, st_atime=1297230295,
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
st_mtime=1297230027, st_ctime=1297230027)
>>> statinfo.st_size
264
```

Δείτε επίσης:*fstat()* and *lstat()* functions.

Νέο στην έκδοση 3.3: Added the *dir_fd* and *follow_symlinks* arguments, specifying a file descriptor instead of a path.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

Άλλαξε στην έκδοση 3.8: On Windows, all reparse points that can be resolved by the operating system are now followed, and passing *follow_symlinks=False* disables following all name surrogate reparse points. If the operating system reaches a reparse point that it is not able to follow, *stat* now returns the information for the original path as if *follow_symlinks=False* had been specified instead of raising an error.

class os.stat_result

Object whose attributes correspond roughly to the members of the *stat* structure. It is used for the result of *os.stat()*, *os.fstat()* and *os.lstat()*.

Attributes:

st_mode

File mode: file type and file mode bits (permissions).

st_ino

Platform dependent, but if non-zero, uniquely identifies the file for a given value of *st_dev*. Typically:

- the inode number on Unix,
- the [file index](#) on Windows

st_dev

Identifier of the device on which this file resides.

st_nlink

Number of hard links.

st_uid

User identifier of the file owner.

st_gid

Group identifier of the file owner.

st_size

Size of the file in bytes, if it is a regular file or a symbolic link. The size of a symbolic link is the length of the pathname it contains, without a terminating null byte.

Timestamps:

st_atime

Time of most recent access expressed in seconds.

st_mtime

Time of most recent content modification expressed in seconds.

st_ctime

Platform dependent:

- the time of most recent metadata change on Unix,

- the time of creation on Windows, expressed in seconds.

st_atime_ns

Time of most recent access expressed in nanoseconds as an integer.

st_mtime_ns

Time of most recent content modification expressed in nanoseconds as an integer.

st_ctime_ns

Platform dependent:

- the time of most recent metadata change on Unix,
- the time of creation on Windows, expressed in nanoseconds as an integer.

Σημείωση: The exact meaning and resolution of the `st_atime`, `st_mtime`, and `st_ctime` attributes depend on the operating system and the file system. For example, on Windows systems using the FAT or FAT32 file systems, `st_mtime` has 2-second resolution, and `st_atime` has only 1-day resolution. See your operating system documentation for details.

Similarly, although `st_atime_ns`, `st_mtime_ns`, and `st_ctime_ns` are always expressed in nanoseconds, many systems do not provide nanosecond precision. On systems that do provide nanosecond precision, the floating-point object used to store `st_atime`, `st_mtime`, and `st_ctime` cannot preserve all of it, and as such will be slightly inexact. If you need the exact timestamps you should always use `st_atime_ns`, `st_mtime_ns`, and `st_ctime_ns`.

On some Unix systems (such as Linux), the following attributes may also be available:

st_blocks

Number of 512-byte blocks allocated for file. This may be smaller than `st_size/512` when the file has holes.

st_blksize

«Preferred» blocksize for efficient file system I/O. Writing to a file in smaller chunks may cause an inefficient read-modify-rewrite.

st_rdev

Type of device if an inode device.

st_flags

User defined flags for file.

On other Unix systems (such as FreeBSD), the following attributes may be available (but may be only filled out if root tries to use them):

st_gen

File generation number.

st_birthtime

Time of file creation.

On Solaris and derivatives, the following attributes may also be available:

st_fstype

String that uniquely identifies the type of the filesystem that contains the file.

On macOS systems, the following attributes may also be available:

st_rsize

Real size of the file.

st_creator

Creator of the file.

st_type

File type.

On Windows systems, the following attributes are also available:

st_file_attributes

Windows file attributes: `dwFileAttributes` member of the `BY_HANDLE_FILE_INFORMATION` structure returned by `GetFileInformationByHandle()`. See the `FILE_ATTRIBUTE_*` constants in the `stat` module.

st_reparse_tag

When `st_file_attributes` has the `FILE_ATTRIBUTE_REPARSE_POINT` set, this field contains the tag identifying the type of reparse point. See the `IO_REPARSE_TAG_*` constants in the `stat` module.

The standard module `stat` defines functions and constants that are useful for extracting information from a `stat` structure. (On Windows, some items are filled with dummy values.)

For backward compatibility, a `stat_result` instance is also accessible as a tuple of at least 10 integers giving the most important (and portable) members of the `stat` structure, in the order `st_mode`, `st_ino`, `st_dev`, `st_nlink`, `st_uid`, `st_gid`, `st_size`, `st_atime`, `st_mtime`, `st_ctime`. More items may be added at the end by some implementations. For compatibility with older Python versions, accessing `stat_result` as a tuple always returns integers.

Νέο στην έκδοση 3.3: Added the `st_atime_ns`, `st_mtime_ns`, and `st_ctime_ns` members.

Νέο στην έκδοση 3.5: Added the `st_file_attributes` member on Windows.

Άλλαξε στην έκδοση 3.5: Windows now returns the file index as `st_ino` when available.

Νέο στην έκδοση 3.7: Added the `st_fstype` member to Solaris/derivatives.

Νέο στην έκδοση 3.8: Added the `st_reparse_tag` member on Windows.

Άλλαξε στην έκδοση 3.8: On Windows, the `st_mode` member now identifies special files as `S_IFCHR`, `S_IFIFO` or `S_IFBLK` as appropriate.

os.statvfs(path)

Perform a `statvfs()` system call on the given path. The return value is an object whose attributes describe the filesystem on the given path, and correspond to the members of the `statvfs` structure, namely: `f_bsize`, `f_frsize`, `f_blocks`, `f_bfree`, `f_bavail`, `f_files`, `f_ffree`, `f_favail`, `f_flag`, `f_namemax`, `f_fsid`.

Two module-level constants are defined for the `f_flag` attribute's bit-flags: if `ST_RDONLY` is set, the filesystem is mounted read-only, and if `ST_NOSUID` is set, the semantics of `setuid`/`setgid` bits are disabled or not supported.

Additional module-level constants are defined for GNU/glibc based systems. These are `ST_NODEV` (disallow access to device special files), `ST_NOEXEC` (disallow program execution), `ST_SYNCHRONOUS` (writes are synced at once), `ST_MANDLOCK` (allow mandatory locks on an FS), `ST_WRITE` (write on file/directory/symlink), `ST_APPEND` (append-only file), `ST_IMMUTABLE` (immutable file), `ST_NOATIME` (do not update access times), `ST_NODIRATIME` (do not update directory access times), `ST_RELATIME` (update atime relative to mtime/ctime).

This function can support *specifying a file descriptor*.

Availability: Unix.

Άλλαξε στην έκδοση 3.2: The `ST_RDONLY` and `ST_NOSUID` constants were added.

Νέο στην έκδοση 3.3: Added support for specifying *path* as an open file descriptor.

Άλλαξε στην έκδοση 3.4: The `ST_NODEV`, `ST_NOEXEC`, `ST_SYNCHRONOUS`, `ST_MANDLOCK`, `ST_WRITE`, `ST_APPEND`, `ST_IMMUTABLE`, `ST_NOATIME`, `ST_NODIRATIME`, and `ST_RELATIME` constants were added.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

Νέο στην έκδοση 3.7: Added `f_fsid`.

`os.supports_dir_fd`

A *set* object indicating which functions in the `os` module accept an open file descriptor for their `dir_fd` parameter. Different platforms provide different features, and the underlying functionality Python uses to implement the `dir_fd` parameter is not available on all platforms Python supports. For consistency's sake, functions that may support `dir_fd` always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `None` for `dir_fd` is always supported on all platforms.)

To check whether a particular function accepts an open file descriptor for its `dir_fd` parameter, use the `in` operator on `supports_dir_fd`. As an example, this expression evaluates to `True` if `os.stat()` accepts open file descriptors for `dir_fd` on the local platform:

```
os.stat in os.supports_dir_fd
```

Currently `dir_fd` parameters only work on Unix platforms; none of them work on Windows.

Νέο στην έκδοση 3.3.

`os.supports_effective_ids`

A *set* object indicating whether `os.access()` permits specifying `True` for its `effective_ids` parameter on the local platform. (Specifying `False` for `effective_ids` is always supported on all platforms.) If the local platform supports it, the collection will contain `os.access()`; otherwise it will be empty.

This expression evaluates to `True` if `os.access()` supports `effective_ids=True` on the local platform:

```
os.access in os.supports_effective_ids
```

Currently `effective_ids` is only supported on Unix platforms; it does not work on Windows.

Νέο στην έκδοση 3.3.

`os.supports_fd`

A *set* object indicating which functions in the `os` module permit specifying their `path` parameter as an open file descriptor on the local platform. Different platforms provide different features, and the underlying functionality Python uses to accept open file descriptors as `path` arguments is not available on all platforms Python supports.

To determine whether a particular function permits specifying an open file descriptor for its `path` parameter, use the `in` operator on `supports_fd`. As an example, this expression evaluates to `True` if `os.chdir()` accepts open file descriptors for `path` on your local platform:

```
os.chdir in os.supports_fd
```

Νέο στην έκδοση 3.3.

`os.supports_follow_symlinks`

A *set* object indicating which functions in the `os` module accept `False` for their `follow_symlinks` parameter on the local platform. Different platforms provide different features, and the underlying functionality Python uses to implement `follow_symlinks` is not available on all platforms Python supports. For consistency's sake, functions that may support `follow_symlinks` always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `True` for `follow_symlinks` is always supported on all platforms.)

To check whether a particular function accepts `False` for its `follow_symlinks` parameter, use the `in` operator on `supports_follow_symlinks`. As an example, this expression evaluates to `True` if you may specify `follow_symlinks=False` when calling `os.stat()` on the local platform:

```
os.stat in os.supports_follow_symlinks
```

Νέο στην έκδοση 3.3.

`os.symlink (src, dst, target_is_directory=False, *, dir_fd=None)`
Create a symbolic link pointing to *src* named *dst*.

On Windows, a symlink represents either a file or a directory, and does not morph to the target dynamically. If the target is present, the type of the symlink will be created to match. Otherwise, the symlink will be created as a directory if *target_is_directory* is `True` or a file symlink (the default) otherwise. On non-Windows platforms, *target_is_directory* is ignored.

This function can support *paths relative to directory descriptors*.

Σημείωση: On newer versions of Windows 10, unprivileged accounts can create symlinks if Developer Mode is enabled. When Developer Mode is not available/enabled, the *SeCreateSymbolicLinkPrivilege* privilege is required, or the process must be run as an administrator.

`OSError` is raised when the function is called by an unprivileged user.

Raises an *auditing event* `os.symlink` with arguments *src*, *dst*, *dir_fd*.

Availability: Unix, Windows.

Άλλαξε στην έκδοση 3.2: Added support for Windows 6.0 (Vista) symbolic links.

Νέο στην έκδοση 3.3: Added the *dir_fd* argument, and now allow *target_is_directory* on non-Windows platforms.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object* for *src* and *dst*.

Άλλαξε στην έκδοση 3.8: Added support for unelevated symlinks on Windows with Developer Mode.

`os.sync ()`
Force write of everything to disk.

Availability: Unix.

Νέο στην έκδοση 3.3.

`os.truncate (path, length)`
Truncate the file corresponding to *path*, so that it is at most *length* bytes in size.

This function can support *specifying a file descriptor*.

Raises an *auditing event* `os.truncate` with arguments *path*, *length*.

Availability: Unix, Windows.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.5: Added support for Windows

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.unlink (path, *, dir_fd=None)`
Remove (delete) the file *path*. This function is semantically identical to *remove ()*; the *unlink* name is its traditional Unix name. Please see the documentation for *remove ()* for further information.

Raises an *auditing event* `os.remove` with arguments *path*, *dir_fd*.

Νέο στην έκδοση 3.3: The *dir_fd* parameter.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.utime(path, times=None, *, ns, dir_fd=None, follow_symlinks=True)`

Set the access and modified times of the file specified by *path*.

utime() takes two optional parameters, *times* and *ns*. These specify the times set on *path* and are used as follows:

- If *ns* is specified, it must be a 2-tuple of the form (*atime_ns*, *mtime_ns*) where each member is an int expressing nanoseconds.
- If *times* is not `None`, it must be a 2-tuple of the form (*atime*, *mtime*) where each member is an int or float expressing seconds.
- If *times* is `None` and *ns* is unspecified, this is equivalent to specifying *ns*=(*atime_ns*, *mtime_ns*) where both times are the current time.

It is an error to specify tuples for both *times* and *ns*.

Note that the exact times you set here may not be returned by a subsequent *stat()* call, depending on the resolution with which your operating system records access and modification times; see *stat()*. The best way to preserve exact times is to use the *st_atime_ns* and *st_mtime_ns* fields from the *os.stat()* result object with the *ns* parameter to *utime*.

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

Raises an *auditing event* *os.utime* with arguments *path*, *times*, *ns*, *dir_fd*.

Νέο στην έκδοση 3.3: Added support for specifying *path* as an open file descriptor, and the *dir_fd*, *follow_symlinks*, and *ns* parameters.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.walk(top, topdown=True, onerror=None, followlinks=False)`

Generate the file names in a directory tree by walking the tree either top-down or bottom-up. For each directory in the tree rooted at directory *top* (including *top* itself), it yields a 3-tuple (*dirpath*, *dirnames*, *filenames*).

dirpath is a string, the path to the directory. *dirnames* is a list of the names of the subdirectories in *dirpath* (excluding '.' and '..'). *filenames* is a list of the names of the non-directory files in *dirpath*. Note that the names in the lists contain no path components. To get a full path (which begins with *top*) to a file or directory in *dirpath*, do *os.path.join(dirpath, name)*. Whether or not the lists are sorted depends on the file system. If a file is removed from or added to the *dirpath* directory during generating the lists, whether a name for that file be included is unspecified.

If optional argument *topdown* is `True` or not specified, the triple for a directory is generated before the triples for any of its subdirectories (directories are generated top-down). If *topdown* is `False`, the triple for a directory is generated after the triples for all of its subdirectories (directories are generated bottom-up). No matter the value of *topdown*, the list of subdirectories is retrieved before the tuples for the directory and its subdirectories are generated.

When *topdown* is `True`, the caller can modify the *dirnames* list in-place (perhaps using *del* or slice assignment), and *walk()* will only recurse into the subdirectories whose names remain in *dirnames*; this can be used to prune the search, impose a specific order of visiting, or even to inform *walk()* about directories the caller creates or renames before it resumes *walk()* again. Modifying *dirnames* when *topdown* is `False` has no effect on the behavior of the walk, because in bottom-up mode the directories in *dirnames* are generated before *dirpath* itself is generated.

By default, errors from the *scandir()* call are ignored. If optional argument *onerror* is specified, it should be a function; it will be called with one argument, an *OSError* instance. It can report the error to continue with the walk, or raise the exception to abort the walk. Note that the filename is available as the *filename* attribute of the exception object.

By default, *walk()* will not walk down into symbolic links that resolve to directories. Set *followlinks* to `True` to visit directories pointed to by symlinks, on systems that support them.

Σημείωση: Be aware that setting *followlinks* to `True` can lead to infinite recursion if a link points to a parent directory of itself. `walk()` does not keep track of the directories it visited already.

Σημείωση: If you pass a relative pathname, don't change the current working directory between resumptions of `walk()`. `walk()` never changes the current directory, and assumes that its caller doesn't either.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
from os.path import join, getsize
for root, dirs, files in os.walk('python/Lib/email'):
    print(root, "consumes", end=" ")
    print(sum(getsize(join(root, name)) for name in files), end=" ")
    print("bytes in", len(files), "non-directory files")
    if 'CVS' in dirs:
        dirs.remove('CVS') # don't visit CVS directories
```

In the next example (simple implementation of `shutil.rmtree()`), walking the tree bottom-up is essential, `rmdir()` doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION: This is dangerous! For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files in os.walk(top, topdown=False):
    for name in files:
        os.remove(os.path.join(root, name))
    for name in dirs:
        os.rmdir(os.path.join(root, name))
```

Raises an *auditing event* `os.walk` with arguments `top`, `topdown`, `onerror`, `followlinks`.

Άλλαξε στην έκδοση 3.5: This function now calls `os.scandir()` instead of `os.listdir()`, making it faster by reducing the number of calls to `os.stat()`.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.fwalk` (`top='.'`, `topdown=True`, `onerror=None`, *, `follow_symlinks=False`, `dir_fd=None`)

This behaves exactly like `walk()`, except that it yields a 4-tuple (`dirpath`, `dirnames`, `filenames`, `dirfd`), and it supports `dir_fd`.

`dirpath`, `dirnames` and `filenames` are identical to `walk()` output, and `dirfd` is a file descriptor referring to the directory `dirpath`.

This function always supports *paths relative to directory descriptors* and *not following symlinks*. Note however that, unlike other functions, the `fwalk()` default value for `follow_symlinks` is `False`.

Σημείωση: Since `fwalk()` yields file descriptors, those are only valid until the next iteration step, so you should duplicate them (e.g. with `dup()`) if you want to keep them longer.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
for root, dirs, files, rootfd in os.fwalk('python/Lib/email'):
    print(root, "consumes", end="")
    print(sum([os.stat(name, dir_fd=rootfd).st_size for name in files]),
          end="")
    print("bytes in", len(files), "non-directory files")
    if 'CVS' in dirs:
        dirs.remove('CVS') # don't visit CVS directories
```

In the next example, walking the tree bottom-up is essential: `rmdir()` doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION: This is dangerous! For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files, rootfd in os.fwalk(top, topdown=False):
    for name in files:
        os.unlink(name, dir_fd=rootfd)
    for name in dirs:
        os.rmdir(name, dir_fd=rootfd)
```

Raises an *auditing event* `os.fwalk` with arguments `top`, `topdown`, `onerror`, `follow_symlinks`, `dir_fd`.

Availability: Unix.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

Άλλαξε στην έκδοση 3.7: Added support for *bytes* paths.

`os.memfd_create(name[, flags=os.MFD_CLOEXEC])`

Create an anonymous file and return a file descriptor that refers to it. *flags* must be one of the `os.MFD_*` constants available on the system (or a bitwise ORed combination of them). By default, the new file descriptor is *non-inheritable*.

The name supplied in *name* is used as a filename and will be displayed as the target of the corresponding symbolic link in the directory `/proc/self/fd/`. The displayed name is always prefixed with `memfd:` and serves only for debugging purposes. Names do not affect the behavior of the file descriptor, and as such multiple files can have the same name without any side effects.

Availability: Linux 3.17 or newer with glibc 2.27 or newer.

Νέο στην έκδοση 3.8.

```
os.MFD_CLOEXEC
os.MFD_ALLOW_SEALING
os.MFD_HUGETLB
os.MFD_HUGE_SHIFT
os.MFD_HUGE_MASK
os.MFD_HUGE_64KB
os.MFD_HUGE_512KB
os.MFD_HUGE_1MB
os.MFD_HUGE_2MB
os.MFD_HUGE_8MB
os.MFD_HUGE_16MB
os.MFD_HUGE_32MB
```

os.MFD_HUGE_256MB
os.MFD_HUGE_512MB
os.MFD_HUGE_1GB
os.MFD_HUGE_2GB
os.MFD_HUGE_16GB

These flags can be passed to `memfd_create()`.

Availability: Linux 3.17 or newer with glibc 2.27 or newer. The MFD_HUGE* flags are only available since Linux 4.14.

Νέο στην έκδοση 3.8.

Linux extended attributes

Νέο στην έκδοση 3.3.

These functions are all available on Linux only.

os.getxattr(*path*, *attribute*, *, *follow_symlinks=True*)

Return the value of the extended filesystem attribute *attribute* for *path*. *attribute* can be bytes or str (directly or indirectly through the *PathLike* interface). If it is str, it is encoded with the filesystem encoding.

This function can support *specifying a file descriptor* and *not following symlinks*.

Raises an *auditing event* os.getxattr with arguments *path*, *attribute*.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object* for *path* and *attribute*.

os.listdirxattr(*path=None*, *, *follow_symlinks=True*)

Return a list of the extended filesystem attributes on *path*. The attributes in the list are represented as strings decoded with the filesystem encoding. If *path* is None, *listxattr()* will examine the current directory.

This function can support *specifying a file descriptor* and *not following symlinks*.

Raises an *auditing event* os.listdirxattr with argument *path*.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

os.removexattr(*path*, *attribute*, *, *follow_symlinks=True*)

Removes the extended filesystem attribute *attribute* from *path*. *attribute* should be bytes or str (directly or indirectly through the *PathLike* interface). If it is a string, it is encoded with the filesystem encoding.

This function can support *specifying a file descriptor* and *not following symlinks*.

Raises an *auditing event* os.removexattr with arguments *path*, *attribute*.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object* for *path* and *attribute*.

os.setxattr(*path*, *attribute*, *value*, *flags=0*, *, *follow_symlinks=True*)

Set the extended filesystem attribute *attribute* on *path* to *value*. *attribute* must be a bytes or str with no embedded NULs (directly or indirectly through the *PathLike* interface). If it is a str, it is encoded with the filesystem encoding. *flags* may be *XATTR_REPLACE* or *XATTR_CREATE*. If *XATTR_REPLACE* is given and the attribute does not exist, ENODATA will be raised. If *XATTR_CREATE* is given and the attribute already exists, the attribute will not be created and EEXISTS will be raised.

This function can support *specifying a file descriptor* and *not following symlinks*.

Σημείωση: A bug in Linux kernel versions less than 2.6.39 caused the flags argument to be ignored on some filesystems.

Raises an *auditing event* os.setxattr with arguments *path*, *attribute*, *value*, *flags*.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object* for *path* and *attribute*.

os.XATTR_SIZE_MAX

The maximum size the value of an extended attribute can be. Currently, this is 64 KiB on Linux.

os.XATTR_CREATE

This is a possible value for the flags argument in `setxattr()`. It indicates the operation must create an attribute.

os.XATTR_REPLACE

This is a possible value for the flags argument in `setxattr()`. It indicates the operation must replace an existing attribute.

16.1.6 Process Management

These functions may be used to create and manage processes.

The various *exec** functions take a list of arguments for the new program loaded into the process. In each case, the first of these arguments is passed to the new program as its own name rather than as an argument a user may have typed on a command line. For the C programmer, this is the `argv[0]` passed to a program's `main()`. For example, `os.execv('/bin/echo', ['foo', 'bar'])` will only print `bar` on standard output; `foo` will seem to be ignored.

os.abort()

Generate a SIGABRT signal to the current process. On Unix, the default behavior is to produce a core dump; on Windows, the process immediately returns an exit code of 3. Be aware that calling this function will not call the Python signal handler registered for SIGABRT with `signal.signal()`.

os.add_dll_directory(path)

Add a path to the DLL search path.

This search path is used when resolving dependencies for imported extension modules (the module itself is resolved through `sys.path`), and also by `ctypes`.

Remove the directory by calling `close()` on the returned object or using it in a `with` statement.

See the [Microsoft documentation](#) for more information about how DLLs are loaded.

Raises an *auditing event* `os.add_dll_directory` with argument `path`.

Availability: Windows.

Νέο στην έκδοση 3.8: Previous versions of CPython would resolve DLLs using the default behavior for the current process. This led to inconsistencies, such as only sometimes searching `PATH` or the current working directory, and OS functions such as `AddDllDirectory` having no effect.

In 3.8, the two primary ways DLLs are loaded now explicitly override the process-wide behavior to ensure consistency. See the porting notes for information on updating libraries.

os.execl(path, arg0, arg1, ...)

os.execl(path, arg0, arg1, ..., env)

os.execlp(file, arg0, arg1, ...)

os.execlpe(file, arg0, arg1, ..., env)

os.execv(path, args)

os.execve(path, args, env)

os.execvp(file, args)

os.execvpe(file, args, env)

These functions all execute a new program, replacing the current process; they do not return. On Unix, the new executable is loaded into the current process, and will have the same process id as the caller. Errors will be reported as *OSError* exceptions.

The current process is replaced immediately. Open file objects and descriptors are not flushed, so if there may be data buffered on these open files, you should flush them using `sys.stdout.flush()` or `os.fsync()` before calling an `exec*` function.

The «l» and «v» variants of the `exec*` functions differ in how command-line arguments are passed. The «l» variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the `execl*()` functions. The «v» variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the `args` parameter. In either case, the arguments to the child process should start with the name of the command being run, but this is not enforced.

The variants which include a «p» near the end (`execlp()`, `execlpe()`, `execvp()`, and `execvpe()`) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the `exec*e` variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, `execl()`, `execle()`, `execv()`, and `execve()`, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For `execle()`, `execlpe()`, `execve()`, and `execvpe()` (note that these all end in «e»), the `env` parameter must be a mapping which is used to define the environment variables for the new process (these are used instead of the current process' environment); the functions `execl()`, `execlp()`, `execv()`, and `execvp()` all cause the new process to inherit the environment of the current process.

For `execve()` on some platforms, *path* may also be specified as an open file descriptor. This functionality may not be supported on your platform; you can check whether or not it is available using `os.supports_fd`. If it is unavailable, using it will raise a `NotImplementedError`.

Raises an *auditing event* `os.exec` with arguments `path`, `args`, `env`.

Availability: Unix, Windows.

Νέο στην έκδοση 3.3: Added support for specifying *path* as an open file descriptor for `execve()`.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os._exit(n)`

Exit the process with status *n*, without calling cleanup handlers, flushing stdio buffers, etc.

Σημείωση: The standard way to exit is `sys.exit(n)`. `_exit()` should normally only be used in the child process after a `fork()`.

The following exit codes are defined and can be used with `_exit()`, although they are not required. These are typically used for system programs written in Python, such as a mail server's external command delivery program.

Σημείωση: Some of these may not be available on all Unix platforms, since there is some variation. These constants are defined where they are defined by the underlying platform.

`os.EX_OK`

Exit code that means no error occurred.

Availability: Unix.

`os.EX_USAGE`

Exit code that means the command was used incorrectly, such as when the wrong number of arguments are given.

Availability: Unix.

`os.EX_DATAERR`

Exit code that means the input data was incorrect.

Availability: Unix.

os.EX_NOINPUT

Exit code that means an input file did not exist or was not readable.

Availability: Unix.

os.EX_NOUSER

Exit code that means a specified user did not exist.

Availability: Unix.

os.EX_NOHOST

Exit code that means a specified host did not exist.

Availability: Unix.

os.EX_UNAVAILABLE

Exit code that means that a required service is unavailable.

Availability: Unix.

os.EX_SOFTWARE

Exit code that means an internal software error was detected.

Availability: Unix.

os.EX_OSERR

Exit code that means an operating system error was detected, such as the inability to fork or create a pipe.

Availability: Unix.

os.EX_OSFILE

Exit code that means some system file did not exist, could not be opened, or had some other kind of error.

Availability: Unix.

os.EX_CANTCREAT

Exit code that means a user specified output file could not be created.

Availability: Unix.

os.EX_IOERR

Exit code that means that an error occurred while doing I/O on some file.

Availability: Unix.

os.EX_TEMPFAIL

Exit code that means a temporary failure occurred. This indicates something that may not really be an error, such as a network connection that couldn't be made during a retryable operation.

Availability: Unix.

os.EX_PROTOCOL

Exit code that means that a protocol exchange was illegal, invalid, or not understood.

Availability: Unix.

os.EX_NOPERM

Exit code that means that there were insufficient permissions to perform the operation (but not intended for file system problems).

Availability: Unix.

os.EX_CONFIG

Exit code that means that some kind of configuration error occurred.

Availability: Unix.

os.EX_NOTFOUND

Exit code that means something like «an entry was not found».

Availability: Unix.

os.fork()

Fork a child process. Return 0 in the child and the child's process id in the parent. If an error occurs *OSError* is raised.

Note that some platforms including FreeBSD <= 6.3 and Cygwin have known issues when using `fork()` from a thread.

Raises an *auditing event* `os.fork` with no arguments.

Άλλαξε στην έκδοση 3.8: Calling `fork()` in a subinterpreter is no longer supported (*RuntimeError* is raised).

Προειδοποίηση: See *ssl* for applications that use the SSL module with `fork()`.

Availability: Unix.

os.forkpty()

Fork a child process, using a new pseudo-terminal as the child's controlling terminal. Return a pair of (*pid*, *fd*), where *pid* is 0 in the child, the new child's process id in the parent, and *fd* is the file descriptor of the master end of the pseudo-terminal. For a more portable approach, use the *pty* module. If an error occurs *OSError* is raised.

Raises an *auditing event* `os.forkpty` with no arguments.

Άλλαξε στην έκδοση 3.8: Calling `forkpty()` in a subinterpreter is no longer supported (*RuntimeError* is raised).

Availability: some flavors of Unix.

os.kill(pid, sig)

Send signal *sig* to the process *pid*. Constants for the specific signals available on the host platform are defined in the *signal* module.

Windows: The *signal.CTRL_C_EVENT* and *signal.CTRL_BREAK_EVENT* signals are special signals which can only be sent to console processes which share a common console window, e.g., some subprocesses. Any other value for *sig* will cause the process to be unconditionally killed by the `TerminateProcess` API, and the exit code will be set to *sig*. The Windows version of `kill()` additionally takes process handles to be killed.

See also *signal.pthread_kill()*.

Raises an *auditing event* `os.kill` with arguments *pid*, *sig*.

Νέο στην έκδοση 3.2: Windows support.

os.killpg(pgid, sig)

Send the signal *sig* to the process group *pgid*.

Raises an *auditing event* `os.killpg` with arguments *pgid*, *sig*.

Availability: Unix.

os.nice(increment)

Add *increment* to the process's «niceness». Return the new niceness.

Availability: Unix.

`os.pidfd_open(pid, flags=0)`

Return a file descriptor referring to the process *pid*. This descriptor can be used to perform process management without races and signals. The *flags* argument is provided for future extensions; no flag values are currently defined.

See the *pidfd_open(2)* man page for more details.

Availability: Linux 5.3+

Νέο στην έκδοση 3.9.

`os.plock(op)`

Lock program segments into memory. The value of *op* (defined in `<sys/lock.h>`) determines which segments are locked.

Availability: Unix.

`os.popen(cmd, mode='r', buffering=-1)`

Open a pipe to or from command *cmd*. The return value is an open file object connected to the pipe, which can be read or written depending on whether *mode* is `'r'` (default) or `'w'`. The *buffering* argument has the same meaning as the corresponding argument to the built-in *open()* function. The returned file object reads or writes text strings rather than bytes.

The `close` method returns *None* if the subprocess exited successfully, or the subprocess's return code if there was an error. On POSIX systems, if the return code is positive it represents the return value of the process left-shifted by one byte. If the return code is negative, the process was terminated by the signal given by the negated value of the return code. (For example, the return value might be `- signal.SIGKILL` if the subprocess was killed.) On Windows systems, the return value contains the signed integer return code from the child process.

On Unix, *waitstatus_to_exitcode()* can be used to convert the `close` method result (exit status) into an exit code if it is not *None*. On Windows, the `close` method result is directly the exit code (or *None*).

This is implemented using *subprocess.Popen*; see that class's documentation for more powerful ways to manage and communicate with subprocesses.

`os.posix_spawn(path, argv, env, *, file_actions=None, setpgroup=None, resetids=False, setsid=False, setsigmask=(), setsigdef=(), scheduler=None)`

Wraps the `posix_spawn()` C library API for use from Python.

Most users should use *subprocess.run()* instead of *posix_spawn()*.

The positional-only arguments *path*, *args*, and *env* are similar to *execve()*.

The *path* parameter is the path to the executable file. The *path* should contain a directory. Use *posix_spawnnp()* to pass an executable file without directory.

The *file_actions* argument may be a sequence of tuples describing actions to take on specific file descriptors in the child process between the C library implementation's `fork()` and `exec()` steps. The first item in each tuple must be one of the three type indicator listed below describing the remaining tuple elements:

`os.POSIX_SPAWN_OPEN`

`(os.POSIX_SPAWN_OPEN, fd, path, flags, mode)`

Performs `os.dup2(os.open(path, flags, mode), fd)`.

`os.POSIX_SPAWN_CLOSE`

`(os.POSIX_SPAWN_CLOSE, fd)`

Performs `os.close(fd)`.

`os.POSIX_SPAWN_DUP2`

`(os.POSIX_SPAWN_DUP2, fd, new_fd)`

Performs `os.dup2(fd, new_fd)`.

These tuples correspond to the C library `posix_spawn_file_actions_addopen()`, `posix_spawn_file_actions_addclose()`, and `posix_spawn_file_actions_adddup2()` API calls used to prepare for the `posix_spawn()` call itself.

The `setpgroup` argument will set the process group of the child to the value specified. If the value specified is 0, the child's process group ID will be made the same as its process ID. If the value of `setpgroup` is not set, the child will inherit the parent's process group ID. This argument corresponds to the C library `POSIX_SPAWN_SETPGROUP` flag.

If the `resetids` argument is `True` it will reset the effective UID and GID of the child to the real UID and GID of the parent process. If the argument is `False`, then the child retains the effective UID and GID of the parent. In either case, if the set-user-ID and set-group-ID permission bits are enabled on the executable file, their effect will override the setting of the effective UID and GID. This argument corresponds to the C library `POSIX_SPAWN_RESETIDS` flag.

If the `setsid` argument is `True`, it will create a new session ID for `posix_spawn`. `setsid` requires `POSIX_SPAWN_SETSID` or `POSIX_SPAWN_SETSID_NP` flag. Otherwise, `NotImplementedError` is raised.

The `setsigmask` argument will set the signal mask to the signal set specified. If the parameter is not used, then the child inherits the parent's signal mask. This argument corresponds to the C library `POSIX_SPAWN_SETSIGMASK` flag.

The `sigdef` argument will reset the disposition of all signals in the set specified. This argument corresponds to the C library `POSIX_SPAWN_SETSIGDEF` flag.

The `scheduler` argument must be a tuple containing the (optional) scheduler policy and an instance of `sched_param` with the scheduler parameters. A value of `None` in the place of the scheduler policy indicates that is not being provided. This argument is a combination of the C library `POSIX_SPAWN_SETSCHEDPARAM` and `POSIX_SPAWN_SETSCHEDULER` flags.

Raises an *auditing event* `os.posix_spawn` with arguments `path`, `argv`, `env`.

Νέο στην έκδοση 3.8.

Availability: Unix.

`os.posix_spawnnp` (*path*, *argv*, *env*, *, *file_actions=None*, *setpgroup=None*, *resetids=False*, *setsid=False*, *setsigmask=()*, *setsigdef=()*, *scheduler=None*)

Wraps the `posix_spawnnp()` C library API for use from Python.

Similar to `posix_spawn()` except that the system searches for the *executable* file in the list of directories specified by the `PATH` environment variable (in the same way as for `execvp(3)`).

Raises an *auditing event* `os.posix_spawn` with arguments `path`, `argv`, `env`.

Νέο στην έκδοση 3.8.

Availability: See `posix_spawn()` documentation.

`os.register_at_fork` (*, *before=None*, *after_in_parent=None*, *after_in_child=None*)

Register callables to be executed when a new child process is forked using `os.fork()` or similar process cloning APIs. The parameters are optional and keyword-only. Each specifies a different call point.

- *before* is a function called before forking a child process.
- *after_in_parent* is a function called from the parent process after forking a child process.
- *after_in_child* is a function called from the child process.

These calls are only made if control is expected to return to the Python interpreter. A typical *subprocess* launch will not trigger them as the child is not going to re-enter the interpreter.

Functions registered for execution before forking are called in reverse registration order. Functions registered for execution after forking (either in the parent or in the child) are called in registration order.

Note that `fork()` calls made by third-party C code may not call those functions, unless it explicitly calls `PyOS_BeforeFork()`, `PyOS_AfterFork_Parent()` and `PyOS_AfterFork_Child()`.

There is no way to unregister a function.

Availability: Unix.

Νέο στην έκδοση 3.7.

```
os.spawnl(mode, path, ...)
os.spawnle(mode, path, ..., env)
os.spawnlp(mode, file, ...)
os.spawnlpe(mode, file, ..., env)
os.spawnv(mode, path, args)
os.spawnve(mode, path, args, env)
os.spawnvp(mode, file, args)
os.spawnvpe(mode, file, args, env)
```

Execute the program *path* in a new process.

(Note that the `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using these functions. Check especially the *Replacing Older Functions with the subprocess Module* section.)

If *mode* is `P_NOWAIT`, this function returns the process id of the new process; if *mode* is `P_WAIT`, returns the process's exit code if it exits normally, or `-signal`, where *signal* is the signal that killed the process. On Windows, the process id will actually be the process handle, so can be used with the `waitpid()` function.

Note on VxWorks, this function doesn't return `-signal` when the new process is killed. Instead it raises `OSError` exception.

The «l» and «v» variants of the `spawn*` functions differ in how command-line arguments are passed. The «l» variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the `spawnl*()` functions. The «v» variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the *args* parameter. In either case, the arguments to the child process must start with the name of the command being run.

The variants which include a second «p» near the end (`spawnlp()`, `spawnlpe()`, `spawnvp()`, and `spawnvpe()`) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the `spawn*e` variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, `spawnl()`, `spawnle()`, `spawnv()`, and `spawnve()`, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For `spawnle()`, `spawnlpe()`, `spawnve()`, and `spawnvpe()` (note that these all end in «e»), the *env* parameter must be a mapping which is used to define the environment variables for the new process (they are used instead of the current process' environment); the functions `spawnl()`, `spawnlp()`, `spawnv()`, and `spawnvp()` all cause the new process to inherit the environment of the current process. Note that keys and values in the *env* dictionary must be strings; invalid keys or values will cause the function to fail, with a return value of 127.

As an example, the following calls to `spawnlp()` and `spawnvpe()` are equivalent:

```
import os
os.spawnlp(os.P_WAIT, 'cp', 'cp', 'index.html', '/dev/null')

L = ['cp', 'index.html', '/dev/null']
os.spawnvpe(os.P_WAIT, 'cp', L, os.environ)
```

Raises an *auditing event* `os.spawn` with arguments `mode`, `path`, `args`, `env`.

Availability: Unix, Windows. `spawnlp()`, `spawnlpe()`, `spawnvp()` and `spawnvpe()` are not available on Windows. `spawnle()` and `spawnve()` are not thread-safe on Windows; we advise you to use the `subprocess` module instead.

Άλλαξε στην έκδοση 3.6: Accepts a *path-like object*.

`os.P_NOWAIT`

`os.P_NOWAITO`

Possible values for the *mode* parameter to the *spawn** family of functions. If either of these values is given, the *spawn** () functions will return as soon as the new process has been created, with the process id as the return value.

Availability: Unix, Windows.

`os.P_WAIT`

Possible value for the *mode* parameter to the *spawn** family of functions. If this is given as *mode*, the *spawn** () functions will not return until the new process has run to completion and will return the exit code of the process the run is successful, or `-signal` if a signal kills the process.

Availability: Unix, Windows.

`os.P_DETACH`

`os.P_OVERLAY`

Possible values for the *mode* parameter to the *spawn** family of functions. These are less portable than those listed above. `P_DETACH` is similar to `P_NOWAIT`, but the new process is detached from the console of the calling process. If `P_OVERLAY` is used, the current process will be replaced; the *spawn** function will not return.

Availability: Windows.

`os.startfile(path[, operation])`

Start a file with its associated application.

When *operation* is not specified or `'open'`, this acts like double-clicking the file in Windows Explorer, or giving the file name as an argument to the `start` command from the interactive command shell: the file is opened with whatever application (if any) its extension is associated.

When another *operation* is given, it must be a «command verb» that specifies what should be done with the file. Common verbs documented by Microsoft are `'print'` and `'edit'` (to be used on files) as well as `'explore'` and `'find'` (to be used on directories).

`startfile()` returns as soon as the associated application is launched. There is no option to wait for the application to close, and no way to retrieve the application's exit status. The *path* parameter is relative to the current directory. If you want to use an absolute path, make sure the first character is not a slash (`'/'`); the underlying `Win32 ShellExecute()` function doesn't work if it is. Use the `os.path.normpath()` function to ensure that the path is properly encoded for Win32.

To reduce interpreter startup overhead, the `Win32 ShellExecute()` function is not resolved until this function is first called. If the function cannot be resolved, *NotImplementedError* will be raised.

Raises an *auditing event* `os.startfile` with arguments `path`, `operation`.

Availability: Windows.

`os.system(command)`

Execute the command (a string) in a subshell. This is implemented by calling the Standard C function `system()`, and has the same limitations. Changes to `sys.stdin`, etc. are not reflected in the environment of the executed command. If *command* generates any output, it will be sent to the interpreter standard output stream. The C standard does not specify the meaning of the return value of the C function, so the return value of the Python function is system-dependent.

On Unix, the return value is the exit status of the process encoded in the format specified for `wait()`.

On Windows, the return value is that returned by the system shell after running *command*. The shell is given by the Windows environment variable COMSPEC: it is usually `cmd.exe`, which returns the exit status of the command run; on systems using a non-native shell, consult your shell documentation.

The `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using this function. See the [Replacing Older Functions with the subprocess Module](#) section in the `subprocess` documentation for some helpful recipes.

On Unix, `waitstatus_to_exitcode()` can be used to convert the result (exit status) into an exit code. On Windows, the result is directly the exit code.

Raises an [auditing event](#) `os.system` with argument `command`.

Availability: Unix, Windows.

`os.times()`

Returns the current global process times. The return value is an object with five attributes:

- `user` - user time
- `system` - system time
- `children_user` - user time of all child processes
- `children_system` - system time of all child processes
- `elapsed` - elapsed real time since a fixed point in the past

For backwards compatibility, this object also behaves like a five-tuple containing `user`, `system`, `children_user`, `children_system`, and `elapsed` in that order.

See the Unix manual page `times(2)` and `times(3)` manual page on Unix or the [GetProcessTimes MSDN](#) on Windows. On Windows, only `user` and `system` are known; the other attributes are zero.

Availability: Unix, Windows.

Άλλαξε στην έκδοση 3.3: Return type changed from a tuple to a tuple-like object with named attributes.

`os.wait()`

Wait for completion of a child process, and return a tuple containing its pid and exit status indication: a 16-bit number, whose low byte is the signal number that killed the process, and whose high byte is the exit status (if the signal number is zero); the high bit of the low byte is set if a core file was produced.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exit code.

Availability: Unix.

Δείτε επίσης:

`waitpid()` can be used to wait for the completion of a specific child process and has more options.

`os.waitid(idtype, id, options)`

Wait for the completion of one or more child processes. *idtype* can be `P_PID`, `P_PGID`, `P_ALL`, or `P_PIDFD` on Linux. *id* specifies the pid to wait on. *options* is constructed from the ORing of one or more of `WEXITED`, `WSTOPPED` or `WCONTINUED` and additionally may be ORed with `WNOHANG` or `WNOWAIT`. The return value is an object representing the data contained in the `siginfo_t` structure, namely: `si_pid`, `si_uid`, `si_signo`, `si_status`, `si_code` or `None` if `WNOHANG` is specified and there are no children in a waitable state.

Availability: Unix.

Νέο στην έκδοση 3.3.

`os.P_PID`

`os.P_PGID`

os.P_ALL

These are the possible values for *idtype* in `waitid()`. They affect how *id* is interpreted.

Availability: Unix.

Νέο στην έκδοση 3.3.

os.P_PIDFD

This is a Linux-specific *idtype* that indicates that *id* is a file descriptor that refers to a process.

Availability: Linux 5.4+

Νέο στην έκδοση 3.9.

os.WEXITED**os.WSTOPPED****os.WNOWAIT**

Flags that can be used in *options* in `waitid()` that specify what child signal to wait for.

Availability: Unix.

Νέο στην έκδοση 3.3.

os.CLD_EXITED**os.CLD_KILLED****os.CLD_DUMPED****os.CLD_TRAPPED****os.CLD_STOPPED****os.CLD_CONTINUED**

These are the possible values for *si_code* in the result returned by `waitid()`.

Availability: Unix.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.9: Added `CLD_KILLED` and `CLD_STOPPED` values.

os.waitpid(*pid*, *options*)

The details of this function differ on Unix and Windows.

On Unix: Wait for completion of a child process given by process id *pid*, and return a tuple containing its process id and exit status indication (encoded as for `wait()`). The semantics of the call are affected by the value of the integer *options*, which should be 0 for normal operation.

If *pid* is greater than 0, `waitpid()` requests status information for that specific process. If *pid* is 0, the request is for the status of any child in the process group of the current process. If *pid* is -1, the request pertains to any child of the current process. If *pid* is less than -1, status is requested for any process in the process group -*pid* (the absolute value of *pid*).

An `OSError` is raised with the value of `errno` when the syscall returns -1.

On Windows: Wait for completion of a process given by process handle *pid*, and return a tuple containing *pid*, and its exit status shifted left by 8 bits (shifting makes cross-platform use of the function easier). A *pid* less than or equal to 0 has no special meaning on Windows, and raises an exception. The value of integer *options* has no effect. *pid* can refer to any process whose id is known, not necessarily a child process. The `spawn*` functions called with `P_NOWAIT` return suitable process handles.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exit code.

Άλλαξε στην έκδοση 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](#) for the rationale).

os.wait3 (options)

Similar to `waitpid()`, except no process id argument is given and a 3-element tuple containing the child's process id, exit status indication, and resource usage information is returned. Refer to `resource.getrusage()` for details on resource usage information. The option argument is the same as that provided to `waitpid()` and `wait4()`.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exitcode.

Availability: Unix.

os.wait4 (pid, options)

Similar to `waitpid()`, except a 3-element tuple, containing the child's process id, exit status indication, and resource usage information is returned. Refer to `resource.getrusage()` for details on resource usage information. The arguments to `wait4()` are the same as those provided to `waitpid()`.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exitcode.

Availability: Unix.

os.waitstatus_to_exitcode (status)

Convert a wait status to an exit code.

On Unix:

- If the process exited normally (if `WIFEXITED(status)` is true), return the process exit status (return `WEXITSTATUS(status)`): result greater than or equal to 0.
- If the process was terminated by a signal (if `WIFSIGNALED(status)` is true), return `-signum` where *signum* is the number of the signal that caused the process to terminate (return `-WTERMSIG(status)`): result less than 0.
- Otherwise, raise a `ValueError`.

On Windows, return *status* shifted right by 8 bits.

On Unix, if the process is being traced or if `waitpid()` was called with `WUNTRACED` option, the caller must first check if `WIFSTOPPED(status)` is true. This function must not be called if `WIFSTOPPED(status)` is true.

Δείτε επίσης:

`WIFEXITED()`, `WEXITSTATUS()`, `WIFSIGNALED()`, `WTERMSIG()`, `WIFSTOPPED()`, `WSTOPSIG()` functions.

Νέο στην έκδοση 3.9.

os.WNOHANG

The option for `waitpid()` to return immediately if no child process status is available immediately. The function returns `(0, 0)` in this case.

Availability: Unix.

os.WCONTINUED

This option causes child processes to be reported if they have been continued from a job control stop since their status was last reported.

Availability: some Unix systems.

os.WUNTRACED

This option causes child processes to be reported if they have been stopped but their current state has not been reported since they were stopped.

Availability: Unix.

The following functions take a process status code as returned by `system()`, `wait()`, or `waitpid()` as a parameter. They may be used to determine the disposition of a process.

os.**WCOREDUMP** (*status*)

Return True if a core dump was generated for the process, otherwise return False.

This function should be employed only if `WIFSIGNALED()` is true.

Availability: Unix.

os.**WIFCONTINUED** (*status*)

Return True if a stopped child has been resumed by delivery of `SIGCONT` (if the process has been continued from a job control stop), otherwise return False.

See `WCONTINUED` option.

Availability: Unix.

os.**WIFSTOPPED** (*status*)

Return True if the process was stopped by delivery of a signal, otherwise return False.

`WIFSTOPPED()` only returns True if the `waitpid()` call was done using `WUNTRACED` option or when the process is being traced (see `ptrace(2)`).

Availability: Unix.

os.**WIFSIGNALED** (*status*)

Return True if the process was terminated by a signal, otherwise return False.

Availability: Unix.

os.**WIFEXITED** (*status*)

Return True if the process exited terminated normally, that is, by calling `exit()` or `_exit()`, or by returning from `main()`; otherwise return False.

Availability: Unix.

os.**WEXITSTATUS** (*status*)

Return the process exit status.

This function should be employed only if `WIFEXITED()` is true.

Availability: Unix.

os.**WSTOPSIG** (*status*)

Return the signal which caused the process to stop.

This function should be employed only if `WIFSTOPPED()` is true.

Availability: Unix.

os.**WTERMSIG** (*status*)

Return the number of the signal that caused the process to terminate.

This function should be employed only if `WIFSIGNALED()` is true.

Availability: Unix.

16.1.7 Interface to the scheduler

These functions control how a process is allocated CPU time by the operating system. They are only available on some Unix platforms. For more detailed information, consult your Unix manpages.

Νέο στην έκδοση 3.3.

The following scheduling policies are exposed if they are supported by the operating system.

`os.SCHED_OTHER`

The default scheduling policy.

`os.SCHED_BATCH`

Scheduling policy for CPU-intensive processes that tries to preserve interactivity on the rest of the computer.

`os.SCHED_IDLE`

Scheduling policy for extremely low priority background tasks.

`os.SCHED_SPORADIC`

Scheduling policy for sporadic server programs.

`os.SCHED_FIFO`

A First In First Out scheduling policy.

`os.SCHED_RR`

A round-robin scheduling policy.

`os.SCHED_RESET_ON_FORK`

This flag can be OR'ed with any other scheduling policy. When a process with this flag set forks, its child's scheduling policy and priority are reset to the default.

class `os.sched_param(sched_priority)`

This class represents tunable scheduling parameters used in `sched_setparam()`, `sched_setscheduler()`, and `sched_getparam()`. It is immutable.

At the moment, there is only one possible parameter:

`sched_priority`

The scheduling priority for a scheduling policy.

`os.sched_get_priority_min(policy)`

Get the minimum priority value for *policy*. *policy* is one of the scheduling policy constants above.

`os.sched_get_priority_max(policy)`

Get the maximum priority value for *policy*. *policy* is one of the scheduling policy constants above.

`os.sched_setscheduler(pid, policy, param)`

Set the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. *policy* is one of the scheduling policy constants above. *param* is a `sched_param` instance.

`os.sched_getscheduler(pid)`

Return the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. The result is one of the scheduling policy constants above.

`os.sched_setparam(pid, param)`

Set the scheduling parameters for the process with PID *pid*. A *pid* of 0 means the calling process. *param* is a `sched_param` instance.

`os.sched_getparam(pid)`

Return the scheduling parameters as a `sched_param` instance for the process with PID *pid*. A *pid* of 0 means the calling process.

`os.sched_rr_get_interval(pid)`

Return the round-robin quantum in seconds for the process with PID *pid*. A *pid* of 0 means the calling process.

`os.sched_yield()`

Voluntarily relinquish the CPU.

`os.sched_setaffinity(pid, mask)`

Restrict the process with PID *pid* (or the current process if zero) to a set of CPUs. *mask* is an iterable of integers representing the set of CPUs to which the process should be restricted.

`os.sched_getaffinity(pid)`

Return the set of CPUs the process with PID *pid* (or the current process if zero) is restricted to.

16.1.8 Miscellaneous System Information

`os.confstr(name)`

Return string-valued system configuration values. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given as the keys of the `confstr_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If the configuration value specified by *name* isn't defined, `None` is returned.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `confstr_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

Availability: Unix.

`os.confstr_names`

Dictionary mapping names accepted by `confstr()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

`os.cpu_count()`

Return the number of CPUs in the system. Returns `None` if undetermined.

This number is not equivalent to the number of CPUs the current process can use. The number of usable CPUs can be obtained with `len(os.sched_getaffinity(0))`

Νέο στην έκδοση 3.4.

`os.getloadavg()`

Return the number of processes in the system run queue averaged over the last 1, 5, and 15 minutes or raises `OSError` if the load average was unobtainable.

Availability: Unix.

`os.sysconf(name)`

Return integer-valued system configuration values. If the configuration value specified by *name* isn't defined, `-1` is returned. The comments regarding the *name* parameter for `confstr()` apply here as well; the dictionary that provides information on the known names is given by `sysconf_names`.

Availability: Unix.

`os.sysconf_names`

Dictionary mapping names accepted by `sysconf()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

The following data values are used to support path manipulation operations. These are defined for all platforms.

Higher-level operations on pathnames are defined in the *os.path* module.

os.curdir

The constant string used by the operating system to refer to the current directory. This is `'.'` for Windows and POSIX. Also available via *os.path*.

os.pardir

The constant string used by the operating system to refer to the parent directory. This is `'..'` for Windows and POSIX. Also available via *os.path*.

os.sep

The character used by the operating system to separate pathname components. This is `'/'` for POSIX and `'\'` for Windows. Note that knowing this is not sufficient to be able to parse or concatenate pathnames — use *os.path.split()* and *os.path.join()* — but it is occasionally useful. Also available via *os.path*.

os.altsep

An alternative character used by the operating system to separate pathname components, or `None` if only one separator character exists. This is set to `'/'` on Windows systems where `sep` is a backslash. Also available via *os.path*.

os.extsep

The character which separates the base filename from the extension; for example, the `'.'` in `os.py`. Also available via *os.path*.

os.pathsep

The character conventionally used by the operating system to separate search path components (as in `PATH`), such as `':'` for POSIX or `';'` for Windows. Also available via *os.path*.

os.defpath

The default search path used by *exec*p** and *spawn*p** if the environment doesn't have a `'PATH'` key. Also available via *os.path*.

os.linesep

The string used to separate (or, rather, terminate) lines on the current platform. This may be a single character, such as `'\n'` for POSIX, or multiple characters, for example, `'\r\n'` for Windows. Do not use *os.linesep* as a line terminator when writing files opened in text mode (the default); use a single `'\n'` instead, on all platforms.

os.devnull

The file path of the null device. For example: `'/dev/null '` for POSIX, `'nul '` for Windows. Also available via *os.path*.

os.RTLD_LAZY

os.RTLD_NOW

os.RTLD_GLOBAL

os.RTLD_LOCAL

os.RTLD_NODELETE

os.RTLD_NOLOAD

os.RTLD_DEEPBIND

Flags for use with the *setdlopenflags()* and *getdlopenflags()* functions. See the Unix manual page *dlopen(3)* for what the different flags mean.

Νέο στην έκδοση 3.3.

16.1.9 Random numbers

`os.getrandom(size, flags=0)`

Get up to *size* random bytes. The function can return less bytes than requested.

These bytes can be used to seed user-space random number generators or for cryptographic purposes.

`getrandom()` relies on entropy gathered from device drivers and other sources of environmental noise. Unnecessarily reading large quantities of data will have a negative impact on other users of the `/dev/random` and `/dev/urandom` devices.

The `flags` argument is a bit mask that can contain zero or more of the following values ORed together: `os.GRND_RANDOM` and `GRND_NONBLOCK`.

See also the [Linux `getrandom\(\)` manual page](#).

Availability: Linux 3.17 and newer.

Νέο στην έκδοση 3.6.

`os.urandom(size)`

Return a bytestring of *size* random bytes suitable for cryptographic use.

This function returns random bytes from an OS-specific randomness source. The returned data should be unpredictable enough for cryptographic applications, though its exact quality depends on the OS implementation.

On Linux, if the `getrandom()` syscall is available, it is used in blocking mode: block until the system urandom entropy pool is initialized (128 bits of entropy are collected by the kernel). See the [PEP 524](#) for the rationale. On Linux, the `getrandom()` function can be used to get random bytes in non-blocking mode (using the `GRND_NONBLOCK` flag) or to poll until the system urandom entropy pool is initialized.

On a Unix-like system, random bytes are read from the `/dev/urandom` device. If the `/dev/urandom` device is not available or not readable, the `NotImplementedError` exception is raised.

On Windows, it will use `CryptGenRandom()`.

Δείτε επίσης:

The `secrets` module provides higher level functions. For an easy-to-use interface to the random number generator provided by your platform, please see [`random.SystemRandom`](#).

Άλλαξε στην έκδοση 3.6.0: On Linux, `getrandom()` is now used in blocking mode to increase the security.

Άλλαξε στην έκδοση 3.5.2: On Linux, if the `getrandom()` syscall blocks (the urandom entropy pool is not initialized yet), fall back on reading `/dev/urandom`.

Άλλαξε στην έκδοση 3.5: On Linux 3.17 and newer, the `getrandom()` syscall is now used when available. On OpenBSD 5.6 and newer, the C `getentropy()` function is now used. These functions avoid the usage of an internal file descriptor.

`os.GRND_NONBLOCK`

By default, when reading from `/dev/random`, `getrandom()` blocks if no random bytes are available, and when reading from `/dev/urandom`, it blocks if the entropy pool has not yet been initialized.

If the `GRND_NONBLOCK` flag is set, then `getrandom()` does not block in these cases, but instead immediately raises `BlockingIOError`.

Νέο στην έκδοση 3.6.

`os.GRND_RANDOM`

If this bit is set, then random bytes are drawn from the `/dev/random` pool instead of the `/dev/urandom` pool.

Νέο στην έκδοση 3.6.

16.2 `io` — Core tools for working with streams

Source code: `Lib/io.py`

16.2.1 Overview

The `io` module provides Python's main facilities for dealing with various types of I/O. There are three main types of I/O: *text I/O*, *binary I/O* and *raw I/O*. These are generic categories, and various backing stores can be used for each of them. A concrete object belonging to any of these categories is called a *file object*. Other common terms are *stream* and *file-like object*.

Independent of its category, each concrete stream object will also have various capabilities: it can be read-only, write-only, or read-write. It can also allow arbitrary random access (seeking forwards or backwards to any location), or only sequential access (for example in the case of a socket or pipe).

All streams are careful about the type of data you give to them. For example giving a `str` object to the `write()` method of a binary stream will raise a `TypeError`. So will giving a `bytes` object to the `write()` method of a text stream.

Αλλάξε στην έκδοση 3.3: Operations that used to raise `IOError` now raise `OSError`, since `IOError` is now an alias of `OSError`.

Text I/O

Text I/O expects and produces `str` objects. This means that whenever the backing store is natively made of bytes (such as in the case of a file), encoding and decoding of data is made transparently as well as optional translation of platform-specific newline characters.

The easiest way to create a text stream is with `open()`, optionally specifying an encoding:

```
f = open("myfile.txt", "r", encoding="utf-8")
```

In-memory text streams are also available as `StringIO` objects:

```
f = io.StringIO("some initial text data")
```

The text stream API is described in detail in the documentation of `TextIOBase`.

Binary I/O

Binary I/O (also called *buffered I/O*) expects *bytes-like objects* and produces `bytes` objects. No encoding, decoding, or newline translation is performed. This category of streams can be used for all kinds of non-text data, and also when manual control over the handling of text data is desired.

The easiest way to create a binary stream is with `open()` with `'b'` in the mode string:

```
f = open("myfile.jpg", "rb")
```

In-memory binary streams are also available as `BytesIO` objects:

```
f = io.BytesIO(b"some initial binary data: \x00\x01")
```

The binary stream API is described in detail in the docs of *BufferedIOBase*.

Other library modules may provide additional ways to create text or binary streams. See *socket.socket.makefile()* for example.

Raw I/O

Raw I/O (also called *unbuffered I/O*) is generally used as a low-level building-block for binary and text streams; it is rarely useful to directly manipulate a raw stream from user code. Nevertheless, you can create a raw stream by opening a file in binary mode with buffering disabled:

```
f = open("myfile.jpg", "rb", buffering=0)
```

The raw stream API is described in detail in the docs of *RawIOBase*.

16.2.2 High-level Module Interface

io.DEFAULT_BUFFER_SIZE

An int containing the default buffer size used by the module's buffered I/O classes. *open()* uses the file's blksize (as obtained by *os.stat()*) if possible.

io.open(file, mode='r', buffering=-1, encoding=None, errors=None, newline=None, closefd=True, opener=None)

This is an alias for the builtin *open()* function.

This function raises an *auditing event* *open* with arguments *path*, *mode* and *flags*. The *mode* and *flags* arguments may have been modified or inferred from the original call.

io.open_code(path)

Opens the provided file with mode `'rb'`. This function should be used when the intent is to treat the contents as executable code.

path should be a *str* and an absolute path.

The behavior of this function may be overridden by an earlier call to the *PyFile_SetOpenCodeHook()*. However, assuming that *path* is a *str* and an absolute path, *open_code(path)* should always behave the same as *open(path, 'rb')*. Overriding the behavior is intended for additional validation or preprocessing of the file.

Νέο στην έκδοση 3.8.

exception io.BlockingIOError

This is a compatibility alias for the builtin *BlockingIOError* exception.

exception io.UnsupportedOperation

An exception inheriting *OSError* and *ValueError* that is raised when an unsupported operation is called on a stream.

Δείτε επίσης:

sys contains the standard IO streams: *sys.stdin*, *sys.stdout*, and *sys.stderr*.

16.2.3 Class hierarchy

The implementation of I/O streams is organized as a hierarchy of classes. First *abstract base classes* (ABCs), which are used to specify the various categories of streams, then concrete classes providing the standard stream implementations.

Σημείωση: The abstract base classes also provide default implementations of some methods in order to help implementation of concrete stream classes. For example, *BufferedIOBase* provides unoptimized implementations of `readinto()` and `readline()`.

At the top of the I/O hierarchy is the abstract base class *IOBase*. It defines the basic interface to a stream. Note, however, that there is no separation between reading and writing to streams; implementations are allowed to raise *UnsupportedOperation* if they do not support a given operation.

The *RawIOBase* ABC extends *IOBase*. It deals with the reading and writing of bytes to a stream. *FileIO* subclasses *RawIOBase* to provide an interface to files in the machine's file system.

The *BufferedIOBase* ABC extends *IOBase*. It deals with buffering on a raw binary stream (*RawIOBase*). Its subclasses, *BufferedWriter*, *BufferedReader*, and *BufferedRWPair* buffer raw binary streams that are readable, writable, and both readable and writable, respectively. *BufferedRandom* provides a buffered interface to seekable streams. Another *BufferedIOBase* subclass, *BytesIO*, is a stream of in-memory bytes.

The *TextIOBase* ABC extends *IOBase*. It deals with streams whose bytes represent text, and handles encoding and decoding to and from strings. *TextIOWrapper*, which extends *TextIOBase*, is a buffered text interface to a buffered raw stream (*BufferedIOBase*). Finally, *StringIO* is an in-memory stream for text.

Argument names are not part of the specification, and only the arguments of `open()` are intended to be used as keyword arguments.

The following table summarizes the ABCs provided by the *io* module:

| ABC | Inherits | Stub Methods | Mixin Methods and Properties |
|-----------------------|---------------|---|--|
| <i>IOBase</i> | | <code>fileno</code> , <code>seek</code> , and <code>truncate</code> | <code>close</code> , <code>closed</code> , <code>__enter__</code> , <code>__exit__</code> , <code>flush</code> , <code>isatty</code> , <code>__iter__</code> , <code>__next__</code> , <code>readable</code> , <code>readline</code> , <code>readlines</code> , <code>seekable</code> , <code>tell</code> , <code>writable</code> , and <code>writelines</code> |
| <i>RawIOBase</i> | <i>IOBase</i> | <code>readinto</code> and <code>write</code> | Inherited <i>IOBase</i> methods, <code>read</code> , and <code>readall</code> |
| <i>BufferedIOBase</i> | <i>IOBase</i> | <code>detach</code> , <code>read</code> , <code>read1</code> , and <code>write</code> | Inherited <i>IOBase</i> methods, <code>readinto</code> , and <code>readinto1</code> |
| <i>TextIOBase</i> | <i>IOBase</i> | <code>detach</code> , <code>read</code> , <code>readline</code> , and <code>write</code> | Inherited <i>IOBase</i> methods, <code>encoding</code> , <code>errors</code> , and <code>newlines</code> |

I/O Base Classes

class `io.IOBase`

The abstract base class for all I/O classes.

This class provides empty abstract implementations for many methods that derived classes can override selectively; the default implementations represent a file that cannot be read, written or seeked.

Even though `IOBase` does not declare `read()` or `write()` because their signatures will vary, implementations and clients should consider those methods part of the interface. Also, implementations may raise a `ValueError` (or `UnsupportedOperation`) when operations they do not support are called.

The basic type used for binary data read from or written to a file is `bytes`. Other *bytes-like objects* are accepted as method arguments too. Text I/O classes work with `str` data.

Note that calling any method (even inquiries) on a closed stream is undefined. Implementations may raise `ValueError` in this case.

`IOBase` (and its subclasses) supports the iterator protocol, meaning that an `IOBase` object can be iterated over yielding the lines in a stream. Lines are defined slightly differently depending on whether the stream is a binary stream (yielding bytes), or a text stream (yielding character strings). See `readline()` below.

`IOBase` is also a context manager and therefore supports the `with` statement. In this example, *file* is closed after the `with` statement's suite is finished—even if an exception occurs:

```
with open('spam.txt', 'w') as file:
    file.write('Spam and eggs!')
```

`IOBase` provides these data attributes and methods:

close()

Flush and close this stream. This method has no effect if the file is already closed. Once the file is closed, any operation on the file (e.g. reading or writing) will raise a `ValueError`.

As a convenience, it is allowed to call this method more than once; only the first call, however, will have an effect.

closed

True if the stream is closed.

fileno()

Return the underlying file descriptor (an integer) of the stream if it exists. An `OSError` is raised if the IO object does not use a file descriptor.

flush()

Flush the write buffers of the stream if applicable. This does nothing for read-only and non-blocking streams.

isatty()

Return True if the stream is interactive (i.e., connected to a terminal/tty device).

readable()

Return True if the stream can be read from. If False, `read()` will raise `OSError`.

readline (*size=-1, /*)

Read and return one line from the stream. If *size* is specified, at most *size* bytes will be read.

The line terminator is always `b'\n'` for binary files; for text files, the *newline* argument to `open()` can be used to select the line terminator(s) recognized.

readlines (*hint=-1, /*)

Read and return a list of lines from the stream. *hint* can be specified to control the number of lines read: no more lines will be read if the total size (in bytes/characters) of all lines so far exceeds *hint*.

hint values of 0 or less, as well as `None`, are treated as no hint.

Note that it's already possible to iterate on file objects using `for line in file: ...` without calling `file.readlines()`.

seek (*offset*, *whence*=`SEEK_SET`, /)

Change the stream position to the given byte *offset*. *offset* is interpreted relative to the position indicated by *whence*. The default value for *whence* is `SEEK_SET`. Values for *whence* are:

- `SEEK_SET` or 0 – start of the stream (the default); *offset* should be zero or positive
- `SEEK_CUR` or 1 – current stream position; *offset* may be negative
- `SEEK_END` or 2 – end of the stream; *offset* is usually negative

Return the new absolute position.

Νέο στην έκδοση 3.1: The `SEEK_*` constants.

Νέο στην έκδοση 3.3: Some operating systems could support additional values, like `os.SEEK_HOLE` or `os.SEEK_DATA`. The valid values for a file could depend on it being open in text or binary mode.

seekable ()

Return `True` if the stream supports random access. If `False`, `seek()`, `tell()` and `truncate()` will raise `OSError`.

tell ()

Return the current stream position.

truncate (*size*=`None`, /)

Resize the stream to the given *size* in bytes (or the current position if *size* is not specified). The current stream position isn't changed. This resizing can extend or reduce the current file size. In case of extension, the contents of the new file area depend on the platform (on most systems, additional bytes are zero-filled). The new file size is returned.

Αλλάξε στην έκδοση 3.5: Windows will now zero-fill files when extending.

writable ()

Return `True` if the stream supports writing. If `False`, `write()` and `truncate()` will raise `OSError`.

writelines (*lines*, /)

Write a list of lines to the stream. Line separators are not added, so it is usual for each of the lines provided to have a line separator at the end.

__del__ ()

Prepare for object destruction. `IOBase` provides a default implementation of this method that calls the instance's `close()` method.

class io.RawIOBase

Base class for raw binary streams. It inherits `IOBase`.

Raw binary streams typically provide low-level access to an underlying OS device or API, and do not try to encapsulate it in high-level primitives (this functionality is done at a higher-level in buffered binary streams and text streams, described later in this page).

`RawIOBase` provides these methods in addition to those from `IOBase`:

read (*size*=-1, /)

Read up to *size* bytes from the object and return them. As a convenience, if *size* is unspecified or -1, all bytes until EOF are returned. Otherwise, only one system call is ever made. Fewer than *size* bytes may be returned if the operating system call returns fewer than *size* bytes.

If 0 bytes are returned, and *size* was not 0, this indicates end of file. If the object is in non-blocking mode and no bytes are available, `None` is returned.

The default implementation defers to `readall()` and `readinto()`.

readall()

Read and return all the bytes from the stream until EOF, using multiple calls to the stream if necessary.

readinto(b, /)

Read bytes into a pre-allocated, writable *bytes-like object* `b`, and return the number of bytes read. For example, `b` might be a `bytearray`. If the object is in non-blocking mode and no bytes are available, `None` is returned.

write(b, /)

Write the given *bytes-like object*, `b`, to the underlying raw stream, and return the number of bytes written. This can be less than the length of `b` in bytes, depending on specifics of the underlying raw stream, and especially if it is in non-blocking mode. `None` is returned if the raw stream is set not to block and no single byte could be readily written to it. The caller may release or mutate `b` after this method returns, so the implementation should only access `b` during the method call.

class io.BufferedIOBase

Base class for binary streams that support some kind of buffering. It inherits `IOBase`.

The main difference with `RawIOBase` is that methods `read()`, `readinto()` and `write()` will try (respectively) to read as much input as requested or to consume all given output, at the expense of making perhaps more than one system call.

In addition, those methods can raise `BlockingIOError` if the underlying raw stream is in non-blocking mode and cannot take or give enough data; unlike their `RawIOBase` counterparts, they will never return `None`.

Besides, the `read()` method does not have a default implementation that defers to `readinto()`.

A typical `BufferedIOBase` implementation should not inherit from a `RawIOBase` implementation, but wrap one, like `BufferedWriter` and `BufferedReader` do.

`BufferedIOBase` provides or overrides these data attributes and methods in addition to those from `IOBase`:

raw

The underlying raw stream (a `RawIOBase` instance) that `BufferedIOBase` deals with. This is not part of the `BufferedIOBase` API and may not exist on some implementations.

detach()

Separate the underlying raw stream from the buffer and return it.

After the raw stream has been detached, the buffer is in an unusable state.

Some buffers, like `BytesIO`, do not have the concept of a single raw stream to return from this method. They raise `UnsupportedOperation`.

Νέο στην έκδοση 3.1.

read(size=-1, /)

Read and return up to `size` bytes. If the argument is omitted, `None`, or negative, data is read and returned until EOF is reached. An empty *bytes* object is returned if the stream is already at EOF.

If the argument is positive, and the underlying raw stream is not interactive, multiple raw reads may be issued to satisfy the byte count (unless EOF is reached first). But for interactive raw streams, at most one raw read will be issued, and a short result does not imply that EOF is imminent.

A `BlockingIOError` is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

read1(size=-1, /)

Read and return up to `size` bytes, with at most one call to the underlying raw stream's `read()` (or `readinto()`) method. This can be useful if you are implementing your own buffering on top of a `BufferedIOBase` object.

If *size* is `-1` (the default), an arbitrary number of bytes are returned (more than zero unless EOF is reached).

readinto (*b*, /)

Read bytes into a pre-allocated, writable *bytes-like object* *b* and return the number of bytes read. For example, *b* might be a *bytearray*.

Like *read()*, multiple reads may be issued to the underlying raw stream, unless the latter is interactive.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

readinto1 (*b*, /)

Read bytes into a pre-allocated, writable *bytes-like object* *b*, using at most one call to the underlying raw stream's *read()* (or *readinto()*) method. Return the number of bytes read.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

Νέο στην έκδοση 3.5.

write (*b*, /)

Write the given *bytes-like object*, *b*, and return the number of bytes written (always equal to the length of *b* in bytes, since if the write fails an *OSError* will be raised). Depending on the actual implementation, these bytes may be readily written to the underlying stream, or held in a buffer for performance and latency reasons.

When in non-blocking mode, a *BlockingIOError* is raised if the data needed to be written to the raw stream but it couldn't accept all the data without blocking.

The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

Raw File I/O

class `io.FileIO` (*name*, *mode*='r', *closefd*=True, *opener*=None)

A raw binary stream representing an OS-level file containing bytes data. It inherits *RawIOBase*.

The *name* can be one of two things:

- a character string or *bytes* object representing the path to the file which will be opened. In this case *closefd* must be `True` (the default) otherwise an error will be raised.
- an integer representing the number of an existing OS-level file descriptor to which the resulting *FileIO* object will give access. When the *FileIO* object is closed this *fd* will be closed as well, unless *closefd* is set to `False`.

The *mode* can be `'r'`, `'w'`, `'x'` or `'a'` for reading (default), writing, exclusive creation or appending. The file will be created if it doesn't exist when opened for writing or appending; it will be truncated when opened for writing. *FileExistsError* will be raised if it already exists when opened for creating. Opening a file for creating implies writing, so this mode behaves in a similar way to `'w'`. Add a `'+'` to the mode to allow simultaneous reading and writing.

The *read()* (when called with a positive argument), *readinto()* and *write()* methods on this class will only make one system call.

A custom opener can be used by passing a callable as *opener*. The underlying file descriptor for the file object is then obtained by calling *opener* with (*name*, *flags*). *opener* must return an open file descriptor (passing *os.open* as *opener* results in functionality similar to passing `None`).

The newly created file is *non-inheritable*.

See the *open()* built-in function for examples on using the *opener* parameter.

Άλλαξε στην έκδοση 3.3: The *opener* parameter was added. The 'x' mode was added.

Άλλαξε στην έκδοση 3.4: The file is now non-inheritable.

FileIO provides these data attributes in addition to those from *RawIOBase* and *IOBase*:

mode

The mode as given in the constructor.

name

The file name. This is the file descriptor of the file when no name is given in the constructor.

Buffered Streams

Buffered I/O streams provide a higher-level interface to an I/O device than raw I/O does.

class `io.BytesIO (initial_bytes=b'')`

A binary stream using an in-memory bytes buffer. It inherits *BufferedIOBase*. The buffer is discarded when the *close()* method is called.

The optional argument *initial_bytes* is a *bytes-like object* that contains initial data.

BytesIO provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

getbuffer()

Return a readable and writable view over the contents of the buffer without copying them. Also, mutating the view will transparently update the contents of the buffer:

```
>>> b = io.BytesIO(b"abcdef")
>>> view = b.getbuffer()
>>> view[2:4] = b"56"
>>> b.getvalue()
b'ab56ef'
```

Σημείωση: As long as the view exists, the *BytesIO* object cannot be resized or closed.

Νέο στην έκδοση 3.2.

getvalue()

Return *bytes* containing the entire contents of the buffer.

read1 (size=-1, /)

In *BytesIO*, this is the same as *read()*.

Άλλαξε στην έκδοση 3.7: The *size* argument is now optional.

readinto1 (b, /)

In *BytesIO*, this is the same as *readinto()*.

Νέο στην έκδοση 3.5.

class `io.BufferedReader (raw, buffer_size=DEFAULT_BUFFER_SIZE)`

A buffered binary stream providing higher-level access to a readable, non seekable *RawIOBase* raw binary stream. It inherits *BufferedIOBase*.

When reading data from this object, a larger amount of data may be requested from the underlying raw stream, and kept in an internal buffer. The buffered data can then be returned directly on subsequent reads.

The constructor creates a *BufferedReader* for the given readable *raw* stream and *buffer_size*. If *buffer_size* is omitted, *DEFAULT_BUFFER_SIZE* is used.

BufferedReader provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

peek (*size=0*, /)

Return bytes from the stream without advancing the position. At most one single read on the raw stream is done to satisfy the call. The number of bytes returned may be less or more than requested.

read (*size=-1*, /)

Read and return *size* bytes, or if *size* is not given or negative, until EOF or if the read call would block in non-blocking mode.

read1 (*size=-1*, /)

Read and return up to *size* bytes with only one call on the raw stream. If at least one byte is buffered, only buffered bytes are returned. Otherwise, one raw stream read call is made.

Αλλάξε στην έκδοση 3.7: The *size* argument is now optional.

class `io.BufferedReader` (*raw*, *buffer_size=DEFAULT_BUFFER_SIZE*)

A buffered binary stream providing higher-level access to a writeable, non seekable *RawIOBase* raw binary stream. It inherits *BufferedIOBase*.

When writing to this object, data is normally placed into an internal buffer. The buffer will be written out to the underlying *RawIOBase* object under various conditions, including:

- when the buffer gets too small for all pending data;
- when *flush()* is called;
- when a *seek()* is requested (for *BufferedRandom* objects);
- when the *BufferedWriter* object is closed or destroyed.

The constructor creates a *BufferedWriter* for the given writeable *raw* stream. If the *buffer_size* is not given, it defaults to *DEFAULT_BUFFER_SIZE*.

BufferedWriter provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

flush ()

Force bytes held in the buffer into the raw stream. A *BlockingIOError* should be raised if the raw stream blocks.

write (*b*, /)

Write the *bytes-like object*, *b*, and return the number of bytes written. When in non-blocking mode, a *BlockingIOError* is raised if the buffer needs to be written out but the raw stream blocks.

class `io.BufferedRandom` (*raw*, *buffer_size=DEFAULT_BUFFER_SIZE*)

A buffered binary stream providing higher-level access to a seekable *RawIOBase* raw binary stream. It inherits *BufferedReader* and *BufferedWriter*.

The constructor creates a reader and writer for a seekable raw stream, given in the first argument. If the *buffer_size* is omitted it defaults to *DEFAULT_BUFFER_SIZE*.

BufferedRandom is capable of anything *BufferedReader* or *BufferedWriter* can do. In addition, *seek()* and *tell()* are guaranteed to be implemented.

class `io.BufferedRWPair` (*reader*, *writer*, *buffer_size=DEFAULT_BUFFER_SIZE*, /)

A buffered binary stream providing higher-level access to two non seekable *RawIOBase* raw binary streams—one readable, the other writeable. It inherits *BufferedIOBase*.

reader and *writer* are *RawIOBase* objects that are readable and writeable respectively. If the *buffer_size* is omitted it defaults to *DEFAULT_BUFFER_SIZE*.

BufferedRWPair implements all of *BufferedIOBase*'s methods except for *detach()*, which raises *UnsupportedOperation*.

Προειδοποίηση: *BufferedRWPair* does not attempt to synchronize accesses to its underlying raw streams. You should not pass it the same object as reader and writer; use *BufferedRandom* instead.

Text I/O

class `io.TextIOBase`

Base class for text streams. This class provides a character and line based interface to stream I/O. It inherits *IOBase*.

TextIOBase provides or overrides these data attributes and methods in addition to those from *IOBase*:

encoding

The name of the encoding used to decode the stream's bytes into strings, and to encode strings into bytes.

errors

The error setting of the decoder or encoder.

newlines

A string, a tuple of strings, or None, indicating the newlines translated so far. Depending on the implementation and the initial constructor flags, this may not be available.

buffer

The underlying binary buffer (a *BufferedIOBase* instance) that *TextIOBase* deals with. This is not part of the *TextIOBase* API and may not exist in some implementations.

detach()

Separate the underlying binary buffer from the *TextIOBase* and return it.

After the underlying buffer has been detached, the *TextIOBase* is in an unusable state.

Some *TextIOBase* implementations, like *StringIO*, may not have the concept of an underlying buffer and calling this method will raise *UnsupportedOperation*.

Νέο στην έκδοση 3.1.

read (*size=-1*, /)

Read and return at most *size* characters from the stream as a single *str*. If *size* is negative or None, reads until EOF.

readline (*size=-1*, /)

Read until newline or EOF and return a single *str*. If the stream is already at EOF, an empty string is returned.

If *size* is specified, at most *size* characters will be read.

seek (*offset*, *whence=SEEK_SET*, /)

Change the stream position to the given *offset*. Behaviour depends on the *whence* parameter. The default value for *whence* is *SEEK_SET*.

- *SEEK_SET* or 0: seek from the start of the stream (the default); *offset* must either be a number returned by *TextIOBase.tell()*, or zero. Any other *offset* value produces undefined behaviour.
- *SEEK_CUR* or 1: «seek» to the current position; *offset* must be zero, which is a no-operation (all other values are unsupported).
- *SEEK_END* or 2: seek to the end of the stream; *offset* must be zero (all other values are unsupported).

Return the new absolute position as an opaque number.

Νέο στην έκδοση 3.1: The `SEEK_*` constants.

tell()

Return the current stream position as an opaque number. The number does not usually represent a number of bytes in the underlying binary storage.

write(s, /)

Write the string *s* to the stream and return the number of characters written.

class io.TextIOWrapper(*buffer*, *encoding=None*, *errors=None*, *newline=None*, *line_buffering=False*, *write_through=False*)

A buffered text stream providing higher-level access to a [BufferedIOBase](#) buffered binary stream. It inherits [TextIOBase](#).

encoding gives the name of the encoding that the stream will be decoded or encoded with. It defaults to [locale.getpreferredencoding\(False\)](#).

errors is an optional string that specifies how encoding and decoding errors are to be handled. Pass 'strict' to raise a [ValueError](#) exception if there is an encoding error (the default of None has the same effect), or pass 'ignore' to ignore errors. (Note that ignoring encoding errors can lead to data loss.) 'replace' causes a replacement marker (such as '?') to be inserted where there is malformed data. 'backslashreplace' causes malformed data to be replaced by a backslashed escape sequence. When writing, 'xmlcharrefreplace' (replace with the appropriate XML character reference) or 'namereplace' (replace with `\N{...}` escape sequences) can be used. Any other error handling name that has been registered with [codecs.register_error\(\)](#) is also valid.

newline controls how line endings are handled. It can be None, '', '\n', '\r', and '\r\n'. It works as follows:

- When reading input from the stream, if *newline* is None, [universal newlines](#) mode is enabled. Lines in the input can end in '\n', '\r', or '\r\n', and these are translated into '\n' before being returned to the caller. If *newline* is '', universal newlines mode is enabled, but line endings are returned to the caller untranslated. If *newline* has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- When writing output to the stream, if *newline* is None, any '\n' characters written are translated to the system default line separator, [os.linesep](#). If *newline* is '' or '\n', no translation takes place. If *newline* is any of the other legal values, any '\n' characters written are translated to the given string.

If *line_buffering* is True, [flush\(\)](#) is implied when a call to write contains a newline character or a carriage return.

If *write_through* is True, calls to [write\(\)](#) are guaranteed not to be buffered: any data written on the [TextIOWrapper](#) object is immediately handled to its underlying binary *buffer*.

Άλλαξε στην έκδοση 3.3: The *write_through* argument has been added.

Άλλαξε στην έκδοση 3.3: The default *encoding* is now [locale.getpreferredencoding\(False\)](#) instead of [locale.getpreferredencoding\(\)](#). Don't change temporarily the locale encoding using [locale.setlocale\(\)](#), use the current locale encoding instead of the user preferred encoding.

[TextIOWrapper](#) provides these data attributes and methods in addition to those from [TextIOBase](#) and [IOBase](#):

line_buffering

Whether line buffering is enabled.

write_through

Whether writes are passed immediately to the underlying binary buffer.

Νέο στην έκδοση 3.7.

reconfigure (*[, encoding][, errors][, newline][, line_buffering][, write_through])

Reconfigure this text stream using new settings for *encoding*, *errors*, *newline*, *line_buffering* and *write_through*.

Parameters not specified keep current settings, except *errors*='strict' is used when *encoding* is specified but *errors* is not specified.

It is not possible to change the encoding or newline if some data has already been read from the stream. On the other hand, changing encoding after write is possible.

This method does an implicit stream flush before setting the new parameters.

Νέο στην έκδοση 3.7.

class io.StringIO(*initial_value*="", *newline*='\n')

A text stream using an in-memory text buffer. It inherits *TextIOBase*.

The text buffer is discarded when the *close()* method is called.

The initial value of the buffer can be set by providing *initial_value*. If newline translation is enabled, newlines will be encoded as if by *write()*. The stream is positioned at the start of the buffer.

The *newline* argument works like that of *TextIOWrapper*, except that when writing output to the stream, if *newline* is None, newlines are written as \n on all platforms.

StringIO provides this method in addition to those from *TextIOBase* and *IOBase*:

getvalue()

Return a str containing the entire contents of the buffer. Newlines are decoded as if by *read()*, although the stream position is not changed.

Example usage:

```
import io

output = io.StringIO()
output.write('First line.\n')
print('Second line.', file=output)

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

class io.IncrementalNewlineDecoder

A helper codec that decodes newlines for *universal newlines* mode. It inherits *codecs.IncrementalDecoder*.

16.2.4 Performance

This section discusses the performance of the provided concrete I/O implementations.

Binary I/O

By reading and writing only large chunks of data even when the user asks for a single byte, buffered I/O hides any inefficiency in calling and executing the operating system's unbuffered I/O routines. The gain depends on the OS and the kind of I/O which is performed. For example, on some modern OSes such as Linux, unbuffered disk I/O can be as fast as buffered I/O. The bottom line, however, is that buffered I/O offers predictable performance regardless of the platform and the backing device. Therefore, it is almost always preferable to use buffered I/O rather than unbuffered I/O for binary data.

Text I/O

Text I/O over a binary storage (such as a file) is significantly slower than binary I/O over the same storage, because it requires conversions between unicode and binary data using a character codec. This can become noticeable handling huge amounts of text data like large log files. Also, `TextIOWrapper.tell()` and `TextIOWrapper.seek()` are both quite slow due to the reconstruction algorithm used.

StringIO, however, is a native in-memory unicode container and will exhibit similar speed to *BytesIO*.

Multi-threading

FileIO objects are thread-safe to the extent that the operating system calls (such as `read(2)` under Unix) they wrap are thread-safe too.

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) protect their internal structures using a lock; it is therefore safe to call them from multiple threads at once.

TextIOWrapper objects are not thread-safe.

Reentrancy

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) are not reentrant. While reentrant calls will not happen in normal situations, they can arise from doing I/O in a *signal* handler. If a thread tries to re-enter a buffered object which it is already accessing, a *RuntimeError* is raised. Note this doesn't prohibit a different thread from entering the buffered object.

The above implicitly extends to text files, since the *open()* function will wrap a buffered object inside a *TextIOWrapper*. This includes standard streams and therefore affects the built-in *print()* function as well.

16.3 time — Time access and conversions

This module provides various time-related functions. For related functionality, see also the *datetime* and *calendar* modules.

Although this module is always available, not all functions are available on all platforms. Most of the functions defined in this module call platform C library functions with the same name. It may sometimes be helpful to consult the platform documentation, because the semantics of these functions varies among platforms.

An explanation of some terminology and conventions is in order.

- The *epoch* is the point where the time starts, and is platform dependent. For Unix, the epoch is January 1, 1970, 00:00:00 (UTC). To find out what the epoch is on a given platform, look at `time.gmtime(0)`.

- The term *seconds since the epoch* refers to the total number of elapsed seconds since the epoch, typically excluding *leap seconds*. Leap seconds are excluded from this total on all POSIX-compliant platforms.
- The functions in this module may not handle dates and times before the epoch or far in the future. The cut-off point in the future is determined by the C library; for 32-bit systems, it is typically in 2038.
- Function `strptime()` can parse 2-digit years when given `%y` format code. When 2-digit years are parsed, they are converted according to the POSIX and ISO C standards: values 69–99 are mapped to 1969–1999, and values 0–68 are mapped to 2000–2068.
- UTC is Coordinated Universal Time (formerly known as Greenwich Mean Time, or GMT). The acronym UTC is not a mistake but a compromise between English and French.
- DST is Daylight Saving Time, an adjustment of the timezone by (usually) one hour during part of the year. DST rules are magic (determined by local law) and can change from year to year. The C library has a table containing the local rules (often it is read from a system file for flexibility) and is the only source of True Wisdom in this respect.
- The precision of the various real-time functions may be less than suggested by the units in which their value or argument is expressed. E.g. on most Unix systems, the clock «ticks» only 50 or 100 times a second.
- On the other hand, the precision of `time()` and `sleep()` is better than their Unix equivalents: times are expressed as floating point numbers, `time()` returns the most accurate time available (using `gettimeofday()` where available), and `sleep()` will accept a time with a nonzero fraction (Unix `select()` is used to implement this, where available).
- The time value as returned by `gmtime()`, `localtime()`, and `strptime()`, and accepted by `asctime()`, `mktime()` and `strftime()`, is a sequence of 9 integers. The return values of `gmtime()`, `localtime()`, and `strptime()` also offer attribute names for individual fields.

See `struct_time` for a description of these objects.

Άλλαξε στην έκδοση 3.3: The `struct_time` type was extended to provide the `tm_gmtoff` and `tm_zone` attributes when platform supports corresponding `struct tm` members.

Άλλαξε στην έκδοση 3.6: The `struct_time` attributes `tm_gmtoff` and `tm_zone` are now available on all platforms.

- Use the following functions to convert between time representations:

| From | To | Use |
|--|--|--------------------------------|
| seconds since the epoch | <code>struct_time</code> in UTC | <code>gmtime()</code> |
| seconds since the epoch | <code>struct_time</code> in local time | <code>localtime()</code> |
| <code>struct_time</code> in UTC | seconds since the epoch | <code>calendar.timegm()</code> |
| <code>struct_time</code> in local time | seconds since the epoch | <code>mktime()</code> |

16.3.1 Functions

`time.asctime([t])`

Convert a tuple or `struct_time` representing a time as returned by `gmtime()` or `localtime()` to a string of the following form: 'Sun Jun 20 23:21:05 1993'. The day field is two characters long and is space padded if the day is a single digit, e.g.: 'Wed Jun 9 04:26:40 1993'.

If `t` is not provided, the current time as returned by `localtime()` is used. Locale information is not used by `asctime()`.

Σημείωση: Unlike the C function of the same name, `asctime()` does not add a trailing newline.

`time.thread_getcpuclockid(thread_id)`

Return the *clk_id* of the thread-specific CPU-time clock for the specified *thread_id*.

Use `threading.get_ident()` or the *ident* attribute of `threading.Thread` objects to get a suitable value for *thread_id*.

Προειδοποίηση: Passing an invalid or expired *thread_id* may result in undefined behavior, such as segmentation fault.

Availability: Unix (see the man page for `pthread_getcpuclockid(3)` for further information).

Νέο στην έκδοση 3.7.

`time.clock_getres(clk_id)`

Return the resolution (precision) of the specified clock *clk_id*. Refer to *Clock ID Constants* for a list of accepted values for *clk_id*.

Availability: Unix.

Νέο στην έκδοση 3.3.

`time.clock_gettime(clk_id) → float`

Return the time of the specified clock *clk_id*. Refer to *Clock ID Constants* for a list of accepted values for *clk_id*.

Availability: Unix.

Νέο στην έκδοση 3.3.

`time.clock_gettime_ns(clk_id) → int`

Similar to `clock_gettime()` but return time as nanoseconds.

Availability: Unix.

Νέο στην έκδοση 3.7.

`time.clock_settime(clk_id, time: float)`

Set the time of the specified clock *clk_id*. Currently, `CLOCK_REALTIME` is the only accepted value for *clk_id*.

Availability: Unix.

Νέο στην έκδοση 3.3.

`time.clock_settime_ns(clk_id, time: int)`

Similar to `clock_settime()` but set time with nanoseconds.

Availability: Unix.

Νέο στην έκδοση 3.7.

`time.ctime([secs])`

Convert a time expressed in seconds since the epoch to a string of a form: 'Sun Jun 20 23:21:05 1993' representing local time. The day field is two characters long and is space padded if the day is a single digit, e.g.: 'Wed Jun 9 04:26:40 1993'.

If *secs* is not provided or `None`, the current time as returned by `time()` is used. `ctime(secs)` is equivalent to `asctime(localtime(secs))`. Locale information is not used by `ctime()`.

`time.get_clock_info(name)`

Get information on the specified clock as a namespace object. Supported clock names and the corresponding functions to read their value are:

- 'monotonic': `time.monotonic()`

- 'perf_counter': `time.perf_counter()`
- 'process_time': `time.process_time()`
- 'thread_time': `time.thread_time()`
- 'time': `time.time()`

The result has the following attributes:

- *adjustable*: `True` if the clock can be changed automatically (e.g. by a NTP daemon) or manually by the system administrator, `False` otherwise
- *implementation*: The name of the underlying C function used to get the clock value. Refer to [Clock ID Constants](#) for possible values.
- *monotonic*: `True` if the clock cannot go backward, `False` otherwise
- *resolution*: The resolution of the clock in seconds (*float*)

Νέο στην έκδοση 3.3.

`time.gmtime([secs])`

Convert a time expressed in seconds since the epoch to a *struct_time* in UTC in which the dst flag is always zero. If *secs* is not provided or *None*, the current time as returned by *time()* is used. Fractions of a second are ignored. See above for a description of the *struct_time* object. See *calendar.timegm()* for the inverse of this function.

`time.localtime([secs])`

Like *gmtime()* but converts to local time. If *secs* is not provided or *None*, the current time as returned by *time()* is used. The dst flag is set to 1 when DST applies to the given time.

localtime() may raise *OverflowError*, if the timestamp is outside the range of values supported by the platform C *localtime()* or *gmtime()* functions, and *OSError* on *localtime()* or *gmtime()* failure. It's common for this to be restricted to years between 1970 and 2038.

`time.mktime(t)`

This is the inverse function of *localtime()*. Its argument is the *struct_time* or full 9-tuple (since the dst flag is needed; use -1 as the dst flag if it is unknown) which expresses the time in *local* time, not UTC. It returns a floating point number, for compatibility with *time()*. If the input value cannot be represented as a valid time, either *OverflowError* or *ValueError* will be raised (which depends on whether the invalid value is caught by Python or the underlying C libraries). The earliest date for which it can generate a time is platform-dependent.

`time.monotonic() → float`

Return the value (in fractional seconds) of a monotonic clock, i.e. a clock that cannot go backwards. The clock is not affected by system clock updates. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Νέο στην έκδοση 3.3.

Άλλαξε στην έκδοση 3.5: The function is now always available and always system-wide.

`time.monotonic_ns() → int`

Similar to *monotonic()*, but return time as nanoseconds.

Νέο στην έκδοση 3.7.

`time.perf_counter() → float`

Return the value (in fractional seconds) of a performance counter, i.e. a clock with the highest available resolution to measure a short duration. It does include time elapsed during sleep and is system-wide. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Νέο στην έκδοση 3.3.

`time.perf_counter_ns()` → int

Similar to `perf_counter()`, but return time as nanoseconds.

Νέο στην έκδοση 3.7.

`time.process_time()` → float

Return the value (in fractional seconds) of the sum of the system and user CPU time of the current process. It does not include time elapsed during sleep. It is process-wide by definition. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Νέο στην έκδοση 3.3.

`time.process_time_ns()` → int

Similar to `process_time()` but return time as nanoseconds.

Νέο στην έκδοση 3.7.

`time.sleep(secs)`

Suspend execution of the calling thread for the given number of seconds. The argument may be a floating point number to indicate a more precise sleep time. The actual suspension time may be less than that requested because any caught signal will terminate the `sleep()` following execution of that signal's catching routine. Also, the suspension time may be longer than requested by an arbitrary amount because of the scheduling of other activity in the system.

Άλλαξε στην έκδοση 3.5: The function now sleeps at least *secs* even if the sleep is interrupted by a signal, except if the signal handler raises an exception (see [PEP 475](#) for the rationale).

`time.strftime(format[, t])`

Convert a tuple or `struct_time` representing a time as returned by `gmtime()` or `localtime()` to a string as specified by the *format* argument. If *t* is not provided, the current time as returned by `localtime()` is used. *format* must be a string. `ValueError` is raised if any field in *t* is outside of the allowed range.

0 is a legal argument for any position in the time tuple; if it is normally illegal the value is forced to a correct one.

The following directives can be embedded in the *format* string. They are shown without the optional field width and precision specification, and are replaced by the indicated characters in the `strftime()` result:

| Directive | Meaning | Notes |
|-----------|--|-------|
| %a | Locale's abbreviated weekday name. | |
| %A | Locale's full weekday name. | |
| %b | Locale's abbreviated month name. | |
| %B | Locale's full month name. | |
| %c | Locale's appropriate date and time representation. | |
| %d | Day of the month as a decimal number [01,31]. | |
| %H | Hour (24-hour clock) as a decimal number [00,23]. | |
| %I | Hour (12-hour clock) as a decimal number [01,12]. | |
| %j | Day of the year as a decimal number [001,366]. | |
| %m | Month as a decimal number [01,12]. | |
| %M | Minute as a decimal number [00,59]. | |
| %p | Locale's equivalent of either AM or PM. | (1) |
| %S | Second as a decimal number [00,61]. | (2) |
| %U | Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0. | (3) |
| %w | Weekday as a decimal number [0(Sunday),6]. | |
| %W | Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0. | (3) |
| %x | Locale's appropriate date representation. | |
| %X | Locale's appropriate time representation. | |
| %y | Year without century as a decimal number [00,99]. | |
| %Y | Year with century as a decimal number. | |
| %z | Time zone offset indicating a positive or negative time difference from UTC/GMT of the form +HHMM or -HHMM, where H represents decimal hour digits and M represents decimal minute digits [-23:59, +23:59]. ¹ | |
| %Z | Time zone name (no characters if no time zone exists). Deprecated. ¹ | |
| %% | A literal '%' character. | |

Notes:

- (1) When used with the `strptime()` function, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.
- (2) The range really is 0 to 61; value 60 is valid in timestamps representing [leap seconds](#) and value 61 is supported for historical reasons.
- (3) When used with the `strptime()` function, `%U` and `%W` are only used in calculations when the day of the week and the year are specified.

Here is an example, a format for dates compatible with that specified in the [RFC 2822](#) Internet email standard.¹

```
>>> from time import gmtime, strftime
>>> strftime("%a, %d %b %Y %H:%M:%S +0000", gmtime())
'Thu, 28 Jun 2001 14:17:15 +0000'
```

Additional directives may be supported on certain platforms, but only the ones listed here have a meaning standardized by ANSI C. To see the full set of format codes supported on your platform, consult the `strftime(3)` documentation.

¹ The use of `%Z` is now deprecated, but the `%z` escape that expands to the preferred hour/minute offset is not supported by all ANSI C libraries. Also, a strict reading of the original 1982 [RFC 822](#) standard calls for a two-digit year (`%y` rather than `%Y`), but practice moved to 4-digit years long before the year 2000. After that, [RFC 822](#) became obsolete and the 4-digit year has been first recommended by [RFC 1123](#) and then mandated by [RFC 2822](#).

On some platforms, an optional field width and precision specification can immediately follow the initial '%' of a directive in the following order; this is also not portable. The field width is normally 2 except for %j where it is 3.

`time.strptime(string[, format])`

Parse a string representing a time according to a format. The return value is a *struct_time* as returned by *gmtime()* or *localtime()*.

The *format* parameter uses the same directives as those used by *strftime()*; it defaults to "%a %b %d %H:%M:%S %Y" which matches the formatting returned by *ctime()*. If *string* cannot be parsed according to *format*, or if it has excess data after parsing, *ValueError* is raised. The default values used to fill in any missing data when more accurate values cannot be inferred are (1900, 1, 1, 0, 0, 0, 0, 1, -1). Both *string* and *format* must be strings.

For example:

```
>>> import time
>>> time.strptime("30 Nov 00", "%d %b %y")
time.struct_time(tm_year=2000, tm_mon=11, tm_mday=30, tm_hour=0, tm_min=0,
                  tm_sec=0, tm_wday=3, tm_yday=335, tm_isdst=-1)
```

Support for the %Z directive is based on the values contained in *tzname* and whether *daylight* is true. Because of this, it is platform-specific except for recognizing UTC and GMT which are always known (and are considered to be non-daylight savings timezones).

Only the directives specified in the documentation are supported. Because *strftime()* is implemented per platform it can sometimes offer more directives than those listed. But *strptime()* is independent of any platform and thus does not necessarily support all directives available that are not documented as supported.

class `time.struct_time`

The type of the time value sequence returned by *gmtime()*, *localtime()*, and *strptime()*. It is an object with a *named tuple* interface: values can be accessed by index and by attribute name. The following values are present:

| Index | Attribute | Values |
|-------|-----------|---|
| 0 | tm_year | (for example, 1993) |
| 1 | tm_mon | range [1, 12] |
| 2 | tm_mday | range [1, 31] |
| 3 | tm_hour | range [0, 23] |
| 4 | tm_min | range [0, 59] |
| 5 | tm_sec | range [0, 61]; see (2) in <i>strftime()</i> description |
| 6 | tm_wday | range [0, 6], Monday is 0 |
| 7 | tm_yday | range [1, 366] |
| 8 | tm_isdst | 0, 1 or -1; see below |
| N/A | tm_zone | abbreviation of timezone name |
| N/A | tm_gmtoff | offset east of UTC in seconds |

Note that unlike the C structure, the month value is a range of [1, 12], not [0, 11].

In calls to *mktime()*, *tm_isdst* may be set to 1 when daylight savings time is in effect, and 0 when it is not. A value of -1 indicates that this is not known, and will usually result in the correct state being filled in.

When a tuple with an incorrect length is passed to a function expecting a *struct_time*, or having elements of the wrong type, a *TypeError* is raised.

`time.time()` → float

Return the time in seconds since the *epoch* as a floating point number. The specific date of the epoch and the handling of *leap seconds* is platform dependent. On Windows and most Unix systems, the epoch is January 1,

1970, 00:00:00 (UTC) and leap seconds are not counted towards the time in seconds since the epoch. This is commonly referred to as [Unix time](#). To find out what the epoch is on a given platform, look at `gmtime(0)`.

Note that even though the time is always returned as a floating point number, not all systems provide time with a better precision than 1 second. While this function normally returns non-decreasing values, it can return a lower value than a previous call if the system clock has been set back between the two calls.

The number returned by `time()` may be converted into a more common time format (i.e. year, month, day, hour, etc...) in UTC by passing it to `gmtime()` function or in local time by passing it to the `localtime()` function. In both cases a `struct_time` object is returned, from which the components of the calendar date may be accessed as attributes.

`time.thread_time()` → float

Return the value (in fractional seconds) of the sum of the system and user CPU time of the current thread. It does not include time elapsed during sleep. It is thread-specific by definition. The reference point of the returned value is undefined, so that only the difference between the results of two calls in the same thread is valid.

Availability: Windows, Linux, Unix systems supporting `CLOCK_THREAD_CPUTIME_ID`.

Νέο στην έκδοση 3.7.

`time.thread_time_ns()` → int

Similar to `thread_time()` but return time as nanoseconds.

Νέο στην έκδοση 3.7.

`time.time_ns()` → int

Similar to `time()` but returns time as an integer number of nanoseconds since the *epoch*.

Νέο στην έκδοση 3.7.

`time.tzset()`

Reset the time conversion rules used by the library routines. The environment variable `TZ` specifies how this is done. It will also set the variables `tzname` (from the `TZ` environment variable), `timezone` (non-DST seconds West of UTC), `altzone` (DST seconds west of UTC) and `daylight` (to 0 if this timezone does not have any daylight saving time rules, or to nonzero if there is a time, past, present or future when daylight saving time applies).

Availability: Unix.

Σημείωση: Although in many cases, changing the `TZ` environment variable may affect the output of functions like `localtime()` without calling `tzset()`, this behavior should not be relied on.

The `TZ` environment variable should contain no whitespace.

The standard format of the `TZ` environment variable is (whitespace added for clarity):

`std offset [dst [offset [,start[/time], end[/time]]]]`

Where the components are:

std and dst Three or more alphanumerics giving the timezone abbreviations. These will be propagated into `time.tzname`

offset The offset has the form: `± hh[:mm[:ss]]`. This indicates the value added the local time to arrive at UTC. If preceded by a “-”, the timezone is east of the Prime Meridian; otherwise, it is west. If no offset follows `dst`, summer time is assumed to be one hour ahead of standard time.

start[/time], end[/time] Indicates when to change to and back from DST. The format of the start and end dates are one of the following:

Jn The Julian day *n* ($1 \leq n \leq 365$). Leap days are not counted, so in all years February 28 is day 59 and March 1 is day 60.

n The zero-based Julian day ($0 \leq n \leq 365$). Leap days are counted, and it is possible to refer to February 29.

Mm.n.d The *d*'th day ($0 \leq d \leq 6$) of week *n* of month *m* of the year ($1 \leq n \leq 5$, $1 \leq m \leq 12$, where week 5 means «the last *d* day in month *m*» which may occur in either the fourth or the fifth week). Week 1 is the first week in which the *d*'th day occurs. Day zero is a Sunday.

`time` has the same format as `offset` except that no leading sign (“-” or “+”) is allowed. The default, if `time` is not given, is 02:00:00.

```
>>> os.environ['TZ'] = 'EST+05EDT,M4.1.0,M10.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'02:07:36 05/08/03 EDT'
>>> os.environ['TZ'] = 'AEST-10AEDT-11,M10.5.0,M3.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'16:08:12 05/08/03 AEST'
```

On many Unix systems (including *BSD, Linux, Solaris, and Darwin), it is more convenient to use the system's `zoneinfo` (`tzfile(5)`) database to specify the timezone rules. To do this, set the `TZ` environment variable to the path of the required timezone datafile, relative to the root of the systems “zoneinfo” timezone database, usually located at `/usr/share/zoneinfo`. For example, `'US/Eastern'`, `'Australia/Melbourne'`, `'Egypt'` or `'Europe/Amsterdam'`.

```
>>> os.environ['TZ'] = 'US/Eastern'
>>> time.tzset()
>>> time.tzname
('EST', 'EDT')
>>> os.environ['TZ'] = 'Egypt'
>>> time.tzset()
>>> time.tzname
('EET', 'EEST')
```

16.3.2 Clock ID Constants

These constants are used as parameters for `clock_getres()` and `clock_gettime()`.

`time.CLOCK_BOOTTIME`

Identical to `CLOCK_MONOTONIC`, except it also includes any time that the system is suspended.

This allows applications to get a suspend-aware monotonic clock without having to deal with the complications of `CLOCK_REALTIME`, which may have discontinuities if the time is changed using `settimeofday()` or similar.

Availability: Linux 2.6.39 or later.

Νέο στην έκδοση 3.7.

`time.CLOCK_HIGHRES`

The Solaris OS has a `CLOCK_HIGHRES` timer that attempts to use an optimal hardware source, and may give close to nanosecond resolution. `CLOCK_HIGHRES` is the nonadjustable, high-resolution clock.

Availability: Solaris.

Νέο στην έκδοση 3.3.

`time.CLOCK_MONOTONIC`

Clock that cannot be set and represents monotonic time since some unspecified starting point.

Availability: Unix.

Νέο στην έκδοση 3.3.

`time.CLOCK_MONOTONIC_RAW`

Similar to `CLOCK_MONOTONIC`, but provides access to a raw hardware-based time that is not subject to NTP adjustments.

Availability: Linux 2.6.28 and newer, macOS 10.12 and newer.

Νέο στην έκδοση 3.3.

`time.CLOCK_PROCESS_CPUTIME_ID`

High-resolution per-process timer from the CPU.

Availability: Unix.

Νέο στην έκδοση 3.3.

`time.CLOCK_PROF`

High-resolution per-process timer from the CPU.

Availability: FreeBSD, NetBSD 7 or later, OpenBSD.

Νέο στην έκδοση 3.7.

`time.CLOCK_TAI`

International Atomic Time

The system must have a current leap second table in order for this to give the correct answer. PTP or NTP software can maintain a leap second table.

Availability: Linux.

Νέο στην έκδοση 3.9.

`time.CLOCK_THREAD_CPUTIME_ID`

Thread-specific CPU-time clock.

Availability: Unix.

Νέο στην έκδοση 3.3.

`time.CLOCK_UPTIME`

Time whose absolute value is the time the system has been running and not suspended, providing accurate uptime measurement, both absolute and interval.

Availability: FreeBSD, OpenBSD 5.5 or later.

Νέο στην έκδοση 3.7.

`time.CLOCK_UPTIME_RAW`

Clock that increments monotonically, tracking the time since an arbitrary point, unaffected by frequency or time adjustments and not incremented while the system is asleep.

Availability: macOS 10.12 and newer.

Νέο στην έκδοση 3.8.

The following constant is the only parameter that can be sent to `clock_settime()`.

`time.CLOCK_REALTIME`

System-wide real-time clock. Setting this clock requires appropriate privileges.

Availability: Unix.

Νέο στην έκδοση 3.3.

16.3.3 Timezone Constants

`time.altzone`

The offset of the local DST timezone, in seconds west of UTC, if one is defined. This is negative if the local DST timezone is east of UTC (as in Western Europe, including the UK). Only use this if `daylight` is nonzero. See note below.

`time.daylight`

Nonzero if a DST timezone is defined. See note below.

`time.timezone`

The offset of the local (non-DST) timezone, in seconds west of UTC (negative in most of Western Europe, positive in the US, zero in the UK). See note below.

`time.tzname`

A tuple of two strings: the first is the name of the local non-DST timezone, the second is the name of the local DST timezone. If no DST timezone is defined, the second string should not be used. See note below.

Σημείωση: For the above Timezone constants (`altzone`, `daylight`, `timezone`, and `tzname`), the value is determined by the timezone rules in effect at module load time or the last time `tzset()` is called and may be incorrect for times in the past. It is recommended to use the `tm_gmtoff` and `tm_zone` results from `localtime()` to obtain timezone information.

Δείτε επίσης:

Module `datetime` More object-oriented interface to dates and times.

Module `locale` Internationalization services. The locale setting affects the interpretation of many format specifiers in `strftime()` and `strptime()`.

Module `calendar` General calendar-related functions. `timegm()` is the inverse of `gmtime()` from this module.

16.4 argparse — Parser for command-line options, arguments and sub-commands

Νέο στην έκδοση 3.2.

Source code: [Lib/argparse.py](#)

Tutorial

This page contains the API reference information. For a more gentle introduction to Python command-line parsing, have a look at the [argparse tutorial](#).

The `argparse` module makes it easy to write user-friendly command-line interfaces. The program defines what arguments it requires, and `argparse` will figure out how to parse those out of `sys.argv`. The `argparse` module also automatically generates help and usage messages and issues errors when users give the program invalid arguments.

16.4.1 Example

The following code is a Python program that takes a list of integers and produces either the sum or the max:

```
import argparse

parser = argparse.ArgumentParser(description='Process some integers.')
parser.add_argument('integers', metavar='N', type=int, nargs='+',
                    help='an integer for the accumulator')
parser.add_argument('--sum', dest='accumulate', action='store_const',
                    const=sum, default=max,
                    help='sum the integers (default: find the max)')

args = parser.parse_args()
print(args.accumulate(args.integers))
```

Assuming the Python code above is saved into a file called `prog.py`, it can be run at the command line and provides useful help messages:

```
$ python prog.py -h
usage: prog.py [-h] [--sum] N [N ...]

Process some integers.

positional arguments:
  N              an integer for the accumulator

optional arguments:
  -h, --help    show this help message and exit
  --sum         sum the integers (default: find the max)
```

When run with the appropriate arguments, it prints either the sum or the max of the command-line integers:

```
$ python prog.py 1 2 3 4
4

$ python prog.py 1 2 3 4 --sum
10
```

If invalid arguments are passed in, it will issue an error:

```
$ python prog.py a b c
usage: prog.py [-h] [--sum] N [N ...]
prog.py: error: argument N: invalid int value: 'a'
```

The following sections walk you through this example.

Creating a parser

The first step in using the `argparse` is creating an `ArgumentParser` object:

```
>>> parser = argparse.ArgumentParser(description='Process some integers.')
```

The `ArgumentParser` object will hold all the information necessary to parse the command line into Python data types.

Adding arguments

Filling an `ArgumentParser` with information about program arguments is done by making calls to the `add_argument()` method. Generally, these calls tell the `ArgumentParser` how to take the strings on the command line and turn them into objects. This information is stored and used when `parse_args()` is called. For example:

```
>>> parser.add_argument('integers', metavar='N', type=int, nargs='+',
...                     help='an integer for the accumulator')
>>> parser.add_argument('--sum', dest='accumulate', action='store_const',
...                     const=sum, default=max,
...                     help='sum the integers (default: find the max)')
```

Later, calling `parse_args()` will return an object with two attributes, `integers` and `accumulate`. The `integers` attribute will be a list of one or more ints, and the `accumulate` attribute will be either the `sum()` function, if `--sum` was specified at the command line, or the `max()` function if it was not.

Parsing arguments

`ArgumentParser` parses arguments through the `parse_args()` method. This will inspect the command line, convert each argument to the appropriate type and then invoke the appropriate action. In most cases, this means a simple `Namespace` object will be built up from attributes parsed out of the command line:

```
>>> parser.parse_args(['--sum', '7', '-1', '42'])
Namespace(accumulate=<built-in function sum>, integers=[7, -1, 42])
```

In a script, `parse_args()` will typically be called with no arguments, and the `ArgumentParser` will automatically determine the command-line arguments from `sys.argv`.

16.4.2 ArgumentParser objects

```
class argparse.ArgumentParser(prog=None, usage=None, description=None, epilog=None,
                             parents=[], formatter_class=argparse.HelpFormatter,
                             prefix_chars='-', fromfile_prefix_chars=None,
                             argument_default=None, conflict_handler='error', add_help=True,
                             allow_abbrev=True, exit_on_error=True)
```

Create a new `ArgumentParser` object. All parameters should be passed as keyword arguments. Each parameter has its own more detailed description below, but in short they are:

- `prog` - The name of the program (default: `sys.argv[0]`)
- `usage` - The string describing the program usage (default: generated from arguments added to parser)
- `description` - Text to display before the argument help (default: none)
- `epilog` - Text to display after the argument help (default: none)
- `parents` - A list of `ArgumentParser` objects whose arguments should also be included

- *formatter_class* - A class for customizing the help output
- *prefix_chars* - The set of characters that prefix optional arguments (default: “-“)
- *fromfile_prefix_chars* - The set of characters that prefix files from which additional arguments should be read (default: None)
- *argument_default* - The global default value for arguments (default: None)
- *conflict_handler* - The strategy for resolving conflicting optionals (usually unnecessary)
- *add_help* - Add a `-h/--help` option to the parser (default: True)
- *allow_abbrev* - Allows long options to be abbreviated if the abbreviation is unambiguous. (default: True)
- *exit_on_error* - Determines whether or not `ArgumentParser` exits with error info when an error occurs. (default: True)

Άλλαξε στην έκδοση 3.5: *allow_abbrev* parameter was added.

Άλλαξε στην έκδοση 3.8: In previous versions, *allow_abbrev* also disabled grouping of short flags such as `-vv` to mean `-v -v`.

Άλλαξε στην έκδοση 3.9: *exit_on_error* parameter was added.

The following sections describe how each of these are used.

prog

By default, *ArgumentParser* objects use `sys.argv[0]` to determine how to display the name of the program in help messages. This default is almost always desirable because it will make the help messages match how the program was invoked on the command line. For example, consider a file named `myprogram.py` with the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

The help for this program will display `myprogram.py` as the program name (regardless of where the program was invoked from):

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   foo help
$ cd ..
$ python subdir/myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   foo help
```

To change this default behavior, another value can be supplied using the `prog=` argument to *ArgumentParser*:

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.print_help()
usage: myprogram [-h]
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
optional arguments:
  -h, --help  show this help message and exit
```

Note that the program name, whether determined from `sys.argv[0]` or from the `prog=` argument, is available to help messages using the `%(prog)s` format specifier.

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.add_argument('--foo', help='foo of the %(prog)s program')
>>> parser.print_help()
usage: myprogram [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   foo of the myprogram program
```

usage

By default, `ArgumentParser` calculates the usage message from the arguments it contains:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [-h] [--foo [FOO]] bar [bar ...]

positional arguments:
  bar                bar help

optional arguments:
  -h, --help  show this help message and exit
  --foo [FOO] foo help
```

The default message can be overridden with the `usage=` keyword argument:

```
>>> parser = argparse.ArgumentParser(prog='PROG', usage='%(prog)s [options]')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [options]

positional arguments:
  bar                bar help

optional arguments:
  -h, --help  show this help message and exit
  --foo [FOO] foo help
```

The `%(prog)s` format specifier is available to fill in the program name in your usage messages.

description

Most calls to the `ArgumentParser` constructor will use the `description=` keyword argument. This argument gives a brief description of what the program does and how it works. In help messages, the description is displayed between the command-line usage string and the help messages for the various arguments:

```
>>> parser = argparse.ArgumentParser(description='A foo that bars')
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

optional arguments:
  -h, --help  show this help message and exit
```

By default, the description will be line-wrapped so that it fits within the given space. To change this behavior, see the `formatter_class` argument.

epilog

Some programs like to display additional description of the program after the description of the arguments. Such text can be specified using the `epilog=` argument to `ArgumentParser`:

```
>>> parser = argparse.ArgumentParser(
...     description='A foo that bars',
...     epilog="And that's how you'd foo a bar")
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

optional arguments:
  -h, --help  show this help message and exit

And that's how you'd foo a bar
```

As with the `description` argument, the `epilog=` text is by default line-wrapped, but this behavior can be adjusted with the `formatter_class` argument to `ArgumentParser`.

parents

Sometimes, several parsers share a common set of arguments. Rather than repeating the definitions of these arguments, a single parser with all the shared arguments and passed to `parents=` argument to `ArgumentParser` can be used. The `parents=` argument takes a list of `ArgumentParser` objects, collects all the positional and optional actions from them, and adds these actions to the `ArgumentParser` object being constructed:

```
>>> parent_parser = argparse.ArgumentParser(add_help=False)
>>> parent_parser.add_argument('--parent', type=int)

>>> foo_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> foo_parser.add_argument('foo')
>>> foo_parser.parse_args(['--parent', '2', 'XXX'])
Namespace(foo='XXX', parent=2)
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> bar_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> bar_parser.add_argument('--bar')
>>> bar_parser.parse_args(['--bar', 'YYY'])
Namespace(bar='YYY', parent=None)
```

Note that most parent parsers will specify `add_help=False`. Otherwise, the *ArgumentParser* will see two `-h/--help` options (one in the parent and one in the child) and raise an error.

Σημείωση: You must fully initialize the parsers before passing them via `parents=`. If you change the parent parsers after the child parser, those changes will not be reflected in the child.

formatter_class

ArgumentParser objects allow the help formatting to be customized by specifying an alternate formatting class. Currently, there are four such classes:

```
class argparse.RawDescriptionHelpFormatter
class argparse.RawTextHelpFormatter
class argparse.ArgumentDefaultsHelpFormatter
class argparse.MetavarTypeHelpFormatter
```

RawDescriptionHelpFormatter and *RawTextHelpFormatter* give more control over how textual descriptions are displayed. By default, *ArgumentParser* objects line-wrap the *description* and *epilog* texts in command-line help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     description='''this description
...         was indented weird
...         but that is okay''',
...     epilog='''
...         likewise for this epilog whose whitespace will
...         be cleaned up and whose words will be wrapped
...         across a couple lines''')
>>> parser.print_help()
usage: PROG [-h]

this description was indented weird but that is okay

optional arguments:
  -h, --help  show this help message and exit

likewise for this epilog whose whitespace will be cleaned up and whose words
will be wrapped across a couple lines
```

Passing *RawDescriptionHelpFormatter* as `formatter_class=` indicates that *description* and *epilog* are already correctly formatted and should not be line-wrapped:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.RawDescriptionHelpFormatter,
...     description=textwrap.dedent('''\
...         Please do not mess up this text!
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

...         -----
...         I have indented it
...         exactly the way
...         I want it
...         ''))
>>> parser.print_help()
usage: PROG [-h]

Please do not mess up this text!
-----
    I have indented it
    exactly the way
    I want it

optional arguments:
  -h, --help  show this help message and exit

```

RawTextHelpFormatter maintains whitespace for all sorts of help text, including argument descriptions. However, multiple new lines are replaced with one. If you wish to preserve multiple blank lines, add spaces between the newlines.

ArgumentDefaultsHelpFormatter automatically adds information about default values to each of the argument help messages:

```

>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.ArgumentDefaultsHelpFormatter)
>>> parser.add_argument('--foo', type=int, default=42, help='FOO!')
>>> parser.add_argument('bar', nargs='*', default=[1, 2, 3], help='BAR!')
>>> parser.print_help()
usage: PROG [-h] [--foo FOO] [bar ...]

positional arguments:
  bar          BAR! (default: [1, 2, 3])

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   FOO! (default: 42)

```

MetavarTypeHelpFormatter uses the name of the *type* argument for each argument as the display name for its values (rather than using the *dest* as the regular formatter does):

```

>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.MetavarTypeHelpFormatter)
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', type=float)
>>> parser.print_help()
usage: PROG [-h] [--foo int] float

positional arguments:
  float

optional arguments:
  -h, --help  show this help message and exit
  --foo int

```

prefix_chars

Most command-line options will use `-` as the prefix, e.g. `-f/--foo`. Parsers that need to support different or additional prefix characters, e.g. for options like `+f` or `/foo`, may specify them using the `prefix_chars=` argument to the `ArgumentParser` constructor:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='+-')
>>> parser.add_argument('+f')
>>> parser.add_argument('++bar')
>>> parser.parse_args('+f X ++bar Y'.split())
Namespace(bar='Y', f='X')
```

The `prefix_chars=` argument defaults to `'-'`. Supplying a set of characters that does not include `-` will cause `-f/--foo` options to be disallowed.

fromfile_prefix_chars

Sometimes, for example when dealing with a particularly long argument list, it may make sense to keep the list of arguments in a file rather than typing it out at the command line. If the `fromfile_prefix_chars=` argument is given to the `ArgumentParser` constructor, then arguments that start with any of the specified characters will be treated as files, and will be replaced by the arguments they contain. For example:

```
>>> with open('args.txt', 'w') as fp:
...     fp.write('-f\nbar')
>>> parser = argparse.ArgumentParser(fromfile_prefix_chars='@')
>>> parser.add_argument('-f')
>>> parser.parse_args(['-f', 'foo', '@args.txt'])
Namespace(f='bar')
```

Arguments read from a file must by default be one per line (but see also `convert_arg_line_to_args()`) and are treated as if they were in the same place as the original file referencing argument on the command line. So in the example above, the expression `['-f', 'foo', '@args.txt']` is considered equivalent to the expression `['-f', 'foo', '-f', 'bar']`.

The `fromfile_prefix_chars=` argument defaults to `None`, meaning that arguments will never be treated as file references.

argument_default

Generally, argument defaults are specified either by passing a default to `add_argument()` or by calling the `set_defaults()` methods with a specific set of name-value pairs. Sometimes however, it may be useful to specify a single parser-wide default for arguments. This can be accomplished by passing the `argument_default=` keyword argument to `ArgumentParser`. For example, to globally suppress attribute creation on `parse_args()` calls, we supply `argument_default=SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(argument_default=argparse.SUPPRESS)
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar', nargs='?')
>>> parser.parse_args(['--foo', '1', 'BAR'])
Namespace(bar='BAR', foo='1')
>>> parser.parse_args([])
Namespace()
```

allow_abbrev

Normally, when you pass an argument list to the `parse_args()` method of an `ArgumentParser`, it *recognizes abbreviations* of long options.

This feature can be disabled by setting `allow_abbrev` to `False`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', allow_abbrev=False)
>>> parser.add_argument('--foobar', action='store_true')
>>> parser.add_argument('--foonley', action='store_false')
>>> parser.parse_args(['--foon'])
usage: PROG [-h] [--foobar] [--foonley]
PROG: error: unrecognized arguments: --foon
```

Νέο στην έκδοση 3.5.

conflict_handler

`ArgumentParser` objects do not allow two actions with the same option string. By default, `ArgumentParser` objects raise an exception if an attempt is made to create an argument with an option string that is already in use:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
Traceback (most recent call last):
..
ArgumentError: argument --foo: conflicting option string(s): --foo
```

Sometimes (e.g. when using *parents*) it may be useful to simply override any older arguments with the same option string. To get this behavior, the value `'resolve'` can be supplied to the `conflict_handler=` argument of `ArgumentParser`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', conflict_handler='resolve')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
>>> parser.print_help()
usage: PROG [-h] [-f FOO] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  -f FOO      old foo help
  --foo FOO   new foo help
```

Note that `ArgumentParser` objects only remove an action if all of its option strings are overridden. So, in the example above, the old `-f/--foo` action is retained as the `-f` action, because only the `--foo` option string was overridden.

add_help

By default, `ArgumentParser` objects add an option which simply displays the parser's help message. For example, consider a file named `myprogram.py` containing the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

If `-h` or `--help` is supplied at the command line, the `ArgumentParser` help will be printed:

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   foo help
```

Occasionally, it may be useful to disable the addition of this help option. This can be achieved by passing `False` as the `add_help=` argument to `ArgumentParser`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> parser.add_argument('--foo', help='foo help')
>>> parser.print_help()
usage: PROG [--foo FOO]

optional arguments:
  --foo FOO   foo help
```

The help option is typically `-h/--help`. The exception to this is if the `prefix_chars=` is specified and does not include `-`, in which case `-h` and `--help` are not valid options. In this case, the first character in `prefix_chars` is used to prefix the help options:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='+/')
>>> parser.print_help()
usage: PROG [+h]

optional arguments:
  +h, ++help  show this help message and exit
```

exit_on_error

Normally, when you pass an invalid argument list to the `parse_args()` method of an `ArgumentParser`, it will exit with error info.

If the user would like to catch errors manually, the feature can be enabled by setting `exit_on_error` to `False`:

```
>>> parser = argparse.ArgumentParser(exit_on_error=False)
>>> parser.add_argument('--integers', type=int)
_StoreAction(option_strings=['--integers'], dest='integers', nargs=None, const=None, _
↪default=None, type=<class 'int'>, choices=None, help=None, metavar=None)
>>> try:
...     parser.parse_args('--integers a'.split())
... except argparse.ArgumentError:
...     print('Catching an argumentError')
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
...
Catching an argumentError
```

16.4.3 The `add_argument()` method

`ArgumentParser.add_argument` (*name or flags...* [, *action*] [, *nargs*] [, *const*] [, *default*] [, *type*] [, *choices*] [, *required*] [, *help*] [, *metavar*] [, *dest*])

Define how a single command-line argument should be parsed. Each parameter has its own more detailed description below, but in short they are:

- *name or flags* - Either a name or a list of option strings, e.g. `foo` or `-f`, `--foo`.
- *action* - The basic type of action to be taken when this argument is encountered at the command line.
- *nargs* - The number of command-line arguments that should be consumed.
- *const* - A constant value required by some *action* and *nargs* selections.
- *default* - The value produced if the argument is absent from the command line and if it is absent from the namespace object.
- *type* - The type to which the command-line argument should be converted.
- *choices* - A container of the allowable values for the argument.
- *required* - Whether or not the command-line option may be omitted (optionals only).
- *help* - A brief description of what the argument does.
- *metavar* - A name for the argument in usage messages.
- *dest* - The name of the attribute to be added to the object returned by `parse_args()`.

The following sections describe how each of these are used.

name or flags

The `add_argument()` method must know whether an optional argument, like `-f` or `--foo`, or a positional argument, like a list of filenames, is expected. The first arguments passed to `add_argument()` must therefore be either a series of flags, or a simple argument name. For example, an optional argument could be created like:

```
>>> parser.add_argument('-f', '--foo')
```

while a positional argument could be created like:

```
>>> parser.add_argument('bar')
```

When `parse_args()` is called, optional arguments will be identified by the `-` prefix, and the remaining arguments will be assumed to be positional:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args(['BAR'])
Namespace(bar='BAR', foo=None)
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> parser.parse_args(['BAR', '--foo', 'FOO'])
Namespace(bar='BAR', foo='FOO')
>>> parser.parse_args(['--foo', 'FOO'])
usage: PROG [-h] [-f FOO] bar
PROG: error: the following arguments are required: bar
```

action

ArgumentParser objects associate command-line arguments with actions. These actions can do just about anything with the command-line arguments associated with them, though most actions simply add an attribute to the object returned by *parse_args()*. The action keyword argument specifies how the command-line arguments should be handled. The supplied actions are:

- 'store' - This just stores the argument's value. This is the default action. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args('--foo 1'.split())
Namespace(foo='1')
```

- 'store_const' - This stores the value specified by the *const* keyword argument. The 'store_const' action is most commonly used with optional arguments that specify some sort of flag. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_const', const=42)
>>> parser.parse_args(['--foo'])
Namespace(foo=42)
```

- 'store_true' and 'store_false' - These are special cases of 'store_const' used for storing the values True and False respectively. In addition, they create default values of False and True respectively. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('--bar', action='store_false')
>>> parser.add_argument('--baz', action='store_false')
>>> parser.parse_args('--foo --bar'.split())
Namespace(foo=True, bar=False, baz=True)
```

- 'append' - This stores a list, and appends each argument value to the list. This is useful to allow an option to be specified multiple times. Example usage:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='append')
>>> parser.parse_args('--foo 1 --foo 2'.split())
Namespace(foo=['1', '2'])
```

- 'append_const' - This stores a list, and appends the value specified by the *const* keyword argument to the list. (Note that the *const* keyword argument defaults to None.) The 'append_const' action is typically useful when multiple arguments need to store constants to the same list. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--str', dest='types', action='append_const', const=str)
>>> parser.add_argument('--int', dest='types', action='append_const', const=int)
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> parser.parse_args('--str --int'.split())
Namespace(types=[<class 'str'>, <class 'int'>])
```

- 'count' - This counts the number of times a keyword argument occurs. For example, this is useful for increasing verbosity levels:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--verbose', '-v', action='count', default=0)
>>> parser.parse_args(['-vvv'])
Namespace(verbose=3)
```

Note, the *default* will be None unless explicitly set to 0.

- 'help' - This prints a complete help message for all the options in the current parser and then exits. By default a help action is automatically added to the parser. See [ArgumentParser](#) for details of how the output is created.
- 'version' - This expects a version= keyword argument in the `add_argument()` call, and prints version information and exits when invoked:

```
>>> import argparse
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--version', action='version', version='% (prog)s 2.0')
>>> parser.parse_args(['--version'])
PROG 2.0
```

- 'extend' - This stores a list, and extends each argument value to the list. Example usage:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument("--foo", action="extend", nargs="+", type=str)
>>> parser.parse_args(["--foo", "f1", "--foo", "f2", "f3", "f4"])
Namespace(foo=['f1', 'f2', 'f3', 'f4'])
```

Νέο στην έκδοση 3.8.

You may also specify an arbitrary action by passing an Action subclass or other object that implements the same interface. The `BooleanOptionalAction` is available in `argparse` and adds support for boolean actions such as `--foo` and `--no-foo`:

```
>>> import argparse
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=argparse.BooleanOptionalAction)
>>> parser.parse_args(['--no-foo'])
Namespace(foo=False)
```

Νέο στην έκδοση 3.9.

The recommended way to create a custom action is to extend `Action`, overriding the `__call__` method and optionally the `__init__` and `format_usage` methods.

An example of a custom action:

```
>>> class FooAction(argparse.Action):
...     def __init__(self, option_strings, dest, nargs=None, **kwargs):
...         if nargs is not None:
...             raise ValueError("nargs not allowed")
...         super().__init__(option_strings, dest, **kwargs)
...     def __call__(self, parser, namespace, values, option_string=None):
...         print('%r %r %r' % (namespace, values, option_string))
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

...         setattr(namespace, self.dest, values)
...
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=FooAction)
>>> parser.add_argument('bar', action=FooAction)
>>> args = parser.parse_args('1 --foo 2'.split())
Namespace(bar=None, foo=None) '1' None
Namespace(bar='1', foo=None) '2' '--foo'
>>> args
Namespace(bar='1', foo='2')

```

For more details, see [Action](#).

nargs

`ArgumentParser` objects usually associate a single command-line argument with a single action to be taken. The `nargs` keyword argument associates a different number of command-line arguments with a single action. The supported values are:

- `N` (an integer). `N` arguments from the command line will be gathered together into a list. For example:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs=2)
>>> parser.add_argument('bar', nargs=1)
>>> parser.parse_args('c --foo a b'.split())
Namespace(bar=['c'], foo=['a', 'b'])

```

Note that `nargs=1` produces a list of one item. This is different from the default, in which the item is produced by itself.

- `'?'`. One argument will be consumed from the command line if possible, and produced as a single item. If no command-line argument is present, the value from *default* will be produced. Note that for optional arguments, there is an additional case - the option string is present but not followed by a command-line argument. In this case the value from *const* will be produced. Some examples to illustrate this:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='?', const='c', default='d')
>>> parser.add_argument('bar', nargs='?', default='d')
>>> parser.parse_args(['XX', '--foo', 'YY'])
Namespace(bar='XX', foo='YY')
>>> parser.parse_args(['XX', '--foo'])
Namespace(bar='XX', foo='c')
>>> parser.parse_args([])
Namespace(bar='d', foo='d')

```

One of the more common uses of `nargs='?'` is to allow optional input and output files:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', nargs='?', type=argparse.FileType('r'),
...                     default=sys.stdin)
>>> parser.add_argument('outfile', nargs='?', type=argparse.FileType('w'),
...                     default=sys.stdout)
>>> parser.parse_args(['input.txt', 'output.txt'])
Namespace(infile=<_io.TextIOWrapper name='input.txt' encoding='UTF-8'>,
          outfile=<_io.TextIOWrapper name='output.txt' encoding='UTF-8'>)

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> parser.parse_args([])
Namespace(infile=<_io.TextIOWrapper name='<stdin>' encoding='UTF-8'>,
          outfile=<_io.TextIOWrapper name='<stdout>' encoding='UTF-8'>)
```

- `'*'`. All command-line arguments present are gathered into a list. Note that it generally doesn't make much sense to have more than one positional argument with `nargs='*'`, but multiple optional arguments with `nargs='*'` is possible. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='*')
>>> parser.add_argument('--bar', nargs='*')
>>> parser.add_argument('baz', nargs='*')
>>> parser.parse_args('a b --foo x y --bar 1 2'.split())
Namespace(bar=['1', '2'], baz=['a', 'b'], foo=['x', 'y'])
```

- `'+'`. Just like `'*'`, all command-line args present are gathered into a list. Additionally, an error message will be generated if there wasn't at least one command-line argument present. For example:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', nargs='+')
>>> parser.parse_args(['a', 'b'])
Namespace(foo=['a', 'b'])
>>> parser.parse_args([])
usage: PROG [-h] foo [foo ...]
PROG: error: the following arguments are required: foo
```

If the `nargs` keyword argument is not provided, the number of arguments consumed is determined by the [action](#). Generally this means a single command-line argument will be consumed and a single item (not a list) will be produced.

const

The `const` argument of `add_argument()` is used to hold constant values that are not read from the command line but are required for the various `ArgumentParser` actions. The two most common uses of it are:

- When `add_argument()` is called with `action='store_const'` or `action='append_const'`. These actions add the `const` value to one of the attributes of the object returned by `parse_args()`. See the [action](#) description for examples.
- When `add_argument()` is called with option strings (like `-f` or `--foo`) and `nargs='?'`. This creates an optional argument that can be followed by zero or one command-line arguments. When parsing the command line, if the option string is encountered with no command-line argument following it, the value of `const` will be assumed instead. See the [nargs](#) description for examples.

With the `'store_const'` and `'append_const'` actions, the `const` keyword argument must be given. For other actions, it defaults to `None`.

default

All optional arguments and some positional arguments may be omitted at the command line. The `default` keyword argument of `add_argument()`, whose value defaults to `None`, specifies what value should be used if the command-line argument is not present. For optional arguments, the `default` value is used when the option string was not present at the command line:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args(['--foo', '2'])
Namespace(foo='2')
>>> parser.parse_args([])
Namespace(foo=42)
```

If the target namespace already has an attribute set, the action *default* will not over write it:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args([], namespace=argparse.Namespace(foo=101))
Namespace(foo=101)
```

If the default value is a string, the parser parses the value as if it were a command-line argument. In particular, the parser applies any *type* conversion argument, if provided, before setting the attribute on the *Namespace* return value. Otherwise, the parser uses the value as is:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--length', default='10', type=int)
>>> parser.add_argument('--width', default=10.5, type=int)
>>> parser.parse_args()
Namespace(length=10, width=10.5)
```

For positional arguments with *nargs* equal to `?` or `*`, the default value is used when no command-line argument was present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', nargs='?', default=42)
>>> parser.parse_args(['a'])
Namespace(foo='a')
>>> parser.parse_args([])
Namespace(foo=42)
```

Providing `default=argparse.SUPPRESS` causes no attribute to be added if the command-line argument was not present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=argparse.SUPPRESS)
>>> parser.parse_args([])
Namespace()
>>> parser.parse_args(['--foo', '1'])
Namespace(foo='1')
```

type

By default, the parser reads command-line arguments in as simple strings. However, quite often the command-line string should instead be interpreted as another type, such as a *float* or *int*. The `type` keyword for `add_argument()` allows any necessary type-checking and type conversions to be performed.

If the *type* keyword is used with the *default* keyword, the type converter is only applied if the default is a string.

The argument to `type` can be any callable that accepts a single string. If the function raises `ArgumentTypeError`, `TypeError`, or `ValueError`, the exception is caught and a nicely formatted error message is displayed. No other exception types are handled.

Common built-in types and functions can be used as type converters:

```
import argparse
import pathlib

parser = argparse.ArgumentParser()
parser.add_argument('count', type=int)
parser.add_argument('distance', type=float)
parser.add_argument('street', type=ascii)
parser.add_argument('code_point', type=ord)
parser.add_argument('source_file', type=open)
parser.add_argument('dest_file', type=argparse.FileType('w', encoding='latin-1'))
parser.add_argument('datapath', type=pathlib.Path)
```

User defined functions can be used as well:

```
>>> def hyphenated(string):
...     return '-'.join([word[:4] for word in string.casefold().split()])
...
>>> parser = argparse.ArgumentParser()
>>> _ = parser.add_argument('short_title', type=hyphenated)
>>> parser.parse_args(['The Tale of Two Cities'])
Namespace(short_title='the-tale-of-two-citi')
```

The `bool()` function is not recommended as a type converter. All it does is convert empty strings to `False` and non-empty strings to `True`. This is usually not what is desired.

In general, the `type` keyword is a convenience that should only be used for simple conversions that can only raise one of the three supported exceptions. Anything with more interesting error-handling or resource management should be done downstream after the arguments are parsed.

For example, JSON or YAML conversions have complex error cases that require better reporting than can be given by the `type` keyword. A `JSONDecodeError` would not be well formatted and a `FileNotFound` exception would not be handled at all.

Even `FileType` has its limitations for use with the `type` keyword. If one argument uses `FileType` and then a subsequent argument fails, an error is reported but the file is not automatically closed. In this case, it would be better to wait until after the parser has run and then use the `with`-statement to manage the files.

For type checkers that simply check against a fixed set of values, consider using the *choices* keyword instead.

choices

Some command-line arguments should be selected from a restricted set of values. These can be handled by passing a container object as the *choices* keyword argument to `add_argument()`. When the command line is parsed, argument values will be checked, and an error message will be displayed if the argument was not one of the acceptable values:

```
>>> parser = argparse.ArgumentParser(prog='game.py')
>>> parser.add_argument('move', choices=['rock', 'paper', 'scissors'])
>>> parser.parse_args(['rock'])
Namespace(move='rock')
>>> parser.parse_args(['fire'])
usage: game.py [-h] {rock,paper,scissors}
game.py: error: argument move: invalid choice: 'fire' (choose from 'rock',
'paper', 'scissors')
```

Note that inclusion in the *choices* container is checked after any *type* conversions have been performed, so the type of the objects in the *choices* container should match the *type* specified:

```
>>> parser = argparse.ArgumentParser(prog='doors.py')
>>> parser.add_argument('door', type=int, choices=range(1, 4))
>>> print(parser.parse_args(['3']))
Namespace(door=3)
>>> parser.parse_args(['4'])
usage: doors.py [-h] {1,2,3}
doors.py: error: argument door: invalid choice: 4 (choose from 1, 2, 3)
```

Any container can be passed as the *choices* value, so *list* objects, *set* objects, and custom containers are all supported.

Use of *enum*, *Enum* is not recommended because it is difficult to control its appearance in usage, help, and error messages.

Formatted choices overrides the default *metavar* which is normally derived from *dest*. This is usually what you want because the user never sees the *dest* parameter. If this display isn't desirable (perhaps because there are many choices), just specify an explicit *metavar*.

required

In general, the *argparse* module assumes that flags like `-f` and `--bar` indicate *optional* arguments, which can always be omitted at the command line. To make an option *required*, `True` can be specified for the `required=` keyword argument to `add_argument()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', required=True)
>>> parser.parse_args(['--foo', 'BAR'])
Namespace(foo='BAR')
>>> parser.parse_args([])
usage: [-h] --foo FOO
: error: the following arguments are required: --foo
```

As the example shows, if an option is marked as *required*, `parse_args()` will report an error if that option is not present at the command line.

Σημείωση: Required options are generally considered bad form because users expect *options* to be *optional*, and thus they should be avoided when possible.

help

The `help` value is a string containing a brief description of the argument. When a user requests help (usually by using `-h` or `--help` at the command line), these help descriptions will be displayed with each argument:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', action='store_true',
...                       help='foo the bars before frobbling')
>>> parser.add_argument('bar', nargs='+',
...                       help='one of the bars to be frobbled')
>>> parser.parse_args(['-h'])
usage: frobble [-h] [--foo] bar [bar ...]

positional arguments:
  bar      one of the bars to be frobbled

optional arguments:
  -h, --help  show this help message and exit
  --foo      foo the bars before frobbling
```

The help strings can include various format specifiers to avoid repetition of things like the program name or the argument *default*. The available specifiers include the program name, `%(prog)s` and most keyword arguments to `add_argument()`, e.g. `%(default)s`, `%(type)s`, etc.:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('bar', nargs='?', type=int, default=42,
...                       help='the bar to %(prog)s (default: %(default)s)')
>>> parser.print_help()
usage: frobble [-h] [bar]

positional arguments:
  bar      the bar to frobble (default: 42)

optional arguments:
  -h, --help  show this help message and exit
```

As the help string supports %-formatting, if you want a literal % to appear in the help string, you must escape it as `%%`.

`argparse` supports silencing the help entry for certain options, by setting the help value to `argparse.SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', help=argparse.SUPPRESS)
>>> parser.print_help()
usage: frobble [-h]

optional arguments:
  -h, --help  show this help message and exit
```

metavar

When `ArgumentParser` generates help messages, it needs some way to refer to each expected argument. By default, `ArgumentParser` objects use the `dest` value as the «name» of each object. By default, for positional argument actions, the `dest` value is used directly, and for optional argument actions, the `dest` value is uppercased. So, a single positional argument with `dest='bar'` will be referred to as `bar`. A single optional argument `--foo` that should be followed by a single command-line argument will be referred to as `FOO`. An example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage: [-h] [--foo FOO] bar

positional arguments:
  bar

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO
```

An alternative name can be specified with `metavar`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', metavar='YYY')
>>> parser.add_argument('bar', metavar='XXX')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage: [-h] [--foo YYY] XXX

positional arguments:
  XXX

optional arguments:
  -h, --help  show this help message and exit
  --foo YYY
```

Note that `metavar` only changes the *displayed* name - the name of the attribute on the `parse_args()` object is still determined by the `dest` value.

Different values of `nargs` may cause the `metavar` to be used multiple times. Providing a tuple to `metavar` specifies a different display for each of the arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', nargs=2)
>>> parser.add_argument('--foo', nargs=2, metavar=('bar', 'baz'))
>>> parser.print_help()
usage: PROG [-h] [-x X X] [--foo bar baz]

optional arguments:
  -h, --help  show this help message and exit
  -x X X
  --foo bar baz
```

dest

Most *ArgumentParser* actions add some value as an attribute of the object returned by *parse_args()*. The name of this attribute is determined by the *dest* keyword argument of *add_argument()*. For positional argument actions, *dest* is normally supplied as the first argument to *add_argument()*:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar')
>>> parser.parse_args(['XXX'])
Namespace(bar='XXX')
```

For optional argument actions, the value of *dest* is normally inferred from the option strings. *ArgumentParser* generates the value of *dest* by taking the first long option string and stripping away the initial `--` string. If no long option strings were supplied, *dest* will be derived from the first short option string by stripping the initial `-` character. Any internal `-` characters will be converted to `_` characters to make sure the string is a valid attribute name. The examples below illustrate this behavior:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('-f', '--foo-bar', '--foo')
>>> parser.add_argument('-x', '-y')
>>> parser.parse_args('-f 1 -x 2'.split())
Namespace(foo_bar='1', x='2')
>>> parser.parse_args('--foo 1 -y 2'.split())
Namespace(foo_bar='1', x='2')
```

dest allows a custom attribute name to be provided:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', dest='bar')
>>> parser.parse_args('--foo XXX'.split())
Namespace(bar='XXX')
```

Action classes

Action classes implement the Action API, a callable which returns a callable which processes arguments from the command-line. Any object which follows this API may be passed as the *action* parameter to *add_argument()*.

class *argparse.Action*(*option_strings*, *dest*, *nargs=None*, *const=None*, *default=None*, *type=None*, *choices=None*, *required=False*, *help=None*, *metavar=None*)

Action objects are used by an *ArgumentParser* to represent the information needed to parse a single argument from one or more strings from the command line. The Action class must accept the two positional arguments plus any keyword arguments passed to *ArgumentParser.add_argument()* except for the action itself.

Instances of Action (or return value of any callable to the *action* parameter) should have attributes «*dest*», «*option_strings*», «*default*», «*type*», «*required*», «*help*», etc. defined. The easiest way to ensure these attributes are defined is to call *Action.__init__*.

Action instances should be callable, so subclasses must override the *__call__* method, which should accept four parameters:

- *parser* - The *ArgumentParser* object which contains this action.
- *namespace* - The *Namespace* object that will be returned by *parse_args()*. Most actions add an attribute to this object using *setattr()*.
- *values* - The associated command-line arguments, with any type conversions applied. Type conversions are specified with the *type* keyword argument to *add_argument()*.

- `option_string` - The option string that was used to invoke this action. The `option_string` argument is optional, and will be absent if the action is associated with a positional argument.

The `__call__` method may perform arbitrary actions, but will typically set attributes on the `namespace` based on `dest` and `values`.

Action subclasses can define a `format_usage` method that takes no argument and return a string which will be used when printing the usage of the program. If such method is not provided, a sensible default will be used.

16.4.4 The `parse_args()` method

`ArgumentParser.parse_args(args=None, namespace=None)`

Convert argument strings to objects and assign them as attributes of the `namespace`. Return the populated `namespace`.

Previous calls to `add_argument()` determine exactly what objects are created and how they are assigned. See the documentation for `add_argument()` for details.

- `args` - List of strings to parse. The default is taken from `sys.argv`.
- `namespace` - An object to take the attributes. The default is a new empty `Namespace` object.

Option value syntax

The `parse_args()` method supports several ways of specifying the value of an option (if it takes one). In the simplest case, the option and its value are passed as two separate arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('--foo')
>>> parser.parse_args(['-x', 'X'])
Namespace(foo=None, x='X')
>>> parser.parse_args(['--foo', 'FOO'])
Namespace(foo='FOO', x=None)
```

For long options (options with names longer than a single character), the option and value can also be passed as a single command-line argument, using `=` to separate them:

```
>>> parser.parse_args(['--foo=FOO'])
Namespace(foo='FOO', x=None)
```

For short options (options only one character long), the option and its value can be concatenated:

```
>>> parser.parse_args(['-xX'])
Namespace(foo=None, x='X')
```

Several short options can be joined together, using only a single `-` prefix, as long as only the last option (or none of them) requires a value:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', action='store_true')
>>> parser.add_argument('-y', action='store_true')
>>> parser.add_argument('-z')
>>> parser.parse_args(['-xyzZ'])
Namespace(x=True, y=True, z='Z')
```

Invalid arguments

While parsing the command line, `parse_args()` checks for a variety of errors, including ambiguous options, invalid types, invalid options, wrong number of positional arguments, etc. When it encounters such an error, it exits and prints the error along with a usage message:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', nargs='?')

>>> # invalid type
>>> parser.parse_args(['--foo', 'spam'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: argument --foo: invalid int value: 'spam'

>>> # invalid option
>>> parser.parse_args(['--bar'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: no such option: --bar

>>> # wrong number of arguments
>>> parser.parse_args(['spam', 'badger'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: extra arguments found: badger
```

Arguments containing –

The `parse_args()` method attempts to give errors whenever the user has clearly made a mistake, but some situations are inherently ambiguous. For example, the command-line argument `-1` could either be an attempt to specify an option or an attempt to provide a positional argument. The `parse_args()` method is cautious here: positional arguments may only begin with `-` if they look like negative numbers and there are no options in the parser that look like negative numbers:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('foo', nargs='?')

>>> # no negative number options, so -1 is a positional argument
>>> parser.parse_args(['-x', '-1'])
Namespace(foo=None, x='-1')

>>> # no negative number options, so -1 and -5 are positional arguments
>>> parser.parse_args(['-x', '-1', '-5'])
Namespace(foo='-5', x='-1')

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-1', dest='one')
>>> parser.add_argument('foo', nargs='?')

>>> # negative number options present, so -1 is an option
>>> parser.parse_args(['-1', 'X'])
Namespace(foo=None, one='X')

>>> # negative number options present, so -2 is an option
>>> parser.parse_args(['-2'])
usage: PROG [-h] [-1 ONE] [foo]
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

PROG: error: no such option: -2

>>> # negative number options present, so both -1s are options
>>> parser.parse_args(['-1', '-1'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: argument -1: expected one argument

```

If you have positional arguments that must begin with `-` and don't look like negative numbers, you can insert the pseudo-argument `--` which tells `parse_args()` that everything after that is a positional argument:

```

>>> parser.parse_args(['--', '-f'])
Namespace(foo='-f', one=None)

```

Argument abbreviations (prefix matching)

The `parse_args()` method *by default* allows long options to be abbreviated to a prefix, if the abbreviation is unambiguous (the prefix matches a unique option):

```

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-bacon')
>>> parser.add_argument('-badger')
>>> parser.parse_args(['-bac MMM'].split())
Namespace(bacon='MMM', badger=None)
>>> parser.parse_args(['-bad WOOD'].split())
Namespace(bacon=None, badger='WOOD')
>>> parser.parse_args(['-ba BA'].split())
usage: PROG [-h] [-bacon BACON] [-badger BADGER]
PROG: error: ambiguous option: -ba could match -badger, -bacon

```

An error is produced for arguments that could produce more than one options. This feature can be disabled by setting `allow_abbrev` to `False`.

Beyond `sys.argv`

Sometimes it may be useful to have an `ArgumentParser` parse arguments other than those of `sys.argv`. This can be accomplished by passing a list of strings to `parse_args()`. This is useful for testing at the interactive prompt:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument(
...     'integers', metavar='int', type=int, choices=range(10),
...     nargs='+', help='an integer in the range 0..9')
>>> parser.add_argument(
...     '--sum', dest='accumulate', action='store_const', const=sum,
...     default=max, help='sum the integers (default: find the max)')
>>> parser.parse_args(['1', '2', '3', '4'])
Namespace(accumulate=<built-in function max>, integers=[1, 2, 3, 4])
>>> parser.parse_args(['1', '2', '3', '4', '--sum'])
Namespace(accumulate=<built-in function sum>, integers=[1, 2, 3, 4])

```

The Namespace object

`class argparse.Namespace`

Simple class used by default by `parse_args()` to create an object holding attributes and return it.

This class is deliberately simple, just an *object* subclass with a readable string representation. If you prefer to have dict-like view of the attributes, you can use the standard Python idiom, `vars()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> args = parser.parse_args(['--foo', 'BAR'])
>>> vars(args)
{'foo': 'BAR'}
```

It may also be useful to have an *ArgumentParser* assign attributes to an already existing object, rather than a new *Namespace* object. This can be achieved by specifying the `namespace=` keyword argument:

```
>>> class C:
...     pass
...
>>> c = C()
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args(args=['--foo', 'BAR'], namespace=c)
>>> c.foo
'BAR'
```

16.4.5 Other utilities

Sub-commands

`ArgumentParser.add_subparsers([title][, description][, prog][, parser_class][, action][, option_string][, dest][, required][, help][, metavar])`

Many programs split up their functionality into a number of sub-commands, for example, the `svn` program can invoke sub-commands like `svn checkout`, `svn update`, and `svn commit`. Splitting up functionality this way can be a particularly good idea when a program performs several different functions which require different kinds of command-line arguments. *ArgumentParser* supports the creation of such sub-commands with the `add_subparsers()` method. The `add_subparsers()` method is normally called with no arguments and returns a special action object. This object has a single method, `add_parser()`, which takes a command name and any *ArgumentParser* constructor arguments, and returns an *ArgumentParser* object that can be modified as usual.

Description of parameters:

- `title` - title for the sub-parser group in help output; by default «subcommands» if description is provided, otherwise uses title for positional arguments
- `description` - description for the sub-parser group in help output, by default `None`
- `prog` - usage information that will be displayed with sub-command help, by default the name of the program and any positional arguments before the subparser argument
- `parser_class` - class which will be used to create sub-parser instances, by default the class of the current parser (e.g. *ArgumentParser*)
- `action` - the basic type of action to be taken when this argument is encountered at the command line

- *dest* - name of the attribute under which sub-command name will be stored; by default `None` and no value is stored
- *required* - Whether or not a subcommand must be provided, by default `False` (added in 3.7)
- *help* - help for sub-parser group in help output, by default `None`
- *metavar* - string presenting available sub-commands in help; by default it is `None` and presents sub-commands in form `{cmd1, cmd2, ...}`

Some example usage:

```
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', action='store_true', help='foo help')
>>> subparsers = parser.add_subparsers(help='sub-command help')
>>>
>>> # create the parser for the "a" command
>>> parser_a = subparsers.add_parser('a', help='a help')
>>> parser_a.add_argument('bar', type=int, help='bar help')
>>>
>>> # create the parser for the "b" command
>>> parser_b = subparsers.add_parser('b', help='b help')
>>> parser_b.add_argument('--baz', choices='XYZ', help='baz help')
>>>
>>> # parse some argument lists
>>> parser.parse_args(['a', '12'])
Namespace(bar=12, foo=False)
>>> parser.parse_args(['--foo', 'b', '--baz', 'Z'])
Namespace(baz='Z', foo=True)
```

Note that the object returned by `parse_args()` will only contain attributes for the main parser and the subparser that was selected by the command line (and not any other subparsers). So in the example above, when the `a` command is specified, only the `foo` and `bar` attributes are present, and when the `b` command is specified, only the `foo` and `baz` attributes are present.

Similarly, when a help message is requested from a subparser, only the help for that particular parser will be printed. The help message will not include parent parser or sibling parser messages. (A help message for each subparser command, however, can be given by supplying the `help=` argument to `add_parser()` as above.)

```
>>> parser.parse_args(['--help'])
usage: PROG [-h] [--foo] {a,b} ...

positional arguments:
  {a,b}    sub-command help
  a        a help
  b        b help

optional arguments:
  -h, --help  show this help message and exit
  --foo       foo help

>>> parser.parse_args(['a', '--help'])
usage: PROG a [-h] bar

positional arguments:
  bar        bar help

optional arguments:
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

-h, --help  show this help message and exit

>>> parser.parse_args(['b', '--help'])
usage: PROG b [-h] [--baz {X,Y,Z}]

optional arguments:
  -h, --help      show this help message and exit
  --baz {X,Y,Z}  baz help

```

The `add_subparsers()` method also supports `title` and `description` keyword arguments. When either is present, the subparser's commands will appear in their own group in the help output. For example:

```

>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(title='subcommands',
...                                   description='valid subcommands',
...                                   help='additional help')
>>> subparsers.add_parser('foo')
>>> subparsers.add_parser('bar')
>>> parser.parse_args(['-h'])
usage:  [-h] {foo,bar} ...

optional arguments:
  -h, --help  show this help message and exit

subcommands:
  valid subcommands

  {foo,bar}  additional help

```

Furthermore, `add_parser` supports an additional `aliases` argument, which allows multiple strings to refer to the same subparser. This example, like `svn`, aliases `co` as a shorthand for `checkout`:

```

>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>> checkout = subparsers.add_parser('checkout', aliases=['co'])
>>> checkout.add_argument('foo')
>>> parser.parse_args(['co', 'bar'])
Namespace(foo='bar')

```

One particularly effective way of handling sub-commands is to combine the use of the `add_subparsers()` method with calls to `set_defaults()` so that each subparser knows which Python function it should execute. For example:

```

>>> # sub-command functions
>>> def foo(args):
...     print(args.x * args.y)
...
>>> def bar(args):
...     print('({s})' % args.z)
...
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>>
>>> # create the parser for the "foo" command
>>> parser_foo = subparsers.add_parser('foo')

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

>>> parser_foo.add_argument('-x', type=int, default=1)
>>> parser_foo.add_argument('y', type=float)
>>> parser_foo.set_defaults(func=foo)
>>>
>>> # create the parser for the "bar" command
>>> parser_bar = subparsers.add_parser('bar')
>>> parser_bar.add_argument('z')
>>> parser_bar.set_defaults(func=bar)
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('foo 1 -x 2'.split())
>>> args.func(args)
2.0
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('bar XYZYX'.split())
>>> args.func(args)
((XYZYX))

```

This way, you can let `parse_args()` do the job of calling the appropriate function after argument parsing is complete. Associating functions with actions like this is typically the easiest way to handle the different actions for each of your subparsers. However, if it is necessary to check the name of the subparser that was invoked, the `dest` keyword argument to the `add_subparsers()` call will work:

```

>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(dest='subparser_name')
>>> subparser1 = subparsers.add_parser('1')
>>> subparser1.add_argument('-x')
>>> subparser2 = subparsers.add_parser('2')
>>> subparser2.add_argument('y')
>>> parser.parse_args(['2', 'frobble'])
Namespace(subparser_name='2', y='frobble')

```

Άλλαξε στην έκδοση 3.7: New *required* keyword argument.

FileType objects

class `argparse.FileType` (*mode='r', bufsize=-1, encoding=None, errors=None*)

The `FileType` factory creates objects that can be passed to the `type` argument of `ArgumentParser.add_argument()`. Arguments that have `FileType` objects as their type will open command-line arguments as files with the requested modes, buffer sizes, encodings and error handling (see the `open()` function for more details):

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--raw', type=argparse.FileType('wb', 0))
>>> parser.add_argument('out', type=argparse.FileType('w', encoding='UTF-8'))
>>> parser.parse_args(['--raw', 'raw.dat', 'file.txt'])
Namespace(out=<_io.TextIOWrapper name='file.txt' mode='w' encoding='UTF-8'>, raw=
↳<_io.FileIO name='raw.dat' mode='wb'>)

```

`FileType` objects understand the pseudo-argument `-` and automatically convert this into `sys.stdin` for readable `FileType` objects and `sys.stdout` for writable `FileType` objects:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', type=argparse.FileType('r'))

```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> parser.parse_args(['-'])
Namespace(infile=<_io.TextIOWrapper name='<stdin>' encoding='UTF-8'>)
```

Νέο στην έκδοση 3.4: The *encodings* and *errors* keyword arguments.

Argument groups

`ArgumentParser.add_argument_group(title=None, description=None)`

By default, *ArgumentParser* groups command-line arguments into «positional arguments» and «optional arguments» when displaying help messages. When there is a better conceptual grouping of arguments than this default one, appropriate groups can be created using the *add_argument_group()* method:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group = parser.add_argument_group('group')
>>> group.add_argument('--foo', help='foo help')
>>> group.add_argument('bar', help='bar help')
>>> parser.print_help()
usage: PROG [--foo FOO] bar

group:
  bar      bar help
  --foo FOO  foo help
```

The *add_argument_group()* method returns an argument group object which has an *add_argument()* method just like a regular *ArgumentParser*. When an argument is added to the group, the parser treats it just like a normal argument, but displays the argument in a separate group for help messages. The *add_argument_group()* method accepts *title* and *description* arguments which can be used to customize this display:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group1 = parser.add_argument_group('group1', 'group1 description')
>>> group1.add_argument('foo', help='foo help')
>>> group2 = parser.add_argument_group('group2', 'group2 description')
>>> group2.add_argument('--bar', help='bar help')
>>> parser.print_help()
usage: PROG [--bar BAR] foo

group1:
  group1 description

  foo      foo help

group2:
  group2 description

  --bar BAR  bar help
```

Note that any arguments not in your user-defined groups will end up back in the usual «positional arguments» and «optional arguments» sections.

Mutual exclusion

`ArgumentParser.add_mutually_exclusive_group(required=False)`

Create a mutually exclusive group. *argparse* will make sure that only one of the arguments in the mutually exclusive group was present on the command line:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group()
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args(['--foo'])
Namespace(bar=True, foo=True)
>>> parser.parse_args(['--bar'])
Namespace(bar=False, foo=False)
>>> parser.parse_args(['--foo', '--bar'])
usage: PROG [-h] [--foo | --bar]
PROG: error: argument --bar: not allowed with argument --foo
```

The `add_mutually_exclusive_group()` method also accepts a *required* argument, to indicate that at least one of the mutually exclusive arguments is required:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group(required=True)
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args([])
usage: PROG [-h] (--foo | --bar)
PROG: error: one of the arguments --foo --bar is required
```

Note that currently mutually exclusive argument groups do not support the *title* and *description* arguments of `add_argument_group()`.

Parser defaults

`ArgumentParser.set_defaults(**kwargs)`

Most of the time, the attributes of the object returned by `parse_args()` will be fully determined by inspecting the command-line arguments and the argument actions. `set_defaults()` allows some additional attributes that are determined without any inspection of the command line to be added:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.set_defaults(bar=42, baz='badger')
>>> parser.parse_args(['736'])
Namespace(bar=42, baz='badger', foo=736)
```

Note that parser-level defaults always override argument-level defaults:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='bar')
>>> parser.set_defaults(foo='spam')
>>> parser.parse_args([])
Namespace(foo='spam')
```

Parser-level defaults can be particularly useful when working with multiple parsers. See the `add_subparsers()` method for an example of this type.

`ArgumentParser.get_default(dest)`

Get the default value for a namespace attribute, as set by either `add_argument()` or by `set_defaults()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='badger')
>>> parser.get_default('foo')
'badger'
```

Printing help

In most typical applications, `parse_args()` will take care of formatting and printing any usage or error messages. However, several formatting methods are available:

`ArgumentParser.print_usage(file=None)`

Print a brief description of how the `ArgumentParser` should be invoked on the command line. If `file` is `None`, `sys.stdout` is assumed.

`ArgumentParser.print_help(file=None)`

Print a help message, including the program usage and information about the arguments registered with the `ArgumentParser`. If `file` is `None`, `sys.stdout` is assumed.

There are also variants of these methods that simply return a string instead of printing it:

`ArgumentParser.format_usage()`

Return a string containing a brief description of how the `ArgumentParser` should be invoked on the command line.

`ArgumentParser.format_help()`

Return a string containing a help message, including the program usage and information about the arguments registered with the `ArgumentParser`.

Partial parsing

`ArgumentParser.parse_known_args(args=None, namespace=None)`

Sometimes a script may only parse a few of the command-line arguments, passing the remaining arguments on to another script or program. In these cases, the `parse_known_args()` method can be useful. It works much like `parse_args()` except that it does not produce an error when extra arguments are present. Instead, it returns a two item tuple containing the populated namespace and the list of remaining argument strings.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('bar')
>>> parser.parse_known_args(['--foo', '--badger', 'BAR', 'spam'])
(Namespace(bar='BAR', foo=True), ['--badger', 'spam'])
```

Προειδοποίηση: *Prefix matching* rules apply to `parse_known_args()`. The parser may consume an option even if it's just a prefix of one of its known options, instead of leaving it in the remaining arguments list.

Customizing file parsing

`ArgumentParser.convert_arg_line_to_args(arg_line)`

Arguments that are read from a file (see the `fromfile_prefix_chars` keyword argument to the `ArgumentParser` constructor) are read one argument per line. `convert_arg_line_to_args()` can be overridden for fancier reading.

This method takes a single argument `arg_line` which is a string read from the argument file. It returns a list of arguments parsed from this string. The method is called once per line read from the argument file, in order.

A useful override of this method is one that treats each space-separated word as an argument. The following example demonstrates how to do this:

```
class MyArgumentParser(argparse.ArgumentParser):
    def convert_arg_line_to_args(self, arg_line):
        return arg_line.split()
```

Exiting methods

`ArgumentParser.exit(status=0, message=None)`

This method terminates the program, exiting with the specified `status` and, if given, it prints a `message` before that. The user can override this method to handle these steps differently:

```
class ErrorCatchingArgumentParser(argparse.ArgumentParser):
    def exit(self, status=0, message=None):
        if status:
            raise Exception(f'Exiting because of an error: {message}')
        exit(status)
```

`ArgumentParser.error(message)`

This method prints a usage message including the `message` to the standard error and terminates the program with a status code of 2.

Intermixed parsing

`ArgumentParser.parse_intermixed_args(args=None, namespace=None)`

`ArgumentParser.parse_known_intermixed_args(args=None, namespace=None)`

A number of Unix commands allow the user to intermix optional arguments with positional arguments. The `parse_intermixed_args()` and `parse_known_intermixed_args()` methods support this parsing style.

These parsers do not support all the `argparse` features, and will raise exceptions if unsupported features are used. In particular, subparsers, `argparse.REMAINDER`, and mutually exclusive groups that include both optionals and positionals are not supported.

The following example shows the difference between `parse_known_args()` and `parse_intermixed_args()`: the former returns `['2', '3']` as unparsed arguments, while the latter collects all the positionals into `rest`.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('cmd')
>>> parser.add_argument('rest', nargs='*', type=int)
>>> parser.parse_known_args('doit 1 --foo bar 2 3'.split())
(Namespace(cmd='doit', foo='bar', rest=[1]), ['2', '3'])
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
>>> parser.parse_intermixed_args('doit 1 --foo bar 2 3'.split())
Namespace(cmd='doit', foo='bar', rest=[1, 2, 3])
```

`parse_known_intermixed_args()` returns a two item tuple containing the populated namespace and the list of remaining argument strings. `parse_intermixed_args()` raises an error if there are any remaining unparsed argument strings.

Νέο στην έκδοση 3.7.

16.4.6 Upgrading optparse code

Originally, the `argparse` module had attempted to maintain compatibility with `optparse`. However, `optparse` was difficult to extend transparently, particularly with the changes required to support the new `nargs=` specifiers and better usage messages. When most everything in `optparse` had either been copy-pasted over or monkey-patched, it no longer seemed practical to try to maintain the backwards compatibility.

The `argparse` module improves on the standard library `optparse` module in a number of ways including:

- Handling positional arguments.
- Supporting sub-commands.
- Allowing alternative option prefixes like `+` and `/`.
- Handling zero-or-more and one-or-more style arguments.
- Producing more informative usage messages.
- Providing a much simpler interface for custom type and action.

A partial upgrade path from `optparse` to `argparse`:

- Replace all `optparse.OptionParser.add_option()` calls with `ArgumentParser.add_argument()` calls.
- Replace `(options, args) = parser.parse_args()` with `args = parser.parse_args()` and add additional `ArgumentParser.add_argument()` calls for the positional arguments. Keep in mind that what was previously called `options`, now in the `argparse` context is called `args`.
- Replace `optparse.OptionParser.disable_interspersed_args()` by using `parse_intermixed_args()` instead of `parse_args()`.
- Replace callback actions and the `callback_*` keyword arguments with `type` or `action` arguments.
- Replace string names for `type` keyword arguments with the corresponding type objects (e.g. `int`, `float`, `complex`, etc).
- Replace `optparse.Values` with `Namespace` and `optparse.OptionError` and `optparse.OptionValueError` with `ArgumentError`.
- Replace strings with implicit arguments such as `%default` or `%prog` with the standard Python syntax to use dictionaries to format strings, that is, `%(default)s` and `%(prog)s`.
- Replace the `OptionParser` constructor `version` argument with a call to `parser.add_argument('--version', action='version', version='<the version>')`.

16.5 getopt — C-style parser for command line options

Source code: [Lib/getopt.py](#)

Σημείωση: The `getopt` module is a parser for command line options whose API is designed to be familiar to users of the C `getopt()` function. Users who are unfamiliar with the C `getopt()` function or who would like to write less code and get better help and error messages should consider using the `argparse` module instead.

This module helps scripts to parse the command line arguments in `sys.argv`. It supports the same conventions as the Unix `getopt()` function (including the special meanings of arguments of the form “-” and “--”). Long options similar to those supported by GNU software may be used as well via an optional third argument.

This module provides two functions and an exception:

`getopt.getopt(args, shortopts, longopts=[])`

Parses command line options and parameter list. *args* is the argument list to be parsed, without the leading reference to the running program. Typically, this means `sys.argv[1:]`. *shortopts* is the string of option letters that the script wants to recognize, with options that require an argument followed by a colon (':'); i.e., the same format that Unix `getopt()` uses).

Σημείωση: Unlike GNU `getopt()`, after a non-option argument, all further arguments are considered also non-options. This is similar to the way non-GNU Unix systems work.

longopts, if specified, must be a list of strings with the names of the long options which should be supported. The leading ‘--’ characters should not be included in the option name. Long options which require an argument should be followed by an equal sign ('='). Optional arguments are not supported. To accept only long options, *shortopts* should be an empty string. Long options on the command line can be recognized so long as they provide a prefix of the option name that matches exactly one of the accepted options. For example, if *longopts* is [`'foo'`, `'frob'`], the option `--fo` will match as `--foo`, but `--f` will not match uniquely, so `GetoptError` will be raised.

The return value consists of two elements: the first is a list of (option, value) pairs; the second is the list of program arguments left after the option list was stripped (this is a trailing slice of *args*). Each option-and-value pair returned has the option as its first element, prefixed with a hyphen for short options (e.g., `'-x'`) or two hyphens for long options (e.g., `'--long-option'`), and the option argument as its second element, or an empty string if the option has no argument. The options occur in the list in the same order in which they were found, thus allowing multiple occurrences. Long and short options may be mixed.

`getopt.gnu_getopt(args, shortopts, longopts=[])`

This function works like `getopt()`, except that GNU style scanning mode is used by default. This means that option and non-option arguments may be intermixed. The `getopt()` function stops processing options as soon as a non-option argument is encountered.

If the first character of the option string is '+', or if the environment variable `POSIIXLY_CORRECT` is set, then option processing stops as soon as a non-option argument is encountered.

exception `getopt.GetoptError`

This is raised when an unrecognized option is found in the argument list or when an option requiring an argument is given none. The argument to the exception is a string indicating the cause of the error. For long options, an argument given to an option which does not require one will also cause this exception to be raised. The attributes `msg` and `opt` give the error message and related option; if there is no specific option to which the exception relates, `opt` is an empty string.

exception `getopt.error`

Alias for `GetoptError`; for backward compatibility.

An example using only Unix style options:

```
>>> import getopt
>>> args = '-a -b -cfoo -d bar a1 a2'.split()
>>> args
['-a', '-b', '-cfoo', '-d', 'bar', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'abc:d:')
>>> optlist
[('-a', ''), ('-b', ''), ('-c', 'foo'), ('-d', 'bar')]
>>> args
['a1', 'a2']
```

Using long option names is equally easy:

```
>>> s = '--condition=foo --testing --output-file abc.def -x a1 a2'
>>> args = s.split()
>>> args
['--condition=foo', '--testing', '--output-file', 'abc.def', '-x', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'x', [
...     'condition=', 'output-file=', 'testing'])
>>> optlist
[('--condition', 'foo'), ('--testing', ''), ('--output-file', 'abc.def'), ('-x', '')]
>>> args
['a1', 'a2']
```

In a script, typical usage is something like this:

```
import getopt, sys

def main():
    try:
        opts, args = getopt.getopt(sys.argv[1:], "ho:v", ["help", "output="])
    except getopt.GetoptError as err:
        # print help information and exit:
        print(err) # will print something like "option -a not recognized"
        usage()
        sys.exit(2)
    output = None
    verbose = False
    for o, a in opts:
        if o == "-v":
            verbose = True
        elif o in ("-h", "--help"):
            usage()
            sys.exit()
        elif o in ("-o", "--output"):
            output = a
        else:
            assert False, "unhandled option"
    # ...

if __name__ == "__main__":
    main()
```

Note that an equivalent command line interface could be produced with less code and more informative help and error messages by using the `argparse` module:

```
import argparse

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument('-o', '--output')
    parser.add_argument('-v', dest='verbose', action='store_true')
    args = parser.parse_args()
    # ... do something with args.output ...
    # ... do something with args.verbose ..
```

16.6 logging — Logging facility for Python

Source code: `Lib/logging/__init__.py`

Important

This page contains the API reference information. For tutorial information and discussion of more advanced topics, see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

This module defines functions and classes which implement a flexible event logging system for applications and libraries.

The key benefit of having the logging API provided by a standard library module is that all Python modules can participate in logging, so your application log can include your own messages integrated with messages from third-party modules.

The module provides a lot of functionality and flexibility. If you are unfamiliar with logging, the best way to get to grips with it is to see the tutorials (see the links on the right).

The basic classes defined by the module, together with their functions, are listed below.

- Loggers expose the interface that application code directly uses.
- Handlers send the log records (created by loggers) to the appropriate destination.
- Filters provide a finer grained facility for determining which log records to output.
- Formatters specify the layout of log records in the final output.

16.6.1 Logger Objects

Loggers have the following attributes and methods. Note that Loggers should *NEVER* be instantiated directly, but always through the module-level function `logging.getLogger(name)`. Multiple calls to `getLogger()` with the same name will always return a reference to the same Logger object.

The name is potentially a period-separated hierarchical value, like `foo.bar.baz` (though it could also be just plain `foo`, for example). Loggers that are further down in the hierarchical list are children of loggers higher up in the list. For example, given a logger with a name of `foo`, loggers with names of `foo.bar`, `foo.bar.baz`, and `foo.bam` are all descendants of `foo`. The logger name hierarchy is analogous to the Python package hierarchy, and identical to it if you organise your loggers on a per-module basis using the recommended construction `logging.getLogger(__name__)`. That's because in a module, `__name__` is the module's name in the Python package namespace.

class `logging.Logger`

propagate

If this attribute evaluates to true, events logged to this logger will be passed to the handlers of higher level (ancestor) loggers, in addition to any handlers attached to this logger. Messages are passed directly to the ancestor loggers' handlers - neither the level nor filters of the ancestor loggers in question are considered.

If this evaluates to false, logging messages are not passed to the handlers of ancestor loggers.

Spelling it out with an example: If the `propagate` attribute of the logger named `A.B.C` evaluates to true, any event logged to `A.B.C` via a method call such as `logging.getLogger('A.B.C').error(...)` will [subject to passing that logger's level and filter settings] be passed in turn to any handlers attached to loggers named `A.B`, `A` and the root logger, after first being passed to any handlers attached to `A.B.C`. If any logger in the chain `A.B.C`, `A.B`, `A` has its `propagate` attribute set to false, then that is the last logger whose handlers are offered the event to handle, and propagation stops at that point.

The constructor sets this attribute to `True`.

Σημείωση: If you attach a handler to a logger *and* one or more of its ancestors, it may emit the same record multiple times. In general, you should not need to attach a handler to more than one logger - if you just attach it to the appropriate logger which is highest in the logger hierarchy, then it will see all events logged by all descendant loggers, provided that their `propagate` setting is left set to `True`. A common scenario is to attach handlers only to the root logger, and to let propagation take care of the rest.

setLevel (*level*)

Sets the threshold for this logger to *level*. Logging messages which are less severe than *level* will be ignored; logging messages which have severity *level* or higher will be emitted by whichever handler or handlers service this logger, unless a handler's level has been set to a higher severity level than *level*.

When a logger is created, the level is set to `NOTSET` (which causes all messages to be processed when the logger is the root logger, or delegation to the parent when the logger is a non-root logger). Note that the root logger is created with level `WARNING`.

The term “delegation to the parent” means that if a logger has a level of `NOTSET`, its chain of ancestor loggers is traversed until either an ancestor with a level other than `NOTSET` is found, or the root is reached.

If an ancestor is found with a level other than `NOTSET`, then that ancestor's level is treated as the effective level of the logger where the ancestor search began, and is used to determine how a logging event is handled.

If the root is reached, and it has a level of `NOTSET`, then all messages will be processed. Otherwise, the root's level will be used as the effective level.

See [Logging Levels](#) for a list of levels.

Άλλαξε στην έκδοση 3.2: The *level* parameter now accepts a string representation of the level such as “INFO” as an alternative to the integer constants such as `INFO`. Note, however, that levels are internally stored as integers, and methods such as e.g. `getEffectiveLevel()` and `isEnabledFor()` will return/expect to be passed integers.

`isEnabledFor (level)`

Indicates if a message of severity *level* would be processed by this logger. This method checks first the module-level level set by `logging.disable(level)` and then the logger’s effective level as determined by `getEffectiveLevel()`.

`getEffectiveLevel ()`

Indicates the effective level for this logger. If a value other than `NOTSET` has been set using `setLevel()`, it is returned. Otherwise, the hierarchy is traversed towards the root until a value other than `NOTSET` is found, and that value is returned. The value returned is an integer, typically one of `logging.DEBUG`, `logging.INFO` etc.

`getChild (suffix)`

Returns a logger which is a descendant to this logger, as determined by the suffix. Thus, `logging.getLogger('abc').getChild('def.ghi')` would return the same logger as would be returned by `logging.getLogger('abc.def.ghi')`. This is a convenience method, useful when the parent logger is named using e.g. `__name__` rather than a literal string.

Νέο στην έκδοση 3.2.

`debug (msg, *args, **kwargs)`

Logs a message with level `DEBUG` on this logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.) No `%` formatting operation is performed on *msg* when no *args* are supplied.

There are four keyword arguments in *kwargs* which are inspected: *exc_info*, *stack_info*, *stacklevel* and *extra*.

If *exc_info* does not evaluate as false, it causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) or an exception instance is provided, it is used; otherwise, `sys.exc_info()` is called to get the exception information.

The second optional keyword argument is *stack_info*, which defaults to `False`. If true, stack information is added to the logging message, including the actual logging call. Note that this is not the same stack information as that displayed through specifying *exc_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify *stack_info* independently of *exc_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback (most recent call last):` which is used when displaying exception frames.

The third optional keyword argument is *stacklevel*, which defaults to 1. If greater than 1, the corresponding number of stack frames are skipped when computing the line number and function name set in the `LogRecord` created for the logging event. This can be used in logging helpers so that the function name, filename and line number recorded are not the information for the helper function/method, but rather its caller. The name of this parameter mirrors the equivalent one in the `warnings` module.

The fourth keyword argument is *extra* which can be used to pass a dictionary which is used to populate the `__dict__` of the `LogRecord` created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)s %(clientip)-15s %(user)-8s %(message)s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logger = logging.getLogger('tcpserver')
logger.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs Protocol problem: connection_
↪reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the *Formatter* documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the *Formatter* has been set up with a format string which expects “clientip” and “user” in the attribute dictionary of the *LogRecord*. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized *Formatters* would be used with particular *Handlers*.

Αλλάξε στην έκδοση 3.2: The *stack_info* parameter was added.

Αλλάξε στην έκδοση 3.5: The *exc_info* parameter can now accept exception instances.

Αλλάξε στην έκδοση 3.8: The *stacklevel* parameter was added.

info (*msg*, **args*, ***kwargs*)

Logs a message with level INFO on this logger. The arguments are interpreted as for *debug()*.

warning (*msg*, **args*, ***kwargs*)

Logs a message with level WARNING on this logger. The arguments are interpreted as for *debug()*.

Σημείωση: There is an obsolete method *warn* which is functionally identical to *warning*. As *warn* is deprecated, please do not use it - use *warning* instead.

error (*msg*, **args*, ***kwargs*)

Logs a message with level ERROR on this logger. The arguments are interpreted as for *debug()*.

critical (*msg*, **args*, ***kwargs*)

Logs a message with level CRITICAL on this logger. The arguments are interpreted as for *debug()*.

log (*level*, *msg*, **args*, ***kwargs*)

Logs a message with integer level *level* on this logger. The other arguments are interpreted as for *debug()*.

exception (*msg*, **args*, ***kwargs*)

Logs a message with level ERROR on this logger. The arguments are interpreted as for *debug()*. Exception info is added to the logging message. This method should only be called from an exception handler.

addFilter (*filter*)

Adds the specified filter *filter* to this logger.

removeFilter (*filter*)

Removes the specified filter *filter* from this logger.

filter (*record*)

Apply this logger's filters to the record and return `True` if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be processed (passed to handlers). If one returns a false value, no further processing of the record occurs.

addHandler (*hdlr*)

Adds the specified handler *hdlr* to this logger.

removeHandler (*hdlr*)

Removes the specified handler *hdlr* from this logger.

findCaller (*stack_info=False, stacklevel=1*)

Finds the caller's source filename and line number. Returns the filename, line number, function name and stack information as a 4-element tuple. The stack information is returned as `None` unless *stack_info* is `True`.

The *stacklevel* parameter is passed from code calling the `debug()` and other APIs. If greater than 1, the excess is used to skip stack frames before determining the values to be returned. This will generally be useful when calling logging APIs from helper/wrapper code, so that the information in the event log refers not to the helper/wrapper code, but to the code that calls it.

handle (*record*)

Handles a record by passing it to all handlers associated with this logger and its ancestors (until a false value of *propagate* is found). This method is used for unpickled records received from a socket, as well as those created locally. Logger-level filtering is applied using `filter()`.

makeRecord (*name, level, fn, lno, msg, args, exc_info, func=None, extra=None, sinfo=None*)

This is a factory method which can be overridden in subclasses to create specialized `LogRecord` instances.

hasHandlers ()

Checks to see if this logger has any handlers configured. This is done by looking for handlers in this logger and its parents in the logger hierarchy. Returns `True` if a handler was found, else `False`. The method stops searching up the hierarchy whenever a logger with the “propagate” attribute set to false is found - that will be the last logger which is checked for the existence of handlers.

Νέο στην έκδοση 3.2.

Άλλαξε στην έκδοση 3.7: Loggers can now be pickled and unpickled.

16.6.2 Logging Levels

The numeric values of logging levels are given in the following table. These are primarily of interest if you want to define your own levels, and need them to have specific values relative to the predefined levels. If you define a level with the same numeric value, it overwrites the predefined value; the predefined name is lost.

| Level | Numeric value |
|----------|---------------|
| CRITICAL | 50 |
| ERROR | 40 |
| WARNING | 30 |
| INFO | 20 |
| DEBUG | 10 |
| NOTSET | 0 |

16.6.3 Handler Objects

Handlers have the following attributes and methods. Note that *Handler* is never instantiated directly; this class acts as a base for more useful subclasses. However, the `__init__()` method in subclasses needs to call *Handler*.
`__init__()`.

class logging.**Handler**

__init__ (*level*=NOTSET)

Initializes the *Handler* instance by setting its level, setting the list of filters to the empty list and creating a lock (using *createLock()*) for serializing access to an I/O mechanism.

createLock ()

Initializes a thread lock which can be used to serialize access to underlying I/O functionality which may not be threadsafe.

acquire ()

Acquires the thread lock created with *createLock()*.

release ()

Releases the thread lock acquired with *acquire()*.

setLevel (*level*)

Sets the threshold for this handler to *level*. Logging messages which are less severe than *level* will be ignored. When a handler is created, the level is set to NOTSET (which causes all messages to be processed).

See *Logging Levels* for a list of levels.

Άλλαξε στην έκδοση 3.2: The *level* parameter now accepts a string representation of the level such as “INFO” as an alternative to the integer constants such as INFO.

setFormatter (*fmt*)

Sets the *Formatter* for this handler to *fmt*.

addFilter (*filter*)

Adds the specified filter *filter* to this handler.

removeFilter (*filter*)

Removes the specified filter *filter* from this handler.

filter (*record*)

Apply this handler’s filters to the record and return True if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be emitted. If one returns a false value, the handler will not emit the record.

flush ()

Ensure all logging output has been flushed. This version does nothing and is intended to be implemented by subclasses.

close ()

Tidy up any resources used by the handler. This version does no output but removes the handler from an internal list of handlers which is closed when *shutdown()* is called. Subclasses should ensure that this gets called from overridden *close()* methods.

handle (*record*)

Conditionally emits the specified logging record, depending on filters which may have been added to the handler. Wraps the actual emission of the record with acquisition/release of the I/O thread lock.

handleError (*record*)

This method should be called from handlers when an exception is encountered during an *emit()* call. If the module-level attribute *raiseExceptions* is False, exceptions get silently ignored. This is what is

mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors. You could, however, replace this with a custom handler if you wish. The specified record is the one which was being processed when the exception occurred. (The default value of `raiseExceptions` is `True`, as that is more useful during development).

format (*record*)

Do formatting for a record - if a formatter is set, use it. Otherwise, use the default formatter for the module.

emit (*record*)

Do whatever it takes to actually log the specified logging record. This version is intended to be implemented by subclasses and so raises a `NotImplementedError`.

For a list of handlers included as standard, see `logging.handlers`.

16.6.4 Formatter Objects

`Formatter` objects have the following attributes and methods. They are responsible for converting a `LogRecord` to (usually) a string which can be interpreted by either a human or an external system. The base `Formatter` allows a formatting string to be specified. If none is supplied, the default value of `'%(message)s'` is used, which just includes the message in the logging call. To have additional items of information in the formatted output (such as a timestamp), keep reading.

A Formatter can be initialized with a format string which makes use of knowledge of the `LogRecord` attributes - such as the default value mentioned above making use of the fact that the user's message and arguments are pre-formatted into a `LogRecord`'s `message` attribute. This format string contains standard Python %-style mapping keys. See section *printf-style String Formatting* for more information on string formatting.

The useful mapping keys in a `LogRecord` are given in the section on *LogRecord attributes*.

class `logging.Formatter` (*fmt=None, datefmt=None, style='%', validate=True*)

Returns a new instance of the `Formatter` class. The instance is initialized with a format string for the message as a whole, as well as a format string for the date/time portion of a message. If no *fmt* is specified, `'%(message)s'` is used. If no *datefmt* is specified, a format is used which is described in the `formatTime()` documentation.

The *style* parameter can be one of `"%"`, `"{"` or `"$"` and determines how the format string will be merged with its data: using one of %-formatting, `str.format()` or `string.Template`. This only applies to the format string *fmt* (e.g. `'%(message)s'` or `{message}`), not to the actual log messages passed to `Logger.debug` etc; see *formatting-styles* for more information on using `{-}` and `$-` formatting for log messages.

Άλλαξε στην έκδοση 3.2: The *style* parameter was added.

Άλλαξε στην έκδοση 3.8: The *validate* parameter was added. Incorrect or mismatched style and *fmt* will raise a `ValueError`. For example: `logging.Formatter('%(asctime)s - %(message)s', style='{')`.

format (*record*)

The record's attribute dictionary is used as the operand to a string formatting operation. Returns the resulting string. Before formatting the dictionary, a couple of preparatory steps are carried out. The *message* attribute of the record is computed using `msg % args`. If the formatting string contains `'(asctime)'`, `formatTime()` is called to format the event time. If there is exception information, it is formatted using `formatException()` and appended to the message. Note that the formatted exception information is cached in attribute `exc_text`. This is useful because the exception information can be pickled and sent across the wire, but you should be careful if you have more than one `Formatter` subclass which customizes the formatting of exception information. In this case, you will have to clear the cached value after a formatter has done its formatting, so that the next formatter to handle the event doesn't use the cached value but recalculates it afresh.

If stack information is available, it's appended after the exception information, using `formatStack()` to transform it if necessary.

formatTime (*record*, *datefmt=None*)

This method should be called from `format()` by a formatter which wants to make use of a formatted time. This method can be overridden in formatters to provide for any specific requirement, but the basic behavior is as follows: if *datefmt* (a string) is specified, it is used with `time.strftime()` to format the creation time of the record. Otherwise, the format “%Y-%m-%d %H:%M:%S,uuu” is used, where the uuu part is a millisecond value and the other letters are as per the `time.strftime()` documentation. An example time in this format is 2003-01-23 00:29:50,411. The resulting string is returned.

This function uses a user-configurable function to convert the creation time to a tuple. By default, `time.localtime()` is used; to change this for a particular formatter instance, set the `converter` attribute to a function with the same signature as `time.localtime()` or `time.gmtime()`. To change it for all formatters, for example if you want all logging times to be shown in GMT, set the `converter` attribute in the `Formatter` class.

Άλλαξε στην έκδοση 3.3: Previously, the default format was hard-coded as in this example: 2010-09-06 22:38:15,292 where the part before the comma is handled by a strftime format string ('%Y-%m-%d %H:%M:%S'), and the part after the comma is a millisecond value. Because strftime does not have a format placeholder for milliseconds, the millisecond value is appended using another format string, '%s,%03d' — and both of these format strings have been hardcoded into this method. With the change, these strings are defined as class-level attributes which can be overridden at the instance level when desired. The names of the attributes are `default_time_format` (for the strftime format string) and `default_msec_format` (for appending the millisecond value).

Άλλαξε στην έκδοση 3.9: The `default_msec_format` can be None.

formatException (*exc_info*)

Formats the specified exception information (a standard exception tuple as returned by `sys.exc_info()`) as a string. This default implementation just uses `traceback.print_exception()`. The resulting string is returned.

formatStack (*stack_info*)

Formats the specified stack information (a string as returned by `traceback.print_stack()`, but with the last newline removed) as a string. This default implementation just returns the input value.

16.6.5 Filter Objects

Filters can be used by Handlers and Loggers for more sophisticated filtering than is provided by levels. The base filter class only allows events which are below a certain point in the logger hierarchy. For example, a filter initialized with “A.B” will allow events logged by loggers “A.B”, “A.B.C”, “A.B.C.D”, “A.B.D” etc. but not “A.BB”, “B.A.B” etc. If initialized with the empty string, all events are passed.

class logging.**Filter** (*name=""*)

Returns an instance of the `Filter` class. If *name* is specified, it names a logger which, together with its children, will have its events allowed through the filter. If *name* is the empty string, allows every event.

filter (*record*)

Is the specified record to be logged? Returns zero for no, nonzero for yes. If deemed appropriate, the record may be modified in-place by this method.

Note that filters attached to handlers are consulted before an event is emitted by the handler, whereas filters attached to loggers are consulted whenever an event is logged (using `debug()`, `info()`, etc.), before sending an event to handlers. This means that events which have been generated by descendant loggers will not be filtered by a logger's filter setting, unless the filter has also been applied to those descendant loggers.

You don't actually need to subclass `Filter`: you can pass any instance which has a `filter` method with the same semantics.

Αλλάξε στην έκδοση 3.2: You don't need to create specialized `Filter` classes, or use other classes with a `filter` method: you can use a function (or other callable) as a filter. The filtering logic will check to see if the filter object has a `filter` attribute: if it does, it's assumed to be a `Filter` and its `filter()` method is called. Otherwise, it's assumed to be a callable and called with the record as the single parameter. The returned value should conform to that returned by `filter()`.

Although filters are used primarily to filter records based on more sophisticated criteria than levels, they get to see every record which is processed by the handler or logger they're attached to: this can be useful if you want to do things like counting how many records were processed by a particular logger or handler, or adding, changing or removing attributes in the `LogRecord` being processed. Obviously changing the `LogRecord` needs to be done with some care, but it does allow the injection of contextual information into logs (see `filters-contextual`).

16.6.6 LogRecord Objects

`LogRecord` instances are created automatically by the `Logger` every time something is logged, and can be created manually via `makeLogRecord()` (for example, from a pickled event received over the wire).

class `logging.LogRecord` (*name, level, pathname, lineno, msg, args, exc_info, func=None, sinfo=None*)
Contains all the information pertinent to the event being logged.

The primary information is passed in `msg` and `args`, which are combined using `msg % args` to create the message field of the record.

Παράμετροι

- **name** – The name of the logger used to log the event represented by this `LogRecord`. Note that this name will always have this value, even though it may be emitted by a handler attached to a different (ancestor) logger.
- **level** – The numeric level of the logging event (one of `DEBUG`, `INFO` etc.) Note that this is converted to *two* attributes of the `LogRecord`: `levelname` for the numeric value and `levelname` for the corresponding level name.
- **pathname** – The full pathname of the source file where the logging call was made.
- **lineno** – The line number in the source file where the logging call was made.
- **msg** – The event description message, possibly a format string with placeholders for variable data.
- **args** – Variable data to merge into the `msg` argument to obtain the event description.
- **exc_info** – An exception tuple with the current exception information, or `None` if no exception information is available.
- **func** – The name of the function or method from which the logging call was invoked.
- **sinfo** – A text string representing stack information from the base of the stack in the current thread, up to the logging call.

`getMessage()`

Returns the message for this `LogRecord` instance after merging any user-supplied arguments with the message. If the user-supplied message argument to the logging call is not a string, `str()` is called on it to convert it to a string. This allows use of user-defined classes as messages, whose `__str__` method can return the actual format string to be used.

Άλλαξε στην έκδοση 3.2: The creation of a *LogRecord* has been made more configurable by providing a factory which is used to create the record. The factory can be set using *getLogRecordFactory()* and *setLogRecordFactory()* (see this for the factory's signature).

This functionality can be used to inject your own values into a *LogRecord* at creation time. You can use the following pattern:

```
old_factory = logging.getLogRecordFactory()

def record_factory(*args, **kwargs):
    record = old_factory(*args, **kwargs)
    record.custom_attribute = 0xdecafbad
    return record

logging.setLogRecordFactory(record_factory)
```

With this pattern, multiple factories could be chained, and as long as they don't overwrite each other's attributes or unintentionally overwrite the standard attributes listed above, there should be no surprises.

16.6.7 LogRecord attributes

The LogRecord has a number of attributes, most of which are derived from the parameters to the constructor. (Note that the names do not always correspond exactly between the LogRecord constructor parameters and the LogRecord attributes.) These attributes can be used to merge data from the record into the format string. The following table lists (in alphabetical order) the attribute names, their meanings and the corresponding placeholder in a %-style format string.

If you are using {}-formatting (*str.format()*), you can use {attrname} as the placeholder in the format string. If you are using \$-formatting (*string.Template*), use the form \${attrname}. In both cases, of course, replace attrname with the actual attribute name you want to use.

In the case of {}-formatting, you can specify formatting flags by placing them after the attribute name, separated from it with a colon. For example: a placeholder of {msecs:03d} would format a millisecond value of 4 as 004. Refer to the *str.format()* documentation for full details on the options available to you.

| Attribute name | Format | Description |
|-----------------|---|--|
| args | You shouldn't need to format this yourself. | The tuple of arguments merged into <code>msg</code> to produce <code>message</code> , or a dict whose values are used for the merge (when there is only one argument, and it is a dictionary). |
| asctime | <code>%(asctime)s</code> | Human-readable time when the <code>LogRecord</code> was created. By default this is of the form “2003-07-08 16:49:45,896” (the numbers after the comma are millisecond portion of the time). |
| created | <code>%(created)f</code> | Time when the <code>LogRecord</code> was created (as returned by <code>time.time()</code>). |
| exc_info | You shouldn't need to format this yourself. | Exception tuple (à la <code>sys.exc_info</code>) or, if no exception has occurred, <code>None</code> . |
| filename | <code>%(filename)s</code> | Filename portion of <code>pathname</code> . |
| funcName | <code>%(funcName)s</code> | Name of function containing the logging call. |
| levelname | <code>%(levelname)s</code> | Text logging level for the message ('DEBUG', 'INFO', 'WARNING', 'ERROR', 'CRITICAL'). |
| levelno | <code>%(levelno)s</code> | Numeric logging level for the message (DEBUG, INFO, WARNING, ERROR, CRITICAL). |
| lineno | <code>%(lineno)d</code> | Source line number where the logging call was issued (if available). |
| message | <code>%(message)s</code> | The logged message, computed as <code>msg % args</code> . This is set when <code>Formatter.format()</code> is invoked. |
| module | <code>%(module)s</code> | Module (name portion of <code>filename</code>). |
| msecs | <code>%(msecs)d</code> | Millisecond portion of the time when the <code>LogRecord</code> was created. |
| msg | You shouldn't need to format this yourself. | The format string passed in the original logging call. Merged with <code>args</code> to produce <code>message</code> , or an arbitrary object (see arbitrary-object-messages). |
| name | <code>%(name)s</code> | Name of the logger used to log the call. |
| pathname | <code>%(pathname)s</code> | Full pathname of the source file where the logging call was issued (if available). |
| process | <code>%(process)d</code> | Process ID (if available). |
| processName | <code>%(processName)s</code> | Process name (if available). |
| relativeCreated | <code>%(relativeCreated)d</code> | Time in milliseconds when the <code>LogRecord</code> was created, relative to the time the logging module was loaded. |
| stack_info | You shouldn't need to format this yourself. | Stack frame information (where available) from the bottom of the stack in the current thread, up to and including the stack frame of the logging call which resulted in the creation of this record. |
| thread | <code>%(thread)d</code> | Thread ID (if available). |
| threadName | <code>%(threadName)s</code> | Thread name (if available). |

Άλλαξε στην έκδοση 3.1: `processName` was added.

16.6.8 LoggerAdapter Objects

`LoggerAdapter` instances are used to conveniently pass contextual information into logging calls. For a usage example, see the section on adding contextual information to your logging output.

class `logging.LoggerAdapter` (*logger*, *extra*)

Returns an instance of `LoggerAdapter` initialized with an underlying `Logger` instance and a dict-like object.

process (*msg*, *kwargs*)

Modifies the message and/or keyword arguments passed to a logging call in order to insert contextual information. This implementation takes the object passed as *extra* to the constructor and adds it to *kwargs*

using key “extra”. The return value is a *(msg, kwargs)* tuple which has the (possibly modified) versions of the arguments passed in.

In addition to the above, *LoggerAdapter* supports the following methods of *Logger*: *debug()*, *info()*, *warning()*, *error()*, *exception()*, *critical()*, *log()*, *isEnabledFor()*, *getEffectiveLevel()*, *setLevel()* and *hasHandlers()*. These methods have the same signatures as their counterparts in *Logger*, so you can use the two types of instances interchangeably.

Άλλαξε στην έκδοση 3.2: The *isEnabledFor()*, *getEffectiveLevel()*, *setLevel()* and *hasHandlers()* methods were added to *LoggerAdapter*. These methods delegate to the underlying logger.

Άλλαξε στην έκδοση 3.6: Attribute manager and method *_log()* were added, which delegate to the underlying logger and allow adapters to be nested.

16.6.9 Thread Safety

The logging module is intended to be thread-safe without any special work needing to be done by its clients. It achieves this though using threading locks; there is one lock to serialize access to the module’s shared data, and each handler also creates a lock to serialize access to its underlying I/O.

If you are implementing asynchronous signal handlers using the *signal* module, you may not be able to use logging from within such handlers. This is because lock implementations in the *threading* module are not always re-entrant, and so cannot be invoked from such signal handlers.

16.6.10 Module-Level Functions

In addition to the classes described above, there are a number of module-level functions.

`logging.getLogger(name=None)`

Return a logger with the specified name or, if name is *None*, return a logger which is the root logger of the hierarchy. If specified, the name is typically a dot-separated hierarchical name like “a”, “a.b” or “a.b.c.d”. Choice of these names is entirely up to the developer who is using logging.

All calls to this function with a given name return the same logger instance. This means that logger instances never need to be passed between different parts of an application.

`logging.getLoggerClass()`

Return either the standard *Logger* class, or the last class passed to *setLoggerClass()*. This function may be called from within a new class definition, to ensure that installing a customized *Logger* class will not undo customizations already applied by other code. For example:

```
class MyLogger(logging.getLoggerClass()):
    # ... override behaviour here
```

`logging.getLogRecordFactory()`

Return a callable which is used to create a *LogRecord*.

Νέο στην έκδοση 3.2: This function has been provided, along with *setLogRecordFactory()*, to allow developers more control over how the *LogRecord* representing a logging event is constructed.

See *setLogRecordFactory()* for more information about the how the factory is called.

`logging.debug(msg, *args, **kwargs)`

Logs a message with level *DEBUG* on the root logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are three keyword arguments in *kwargs* which are inspected: *exc_info* which, if it does not evaluate as false, causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) or an exception instance is provided, it is used; otherwise, `sys.exc_info()` is called to get the exception information.

The second optional keyword argument is *stack_info*, which defaults to `False`. If true, stack information is added to the logging message, including the actual logging call. Note that this is not the same stack information as that displayed through specifying *exc_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify *stack_info* independently of *exc_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback (most recent call last):` which is used when displaying exception frames.

The third optional keyword argument is *extra* which can be used to pass a dictionary which is used to populate the `__dict__` of the `LogRecord` created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)s %(clientip)-15s %(user)-8s %(message)s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logging.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like:

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs Protocol problem: connection reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the *Formatter* documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the *Formatter* has been set up with a format string which expects “clientip” and “user” in the attribute dictionary of the `LogRecord`. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized *Formatters* would be used with particular *Handlers*.

Αλλάξε στην έκδοση 3.2: The *stack_info* parameter was added.

`logging.info(msg, *args, **kwargs)`

Logs a message with level INFO on the root logger. The arguments are interpreted as for `debug()`.

`logging.warning(msg, *args, **kwargs)`

Logs a message with level WARNING on the root logger. The arguments are interpreted as for `debug()`.

Σημείωση: There is an obsolete function `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

`logging.error(msg, *args, **kwargs)`

Logs a message with level ERROR on the root logger. The arguments are interpreted as for `debug()`.

`logging.critical(msg, *args, **kwargs)`

Logs a message with level `CRITICAL` on the root logger. The arguments are interpreted as for `debug()`.

`logging.exception(msg, *args, **kwargs)`

Logs a message with level `ERROR` on the root logger. The arguments are interpreted as for `debug()`. Exception info is added to the logging message. This function should only be called from an exception handler.

`logging.log(level, msg, *args, **kwargs)`

Logs a message with level `level` on the root logger. The other arguments are interpreted as for `debug()`.

`logging.disable(level=CRITICAL)`

Provides an overriding level `level` for all loggers which takes precedence over the logger's own level. When the need arises to temporarily throttle logging output down across the whole application, this function can be useful. Its effect is to disable all logging calls of severity `level` and below, so that if you call it with a value of `INFO`, then all `INFO` and `DEBUG` events would be discarded, whereas those of severity `WARNING` and above would be processed according to the logger's effective level. If `logging.disable(logging.NOTSET)` is called, it effectively removes this overriding level, so that logging output again depends on the effective levels of individual loggers.

Note that if you have defined any custom logging level higher than `CRITICAL` (this is not recommended), you won't be able to rely on the default value for the `level` parameter, but will have to explicitly supply a suitable value.

Άλλαξε στην έκδοση 3.7: The `level` parameter was defaulted to level `CRITICAL`. See [bpo-28524](#) for more information about this change.

`logging.addLevelName(level, levelName)`

Associates level `level` with text `levelName` in an internal dictionary, which is used to map numeric levels to a textual representation, for example when a `Formatter` formats a message. This function can also be used to define your own levels. The only constraints are that all levels used must be registered using this function, levels should be positive integers and they should increase in increasing order of severity.

Σημείωση: If you are thinking of defining your own levels, please see the section on custom-levels.

`logging.getLevelName(level)`

Returns the textual or numeric representation of logging level `level`.

If `level` is one of the predefined levels `CRITICAL`, `ERROR`, `WARNING`, `INFO` or `DEBUG` then you get the corresponding string. If you have associated levels with names using `addLevelName()` then the name you have associated with `level` is returned. If a numeric value corresponding to one of the defined levels is passed in, the corresponding string representation is returned.

The `level` parameter also accepts a string representation of the level such as "INFO". In such cases, this functions returns the corresponding numeric value of the level.

If no matching numeric or string value is passed in, the string "Level %s" % level is returned.

Σημείωση: Levels are internally integers (as they need to be compared in the logging logic). This function is used to convert between an integer level and the level name displayed in the formatted log output by means of the `%(levelname)s` format specifier (see [LogRecord attributes](#)), and vice versa.

Άλλαξε στην έκδοση 3.4: In Python versions earlier than 3.4, this function could also be passed a text level, and would return the corresponding numeric value of the level. This undocumented behaviour was considered a mistake, and was removed in Python 3.4, but reinstated in 3.4.2 due to retain backward compatibility.

`logging.makeLogRecord(attrdict)`

Creates and returns a new `LogRecord` instance whose attributes are defined by `attrdict`. This function is useful for taking a pickled `LogRecord` attribute dictionary, sent over a socket, and reconstituting it as a `LogRecord` instance at the receiving end.

When the logging module is imported, it registers this function as an exit handler (see `atexit`), so normally there's no need to do that manually.

`logging.setLoggerClass` (*klass*)

Tells the logging system to use the class *klass* when instantiating a logger. The class should define `__init__()` such that only a name argument is required, and the `__init__()` should call `Logger.__init__()`. This function is typically called before any loggers are instantiated by applications which need to use custom logger behavior. After this call, as at any other time, do not instantiate loggers directly using the subclass: continue to use the `logging.getLogger()` API to get your loggers.

`logging.setLogRecordFactory` (*factory*)

Set a callable which is used to create a `LogRecord`.

Παράμετροι **factory** – The factory callable to be used to instantiate a log record.

Νέο στην έκδοση 3.2: This function has been provided, along with `getLogRecordFactory()`, to allow developers more control over how the `LogRecord` representing a logging event is constructed.

The factory has the following signature:

```
factory(name, level, fn, lno, msg, args, exc_info, func=None, sinfo=None,
**kwargs)
```

name The logger name.

level The logging level (numeric).

fn The full pathname of the file where the logging call was made.

lno The line number in the file where the logging call was made.

msg The logging message.

args The arguments for the logging message.

exc_info An exception tuple, or `None`.

func The name of the function or method which invoked the logging call.

sinfo A stack traceback such as is provided by `traceback.print_stack()`, showing the call hierarchy.

kwargs Additional keyword arguments.

16.6.11 Module-Level Attributes

`logging.lastResort`

A «handler of last resort» is available through this attribute. This is a `StreamHandler` writing to `sys.stderr` with a level of `WARNING`, and is used to handle logging events in the absence of any logging configuration. The end result is to just print the message to `sys.stderr`. This replaces the earlier error message saying that «no handlers could be found for logger XYZ». If you need the earlier behaviour for some reason, `lastResort` can be set to `None`.

Νέο στην έκδοση 3.2.

16.6.12 Integration with the warnings module

The `captureWarnings()` function can be used to integrate `logging` with the `warnings` module.

`logging.captureWarnings(capture)`

This function is used to turn the capture of warnings by logging on and off.

If `capture` is `True`, warnings issued by the `warnings` module will be redirected to the logging system. Specifically, a warning will be formatted using `warnings.formatwarning()` and the resulting string logged to a logger named `'py.warnings'` with a severity of `WARNING`.

If `capture` is `False`, the redirection of warnings to the logging system will stop, and warnings will be redirected to their original destinations (i.e. those in effect before `captureWarnings(True)` was called).

- Logging Cookbook

This section describes the API for configuring the logging module.

16.7.1 Configuration functions

The following functions configure the logging module. They are located in the `logging.config` module. Their use is optional — you can configure the logging module using these functions or by making calls to the main API (defined in `logging` itself) and defining handlers which are declared either in `logging` or `logging.handlers`.

`logging.config.dictConfig(config)`

Takes the logging configuration from a dictionary. The contents of this dictionary are described in [Configuration dictionary schema](#) below.

If an error is encountered during configuration, this function will raise a `ValueError`, `TypeError`, `AttributeError` or `ImportError` with a suitably descriptive message. The following is a (possibly incomplete) list of conditions which will raise an error:

- A level which is not a string or which is a string not corresponding to an actual logging level.
- A propagate value which is not a boolean.
- An id which does not have a corresponding destination.
- A non-existent handler id found during an incremental call.
- An invalid logger name.
- Inability to resolve to an internal or external object.

Parsing is performed by the `DictConfigurator` class, whose constructor is passed the dictionary used for configuration, and has a `configure()` method. The `logging.config` module has a callable attribute `dictConfigClass` which is initially set to `DictConfigurator`. You can replace the value of `dictConfigClass` with a suitable implementation of your own.

`dictConfig()` calls `dictConfigClass` passing the specified dictionary, and then calls the `configure()` method on the returned object to put the configuration into effect:

```
def dictConfig(config):
    dictConfigClass(config).configure()
```

For example, a subclass of `DictConfigurator` could call `DictConfigurator.__init__()` in its own `__init__()`, then set up custom prefixes which would be usable in the subsequent `configure()` call. `dictConfigClass` would be bound to this new subclass, and then `dictConfig()` could be called exactly as in the default, uncusomized state.

Νέο στην έκδοση 3.2.

`logging.config.fileConfig(fname, defaults=None, disable_existing_loggers=True)`

Reads the logging configuration from a `configparser`-format file. The format of the file should be as described in *Configuration file format*. This function can be called several times from an application, allowing an end user to select from various pre-canned configurations (if the developer provides a mechanism to present the choices and load the chosen configuration).

Παράμετροι

- **fname** – A filename, or a file-like object, or an instance derived from `RawConfigParser`. If a `RawConfigParser`-derived instance is passed, it is used as is. Otherwise, a `Configparser` is instantiated, and the configuration read by it from the object passed in `fname`. If that has a `readline()` method, it is assumed to be a file-like object and read using `read_file()`; otherwise, it is assumed to be a filename and passed to `read()`.
- **defaults** – Defaults to be passed to the `ConfigParser` can be specified in this argument.
- **disable_existing_loggers** – If specified as `False`, loggers which exist when this call is made are left enabled. The default is `True` because this enables old behaviour in a backward-compatible way. This behaviour is to disable any existing non-root loggers unless they or their ancestors are explicitly named in the logging configuration.

Άλλαξε στην έκδοση 3.4: An instance of a subclass of `RawConfigParser` is now accepted as a value for `fname`. This facilitates:

- Use of a configuration file where logging configuration is just part of the overall application configuration.
- Use of a configuration read from a file, and then modified by the using application (e.g. based on command-line parameters or other aspects of the runtime environment) before being passed to `fileConfig`.

`logging.config.listen(port=DEFAULT_LOGGING_CONFIG_PORT, verify=None)`

Starts up a socket server on the specified port, and listens for new configurations. If no port is specified, the module's default `DEFAULT_LOGGING_CONFIG_PORT` is used. Logging configurations will be sent as a file suitable for processing by `dictConfig()` or `fileConfig()`. Returns a `Thread` instance on which you

can call `start()` to start the server, and which you can `join()` when appropriate. To stop the server, call `stopListening()`.

The `verify` argument, if specified, should be a callable which should verify whether bytes received across the socket are valid and should be processed. This could be done by encrypting and/or signing what is sent across the socket, such that the `verify` callable can perform signature verification and/or decryption. The `verify` callable is called with a single argument - the bytes received across the socket - and should return the bytes to be processed, or `None` to indicate that the bytes should be discarded. The returned bytes could be the same as the passed in bytes (e.g. when only verification is done), or they could be completely different (perhaps if decryption were performed).

To send a configuration to the socket, read in the configuration file and send it to the socket as a sequence of bytes preceded by a four-byte length string packed in binary using `struct.pack('>L', n)`.

Σημείωση: Because portions of the configuration are passed through `eval()`, use of this function may open its users to a security risk. While the function only binds to a socket on `localhost`, and so does not accept connections from remote machines, there are scenarios where untrusted code could be run under the account of the process which calls `listen()`. Specifically, if the process calling `listen()` runs on a multi-user machine where users cannot trust each other, then a malicious user could arrange to run essentially arbitrary code in a victim user's process, simply by connecting to the victim's `listen()` socket and sending a configuration which runs whatever code the attacker wants to have executed in the victim's process. This is especially easy to do if the default port is used, but not hard even if a different port is used. To avoid the risk of this happening, use the `verify` argument to `listen()` to prevent unrecognised configurations from being applied.

Άλλαξε στην έκδοση 3.4: The `verify` argument was added.

Σημείωση: If you want to send configurations to the listener which don't disable existing loggers, you will need to use a JSON format for the configuration, which will use `dictConfig()` for configuration. This method allows you to specify `disable_existing_loggers` as `False` in the configuration you send.

```
logging.config.stopListening()
```

Stops the listening server which was created with a call to `listen()`. This is typically called before calling `join()` on the return value from `listen()`.

16.7.2 Security considerations

The logging configuration functionality tries to offer convenience, and in part this is done by offering the ability to convert text in configuration files into Python objects used in logging configuration - for example, as described in *User-defined objects*. However, these same mechanisms (importing callables from user-defined modules and calling them with parameters from the configuration) could be used to invoke any code you like, and for this reason you should treat configuration files from untrusted sources with *extreme caution* and satisfy yourself that nothing bad can happen if you load them, before actually loading them.

16.7.3 Configuration dictionary schema

Describing a logging configuration requires listing the various objects to create and the connections between them; for example, you may create a handler named “console” and then say that the logger named “startup” will send its messages to the “console” handler. These objects aren’t limited to those provided by the `logging` module because you might write your own formatter or handler class. The parameters to these classes may also need to include external objects such as `sys.stderr`. The syntax for describing these objects and connections is defined in *Object connections* below.

Dictionary Schema Details

The dictionary passed to `dictConfig()` must contain the following keys:

- *version* - to be set to an integer value representing the schema version. The only valid value at present is 1, but having this key allows the schema to evolve while still preserving backwards compatibility.

All other keys are optional, but if present they will be interpreted as described below. In all cases below where a “configuring dict” is mentioned, it will be checked for the special `'()'` key to see if a custom instantiation is required. If so, the mechanism described in *User-defined objects* below is used to create an instance; otherwise, the context is used to determine what to instantiate.

- *formatters* - the corresponding value will be a dict in which each key is a formatter id and each value is a dict describing how to configure the corresponding *Formatter* instance.

The configuring dict is searched for keys `format` and `datefmt` (with defaults of `None`) and these are used to construct a *Formatter* instance.

Αλλάξε στην έκδοση 3.8: a `validate` key (with default of `True`) can be added into the `formatters` section of the configuring dict, this is to validate the format.

- *filters* - the corresponding value will be a dict in which each key is a filter id and each value is a dict describing how to configure the corresponding *Filter* instance.

The configuring dict is searched for the key `name` (defaulting to the empty string) and this is used to construct a *logging.Filter* instance.

- *handlers* - the corresponding value will be a dict in which each key is a handler id and each value is a dict describing how to configure the corresponding *Handler* instance.

The configuring dict is searched for the following keys:

- `class` (mandatory). This is the fully qualified name of the handler class.
- `level` (optional). The level of the handler.
- `formatter` (optional). The id of the formatter for this handler.
- `filters` (optional). A list of ids of the filters for this handler.

All *other* keys are passed through as keyword arguments to the handler’s constructor. For example, given the snippet:

```
handlers:
  console:
    class : logging.StreamHandler
    formatter: brief
    level  : INFO
    filters: [allow_foo]
    stream : ext://sys.stdout
  file:
    class : logging.handlers.RotatingFileHandler
    formatter: precise
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```
filename: logconfig.log
maxBytes: 1024
backupCount: 3
```

the handler with id `console` is instantiated as a `logging.StreamHandler`, using `sys.stdout` as the underlying stream. The handler with id `file` is instantiated as a `logging.handlers.RotatingFileHandler` with the keyword arguments `filename='logconfig.log'`, `maxBytes=1024`, `backupCount=3`.

- *loggers* - the corresponding value will be a dict in which each key is a logger name and each value is a dict describing how to configure the corresponding Logger instance.

The configuring dict is searched for the following keys:

- `level` (optional). The level of the logger.
- `propagate` (optional). The propagation setting of the logger.
- `filters` (optional). A list of ids of the filters for this logger.
- `handlers` (optional). A list of ids of the handlers for this logger.

The specified loggers will be configured according to the level, propagation, filters and handlers specified.

- *root* - this will be the configuration for the root logger. Processing of the configuration will be as for any logger, except that the `propagate` setting will not be applicable.
- *incremental* - whether the configuration is to be interpreted as incremental to the existing configuration. This value defaults to `False`, which means that the specified configuration replaces the existing configuration with the same semantics as used by the existing `fileConfig()` API.

If the specified value is `True`, the configuration is processed as described in the section on [Incremental Configuration](#).

- *disable_existing_loggers* - whether any existing non-root loggers are to be disabled. This setting mirrors the parameter of the same name in `fileConfig()`. If absent, this parameter defaults to `True`. This value is ignored if *incremental* is `True`.

Incremental Configuration

It is difficult to provide complete flexibility for incremental configuration. For example, because objects such as filters and formatters are anonymous, once a configuration is set up, it is not possible to refer to such anonymous objects when augmenting a configuration.

Furthermore, there is not a compelling case for arbitrarily altering the object graph of loggers, handlers, filters, formatters at run-time, once a configuration is set up; the verbosity of loggers and handlers can be controlled just by setting levels (and, in the case of loggers, propagation flags). Changing the object graph arbitrarily in a safe way is problematic in a multi-threaded environment; while not impossible, the benefits are not worth the complexity it adds to the implementation.

Thus, when the `incremental` key of a configuration dict is present and is `True`, the system will completely ignore any `formatters` and `filters` entries, and process only the `level` settings in the `handlers` entries, and the `level` and `propagate` settings in the `loggers` and `root` entries.

Using a value in the configuration dict lets configurations to be sent over the wire as pickled dicts to a socket listener. Thus, the logging verbosity of a long-running application can be altered over time with no need to stop and restart the application.

Object connections

The schema describes a set of logging objects - loggers, handlers, formatters, filters - which are connected to each other in an object graph. Thus, the schema needs to represent connections between the objects. For example, say that, once configured, a particular logger has attached to it a particular handler. For the purposes of this discussion, we can say that the logger represents the source, and the handler the destination, of a connection between the two. Of course in the configured objects this is represented by the logger holding a reference to the handler. In the configuration dict, this is done by giving each destination object an id which identifies it unambiguously, and then using the id in the source object's configuration to indicate that a connection exists between the source and the destination object with that id.

So, for example, consider the following YAML snippet:

```
formatters:
  brief:
    # configuration for formatter with id 'brief' goes here
  precise:
    # configuration for formatter with id 'precise' goes here
handlers:
  h1: #This is an id
    # configuration of handler with id 'h1' goes here
    formatter: brief
  h2: #This is another id
    # configuration of handler with id 'h2' goes here
    formatter: precise
loggers:
  foo.bar.baz:
    # other configuration for logger 'foo.bar.baz'
    handlers: [h1, h2]
```

(Note: YAML used here because it's a little more readable than the equivalent Python source form for the dictionary.)

The ids for loggers are the logger names which would be used programmatically to obtain a reference to those loggers, e.g. `foo.bar.baz`. The ids for Formatters and Filters can be any string value (such as `brief`, `precise` above) and they are transient, in that they are only meaningful for processing the configuration dictionary and used to determine connections between objects, and are not persisted anywhere when the configuration call is complete.

The above snippet indicates that logger named `foo.bar.baz` should have two handlers attached to it, which are described by the handler ids `h1` and `h2`. The formatter for `h1` is that described by id `brief`, and the formatter for `h2` is that described by id `precise`.

User-defined objects

The schema supports user-defined objects for handlers, filters and formatters. (Loggers do not need to have different types for different instances, so there is no support in this configuration schema for user-defined logger classes.)

Objects to be configured are described by dictionaries which detail their configuration. In some places, the logging system will be able to infer from the context how an object is to be instantiated, but when a user-defined object is to be instantiated, the system will not know how to do this. In order to provide complete flexibility for user-defined object instantiation, the user needs to provide a “factory” - a callable which is called with a configuration dictionary and which returns the instantiated object. This is signalled by an absolute import path to the factory being made available under the special key `'()'`. Here's a concrete example:

```
formatters:
  brief:
    format: '%(message)s'
  default:
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

format: '%(asctime)s %(levelname)-8s %(name)-15s %(message)s'
datefmt: '%Y-%m-%d %H:%M:%S'
custom:
    (): my.package.customFormatterFactory
    bar: baz
    spam: 99.9
    answer: 42

```

The above YAML snippet defines three formatters. The first, with id `brief`, is a standard `logging.Formatter` instance with the specified format string. The second, with id `default`, has a longer format and also defines the time format explicitly, and will result in a `logging.Formatter` initialized with those two format strings. Shown in Python source form, the `brief` and `default` formatters have configuration sub-dictionaries:

```

{
  'format' : '%(message)s'
}

```

and:

```

{
  'format' : '%(asctime)s %(levelname)-8s %(name)-15s %(message)s',
  'datefmt' : '%Y-%m-%d %H:%M:%S'
}

```

respectively, and as these dictionaries do not contain the special key '()', the instantiation is inferred from the context: as a result, standard `logging.Formatter` instances are created. The configuration sub-dictionary for the third formatter, with id `custom`, is:

```

{
  '()' : 'my.package.customFormatterFactory',
  'bar' : 'baz',
  'spam' : 99.9,
  'answer' : 42
}

```

and this contains the special key '()', which means that user-defined instantiation is wanted. In this case, the specified factory callable will be used. If it is an actual callable it will be used directly - otherwise, if you specify a string (as in the example) the actual callable will be located using normal import mechanisms. The callable will be called with the **remaining** items in the configuration sub-dictionary as keyword arguments. In the above example, the formatter with id `custom` will be assumed to be returned by the call:

```
my.package.customFormatterFactory(bar='baz', spam=99.9, answer=42)
```

The key '()' has been used as the special key because it is not a valid keyword parameter name, and so will not clash with the names of the keyword arguments used in the call. The '()' also serves as a mnemonic that the corresponding value is a callable.

Access to external objects

There are times where a configuration needs to refer to objects external to the configuration, for example `sys.stderr`. If the configuration dict is constructed using Python code, this is straightforward, but a problem arises when the configuration is provided via a text file (e.g. JSON, YAML). In a text file, there is no standard way to distinguish `sys.stderr` from the literal string `'sys.stderr'`. To facilitate this distinction, the configuration system looks for certain special prefixes in string values and treat them specially. For example, if the literal string `'ext://sys.stderr'` is provided as a value in the configuration, then the `ext://` will be stripped off and the remainder of the value processed using normal import mechanisms.

The handling of such prefixes is done in a way analogous to protocol handling: there is a generic mechanism to look for prefixes which match the regular expression `^(?P<prefix>[a-z]+):/(?P<suffix>.*)$` whereby, if the `prefix` is recognised, the `suffix` is processed in a prefix-dependent manner and the result of the processing replaces the string value. If the prefix is not recognised, then the string value will be left as-is.

Access to internal objects

As well as external objects, there is sometimes also a need to refer to objects in the configuration. This will be done implicitly by the configuration system for things that it knows about. For example, the string value `'DEBUG'` for a level in a logger or handler will automatically be converted to the value `logging.DEBUG`, and the `handlers`, `filters` and `formatter` entries will take an object id and resolve to the appropriate destination object.

However, a more generic mechanism is needed for user-defined objects which are not known to the `logging` module. For example, consider `logging.handlers.MemoryHandler`, which takes a `target` argument which is another handler to delegate to. Since the system already knows about this class, then in the configuration, the given `target` just needs to be the object id of the relevant target handler, and the system will resolve to the handler from the id. If, however, a user defines a `my.package.MyHandler` which has an `alternate` handler, the configuration system would not know that the `alternate` referred to a handler. To cater for this, a generic resolution system allows the user to specify:

```
handlers:
  file:
    # configuration of file handler goes here

  custom:
    (): my.package.MyHandler
    alternate: cfg://handlers.file
```

The literal string `'cfg://handlers.file'` will be resolved in an analogous way to strings with the `ext://` prefix, but looking in the configuration itself rather than the import namespace. The mechanism allows access by dot or by index, in a similar way to that provided by `str.format`. Thus, given the following snippet:

```
handlers:
  email:
    class: logging.handlers.SMTPHandler
    mailhost: localhost
    fromaddr: my_app@domain.tld
    toaddrs:
      - support_team@domain.tld
      - dev_team@domain.tld
    subject: Houston, we have a problem.
```

in the configuration, the string `'cfg://handlers'` would resolve to the dict with key `handlers`, the string `'cfg://handlers.email'` would resolve to the dict with key `email` in the `handlers` dict, and so on. The string `'cfg://handlers.email.toaddrs[1]'` would resolve to `'dev_team.domain.tld'` and the string `'cfg://handlers.email.toaddrs[0]'` would resolve to the value `'support_team@domain.tld'`. The `subject` value could be accessed using either `'cfg://handlers.email.subject'` or, equivalently,

'cfg://handlers.email[subject]'. The latter form only needs to be used if the key contains spaces or non-alphanumeric characters. If an index value consists only of decimal digits, access will be attempted using the corresponding integer value, falling back to the string value if needed.

Given a string `cfg://handlers.myhandler.mykey.123`, this will resolve to `config_dict['handlers']['myhandler']['mykey']['123']`. If the string is specified as `cfg://handlers.myhandler.mykey[123]`, the system will attempt to retrieve the value from `config_dict['handlers']['myhandler']['mykey'][123]`, and fall back to `config_dict['handlers']['myhandler']['mykey']['123']` if that fails.

Import resolution and custom importers

Import resolution, by default, uses the builtin `__import__()` function to do its importing. You may want to replace this with your own importing mechanism: if so, you can replace the `importer` attribute of the `DictConfigurator` or its superclass, the `BaseConfigurator` class. However, you need to be careful because of the way functions are accessed from classes via descriptors. If you are using a Python callable to do your imports, and you want to define it at class level rather than instance level, you need to wrap it with `staticmethod()`. For example:

```
from importlib import import_module
from logging.config import BaseConfigurator

BaseConfigurator.importer = staticmethod(import_module)
```

You don't need to wrap with `staticmethod()` if you're setting the import callable on a configurator *instance*.

16.7.4 Configuration file format

The configuration file format understood by `fileConfig()` is based on `configparser` functionality. The file must contain sections called `[loggers]`, `[handlers]` and `[formatters]` which identify by name the entities of each type which are defined in the file. For each such entity, there is a separate section which identifies how that entity is configured. Thus, for a logger named `log01` in the `[loggers]` section, the relevant configuration details are held in a section `[logger_log01]`. Similarly, a handler called `hand01` in the `[handlers]` section will have its configuration held in a section called `[handler_hand01]`, while a formatter called `form01` in the `[formatters]` section will have its configuration specified in a section called `[formatter_form01]`. The root logger configuration must be specified in a section called `[logger_root]`.

Σημείωση: The `fileConfig()` API is older than the `dictConfig()` API and does not provide functionality to cover certain aspects of logging. For example, you cannot configure `Filter` objects, which provide for filtering of messages beyond simple integer levels, using `fileConfig()`. If you need to have instances of `Filter` in your logging configuration, you will need to use `dictConfig()`. Note that future enhancements to configuration functionality will be added to `dictConfig()`, so it's worth considering transitioning to this newer API when it's convenient to do so.

Examples of these sections in the file are given below.

```
[loggers]
keys=root,log02,log03,log04,log05,log06,log07

[handlers]
keys=hand01,hand02,hand03,hand04,hand05,hand06,hand07,hand08,hand09

[formatters]
keys=form01,form02,form03,form04,form05,form06,form07,form08,form09
```

The root logger must specify a level and a list of handlers. An example of a root logger section is given below.

```
[logger_root]
level=NOTSET
handlers=hand01
```

The `level` entry can be one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL` or `NOTSET`. For the root logger only, `NOTSET` means that all messages will be logged. Level values are *eval()*uated in the context of the logging package's namespace.

The `handlers` entry is a comma-separated list of handler names, which must appear in the `[handlers]` section. These names must appear in the `[handlers]` section and have corresponding sections in the configuration file.

For loggers other than the root logger, some additional information is required. This is illustrated by the following example.

```
[logger_parser]
level=DEBUG
handlers=hand01
propagate=1
qualname=compiler.parser
```

The `level` and `handlers` entries are interpreted as for the root logger, except that if a non-root logger's level is specified as `NOTSET`, the system consults loggers higher up the hierarchy to determine the effective level of the logger. The `propagate` entry is set to 1 to indicate that messages must propagate to handlers higher up the logger hierarchy from this logger, or 0 to indicate that messages are **not** propagated to handlers up the hierarchy. The `qualname` entry is the hierarchical channel name of the logger, that is to say the name used by the application to get the logger.

Sections which specify handler configuration are exemplified by the following.

```
[handler_hand01]
class=StreamHandler
level=NOTSET
formatter=form01
args=(sys.stdout,)
```

The `class` entry indicates the handler's class (as determined by *eval()* in the logging package's namespace). The `level` is interpreted as for loggers, and `NOTSET` is taken to mean "log everything".

The `formatter` entry indicates the key name of the formatter for this handler. If blank, a default formatter (`logging._defaultFormatter`) is used. If a name is specified, it must appear in the `[formatters]` section and have a corresponding section in the configuration file.

The `args` entry, when *eval()*uated in the context of the logging package's namespace, is the list of arguments to the constructor for the handler class. Refer to the constructors for the relevant handlers, or to the examples below, to see how typical entries are constructed. If not provided, it defaults to `()`.

The optional `kwargs` entry, when *eval()*uated in the context of the logging package's namespace, is the keyword argument dict to the constructor for the handler class. If not provided, it defaults to `{}`.

```
[handler_hand02]
class=FileHandler
level=DEBUG
formatter=form02
args=('python.log', 'w')

[handler_hand03]
class=handlers.SocketHandler
level=INFO
formatter=form03
```

(συνέχεια στην επόμενη σελίδα)

(συνεχίζεται από την προηγούμενη σελίδα)

```

args=('localhost', handlers.DEFAULT_TCP_LOGGING_PORT)

[handler_hand04]
class=handlers.DatagramHandler
level=WARN
formatter=form04
args=('localhost', handlers.DEFAULT_UDP_LOGGING_PORT)

[handler_hand05]
class=handlers.SysLogHandler
level=ERROR
formatter=form05
args= (('localhost', handlers.SYSLOG_UDP_PORT), handlers.SysLogHandler.LOG_USER)

[handler_hand06]
class=handlers.NTEventLogHandler
level=CRITICAL
formatter=form06
args=('Python Application', '', 'Application')

[handler_hand07]
class=handlers.SMTPHandler
level=WARN
formatter=form07
args=('localhost', 'from@abc', ['user1@abc', 'user2@xyz'], 'Logger Subject')
kwargs={'timeout': 10.0}

[handler_hand08]
class=handlers.MemoryHandler
level=NOTSET
formatter=form08
target=
args=(10, ERROR)

[handler_hand09]
class=handlers.HTTPHandler
level=NOTSET
formatter=form09
args=('localhost:9022', '/log', 'GET')
kwargs={'secure': True}

```

Sections which specify formatter configuration are typified by the following.

```

[formatter_form01]
format=F1 %(asctime)s %(levelname)s %(message)s
datefmt=
class=logging.Formatter

```

The `format` entry is the overall format string, and the `datefmt` entry is the `strftime()`-compatible date/time format string. If empty, the package substitutes something which is almost equivalent to specifying the date format string `'%Y-%m-%d %H:%M:%S'`. This format also specifies milliseconds, which are appended to the result of using the above format string, with a comma separator. An example time in this format is `2003-01-23 00:29:50,411`.

The `class` entry is optional. It indicates the name of the formatter's class (as a dotted module and class name.) This option is useful for instantiating a *Formatter* subclass. Subclasses of *Formatter* can present exception tracebacks in an expanded or condensed format.

Σημείωση: Due to the use of `eval()` as described above, there are potential security risks which result from using the `listen()` to send and receive configurations via sockets. The risks are limited to where multiple users with no mutual trust run code on the same machine; see the `listen()` documentation for more information.

16.8 `logging.handlers` — Logging handlers

Source code: `Lib/logging/handlers.py`

Important

This page contains only reference information. For tutorials, please see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

The following useful handlers are provided in the package. Note that three of the handlers (`StreamHandler`, `FileHandler` and `NullHandler`) are actually defined in the `logging` module itself, but have been documented here along with the other handlers.

16.8.1 `StreamHandler`

The `StreamHandler` class, located in the core `logging` package, sends logging output to streams such as `sys.stdout`, `sys.stderr` or any file-like object (or, more precisely, any object which supports `write()` and `flush()` methods).

class `logging.StreamHandler` (*stream=None*)

Returns a new instance of the `StreamHandler` class. If *stream* is specified, the instance will use it for logging output; otherwise, `sys.stderr` will be used.

emit (*record*)

If a formatter is specified, it is used to format the record. The record is then written to the stream followed by *terminator*. If exception information is present, it is formatted using `traceback.print_exception()` and appended to the stream.

flush ()

Flushes the stream by calling its `flush()` method. Note that the `close()` method is inherited from `Handler` and so does no output, so an explicit `flush()` call may be needed at times.

setStream (*stream*)

Sets the instance's stream to the specified value, if it is different. The old stream is flushed before the new stream is set.

Παράμετροι *stream* – The stream that the handler should use.

Επιστρέφει the old stream, if the stream was changed, or `None` if it wasn't.

Νέο στην έκδοση 3.7.

terminator

String used as the terminator when writing a formatted record to a stream. Default value is `'\n'`.

If you don't want a newline termination, you can set the handler instance's `terminator` attribute to the empty string.

In earlier versions, the terminator was hardcoded as `'\n'`.

Νέο στην έκδοση 3.2.

16.8.2 FileHandler

The `FileHandler` class, located in the core `logging` package, sends logging output to a disk file. It inherits the output functionality from `StreamHandler`.

class `logging.FileHandler` (*filename*, *mode*='a', *encoding*=None, *delay*=False, *errors*=None)

Returns a new instance of the `FileHandler` class. The specified file is opened and used as the stream for logging. If *mode* is not specified, 'a' is used. If *encoding* is not None, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely. If *errors* is specified, it's used to determine how encoding errors are handled.

Αλλάξε στην έκδοση 3.6: As well as string values, `Path` objects are also accepted for the *filename* argument.

Αλλάξε στην έκδοση 3.9: The *errors* parameter was added.

close()

Closes the file.

emit (*record*)

Outputs the record to the file.

16.8.3 NullHandler

Νέο στην έκδοση 3.1.

The `NullHandler` class, located in the core `logging` package, does not do any formatting or output. It is essentially a “no-op” handler for use by library developers.

class `logging.NullHandler`

Returns a new instance of the `NullHandler` class.

emit (*record*)

This method does nothing.

handle (*record*)

This method does nothing.

createLock ()

This method returns None for the lock, since there is no underlying I/O to which access needs to be serialized.

See `library-config` for more information on how to use `NullHandler`.

16.8.4 WatchedFileHandler

The `WatchedFileHandler` class, located in the `logging.handlers` module, is a `FileHandler` which watches the file it is logging to. If the file changes, it is closed and reopened using the file name.

A file change can happen because of usage of programs such as `newsyslog` and `logrotate` which perform log file rotation. This handler, intended for use under Unix/Linux, watches the file to see if it has changed since the last emit. (A file is deemed to have changed if its device or inode have changed.) If the file has changed, the old file stream is closed, and the file opened to get a new stream.

This handler is not appropriate for use under Windows, because under Windows open log files cannot be moved or renamed - logging opens the files with exclusive locks - and so there is no need for such a handler. Furthermore, `ST_INO` is not supported under Windows; `stat()` always returns zero for this value.

class `logging.handlers.WatchedFileHandler` (*filename, mode='a', encoding=None, delay=False, errors=None*)

Returns a new instance of the `WatchedFileHandler` class. The specified file is opened and used as the stream for logging. If *mode* is not specified, 'a' is used. If *encoding* is not None, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely. If *errors* is provided, it determines how encoding errors are handled.

Αλλάξε στην έκδοση 3.6: As well as string values, `Path` objects are also accepted for the *filename* argument.

Αλλάξε στην έκδοση 3.9: The *errors* parameter was added.

reopenIfNeeded()

Checks to see if the file has changed. If it has, the existing stream is flushed and closed and the file opened again, typically as a precursor to outputting the record to the file.

Νέο στην έκδοση 3.6.

emit (*record*)

Outputs the record to the file, but first calls `reopenIfNeeded()` to reopen the file if it has changed.

16.8.5 BaseRotatingHandler

The `BaseRotatingHandler` class, located in the `logging.handlers` module, is the base class for the rotating file handlers, `RotatingFileHandler` and `TimedRotatingFileHandler`. You should not need to instantiate this class, but it has attributes and methods you may need to override.

class `logging.handlers.BaseRotatingHandler` (*filename, mode, encoding=None, delay=False, errors=None*)

The parameters are as for `FileHandler`. The attributes are:

namer

If this attribute is set to a callable, the `rotation_filename()` method delegates to this callable. The parameters passed to the callable are those passed to `rotation_filename()`.

Σημείωση: The namer function is called quite a few times during rollover, so it should be as simple and as fast as possible. It should also return the same output every time for a given input, otherwise the rollover behaviour may not work as expected.

It's also worth noting that care should be taken when using a namer to preserve certain attributes in the filename which are used during rotation. For example, `RotatingFileHandler` expects to have a set of log files whose names contain successive integers, so that rotation works as expected, and `TimedRotatingFileHandler` deletes old log files (based on the `backupCount` parameter passed to the handler's initializer) by determining the oldest files to delete. For this to happen, the filenames should be sortable using the date/time portion of the filename, and a namer needs to respect this. (If a namer is wanted

that doesn't respect this scheme, it will need to be used in a subclass of *TimedRotatingFileHandler* which overrides the *getFilesToDelete()* method to fit in with the custom naming scheme.)

Νέο στην έκδοση 3.3.

rotator

If this attribute is set to a callable, the *rotate()* method delegates to this callable. The parameters passed to the callable are those passed to *rotate()*.

Νέο στην έκδοση 3.3.

rotation_filename (*default_name*)

Modify the filename of a log file when rotating.

This is provided so that a custom filename can be provided.

The default implementation calls the “namer” attribute of the handler, if it's callable, passing the default name to it. If the attribute isn't callable (the default is *None*), the name is returned unchanged.

Παράμετροι **default_name** – The default name for the log file.

Νέο στην έκδοση 3.3.

rotate (*source, dest*)

When rotating, rotate the current log.

The default implementation calls the “rotator” attribute of the handler, if it's callable, passing the source and dest arguments to it. If the attribute isn't callable (the default is *None*), the source is simply renamed to the destination.

Παράμετροι

- **source** – The source filename. This is normally the base filename, e.g. “test.log”.
- **dest** – The destination filename. This is normally what the source is rotated to, e.g. “test.log.1”.

Νέο στην έκδοση 3.3.

The reason the attributes exist is to save you having to subclass - you can use the same callables for instances of *RotatingFileHandler* and *TimedRotatingFileHandler*. If either the namer or rotator callable raises an exception, this will be handled in the same way as any other exception during an *emit()* call, i.e. via the *handleError()* method of the handler.

If you need to make more significant changes to rotation processing, you can override the methods.

For an example, see *cookbook-rotator-namer*.

16.8.6 RotatingFileHandler

The *RotatingFileHandler* class, located in the *logging.handlers* module, supports rotation of disk log files.

```
class logging.handlers.RotatingFileHandler (filename,           mode='a',           maxBytes=0,
                                           backupCount=0, encoding=None, delay=False,
                                           errors=None)
```

Returns a new instance of the *RotatingFileHandler* class. The specified file is opened and used as the stream for logging. If *mode* is not specified, 'a' is used. If *encoding* is not *None*, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to *emit()*. By default, the file grows indefinitely. If *errors* is provided, it determines how encoding errors are handled.

You can use the *maxBytes* and *backupCount* values to allow the file to *rollover* at a predetermined size. When the size is about to be exceeded, the file is closed and a new file is silently opened for output. Rollover occurs whenever the current log file is nearly *maxBytes* in length; but if either of *maxBytes* or *backupCount* is zero, rollover never occurs, so you generally want to set *backupCount* to at least 1, and have a non-zero *maxBytes*. When *backupCount* is non-zero, the system will save old log files by appending the extensions “.1”, “.2” etc., to the filename. For example, with a *backupCount* of 5 and a base file name of `app.log`, you would get `app.log`, `app.log.1`, `app.log.2`, up to `app.log.5`. The file being written to is always `app.log`. When this file is filled, it is closed and renamed to `app.log.1`, and if files `app.log.1`, `app.log.2`, etc. exist, then they are renamed to `app.log.2`, `app.log.3` etc. respectively.

Άλλαξε στην έκδοση 3.6: As well as string values, *Path* objects are also accepted for the *filename* argument.

Άλλαξε στην έκδοση 3.9: The *errors* parameter was added.

doRollover()

Does a rollover, as described above.

emit(record)

Outputs the record to the file, catering for rollover as described previously.

16.8.7 TimedRotatingFileHandler

The *TimedRotatingFileHandler* class, located in the `logging.handlers` module, supports rotation of disk log files at certain timed intervals.

```
class logging.handlers.TimedRotatingFileHandler(filename, when='h', interval=1,
                                                backupCount=0, encoding=None,
                                                delay=False, utc=False, atTime=None,
                                                errors=None)
```

Returns a new instance of the *TimedRotatingFileHandler* class. The specified file is opened and used as the stream for logging. On rotating it also sets the filename suffix. Rotating happens based on the product of *when* and *interval*.

You can use the *when* to specify the type of *interval*. The list of possible values is below. Note that they are not case sensitive.

| Value | Type of interval | If/how <i>atTime</i> is used |
|----------------|---|---------------------------------------|
| 'S' | Seconds | Ignored |
| 'M' | Minutes | Ignored |
| 'H' | Hours | Ignored |
| 'D' | Days | Ignored |
| 'W0' – 'W6' | Weekday (0=Monday) | Used to compute initial rollover time |
| 'midnight' | Roll over at midnight, if <i>atTime</i> not specified, else at time <i>atTime</i> | Used to compute initial rollover time |

When using weekday-based rotation, specify “W0” for Monday, “W1” for Tuesday, and so on up to “W6” for Sunday. In this case, the value passed for *interval* isn’t used.

The system will save old log files by appending extensions to the filename. The extensions are date-and-time based, using the strftime format `%Y-%m-%d_%H-%M-%S` or a leading portion thereof, depending on the rollover interval.

When computing the next rollover time for the first time (when the handler is created), the last modification time of an existing log file, or else the current time, is used to compute when the next rotation will occur.

If the *utc* argument is true, times in UTC will be used; otherwise local time is used.

If *backupCount* is nonzero, at most *backupCount* files will be kept, and if more would be created when rollover occurs, the oldest one is deleted. The deletion logic uses the interval to determine which files to delete, so changing the interval may leave old files lying around.

If *delay* is true, then file opening is deferred until the first call to `emit()`.

If *atTime* is not `None`, it must be a `datetime.time` instance which specifies the time of day when rollover occurs, for the cases where rollover is set to happen «at midnight» or «on a particular weekday». Note that in these cases, the *atTime* value is effectively used to compute the *initial* rollover, and subsequent rollovers would be calculated via the normal interval calculation.

If *errors* is specified, it's used to determine how encoding errors are handled.

Σημείωση: Calculation of the initial rollover time is done when the handler is initialised. Calculation of subsequent rollover times is done only when rollover occurs, and rollover occurs only when emitting output. If this is not kept in mind, it might lead to some confusion. For example, if an interval of «every minute» is set, that does not mean you will always see log files with times (in the filename) separated by a minute; if, during application execution, logging output is generated more frequently than once a minute, *then* you can expect to see log files with times separated by a minute. If, on the other hand, logging messages are only output once every five minutes (say), then there will be gaps in the file times corresponding to the minutes where no output (and hence no rollover) occurred.

Άλλαξε στην έκδοση 3.4: *atTime* parameter was added.

Άλλαξε στην έκδοση 3.6: As well as string values, *Path* objects are also accepted for the *filename* argument.

Άλλαξε στην έκδοση 3.9: The *errors* parameter was added.

doRollover()

Does a rollover, as described above.

emit(record)

Outputs the record to the file, catering for rollover as described above.

getFilesToDelete()

Returns a list of filenames which should be deleted as part of rollover. These are the absolute paths of the oldest backup log files written by the handler.

16.8.8 SocketHandler

The *SocketHandler* class, located in the `logging.handlers` module, sends logging output to a network socket. The base class uses a TCP socket.

class `logging.handlers.SocketHandler(host, port)`

Returns a new instance of the *SocketHandler* class intended to communicate with a remote machine whose address is given by *host* and *port*.

Άλλαξε στην έκδοση 3.4: If *port* is specified as `None`, a Unix domain socket is created using the value in *host* - otherwise, a TCP socket is created.

close()

Closes the socket.

emit()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. If the connection was previously lost, re-establishes the connection. To unpickle the record at the receiving end into a *LogRecord*, use the `makeLogRecord()` function.

handleError()

Handles an error which has occurred during `emit()`. The most likely cause is a lost connection. Closes the socket so that we can retry on the next event.

makeSocket()

This is a factory method which allows subclasses to define the precise type of socket they want. The default implementation creates a TCP socket (`socket.SOCK_STREAM`).

makePickle(record)

Pickles the record's attribute dictionary in binary format with a length prefix, and returns it ready for transmission across the socket. The details of this operation are equivalent to:

```
data = pickle.dumps(record_attr_dict, 1)
datalen = struct.pack('>L', len(data))
return datalen + data
```

Note that pickles aren't completely secure. If you are concerned about security, you may want to override this method to implement a more secure mechanism. For example, you can sign pickles using HMAC and then verify them on the receiving end, or alternatively you can disable unpickling of global objects on the receiving end.

send(packet)

Send a pickled byte-string *packet* to the socket. The format of the sent byte-string is as described in the documentation for `makePickle()`.

This function allows for partial sends, which can happen when the network is busy.

createSocket()

Tries to create a socket; on failure, uses an exponential back-off algorithm. On initial failure, the handler will drop the message it was trying to send. When subsequent messages are handled by the same instance, it will not try connecting until some time has passed. The default parameters are such that the initial delay is one second, and if after that delay the connection still can't be made, the handler will double the delay each time up to a maximum of 30 seconds.

This behaviour is controlled by the following handler attributes:

- `retryStart` (initial delay, defaulting to 1.0 seconds).
- `retryFactor` (multiplier, defaulting to 2.0).
- `retryMax` (maximum delay, defaulting to 30.0 seconds).

This means that if the remote listener starts up *after* the handler has been used, you could lose messages (since the handler won't even attempt a connection until the delay has elapsed, but just silently drop messages during the delay period).

16.8.9 DatagramHandler

The `DatagramHandler` class, located in the `logging.handlers` module, inherits from `SocketHandler` to support sending logging messages over UDP sockets.

class logging.handlers.DatagramHandler(host, port)

Returns a new instance of the `DatagramHandler` class intended to communicate with a remote machine whose address is given by *host* and *port*.

Αλλαξε στην έκδοση 3.4: If *port* is specified as `None`, a Unix domain socket is created using the value in *host* - otherwise, a UDP socket is created.

emit()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with

the socket, silently drops the packet. To unpickle the record at the receiving end into a *LogRecord*, use the *makeLogRecord()* function.

makeSocket()

The factory method of *SocketHandler* is here overridden to create a UDP socket (*socket.SOCK_DGRAM*).

send(s)

Send a pickled byte-string to a socket. The format of the sent byte-string is as described in the documentation for *SocketHandler.makePickle()*.

16.8.10 SysLogHandler

The *SysLogHandler* class, located in the *logging.handlers* module, supports sending logging messages to a remote or local Unix syslog.

```
class logging.handlers.SysLogHandler (address=('localhost',          SYSLOG_UDP_PORT),
                                       facility=LOG_USER, socktype=socket.SOCK_DGRAM)
```

Returns a new instance of the *SysLogHandler* class intended to communicate with a remote Unix machine whose address is given by *address* in the form of a (host, port) tuple. If *address* is not specified, ('localhost', 514) is used. The address is used to open a socket. An alternative to providing a (host, port) tuple is providing an address as a string, for example “/dev/log”. In this case, a Unix domain socket is used to send the message to the syslog. If *facility* is not specified, LOG_USER is used. The type of socket opened depends on the *socktype* argument, which defaults to *socket.SOCK_DGRAM* and thus opens a UDP socket. To open a TCP socket (for use with the newer syslog daemons such as rsyslog), specify a value of *socket.SOCK_STREAM*.

Note that if your server is not listening on UDP port 514, *SysLogHandler* may appear not to work. In that case, check what address you should be using for a domain socket - it's system dependent. For example, on Linux it's usually “/dev/log” but on OS/X it's “/var/run/syslog”. You'll need to check your platform and use the appropriate address (you may need to do this check at runtime if your application needs to run on several platforms). On Windows, you pretty much have to use the UDP option.

Άλλαξε στην έκδοση 3.2: *socktype* was added.

close()

Closes the socket to the remote host.

emit(record)

The record is formatted, and then sent to the syslog server. If exception information is present, it is *not* sent to the server.

Άλλαξε στην έκδοση 3.2.1: (See: [bpo-12168](#).) In earlier versions, the message sent to the syslog daemons was always terminated with a NUL byte, because early versions of these daemons expected a NUL terminated message - even though it's not in the relevant specification ([RFC 5424](#)). More recent versions of these daemons don't expect the NUL byte but strip it off if it's there, and even more recent daemons (which adhere more closely to RFC 5424) pass the NUL byte on as part of the message.

To enable easier handling of syslog messages in the face of all these differing daemon behaviours, the appending of the NUL byte has been made configurable, through the use of a class-level attribute, *append_nul*. This defaults to *True* (preserving the existing behaviour) but can be set to *False* on a *SysLogHandler* instance in order for that instance to *not* append the NUL terminator.

Άλλαξε στην έκδοση 3.3: (See: [bpo-12419](#).) In earlier versions, there was no facility for an «ident» or «tag» prefix to identify the source of the message. This can now be specified using a class-level attribute, defaulting to "" to preserve existing behaviour, but which can be overridden on a *SysLogHandler* instance in order for that instance to prepend the ident to every message handled. Note that the provided ident must be text, not bytes, and is prepended to the message exactly as is.

encodePriority (*facility, priority*)

Encodes the facility and priority into an integer. You can pass in strings or integers - if strings are passed, internal mapping dictionaries are used to convert them to integers.

The symbolic LOG_ values are defined in *SysLogHandler* and mirror the values defined in the `sys/syslog.h` header file.

Priorities

| Name (string) | Symbolic value |
|------------------|----------------|
| alert | LOG_ALERT |
| crit or critical | LOG_CRIT |
| debug | LOG_DEBUG |
| emerg or panic | LOG_EMERG |
| err or error | LOG_ERR |
| info | LOG_INFO |
| notice | LOG_NOTICE |
| warn or warning | LOG_WARNING |

Facilities

| Name (string) | Symbolic value |
|---------------|----------------|
| auth | LOG_AUTH |
| authpriv | LOG_AUTHPRIV |
| cron | LOG_CRON |
| daemon | LOG_DAEMON |
| ftp | LOG_FTP |
| kern | LOG_KERN |
| lpr | LOG_LPR |
| mail | LOG_MAIL |
| news | LOG_NEWS |
| syslog | LOG_SYSLOG |
| user | LOG_USER |
| uucp | LOG_UUCP |
| local0 | LOG_LOCAL0 |
| local1 | LOG_LOCAL1 |
| local2 | LOG_LOCAL2 |
| local3 | LOG_LOCAL3 |
| local4 | LOG_LOCAL4 |
| local5 | LOG_LOCAL5 |
| local6 | LOG_LOCAL6 |
| local7 | LOG_LOCAL7 |

mapPriority (*levelname*)

Maps a logging level name to a syslog priority name. You may need to override this if you are using custom levels, or if the default algorithm is not suitable for your needs. The default algorithm maps DEBUG, INFO, WARNING, ERROR and CRITICAL to the equivalent syslog names, and all other level names to “warning”.

16.8.11 NTEventLogHandler

The *NTEventLogHandler* class, located in the *logging.handlers* module, supports sending logging messages to a local Windows NT, Windows 2000 or Windows XP event log. Before you can use it, you need Mark Hammond's Win32 extensions for Python installed.

class *logging.handlers.NTEventLogHandler* (*appname*, *dllname=None*, *logtype='Application'*)

Returns a new instance of the *NTEventLogHandler* class. The *appname* is used to define the application name as it appears in the event log. An appropriate registry entry is created using this name. The *dllname* should give the fully qualified pathname of a .dll or .exe which contains message definitions to hold in the log (if not specified, 'win32service.pyd' is used - this is installed with the Win32 extensions and contains some basic placeholder message definitions. Note that use of these placeholders will make your event logs big, as the entire message source is held in the log. If you want slimmer logs, you have to pass in the name of your own .dll or .exe which contains the message definitions you want to use in the event log). The *logtype* is one of 'Application', 'System' or 'Security', and defaults to 'Application'.

close ()

At this point, you can remove the application name from the registry as a source of event log entries. However, if you do this, you will not be able to see the events as you intended in the Event Log Viewer - it needs to be able to access the registry to get the .dll name. The current version does not do this.

emit (*record*)

Determines the message ID, event category and event type, and then logs the message in the NT event log.

getEventCategory (*record*)

Returns the event category for the record. Override this if you want to specify your own categories. This version returns 0.

getEventType (*record*)

Returns the event type for the record. Override this if you want to specify your own types. This version does a mapping using the handler's *typemap* attribute, which is set up in *__init__* () to a dictionary which contains mappings for DEBUG, INFO, WARNING, ERROR and CRITICAL. If you are using your own levels, you will either need to override this method or place a suitable dictionary in the handler's *typemap* attribute.

getMessageID (*record*)

Returns the message ID for the record. If you are using your own messages, you could do this by having the *msg* passed to the logger being an ID rather than a format string. Then, in here, you could use a dictionary lookup to get the message ID. This version returns 1, which is the base message ID in *win32service.pyd*.

16.8.12 SMTPHandler

The *SMTPHandler* class, located in the *logging.handlers* module, supports sending logging messages to an email address via SMTP.

class *logging.handlers.SMTPHandler* (*mailhost*, *fromaddr*, *toaddrs*, *subject*, *credentials=None*,
secure=None, *timeout=1.0*)

Returns a new instance of the *SMTPHandler* class. The instance is initialized with the from and to addresses and subject line of the email. The *toaddrs* should be a list of strings. To specify a non-standard SMTP port, use the (host, port) tuple format for the *mailhost* argument. If you use a string, the standard SMTP port is used. If your SMTP server requires authentication, you can specify a (username, password) tuple for the *credentials* argument.

To specify the use of a secure protocol (TLS), pass in a tuple to the *secure* argument. This will only be used when authentication credentials are supplied. The tuple should be either an empty tuple, or a single-value tuple with the name of a keyfile, or a 2-value tuple with the names of the keyfile and certificate file. (This tuple is passed to the *smtplib.SMTP.starttls* () method.)

A timeout can be specified for communication with the SMTP server using the *timeout* argument.

Νέο στην έκδοση 3.3: The *timeout* argument was added.

emit (*record*)

Formats the record and sends it to the specified addressees.

getSubject (*record*)

If you want to specify a subject line which is record-dependent, override this method.

16.8.13 MemoryHandler

The *MemoryHandler* class, located in the *logging.handlers* module, supports buffering of logging records in memory, periodically flushing them to a *target* handler. Flushing occurs whenever the buffer is full, or when an event of a certain severity or greater is seen.

MemoryHandler is a subclass of the more general *BufferingHandler*, which is an abstract class. This buffers logging records in memory. Whenever each record is added to the buffer, a check is made by calling *shouldFlush()* to see if the buffer should be flushed. If it should, then *flush()* is expected to do the flushing.

class logging.handlers.**BufferingHandler** (*capacity*)

Initializes the handler with a buffer of the specified capacity. Here, *capacity* means the number of logging records buffered.

emit (*record*)

Append the record to the buffer. If *shouldFlush()* returns true, call *flush()* to process the buffer.

flush ()

You can override this to implement custom flushing behavior. This version just zaps the buffer to empty.

shouldFlush (*record*)

Return True if the buffer is up to capacity. This method can be overridden to implement custom flushing strategies.

class logging.handlers.**MemoryHandler** (*capacity*, *flushLevel=ERROR*, *target=None*,
flushOnClose=True)

Returns a new instance of the *MemoryHandler* class. The instance is initialized with a buffer size of *capacity* (number of records buffered). If *flushLevel* is not specified, *ERROR* is used. If no *target* is specified, the target will need to be set using *setTarget()* before this handler does anything useful. If *flushOnClose* is specified as *False*, then the buffer is *not* flushed when the handler is closed. If not specified or specified as *True*, the previous behaviour of flushing the buffer will occur when the handler is closed.

Άλλαξε στην έκδοση 3.6: The *flushOnClose* parameter was added.

close ()

Calls *flush()*, sets the target to *None* and clears the buffer.

flush ()

For a *MemoryHandler*, flushing means just sending the buffered records to the target, if there is one. The buffer is also cleared when this happens. Override if you want different behavior.

setTarget (*target*)

Sets the target handler for this handler.

shouldFlush (*record*)

Checks for buffer full or a record at the *flushLevel* or higher.

16.8.14 HTTPHandler

The `HTTPHandler` class, located in the `logging.handlers` module, supports sending logging messages to a Web server, using either GET or POST semantics.

class `logging.handlers.HTTPHandler` (*host*, *url*, *method*='GET', *secure*=False, *credentials*=None, *context*=None)

Returns a new instance of the `HTTPHandler` class. The *host* can be of the form `host:port`, should you need to use a specific port number. If no *method* is specified, GET is used. If *secure* is true, a HTTPS connection will be used. The *context* parameter may be set to a `ssl.SSLContext` instance to configure the SSL settings used for the HTTPS connection. If *credentials* is specified, it should be a 2-tuple consisting of userid and password, which will be placed in a HTTP “Authorization” header using Basic authentication. If you specify credentials, you should also specify *secure*=True so that your userid and password are not passed in cleartext across the wire.

Άλλαξε στην έκδοση 3.5: The *context* parameter was added.

mapLogRecord (*record*)

Provides a dictionary, based on *record*, which is to be URL-encoded and sent to the web server. The default implementation just returns `record.__dict__`. This method can be overridden if e.g. only a subset of `LogRecord` is to be sent to the web server, or if more specific customization of what’s sent to the server is required.

emit (*record*)

Sends the record to the Web server as a URL-encoded dictionary. The `mapLogRecord()` method is used to convert the record to the dictionary to be sent.

Σημείωση: Since preparing a record for sending it to a Web server is not the same as a generic formatting operation, using `setFormatter()` to specify a `Formatter` for a `HTTPHandler` has no effect. Instead of calling `format()`, this handler calls `mapLogRecord()` and then `urllib.parse.urlencode()` to encode the dictionary in a form suitable for sending to a Web server.

16.8.15 QueueHandler

Νέο στην έκδοση 3.2.

The `QueueHandler` class, located in the `logging.handlers` module, supports sending logging messages to a queue, such as those implemented in the `queue` or `multiprocessing` modules.

Along with the `QueueListener` class, `QueueHandler` can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in Web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via `SMTPHandler`) are done on a separate thread.

class `logging.handlers.QueueHandler` (*queue*)

Returns a new instance of the `QueueHandler` class. The instance is initialized with the queue to send messages to. The *queue* can be any queue-like object; it’s used as-is by the `enqueue()` method, which needs to know how to send messages to it. The queue is not *required* to have the task tracking API, which means that you can use `SimpleQueue` instances for *queue*.

emit (*record*)

Enqueues the result of preparing the LogRecord. Should an exception occur (e.g. because a bounded queue has filled up), the `handleError()` method is called to handle the error. This can result in the record silently being dropped (if `logging.raiseExceptions` is False) or a message printed to `sys.stderr` (if `logging.raiseExceptions` is True).

prepare (*record*)

Prepares a record for queuing. The object returned by this method is enqueued.

The base implementation formats the record to merge the message, arguments, and exception information, if present. It also removes unpickleable items from the record in-place.

You might want to override this method if you want to convert the record to a dict or JSON string, or send a modified copy of the record while leaving the original intact.

enqueue (*record*)

Enqueues the record on the queue using `put_nowait()`; you may want to override this if you want to use blocking behaviour, or a timeout, or a customized queue implementation.

16.8.16 QueueListener

Νέο στην έκδοση 3.2.

The `QueueListener` class, located in the `logging.handlers` module, supports receiving logging messages from a queue, such as those implemented in the `queue` or `multiprocessing` modules. The messages are received from a queue in an internal thread and passed, on the same thread, to one or more handlers for processing. While `QueueListener` is not itself a handler, it is documented here because it works hand-in-hand with `QueueHandler`.

Along with the `QueueHandler` class, `QueueListener` can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in Web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via `SMTPHandler`) are done on a separate thread.

class `logging.handlers.QueueListener` (*queue*, **handlers*, *respect_handler_level=False*)

Returns a new instance of the `QueueListener` class. The instance is initialized with the queue to send messages to and a list of handlers which will handle entries placed on the queue. The queue can be any queue-like object; it's passed as-is to the `dequeue()` method, which needs to know how to get messages from it. The queue is not *required* to have the task tracking API (though it's used if available), which means that you can use `SimpleQueue` instances for *queue*.

If `respect_handler_level` is `True`, a handler's level is respected (compared with the level for the message) when deciding whether to pass messages to that handler; otherwise, the behaviour is as in previous Python versions - to always pass each message to each handler.

Άλλαξε στην έκδοση 3.5: The `respect_handler_level` argument was added.

dequeue (*block*)

Dequeues a record and return it, optionally blocking.

The base implementation uses `get()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

prepare (*record*)

Prepare a record for handling.

This implementation just returns the passed-in record. You may want to override this method if you need to do any custom marshalling or manipulation of the record before passing it to the handlers.

handle (*record*)

Handle a record.

This just loops through the handlers offering them the record to handle. The actual object passed to the handlers is that which is returned from `prepare()`.

start ()

Starts the listener.

This starts up a background thread to monitor the queue for LogRecords to process.

stop()

Stops the listener.

This asks the thread to terminate, and then waits for it to do so. Note that if you don't call this before your application exits, there may be some records still left on the queue, which won't be processed.

enqueue_sentinel()

Writes a sentinel to the queue to tell the listener to quit. This implementation uses `put_nowait()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

16.9 getpass — Portable password input

Source code: [Lib/getpass.py](#)

The *getpass* module provides two functions:

`getpass.getpass(prompt='Password: ', stream=None)`

Prompt the user for a password without echoing. The user is prompted using the string *prompt*, which defaults to 'Password: '. On Unix, the prompt is written to the file-like object *stream* using the replace error handler if needed. *stream* defaults to the controlling terminal (`/dev/tty`) or if that is unavailable to `sys.stderr` (this argument is ignored on Windows).

If echo free input is unavailable `getpass()` falls back to printing a warning message to *stream* and reading from `sys.stdin` and issuing a *GetPassWarning*.

Σημείωση: If you call `getpass` from within IDLE, the input may be done in the terminal you launched IDLE from rather than the idle window itself.

exception `getpass.GetPassWarning`

A *UserWarning* subclass issued when password input may be echoed.

`getpass.getuser()`

Return the «login name» of the user.

This function checks the environment variables `LOGNAME`, `USER`, `LNAME` and `USERNAME`, in order, and returns the value of the first one which is set to a non-empty string. If none are set, the login name from the password database is returned on systems which support the *pwd* module, otherwise, an exception is raised.

In general, this function should be preferred over `os.getlogin()`.

16.10 `curses` — Terminal handling for character-cell displays

The `curses` module provides an interface to the curses library, the de-facto standard for portable advanced terminal handling.

While curses is most widely used in the Unix environment, versions are available for Windows, DOS, and possibly other systems as well. This extension module is designed to match the API of ncurses, an open-source curses library hosted on Linux and the BSD variants of Unix.

Σημείωση: Whenever the documentation mentions a *character* it can be specified as an integer, a one-character Unicode string or a one-byte byte string.

Whenever the documentation mentions a *character string* it can be specified as a Unicode string or a byte string.

Σημείωση: Since version 5.4, the ncurses library decides how to interpret non-ASCII data using the `nl_langinfo` function. That means that you have to call `locale.setlocale()` in the application and encode Unicode strings using one of the system's available encodings. This example uses the system's default encoding:

```
import locale
locale.setlocale(locale.LC_ALL, '')
code = locale.getpreferredencoding()
```

Then use `code` as the encoding for `str.encode()` calls.

curses-howto Tutorial material on using curses with Python, by Andrew Kuchling and Eric Raymond.

The `Tools/demo/` directory in the Python source distribution contains some example programs using the curses bindings provided by this module.

16.10.1 Functions

The module `curses` defines the following exception:

exception `curses.error`

Exception raised when a curses library function returns an error.

Σημείωση: Whenever *x* or *y* arguments to a function or a method are optional, they default to the current cursor location. Whenever *attr* is optional, it defaults to `A_NORMAL`.

The module `curses` defines the following functions:

`curses.baudrate()`

Return the output speed of the terminal in bits per second. On software terminal emulators it will have a fixed

high value. Included for historical reasons; in former times, it was used to write output loops for time delays and occasionally to change interfaces depending on the line speed.

`curses.beep()`

Emit a short attention sound.

`curses.can_change_color()`

Return True or False, depending on whether the programmer can change the colors displayed by the terminal.

`curses.cbreak()`

Enter cbreak mode. In cbreak mode (sometimes called «rare» mode) normal tty line buffering is turned off and characters are available to be read one by one. However, unlike raw mode, special characters (interrupt, quit, suspend, and flow control) retain their effects on the tty driver and calling program. Calling first `raw()` then `cbreak()` leaves the terminal in cbreak mode.

`curses.color_content(color_number)`

Return the intensity of the red, green, and blue (RGB) components in the color *color_number*, which must be between 0 and `COLORS - 1`. Return a 3-tuple, containing the R,G,B values for the given color, which will be between 0 (no component) and 1000 (maximum amount of component).

`curses.color_pair(pair_number)`

Return the attribute value for displaying text in the specified color pair. Only the first 256 color pairs are supported. This attribute value can be combined with `A_STANDOUT`, `A_REVERSE`, and the other `A_*` attributes. `pair_number()` is the counterpart to this function.

`curses.curs_set(visibility)`

Set the cursor state. *visibility* can be set to 0, 1, or 2, for invisible, normal, or very visible. If the terminal supports the visibility requested, return the previous cursor state; otherwise raise an exception. On many terminals, the «visible» mode is an underline cursor and the «very visible» mode is a block cursor.

`curses.def_prog_mode()`

Save the current terminal mode as the «program» mode, the mode when the running program is using curses. (Its counterpart is the «shell» mode, for when the program is not in curses.) Subsequent calls to `reset_prog_mode()` will restore this mode.

`curses.def_shell_mode()`

Save the current terminal mode as the «shell» mode, the mode when the running program is not using curses. (Its counterpart is the «program» mode, when the program is using curses capabilities.) Subsequent calls to `reset_shell_mode()` will restore this mode.

`curses.delay_output(ms)`

Insert an *ms* millisecond pause in output.

`curses.doupdate()`

Update the physical screen. The curses library keeps two data structures, one representing the current physical screen contents and a virtual screen representing the desired next state. The `doupdate()` ground updates the physical screen to match the virtual screen.

The virtual screen may be updated by a `noutrefresh()` call after write operations such as `addstr()` have been performed on a window. The normal `refresh()` call is simply `noutrefresh()` followed by `doupdate()`; if you have to update multiple windows, you can speed performance and perhaps reduce screen flicker by issuing `noutrefresh()` calls on all windows, followed by a single `doupdate()`.

`curses.echo()`

Enter echo mode. In echo mode, each character input is echoed to the screen as it is entered.

`curses.endwin()`

De-initialize the library, and return terminal to normal status.

`curses.erasechar()`

Return the user's current erase character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

`curses.filter()`

The `filter()` routine, if used, must be called before `initscr()` is called. The effect is that, during those calls, `LINES` is set to 1; the capabilities `clear`, `cup`, `cud`, `cud1`, `cuu1`, `cuu`, `vpa` are disabled; and the home string is set to the value of `cr`. The effect is that the cursor is confined to the current line, and so are screen updates. This may be used for enabling character-at-a-time line editing without touching the rest of the screen.

`curses.flash()`

Flash the screen. That is, change it to reverse-video and then change it back in a short interval. Some people prefer such as “visible bell” to the audible attention signal produced by `beep()`.

`curses.flushinp()`

Flush all input buffers. This throws away any typeahead that has been typed by the user and has not yet been processed by the program.

`curses.getmouse()`

After `getch()` returns `KEY_MOUSE` to signal a mouse event, this method should be called to retrieve the queued mouse event, represented as a 5-tuple (`id`, `x`, `y`, `z`, `bstate`). `id` is an ID value used to distinguish multiple devices, and `x`, `y`, `z` are the event's coordinates. (`z` is currently unused.) `bstate` is an integer value whose bits will be set to indicate the type of event, and will be the bitwise OR of one or more of the following constants, where `n` is the button number from 1 to 4: `BUTTONn_PRESSED`, `BUTTONn_RELEASED`, `BUTTONn_CLICKED`, `BUTTONn_DOUBLE_CLICKED`, `BUTTONn_TRIPLE_CLICKED`, `BUTTON_SHIFT`, `BUTTON_CTRL`, `BUTTON_ALT`.

`curses.getsyx()`

Return the current coordinates of the virtual screen cursor as a tuple (`y`, `x`). If `leaveok` is currently `True`, then return `(-1, -1)`.

`curses.getwin(file)`

Read window related data stored in the file by an earlier `putwin()` call. The routine then creates and initializes a new window using that data, returning the new window object.

`curses.has_colors()`

Return `True` if the terminal can display colors; otherwise, return `False`.

`curses.has_ic()`

Return `True` if the terminal has insert- and delete-character capabilities. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.has_il()`

Return `True` if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.has_key(ch)`

Take a key value `ch`, and return `True` if the current terminal type recognizes a key with that value.

`curses.halfdelay(tenths)`

Used for half-delay mode, which is similar to `cbreak` mode in that characters typed by the user are immediately available to the program. However, after blocking for `tenths` tenths of seconds, raise an exception if nothing has been typed. The value of `tenths` must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

`curses.init_color(color_number, r, g, b)`

Change the definition of a color, taking the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of `color_number` must be between 0 and `COLORS - 1`. Each of `r`, `g`, `b`, must be a value between 0 and 1000. When `init_color()` is used, all occurrences of

that color on the screen immediately change to the new definition. This function is a no-op on most terminals; it is active only if `can_change_color()` returns True.

`curses.init_pair(pair_number, fg, bg)`

Change the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of *pair_number* must be between 1 and `COLOR_PAIRS - 1` (the 0 color pair is wired to white on black and cannot be changed). The value of *fg* and *bg* arguments must be between 0 and `COLORS - 1`, or, after calling `use_default_colors()`, -1. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair are changed to the new definition.

`curses.initscr()`

Initialize the library. Return a *window* object which represents the whole screen.

Σημείωση: If there is an error opening the terminal, the underlying curses library may cause the interpreter to exit.

`curses.is_term_resized(nlines, ncols)`

Return True if `resize_term()` would modify the window structure, False otherwise.

`curses.isendwin()`

Return True if `endwin()` has been called (that is, the curses library has been deinitialized).

`curses.keyname(k)`

Return the name of the key numbered *k* as a bytes object. The name of a key generating printable ASCII character is the key's character. The name of a control-key combination is a two-byte bytes object consisting of a caret (b'^') followed by the corresponding printable ASCII character. The name of an alt-key combination (128–255) is a bytes object consisting of the prefix b'M-' followed by the name of the corresponding ASCII character.

`curses.killchar()`

Return the user's current line kill character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

`curses.longname()`

Return a bytes object containing the terminfo long name field describing the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to `initscr()`.

`curses.meta(flag)`

If *flag* is True, allow 8-bit characters to be input. If *flag* is False, allow only 7-bit chars.

`curses.mouseinterval(interval)`

Set the maximum time in milliseconds that can elapse between press and release events in order for them to be recognized as a click, and return the previous interval value. The default value is 200 msec, or one fifth of a second.

`curses.mousemask(mousemask)`

Set the mouse events to be reported, and return a tuple (*availmask*, *oldmask*). *availmask* indicates which of the specified mouse events can be reported; on complete failure it returns 0. *oldmask* is the previous value of the given window's mouse event mask. If this function is never called, no mouse events are ever reported.

`curses.napms(ms)`

Sleep for *ms* milliseconds.

`curses.newpad(nlines, ncols)`

Create and return a pointer to a new pad data structure with the given number of lines and columns. Return a pad as a window object.

A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (such as from scrolling or echoing of input) do

not occur. The `refresh()` and `noutrefresh()` methods of a pad require 6 arguments to specify the part of the pad to be displayed and the location on the screen to be used for the display. The arguments are *pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*; the *p* arguments refer to the upper left corner of the pad region to be displayed and the *s* arguments define a clipping box on the screen within which the pad region is to be displayed.

`curses.newwin(nlines, ncols)`

`curses.newwin(nlines, ncols, begin_y, begin_x)`

Return a new *window*, whose left-upper corner is at (*begin_y*, *begin_x*), and whose height/width is *nlines/ncols*.

By default, the window will extend from the specified position to the lower right corner of the screen.

`curses.nl()`

Enter newline mode. This mode translates the return key into newline on input, and translates newline into return and line-feed on output. Newline mode is initially on.

`curses.nocbreak()`

Leave cbreak mode. Return to normal «cooked» mode with line buffering.

`curses.noecho()`

Leave echo mode. Echoing of input characters is turned off.

`curses.nonl()`

Leave newline mode. Disable translation of return into newline on input, and disable low-level translation of newline into newline/return on output (but this does not change the behavior of `addch('\n')`, which always does the equivalent of return and line feed on the virtual screen). With translation off, curses can sometimes speed up vertical motion a little; also, it will be able to detect the return key on input.

`curses.noqiflush()`

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the INTR, QUIT and SUSP characters will not be done. You may want to call `noqiflush()` in a signal handler if you want output to continue as though the interrupt had not occurred, after the handler exits.

`curses.noraw()`

Leave raw mode. Return to normal «cooked» mode with line buffering.

`curses.pair_content(pair_number)`

Return a tuple (*fg*, *bg*) containing the colors for the requested color pair. The value of *pair_number* must be between 0 and `COLOR_PAIRS - 1`.

`curses.pair_number(attr)`

Return the number of the color-pair set by the attribute value *attr*. `color_pair()` is the counterpart to this function.

`curses.putp(str)`

Equivalent to `tputs(str, 1, putchar)`; emit the value of a specified terminfo capability for the current terminal. Note that the output of `putp()` always goes to standard output.

`curses.qiflush([flag])`

If *flag* is `False`, the effect is the same as calling `noqiflush()`. If *flag* is `True`, or no argument is provided, the queues will be flushed when these control characters are read.

`curses.raw()`

Enter raw mode. In raw mode, normal line buffering and processing of interrupt, quit, suspend, and flow control keys are turned off; characters are presented to curses input functions one by one.

`curses.reset_prog_mode()`

Restore the terminal to «program» mode, as previously saved by `def_prog_mode()`.

`curses.reset_shell_mode()`

Restore the terminal to «shell» mode, as previously saved by `def_shell_mode()`.

`curses.resetty()`

Restore the state of the terminal modes to what it was at the last call to `savetty()`.

`curses.resize_term(nlines, ncols)`

Backend function used by `resizeterm()`, performing most of the work; when resizing the windows, `resize_term()` blank-fills the areas that are extended. The calling application should fill in these areas with appropriate data. The `resize_term()` function attempts to resize all windows. However, due to the calling convention of pads, it is not possible to resize these without additional interaction with the application.

`curses.resizeterm(nlines, ncols)`

Resize the standard and current windows to the specified dimensions, and adjusts other bookkeeping data used by the curses library that record the window dimensions (in particular the SIGWINCH handler).

`curses.savetty()`

Save the current state of the terminal modes in a buffer, usable by `resetty()`.

`curses.get_escdelay()`

Retrieves the value set by `set_escdelay()`.

Νέο στην έκδοση 3.9.

`curses.set_escdelay(ms)`

Sets the number of milliseconds to wait after reading an escape character, to distinguish between an individual escape character entered on the keyboard from escape sequences sent by cursor and function keys.

Νέο στην έκδοση 3.9.

`curses.get_tabsize()`

Retrieves the value set by `set_tabsize()`.

Νέο στην έκδοση 3.9.

`curses.set_tabsize(size)`

Sets the number of columns used by the curses library when converting a tab character to spaces as it adds the tab to a window.

Νέο στην έκδοση 3.9.

`curses.setsyx(y, x)`

Set the virtual screen cursor to `y, x`. If `y` and `x` are both `-1`, then `leaveok` is set `True`.

`curses.setupterm(term=None, fd=-1)`

Initialize the terminal. `term` is a string giving the terminal name, or `None`; if omitted or `None`, the value of the `TERM` environment variable will be used. `fd` is the file descriptor to which any initialization sequences will be sent; if not supplied or `-1`, the file descriptor for `sys.stdout` will be used.

`curses.start_color()`

Must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after `initscr()`.

`start_color()` initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables in the `curses` module, `COLORS` and `COLOR_PAIRS`, containing the maximum number of colors and color-pairs the terminal can support. It also restores the colors on the terminal to the values they had when the terminal was just turned on.

`curses.termattrs()`

Return a logical OR of all video attributes supported by the terminal. This information is useful when a curses program needs complete control over the appearance of the screen.

`curses.termname()`

Return the value of the environment variable `TERM`, as a bytes object, truncated to 14 characters.

`curses.tigetflag(capname)`

Return the value of the Boolean capability corresponding to the terminfo capability name *capname* as an integer. Return the value `-1` if *capname* is not a Boolean capability, or `0` if it is canceled or absent from the terminal description.

`curses.tigetnum(capname)`

Return the value of the numeric capability corresponding to the terminfo capability name *capname* as an integer. Return the value `-2` if *capname* is not a numeric capability, or `-1` if it is canceled or absent from the terminal description.

`curses.tigetstr(capname)`

Return the value of the string capability corresponding to the terminfo capability name *capname* as a bytes object. Return `None` if *capname* is not a terminfo «string capability», or is canceled or absent from the terminal description.

`curses.tparm(str[, ...])`

Instantiate the bytes object *str* with the supplied parameters, where *str* should be a parameterized string obtained from the terminfo database. E.g. `tparm(tigetstr("cup"), 5, 3)` could result in `b'\033[6;4H'`, the exact result depending on terminal type.

`curses.typeahead(fd)`

Specify that the file descriptor *fd* be used for typeahead checking. If *fd* is `-1`, then no typeahead checking is done.

The curses library does «line-breakout optimization» by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh` or `doupdate` is called again, allowing faster response to commands typed in advance. This function allows specifying a different file descriptor for typeahead checking.

`curses.unctrl(ch)`

Return a bytes object which is a printable representation of the character *ch*. Control characters are represented as a caret followed by the character, for example as `b'^C'`. Printing characters are left as they are.

`curses.ungetch(ch)`

Push *ch* so the next `getch()` will return it.

Σημείωση: Only one *ch* can be pushed before `getch()` is called.

`curses.update_lines_cols()`

Update `LINES` and `COLS`. Useful for detecting manual screen resize.

Νέο στην έκδοση 3.5.

`curses.unget_wch(ch)`

Push *ch* so the next `get_wch()` will return it.

Σημείωση: Only one *ch* can be pushed before `get_wch()` is called.

Νέο στην έκδοση 3.3.

`curses.ungetmouse(id, x, y, z, bstate)`

Push a `KEY_MOUSE` event onto the input queue, associating the given state data with it.

`curses.use_env(flag)`

If used, this function should be called before `initscr()` or `newterm` are called. When *flag* is `False`, the values of lines and columns specified in the terminfo database will be used, even if environment variables `LINES` and `COLUMNS` (used by default) are set, or if curses is running in a window (in which case default behavior would be to use the window size if `LINES` and `COLUMNS` are not set).

`curses.use_default_colors()`

Allow use of default values for colors on terminals supporting this feature. Use this to support transparency in your application. The default color is assigned to the color number `-1`. After calling this function, `init_pair(x, curses.COLOR_RED, -1)` initializes, for instance, color pair `x` to a red foreground color on the default background.

`curses.wrapper(func, /, *args, **kwargs)`

Initialize curses and call another callable object, *func*, which should be the rest of your curses-using application. If the application raises an exception, this function will restore the terminal to a sane state before re-raising the exception and generating a traceback. The callable object *func* is then passed the main window “`stdscr`” as its first argument, followed by any other arguments passed to `wrapper()`. Before calling *func*, `wrapper()` turns on cbreak mode, turns off echo, enables the terminal keypad, and initializes colors if the terminal has color support. On exit (whether normally or by exception) it restores cooked mode, turns on echo, and disables the terminal keypad.

16.10.2 Window Objects

Window objects, as returned by `initscr()` and `newwin()` above, have the following methods and attributes:

`window.addch(ch[, attr])`

`window.addch(y, x, ch[, attr])`

Paint character *ch* at (*y*, *x*) with attributes *attr*, overwriting any character previously painted at that location. By default, the character position and attributes are the current settings for the window object.

Σημείωση: Writing outside the window, subwindow, or pad raises a `curses.error`. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the character is printed.

`window.addnstr(str, n[, attr])`

`window.addnstr(y, x, str, n[, attr])`

Paint at most *n* characters of the character string *str* at (*y*, *x*) with attributes *attr*, overwriting anything previously on the display.

`window.addstr(str[, attr])`

`window.addstr(y, x, str[, attr])`

Paint the character string *str* at (*y*, *x*) with attributes *attr*, overwriting anything previously on the display.

Σημείωση:

- Writing outside the window, subwindow, or pad raises `curses.error`. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the string is printed.
 - A bug in `ncurses`, the backend for this Python module, can cause SegFaults when resizing windows. This is fixed in `ncurses-6.1-20190511`. If you are stuck with an earlier `ncurses`, you can avoid triggering this if you do not call `addstr()` with a *str* that has embedded newlines. Instead, call `addstr()` separately for each line.
-

`window.attroff(attr)`

Remove attribute *attr* from the «background» set applied to all writes to the current window.

`window.attron(attr)`

Add attribute *attr* from the «background» set applied to all writes to the current window.

`window.attrset(attr)`

Set the «background» set of attributes to *attr*. This set is initially 0 (no attributes).

`window.bkgd(ch[, attr])`

Set the background property of the window to the character *ch*, with attributes *attr*. The change is then applied to every character position in that window:

- The attribute of every character in the window is changed to the new background attribute.
- Wherever the former background character appears, it is changed to the new background character.

`window.bkgdset(ch[, attr])`

Set the window's background. A window's background consists of a character and any combination of attributes. The attribute part of the background is combined (OR'ed) with all non-blank characters that are written into the window. Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations.

`window.border([ls[, rs[, ts[, bs[, tl[, tr[, bl[, br]]]]]]])`

Draw a border around the edges of the window. Each parameter specifies the character to use for a specific part of the border; see the table below for more details.

Σημείωση: A 0 value for any parameter will cause the default character to be used for that parameter. Keyword parameters can *not* be used. The defaults are listed in this table:

| Parameter | Description | Default value |
|-----------|---------------------|---------------|
| <i>ls</i> | Left side | ACS_VLINE |
| <i>rs</i> | Right side | ACS_VLINE |
| <i>ts</i> | Top | ACS_HLINE |
| <i>bs</i> | Bottom | ACS_HLINE |
| <i>tl</i> | Upper-left corner | ACS_ULCORNER |
| <i>tr</i> | Upper-right corner | ACS_URCORNER |
| <i>bl</i> | Bottom-left corner | ACS_LLCORNER |
| <i>br</i> | Bottom-right corner | ACS_LRCORNER |

`window.box([vertch, horch])`

Similar to `border()`, but both *ls* and *rs* are *vertch* and both *ts* and *bs* are *horch*. The default corner characters are always used by this function.

`window.chgat(attr)`

`window.chgat(num, attr)`

`window.chgat(y, x, attr)`

`window.chgat(y, x, num, attr)`

Set the attributes of *num* characters at the current cursor position, or at position (*y*, *x*) if supplied. If *num* is not given or is -1, the attribute will be set on all the characters to the end of the line. This function moves cursor to position (*y*, *x*) if supplied. The changed line will be touched using the `touchline()` method so that the contents will be redisplayed by the next window refresh.

`window.clear()`

Like `erase()`, but also cause the whole window to be repainted upon next call to `refresh()`.

`window.clearok(flag)`

If *flag* is True, the next call to `refresh()` will clear the window completely.

`window.clrtoeol()`

Erase from cursor to the end of the window: all lines below the cursor are deleted, and then the equivalent of `clrtoeol()` is performed.

`window.clrtoeol()`
Erase from cursor to the end of the line.

`window.cursyncup()`
Update the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

`window.delch([y, x])`
Delete any character at (y, x) .

`window.deleteln()`
Delete the line under the cursor. All following lines are moved up by one line.

`window.derwin(begin_y, begin_x)`
`window.derwin(nlines, ncols, begin_y, begin_x)`
An abbreviation for «derive window», `derwin()` is the same as calling `subwin()`, except that `begin_y` and `begin_x` are relative to the origin of the window, rather than relative to the entire screen. Return a window object for the derived window.

`window.echochar(ch[, attr])`
Add character `ch` with attribute `attr`, and immediately call `refresh()` on the window.

`window.enclose(y, x)`
Test whether the given pair of screen-relative character-cell coordinates are enclosed by the given window, returning True or False. It is useful for determining what subset of the screen windows enclose the location of a mouse event.

`window.encoding`
Encoding used to encode method arguments (Unicode strings and characters). The encoding attribute is inherited from the parent window when a subwindow is created, for example with `window.subwin()`. By default, the locale encoding is used (see `locale.getpreferredencoding()`).
Νέο στην έκδοση 3.3.

`window.erase()`
Clear the window.

`window.getbegyx()`
Return a tuple (y, x) of co-ordinates of upper-left corner.

`window.getbkgd()`
Return the given window's current background character/attribute pair.

`window.getch([y, x])`
Get a character. Note that the integer returned does *not* have to be in ASCII range: function keys, keypad keys and so on are represented by numbers higher than 255. In no-delay mode, return `-1` if there is no input, otherwise wait until a key is pressed.

`window.get_wch([y, x])`
Get a wide character. Return a character for most keys, or an integer for function keys, keypad keys, and other special keys. In no-delay mode, raise an exception if there is no input.
Νέο στην έκδοση 3.3.

`window.getkey([y, x])`
Get a character, returning a string instead of an integer, as `getch()` does. Function keys, keypad keys and other special keys return a multibyte string containing the key name. In no-delay mode, raise an exception if there is no input.

`window.getmaxyx()`
Return a tuple (y, x) of the height and width of the window.

`window.getparyx()`

Return the beginning coordinates of this window relative to its parent window as a tuple (y, x) . Return $(-1, -1)$ if this window has no parent.

`window.getstr()`

`window.getstr(n)`

`window.getstr(y, x)`

`window.getstr(y, x, n)`

Read a bytes object from the user, with primitive line editing capacity.

`window.getyx()`

Return a tuple (y, x) of current cursor position relative to the window's upper-left corner.

`window.hline(ch, n)`

`window.hline(y, x, ch, n)`

Display a horizontal line starting at (y, x) with length n consisting of the character ch .

`window.idcok(flag)`

If $flag$ is `False`, curses no longer considers using the hardware insert/delete character feature of the terminal; if $flag$ is `True`, use of character insertion and deletion is enabled. When curses is first initialized, use of character insert/delete is enabled by default.

`window.idlok(flag)`

If $flag$ is `True`, `curses` will try and use hardware line editing facilities. Otherwise, line insertion/deletion are disabled.

`window.immedok(flag)`

If $flag$ is `True`, any change in the window image automatically causes the window to be refreshed; you no longer have to call `refresh()` yourself. However, it may degrade performance considerably, due to repeated calls to `wrefresh`. This option is disabled by default.

`window.inch([y, x])`

Return the character at the given position in the window. The bottom 8 bits are the character proper, and upper bits are the attributes.

`window.insch(ch[, attr])`

`window.insch(y, x, ch[, attr])`

Paint character ch at (y, x) with attributes $attr$, moving the line from position x right by one character.

`window.insdelln(nlines)`

Insert $nlines$ lines into the specified window above the current line. The $nlines$ bottom lines are lost. For negative $nlines$, delete $nlines$ lines starting with the one under the cursor, and move the remaining lines up. The bottom $nlines$ lines are cleared. The current cursor position remains the same.

`window.insertln()`

Insert a blank line under the cursor. All following lines are moved down by one line.

`window.insnstr(str, n[, attr])`

`window.insnstr(y, x, str, n[, attr])`

Insert a character string (as many characters as will fit on the line) before the character under the cursor, up to n characters. If n is zero or negative, the entire string is inserted. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to y, x , if specified).

`window.insstr(str[, attr])`

`window.insstr(y, x, str[, attr])`

Insert a character string (as many characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to y, x , if specified).

`window.instr([n])`
`window.instr(y, x[, n])`
 Return a bytes object of characters, extracted from the window starting at the current cursor position, or at *y, x* if specified. Attributes are stripped from the characters. If *n* is specified, `instr()` returns a string at most *n* characters long (exclusive of the trailing NUL).

`window.is_linetouched(line)`
 Return True if the specified line was modified since the last call to `refresh()`; otherwise return False. Raise a `curses.error` exception if *line* is not valid for the given window.

`window.is_wintouched()`
 Return True if the specified window was modified since the last call to `refresh()`; otherwise return False.

`window.keypad(flag)`
 If *flag* is True, escape sequences generated by some keys (keypad, function keys) will be interpreted by `curses`. If *flag* is False, escape sequences will be left as is in the input stream.

`window.leaveok(flag)`
 If *flag* is True, cursor is left where it is on update, instead of being at «cursor position.» This reduces cursor movement where possible. If possible the cursor will be made invisible.
 If *flag* is False, cursor will always be at «cursor position» after an update.

`window.move(new_y, new_x)`
 Move cursor to (*new_y*, *new_x*).

`window.mvderwin(y, x)`
 Move the window inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

`window.mvwin(new_y, new_x)`
 Move the window so its upper-left corner is at (*new_y*, *new_x*).

`window.nodelay(flag)`
 If *flag* is True, `getch()` will be non-blocking.

`window.notimeout(flag)`
 If *flag* is True, escape sequences will not be timed out.
 If *flag* is False, after a few milliseconds, an escape sequence will not be interpreted, and will be left in the input stream as is.

`window.noutrefresh()`
 Mark for refresh but wait. This function updates the data structure representing the desired state of the window, but does not force an update of the physical screen. To accomplish that, call `doupdate()`.

`window.overlay(destwin[, sminrow, smincol, dminrow, dmincol, dmaxrow, dmaxcol])`
 Overlay the window on top of *destwin*. The windows need not be the same size, only the overlapping region is copied. This copy is non-destructive, which means that the current background character does not overwrite the old contents of *destwin*.
 To get fine-grained control over the copied region, the second form of `overlay()` can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, and the other variables mark a rectangle in the destination window.

`window.overwrite(destwin[, sminrow, smincol, dminrow, dmincol, dmaxrow, dmaxcol])`
 Overwrite the window on top of *destwin*. The windows need not be the same size, in which case only the overlapping region is copied. This copy is destructive, which means that the current background character overwrites the old contents of *destwin*.
 To get fine-grained control over the copied region, the second form of `overwrite()` can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, the other variables mark a rectangle in the destination

window.

window.**putwin**(*file*)

Write all data associated with the window into the provided file object. This information can be later retrieved using the *getwin()* function.

window.**redrawln**(*beg*, *num*)

Indicate that the *num* screen lines, starting at line *beg*, are corrupted and should be completely redrawn on the next *refresh()* call.

window.**redrawwin**()

Touch the entire window, causing it to be completely redrawn on the next *refresh()* call.

window.**refresh**([*pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*])

Update the display immediately (sync actual screen with previous drawing/deleting methods).

The 6 optional arguments can only be specified when the window is a pad created with *newpad()*. The additional parameters are needed to indicate what part of the pad and screen are involved. *pminrow* and *pmincol* specify the upper left-hand corner of the rectangle to be displayed in the pad. *sminrow*, *smincol*, *smaxrow*, and *smaxcol* specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of *pminrow*, *pmincol*, *sminrow*, or *smincol* are treated as if they were zero.

window.**resize**(*nlines*, *ncols*)

Reallocate storage for a curses window to adjust its dimensions to the specified values. If either dimension is larger than the current values, the window's data is filled with blanks that have the current background rendition (as set by *bkgdset()*) merged into them.

window.**scroll**([*lines=1*])

Scroll the screen or scrolling region upward by *lines* lines.

window.**scrollok**(*flag*)

Control what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If *flag* is *False*, the cursor is left on the bottom line. If *flag* is *True*, the window is scrolled up one line. Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call *idlok()*.

window.**setscrreg**(*top*, *bottom*)

Set the scrolling region from line *top* to line *bottom*. All scrolling actions will take place in this region.

window.**standend**()

Turn off the standout attribute. On some terminals this has the side effect of turning off all attributes.

window.**standout**()

Turn on attribute *A_STANDOUT*.

window.**subpad**(*begin_y*, *begin_x*)

window.**subpad**(*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a sub-window, whose upper-left corner is at (*begin_y*, *begin_x*), and whose width/height is *ncols/nlines*.

window.**subwin**(*begin_y*, *begin_x*)

window.**subwin**(*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a sub-window, whose upper-left corner is at (*begin_y*, *begin_x*), and whose width/height is *ncols/nlines*.

By default, the sub-window will extend from the specified position to the lower right corner of the window.

window.**syncdown**()

Touch each location in the window that has been touched in any of its ancestor windows. This routine is called by

`refresh()`, so it should almost never be necessary to call it manually.

`window.syncok(flag)`

If `flag` is `True`, then `syncup()` is called automatically whenever there is a change in the window.

`window.syncup()`

Touch all locations in ancestors of the window that have been changed in the window.

`window.timeout(delay)`

Set blocking or non-blocking read behavior for the window. If `delay` is negative, blocking read is used (which will wait indefinitely for input). If `delay` is zero, then non-blocking read is used, and `getch()` will return `-1` if no input is waiting. If `delay` is positive, then `getch()` will block for `delay` milliseconds, and return `-1` if there is still no input at the end of that time.

`window.touchline(start, count[, changed])`

Pretend `count` lines have been changed, starting with line `start`. If `changed` is supplied, it specifies whether the affected lines are marked as having been changed (`changed=True`) or unchanged (`changed=False`).

`window.touchwin()`

Pretend the whole window has been changed, for purposes of drawing optimizations.

`window.untouchwin()`

Mark all lines in the window as unchanged since the last call to `refresh()`.

`window.vline(ch, n)`

`window.vline(y, x, ch, n)`

Display a vertical line starting at `(y, x)` with length `n` consisting of the character `ch`.

16.10.3 Constants

The `curses` module defines the following data members:

`curses.ERR`

Some curses routines that return an integer, such as `getch()`, return `ERR` upon failure.

`curses.OK`

Some curses routines that return an integer, such as `napms()`, return `OK` upon success.

`curses.version`

A bytes object representing the current version of the module. Also available as `__version__`.

`curses.ncurses_version`

A named tuple containing the three components of the ncurses library version: *major*, *minor*, and *patch*. All values are integers. The components can also be accessed by name, so `curses.ncurses_version[0]` is equivalent to `curses.ncurses_version.major` and so on.

Availability: if the ncurses library is used.

Νέο στην έκδοση 3.8.

Some constants are available to specify character cell attributes. The exact constants available are system dependent.

| Attribute | Meaning |
|--------------|--|
| A_ALTCHARSET | Alternate character set mode |
| A_BLINK | Blink mode |
| A_BOLD | Bold mode |
| A_DIM | Dim mode |
| A_INVIS | Invisible or blank mode |
| A_ITALIC | Italic mode |
| A_NORMAL | Normal attribute |
| A_PROTECT | Protected mode |
| A_REVERSE | Reverse background and foreground colors |
| A_STANDOUT | Standout mode |
| A_UNDERLINE | Underline mode |
| A_HORIZONTAL | Horizontal highlight |
| A_LEFT | Left highlight |
| A_LOW | Low highlight |
| A_RIGHT | Right highlight |
| A_TOP | Top highlight |
| A_VERTICAL | Vertical highlight |
| A_CHARTEXT | Bit-mask to extract a character |

Νέο στην έκδοση 3.7: A_ITALIC was added.

Several constants are available to extract corresponding attributes returned by some methods.

| Bit-mask | Meaning |
|--------------|--|
| A_ATTRIBUTES | Bit-mask to extract attributes |
| A_CHARTEXT | Bit-mask to extract a character |
| A_COLOR | Bit-mask to extract color-pair field information |

Keys are referred to by integer constants with names starting with KEY_. The exact keycaps available are system dependent.

| Key constant | Key |
|---------------|--|
| KEY_MIN | Minimum key value |
| KEY_BREAK | Break key (unreliable) |
| KEY_DOWN | Down-arrow |
| KEY_UP | Up-arrow |
| KEY_LEFT | Left-arrow |
| KEY_RIGHT | Right-arrow |
| KEY_HOME | Home key (upward+left arrow) |
| KEY_BACKSPACE | Backspace (unreliable) |
| KEY_F0 | Function keys. Up to 64 function keys are supported. |
| KEY_Fn | Value of function key <i>n</i> |
| KEY_DL | Delete line |
| KEY_IL | Insert line |
| KEY_DC | Delete character |
| KEY_IC | Insert char or enter insert mode |
| KEY_EIC | Exit insert char mode |
| KEY_CLEAR | Clear screen |
| KEY_EOS | Clear to end of screen |

| KEY_SUNDO | Shifted Undo |
| KEY_SUSPEND | Suspend |
| KEY_UNDO | Undo |
| KEY_MOUSE | Mouse event has occurred |
| KEY_RESIZE | Terminal resize event |
| KEY_MAX | Maximum key value |

On VT100s and their software emulations, such as X terminal emulators, there are normally at least four function keys (`KEY_F1`, `KEY_F2`, `KEY_F3`, `KEY_F4`) available, and the arrow keys mapped to `KEY_UP`, `KEY_DOWN`, `KEY_LEFT` and `KEY_RIGHT` in the obvious way. If your machine has a PC keyboard, it is safe to expect arrow keys and twelve function keys (older PC keyboards may have only ten function keys); also, the following keypad mappings are standard:

| Keycap | Constant |
|-----------|------------------------|
| Insert | <code>KEY_IC</code> |
| Delete | <code>KEY_DC</code> |
| Home | <code>KEY_HOME</code> |
| End | <code>KEY_END</code> |
| Page Up | <code>KEY_PPAGE</code> |
| Page Down | <code>KEY_NPAGE</code> |

The following table lists characters from the alternate character set. These are inherited from the VT100 terminal, and will generally be available on software emulations such as X terminals. When there is no graphic available, curses falls back on a crude printable ASCII approximation.

Σημείωση: These are available only after `initscr()` has been called.

| ACS code | Meaning |
|--------------|--|
| ACS_BBSS | alternate name for upper right corner |
| ACS_BLOCK | solid square block |
| ACS_BOARD | board of squares |
| ACS_BSBS | alternate name for horizontal line |
| ACS_BSSB | alternate name for upper left corner |
| ACS_BSSS | alternate name for top tee |
| ACS_BTEE | bottom tee |
| ACS_BULLET | bullet |
| ACS_CKBOARD | checker board (stipple) |
| ACS_DARROW | arrow pointing down |
| ACS_DEGREE | degree symbol |
| ACS_DIAMOND | diamond |
| ACS_GEQUAL | greater-than-or-equal-to |
| ACS_HLINE | horizontal line |
| ACS_LANTERN | lantern symbol |
| ACS_LARROW | left arrow |
| ACS_LEQUAL | less-than-or-equal-to |
| ACS_LLCORNER | lower left-hand corner |
| ACS_LRCORNER | lower right-hand corner |
| ACS_LTEE | left tee |
| ACS_NEQUAL | not-equal sign |
| ACS_PI | letter pi |
| ACS_PLMINUS | plus-or-minus sign |
| ACS_PLUS | big plus sign |
| ACS_RARROW | right arrow |
| ACS_RTEE | right tee |
| ACS_S1 | scan line 1 |
| ACS_S3 | scan line 3 |
| ACS_S7 | scan line 7 |
| ACS_S9 | scan line 9 |
| ACS_SBBS | alternate name for lower right corner |
| ACS_SBSB | alternate name for vertical line |
| ACS_SBSS | alternate name for right tee |
| ACS_SSBB | alternate name for lower left corner |
| ACS_SSBS | alternate name for bottom tee |
| ACS_SSSB | alternate name for left tee |
| ACS_SSSS | alternate name for crossover or big plus |
| ACS_STERLING | pound sterling |
| ACS_TTEE | top tee |
| ACS_UARROW | up arrow |
| ACS_ULCORNER | upper left corner |
| ACS_URCORNER | upper right corner |
| ACS_VLINE | vertical line |

The following table lists the predefined colors:

| Constant | Color |
|---------------|----------------------------|
| COLOR_BLACK | Black |
| COLOR_BLUE | Blue |
| COLOR_CYAN | Cyan (light greenish blue) |
| COLOR_GREEN | Green |
| COLOR_MAGENTA | Magenta (purplish red) |
| COLOR_RED | Red |
| COLOR_WHITE | White |
| COLOR_YELLOW | Yellow |

16.11 `curses.textpad` — Text input widget for curses programs

The `curses.textpad` module provides a `Textbox` class that handles elementary text editing in a curses window, supporting a set of keybindings resembling those of Emacs (thus, also of Netscape Navigator, BBedit 6.x, FrameMaker, and many other programs). The module also provides a rectangle-drawing function useful for framing text boxes or for other purposes.

The module `curses.textpad` defines the following function:

`curses.textpad.rectangle` (*win, uly, ulx, lry, lrx*)

Draw a rectangle. The first argument must be a window object; the remaining arguments are coordinates relative to that window. The second and third arguments are the y and x coordinates of the upper left hand corner of the rectangle to be drawn; the fourth and fifth arguments are the y and x coordinates of the lower right hand corner. The rectangle will be drawn using VT100/IBM PC forms characters on terminals that make this possible (including xterm and most other software terminal emulators). Otherwise it will be drawn with ASCII dashes, vertical bars, and plus signs.

16.11.1 Textbox objects

You can instantiate a `Textbox` object as follows:

class `curses.textpad.Textbox` (*win*)

Return a textbox widget object. The *win* argument should be a curses *window* object in which the textbox is to be contained. The edit cursor of the textbox is initially located at the upper left hand corner of the containing window, with coordinates (0, 0). The instance's `stripspaces` flag is initially on.

`Textbox` objects have the following methods:

edit ([*validator*])

This is the entry point you will normally use. It accepts editing keystrokes until one of the termination keystrokes is entered. If *validator* is supplied, it must be a function. It will be called for each keystroke entered with the keystroke as a parameter; command dispatch is done on the result. This method returns the window contents as a string; whether blanks in the window are included is affected by the `stripspaces` attribute.

do_command (*ch*)

Process a single command keystroke. Here are the supported special keystrokes:

| Keystroke | Action |
|-----------|---|
| Control-A | Go to left edge of window. |
| Control-B | Cursor left, wrapping to previous line if appropriate. |
| Control-D | Delete character under cursor. |
| Control-E | Go to right edge (stripspaces off) or end of line (stripspaces on). |
| Control-F | Cursor right, wrapping to next line when appropriate. |
| Control-G | Terminate, returning the window contents. |
| Control-H | Delete character backward. |
| Control-J | Terminate if the window is 1 line, otherwise insert newline. |
| Control-K | If line is blank, delete it, otherwise clear to end of line. |
| Control-L | Refresh screen. |
| Control-N | Cursor down; move down one line. |
| Control-O | Insert a blank line at cursor location. |
| Control-P | Cursor up; move up one line. |

Move operations do nothing if the cursor is at an edge where the movement is not possible. The following synonyms are supported where possible:

| Constant | Keystroke |
|---------------|-----------|
| KEY_LEFT | Control-B |
| KEY_RIGHT | Control-F |
| KEY_UP | Control-P |
| KEY_DOWN | Control-N |
| KEY_BACKSPACE | Control-h |

All other keystrokes are treated as a command to insert the given character and move right (with line wrapping).

gather()

Return the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* member.

stripspaces

This attribute is a flag which controls the interpretation of blanks in the window. When it is on, trailing blanks on each line are ignored; any cursor motion that would land the cursor on a trailing blank goes to the end of that line instead, and trailing blanks are stripped when the window contents are gathered.

16.12 `curses.ascii` — Utilities for ASCII characters

The `curses.ascii` module supplies name constants for ASCII characters and functions to test membership in various ASCII character classes. The constants supplied are names for control characters as follows:

| Name | Meaning |
|------|-------------------------------------|
| NUL | |
| SOH | Start of heading, console interrupt |
| STX | Start of text |
| ETX | End of text |
| EOT | End of transmission |

Συνεχίζεται στην επόμενη σελίδα

Πίνακας 3 – συνεχίζεται από την προηγούμενη σελίδα

| Name | Meaning |
|------|---|
| ENQ | Enquiry, goes with ACK flow control |
| ACK | Acknowledgement |
| BEL | Bell |
| BS | Backspace |
| TAB | Tab |
| HT | Alias for TAB: «Horizontal tab» |
| LF | Line feed |
| NL | Alias for LF: «New line» |
| VT | Vertical tab |
| FF | Form feed |
| CR | Carriage return |
| SO | Shift-out, begin alternate character set |
| SI | Shift-in, resume default character set |
| DLE | Data-link escape |
| DC1 | XON, for flow control |
| DC2 | Device control 2, block-mode flow control |
| DC3 | XOFF, for flow control |
| DC4 | Device control 4 |
| NAK | Negative acknowledgement |
| SYN | Synchronous idle |
| ETB | End transmission block |
| CAN | Cancel |
| EM | End of medium |
| SUB | Substitute |
| ESC | Escape |
| FS | File separator |
| GS | Group separator |
| RS | Record separator, block-mode terminator |
| US | Unit separator |
| SP | Space |
| DEL | Delete |

Note that many of these have little practical significance in modern usage. The mnemonics derive from teleprinter conventions that predate digital computers.

The module supplies the following functions, patterned on those in the standard C library:

`curses.ascii.isalnum(c)`

Checks for an ASCII alphanumeric character; it is equivalent to `isalpha(c)` or `isdigit(c)`.

`curses.ascii.isalpha(c)`

Checks for an ASCII alphabetic character; it is equivalent to `isupper(c)` or `islower(c)`.

`curses.ascii.isascii(c)`

Checks for a character value that fits in the 7-bit ASCII set.

`curses.ascii.isblank(c)`

Checks for an ASCII whitespace character; space or horizontal tab.

`curses.ascii.iscntrl(c)`

Checks for an ASCII control character (in the range 0x00 to 0x1f or 0x7f).

`curses.ascii.isdigit(c)`

Checks for an ASCII decimal digit, '0' through '9'. This is equivalent to `c in string.digits`.

`curses.ascii.isgraph(c)`

Checks for ASCII any printable character except space.

`curses.ascii.islower(c)`

Checks for an ASCII lower-case character.

`curses.ascii.isprint(c)`

Checks for any ASCII printable character including space.

`curses.ascii.ispunct(c)`

Checks for any printable ASCII character which is not a space or an alphanumeric character.

`curses.ascii.isspace(c)`

Checks for ASCII white-space characters; space, line feed, carriage return, form feed, horizontal tab, vertical tab.

`curses.ascii.isupper(c)`

Checks for an ASCII uppercase letter.

`curses.ascii.isxdigit(c)`

Checks for an ASCII hexadecimal digit. This is equivalent to `c in string.hexdigits`.

`curses.ascii.isctrl(c)`

Checks for an ASCII control character (ordinal values 0 to 31).

`curses.ascii.ismeta(c)`

Checks for a non-ASCII character (ordinal values 0x80 and above).

These functions accept either integers or single-character strings; when the argument is a string, it is first converted using the built-in function `ord()`.

Note that all these functions check ordinal bit values derived from the character of the string you pass in; they do not actually know anything about the host machine's character encoding.

The following two functions take either a single-character string or integer byte value; they return a value of the same type.

`curses.ascii.asciic(c)`

Return the ASCII value corresponding to the low 7 bits of *c*.

`curses.ascii.ctrl(c)`

Return the control character corresponding to the given character (the character bit value is bitwise-anded with 0x1f).

`curses.ascii.alt(c)`

Return the 8-bit character corresponding to the given ASCII character (the character bit value is bitwise-ored with 0x80).

The following function takes either a single-character string or integer value; it returns a string.

`curses.ascii.unctrl(c)`

Return a string representation of the ASCII character *c*. If *c* is printable, this string is the character itself. If the character is a control character (0x00–0x1f) the string consists of a caret ('^') followed by the corresponding uppercase letter. If the character is an ASCII delete (0x7f) the string is '^?'. If the character has its meta bit (0x80) set, the meta bit is stripped, the preceding rules applied, and '!' prepended to the result.

`curses.ascii.controlnames`

A 33-element string array that contains the ASCII mnemonics for the thirty-two ASCII control characters from 0 (NUL) to 0x1f (US), in order, plus the mnemonic SP for the space character.

16.13 `curses.panel` — A panel stack extension for curses

Panels are windows with the added feature of depth, so they can be stacked on top of each other, and only the visible portions of each window will be displayed. Panels can be added, moved up or down in the stack, and removed.

16.13.1 Functions

The module `curses.panel` defines the following functions:

`curses.panel.bottom_panel()`

Returns the bottom panel in the panel stack.

`curses.panel.new_panel(win)`

Returns a panel object, associating it with the given window *win*. Be aware that you need to keep the returned panel object referenced explicitly. If you don't, the panel object is garbage collected and removed from the panel stack.

`curses.panel.top_panel()`

Returns the top panel in the panel stack.

`curses.panel.update_panels()`

Updates the virtual screen after changes in the panel stack. This does not call `curses.doupdate()`, so you'll have to do this yourself.

16.13.2 Panel Objects

Panel objects, as returned by `new_panel()` above, are windows with a stacking order. There's always a window associated with a panel which determines the content, while the panel methods are responsible for the window's depth in the panel stack.

Panel objects have the following methods:

`Panel.above()`

Returns the panel above the current panel.

`Panel.below()`

Returns the panel below the current panel.

`Panel.bottom()`

Push the panel to the bottom of the stack.

`Panel.hidden()`

Returns True if the panel is hidden (not visible), False otherwise.

`Panel.hide()`

Hide the panel. This does not delete the object, it just makes the window on screen invisible.

`Panel.move(y, x)`

Move the panel to the screen coordinates `(y, x)`.

`Panel.replace(win)`

Change the window associated with the panel to the window *win*.

`Panel.set_userptr(obj)`

Set the panel's user pointer to *obj*. This is used to associate an arbitrary piece of data with the panel, and can be any Python object.

`Panel.show()`
Display the panel (which might have been hidden).

`Panel.top()`
Push panel to the top of the stack.

`Panel.userptr()`
Returns the user pointer for the panel. This might be any Python object.

`Panel.window()`
Returns the window object associated with the panel.

16.14 platform — Access to underlying platform’s identifying data

Πηγαίος κώδικας: [Lib/platform.py](#)

Σημείωση: Συγκεκριμένες πλατφόρμες καταγεγραμμένες αλφαβητικά, με το Linux να περιλαμβάνεται στην ενότητα Unix.

16.14.1 Cross Platform

`platform.architecture(executable=sys.executable, bits="", linkage="")`
Υποβάλλει ερώτημα στο δεδομένο εκτελέσιμο αρχείο (προεπιλογή είναι το εκτελέσιμο του δυαδικού διεργασιών Python) για διάφορες πληροφορίες αρχιτεκτονικής.

Επιστρέφει μια πλειάδα (`bits`, `linkage`) που περιέχει πληροφορίες για την αρχιτεκτονική των bit και την μορφή σύνδεσης που χρησιμοποιείται για το εκτελέσιμο αρχείο. Και οι δύο τιμές επιστρέφονται ως συμβολοσειρές.

Οι τιμές που δεν μπορούν να προσδιοριστούν επιστρέφονται όπως δίνονται από τις προκαθορισμένες παραμέτρους. Αν η τιμή του `bits` δοθεί ως `' '`, τότε χρησιμοποιείται το `sizeof(pointer)` (ή το `sizeof(long)` στην έκδοση Python < 1.5.2) ως δείκτης για το υποστηριζόμενο μέγεθος δεικτών.

Η συνάρτηση βασίζεται στην εντολή του συστήματος `file` για την εκτέλεση της πραγματικής εργασίας. Αυτή είναι διαθέσιμη στα περισσότερα αν όχι σε όλα τα συστήματα Unix και σε ορισμένα μη-Unix συστήματα, και μόνο αν το εκτελέσιμο δείχνει στον διεργασιών της Python. Χρησιμοποιούνται εύλογες προεπιλεγμένες τιμές όταν οι παραπάνω προϋποθέσεις δεν πληρούνται.
