## Table des matières

---

<b>1</b>	<b>Introduction</b>	<b>3</b>
<b>2</b>	<b>Fonctions natives</b>	<b>5</b>
<b>3</b>	<b>Non-essential Built-in Functions</b>	<b>27</b>
<b>4</b>	<b>Constantes natives</b>	<b>29</b>
4.1	Constantes ajoutées par le module <code>site</code>	30
<b>5</b>	<b>Types natifs</b>	<b>31</b>
5.1	Valeurs booléennes	31
5.2	Opérations booléennes — <code>and</code> , <code>or</code> , <code>not</code>	32
5.3	Comparaisons	32
5.4	Numeric Types — <code>int</code> , <code>float</code> , <code>long</code> , <code>complex</code>	33
5.5	Les types itérateurs	37
5.6	Sequence Types — <code>str</code> , <code>unicode</code> , <code>list</code> , <code>tuple</code> , <code>bytearray</code> , <code>buffer</code> , <code>xrange</code>	37
5.7	Types d'ensembles — <code>set</code> , <code>frozenset</code>	49
5.8	Les types de correspondances — <code>dict</code>	51
5.9	Objets fichiers	56
5.10	<code>memoryview</code> type	59
5.11	Le type gestionnaire de contexte	61
5.12	Autres types natifs	62
5.13	Attributs Spéciaux	64
<b>6</b>	<b>Exceptions natives</b>	<b>67</b>
6.1	Hierarchie des exceptions	72
<b>7</b>	<b>String Services</b>	<b>75</b>
7.1	<code>string</code> — Opérations usuelles sur des chaînes	75
7.2	<code>re</code> — Opérations à base d'expressions rationnelles	88
7.3	<code>struct</code> — Interpret strings as packed binary data	105
7.4	<code>difflib</code> — Helpers for computing deltas	109
7.5	<code>StringIO</code> — Read and write strings as files	119
7.6	<code>cStringIO</code> — Faster version of <code>StringIO</code>	120
7.7	<code>textwrap</code> — Text wrapping and filling	121
7.8	<code>codecs</code> — Codec registry and base classes	123
7.9	<code>unicodedata</code> — Base de données Unicode	137

7.10	<code>stringprep</code> — Internet String Preparation . . . . .	139
7.11	<code>fpformat</code> — Floating point conversions . . . . .	140
<b>8</b>	<b>Types de données</b>	<b>143</b>
8.1	<code>datetime</code> — Types de base pour la date et l’heure . . . . .	143
8.2	<code>calendar</code> — General calendar-related functions . . . . .	168
8.3	<code>collections</code> — High-performance container datatypes . . . . .	172
8.4	<code>heapq</code> — Heap queue algorithm . . . . .	187
8.5	<code>bisect</code> — Algorithme de bisection de listes . . . . .	191
8.6	<code>array</code> — Tableaux efficaces de valeurs numériques . . . . .	193
8.7	<code>sets</code> — Unordered collections of unique elements . . . . .	196
8.8	<code>sched</code> — Event scheduler . . . . .	199
8.9	<code>mutex</code> — Mutual exclusion support . . . . .	201
8.10	<code>Queue</code> — A synchronized queue class . . . . .	202
8.11	<code>weakref</code> — Weak references . . . . .	204
8.12	<code>UserDict</code> — Class wrapper for dictionary objects . . . . .	208
8.13	<code>UserList</code> — Class wrapper for list objects . . . . .	209
8.14	<code>UserString</code> — Class wrapper for string objects . . . . .	210
8.15	<code>types</code> — Names for built-in types . . . . .	211
8.16	<code>new</code> — Creation of runtime internal objects . . . . .	213
8.17	<code>copy</code> — Opérations de copie superficielle et récursive . . . . .	214
8.18	<code>pprint</code> — Data pretty printer . . . . .	215
8.19	<code>repr</code> — Alternate <code>repr()</code> implementation . . . . .	218
<b>9</b>	<b>Modules numériques et mathématiques</b>	<b>221</b>
9.1	<code>numbers</code> — Numeric abstract base classes . . . . .	221
9.2	Fonctions mathématiques — <code>math</code> . . . . .	224
9.3	Fonctions mathématiques pour nombres complexes — <code>cmath</code> . . . . .	228
9.4	<code>decimal</code> — Arithmétique décimale en virgule fixe et flottante . . . . .	231
9.5	<code>fractions</code> — Nombres rationnels . . . . .	256
9.6	<code>random</code> — Generate pseudo-random numbers . . . . .	258
9.7	<code>itertools</code> — Fonctions créant des itérateurs pour boucler efficacement. . . . .	262
9.8	<code>functools</code> — Fonctions de haut niveau et opérations sur des objets appelables . . . . .	277
9.9	<code>operator</code> — Standard operators as functions . . . . .	279
<b>10</b>	<b>Accès aux Fichiers et aux Dossiers</b>	<b>289</b>
10.1	<code>os.path</code> — Common pathname manipulations . . . . .	289
10.2	<code>fileinput</code> — Iterate over lines from multiple input streams . . . . .	293
10.3	<code>stat</code> — Interpreting <code>stat()</code> results . . . . .	295
10.4	<code>statvfs</code> — Constants used with <code>os.statvfs()</code> . . . . .	299
10.5	<code>filecmp</code> — File and Directory Comparisons . . . . .	300
10.6	<code>tempfile</code> — Generate temporary files and directories . . . . .	301
10.7	<code>glob</code> — Recherche de chemins de style Unix selon certains motifs . . . . .	304
10.8	<code>fnmatch</code> — Filtrage par motif des noms de fichiers Unix . . . . .	305
10.9	<code>linecache</code> — Accès direct aux lignes d’un texte . . . . .	306
10.10	<code>shutil</code> — High-level file operations . . . . .	307
10.11	<code>dircache</code> — Cached directory listings . . . . .	311
10.12	<code>macpath</code> — Fonctions de manipulation de chemins pour Mac OS 9 . . . . .	312
<b>11</b>	<b>Persistance des données</b>	<b>313</b>
11.1	<code>pickle</code> — Python object serialization . . . . .	313
11.2	<code>cPickle</code> — A faster <code>pickle</code> . . . . .	323
11.3	<code>copy_reg</code> — Register <code>pickle</code> support functions . . . . .	324
11.4	<code>shelve</code> — Objet Python persistant . . . . .	325
11.5	<code>marshal</code> — Internal Python object serialization . . . . .	327

11.6	<code>anydbm</code> — Generic access to DBM-style databases	329
11.7	<code>whichdb</code> — Guess which DBM module created a database	330
11.8	<code>dbm</code> — Simple « database » interface	330
11.9	<code>gdbm</code> — GNU's reinterpretation of <code>dbm</code>	331
11.10	<code>dbhash</code> — DBM-style interface to the BSD database library	332
11.11	<code>bsddb</code> — Interface to Berkeley DB library	334
11.12	<code>dumbdbm</code> — Portable DBM implementation	336
11.13	<code>sqlite3</code> — DB-API 2.0 interface for SQLite databases	337
<b>12</b>	<b>Compression de donnée et archivage</b>	<b>357</b>
12.1	<code>zlib</code> — Compression compatible avec <code>gzip</code>	357
12.2	<code>gzip</code> — Support pour les fichiers <code>gzip</code>	360
12.3	<code>bz2</code> — Compression compatible with <code>bzip2</code>	362
12.4	<code>zipfile</code> — Work with ZIP archives	364
12.5	<code>tarfile</code> — Read and write tar archive files	370
<b>13</b>	<b>Formats de fichiers</b>	<b>379</b>
13.1	<code>csv</code> — Lecture et écriture de fichiers CSV	379
13.2	<code>ConfigParser</code> — Configuration file parser	387
13.3	<code>robotparser</code> — Parser for robots.txt	394
13.4	<code>netrc</code> — traitement de fichier <code>netrc</code>	395
13.5	<code>xdrllib</code> — Encode and decode XDR data	396
13.6	<code>plistlib</code> — Generate and parse Mac OS X .plist files	399
<b>14</b>	<b>Service de cryptographie</b>	<b>401</b>
14.1	<code>hashlib</code> — Secure hashes and message digests	401
14.2	<code>hmac</code> — Keyed-Hashing for Message Authentication	404
14.3	<code>md5</code> — MD5 message digest algorithm	405
14.4	<code>sha</code> — SHA-1 message digest algorithm	406
<b>15</b>	<b>Services génériques du système d'exploitation</b>	<b>407</b>
15.1	<code>os</code> — Diverses interfaces pour le système d'exploitation	407
15.2	<code>io</code> — Core tools for working with streams	435
15.3	<code>time</code> — Time access and conversions	445
15.4	<code>argparse</code> — Parseur d'arguments, d'options, et de sous-commandes de ligne de commande	451
15.5	<code>optparse</code> — Parser for command line options	481
15.6	<code>getopt</code> — C-style parser for command line options	507
15.7	<code>logging</code> — Logging facility for Python	509
15.8	<code>logging.config</code> — Logging configuration	520
15.9	<code>logging.handlers</code> — Logging handlers	530
15.10	Saisie de mot de passe portable	538
15.11	<code>curses</code> — Terminal handling for character-cell displays	539
15.12	<code>curses.textpad</code> — Text input widget for curses programs	556
15.13	<code>curses.ascii</code> — Utilities for ASCII characters	557
15.14	<code>curses.panel</code> — A panel stack extension for curses	560
15.15	<code>platform</code> — Access to underlying platform's identifying data	561
15.16	<code>errno</code> — Standard errno system symbols	564
15.17	<code>ctypes</code> — A foreign function library for Python	570
<b>16</b>	<b>Optional Operating System Services</b>	<b>605</b>
16.1	<code>select</code> — Waiting for I/O completion	605
16.2	<code>threading</code> — Higher-level threading interface	610
16.3	<code>thread</code> — Multiple threads of control	619
16.4	<code>dummy_threading</code> — Module de substitution au module <code>threading</code>	621
16.5	<code>dummy_thread</code> — Drop-in replacement for the <code>thread</code> module	621

16.6	<code>multiprocessing</code> — Process-based « threading » interface	622
16.7	<code>mmap</code> — Memory-mapped file support	675
16.8	<code>readline</code> — interface pour GNU <i>readline</i>	677
16.9	<code>rlcompleter</code> — Fonction de complétion pour <i>GNU readline</i>	681
<b>17</b>	<b>Communication et réseau entre processus</b>	<b>683</b>
17.1	<code>subprocess</code> — Gestion de sous-processus	683
17.2	<code>socket</code> — Low-level networking interface	695
17.3	<code>ssl</code> — TLS/SSL wrapper for socket objects	707
17.4	<code>signal</code> — Set handlers for asynchronous events	730
17.5	<code>popen2</code> — Subprocesses with accessible I/O streams	733
17.6	<code>asyncore</code> — Gestionnaire de socket asynchrone	735
17.7	<code>asynchat</code> — Gestionnaire d'interfaces de connexion ( <i>socket</i> ) commande/réponse asynchrones	739
<b>18</b>	<b>Traitement des données provenant d'Internet</b>	<b>743</b>
18.1	<code>email</code> — An email and MIME handling package	743
18.2	<code>json</code> — Encodage et décodage JSON	773
18.3	<code>mailcap</code> — Manipulation de fichiers Mailcap	781
18.4	<code>mailbox</code> — Manipulate mailboxes in various formats	782
18.5	<code>mhlib</code> — Access to MH mailboxes	801
18.6	<code>minetools</code> — Tools for parsing MIME messages	803
18.7	<code>mimetypes</code> — Map filenames to MIME types	804
18.8	<code>MimeWriter</code> — Generic MIME file writer	807
18.9	<code>mimify</code> — MIME processing of mail messages	807
18.10	<code>multifile</code> — Support for files containing distinct parts	809
18.11	<code>rfc822</code> — Parse RFC 2822 mail headers	811
18.12	<code>base64</code> — RFC 3548 : Base16, Base32, Base64 Data Encodings	814
18.13	<code>binhex</code> — Encode et décode les fichiers <i>binhex4</i>	816
18.14	<code>binascii</code> — Convert between binary and ASCII	817
18.15	<code>quopri</code> — Encode et décode des données <i>MIME quoted-printable</i>	819
18.16	<code>uu</code> — Encode et décode les fichiers <i>uuencode</i>	820
<b>19</b>	<b>Outils de traitement de balises structurées</b>	<b>821</b>
19.1	<code>HTMLParser</code> — Simple HTML and XHTML parser	821
19.2	<code>sgmlib</code> — Simple SGML parser	826
19.3	<code>htmlib</code> — A parser for HTML documents	829
19.4	<code>htmlentitydefs</code> — Definitions of HTML general entities	830
19.5	Modules de traitement XML	831
19.6	Vulnérabilités XML	831
19.7	<code>xml.etree.ElementTree</code> — The ElementTree XML API	832
19.8	<code>xml.dom</code> — L'API Document Object Model	845
19.9	<code>xml.dom.minidom</code> — Minimal DOM implementation	856
19.10	<code>xml.dom.pulldom</code> — Support for building partial DOM trees	860
19.11	<code>xml.sax</code> — Prise en charge des analyseurs SAX2	861
19.12	<code>xml.sax.handler</code> — Base classes for SAX handlers	863
19.13	<code>xml.sax.saxutils</code> — SAX Utilities	868
19.14	<code>xml.sax.xmlreader</code> — Interface for XML parsers	869
19.15	<code>xml.parsers.expat</code> — Fast XML parsing using Expat	872
<b>20</b>	<b>Gestion des protocoles internet</b>	<b>883</b>
20.1	<code>webbrowser</code> — Convenient Web-browser controller	883
20.2	<code>cgi</code> — Common Gateway Interface support	886
20.3	<code>cgitb</code> — Gestionnaire d'exceptions pour les scripts CGI	893
20.4	<code>wsgiref</code> — WSGI Utilities and Reference Implementation	893
20.5	<code>urllib</code> — Open arbitrary resources by URL	902

20.6	<code>urllib2</code> — extensible library for opening URLs	908
20.7	<code>httplib</code> — HTTP protocol client	919
20.8	<code>ftplib</code> — FTP protocol client	925
20.9	<code>poplib</code> — POP3 protocol client	930
20.10	<code>imaplib</code> — IMAP4 protocol client	932
20.11	<code>nntplib</code> — NNTP protocol client	938
20.12	<code>smtplib</code> — SMTP protocol client	942
20.13	<code>smtpd</code> — SMTP Server	946
20.14	<code>telnetlib</code> — Telnet client	947
20.15	<code>uuid</code> — UUID objects according to RFC 4122	950
20.16	<code>urlparse</code> — Parse URLs into components	952
20.17	<code>SocketServer</code> — A framework for network servers	957
20.18	<code>BaseHTTPServer</code> — Basic HTTP server	965
20.19	<code>SimpleHTTPServer</code> — Simple HTTP request handler	968
20.20	<code>CGIHTTPServer</code> — CGI-capable HTTP request handler	969
20.21	<code>cookielib</code> — Cookie handling for HTTP clients	970
20.22	<code>Cookie</code> — HTTP state management	978
20.23	<code>xmlrpclib</code> — XML-RPC client access	982
20.24	<code>SimpleXMLRPCServer</code> — Basic XML-RPC server	990
20.25	<code>DocXMLRPCServer</code> — Self-documenting XML-RPC server	994
<b>21</b>	<b>Services multimédia</b>	<b>997</b>
21.1	<code>audioloop</code> — Manipulation de données audio brutes	997
21.2	<code>imageop</code> — Manipulate raw image data	1000
21.3	<code>aifc</code> — Lis et écrit dans les fichiers AIFF et AIFC	1001
21.4	<code>sunau</code> — Read and write Sun AU files	1004
21.5	<code>wave</code> — Read and write WAV files	1006
21.6	<code>chunk</code> — Read IFF chunked data	1008
21.7	<code>coloursys</code> — Conversions entre les systèmes de couleurs	1009
21.8	<code>imghdr</code> — Determine the type of an image	1010
21.9	<code>sndhdr</code> — Détermine le type d'un fichier audio	1011
21.10	<code>ossaudiodev</code> — Access to OSS-compatible audio devices	1012
<b>22</b>	<b>Internationalisation</b>	<b>1017</b>
22.1	<code>gettext</code> — Services d'internationalisation multilingue	1017
22.2	<code>locale</code> — Internationalization services	1026
<b>23</b>	<b><i>Frameworks</i> d'applications</b>	<b>1035</b>
23.1	<code>cmd</code> — Interpréteurs en ligne de commande.	1035
23.2	<code>shlex</code> — Simple lexical analysis	1037
<b>24</b>	<b>Interfaces Utilisateur Graphiques avec Tk</b>	<b>1043</b>
24.1	<code>Tkinter</code> — Python interface to Tcl/Tk	1043
24.2	<code>ttk</code> — Tk themed widgets	1054
24.3	<code>Tix</code> — Extension widgets for Tk	1071
24.4	<code>ScrolledText</code> — Scrolled Text Widget	1076
24.5	<code>turtle</code> — Turtle graphics for Tk	1076
24.6	<code>IDLE</code>	1105
24.7	Autres paquets d'interface graphique utilisateur	1112
<b>25</b>	<b>Outils de développement</b>	<b>1115</b>
25.1	<code>pydoc</code> — Générateur de documentation et système d'aide en ligne	1115
25.2	<code>doctest</code> — Test interactive Python examples	1116
25.3	<code>unittest</code> — <i>Framework</i> de tests unitaires	1140
25.4	<code>2to3</code> — Traduction automatique de code en Python 2 vers Python 3	1164

25.5	<code>test</code> — Regression tests package for Python	1169
25.6	<code>test.support</code> — Utility functions for tests	1172
<b>26</b>	<b>Débogueur et instrumentation</b>	<b>1177</b>
26.1	<code>bdb</code> — Framework de débogage	1177
26.2	<code>pdb</code> — Le débogueur Python	1181
26.3	Commande du débogueur	1183
26.4	The Python Profilers	1186
26.5	<code>hotshot</code> — High performance logging profiler	1194
26.6	<code>timeit</code> — Measure execution time of small code snippets	1195
26.7	<code>trace</code> — Trace or track Python statement execution	1200
<b>27</b>	<b>Paquets et distribution de paquets logiciels</b>	<b>1203</b>
27.1	<code>distutils</code> — Création et installation des modules Python	1203
27.2	<code>ensurepip</code> — Bootstrapping the <code>pip</code> installer	1204
<b>28</b>	<b>Environnement d'exécution Python</b>	<b>1207</b>
28.1	<code>sys</code> — Paramètres et fonctions propres à des systèmes	1207
28.2	<code>sysconfig</code> — Provide access to Python's configuration information	1219
28.3	<code>__builtin__</code> — Objets natifs	1222
28.4	<code>future_builtins</code> — Python 3 builtins	1222
28.5	<code>__main__</code> — Point d'entrée des scripts	1223
28.6	<code>warnings</code> — Warning control	1223
28.7	<code>contextlib</code> — Utilities for <code>with</code> -statement contexts	1228
28.8	<code>abc</code> — Classes de Base Abstraites	1230
28.9	<code>atexit</code> — Gestionnaire de fin de programme	1233
28.10	<code>traceback</code> — Print or retrieve a stack traceback	1235
28.11	<code>__future__</code> — Définitions des futurs	1239
28.12	<code>gc</code> — Garbage Collector interface	1240
28.13	<code>inspect</code> — Inspect live objects	1243
28.14	<code>site</code> — Site-specific configuration hook	1249
28.15	<code>user</code> — User-specific configuration hook	1251
28.16	<code>fpectl</code> — Floating point exception control	1252
<b>29</b>	<b>Interpréteurs Python personnalisés</b>	<b>1255</b>
29.1	<code>code</code> — Interpreter base classes	1255
29.2	<code>codeop</code> — Compile Python code	1257
<b>30</b>	<b>Restricted Execution</b>	<b>1259</b>
30.1	<code>rexec</code> — Restricted execution framework	1260
30.2	<code>Bastion</code> — Restricting access to objects	1263
<b>31</b>	<b>Importer des modules</b>	<b>1265</b>
31.1	<code>imp</code> — Access the <code>import</code> internals	1265
31.2	<code>importlib</code> — Convenience wrappers for <code>__import__()</code>	1268
31.3	<code>imputil</code> — Import utilities	1269
31.4	<code>zipimport</code> — Import modules from Zip archives	1272
31.5	<code>pkgutil</code> — Package extension utility	1274
31.6	<code>modulefinder</code> — Identifie les modules utilisés par un script	1276
31.7	<code>runpy</code> — Locating and executing Python modules	1278
<b>32</b>	<b>Services du Langage Python</b>	<b>1281</b>
32.1	<code>parser</code> — Access Python parse trees	1281
32.2	<code>ast</code> — Arbres Syntaxiques Abstraits	1285
32.3	<code>symtable</code> — Access to the compiler's symbol tables	1290

32.4	<code>symbol</code> — Constantes utilisées dans les Arbres Syntaxiques . . . . .	1292
32.5	<code>token</code> — Constantes utilisées avec les arbres d'analyse Python ( <i>parse trees</i> ) . . . . .	1293
32.6	<code>keyword</code> — Tester si des chaînes sont des mot-clés Python . . . . .	1294
32.7	<code>tokenize</code> — Analyseur lexical de Python . . . . .	1295
32.8	<code>tabnanny</code> — Détection d'indentation ambiguë . . . . .	1296
32.9	<code>pyclbr</code> — Python class browser support . . . . .	1297
32.10	<code>py_compile</code> — Compile Python source files . . . . .	1298
32.11	<code>compileall</code> — Byte-compile Python libraries . . . . .	1299
32.12	<code>dis</code> — Disassembler for Python bytecode . . . . .	1300
32.13	<code>pickletools</code> — Tools for pickle developers . . . . .	1309
<b>33</b>	<b>Python compiler package</b> . . . . .	<b>1311</b>
33.1	The basic interface . . . . .	1311
33.2	Limitations . . . . .	1312
33.3	Python Abstract Syntax . . . . .	1312
33.4	Using Visitors to Walk ASTs . . . . .	1317
33.5	Bytecode Generation . . . . .	1318
<b>34</b>	<b>Services divers</b> . . . . .	<b>1319</b>
34.1	<code>formatter</code> — Generic output formatting . . . . .	1319
<b>35</b>	<b>Services spécifiques à MS Windows</b> . . . . .	<b>1325</b>
35.1	<code>msilib</code> — Read and write Microsoft Installer files . . . . .	1325
35.2	<code>msvcrt</code> — Useful routines from the MS VC++ runtime . . . . .	1330
35.3	<code>_winreg</code> — Windows registry access . . . . .	1332
35.4	<code>winsound</code> — Sound-playing interface for Windows . . . . .	1339
<b>36</b>	<b>Services spécifiques à Unix</b> . . . . .	<b>1343</b>
36.1	<code>posix</code> — Les appels système POSIX les plus courants . . . . .	1343
36.2	<code>pwd</code> — The password database . . . . .	1344
36.3	<code>spwd</code> — The shadow password database . . . . .	1345
36.4	<code>grp</code> — The group database . . . . .	1345
36.5	<code>crypt</code> — Function to check Unix passwords . . . . .	1346
36.6	<code>dl</code> — Call C functions in shared objects . . . . .	1347
36.7	<code>termios</code> — Le style POSIX le contrôle TTY . . . . .	1348
36.8	<code>tty</code> — Fonctions de gestion du terminal . . . . .	1349
36.9	<code>pty</code> — Outils de manipulation de pseudo-terminaux . . . . .	1350
36.10	<code>fcntl</code> — The <code>fcntl</code> and <code>ioctl</code> system calls . . . . .	1350
36.11	<code>pipes</code> — Interface au <i>pipelines</i> shell . . . . .	1352
36.12	<code>posixfile</code> — File-like objects with locking support . . . . .	1354
36.13	<code>resource</code> — Resource usage information . . . . .	1356
36.14	<code>nis</code> — Interface à Sun's NIS (pages jaunes) . . . . .	1358
36.15	<code>syslog</code> — Unix syslog library routines . . . . .	1359
36.16	<code>commands</code> — Utilities for running commands . . . . .	1360
<b>37</b>	<b>Mac OS X specific services</b> . . . . .	<b>1363</b>
37.1	<code>ic</code> — Access to the Mac OS X Internet Config . . . . .	1363
37.2	<code>MacOS</code> — Access to Mac OS interpreter features . . . . .	1365
37.3	<code>macostools</code> — Convenience routines for file manipulation . . . . .	1366
37.4	<code>findertools</code> — The <b>finder</b> 's Apple Events interface . . . . .	1367
37.5	<code>EasyDialogs</code> — Basic Macintosh dialogs . . . . .	1367
37.6	<code>FrameWork</code> — Interactive application framework . . . . .	1370

<b>Index des modules Python</b>	<b>1443</b>
<b>Index</b>	<b>1449</b>

Alors que `reference-index` décrit exactement la syntaxe et la sémantique du langage Python, ce manuel de référence de la Bibliothèque décrit la bibliothèque standard distribuée avec Python. Il décrit aussi certains composants optionnels typiquement inclus dans les distributions de Python.

La bibliothèque standard de Python est très grande, elle offre un large éventail d'outils comme le montre la longueur de la table des matières ci-dessous. La bibliothèque contient des modules natifs (écrits en C) exposant les fonctionnalités du système telles que les interactions avec les fichiers qui autrement ne seraient pas accessibles aux développeurs Python, ainsi que des modules écrits en Python exposant des solutions standardisées à de nombreux problèmes du quotidien du développeur. Certains de ces modules sont définis explicitement pour encourager et améliorer la portabilité des programmes Python en abstrayant des spécificités sous-jacentes en API neutres.

Les installateurs de Python pour Windows incluent généralement la bibliothèque standard en entier, et y ajoutent souvent d'autres composants. Pour les systèmes d'exploitation Unix, Python est typiquement fourni sous forme d'une collection de paquets, il peut donc être nécessaire d'utiliser le gestionnaire de paquets fourni par le système d'exploitation pour obtenir certains composants optionnels.

In addition to the standard library, there is a growing collection of several thousand components (from individual programs and modules to packages and entire application development frameworks), available from the [Python Package Index](#).

# CHAPITRE 1

---

## Introduction

---

La « Bibliothèque Python » contient divers composants dans différentes catégories.

Elle contient des types de données qui seraient normalement considérés comme « fondamentaux » au langage, tel que les nombres et les listes. Pour ces types, le cœur du langage en définit les écritures littérales et impose quelques contraintes sémantiques, sans les définir exhaustivement. (Cependant le cœur du langage impose quelques propriétés comme l'orthographe des attributs ou les caractéristiques des opérateurs.)

La bibliothèque contient aussi des fonctions et des exceptions natives, pouvant être utilisées par tout code Python sans `import`. Certaines sont définies par le noyau de Python, bien qu'elles ne soient pas toutes essentielles.

La grande majorité de la bibliothèque consiste cependant en une collection de modules. Cette collection peut être parcourue de différentes manières. Certains modules sont rédigés en C et inclus dans l'interpréteur Python, d'autres sont écrits en Python et leur source est importée. Certains modules fournissent des interfaces extrêmement spécifiques à Python, tel que l'affichage d'une pile d'appels, d'autres fournissent des interfaces spécifiques à un système d'exploitation, comme l'accès à du matériel spécifique. D'autres fournissent des interfaces spécifiques à un domaine d'application, comme le *World Wide Web*. Certains modules sont disponibles dans toutes les versions et implémentations de Python, d'autres ne sont disponibles que si le système sous-jacent les gère ou en a besoin. Enfin, d'autres ne sont disponibles que si Python a été compilé avec une certaine option.

This manual is organized « from the inside out : » it first describes the built-in data types, then the built-in functions and exceptions, and finally the modules, grouped in chapters of related modules. The ordering of the chapters as well as the ordering of the modules within each chapter is roughly from most relevant to least important.

Ça signifie que si vous commencez à lire cette documentation du début, et sautez au chapitre suivant lorsqu'elle vous ennuie, vous aurez un aperçu global des modules et domaines couverts par cette bibliothèque. Bien sûr vous n'avez pas à la lire comme un roman, vous pouvez simplement survoler la table des matières (au début), ou chercher une fonction, un module, ou un mot dans l'index (à la fin). Et si vous appréciez apprendre sur des sujets au hasard, choisissez une page au hasard (avec le module *random*) et lisez un chapitre ou deux. Peu importe l'ordre que vous adopterez, commencez par le chapitre *Fonctions natives*, car les autres chapitres présument que vous en avez une bonne connaissance.

Que le spectacle commence !

## CHAPITRE 2

---

### Fonctions natives

---

The Python interpreter has a number of functions built into it that are always available. They are listed here in alphabetical order.

Fonctions natives				
<i>abs()</i>	<i>divmod()</i>	<i>input()</i>	<i>open()</i>	<i>staticmethod()</i>
<i>all()</i>	<i>enumerate()</i>	<i>int()</i>	<i>ord()</i>	<i>str()</i>
<i>any()</i>	<i>eval()</i>	<i>isinstance()</i>	<i>pow()</i>	<i>sum()</i>
<i>basestring()</i>	<i>execfile()</i>	<i>issubclass()</i>	<i>print()</i>	<i>super()</i>
<i>bin()</i>	<i>file()</i>	<i>iter()</i>	<i>property()</i>	<i>tuple()</i>
<i>bool()</i>	<i>filter()</i>	<i>len()</i>	<i>range()</i>	<i>type()</i>
<i>bytearray()</i>	<i>float()</i>	<i>list()</i>	<i>raw_input()</i>	<i>unichr()</i>
<i>callable()</i>	<i>format()</i>	<i>locals()</i>	<i>reduce()</i>	<i>unicode()</i>
<i>chr()</i>	<i>frozenset()</i>	<i>long()</i>	<i>reload()</i>	<i>vars()</i>
<i>classmethod()</i>	<i>getattr()</i>	<i>map()</i>	<i>repr()</i>	<i>xrange()</i>
<i>cmp()</i>	<i>globals()</i>	<i>max()</i>	<i>reversed()</i>	<i>zip()</i>
<i>compile()</i>	<i>hasattr()</i>	<i>memoryview()</i>	<i>round()</i>	<i>__import__()</i>
<i>complex()</i>	<i>hash()</i>	<i>min()</i>	<i>set()</i>	
<i>delattr()</i>	<i>help()</i>	<i>next()</i>	<i>setattr()</i>	
<i>dict()</i>	<i>hex()</i>	<i>object()</i>	<i>slice()</i>	
<i>dir()</i>	<i>id()</i>	<i>oct()</i>	<i>sorted()</i>	

In addition, there are other four built-in functions that are no longer considered essential : *apply()*, *buffer()*, *coerce()*, and *intern()*. They are documented in the *Non-essential Built-in Functions* section.

#### **abs(*x*)**

Return the absolute value of a number. The argument may be a plain or long integer or a floating point number. If the argument is a complex number, its magnitude is returned.

#### **all(*iterable*)**

Donne **True** si tous les éléments de *iterable* sont vrais (ou s'il est vide), équivaut à :

```
def all(iterable):
    for element in iterable:
        if not element:
            return False
    return True
```

Nouveau dans la version 2.5.

#### `any(iterable)`

Donne `True` si au moins un élément de *iterable* est vrai. Faux est aussi donné dans le cas où *iterable* est vide, équivaut à :

```
def any(iterable):
    for element in iterable:
        if element:
            return True
    return False
```

Nouveau dans la version 2.5.

#### `basestring()`

This abstract type is the superclass for `str` and `unicode`. It cannot be called or instantiated, but it can be used to test whether an object is an instance of `str` or `unicode`. `isinstance(obj, basestring)` is equivalent to `isinstance(obj, (str, unicode))`.

Nouveau dans la version 2.3.

#### `bin(x)`

Convertit un nombre entier en binaire dans une chaîne. Le résultat est une expression Python valide. Si *x* n'est pas un `int`, il doit définir une méthode `__index__()` donnant un nombre entier.

Nouveau dans la version 2.6.

#### `class bool([x])`

Return a Boolean value, i.e. one of `True` or `False`. *x* is converted using the standard truth testing procedure. If *x* is false or omitted, this returns `False`; otherwise it returns `True`. `bool` is also a class, which is a subclass of `int`. Class `bool` cannot be subclassed further. Its only instances are `False` and `True`.

Nouveau dans la version 2.2.1.

Modifié dans la version 2.3 : If no argument is given, this function returns `False`.

#### `class bytearray([source[, encoding[, errors]]])`

Return a new array of bytes. The `bytearray` class is a mutable sequence of integers in the range  $0 \leq x < 256$ . It has most of the usual methods of mutable sequences, described in *Types de séquences muables*, as well as most methods that the `str` type has, see *Méthodes de chaînes de caractères*.

Le paramètre optionnel *source* peut être utilisé pour initialiser l'*array* de quelques manières différentes :

- If it is *unicode*, you must also give the *encoding* (and optionally, *errors*) parameters; `bytearray()` then converts the unicode to bytes using `unicode.encode()`.
- Si c'est un *entier*, l'*array* aura cette taille et sera initialisé de *null bytes*.
- Si c'est un objet conforme à l'interface *buffer*, un *buffer* en lecture seule de l'objet sera utilisé pour initialiser l'*array*.
- Si c'est un *itérable*, il doit itérer sur des nombres entier dans l'intervalle  $0 \leq x < 256$ , qui seront utilisés pour initialiser le contenu de l'*array*.

Sans argument, un *array* de taille vide est créé.

Nouveau dans la version 2.6.

#### `callable(object)`

Return `True` if the *object* argument appears callable, `False` if not. If this returns true, it is still possible

that a call fails, but if it is false, calling *object* will never succeed. Note that classes are callable (calling a class returns a new instance); class instances are callable if they have a `__call__()` method.

**chr(*i*)**

Return a string of one character whose ASCII code is the integer *i*. For example, `chr(97)` returns the string `'a'`. This is the inverse of `ord()`. The argument must be in the range `[0..255]`, inclusive; `ValueError` will be raised if *i* is outside that range. See also `unichr()`.

**classmethod(*function*)**

Donne une méthode de classe pour *function*.

Une méthode de classe reçoit implicitement la classe en premier argument, tout comme une méthode d'instance reçoit l'instance. Voici comment déclarer une méthode de classe :

```
class C(object):
    @classmethod
    def f(cls, arg1, arg2, ...):
        ...
```

La forme `@classmethod` est un *decorator* – consultez la documentation sur la définition de fonctions dans *function* pour plus de détails.

Elle peut être appelée soit sur la classe (comme `C.f()`) ou sur une instance (comme `C().f()`). L'instance est ignorée, sauf pour déterminer sa classe. Si la méthode est appelée sur une instance de classe fille, c'est la classe fille qui sera donnée en premier argument implicite.

Les méthodes de classe sont différentes des méthodes statiques du C++ ou du Java. Si c'est elles sont vous avez besoin, regardez du côté de `staticmethod()`.

Pour plus d'informations sur les méthodes de classe, consultez la documentation sur la hiérarchie des types standards dans *types*.

Nouveau dans la version 2.2.

Modifié dans la version 2.4 : Function decorator syntax added.

**cmp(*x*, *y*)**

Compare the two objects *x* and *y* and return an integer according to the outcome. The return value is negative if `x < y`, zero if `x == y` and strictly positive if `x > y`.

**compile(*source*, *filename*, *mode*[, *flags*[, *dont\_inherit*]])**

Compile the *source* into a code or AST object. Code objects can be executed by an `exec` statement or evaluated by a call to `eval()`. *source* can either be a Unicode string, a *Latin-1* encoded string or an AST object. Refer to the *ast* module documentation for information on how to work with AST objects.

L'argument *filename* doit nommer le fichier duquel le code a été lu. Donnez quelque chose de reconnaissable lorsqu'il n'a pas été lu depuis un fichier (typiquement `"<string>"`).

L'argument *mode* indique quel type de code doit être compilé : `'exec'` si *source* est une suite d'instructions, `'eval'` pour une seule expression, ou `'single'` si il ne contient qu'une instruction interactive (dans ce dernier cas, les résultats d'expressions donnant autre chose que `None` seront affichés).

Les arguments optionnels *flags* et *dont\_inherit* contrôlent quelle instructions *future* (voir [PEP 236](#)) affecte la compilation de *source*. Si aucun des deux n'est présent (ou que les deux sont à 0) le code est compilé avec les mêmes instructions *future* que le code appelant `compile()`. Si l'argument *flags* est fourni mais que *dont\_inherit* ne l'est pas (ou vaut 0), alors les instructions *futures* utilisées seront celles spécifiées par *flags* en plus de celles qui auraient été utilisées. Si *dont\_inherit* est un entier différent de zéro, *flags* est utilisé seul – les instructions futures déclarées autour de l'appel à `compile` sont ignorées.

Les instructions futures sont spécifiées par des bits, il est ainsi possible d'en spécifier plusieurs en les combinant avec un *ou* binaire. Les bits requis pour spécifier une certaine fonctionnalité se trouvent dans l'attribut `compiler_flag` de la classe `Feature` du module `__future__`.

Cette fonction lève une `SyntaxError` si la source n'est pas valide, et `TypeError` si la source contient des octets null.

Si vous voulez transformer du code Python en sa représentation AST, voyez `ast.parse()`.

---

**Note :** Lors de la compilation d'une chaîne de plusieurs lignes de code avec les modes `'single'` ou `'eval'`, celle-ci doit être terminée d'au moins un retour à la ligne. Cela permet de faciliter la distinction entre les instructions complètes et incomplètes dans le module `code`.

---

Modifié dans la version 2.3 : The `flags` and `dont_inherit` arguments were added.

Modifié dans la version 2.6 : Support for compiling AST objects.

Modifié dans la version 2.7 : Allowed use of Windows and Mac newlines. Also input in `'exec'` mode does not have to end in a newline anymore.

**class** `complex`(`[real[, imag]]`)

Return a complex number with the value `real + imag*1j` or convert a string or number to a complex number. If the first parameter is a string, it will be interpreted as a complex number and the function must be called without a second parameter. The second parameter can never be a string. Each argument may be any numeric type (including complex). If `imag` is omitted, it defaults to zero and the function serves as a numeric conversion function like `int()`, `long()` and `float()`. If both arguments are omitted, returns `0j`.

---

**Note :** Lors de la conversion depuis une chaîne, elle ne doit pas contenir d'espaces autour des opérateurs binaires `+` ou `-`. Par exemple `complex('1+2j')` est bon, mais `complex('1 + 2j')` lève une `ValueError`.

---

Le type complexe est décrit dans *Numeric Types — int, float, long, complex*.

**delattr**(`object, name`)

C'est un cousin de `setattr()`. Les arguments sont un objet et une chaîne. La chaîne doit être le nom de l'un des attributs de l'objet. La fonction supprime l'attribut nommé, si l'objet l'y autorise. Par exemple `delattr(x, 'foobar')` est l'équivalent de `del x.foobar`.

**class** `dict`(`**kwarg`)

**class** `dict`(`mapping, **kwarg`)

**class** `dict`(`iterable, **kwarg`)

Crée un nouveau dictionnaire. L'objet `dict` est la classe du dictionnaire. Voir `dict` et *Les types de correspondances — dict* pour vous documenter sur cette classe.

Pour les autres conteneurs, voir les classes natives `list`, `set`, et `tuple`, ainsi que le module `collections`.

**dir**(`[object]`)

Sans arguments, elle donne la liste des noms dans l'espace de noms local. Avec un argument, elle essaye de donner une liste d'attributs valides pour cet objet.

Si l'objet à une méthode `__dir__()`, elle est appelée et doit donner une liste d'attributs. Cela permet aux objets implémentant `__getattr__()` ou `__getattribute__()` de personnaliser ce que donnera `dir()`.

Si l'objet ne fournit pas de méthode `__dir__()`, la fonction fait de son mieux en rassemblant les informations de l'attribut `__dict__` de l'objet, si défini, et depuis son type. La liste résultante n'est pas nécessairement complète, et peut être inadaptée quand l'objet a un `__getattr__()` personnalisé. Le mécanisme par défaut de `dir()` se comporte différemment avec différents types d'objets, car elle préfère donner une information pertinente plutôt qu'exhaustive :

- Si l'objet est un module, la liste contiendra les noms des attributs du module.
- Si l'objet est un type ou une classe, la liste contiendra les noms de ses attributs, et récursivement, des attributs de ses parents.
- Autrement, la liste contient les noms des attributs de l'objet, le nom des attributs de la classe, et récursivement des attributs des parents de la classe.

La liste donnée est triée par ordre alphabétique, par exemple :

```

>>> import struct
>>> dir()      # show the names in the module namespace
['__builtins__', '__doc__', '__name__', 'struct']
>>> dir(struct) # show the names in the struct module
['Struct', '__builtins__', '__doc__', '__file__', '__name__',
 '__package__', '_clearcache', 'calcsize', 'error', 'pack', 'pack_into',
 'unpack', 'unpack_from']
>>> class Shape(object):
    def __dir__(self):
        return ['area', 'perimeter', 'location']
>>> s = Shape()
>>> dir(s)
['area', 'perimeter', 'location']

```

**Note :** Étant donné que *dir()* est d'abord fournie pour son côté pratique en mode interactif, elle a tendance à fournir un jeu intéressant de noms plutôt qu'un ensemble consistant et rigoureusement défini, son comportement peut aussi changer d'une version à l'autre. Par exemple, les attributs de méta-classes ne sont pas données lorsque l'argument est une classe.

#### **divmod(a, b)**

Take two (non complex) numbers as arguments and return a pair of numbers consisting of their quotient and remainder when using long division. With mixed operand types, the rules for binary arithmetic operators apply. For plain and long integers, the result is the same as  $(a // b, a \% b)$ . For floating point numbers the result is  $(q, a \% b)$ , where  $q$  is usually `math.floor(a / b)` but may be 1 less than that. In any case  $q * b + a \% b$  is very close to  $a$ , if  $a \% b$  is non-zero it has the same sign as  $b$ , and  $0 \leq \text{abs}(a \% b) < \text{abs}(b)$ .

Modifié dans la version 2.3 : Using *divmod()* with complex numbers is deprecated.

#### **enumerate(sequence, start=0)**

Return an enumerate object. *sequence* must be a sequence, an *iterator*, or some other object which supports iteration. The `next()` method of the iterator returned by *enumerate()* returns a tuple containing a count (from *start* which defaults to 0) and the values obtained from iterating over *sequence* :

```

>>> seasons = ['Spring', 'Summer', 'Fall', 'Winter']
>>> list(enumerate(seasons))
[(0, 'Spring'), (1, 'Summer'), (2, 'Fall'), (3, 'Winter')]
>>> list(enumerate(seasons, start=1))
[(1, 'Spring'), (2, 'Summer'), (3, 'Fall'), (4, 'Winter')]

```

Équivalent à :

```

def enumerate(sequence, start=0):
    n = start
    for elem in sequence:
        yield n, elem
        n += 1

```

Nouveau dans la version 2.3.

Modifié dans la version 2.6 : The *start* parameter was added.

#### **eval(expression[, globals[, locals]])**

The arguments are a Unicode or *Latin-1* encoded string and optional globals and locals. If provided, *globals* must be a dictionary. If provided, *locals* can be any mapping object.

Modifié dans la version 2.4 : formerly *locals* was required to be a dictionary.

The *expression* argument is parsed and evaluated as a Python expression (technically speaking, a condition list) using the *globals* and *locals* dictionaries as global and local namespace. If the *globals* dictionary is present and lacks “`__builtins__`”, the current globals are copied into *globals* before *expression* is parsed. This means that *expression* normally has full access to the standard `__builtin__` module and restricted environments are propagated. If the *locals* dictionary is omitted it defaults to the *globals* dictionary. If both dictionaries are omitted, the expression is executed in the environment where `eval()` is called. The return value is the result of the evaluated expression. Syntax errors are reported as exceptions. Example :

```
>>> x = 1
>>> print eval('x+1')
2
```

Cette fonction peut aussi être utilisée pour exécuter n'importe quel objet code (tel que ceux créés par `compile()`). Dans ce cas, donnez un objet code plutôt qu'une chaîne. Si l'objet code à été compilé avec 'exec' en argument pour *mode*, `eval()` donnera `None`.

Hints : dynamic execution of statements is supported by the `exec` statement. Execution of statements from a file is supported by the `execfile()` function. The `globals()` and `locals()` functions returns the current global and local dictionary, respectively, which may be useful to pass around for use by `eval()` or `execfile()`.

Utilisez `ast.literal_eval()` si vous avez besoin d'une fonction qui peut évaluer en toute sécurité des chaînes avec des expressions ne contenant que des valeurs littérales.

**execfile**(*filename*[, *globals*[, *locals*]])

This function is similar to the `exec` statement, but parses a file instead of a string. It is different from the `import` statement in that it does not use the module administration — it reads the file unconditionally and does not create a new module.<sup>1</sup>

The arguments are a file name and two optional dictionaries. The file is parsed and evaluated as a sequence of Python statements (similarly to a module) using the *globals* and *locals* dictionaries as global and local namespace. If provided, *locals* can be any mapping object. Remember that at module level, globals and locals are the same dictionary. If two separate objects are passed as *globals* and *locals*, the code will be executed as if it were embedded in a class definition.

Modifié dans la version 2.4 : formerly *locals* was required to be a dictionary.

If the *locals* dictionary is omitted it defaults to the *globals* dictionary. If both dictionaries are omitted, the expression is executed in the environment where `execfile()` is called. The return value is `None`.

---

**Note :** The default *locals* act as described for function `locals()` below : modifications to the default *locals* dictionary should not be attempted. Pass an explicit *locals* dictionary if you need to see effects of the code on *locals* after function `execfile()` returns. `execfile()` cannot be used reliably to modify a function's locals.

---

**file**(*name*[, *mode*[, *buffering*]])

Constructor function for the *file* type, described further in section *Objets fichiers*. The constructor's arguments are the same as those of the `open()` built-in function described below.

When opening a file, it's preferable to use `open()` instead of invoking this constructor directly. *file* is more suited to type testing (for example, writing `isinstance(f, file)`).

Nouveau dans la version 2.2.

**filter**(*function*, *iterable*)

Construct a list from those elements of *iterable* for which *function* returns true. *iterable* may be either a sequence, a container which supports iteration, or an iterator. If *iterable* is a string or a tuple, the result also has that type; otherwise it is always a list. If *function* is `None`, the identity function is assumed, that is, all elements of *iterable* that are false are removed.

---

1. It is used relatively rarely so does not warrant being made into a statement.

Note that `filter(function, iterable)` is equivalent to `[item for item in iterable if function(item)]` if `function` is not `None` and `[item for item in iterable if item]` if `function` is `None`.

See `itertools.ifilter()` and `itertools.ifilterfalse()` for iterator versions of this function, including a variation that filters for elements where the *function* returns false.

**class** `float`(`[x]`)

Donne un nombre à virgule flottante depuis un nombre ou une chaîne `x`.

If the argument is a string, it must contain a possibly signed decimal or floating point number, possibly embedded in whitespace. The argument may also be `[+|-]nan` or `[+|-]inf`. Otherwise, the argument may be a plain or long integer or a floating point number, and a floating point number with the same value (within Python's floating point precision) is returned. If no argument is given, returns `0.0`.

---

**Note :** When passing in a string, values for NaN and Infinity may be returned, depending on the underlying C library. Float accepts the strings `nan`, `inf` and `-inf` for NaN and positive or negative infinity. The case and a leading `+` are ignored as well as a leading `-` is ignored for NaN. Float always represents NaN and infinity as `nan`, `inf` or `-inf`.

---

Le type *float* est décrit dans *Numeric Types — int, float, long, complex*.

**format**(`value``[, format_spec]`)

Convertit une valeur en sa représentation « formatée », tel que décrit par *format\_spec*. L'interprétation de *format\_spec* dépend du type de la valeur, cependant il existe une syntaxe standard utilisée par la plupart des types natifs : *Mini-langage de spécification de format*.

---

**Note :** `format(value, format_spec)` merely calls `value.__format__(format_spec)`.

---

Nouveau dans la version 2.6.

**class** `frozenset`(`[iterable]`)

Donne un nouveau *frozenset*, dont les objets sont éventuellement tirés d'*iterable*. *frozenset* est une classe native. Voir *frozenset* et *Types d'ensembles — set, frozenset* pour leurs documentation.

Pour d'autres conteneurs, voyez les classes natives *set*, *list*, *tuple*, et *dict*, ainsi que le module *collections*.

Nouveau dans la version 2.4.

**getattr**(`object`, `name``[, default]`)

Donne la valeur de l'attribut nommé *name* de l'objet *object*. *name* doit être une chaîne. Si la chaîne est le nom d'un des attributs de l'objet, le résultat est la valeur de cet attribut. Par exemple, `getattr(x, 'foobar')` est équivalent à `x.foobar`. Si l'attribut n'existe pas, et que *default* est fourni, il est renvoyé, sinon l'exception *AttributeError* est levée.

**globals**()

Donne une représentation de la table de symboles globaux sous forme d'un dictionnaire. C'est toujours le dictionnaire du module courant (dans une fonction ou méthode, c'est le module où elle est définie, et non le module d'où elle est appelée).

**hasattr**(`object`, `name`)

The arguments are an object and a string. The result is `True` if the string is the name of one of the object's attributes, `False` if not. (This is implemented by calling `getattr(object, name)` and seeing whether it raises an exception or not.)

**hash**(`object`)

Return the hash value of the object (if it has one). Hash values are integers. They are used to quickly compare dictionary keys during a dictionary lookup. Numeric values that compare equal have the same hash value (even if they are of different types, as is the case for 1 and 1.0).

**help**(*[object]*)

Invoque le système d'aide natif. (Cette fonction est destinée à l'usage en mode interactif.) Si aucun argument n'est fourni, le système d'aide démarre dans l'interpréteur. Si l'argument est une chaîne, un module, une fonction, une classe, une méthode, un mot clef, ou un sujet de documentation pour lequel ce nom est recherché, et une page d'aide est affichée sur la console. Si l'argument est d'un autre type, une page d'aide sur cet objet est générée.

Cette fonction est ajoutée à l'espace de noms natif par le module *site*.

Nouveau dans la version 2.2.

**hex**(*x*)

Convert an integer number (of any size) to a lowercase hexadecimal string prefixed with « 0x », for example :

```
>>> hex(255)
'0xff'
>>> hex(-42)
'-0x2a'
>>> hex(1L)
'0x1L'
```

If *x* is not a Python *int* or *long* object, it has to define a `__hex__()` method that returns a string. Voir aussi *int()* pour convertir une chaîne hexadécimale en un entier en lui spécifiant 16 comme base.

---

**Note :** Pour obtenir une représentation hexadécimale sous forme de chaîne d'un nombre à virgule flottante, utilisez la méthode *float.hex()*.

---

Modifié dans la version 2.4 : Formerly only returned an unsigned literal.

**id**(*object*)

Return the « identity » of an object. This is an integer (or long integer) which is guaranteed to be unique and constant for this object during its lifetime. Two objects with non-overlapping lifetimes may have the same *id()* value.

**CPython implementation detail :** This is the address of the object in memory.

**input**(*[prompt]*)

Equivalent to `eval(raw_input(prompt))`.

This function does not catch user errors. If the input is not syntactically valid, a *SyntaxError* will be raised. Other exceptions may be raised if there is an error during evaluation.

Si le module *readline* est chargé, *input()* l'utilisera pour fournir des fonctionnalités d'édition et d'historique élaborées.

Consider using the *raw\_input()* function for general input from users.

**class int**(*x=0*)**class int**(*x, base=10*)

Return an integer object constructed from a number or string *x*, or return 0 if no arguments are given. If *x* is a number, it can be a plain integer, a long integer, or a floating point number. If *x* is floating point, the conversion truncates towards zero. If the argument is outside the integer range, the function returns a long object instead.

If *x* is not a number or if *base* is given, then *x* must be a string or Unicode object representing an integer literal in radix *base*. Optionally, the literal can be preceded by + or - (with no space in between) and surrounded by whitespace. A base-*n* literal consists of the digits 0 to *n*-1, with a to z (or A to Z) having values 10 to 35. The default *base* is 10. The allowed values are 0 and 2-36. Base-2, -8, and -16 literals can be optionally prefixed with 0b/0B, 0o/0O/0, or 0x/0X, as with integer literals in code. Base 0 means to interpret the string exactly as an integer literal, so that the actual base is 2, 8, 10, or 16.

Le type des entiers est décrit dans *Numeric Types — int, float, long, complex*.

**isinstance(object, classinfo)**

Return true if the *object* argument is an instance of the *classinfo* argument, or of a (direct, indirect or *virtual*) subclass thereof. Also return true if *classinfo* is a type object (new-style class) and *object* is an object of that type or of a (direct, indirect or *virtual*) subclass thereof. If *object* is not a class instance or an object of the given type, the function always returns false. If *classinfo* is a tuple of class or type objects (or recursively, other such tuples), return true if *object* is an instance of any of the classes or types. If *classinfo* is not a class, type, or tuple of classes, types, and such tuples, a *TypeError* exception is raised.

Modifié dans la version 2.2 : Support for a tuple of type information was added.

**issubclass(class, classinfo)**

Donne True si *class* est une classe fille (directe, indirecte, ou *virtual*) de *classinfo*. Une classe est considérée sous-classe d'elle même. *classinfo* peut être un tuple de classes, dans ce cas la vérification sera faite pour chaque classe de *classinfo*. Dans tous les autres cas, *TypeError* est levée.

Modifié dans la version 2.3 : Support for a tuple of type information was added.

**iter(o[, sentinel])**

Return an *iterator* object. The first argument is interpreted very differently depending on the presence of the second argument. Without a second argument, *o* must be a collection object which supports the iteration protocol (the `__iter__()` method), or it must support the sequence protocol (the `__getitem__()` method with integer arguments starting at 0). If it does not support either of those protocols, *TypeError* is raised. If the second argument, *sentinel*, is given, then *o* must be a callable object. The iterator created in this case will call *o* with no arguments for each call to its `next()` method; if the value returned is equal to *sentinel*, *StopIteration* will be raised, otherwise the value will be returned.

Une autre application utile de la deuxième forme de `iter()` est de lire les lignes d'un fichier jusqu'à ce qu'une certaine ligne soit atteinte. L'exemple suivant lis un fichier jusqu'à ce que `readline()` donne une ligne vide :

```
with open('mydata.txt') as fp:
    for line in iter(fp.readline, ''):
        process_line(line)
```

Nouveau dans la version 2.2.

**len(s)**

Donne la longueur (nombre d'éléments) d'un objet. L'argument peut être une séquence (tel qu'une chaîne, un objet `bytes`, `tuple`, `list` ou `range`) ou une collection (tel qu'un `dict`, `set` ou `frozenset`).

**class list([iterable])**

Return a list whose items are the same and in the same order as *iterable*'s items. *iterable* may be either a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a list, a copy is made and returned, similar to `iterable[:]`. For instance, `list('abc')` returns `['a', 'b', 'c']` and `list( (1, 2, 3) )` returns `[1, 2, 3]`. If no argument is given, returns a new empty list, `[]`.

`list` is a mutable sequence type, as documented in *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange*. For other containers see the built in `dict`, `set`, and `tuple` classes, and the *collections* module.

**locals()**

Met à jour et donne un dictionnaire représentant la table des symboles locaux. Les variables libres sont données par `locals()` lorsqu'elle est appelée dans le corps d'une fonction, mais pas dans le corps d'une classe.

---

**Note :** Le contenu de ce dictionnaire ne devrait pas être modifié, les changements peuvent ne pas affecter les valeurs des variables locales ou libres utilisées par l'interpréteur.

---

**class** `long(x=0)`

**class** `long(x, base=10)`

Return a long integer object constructed from a string or number *x*. If the argument is a string, it must contain a possibly signed number of arbitrary size, possibly embedded in whitespace. The *base* argument is interpreted in the same way as for `int()`, and may only be given when *x* is a string. Otherwise, the argument may be a plain or long integer or a floating point number, and a long integer with the same value is returned. Conversion of floating point numbers to integers truncates (towards zero). If no arguments are given, returns 0L.

The long type is described in *Numeric Types — int, float, long, complex*.

**map**(*function, iterable, ...*)

Apply *function* to every item of *iterable* and return a list of the results. If additional *iterable* arguments are passed, *function* must take that many arguments and is applied to the items from all iterables in parallel. If one iterable is shorter than another it is assumed to be extended with `None` items. If *function* is `None`, the identity function is assumed; if there are multiple arguments, `map()` returns a list consisting of tuples containing the corresponding items from all iterables (a kind of transpose operation). The *iterable* arguments may be a sequence or any iterable object; the result is always a list.

**max**(*iterable*[, *key*])

**max**(*arg1, arg2, \*args*[, *key*])

Donne l'élément le plus grand dans un itérable, ou l'argument le plus grand parmi au moins deux arguments.

If one positional argument is provided, *iterable* must be a non-empty iterable (such as a non-empty string, tuple or list). The largest item in the iterable is returned. If two or more positional arguments are provided, the largest of the positional arguments is returned.

The optional *key* argument specifies a one-argument ordering function like that used for `list.sort()`. The *key* argument, if supplied, must be in keyword form (for example, `max(a,b,c,key=func)`).

Modifié dans la version 2.5 : Added support for the optional *key* argument.

**memoryview**(*obj*)

Donne une « vue mémoire » (*memory view*) créée depuis l'argument. Voir *memoryview type* pour plus d'informations.

**min**(*iterable*[, *key*])

**min**(*arg1, arg2, \*args*[, *key*])

Donne le plus petit élément d'un itérable ou le plus petit d'au moins deux arguments.

If one positional argument is provided, *iterable* must be a non-empty iterable (such as a non-empty string, tuple or list). The smallest item in the iterable is returned. If two or more positional arguments are provided, the smallest of the positional arguments is returned.

The optional *key* argument specifies a one-argument ordering function like that used for `list.sort()`. The *key* argument, if supplied, must be in keyword form (for example, `min(a,b,c,key=func)`).

Modifié dans la version 2.5 : Added support for the optional *key* argument.

**next**(*iterator*[, *default*])

Retrieve the next item from the *iterator* by calling its `next()` method. If *default* is given, it is returned if the iterator is exhausted, otherwise *StopIteration* is raised.

Nouveau dans la version 2.6.

**class** `object`

Return a new featureless object. *object* is a base for all new style classes. It has the methods that are common to all instances of new style classes.

Nouveau dans la version 2.2.

Modifié dans la version 2.3 : This function does not accept any arguments. Formerly, it accepted arguments but ignored them.

**oct(*x*)**

Convert an integer number (of any size) to an octal string. The result is a valid Python expression.

Modifié dans la version 2.4 : Formerly only returned an unsigned literal.

**open(*name*[, *mode*[, *buffering*]])**

Open a file, returning an object of the *file* type described in section *Objets fichiers*. If the file cannot be opened, *IOError* is raised. When opening a file, it's preferable to use *open()* instead of invoking the *file* constructor directly.

The first two arguments are the same as for *stdio*'s *fopen()* : *name* is the file name to be opened, and *mode* is a string indicating how the file is to be opened.

The most commonly-used values of *mode* are 'r' for reading, 'w' for writing (truncating the file if it already exists), and 'a' for appending (which on *some* Unix systems means that *all* writes append to the end of the file regardless of the current seek position). If *mode* is omitted, it defaults to 'r'. The default is to use text mode, which may convert '\n' characters to a platform-specific representation on writing and back on reading. Thus, when opening a binary file, you should append 'b' to the *mode* value to open the file in binary mode, which will improve portability. (Appending 'b' is useful even on systems that don't treat binary and text files differently, where it serves as documentation.) See below for more possible values of *mode*.

The optional *buffering* argument specifies the file's desired buffer size : 0 means unbuffered, 1 means line buffered, any other positive value means use a buffer of (approximately) that size (in bytes). A negative *buffering* means to use the system default, which is usually line buffered for tty devices and fully buffered for other files. If omitted, the system default is used.<sup>2</sup>

Modes 'r+', 'w+' and 'a+' open the file for updating (reading and writing); note that 'w+' truncates the file. Append 'b' to the mode to open the file in binary mode, on systems that differentiate between binary and text files; on systems that don't have this distinction, adding the 'b' has no effect.

In addition to the standard *fopen()* values *mode* may be 'U' or 'rU'. Python is usually built with *universal newlines* support; supplying 'U' opens the file as a text file, but lines may be terminated by any of the following : the Unix end-of-line convention '\n', the Macintosh convention '\r', or the Windows convention '\r\n'. All of these external representations are seen as '\n' by the Python program. If Python is built without universal newlines support a *mode* with 'U' is the same as normal text mode. Note that file objects so opened also have an attribute called *newlines* which has a value of *None* (if no newlines have yet been seen), '\n', '\r', '\r\n', or a tuple containing all the newline types seen.

Python enforces that the mode, after stripping 'U', begins with 'r', 'w' or 'a'.

Python provides many file handling modules including *fileinput*, *os*, *os.path*, *tempfile*, and *shutil*.

Modifié dans la version 2.5 : Restriction on first letter of mode string introduced.

**ord(*c*)**

Given a string of length one, return an integer representing the Unicode code point of the character when the argument is a unicode object, or the value of the byte when the argument is an 8-bit string. For example, *ord*('a') returns the integer 97, *ord*(u'\u2020') returns 8224. This is the inverse of *chr()* for 8-bit strings and of *unichr()* for unicode objects. If a unicode argument is given and Python was built with UCS2 Unicode, then the character's code point must be in the range [0..65535] inclusive; otherwise the string length is two, and a *TypeError* will be raised.

**pow(*x*, *y*[, *z*])**

Donne *x* puissance *y*, et si *z* est présent, donne *x* puissance *y* modulo *z* (calculé de manière plus efficiente que *pow(x, y) % z*). La forme à deux arguments est équivalent à *x\*\*y*.

The arguments must have numeric types. With mixed operand types, the coercion rules for binary arithmetic operators apply. For int and long int operands, the result has the same type as the operands (after coercion) unless the second argument is negative; in that case, all arguments are converted to

2. Specifying a buffer size currently has no effect on systems that don't have *setvbuf()*. The interface to specify the buffer size is not done using a method that calls *setvbuf()*, because that may dump core when called after any I/O has been performed, and there's no reliable way to determine whether this is the case.

float and a float result is delivered. For example, `10**2` returns 100, but `10**-2` returns 0.01. (This last feature was added in Python 2.2. In Python 2.1 and before, if both arguments were of integer types and the second argument was negative, an exception was raised.) If the second argument is negative, the third argument must be omitted. If *z* is present, *x* and *y* must be of integer types, and *y* must be non-negative. (This restriction was added in Python 2.2. In Python 2.1 and before, floating 3-argument `pow()` returned platform-dependent results depending on floating-point rounding accidents.)

`print(*objects, sep=' ', end='\n', file=sys.stdout)`

Print *objects* to the stream *file*, separated by *sep* and followed by *end*. *sep*, *end* and *file*, if present, must be given as keyword arguments.

Tous les arguments positionnels sont convertis en chaîne comme le fait `str()`, puis écrits sur le flux, séparés par *sep* et terminés par *end*. *sep* et *end* doivent être des chaînes, ou `None`, indiquant de prendre les valeurs par défaut. Si aucun *objects* n'est donné `print()` écrit seulement *end*.

The *file* argument must be an object with a `write(string)` method; if it is not present or `None`, `sys.stdout` will be used. Output buffering is determined by *file*. Use `file.flush()` to ensure, for instance, immediate appearance on a screen.

**Note :** This function is not normally available as a built-in since the name `print` is recognized as the `print` statement. To disable the statement and use the `print()` function, use this future statement at the top of your module :

```
from __future__ import print_function
```

Nouveau dans la version 2.6.

`class property([fget[, fset[, fdel[, doc]]]])`

Return a property attribute for *new-style classes* (classes that derive from `object`).

*fget* est une fonction permettant d'obtenir la valeur d'un attribut. *fset* est une fonction pour en définir la valeur. *fdel* quand à elle permet de supprimer la valeur d'un attribut, et *doc* crée une *docstring* pour l'attribut.

Une utilisation typique : définir un attribut managé *x* :

```
class C(object):
    def __init__(self):
        self._x = None

    def getx(self):
        return self._x

    def setx(self, value):
        self._x = value

    def delx(self):
        del self._x

    x = property(getx, setx, delx, "I'm the 'x' property.")
```

Si *c* est une instance de *C*, *c.x* appellera le *getter*, *c.x = value* invoquera le *setter*, et `del x` le *deleter*. S'il est donné, *doc* sera la *docstring* de l'attribut. Autrement la propriété copiera celle de *fget* (si elle existe). Cela rend possible la création de propriétés en lecture seule en utilisant simplement `property()` comme un *decorator* :

```
class Parrot(object):
    def __init__(self):
```

(suite sur la page suivante)

(suite de la page précédente)

```

self._voltage = 100000

@property
def voltage(self):
    """Get the current voltage."""
    return self._voltage

```

Le décorateur `@property` transforme la méthode `voltage()` en un *getter* d'un attribut du même nom, et donne « *Get the current voltage* » comme *docstring* de `voltage`.

Un objet propriété à les méthodes `getter`, `setter` et `deleter` utilisables comme décorateurs créant une copie de la propriété avec les accesseurs correspondants définis par la fonction de décoration. C'est plus clair avec un exemple :

```

class C(object):
    def __init__(self):
        self._x = None

    @property
    def x(self):
        """I'm the 'x' property."""
        return self._x

    @x.setter
    def x(self, value):
        self._x = value

    @x.deleter
    def x(self):
        del self._x

```

Ce code est l'exact équivalent du premier exemple. Soyez attentifs à bien donner aux fonctions additionnelles le même nom que la propriété (`x` dans ce cas.)

L'objet propriété donné à aussi les attributs `fget`, `fset` et `fdel` correspondant correspondants aux arguments du constructeur.

Nouveau dans la version 2.2.

Modifié dans la version 2.5 : Use *fget*'s *docstring* if no *doc* given.

Modifié dans la version 2.6 : The `getter`, `setter`, and `deleter` attributes were added.

`range(stop)`

`range(start, stop[, step])`

This is a versatile function to create lists containing arithmetic progressions. It is most often used in `for` loops. The arguments must be plain integers. If the *step* argument is omitted, it defaults to 1. If the *start* argument is omitted, it defaults to 0. The full form returns a list of plain integers `[start, start + step, start + 2 * step, ...]`. If *step* is positive, the last element is the largest `start + i * step` less than *stop*; if *step* is negative, the last element is the smallest `start + i * step` greater than *stop*. *step* must not be zero (or else *ValueError* is raised). Example :

```

>>> range(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> range(1, 11)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> range(0, 30, 5)
[0, 5, 10, 15, 20, 25]

```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> range(0, 10, 3)
[0, 3, 6, 9]
>>> range(0, -10, -1)
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
>>> range(0)
[]
>>> range(1, 0)
[]
```

**raw\_input**(*[prompt]*)

If the *prompt* argument is present, it is written to standard output without a trailing newline. The function then reads a line from input, converts it to a string (stripping a trailing newline), and returns that. When EOF is read, *EOFError* is raised. Example :

```
>>> s = raw_input('--> ')
--> Monty Python's Flying Circus
>>> s
"Monty Python's Flying Circus"
```

If the *readline* module was loaded, then *raw\_input()* will use it to provide elaborate line editing and history features.

**reduce**(*function, iterable*[, *initializer*])

Apply *function* of two arguments cumulatively to the items of *iterable*, from left to right, so as to reduce the iterable to a single value. For example, *reduce(lambda x, y: x+y, [1, 2, 3, 4, 5])* calculates (((1+2)+3)+4)+5). The left argument, *x*, is the accumulated value and the right argument, *y*, is the update value from the *iterable*. If the optional *initializer* is present, it is placed before the items of the iterable in the calculation, and serves as a default when the iterable is empty. If *initializer* is not given and *iterable* contains only one item, the first item is returned. Roughly equivalent to :

```
def reduce(function, iterable, initializer=None):
    it = iter(iterable)
    if initializer is None:
        try:
            initializer = next(it)
        except StopIteration:
            raise TypeError('reduce() of empty sequence with no initial value')
    accum_value = initializer
    for x in it:
        accum_value = function(accum_value, x)
    return accum_value
```

**reload**(*module*)

Reload a previously imported *module*. The argument must be a module object, so it must have been successfully imported before. This is useful if you have edited the module source file using an external editor and want to try out the new version without leaving the Python interpreter. The return value is the module object (the same as the *module* argument).

When *reload(module)* is executed :

- Python modules' code is recompiled and the module-level code reexecuted, defining a new set of objects which are bound to names in the module's dictionary. The *init* function of extension modules is not called a second time.
- As with all other objects in Python the old objects are only reclaimed after their reference counts drop to zero.
- The names in the module namespace are updated to point to any new or changed objects.

- Other references to the old objects (such as names external to the module) are not rebound to refer to the new objects and must be updated in each namespace where they occur if that is desired.

There are a number of other caveats :

When a module is reloaded, its dictionary (containing the module's global variables) is retained. Redefinitions of names will override the old definitions, so this is generally not a problem. If the new version of a module does not define a name that was defined by the old version, the old definition remains. This feature can be used to the module's advantage if it maintains a global table or cache of objects — with a `try` statement it can test for the table's presence and skip its initialization if desired :

```
try:
    cache
except NameError:
    cache = {}
```

It is generally not very useful to reload built-in or dynamically loaded modules. Reloading `sys`, `__main__`, `builtins` and other key modules is not recommended. In many cases extension modules are not designed to be initialized more than once, and may fail in arbitrary ways when reloaded.

If a module imports objects from another module using `from ... import ...`, calling `reload()` for the other module does not redefine the objects imported from it — one way around this is to re-execute the `from` statement, another is to use `import` and qualified names (`module.*name*`) instead.

If a module instantiates instances of a class, reloading the module that defines the class does not affect the method definitions of the instances — they continue to use the old class definition. The same is true for derived classes.

#### `repr(object)`

Return a string containing a printable representation of an object. This is the same value yielded by conversions (reverse quotes). It is sometimes useful to be able to access this operation as an ordinary function. For many types, this function makes an attempt to return a string that would yield an object with the same value when passed to `eval()`, otherwise the representation is a string enclosed in angle brackets that contains the name of the type of the object together with additional information often including the name and address of the object. A class can control what this function returns for its instances by defining a `__repr__()` method.

#### `reversed(seq)`

Donne un *iterator* inversé. *seq* doit être un objet ayant une méthode `__reverse__()` ou supportant le protocole séquence (la méthode `__len__()` et la méthode `__getitem__()` avec des arguments entiers commençant à zéro).

Nouveau dans la version 2.4.

Modifié dans la version 2.6 : Added the possibility to write a custom `__reversed__()` method.

#### `round(number[, ndigits])`

Return the floating point value *number* rounded to *ndigits* digits after the decimal point. If *ndigits* is omitted, it defaults to zero. The result is a floating point number. Values are rounded to the closest multiple of 10 to the power minus *ndigits*; if two multiples are equally close, rounding is done away from 0 (so, for example, `round(0.5)` is 1.0 and `round(-0.5)` is -1.0).

---

**Note :** Le comportement de `round()` avec les nombres à virgule flottante peut être surprenant : par exemple `round(2.675, 2)` donne 2.67 au lieu de 2.68. Ce n'est pas un bug, mais dû au fait que la plupart des fractions de décimaux ne peuvent pas être représentés exactement en nombre à virgule flottante. Voir tut-fp-issues pour plus d'information.

---

#### `class set([iterable])`

Donne un nouveau *set*, dont les éléments peuvent être extraits d'*iterable*. *set* est une classe native. Voir *set* et *Types d'ensembles* — *set*, *frozenset* pour la documentation de cette classe.

D'autres conteneurs existent, typiquement : *frozenset*, *list*, *tuple*, et *dict*, ainsi que le module *collections*.

Nouveau dans la version 2.4.

**setattr**(*object*, *name*, *value*)

C'est le complément de *getattr()*. Les arguments sont : un objet, une chaîne, et une valeur de type arbitraire. La chaîne peut nommer un attribut existant ou un nouvel attribut. La fonction assigne la valeur à l'attribut, si l'objet l'autorise. Par exemple, *setattr*(*x*, 'foobar', 123) équivaut à *x.foobar* = 123.

**class slice**(*stop*)

**class slice**(*start*, *stop*[, *step*])

Donne un objet *slice* représentant un ensemble d'indices spécifiés par *range(start, stop, step)*. Les arguments *start* et *step* valent *None* par défaut. Les objets *slice* (tranches) ont les attributs suivants en lecture seule : *start*, *stop*, et *step* qui valent simplement les trois arguments (ou leurs valeur par défaut). Ils n'ont pas d'autres fonctionnalité explicite, cependant ils sont utilisés par *Numerical Python* et d'autres bibliothèques tierces. Les objets *slice* sont aussi générés par la notation par indices étendue. Par exemple *a[start:stop:step]* ou *a[start:stop, i]*. Voir *itertools.islice()* pour une version alternative donnant un itérateur.

**sorted**(*iterable*[, *cmp*[, *key*[, *reverse*]]])

Donne une nouvelle liste triée depuis les éléments d'*iterable*.

The optional arguments *cmp*, *key*, and *reverse* have the same meaning as those for the *list.sort()* method (described in section *Types de séquences muables*).

*cmp* specifies a custom comparison function of two arguments (iterable elements) which should return a negative, zero or positive number depending on whether the first argument is considered smaller than, equal to, or larger than the second argument : *cmp*=*lambda x,y: cmp(x.lower(), y.lower())*. The default value is *None*.

*key* spécifie une fonction d'un argument utilisé pour extraire une clef de comparaison de chaque élément de la liste : *key*=*str.lower*. La valeur par défaut est *None* (compare les éléments directement).

*reverse*, une valeur booléenne. Si elle est *True*, la liste d'éléments est triée comme si toutes les comparaisons étaient inversées.

In general, the *key* and *reverse* conversion processes are much faster than specifying an equivalent *cmp* function. This is because *cmp* is called multiple times for each list element while *key* and *reverse* touch each element only once. Use *functools.cmp\_to\_key()* to convert an old-style *cmp* function to a *key* function.

La fonction native *sorted()* est garantie stable. Un tri est stable s'il garantie de ne pas changer l'ordre relatif des éléments égaux entre eux. C'est utile pour trier en plusieurs passes, par exemple par département puis par salaire).

Pour des exemples de tris et un bref tutoriel, consultez *sortinghowto*.

Nouveau dans la version 2.4.

**staticmethod**(*function*)

Donne une méthode statique pour *function*.

Une méthode statique ne reçoit pas de premier argument implicitement. Voilà comment déclarer une méthode statique :

```
class C(object):
    @staticmethod
    def f(arg1, arg2, ...):
        ...
```

La forme *@staticmethod* est un *decorator* de fonction. Voir la description des définitions de fonction dans *function* pour plus de détails.

Elle peut être appelée soit sur une classe (tel que `C.f()`) ou sur une instance (tel que `C().f()`). L'instance est ignorée, sauf pour sa classe.

Les méthodes statiques en Python sont similaires à celles trouvées en Java ou en C++. Consultez `classmethod()` pour une variante utile pour créer des constructeurs alternatifs.

Pour plus d'informations sur les méthodes statiques, consultez la documentation de la hiérarchie des types standards dans types.

Nouveau dans la version 2.2.

Modifié dans la version 2.4 : Function decorator syntax added.

**class** `str(object=)`

Return a string containing a nicely printable representation of an object. For strings, this returns the string itself. The difference with `repr(object)` is that `str(object)` does not always attempt to return a string that is acceptable to `eval()`; its goal is to return a printable string. If no argument is given, returns the empty string, `''`.

For more information on strings see *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange* which describes sequence functionality (strings are sequences), and also the string-specific methods described in the *Méthodes de chaînes de caractères* section. To output formatted strings use template strings or the `%` operator described in the *String Formatting Operations* section. In addition see the *String Services* section. See also `unicode()`.

**sum**(`iterable`[, `start`])

Additionne `start` et les éléments d'`iterable` de gauche à droite et en donne le total. `start` vaut 0 par défaut. Les éléments d'`iterable` sont normalement des nombres, et la valeur de `start` ne peut pas être une chaîne.

Pour certains cas, il existe de bonnes alternatives à `sum()`. La bonne méthode, et rapide, de concaténer une séquence de chaînes est d'appeler `''.join(séquence)`. Pour additionner des nombres à virgule flottante avec une meilleure précision, voir `math.fsum()`. Pour concaténer une série d'itérables, utilisez plutôt `itertools.chain()`.

Nouveau dans la version 2.3.

**super**(`type`[, `object-or-type`])

Donne un objet mandataire (*proxy object* en anglais) déléguant les appels de méthode à une classe parente ou sœur de type `type`. C'est utile pour accéder à des méthodes héritées et substituées dans la classe. L'ordre de recherche est le même que celui utilisé par `getattr()` sauf que `type` lui-même est sauté.

L'attribut `__mro__` de `type` liste l'ordre de recherche de la méthode de résolution utilisée par `getattr()` et `super()`. L'attribut est dynamique et peut changer lorsque la hiérarchie d'héritage est modifiée.

Si le second argument est omis, l'objet `super` obtenu n'est pas lié. Si le second argument est un objet, `isinstance(obj, type)` doit être vrai. Si le second argument est un type, `issubclass(type2, type)` doit être vrai (c'est utile pour les méthodes de classe).

---

**Note :** `super()` only works for *new-style classes*.

---

Il existe deux autres cas d'usage typiques pour `super`. Dans une hiérarchie de classes à héritage simple, `super` peut être utilisé pour obtenir la classe parente sans avoir à la nommer explicitement, rendant le code plus maintenable. Cet usage se rapproche de l'usage de `super` dans d'autres langages de programmation.

Le second est la gestion d'héritage multiple coopératif dans un environnement d'exécution dynamique. Cet usage est unique à Python, il ne se retrouve ni dans les langages compilés statiquement, ni dans les langages ne gérant que l'héritage simple. Cela rend possible d'implémenter un héritage en diamant dans lequel plusieurs classes parentes implémentent la même méthode. Une bonne conception implique que chaque méthode doit avoir la même signature lors de leur appels dans tous les cas (parce que l'ordre des appels est déterminée à l'exécution, parce que l'ordre s'adapte aux changements dans la hiérarchie, et parce que l'ordre peut inclure des classes sœurs inconnues avant l'exécution).

Dans tous les cas, un appel typique à une classe parente ressemble à :

```
class C(B):
    def method(self, arg):
        super(C, self).method(arg)
```

Notez que `super()` fait partie de l'implémentation du processus de liaison de recherche d'attributs pointés explicitement tel que `super().__getitem__(name)`. Il le fait en implémentant sa propre méthode `__getattr__()` pour rechercher les classes dans un ordre prévisible supportant l'héritage multiple coopératif. En conséquence, `super()` n'est pas défini pour les recherches implicites via des instructions ou des opérateurs tel que `super()[name]`.

Also note that `super()` is not limited to use inside methods. The two argument form specifies the arguments exactly and makes the appropriate references.

Pour des suggestions pratiques sur la conception de classes coopératives utilisant `super()`, consultez [guide to using super\(\)](#).

Nouveau dans la version 2.2.

**tuple**(*iterable*)

Return a tuple whose items are the same and in the same order as *iterable*'s items. *iterable* may be a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a tuple, it is returned unchanged. For instance, `tuple('abc')` returns ('a', 'b', 'c') and `tuple([1, 2, 3])` returns (1, 2, 3). If no argument is given, returns a new empty tuple, ().

`tuple` is an immutable sequence type, as documented in [Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange](#). For other containers see the built in `dict`, `list`, and `set` classes, and the `collections` module.

**class type**(*object*)

**class type**(*name*, *bases*, *dict*)

With one argument, return the type of an *object*. The return value is a type object. The `isinstance()` built-in function is recommended for testing the type of an object.

With three arguments, return a new type object. This is essentially a dynamic form of the `class` statement. The *name* string is the class name and becomes the `__name__` attribute; the *bases* tuple itemizes the base classes and becomes the `__bases__` attribute; and the *dict* dictionary is the namespace containing definitions for class body and becomes the `__dict__` attribute. For example, the following two statements create identical `type` objects :

```
>>> class X(object):
...     a = 1
...
>>> X = type('X', (object,), dict(a=1))
```

Nouveau dans la version 2.2.

**unichr**(*i*)

Return the Unicode string of one character whose Unicode code is the integer *i*. For example, `unichr(97)` returns the string `u'a'`. This is the inverse of `ord()` for Unicode strings. The valid range for the argument depends how Python was configured – it may be either UCS2 [0..0xFFFF] or UCS4 [0..0x10FFFF]. `ValueError` is raised otherwise. For ASCII and 8-bit strings see `chr()`.

Nouveau dans la version 2.0.

**unicode**(*object*=")

**unicode**(*object*[, *encoding*[, *errors*]])

Return the Unicode string version of *object* using one of the following modes :

If *encoding* and/or *errors* are given, `unicode()` will decode the object which can either be an 8-bit string or a character buffer using the codec for *encoding*. The *encoding* parameter is a string giving the name of an encoding; if the encoding is not known, `LookupError` is raised. Error handling is done according

to *errors*; this specifies the treatment of characters which are invalid in the input encoding. If *errors* is 'strict' (the default), a *ValueError* is raised on errors, while a value of 'ignore' causes errors to be silently ignored, and a value of 'replace' causes the official Unicode replacement character, U+FFFD, to be used to replace input characters which cannot be decoded. See also the *codecs* module.

If no optional parameters are given, `unicode()` will mimic the behaviour of `str()` except that it returns Unicode strings instead of 8-bit strings. More precisely, if *object* is a Unicode string or subclass it will return that Unicode string without any additional decoding applied.

For objects which provide a `__unicode__()` method, it will call this method without arguments to create a Unicode string. For all other objects, the 8-bit string version or representation is requested and then converted to a Unicode string using the codec for the default encoding in 'strict' mode.

For more information on Unicode strings see *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange* which describes sequence functionality (Unicode strings are sequences), and also the string-specific methods described in the *Méthodes de chaînes de caractères* section. To output formatted strings use template strings or the % operator described in the *String Formatting Operations* section. In addition see the *String Services* section. See also `str()`.

Nouveau dans la version 2.0.

Modifié dans la version 2.2 : Support for `__unicode__()` added.

`vars([object])`

Renvoie l'attribut `__dict__` d'un module, d'une classe, d'une instance ou de n'importe quel objet avec un attribut `__dict__`.

Objects such as modules and instances have an updateable `__dict__` attribute; however, other objects may have write restrictions on their `__dict__` attributes (for example, new-style classes use a dictproxy to prevent direct dictionary updates).

Sans augment, `vars()` se comporte comme `locals()`. Notez que le dictionnaire des variables locales n'est utile qu'en lecture, car ses écritures sont ignorées.

`xrange(stop)`

`xrange(start, stop[, step])`

This function is very similar to `range()`, but returns an *xrange object* instead of a list. This is an opaque sequence type which yields the same values as the corresponding list, without actually storing them all simultaneously. The advantage of `xrange()` over `range()` is minimal (since `xrange()` still has to create the values when asked for them) except when a very large range is used on a memory-starved machine or when all of the range's elements are never used (such as when the loop is usually terminated with `break`). For more information on xrange objects, see *XRange Type* and *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange*.

**CPython implementation detail :** `xrange()` is intended to be simple and fast. Implementations may impose restrictions to achieve this. The C implementation of Python restricts all arguments to native C longs (« short » Python integers), and also requires that the number of elements fit in a native C long. If a larger range is needed, an alternate version can be crafted using the *itertools* module: `islice(count(start, step), (stop-start+step-1+2*(step<0))//step)`.

`zip([iterable, ...])`

This function returns a list of tuples, where the *i*-th tuple contains the *i*-th element from each of the argument sequences or iterables. The returned list is truncated in length to the length of the shortest argument sequence. When there are multiple arguments which are all of the same length, `zip()` is similar to `map()` with an initial argument of `None`. With a single sequence argument, it returns a list of 1-tuples. With no arguments, it returns an empty list.

The left-to-right evaluation order of the iterables is guaranteed. This makes possible an idiom for clustering a data series into n-length groups using `zip(*(iter(s))*n)`.

`zip()` peut être utilisée conjointement avec l'opérateur \* pour dézipper une liste :

```

>>> x = [1, 2, 3]
>>> y = [4, 5, 6]
>>> zipped = zip(x, y)
>>> zipped
[(1, 4), (2, 5), (3, 6)]
>>> x2, y2 = zip(*zipped)
>>> x == list(x2) and y == list(y2)
True

```

Nouveau dans la version 2.0.

Modifié dans la version 2.4 : Formerly, `zip()` required at least one argument and `zip()` raised a `TypeError` instead of returning an empty list.

```
__import__(name[, globals[, locals[, fromlist[, level]]]])
```

**Note :** C'est une fonction avancée qui n'est pas fréquemment nécessaire, contrairement à `importlib.import_module()`.

This function is invoked by the `import` statement. It can be replaced (by importing the `__builtin__` module and assigning to `__builtin__.__import__`) in order to change semantics of the `import` statement, but nowadays it is usually simpler to use import hooks (see [PEP 302](#)). Direct use of `__import__()` is rare, except in cases where you want to import a module whose name is only known at runtime.

La fonction importe le module *name*, utilisant potentiellement *globals* et *locals* pour déterminer comment interpréter le nom dans le contexte d'un paquet. *fromlist* donne le nom des objets ou sous-modules qui devraient être importés du module *name*. L'implémentation standard n'utilise pas l'argument *locals* et n'utilise *globals* que pour déterminer le contexte du paquet de l'instruction `import`.

*level* specifies whether to use absolute or relative imports. The default is `-1` which indicates both absolute and relative imports will be attempted. `0` means only perform absolute imports. Positive values for *level* indicate the number of parent directories to search relative to the directory of the module calling `__import__()`.

Lorsque la variable *name* est de la forme `package.module`, normalement, le paquet le plus haut (le nom jusqu'au premier point) est donné, et *pas* le module nommé par *name*. Cependant, lorsqu'un argument *fromlist* est fourni, le module nommé par *name* est donné.

Par exemple, l'instruction `import spam` donne un code intermédiaire (*bytecode* en anglais) ressemblant au code suivant :

```
spam = __import__('spam', globals(), locals(), [], -1)
```

L'instruction `import ham.ham` appelle :

```
spam = __import__('spam.ham', globals(), locals(), [], -1)
```

Notez comment `__import__()` donne le module le plus haut ici parce que c'est l'objet lié à un nom par l'instruction `import`.

En revanche, l'instruction `from spam.ham import eggs, sausage as saus` donne :

```

_temp = __import__('spam.ham', globals(), locals(), ['eggs', 'sausage'], -1)
eggs = _temp.eggs
saus = _temp.sausage

```

Ici le module `spam.ham` est donné par `__import__()`. De cet objet, les noms à importer sont récupérés et assignés à leurs noms respectifs.

Si vous voulez simplement importer un module (potentiellement dans un paquet) par son nom, utilisez *importlib.import\_module()*.

Modifié dans la version 2.5 : The level parameter was added.

Modifié dans la version 2.5 : Keyword support for parameters was added.

---

Non-essential Built-in Functions

---

There are several built-in functions that are no longer essential to learn, know or use in modern Python programming. They have been kept here to maintain backwards compatibility with programs written for older versions of Python.

Python programmers, trainers, students and book writers should feel free to bypass these functions without concerns about missing something important.

**apply**(*function*, *args*[, *keywords*])

The *function* argument must be a callable object (a user-defined or built-in function or method, or a class object) and the *args* argument must be a sequence. The *function* is called with *args* as the argument list; the number of arguments is the length of the tuple. If the optional *keywords* argument is present, it must be a dictionary whose keys are strings. It specifies keyword arguments to be added to the end of the argument list. Calling *apply()* is different from just calling *function(args)*, since in that case there is always exactly one argument. The use of *apply()* is equivalent to *function(\*args, \*\*keywords)*.

Obsolète depuis la version 2.3 : Use *function(\*args, \*\*keywords)* instead of *apply(function, args, keywords)* (see *tut-unpacking-arguments*).

**buffer**(*object*[, *offset*[, *size*]])

The *object* argument must be an object that supports the buffer call interface (such as strings, arrays, and buffers). A new buffer object will be created which references the *object* argument. The buffer object will be a slice from the beginning of *object* (or from the specified *offset*). The slice will extend to the end of *object* (or will have a length given by the *size* argument).

**coerce**(*x*, *y*)

Return a tuple consisting of the two numeric arguments converted to a common type, using the same rules as used by arithmetic operations. If coercion is not possible, raise *TypeError*.

**intern**(*string*)

Ajoute *string* dans le tableau des chaînes « internées » et renvoie la chaîne internée – qui peut être *string* elle-même ou une copie. Interner une chaîne de caractères permet de gagner un peu de performance lors de l'accès aux dictionnaires – si les clés du dictionnaire et la clé recherchée sont internées, les comparaisons de clés (après le hachage) pourront se faire en comparant les pointeurs plutôt que

caractère par caractère. Normalement, les noms utilisés dans les programmes Python sont automatiquement internés, et les dictionnaires utilisés pour stocker les attributs de modules, de classes, ou d'instances ont aussi leurs clés internées.

Modifié dans la version 2.3 : Interned strings are not immortal (like they used to be in Python 2.2 and before) ; you must keep a reference to the return value of *intern()* around to benefit from it.

## Notes

## CHAPITRE 4

---

### Constantes natives

---

Un petit nombre de constantes existent dans le *namespace* natif. Elles sont :

#### **False**

The false value of the *bool* type.

Nouveau dans la version 2.3.

#### **True**

The true value of the *bool* type.

Nouveau dans la version 2.3.

#### **None**

The sole value of *types.NoneType*. **None** is frequently used to represent the absence of a value, as when default arguments are not passed to a function.

Modifié dans la version 2.4 : Assignments to **None** are illegal and raise a *SyntaxError*.

#### **NotImplemented**

Special value which can be returned by the « rich comparison » special methods (*\_\_eq\_\_()*, *\_\_lt\_\_()*, and friends), to indicate that the comparison is not implemented with respect to the other type.

#### **Ellipsis**

Special value used in conjunction with extended slicing syntax.

#### ***\_\_debug\_\_***

Cette constante est vraie si Python n'a pas été démarré avec une option *-O*. Voir aussi l'expression *assert*.

---

**Note :** The names *None* and *\_\_debug\_\_* cannot be reassigned (assignments to them, even as an attribute name, raise *SyntaxError*), so they can be considered « true » constants.

Modifié dans la version 2.7 : Assignments to *\_\_debug\_\_* as an attribute became illegal.

---

## 4.1 Constantes ajoutées par le module `site`

Le module `site` (qui est importé automatiquement au démarrage, sauf si l'option de ligne de commande `-S` est donnée ajoute un certain nombre de constantes au *namespace* natif. Elles sont utiles pour l'interpréteur interactif et ne devraient pas être utilisées par des programmes.

`quit([code=None])`

`exit([code=None])`

Objets qui, lorsqu'ils sont représentés, affichent un message comme « *Use quit() or Ctrl-D (i.e. EOF) to exit* », et lorsqu'ils sont appelés, lèvent un `SystemExit` avec le code de retour spécifié.

`copyright`

`credits`

Objects that when printed or called, print the text of copyright or credits, respectively.

`license`

Object that when printed, prints the message « Type `license()` to see the full license text », and when called, displays the full license text in a pager-like fashion (one screen at a time).

Les sections suivantes décrivent les types standards intégrés à l'interpréteur.

**Note :** Historically (until release 2.2), Python's built-in types have differed from user-defined types because it was not possible to use the built-in types as the basis for object-oriented inheritance. This limitation no longer exists.

The principal built-in types are numerics, sequences, mappings, files, classes, instances and exceptions.

Some operations are supported by several object types ; in particular, practically all objects can be compared, tested for truth value, and converted to a string (with the `repr()` function or the slightly different `str()` function). The latter function is implicitly used when an object is written by the `print()` function.

## 5.1 Valeurs booléennes

Tout objet peut être testé typiquement dans une condition `if` ou `while` ou comme opérande des opérations booléennes ci-dessous. Les valeurs suivantes sont considérées comme fausses :

- `None`
- `False`
- zero of any numeric type, for example, `0`, `0L`, `0.0`, `0j`.
- toute séquence vide, par exemple, `''`, `()`, `[]`.
- toute dictionnaire vide, par exemple, `{}`.
- instances of user-defined classes, if the class defines a `__nonzero__()` or `__len__()` method, when that method returns the integer zero or `bool` value `False`.<sup>1</sup>

Toutes les autres valeurs sont considérées comme vraies — donc des objets de beaucoup de types sont toujours vrais.

1. Plus d'informations sur ces méthodes spéciales peuvent être trouvées dans le *Python Reference Manual* (customization).

Les opérations et fonctions natives dont le résultat est booléen donnent toujours 0 ou `False` pour faux et 1 ou `True` pour vrai, sauf indication contraire. (Exception importante : les opérations booléennes `or` et `and` renvoient toujours l'une de leurs opérandes.)

## 5.2 Opérations booléennes — `and`, `or`, `not`

Ce sont les opérations booléennes, classées par priorité ascendante :

Opération	Résultat	Notes
<code>x or y</code>	si <i>x</i> est faux, alors <i>y</i> , sinon <i>x</i>	(1)
<code>x and y</code>	si <i>x</i> est faux, alors <i>x</i> , sinon <i>y</i>	(2)
<code>not x</code>	si <i>x</i> est faux, alors <code>True</code> , sinon <code>False</code>	(3)

Notes :

- (1) This is a short-circuit operator, so it only evaluates the second argument if the first one is false.
- (2) This is a short-circuit operator, so it only evaluates the second argument if the first one is true.
- (3) `not a` a une priorité inférieure à celle des opérateurs non-booléens, donc `not a == b` est interprété comme `not (a == b)` et `a == not b` est une erreur de syntaxe.

## 5.3 Comparaisons

Comparison operations are supported by all objects. They all have the same priority (which is higher than that of the Boolean operations). Comparisons can be chained arbitrarily ; for example, `x < y <= z` is equivalent to `x < y and y <= z`, except that *y* is evaluated only once (but in both cases *z* is not evaluated at all when `x < y` is found to be false).

Ce tableau résume les opérations de comparaison :

Opération	Signification	Notes
<code>&lt;</code>	strictement inférieur	
<code>&lt;=</code>	inférieur ou égal	
<code>&gt;</code>	strictement supérieur	
<code>&gt;=</code>	supérieur ou égal	
<code>==</code>	égal	
<code>!=</code>	différent	(1)
<code>is</code>	identité d'objet	
<code>is not</code>	contraire de l'identité d'objet	

Notes :

- (1) `!=` can also be written `<>`, but this is an obsolete usage kept for backwards compatibility only. New code should always use `!=`.

Objects of different types, except different numeric types and different string types, never compare equal ; such objects are ordered consistently but arbitrarily (so that sorting a heterogeneous array yields a consistent result). Furthermore, some types (for example, file objects) support only a degenerate notion of comparison where any two objects of that type are unequal. Again, such objects are ordered arbitrarily but consistently. The `<`, `<=`, `>` and `>=` operators will raise a *[TypeError](#)* exception when any operand is a complex number.

Non-identical instances of a class normally compare as non-equal unless the class defines the `__eq__()` method or the `__cmp__()` method.

Instances of a class cannot be ordered with respect to other instances of the same class, or other types of object, unless the class defines either enough of the rich comparison methods (`__lt__()`, `__le__()`, `__gt__()`, and `__ge__()`) or the `__cmp__()` method.

**CPython implementation detail :** Objects of different types except numbers are ordered by their type names; objects of the same types that don't support proper comparison are ordered by their address.

Two more operations with the same syntactic priority, `in` and `not in`, are supported only by sequence types (below).

## 5.4 Numeric Types — `int`, `float`, `long`, `complex`

There are four distinct numeric types : *plain integers*, *long integers*, *floating point numbers*, and *complex numbers*. In addition, Booleans are a subtype of plain integers. Plain integers (also just called *integers*) are implemented using `long` in C, which gives them at least 32 bits of precision (`sys.maxint` is always set to the maximum plain integer value for the current platform, the minimum value is `-sys.maxint - 1`). Long integers have unlimited precision. Floating point numbers are usually implemented using `double` in C; information about the precision and internal representation of floating point numbers for the machine on which your program is running is available in `sys.float_info`. Complex numbers have a real and imaginary part, which are each a floating point number. To extract these parts from a complex number `z`, use `z.real` and `z.imag`. (The standard library includes additional numeric types, *fractions* that hold rationals, and *decimal* that hold floating-point numbers with user-definable precision.)

Numbers are created by numeric literals or as the result of built-in functions and operators. Unadorned integer literals (including binary, hex, and octal numbers) yield plain integers unless the value they denote is too large to be represented as a plain integer, in which case they yield a long integer. Integer literals with an 'L' or 'l' suffix yield long integers ('L' is preferred because 11 looks too much like eleven!). Numeric literals containing a decimal point or an exponent sign yield floating point numbers. Appending 'j' or 'J' to a numeric literal yields an imaginary number (a complex number with a zero real part) which you can add to an integer or float to get a complex number with real and imaginary parts.

Python fully supports mixed arithmetic : when a binary arithmetic operator has operands of different numeric types, the operand with the « narrower » type is widened to that of the other, where plain integer is narrower than long integer is narrower than floating point is narrower than complex. Comparisons between numbers of mixed type use the same rule.<sup>2</sup> The constructors `int()`, `long()`, `float()`, and `complex()` can be used to produce numbers of a specific type.

All built-in numeric types support the following operations. See power and later sections for the operators' priorities.

2. Par conséquent, la liste `[1, 2]` est considérée égale à `[1.0, 2.0]`. Idem avec des tuples.

Opération	Résultat	Notes
<code>x + y</code>	somme de $x$ et $y$	
<code>x - y</code>	différence de $x$ et $y$	
<code>x * y</code>	produit de $x$ et $y$	
<code>x / y</code>	quotient de $x$ et $y$	(1)
<code>x // y</code>	(floored) quotient of $x$ and $y$	(4)(5)
<code>x % y</code>	reste de $x / y$	(4)
<code>-x</code>	négatif de $x$	
<code>+x</code>	$x$ inchangé	
<code>abs(x)</code>	valeur absolue de $x$	(3)
<code>int(x)</code>	$x$ converti en nombre entier	(2)
<code>long(x)</code>	$x$ converted to long integer	(2)
<code>float(x)</code>	$x$ converti en nombre à virgule flottante	(6)
<code>complex(re, im)</code>	un nombre complexe avec $re$ pour partie réelle et $im$ pour partie imaginaire. $im$ vaut zéro par défaut.	
<code>c.conjugate()</code>	conjugate of the complex number $c$ . (Identity on real numbers)	
<code>divmod(x, y)</code>	la paire ( $x // y$ , $x % y$ )	(3)(4)
<code>pow(x, y)</code>	$x$ à la puissance $y$	(3)(7)
<code>x ** y</code>	$x$ à la puissance $y$	(7)

Notes :

- (1) For (plain or long) integer division, the result is an integer. The result is always rounded towards minus infinity :  $1/2$  is 0,  $(-1)/2$  is -1,  $1/(-2)$  is -1, and  $(-1)/(-2)$  is 0. Note that the result is a long integer if either operand is a long integer, regardless of the numeric value.
- (2) Conversion from floats using `int()` or `long()` truncates toward zero like the related function, `math.trunc()`. Use the function `math.floor()` to round downward and `math.ceil()` to round upward.
- (3) See *Fonctions natives* for a full description.
- (4) Obsolète depuis la version 2.3 : The floor division operator, the modulo operator, and the `divmod()` function are no longer defined for complex numbers. Instead, convert to a floating point number using the `abs()` function if appropriate.
- (5) Also referred to as integer division. The resultant value is a whole integer, though the result's type is not necessarily int.
- (6) `float` accepte aussi les chaînes `nan` et `inf` avec un préfixe optionnel + ou - pour *Not a Number* (NaN) et les infinis positif ou négatif.  
Nouveau dans la version 2.6.
- (7) Python définit `pow(0, 0)` et `0 ** 0` valant 1, puisque c'est courant pour les langages de programmation, et logique.

All *numbers.Real* types (`int`, `long`, and `float`) also include the following operations :

Opération	Résultat
<code>math.trunc(x)</code>	$x$ tronqué à l'Integral
<code>round(x[, n])</code>	$x$ rounded to $n$ digits, rounding ties away from zero. If $n$ is omitted, it defaults to 0.
<code>math.floor(x)</code>	the greatest integer as a float $\leq x$
<code>math.ceil(x)</code>	the least integer as a float $\geq x$

### 5.4.1 Opérations sur les bits des nombres entiers

Les opérations sur les bits n'ont de sens que pour les entiers. Les nombres négatifs sont traités comme leur complément à 2 (ce qui suppose un assez grand nombre de bits afin qu'aucun débordement ne se produise

pendant l'opération).

Les priorités de toutes les opération à deux opérandes sur des bits sont inférieures aux opérations numériques et plus élevées que les comparaisons ; l'opération unaire `~` a la même priorité que les autres opérations numériques unaires (`+` et `-`).

Ce tableau répertorie les opérations binaires triées par priorité ascendante :

Opération	Résultat	Notes
<code>x   y</code>	<i>ou &lt;or&gt; binaire de <math>x</math> et <math>y</math></i>	
<code>x ^ y</code>	<i>ou &lt;or&gt; exclusive binaire de <math>x</math> et <math>y</math></i>	
<code>x &amp; y</code>	<i>et binaire &lt;and&gt; de <math>x</math> et <math>y</math></i>	
<code>x &lt;&lt; n</code>	<i><math>x</math> décalé vers la gauche de <math>n</math> bits</i>	(1)(2)
<code>x &gt;&gt; n</code>	<i><math>x</math> décalé vers la droite de <math>n</math> bits</i>	(1)(3)
<code>~x</code>	les bits de $x$ , inversés	

Notes :

- (1) Des valeurs de décalage négatives sont illégales et provoquent une exception `ValueError`.
- (2) A left shift by  $n$  bits is equivalent to multiplication by `pow(2, n)`. A long integer is returned if the result exceeds the range of plain integers.
- (3) A right shift by  $n$  bits is equivalent to division by `pow(2, n)`.

## 5.4.2 Méthodes supplémentaires sur les entiers

The integer types implement the `numbers.Integral abstract base class`. In addition, they provide one more method :

`int.bit_length()`

`long.bit_length()`

Renvoie le nombre de bits nécessaires pour représenter un nombre entier en binaire, à l'exclusion du signe et des zéros non significatifs :

```
>>> n = -37
>>> bin(n)
'-0b100101'
>>> n.bit_length()
6
```

Plus précisément, si  $x$  est différent de zéro, `x.bit_length()` est le nombre entier positif unique,  $k$  tel que  $2^{k-1} \leq \text{abs}(x) < 2^k$ . Équivalentement, quand `abs(x)` est assez petit pour avoir un logarithme correctement arrondi,  $k = 1 + \text{int}(\log(\text{abs}(x), 2))$ . Si  $x$  est nul, alors `x.bit_length()` donne 0.

Équivalent à :

```
def bit_length(self):
    s = bin(self)          # binary representation: bin(-37) --> '-0b100101'
    s = s.lstrip('-0b')    # remove leading zeros and minus sign
    return len(s)          # len('100101') --> 6
```

Nouveau dans la version 2.7.

## 5.4.3 Méthodes supplémentaires sur les nombres à virgule flottante

Le type `float` implémente la *classe de base abstraite* `numbers.Real` et a également les méthodes suivantes.

`float.as_integer_ratio()`

Renvoie une paire de nombres entiers dont le rapport est exactement égal au nombre d'origine et avec un dénominateur positif. Lève *OverflowError* avec un infini et *ValueError* avec un NaN.

Nouveau dans la version 2.6.

`float.is_integer()`

Donne *True* si l'instance de *float* est finie avec une valeur entière, et *False* autrement :

```
>>> (-2.0).is_integer()
True
>>> (3.2).is_integer()
False
```

Nouveau dans la version 2.6.

Deux méthodes prennent en charge la conversion vers et à partir de chaînes hexadécimales. Étant donné que les *float* de Python sont stockés en interne sous forme de nombres binaires, la conversion d'un *float* depuis ou vers une chaîne décimale implique généralement une petite erreur d'arrondi. En revanche, les chaînes hexadécimales permettent de représenter exactement les nombres à virgule flottante. Cela peut être utile lors du débogage, et dans un travail numérique.

`float.hex()`

Donne une représentation d'un nombre à virgule flottante sous forme de chaîne hexadécimale. Pour les nombres à virgule flottante finis, cette représentation comprendra toujours un préfixe *0x*, un suffixe *p*, et un exposant.

Nouveau dans la version 2.6.

`float.fromhex(s)`

Méthode de classe pour obtenir le *float* représenté par une chaîne de caractères hexadécimale *s*. La chaîne *s* peut contenir des espaces avant et après le chiffre.

Nouveau dans la version 2.6.

Notez que *float.hex()* est une méthode d'instance, alors que *float.fromhex()* est une méthode de classe.

Une chaîne hexadécimale prend la forme :

```
[sign] ['0x'] integer ['.' fraction] ['p' exponent]
```

où *sign* peut être soit *+* soit *-*, *integer* et *fraction* sont des chaînes de chiffres hexadécimales, et *exponent* est un entier décimal facultativement signé. La casse n'est pas significative, et il doit y avoir au moins un chiffre hexadécimal soit dans le nombre entier soit dans la fraction. Cette syntaxe est similaire à la syntaxe spécifiée dans la section 6.4.4.2 de la norme C99, et est aussi la syntaxe utilisée à partir de Java 1.5. En particulier, la sortie de *float.hex()* est utilisable comme valeur hexadécimale à virgule flottante littérale en C ou Java, et des chaînes hexadécimales produites en C via un format *%a* ou Java via *Double.toHexString* sont acceptées par *float.fromhex()*.

Notez que l'exposant est écrit en décimal plutôt qu'en hexadécimal, et qu'il donne la puissance de 2 par lequel multiplier le coefficient. Par exemple, la chaîne hexadécimale *0x3.a7p10* représente le nombre à virgule flottante  $(3 + 10./16 + 7./16**2) * 2.0**10$ , ou 3740.0 :

```
>>> float.fromhex('0x3.a7p10')
3740.0
```

L'application de la conversion inverse à 3740.0 donne une chaîne hexadécimale différente représentant le même nombre :

```
>>> float.hex(3740.0)
'0x1.d380000000000p+11'
```

## 5.5 Les types itérateurs

Nouveau dans la version 2.2.

Python supporte un concept d'itération sur les conteneurs. C'est implémenté en utilisant deux méthodes distinctes qui permettent aux classes définies par l'utilisateur de devenir itérables. Les séquences, décrites plus bas en détail, supportent toujours les méthodes d'itération.

Une méthode doit être définie afin que les objets conteneurs supportent l'itération :

`container.__iter__()`

Donne un objet itérateur. L'objet doit implémenter le protocole d'itération décrit ci-dessous. Si un conteneur prend en charge différents types d'itération, d'autres méthodes peuvent être fournies pour obtenir spécifiquement les itérateurs pour ces types d'itération. (Exemple d'un objet supportant plusieurs formes d'itération : une structure d'arbre pouvant être parcourue en largeur ou en profondeur.) Cette méthode correspond à l'attribut `tp_iter` de la structure du type des objets Python dans l'API Python/C.

Les itérateurs eux-mêmes doivent implémenter les deux méthodes suivantes, qui forment ensemble le *protocole d'itérateur* `<iterator protocol>` :

`iterator.__iter__()`

Donne l'objet itérateur lui-même. Cela est nécessaire pour permettre à la fois à des conteneurs et des itérateurs d'être utilisés avec les instructions `for` et `in`. Cette méthode correspond à l'attribut `tp_iter` de la structure des types des objets Python dans l'API Python/C.

`iterator.next()`

Donne l'élément suivant du conteneur. S'il n'y a pas d'autres éléments, une exception `StopIteration` est levée. Cette méthode correspond à l'attribut `PyTypeObject.tp_iternext` de la structure du type des objets Python dans l'API Python/C.

Python définit plusieurs objets itérateurs pour itérer sur les types standards ou spécifiques de séquence, de dictionnaires et d'autres formes plus spécialisées. Les types spécifiques ne sont pas importants au-delà de leur implémentation du protocole d'itération.

The intention of the protocol is that once an iterator's `next()` method raises `StopIteration`, it will continue to do so on subsequent calls. Implementations that do not obey this property are deemed broken. (This constraint was added in Python 2.3; in Python 2.2, various iterators are broken according to this rule.)

### 5.5.1 Types générateurs

Python's *generators* provide a convenient way to implement the iterator protocol. If a container object's `__iter__()` method is implemented as a generator, it will automatically return an iterator object (technically, a generator object) supplying the `__iter__()` and `next()` methods. More information about generators can be found in the documentation for the `yield` expression.

## 5.6 Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange

There are seven sequence types : strings, Unicode strings, lists, tuples, bytearrays, buffers, and xrange objects.

For other containers see the built in `dict` and `set` classes, and the `collections` module.

String literals are written in single or double quotes : `'xyzyz'`, `"frobozz"`. See strings for more about string literals. Unicode strings are much like strings, but are specified in the syntax using a preceding `'u'` character : `u'abc'`, `u"def"`. In addition to the functionality described here, there are also string-specific methods described in the *Méthodes de chaînes de caractères* section. Lists are constructed with square brackets, separating items with commas : `[a, b, c]`. Tuples are constructed by the comma operator (not

within square brackets), with or without enclosing parentheses, but an empty tuple must have the enclosing parentheses, such as `a`, `b`, `c` or `()`. A single item tuple must have a trailing comma, such as `(d,)`.

Bytearray objects are created with the built-in function `bytearray()`.

Buffer objects are not directly supported by Python syntax, but can be created by calling the built-in function `buffer()`. They don't support concatenation or repetition.

Objects of type `xrange` are similar to buffers in that there is no specific syntax to create them, but they are created using the `xrange()` function. They don't support slicing, concatenation or repetition, and using `in`, `not in`, `min()` or `max()` on them is inefficient.

Most sequence types support the following operations. The `in` and `not in` operations have the same priorities as the comparison operations. The `+` and `*` operations have the same priority as the corresponding numeric operations.<sup>3</sup> Additional methods are provided for *Types de séquences muables*.

This table lists the sequence operations sorted in ascending priority. In the table, *s* and *t* are sequences of the same type; *n*, *i* and *j* are integers :

Opération	Résultat	Notes
<code>x in s</code>	<code>True</code> si un élément de <i>s</i> est égal à <i>x</i> , sinon <code>False</code>	(1)
<code>x not in s</code>	<code>False</code> si un élément de <i>s</i> est égal à <i>x</i> , sinon <code>True</code>	(1)
<code>s + t</code>	la concaténation de <i>s</i> et <i>t</i>	(6)
<code>s * n</code> , <code>n * s</code>	équivalent à ajouter <i>s</i> <i>n</i> fois à lui même	(2)
<code>s[i]</code>	<i>i</i> <sup>e</sup> élément de <i>s</i> en commençant par 0	(3)
<code>s[i:j]</code>	tranche ( <i>slice</i> ) de <i>s</i> de <i>i</i> à <i>j</i>	(3)(4)
<code>s[i:j:k]</code>	tranche ( <i>slice</i> ) de <i>s</i> de <i>i</i> à <i>j</i> avec un pas de <i>k</i>	(3)(5)
<code>len(s)</code>	longueur de <i>s</i>	
<code>min(s)</code>	plus petit élément de <i>s</i>	
<code>max(s)</code>	plus grand élément de <i>s</i>	
<code>s.index(x)</code>	index of the first occurrence of <i>x</i> in <i>s</i>	
<code>s.count(x)</code>	nombre total d'occurrences de <i>x</i> dans <i>s</i>	

Sequence types also support comparisons. In particular, tuples and lists are compared lexicographically by comparing corresponding elements. This means that to compare equal, every element must compare equal and the two sequences must be of the same type and have the same length. (For full details see comparisons in the language reference.)

Notes :

- (1) When *s* is a string or Unicode string object the `in` and `not in` operations act like a substring test. In Python versions before 2.3, *x* had to be a string of length 1. In Python 2.3 and beyond, *x* may be a string of any length.
- (2) Values of *n* less than 0 are treated as 0 (which yields an empty sequence of the same type as *s*). Note that items in the sequence *s* are not copied; they are referenced multiple times. This often haunts new Python programmers; consider :

```
>>> lists = [[]] * 3
>>> lists
[[], [], []]
>>> lists[0].append(3)
>>> lists
[[3], [3], [3]]
```

---

3. Nécessairement, puisque l'analyseur ne peut pas discerner le type des opérandes.

What has happened is that `[]` is a one-element list containing an empty list, so all three elements of `[] * 3` are references to this single empty list. Modifying any of the elements of `lists` modifies this single list. You can create a list of different lists this way :

```
>>> lists = [[] for i in range(3)]
>>> lists[0].append(3)
>>> lists[1].append(5)
>>> lists[2].append(7)
>>> lists
[[3], [5], [7]]
```

De plus amples explications sont disponibles dans la FAQ à la question `faq-multidimensional-list`.

- (3) If  $i$  or  $j$  is negative, the index is relative to the end of sequence  $s$  : `len(s) + i` or `len(s) + j` is substituted. But note that `-0` is still `0`.
- (4) La tranche de  $s$  de  $i$  à  $j$  est définie comme la séquence d'éléments d'indice  $k$  tels que  $i \leq k < j$ . Si  $i$  ou  $j$  est supérieur à `len(s)`, `len(s)` est utilisé. Si  $i$  est omis ou `None`, `0` est utilisé. Si  $j$  est omis ou `None`, `len(s)` est utilisé. Si  $i$  est supérieure ou égale à  $j$ , la tranche est vide.
- (5) The slice of  $s$  from  $i$  to  $j$  with step  $k$  is defined as the sequence of items with index  $x = i + n*k$  such that  $0 \leq n < (j-i)/k$ . In other words, the indices are  $i$ ,  $i+k$ ,  $i+2*k$ ,  $i+3*k$  and so on, stopping when  $j$  is reached (but never including  $j$ ). When  $k$  is positive,  $i$  and  $j$  are reduced to `len(s)` if they are greater. When  $k$  is negative,  $i$  and  $j$  are reduced to `len(s) - 1` if they are greater. If  $i$  or  $j$  are omitted or `None`, they become « end » values (which end depends on the sign of  $k$ ). Note,  $k$  cannot be zero. If  $k$  is `None`, it is treated like `1`.
- (6) **CPython implementation detail** : If  $s$  and  $t$  are both strings, some Python implementations such as CPython can usually perform an in-place optimization for assignments of the form  $s = s + t$  or  $s += t$ . When applicable, this optimization makes quadratic run-time much less likely. This optimization is both version and implementation dependent. For performance sensitive code, it is preferable to use the `str.join()` method which assures consistent linear concatenation performance across versions and implementations.

Modifié dans la version 2.4 : Formerly, string concatenation never occurred in-place.

## 5.6.1 Méthodes de chaînes de caractères

Below are listed the string methods which both 8-bit strings and Unicode objects support. Some of them are also available on `bytearray` objects.

In addition, Python's strings support the sequence type methods described in the *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange* section. To output formatted strings use template strings or the `%` operator described in the *String Formatting Operations* section. Also, see the `re` module for string functions based on regular expressions.

**str.capitalize()**

Renvoie une copie de la chaîne avec son premier caractère en majuscule et le reste en minuscule.

For 8-bit strings, this method is locale-dependent.

**str.center(*width*[, *fillchar*])**

Return centered in a string of length *width*. Padding is done using the specified *fillchar* (default is a space).

Modifié dans la version 2.4 : Support for the *fillchar* argument.

**str.count(*sub*[, *start*[, *end*]])**

Donne le nombre d'occurrences de *sub* ne se chevauchant pas dans le *range* [*start*, *end*]. Les arguments facultatifs *start* et *end* sont interprétés comme pour des *slices*.

**str.decode([*encoding*[, *errors*]])**

Decodes the string using the codec registered for *encoding*. *encoding* defaults to the default string

encoding. *errors* may be given to set a different error handling scheme. The default is 'strict', meaning that encoding errors raise *UnicodeError*. Other possible values are 'ignore', 'replace' and any other name registered via *codecs.register\_error()*, see section *Codec Base Classes*.

Nouveau dans la version 2.2.

Modifié dans la version 2.3 : Support for other error handling schemes added.

Modifié dans la version 2.7 : Gestion des arguments par mot clef.

**str.encode**(*[encoding[, errors]]*)

Return an encoded version of the string. Default encoding is the current default string encoding. *errors* may be given to set a different error handling scheme. The default for *errors* is 'strict', meaning that encoding errors raise a *UnicodeError*. Other possible values are 'ignore', 'replace', 'xmlcharrefreplace', 'backslashreplace' and any other name registered via *codecs.register\_error()*, see section *Codec Base Classes*. For a list of possible encodings, see section *Standard Encodings*.

Nouveau dans la version 2.0.

Modifié dans la version 2.3 : Support for 'xmlcharrefreplace' and 'backslashreplace' and other error handling schemes added.

Modifié dans la version 2.7 : Gestion des arguments par mot clef.

**str.endswith**(*suffix[, start[, end]]*)

Donne **True** si la chaîne se termine par *suffix*, sinon **False**. *suffix* peut aussi être un tuple de suffixes à rechercher. Si l'argument optionnel *start* est donné, le test se fait à partir de cette position. Si l'argument optionnel *end* est fourni, la comparaison s'arrête à cette position.

Modifié dans la version 2.5 : Accept tuples as *suffix*.

**str.expandtabs**(*[tabsize]*)

Donne une copie de la chaîne où toutes les tabulations sont remplacées par un ou plusieurs espaces, en fonction de la colonne courante et de la taille de tabulation donnée. Les positions des tabulations se trouvent tous les *tabsize* caractères (8 par défaut, ce qui donne les positions de tabulations aux colonnes 0, 8, 16 et ainsi de suite). Pour travailler sur la chaîne, la colonne en cours est mise à zéro et la chaîne est examinée caractère par caractère. Si le caractère est une tabulation (`\t`), un ou plusieurs caractères d'espacement sont insérés dans le résultat jusqu'à ce que la colonne courante soit égale à la position de tabulation suivante. (Le caractère tabulation lui-même n'est pas copié.) Si le caractère est un saut de ligne (`\n`) ou un retour chariot (`\r`), il est copié et la colonne en cours est remise à zéro. Tout autre caractère est copié inchangé et la colonne en cours est incrémentée de un indépendamment de la façon dont le caractère est représenté lors de l'affichage.

```
>>> '01\t012\t0123\t01234'.expandtabs()
'01      012      0123      01234'
>>> '01\t012\t0123\t01234'.expandtabs(4)
'01  012 0123   01234'
```

**str.find**(*sub[, start[, end]]*)

Donne la première la position dans la chaîne où *sub* est trouvé dans le *slice* *s[start:end]*. Les arguments facultatifs *start* et *end* sont interprétés comme dans la notation des *slice*. Donne -1 si *sub* n'est pas trouvé.

---

**Note :** La méthode *find()* ne doit être utilisée que si vous avez besoin de connaître la position de *sub*. Pour vérifier si *sub* est une sous chaîne ou non, utilisez l'opérateur **in** :

```
>>> 'Py' in 'Python'
True
```

---

**str.format(\*args, \*\*kwargs)**

Formate une chaîne. La chaîne sur laquelle cette méthode est appelée peut contenir du texte littéral ou des emplacements de remplacement délimités par des accolades {}. Chaque champ de remplacement contient soit l'indice numérique d'un argument positionnel, ou le nom d'un argument donné par mot-clé. Renvoie une copie de la chaîne où chaque champ de remplacement est remplacé par la valeur de chaîne de l'argument correspondant.

```
>>> "The sum of 1 + 2 is {}".format(1+2)
'The sum of 1 + 2 is 3'
```

Voir *Syntaxe de formatage de chaîne* pour une description des options de formatage qui peuvent être spécifiées dans les chaînes de format.

This method of string formatting is the new standard in Python 3, and should be preferred to the % formatting described in *String Formatting Operations* in new code.

Nouveau dans la version 2.6.

**str.index(sub[, start[, end]])**

Like *find()*, but raise *ValueError* when the substring is not found.

**str.isalnum()**

Return true if all characters in the string are alphanumeric and there is at least one character, false otherwise.

For 8-bit strings, this method is locale-dependent.

**str.isalpha()**

Return true if all characters in the string are alphabetic and there is at least one character, false otherwise.

For 8-bit strings, this method is locale-dependent.

**str.isdigit()**

Return true if all characters in the string are digits and there is at least one character, false otherwise.

For 8-bit strings, this method is locale-dependent.

**str.islower()**

Donne **True** si tous les caractères capitalisables<sup>4</sup> de la chaîne sont en minuscules et qu'elle contient au moins un caractère capitalisable. Donne **False** dans le cas contraire.

For 8-bit strings, this method is locale-dependent.

**str.isspace()**

Return true if there are only whitespace characters in the string and there is at least one character, false otherwise.

For 8-bit strings, this method is locale-dependent.

**str.istitle()**

Donne **True** si la chaîne est une chaîne *titlecased* et qu'elle contient au moins un caractère, par exemple les caractères majuscules ne peuvent suivre les caractères non capitalisables et les caractères minuscules ne peuvent suivre que des caractères capitalisables. Donne **False** dans le cas contraire.

For 8-bit strings, this method is locale-dependent.

**str.isupper()**

Donne **True** si tous les caractères différenciables sur la casse<sup>4</sup> de la chaîne sont en majuscules et il y a au moins un caractère différenciable sur la casse, sinon **False**.

For 8-bit strings, this method is locale-dependent.

**str.join(iterable)**

Return a string which is the concatenation of the strings in *iterable*. If there is any Unicode object

4. Les caractères capitalisables sont ceux dont la propriété Unicode *general category* est soit « Lu » (pour *Letter, uppercase*), soit « Ll » (pour *Letter, lowercase*), soit « Lt » (pour *Letter, titlecase*).

in *iterable*, return a Unicode instead. A *TypeError* will be raised if there are any non-string or non-Unicode object values in *iterable*. The separator between elements is the string providing this method.

**str.ljust(*width*, *fillchar*)**

Return the string left justified in a string of length *width*. Padding is done using the specified *fillchar* (default is a space). The original string is returned if *width* is less than or equal to **len(s)**.

Modifié dans la version 2.4 : Support for the *fillchar* argument.

**str.lower()**

Renvoie une copie de la chaîne avec tous les caractères capitalisables<sup>4</sup> convertis en minuscules.

For 8-bit strings, this method is locale-dependent.

**str.lstrip([*chars*])**

Return a copy of the string with leading characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or *None*, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix; rather, all combinations of its values are stripped :

```
>>> '   spacious   '.lstrip()
'spacious'
>>> 'www.example.com'.lstrip('cmowz.')
'example.com'
```

Modifié dans la version 2.2.2 : Support for the *chars* argument.

**str.partition(*sep*)**

Divise la chaîne à la première occurrence de *sep*, et donne un *tuple* de trois éléments contenant la partie avant le séparateur, le séparateur lui-même, et la partie après le séparateur. Si le séparateur n'est pas trouvé, le *tuple* contiendra la chaîne elle-même, suivie de deux chaînes vides.

Nouveau dans la version 2.5.

**str.replace(*old*, *new*, [*count*])**

Renvoie une copie de la chaîne dont toutes les occurrences de la sous-chaîne *old* sont remplacés par *new*. Si l'argument optionnel *count* est donné, seules les *count* premières occurrences sont remplacées.

**str.rfind(*sub*, [*start*, *end*])**

Donne l'indice le plus élevé dans la chaîne où la sous-chaîne *sub* se trouve, de telle sorte que *sub* soit contenue dans **s[start:end]**. Les arguments facultatifs *start* et *end* sont interprétés comme dans la notation des *slices*. Donne -1 en cas d'échec.

**str.rindex(*sub*, [*start*, *end*])**

Comme *rfind()* mais lève une exception *ValueError* lorsque la sous-chaîne *sub* est introuvable.

**str.rjust(*width*, *fillchar*)**

Return the string right justified in a string of length *width*. Padding is done using the specified *fillchar* (default is a space). The original string is returned if *width* is less than or equal to **len(s)**.

Modifié dans la version 2.4 : Support for the *fillchar* argument.

**str.rpartition(*sep*)**

Divise la chaîne à la dernière occurrence de *sep*, et donne un *tuple* de trois éléments contenant la partie avant le séparateur, le séparateur lui-même, et la partie après le séparateur. Si le séparateur n'est pas trouvé, le *tuple* contiendra deux chaînes vides, puis par la chaîne elle-même.

Nouveau dans la version 2.5.

**str.split([*sep*, *maxsplit*])**

Renvoie une liste des mots de la chaîne, en utilisant *sep* comme séparateur. Si *maxsplit* est donné, c'est le nombre maximum de divisions qui pourront être faites, celles « à droite ». Si *sep* est pas spécifié ou est *None*, tout espace est un séparateur. En dehors du fait qu'il découpe par la droite, *rsplit()* se comporte comme *split()* qui est décrit en détail ci-dessous.

Nouveau dans la version 2.4.

`str.rstrip([chars])`

Return a copy of the string with trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a suffix; rather, all combinations of its values are stripped :

```
>>> '   spacious   '.rstrip()
'   spacious'
>>> 'mississippi'.rstrip('ipz')
'mississ'
```

Modifié dans la version 2.2.2 : Support for the *chars* argument.

`str.split([sep[, maxsplit]])`

Renvoie une liste des mots de la chaîne, en utilisant *sep* comme séparateur de mots. Si *maxsplit* est donné, c'est le nombre maximum de divisions qui pourront être effectuées, (donnant ainsi une liste de longueur `maxsplit+1`). Si *maxsplit* n'est pas fourni, ou vaut `-1`, le nombre de découpes n'est pas limité (Toutes les découpes possibles sont faites).

Si *sep* est donné, les délimiteurs consécutifs ne sont pas regroupés et ainsi délimitent des chaînes vides (par exemple, `'1,,2'.split(',')` donne `['1', '', '2']`). L'argument *sep* peut contenir plusieurs caractères (par exemple, `'1<>2<>3'.split('<>')` renvoie `['1', '2', '3']`). Découper une chaîne vide en spécifiant *sep* donne `['']`.

Si *sep* n'est pas spécifié ou est `None`, un autre algorithme de découpage est appliqué : les espaces consécutifs sont considérés comme un seul séparateur, et le résultat ne contiendra pas les chaînes vides de début ou de la fin si la chaîne est préfixée ou suffixée d'espaces. Par conséquent, diviser une chaîne vide ou une chaîne composée d'espaces avec un séparateur `None` renvoie `[]`.

For example, `' 1 2 3 '.split()` returns `['1', '2', '3']`, and `' 1 2 3 '.split(None, 1)` returns `['1', '2 3 ']`.

`str.splitlines([keepends])`

Return a list of the lines in the string, breaking at line boundaries. This method uses the *universal newlines* approach to splitting lines. Line breaks are not included in the resulting list unless *keepends* is given and true.

Python recognizes `"\r"`, `"\n"`, and `"\r\n"` as line boundaries for 8-bit strings.

Par exemple :

```
>>> 'ab c\nnde fg\rkl\r\n'.splitlines()
['ab c', '', 'de fg', 'kl']
>>> 'ab c\nnde fg\rkl\r\n'.splitlines(True)
['ab c\n', '\n', 'de fg\r', 'kl\r\n']
```

Contrairement à *split()* lorsque *sep* est fourni, cette méthode renvoie une liste vide pour la chaîne vide, et un saut de ligne à la fin ne se traduit pas par une ligne supplémentaire :

```
>>> "".splitlines()
[]
>>> "One line\n".splitlines()
['One line']
```

À titre de comparaison, `split('\n')` donne :

```
>>> ''.split('\n')
['']
>>> 'Two lines\n'.split('\n')
['Two lines', '']
```

`unicode.splitlines([keepends])`

Return a list of the lines in the string, like `str.splitlines()`. However, the Unicode method splits on the following line boundaries, which are a superset of the *universal newlines* recognized for 8-bit strings.

Représentation	Description
<code>\n</code>	Saut de ligne
<code>\r</code>	Retour chariot
<code>\r\n</code>	Retour chariot + saut de ligne
<code>\v</code> or <code>\x0b</code>	Tabulation verticale
<code>\f</code> or <code>\x0c</code>	Saut de page
<code>\x1c</code>	Séparateur de fichiers
<code>\x1d</code>	Séparateur de groupes
<code>\x1e</code>	Séparateur d'enregistrements
<code>\x85</code>	Ligne suivante (code de contrôle <i>C1</i> )
<code>\u2028</code>	Séparateur de ligne
<code>\u2029</code>	Séparateur de paragraphe

Modifié dans la version 2.7 : `\v` et `\f` ajoutés à la liste des limites de lignes.

`str.startswith(prefix[, start[, end]])`

Donne `True` si la chaîne commence par *prefix*, sinon `False`. *prefix* peut aussi être un tuple de préfixes à rechercher. Lorsque *start* est donné, la comparaison commence à cette position, et lorsque *end* est donné, la comparaison s'arrête à celle ci.

Modifié dans la version 2.5 : Accept tuples as *prefix*.

`str.strip([chars])`

Return a copy of the string with the leading and trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped :

```
>>> '   spacious   '.strip()
'spacious'
>>> 'www.example.com'.strip('cmowz.')
'example'
```

Modifié dans la version 2.2.2 : Support for the *chars* argument.

`str.swapcase()`

Return a copy of the string with uppercase characters converted to lowercase and vice versa.

For 8-bit strings, this method is locale-dependent.

`str.title()`

Renvoie une version en initiales majuscules de la chaîne où les mots commencent par une capitale et les caractères restants sont en minuscules.

Pour l'algorithme, la notion de mot est définie simplement et indépendamment de la langue comme un groupe de lettres consécutives. La définition fonctionne dans de nombreux contextes, mais cela signifie que les apostrophes (typiquement de la forme possessive en Anglais) forment les limites de mot, ce qui n'est pas toujours le résultat souhaité :

```
>>> "they're bill's friends from the UK".title()
'They'Re Bill'S Friends From The Uk'
```

Une solution pour contourner le problème des apostrophes peut être obtenue en utilisant des expressions rationnelles :

```
>>> import re
>>> def titlecase(s):
...     return re.sub(r"[A-Za-z]+(' [A-Za-z]+)?",
...                   lambda mo: mo.group(0)[0].upper() +
...                               mo.group(0)[1:].lower(),
...                   s)
...
>>> titlecase("they're bill's friends.")
'They're Bill's Friends.'
```

For 8-bit strings, this method is locale-dependent.

**str.translate(table[, deletechars])**

Return a copy of the string where all characters occurring in the optional argument *deletechars* are removed, and the remaining characters have been mapped through the given translation table, which must be a string of length 256.

You can use the *maketrans()* helper function in the *string* module to create a translation table. For string objects, set the *table* argument to *None* for translations that only delete characters :

```
>>> 'read this short text'.translate(None, 'aeiou')
'rd ths shrt txt'
```

Nouveau dans la version 2.6 : Support for a *None table* argument.

For Unicode objects, the *translate()* method does not accept the optional *deletechars* argument. Instead, it returns a copy of the *s* where all characters have been mapped through the given translation table which must be a mapping of Unicode ordinals to Unicode ordinals, Unicode strings or *None*. Unmapped characters are left untouched. Characters mapped to *None* are deleted. Note, a more flexible approach is to create a custom character mapping codec using the *codecs* module (see *encodings.cp1251* for an example).

**str.upper()**

Return a copy of the string with all the cased characters<sup>4</sup> converted to uppercase. Note that *s.upper().isupper()* might be *False* if *s* contains uncased characters or if the Unicode category of the resulting character(s) is not « Lu » (Letter, uppercase), but e.g. « Lt » (Letter, titlecase).

For 8-bit strings, this method is locale-dependent.

**str.zfill(width)**

Return the numeric string left filled with zeros in a string of length *width*. A sign prefix is handled correctly. The original string is returned if *width* is less than or equal to *len(s)*.

Nouveau dans la version 2.2.2.

The following methods are present only on unicode objects :

**unicode.isnumeric()**

Return *True* if there are only numeric characters in *S*, *False* otherwise. Numeric characters include digit characters, and all characters that have the Unicode numeric value property, e.g. U+2155, VULGAR FRACTION ONE FIFTH.

**unicode.isdecimal()**

Return *True* if there are only decimal characters in *S*, *False* otherwise. Decimal characters include digit characters, and all characters that can be used to form decimal-radix numbers, e.g. U+0660, ARABIC-INDIC DIGIT ZERO.

## 5.6.2 String Formatting Operations

String and Unicode objects have one unique built-in operation : the *%* operator (modulo). This is also known as the string *formatting* or *interpolation* operator. Given *format % values* (where *format* is a string or

Unicode object), % conversion specifications in *format* are replaced with zero or more elements of *values*. The effect is similar to the using `sprintf()` in the C language. If *format* is a Unicode object, or if any of the objects being converted using the %s conversion are Unicode objects, the result will also be a Unicode object.

Si *format* ne nécessite qu'un seul argument, *values* peut être un objet unique.<sup>5</sup> Si *values* est un tuple, il doit contenir exactement le nombre d'éléments spécifiés par la chaîne de format, ou un seul objet de correspondances ( *mapping object*, par exemple, un dictionnaire).

Un indicateur de conversion contient deux ou plusieurs caractères et comporte les éléments suivants, qui doivent apparaître dans cet ordre :

1. Le caractère '%', qui marque le début du marqueur.
2. La clé de correspondance (facultative), composée d'une suite de caractères entre parenthèse (par exemple, (somename)).
3. Des options de conversion, facultatives, qui affectent le résultat de certains types de conversion.
4. Largeur minimum (facultative). Si elle vaut '\*' (astérisque), la largeur est lue de l'élément suivant du tuple *values*, et l'objet à convertir vient après la largeur de champ minimale et la précision facultative.
5. Precision (optional), given as a '.' (dot) followed by the precision. If specified as '\*' (an asterisk), the actual width is read from the next element of the tuple in *values*, and the value to convert comes after the precision.
6. Modificateur de longueur (facultatif).
7. Type de conversion.

Lorsque l'argument de droite est un dictionnaire (ou un autre type de *mapping*), les marqueurs dans la chaîne *doivent* inclure une clé présente dans le dictionnaire, écrite entre parenthèses, immédiatement après le caractère '%'. La clé indique quelle valeur du dictionnaire doit être formatée. Par exemple :

```
>>> print '%(language)s has %(number)03d quote types.' % \
...     {"language": "Python", "number": 2}
Python has 002 quote types.
```

Dans ce cas, aucune \* ne peuvent se trouver dans le format (car ces \* nécessitent une liste (accès séquentiel) de paramètres).

Les caractères indicateurs de conversion sont :

Op-tion	Signification
'#'	La conversion utilisera la « forme alternative » (définie ci-dessous).
'0'	Les valeurs numériques converties seront complétée de zéros.
'-'	La valeur convertie est ajustée à gauche (remplace la conversion '0' si les deux sont données).
' '	(un espace) Un espace doit être laissé avant un nombre positif (ou chaîne vide) produite par la conversion d'une valeur signée.
'+'	Un caractère de signe ('+' ou '-') précède la valeur convertie (remplace le marqueur « espace »).

Un modificateur de longueur (h, l ou L) peut être présent, mais est ignoré car il est pas nécessaire pour Python, donc par exemple %ld est identique à %d.

Les types utilisables dans les conversion sont :

- 
5. Pour insérer un *tuple*, vous devez donc donner un *tuple* d'un seul élément, contenant le *tuple* à insérer.

Conversion	Signification	Notes
'd'	Entier décimal signé.	
'i'	Entier décimal signé.	
'o'	Valeur octale signée.	(1)
'u'	Type obsolète — identique à 'd'.	(7)
'x'	Hexadécimal signé (en minuscules).	(2)
'X'	Hexadécimal signé (capitales).	(2)
'e'	Format exponentiel pour un <i>float</i> (minuscule).	(3)
'E'	Format exponentiel pour un <i>float</i> (en capitales).	(3)
'f'	Format décimal pour un <i>float</i> .	(3)
'F'	Format décimal pour un <i>float</i> .	(3)
'g'	Format <i>float</i> . Utilise le format exponentiel minuscules si l'exposant est inférieur à -4 ou pas plus petit que la précision, sinon le format décimal.	(4)
'G'	Format <i>float</i> . Utilise le format exponentiel en capitales si l'exposant est inférieur à -4 ou pas plus petit que la précision, sinon le format décimal.	(4)
'c'	Un seul caractère (accepte des entiers ou une chaîne d'un seul caractère).	
'r'	String (converts any Python object using <i>repr()</i> ).	(5)
's'	String (convertit n'importe quel objet Python avec <i>str()</i> ).	(6)
'%'	Aucun argument n'est converti, donne un caractère de '%' dans le résultat.	

Notes :

- (1) La forme alternative insère un zéro ('0') entre le rembourrage gauche et le formatage du nombre si son premier caractère n'est pas déjà un zéro.
- (2) The alternate form causes a leading '0x' or '0X' (depending on whether the 'x' or 'X' format was used) to be inserted before the first digit.
- (3) La forme alternative implique la présence d'un point décimal, même si aucun chiffre ne le suit.  
La précision détermine le nombre de chiffres après la virgule, 6 par défaut.
- (4) La forme alternative implique la présence d'un point décimal et les zéros non significatifs sont conservés (ils ne le seraient pas autrement).  
La précision détermine le nombre de chiffres significatifs avant et après la virgule. 6 par défaut.
- (5) The `%r` conversion was added in Python 2.0.  
The precision determines the maximal number of characters used.
- (6) If the object or format provided is a *unicode* string, the resulting string will also be *unicode*.  
The precision determines the maximal number of characters used.
- (7) Voir la [PEP 237](#).

Puisque les chaînes Python ont une longueur explicite, les conversions `%s` ne considèrent pas `'\0'` comme la fin de la chaîne.

Modifié dans la version 2.7 : Les conversions `%f` pour nombres dont la valeur absolue est supérieure à `1e50` ne sont plus remplacés par des conversions `%g`.

Additional string operations are defined in standard modules *string* and *re*.

### 5.6.3 xrange Type

The *xrange* type is an immutable sequence which is commonly used for looping. The advantage of the *xrange* type is that an *xrange* object will always take the same amount of memory, no matter the size of the range it represents. There are no consistent performance advantages.

Xrange objects have very little behavior : they only support indexing, iteration, and the *len()* function.

### 5.6.4 Types de séquences muables

List and *bytearray* objects support additional operations that allow in-place modification of the object. Other mutable sequence types (when added to the language) should also support these operations. Strings and tuples are immutable sequence types : such objects cannot be modified once created. The following operations are defined on mutable sequence types (where *x* is an arbitrary object) :

Opération	Résultat	Notes
<code>s[i] = x</code>	élément <i>i</i> de <i>s</i> est remplacé par <i>x</i>	
<code>s[i:j] = t</code>	tranche de <i>s</i> de <i>i</i> à <i>j</i> est remplacée par le contenu de l'itérable <i>t</i>	
<code>del s[i:j]</code>	identique à <code>s[i:j] = []</code>	
<code>s[i:j:k] = t</code>	les éléments de <code>s[i:j:k]</code> sont remplacés par ceux de <i>t</i>	(1)
<code>del s[i:j:k]</code>	supprime les éléments de <code>s[i:j:k]</code> de la liste	
<code>s.append(x)</code>	same as <code>s[len(s):len(s)] = [x]</code>	(2)
<code>s.extend(t)</code> or <code>s += t</code>	for the most part the same as <code>s[len(s):len(s)] = t</code>	(3)
<code>s *= n</code>	met à jour <i>s</i> avec son contenu répété <i>n</i> fois	(11)
<code>s.count(x)</code>	return number of <i>i</i> 's for which <code>s[i] == x</code>	
<code>s.index(x[, i[, j]])</code>	return smallest <i>k</i> such that <code>s[k] == x</code> and <code>i &lt;= k &lt; j</code>	(4)
<code>s.insert(i, x)</code>	same as <code>s[i:i] = [x]</code>	(5)
<code>s.pop([i])</code>	same as <code>x = s[i]; del s[i]; return x</code>	(6)
<code>s.remove(x)</code>	same as <code>del s[s.index(x)]</code>	(4)
<code>s.reverse()</code>	inverse sur place les éléments de <i>s</i>	(7)
<code>s.sort([cmp[, key[, reverse]])</code>	sort the items of <i>s</i> in place	(7)(8)(9)(10)

Notes :

- (1) *t* must have the same length as the slice it is replacing.
- (2) The C implementation of Python has historically accepted multiple parameters and implicitly joined them into a tuple; this no longer works in Python 2.0. Use of this misfeature has been deprecated since Python 1.4.
- (3) *t* can be any iterable object.
- (4) Raises *ValueError* when *x* is not found in *s*. When a negative index is passed as the second or third parameter to the `index()` method, the list length is added, as for slice indices. If it is still negative, it is truncated to zero, as for slice indices.  
Modifié dans la version 2.3 : Previously, `index()` didn't have arguments for specifying start and stop positions.
- (5) When a negative index is passed as the first parameter to the `insert()` method, the list length is added, as for slice indices. If it is still negative, it is truncated to zero, as for slice indices.  
Modifié dans la version 2.3 : Previously, all negative indices were truncated to zero.
- (6) The `pop()` method's optional argument *i* defaults to `-1`, so that by default the last item is removed and returned.
- (7) The `sort()` and `reverse()` methods modify the list in place for economy of space when sorting or reversing a large list. To remind you that they operate by side effect, they don't return the sorted or reversed list.
- (8) The `sort()` method takes optional arguments for controlling the comparisons.  
*cmp* specifies a custom comparison function of two arguments (list items) which should return a negative, zero or positive number depending on whether the first argument is considered smaller than, equal to, or larger than the second argument : `cmp=lambda x,y: cmp(x.lower(), y.lower())`. The default value is `None`.

*key* specifies a function of one argument that is used to extract a comparison key from each list element : `key=str.lower`. The default value is `None`.

*reverse*, une valeur booléenne. Si elle est `True`, la liste d'éléments est triée comme si toutes les comparaisons étaient inversées.

In general, the *key* and *reverse* conversion processes are much faster than specifying an equivalent *cmp* function. This is because *cmp* is called multiple times for each list element while *key* and *reverse* touch each element only once. Use `functools.cmp_to_key()` to convert an old-style *cmp* function to a *key* function.

Modifié dans la version 2.3 : Support for `None` as an equivalent to omitting *cmp* was added.

Modifié dans la version 2.4 : Support for *key* and *reverse* was added.

- (9) Starting with Python 2.3, the `sort()` method is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal — this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).
- (10) **CPython implementation detail** : While a list is being sorted, the effect of attempting to mutate, or even inspect, the list is undefined. The C implementation of Python 2.3 and newer makes the list appear empty for the duration, and raises `ValueError` if it can detect that the list has been mutated during a sort.
- (11) The value *n* is an integer, or an object implementing `__index__()`. Zero and negative values of *n* clear the sequence. Items in the sequence are not copied ; they are referenced multiple times, as explained for `s * n` under *Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange*.

## 5.7 Types d'ensembles — set, frozenset

A *set* object is an unordered collection of distinct *hashable* objects. Common uses include membership testing, removing duplicates from a sequence, and computing mathematical operations such as intersection, union, difference, and symmetric difference. (For other containers see the built in *dict*, *list*, and *tuple* classes, and the *collections* module.)

Nouveau dans la version 2.4.

Comme pour les autres collections, les ensembles supportent `x in set`, `len(set)`, et `for x in set`. En tant que collection non-triée, les ensembles n'enregistrent pas la position des éléments ou leur ordre d'insertion. En conséquence, les *sets* n'autorisent ni l'indexation, ni le découpage, ou tout autre comportement de séquence.

Il existe actuellement deux types natifs pour les ensembles, *set* et *frozenset*. Le type *set* est muable — son contenu peut changer en utilisant des méthodes comme `add()` et `remove()`. Puisqu'il est muable, il n'a pas de valeur de hachage et ne peut donc pas être utilisé ni comme clef de dictionnaire ni comme élément d'un autre ensemble. Le type *frozenset* est immuable et *hashable* — son contenu ne peut être modifié après sa création, il peut ainsi être utilisé comme clef de dictionnaire ou élément d'un autre *set*.

As of Python 2.7, non-empty sets (not frozensets) can be created by placing a comma-separated list of elements within braces, for example : `{'jack', 'sjoerd'}`, in addition to the *set* constructor.

Les constructeurs des deux classes fonctionnent pareil :

```
class set([iterable])
```

```
class frozenset([iterable])
```

Renvoie un nouveau *set* ou *frozenset* dont les éléments viennent d'*iterable*. Les éléments d'un *set* doivent être *hashable*. Pour représenter des *sets* de *sets* les *sets* intérieurs doivent être des *frozenset*. Si *iterable* n'est pas spécifié, un nouveau *set* vide est renvoyé.

Les instances de *set* et *frozenset* fournissent les opérations suivantes :

```
len(s)
```

Donne le nombre d'éléments dans le *set* *s* (cardinalité de *s*).

`x in s`  
Test d'appartenance de *x* dans *s*.

`x not in s`  
Test de non-appartenance de *x* dans *s*.

`isdisjoint(other)`  
Renvoie `True` si l'ensemble n'a aucun élément en commun avec *other*. Les ensembles sont disjoints si et seulement si leur intersection est un ensemble vide.  
Nouveau dans la version 2.6.

`issubset(other)`

`set <= other`  
Teste si tous les éléments du `set` sont dans *other*.

`set < other`  
Teste si l'ensemble est un sous-ensemble de *other*, c'est-à-dire, `set <= other and set != other`.

`issuperset(other)`

`set >= other`  
Teste si tous les éléments de *other* sont dans l'ensemble.

`set > other`  
Teste si l'ensemble est un sur-ensemble de *other*, c'est-à-dire, `set >= other and set != other`.

`union(*others)`  
`set | other | ...`  
Renvoie un nouvel ensemble dont les éléments viennent de l'ensemble et de tous les autres.  
Modifié dans la version 2.6 : Accepts multiple input iterables.

`intersection(*others)`  
`set & other & ...`  
Renvoie un nouvel ensemble dont les éléments sont communs à l'ensemble et à tous les autres.  
Modifié dans la version 2.6 : Accepts multiple input iterables.

`difference(*others)`  
`set - other - ...`  
Renvoie un nouvel ensemble dont les éléments sont dans l'ensemble mais ne sont dans aucun des autres.  
Modifié dans la version 2.6 : Accepts multiple input iterables.

`symmetric_difference(other)`  
`set ^ other`  
Renvoie un nouvel ensemble dont les éléments sont soit dans l'ensemble, soit dans les autres, mais pas dans les deux.

`copy()`  
Renvoie un nouvel ensemble, copie de surface de *s*.

Remarque : Les méthodes `union()`, `intersection()`, `difference()`, et `symmetric_difference()`, `issubset()`, et `issuperset` acceptent n'importe quel itérable comme argument, contrairement aux opérateurs équivalents qui n'acceptent que des `*sets*`. Il est donc préférable d'éviter les constructions comme `set('abc') & 'cbs'()`, sources typiques d'erreurs, en faveur d'une construction plus lisible : `set('abc').intersection('cbs')`.

Les classes `set` et `frozenset` supportent les comparaisons d'ensemble à ensemble. Deux ensembles sont égaux si et seulement si chaque élément de chaque ensemble est contenu dans l'autre (autrement dit que chaque ensemble est un sous-ensemble de l'autre). Un ensemble est plus petit qu'un autre ensemble si et seulement si le premier est un sous-ensemble du second (un sous-ensemble, mais pas égal). Un ensemble est plus grand qu'un autre ensemble si et seulement si le premier est un sur-ensemble du second (est un sur-ensemble mais n'est pas égal).

Les instances de `set` se comparent aux instances de `frozenset` en fonction de leurs membres. Par exemple, `set('abc') == frozenset('abc')` envoie `True`, ainsi que `set('abc') in set([frozenset('abc')])`.

The subset and equality comparisons do not generalize to a total ordering function. For example, any two non-empty disjoint sets are not equal and are not subsets of each other, so *all* of the following return `False` : `a<b`, `a==b`, or `a>b`. Accordingly, sets do not implement the `__cmp__()` method.

Puisque les *sets* ne définissent qu'un ordre partiel (par leurs relations de sous-ensembles), la sortie de la méthode `list.sort()` n'est pas définie pour des listes d'ensembles.

Les éléments des *sets*, comme les clefs de dictionnaires, doivent être *hashable*.

Les opérations binaires mélangeant des instances de *set* et *frozenset* renvoient le type de la première opérande. Par exemple : `frozenset('ab') | set('bc')` renvoie une instance de *frozenset*.

La table suivante liste les opérations disponibles pour les *set* mais qui ne s'appliquent pas aux instances de *frozenset* :

**update(\*others)**

`set |= other | ...`

Met à jour l'ensemble, ajoutant les éléments de tous les autres.

Modifié dans la version 2.6 : Accepts multiple input iterables.

**intersection\_update(\*others)**

`set &= other & ...`

Met à jour l'ensemble, ne gardant que les éléments trouvés dans tous les autres.

Modifié dans la version 2.6 : Accepts multiple input iterables.

**difference\_update(\*others)**

`set -= other | ...`

Met à jour l'ensemble, retirant les éléments trouvés dans les autres.

Modifié dans la version 2.6 : Accepts multiple input iterables.

**symmetric\_difference\_update(other)**

`set ^= other`

Met à jour le set, ne gardant que les éléments trouvés dans un des ensembles mais pas dans les deux.

**add(elem)**

Ajoute l'élément *elem* au set.

**remove(elem)**

Retire l'élément *elem* de l'ensemble. Lève une exception *KeyError* si *elem* n'est pas dans l'ensemble.

**discard(elem)**

Retire l'élément *elem* de l'ensemble s'il y est.

**pop()**

Retire et renvoie un élément arbitraire de l'ensemble. Lève une exception *KeyError* si l'ensemble est vide.

**clear()**

Supprime tous les éléments du *set*.

Notez que les versions non-opérateurs des méthodes *update()*, *intersection\_update()*, *difference\_update()*, et *symmetric\_difference\_update()* acceptent n'importe quel itérable comme argument.

Note, the *elem* argument to the `__contains__()`, *remove()*, and *discard()* methods may be a set. To support searching for an equivalent frozenset, a temporary one is created from *elem*.

Voir aussi :

*Comparison to the built-in set types* Differences between the *sets* module and the built-in set types.

## 5.8 Les types de correspondances — dict

A *mapping* object maps *hashable* values to arbitrary objects. Mappings are mutable objects. There is currently only one standard mapping type, the *dictionary*. (For other containers see the built in *list*, *set*, and *tuple*

classes, and the *collections* module.)

Les clefs d'un dictionnaire sont *presque* des données arbitraires. Les valeurs qui ne sont pas *hashable*, c'est-à-dire qui contiennent les listes, des dictionnaires ou autre type muable (qui sont comparés par valeur plutôt que par leur identité) ne peuvent pas être utilisées comme clef de dictionnaire. Les types numériques utilisés comme clef obéissent aux règles classiques en ce qui concerne les comparaisons : si deux nombres sont égaux (comme 1 et 1.0) ils peuvent tous les deux être utilisés pour obtenir la même entrée d'un dictionnaire. (Notez cependant que puisque les ordinateurs stockent les nombres à virgule flottante sous forme d'approximations, il est généralement imprudent de les utiliser comme clefs de dictionnaires.)

Il est possible de créer des dictionnaires en plaçant entre accolades une liste de paires de **key: value** séparés par des virgules, par exemple : {'jack': 4098, 'sjoerd': 4127} ou {4098: 'jack', 4127: 'sjoerd'}, ou en utilisant le constructeur de *dict*.

```
class dict(**kwarg)
class dict(mapping, **kwarg)
class dict(iterable, **kwarg)
```

Renvoie un nouveau dictionnaire initialisé depuis un argument positionnel optionnel, et un ensemble (vide ou non) d'arguments par mot clef.

Si aucun argument positionnel n'est donné, un dictionnaire vide est créé. Si un argument positionnel est donné et est un *mapping object*, un dictionnaire est créé avec les mêmes paires de clef-valeurs que le *mapping* donné. Autrement, l'argument positionnel doit être un objet *iterable*. Chaque élément de cet itérable doit lui-même être un itérable contenant exactement deux objets. Le premier objet de chaque élément devient la clef du nouveau dictionnaire, et le second devient sa valeur correspondante. Si une clef apparaît plus d'une fois, la dernière valeur pour cette clef devient la valeur correspondante à cette clef dans le nouveau dictionnaire.

Si des arguments nommés sont donnés, ils sont ajoutés au dictionnaire créé depuis l'argument positionnel. Si une clef est déjà présente, la valeur de l'argument nommé remplace la valeur reçue par l'argument positionnel.

Typiquement, les exemples suivants renvoient tous un dictionnaire valant {"one": 1, "two": 2, "three": 3} :

```
>>> a = dict(one=1, two=2, three=3)
>>> b = {'one': 1, 'two': 2, 'three': 3}
>>> c = dict(zip(['one', 'two', 'three'], [1, 2, 3]))
>>> d = dict([('two', 2), ('one', 1), ('three', 3)])
>>> e = dict({'three': 3, 'one': 1, 'two': 2})
>>> a == b == c == d == e
True
```

Fournir les arguments nommés comme dans le premier exemple en fonctionne que pour des clefs qui sont des identifiants valide en Python. Dans les autres cas, toutes les clefs valides sont utilisables.

Nouveau dans la version 2.2.

Modifié dans la version 2.3 : Support for building a dictionary from keyword arguments added.

Voici les opérations gérées par les dictionnaires, (par conséquent, d'autres types de *mapping* peuvent les gérer aussi) :

**len(d)**

Renvoie le nombre d'éléments dans le dictionnaire *d*.

**d[key]**

Donne l'élément de *d* dont la clef est *key*. Lève une exception *KeyError* si *key* n'est pas dans le dictionnaire.

Si une sous-classe de *dict* définit une méthode *\_\_missing\_\_()* et que *key* manque, l'opération *d[key]* appelle cette méthode avec la clef *key* en argument. L'opération *d[key]* renverra la valeur, ou lèvera l'exception renvoyée ou levée par l'appel à *\_\_missing\_\_(key)*. Aucune autre opération ni

méthode n'appellent `__missing__()`. If `__missing__()` n'est pas définie, une exception `KeyError` est levée. `__missing__()` doit être une méthode; ça ne peut être une variable d'instance :

```
>>> class Counter(dict):
...     def __missing__(self, key):
...         return 0
>>> c = Counter()
>>> c['red']
0
>>> c['red'] += 1
>>> c['red']
1
```

L'exemple ci-dessus montre une partie de l'implémentation de `collections.Counter`. `collections.defaultdict` implémente aussi `__missing__`.

Nouveau dans la version 2.5 : Recognition of `__missing__` methods of dict subclasses.

**d[key] = value**

Assigne `d[key]` à *value*.

**del d[key]**

Supprime `d[key]` de *d*. Lève une exception `KeyError` si *key* n'est pas dans le dictionnaire.

**key in d**

Renvoie `True` si *d* a la clef *key*, sinon `False`.

Nouveau dans la version 2.2.

**key not in d**

Équivalent à `not key in d`.

Nouveau dans la version 2.2.

**iter(d)**

Return an iterator over the keys of the dictionary. This is a shortcut for `iterkeys()`.

**clear()**

Supprime tous les éléments du dictionnaire.

**copy()**

Renvoie une copie de surface du dictionnaire.

**fromkeys(seq[, value])**

Crée un nouveau dictionnaire avec les clefs de *seq* et les valeurs à *value*.

`fromkeys()` is a class method that returns a new dictionary. *value* defaults to `None`.

Nouveau dans la version 2.3.

**get(key[, default])**

Renvoie la valeur de *key* si *key* est dans le dictionnaire, sinon *default*. Si *default* n'est pas donné, il vaut `None` par défaut, de manière à ce que cette méthode ne lève jamais `KeyError`.

**has\_key(key)**

Test for the presence of *key* in the dictionary. `has_key()` is deprecated in favor of `key in d`.

**items()**

Return a copy of the dictionary's list of (*key*, *value*) pairs.

**CPython implementation detail :** Keys and values are listed in an arbitrary order which is non-random, varies across Python implementations, and depends on the dictionary's history of insertions and deletions.

If `items()`, `keys()`, `values()`, `iteritems()`, `iterkeys()`, and `itervalues()` are called with no intervening modifications to the dictionary, the lists will directly correspond. This allows the creation of (*value*, *key*) pairs using `zip()`: `pairs = zip(d.values(), d.keys())`. The same relationship holds for the `iterkeys()` and `itervalues()` methods: `pairs = zip(d.itervalues(), d.iterkeys())` provides the same value for `pairs`. Another way to create the same list is `pairs = [(v, k) for (k, v) in d.iteritems()]`.

**iteritems()**

Return an iterator over the dictionary's (key, value) pairs. See the note for *dict.items()*.

Using *iteritems()* while adding or deleting entries in the dictionary may raise a *RuntimeError* or fail to iterate over all entries.

Nouveau dans la version 2.2.

**iterkeys()**

Return an iterator over the dictionary's keys. See the note for *dict.items()*.

Using *iterkeys()* while adding or deleting entries in the dictionary may raise a *RuntimeError* or fail to iterate over all entries.

Nouveau dans la version 2.2.

**itervalues()**

Return an iterator over the dictionary's values. See the note for *dict.items()*.

Using *itervalues()* while adding or deleting entries in the dictionary may raise a *RuntimeError* or fail to iterate over all entries.

Nouveau dans la version 2.2.

**keys()**

Return a copy of the dictionary's list of keys. See the note for *dict.items()*.

**pop(key[, default])**

Si *key* est dans le dictionnaire elle est supprimée et sa valeur est renvoyée, sinon renvoie *default*. Si *default* n'est pas donné et que *key* n'est pas dans le dictionnaire, une *KeyError* est levée.

Nouveau dans la version 2.3.

**popitem()**

Supprime et renvoie une (key, value) arbitraire du dictionnaire.

*popitem()* is useful to destructively iterate over a dictionary, as often used in set algorithms. If the dictionary is empty, calling *popitem()* raises a *KeyError*.

**setdefault(key[, default])**

Si *key* est dans le dictionnaire, sa valeur est renvoyée. Sinon, insère *key* avec comme valeur *default* et renvoie *default*. *default* vaut *None* par défaut.

**update([other])**

Met à jour le dictionnaire avec les paires de clef/valeur d'*other*, écrasant les clefs existantes. Renvoie *None*.

*update()* accepts either another dictionary object or an iterable of key/value pairs (as tuples or other iterables of length two). If keyword arguments are specified, the dictionary is then updated with those key/value pairs : *d.update(red=1, blue=2)*.

Modifié dans la version 2.4 : Allowed the argument to be an iterable of key/value pairs and allowed keyword arguments.

**values()**

Return a copy of the dictionary's list of values. See the note for *dict.items()*.

**viewitems()**

Return a new view of the dictionary's items ((key, value) pairs). See below for documentation of view objects.

Nouveau dans la version 2.7.

**viewkeys()**

Return a new view of the dictionary's keys. See below for documentation of view objects.

Nouveau dans la version 2.7.

**viewvalues()**

Return a new view of the dictionary's values. See below for documentation of view objects.

Nouveau dans la version 2.7.

Dictionaries compare equal if and only if they have the same (key, value) pairs.

### 5.8.1 Les vues de dictionnaires

The objects returned by `dict.viewkeys()`, `dict.viewvalues()` and `dict.viewitems()` are *view objects*. They provide a dynamic view on the dictionary's entries, which means that when the dictionary changes, the view reflects these changes.

Les vues de dictionnaires peuvent être itérées et ainsi renvoyer les données du dictionnaire, elle gèrent aussi les tests de présence :

**len(dictview)**

Renvoie le nombre d'entrées du dictionnaire.

**iter(dictview)**

Renvoie un itérateur sur les clefs, les valeurs, ou les éléments (représentés par des *tuples* de (*key*, *value*) du dictionnaire.

Les clefs et les valeurs sont itérées dans un ordre arbitraire qui n'est pas aléatoire, qui peut varier d'une implémentation de Python à l'autre, et qui dépend de l'historique d'insertion et de suppressions d'éléments. Si les vues de clefs, de valeurs, et d'éléments sont parcourues sans que le dictionnaire ne soit modifié, l'ordre des éléments correspondra directement. Ceci permet la création de paires de (*key*, *value*) en utilisant `zip()` : `pairs = zip(d.values(), d.keys())`. Un autre moyen de construire la même liste est `pairs = [(v, k) for (k, v) in d.items()]`.

Parcourir des vues tout en ajoutant ou supprimant des entrées dans un dictionnaire peut lever une *RuntimeError* ou ne pas fournir toutes les entrées.

**x in dictview**

Renvoie `True` si *x* est dans les clefs, les valeurs, ou les éléments du dictionnaire sous-jacent (dans le dernier cas, *x* doit être un *tuple* (*key*, *value*)).

Keys views are set-like since their entries are unique and hashable. If all values are hashable, so that (key, value) pairs are unique and hashable, then the items view is also set-like. (Values views are not treated as set-like since the entries are generally not unique.) Then these set operations are available (« other » refers either to another view or a set) :

**dictview & other**

Return the intersection of the dictview and the other object as a new set.

**dictview | other**

Return the union of the dictview and the other object as a new set.

**dictview - other**

Return the difference between the dictview and the other object (all elements in *dictview* that aren't in *other*) as a new set.

**dictview ^ other**

Return the symmetric difference (all elements either in *dictview* or *other*, but not in both) of the dictview and the other object as a new set.

Exemple d'utilisation de vue de dictionnaire :

```
>>> dishes = {'eggs': 2, 'sausage': 1, 'bacon': 1, 'spam': 500}
>>> keys = dishes.viewkeys()
>>> values = dishes.viewvalues()

>>> # iteration
>>> n = 0
>>> for val in values:
...     n += val
>>> print(n)
```

(suite sur la page suivante)

504

```

>>> # keys and values are iterated over in the same order
>>> list(keys)
['eggs', 'bacon', 'sausage', 'spam']
>>> list(values)
[2, 1, 1, 500]

>>> # view objects are dynamic and reflect dict changes
>>> del dishes['eggs']
>>> del dishes['sausage']
>>> list(keys)
['spam', 'bacon']

>>> # set operations
>>> keys & {'eggs', 'bacon', 'salad'}
{'bacon'}

```

## 5.9 Objets fichiers

File objects are implemented using C's `stdio` package and can be created with the built-in `open()` function. File objects are also returned by some other built-in functions and methods, such as `os.popen()` and `os.fdopen()` and the `makefile()` method of socket objects. Temporary files can be created using the `tempfile` module, and high-level file operations such as copying, moving, and deleting files and directories can be achieved with the `shutil` module.

When a file operation fails for an I/O-related reason, the exception `IOError` is raised. This includes situations where the operation is not defined for some reason, like `seek()` on a tty device or writing a file opened for reading.

Files have the following methods :

`file.close()`

Close the file. A closed file cannot be read or written any more. Any operation which requires that the file be open will raise a `ValueError` after the file has been closed. Calling `close()` more than once is allowed.

As of Python 2.5, you can avoid having to call this method explicitly if you use the `with` statement. For example, the following code will automatically close `f` when the `with` block is exited :

```

from __future__ import with_statement # This isn't required in Python 2.6

with open("hello.txt") as f:
    for line in f:
        print line,

```

In older versions of Python, you would have needed to do this to get the same effect :

```

f = open("hello.txt")
try:
    for line in f:
        print line,
finally:
    f.close()

```

---

**Note :** Not all « file-like » types in Python support use as a context manager for the `with` statement. If your code is intended to work with any file-like object, you can use the function `contextlib.closing()` instead of using the object directly.

---

`file.flush()`

Flush the internal buffer, like `stdio`'s `fflush()`. This may be a no-op on some file-like objects.

---

**Note :** `flush()` does not necessarily write the file's data to disk. Use `flush()` followed by `os.fsync()` to ensure this behavior.

---

`file.fileno()`

Return the integer « file descriptor » that is used by the underlying implementation to request I/O operations from the operating system. This can be useful for other, lower level interfaces that use file descriptors, such as the `fcntl` module or `os.read()` and friends.

---

**Note :** File-like objects which do not have a real file descriptor should *not* provide this method!

---

`file.isatty()`

Return `True` if the file is connected to a tty(-like) device, else `False`.

---

**Note :** If a file-like object is not associated with a real file, this method should *not* be implemented.

---

`file.next()`

A file object is its own iterator, for example `iter(f)` returns `f` (unless `f` is closed). When a file is used as an iterator, typically in a `for` loop (for example, `for line in f: print line.strip()`), the `next()` method is called repeatedly. This method returns the next input line, or raises `StopIteration` when EOF is hit when the file is open for reading (behavior is undefined when the file is open for writing). In order to make a `for` loop the most efficient way of looping over the lines of a file (a very common operation), the `next()` method uses a hidden read-ahead buffer. As a consequence of using a read-ahead buffer, combining `next()` with other file methods (like `readline()`) does not work right. However, using `seek()` to reposition the file to an absolute position will flush the read-ahead buffer.

Nouveau dans la version 2.3.

`file.read([size])`

Read at most `size` bytes from the file (less if the read hits EOF before obtaining `size` bytes). If the `size` argument is negative or omitted, read all data until EOF is reached. The bytes are returned as a string object. An empty string is returned when EOF is encountered immediately. (For certain files, like ttys, it makes sense to continue reading after an EOF is hit.) Note that this method may call the underlying C function `fread()` more than once in an effort to acquire as close to `size` bytes as possible. Also note that when in non-blocking mode, less data than was requested may be returned, even if no `size` parameter was given.

---

**Note :** This function is simply a wrapper for the underlying `fread()` C function, and will behave the same in corner cases, such as whether the EOF value is cached.

---

`file.readline([size])`

Read one entire line from the file. A trailing newline character is kept in the string (but may be absent when a file ends with an incomplete line).<sup>6</sup> If the `size` argument is present and non-negative, it is a

---

6. The advantage of leaving the newline on is that returning an empty string is then an unambiguous EOF indication. It is also possible (in cases where it might matter, for example, if you want to make an exact copy of a file while scanning its lines)

maximum byte count (including the trailing newline) and an incomplete line may be returned. When *size* is not 0, an empty string is returned *only* when EOF is encountered immediately.

---

**Note :** Unlike `stdio`'s `fgets()`, the returned string contains null characters (`'\0'`) if they occurred in the input.

---

`file.readlines([sizehint])`

Read until EOF using `readline()` and return a list containing the lines thus read. If the optional *sizehint* argument is present, instead of reading up to EOF, whole lines totalling approximately *sizehint* bytes (possibly after rounding up to an internal buffer size) are read. Objects implementing a file-like interface may choose to ignore *sizehint* if it cannot be implemented, or cannot be implemented efficiently.

`file.xreadlines()`

This method returns the same thing as `iter(f)`.

Nouveau dans la version 2.1.

Obsolète depuis la version 2.3 : Use `for line in file` instead.

`file.seek(offset, whence)`

Set the file's current position, like `stdio`'s `fseek()`. The *whence* argument is optional and defaults to `os.SEEK_SET` or 0 (absolute file positioning); other values are `os.SEEK_CUR` or 1 (seek relative to the current position) and `os.SEEK_END` or 2 (seek relative to the file's end). There is no return value.

For example, `f.seek(2, os.SEEK_CUR)` advances the position by two and `f.seek(-3, os.SEEK_END)` sets the position to the third to last.

Note that if the file is opened for appending (mode `'a'` or `'a+'`), any `seek()` operations will be undone at the next write. If the file is only opened for writing in append mode (mode `'a'`), this method is essentially a no-op, but it remains useful for files opened in append mode with reading enabled (mode `'a+'`). If the file is opened in text mode (without `'b'`), only offsets returned by `tell()` are legal. Use of other offsets causes undefined behavior.

Note that not all file objects are seekable.

Modifié dans la version 2.6 : Passing float values as offset has been deprecated.

`file.tell()`

Return the file's current position, like `stdio`'s `ftell()`.

---

**Note :** On Windows, `tell()` can return illegal values (after an `fgets()`) when reading files with Unix-style line-endings. Use binary mode (`'rb'`) to circumvent this problem.

---

`file.truncate([size])`

Truncate the file's size. If the optional *size* argument is present, the file is truncated to (at most) that size. The size defaults to the current position. The current file position is not changed. Note that if a specified size exceeds the file's current size, the result is platform-dependent : possibilities include that the file may remain unchanged, increase to the specified size as if zero-filled, or increase to the specified size with undefined new content. Availability : Windows, many Unix variants.

`file.write(str)`

Write a string to the file. There is no return value. Due to buffering, the string may not actually show up in the file until the `flush()` or `close()` method is called.

`file.writelines(sequence)`

Write a sequence of strings to the file. The sequence can be any iterable object producing strings, typically a list of strings. There is no return value. (The name is intended to match `readlines()`; `writelines()` does not add line separators.)

---

to tell whether the last line of a file ended in a newline or not (yes this happens!).

Files support the iterator protocol. Each iteration returns the same result as `readline()`, and iteration ends when the `readline()` method returns an empty string.

File objects also offer a number of other interesting attributes. These are not required for file-like objects, but should be implemented if they make sense for the particular object.

**file.closed**

bool indicating the current state of the file object. This is a read-only attribute; the `close()` method changes the value. It may not be available on all file-like objects.

**file.encoding**

The encoding that this file uses. When Unicode strings are written to a file, they will be converted to byte strings using this encoding. In addition, when the file is connected to a terminal, the attribute gives the encoding that the terminal is likely to use (that information might be incorrect if the user has misconfigured the terminal). The attribute is read-only and may not be present on all file-like objects. It may also be `None`, in which case the file uses the system default encoding for converting Unicode strings.

Nouveau dans la version 2.3.

**file.errors**

The Unicode error handler used along with the encoding.

Nouveau dans la version 2.6.

**file.mode**

The I/O mode for the file. If the file was created using the `open()` built-in function, this will be the value of the `mode` parameter. This is a read-only attribute and may not be present on all file-like objects.

**file.name**

If the file object was created using `open()`, the name of the file. Otherwise, some string that indicates the source of the file object, of the form `<...>`. This is a read-only attribute and may not be present on all file-like objects.

**file.newlines**

If Python was built with *universal newlines* enabled (the default) this read-only attribute exists, and for files opened in universal newline read mode it keeps track of the types of newlines encountered while reading the file. The values it can take are `'\r'`, `'\n'`, `'\r\n'`, `None` (unknown, no newlines read yet) or a tuple containing all the newline types seen, to indicate that multiple newline conventions were encountered. For files not opened in universal newlines read mode the value of this attribute will be `None`.

**file.softspace**

Boolean that indicates whether a space character needs to be printed before another value when using the `print` statement. Classes that are trying to simulate a file object should also have a writable *softspace* attribute, which should be initialized to zero. This will be automatic for most classes implemented in Python (care may be needed for objects that override attribute access); types implemented in C will have to provide a writable *softspace* attribute.

---

**Note :** This attribute is not used to control the `print` statement, but to allow the implementation of `print` to keep track of its internal state.

---

## 5.10 memoryview type

Nouveau dans la version 2.7.

*memoryview* objects allow Python code to access the internal data of an object that supports the buffer protocol without copying. Memory is generally interpreted as simple bytes.

**class** `memoryview(obj)`

Create a *memoryview* that references *obj*. *obj* must support the buffer protocol. Built-in objects that support the buffer protocol include *str* and *bytearray* (but not *unicode*).

A *memoryview* has the notion of an *element*, which is the atomic memory unit handled by the originating object *obj*. For many simple types such as *str* and *bytearray*, an element is a single byte, but other third-party types may expose larger elements.

`len(view)` returns the total number of elements in the memoryview, *view*. The *itemsize* attribute will give you the number of bytes in a single element.

A *memoryview* supports slicing to expose its data. Taking a single index will return a single element as a *str* object. Full slicing will result in a subview :

```
>>> v = memoryview('abcefg')
>>> v[1]
'b'
>>> v[-1]
'g'
>>> v[1:4]
<memory at 0x77ab28>
>>> v[1:4].tobytes()
'bce'
```

If the object the memoryview is over supports changing its data, the memoryview supports slice assignment :

```
>>> data = bytearray('abcefg')
>>> v = memoryview(data)
>>> v.readonly
False
>>> v[0] = 'z'
>>> data
bytearray(b'zbcefg')
>>> v[1:4] = '123'
>>> data
bytearray(b'z123fg')
>>> v[2] = 'spam'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: cannot modify size of memoryview object
```

Notice how the size of the memoryview object cannot be changed.

*memoryview* has two methods :

**tobytes()**

Return the data in the buffer as a bytestring (an object of class *str*).

```
>>> m = memoryview("abc")
>>> m.tobytes()
'abc'
```

**tolist()**

Return the data in the buffer as a list of integers.

```
>>> memoryview("abc").tolist()
[97, 98, 99]
```

Plusieurs attributs en lecture seule sont également disponibles :

**format**

A string containing the format (in *struct* module style) for each element in the view. This defaults to 'B', a simple bytestring.

**itemsiz**

The size in bytes of each element of the memoryview.

**shape**

Un *tuple* d'entiers de longueur *ndim* donnant la forme de la *memoryview* sous forme d'un tableau à N dimensions.

**ndim**

Un nombre entier indiquant le nombre de dimensions d'un tableau multi-dimensionnel représenté par la *memoryview*.

**strides**

Un *tuple* d'entiers de longueur *ndim* donnant la taille en octets permettant d'accéder à chaque dimensions du tableau.

**readonly**

Un booléen indiquant si la mémoire est en lecture seule.

## 5.11 Le type gestionnaire de contexte

Nouveau dans la version 2.5.

Python's **with** statement supports the concept of a runtime context defined by a context manager. This is implemented using two separate methods that allow user-defined classes to define a runtime context that is entered before the statement body is executed and exited when the statement ends.

The *context management protocol* consists of a pair of methods that need to be provided for a context manager object to define a runtime context :

**contextmanager.\_\_enter\_\_()**

Entre dans le contexte à l'exécution, soit se renvoyant lui-même, soit en renvoyant un autre objet en lien avec ce contexte. La valeur renvoyée par cette méthode est liée à l'identifiant donné au **as** de l'instruction **with** utilisant ce gestionnaire de contexte.

An example of a context manager that returns itself is a file object. File objects return themselves from `__enter__()` to allow `open()` to be used as the context expression in a **with** statement.

Un exemple de gestionnaire de contexte renvoyant un objet connexe est celui renvoyé par `decimal.localcontext()`. Ces gestionnaires remplacent le contexte décimal courant par une copie de l'original, copie qui est renvoyée. Ça permet de changer le contexte courant dans le corps du **with** sans affecter le code en dehors de l'instruction **with**.

**contextmanager.\_\_exit\_\_(exc\_type, exc\_val, exc\_tb)**

Sort du contexte et renvoie un booléen indiquant si une exception survenue doit être supprimée. Si une exception est survenue lors de l'exécution du corps de l'instruction **with**, les arguments contiennent le type de l'exception, sa valeur, et la trace de la pile (*traceback*). Sinon les trois arguments valent `None`. L'instruction **with** inhibera l'exception si cette méthode renvoie une valeur vraie, l'exécution continuera ainsi à l'instruction suivant immédiatement l'instruction **with**. Sinon, l'exception continuera de se propager après la fin de cette méthode. Les exceptions se produisant pendant l'exécution de cette méthode remplaceront toute exception qui s'est produite dans le corps du **with**.

The exception passed in should never be reraised explicitly - instead, this method should return a false value to indicate that the method completed successfully and does not want to suppress the raised exception. This allows context management code (such as `contextlib.nested`) to easily detect whether or not an `__exit__()` method has actually failed.

Python définit plusieurs gestionnaires de contexte pour faciliter la synchronisation des fils d'exécution, la fermeture des fichiers ou d'autres objets, et la configuration du contexte arithmétique décimal. Ces types

spécifiques ne sont pas traités différemment, ils respectent simplement le protocole de gestion du contexte. Voir les exemples dans la documentation du module `contextlib`.

Python's *generators* and the `contextlib.contextmanager` *decorator* provide a convenient way to implement these protocols. If a generator function is decorated with the `contextlib.contextmanager` decorator, it will return a context manager implementing the necessary `__enter__()` and `__exit__()` methods, rather than the iterator produced by an undecorated generator function.

Notez qu'il n'y a pas d'emplacement spécifique pour ces méthodes dans la structure de type pour les objets Python dans l'API Python/C. Les types souhaitant définir ces méthodes doivent les fournir comme une méthode accessible en Python. Comparé au coût de la mise en place du contexte d'exécution, le coût d'un accès au dictionnaire d'une classe unique est négligeable.

## 5.12 Autres types natifs

L'interpréteur gère aussi d'autres types d'objets, la plupart ne supportant cependant qu'une ou deux opérations.

### 5.12.1 Modules

La seule opération spéciale sur un module est l'accès à ses attributs : `m.name`, où *m* est un module et *name* donne accès un nom défini dans la table des symboles de *m*. Il est possible d'assigner un attribut de module. (Notez que l'instruction `import` n'est pas strictement une opération sur un objet module. `import foo` ne nécessite pas qu'un objet module nommé *foo* existe, il nécessite cependant une *définition* (externe) d'un module nommé *foo* quelque part.)

Un attribut spécial à chaque module est `__dict__`. C'est le dictionnaire contenant la table des symboles du module. Modifier ce dictionnaire changera la table des symboles du module, mais assigner directement `__dict__` n'est pas possible (vous pouvez écrire `m.__dict__['a'] = 1`, qui donne 1 comme valeur pour `m.a`, mais vous ne pouvez pas écrire `m.__dict__ = {}`). Modifier `__dict__` directement n'est pas recommandé.

Les modules natifs à l'interpréteur sont représentés `<module 'sys' (built-in)>`. S'ils sont chargés depuis un fichier, ils sont représentés `<module 'os' from '/usr/local/lib/pythonX.Y/os.pyc'>`.

### 5.12.2 Les classes et instances de classes

Voir `objects` et `class`.

### 5.12.3 Fonctions

Les objets fonctions sont créés par les définitions de fonctions. La seule opération applicable à un objet fonction est de l'appeler : `func(argument-list)`.

Il existe en fait deux catégories d'objets fonctions : Les fonctions natives et les fonctions définies par l'utilisateur. Les deux gèrent les mêmes opérations (l'appel à la fonction), mais leur implémentation est différente, d'où les deux types distincts.

Voir `function` pour plus d'information.

### 5.12.4 Méthodes

Les méthodes sont des fonctions appelées via la notation d'attribut. Il en existe deux variantes : Les méthodes natives (tel que `append()` sur les listes), et les méthodes d'instances de classes. Les méthodes natives sont représentées avec le type qui les supporte.

The implementation adds two special read-only attributes to class instance methods : `m.im_self` is the object on which the method operates, and `m.im_func` is the function implementing the method. Calling

`m(arg-1, arg-2, ..., arg-n)` is completely equivalent to calling `m.im_func(m.im_self, arg-1, arg-2, ..., arg-n)`.

Class instance methods are either *bound* or *unbound*, referring to whether the method was accessed through an instance or a class, respectively. When a method is unbound, its `im_self` attribute will be `None` and if called, an explicit `self` object must be passed as the first argument. In this case, `self` must be an instance of the unbound method's class (or a subclass of that class), otherwise a *`TypeError`* is raised.

Like function objects, methods objects support getting arbitrary attributes. However, since method attributes are actually stored on the underlying function object (`meth.im_func`), setting method attributes on either bound or unbound methods is disallowed. Attempting to set an attribute on a method results in an *`AttributeError`* being raised. In order to set a method attribute, you need to explicitly set it on the underlying function object :

```
>>> class C:
...     def method(self):
...         pass
...
>>> c = C()
>>> c.method.whoami = 'my name is method' # can't set on the method
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
AttributeError: 'instancemethod' object has no attribute 'whoami'
>>> c.method.im_func.whoami = 'my name is method'
>>> c.method.whoami
'my name is method'
```

Voir types pour plus d'information.

### 5.12.5 Objets code

Code objects are used by the implementation to represent « pseudo-compiled » executable Python code such as a function body. They differ from function objects because they don't contain a reference to their global execution environment. Code objects are returned by the built-in *`compile()`* function and can be extracted from function objects through their `func_code` attribute. See also the *`code`* module.

A code object can be executed or evaluated by passing it (instead of a source string) to the `exec` statement or the built-in *`eval()`* function.

Voir types pour plus d'information.

### 5.12.6 Objets type

Les objets types représentent les différents types d'objets. Le type d'un objet est obtenu via la fonction native *`type()`*. Il n'existe aucune opération spéciale sur les types. Le module standard *`types`* définit les noms de tous les types natifs.

Types are written like this : `<type 'int'>`.

### 5.12.7 L'objet Null

This object is returned by functions that don't explicitly return a value. It supports no special operations. There is exactly one null object, named `None` (a built-in name).

C'est écrit `None`.

### 5.12.8 L'objet points de suspension

This object is used by extended slice notation (see slicings). It supports no special operations. There is exactly one ellipsis object, named *Ellipsis* (a built-in name).

It is written as `Ellipsis`. When in a subscript, it can also be written as `...`, for example `seq[...]`.

### 5.12.9 L'objet *NotImplemented*

This object is returned from comparisons and binary operations when they are asked to operate on types they don't support. See comparisons for more information.

C'est écrit `NotImplemented`.

### 5.12.10 Valeurs Booléennes

Les valeurs booléennes sont les deux objet constants `False` et `True`. Ils son utilisés pour représenter les valeurs de vérité (bien que d'autres valeurs peuvent être considérées vraies ou fausses). Dans des contextes numériques (par exemple en argument d'un opérateur arithmétique), ils se comportent comme les nombres entiers 0 et 1, respectivement. La fonction native `bool()` peut être utilisée pour convertir n'importe quelle valeur en booléen tant que la valeur peut être interprétée en une valeur de vérité (voir *Valeurs booléennes* au dessus).

Ils s'écrivent `False` et `True`, respectivement.

### 5.12.11 Objets Internes

Voir types. Ils décrivent les objets *stack frame*, *traceback*, et *slice*.

## 5.13 Attributs Spéciaux

L'implémentation ajoute quelques attributs spéciaux et en lecture seule, à certains types, lorsque ça a du sens. Certains ne sont *pas* listés par la fonction native `dir()`.

`object.__dict__`

Un dictionnaire ou un autre *mapping object* utilisé pour stocker les attributs (modifiables) de l'objet.

`object.__methods__`

Obsolète depuis la version 2.2 : Use the built-in function `dir()` to get a list of an object's attributes. This attribute is no longer available.

`object.__members__`

Obsolète depuis la version 2.2 : Use the built-in function `dir()` to get a list of an object's attributes. This attribute is no longer available.

`instance.__class__`

La classe de l'instance de classe.

`class.__bases__`

Le *tuple* des classes parentes d'un objet classe.

`definition.__name__`

The name of the class, type, function, method, descriptor, or generator instance.

The following attributes are only supported by *new-style classes*.

`class.__mro__`

Cet attribut est un *tuple* contenant les classes parents prises en compte lors de la résolution de méthode.

`class.mro()`

Cette méthode peut être surchargée par une méta-classe pour personnaliser l'ordre de la recherche de méthode pour ses instances. Elle est appelée à la l'initialisation de la classe, et son résultat est stocké dans l'attribut `__mro__`.

`class.__subclasses__()`

Each new-style class keeps a list of weak references to its immediate subclasses. This method returns a list of all those references still alive. Example :

```
>>> int.__subclasses__()
[<type 'bool'>]
```

## Notes

---

## Exceptions natives

---

Exceptions should be class objects. The exceptions are defined in the module `exceptions`. This module never needs to be imported explicitly : the exceptions are provided in the built-in namespace as well as the `exceptions` module.

For class exceptions, in a `try` statement with an `except` clause that mentions a particular class, that clause also handles any exception classes derived from that class (but not exception classes from which *it* is derived). Two exception classes that are not related via subclassing are never equivalent, even if they have the same name.

The built-in exceptions listed below can be generated by the interpreter or built-in functions. Except where mentioned, they have an « associated value » indicating the detailed cause of the error. This may be a string or a tuple containing several items of information (e.g., an error code and a string explaining the code). The associated value is the second argument to the `raise` statement. If the exception class is derived from the standard root class `BaseException`, the associated value is present as the exception instance's `args` attribute.

Du code utilisateur peut lever des exceptions natives. Cela peut être utilisé pour tester un gestionnaire d'exception ou pour rapporter une condition d'erreur « comme si » c'était l'interpréteur qui levait cette exception ; mais attention car rien n'empêche du code utilisateur de lever une erreur inappropriée.

Les classes d'exception natives peuvent être héritées pour définir de nouvelles exceptions ; les programmeurs sont encouragés à faire dériver les nouvelles exceptions de la classe `Exception` ou d'une de ses sous-classes, et non de `BaseException`. Plus d'informations sur la définition des exceptions sont disponibles dans le Tutoriel Python sous `tut-userexceptions`.

The following exceptions are only used as base classes for other exceptions.

### **exception BaseException**

The base class for all built-in exceptions. It is not meant to be directly inherited by user-defined classes (for that, use `Exception`). If `str()` or `unicode()` is called on an instance of this class, the representation of the argument(s) to the instance are returned, or the empty string when there were no arguments.

Nouveau dans la version 2.5.

#### **args**

The tuple of arguments given to the exception constructor. Some built-in exceptions (like `IOError`)

expect a certain number of arguments and assign a special meaning to the elements of this tuple, while others are usually called only with a single string giving an error message.

**exception Exception**

Toutes les exceptions natives, qui n'entraînent pas une sortie du système dérivent de cette classe. Toutes les exceptions définies par l'utilisateur devraient également être dérivées de cette classe.

Modifié dans la version 2.5 : Changed to inherit from *BaseException*.

**exception StandardError**

The base class for all built-in exceptions except *StopIteration*, *GeneratorExit*, *KeyboardInterrupt* and *SystemExit*. *StandardError* itself is derived from *Exception*.

**exception ArithmeticError**

La classe de base pour les exceptions natives qui sont levées pour diverses erreurs arithmétiques : *OverflowError*, *ZeroDivisionError*, *FloatingPointError*.

**exception BufferError**

Levée lorsqu'une opération liée à un tampon ne peut pas être exécutée.

**exception LookupError**

La classe de base pour les exceptions qui sont levées lorsqu'une clé ou un index utilisé sur un tableau de correspondances ou une séquence est invalide : *IndexError*, *KeyError*. Peut être levée directement par *codecs.lookup()*.

**exception EnvironmentError**

The base class for exceptions that can occur outside the Python system : *IOError*, *OSError*. When exceptions of this type are created with a 2-tuple, the first item is available on the instance's *errno* attribute (it is assumed to be an error number), and the second item is available on the *strerror* attribute (it is usually the associated error message). The tuple itself is also available on the *args* attribute.

Nouveau dans la version 1.5.2.

When an *EnvironmentError* exception is instantiated with a 3-tuple, the first two items are available as above, while the third item is available on the *filename* attribute. However, for backwards compatibility, the *args* attribute contains only a 2-tuple of the first two constructor arguments.

The *filename* attribute is *None* when this exception is created with other than 3 arguments. The *errno* and *strerror* attributes are also *None* when the instance was created with other than 2 or 3 arguments. In this last case, *args* contains the verbatim constructor arguments as a tuple.

The following exceptions are the exceptions that are actually raised.

**exception AssertionError**

Levée lorsqu'une instruction *assert* échoue.

**exception AttributeError**

Levée lorsqu'une référence ou une assignation d'attribut (voir attribute-references) échoue. (Lorsqu'un objet ne supporte pas du tout la référence ou l'assignation d'attribut, *TypeError* est levé.)

**exception EOFError**

Raised when one of the built-in functions (*input()* or *raw\_input()*) hits an end-of-file condition (EOF) without reading any data. (N.B. : the *file.read()* and *file.readline()* methods return an empty string when they hit EOF.)

**exception FloatingPointError**

Levée lorsqu'une opération en virgule flottante échoue. Cette exception est toujours définie, mais ne peut être levée que lorsque Python est configuré avec l'option *--with-fpectl*, ou que le symbole *WANT\_SIGFPE\_HANDLER* est défini dans le fichier *pyconfig.h*.

**exception GeneratorExit**

Raised when a *generator*'s *close()* method is called. It directly inherits from *BaseException* instead of *StandardError* since it is technically not an error.

Nouveau dans la version 2.5.

Modifié dans la version 2.6 : Changed to inherit from *BaseException*.

#### **exception IOError**

Raised when an I/O operation (such as a `print` statement, the built-in `open()` function or a method of a file object) fails for an I/O-related reason, e.g., « file not found » or « disk full ».

This class is derived from *EnvironmentError*. See the discussion above for more information on exception instance attributes.

Modifié dans la version 2.6 : Changed *socket.error* to use this as a base class.

#### **exception ImportError**

Raised when an `import` statement fails to find the module definition or when a `from ... import` fails to find a name that is to be imported.

#### **exception IndexError**

Raised when a sequence subscript is out of range. (Slice indices are silently truncated to fall in the allowed range; if an index is not a plain integer, *TypeError* is raised.)

#### **exception KeyError**

Levée lorsqu'une clef (de dictionnaire) n'est pas trouvée dans l'ensemble des clefs existantes.

#### **exception KeyboardInterrupt**

Raised when the user hits the interrupt key (normally **Control-C** or **Delete**). During execution, a check for interrupts is made regularly. Interrupts typed when a built-in function `input()` or `raw_input()` is waiting for input also raise this exception. The exception inherits from *BaseException* so as to not be accidentally caught by code that catches *Exception* and thus prevent the interpreter from exiting.

Modifié dans la version 2.5 : Changed to inherit from *BaseException*.

#### **exception MemoryError**

Levée lorsqu'une opération est à court de mémoire mais que la situation peut encore être rattrapée (en supprimant certains objets). La valeur associée est une chaîne de caractères indiquant quel type d'opération (interne) est à court de mémoire. À noter qu'en raison de l'architecture interne de gestion de la mémoire (la fonction `malloc()` du C), l'interpréteur peut ne pas toujours être capable de rattraper cette situation; il lève néanmoins une exception pour qu'une pile d'appels puisse être affichée, dans le cas où un programme en cours d'exécution en était la cause.

#### **exception NameError**

Levée lorsqu'un nom local ou global n'est pas trouvé. Ceci ne s'applique qu'aux noms non qualifiés. La valeur associée est un message d'erreur qui inclut le nom qui n'a pas pu être trouvé.

#### **exception NotImplementedError**

This exception is derived from *RuntimeError*. In user defined base classes, abstract methods should raise this exception when they require derived classes to override the method.

Nouveau dans la version 1.5.2.

#### **exception OSError**

This exception is derived from *EnvironmentError*. It is raised when a function returns a system-related error (not for illegal argument types or other incidental errors). The *errno* attribute is a numeric error code from *errno*, and the *strerror* attribute is the corresponding string, as would be printed by the C function `perror()`. See the module *errno*, which contains names for the error codes defined by the underlying operating system.

For exceptions that involve a file system path (such as `chdir()` or `unlink()`), the exception instance will contain a third attribute, *filename*, which is the file name passed to the function.

Nouveau dans la version 1.5.2.

#### **exception OverflowError**

Raised when the result of an arithmetic operation is too large to be represented. This cannot occur for long integers (which would rather raise *MemoryError* than give up) and for most operations with plain

integers, which return a long integer instead. Because of the lack of standardization of floating point exception handling in C, most floating point operations also aren't checked.

**exception `ReferenceError`**

Cette exception est levée lorsqu'un pointeur faible d'un objet proxy, créé par la fonction `weakref.proxy()`, est utilisé pour accéder à un attribut du référent après qu'il ait été récupéré par le ramasse-miettes. Pour plus d'informations sur les pointeurs faibles, voir le module `weakref`.

Nouveau dans la version 2.2 : Previously known as the `weakref.ReferenceError` exception.

**exception `RuntimeError`**

Levée lorsqu'une erreur qui n'appartient à aucune des autres catégories est détectée. La valeur associée est une chaîne de caractères indiquant précisément ce qui s'est mal passé.

**exception `StopIteration`**

Raised by an *iterator*'s `next()` method to signal that there are no further values. This is derived from `Exception` rather than `StandardError`, since this is not considered an error in its normal application.

Nouveau dans la version 2.2.

**exception `SyntaxError`**

Raised when the parser encounters a syntax error. This may occur in an `import` statement, in an `exec` statement, in a call to the built-in function `eval()` or `input()`, or when reading the initial script or standard input (also interactively).

Les instances de cette classe ont des attributs `filename`, `lineno`, `offset` et `text` pour accéder plus facilement aux détails. La représentation `str()` de l'instance de l'exception retourne seulement le message.

**exception `IndentationError`**

Classe de base pour les erreurs de syntaxe liées à une indentation incorrecte. C'est une sous-classe de `SyntaxError`.

**exception `TabError`**

Levée lorsqu'une indentation contient une utilisation incohérente des tabulations et des espaces. C'est une sous-classe de `IndentationError`.

**exception `SystemError`**

Levée lorsque l'interpréteur trouve une erreur interne, mais que la situation ne semble pas si grave au point de lui faire abandonner tout espoir. La valeur associée est une chaîne de caractères indiquant l'erreur qui est survenue (en termes bas niveau).

Vous devriez le signaler à l'auteur ou au responsable de votre interpréteur Python. Assurez-vous de signaler la version de l'interpréteur (`sys.version`; elle est également affichée au lancement d'une session interactive), le message d'erreur exact (la valeur associée à l'exception) et si possible le code source du programme qui a déclenché l'erreur.

**exception `SystemExit`**

This exception is raised by the `sys.exit()` function. When it is not handled, the Python interpreter exits; no stack traceback is printed. If the associated value is a plain integer, it specifies the system exit status (passed to C's `exit()` function); if it is `None`, the exit status is zero; if it has another type (such as a string), the object's value is printed and the exit status is one.

Instances have an attribute `code` which is set to the proposed exit status or error message (defaulting to `None`). Also, this exception derives directly from `BaseException` and not `StandardError`, since it is not technically an error.

Un appel à `sys.exit()` est traduit en une exception pour que les gestionnaires de nettoyage (les clauses `finally` des instructions `try`) puissent être exécutés, et pour qu'un débogueur puisse exécuter un script sans courir le risque de perdre le contrôle. La fonction `os._exit()` peut être utilisée s'il est absolument nécessaire de sortir immédiatement (par exemple, dans le processus enfant après un appel à `os.fork()`).

The exception inherits from *BaseException* instead of *StandardError* or *Exception* so that it is not accidentally caught by code that catches *Exception*. This allows the exception to properly propagate up and cause the interpreter to exit.

Modifié dans la version 2.5 : Changed to inherit from *BaseException*.

**exception *TypeError***

Levée lorsqu'une opération ou fonction est appliquée à un objet d'un type inapproprié. La valeur associée est une chaîne de caractères donnant des détails sur le type d'inadéquation.

**exception *UnboundLocalError***

Levée lorsqu'une référence est faite à une variable locale dans une fonction ou une méthode, mais qu'aucune valeur n'a été liée à cette variable. C'est une sous-classe de *NameError*.

Nouveau dans la version 2.0.

**exception *UnicodeError***

Levée lorsqu'une erreur d'encodage ou de décodage liée à Unicode se produit. C'est une sous-classe de *ValueError*.

*UnicodeError* a des attributs qui décrivent l'erreur d'encodage ou de décodage. Par exemple, `err.object[err.start:err.end]` donne l'entrée particulière invalide sur laquelle le codec a échoué.

**encoding**

Le nom de l'encodage qui a provoqué l'erreur.

**reason**

Une chaîne de caractères décrivant l'erreur de codec spécifique.

**object**

L'objet que le codec essayait d'encoder ou de décoder.

**start**

Le premier index des données invalides dans *object*.

**end**

L'index après la dernière donnée invalide dans *object*.

Nouveau dans la version 2.0.

**exception *UnicodeEncodeError***

Levée lorsqu'une erreur liée à Unicode se produit durant l'encodage. C'est une sous-classe d'*UnicodeError*.

Nouveau dans la version 2.3.

**exception *UnicodeDecodeError***

Levée lorsqu'une erreur liée à Unicode se produit durant le décodage. C'est une sous-classe d'*UnicodeError*.

Nouveau dans la version 2.3.

**exception *UnicodeTranslateError***

Levée lorsqu'une erreur liée à Unicode se produit durant la traduction. C'est une sous-classe d'*UnicodeError*.

Nouveau dans la version 2.3.

**exception *ValueError***

Raised when an operation or function receives an argument that has the right type but an inappropriate value, and the situation is not described by a more precise exception such as *IndexError*.

**exception *VMSError***

Only available on VMS. Raised when a VMS-specific error occurs.

**exception *WindowsError***

Raised when a Windows-specific error occurs or when the error number does not correspond to an `errno` value. The `winerror` and `strerror` values are created from the return values of the `GetLastError()`

and `FormatMessage()` functions from the Windows Platform API. The `errno` value maps the `winerror` value to corresponding `errno.h` values. This is a subclass of `OSError`.

Nouveau dans la version 2.0.

Modifié dans la version 2.5 : Previous versions put the `GetLastError()` codes into `errno`.

**exception `ZeroDivisionError`**

Levée lorsque le second argument d'une opération de division ou d'un modulo est zéro. La valeur associée est une chaîne indiquant le type des opérandes et de l'opération.

Les exceptions suivantes sont utilisées comme catégories d'avertissement ; voir le module `warnings` pour plus d'informations.

**exception `Warning`**

Classe de base pour les catégories d'avertissement.

**exception `UserWarning`**

Classe de base pour les avertissements générés par du code utilisateur.

**exception `DeprecationWarning`**

Classe de base pour les avertissements sur les fonctionnalités obsolètes.

**exception `PendingDeprecationWarning`**

Classe de base pour les avertissements sur les fonctionnalités qui seront obsolètes dans le futur.

**exception `SyntaxWarning`**

Classe de base pour les avertissements sur de la syntaxe douteuse.

**exception `RuntimeWarning`**

Classe de base pour les avertissements sur les comportements d'exécution douteux.

**exception `FutureWarning`**

Classe de base pour les avertissements sur les constructions qui changeront sémantiquement dans le futur.

**exception `ImportWarning`**

Classe de base pour les avertissements sur des erreurs probables dans les imports de modules.

Nouveau dans la version 2.5.

**exception `UnicodeWarning`**

Classe de base pour les avertissements liés à l'Unicode.

Nouveau dans la version 2.5.

## 6.1 Hiérarchie des exceptions

La hiérarchie de classes pour les exceptions natives est la suivante :

```
BaseException
+-- SystemExit
+-- KeyboardInterrupt
+-- GeneratorExit
+-- Exception
    +-- StopIteration
    +-- StandardError
        | +-- BufferError
        | +-- ArithmeticError
        | | +-- FloatingPointError
        | | +-- OverflowError
        | | +-- ZeroDivisionError
```

(suite sur la page suivante)

(suite de la page précédente)

```

|   +-- AssertionError
|   +-- AttributeError
|   +-- EnvironmentError
|       |   +-- IOError
|       |   +-- OSError
|       |       +-- WindowsError (Windows)
|       |       +-- VMSError (VMS)
|   +-- EOFError
|   +-- ImportError
|   +-- LookupError
|       |   +-- IndexError
|       |   +-- KeyError
|   +-- MemoryError
|   +-- NameError
|       |   +-- UnboundLocalError
|   +-- ReferenceError
|   +-- RuntimeError
|       |   +-- NotImplementedError
|   +-- SyntaxError
|       |   +-- IndentationError
|       |   +-- TabError
|   +-- SystemError
|   +-- TypeError
|   +-- ValueError
|       |   +-- UnicodeError
|       |       +-- UnicodeDecodeError
|       |       +-- UnicodeEncodeError
|       |       +-- UnicodeTranslateError
+-- Warning
    +-- DeprecationWarning
    +-- PendingDeprecationWarning
    +-- RuntimeWarning
    +-- SyntaxWarning
    +-- UserWarning
    +-- FutureWarning
    +-- ImportWarning
    +-- UnicodeWarning
    +-- BytesWarning

```

The modules described in this chapter provide a wide range of string manipulation operations.

In addition, Python's built-in string classes support the sequence type methods described in the *Sequence Types* — *str*, *unicode*, *list*, *tuple*, *bytearray*, *buffer*, *xrange* section, and also the string-specific methods described in the *Méthodes de chaînes de caractères* section. To output formatted strings use template strings or the % operator described in the *String Formatting Operations* section. Also, see the *re* module for string functions based on regular expressions.

## 7.1 string — Opérations usuelles sur des chaînes

Code source : [Lib/string.py](#)

---

The *string* module contains a number of useful constants and classes, as well as some deprecated legacy functions that are also available as methods on strings. In addition, Python's built-in string classes support the sequence type methods described in the *Sequence Types* — *str*, *unicode*, *list*, *tuple*, *bytearray*, *buffer*, *xrange* section, and also the string-specific methods described in the *Méthodes de chaînes de caractères* section. To output formatted strings use template strings or the % operator described in the *String Formatting Operations* section. Also, see the *re* module for string functions based on regular expressions.

### 7.1.1 Chaînes constantes

Les constantes définies dans ce module sont :

`string.ascii_letters`

La concaténation des constantes *ascii\_lowercase* et *ascii\_uppercase* décrites ci-dessous. Cette valeur n'est pas dépendante de l'environnement linguistique.

`string.ascii_lowercase`

Les lettres minuscules 'abcdefghijklmnopqrstuvwxyz'. Cette valeur ne dépend pas de l'environnement linguistique et ne changera pas.

**string.ascii\_uppercase**

Les lettres majuscules 'ABCDEFGHIJKLMNOPQRSTUVWXYZ'. Cette valeur de dépend pas de l'environnement linguistique et ne changera pas.

**string.digits**

La chaîne '0123456789'.

**string.hexdigits**

La chaîne '0123456789abcdefABCDEF'.

**string.letters**

The concatenation of the strings *lowercase* and *uppercase* described below. The specific value is locale-dependent, and will be updated when *locale.setlocale()* is called.

**string.lowercase**

A string containing all the characters that are considered lowercase letters. On most systems this is the string 'abcdefghijklmnopqrstuvwxyz'. The specific value is locale-dependent, and will be updated when *locale.setlocale()* is called.

**string.octdigits**

La chaîne '01234567'.

**string.punctuation**

Chaîne de caractères ASCII considérés comme ponctuation dans l'environnement linguistique C.

**string.printable**

String of characters which are considered printable. This is a combination of *digits*, *letters*, *punctuation*, and *whitespace*.

**string.uppercase**

A string containing all the characters that are considered uppercase letters. On most systems this is the string 'ABCDEFGHIJKLMNOPQRSTUVWXYZ'. The specific value is locale-dependent, and will be updated when *locale.setlocale()* is called.

**string.whitespace**

A string containing all characters that are considered whitespace. On most systems this includes the characters space, tab, linefeed, return, formfeed, and vertical tab.

## 7.1.2 Formatage personnalisé de chaîne

Nouveau dans la version 2.6.

The built-in str and unicode classes provide the ability to do complex variable substitutions and value formatting via the *str.format()* method described in [PEP 3101](#). The *Formatter* class in the *string* module allows you to create and customize your own string formatting behaviors using the same implementation as the built-in *format()* method.

**class string.Formatter**

La classe *Formatter* a les méthodes publiques suivantes :

**format(format\_string, \*args, \*\*kwargs)**

La méthode principale de l'API. Elle prend une chaîne de format et un ensemble arbitraire d'arguments positions et mot-clefs. C'est uniquement un conteneur qui appelle *vformat()*.

**vformat(format\_string, args, kwargs)**

Cette fonction fait le travail effectif du formatage. Elle existe comme méthode séparée au cas où vous voudriez passer un dictionnaire d'arguments prédéfini plutôt que décompresser et recompresser le dictionnaire en arguments individuels en utilisant la syntaxe *\*args* et *\*\*kwargs*. *vformat()* s'occupe de découper la chaîne de format en données de caractères et champs de remplacement. Elle appelle les différentes méthodes décrites ci-dessous.

De plus, la classe `Formatter` définit un certain nombre de méthodes qui ont pour vocation d'être remplacées par des sous-classes :

**parse**(*format\_string*)

Boucle sur la chaîne de format et renvoie un itérable de *tuples* (*literal\_text*, *field\_name*, *format\_spec*, *conversion*). Ceci est utilisé par `vformat()` pour découper la chaîne de format en littéraux ou en champs de remplacement.

Les valeurs dans le *tuple* représentent conceptuellement un ensemble de littéraux suivis d'un unique champ de remplacement. S'il n'y a pas de littéral, (ce qui peut arriver si deux champs de remplacement sont placés côte à côte), alors *literal\_text* est une chaîne vide. S'il n'y a pas de champ de remplacement, les valeurs *field\_name*, *format\_spec* et *conversion* sont mises à `None`.

**get\_field**(*field\_name*, *args*, *kwargs*)

Récupère le champ *field\_name* du *tuple* renvoyé par `parse()` (voir ci-dessus), le convertit en un objet à formater. Renvoie un *tuple* (*obj*, *used\_key*). La version par défaut prend une chaîne de la forme définie par **PEP 3101**, telle que « *0[name]* » ou « *label.title* ». *args* et *kwargs* sont tels que ceux passés à `vformat()`. La valeur renvoyée *used\_key* a le même sens que le paramètre *key* de `get_value()`.

**get\_value**(*key*, *args*, *kwargs*)

récupère la valeur d'un champ donné. L'argument *key* est soit un entier, soit une chaîne. Si c'est un entier, il représente l'indice de la l'argument dans *args*. Si c'est une chaîne de caractères, elle représente le nom de l'argument dans *kwargs*.

Le paramètre *args* est défini par la liste des arguments positionnels de `vformat()`, et le paramètre *kwargs* est défini par le dictionnaire des arguments mot-clefs.

Pour les noms de champs composés, ces fonctions sont uniquement appelées sur la première composante du nom. Les composantes suivantes sont manipulées au travers des attributs normaux et des opérations sur les indices.

Donc par exemple, le champ-expression `0.name` amènerait `get_value()` à être appelée avec un argument *key* valant `0`. L'attribut `name` sera recherché après l'appel `get_value()` en faisant appel à la primitive `getattr()`.

Si l'indice ou le mot-clef fait référence à un objet qui n'existe pas, alors une exception `IndexError` ou `KeyError` doit être levée.

**check\_unused\_args**(*used\_args*, *args*, *kwargs*)

Implémente une vérification pour les arguments non utilisés si désiré. L'argument de cette fonction est l'ensemble des clefs qui ont été effectivement référencées dans la chaîne de format (des entiers pour les indices et des chaînes de caractères pour les arguments nommés), et une référence vers les arguments *args* et *kwargs* qui ont été passés à `vformat`. L'ensemble des arguments non utilisés peut être calculé sur base de ces paramètres. `check_unused_args()` est censée lever une exception si la vérification échoue.

**format\_field**(*value*, *format\_spec*)

La méthode `format_field()` fait simplement appel à la primitive globale `format()`. Cette méthode est fournie afin que les sous-classes puisse la redéfinir.

**convert\_field**(*value*, *conversion*)

Convertit la valeur (renvoyée par `get_field()`) selon un type de conversion donné (comme dans le *tuple* renvoyé par la méthode `parse()`). La version par défaut comprend "s" (*str*), "r" (*repr*) et "a" (ASCII) comme types de conversion.

### 7.1.3 Syntaxe de formatage de chaîne

La méthode `str.format()` et la classe `Formatter` utilisent la même syntaxe pour le formatage de chaînes (même si pour `Formatter`, les sous-classes peuvent définir leur propre syntaxe de chaînes de format).

Les chaînes de formatage contiennent des « champs de remplacement » entourés d'accolades `{}`. Tout ce qui n'est pas placé entre deux accolades est considéré comme littéral, qui est copié tel quel dans le résultat. Si vous avez besoin d'inclure une accolade en littéral, elles peuvent être échappées en les doublant : `{{` et `}}`.

La grammaire pour un champ de remplacement est défini comme suit :

```
replacement_field ::= "{" [field_name] ["!" conversion] [":" format_spec] "}"
field_name         ::= arg_name ( "." attribute_name | "[" element_index "]" ) *
arg_name           ::= [identifiant | integer]
attribute_name     ::= identifiant
element_index      ::= integer | index_string
index_string       ::= <any source character except "]"> +
conversion         ::= "r" | "s"
format_spec        ::= <described in the next section>
```

En termes moins formels, un champ de remplacement peut débiter par un *field\_name* qui spécifie l'objet dont la valeur va être formatée et insérée dans le résultat à l'endroit du champ de remplacement. Le *field\_name* peut éventuellement être suivi d'un champ *conversion* qui est précédé d'un point d'exclamation '!', et d'un *format\_spec* qui est précédé par deux-points ':'. Cela définit un format personnalisé pour le remplacement d'une valeur.

Voir également la section *Mini-langage de spécification de format*.

Le champ *field\_name* débute par un *arg\_name* qui est soit un nombre, soit un mot-clef. Si c'est un nombre, il fait référence à un des arguments positionnels et si c'est un mot-clef, il fait référence à un des arguments nommés. Si les valeurs numériques de *arg\_name* dans une chaîne de format sont 0, 1, 2, ... dans l'ordre, elles peuvent être omises (toutes ou aucune), et les nombres 0, 1, 2, ... seront automatiquement insérés dans cet ordre. Puisque *arg\_name* n'est pas délimité par des guillemets, il n'est pas possible de spécifier des clefs de dictionnaire arbitraires (par exemple les chaînes '10' ou ':-]') dans une chaîne de format. La valeur *arg\_name* peut être suivie par un nombre d'indices ou d'expressions quelconque. Une expression de la forme '.name' sélectionne l'attribut nommé en utilisant *getattr()* alors qu'une expression de la forme '[index]' recherche l'indice en utilisant *\_\_getitem\_\_()*.

Modifié dans la version 2.7 : The positional argument specifiers can be omitted for *str.format()* and *unicode.format()*, so '{0} {1}' is equivalent to '{0} {1}', u'{0} {1}' is equivalent to u'{0} {1}'.

Quelques exemples simples de formatage de chaînes :

```
"First, thou shalt count to {0}"    # References first positional argument
"Bring me a {}"                    # Implicitly references the first positional argument
"From {} to {}".format(0, 1)        # Same as "From {0} to {1}"
"My quest is {name}"                # References keyword argument 'name'
"Weight in tons {0.weight}"         # 'weight' attribute of first positional arg
"Units destroyed: {players[0]}"     # First element of keyword argument 'players'.
```

Le champ *conversion* crée une contrainte de type avant de formater. Normalement, le travail de formatage d'une valeur est fait par la méthode *\_\_format\_\_()* de la valeur elle-même. Cependant, dans certains cas, il est désirable de forcer un type à être formaté en une chaîne, en ré-définissant sa propre définition de formatage. En convertissant une valeur en chaîne de caractère avant d'appeler la méthode *\_\_format\_\_()*, on outrepassa la logique usuelle de formatage.

Two conversion flags are currently supported : '!s' which calls *str()* on the value, and '!r' which calls *repr()*.

Quelques exemples :

```
"Harold's a clever {0!s}"           # Calls str() on the argument first
"Bring out the holy {name!r}"       # Calls repr() on the argument first
```

Le champ *format\_spec* contient une spécification sur la manière selon laquelle la valeur devrait être représentée : des informations telles que la longueur du champ, l'alignement, le remplissage, la précision décimale,

etc. Chaque type peut définir son propre « mini-langage de formatage » ou sa propre interprétation de *format\_spec*.

La plupart des types natifs supportent un mini-langage de formatage usuel qui est décrit dans la section suivante.

Un champ *format\_spec* peut contenir un champ de remplacement imbriqué. Ces champs de remplacement imbriqués peuvent contenir un nom de champ, un indicateur de conversion, mais une imbrication récursive plus profonde n'est pas permise. Les champs de remplacement au sein de *format\_spec* sont substitués avant que la chaîne *format\_spec* ne soit interprétée. Cela permet que le formatage d'une valeur soit dynamiquement spécifié.

Voir la section *Exemples de formats* pour des exemples.

### Mini-langage de spécification de format

Les « spécifications de format » sont utilisées pour les champs de remplacement contenus dans une chaîne de format pour définir comment la valeur doit être représentée (voir *Syntaxe de formatage de chaîne*). Elles peuvent également être passées directement à la primitive *format()*. Chaque type formattable peut définir comment interpréter la spécification de format.

La plupart des primitives implémentent les options suivantes, même si certaines options de formatage ne sont supportées que pour les types numériques.

Une convention généralement admise est qu'une chaîne vide ("" ) produit le même résultat que si vous aviez appelé *str()* sur la valeur. Une chaîne de format non vide modifie typiquement le résultat.

La forme générale d'un *spécificateur de format standard* est :

```
format_spec ::= [[fill] align] [sign] [#] [0] [width] [,] [.precision] [type]
```

```
fill        ::= <any character>
```

```
align       ::= "<" | ">" | "=" | "^"
```

```
sign        ::= "+" | "-" | " "
```

```
width       ::= integer
```

```
precision   ::= integer
```

```
type        ::= "b" | "c" | "d" | "e" | "E" | "f" | "F" | "g" | "G" | "n" | "o" | "s" | "x" | "X"
```

Si une valeur *align* valide est spécifiée, la valeur peut être représentée par un caractère *fill* de remplissage qui peut être n'importe quel caractère et qui vaut espace par défaut si il est omis. Il est impossible d'utiliser un littéral « accolade » (« { » ou « } ») en tant que caractère *fill* quand la méthode *str.format()* est utilisée. Cependant, il est possible d'insérer une accolade avec un champ de remplacement imbriqué. Cette limite n'affecte pas la fonction *format()*.

Le sens des différentes options d'alignement est donné comme suit :

Op-tion	Signification
'<'	Force le champ à être aligné à gauche dans l'espace disponible (c'est le spécificateur par défaut pour la plupart des objets).
'>'	Force le champ à être aligné à droite dans l'espace disponible (c'est le spécificateur par défaut pour les nombres).
'='	Force le remplissage ( <i>padding</i> ) à être placé après le signe (si signe il y a) mais avant les chiffres. L'option est utilisée pour afficher les champs sous la forme « +000000120 ». Cette option d'alignement est valide uniquement pour les types numériques. Elle devient activée par défaut quand « 0 » précède directement la largeur de champ.
'^'	Force le champ à être centré dans l'espace disponible.

Notons que la longueur du champ est toujours égale à la la taille nécessaire pour remplir le champ avec l'objet à moins que la valeur minimum ne soit précisée. Ainsi, si aucune valeur n'est précisée, l'option d'alignement n'a aucun sens.

L'option *sign* est uniquement valide pour les type numériques, et peut valoir :

Op-tion	Signification
'+'	Indique que le signe doit être affiché pour les nombres tant positifs que négatifs.
'-'	Indique que le signe doit être affiché uniquement pour les nombres négatifs (c'est le comportement par défaut).
es-space	Indique qu'un espace doit précéder les nombres positifs et qu'un signe moins doit précéder les nombres négatifs.

The '#' option is only valid for integers, and only for binary, octal, or hexadecimal output. If present, it specifies that the output will be prefixed by '0b', '0o', or '0x', respectively.

L'option ',' signale l'utilisation d'une virgule comme séparateur des milliers. Pour un séparateur conscient de l'environnement linguistique, utilisez plutôt le type de présentation entière 'n'.

Modifié dans la version 2.7 : Ajout de l'option ',' (voir [PEP 378](#)).

*width* est un entier en base 10 qui définit la longueur minimale du champ. Si elle n'est pas spécifiée, alors le champ *width* est déterminé par le contenu.

Quand aucun alignement explicite n'est donné, précéder le champs *width* d'un caractère zéro ('0') active le remplissage par zéro des types numériques selon leur signe. Cela est équivalent à un caractère de remplissage *fill* valant '0' avec le type d'alignement *alignment* valant '='.

La valeur *precision* est un nombre en base 10 indiquant combien de chiffres doivent être affichés après la virgule pour une valeur à virgule flottante formatée avec 'f' ou 'F', ou avant et après le point-décimal pour une valeur à virgule flottante formatée avec 'g' ou 'G'. Pour les types non numériques, ce champ indique la taille maximale du champ, autrement dit, combien de caractères du champ sont utilisés. Le spécificateur *precision* n'est pas autorisé sur les entiers.

Finalement, le spécificateur *type* détermine comment la donnée doit être représentée.

Les types disponibles de représentation de chaîne sont :

Type	Signification
's'	Format de chaîne. C'est le type par défaut pour les chaînes de caractères et peut être omis.
<i>None</i>	Pareil que 's'.

Les types disponibles de représentation d'entier sont :

Type	Signification
'b'	Format binaire. Affiche le nombre en base 2.
'c'	Caractère. Convertit l'entier en le caractère Unicode associé avant de l'afficher.
'd'	Entier décimal. Affiche le nombre en base 10.
'o'	Format octal. Affiche le nombre en base 8.
'x'	Format hexadécimal. Affiche le nombre en base 16 en utilisant les lettres minuscules pour les chiffres au-dessus de 9.
'X'	Format hexadécimal. Affiche le nombre en base 16 en utilisant les lettres majuscules pour les chiffres au-dessus de 9.
'n'	Nombre. Pareil que 'd' si ce n'est que l'environnement linguistique est utilisé afin de déterminer le séparateur de nombres approprié.
<i>None</i>	Pareil que 'd'.

En plus des types de représentation ci-dessus, les entiers peuvent aussi être formatés avec les types de représentation des flottants listés ci-dessous (à l'exception de 'n' et None). Dans ce cas, la fonction `float()` est utilisée pour convertir l'entier en flottant avant le formatage.

les types de représentation pour les nombres flottants et les valeurs décimales sont :

Type	Signification
'e'	Notation par exposant. Affiche le nombre dans sa notation scientifique en utilisant la lettre "e" pour indiquer l'exposant. La précision par défaut est 6.
'E'	Notation par exposant. Pareil que 'e' sauf l'utilisation de la lettre majuscule "E" comme séparateur.
'f'	Fixed-point notation. Displays the number as a fixed-point number. The default precision is 6.
'F'	Fixed point notation. Same as 'f'.
'g'	Format général. Pour une précision donnée $p \geq 1$ , ceci arrondit le nombre à $p$ chiffres significatifs et puis formate le résultat soit en virgule fixe soit en notation scientifique, en fonction de la magnitude. Les règles précises sont les suivantes : supposons que le résultat formaté avec le type de représentation 'e' et une précision 1 ait un exposant $\text{exp}$ . Alors, si $-4 \leq \text{exp} \leq p$ , le nombre est formaté avec le type de représentation 'f' et une précision $p-1-\text{exp}$ . Sinon, le nombre est formaté avec le type de représentation 'e' et une précision $p-1$ . Dans les deux cas, les zéros finaux et non significatifs sont retirés, et la virgule est également retirée s'il n'y a aucun chiffre la suivant. Les valeurs suivantes : infini négatif, infini positif, zéro positif, zéro négatif, <i>not a number</i> sont formatées respectivement par <code>inf</code> , <code>-inf</code> , <code>0</code> , <code>-0</code> et <code>nan</code> , peu importe la précision. Une précision de 0 est interprétée comme une précision de 1. La précision par défaut est 6.
'G'	Format général. Pareil que 'G' si ce n'est que 'E' est utilisé si le nombre est trop grand. Également, la représentation des infinis et de Nan sont en majuscules également.
'n'	Nombre. Pareil que 'g', si ce n'est que l'environnement linguistique est pris en compte pour insérer le séparateur approprié.
'%'	Pourcentage. Multiplie le nombre par 100 et l'affiche en virgule fixe ('f'), suivi d'un symbole pourcent '%'
None	The same as 'g'.

## Exemples de formats

Cette section contient des exemples de la syntaxe de `str.format()` et des comparaisons avec l'ancien formatage par %.

Dans la plupart des cases, la syntaxe est similaire à l'ancien formatage par %, avec l'ajout de {} et avec : au lieu de %. Par exemple : '%03.2f' peut être changé en '{03.2f}'.

The new format syntax also supports new and different options, shown in the following examples.

Accéder à un argument par sa position :

```
>>> '{0}, {1}, {2}'.format('a', 'b', 'c')
'a, b, c'
>>> '{}, {}, {}'.format('a', 'b', 'c') # 2.7+ only
'a, b, c'
>>> '{2}, {1}, {0}'.format('a', 'b', 'c')
'c, b, a'
>>> '{2}, {1}, {0}'.format(*'abc')      # unpacking argument sequence
'c, b, a'
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> '{0}{1}{0}'.format('abra', 'cad')  # arguments' indices can be repeated
'abracadabra'
```

Accéder à un argument par son nom :

```
>>> 'Coordinates: {latitude}, {longitude}'.format(latitude='37.24N', longitude='-115.81W')
'Coordinates: 37.24N, -115.81W'
>>> coord = {'latitude': '37.24N', 'longitude': '-115.81W'}
>>> 'Coordinates: {latitude}, {longitude}'.format(**coord)
'Coordinates: 37.24N, -115.81W'
```

Accéder aux attributs d'un argument :

```
>>> c = 3-5j
>>> ('The complex number {0} is formed from the real part {0.real} '
... 'and the imaginary part {0.imag}.').format(c)
'The complex number (3-5j) is formed from the real part 3.0 and the imaginary part -5.0.'
>>> class Point(object):
...     def __init__(self, x, y):
...         self.x, self.y = x, y
...     def __str__(self):
...         return 'Point({self.x}, {self.y})'.format(self=self)
...
>>> str(Point(4, 2))
'Point(4, 2)'
```

Accéder aux éléments d'un argument :

```
>>> coord = (3, 5)
>>> 'X: {0[0]}; Y: {0[1]}'.format(coord)
'X: 3; Y: 5'
```

Remplacer %s et %r :

```
>>> "repr() shows quotes: {!r}; str() doesn't: {!s}".format('test1', 'test2')
'repr() shows quotes: \'test1\'; str() doesn\'t: test2'
```

Aligner le texte et spécifier une longueur minimale :

```
>>> '{:<30}'.format('left aligned')
'left aligned'
>>> '{:>30}'.format('right aligned')
'right aligned'
>>> '{:~30}'.format('centered')
'centered'
>>> '{:*~30}'.format('centered')  # use '*' as a fill char
'*****centered*****'
```

Remplacer %+f, %-f, et %f et spécifier un signe :

```
>>> '{:+f}; {:+f}'.format(3.14, -3.14)  # show it always
'+3.140000; -3.140000'
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> '{: f}; {: f}'.format(3.14, -3.14) # show a space for positive numbers
' 3.140000; -3.140000'
>>> '{:-f}; {:-f}'.format(3.14, -3.14) # show only the minus -- same as '{:f}; {:f}'
'3.140000; -3.140000'
```

Remplacer %x et %o et convertir la valeur dans différentes bases :

```
>>> # format also supports binary numbers
>>> "int: {0:d}; hex: {0:x}; oct: {0:o}; bin: {0:b}".format(42)
'int: 42; hex: 2a; oct: 52; bin: 101010'
>>> # with 0x, 0o, or 0b as prefix:
>>> "int: {0:d}; hex: {0:#x}; oct: {0:#o}; bin: {0:#b}".format(42)
'int: 42; hex: 0x2a; oct: 0o52; bin: 0b101010'
```

Utiliser une virgule comme séparateur des milliers :

```
>>> '{:,}'.format(1234567890)
'1,234,567,890'
```

Exprimer un pourcentage :

```
>>> points = 19.5
>>> total = 22
>>> 'Correct answers: {:.2%}'.format(points/total)
'Correct answers: 88.64%'
```

Utiliser un formatage propre au type :

```
>>> import datetime
>>> d = datetime.datetime(2010, 7, 4, 12, 15, 58)
>>> '{:%Y-%m-%d %H:%M:%S}'.format(d)
'2010-07-04 12:15:58'
```

Arguments imbriqués et des exemples plus complexes :

```
>>> for align, text in zip('<^>', ['left', 'center', 'right']):
...     '{0:{fill}{align}16}'.format(text, fill=align, align=align)
...
'left<<<<<<<<<<<<'
'~~~~~center~~~~~'
'>>>>>>>>>>>>right'
>>>
>>> octets = [192, 168, 0, 1]
>>> '{:02X}{:02X}{:02X}{:02X}'.format(*octets)
'COA80001'
>>> int(_, 16)
3232235521
>>>
>>> width = 5
>>> for num in range(5,12):
...     for base in 'dXob':
...         print '{0:{width}{base}}'.format(num, base=base, width=width),
...     print
```

(suite sur la page suivante)

(suite de la page précédente)

```

...
5      5      5    101
6      6      6    110
7      7      7    111
8      8     10   1000
9      9     11   1001
10     A     12   1010
11     B     13   1011

```

### 7.1.4 Chaînes modèles

Nouveau dans la version 2.4.

Les modèles (*templates*) fournissent des substitutions de chaînes plus simples comme décrit dans [PEP 292](#). À la place des substitutions habituelles basées sur %, les *Templates* supportent les substitutions basées sur \$ en utilisant les règles suivantes :

- \$\$ est un échappement ; il est remplacé par un simple \$.
- \$identifiant names a substitution placeholder matching a mapping key of "identifiant". By default, "identifiant" must spell a Python identifier. The first non-identifier character after the \$ character terminates this placeholder specification.
- \${identifiant} est équivalent à \$identifiant. Cette notation est requise quand un caractère valide pour une clef de substituant suit directement le substituant mais ne fait pas partie du substituant, comme "\${noun}ification".

Tout autre présence du symbole \$ dans une chaîne résultera en la levée d'une *ValueError*.

Le module *string* fournit une classe *Template* qui implémente ces règles. Les méthodes de *Template* sont :

**class** *string.Template*(*template*)

Le constructeur prend un seul argument qui est la chaîne du *template*.

**substitute**(*mapping*[, *\*\*kws*])

Performs the template substitution, returning a new string. *mapping* is any dictionary-like object with keys that match the placeholders in the template. Alternatively, you can provide keyword arguments, where the keywords are the placeholders. When both *mapping* and *kws* are given and there are duplicates, the placeholders from *kws* take precedence.

**safe\_substitute**(*mapping*[, *\*\*kws*])

Like *substitute()*, except that if placeholders are missing from *mapping* and *kws*, instead of raising a *KeyError* exception, the original placeholder will appear in the resulting string intact. Also, unlike with *substitute()*, any other appearances of the \$ will simply return \$ instead of raising *ValueError*.

While other exceptions may still occur, this method is called « safe » because it always tries to return a usable string instead of raising an exception. In another sense, *safe\_substitute()* may be anything other than safe, since it will silently ignore malformed templates containing dangling delimiters, unmatched braces, or placeholders that are not valid Python identifiers.

Les instances de la classe *Template* fournissent également un attribut public :

**template**

C'est l'objet *template* passé comme argument au constructeur. En général, vous ne devriez pas le changer, mais un accès en lecture-seule n'est pas possible à fournir.

Voici un exemple de comment utiliser un *Template* :

```

>>> from string import Template
>>> s = Template('$who likes $what')
>>> s.substitute(who='tim', what='kung pao')

```

(suite sur la page suivante)

(suite de la page précédente)

```
'tim likes kung pao'
>>> d = dict(who='tim')
>>> Template('Give $who $100').substitute(d)
Traceback (most recent call last):
...
ValueError: Invalid placeholder in string: line 1, col 11
>>> Template('$who likes $what').substitute(d)
Traceback (most recent call last):
...
KeyError: 'what'
>>> Template('$who likes $what').safe_substitute(d)
'tim likes $what'
```

Usage avancé : vous pouvez faire dériver vos sous-classes de *Template* pour personnaliser la syntaxe des substituants, les caractères délimiteurs, ou l'entière de l'expression rationnelle utilisée pour analyser les chaînes *templates*. Pour faire cela, vous pouvez redéfinir les attributs suivants :

- *delimiter* – La chaîne littérale décrivant le délimiteur pour introduire un substituant. Sa valeur par défaut est `$`. Notez qu'il ne doit *pas* être une expression rationnelle, puisque l'implémentation appellera *re.escape()* sur cette chaîne si nécessaire.
- *idpattern* – L'expression rationnelle décrivant le motif pour les substituants non entourés d'accolades (les accolades sont ajoutées automatiquement si c'est approprié). La valeur par défaut de cette expression rationnelle est `[_a-z][_a-z0-9]*`.

Également, vous pouvez fournir le motif d'expression rationnelle en entier en redéfinissant l'attribut *pattern*. Si vous faites cela, la valeur doit être un objet "expression rationnelle" avec quatre groupes de capture de noms. Les groupes de capture correspondent aux règles données au-dessus, ainsi qu'à la règle du substituant invalide :

- *escaped* – Ce groupe lie les séquences échappées (par exemple `$$`) dans le motif par défaut.
- *named* – Ce groupe lie les substituants non entourés d'accolades ; il ne devrait pas inclure le délimiteur dans le groupe de capture.
- *braced* – Ce groupe lie le nom entouré d'accolades ; il ne devrait inclure ni le délimiteur, ni les accolades dans le groupe de capture.
- *invalid* – Ce groupe lie tout autre motif de délimitation (habituellement, un seul délimiteur) et il devrait apparaître en dernier dans l'expression rationnelle.

### 7.1.5 String functions

The following functions are available to operate on string and Unicode objects. They are not available as string methods.

**string.capwords(*s* [, *sep*])**

Divise l'argument en mots en utilisant *str.split()*, capitalise chaque mot en utilisant *str.capitalize()* et assemble les mots capitalisés en utilisant *str.join()*. Si le second argument optionnel *sep* est absent ou vaut `None`, les séquences de caractères blancs sont remplacées par un seul espace et les espaces débutant et finissant la chaîne sont retirés. Sinon, *sep* est utilisé pour séparer et ré-assembler les mots.

**string.maketrans(*from*, *to*)**

Return a translation table suitable for passing to *translate()*, that will map each character in *from* into the character at the same position in *to*; *from* and *to* must have the same length.

---

**Note :** Don't use strings derived from *lowercase* and *uppercase* as arguments; in some locales, these don't have the same length. For case conversions, always use *str.lower()* and *str.upper()*.

---

### 7.1.6 Deprecated string functions

The following list of functions are also defined as methods of string and Unicode objects ; see section *Méthodes de chaînes de caractères* for more information on those. You should consider these functions as deprecated, although they will not be removed until Python 3. The functions defined in this module are :

**string.atof(*s*)**

Obsolète depuis la version 2.0 : Use the *float()* built-in function.

Convert a string to a floating point number. The string must have the standard syntax for a floating point literal in Python, optionally preceded by a sign (+ or -). Note that this behaves identical to the built-in function *float()* when passed a string.

---

**Note :** When passing in a string, values for NaN and Infinity may be returned, depending on the underlying C library. The specific set of strings accepted which cause these values to be returned depends entirely on the C library and is known to vary.

---

**string.atoi(*s*[, *base*])**

Obsolète depuis la version 2.0 : Use the *int()* built-in function.

Convert string *s* to an integer in the given *base*. The string must consist of one or more digits, optionally preceded by a sign (+ or -). The *base* defaults to 10. If it is 0, a default base is chosen depending on the leading characters of the string (after stripping the sign) : 0x or 0X means 16, 0 means 8, anything else means 10. If *base* is 16, a leading 0x or 0X is always accepted, though not required. This behaves identically to the built-in function *int()* when passed a string. (Also note : for a more flexible interpretation of numeric literals, use the built-in function *eval()*.)

**string.atol(*s*[, *base*])**

Obsolète depuis la version 2.0 : Use the *long()* built-in function.

Convert string *s* to a long integer in the given *base*. The string must consist of one or more digits, optionally preceded by a sign (+ or -). The *base* argument has the same meaning as for *atoi()*. A trailing l or L is not allowed, except if the base is 0. Note that when invoked without *base* or with *base* set to 10, this behaves identical to the built-in function *long()* when passed a string.

**string.capitalize(*word*)**

Return a copy of *word* with only its first character capitalized.

**string.expandtabs(*s*[, *tabsize*])**

Expand tabs in a string replacing them by one or more spaces, depending on the current column and the given tab size. The column number is reset to zero after each newline occurring in the string. This doesn't understand other non-printing characters or escape sequences. The tab size defaults to 8.

**string.find(*s*, *sub*[, *start*[, *end*]])**

Return the lowest index in *s* where the substring *sub* is found such that *sub* is wholly contained in *s*[*start*:*end*]. Return -1 on failure. Defaults for *start* and *end* and interpretation of negative values is the same as for slices.

**string.rfind(*s*, *sub*[, *start*[, *end*]])**

Like *find()* but find the highest index.

**string.index(*s*, *sub*[, *start*[, *end*]])**

Like *find()* but raise *ValueError* when the substring is not found.

**string.rindex(*s*, *sub*[, *start*[, *end*]])**

Like *rfind()* but raise *ValueError* when the substring is not found.

**string.count(*s*, *sub*[, *start*[, *end*]])**

Return the number of (non-overlapping) occurrences of substring *sub* in string *s*[*start*:*end*]. Defaults for *start* and *end* and interpretation of negative values are the same as for slices.

`string.lower(s)`

Return a copy of *s*, but with upper case letters converted to lower case.

`string.split(s[, sep[, maxsplit]])`

Return a list of the words of the string *s*. If the optional second argument *sep* is absent or `None`, the words are separated by arbitrary strings of whitespace characters (space, tab, newline, return, formfeed). If the second argument *sep* is present and not `None`, it specifies a string to be used as the word separator. The returned list will then have one more item than the number of non-overlapping occurrences of the separator in the string. If *maxsplit* is given, at most *maxsplit* number of splits occur, and the remainder of the string is returned as the final element of the list (thus, the list will have at most *maxsplit*+1 elements). If *maxsplit* is not specified or `-1`, then there is no limit on the number of splits (all possible splits are made).

The behavior of `split` on an empty string depends on the value of *sep*. If *sep* is not specified, or specified as `None`, the result will be an empty list. If *sep* is specified as any string, the result will be a list containing one element which is an empty string.

`string.rsplit(s[, sep[, maxsplit]])`

Return a list of the words of the string *s*, scanning *s* from the end. To all intents and purposes, the resulting list of words is the same as returned by `split()`, except when the optional third argument *maxsplit* is explicitly specified and nonzero. If *maxsplit* is given, at most *maxsplit* number of splits – the *rightmost* ones – occur, and the remainder of the string is returned as the first element of the list (thus, the list will have at most *maxsplit*+1 elements).

Nouveau dans la version 2.4.

`string.splitfields(s[, sep[, maxsplit]])`

This function behaves identically to `split()`. (In the past, `split()` was only used with one argument, while `splitfields()` was only used with two arguments.)

`string.join(words[, sep])`

Concatenate a list or tuple of words with intervening occurrences of *sep*. The default value for *sep* is a single space character. It is always true that `string.join(string.split(s, sep), sep)` equals *s*.

`string.joinfields(words[, sep])`

This function behaves identically to `join()`. (In the past, `join()` was only used with one argument, while `joinfields()` was only used with two arguments.) Note that there is no `joinfields()` method on string objects; use the `join()` method instead.

`string.lstrip(s[, chars])`

Return a copy of the string with leading characters removed. If *chars* is omitted or `None`, whitespace characters are removed. If given and not `None`, *chars* must be a string; the characters in the string will be stripped from the beginning of the string this method is called on.

Modifié dans la version 2.2.3 : The *chars* parameter was added. The *chars* parameter cannot be passed in earlier 2.2 versions.

`string.rstrip(s[, chars])`

Return a copy of the string with trailing characters removed. If *chars* is omitted or `None`, whitespace characters are removed. If given and not `None`, *chars* must be a string; the characters in the string will be stripped from the end of the string this method is called on.

Modifié dans la version 2.2.3 : The *chars* parameter was added. The *chars* parameter cannot be passed in earlier 2.2 versions.

`string.strip(s[, chars])`

Return a copy of the string with leading and trailing characters removed. If *chars* is omitted or `None`, whitespace characters are removed. If given and not `None`, *chars* must be a string; the characters in the string will be stripped from the both ends of the string this method is called on.

Modifié dans la version 2.2.3 : The *chars* parameter was added. The *chars* parameter cannot be passed in earlier 2.2 versions.

`string.swapcase(s)`

Return a copy of *s*, but with lower case letters converted to upper case and vice versa.

`string.translate(s, table[, deletechars])`

Delete all characters from *s* that are in *deletechars* (if present), and then translate the characters using *table*, which must be a 256-character string giving the translation for each character value, indexed by its ordinal. If *table* is `None`, then only the character deletion step is performed.

`string.upper(s)`

Return a copy of *s*, but with lower case letters converted to upper case.

`string.ljust(s, width[, fillchar])`

`string.rjust(s, width[, fillchar])`

`string.center(s, width[, fillchar])`

These functions respectively left-justify, right-justify and center a string in a field of given width. They return a string that is at least *width* characters wide, created by padding the string *s* with the character *fillchar* (default is a space) until the given width on the right, left or both sides. The string is never truncated.

`string.zfill(s, width)`

Pad a numeric string *s* on the left with zero digits until the given *width* is reached. Strings starting with a sign are handled correctly.

`string.replace(s, old, new[, maxreplace])`

Return a copy of string *s* with all occurrences of substring *old* replaced by *new*. If the optional argument *maxreplace* is given, the first *maxreplace* occurrences are replaced.

## 7.2 re — Opérations à base d'expressions rationnelles

This module provides regular expression matching operations similar to those found in Perl. Both patterns and strings to be searched can be Unicode strings as well as 8-bit strings.

Les expressions rationnelles utilisent le caractère *backslash* (`'\'`) pour indiquer des formes spéciales ou permettre d'utiliser des caractères spéciaux sans en invoquer le sens. Cela entre en conflit avec l'utilisation en Python du même caractère pour la même raison dans les chaînes littérales ; par exemple, pour rechercher un *backslash* littéral il faudrait écrire `'\\\\'` comme motif, parce que l'expression rationnelle devrait être `\\` et chaque *backslash* doit être représenté par `\\` au sein des chaînes littérales Python.

La solution est d'utiliser la notation des chaînes brutes en Python pour les expressions rationnelles ; Les *backslashes* ne provoquent aucun traitement spécifique dans les chaînes littérales préfixées par `'r'`. Ainsi, `r"\n"` est une chaîne de deux caractères contenant `'\'` et `'n'`, tandis que `"\n"` est une chaîne contenant un unique caractère : un saut de ligne. Généralement, les motifs seront exprimés en Python à l'aide de chaînes brutes.

It is important to note that most regular expression operations are available as module-level functions and *RegexObject* methods. The functions are shortcuts that don't require you to compile a regex object first, but miss some fine-tuning parameters.

**Voir aussi :**

The third-party `regex` module, which has an API compatible with the standard library `re` module, but offers additional functionality and a more thorough Unicode support.

### 7.2.1 Syntaxe des expressions rationnelles

Une expression rationnelle (*regular expression* ou *RE*) spécifie un ensemble de chaînes de caractères qui lui correspondent ; les fonctions de ce module vous permettent de vérifier si une chaîne particulière corres-

pond à une expression rationnelle donnée (ou si une expression rationnelle donnée correspond à une chaîne particulière, ce qui revient à la même chose).

Les expressions rationnelles peuvent être concaténées pour former de nouvelles expressions : si  $A$  et  $B$  sont deux expressions rationnelles, alors  $AB$  est aussi une expression rationnelle. En général, si une chaîne  $p$  valide  $A$  et qu'une autre chaîne  $q$  valide  $B$ , la chaîne  $pq$  validera  $AB$ . Cela est vrai tant que  $A$  et  $B$  ne contiennent pas d'opérations de précédence ; de conditions liées entre  $A$  et  $B$  ; ou de références vers des groupes numérotés. Ainsi, des expressions complexes peuvent facilement être construites depuis de plus simples expressions primitives comme celles décrites ici. Pour plus de détails sur la théorie et l'implémentation des expressions rationnelles, consultez le livre de Frieid référencé plus tôt, ou à peu près n'importe quel livre dédié à la construction de compilateurs.

Une brève explication sur le format des expressions rationnelles suit. Pour de plus amples informations et une présentation plus simple, référez-vous au `regex-howto`.

Les expressions rationnelles peuvent contenir à la fois des caractères spéciaux et ordinaires. Les plus ordinaires, comme `'A'`, `'a'` ou `'0'` sont les expressions rationnelles les plus simples : elles correspondent simplement à elles-mêmes. Vous pouvez concaténer des caractères ordinaires, ainsi `last` correspond à la chaîne `'last'`. (Dans la suite de cette section, nous écrirons les expressions rationnelles dans **ce style spécifique**, généralement sans guillemets, et les chaînes à tester **'entourées de simples guillemets'**.)

Some characters, like `'|'` or `'('`, are special. Special characters either stand for classes of ordinary characters, or affect how the regular expressions around them are interpreted. Regular expression pattern strings may not contain null bytes, but can specify the null byte using the `\number` notation, e.g., `'\x00'`.

Les caractères de répétition (`*`, `+`, `?`, `{m,n}`, etc.) ne peuvent être directement imbriqués. Cela empêche l'ambiguïté avec le suffixe modificateur non gourmand `?` et avec les autres modificateurs dans d'autres implémentations. Pour appliquer une seconde répétition à une première, des parenthèses peuvent être utilisées. Par exemple, l'expression `(?:a{6})*` valide toutes les chaînes composées d'un nombre de caractères `'a'` multiple de six.

Les caractères spéciaux sont :

- `'.'` (Point.) Dans le mode par défaut, il valide tout caractère à l'exception du saut de ligne. Si l'option `DOTALL` a été spécifiée, il valide tout caractère, saut de ligne compris.
- `'^'` (Accent circonflexe.) Valide le début d'une chaîne de caractères, ainsi que ce qui suit chaque saut de ligne en mode `MULTILINE`.
- `'$'` Valide la fin d'une chaîne de caractères, ou juste avant le saut de ligne à la fin de la chaîne, ainsi qu'avant chaque saut de ligne en mode `MULTILINE`. `foo` valide à la fois `foo` et `foobar`, tandis que l'expression rationnelle `foo$` ne correspond qu'à `'foo'`. Plus intéressant, chercher `foo.$` dans `'foo1\nfoo2\n'` trouve normalement `'foo2'`, mais `'foo1'` en mode `MULTILINE` ; chercher un simple `$` dans `'foo\n'` trouvera deux correspondances (vides) : une juste avant le saut de ligne, et une à la fin de la chaîne.
- `'*'` Fait valider par l'expression rationnelle résultante 0 répétition ou plus de l'expression qui précède, avec autant de répétitions que possible. `ab*` validera `"a"`, `"ab"` ou `"a"` suivi de n'importe quel nombre de `"b"`.
- `'+'` Fait valider par l'expression rationnelle résultante 1 répétition ou plus de l'expression qui précède. `ab+` validera `"a"` suivi de n'importe quel nombre non nul de `"b"` ; cela ne validera pas la chaîne `"a"`.
- `'?'` Fait valider par l'expression rationnelle résultante 0 ou 1 répétition de l'expression qui précède. `ab?` correspondra à `"a"` ou `"ab"`.
- `*?`, `+?`, `??` Les qualificateurs `'*'`, `'+'` et `'?'` sont tous *greedy* (gourmands) ; ils valident autant de texte que possible. Parfois ce comportement n'est pas désiré ; si l'expression rationnelle `<.*>` est testée avec la chaîne `<a> b <c>`, cela correspondra à la chaîne entière, et non juste à `<a>`. Ajouter `?` derrière le qualificateur lui fait réaliser l'opération de façon *non-greedy* (ou *minimal*) ; le *moins* de caractères possibles seront validés. Utiliser l'expression rationnelle `<.*?>` validera uniquement `<a>`.

- `{m}` Spécifie qu'exactly  $m$  copies de l'expression rationnelle qui précède devront être validées ; un nombre plus faible de correspondances empêche l'expression entière de correspondre. Par exemple, `a{6}` correspondra exactement à six caractères 'a', mais pas à cinq.
- `{m,n}` Implique à l'expression rationnelle résultante de valider entre  $m$  et  $n$  répétitions de l'expression qui précède, cherchant à en valider le plus possible. Par exemple, `a{3,5}` validera entre 3 et 5 caractères 'a'. Omettre  $m$  revient à spécifier 0 comme borne inférieure, et omettre  $n$  à avoir une borne supérieure infinie. Par exemple, `a{4,}b` correspondra à `aaaab` ou à un millier de caractères 'a' suivis d'un `b`, mais pas à `aaab`. La virgule ne doit pas être omise, auquel cas le modificateur serait confondu avec la forme décrite précédemment.
- `{m,n}?` Fait valider par l'expression rationnelle résultante entre  $m$  et  $n$  répétitions de l'expression qui précède, cherchant à en valider le moins possible. Il s'agit de la version non gourmande du précédent qualificateur. Par exemple, dans la chaîne de 6 caractères 'aaaaaa', `a{3,5}` trouvera 5 caractères 'a', alors que `a{3,5}?` n'en trouvera que 3.
- `'\'` Échappe les caractères spéciaux (permettant d'identifier des caractères comme '\*', '?' et autres) ou signale une séquence spéciale ; les séquences spéciales sont décrites ci-dessous.  
Si vous n'utilisez pas de chaînes brutes pour exprimer le motif, souvenez-vous que Python utilise aussi le *backslash* comme une séquence d'échappement dans les chaînes littérales ; si la séquence d'échappement n'est pas reconnue par l'interpréteur Python, le *backslash* et les caractères qui le suivent sont inclus dans la chaîne renvoyée. Cependant, si Python reconnaît la séquence, le *backslash* doit être doublé (pour ne plus être reconnu). C'est assez compliqué et difficile à comprendre, c'est pourquoi il est hautement recommandé d'utiliser des chaînes brutes pour tout sauf les expressions les plus simples.
- `[]` Utilisé pour indiquer un ensemble de caractères. Dans un ensemble :
  - Les caractères peuvent être listés individuellement, e.g. `[amk]` correspondra à 'a', 'm' ou 'k'.
  - Des intervalles de caractères peuvent être indiqués en donnant deux caractères et les séparant par un '-', par exemple `[a-z]` correspondra à toute lettre minuscule *ASCII*, `[0-5]` `[0-9]` à tous nombres de deux chiffres entre 00 et 59, et `[0-9A-Fa-f]` correspondra à n'importe quel chiffre hexadécimal. Si '-' est échappé (`[a\ -z]`) ou s'il est placé comme premier ou dernier caractère (e.g. `[a-]`), il correspondra à un '-' littéral.
  - Les caractères spéciaux perdent leur sens à l'intérieur des ensembles. Par exemple, `[(+*)]` validera chacun des caractères littéraux '(', '+', '\*' ou ')'
  - Character classes such as `\w` or `\S` (defined below) are also accepted inside a set, although the characters they match depends on whether *LOCALE* or *UNICODE* mode is in force.
  - Les caractères qui ne sont pas dans un intervalle peuvent être trouvés avec l'ensemble complémentaire (*complementing*). Si le premier caractère de l'ensemble est '^', tous les caractères qui *ne sont pas* dans l'ensemble seront validés. Par exemple, `[^5]` correspondra à tout caractère autre que '5' et `[^^]` validera n'importe quel caractère excepté '^'. ^ n'a pas de sens particulier s'il n'est pas le premier caractère de l'ensemble.
  - Pour insérer un ')' littéral dans un ensemble, il faut le précéder d'un *backslash* ou le placer au début de l'ensemble. Par exemple, `[(\)]{}` et `[](\){}` vont tous deux correspondre à une parenthèse, un crochet ou une accolade.
- `'|'` `A|B`, où A et B peuvent être deux expressions rationnelles arbitraires, crée une expression rationnelle qui validera à la fois A et B. Un nombre arbitraire d'expressions peuvent être séparées de cette façon par des '|'. Cela peut aussi être utilisé au sein de groupes (voir ci-dessous). Quand une chaîne cible est analysée, les expressions séparées par '|' sont essayées de la gauche vers la droite. Quand un motif correspond complètement, cette branche est acceptée. Cela signifie qu'une fois que A correspond, B ne sera pas testée plus loin, même si elle pourrait provoquer une plus ample correspondance. En d'autres termes, l'opérateur '|' n'est jamais gourmand. Pour valider un '|' littéral, utilisez `\|`, ou enveloppez-le dans une classe de caractères, comme `[|]`.
- `(...)` Valide n'importe quelle expression rationnelle comprise entre les parenthèses, et indique le début et la fin d'un groupe ; le contenu d'un groupe peut être récupéré après qu'une analyse a été effectuée, et peut être réutilisé plus loin dans la chaîne avec une séquence spéciale `\number`, décrite ci-dessous. Pour

écrire des '(' ou ')' littéraux, utilisez \ ( ou \ ), ou enveloppez-les dans une classe de caractères : `[( ]`).

(?... ) Il s'agit d'une notation pour les extensions (un '?' suivant une '(' n'a pas de sens autrement). Le premier caractère après le '?' détermine quel sens donner à l'expression. Les extensions ne créent généralement pas de nouveaux groupes ; (?P<name>...) est la seule exception à la règle. Retrouvez ci-dessous la liste des extensions actuellement supportées.

(?iLmsux) (One or more letters from the set 'i', 'L', 'm', 's', 'u', 'x'.) The group matches the empty string; the letters set the corresponding flags : *re.I* (ignore case), *re.L* (locale dependent), *re.M* (multi-line), *re.S* (dot matches all), *re.U* (Unicode dependent), and *re.X* (verbose), for the entire regular expression. (The flags are described in *Contenu du module*.) This is useful if you wish to include the flags as part of the regular expression, instead of passing a *flag* argument to the *re.compile()* function.

Note that the (?x) flag changes how the expression is parsed. It should be used first in the expression string, or after one or more whitespace characters. If there are non-whitespace characters before the flag, the results are undefined.

(?:...) Une version sans capture des parenthèses habituelles. Valide n'importe quelle expression rationnelle à l'intérieur des parenthèses, mais la sous-chaîne correspondant au groupe *ne peut pas* être récupérée après l'analyse ou être référencée plus loin dans le motif.

(?P<name>...) Similaires aux parenthèses habituelles, mais la sous-chaîne validée par le groupe est accessible via le nom *name* du groupe symbolique. Les noms de groupes doivent être des identifiants Python valides, et chaque nom de groupe ne doit être défini qu'une seule fois dans une expression rationnelle. Un groupe symbolique est aussi un groupe numéroté, de la même manière que si le groupe n'était pas nommé.

Les groupes nommés peuvent être référencés dans trois contextes. Si le motif est (?P<quote>["']). \*?(?P=quote) (i.e. correspondant à une chaîne entourée de guillemets simples ou doubles) :

Contexte de référence au groupe <i>quote</i>	Manières de le référencer
lui-même dans le même motif	— (?P=quote) (comme vu) — \1
en analysant l'objet résultat <i>m</i>	— <i>m.group('quote')</i> — <i>m.end('quote')</i> (etc.)
dans une chaîne passée à l'argument <i>repl</i> de <i>re.sub()</i>	— \g<quote> — \g<1> — \1

(?P=name) Une référence arrière à un groupe nommé ; elle correspond à n'importe quel texte validé plus tôt par le groupe nommé *name*.

(?#...) Un commentaire ; le contenu des parenthèses est simplement ignoré.

(?=...) Valide si ... valide la suite, mais ne consomme rien de la chaîne. On appelle cela une *assertion lookahead*. Par exemple, *Isaac* (?=Asimov) correspondra à la chaîne '*Isaac*' seulement si elle est suivie par '*Asimov*'.

(?!...) Valide si ... ne valide pas la suite. C'est une *assertion lookahead* négative. Par exemple, *Isaac* (?!Asimov) correspondra à la chaîne '*Isaac*' seulement si elle *n'est pas* suivie par '*Asimov*'.

(?<=...) Matches if the current position in the string is preceded by a match for ... that ends at the current position. This is called a *positive lookbehind assertion*. (?<=abc)def will find a match in abcdef, since the lookbehind will back up 3 characters and check if the contained pattern matches. The contained pattern must only match strings of some fixed length, meaning that abc or a|b are

allowed, but `a*` and `a{3,4}` are not. Group references are not supported even if they match strings of some fixed length. Note that patterns which start with positive lookbehind assertions will not match at the beginning of the string being searched; you will most likely want to use the `search()` function rather than the `match()` function :

```
>>> import re
>>> m = re.search('(?!<=abc)def', 'abcdef')
>>> m.group(0)
'def'
```

Cet exemple recherche un mot suivi d'un trait d'union :

```
>>> m = re.search('(?!<=)\w+', 'spam-egg')
>>> m.group(0)
'egg'
```

**(?!...)** Matches if the current position in the string is not preceded by a match for .... This is called a *negative lookbehind assertion*. Similar to positive lookbehind assertions, the contained pattern must only match strings of some fixed length and shouldn't contain group references. Patterns which start with negative lookbehind assertions may match at the beginning of the string being searched.

**(?(id/name)yes-pattern|no-pattern)** Will try to match with **yes-pattern** if the group with given *id* or *name* exists, and with **no-pattern** if it doesn't. **no-pattern** is optional and can be omitted. For example, `(<)?(\w+@(\w+)?(\.|\w+)+)(?(1)>)` is a poor email matching pattern, which will match with `'<user@host.com>'` as well as `'user@host.com'`, but not with `'<user@host.com'`.

Nouveau dans la version 2.4.

The special sequences consist of `'\'` and a character from the list below. If the ordinary character is not on the list, then the resulting RE will match the second character. For example, `\$` matches the character `'$'`.

**\number** Correspond au contenu du groupe du même nombre. Les groupes sont numérotés à partir de 1. Par exemple, `(.+)\1` correspond à `'the the'` ou `'55 55'`, mais pas à `'thethe'` (notez l'espace après le groupe). Cette séquence spéciale ne peut être utilisée que pour faire référence aux 99 premiers groupes. Si le premier chiffre de *number* est 0, ou si *number* est un nombre octal de 3 chiffres, il ne sera pas interprété comme une référence à un groupe, mais comme le caractère à la valeur octale *number*. À l'intérieur des `'['` et `']'` d'une classe de caractères, tous les échappements numériques sont traités comme des caractères.

**\A** Correspond uniquement au début d'une chaîne de caractères.

**\b** Matches the empty string, but only at the beginning or end of a word. A word is defined as a sequence of alphanumeric or underscore characters, so the end of a word is indicated by whitespace or a non-alphanumeric, non-underscore character. Note that formally, `\b` is defined as the boundary between a `\w` and a `\W` character (or vice versa), or between `\w` and the beginning/end of the string, so the precise set of characters deemed to be alphanumeric depends on the values of the `UNICODE` and `LOCALE` flags. For example, `r'\bfoo\b'` matches `'foo'`, `'foo.'`, `'(foo)'`, `'bar foo baz'` but not `'foobar'` or `'foo3'`. Inside a character range, `\b` represents the backspace character, for compatibility with Python's string literals.

**\B** Matches the empty string, but only when it is *not* at the beginning or end of a word. This means that `r'py\B'` matches `'python'`, `'py3'`, `'py2'`, but not `'py'`, `'py.'`, or `'py!'`. `\B` is just the opposite of `\b`, so is also subject to the settings of `LOCALE` and `UNICODE`.

**\d** When the `UNICODE` flag is not specified, matches any decimal digit; this is equivalent to the set `[0-9]`. With `UNICODE`, it will match whatever is classified as a decimal digit in the Unicode character properties database.

**\D** When the `UNICODE` flag is not specified, matches any non-digit character; this is equivalent to the set `[^0-9]`. With `UNICODE`, it will match anything other than character marked as digits in the Unicode character properties database.

- `\s` When the [UNICODE](#) flag is not specified, it matches any whitespace character, this is equivalent to the set `[\t\n\r\f\v]`. The [LOCALE](#) flag has no extra effect on matching of the space. If [UNICODE](#) is set, this will match the characters `[\t\n\r\f\v]` plus whatever is classified as space in the Unicode character properties database.
- `\S` When the [UNICODE](#) flag is not specified, matches any non-whitespace character; this is equivalent to the set `[^\t\n\r\f\v]`. The [LOCALE](#) flag has no extra effect on non-whitespace match. If [UNICODE](#) is set, then any character not marked as space in the Unicode character properties database is matched.
- `\w` When the [LOCALE](#) and [UNICODE](#) flags are not specified, matches any alphanumeric character and the underscore; this is equivalent to the set `[a-zA-Z0-9_]`. With [LOCALE](#), it will match the set `[0-9_]` plus whatever characters are defined as alphanumeric for the current locale. If [UNICODE](#) is set, this will match the characters `[0-9_]` plus whatever is classified as alphanumeric in the Unicode character properties database.
- `\W` When the [LOCALE](#) and [UNICODE](#) flags are not specified, matches any non-alphanumeric character; this is equivalent to the set `[^a-zA-Z0-9_]`. With [LOCALE](#), it will match any character not in the set `[0-9_]`, and not defined as alphanumeric for the current locale. If [UNICODE](#) is set, this will match anything other than `[0-9_]` plus characters classified as not alphanumeric in the Unicode character properties database.
- `\Z` Correspond uniquement à la fin d'une chaîne de caractères.

If both [LOCALE](#) and [UNICODE](#) flags are included for a particular sequence, then [LOCALE](#) flag takes effect first followed by the [UNICODE](#).

La plupart des échappements standards supportés par les chaînes littérales sont aussi acceptés par l'analyseur d'expressions rationnelles :

<code>\a</code>	<code>\b</code>	<code>\f</code>	<code>\n</code>
<code>\r</code>	<code>\t</code>	<code>\v</code>	<code>\x</code>
<code>\\</code>			

(Notez que `\b` est utilisé pour représenter les bornes d'un mot, et signifie « *backspace* » uniquement à l'intérieur d'une classe de caractères.)

Octal escapes are included in a limited form : If the first digit is a 0, or if there are three octal digits, it is considered an octal escape. Otherwise, it is a group reference. As for string literals, octal escapes are always at most three digits in length.

**Voir aussi :**

**Maîtriser les expression rationnelles** Livre sur les expressions rationnelles par Jeffrey Friedl, publié chez O'Reilly. La seconde édition de ce livre ne couvre plus du tout Python, mais la première version explique en détails comment écrire de bonnes expressions rationnelles.

## 7.2.2 Contenu du module

Le module définit plusieurs fonctions, constantes, et une exception. Certaines fonctions sont des versions simplifiées des méthodes plus complètes des expressions rationnelles compilées. La plupart des applications non triviales utilisent toujours la version compilée.

`re.compile(pattern, flags=0)`

Compile a regular expression pattern into a regular expression object, which can be used for matching using its `match()` and `search()` methods, described below.

Le comportement des expressions peut être modifié en spécifiant une valeur `flags`. Les valeurs sont comprises dans les variables suivantes, et peuvent être combinées avec un *ou* bit-à-bit (opérateur `|`).

La séquence :

```
prog = re.compile(pattern)
result = prog.match(string)
```

est équivalente à :

```
result = re.match(pattern, string)
```

mais utiliser `re.compile()` et sauvegarder l'expression rationnelle renvoyée pour la réutiliser est plus efficace quand l'expression est amenée à être utilisée plusieurs fois dans un même programme.

---

**Note :** The compiled versions of the most recent patterns passed to `re.match()`, `re.search()` or `re.compile()` are cached, so programs that use only a few regular expressions at a time needn't worry about compiling regular expressions.

---

**re.DEBUG**

Affiche des informations de debug à propos de l'expression compilée.

**re.I**

**re.IGNORECASE**

Perform case-insensitive matching ; expressions like `[A-Z]` will match lowercase letters, too. This is not affected by the current locale. To get this effect on non-ASCII Unicode characters such as `ü` and `Û`, add the `UNICODE` flag.

**re.L**

**re.LOCALE**

Make `\w`, `\W`, `\b`, `\B`, `\s` and `\S` dependent on the current locale.

**re.M**

**re.MULTILINE**

Quand spécifiée, le caractère `^` correspond au début d'une chaîne et au début d'une ligne (caractère suivant directement le saut de ligne) ; et le caractère `$` correspond à la fin d'une chaîne et à la fin d'une ligne (juste avant le saut de ligne). Par défaut, `^` correspond uniquement au début de la chaîne, et `$` uniquement à la fin de la chaîne, ou immédiatement avant le saut de ligne (s'il y a) à la fin de la chaîne.

**re.S**

**re.DOTALL**

Fait correspondre tous les caractères possibles à `.`, incluant le saut de ligne ; sans cette option, `.` correspondrait à tout caractère à l'exception du saut de ligne.

**re.U**

**re.UNICODE**

Make the `\w`, `\W`, `\b`, `\B`, `\d`, `\D`, `\s` and `\S` sequences dependent on the Unicode character properties database. Also enables non-ASCII matching for `IGNORECASE`.

Nouveau dans la version 2.0.

**re.X**

**re.VERBOSE**

This flag allows you to write regular expressions that look nicer and are more readable by allowing you to visually separate logical sections of the pattern and add comments. Whitespace within the pattern is ignored, except when in a character class, or when preceded by an unescaped backslash, or within tokens like `*?`, `(?:` or `(?P<...>`. When a line contains a `#` that is not in a character class and is not preceded by an unescaped backslash, all characters from the leftmost such `#` through the end of the line are ignored.

Cela signifie que les deux expressions rationnelles suivantes qui valident un nombre décimal sont fonctionnellement égales :

```
a = re.compile(r"""\d + # the integral part
               \.  # the decimal point
               \d * # some fractional digits""", re.X)
b = re.compile(r"\d+\.\d*")
```

**re.search(*pattern*, *string*, *flags*=0)**

Scan through *string* looking for the first location where the regular expression *pattern* produces a match, and return a corresponding *MatchObject* instance. Return *None* if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

**re.match(*pattern*, *string*, *flags*=0)**

If zero or more characters at the beginning of *string* match the regular expression *pattern*, return a corresponding *MatchObject* instance. Return *None* if the string does not match the pattern; note that this is different from a zero-length match.

Notez que même en mode *MULTILINE*, *re.match()* ne validera qu'au début de la chaîne et non au début de chaque ligne.

Si vous voulez trouver une correspondance n'importe où dans *string*, utilisez plutôt *search()* (voir aussi *search()* vs. *match()*).

**re.split(*pattern*, *string*, *maxsplit*=0, *flags*=0)**

Split *string* by the occurrences of *pattern*. If capturing parentheses are used in *pattern*, then the text of all groups in the pattern are also returned as part of the resulting list. If *maxsplit* is nonzero, at most *maxsplit* splits occur, and the remainder of the string is returned as the final element of the list. (Incompatibility note : in the original Python 1.5 release, *maxsplit* was ignored. This has been fixed in later releases.)

```
>>> re.split('\W+', 'Words, words, words.')
['Words', 'words', 'words', '']
>>> re.split('(\W+)', 'Words, words, words.')
['Words', ', ', 'words', ', ', 'words', '. ', '']
>>> re.split('\W+', 'Words, words, words.', 1)
['Words', 'words, words.']
>>> re.split('[a-f]+', '0a3B9', flags=re.IGNORECASE)
['0', '3', '9']
```

S'il y a des groupes capturants dans le séparateur et qu'ils trouvent une correspondance au début de la chaîne, le résultat commencera par une chaîne vide. La même chose se produit pour la fin de la chaîne :

```
>>> re.split('(\W+)', '...words, words...')
['', '...', 'words', ', ', 'words', '...', '']
```

That way, separator components are always found at the same relative indices within the result list (e.g., if there's one capturing group in the separator, the 0th, the 2nd and so forth).

Note that *split* will never split a string on an empty pattern match. For example :

```
>>> re.split('x*', 'foo')
['foo']
>>> re.split("(?m)~$", "foo\n\nbar\n")
['foo\n\nbar\n']
```

Modifié dans la version 2.7 : Ajout de l'argument optionnel *flags*.

**re.findall(*pattern*, *string*, *flags*=0)**

Return all non-overlapping matches of *pattern* in *string*, as a list of strings. The *string* is scanned

left-to-right, and matches are returned in the order found. If one or more groups are present in the pattern, return a list of groups; this will be a list of tuples if the pattern has more than one group. Empty matches are included in the result.

**Note :** Due to the limitation of the current implementation the character following an empty match is not included in a next match, so `findall(r'^|\w+', 'two words')` returns `['', 'wo', 'words']` (note missed « t »). This is changed in Python 3.7.

Nouveau dans la version 1.5.2.

Modifié dans la version 2.4 : Ajout de l'argument optionnel *flags*.

**re.finditer**(*pattern*, *string*, *flags*=0)

Return an *iterator* yielding *MatchObject* instances over all non-overlapping matches for the RE *pattern* in *string*. The *string* is scanned left-to-right, and matches are returned in the order found. Empty matches are included in the result. See also the note about *findall()*.

Nouveau dans la version 2.2.

Modifié dans la version 2.4 : Ajout de l'argument optionnel *flags*.

**re.sub**(*pattern*, *repl*, *string*, *count*=0, *flags*=0)

Return the string obtained by replacing the leftmost non-overlapping occurrences of *pattern* in *string* by the replacement *repl*. If the pattern isn't found, *string* is returned unchanged. *repl* can be a string or a function; if it is a string, any backslash escapes in it are processed. That is, `\n` is converted to a single newline character, `\r` is converted to a carriage return, and so forth. Unknown escapes such as `\j` are left alone. Backreferences, such as `\6`, are replaced with the substring matched by group 6 in the pattern. For example :

```
>>> re.sub(r'def\s+([a-zA-Z_][a-zA-Z_0-9]*)\s*(\s*):',
...        r'static PyObject*\npy_l(void)\n{',
...        'def myfunc():')
'static PyObject*\npy_myfunc(void)\n{'
```

Si *repl* est une fonction, elle est appelée pour chaque occurrence non chevauchante de *pattern*. La fonction prend comme argument un objet de correspondance, et renvoie la chaîne de remplacement. Par exemple :

```
>>> def dashrepl(matchobj):
...     if matchobj.group(0) == '-': return ' '
...     else: return '-'
>>> re.sub('-{1,2}', dashrepl, 'pro----gram-files')
'pro--gram files'
>>> re.sub(r'\sAND\s', ' & ', 'Baked Beans And Spam', flags=re.IGNORECASE)
'Baked Beans & Spam'
```

Le motif peut être une chaîne de caractères ou un objet expression rationnelle.

L'argument optionnel *count* est le nombre maximum d'occurrences du motif à remplacer : *count* ne doit pas être un nombre négatif. Si omis ou nul, toutes les occurrences seront remplacées. Les correspondances vides avec le motif sont remplacées uniquement quand elles ne sont pas adjacentes à une précédente correspondance, ainsi `sub('x*', '-', 'abc')` renvoie `'-a-b-c-'`.

Dans les arguments *repl* de type *string*, en plus des séquences d'échappement et références arrières décrites au-dessus, `\g<name>` utilisera la sous-chaîne correspondant au groupe nommé *name*, comme défini par la syntaxe `(?P<name>...)`. `\g<number>` utilise le groupe numéroté associé ; `\g<2>` est ainsi équivalent à `\2`, mais n'est pas ambigu dans un remplacement tel que `\g<2>0`, `\20` serait interprété comme une référence au groupe 20, et non une référence au groupe 2 suivie par un caractère littéral '0'. La référence arrière `\g<0>` est remplacée par la sous-chaîne entière validée par l'expression rationnelle.

Modifié dans la version 2.7 : Ajout de l'argument optionnel *flags*.

The optional *pos* and *endpos* parameters have the same meaning as for the *search()* method.

```
>>> pattern = re.compile("o")
>>> pattern.match("dog")          # No match as "o" is not at the start of "dog".
>>> pattern.match("dog", 1)       # Match as "o" is the 2nd character of "dog".
<_sre.SRE_Match object at ...>
```

If you want to locate a match anywhere in *string*, use *search()* instead (see also *search()* vs. *match()*).

**split**(*string*, *maxsplit*=0)

Identique à la fonction *split()*, en utilisant le motif compilé.

**findall**(*string*[, *pos*[, *endpos*]])

Similaire à la fonction *findall()*, en utilisant le motif compilé, mais accepte aussi des paramètres *pos* et *endpos* optionnels qui limitent la région de recherche comme pour *match()*.

**finditer**(*string*[, *pos*[, *endpos*]])

Similaire à la fonction *finditer()*, en utilisant le motif compilé, mais accepte aussi des paramètres *pos* et *endpos* optionnels qui limitent la région de recherche comme pour *match()*.

**sub**(*repl*, *string*, *count*=0)

Identique à la fonction *sub()*, en utilisant le motif compilé.

**subn**(*repl*, *string*, *count*=0)

Identique à la fonction *subn()*, en utilisant le motif compilé.

**flags**

The regex matching flags. This is a combination of the flags given to *compile()* and any (?...) inline flags in the pattern.

**groups**

Le nombre de groupes de capture dans le motif.

**groupindex**

Un dictionnaire associant les noms de groupes symboliques définis par (?P<id>) aux groupes numérotés. Le dictionnaire est vide si aucun groupe symbolique n'est utilisé dans le motif.

**pattern**

La chaîne de motif depuis laquelle l'objet expression rationnelle a été compilé.

## 7.2.4 Objets de correspondance

**class re.MatchObject**

Les objets de correspondance ont toujours une valeur booléenne **True**. Puisque *match()* et *search()* renvoient **None** quand il n'y a pas de correspondance, vous pouvez tester s'il y a eu correspondance avec une simple instruction **if** :

```
match = re.search(pattern, string)
if match:
    process(match)
```

Les objets de correspondance supportent les méthodes et attributs suivants :

**expand**(*template*)

Return the string obtained by doing backslash substitution on the template string *template*, as done by the *sub()* method. Escapes such as `\n` are converted to the appropriate characters, and numeric backreferences (`\1`, `\2`) and named backreferences (`\g<1>`, `\g<name>`) are replaced by the contents of the corresponding group.

**group**([*group1*, ...])

Renvoie un ou plus sous-groupes de la correspondance. Si un seul argument est donné, le résultat est une chaîne simple ; s'il y a plusieurs arguments, le résultat est un *tuple* comprenant un élément par argument. Sans arguments, *group1* vaut par défaut zéro (la correspondance entière est

renvoyée). Si un argument *groupN* vaut zéro, l'élément associé sera la chaîne de correspondance entière ; s'il est dans l'intervalle fermé [1..99], c'est la correspondance avec le groupe de parenthèses associé. Si un numéro de groupe est négatif ou supérieur au nombre de groupes définis dans le motif, une exception `IndexError` est levée. Si un groupe est contenu dans une partie du motif qui n'a aucune correspondance, l'élément associé sera `None`. Si un groupe est contenu dans une partie du motif qui a plusieurs correspondances, seule la dernière correspondance est renvoyée.

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m.group(0)           # The entire match
'Isaac Newton'
>>> m.group(1)           # The first parenthesized subgroup.
'Isaac'
>>> m.group(2)           # The second parenthesized subgroup.
'Newton'
>>> m.group(1, 2)        # Multiple arguments give us a tuple.
('Isaac', 'Newton')
```

Si l'expression rationnelle utilise la syntaxe `(?P<name>...)`, les arguments *groupN* peuvent alors aussi être des chaînes identifiant les groupes par leurs noms. Si une chaîne donnée en argument n'est pas utilisée comme nom de groupe dans le motif, une exception `IndexError` est levée.

Un exemple modérément compliqué :

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.group('first_name')
'Malcolm'
>>> m.group('last_name')
'Reynolds'
```

Les groupes nommés peuvent aussi être référencés par leur index :

```
>>> m.group(1)
'Malcolm'
>>> m.group(2)
'Reynolds'
```

Si un groupe a plusieurs correspondances, seule la dernière est accessible :

```
>>> m = re.match(r"(..)+", "a1b2c3") # Matches 3 times.
>>> m.group(1)                       # Returns only the last match.
'c3'
```

**groups([default])**

Return a tuple containing all the subgroups of the match, from 1 up to however many groups are in the pattern. The *default* argument is used for groups that did not participate in the match ; it defaults to `None`. (Incompatibility note : in the original Python 1.5 release, if the tuple was one element long, a string would be returned instead. In later versions (from 1.5.1 on), a singleton tuple is returned in such cases.)

Par exemple :

```
>>> m = re.match(r"(\d+)\.(\d+)", "24.1632")
>>> m.groups()
('24', '1632')
```

Si on rend la partie décimale et tout ce qui la suit optionnels, tous les groupes ne figureront pas dans la correspondance. Ces groupes sans correspondance vaudront `None` sauf si une autre valeur est donnée à l'argument *default* :

```
>>> m = re.match(r"(\d+)\.?(\\d+)?", "24")
>>> m.groups()      # Second group defaults to None.
('24', None)
>>> m.groups('0')   # Now, the second group defaults to '0'.
('24', '0')
```

**groupdict**([*default*])

Renvoie un dictionnaire contenant tous les sous-groupes *nommés* de la correspondance, accessibles par leurs noms. L'argument *default* est utilisé pour les groupes qui ne figurent pas dans la correspondance ; il vaut *None* par défaut. Par exemple :

```
>>> m = re.match(r"(?P<first_name>\\w+) (?P<last_name>\\w+)", "Malcolm Reynolds")
>>> m.groupdict()
{'first_name': 'Malcolm', 'last_name': 'Reynolds'}
```

**start**([*group*])

**end**([*group*])

Renvoie les indices de début et de fin de la sous-chaîne correspondant au groupe *group* ; *group* vaut par défaut zéro (pour récupérer les indices de la correspondance complète). Renvoie -1 si *group* existe mais ne figure pas dans la correspondance. Pour un objet de correspondance *m*, et un groupe *g* qui y figure, la sous-chaîne correspondant au groupe *g* (équivalente à *m.group(g)*) est :

```
m.string[m.start(g):m.end(g)]
```

Notez que *m.start(group)* sera égal à *m.end(group)* si *group* correspond à une chaîne vide. Par exemple, après *m = re.search('b(c?)', 'cba')*, *m.start(0)* vaut 1, *m.end(0)* vaut 2, *m.start(1)* et *m.end(1)* valent tous deux 2, et *m.start(2)* lève une exception *IndexError*.

Un exemple qui supprimera *remove\_this* d'une adresse email :

```
>>> email = "tony@tiremove_thisger.net"
>>> m = re.search("remove_this", email)
>>> email[:m.start()] + email[m.end():]
'tony@tiger.net'
```

**span**([*group*])

For *MatchObject m*, return the 2-tuple (*m.start(group)*, *m.end(group)*). Note that if *group* did not contribute to the match, this is (-1, -1). *group* defaults to zero, the entire match.

**pos**

The value of *pos* which was passed to the *search()* or *match()* method of the *RegexObject*. This is the index into the string at which the RE engine started looking for a match.

**endpos**

The value of *endpos* which was passed to the *search()* or *match()* method of the *RegexObject*. This is the index into the string beyond which the RE engine will not go.

**lastindex**

L'index entier du dernier groupe de capture validé, ou *None* si aucun groupe ne correspondait. Par exemple, les expressions (a)b, ((a)(b)) et ((ab)) auront un *lastindex* == 1 si appliquées à la chaîne 'ab', alors que l'expression (a)(b) aura un *lastindex* == 2 si appliquée à la même chaîne.

**lastgroup**

Le nom du dernier groupe capturant validé, ou *None* si le groupe n'a pas de nom, ou si aucun groupe ne correspondait.

**re**

The regular expression object whose *match()* or *search()* method produced this *MatchObject* instance.

**string**

The string passed to `match()` or `search()`.

## 7.2.5 Exemples

### Checking For a Pair

Dans cet exemple, nous utiliserons cette fonction de facilité pour afficher les objets de correspondance sous une meilleure forme :

```
def displaymatch(match):
    if match is None:
        return None
    return '<Match: %r, groups=%r>' % (match.group(), match.groups())
```

Supposez que vous écriviez un jeu de poker où la main d'un joueur est représentée par une chaîne de 5 caractères avec chaque caractère représentant une carte, « a » pour l'as, « k » pour le roi (*king*), « q » pour la reine (*queen*), « j » pour le valet (*jack*), « t » pour 10 (*ten*), et les caractères de « 2 » à « 9 » représentant les cartes avec ces valeurs.

Pour vérifier qu'une chaîne donnée est une main valide, on pourrait faire comme suit :

```
>>> valid = re.compile(r"[a2-9tjqk]{5}$")
>>> displaymatch(valid.match("akt5q")) # Valid.
"<Match: 'akt5q', groups=()>"
>>> displaymatch(valid.match("akt5e")) # Invalid.
>>> displaymatch(valid.match("akt"))   # Invalid.
>>> displaymatch(valid.match("727ak")) # Valid.
"<Match: '727ak', groups=()>"
```

La dernière main, "727ak", contenait une paire, deux cartes de la même valeur. Pour valider cela avec une expression rationnelle, on pourrait utiliser des références arrière comme :

```
>>> pair = re.compile(r".*(.)\1")
>>> displaymatch(pair.match("717ak")) # Pair of 7s.
"<Match: '717', groups=('7',)>"
>>> displaymatch(pair.match("718ak")) # No pairs.
>>> displaymatch(pair.match("354aa")) # Pair of aces.
"<Match: '354aa', groups=('a',)>"
```

To find out what card the pair consists of, one could use the `group()` method of *MatchObject* in the following manner :

```
>>> pair.match("717ak").group(1)
'7'

# Error because re.match() returns None, which doesn't have a group() method:
>>> pair.match("718ak").group(1)
Traceback (most recent call last):
  File "<pyshell#23>", line 1, in <module>
    re.match(r".*(.)\1", "718ak").group(1)
AttributeError: 'NoneType' object has no attribute 'group'

>>> pair.match("354aa").group(1)
'a'
```

### Simuler `scanf()`

Python n'a actuellement pas d'équivalent à la fonction C `scanf()`. Les expressions rationnelles sont généralement plus puissantes, mais aussi plus verbeuses, que les chaînes de format `scanf()`. Le tableau suivant présente des expressions rationnelles plus ou moins équivalentes aux éléments de formats de `scanf()`.

Élément de <code>scanf()</code>	Expression rationnelle
<code>%c</code>	<code>.</code>
<code>%5c</code>	<code>.{5}</code>
<code>%d</code>	<code>[-+]? \d+</code>
<code>%e, %E, %f, %g</code>	<code>[-+]? (\d+(\.\d*)? \.\d+) ([eE] [-+]? \d+)?</code>
<code>%i</code>	<code>[-+]? (0[xX] [\dA-Fa-f]+ 0[0-7]* \d+)</code>
<code>%o</code>	<code>[-+]? [0-7]+</code>
<code>%s</code>	<code>\S+</code>
<code>%u</code>	<code>\d+</code>
<code>%x, %X</code>	<code>[-+]? (0[xX])? [\dA-Fa-f]+</code>

Pour extraire le nom de fichier et les nombres depuis une chaîne comme :

```
/usr/sbin/sendmail - 0 errors, 4 warnings
```

vous utiliseriez un format `scanf()` comme :

```
%s - %d errors, %d warnings
```

L'expression rationnelle équivalente serait :

```
(\S+) - (\d+) errors, (\d+) warnings
```

### `search()` vs. `match()`

Python offre deux opérations primitives basées sur les expressions rationnelles : `re.match()` cherche une correspondance uniquement au début de la chaîne, tandis que `re.search()` en recherche une n'importe où dans la chaîne (ce que fait Perl par défaut).

Par exemple :

```
>>> re.match("c", "abcdef")    # No match
>>> re.search("c", "abcdef")   # Match
<_sre.SRE_Match object at ...>
```

Les expressions rationnelles commençant par '^' peuvent être utilisées avec `search()` pour restreindre la recherche au début de la chaîne :

```
>>> re.match("c", "abcdef")    # No match
>>> re.search("^c", "abcdef")  # No match
>>> re.search("^a", "abcdef")  # Match
<_sre.SRE_Match object at ...>
```

Notez cependant qu'en mode `MULTILINE`, `match()` ne recherche qu'au début de la chaîne, alors que `search()` avec une expression rationnelle commençant par '^' recherchera au début de chaque ligne.

```
>>> re.match('X', 'A\nB\nX', re.MULTILINE) # No match
>>> re.search('^X', 'A\nB\nX', re.MULTILINE) # Match
<_sre.SRE_Match object at ...>
```

## Construire un répertoire téléphonique

`split()` découpe une chaîne en une liste délimitée par le motif donné. La méthode est inestimable pour convertir des données textuelles vers des structures de données qui peuvent être lues et modifiées par Python comme démontré dans l'exemple suivant qui crée un répertoire téléphonique.

Premièrement, voici l'entrée. Elle provient normalement d'un fichier, nous utilisons ici une chaîne à guillemets triples :

```
>>> text = """Ross McFluff: 834.345.1254 155 Elm Street
...
... Ronald Heathmore: 892.345.3428 436 Finley Avenue
... Frank Burger: 925.541.7625 662 South Dogwood Way
...
...
... Heather Albrecht: 548.326.4584 919 Park Place"""
```

Les entrées sont séparées par un saut de ligne ou plus. Nous convertissons maintenant la chaîne en une liste où chaque ligne non vide aura sa propre entrée :

```
>>> entries = re.split("\n+", text)
>>> entries
['Ross McFluff: 834.345.1254 155 Elm Street',
'Ronald Heathmore: 892.345.3428 436 Finley Avenue',
'Frank Burger: 925.541.7625 662 South Dogwood Way',
'Heather Albrecht: 548.326.4584 919 Park Place']
```

Finalement, on sépare chaque entrée en une liste avec prénom, nom, numéro de téléphone et adresse. Nous utilisons le paramètre `maxsplit` de `split()` parce que l'adresse contient des espaces, qui sont notre motif de séparation :

```
>>> [re.split("?: ", entry, 3) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155 Elm Street'],
['Ronald', 'Heathmore', '892.345.3428', '436 Finley Avenue'],
['Frank', 'Burger', '925.541.7625', '662 South Dogwood Way'],
['Heather', 'Albrecht', '548.326.4584', '919 Park Place']]
```

Le motif `?:` trouve les deux points derrière le nom de famille, pour qu'ils n'apparaissent pas dans la liste résultante. Avec un `maxsplit` de 4, nous pourrions séparer le numéro du nom de la rue :

```
>>> [re.split("?: ", entry, 4) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155', 'Elm Street'],
['Ronald', 'Heathmore', '892.345.3428', '436', 'Finley Avenue'],
['Frank', 'Burger', '925.541.7625', '662', 'South Dogwood Way'],
['Heather', 'Albrecht', '548.326.4584', '919', 'Park Place']]
```

## Mélanger les lettres des mots

`sub()` remplace toutes les occurrences d'un motif par une chaîne ou le résultat d'une fonction. Cet exemple le montre, en utilisant `sub()` avec une fonction qui mélange aléatoirement les caractères de chaque mot dans une phrase (à l'exception des premiers et derniers caractères) :

```
>>> def repl(m):
...     inner_word = list(m.group(2))
...     random.shuffle(inner_word)
```

(suite sur la page suivante)

(suite de la page précédente)

```
...     return m.group(1) + ".".join(inner_word) + m.group(3)
>>> text = "Professor Abdolmalek, please report your absences promptly."
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Poefsrosr Aealmlodbk, pslae reorpt your abnseces plmrptoy.'
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Pofsrosr Aodlambelk, plasee reorpt yuor asnebcas potlmpy.'
```

### Trouver tous les adverbes

*findall()* matches *all* occurrences of a pattern, not just the first one as *search()* does. For example, if a writer wanted to find all of the adverbs in some text, they might use *findall()* in the following manner :

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> re.findall(r"\w+ly", text)
['carefully', 'quickly']
```

### Trouver tous les adverbes et leurs positions

If one wants more information about all matches of a pattern than the matched text, *finditer()* is useful as it provides instances of *MatchObject* instead of strings. Continuing with the previous example, if a writer wanted to find all of the adverbs *and their positions* in some text, they would use *finditer()* in the following manner :

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> for m in re.finditer(r"\w+ly", text):
...     print '%02d-%02d: %s' % (m.start(), m.end(), m.group(0))
07-16: carefully
40-47: quickly
```

### Notation brutes de chaînes

La notation brute de chaînes (*r"text"*) garde saines les expressions rationnelles. Sans elle, chaque *backslash* (*'\'*) dans une expression rationnelle devrait être préfixé d'un autre *backslash* pour l'échapper. Par exemple, les deux lignes de code suivantes sont fonctionnellement identiques :

```
>>> re.match(r"\W(.\)\1\W", " ff ")
<_sre.SRE_Match object at ...>
>>> re.match("\\W(.\)\1\\W", " ff ")
<_sre.SRE_Match object at ...>
```

Pour rechercher un *backslash* littéral, il faut l'échapper dans l'expression rationnelle. Avec la notation brute, cela signifie *r"\"*. Sans elle, il faudrait utiliser *"\\\"*, faisant que les deux lignes de code suivantes sont fonctionnellement identiques :

```
>>> re.match(r"\"", r"\"")
<_sre.SRE_Match object at ...>
>>> re.match("\\\"", r"\"")
<_sre.SRE_Match object at ...>
```

## 7.3 struct — Interpret strings as packed binary data

This module performs conversions between Python values and C structs represented as Python strings. This can be used in handling binary data stored in files or from network connections, among other sources. It uses *Format Strings* as compact descriptions of the layout of the C structs and the intended conversion to/from Python values.

---

**Note :** By default, the result of packing a given C struct includes pad bytes in order to maintain proper alignment for the C types involved ; similarly, alignment is taken into account when unpacking. This behavior is chosen so that the bytes of a packed struct correspond exactly to the layout in memory of the corresponding C struct. To handle platform-independent data formats or omit implicit pad bytes, use `standard` size and alignment instead of `native` size and alignment : see *Byte Order, Size, and Alignment* for details.

---

### 7.3.1 Functions and Exceptions

The module defines the following exception and functions :

**exception struct.error**

Exception raised on various occasions ; argument is a string describing what is wrong.

**struct.pack(fmt, v1, v2, ...)**

Return a string containing the values `v1`, `v2`, ... packed according to the given format. The arguments must match the values required by the format exactly.

**struct.pack\_into(fmt, buffer, offset, v1, v2, ...)**

Pack the values `v1`, `v2`, ... according to the given format, write the packed bytes into the writable `buffer` starting at `offset`. Note that the offset is a required argument.

Nouveau dans la version 2.5.

**struct.unpack(fmt, string)**

Unpack the string (presumably packed by `pack(fmt, ...)`) according to the given format. The result is a tuple even if it contains exactly one item. The string must contain exactly the amount of data required by the format (`len(string)` must equal `calcsz(fmt)`).

**struct.unpack\_from(fmt, buffer[, offset=0])**

Unpack the `buffer` according to the given format. The result is a tuple even if it contains exactly one item. The `buffer` must contain at least the amount of data required by the format (`len(buffer[offset:])` must be at least `calcsz(fmt)`).

Nouveau dans la version 2.5.

**struct.calcsz(fmt)**

Return the size of the struct (and hence of the string) corresponding to the given format.

### 7.3.2 Format Strings

Format strings are the mechanism used to specify the expected layout when packing and unpacking data. They are built up from *Format Characters*, which specify the type of data being packed/unpacked. In addition, there are special characters for controlling the *Byte Order, Size, and Alignment*.

#### Byte Order, Size, and Alignment

By default, C types are represented in the machine's native format and byte order, and properly aligned by skipping pad bytes if necessary (according to the rules used by the C compiler).

Alternatively, the first character of the format string can be used to indicate the byte order, size and alignment of the packed data, according to the following table :

Caractère	Byte order	Size	Alignment
@	native	native	native
=	native	standard	none
<	little-endian	standard	none
>	big-endian	standard	none
!	network (= big-endian)	standard	none

If the first character is not one of these, '@' is assumed.

Native byte order is big-endian or little-endian, depending on the host system. For example, Intel x86 and AMD64 (x86-64) are little-endian ; Motorola 68000 and PowerPC G5 are big-endian ; ARM and Intel Itanium feature switchable endianness (bi-endian). Use `sys.byteorder` to check the endianness of your system.

Native size and alignment are determined using the C compiler's `sizeof` expression. This is always combined with native byte order.

Standard size depends only on the format character ; see the table in the *Format Characters* section.

Note the difference between '@' and '=' : both use native byte order, but the size and alignment of the latter is standardized.

The form '!' is available for those poor souls who claim they can't remember whether network byte order is big-endian or little-endian.

There is no way to indicate non-native byte order (force byte-swapping) ; use the appropriate choice of '<' or '>'.

Notes :

- (1) Padding is only automatically added between successive structure members. No padding is added at the beginning or the end of the encoded struct.
- (2) No padding is added when using non-native size and alignment, e.g. with "<", ">", "=", and "!".
- (3) To align the end of a structure to the alignment requirement of a particular type, end the format with the code for that type with a repeat count of zero. See *Examples*.

## Format Characters

Format characters have the following meaning ; the conversion between C and Python values should be obvious given their types. The "Standard size" column refers to the size of the packed value in bytes when using standard size ; that is, when the format string starts with one of '<', '>', '!' or '='. When using native size, the size of the packed value is platform-dependent.

Format	Type C	Type Python	Standard size	Notes
x	pad byte	no value		
c	char	string of length 1	1	
b	signed char	integer	1	(3)
B	unsigned char	integer	1	(3)
?	_Bool	bool	1	(1)
h	short	integer	2	(3)
H	unsigned short	integer	2	(3)
i	int	integer	4	(3)
I	unsigned int	integer	4	(3)
l	long	integer	4	(3)
L	unsigned long	integer	4	(3)
q	long long	integer	8	(2), (3)
Q	unsigned long long	integer	8	(2), (3)
f	float	<i>float</i>	4	(4)
d	double	<i>float</i>	8	(4)
s	char[]	<i>string</i>		
p	char[]	<i>string</i>		
P	void *	integer		(5), (3)

Notes :

- (1) The '?' conversion code corresponds to the `_Bool` type defined by C99. If this type is not available, it is simulated using a `char`. In standard mode, it is always represented by one byte.  
Nouveau dans la version 2.6.
- (2) The 'q' and 'Q' conversion codes are available in native mode only if the platform C compiler supports C `long long`, or, on Windows, `__int64`. They are always available in standard modes.  
Nouveau dans la version 2.2.
- (3) When attempting to pack a non-integer using any of the integer conversion codes, if the non-integer has a `__index__()` method then that method is called to convert the argument to an integer before packing. If no `__index__()` method exists, or the call to `__index__()` raises *TypeError*, then the `__int__()` method is tried. However, the use of `__int__()` is deprecated, and will raise *DeprecationWarning*.  
Modifié dans la version 2.7 : Use of the `__index__()` method for non-integers is new in 2.7.  
Modifié dans la version 2.7 : Prior to version 2.7, not all integer conversion codes would use the `__int__()` method to convert, and *DeprecationWarning* was raised only for float arguments.
- (4) For the 'f' and 'd' conversion codes, the packed representation uses the IEEE 754 binary32 (for 'f') or binary64 (for 'd') format, regardless of the floating-point format used by the platform.
- (5) The 'P' format character is only available for the native byte ordering (selected as the default or with the '@' byte order character). The byte order character '=' chooses to use little- or big-endian ordering based on the host system. The struct module does not interpret this as native ordering, so the 'P' format is not available.

A format character may be preceded by an integral repeat count. For example, the format string '4h' means exactly the same as 'hhhh'.

Whitespace characters between formats are ignored; a count and its format must not contain whitespace though.

For the 's' format character, the count is interpreted as the size of the string, not a repeat count like for the other format characters; for example, '10s' means a single 10-byte string, while '10c' means 10 characters. If a count is not given, it defaults to 1. For packing, the string is truncated or padded with null bytes as appropriate to make it fit. For unpacking, the resulting string always has exactly the specified number of bytes. As a special case, '0s' means a single, empty string (while '0c' means 0 characters).

The 'p' format character encodes a « Pascal string », meaning a short variable-length string stored in a *fixed number of bytes*, given by the count. The first byte stored is the length of the string, or 255, whichever is smaller. The bytes of the string follow. If the string passed in to `pack()` is too long (longer than the count minus 1), only the leading `count-1` bytes of the string are stored. If the string is shorter than `count-1`, it is padded with null bytes so that exactly `count` bytes in all are used. Note that for `unpack()`, the 'p' format character consumes `count` bytes, but that the string returned can never contain more than 255 characters.

For the 'P' format character, the return value is a Python integer or long integer, depending on the size needed to hold a pointer when it has been cast to an integer type. A *NULL* pointer will always be returned as the Python integer 0. When packing pointer-sized values, Python integer or long integer objects may be used. For example, the Alpha and Merced processors use 64-bit pointer values, meaning a Python long integer will be used to hold the pointer; other platforms use 32-bit pointers and will use a Python integer.

For the '?' format character, the return value is either *True* or *False*. When packing, the truth value of the argument object is used. Either 0 or 1 in the native or standard bool representation will be packed, and any non-zero value will be *True* when unpacking.

### Examples

---

**Note :** All examples assume a native byte order, size, and alignment with a big-endian machine.

---

A basic example of packing/unpacking three integers :

```
>>> from struct import *
>>> pack('hhl', 1, 2, 3)
'\x00\x01\x00\x02\x00\x00\x00\x03'
>>> unpack('hhl', '\x00\x01\x00\x02\x00\x00\x00\x03')
(1, 2, 3)
>>> calcsize('hhl')
8
```

Unpacked fields can be named by assigning them to variables or by wrapping the result in a named tuple :

```
>>> record = 'raymond \x32\x12\x08\x01\x08'
>>> name, serialnum, school, gradelevel = unpack('<10sHHb', record)

>>> from collections import namedtuple
>>> Student = namedtuple('Student', 'name serialnum school gradelevel')
>>> Student._make(unpack('<10sHHb', record))
Student(name='raymond ', serialnum=4658, school=264, gradelevel=8)
```

The ordering of format characters may have an impact on size since the padding needed to satisfy alignment requirements is different :

```
>>> pack('ci', '*', 0x12131415)
'*\x00\x00\x00\x12\x13\x14\x15'
>>> pack('ic', 0x12131415, '*')
'\x12\x13\x14\x15*'
>>> calcsize('ci')
8
>>> calcsize('ic')
5
```

The following format 'llh01' specifies two pad bytes at the end, assuming longs are aligned on 4-byte boundaries :

```
>>> pack('llh01', 1, 2, 3)
'\x00\x00\x00\x01\x00\x00\x00\x02\x00\x03\x00\x00'
```

This only works when native size and alignment are in effect ; standard size and alignment does not enforce any alignment.

### 7.3.3 Classes

The `struct` module also defines the following type :

**class** `struct.Struct(format)`

Return a new Struct object which writes and reads binary data according to the format string *format*. Creating a Struct object once and calling its methods is more efficient than calling the `struct` functions with the same format since the format string only needs to be compiled once.

Nouveau dans la version 2.5.

Compiled Struct objects support the following methods and attributes :

**pack(v1, v2, ...)**

Identical to the `pack()` function, using the compiled format. (`len(result)` will equal `self.size`.)

**pack\_into(buffer, offset, v1, v2, ...)**

Identical to the `pack_into()` function, using the compiled format.

**unpack(string)**

Identical to the `unpack()` function, using the compiled format. (`len(string)` must equal `self.size`).

**unpack\_from(buffer, offset=0)**

Identical to the `unpack_from()` function, using the compiled format. (`len(buffer[offset:])` must be at least `self.size`).

**format**

The format string used to construct this Struct object.

**size**

The calculated size of the struct (and hence of the string) corresponding to *format*.

## 7.4 difflib — Helpers for computing deltas

Nouveau dans la version 2.1.

This module provides classes and functions for comparing sequences. It can be used for example, for comparing files, and can produce difference information in various formats, including HTML and context and unified diffs. For comparing directories and files, see also, the `filecmp` module.

**class** `difflib.SequenceMatcher`

This is a flexible class for comparing pairs of sequences of any type, so long as the sequence elements are *hashable*. The basic algorithm predates, and is a little fancier than, an algorithm published in the late 1980's by Ratcliff and Obershelp under the hyperbolic name « gestalt pattern matching. » The idea is to find the longest contiguous matching subsequence that contains no « junk » elements (the Ratcliff and Obershelp algorithm doesn't address junk). The same idea is then applied recursively to the pieces of the sequences to the left and to the right of the matching subsequence. This does not yield minimal edit sequences, but does tend to yield matches that « look right » to people.

**Timing :** The basic Ratcliff-Obershelp algorithm is cubic time in the worst case and quadratic time in the expected case. `SequenceMatcher` is quadratic time for the worst case and has expected-case

behavior dependent in a complicated way on how many elements the sequences have in common ; best case time is linear.

**Automatic junk heuristic :** *SequenceMatcher* supports a heuristic that automatically treats certain sequence items as junk. The heuristic counts how many times each individual item appears in the sequence. If an item's duplicates (after the first one) account for more than 1% of the sequence and the sequence is at least 200 items long, this item is marked as « popular » and is treated as junk for the purpose of sequence matching. This heuristic can be turned off by setting the `autojunk` argument to `False` when creating the *SequenceMatcher*.

Nouveau dans la version 2.7.1 : The *autojunk* parameter.

#### `class difflib.Differ`

This is a class for comparing sequences of lines of text, and producing human-readable differences or deltas. Differ uses *SequenceMatcher* both to compare sequences of lines, and to compare sequences of characters within similar (near-matching) lines.

Each line of a *Differ* delta begins with a two-letter code :

Code	Signification
'- '	line unique to sequence 1
'+'	line unique to sequence 2
' '	line common to both sequences
'? '	line not present in either input sequence

Lines beginning with “?” attempt to guide the eye to intraline differences, and were not present in either input sequence. These lines can be confusing if the sequences contain tab characters.

#### `class difflib.HtmlDiff`

This class can be used to create an HTML table (or a complete HTML file containing the table) showing a side by side, line by line comparison of text with inter-line and intra-line change highlights. The table can be generated in either full or contextual difference mode.

The constructor for this class is :

`__init__(tabsize=8, wrapcolumn=None, linejunk=None, charjunk=IS_CHARACTER_JUNK)`

Initializes instance of *HtmlDiff*.

*tabsize* is an optional keyword argument to specify tab stop spacing and defaults to 8.

*wrapcolumn* is an optional keyword to specify column number where lines are broken and wrapped, defaults to `None` where lines are not wrapped.

*linejunk* and *charjunk* are optional keyword arguments passed into *ndiff()* (used by *HtmlDiff* to generate the side by side HTML differences). See *ndiff()* documentation for argument default values and descriptions.

The following methods are public :

`make_file(fromlines, tolines [, fromdesc][, todesc][, context][, numlines])`

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML file containing a table showing line by line differences with inter-line and intra-line changes highlighted. *fromdesc* and *todesc* are optional keyword arguments to specify from/to file column header strings (both default to an empty string).

*context* and *numlines* are both optional keyword arguments. Set *context* to `True` when contextual differences are to be shown, else the default is `False` to show the full files. *numlines* defaults to 5. When *context* is `True` *numlines* controls the number of context lines which surround the difference highlights. When *context* is `False` *numlines* controls the number of lines which are shown before a difference highlight when using the « next » hyperlinks (setting to zero would cause the « next » hyperlinks to place the next difference highlight at the top of the browser without any leading context).

`make_table(fromlines, tolines [, fromdesc][, todesc][, context][, numlines])`

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML table showing line by line differences with inter-line and intra-line changes highlighted.

The arguments for this method are the same as those for the `make_file()` method.

`Tools/scripts/diff.py` is a command-line front-end to this class and contains a good example of its use.

Nouveau dans la version 2.4.

`difflib.context_diff(a, b[, fromfile][, tofile][, fromfiledate][, tofiledate][, n][, lineterm])`

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in context diff format.

Context diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in a before/after style. The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with `***` or `---`) are created with a trailing newline. This is helpful so that inputs created from `file.readlines()` result in diffs that are suitable for use with `file.writelines()` since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to `"` so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> for line in context_diff(s1, s2, fromfile='before.py', tofile='after.py'):
...     sys.stdout.write(line) # doctest: +NORMALIZE_WHITESPACE
*** before.py
--- after.py
*****
*** 1,4 ****
! bacon
! eggs
! ham
! guido
--- 1,4 ----
! python
! eggy
! hamster
! guido
```

See [A command-line interface to difflib](#) for a more detailed example.

Nouveau dans la version 2.3.

`difflib.get_close_matches(word, possibilities[, n][, cutoff])`

Return a list of the best « good enough » matches. *word* is a sequence for which close matches are desired (typically a string), and *possibilities* is a list of sequences against which to match *word* (typically a list of strings).

Optional argument *n* (default 3) is the maximum number of close matches to return; *n* must be greater than 0.

Optional argument *cutoff* (default 0.6) is a float in the range [0, 1]. Possibilities that don't score at least that similar to *word* are ignored.

The best (no more than *n*) matches among the possibilities are returned in a list, sorted by similarity score, most similar first.

```
>>> get_close_matches('appel', ['ape', 'apple', 'peach', 'puppy'])
['apple', 'ape']
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> import keyword
>>> get_close_matches('wheel', keyword.kwlist)
['while']
>>> get_close_matches('apple', keyword.kwlist)
[]
>>> get_close_matches('accept', keyword.kwlist)
['except']
```

`difflib.ndiff(a, b[, linejunk[, charjunk]])`

Compare *a* and *b* (lists of strings); return a *Differ*-style delta (a *generator* generating the delta lines).

Optional keyword parameters *linejunk* and *charjunk* are for filter functions (or `None`) :

*linejunk* : A function that accepts a single string argument, and returns true if the string is junk, or false if not. The default is (`None`), starting with Python 2.3. Before then, the default was the module-level function `IS_LINE_JUNK()`, which filters out lines without visible characters, except for at most one pound character ('#'). As of Python 2.3, the underlying *SequenceMatcher* class does a dynamic analysis of which lines are so frequent as to constitute noise, and this usually works better than the pre-2.3 default.

*charjunk* : A function that accepts a character (a string of length 1), and returns if the character is junk, or false if not. The default is module-level function `IS_CHARACTER_JUNK()`, which filters out whitespace characters (a blank or tab; note : bad idea to include newline in this!).

`Tools/scripts/ndiff.py` is a command-line front-end to this function.

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(1),
...             'ore\ntree\nemu\n'.splitlines(1))
>>> print ''.join(diff),
- one
? ^
+ ore
? ^
- two
- three
? -
+ tree
+ emu
```

`difflib.restore(sequence, which)`

Return one of the two sequences that generated a delta.

Given a *sequence* produced by *Differ.compare()* or *ndiff()*, extract lines originating from file 1 or 2 (parameter *which*), stripping off line prefixes.

Exemple :

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(1),
...             'ore\ntree\nemu\n'.splitlines(1))
>>> diff = list(diff) # materialize the generated delta into a list
>>> print ''.join	restore(diff, 1)),
one
two
three
>>> print ''.join	restore(diff, 2)),
ore
tree
emu
```

`difflib.unified_diff(a, b[, fromfile[, tofile[, fromfiledate[, tofiledate[, n[, lineterm]])`

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in unified diff format.

Unified diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in an inline style (instead of separate before/after blocks). The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with ---, +++, or @@) are created with a trailing newline. This is helpful so that inputs created from `file.readlines()` result in diffs that are suitable for use with `file.writelines()` since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to "" so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> for line in unified_diff(s1, s2, fromfile='before.py', tofile='after.py'):
...     sys.stdout.write(line)    # doctest: +NORMALIZE_WHITESPACE
--- before.py
+++ after.py
@@ -1,4 +1,4 @@
-bacon
-eggs
-ham
+python
+eggy
+hamster
 guido
```

See [A command-line interface to difflib](#) for a more detailed example.

Nouveau dans la version 2.3.

`difflib.IS_LINE_JUNK(line)`

Return true for ignorable lines. The line *line* is ignorable if *line* is blank or contains a single '#', otherwise it is not ignorable. Used as a default for parameter *linejunk* in `ndiff()` before Python 2.3.

`difflib.IS_CHARACTER_JUNK(ch)`

Return true for ignorable characters. The character *ch* is ignorable if *ch* is a space or tab, otherwise it is not ignorable. Used as a default for parameter *charjunk* in `ndiff()`.

Voir aussi :

**Pattern Matching : The Gestalt Approach** Discussion of a similar algorithm by John W. Ratcliff and D. E. Metzener. This was published in *Dr. Dobb's Journal* in July, 1988.

## 7.4.1 SequenceMatcher Objects

The `SequenceMatcher` class has this constructor :

`class difflib.SequenceMatcher(isjunk=None, a="", b="", autojunk=True)`

Optional argument *isjunk* must be `None` (the default) or a one-argument function that takes a sequence element and returns true if and only if the element is « junk » and should be ignored. Passing `None` for *isjunk* is equivalent to passing `lambda x: 0`; in other words, no elements are ignored. For example, pass :

```
lambda x: x in " \t"
```

if you're comparing lines as sequences of characters, and don't want to synch up on blanks or hard tabs.

The optional arguments *a* and *b* are sequences to be compared; both default to empty strings. The elements of both sequences must be *hashable*.

The optional argument *autojunk* can be used to disable the automatic junk heuristic.

Nouveau dans la version 2.7.1 : The *autojunk* parameter.

*SequenceMatcher* objects have the following methods :

**set\_seqs(a, b)**

Set the two sequences to be compared.

*SequenceMatcher* computes and caches detailed information about the second sequence, so if you want to compare one sequence against many sequences, use *set\_seq2()* to set the commonly used sequence once and call *set\_seq1()* repeatedly, once for each of the other sequences.

**set\_seq1(a)**

Set the first sequence to be compared. The second sequence to be compared is not changed.

**set\_seq2(b)**

Set the second sequence to be compared. The first sequence to be compared is not changed.

**find\_longest\_match(a**lo**, a**hi**, b**lo**, b**hi**)**

Find longest matching block in *a*[*a***lo**:*a***hi**] and *b*[*b***lo**:*b***hi**].

If *isjunk* was omitted or None, *find\_longest\_match()* returns (*i*, *j*, *k*) such that *a*[*i*:*i*+*k*] is equal to *b*[*j*:*j*+*k*], where *a***lo** ≤ *i* ≤ *i*+*k* ≤ *a***hi** and *b***lo** ≤ *j* ≤ *j*+*k* ≤ *b***hi**. For all (*i*', *j*', *k*') meeting those conditions, the additional conditions *k* ≥ *k*', *i* ≤ *i*', and if *i* == *i*', *j* ≤ *j*' are also met. In other words, of all maximal matching blocks, return one that starts earliest in *a*, and of all those maximal matching blocks that start earliest in *a*, return the one that starts earliest in *b*.

```
>>> s = SequenceMatcher(None, " abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=0, b=4, size=5)
```

If *isjunk* was provided, first the longest matching block is determined as above, but with the additional restriction that no junk element appears in the block. Then that block is extended as far as possible by matching (only) junk elements on both sides. So the resulting block never matches on junk except as identical junk happens to be adjacent to an interesting match.

Here's the same example as before, but considering blanks to be junk. That prevents ' abcd' from matching the ' abcd' at the tail end of the second sequence directly. Instead only the 'abcd' can match, and matches the leftmost 'abcd' in the second sequence :

```
>>> s = SequenceMatcher(lambda x: x==" ", " abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=1, b=0, size=4)
```

If no blocks match, this returns (*a***lo**, *b***lo**, 0).

Modifié dans la version 2.6 : This method returns a *named tuple* *Match(a, b, size)*.

**get\_matching\_blocks()**

Return list of triples describing non-overlapping matching subsequences. Each triple is of the form (*i*, *j*, *n*), and means that *a*[*i*:*i*+*n*] == *b*[*j*:*j*+*n*]. The triples are monotonically increasing in *i* and *j*.

The last triple is a dummy, and has the value (*len(a)*, *len(b)*, 0). It is the only triple with *n* == 0. If (*i*, *j*, *n*) and (*i*', *j*', *n*') are adjacent triples in the list, and the second is not the last triple in the list, then *i*+*n* < *i*' or *j*+*n* < *j*'; in other words, adjacent triples always describe non-adjacent equal blocks.

Modifié dans la version 2.5 : The guarantee that adjacent triples always describe non-adjacent blocks was implemented.

```
>>> s = SequenceMatcher(None, "abxcd", "abcd")
>>> s.get_matching_blocks()
[Match(a=0, b=0, size=2), Match(a=3, b=2, size=2), Match(a=5, b=4, size=0)]
```

#### `get_opcodes()`

Return list of 5-tuples describing how to turn *a* into *b*. Each tuple is of the form (*tag*, *i1*, *i2*, *j1*, *j2*). The first tuple has *i1* == *j1* == 0, and remaining tuples have *i1* equal to the *i2* from the preceding tuple, and, likewise, *j1* equal to the previous *j2*.

The *tag* values are strings, with these meanings :

Valeur	Signification
'replace'	<code>a[i1:i2]</code> should be replaced by <code>b[j1:j2]</code> .
'delete'	<code>a[i1:i2]</code> should be deleted. Note that <code>j1</code> == <code>j2</code> in this case.
'insert'	<code>b[j1:j2]</code> should be inserted at <code>a[i1:i1]</code> . Note that <code>i1</code> == <code>i2</code> in this case.
'equal'	<code>a[i1:i2]</code> == <code>b[j1:j2]</code> (the sub-sequences are equal).

Par exemple :

```
>>> a = "qabxcd"
>>> b = "abycdf"
>>> s = SequenceMatcher(None, a, b)
>>> for tag, i1, i2, j1, j2 in s.get_opcodes():
...     print ("%7s a[%d:%d] (%s) b[%d:%d] (%s)" %
...             (tag, i1, i2, a[i1:i2], j1, j2, b[j1:j2]))
delete a[0:1] (q) b[0:0] ()
equal a[1:3] (ab) b[0:2] (ab)
replace a[3:4] (x) b[2:3] (y)
equal a[4:6] (cd) b[3:5] (cd)
insert a[6:6] () b[5:6] (f)
```

#### `get_grouped_opcodes([n])`

Return a *generator* of groups with up to *n* lines of context.

Starting with the groups returned by `get_opcodes()`, this method splits out smaller change clusters and eliminates intervening ranges which have no changes.

The groups are returned in the same format as `get_opcodes()`.

Nouveau dans la version 2.3.

#### `ratio()`

Return a measure of the sequences' similarity as a float in the range [0, 1].

Where T is the total number of elements in both sequences, and M is the number of matches, this is  $2.0 * M / T$ . Note that this is 1.0 if the sequences are identical, and 0.0 if they have nothing in common.

This is expensive to compute if `get_matching_blocks()` or `get_opcodes()` hasn't already been called, in which case you may want to try `quick_ratio()` or `real_quick_ratio()` first to get an upper bound.

#### `quick_ratio()`

Return an upper bound on `ratio()` relatively quickly.

#### `real_quick_ratio()`

Return an upper bound on `ratio()` very quickly.

The three methods that return the ratio of matching to total characters can give different results due to differing levels of approximation, although `quick_ratio()` and `real_quick_ratio()` are always at least as large as `ratio()` :

```
>>> s = SequenceMatcher(None, "abcd", "bcde")
>>> s.ratio()
0.75
>>> s.quick_ratio()
0.75
>>> s.real_quick_ratio()
1.0
```

### 7.4.2 SequenceMatcher Examples

This example compares two strings, considering blanks to be « junk : »

```
>>> s = SequenceMatcher(lambda x: x == " ",
...                      "private Thread currentThread;",
...                      "private volatile Thread currentThread;")
```

`ratio()` returns a float in  $[0, 1]$ , measuring the similarity of the sequences. As a rule of thumb, a `ratio()` value over 0.6 means the sequences are close matches :

```
>>> print round(s.ratio(), 3)
0.866
```

If you're only interested in where the sequences match, `get_matching_blocks()` is handy :

```
>>> for block in s.get_matching_blocks():
...     print "a[%d] and b[%d] match for %d elements" % block
a[0] and b[0] match for 8 elements
a[8] and b[17] match for 21 elements
a[29] and b[38] match for 0 elements
```

Note that the last tuple returned by `get_matching_blocks()` is always a dummy, `(len(a), len(b), 0)`, and this is the only case in which the last tuple element (number of elements matched) is 0.

If you want to know how to change the first sequence into the second, use `get_opcodes()` :

```
>>> for opcode in s.get_opcodes():
...     print "%6s a[%d:%d] b[%d:%d]" % opcode
equal a[0:8] b[0:8]
insert a[8:8] b[8:17]
equal a[8:29] b[17:38]
```

### 7.4.3 Differ Objects

Note that *Differ*-generated deltas make no claim to be **minimal** diffs. To the contrary, minimal diffs are often counter-intuitive, because they synch up anywhere possible, sometimes accidental matches 100 pages apart. Restricting synch points to contiguous matches preserves some notion of locality, at the occasional cost of producing a longer diff.

The *Differ* class has this constructor :

```
class difflib.Differ([linejunk[, charjunk]])
```

Optional keyword parameters *linejunk* and *charjunk* are for filter functions (or `None`) :

*linejunk* : A function that accepts a single string argument, and returns true if the string is junk. The default is `None`, meaning that no line is considered junk.

*charjunk* : A function that accepts a single character argument (a string of length 1), and returns true if the character is junk. The default is `None`, meaning that no character is considered junk.

*Differ* objects are used (deltas generated) via a single method :

```
compare(a, b)
```

Compare two sequences of lines, and generate the delta (a sequence of lines).

Each sequence must contain individual single-line strings ending with newlines. Such sequences can be obtained from the *readlines()* method of file-like objects. The delta generated also consists of newline-terminated strings, ready to be printed as-is via the *writelines()* method of a file-like object.

#### 7.4.4 Differ Example

This example compares two texts. First we set up the texts, sequences of individual single-line strings ending with newlines (such sequences can also be obtained from the *readlines()* method of file-like objects) :

```
>>> text1 = ''' 1. Beautiful is better than ugly.
... 2. Explicit is better than implicit.
... 3. Simple is better than complex.
... 4. Complex is better than complicated.
... '''.splitlines(1)
>>> len(text1)
4
>>> text1[0][-1]
'\n'
>>> text2 = ''' 1. Beautiful is better than ugly.
... 3. Simple is better than complex.
... 4. Complicated is better than complex.
... 5. Flat is better than nested.
... '''.splitlines(1)
```

Next we instantiate a *Differ* object :

```
>>> d = Differ()
```

Note that when instantiating a *Differ* object we may pass functions to filter out line and character « junk. » See the *Differ()* constructor for details.

Finally, we compare the two :

```
>>> result = list(d.compare(text1, text2))
```

*result* is a list of strings, so let's pretty-print it :

```
>>> from pprint import pprint
>>> pprint(result)
[' 1. Beautiful is better than ugly.\n',
'- 2. Explicit is better than implicit.\n',
'- 3. Simple is better than complex.\n',
'+ 3. Simple is better than complex.\n',
'? ++\n',
```

(suite sur la page suivante)

(suite de la page précédente)

```
'- 4. Complex is better than complicated.\n',
'?      ^              ---- ^\n',
'+ 4. Complicated is better than complex.\n',
'?      ++++ ^              ^\n',
'+ 5. Flat is better than nested.\n']
```

As a single multi-line string it looks like this :

```
>>> import sys
>>> sys.stdout.writelines(result)
1. Beautiful is better than ugly.
- 2. Explicit is better than implicit.
- 3. Simple is better than complex.
+ 3.   Simple is better than complex.
?    ++
- 4. Complex is better than complicated.
?      ^              ---- ^
+ 4. Complicated is better than complex.
?      ++++ ^              ^
+ 5. Flat is better than nested.
```

### 7.4.5 A command-line interface to difflib

This example shows how to use difflib to create a diff-like utility. It is also contained in the Python source distribution, as Tools/scripts/diff.py.

```
""" Command line interface to difflib.py providing diffs in four formats:

* ndiff:    lists every line and highlights interline changes.
* context:  highlights clusters of changes in a before/after format.
* unified:  highlights clusters of changes in an inline format.
* html:     generates side by side comparison with change highlights.

"""

import sys, os, time, difflib, optparse

def main():
    # Configure the option parser
    usage = "usage: %prog [options] fromfile tofile"
    parser = optparse.OptionParser(usage)
    parser.add_option("-c", action="store_true", default=False,
                      help='Produce a context format diff (default)')
    parser.add_option("-u", action="store_true", default=False,
                      help='Produce a unified format diff')
    hlp = 'Produce HTML side by side diff (can use -c and -l in conjunction)'
    parser.add_option("-m", action="store_true", default=False, help=hlp)
    parser.add_option("-n", action="store_true", default=False,
                      help='Produce a ndiff format diff')
    parser.add_option("-l", "--lines", type="int", default=3,
                      help='Set number of context lines (default 3)')
    (options, args) = parser.parse_args()
```

(suite sur la page suivante)

(suite de la page précédente)

```

if len(args) == 0:
    parser.print_help()
    sys.exit(1)
if len(args) != 2:
    parser.error("need to specify both a fromfile and tofile")

n = options.lines
fromfile, tofile = args # as specified in the usage string

# we're passing these as arguments to the diff function
fromdate = time.ctime(os.stat(fromfile).st_mtime)
todate = time.ctime(os.stat(tofile).st_mtime)
with open(fromfile, 'U') as f:
    fromlines = f.readlines()
with open(tofile, 'U') as f:
    tolines = f.readlines()

if options.u:
    diff = difflib.unified_diff(fromlines, tolines, fromfile, tofile,
                                fromdate, todate, n=n)
elif options.n:
    diff = difflib.ndiff(fromlines, tolines)
elif options.m:
    diff = difflib.HtmlDiff().make_file(fromlines, tolines, fromfile,
                                         tofile, context=options.c,
                                         numlines=n)
else:
    diff = difflib.context_diff(fromlines, tolines, fromfile, tofile,
                                fromdate, todate, n=n)

# we're using writelines because diff is a generator
sys.stdout.writelines(diff)

if __name__ == '__main__':
    main()

```

## 7.5 StringIO — Read and write strings as files

This module implements a file-like class, *StringIO*, that reads and writes a string buffer (also known as *memory files*). See the description of file objects for operations (section *Objets fichiers*). (For standard strings, see *str* and *unicode*.)

**class** StringIO.StringIO(*buffer*)

When a *StringIO* object is created, it can be initialized to an existing string by passing the string to the constructor. If no string is given, the *StringIO* will start empty. In both cases, the initial file position starts at zero.

The *StringIO* object can accept either Unicode or 8-bit strings, but mixing the two may take some care. If both are used, 8-bit strings that cannot be interpreted as 7-bit ASCII (that use the 8th bit) will cause a *UnicodeError* to be raised when *getvalue()* is called.

The following methods of *StringIO* objects require special mention :

**StringIO.getvalue()**

Retrieve the entire contents of the « file » at any time before the *StringIO* object's *close()* method is called. See the note above for information about mixing Unicode and 8-bit strings ; such mixing can cause this method to raise *UnicodeError*.

**StringIO.close()**

Free the memory buffer. Attempting to do further operations with a closed *StringIO* object will raise a *ValueError*.

Example usage :

```
import StringIO

output = StringIO.StringIO()
output.write('First line.\n')
print >>output, 'Second line.'

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

## 7.6 cStringIO — Faster version of StringIO

The module *cStringIO* provides an interface similar to that of the *StringIO* module. Heavy use of *StringIO*. *StringIO* objects can be made more efficient by using the function *StringIO()* from this module instead.

**cStringIO.StringIO(*s*)**

Return a StringIO-like stream for reading or writing.

Since this is a factory function which returns objects of built-in types, there's no way to build your own version using subclassing. It's not possible to set attributes on it. Use the original *StringIO* module in those cases.

Unlike the *StringIO* module, this module is not able to accept Unicode strings that cannot be encoded as plain ASCII strings.

Another difference from the *StringIO* module is that calling *StringIO()* with a string parameter creates a read-only object. Unlike an object created without a string parameter, it does not have write methods. These objects are not generally visible. They turn up in tracebacks as *StringI* and *String0*.

The following data objects are provided as well :

**cStringIO.InputType**

The type object of the objects created by calling *StringIO()* with a string parameter.

**cStringIO.OutputType**

The type object of the objects returned by calling *StringIO()* with no parameters.

There is a C API to the module as well ; refer to the module source for more information.

Example usage :

```
import cStringIO
```

(suite sur la page suivante)

(suite de la page précédente)

```

output = cStringIO.StringIO()
output.write('First line.\n')
print >>output, 'Second line.'

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()

```

## 7.7 textwrap — Text wrapping and filling

Nouveau dans la version 2.3.

**Source code :** [Lib/textwrap.py](#)

The *textwrap* module provides two convenience functions, *wrap()* and *fill()*, as well as *TextWrapper*, the class that does all the work, and a utility function *dedent()*. If you're just wrapping or filling one or two text strings, the convenience functions should be good enough; otherwise, you should use an instance of *TextWrapper* for efficiency.

**textwrap.wrap(text[, width[, ...]])**

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. Returns a list of output lines, without final newlines.

Optional keyword arguments correspond to the instance attributes of *TextWrapper*, documented below. *width* defaults to 70.

See the *TextWrapper.wrap()* method for additional details on how *wrap()* behaves.

**textwrap.fill(text[, width[, ...]])**

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph. *fill()* is shorthand for

```
"\n".join(wrap(text, ...))
```

In particular, *fill()* accepts exactly the same keyword arguments as *wrap()*.

Both *wrap()* and *fill()* work by creating a *TextWrapper* instance and calling a single method on it. That instance is not reused, so for applications that wrap/fill many text strings, it will be more efficient for you to create your own *TextWrapper* object.

Text is preferably wrapped on whitespaces and right after the hyphens in hyphenated words; only then will long words be broken if necessary, unless *TextWrapper.break\_long\_words* is set to false.

An additional utility function, *dedent()*, is provided to remove indentation from strings that have unwanted whitespace to the left of the text.

**textwrap.dedent(text)**

Remove any common leading whitespace from every line in *text*.

This can be used to make triple-quoted strings line up with the left edge of the display, while still presenting them in the source code in indented form.

Note that tabs and spaces are both treated as whitespace, but they are not equal: the lines " hello" and "\thello" are considered to have no common leading whitespace. (This behaviour is new in

Python 2.5; older versions of this module incorrectly expanded tabs before searching for common leading whitespace.)

Par exemple :

```
def test():
    # end first line with \ to avoid the empty line!
    s = '''\
hello
    world
    '''
    print repr(s)          # prints '    hello\n        world\n    '
    print repr(dedent(s))  # prints 'hello\n world\n'
```

`class textwrap.TextWrapper(...)`

The *TextWrapper* constructor accepts a number of optional keyword arguments. Each argument corresponds to one instance attribute, so for example

```
wrapper = TextWrapper(initial_indent="* ")
```

is the same as

```
wrapper = TextWrapper()
wrapper.initial_indent = "* "
```

You can re-use the same *TextWrapper* object many times, and you can change any of its options through direct assignment to instance attributes between uses.

The *TextWrapper* instance attributes (and keyword arguments to the constructor) are as follows :

**width**

(default : 70) The maximum length of wrapped lines. As long as there are no individual words in the input text longer than *width*, *TextWrapper* guarantees that no output line will be longer than *width* characters.

**expand\_tabs**

(default : True) If true, then all tab characters in *text* will be expanded to spaces using the `expandtabs()` method of *text*.

**replace\_whitespace**

(default : True) If true, after tab expansion but before wrapping, the *wrap()* method will replace each whitespace character with a single space. The whitespace characters replaced are as follows : tab, newline, vertical tab, formfeed, and carriage return ('`\t\n\v\f\r`').

---

**Note :** If *expand\_tabs* is false and *replace\_whitespace* is true, each tab character will be replaced by a single space, which is *not* the same as tab expansion.

---

---

**Note :** If *replace\_whitespace* is false, newlines may appear in the middle of a line and cause strange output. For this reason, text should be split into paragraphs (using *str.splitlines()* or similar) which are wrapped separately.

---

**drop\_whitespace**

(default : True) If true, whitespace at the beginning and ending of every line (after wrapping but before indenting) is dropped. Whitespace at the beginning of the paragraph, however, is not dropped if non-whitespace follows it. If whitespace being dropped takes up an entire line, the whole line is dropped.

Nouveau dans la version 2.6 : Whitespace was always dropped in earlier versions.

**initial\_indent**

(default : '') String that will be prepended to the first line of wrapped output. Counts towards the length of the first line. The empty string is not indented.

**subsequent\_indent**

(default : '') String that will be prepended to all lines of wrapped output except the first. Counts towards the length of each line except the first.

**fix\_sentence\_endings**

(default : False) If true, *TextWrapper* attempts to detect sentence endings and ensure that sentences are always separated by exactly two spaces. This is generally desired for text in a monospaced font. However, the sentence detection algorithm is imperfect : it assumes that a sentence ending consists of a lowercase letter followed by one of '.', '!', or '?', possibly followed by one of '"' or "'", followed by a space. One problem with this is algorithm is that it is unable to detect the difference between « Dr. » in

```
[...] Dr. Frankenstein's monster [...]
```

and « Spot. » in

```
[...] See Spot. See Spot run [...]
```

*fix\_sentence\_endings* is false by default.

Since the sentence detection algorithm relies on `string.lowercase` for the definition of « lowercase letter, » and a convention of using two spaces after a period to separate sentences on the same line, it is specific to English-language texts.

**break\_long\_words**

(default : True) If true, then words longer than *width* will be broken in order to ensure that no lines are longer than *width*. If it is false, long words will not be broken, and some lines may be longer than *width*. (Long words will be put on a line by themselves, in order to minimize the amount by which *width* is exceeded.)

**break\_on\_hyphens**

(default : True) If true, wrapping will occur preferably on whitespaces and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set *break\_long\_words* to false if you want truly insecable words. Default behaviour in previous versions was to always allow breaking hyphenated words.

Nouveau dans la version 2.6.

*TextWrapper* also provides two public methods, analogous to the module-level convenience functions :

**wrap(text)**

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. All wrapping options are taken from instance attributes of the *TextWrapper* instance. Returns a list of output lines, without final newlines. If the wrapped output has no content, the returned list is empty.

**fill(text)**

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph.

## 7.8 codecs — Codec registry and base classes

This module defines base classes for standard Python codecs (encoders and decoders) and provides access to the internal Python codec registry which manages the codec and error handling lookup process.

It defines the following functions :

`codecs.encode(obj[, encoding[, errors]])`

Encodes *obj* using the codec registered for *encoding*. The default encoding is 'ascii'.

*Errors* may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that encoding errors raise *ValueError* (or a more codec specific subclass, such as *UnicodeEncodeError*). Refer to *Codec Base Classes* for more information on codec error handling. Nouveau dans la version 2.4.

`codecs.decode(obj[, encoding[, errors]])`

Decodes *obj* using the codec registered for *encoding*. The default encoding is 'ascii'.

*Errors* may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that decoding errors raise *ValueError* (or a more codec specific subclass, such as *UnicodeDecodeError*). Refer to *Codec Base Classes* for more information on codec error handling. Nouveau dans la version 2.4.

`codecs.register(search_function)`

Register a codec search function. Search functions are expected to take one argument, the encoding name in all lower case letters, and return a *CodecInfo* object having the following attributes :

- **name** The name of the encoding ;
- **encode** The stateless encoding function ;
- **decode** The stateless decoding function ;
- **incrementalencoder** An incremental encoder class or factory function ;
- **incrementaldecoder** An incremental decoder class or factory function ;
- **streamwriter** A stream writer class or factory function ;
- **streamreader** A stream reader class or factory function.

The various functions or classes take the following arguments :

*encode* and *decode* : These must be functions or methods which have the same interface as the *encode()*/*decode()* methods of *Codec* instances (see *Codec Interface*). The functions/methods are expected to work in a stateless mode.

*incrementalencoder* and *incrementaldecoder* : These have to be factory functions providing the following interface :

`factory(errors='strict')`

The factory functions must return objects providing the interfaces defined by the base classes *IncrementalEncoder* and *IncrementalDecoder*, respectively. Incremental codecs can maintain state.

*streamreader* and *streamwriter* : These have to be factory functions providing the following interface :

`factory(stream, errors='strict')`

The factory functions must return objects providing the interfaces defined by the base classes *StreamReader* and *StreamWriter*, respectively. Stream codecs can maintain state.

Possible values for errors are

- 'strict' : raise an exception in case of an encoding error
- 'replace' : replace malformed data with a suitable replacement marker, such as '?' or '\ufffd'
- 'ignore' : ignore malformed data and continue without further notice
- 'xmlcharrefreplace' : replace with the appropriate XML character reference (for encoding only)
- 'backslashreplace' : replace with backslashed escape sequences (for encoding only)

as well as any other error handling name defined via *register\_error()*.

In case a search function cannot find a given encoding, it should return *None*.

`codecs.lookup(encoding)`

Looks up the codec info in the Python codec registry and returns a *CodecInfo* object as defined above.

Encodings are first looked up in the registry's cache. If not found, the list of registered search functions is scanned. If no *CodecInfo* object is found, a *LookupError* is raised. Otherwise, the *CodecInfo* object is stored in the cache and returned to the caller.

To simplify access to the various codecs, the module provides these additional functions which use *lookup()* for the codec lookup :

`codecs.getencoder(encoding)`

Look up the codec for the given encoding and return its encoder function.

Raises a [`LookupError`](#) in case the encoding cannot be found.

`codecs.getdecoder(encoding)`

Look up the codec for the given encoding and return its decoder function.

Raises a [`LookupError`](#) in case the encoding cannot be found.

`codecs.getincrementalencoder(encoding)`

Look up the codec for the given encoding and return its incremental encoder class or factory function.

Raises a [`LookupError`](#) in case the encoding cannot be found or the codec doesn't support an incremental encoder.

Nouveau dans la version 2.5.

`codecs.getincrementaldecoder(encoding)`

Look up the codec for the given encoding and return its incremental decoder class or factory function.

Raises a [`LookupError`](#) in case the encoding cannot be found or the codec doesn't support an incremental decoder.

Nouveau dans la version 2.5.

`codecs.getreader(encoding)`

Look up the codec for the given encoding and return its `StreamReader` class or factory function.

Raises a [`LookupError`](#) in case the encoding cannot be found.

`codecs.getwriter(encoding)`

Look up the codec for the given encoding and return its `StreamWriter` class or factory function.

Raises a [`LookupError`](#) in case the encoding cannot be found.

`codecs.register_error(name, error_handler)`

Register the error handling function *error\_handler* under the name *name*. *error\_handler* will be called during encoding and decoding in case of an error, when *name* is specified as the errors parameter.

For encoding *error\_handler* will be called with a [`UnicodeEncodeError`](#) instance, which contains information about the location of the error. The error handler must either raise this or a different exception or return a tuple with a replacement for the unencodable part of the input and a position where encoding should continue. The encoder will encode the replacement and continue encoding the original input at the specified position. Negative position values will be treated as being relative to the end of the input string. If the resulting position is out of bound an [`IndexError`](#) will be raised.

Decoding and translating works similar, except [`UnicodeDecodeError`](#) or [`UnicodeTranslateError`](#) will be passed to the handler and that the replacement from the error handler will be put into the output directly.

`codecs.lookup_error(name)`

Return the error handler previously registered under the name *name*.

Raises a [`LookupError`](#) in case the handler cannot be found.

`codecs.strict_errors(exception)`

Implements the **strict** error handling : each encoding or decoding error raises a [`UnicodeError`](#).

`codecs.replace_errors(exception)`

Implements the **replace** error handling : malformed data is replaced with a suitable replacement character such as '?' in bytestrings and '\ufffd' in Unicode strings.

`codecs.ignore_errors(exception)`

Implements the **ignore** error handling : malformed data is ignored and encoding or decoding is continued without further notice.

`codecs.xmlcharrefreplace_errors(exception)`

Implements the **xmlcharrefreplace** error handling (for encoding only) : the unencodable character is replaced by an appropriate XML character reference.

`codecs.backslashreplace_errors(exception)`

Implements the `backslashreplace` error handling (for encoding only) : the unencodable character is replaced by a backslashed escape sequence.

To simplify working with encoded files or stream, the module also defines these utility functions :

`codecs.open(filename, mode[, encoding[, errors[, buffering]]])`

Open an encoded file using the given *mode* and return a wrapped version providing transparent encoding/decoding. The default file mode is `'r'` meaning to open the file in read mode.

---

**Note :** The wrapped version will only accept the object format defined by the codecs, i.e. Unicode objects for most built-in codecs. Output is also codec-dependent and will usually be Unicode as well.

---

---

**Note :** Files are always opened in binary mode, even if no binary mode was specified. This is done to avoid data loss due to encodings using 8-bit values. This means that no automatic conversion of `'\n'` is done on reading and writing.

---

*encoding* specifies the encoding which is to be used for the file.

*errors* may be given to define the error handling. It defaults to `'strict'` which causes a *ValueError* to be raised in case an encoding error occurs.

*buffering* has the same meaning as for the built-in *open()* function. It defaults to line buffered.

`codecs.EncodedFile(file, input[, output[, errors]])`

Return a wrapped version of file which provides transparent encoding translation.

Strings written to the wrapped file are interpreted according to the given *input* encoding and then written to the original file as strings using the *output* encoding. The intermediate encoding will usually be Unicode but depends on the specified codecs.

If *output* is not given, it defaults to *input*.

*errors* may be given to define the error handling. It defaults to `'strict'`, which causes *ValueError* to be raised in case an encoding error occurs.

`codecs.iterencode(iterable, encoding[, errors])`

Uses an incremental encoder to iteratively encode the input provided by *iterable*. This function is a *generator*. *errors* (as well as any other keyword argument) is passed through to the incremental encoder.

Nouveau dans la version 2.5.

`codecs.iterdecode(iterable, encoding[, errors])`

Uses an incremental decoder to iteratively decode the input provided by *iterable*. This function is a *generator*. *errors* (as well as any other keyword argument) is passed through to the incremental decoder.

Nouveau dans la version 2.5.

The module also provides the following constants which are useful for reading and writing to platform dependent files :

`codecs.BOM`

`codecs.BOM_BE`

`codecs.BOM_LE`

`codecs.BOM_UTF8`

`codecs.BOM_UTF16`

`codecs.BOM_UTF16_BE`

`codecs.BOM_UTF16_LE`

`codecs.BOM_UTF32`

`codecs.BOM_UTF32_BE`

`codecs.BOM_UTF32_LE`

These constants define various encodings of the Unicode byte order mark (BOM) used in UTF-16 and

UTF-32 data streams to indicate the byte order used in the stream or file and in UTF-8 as a Unicode signature. `BOM_UTF16` is either `BOM_UTF16_BE` or `BOM_UTF16_LE` depending on the platform's native byte order, `BOM` is an alias for `BOM_UTF16`, `BOM_LE` for `BOM_UTF16_LE` and `BOM_BE` for `BOM_UTF16_BE`. The others represent the BOM in UTF-8 and UTF-32 encodings.

### 7.8.1 Codec Base Classes

The `codecs` module defines a set of base classes which define the interface and can also be used to easily write your own codecs for use in Python.

Each codec has to define four interfaces to make it usable as codec in Python : stateless encoder, stateless decoder, stream reader and stream writer. The stream reader and writers typically reuse the stateless encoder/decoder to implement the file protocols.

The `Codec` class defines the interface for stateless encoders/decoders.

To simplify and standardize error handling, the `encode()` and `decode()` methods may implement different error handling schemes by providing the `errors` string argument. The following string values are defined and implemented by all standard Python codecs :

Valeur	Signification
'strict'	Raise <code>UnicodeError</code> (or a subclass) ; this is the default.
'ignore'	Ignore the character and continue with the next.
'replace'	Replace with a suitable replacement character ; Python will use the official U+FFFD REPLACEMENT CHARACTER for the built-in Unicode codecs on decoding and “?” on encoding.
'xmlcharrefreplace'	Replace with the appropriate XML character reference (only for encoding).
'backslashreplace'	Replace with backslashed escape sequences (only for encoding).

The set of allowed values can be extended via `register_error()`.

#### Codec Objects

The `Codec` class defines these methods which also define the function interfaces of the stateless encoder and decoder :

`Codec.encode(input[, errors])`

Encodes the object `input` and returns a tuple (output object, length consumed). While codecs are not restricted to use with Unicode, in a Unicode context, encoding converts a Unicode object to a plain string using a particular character set encoding (e.g., `cp1252` or `iso-8859-1`).

`errors` defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the `Codec` instance. Use `StreamWriter` for codecs which have to keep state in order to make encoding efficient.

The encoder must be able to handle zero length input and return an empty object of the output object type in this situation.

`Codec.decode(input[, errors])`

Decodes the object `input` and returns a tuple (output object, length consumed). In a Unicode context, decoding converts a plain string encoded using a particular character set encoding to a Unicode object.

`input` must be an object which provides the `bf_getreadbuf` buffer slot. Python strings, buffer objects and memory mapped files are examples of objects providing this slot.

`errors` defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the `Codec` instance. Use `StreamReader` for codecs which have to keep state in order to make decoding efficient.

The decoder must be able to handle zero length input and return an empty object of the output object type in this situation.

The *IncrementalEncoder* and *IncrementalDecoder* classes provide the basic interface for incremental encoding and decoding. Encoding/decoding the input isn't done with one call to the stateless encoder/decoder function, but with multiple calls to the *encode()/decode()* method of the incremental encoder/decoder. The incremental encoder/decoder keeps track of the encoding/decoding process during method calls.

The joined output of calls to the *encode()/decode()* method is the same as if all the single inputs were joined into one, and this input was encoded/decoded with the stateless encoder/decoder.

### IncrementalEncoder Objects

Nouveau dans la version 2.5.

The *IncrementalEncoder* class is used for encoding an input in multiple steps. It defines the following methods which every incremental encoder must define in order to be compatible with the Python codec registry.

```
class codecs.IncrementalEncoder([errors])
```

Constructor for an *IncrementalEncoder* instance.

All incremental encoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *IncrementalEncoder* may implement different error handling schemes by providing the *errors* keyword argument. These parameters are predefined :

- 'strict' Raise *ValueError* (or a subclass); this is the default.
- 'ignore' Ignore the character and continue with the next.
- 'replace' Replace with a suitable replacement character
- 'xmlcharrefreplace' Replace with the appropriate XML character reference
- 'backslashreplace' Replace with backslashed escape sequences.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *IncrementalEncoder* object.

The set of allowed values for the *errors* argument can be extended with *register\_error()*.

```
encode(object[, final])
```

Encodes *object* (taking the current state of the encoder into account) and returns the resulting encoded object. If this is the last call to *encode()* *final* must be true (the default is false).

```
reset()
```

Reset the encoder to the initial state.

### IncrementalDecoder Objects

The *IncrementalDecoder* class is used for decoding an input in multiple steps. It defines the following methods which every incremental decoder must define in order to be compatible with the Python codec registry.

```
class codecs.IncrementalDecoder([errors])
```

Constructor for an *IncrementalDecoder* instance.

All incremental decoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *IncrementalDecoder* may implement different error handling schemes by providing the *errors* keyword argument. These parameters are predefined :

- 'strict' Raise *ValueError* (or a subclass); this is the default.
- 'ignore' Ignore the character and continue with the next.
- 'replace' Replace with a suitable replacement character.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *IncrementalDecoder* object.

The set of allowed values for the *errors* argument can be extended with *register\_error()*.

**decode**(*object*[, *final*])

Decodes *object* (taking the current state of the decoder into account) and returns the resulting decoded object. If this is the last call to *decode()* *final* must be true (the default is false). If *final* is true the decoder must decode the input completely and must flush all buffers. If this isn't possible (e.g. because of incomplete byte sequences at the end of the input) it must initiate error handling just like in the stateless case (which might raise an exception).

**reset**()

Reset the decoder to the initial state.

The *StreamWriter* and *StreamReader* classes provide generic working interfaces which can be used to implement new encoding submodules very easily. See `encodings.utf_8` for an example of how this is done.

## StreamWriter Objects

The *StreamWriter* class is a subclass of *Codec* and defines the following methods which every stream writer must define in order to be compatible with the Python codec registry.

**class** `codecs.StreamWriter`(*stream*[, *errors*])

Constructor for a *StreamWriter* instance.

All stream writers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

*stream* must be a file-like object open for writing binary data.

The *StreamWriter* may implement different error handling schemes by providing the *errors* keyword argument. These parameters are predefined :

- 'strict' Raise *ValueError* (or a subclass) ; this is the default.
- 'ignore' Ignore the character and continue with the next.
- 'replace' Replace with a suitable replacement character
- 'xmlcharrefreplace' Replace with the appropriate XML character reference
- 'backslashreplace' Replace with backslashed escape sequences.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *StreamWriter* object.

The set of allowed values for the *errors* argument can be extended with *register\_error()*.

**write**(*object*)

Writes the object's contents encoded to the stream.

**writelines**(*list*)

Writes the concatenated list of strings to the stream (possibly by reusing the *write()* method).

**reset**()

Flushes and resets the codec buffers used for keeping state.

Calling this method should ensure that the data on the output is put into a clean state that allows appending of new fresh data without having to rescan the whole stream to recover state.

In addition to the above methods, the *StreamWriter* must also inherit all other methods and attributes from the underlying stream.

## StreamReader Objects

The *StreamReader* class is a subclass of *Codec* and defines the following methods which every stream reader must define in order to be compatible with the Python codec registry.

**class** `codecs.StreamReader`(*stream*[, *errors*])

Constructor for a *StreamReader* instance.

All stream readers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

*stream* must be a file-like object open for reading (binary) data.

The *StreamReader* may implement different error handling schemes by providing the *errors* keyword argument. These parameters are defined :

- 'strict' Raise *ValueError* (or a subclass) ; this is the default.
- 'ignore' Ignore the character and continue with the next.
- 'replace' Replace with a suitable replacement character.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *StreamReader* object.

The set of allowed values for the *errors* argument can be extended with *register\_error()*.

**read**([*size*[, *chars*[, *firstline*]]])

Decodes data from the stream and returns the resulting object.

*chars* indicates the number of characters to read from the stream. *read()* will never return more than *chars* characters, but it might return less, if there are not enough characters available.

*size* indicates the approximate maximum number of bytes to read from the stream for decoding purposes. The decoder can modify this setting as appropriate. The default value -1 indicates to read and decode as much as possible. *size* is intended to prevent having to decode huge files in one step.

*firstline* indicates that it would be sufficient to only return the first line, if there are decoding errors on later lines.

The method should use a greedy read strategy meaning that it should read as much data as is allowed within the definition of the encoding and the given size, e.g. if optional encoding endings or state markers are available on the stream, these should be read too.

Modifié dans la version 2.4 : *chars* argument added.

Modifié dans la version 2.4.2 : *firstline* argument added.

**readline**([*size*[, *keepends*]])

Read one line from the input stream and return the decoded data.

*size*, if given, is passed as size argument to the stream's *read()* method.

If *keepends* is false line-endings will be stripped from the lines returned.

Modifié dans la version 2.4 : *keepends* argument added.

**readlines**([*sizehint*[, *keepends*]])

Read all lines available on the input stream and return them as a list of lines.

Line-endings are implemented using the codec's decoder method and are included in the list entries if *keepends* is true.

*sizehint*, if given, is passed as the *size* argument to the stream's *read()* method.

**reset()**

Resets the codec buffers used for keeping state.

Note that no stream repositioning should take place. This method is primarily intended to be able to recover from decoding errors.

In addition to the above methods, the *StreamReader* must also inherit all other methods and attributes from the underlying stream.

The next two base classes are included for convenience. They are not needed by the codec registry, but may provide useful in practice.

### StreamReaderWriter Objects

The *StreamReaderWriter* allows wrapping streams which work in both read and write modes.

The design is such that one can use the factory functions returned by the *lookup()* function to construct the instance.

**class** codecs.*StreamReaderWriter*(*stream*, *Reader*, *Writer*, *errors*)

Creates a *StreamReaderWriter* instance. *stream* must be a file-like object. *Reader* and *Writer* must

be factory functions or classes providing the *StreamReader* and *StreamWriter* interface resp. Error handling is done in the same way as defined for the stream readers and writers.

*StreamReaderWriter* instances define the combined interfaces of *StreamReader* and *StreamWriter* classes. They inherit all other methods and attributes from the underlying stream.

### StreamRecoder Objects

The *StreamRecoder* provide a frontend - backend view of encoding data which is sometimes useful when dealing with different encoding environments.

The design is such that one can use the factory functions returned by the *lookup()* function to construct the instance.

**class** `codecs.StreamRecoder`(*stream, encode, decode, Reader, Writer, errors*)

Creates a *StreamRecoder* instance which implements a two-way conversion : *encode* and *decode* work on the frontend (the input to *read()* and output of *write()*) while *Reader* and *Writer* work on the backend (reading and writing to the stream).

You can use these objects to do transparent direct recodings from e.g. Latin-1 to UTF-8 and back.

*stream* must be a file-like object.

*encode*, *decode* must adhere to the *Codec* interface. *Reader*, *Writer* must be factory functions or classes providing objects of the *StreamReader* and *StreamWriter* interface respectively.

*encode* and *decode* are needed for the frontend translation, *Reader* and *Writer* for the backend translation. The intermediate format used is determined by the two sets of codecs, e.g. the Unicode codecs will use Unicode as the intermediate encoding.

Error handling is done in the same way as defined for the stream readers and writers.

*StreamRecoder* instances define the combined interfaces of *StreamReader* and *StreamWriter* classes. They inherit all other methods and attributes from the underlying stream.

## 7.8.2 Encodings and Unicode

Unicode strings are stored internally as sequences of code points (to be precise as `Py_UNICODE` arrays). Depending on the way Python is compiled (either via `--enable-unicode=ucs2` or `--enable-unicode=ucs4`, with the former being the default) `Py_UNICODE` is either a 16-bit or 32-bit data type. Once a Unicode object is used outside of CPU and memory, CPU endianness and how these arrays are stored as bytes become an issue. Transforming a unicode object into a sequence of bytes is called encoding and recreating the unicode object from the sequence of bytes is known as decoding. There are many different methods for how this transformation can be done (these methods are also called encodings). The simplest method is to map the code points 0-255 to the bytes 0x0-0xff. This means that a unicode object that contains code points above U+00FF can't be encoded with this method (which is called 'latin-1' or 'iso-8859-1'). `unicode.encode()` will raise a *UnicodeEncodeError* that looks like this : `UnicodeEncodeError: 'latin-1' codec can't encode character u'\u1234' in position 3: ordinal not in range(256)`.

There's another group of encodings (the so called charmap encodings) that choose a different subset of all unicode code points and how these code points are mapped to the bytes 0x0-0xff. To see how this is done simply open e.g. `encodings/cp1252.py` (which is an encoding that is used primarily on Windows). There's a string constant with 256 characters that shows you which character is mapped to which byte value.

All of these encodings can only encode 256 of the 1114112 code points defined in unicode. A simple and straightforward way that can store each Unicode code point, is to store each code point as four consecutive bytes. There are two possibilities : store the bytes in big endian or in little endian order. These two encodings are called UTF-32-BE and UTF-32-LE respectively. Their disadvantage is that if e.g. you use UTF-32-BE on a little endian machine you will always have to swap bytes on encoding and decoding. UTF-32 avoids this problem : bytes will always be in natural endianness. When these bytes are read by a CPU with a different endianness, then bytes have to be swapped though. To be able to detect the endianness of a UTF-16 or UTF-32 byte sequence, there's the so called BOM (« Byte Order Mark »). This is the Unicode character U+FEFF.

This character can be prepended to every UTF-16 or UTF-32 byte sequence. The byte swapped version of this character (0xFFFE) is an illegal character that may not appear in a Unicode text. So when the first character in an UTF-16 or UTF-32 byte sequence appears to be a U+FFFE the bytes have to be swapped on decoding. Unfortunately the character U+FEFF had a second purpose as a ZERO WIDTH NO-BREAK SPACE : a character that has no width and doesn't allow a word to be split. It can e.g. be used to give hints to a ligature algorithm. With Unicode 4.0 using U+FEFF as a ZERO WIDTH NO-BREAK SPACE has been deprecated (with U+2060 (WORD JOINER) assuming this role). Nevertheless Unicode software still must be able to handle U+FEFF in both roles : as a BOM it's a device to determine the storage layout of the encoded bytes, and vanishes once the byte sequence has been decoded into a Unicode string ; as a ZERO WIDTH NO-BREAK SPACE it's a normal character that will be decoded like any other.

There's another encoding that is able to encoding the full range of Unicode characters : UTF-8. UTF-8 is an 8-bit encoding, which means there are no issues with byte order in UTF-8. Each byte in a UTF-8 byte sequence consists of two parts : marker bits (the most significant bits) and payload bits. The marker bits are a sequence of zero to four 1 bits followed by a 0 bit. Unicode characters are encoded like this (with x being payload bits, which when concatenated give the Unicode character) :

Range	Encoding
U-00000000 ... U-0000007F	0xxxxxxx
U-00000080 ... U-000007FF	110xxxxx 10xxxxxx
U-00000800 ... U-0000FFFF	1110xxxx 10xxxxxx 10xxxxxx
U-00010000 ... U-0010FFFF	11110xxx 10xxxxxx 10xxxxxx 10xxxxxx

The least significant bit of the Unicode character is the rightmost x bit.

As UTF-8 is an 8-bit encoding no BOM is required and any U+FEFF character in the decoded Unicode string (even if it's the first character) is treated as a ZERO WIDTH NO-BREAK SPACE.

Without external information it's impossible to reliably determine which encoding was used for encoding a Unicode string. Each charmap encoding can decode any random byte sequence. However that's not possible with UTF-8, as UTF-8 byte sequences have a structure that doesn't allow arbitrary byte sequences. To increase the reliability with which a UTF-8 encoding can be detected, Microsoft invented a variant of UTF-8 (that Python 2.5 calls "utf-8-sig") for its Notepad program : Before any of the Unicode characters is written to the file, a UTF-8 encoded BOM (which looks like this as a byte sequence : 0xef, 0xbb, 0xbf) is written. As it's rather improbable that any charmap encoded file starts with these byte values (which would e.g. map to

LATIN SMALL LETTER I WITH DIAERESIS  
RIGHT-POINTING DOUBLE ANGLE QUOTATION MARK  
INVERTED QUESTION MARK

in iso-8859-1), this increases the probability that a utf-8-sig encoding can be correctly guessed from the byte sequence. So here the BOM is not used to be able to determine the byte order used for generating the byte sequence, but as a signature that helps in guessing the encoding. On encoding the utf-8-sig codec will write 0xef, 0xbb, 0xbf as the first three bytes to the file. On decoding utf-8-sig will skip those three bytes if they appear as the first three bytes in the file. In UTF-8, the use of the BOM is discouraged and should generally be avoided.

## 7.8.3 Standard Encodings

Python comes with a number of codecs built-in, either implemented as C functions or with dictionaries as mapping tables. The following table lists the codecs by name, together with a few common aliases, and the languages for which the encoding is likely used. Neither the list of aliases nor the list of languages is meant to be exhaustive. Notice that spelling alternatives that only differ in case or use a hyphen instead of an underscore are also valid aliases ; therefore, e.g. 'utf-8' is a valid alias for the 'utf\_8' codec.

Many of the character sets support the same languages. They vary in individual characters (e.g. whether the EURO SIGN is supported or not), and in the assignment of characters to code positions. For the European languages in particular, the following variants typically exist :

- an ISO 8859 codeset
- a Microsoft Windows code page, which is typically derived from an 8859 codeset, but replaces control characters with additional graphic characters
- an IBM EBCDIC code page
- an IBM PC code page, which is ASCII compatible

Codec	Aliases	Languages
ascii	646, us-ascii	Anglais
big5	big5-tw, csbig5	Chinois Traditionnel
big5hkscs	big5-hkscs, hkscs	Chinois Traditionnel

### 7.8.4 Python Specific Encodings

A number of predefined codecs are specific to Python, so their codec names have no meaning outside Python. These are listed in the tables below based on the expected input and output types (note that while text encodings are the most common use case for codecs, the underlying codec infrastructure supports arbitrary data transforms rather than just text encodings). For asymmetric codecs, the stated purpose describes the encoding direction.

The following codecs provide unicode-to-str encoding<sup>1</sup> and str-to-unicode decoding<sup>2</sup>, similar to the Unicode text encodings.

Codec	Aliases	Objectif
idna		Implements <a href="#">RFC 3490</a> , see also <a href="#">encodings.idna</a>
mbcs	dbcs	Windows only : Encode operand according to the ANSI codepage (CP_ACP)
palmos		Encoding of PalmOS 3.5
punycode		Implements <a href="#">RFC 3492</a>
raw_unicode_escape		Produce a string that is suitable as raw Unicode literal in Python source code
rot_13	rot13	Returns the Caesar-cypher encryption of the operand
undefined		Raise an exception for all conversions. Can be used as the system encoding if no automatic <a href="#">coercion</a> between byte and Unicode strings is desired.
unicode_escape		Produce a string that is suitable as Unicode literal in Python source code
unicode_internal		Return the internal representation of the operand

1. str objects are also accepted as input in place of unicode objects. They are implicitly converted to unicode by decoding them using the default encoding. If this conversion fails, it may lead to encoding operations raising [UnicodeDecodeError](#).

2. unicode objects are also accepted as input in place of str objects. They are implicitly converted to str by encoding them using the default encoding. If this conversion fails, it may lead to decoding operations raising [UnicodeEncodeError](#).

Nouveau dans la version 2.3 : The `idna` and `punycode` encodings.

The following codecs provide str-to-str encoding and decoding<sup>2</sup>.

Codec	Aliases	Objectif	Encoder/decoder
<code>base64_codec</code>	<code>base64</code> , <code>base-64</code>	Convert operand to multiline MIME base64 (the result always includes a trailing <code>'\n'</code> )	<code>base64.encodestring()</code> , <code>base64.decodestring()</code>
<code>bz2_codec</code>	<code>bz2</code>	Compress the operand using bz2	<code>bz2.compress()</code> , <code>bz2.decompress()</code>
<code>hex_codec</code>	<code>hex</code>	Convert operand to hexadecimal representation, with two digits per byte	<code>binascii.b2a_hex()</code> , <code>binascii.a2b_hex()</code>
<code>quopri_codec</code>	<code>quopri</code> , <code>quoted-printable</code> , <code>quotedprintable</code>	Convert operand to MIME quoted printable	<code>quopri.encode()</code> with <code>quotetabs=True</code> , <code>quopri.decode()</code>
<code>string_escape</code>		Produce a string that is suitable as string literal in Python source code	
<code>uu_codec</code>	<code>uu</code>	Convert the operand using uuencode	<code>uu.encode()</code> , <code>uu.decode()</code>
<code>zlib_codec</code>	<code>zip</code> , <code>zlib</code>	Compress the operand using gzip	<code>zlib.compress()</code> , <code>zlib.decompress()</code>

### 7.8.5 `encodings.idna` — Internationalized Domain Names in Applications

Nouveau dans la version 2.3.

This module implements [RFC 3490](#) (Internationalized Domain Names in Applications) and [RFC 3492](#) (Nameprep : A Stringprep Profile for Internationalized Domain Names (IDN)). It builds upon the `punycode` encoding and `stringprep`.

These RFCs together define a protocol to support non-ASCII characters in domain names. A domain name containing non-ASCII characters (such as `www.Alliancefrançaise.nu`) is converted into an ASCII-compatible encoding (ACE, such as `www.xn--alliancefranaise-npb.nu`). The ACE form of the domain name is then used in all places where arbitrary characters are not allowed by the protocol, such as DNS queries, HTTP *Host* fields, and so on. This conversion is carried out in the application ; if possible invisible to the user : The application should transparently convert Unicode domain labels to IDNA on the wire, and convert back ACE labels to Unicode before presenting them to the user.

Python supports this conversion in several ways : the `idna` codec performs conversion between Unicode and ACE, separating an input string into labels based on the separator characters defined in [section 3.1 \(1\)](#) of [RFC 3490](#) and converting each label to ACE as required, and conversely separating an input byte string into labels based on the `.` separator and converting any ACE labels found into unicode. Furthermore, the `socket` module transparently converts Unicode host names to ACE, so that applications need not be concerned about converting host names themselves when they pass them to the socket module. On top of that, modules that have host names as function parameters, such as `httpplib` and `ftplib`, accept Unicode host names (`httpplib` then also transparently sends an IDNA hostname in the *Host* field if it sends that field at all).

When receiving host names from the wire (such as in reverse name lookup), no automatic conversion to Unicode is performed : Applications wishing to present such host names to the user should decode them to Unicode.

The module `encodings.idna` also implements the nameprep procedure, which performs certain normalizations on host names, to achieve case-insensitivity of international domain names, and to unify similar characters. The nameprep functions can be used directly if desired.

`encodings.idna.nameprep(label)`

Return the nameprepped version of *label*. The implementation currently assumes query strings, so `AllowUnassigned` is true.

`encodings.idna.ToASCII(label)`

Convert a label to ASCII, as specified in [RFC 3490](#). `UseSTD3ASCIIRules` is assumed to be false.

`encodings.idna.ToUnicode(label)`

Convert a label to Unicode, as specified in [RFC 3490](#).

## 7.8.6 `encodings.utf_8_sig` — UTF-8 codec with BOM signature

Nouveau dans la version 2.5.

This module implements a variant of the UTF-8 codec : On encoding a UTF-8 encoded BOM will be prepended to the UTF-8 encoded bytes. For the stateful encoder this is only done once (on the first write to the byte stream). For decoding an optional UTF-8 encoded BOM at the start of the data will be skipped.

## 7.9 `unicodedata` — Base de données Unicode

This module provides access to the Unicode Character Database which defines character properties for all Unicode characters. The data in this database is based on the `UnicodeData.txt` file version 5.2.0 which is publicly available from <ftp://ftp.unicode.org/>.

The module uses the same names and symbols as defined by the UnicodeData File Format 5.2.0 (see <http://www.unicode.org/reports/tr44/tr44-4.html>). It defines the following functions :

`unicodedata.lookup(name)`

Look up character by name. If a character with the given name is found, return the corresponding Unicode character. If not found, `KeyError` is raised.

`unicodedata.name(unichr[, default])`

Returns the name assigned to the Unicode character *unichr* as a string. If no name is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.decimal(unichr[, default])`

Returns the decimal value assigned to the Unicode character *unichr* as integer. If no such value is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.digit(unichr[, default])`

Returns the digit value assigned to the Unicode character *unichr* as integer. If no such value is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.numeric(unichr[, default])`

Returns the numeric value assigned to the Unicode character *unichr* as float. If no such value is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.category(unichr)`

Returns the general category assigned to the Unicode character *unichr* as string.

`unicodedata.bidirectional(unichr)`

Returns the bidirectional class assigned to the Unicode character *unichr* as string. If no such value is defined, an empty string is returned.

`unicodedata.combining(unichr)`

Returns the canonical combining class assigned to the Unicode character *unichr* as integer. Returns 0 if no combining class is defined.

`unicodedata.east_asian_width(unichr)`

Returns the east asian width assigned to the Unicode character *unichr* as string.

Nouveau dans la version 2.4.

`unicodedata.mirrored(unichr)`

Returns the mirrored property assigned to the Unicode character *unichr* as integer. Returns 1 if the character has been identified as a « mirrored » character in bidirectional text, 0 otherwise.

`unicodedata.decomposition(unichr)`

Returns the character decomposition mapping assigned to the Unicode character *unichr* as string. An empty string is returned in case no such mapping is defined.

`unicodedata.normalize(form, unistr)`

Renvoie la forme normale *form* de la chaîne de caractère Unicode *unistr*. Les valeurs valides de *form* sont *NFC*, *NFKC*, *NFD*, et *NFKD*.

Le standard Unicode définit les différentes variantes de normalisation d'une chaîne de caractères Unicode en se basant sur les définitions d'équivalence canonique et d'équivalence de compatibilité. En Unicode, plusieurs caractères peuvent être exprimés de différentes façons. Par exemple, le caractère *U+00C7* (*LATIN CAPITAL LETTER C WITH CEDILLA*) peut aussi être exprimé comme la séquence *U+0043* (*LATIN CAPITAL LETTER C*) *U+0327* (*COMBINING CEDILLA*).

Pour chaque caractère, il existe deux formes normales : la forme normale C et la forme normale D. La forme normale D (NFD) est aussi appelée décomposition canonique, et traduit chaque caractère dans sa forme décomposée. La forme normale C (NFC) applique d'abord la décomposition canonique, puis compose à nouveau les caractères pré-combinés.

En plus de ces deux formes, il existe deux formes nominales basées sur l'équivalence de compatibilité. En Unicode, certains caractères sont gérés alors qu'ils sont normalement unifiés avec d'autres caractères. Par exemple, *U+2160* (*ROMAN NUMERAL ONE*) est vraiment la même chose que *U+0049* (*LATIN CAPITAL LETTER I*). Cependant, ce caractère est supporté par souci de compatibilité avec les jeux de caractères existants (par exemple *gb2312*).

La forme normale KD (NFKD) applique la décomposition de compatibilité, c'est-à-dire remplacer les caractères de compatibilités avec leurs équivalents. La forme normale KC (NFKC) applique d'abord la décomposition de compatibilité, puis applique la composition canonique.

Même si deux chaînes de caractères Unicode sont normalisées et ont la même apparence pour un lecteur humain, si un a des caractères combinés alors que l'autre n'en a pas, elles peuvent ne pas être égales lors d'une comparaison.

Nouveau dans la version 2.3.

De plus, ce module expose la constante suivante :

`unicodedata.unidata_version`

La version de la base de données Unicode utilisée dans ce module.

Nouveau dans la version 2.3.

`unicodedata.ucd_3_2_0`

Ceci est un objet qui a les mêmes méthodes que le module, mais qui utilise la version 3.2 de la base de données Unicode, pour les applications qui nécessitent cette version spécifique de la base de données Unicode (comme l'IDNA).

Nouveau dans la version 2.5.

Exemples :

```
>>> import unicodedata
>>> unicodedata.lookup('LEFT CURLY BRACKET')
u'{'
>>> unicodedata.name(u'/')
'SOLIDUS'
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> unicodedata.decimal(u'9')
9
>>> unicodedata.decimal(u'a')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: not a decimal
>>> unicodedata.category(u'A') # 'L'etter, 'u'ppercase
'Lu'
>>> unicodedata.bidirectional(u'\u0660') # 'A'rabic, 'N'umber
'AN'
```

## 7.10 stringprep — Internet String Preparation

Nouveau dans la version 2.3.

When identifying things (such as host names) in the internet, it is often necessary to compare such identifications for « equality ». Exactly how this comparison is executed may depend on the application domain, e.g. whether it should be case-insensitive or not. It may be also necessary to restrict the possible identifications, to allow only identifications consisting of « printable » characters.

**RFC 3454** defines a procedure for « preparing » Unicode strings in internet protocols. Before passing strings onto the wire, they are processed with the preparation procedure, after which they have a certain normalized form. The RFC defines a set of tables, which can be combined into profiles. Each profile must define which tables it uses, and what other optional parts of the **stringprep** procedure are part of the profile. One example of a **stringprep** profile is **nameprep**, which is used for internationalized domain names.

The module *stringprep* only exposes the tables from RFC 3454. As these tables would be very large to represent them as dictionaries or lists, the module uses the Unicode character database internally. The module source code itself was generated using the **mkstringprep.py** utility.

As a result, these tables are exposed as functions, not as data structures. There are two kinds of tables in the RFC : sets and mappings. For a set, *stringprep* provides the « characteristic function », i.e. a function that returns true if the parameter is part of the set. For mappings, it provides the mapping function : given the key, it returns the associated value. Below is a list of all functions available in the module.

**stringprep.in\_table\_a1(*code*)**

Determine whether *code* is in tableA.1 (Unassigned code points in Unicode 3.2).

**stringprep.in\_table\_b1(*code*)**

Determine whether *code* is in tableB.1 (Commonly mapped to nothing).

**stringprep.map\_table\_b2(*code*)**

Return the mapped value for *code* according to tableB.2 (Mapping for case-folding used with NFKC).

**stringprep.map\_table\_b3(*code*)**

Return the mapped value for *code* according to tableB.3 (Mapping for case-folding used with no normalization).

**stringprep.in\_table\_c11(*code*)**

Determine whether *code* is in tableC.1.1 (ASCII space characters).

**stringprep.in\_table\_c12(*code*)**

Determine whether *code* is in tableC.1.2 (Non-ASCII space characters).

**stringprep.in\_table\_c11\_c12(*code*)**

Determine whether *code* is in tableC.1 (Space characters, union of C.1.1 and C.1.2).

`stringprep.in_table_c21(code)`  
Determine whether *code* is in tableC.2.1 (ASCII control characters).

`stringprep.in_table_c22(code)`  
Determine whether *code* is in tableC.2.2 (Non-ASCII control characters).

`stringprep.in_table_c21_c22(code)`  
Determine whether *code* is in tableC.2 (Control characters, union of C.2.1 and C.2.2).

`stringprep.in_table_c3(code)`  
Determine whether *code* is in tableC.3 (Private use).

`stringprep.in_table_c4(code)`  
Determine whether *code* is in tableC.4 (Non-character code points).

`stringprep.in_table_c5(code)`  
Determine whether *code* is in tableC.5 (Surrogate codes).

`stringprep.in_table_c6(code)`  
Determine whether *code* is in tableC.6 (Inappropriate for plain text).

`stringprep.in_table_c7(code)`  
Determine whether *code* is in tableC.7 (Inappropriate for canonical representation).

`stringprep.in_table_c8(code)`  
Determine whether *code* is in tableC.8 (Change display properties or are deprecated).

`stringprep.in_table_c9(code)`  
Determine whether *code* is in tableC.9 (Tagging characters).

`stringprep.in_table_d1(code)`  
Determine whether *code* is in tableD.1 (Characters with bidirectional property « R » or « AL »).

`stringprep.in_table_d2(code)`  
Determine whether *code* is in tableD.2 (Characters with bidirectional property « L »).

## 7.11 `fpformat` — Floating point conversions

Obsolète depuis la version 2.6 : The `fpformat` module has been removed in Python 3.

The `fpformat` module defines functions for dealing with floating point numbers representations in 100% pure Python.

---

**Note :** This module is unnecessary : everything here can be done using the `%` string interpolation operator described in the *String Formatting Operations* section.

---

The `fpformat` module defines the following functions and an exception :

`fpformat.fix(x, digs)`  
Format *x* as `[-]ddd.ddd` with *digs* digits after the point and at least one digit before. If *digs*  $\leq$  0, the decimal point is suppressed.  
*x* can be either a number or a string that looks like one. *digs* is an integer.  
Return value is a string.

`fpformat.sci(x, digs)`  
Format *x* as `[-]d.dddE[+-]ddd` with *digs* digits after the point and exactly one digit before. If *digs*  $\leq$  0, one digit is kept and the point is suppressed.  
*x* can be either a real number, or a string that looks like one. *digs* is an integer.  
Return value is a string.

**exception `fpformat.NotANumber`**

Exception raised when a string passed to *fix()* or *sci()* as the *x* parameter does not look like a number. This is a subclass of *ValueError* when the standard exceptions are strings. The exception value is the improperly formatted string that caused the exception to be raised.

Example :

```
>>> import fpformat
>>> fpformat.fix(1.23, 1)
'1.2'
```

Les modules documentés dans ce chapitre fournissent une gamme de types de données spécialisés tel que les dates et les heures, les listes à type prédéfini, les *heap queue*, les queues synchronisées, et les ensembles.

Python also provides some built-in data types, in particular, *dict*, *list*, *set* (which along with *frozenset*, replaces the deprecated *sets* module), and *tuple*. The *str* class can be used to handle binary data and 8-bit text, and the *unicode* class to handle Unicode text.

Les modules suivants sont documentés dans ce chapitre :

## 8.1 *datetime* — Types de base pour la date et l'heure

Nouveau dans la version 2.3.

Le module *datetime* fournit des classes pour manipuler de façon simple ou plus complexe des dates et des heures. Bien que les calculs de date et d'heure sont supportés, l'implémentation est essentiellement tournée vers l'efficacité pour extraire des attributs pour les manipuler et les formater pour l'affichage. Pour d'autres fonctionnalités associées, voir aussi les modules *time* et *calendar*.

Il y a deux sortes d'objets *date* et *time* : les « naïfs » et les « avisés ».

Un objet avisé possède suffisamment de connaissance des règles à appliquer et des politiques d'ajustement de l'heure comme les informations sur les fuseaux horaires et l'heure d'été pour se situer de façon relative par rapport à d'autres objets avisés. Un objet avisé est utilisé pour représenter un moment précis de l'histoire qui n'est pas ouvert à l'interprétation<sup>1</sup>.

A naive object does not contain enough information to unambiguously locate itself relative to other date/time objects. Whether a naive object represents Coordinated Universal Time (UTC), local time, or time in some other timezone is purely up to the program, just like it's up to the program whether a particular number represents metres, miles, or mass. Naive objects are easy to understand and to work with, at the cost of ignoring some aspects of reality.

For applications requiring aware objects, *datetime* and *time* objects have an optional time zone information attribute, *tzinfo*, that can be set to an instance of a subclass of the abstract *tzinfo* class. These *tzinfo*

---

1. Si on ignore les effets de la Relativité

objects capture information about the offset from UTC time, the time zone name, and whether Daylight Saving Time is in effect. Note that no concrete *tzinfo* classes are supplied by the *datetime* module. Supporting timezones at whatever level of detail is required is up to the application. The rules for time adjustment across the world are more political than rational, and there is no standard suitable for every application.

Le module *datetime* exporte les constantes suivantes :

`datetime.MINYEAR`

Le numéro d'année le plus petit autorisé dans un objet *date* ou *datetime*. *MINYEAR* vaut 1.

`datetime.MAXYEAR`

Le numéro d'année le plus grand autorisé dans un objet *date* ou *datetime*. *MAXYEAR* vaut 9999.

Voir aussi :

Module *calendar* Fonctions génériques associées au calendrier.

Module *time* Accès aux données d'horaires et aux conversions associées.

### 8.1.1 Types disponibles

**class `datetime.date`**

Une date naïve idéalisée, en supposant que le calendrier Grégorien actuel a toujours existé et qu'il existera toujours. Attributs : *year*, *month* et *day*.

**class `datetime.time`**

Un temps idéalisé, indépendant d'une date particulière, en supposant qu'une journée est composée d'exactly 24\*60\*60 secondes (il n'y a pas ici de notion de « seconde bissextile »). Attributs : *hour*, *minute*, *second*, *microsecond* et *tzinfo*.

**class `datetime.datetime`**

Une combinaison d'une date et d'une heure. Attributs : *year*, *month*, *day*, *hour*, *minute*, *second*, *microsecond*, et *tzinfo*.

**class `datetime.timedelta`**

Une durée qui exprime la différence entre deux instances de *date*, *time* ou *datetime* en microsecondes.

**class `datetime.tzinfo`**

Une classe de base abstraite pour les objets portant des informations sur les fuseaux horaires. Ceux-ci sont utilisés par les classes *datetime* et *time* pour donner une notion personnalisable d'ajustement d'horaire (par exemple la prise en compte d'un fuseau horaire et/ou de l'heure d'été).

Les objets issus de ces types sont immuables.

Les objets de type *date* sont toujours naïfs.

Un objet de type *time* ou *datetime* peut être naïf ou avisé. Un objet *datetime* *d* est avisé si *d.tzinfo* ne vaut pas *None* et que *d.tzinfo.utcoffset(d)* ne renvoie pas *None*. Si *d.tzinfo* vaut *None* ou que *d.tzinfo* ne vaut pas *None* mais que *d.tzinfo.utcoffset(d)* renvoie *None*, alors *d* est naïf. Un objet *time* *t* est avisé si *t.tzinfo* ne vaut pas *None* et que *t.tzinfo.utcoffset(None)* ne renvoie pas *None*. Sinon, *t* est naïf.

La distinction entre naïf et avisé ne s'applique pas aux objets de type *timedelta*.

Relations entre les sous-classes :

```
graph TD
    object --> timedelta
    object --> tzinfo
    object --> time
    object --> date
    object --> datetime
```

### 8.1.2 Objets `timedelta`

Un objet `timedelta` représente une durée, c'est-à-dire la différence entre deux dates ou heures.

```
class datetime.timedelta([days[, seconds[, microseconds[, milliseconds[, minutes[, hours[, weeks]]]]]])
```

All arguments are optional and default to 0. Arguments may be ints, longs, or floats, and may be positive or negative.

Seuls les *jours*, les *secondes* et les *microsecondes* sont stockés en interne. Tous les paramètres sont convertis dans ces unités :

- Une milliseconde est convertie en 1000 microsecondes.
- Une minute est convertie en 60 secondes.
- Une heure est convertie en 3600 secondes.
- Une semaine est convertie en 7 jours.

et ensuite les jours, secondes et microsecondes sont normalisés pour que la représentation soit unique avec

- `0 <= microseconds < 1000000`
- `0 <= secondes < 3600*24` (le nombre de secondes dans une journée)
- `-999999999 <= days <= 999999999`

If any argument is a float and there are fractional microseconds, the fractional microseconds left over from all arguments are combined and their sum is rounded to the nearest microsecond. If no argument is a float, the conversion and normalization processes are exact (no information is lost).

Si la valeur normalisée des jours déborde de l'intervalle indiqué, une `OverflowError` est levée.

Notez que la normalisation de valeurs négatives peut être surprenante au premier abord. Par exemple,

```
>>> from datetime import timedelta
>>> d = timedelta(microseconds=-1)
>>> (d.days, d.seconds, d.microseconds)
(-1, 86399, 999999)
```

Les attributs de la classe sont :

`timedelta.min`

L'objet `timedelta` le plus négatif, `timedelta(-999999999)`.

`timedelta.max`

L'objet `timedelta` le plus positif, `timedelta(days=999999999, hours=23, minutes=59, seconds=59, microseconds=999999)`.

`timedelta.resolution`

La plus petite différence entre des objets `timedelta` non égaux, `timedelta(microseconds=1)`.

Il est à noter, du fait de la normalisation, que `timedelta.max > -timedelta.min`. `-timedelta.max` n'est pas représentable sous la forme d'un objet `timedelta`.

Attributs de l'instance (en lecture seule) :

Attribut	Valeur
<code>days</code>	Entre -999999999 et 999999999 inclus
<code>seconds</code>	Entre 0 et 86399 inclus
<code>microseconds</code>	Entre 0 et 999999 inclus

Opérations supportées :

Opération	Résultat
<code>t1 = t2 + t3</code>	Somme de <i>t2</i> et <i>t3</i> . Ensuite <code>t1 - t2 == t3</code> et <code>t1 - t3 == t2</code> sont des expressions vraies. (1)
<code>t1 = t2 - t3</code>	Différence entre <i>t2</i> et <i>t3</i> . Ensuite <code>t1 == t2 - t3</code> et <code>t2 == t1 + t3</code> sont des expressions vraies. (1)
<code>t1 = t2 * i</code> or <code>t1 = i * t2</code>	Delta multiplied by an integer or long. Afterwards <code>t1 // i == t2</code> is true, provided <code>i != 0</code> .
	De manière générale, <code>t1 * i == t1 * (i-1) + t1</code> est vrai. (1)
<code>t1 = t2 // i</code>	The floor is computed and the remainder (if any) is thrown away. (3)
<code>+t1</code>	Renvoie un objet <i>timedelta</i> avec la même valeur. (2)
<code>-t1</code>	équivalent à <i>timedelta</i> (- <i>t1.days</i> , - <i>t1.seconds</i> , - <i>t1.microseconds</i> ), et à <code>t1 * -1</code> . (1)(4)
<code>abs(t)</code>	équivalent à <code>+t</code> quand <code>t.days &gt;= 0</code> , et à <code>-t</code> quand <code>t.days &lt; 0</code> . (2)
<code>str(t)</code>	Renvoie une chaîne de la forme <code>[D day[s], ] [H]H:MM:SS[.UUUUUU]</code> , où D est négatif pour <i>t</i> négatif. (5)
<code>repr(t)</code>	Renvoie une chaîne de la forme <code>datetime.timedelta(D[, S[, U]])</code> , où D est négatif pour <i>t</i> négatif. (5)

Notes :

- (1) Ceci est exact, mais peut provoquer un débordement.
- (2) Ceci est exact, et ne peut pas provoquer un débordement.
- (3) Une division par 0 provoque *ZeroDivisionError*.
- (4) *-timedelta.max* n'est pas représentable avec un objet *timedelta*.
- (5) La représentation en chaîne de caractères des objets *timedelta* est normalisée similairement à leur représentation interne. Cela amène à des résultats inhabituels pour des *timedeltas* négatifs. Par exemple :

```
>>> timedelta(hours=-5)
datetime.timedelta(-1, 68400)
>>> print(_)
-1 day, 19:00:00
```

En plus des opérations listées ci-dessus, les objets *timedelta* supportent certaines additions et soustractions avec des objets *date* et *datetime* (voir ci-dessous).

Les comparaisons entre objets *timedelta* sont maintenant supportées avec le *timedelta* représentant la plus courte durée considéré comme le plus petit. Afin d'empêcher les comparaisons de types mixtes de retomber sur la comparaison par défaut par l'adresse de l'objet, quand un objet *timedelta* est comparé à un objet de type différent, une *TypeError* est levée à moins que la comparaison soit `==` ou `!=`. Ces derniers cas renvoient respectivement *False* et *True*.

Les objets *timedelta* sont *hashable* (utilisables comme clés de dictionnaires), supportent le protocole *pickle*, et dans un contexte booléen, un *timedelta* est considéré vrai si et seulement si il n'est pas égal à *timedelta(0)*.

Méthodes de l'instance :

**timedelta.total\_seconds()**

Return the total number of seconds contained in the duration. Equivalent to `(td.microseconds + (td.seconds + td.days * 24 * 3600) * 10**6) / 10**6` computed with true division enabled.

Notez que pour des intervalles de temps très larges (supérieurs à 270 ans sur la plupart des plateformes), cette méthode perdra la précision des microsecondes.

Nouveau dans la version 2.7.

Exemple d'utilisation :

```
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> another_year = timedelta(weeks=40, days=84, hours=23,
...                           minutes=50, seconds=600) # adds up to 365 days
>>> year.total_seconds()
31536000.0
>>> year == another_year
True
>>> ten_years = 10 * year
>>> ten_years, ten_years.days // 365
(datetime.timedelta(3650), 10)
>>> nine_years = ten_years - year
>>> nine_years, nine_years.days // 365
(datetime.timedelta(3285), 9)
>>> three_years = nine_years // 3;
>>> three_years, three_years.days // 365
(datetime.timedelta(1095), 3)
>>> abs(three_years - ten_years) == 2 * three_years + year
True
```

### 8.1.3 Objets date

Un objet *date* représente une date (année, mois et jour) dans un calendrier idéal, l'actuel calendrier grégorien étendu indéfiniment dans les deux directions. Le 1er janvier de l'an 1 est appelé le jour numéro 1, le 2 janvier de l'an 1 est appelé le jour numéro 2, et ainsi de suite. Cela correspond à la définition du calendrier « grégorien proleptique » dans le livre *Calendrical Calculations* de Dershowitz et Reingold, où il est la base de tous les calculs. Référez-vous au livre pour les algorithmes de conversion entre calendriers grégorien proleptique et les autres systèmes.

**class** `datetime.date(year, month, day)`

All arguments are required. Arguments may be ints or longs, in the following ranges :

- `MINYEAR <= year <= MAXYEAR`
- `1 <= month <= 12`
- `1 <= day <= nombre de jours dans le mois et l'année donnés`

Si un argument est donné en dehors de ces intervalles, une `valueError` est levée.

Autres constructeurs, méthodes de classe :

**classmethod** `date.today()`

Renvoie la date locale courante. Cela est équivalent à `date.fromtimestamp(time.time())`.

**classmethod** `date.fromtimestamp(timestamp)`

Return the local date corresponding to the POSIX timestamp, such as is returned by `time.time()`. This may raise `ValueError`, if the timestamp is out of the range of values supported by the platform C `localtime()` function. It's common for this to be restricted to years from 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`.

**classmethod** `date.fromordinal(ordinal)`

Renvoie la date correspondant à l'ordinal grégorien proleptique, où le 1er janvier de l'an 1 a l'ordinal 1. `ValueError` est levée à moins que `1 <= ordinal <= date.max.toordinal()`. Pour toute date `d`, `date.fromordinal(d.toordinal()) == d`.

Attributs de la classe :

`date.min`

La plus vieille date représentable, `date(MINYEAR, 1, 1)`.

`date.max`

La dernière date représentable, `date(MAXYEAR, 12, 31)`.

`date.resolution`

La plus petite différence possible entre deux objets dates non-égaux, `timedelta(days=1)`.

Attributs de l'instance (en lecture seule) :

`date.year`

Entre *MINYEAR* et *MAXYEAR* inclus.

`date.month`

Entre 1 et 12 inclus.

`date.day`

Entre 1 et le nombre de jours du mois donné de l'année donnée.

Opérations supportées :

Opération	Résultat
<code>date2 = date1 + timedelta</code>	<i>date2</i> est décalée de <code>timedelta.days</code> jours par rapport à <i>date1</i> . (1)
<code>date2 = date1 - timedelta</code>	Calcule <i>date2</i> de façon à avoir <code>date2 + timedelta == date1</code> . (2)
<code>timedelta = date1 - date2</code>	(3)
<code>date1 &lt; date2</code>	<i>date1</i> est considérée comme inférieure à <i>date2</i> quand <i>date1</i> précède <i>date2</i> dans le temps. (4)

Notes :

- (1) *date2* est déplacée en avant dans le temps si `timedelta.days > 0`, ou en arrière si `timedelta.days < 0`. Après quoi `date2 - date1 == timedelta.days`, `timedelta.seconds` et `timedelta.microseconds` sont ignorés. Une *OverflowError* est levée si `date2.year` devait être inférieure à *MINYEAR* ou supérieure à *MAXYEAR*.
- (2) Cela n'est pas vraiment équivalent à `date1 + (-timedelta)`, parce que `-timedelta` isolé peut dépasser les bornes dans des cas où `date1 - timedelta` ne les dépasserait pas. `timedelta.seconds` et `timedelta.microseconds` sont ignorés.
- (3) Cela est exact, et ne peut pas dépasser les bornes. `timedelta.seconds` et `timedelta.microseconds` valent 0, et `date2 + timedelta == date1` après cela.
- (4) En d'autres termes, `date1 < date2` si et seulement si `date1.toordinal() < date2.toordinal()`. Afin d'empêcher les comparaisons de retomber sur la comparaison par défaut par l'adresse des objets, la comparaison de dates lève normalement une *TypeError* si l'autre opérande n'est pas un objet *date*. Cependant, *NotImplemented* est renvoyé à la place si l'autre opérande a un attribut `timetuple()`. Cela permet à d'autres types d'objets dates d'avoir une chance d'implémenter une comparaison entre types différents. Sinon, quand un objet *date* est comparé à un objet d'un type différent, une *TypeError* est levée à moins que la comparaison soit `==` ou `!=`. Ces derniers cas renvoient respectivement *False* et *True*.

Les dates peuvent être utilisées en tant que clés de dictionnaires. Dans un contexte booléen, tous les objets *date* sont considérés comme vrais.

Méthodes de l'instance :

`date.replace(year, month, day)`

Renvoie une date avec la même valeur, excepté pour les valeurs spécifiées par arguments nommés. Par exemple, si `d == date(2002, 12, 31)`, alors `d.replace(day=26) == date(2002, 12, 26)`.

`date.timetuple()`

Renvoie une `time.struct_time` telle que renvoyée par `time.localtime()`. Les heures, minutes et secondes valent 0, et le *flag DST* (heure d'été) est -1. `d.timetuple()` est équivalent à `time.struct_time((d.year, d.month, d.day, 0, 0, 0, d.weekday(), yday, -1))`, où `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` est le numéro du jour dans l'année courante, commençant avec 1 pour le 1er janvier.

`date.toordinal()`

Renvoie l'ordinal grégorien proleptique de la date, où le 1er janvier de l'an 1 a l'ordinal 1. Pour tout objet *date* `d`, `date.fromordinal(d.toordinal()) == d`.

`date.weekday()`

Renvoie le jour de la semaine sous forme de nombre, où lundi vaut 0 et dimanche vaut 6. Par exemple, `date(2002, 12, 4).weekday() == 2`, un mercredi. Voir aussi `isoweekday()`.

`date.isoweekday()`

Renvoie le jour de la semaine sous forme de nombre, où lundi vaut 1 et dimanche vaut 7. Par exemple, `date(2002, 12, 4).isoweekday() == 3`, un mercredi. Voir aussi `weekday()`, `isocalendar()`.

`date.isocalendar()`

Renvoie un *tuple* de 3 éléments, (année ISO, numéro de semaine ISO, jour de la semaine ISO).

Le calendrier ISO est une variante largement utilisée du calendrier grégorien. Voir <https://www.staff.science.uu.nl/~gent0113/calendar/isocalendar.htm> pour une bonne explication.

Une année ISO est composée de 52 ou 53 semaines pleines, où chaque semaine débute un lundi et se termine un dimanche. La première semaine d'une année ISO est la première semaine calendaire (grégorienne) de l'année comportant un jeudi. Elle est appelée la semaine numéro 1, et l'année ISO de ce mercredi est la même que son année grégorienne.

Par exemple, l'année 2004 débute un jeudi, donc la première semaine de l'année ISO 2004 débute le lundi 29 décembre 2003 et se termine le dimanche 4 janvier 2004, ainsi `date(2003, 12, 29).isocalendar() == (2004, 1, 1)` et `date(2004, 1, 4).isocalendar() == (2004, 1, 7)`.

`date.isoformat()`

Renvoie une chaîne de caractères représentant la date au format ISO 8601, « YYYY-MM-DD ». Par exemple, `date(2002, 12, 4).isoformat() == '2002-12-04'`.

`date.__str__()`

Pour une date `d`, `str(d)` est équivalent à `d.isoformat()`.

`date.ctime()`

Renvoie une chaîne de caractères représentant la date, par exemple `date(2002, 12, 4).ctime() == 'Wed Dec 4 00:00:00 2002'`. `d.ctime()` est équivalent à `time.ctime(time.mktime(d.timetuple()))` sur les plateformes où la fonction C native `ctime()` (que `time.ctime()` invoque, mais pas `date.ctime()`) est conforme au standard C.

`date.strftime(format)`

Return a string representing the date, controlled by an explicit format string. Format codes referring to hours, minutes or seconds will see 0 values. For a complete list of formatting directives, see section *Comportement de strftime() et strptime()*.

`date.__format__(format)`

Same as `date.strftime()`. This makes it possible to specify a format string for a *date* object when using `str.format()`. See section *Comportement de strftime() et strptime()*.

Exemple de décompte des jours avant un événement :

```
>>> import time
>>> from datetime import date
>>> today = date.today()
>>> today
datetime.date(2007, 12, 5)
>>> today == date.fromtimestamp(time.time())
True
>>> my_birthday = date(today.year, 6, 24)
>>> if my_birthday < today:
...     my_birthday = my_birthday.replace(year=today.year + 1)
>>> my_birthday
datetime.date(2008, 6, 24)
>>> time_to_birthday = abs(my_birthday - today)
>>> time_to_birthday.days
202
```

Exemple d'utilisation de la classe `date` :

```
>>> from datetime import date
>>> d = date.fromordinal(730920) # 730920th day after 1. 1. 0001
>>> d
datetime.date(2002, 3, 11)
>>> t = d.timetuple()
>>> for i in t:
...     print i
2002                # year
3                   # month
11                  # day
0
0
0
0                   # weekday (0 = Monday)
70                  # 70th day in the year
-1
>>> ic = d.isocalendar()
>>> for i in ic:
...     print i
2002                # ISO year
11                  # ISO week number
1                   # ISO day number ( 1 = Monday )
>>> d.isoformat()
'2002-03-11'
>>> d.strftime("%d/%m/%y")
'11/03/02'
>>> d.strftime("%A %d. %B %Y")
'Monday 11. March 2002'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}.'.format(d, "day", "month")
'The day is 11, the month is March.'
```

### 8.1.4 Objets `datetime`

Un objet `datetime` est un objet comportant toutes les informations d'un objet `date` et d'un objet `time`. Comme un objet `date`, un objet `datetime` utilise l'actuel calendrier Grégorien étendu vers le passé et le

futur ; comme un objet `time`, un objet `datetime` suppose qu'il y a exactement 3600\*24 secondes chaque jour.

Constructeur :

```
class datetime.datetime(year, month, day[, hour[, minute[, second[, microsecond[, tzinfo]]]]])
```

The year, month and day arguments are required. *tzinfo* may be `None`, or an instance of a *tzinfo* subclass. The remaining arguments may be ints or longs, in the following ranges :

- `MINYEAR <= year <= MAXYEAR`
- `1 <= month <= 12`
- `1 <= day <= nombre de jours dans le mois et l'année donnés`
- `0 <= hour < 24`
- `0 <= minute < 60`
- `0 <= second < 60`
- `0 <= microsecond < 1000000`

Si un argument est donné en dehors de ces intervalles, une `valueError` est levée.

Autres constructeurs, méthodes de classe :

```
classmethod datetime.today()
```

Renvoie le *datetime* local courant, avec *tzinfo* à `None`. Cela est équivalent à `datetime.fromtimestamp(time.time())`. Voir aussi `now()`, `fromtimestamp()`.

```
classmethod datetime.now([tz])
```

Renvoie la date et l'heure courantes locales. Si l'argument optionnel *tz* est `None` ou n'est pas spécifié, la méthode est similaire à `today()`, mais, si possible, apporte plus de précisions que ce qui peut être trouvé à travers un *timestamp* `time.time()` (par exemple, cela peut être possible sur des plateformes fournissant la fonction C `gettimeofday()`).

Si *tz* n'est pas `None`, il doit être une instance d'une sous-classe *tzinfo*, et la date et l'heure courantes sont converties vers le fuseau horaire *tz*. Dans ce cas le résultat est équivalent à `tz.fromutc(datetime.utcnow().replace(tzinfo=tz))`. Voir aussi `today()`, `utcnow()`.

```
classmethod datetime.utcnow()
```

Return the current UTC date and time, with *tzinfo* `None`. This is like `now()`, but returns the current UTC date and time, as a naive *datetime* object. See also `now()`.

```
classmethod datetime.fromtimestamp(timestamp[, tz])
```

Renvoie la date et l'heure locales correspondant au *timestamp* *POSIX*, comme renvoyé par `time.time()`. Si l'argument optionnel *tz* est `None` ou n'est pas spécifié, le *timestamp* est converti vers la date et l'heure locales de la plateforme, et l'objet *datetime* renvoyé est naïf.

Si *tz* n'est pas `None`, il doit être une instance d'une sous-classe *tzinfo*, et le *timestamp* est converti vers le fuseau horaire *tz*. Dans ce cas le résultat est équivalent à `tz.fromutc(datetime.utcfromtimestamp(timestamp).replace(tzinfo=tz))`.

`fromtimestamp()` may raise `ValueError`, if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions. It's common for this to be restricted to years in 1970 through 2038. Note that on non-*POSIX* systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`, and then it's possible to have two timestamps differing by a second that yield identical *datetime* objects. See also `utcfromtimestamp()`.

```
classmethod datetime.utcfromtimestamp(timestamp)
```

Return the UTC *datetime* corresponding to the *POSIX* timestamp, with *tzinfo* `None`. This may raise `ValueError`, if the timestamp is out of the range of values supported by the platform C `gmtime()` function. It's common for this to be restricted to years in 1970 through 2038. See also `fromtimestamp()`.

```
classmethod datetime.fromordinal(ordinal)
```

Renvoie le *datetime* correspondant à l'ordinal du calendrier grégorien proleptique, où le 1er janvier de l'an 1 a l'ordinal 1. Une `ValueError` est levée à moins que `1 <= ordinal <= datetime.max.toordinal()`. Les heures, minutes, secondes et microsecondes du résultat valent toutes 0, et *tzinfo* est `None`.

**classmethod** `datetime.combine(date, time)`

Return a new *datetime* object whose date components are equal to the given *date* object's, and whose time components and *tzinfo* attributes are equal to the given *time* object's. For any *datetime* object *d*, `d == datetime.combine(d.date(), d.timetz())`. If *date* is a *datetime* object, its time components and *tzinfo* attributes are ignored.

**classmethod** `datetime.strptime(date_string, format)`

Return a *datetime* corresponding to *date\_string*, parsed according to *format*. This is equivalent to `datetime(*(time.strptime(date_string, format)[0:6]))`. *ValueError* is raised if the *date\_string* and *format* can't be parsed by *time.strptime()* or if it returns a value which isn't a time tuple. For a complete list of formatting directives, see section *Comportement de strptime() et strptime()*.

Nouveau dans la version 2.5.

Attributs de la classe :

`datetime.min`

Le plus ancien *datetime* représentable, `datetime(MINYEAR, 1, 1, tzinfo=None)`.

`datetime.max`

Le dernier *datetime* représentable, `datetime(MAXYEAR, 12, 31, 23, 59, 59, 999999, tzinfo=None)`.

`datetime.resolution`

La plus petite différence possible entre deux objets *datetime* non-égaux, `timedelta(microseconds=1)`.

Attributs de l'instance (en lecture seule) :

`datetime.year`

Entre *MINYEAR* et *MAXYEAR* inclus.

`datetime.month`

Entre 1 et 12 inclus.

`datetime.day`

Entre 1 et le nombre de jours du mois donné de l'année donnée.

`datetime.hour`

Dans `range(24)`.

`datetime.minute`

Dans `range(60)`.

`datetime.second`

Dans `range(60)`.

`datetime.microsecond`

Dans `range(1000000)`.

`datetime.tzinfo`

L'objet passé en tant que paramètre *tzinfo* du constructeur de la classe *datetime* ou *None* si aucun n'a été donné.

Opérations supportées :

Opération	Résultat
<code>datetime2 = datetime1 + timedelta</code>	(1)
<code>datetime2 = datetime1 - timedelta</code>	(2)
<code>timedelta = datetime1 - datetime2</code>	(3)
<code>datetime1 &lt; datetime2</code>	Compare <i>datetime</i> à <i>datetime</i> . (4)

- (1) *datetime2* est décalé d'une durée *timedelta* par rapport à *datetime1*, en avant dans le temps si *timedelta.days > 0*, ou en arrière si *timedelta.days < 0*. Le résultat a le même attribut *tzinfo* que le *datetime* d'entrée, et *datetime2 - datetime1 == timedelta* après l'opération. Une *OverflowError* est levée si *datetime2.year* devait être inférieure à *MINYEAR* ou supérieure à *MAXYEAR*. Notez qu'aucun ajustement de fuseau horaire n'est réalisé même si l'entrée est avisée.
- (2) Calcule *datetime2* tel que *datetime2 + timedelta == datetime1*. Comme pour l'addition, le résultat a le même attribut *tzinfo* que le *datetime* d'entrée, et aucun ajustement de fuseau horaire n'est réalisé même si l'entrée est avisée. Ce n'est pas vraiment équivalent à *datetime1 + (-timedelta)*, parce que *-timedelta* isolé peut déborder dans des cas où *datetime1 - timedelta* ne déborde pas.
- (3) La soustraction d'un *datetime* à un autre *datetime* n'est définie que si les deux opérandes sont naïfs, ou s'ils sont les deux avisés. Si l'un est avisé et que l'autre est naïf, une *TypeError* est levée.  
Si les deux sont naïfs, ou que les deux sont avisés et ont le même attribut *tzinfo*, les attributs *tzinfo* sont ignorés, et le résultat est un objet *timedelta t* tel que *datetime2 + t == datetime1*. Aucun ajustement de fuseau horaire n'a lieu dans ce cas.  
Si les deux sont avisés mais ont des attributs *tzinfo* différents, *a-b* agit comme si *a* et *b* étaient premièrement convertis vers des *datetimes* UTC naïfs. Le résultat est *(a.replace(tzinfo=None) - a.utcoffset()) - (b.replace(tzinfo=None) - b.utcoffset())* à l'exception que l'implémentation ne produit jamais de débordement.
- (4) *datetime1* est considéré inférieur à *datetime2* quand il le précède dans le temps.  
If one comparand is naive and the other is aware, *TypeError* is raised. If both comparands are aware, and have the same *tzinfo* attribute, the common *tzinfo* attribute is ignored and the base datetimes are compared. If both comparands are aware and have different *tzinfo* attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from *self.utcoffset()*).

---

**Note :** Afin d'empêcher la comparaison de retomber sur le schéma par défaut de comparaison des adresses des objets, la comparaison *datetime* lève normalement une *TypeError* si l'autre opérande n'est pas aussi un objet *datetime*. Cependant, *NotImplemented* est renvoyé à la place si l'autre opérande a un attribut *timetuple()*. Cela permet à d'autres types d'objets dates d'implémenter la comparaison entre types mixtes. Sinon, quand un objet *datetime* est comparé à un objet d'un type différent, une *TypeError* est levée à moins que la comparaison soit *==* ou *!=*. Ces derniers cas renvoient respectivement *False* et *True*.

---

Les objets *datetime* peuvent être utilisés comme clés de dictionnaires. Dans les contextes booléens, tous les objets *datetime* sont considérés vrais.

Méthodes de l'instance :

**datetime.date()**

Renvoie un objet *date* avec les mêmes année, mois et jour.

**datetime.time()**

Return *time* object with same hour, minute, second and microsecond. *tzinfo* is None. See also method *timetz()*.

**datetime.timetz()**

Return *time* object with same hour, minute, second, microsecond, and *tzinfo* attributes. See also method *time()*.

**datetime.replace([year[, month[, day[, hour[, minute[, second[, microsecond[, tzinfo]]]]]]]))**

Renvoie un *datetime* avec les mêmes attributs, exceptés ceux dont de nouvelles valeurs sont données par les arguments nommés correspondant. Notez que *tzinfo=None* peut être spécifié pour créer un *datetime* naïf depuis un *datetime* avisé sans conversion de la date ou de l'heure.

`datetime.astimezone(tz)`

Renvoie un objet *datetime* avec un nouvel attribut *tzinfo* valant *tz*, ajustant la date et l'heure pour que le résultat soit le même temps UTC que *self*, mais dans le temps local au fuseau *tz*.

*tz* must be an instance of a *tzinfo* subclass, and its *utcoffset()* and *dst()* methods must not return *None*. *self* must be aware (*self.tzinfo* must not be *None*, and *self.utcoffset()* must not return *None*).

If *self.tzinfo* is *tz*, *self.astimezone(tz)* is equal to *self* : no adjustment of date or time data is performed. Else the result is local time in time zone *tz*, representing the same UTC time as *self* : after *astz = dt.astimezone(tz)*, *astz - astz.utcoffset()* will usually have the same date and time data as *dt - dt.utcoffset()*. The discussion of class *tzinfo* explains the cases at Daylight Saving Time transition boundaries where this cannot be achieved (an issue only if *tz* models both standard and daylight time).

Si vous voulez seulement associer un fuseau horaire *tz* à un *datetime dt* sans ajustement des données de date et d'heure, utilisez *dt.replace(tzinfo=tz)*. Si vous voulez seulement supprimer le fuseau horaire d'un *datetime dt* avisé sans conversion des données de date et d'heure, utilisez *dt.replace(tzinfo=None)*.

Notez que la méthode par défaut *tzinfo.fromutc()* peut être redéfinie dans une sous-classe *tzinfo* pour affecter le résultat renvoyé par *astimezone()*. En ignorant les cas d'erreurs, *astimezone()* se comporte comme :

```
def astimezone(self, tz):
    if self.tzinfo is tz:
        return self
    # Convert self to UTC, and attach the new time zone object.
    utc = (self - self.utcoffset()).replace(tzinfo=tz)
    # Convert from UTC to tz's local time.
    return tz.fromutc(utc)
```

`datetime.utcoffset()`

Si *tzinfo* est *None*, renvoie *None*, sinon renvoie *self.tzinfo.utcoffset(self)*, et lève une exception si l'expression précédente ne renvoie pas *None* ou un objet *timedelta* représentant un nombre entier de minutes de magnitude inférieure à un jour.

`datetime.dst()`

Si *tzinfo* est *None*, renvoie *None*, sinon renvoie *self.tzinfo.dst(self)*, et lève une exception si l'expression précédente ne renvoie pas *None* ou un objet *timedelta* représentant un nombre entier de minutes de magnitude inférieure à un jour.

`datetime.tzname()`

Si *tzinfo* est *None*, renvoie *None*, sinon renvoie *self.tzinfo.tzname(self)*, lève une exception si l'expression précédente ne renvoie pas *None* ou une chaîne de caractères.

`datetime.timetuple()`

Renvoie un *time.struct\_time* comme renvoyé par *time.localtime()*. *d.timetuple()* est équivalent à *time.struct\_time((d.year, d.month, d.day, d.hour, d.minute, d.second, d.weekday(), yday, dst))*, où *yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1* est le numéro de jour dans l'année courante commençant avec 1 pour le 1er janvier. L'option *tm\_isdst* du résultat est attribuée selon la méthode *dst()* : si *tzinfo* est *None* ou que *dst()* renvoie *None*, *tm\_isdst* est mise à -1 ; sinon, si *dst()* renvoie une valeur non-nulle, *tm\_isdst* est mise à 1 ; sinon *tm\_isdst* est mise à 0.

`datetime.utctimetuple()`

Si l'instance de *datetime d* est naïve, cela est équivalent à *d.timetuple()*, excepté que *tm\_isdst* est forcé à 0 sans tenir compte de ce que renvoie *d.dst()*. L'heure d'été n'est jamais effective pour un temps UTC.

If *d* is aware, *d* is normalized to UTC time, by subtracting `d.utcoffset()`, and a `time.struct_time` for the normalized time is returned. `tm_isdst` is forced to 0. Note that the result's `tm_year` member may be `MINYEAR-1` or `MAXYEAR+1`, if *d*.year was `MINYEAR` or `MAXYEAR` and UTC adjustment spills over a year boundary.

`datetime.toordinal()`

Renvoie l'ordinal du calendrier géorgien proleptique de cette date. Identique à `self.date().toordinal()`.

`datetime.weekday()`

Renvoie le jour de la semaine sous forme de nombre, où lundi vaut 0 et dimanche vaut 6. Identique à `self.date().weekday()`. Voir aussi `isoweekday()`.

`datetime.isoweekday()`

Renvoie le jour de la semaine sous forme de nombre, où lundi vaut 1 et dimanche vaut 7. Identique à `self.date().isoweekday()`. Voir aussi `weekday()`, `isocalendar()`.

`datetime.isocalendar()`

Renvoie un *tuple* de 3 éléments, (année ISO, numéro de semaine ISO, jour de la semaine ISO). Identique à `self.date().isocalendar()`.

`datetime.isoformat([sep])`

Renvoie une chaîne représentant la date et l'heure au format ISO 8601, `YYYY-MM-DDTHH:MM:SS.mmmmmmm` ou, si `microsecond` vaut 0, `YYYY-MM-DDTHH:MM:SS`

Si `utcoffset()` ne renvoie pas `None`, une chaîne de 6 caractères est ajoutée, donnant le décalage UTC en heures et minutes (relatives) : `YYYY-MM-DDTHH:MM:SS.mmmmmmm+HH:MM` ou, si `microsecond` vaut 0, `YYYY-MM-DDTHH:MM:SS+HH:MM`

L'argument optionnel *sep* (valant par défaut 'T') est un séparateur d'un caractère, placé entre les portions du résultat correspondant à la date et à l'heure. Par exemple,

```
>>> from datetime import tzinfo, timedelta, datetime
>>> class TZ(tzinfo):
...     def utcoffset(self, dt): return timedelta(minutes=-399)
...
>>> datetime(2002, 12, 25, tzinfo=TZ()).isoformat(' ')
'2002-12-25 00:00:00-06:39'
```

`datetime.__str__()`

Pour une instance *d* de `datetime`, `str(d)` est équivalent à `d.isoformat(' ')`.

`datetime.ctime()`

Renvoie une chaîne représentant la date et l'heure, par exemple `datetime(2002, 12, 4, 20, 30, 40).ctime() == 'Wed Dec 4 20:30:40 2002'`. `d.ctime()` est équivalent à `time.ctime(time.mktime(d.timetuple()))` sur les plateformes où la fonction C native `ctime()` (invoquée par `time.ctime()` mais pas par `datetime.ctime()`) est conforme au standard C.

`datetime.strftime(format)`

Return a string representing the date and time, controlled by an explicit format string. For a complete list of formatting directives, see section *Comportement de strftime() et strptime()*.

`datetime.__format__(format)`

Same as `datetime.strftime()`. This makes it possible to specify a format string for a `datetime` object when using `str.format()`. See section *Comportement de strftime() et strptime()*.

Exemples d'utilisation des objets `datetime` :

```
>>> from datetime import datetime, date, time
>>> # Using datetime.combine()
```

(suite sur la page suivante)

(suite de la page précédente)

```

>>> d = date(2005, 7, 14)
>>> t = time(12, 30)
>>> datetime.combine(d, t)
datetime.datetime(2005, 7, 14, 12, 30)
>>> # Using datetime.now() or datetime.utcnow()
>>> datetime.now()
datetime.datetime(2007, 12, 6, 16, 29, 43, 79043)    # GMT +1
>>> datetime.utcnow()
datetime.datetime(2007, 12, 6, 15, 29, 43, 79060)
>>> # Using datetime.strptime()
>>> dt = datetime.strptime("21/11/06 16:30", "%d/%m/%y %H:%M")
>>> dt
datetime.datetime(2006, 11, 21, 16, 30)
>>> # Using datetime.timetuple() to get tuple of all attributes
>>> tt = dt.timetuple()
>>> for it in tt:
...     print it
...
2006    # year
11      # month
21      # day
16      # hour
30      # minute
0       # second
1       # weekday (0 = Monday)
325     # number of days since 1st January
-1      # dst - method tzinfo.dst() returned None
>>> # Date in ISO format
>>> ic = dt.isocalendar()
>>> for it in ic:
...     print it
...
2006    # ISO year
47      # ISO week
2       # ISO weekday
>>> # Formatting datetime
>>> dt.strftime("%A, %d. %B %Y %I:%M%p")
'Tuesday, 21. November 2006 04:30PM'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}, the {3} is {0:%I:%M%p}.'.format(dt, "day",
↪ "month", "time")
'The day is 21, the month is November, the time is 04:30PM.'

```

Utilisation de *datetime* avec *tzinfo* :

```

>>> from datetime import timedelta, datetime, tzinfo
>>> class GMT1(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=1) + self.dst(dt)
...     def dst(self, dt):
...         # DST starts last Sunday in March
...         d = datetime(dt.year, 4, 1)    # ends last Sunday in October
...         self.dston = d - timedelta(days=d.weekday() + 1)

```

(suite sur la page suivante)

(suite de la page précédente)

```

...     d = datetime(dt.year, 11, 1)
...     self.dstoff = d - timedelta(days=d.weekday() + 1)
...     if self.dston <= dt.replace(tzinfo=None) < self.dstoff:
...         return timedelta(hours=1)
...     else:
...         return timedelta(0)
...     def tzname(self,dt):
...         return "GMT +1"
...
>>> class GMT2(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=2) + self.dst(dt)
...     def dst(self, dt):
...         d = datetime(dt.year, 4, 1)
...         self.dston = d - timedelta(days=d.weekday() + 1)
...         d = datetime(dt.year, 11, 1)
...         self.dstoff = d - timedelta(days=d.weekday() + 1)
...         if self.dston <= dt.replace(tzinfo=None) < self.dstoff:
...             return timedelta(hours=1)
...         else:
...             return timedelta(0)
...     def tzname(self,dt):
...         return "GMT +2"
...
>>> gmt1 = GMT1()
>>> # Daylight Saving Time
>>> dt1 = datetime(2006, 11, 21, 16, 30, tzinfo=gmt1)
>>> dt1.dst()
datetime.timedelta(0)
>>> dt1.utcoffset()
datetime.timedelta(0, 3600)
>>> dt2 = datetime(2006, 6, 14, 13, 0, tzinfo=gmt1)
>>> dt2.dst()
datetime.timedelta(0, 3600)
>>> dt2.utcoffset()
datetime.timedelta(0, 7200)
>>> # Convert datetime to another time zone
>>> dt3 = dt2.astimezone(GMT2())
>>> dt3      # doctest: +ELLIPSIS
datetime.datetime(2006, 6, 14, 14, 0, tzinfo=<GMT2 object at 0x...>)
>>> dt2      # doctest: +ELLIPSIS
datetime.datetime(2006, 6, 14, 13, 0, tzinfo=<GMT1 object at 0x...>)
>>> dt2.utctimetuple() == dt3.utctimetuple()
True

```

### 8.1.5 time Objects

Un objet *time* représente une heure (locale) du jour, indépendante de tout jour particulier, et sujette à des ajustements par un objet *tzinfo*.

```
class datetime.time([hour[, minute[, second[, microsecond[, tzinfo]]]]])
```

All arguments are optional. *tzinfo* may be None, or an instance of a *tzinfo* subclass. The remaining arguments may be ints or longs, in the following ranges :

```
— 0 <= hour < 24
— 0 <= minute < 60
— 0 <= second < 60
— 0 <= microsecond < 1000000.
```

Si un argument est fourni en dehors de ces bornes, une *ValueError* est levée. Ils valent tous 0 par défaut, à l'exception de *tzinfo* qui vaut *None*.

Attributs de la classe :

**time.min**

Le plus petit objet *time* représentable, `time(0, 0, 0, 0)`.

**time.max**

Le plus grand objet *time* représentable, `time(23, 59, 59, 999999)`.

**time.resolution**

La plus petite différence possible entre deux objets *time* non-égaux, `timedelta(microseconds=1)`, notez cependant que les objets *time* ne supportent pas d'opérations arithmétiques.

Attributs de l'instance (en lecture seule) :

**time.hour**

Dans `range(24)`.

**time.minute**

Dans `range(60)`.

**time.second**

Dans `range(60)`.

**time.microsecond**

Dans `range(1000000)`.

**time.tzinfo**

L'objet passé comme argument *tzinfo* au constructeur de *time*, ou *None* si aucune valeur n'a été passée.

Opérations supportées :

- comparison of *time* to *time*, where *a* is considered less than *b* when *a* precedes *b* in time. If one comparand is naive and the other is aware, *TypeError* is raised. If both comparands are aware, and have the same *tzinfo* attribute, the common *tzinfo* attribute is ignored and the base times are compared. If both comparands are aware and have different *tzinfo* attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`). In order to stop mixed-type comparisons from falling back to the default comparison by object address, when a *time* object is compared to an object of a different type, *TypeError* is raised unless the comparison is `==` or `!=`. The latter cases return *False* or *True*, respectively.
- hachage, utilisation comme clef de dictionnaire
- sérialisation (*pickling*) efficace
- in Boolean contexts, a *time* object is considered to be true if and only if, after converting it to minutes and subtracting `utcoffset()` (or 0 if that's *None*), the result is non-zero.

Méthodes de l'instance :

**time.replace([hour[, minute[, second[, microsecond[, tzinfo]]]])**

Renvoie un objet *time* avec la même valeur, à l'exception des attributs dont une nouvelle valeur est spécifiée par les arguments nommés. Notez que `tzinfo=None` peut être spécifié pour créer une instance *time* naïve à partir d'une instance *time* avisée, sans conversion des données de temps.

**time.isoformat()**

Return a string representing the time in ISO 8601 format, HH :MM :SS.mmmmmmm or, if `self.microsecond` is 0, HH :MM :SS If `utcoffset()` does not return *None*, a 6-character string is ap-

pended, giving the UTC offset in (signed) hours and minutes : HH :MM :SS.mmmmmmm+HH :MM or, if self.microsecond is 0, HH :MM :SS+HH :MM

`time.__str__()`

Pour un temps `t`, `str(t)` est équivalent à `t.isoformat()`.

`time.strftime(format)`

Return a string representing the time, controlled by an explicit format string. For a complete list of formatting directives, see section *Comportement de strftime() et strptime()*.

`time.__format__(format)`

Same as `time.strftime()`. This makes it possible to specify a format string for a `time` object when using `str.format()`. See section *Comportement de strftime() et strptime()*.

`time.utcoffset()`

Si `tzinfo` est `None`, renvoie `None`, sinon renvoie `self.tzinfo.utcoffset(None)`, et lève une exception si l'expression précédente ne renvoie pas `None` ou un objet `timedelta` représentant un nombre entier de minutes de magnitude inférieure à un jour.

`time.dst()`

Si `tzinfo` est `None`, renvoie `None`, sinon renvoie `self.tzinfo.dst(None)`, et lève une exception si l'expression précédente ne renvoie pas `None` ou un objet `timedelta` représentant un nombre entier de minutes de magnitude inférieure à un jour.

`time.tzname()`

Si `tzinfo` est `None`, renvoie `None`, sinon renvoie `self.tzinfo.tzname(None)`, et lève une exception si l'expression précédente ne renvoie pas `None` ou une chaîne de caractères.

Exemple :

```
>>> from datetime import time, tzinfo, timedelta
>>> class GMT1(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=1)
...     def dst(self, dt):
...         return timedelta(0)
...     def tzname(self, dt):
...         return "Europe/Prague"
...
>>> t = time(12, 10, 30, tzinfo=GMT1())
>>> t                                     # doctest: +ELLIPSIS
datetime.time(12, 10, 30, tzinfo=<GMT1 object at 0x...>)
>>> gmt = GMT1()
>>> t.isoformat()
'12:10:30+01:00'
>>> t.dst()
datetime.timedelta(0)
>>> t.tzname()
'Europe/Prague'
>>> t.strftime("%H:%M:%S %Z")
'12:10:30 Europe/Prague'
>>> 'The {} is {:%H:%M}.'.format("time", t)
'The time is 12:10.'
```

### 8.1.6 Objets `tzinfo`

`class datetime.tzinfo`

This is an abstract base class, meaning that this class should not be instantiated directly. You need to derive a concrete subclass, and (at least) supply implementations of the standard `tzinfo` methods needed by the `datetime` methods you use. The `datetime` module does not supply any concrete subclasses of `tzinfo`.

Une instance (d'une sous-classe concrète) de `tzinfo` peut être passée aux constructeurs des objets `datetime` et `time`. Les objets en question voient leurs attributs comme étant en temps local, et l'objet `tzinfo` contient des méthodes pour obtenir le décalage du temps local par rapport à UTC, le nom du fuseau horaire, le décalage d'heure d'été, tous relatifs à un objet de date ou d'heure qui leur est passé.

Prérequis spécifique au *pickling* : Une sous-classe `tzinfo` doit avoir une méthode `__init__()` qui peut être appelée sans arguments, sans quoi un objet sérialisé ne pourrait pas toujours être désérialisé. C'est un prérequis technique qui pourrait être assoupli dans le futur.

Une sous-classe concrète de `tzinfo` peut devoir implémenter les méthodes suivantes. Les méthodes réellement nécessaires dépendent de l'utilisation qui est faite des objets `datetime` avisés. Dans le doute, implémentez-les toutes.

`tzinfo.utcoffset(self, dt)`

Renvoie le décalage entre le temps local et UTC, en minutes vers l'est d'UTC. Si le temps local se situe à l'ouest d'UTC, le décalage devrait être négatif. Notez que cela est prévu pour être le décalage total par rapport à UTC ; par exemple, si un objet `tzinfo` représente à la fois un fuseau horaire et son ajustement à l'heure d'été, `utcoffset()` devrait renvoyer leur somme. Si le décalage UTC n'est pas connu, renvoie `None`. Sinon, la valeur renvoyée doit être un objet `timedelta` spécifiant un nombre entier de minutes dans l'intervalle de -1439 à 1439 inclus ( $1440 = 24 \times 60$  ; la magnitude du décalage doit être inférieure à un jour). La plupart des implémentations de `utcoffset()` ressembleront probablement à l'une des deux suivantes :

```
return CONSTANT                # fixed-offset class
return CONSTANT + self.dst(dt) # daylight-aware class
```

Si `utcoffset()` ne renvoie pas `None`, `dst()` ne doit pas non plus renvoyer `None`.

L'implémentation par défaut de `utcoffset()` lève une `NotImplementedError`.

`tzinfo.dst(self, dt)`

Renvoie l'ajustement d'heure d'été (DST, *daylight saving time*), en minutes vers l'est d'UTC, ou `None` si l'information n'est pas connue. Renvoie `timedelta(0)` si l'heure d'été n'est pas effective. Si elle est effective, renvoie un décalage sous forme d'un objet `timedelta` (voir `utcoffset()` pour les détails). Notez que ce décalage, si applicable, est déjà compris dans le décalage UTC renvoyé par `utcoffset()`, il n'est donc pas nécessaire de faire appel à `dst()` à moins que vous ne souhaitiez obtenir les informations séparément. Par exemple, `datetime.timetuple()` appelle la méthode `dst()` de son attribut `tzinfo` pour déterminer si l'option `tm_isdst` doit être activée, et `tzinfo.fromutc()` fait appel à `dst()` pour tenir compte des heures d'été quand elle traverse des fuseaux horaires.

Une instance `tz` d'une sous-classe `tzinfo` convenant à la fois pour une heure standard et une heure d'été doit être cohérente :

`tz.utcoffset(dt) - tz.dst(dt)`

doit renvoyer le même résultat pour tout objet `datetime dt` avec `dt.tzinfo == tz`. Pour les sous-classes saines de `tzinfo`, cette expression calcule le « décalage standard » du fuseau horaire, qui ne doit pas dépendre de la date ou de l'heure, mais seulement de la position géographique. L'implémentation de `datetime.astimezone()` se base là-dessus, mais ne peut pas détecter les violations ; il est de la responsabilité du programmeur de l'assurer. Si une sous-classe `tzinfo` ne le garantit pas, il doit être possible de redéfinir l'implémentation par défaut de `tzinfo.fromutc()` pour tout de même fonctionner correctement avec `astimezone()`.

La plupart des implémentations de `dst()` ressembleront probablement à l'une des deux suivantes :

```
def dst(self, dt):
    # a fixed-offset class: doesn't account for DST
    return timedelta(0)
```

ou :

```
def dst(self, dt):
    # Code to set dston and dstoff to the time zone's DST
    # transition times based on the input dt.year, and expressed
    # in standard local time. Then

    if dston <= dt.replace(tzinfo=None) < dstoff:
        return timedelta(hours=1)
    else:
        return timedelta(0)
```

L'implémentation par défaut de `dst()` lève une `NotImplementedError`.

`tzinfo.tzname(self, dt)`

Renvoie le nom du fuseau horaire correspondant à l'objet `datetime` `dt`, sous forme d'une chaîne de caractères. rien n'est défini sur les noms par le module `datetime`, et il n'est pas nécessaire que ces noms signifient quelque chose en particulier. Par exemple, « `GMT` », « `UTC` », « `-500` », « `-5:00` », « `EDT` », « `US/Eastern` » et « `America/New York` » sont toutes des valeurs de retour valides. Renvoie `None` si un nom est inconnu. Notez qu'il s'agit d'une méthode et non d'une chaîne fixée en amont, parce que les sous-classes de `tzinfo` peuvent souhaiter renvoyer des noms différents en fonction de valeurs de `dt` spécifiques, en particulier si la classe `tzinfo` tient compte de l'heure d'été.

L'implémentation par défaut de `tzname()` lève une `NotImplementedError`.

Ces méthodes sont appelées par les objets `datetime` et `time`, en réponse à leurs méthodes aux mêmes noms. Un objet `datetime` se passe lui-même en tant qu'argument, et un objet `time` passe `None`. Les méthodes des sous-classes `tzinfo` doivent alors être prêtes à recevoir un argument `None` pour `dt`, ou une instance de `datetime`.

Quand `None` est passé, il est de la responsabilité du designer de la classe de choisir la meilleure réponse. Par exemple, renvoyer `None` est approprié si la classe souhaite signaler que les objets de temps ne participent pas au protocole `tzinfo`. Il peut être plus utile pour `utcoffset(None)` de renvoyer le décalage UTC standard, comme il n'existe aucune autre convention pour obtenir ce décalage.

Quand un objet `datetime` est passé en réponse à une méthode de `datetime`, `dt.tzinfo` est le même objet que `self`. Les méthodes de `tzinfo` peuvent se baser là-dessus, à moins que le code utilisateur appelle directement des méthodes de `tzinfo`. L'intention est que les méthodes de `tzinfo` interprètent `dt` comme étant le temps local, et n'aient pas à se soucier des objets dans d'autres fuseaux horaires.

Il y a une dernière méthode de `tzinfo` que les sous-classes peuvent vouloir redéfinir :

`tzinfo.fromutc(self, dt)`

Elle est appelée par l'implémentation par défaut de `datetime.astimezone()`. Quand appelée depuis cette méthode, `dt.tzinfo` est `self`, et les données de date et d'heure de `dt` sont vues comme exprimant un temps UTC. Le rôle de `fromutc()` est d'ajuster les données de date et d'heure, renvoyant un objet `datetime` équivalent à `self`, dans le temps local.

La plupart des sous-classes `tzinfo` doivent être en mesure d'hériter sans problème de l'implémentation par défaut de `fromutc()`. Elle est suffisamment robuste pour gérer les fuseaux horaires à décalage fixe, et les fuseaux représentant à la fois des heures standards et d'été, et ce même si le décalage de l'heure d'été est différent suivant les années. Un exemple de fuseau horaire qui ne serait pas géré correctement dans tous les cas par l'implémentation par défaut de `fromutc()` en est un où le décalage standard (par rapport à UTC) dépend de valeurs spécifiques de date et d'heure passées, ce qui peut arriver pour

des raisons politiques. Les implémentations par défaut de `astimezone()` et `fromutc()` peuvent ne pas produire les résultats attendus si le résultat est l'une des heures affectées par le changement d'heure. En omettant le code des cas d'erreurs, l'implémentation par défaut de `fromutc()` se comporte comme suit :

```
def fromutc(self, dt):
    # raise ValueError error if dt.tzinfo is not self
    dtoff = dt.utcoffset()
    dtdst = dt.dst()
    # raise ValueError if dtoff is None or dtdst is None
    delta = dtoff - dtdst # this is self's standard offset
    if delta:
        dt += delta # convert to standard local time
        dtdst = dt.dst()
        # raise ValueError if dtdst is None
    if dtdst:
        return dt + dtdst
    else:
        return dt
```

Exemple de classes `tzinfo` :

```
from datetime import tzinfo, timedelta, datetime

ZERO = timedelta(0)
HOUR = timedelta(hours=1)

# A UTC class.

class UTC(tzinfo):
    """UTC"""

    def utcoffset(self, dt):
        return ZERO

    def tzname(self, dt):
        return "UTC"

    def dst(self, dt):
        return ZERO

utc = UTC()

# A class building tzinfo objects for fixed-offset time zones.
# Note that FixedOffset(0, "UTC") is a different way to build a
# UTC tzinfo object.

class FixedOffset(tzinfo):
    """Fixed offset in minutes east from UTC."""

    def __init__(self, offset, name):
        self.__offset = timedelta(minutes = offset)
        self.__name = name
```

(suite sur la page suivante)

(suite de la page précédente)

```

def utcoffset(self, dt):
    return self.__offset

def tzname(self, dt):
    return self.__name

def dst(self, dt):
    return ZERO

# A class capturing the platform's idea of local time.

import time as _time

STDOFFSET = timedelta(seconds = -_time.timezone)
if _time.daylight:
    DSTOFFSET = timedelta(seconds = -_time.altzone)
else:
    DSTOFFSET = STDOFFSET

DSTDIFF = DSTOFFSET - STDOFFSET

class LocalTimezone(tzinfo):

    def utcoffset(self, dt):
        if self._isdst(dt):
            return DSTOFFSET
        else:
            return STDOFFSET

    def dst(self, dt):
        if self._isdst(dt):
            return DSTDIFF
        else:
            return ZERO

    def tzname(self, dt):
        return _time.tzname[self._isdst(dt)]

    def _isdst(self, dt):
        tt = (dt.year, dt.month, dt.day,
              dt.hour, dt.minute, dt.second,
              dt.weekday(), 0, 0)
        stamp = _time.mktime(tt)
        tt = _time.localtime(stamp)
        return tt.tm_isdst > 0

Mountain = USTimeZone(-7, "Mountain", "MST", "MDT")
Pacific = USTimeZone(-8, "Pacific", "PST", "PDT")

```

Notez que, deux fois par an, on rencontre des subtilités inévitables dans les sous-classes de `tzinfo` représentant à la fois des heures standard et d'été, au passage de l'une à l'autre. Concrètement, considérez le fuseau de l'est des États-Unis (UTC -0500), où EDT (heure d'été) débute à la minute qui suit 1 :59 (EST) le second dimanche de mars, et se termine à la minute qui suit 1 :59 (EDT) le premier dimanche de novembre :

UTC	3:MM	4:MM	5:MM	6:MM	7:MM	8:MM
EST	22:MM	23:MM	0:MM	1:MM	2:MM	3:MM
EDT	23:MM	0:MM	1:MM	2:MM	3:MM	4:MM
start	22:MM	23:MM	0:MM	1:MM	3:MM	4:MM
end	23:MM	0:MM	1:MM	1:MM	2:MM	3:MM

When DST starts (the « start » line), the local wall clock leaps from 1 :59 to 3 :00. A wall time of the form 2 :MM doesn't really make sense on that day, so `astimezone(Eastern)` won't deliver a result with `hour == 2` on the day DST begins. In order for `astimezone()` to make this guarantee, the `tzinfo.dst()` method must consider times in the « missing hour » (2 :MM for Eastern) to be in daylight time.

When DST ends (the « end » line), there's a potentially worse problem : there's an hour that can't be spelled unambiguously in local wall time : the last hour of daylight time. In Eastern, that's times of the form 5 :MM UTC on the day daylight time ends. The local wall clock leaps from 1 :59 (daylight time) back to 1 :00 (standard time) again. Local times of the form 1 :MM are ambiguous. `astimezone()` mimics the local clock's behavior by mapping two adjacent UTC hours into the same local hour then. In the Eastern example, UTC times of the form 5 :MM and 6 :MM both map to 1 :MM when converted to Eastern. In order for `astimezone()` to make this guarantee, the `tzinfo.dst()` method must consider times in the « repeated hour » to be in standard time. This is easily arranged, as in the example, by expressing DST switch times in the time zone's standard local time.

Applications that can't bear such ambiguities should avoid using hybrid `tzinfo` subclasses; there are no ambiguities when using UTC, or any other fixed-offset `tzinfo` subclass (such as a class representing only EST (fixed offset -5 hours), or only EDT (fixed offset -4 hours)).

**Voir aussi :**

**pytz** The standard library has no `tzinfo` instances, but there exists a third-party library which brings the *IANA time zone database* (also known as the Olson database) to Python : `pytz`.

`pytz` contains up-to-date information and its usage is recommended.

**Base de données des fuseaux horaires de l'IANA** The Time Zone Database (often called `tz` or `zoneinfo`) contains code and data that represent the history of local time for many representative locations around the globe. It is updated periodically to reflect changes made by political bodies to time zone boundaries, UTC offsets, and daylight-saving rules.

### 8.1.7 Comportement de `strftime()` et `strptime()`

Les objets `date`, `datetime` et `time` comportent tous une méthode `strftime(format)`, pour créer une représentation du temps sous forme d'une chaîne de caractères, contrôlée par une chaîne de formatage explicite. Grossièrement, `d.strftime(fmt)` se comporte comme la fonction `time.strftime(fmt, d.timetuple())` du module `time`, bien que tous les objets ne comportent pas de méthode `timetuple()`.

Conversely, the `datetime.strptime()` class method creates a `datetime` object from a string representing a date and time and a corresponding format string. `datetime.strptime(date_string, format)` is equivalent to `datetime(*(time.strptime(date_string, format)[0:6]))`, except when the format includes sub-second components or timezone offset information, which are supported in `datetime.strptime` but are discarded by `time.strptime`.

Pour les objets `time`, les codes de formatage pour l'année, le mois et le jour ne devraient pas être utilisés, puisque les objets de temps ne possèdent pas de telles valeurs. S'ils sont tout de même utilisés, 1900 est substitué à l'année, et 1 au mois et au jour.

Pour les objets `date`, les codes de formatage pour les heures, minutes, secondes et microsecondes ne devraient pas être utilisés, puisque les objets `date` ne possèdent pas de telles valeurs. S'ils sont tous de même utilisés, ils sont substitués par 0.

L'ensemble complet des codes de formatage supportés varie selon les plateformes, parce que Python appelle la fonction `strftime()` de la bibliothèque C de la plateforme, et les variations sont courantes. Pour voir un ensemble complet des codes de formatage supportés par votre plateforme, consultez la documentation de `strftime(3)`.

La liste suivante est la liste de tous les codes de formatage requis par le standard C (version 1989), ils fonctionnent sur toutes les plateformes possédant une implémentation de C standard. Notez que la version 1999 du standard C a ajouté des codes de formatage additionnels.

The exact range of years for which `strftime()` works also varies across platforms. Regardless of platform, years before 1900 cannot be used.

Directive	Signification	Exemple	Notes
%a	Jour de la semaine abrégé dans la langue locale.	Sun, Mon, ..., Sat (en_US); Lu, Ma, ..., Di (fr_FR)	(1)
%A	Jour de la semaine complet dans la langue locale.	Sunday, Monday, ..., Saturday (en_US); Lundi, Mardi, ..., Dimanche (fr_FR)	(1)
%w	Jour de la semaine en chiffre, avec 0 pour le dimanche et 6 pour le samedi.	0, 1, ..., 6	
%d	Jour du mois sur deux chiffres.	01, 02, ..., 31	
%b	Nom du mois abrégé dans la langue locale.	Jan, Feb, ..., Dec (en_US); janv., févr., ..., déc. (fr_FR)	(1)
%B	Nom complet du mois dans la langue locale.	January, February, ..., December (en_US); janvier, février, ..., décembre (fr_FR)	(1)
%m	Numéro du mois sur deux chiffres.	01, 02, ..., 12	
%y	Année sur deux chiffres (sans le siècle).	00, 01, ..., 99	
%Y	Année complète sur quatre chiffres.	1970, 1988, 2001, 2013	
%H	Heure à deux chiffres de 00 à 23.	00, 01, ..., 23	
%I	Heure à deux chiffres pour les horloges 12h (01 à 12).	01, 02, ..., 12	
%p	Équivalent local à AM/PM.	AM, PM (en_US); am, pm (de_DE)	(1), (2)
%M	Minutes sur deux chiffres.	00, 01, ..., 59	
%S	Secondes sur deux chiffres.	00, 01, ..., 59	(3)
%f	Microsecondes sur 6 chiffres.	000000, 000001, ..., 999999	(4)
%z	Time offset in the form +HHMM or -HHMM (empty string if the object is naive).	(-0000), +0000, -0400, +1030	(5)

Notes :

- (1) Comme le format dépend de la locale courante, les assumptions sur la valeur de retour doivent être prises soigneusement. L'ordre des champs variera (par exemple, « mois/jour/année » versus « année/mois/jour »), et le retour pourrait contenir des caractères Unicode encodés en utilisant l'encodage par défaut de la locale (par exemple, si la locale courante est `ja_JP`, l'encodage par défaut pourrait être `eucJP`, `SJIS` ou `utf-8` ; utilisez `locale.getlocale()` pour déterminer l'encodage de la locale courante).
- (2) Quand utilisée avec la méthode `strptime()`, la directive `%p` n'affecte l'heure extraite que si la directive `%I` est utilisée pour analyser l'heure.
- (3) À l'inverse du module `time`, le module `datetime` ne supporte pas les secondes intercalaires.
- (4) `%f` is an extension to the set of format characters in the C standard (but implemented separately in datetime objects, and therefore always available). When used with the `strptime()` method, the `%f` directive accepts from one to six digits and zero pads on the right.

Nouveau dans la version 2.6.

- (5) Pour les objets naïfs, les codes de formatage `%z` et `%Z` sont remplacés par des chaînes vides.

Pour un objet avisé :

**%z** Le résultat de `utcoffset()` est transformé en une chaîne de 5 caractères de la forme `+HHMM` ou `-HHMM`, où `HH` est une chaîne de deux chiffres donnant le nombre d'heures du décalage UTC, et `MM` est une chaîne de deux chiffres donnant le nombre de minutes de ce décalage. Par exemple, si `utcoffset()` renvoie `timedelta(hours=-3, minutes=-30)`, `%z` est remplacé par la chaîne `"-0330"`.

**%Z** Si `tzname()` renvoie `None`, `%Z` est remplacé par une chaîne vide. Autrement `%Z` est remplacé par la valeur renvoyée, qui doit être une chaîne.

- (6) When used with the `strptime()` method, `%U` and `%W` are only used in calculations when the day of the week and the year are specified.

## Notes

## 8.2 calendar — General calendar-related functions

Code source : [Lib/calendar.py](#)

---

This module allows you to output calendars like the Unix `cal` program, and provides additional useful functions related to the calendar. By default, these calendars have Monday as the first day of the week, and Sunday as the last (the European convention). Use `setfirstweekday()` to set the first day of the week to Sunday (6) or to any other weekday. Parameters that specify dates are given as integers. For related functionality, see also the `datetime` and `time` modules.

Most of these functions and classes rely on the `datetime` module which uses an idealized calendar, the current Gregorian calendar indefinitely extended in both directions. This matches the definition of the « proleptic Gregorian » calendar in Dershowitz and Reingold's book « Calendrical Calculations », where it's the base calendar for all computations.

**class** `calendar.Calendar`(`[firstweekday]`)

Creates a `Calendar` object. `firstweekday` is an integer specifying the first day of the week. 0 is Monday (the default), 6 is Sunday.

A `Calendar` object provides several methods that can be used for preparing the calendar data for formatting. This class doesn't do any formatting itself. This is the job of subclasses.

Nouveau dans la version 2.5.

`Calendar` instances have the following methods :

**iterweekdays()**  
 Return an iterator for the week day numbers that will be used for one week. The first value from the iterator will be the same as the value of the *firstweekday* property.

**itermonthdates(*year*, *month*)**  
 Return an iterator for the month *month* (1–12) in the year *year*. This iterator will return all days (as *datetime.date* objects) for the month and all days before the start of the month or after the end of the month that are required to get a complete week.

**itermonthdays2(*year*, *month*)**  
 Return an iterator for the month *month* in the year *year* similar to *itermonthdates()*. Days returned will be tuples consisting of a day number and a week day number.

**itermonthdays(*year*, *month*)**  
 Return an iterator for the month *month* in the year *year* similar to *itermonthdates()*. Days returned will simply be day numbers.

**monthdatescalendar(*year*, *month*)**  
 Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven *datetime.date* objects.

**monthdays2calendar(*year*, *month*)**  
 Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven tuples of day numbers and weekday numbers.

**monthdayscalendar(*year*, *month*)**  
 Return a list of the weeks in the month *month* of the *year* as full weeks. Weeks are lists of seven day numbers.

**yeardatescalendar(*year*[, *width*])**  
 Return the data for the specified year ready for formatting. The return value is a list of month rows. Each month row contains up to *width* months (defaulting to 3). Each month contains between 4 and 6 weeks and each week contains 1–7 days. Days are *datetime.date* objects.

**yeardays2calendar(*year*[, *width*])**  
 Return the data for the specified year ready for formatting (similar to *yeardatescalendar()*). Entries in the week lists are tuples of day numbers and weekday numbers. Day numbers outside this month are zero.

**yeardayscalendar(*year*[, *width*])**  
 Return the data for the specified year ready for formatting (similar to *yeardatescalendar()*). Entries in the week lists are day numbers. Day numbers outside this month are zero.

**class calendar.TextCalendar([*firstweekday*])**  
 This class can be used to generate plain text calendars.  
 Nouveau dans la version 2.5.  
*TextCalendar* instances have the following methods :

**formatmonth(*theyear*, *themonth*[, *w*[, *l*]])**  
 Return a month's calendar in a multi-line string. If *w* is provided, it specifies the width of the date columns, which are centered. If *l* is given, it specifies the number of lines that each week will use. Depends on the first weekday as specified in the constructor or set by the *setfirstweekday()* method.

**prmonth(*theyear*, *themonth*[, *w*[, *l*]])**  
 Print a month's calendar as returned by *formatmonth()*.

**formatyear(*theyear*[, *w*[, *l*[, *c*[, *m*]]]])**  
 Return a *m*-column calendar for an entire year as a multi-line string. Optional parameters *w*, *l*, and *c* are for date column width, lines per week, and number of spaces between month columns, respectively. Depends on the first weekday as specified in the constructor or set by the *setfirstweekday()* method. The earliest year for which a calendar can be generated is platform-dependent.

```
pryear(theyear[, w[, l[, c[, m]]]])
```

Print the calendar for an entire year as returned by *formatyear()*.

```
class calendar.HTMLCalendar([firstweekday])
```

Cette classe peut être utilisée pour générer des calendriers HTML.

Nouveau dans la version 2.5.

*HTMLCalendar* instances have the following methods :

```
formatmonth(theyear, themonth[, withyear])
```

Return a month's calendar as an HTML table. If *withyear* is true the year will be included in the header, otherwise just the month name will be used.

```
formatyear(theyear[, width])
```

Return a year's calendar as an HTML table. *width* (defaulting to 3) specifies the number of months per row.

```
formatyearpage(theyear[, width[, css[, encoding]]])
```

Return a year's calendar as a complete HTML page. *width* (defaulting to 3) specifies the number of months per row. *css* is the name for the cascading style sheet to be used. *None* can be passed if no style sheet should be used. *encoding* specifies the encoding to be used for the output (defaulting to the system default encoding).

```
class calendar.LocaleTextCalendar([firstweekday[, locale]])
```

This subclass of *TextCalendar* can be passed a locale name in the constructor and will return month and weekday names in the specified locale. If this locale includes an encoding all strings containing month and weekday names will be returned as unicode.

Nouveau dans la version 2.5.

```
class calendar.LocaleHTMLCalendar([firstweekday[, locale]])
```

This subclass of *HTMLCalendar* can be passed a locale name in the constructor and will return month and weekday names in the specified locale. If this locale includes an encoding all strings containing month and weekday names will be returned as unicode.

Nouveau dans la version 2.5.

---

**Note :** The *formatweekday()* and *formatmonthname()* methods of these two classes temporarily change the current locale to the given *locale*. Because the current locale is a process-wide setting, they are not thread-safe.

---

For simple text calendars this module provides the following functions.

```
calendar.setfirstweekday(weekday)
```

Sets the weekday (0 is Monday, 6 is Sunday) to start each week. The values *MONDAY*, *TUESDAY*, *WEDNESDAY*, *THURSDAY*, *FRIDAY*, *SATURDAY*, and *SUNDAY* are provided for convenience. For example, to set the first weekday to Sunday :

```
import calendar
calendar.setfirstweekday(calendar.SUNDAY)
```

Nouveau dans la version 2.0.

```
calendar.firstweekday()
```

Returns the current setting for the weekday to start each week.

Nouveau dans la version 2.0.

```
calendar.isleap(year)
```

Returns *True* if *year* is a leap year, otherwise *False*.

`calendar.leapdays(y1, y2)`

Returns the number of leap years in the range from *y1* to *y2* (exclusive), where *y1* and *y2* are years.

Modifié dans la version 2.0 : This function didn't work for ranges spanning a century change in Python 1.5.2.

`calendar.weekday(year, month, day)`

Returns the day of the week (0 is Monday) for *year* (1970–...), *month* (1–12), *day* (1–31).

`calendar.weekheader(n)`

Return a header containing abbreviated weekday names. *n* specifies the width in characters for one weekday.

`calendar.monthrange(year, month)`

Returns weekday of first day of the month and number of days in month, for the specified *year* and *month*.

`calendar.monthcalendar(year, month)`

Returns a matrix representing a month's calendar. Each row represents a week; days outside of the month are represented by zeros. Each week begins with Monday unless set by `setfirstweekday()`.

`calendar.prmonth(theyear, themonth[, w[, l]])`

Prints a month's calendar as returned by `month()`.

`calendar.month(theyear, themonth[, w[, l]])`

Returns a month's calendar in a multi-line string using the `formatmonth()` of the `TextCalendar` class. Nouveau dans la version 2.0.

`calendar.prcal(year[, w[, l[c]]])`

Prints the calendar for an entire year as returned by `calendar()`.

`calendar.calendar(year[, w[, l[c]]])`

Returns a 3-column calendar for an entire year as a multi-line string using the `formatyear()` of the `TextCalendar` class.

Nouveau dans la version 2.0.

`calendar.timegm(tuple)`

An unrelated but handy function that takes a time tuple such as returned by the `gmtime()` function in the `time` module, and returns the corresponding Unix timestamp value, assuming an epoch of 1970, and the POSIX encoding. In fact, `time.gmtime()` and `timegm()` are each others' inverse.

Nouveau dans la version 2.0.

The `calendar` module exports the following data attributes :

`calendar.day_name`

An array that represents the days of the week in the current locale.

`calendar.day_abbr`

An array that represents the abbreviated days of the week in the current locale.

`calendar.month_name`

An array that represents the months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_name[0]` is the empty string.

`calendar.month_abbr`

An array that represents the abbreviated months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_abbr[0]` is the empty string.

Module `datetime` Object-oriented interface to dates and times with similar functionality to the `time` module.

Module `time` Low-level time related functions.

## 8.3 collections — High-performance container datatypes

Nouveau dans la version 2.4.

Source code : `Lib/collections.py` and `Lib/_abcoll.py`

---

Ce module implémente des types de données de conteneurs spécialisés qui apportent des alternatives aux conteneurs natifs de Python plus généraux `dict`, `list`, `set` et `tuple`.

<code>namedtuple</code>	Fonction permettant de créer des sous-classes de <code>tuple</code> avec des champs nommés	Nouveau dans la version 2.6.
<code>deque</code>	conteneur se comportant comme une liste avec des ajouts et retraits rapides à chaque extrémité	Nouveau dans la version 2.4.
<code>Counter</code>	sous-classe de <code>dict</code> pour compter des objets hachables	Nouveau dans la version 2.7.
<code>OrderedDict</code>	sous-classe de <code>dict</code> qui garde en mémoire l'ordre dans lequel les entrées ont été ajoutées	Nouveau dans la version 2.7.
<code>defaultdict</code>	sous-classe de <code>dict</code> qui appelle une fonction de fabrication en cas de valeur manquante	Nouveau dans la version 2.5.

In addition to the concrete container classes, the collections module provides *abstract base classes* that can be used to test whether a class provides a particular interface, for example, whether it is hashable or a mapping.

### 8.3.1 Objets Counter

Ce module fournit un outil pour effectuer rapidement et facilement des dénombrements. Par exemple :

```
>>> # Tally occurrences of words in a list
>>> cnt = Counter()
>>> for word in ['red', 'blue', 'red', 'green', 'blue', 'blue']:
...     cnt[word] += 1
>>> cnt
Counter({'blue': 3, 'red': 2, 'green': 1})

>>> # Find the ten most common words in Hamlet
>>> import re
>>> words = re.findall(r'\w+', open('hamlet.txt').read().lower())
>>> Counter(words).most_common(10)
[('the', 1143), ('and', 966), ('to', 762), ('of', 669), ('i', 631),
 ('you', 554), ('a', 546), ('my', 514), ('hamlet', 471), ('in', 451)]
```

`class collections.Counter([iterable-or-mapping])`

La classe `Counter` est une sous-classe de `dict` qui permet le dénombrement d'objets hachables. Il s'agit d'une collection non ordonnée dans laquelle les éléments sont stockés comme des clés de dictionnaire et leurs nombres d'occurrences respectifs comme leurs valeurs. Ceux-ci peuvent être des entiers relatifs (positifs, négatifs ou nuls). La classe `Counter` est similaire aux sacs ou aux multienssembles dans d'autres langages.

Les éléments sont comptés à partir d'un itérable ou initialisés à partir d'un autre dictionnaire (ou compteur) :

```
>>> c = Counter()                # a new, empty counter
>>> c = Counter('gallahad')      # a new counter from an iterable
>>> c = Counter({'red': 4, 'blue': 2}) # a new counter from a mapping
>>> c = Counter(cats=4, dogs=8)   # a new counter from keyword args
```

Les objets Counter ont une interface de dictionnaire, à l'exception près qu'ils renvoient zéro au lieu de lever une exception `KeyError` pour des éléments manquants :

```
>>> c = Counter(['eggs', 'ham'])
>>> c['bacon']                    # count of a missing element is zero
0
```

Mettre un comptage à zéro pour un élément ne le retire pas de l'objet Counter. Il faut utiliser `del` pour le supprimer complètement :

```
>>> c['sausage'] = 0              # counter entry with a zero count
>>> del c['sausage']              # del actually removes the entry
```

Nouveau dans la version 2.7.

En plus des méthodes disponibles pour tous les dictionnaires, les objets compteurs gèrent trois méthodes supplémentaires :

#### **elements()**

Renvoie un itérateur sur chaque élément en le répétant autant de fois que la valeur du compteur associé. Les éléments sont renvoyés dans un ordre arbitraire. Si le comptage d'un élément est strictement inférieur à 1, alors `elements()` l'ignore.

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> list(c.elements())
['a', 'a', 'a', 'a', 'b', 'b']
```

#### **most\_common(*n*)**

Return a list of the *n* most common elements and their counts from the most common to the least. If *n* is omitted or None, `most_common()` returns *all* elements in the counter. Elements with equal counts are ordered arbitrarily :

```
>>> Counter('abracadabra').most_common(3)
[('a', 5), ('r', 2), ('b', 2)]
```

#### **subtract(*[iterable-or-mapping]*)**

Les éléments sont soustraits à partir d'un itérable ou d'un autre dictionnaire (ou compteur). Cette méthode se comporte comme `dict.update()` mais soustrait les nombres d'occurrences au lieu de les remplacer. Les entrées et sorties peuvent être négatives ou nulles.

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> d = Counter(a=1, b=2, c=3, d=4)
>>> c.subtract(d)
>>> c
Counter({'a': 3, 'b': 0, 'c': -3, 'd': -6})
```

Les méthodes usuelles des dictionnaires sont disponibles pour les objets `Counter` à l'exception de deux méthodes qui fonctionnent différemment pour les compteurs.

#### **fromkeys(*iterable*)**

Cette méthode de classe n'est pas implémentée pour les objets `Counter`.

`update([iterable-or-mapping])`

Les éléments sont comptés à partir d'un itérable ou ajoutés d'un autre dictionnaire (ou compteur). Cette méthode se comporte comme `dict.update()` mais additionne les nombres d'occurrences au lieu de les remplacer. De plus, l'itérable doit être une séquence d'éléments et non une séquence de paires (clé, valeur).

Opérations usuelles sur les objets `Counter` :

```
sum(c.values())           # total of all counts
c.clear()                 # reset all counts
list(c)                   # list unique elements
set(c)                    # convert to a set
dict(c)                   # convert to a regular dictionary
c.items()                 # convert to a list of (elem, cnt) pairs
Counter(dict(list_of_pairs)) # convert from a list of (elem, cnt) pairs
c.most_common()[:n-1:-1]  # n least common elements
c -= Counter()             # remove zero and negative counts
```

Quelques opérations mathématiques sont fournies pour combiner des objets `Counter` afin de créer des multiensembles (des compteurs dont les dénombrements des éléments sont strictement supérieurs à zéro). Les additions et soustractions combinent les compteurs en ajoutant ou retranchant les nombres d'occurrences des éléments correspondants. Les intersections et unions renvoient les minimums et maximums des comptages correspondants. Chaque opération peut accepter des entrées avec des comptages relatifs, mais la sortie exclut les résultats avec des comptages négatifs ou nuls.

```
>>> c = Counter(a=3, b=1)
>>> d = Counter(a=1, b=2)
>>> c + d                      # add two counters together: c[x] + d[x]
Counter({'a': 4, 'b': 3})
>>> c - d                      # subtract (keeping only positive counts)
Counter({'a': 2})
>>> c & d                      # intersection: min(c[x], d[x])
Counter({'a': 1, 'b': 1})
>>> c | d                      # union: max(c[x], d[x])
Counter({'a': 3, 'b': 2})
```

---

**Note :** Les compteurs ont été conçus essentiellement pour fonctionner avec des entiers naturels pour représenter les dénombrements en cours; cependant, les cas d'utilisation nécessitant d'autres types ou des valeurs négatives n'ont pas été écartés. Pour vous aider dans ces cas particuliers, cette section documente la plage minimale et les restrictions de type.

- La classe `Counter` est elle-même une sous-classe de dictionnaire sans restriction particulière sur ces clés ou valeurs. Les valeurs ont vocation à être des nombres représentant des comptages, mais il est possible de stocker n'importe quel type de valeur.
  - The `most_common()` method requires only that the values be orderable.
  - For in-place operations such as `c[key] += 1`, the value type need only support addition and subtraction. So fractions, floats, and decimals would work and negative values are supported. The same is also true for `update()` and `subtract()` which allow negative and zero values for both inputs and outputs.
  - Les méthodes de multiensembles sont uniquement conçues pour les cas d'utilisation avec des valeurs positives. Les entrées peuvent contenir des valeurs négatives ou nulles, mais seules les sorties avec des valeurs positives sont créées. Il n'y a pas de restriction de type, mais les types des valeurs doivent gérer l'addition, la soustraction et la comparaison.
  - The `elements()` method requires integer counts. It ignores zero and negative counts.

### 8.3.2 Objets deque

**class** `collections.deque([iterable[, maxlen]])`

Renvoie un nouvel objet *deque* initialisé de gauche à droite (en utilisant [append\(\)](#)) avec les données d'*iterable*. Si *iterable* n'est pas spécifié, alors la nouvelle *deque* est vide.

Les *deques* sont une généralisation des piles et des files (*deque* se prononce « *dèque* » et est l'abréviation de l'anglais *double-ended queue*) : il est possible d'ajouter et retirer des éléments par les deux bouts des *deques*. Celles-ci gèrent des ajouts et des retraits utilisables par de multiples fils d'exécution (*thread-safe*) et efficaces du point de vue de la mémoire des deux côtés de la *deque*, avec approximativement la même performance en  $O(1)$  dans les deux sens.

Bien que les les objets `list` gèrent des opérations similaires, ils sont optimisés pour des opérations qui ne changent pas la taille de la liste. Les opérations `pop()` et `insert(0, v)` qui changent la taille et la position de la représentation des données sous-jacentes entraînent des coûts de déplacement de mémoire en  $O(n)$ .

Nouveau dans la version 2.4.

Si *maxlen* n'est pas spécifié ou vaut *None*, les *deques* peuvent atteindre une taille arbitraire. Sinon, la *deque* est limitée par cette taille maximale. Une fois que celle-ci est atteinte, un ajout d'un ou plusieurs éléments engendre la suppression du nombre correspondant d'éléments à l'autre extrémité de la *deque*. Les *deques* à longueur limitée apportent des fonctionnalités similaire au filtre `tail` d'Unix. Elles sont aussi utiles pour le suivi de transactions et autres lots de données où seule l'activité récente est intéressante.

Modifié dans la version 2.6 : Added *maxlen* parameter.

Les objets *deques* gèrent les méthodes suivantes :

**append(x)**

Ajoute *x* à l'extrémité droite de la *deque*.

**appendleft(x)**

Ajoute *x* à l'extrémité gauche de la *deque*.

**clear()**

Supprime tous les éléments de la *deque* et la laisse avec une longueur de 0.

**count(x)**

Compte le nombre d'éléments de la *deque* égaux à *x*.

Nouveau dans la version 2.7.

**extend(iterable)**

Étend la *deque* en ajoutant les éléments de l'itérable en argument à son extrémité droite.

**extendleft(iterable)**

Étend la *deque* en ajoutant les éléments d'*iterable* à son extrémité gauche. Dans ce cas, notez que la série d'ajouts inverse l'ordre des éléments de l'argument itérable.

**pop()**

Retire et renvoie un élément de l'extrémité droite de la *deque*. S'il n'y a aucun élément, lève une exception [IndexError](#).

**popleft()**

Retire et renvoie un élément de l'extrémité gauche de la *deque*. S'il n'y a aucun élément, lève une exception *IndexError*.

**remove(value)**

Remove the first occurrence of *value*. If not found, raises a *ValueError*.

Nouveau dans la version 2.5.

**reverse()**

Inverse le sens des éléments de la *deque* sans créer de copie et renvoie *None*.

Nouveau dans la version 2.7.

**rotate(n=1)**

Rotate the deque *n* steps to the right. If *n* is negative, rotate to the left.

When the deque is not empty, rotating one step to the right is equivalent to `d.appendleft(d.pop())`, and rotating one step to the left is equivalent to `d.append(d.popleft())`.

Les objets *deques* fournissent également un attribut en lecture seule :

**maxlen**

La taille maximale d'une *deque*, ou *None* si illimitée.

Nouveau dans la version 2.7.

En plus des méthodes précédentes, les *deques* gèrent l'itération, la sérialisation, `len(d)`, `reversed(d)`, `copy.copy(d)`, `copy.deepcopy(d)`, le test d'appartenance avec l'opérateur `in`, et les références en indice comme `d[-1]`. L'accès par indice est en  $O(1)$  aux extrémités mais en  $O(n)$  au milieu. Pour des accès aléatoires rapides, il est préférable d'utiliser des listes.

Exemple :

```
>>> from collections import deque
>>> d = deque('ghi')           # make a new deque with three items
>>> for elem in d:             # iterate over the deque's elements
...     print elem.upper()
G
H
I

>>> d.append('j')              # add a new entry to the right side
>>> d.appendleft('f')          # add a new entry to the left side
>>> d                          # show the representation of the deque
deque(['f', 'g', 'h', 'i', 'j'])

>>> d.pop()                    # return and remove the rightmost item
'j'
>>> d.popleft()                # return and remove the leftmost item
'f'
>>> list(d)                    # list the contents of the deque
['g', 'h', 'i']
>>> d[0]                       # peek at leftmost item
'g'
>>> d[-1]                      # peek at rightmost item
'i'

>>> list(reversed(d))          # list the contents of a deque in reverse
['i', 'h', 'g']
>>> 'h' in d                   # search the deque
True
```

(suite sur la page suivante)

(suite de la page précédente)

```

>>> d.extend('jkl')           # add multiple elements at once
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])
>>> d.rotate(1)               # right rotation
>>> d
deque(['l', 'g', 'h', 'i', 'j', 'k'])
>>> d.rotate(-1)              # left rotation
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])

>>> deque(reversed(d))        # make a new deque in reverse order
deque(['l', 'k', 'j', 'i', 'h', 'g'])
>>> d.clear()                  # empty the deque
>>> d.pop()                    # cannot pop from an empty deque
Traceback (most recent call last):
  File "<pyshell#6>", line 1, in <module>
    d.pop()
IndexError: pop from an empty deque

>>> d.extendleft('abc')       # extendleft() reverses the input order
>>> d
deque(['c', 'b', 'a'])

```

### Cas pratiques utilisant deque

Cette partie montre diverses approches afin de travailler avec les *deques*.

Les *deques* à taille limitée apportent une fonctionnalité similaire au filtre `tail` d'Unix :

```

def tail(filename, n=10):
    'Return the last n lines of a file'
    return deque(open(filename), n)

```

Une autre approche d'utilisation des *deques* est de maintenir une séquence d'éléments récemment ajoutés en les ajoutant à droite et en retirant les anciens par la gauche :

```

def moving_average(iterable, n=3):
    # moving_average([40, 30, 50, 46, 39, 44]) --> 40.0 42.0 45.0 43.0
    # http://en.wikipedia.org/wiki/Moving_average
    it = iter(iterable)
    d = deque(itertools.islice(it, n-1))
    d.appendleft(0)
    s = sum(d)
    for elem in it:
        s += elem - d.popleft()
        d.append(elem)
        yield s / float(n)

```

The `rotate()` method provides a way to implement *deque* slicing and deletion. For example, a pure Python implementation of `del d[n]` relies on the `rotate()` method to position elements to be popped :

```

def delete_nth(d, n):
    d.rotate(-n)

```

(suite sur la page suivante)

```
d.popleft()
d.rotate(n)
```

To implement *deque* slicing, use a similar approach applying `rotate()` to bring a target element to the left side of the deque. Remove old entries with `popleft()`, add new entries with `extend()`, and then reverse the rotation. With minor variations on that approach, it is easy to implement Forth style stack manipulations such as `dup`, `drop`, `swap`, `over`, `pick`, `rot`, and `roll`.

### 8.3.3 Objets defaultdict

```
class collections.defaultdict([default_factory[, ...]])
```

Renvoie un nouvel objet qui se comporte comme un dictionnaire. `defaultdict` est une sous-classe de la classe native `dict`. Elle surcharge une méthode et ajoute une variable d'instance modifiable. Les autres fonctionnalités sont les mêmes que celles des objets `dict` et ne sont pas documentées ici.

Le premier argument fournit la valeur initiale de l'attribut `default_factory` qui doit être un objet callable sans paramètre ou `None`, sa valeur par défaut. Tous les autres arguments sont traités comme si on les passait au constructeur de `dict`, y compris les arguments nommés.

Nouveau dans la version 2.5.

En plus des opérations usuelles de `dict`, les objets `defaultdict` gèrent les méthodes supplémentaires suivantes :

`__missing__(key)`

Si l'attribut `default_factory` est `None`, lève une exception `KeyError` avec `key` comme argument.

Si `default_factory` ne vaut pas `None`, cet attribut est appelé sans argument pour fournir une valeur par défaut pour la `key` demandée. Cette valeur est insérée dans le dictionnaire avec pour clé `key` et est renvoyée.

Si appeler `default_factory` lève une exception, celle-ci est transmise inchangée.

Cette méthode est appelée par la méthode `__getitem__()` de la classe `dict` lorsque la clé demandée n'est pas trouvée. Ce qu'elle renvoie ou lève est alors renvoyé ou levé par `__getitem__()`.

Remarquez que `__missing__()` n'est *pas* appelée pour les opérations autres que `__getitem__()`. Cela signifie que `get()` renvoie `None` comme les dictionnaires natifs dans les cas triviaux et n'utilise pas `default_factory`.

Les objets `defaultdict` gèrent la variable d'instance :

`default_factory`

Cet attribut est utilisé par la méthode `__missing__()` ; il est initialisé par le premier argument passé au constructeur, s'il est spécifié, sinon par `None`.

#### Exemples utilisant defaultdict

Using `list` as the `default_factory`, it is easy to group a sequence of key-value pairs into a dictionary of lists :

```
>>> s = [('yellow', 1), ('blue', 2), ('yellow', 3), ('blue', 4), ('red', 1)]
>>> d = defaultdict(list)
>>> for k, v in s:
...     d[k].append(v)
...
>>> d.items()
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

When each key is encountered for the first time, it is not already in the mapping ; so an entry is automatically created using the `default_factory` function which returns an empty `list`. The `list.append()` operation then attaches the value to the new list. When keys are encountered again, the look-up proceeds normally

(returning the list for that key) and the `list.append()` operation adds another value to the list. This technique is simpler and faster than an equivalent technique using `dict.setdefault()` :

```
>>> d = {}
>>> for k, v in s:
...     d.setdefault(k, []).append(v)
...
>>> d.items()
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

Setting the `default_factory` to `int` makes the `defaultdict` useful for counting (like a bag or multiset in other languages) :

```
>>> s = 'mississippi'
>>> d = defaultdict(int)
>>> for k in s:
...     d[k] += 1
...
>>> d.items()
[('i', 4), ('p', 2), ('s', 4), ('m', 1)]
```

When a letter is first encountered, it is missing from the mapping, so the `default_factory` function calls `int()` to supply a default count of zero. The increment operation then builds up the count for each letter.

The function `int()` which always returns zero is just a special case of constant functions. A faster and more flexible way to create constant functions is to use `itertools.repeat()` which can supply any constant value (not just zero) :

```
>>> def constant_factory(value):
...     return itertools.repeat(value).next
>>> d = defaultdict(constant_factory('<missing>'))
>>> d.update(name='John', action='ran')
>>> '%(name)s %(action)s to %(object)s' % d
'John ran to <missing>'
```

Setting the `default_factory` to `set` makes the `defaultdict` useful for building a dictionary of sets :

```
>>> s = [('red', 1), ('blue', 2), ('red', 3), ('blue', 4), ('red', 1), ('blue', 4)]
>>> d = defaultdict(set)
>>> for k, v in s:
...     d[k].add(v)
...
>>> d.items()
[('blue', set([2, 4])), ('red', set([1, 3]))]
```

### 8.3.4 `namedtuple()` : fonction de construction pour *n-uplets* (*tuples*) avec des champs nommés

Les tuples nommés assignent une signification à chacun de leur élément, ce qui rend le code plus lisible et explicite. Ils peuvent être utilisés partout où les tuples natifs sont utilisés, et ils ajoutent la possibilité d'accéder à leurs champs grâce à leur nom au lieu de leur index de position.

`collections.namedtuple(typename, field_names[, verbose=False][, rename=False])`

Renvoie une nouvelle sous-classe de `tuple` appelée `typename`. Elle est utilisée pour créer des objets se comportant comme les *tuples* qui ont des champs accessibles par recherche d'attribut en plus d'être

indexables et itérables. Les instances de cette sous-classe possèdent aussi une *docstring* explicite (avec *type\_name* et les *field\_names*) et une méthode `__repr__()` pratique qui liste le contenu du tuple au format `nom=valeur`.

*field\_names* peut être une séquence de chaînes de caractères telle que `['x', 'y']` ou bien une unique chaîne de caractères où les noms de champs sont séparés par un espace et/ou une virgule, par exemple `'x y'` ou `'x, y'`.

Any valid Python identifier may be used for a fieldname except for names starting with an underscore. Valid identifiers consist of letters, digits, and underscores but do not start with a digit or underscore and cannot be a *keyword* such as *class*, *for*, *return*, *global*, *pass*, *print*, or *raise*.

Si *rename* vaut `True`, alors les noms de champs invalides sont automatiquement renommés en noms positionnels. Par exemple, `['abc', 'def', 'ghi', 'abc']` est converti en `['abc', '_1', 'ghi', '_3']` afin d'éliminer le mot-clé `def` et le doublon de `abc`.

If *verbose* is true, the class definition is printed just before being built.

Les instances de tuples nommés n'ont pas de dictionnaires propres, elles sont donc légères et ne requièrent pas plus de mémoire que les tuples natifs.

Nouveau dans la version 2.6.

Modifié dans la version 2.7 : added support for *rename*.

Exemple :

```
>>> Point = namedtuple('Point', ['x', 'y'], verbose=True)
class Point(tuple):
    'Point(x, y)'

    __slots__ = ()

    _fields = ('x', 'y')

    def __new__(_cls, x, y):
        'Create new instance of Point(x, y)'
        return _tuple.__new__(_cls, (x, y))

    @classmethod
    def _make(cls, iterable, new=tuple.__new__, len=len):
        'Make a new Point object from a sequence or iterable'
        result = new(cls, iterable)
        if len(result) != 2:
            raise TypeError('Expected 2 arguments, got %d' % len(result))
        return result

    def __repr__(self):
        'Return a nicely formatted representation string'
        return 'Point(x=%r, y=%r)' % self

    def _asdict(self):
        'Return a new OrderedDict which maps field names to their values'
        return OrderedDict(zip(self._fields, self))

    def _replace(_self, **kwds):
        'Return a new Point object replacing specified fields with new values'
        result = _self._make(map(kwds.pop, ('x', 'y'), _self))
        if kwds:
            raise ValueError('Got unexpected field names: %r' % kwds.keys())
```

(suite sur la page suivante)

(suite de la page précédente)

```

        return result

    def __getnewargs__(self):
        'Return self as a plain tuple.  Used by copy and pickle.'
        return tuple(self)

    __dict__ = _property(_asdict)

    def __getstate__(self):
        'Exclude the OrderedDict from pickling'
        pass

    x = _property(_itemgetter(0), doc='Alias for field number 0')

    y = _property(_itemgetter(1), doc='Alias for field number 1')

>>> p = Point(11, y=22)           # instantiate with positional or keyword arguments
>>> p[0] + p[1]                   # indexable like the plain tuple (11, 22)
33
>>> x, y = p                      # unpack like a regular tuple
>>> x, y
(11, 22)
>>> p.x + p.y                    # fields also accessible by name
33
>>> p                             # readable __repr__ with a name=value style
Point(x=11, y=22)

```

Les tuples nommés sont particulièrement utiles pour associer des noms de champs à des tuples renvoyés par les modules `csv` ou `sqlite3` :

```

EmployeeRecord = namedtuple('EmployeeRecord', 'name, age, title, department, paygrade')

import csv
for emp in map(EmployeeRecord._make, csv.reader(open("employees.csv", "rb"))):
    print emp.name, emp.title

import sqlite3
conn = sqlite3.connect('/companydata')
cursor = conn.cursor()
cursor.execute('SELECT name, age, title, department, paygrade FROM employees')
for emp in map(EmployeeRecord._make, cursor.fetchall()):
    print emp.name, emp.title

```

In addition to the methods inherited from tuples, named tuples support three additional methods and one attribute. To prevent conflicts with field names, the method and attribute names start with an underscore.

**classmethod** `somenamedtuple._make(iterable)`

Méthode de classe qui construit une nouvelle instance à partir d'une séquence ou d'un itérable existant.

```

>>> t = [11, 22]
>>> Point._make(t)

```

(suite sur la page suivante)

(suite de la page précédente)

```
Point(x=11, y=22)
```

`somenamedtuple._asdict()`

Return a new *OrderedDict* which maps field names to their corresponding values :

```
>>> p = Point(x=11, y=22)
>>> p._asdict()
OrderedDict([('x', 11), ('y', 22)])
```

Modifié dans la version 2.7 : Renvoie un *OrderedDict* au lieu d'un *dict* natif.

`somenamedtuple._replace(**kwargs)`

Renvoie une nouvelle instance du tuple nommé en remplaçant les champs spécifiés par leurs nouvelles valeurs :

```
>>> p = Point(x=11, y=22)
>>> p._replace(x=33)
Point(x=33, y=22)

>>> for partnum, record in inventory.items():
...     inventory[partnum] = record._replace(price=newprices[partnum],
→timestamp=time.now())
```

`somenamedtuple._fields`

Tuple de chaînes de caractères listant les noms de champs. Pratique pour l'introspection et pour créer de nouveaux types de tuples nommés à partir d'existants.

```
>>> p._fields           # view the field names
('x', 'y')

>>> Color = namedtuple('Color', 'red green blue')
>>> Pixel = namedtuple('Pixel', Point._fields + Color._fields)
>>> Pixel(11, 22, 128, 255, 0)
Pixel(x=11, y=22, red=128, green=255, blue=0)
```

Pour récupérer un champ dont le nom est une chaîne de caractères, utilisez la fonction *getattr()* :

```
>>> getattr(p, 'x')
11
```

Pour convertir un dictionnaire en tuple nommé, utilisez l'opérateur double-étoile (comme expliqué dans *tut-unpacking-arguments*) :

```
>>> d = {'x': 11, 'y': 22}
>>> Point(**d)
Point(x=11, y=22)
```

Il est aisé d'ajouter ou de modifier les fonctionnalités des tuples nommés grâce à l'héritage puisqu'il s'agit de simples classes. Voici comment ajouter un champ calculé avec une longueur fixe d'affichage :

```
>>> class Point(namedtuple('Point', 'x y')):
...     __slots__ = ()
...     @property
...     def hypot(self):
```

(suite sur la page suivante)

(suite de la page précédente)

```

...     return (self.x ** 2 + self.y ** 2) ** 0.5
...     def __str__(self):
...         return 'Point: x=%6.3f y=%6.3f hypot=%6.3f' % (self.x, self.y, self.hypot)
...
>>> for p in Point(3, 4), Point(14, 5/7.):
...     print p
Point: x= 3.000 y= 4.000 hypot= 5.000
Point: x=14.000 y= 0.714 hypot=14.018

```

La sous-classe ci-dessus définit `__slots__` comme un tuple vide. Cela permet de garder une empreinte mémoire faible en empêchant la création de dictionnaire d'instance.

Subclassing is not useful for adding new, stored fields. Instead, simply create a new named tuple type from the `_fields` attribute :

```
>>> Point3D = namedtuple('Point3D', Point._fields + ('z',))
```

Default values can be implemented by using `_replace()` to customize a prototype instance :

```

>>> Account = namedtuple('Account', 'owner balance transaction_count')
>>> default_account = Account('<owner name>', 0.0, 0)
>>> johns_account = default_account._replace(owner='John')

```

Enumerated constants can be implemented with named tuples, but it is simpler and more efficient to use a simple class declaration :

```

>>> Status = namedtuple('Status', 'open pending closed')._make(range(3))
>>> Status.open, Status.pending, Status.closed
(0, 1, 2)
>>> class Status:
...     open, pending, closed = range(3)

```

Voir aussi :

[Named tuple recipe](#) adapted for Python 2.4.

### 8.3.5 Objets `OrderedDict`

En plus de se comporter comme des dictionnaires natifs, les dictionnaires ordonnés mémorisent l'ordre dans lequel les éléments ont été insérés. Quand on itère sur un dictionnaire ordonné, les éléments sont renvoyés dans l'ordre d'insertion des clés.

```
class collections.OrderedDict([items])
```

Renvoie une instance d'une sous-classe de `dict` qui gère les méthodes usuelles de *dict*. Un objet *OrderedDict* est un dictionnaire qui mémorise l'ordre d'insertion des clés. Si une nouvelle entrée écrase une autre, sa position reste inchangé. Si une entrée est supprimée puis réinsérée, elle est placée en dernière position.

Nouveau dans la version 2.7.

```
OrderedDict.popitem(last=True)
```

The *popitem()* method for ordered dictionaries returns and removes a (key, value) pair. The pairs are returned in LIFO order if *last* is true or FIFO order if false.

En plus des méthodes usuelles des dictionnaires, les dictionnaires ordonnés gèrent l'itération en sens inverse grâce à *reversed()*.

Equality tests between `OrderedDict` objects are order-sensitive and are implemented as `list(od1.items())==list(od2.items())`. Equality tests between `OrderedDict` objects and other `Mapping` objects are order-insensitive like regular dictionaries. This allows `OrderedDict` objects to be substituted anywhere a regular dictionary is used.

The `OrderedDict` constructor and `update()` method both accept keyword arguments, but their order is lost because Python's function call semantics pass-in keyword arguments using a regular unordered dictionary.

**Voir aussi :**

Equivalent `OrderedDict` recipe that runs on Python 2.4 or later.

### Exemples et cas pratiques utilisant `OrderDict`

Puisqu'un dictionnaire ordonné mémorise l'ordre d'insertion de ses éléments, il peut être utilisé conjointement avec un classement pour créer un dictionnaire trié :

```
>>> # regular unsorted dictionary
>>> d = {'banana': 3, 'apple': 4, 'pear': 1, 'orange': 2}

>>> # dictionary sorted by key
>>> OrderedDict(sorted(d.items(), key=lambda t: t[0]))
OrderedDict([('apple', 4), ('banana', 3), ('orange', 2), ('pear', 1)])

>>> # dictionary sorted by value
>>> OrderedDict(sorted(d.items(), key=lambda t: t[1]))
OrderedDict([('pear', 1), ('orange', 2), ('banana', 3), ('apple', 4)])

>>> # dictionary sorted by length of the key string
>>> OrderedDict(sorted(d.items(), key=lambda t: len(t[0])))
OrderedDict([('pear', 1), ('apple', 4), ('orange', 2), ('banana', 3)])
```

Les nouveaux dictionnaires triés gardent leur classement quand des entrées sont supprimées, mais si de nouvelles clés sont ajoutées, celles-ci sont ajoutée à la fin et le classement est perdu.

Il est également facile de créer une variante de dictionnaire ordonné qui retient l'ordre dans lequel les clés ont été insérées *en dernier*. Si une nouvelle entrée écrase une existante, la position d'insertion d'origine est modifiée et déplacée à la fin :

```
class LastUpdatedOrderedDict(OrderedDict):
    'Store items in the order the keys were last added'

    def __setitem__(self, key, value):
        if key in self:
            del self[key]
        OrderedDict.__setitem__(self, key, value)
```

Un dictionnaire ordonné peut être combiné avec la classe `Counter` afin de mémoriser l'ordre dans lequel les éléments ont été ajoutés pour la première fois :

```
class OrderedCounter(Counter, OrderedDict):
    'Counter that remembers the order elements are first encountered'

    def __repr__(self):
        return '%s(%r)' % (self.__class__.__name__, OrderedDict(self))
```

(suite sur la page suivante)

(suite de la page précédente)

```
def __reduce__(self):
    return self.__class__, (OrderedDict(self),)
```

### 8.3.6 Classes de base abstraites de collections

Le module collections apporte les *ABC* suivantes :

ABC	Hérite de	Méthodes abstraites	Méthodes <i>mixin</i>
<i>Container</i>		<code>__contains__</code>	
<i>Hashable</i>		<code>__hash__</code>	
<i>Iterable</i>		<code>__iter__</code>	
<i>Iterator</i>	<i>Iterable</i>	<code>next</code>	<code>__iter__</code>
<i>Sized</i>		<code>__len__</code>	
<i>Callable</i>		<code>__call__</code>	
<i>Sequence</i>	<i>Sized</i> , <i>Iterable</i> , <i>Container</i>	<code>__getitem__</code> , <code>__len__</code>	<code>__contains__</code> , <code>__iter__</code> , <code>__reversed__</code> , index et count
<i>MutableSequence</i>	<i>Sequence</i>	<code>__getitem__</code> , <code>__setitem__</code> , <code>__delitem__</code> , <code>__len__</code> , insert	Méthodes héritées de <i>Sequence</i> , et <code>append</code> , <code>reverse</code> , <code>extend</code> , <code>pop</code> , <code>remove</code> et <code>__iadd__</code>
<i>Set</i>	<i>Sized</i> , <i>Iterable</i> , <i>Container</i>	<code>__contains__</code> , <code>__iter__</code> , <code>__len__</code>	<code>__le__</code> , <code>__lt__</code> , <code>__eq__</code> , <code>__ne__</code> , <code>__gt__</code> , <code>__ge__</code> , <code>__and__</code> , <code>__or__</code> , <code>__sub__</code> , <code>__xor__</code> et <code>isdisjoint</code>
<i>MutableSet</i>	<i>Set</i>	<code>__contains__</code> , <code>__iter__</code> , <code>__len__</code> , <code>add</code> , <code>discard</code>	Méthodes héritées de <i>Set</i> , et <code>clear</code> , <code>pop</code> , <code>remove</code> , <code>__ior__</code> , <code>__iand__</code> , <code>__ixor__</code> et <code>__isub__</code>
<i>Mapping</i>	<i>Sized</i> , <i>Iterable</i> , <i>Container</i>	<code>__getitem__</code> , <code>__iter__</code> , <code>__len__</code>	<code>__contains__</code> , <code>keys</code> , <code>items</code> , <code>values</code> , <code>get</code> , <code>__eq__</code> et <code>__ne__</code>
<i>MutableMapping</i>	<i>Mapping</i>	<code>__getitem__</code> , <code>__setitem__</code> , <code>__delitem__</code> , <code>__iter__</code> , <code>__len__</code>	Méthodes héritées de <i>Mapping</i> , et <code>pop</code> , <code>popitem</code> , <code>clear</code> , <code>update</code> et <code>setdefault</code>
<i>MappingView</i>	<i>Sized</i>		<code>__len__</code>
<i>ItemsView</i>	<i>MappingView</i> , <i>Set</i>		<code>__contains__</code> , <code>__iter__</code>
<i>KeysView</i>	<i>MappingView</i> , <i>Set</i>		<code>__contains__</code> , <code>__iter__</code>
<i>ValuesView</i>	<i>MappingView</i>		<code>__contains__</code> , <code>__iter__</code>

```
class collections.Container
```

```
class collections.Hashable
```

```
class collections.Sized
```

```
class collections.Callable
```

ABC pour les classes qui définissent respectivement les méthodes `__contains__()`, `__hash__()`, `__len__()` et `__call__()`.

```
class collections.Iterable
```

ABC for classes that provide the `__iter__()` method. See also the definition of *iterable*.

```
class collections.Iterator
```

ABC for classes that provide the `__iter__()` and `next()` methods. See also the definition of *iterator*.

```
class collections.Sequence
```

```
class collections.MutableSequence
    ABC pour les séquences immuables et muables.

class collections.Set
class collections.MutableSet
    ABC pour les ensembles immuables et muables.

class collections.Mapping
class collections.MutableMapping
    ABC pour les tables de correspondances immuables et muables.

class collections.MappingView
class collections.ItemsView
class collections.KeysView
class collections.ValuesView
    ABC pour les vues de mappings (tableaux de correspondances), d'éléments, de clés et de valeurs.
```

Ces ABC permettent de demander à des classes ou à des instances si elles fournissent des fonctionnalités particulières, par exemple

```
size = None
if isinstance(myvar, collections.Sized):
    size = len(myvar)
```

Several of the ABCs are also useful as mixins that make it easier to develop classes supporting container APIs. For example, to write a class supporting the full *Set* API, it only necessary to supply the three underlying abstract methods: `__contains__()`, `__iter__()`, and `__len__()`. The ABC supplies the remaining methods such as `__and__()` and `isdisjoint()`

```
class ListBasedSet(collections.Set):
    ''' Alternate set implementation favoring space over speed
        and not requiring the set elements to be hashable. '''
    def __init__(self, iterable):
        self.elements = lst = []
        for value in iterable:
            if value not in lst:
                lst.append(value)

    def __iter__(self):
        return iter(self.elements)

    def __contains__(self, value):
        return value in self.elements

    def __len__(self):
        return len(self.elements)

s1 = ListBasedSet('abcdef')
s2 = ListBasedSet('defghi')
overlap = s1 & s2           # The __and__() method is supported automatically
```

Notes à propos de l'utilisation de *Set* et *MutableSet* comme *mixin* :

- (1) Comme une partie des opérations sur les ensembles créent de nouveaux ensembles, les méthodes *mixins* par défaut ont besoin d'un moyen de créer de nouvelles instances à partir d'un itérable. Le constructeur de classe est supposé avoir une signature de la forme `ClassName(iterable)`. Cette supposition est faite par une méthode de classe interne appelée `_from_iterable()` qui appelle `cls(iterable)` pour

construire un nouvel ensemble. Si le *Set mixin* est utilisé dans une classe avec un constructeur de signature différente, vous devrez surcharger `_from_iterable()` avec une méthode de classe qui peut construire de nouvelles instances à partir d'un argument itérable.

- (2) Pour surcharger les comparaisons (a priori pour la rapidité, puisque la sémantique est fixe), il faut redéfinir `__le__()` et `__ge__()`, puis les autres opérations seront automatiquement adaptées.
- (3) La classe *mixin Set* apporte une méthode `_hash()` pour calculer une valeur de hachage pour l'ensemble; cependant `__hash__()` n'est pas défini car tous les ensembles ne sont pas hachables ou immuables. Pour rendre un ensemble hachable en utilisant les *mixins*, héritez de `Set()` et de `Hashable()`, puis définissez `__hash__ = Set._hash`.

## 8.4 heapq — Heap queue algorithm

Nouveau dans la version 2.3.

Code source : [Lib/heapq.py](#)

This module provides an implementation of the heap queue algorithm, also known as the priority queue algorithm.

Heaps are binary trees for which every parent node has a value less than or equal to any of its children. This implementation uses arrays for which `heap[k] <= heap[2*k+1]` and `heap[k] <= heap[2*k+2]` for all *k*, counting elements from zero. For the sake of comparison, non-existing elements are considered to be infinite. The interesting property of a heap is that its smallest element is always the root, `heap[0]`.

The API below differs from textbook heap algorithms in two aspects : (a) We use zero-based indexing. This makes the relationship between the index for a node and the indexes for its children slightly less obvious, but is more suitable since Python uses zero-based indexing. (b) Our pop method returns the smallest item, not the largest (called a « min heap » in textbooks; a « max heap » is more common in texts because of its suitability for in-place sorting).

These two make it possible to view the heap as a regular Python list without surprises : `heap[0]` is the smallest item, and `heap.sort()` maintains the heap invariant!

To create a heap, use a list initialized to [], or you can transform a populated list into a heap via function `heapify()`.

Les fonctions suivantes sont fournies :

`heapq.heappush(heap, item)`

Push the value *item* onto the *heap*, maintaining the heap invariant.

`heapq.heappop(heap)`

Pop and return the smallest item from the *heap*, maintaining the heap invariant. If the heap is empty, *IndexError* is raised. To access the smallest item without popping it, use `heap[0]`.

`heapq.heappushpop(heap, item)`

Push *item* on the heap, then pop and return the smallest item from the *heap*. The combined action runs more efficiently than `heappush()` followed by a separate call to `heappop()`.

Nouveau dans la version 2.6.

`heapq.heapify(x)`

Transform list *x* into a heap, in-place, in linear time.

`heapq.heapreplace(heap, item)`

Pop and return the smallest item from the *heap*, and also push the new *item*. The heap size doesn't change. If the heap is empty, `IndexError` is raised.

This one step operation is more efficient than a `heappop()` followed by `heappush()` and can be more appropriate when using a fixed-size heap. The pop/push combination always returns an element from the heap and replaces it with *item*.

The value returned may be larger than the *item* added. If that isn't desired, consider using `heappushpop()` instead. Its push/pop combination returns the smaller of the two values, leaving the larger value on the heap.

The module also offers three general purpose functions based on heaps.

`heapq.merge(*iterables)`

Merge multiple sorted inputs into a single sorted output (for example, merge timestamped entries from multiple log files). Returns an *iterator* over the sorted values.

Similar to `sorted(itertools.chain(*iterables))` but returns an iterable, does not pull the data into memory all at once, and assumes that each of the input streams is already sorted (smallest to largest).

Nouveau dans la version 2.6.

`heapq.nlargest(n, iterable[, key])`

Return a list with the *n* largest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in the iterable : `key=str.lower` Equivalent to : `sorted(iterable, key=key, reverse=True)[:n]`

Nouveau dans la version 2.4.

Modifié dans la version 2.5 : Added the optional *key* argument.

`heapq.nsmallest(n, iterable[, key])`

Return a list with the *n* smallest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in the iterable : `key=str.lower` Equivalent to : `sorted(iterable, key=key)[:n]`

Nouveau dans la version 2.4.

Modifié dans la version 2.5 : Added the optional *key* argument.

The latter two functions perform best for smaller values of *n*. For larger values, it is more efficient to use the `sorted()` function. Also, when `n==1`, it is more efficient to use the built-in `min()` and `max()` functions. If repeated usage of these functions is required, consider turning the iterable into an actual heap.

### 8.4.1 Basic Examples

A `heapsort` can be implemented by pushing all values onto a heap and then popping off the smallest values one at a time :

```
>>> def heapsort(iterable):
...     h = []
...     for value in iterable:
...         heappush(h, value)
...     return [heappop(h) for i in range(len(h))]
...
>>> heapsort([1, 3, 5, 7, 9, 2, 4, 6, 8, 0])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

This is similar to `sorted(iterable)`, but unlike `sorted()`, this implementation is not stable.

Heap elements can be tuples. This is useful for assigning comparison values (such as task priorities) alongside the main record being tracked :

```
>>> h = []
>>> heappush(h, (5, 'write code'))
>>> heappush(h, (7, 'release product'))
>>> heappush(h, (1, 'write spec'))
>>> heappush(h, (3, 'create tests'))
>>> heappop(h)
(1, 'write spec')
```

## 8.4.2 Priority Queue Implementation Notes

A [priority queue](#) is common use for a heap, and it presents several implementation challenges :

- Sort stability : how do you get two tasks with equal priorities to be returned in the order they were originally added ?
- In the future with Python 3, tuple comparison breaks for (priority, task) pairs if the priorities are equal and the tasks do not have a default comparison order.
- If the priority of a task changes, how do you move it to a new position in the heap ?
- Or if a pending task needs to be deleted, how do you find it and remove it from the queue ?

A solution to the first two challenges is to store entries as 3-element list including the priority, an entry count, and the task. The entry count serves as a tie-breaker so that two tasks with the same priority are returned in the order they were added. And since no two entry counts are the same, the tuple comparison will never attempt to directly compare two tasks.

The remaining challenges revolve around finding a pending task and making changes to its priority or removing it entirely. Finding a task can be done with a dictionary pointing to an entry in the queue.

Removing the entry or changing its priority is more difficult because it would break the heap structure invariants. So, a possible solution is to mark the existing entry as removed and add a new entry with the revised priority :

```
pq = []                                # list of entries arranged in a heap
entry_finder = {}                      # mapping of tasks to entries
REMOVED = '<removed-task>'             # placeholder for a removed task
counter = itertools.count()            # unique sequence count

def add_task(task, priority=0):
    'Add a new task or update the priority of an existing task'
    if task in entry_finder:
        remove_task(task)
    count = next(counter)
    entry = [priority, count, task]
    entry_finder[task] = entry
    heappush(pq, entry)

def remove_task(task):
    'Mark an existing task as REMOVED. Raise KeyError if not found.'
    entry = entry_finder.pop(task)
    entry[-1] = REMOVED

def pop_task():
    'Remove and return the lowest priority task. Raise KeyError if empty.'
    while pq:
        priority, count, task = heappop(pq)
        if task is not REMOVED:
```

(suite sur la page suivante)

(suite de la page précédente)

```

del entry_finder[task]
return task
raise KeyError('pop from an empty priority queue')

```

### 8.4.3 Theory

Heaps are arrays for which  $a[k] \leq a[2k+1]$  and  $a[k] \leq a[2k+2]$  for all  $k$ , counting elements from 0. For the sake of comparison, non-existing elements are considered to be infinite. The interesting property of a heap is that  $a[0]$  is always its smallest element.

The strange invariant above is meant to be an efficient memory representation for a tournament. The numbers below are  $k$ , not  $a[k]$  :

In the tree above, each cell  $k$  is topping  $2k+1$  and  $2k+2$ . In a usual binary tournament we see in sports, each cell is the winner over the two cells it tops, and we can trace the winner down the tree to see all opponents s/he had. However, in many computer applications of such tournaments, we do not need to trace the history of a winner. To be more memory efficient, when a winner is promoted, we try to replace it by something else at a lower level, and the rule becomes that a cell and the two cells it tops contain three different items, but the top cell « wins » over the two topped cells.

If this heap invariant is protected at all time, index 0 is clearly the overall winner. The simplest algorithmic way to remove it and find the « next » winner is to move some loser (let's say cell 30 in the diagram above) into the 0 position, and then percolate this new 0 down the tree, exchanging values, until the invariant is re-established. This is clearly logarithmic on the total number of items in the tree. By iterating over all items, you get an  $O(n \log n)$  sort.

A nice feature of this sort is that you can efficiently insert new items while the sort is going on, provided that the inserted items are not « better » than the last 0'th element you extracted. This is especially useful in simulation contexts, where the tree holds all incoming events, and the « win » condition means the smallest scheduled time. When an event schedules other events for execution, they are scheduled into the future, so they can easily go into the heap. So, a heap is a good structure for implementing schedulers (this is what I used for my MIDI sequencer :-).

Various structures for implementing schedulers have been extensively studied, and heaps are good for this, as they are reasonably speedy, the speed is almost constant, and the worst case is not much different than the average case. However, there are other representations which are more efficient overall, yet the worst cases might be terrible.

Heaps are also very useful in big disk sorts. You most probably all know that a big sort implies producing « runs » (which are pre-sorted sequences, whose size is usually related to the amount of CPU memory), followed by a merging passes for these runs, which merging is often very cleverly organised<sup>1</sup>. It is very

1. The disk balancing algorithms which are current, nowadays, are more annoying than clever, and this is a consequence of the seeking capabilities of the disks. On devices which cannot seek, like big tape drives, the story was quite different, and one had to be very clever to ensure (far in advance) that each tape movement will be the most effective possible (that is, will best participate at « progressing » the merge). Some tapes were even able to read backwards, and this was also used to avoid the

important that the initial sort produces the longest runs possible. Tournaments are a good way to achieve that. If, using all the memory available to hold a tournament, you replace and percolate items that happen to fit the current run, you'll produce runs which are twice the size of the memory for random input, and much better for input fuzzily ordered.

Moreover, if you output the 0'th item on disk and get an input which may not fit in the current tournament (because the value « wins » over the last output value), it cannot fit in the heap, so the size of the heap decreases. The freed memory could be cleverly reused immediately for progressively building a second heap, which grows at exactly the same rate the first heap is melting. When the first heap completely vanishes, you switch heaps and start a new run. Clever and quite effective!

In a word, heaps are useful memory structures to know. I use them in a few applications, and I think it is good to keep a “heap” module around. :-)

## Notes

## 8.5 bisect — Algorithme de bisection de listes

Nouveau dans la version 2.1.

**Code source** : [Lib/bisect.py](#)

Ce module fournit des outils pour maintenir une liste triée sans avoir à la trier à chaque insertion. Il pourrait être plus rapide que l'approche classique pour de longues listes d'éléments dont les opérations de comparaison sont lourdes. Le module se nomme *bisect* car il utilise une approche simple par bisection. Si vous voulez un exemple de cet algorithme, le mieux est d'aller lire le code source de ce module (les conditions sur les limites y étant justes !).

Les fonctions suivantes sont fournies :

**bisect.bisect\_left**(*a*, *x*, *lo*=0, *hi*=len(*a*))

Trouve le point d'insertion de *x* dans *a* permettant de conserver l'ordre. Les paramètres *lo* et *hi* permettent de limiter les emplacements à vérifier dans la liste, par défaut toute la liste est utilisée. Si *x* est déjà présent dans *a*, le point d'insertion proposé sera avant (à gauche) de l'entrée existante. Si *a* est déjà triée, la valeur renvoyée peut directement être utilisée comme premier paramètre de `list.insert()`.

Le point d'insertion renvoyé, *i*, coupe la liste *a* en deux moitiés telles que, pour la moitié de gauche : `all(val < x for val in a[lo:i])`, et pour la partie de droite : `all(val >= x for val in a[i:hi])`.

**bisect.bisect\_right**(*a*, *x*, *lo*=0, *hi*=len(*a*))

**bisect.bisect**(*a*, *x*, *lo*=0, *hi*=len(*a*))

Semblable à *bisect\_left()*, mais renvoie un point d'insertion après (à droite) d'une potentielle entrée existante valant *x* dans *a*.

Le point d'insertion renvoyé, *i*, coupe la liste *a* en deux moitiés telles que, pour la moitié de gauche : `all(val <= x for val in a[lo:i])` et pour la moitié de droite : `all(val > x for val in a[i:hi])`.

**bisect.insort\_left**(*a*, *x*, *lo*=0, *hi*=len(*a*))

Insère *x* dans *a* en conservant le tri. C'est l'équivalent de `a.insert(bisect.bisect_left(a, x, lo, hi), x)`, tant que *a* est déjà triée. Gardez en tête que bien que la recherche ne coûte que  $O(\log n)$ , l'insertion coûte  $O(n)$ .

**bisect.insort\_right**(*a*, *x*, *lo*=0, *hi*=len(*a*))

rewinding time. Believe me, real good tape sorts were quite spectacular to watch! From all times, sorting has always been a Great Art! :-)

```
bisect.insort(a, x, lo=0, hi=len(a))
```

Similaire à `insort_left()`, mais en insérant `x` dans `a` après une potentielle entrée existante égale à `x`.

Voir aussi :

`SortedCollection` recipe utilise le module `bisect` pour construire une classe collection exposant des méthodes de recherches naturelles et gérant une fonction clef. Les clefs sont pré-calculées pour économiser des appels inutiles à la fonction clef durant les recherches.

### 8.5.1 Chercher dans des listes triées

Les fonctions `bisect()` ci-dessus sont utiles pour insérer des éléments, mais peuvent être étranges et peu naturelles à utiliser pour rechercher des éléments. Les cinq fonctions suivantes montrent comment les transformer en recherche plus classique pour les listes triées :

```
def index(a, x):
    'Locate the leftmost value exactly equal to x'
    i = bisect_left(a, x)
    if i != len(a) and a[i] == x:
        return i
    raise ValueError

def find_lt(a, x):
    'Find rightmost value less than x'
    i = bisect_left(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_le(a, x):
    'Find rightmost value less than or equal to x'
    i = bisect_right(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_gt(a, x):
    'Find leftmost value greater than x'
    i = bisect_right(a, x)
    if i != len(a):
        return a[i]
    raise ValueError

def find_ge(a, x):
    'Find leftmost item greater than or equal to x'
    i = bisect_left(a, x)
    if i != len(a):
        return a[i]
    raise ValueError
```

### 8.5.2 Autres Exemples

La fonction `bisect()` peut être utile pour des recherches dans des tableaux de nombres. Cet exemple utilise `bisect()` pour rechercher la note (sous forme de lettre) correspondant à un note sous forme de points, en se basant sur une échelle prédéfinie : plus de 90 vaut "A", de 80 à 89 vaut "B", etc... :

```
>>> def grade(score, breakpoints=[60, 70, 80, 90], grades='FDCBA'):
    i = bisect(breakpoints, score)
    return grades[i]

>>> [grade(score) for score in [33, 99, 77, 70, 89, 90, 100]]
['F', 'A', 'C', 'C', 'B', 'A', 'A']
```

Contrairement à la fonction `sorted()`, ça n'aurait pas de sens pour la fonction `bisect()` d'avoir un paramètre `key` ou `reversed`, qui conduiraient à une utilisation inefficace (des appels successifs à la fonction `bisect` n'auraient aucun moyen de se « souvenir » des recherches de clef précédentes).

Il est préférable d'utiliser une liste de clefs pré-calculée pour chercher l'index de l'enregistrement en question :

```
>>> data = [('red', 5), ('blue', 1), ('yellow', 8), ('black', 0)]
>>> data.sort(key=lambda r: r[1])
>>> keys = [r[1] for r in data]           # precomputed list of keys
>>> data[bisect_left(keys, 0)]
('black', 0)
>>> data[bisect_left(keys, 1)]
('blue', 1)
>>> data[bisect_left(keys, 5)]
('red', 5)
>>> data[bisect_left(keys, 8)]
('yellow', 8)
```

## 8.6 array — Tableaux efficaces de valeurs numériques

Ce module définit un type d'objet qui permet de représenter de façon compacte un tableau (*array*) de valeurs élémentaires : caractères, entiers, flottants. Les tableaux sont de type séquence et se comportent de manière très similaire aux listes, sauf que les types d'objets qui y sont stockés sont limités. Le type est spécifié au moment de la création de l'objet en utilisant *type code*, qui est un caractère unique. Voir ci-dessous pour la définition des types :

Code d'indication du type	Type C	Type Python	Taille minimum en octets
'c'	char	character	1
'b'	signed char	int	1
'B'	unsigned char	int	1
'u'	Py_UNICODE	Caractère Unicode	2 (see note)
'h'	signed short	int	2
'H'	unsigned short	int	2
'i'	signed int	int	2
'I'	unsigned int	long	2
'l'	signed long	int	4
'L'	unsigned long	long	4
'f'	float	float	4
'd'	double	float	8

**Note :** The 'u' typecode corresponds to Python's unicode character. On narrow Unicode builds this is 2-bytes, on wide builds this is 4-bytes.

The actual representation of values is determined by the machine architecture (strictly speaking, by the C implementation). The actual size can be accessed through the `itemsize` attribute. The values stored for 'L' and 'I' items will be represented as Python long integers when retrieved, because Python's plain integer type cannot represent the full range of C's unsigned (long) integers.

Le module définit le type suivant :

`class array.array(typecode[, initializer])`

A new array whose items are restricted by *typecode*, and initialized from the optional *initializer* value, which must be a list, string, or iterable over elements of the appropriate type.

Modifié dans la version 2.4 : Formerly, only lists or strings were accepted.

If given a list or string, the initializer is passed to the new array's `fromlist()`, `fromstring()`, or `fromunicode()` method (see below) to add initial items to the array. Otherwise, the iterable initializer is passed to the `extend()` method.

`array.ArrayType`

Obsolete alias for `array`.

Array objects support the ordinary sequence operations of indexing, slicing, concatenation, and multiplication. When using slice assignment, the assigned value must be an array object with the same type code; in all other cases, `TypeError` is raised. Array objects also implement the buffer interface, and may be used wherever buffer objects are supported.

Les éléments de données et méthodes suivants sont également supportés :

`array.typecode`

Le code (de type Python caractère) utilisé pour spécifier le type des éléments du tableau.

`array.itemsize`

La longueur en octets d'un élément du tableau dans la représentation interne.

`array.append(x)`

Ajoute un nouvel élément avec la valeur *x* à la fin du tableau.

`array.buffer_info()`

Renvoie un tuple (`address`, `length`) indiquant l'adresse mémoire courante et la longueur en éléments du tampon utilisé pour contenir le contenu du tableau. La taille du tampon mémoire en octets peut être calculée par `array.buffer_info()[1] * array.itemsize`. Ceci est parfois utile lorsque vous travaillez sur des interfaces E/S de bas niveau (et intrinsèquement dangereuses) qui nécessitent des adresses mémoire, telles que certaines opérations `ioctl()`. Les nombres renvoyés sont valides tant que le tableau existe et qu'aucune opération qui modifie sa taille ne lui est appliquée.

---

**Note :** Lors de l'utilisation d'objets tableaux provenant de codes écrits en C ou C++ (le seul moyen d'utiliser efficacement ces informations), il est plus logique d'utiliser l'interface tampon supportée par les objets tableaux. Cette méthode est maintenue pour des raisons de rétrocompatibilité et devrait être évitée dans un nouveau code. L'interface tampon est documentée dans `bufferobjects`.

---

`array.byteswap()`

Boutisme de tous les éléments du tableau. Ceci n'est pris en charge que pour les valeurs de 1, 2, 4 ou 8 octets ; pour les autres types de valeur, `RuntimeError` est levée. Il est utile lors de la lecture de données à partir d'un fichier écrit sur une machine avec un ordre d'octets différent.

`array.count(x)`

Renvoie le nombre d'occurrences de *x* dans le tableau.

`array.extend(iterable)`

Ajoute les éléments de *iterable* à la fin du tableau. Si *iterable* est un autre tableau, il doit le même code

d'indication du type ; dans le cas contraire, *TypeError* sera levée. Si *iterable* n'est pas un tableau, il doit être itérable et ces éléments doivent être du bon type pour être ajoutés dans le tableau.

Modifié dans la version 2.4 : Formerly, the argument could only be another array.

`array.fromfile(f, n)`

Read *n* items (as machine values) from the file object *f* and append them to the end of the array. If less than *n* items are available, *EOFError* is raised, but the items that were available are still inserted into the array. *f* must be a real built-in file object ; something else with a *read()* method won't do.

`array.fromlist(list)`

Ajoute les éléments de la liste. C'est l'équivalent de `for x in list: a.append(x)` sauf que s'il y a une erreur de type, le tableau est inchangé.

`array.fromstring(s)`

Ajoute des éléments de la chaîne, interprétant la chaîne comme un tableau de valeurs machine (comme si elle avait été lue depuis le fichier en utilisant la méthode `from file()`).

`array.fromunicode(s)`

Extends this array with data from the given unicode string. The array must be a type 'u' array ; otherwise a *ValueError* is raised. Use `array.fromstring(unicodestring.encode(enc))` to append Unicode data to an array of some other type.

`array.index(x)`

Renvoie le plus petit *i* tel que *i* est l'index de la première occurrence de *x* dans le tableau.

`array.insert(i, x)`

Ajoute un nouvel élément avec la valeur *x* dans le tableau avant la position *i*. Les valeurs négatives sont traitées relativement à la fin du tableau.

`array.pop([i])`

Supprime l'élément du tableau avec l'index *i* et le renvoie. L'argument optionnel par défaut est à -1, de sorte que par défaut le dernier élément est supprimé et renvoyé.

`array.read(f, n)`

Obsolète depuis la version 1.5.1 : Use the *fromfile()* method.

Read *n* items (as machine values) from the file object *f* and append them to the end of the array. If less than *n* items are available, *EOFError* is raised, but the items that were available are still inserted into the array. *f* must be a real built-in file object ; something else with a *read()* method won't do.

`array.remove(x)`

Supprime la première occurrence de *x* du tableau.

`array.reverse()`

Inverse l'ordre des éléments du tableau.

`array.tofile(f)`

Write all items (as machine values) to the file object *f*.

`array.tolist()`

Convertit le tableau en une liste ordinaire avec les mêmes éléments.

`array.tostring()`

Convert the array to an array of machine values and return the string representation (the same sequence of bytes that would be written to a file by the *tofile()* method.)

`array.tounicode()`

Convert the array to a unicode string. The array must be a type 'u' array ; otherwise a *ValueError* is raised. Use `array.tostring().decode(enc)` to obtain a unicode string from an array of some other type.

`array.write(f)`

Obsolète depuis la version 1.5.1 : Use the *tofile()* method.

Write all items (as machine values) to the file object *f*.

When an array object is printed or converted to a string, it is represented as `array(typecode, initializer)`. The *initializer* is omitted if the array is empty, otherwise it is a string if the *typecode* is 'c', otherwise it is a list of numbers. The string is guaranteed to be able to be converted back to an array with the same type and value using *eval()*, so long as the *array* class has been imported using `from array import array`. Examples :

```
array('l')
array('c', 'hello world')
array('u', u'hello \u2641')
array('l', [1, 2, 3, 4, 5])
array('d', [1.0, 2.0, 3.14])
```

**Module *struct*** Empaquetage et dépaquetage de données binaires hétérogènes.

**Module *xdrlib*** Empaquetage et dépaquetage des données XDR (External Data Representation) telles qu'elles sont utilisées dans certains systèmes d'appels de procédures à distance (ou RPC pour *remote procedure call* en anglais).

**The Numerical Python Documentation** L'extension *Numeric Python* (NumPy) définit un autre type de tableau ; voir <http://www.numpy.org/> pour plus d'informations sur *Numeric Python*.

## 8.7 sets — Unordered collections of unique elements

Nouveau dans la version 2.3.

Obsolète depuis la version 2.6 : The built-in *set/frozenset* types replace this module.

The *sets* module provides classes for constructing and manipulating unordered collections of unique elements. Common uses include membership testing, removing duplicates from a sequence, and computing standard math operations on sets such as intersection, union, difference, and symmetric difference.

Comme pour les autres collections, les ensembles supportent `x in set`, `len(set)`, et `for x in set`. En tant que collection non-triée, les ensembles n'enregistrent pas la position des éléments ou leur ordre d'insertion. En conséquence, les *sets* n'autorisent ni l'indexation, ni le découpage, ou tout autre comportement de séquence.

Most set applications use the *Set* class which provides every set method except for `__hash__()`. For advanced applications requiring a hash method, the *ImmutableSet* class adds a `__hash__()` method but omits methods which alter the contents of the set. Both *Set* and *ImmutableSet* derive from *BaseSet*, an abstract class useful for determining whether something is a set : `isinstance(obj, BaseSet)`.

The set classes are implemented using dictionaries. Accordingly, the requirements for set elements are the same as those for dictionary keys; namely, that the element defines both `__eq__()` and `__hash__()`. As a result, sets cannot contain mutable elements such as lists or dictionaries. However, they can contain immutable collections such as tuples or instances of *ImmutableSet*. For convenience in implementing sets of sets, inner sets are automatically converted to immutable form, for example, `Set([Set(['dog'])])` is transformed to `Set([ImmutableSet(['dog'])])`.

**class *sets.Set***(*[iterable]*)

Constructs a new empty *Set* object. If the optional *iterable* parameter is supplied, updates the set with elements obtained from iteration. All of the elements in *iterable* should be immutable or be transformable to an immutable using the protocol described in section *Protocol for automatic conversion to immutable*.

```
class sets.ImmutableSet([iterable])
```

Constructs a new empty *ImmutableSet* object. If the optional *iterable* parameter is supplied, updates the set with elements obtained from iteration. All of the elements in *iterable* should be immutable or be transformable to an immutable using the protocol described in section *Protocol for automatic conversion to immutable*.

Because *ImmutableSet* objects provide a `__hash__()` method, they can be used as set elements or as dictionary keys. *ImmutableSet* objects do not have methods for adding or removing elements, so all of the elements must be known when the constructor is called.

### 8.7.1 Set Objects

Instances of *Set* and *ImmutableSet* both provide the following operations :

Opération	Equivalent	Résultat
<code>len(s)</code>		number of elements in set <i>s</i> (cardinality)
<code>x in s</code>		test <i>x</i> for membership in <i>s</i>
<code>x not in s</code>		test <i>x</i> for non-membership in <i>s</i>
<code>s.issubset(t)</code>	<code>s &lt;= t</code>	test whether every element in <i>s</i> is in <i>t</i>
<code>s.issuperset(t)</code>	<code>s &gt;= t</code>	test whether every element in <i>t</i> is in <i>s</i>
<code>s.union(t)</code>	<code>s   t</code>	new set with elements from both <i>s</i> and <i>t</i>
<code>s.intersection(t)</code>	<code>s &amp; t</code>	new set with elements common to <i>s</i> and <i>t</i>
<code>s.difference(t)</code>	<code>s - t</code>	new set with elements in <i>s</i> but not in <i>t</i>
<code>s.symmetric_difference(t)</code>	<code>s ^ t</code>	new set with elements in either <i>s</i> or <i>t</i> but not both
<code>s.copy()</code>		new set with a shallow copy of <i>s</i>

Note, the non-operator versions of `union()`, `intersection()`, `difference()`, and `symmetric_difference()` will accept any iterable as an argument. In contrast, their operator based counterparts require their arguments to be sets. This precludes error-prone constructions like `Set('abc') & 'cbs'` in favor of the more readable `Set('abc').intersection('cbs')`.

Modifié dans la version 2.3.1 : Formerly all arguments were required to be sets.

In addition, both *Set* and *ImmutableSet* support set to set comparisons. Two sets are equal if and only if every element of each set is contained in the other (each is a subset of the other). A set is less than another set if and only if the first set is a proper subset of the second set (is a subset, but is not equal). A set is greater than another set if and only if the first set is a proper superset of the second set (is a superset, but is not equal).

The subset and equality comparisons do not generalize to a complete ordering function. For example, any two disjoint sets are not equal and are not subsets of each other, so *all* of the following return **False** : `a < b`, `a == b`, or `a > b`. Accordingly, sets do not implement the `__cmp__()` method.

Puisque les *sets* ne définissent qu'un ordre partiel (par leurs relations de sous-ensembles), la sortie de la méthode `list.sort()` n'est pas définie pour des listes d'ensembles.

The following table lists operations available in *ImmutableSet* but not found in *Set* :

Opération	Résultat
<code>hash(s)</code>	returns a hash value for <i>s</i>

The following table lists operations available in *Set* but not found in *ImmutableSet* :

Opération	Equiva- lent	Résultat
<code>s.update(t)</code>	$s \mid= t$	return set <i>s</i> with elements added from <i>t</i>
<code>s.intersection_update(t)</code>	$s \&= t$	return set <i>s</i> keeping only elements also found in <i>t</i>
<code>s.difference_update(t)</code>	$s -= t$	return set <i>s</i> after removing elements found in <i>t</i>
<code>s.symmetric_difference_update(t)</code>	$s \hat{=} t$	return set <i>s</i> with elements from <i>s</i> or <i>t</i> but not both
<code>s.add(x)</code>		add element <i>x</i> to set <i>s</i>
<code>s.remove(x)</code>		remove <i>x</i> from set <i>s</i> ; raises <i>KeyError</i> if not present
<code>s.discard(x)</code>		removes <i>x</i> from set <i>s</i> if present
<code>s.pop()</code>		remove and return an arbitrary element from <i>s</i> ; raises <i>KeyError</i> if empty
<code>s.clear()</code>		remove all elements from set <i>s</i>

Note, the non-operator versions of `update()`, `intersection_update()`, `difference_update()`, and `symmetric_difference_update()` will accept any iterable as an argument.

Modifié dans la version 2.3.1 : Formerly all arguments were required to be sets.

Also note, the module also includes a `union_update()` method which is an alias for `update()`. The method is included for backwards compatibility. Programmers should prefer the `update()` method because it is supported by the built-in `set()` and `frozenset()` types.

## 8.7.2 Exemple

```
>>> from sets import Set
>>> engineers = Set(['John', 'Jane', 'Jack', 'Janice'])
>>> programmers = Set(['Jack', 'Sam', 'Susan', 'Janice'])
>>> managers = Set(['Jane', 'Jack', 'Susan', 'Zack'])
>>> employees = engineers | programmers | managers           # union
>>> engineering_management = engineers & managers           # intersection
>>> fulltime_management = managers - engineers - programmers # difference
>>> engineers.add('Marvin')                                  # add element
>>> print engineers # doctest: +SKIP
Set(['Jane', 'Marvin', 'Janice', 'John', 'Jack'])
>>> employees.issuperset(engineers)                          # superset test
False
>>> employees.update(engineers)                               # update from another set
>>> employees.issuperset(engineers)
True
>>> for group in [engineers, programmers, managers, employees]: # doctest: +SKIP
...     group.discard('Susan')                               # unconditionally remove element
...     print group
...
Set(['Jane', 'Marvin', 'Janice', 'John', 'Jack'])
Set(['Janice', 'Jack', 'Sam'])
Set(['Jane', 'Zack', 'Jack'])
Set(['Jack', 'Sam', 'Jane', 'Marvin', 'Janice', 'John', 'Zack'])
```

## 8.7.3 Protocol for automatic conversion to immutable

Sets can only contain immutable elements. For convenience, mutable `Set` objects are automatically copied to an `ImmutableSet` before being added as a set element.

The mechanism is to always add a *hashable* element, or if it is not hashable, the element is checked to see if it has an `__as_immutable__()` method which returns an immutable equivalent.

Since *Set* objects have a `__as_immutable__()` method returning an instance of *ImmutableSet*, it is possible to construct sets of sets.

A similar mechanism is needed by the `__contains__()` and `remove()` methods which need to hash an element to check for membership in a set. Those methods check an element for hashability and, if not, check for a `__as_temporarily_immutable__()` method which returns the element wrapped by a class that provides temporary methods for `__hash__()`, `__eq__()`, and `__ne__()`.

The alternate mechanism spares the need to build a separate copy of the original mutable object.

*Set* objects implement the `__as_temporarily_immutable__()` method which returns the *Set* object wrapped by a new class `_TemporarilyImmutableSet`.

The two mechanisms for adding hashability are normally invisible to the user; however, a conflict can arise in a multi-threaded environment where one thread is updating a set while another has temporarily wrapped it in `_TemporarilyImmutableSet`. In other words, sets of mutable sets are not thread-safe.

### 8.7.4 Comparison to the built-in set types

The built-in *set* and *frozenset* types were designed based on lessons learned from the *sets* module. The key differences are :

- *Set* and *ImmutableSet* were renamed to *set* and *frozenset*.
- There is no equivalent to `BaseSet`. Instead, use `isinstance(x, (set, frozenset))`.
- The hash algorithm for the built-ins performs significantly better (fewer collisions) for most datasets.
- The built-in versions have more space efficient pickles.
- The built-in versions do not have a `union_update()` method. Instead, use the `update()` method which is equivalent.
- The built-in versions do not have a `_repr(sorted=True)` method. Instead, use the built-in `repr()` and `sorted()` functions : `repr(sorted(s))`.
- The built-in version does not have a protocol for automatic conversion to immutable. Many found this feature to be confusing and no one in the community reported having found real uses for it.

## 8.8 sched — Event scheduler

Code source : [Lib/sched.py](#)

The *sched* module defines a class which implements a general purpose event scheduler :

**class** `sched.scheduler`(*timefunc*, *delayfunc*)

The *scheduler* class defines a generic interface to scheduling events. It needs two functions to actually deal with the « outside world » — *timefunc* should be callable without arguments, and return a number (the « time », in any units whatsoever). The *delayfunc* function should be callable with one argument, compatible with the output of *timefunc*, and should delay that many time units. *delayfunc* will also be called with the argument 0 after each event is run to allow other threads an opportunity to run in multi-threaded applications.

Exemple :

```
>>> import sched, time
>>> s = sched.scheduler(time.time, time.sleep)
>>> def print_time(): print "From print_time", time.time()
...

```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> def print_some_times():
...     print time.time()
...     s.enter(5, 1, print_time, ())
...     s.enter(10, 1, print_time, ())
...     s.run()
...     print time.time()
...
>>> print_some_times()
930343690.257
From print_time 930343695.274
From print_time 930343700.273
930343700.276
```

In multi-threaded environments, the *scheduler* class has limitations with respect to thread-safety, inability to insert a new task before the one currently pending in a running scheduler, and holding up the main thread until the event queue is empty. Instead, the preferred approach is to use the *threading.Timer* class instead.

Exemple :

```
>>> import time
>>> from threading import Timer
>>> def print_time():
...     print "From print_time", time.time()
...
>>> def print_some_times():
...     print time.time()
...     Timer(5, print_time, ()).start()
...     Timer(10, print_time, ()).start()
...     time.sleep(11) # sleep while time-delay events execute
...     print time.time()
...
>>> print_some_times()
930343690.257
From print_time 930343695.274
From print_time 930343700.273
930343701.301
```

### 8.8.1 Scheduler Objects

*scheduler* instances have the following methods and attributes :

***scheduler.enterabs***(*time*, *priority*, *action*, *argument*)

Schedule a new event. The *time* argument should be a numeric type compatible with the return value of the *timefunc* function passed to the constructor. Events scheduled for the same *time* will be executed in the order of their *priority*. A lower number represents a higher priority.

Executing the event means executing *action*(*\*argument*). *argument* must be a sequence holding the parameters for *action*.

Return value is an event which may be used for later cancellation of the event (see *cancel()*).

***scheduler.enter***(*delay*, *priority*, *action*, *argument*)

Schedule an event for *delay* more time units. Other than the relative time, the other arguments, the effect and the return value are the same as those for *enterabs()*.

***scheduler.cancel***(*event*)

Remove the event from the queue. If *event* is not an event currently in the queue, this method will raise a *ValueError*.

`scheduler.empty()`

Return true if the event queue is empty.

`scheduler.run()`

Run all scheduled events. This function will wait (using the `delayfunc()` function passed to the constructor) for the next event, then execute it and so on until there are no more scheduled events.

Either *action* or *delayfunc* can raise an exception. In either case, the scheduler will maintain a consistent state and propagate the exception. If an exception is raised by *action*, the event will not be attempted in future calls to `run()`.

If a sequence of events takes longer to run than the time available before the next event, the scheduler will simply fall behind. No events will be dropped; the calling code is responsible for canceling events which are no longer pertinent.

`scheduler.queue`

Read-only attribute returning a list of upcoming events in the order they will be run. Each event is shown as a *named tuple* with the following fields : time, priority, action, argument.

Nouveau dans la version 2.6.

## 8.9 mutex — Mutual exclusion support

Obsolète depuis la version 2.6 : The *mutex* module has been removed in Python 3.

The *mutex* module defines a class that allows mutual-exclusion via acquiring and releasing locks. It does not require (or imply) *threading* or multi-tasking, though it could be useful for those purposes.

The *mutex* module defines the following class :

`class mutex.mutex`

Create a new (unlocked) mutex.

A mutex has two pieces of state — a « locked » bit and a queue. When the mutex is not locked, the queue is empty. Otherwise, the queue contains zero or more (`function`, `argument`) pairs representing functions (or methods) waiting to acquire the lock. When the mutex is unlocked while the queue is not empty, the first queue entry is removed and its `function(argument)` pair called, implying it now has the lock.

Of course, no multi-threading is implied – hence the funny interface for `lock()`, where a function is called once the lock is acquired.

### 8.9.1 Mutex Objects

*mutex* objects have following methods :

`mutex.test()`

Check whether the mutex is locked.

`mutex.testandset()`

« Atomic » test-and-set, grab the lock if it is not set, and return `True`, otherwise, return `False`.

`mutex.lock(function, argument)`

Execute `function(argument)`, unless the mutex is locked. In the case it is locked, place the function and argument on the queue. See `unlock()` for explanation of when `function(argument)` is executed in that case.

`mutex.unlock()`

Unlock the mutex if queue is empty, otherwise execute the first element in the queue.

## 8.10 Queue — A synchronized queue class

---

**Note :** The `Queue` module has been renamed to `queue` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

---

**Source code :** `Lib/Queue.py`

---

The `Queue` module implements multi-producer, multi-consumer queues. It is especially useful in threaded programming when information must be exchanged safely between multiple threads. The `Queue` class in this module implements all the required locking semantics. It depends on the availability of thread support in Python; see the `threading` module.

The module implements three types of queue, which differ only in the order in which the entries are retrieved. In a FIFO queue, the first tasks added are the first retrieved. In a LIFO queue, the most recently added entry is the first retrieved (operating like a stack). With a priority queue, the entries are kept sorted (using the `heapq` module) and the lowest valued entry is retrieved first.

The `Queue` module defines the following classes and exceptions :

**class** `Queue.Queue(maxsize=0)`

Constructor for a FIFO queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

**class** `Queue.LifoQueue(maxsize=0)`

Constructor for a LIFO queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

Nouveau dans la version 2.6.

**class** `Queue.PriorityQueue(maxsize=0)`

Constructeur pour une file de priorité. *maxsize* est un entier définissant le nombre maximal d'éléments pouvant être mis dans la file. L'insertion sera bloquée lorsque cette borne supérieure sera atteinte, jusqu'à ce que des éléments soient consommés. Si *maxsize* est inférieur ou égal à 0, la taille de la file sera infinie.

Les éléments de valeurs les plus faibles sont extraits en premier (l'élément de valeur la plus faible est celui renvoyé par `sorted(list(entries))[0]`). Un cas typique est d'utiliser des tuple de la forme : `(priority_number, data)`.

Nouveau dans la version 2.6.

**exception** `Queue.Empty`

Exception raised when non-blocking `get()` (or `get_nowait()`) is called on a `Queue` object which is empty.

**exception** `Queue.Full`

Exception raised when non-blocking `put()` (or `put_nowait()`) is called on a `Queue` object which is full.

**Voir aussi :**

`collections.deque` is an alternative implementation of unbounded queues with fast atomic `append()` and `popleft()` operations that do not require locking.

### 8.10.1 Objets Queue

Queue objects (`Queue`, `LifoQueue`, or `PriorityQueue`) provide the public methods described below.

**Queue.qsize()**

Renvoie la taille approximative de la file. Notez que `qsize() > 0` ne garantit pas qu'un `get()` ultérieur ne sera pas bloquant et que `qsize() < maxsize` ne garantit pas non plus qu'un `put()` ne sera pas bloquant.

**Queue.empty()**

Renvoie `True` si la file est vide, `False` sinon. Si `empty()` renvoie `True`, cela ne garantit pas qu'un appel ultérieur à `put()` ne sera pas bloquant. Similairement, si `empty()` renvoie `False`, cela ne garantit pas qu'un appel ultérieur à `get()` ne sera pas bloquant.

**Queue.full()**

Renvoie `True` si la file est pleine, `False` sinon. Si `full()` renvoie `True`, cela ne garantit pas qu'un appel ultérieur à `get()` ne sera pas bloquant. Similairement, si `full()` retourne `False`, cela ne garantit pas qu'un appel ultérieur à `put()` ne sera pas bloquant.

**Queue.put(item[, block[, timeout]])**

Met *item* dans la file. Si les arguments optionnels *block* et *timeout* sont respectivement `True` et `None` (les valeurs par défaut), la méthode bloque si nécessaire jusqu'à ce qu'un emplacement libre soit disponible. Si *timeout* est un nombre positif, elle bloque au plus *timeout* secondes et lève l'exception `Full` s'il n'y avait pas d'emplacement libre pendant cette période de temps. Sinon (*block* est `False`), elle met un élément dans la file s'il y a un emplacement libre immédiatement disponible. Si ce n'est pas le cas, elle lève l'exception `Full` (*timeout* est ignoré dans ce cas).

Nouveau dans la version 2.3 : The *timeout* parameter.

**Queue.put\_nowait(item)**

Équivalent à `put(item, False)`.

**Queue.get([block[, timeout]])**

Retire et renvoie un élément de la file. Si les arguments optionnels *block* et *timeout* valent respectivement `True` et `None` (les valeurs par défaut), la méthode bloque si nécessaire jusqu'à ce qu'un élément soit disponible. Si *timeout* est un entier positif, elle bloque au plus *timeout* secondes et lève l'exception `Empty` s'il n'y avait pas d'élément disponible pendant cette période de temps. Sinon (*block* vaut `False`), elle renvoie un élément s'il y en a un immédiatement disponible. Si ce n'est pas le cas, elle lève l'exception `Empty` (*timeout* est ignoré dans ce cas).

Nouveau dans la version 2.3 : The *timeout* parameter.

**Queue.get\_nowait()**

Équivalent à `get(False)`.

Deux méthodes sont proposées afin de savoir si les tâches mises dans la file ont été entièrement traitées par les fils d'exécution consommateurs du démon.

**Queue.task\_done()**

Indique qu'une tâche précédemment mise dans la file est terminée. Utilisé par les fils d'exécution consommateurs de la file. Pour chaque appel à `get()` effectué afin de récupérer une tâche, un appel ultérieur à `task_done()` informe la file que le traitement de la tâche est terminé.

Si un `join()` est actuellement bloquant, on reprendra lorsque tous les éléments auront été traités (ce qui signifie qu'un appel à `task_done()` a été effectué pour chaque élément qui a été `put()` dans la file).

Lève une exception `ValueError` si appelée plus de fois qu'il y avait d'éléments dans la file.

Nouveau dans la version 2.5.

**Queue.join()**

Bloque jusqu'à ce que tous les éléments de la file aient été obtenus et traités.

Le nombre de tâches inachevées augmente chaque fois qu'un élément est ajouté à la file. Ce nombre diminue chaque fois qu'un fil d'exécution consommateur appelle `task_done()` pour indiquer que l'élément a été extrait et que tout le travail à effectuer dessus est terminé. Lorsque le nombre de tâches non terminées devient nul, `join()` débloque.

Nouveau dans la version 2.5.

Exemple montrant comment attendre que les tâches mises dans la file soient terminées :

```
def worker():
    while True:
        item = q.get()
        do_work(item)
        q.task_done()

q = Queue()
for i in range(num_worker_threads):
    t = Thread(target=worker)
    t.daemon = True
    t.start()

for item in source():
    q.put(item)

q.join()          # block until all tasks are done
```

## 8.11 weakref — Weak references

Nouveau dans la version 2.1.

Code source : [Lib/weakref.py](#)

---

The *weakref* module allows the Python programmer to create *weak references* to objects.

In the following, the term *referent* means the object which is referred to by a weak reference.

A weak reference to an object is not enough to keep the object alive : when the only remaining references to a referent are weak references, *garbage collection* is free to destroy the referent and reuse its memory for something else. A primary use for weak references is to implement caches or mappings holding large objects, where it's desired that a large object not be kept alive solely because it appears in a cache or mapping.

For example, if you have a number of large binary image objects, you may wish to associate a name with each. If you used a Python dictionary to map names to images, or images to names, the image objects would remain alive just because they appeared as values or keys in the dictionaries. The *WeakKeyDictionary* and *WeakValueDictionary* classes supplied by the *weakref* module are an alternative, using weak references to construct mappings that don't keep objects alive solely because they appear in the mapping objects. If, for example, an image object is a value in a *WeakValueDictionary*, then when the last remaining references to that image object are the weak references held by weak mappings, garbage collection can reclaim the object, and its corresponding entries in weak mappings are simply deleted.

*WeakKeyDictionary* and *WeakValueDictionary* use weak references in their implementation, setting up callback functions on the weak references that notify the weak dictionaries when a key or value has been reclaimed by garbage collection. Most programs should find that using one of these weak dictionary types is all they need – it's not usually necessary to create your own weak references directly. The low-level machinery used by the weak dictionary implementations is exposed by the *weakref* module for the benefit of advanced uses.

Not all objects can be weakly referenced ; those objects which can include class instances, functions written in Python (but not in C), methods (both bound and unbound), sets, frozensets, file objects, *generators*, type objects, *DBcursor* objects from the *bsddb* module, sockets, arrays, dequeues, regular expression pattern objects, and code objects.

Modifié dans la version 2.4 : Added support for files, sockets, arrays, and patterns.

Modifié dans la version 2.7 : Added support for `thread.lock`, `threading.Lock`, and code objects.

Several built-in types such as `list` and `dict` do not directly support weak references but can add support through subclassing :

```
class Dict(dict):
    pass

obj = Dict(red=1, green=2, blue=3)    # this object is weak referenceable
```

**CPython implementation detail :** Other built-in types such as `tuple` and `long` do not support weak references even when subclassed.

Extension types can easily be made to support weak references ; see `weakref-support`.

`class weakref.ref(object[, callback])`

Return a weak reference to *object*. The original object can be retrieved by calling the reference object if the referent is still alive ; if the referent is no longer alive, calling the reference object will cause `None` to be returned. If *callback* is provided and not `None`, and the returned weakref object is still alive, the callback will be called when the object is about to be finalized ; the weak reference object will be passed as the only parameter to the callback ; the referent will no longer be available.

It is allowable for many weak references to be constructed for the same object. Callbacks registered for each weak reference will be called from the most recently registered callback to the oldest registered callback.

Exceptions raised by the callback will be noted on the standard error output, but cannot be propagated ; they are handled in exactly the same way as exceptions raised from an object's `__del__()` method.

Weak references are *hashable* if the *object* is hashable. They will maintain their hash value even after the *object* was deleted. If `hash()` is called the first time only after the *object* was deleted, the call will raise `TypeError`.

Weak references support tests for equality, but not ordering. If the referents are still alive, two references have the same equality relationship as their referents (regardless of the *callback*). If either referent has been deleted, the references are equal only if the reference objects are the same object.

Modifié dans la version 2.4 : This is now a subclassable type rather than a factory function ; it derives from `object`.

`weakref.proxy(object[, callback])`

Return a proxy to *object* which uses a weak reference. This supports use of the proxy in most contexts instead of requiring the explicit dereferencing used with weak reference objects. The returned object will have a type of either `ProxyType` or `CallableProxyType`, depending on whether *object* is callable. Proxy objects are not *hashable* regardless of the referent ; this avoids a number of problems related to their fundamentally mutable nature, and prevent their use as dictionary keys. *callback* is the same as the parameter of the same name to the `ref()` function.

`weakref.getweakrefcount(object)`

Return the number of weak references and proxies which refer to *object*.

`weakref.getweakrefs(object)`

Return a list of all weak reference and proxy objects which refer to *object*.

`class weakref.WeakKeyDictionary([dict])`

Mapping class that references keys weakly. Entries in the dictionary will be discarded when there is no longer a strong reference to the key. This can be used to associate additional data with an object owned by other parts of an application without adding attributes to those objects. This can be especially useful with objects that override attribute accesses.

---

**Note :** Caution : Because a *WeakKeyDictionary* is built on top of a Python dictionary, it must not change size when iterating over it. This can be difficult to ensure for a *WeakKeyDictionary* because actions performed by the program during iteration may cause items in the dictionary to vanish « by magic » (as a side effect of garbage collection).

---

*WeakKeyDictionary* objects have the following additional methods. These expose the internal references directly. The references are not guaranteed to be « live » at the time they are used, so the result of calling the references needs to be checked before being used. This can be used to avoid creating references that will cause the garbage collector to keep the keys around longer than needed.

`WeakKeyDictionary.iterkeyrefs()`

Return an iterable of the weak references to the keys.

Nouveau dans la version 2.5.

`WeakKeyDictionary.keyrefs()`

Return a list of weak references to the keys.

Nouveau dans la version 2.5.

`class weakref.WeakValueDictionary([dict])`

Mapping class that references values weakly. Entries in the dictionary will be discarded when no strong reference to the value exists any more.

---

**Note :** Caution : Because a *WeakValueDictionary* is built on top of a Python dictionary, it must not change size when iterating over it. This can be difficult to ensure for a *WeakValueDictionary* because actions performed by the program during iteration may cause items in the dictionary to vanish « by magic » (as a side effect of garbage collection).

---

*WeakValueDictionary* objects have the following additional methods. These methods have the same issues as the `iterkeyrefs()` and `keyrefs()` methods of *WeakKeyDictionary* objects.

`WeakValueDictionary.itervaluerefs()`

Return an iterable of the weak references to the values.

Nouveau dans la version 2.5.

`WeakValueDictionary.valuerefs()`

Return a list of weak references to the values.

Nouveau dans la version 2.5.

`class weakref.WeakSet([elements])`

Set class that keeps weak references to its elements. An element will be discarded when no strong reference to it exists any more.

Nouveau dans la version 2.7.

`weakref.ReferenceType`

The type object for weak references objects.

`weakref.ProxyType`

The type object for proxies of objects which are not callable.

`weakref.CallableProxyType`

The type object for proxies of callable objects.

`weakref.ProxyTypes`

Sequence containing all the type objects for proxies. This can make it simpler to test if an object is a proxy without being dependent on naming both proxy types.

**exception `weakref.ReferenceError`**

Exception raised when a proxy object is used but the underlying object has been collected. This is the same as the standard [\*ReferenceError\*](#) exception.

Voir aussi :

**PEP 205 - Weak References** The proposal and rationale for this feature, including links to earlier implementations and information about similar features in other languages.

### 8.11.1 Weak Reference Objects

Weak reference objects have no attributes or methods, but do allow the referent to be obtained, if it still exists, by calling it :

```
>>> import weakref
>>> class Object:
...     pass
...
>>> o = Object()
>>> r = weakref.ref(o)
>>> o2 = r()
>>> o is o2
True
```

If the referent no longer exists, calling the reference object returns *None* :

```
>>> del o, o2
>>> print r()
None
```

Testing that a weak reference object is still live should be done using the expression `ref() is not None`. Normally, application code that needs to use a reference object should follow this pattern :

```
# r is a weak reference object
o = r()
if o is None:
    # referent has been garbage collected
    print "Object has been deallocated; can't frobnicate."
else:
    print "Object is still live!"
    o.do_something_useful()
```

Using a separate test for « liveness » creates race conditions in threaded applications; another thread can cause a weak reference to become invalidated before the weak reference is called; the idiom shown above is safe in threaded applications as well as single-threaded applications.

Specialized versions of *ref* objects can be created through subclassing. This is used in the implementation of the [\*WeakValueDictionary\*](#) to reduce the memory overhead for each entry in the mapping. This may be most useful to associate additional information with a reference, but could also be used to insert additional processing on calls to retrieve the referent.

This example shows how a subclass of *ref* can be used to store additional information about an object and affect the value that's returned when the referent is accessed :

```
import weakref
```

(suite sur la page suivante)

(suite de la page précédente)

```

class ExtendedRef(weakref.ref):
    def __init__(self, ob, callback=None, **annotations):
        super(ExtendedRef, self).__init__(ob, callback)
        self.__counter = 0
        for k, v in annotations.iteritems():
            setattr(self, k, v)

    def __call__(self):
        """Return a pair containing the referent and the number of
        times the reference has been called.
        """
        ob = super(ExtendedRef, self).__call__()
        if ob is not None:
            self.__counter += 1
            ob = (ob, self.__counter)
        return ob

```

### 8.11.2 Exemple

This simple example shows how an application can use object IDs to retrieve objects that it has seen before. The IDs of the objects can then be used in other data structures without forcing the objects to remain alive, but the objects can still be retrieved by ID if they do.

```

import weakref

_id2obj_dict = weakref.WeakValueDictionary()

def remember(obj):
    oid = id(obj)
    _id2obj_dict[oid] = obj
    return oid

def id2obj(oid):
    return _id2obj_dict[oid]

```

## 8.12 UserDict — Class wrapper for dictionary objects

Source code : [Lib/UserDict.py](#)

The module defines a mixin, *DictMixin*, defining all dictionary methods for classes that already have a minimum mapping interface. This greatly simplifies writing classes that need to be substitutable for dictionaries (such as the *shelve* module).

This module also defines a class, *UserDict*, that acts as a wrapper around dictionary objects. The need for this class has been largely supplanted by the ability to subclass directly from *dict* (a feature that became available starting with Python version 2.2). Prior to the introduction of *dict*, the *UserDict* class was used to create dictionary-like sub-classes that obtained new behaviors by overriding existing methods or adding new ones.

The *UserDict* module defines the *UserDict* class and *DictMixin* :

---

```
class UserDict.UserDict([initialdata])
```

Class that simulates a dictionary. The instance's contents are kept in a regular dictionary, which is accessible via the `data` attribute of *UserDict* instances. If *initialdata* is provided, `data` is initialized with its contents; note that a reference to *initialdata* will not be kept, allowing it be used for other purposes.

---

**Note :** For backward compatibility, instances of *UserDict* are not iterable.

---

```
class UserDict.IterableUserDict([initialdata])
```

Subclass of *UserDict* that supports direct iteration (e.g. `for key in myDict`).

In addition to supporting the methods and operations of mappings (see section *Les types de correspondances — dict*), *UserDict* and *IterableUserDict* instances provide the following attribute :

**IterableUserDict.data**

A real dictionary used to store the contents of the *UserDict* class.

```
class UserDict.DictMixin
```

Mixin defining all dictionary methods for classes that already have a minimum dictionary interface including `__getitem__()`, `__setitem__()`, `__delitem__()`, and `keys()`.

This mixin should be used as a superclass. Adding each of the above methods adds progressively more functionality. For instance, defining all but `__delitem__()` will preclude only `pop()` and `popitem()` from the full interface.

In addition to the four base methods, progressively more efficiency comes with defining `__contains__()`, `__iter__()`, and `iteritems()`.

Since the mixin has no knowledge of the subclass constructor, it does not define `__init__()` or `copy()`. Starting with Python version 2.6, it is recommended to use *collections.MutableMapping* instead of *DictMixin*.

Note that DictMixin does not implement the *viewkeys()*, *viewvalues()*, or *viewitems()* methods.

## 8.13 UserList — Class wrapper for list objects

---

**Note :** When Python 2.2 was released, many of the use cases for this class were subsumed by the ability to subclass `list` directly. However, a handful of use cases remain.

This module provides a list-interface around an underlying data store. By default, that data store is a `list`; however, it can be used to wrap a list-like interface around other objects (such as persistent storage).

In addition, this class can be mixed-in with built-in classes using multiple inheritance. This can sometimes be useful. For example, you can inherit from *UserList* and *str* at the same time. That would not be possible with both a real `list` and a real *str*.

---

This module defines a class that acts as a wrapper around list objects. It is a useful base class for your own list-like classes, which can inherit from them and override existing methods or add new ones. In this way one can add new behaviors to lists.

The *UserList* module defines the *UserList* class :

```
class UserList.UserList([list])
```

Class that simulates a list. The instance's contents are kept in a regular list, which is accessible via the `data` attribute of *UserList* instances. The instance's contents are initially set to a copy of *list*, defaulting to the empty list `[]`. *list* can be any iterable, e.g. a real Python list or a *UserList* object.

---

**Note :** The `UserList` class has been moved to the `collections` module in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

---

In addition to supporting the methods and operations of mutable sequences (see section *Sequence Types* — `str`, `unicode`, `list`, `tuple`, `bytearray`, `buffer`, `xrange`), `UserList` instances provide the following attribute :

`UserList.data`

A real Python list object used to store the contents of the `UserList` class.

**Subclassing requirements :** Subclasses of `UserList` are expected to offer a constructor which can be called with either no arguments or one argument. List operations which return a new sequence attempt to create an instance of the actual implementation class. To do so, it assumes that the constructor can be called with a single parameter, which is a sequence object used as a data source.

Si une classe fille ne remplit pas cette condition, toutes les méthodes spéciales gérées par cette classe devront être implémentées à nouveau. Merci de consulter les sources pour obtenir des informations sur les méthodes qui doivent être fournies dans ce cas.

Modifié dans la version 2.0 : Python versions 1.5.2 and 1.6 also required that the constructor be callable with no parameters, and offer a mutable `data` attribute. Earlier versions of Python did not attempt to create instances of the derived class.

## 8.14 UserString — Class wrapper for string objects

---

**Note :** This `UserString` class from this module is available for backward compatibility only. If you are writing code that does not need to work with versions of Python earlier than Python 2.2, please consider subclassing directly from the built-in `str` type instead of using `UserString` (there is no built-in equivalent to `MutableString`).

---

This module defines a class that acts as a wrapper around string objects. It is a useful base class for your own string-like classes, which can inherit from them and override existing methods or add new ones. In this way one can add new behaviors to strings.

It should be noted that these classes are highly inefficient compared to real string or Unicode objects; this is especially the case for `MutableString`.

The `UserString` module defines the following classes :

`class UserString.UserString([sequence])`

Class that simulates a string or a Unicode string object. The instance's content is kept in a regular string or Unicode string object, which is accessible via the `data` attribute of `UserString` instances. The instance's contents are initially set to a copy of `sequence`. `sequence` can be either a regular Python string or Unicode string, an instance of `UserString` (or a subclass) or an arbitrary sequence which can be converted into a string using the built-in `str()` function.

---

**Note :** The `UserString` class has been moved to the `collections` module in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

---

`class UserString.MutableString([sequence])`

This class is derived from the `UserString` above and redefines strings to be *mutable*. Mutable strings can't be used as dictionary keys, because dictionaries require *immutable* objects as keys. The main intention of this class is to serve as an educational example for inheritance and necessity to remove

(override) the `__hash__()` method in order to trap attempts to use a mutable object as dictionary key, which would be otherwise very error prone and hard to track down.

Obsolète depuis la version 2.6 : The *MutableString* class has been removed in Python 3.

In addition to supporting the methods and operations of string and Unicode objects (see section *Méthodes de chaînes de caractères*), *UserString* instances provide the following attribute :

**MutableString.data**

A real Python string or Unicode object used to store the content of the *UserString* class.

## 8.15 types — Names for built-in types

Code source : [Lib/types.py](#)

This module defines names for some object types that are used by the standard Python interpreter, but not for the types defined by various extension modules. Also, it does not include some of the types that arise during processing such as the `listiterator` type. It is safe to use `from types import *` — the module does not export any names besides the ones listed here. New names exported by future versions of this module will all end in `Type`.

Typical use is for functions that do different things depending on their argument types, like the following :

```
from types import *
def delete(mylist, item):
    if type(item) is IntType:
        del mylist[item]
    else:
        mylist.remove(item)
```

Starting in Python 2.2, built-in factory functions such as `int()` and `str()` are also names for the corresponding types. This is now the preferred way to access the type instead of using the *types* module. Accordingly, the example above should be written as follows :

```
def delete(mylist, item):
    if isinstance(item, int):
        del mylist[item]
    else:
        mylist.remove(item)
```

The module defines the following names :

**types.NoneType**

The type of `None`.

**types.TypeType**

The type of type objects (such as returned by `type()`); alias of the built-in `type`.

**types.BooleanType**

The type of the `bool` values `True` and `False`; alias of the built-in `bool`.

Nouveau dans la version 2.3.

**types.IntType**

The type of integers (e.g. `1`); alias of the built-in `int`.

**types.LongType**

The type of long integers (e.g. `1L`); alias of the built-in `long`.

**types.FloatType**

The type of floating point numbers (e.g. 1.0); alias of the built-in *float*.

**types.ComplexType**

The type of complex numbers (e.g. 1.0j). This is not defined if Python was built without complex number support.

**types.StringType**

The type of character strings (e.g. 'Spam'); alias of the built-in *str*.

**types.UnicodeType**

The type of Unicode character strings (e.g. u'Spam'). This is not defined if Python was built without Unicode support. It's an alias of the built-in *unicode*.

**types.TupleType**

The type of tuples (e.g. (1, 2, 3, 'Spam')); alias of the built-in *tuple*.

**types.ListType**

The type of lists (e.g. [0, 1, 2, 3]); alias of the built-in *list*.

**types.DictType**

The type of dictionaries (e.g. {'Bacon': 1, 'Ham': 0}); alias of the built-in *dict*.

**types.DictionaryType**

An alternate name for DictType.

**types.FunctionType**

**types.LambdaType**

The type of user-defined functions and functions created by *lambda* expressions.

**types.GeneratorType**

The type of *generator*-iterator objects, produced by calling a generator function.  
Nouveau dans la version 2.2.

**types.CodeType**

The type for code objects such as returned by *compile()*.

**types.ClassType**

The type of user-defined old-style classes.

**types.InstanceType**

The type of instances of user-defined old-style classes.

**types.MethodType**

The type of methods of user-defined class instances.

**types.UnboundMethodType**

An alternate name for MethodType.

**types.BuiltinFunctionType**

**types.BuiltinMethodType**

The type of built-in functions like *len()* or *sys.exit()*, and methods of built-in classes. (Here, the term « built-in » means « written in C ».)

**types.ModuleType**

The type of modules.

**types.FileType**

The type of open file objects such as *sys.stdout*; alias of the built-in *file*.

**types.XRangeType**

The type of range objects returned by *xrange()*; alias of the built-in *xrange*.

**types.SliceType**

The type of objects returned by `slice()`; alias of the built-in `slice`.

**types.EllipsisType**

The type of `Ellipsis`.

**types.TracebackType**

The type of traceback objects such as found in `sys.exc_traceback`.

**types.FrameType**

The type of frame objects such as found in `tb.tb_frame` if `tb` is a traceback object.

**types.BufferType**

The type of buffer objects created by the `buffer()` function.

**types.DictProxyType**

The type of dict proxies, such as `TypeType.__dict__`.

**types.NotImplementedType**

The type of `NotImplemented`

**types.GetSetDescriptorType**

The type of objects defined in extension modules with `PyGetSetDef`, such as `FrameType.f_locals` or `array.array.typecode`. This type is used as descriptor for object attributes; it has the same purpose as the `property` type, but for classes defined in extension modules.

Nouveau dans la version 2.5.

**types.MemberDescriptorType**

The type of objects defined in extension modules with `PyMemberDef`, such as `datetime.timedelta.days`. This type is used as descriptor for simple C data members which use standard conversion functions; it has the same purpose as the `property` type, but for classes defined in extension modules.

**CPython implementation detail :** In other implementations of Python, this type may be identical to `GetSetDescriptorType`.

Nouveau dans la version 2.5.

**types.StringTypes**

A sequence containing `StringType` and `UnicodeType` used to facilitate easier checking for any string object. Using this is more portable than using a sequence of the two string types constructed elsewhere since it only contains `UnicodeType` if it has been built in the running version of Python. For example : `isinstance(s, types.StringTypes)`.

Nouveau dans la version 2.2.

## 8.16 new — Creation of runtime internal objects

Obsolète depuis la version 2.6 : The `new` module has been removed in Python 3. Use the `types` module's classes instead.

The `new` module allows an interface to the interpreter object creation functions. This is for use primarily in marshal-type functions, when a new object needs to be created « magically » and not by using the regular creation functions. This module provides a low-level interface to the interpreter, so care must be exercised when using this module. It is possible to supply non-sensical arguments which crash the interpreter when the object is used.

The `new` module defines the following functions :

**new.instance(*class*[, *dict*])**

This function creates an instance of `class` with dictionary `dict` without calling the `__init__()` constructor. If `dict` is omitted or `None`, a new, empty dictionary is created for the new instance. Note that there are no guarantees that the object will be in a consistent state.

**new.instancemethod**(*function*, *instance*, *class*)

This function will return a method object, bound to *instance*, or unbound if *instance* is **None**. *function* must be callable.

**new.function**(*code*, *globals*[, *name*[, *argdefs*[, *closure*]]])

Returns a (Python) function with the given code and globals. If *name* is given, it must be a string or **None**. If it is a string, the function will have the given name, otherwise the function name will be taken from *code.co\_name*. If *argdefs* is given, it must be a tuple and will be used to determine the default values of parameters. If *closure* is given, it must be **None** or a tuple of cell objects containing objects to bind to the names in *code.co\_freevars*.

**new.code**(*argcount*, *nlocals*, *stacksize*, *flags*, *codestring*, *constants*, *names*, *varnames*, *filename*, *name*, *firstlineno*, *lnotab*)

This function is an interface to the `PyCode_New()` C function.

**new.module**(*name*[, *doc*])

This function returns a new module object with name *name*. *name* must be a string. The optional *doc* argument can have any type.

**new.classobj**(*name*, *baseclasses*, *dict*)

This function returns a new class object, with name *name*, derived from *baseclasses* (which should be a tuple of classes) and with namespace *dict*.

## 8.17 copy — Opérations de copie superficielle et récursive

Les instructions d'affectation en Python ne copient pas les objets, elles créent des liens entre la cible et l'objet. Concernant les collections qui sont muables ou contiennent des éléments muables, une copie est parfois nécessaire, pour pouvoir modifier une copie sans modifier l'autre. Ce module met à disposition des opérations de copie génériques superficielle et récursive (comme expliqué ci-dessous).

Résumé de l'interface :

**copy.copy**(*x*)

Renvoie une copie superficielle de *x*.

**copy.deepcopy**(*x*)

Renvoie une copie récursive de *x*.

**exception copy.error**

Levée pour les erreurs spécifiques au module.

La différence entre copie superficielle et récursive n'est pertinente que pour les objets composés (objets contenant d'autres objets, comme des listes ou des instances de classe) :

- Une *copie superficielle* construit un nouvel objet composé puis (dans la mesure du possible) insère dans l'objet composé des *références* aux objets trouvés dans l'original.
- Une *copie récursive (ou profonde)* construit un nouvel objet composé puis, récursivement, insère dans l'objet composé des *copies* des objets trouvés dans l'objet original.

On rencontre souvent deux problèmes avec les opérations de copie récursive qui n'existent pas avec les opérations de copie superficielle :

- Les objets récursifs (objets composés qui, directement ou indirectement, contiennent une référence à eux-mêmes) peuvent causer une boucle récursive.
- Because deep copy copies everything it may copy too much, such as data which is intended to be shared between copies.

La fonction `deepcopy()` évite ces problèmes en :

- gardant en mémoire dans un dictionnaire les objets déjà copiés durant la phase de copie actuelle ; et
- laissant les classes créées par l'utilisateur écraser l'opération de copie ou l'ensemble de composants copiés.

Ce module ne copie pas les types tels que module, méthode, trace d'appels, cadre de pile, fichier, socket, fenêtre, tableau, ou tout autre type similaire. Il « copie » les fonctions et les classes (superficiellement et récursivement), en retournant l'objet original inchangé ; c'est compatible avec la manière dont ils sont traités par le module *pickle*.

Les copies superficielles de dictionnaires peuvent être faites en utilisant *dict.copy()*, et de listes en affectant un slice de la liste, par exemple, *copied\_list = original\_list[:]*.

Modifié dans la version 2.5 : Added copying functions.

Classes can use the same interfaces to control copying that they use to control pickling. See the description of module *pickle* for information on these methods. The *copy* module does not use the *copy\_reg* registration module.

Afin qu'une classe définisse sa propre implémentation de copie, elle peut définir les méthodes spéciales *\_\_copy\_\_()* et *\_\_deepcopy\_\_()*. La première est appelée pour implémenter l'opération de copie superficielle ; aucun argument supplémentaire n'est passé. La seconde est appelée pour implémenter l'opération de copie récursive ; elle reçoit un argument, le dictionnaire *memo*. Si l'implémentation de *\_\_deepcopy\_\_()* a besoin de faire une copie récursive d'un composant, elle devrait appeler la fonction *deepcopy()* avec le composant comme premier argument et le dictionnaire *memo* comme second argument.

Voir aussi :

**Module *pickle*** Discussion sur les méthodes spéciales utilisées pour gérer la récupération et la restauration de l'état d'un objet.

## 8.18 pprint — Data pretty printer

Code source : [Lib/pprint.py](#)

The *pprint* module provides a capability to « pretty-print » arbitrary Python data structures in a form which can be used as input to the interpreter. If the formatted structures include objects which are not fundamental Python types, the representation may not be loadable. This may be the case if objects such as files, sockets, classes, or instances are included, as well as many other built-in objects which are not representable as Python constants.

The formatted representation keeps objects on a single line if it can, and breaks them onto multiple lines if they don't fit within the allowed width. Construct *PrettyPrinter* objects explicitly if you need to adjust the width constraint.

Modifié dans la version 2.5 : Dictionaries are sorted by key before the display is computed ; before 2.5, a dictionary was sorted only if its display required more than one line, although that wasn't documented.

Modifié dans la version 2.6 : Added support for *set* and *frozenset*.

The *pprint* module defines one class :

**class pprint.PrettyPrinter(indent=1, width=80, depth=None, stream=None)**

Construct a *PrettyPrinter* instance. This constructor understands several keyword parameters. An output stream may be set using the *stream* keyword ; the only method used on the stream object is the file protocol's *write()* method. If not specified, the *PrettyPrinter* adopts *sys.stdout*. Three additional parameters may be used to control the formatted representation. The keywords are *indent*, *depth*, and *width*. The amount of indentation added for each recursive level is specified by *indent* ; the default is one. Other values can cause output to look a little odd, but can make nesting easier to spot. The number of levels which may be printed is controlled by *depth* ; if the data structure being printed is too deep, the next contained level is replaced by *...* By default, there is no constraint on the depth of the objects being formatted. The desired output width is constrained using the *width* parameter ;

the default is 80 characters. If a structure cannot be formatted within the constrained width, a best effort will be made.

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff[:])
>>> pp = pprint.PrettyPrinter(indent=4)
>>> pp.pprint(stuff)
[ ['spam', 'eggs', 'lumberjack', 'knights', 'ni'],
  'spam',
  'eggs',
  'lumberjack',
  'knights',
  'ni']
>>> tup = ('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead',
... ('parrot', ('fresh fruit',))))))))))
>>> pp = pprint.PrettyPrinter(depth=6)
>>> pp.pprint(tup)
('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead', (...)))))))
```

The *PrettyPrinter* class supports several derivative functions :

`pprint.pformat(object, indent=1, width=80, depth=None)`

Return the formatted representation of *object* as a string. *indent*, *width* and *depth* will be passed to the *PrettyPrinter* constructor as formatting parameters.

Modifié dans la version 2.4 : The parameters *indent*, *width* and *depth* were added.

`pprint.pprint(object, stream=None, indent=1, width=80, depth=None)`

Prints the formatted representation of *object* on *stream*, followed by a newline. If *stream* is *None*, *sys.stdout* is used. This may be used in the interactive interpreter instead of a `print` statement for inspecting values. *indent*, *width* and *depth* will be passed to the *PrettyPrinter* constructor as formatting parameters.

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff)
>>> pprint.pprint(stuff)
[<Recursion on list with id=...>,
  'spam',
  'eggs',
  'lumberjack',
  'knights',
  'ni']
```

Modifié dans la version 2.4 : The parameters *indent*, *width* and *depth* were added.

`pprint.isreadable(object)`

Determine if the formatted representation of *object* is « readable, » or can be used to reconstruct the value using *eval()*. This always returns **False** for recursive objects.

```
>>> pprint.isreadable(stuff)
False
```

`pprint.isrecursive(object)`

Determine if *object* requires a recursive representation.

One more support function is also defined :

`pprint.saferepr(object)`

Return a string representation of *object*, protected against recursive data structures. If the representation of *object* exposes a recursive entry, the recursive reference will be represented as `<Recursion on typename with id=number>`. The representation is not otherwise formatted.

```
>>> pprint.saferepr(stuff)
" [<Recursion on list with id=...>, 'spam', 'eggs', 'lumberjack', 'knights', 'ni'] "
```

### 8.18.1 PrettyPrinter Objects

*PrettyPrinter* instances have the following methods :

`PrettyPrinter.pformat(object)`

Return the formatted representation of *object*. This takes into account the options passed to the *PrettyPrinter* constructor.

`PrettyPrinter.pprint(object)`

Print the formatted representation of *object* on the configured stream, followed by a newline.

The following methods provide the implementations for the corresponding functions of the same names. Using these methods on an instance is slightly more efficient since new *PrettyPrinter* objects don't need to be created.

`PrettyPrinter.isreadable(object)`

Determine if the formatted representation of the object is « readable, » or can be used to reconstruct the value using `eval()`. Note that this returns `False` for recursive objects. If the *depth* parameter of the *PrettyPrinter* is set and the object is deeper than allowed, this returns `False`.

`PrettyPrinter.isrecursive(object)`

Determine if the object requires a recursive representation.

This method is provided as a hook to allow subclasses to modify the way objects are converted to strings. The default implementation uses the internals of the *saferepr()* implementation.

`PrettyPrinter.format(object, context, maxlevels, level)`

Returns three values : the formatted version of *object* as a string, a flag indicating whether the result is readable, and a flag indicating whether recursion was detected. The first argument is the object to be presented. The second is a dictionary which contains the *id()* of objects that are part of the current presentation context (direct and indirect containers for *object* that are affecting the presentation) as the keys ; if an object needs to be presented which is already represented in *context*, the third return value should be `True`. Recursive calls to the *format()* method should add additional entries for containers to this dictionary. The third argument, *maxlevels*, gives the requested limit to recursion ; this will be 0 if there is no requested limit. This argument should be passed unmodified to recursive calls. The fourth argument, *level*, gives the current level ; recursive calls should be passed a value less than that of the current call.

Nouveau dans la version 2.3.

### 8.18.2 pprint Example

This example demonstrates several uses of the *pprint()* function and its parameters.

```
>>> import pprint
>>> tup = ('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead',
... ('parrot', ('fresh fruit',))))))))
>>> stuff = ['a' * 10, tup, ['a' * 30, 'b' * 30], ['c' * 20, 'd' * 20]]
>>> pprint.pprint(stuff)
['aaaaaaaaaa',
```

(suite sur la page suivante)

(suite de la page précédente)

```

('spam',
 ('eggs',
  ('lumberjack',
   ('knights', ('ni', ('dead', ('parrot', ('fresh fruit',))))))),
 ['aaaaaaaaaaaaaaaaaaaaaaaaaaaaa', 'bbbbbbbbbbbbbbbbbbbbbbbbbbbbbb'],
 ['cccccccccccccccccccc', 'dddddddddddddddddddd'])
>>> pprint.pprint(stuff, depth=3)
['aaaaaaaa',
 ('spam', ('eggs', (...))),
 ['aaaaaaaaaaaaaaaaaaaaaaaaaaaaa', 'bbbbbbbbbbbbbbbbbbbbbbbbbbbbbb'],
 ['cccccccccccccccccccc', 'dddddddddddddddddddd')]
>>> pprint.pprint(stuff, width=60)
['aaaaaaaa',
 ('spam',
  ('eggs',
   ('lumberjack',
    ('knights',
     ('ni', ('dead', ('parrot', ('fresh fruit',))))))),
 ['aaaaaaaaaaaaaaaaaaaaaaaaaaaaa',
  'bbbbbbbbbbbbbbbbbbbbbbbbbbbbbb'],
 ['cccccccccccccccccccc', 'dddddddddddddddddddd')]

```

## 8.19 repr — Alternate repr() implementation

**Note :** The `repr` module has been renamed to `reprlib` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

**Source code :** [Lib/repr.py](#)

The `repr` module provides a means for producing object representations with limits on the size of the resulting strings. This is used in the Python debugger and may be useful in other contexts as well.

This module provides a class, an instance, and a function :

### `class repr.Repr`

Class which provides formatting services useful in implementing functions similar to the built-in `repr()`; size limits for different object types are added to avoid the generation of representations which are excessively long.

### `repr.aRepr`

This is an instance of `Repr` which is used to provide the `repr()` function described below. Changing the attributes of this object will affect the size limits used by `repr()` and the Python debugger.

### `repr.repr(obj)`

This is the `repr()` method of `aRepr`. It returns a string similar to that returned by the built-in function of the same name, but with limits on most sizes.

### 8.19.1 Repr Objects

`Repr` instances provide several attributes which can be used to provide size limits for the representations of different object types, and methods which format specific object types.

`Repr.maxlevel`

Depth limit on the creation of recursive representations. The default is 6.

`Repr.maxdict`

`Repr.maxlist`

`Repr.maxtuple`

`Repr.maxset`

`Repr.maxfrozenset`

`Repr.maxdeque`

`Repr.maxarray`

Limits on the number of entries represented for the named object type. The default is 4 for *maxdict*, 5 for *maxarray*, and 6 for the others.

Nouveau dans la version 2.4 : *maxset*, *maxfrozenset*, and *set*.

`Repr.maxlong`

Maximum number of characters in the representation for a long integer. Digits are dropped from the middle. The default is 40.

`Repr.maxstring`

Limit on the number of characters in the representation of the string. Note that the « normal » representation of the string is used as the character source : if escape sequences are needed in the representation, these may be mangled when the representation is shortened. The default is 30.

`Repr.maxother`

This limit is used to control the size of object types for which no specific formatting method is available on the *Repr* object. It is applied in a similar manner as *maxstring*. The default is 20.

`Repr.repr(obj)`

The equivalent to the built-in *repr()* that uses the formatting imposed by the instance.

`Repr.repr1(obj, level)`

Recursive implementation used by *repr()*. This uses the type of *obj* to determine which formatting method to call, passing it *obj* and *level*. The type-specific methods should call *repr1()* to perform recursive formatting, with *level - 1* for the value of *level* in the recursive call.

`Repr.repr_TYPE(obj, level)`

Formatting methods for specific types are implemented as methods with a name based on the type name. In the method name, **TYPE** is replaced by `string.join(string.split(type(obj).__name__, '_'))`. Dispatch to these methods is handled by *repr1()*. Type-specific methods which need to recursively format a value should call `self.repr1(subobj, level - 1)`.

## 8.19.2 Subclassing Repr Objects

The use of dynamic dispatching by *Repr.repr1()* allows subclasses of *Repr* to add support for additional built-in object types or to modify the handling of types already supported. This example shows how special support for file objects could be added :

```

import repr as reprlib
import sys

class MyRepr(reprlib.Repr):
    def repr_file(self, obj, level):
        if obj.name in ['<stdin>', '<stdout>', '<stderr>']:
            return obj.name
        else:
            return repr(obj)

```

(suite sur la page suivante)

(suite de la page précédente)

```
aRepr = MyRepr()
print aRepr.repr(sys.stdin)           # prints '<stdin>'
```

---

Modules numériques et mathématiques

---

The modules described in this chapter provide numeric and math-related functions and data types. The *numbers* module defines an abstract hierarchy of numeric types. The *math* and *cmath* modules contain various mathematical functions for floating-point and complex numbers. For users more interested in decimal accuracy than in speed, the *decimal* module supports exact representations of decimal numbers.

Les modules suivants sont documentés dans ce chapitre :

## 9.1 numbers — Numeric abstract base classes

Nouveau dans la version 2.6.

The *numbers* module ([PEP 3141](#)) defines a hierarchy of numeric *abstract base classes* which progressively define more operations. None of the types defined in this module can be instantiated.

**class numbers.Number**

The root of the numeric hierarchy. If you just want to check if an argument *x* is a number, without caring what kind, use `isinstance(x, Number)`.

### 9.1.1 The numeric tower

**class numbers.Complex**

Subclasses of this type describe complex numbers and include the operations that work on the built-in *complex* type. These are : conversions to *complex* and *bool*, *real*, *imag*, *+*, *-*, *\**, */*, *abs()*, *conjugate()*, *==*, and *!=*. All except *-* and *!=* are abstract.

**real**

Abstract. Retrieves the real component of this number.

**imag**

Abstract. Retrieves the imaginary component of this number.

**conjugate()**

Abstract. Returns the complex conjugate. For example, `(1+3j).conjugate() == (1-3j)`.

**class numbers.Real**

To *Complex*, *Real* adds the operations that work on real numbers.

In short, those are : a conversion to *float*, *math.trunc()*, *round()*, *math.floor()*, *math.ceil()*, *divmod()*, *//*, *%*, *<*, *<=*, *>*, and *>=*.

Real also provides defaults for *complex()*, *real*, *imag*, and *conjugate()*.

**class numbers.Rational**

Subtypes *Real* and adds *numerator* and *denominator* properties, which should be in lowest terms. With these, it provides a default for *float()*.

**numerator**

Résumé.

**denominator**

Résumé.

**class numbers.Integral**

Subtypes *Rational* and adds a conversion to *int*. Provides defaults for *float()*, *numerator*, and *denominator*. Adds abstract methods for *\*\** and bit-string operations : *<<*, *>>*, *&*, *^*, *|*, *~*.

## 9.1.2 Notes for type implementors

Implementors should be careful to make equal numbers equal and hash them to the same values. This may be subtle if there are two different extensions of the real numbers. For example, *fractions.Fraction* implements *hash()* as follows :

```
def __hash__(self):
    if self.denominator == 1:
        # Get integers right.
        return hash(self.numerator)
    # Expensive check, but definitely correct.
    if self == float(self):
        return hash(float(self))
    else:
        # Use tuple's hash to avoid a high collision rate on
        # simple fractions.
        return hash((self.numerator, self.denominator))
```

### Adding More Numeric ABCs

There are, of course, more possible ABCs for numbers, and this would be a poor hierarchy if it precluded the possibility of adding those. You can add *MyFoo* between *Complex* and *Real* with :

```
class MyFoo(Complex): ...
MyFoo.register(Real)
```

### Implementing the arithmetic operations

We want to implement the arithmetic operations so that mixed-mode operations either call an implementation whose author knew about the types of both arguments, or convert both to the nearest built in type and do the operation there. For subtypes of *Integral*, this means that *\_\_add\_\_()* and *\_\_radd\_\_()* should be defined as :

```
class MyIntegral(Integral):

    def __add__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(self, other)
```

(suite sur la page suivante)

(suite de la page précédente)

```

elif isinstance(other, OtherTypeIKnowAbout):
    return do_my_other_adding_stuff(self, other)
else:
    return NotImplemented

def __radd__(self, other):
    if isinstance(other, MyIntegral):
        return do_my_adding_stuff(other, self)
    elif isinstance(other, OtherTypeIKnowAbout):
        return do_my_other_adding_stuff(other, self)
    elif isinstance(other, Integral):
        return int(other) + int(self)
    elif isinstance(other, Real):
        return float(other) + float(self)
    elif isinstance(other, Complex):
        return complex(other) + complex(self)
    else:
        return NotImplemented

```

There are 5 different cases for a mixed-type operation on subclasses of *Complex*. I'll refer to all of the above code that doesn't refer to *MyIntegral* and *OtherTypeIKnowAbout* as « boilerplate ». *a* will be an instance of *A*, which is a subtype of *Complex* (*a* : *A* <: *Complex*), and *b* : *B* <: *Complex*. I'll consider *a* + *b* :

1. If *A* defines an `__add__()` which accepts *b*, all is well.
2. If *A* falls back to the boilerplate code, and it were to return a value from `__add__()`, we'd miss the possibility that *B* defines a more intelligent `__radd__()`, so the boilerplate should return *NotImplemented* from `__add__()`. (Or *A* may not implement `__add__()` at all.)
3. Then *B*'s `__radd__()` gets a chance. If it accepts *a*, all is well.
4. If it falls back to the boilerplate, there are no more possible methods to try, so this is where the default implementation should live.
5. If *B* <: *A*, Python tries *B*.`__radd__` before *A*.`__add__`. This is ok, because it was implemented with knowledge of *A*, so it can handle those instances before delegating to *Complex*.

If *A* <: *Complex* and *B* <: *Real* without sharing any other knowledge, then the appropriate shared operation is the one involving the built in *complex*, and both `__radd__()` s land there, so *a*+*b* == *b*+*a*.

Because most of the operations on any given type will be very similar, it can be useful to define a helper function which generates the forward and reverse instances of any given operator. For example, *Fraction*.*Fraction* uses :

```

def _operator_fallbacks(monomorphic_operator, fallback_operator):
    def forward(a, b):
        if isinstance(b, (int, long, Fraction)):
            return monomorphic_operator(a, b)
        elif isinstance(b, float):
            return fallback_operator(float(a), b)
        elif isinstance(b, complex):
            return fallback_operator(complex(a), b)
        else:
            return NotImplemented
    forward.__name__ = '__' + fallback_operator.__name__ + '__'
    forward.__doc__ = monomorphic_operator.__doc__

```

(suite sur la page suivante)

(suite de la page précédente)

```

def reverse(b, a):
    if isinstance(a, Rational):
        # Includes ints.
        return monomorphic_operator(a, b)
    elif isinstance(a, numbers.Real):
        return fallback_operator(float(a), float(b))
    elif isinstance(a, numbers.Complex):
        return fallback_operator(complex(a), complex(b))
    else:
        return NotImplemented
reverse.__name__ = '__r' + fallback_operator.__name__ + '__'
reverse.__doc__ = monomorphic_operator.__doc__

return forward, reverse

def _add(a, b):
    """a + b"""
    return Fraction(a.numerator * b.denominator +
                    b.numerator * a.denominator,
                    a.denominator * b.denominator)

__add__, __radd__ = _operator_fallbacks(_add, operator.add)

# ...

```

## 9.2 Fonctions mathématiques — math

Ce module est toujours disponible. Il fournit l'accès aux fonctions mathématiques définies par le standard C.

Ces fonctions ne peuvent être utilisées avec les nombres complexes, utilisez les fonctions du même nom du module `cmath` si vous souhaitez un support des nombres complexes. La distinction entre les fonctions supportant les nombres complexes et celles ne les supportant pas set née du fait que tous les utilisateurs ne désirent pas acquérir le niveau mathématique suffisant pour comprendre les nombres complexes. Recevoir une exception à la place d'un nombre complexe permet de détecter un nombre complexe non désiré en paramètre, ainsi le programmeur peut déterminer comment et pourquoi il a été généré.

Les fonctions suivantes sont fournies dans ce module. Sauf mention contraire explicite, toutes les valeurs de retour sont des flottants.

### 9.2.1 Fonctions arithmétiques et de représentation

`math.ceil(x)`

Return the ceiling of  $x$  as a float, the smallest integer value greater than or equal to  $x$ .

`math.copysign(x, y)`

Return  $x$  with the sign of  $y$ . On a platform that supports signed zeros, `copysign(1.0, -0.0)` returns `-1.0`.

Nouveau dans la version 2.6.

`math.fabs(x)`

Renvoie la valeur absolue de  $x$ .

`math.factorial(x)`

Renvoie la factorielle de  $x$ . Lève une *ValueError* si  $x$  n'est pas entier ou s'il est négatif.  
Nouveau dans la version 2.6.

`math.floor(x)`

Return the floor of  $x$  as a float, the largest integer value less than or equal to  $x$ .

`math.fmod(x, y)`

Renvoie `fmod(x, y)`, tel que défini par la bibliothèque C de la plate-forme. Notez que l'expression Python `x % y` peut ne pas renvoyer le même résultat. Le sens du standard C pour `fmod(x, y)` est d'être exactement (mathématiquement, à une précision infinie) égal à  $x - n*y$  pour un entier  $n$  tel que le résultat a le signe de  $x$  et une magnitude inférieure à `abs(y)`. L'expression Python `x % y` renvoie un résultat avec le signe de  $y$ , et peut ne pas être calculable exactement pour des arguments flottants. Par exemple : `fmod(-1e-100, 1e100)` est `-1e-100`, mais le résultat de l'expression Python `-1e-100 % 1e100` est `1e100-1e-100`, qui ne peut pas être représenté exactement par un flottant et donc qui est arrondi à `1e100`. Pour cette raison, la fonction `fmod()` est généralement préférée quand des flottants sont manipulés, alors que l'expression Python `x % y` est préféré quand des entiers sont manipulés.

`math.frexp(x)`

Renvoie la mantisse et l'exposant de  $x$  dans un couple `(m, e)`.  $m$  est un flottant et  $e$  est un entier tels que  $x == m * 2**e$  exactement. Si  $x$  vaut zéro, renvoie `(0, 0)`, sinon  $0.5 <= \text{abs}(m) < 1$ . Ceci est utilisé pour « extraire » la représentation interne d'un flottant de manière portable.

`math.fsum(iterable)`

Renvoie une somme flottante exacte des valeurs dans l'itérable. Évite la perte de précision en gardant plusieurs sommes partielles intermédiaires :

```
>>> sum([.1, .1, .1, .1, .1, .1, .1, .1, .1, .1])
0.9999999999999999
>>> fsum([.1, .1, .1, .1, .1, .1, .1, .1, .1, .1])
1.0
```

L'exactitude de cet algorithme dépend des garanties arithmétiques de IEEE-754 et des cas typiques où le mode d'arrondi est *half-even*. Sur certaines versions non Windows, la bibliothèque C sous-jacente utilise une addition par précision étendue et peut occasionnellement effectuer un double-arrondi sur une somme intermédiaire causant la prise d'une mauvaise valeur du bit de poids faible.

Pour de plus amples discussions et deux approches alternatives, voir [ASPN cookbook recipes for accurate floating point summation](#).

Nouveau dans la version 2.6.

`math.isinf(x)`

Check if the float  $x$  is positive or negative infinity.  
Nouveau dans la version 2.6.

`math.isnan(x)`

Check if the float  $x$  is a NaN (not a number). For more information on NaNs, see the IEEE 754 standards.  
Nouveau dans la version 2.6.

`math.ldexp(x, i)`

Renvoie  $x * (2**i)$ . C'est essentiellement l'inverse de la fonction `frexp()`.

`math.modf(x)`

Renvoie les parties entières et fractionnelle de  $x$ . Les deux résultats ont le signe de  $x$  et sont flottants.

`math.trunc(x)`

Return the *Real* value  $x$  truncated to an *Integral* (usually a long integer). Uses the `__trunc__` method.

Nouveau dans la version 2.6.

Notez que les fonctions `frex()` et `modf()` ont un système d'appel différent de leur homologue C : elles prennent un simple argument et renvoient une paire de valeurs au lieu de renvoyer leur seconde valeur de retour dans un “paramètre de sortie” (il n’y a pas de telle possibilité en Python).

Pour les fonctions `ceil()`, `floor()`, et `modf()`, notez que *tous* les nombres flottants de magnitude suffisamment grande sont des entiers exacts. Les flottants de Python n’ont typiquement pas plus de 53 *bits* de précision (tels que le type C `double` de la plate-forme), en quel cas tout flottant  $x$  tel que `abs(x) >= 2**52` n’a aucun *bit* fractionnel.

## 9.2.2 Fonctions logarithme et exponentielle

`math.exp(x)`  
Renvoie  $e^{**x}$ .

`math.expm1(x)`  
Return  $e^{**x} - 1$ . For small floats  $x$ , the subtraction in `exp(x) - 1` can result in a significant loss of precision; the `expm1()` function provides a way to compute this quantity to full precision :

```
>>> from math import exp, expm1
>>> exp(1e-5) - 1 # gives result accurate to 11 places
1.0000050000069649e-05
>>> expm1(1e-5) # result accurate to full precision
1.0000050000166668e-05
```

Nouveau dans la version 2.7.

`math.log(x[, base])`  
Avec un argument, renvoie le logarithme naturel de  $x$  (en base  $e$ ).  
Avec deux arguments, renvoie le logarithme de  $x$  en la *base* donnée, calculé par  $\log(x)/\log(\text{base})$ .  
Modifié dans la version 2.3 : *base* argument added.

`math.log1p(x)`  
Renvoie le logarithme naturel de  $1+x$  (en base  $e$ ). Le résultat est calculé par un moyen qui reste exact pour  $x$  proche de zéro.  
Nouveau dans la version 2.6.

`math.log10(x)`  
Renvoie le logarithme de  $x$  en base 10. C’est habituellement plus exact que `log(x, 10)`.

`math.pow(x, y)`  
Renvoie  $x$  élevé à la puissance  $y$ . Les cas exceptionnels suivent l’annexe “F” du standard C99 autant que possible. En particulier, `pow(1.0, x)` et `pow(x, 0.0)` renvoient toujours 1.0, même si  $x$  est zéro ou NaN. Si à la fois  $x$  et  $y$  sont finis,  $x$  est négatif et  $y$  n’est pas entier, alors `pow(x, y)` est non défini et lève une `ValueError`.  
À l’inverse de l’opérateur interne `**`, la fonction `math.pow()` convertit ses deux arguments en *float*. Utilisez `**` ou la primitive `pow()` pour calculer des puissances exactes d’entiers.  
Modifié dans la version 2.6 : The outcome of `1**nan` and `nan**0` was undefined.

`math.sqrt(x)`  
Renvoie la racine carrée de  $x$ .

## 9.2.3 Fonctions trigonométriques

`math.acos(x)`  
Renvoie l’arc cosinus de  $x$ , en radians.

`math.asin(x)`  
Renvoie l’arc sinus de  $x$ , en radians.

`math.atan(x)`

Renvoie l'arc tangente de *x*, en radians.

`math.atan2(y, x)`

Renvoie `atan(y / x)`, en radians. Le résultat est entre `-pi` et `pi`. Le vecteur du plan allant de l'origine vers le point (*x*, *y*) forme cet angle avec l'axe X positif. L'intérêt de `atan2()` est que le signe des deux entrées est connu. Donc elle peut calculer le bon quadrant pour l'angle. par exemple `atan(1)` et `atan2(1, 1)` donnent tous deux `pi/4`, mais `atan2(-1, -1)` donne `-3*pi/4`.

`math.cos(x)`

Renvoie le cosinus de *x* radians.

`math.hypot(x, y)`

Renvoie la norme euclidienne `sqrt(x*x + y*y)`. C'est la longueur du vecteur allant de l'origine au point (*x*, *y*).

`math.sin(x)`

Renvoie le sinus de *x* radians.

`math.tan(x)`

Renvoie la tangente de *x* radians.

## 9.2.4 Conversion angulaire

`math.degrees(x)`

Convertit l'angle *x* de radians en degrés.

`math.radians(x)`

Convertit l'angle *x* de degrés en radians.

## 9.2.5 Fonctions hyperboliques

`math.acosh(x)`

Renvoie l'arc cosinus hyperbolique de *x*.  
Nouveau dans la version 2.6.

`math.asinh(x)`

Renvoie l'arc sinus hyperbolique de *x*.  
Nouveau dans la version 2.6.

`math.atanh(x)`

Renvoie l'arc tangente hyperbolique de *x*.  
Nouveau dans la version 2.6.

`math.cosh(x)`

Renvoie le cosinus hyperbolique de *x*.

`math.sinh(x)`

Renvoie le sinus hyperbolique de *x*.

`math.tanh(x)`

Renvoie la tangente hyperbolique de *x*.

## 9.2.6 Fonctions spéciales

`math.erf(x)`

Return the error function at *x*.  
Nouveau dans la version 2.7.

`math.erfc(x)`

Return the complementary error function at  $x$ .

Nouveau dans la version 2.7.

`math.gamma(x)`

Return the Gamma function at  $x$ .

Nouveau dans la version 2.7.

`math.lgamma(x)`

Renvoie le logarithme naturel de la valeur absolue de la fonction gamma en  $x$ .

Nouveau dans la version 2.7.

## 9.2.7 Constantes

`math.pi`

La constante mathématique  $\pi = 3.141592\dots$ , à la précision disponible.

`math.e`

La constante mathématique  $e = 2.718281\dots$ , à la précision disponible.

Le module `math` consiste majoritairement en un conteneur pour les fonctions mathématiques de la bibliothèque C de la plate-forme. Le comportement dans les cas spéciaux suit l'annexe "F" du standard C99 quand c'est approprié. L'implémentation actuelle lève une `ValueError` pour les opérations invalides telles que `sqrt(-1.0)` ou `log(0.0)` (où le standard C99 recommande de signaler que l'opération est invalide ou qu'il y a division par zéro), et une `OverflowError` pour les résultats qui débordent (par exemple `exp(1000.0)`). `NaN` ne sera renvoyé pour toute les fonctions ci-dessus sauf si au moins un des arguments de la fonction vaut `NaN`. Dans ce cas, la plupart des fonctions renvoient `NaN`, mais (à nouveau, selon l'annexe "F" du standard C99) il y a quelques exceptions à cette règle, par exemple `pow(float('nan'), 0.0)` ou `hypot(float('nan'), float('inf'))`.

Notez que Python ne fait aucun effort pour distinguer les NaNs signalétiques des NaNs silencieux, et le comportement de signalement des NaNs reste non-spécifié. le comportement typique est de traiter tous les NaNs comme s'ils étaient silencieux.

Modifié dans la version 2.6 : Behavior in special cases now aims to follow C99 Annex F. In earlier versions of Python the behavior in special cases was loosely specified.

**Voir aussi :**

Module `cmath` Version complexe de beaucoup de ces fonctions.

## 9.3 Fonctions mathématiques pour nombres complexes — `cmath`

Ce module est toujours disponible. Il fournit l'accès aux fonctions mathématiques pour les nombres complexes. Les fonctions de ce module acceptent les entiers, les nombres flottants ou les nombres complexes comme arguments. Elles accepteront également tout objet Python ayant une méthode `__complex__()` ou `__float__()` : ces méthodes sont utilisées pour convertir l'objet en un nombre complexe ou respectivement un nombre flottant, et la fonction est ensuite appliquée sur le résultat de la conversion.

---

**Note :** Sur les plate-formes avec un support système et matériel des zéros signés, les fonctions incluant une coupure complexe sont continues *de chaque* côté de la coupure : le signe du zéro distingue les deux extrémités de la coupure. Sur les plate-formes ne supportant pas les zéros signés, la continuité est spécifiée en-dessous.

---

### 9.3.1 Conversion vers et à partir de coordonnées polaires

Un nombre complexe Python `z` est stocké de manière interne en coordonnées *cartésiennes*. Il est entièrement défini par sa *partie réelle* `z.real` et sa *partie complexe* `z.imag`. En d'autres termes :

```
z == z.real + z.imag*1j
```

Les *coordonnées polaires* donnent une manière alternative de représenter un nombre complexe. En coordonnées polaires, un nombre complexe  $z$  est défini par son module  $r$  et par son argument (*angle de phase*)  $\phi$ . Le module  $r$  est la distance entre  $z$  et l'origine, alors que l'argument  $\phi$  est l'angle (dans le sens inverse des aiguilles d'une montre, ou sens trigonométrique), mesuré en radians, à partir de l'axe X positif, et vers le segment de droite joignant  $z$  à l'origine.

Les fonctions suivantes peuvent être utilisées pour convertir à partir des coordonnées rectangulaires natives vers les coordonnées polaires, et vice-versa.

`cmath.phase(x)`

Renvoie l'argument de  $x$ , dans un nombre flottant. `phase(x)` est équivalent à `math.atan2(x.imag, x.real)`. Le résultat se situe dans l'intervalle  $[-\pi, +\pi]$ , et la coupure par cette opération se situe sur l'axe X négatif, continue par au-dessus. Sur les systèmes supportant les zéros signés (ce qui inclut la plupart des systèmes utilisés actuellement), cela signifie que le signe du résultat est le même que `x.imag` même quand `x.imag` vaut zéro :

```
>>> phase(complex(-1.0, 0.0))
3.1415926535897931
>>> phase(complex(-1.0, -0.0))
-3.1415926535897931
```

Nouveau dans la version 2.6.

**Note :** Le module (valeur absolue) d'un nombre complexe  $x$  peut être calculé en utilisant la primitive `abs()`. Il n'y a pas de fonction spéciale du module `cmath` pour cette opération.

`cmath.polar(x)`

Renvoie la représentation de  $x$  en coordonnées polaires. Renvoie une paire (`r`, `phi`) où  $r$  est le module de  $x$  et  $\phi$  est l'argument de  $x$ . `polar(x)` est équivalent à `(abs(x), phase(x))`.

Nouveau dans la version 2.6.

`cmath.rect(r, phi)`

Renvoie le nombre complexe  $x$  dont les coordonnées polaires sont  $r$  et  $\phi$ . Équivalent à `r * (math.cos(phi) + math.sin(phi)*1j)`.

Nouveau dans la version 2.6.

### 9.3.2 Fonctions logarithme et exponentielle

`cmath.exp(x)`

Renvoie la valeur exponentielle `e**x`.

`cmath.log(x[, base])`

Renvoie le logarithme de  $x$  dans la *base* précisée. Si la *base* n'est pas précisée, le logarithme *naturel* (népérien) de  $x$  est renvoyé. Il y a une coupure, partant de 0 sur l'axe réel négatif et vers  $-\infty$ , continue par au-dessus.

Modifié dans la version 2.4 : *base* argument added.

`cmath.log10(x)`

Renvoie le logarithme en base 10 de  $x$ . Elle a la même coupure que `log()`.

`cmath.sqrt(x)`

Renvoie la racine carrée de  $x$ . Elle a la même coupure que `log()`.

### 9.3.3 Fonctions trigonométriques

`cmath.acos(x)`

Renvoie l'arc cosinus de  $x$ . Il y a deux coupures : une allant de 1 sur l'axe réel vers  $\infty$ , continue par en-dessous ; l'autre allant de  $-1$  sur l'axe réel vers  $-\infty$ , continue par au-dessus.

`cmath.asin(x)`

Renvoie l'arc sinus de  $x$ . Elle a les mêmes coupures que `acos()`.

`cmath.atan(x)`

Renvoie la tangente de  $x$ . Il y a deux coupures : une allant de  $1j$  sur l'axe imaginaire vers  $\infty j$ , continue par la droite ; l'autre allant de  $-1j$  sur l'axe imaginaire vers  $-\infty j$ , continue par la gauche.

Modifié dans la version 2.6 : direction of continuity of upper cut reversed

`cmath.cos(x)`

Renvoie le cosinus de  $x$ .

`cmath.sin(x)`

Renvoie le sinus de  $x$ .

`cmath.tan(x)`

Renvoie la tangente de  $x$ .

### 9.3.4 Fonctions hyperboliques

`cmath.acosh(x)`

Renvoie l'arc cosinus hyperbolique de  $x$ . Il y a une coupure, allant de 1 sur l'axe réel vers  $-\infty$ , continue par au-dessus.

`cmath.asinh(x)`

Renvoie l'arc sinus hyperbolique de  $x$ . Il y a deux coupures : une allant de  $1j$  sur l'axe imaginaire vers  $\infty j$ , continue par la droite ; l'autre allant de  $-1j$  sur l'axe imaginaire vers  $-\infty j$ , continue par la gauche.

Modifié dans la version 2.6 : branch cuts moved to match those recommended by the C99 standard

`cmath.atanh(x)`

Renvoie l'arc tangente hyperbolique de  $x$ . Il y a deux coupures : une allant de 1 sur l'axe réel allant vers  $\infty$ , continue par en-dessous ; l'autre allant de  $-1$  sur l'axe réel vers  $-\infty$ , continue par au-dessus.

Modifié dans la version 2.6 : direction of continuity of right cut reversed

`cmath.cosh(x)`

Renvoie le cosinus hyperbolique de  $x$ .

`cmath.sinh(x)`

Renvoie le sinus hyperbolique de  $x$ .

`cmath.tanh(x)`

Renvoie la tangente hyperbolique de  $x$ .

### 9.3.5 Fonctions de classifications

`cmath.isinf(x)`

Return `True` if the real or the imaginary part of  $x$  is positive or negative infinity.

Nouveau dans la version 2.6.

`cmath.isnan(x)`

Return `True` if the real or imaginary part of  $x$  is not a number (NaN).

Nouveau dans la version 2.6.

### 9.3.6 Constantes

`cmath.pi`

La constante mathématique  $\pi$ , en tant que flottant.

`cmath.e`

La constante mathématique  $e$ , en tant que flottant.

Notez que la sélection de fonctions est similaire, mais pas identique, à celles du module `math`. La raison d'avoir deux modules est que certains utilisateurs ne sont pas intéressés par les nombres complexes, et peut-être ne savent même pas ce qu'ils sont. Ils préféreraient alors que `math.sqrt(-1)` lève une exception au lieu de renvoyer un nombre complexe. Également, notez que les fonctions définies dans `cmath` renvoient toujours un nombre complexe, même si le résultat peut être exprimé à l'aide d'un nombre réel (en quel cas la partie imaginaire du complexe vaut zéro).

Une note sur les *coupures* : ce sont des courbes sur lesquelles la fonction n'est pas continue. Ce sont des caractéristiques nécessaires de beaucoup de fonctions complexes. Il est supposé que si vous avez besoin d'utiliser des fonctions complexes, vous comprendrez ce que sont les coupures. Consultez n'importe quel livre (pas trop élémentaire) sur les variables complexes pour plus d'informations. Pour des informations sur les choix des coupures à des fins numériques, voici une bonne référence :

## 9.4 decimal — Arithmétique décimale en virgule fixe et flottante

Nouveau dans la version 2.4.

The `decimal` module provides support for decimal floating point arithmetic. It offers several advantages over the `float` datatype :

- Le module `decimal` « est basé sur un modèle en virgule flottante conçu pour les humains, qui suit ce principe directeur : l'ordinateur doit fournir un modèle de calcul qui fonctionne de la même manière que le calcul qu'on apprend à l'école » – extrait (traduit) de la spécification de l'arithmétique décimale.
- Decimal numbers can be represented exactly. In contrast, numbers like 1.1 and 2.2 do not have exact representations in binary floating point. End users typically would not expect 1.1 + 2.2 to display as 3.3000000000000003 as it does with binary floating point.
- Ces inexactitudes ont des conséquences en arithmétique. En base décimale à virgule flottante, 0.1 + 0.1 + 0.1 - 0.3 est exactement égal à zéro. En virgule flottante binaire, l'ordinateur l'évalue à 5.5511151231257827e-017. Bien que très proche de zéro, cette différence induit des erreurs lors des tests d'égalité, erreurs qui peuvent s'accumuler. Pour ces raisons `decimal` est le module utilisé pour des applications comptables ayant des contraintes strictes de fiabilité.
- Le module `decimal` incorpore la notion de chiffres significatifs, tels que 1.30 + 1.20 est égal à 2.50. Le dernier zéro n'est conservé que pour respecter le nombre de chiffres significatifs. C'est également l'affichage préféré pour représenter des sommes d'argent. Pour la multiplication, l'approche « scolaire » utilise tout les chiffres présents dans les facteurs. Par exemple, 1.3 \* 1.2 donnerait 1.56 tandis que 1.30 \* 1.20 donnerait 1.5600.
- Contrairement à l'arithmétique en virgule flottante binaire, le module `decimal` possède un paramètre de précision ajustable (par défaut à 28 chiffres significatifs) qui peut être aussi élevée que nécessaire pour un problème donné :

```
>>> from decimal import *
>>> getcontext().prec = 6
>>> Decimal(1) / Decimal(7)
Decimal('0.142857')
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> getcontext().prec = 28
>>> Decimal(1) / Decimal(7)
Decimal('0.1428571428571428571428571429')
```

- L'arithmétique binaire et décimale en virgule flottante sont implémentées selon des standards publiés. Alors que le type `float` n'expose qu'une faible portion de ses capacités, le module `decimal` expose tous les composants nécessaires du standard. Lorsque nécessaire, le développeur a un contrôle total de la gestion de signal et de l'arrondi. Cela inclut la possibilité de forcer une arithmétique exacte en utilisant des exceptions pour bloquer toute opération inexacte.
- Le module `decimal` a été conçu pour gérer « sans préjugé, à la fois une arithmétique décimale non-arrondie (aussi appelée arithmétique en virgule fixe) et à la fois une arithmétique en virgule flottante. » (extrait traduit de la spécification de l'arithmétique décimale).

Le module est conçu autour de trois concepts : le nombre décimal, le contexte arithmétique et les signaux.

Un `Decimal` est immuable. Il a un signe, un coefficient, et un exposant. Pour préserver le nombre de chiffres significatifs, les zéros en fin de chaîne ne sont pas tronqués. Les décimaux incluent aussi des valeurs spéciales telles que `Infinity`, `-Infinity`, et `NaN`. Le standard fait également la différence entre `-0` et `+0`.

Le contexte de l'arithmétique est un environnement qui permet de configurer une précision, une règle pour l'arrondi, des limites sur l'exposant, des options indiquant le résultat des opérations et si les signaux (remontés lors d'opérations illégales) sont traités comme des exceptions Python. Les options d'arrondi incluent `ROUND_CEILING`, `ROUND_DOWN`, `ROUND_FLOOR`, `ROUND_HALF_DOWN`, `ROUND_HALF_EVEN`, `ROUND_HALF_UP`, `ROUND_UP`, et `ROUND_05UP`.

Signals are groups of exceptional conditions arising during the course of computation. Depending on the needs of the application, signals may be ignored, considered as informational, or treated as exceptions. The signals in the decimal module are : *Clamped*, *InvalidOperation*, *DivisionByZero*, *Inexact*, *Rounded*, *Subnormal*, *Overflow*, and *Underflow*.

Chaque signal est configurable indépendamment. Quand une opération illégale survient, le signal est mis à 1, puis s'il est configuré pour, une exception est levée. La mise à 1 est persistante, l'utilisateur doit donc les remettre à zéro avant de commencer un calcul qu'il souhaite surveiller.

- IBM's General Decimal Arithmetic Specification, [The General Decimal Arithmetic Specification](#).

### 9.4.1 Introduction pratique

Commençons par importer le module, regarder le contexte actuel avec `getcontext()`, et si nécessaire configurer la précision, l'arrondi, et la gestion des signaux :

```
>>> from decimal import *
>>> getcontext()
Context(prec=28, rounding=ROUND_HALF_EVEN, Emin=-999999999, Emax=999999999,
        capitals=1, flags=[], traps=[Overflow, DivisionByZero,
        InvalidOperation])

>>> getcontext().prec = 7           # Set a new precision
```

Decimal instances can be constructed from integers, strings, floats, or tuples. Construction from an integer or a float performs an exact conversion of the value of that integer or float. Decimal numbers include special values such as `NaN` which stands for « Not a number », positive and negative `Infinity`, and `-0`.

```
>>> getcontext().prec = 28
>>> Decimal(10)
```

(suite sur la page suivante)

(suite de la page précédente)

```

Decimal('10')
>>> Decimal('3.14')
Decimal('3.14')
>>> Decimal(3.14)
Decimal('3.140000000000000124344978758017532527446746826171875')
>>> Decimal((0, (3, 1, 4), -2))
Decimal('3.14')
>>> Decimal(str(2.0 ** 0.5))
Decimal('1.41421356237')
>>> Decimal(2) ** Decimal('0.5')
Decimal('1.414213562373095048801688724')
>>> Decimal('NaN')
Decimal('NaN')
>>> Decimal('-Infinity')
Decimal('-Infinity')

```

Le nombre de chiffres significatifs d'un nouvel objet `Decimal` est déterminé entièrement par le nombre de chiffres saisis. La précision et les règles d'arrondis n'interviennent que lors d'opérations arithmétiques.

```

>>> getcontext().prec = 6
>>> Decimal('3.0')
Decimal('3.0')
>>> Decimal('3.1415926535')
Decimal('3.1415926535')
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85987')
>>> getcontext().rounding = ROUND_UP
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85988')

```

Les objets `Decimal` interagissent très bien avec le reste de Python. Voici quelques exemple d'opérations avec des décimaux :

```

>>> data = map(Decimal, '1.34 1.87 3.45 2.35 1.00 0.03 9.25'.split())
>>> max(data)
Decimal('9.25')
>>> min(data)
Decimal('0.03')
>>> sorted(data)
[Decimal('0.03'), Decimal('1.00'), Decimal('1.34'), Decimal('1.87'),
 Decimal('2.35'), Decimal('3.45'), Decimal('9.25')]
>>> sum(data)
Decimal('19.29')
>>> a,b,c = data[:3]
>>> str(a)
'1.34'
>>> float(a)
1.34
>>> round(a, 1)      # round() first converts to binary floating point
1.3
>>> int(a)
1

```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> a * 5
Decimal('6.70')
>>> a * b
Decimal('2.5058')
>>> c % a
Decimal('0.77')
```

Et certaines fonctions mathématiques sont également disponibles sur des instances de `Decimal` :

```
>>> getcontext().prec = 28
>>> Decimal(2).sqrt()
Decimal('1.414213562373095048801688724')
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal('10').ln()
Decimal('2.302585092994045684017991455')
>>> Decimal('10').log10()
Decimal('1')
```

La méthode `quantize()` arrondit un nombre à un exposant fixe. Cette méthode est utile pour des applications monétaires qui arrondissent souvent un résultat à un nombre de chiffres significatifs exact :

```
>>> Decimal('7.325').quantize(Decimal('.01'), rounding=ROUND_DOWN)
Decimal('7.32')
>>> Decimal('7.325').quantize(Decimal('1.'), rounding=ROUND_UP)
Decimal('8')
```

Comme montré plus haut, la fonction `getcontext()` accède au contexte actuel et permet de modifier les paramètres. Cette approche répond aux besoins de la plupart des applications.

Pour un travail plus avancé, il peut être utile de créer des contextes alternatifs en utilisant le constructeur de `Context`. Pour activer cet objet `Context`, utilisez la fonction `setcontext()`.

En accord avec le standard, le module `decimal` fournit des objets `Context` standards, `BasicContext` et `ExtendedContext`. Le premier est particulièrement utile pour le débogage car beaucoup des pièges sont activés dans cet objet.

```
>>> myothercontext = Context(prec=60, rounding=ROUND_HALF_DOWN)
>>> setcontext(myothercontext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857142857142857142857142857142857142857142857142857')

>>> ExtendedContext
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999999, Emax=999999999,
       capitals=1, flags=[], traps=[])
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857143')
>>> Decimal(42) / Decimal(0)
Decimal('Infinity')

>>> setcontext(BasicContext)
>>> Decimal(42) / Decimal(0)
```

(suite sur la page suivante)

(suite de la page précédente)

```
Traceback (most recent call last):
  File "<pyshell#143>", line 1, in -toplevel-
    Decimal(42) / Decimal(0)
DivisionByZero: x / 0
```

Les objets `Context` ont aussi des options pour détecter des opérations illégales lors des calculs. Ces options restent activées jusqu'à ce qu'elles soit remises à zéro de manière explicite. Il convient donc de remettre à zéro ces options avant chaque inspection de chaque calcul, avec la méthode `clear_flags()`.

```
>>> setcontext(ExtendedContext)
>>> getcontext().clear_flags()
>>> Decimal(355) / Decimal(113)
Decimal('3.14159292')
>>> getcontext()
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999999, Emax=999999999,
        capitals=1, flags=[Rounded, Inexact], traps=[])
```

Les options montrent que l'approximation de Pi par une fraction a été arrondie (les chiffres au delà de la précision spécifiée par l'objet `Context` ont été tronqués) et que le résultat est différent (certains des chiffres tronqués étaient différents de zéro).

L'activation des pièges se fait en utilisant un dictionnaire dans l'attribut `traps` de l'objet `Context` :

```
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(0)
Decimal('Infinity')
>>> getcontext().traps[DivisionByZero] = 1
>>> Decimal(1) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#112>", line 1, in -toplevel-
    Decimal(1) / Decimal(0)
DivisionByZero: x / 0
```

La plupart des applications n'ajustent l'objet `Context` qu'une seule fois, au démarrage. Et, dans beaucoup d'applications, les données sont convertie une fois pour toutes en *Decimal*. Une fois le `Context` initialisé, et les objets `Decimal` créés, l'essentiel du programme manipule la donnée de la même manière qu'avec les autres types numériques Python.

## 9.4.2 Les objets Decimal

`class decimal.Decimal([value[, context]])`

Construire un nouvel objet *Decimal* à partir de *value*.

*value* can be an integer, string, tuple, *float*, or another *Decimal* object. If no *value* is given, returns `Decimal('0')`. If *value* is a string, it should conform to the decimal numeric string syntax after leading and trailing whitespace characters are removed :

```
sign          ::= '+' | '-'
digit         ::= '0' | '1' | '2' | '3' | '4' | '5' | '6' | '7' | '8' | '9'
indicator     ::= 'e' | 'E'
digits        ::= digit [digit]...
decimal-part  ::= digits '.' [digits] | ['.'] digits
exponent-part ::= indicator [sign] digits
infinity      ::= 'Infinity' | 'Inf'
```

(suite sur la page suivante)

(suite de la page précédente)

```
nan          ::= 'NaN' [digits] | 'sNaN' [digits]
numeric-value ::= decimal-part [exponent-part] | infinity
numeric-string ::= [sign] numeric-value | [sign] nan
```

If *value* is a unicode string then other Unicode decimal digits are also permitted where *digit* appears above. These include decimal digits from various other alphabets (for example, Arabic-Indic and Devanāgarī digits) along with the fullwidth digits u'\uff10' through u'\uff19'.

Si *value* est un *tuple*, il doit avoir 3 éléments, le signe (0 pour positif ou 1 pour négatif), un *tuple* de chiffres, et un entier représentant l'exposant. Par exemple, `Decimal((0, (1, 4, 1, 4), -3))` construit l'objet `Decimal('1.414')`.

Si *value* est un *float*, la valeur en binaire flottant est convertie exactement à son équivalent décimal. Cette conversion peut parfois nécessiter 53 chiffres significatifs ou plus. Par exemple, `Decimal(float('1.1'))` devient `Decimal('1.100000000000000088817841970012523233890533447265625')`.

La précision spécifiée dans *Context* n'affecte pas le nombre de chiffres stockés. Cette valeur est déterminée exclusivement par le nombre de chiffres dans *value*. Par exemple, `Decimal('3.00000')` enregistre les 5 zéros même si la précision du contexte est de 3.

L'objectif de l'argument *context* est de déterminer ce que Python doit faire si *value* est une chaîne avec un mauvais format. Si l'option *InvalidOperation* est activée, une exception est levée, sinon le constructeur renvoie un objet `Decimal` avec la valeur NaN.

Une fois construit, les objets *Decimal* sont immuables.

Modifié dans la version 2.6 : leading and trailing whitespace characters are permitted when creating a `Decimal` instance from a string.

Modifié dans la version 2.7 : L'argument du constructeur peut désormais être un objet *float*.

`Decimal` floating point objects share many properties with the other built-in numeric types such as *float* and *int*. All of the usual math operations and special methods apply. Likewise, decimal objects can be copied, pickled, printed, used as dictionary keys, used as set elements, compared, sorted, and coerced to another type (such as *float* or *long*).

Il existe quelques différences mineures entre l'arithmétique entre les objets décimaux et l'arithmétique avec les entiers et les *float*. Quand l'opérateur modulo % est appliqué sur des objets décimaux, le signe du résultat est le signe du *dividend* plutôt que le signe du diviseur :

```
>>> (-7) % 4
1
>>> Decimal(-7) % Decimal(4)
Decimal('-3')
```

L'opérateur division entière, // se comporte de la même manière, retournant la partie entière du quotient, plutôt que son arrondi, de manière à préserver l'identité d'Euclide `x == (x // y) * y + x % y` :

```
>>> -7 // 4
-2
>>> Decimal(-7) // Decimal(4)
Decimal('-1')
```

Les opérateurs // et % implémentent la division entière et le reste (ou modulo), respectivement, tel que décrit dans la spécification.

`Decimal` objects cannot generally be combined with floats in arithmetic operations : an attempt to add a *Decimal* to a *float*, for example, will raise a *TypeError*. There's one exception to this rule : it's possible to use Python's comparison operators to compare a *float* instance *x* with a *Decimal* instance *y*. Without this exception, comparisons between *Decimal* and *float* instances would follow the general rules for comparing objects of different types described in the expressions section of the reference manual, leading to confusing results.

Modifié dans la version 2.7 : A comparison between a *float* instance *x* and a *Decimal* instance *y* now returns a result based on the values of *x* and *y*. In earlier versions *x* < *y* returned the same (arbitrary) result for any *Decimal* instance *x* and any *float* instance *y*.

In addition to the standard numeric properties, decimal floating point objects also have a number of specialized methods :

**adjusted()**

Return the adjusted exponent after shifting out the coefficient's rightmost digits until only the lead digit remains : `Decimal('321e+5').adjusted()` returns seven. Used for determining the position of the most significant digit with respect to the decimal point.

**as\_tuple()**

Return a *named tuple* representation of the number : `DecimalTuple(sign, digits, exponent)`.

Modifié dans la version 2.6 : Use a named tuple.

**canonical()**

Return the canonical encoding of the argument. Currently, the encoding of a *Decimal* instance is always canonical, so this operation returns its argument unchanged.

Nouveau dans la version 2.6.

**compare(*other*[, *context*])**

Compare the values of two Decimal instances. This operation behaves in the same way as the usual comparison method `__cmp__()`, except that *compare()* returns a Decimal instance rather than an integer, and if either operand is a NaN then the result is a NaN :

```
a or b is a NaN ==> Decimal('NaN')
a < b           ==> Decimal('-1')
a == b          ==> Decimal('0')
a > b           ==> Decimal('1')
```

**compare\_signal(*other*[, *context*])**

This operation is identical to the *compare()* method, except that all NaNs signal. That is, if neither operand is a signaling NaN then any quiet NaN operand is treated as though it were a signaling NaN.

Nouveau dans la version 2.6.

**compare\_total(*other*)**

Compare two operands using their abstract representation rather than their numerical value. Similar to the *compare()* method, but the result gives a total ordering on *Decimal* instances. Two *Decimal* instances with the same numeric value but different representations compare unequal in this ordering :

```
>>> Decimal('12.0').compare_total(Decimal('12'))
Decimal('-1')
```

Quiet and signaling NaNs are also included in the total ordering. The result of this function is `Decimal('0')` if both operands have the same representation, `Decimal('-1')` if the first operand is lower in the total order than the second, and `Decimal('1')` if the first operand is higher in the total order than the second operand. See the specification for details of the total order.

Nouveau dans la version 2.6.

**compare\_total\_mag(*other*)**

Compare two operands using their abstract representation rather than their value as in *compare\_total()*, but ignoring the sign of each operand. `x.compare_total_mag(y)` is equivalent to `x.copy_abs().compare_total(y.copy_abs())`.

Nouveau dans la version 2.6.

**conjugate()**

Just returns self, this method is only to comply with the Decimal Specification.

Nouveau dans la version 2.6.

**copy\_abs()**

Return the absolute value of the argument. This operation is unaffected by the context and is quiet : no flags are changed and no rounding is performed.

Nouveau dans la version 2.6.

**copy\_negate()**

Return the negation of the argument. This operation is unaffected by the context and is quiet : no flags are changed and no rounding is performed.

Nouveau dans la version 2.6.

**copy\_sign(*other*)**

Return a copy of the first operand with the sign set to be the same as the sign of the second operand. For example :

```
>>> Decimal('2.3').copy_sign(Decimal('-1.5'))
Decimal('-2.3')
```

This operation is unaffected by the context and is quiet : no flags are changed and no rounding is performed.

Nouveau dans la version 2.6.

**exp([*context*])**

Return the value of the (natural) exponential function  $e^{**x}$  at the given number. The result is correctly rounded using the ROUND\_HALF\_EVEN rounding mode.

```
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal(321).exp()
Decimal('2.561702493119680037517373933E+139')
```

Nouveau dans la version 2.6.

**from\_float(*f*)**

Classmethod that converts a float to a decimal number, exactly.

Note *Decimal.from\_float(0.1)* is not the same as *Decimal("0.1")*. Since 0.1 is not exactly representable in binary floating point, the value is stored as the nearest representable value which is  $0x1.999999999999ap-4$ . That equivalent value in decimal is *0.1000000000000000055511151231257827021181583404541015625*.

---

**Note :** From Python 2.7 onwards, a *Decimal* instance can also be constructed directly from a *float*.

---

```
>>> Decimal.from_float(0.1)
Decimal('0.1000000000000000055511151231257827021181583404541015625')
>>> Decimal.from_float(float('nan'))
Decimal('NaN')
>>> Decimal.from_float(float('inf'))
Decimal('Infinity')
>>> Decimal.from_float(float('-inf'))
Decimal('-Infinity')
```

Nouveau dans la version 2.7.

**fma(*other*, *third*[, *context*])**

Fused multiply-add. Return  $self*other+third$  with no rounding of the intermediate product  $self*other$ .

```
>>> Decimal(2).fma(3, 5)
Decimal('11')
```

Nouveau dans la version 2.6.

**is\_canonical()**

Return *True* if the argument is canonical and *False* otherwise. Currently, a *Decimal* instance is always canonical, so this operation always returns *True*.

Nouveau dans la version 2.6.

**is\_finite()**

Return *True* if the argument is a finite number, and *False* if the argument is an infinity or a NaN.

Nouveau dans la version 2.6.

**is\_infinite()**

Return *True* if the argument is either positive or negative infinity and *False* otherwise.

Nouveau dans la version 2.6.

**is\_nan()**

Return *True* if the argument is a (quiet or signaling) NaN and *False* otherwise.

Nouveau dans la version 2.6.

**is\_normal()**

Return *True* if the argument is a *normal* finite non-zero number with an adjusted exponent greater than or equal to *Emin*. Return *False* if the argument is zero, subnormal, infinite or a NaN. Note, the term *normal* is used here in a different sense with the *normalize()* method which is used to create canonical values.

Nouveau dans la version 2.6.

**is\_qnan()**

Return *True* if the argument is a quiet NaN, and *False* otherwise.

Nouveau dans la version 2.6.

**is\_signed()**

Return *True* if the argument has a negative sign and *False* otherwise. Note that zeros and NaNs can both carry signs.

Nouveau dans la version 2.6.

**is\_snan()**

Return *True* if the argument is a signaling NaN and *False* otherwise.

Nouveau dans la version 2.6.

**is\_subnormal()**

Return *True* if the argument is subnormal, and *False* otherwise. A number is subnormal is if it is nonzero, finite, and has an adjusted exponent less than *Emin*.

Nouveau dans la version 2.6.

**is\_zero()**

Return *True* if the argument is a (positive or negative) zero and *False* otherwise.

Nouveau dans la version 2.6.

**ln([context])**

Return the natural (base e) logarithm of the operand. The result is correctly rounded using the ROUND\_HALF\_EVEN rounding mode.

Nouveau dans la version 2.6.

**log10([context])**

Return the base ten logarithm of the operand. The result is correctly rounded using the ROUND\_HALF\_EVEN rounding mode.

Nouveau dans la version 2.6.

**logb([context])**

For a nonzero number, return the adjusted exponent of its operand as a *Decimal* instance. If the

operand is a zero then `Decimal('-Infinity')` is returned and the *DivisionByZero* flag is raised. If the operand is an infinity then `Decimal('Infinity')` is returned.

Nouveau dans la version 2.6.

`logical_and(other[, context])`

*logical\_and()* is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise **and** of the two operands.

Nouveau dans la version 2.6.

`logical_invert([context])`

*logical\_invert()* is a logical operation. The result is the digit-wise inversion of the operand.

Nouveau dans la version 2.6.

`logical_or(other[, context])`

*logical\_or()* is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise **or** of the two operands.

Nouveau dans la version 2.6.

`logical_xor(other[, context])`

*logical\_xor()* is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise exclusive or of the two operands.

Nouveau dans la version 2.6.

`max(other[, context])`

Like `max(self, other)` except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

`max_mag(other[, context])`

Similar to the *max()* method, but the comparison is done using the absolute values of the operands.

Nouveau dans la version 2.6.

`min(other[, context])`

Like `min(self, other)` except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

`min_mag(other[, context])`

Similar to the *min()* method, but the comparison is done using the absolute values of the operands.

Nouveau dans la version 2.6.

`next_minus([context])`

Return the largest number representable in the given context (or in the current thread's context if no context is given) that is smaller than the given operand.

Nouveau dans la version 2.6.

`next_plus([context])`

Return the smallest number representable in the given context (or in the current thread's context if no context is given) that is larger than the given operand.

Nouveau dans la version 2.6.

`next_toward(other[, context])`

If the two operands are unequal, return the number closest to the first operand in the direction of the second operand. If both operands are numerically equal, return a copy of the first operand with the sign set to be the same as the sign of the second operand.

Nouveau dans la version 2.6.

`normalize([context])`

Normalize the number by stripping the rightmost trailing zeros and converting any result equal to `Decimal('0')` to `Decimal('0e0')`. Used for producing canonical values for attributes of an equivalence class. For example, `Decimal('32.100')` and `Decimal('0.321000e+2')` both normalize to the equivalent value `Decimal('32.1')`.

**number\_class**(*context*)

Return a string describing the *class* of the operand. The returned value is one of the following ten strings.

- "-Infinity", indicating that the operand is negative infinity.
- "-Normal", indicating that the operand is a negative normal number.
- "-Subnormal", indicating that the operand is negative and subnormal.
- "-Zero", indicating that the operand is a negative zero.
- "+Zero", indicating that the operand is a positive zero.
- "+Subnormal", indicating that the operand is positive and subnormal.
- "+Normal", indicating that the operand is a positive normal number.
- "+Infinity", indicating that the operand is positive infinity.
- "NaN", indicating that the operand is a quiet NaN (Not a Number).
- "sNaN", indicating that the operand is a signaling NaN.

Nouveau dans la version 2.6.

**quantize**(*exp*[, *rounding*[, *context*[, *watchexp*]]])

Return a value equal to the first operand after rounding and having the exponent of the second operand.

```
>>> Decimal('1.41421356').quantize(Decimal('1.000'))
Decimal('1.414')
```

Unlike other operations, if the length of the coefficient after the quantize operation would be greater than precision, then an *InvalidOperation* is signaled. This guarantees that, unless there is an error condition, the quantized exponent is always equal to that of the right-hand operand.

Also unlike other operations, quantize never signals Underflow, even if the result is subnormal and inexact.

If the exponent of the second operand is larger than that of the first then rounding may be necessary. In this case, the rounding mode is determined by the **rounding** argument if given, else by the given **context** argument; if neither argument is given the rounding mode of the current thread's context is used.

If *watchexp* is set (default), then an error is returned whenever the resulting exponent is greater than *E<sub>max</sub>* or less than *E<sub>tiny</sub>*.

**radix**()

Return `Decimal(10)`, the radix (base) in which the *Decimal* class does all its arithmetic. Included for compatibility with the specification.

Nouveau dans la version 2.6.

**remainder\_near**(*other*[, *context*])

Return the remainder from dividing *self* by *other*. This differs from `self % other` in that the sign of the remainder is chosen so as to minimize its absolute value. More precisely, the return value is `self - n * other` where *n* is the integer nearest to the exact value of `self / other`, and if two integers are equally near then the even one is chosen.

If the result is zero then its sign will be the sign of *self*.

```
>>> Decimal(18).remainder_near(Decimal(10))
Decimal('-2')
>>> Decimal(25).remainder_near(Decimal(10))
Decimal('5')
>>> Decimal(35).remainder_near(Decimal(10))
Decimal('-5')
```

**rotate**(*other*[, *context*])

Return the result of rotating the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range `-precision` through `precision`. The absolute value of the second operand gives the number of places to rotate. If the second operand

is positive then rotation is to the left ; otherwise rotation is to the right. The coefficient of the first operand is padded on the left with zeros to length precision if necessary. The sign and exponent of the first operand are unchanged.

Nouveau dans la version 2.6.

`same_quantum(other[, context])`

Test whether self and other have the same exponent or whether both are NaN.

`scaleb(other[, context])`

Return the first operand with exponent adjusted by the second. Equivalently, return the first operand multiplied by `10**other`. The second operand must be an integer.

Nouveau dans la version 2.6.

`shift(other[, context])`

Return the result of shifting the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range `-precision` through `precision`. The absolute value of the second operand gives the number of places to shift. If the second operand is positive then the shift is to the left ; otherwise the shift is to the right. Digits shifted into the coefficient are zeros. The sign and exponent of the first operand are unchanged.

Nouveau dans la version 2.6.

`sqrt([context])`

Return the square root of the argument to full precision.

`to_eng_string([context])`

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

For example, this converts `Decimal('123E+1')` to `Decimal('1.23E+3')`.

`to_integral([rounding[, context]])`

Identical to the `to_integral_value()` method. The `to_integral` name has been kept for compatibility with older versions.

`to_integral_exact([rounding[, context]])`

Round to the nearest integer, signaling *Inexact* or *Rounded* as appropriate if rounding occurs. The rounding mode is determined by the `rounding` parameter if given, else by the given `context`. If neither parameter is given then the rounding mode of the current context is used.

Nouveau dans la version 2.6.

`to_integral_value([rounding[, context]])`

Round to the nearest integer without signaling *Inexact* or *Rounded*. If given, applies *rounding*; otherwise, uses the rounding method in either the supplied *context* or the current context.

Modifié dans la version 2.6 : renommé de `to_integral` à `to_integral_value`. The old name remains valid for compatibility.

## Logical operands

The `logical_and()`, `logical_invert()`, `logical_or()`, and `logical_xor()` methods expect their arguments to be *logical operands*. A *logical operand* is a *Decimal* instance whose exponent and sign are both zero, and whose digits are all either 0 or 1.

### 9.4.3 Context objects

Contexts are environments for arithmetic operations. They govern precision, set rules for rounding, determine which signals are treated as exceptions, and limit the range for exponents.

Each thread has its own current context which is accessed or changed using the `getcontext()` and `setcontext()` functions :

`decimal.getcontext()`

Return the current context for the active thread.

`decimal.setcontext(c)`

Set the current context for the active thread to *c*.

Beginning with Python 2.5, you can also use the `with` statement and the `localcontext()` function to temporarily change the active context.

`decimal.localcontext([c])`

Return a context manager that will set the current context for the active thread to a copy of *c* on entry to the with-statement and restore the previous context when exiting the with-statement. If no context is specified, a copy of the current context is used.

Nouveau dans la version 2.5.

For example, the following code sets the current decimal precision to 42 places, performs a calculation, and then automatically restores the previous context :

```
from decimal import localcontext

with localcontext() as ctx:
    ctx.prec = 42  # Perform a high precision calculation
    s = calculate_something()
s = +s  # Round the final result back to the default precision

with localcontext(BasicContext):  # temporarily use the BasicContext
    print Decimal(1) / Decimal(7)
    print Decimal(355) / Decimal(113)
```

New contexts can also be created using the `Context` constructor described below. In addition, the module provides three pre-made contexts :

**class decimal.BasicContext**

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to `ROUND_HALF_UP`. All flags are cleared. All traps are enabled (treated as exceptions) except *Inexact*, *Rounded*, and *Subnormal*.

Because many of the traps are enabled, this context is useful for debugging.

**class decimal.ExtendedContext**

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to `ROUND_HALF_EVEN`. All flags are cleared. No traps are enabled (so that exceptions are not raised during computations).

Because the traps are disabled, this context is useful for applications that prefer to have result value of NaN or Infinity instead of raising exceptions. This allows an application to complete a run in the presence of conditions that would otherwise halt the program.

**class decimal.DefaultContext**

This context is used by the `Context` constructor as a prototype for new contexts. Changing a field (such as a precision) has the effect of changing the default for new contexts created by the `Context` constructor. This context is most useful in multi-threaded environments. Changing one of the fields before threads are started has the effect of setting system-wide defaults. Changing the fields after threads have started is not recommended as it would require thread synchronization to prevent race conditions.

In single threaded environments, it is preferable to not use this context at all. Instead, simply create contexts explicitly as described below.

The default values are precision=28, rounding=ROUND\_HALF\_EVEN, and enabled traps for Overflow, InvalidOperation, and DivisionByZero.

In addition to the three supplied contexts, new contexts can be created with the `Context` constructor.

```
class decimal.Context(prec=None, rounding=None, traps=None, flags=None, Emin=None,
                    Emax=None, capitals=1)
```

Creates a new context. If a field is not specified or is *None*, the default values are copied from the *DefaultContext*. If the *flags* field is not specified or is *None*, all flags are cleared.

The *prec* field is a positive integer that sets the precision for arithmetic operations in the context.

The *rounding* option is one of :

- *ROUND\_CEILING* (towards *Infinity*),
- *ROUND\_DOWN* (towards zero),
- *ROUND\_FLOOR* (towards *-Infinity*),
- *ROUND\_HALF\_DOWN* (to nearest with ties going towards zero),
- *ROUND\_HALF\_EVEN* (to nearest with ties going to nearest even integer),
- *ROUND\_HALF\_UP* (to nearest with ties going away from zero), or
- *ROUND\_UP* (away from zero).
- *ROUND\_05UP* (away from zero if last digit after rounding towards zero would have been 0 or 5; otherwise towards zero)

The *traps* and *flags* fields list any signals to be set. Generally, new contexts should only set traps and leave the flags clear.

The *Emin* and *Emax* fields are integers specifying the outer limits allowable for exponents.

The *capitals* field is either 0 or 1 (the default). If set to 1, exponents are printed with a capital E; otherwise, a lowercase e is used : *Decimal('6.02e+23')*.

Modifié dans la version 2.6 : The *ROUND\_05UP* rounding mode was added.

The *Context* class defines several general purpose methods as well as a large number of methods for doing arithmetic directly in a given context. In addition, for each of the *Decimal* methods described above (with the exception of the *adjusted()* and *as\_tuple()* methods) there is a corresponding *Context* method. For example, for a *Context* instance *C* and *Decimal* instance *x*, *C.exp(x)* is equivalent to *x.exp(context=C)*. Each *Context* method accepts a Python integer (an instance of *int* or *long*) anywhere that a *Decimal* instance is accepted.

```
clear_flags()
```

Resets all of the flags to 0.

```
copy()
```

Return a duplicate of the context.

```
copy_decimal(num)
```

Return a copy of the *Decimal* instance *num*.

```
create_decimal(num)
```

Creates a new *Decimal* instance from *num* but using *self* as context. Unlike the *Decimal* constructor, the context precision, rounding method, flags, and traps are applied to the conversion.

This is useful because constants are often given to a greater precision than is needed by the application. Another benefit is that rounding immediately eliminates unintended effects from digits beyond the current precision. In the following example, using unrounded inputs means that adding zero to a sum can change the result :

```
>>> getcontext().prec = 3
>>> Decimal('3.4445') + Decimal('1.0023')
Decimal('4.45')
>>> Decimal('3.4445') + Decimal(0) + Decimal('1.0023')
Decimal('4.44')
```

This method implements the to-number operation of the IBM specification. If the argument is a string, no leading or trailing whitespace is permitted.

```
create_decimal_from_float(f)
```

Creates a new *Decimal* instance from a float *f* but rounding using *self* as the context. Unlike the *Decimal.from\_float()* class method, the context precision, rounding method, flags, and traps are applied to the conversion.

```

>>> context = Context(prec=5, rounding=ROUND_DOWN)
>>> context.create_decimal_from_float(math.pi)
Decimal('3.1415')
>>> context = Context(prec=5, traps=[Inexact])
>>> context.create_decimal_from_float(math.pi)
Traceback (most recent call last):
...
Inexact: None

```

Nouveau dans la version 2.7.

#### **Etiny()**

Returns a value equal to  $E_{\min} - \text{prec} + 1$  which is the minimum exponent value for subnormal results. When underflow occurs, the exponent is set to *Etiny*.

#### **Etop()**

Returns a value equal to  $E_{\max} - \text{prec} + 1$ .

The usual approach to working with decimals is to create *Decimal* instances and then apply arithmetic operations which take place within the current context for the active thread. An alternative approach is to use context methods for calculating within a specific context. The methods are similar to those for the *Decimal* class and are only briefly recounted here.

#### **abs(*x*)**

Renvoie la valeur absolue de *x*.

#### **add(*x*, *y*)**

Return the sum of *x* and *y*.

#### **canonical(*x*)**

Returns the same *Decimal* object *x*.

#### **compare(*x*, *y*)**

Compares *x* and *y* numerically.

#### **compare\_signal(*x*, *y*)**

Compares the values of the two operands numerically.

#### **compare\_total(*x*, *y*)**

Compares two operands using their abstract representation.

#### **compare\_total\_mag(*x*, *y*)**

Compares two operands using their abstract representation, ignoring sign.

#### **copy\_abs(*x*)**

Returns a copy of *x* with the sign set to 0.

#### **copy\_negate(*x*)**

Returns a copy of *x* with the sign inverted.

#### **copy\_sign(*x*, *y*)**

Copies the sign from *y* to *x*.

#### **divide(*x*, *y*)**

Return *x* divided by *y*.

#### **divide\_int(*x*, *y*)**

Return *x* divided by *y*, truncated to an integer.

#### **divmod(*x*, *y*)**

Divides two numbers and returns the integer part of the result.

#### **exp(*x*)**

Returns  $e^{**x}$ .

#### **fma(*x*, *y*, *z*)**

Returns *x* multiplied by *y*, plus *z*.

#### **is\_canonical(*x*)**

Returns True if *x* is canonical; otherwise returns False.

**is\_finite(*x*)**  
Returns **True** if *x* is finite; otherwise returns **False**.

**is\_infinite(*x*)**  
Returns **True** if *x* is infinite; otherwise returns **False**.

**is\_nan(*x*)**  
Returns **True** if *x* is a qNaN or sNaN; otherwise returns **False**.

**is\_normal(*x*)**  
Returns **True** if *x* is a normal number; otherwise returns **False**.

**is\_qnan(*x*)**  
Returns **True** if *x* is a quiet NaN; otherwise returns **False**.

**is\_signed(*x*)**  
Returns **True** if *x* is negative; otherwise returns **False**.

**is\_snan(*x*)**  
Returns **True** if *x* is a signaling NaN; otherwise returns **False**.

**is\_subnormal(*x*)**  
Returns **True** if *x* is subnormal; otherwise returns **False**.

**is\_zero(*x*)**  
Returns **True** if *x* is a zero; otherwise returns **False**.

**ln(*x*)**  
Returns the natural (base e) logarithm of *x*.

**log10(*x*)**  
Returns the base 10 logarithm of *x*.

**logb(*x*)**  
Returns the exponent of the magnitude of the operand's MSD.

**logical\_and(*x*, *y*)**  
Applies the logical operation *and* between each operand's digits.

**logical\_invert(*x*)**  
Invert all the digits in *x*.

**logical\_or(*x*, *y*)**  
Applies the logical operation *or* between each operand's digits.

**logical\_xor(*x*, *y*)**  
Applies the logical operation *xor* between each operand's digits.

**max(*x*, *y*)**  
Compares two values numerically and returns the maximum.

**max\_mag(*x*, *y*)**  
Compares the values numerically with their sign ignored.

**min(*x*, *y*)**  
Compares two values numerically and returns the minimum.

**min\_mag(*x*, *y*)**  
Compares the values numerically with their sign ignored.

**minus(*x*)**  
Minus corresponds to the unary prefix minus operator in Python.

**multiply(*x*, *y*)**  
Return the product of *x* and *y*.

**next\_minus(*x*)**  
Returns the largest representable number smaller than *x*.

**next\_plus(*x*)**  
Returns the smallest representable number larger than *x*.

**next\_toward(*x*, *y*)**  
Returns the number closest to *x*, in direction towards *y*.

**normalize(*x*)**

Reduces *x* to its simplest form.

**number\_class(*x*)**

Returns an indication of the class of *x*.

**plus(*x*)**

Plus corresponds to the unary prefix plus operator in Python. This operation applies the context precision and rounding, so it is *not* an identity operation.

**power(*x*, *y*[, *modulo*])**

Return *x* to the power of *y*, reduced modulo *modulo* if given.

With two arguments, compute *x\*\*y*. If *x* is negative then *y* must be integral. The result will be inexact unless *y* is integral and the result is finite and can be expressed exactly in “precision” digits. The result should always be correctly rounded, using the rounding mode of the current thread’s context.

With three arguments, compute *(x\*\*y) % modulo*. For the three argument form, the following restrictions on the arguments hold :

- all three arguments must be integral
- *y* must be nonnegative
- at least one of *x* or *y* must be nonzero
- *modulo* must be nonzero and have at most “precision” digits

The value resulting from `Context.power(x, y, modulo)` is equal to the value that would be obtained by computing *(x\*\*y) % modulo* with unbounded precision, but is computed more efficiently. The exponent of the result is zero, regardless of the exponents of *x*, *y* and *modulo*. The result is always exact.

Modifié dans la version 2.6 : *y* may now be nonintegral in *x\*\*y*. Stricter requirements for the three-argument version.

**quantize(*x*, *y*)**

Returns a value equal to *x* (rounded), having the exponent of *y*.

**radix()**

Just returns 10, as this is Decimal, :)

**remainder(*x*, *y*)**

Returns the remainder from integer division.

The sign of the result, if non-zero, is the same as that of the original dividend.

**remainder\_near(*x*, *y*)**

Returns *x - y \* n*, where *n* is the integer nearest the exact value of *x / y* (if the result is 0 then its sign will be the sign of *x*).

**rotate(*x*, *y*)**

Returns a rotated copy of *x*, *y* times.

**same\_quantum(*x*, *y*)**

Returns `True` if the two operands have the same exponent.

**scaleb(*x*, *y*)**

Returns the first operand after adding the second value its exp.

**shift(*x*, *y*)**

Returns a shifted copy of *x*, *y* times.

**sqrt(*x*)**

Square root of a non-negative number to context precision.

**subtract(*x*, *y*)**

Return the difference between *x* and *y*.

**to\_eng\_string(*x*)**

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

`to_integral_exact(x)`  
Rounds to an integer.

`to_sci_string(x)`  
Converts a number to a string using scientific notation.

### 9.4.4 Signals

Signals represent conditions that arise during computation. Each corresponds to one context flag and one context trap enabler.

The context flag is set whenever the condition is encountered. After the computation, flags may be checked for informational purposes (for instance, to determine whether a computation was exact). After checking the flags, be sure to clear all flags before starting the next computation.

If the context's trap enabler is set for the signal, then the condition causes a Python exception to be raised. For example, if the *DivisionByZero* trap is set, then a *DivisionByZero* exception is raised upon encountering the condition.

**class decimal.Clamped**  
Altered an exponent to fit representation constraints.  
Typically, clamping occurs when an exponent falls outside the context's *Emin* and *Emax* limits. If possible, the exponent is reduced to fit by adding zeros to the coefficient.

**class decimal.DecimalException**  
Base class for other signals and a subclass of *ArithmeticError*.

**class decimal.DivisionByZero**  
Signals the division of a non-infinite number by zero.  
Can occur with division, modulo division, or when raising a number to a negative power. If this signal is not trapped, returns *Infinity* or *-Infinity* with the sign determined by the inputs to the calculation.

**class decimal.Inexact**  
Indicates that rounding occurred and the result is not exact.  
Signals when non-zero digits were discarded during rounding. The rounded result is returned. The signal flag or trap is used to detect when results are inexact.

**class decimal.InvalidOperation**  
An invalid operation was performed.  
Indicates that an operation was requested that does not make sense. If not trapped, returns *NaN*. Possible causes include :

```
Infinity - Infinity
0 * Infinity
Infinity / Infinity
x % 0
Infinity % x
x._rescale( non-integer )
sqrt(-x) and x > 0
0 ** 0
x ** (non-integer)
x ** Infinity
```

**class decimal.Overflow**  
Numerical overflow.  
Indicates the exponent is larger than *Emax* after rounding has occurred. If not trapped, the result depends on the rounding mode, either pulling inward to the largest representable finite number or rounding outward to *Infinity*. In either case, *Inexact* and *Rounded* are also signaled.

**class decimal.Rounded**

Rounding occurred though possibly no information was lost.

Signaled whenever rounding discards digits; even if those digits are zero (such as rounding 5.00 to 5.0). If not trapped, returns the result unchanged. This signal is used to detect loss of significant digits.

**class decimal.Subnormal**

Exponent was lower than `Emin` prior to rounding.

Occurs when an operation result is subnormal (the exponent is too small). If not trapped, returns the result unchanged.

**class decimal.Underflow**

Numerical underflow with result rounded to zero.

Occurs when a subnormal result is pushed to zero by rounding. *Inexact* and *Subnormal* are also signaled.

The following table summarizes the hierarchy of signals :

```
exceptions.ArithmeticError(exceptions.StandardError)
    DecimalException
        Clamped
        DivisionByZero(DecimalException, exceptions.ZeroDivisionError)
        Inexact
            Overflow(Inexact, Rounded)
            Underflow(Inexact, Rounded, Subnormal)
        InvalidOperation
        Rounded
        Subnormal
```

## 9.4.5 Floating Point Notes

### Mitigating round-off error with increased precision

The use of decimal floating point eliminates decimal representation error (making it possible to represent 0.1 exactly); however, some operations can still incur round-off error when non-zero digits exceed the fixed precision.

The effects of round-off error can be amplified by the addition or subtraction of nearly offsetting quantities resulting in loss of significance. Knuth provides two instructive examples where rounded floating point arithmetic with insufficient precision causes the breakdown of the associative and distributive properties of addition :

```
# Examples from Seminumerical Algorithms, Section 4.2.2.
>>> from decimal import Decimal, getcontext
>>> getcontext().prec = 8

>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.5111111')
>>> u + (v + w)
Decimal('10')

>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.01')
>>> u * (v+w)
Decimal('0.0060000')
```

The `decimal` module makes it possible to restore the identities by expanding the precision sufficiently to avoid loss of significance :

```
>>> getcontext().prec = 20
>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.51111111')
>>> u + (v + w)
Decimal('9.51111111')
>>>
>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.0060000')
>>> u * (v+w)
Decimal('0.0060000')
```

### Special values

The number system for the `decimal` module provides special values including NaN, sNaN, -Infinity, Infinity, and two zeros, +0 and -0.

Infinities can be constructed directly with : `Decimal('Infinity')`. Also, they can arise from dividing by zero when the `DivisionByZero` signal is not trapped. Likewise, when the `Overflow` signal is not trapped, infinity can result from rounding beyond the limits of the largest representable number.

The infinities are signed (affine) and can be used in arithmetic operations where they get treated as very large, indeterminate numbers. For instance, adding a constant to infinity gives another infinite result.

Some operations are indeterminate and return NaN, or if the `InvalidOperation` signal is trapped, raise an exception. For example, `0/0` returns NaN which means « not a number ». This variety of NaN is quiet and, once created, will flow through other computations always resulting in another NaN. This behavior can be useful for a series of computations that occasionally have missing inputs — it allows the calculation to proceed while flagging specific results as invalid.

A variant is sNaN which signals rather than remaining quiet after every operation. This is a useful return value when an invalid result needs to interrupt a calculation for special handling.

The behavior of Python's comparison operators can be a little surprising where a NaN is involved. A test for equality where one of the operands is a quiet or signaling NaN always returns `False` (even when doing `Decimal('NaN')==Decimal('NaN')`), while a test for inequality always returns `True`. An attempt to compare two Decimals using any of the `<`, `<=`, `>` or `>=` operators will raise the `InvalidOperation` signal if either operand is a NaN, and return `False` if this signal is not trapped. Note that the General Decimal Arithmetic specification does not specify the behavior of direct comparisons ; these rules for comparisons involving a NaN were taken from the IEEE 854 standard (see Table 3 in section 5.7). To ensure strict standards-compliance, use the `compare()` and `compare-signal()` methods instead.

The signed zeros can result from calculations that underflow. They keep the sign that would have resulted if the calculation had been carried out to greater precision. Since their magnitude is zero, both positive and negative zeros are treated as equal and their sign is informational.

In addition to the two signed zeros which are distinct yet equal, there are various representations of zero with differing precisions yet equivalent in value. This takes a bit of getting used to. For an eye accustomed to normalized floating point representations, it is not immediately obvious that the following calculation returns a value equal to zero :

```
>>> 1 / Decimal('Infinity')
Decimal('0E-10000000026')
```

### 9.4.6 Working with threads

The `getcontext()` function accesses a different *Context* object for each thread. Having separate thread contexts means that threads may make changes (such as `getcontext().prec=10`) without interfering with other threads.

Likewise, the `setcontext()` function automatically assigns its target to the current thread.

If `setcontext()` has not been called before `getcontext()`, then `getcontext()` will automatically create a new context for use in the current thread.

The new context is copied from a prototype context called *DefaultContext*. To control the defaults so that each thread will use the same values throughout the application, directly modify the *DefaultContext* object. This should be done *before* any threads are started so that there won't be a race condition between threads calling `getcontext()`. For example :

```
# Set applicationwide defaults for all threads about to be launched
DefaultContext.prec = 12
DefaultContext.rounding = ROUND_DOWN
DefaultContext.traps = ExtendedContext.traps.copy()
DefaultContext.traps[InvalidOperation] = 1
setcontext(DefaultContext)

# Afterwards, the threads can be started
t1.start()
t2.start()
t3.start()
. . .
```

### 9.4.7 Cas pratiques

Here are a few recipes that serve as utility functions and that demonstrate ways to work with the *Decimal* class :

```
def moneyfmt(value, places=2, curr='', sep=',', dp='.',
             pos='', neg='-', trailneg=''):
    """Convert Decimal to a money formatted string.

    places:  required number of places after the decimal point
    curr:    optional currency symbol before the sign (may be blank)
    sep:     optional grouping separator (comma, period, space, or blank)
    dp:      decimal point indicator (comma or period)
             only specify as blank when places is zero
    pos:     optional sign for positive numbers: '+', space or blank
    neg:     optional sign for negative numbers: '-', '(', space or blank
    trailneg: optional trailing minus indicator:  '-', ')', space or blank

    >>> d = Decimal('-1234567.8901')
    >>> moneyfmt(d, curr='$')
    '-$1,234,567.89'
    >>> moneyfmt(d, places=0, sep='.', dp='', neg='', trailneg='-')
    '1.234.568-'
    >>> moneyfmt(d, curr='$', neg='(', trailneg=')')
    '($1,234,567.89)'
    >>> moneyfmt(Decimal(123456789), sep=' ')
```

(suite sur la page suivante)

(suite de la page précédente)

```

'123 456 789.00'
>>> moneyfmt(Decimal('-0.02'), neg='<', trailneg='>')
'<0.02>'

"""
q = Decimal(10) ** -places      # 2 places --> '0.01'
sign, digits, exp = value.quantize(q).as_tuple()
result = []
digits = map(str, digits)
build, next = result.append, digits.pop
if sign:
    build(trailneg)
for i in range(places):
    build(next() if digits else '0')
build(dp)
if not digits:
    build('0')
i = 0
while digits:
    build(next())
    i += 1
    if i == 3 and digits:
        i = 0
        build(sep)

return +s

```

### 9.4.8 FAQ *decimal*

Q. C'est fastidieux de taper `decimal.Decimal('1234.5')`. Y a-t-il un moyen de réduire la frappe quand on utilise l'interpréteur interactif ?

R. Certains utilisateurs abrègent le constructeur en une seule lettre :

```

>>> D = decimal.Decimal
>>> D('1.23') + D('3.45')
Decimal('4.68')

```

Q. In a fixed-point application with two decimal places, some inputs have many places and need to be rounded. Others are not supposed to have excess digits and need to be validated. What methods should be used ?

A. The `quantize()` method rounds to a fixed number of decimal places. If the *Inexact* trap is set, it is also useful for validation :

```

>>> TWOPLACES = Decimal(10) ** -2      # same as Decimal('0.01')

```

```

>>> # Round to two places
>>> Decimal('3.214').quantize(TWOPLACES)
Decimal('3.21')

```

```

>>> # Validate that a number does not exceed two places
>>> Decimal('3.21').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Decimal('3.21')

```

```

>>> Decimal('3.214').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Traceback (most recent call last):
...
Inexact: None

```

Q. Once I have valid two place inputs, how do I maintain that invariant throughout an application ?

A. Some operations like addition, subtraction, and multiplication by an integer will automatically preserve fixed point. Others operations, like division and non-integer multiplication, will change the number of decimal places and need to be followed-up with a `quantize()` step :

```

>>> a = Decimal('102.72')           # Initial fixed-point values
>>> b = Decimal('3.17')
>>> a + b                             # Addition preserves fixed-point
Decimal('105.89')
>>> a - b
Decimal('99.55')
>>> a * 42                            # So does integer multiplication
Decimal('4314.24')
>>> (a * b).quantize(TWOPLACES)       # Must quantize non-integer multiplication
Decimal('325.62')
>>> (b / a).quantize(TWOPLACES)       # And quantize division
Decimal('0.03')

```

In developing fixed-point applications, it is convenient to define functions to handle the `quantize()` step :

```

>>> def mul(x, y, fp=TWOPLACES):
...     return (x * y).quantize(fp)
>>> def div(x, y, fp=TWOPLACES):
...     return (x / y).quantize(fp)

```

```

>>> mul(a, b)                         # Automatically preserve fixed-point
Decimal('325.62')
>>> div(b, a)
Decimal('0.03')

```

Q. There are many ways to express the same value. The numbers 200, 200.000, 2E2, and 02E+4 all have the same value at various precisions. Is there a way to transform them to a single recognizable canonical value?

A. The `normalize()` method maps all equivalent values to a single representative :

```

>>> values = map(Decimal, '200 200.000 2E2 .02E+4'.split())
>>> [v.normalize() for v in values]
[Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2')]

```

Q. Some decimal values always print with exponential notation. Is there a way to get a non-exponential representation?

A. For some values, exponential notation is the only way to express the number of significant places in the coefficient. For example, expressing 5.0E+3 as 5000 keeps the value constant but cannot show the original's two-place significance.

If an application does not care about tracking significance, it is easy to remove the exponent and trailing zeros, losing significance, but keeping the value unchanged :

```

def remove_exponent(d):
    '''Remove exponent and trailing zeros.

    >>> remove_exponent(Decimal('5E+3'))
    Decimal('5000')

    '''
    return d.quantize(Decimal(1)) if d == d.to_integral() else d.normalize()

```

Q. Is there a way to convert a regular float to a *Decimal*?

A. Yes, any binary floating point number can be exactly expressed as a Decimal though an exact conversion may take more precision than intuition would suggest :

```
>>> Decimal(math.pi)
Decimal('3.141592653589793115997963468544185161590576171875')
```

Q. Within a complex calculation, how can I make sure that I haven't gotten a spurious result because of insufficient precision or rounding anomalies.

A. The decimal module makes it easy to test results. A best practice is to re-run calculations using greater precision and with various rounding modes. Widely differing results indicate insufficient precision, rounding mode issues, ill-conditioned inputs, or a numerically unstable algorithm.

Q. I noticed that context precision is applied to the results of operations but not to the inputs. Is there anything to watch out for when mixing values of different precisions ?

A. Yes. The principle is that all values are considered to be exact and so is the arithmetic on those values. Only the results are rounded. The advantage for inputs is that « what you type is what you get ». A disadvantage is that the results can look odd if you forget that the inputs haven't been rounded :

```
>>> getcontext().prec = 3
>>> Decimal('3.104') + Decimal('2.104')
Decimal('5.21')
>>> Decimal('3.104') + Decimal('0.000') + Decimal('2.104')
Decimal('5.20')
```

The solution is either to increase precision or to force rounding of inputs using the unary plus operation :

```
>>> getcontext().prec = 3
>>> +Decimal('1.23456789')      # unary plus triggers rounding
Decimal('1.23')
```

Alternatively, inputs can be rounded upon creation using the `Context.create_decimal()` method :

```
>>> Context(prec=5, rounding=ROUND_DOWN).create_decimal('1.2345678')
Decimal('1.2345')
```

## 9.5 fractions — Nombres rationnels

Nouveau dans la version 2.6.

Code source : [Lib/fractions.py](#)

---

Le module `fractions` fournit un support de l'arithmétique des nombres rationnels.

Une instance de `Fraction` peut être construite depuis une paire d'entiers, depuis un autre nombre rationnel, ou depuis une chaîne de caractères.

```
class fractions.Fraction(numerator=0, denominator=1)
class fractions.Fraction(other_fraction)
class fractions.Fraction(float)
class fractions.Fraction(decimal)
class fractions.Fraction(string)
```

La première version demande que `numerator` et `denominator` soient des instance de `numbers.Rational` et renvoie une instance de `Fraction` valant `numerator/denominator`. Si `denominator` vaut 0, une

`ZeroDivisionError` est levée. La seconde version demande que `other_fraction` soit une instance de `numbers.Rational` et renvoie une instance de `Fraction` avec la même valeur. Les deux versions suivantes acceptent un `float` ou une instance de `decimal.Decimal`, et renvoient une instance de `Fraction` avec exactement la même valeur. Notez que les problèmes usuels des virgules flottantes binaires (voir `tut-fp-issues`) font que `Fraction(1.1)` n'est pas exactement égal à  $11/10$ , et donc `Fraction(1.1)` ne renvoie pas `Fraction(11, 10)` comme on pourrait le penser. (Mais référez-vous à la documentation de la méthode `limit_denominator()` ci-dessous.) La dernière version du constructeur attend une chaîne de caractères ou Unicode. La représentation habituelle de cette forme est :

```
[sign] numerator ['/' denominator]
```

où le `sign` optionnel peut être soit `+` soit `-`, et `numerator` et `denominator` (si présent) sont des chaînes de chiffres décimaux. De plus, toute chaîne qui représente une valeur finie et acceptée par le constructeur de `float` est aussi acceptée par celui de `Fraction`. Dans ces deux formes, la chaîne d'entrée peut aussi contenir des espaces en début ou en fin de chaîne. Voici quelques exemples :

```
>>> from fractions import Fraction
>>> Fraction(16, -10)
Fraction(-8, 5)
>>> Fraction(123)
Fraction(123, 1)
>>> Fraction()
Fraction(0, 1)
>>> Fraction('3/7')
Fraction(3, 7)
>>> Fraction(' -3/7 ')
Fraction(-3, 7)
>>> Fraction('1.414213 \t\n')
Fraction(1414213, 1000000)
>>> Fraction('-.125')
Fraction(-1, 8)
>>> Fraction('7e-6')
Fraction(7, 1000000)
>>> Fraction(2.25)
Fraction(9, 4)
>>> Fraction(1.1)
Fraction(2476979795053773, 2251799813685248)
>>> from decimal import Decimal
>>> Fraction(Decimal('1.1'))
Fraction(11, 10)
```

The `Fraction` class inherits from the abstract base class `numbers.Rational`, and implements all of the methods and operations from that class. `Fraction` instances are hashable, and should be treated as immutable. In addition, `Fraction` has the following methods :

Modifié dans la version 2.7 : Le constructeur de `Fraction` accepte maintenant des instances de `float` et `decimal.Decimal`.

#### `from_float(flt)`

Cette méthode de classe construit un objet `Fraction` représentant la valeur exacte de `flt`, qui doit être de type `float`. Attention, `Fraction.from_float(0.3)` n'est pas la même valeur que `Fraction(3, 10)`.

**Note :** From Python 2.7 onwards, you can also construct a `Fraction` instance directly from a `float`.

#### `from_decimal(dec)`

This class method constructs a *Fraction* representing the exact value of *dec*, which must be a *decimal.Decimal*.

---

**Note :** From Python 2.7 onwards, you can also construct a *Fraction* instance directly from a *decimal.Decimal* instance.

---

`limit_denominator(max_denominator=1000000)`

Trouve et renvoie la *Fraction* la plus proche de `self` qui a au plus *max\_denominator* comme dénominateur. Cette méthode est utile pour trouver des approximations rationnelles de nombres flottants donnés :

```
>>> from fractions import Fraction
>>> Fraction('3.1415926535897932').limit_denominator(1000)
Fraction(355, 113)
```

ou pour retrouver un nombre rationnel représenté par un flottant :

```
>>> from math import pi, cos
>>> Fraction(cos(pi/3))
Fraction(4503599627370497, 9007199254740992)
>>> Fraction(cos(pi/3)).limit_denominator()
Fraction(1, 2)
>>> Fraction(1.1).limit_denominator()
Fraction(11, 10)
```

`fractions.gcd(a, b)`

Renvoie le plus grand diviseur commun (PGCD) des entiers *a* et *b*. Si *a* et *b* sont tous deux non nuls, alors la valeur absolue de `gcd(a, b)` est le plus grand entier qui divise à la fois *a* et *b*. `gcd(a,b)` a le même signe que *b* si *b* n'est pas nul ; autrement il prend le signe de *a*. `gcd(0, 0)` renvoie 0.

**Module *numbers*** Les classes abstraites représentant la hiérarchie des nombres.

## 9.6 random — Generate pseudo-random numbers

**Code source :** [Lib/random.py](#)

---

This module implements pseudo-random number generators for various distributions.

For integers, uniform selection from a range. For sequences, uniform selection of a random element, a function to generate a random permutation of a list in-place, and a function for random sampling without replacement.

On the real line, there are functions to compute uniform, normal (Gaussian), lognormal, negative exponential, gamma, and beta distributions. For generating distributions of angles, the von Mises distribution is available.

Almost all module functions depend on the basic function `random()`, which generates a random float uniformly in the semi-open range [0.0, 1.0). Python uses the Mersenne Twister as the core generator. It produces 53-bit precision floats and has a period of  $2^{19937}-1$ . The underlying implementation in C is both fast and threadsafe. The Mersenne Twister is one of the most extensively tested random number generators in existence. However, being completely deterministic, it is not suitable for all purposes, and is completely unsuitable for cryptographic purposes.

The functions supplied by this module are actually bound methods of a hidden instance of the `random.Random` class. You can instantiate your own instances of `Random` to get generators that don't share state.

This is especially useful for multi-threaded programs, creating a different instance of `Random` for each thread, and using the `jumpahead()` method to make it likely that the generated sequences seen by each thread don't overlap.

Class `Random` can also be subclassed if you want to use a different basic generator of your own devising : in that case, override the `random()`, `seed()`, `getstate()`, `setstate()` and `jumpahead()` methods. Optionally, a new generator can supply a `getrandbits()` method — this allows `randrange()` to produce selections over an arbitrarily large range.

Nouveau dans la version 2.4 : the `getrandbits()` method.

As an example of subclassing, the `random` module provides the `WichmannHill` class that implements an alternative generator in pure Python. The class provides a backward compatible way to reproduce results from earlier versions of Python, which used the Wichmann-Hill algorithm as the core generator. Note that this Wichmann-Hill generator can no longer be recommended : its period is too short by contemporary standards, and the sequence generated is known to fail some stringent randomness tests. See the references below for a recent variant that repairs these flaws.

Modifié dans la version 2.3 : MersenneTwister replaced Wichmann-Hill as the default generator.

The `random` module also provides the `SystemRandom` class which uses the system function `os.urandom()` to generate random numbers from sources provided by the operating system.

**Avertissement :** The pseudo-random generators of this module should not be used for security purposes. Use `os.urandom()` or `SystemRandom` if you require a cryptographically secure pseudo-random number generator.

Bookkeeping functions :

`random.seed(a=None)`

Initialize internal state of the random number generator.

`None` or no argument seeds from current time or from an operating system specific randomness source if available (see the `os.urandom()` function for details on availability).

If `a` is not `None` or an `int` or a `long`, then `hash(a)` is used instead. Note that the hash values for some types are nondeterministic when `PYTHONHASHSEED` is enabled.

Modifié dans la version 2.4 : formerly, operating system resources were not used.

`random.getstate()`

Return an object capturing the current internal state of the generator. This object can be passed to `setstate()` to restore the state.

Nouveau dans la version 2.1.

Modifié dans la version 2.6 : State values produced in Python 2.6 cannot be loaded into earlier versions.

`random.setstate(state)`

`state` should have been obtained from a previous call to `getstate()`, and `setstate()` restores the internal state of the generator to what it was at the time `getstate()` was called.

Nouveau dans la version 2.1.

`random.jumpahead(n)`

Change the internal state to one different from and likely far away from the current state. `n` is a non-negative integer which is used to scramble the current state vector. This is most useful in multi-threaded programs, in conjunction with multiple instances of the `Random` class : `setstate()` or `seed()` can be used to force all instances into the same internal state, and then `jumpahead()` can be used to force the instances' states far apart.

Nouveau dans la version 2.1.

Modifié dans la version 2.3 : Instead of jumping to a specific state, *n* steps ahead, `jumpahead(n)` jumps to another state likely to be separated by many steps.

`random.getrandbits(k)`

Returns a python *long* int with *k* random bits. This method is supplied with the MersenneTwister generator and some other generators may also provide it as an optional part of the API. When available, `getrandbits()` enables `randrange()` to handle arbitrarily large ranges.

Nouveau dans la version 2.4.

Functions for integers :

`random.randrange(stop)`

`random.randrange(start, stop[, step])`

Return a randomly selected element from `range(start, stop, step)`. This is equivalent to `choice(range(start, stop, step))`, but doesn't actually build a range object.

Nouveau dans la version 1.5.2.

`random.randint(a, b)`

Return a random integer *N* such that `a <= N <= b`.

Functions for sequences :

`random.choice(seq)`

Return a random element from the non-empty sequence *seq*. If *seq* is empty, raises *IndexError*.

`random.shuffle(x[, random])`

Shuffle the sequence *x* in place. The optional argument *random* is a 0-argument function returning a random float in [0.0, 1.0) ; by default, this is the function `random()`.

Note that for even rather small `len(x)`, the total number of permutations of *x* is larger than the period of most random number generators ; this implies that most permutations of a long sequence can never be generated.

`random.sample(population, k)`

Return a *k* length list of unique elements chosen from the population sequence. Used for random sampling without replacement.

Nouveau dans la version 2.3.

Returns a new list containing elements from the population while leaving the original population unchanged. The resulting list is in selection order so that all sub-slices will also be valid random samples. This allows raffle winners (the sample) to be partitioned into grand prize and second place winners (the subslices).

Members of the population need not be *hashable* or unique. If the population contains repeats, then each occurrence is a possible selection in the sample.

To choose a sample from a range of integers, use an `xrange()` object as an argument. This is especially fast and space efficient for sampling from a large population : `sample(xrange(10000000), 60)`.

The following functions generate specific real-valued distributions. Function parameters are named after the corresponding variables in the distribution's equation, as used in common mathematical practice ; most of these equations can be found in any statistics text.

`random.random()`

Return the next random floating point number in the range [0.0, 1.0).

`random.uniform(a, b)`

Return a random floating point number *N* such that `a <= N <= b` for `a <= b` and `b <= N <= a` for `b < a`.

The end-point value *b* may or may not be included in the range depending on floating-point rounding in the equation `a + (b-a) * random()`.

`random.triangular(low, high, mode)`

Return a random floating point number  $N$  such that  $\text{low} \leq N \leq \text{high}$  and with the specified *mode* between those bounds. The *low* and *high* bounds default to zero and one. The *mode* argument defaults to the midpoint between the bounds, giving a symmetric distribution.

Nouveau dans la version 2.6.

`random.betavariate(alpha, beta)`

Beta distribution. Conditions on the parameters are  $\alpha > 0$  and  $\beta > 0$ . Returned values range between 0 and 1.

`random.expovariate(lambd)`

Exponential distribution. *lambd* is 1.0 divided by the desired mean. It should be nonzero. (The parameter would be called « *lambda* », but that is a reserved word in Python.) Returned values range from 0 to positive infinity if *lambd* is positive, and from negative infinity to 0 if *lambd* is negative.

`random.gammavariate(alpha, beta)`

Gamma distribution. (Not the gamma function!) Conditions on the parameters are  $\alpha > 0$  and  $\beta > 0$ .

The probability distribution function is :

$$\text{pdf}(x) = \frac{x^{(\alpha - 1)} * \text{math.exp}(-x / \beta)}{\text{math.gamma}(\alpha) * \beta^{\alpha}}$$

`random.gauss(mu, sigma)`

Gaussian distribution. *mu* is the mean, and *sigma* is the standard deviation. This is slightly faster than the `normalvariate()` function defined below.

`random.lognormvariate(mu, sigma)`

Log normal distribution. If you take the natural logarithm of this distribution, you'll get a normal distribution with mean *mu* and standard deviation *sigma*. *mu* can have any value, and *sigma* must be greater than zero.

`random.normalvariate(mu, sigma)`

Normal distribution. *mu* is the mean, and *sigma* is the standard deviation.

`random.vonmisesvariate(mu, kappa)`

*mu* is the mean angle, expressed in radians between 0 and  $2\pi$ , and *kappa* is the concentration parameter, which must be greater than or equal to zero. If *kappa* is equal to zero, this distribution reduces to a uniform random angle over the range 0 to  $2\pi$ .

`random.paretovariate(alpha)`

Pareto distribution. *alpha* is the shape parameter.

`random.weibullvariate(alpha, beta)`

Weibull distribution. *alpha* is the scale parameter and *beta* is the shape parameter.

Alternative Generators :

`class random.WichmannHill([seed])`

Class that implements the Wichmann-Hill algorithm as the core generator. Has all of the same methods as `Random` plus the `whseed()` method described below. Because this class is implemented in pure Python, it is not threadsafe and may require locks between calls. The period of the generator is 6,953,607,871,644 which is small enough to require care that two independent random sequences do not overlap.

`random.whseed([x])`

This is obsolete, supplied for bit-level compatibility with versions of Python prior to 2.1. See `seed()`

for details. `whseed()` does not guarantee that distinct integer arguments yield distinct internal states, and can yield no more than about  $2^{24}$  distinct internal states in all.

**class** `random.SystemRandom([seed])`

Class that uses the `os.urandom()` function for generating random numbers from sources provided by the operating system. Not available on all systems. Does not rely on software state and sequences are not reproducible. Accordingly, the `seed()` and `jumpahead()` methods have no effect and are ignored. The `getstate()` and `setstate()` methods raise `NotImplementedError` if called.

Nouveau dans la version 2.4.

Examples of basic usage :

```
>>> random.random()           # Random float x, 0.0 <= x < 1.0
0.37444887175646646
>>> random.uniform(1, 10)    # Random float x, 1.0 <= x < 10.0
1.1800146073117523
>>> random.randint(1, 10)    # Integer from 1 to 10, endpoints included
7
>>> random.randrange(0, 101, 2) # Even integer from 0 to 100
26
>>> random.choice('abcdefghij') # Choose a random element
'c'

>>> items = [1, 2, 3, 4, 5, 6, 7]
>>> random.shuffle(items)
>>> items
[7, 3, 2, 5, 6, 4, 1]

>>> random.sample([1, 2, 3, 4, 5], 3) # Choose 3 elements
[4, 1, 5]
```

[Complementary-Multiply-with-Carry](#) recipe for a compatible alternative random number generator with a long period and comparatively simple update operations.

## 9.7 itertools — Fonctions créant des itérateurs pour boucler efficacement.

Nouveau dans la version 2.3.

Ce module implémente de nombreuses briques *d'itérateurs* inspirées par des constructions de APL, Haskell et SML. Toutes ont été retravaillées dans un format adéquat pour Python.

Ce module standardise un noyau d'outils rapide, efficaces en mémoire qui sont utiles d'eux-mêmes ou en les combinant. Ensemble, ils forment une « algèbre d'itérateurs » rendant possible la construction succincte et efficace d'outils spécialisés en Python seulement.

For instance, SML provides a tabulation tool : `tabulate(f)` which produces a sequence `f(0)`, `f(1)`, .... The same effect can be achieved in Python by combining `imap()` and `count()` to form `imap(f, count())`.

These tools and their built-in counterparts also work well with the high-speed functions in the `operator` module. For example, the multiplication operator can be mapped across two vectors to form an efficient dot-product : `sum(imap(operator.mul, vector1, vector2))`.

### Itérateurs infinis :

Itérateur	Argu-ments	Résultats	Exemple
<code>count()</code>	start, [step]	start, start+step, start+2*step, ...	<code>count(10) --&gt; 10 11 12 13 14 ...</code>
<code>cycle()</code>	p	p0, p1, ... plast, p0, p1, ...	<code>cycle('ABCD') --&gt; A B C D A B C D ...</code>
<code>repeat()</code>	elem [n]	<i>elem, elem, elem, ...</i> à l'infini ou jusqu'à n fois	<code>repeat(10, 3) --&gt; 10 10 10</code>

### Itérateurs se terminant par la séquence d'entrée la plus courte :

Itérateur	Arguments	Résultats	Exemple
<code>chain()</code>	p, q, ...	p0, p1, ... plast, q0, q1, ...	<code>chain('ABC', 'DEF') --&gt; A B C D E F</code>
<code>compress()</code>	data, selectors	(d[0] if s[0]), (d[1] if s[1]), ...	<code>compress('ABCDEF', [1,0,1,0,1,1]) --&gt; A C E F</code>
<code>dropwhile()</code>	pred, seq	<b>seq[n], seq[n+1],</b> commençant quand <i>pred</i> échoue	<code>dropwhile(lambda x: x&lt;5, [1,4,6,4,1]) --&gt; 6 4 1</code>
<code>groupby()</code>	iterable[, key-func]	sous-itérateurs groupés par la valeur de <i>keyfunc(v)</i>	
<code>ifilter()</code>	pred, seq	elements of seq where <i>pred(elem)</i> is true	<code>ifilter(lambda x: x%2, range(10)) --&gt; 1 3 5 7 9</code>
<code>ifilterfalse()</code>	pred, seq	éléments de <i>seq</i> quand <i>pred(elem)</i> est faux	<code>ifilterfalse(lambda x: x%2, range(10)) --&gt; 0 2 4 6 8</code>
<code>islice()</code>	seq, [start,] stop [, step]	éléments de <b>seq[start:stop:step]</b>	<code>islice('ABCDEFGH', 2, None) --&gt; C D E F G</code>
<code>imap()</code>	func, p, q, ...	func(p0, q0), func(p1, q1), ...	<code>imap(pow, (2,3,10), (5,2,3)) --&gt; 32 9 1000</code>
<code>starmap()</code>	func, seq	func(*seq[0]), func(*seq[1]), ...	<code>starmap(pow, [(2,5), (3,2), (10,3)]) --&gt; 32 9 1000</code>
<code>tee()</code>	it, n	<i>it1, it2, ... itn</i> sépare un itérateur en <i>n</i>	
<code>takewhile()</code>	pred, seq	<b>seq[0], seq[1],</b> jusqu'à ce que <i>pred</i> échoue	<code>takewhile(lambda x: x&lt;5, [1,4,6,4,1]) --&gt; 1 4</code>
<code>izip()</code>	p, q, ...	(p[0], q[0]), (p[1], q[1]), ...	<code>izip('ABCD', 'xy') --&gt; Ax By</code>
<code>izip_longest()</code>	p, q, ...	(p[0], q[0]), (p[1], q[1]), ...	<code>izip_longest('ABCD', 'xy', fillvalue='-') --&gt; Ax By C- D-</code>

### Générateurs combinatoires :

Itérateur	Arguments	Résultats
<code>product()</code>	<code>p, q, ... [repeat=1]</code>	produit cartésien, équivalent à une boucle <i>for</i> imbriquée
<code>permutations()</code>	<code>p[, r]</code>	<i>tuples</i> de longueur <i>r</i> , tous les ré-arrangements possibles, sans répétition d'éléments
<code>combinations()</code>	<code>p, r</code>	tuples de longueur <i>r</i> , triés, sans répétition d'éléments
<code>combinations_with_replacement()</code>	<code>p, r</code>	tuples de longueur <i>r</i> , triés, avec répétition d'éléments
<code>product('ABCD', repeat=2)</code>		AA AB AC AD BA BB BC BD CA CB CC CD DA DB DC DD
<code>permutations('ABCD', 2)</code>		AB AC AD BA BC BD CA CB CD DA DB DC
<code>combinations('ABCD', 2)</code>		AB AC AD BC BD CD
<code>combinations_with_replacement('ABCD', 2)</code>		AA AB AC AD BB BC BD CC CD DD

### 9.7.1 Fonctions d'*itertools*

Toutes les fonctions de module qui suivent construisent et renvoient des itérateurs. Certaines fournissent des flux de longueur infinie, elles devraient seulement être accédées par des fonctions ou boucles qui tronquent le flux.

`itertools.chain(*iterables)`

Créer un itérateur qui renvoie les éléments du premier itérable jusqu'à son épuisement, puis continue avec l'itérable suivant jusqu'à ce que tous les itérables soient épuisés. Utilisée pour traiter des séquences consécutives comme une seule séquence. Sensiblement équivalente à :

```
def chain(*iterables):
    # chain('ABC', 'DEF') --> A B C D E F
    for it in iterables:
        for element in it:
            yield element
```

`classmethod chain.from_iterable(iterable)`

Constructeur alternatif pour `chain()`. Récupère des entrées chaînées d'un unique argument itérable qui est évalué de manière paresseuse. Sensiblement équivalente à :

```
def from_iterable(iterables):
    # chain.from_iterable(['ABC', 'DEF']) --> A B C D E F
    for it in iterables:
        for element in it:
            yield element
```

Nouveau dans la version 2.6.

`itertools.combinations(iterable, r)`

Renvoyer les sous-séquences de longueur *r* de l'itérable *iterable*.

Les combinaisons sont émises dans l'ordre lexicographique. Ainsi, si l'itérable *iterable* est trié, les *tuples* de combinaison seront produits dans l'ordre.

Les éléments sont considérés comme uniques en fonction de leur position, et non pas de leur valeur. Ainsi, si les éléments en entrée sont uniques, il n'y aura pas de valeurs répétées dans chaque combinaison. Sensiblement équivalent à :

```
def combinations(iterable, r):
    # combinations('ABCD', 2) --> AB AC AD BC BD CD
    # combinations(range(4), 3) --> 012 013 023 123
```

(suite sur la page suivante)

(suite de la page précédente)

```

pool = tuple(iterable)
n = len(pool)
if r > n:
    return
indices = range(r)
yield tuple(pool[i] for i in indices)
while True:
    for i in reversed(range(r)):
        if indices[i] != i + n - r:
            break
    else:
        return
    indices[i] += 1
    for j in range(i+1, r):
        indices[j] = indices[j-1] + 1
    yield tuple(pool[i] for i in indices)

```

Le code de `combinations()` peut aussi être exprimé comme une sous-séquence de `permutations()` après avoir filtré les entrées dont les éléments ne sont pas triés (selon leur position dans le *pool* d'entrée) :

```

def combinations(iterable, r):
    pool = tuple(iterable)
    n = len(pool)
    for indices in permutations(range(n), r):
        if sorted(indices) == list(indices):
            yield tuple(pool[i] for i in indices)

```

Le nombre d'éléments renvoyés est  $n! / r! / (n-r)!$  quand  $0 \leq r \leq n$  ou zéro quand  $r > n$ .  
Nouveau dans la version 2.6.

`itertools.combinations_with_replacement(iterable, r)`

Renvoyer les sous-séquences de longueur *r* des éléments de l'itérable *iterable* d'entrée, permettant aux éléments individuels d'être répétés plus d'une fois.

Les combinaisons sont émises dans l'ordre lexicographique. Ainsi, si l'itérable *iterable* est trié, les *tuples* de combinaison seront produits dans l'ordre.

Les éléments sont considérés comme uniques en fonction de leur position, et non pas de leur valeur. Ainsi si les éléments d'entrée sont uniques, les combinaisons générées seront aussi uniques.

Sensiblement équivalent à :

```

def combinations_with_replacement(iterable, r):
    # combinations_with_replacement('ABC', 2) --> AA AB AC BB BC CC
    pool = tuple(iterable)
    n = len(pool)
    if not n and r:
        return
    indices = [0] * r
    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != n - 1:
                break
        else:
            return
        indices[i] += 1

```

(suite sur la page suivante)

(suite de la page précédente)

```
indices[i:] = [indices[i] + 1] * (r - i)
yield tuple(pool[i] for i in indices)
```

Le code pour `combinations_with_replacement()` peut aussi être exprimé comme une sous-séquence de `product()` après avoir filtré les entrées où les éléments ne sont pas dans triés (selon leur position dans le *pool* d'entrée) :

```
def combinations_with_replacement(iterable, r):
    pool = tuple(iterable)
    n = len(pool)
    for indices in product(range(n), repeat=r):
        if sorted(indices) == list(indices):
            yield tuple(pool[i] for i in indices)
```

Le nombre d'éléments renvoyés est  $(n+r-1)! / r! / (n-1)!$  quand  $n > 0$ .

Nouveau dans la version 2.7.

`itertools.compress(data, selectors)`

Créer un itérateur qui filtre les éléments de *data*, renvoyant seulement ceux qui ont un élément correspondant dans *selectors* qui évalue à `True`. S'arrête quand l'itérable *data* ou *selectors* a été épuisé. Sensiblement équivalent à :

```
def compress(data, selectors):
    # compress('ABCDEF', [1,0,1,0,1,1]) --> A C E F
    return (d for d, s in izip(data, selectors) if s)
```

Nouveau dans la version 2.7.

`itertools.count(start=0, step=1)`

Make an iterator that returns evenly spaced values starting with *n*. Often used as an argument to `imap()` to generate consecutive data points. Also, used with `izip()` to add sequence numbers. Equivalent to :

```
def count(start=0, step=1):
    # count(10) --> 10 11 12 13 14 ...
    # count(2.5, 0.5) -> 2.5 3.0 3.5 ...
    n = start
    while True:
        yield n
        n += step
```

Quand on compte avec des nombres à virgule flottante, il est parfois possible d'obtenir une meilleure précision en substituant du code multiplicateur comme : `(start + step * i for i in count())`.

Modifié dans la version 2.7 : added *step* argument and allowed non-integer arguments.

`itertools.cycle(iterable)`

Créer un itérateur qui renvoie les éléments de l'itérable et qui sauvegarde une copie de chaque. Quand l'itérable est épuisé, renvoyer les éléments depuis la copie sauvegardée. Répète à l'infini. Sensiblement équivalent à :

```
def cycle(iterable):
    # cycle('ABCD') --> A B C D A B C D A B C D ...
    saved = []
    for element in iterable:
        yield element
        saved.append(element)
```

(suite sur la page suivante)

(suite de la page précédente)

```

while saved:
    for element in saved:
        yield element

```

Note, cette fonction pourrait avoir besoin d'un stockage auxiliaire important (en fonction de la longueur de l'itérable).

`itertools.dropwhile(predicate, iterable)`

Créer un itérateur qui saute les éléments de l'itérable tant que le prédicat est vrai ; ensuite, renvoyer chaque élément. Note, l'itérateur ne produit *aucune* sortie avant que le prédicat ne devienne faux, il peut donc avoir un temps de démarrage long. Sensiblement équivalent à :

```

def dropwhile(predicate, iterable):
    # dropwhile(lambda x: x<5, [1,4,6,4,1]) --> 6 4 1
    iterable = iter(iterable)
    for x in iterable:
        if not predicate(x):
            yield x
            break
    for x in iterable:
        yield x

```

`itertools.groupby(iterable[, key])`

Créer un itérateur qui renvoie les clés et les groupes de l'itérable *iterable*. La clé *key* est une fonction qui génère une clé pour chaque élément. Si *key* n'est pas spécifié ou est `None`, elle vaut par défaut une fonction d'identité qui renvoie l'élément sans le modifier. Généralement, l'itérable a besoin d'être déjà trié selon cette même fonction de clé.

L'opération de `groupby()` est similaire au filtre `uniq` dans Unix. Elle génère un nouveau groupe à chaque fois que la valeur de la fonction *key* change (ce pourquoi il est souvent nécessaire d'avoir trié les données selon la même fonction de clé). Ce comportement est différent de celui de GROUP BY de SQL qui agrège les éléments sans prendre compte de leur ordre d'entrée.

Le groupe renvoyé est lui-même un itérateur qui partage l'itérable sous-jacent avec `groupby()`. Puisque que la source est partagée, quand l'objet `groupby()` est avancé, le groupe précédent n'est plus visible. Ainsi, si cette donnée doit être utilisée plus tard, elle devrait être stockée comme une liste :

```

groups = []
uniquekeys = []
data = sorted(data, key=keyfunc)
for k, g in groupby(data, keyfunc):
    groups.append(list(g))      # Store group iterator as a list
    uniquekeys.append(k)

```

`groupby()` est sensiblement équivalent à :

```

class groupby(object):
    # [k for k, g in groupby('AAAABBBCCDAABBB')] --> A B C D A B
    # [list(g) for k, g in groupby('AAAABBBCCD')] --> AAAA BBB CC D
    def __init__(self, iterable, key=None):
        if key is None:
            key = lambda x: x
        self.keyfunc = key
        self.it = iter(iterable)
        self.tgtkey = self.currkey = self.currvalue = object()

```

(suite sur la page suivante)

(suite de la page précédente)

```

def __iter__(self):
    return self
def next(self):
    while self.currkey == self.tgtkey:
        self.currvalue = next(self.it)      # Exit on StopIteration
        self.currkey = self.keyfunc(self.currvalue)
    self.tgtkey = self.currkey
    return (self.currkey, self._grouper(self.tgtkey))
def _grouper(self, tgtkey):
    while self.currkey == tgtkey:
        yield self.currvalue
        self.currvalue = next(self.it)      # Exit on StopIteration
        self.currkey = self.keyfunc(self.currvalue)

```

Nouveau dans la version 2.4.

`itertools.ifilter(predicate, iterable)`

Make an iterator that filters elements from *iterable* returning only those for which the predicate is True. If *predicate* is None, return the items that are true. Roughly equivalent to :

```

def ifilter(predicate, iterable):
    # ifilter(lambda x: x%2, range(10)) --> 1 3 5 7 9
    if predicate is None:
        predicate = bool
    for x in iterable:
        if predicate(x):
            yield x

```

`itertools.ifilterfalse(predicate, iterable)`

Créer un itérateur qui filtre les éléments de *iterable*, ne renvoyant seulement ceux pour lesquels le prédicat est Faux. Si *predicate* vaut None, renvoyer les éléments qui sont faux. Sensiblement équivalent à :

```

def ifilterfalse(predicate, iterable):
    # ifilterfalse(lambda x: x%2, range(10)) --> 0 2 4 6 8
    if predicate is None:
        predicate = bool
    for x in iterable:
        if not predicate(x):
            yield x

```

`itertools.imap(function, *iterables)`

Make an iterator that computes the function using arguments from each of the iterables. If *function* is set to None, then *imap()* returns the arguments as a tuple. Like *map()* but stops when the shortest iterable is exhausted instead of filling in None for shorter iterables. The reason for the difference is that infinite iterator arguments are typically an error for *map()* (because the output is fully evaluated) but represent a common and useful way of supplying arguments to *imap()*. Roughly equivalent to :

```

def imap(function, *iterables):
    # imap(pow, (2,3,10), (5,2,3)) --> 32 9 1000
    iterables = map(iter, iterables)
    while True:
        args = [next(it) for it in iterables]

```

(suite sur la page suivante)

(suite de la page précédente)

```

if function is None:
    yield tuple(args)
else:
    yield function(*args)

```

`itertools.islice(iterable, stop)`

`itertools.islice(iterable, start, stop[, step])`

Créer un itérateur qui renvoie les éléments sélectionnés de l'itérable. Si *start* est non-nul, alors les éléments de l'itérable sont sautés jusqu'à ce que *start* soit atteint. Ensuite, les éléments sont renvoyés consécutivement sauf si *step* est plus grand que 1, auquel cas certains éléments seront sautés. Si *stop* est `None`, alors l'itération continue jusqu'à ce que l'itérateur soit épuisé s'il ne l'est pas déjà ; sinon, il s'arrête à la position spécifiée. À la différence du *slicing* standard, `slice()` ne supporte pas les valeurs négatives pour *start*, *stop* ou *step*. Peut être utilisée pour extraire les champs apparentés depuis des données dont la structure interne a été aplatie (par exemple, un rapport multi-ligne pourrait lister un nom de champ toutes les trois lignes). Sensiblement similaire à :

```

def islice(iterable, *args):
    # islice('ABCDEFGH', 2) --> A B
    # islice('ABCDEFGH', 2, 4) --> C D
    # islice('ABCDEFGH', 2, None) --> C D E F G
    # islice('ABCDEFGH', 0, None, 2) --> A C E G
    s = slice(*args)
    start, stop, step = s.start or 0, s.stop or sys.maxint, s.step or 1
    it = iter(xrange(start, stop, step))
    try:
        nexti = next(it)
    except StopIteration:
        # Consume *iterable* up to the *start* position.
        for i, element in izip(xrange(start), iterable):
            pass
        return
    try:
        for i, element in enumerate(iterable):
            if i == nexti:
                yield element
                nexti = next(it)
    except StopIteration:
        # Consume to *stop*.
        for i, element in izip(xrange(i + 1, stop), iterable):
            pass

```

Si *start* vaut `None`, alors l'itération commence à zéro. Si *step* vaut `None`, alors le pas est à 1 par défaut. Modifié dans la version 2.5 : accept `None` values for default *start* and *step*.

`itertools.izip(*iterables)`

Make an iterator that aggregates elements from each of the iterables. Like `zip()` except that it returns an iterator instead of a list. Used for lock-step iteration over several iterables at a time. Roughly equivalent to :

```

def izip(*iterables):
    # izip('ABCD', 'xy') --> Ax By
    iterators = map(iter, iterables)
    while iterators:

```

(suite sur la page suivante)

(suite de la page précédente)

```
yield tuple(map(next, iterators))
```

Modifié dans la version 2.4 : When no iterables are specified, returns a zero length iterator instead of raising a *TypeError* exception.

The left-to-right evaluation order of the iterables is guaranteed. This makes possible an idiom for clustering a data series into n-length groups using `izip(*[iter(s)]*n)`.

`izip()` should only be used with unequal length inputs when you don't care about trailing, unmatched values from the longer iterables. If those values are important, use `izip_longest()` instead.

`itertools.izip_longest(*iterables[, fillvalue])`

Créer un itérateur qui agrège les éléments de chacun des itérables. Si les itérables sont de longueurs différentes, les valeurs manquantes sont remplacées par *fillvalue*. L'itération continue jusqu'à ce que l'itérable le plus long soit épuisé. Sensiblement équivalent à :

```
class ZipExhausted(Exception):
    pass

def izip_longest(*args, **kwargs):
    # izip_longest('ABCD', 'xy', fillvalue='-') --> Ax By C- D-
    fillvalue = kwargs.get('fillvalue')
    counter = [len(args) - 1]
    def sentinel():
        if not counter[0]:
            raise ZipExhausted
        counter[0] -= 1
        yield fillvalue
    fillers = repeat(fillvalue)
    iterators = [chain(it, sentinel(), fillers) for it in args]
    try:
        while iterators:
            yield tuple(map(next, iterators))
    except ZipExhausted:
        pass
```

If one of the iterables is potentially infinite, then the `izip_longest()` function should be wrapped with something that limits the number of calls (for example `islice()` or `takewhile()`). If not specified, *fillvalue* defaults to `None`.

Nouveau dans la version 2.6.

`itertools.permutations(iterable[, r])`

Renvoyer les permutations successives de longueur *r* des éléments de *iterable*.

Si *r* n'est pas spécifié ou vaut `None`, alors *r* a pour valeur la longueur de *iterable* et toutes les permutations de longueur *r* possibles sont générées.

Les permutations sont émises dans l'ordre lexicographique. Ainsi, si l'itérable d'entrée *iterable* est trié, les *tuples* de permutation seront produits dans l'ordre.

Les éléments sont considérés comme uniques en fonction de leur position, et non pas de leur valeur. Ainsi, si l'élément est unique, il n'y aura pas de valeurs répétées dans chaque permutation.

Sensiblement équivalent à :

```
def permutations(iterable, r=None):
    # permutations('ABCD', 2) --> AB AC AD BA BC BD CA CB CD DA DB DC
    # permutations(range(3)) --> 012 021 102 120 201 210
    pool = tuple(iterable)
```

(suite sur la page suivante)

(suite de la page précédente)

```

n = len(pool)
r = n if r is None else r
if r > n:
    return
indices = range(n)
cycles = range(n, n-r, -1)
yield tuple(pool[i] for i in indices[:r])
while n:
    for i in reversed(range(r)):
        cycles[i] -= 1
        if cycles[i] == 0:
            indices[i:] = indices[i+1:] + indices[i:i+1]
            cycles[i] = n - i
        else:
            j = cycles[i]
            indices[i], indices[-j] = indices[-j], indices[i]
            yield tuple(pool[i] for i in indices[:r])
            break
    else:
        return

```

Le code pour `permutations()` peut aussi être exprimé comme une sous-séquence de `product()`, filtré pour exclure les entrées avec des éléments répétés (celles de la même position dans la *pool* d'entrée) :

```

def permutations(iterable, r=None):
    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    for indices in product(range(n), repeat=r):
        if len(set(indices)) == r:
            yield tuple(pool[i] for i in indices)

```

Le nombre d'éléments renvoyés est  $n! / (n-r)!$  quand  $0 \leq r \leq n$  ou zéro quand  $r > n$ .

Nouveau dans la version 2.6.

`itertools.product(*iterables[, repeat])`

Produit cartésien des itérables d'entrée.

Sensiblement équivalent à des boucles *for* imbriquées dans une expression de générateur. Par exemple `product(A, B)` renvoie la même chose que `((x, y) for x in A for y in B)`.

Les boucles imbriquées tournent comme un compteur kilométrique avec l'élément le plus à droite avançant à chaque itération. ce motif crée un tri lexicographique afin que si les itérables de l'entrée sont triés, les *tuples* de produit sont émis dans l'ordre.

Pour générer le produit d'un itérable avec lui-même, spécifier le nombre de répétitions avec le paramètre nommé optionnel *repeat*. Par exemple, `product(A, repeat=4)` veut dire la même chose que `product(A, A, A, A)`.

Cette fonction est sensiblement équivalente au code suivant, sauf que la vraie implémentation ne crée pas les résultats intermédiaires en mémoire :

```

def product(*args, **kwargs):
    # product('ABCD', 'xy') --> Ax Ay Bx By Cx Cy Dx Dy
    # product(range(2), repeat=3) --> 000 001 010 011 100 101 110 111
    pools = map(tuple, args) * kwargs.get('repeat', 1)
    result = [[]]

```

(suite sur la page suivante)

(suite de la page précédente)

```

for pool in pools:
    result = [x+[y] for x in result for y in pool]
for prod in result:
    yield tuple(prod)

```

Nouveau dans la version 2.6.

`itertools.repeat(object[, times])`

Make an iterator that returns *object* over and over again. Runs indefinitely unless the *times* argument is specified. Used as argument to *imap()* for invariant function parameters. Also used with *izip()* to create constant fields in a tuple record. Roughly equivalent to :

```

def repeat(object, times=None):
    # repeat(10, 3) --> 10 10 10
    if times is None:
        while True:
            yield object
    else:
        for i in xrange(times):
            yield object

```

A common use for *repeat* is to supply a stream of constant values to *imap* or *zip* :

```

>>> list(imap(pow, xrange(10), repeat(2)))
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]

```

`itertools.starmap(function, iterable)`

Make an iterator that computes the function using arguments obtained from the iterable. Used instead of *imap()* when argument parameters are already grouped in tuples from a single iterable (the data has been « pre-zipped »). The difference between *imap()* and *starmap()* parallels the distinction between *function(a,b)* and *function(\*c)*. Roughly equivalent to :

```

def starmap(function, iterable):
    # starmap(pow, [(2,5), (3,2), (10,3)]) --> 32 9 1000
    for args in iterable:
        yield function(*args)

```

Modifié dans la version 2.6 : Previously, *starmap()* required the function arguments to be tuples. Now, any iterable is allowed.

`itertools.takewhile(predicate, iterable)`

Créer un itérateur qui renvoie les éléments d'un itérable tant que le prédicat est vrai. Sensiblement équivalent à :

```

def takewhile(predicate, iterable):
    # takewhile(lambda x: x<5, [1,4,6,4,1]) --> 1 4
    for x in iterable:
        if predicate(x):
            yield x
        else:
            break

```

`itertools.tee(iterable[, n=2])`

Return *n* independent iterators from a single iterable. Roughly equivalent to :

```
def tee(iterable, n=2):
    it = iter(iterable)
    deques = [collections.deque() for i in range(n)]
    def gen(mydeque):
        while True:
            if not mydeque:          # when the local deque is empty
                newval = next(it)    # fetch a new value and
                for d in deques:    # load it to all the deques
                    d.append(newval)
            yield mydeque.popleft()
    return tuple(gen(d) for d in deques)
```

Une fois que `tee()` a créé un branchement, l'itérable *iterable* ne devrait être utilisé nulle part ailleurs ; sinon, *iterable* pourrait être avancé sans que les objets *tee* soient informés.

Cet outil pourrait avoir besoin d'un stockage auxiliaire important (en fonction de la taille des données temporaires nécessaires). En général, si un itérateur utilise la majorité ou toute la donnée avant qu'un autre itérateur ne commence, il est plus rapide d'utiliser `list()` à la place de `tee()`.

Nouveau dans la version 2.4.

## 9.7.2 Cas pratiques

Cette section montre des recettes pour créer une boîte à outil étendue en se servant des *itertools* existants comme de briques.

Ces outils dérivés offrent la même bonne performance que les outils sous-jacents. La performance mémoire supérieure est gardée en traitant les éléments un à la fois plutôt que de charger tout l'itérable en mémoire en même temps. Le volume de code reste bas grâce à un chaînage de style fonctionnel qui aide à éliminer des variables temporaires. La grande vitesse est gardée en préférant les briques « vectorisées » plutôt que les boucles *for* et les *générateurs* qui engendrent du sur-coût de traitement.

```
def take(n, iterable):

            seen_add(element)
            yield element
    else:
        for element in iterable:
            k = key(element)
            if k not in seen:
                seen_add(k)
                yield element

def unique_justseen(iterable, key=None):
    "List unique elements, preserving order. Remember only the element just seen."
    # unique_justseen('AAAABBBCCDAABBB') --> A B C D A B
    # unique_justseen('ABBCcAD', str.lower) --> A B C A D
    return imap(next, imap(itemgetter(1), groupby(iterable, key)))

def iter_except(func, exception, first=None):
    """ Call a function repeatedly until an exception is raised.

    Converts a call-until-exception interface to an iterator interface.
    Like __builtin__.iter(func, sentinel) but uses an exception instead
    of a sentinel to end the loop.

    Examples:
    bsddbiter = iter_except(db.next, bsddb.error, db.first)
    heapiter = iter_except(functools.partial(heapop, h), IndexError)
    dictiter = iter_except(d.popitem, KeyError)
    dequeiter = iter_except(d.popleft, IndexError)
    queueiter = iter_except(q.get_nowait, Queue.Empty)
    setiter = iter_except(s.pop, KeyError)

    """
    try:

```

(suite sur la page suivante)

```

        if first is not None:
            yield first()
        while 1:
            yield func()
    except exception:
        pass

def random_product(*args, **kwargs):
    "Random selection from itertools.product(*args, **kwargs)"
    pools = map(tuple, args) * kwargs.get('repeat', 1)
    return tuple(random.choice(pool) for pool in pools)

def random_permutation(iterable, r=None):
    "Random selection from itertools.permutations(iterable, r)"
    pool = tuple(iterable)
    r = len(pool) if r is None else r
    return tuple(random.sample(pool, r))

def random_combination(iterable, r):
    "Random selection from itertools.combinations(iterable, r)"
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.sample(xrange(n), r))
    return tuple(pool[i] for i in indices)

def random_combination_with_replacement(iterable, r):
    "Random selection from itertools.combinations_with_replacement(iterable, r)"
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.randrange(n) for i in xrange(r))
    return tuple(pool[i] for i in indices)

def tee_lookahead(t, i):
    """Inspect the i-th upcoming value from a tee object
       while leaving the tee object at its current position.

       Raise an IndexError if the underlying iterator doesn't
       have enough values.

    """
    for value in islice(t.__copy__(), i, None):
        return value
    raise IndexError(i)

```

Note, beaucoup des recettes ci-dessus peuvent être optimisées en remplaçant les recherches globales par des recherches locales avec des variables locales définies comme des valeurs par défaut. Par exemple, la recette *dotproduct* peut être écrite comme :

```

def dotproduct(vec1, vec2, sum=sum, imap=imap, mul=operator.mul):
    return sum(imap(mul, vec1, vec2))

```

## 9.8 functools — Fonctions de haut niveau et opérations sur des objets appelables

Nouveau dans la version 2.5.

**Code source :** [Lib/functools.py](#)

Le module `functools` est utilisé pour des fonctions de haut niveau : des fonctions qui agissent sur ou renvoient d'autres fonctions. En général, tout objet callable peut être utilisé comme une fonction pour les besoins de ce module.

Le module `functools` définit les fonctions suivantes :

`functools.cmp_to_key(func)`

Transform an old-style comparison function to a *key function*. Used with tools that accept key functions (such as `sorted()`, `min()`, `max()`, `heapq.nlargest()`, `heapq.nsmallest()`, `itertools.groupby()`). This function is primarily used as a transition tool for programs being converted to Python 3 where comparison functions are no longer supported.

Une fonction de comparaison est un callable qui prend deux arguments, les compare, et renvoie un nombre négatif pour l'infériorité, zéro pour l'égalité ou un nombre positif pour la supériorité. Une fonction de clé est un callable qui prend un argument et retourne une autre valeur qui sera utilisée comme clé de tri.

Exemple :

```
sorted(iterable, key=cmp_to_key(locale.strcoll)) # locale-aware sort order
```

Pour des exemples de tris et un bref tutoriel, consultez [sortinghowto](#).

Nouveau dans la version 2.7.

`functools.total_ordering(cls)`

A partir d'une classe définissant une ou plusieurs méthodes de comparaison riches, ce décorateur de classe fournit le reste. Ceci simplifie l'effort à fournir dans la spécification de toutes les opérations de comparaison riche :

La classe doit définir au moins une de ces méthodes `__lt__()`, `__le__()`, `__gt__()`, or `__ge__()`. De plus, la classe doit fournir une méthode `__eq__()`.

Par exemple :

```
@total_ordering
class Student:
    def __eq__(self, other):
        return ((self.lastname.lower(), self.firstname.lower()) ==
                (other.lastname.lower(), other.firstname.lower()))
    def __lt__(self, other):
        return ((self.lastname.lower(), self.firstname.lower()) <
                (other.lastname.lower(), other.firstname.lower()))
```

Nouveau dans la version 2.7.

`functools.reduce(function, iterable[, initializer])`

This is the same function as `reduce()`. It is made available in this module to allow writing code more forward-compatible with Python 3.

Nouveau dans la version 2.6.

`functools.partial(func[, *args][, **keywords])`

Return a new *partial object* which when called will behave like `func` called with the positional arguments

*args* and keyword arguments *keywords*. If more arguments are supplied to the call, they are appended to *args*. If additional keyword arguments are supplied, they extend and override *keywords*. Roughly equivalent to :

```
def partial(func, *args, **keywords):
    def newfunc(*fargs, **fkeywords):
        newkeywords = keywords.copy()
        newkeywords.update(fkeywords)
        return func(*(args + fargs), **newkeywords)
    newfunc.func = func
    newfunc.args = args
    newfunc.keywords = keywords
    return newfunc
```

`partial()` est utilisé pour une application de fonction partielle qui « gèle » une portion des arguments et/ou mots-clés d'une fonction donnant un nouvel objet avec une signature simplifiée. Par exemple, `partial()` peut être utilisé pour créer un callable qui se comporte comme la fonction `int()` ou l'argument `base` est deux par défaut :

```
>>> from functools import partial
>>> basetwo = partial(int, base=2)
>>> basetwo.__doc__ = 'Convert base 2 string to an int.'
>>> basetwo('10010')
18
```

`functools.update_wrapper(wrapper, wrapped[, assigned][, updated])`

Update a *wrapper* function to look like the *wrapped* function. The optional arguments are tuples to specify which attributes of the original function are assigned directly to the matching attributes on the wrapper function and which attributes of the wrapper function are updated with the corresponding attributes from the original function. The default values for these arguments are the module level constants `WRAPPER_ASSIGNMENTS` (which assigns to the wrapper function's `__name__`, `__module__` and `__doc__`, the documentation string) and `WRAPPER_UPDATES` (which updates the wrapper function's `__dict__`, i.e. the instance dictionary).

La principale utilisation de cette fonction est dans les *décorateurs* qui renvoient une nouvelle fonction. Si la fonction créée n'est pas mise à jour, ses métadonnées reflèteront sa définition dans le décorateur, au lieu de la définition originale, métadonnées souvent bien moins utiles.

`functools.wraps(wrapped[, assigned][, updated])`

Ceci est une fonction d'aide pour appeler `update_wrapper()` comme décorateur de fonction lors de la définition d'une fonction englobante. C'est équivalent à `partial(update_wrapper, wrapped=wrapped, assigned=assigned, updated=updated)`. Par exemple :

```
>>> from functools import wraps
>>> def my_decorator(f):
...     @wraps(f)
...     def wrapper(*args, **kws):
...         print 'Calling decorated function'
...         return f(*args, **kws)
...     return wrapper
...
>>> @my_decorator
... def example():
...     """Docstring"""
...     print 'Called example function'
... 
```

(suite sur la page suivante)

(suite de la page précédente)

```

>>> example()
Calling decorated function
Called example function
>>> example.__name__
'example'
>>> example.__doc__
'Docstring'

```

Sans l'utilisation de cette usine à décorateur, le nom de la fonction d'exemple aurait été `'wrapper'`, et la chaîne de documentation de la fonction `example()` originale aurait été perdue.

### 9.8.1 Objets *partial*

Les objets *partial* sont des objets appelables créés par *partial()*. Ils ont trois attributs en lecture seule :

***partial.func***

Un objet ou une fonction callable. Les appels à l'objet *partial* seront transmis à *func* avec les nouveaux arguments et mots-clés.

***partial.args***

Les arguments positionnels qui seront ajoutés avant les arguments fournis lors de l'appel d'un objet *partial*.

***partial.keywords***

Les arguments nommés qui seront fournis quand l'objet *partial* est appelé.

Les objets *partial* sont comme des objets *function* de par le fait qu'il sont appelables, référençables, et peuvent avoir des attributs. Il y a cependant des différences importantes. Par exemple, les attributs `__name__` et `__doc__` ne sont pas créés automatiquement. De plus, les objets *partial* définis dans les classes se comportent comme des méthodes statiques et ne se transforment pas en méthodes liées durant la recherche d'attributs dans l'instance.

## 9.9 operator — Standard operators as functions

The *operator* module exports a set of efficient functions corresponding to the intrinsic operators of Python. For example, `operator.add(x, y)` is equivalent to the expression `x+y`. The function names are those used for special class methods; variants without leading and trailing `__` are also provided for convenience.

The functions fall into categories that perform object comparisons, logical operations, mathematical operations, sequence operations, and abstract type tests.

The object comparison functions are useful for all objects, and are named after the rich comparison operators they support :

```

operator.lt(a, b)
operator.le(a, b)
operator.eq(a, b)
operator.ne(a, b)
operator.ge(a, b)
operator.gt(a, b)
operator.__lt__(a, b)
operator.__le__(a, b)
operator.__eq__(a, b)
operator.__ne__(a, b)
operator.__ge__(a, b)

```

`operator.__gt__(a, b)`

Perform « rich comparisons » between *a* and *b*. Specifically, `lt(a, b)` is equivalent to `a < b`, `le(a, b)` is equivalent to `a <= b`, `eq(a, b)` is equivalent to `a == b`, `ne(a, b)` is equivalent to `a != b`, `gt(a, b)` is equivalent to `a > b` and `ge(a, b)` is equivalent to `a >= b`. Note that unlike the built-in `cmp()`, these functions can return any value, which may or may not be interpretable as a Boolean value. See comparisons for more information about rich comparisons.

Nouveau dans la version 2.2.

The logical operations are also generally applicable to all objects, and support truth tests, identity tests, and boolean operations :

`operator.not_(obj)`

`operator.__not__(obj)`

Return the outcome of `not obj`. (Note that there is no `__not__()` method for object instances; only the interpreter core defines this operation. The result is affected by the `__nonzero__()` and `__len__()` methods.)

`operator.truth(obj)`

Return *True* if *obj* is true, and *False* otherwise. This is equivalent to using the *bool* constructor.

`operator.is_(a, b)`

Return `a is b`. Tests object identity.

Nouveau dans la version 2.3.

`operator.is_not(a, b)`

Return `a is not b`. Tests object identity.

Nouveau dans la version 2.3.

The mathematical and bitwise operations are the most numerous :

`operator.abs(obj)`

`operator.__abs__(obj)`

Renvoie la valeur absolue de *obj*.

`operator.add(a, b)`

`operator.__add__(a, b)`

Return `a + b`, for *a* and *b* numbers.

`operator.and_(a, b)`

`operator.__and__(a, b)`

Return the bitwise and of *a* and *b*.

`operator.div(a, b)`

`operator.__div__(a, b)`

Return `a / b` when `__future__.division` is not in effect. This is also known as « classic » division.

`operator.floordiv(a, b)`

`operator.__floordiv__(a, b)`

Return `a // b`.

Nouveau dans la version 2.2.

`operator.index(a)`

`operator.__index__(a)`

Return *a* converted to an integer. Equivalent to `a.__index__()`.

Nouveau dans la version 2.5.

`operator.inv(obj)`

`operator.invert(obj)`

`operator.__inv__(obj)`

`operator.__invert__(obj)`

Return the bitwise inverse of the number *obj*. This is equivalent to `~obj`.

Nouveau dans la version 2.0 : The names `invert()` and `__invert__()`.

`operator.lshift(a, b)`

`operator.__lshift__(a, b)`

Return *a* shifted left by *b*.

`operator.mod(a, b)`

`operator.__mod__(a, b)`

Return `a % b`.

`operator.mul(a, b)`

`operator.__mul__(a, b)`

Return `a * b`, for *a* and *b* numbers.

`operator.neg(obj)`

`operator.__neg__(obj)`

Return *obj* negated (`-obj`).

`operator.or_(a, b)`

`operator.__or__(a, b)`

Return the bitwise or of *a* and *b*.

`operator.pos(obj)`

`operator.__pos__(obj)`

Return *obj* positive (`+obj`).

`operator.pow(a, b)`

`operator.__pow__(a, b)`

Return `a ** b`, for *a* and *b* numbers.

Nouveau dans la version 2.3.

`operator.rshift(a, b)`

`operator.__rshift__(a, b)`

Return *a* shifted right by *b*.

`operator.sub(a, b)`

`operator.__sub__(a, b)`

Return `a - b`.

`operator.truediv(a, b)`

`operator.__truediv__(a, b)`

Return `a / b` when `__future__.division` is in effect. This is also known as « true » division.

Nouveau dans la version 2.2.

`operator.xor(a, b)`

`operator.__xor__(a, b)`

Return the bitwise exclusive or of *a* and *b*.

Operations which work with sequences (some of them with mappings too) include :

`operator.concat(a, b)`

`operator.__concat__(a, b)`

Return `a + b` for *a* and *b* sequences.

`operator.contains(a, b)`

`operator.__contains__(a, b)`

Return the outcome of the test `b in a`. Note the reversed operands.

Nouveau dans la version 2.0 : The name `__contains__()`.

`operator.countOf(a, b)`

Return the number of occurrences of *b* in *a*.

`operator.delitem(a, b)`

`operator.__delitem__(a, b)`

Remove the value of *a* at index *b*.

`operator.delslice(a, b, c)`

`operator.__delslice__(a, b, c)`

Delete the slice of *a* from index *b* to index *c-1*.

Obsolète depuis la version 2.6 : This function is removed in Python 3.x. Use `delitem()` with a slice index.

`operator.getitem(a, b)`

`operator.__getitem__(a, b)`

Return the value of *a* at index *b*.

`operator.getslice(a, b, c)`

`operator.__getslice__(a, b, c)`

Return the slice of *a* from index *b* to index *c-1*.

Obsolète depuis la version 2.6 : This function is removed in Python 3.x. Use `getitem()` with a slice index.

`operator.indexOf(a, b)`

Return the index of the first of occurrence of *b* in *a*.

`operator.repeat(a, b)`

`operator.__repeat__(a, b)`

Obsolète depuis la version 2.7 : Use `__mul__()` instead.

Return *a* \* *b* where *a* is a sequence and *b* is an integer.

`operator.sequenceIncludes(...)`

Obsolète depuis la version 2.0 : Use `contains()` instead.

Alias for `contains()`.

`operator.setitem(a, b, c)`

`operator.__setitem__(a, b, c)`

Set the value of *a* at index *b* to *c*.

`operator.setslice(a, b, c, v)`

`operator.__setslice__(a, b, c, v)`

Set the slice of *a* from index *b* to index *c-1* to the sequence *v*.

Obsolète depuis la version 2.6 : This function is removed in Python 3.x. Use `setitem()` with a slice index.

Example use of operator functions :

```
>>> # Elementwise multiplication
>>> map(mul, [0, 1, 2, 3], [10, 20, 30, 40])
[0, 20, 60, 120]

>>> # Dot product
>>> sum(map(mul, [0, 1, 2, 3], [10, 20, 30, 40]))
200
```

Many operations have an « in-place » version. The following functions provide a more primitive access to in-place operators than the usual syntax does; for example, the *statement* `x += y` is equivalent to `x = operator.iadd(x, y)`. Another way to put it is to say that `z = operator.iadd(x, y)` is equivalent to the compound statement `z = x; z += y`.

`operator.iadd(a, b)`  
`operator.__iadd__(a, b)`  
`a = iadd(a, b)` is equivalent to `a += b`.  
 Nouveau dans la version 2.5.

`operator.iand(a, b)`  
`operator.__iand__(a, b)`  
`a = iand(a, b)` is equivalent to `a &= b`.  
 Nouveau dans la version 2.5.

`operator.iconcat(a, b)`  
`operator.__iconcat__(a, b)`  
`a = iconcat(a, b)` is equivalent to `a += b` for *a* and *b* sequences.  
 Nouveau dans la version 2.5.

`operator.idiv(a, b)`  
`operator.__idiv__(a, b)`  
`a = idiv(a, b)` is equivalent to `a /= b` when `__future__.division` is not in effect.  
 Nouveau dans la version 2.5.

`operator.ifloordiv(a, b)`  
`operator.__ifloordiv__(a, b)`  
`a = ifloordiv(a, b)` is equivalent to `a //= b`.  
 Nouveau dans la version 2.5.

`operator.ilshift(a, b)`  
`operator.__ilshift__(a, b)`  
`a = ilshift(a, b)` is equivalent to `a <<= b`.  
 Nouveau dans la version 2.5.

`operator.imod(a, b)`  
`operator.__imod__(a, b)`  
`a = imod(a, b)` is equivalent to `a %= b`.  
 Nouveau dans la version 2.5.

`operator.imul(a, b)`  
`operator.__imul__(a, b)`  
`a = imul(a, b)` is equivalent to `a *= b`.  
 Nouveau dans la version 2.5.

`operator.ior(a, b)`  
`operator.__ior__(a, b)`  
`a = ior(a, b)` is equivalent to `a |= b`.  
 Nouveau dans la version 2.5.

`operator.ipow(a, b)`  
`operator.__ipow__(a, b)`  
`a = ipow(a, b)` is equivalent to `a **= b`.  
 Nouveau dans la version 2.5.

`operator.irepeat(a, b)`  
`operator.__irepeat__(a, b)`  
 Obsolète depuis la version 2.7 : Use `__imul__()` instead.  
`a = irepeat(a, b)` is equivalent to `a *= b` where *a* is a sequence and *b* is an integer.  
 Nouveau dans la version 2.5.

`operator.irshift(a, b)`

`operator.irshift(a, b)`  
    `a = irshift(a, b)` is equivalent to `a >>= b`.  
Nouveau dans la version 2.5.

`operator.isub(a, b)`  
`operator.__isub__(a, b)`  
    `a = isub(a, b)` is equivalent to `a -= b`.  
Nouveau dans la version 2.5.

`operator.itruediv(a, b)`  
`operator.__itruediv__(a, b)`  
    `a = itrueidiv(a, b)` is equivalent to `a /= b` when `__future__.division` is in effect.  
Nouveau dans la version 2.5.

`operator.ior(a, b)`  
`operator.__ior__(a, b)`  
    `a = ior(a, b)` is equivalent to `a ^= b`.  
Nouveau dans la version 2.5.

The `operator` module also defines a few predicates to test the type of objects; however, these are not all reliable. It is preferable to test abstract base classes instead (see `collections` and `numbers` for details).

`operator.isCallable(obj)`  
    Obsolète depuis la version 2.0 : Use `isinstance(x, collections.Callable)` instead.  
    Returns true if the object `obj` can be called like a function, otherwise it returns false. True is returned for functions, bound and unbound methods, class objects, and instance objects which support the `__call__()` method.

`operator.isMappingType(obj)`  
    Obsolète depuis la version 2.7 : Use `isinstance(x, collections.Mapping)` instead.  
    Returns true if the object `obj` supports the mapping interface. This is true for dictionaries and all instance objects defining `__getitem__()`.

`operator.isNumberType(obj)`  
    Obsolète depuis la version 2.7 : Use `isinstance(x, numbers.Number)` instead.  
    Returns true if the object `obj` represents a number. This is true for all numeric types implemented in C.

`operator.isSequenceType(obj)`  
    Obsolète depuis la version 2.7 : Use `isinstance(x, collections.Sequence)` instead.  
    Returns true if the object `obj` supports the sequence protocol. This returns true for all objects which define sequence methods in C, and for all instance objects defining `__getitem__()`.

The `operator` module also defines tools for generalized attribute and item lookups. These are useful for making fast field extractors as arguments for `map()`, `sorted()`, `itertools.groupby()`, or other functions that expect a function argument.

`operator.attrgetter(attr)`  
`operator.attrgetter(*attrs)`  
    Return a callable object that fetches `attr` from its operand. If more than one attribute is requested, returns a tuple of attributes. The attribute names can also contain dots. For example :  
    — After `f = attrgetter('name')`, the call `f(b)` returns `b.name`.  
    — After `f = attrgetter('name', 'date')`, the call `f(b)` returns `(b.name, b.date)`.  
    — After `f = attrgetter('name.first', 'name.last')`, the call `f(b)` returns `(b.name.first, b.name.last)`.  
    Équivalent à :

```
def attrgetter(*items):
    if len(items) == 1:
        attr = items[0]
        def g(obj):
            return resolve_attr(obj, attr)
    else:
        def g(obj):
            return tuple(resolve_attr(obj, attr) for attr in items)
    return g

def resolve_attr(obj, attr):
    for name in attr.split("."):
        obj = getattr(obj, name)
    return obj
```

Nouveau dans la version 2.4.

Modifié dans la version 2.5 : Added support for multiple attributes.

Modifié dans la version 2.6 : Added support for dotted attributes.

`operator.itemgetter(item)`

`operator.itemgetter(*items)`

Return a callable object that fetches *item* from its operand using the operand's `__getitem__()` method.

If multiple items are specified, returns a tuple of lookup values. For example :

— After `f = itemgetter(2)`, the call `f(r)` returns `r[2]`.

— After `g = itemgetter(2, 5, 3)`, the call `g(r)` returns `(r[2], r[5], r[3])`.

Équivalent à :

```
def itemgetter(*items):
    if len(items) == 1:
        item = items[0]
        def g(obj):
            return obj[item]
    else:
        def g(obj):
            return tuple(obj[item] for item in items)
    return g
```

The items can be any type accepted by the operand's `__getitem__()` method. Dictionaries accept any hashable value. Lists, tuples, and strings accept an index or a slice :

```
>>> itemgetter(1)('ABCDEFGH')
'B'
>>> itemgetter(1,3,5)('ABCDEFGH')
('B', 'D', 'F')
>>> itemgetter(slice(2,None))('ABCDEFGH')
'CDEFG'
```

Nouveau dans la version 2.4.

Modifié dans la version 2.5 : Added support for multiple item extraction.

Example of using `itemgetter()` to retrieve specific fields from a tuple record :

```
>>> inventory = [('apple', 3), ('banana', 2), ('pear', 5), ('orange', 1)]
>>> getcount = itemgetter(1)
>>> map(getcount, inventory)
```

(suite sur la page suivante)

(suite de la page précédente)

```
[3, 2, 5, 1]
>>> sorted(inventory, key=getcount)
[('orange', 1), ('banana', 2), ('apple', 3), ('pear', 5)]
```

`operator.methodcaller(name[, args...])`

Return a callable object that calls the method *name* on its operand. If additional arguments and/or keyword arguments are given, they will be given to the method as well. For example :

- After `f = methodcaller('name')`, the call `f(b)` returns `b.name()`.
  - After `f = methodcaller('name', 'foo', bar=1)`, the call `f(b)` returns `b.name('foo', bar=1)`.
- Équivalent à :

```
def methodcaller(name, *args, **kwargs):
    def caller(obj):
        return getattr(obj, name)(*args, **kwargs)
    return caller
```

Nouveau dans la version 2.6.

### 9.9.1 Mapping Operators to Functions

This table shows how abstract operations correspond to operator symbols in the Python syntax and the functions in the `operator` module.

Opération	Syntax	Fonction
Addition	<code>a + b</code>	<code>add(a, b)</code>
Concatenation	<code>seq1 + seq2</code>	<code>concat(seq1, seq2)</code>
Containment Test	<code>obj in seq</code>	<code>contains(seq, obj)</code>
Division	<code>a / b</code>	<code>div(a, b)</code> (without <code>__future__.division</code> )
Division	<code>a / b</code>	<code>truediv(a, b)</code> (with <code>__future__.division</code> )
Division	<code>a // b</code>	<code>floordiv(a, b)</code>
Bitwise And	<code>a &amp; b</code>	<code>and_(a, b)</code>
Bitwise Exclusive Or	<code>a ^ b</code>	<code>xor(a, b)</code>
Bitwise Inversion	<code>~ a</code>	<code>invert(a)</code>
Bitwise Or	<code>a   b</code>	<code>or_(a, b)</code>
Exponentiation	<code>a ** b</code>	<code>pow(a, b)</code>
Identity	<code>a is b</code>	<code>is_(a, b)</code>
Identity	<code>a is not b</code>	<code>is_not(a, b)</code>
Indexed Assignment	<code>obj[k] = v</code>	<code>setitem(obj, k, v)</code>
Indexed Deletion	<code>del obj[k]</code>	<code>delitem(obj, k)</code>
Indexing	<code>obj[k]</code>	<code>getitem(obj, k)</code>
Left Shift	<code>a &lt;&lt; b</code>	<code>lshift(a, b)</code>
Modulo	<code>a % b</code>	<code>mod(a, b)</code>
Multiplication	<code>a * b</code>	<code>mul(a, b)</code>
Negation (Arithmetic)	<code>- a</code>	<code>neg(a)</code>
Negation (Logical)	<code>not a</code>	<code>not_(a)</code>
Positive	<code>+ a</code>	<code>pos(a)</code>
Right Shift	<code>a &gt;&gt; b</code>	<code>rshift(a, b)</code>
Sequence Repetition	<code>seq * i</code>	<code>repeat(seq, i)</code>
Slice Assignment	<code>seq[i:j] = values</code>	<code>setitem(seq, slice(i, j), values)</code>
Slice Deletion	<code>del seq[i:j]</code>	<code>delitem(seq, slice(i, j))</code>
Slicing	<code>seq[i:j]</code>	<code>getitem(seq, slice(i, j))</code>

Suite sur la page suivante

Tableau 1 – suite de la page précédente

Opération	Syntax	Fonction
String Formatting	<code>s % obj</code>	<code>mod(s, obj)</code>
Subtraction	<code>a - b</code>	<code>sub(a, b)</code>
Truth Test	<code>obj</code>	<code>truth(obj)</code>
Ordering	<code>a &lt; b</code>	<code>lt(a, b)</code>
Ordering	<code>a &lt;= b</code>	<code>le(a, b)</code>
Equality	<code>a == b</code>	<code>eq(a, b)</code>
Différence	<code>a != b</code>	<code>ne(a, b)</code>
Ordering	<code>a &gt;= b</code>	<code>ge(a, b)</code>
Ordering	<code>a &gt; b</code>	<code>gt(a, b)</code>

Les modules décrits dans ce chapitre servent à accéder aux fichiers et aux dossiers. Des modules, par exemple, pour lire les propriétés des fichiers, manipuler des chemins de manière portable, et créer des fichiers temporaires. La liste exhaustive des modules de ce chapitre est :

### 10.1 `os.path` — Common pathname manipulations

This module implements some useful functions on pathnames. To read or write files see `open()`, and for accessing the filesystem see the `os` module.

---

**Note :** On Windows, many of these functions do not properly support UNC pathnames. `splitunc()` and `ismount()` do handle them correctly.

---

Unlike a unix shell, Python does not do any *automatic* path expansions. Functions such as `expanduser()` and `expandvars()` can be invoked explicitly when an application desires shell-like path expansion. (See also the `glob` module.)

---

**Note :** Since different operating systems have different path name conventions, there are several versions of this module in the standard library. The `os.path` module is always the path module suitable for the operating system Python is running on, and therefore usable for local paths. However, you can also import and use the individual modules if you want to manipulate a path that is *always* in one of the different formats. They all have the same interface :

- `posixpath` for UNIX-style paths
  - `ntpath` for Windows paths
  - `macpath` for old-style MacOS paths
  - `os2emxpath` for OS/2 EMX paths
- 

`os.path.abspath(path)`

Return a normalized absolutized version of the pathname `path`. On most platforms, this is equivalent to calling the function `normpath(join(os.getcwd(), path))`.

Nouveau dans la version 1.5.2.

**os.path.basename(*path*)**

Return the base name of pathname *path*. This is the second element of the pair returned by passing *path* to the function *split()*. Note that the result of this function is different from the Unix **basename** program; where **basename** for `'/foo/bar/'` returns `'bar'`, the *basename()* function returns an empty string `''`.

**os.path.commonprefix(*list*)**

Return the longest path prefix (taken character-by-character) that is a prefix of all paths in *list*. If *list* is empty, return the empty string `''`. Note that this may return invalid paths because it works a character at a time.

**os.path.dirname(*path*)**

Return the directory name of pathname *path*. This is the first element of the pair returned by passing *path* to the function *split()*.

**os.path.exists(*path*)**

Return **True** if *path* refers to an existing path. Returns **False** for broken symbolic links. On some platforms, this function may return **False** if permission is not granted to execute *os.stat()* on the requested file, even if the *path* physically exists.

**os.path.lexists(*path*)**

Return **True** if *path* refers to an existing path. Returns **True** for broken symbolic links. Equivalent to *exists()* on platforms lacking *os.lstat()*.

Nouveau dans la version 2.4.

**os.path.expanduser(*path*)**

On Unix and Windows, return the argument with an initial component of `~` or `~user` replaced by that *user*'s home directory.

On Unix, an initial `~` is replaced by the environment variable `HOME` if it is set; otherwise the current user's home directory is looked up in the password directory through the built-in module *pwd*. An initial `~user` is looked up directly in the password directory.

On Windows, `HOME` and `USERPROFILE` will be used if set, otherwise a combination of `HOMEPATH` and `HOMEDRIVE` will be used. An initial `~user` is handled by stripping the last directory component from the created user path derived above.

If the expansion fails or if the path does not begin with a tilde, the path is returned unchanged.

**os.path.expandvars(*path*)**

Return the argument with environment variables expanded. Substrings of the form `$name` or `${name}` are replaced by the value of environment variable *name*. Malformed variable names and references to non-existing variables are left unchanged.

On Windows, `%name%` expansions are supported in addition to `$name` and `${name}`.

**os.path.getatime(*path*)**

Return the time of last access of *path*. The return value is a number giving the number of seconds since the epoch (see the *time* module). Raise *os.error* if the file does not exist or is inaccessible.

Nouveau dans la version 1.5.2.

Modifié dans la version 2.3 : If *os.stat\_float\_times()* returns **True**, the result is a floating point number.

**os.path.getmtime(*path*)**

Return the time of last modification of *path*. The return value is a number giving the number of seconds since the epoch (see the *time* module). Raise *os.error* if the file does not exist or is inaccessible.

Nouveau dans la version 1.5.2.

Modifié dans la version 2.3 : If *os.stat\_float\_times()* returns **True**, the result is a floating point number.

**os.path.getctime(*path*)**

Return the system's ctime which, on some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time for *path*. The return value is a number giving the number of seconds since the epoch (see the *time* module). Raise *os.error* if the file does not exist or is inaccessible.

Nouveau dans la version 2.3.

**os.path.getsize(*path*)**

Return the size, in bytes, of *path*. Raise *os.error* if the file does not exist or is inaccessible.

Nouveau dans la version 1.5.2.

**os.path.isabs(*path*)**

Return *True* if *path* is an absolute pathname. On Unix, that means it begins with a slash, on Windows that it begins with a (back)slash after chopping off a potential drive letter.

**os.path.isfile(*path*)**

Return *True* if *path* is an existing regular file. This follows symbolic links, so both *islink()* and *isfile()* can be true for the same path.

**os.path.isdir(*path*)**

Return *True* if *path* is an existing directory. This follows symbolic links, so both *islink()* and *isdir()* can be true for the same path.

**os.path.islink(*path*)**

Return *True* if *path* refers to a directory entry that is a symbolic link. Always *False* if symbolic links are not supported by the Python runtime.

**os.path.ismount(*path*)**

Return *True* if pathname *path* is a *mount point* : a point in a file system where a different file system has been mounted. The function checks whether *path*'s parent, *path/..*, is on a different device than *path*, or whether *path/..* and *path* point to the same i-node on the same device — this should detect mount points for all Unix and POSIX variants.

**os.path.join(*path*, \**paths*)**

Join one or more path components intelligently. The return value is the concatenation of *path* and any members of \**paths* with exactly one directory separator (*os.sep*) following each non-empty part except the last, meaning that the result will only end in a separator if the last part is empty. If a component is an absolute path, all previous components are thrown away and joining continues from the absolute path component.

On Windows, the drive letter is not reset when an absolute path component (e.g., *r'\foo'*) is encountered. If a component contains a drive letter, all previous components are thrown away and the drive letter is reset. Note that since there is a current directory for each drive, *os.path.join("c:", "foo")* represents a path relative to the current directory on drive C: (*c:foo*), not *c:\foo*.

**os.path.normcase(*path*)**

Normalize the case of a pathname. On Unix and Mac OS X, this returns the path unchanged; on case-insensitive filesystems, it converts the path to lowercase. On Windows, it also converts forward slashes to backward slashes.

**os.path.normpath(*path*)**

Normalize a pathname by collapsing redundant separators and up-level references so that *A//B*, *A/B/*, *A/./B* and *A/foo/../B* all become *A/B*. This string manipulation may change the meaning of a path that contains symbolic links. On Windows, it converts forward slashes to backward slashes. To normalize case, use *normcase()*.

**os.path.realpath(*path*)**

Return the canonical path of the specified filename, eliminating any symbolic links encountered in the path (if they are supported by the operating system).

Nouveau dans la version 2.2.

`os.path.relpath(path[, start])`

Return a relative filepath to *path* either from the current directory or from an optional *start* directory. This is a path computation : the filesystem is not accessed to confirm the existence or nature of *path* or *start*.

*start* defaults to `os.curdir`.

Availability : Windows, Unix.

Nouveau dans la version 2.6.

`os.path.samefile(path1, path2)`

Return `True` if both pathname arguments refer to the same file or directory (as indicated by device number and i-node number). Raise an exception if an `os.stat()` call on either pathname fails.

Disponibilité : Unix.

`os.path.sameopenfile(fp1, fp2)`

Return `True` if the file descriptors *fp1* and *fp2* refer to the same file.

Disponibilité : Unix.

`os.path.samestat(stat1, stat2)`

Return `True` if the stat tuples *stat1* and *stat2* refer to the same file. These structures may have been returned by `os.fstat()`, `os.lstat()`, or `os.stat()`. This function implements the underlying comparison used by `samefile()` and `sameopenfile()`.

Disponibilité : Unix.

`os.path.split(path)`

Split the pathname *path* into a pair, (*head*, *tail*) where *tail* is the last pathname component and *head* is everything leading up to that. The *tail* part will never contain a slash; if *path* ends in a slash, *tail* will be empty. If there is no slash in *path*, *head* will be empty. If *path* is empty, both *head* and *tail* are empty. Trailing slashes are stripped from *head* unless it is the root (one or more slashes only). In all cases, `join(head, tail)` returns a path to the same location as *path* (but the strings may differ). Also see the functions `dirname()` and `basename()`.

`os.path.splitdrive(path)`

Split the pathname *path* into a pair (*drive*, *tail*) where *drive* is either a drive specification or the empty string. On systems which do not use drive specifications, *drive* will always be the empty string. In all cases, *drive* + *tail* will be the same as *path*.

Nouveau dans la version 1.3.

`os.path.splitext(path)`

Split the pathname *path* into a pair (*root*, *ext*) such that *root* + *ext* == *path*, and *ext* is empty or begins with a period and contains at most one period. Leading periods on the basename are ignored; `splitext('.cshrc')` returns `('cshrc', '')`.

Modifié dans la version 2.6 : Earlier versions could produce an empty root when the only period was the first character.

`os.path.splitunc(path)`

Split the pathname *path* into a pair (*unc*, *rest*) so that *unc* is the UNC mount point (such as `r'\\host\mount'`), if present, and *rest* the rest of the path (such as `r'\path\file.ext'`). For paths containing drive letters, *unc* will always be the empty string.

Disponibilité : Windows.

`os.path.walk(path, visit, arg)`

Calls the function *visit* with arguments (*arg*, *dirname*, *names*) for each directory in the directory tree rooted at *path* (including *path* itself, if it is a directory). The argument *dirname* specifies the visited directory, the argument *names* lists the files in the directory (gotten from `os.listdir(dirname)`). The *visit* function may modify *names* to influence the set of directories visited below *dirname*, e.g. to avoid visiting certain parts of the tree. (The object referred to by *names* must be modified in place, using `del` or slice assignment.)

---

**Note :** Symbolic links to directories are not treated as subdirectories, and that `walk()` therefore will not visit them. To visit linked directories you must identify them with `os.path.islink(file)` and `os.path.isdir(file)`, and invoke `walk()` as necessary.

---

---

**Note :** This function is deprecated and has been removed in Python 3 in favor of `os.walk()`.

---

`os.path.supports_unicode_filenames`

True if arbitrary Unicode strings can be used as file names (within limitations imposed by the file system).

Nouveau dans la version 2.3.

## 10.2 fileinput — Iterate over lines from multiple input streams

**Code source :** [Lib/fileinput.py](#)

---

This module implements a helper class and functions to quickly write a loop over standard input or a list of files. If you just want to read or write one file see `open()`.

The typical use is :

```
import fileinput
for line in fileinput.input():
    process(line)
```

This iterates over the lines of all files listed in `sys.argv[1:]`, defaulting to `sys.stdin` if the list is empty. If a filename is '-', it is also replaced by `sys.stdin`. To specify an alternative list of filenames, pass it as the first argument to `input()`. A single file name is also allowed.

All files are opened in text mode by default, but you can override this by specifying the `mode` parameter in the call to `input()` or `FileInput()`. If an I/O error occurs during opening or reading a file, `IOError` is raised.

If `sys.stdin` is used more than once, the second and further use will return no lines, except perhaps for interactive use, or if it has been explicitly reset (e.g. using `sys.stdin.seek(0)`).

Empty files are opened and immediately closed; the only time their presence in the list of filenames is noticeable at all is when the last file opened is empty.

Lines are returned with any newlines intact, which means that the last line in a file may not have one.

You can control how files are opened by providing an opening hook via the `openhook` parameter to `fileinput.input()` or `FileInput()`. The hook must be a function that takes two arguments, `filename` and `mode`, and returns an accordingly opened file-like object. Two useful hooks are already provided by this module.

The following function is the primary interface of this module :

```
fileinput.input([files[, inplace[, backup[, bufsize[, mode[, openhook]]]]]])
```

Create an instance of the `FileInput` class. The instance will be used as global state for the functions of this module, and is also returned to use during iteration. The parameters to this function will be passed along to the constructor of the `FileInput` class.

Modifié dans la version 2.5 : Added the `mode` and `openhook` parameters.

Modifié dans la version 2.7.12 : Le paramètre `bufsize` n'est plus utilisé.

The following functions use the global state created by `fileinput.input()`; if there is no active state, `RuntimeError` is raised.

`fileinput.filename()`

Return the name of the file currently being read. Before the first line has been read, returns `None`.

`fileinput.fileno()`

Return the integer « file descriptor » for the current file. When no file is opened (before the first line and between files), returns `-1`.

Nouveau dans la version 2.5.

`fileinput.lineno()`

Return the cumulative line number of the line that has just been read. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line.

`fileinput.filelineno()`

Return the line number in the current file. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line within the file.

`fileinput.isfirstline()`

Returns true if the line just read is the first line of its file, otherwise returns false.

`fileinput.isstdin()`

Returns true if the last line was read from `sys.stdin`, otherwise returns false.

`fileinput.nextfile()`

Close the current file so that the next iteration will read the first line from the next file (if any); lines not read from the file will not count towards the cumulative line count. The filename is not changed until after the first line of the next file has been read. Before the first line has been read, this function has no effect; it cannot be used to skip the first file. After the last line of the last file has been read, this function has no effect.

`fileinput.close()`

Close the sequence.

The class which implements the sequence behavior provided by the module is available for subclassing as well :

`class fileinput.FileInput([files[, inplace[, backup[, bufsize[, mode[, openhook]]]]])`

Class `FileInput` is the implementation; its methods `filename()`, `fileno()`, `lineno()`, `filelineno()`, `isfirstline()`, `isstdin()`, `nextfile()` and `close()` correspond to the functions of the same name in the module. In addition it has a `readline()` method which returns the next input line, and a `__getitem__()` method which implements the sequence behavior. The sequence must be accessed in strictly sequential order; random access and `readline()` cannot be mixed.

With `mode` you can specify which file mode will be passed to `open()`. It must be one of `'r'`, `'rU'`, `'U'` and `'rb'`.

The `openhook`, when given, must be a function that takes two arguments, `filename` and `mode`, and returns an accordingly opened file-like object. You cannot use `inplace` and `openhook` together.

Modifié dans la version 2.5 : Added the `mode` and `openhook` parameters.

Modifié dans la version 2.7.12 : Le paramètre `bufsize` n'est plus utilisé.

**Optional in-place filtering :** if the keyword argument `inplace=1` is passed to `fileinput.input()` or to the `FileInput` constructor, the file is moved to a backup file and standard output is directed to the input file (if a file of the same name as the backup file already exists, it will be replaced silently). This makes it possible to write a filter that rewrites its input file in place. If the `backup` parameter is given (typically as `backup='.<some extension>'`), it specifies the extension for the backup file, and the backup file remains around; by default, the extension is `'.bak'` and it is deleted when the output file is closed. In-place filtering is disabled when standard input is read.

---

**Note :** The current implementation does not work for MS-DOS 8+3 filesystems.

---

The two following opening hooks are provided by this module :

`fileinput.hook_compressed(filename, mode)`

Transparently opens files compressed with gzip and bzip2 (recognized by the extensions `'.gz'` and `'.bz2'`) using the `gzip` and `bz2` modules. If the filename extension is not `'.gz'` or `'.bz2'`, the file is opened normally (ie, using `open()` without any decompression).

Usage example : `fi = fileinput.FileInput(openhook=fileinput.hook_compressed)`

Nouveau dans la version 2.5.

`fileinput.hook_encoded(encoding)`

Returns a hook which opens each file with `io.open()`, using the given `encoding` to read the file.

Usage example : `fi = fileinput.FileInput(openhook=fileinput.hook_encoded("iso-8859-1"))`

---

**Note :** With this hook, `FileInput` might return Unicode strings depending on the specified `encoding`.

---

Nouveau dans la version 2.5.

## 10.3 stat — Interpreting stat() results

**Source code :** [Lib/stat.py](#)

---

The `stat` module defines constants and functions for interpreting the results of `os.stat()`, `os.fstat()` and `os.lstat()` (if they exist). For complete details about the `stat()`, `fstat()` and `lstat()` calls, consult the documentation for your system.

The `stat` module defines the following functions to test for specific file types :

`stat.S_ISDIR(mode)`

Return non-zero if the mode is from a directory.

`stat.S_ISCHR(mode)`

Return non-zero if the mode is from a character special device file.

`stat.S_ISBLK(mode)`

Return non-zero if the mode is from a block special device file.

`stat.S_ISREG(mode)`

Return non-zero if the mode is from a regular file.

`stat.S_ISFIFO(mode)`

Return non-zero if the mode is from a FIFO (named pipe).

`stat.S_ISLNK(mode)`

Return non-zero if the mode is from a symbolic link.

`stat.S_ISSOCK(mode)`

Return non-zero if the mode is from a socket.

Two additional functions are defined for more general manipulation of the file's mode :

`stat.S_IMODE(mode)`

Return the portion of the file's mode that can be set by `os.chmod()`—that is, the file's permission bits, plus the sticky bit, set-group-id, and set-user-id bits (on systems that support them).

`stat.S_IFMT(mode)`

Return the portion of the file's mode that describes the file type (used by the `S_IS*()` functions above).

Normally, you would use the `os.path.is*()` functions for testing the type of a file; the functions here are useful when you are doing multiple tests of the same file and wish to avoid the overhead of the `stat()` system call for each test. These are also useful when checking for information about a file that isn't handled by *os.path*, like the tests for block and character devices.

Exemple :

```
import os, sys
from stat import *

def walktree(top, callback):
    '''recursively descend the directory tree rooted at top,
        calling the callback function for each regular file'''

    for f in os.listdir(top):
        pathname = os.path.join(top, f)
        mode = os.stat(pathname).st_mode
        if S_ISDIR(mode):
            # It's a directory, recurse into it
            walktree(pathname, callback)
        elif S_ISREG(mode):
            # It's a file, call the callback function
            callback(pathname)
        else:
            # Unknown file type, print a message
            print 'Skipping %s' % pathname

def visitfile(file):
    print 'visiting', file

if __name__ == '__main__':
    walktree(sys.argv[1], visitfile)
```

All the variables below are simply symbolic indexes into the 10-tuple returned by `os.stat()`, `os.fstat()` or `os.lstat()`.

`stat.ST_MODE`

Inode protection mode.

`stat.ST_INO`

Numéro d'inode.

`stat.ST_DEV`

Device inode resides on.

`stat.ST_NLINK`

Number of links to the inode.

`stat.ST_UID`

User id of the owner.

`stat.ST_GID`

Group id of the owner.

`stat.ST_SIZE`

Size in bytes of a plain file; amount of data waiting on some special files.

`stat.ST_ATIME`

Time of last access.

`stat.ST_MTIME`

Time of last modification.

`stat.ST_CTIME`

The « ctime » as reported by the operating system. On some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time (see platform documentation for details).

The interpretation of « file size » changes according to the file type. For plain files this is the size of the file in bytes. For FIFOs and sockets under most flavors of Unix (including Linux in particular), the « size » is the number of bytes waiting to be read at the time of the call to `os.stat()`, `os.fstat()`, or `os.lstat()`; this can sometimes be useful, especially for polling one of these special files after a non-blocking open. The meaning of the size field for other character and block devices varies more, depending on the implementation of the underlying system call.

The variables below define the flags used in the `ST_MODE` field.

Use of the functions above is more portable than use of the first set of flags :

`stat.S_IFSOCK`

Socket.

`stat.S_IFLNK`

Symbolic link.

`stat.S_IFREG`

Regular file.

`stat.S_IFBLK`

Block device.

`stat.S_IFDIR`

Dossier.

`stat.S_IFCHR`

Character device.

`stat.S_IFIFO`

FIFO.

The following flags can also be used in the *mode* argument of `os.chmod()` :

`stat.S_ISUID`

Set UID bit.

`stat.S_ISGID`

Set-group-ID bit. This bit has several special uses. For a directory it indicates that BSD semantics is to be used for that directory : files created there inherit their group ID from the directory, not from the effective group ID of the creating process, and directories created there will also get the `S_ISGID` bit set. For a file that does not have the group execution bit (`S_IXGRP`) set, the set-group-ID bit indicates mandatory file/record locking (see also `S_ENFMT`).

`stat.S_ISVTX`

Sticky bit. When this bit is set on a directory it means that a file in that directory can be renamed or deleted only by the owner of the file, by the owner of the directory, or by a privileged process.

`stat.S_IRWXU`

Mask for file owner permissions.

`stat.S_IRUSR`  
Owner has read permission.

`stat.S_IWUSR`  
Owner has write permission.

`stat.S_IXUSR`  
Owner has execute permission.

`stat.S_IRWXG`  
Mask for group permissions.

`stat.S_IRGRP`  
Group has read permission.

`stat.S_IWGRP`  
Group has write permission.

`stat.S_IXGRP`  
Group has execute permission.

`stat.S_IRWXO`  
Mask for permissions for others (not in group).

`stat.S_IROTH`  
Others have read permission.

`stat.S_IWOTH`  
Others have write permission.

`stat.S_IXOTH`  
Others have execute permission.

`stat.S_ENFMT`  
System V file locking enforcement. This flag is shared with `S_ISGID` : file/record locking is enforced on files that do not have the group execution bit (`S_IXGRP`) set.

`stat.S_IREAD`  
Unix V7 synonym for `S_IRUSR`.

`stat.S_IWRITE`  
Unix V7 synonym for `S_IWUSR`.

`stat.S_IEXEC`  
Unix V7 synonym for `S_IXUSR`.

The following flags can be used in the *flags* argument of `os.chflags()` :

`stat.UF_NODUMP`  
Do not dump the file.

`stat.UF_IMMUTABLE`  
The file may not be changed.

`stat.UF_APPEND`  
The file may only be appended to.

`stat.UF_OPAQUE`  
The directory is opaque when viewed through a union stack.

`stat.UF_NOUNLINK`  
The file may not be renamed or deleted.

`stat.UF_COMPRESSED`

The file is stored compressed (Mac OS X 10.6+).

`stat.UF_HIDDEN`

The file should not be displayed in a GUI (Mac OS X 10.5+).

`stat.SF_ARCHIVED`

The file may be archived.

`stat.SF_IMMUTABLE`

The file may not be changed.

`stat.SF_APPEND`

The file may only be appended to.

`stat.SF_NOUNLINK`

The file may not be renamed or deleted.

`stat.SF_SNAPSHOT`

The file is a snapshot file.

See the \*BSD or Mac OS systems man page *chflags(2)* for more information.

## 10.4 statvfs — Constants used with `os.statvfs()`

Obsolète depuis la version 2.6 : The *statvfs* module has been removed in Python 3.

The *statvfs* module defines constants so interpreting the result if *os.statvfs()*, which returns a tuple, can be made without remembering « magic numbers. » Each of the constants defined in this module is the *index* of the entry in the tuple returned by *os.statvfs()* that contains the specified information.

`statvfs.F_BSIZE`

Preferred file system block size.

`statvfs.F_FRSIZE`

Fundamental file system block size.

`statvfs.F_BLOCKS`

Total number of blocks in the filesystem.

`statvfs.F_BFREE`

Total number of free blocks.

`statvfs.F_BAVAIL`

Free blocks available to non-super user.

`statvfs.F_FILES`

Total number of file nodes.

`statvfs.F_FFREE`

Total number of free file nodes.

`statvfs.F_FAVAIL`

Free nodes available to non-super user.

`statvfs.F_FLAG`

Flags. System dependent : see *statvfs()* man page.

`statvfs.F_NAMEMAX`

Maximum file name length.

## 10.5 filecmp — File and Directory Comparisons

Code source : [Lib/filecmp.py](#)

---

The *filecmp* module defines functions to compare files and directories, with various optional time/correctness trade-offs. For comparing files, see also the *difflib* module.

The *filecmp* module defines the following functions :

`filecmp.cmp(f1, f2[, shallow])`

Compare the files named *f1* and *f2*, returning **True** if they seem equal, **False** otherwise.

Unless *shallow* is given and is false, files with identical *os.stat()* signatures are taken to be equal.

Files that were compared using this function will not be compared again unless their *os.stat()* signature changes.

Note that no external programs are called from this function, giving it portability and efficiency.

`filecmp.cmpfiles(dir1, dir2, common[, shallow])`

Compare the files in the two directories *dir1* and *dir2* whose names are given by *common*.

Returns three lists of file names : *match*, *mismatch*, *errors*. *match* contains the list of files that match, *mismatch* contains the names of those that don't, and *errors* lists the names of files which could not be compared. Files are listed in *errors* if they don't exist in one of the directories, the user lacks permission to read them or if the comparison could not be done for some other reason.

The *shallow* parameter has the same meaning and default value as for *filecmp.cmp()*.

For example, `cmpfiles('a', 'b', ['c', 'd/e'])` will compare *a/c* with *b/c* and *a/d/e* with *b/d/e*. 'c' and 'd/e' will each be in one of the three returned lists.

Exemple :

```
>>> import filecmp
>>> filecmp.cmp('undoc.rst', 'undoc.rst')
True
>>> filecmp.cmp('undoc.rst', 'index.rst')
False
```

### 10.5.1 The dircmp class

*dircmp* instances are built using this constructor :

`class filecmp.dircmp(a, b[, ignore[, hide]])`

Construct a new directory comparison object, to compare the directories *a* and *b*. *ignore* is a list of names to ignore, and defaults to ['RCS', 'CVS', 'tags']. *hide* is a list of names to hide, and defaults to [os.curdir, os.pardir].

The *dircmp* class compares files by doing *shallow* comparisons as described for *filecmp.cmp()*.

The *dircmp* class provides the following methods :

**report()**

Print (to *sys.stdout*) a comparison between *a* and *b*.

**report\_partial\_closure()**

Print a comparison between *a* and *b* and common immediate subdirectories.

**report\_full\_closure()**

Print a comparison between *a* and *b* and common subdirectories (recursively).

The *dircmp* class offers a number of interesting attributes that may be used to get various bits of information about the directory trees being compared.

Note that via *\_\_getattr\_\_()* hooks, all attributes are computed lazily, so there is no speed penalty if only those attributes which are lightweight to compute are used.

**left**  
The directory *a*.

**right**  
The directory *b*.

**left\_list**  
Files and subdirectories in *a*, filtered by *hide* and *ignore*.

**right\_list**  
Files and subdirectories in *b*, filtered by *hide* and *ignore*.

**common**  
Files and subdirectories in both *a* and *b*.

**left\_only**  
Files and subdirectories only in *a*.

**right\_only**  
Files and subdirectories only in *b*.

**common\_dirs**  
Subdirectories in both *a* and *b*.

**common\_files**  
Files in both *a* and *b*

**common\_funny**  
Names in both *a* and *b*, such that the type differs between the directories, or names for which *os.stat()* reports an error.

**same\_files**  
Files which are identical in both *a* and *b*, using the class's file comparison operator.

**diff\_files**  
Files which are in both *a* and *b*, whose contents differ according to the class's file comparison operator.

**funny\_files**  
Files which are in both *a* and *b*, but could not be compared.

**subdirs**  
A dictionary mapping names in *common\_dirs* to *dircmp* objects.

Here is a simplified example of using the **subdirs** attribute to search recursively through two directories to show common different files :

```
>>> from filecmp import dircmp
>>> def print_diff_files(dcmp):
...     for name in dcmp.diff_files:
...         print "diff_file %s found in %s and %s" % (name, dcmp.left,
...             dcmp.right)
...     for sub_dcmp in dcmp.subdirs.values():
...         print_diff_files(sub_dcmp)
...
>>> dcmp = dircmp('dir1', 'dir2')
>>> print_diff_files(dcmp)
```

## 10.6 tempfile — Generate temporary files and directories

Code source : [Lib/tempfile.py](#)

This module generates temporary files and directories. It works on all supported platforms.

In version 2.3 of Python, this module was overhauled for enhanced security. It now provides three new functions, `NamedTemporaryFile()`, `mkstemp()`, and `mkdtemp()`, which should eliminate all remaining need to use the insecure `mktemp()` function. Temporary file names created by this module no longer contain the process ID; instead a string of six random characters is used.

Also, all the user-callable functions now take additional arguments which allow direct control over the location and name of temporary files. It is no longer necessary to use the global `tempdir` and `template` variables. To maintain backward compatibility, the argument order is somewhat odd; it is recommended to use keyword arguments for clarity.

The module defines the following user-callable functions :

```
tempfile.TemporaryFile([mode='w+b', bufsize=-1, suffix='', prefix='tmp', dir=None])
```

Return a file-like object that can be used as a temporary storage area. The file is created using `mkstemp()`. It will be destroyed as soon as it is closed (including an implicit close when the object is garbage collected). Under Unix, the directory entry for the file is removed immediately after the file is created. Other platforms do not support this; your code should not rely on a temporary file created using this function having or not having a visible name in the file system.

The `mode` parameter defaults to `'w+b'` so that the file created can be read and written without being closed. Binary mode is used so that it behaves consistently on all platforms without regard for the data that is stored. `bufsize` defaults to `-1`, meaning that the operating system default is used.

The `dir`, `prefix` and `suffix` parameters are passed to `mkstemp()`.

The returned object is a true file object on POSIX platforms. On other platforms, it is a file-like object whose `file` attribute is the underlying true file object. This file-like object can be used in a `with` statement, just like a normal file.

```
tempfile.NamedTemporaryFile([mode='w+b', bufsize=-1, suffix='', prefix='tmp', dir=None, delete=True])
```

This function operates exactly as `TemporaryFile()` does, except that the file is guaranteed to have a visible name in the file system (on Unix, the directory entry is not unlinked). That name can be retrieved from the `name` attribute of the returned file-like object. Whether the name can be used to open the file a second time, while the named temporary file is still open, varies across platforms (it can be so used on Unix; it cannot on Windows NT or later). If `delete` is true (the default), the file is deleted as soon as it is closed.

The returned object is always a file-like object whose `file` attribute is the underlying true file object. This file-like object can be used in a `with` statement, just like a normal file.

Nouveau dans la version 2.3.

Nouveau dans la version 2.6 : The `delete` parameter.

```
tempfile.SpooledTemporaryFile([max_size=0, mode='w+b', bufsize=-1, suffix='', prefix='tmp', dir=None])
```

This function operates exactly as `TemporaryFile()` does, except that data is spooled in memory until the file size exceeds `max_size`, or until the file's `fileno()` method is called, at which point the contents are written to disk and operation proceeds as with `TemporaryFile()`. Also, its `truncate` method does not accept a `size` argument.

The resulting file has one additional method, `rollover()`, which causes the file to roll over to an on-disk file regardless of its size.

The returned object is a file-like object whose `_file` attribute is either a `StringIO` object or a true file object, depending on whether `rollover()` has been called. This file-like object can be used in a `with` statement, just like a normal file.

Nouveau dans la version 2.6.

```
tempfile.mkstemp([suffix='', prefix='tmp', dir=None, text=False])
```

Creates a temporary file in the most secure manner possible. There are no race conditions in the file's creation, assuming that the platform properly implements the `os.O_EXCL` flag for `os.open()`. The file

is readable and writable only by the creating user ID. If the platform uses permission bits to indicate whether a file is executable, the file is executable by no one. The file descriptor is not inherited by child processes.

Unlike `TemporaryFile()`, the user of `mkstemp()` is responsible for deleting the temporary file when done with it.

If `suffix` is specified, the file name will end with that suffix, otherwise there will be no suffix. `mkstemp()` does not put a dot between the file name and the suffix; if you need one, put it at the beginning of `suffix`.

If `prefix` is specified, the file name will begin with that prefix; otherwise, a default prefix is used.

If `dir` is specified, the file will be created in that directory; otherwise, a default directory is used. The default directory is chosen from a platform-dependent list, but the user of the application can control the directory location by setting the `TMPDIR`, `TEMP` or `TMP` environment variables. There is thus no guarantee that the generated filename will have any nice properties, such as not requiring quoting when passed to external commands via `os.popen()`.

If `text` is specified, it indicates whether to open the file in binary mode (the default) or text mode. On some platforms, this makes no difference.

`mkstemp()` returns a tuple containing an OS-level handle to an open file (as would be returned by `os.open()`) and the absolute pathname of that file, in that order.

Nouveau dans la version 2.3.

```
tempfile.mkdtemp([suffix="", prefix='tmp', dir=None]))
```

Creates a temporary directory in the most secure manner possible. There are no race conditions in the directory's creation. The directory is readable, writable, and searchable only by the creating user ID.

The user of `mkdtemp()` is responsible for deleting the temporary directory and its contents when done with it.

The `prefix`, `suffix`, and `dir` arguments are the same as for `mkstemp()`.

`mkdtemp()` returns the absolute pathname of the new directory.

Nouveau dans la version 2.3.

```
tempfile.mktemp([suffix="", prefix='tmp', dir=None]))
```

Obsolète depuis la version 2.3 : Use `mkstemp()` instead.

Return an absolute pathname of a file that did not exist at the time the call is made. The `prefix`, `suffix`, and `dir` arguments are the same as for `mkstemp()`.

**Avertissement :** Use of this function may introduce a security hole in your program. By the time you get around to doing anything with the file name it returns, someone else may have beaten you to the punch. `mktemp()` usage can be replaced easily with `NamedTemporaryFile()`, passing it the `delete=False` parameter :

```
>>> f = NamedTemporaryFile(delete=False)
>>> f
<open file '<fdopen>', mode 'w+b' at 0x384698>
>>> f.name
'/var/folders/5q/5qTPn6xq2RaWqk+1Ytw3-U+++TI/-Tmp-/tmpG7V1Y0'
>>> f.write("Hello World!\n")
>>> f.close()
>>> os.unlink(f.name)
>>> os.path.exists(f.name)
False
```

The module uses a global variable that tell it how to construct a temporary name. They are initialized at the first call to any of the functions above. The caller may change them, but this is discouraged; use the appropriate function arguments, instead.

**tempfile.tempdir**

When set to a value other than `None`, this variable defines the default value for the *dir* argument to all the functions defined in this module.

If `tempdir` is unset or `None` at any call to any of the above functions, Python searches a standard list of directories and sets *tempdir* to the first one which the calling user can create files in. The list is :

1. The directory named by the `TMPDIR` environment variable.
2. The directory named by the `TEMP` environment variable.
3. The directory named by the `TMP` environment variable.
4. A platform-specific location :
  - On RiscOS, the directory named by the `Wimp$ScrapDir` environment variable.
  - On Windows, the directories `C:\TEMP`, `C:\TMP`, `\TEMP`, and `\TMP`, in that order.
  - On all other platforms, the directories `/tmp`, `/var/tmp`, and `/usr/tmp`, in that order.
5. As a last resort, the current working directory.

**tempfile.gettempdir()**

Return the directory currently selected to create temporary files in. If *tempdir* is not `None`, this simply returns its contents; otherwise, the search described above is performed, and the result returned.

Nouveau dans la version 2.3.

**tempfile.template**

Obsolète depuis la version 2.0 : Use *gettempprefix()* instead.

When set to a value other than `None`, this variable defines the prefix of the final component of the filenames returned by *mktemp()*. A string of six random letters and digits is appended to the prefix to make the filename unique. The default prefix is `tmp`.

Older versions of this module used to require that `template` be set to `None` after a call to *os.fork()*; this has not been necessary since version 1.5.2.

**tempfile.gettempprefix()**

Return the filename prefix used to create temporary files. This does not contain the directory component. Using this function is preferred over reading the *template* variable directly.

Nouveau dans la version 1.5.2.

## 10.7 glob — Recherche de chemins de style Unix selon certains motifs

Code source : [Lib/glob.py](#)

---

The *glob* module finds all the pathnames matching a specified pattern according to the rules used by the Unix shell, although results are returned in arbitrary order. No tilde expansion is done, but `*`, `?`, and character ranges expressed with `[]` will be correctly matched. This is done by using the *os.listdir()* and *fnmatch.fnmatch()* functions in concert, and not by actually invoking a subshell. Note that unlike *fnmatch.fnmatch()*, *glob* treats filenames beginning with a dot (`.`) as special cases. (For tilde and shell variable expansion, use *os.path.expanduser()* and *os.path.expandvars()*.)

Pour une correspondance littérale, il faut entourer le métacaractère par des crochets. Par exemple, `'[?]'` reconnaît le caractère `'?'`.

**glob.glob(pathname)**

Renvoie une liste, potentiellement vide, de chemins correspondant au motif *pathname*, qui doit être une chaîne de caractères contenant la spécification du chemin. *pathname* peut être soit absolu (comme `/usr/src/Python-1.5/Makefile`) soit relatif (comme `../Tools/**/*.gif`), et contenir un caractère de remplacement de style shell. Les liens symboliques cassés sont aussi inclus dans les résultats (comme pour le shell).

`glob.iglob(pathname)`

Renvoie un *iterator* qui produit les mêmes valeurs que `glob()`, sans toutes les charger en mémoire simultanément.

Nouveau dans la version 2.5.

For example, consider a directory containing only the following files : `1.gif`, `2.txt`, and `card.gif`. `glob()` will produce the following results. Notice how any leading components of the path are preserved.

```
>>> import glob
>>> glob.glob('./[0-9].*')
['./1.gif', './2.txt']
>>> glob.glob('*.gif')
['1.gif', 'card.gif']
>>> glob.glob('?.gif')
['1.gif']
```

Si le répertoire contient des fichiers commençant par `.`, ils ne sont pas reconnus par défaut. Par exemple, considérons un répertoire contenant `card.gif` et `.card.gif` :

```
>>> import glob
>>> glob.glob('*.gif')
['card.gif']
>>> glob.glob('.c*')
['.card.gif']
```

Voir aussi :

Module `fnmatch` Recherche de noms de fichiers de style shell (ne concerne pas les chemins)

## 10.8 fnmatch — Filtrage par motif des noms de fichiers Unix

Code source : [Lib/fnmatch.py](#)

Ce module fournit la gestion des caractères de remplacement de style shell Unix, qui ne sont *pas* identiques à ceux utilisés dans les expressions régulières (documentés dans le module `re`). Les caractères spéciaux utilisés comme caractères de remplacement de style shell sont :

Motif	Signification
<code>*</code>	reconnaît n'importe quoi
<code>?</code>	reconnaît n'importe quel caractère unique
<code>[seq]</code>	reconnaît n'importe quel caractère dans <i>seq</i>
<code>[!seq]</code>	reconnaît n'importe quel caractère qui n'est pas dans <i>seq</i>

Pour une correspondance littérale, il faut entourer le métacaractère par des crochets. Par exemple, `'[?]` reconnaît le caractère `'?'`.

Note that the filename separator (`'/'` on Unix) is *not* special to this module. See module `glob` for pathname expansion (`glob` uses `filter()` to match pathname segments). Similarly, filenames starting with a period are not special for this module, and are matched by the `*` and `?` patterns.

`fnmatch.fnmatch(filename, pattern)`

Test whether the *filename* string matches the *pattern* string, returning `True` or `False`. Both parameters are case-normalized using `os.path.normcase()`. `fnmatchcase()` can be used to perform a case-sensitive comparison, regardless of whether that's standard for the operating system.

Cet exemple affiche tous les noms de fichiers du répertoire courant ayant pour extension `.txt` :

```
import fnmatch
import os

for file in os.listdir('.'):
    if fnmatch.fnmatch(file, '*.txt'):
        print file
```

`fnmatch.fnmatchcase(filename, pattern)`

Test whether *filename* matches *pattern*, returning *True* or *False*; the comparison is case-sensitive and does not apply `os.path.normcase()`.

`fnmatch.filter(names, pattern)`

Renvoie un sous-ensemble de la liste *names* correspondant au motif *pattern*. Similaire à `[n for n in names if fnmatch(n, pattern)]`, mais implémenté plus efficacement.

Nouveau dans la version 2.2.

`fnmatch.translate(pattern)`

Return the shell-style *pattern* converted to a regular expression for using with `re.match()`.

Exemple :

```
>>> import fnmatch, re
>>>
>>> regex = fnmatch.translate('*.txt')
>>> regex
'.*\\.txt\\Z(?ms)'
>>> reobj = re.compile(regex)
>>> reobj.match('foobar.txt')
<_sre.SRE_Match object at 0x...>
```

Module `glob` Recherche de chemins de style shell Unix

## 10.9 linecache — Accès direct aux lignes d'un texte

Code source : `Lib/linecache.py`

---

The `linecache` module allows one to get any line from any file, while attempting to optimize internally, using a cache, the common case where many lines are read from a single file. This is used by the `traceback` module to retrieve source lines for inclusion in the formatted traceback.

Le module `linecache` définit les fonctions suivantes :

`linecache.getline(filename, lineno[, module_globals])`

Récupère la ligne *lineno* du fichier *filename*. Cette fonction ne lèvera jamais d'exception, elle préférera renvoyer `' '` en cas d'erreur (le caractère de retour à la ligne sera inclus pour les lignes existantes).

Si le fichier *filename* n'est pas trouvé, la fonction le cherchera dans les chemins de recherche de modules, `sys.path`, après avoir vérifié si un `__loader__` (de la [PEP 302](#)) se trouve dans *module\_globals*, dans le cas où le module a été importé depuis un fichier zip, ou une autre source hors du système de fichier.

Nouveau dans la version 2.5 : The *module\_globals* parameter was added.

`linecache.clearcache()`

Nettoie le cache. Utilisez cette fonction si vous n'avez plus besoin des lignes des fichiers précédemment lus via `getline()`.

`linecache.checkcache([filename])`

Vérifie la validité du cache. Utilisez cette fonction si les fichiers du cache pourraient avoir changé sur le disque, et que vous en voudriez une version à jour. Sans *filename*, toutes les entrées du cache seront vérifiées.

Exemple :

```
>>> import linecache
>>> linecache.getline('/etc/passwd', 4)
'sys:x:3:3:sys:/dev:/bin/sh\n'
```

## 10.10 shutil — High-level file operations

Code source : [Lib/shutil.py](#)

The *shutil* module offers a number of high-level operations on files and collections of files. In particular, functions are provided which support file copying and removal. For operations on individual files, see also the *os* module.

**Avertissement :** Even the higher-level file copying functions (*shutil.copy()*, *shutil.copy2()*) can't copy all file metadata.

On POSIX platforms, this means that file owner and group are lost as well as ACLs. On Mac OS, the resource fork and other metadata are not used. This means that resources will be lost and file type and creator codes will not be correct. On Windows, file owners, ACLs and alternate data streams are not copied.

### 10.10.1 Directory and files operations

`shutil.copyfileobj(fsrc, fdst[, length])`

Copy the contents of the file-like object *fsrc* to the file-like object *fdst*. The integer *length*, if given, is the buffer size. In particular, a negative *length* value means to copy the data without looping over the source data in chunks; by default the data is read in chunks to avoid uncontrolled memory consumption. Note that if the current file position of the *fsrc* object is not 0, only the contents from the current file position to the end of the file will be copied.

`shutil.copyfile(src, dst)`

Copy the contents (no metadata) of the file named *src* to a file named *dst*. *dst* must be the complete target file name; look at *shutil.copy()* for a copy that accepts a target directory path. If *src* and *dst* are the same files, *Error* is raised. The destination location must be writable; otherwise, an *IOError* exception will be raised. If *dst* already exists, it will be replaced. Special files such as character or block devices and pipes cannot be copied with this function. *src* and *dst* are path names given as strings.

`shutil.copymode(src, dst)`

Copy the permission bits from *src* to *dst*. The file contents, owner, and group are unaffected. *src* and *dst* are path names given as strings.

`shutil.copystat(src, dst)`

Copy the permission bits, last access time, last modification time, and flags from *src* to *dst*. The file contents, owner, and group are unaffected. *src* and *dst* are path names given as strings.

`shutil.copy(src, dst)`

Copy the file *src* to the file or directory *dst*. If *dst* is a directory, a file with the same basename as *src* is created (or overwritten) in the directory specified. Permission bits are copied. *src* and *dst* are path names given as strings.

`shutil.copy2(src, dst)`

Identical to `copy()` except that `copy2()` also attempts to preserve file metadata.

`copy2()` uses `copystat()` to copy the file metadata. Please see `copystat()` for more information.

`shutil.ignore_patterns(*patterns)`

This factory function creates a function that can be used as a callable for `copytree()`'s *ignore* argument, ignoring files and directories that match one of the glob-style *patterns* provided. See the example below.

Nouveau dans la version 2.6.

`shutil.copytree(src, dst, symlinks=False, ignore=None)`

Recursively copy an entire directory tree rooted at *src*. The destination directory, named by *dst*, must not already exist; it will be created as well as missing parent directories. Permissions and times of directories are copied with `copystat()`, individual files are copied using `shutil.copy2()`.

If *symlinks* is true, symbolic links in the source tree are represented as symbolic links in the new tree, but the metadata of the original links is NOT copied; if false or omitted, the contents and metadata of the linked files are copied to the new tree.

If *ignore* is given, it must be a callable that will receive as its arguments the directory being visited by `copytree()`, and a list of its contents, as returned by `os.listdir()`. Since `copytree()` is called recursively, the *ignore* callable will be called once for each directory that is copied. The callable must return a sequence of directory and file names relative to the current directory (i.e. a subset of the items in its second argument); these names will then be ignored in the copy process. `ignore_patterns()` can be used to create such a callable that ignores names based on glob-style patterns.

If exception(s) occur, an `Error` is raised with a list of reasons.

The source code for this should be considered an example rather than the ultimate tool.

Modifié dans la version 2.3 : `Error` is raised if any exceptions occur during copying, rather than printing a message.

Modifié dans la version 2.5 : Create intermediate directories needed to create *dst*, rather than raising an error. Copy permissions and times of directories using `copystat()`.

Modifié dans la version 2.6 : Added the *ignore* argument to be able to influence what is being copied.

`shutil.rmtree(path[, ignore_errors[, onerror]])`

Delete an entire directory tree; *path* must point to a directory (but not a symbolic link to a directory).

If *ignore\_errors* is true, errors resulting from failed removals will be ignored; if false or omitted, such errors are handled by calling a handler specified by *onerror* or, if that is omitted, they raise an exception.

If *onerror* is provided, it must be a callable that accepts three parameters : *function*, *path*, and *excinfo*. The first parameter, *function*, is the function which raised the exception; it will be `os.path.islink()`, `os.listdir()`, `os.remove()` or `os.rmdir()`. The second parameter, *path*, will be the path name passed to *function*. The third parameter, *excinfo*, will be the exception information return by `sys.exc_info()`. Exceptions raised by *onerror* will not be caught.

Modifié dans la version 2.6 : Explicitly check for *path* being a symbolic link and raise `OSError` in that case.

`shutil.move(src, dst)`

Recursively move a file or directory (*src*) to another location (*dst*).

If the destination is an existing directory, then *src* is moved inside that directory. If the destination already exists but is not a directory, it may be overwritten depending on `os.rename()` semantics.

If the destination is on the current filesystem, then `os.rename()` is used. Otherwise, *src* is copied (using `shutil.copy2()`) to *dst* and then removed.

Nouveau dans la version 2.3.

#### **exception `shutil.Error`**

This exception collects exceptions that are raised during a multi-file operation. For `copytree()`, the exception argument is a list of 3-tuples (*srcname*, *dstname*, *exception*).

Nouveau dans la version 2.3.

#### **copytree example**

This example is the implementation of the `copytree()` function, described above, with the docstring omitted. It demonstrates many of the other functions provided by this module.

```
def copytree(src, dst, symlinks=False, ignore=None):
    names = os.listdir(src)
    if ignore is not None:
        ignored_names = ignore(src, names)
    else:
        ignored_names = set()

    os.makedirs(dst)
    errors = []
    for name in names:
        if name in ignored_names:
            continue
        srcname = os.path.join(src, name)
        dstname = os.path.join(dst, name)
        try:
            if symlinks and os.path.islink(srcname):
                linkto = os.readlink(srcname)
                os.symlink(linkto, dstname)
            elif os.path.isdir(srcname):
                copytree(srcname, dstname, symlinks, ignore)
            else:
                copy2(srcname, dstname)
                # XXX What about devices, sockets etc.?
        except (IOError, os.error) as why:
            errors.append((srcname, dstname, str(why)))
        # catch the Error from the recursive copytree so that we can
        # continue with other files
        except Error as err:
            errors.extend(err.args[0])
    try:
        copystat(src, dst)
    except WindowsError:
        # can't copy file access times on Windows
        pass
    except OSError as why:
        errors.extend((src, dst, str(why)))
    if errors:
        raise Error(errors)
```

Another example that uses the `ignore_patterns()` helper :

```
from shutil import copytree, ignore_patterns

copytree(source, destination, ignore=ignore_patterns('*.pyc', 'tmp*'))
```

This will copy everything except `.pyc` files and files or directories whose name starts with `tmp`.

Another example that uses the `ignore` argument to add a logging call :

```
from shutil import copytree
import logging

def _logpath(path, names):
    logging.info('Working in %s' % path)
    return [] # nothing will be ignored

copytree(source, destination, ignore=_logpath)
```

### 10.10.2 Archiving operations

High-level utilities to create and read compressed and archived files are also provided. They rely on the `zipfile` and `tarfile` modules.

```
shutil.make_archive(base_name, format[, root_dir[, base_dir[, verbose[, dry_run[, owner[, group[,
                                                                    logger]]]]]])
```

Create an archive file (eg. zip or tar) and returns its name.

*base\_name* is the name of the file to create, including the path, minus any format-specific extension. *format* is the archive format : one of « zip » (if the `zlib` module or external `zip` executable is available), « tar », « gztar » (if the `zlib` module is available), or « bztar » (if the `bz2` module is available).

*root\_dir* is a directory that will be the root directory of the archive ; ie. we typically `chdir` into *root\_dir* before creating the archive.

*base\_dir* is the directory where we start archiving from ; ie. *base\_dir* will be the common prefix of all files and directories in the archive.

*root\_dir* and *base\_dir* both default to the current directory.

*owner* and *group* are used when creating a tar archive. By default, uses the current owner and group.

*logger* must be an object compatible with **PEP 282**, usually an instance of `logging.Logger`.

Nouveau dans la version 2.7.

```
shutil.get_archive_formats()
```

Return a list of supported formats for archiving. Each element of the returned sequence is a tuple (name, description).

By default `shutil` provides these formats :

- *zip* : ZIP file (if the `zlib` module or external `zip` executable is available).
- *tar* : uncompressed tar file.
- *gztar* : gzip'ed tar-file (if the `zlib` module is available).
- *bztar* : bzip2'ed tar-file (if the `bz2` module is available).

You can register new formats or provide your own archiver for any existing formats, by using `register_archive_format()`.

Nouveau dans la version 2.7.

```
shutil.register_archive_format(name, function[, extra_args[, description]])
```

Register an archiver for the format *name*. *function* is a callable that will be used to invoke the archiver.

If given, *extra\_args* is a sequence of (name, value) that will be used as extra keywords arguments when the archiver callable is used.

*description* is used by `get_archive_formats()` which returns the list of archivers. Defaults to an empty list.

Nouveau dans la version 2.7.

`shutil.unregister_archive_format(name)`

Remove the archive format *name* from the list of supported formats.

Nouveau dans la version 2.7.

### Archiving example

In this example, we create a gzip'ed tar-file archive containing all files found in the `.ssh` directory of the user :

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~', 'myarchive'))
>>> root_dir = os.path.expanduser(os.path.join('~', '.ssh'))
>>> make_archive(archive_name, 'gztar', root_dir)
'/Users/tarek/myarchive.tar.gz'
```

The resulting archive contains :

```
$ tar -tzvf /Users/tarek/myarchive.tar.gz
drwx----- tarek/staff      0 2010-02-01 16:23:40 ./
-rw-r--r-- tarek/staff    609 2008-06-09 13:26:54 ./authorized_keys
-rwxr-xr-x tarek/staff     65 2008-06-09 13:26:54 ./config
-rwx----- tarek/staff    668 2008-06-09 13:26:54 ./id_dsa
-rwxr-xr-x tarek/staff    609 2008-06-09 13:26:54 ./id_dsa.pub
-rw----- tarek/staff   1675 2008-06-09 13:26:54 ./id_rsa
-rw-r--r-- tarek/staff    397 2008-06-09 13:26:54 ./id_rsa.pub
-rw-r--r-- tarek/staff  37192 2010-02-06 18:23:10 ./known_hosts
```

## 10.11 dircache — Cached directory listings

Obsolète depuis la version 2.6 : The *dircache* module has been removed in Python 3.

The *dircache* module defines a function for reading directory listing using a cache, and cache invalidation using the *mtime* of the directory. Additionally, it defines a function to annotate directories by appending a slash.

The *dircache* module defines the following functions :

`dircache.reset()`

Resets the directory cache.

`dircache.listdir(path)`

Return a directory listing of *path*, as gotten from `os.listdir()`. Note that unless *path* changes, further call to `.listdir()` will not re-read the directory structure.

Note that the list returned should be regarded as read-only. (Perhaps a future version should change it to return a tuple?)

`dircache.opendir(path)`

Same as `.listdir()`. Defined for backwards compatibility.

`dircache.annotate(head, list)`

Assume *list* is a list of paths relative to *head*, and append, in place, a `'/'` to each path which points to a directory.

```
>>> import dircache
>>> a = dircache.listdir('/')
>>> a = a[:] # Copy the return value so we can change 'a'
>>> a
['bin', 'boot', 'cdrom', 'dev', 'etc', 'floppy', 'home', 'initrd', 'lib', 'lost+
found', 'mnt', 'proc', 'root', 'sbin', 'tmp', 'usr', 'var', 'vmlinuz']
>>> dircache.annotate('/', a)
>>> a
['bin/', 'boot/', 'cdrom/', 'dev/', 'etc/', 'floppy/', 'home/', 'initrd/', 'lib/
', 'lost+found/', 'mnt/', 'proc/', 'root/', 'sbin/', 'tmp/', 'usr/', 'var/', 'vm
linuz']
```

## 10.12 macpath — Fonctions de manipulation de chemins pour Mac OS 9

Ce module est une implémentation du module *os.path* pour Mac OS 9 (ou plus ancien). Il peut être utilisé pour manipuler des chemins dans l'ancien style Macintosh sur Mac OS X (ou n'importe quelle autre plateforme).

Les fonctions suivantes sont disponibles dans ce module : *normcase()*, *normpath()*, *isabs()*, *join()*, *split()*, *isdir()*, *isfile()*, *walk()*, *exists()*. Toutes les autres fonctions d'*os.path* sont aussi disponibles, mais vides, pour garder la compatibilité.

**Voir aussi :**

**Section** *Objets fichiers* A description of Python's built-in file objects.

**Module** *os* Operating system interfaces, including functions to work with files at a lower level than the built-in file object.

The modules described in this chapter support storing Python data in a persistent form on disk. The *pickle* and *marshal* modules can turn many Python data types into a stream of bytes and then recreate the objects from the bytes. The various DBM-related modules support a family of hash-based file formats that store a mapping of strings to other strings. The *bsddb* module also provides such disk-based string-to-string mappings based on hashing, and also supports B-Tree and record-based formats.

La liste des modules documentés dans ce chapitre est :

### 11.1 pickle — Python object serialization

The *pickle* module implements a fundamental, but powerful algorithm for serializing and de-serializing a Python object structure. « Pickling » is the process whereby a Python object hierarchy is converted into a byte stream, and « unpickling » is the inverse operation, whereby a byte stream is converted back into an object hierarchy. Pickling (and unpickling) is alternatively known as « serialization », « marshallng, »<sup>1</sup> or « flattening », however, to avoid confusion, the terms used here are « pickling » and « unpickling ».

This documentation describes both the *pickle* module and the *cPickle* module.

**Avertissement :** The *pickle* module is not secure against erroneous or maliciously constructed data. Never unpickle data received from an untrusted or unauthenticated source.

#### 11.1.1 Relationship to other Python modules

The *pickle* module has an optimized cousin called the *cPickle* module. As its name implies, *cPickle* is written in C, so it can be up to 1000 times faster than *pickle*. However it does not support subclassing of the *Pickler()* and *Unpickler()* classes, because in *cPickle* these are functions, not classes. Most applications have no need for this functionality, and can benefit from the improved performance of *cPickle*. Other than that, the interfaces of the two modules are nearly identical; the common interface is described in this manual and differences are pointed out where necessary. In the following discussions, we use the term « pickle » to collectively describe the *pickle* and *cPickle* modules.

---

1. Don't confuse this with the *marshal* module

The data streams the two modules produce are guaranteed to be interchangeable.

Python has a more primitive serialization module called *marshal*, but in general *pickle* should always be the preferred way to serialize Python objects. *marshal* exists primarily to support Python's .pyc files.

The *pickle* module differs from *marshal* in several significant ways :

- The *pickle* module keeps track of the objects it has already serialized, so that later references to the same object won't be serialized again. *marshal* doesn't do this.  
This has implications both for recursive objects and object sharing. Recursive objects are objects that contain references to themselves. These are not handled by *marshal*, and in fact, attempting to marshal recursive objects will crash your Python interpreter. Object sharing happens when there are multiple references to the same object in different places in the object hierarchy being serialized. *pickle* stores such objects only once, and ensures that all other references point to the master copy. Shared objects remain shared, which can be very important for mutable objects.
- *marshal* cannot be used to serialize user-defined classes and their instances. *pickle* can save and restore class instances transparently, however the class definition must be importable and live in the same module as when the object was stored.
- The *marshal* serialization format is not guaranteed to be portable across Python versions. Because its primary job in life is to support .pyc files, the Python implementers reserve the right to change the serialization format in non-backwards compatible ways should the need arise. The *pickle* serialization format is guaranteed to be backwards compatible across Python releases.

Note that serialization is a more primitive notion than persistence; although *pickle* reads and writes file objects, it does not handle the issue of naming persistent objects, nor the (even more complicated) issue of concurrent access to persistent objects. The *pickle* module can transform a complex object into a byte stream and it can transform the byte stream into an object with the same internal structure. Perhaps the most obvious thing to do with these byte streams is to write them onto a file, but it is also conceivable to send them across a network or store them in a database. The module *shelve* provides a simple interface to pickle and unpickle objects on DBM-style database files.

### 11.1.2 Data stream format

The data format used by *pickle* is Python-specific. This has the advantage that there are no restrictions imposed by external standards such as XDR (which can't represent pointer sharing); however it means that non-Python programs may not be able to reconstruct pickled Python objects.

By default, the *pickle* data format uses a printable ASCII representation. This is slightly more voluminous than a binary representation. The big advantage of using printable ASCII (and of some other characteristics of *pickle*'s representation) is that for debugging or recovery purposes it is possible for a human to read the pickled file with a standard text editor.

There are currently 3 different protocols which can be used for pickling.

- Protocol version 0 is the original ASCII protocol and is backwards compatible with earlier versions of Python.
- Protocol version 1 is the old binary format which is also compatible with earlier versions of Python.
- Protocol version 2 was introduced in Python 2.3. It provides much more efficient pickling of *new-style classes*.

Refer to **PEP 307** for more information.

If a *protocol* is not specified, protocol 0 is used. If *protocol* is specified as a negative value or *HIGHEST\_PROTOCOL*, the highest protocol version available will be used.

Modifié dans la version 2.3 : Introduced the *protocol* parameter.

A binary format, which is slightly more efficient, can be chosen by specifying a *protocol* version  $\geq 1$ .

### 11.1.3 Usage

To serialize an object hierarchy, you first create a pickler, then you call the pickler's `dump()` method. To de-serialize a data stream, you first create an unpickler, then you call the unpickler's `load()` method. The `pickle` module provides the following constant :

`pickle.HIGHEST_PROTOCOL`

The highest protocol version available. This value can be passed as a *protocol* value.  
Nouveau dans la version 2.3.

---

**Note :** Be sure to always open pickle files created with protocols  $\geq 1$  in binary mode. For the old ASCII-based pickle protocol 0 you can use either text mode or binary mode as long as you stay consistent.

A pickle file written with protocol 0 in binary mode will contain lone linefeeds as line terminators and therefore will look « funny » when viewed in Notepad or other editors which do not support this format.

---

The `pickle` module provides the following functions to make the pickling process more convenient :

`pickle.dump(obj, file[, protocol])`

Write a pickled representation of *obj* to the open file object *file*. This is equivalent to `Pickler(file, protocol).dump(obj)`.

If the *protocol* parameter is omitted, protocol 0 is used. If *protocol* is specified as a negative value or `HIGHEST_PROTOCOL`, the highest protocol version will be used.

Modifié dans la version 2.3 : Introduced the *protocol* parameter.

*file* must have a `write()` method that accepts a single string argument. It can thus be a file object opened for writing, a `StringIO` object, or any other custom object that meets this interface.

`pickle.load(file)`

Read a string from the open file object *file* and interpret it as a pickle data stream, reconstructing and returning the original object hierarchy. This is equivalent to `Unpickler(file).load()`.

*file* must have two methods, a `read()` method that takes an integer argument, and a `readline()` method that requires no arguments. Both methods should return a string. Thus *file* can be a file object opened for reading, a `StringIO` object, or any other custom object that meets this interface.

This function automatically determines whether the data stream was written in binary mode or not.

`pickle.dumps(obj[, protocol])`

Return the pickled representation of the object as a string, instead of writing it to a file.

If the *protocol* parameter is omitted, protocol 0 is used. If *protocol* is specified as a negative value or `HIGHEST_PROTOCOL`, the highest protocol version will be used.

Modifié dans la version 2.3 : The *protocol* parameter was added.

`pickle.loads(string)`

Read a pickled object hierarchy from a string. Characters in the string past the pickled object's representation are ignored.

The `pickle` module also defines three exceptions :

**exception** `pickle.PickleError`

A common base class for the other exceptions defined below. This inherits from `Exception`.

**exception** `pickle.PicklingError`

This exception is raised when an unpicklable object is passed to the `dump()` method.

**exception** `pickle.UnpicklingError`

This exception is raised when there is a problem unpickling an object. Note that other exceptions may also be raised during unpickling, including (but not necessarily limited to) `AttributeError`, `EOFError`, `ImportError`, and `IndexError`.

The `pickle` module also exports two callables<sup>2</sup>, `Pickler` and `Unpickler` :

```
class pickle.Pickler(file[, protocol])
```

This takes a file-like object to which it will write a pickle data stream.

If the `protocol` parameter is omitted, protocol 0 is used. If `protocol` is specified as a negative value or `HIGHEST_PROTOCOL`, the highest protocol version will be used.

Modifié dans la version 2.3 : Introduced the `protocol` parameter.

`file` must have a `write()` method that accepts a single string argument. It can thus be an open file object, a `StringIO` object, or any other custom object that meets this interface.

`Pickler` objects define one (or two) public methods :

```
dump(obj)
```

Write a pickled representation of `obj` to the open file object given in the constructor. Either the binary or ASCII format will be used, depending on the value of the `protocol` argument passed to the constructor.

```
clear_memo()
```

Clears the pickler's « memo ». The memo is the data structure that remembers which objects the pickler has already seen, so that shared or recursive objects pickled by reference and not by value. This method is useful when re-using picklers.

---

**Note :** Prior to Python 2.3, `clear_memo()` was only available on the picklers created by `cPickle`. In the `pickle` module, picklers have an instance variable called `memo` which is a Python dictionary. So to clear the memo for a `pickle` module pickler, you could do the following :

```
mypickler.memo.clear()
```

---

Code that does not need to support older versions of Python should simply use `clear_memo()`.

---

It is possible to make multiple calls to the `dump()` method of the same `Pickler` instance. These must then be matched to the same number of calls to the `load()` method of the corresponding `Unpickler` instance. If the same object is pickled by multiple `dump()` calls, the `load()` will all yield references to the same object.<sup>3</sup>

`Unpickler` objects are defined as :

```
class pickle.Unpickler(file)
```

This takes a file-like object from which it will read a pickle data stream. This class automatically determines whether the data stream was written in binary mode or not, so it does not need a flag as in the `Pickler` factory.

`file` must have two methods, a `read()` method that takes an integer argument, and a `readline()` method that requires no arguments. Both methods should return a string. Thus `file` can be a file object opened for reading, a `StringIO` object, or any other custom object that meets this interface.

`Unpickler` objects have one (or two) public methods :

```
load()
```

Read a pickled object representation from the open file object given in the constructor, and return the reconstituted object hierarchy specified therein.

This method automatically determines whether the data stream was written in binary mode or not.

```
noload()
```

This is just like `load()` except that it doesn't actually create any objects. This is useful primarily

---

2. In the `pickle` module these callables are classes, which you could subclass to customize the behavior. However, in the `cPickle` module these callables are factory functions and so cannot be subclassed. One common reason to subclass is to control what objects can actually be unpickled. See section *Subclassing Unpicklers* for more details.

3. *Warning* : this is intended for pickling multiple objects without intervening modifications to the objects or their parts. If you modify an object and then pickle it again using the same `Pickler` instance, the object is not pickled again — a reference to it is pickled and the `Unpickler` will return the old value, not the modified one. There are two problems here : (1) detecting changes, and (2) marshalling a minimal set of changes. Garbage Collection may also become a problem here.

for finding what's called « persistent ids » that may be referenced in a pickle data stream. See section *The pickle protocol* below for more details.

**Note :** the `noload()` method is currently only available on *Unpickler* objects created with the *cPickle* module. *pickle* module *Unpicklers* do not have the `noload()` method.

### 11.1.4 What can be pickled and unpickled ?

The following types can be pickled :

- `None`, `True`, and `False`
- integers, long integers, floating point numbers, complex numbers
- normal and Unicode strings
- tuples, lists, sets, and dictionaries containing only picklable objects
- functions defined at the top level of a module
- built-in functions defined at the top level of a module
- classes that are defined at the top level of a module
- instances of such classes whose `__dict__` or the result of calling `__getstate__()` is picklable (see section *The pickle protocol* for details).

Attempts to pickle unpicklable objects will raise the *PicklingError* exception; when this happens, an unspecified number of bytes may have already been written to the underlying file. Trying to pickle a highly recursive data structure may exceed the maximum recursion depth, a *RuntimeError* will be raised in this case. You can carefully raise this limit with `sys.setrecursionlimit()`.

Note that functions (built-in and user-defined) are pickled by « fully qualified » name reference, not by value. This means that only the function name is pickled, along with the name of the module the function is defined in. Neither the function's code, nor any of its function attributes are pickled. Thus the defining module must be importable in the unpickling environment, and the module must contain the named object, otherwise an exception will be raised.<sup>4</sup>

Similarly, classes are pickled by named reference, so the same restrictions in the unpickling environment apply. Note that none of the class's code or data is pickled, so in the following example the class attribute `attr` is not restored in the unpickling environment :

```
class Foo:
    attr = 'a class attr'

picklestring = pickle.dumps(Foo)
```

These restrictions are why picklable functions and classes must be defined in the top level of a module.

Similarly, when class instances are pickled, their class's code and data are not pickled along with them. Only the instance data are pickled. This is done on purpose, so you can fix bugs in a class or add methods to the class and still load objects that were created with an earlier version of the class. If you plan to have long-lived objects that will see many versions of a class, it may be worthwhile to put a version number in the objects so that suitable conversions can be made by the class's `__setstate__()` method.

### 11.1.5 The pickle protocol

This section describes the « pickling protocol » that defines the interface between the pickler/unpickler and the objects that are being serialized. This protocol provides a standard way for you to define, customize, and control how your objects are serialized and de-serialized. The description in this section doesn't cover specific customizations that you can employ to make the unpickling environment slightly safer from untrusted pickle data streams; see section *Subclassing Unpicklers* for more details.

4. The exception raised will likely be an *ImportError* or an *AttributeError* but it could be something else.

### Pickling and unpickling normal class instances

#### `object.__getinitargs__()`

When a pickled class instance is unpickled, its `__init__()` method is normally *not* invoked. If it is desirable that the `__init__()` method be called on unpickling, an old-style class can define a method `__getinitargs__()`, which should return a *tuple* of positional arguments to be passed to the class constructor (`__init__()` for example). Keyword arguments are not supported. The `__getinitargs__()` method is called at pickle time; the tuple it returns is incorporated in the pickle for the instance.

#### `object.__getnewargs__()`

New-style types can provide a `__getnewargs__()` method that is used for protocol 2. Implementing this method is needed if the type establishes some internal invariants when the instance is created, or if the memory allocation is affected by the values passed to the `__new__()` method for the type (as it is for tuples and strings). Instances of a *new-style class* `C` are created using

```
obj = C.__new__(C, *args)
```

where *args* is the result of calling `__getnewargs__()` on the original object; if there is no `__getnewargs__()`, an empty tuple is assumed.

#### `object.__getstate__()`

Classes can further influence how their instances are pickled; if the class defines the method `__getstate__()`, it is called and the return state is pickled as the contents for the instance, instead of the contents of the instance's dictionary. If there is no `__getstate__()` method, the instance's `__dict__` is pickled.

#### `object.__setstate__(state)`

Upon unpickling, if the class also defines the method `__setstate__()`, it is called with the unpickled state.<sup>5</sup> If there is no `__setstate__()` method, the pickled state must be a dictionary and its items are assigned to the new instance's dictionary. If a class defines both `__getstate__()` and `__setstate__()`, the state object needn't be a dictionary and these methods can do what they want.<sup>6</sup>

---

**Note :** For *new-style classes*, if `__getstate__()` returns a false value, the `__setstate__()` method will not be called.

---

---

**Note :** At unpickling time, some methods like `__getattr__()`, `__getattribute__()`, or `__setattr__()` may be called upon the instance. In case those methods rely on some internal invariant being true, the type should implement either `__getinitargs__()` or `__getnewargs__()` to establish such an invariant; otherwise, neither `__new__()` nor `__init__()` will be called.

---

### Pickling and unpickling extension types

#### `object.__reduce__()`

When the `Pickler` encounters an object of a type it knows nothing about — such as an extension type — it looks in two places for a hint of how to pickle it. One alternative is for the object to implement a `__reduce__()` method. If provided, at pickling time `__reduce__()` will be called with no arguments, and it must return either a string or a tuple.

If a string is returned, it names a global variable whose contents are pickled as normal. The string returned by `__reduce__()` should be the object's local name relative to its module; the pickle module searches the module namespace to determine the object's module.

---

5. These methods can also be used to implement copying class instances.

6. This protocol is also used by the shallow and deep copying operations defined in the `copy` module.

When a tuple is returned, it must be between two and five elements long. Optional elements can either be omitted, or `None` can be provided as their value. The contents of this tuple are pickled as normal and used to reconstruct the object at unpickling time. The semantics of each element are :

- A callable object that will be called to create the initial version of the object. The next element of the tuple will provide arguments for this callable, and later elements provide additional state information that will subsequently be used to fully reconstruct the pickled data.  
In the unpickling environment this object must be either a class, a callable registered as a « safe constructor » (see below), or it must have an attribute `__safe_for_unpickling__` with a true value. Otherwise, an `UnpicklingError` will be raised in the unpickling environment. Note that as usual, the callable itself is pickled by name.
- A tuple of arguments for the callable object.  
Modifié dans la version 2.5 : Formerly, this argument could also be `None`.
- Optionally, the object's state, which will be passed to the object's `__setstate__()` method as described in section *Pickling and unpickling normal class instances*. If the object has no `__setstate__()` method, then, as above, the value must be a dictionary and it will be added to the object's `__dict__`.
- Optionally, an iterator (and not a sequence) yielding successive list items. These list items will be pickled, and appended to the object using either `obj.append(item)` or `obj.extend(list_of_items)`. This is primarily used for list subclasses, but may be used by other classes as long as they have `append()` and `extend()` methods with the appropriate signature. (Whether `append()` or `extend()` is used depends on which pickle protocol version is used as well as the number of items to append, so both must be supported.)
- Optionally, an iterator (not a sequence) yielding successive dictionary items, which should be tuples of the form `(key, value)`. These items will be pickled and stored to the object using `obj[key] = value`. This is primarily used for dictionary subclasses, but may be used by other classes as long as they implement `__setitem__()`.

`object.__reduce_ex__(protocol)`

It is sometimes useful to know the protocol version when implementing `__reduce__()`. This can be done by implementing a method named `__reduce_ex__()` instead of `__reduce__()`. `__reduce_ex__()`, when it exists, is called in preference over `__reduce__()` (you may still provide `__reduce__()` for backwards compatibility). The `__reduce_ex__()` method will be called with a single integer argument, the protocol version.

The `object` class implements both `__reduce__()` and `__reduce_ex__()`; however, if a subclass overrides `__reduce__()` but not `__reduce_ex__()`, the `__reduce_ex__()` implementation detects this and calls `__reduce__()`.

An alternative to implementing a `__reduce__()` method on the object to be pickled, is to register the callable with the `copy_reg` module. This module provides a way for programs to register « reduction functions » and constructors for user-defined types. Reduction functions have the same semantics and interface as the `__reduce__()` method described above, except that they are called with a single argument, the object to be pickled.

The registered constructor is deemed a « safe constructor » for purposes of unpickling as described above.

### Pickling and unpickling external objects

For the benefit of object persistence, the `pickle` module supports the notion of a reference to an object outside the pickled data stream. Such objects are referenced by a « persistent id », which is just an arbitrary string of printable ASCII characters. The resolution of such names is not defined by the `pickle` module; it will delegate this resolution to user defined functions on the pickler and unpickler.<sup>7</sup>

To define external persistent id resolution, you need to set the `persistent_id` attribute of the pickler object and the `persistent_load` attribute of the unpickler object.

7. The actual mechanism for associating these user defined functions is slightly different for `pickle` and `cPickle`. The description given here works the same for both implementations. Users of the `pickle` module could also use subclassing to effect the same results, overriding the `persistent_id()` and `persistent_load()` methods in the derived classes.

To pickle objects that have an external persistent id, the pickler must have a custom `persistent_id()` method that takes an object as an argument and returns either `None` or the persistent id for that object. When `None` is returned, the pickler simply pickles the object as normal. When a persistent id string is returned, the pickler will pickle that string, along with a marker so that the unpickler will recognize the string as a persistent id.

To unpickle external objects, the unpickler must have a custom `persistent_load()` function that takes a persistent id string and returns the referenced object.

Here's a silly example that *might* shed more light :

```
import pickle
from cStringIO import StringIO

src = StringIO()
p = pickle.Pickler(src)

def persistent_id(obj):
    if hasattr(obj, 'x'):
        return 'the value %d' % obj.x
    else:
        return None

p.persistent_id = persistent_id

class Integer:
    def __init__(self, x):
        self.x = x
    def __str__(self):
        return 'My name is integer %d' % self.x

i = Integer(7)
print i
p.dump(i)

datastream = src.getvalue()
print repr(datastream)
dst = StringIO(datastream)

up = pickle.Unpickler(dst)

class FancyInteger(Integer):
    def __str__(self):
        return 'I am the integer %d' % self.x

def persistent_load(persid):
    if persid.startswith('the value '):
        value = int(persid.split()[2])
        return FancyInteger(value)
    else:
        raise pickle.UnpicklingError, 'Invalid persistent id'

up.persistent_load = persistent_load
```

(suite sur la page suivante)

(suite de la page précédente)

```
j = up.load()
print j
```

In the `cPickle` module, the unpickler's `persistent_load` attribute can also be set to a Python list, in which case, when the unpickler reaches a persistent id, the persistent id string will simply be appended to this list. This functionality exists so that a pickle data stream can be « sniffed » for object references without actually instantiating all the objects in a pickle.<sup>8</sup> Setting `persistent_load` to a list is usually used in conjunction with the `noload()` method on the Unpickler.

### 11.1.6 Subclassing Unpicklers

By default, unpickling will import any class that it finds in the pickle data. You can control exactly what gets unpickled and what gets called by customizing your unpickler. Unfortunately, exactly how you do this is different depending on whether you're using `pickle` or `cPickle`.<sup>9</sup>

In the `pickle` module, you need to derive a subclass from `Unpickler`, overriding the `load_global()` method. `load_global()` should read two lines from the pickle data stream where the first line will be the name of the module containing the class and the second line will be the name of the instance's class. It then looks up the class, possibly importing the module and digging out the attribute, then it appends what it finds to the unpickler's stack. Later on, this class will be assigned to the `__class__` attribute of an empty class, as a way of magically creating an instance without calling its class's `__init__()`. Your job (should you choose to accept it), would be to have `load_global()` push onto the unpickler's stack, a known safe version of any class you deem safe to unpickle. It is up to you to produce such a class. Or you could raise an error if you want to disallow all unpickling of instances. If this sounds like a hack, you're right. Refer to the source code to make this work.

Things are a little cleaner with `cPickle`, but not by much. To control what gets unpickled, you can set the unpickler's `find_global` attribute to a function or `None`. If it is `None` then any attempts to unpickle instances will raise an `UnpicklingError`. If it is a function, then it should accept a module name and a class name, and return the corresponding class object. It is responsible for looking up the class and performing any necessary imports, and it may raise an error to prevent instances of the class from being unpickled.

The moral of the story is that you should be really careful about the source of the strings your application unpickles.

### 11.1.7 Example

For the simplest code, use the `dump()` and `load()` functions. Note that a self-referencing list is pickled and restored correctly.

```
import pickle

data1 = {'a': [1, 2.0, 3, 4+6j],
        'b': ('string', u'Unicode string'),
        'c': None}

selfref_list = [1, 2, 3]
selfref_list.append(selfref_list)

output = open('data.pkl', 'wb')
```

(suite sur la page suivante)

8. We'll leave you with the image of Guido and Jim sitting around sniffing pickles in their living rooms.

9. A word of caution : the mechanisms described here use internal attributes and methods, which are subject to change in future versions of Python. We intend to someday provide a common interface for controlling this behavior, which will work in either `pickle` or `cPickle`.

(suite de la page précédente)

```
# Pickle dictionary using protocol 0.
pickle.dump(data1, output)

# Pickle the list using the highest protocol available.
pickle.dump(selfref_list, output, -1)

output.close()
```

The following example reads the resulting pickled data. When reading a pickle-containing file, you should open the file in binary mode because you can't be sure if the ASCII or binary format was used.

```
import pprint, pickle

pkl_file = open('data.pkl', 'rb')

data1 = pickle.load(pkl_file)
pprint.pprint(data1)

data2 = pickle.load(pkl_file)
pprint.pprint(data2)

pkl_file.close()
```

Here's a larger example that shows how to modify pickling behavior for a class. The `TextReader` class opens a text file, and returns the line number and line contents each time its `readline()` method is called. If a `TextReader` instance is pickled, all attributes *except* the file object member are saved. When the instance is unpickled, the file is reopened, and reading resumes from the last location. The `__setstate__()` and `__getstate__()` methods are used to implement this behavior.

```
#!/usr/local/bin/python

class TextReader:
    """Print and number lines in a text file."""
    def __init__(self, file):
        self.file = file
        self.fh = open(file)
        self.lineno = 0

    def readline(self):
        self.lineno = self.lineno + 1
        line = self.fh.readline()
        if not line:
            return None
        if line.endswith("\n"):
            line = line[:-1]
        return "%d: %s" % (self.lineno, line)

    def __getstate__(self):
        odict = self.__dict__.copy() # copy the dict since we change it
        del odict['fh']              # remove filehandle entry
        return odict
```

(suite sur la page suivante)

(suite de la page précédente)

```

def __setstate__(self, dict):
    fh = open(dict['file'])          # reopen file
    count = dict['lineno']           # read from file...
    while count:                     # until line count is restored
        fh.readline()
        count = count - 1
    self.__dict__.update(dict)      # update attributes
    self.fh = fh                    # save the file object

```

A sample usage might be something like this :

```

>>> import TextReader
>>> obj = TextReader.TextReader("TextReader.py")
>>> obj.readline()
'1: #!/usr/local/bin/python'
>>> obj.readline()
'2: '
>>> obj.readline()
'3: class TextReader:'
>>> import pickle
>>> pickle.dump(obj, open('save.p', 'wb'))

```

If you want to see that `pickle` works across Python processes, start another Python session, before continuing. What follows can happen from either the same process or a new process.

```

>>> import pickle
>>> reader = pickle.load(open('save.p', 'rb'))
>>> reader.readline()
'4:      """Print and number lines in a text file."""'

```

Module `copy_reg` Pickle interface constructor registration for extension types.

Module `shelve` Indexed databases of objects; uses `pickle`.

Module `copy` Shallow and deep object copying.

Module `marshal` High-performance serialization of built-in types.

## 11.2 cPickle — A faster pickle

The `cPickle` module supports serialization and de-serialization of Python objects, providing an interface and functionality nearly identical to the `pickle` module. There are several differences, the most important being performance and subclassability.

First, `cPickle` can be up to 1000 times faster than `pickle` because the former is implemented in C. Second, in the `cPickle` module the callables `Pickler()` and `Unpickler()` are functions, not classes. This means that you cannot use them to derive custom pickling and unpickling subclasses. Most applications have no need for this functionality and should benefit from the greatly improved performance of the `cPickle` module.

The pickle data stream produced by `pickle` and `cPickle` are identical, so it is possible to use `pickle` and `cPickle` interchangeably with existing pickles.<sup>10</sup>

10. Since the pickle data format is actually a tiny stack-oriented programming language, and some freedom is taken in the

There are additional minor differences in API between `cPickle` and `pickle`, however for most applications, they are interchangeable. More documentation is provided in the `pickle` module documentation, which includes a list of the documented differences.

## Notes

### 11.3 copy\_reg — Register pickle support functions

---

**Note :** The `copy_reg` module has been renamed to `copyreg` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

---

The `copy_reg` module offers a way to define functions used while pickling specific objects. The `pickle`, `cPickle`, and `copy` modules use those functions when pickling/copying those objects. The module provides configuration information about object constructors which are not classes. Such constructors may be factory functions or class instances.

`copy_reg.constructor(object)`

Declares *object* to be a valid constructor. If *object* is not callable (and hence not valid as a constructor), raises `TypeError`.

`copy_reg.pickle(type, function[, constructor])`

Declares that *function* should be used as a « reduction » function for objects of type *type*; *type* must not be a « classic » class object. (Classic classes are handled differently; see the documentation for the `pickle` module for details.) *function* should return either a string or a tuple containing two or three elements.

The optional *constructor* parameter, if provided, is a callable object which can be used to reconstruct the object when called with the tuple of arguments returned by *function* at pickling time. `TypeError` will be raised if *object* is a class or *constructor* is not callable.

See the `pickle` module for more details on the interface expected of *function* and *constructor*.

#### 11.3.1 Example

The example below would like to show how to register a pickle function and how it will be used :

```
>>> import copy_reg, copy, pickle
>>> class C(object):
...     def __init__(self, a):
...         self.a = a
...
>>> def pickle_c(c):
...     print("pickling a C instance...")
...     return C, (c.a,)
...
>>> copy_reg.pickle(C, pickle_c)
>>> c = C(1)
>>> d = copy.copy(c)
pickling a C instance...
>>> p = pickle.dumps(c)
pickling a C instance...
```

---

encodings of certain objects, it is possible that the two modules produce different data streams for the same input objects. However it is guaranteed that they will always be able to read each other's data streams.

## 11.4 `shelve` — Objet Python persistant

Code source : [Lib/shelve.py](#)

Un *shelf* est un objet persistant, dictionnaire-compatible. La différence avec les bases de données *dbm* est que les valeurs (pas les clés!) dans un *shelf* peuvent être des objets Python arbitraires — n'importe quoi que le module *pickle* peut gérer. Cela inclut la plupart des instances de classe, des types de données récursives, et les objets contenant beaucoup de sous-objets partagés. Les clés sont des chaînes de caractères ordinaires.

`shelve.open(filename, flag='c', protocol=None, writeback=False)`

Open a persistent dictionary. The filename specified is the base filename for the underlying database. As a side-effect, an extension may be added to the filename and more than one file may be created. By default, the underlying database file is opened for reading and writing. The optional *flag* parameter has the same interpretation as the *flag* parameter of *anydbm.open()*.

By default, version 0 pickles are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter.

Modifié dans la version 2.3 : The *protocol* parameter was added.

À cause de la sémantique Python, un *shelf* ne peut pas savoir lorsqu'une entrée modifiable de dictionnaire persistant est modifiée. Par défaut les objets modifiés sont écrits *seulement* lorsqu'ils sont assignés à une *shelf* (voir *Exemple*). Si le paramètre optionnel *writeback* est mis à *True*, toutes les entrées déjà accédées sont aussi mises en cache en mémoire, et ré-écrites sur *sync()* et *close()*; cela peut faciliter la modification des entrées modifiables dans le dictionnaire persistant, mais, si vous accédez à beaucoup d'entrées, cela peut consommer beaucoup de mémoire cache, et cela peut rendre l'opération de fermeture très lente puisque toutes les entrées déjà accédées sont ré-écrites (il n'y a aucun moyen de savoir quelles entrées déjà accédées sont mutables, ni lesquelles ont été vraiment modifiées).

Like file objects, shelve objects should be closed explicitly to ensure that the persistent data is flushed to disk.

**Avertissement :** Puisque le module *shelve* utilise en arrière plan *pickle*, il n'est pas sûr de charger un *shelf* depuis une source non fiable. Comme avec *pickle*, charger un *shelf* peut exécuter du code arbitraire.

Shelf objects support most of the methods supported by dictionaries. This eases the transition from dictionary based scripts to those requiring persistent storage.

Note, the Python 3 transition methods (*viewkeys()*, *viewvalues()*, and *viewitems()*) are not supported.

Deux méthodes supplémentaires sont supportées :

`Shelf.sync()`

Réécrit toutes les entrées dans le cache si le *shelf* a été ouvert avec *writeback* passé à *True*. Vide le cache et synchronise le dictionnaire persistant sur le disque, si faisable. Elle est appelée automatiquement quand le *shelf* est fermé avec *close()*.

`Shelf.close()`

Synchronise et ferme l'objet *dict* persistant. Les opérations sur un *shelf* fermé échouent avec une *ValueError*.

**Voir aussi :**

[Recette pour un dictionnaire persistant](#) avec un large panel de formats de stockage et ayant la vitesse des dictionnaires natifs.

### 11.4.1 Limites

- The choice of which database package will be used (such as *dbm*, *gdbm* or *bsddb*) depends on which interface is available. Therefore it is not safe to open the database directly using *dbm*. The database is also (unfortunately) subject to the limitations of *dbm*, if it is used — this means that (the pickled representation of) the objects stored in the database should be fairly small, and in rare cases key collisions may cause the database to refuse updates.
- Le module *shelve* ne gère pas l'accès *concurrent* en lecture/écriture sur les objets stockés (les accès simultanés en lecture sont sûrs). Lorsqu'un programme a un *shelf* ouvert en écriture, aucun autre programme ne doit l'avoir ouvert en écriture ou lecture. Le verrouillage des fichier Unix peut être utilisé pour résoudre ce problème, mais cela dépend de la version Unix et nécessite des connaissances à propos de l'implémentation de la base de données utilisée.

**class shelve.Shelf**(*dict*, *protocol=None*, *writeback=False*)

A subclass of *UserDict.DictMixin* which stores pickled values in the *dict* object.

By default, version 0 pickles are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter. See the *pickle* documentation for a discussion of the pickle protocols.

Modifié dans la version 2.3 : The *protocol* parameter was added.

Si le paramètre *writeback* est *True*, l'objet garde en cache toutes les entrées accédées et les écrit dans le *dict* aux moments de synchronisation et de fermeture. Cela permet des opérations naturelles sur les entrées modifiables, mais peut consommer beaucoup plus de mémoire et rendre les temps de synchronisation et de fermeture très longs.

**class shelve.BsdDbShelf**(*dict*, *protocol=None*, *writeback=False*)

A subclass of *Shelf* which exposes *first()*, *next()*, *previous()*, *last()* and *set\_location()* which are available in the *bsddb* module but not in other database modules. The *dict* object passed to the constructor must support those methods. This is generally accomplished by calling one of *bsddb.hashopen()*, *bsddb.btopen()* or *bsddb.rnopen()*. The optional *protocol* and *writeback* parameters have the same interpretation as for the *Shelf* class.

**class shelve.DbfilenameShelf**(*filename*, *flag='c'*, *protocol=None*, *writeback=False*)

A subclass of *Shelf* which accepts a *filename* instead of a dict-like object. The underlying file will be opened using *anydbm.open()*. By default, the file will be created and opened for both read and write. The optional *flag* parameter has the same interpretation as for the *open()* function. The optional *protocol* and *writeback* parameters have the same interpretation as for the *Shelf* class.

### 11.4.2 Exemple

Pour résumer l'interface (*key* est une chaîne de caractère, *data* est un objet arbitraire)

```
import shelve

d = shelve.open(filename) # open -- file may get suffix added by low-level
                           # library

d[key] = data             # store data at key (overwrites old data if
                           # using an existing key)
data = d[key]             # retrieve a COPY of data at key (raise KeyError if no
                           # such key)
del d[key]                # delete data stored at key (raises KeyError
                           # if no such key)
flag = d.has_key(key)     # true if the key exists
klist = d.keys()          # a list of all existing keys (slow!)
```

(suite sur la page suivante)

(suite de la page précédente)

```
# as d was opened WITHOUT writeback=True, beware:
d['xx'] = range(4) # this works as expected, but...
d['xx'].append(5)  # *this doesn't!* -- d['xx'] is STILL range(4)!

# having opened d without writeback=True, you need to code carefully:
temp = d['xx']      # extracts the copy
temp.append(5)      # mutates the copy
d['xx'] = temp      # stores the copy right back, to persist it

# or, d=shelve.open(filename,writeback=True) would let you just code
# d['xx'].append(5) and have it work as expected, BUT it would also
# consume more memory and make the d.close() operation slower.

d.close()          # close it
```

Module `gdbm` GNU database interface, based on the dbm interface.

Module `pickle` Sérialisation d'objet utilisé par `shelve`.

Module `cPickle` High-performance version of `pickle`.

## 11.5 marshal — Internal Python object serialization

This module contains functions that can read and write Python values in a binary format. The format is specific to Python, but independent of machine architecture issues (e.g., you can write a Python value to a file on a PC, transport the file to a Sun, and read it back there). Details of the format are undocumented on purpose; it may change between Python versions (although it rarely does).<sup>1</sup>

This is not a general « persistence » module. For general persistence and transfer of Python objects through RPC calls, see the modules `pickle` and `shelve`. The `marshal` module exists mainly to support reading and writing the « pseudo-compiled » code for Python modules of `.pyc` files. Therefore, the Python maintainers reserve the right to modify the marshal format in backward incompatible ways should the need arise. If you're serializing and de-serializing Python objects, use the `pickle` module instead – the performance is comparable, version independence is guaranteed, and pickle supports a substantially wider range of objects than marshal.

**Avertissement :** The `marshal` module is not intended to be secure against erroneous or maliciously constructed data. Never unmarshal data received from an untrusted or unauthenticated source.

1. The name of this module stems from a bit of terminology used by the designers of Modula-3 (amongst others), who use the term « marshalling » for shipping of data around in a self-contained form. Strictly speaking, « to marshal » means to convert some data from internal to external form (in an RPC buffer for instance) and « unmarshalling » for the reverse process.

Not all Python object types are supported ; in general, only objects whose value is independent from a particular invocation of Python can be written and read by this module. The following types are supported : booleans, integers, long integers, floating point numbers, complex numbers, strings, Unicode objects, tuples, lists, sets, frozensets, dictionaries, and code objects, where it should be understood that tuples, lists, sets, frozensets and dictionaries are only supported as long as the values contained therein are themselves supported ; and recursive lists, sets and dictionaries should not be written (they will cause infinite loops). The singletons *None*, *Ellipsis* and *StopIteration* can also be marshalled and unmarshalled.

**Avertissement :** On machines where C's `long int` type has more than 32 bits (such as the DEC Alpha), it is possible to create plain Python integers that are longer than 32 bits. If such an integer is marshalled and read back in on a machine where C's `long int` type has only 32 bits, a Python long integer object is returned instead. While of a different type, the numeric value is the same. (This behavior is new in Python 2.2. In earlier versions, all but the least-significant 32 bits of the value were lost, and a warning message was printed.)

There are functions that read/write files as well as functions operating on strings.

The module defines these functions :

`marshal.dump(value, file[, version])`

Write the value on the open file. The value must be a supported type. The file must be an open file object such as `sys.stdout` or returned by `open()` or `os.popen()`. It may not be a wrapper such as `TemporaryFile` on Windows. It must be opened in binary mode ('wb' or 'w+b').

If the value has (or contains an object that has) an unsupported type, a *ValueError* exception is raised — but garbage data will also be written to the file. The object will not be properly read back by `load()`.

Nouveau dans la version 2.4 : The *version* argument indicates the data format that `dump` should use (see below).

`marshal.load(file)`

Read one value from the open file and return it. If no valid value is read (e.g. because the data has a different Python version's incompatible marshal format), raise *EOFError*, *ValueError* or *TypeError*. The file must be an open file object opened in binary mode ('rb' or 'r+b').

---

**Note :** If an object containing an unsupported type was marshalled with `dump()`, `load()` will substitute *None* for the unmarshallable type.

---

`marshal.dumps(value[, version])`

Return the string that would be written to a file by `dump(value, file)`. The value must be a supported type. Raise a *ValueError* exception if value has (or contains an object that has) an unsupported type.

Nouveau dans la version 2.4 : The *version* argument indicates the data format that `dumps` should use (see below).

`marshal.loads(string)`

Convert the string to a value. If no valid value is found, raise *EOFError*, *ValueError* or *TypeError*. Extra characters in the string are ignored.

In addition, the following constants are defined :

`marshal.version`

Indicates the format that the module uses. Version 0 is the historical format, version 1 (added in Python 2.4) shares interned strings and version 2 (added in Python 2.5) uses a binary format for floating point numbers. The current version is 2.

Nouveau dans la version 2.4.

## Notes

## 11.6 anydbm — Generic access to DBM-style databases

**Note :** The `anydbm` module has been renamed to `dbm` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

`anydbm` is a generic interface to variants of the DBM database — `dbhash` (requires `bsddb`), `gdbm`, or `dbm`. If none of these modules is installed, the slow-but-simple implementation in module `dumbdbm` will be used.

`anydbm.open(filename[, flag[, mode]])`

Open the database file `filename` and return a corresponding object.

If the database file already exists, the `whichdb` module is used to determine its type and the appropriate module is used ; if it does not exist, the first module listed above that can be imported is used.

The optional `flag` argument must be one of these values :

Valeur	Signification
'r'	Open existing database for reading only (default)
'w'	Open existing database for reading and writing
'c'	Open database for reading and writing, creating it if it doesn't exist
'n'	Always create a new, empty database, open for reading and writing

If not specified, the default value is 'r'.

The optional `mode` argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal 0666 (and will be modified by the prevailing umask).

**exception anydbm.error**

A tuple containing the exceptions that can be raised by each of the supported modules, with a unique exception also named `anydbm.error` as the first item — the latter is used when `anydbm.error` is raised.

The object returned by `open()` supports most of the same functionality as dictionaries; keys and their corresponding values can be stored, retrieved, and deleted, and the `has_key()` and `keys()` methods are available. Keys and values must always be strings.

The following example records some hostnames and a corresponding title, and then prints out the contents of the database :

```
import anydbm

# Open database, creating it if necessary.
db = anydbm.open('cache', 'c')

# Record some values
db['www.python.org'] = 'Python Website'
db['www.cnn.com'] = 'Cable News Network'

# Loop through contents. Other dictionary methods
# such as .keys(), .values() also work.
for k, v in db.iteritems():
    print k, '\t', v

# Storing a non-string key or value will raise an exception (most
# likely a TypeError).
```

(suite sur la page suivante)

(suite de la page précédente)

```
db['www.yahoo.com'] = 4

# Close when done.
db.close()
```

In addition to the dictionary-like methods, **anydbm** objects provide the following method :

**anydbm.close()**  
Close the **anydbm** database.

**Voir aussi :**

Module **dbhash** BSD db database interface.

Module **dbm** Standard Unix database interface.

Module **dumbdbm** Portable implementation of the **dbm** interface.

Module **gdbm** GNU database interface, based on the **dbm** interface.

Module **shelve** General object persistence built on top of the Python **dbm** interface.

Module **whichdb** Utility module used to determine the type of an existing database.

## 11.7 whichdb — Guess which DBM module created a database

---

**Note :** The **whichdb** module's only function has been put into the **dbm** module in Python 3. The **2to3** tool will automatically adapt imports when converting your sources to Python 3.

---

The single function in this module attempts to guess which of the several simple database modules available—**dbm**, **gdbm**, or **dbhash**—should be used to open a given file.

**whichdb.whichdb(filename)**

Returns one of the following values : **None** if the file can't be opened because it's unreadable or doesn't exist; the empty string ( **' '** ) if the file's format can't be guessed; or a string containing the required module name, such as **'dbm'** or **'gdbm'**.

## 11.8 dbm — Simple « database » interface

---

**Note :** The **dbm** module has been renamed to **dbm.ndbm** in Python 3. The **2to3** tool will automatically adapt imports when converting your sources to Python 3.

---

The **dbm** module provides an interface to the Unix « (n)dbm » library. Dbm objects behave like mappings (dictionaries), except that keys and values are always strings. Printing a dbm object doesn't print the keys and values, and the **items()** and **values()** methods are not supported.

This module can be used with the « classic » **ndbm** interface, the BSD DB compatibility interface, or the GNU GDBM compatibility interface. On Unix, the **configure** script will attempt to locate the appropriate header file to simplify building this module.

Le module définit :

**exception dbm.error**

Raised on dbm-specific errors, such as I/O errors. **KeyError** is raised for general mapping errors like specifying an incorrect key.

**dbm.library**

Name of the `ndbm` implementation library used.

**dbm.open**(*filename*[, *flag*[, *mode*]])

Open a dbm database and return a dbm object. The *filename* argument is the name of the database file (without the `.dir` or `.pag` extensions; note that the BSD DB implementation of the interface will append the extension `.db` and only create one file).

The optional *flag* argument must be one of these values :

Valeur	Signification
'r'	Open existing database for reading only (default)
'w'	Open existing database for reading and writing
'c'	Open database for reading and writing, creating it if it doesn't exist
'n'	Always create a new, empty database, open for reading and writing

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal 0666 (and will be modified by the prevailing umask).

In addition to the dictionary-like methods, `dbm` objects provide the following method :

**dbm.close()**

Close the `dbm` database.

**Voir aussi :**

**Module** `anydbm` Generic interface to `dbm`-style databases.

**Module** `gdbm` Similar interface to the GNU GDBM library.

**Module** `whichdb` Utility module used to determine the type of an existing database.

## 11.9 gdbm — GNU's reinterpretation of dbm

---

**Note :** The `gdbm` module has been renamed to `dbm.gnu` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

---

This module is quite similar to the `dbm` module, but uses `gdbm` instead to provide some additional functionality. Please note that the file formats created by `gdbm` and `dbm` are incompatible.

The `gdbm` module provides an interface to the GNU DBM library. `gdbm` objects behave like mappings (dictionaries), except that keys and values are always strings. Printing a `gdbm` object doesn't print the keys and values, and the `items()` and `values()` methods are not supported.

The module defines the following constant and functions :

**exception gdbm.error**

Raised on `gdbm`-specific errors, such as I/O errors. `KeyError` is raised for general mapping errors like specifying an incorrect key.

**gdbm.open**(*filename*[, *flag*[, *mode*]])

Open a `gdbm` database and return a `gdbm` object. The *filename* argument is the name of the database file.

The optional *flag* argument can be :

Valeur	Signification
'r'	Open existing database for reading only (default)
'w'	Open existing database for reading and writing
'c'	Open database for reading and writing, creating it if it doesn't exist
'n'	Always create a new, empty database, open for reading and writing

The following additional characters may be appended to the flag to control how the database is opened :

Valeur	Signification
'f'	Open the database in fast mode. Writes to the database will not be synchronized.
's'	Synchronized mode. This will cause changes to the database to be immediately written to the file.
'u'	Do not lock database.

Not all flags are valid for all versions of `gdbm`. The module constant `open_flags` is a string of supported flag characters. The exception `error` is raised if an invalid flag is specified.

The optional `mode` argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal 0666.

In addition to the dictionary-like methods, `gdbm` objects have the following methods :

`gdbm.firstkey()`

It's possible to loop over every key in the database using this method and the `nextkey()` method. The traversal is ordered by `gdbm`'s internal hash values, and won't be sorted by the key values. This method returns the starting key.

`gdbm.nextkey(key)`

Returns the key that follows `key` in the traversal. The following code prints every key in the database `db`, without having to create a list in memory that contains them all :

```
k = db.firstkey()
while k != None:
    print k
    k = db.nextkey(k)
```

`gdbm.reorganize()`

If you have carried out a lot of deletions and would like to shrink the space used by the `gdbm` file, this routine will reorganize the database. `gdbm` will not shorten the length of a database file except by using this reorganization; otherwise, deleted file space will be kept and reused as new (key, value) pairs are added.

`gdbm.sync()`

When the database has been opened in fast mode, this method forces any unwritten data to be written to the disk.

`gdbm.close()`

Close the `gdbm` database.

Voir aussi :

Module `anydbm` Generic interface to `dbm`-style databases.

Module `whichdb` Utility module used to determine the type of an existing database.

## 11.10 dbhash — DBM-style interface to the BSD database library

Obsolète depuis la version 2.6 : The `dbhash` module has been removed in Python 3.

The `dbhash` module provides a function to open databases using the BSD `db` library. This module mirrors the interface of the other Python database modules that provide access to DBM-style databases. The `bsddb` module is required to use `dbhash`.

This module provides an exception and a function :

**exception `dbhash.error`**

Exception raised on database errors other than [`KeyError`](#). It is a synonym for `bsddb.error`.

**`dbhash.open(path[, flag[, mode]])`**

Open a db database and return the database object. The *path* argument is the name of the database file.

The *flag* argument can be :

Valeur	Signification
'r'	Open existing database for reading only (default)
'w'	Open existing database for reading and writing
'c'	Open database for reading and writing, creating it if it doesn't exist
'n'	Always create a new, empty database, open for reading and writing

For platforms on which the BSD db library supports locking, an 'l' can be appended to indicate that locking should be used.

The optional *mode* parameter is used to indicate the Unix permission bits that should be set if a new database must be created; this will be masked by the current umask value for the process.

**Voir aussi :**

**Module [anydbm](#)** Generic interface to dbm-style databases.

**Module [bsddb](#)** Lower-level interface to the BSD db library.

**Module [whichdb](#)** Utility module used to determine the type of an existing database.

### 11.10.1 Database Objects

The database objects returned by [`open\(\)`](#) provide the methods common to all the DBM-style databases and mapping objects. The following methods are available in addition to the standard methods.

**`dbhash.first()`**

It's possible to loop over every key/value pair in the database using this method and the [`next\(\)`](#) method. The traversal is ordered by the databases internal hash values, and won't be sorted by the key values. This method returns the starting key.

**`dbhash.last()`**

Return the last key/value pair in a database traversal. This may be used to begin a reverse-order traversal; see [`previous\(\)`](#).

**`dbhash.next()`**

Returns the key next key/value pair in a database traversal. The following code prints every key in the database db, without having to create a list in memory that contains them all :

```
print db.first()
for i in xrange(1, len(db)):
    print db.next()
```

**`dbhash.previous()`**

Returns the previous key/value pair in a forward-traversal of the database. In conjunction with [`last\(\)`](#), this may be used to implement a reverse-order traversal.

**`dbhash.sync()`**

This method forces any unwritten data to be written to the disk.

## 11.11 bsddb — Interface to Berkeley DB library

Obsolète depuis la version 2.6 : The `bsddb` module has been removed in Python 3.

The `bsddb` module provides an interface to the Berkeley DB library. Users can create hash, btree or record based library files using the appropriate open call. Bsddb objects behave generally like dictionaries. Keys and values must be strings, however, so to use other objects as keys or to store other kinds of objects the user must serialize them somehow, typically using `marshal.dumps()` or `pickle.dumps()`.

The `bsddb` module requires a Berkeley DB library version from 4.0 thru 4.7.

Voir aussi :

<http://www.jcea.es/programacion/pybsddb.htm> The website with documentation for the `bsddb.db` Python Berkeley DB interface that closely mirrors the object oriented interface provided in Berkeley DB 4.x itself.

<http://www.oracle.com/database/berkeley-db/> The Berkeley DB library.

A more modern DB, DBEnv and DBSequence object interface is available in the `bsddb.db` module which closely matches the Berkeley DB C API documented at the above URLs. Additional features provided by the `bsddb.db` API include fine tuning, transactions, logging, and multiprocess concurrent database access.

The following is a description of the legacy `bsddb` interface compatible with the old Python `bsddb` module. Starting in Python 2.5 this interface should be safe for multithreaded access. The `bsddb.db` API is recommended for threading users as it provides better control.

The `bsddb` module defines the following functions that create objects that access the appropriate type of Berkeley DB file. The first two arguments of each function are the same. For ease of portability, only the first two arguments should be used in most instances.

```
bsddb.hashopen(filename[, flag[, mode[, pgsz[, ffactor[, nelem[, cachesize[, lorder[, hflags]]]]]]])
```

Open the hash format file named *filename*. Files never intended to be preserved on disk may be created by passing `None` as the *filename*. The optional *flag* identifies the mode used to open the file. It may be 'r' (read only), 'w' (read-write), 'c' (read-write - create if necessary ; the default) or 'n' (read-write - truncate to zero length). The other arguments are rarely used and are just passed to the low-level `dbopen()` function. Consult the Berkeley DB documentation for their use and interpretation.

```
bsddb.btopen(filename[, flag[, mode[, btflags[, cachesize[, maxkeypage[, minkeypage[, pgsz[, lorder]]]]]]])
```

Open the btree format file named *filename*. Files never intended to be preserved on disk may be created by passing `None` as the *filename*. The optional *flag* identifies the mode used to open the file. It may be 'r' (read only), 'w' (read-write), 'c' (read-write - create if necessary ; the default) or 'n' (read-write - truncate to zero length). The other arguments are rarely used and are just passed to the low-level `dbopen` function. Consult the Berkeley DB documentation for their use and interpretation.

```
bsddb.rnopen(filename[, flag[, mode[, rnflags[, cachesize[, pgsz[, lorder[, rlen[, delim[, source[, pad]]]]]]]]])
```

Open a DB record format file named *filename*. Files never intended to be preserved on disk may be created by passing `None` as the *filename*. The optional *flag* identifies the mode used to open the file. It may be 'r' (read only), 'w' (read-write), 'c' (read-write - create if necessary ; the default) or 'n' (read-write - truncate to zero length). The other arguments are rarely used and are just passed to the low-level `dbopen` function. Consult the Berkeley DB documentation for their use and interpretation.

---

**Note :** Beginning in 2.3 some Unix versions of Python may have a `bsddb185` module. This is present *only* to allow backwards compatibility with systems which ship with the old Berkeley DB 1.85 database library.

The `bsddb185` module should never be used directly in new code. The module has been removed in Python 3. If you find you still need it look in PyPI.

Voir aussi :

Module `dbhash` DBM-style interface to the `bsddb`

### 11.11.1 Hash, BTree and Record Objects

Once instantiated, hash, btree and record objects support the same methods as dictionaries. In addition, they support the methods listed below.

Modifié dans la version 2.3.1 : Added dictionary methods.

`bsddbobject.close()`

Close the underlying file. The object can no longer be accessed. Since there is no open `open()` method for these objects, to open the file again a new `bsddb` module open function must be called.

`bsddbobject.keys()`

Return the list of keys contained in the DB file. The order of the list is unspecified and should not be relied on. In particular, the order of the list returned is different for different file formats.

`bsddbobject.has_key(key)`

Return 1 if the DB file contains the argument as a key.

`bsddbobject.set_location(key)`

Set the cursor to the item indicated by `key` and return a tuple containing the key and its value. For binary tree databases (opened using `btopen()`), if `key` does not actually exist in the database, the cursor will point to the next item in sorted order and return that key and value. For other databases, `KeyError` will be raised if `key` is not found in the database.

`bsddbobject.first()`

Set the cursor to the first item in the DB file and return it. The order of keys in the file is unspecified, except in the case of B-Tree databases. This method raises `bsddb.error` if the database is empty.

`bsddbobject.next()`

Set the cursor to the next item in the DB file and return it. The order of keys in the file is unspecified, except in the case of B-Tree databases.

`bsddbobject.previous()`

Set the cursor to the previous item in the DB file and return it. The order of keys in the file is unspecified, except in the case of B-Tree databases. This is not supported on hashtable databases (those opened with `hashopen()`).

`bsddbobject.last()`

Set the cursor to the last item in the DB file and return it. The order of keys in the file is unspecified. This is not supported on hashtable databases (those opened with `hashopen()`). This method raises `bsddb.error` if the database is empty.

`bsddbobject.sync()`

Synchronize the database on disk.

Exemple :

```
>>> import bsddb
>>> db = bsddb.btopen('spam.db', 'c')
>>> for i in range(10): db['%d%i'] = '%d%' (i*i)
...

```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> db['3']
'9'
>>> db.keys()
['0', '1', '2', '3', '4', '5', '6', '7', '8', '9']
>>> db.first()
('0', '0')
>>> db.next()
('1', '1')
>>> db.last()
('9', '81')
>>> db.set_location('2')
('2', '4')
>>> db.previous()
('1', '1')
>>> for k, v in db.iteritems():
...     print k, v
0 0
1 1
2 4
3 9
4 16
5 25
6 36
7 49
8 64
9 81
>>> '8' in db
True
>>> db.sync()
0
```

## 11.12 dumbdbm — Portable DBM implementation

---

**Note :** The *dumbdbm* module has been renamed to `dbm.dumb` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

---

**Note :** The *dumbdbm* module is intended as a last resort fallback for the *anydbm* module when no more robust module is available. The *dumbdbm* module is not written for speed and is not nearly as heavily used as the other database modules.

---

The *dumbdbm* module provides a persistent dictionary-like interface which is written entirely in Python. Unlike other modules such as *gdbm* and *bsddb*, no external library is required. As with other persistent mappings, the keys and values must always be strings.

Le module définit :

**exception `dumbdbm.error`**

Raised on dumbdbm-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

```
dumbdbm.open(filename[, flag[, mode]])
```

Open a dumbdbm database and return a dumbdbm object. The *filename* argument is the basename of the database file (without any specific extensions). When a dumbdbm database is created, files with *.dat* and *.dir* extensions are created.

The optional *flag* argument is currently ignored; the database is always opened for update, and will be created if it does not exist.

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal 0666 (and will be modified by the prevailing umask).

Modifié dans la version 2.2 : The *mode* argument was ignored in earlier versions.

In addition to the dictionary-like methods, **dumbdbm** objects provide the following method :

```
dumbdbm.close()
```

Close the dumbdbm database.

Voir aussi :

Module **anydbm** Generic interface to dbm-style databases.

Module **dbm** Similar interface to the DBM/NDBM library.

Module **gdbm** Similar interface to the GNU GDBM library.

Module **shelve** Persistence module which stores non-string data.

Module **whichdb** Utility module used to determine the type of an existing database.

### 11.12.1 Dumbdbm Objects

In addition to the methods provided by the *UserDict.DictMixin* class, **dumbdbm** objects provide the following methods.

```
dumbdbm.sync()
```

Synchronize the on-disk directory and data files. This method is called by the *sync()* method of **Shelve** objects.

## 11.13 sqlite3 — DB-API 2.0 interface for SQLite databases

Nouveau dans la version 2.5.

SQLite is a C library that provides a lightweight disk-based database that doesn't require a separate server process and allows accessing the database using a nonstandard variant of the SQL query language. Some applications can use SQLite for internal data storage. It's also possible to prototype an application using SQLite and then port the code to a larger database such as PostgreSQL or Oracle.

The *sqlite3* module was written by Gerhard Häring. It provides a SQL interface compliant with the DB-API 2.0 specification described by **PEP 249**.

To use the module, you must first create a *Connection* object that represents the database. Here the data will be stored in the *example.db* file :

```
import sqlite3
conn = sqlite3.connect('example.db')
```

You can also supply the special name *:memory:* to create a database in RAM.

Once you have a *Connection*, you can create a *Cursor* object and call its *execute()* method to perform SQL commands :

```
c = conn.cursor()

# Create table
c.execute('CREATE TABLE stocks
          (date text, trans text, symbol text, qty real, price real)')

# Insert a row of data
c.execute("INSERT INTO stocks VALUES ('2006-01-05','BUY','RHAT',100,35.14)")

# Save (commit) the changes
conn.commit()

# We can also close the connection if we are done with it.
# Just be sure any changes have been committed or they will be lost.
conn.close()
```

The data you've saved is persistent and is available in subsequent sessions :

```
import sqlite3
conn = sqlite3.connect('example.db')
c = conn.cursor()
```

Usually your SQL operations will need to use values from Python variables. You shouldn't assemble your query using Python's string operations because doing so is insecure; it makes your program vulnerable to an SQL injection attack (see <https://xkcd.com/327/> for humorous example of what can go wrong).

Instead, use the DB-API's parameter substitution. Put ? as a placeholder wherever you want to use a value, and then provide a tuple of values as the second argument to the cursor's `execute()` method. (Other database modules may use a different placeholder, such as %s or :1.) For example :

```
# Never do this -- insecure!
symbol = 'RHAT'
c.execute("SELECT * FROM stocks WHERE symbol = '%s'" % symbol)

# Do this instead
t = ('RHAT',)
c.execute('SELECT * FROM stocks WHERE symbol=?', t)
print c.fetchone()

# Larger example that inserts many records at a time
purchases = [('2006-03-28', 'BUY', 'IBM', 1000, 45.00),
              ('2006-04-05', 'BUY', 'MSFT', 1000, 72.00),
              ('2006-04-06', 'SELL', 'IBM', 500, 53.00),
              ]
c.executemany('INSERT INTO stocks VALUES (?, ?, ?, ?, ?)', purchases)
```

To retrieve data after executing a SELECT statement, you can either treat the cursor as an *iterator*, call the cursor's `fetchone()` method to retrieve a single matching row, or call `fetchall()` to get a list of the matching rows.

This example uses the iterator form :

```
>>> for row in c.execute('SELECT * FROM stocks ORDER BY price'):
      print row
```

(suite sur la page suivante)

(suite de la page précédente)

```
(u'2006-01-05', u'BUY', u'RHAT', 100, 35.14)
(u'2006-03-28', u'BUY', u'IBM', 1000, 45.0)
(u'2006-04-06', u'SELL', u'IBM', 500, 53.0)
(u'2006-04-05', u'BUY', u'MSFT', 1000, 72.0)
```

### 11.13.1 Module functions and constants

#### `sqlite3.version`

The version number of this module, as a string. This is not the version of the SQLite library.

#### `sqlite3.version_info`

The version number of this module, as a tuple of integers. This is not the version of the SQLite library.

#### `sqlite3.sqlite_version`

The version number of the run-time SQLite library, as a string.

#### `sqlite3.sqlite_version_info`

The version number of the run-time SQLite library, as a tuple of integers.

#### `sqlite3.PARSE_DECLTYPES`

This constant is meant to be used with the `detect_types` parameter of the `connect()` function.

Setting it makes the `sqlite3` module parse the declared type for each column it returns. It will parse out the first word of the declared type, i. e. for « integer primary key », it will parse out « integer », or for « number(10) » it will parse out « number ». Then for that column, it will look into the converters dictionary and use the converter function registered for that type there.

#### `sqlite3.PARSE_COLNAMES`

This constant is meant to be used with the `detect_types` parameter of the `connect()` function.

Setting this makes the SQLite interface parse the column name for each column it returns. It will look for a string formed [mytype] in there, and then decide that “mytype” is the type of the column. It will try to find an entry of “mytype” in the converters dictionary and then use the converter function found there to return the value. The column name found in `Cursor.description` is only the first word of the column name, i. e. if you use something like 'as "x [datetime]"' in your SQL, then we will parse out everything until the first blank for the column name : the column name would simply be « x ».

#### `sqlite3.connect(database[, timeout, detect_types, isolation_level, check_same_thread, factory, cached_statements])`

Opens a connection to the SQLite database file *database*. You can use `":memory:"` to open a database connection to a database that resides in RAM instead of on disk.

When a database is accessed by multiple connections, and one of the processes modifies the database, the SQLite database is locked until that transaction is committed. The `timeout` parameter specifies how long the connection should wait for the lock to go away until raising an exception. The default for the timeout parameter is 5.0 (five seconds).

For the *isolation\_level* parameter, please see the *Connection.isolation\_level* property of *Connection* objects.

SQLite natively supports only the types TEXT, INTEGER, REAL, BLOB and NULL. If you want to use other types you must add support for them yourself. The *detect\_types* parameter and the using custom **converters** registered with the module-level *register\_converter()* function allow you to easily do that.

*detect\_types* defaults to 0 (i. e. off, no type detection), you can set it to any combination of *PARSE\_DECLTYPES* and *PARSE\_COLNAMES* to turn type detection on.

By default, the *sqlite3* module uses its *Connection* class for the connect call. You can, however, subclass the *Connection* class and make *connect()* use your class instead by providing your class for the *factory* parameter.

Consult the section *SQLite and Python types* of this manual for details.

The *sqlite3* module internally uses a statement cache to avoid SQL parsing overhead. If you want to explicitly set the number of statements that are cached for the connection, you can set the *cached\_statements* parameter. The currently implemented default is to cache 100 statements.

**sqlite3.register\_converter(*typename*, *callable*)**

Registers a callable to convert a bytestring from the database into a custom Python type. The callable will be invoked for all database values that are of the type *typename*. Confer the parameter *detect\_types* of the *connect()* function for how the type detection works. Note that *typename* and the name of the type in your query are matched in case-insensitive manner.

**sqlite3.register\_adapter(*type*, *callable*)**

Registers a callable to convert the custom Python type *type* into one of SQLite's supported types. The callable *callable* accepts as single parameter the Python value, and must return a value of the following types : int, long, float, str (UTF-8 encoded), unicode or buffer.

**sqlite3.complete\_statement(*sql*)**

Returns *True* if the string *sql* contains one or more complete SQL statements terminated by semicolons. It does not verify that the SQL is syntactically correct, only that there are no unclosed string literals and the statement is terminated by a semicolon.

This can be used to build a shell for SQLite, as in the following example :

```
# A minimal SQLite shell for experiments

import sqlite3

con = sqlite3.connect(":memory:")
con.isolation_level = None
cur = con.cursor()

buffer = ""

print "Enter your SQL commands to execute in sqlite3."
print "Enter a blank line to exit."

while True:
    line = raw_input()
    if line == "":
        break
    buffer += line
    if sqlite3.complete_statement(buffer):
        try:
            buffer = buffer.strip()
```

(suite sur la page suivante)

(suite de la page précédente)

```

        cur.execute(buffer)

        if buffer.lstrip().upper().startswith("SELECT"):
            print cur.fetchall()
        except sqlite3.Error as e:
            print "An error occurred:", e.args[0]
        buffer = ""

con.close()

```

**sqlite3.enable\_callback\_tracebacks(flag)**

By default you will not get any tracebacks in user-defined functions, aggregates, converters, authorizer callbacks etc. If you want to debug them, you can call this function with *flag* set to **True**. Afterwards, you will get tracebacks from callbacks on `sys.stderr`. Use **False** to disable the feature again.

**11.13.2 Connection Objects****class sqlite3.Connection**

A SQLite database connection has the following attributes and methods :

**isolation\_level**

Get or set the current isolation level. *None* for autocommit mode or one of « DEFERRED », « IMMEDIATE » or « EXCLUSIVE ». See section *Controlling Transactions* for a more detailed explanation.

**cursor(factory=Cursor)**

The cursor method accepts a single optional parameter *factory*. If supplied, this must be a callable returning an instance of *Cursor* or its subclasses.

**commit()**

This method commits the current transaction. If you don't call this method, anything you did since the last call to `commit()` is not visible from other database connections. If you wonder why you don't see the data you've written to the database, please check you didn't forget to call this method.

**rollback()**

This method rolls back any changes to the database since the last call to `commit()`.

**close()**

This closes the database connection. Note that this does not automatically call `commit()`. If you just close your database connection without calling `commit()` first, your changes will be lost !

**execute(sql[, parameters])**

This is a nonstandard shortcut that creates an intermediate cursor object by calling the cursor method, then calls the cursor's `execute` method with the parameters given.

**executemany(sql[, parameters])**

This is a nonstandard shortcut that creates an intermediate cursor object by calling the cursor method, then calls the cursor's `executemany` method with the parameters given.

**executescript(sql\_script)**

This is a nonstandard shortcut that creates an intermediate cursor object by calling the cursor method, then calls the cursor's `executescript` method with the parameters given.

**create\_function(name, num\_params, func)**

Creates a user-defined function that you can later use from within SQL statements under the function name *name*. *num\_params* is the number of parameters the function accepts, and *func* is a Python callable that is called as the SQL function.

The function can return any of the types supported by SQLite : unicode, str, int, long, float, buffer and None.

Exemple :

```
import sqlite3
import md5

def md5sum(t):
    return md5.md5(t).hexdigest()

con = sqlite3.connect(":memory:")
con.create_function("md5", 1, md5sum)
cur = con.cursor()
cur.execute("select md5(?)", ("foo",))
print cur.fetchone()[0]
```

**create\_aggregate**(*name*, *num\_params*, *aggregate\_class*)

Creates a user-defined aggregate function.

The aggregate class must implement a **step** method, which accepts the number of parameters *num\_params*, and a **finalize** method which will return the final result of the aggregate.

The **finalize** method can return any of the types supported by SQLite : unicode, str, int, long, float, buffer and None.

Exemple :

```
import sqlite3

class MySum:
    def __init__(self):
        self.count = 0

    def step(self, value):
        self.count += value

    def finalize(self):
        return self.count

con = sqlite3.connect(":memory:")
con.create_aggregate("mysum", 1, MySum)
cur = con.cursor()
cur.execute("create table test(i)")
cur.execute("insert into test(i) values (1)")
cur.execute("insert into test(i) values (2)")
cur.execute("select mysum(i) from test")
print cur.fetchone()[0]
```

**create\_collation**(*name*, *callable*)

Creates a collation with the specified *name* and *callable*. The callable will be passed two string arguments. It should return -1 if the first is ordered lower than the second, 0 if they are ordered equal and 1 if the first is ordered higher than the second. Note that this controls sorting (ORDER BY in SQL) so your comparisons don't affect other SQL operations.

Note that the callable will get its parameters as Python bytestrings, which will normally be encoded in UTF-8.

The following example shows a custom collation that sorts « the wrong way » :

```
import sqlite3
```

(suite sur la page suivante)

(suite de la page précédente)

```
def collate_reverse(string1, string2):
    return -cmp(string1, string2)

con = sqlite3.connect(":memory:")
con.create_collation("reverse", collate_reverse)

cur = con.cursor()
cur.execute("create table test(x)")
cur.executemany("insert into test(x) values (?)", [("a",), ("b",)])
cur.execute("select x from test order by x collate reverse")
for row in cur:
    print row
con.close()
```

To remove a collation, call `create_collation` with `None` as callable :

```
con.create_collation("reverse", None)
```

#### `interrupt()`

You can call this method from a different thread to abort any queries that might be executing on the connection. The query will then abort and the caller will get an exception.

#### `set_authorizer(authorizer_callback)`

This routine registers a callback. The callback is invoked for each attempt to access a column of a table in the database. The callback should return `SQLITE_OK` if access is allowed, `SQLITE_DENY` if the entire SQL statement should be aborted with an error and `SQLITE_IGNORE` if the column should be treated as a NULL value. These constants are available in the `sqlite3` module.

The first argument to the callback signifies what kind of operation is to be authorized. The second and third argument will be arguments or `None` depending on the first argument. The 4th argument is the name of the database (« main », « temp », etc.) if applicable. The 5th argument is the name of the inner-most trigger or view that is responsible for the access attempt or `None` if this access attempt is directly from input SQL code.

Please consult the SQLite documentation about the possible values for the first argument and the meaning of the second and third argument depending on the first one. All necessary constants are available in the `sqlite3` module.

#### `set_progress_handler(handler, n)`

This routine registers a callback. The callback is invoked for every *n* instructions of the SQLite virtual machine. This is useful if you want to get called from SQLite during long-running operations, for example to update a GUI.

If you want to clear any previously installed progress handler, call the method with `None` for *handler*.

Nouveau dans la version 2.6.

#### `enable_load_extension(enabled)`

This routine allows/disallows the SQLite engine to load SQLite extensions from shared libraries. SQLite extensions can define new functions, aggregates or whole new virtual table implementations. One well-known extension is the fulltext-search extension distributed with SQLite.

Loadable extensions are disabled by default. See <sup>1</sup>.

Nouveau dans la version 2.7.

1. The `sqlite3` module is not built with loadable extension support by default, because some platforms (notably Mac OS X) have SQLite libraries which are compiled without this feature. To get loadable extension support, you must modify `setup.py` and remove the line that sets `SQLITE_OMIT_LOAD_EXTENSION`.

```

import sqlite3

con = sqlite3.connect(":memory:")

# enable extension loading
con.enable_load_extension(True)

# Load the fulltext search extension
con.execute("select load_extension('./fts3.so')")

# alternatively you can load the extension using an API call:
# con.load_extension("./fts3.so")

# disable extension loading again
con.enable_load_extension(False)

# example from SQLite wiki
con.execute("create virtual table recipe using fts3(name, ingredients)")
con.executescript("""
    insert into recipe (name, ingredients) values ('broccoli stew', 'broccoli
↪peppers cheese tomatoes');
    insert into recipe (name, ingredients) values ('pumpkin stew', 'pumpkin
↪onions garlic celery');
    insert into recipe (name, ingredients) values ('broccoli pie', 'broccoli
↪cheese onions flour');
    insert into recipe (name, ingredients) values ('pumpkin pie', 'pumpkin
↪sugar flour butter');
""")
for row in con.execute("select rowid, name, ingredients from recipe where name
↪match 'pie'"):
    print row

```

**load\_extension(path)**

This routine loads a SQLite extension from a shared library. You have to enable extension loading with `enable_load_extension()` before you can use this routine.

Loadable extensions are disabled by default. See<sup>1</sup>.

Nouveau dans la version 2.7.

**row\_factory**

You can change this attribute to a callable that accepts the cursor and the original row as a tuple and will return the real result row. This way, you can implement more advanced ways of returning results, such as returning an object that can also access columns by name.

Exemple :

```

import sqlite3

def dict_factory(cursor, row):
    d = {}
    for idx, col in enumerate(cursor.description):
        d[col[0]] = row[idx]
    return d

con = sqlite3.connect(":memory:")
con.row_factory = dict_factory

```

(suite sur la page suivante)

(suite de la page précédente)

```
cur = con.cursor()
cur.execute("select 1 as a")
print cur.fetchone()["a"]
```

If returning a tuple doesn't suffice and you want name-based access to columns, you should consider setting `row_factory` to the highly-optimized `sqlite3.Row` type. `Row` provides both index-based and case-insensitive name-based access to columns with almost no memory overhead. It will probably be better than your own custom dictionary-based approach or even a `db_row` based solution.

#### `text_factory`

Using this attribute you can control what objects are returned for the `TEXT` data type. By default, this attribute is set to `unicode` and the `sqlite3` module will return Unicode objects for `TEXT`. If you want to return bytestrings instead, you can set it to `str`.

For efficiency reasons, there's also a way to return Unicode objects only for non-ASCII data, and bytestrings otherwise. To activate it, set this attribute to `sqlite3.OptimizedUnicode`.

You can also set it to any other callable that accepts a single bytestring parameter and returns the resulting object.

See the following example code for illustration :

```
import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()

AUSTRIA = u"\xd6sterreich"

# by default, rows are returned as Unicode
cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert row[0] == AUSTRIA

# but we can make sqlite3 always return bytestrings ...
con.text_factory = str
cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert type(row[0]) is str
# the bytestrings will be encoded in UTF-8, unless you stored garbage in the
# database ...
assert row[0] == AUSTRIA.encode("utf-8")

# we can also implement a custom text_factory ...
# here we implement one that will ignore Unicode characters that cannot be
# decoded from UTF-8
con.text_factory = lambda x: unicode(x, "utf-8", "ignore")
cur.execute("select ?", ("this is latin1 and would normally create errors" +
                        u"\xe4\xfc\xfc".encode("latin1"),))
row = cur.fetchone()
assert type(row[0]) is unicode

# sqlite3 offers a built-in optimized text_factory that will return bytestring
# objects, if the data is in ASCII only, and otherwise return unicode objects
con.text_factory = sqlite3.OptimizedUnicode
```

(suite sur la page suivante)

(suite de la page précédente)

```

cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert type(row[0]) is unicode

cur.execute("select ?", ("Germany",))
row = cur.fetchone()
assert type(row[0]) is str

```

**total\_changes**

Returns the total number of database rows that have been modified, inserted, or deleted since the database connection was opened.

**iterdump**

Returns an iterator to dump the database in an SQL text format. Useful when saving an in-memory database for later restoration. This function provides the same capabilities as the `.dump` command in the `sqlite3` shell.

Nouveau dans la version 2.6.

Exemple :

```

# Convert file existing_db.db to SQL dump file dump.sql
import sqlite3, os

con = sqlite3.connect('existing_db.db')
with open('dump.sql', 'w') as f:
    for line in con.iterdump():
        f.write('%s\n' % line)

```

### 11.13.3 Cursor Objects

**class sqlite3.Cursor**

A *Cursor* instance has the following attributes and methods.

**execute(sql[, parameters])**

Executes an SQL statement. The SQL statement may be parameterized (i. e. placeholders instead of SQL literals). The `sqlite3` module supports two kinds of placeholders : question marks (qmark style) and named placeholders (named style).

Here's an example of both styles :

```

import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table people (name_last, age)")

who = "Yeltsin"
age = 72

# This is the qmark style:
cur.execute("insert into people values (?, ?)", (who, age))

# And this is the named style:
cur.execute("select * from people where name_last=:who and age=:age", {"who": who,
↵:who, "age": age})

```

(suite sur la page suivante)

(suite de la page précédente)

```
print cur.fetchone()
```

`execute()` will only execute a single SQL statement. If you try to execute more than one statement with it, it will raise a `Warning`. Use `executescript()` if you want to execute multiple SQL statements with one call.

**executemany**(*sql*, *seq\_of\_parameters*)

Executes an SQL command against all parameter sequences or mappings found in the sequence *sql*. The `sqlite3` module also allows using an *iterator* yielding parameters instead of a sequence.

```
import sqlite3

class IterChars:
    def __init__(self):
        self.count = ord('a')

    def __iter__(self):
        return self

    def next(self):
        if self.count > ord('z'):
            raise StopIteration
        self.count += 1
        return (chr(self.count - 1),) # this is a 1-tuple

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table characters(c)")

theIter = IterChars()
cur.executemany("insert into characters(c) values (?)", theIter)

cur.execute("select c from characters")
print cur.fetchall()
```

Here's a shorter example using a *generator* :

```
import sqlite3
import string

def char_generator():
    for c in string.lowercase:
        yield (c,)

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table characters(c)")

cur.executemany("insert into characters(c) values (?)", char_generator())

cur.execute("select c from characters")
print cur.fetchall()
```

**executescript**(*sql\_script*)

This is a nonstandard convenience method for executing multiple SQL statements at once. It

issues a `COMMIT` statement first, then executes the SQL script it gets as a parameter.

`sql_script` can be a bytestring or a Unicode string.

Exemple :

```
import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.executescript("""
    create table person(
        firstname,
        lastname,
        age
    );

    create table book(
        title,
        author,
        published
    );

    insert into book(title, author, published)
    values (
        'Dirk Gently's Holistic Detective Agency',
        'Douglas Adams',
        1987
    );
""")
```

#### **fetchone()**

Fetches the next row of a query result set, returning a single sequence, or *None* when no more data is available.

#### **fetchmany([size=cursor.arraysize])**

Fetches the next set of rows of a query result, returning a list. An empty list is returned when no more rows are available.

The number of rows to fetch per call is specified by the *size* parameter. If it is not given, the cursor's *arraysize* determines the number of rows to be fetched. The method should try to fetch as many rows as indicated by the *size* parameter. If this is not possible due to the specified number of rows not being available, fewer rows may be returned.

Note there are performance considerations involved with the *size* parameter. For optimal performance, it is usually best to use the *arraysize* attribute. If the *size* parameter is used, then it is best for it to retain the same value from one *fetchmany()* call to the next.

#### **fetchall()**

Fetches all (remaining) rows of a query result, returning a list. Note that the cursor's *arraysize* attribute can affect the performance of this operation. An empty list is returned when no rows are available.

#### **rowcount**

Although the *Cursor* class of the *sqlite3* module implements this attribute, the database engine's own support for the determination of « rows affected »/ « rows selected » is quirky.

For *executemany()* statements, the number of modifications are summed up into *rowcount*.

As required by the Python DB API Spec, the *rowcount* attribute « is -1 in case no *executeXX()* has been performed on the cursor or the rowcount of the last operation is not determinable by the interface ». This includes `SELECT` statements because we cannot determine the number of rows a query produced until all rows were fetched.

With SQLite versions before 3.6.5, *rowcount* is set to 0 if you make a `DELETE FROM table` without any condition.

#### **lastrowid**

This read-only attribute provides the rowid of the last modified row. It is only set if you issued an `INSERT` statement using the *execute()* method. For operations other than `INSERT` or when *executemany()* is called, *lastrowid* is set to *None*.

#### **description**

This read-only attribute provides the column names of the last query. To remain compatible with the Python DB API, it returns a 7-tuple for each column where the last six items of each tuple are *None*.

It is set for `SELECT` statements without any matching rows as well.

#### **connection**

This read-only attribute provides the SQLite database *Connection* used by the *Cursor* object. A *Cursor* object created by calling *con.cursor()* will have a *connection* attribute that refers to *con* :

```
>>> con = sqlite3.connect(":memory:")
>>> cur = con.cursor()
>>> cur.connection == con
True
```

### 11.13.4 Row Objects

#### **class sqlite3.Row**

A *Row* instance serves as a highly optimized *row\_factory* for *Connection* objects. It tries to mimic a tuple in most of its features.

It supports mapping access by column name and index, iteration, representation, equality testing and *len()*.

If two *Row* objects have exactly the same columns and their members are equal, they compare equal.

Modifié dans la version 2.6 : Added iteration and equality (hashability).

#### **keys()**

This method returns a list of column names. Immediately after a query, it is the first member of each tuple in *Cursor.description*.

Nouveau dans la version 2.6.

Let's assume we initialize a table as in the example given above :

```
conn = sqlite3.connect(":memory:")
c = conn.cursor()
c.execute('create table stocks
(date text, trans text, symbol text,
 qty real, price real)')
c.execute("""insert into stocks
          values ('2006-01-05','BUY','RHAT',100,35.14)""")
conn.commit()
c.close()
```

Now we plug *Row* in :

```
>>> conn.row_factory = sqlite3.Row
>>> c = conn.cursor()
>>> c.execute('select * from stocks')
<sqlite3.Cursor object at 0x7f4e7dd8fa80>
```

(suite sur la page suivante)

(suite de la page précédente)

```

>>> r = c.fetchone()
>>> type(r)
<type 'sqlite3.Row'>
>>> r
(u'2006-01-05', u'BUY', u'RHAT', 100.0, 35.14)
>>> len(r)
5
>>> r[2]
u'RHAT'
>>> r.keys()
['date', 'trans', 'symbol', 'qty', 'price']
>>> r['qty']
100.0
>>> for member in r:
...     print member
...
2006-01-05
BUY
RHAT
100.0
35.14

```

### 11.13.5 SQLite and Python types

#### Introduction

SQLite natively supports the following types : NULL, INTEGER, REAL, TEXT, BLOB.

The following Python types can thus be sent to SQLite without any problem :

Type Python	SQLite type
<i>None</i>	NULL
<i>int</i>	INTEGER
<i>long</i>	INTEGER
<i>float</i>	REAL
<i>str</i> (UTF8-encoded)	TEXT
<i>unicode</i>	TEXT
<i>buffer</i>	BLOB

This is how SQLite types are converted to Python types by default :

SQLite type	Type Python
NULL	<i>None</i>
INTEGER	<i>int</i> or <i>long</i> , depending on size
REAL	<i>float</i>
TEXT	depends on <i>text_factory</i> , <i>unicode</i> by default
BLOB	<i>buffer</i>

The type system of the *sqlite3* module is extensible in two ways : you can store additional Python types in a SQLite database via object adaptation, and you can let the *sqlite3* module convert SQLite types to different Python types via converters.

### Using adapters to store additional Python types in SQLite databases

As described before, SQLite supports only a limited set of types natively. To use other Python types with SQLite, you must **adapt** them to one of the `sqlite3` module's supported types for SQLite : one of `NoneType`, `int`, `long`, `float`, `str`, `unicode`, `buffer`.

There are two ways to enable the `sqlite3` module to adapt a custom Python type to one of the supported ones.

#### Letting your object adapt itself

This is a good approach if you write the class yourself. Let's suppose you have a class like this :

```
class Point(object):
    def __init__(self, x, y):
        self.x, self.y = x, y
```

Now you want to store the point in a single SQLite column. First you'll have to choose one of the supported types first to be used for representing the point. Let's just use `str` and separate the coordinates using a semicolon. Then you need to give your class a method `__conform__(self, protocol)` which must return the converted value. The parameter `protocol` will be `PrepareProtocol`.

```
import sqlite3

class Point(object):
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __conform__(self, protocol):
        if protocol is sqlite3.PrepareProtocol:
            return "%f;%f" % (self.x, self.y)

con = sqlite3.connect(":memory:")
cur = con.cursor()

p = Point(4.0, -3.2)
cur.execute("select ?", (p,))
print cur.fetchone()[0]
```

#### Registering an adapter callable

The other possibility is to create a function that converts the type to the string representation and register the function with `register_adapter()`.

---

**Note :** The type/class to adapt must be a *new-style class*, i. e. it must have `object` as one of its bases.

---

```
import sqlite3

class Point(object):
    def __init__(self, x, y):
        self.x, self.y = x, y

def adapt_point(point):
```

(suite sur la page suivante)

(suite de la page précédente)

```
    return "%f;%f" % (point.x, point.y)

sqlite3.register_adapter(Point, adapt_point)

con = sqlite3.connect(":memory:")
cur = con.cursor()

p = Point(4.0, -3.2)
cur.execute("select ?", (p,))
print cur.fetchone()[0]
```

The `sqlite3` module has two default adapters for Python's built-in `datetime.date` and `datetime.datetime` types. Now let's suppose we want to store `datetime.datetime` objects not in ISO representation, but as a Unix timestamp.

```
import sqlite3
import datetime, time

def adapt_datetime(ts):
    return time.mktime(ts.timetuple())

sqlite3.register_adapter(datetime.datetime, adapt_datetime)

con = sqlite3.connect(":memory:")
cur = con.cursor()

now = datetime.datetime.now()
cur.execute("select ?", (now,))
print cur.fetchone()[0]
```

### Converting SQLite values to custom Python types

Writing an adapter lets you send custom Python types to SQLite. But to make it really useful we need to make the Python to SQLite to Python roundtrip work.

Enter converters.

Let's go back to the `Point` class. We stored the `x` and `y` coordinates separated via semicolons as strings in SQLite.

First, we'll define a converter function that accepts the string as a parameter and constructs a `Point` object from it.

---

**Note :** Converter functions **always** get called with a string, no matter under which data type you sent the value to SQLite.

---

```
def convert_point(s):
    x, y = map(float, s.split(";"))
    return Point(x, y)
```

Now you need to make the `sqlite3` module know that what you select from the database is actually a point. There are two ways of doing this :

- Implicitly via the declared type

— Explicitly via the column name

Both ways are described in section *Module functions and constants*, in the entries for the constants `PARSE_DECLTYPES` and `PARSE_COLNAMES`.

The following example illustrates both approaches.

```
import sqlite3

class Point(object):
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __repr__(self):
        return "(%f;%f)" % (self.x, self.y)

def adapt_point(point):
    return "%f;%f" % (point.x, point.y)

def convert_point(s):
    x, y = map(float, s.split(";"))
    return Point(x, y)

# Register the adapter
sqlite3.register_adapter(Point, adapt_point)

# Register the converter
sqlite3.register_converter("point", convert_point)

p = Point(4.0, -3.2)

#####
# 1) Using declared types
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES)
cur = con.cursor()
cur.execute("create table test(p point)")

cur.execute("insert into test(p) values (?)", (p,))
cur.execute("select p from test")
print "with declared types:", cur.fetchone()[0]
cur.close()
con.close()

#####
# 1) Using column names
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_COLNAMES)
cur = con.cursor()
cur.execute("create table test(p)")

cur.execute("insert into test(p) values (?)", (p,))
cur.execute('select p as "p [point]" from test')
print "with column names:", cur.fetchone()[0]
cur.close()
con.close()
```

### Default adapters and converters

There are default adapters for the date and datetime types in the `datetime` module. They will be sent as ISO dates/ISO timestamps to SQLite.

The default converters are registered under the name « `date` » for `datetime.date` and under the name « `timestamp` » for `datetime.datetime`.

This way, you can use date/timestamps from Python without any additional fiddling in most cases. The format of the adapters is also compatible with the experimental SQLite date/time functions.

The following example demonstrates this.

```
import sqlite3
import datetime

con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES|sqlite3.PARSE_
    ↳COLNAMES)
cur = con.cursor()
cur.execute("create table test(d date, ts timestamp)")

today = datetime.date.today()
now = datetime.datetime.now()

cur.execute("insert into test(d, ts) values (?, ?)", (today, now))
cur.execute("select d, ts from test")
row = cur.fetchone()
print today, "=>", row[0], type(row[0])
print now, "=>", row[1], type(row[1])

cur.execute('select current_date as "d [date]", current_timestamp as "ts [timestamp]"')
row = cur.fetchone()
print "current_date", row[0], type(row[0])
print "current_timestamp", row[1], type(row[1])
```

If a timestamp stored in SQLite has a fractional part longer than 6 numbers, its value will be truncated to microsecond precision by the timestamp converter.

### 11.13.6 Controlling Transactions

By default, the `sqlite3` module opens transactions implicitly before a Data Modification Language (DML) statement (i.e. `INSERT/UPDATE/DELETE/REPLACE`), and commits transactions implicitly before a non-DML, non-query statement (i. e. anything other than `SELECT` or the aforementioned).

So if you are within a transaction and issue a command like `CREATE TABLE ...`, `VACUUM`, `PRAGMA`, the `sqlite3` module will commit implicitly before executing that command. There are two reasons for doing that. The first is that some of these commands don't work within transactions. The other reason is that `sqlite3` needs to keep track of the transaction state (if a transaction is active or not).

You can control which kind of `BEGIN` statements `sqlite3` implicitly executes (or none at all) via the `isolation_level` parameter to the `connect()` call, or via the `isolation_level` property of connections.

If you want **autocommit mode**, then set `isolation_level` to `None`.

Otherwise leave it at its default, which will result in a plain « `BEGIN` » statement, or set it to one of SQLite's supported isolation levels : « `DEFERRED` », « `IMMEDIATE` » or « `EXCLUSIVE` ».

### 11.13.7 Using `sqlite3` efficiently

#### Using shortcut methods

Using the nonstandard `execute()`, `executemany()` and `executescript()` methods of the *Connection* object, your code can be written more concisely because you don't have to create the (often superfluous) *Cursor* objects explicitly. Instead, the *Cursor* objects are created implicitly and these shortcut methods return the cursor objects. This way, you can execute a `SELECT` statement and iterate over it directly using only a single call on the *Connection* object.

```
import sqlite3

persons = [
    ("Hugo", "Boss"),
    ("Calvin", "Klein")
]

con = sqlite3.connect(":memory:")

# Create the table
con.execute("create table person(firstname, lastname)")

# Fill the table
con.executemany("insert into person(firstname, lastname) values (?, ?)", persons)

# Print the table contents
for row in con.execute("select firstname, lastname from person"):
    print row

print "I just deleted", con.execute("delete from person").rowcount, "rows"
```

#### Accessing columns by name instead of by index

One useful feature of the *sqlite3* module is the built-in *sqlite3.Row* class designed to be used as a row factory.

Rows wrapped with this class can be accessed both by index (like tuples) and case-insensitively by name :

```
import sqlite3

con = sqlite3.connect(":memory:")
con.row_factory = sqlite3.Row

cur = con.cursor()
cur.execute("select 'John' as name, 42 as age")
for row in cur:
    assert row[0] == row["name"]
    assert row["name"] == row["nAmE"]
    assert row[1] == row["age"]
    assert row[1] == row["AgE"]
```

#### Using the connection as a context manager

Nouveau dans la version 2.6.

Connection objects can be used as context managers that automatically commit or rollback transactions. In the event of an exception, the transaction is rolled back; otherwise, the transaction is committed :

```
import sqlite3

con = sqlite3.connect(":memory:")
con.execute("create table person (id integer primary key, firstname varchar unique)")

# Successful, con.commit() is called automatically afterwards
with con:
    con.execute("insert into person(firstname) values (?)", ("Joe",))

# con.rollback() is called after the with block finishes with an exception, the
# exception is still raised and must be caught
try:
    with con:
        con.execute("insert into person(firstname) values (?)", ("Joe",))
except sqlite3.IntegrityError:
    print "couldn't add Joe twice"
```

### 11.13.8 Common issues

#### Fils d'exécution

Older SQLite versions had issues with sharing connections between threads. That's why the Python module disallows sharing connections and cursors between threads. If you still try to do so, you will get an exception at runtime.

The only exception is calling the *interrupt()* method, which only makes sense to call from a different thread.

#### Notes

---

Compression de donnée et archivage

---

The modules described in this chapter support data compression with the `zlib`, `gzip`, and `bzip2` algorithms, and the creation of ZIP- and tar-format archives. See also *Archiving operations* provided by the `shutil` module.

## 12.1 `zlib` — Compression compatible avec `gzip`

Pour des applications nécessitant de compresser des données, les fonctions de ce module permettent la compression et la décompression via la bibliothèque `zlib`. La bibliothèque `zlib` a sa propre page web sur <http://www.zlib.net>. Il existe des incompatibilités connues entre le module Python et les versions de la bibliothèque `zlib` plus anciennes que la 1.1.3; 1.1.3 contient des failles de sécurité et nous recommandons d'utiliser plutôt la version 1.14 ou plus récente.

les fonctions `zlib` recèlent de nombreuses options et il est nécessaire de suivre un ordre précis. Cette documentation n'a pas pour but de couvrir la globalité des possibilités. Aussi, veuillez consulter le manuel `zlib` en ligne sur <http://www.zlib.net/manual.html> pour compléter davantage son utilisation.

Pour lire ou écrire des fichiers `.gz` veuillez consulter le module `gzip`.

Les exceptions et fonctions disponibles dans ce module sont :

**exception `zlib.error`**

Exception levée lors d'erreurs de compression et de décompression.

**`zlib.adler32(data[, value])`**

Computes an Adler-32 checksum of *data*. (An Adler-32 checksum is almost as reliable as a CRC32 but can be computed much more quickly.) If *value* is present, it is used as the starting value of the checksum; otherwise, a fixed default value is used. This allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm.

This function always returns an integer object.

---

**Note :** To generate the same numeric value across all Python versions and platforms use `adler32(data) &`

---

0xffffffff. If you are only using the checksum in packed binary format this is not necessary as the return value is the correct 32bit binary representation regardless of sign.

---

Modifié dans la version 2.6 : The return value is in the range  $[-2^{31}, 2^{31}-1]$  regardless of platform. In older versions the value is signed on some platforms and unsigned on others.

Modifié dans la version 3.0 : The return value is unsigned and in the range  $[0, 2^{32}-1]$  regardless of platform.

`zlib.compress(string[, level])`

Compresses the data in *string*, returning a string contained compressed data. *level* is an integer from 0 to 9 controlling the level of compression; 1 is fastest and produces the least compression, 9 is slowest and produces the most. 0 is no compression. The default value is 6. Raises the *error* exception if any error occurs.

`zlib.compressobj([level[, method[, wbits[, memlevel[, strategy]]]])`

Returns a compression object, to be used for compressing data streams that won't fit into memory at once. *level* is an integer from 0 to 9 or -1, controlling the level of compression; 1 is fastest and produces the least compression, 9 is slowest and produces the most. 0 is no compression. The default value is -1 (Z\_DEFAULT\_COMPRESSION). Z\_DEFAULT\_COMPRESSION represents a default compromise between speed and compression (currently equivalent to level 6).

*method* is the compression algorithm. Currently, the only supported value is DEFLATED.

The *wbits* argument controls the size of the history buffer (or the « window size ») used when compressing data, and whether a header and trailer is included in the output. It can take several ranges of values. The default is 15.

- De +9 à +15 : le logarithme binaire de la taille du tampon, par conséquent compris entre 512 et 32768. Des valeurs plus grandes produisent de meilleures compressions au dépens d'une utilisation mémoire plus grande. Le résultat final inclus des en-tête et des blocs spécifiques à *zlib*.
- De -9 à -15 : utilise la valeur absolue de *wbits* comme logarithme binaire de la taille du tampon, et ne produit pas d'entêtes ni de bloc final.
- De +25 à +31 = 16 + (9 à 15) : utilise les 4 bits de poids faible comme logarithme binaire de la taille du tampon, tout en incluant une entête **gzip** et une somme de contrôle finale.

*memlevel* controls the amount of memory used for internal compression state. Valid values range from 1 to 9. Higher values using more memory, but are faster and produce smaller output. The default is 8.

*strategy* is used to tune the compression algorithm. Possible values are Z\_DEFAULT\_STRATEGY, Z\_FILTERED, and Z\_HUFFMAN\_ONLY. The default is Z\_DEFAULT\_STRATEGY.

`zlib.crc32(data[, value])`

Computes a CRC (Cyclic Redundancy Check) checksum of *data*. If *value* is present, it is used as the starting value of the checksum; otherwise, a fixed default value is used. This allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm.

This function always returns an integer object.

---

**Note :** To generate the same numeric value across all Python versions and platforms use `crc32(data) & 0xffffffff`. If you are only using the checksum in packed binary format this is not necessary as the return value is the correct 32bit binary representation regardless of sign.

---

Modifié dans la version 2.6 : The return value is in the range  $[-2^{31}, 2^{31}-1]$  regardless of platform. In older versions the value would be signed on some platforms and unsigned on others.

Modifié dans la version 3.0 : The return value is unsigned and in the range  $[0, 2^{32}-1]$  regardless of platform.

`zlib.decompress(string[, wbits[, bufsize]])`

Decompresses the data in *string*, returning a string containing the uncompressed data. The *wbits* parameter depends on the format of *string*, and is discussed further below. If *bufsize* is given, it is used as the initial size of the output buffer. Raises the *error* exception if any error occurs.

L'argument *wbits* contrôle la taille du tampon d'historique (« *window size* ») utilisé lors de la compression, et si un en-tête et un bloc final sont attendus. Similaire au paramètre de *compressobj()*, mais accepte une gamme plus large de valeurs :

- De +8 à +15 : logarithme binaire pour la taille du tampon. L'entrée doit contenir un en-tête et un bloc *zlib*.
- 0 : détermine automatiquement la taille du tampon à partir de l'en-tête *zlib*. Géré uniquement depuis *zlib* 1.2.3.5.
- De -8 à -15 : utilise la valeur absolue de *wbits* comme logarithme binaire pour la taille du tampon. L'entrée doit être un flux brut, sans en-tête ni bloc final.
- De +24 à +31 = 16 + (8 à 15) : utilise les 4 de poids faible comme logarithme binaire pour la taille du tampon. L'entrée doit contenir un en-tête *gzip* et son bloc final.
- De +40 à +47 = 32 + (8 à 15) : utilise les 4 bits de poids faible comme logarithme binaire pour la taille du tampon, et accepte automatiquement les formats *zlib* ou *gzip*.

When decompressing a stream, the window size must not be smaller than the size originally used to compress the stream; using a too-small value may result in an *error* exception. The default *wbits* value is 15, which corresponds to the largest window size and requires a *zlib* header and trailer to be included.

*bufsize* is the initial size of the buffer used to hold decompressed data. If more space is required, the buffer size will be increased as needed, so you don't have to get this value exactly right; tuning it will only save a few calls to *malloc()*. The default size is 16384.

`zlib.decompressobj([wbits])`

Renvoie un objet « décompresseur », à utiliser pour décompresser des flux de données qui ne rentrent pas entièrement en mémoire.

Le paramètre *wbits* contrôle la taille du tampon, et détermine quel format d'en-tête et de bloc sont prévus. Il a la même signification que *décrit pour decompress()*.

Les objets de compression gèrent les méthodes suivantes :

`Compress.compress(string)`

Compress *string*, returning a string containing compressed data for at least part of the data in *string*. This data should be concatenated to the output produced by any preceding calls to the *compress()* method. Some input may be kept in internal buffers for later processing.

`Compress.flush([mode])`

All pending input is processed, and a string containing the remaining compressed output is returned. *mode* can be selected from the constants *Z\_SYNC\_FLUSH*, *Z\_FULL\_FLUSH*, or *Z\_FINISH*, defaulting to *Z\_FINISH*. *Z\_SYNC\_FLUSH* and *Z\_FULL\_FLUSH* allow compressing further strings of data, while *Z\_FINISH* finishes the compressed stream and prevents compressing any more data. After calling *flush()* with *mode* set to *Z\_FINISH*, the *compress()* method cannot be called again; the only realistic action is to delete the object.

`Compress.copy()`

Renvoie une copie de l'objet « compresseur ». Utile pour compresser efficacement un ensemble de données qui partagent un préfixe initial commun.

Nouveau dans la version 2.5.

Decompression objects support the following methods, and two attributes :

`Decompress.unused_data`

A string which contains any bytes past the end of the compressed data. That is, this remains "" until the last byte that contains compression data is available. If the whole string turned out to contain compressed data, this is "", the empty string.

The only way to determine where a string of compressed data ends is by actually decompressing it. This means that when compressed data is contained part of a larger file, you can only find the end of it by reading data and feeding it followed by some non-empty string into a decompression object's `decompress()` method until the `unused_data` attribute is no longer the empty string.

#### `Decompress.unconsumed_tail`

A string that contains any data that was not consumed by the last `decompress()` call because it exceeded the limit for the uncompressed data buffer. This data has not yet been seen by the zlib machinery, so you must feed it (possibly with further data concatenated to it) back to a subsequent `decompress()` method call in order to get correct output.

#### `Decompress.decompress(string[, max_length])`

Decompress *string*, returning a string containing the uncompressed data corresponding to at least part of the data in *string*. This data should be concatenated to the output produced by any preceding calls to the `decompress()` method. Some of the input data may be preserved in internal buffers for later processing.

If the optional parameter *max\_length* is non-zero then the return value will be no longer than *max\_length*. This may mean that not all of the compressed input can be processed; and unconsumed data will be stored in the attribute `unconsumed_tail`. This string must be passed to a subsequent call to `decompress()` if decompression is to continue. If *max\_length* is not supplied then the whole input is decompressed, and `unconsumed_tail` is an empty string.

#### `Decompress.flush([length])`

All pending input is processed, and a string containing the remaining uncompressed output is returned. After calling `flush()`, the `decompress()` method cannot be called again; the only realistic action is to delete the object.

Le paramètre optionnel *length* définit la taille initiale du tampon de sortie.

#### `Decompress.copy()`

Renvoie une copie du décompresseur. Vous pouvez l'utiliser pour sauvegarder l'état de la décompression en cours, afin de pouvoir revenir rapidement à cet endroit plus tard.

Nouveau dans la version 2.5.

Module `gzip` Lire et écrire des fichiers au format `gzip`.

<http://www.zlib.net> Page officielle de la bibliothèque `zlib`.

<http://www.zlib.net/manual.html> La documentation de `zlib` explique le sens et l'utilisation des nombreuses fonctions fournies par la bibliothèque.

## 12.2 gzip — Support pour les fichiers gzip

Code source : [Lib/gzip.py](#)

---

Ce module fournit une interface simple pour compresser et décompresser des fichiers tout comme le font les programmes GNU `gzip` et `gunzip`.

La compression de données est fournie par le module `zlib`.

The `gzip` module provides the `GzipFile` class which is modeled after Python's File Object. The `GzipFile` class reads and writes `gzip`-format files, automatically compressing or decompressing the data so that it looks like an ordinary file object.

Notez que les formats de fichier supplémentaires qui peuvent être décompressés par les programmes `gzip` et `gunzip`, comme ceux produits par les programmes `compress` et `pack`, ne sont pas gérés par ce module.

Le module définit les éléments suivants :

```
class gzip.GzipFile([filename[, mode[, compresslevel[, fileobj[, mtime]]]]])
```

Constructor for the *GzipFile* class, which simulates most of the methods of a file object, with the exception of the *readinto()* and *truncate()* methods. At least one of *fileobj* and *filename* must be given a non-trivial value.

The new class instance is based on *fileobj*, which can be a regular file, a *StringIO* object, or any other object which simulates a file. It defaults to *None*, in which case *filename* is opened to provide a file object.

Quand *fileobj* n'est pas à *None*, l'argument *filename* est uniquement utilisé pour être inclus dans l'entête du fichier *gzip*, qui peut inclure le nom original du fichier décompressé. Il est par défaut défini avec le nom de fichier de *fileobj* s'il est discernable, sinon il est par défaut défini à une chaîne de caractères vide et dans ce cas le nom du fichier original n'est pas inclus dans l'entête.

The *mode* argument can be any of 'r', 'rb', 'a', 'ab', 'w', or 'wb', depending on whether the file will be read or written. The default is the mode of *fileobj* if discernible; otherwise, the default is 'rb'. If not given, the "b" flag will be added to the mode to ensure the file is opened in binary mode for cross-platform portability.

L'argument *compresslevel* est un entier de 0 à 9 contrôlant le niveau de compression, "1" est le plus rapide et produit la compression la plus faible et 9 est le plus rapide et produit la compression la plus élevée. 0 désactive la compression. Par défaut à 9.

The *mtime* argument is an optional numeric timestamp to be written to the stream when compressing. All *gzip* compressed streams are required to contain a timestamp. If omitted or *None*, the current time is used. This module ignores the timestamp when decompressing; however, some programs, such as *gunzip*, make use of it. The format of the timestamp is the same as that of the return value of *time.time()* and of the *st\_mtime* attribute of the object returned by *os.stat()*.

Calling a *GzipFile* object's *close()* method does not close *fileobj*, since you might wish to append more material after the compressed data. This also allows you to pass a *StringIO* object opened for writing as *fileobj*, and retrieve the resulting memory buffer using the *StringIO* object's *getvalue()* method.

*GzipFile* supports iteration and the *with* statement.

Modifié dans la version 2.7 : Support for the *with* statement was added.

Modifié dans la version 2.7 : Support for zero-padded files was added.

Nouveau dans la version 2.7 : The *mtime* argument.

```
gzip.open(filename[, mode[, compresslevel]])
```

This is a shorthand for *GzipFile(filename, mode, compresslevel)*. The *filename* argument is required; *mode* defaults to 'rb' and *compresslevel* defaults to 9.

### 12.2.1 Exemples d'utilisation

Exemple montrant comment lire un fichier compressé :

```
import gzip
with gzip.open('file.txt.gz', 'rb') as f:
    file_content = f.read()
```

Exemple montrant comment créer un fichier GZIP :

```
import gzip
content = "Lots of content here"
with gzip.open('file.txt.gz', 'wb') as f:
    f.write(content)
```

Exemple montrant comment compresser dans un GZIP un fichier existant :

```
import gzip
import shutil
with open('file.txt', 'rb') as f_in, gzip.open('file.txt.gz', 'wb') as f_out:
    shutil.copyfileobj(f_in, f_out)
```

Voir aussi :

Module [zlib](#) Le module de compression de données de base nécessaire pour gérer le format de fichier [gzip](#).

## 12.3 bz2 — Compression compatible with bzip2

Nouveau dans la version 2.3.

This module provides a comprehensive interface for the bz2 compression library. It implements a complete file interface, one-shot (de)compression functions, and types for sequential (de)compression.

Here is a summary of the features offered by the bz2 module :

- [BZ2File](#) class implements a complete file interface, including [readline\(\)](#), [readlines\(\)](#), [writelines\(\)](#), [seek\(\)](#), etc;
- [BZ2File](#) class implements emulated [seek\(\)](#) support;
- [BZ2File](#) class implements universal newline support;
- [BZ2File](#) class offers an optimized line iteration using the readahead algorithm borrowed from file objects;
- Sequential (de)compression supported by [BZ2Compressor](#) and [BZ2Decompressor](#) classes;
- One-shot (de)compression supported by [compress\(\)](#) and [decompress\(\)](#) functions;
- Thread safety uses individual locking mechanism.

---

**Note :** Handling of multi-stream bzip2 files is not supported. Modules such as [bz2file](#) let you overcome this.

---

### 12.3.1 (Dé)compression de fichiers

Handling of compressed files is offered by the [BZ2File](#) class.

```
class bz2.BZ2File(filename[, mode[, buffering[, compresslevel]]])
```

Open a bz2 file. Mode can be either 'r' or 'w', for reading (default) or writing. When opened for writing, the file will be created if it doesn't exist, and truncated otherwise. If *buffering* is given, 0 means unbuffered, and larger numbers specify the buffer size; the default is 0. If *compresslevel* is given, it must be a number between 1 and 9; the default is 9. Add a 'U' to mode to open the file for input in *universal newlines* mode. Any line ending in the input file will be seen as a '\n' in Python. Also, a file so opened gains the attribute `newlines`; the value for this attribute is one of `None` (no newline read yet), '\r', '\n', '\r\n' or a tuple containing all the newline types seen. Universal newlines are available only when reading. Instances support iteration in the same way as normal *file* instances.

[BZ2File](#) supports the `with` statement.

Modifié dans la version 2.7 : Support for the `with` statement was added.

---

**Note :** This class does not support input files containing multiple streams (such as those produced by the `pbzip2` tool). When reading such an input file, only the first stream will be accessible. If you require support for multi-stream files, consider using the third-party `bz2file` module (available from [PyPI](#)). This module provides a backport of Python 3.3's [BZ2File](#) class, which does support multi-stream files.

---

**close()**  
Close the file. Sets data attribute `closed` to true. A closed file cannot be used for further I/O operations. `close()` may be called more than once without error.

**read(*[size]*)**  
Read at most *size* uncompressed bytes, returned as a string. If the *size* argument is negative or omitted, read until EOF is reached.

**readline(*[size]*)**  
Return the next line from the file, as a string, retaining newline. A non-negative *size* argument limits the maximum number of bytes to return (an incomplete line may be returned then). Return an empty string at EOF.

**readlines(*[size]*)**  
Return a list of lines read. The optional *size* argument, if given, is an approximate bound on the total number of bytes in the lines returned.

**xreadlines()**  
For backward compatibility. `BZ2File` objects now include the performance optimizations previously implemented in the `xreadlines` module.  
Obsolète depuis la version 2.3 : This exists only for compatibility with the method by this name on `file` objects, which is deprecated. Use `for line in file` instead.

**seek(*offset*, *whence*)**  
Move to new file position. Argument *offset* is a byte count. Optional argument *whence* defaults to `os.SEEK_SET` or 0 (offset from start of file; offset should be  $\geq 0$ ); other values are `os.SEEK_CUR` or 1 (move relative to current position; offset can be positive or negative), and `os.SEEK_END` or 2 (move relative to end of file; offset is usually negative, although many platforms allow seeking beyond the end of a file).  
Note that seeking of bz2 files is emulated, and depending on the parameters the operation may be extremely slow.

**tell()**  
Return the current file position, an integer (may be a long integer).

**write(*data*)**  
Write string *data* to file. Note that due to buffering, `close()` may be needed before the file on disk reflects the data written.

**writelines(*sequence\_of\_strings*)**  
Write the sequence of strings to the file. Note that newlines are not added. The sequence can be any iterable object producing strings. This is equivalent to calling `write()` for each string.

### 12.3.2 Sequential (de)compression

Sequential compression and decompression is done using the classes `BZ2Compressor` and `BZ2Decompressor`.

**class bz2.BZ2Compressor(*[compresslevel]*)**  
Create a new compressor object. This object may be used to compress data sequentially. If you want to compress data in one shot, use the `compress()` function instead. The *compresslevel* parameter, if given, must be a number between 1 and 9; the default is 9.

**compress(*data*)**  
Provide more data to the compressor object. It will return chunks of compressed data whenever possible. When you've finished providing data to compress, call the `flush()` method to finish the compression process, and return what is left in internal buffers.

**flush()**  
Finish the compression process and return what is left in internal buffers. You must not use the compressor object after calling this method.

**class bz2.BZ2Decompressor**

Create a new decompressor object. This object may be used to decompress data sequentially. If you want to decompress data in one shot, use the [`decompress\(\)`](#) function instead.

**decompress(data)**

Provide more data to the decompressor object. It will return chunks of decompressed data whenever possible. If you try to decompress data after the end of stream is found, [`EOFError`](#) will be raised. If any data was found after the end of stream, it'll be ignored and saved in `unused_data` attribute.

### 12.3.3 (Dé)compression en une fois

One-shot compression and decompression is provided through the [`compress\(\)`](#) and [`decompress\(\)`](#) functions.

**bz2.compress(data[, compresslevel])**

Compress *data* in one shot. If you want to compress data sequentially, use an instance of [`BZ2Compressor`](#) instead. The *compresslevel* parameter, if given, must be a number between 1 and 9; the default is 9.

**bz2.decompress(data)**

Decompress *data* in one shot. If you want to decompress data sequentially, use an instance of [`BZ2Decompressor`](#) instead.

## 12.4 zipfile — Work with ZIP archives

Nouveau dans la version 1.6.

**Code source :** [Lib/zipfile.py](#)

---

The ZIP file format is a common archive and compression standard. This module provides tools to create, read, write, append, and list a ZIP file. Any advanced use of this module will require an understanding of the format, as defined in [PKZIP Application Note](#).

This module does not currently handle multi-disk ZIP files. It can handle ZIP files that use the ZIP64 extensions (that is ZIP files that are more than 4 GByte in size). It supports decryption of encrypted files in ZIP archives, but it currently cannot create an encrypted file. Decryption is extremely slow as it is implemented in native Python rather than C.

Le module définit les éléments suivants :

**exception zipfile.BadZipfile**

The error raised for bad ZIP files (old name : `zipfile.error`).

**exception zipfile.LargeZipFile**

The error raised when a ZIP file would require ZIP64 functionality but that has not been enabled.

**class zipfile.ZipFile**

The class for reading and writing ZIP files. See section [ZipFile Objects](#) for constructor details.

**class zipfile.PyZipFile**

Class for creating ZIP archives containing Python libraries.

**class zipfile.ZipInfo([filename[, date\_time]])**

Class used to represent information about a member of an archive. Instances of this class are returned by the [`getinfo\(\)`](#) and [`infolist\(\)`](#) methods of [ZipFile](#) objects. Most users of the *zipfile* module will not need to create these, but only use those created by this module. *filename* should be the full name of the archive member, and *date\_time* should be a tuple containing six fields which describe the time of the last modification to the file; the fields are described in section [ZipInfo Objects](#).

`zipfile.is_zipfile(filename)`

Returns `True` if *filename* is a valid ZIP file based on its magic number, otherwise returns `False`. *filename* may be a file or file-like object too.

Modifié dans la version 2.7 : Support for file and file-like objects.

`zipfile.ZIP_STORED`

The numeric constant for an uncompressed archive member.

`zipfile.ZIP_DEFLATED`

The numeric constant for the usual ZIP compression method. This requires the `zlib` module. No other compression methods are currently supported.

Voir aussi :

**PKZIP Application Note** Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

**Info-ZIP Home Page** Information about the Info-ZIP project's ZIP archive programs and development libraries.

### 12.4.1 ZipFile Objects

`class zipfile.ZipFile(file[, mode[, compression[, allowZip64]]])`

Open a ZIP file, where *file* can be either a path to a file (a string) or a file-like object. The *mode* parameter should be `'r'` to read an existing file, `'w'` to truncate and write a new file, or `'a'` to append to an existing file. If *mode* is `'a'` and *file* refers to an existing ZIP file, then additional files are added to it. If *file* does not refer to a ZIP file, then a new ZIP archive is appended to the file. This is meant for adding a ZIP archive to another file (such as `python.exe`).

Modifié dans la version 2.6 : If *mode* is `a` and the file does not exist at all, it is created.

*compression* is the ZIP compression method to use when writing the archive, and should be `ZIP_STORED` or `ZIP_DEFLATED`; unrecognized values will cause `RuntimeError` to be raised. If `ZIP_DEFLATED` is specified but the `zlib` module is not available, `RuntimeError` is also raised. The default is `ZIP_STORED`. If *allowZip64* is `True` `zipfile` will create ZIP files that use the ZIP64 extensions when the zipfile is larger than 2 GB. If it is false (the default) `zipfile` will raise an exception when the ZIP file would require ZIP64 extensions. ZIP64 extensions are disabled by default because the default `zip` and `unzip` commands on Unix (the InfoZIP utilities) don't support these extensions.

Modifié dans la version 2.7.1 : If the file is created with mode `'a'` or `'w'` and then `closed` without adding any files to the archive, the appropriate ZIP structures for an empty archive will be written to the file.

`ZipFile` is also a context manager and therefore supports the `with` statement. In the example, *myzip* is closed after the `with` statement's suite is finished—even if an exception occurs :

```
with ZipFile('spam.zip', 'w') as myzip:
    myzip.write('eggs.txt')
```

Nouveau dans la version 2.7 : Added the ability to use `ZipFile` as a context manager.

`ZipFile.close()`

Close the archive file. You must call `close()` before exiting your program or essential records will not be written.

`ZipFile.getinfo(name)`

Return a `ZipInfo` object with information about the archive member *name*. Calling `getinfo()` for a name not currently contained in the archive will raise a `KeyError`.

`ZipFile.infolist()`

Return a list containing a `ZipInfo` object for each member of the archive. The objects are in the same order as their entries in the actual ZIP file on disk if an existing archive was opened.

`ZipFile.namelist()`

Return a list of archive members by name.

`ZipFile.open(name[, mode[, pwd]])`

Extract a member from the archive as a file-like object (`ZipExtFile`). *name* is the name of the file in the archive, or a `ZipInfo` object. The *mode* parameter, if included, must be one of the following : 'r' (the default), 'U', or 'rU'. Choosing 'U' or 'rU' will enable *universal newline* support in the read-only object. *pwd* is the password used for encrypted files. Calling `open()` on a closed `ZipFile` will raise a `RuntimeError`.

---

**Note :** The file-like object is read-only and provides the following methods : `read()`, `readline()`, `readlines()`, `__iter__()`, `next()`.

---

---

**Note :** If the `ZipFile` was created by passing in a file-like object as the first argument to the constructor, then the object returned by `open()` shares the `ZipFile`'s file pointer. Under these circumstances, the object returned by `open()` should not be used after any additional operations are performed on the `ZipFile` object. If the `ZipFile` was created by passing in a string (the filename) as the first argument to the constructor, then `open()` will create a new file object that will be held by the `ZipExtFile`, allowing it to operate independently of the `ZipFile`.

---

---

**Note :** The `open()`, `read()` and `extract()` methods can take a filename or a `ZipInfo` object. You will appreciate this when trying to read a ZIP file that contains members with duplicate names.

---

Nouveau dans la version 2.6.

`ZipFile.extract(member[, path[, pwd]])`

Extract a member from the archive to the current working directory ; *member* must be its full name or a `ZipInfo` object). Its file information is extracted as accurately as possible. *path* specifies a different directory to extract to. *member* can be a filename or a `ZipInfo` object. *pwd* is the password used for encrypted files.

Returns the normalized path created (a directory or new file).

Nouveau dans la version 2.6.

---

**Note :** If a member filename is an absolute path, a drive/UNC sharepoint and leading (back)slashes will be stripped, e.g. : `///foo/bar` becomes `foo/bar` on Unix, and `C:\foo\bar` becomes `foo\bar` on Windows. And all `".."` components in a member filename will be removed, e.g. : `../../foo../../ba..r` becomes `foo../ba..r`. On Windows illegal characters (`:`, `<`, `>`, `|`, `"`, `?`, and `*`) replaced by underscore (`_`).

---

`ZipFile.extractall([path[, members[, pwd]]])`

Extract all members from the archive to the current working directory. *path* specifies a different directory to extract to. *members* is optional and must be a subset of the list returned by `namelist()`. *pwd* is the password used for encrypted files.

**Avertissement :** Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `".."`.

Modifié dans la version 2.7.4 : The zipfile module attempts to prevent that. See `extract()` note.

Nouveau dans la version 2.6.

`ZipFile.printdir()`

Print a table of contents for the archive to `sys.stdout`.

`ZipFile.setpassword(pwd)`

Set *pwd* as default password to extract encrypted files.

Nouveau dans la version 2.6.

`ZipFile.read(name[, pwd])`

Return the bytes of the file *name* in the archive. *name* is the name of the file in the archive, or a *ZipInfo* object. The archive must be open for read or append. *pwd* is the password used for encrypted files and, if specified, it will override the default password set with *setpassword()*. Calling *read()* on a closed *ZipFile* will raise a *RuntimeError*.

Modifié dans la version 2.6 : *pwd* was added, and *name* can now be a *ZipInfo* object.

`ZipFile.testzip()`

Read all the files in the archive and check their CRC's and file headers. Return the name of the first bad file, or else return `None`. Calling *testzip()* on a closed *ZipFile* will raise a *RuntimeError*.

`ZipFile.write(filename[, arcname[, compress_type]])`

Write the file named *filename* to the archive, giving it the archive name *arcname* (by default, this will be the same as *filename*, but without a drive letter and with leading path separators removed). If given, *compress\_type* overrides the value given for the *compression* parameter to the constructor for the new entry. The archive must be open with mode 'w' or 'a' – calling *write()* on a *ZipFile* created with mode 'r' will raise a *RuntimeError*. Calling *write()* on a closed *ZipFile* will raise a *RuntimeError*.

---

**Note :** There is no official file name encoding for ZIP files. If you have unicode file names, you must convert them to byte strings in your desired encoding before passing them to *write()*. WinZip interprets all file names as encoded in CP437, also known as DOS Latin.

---

---

**Note :** Archive names should be relative to the archive root, that is, they should not start with a path separator.

---

---

**Note :** If *arcname* (or *filename*, if *arcname* is not given) contains a null byte, the name of the file in the archive will be truncated at the null byte.

---

`ZipFile.writestr(zinfo_or_arcname, bytes[, compress_type])`

Write the string *bytes* to the archive; *zinfo\_or\_arcname* is either the file name it will be given in the archive, or a *ZipInfo* instance. If it's an instance, at least the filename, date, and time must be given. If it's a name, the date and time is set to the current date and time. The archive must be opened with mode 'w' or 'a' – calling *writestr()* on a *ZipFile* created with mode 'r' will raise a *RuntimeError*. Calling *writestr()* on a closed *ZipFile* will raise a *RuntimeError*.

If given, *compress\_type* overrides the value given for the *compression* parameter to the constructor for the new entry, or in the *zinfo\_or\_arcname* (if that is a *ZipInfo* instance).

---

**Note :** When passing a *ZipInfo* instance as the *zinfo\_or\_arcname* parameter, the compression method used will be that specified in the *compress\_type* member of the given *ZipInfo* instance. By default, the *ZipInfo* constructor sets this member to *ZIP\_STORED*.

---

Modifié dans la version 2.7 : The *compress\_type* argument.

The following data attributes are also available :

`ZipFile.debug`

The level of debug output to use. This may be set from 0 (the default, no output) to 3 (the most output). Debugging information is written to `sys.stdout`.

**ZipFile.comment**

The comment text associated with the ZIP file. If assigning a comment to a *ZipFile* instance created with mode “a” or “w”, this should be a string no longer than 65535 bytes. Comments longer than this will be truncated in the written archive when *close()* is called.

## 12.4.2 PyZipFile Objects

The *PyZipFile* constructor takes the same parameters as the *ZipFile* constructor. Instances have one method in addition to those of *ZipFile* objects.

**PyZipFile.writepy(pathname[, basename])**

Search for files `*.py` and add the corresponding file to the archive. The corresponding file is a `*.pyo` file if available, else a `*.pyc` file, compiling if necessary. If the pathname is a file, the filename must end with `.py`, and just the (corresponding `*.py[co]`) file is added at the top level (no path information). If the pathname is a file that does not end with `.py`, a *RuntimeError* will be raised. If it is a directory, and the directory is not a package directory, then all the files `*.py[co]` are added at the top level. If the directory is a package directory, then all `*.py[co]` are added under the package name as a file path, and if any subdirectories are package directories, all of these are added recursively. *basename* is intended for internal use only. The *writepy()* method makes archives with file names like this :

<code>string.pyc</code>	<i># Top level name</i>
<code>test/__init__.pyc</code>	<i># Package directory</i>
<code>test/test_support.pyc</code>	<i># Module test.test_support</i>
<code>test/bogus/__init__.pyc</code>	<i># Subpackage directory</i>
<code>test/bogus/myfile.pyc</code>	<i># Submodule test.bogus.myfile</i>

## 12.4.3 ZipInfo Objects

Instances of the *ZipInfo* class are returned by the *getinfo()* and *infolist()* methods of *ZipFile* objects. Each object stores information about a single member of the ZIP archive.

Instances have the following attributes :

**ZipInfo.filename**

Name of the file in the archive.

**ZipInfo.date\_time**

The time and date of the last modification to the archive member. This is a tuple of six values :

Index	Valeur
0	Year ( $\geq 1980$ )
1	Month (one-based)
2	Day of month (one-based)
3	Hours (zero-based)
4	Minutes (zero-based)
5	Seconds (zero-based)

---

**Note :** The ZIP file format does not support timestamps before 1980.

---

**ZipInfo.compress\_type**

Type of compression for the archive member.

**ZipInfo.comment**  
Comment for the individual archive member.

**ZipInfo.extra**  
Expansion field data. The [PKZIP Application Note](#) contains some comments on the internal structure of the data contained in this string.

**ZipInfo.create\_system**  
System which created ZIP archive.

**ZipInfo.create\_version**  
PKZIP version which created ZIP archive.

**ZipInfo.extract\_version**  
PKZIP version needed to extract archive.

**ZipInfo.reserved**  
Must be zero.

**ZipInfo.flag\_bits**  
ZIP flag bits.

**ZipInfo.volume**  
Volume number of file header.

**ZipInfo.internal\_attr**  
Internal attributes.

**ZipInfo.external\_attr**  
External file attributes.

**ZipInfo.header\_offset**  
Byte offset to the file header.

**ZipInfo.CRC**  
CRC-32 of the uncompressed file.

**ZipInfo.compress\_size**  
Size of the compressed data.

**ZipInfo.file\_size**  
Size of the uncompressed file.

#### 12.4.4 Command-Line Interface

The *zipfile* module provides a simple command-line interface to interact with ZIP archives.

If you want to create a new ZIP archive, specify its name after the `-c` option and then list the filename(s) that should be included :

```
$ python -m zipfile -c monty.zip spam.txt eggs.txt
```

Passing a directory is also acceptable :

```
$ python -m zipfile -c monty.zip life-of-brian_1979/
```

If you want to extract a ZIP archive into the specified directory, use the `-e` option :

```
$ python -m zipfile -e monty.zip target-dir/
```

For a list of the files in a ZIP archive, use the `-l` option :

```
$ python -m zipfile -l monty.zip
```

### Command-line options

- l** <zipfile>  
List files in a zipfile.
- c** <zipfile> <source1> ... <sourceN>  
Create zipfile from source files.
- e** <zipfile> <output\_dir>  
Extract zipfile into target directory.
- t** <zipfile>  
Test whether the zipfile is valid or not.

## 12.5 tarfile — Read and write tar archive files

Nouveau dans la version 2.3.

**Code source :** [Lib/tarfile.py](#)

---

The *tarfile* module makes it possible to read and write tar archives, including those using gzip or bz2 compression. Use the *zipfile* module to read or write .zip files, or the higher-level functions in *shutil*.

Some facts and figures :

- reads and writes *gzip* and *bz2* compressed archives if the respective modules are available.
- read/write support for the POSIX.1-1988 (ustar) format.
- read/write support for the GNU tar format including *longname* and *longlink* extensions, read-only support for the *sparse* extension.
- read/write support for the POSIX.1-2001 (pax) format.  
Nouveau dans la version 2.6.
- handles directories, regular files, hardlinks, symbolic links, fifos, character devices and block devices and is able to acquire and restore file information like timestamp, access permissions and owner.

---

**Note :** Handling of multi-stream bzip2 files is not supported. Modules such as *bz2file* let you overcome this.

---

**tarfile.open**(name=None, mode='r', fileobj=None, bufsize=10240, \*\*kwargs)

Return a *TarFile* object for the pathname *name*. For detailed information on *TarFile* objects and the keyword arguments that are allowed, see *TarFile Objects*.

*mode* has to be a string of the form 'filemode[:compression]', it defaults to 'r'. Here is a full list of mode combinations :

mode	action
'r' ou 'r:*	Open for reading with transparent compression (recommended).
'r: '	Open for reading exclusively without compression.
'r:gzip'	Open for reading with gzip compression.
'r:bz2'	Open for reading with bzip2 compression.
'a' ou 'a: '	Open for appending with no compression. The file is created if it does not exist.
'w' ou 'w: '	Open for uncompressed writing.
'w:gzip'	Open for gzip compressed writing.
'w:bz2'	Open for bzip2 compressed writing.

Note that `'a:gz'` or `'a:bz2'` is not possible. If *mode* is not suitable to open a certain (compressed) file for reading, `ReadError` is raised. Use *mode* `'r'` to avoid this. If a compression method is not supported, `CompressionError` is raised.

If *fileobj* is specified, it is used as an alternative to a file object opened for *name*. It is supposed to be at position 0.

For modes `'w:gz'`, `'r:gz'`, `'w:bz2'`, `'r:bz2'`, `tarfile.open()` accepts the keyword argument *compresslevel* (default 9) to specify the compression level of the file.

For special purposes, there is a second format for *mode* : `'filemode|[compression]'`. `tarfile.open()` will return a `TarFile` object that processes its data as a stream of blocks. No random seeking will be done on the file. If given, *fileobj* may be any object that has a `read()` or `write()` method (depending on the *mode*). *bufsize* specifies the blocksize and defaults to `20 * 512` bytes. Use this variant in combination with e.g. `sys.stdin`, a socket file object or a tape device. However, such a `TarFile` object is limited in that it does not allow random access, see *Examples*. The currently possible modes :

Mode	Action
<code>'r *'</code>	Open a <i>stream</i> of tar blocks for reading with transparent compression.
<code>'r '</code>	Open a <i>stream</i> of uncompressed tar blocks for reading.
<code>'r gz'</code>	Open a gzip compressed <i>stream</i> for reading.
<code>'r bz2'</code>	Open a bzip2 compressed <i>stream</i> for reading.
<code>'w '</code>	Open an uncompressed <i>stream</i> for writing.
<code>'w gz'</code>	Open a gzip compressed <i>stream</i> for writing.
<code>'w bz2'</code>	Open a bzip2 compressed <i>stream</i> for writing.

**class** `tarfile.TarFile`

Class for reading and writing tar archives. Do not use this class directly, better use `tarfile.open()` instead. See *TarFile Objects*.

`tarfile.is_tarfile(name)`

Return `True` if *name* is a tar archive file, that the `tarfile` module can read.

**class** `tarfile.TarFileCompat(filename, mode='r', compression=TAR_PLAIN)`

Class for limited access to tar archives with a *zipfile*-like interface. Please consult the documentation of the *zipfile* module for more details. *compression* must be one of the following constants :

**TAR\_PLAIN**

Constant for an uncompressed tar archive.

**TAR\_GZIPPED**

Constant for a *gzip* compressed tar archive.

Obsolète depuis la version 2.6 : The `TarFileCompat` class has been removed in Python 3.

**exception** `tarfile.TarError`

Base class for all `tarfile` exceptions.

**exception** `tarfile.ReadError`

Is raised when a tar archive is opened, that either cannot be handled by the `tarfile` module or is somehow invalid.

**exception** `tarfile.CompressionError`

Is raised when a compression method is not supported or when the data cannot be decoded properly.

**exception** `tarfile.StreamError`

Is raised for the limitations that are typical for stream-like `TarFile` objects.

**exception** `tarfile.ExtractError`

Is raised for *non-fatal* errors when using `TarFile.extract()`, but only if `TarFile.errorlevel== 2`.

The following constants are available at the module level :

`tarfile.ENCODING`

The default character encoding : 'utf-8' on Windows, the value returned by `sys.getfilesystemencoding()` otherwise.

**exception** `tarfile.HeaderError`

Is raised by `TarInfo.frombuf()` if the buffer it gets is invalid.

Nouveau dans la version 2.6.

Each of the following constants defines a tar archive format that the `tarfile` module is able to create. See section *Supported tar formats* for details.

`tarfile.USTAR_FORMAT`

POSIX.1-1988 (ustar) format.

`tarfile.GNU_FORMAT`

GNU tar format.

`tarfile.PAX_FORMAT`

POSIX.1-2001 (pax) format.

`tarfile.DEFAULT_FORMAT`

The default format for creating archives. This is currently `GNU_FORMAT`.

**Voir aussi :**

**Module `zipfile`** Documentation of the `zipfile` standard module.

**Archiving operations** Documentation of the higher-level archiving facilities provided by the standard `shutil` module.

**GNU tar manual, Basic Tar Format** Documentation for tar archive files, including GNU tar extensions.

### 12.5.1 TarFile Objects

The `TarFile` object provides an interface to a tar archive. A tar archive is a sequence of blocks. An archive member (a stored file) is made up of a header block followed by data blocks. It is possible to store a file in a tar archive several times. Each archive member is represented by a `TarInfo` object, see *TarInfo Objects* for details.

A `TarFile` object can be used as a context manager in a `with` statement. It will automatically be closed when the block is completed. Please note that in the event of an exception an archive opened for writing will not be finalized ; only the internally used file object will be closed. See the *Exemples* section for a use case.

Nouveau dans la version 2.7 : Added support for the context management protocol.

```
class tarfile.TarFile(name=None, mode='r', fileobj=None, format=DEFAULT_FORMAT,
                    tarinfo=TarInfo, dereference=False, ignore_zeros=False, encoding=ENCODING,
                    errors=None, pax_headers=None, debug=0, errorlevel=0)
```

All following arguments are optional and can be accessed as instance attributes as well.

`name` is the pathname of the archive. It can be omitted if `fileobj` is given. In this case, the file object's `name` attribute is used if it exists.

`mode` is either 'r' to read from an existing archive, 'a' to append data to an existing file or 'w' to create a new file overwriting an existing one.

If `fileobj` is given, it is used for reading or writing data. If it can be determined, `mode` is overridden by `fileobj`'s mode. `fileobj` will be used from position 0.

---

**Note :** `fileobj` is not closed, when `TarFile` is closed.

---

*format* controls the archive format. It must be one of the constants `USTAR_FORMAT`, `GNU_FORMAT` or `PAX_FORMAT` that are defined at module level.

Nouveau dans la version 2.6.

The *tarinfo* argument can be used to replace the default `TarInfo` class with a different one.

Nouveau dans la version 2.6.

If *dereference* is `False`, add symbolic and hard links to the archive. If it is `True`, add the content of the target files to the archive. This has no effect on systems that do not support symbolic links.

If *ignore\_zeros* is `False`, treat an empty block as the end of the archive. If it is `True`, skip empty (and invalid) blocks and try to get as many members as possible. This is only useful for reading concatenated or damaged archives.

*debug* can be set from 0 (no debug messages) up to 3 (all debug messages). The messages are written to `sys.stderr`.

If *errorlevel* is 0, all errors are ignored when using `TarFile.extract()`. Nevertheless, they appear as error messages in the debug output, when debugging is enabled. If 1, all *fatal* errors are raised as `OSError` or `IOError` exceptions. If 2, all *non-fatal* errors are raised as `TarError` exceptions as well.

The *encoding* and *errors* arguments control the way strings are converted to unicode objects and vice versa. The default settings will work for most users. See section *Unicode issues* for in-depth information.

Nouveau dans la version 2.6.

The *pax\_headers* argument is an optional dictionary of unicode strings which will be added as a pax global header if *format* is `PAX_FORMAT`.

Nouveau dans la version 2.6.

**classmethod** `TarFile.open(...)`

Alternative constructor. The `tarfile.open()` function is actually a shortcut to this classmethod.

`TarFile.getmember(name)`

Return a `TarInfo` object for member *name*. If *name* can not be found in the archive, `KeyError` is raised.

---

**Note :** If a member occurs more than once in the archive, its last occurrence is assumed to be the most up-to-date version.

---

`TarFile.getmembers()`

Return the members of the archive as a list of `TarInfo` objects. The list has the same order as the members in the archive.

`TarFile.getnames()`

Return the members as a list of their names. It has the same order as the list returned by `getmembers()`.

`TarFile.list(verbose=True)`

Print a table of contents to `sys.stdout`. If *verbose* is `False`, only the names of the members are printed. If it is `True`, output similar to that of `ls -l` is produced.

`TarFile.next()`

Return the next member of the archive as a `TarInfo` object, when `TarFile` is opened for reading. Return `None` if there is no more available.

`TarFile.extractall(path=".", members=None)`

Extract all members from the archive to the current working directory or directory *path*. If optional *members* is given, it must be a subset of the list returned by `getmembers()`. Directory information like owner, modification time and permissions are set after all members have been extracted. This is done to work around two problems : A directory's modification time is reset each time a file is created in it. And, if a directory's permissions do not allow writing, extracting files to it will fail.

**Avertissement :** Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with "/" or filenames with two dots ". .".

Nouveau dans la version 2.5.

`TarFile.extract(member, path="")`

Extract a member from the archive to the current working directory, using its full name. Its file information is extracted as accurately as possible. *member* may be a filename or a *TarInfo* object. You can specify a different directory using *path*.

---

**Note :** The *extract()* method does not take care of several extraction issues. In most cases you should consider using the *extractall()* method.

---

**Avertissement :** See the warning for *extractall()*.

`TarFile.extractfile(member)`

Extract a member from the archive as a file object. *member* may be a filename or a *TarInfo* object. If *member* is a regular file, a file-like object is returned. If *member* is a link, a file-like object is constructed from the link's target. If *member* is none of the above, *None* is returned.

---

**Note :** The file-like object is read-only. It provides the methods *read()*, *readline()*, *readlines()*, *seek()*, *tell()*, and *close()*, and also supports iteration over its lines.

---

`TarFile.add(name, arcname=None, recursive=True, exclude=None, filter=None)`

Add the file *name* to the archive. *name* may be any type of file (directory, fifo, symbolic link, etc.). If given, *arcname* specifies an alternative name for the file in the archive. Directories are added recursively by default. This can be avoided by setting *recursive* to *False*. If *exclude* is given it must be a function that takes one filename argument and returns a boolean value. Depending on this value the respective file is either excluded (*True*) or added (*False*). If *filter* is specified it must be a function that takes a *TarInfo* object argument and returns the changed *TarInfo* object. If it instead returns *None* the *TarInfo* object will be excluded from the archive. See *Exemples* for an example.

Modifié dans la version 2.6 : Added the *exclude* parameter.

Modifié dans la version 2.7 : Added the *filter* parameter.

Obsolète depuis la version 2.7 : The *exclude* parameter is deprecated, please use the *filter* parameter instead. For maximum portability, *filter* should be used as a keyword argument rather than as a positional argument so that code won't be affected when *exclude* is ultimately removed.

`TarFile.addfile(tarinfo, fileobj=None)`

Add the *TarInfo* object *tarinfo* to the archive. If *fileobj* is given, *tarinfo.size* bytes are read from it and added to the archive. You can create *TarInfo* objects directly, or by using *gettaringfo()*.

---

**Note :** On Windows platforms, *fileobj* should always be opened with mode 'rb' to avoid irritation about the file size.

---

`TarFile.gettarinfo(name=None, arcname=None, fileobj=None)`

Create a *TarInfo* object from the result of *os.stat()* or equivalent on an existing file. The file is either named by *name*, or specified as a file object *fileobj* with a file descriptor. If given, *arcname* specifies an alternative name for the file in the archive, otherwise, the name is taken from *fileobj*'s *name* attribute, or the *name* argument.

You can modify some of the *TarInfo*'s attributes before you add it using *addfile()*. If the file object is not an ordinary file object positioned at the beginning of the file, attributes such as *size* may need modifying. This is the case for objects such as *GzipFile*. The *name* may also be modified, in which case *arcname* could be a dummy string.

**TarFile.close()**

Close the *TarFile*. In write mode, two finishing zero blocks are appended to the archive.

**TarFile.posix**

Setting this to *True* is equivalent to setting the *format* attribute to *USTAR\_FORMAT*, *False* is equivalent to *GNU\_FORMAT*.

Modifié dans la version 2.4 : *posix* defaults to *False*.

Obsolète depuis la version 2.6 : Use the *format* attribute instead.

**TarFile.pax\_headers**

A dictionary containing key-value pairs of pax global headers.

Nouveau dans la version 2.6.

## 12.5.2 TarInfo Objects

A *TarInfo* object represents one member in a *TarFile*. Aside from storing all required attributes of a file (like file type, size, time, permissions, owner etc.), it provides some useful methods to determine its type. It does *not* contain the file's data itself.

*TarInfo* objects are returned by *TarFile*'s methods *getmember()*, *getmembers()* and *gettartinfo()*.

**class tarfile.TarInfo(name="")**

Create a *TarInfo* object.

**TarInfo.frombuf(buf)**

Create and return a *TarInfo* object from string buffer *buf*.

Nouveau dans la version 2.6 : Raises *HeaderError* if the buffer is invalid..

**TarInfo.fromtarfile(tarfile)**

Read the next member from the *TarFile* object *tarfile* and return it as a *TarInfo* object.

Nouveau dans la version 2.6.

**TarInfo.tobuf(format=DEFAULT\_FORMAT, encoding=ENCODING, errors='strict')**

Create a string buffer from a *TarInfo* object. For information on the arguments see the constructor of the *TarFile* class.

Modifié dans la version 2.6 : The arguments were added.

A *TarInfo* object has the following public data attributes :

**TarInfo.name**

Name of the archive member.

**TarInfo.size**

Size in bytes.

**TarInfo.mtime**

Time of last modification.

**TarInfo.mode**

Permission bits.

**TarInfo.type**

File type. *type* is usually one of these constants : *REGTYPE*, *AREGTYPE*, *LNKTYPE*, *SYMTYPE*, *DIRTYPE*, *FIFOTYPE*, *CONTTYPE*, *CHRTYPE*, *BLKTYPE*, *GNUTYPE\_SPARSE*. To determine the type of a *TarInfo* object more conveniently, use the *is\*()* methods below.

`TarInfo.linkname`

Name of the target file name, which is only present in *TarInfo* objects of type LNKTYPE and SYMTYPE.

`TarInfo.uid`

User ID of the user who originally stored this member.

`TarInfo.gid`

Group ID of the user who originally stored this member.

`TarInfo.uname`

User name.

`TarInfo.gname`

Group name.

`TarInfo.pax_headers`

A dictionary containing key-value pairs of an associated pax extended header.

Nouveau dans la version 2.6.

A *TarInfo* object also provides some convenient query methods :

`TarInfo.isfile()`

Return *True* if the *Tarinfo* object is a regular file.

`TarInfo.isreg()`

Same as *isfile()*.

`TarInfo.isdir()`

Return *True* if it is a directory.

`TarInfo.issym()`

Return *True* if it is a symbolic link.

`TarInfo.islnk()`

Return *True* if it is a hard link.

`TarInfo.ischr()`

Return *True* if it is a character device.

`TarInfo.isblk()`

Return *True* if it is a block device.

`TarInfo.isfifo()`

Return *True* if it is a FIFO.

`TarInfo.isdev()`

Return *True* if it is one of character device, block device or FIFO.

### 12.5.3 Exemples

How to extract an entire tar archive to the current working directory :

```
import tarfile
tar = tarfile.open("sample.tar.gz")
tar.extractall()
tar.close()
```

How to extract a subset of a tar archive with *TarFile.extractall()* using a generator function instead of a list :

```
import os
import tarfile

def py_files(members):
    for tarinfo in members:
        if os.path.splitext(tarinfo.name)[1] == ".py":
            yield tarinfo

tar = tarfile.open("sample.tar.gz")
tar.extractall(members=py_files(tar))
tar.close()
```

How to create an uncompressed tar archive from a list of filenames :

```
import tarfile
tar = tarfile.open("sample.tar", "w")
for name in ["foo", "bar", "quux"]:
    tar.add(name)
tar.close()
```

The same example using the `with` statement :

```
import tarfile
with tarfile.open("sample.tar", "w") as tar:
    for name in ["foo", "bar", "quux"]:
        tar.add(name)
```

How to read a gzip compressed tar archive and display some member information :

```
import tarfile
tar = tarfile.open("sample.tar.gz", "r:gz")
for tarinfo in tar:
    print tarinfo.name, "is", tarinfo.size, "bytes in size and is",
    if tarinfo.isreg():
        print "a regular file."
    elif tarinfo.isdir():
        print "a directory."
    else:
        print "something else."
tar.close()
```

How to create an archive and reset the user information using the *filter* parameter in *TarFile.add()* :

```
import tarfile
def reset(tarinfo):
    tarinfo.uid = tarinfo.gid = 0
    tarinfo.uname = tarinfo.gname = "root"
    return tarinfo
tar = tarfile.open("sample.tar.gz", "w:gz")
tar.add("foo", filter=reset)
tar.close()
```

### 12.5.4 Supported tar formats

There are three tar formats that can be created with the `tarfile` module :

- The POSIX.1-1988 ustar format (*USTAR\_FORMAT*). It supports filenames up to a length of at best 256 characters and linknames up to 100 characters. The maximum file size is 8 gigabytes. This is an old and limited but widely supported format.
- The GNU tar format (*GNU\_FORMAT*). It supports long filenames and linknames, files bigger than 8 gigabytes and sparse files. It is the de facto standard on GNU/Linux systems. `tarfile` fully supports the GNU tar extensions for long names, sparse file support is read-only.
- The POSIX.1-2001 pax format (*PAX\_FORMAT*). It is the most flexible format with virtually no limits. It supports long filenames and linknames, large files and stores pathnames in a portable way. However, not all tar implementations today are able to handle pax archives properly. The *pax* format is an extension to the existing *ustar* format. It uses extra headers for information that cannot be stored otherwise. There are two flavours of pax headers : Extended headers only affect the subsequent file header, global headers are valid for the complete archive and affect all following files. All the data in a pax header is encoded in *UTF-8* for portability reasons.

There are some more variants of the tar format which can be read, but not created :

- The ancient V7 format. This is the first tar format from Unix Seventh Edition, storing only regular files and directories. Names must not be longer than 100 characters, there is no user/group name information. Some archives have miscalculated header checksums in case of fields with non-ASCII characters.
- The SunOS tar extended format. This format is a variant of the POSIX.1-2001 pax format, but is not compatible.

### 12.5.5 Unicode issues

The tar format was originally conceived to make backups on tape drives with the main focus on preserving file system information. Nowadays tar archives are commonly used for file distribution and exchanging archives over networks. One problem of the original format (that all other formats are merely variants of) is that there is no concept of supporting different character encodings. For example, an ordinary tar archive created on a *UTF-8* system cannot be read correctly on a *Latin-1* system if it contains non-ASCII characters. Names (i.e. filenames, linknames, user/group names) containing these characters will appear damaged. Unfortunately, there is no way to autodetect the encoding of an archive.

The pax format was designed to solve this problem. It stores non-ASCII names using the universal character encoding *UTF-8*. When a pax archive is read, these *UTF-8* names are converted to the encoding of the local file system.

The details of unicode conversion are controlled by the *encoding* and *errors* keyword arguments of the *TarFile* class.

The default value for *encoding* is the local character encoding. It is deduced from `sys.getfilesystemencoding()` and `sys.getdefaultencoding()`. In read mode, *encoding* is used exclusively to convert unicode names from a pax archive to strings in the local character encoding. In write mode, the use of *encoding* depends on the chosen archive format. In case of *PAX\_FORMAT*, input names that contain non-ASCII characters need to be decoded before being stored as *UTF-8* strings. The other formats do not make use of *encoding* unless unicode objects are used as input names. These are converted to 8-bit character strings before they are added to the archive.

The *errors* argument defines how characters are treated that cannot be converted to or from *encoding*. Possible values are listed in section *Codec Base Classes*. In read mode, there is an additional scheme '*utf-8*' which means that bad characters are replaced by their *UTF-8* representation. This is the default scheme. In write mode the default value for *errors* is '*strict*' to ensure that name information is not altered unnoticed.

The modules described in this chapter parse various miscellaneous file formats that aren't markup languages or are related to e-mail.

## 13.1 `csv` — Lecture et écriture de fichiers CSV

Nouveau dans la version 2.3.

The so-called CSV (Comma Separated Values) format is the most common import and export format for spreadsheets and databases. There is no « CSV standard », so the format is operationally defined by the many applications which read and write it. The lack of a standard means that subtle differences often exist in the data produced and consumed by different applications. These differences can make it annoying to process CSV files from multiple sources. Still, while the delimiters and quoting characters vary, the overall format is similar enough that it is possible to write a single module which can efficiently manipulate such data, hiding the details of reading and writing the data from the programmer.

Le module `csv` implémente des classes pour lire et écrire des données tabulaires au format CSV. Il vous permet de dire « écris ces données dans le format préféré par Excel » ou « lis les données de ce fichier généré par Excel », sans connaître les détails précis du format CSV utilisé par Excel. Vous pouvez aussi décrire les formats CSV utilisés par d'autres application ou définir vos propres spécialisations.

Les objets `reader` et `writer` du module `csv` lisent et écrivent des séquences. Vous pouvez aussi lire/écrire les données dans un dictionnaire en utilisant les classes `DictReader` et `DictWriter`.

---

**Note :** This version of the `csv` module doesn't support Unicode input. Also, there are currently some issues regarding ASCII NUL characters. Accordingly, all input should be UTF-8 or printable ASCII to be safe ; see the examples in section [Examples](#).

---

**Voir aussi :**

**PEP 305 – Interface des fichiers CSV** La proposition d'amélioration de Python (PEP) qui a proposé cet ajout au langage.

### 13.1.1 Contenu du module

Le module `csv` définit les fonctions suivantes :

`csv.reader(csvfile, dialect='excel', **fmtparams)`

Return a reader object which will iterate over lines in the given *csvfile*. *csvfile* can be any object which supports the *iterator* protocol and returns a string each time its `next()` method is called — file objects and list objects are both suitable. If *csvfile* is a file object, it must be opened with the “b” flag on platforms where that makes a difference. An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the *Dialect* class or one of the strings returned by the *list\_dialects()* function. The other optional *fmtparams* keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section *Dialectes et paramètres de formatage*.

Each row read from the csv file is returned as a list of strings. No automatic data type conversion is performed.

Un court exemple d'utilisation :

```
>>> import csv
>>> with open('eggs.csv', 'rb') as csvfile:
...     spamreader = csv.reader(csvfile, delimiter=' ', quotechar='|')
...     for row in spamreader:
...         print ', '.join(row)
Spam, Spam, Spam, Spam, Spam, Baked Beans
Spam, Lovely Spam, Wonderful Spam
```

Modifié dans la version 2.5 : The parser is now stricter with respect to multi-line quoted fields. Previously, if a line ended within a quoted field without a terminating newline character, a newline would be inserted into the returned field. This behavior caused problems when reading files which contained carriage return characters within fields. The behavior was changed to return the field without inserting newlines. As a consequence, if newlines embedded within fields are important, the input should be split into lines in a manner which preserves the newline characters.

`csv.writer(csvfile, dialect='excel', **fmtparams)`

Return a writer object responsible for converting the user's data into delimited strings on the given file-like object. *csvfile* can be any object with a `write()` method. If *csvfile* is a file object, it must be opened with the “b” flag on platforms where that makes a difference. An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the *Dialect* class or one of the strings returned by the *list\_dialects()* function. The other optional *fmtparams* keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section *Dialectes et paramètres de formatage*. To make it as easy as possible to interface with modules which implement the DB API, the value *None* is written as the empty string. While this isn't a reversible transformation, it makes it easier to dump SQL NULL data values to CSV files without preprocessing the data returned from a `cursor.fetch*` call. Floats are stringified with *repr()* before being written. All other non-string data are stringified with *str()* before being written.

Un court exemple d'utilisation :

```
import csv
with open('eggs.csv', 'wb') as csvfile:
    spamwriter = csv.writer(csvfile, delimiter=' ',
                           quotechar='|', quoting=csv.QUOTE_MINIMAL)
    spamwriter.writerow(['Spam'] * 5 + ['Baked Beans'])
    spamwriter.writerow(['Spam', 'Lovely Spam', 'Wonderful Spam'])
```

`csv.register_dialect(name[, dialect], **fmtparams)`

Associate *dialect* with *name*. *name* must be a string or Unicode object. The dialect can be specified either by passing a sub-class of *Dialect*, or by *fmtparams* keyword arguments, or both, with keyword arguments overriding parameters of the dialect. For full details about the dialect and formatting parameters, see section *Dialectes et paramètres de formatage*.

`csv.unregister_dialect(name)`

Supprime le dialecte associé à *name* depuis le registre des dialectes. Une *Error* est levée si *name* n'est pas un nom de dialecte enregistré.

`csv.get_dialect(name)`

Return the dialect associated with *name*. An *Error* is raised if *name* is not a registered dialect name.

Modifié dans la version 2.5 : This function now returns an immutable *Dialect*. Previously an instance of the requested dialect was returned. Users could modify the underlying class, changing the behavior of active readers and writers.

`csv.list_dialects()`

Renvoie les noms de tous les dialectes enregistrés.

`csv.field_size_limit([new_limit])`

Renvoie la taille de champ maximale courante autorisée par l'analyseur. Si *new\_limit* est donnée, elle devient la nouvelle limite.

Nouveau dans la version 2.5.

Le module *csv* définit les classes suivantes :

`class csv.DictReader(f, fieldnames=None, restkey=None, restval=None, dialect='excel', *args, **kws)`

Create an object which operates like a regular reader but maps the information read into a dict whose keys are given by the optional *fieldnames* parameter. The *fieldnames* parameter is a *sequence* whose elements are associated with the fields of the input data in order. These elements become the keys of the resulting dictionary. If the *fieldnames* parameter is omitted, the values in the first row of the file *f* will be used as the fieldnames. If the row read has more fields than the fieldnames sequence, the remaining data is added as a sequence keyed by the value of *restkey*. If the row read has fewer fields than the fieldnames sequence, the remaining keys take the value of the optional *restval* parameter. Any other optional or keyword arguments are passed to the underlying *reader* instance.

Un court exemple d'utilisation :

```
>>> import csv
>>> with open('names.csv') as csvfile:
...     reader = csv.DictReader(csvfile)
...     for row in reader:
...         print(row['first_name'], row['last_name'])
...
Baked Beans
Lovely Spam
Wonderful Spam
```

`class csv.DictWriter(f, fieldnames, restval="", extrasaction='raise', dialect='excel', *args, **kws)`

Create an object which operates like a regular writer but maps dictionaries onto output rows. The *fieldnames* parameter is a *sequence* of keys that identify the order in which values in the dictionary passed to the *writerow()* method are written to the file *f*. The optional *restval* parameter specifies the value to be written if the dictionary is missing a key in *fieldnames*. If the dictionary passed to the *writerow()* method contains a key not found in *fieldnames*, the optional *extrasaction* parameter indicates what action to take. If it is set to 'raise' a *ValueError* is raised. If it is set to 'ignore', extra values in the dictionary are ignored. Any other optional or keyword arguments are passed to the underlying *writer* instance.

Note that unlike the *DictReader* class, the *fieldnames* parameter of the *DictWriter* is not optional. Since Python's *dict* objects are not ordered, there is not enough information available to deduce the order in which the row should be written to the file *f*.

Un court exemple d'utilisation :

```
import csv

with open('names.csv', 'w') as csvfile:
    fieldnames = ['first_name', 'last_name']
    writer = csv.DictWriter(csvfile, fieldnames=fieldnames)

    writer.writeheader()
    writer.writerow({'first_name': 'Baked', 'last_name': 'Beans'})
    writer.writerow({'first_name': 'Lovely', 'last_name': 'Spam'})
    writer.writerow({'first_name': 'Wonderful', 'last_name': 'Spam'})
```

#### **class** csv.Dialect

La classe *Dialect* est une classe de conteneurs utilisée principalement pour ses attributs, qui servent à définir des paramètres pour des instances spécifiques de *reader* ou *writer*.

#### **class** csv.excel

La classe *excel* définit les propriétés usuelles d'un fichier CSV généré par Excel. Elle est enregistrée avec le nom de dialecte 'excel'.

#### **class** csv.excel\_tab

La classe *excel\_tab* définit les propriétés usuelles d'un fichier CSV généré par Excel avec des tabulations comme séparateurs. Elle est enregistrée avec le nom de dialecte 'excel-tab'.

#### **class** csv.Sniffer

La classe *Sniffer* est utilisée pour déduire le format d'un fichier CSV.

La classe *Sniffer* fournit deux méthodes :

**sniff**(*sample*, *delimiters=None*)

Analyse l'extrait donné (*sample*) et renvoie une sous-classe *Dialect* reflétant les paramètres trouvés. Si le paramètre optionnel *delimiters* est donné, il est interprété comme une chaîne contenant tous les caractères valides de séparation possibles.

**has\_header**(*sample*)

Analyse l'extrait de texte (présupposé être au format CSV) et renvoie *True* si la première ligne semble être une série d'en-têtes de colonnes.

Un exemple d'utilisation de *Sniffer* :

```
with open('example.csv', 'rb') as csvfile:
    dialect = csv.Sniffer().sniff(csvfile.read(1024))
    csvfile.seek(0)
    reader = csv.reader(csvfile, dialect)
    # ... process CSV file contents here ...
```

Le module *csv* définit les constantes suivantes :

#### **csv.QUOTE\_ALL**

Indique aux objets *writer* de délimiter tous les champs par des guillemets.

#### **csv.QUOTE\_MINIMAL**

Indique aux objets *writer* de ne délimiter ainsi que les champs contenant un caractère spécial comme *delimiter*, *quotechar* ou n'importe quel caractère de *lineterminator*.

#### **csv.QUOTE\_NONNUMERIC**

Indique aux objets *writer* de délimiter ainsi tous les champs non-numériques.

Indique au lecteur de convertir tous les champs non délimités par des guillemets vers des *float*.

#### `csv.QUOTE_NONE`

Indique aux objets *writer* de ne jamais délimiter les champs par des guillemets. Quand le *delimiter* courant apparaît dans les données, il est précédé sur la sortie par un caractère *escapechar*. Si *escapechar* n'est pas précisé, le transcritteur lèvera une *Error* si un caractère nécessitant un échappement est rencontré.

Indique au *reader* de ne pas opérer de traitement spécial sur les guillemets.

Le module *csv* définit les exceptions suivantes :

#### `exception csv.Error`

Levée par les fonctions du module quand une erreur détectée.

### 13.1.2 Dialectes et paramètres de formatage

Pour faciliter la spécification du format des entrées et sorties, les paramètres de formatage spécifiques sont regroupés en dialectes. Un dialecte est une sous-classe de *Dialect* avec un ensemble de méthodes spécifiques et une méthode *validate()*. Quand un objet *reader* ou *writer* est créé, vous pouvez spécifier une chaîne ou une sous-classe de *Dialect* comme paramètre *dialect*. En plus du paramètre *dialect*, ou à sa place, vous pouvez aussi préciser des paramètres de formatage individuels, qui ont les mêmes noms que les attributs de *Dialect* définis ci-dessous.

Les dialectes supportent les attributs suivants :

#### `Dialect.delimiter`

Une chaîne d'un seul caractère utilisée pour séparer les champs. Elle vaut *' , '* par défaut.

#### `Dialect.doublequote`

Contrôle comment les caractères *quotechar* dans le champ doivent être retranscrits. Quand ce paramètre vaut *True*, le caractère est doublé. Quand il vaut *False*, le caractère *escapechar* est utilisé comme préfixe à *quotechar*. Il vaut *True* par défaut.

En écriture, si *doublequote* vaut *False* et qu'aucun *escapechar* n'est précisé, une *Error* est levée si un *quotechar* est trouvé dans le champ.

#### `Dialect.escapechar`

Une chaîne d'un seul caractère utilisée par le transcritteur pour échapper *delimiter* si *quoting* vaut *QUOTE\_NONE*, et pour échapper *quotechar* si *doublequote* vaut *False*. À la lecture, *escapechar* retire toute signification spéciale au caractère qui le suit. Elle vaut par défaut *None*, ce qui désactive l'échappement.

#### `Dialect.lineterminator`

La chaîne utilisée pour terminer les lignes produites par un *writer*. Elle vaut par défaut *'\r\n'*.

---

**Note :** La classe *reader* est codée en dur pour reconnaître *'\r'* et *'\n'* comme marqueurs de fin de ligne, et ignorer *lineterminator*. Ce comportement pourrait changer dans le futur.

---

#### `Dialect.quotechar`

Une chaîne d'un seul caractère utilisée pour délimiter les champs contenant des caractères spéciaux, comme *delimiter* ou *quotechar*, ou contenant un caractère de fin de ligne. Elle vaut *'"'* par défaut.

#### `Dialect.quoting`

Contrôle quand les guillemets doivent être générés par le transcritteur et reconnus par le lecteur. Il peut prendre comme valeur l'une des constantes *QUOTE\_\** (voir la section *Contenu du module*) et vaut par défaut *QUOTE\_MINIMAL*.

#### `Dialect.skipinitialspace`

Quand il vaut *True*, les espaces suivant directement *delimiter* sont ignorés. Il vaut *False* par défaut.

`Dialect.strict`

Quand il vaut `True`, une exception *Error* est levée lors de mauvaises entrées CSV. Il vaut `False` par défaut.

### 13.1.3 Objets lecteurs

Les objets lecteurs (instances de *DictReader* ou objets renvoyés par la fonction *reader()*) ont les méthodes publiques suivantes :

`csvreader.next()`

Return the next row of the reader's iterable object as a list, parsed according to the current dialect.

Les objets lecteurs ont les attributs publics suivants :

`csvreader.dialect`

Une description en lecture seule du dialecte utilisé par l'analyseur.

`csvreader.line_num`

Le nombre de lignes lues depuis l'itérateur source. Ce n'est pas équivalent au nombre d'enregistrements renvoyés, puisque certains enregistrements peuvent s'étendre sur plusieurs lignes.

Nouveau dans la version 2.5.

Les objets *DictReader* ont les attributs publics suivants :

`csvreader.fieldnames`

S'il n'est pas passé comme paramètre à la création de l'objet, cet attribut est initialisé lors du premier accès ou quand le premier enregistrement est lu depuis le fichier.

Modifié dans la version 2.6.

### 13.1.4 Objets transpositeurs

*Writer* objects (*DictWriter* instances and objects returned by the *writer()* function) have the following public methods. A *row* must be a sequence of strings or numbers for *Writer* objects and a dictionary mapping fieldnames to strings or numbers (by passing them through *str()* first) for *DictWriter* objects. Note that complex numbers are written out surrounded by parens. This may cause some problems for other programs which read CSV files (assuming they support complex numbers at all).

`csvwriter.writerow(row)`

Écrit le paramètre *row* vers le fichier associé au transpositeur, formaté selon le dialecte courant.

`csvwriter.writerows(rows)`

Write all elements in *rows* (an iterable of *row* objects as described above) to the writer's file object, formatted according to the current dialect.

Les objets transpositeurs ont les attributs publics suivants :

`csvwriter.dialect`

Une description en lecture seule du dialecte utilisé par le transpositeur.

Les objets *DictWriter* ont les attributs publics suivants :

`DictWriter.writeheader()`

Écrit une ligne contenant les noms de champs (comme spécifiés au constructeur).

Nouveau dans la version 2.7.

### 13.1.5 Exemples

Le plus simple exemple de lecture d'un fichier CSV :

```
import csv
with open('some.csv', 'rb') as f:
    reader = csv.reader(f)
    for row in reader:
        print row
```

Lire un fichier avec un format alternatif :

```
import csv
with open('passwd', 'rb') as f:
    reader = csv.reader(f, delimiter=':', quoting=csv.QUOTE_NONE)
    for row in reader:
        print row
```

Le plus simple exemple d'écriture correspondant est :

```
import csv
with open('some.csv', 'wb') as f:
    writer = csv.writer(f)
    writer.writerows(someiterable)
```

Enregistrer un nouveau dialecte :

```
import csv
csv.register_dialect('unixpwd', delimiter=':', quoting=csv.QUOTE_NONE)
with open('passwd', 'rb') as f:
    reader = csv.reader(f, 'unixpwd')
```

Un exemple d'utilisation un peu plus avancé du lecteur — attrapant et notifiant les erreurs :

```
import csv, sys
filename = 'some.csv'
with open(filename, 'rb') as f:
    reader = csv.reader(f)
    try:
        for row in reader:
            print row
    except csv.Error as e:
        sys.exit('file %s, line %d: %s' % (filename, reader.line_num, e))
```

Et bien que le module ne permette pas d'analyser directement des chaînes, cela peut être fait facilement :

```
import csv
for row in csv.reader(['one,two,three']):
    print row
```

The `csv` module doesn't directly support reading and writing Unicode, but it is 8-bit-clean save for some problems with ASCII NUL characters. So you can write functions or classes that handle the encoding and decoding for you as long as you avoid encodings like UTF-16 that use NULs. UTF-8 is recommended.

`unicode_csv_reader()` below is a *generator* that wraps `csv.reader` to handle Unicode CSV data (a list of Unicode strings). `utf_8_encoder()` is a *generator* that encodes the Unicode strings as UTF-8, one string (or row) at a time. The encoded strings are parsed by the CSV reader, and `unicode_csv_reader()` decodes the UTF-8-encoded cells back into Unicode :

```
import csv

def unicode_csv_reader(unicode_csv_data, dialect=csv.excel, **kwargs):
    # csv.py doesn't do Unicode; encode temporarily as UTF-8:
    csv_reader = csv.reader(utf_8_encoder(unicode_csv_data),
                            dialect=dialect, **kwargs)

    for row in csv_reader:
        # decode UTF-8 back to Unicode, cell by cell:
        yield [unicode(cell, 'utf-8') for cell in row]

def utf_8_encoder(unicode_csv_data):
    for line in unicode_csv_data:
        yield line.encode('utf-8')
```

For all other encodings the following `UnicodeReader` and `UnicodeWriter` classes can be used. They take an additional *encoding* parameter in their constructor and make sure that the data passes the real reader or writer encoded as UTF-8 :

```
import csv, codecs, cStringIO

class UTF8Recoder:
    """
    Iterator that reads an encoded stream and reencodes the input to UTF-8
    """
    def __init__(self, f, encoding):
        self.reader = codecs.getreader(encoding)(f)

    def __iter__(self):
        return self

    def next(self):
        return self.reader.next().encode("utf-8")

class UnicodeReader:
    """
    A CSV reader which will iterate over lines in the CSV file "f",
    which is encoded in the given encoding.
    """
    def __init__(self, f, dialect=csv.excel, encoding="utf-8", **kwds):
        f = UTF8Recoder(f, encoding)
        self.reader = csv.reader(f, dialect=dialect, **kwds)

    def next(self):
        row = self.reader.next()
        return [unicode(s, "utf-8") for s in row]

    def __iter__(self):
        return self

class UnicodeWriter:
    """
    A CSV writer which will write rows to CSV file "f",
```

(suite sur la page suivante)

(suite de la page précédente)

```

which is encoded in the given encoding.
"""

def __init__(self, f, dialect=csv.excel, encoding="utf-8", **kwds):
    # Redirect output to a queue
    self.queue = cStringIO.StringIO()
    self.writer = csv.writer(self.queue, dialect=dialect, **kwds)
    self.stream = f
    self.encoder = codecs.getincrementalencoder(encoding)()

def writerow(self, row):
    self.writer.writerow([s.encode("utf-8") for s in row])
    # Fetch UTF-8 output from the queue ...
    data = self.queue.getvalue()
    data = data.decode("utf-8")
    # ... and reencode it into the target encoding
    data = self.encoder.encode(data)
    # write to the target stream
    self.stream.write(data)
    # empty queue
    self.queue.truncate(0)

def writerows(self, rows):
    for row in rows:
        self.writerow(row)

```

## 13.2 ConfigParser — Configuration file parser

**Note :** The *ConfigParser* module has been renamed to `configparser` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

This module defines the class *ConfigParser*. The *ConfigParser* class implements a basic configuration file parser language which provides a structure similar to what you would find on Microsoft Windows INI files. You can use this to write Python programs which can be customized by end users easily.

**Note :** This library does *not* interpret or write the value-type prefixes used in the Windows Registry extended version of INI syntax.

**Voir aussi :**

**Module *shlex*** Support for creating Unix shell-like mini-languages which can be used as an alternate format for application configuration files.

**Module *json*** The *json* module implements a subset of JavaScript syntax which can also be used for this purpose.

The configuration file consists of sections, led by a `[section]` header and followed by `name: value` entries, with continuations in the style of [RFC 822](#) (see section 3.1.1, « LONG HEADER FIELDS »); `name=value` is also accepted. Note that leading whitespace is removed from values. The optional values can contain format strings which refer to other values in the same section, or values in a special `DEFAULT` section. Additional

defaults can be provided on initialization and retrieval. Lines beginning with '#' or ';' are ignored and may be used to provide comments.

Configuration files may include comments, prefixed by specific characters (# and ;). Comments may appear on their own in an otherwise empty line, or may be entered in lines holding values or section names. In the latter case, they need to be preceded by a whitespace character to be recognized as a comment. (For backwards compatibility, only ; starts an inline comment, while # does not.)

On top of the core functionality, *SafeConfigParser* supports interpolation. This means values can contain format strings which refer to other values in the same section, or values in a special DEFAULT section. Additional defaults can be provided on initialization.

Par exemple :

```
[My Section]
foodir: %(dir)s/whatever
dir=frob
long: this value continues
    in the next line
```

would resolve the %(dir)s to the value of dir (frob in this case). All reference expansions are done on demand.

Default values can be specified by passing them into the *ConfigParser* constructor as a dictionary. Additional defaults may be passed into the *get()* method which will override all others.

Sections are normally stored in a built-in dictionary. An alternative dictionary type can be passed to the *ConfigParser* constructor. For example, if a dictionary type is passed that sorts its keys, the sections will be sorted on write-back, as will be the keys within each section.

**class** *ConfigParser.RawConfigParser*([*defaults*[, *dict\_type*[, *allow\_no\_value*]]])

The basic configuration object. When *defaults* is given, it is initialized into the dictionary of intrinsic defaults. When *dict\_type* is given, it will be used to create the dictionary objects for the list of sections, for the options within a section, and for the default values. When *allow\_no\_value* is true (default : **False**), options without values are accepted; the value presented for these is **None**.

This class does not support the magical interpolation behavior.

All option names are passed through the *optionxform()* method. Its default implementation converts option names to lower case.

Nouveau dans la version 2.3.

Modifié dans la version 2.6 : *dict\_type* was added.

Modifié dans la version 2.7 : The default *dict\_type* is *collections.OrderedDict*. *allow\_no\_value* was added.

**class** *ConfigParser.ConfigParser*([*defaults*[, *dict\_type*[, *allow\_no\_value*]]])

Derived class of *RawConfigParser* that implements the magical interpolation feature and adds optional arguments to the *get()* and *items()* methods. The values in *defaults* must be appropriate for the %( )s string interpolation. Note that *\_\_name\_\_* is an intrinsic default; its value is the section name, and will override any value provided in *defaults*.

All option names used in interpolation will be passed through the *optionxform()* method just like any other option name reference. Using the default implementation of *optionxform()*, the values foo %(bar)s and foo %(BAR)s are equivalent.

Nouveau dans la version 2.3.

Modifié dans la version 2.6 : *dict\_type* was added.

Modifié dans la version 2.7 : The default *dict\_type* is *collections.OrderedDict*. *allow\_no\_value* was added.

```
class ConfigParser.SafeConfigParser([defaults[, dict_type[, allow_no_value]]])
```

Derived class of *ConfigParser* that implements a more-sane variant of the magical interpolation feature. This implementation is more predictable as well. New applications should prefer this version if they don't need to be compatible with older versions of Python.

Nouveau dans la version 2.3.

Modifié dans la version 2.6 : *dict\_type* was added.

Modifié dans la version 2.7 : The default *dict\_type* is *collections.OrderedDict*. *allow\_no\_value* was added.

```
exception ConfigParser.Error
```

Base class for all other configparser exceptions.

```
exception ConfigParser.NoSectionError
```

Exception raised when a specified section is not found.

```
exception ConfigParser.DuplicateSectionError
```

Exception raised if *add\_section()* is called with the name of a section that is already present.

```
exception ConfigParser.NoOptionError
```

Exception raised when a specified option is not found in the specified section.

```
exception ConfigParser.InterpolationError
```

Base class for exceptions raised when problems occur performing string interpolation.

```
exception ConfigParser.InterpolationDepthError
```

Exception raised when string interpolation cannot be completed because the number of iterations exceeds *MAX\_INTERPOLATION\_DEPTH*. Subclass of *InterpolationError*.

```
exception ConfigParser.InterpolationMissingOptionError
```

Exception raised when an option referenced from a value does not exist. Subclass of *InterpolationError*.

Nouveau dans la version 2.3.

```
exception ConfigParser.InterpolationSyntaxError
```

Exception raised when the source text into which substitutions are made does not conform to the required syntax. Subclass of *InterpolationError*.

Nouveau dans la version 2.3.

```
exception ConfigParser.MissingSectionHeaderError
```

Exception raised when attempting to parse a file which has no section headers.

```
exception ConfigParser.ParsingError
```

Exception raised when errors occur attempting to parse a file.

```
ConfigParser.MAX_INTERPOLATION_DEPTH
```

The maximum depth for recursive interpolation for *get()* when the *raw* parameter is false. This is relevant only for the *ConfigParser* class.

**Voir aussi :**

Module *shlex* Support for a creating Unix shell-like mini-languages which can be used as an alternate format for application configuration files.

### 13.2.1 RawConfigParser Objects

*RawConfigParser* instances have the following methods :

```
RawConfigParser.defaults()
```

Return a dictionary containing the instance-wide defaults.

`RawConfigParser.sections()`

Return a list of the sections available; `DEFAULT` is not included in the list.

`RawConfigParser.add_section(section)`

Add a section named *section* to the instance. If a section by the given name already exists, `DuplicateSectionError` is raised. If the name `DEFAULT` (or any of its case-insensitive variants) is passed, `ValueError` is raised.

`RawConfigParser.has_section(section)`

Indicates whether the named section is present in the configuration. The `DEFAULT` section is not acknowledged.

`RawConfigParser.options(section)`

Returns a list of options available in the specified *section*.

`RawConfigParser.has_option(section, option)`

If the given section exists, and contains the given option, return `True`; otherwise return `False`.

Nouveau dans la version 1.6.

`RawConfigParser.read(filenamees)`

Attempt to read and parse a list of filenames, returning a list of filenames which were successfully parsed. If *filenamees* is a string or Unicode string, it is treated as a single filename. If a file named in *filenamees* cannot be opened, that file will be ignored. This is designed so that you can specify a list of potential configuration file locations (for example, the current directory, the user's home directory, and some system-wide directory), and all existing configuration files in the list will be read. If none of the named files exist, the `ConfigParser` instance will contain an empty dataset. An application which requires initial values to be loaded from a file should load the required file or files using `readfp()` before calling `read()` for any optional files :

```
import ConfigParser, os

config = ConfigParser.ConfigParser()
config.readfp(open('defaults.cfg'))
config.read(['site.cfg', os.path.expanduser('~/.myapp.cfg')])
```

Modifié dans la version 2.4 : Returns list of successfully parsed filenames.

`RawConfigParser.readfp(fp[, filename])`

Read and parse configuration data from the file or file-like object in *fp* (only the `readline()` method is used). If *filename* is omitted and *fp* has a `name` attribute, that is used for *filename*; the default is `<??>`.

`RawConfigParser.get(section, option)`

Get an *option* value for the named *section*.

`RawConfigParser.getint(section, option)`

A convenience method which coerces the *option* in the specified *section* to an integer.

`RawConfigParser.getfloat(section, option)`

A convenience method which coerces the *option* in the specified *section* to a floating point number.

`RawConfigParser.getboolean(section, option)`

A convenience method which coerces the *option* in the specified *section* to a Boolean value. Note that the accepted values for the option are "1", "yes", "true", and "on", which cause this method to return `True`, and "0", "no", "false", and "off", which cause it to return `False`. These string values are checked in a case-insensitive manner. Any other value will cause it to raise `ValueError`.

`RawConfigParser.items(section)`

Return a list of (name, value) pairs for each option in the given *section*.

`RawConfigParser.set(section, option, value)`

If the given section exists, set the given option to the specified value; otherwise raise `NoSectionError`. While it is possible to use `RawConfigParser` (or `ConfigParser` with `raw` parameters set to true) for *internal* storage of non-string values, full functionality (including interpolation and output to files) can only be achieved using string values.

Nouveau dans la version 1.6.

`RawConfigParser.write(fileobject)`

Write a representation of the configuration to the specified file object. This representation can be parsed by a future `read()` call.

Nouveau dans la version 1.6.

`RawConfigParser.remove_option(section, option)`

Remove the specified *option* from the specified *section*. If the section does not exist, raise `NoSectionError`. If the option existed to be removed, return `True`; otherwise return `False`.

Nouveau dans la version 1.6.

`RawConfigParser.remove_section(section)`

Remove the specified *section* from the configuration. If the section in fact existed, return `True`. Otherwise return `False`.

`RawConfigParser.optionxform(option)`

Transforms the option name *option* as found in an input file or as passed in by client code to the form that should be used in the internal structures. The default implementation returns a lower-case version of *option*; subclasses may override this or client code can set an attribute of this name on instances to affect this behavior.

You don't necessarily need to subclass a `ConfigParser` to use this method, you can also re-set it on an instance, to a function that takes a string argument. Setting it to `str`, for example, would make option names case sensitive :

```
cfgparser = ConfigParser()
...
cfgparser.optionxform = str
```

Note that when reading configuration files, whitespace around the option names are stripped before `optionxform()` is called.

### 13.2.2 ConfigParser Objects

The `ConfigParser` class extends some methods of the `RawConfigParser` interface, adding some optional arguments.

`ConfigParser.get(section, option[, raw[, vars]])`

Get an *option* value for the named *section*. If *vars* is provided, it must be a dictionary. The *option* is looked up in *vars* (if provided), *section*, and in *defaults* in that order.

All the '%' interpolations are expanded in the return values, unless the *raw* argument is true. Values for interpolation keys are looked up in the same manner as the option.

`ConfigParser.items(section[, raw[, vars]])`

Return a list of (name, value) pairs for each option in the given *section*. Optional arguments have the same meaning as for the `get()` method.

Nouveau dans la version 2.3.

### 13.2.3 SafeConfigParser Objects

The `SafeConfigParser` class implements the same extended interface as `ConfigParser`, with the following addition :

`SafeConfigParser.set(section, option, value)`

If the given section exists, set the given option to the specified value ; otherwise raise *NoSectionError*. *value* must be a string (*str* or *unicode*) ; if not, *TypeError* is raised.

Nouveau dans la version 2.4.

### 13.2.4 Exemples

An example of writing to a configuration file :

```
import ConfigParser

config = ConfigParser.RawConfigParser()

# When adding sections or items, add them in the reverse order of
# how you want them to be displayed in the actual file.
# In addition, please note that using RawConfigParser's and the raw
# mode of ConfigParser's respective set functions, you can assign
# non-string values to keys internally, but will receive an error
# when attempting to write to a file or when you get it in non-row
# mode. SafeConfigParser does not allow such assignments to take place.
config.add_section('Section1')
config.set('Section1', 'an_int', '15')
config.set('Section1', 'a_bool', 'true')
config.set('Section1', 'a_float', '3.1415')
config.set('Section1', 'baz', 'fun')
config.set('Section1', 'bar', 'Python')
config.set('Section1', 'foo', '%(bar)s is %(baz)s!')

# Writing our configuration file to 'example.cfg'
with open('example.cfg', 'wb') as configfile:
    config.write(configfile)
```

An example of reading the configuration file again :

```
import ConfigParser

config = ConfigParser.RawConfigParser()
config.read('example.cfg')

# getfloat() raises an exception if the value is not a float
# getint() and getboolean() also do this for their respective types
a_float = config.getfloat('Section1', 'a_float')
an_int = config.getint('Section1', 'an_int')
print a_float + an_int

# Notice that the next output does not interpolate '%(bar)s' or '%(baz)s'.
# This is because we are using a RawConfigParser().
if config.getboolean('Section1', 'a_bool'):
    print config.get('Section1', 'foo')
```

To get interpolation, you will need to use a *ConfigParser* or *SafeConfigParser* :

```
import ConfigParser
```

(suite sur la page suivante)

(suite de la page précédente)

```

config = ConfigParser.ConfigParser()
config.read('example.cfg')

# Set the third, optional argument of get to 1 if you wish to use raw mode.
print config.get('Section1', 'foo', 0) # -> "Python is fun!"
print config.get('Section1', 'foo', 1) # -> "%(bar)s is %(baz)s!"

# The optional fourth argument is a dict with members that will take
# precedence in interpolation.
print config.get('Section1', 'foo', 0, {'bar': 'Documentation',
                                       'baz': 'evil'})

```

Defaults are available in all three types of ConfigParsers. They are used in interpolation if an option used is not defined elsewhere.

```

import ConfigParser

# New instance with 'bar' and 'baz' defaulting to 'Life' and 'hard' each
config = ConfigParser.SafeConfigParser({'bar': 'Life', 'baz': 'hard'})
config.read('example.cfg')

print config.get('Section1', 'foo') # -> "Python is fun!"
config.remove_option('Section1', 'bar')
config.remove_option('Section1', 'baz')
print config.get('Section1', 'foo') # -> "Life is hard!"

```

The function `opt_move` below can be used to move options between sections :

```

def opt_move(config, section1, section2, option):
    try:
        config.set(section2, option, config.get(section1, option, 1))
    except ConfigParser.NoSectionError:
        # Create non-existent section
        config.add_section(section2)
        opt_move(config, section1, section2, option)
    else:
        config.remove_option(section1, option)

```

Some configuration files are known to include settings without values, but which otherwise conform to the syntax supported by `ConfigParser`. The `allow_no_value` parameter to the constructor can be used to indicate that such values should be accepted :

```

>>> import ConfigParser
>>> import io

>>> sample_config = """
... [mysqld]
... user = mysql
... pid-file = /var/run/mysqld/mysqld.pid
... skip-external-locking
... old_passwords = 1
... skip-bdb

```

(suite sur la page suivante)

(suite de la page précédente)

```

... skip-innodb
... """
>>> config = ConfigParser.RawConfigParser(allow_no_value=True)
>>> config.readfp(io.BytesIO(sample_config))

>>> # Settings with values are treated as before:
>>> config.get("mysqld", "user")
'mysql'

>>> # Settings without values provide None:
>>> config.get("mysqld", "skip-bdb")

>>> # Settings which aren't specified still raise an error:
>>> config.get("mysqld", "does-not-exist")
Traceback (most recent call last):
...
ConfigParser.NoOptionError: No option 'does-not-exist' in section: 'mysqld'

```

## 13.3 robotparser — Parser for robots.txt

**Note :** The *robotparser* module has been renamed `urllib.robotparser` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

Ce module fournit une simple classe, *RobotFileParser*, qui permet de savoir si un *user-agent* particulier peut accéder à une URL du site web qui a publié ce fichier `robots.txt`. Pour plus de détails sur la structure des fichiers `robots.txt`, voir <http://www.robotstxt.org/orig.html>.

**class** `robotparser.RobotFileParser(url=)`

Cette classe fournit des méthodes pour lire, analyser et répondre aux questions à propos du fichier `robots.txt` disponible à l'adresse `url`.

**set\_url(url)**

Modifie l'URL référençant le fichier `robots.txt`.

**read()**

Lit le fichier `robots.txt` depuis son URL et envoie le contenu à l'analyseur.

**parse(lines)**

Analyse les lignes données en argument.

**can\_fetch(useragent, url)**

Renvoie `True` si *useragent* est autorisé à accéder à `url` selon les règles contenues dans le fichier `robots.txt` analysé.

**mtime()**

Renvoie le temps auquel le fichier `robots.txt` a été téléchargé pour la dernière fois. Cela est utile pour des *web spiders* de longue durée qui doivent vérifier périodiquement si le fichier est mis à jour.

**modified()**

Indique que le fichier `robots.txt` a été téléchargé pour la dernière fois au temps courant.

The following example demonstrates basic use of the `RobotFileParser` class.

```

>>> import robotparser
>>> rp = robotparser.RobotFileParser()

```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> rp.set_url("http://www.musi-cal.com/robots.txt")
>>> rp.read()
>>> rp.can_fetch("*", "http://www.musi-cal.com/cgi-bin/search?city=San+Francisco")
False
>>> rp.can_fetch("*", "http://www.musi-cal.com/")
True
```

## 13.4 netrc — traitement de fichier *netrc*

Nouveau dans la version 1.5.2.

Code source : [Lib/netrc.py](#)

The *netrc* class parses and encapsulates the netrc file format used by the Unix **ftp** program and other FTP clients.

**class netrc.netrc**(*[file]*)

A *netrc* instance or subclass instance encapsulates data from a netrc file. The initialization argument, if present, specifies the file to parse. If no argument is given, the file *.netrc* in the user's home directory will be read. Parse errors will raise *NetrcParseError* with diagnostic information including the file name, line number, and terminating token. If no argument is specified on a POSIX system, the presence of passwords in the *.netrc* file will raise a *NetrcParseError* if the file ownership or permissions are insecure (owned by a user other than the user running the process, or accessible for read or write by any other user). This implements security behavior equivalent to that of ftp and other programs that use *.netrc*.

Modifié dans la version 2.7.6 : Added the POSIX permissions check.

**exception netrc.NetrcParseError**

Exception raised by the *netrc* class when syntactical errors are encountered in source text. Instances of this exception provide three interesting attributes : *msg* is a textual explanation of the error, *filename* is the name of the source file, and *lineno* gives the line number on which the error was found.

### 13.4.1 Objets *netrc*

A *netrc* instance has the following methods :

**netrc.authenticators**(*host*)

Renvoie un triplet (*login*, *account*, *password*) pour s'authentifier auprès de l'hôte *host*. Si le fichier *netrc* ne contient pas d'entrée pour l'hôte donné, renvoie le tuple associé à l'entrée par défaut. Si aucun hôte correspondant ni aucune entrée par défaut n'est disponible, renvoie *None*.

**netrc.\_\_repr\_\_**()

Déverse les données de la classe sous forme de chaîne dans le format d'un fichier *netrc*. (Ceci ignore les commentaires et peut réorganiser les entrées).

Instances of *netrc* have public instance variables :

**netrc.hosts**

Dictionnaire faisant correspondre les noms d'hôtes dans des tuples (*login*, *account*, *password*). L'entrée par défaut, le cas échéant, est représentée en tant que pseudo-hôte par ce nom.

**netrc.macros**

Dictionnaire faisant correspondre les noms de macro en listes de chaînes.

---

**Note :** Passwords are limited to a subset of the ASCII character set. Versions of this module prior to 2.3 were extremely limited. Starting with 2.3, all ASCII punctuation is allowed in passwords. However, note that whitespace and non-printable characters are not allowed in passwords. This is a limitation of the way the .netrc file is parsed and may be removed in the future.

---

## 13.5 xdrlib — Encode and decode XDR data

**Code source :** [Lib/xdrlib.py](#)

---

The *xdrlib* module supports the External Data Representation Standard as described in [RFC 1014](#), written by Sun Microsystems, Inc. June 1987. It supports most of the data types described in the RFC.

The *xdrlib* module defines two classes, one for packing variables into XDR representation, and another for unpacking from XDR representation. There are also two exception classes.

**class xdrlib.Packer**

*Packer* is the class for packing data into XDR representation. The *Packer* class is instantiated with no arguments.

**class xdrlib.Unpacker(*data*)**

*Unpacker* is the complementary class which unpacks XDR data values from a string buffer. The input buffer is given as *data*.

**Voir aussi :**

**RFC 1014 - XDR : External Data Representation Standard** This RFC defined the encoding of data which was XDR at the time this module was originally written. It has apparently been obsoleted by [RFC 1832](#).

**RFC 1832 - XDR : External Data Representation Standard** Newer RFC that provides a revised definition of XDR.

### 13.5.1 Packer Objects

*Packer* instances have the following methods :

**Packer.get\_buffer()**

Returns the current pack buffer as a string.

**Packer.reset()**

Resets the pack buffer to the empty string.

In general, you can pack any of the most common XDR data types by calling the appropriate *pack\_type()* method. Each method takes a single argument, the value to pack. The following simple data type packing methods are supported : *pack\_uint()*, *pack\_int()*, *pack\_enum()*, *pack\_bool()*, *pack\_uhyper()*, and *pack\_hyper()*.

**Packer.pack\_float(*value*)**

Packs the single-precision floating point number *value*.

**Packer.pack\_double(*value*)**

Packs the double-precision floating point number *value*.

The following methods support packing strings, bytes, and opaque data :

`Packer.pack_fstring(n, s)`

Packs a fixed length string, *s*. *n* is the length of the string but it is *not* packed into the data buffer. The string is padded with null bytes if necessary to guaranteed 4 byte alignment.

`Packer.pack_fopaque(n, data)`

Packs a fixed length opaque data stream, similarly to `pack_fstring()`.

`Packer.pack_string(s)`

Packs a variable length string, *s*. The length of the string is first packed as an unsigned integer, then the string data is packed with `pack_fstring()`.

`Packer.pack_opaque(data)`

Packs a variable length opaque data string, similarly to `pack_string()`.

`Packer.pack_bytes(bytes)`

Packs a variable length byte stream, similarly to `pack_string()`.

The following methods support packing arrays and lists :

`Packer.pack_list(list, pack_item)`

Packs a *list* of homogeneous items. This method is useful for lists with an indeterminate size ; i.e. the size is not available until the entire list has been walked. For each item in the list, an unsigned integer 1 is packed first, followed by the data value from the list. *pack\_item* is the function that is called to pack the individual item. At the end of the list, an unsigned integer 0 is packed.

For example, to pack a list of integers, the code might appear like this :

```
import xdrlib
p = xdrlib.Packer()
p.pack_list([1, 2, 3], p.pack_int)
```

`Packer.pack_farray(n, array, pack_item)`

Packs a fixed length list (*array*) of homogeneous items. *n* is the length of the list ; it is *not* packed into the buffer, but a `ValueError` exception is raised if `len(array)` is not equal to *n*. As above, *pack\_item* is the function used to pack each element.

`Packer.pack_array(list, pack_item)`

Packs a variable length *list* of homogeneous items. First, the length of the list is packed as an unsigned integer, then each element is packed as in `pack_farray()` above.

## 13.5.2 Unpacker Objects

The `Unpacker` class offers the following methods :

`Unpacker.reset(data)`

Resets the string buffer with the given *data*.

`Unpacker.get_position()`

Returns the current unpack position in the data buffer.

`Unpacker.set_position(position)`

Sets the data buffer unpack position to *position*. You should be careful about using `get_position()` and `set_position()`.

`Unpacker.get_buffer()`

Returns the current unpack data buffer as a string.

`Unpacker.done()`

Indicates unpack completion. Raises an `Error` exception if all of the data has not been unpacked.

In addition, every data type that can be packed with a *Packer*, can be unpacked with an *Unpacker*. Unpacking methods are of the form `unpack_type()`, and take no arguments. They return the unpacked object.

`Unpacker.unpack_float()`

Unpacks a single-precision floating point number.

`Unpacker.unpack_double()`

Unpacks a double-precision floating point number, similarly to `unpack_float()`.

In addition, the following methods unpack strings, bytes, and opaque data :

`Unpacker.unpack_fstring(n)`

Unpacks and returns a fixed length string. *n* is the number of characters expected. Padding with null bytes to guaranteed 4 byte alignment is assumed.

`Unpacker.unpack_fopaque(n)`

Unpacks and returns a fixed length opaque data stream, similarly to `unpack_fstring()`.

`Unpacker.unpack_string()`

Unpacks and returns a variable length string. The length of the string is first unpacked as an unsigned integer, then the string data is unpacked with `unpack_fstring()`.

`Unpacker.unpack_opaque()`

Unpacks and returns a variable length opaque data string, similarly to `unpack_string()`.

`Unpacker.unpack_bytes()`

Unpacks and returns a variable length byte stream, similarly to `unpack_string()`.

The following methods support unpacking arrays and lists :

`Unpacker.unpack_list(unpack_item)`

Unpacks and returns a list of homogeneous items. The list is unpacked one element at a time by first unpacking an unsigned integer flag. If the flag is 1, then the item is unpacked and appended to the list. A flag of 0 indicates the end of the list. *unpack\_item* is the function that is called to unpack the items.

`Unpacker.unpack_farray(n, unpack_item)`

Unpacks and returns (as a list) a fixed length array of homogeneous items. *n* is number of list elements to expect in the buffer. As above, *unpack\_item* is the function used to unpack each element.

`Unpacker.unpack_array(unpack_item)`

Unpacks and returns a variable length *list* of homogeneous items. First, the length of the list is unpacked as an unsigned integer, then each element is unpacked as in `unpack_farray()` above.

### 13.5.3 Exceptions

Exceptions in this module are coded as class instances :

**exception `xdrlib.Error`**

The base exception class. *Error* has a single public attribute `msg` containing the description of the error.

**exception `xdrlib.ConversionError`**

Class derived from *Error*. Contains no additional instance variables.

Here is an example of how you would catch one of these exceptions :

```
import xdrlib
p = xdrlib.Packer()
try:
```

(suite sur la page suivante)

(suite de la page précédente)

```
p.pack_double(8.01)
except xdrlib.ConversionError as instance:
    print 'packing the double failed:', instance.msg
```

## 13.6 plistlib — Generate and parse Mac OS X .plist files

Modifié dans la version 2.6 : This module was previously only available in the Mac-specific library, it is now available for all platforms.

**Code source :** [Lib/plistlib.py](#)

This module provides an interface for reading and writing the « property list » XML files used mainly by Mac OS X.

The property list (**.plist**) file format is a simple XML pickle supporting basic object types, like dictionaries, lists, numbers and strings. Usually the top level object is a dictionary.

Values can be strings, integers, floats, booleans, tuples, lists, dictionaries (but only with string keys), *Data* or *datetime.datetime* objects. String values (including dictionary keys) may be unicode strings – they will be written out as UTF-8.

The **<data>** plist type is supported through the *Data* class. This is a thin wrapper around a Python string. Use *Data* if your strings contain control characters.

**Voir aussi :**

**PList manual page** Apple's documentation of the file format.

This module defines the following functions :

**plistlib.readPlist(*pathOrFile*)**

Read a plist file. *pathOrFile* may either be a file name or a (readable) file object. Return the unpacked root object (which usually is a dictionary).

The XML data is parsed using the Expat parser from *xml.parsers.expat* – see its documentation for possible exceptions on ill-formed XML. Unknown elements will simply be ignored by the plist parser.

**plistlib.writePlist(*rootObject*, *pathOrFile*)**

Write *rootObject* to a plist file. *pathOrFile* may either be a file name or a (writable) file object.

A *TypeError* will be raised if the object is of an unsupported type or a container that contains objects of unsupported types.

**plistlib.readPlistFromString(*data*)**

Read a plist from a string. Return the root object.

**plistlib.writePlistToString(*rootObject*)**

Return *rootObject* as a plist-formatted string.

**plistlib.readPlistFromResource(*path*, *restype*='plst', *resid*=0)**

Read a plist from the resource with type *restype* from the resource fork of *path*. Availability : Mac OS X.

---

**Note :** In Python 3.x, this function has been removed.

---

`plistlib.writePlistToResource(rootObject, path, restype='plst', resid=0)`

Write *rootObject* as a resource with type *restype* to the resource fork of *path*. Availability : Mac OS X.

---

**Note :** In Python 3.x, this function has been removed.

---

The following class is available :

`class plistlib.Data(data)`

Return a « data » wrapper object around the string *data*. This is used in functions converting from/to plists to represent the <data> type available in plists.

It has one attribute, *data*, that can be used to retrieve the Python string stored in it.

### 13.6.1 Examples

Generating a plist :

```
pl = dict(
    aString="Doodah",
    aList=["A", "B", 12, 32.1, [1, 2, 3]],
    aFloat = 0.1,
    anInt = 728,
    aDict=dict(
        anotherString="<hello & hi there!>",
        aUnicodeValue=u'M\xe4ssig, Ma\xdf',
        aTrueValue=True,
        aFalseValue=False,
    ),
    someData = Data("<binary gunk>"),
    someMoreData = Data("<lots of binary gunk>" * 10),
    aDate = datetime.datetime.fromtimestamp(time.mktime(time.gmtime()))),
)
# unicode keys are possible, but a little awkward to use:
pl[u'\xc5benraa'] = "That was a unicode key."
writePlist(pl, fileName)
```

Parsing a plist :

```
pl = readPlist(pathOrFile)
print pl["aKey"]
```

The modules described in this chapter implement various algorithms of a cryptographic nature. They are available at the discretion of the installation. Here's an overview :

## 14.1 hashlib — Secure hashes and message digests

Nouveau dans la version 2.5.

**Code source :** [Lib/hashlib.py](#)

---

This module implements a common interface to many different secure hash and message digest algorithms. Included are the FIPS secure hash algorithms SHA1, SHA224, SHA256, SHA384, and SHA512 (defined in FIPS 180-2) as well as RSA's MD5 algorithm (defined in Internet [RFC 1321](#)). The terms secure hash and message digest are interchangeable. Older algorithms were called message digests. The modern term is secure hash.

---

**Note :** If you want the `adler32` or `crc32` hash functions, they are available in the `zlib` module.

---

**Avertissement :** Some algorithms have known hash collision weaknesses, refer to the « See also » section at the end.

There is one constructor method named for each type of *hash*. All return a hash object with the same simple interface. For example : use `sha1()` to create a SHA1 hash object. You can now feed this object with arbitrary strings using the `update()` method. At any point you can ask it for the *digest* of the concatenation of the strings fed to it so far using the `digest()` or `hexdigest()` methods.

Constructors for hash algorithms that are always present in this module are `md5()`, `sha1()`, `sha224()`, `sha256()`, `sha384()`, and `sha512()`. Additional algorithms may also be available depending upon the OpenSSL library that Python uses on your platform.

For example, to obtain the digest of the string 'Nobody inspects the spammish repetition' :

```
>>> import hashlib
>>> m = hashlib.md5()
>>> m.update("Nobody inspects")
>>> m.update(" the spammish repetition")
>>> m.digest()
'\xbbd\x9c\x83\xdd\x1e\xa5\xc9\xd9\xde\xc9\xa1\x8d\xf0\xff\xe9'
>>> m.digest_size
16
>>> m.block_size
64
```

More condensed :

```
>>> hashlib.sha224("Nobody inspects the spammish repetition").hexdigest()
'a4337bc45a8fc544c03f52dc550cd6e1e87021bc896588bd79e901e2'
```

A generic `new()` constructor that takes the string name of the desired algorithm as its first parameter also exists to allow access to the above listed hashes as well as *any* other algorithms that your OpenSSL library may offer. The named constructors are much faster than `new()` and should be preferred.

Using `new()` with an algorithm provided by OpenSSL :

```
>>> h = hashlib.new('ripemd160')
>>> h.update("Nobody inspects the spammish repetition")
>>> h.hexdigest()
'cc4a5ce1b3df48aec5d22d1f16b894a0b894eccc'
```

This module provides the following constant attribute :

**hashlib.algorithms**

A tuple providing the names of the hash algorithms guaranteed to be supported by this module.  
Nouveau dans la version 2.7.

**hashlib.algorithms\_guaranteed**

A set containing the names of the hash algorithms guaranteed to be supported by this module on all platforms.  
Nouveau dans la version 2.7.9.

**hashlib.algorithms\_available**

A set containing the names of the hash algorithms that are available in the running Python interpreter. These names will be recognized when passed to `new()`. *algorithms\_guaranteed* will always be a subset. The same algorithm may appear multiple times in this set under different names (thanks to OpenSSL).  
Nouveau dans la version 2.7.9.

The following values are provided as constant attributes of the hash objects returned by the constructors :

**hash.digest\_size**

The size of the resulting hash in bytes.

**hash.block\_size**

The internal block size of the hash algorithm in bytes.

A hash object has the following methods :

**hash.update(*arg*)**

Update the hash object with the string *arg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments : `m.update(a)` ; `m.update(b)` is equivalent to `m.update(a+b)`.

Modifié dans la version 2.7 : The Python GIL is released to allow other threads to run while hash updates on data larger than 2048 bytes is taking place when using hash algorithms supplied by OpenSSL.

`hash.digest()`

Return the digest of the strings passed to the `update()` method so far. This is a string of `digest_size` bytes which may contain non-ASCII characters, including null bytes.

`hash.hexdigest()`

Like `digest()` except the digest is returned as a string of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

`hash.copy()`

Return a copy (« clone ») of the hash object. This can be used to efficiently compute the digests of strings that share a common initial substring.

### 14.1.1 Key derivation

Key derivation and key stretching algorithms are designed for secure password hashing. Naive algorithms such as `sha1(password)` are not resistant against brute-force attacks. A good password hashing function must be tunable, slow, and include a `salt`.

`hashlib.pbkdf2_hmac(name, password, salt, rounds, dklen=None)`

The function provides PKCS#5 password-based key derivation function 2. It uses HMAC as pseudo-random function.

The string `name` is the desired name of the hash digest algorithm for HMAC, e.g. “sha1” or “sha256”. `password` and `salt` are interpreted as buffers of bytes. Applications and libraries should limit `password` to a sensible value (e.g. 1024). `salt` should be about 16 or more bytes from a proper source, e.g. `os.urandom()`.

The number of `rounds` should be chosen based on the hash algorithm and computing power. As of 2013, at least 100,000 rounds of SHA-256 is suggested.

`dklen` is the length of the derived key. If `dklen` is `None` then the digest size of the hash algorithm `name` is used, e.g. 64 for SHA-512.

```
>>> import hashlib, binascii
>>> dk = hashlib.pbkdf2_hmac('sha256', b'password', b'salt', 100000)
>>> binascii.hexlify(dk)
b'0394a2ede332c9a13eb82e9b24631604c31df978b4e2f0fbd2c549944f9d79a5'
```

Nouveau dans la version 2.7.8.

**Note :** A fast implementation of `pbkdf2_hmac` is available with OpenSSL. The Python implementation uses an inline version of `hmac`. It is about three times slower and doesn't release the GIL.

Voir aussi :

**Module `hmac`** A module to generate message authentication codes using hashes.

**Module `base64`** Another way to encode binary hashes for non-binary environments.

## 14.2 hmac — Keyed-Hashing for Message Authentication

Nouveau dans la version 2.2.

Code source : [Lib/hmac.py](#)

---

This module implements the HMAC algorithm as described by [RFC 2104](#).

`hmac.new(key[, msg[, digestmod]])`

Return a new hmac object. If *msg* is present, the method call `update(msg)` is made. *digestmod* is the digest constructor or module for the HMAC object to use. It defaults to the `hashlib.md5` constructor.

An HMAC object has the following methods :

`HMAC.update(msg)`

Update the hmac object with the string *msg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments : `m.update(a)` ; `m.update(b)` is equivalent to `m.update(a + b)`.

`HMAC.digest()`

Return the digest of the strings passed to the `update()` method so far. This string will be the same length as the `digest_size` of the digest given to the constructor. It may contain non-ASCII characters, including NUL bytes.

**Avertissement :** When comparing the output of `digest()` to an externally-supplied digest during a verification routine, it is recommended to use the `compare_digest()` function instead of the `==` operator to reduce the vulnerability to timing attacks.

`HMAC.hexdigest()`

Like `digest()` except the digest is returned as a string twice the length containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

**Avertissement :** When comparing the output of `hexdigest()` to an externally-supplied digest during a verification routine, it is recommended to use the `compare_digest()` function instead of the `==` operator to reduce the vulnerability to timing attacks.

`HMAC.copy()`

Return a copy (« clone ») of the hmac object. This can be used to efficiently compute the digests of strings that share a common initial substring.

This module also provides the following helper function :

`hmac.compare_digest(a, b)`

Return `a == b`. This function uses an approach designed to prevent timing analysis by avoiding content-based short circuiting behaviour, making it appropriate for cryptography. *a* and *b* must both be of the same type : either *unicode* or a *bytes-like object*.

---

**Note :** If *a* and *b* are of different lengths, or if an error occurs, a timing attack could theoretically reveal information about the types and lengths of *a* and *b*—but not their values.

---

Nouveau dans la version 2.7.7.

Voir aussi :

Module [hashlib](#) The Python module providing secure hash functions.

## 14.3 md5 — MD5 message digest algorithm

Obsolète depuis la version 2.5 : Use the *hashlib* module instead.

This module implements the interface to RSA's MD5 message digest algorithm (see also Internet [RFC 1321](#)). Its use is quite straightforward : use *new()* to create an md5 object. You can now feed this object with arbitrary strings using the *update()* method, and at any point you can ask it for the *digest* (a strong kind of 128-bit checksum, a.k.a. « fingerprint ») of the concatenation of the strings fed to it so far using the *digest()* method.

For example, to obtain the digest of the string 'Nobody inspects the spammish repetition' :

```
>>> import md5
>>> m = md5.new()
>>> m.update("Nobody inspects")
>>> m.update(" the spammish repetition")
>>> m.digest()
'\xbbd\x9c\x83\xdd\x1e\xa5\xc9\xd9\xde\xc9\xa1\x8d\xf0\xff\xe9'
```

More condensed :

```
>>> md5.new("Nobody inspects the spammish repetition").digest()
'\xbbd\x9c\x83\xdd\x1e\xa5\xc9\xd9\xde\xc9\xa1\x8d\xf0\xff\xe9'
```

The following values are provided as constants in the module and as attributes of the md5 objects returned by *new()* :

**md5.digest\_size**

The size of the resulting digest in bytes. This is always 16.

The md5 module provides the following functions :

**md5.new([arg])**

Return a new md5 object. If *arg* is present, the method call *update(arg)* is made.

**md5.md5([arg])**

For backward compatibility reasons, this is an alternative name for the *new()* function.

An md5 object has the following methods :

**md5.update(arg)**

Update the md5 object with the string *arg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments : *m.update(a)* ; *m.update(b)* is equivalent to *m.update(a+b)*.

**md5.digest()**

Return the digest of the strings passed to the *update()* method so far. This is a 16-byte string which may contain non-ASCII characters, including null bytes.

**md5.hexdigest()**

Like *digest()* except the digest is returned as a string of length 32, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

**md5.copy()**

Return a copy (« clone ») of the md5 object. This can be used to efficiently compute the digests of strings that share a common initial substring.

**Voir aussi :**

**Module *sha*** Similar module implementing the Secure Hash Algorithm (SHA). The SHA algorithm is considered a more secure hash.

## 14.4 sha — SHA-1 message digest algorithm

Obsolète depuis la version 2.5 : Use the [\*hashlib\*](#) module instead.

This module implements the interface to NIST's secure hash algorithm, known as SHA-1. SHA-1 is an improved version of the original SHA hash algorithm. It is used in the same way as the [\*md5\*](#) module : use [\*new\(\)\*](#) to create an sha object, then feed this object with arbitrary strings using the [\*update\(\)\*](#) method, and at any point you can ask it for the *digest* of the concatenation of the strings fed to it so far. SHA-1 digests are 160 bits instead of MD5's 128 bits.

**sha.new(*string*)**

Return a new sha object. If *string* is present, the method call [\*update\(string\)\*](#) is made.

The following values are provided as constants in the module and as attributes of the sha objects returned by [\*new\(\)\*](#) :

**sha.blocksize**

Size of the blocks fed into the hash function ; this is always 1. This size is used to allow an arbitrary string to be hashed.

**sha.digest\_size**

The size of the resulting digest in bytes. This is always 20.

An sha object has the same methods as md5 objects :

**sha.update(*arg*)**

Update the sha object with the string *arg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments : [\*m.update\(a\)\*](#) ; [\*m.update\(b\)\*](#) is equivalent to [\*m.update\(a+b\)\*](#).

**sha.digest()**

Return the digest of the strings passed to the [\*update\(\)\*](#) method so far. This is a 20-byte string which may contain non-ASCII characters, including null bytes.

**sha.hexdigest()**

Like [\*digest\(\)\*](#) except the digest is returned as a string of length 40, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

**sha.copy()**

Return a copy (« clone ») of the sha object. This can be used to efficiently compute the digests of strings that share a common initial substring.

**Cryptographic Toolkit (Secure Hashing)** Links from NIST to various information on secure hashing.

---

## Services génériques du système d'exploitation

---

Les modules documentés dans ce chapitre fournissent des interfaces vers des fonctionnalités communes à la grande majorité des systèmes d'exploitation, telles que les fichiers et l'horloge. Bien que ces interfaces soient classiquement calquées sur les interfaces Unix ou C, elles sont aussi disponibles sur la plupart des autres systèmes. En voici un aperçu.

### 15.1 `os` — Diverses interfaces pour le système d'exploitation

Ce module fournit une manière portable d'utiliser les fonctionnalités dépendantes du système d'exploitation. Si vous voulez uniquement lire ou écrire dans un fichier, voir `open()`, si vous voulez manipuler des chemins, voir le module `os.path`, et si vous voulez lire toutes les lignes de tous les fichiers listés par l'invite de commande, voir le module `fileinput`. Pour créer des fichiers temporaires, voir le module `tempfile`, et pour une manipulation haut niveau des fichiers et dossiers, voir le module `shutil`.

Notes sur la disponibilité de ces fonctions :

- La conception des modules natifs Python dépendants du système d'exploitation est qu'une même fonctionnalité utilise une même interface. Par exemple, la fonction `os.stat(path)` renvoie des informations sur les statistiques de `path` dans le même format (qui est originaire de l'interface POSIX).
- Les extensions propres à un certain système d'exploitation sont également disponible par le module `os`, mais les utiliser est bien entendu une menace pour la portabilité.
- Une note « Disponibilité : Unix » signifie que cette fonction est communément implémentée dans les systèmes Unix. Une telle note ne prétend pas l'existence de la fonction sur un système d'exploitation particulier.
- Si ce n'est pas mentionné séparément, toutes les fonctions se réclamant « Disponibilité : Unix » sont gérées sur Mac OS X, qui est basé sur Unix.

---

**Note :** Toutes les fonctions de ce module lèvent une `OSError` dans le cas d'un chemin ou nom de fichier invalide ou inaccessible, ou si d'autres arguments sont de type correct mais non géré par le système d'exploitation.

---

#### exception `os.error`

Un alias pour les exceptions natives `OSError`.

**os.name**

The name of the operating system dependent module imported. The following names have currently been registered : 'posix', 'nt', 'os2', 'ce', 'java', 'riscos'.

**Voir aussi :**

*sys.platform* a une granularité plus fine. *os.uname()* donne des informations de version dépendantes de système.

Le module *platform* fournit des vérifications détaillées pour l'identité du système.

### 15.1.1 Paramètres de processus

Ces fonctions et valeurs fournissent des informations et agissent sur le processus actuel et sur l'utilisateur.

**os.environ**

Un objet *mapping* représentant la variable d'environnement. Par exemple `environ['HOME']` est le chemin vers votre répertoire personnel (sur certaines plate-formes), et est équivalent à `getenv("HOME")` en C.

Ce *mapping* est capturé la première fois que le module *os* est importé, typiquement pendant le démarrage de Python, lors de l'exécution de `site.py`. Les changements de l'environnement opérés après cette capture ne sont pas répercutés dans `os.environ`, à part les modifications directes de `os.environ`.

Si la plate-forme prend en charge la fonction *putenv()*, ce *mapping* peut être utilisé pour modifier l'environnement autant que pour l'interroger. *putenv()* sera appelée automatiquement quand le *mapping* sera modifié.

---

**Note :** Appeler *putenv()* ne change pas directement `os.environ`, donc il est préférable de modifier `os.environ`.

---

---

**Note :** Sur certaines plate-formes, dont FreeBSD et Mac OS X, procéder à des assignations sur `environ` peut causer des fuites de mémoire. Reférez-vous à la documentation système de *putenv()*.

---

Si *putenv()* n'est pas fourni, une copie modifiée de ce dictionnaire peut être passé aux fonctions appropriées de création de processus pour forcer l'utilisation d'un environnement modifié pour le processus fils.

Si la plate-forme prend en charge la fonction *unsetenv()*, vous pouvez supprimer des éléments de ce dictionnaire pour supprimer des variables d'environnement. La fonction *unsetenv()* sera appelée automatiquement quand un élément est supprimé de `os.environ`, ou quand l'une des méthodes `pop()` ou `clear()` est appelée.

Modifié dans la version 2.6 : Also unset environment variables when calling `os.environ.clear()` and `os.environ.pop()`.

**os.chdir(path)****os.fchdir(fd)****os.getcwd()**

Ces fonctions sont décrites dans *Fichiers et répertoires*.

**os.ctermid()**

Renvoie l'identifiant de fichier correspondant au terminal contrôlant le processus.

Disponibilité : Unix.

**os.getegid()**

Renvoie l'identifiant du groupe effectif du processus actuel. Ça correspond au bit « *set id* » du fichier qui s'exécute dans le processus actuel.

Disponibilité : Unix.

**os.geteuid()**

Renvoie l'identifiant de l'utilisateur effectif du processus actuel.

Disponibilité : Unix.

**os.getgid()**

Renvoie l'identifiant de groupe réel du processus actuel.

Disponibilité : Unix.

**os.getgroups()**

Renvoie une liste d'identifiants de groupes additionnels associés au processus actuel.

Disponibilité : Unix.

---

**Note :** Sur Mac OS X, le comportement de `getgroups()` diffère légèrement des autres plateformes Unix. Si l'interpréteur Python était compilé avec une cible de déploiement de 10.5 ou moins, `getgroups()` renverrait la liste des identifiants de groupes effectifs associés au processus courant de l'utilisateur ; le nombre d'éléments de cette liste est limité par le système, typiquement 16, et peut être modifié par des appels à `setgroups()` si les privilèges ont été convenablement assignés. Si compilé avec une cible de déploiement supérieure à 10.5, la fonction `getgroups()` renvoie la liste des accès du groupe actuel pour l'utilisateur associé à l'identifiant utilisateur du processus ; la liste d'accès du groupe peut changer durant la vie du processus, elle n'est pas affectée par les appels à `setgroups()` et sa longueur n'est pas limitée à 16. La valeur de la cible de déploiement, `MACOSX_DEPLOYMENT_TARGET`, peut être obtenue par la fonction `sysconfig.get_config_var()`.

---

**os.initgroups(username, gid)**

Appelle la fonction système `initgroups` pour initialiser la liste des groupes d'accès des groupes dont `username` est membre, plus le groupe spécifié par `gid`.

Disponibilité : Unix.

Nouveau dans la version 2.7.

**os.getlogin()**

Return the name of the user logged in on the controlling terminal of the process. For most purposes, it is more useful to use the environment variable `LOGNAME` to find out who the user is, or `pwd.getpwuid(os.getuid())[0]` to get the login name of the process's real user id.

Disponibilité : Unix.

**os.getpgid(pid)**

Renvoie l'identifiant de groupe de processus du processus de PID `pid`. Si `pid` vaut 0, l'identifiant de groupe de processus du processus actuel est renvoyé.

Disponibilité : Unix.

Nouveau dans la version 2.3.

**os.getpgrp()**

Renvoie l'identifiant du groupe de processus actuel.

Disponibilité : Unix.

**os.getpid()**

Renvoie l'identifiant du processus actuel.

Disponibilité : Unix, Windows.

**os.getppid()**

Return the parent's process id.

Disponibilité : Unix.

**os.getresuid()**

Renvoie un *tuple* (`ruid`, `euid`, `suid`) dénotant les identifiants de l'utilisateur réel, effectif et sauvé du processus actuel.

Disponibilité : Unix.

Nouveau dans la version 2.7.

`os.getresgid()`

Renvoie un *tuple* (*rgid*, *egid*, *sgid*) dénotant les identifiants des groupes de processus réel effectif, et sauvé du processus actuel.

Disponibilité : Unix.

Nouveau dans la version 2.7.

`os.getuid()`

Renvoie l'identifiant réel du processus actuel.

Disponibilité : Unix.

`os.getenv(varname[, value])`

Return the value of the environment variable *varname* if it exists, or *value* if it doesn't. *value* defaults to `None`.

Disponibilité : la plupart des dérivés Unix, Windows.

`os.putenv(varname, value)`

Set the environment variable named *varname* to the string *value*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

Disponibilité : la plupart des dérivés Unix, Windows.

---

**Note :** Sur certaines plate-formes, incluant FreeBSD et Mac OS X, assigner `environ` peut causer des fuites de mémoire. Reférez-vous à la documentation système de `putenv`.

---

Quand `putenv()` est géré, les assignations d'éléments dans `os.environ` sont automatiquement traduites en appels correspondants à `putenv()`. Cependant, des appels à `putenv()` ne mettent pas `os.environ` à jour. Il est donc préférable d'assigner les éléments de `os.environ`.

`os.setegid(egid)`

Définit l'identifiant du groupe de processus effectif du processus actuel.

Disponibilité : Unix.

`os.seteuid(euid)`

Définit l'identifiant de l'utilisateur effectif du processus actuel.

Disponibilité : Unix.

`os.setgid(gid)`

Définit l'identifiant du groupe de processus actuel.

Disponibilité : Unix.

`os.setgroups(groups)`

Place *groups* dans la liste d'identifiants de groupes additionnels associée. *groups* doit être une séquence, et chaque élément doit être un nombre entier identifiant un groupe. Cette opération est typiquement disponible uniquement pour le super utilisateur.

Disponibilité : Unix.

Nouveau dans la version 2.2.

---

**Note :** Sur Mac OS X, la longueur de *groups* ne peut pas dépasser le nombre maximum d'identifiants effectifs de groupes défini par le système, typiquement 16. Voir la documentation de `getgroups()` pour les cas où `getgroups` ne renvoie pas la même liste de groupes que celle définie par l'appel à `setgroups`.

---

`os.setpgrp()`

Call the system call `setpgrp()` or `setpgrp(0, 0)` depending on which version is implemented (if any). See the Unix manual for the semantics.

Disponibilité : Unix.

**os.setpgid(*pid*, *pgrp*)**

Produit l'appel système `setpgid()` pour placer l'identifiant du groupe de processus contenant le processus d'identifiant *pid* dans le groupe de processus d'identifiant *pgrp*. Voir le manuel Unix pour la sémantique.

Disponibilité : Unix.

**os.setregid(*rgid*, *egid*)**

Définit l'identifiant des groupes réel et effectif du processus actuel.

Disponibilité : Unix.

**os.setresgid(*rgid*, *egid*, *sgid*)**

Définit l'identifiant des groupes réel, effectif et sauvé du processus actuel.

Disponibilité : Unix.

Nouveau dans la version 2.7.

**os.setresuid(*ruid*, *euid*, *suid*)**

Définit l'identifiant des utilisateurs réel, effectif et sauvé du processus actuel.

Disponibilité : Unix.

Nouveau dans la version 2.7.

**os.setreuid(*ruid*, *euid*)**

Définit l'identifiant des utilisateurs réel et effectif du processus actuel.

Disponibilité : Unix.

**os.getsid(*pid*)**

Produit l'appel système `getsid()`. Voir le manuel Unix pour la sémantique.

Disponibilité : Unix.

Nouveau dans la version 2.4.

**os.setsid()**

Produit l'appel système `setsid()`. Voir le manuel Unix pour la sémantique.

Disponibilité : Unix.

**os.setuid(*uid*)**

Définit l'identifiant de l'utilisateur du processus actuel.

Disponibilité : Unix.

**os.strerror(*code*)**

Renvoie le message d'erreur correspondant au code d'erreur *code*. Sur les plate-formes où `strerror()` renvoie NULL quand un numéro d'erreur inconnu est donné, une *ValueError* est levée.

Disponibilité : Unix, Windows.

**os.umask(*mask*)**

Définit le *umask* actuel et renvoie la valeur précédente.

Disponibilité : Unix, Windows.

**os.uname()**

Return a 5-tuple containing information identifying the current operating system. The tuple contains 5 strings : (*sysname*, *nodename*, *release*, *version*, *machine*). Some systems truncate the node-name to 8 characters or to the leading component; a better way to get the hostname is `socket.gethostname()` or even `socket.gethostbyaddr(socket.gethostname())`.

Disponibilité : dérivés récents de Unix.

**os.unsetenv(*varname*)**

Unset (delete) the environment variable named *varname*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

Quand `unsetenv()` est gérée, la suppression d'éléments dans `os.environ` est automatiquement interprétée en un appel correspondant à `unsetenv()`, mais les appels à `unsetenv()` ne mettent pas `os.environ` à jour. Donc il est préférable de supprimer les éléments de `os.environ`.

Disponibilité : la plupart des dérivés Unix, Windows.

### 15.1.2 Création de fichiers objets

These functions create new file objects. (See also `open()`.)

`os.fdopen(fd[, mode[, bufsize]])`

Return an open file object connected to the file descriptor *fd*. The *mode* and *bufsize* arguments have the same meaning as the corresponding arguments to the built-in `open()` function. If `fdopen()` raises an exception, it leaves *fd* untouched (unclosed).

Disponibilité : Unix, Windows.

Modifié dans la version 2.3 : When specified, the *mode* argument must now start with one of the letters 'r', 'w', or 'a', otherwise a `ValueError` is raised.

Modifié dans la version 2.5 : On Unix, when the *mode* argument starts with 'a', the `O_APPEND` flag is set on the file descriptor (which the `fdopen()` implementation already does on most platforms).

`os.popen(command[, mode[, bufsize]])`

Open a pipe to or from *command*. The return value is an open file object connected to the pipe, which can be read or written depending on whether *mode* is 'r' (default) or 'w'. The *bufsize* argument has the same meaning as the corresponding argument to the built-in `open()` function. The exit status of the command (encoded in the format specified for `wait()`) is available as the return value of the `close()` method of the file object, except that when the exit status is zero (termination without errors), `None` is returned.

Disponibilité : Unix, Windows.

Obsolète depuis la version 2.6 : This function is obsolete. Use the `subprocess` module. Check especially the *Remplacer les fonctions plus anciennes par le module subprocess* section.

Modifié dans la version 2.0 : This function worked unreliably under Windows in earlier versions of Python. This was due to the use of the `_popen()` function from the libraries provided with Windows. Newer versions of Python do not use the broken implementation from the Windows libraries.

`os.tmpfile()`

Return a new file object opened in update mode (`w+b`). The file has no directory entries associated with it and will be automatically deleted once there are no file descriptors for the file.

Disponibilité : Unix, Windows.

There are a number of different `popen*`() functions that provide slightly different ways to create subprocesses.

Obsolète depuis la version 2.6 : All of the `popen*`() functions are obsolete. Use the `subprocess` module.

For each of the `popen*`() variants, if *bufsize* is specified, it specifies the buffer size for the I/O pipes. *mode*, if provided, should be the string 'b' or 't'; on Windows this is needed to determine whether the file objects should be opened in binary or text mode. The default value for *mode* is 't'.

Also, for each of these variants, on Unix, *cmd* may be a sequence, in which case arguments will be passed directly to the program without shell intervention (as with `os.spawnv()`). If *cmd* is a string it will be passed to the shell (as with `os.system()`).

These methods do not make it possible to retrieve the exit status from the child processes. The only way to control the input and output streams and also retrieve the return codes is to use the `subprocess` module; these are only available on Unix.

For a discussion of possible deadlock conditions related to the use of these functions, see *Flow Control Issues*.

`os.popen2(cmd[, mode[, bufsize]])`

Execute *cmd* as a sub-process and return the file objects (*child\_stdin*, *child\_stdout*).

Obsolète depuis la version 2.6 : This function is obsolete. Use the *subprocess* module. Check especially the *Remplacer les fonctions plus anciennes par le module subprocess* section.

Disponibilité : Unix, Windows.

Nouveau dans la version 2.0.

`os.popen3(cmd[, mode[, bufsize]])`

Execute *cmd* as a sub-process and return the file objects (*child\_stdin*, *child\_stdout*, *child\_stderr*).

Obsolète depuis la version 2.6 : This function is obsolete. Use the *subprocess* module. Check especially the *Remplacer les fonctions plus anciennes par le module subprocess* section.

Disponibilité : Unix, Windows.

Nouveau dans la version 2.0.

`os.popen4(cmd[, mode[, bufsize]])`

Execute *cmd* as a sub-process and return the file objects (*child\_stdin*, *child\_stdout\_and\_stderr*).

Obsolète depuis la version 2.6 : This function is obsolete. Use the *subprocess* module. Check especially the *Remplacer les fonctions plus anciennes par le module subprocess* section.

Disponibilité : Unix, Windows.

Nouveau dans la version 2.0.

(Note that *child\_stdin*, *child\_stdout*, and *child\_stderr* are named from the point of view of the child process, so *child\_stdin* is the child's standard input.)

This functionality is also available in the *popen2* module using functions of the same names, but the return values of those functions have a different order.

### 15.1.3 Opérations sur les descripteurs de fichiers

Ces fonctions opèrent sur des flux d'entrées/sorties référencés par des descripteurs de fichiers.

Les descripteurs de fichiers sont de petits entiers correspondant à un fichier qui a été ouvert par le processus courant. Par exemple, l'entrée standard est habituellement le descripteur de fichier 0, la sortie standard est 1, et le flux standard d'erreur est 2. Les autres fichiers ouverts par un processus vont se voir assigner 3, 4, 5, etc. Le nom « descripteur de fichier » est légèrement trompeur : sur les plate-formes Unix, les *sockets* et les *pipes* sont également référencés par des descripteurs.

The *fileno()* method can be used to obtain the file descriptor associated with a file object when required. Note that using the file descriptor directly will bypass the file object methods, ignoring aspects such as internal buffering of data.

`os.close(fd)`

Ferme le descripteur de fichier *fd*.

Disponibilité : Unix, Windows.

---

**Note :** Cette fonction est destinée aux opérations d'entrées/sorties de bas niveau et doit être appliquée à un descripteur de fichier comme ceux donnés par *os.open()* ou *pipe()*. Pour fermer un « fichier objet » renvoyé par la primitive *open()*, *popen()* ou *fdopen()*, il faut utiliser sa méthode *close()*.

---

`os.closerange(fd_low, fd_high)`

Close all file descriptors from *fd\_low* (inclusive) to *fd\_high* (exclusive), ignoring errors. Equivalent to :

```
for fd in xrange(fd_low, fd_high):
    try:
```

(suite sur la page suivante)

(suite de la page précédente)

```
os.close(fd)
except OSError:
    pass
```

Disponibilité : Unix, Windows.

Nouveau dans la version 2.6.

**os.dup(*fd*)**

Return a duplicate of file descriptor *fd*.

Disponibilité : Unix, Windows.

**os.dup2(*fd*, *fd2*)**

Duplicate file descriptor *fd* to *fd2*, closing the latter first if necessary.

Disponibilité : Unix, Windows.

**os.fchmod(*fd*, *mode*)**

Change the mode of the file given by *fd* to the numeric *mode*. See the docs for [chmod\(\)](#) for possible values of *mode*.

Disponibilité : Unix.

Nouveau dans la version 2.6.

**os.fchown(*fd*, *uid*, *gid*)**

Change the owner and group id of the file given by *fd* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1.

Disponibilité : Unix.

Nouveau dans la version 2.6.

**os.fdatasync(*fd*)**

Force l'écriture du fichier ayant le descripteur *fd* sur le disque. Ne force pas la mise à jour des méta-données.

Disponibilité : Unix.

---

**Note :** Cette fonction n'est pas disponible sur MacOS.

---

**os.fpathconf(*fd*, *name*)**

Renvoie les informations de la configuration du système pour un fichier ouvert. *name* spécifie la valeur de la configuration à récupérer, ça peut être une chaîne de caractères avec le nom d'une valeur système définie ; ces valeurs sont spécifiées dans certains standards (POSIX.1, Unix 95, Unix 98, et d'autres). Certaines plate-formes définissent des noms additionnels également. Les noms connus par le système d'exploitation sont donnés dans le dictionnaire `pathconf_names`. Pour les variables de configuration qui ne sont pas incluses dans ce *mapping*, passer un entier pour *name* est également accepté.

Si *name* est une chaîne de caractères et n'est pas connu, une [ValueError](#) est levée. Si une valeur spécifique de *name* n'est pas gérée par le système hôte, même si elle est incluse dans `pathconf_names`, une [OSError](#) est levée avec `errno.EINVAL` pour code d'erreur.

Disponibilité : Unix.

**os.fstat(*fd*)**

Return status for file descriptor *fd*, like [stat\(\)](#).

Disponibilité : Unix, Windows.

**os.fstatvfs(*fd*)**

Return information about the filesystem containing the file associated with file descriptor *fd*, like [statvfs\(\)](#).

Disponibilité : Unix.

**os.fsync(*fd*)**

Force l'écriture du fichier ayant le descripteur *fd* sur le disque. Sur Unix, cet appel appelle la fonction native `fsync()`, sur Windows, la fonction `MS _commit()`.

If you're starting with a Python file object *f*, first do `f.flush()`, and then do `os.fsync(f.fileno())`, to ensure that all internal buffers associated with *f* are written to disk.

Availability : Unix, and Windows starting in 2.2.3.

**os.ftruncate(*fd*, *length*)**

Truncate the file corresponding to file descriptor *fd*, so that it is at most *length* bytes in size.

Disponibilité : Unix.

**os.isatty(*fd*)**

Renvoie `True` si le descripteur de fichier *fd* est ouvert et connecté à un périphérique TTY (ou compatible), sinon `False`.

**os.lseek(*fd*, *pos*, *how*)**

Place la position actuelle du descripteur de fichier *fd* à la position *pos*, modifié par *how* : `SEEK_SET` ou 0 pour placer la position à partir du début du fichier, `SEEK_CUR` ou 1 pour la placer à partir de la position actuelle, et `SEEK_END` ou 2 pour la placer par rapport à la fin du fichier. Renvoie la nouvelle position du curseur en bytes, à partir du début.

Disponibilité : Unix, Windows.

**os.SEEK\_SET****os.SEEK\_CUR****os.SEEK\_END**

Paramètres de la fonction `lseek()`. Leur valeur est respectivement 0, 1, et 2.

Availability : Windows, Unix.

Nouveau dans la version 2.5.

**os.open(*file*, *flags*[, *mode*])**

Open the file *file* and set various flags according to *flags* and possibly its mode according to *mode*. The default *mode* is `0777` (octal), and the current umask value is first masked out. Return the file descriptor for the newly opened file.

For a description of the flag and mode values, see the C run-time documentation; flag constants (like `O_RDONLY` and `O_WRONLY`) are defined in this module too (see `open()` *flag constants*). In particular, on Windows adding `O_BINARY` is needed to open files in binary mode.

Disponibilité : Unix, Windows.

---

**Note :** This function is intended for low-level I/O. For normal usage, use the built-in function `open()`, which returns a « file object » with `read()` and `write()` methods (and many more). To wrap a file descriptor in a « file object », use `fdopen()`.

---

**os.openpty()**

Open a new pseudo-terminal pair. Return a pair of file descriptors (`master`, `slave`) for the pty and the tty, respectively. For a (slightly) more portable approach, use the `pty` module.

Disponibilité : certains dérivés Unix.

**os.pipe()**

Create a pipe. Return a pair of file descriptors (`r`, `w`) usable for reading and writing, respectively.

Disponibilité : Unix, Windows.

**os.read(*fd*, *n*)**

Read at most *n* bytes from file descriptor *fd*. Return a string containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty string is returned.

Disponibilité : Unix, Windows.

---

**Note :** Cette fonction est destinée aux E/S bas niveau et doit être appliquée à un descripteur de fichier comme renvoyé par `os.open()` ou `pipe()`. Pour lire dans un « fichier objet » renvoyé par la primitive `open()`, `popen()` ou `fdopen()`, ou par `stdin`, utilisez sa méthode `read()` ou `readline()`.

---

`os.tcgetpgrp(fd)`

Renvoie le groupe de processus associé au terminal donné par `fd` (un descripteur de fichier ouvert comme renvoyé par `os.open()`).

Disponibilité : Unix.

`os.tcsetpgrp(fd, pg)`

Place `pg` dans le groupe de processus associé au terminal donné par `fd` (un descripteur de fichier ouvert comme renvoyé par `os.open()`).

Disponibilité : Unix.

`os.ttyname(fd)`

Renvoie une chaîne de caractères spécifiant le périphérique terminal associé au descripteur de fichier `fd`. Si `fd` n'est pas associé à un périphérique terminal, une exception est levée.

Disponibilité : Unix.

`os.write(fd, str)`

Write the string `str` to file descriptor `fd`. Return the number of bytes actually written.

Disponibilité : Unix, Windows.

---

**Note :** cette fonction est destinée aux E/S bas niveau et doit être appliquée à un descripteur de fichier comme renvoyé par `os.open()` ou `pipe()`. Pour écrire dans un « fichier objet » renvoyé par la primitive `open()`, `popen()`, ou par `fdopen()`, ou par `sys.stdout` ou `sys.stderr`, utilisez sa méthode `write()`.

---

### `open()` flag constants

The following constants are options for the `flags` parameter to the `open()` function. They can be combined using the bitwise OR operator `|`. Some of them are not available on all platforms. For descriptions of their availability and use, consult the `open(2)` manual page on Unix or [the MSDN](#) on Windows.

`os.O_RDONLY`

`os.O_WRONLY`

`os.O_RDWR`

`os.O_APPEND`

`os.O_CREAT`

`os.O_EXCL`

`os.O_TRUNC`

Les constantes ci-dessus sont disponibles sur Unix et Windows.

`os.O_DSYNC`

`os.O_RSYNC`

`os.O_SYNC`

`os.O_NDELAY`

`os.O_NONBLOCK`

`os.O_NOCTTY`

Les constantes ci-dessus sont uniquement disponibles sur Unix.

`os.O_BINARY`

`os.O_NOINHERIT`

`os.O_SHORT_LIVED`

```
os.O_TEMPORARY
os.O_RANDOM
os.O_SEQUENTIAL
os.O_TEXT
```

Les constantes ci-dessus sont uniquement disponibles sur Windows.

```
os.O_ASYNC
os.O_DIRECT
os.O_DIRECTORY
os.O_NOFOLLOW
os.O_NOATIME
os.O_SHLOCK
os.O_EXLOCK
```

Les constantes ci-dessus sont des extensions et ne sont pas présentes si elles ne sont pas définies par la bibliothèque C.

### 15.1.4 Fichiers et répertoires

`os.access(path, mode)`

Utilise l'*uid/gid* réel pour tester l'accès à *path*. Notez que la plupart des opérations utiliseront l'*uid/gid* effectif, dès lors cette méthode peut être utilisée dans un environnement *suid/sgid* pour tester si l'utilisateur invoquant a les droits d'accès pour accéder à *path*. *mode* devrait être *F\_OK* pour tester l'existence de *path*, ou il peut être le OR (OU inclusif) d'une ou plusieurs des constantes suivantes : *R\_OK*, *W\_OK*, et *X\_OK* pour tester les permissions. Renvoie *True* si l'accès est permis, et *False* s'il ne l'est pas. Voir la page de manuel Unix *access(2)* pour plus d'informations.

Disponibilité : Unix, Windows.

**Note :** Utiliser *access()* pour vérifier si un utilisateur est autorisé (par exemple) à ouvrir un fichier avant d'effectivement le faire en utilisant *open()* crée une faille de sécurité : l'utilisateur peut exploiter le court intervalle de temps entre la vérification et l'ouverture du fichier pour le manipuler. Il est préférable d'utiliser les techniques *EAFP*. Par exemple :

```
if os.access("myfile", os.R_OK):
    with open("myfile") as fp:
        return fp.read()
return "some default data"
```

est mieux écrit comme suit :

```
try:
    fp = open("myfile")
except IOError as e:
    if e.errno == errno.EACCES:
        return "some default data"
    # Not a permission error.
    raise
else:
    with fp:
        return fp.read()
```

**Note :** Les opérations d'entrées/sorties peuvent échouer même quand *access()* indique qu'elles devraient réussir, particulièrement pour les opérations sur les systèmes de fichiers réseaux qui peuvent avoir une sémantique de permissions au-delà du modèle de bits de permission usuel POSIX.

`os.F_OK`

Value to pass as the *mode* parameter of `access()` to test the existence of *path*.

`os.R_OK`

Value to include in the *mode* parameter of `access()` to test the readability of *path*.

`os.W_OK`

Value to include in the *mode* parameter of `access()` to test the writability of *path*.

`os.X_OK`

Value to include in the *mode* parameter of `access()` to determine if *path* can be executed.

`os.chdir(path)`

Change le répertoire de travail actuel par *path*.

Disponibilité : Unix, Windows.

`os.fchdir(fd)`

Change the current working directory to the directory represented by the file descriptor *fd*. The descriptor must refer to an opened directory, not an open file.

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.getcwd()`

Renvoie une chaîne de caractères représentant le répertoire de travail actuel.

Disponibilité : Unix, Windows.

`os.getcwdu()`

Return a Unicode object representing the current working directory.

Disponibilité : Unix, Windows.

Nouveau dans la version 2.3.

`os.chflags(path, flags)`

Définit les marqueurs de *path* par la valeur numérique *flags*. *flags* peut prendre une combinaison (OU bit-à-bit) des valeurs suivantes (comme défini dans le module `stat`) :

- `stat.UF_NODUMP`
- `stat.UF_IMMUTABLE`
- `stat.UF_APPEND`
- `stat.UF_OPAQUE`
- `stat.UF_NOUNLINK`
- `stat.UF_COMPRESSED`
- `stat.UF_HIDDEN`
- `stat.SF_ARCHIVED`
- `stat.SF_IMMUTABLE`
- `stat.SF_APPEND`
- `stat.SF_NOUNLINK`
- `stat.SF_SNAPSHOT`

Disponibilité : Unix.

Nouveau dans la version 2.6.

`os.chroot(path)`

Change the root directory of the current process to *path*. Availability : Unix.

Nouveau dans la version 2.2.

`os.chmod(path, mode)`

Change le mode de *path* par la valeur numérique *mode*. *mode* peut prendre une des valeurs suivantes (comme défini dans le module `stat`) ou une combinaison (OU bit-à-bit) de ces valeurs :

- `stat.S_ISUID`
- `stat.S_ISGID`

---

```

— stat.S_ENFMT
— stat.S_ISVTX
— stat.S_IREAD
— stat.S_IWRITE
— stat.S_IXEXEC
— stat.S_IRWXU
— stat.S_IRUSR
— stat.S_IWUSR
— stat.S_IXUSR
— stat.S_IRWXG
— stat.S_IRGRP
— stat.S_IWGRP
— stat.S_IXGRP
— stat.S_IRWXO
— stat.S_IROTH
— stat.S_IWOTH
— stat.S_IXOTH

```

Disponibilité : Unix, Windows.

---

**Note :** Although Windows supports `chmod()`, you can only set the file's read-only flag with it (via the `stat.S_IWRITE` and `stat.S_IREAD` constants or a corresponding integer value). All other bits are ignored.

---

`os.chown(path, uid, gid)`

Change the owner and group id of *path* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1.

Disponibilité : Unix.

`os.chflags(path, flags)`

Set the flags of *path* to the numeric *flags*, like `chflags()`, but do not follow symbolic links.

Disponibilité : Unix.

Nouveau dans la version 2.6.

`os.lchmod(path, mode)`

Change the mode of *path* to the numeric *mode*. If *path* is a symlink, this affects the symlink rather than the target. See the docs for `chmod()` for possible values of *mode*.

Disponibilité : Unix.

Nouveau dans la version 2.6.

`os.lchown(path, uid, gid)`

Change the owner and group id of *path* to the numeric *uid* and *gid*. This function will not follow symbolic links.

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.link(source, link_name)`

Create a hard link pointing to *source* named *link\_name*.

Disponibilité : Unix.

`os.listdir(path)`

Return a list containing the names of the entries in the directory given by *path*. The list is in arbitrary order. It does not include the special entries '.' and '..' even if they are present in the directory.

Disponibilité : Unix, Windows.

Modifié dans la version 2.3 : On Windows NT/2k/XP and Unix, if *path* is a Unicode object, the result will be a list of Unicode objects. Undecodable filenames will still be returned as string objects.

**os.lstat(*path*)**

Perform the equivalent of an `lstat()` system call on the given path. Similar to `stat()`, but does not follow symbolic links. On platforms that do not support symbolic links, this is an alias for `stat()`.

**os.mkfifo(*path*[, *mode*])**

Create a FIFO (a named pipe) named *path* with numeric mode *mode*. The default *mode* is 0666 (octal). The current umask value is first masked out from the mode.

Disponibilité : Unix.

Les FIFOs sont des tubes qui peuvent être accédés comme des fichiers normaux. Les FIFOs existent jusqu'à ce qu'ils soient retirés (par exemple, à l'aide de `os.unlink()`). Généralement, les FIFOs sont utilisés comme communication entre des processus de type « client » et « serveur » : le serveur ouvre le FIFO pour le lire, et le client l'ouvre pour écrire dedans. Notez que `mkfifo()` n'ouvre pas le FIFO — il crée juste un point de rendez-vous.

**os.mknod(*filename*[, *mode*=0600[, *device*=0]])**

Create a filesystem node (file, device special file or named pipe) named *filename*. *mode* specifies both the permissions to use and the type of node to be created, being combined (bitwise OR) with one of `stat.S_IFREG`, `stat.S_IFCHR`, `stat.S_IFBLK`, and `stat.S_IFIFO` (those constants are available in `stat`). For `stat.S_IFCHR` and `stat.S_IFBLK`, *device* defines the newly created device special file (probably using `os.makedev()`), otherwise it is ignored.

Nouveau dans la version 2.3.

**os.major(*device*)**

Extrait le nombre majeur de périphérique d'un nombre de périphérique brut (habituellement le champ `st_dev` ou `st_rdev` de `stat`).

Nouveau dans la version 2.3.

**os.minor(*device*)**

Extrait le nombre mineur de périphérique d'un nombre de périphérique brut (habituellement le champ `st_dev` ou `st_rdev` de `stat`).

Nouveau dans la version 2.3.

**os.makedev(*major*, *minor*)**

Compose un nombre de périphérique brut à partir des nombres de périphérique mineur et majeur.

Nouveau dans la version 2.3.

**os.mkdir(*path*[, *mode*])**

Create a directory named *path* with numeric mode *mode*. The default *mode* is 0777 (octal). If the directory already exists, `OSError` is raised.

Sous certains systèmes, *mode* est ignoré. Quand il est utilisé, il lui est premièrement appliqué le masque courant *umask*. Si des bits autres que les 9 derniers sont activés (i.e. les 3 derniers chiffres de la représentation octale de *mode*), leur signification sera dépendante de la plate-forme. Sous certaines plate-formes, ils seront ignorés et vous devrez appeler explicitement `chmod()` pour les modifier.

Il est également possible de créer des répertoires temporaires, voir la fonction `tempfile.mkdtemp()` du module `tempfile`.

Disponibilité : Unix, Windows.

**os.makedirs(*path*[, *mode*])**

Recursive directory creation function. Like `mkdir()`, but makes all intermediate-level directories needed to contain the leaf directory. Raises an `error` exception if the leaf directory already exists or cannot be created. The default *mode* is 0777 (octal).

Le paramètre *mode* est passé à `mkdir()` ; voir la description de `mkdir()` pour comprendre comment cela est interprété.

---

**Note :** `makedirs()` will become confused if the path elements to create include `os.pardir`.

---

Nouveau dans la version 1.5.2.

Modifié dans la version 2.3 : This function now handles UNC paths correctly.

#### `os.pathconf(path, name)`

Renvoie des informations sur la configurations relatives à un fichier déterminé. *name* spécifie la valeur de configuration à récupérer ; ce peut être une chaîne de caractères qui est le nom d'une valeur système particulière. Ces noms sont spécifiés dans certains standards (POSIX.1, Unix 95, Unix 98, etc). Certaines plate-formes définissent des noms supplémentaires également. Les noms connus du système d'exploitation hôte sont donnés dans le dictionnaire `pathconf_names`. Pour les variables de configuration non incluses dans ce *mapping*, passer un entier pour *name* est également accepté.

Si *name* est une chaîne de caractères et n'est pas connu, une `ValueError` est levée. Si une valeur spécifique de *name* n'est pas gérée par le système hôte, même si elle est incluse dans `pathconf_names`, une `OSError` est levée avec `errno.EINVAL` pour code d'erreur.

Disponibilité : Unix.

#### `os.pathconf_names`

Dictionary mapping names accepted by `pathconf()` and `fpathconf()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system. Availability : Unix.

#### `os.readlink(path)`

Renvoie une chaîne de caractères représentant le chemin vers lequel le lien symbolique pointe. Le résultat peut être soit un chemin relatif, soit un chemin absolu. S'il est relatif, il peut être converti en chemin absolu en utilisant `os.path.join(os.path.dirname(path), result)`.

Modifié dans la version 2.6 : If the *path* is a Unicode object the result will also be a Unicode object.

Disponibilité : Unix.

#### `os.remove(path)`

Remove (delete) the file *path*. If *path* is a directory, `OSError` is raised ; see `rmdir()` below to remove a directory. This is identical to the `unlink()` function documented below. On Windows, attempting to remove a file that is in use causes an exception to be raised ; on Unix, the directory entry is removed but the storage allocated to the file is not made available until the original file is no longer in use.

Disponibilité : Unix, Windows.

#### `os.removedirs(path)`

Supprime des répertoires récursivement. Fonctionne comme `rmdir()` si ce n'est que si le répertoire feuille est retiré avec succès, `removedirs()` essaye de supprimer successivement chaque répertoire parent mentionné dans *path* jusqu'à ce qu'un erreur ne soit levée (ce qui est ignoré car la signification générale en est qu'un répertoire parent n'est pas vide). Par exemple, `os.removedirs('foo/bar/baz')` supprimera d'abord le répertoire 'foo/bar/baz', et ensuite supprimera 'foo/bar' et puis 'foo' s'ils sont vides. Lève une `OSError` si le répertoire feuille n'a pas pu être supprimé avec succès.

Nouveau dans la version 1.5.2.

#### `os.rename(src, dst)`

Rename the file or directory *src* to *dst*. If *dst* is a directory, `OSError` will be raised. On Unix, if *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail on some Unix flavors if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement). On Windows, if *dst* already exists, `OSError` will be raised even if it is a file ; there may be no way to implement an atomic rename when *dst* names an existing file.

Disponibilité : Unix, Windows.

#### `os.rename(old, new)`

Fonction récursive de renommage de fichiers ou répertoires. Fonctionne comme `rename()`, si ce n'est que la création d'un répertoire intermédiaire nécessaire pour rendre le nouveau chemin correct est essayé en premier. Après le renommage, les répertoires correspondant aux segments de chemin les plus à droite de l'ancien nom seront élagués en utilisant `removedirs()`.

Nouveau dans la version 1.5.2.

---

**Note :** Cette fonction peut échouer avec la nouvelle structure de dictionnaire définie si vous n'avez pas les permissions nécessaires pour supprimer le répertoire ou fichier feuille.

---

`os.rmdir(path)`

Supprime (retire) le répertoire *path*. Ne fonctionne que lorsque le répertoire est vide, sinon une *OSError* est levée. Afin de supprimer toute la hiérarchie de dossier, la fonction *shutil.rmtree()* peut être utilisée.

Disponibilité : Unix, Windows.

`os.stat(path)`

Perform the equivalent of a `stat()` system call on the given path. (This function follows symlinks; to stat a symlink use *lstat()*.)

The return value is an object whose attributes correspond to the members of the `stat` structure, namely :

- `st_mode` - protection bits,
- `st_ino` - inode number,
- `st_dev` - device,
- `st_nlink` - number of hard links,
- `st_uid` - user id of owner,
- `st_gid` - group id of owner,
- `st_size` - size of file, in bytes,
- `st_atime` - time of most recent access,
- `st_mtime` - time of most recent content modification,
- `st_ctime` - platform dependent; time of most recent metadata change on Unix, or the time of creation on Windows)

Modifié dans la version 2.3 : If *stat\_float\_times()* returns `True`, the time values are floats, measuring seconds. Fractions of a second may be reported if the system supports that. See *stat\_float\_times()* for further discussion.

Sur certains systèmes Unix (tels que Linux), les attributs suivants peuvent également être disponibles :

- `st_blocks` - number of 512-byte blocks allocated for file
- `st_blksize` - filesystem blocksize for efficient file system I/O
- `st_rdev` - type of device if an inode device
- `st_flags` - user defined flags for file

Sur d'autres systèmes Unix (tels que FreeBSD), les attributs suivants peuvent être disponibles (mais peuvent être complétés uniquement lorsque le super-utilisateur *root* tente de les utiliser).

- `st_gen` - file generation number
- `st_birthtime` - time of file creation

On RISCOS systems, the following attributes are also available :

- `st_ftype` (file type)
- `st_attrs` (attributes)
- `st_obtype` (object type).

---

**Note :** La signification et la précision exacte des attributs `st_atime`, `st_mtime`, et `st_ctime` dépendent du système d'exploitation et du système de fichier. Par exemple sur les systèmes Windows qui utilisent un système de fichier FAT ou FAT32, `st_mtime` a une précision de 2 secondes, et `st_atime` a une précision de 1 jour. Regardez la documentation de votre système d'exploitation pour plus de détails.

---

For backward compatibility, the return value of *stat()* is also accessible as a tuple of at least 10 integers giving the most important (and portable) members of the `stat` structure, in the order `st_mode`, `st_ino`, `st_dev`, `st_nlink`, `st_uid`, `st_gid`, `st_size`, `st_atime`, `st_mtime`, `st_ctime`. More items may be added at the end by some implementations.

Le module standard `stat` définit des fonctions et des constantes qui sont utiles pour l'extraction d'informations d'une structure `stat`. (Sur Windows, certains éléments sont remplis avec des valeurs factices.)

Exemple :

```
>>> import os
>>> statinfo = os.stat('somefile.txt')
>>> statinfo
(33188, 422511, 769, 1, 1032, 100, 926, 1105022698, 1105022732, 1105022732)
>>> statinfo.st_size
926
```

Disponibilité : Unix, Windows.

Modifié dans la version 2.2 : Added access to values as attributes of the returned object.

Modifié dans la version 2.5 : Added `st_gen` and `st_birthtime`.

`os.stat_float_times([newvalue])`

Détermine si `stat_result` représente les horodatages par des objets à virgule flottante. Si *newvalue* vaut `True`, les appels à `stat()` qui suivront renverront des flottants. Si *newvalue* vaut `False`, les appels qui suivront renverront des entiers. Si *newvalue* est omise, la valeur actuelle est renvoyée.

Pour des raisons de compatibilité avec les anciennes versions de Python, accéder un objet de type `stat_result` renvoie toujours des entiers.

Modifié dans la version 2.5 : Python renvoie des valeurs flottantes par défaut maintenant. Les applications qui ne fonctionnent pas correctement avec des horodatages flottants peuvent utiliser cette fonction pour restaurer l'ancien comportement.

La précision des horodatages (qui est la plus petite fraction possible) dépend du système. Certains systèmes supportent uniquement une précision à la seconde ; sur ces systèmes, la fraction sera toujours zéro.

Il est recommandé que cette option ne soit changée qu'au lancement du programme dans le module `__main__`. Les bibliothèques ne devraient jamais changer cette option. Si une application utilise une bibliothèque qui fonctionne mal avec les horodatages en nombres flottants, cette application devrait temporairement retirer cette possibilité jusqu'à ce que la bibliothèque ait été corrigée.

`os.statvfs(path)`

Exécute un appel système `statvfs()` sur le chemin donné par *path*. La valeur de retour est un objet dont les attributs décrivent le système de fichier sur le chemin donné, et correspondent aux membres de la structure `statvfs` nommés : `f_bsize`, `f_frsize`, `f_blocks`, `f_bfree`, `f_bavail`, `f_files`, `f_ffree`, `f_favail`, `f_flag`, `f_namemax`.

For backward compatibility, the return value is also accessible as a tuple whose values correspond to the attributes, in the order given above. The standard module `statvfs` defines constants that are useful for extracting information from a `statvfs` structure when accessing it as a sequence ; this remains useful when writing code that needs to work with versions of Python that don't support accessing the fields as attributes.

Disponibilité : Unix.

Modifié dans la version 2.2 : Added access to values as attributes of the returned object.

`os.symlink(source, link_name)`

Create a symbolic link pointing to *source* named *link\_name*.

Disponibilité : Unix.

`os.tempnam(dir, [prefix])`

Return a unique path name that is reasonable for creating a temporary file. This will be an absolute path that names a potential directory entry in the directory *dir* or a common location for temporary files if *dir* is omitted or `None`. If given and not `None`, *prefix* is used to provide a short prefix to the filename. Applications are responsible for properly creating and managing files created using paths

returned by `tempnam()`; no automatic cleanup is provided. On Unix, the environment variable `TMPDIR` overrides `dir`, while on Windows `TMP` is used. The specific behavior of this function depends on the C library implementation; some aspects are underspecified in system documentation.

**Avertissement :** Use of `tempnam()` is vulnerable to symlink attacks; consider using `tmpfile()` (section *Création de fichiers objets*) instead.

Disponibilité : Unix, Windows.

#### `os.tempnam()`

Return a unique path name that is reasonable for creating a temporary file. This will be an absolute path that names a potential directory entry in a common location for temporary files. Applications are responsible for properly creating and managing files created using paths returned by `tempnam()`; no automatic cleanup is provided.

**Avertissement :** Use of `tempnam()` is vulnerable to symlink attacks; consider using `tmpfile()` (section *Création de fichiers objets*) instead.

Availability : Unix, Windows. This function probably shouldn't be used on Windows, though : Microsoft's implementation of `tempnam()` always creates a name in the root directory of the current drive, and that's generally a poor location for a temp file (depending on privileges, you may not even be able to open a file using this name).

#### `os.TMP_MAX`

The maximum number of unique names that `tempnam()` will generate before reusing names.

#### `os.unlink(path)`

Remove (delete) the file `path`. This is the same function as `remove()`; the `unlink()` name is its traditional Unix name.

Disponibilité : Unix, Windows.

#### `os.utime(path, times)`

Set the access and modified times of the file specified by `path`. If `times` is `None`, then the file's access and modified times are set to the current time. (The effect is similar to running the Unix program `touch` on the path.) Otherwise, `times` must be a 2-tuple of numbers, of the form `(atime, mtime)` which is used to set the access and modified times, respectively. Whether a directory can be given for `path` depends on whether the operating system implements directories as files (for example, Windows does not). Note that the exact times you set here may not be returned by a subsequent `stat()` call, depending on the resolution with which your operating system records access and modification times; see `stat()`.

Modifié dans la version 2.0 : Added support for `None` for `times`.

Disponibilité : Unix, Windows.

#### `os.walk(top, topdown=True, onerror=None, followlinks=False)`

Génère les noms de fichier dans un arbre de répertoire en parcourant l'arbre soit de bas-en-haut, soit de haut-en-bas. Pour chaque répertoire dans l'arbre enraciné en le répertoire `top` (incluant ledit répertoire `top`), fournit un triplet `(dirpath, dirnames, filenames)`.

`dirpath` est une chaîne de caractères contenant le chemin vers le répertoire. `dirnames` est une liste de noms de sous-répertoires dans `dirpath` (en excluant `'.'` et `'..'`). `filenames` est une liste de fichiers (non-répertoires) dans `dirpath`. Notez que les noms dans la liste ne contiennent aucune composante de chemin. Pour récupérer le chemin complet (qui commence à `top`) vers un répertoire dans `dirpath`, faites `os.path.join(dirpath, name)`.

Si l'argument optionnel `topdown` vaut `True` ou n'est pas spécifié, le triplet pour un répertoire est généré avant les triplets de tous ses sous-répertoires (les répertoires sont générés de haut-en-bas). Si `topdown` vaut `False`, le triplet pour un répertoire est généré après les triplets de tous ses sous-répertoires (les

répertoires sont générés de bas-en-haut). Peu importe la valeur de *topdown*, la liste des sous-répertoires est récupérée avant que les tuples pour le répertoire et ses sous-répertoires ne soient générés.

Quand *topdown* vaut **True**, l'appelant peut modifier la liste *dirnames* en place (par exemple en utilisant *del* ou l'assignation par *slicing* (par tranches)) et *walk()* ne fera sa récursion que dans les sous-répertoires dont le nom reste dans *dirnames*; cela peut être utilisé pour élaguer la recherche, imposer un ordre particulier de visite, ou encore pour informer *walk()* des répertoires créés par l'appelant ou renommés avant qu'il quitte *walk()* à nouveau. Modifier *dirnames* quand *topdown* vaut **False** n'a aucun effet sur le comportement du parcours parce qu'en mode bas-en-haut, les répertoires dans *dirnames* sont générés avant que *dirpath* ne soit lui-même généré.

Par défaut, les erreurs d'un appel à *listdir()* sont ignorées. Si l'argument optionnel *onerror* est spécifié, il devrait être une fonction, il sera appelé avec un argument, une instance de *OSError*. Il peut reporter l'erreur ou continuer le parcours, ou lever l'exception pour avorter le parcours. Notez que le nom de fichier est disponible par "attribut *filename* de l'objet exception.

Par défaut, *walk()* ne parcourra pas les liens symboliques qui mènent à un répertoire. Définissez *followlinks* avec **True** pour visiter les répertoires pointés par des liens symboliques sur les systèmes qui le gère.

Nouveau dans la version 2.6 : The *followlinks* parameter.

---

**Note :** Soyez au courant que définir *followlinks* avec **True** peut mener à une récursion infinie si un lien pointe vers un répertoire parent de lui-même. *walk()* ne garde pas de trace des répertoires qu'il a déjà visité.

---

---

**Note :** Si vous passez un chemin relatif, ne changez pas le répertoire de travail actuel entre deux exécutions de *walk()*. *walk()* ne change jamais le répertoire actuel, et suppose que l'appelant ne le fait pas non plus.

---

Cet exemple affiche le nombre de bytes pris par des fichiers non-répertoires dans chaque répertoire à partir du répertoire de départ, si ce n'est qu'il ne cherche pas après un sous-répertoire CSV :

```
import os
from os.path import join, getsize
for root, dirs, files in os.walk('python/Lib/email'):
    print root, "consumes",
    print sum(getsize(join(root, name)) for name in files),
    print "bytes in", len(files), "non-directory files"
    if 'CVS' in dirs:
        dirs.remove('CVS') # don't visit CVS directories
```

Dans le prochain exemple, parcourir l'arbre de bas-en-haut est essentiel : *rmdir()* ne permet pas de supprimer un répertoire avant qu'il ne soit vide :

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION: This is dangerous! For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files in os.walk(top, topdown=False):
    for name in files:
        os.remove(os.path.join(root, name))
    for name in dirs:
        os.rmdir(os.path.join(root, name))
```

Nouveau dans la version 2.3.

### 15.1.5 Gestion des processus

Ces fonctions peuvent être utilisées pour créer et gérer des processus.

Les variantes des fonctions `exec*` prennent une liste d'arguments pour le nouveau programme chargé dans le processus. Dans tous les cas, le premier de ces arguments est passé au nouveau programme comme son propre nom plutôt que comme un argument qu'un utilisateur peut avoir tapé en ligne de commande. Pour les programmeurs C, c'est l'argument `argv[0]` qui est passé à la fonction `main()` du programme. Par exemple, `os.execv('/bin/echo/', ['foo', 'bar'])` affichera uniquement `bar` sur la sortie standard ; `foo` semblera être ignoré.

`os.abort()`

Génère un signal `SIGABRT` au processus actuel. Sur Linux, le comportement par défaut est de produire un vidage système (*Core Dump*) ; sur Windows, le processus renvoie immédiatement un code d'erreur 3. Attention : appeler cette fonction n'appellera pas le gestionnaire de signal Python enregistré par `SIGABRT` à l'aide de `signal.signal()`.

Disponibilité : Unix, Windows.

`os.execl(path, arg0, arg1, ...)`

`os.execle(path, arg0, arg1, ..., env)`

`os.execlp(file, arg0, arg1, ...)`

`os.execlpe(file, arg0, arg1, ..., env)`

`os.execv(path, args)`

`os.execve(path, args, env)`

`os.execvp(file, args)`

`os.execvpe(file, args, env)`

Ces fonctions exécutent toutes un nouveau programme, remplaçant le processus actuel, elles ne renvoient pas. Sur Unix, le nouvel exécutable est chargé dans le processus actuel, et aura le même identifiant de processus (PID) que l'appelant. Les erreurs seront reportées par des exceptions `OSError`.

Le processus actuel est remplacé immédiatement. Les fichiers objets et descripteurs de fichiers ne sont pas purgés, donc s'il est possible que des données aient été mises en tampon pour ces fichiers, vous devriez les purger manuellement en utilisant `sys.stdout.flush()` ou `os.fsync()` avant d'appeler une fonction `exec*`.

Les variantes « l » et « v » des fonctions `exec*` diffèrent sur la manière de passer les arguments de ligne de commande. Les variantes « l » sont probablement les plus simples à utiliser si le nombre de paramètres est fixé lors de l'écriture du code. Les paramètres individuels deviennent alors des paramètres additionnels aux fonctions `exec*()`. Les variantes « v » sont préférables quand le nombre de paramètres est variable et qu'ils sont passés dans une liste ou un *tuple* dans le paramètre `args`. Dans tous les cas, les arguments aux processus fils devraient commencer avec le nom de la commande à lancer, mais ce n'est pas obligatoire.

Les variantes qui incluent un « p » vers la fin (`execlp()`, `execlpe()`, `execvp()`, et `execvpe()`) utiliseront la variable d'environnement `PATH` pour localiser le programme *file*. Quand l'environnement est remplacé (en utilisant une des variantes `exec*e`, discutées dans le paragraphe suivant), le nouvel environnement est utilisé comme source de la variable d'environnement `PATH`. Les autres variantes `execl()`, `execle()`, `execv()`, et `execve()` n'utiliseront pas la variable d'environnement `PATH` pour localiser l'exécutable. *path* doit contenir un chemin absolu ou relatif approprié.

Pour les fonctions `execle()`, `execlpe()`, `execve()`, et `execvpe()` (notez qu'elles finissent toutes par « e »), le paramètre *env* doit être un *mapping* qui est utilisé pour définir les variables d'environnement du nouveau processus (celles-ci sont utilisées à la place de l'environnement du nouveau processus). Les fonctions `execl()`, `execlp()`, `execv()`, et `execvp()` causent toutes un héritage de l'environnement du processus actuel par le processus fils.

Disponibilité : Unix, Windows.

`os._exit(n)`

Quitte le processus avec le statut *n*, sans appeler les gestionnaires de nettoyage, sans purger les tampons des fichiers, etc.

Disponibilité : Unix, Windows.

---

**Note :** La méthode standard pour quitter est `sys.exit(n)`. `_exit()` devrait normalement être utilisé uniquement par le processus fils après un `fork()`.

---

Les codes de sortie suivants sont définis et peuvent être utilisés avec `_exit()`, mais ils ne sont pas nécessaires. Ils sont typiquement utilisés pour les programmes systèmes écrits en Python, comme un programme de gestion de l'exécution des commandes d'un serveur de mails.

---

**Note :** Certaines de ces valeurs peuvent ne pas être disponibles sur toutes les plate-formes Unix étant donné qu'il en existe des variations. Ces constantes sont définies là où elles sont définies par la plate-forme sous-jacente.

---

**os.EX\_OK**

Code de sortie signifiant qu'aucune erreur n'est arrivée.

Disponibilité : Unix.

Nouveau dans la version 2.3.

**os.EX\_USAGE**

Code de sortie signifiant que les commandes n'ont pas été utilisées correctement, comme quand le mauvais nombre d'arguments a été donné.

Disponibilité : Unix.

Nouveau dans la version 2.3.

**os.EX\_DATAERR**

Code de sortie signifiant que les données en entrées étaient incorrectes.

Disponibilité : Unix.

Nouveau dans la version 2.3.

**os.EX\_NOINPUT**

Code de sortie signifiant qu'un des fichiers d'entrée n'existe pas ou n'est pas lisible.

Disponibilité : Unix.

Nouveau dans la version 2.3.

**os.EX\_NOUSER**

Code de sortie signifiant qu'un utilisateur spécifié n'existe pas.

Disponibilité : Unix.

Nouveau dans la version 2.3.

**os.EX\_NOHOST**

Code de sortie signifiant qu'un hôte spécifié n'existe pas.

Disponibilité : Unix.

Nouveau dans la version 2.3.

**os.EX\_UNAVAILABLE**

Code de sortie signifiant qu'un service requis n'est pas disponible.

Disponibilité : Unix.

Nouveau dans la version 2.3.

**os.EX\_SOFTWARE**

Code de sortie signifiant qu'une erreur interne d'un programme a été détectée.

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.EX_OSERR`

Code de sortie signifiant qu'une erreur du système d'exploitation a été détectée, comme l'incapacité à réaliser un *fork* ou à créer un tuyau (*pipe*).

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.EX_OSFILE`

Code de sortie signifiant qu'un fichier n'existe pas, n'a pas pu être ouvert, ou avait une autre erreur.

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.EX_CANTCREAT`

Code de sortie signifiant qu'un fichier spécifié par l'utilisateur n'a pas pu être créé.

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.EX_IOERR`

Code de sortie signifiant qu'une erreur est apparue pendant une E/S sur un fichier.

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.EX_TEMPFAIL`

Code de sortie signifiant qu'un échec temporaire est apparu. Cela indique quelque chose qui pourrait ne pas être une erreur, comme une connexion au réseau qui n'a pas pu être établie pendant une opération réessayable.

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.EX_PROTOCOL`

Code de sortie signifiant qu'un protocole d'échange est illégal, invalide, ou non-compris.

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.EX_NOPERM`

Code de sortie signifiant qu'il manque certaines permissions pour réaliser une opération (mais n'est pas destiné aux problèmes de système de fichiers).

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.EX_CONFIG`

Code de sortie signifiant qu'une erreur de configuration est apparue.

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.EX_NOTFOUND`

Code de sortie signifiant quelque chose comme « une entrée n'a pas été trouvée ».

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.fork()`

*Fork* un processus fils. Renvoie 0 dans le processus fils et le PID du processus fils dans le processus père. Si une erreur apparaît, une *OSError* est levée.

Note that some platforms including FreeBSD <= 6.3, Cygwin and OS/2 EMX have known issues when using `fork()` from a thread.

**Avertissement :** Voit `ssl` pour les application qui utilisent le module SSL avec `fork()`.

Disponibilité : Unix.

#### `os.forkpty()`

*Fork* un processus fils, en utilisant un nouveau pseudo-terminal comme terminal contrôlant le fils. Renvoie une paire (`pid`, `fd`) où `pid` vaut 0 dans le fils et le PID du processus fils dans le parent, et `fd` est le descripteur de fichier de la partie maître du pseudo-terminal. Pour une approche plus portable, utilisez le module `pty`. Si une erreur apparaît, une `OSError` est levée.

Disponibilité : certains dérivés Unix.

#### `os.kill(pid, sig)`

Envoie le signal `sig` au processus `pid`. Les constantes pour les signaux spécifiques à la plate-forme hôte sont définies dans le module `signal`.

Windows : les signaux `signal.CTRL_C_EVENT` et `signal.CTRL_BREAK_EVENT` sont des signaux spéciaux qui ne peuvent être envoyés qu'aux processus consoles qui partagent une console commune (par exemple, certains sous-processus). Toute autre valeur pour `sig` amènera le processus à être tué sans condition par l'API `TerminateProcess`, et le code de retour sera mis à `sig`. La version Windows de `kill()` prend en plus les identificateurs de processus à tuer.

Nouveau dans la version 2.7 : Windows support

#### `os.killpg(pgid, sig)`

Envoie le signal `sig` au groupe de processus `pgid`.

Disponibilité : Unix.

Nouveau dans la version 2.3.

#### `os.nice(increment)`

Ajoute `increment` à la priorité du processus. Renvoie la nouvelle priorité.

Disponibilité : Unix.

#### `os.plock(op)`

Verrouille les segments du programme en mémoire. La valeur de `op` (définie dans `<sys/lock.h>`) détermine quels segments sont verrouillés.

Disponibilité : Unix.

#### `os.popen(...)`

#### `os.popen2(...)`

#### `os.popen3(...)`

#### `os.popen4(...)`

Run child processes, returning opened pipes for communications. These functions are described in section *Création de fichiers objets*.

#### `os.spawnl(mode, path, ...)`

#### `os.spawnle(mode, path, ..., env)`

#### `os.spawnlp(mode, file, ...)`

#### `os.spawnlpe(mode, file, ..., env)`

#### `os.spawnv(mode, path, args)`

#### `os.spawnve(mode, path, args, env)`

#### `os.spawnvp(mode, file, args)`

#### `os.spawnvpe(mode, file, args, env)`

Exécute le programme `path` dans un nouveau processus.

(Notez que le module `subprocess` fournit des outils plus puissants pour générer de nouveaux processus et récupérer leur valeur de retour. Il est préférable d'utiliser ce module que ces fonctions. Voyez surtout la section *Remplacer les fonctions plus anciennes par le module subprocess*.)

Si `mode` vaut `P_NOWAIT`, cette fonction renvoie le PID du nouveau processus, et si `mode` vaut `P_WAIT`, la fonction renvoie le code de sortie du processus s'il se termine normalement, ou `-signal` où `signal`

est le signal qui a tué le processus. Sur Windows, le PID du processus sera en fait l'identificateur du processus (*process handle*) et peut donc être utilisé avec la fonction `waitpid()`.

Les variantes « l » et « v » des fonctions `spawn*` diffèrent sur la manière de passer les arguments de ligne de commande. Les variantes « l » sont probablement les plus simples à utiliser si le nombre de paramètres est fixé lors de l'écriture du code. Les paramètres individuels deviennent alors des paramètres additionnels aux fonctions `spawn*()`. Les variantes « v » sont préférables quand le nombre de paramètres est variable et qu'ils sont passés dans une liste ou un *tuple* dans le paramètre `args`. Dans tous les cas, les arguments aux processus fils devraient commencer avec le nom de la commande à lancer, mais ce n'est pas obligatoire.

Les variantes qui incluent un « p » vers la fin (`spawnlp()`, `spawnlpe()`, `spawnvp()`, et `spawnvpe()`) utiliseront la variable d'environnement `PATH` pour localiser le programme *file*. Quand l'environnement est remplacé (en utilisant une des variantes `spawn*e`, discutées dans le paragraphe suivant), le nouvel environnement est utilisé comme source de la variable d'environnement `PATH`. Les autres variantes `spawnl()`, `spawnle()`, `spawnv()`, et `spawnve()` n'utiliseront pas la variable d'environnement `PATH` pour localiser l'exécutable. *path* doit contenir un chemin absolue ou relatif approprié.

Pour les fonctions `spawnle()`, `spawnlpe()`, `spawnve()`, et `spawnvpe()` (notez qu'elles finissent toutes par « e »), le paramètre `env` doit être un *mapping* qui est utilisé pour définir les variables d'environnement du nouveau processus (celles-ci sont utilisées à la place de l'environnement du nouveau processus). Les fonctions `spawnl()`, `spawnlp()`, `spawnv()`, et `spawnvp()` causent toutes un héritage de l'environnement du processus actuel par le processus fils. Notez que les clefs et les valeurs du dictionnaire `env` doivent être des chaînes de caractères. Des valeurs invalides pour les clefs ou les valeurs met la fonction en échec et renvoie 127.

Par exemple, les appels suivants à `spawnlp()` et `spawnvpe()` sont équivalents :

```
import os
os.spawnlp(os.P_WAIT, 'cp', 'cp', 'index.html', '/dev/null')

L = ['cp', 'index.html', '/dev/null']
os.spawnvpe(os.P_WAIT, 'cp', L, os.environ)
```

Disponibilité : Unix, Windows. `spawnlp()`, `spawnlpe()`, `spawnvp()`, et `spawnvpe()` ne sont pas disponibles sur Windows. `spawnle()` et `spawnve()` ne sont pas sécurisés pour les appels concurrents (*thread-safe*) sur Windows, il est conseillé d'utiliser le module `subprocess` à la place.

Nouveau dans la version 1.6.

`os.P_NOWAIT`

`os.P_NOWAITO`

Valeurs possibles pour le paramètre *mode* de la famille de fonctions `spawn*`. Si l'une de ces valeurs est donnée, les fonctions `spawn*()` sortiront dès que le nouveau processus est créé, avec le PID du processus comme valeur de retour.

Disponibilité : Unix, Windows.

Nouveau dans la version 1.6.

`os.P_WAIT`

Valeur possible pour le paramètre *mode* de la famille de fonctions `spawn*`. Si *mode* est défini par cette valeur, les fonctions `spawn*` ne se terminent pas tant que le nouveau processus n'a pas été complété et renvoient le code de sortie du processus si l'exécution est effectuée avec succès, ou **-signal** si un signal tue le processus.

Disponibilité : Unix, Windows.

Nouveau dans la version 1.6.

`os.P_DETACH`

`os.P_OVERLAY`

Possible values for the *mode* parameter to the `spawn*` family of functions. These are less portable than those listed above. `P_DETACH` is similar to `P_NOWAIT`, but the new process is detached from the console

of the calling process. If *P\_OVERLAY* is used, the current process will be replaced ; the `spawn*()` function will not return.

Disponibilité : Windows.

Nouveau dans la version 1.6.

`os.startfile(path[, operation])`

lance un fichier avec son application associée.

Quand *operation* n'est pas spécifié ou vaut `'open'`, l'effet est le même qu'un double clic sur le fichier dans Windows Explorer, ou que de passer le nom du fichier en argument du programme `start` depuis l'invite de commande interactif : le fichier est ouvert avec l'application associée à l'extension (s'il y en a une).

Quand une autre *operation* est donnée, ce doit être une « commande-verbe » qui spécifie ce qui devrait être fait avec le fichier. Les verbes habituels documentés par Microsoft sont `'print'` et `'edit'` (qui doivent être utilisés sur des fichiers) ainsi que `'explore'` et `'find'` (qui doivent être utilisés sur des répertoires).

`startfile()` termine dès que l'application associée est lancée. Il n'y a aucune option permettant d'attendre que l'application ne se ferme et aucun moyen de récupérer le statu de sortie de l'application. Le paramètre *path* est relatif au répertoire actuel. Si vous voulez utiliser un chemin absolu, assurez-vous que le premier caractère ne soit pas un slash (`'/'`). La fonction Win32 `ShellExecute()` sous-jacente ne fonctionne pas sinon. Utilisez la fonction `os.path.normpath()` pour vous assurer que le chemin est encodé correctement pour Win32.

Disponibilité : Windows.

Nouveau dans la version 2.0.

Nouveau dans la version 2.5 : The *operation* parameter.

`os.system(command)`

Execute the command (a string) in a subshell. This is implemented by calling the Standard C function `system()`, and has the same limitations. Changes to `sys.stdin`, etc. are not reflected in the environment of the executed command.

Sur Unix, la valeur de retour est le statut de sortie du processus encodé dans le format spécifié pour `wait()`. Notez que POSIX ne spécifie pas le sens de la valeur de retour de la fonction C `system()`, donc la valeur de retour de la fonction Python est dépendante du système.

On Windows, the return value is that returned by the system shell after running *command*, given by the Windows environment variable `COMSPEC` : on `command.com` systems (Windows 95, 98 and ME) this is always 0 ; on `cmd.exe` systems (Windows NT, 2000 and XP) this is the exit status of the command run ; on systems using a non-native shell, consult your shell documentation.

Le module `subprocess` fournit des outils plus puissants pour générer de nouveaux processus et pour récupérer leur résultat. Il est préférable d'utiliser ce module plutôt que d'utiliser cette fonction. Voir la section *Remplacer les fonctions plus anciennes par le module subprocess* de la documentation du module `subprocess` pour des informations plus précises et utiles.

Disponibilité : Unix, Windows.

`os.times()`

Return a 5-tuple of floating point numbers indicating accumulated (processor or other) times, in seconds. The items are : user time, system time, children's user time, children's system time, and elapsed real time since a fixed point in the past, in that order. See the Unix manual page `times(2)` or the corresponding Windows Platform API documentation. On Windows, only the first two items are filled, the others are zero.

Disponibilité Unix, Windows

`os.wait()`

Attend qu'un processus fils soit complété, et renvoie un *tuple* contenant son PID et son état de sortie : un nombre de 16 bits dont le *byte* de poids faible est le nombre correspondant au signal qui a tué le processus, et dont le *byte* de poids fort est le statut de sortie (si la signal vaut 0). Le bit de poids fort du *byte* de poids faible est mis à 1 si un (fichier système) *core file* a été produit.

Disponibilité : Unix.

#### `os.waitpid(pid, options)`

Les détails de cette fonction diffèrent sur Unix et Windows.

Sur Unix : attend qu'un processus fils donné par son id de processus *pid* soit terminé, et renvoie un *tuple* contenant son PID et son statut de sortie (encodé comme pour *wait()*). La sémantique de cet appel est affecté par la valeur de l'argument entier *options*, qui devrait valoir 0 pour les opérations normales.

Si *pid* est plus grand que 0, *waitpid()* introduit une requête pour des informations sur le statut du processus spécifié. Si *pid* vaut 0, la requête est pour le statut de tous les fils dans le groupe de processus du processus actuel. Si *pid* vaut -1, la requête concerne tous les processus fils du processus actuel. Si *pid* est inférieur à -1, une requête est faite pour le statut de chaque processus du groupe de processus donné par *-pid* (la valeur absolue de *pid*).

Une *OSError* est levée avec la valeur de *errno* quand l'appel système renvoie -1.

Sur Windows : attend que qu'un processus donné par l'identificateur de processus (*process handle*) *pid* soit complété, et renvoie un *tuple* contenant *pid* et son statut de sortie décalé de 8 bits vers la gauche (le décalage rend l'utilisation multiplate-forme plus facile). Un *pid* inférieur ou égal à 0 n'a aucune signification particulière sur Windows, et lève une exception. L'argument entier *options* n'a aucun effet. *pid* peut faire référence à tout processus dont l'identifiant est connue pas nécessairement un processus fils. Les fonctions *spawn\** appelées avec *P\_NOWAIT* renvoient des identificateurs de processus appropriés.

#### `os.wait3(options)`

Similaire à la fonction *waitpid()*, si ce n'est que qu'aucun argument *id* n'est donné, et qu'un triplet contenant l'identifiant du processus fils, son statut de sortie, et une information sur l'utilisation des ressources est renvoyé. Référez-vous à *resource.getrusage()* pour des détails sur les informations d'utilisation des ressources. L'argument *options* est le même que celui fourni à *waitpid()* et *wait4()*.

Disponibilité : Unix.

Nouveau dans la version 2.5.

#### `os.wait4(pid, options)`

Similaire à *waitpid()*, si ce n'est qu'un triplet contenant l'identifiant du processus fils, son statut de sortie, et des informations d'utilisation des ressources est renvoyé. Référez-vous à *resource.getrusage()* pour des détails sur les informations d'utilisation des ressources. Les arguments de *wait4()* sont les mêmes que ceux fournis à *waitpid()*.

Disponibilité : Unix.

Nouveau dans la version 2.5.

#### `os.WNOHANG`

L'option de *waitpid()* pour terminer immédiatement si aucun statut de processus fils n'est disponible dans l'immédiat. La fonction renvoie (0, 0) dans ce cas.

Disponibilité : Unix.

#### `os.WCONTINUED`

Cette option cause les processus fils à être reportés s'ils ont été continués après un arrêt du *job control* depuis leurs derniers reports de statuts.

Availability : Some Unix systems.

Nouveau dans la version 2.3.

#### `os.WUNTRACED`

Cette option cause les processus fils à être reportés s'ils ont été stoppés mais que leur état actuel n'a pas été reporté depuis qu'ils ont été stoppés.

Disponibilité : Unix.

Nouveau dans la version 2.3.

Les fonctions suivantes prennent un code de statu tel que renvoyé par `system()`, `wait()`, ou `waitpid()` en paramètre. Ils peuvent être utilisés pour déterminer la disposition d'un processus.

`os.WCOREDUMP(status)`

Renvoie `True` si un vidage système (*core dump*) a été généré pour le processus, sinon, renvoie `False`.

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.WIFCONTINUED(status)`

Renvoie `True` si le processus a été continué après un arrêt du *job control*, renvoie `False` autrement.

Disponibilité : Unix.

Nouveau dans la version 2.3.

`os.WIFSTOPPED(status)`

Renvoie `True` si le processus a été arrêté, sinon renvoie `False`.

Disponibilité : Unix.

`os.WIFSIGNALED(status)`

Renvoie `True` si le processus s'est terminé à cause d'un signal, sinon, renvoie `False`.

Disponibilité : Unix.

`os.WIFEXITED(status)`

Renvoie `True` si le processus s'est terminé en faisant un appel système `exit(2)`, sinon, renvoie `False`.

Disponibilité : Unix.

`os.WEXITSTATUS(status)`

Si `WIFEXITED(status)` vaut `True`, renvoie le paramètre entier de l'appel système `exit(2)`. Sinon, la valeur de retour n'a pas de signification.

Disponibilité : Unix.

`os.WSTOPSIG(status)`

Renvoie le signal qui a causé l'arrêt du processus.

Disponibilité : Unix.

`os.WTERMSIG(status)`

Renvoie le signal qui a amené le processus à quitter.

Disponibilité : Unix.

### 15.1.6 Diverses informations sur le système

`os.confstr(name)`

Renvoie les valeurs de configuration en chaînes de caractères. *name* spécifie la valeur de configuration à récupérer. Ce peut être une chaîne de caractères représentant le nom d'une valeur système définie dans un nombre de standards (POSIX, Unix 95, Unix 98, et d'autres). Certaines plate-formes définissent des noms supplémentaires également. Les noms connus par le système d'exploitation hôte sont données dans les clefs du dictionnaire `confstr_names`. Pour les variables de configuration qui ne sont pas incluses dans ce *mapping*, passer un entier pour *name* est également accepté.

Si la valeur de configuration spécifiée par *name* n'est pas définie, `None` est renvoyé.

Si *name* est une chaîne de caractères et n'est pas connue, une `ValueError` est levée. Si une valeur spécifique pour *name* n'est pas gérée par le système hôte, même si elle est incluse dans `confstr_names`, une `OSError` est levée avec `errno.EINVAL` pour numéro d'erreur.

Disponibilité : Unix

`os.confstr_names`

Dictionnaire liant les noms acceptés par `confstr()` aux valeurs entières définies pour ces noms par le système d'exploitation hôte. Cela peut être utilisé pour déterminer l'ensemble des noms connus du système.

Disponibilité : Unix.

**os.getloadavg()**

Renvoie le nombre de processus dans la file d'exécution du système en moyenne dans les dernières 1, 5, et 15 minutes, ou lève une *OSError* si la charge moyenne est impossible à récupérer.

Disponibilité : Unix.

Nouveau dans la version 2.3.

**os.sysconf(name)**

Renvoie les valeurs de configuration en nombres entiers. Si la valeur de configuration définie par *name* n'est pas spécifiée, -1 est renvoyé. Les commentaires concernant le paramètre *name* de *confstr()* s'appliquent également ici, le dictionnaire qui fournit les informations sur les noms connus est donné par *sysconf\_names*.

Disponibilité : Unix.

**os.sysconf\_names**

Dictionnaire liant les noms acceptés par *sysconf()* aux valeurs entières définies pour ces noms par le système d'exploitation hôte. Cela peut être utilisé pour déterminer l'ensemble des noms connus du système.

Disponibilité : Unix.

Les valeurs suivantes sont utilisées pour gérer les opérations de manipulations de chemins. Elles sont définies pour toutes les plate-formes.

Des opérations de plus haut niveau sur les chemins sont définies dans le module *os.path*.

**os.curdir**

La chaîne de caractère constante utilisée par le système d'exploitation pour référencer le répertoire actuel. Ça vaut '.' pour Windows et POSIX. Également disponible par *os.path*.

**os.pardir**

La chaîne de caractère constante utilisée par le système d'exploitation pour référencer le répertoire parent. Ça vaut '..' pour Windows et POSIX. Également disponible par *os.path*.

**os.sep**

Le caractère utilisé par le système d'exploitation pour séparer les composantes des chemins. C'est '/' pour POSIX, et '\\' pour Windows. Notez que ce n'est pas suffisant pour pouvoir analyser ou concaténer correctement des chemins (utilisez alors *os.path.split()* et *os.path.join()*), mais ça peut s'avérer utile occasionnellement. Également disponible par *os.path*.

**os.altsep**

Un caractère alternatif utilisé par le système d'exploitation pour séparer les composantes des chemins, ou *None* si un seul séparateur existe. Ça vaut '/' sur Windows où *sep* est un antislash '\\'. Également disponible par *os.path*.

**os.extsep**

Le caractère qui sépare la base du nom d'un fichier et son extension. Par exemple, le '.' de *os.py*. Également disponible par *os.path*.

Nouveau dans la version 2.2.

**os.pathsep**

Le caractère conventionnellement utilisé par le système d'exploitation pour séparer la recherche des composantes de chemin (comme dans la variable d'environnement *PATH*). Cela vaut ':' pour POSIX, ou ';' pour Windows. Également disponible par *os.path*.

**os.defpath**

Le chemin de recherche par défaut utilisé par *exec\** et *spawn\** si l'environnement n'a pas une clef 'PATH'. Également disponible par *os.path*.

**os.linesep**

La chaîne de caractères utilisée pour séparer (ou plutôt pour terminer) les lignes sur la plate-forme actuelle. Ce peut être un caractère unique (comme `'\n'` pour POSIX,) ou plusieurs caractères (comme `'\r\n'` pour Windows). N'utilisez pas `os.linesep` comme terminateur de ligne quand vous écrivez dans un fichier ouvert en mode *texte* (par défaut). Utilisez un unique `'\n'` à la place, sur toutes les plate-formes.

**os.devnull**

Le chemin de fichier du périphérique *null*. Par exemple : `'/dev/null'` pour POSIX, `'nul'` pour Windows. Également disponible par `os.path`.

Nouveau dans la version 2.4.

### 15.1.7 Diverses fonctions

**os.urandom(*n*)**

Retourne une chaîne de *n* bytes aléatoires applicables à un usage cryptographique.

This function returns random bytes from an OS-specific randomness source. The returned data should be unpredictable enough for cryptographic applications, though its exact quality depends on the OS implementation. On a UNIX-like system this will query `/dev/urandom`, and on Windows it will use `CryptGenRandom()`. If a randomness source is not found, `NotImplementedError` will be raised.

Pour une interface facile d'utilisation aux générateurs de nombres aléatoires fournis par votre plate-forme, voir `random.SystemRandom`.

Nouveau dans la version 2.4.

## 15.2 io — Core tools for working with streams

Nouveau dans la version 2.6.

The *io* module provides the Python interfaces to stream handling. Under Python 2.x, this is proposed as an alternative to the built-in *file* object, but in Python 3.x it is the default interface to access files and streams.

---

**Note :** Since this module has been designed primarily for Python 3.x, you have to be aware that all uses of « bytes » in this document refer to the *str* type (of which `bytes` is an alias), and all uses of « text » refer to the *unicode* type. Furthermore, those two types are not interchangeable in the *io* APIs.

---

At the top of the I/O hierarchy is the abstract base class *IOBase*. It defines the basic interface to a stream. Note, however, that there is no separation between reading and writing to streams; implementations are allowed to raise an *IOError* if they do not support a given operation.

Extending *IOBase* is *RawIOBase* which deals simply with the reading and writing of raw bytes to a stream. *FileIO* subclasses *RawIOBase* to provide an interface to files in the machine's file system.

*BufferedIOBase* deals with buffering on a raw byte stream (*RawIOBase*). Its subclasses, *BufferedWriter*, *BufferedReader*, and *BufferedRWPair* buffer streams that are readable, writable, and both readable and writable. *BufferedRandom* provides a buffered interface to random access streams. *BytesIO* is a simple stream of in-memory bytes.

Another *IOBase* subclass, *TextIOBase*, deals with streams whose bytes represent text, and handles encoding and decoding from and to *unicode* strings. *TextIOWrapper*, which extends it, is a buffered text interface to a buffered raw stream (*BufferedIOBase*). Finally, *StringIO* is an in-memory stream for unicode text.

Argument names are not part of the specification, and only the arguments of `open()` are intended to be used as keyword arguments.

## 15.2.1 Module Interface

### `io.DEFAULT_BUFFER_SIZE`

An int containing the default buffer size used by the module's buffered I/O classes. `open()` uses the file's blksize (as obtained by `os.stat()`) if possible.

### `io.open(file, mode='r', buffering=-1, encoding=None, errors=None, newline=None, closefd=True)`

Open *file* and return a corresponding stream. If the file cannot be opened, an `IOError` is raised.

*file* is either a string giving the pathname (absolute or relative to the current working directory) of the file to be opened or an integer file descriptor of the file to be wrapped. (If a file descriptor is given, it is closed when the returned I/O object is closed, unless *closefd* is set to `False`.)

*mode* is an optional string that specifies the mode in which the file is opened. It defaults to `'r'` which means open for reading in text mode. Other common values are `'w'` for writing (truncating the file if it already exists), and `'a'` for appending (which on *some* Unix systems, means that *all* writes append to the end of the file regardless of the current seek position). In text mode, if *encoding* is not specified the encoding used is platform dependent. (For reading and writing raw bytes use binary mode and leave *encoding* unspecified.) The available modes are :

Carac- tère	Signification
<code>'r'</code>	ouvre en lecture (par défaut)
<code>'w'</code>	ouvre en écriture, tronquant le fichier
<code>'a'</code>	ouvre en écriture, ajoutant à la fin du fichier s'il existe
<code>'b'</code>	mode binaire
<code>'t'</code>	mode texte (par défaut)
<code>'+'</code>	ouvre un fichier pour le modifier (lire et écrire)
<code>'U'</code>	universal newlines mode (for backwards compatibility ; should not be used in new code)

The default mode is `'rt'` (open for reading text). For binary random access, the mode `'w+b'` opens and truncates the file to 0 bytes, while `'r+b'` opens the file without truncation.

Python distinguishes between files opened in binary and text modes, even when the underlying operating system doesn't. Files opened in binary mode (including `'b'` in the *mode* argument) return contents as `bytes` objects without any decoding. In text mode (the default, or when `'t'` is included in the *mode* argument), the contents of the file are returned as `unicode` strings, the bytes having been first decoded using a platform-dependent encoding or using the specified *encoding* if given.

*buffering* is an optional integer used to set the buffering policy. Pass 0 to switch buffering off (only allowed in binary mode), 1 to select line buffering (only usable in text mode), and an integer  $> 1$  to indicate the size of a fixed-size chunk buffer. When no *buffering* argument is given, the default buffering policy works as follows :

- Binary files are buffered in fixed-size chunks ; the size of the buffer is chosen using a heuristic trying to determine the underlying device's « block size » and falling back on `DEFAULT_BUFFER_SIZE`. On many systems, the buffer will typically be 4096 or 8192 bytes long.
- « Interactive » text files (files for which `isatty()` returns `True`) use line buffering. Other text files use the policy described above for binary files.

*encoding* is the name of the encoding used to decode or encode the file. This should only be used in text mode. The default encoding is platform dependent (whatever `locale.getpreferredencoding()` returns), but any encoding supported by Python can be used. See the `codecs` module for the list of supported encodings.

*errors* is an optional string that specifies how encoding and decoding errors are to be handled—this cannot be used in binary mode. Pass `'strict'` to raise a `ValueError` exception if there is an encoding error (the default of `None` has the same effect), or pass `'ignore'` to ignore errors. (Note that ignoring encoding errors can lead to data loss.) `'replace'` causes a replacement marker (such as `'?'`) to be inserted where there is malformed data. When writing, `'xmlcharrefreplace'` (replace with the appropriate XML character reference) or `'backslashreplace'` (replace with backslashed

escape sequences) can be used. Any other error handling name that has been registered with `codecs.register_error()` is also valid.

`newline` controls how *universal newlines* works (it only applies to text mode). It can be `None`, `''`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows :

- On input, if `newline` is `None`, universal newlines mode is enabled. Lines in the input can end in `'\n'`, `'\r'`, or `'\r\n'`, and these are translated into `'\n'` before being returned to the caller. If it is `''`, universal newlines mode is enabled, but line endings are returned to the caller untranslating. If it has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslating.
- On output, if `newline` is `None`, any `'\n'` characters written are translated to the system default line separator, `os.linesep`. If `newline` is `''`, no translation takes place. If `newline` is any of the other legal values, any `'\n'` characters written are translated to the given string.

If `closefd` is `False` and a file descriptor rather than a filename was given, the underlying file descriptor will be kept open when the file is closed. If a filename is given `closefd` has no effect and must be `True` (the default).

The type of file object returned by the `open()` function depends on the mode. When `open()` is used to open a file in a text mode (`'w'`, `'r'`, `'wt'`, `'rt'`, etc.), it returns a subclass of `TextIOBase` (specifically `TextIOWrapper`). When used to open a file in a binary mode with buffering, the returned class is a subclass of `BufferedIOBase`. The exact class varies : in read binary mode, it returns a `BufferedReader`; in write binary and append binary modes, it returns a `BufferedWriter`, and in read/write mode, it returns a `BufferedRandom`. When buffering is disabled, the raw stream, a subclass of `RawIOBase`, `FileIO`, is returned.

It is also possible to use an *unicode* or *bytes* string as a file for both reading and writing. For *unicode* strings `StringIO` can be used like a file opened in text mode, and for *bytes* a `BytesIO` can be used like a file opened in a binary mode.

#### exception `io.BlockingIOError`

Error raised when blocking would occur on a non-blocking stream. It inherits `IOError`.

In addition to those of `IOError`, `BlockingIOError` has one attribute :

##### `characters_written`

An integer containing the number of characters written to the stream before it blocked.

#### exception `io.UnsupportedOperation`

An exception inheriting `IOError` and `ValueError` that is raised when an unsupported operation is called on a stream.

## 15.2.2 I/O Base Classes

### class `io.IOBase`

The abstract base class for all I/O classes, acting on streams of bytes. There is no public constructor. This class provides empty abstract implementations for many methods that derived classes can override selectively; the default implementations represent a file that cannot be read, written or seeked.

Even though `IOBase` does not declare `read()`, `readinto()`, or `write()` because their signatures will vary, implementations and clients should consider those methods part of the interface. Also, implementations may raise an `IOError` when operations they do not support are called.

The basic type used for binary data read from or written to a file is `bytes` (also known as `str`). Method arguments may also be `bytearray` or `memoryview` of arrays of bytes. In some cases, such as `readinto()`, a writable object such as `bytearray` is required. Text I/O classes work with *unicode* data.

Modifié dans la version 2.7 : Implementations should support `memoryview` arguments.

Note that calling any method (even inquiries) on a closed stream is undefined. Implementations may raise `IOError` in this case.

`IOBase` (and its subclasses) support the iterator protocol, meaning that an `IOBase` object can be iterated over yielding the lines in a stream. Lines are defined slightly differently depending on whether the

stream is a binary stream (yielding `bytes`), or a text stream (yielding `unicode` strings). See `readline()` below.

`IOBase` is also a context manager and therefore supports the `with` statement. In this example, `file` is closed after the `with` statement's suite is finished—even if an exception occurs :

```
with io.open('spam.txt', 'w') as file:
    file.write(u'Spam and eggs!')
```

`IOBase` provides these data attributes and methods :

**close()**

Flush and close this stream. This method has no effect if the file is already closed. Once the file is closed, any operation on the file (e.g. reading or writing) will raise a `ValueError`.

As a convenience, it is allowed to call this method more than once; only the first call, however, will have an effect.

**closed**

True if the stream is closed.

**fileno()**

Return the underlying file descriptor (an integer) of the stream if it exists. An `IOError` is raised if the IO object does not use a file descriptor.

**flush()**

Flush the write buffers of the stream if applicable. This does nothing for read-only and non-blocking streams.

**isatty()**

Return `True` if the stream is interactive (i.e., connected to a terminal/tty device).

**readable()**

Return `True` if the stream can be read from. If `False`, `read()` will raise `IOError`.

**readline(*limit=-1*)**

Read and return one line from the stream. If *limit* is specified, at most *limit* bytes will be read.

The line terminator is always `b'\n'` for binary files; for text files, the *newline* argument to `open()` can be used to select the line terminator(s) recognized.

**readlines(*hint=-1*)**

Read and return a list of lines from the stream. *hint* can be specified to control the number of lines read : no more lines will be read if the total size (in bytes/characters) of all lines so far exceeds *hint*.

Note that it's already possible to iterate on file objects using `for line in file: ...` without calling `file.readlines()`.

**seek(*offset*[, *whence*])**

Change the stream position to the given byte *offset*. *offset* is interpreted relative to the position indicated by *whence*. The default value for *whence* is `SEEK_SET`. Values for *whence* are :

- `SEEK_SET` or 0 – start of the stream (the default); *offset* should be zero or positive
- `SEEK_CUR` or 1 – current stream position; *offset* may be negative
- `SEEK_END` or 2 – end of the stream; *offset* is usually negative

Return the new absolute position.

Nouveau dans la version 2.7 : The `SEEK_*` constants

**seekable()**

Return `True` if the stream supports random access. If `False`, `seek()`, `tell()` and `truncate()` will raise `IOError`.

**tell()**

Return the current stream position.

**truncate(*size=None*)**

Resize the stream to the given *size* in bytes (or the current position if *size* is not specified). The current stream position isn't changed. This resizing can extend or reduce the current file size. In

case of extension, the contents of the new file area depend on the platform (on most systems, additional bytes are zero-filled, on Windows they're undetermined). The new file size is returned.

**writable()**

Return **True** if the stream supports writing. If **False**, **write()** and **truncate()** will raise **IOError**.

**writelines(*lines*)**

Write a list of lines to the stream. Line separators are not added, so it is usual for each of the lines provided to have a line separator at the end.

**\_\_del\_\_()**

Prepare for object destruction. **IOBase** provides a default implementation of this method that calls the instance's **close()** method.

**class io.RawIOBase**

Base class for raw binary I/O. It inherits **IOBase**. There is no public constructor.

Raw binary I/O typically provides low-level access to an underlying OS device or API, and does not try to encapsulate it in high-level primitives (this is left to Buffered I/O and Text I/O, described later in this page).

In addition to the attributes and methods from **IOBase**, **RawIOBase** provides the following methods :

**read(*n=-1*)**

Read up to *n* bytes from the object and return them. As a convenience, if *n* is unspecified or -1, **readall()** is called. Otherwise, only one system call is ever made. Fewer than *n* bytes may be returned if the operating system call returns fewer than *n* bytes.

If 0 bytes are returned, and *n* was not 0, this indicates end of file. If the object is in non-blocking mode and no bytes are available, **None** is returned.

**readall()**

Read and return all the bytes from the stream until EOF, using multiple calls to the stream if necessary.

**readinto(*b*)**

Read up to **len(b)** bytes into *b*, and return the number of bytes read. The object *b* should be a pre-allocated, writable array of bytes, either **bytearray** or **memoryview**. If the object is in non-blocking mode and no bytes are available, **None** is returned.

**write(*b*)**

Write *b* to the underlying raw stream, and return the number of bytes written. The object *b* should be an array of bytes, either **bytes**, **bytearray**, or **memoryview**. The return value can be less than **len(b)**, depending on specifics of the underlying raw stream, and especially if it is in non-blocking mode. **None** is returned if the raw stream is set not to block and no single byte could be readily written to it. The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

**class io.BufferedIOBase**

Base class for binary streams that support some kind of buffering. It inherits **IOBase**. There is no public constructor.

The main difference with **RawIOBase** is that methods **read()**, **readinto()** and **write()** will try (respectively) to read as much input as requested or to consume all given output, at the expense of making perhaps more than one system call.

In addition, those methods can raise **BlockingIOError** if the underlying raw stream is in non-blocking mode and cannot take or give enough data ; unlike their **RawIOBase** counterparts, they will never return **None**.

Besides, the **read()** method does not have a default implementation that defers to **readinto()**.

A typical **BufferedIOBase** implementation should not inherit from a **RawIOBase** implementation, but wrap one, like **BufferedWriter** and **BufferedReader** do.

**BufferedIOBase** provides or overrides these methods and attribute in addition to those from **IOBase** :

**raw**

The underlying raw stream (a *RawIOBase* instance) that *BufferedIOBase* deals with. This is not part of the *BufferedIOBase* API and may not exist on some implementations.

**detach()**

Separate the underlying raw stream from the buffer and return it.

After the raw stream has been detached, the buffer is in an unusable state.

Some buffers, like *BytesIO*, do not have the concept of a single raw stream to return from this method. They raise *UnsupportedOperation*.

Nouveau dans la version 2.7.

**read(*n*=-1)**

Read and return up to *n* bytes. If the argument is omitted, *None*, or negative, data is read and returned until EOF is reached. An empty bytes object is returned if the stream is already at EOF.

If the argument is positive, and the underlying raw stream is not interactive, multiple raw reads may be issued to satisfy the byte count (unless EOF is reached first). But for interactive raw streams, at most one raw read will be issued, and a short result does not imply that EOF is imminent.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

**read1(*n*=-1)**

Read and return up to *n* bytes, with at most one call to the underlying raw stream's *read()* method. This can be useful if you are implementing your own buffering on top of a *BufferedIOBase* object.

**readinto(*b*)**

Read up to *len(b)* bytes into *b*, and return the number of bytes read. The object *b* should be a pre-allocated, writable array of bytes, either *bytearray* or *memoryview*.

Like *read()*, multiple reads may be issued to the underlying raw stream, unless the latter is “interactive”.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

**write(*b*)**

Write *b*, and return the number of bytes written (always equal to *len(b)*, since if the write fails an *IOError* will be raised). The object *b* should be an array of bytes, either *bytes*, *bytearray*, or *memoryview*. Depending on the actual implementation, these bytes may be readily written to the underlying stream, or held in a buffer for performance and latency reasons.

When in non-blocking mode, a *BlockingIOError* is raised if the data needed to be written to the raw stream but it couldn't accept all the data without blocking.

The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

### 15.2.3 Raw File I/O

**class** *io.FileIO*(*name*, *mode*='r', *closefd*=True)

*FileIO* represents an OS-level file containing bytes data. It implements the *RawIOBase* interface (and therefore the *IOBase* interface, too).

The *name* can be one of two things :

- a string representing the path to the file which will be opened ;
- an integer representing the number of an existing OS-level file descriptor to which the resulting *FileIO* object will give access.

The *mode* can be 'r', 'w' or 'a' for reading (default), writing, or appending. The file will be created if it doesn't exist when opened for writing or appending ; it will be truncated when opened for writing. Add a '+' to the mode to allow simultaneous reading and writing.

The *read()* (when called with a positive argument), *readinto()* and *write()* methods on this class will only make one system call.

In addition to the attributes and methods from *IOBase* and *RawIOBase*, *FileIO* provides the following data attributes and methods :

**mode**

The mode as given in the constructor.

**name**

The file name. This is the file descriptor of the file when no name is given in the constructor.

### 15.2.4 Buffered Streams

Buffered I/O streams provide a higher-level interface to an I/O device than raw I/O does.

**class** `io.BytesIO([initial_bytes])`

A stream implementation using an in-memory bytes buffer. It inherits *BufferedIOBase*.

The optional argument *initial\_bytes* is a **bytes** object that contains initial data.

*BytesIO* provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase* :

**getvalue()**

Return **bytes** containing the entire contents of the buffer.

**read1()**

In *BytesIO*, this is the same as **read()**.

**class** `io.BufferedReader(raw, buffer_size=DEFAULT_BUFFER_SIZE)`

A buffer providing higher-level access to a readable, sequential *RawIOBase* object. It inherits *BufferedIOBase*. When reading data from this object, a larger amount of data may be requested from the underlying raw stream, and kept in an internal buffer. The buffered data can then be returned directly on subsequent reads.

The constructor creates a *BufferedReader* for the given readable *raw* stream and *buffer\_size*. If *buffer\_size* is omitted, *DEFAULT\_BUFFER\_SIZE* is used.

*BufferedReader* provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase* :

**peek([n])**

Return bytes from the stream without advancing the position. At most one single read on the raw stream is done to satisfy the call. The number of bytes returned may be less or more than requested.

**read([n])**

Read and return *n* bytes, or if *n* is not given or negative, until EOF or if the read call would block in non-blocking mode.

**read1(n)**

Read and return up to *n* bytes with only one call on the raw stream. If at least one byte is buffered, only buffered bytes are returned. Otherwise, one raw stream read call is made.

**class** `io.BufferedWriter(raw, buffer_size=DEFAULT_BUFFER_SIZE)`

A buffer providing higher-level access to a writeable, sequential *RawIOBase* object. It inherits *BufferedIOBase*. When writing to this object, data is normally held into an internal buffer. The buffer will be written out to the underlying *RawIOBase* object under various conditions, including :

- when the buffer gets too small for all pending data ;
- when *flush()* is called ;
- when a *seek()* is requested (for *BufferedRandom* objects) ;
- when the *BufferedWriter* object is closed or destroyed.

The constructor creates a *BufferedWriter* for the given writeable *raw* stream. If the *buffer\_size* is not given, it defaults to *DEFAULT\_BUFFER\_SIZE*.

A third argument, *max\_buffer\_size*, is supported, but unused and deprecated.

*BufferedWriter* provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase* :

**flush()**

Force bytes held in the buffer into the raw stream. A *BlockingIOError* should be raised if the raw stream blocks.

**write(b)**

Write *b*, and return the number of bytes written. The object *b* should be an array of bytes, either *bytes*, *bytearray*, or *memoryview*. When in non-blocking mode, a *BlockingIOError* is raised if the buffer needs to be written out but the raw stream blocks.

**class** *io.BufferedRandom*(*raw*, *buffer\_size*=*DEFAULT\_BUFFER\_SIZE*)

A buffered interface to random access streams. It inherits *BufferedReader* and *BufferedWriter*, and further supports *seek()* and *tell()* functionality.

The constructor creates a reader and writer for a seekable raw stream, given in the first argument. If the *buffer\_size* is omitted it defaults to *DEFAULT\_BUFFER\_SIZE*.

A third argument, *max\_buffer\_size*, is supported, but unused and deprecated.

*BufferedRandom* is capable of anything *BufferedReader* or *BufferedWriter* can do.

**class** *io.BufferedRWPair*(*reader*, *writer*, *buffer\_size*=*DEFAULT\_BUFFER\_SIZE*)

A buffered I/O object combining two unidirectional *RawIOBase* objects – one readable, the other writeable – into a single bidirectional endpoint. It inherits *BufferedIOBase*.

*reader* and *writer* are *RawIOBase* objects that are readable and writeable respectively. If the *buffer\_size* is omitted it defaults to *DEFAULT\_BUFFER\_SIZE*.

A fourth argument, *max\_buffer\_size*, is supported, but unused and deprecated.

*BufferedRWPair* implements all of *BufferedIOBase*'s methods except for *detach()*, which raises *UnsupportedOperation*.

**Avertissement :** *BufferedRWPair* does not attempt to synchronize accesses to its underlying raw streams. You should not pass it the same object as reader and writer ; use *BufferedRandom* instead.

## 15.2.5 Text I/O

**class** *io.TextIOBase*

Base class for text streams. This class provides a unicode character and line based interface to stream I/O. There is no *readinto()* method because Python's *unicode* strings are immutable. It inherits *IOBase*. There is no public constructor.

*TextIOBase* provides or overrides these data attributes and methods in addition to those from *IOBase* :

**encoding**

The name of the encoding used to decode the stream's bytes into strings, and to encode strings into bytes.

**errors**

The error setting of the decoder or encoder.

**newlines**

A string, a tuple of strings, or *None*, indicating the newlines translated so far. Depending on the implementation and the initial constructor flags, this may not be available.

**buffer**

The underlying binary buffer (a *BufferedIOBase* instance) that *TextIOBase* deals with. This is not part of the *TextIOBase* API and may not exist on some implementations.

**detach()**

Separate the underlying binary buffer from the *TextIOBase* and return it.

After the underlying buffer has been detached, the *TextIOBase* is in an unusable state.

Some *TextIOBase* implementations, like *StringIO*, may not have the concept of an underlying buffer and calling this method will raise *UnsupportedOperation*.

Nouveau dans la version 2.7.

**read(*n=-1*)**

Read and return at most *n* characters from the stream as a single *unicode*. If *n* is negative or *None*, reads until EOF.

**readline(*limit=-1*)**

Read until newline or EOF and return a single *unicode*. If the stream is already at EOF, an empty string is returned.

If *limit* is specified, at most *limit* characters will be read.

**seek(*offset[, whence]*)**

Change the stream position to the given *offset*. Behaviour depends on the *whence* parameter. The default value for *whence* is *SEEK\_SET*.

- *SEEK\_SET* or 0 : seek from the start of the stream (the default); *offset* must either be a number returned by *TextIOBase.tell()*, or zero. Any other *offset* value produces undefined behaviour.
- *SEEK\_CUR* or 1 : « seek » to the current position; *offset* must be zero, which is a no-operation (all other values are unsupported).
- *SEEK\_END* or 2 : seek to the end of the stream; *offset* must be zero (all other values are unsupported).

Return the new absolute position as an opaque number.

Nouveau dans la version 2.7 : The *SEEK\_\** constants.

**tell()**

Return the current stream position as an opaque number. The number does not usually represent a number of bytes in the underlying binary storage.

**write(*s*)**

Write the *unicode* string *s* to the stream and return the number of characters written.

**class io.TextIOWrapper(*buffer, encoding=None, errors=None, newline=None, line\_buffering=False*)**

A buffered text stream over a *BufferedIOBase* binary stream. It inherits *TextIOBase*.

*encoding* gives the name of the encoding that the stream will be decoded or encoded with. It defaults to *locale.getpreferredencoding()*.

*errors* is an optional string that specifies how encoding and decoding errors are to be handled. Pass 'strict' to raise a *ValueError* exception if there is an encoding error (the default of *None* has the same effect), or pass 'ignore' to ignore errors. (Note that ignoring encoding errors can lead to data loss.) 'replace' causes a replacement marker (such as '?') to be inserted where there is malformed data. When writing, 'xmlcharrefreplace' (replace with the appropriate XML character reference) or 'backslashreplace' (replace with backslashed escape sequences) can be used. Any other error handling name that has been registered with *codecs.register\_error()* is also valid.

*newline* controls how line endings are handled. It can be *None*, ' ', '\n', '\r', and '\r\n'. It works as follows :

- On input, if *newline* is *None*, *universal newlines* mode is enabled. Lines in the input can end in '\n', '\r', or '\r\n', and these are translated into '\n' before being returned to the caller. If it is ' ', universal newlines mode is enabled, but line endings are returned to the caller untranslating. If it has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslating.
- On output, if *newline* is *None*, any '\n' characters written are translated to the system default line separator, *os.linesep*. If *newline* is ' ', no translation takes place. If *newline* is any of the other legal values, any '\n' characters written are translated to the given string.

If *line\_buffering* is *True*, *flush()* is implied when a call to write contains a newline character or a carriage return.

*TextIOWrapper* provides one attribute in addition to those of *TextIOBase* and its parents :

**line\_buffering**

Whether line buffering is enabled.

`class io.StringIO(initial_value=u'', newline=u'\n')`

An in-memory stream for unicode text. It inherits *TextIOWrapper*.

The initial value of the buffer can be set by providing *initial\_value*. If newline translation is enabled, newlines will be encoded as if by *write()*. The stream is positioned at the start of the buffer.

The *newline* argument works like that of *TextIOWrapper*. The default is to consider only `\n` characters as ends of lines and to do no newline translation. If *newline* is set to `None`, newlines are written as `\n` on all platforms, but universal newline decoding is still performed when reading.

*StringIO* provides this method in addition to those from *TextIOWrapper* and its parents :

*getvalue()*

Return a unicode containing the entire contents of the buffer at any time before the *StringIO* object's *close()* method is called. Newlines are decoded as if by *read()*, although the stream position is not changed.

Example usage :

```
import io

output = io.StringIO()
output.write(u'First line.\n')
output.write(u'Second line.\n')

# Retrieve file contents -- this will be
# u'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

`class io.IncrementalNewlineDecoder`

A helper codec that decodes newlines for *universal newlines* mode. It inherits *codecs.IncrementalDecoder*.

## 15.2.6 Advanced topics

Here we will discuss several advanced topics pertaining to the concrete I/O implementations described above.

### Performance

#### Binary I/O

By reading and writing only large chunks of data even when the user asks for a single byte, buffered I/O is designed to hide any inefficiency in calling and executing the operating system's unbuffered I/O routines. The gain will vary very much depending on the OS and the kind of I/O which is performed (for example, on some contemporary OSes such as Linux, unbuffered disk I/O can be as fast as buffered I/O). The bottom line, however, is that buffered I/O will offer you predictable performance regardless of the platform and the backing device. Therefore, it is most always preferable to use buffered I/O rather than unbuffered I/O.

#### Text I/O

Text I/O over a binary storage (such as a file) is significantly slower than binary I/O over the same storage, because it implies conversions from unicode to binary data using a character codec. This can become noticeable if you handle huge amounts of text data (for example very large log files). Also, *TextIOWrapper*.*tell()* and *TextIOWrapper*.*seek()* are both quite slow due to the reconstruction algorithm used.

*StringIO*, however, is a native in-memory unicode container and will exhibit similar speed to *BytesIO*.

## Fils d'exécution

*FileIO* objects are thread-safe to the extent that the operating system calls (such as `read(2)` under Unix) they are wrapping are thread-safe too.

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) protect their internal structures using a lock ; it is therefore safe to call them from multiple threads at once.

*TextIOWrapper* objects are not thread-safe.

## Reentrancy

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) are not reentrant. While reentrant calls will not happen in normal situations, they can arise if you are doing I/O in a *signal* handler. If it is attempted to enter a buffered object again while already being accessed *from the same thread*, then a *RuntimeError* is raised.

The above implicitly extends to text files, since the *open()* function will wrap a buffered object inside a *TextIOWrapper*. This includes standard streams and therefore affects the built-in function *print()* as well.

## 15.3 time — Time access and conversions

This module provides various time-related functions. For related functionality, see also the *datetime* and *calendar* modules.

Although this module is always available, not all functions are available on all platforms. Most of the functions defined in this module call platform C library functions with the same name. It may sometimes be helpful to consult the platform documentation, because the semantics of these functions varies among platforms.

An explanation of some terminology and conventions is in order.

- The *epoch* is the point where the time starts. On January 1st of that year, at 0 hours, the « time since the epoch » is zero. For Unix, the epoch is 1970. To find out what the epoch is, look at `gmtime(0)`.
- The functions in this module do not handle dates and times before the epoch or far in the future. The cut-off point in the future is determined by the C library ; for Unix, it is typically in 2038.
- **Year 2000 (Y2K) issues** : Python depends on the platform's C library, which generally doesn't have year 2000 issues, since all dates and times are represented internally as seconds since the epoch. Functions accepting a *struct\_time* (see below) generally require a 4-digit year. For backward compatibility, 2-digit years are supported if the module variable `accept2dyear` is a non-zero integer ; this variable is initialized to 1 unless the environment variable `PYTHONY2K` is set to a non-empty string, in which case it is initialized to 0. Thus, you can set `PYTHONY2K` to a non-empty string in the environment to require 4-digit years for all year input. When 2-digit years are accepted, they are converted according to the POSIX or X/Open standard : values 69-99 are mapped to 1969-1999, and values 0-68 are mapped to 2000-2068. Values 100-1899 are always illegal.
- UTC is Coordinated Universal Time (formerly known as Greenwich Mean Time, or GMT). The acronym UTC is not a mistake but a compromise between English and French.
- DST is Daylight Saving Time, an adjustment of the timezone by (usually) one hour during part of the year. DST rules are magic (determined by local law) and can change from year to year. The C library has a table containing the local rules (often it is read from a system file for flexibility) and is the only source of True Wisdom in this respect.
- The precision of the various real-time functions may be less than suggested by the units in which their value or argument is expressed. E.g. on most Unix systems, the clock « ticks » only 50 or 100 times a second.

- On the other hand, the precision of `time()` and `sleep()` is better than their Unix equivalents : times are expressed as floating point numbers, `time()` returns the most accurate time available (using Unix `gettimeofday()` where available), and `sleep()` will accept a time with a nonzero fraction (Unix `select()` is used to implement this, where available).
- The time value as returned by `gmtime()`, `localtime()`, and `strptime()`, and accepted by `asctime()`, `mktime()` and `strftime()`, may be considered as a sequence of 9 integers. The return values of `gmtime()`, `localtime()`, and `strptime()` also offer attribute names for individual fields. See `struct_time` for a description of these objects.  
Modifié dans la version 2.2 : The time value sequence was changed from a tuple to a `struct_time`, with the addition of attribute names for the fields.
- Use the following functions to convert between time representations :

De	À	Use
seconds since the epoch	<code>struct_time</code> in UTC	<code>gmtime()</code>
seconds since the epoch	<code>struct_time</code> in local time	<code>localtime()</code>
<code>struct_time</code> in UTC	seconds since the epoch	<code>calendar.timegm()</code>
<code>struct_time</code> in local time	seconds since the epoch	<code>mktime()</code>

The module defines the following functions and data items :

**time.accept2dayear**

Boolean value indicating whether two-digit year values will be accepted. This is true by default, but will be set to false if the environment variable `PYTHONY2K` has been set to a non-empty string. It may also be modified at run time.

**time.altzone**

The offset of the local DST timezone, in seconds west of UTC, if one is defined. This is negative if the local DST timezone is east of UTC (as in Western Europe, including the UK). Only use this if daylight is nonzero.

**time.asctime([t])**

Convert a tuple or `struct_time` representing a time as returned by `gmtime()` or `localtime()` to a 24-character string of the following form : 'Sun Jun 20 23:21:05 1993'. If `t` is not provided, the current time as returned by `localtime()` is used. Locale information is not used by `asctime()`.

---

**Note :** Unlike the C function of the same name, there is no trailing newline.

---

Modifié dans la version 2.1 : Allowed `t` to be omitted.

**time.clock()**

On Unix, return the current processor time as a floating point number expressed in seconds. The precision, and in fact the very definition of the meaning of « processor time », depends on that of the C function of the same name, but in any case, this is the function to use for benchmarking Python or timing algorithms.

On Windows, this function returns wall-clock seconds elapsed since the first call to this function, as a floating point number, based on the Win32 function `QueryPerformanceCounter()`. The resolution is typically better than one microsecond.

**time.ctime([secs])**

Convert a time expressed in seconds since the epoch to a string representing local time. If `secs` is not provided or `None`, the current time as returned by `time()` is used. `ctime(secs)` is equivalent to `asctime(localtime(secs))`. Locale information is not used by `ctime()`.

Modifié dans la version 2.1 : Allowed `secs` to be omitted.

Modifié dans la version 2.4 : If `secs` is `None`, the current time is used.

**time.daylight**

Nonzero if a DST timezone is defined.

`time.gmtime([secs])`

Convert a time expressed in seconds since the epoch to a *struct\_time* in UTC in which the dst flag is always zero. If *secs* is not provided or *None*, the current time as returned by *time()* is used. Fractions of a second are ignored. See above for a description of the *struct\_time* object. See *calendar.timegm()* for the inverse of this function.

Modifié dans la version 2.1 : Allowed *secs* to be omitted.

Modifié dans la version 2.4 : If *secs* is *None*, the current time is used.

`time.localtime([secs])`

Like *gmtime()* but converts to local time. If *secs* is not provided or *None*, the current time as returned by *time()* is used. The dst flag is set to 1 when DST applies to the given time.

Modifié dans la version 2.1 : Allowed *secs* to be omitted.

Modifié dans la version 2.4 : If *secs* is *None*, the current time is used.

`time.mktime(t)`

This is the inverse function of *localtime()*. Its argument is the *struct\_time* or full 9-tuple (since the dst flag is needed; use -1 as the dst flag if it is unknown) which expresses the time in *local* time, not UTC. It returns a floating point number, for compatibility with *time()*. If the input value cannot be represented as a valid time, either *OverflowError* or *ValueError* will be raised (which depends on whether the invalid value is caught by Python or the underlying C libraries). The earliest date for which it can generate a time is platform-dependent.

`time.sleep(secs)`

Suspend execution of the current thread for the given number of seconds. The argument may be a floating point number to indicate a more precise sleep time. The actual suspension time may be less than that requested because any caught signal will terminate the *sleep()* following execution of that signal's catching routine. Also, the suspension time may be longer than requested by an arbitrary amount because of the scheduling of other activity in the system.

`time.strftime(format[, t])`

Convert a tuple or *struct\_time* representing a time as returned by *gmtime()* or *localtime()* to a string as specified by the *format* argument. If *t* is not provided, the current time as returned by *localtime()* is used. *format* must be a string. *ValueError* is raised if any field in *t* is outside of the allowed range. *strftime()* returns a locale dependent byte string; the result may be converted to unicode by doing *strftime(<myformat>).decode(locale.getlocale()[1])*.

Modifié dans la version 2.1 : Allowed *t* to be omitted.

Modifié dans la version 2.4 : *ValueError* raised if a field in *t* is out of range.

Modifié dans la version 2.5 : 0 is now a legal argument for any position in the time tuple; if it is normally illegal the value is forced to a correct one.

The following directives can be embedded in the *format* string. They are shown without the optional field width and precision specification, and are replaced by the indicated characters in the *strftime()* result :

Directive	Signification	Notes
%a	Locale's abbreviated weekday name.	
%A	Locale's full weekday name.	
%b	Locale's abbreviated month name.	
%B	Locale's full month name.	
%c	Représentation locale de la date et de l'heure.	
%d	Day of the month as a decimal number [01,31].	
%H	Hour (24-hour clock) as a decimal number [00,23].	
%I	Hour (12-hour clock) as a decimal number [01,12].	
%j	Day of the year as a decimal number [001,366].	
%m	Month as a decimal number [01,12].	
%M	Minute as a decimal number [00,59].	
%p	Équivalent local à AM/PM.	(1)
%S	Second as a decimal number [00,61].	(2)
%U	Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.	(3)
%w	Weekday as a decimal number [0(Sunday),6].	
%W	Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.	(3)
%x	Représentation locale de la date.	
%X	Représentation locale de l'heure.	
%y	Year without century as a decimal number [00,99].	
%Y	Année complète sur quatre chiffres.	
%Z	Time zone name (no characters if no time zone exists).	
%%	Un caractère '%' littéral.	

Notes :

- (1) When used with the `strptime()` function, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.
- (2) The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.
- (3) When used with the `strptime()` function, `%U` and `%W` are only used in calculations when the day of the week and the year are specified.

Here is an example, a format for dates compatible with that specified in the [RFC 2822](#) Internet email standard.<sup>1</sup>

```
>>> from time import gmtime, strftime
>>> strftime("%a, %d %b %Y %H:%M:%S +0000", gmtime())
'Thu, 28 Jun 2001 14:17:15 +0000'
```

Additional directives may be supported on certain platforms, but only the ones listed here have a meaning standardized by ANSI C. To see the full set of format codes supported on your platform, consult the `strftime(3)` documentation.

On some platforms, an optional field width and precision specification can immediately follow the initial '%' of a directive in the following order; this is also not portable. The field width is normally 2 except for `%j` where it is 3.

1. The use of `%Z` is now deprecated, but the `%z` escape that expands to the preferred hour/minute offset is not supported by all ANSI C libraries. Also, a strict reading of the original 1982 [RFC 822](#) standard calls for a two-digit year (`%y` rather than `%Y`), but practice moved to 4-digit years long before the year 2000. After that, [RFC 822](#) became obsolete and the 4-digit year has been first recommended by [RFC 1123](#) and then mandated by [RFC 2822](#).

`time.strptime(string[, format])`

Parse a string representing a time according to a format. The return value is a *struct\_time* as returned by *gmtime()* or *localtime()*.

The *format* parameter uses the same directives as those used by *strftime()*; it defaults to `"%a %b %d %H:%M:%S %Y"` which matches the formatting returned by *ctime()*. If *string* cannot be parsed according to *format*, or if it has excess data after parsing, *ValueError* is raised. The default values used to fill in any missing data when more accurate values cannot be inferred are (1900, 1, 1, 0, 0, 0, 0, 1, -1).

Par exemple :

```
>>> import time
>>> time.strptime("30 Nov 00", "%d %b %y")    # doctest: +NORMALIZE_WHITESPACE
time.struct_time(tm_year=2000, tm_mon=11, tm_mday=30, tm_hour=0, tm_min=0,
                  tm_sec=0, tm_wday=3, tm_yday=335, tm_isdst=-1)
```

Support for the `%Z` directive is based on the values contained in `tzname` and whether `daylight` is true. Because of this, it is platform-specific except for recognizing UTC and GMT which are always known (and are considered to be non-daylight savings timezones).

Only the directives specified in the documentation are supported. Because *strftime()* is implemented per platform it can sometimes offer more directives than those listed. But *strptime()* is independent of any platform and thus does not necessarily support all directives available that are not documented as supported.

`class time.struct_time`

The type of the time value sequence returned by *gmtime()*, *localtime()*, and *strptime()*. It is an object with a *named tuple* interface : values can be accessed by index and by attribute name. The following values are present :

Index	Attribut	Valeurs
0	<code>tm_year</code>	(for example, 1993)
1	<code>tm_mon</code>	range [1, 12]
2	<code>tm_mday</code>	range [1, 31]
3	<code>tm_hour</code>	range [0, 23]
4	<code>tm_min</code>	range [0, 59]
5	<code>tm_sec</code>	range [0, 61]; see (2) in <i>strftime()</i> description
6	<code>tm_wday</code>	range [0, 6], Monday is 0
7	<code>tm_yday</code>	range [1, 366]
8	<code>tm_isdst</code>	0, 1 or -1; see below

Nouveau dans la version 2.2.

Note that unlike the C structure, the month value is a range of [1, 12], not [0, 11]. A year value will be handled as described under *Year 2000 (Y2K) issues* above.

In calls to *mktime()*, `tm_isdst` may be set to 1 when daylight savings time is in effect, and 0 when it is not. A value of -1 indicates that this is not known, and will usually result in the correct state being filled in.

When a tuple with an incorrect length is passed to a function expecting a *struct\_time*, or having elements of the wrong type, a *TypeError* is raised.

`time.time()`

Return the time in seconds since the epoch as a floating point number. Note that even though the time is always returned as a floating point number, not all systems provide time with a better precision than 1 second. While this function normally returns non-decreasing values, it can return a lower value than a previous call if the system clock has been set back between the two calls.

`time.timezone`

The offset of the local (non-DST) timezone, in seconds west of UTC (negative in most of Western Europe, positive in the US, zero in the UK).

**time.tzname**

A tuple of two strings : the first is the name of the local non-DST timezone, the second is the name of the local DST timezone. If no DST timezone is defined, the second string should not be used.

**time.tzset()**

Reset the time conversion rules used by the library routines. The environment variable TZ specifies how this is done. It will also set the variables **tzname** (from the TZ environment variable), **timezone** (non-DST seconds West of UTC), **altzone** (DST seconds west of UTC) and **daylight** (to 0 if this timezone does not have any daylight saving time rules, or to nonzero if there is a time, past, present or future when daylight saving time applies).

Nouveau dans la version 2.3.

Disponibilité : Unix.

---

**Note :** Although in many cases, changing the TZ environment variable may affect the output of functions like *localtime()* without calling *tzset()*, this behavior should not be relied on.

The TZ environment variable should contain no whitespace.

---

The standard format of the TZ environment variable is (whitespace added for clarity) :

```
std offset [dst [offset [,start[/time], end[/time]]]]
```

Where the components are :

**std and dst** Three or more alphanumerics giving the timezone abbreviations. These will be propagated into **time.tzname**

**offset** The offset has the form :  $\pm \text{hh}[:\text{mm}[:\text{ss}]]$ . This indicates the value added the local time to arrive at UTC. If preceded by a “-“, the timezone is east of the Prime Meridian ; otherwise, it is west. If no offset follows **dst**, summer time is assumed to be one hour ahead of standard time.

**start[/time], end[/time]** Indicates when to change to and back from DST. The format of the start and end dates are one of the following :

**Jn** The Julian day *n* ( $1 \leq n \leq 365$ ). Leap days are not counted, so in all years February 28 is day 59 and March 1 is day 60.

**n** The zero-based Julian day ( $0 \leq n \leq 365$ ). Leap days are counted, and it is possible to refer to February 29.

**Mm.n.d** The *d*'th day ( $0 \leq d \leq 6$ ) or week *n* of month *m* of the year ( $1 \leq n \leq 5$ ,  $1 \leq m \leq 12$ , where week 5 means « the last *d* day in month *m* » which may occur in either the fourth or the fifth week). Week 1 is the first week in which the *d*'th day occurs. Day zero is Sunday.

**time** has the same format as **offset** except that no leading sign (“-“ or “+”) is allowed. The default, if time is not given, is 02 :00 :00.

```
>>> os.environ['TZ'] = 'EST+05EDT,M4.1.0,M10.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'02:07:36 05/08/03 EDT'
>>> os.environ['TZ'] = 'AEST-10AEDT-11,M10.5.0,M3.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'16:08:12 05/08/03 AEST'
```

On many Unix systems (including \*BSD, Linux, Solaris, and Darwin), it is more convenient to use the system's zoneinfo (*tzfile(5)*) database to specify the timezone rules. To do this, set the TZ environment variable to the path of the required timezone datafile, relative to the root of the systems

“zoneinfo” timezone database, usually located at `/usr/share/zoneinfo`. For example, `'US/Eastern'`, `'Australia/Melbourne'`, `'Egypt'` or `'Europe/Amsterdam'`.

```
>>> os.environ['TZ'] = 'US/Eastern'
>>> time.tzset()
>>> time.tzname
('EST', 'EDT')
>>> os.environ['TZ'] = 'Egypt'
>>> time.tzset()
>>> time.tzname
('EET', 'EEST')
```

Module `calendar` General calendar-related functions. `timegm()` is the inverse of `gmtime()` from this module.

## Notes

# 15.4 argparse – Parseur d’arguments, d’options, et de sous-commandes de ligne de commande

Nouveau dans la version 2.7.

Code source : [Lib/argparse.py](#)

## Tutoriel

Cette page est la référence de l’API. Pour une introduction plus en douceur à l’analyse des arguments de la ligne de commande, regardez le tutoriel `argparse`.

The `argparse` module makes it easy to write user-friendly command-line interfaces. The program defines what arguments it requires, and `argparse` will figure out how to parse those out of `sys.argv`. The `argparse` module also automatically generates help and usage messages and issues errors when users give the program invalid arguments.

## 15.4.1 Exemple

Le code suivant est un programme Python acceptant une liste de nombre entiers et en donnant soit la somme, soit le maximum :

```
import argparse

parser = argparse.ArgumentParser(description='Process some integers.')
parser.add_argument('integers', metavar='N', type=int, nargs='+',
                    help='an integer for the accumulator')
parser.add_argument('--sum', dest='accumulate', action='store_const',
                    const=sum, default=max,
```

(suite sur la page suivante)

(suite de la page précédente)

```
help='sum the integers (default: find the max)')

args = parser.parse_args()
print args.accumulate(args.integers)
```

Assuming the Python code above is saved into a file called `prog.py`, it can be run at the command line and provides useful help messages :

```
$ python prog.py -h
usage: prog.py [-h] [--sum] N [N ...]

Process some integers.

positional arguments:
  N              an integer for the accumulator

optional arguments:
  -h, --help    show this help message and exit
  --sum         sum the integers (default: find the max)
```

When run with the appropriate arguments, it prints either the sum or the max of the command-line integers :

```
$ python prog.py 1 2 3 4
4

$ python prog.py 1 2 3 4 --sum
10
```

If invalid arguments are passed in, it will issue an error :

```
$ python prog.py a b c
usage: prog.py [-h] [--sum] N [N ...]
prog.py: error: argument N: invalid int value: 'a'
```

The following sections walk you through this example.

### Créer un analyseur (*parser en anglais*)

The first step in using the `argparse` is creating an `ArgumentParser` object :

```
>>> parser = argparse.ArgumentParser(description='Process some integers.')
```

The `ArgumentParser` object will hold all the information necessary to parse the command line into Python data types.

### Ajouter des arguments

Filling an `ArgumentParser` with information about program arguments is done by making calls to the `add_argument()` method. Generally, these calls tell the `ArgumentParser` how to take the strings on the command line and turn them into objects. This information is stored and used when `parse_args()` is called. For example :

```
>>> parser.add_argument('integers', metavar='N', type=int, nargs='+',
...                       help='an integer for the accumulator')
>>> parser.add_argument('--sum', dest='accumulate', action='store_const',
...                       const=sum, default=max,
...                       help='sum the integers (default: find the max)')
```

Later, calling `parse_args()` will return an object with two attributes, `integers` and `accumulate`. The `integers` attribute will be a list of one or more ints, and the `accumulate` attribute will be either the `sum()` function, if `--sum` was specified at the command line, or the `max()` function if it was not.

## Analyse des arguments

`ArgumentParser` parses arguments through the `parse_args()` method. This will inspect the command line, convert each argument to the appropriate type and then invoke the appropriate action. In most cases, this means a simple `Namespace` object will be built up from attributes parsed out of the command line :

```
>>> parser.parse_args(['--sum', '7', '-1', '42'])
Namespace(accumulate=<built-in function sum>, integers=[7, -1, 42])
```

In a script, `parse_args()` will typically be called with no arguments, and the `ArgumentParser` will automatically determine the command-line arguments from `sys.argv`.

### 15.4.2 Objets ArgumentParser

```
class argparse.ArgumentParser(prog=None, usage=None, description=None, epilog=None,
                             parents=[], formatter_class=argparse.HelpFormatter,
                             prefix_chars='-', fromfile_prefix_chars=None, argument_default=None, conflict_handler='error', add_help=True)
```

Create a new `ArgumentParser` object. All parameters should be passed as keyword arguments. Each parameter has its own more detailed description below, but in short they are :

- `prog` - The name of the program (default : `sys.argv[0]`)
- `usage` - The string describing the program usage (default : generated from arguments added to parser)
- `description` - Text to display before the argument help (default : none)
- `epilog` - Text to display after the argument help (default : none)
- `parents` - A list of `ArgumentParser` objects whose arguments should also be included
- `formatter_class` - A class for customizing the help output
- `prefix_chars` - The set of characters that prefix optional arguments (default : “-“)
- `fromfile_prefix_chars` - The set of characters that prefix files from which additional arguments should be read (default : None)
- `argument_default` - The global default value for arguments (default : None)
- `conflict_handler` - The strategy for resolving conflicting optionals (usually unnecessary)
- `add_help` - Add a `-h/--help` option to the parser (default : True)

The following sections describe how each of these are used.

#### prog

By default, `ArgumentParser` objects use `sys.argv[0]` to determine how to display the name of the program in help messages. This default is almost always desirable because it will make the help messages match how the program was invoked on the command line. For example, consider a file named `myprogram.py` with the following code :

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

The help for this program will display `myprogram.py` as the program name (regardless of where the program was invoked from) :

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo F00]

optional arguments:
  -h, --help  show this help message and exit
  --foo F00   foo help
$ cd ..
$ python subdir/myprogram.py --help
usage: myprogram.py [-h] [--foo F00]

optional arguments:
  -h, --help  show this help message and exit
  --foo F00   foo help
```

To change this default behavior, another value can be supplied using the `prog=` argument to *ArgumentParser* :

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.print_help()
usage: myprogram [-h]

optional arguments:
  -h, --help  show this help message and exit
```

Note that the program name, whether determined from `sys.argv[0]` or from the `prog=` argument, is available to help messages using the `%(prog)s` format specifier.

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.add_argument('--foo', help='foo of the %(prog)s program')
>>> parser.print_help()
usage: myprogram [-h] [--foo F00]

optional arguments:
  -h, --help  show this help message and exit
  --foo F00   foo of the myprogram program
```

## usage

By default, *ArgumentParser* calculates the usage message from the arguments it contains :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [-h] [--foo [F00]] bar [bar ...]
```

(suite sur la page suivante)

(suite de la page précédente)

```
positional arguments:
  bar            bar help

optional arguments:
  -h, --help    show this help message and exit
  --foo [F00]   foo help
```

The default message can be overridden with the `usage=` keyword argument :

```
>>> parser = argparse.ArgumentParser(prog='PROG', usage='%(prog)s [options]')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [options]

positional arguments:
  bar            bar help

optional arguments:
  -h, --help    show this help message and exit
  --foo [F00]   foo help
```

The `%(prog)s` format specifier is available to fill in the program name in your usage messages.

### description

Most calls to the `ArgumentParser` constructor will use the `description=` keyword argument. This argument gives a brief description of what the program does and how it works. In help messages, the description is displayed between the command-line usage string and the help messages for the various arguments :

```
>>> parser = argparse.ArgumentParser(description='A foo that bars')
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

optional arguments:
  -h, --help    show this help message and exit
```

By default, the description will be line-wrapped so that it fits within the given space. To change this behavior, see the `formatter_class` argument.

### epilog

Some programs like to display additional description of the program after the description of the arguments. Such text can be specified using the `epilog=` argument to `ArgumentParser` :

```
>>> parser = argparse.ArgumentParser(
...     description='A foo that bars',
...     epilog="And that's how you'd foo a bar")
>>> parser.print_help()
usage: argparse.py [-h]
```

(suite sur la page suivante)

(suite de la page précédente)

```
A foo that bars

optional arguments:
  -h, --help  show this help message and exit

And that's how you'd foo a bar
```

As with the *description* argument, the `epilog=` text is by default line-wrapped, but this behavior can be adjusted with the *formatter\_class* argument to *ArgumentParser*.

### parents

Sometimes, several parsers share a common set of arguments. Rather than repeating the definitions of these arguments, a single parser with all the shared arguments and passed to `parents=` argument to *ArgumentParser* can be used. The `parents=` argument takes a list of *ArgumentParser* objects, collects all the positional and optional actions from them, and adds these actions to the *ArgumentParser* object being constructed :

```
>>> parent_parser = argparse.ArgumentParser(add_help=False)
>>> parent_parser.add_argument('--parent', type=int)

>>> foo_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> foo_parser.add_argument('foo')
>>> foo_parser.parse_args(['--parent', '2', 'XXX'])
Namespace(foo='XXX', parent=2)

>>> bar_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> bar_parser.add_argument('--bar')
>>> bar_parser.parse_args(['--bar', 'YYY'])
Namespace(bar='YYY', parent=None)
```

Note that most parent parsers will specify `add_help=False`. Otherwise, the *ArgumentParser* will see two `-h/--help` options (one in the parent and one in the child) and raise an error.

---

**Note :** You must fully initialize the parsers before passing them via `parents=`. If you change the parent parsers after the child parser, those changes will not be reflected in the child.

---

### formatter\_class

*ArgumentParser* objects allow the help formatting to be customized by specifying an alternate formatting class. Currently, there are three such classes :

```
class argparse.RawDescriptionHelpFormatter
class argparse.RawTextHelpFormatter
class argparse.ArgumentDefaultsHelpFormatter
```

The first two allow more control over how textual descriptions are displayed, while the last automatically adds information about argument default values.

By default, *ArgumentParser* objects line-wrap the *description* and *epilog* texts in command-line help messages :

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     description='''this description
...         was indented weird
...         but that is okay''',
...     epilog='''
...         likewise for this epilog whose whitespace will
...         be cleaned up and whose words will be wrapped
...         across a couple lines''')
>>> parser.print_help()
usage: PROG [-h]

this description was indented weird but that is okay

optional arguments:
  -h, --help  show this help message and exit

likewise for this epilog whose whitespace will be cleaned up and whose words
will be wrapped across a couple lines
```

Passing *RawDescriptionHelpFormatter* as `formatter_class=` indicates that *description* and *epilog* are already correctly formatted and should not be line-wrapped :

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.RawDescriptionHelpFormatter,
...     description=textwrap.dedent('''\
...         Please do not mess up this text!
...         -----
...         I have indented it
...         exactly the way
...         I want it
...     '''))
>>> parser.print_help()
usage: PROG [-h]

Please do not mess up this text!
-----

    I have indented it
    exactly the way
    I want it

optional arguments:
  -h, --help  show this help message and exit
```

*RawTextHelpFormatter* maintains whitespace for all sorts of help text, including argument descriptions. However, multiple new lines are replaced with one. If you wish to preserve multiple blank lines, add spaces between the newlines.

The other formatter class available, *ArgumentDefaultsHelpFormatter*, will add information about the default value of each of the arguments :

```
>>> parser = argparse.ArgumentParser(
```

(suite sur la page suivante)

(suite de la page précédente)

```

...     prog='PROG',
...     formatter_class=argparse.ArgumentDefaultsHelpFormatter)
>>> parser.add_argument('--foo', type=int, default=42, help='FOO!')
>>> parser.add_argument('bar', nargs='*', default=[1, 2, 3], help='BAR!')
>>> parser.print_help()
usage: PROG [-h] [--foo FOO] [bar [bar ...]]

positional arguments:
  bar                BAR! (default: [1, 2, 3])

optional arguments:
  -h, --help        show this help message and exit
  --foo FOO         FOO! (default: 42)

```

### prefix\_chars

Most command-line options will use `-` as the prefix, e.g. `-f/--foo`. Parsers that need to support different or additional prefix characters, e.g. for options like `+f` or `/foo`, may specify them using the `prefix_chars=` argument to the `ArgumentParser` constructor :

```

>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='+-')
>>> parser.add_argument('+f')
>>> parser.add_argument('++bar')
>>> parser.parse_args('+f X ++bar Y'.split())
Namespace(bar='Y', f='X')

```

The `prefix_chars=` argument defaults to `'-'`. Supplying a set of characters that does not include `-` will cause `-f/--foo` options to be disallowed.

### fromfile\_prefix\_chars

Sometimes, for example when dealing with a particularly long argument lists, it may make sense to keep the list of arguments in a file rather than typing it out at the command line. If the `fromfile_prefix_chars=` argument is given to the `ArgumentParser` constructor, then arguments that start with any of the specified characters will be treated as files, and will be replaced by the arguments they contain. For example :

```

>>> with open('args.txt', 'w') as fp:
...     fp.write('-f\nbar')
>>> parser = argparse.ArgumentParser(fromfile_prefix_chars='@')
>>> parser.add_argument('-f')
>>> parser.parse_args(['-f', 'foo', '@args.txt'])
Namespace(f='bar')

```

Arguments read from a file must by default be one per line (but see also `convert_arg_line_to_args()`) and are treated as if they were in the same place as the original file referencing argument on the command line. So in the example above, the expression `['-f', 'foo', '@args.txt']` is considered equivalent to the expression `['-f', 'foo', '-f', 'bar']`.

The `fromfile_prefix_chars=` argument defaults to `None`, meaning that arguments will never be treated as file references.

### argument\_default

Generally, argument defaults are specified either by passing a default to `add_argument()` or by calling the `set_defaults()` methods with a specific set of name-value pairs. Sometimes however, it may be useful to specify a single parser-wide default for arguments. This can be accomplished by passing the `argument_default=` keyword argument to `ArgumentParser`. For example, to globally suppress attribute creation on `parse_args()` calls, we supply `argument_default=SUPPRESS` :

```
>>> parser = argparse.ArgumentParser(argument_default=argparse.SUPPRESS)
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar', nargs='?')
>>> parser.parse_args(['--foo', '1', 'BAR'])
Namespace(bar='BAR', foo='1')
>>> parser.parse_args([])
Namespace()
```

### conflict\_handler

`ArgumentParser` objects do not allow two actions with the same option string. By default, `ArgumentParser` objects raise an exception if an attempt is made to create an argument with an option string that is already in use :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
Traceback (most recent call last):
..
ArgumentError: argument --foo: conflicting option string(s): --foo
```

Sometimes (e.g. when using `parents`) it may be useful to simply override any older arguments with the same option string. To get this behavior, the value `'resolve'` can be supplied to the `conflict_handler=` argument of `ArgumentParser` :

```
>>> parser = argparse.ArgumentParser(prog='PROG', conflict_handler='resolve')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
>>> parser.print_help()
usage: PROG [-h] [-f F00] [--foo F00]

optional arguments:
  -h, --help  show this help message and exit
  -f F00      old foo help
  --foo F00   new foo help
```

Note that `ArgumentParser` objects only remove an action if all of its option strings are overridden. So, in the example above, the old `-f/--foo` action is retained as the `-f` action, because only the `--foo` option string was overridden.

### add\_help

By default, `ArgumentParser` objects add an option which simply displays the parser's help message. For example, consider a file named `myprogram.py` containing the following code :

```
import argparse
parser = argparse.ArgumentParser()
```

(suite sur la page suivante)

(suite de la page précédente)

```
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

If `-h` or `--help` is supplied at the command line, the `ArgumentParser` help will be printed :

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo F00]

optional arguments:
  -h, --help  show this help message and exit
  --foo F00   foo help
```

Occasionally, it may be useful to disable the addition of this help option. This can be achieved by passing `False` as the `add_help=` argument to `ArgumentParser` :

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> parser.add_argument('--foo', help='foo help')
>>> parser.print_help()
usage: PROG [--foo F00]

optional arguments:
  --foo F00   foo help
```

The help option is typically `-h/--help`. The exception to this is if the `prefix_chars=` is specified and does not include `-`, in which case `-h` and `--help` are not valid options. In this case, the first character in `prefix_chars` is used to prefix the help options :

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='+/')
>>> parser.print_help()
usage: PROG [+h]

optional arguments:
  +h, ++help  show this help message and exit
```

### 15.4.3 La méthode `add_argument()`

`ArgumentParser.add_argument(name or flags...[, action][, nargs][, const][, default][, type][, choices][, required][, help][, metavar][, dest])`

Define how a single command-line argument should be parsed. Each parameter has its own more detailed description below, but in short they are :

- *name or flags* - Either a name or a list of option strings, e.g. `foo` or `-f`, `--foo`.
- *action* - The basic type of action to be taken when this argument is encountered at the command line.
- *nargs* - The number of command-line arguments that should be consumed.
- *const* - A constant value required by some *action* and *nargs* selections.
- *default* - The value produced if the argument is absent from the command line.
- *type* - The type to which the command-line argument should be converted.
- *choices* - A container of the allowable values for the argument.
- *required* - Whether or not the command-line option may be omitted (optionals only).
- *help* - A brief description of what the argument does.
- *metavar* - A name for the argument in usage messages.
- *dest* - The name of the attribute to be added to the object returned by `parse_args()`.

The following sections describe how each of these are used.

### nom ou option

The `add_argument()` method must know whether an optional argument, like `-f` or `--foo`, or a positional argument, like a list of filenames, is expected. The first arguments passed to `add_argument()` must therefore be either a series of flags, or a simple argument name. For example, an optional argument could be created like :

```
>>> parser.add_argument('-f', '--foo')
```

while a positional argument could be created like :

```
>>> parser.add_argument('bar')
```

When `parse_args()` is called, optional arguments will be identified by the `-` prefix, and the remaining arguments will be assumed to be positional :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args(['BAR'])
Namespace(bar='BAR', foo=None)
>>> parser.parse_args(['BAR', '--foo', 'FOO'])
Namespace(bar='BAR', foo='FOO')
>>> parser.parse_args(['--foo', 'FOO'])
usage: PROG [-h] [-f FOO] bar
PROG: error: too few arguments
```

### action

`ArgumentParser` objects associate command-line arguments with actions. These actions can do just about anything with the command-line arguments associated with them, though most actions simply add an attribute to the object returned by `parse_args()`. The `action` keyword argument specifies how the command-line arguments should be handled. The supplied actions are :

- `'store'` - This just stores the argument's value. This is the default action. For example :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args('--foo 1'.split())
Namespace(foo='1')
```

- `'store_const'` - This stores the value specified by the `const` keyword argument. The `'store_const'` action is most commonly used with optional arguments that specify some sort of flag. For example :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_const', const=42)
>>> parser.parse_args(['--foo'])
Namespace(foo=42)
```

- `'store_true'` and `'store_false'` - These are special cases of `'store_const'` using for storing the values `True` and `False` respectively. In addition, they create default values of `False` and `True` respectively. For example :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('--bar', action='store_false')
>>> parser.add_argument('--baz', action='store_false')
>>> parser.parse_args('--foo --bar'.split())
Namespace(bar=False, baz=True, foo=True)
```

- 'append' - This stores a list, and appends each argument value to the list. This is useful to allow an option to be specified multiple times. Example usage :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='append')
>>> parser.parse_args('--foo 1 --foo 2'.split())
Namespace(foo=['1', '2'])
```

- 'append\_const' - This stores a list, and appends the value specified by the *const* keyword argument to the list. (Note that the *const* keyword argument defaults to None.) The 'append\_const' action is typically useful when multiple arguments need to store constants to the same list. For example :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--str', dest='types', action='append_const', const=str)
>>> parser.add_argument('--int', dest='types', action='append_const', const=int)
>>> parser.parse_args('--str --int'.split())
Namespace(types=[<type 'str'>, <type 'int'>])
```

- 'count' - This counts the number of times a keyword argument occurs. For example, this is useful for increasing verbosity levels :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--verbose', '-v', action='count')
>>> parser.parse_args(['-vvv'])
Namespace(verbose=3)
```

- 'help' - This prints a complete help message for all the options in the current parser and then exits. By default a help action is automatically added to the parser. See *ArgumentParser* for details of how the output is created.
- 'version' - This expects a *version=* keyword argument in the *add\_argument()* call, and prints version information and exits when invoked :

```
>>> import argparse
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--version', action='version', version='%s 2.0')
>>> parser.parse_args(['--version'])
PROG 2.0
```

You may also specify an arbitrary action by passing an Action subclass or other object that implements the same interface. The recommended way to do this is to extend *Action*, overriding the *\_\_call\_\_* method and optionally the *\_\_init\_\_* method.

Un exemple d'action personnalisée :

```
>>> class FooAction(argparse.Action):
...     def __init__(self, option_strings, dest, nargs=None, **kwargs):
...         if nargs is not None:
...             raise ValueError("nargs not allowed")
...         super(FooAction, self).__init__(option_strings, dest, **kwargs)
...     def __call__(self, parser, namespace, values, option_string=None):
```

(suite sur la page suivante)

(suite de la page précédente)

```

...     print '%r %r %r' % (namespace, values, option_string)
...     setattr(namespace, self.dest, values)
...
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=FooAction)
>>> parser.add_argument('bar', action=FooAction)
>>> args = parser.parse_args('1 --foo 2'.split())
Namespace(bar=None, foo=None) '1' None
Namespace(bar='1', foo=None) '2' '--foo'
>>> args
Namespace(bar='1', foo='2')

```

Pour plus d'information, voir [Action](#).

### nargs

ArgumentParser objects usually associate a single command-line argument with a single action to be taken. The **nargs** keyword argument associates a different number of command-line arguments with a single action. The supported values are :

- N (an integer). N arguments from the command line will be gathered together into a list. For example :

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs=2)
>>> parser.add_argument('bar', nargs=1)
>>> parser.parse_args('c --foo a b'.split())
Namespace(bar=['c'], foo=['a', 'b'])

```

Note that **nargs=1** produces a list of one item. This is different from the default, in which the item is produced by itself.

- '?'. One argument will be consumed from the command line if possible, and produced as a single item. If no command-line argument is present, the value from *default* will be produced. Note that for optional arguments, there is an additional case - the option string is present but not followed by a command-line argument. In this case the value from *const* will be produced. Some examples to illustrate this :

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='?', const='c', default='d')
>>> parser.add_argument('bar', nargs='?', default='d')
>>> parser.parse_args(['XX', '--foo', 'YY'])
Namespace(bar='XX', foo='YY')
>>> parser.parse_args(['XX', '--foo'])
Namespace(bar='XX', foo='c')
>>> parser.parse_args([])
Namespace(bar='d', foo='d')

```

One of the more common uses of **nargs='?'** is to allow optional input and output files :

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', nargs='?', type=argparse.FileType('r'),
...                     default=sys.stdin)
>>> parser.add_argument('outfile', nargs='?', type=argparse.FileType('w'),
...                     default=sys.stdout)
>>> parser.parse_args(['input.txt', 'output.txt'])
Namespace(infile=<open file 'input.txt', mode 'r' at 0x...>,

```

(suite sur la page suivante)

(suite de la page précédente)

```

        outfile=<open file 'output.txt', mode 'w' at 0x...>)
>>> parser.parse_args([])
Namespace(infile=<open file '<stdin>', mode 'r' at 0x...>,
          outfile=<open file '<stdout>', mode 'w' at 0x...>)

```

- `'*'`. All command-line arguments present are gathered into a list. Note that it generally doesn't make much sense to have more than one positional argument with `nargs='*'`, but multiple optional arguments with `nargs='*'` is possible. For example :

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='*')
>>> parser.add_argument('--bar', nargs='*')
>>> parser.add_argument('baz', nargs='*')
>>> parser.parse_args('a b --foo x y --bar 1 2'.split())
Namespace(bar=['1', '2'], baz=['a', 'b'], foo=['x', 'y'])

```

- `'+'`. Just like `'*'`, all command-line args present are gathered into a list. Additionally, an error message will be generated if there wasn't at least one command-line argument present. For example :

```

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', nargs='+')
>>> parser.parse_args(['a', 'b'])
Namespace(foo=['a', 'b'])
>>> parser.parse_args([])
usage: PROG [-h] foo [foo ...]
PROG: error: too few arguments

```

- `argparse.REMAINDER`. All the remaining command-line arguments are gathered into a list. This is commonly useful for command line utilities that dispatch to other command line utilities :

```

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo')
>>> parser.add_argument('command')
>>> parser.add_argument('args', nargs=argparse.REMAINDER)
>>> print parser.parse_args('--foo B cmd --arg1 XX ZZ'.split())
Namespace(args=['--arg1', 'XX', 'ZZ'], command='cmd', foo='B')

```

If the `nargs` keyword argument is not provided, the number of arguments consumed is determined by the *action*. Generally this means a single command-line argument will be consumed and a single item (not a list) will be produced.

## const

The `const` argument of `add_argument()` is used to hold constant values that are not read from the command line but are required for the various *ArgumentParser* actions. The two most common uses of it are :

- When `add_argument()` is called with `action='store_const'` or `action='append_const'`. These actions add the `const` value to one of the attributes of the object returned by `parse_args()`. See the *action* description for examples.
- When `add_argument()` is called with option strings (like `-f` or `--foo`) and `nargs='?'`. This creates an optional argument that can be followed by zero or one command-line arguments. When parsing the command line, if the option string is encountered with no command-line argument following it, the value of `const` will be assumed instead. See the *nargs* description for examples.

With the `'store_const'` and `'append_const'` actions, the `const` keyword argument must be given. For other actions, it defaults to `None`.

## default

All optional arguments and some positional arguments may be omitted at the command line. The `default` keyword argument of `add_argument()`, whose value defaults to `None`, specifies what value should be used if the command-line argument is not present. For optional arguments, the `default` value is used when the option string was not present at the command line :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args(['--foo', '2'])
Namespace(foo='2')
>>> parser.parse_args([])
Namespace(foo=42)
```

If the `default` value is a string, the parser parses the value as if it were a command-line argument. In particular, the parser applies any *type* conversion argument, if provided, before setting the attribute on the *Namespace* return value. Otherwise, the parser uses the value as is :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--length', default='10', type=int)
>>> parser.add_argument('--width', default=10.5, type=int)
>>> parser.parse_args()
Namespace(length=10, width=10.5)
```

For positional arguments with *nargs* equal to `?` or `*`, the `default` value is used when no command-line argument was present :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', nargs='?', default=42)
>>> parser.parse_args(['a'])
Namespace(foo='a')
>>> parser.parse_args([])
Namespace(foo=42)
```

Providing `default=argparse.SUPPRESS` causes no attribute to be added if the command-line argument was not present. :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=argparse.SUPPRESS)
>>> parser.parse_args([])
Namespace()
>>> parser.parse_args(['--foo', '1'])
Namespace(foo='1')
```

## type

By default, *ArgumentParser* objects read command-line arguments in as simple strings. However, quite often the command-line string should instead be interpreted as another type, like a *float* or *int*. The `type` keyword argument of `add_argument()` allows any necessary type-checking and type conversions to be performed. Common built-in types and functions can be used directly as the value of the `type` argument :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.add_argument('bar', type=file)
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> parser.parse_args('2 temp.txt'.split())
Namespace(bar=<open file 'temp.txt', mode 'r' at 0x...>, foo=2)
```

See the section on the [default](#) keyword argument for information on when the `type` argument is applied to default arguments.

To ease the use of various types of files, the `argparse` module provides the factory `FileType` which takes the `mode=` and `bufsize=` arguments of the `file` object. For example, `FileType('w')` can be used to create a writable file :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar', type=argparse.FileType('w'))
>>> parser.parse_args(['out.txt'])
Namespace(bar=<open file 'out.txt', mode 'w' at 0x...>)
```

`type=` can take any callable that takes a single string argument and returns the converted value :

```
>>> def perfect_square(string):
...     value = int(string)
...     sqrt = math.sqrt(value)
...     if sqrt != int(sqrt):
...         msg = "%r is not a perfect square" % string
...         raise argparse.ArgumentTypeError(msg)
...     return value
...
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', type=perfect_square)
>>> parser.parse_args(['9'])
Namespace(foo=9)
>>> parser.parse_args(['7'])
usage: PROG [-h] foo
PROG: error: argument foo: '7' is not a perfect square
```

The [choices](#) keyword argument may be more convenient for type checkers that simply check against a range of values :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', type=int, choices=xrange(5, 10))
>>> parser.parse_args(['7'])
Namespace(foo=7)
>>> parser.parse_args(['11'])
usage: PROG [-h] {5,6,7,8,9}
PROG: error: argument foo: invalid choice: 11 (choose from 5, 6, 7, 8, 9)
```

Voir la section [choices](#) pour plus de détails.

### choices

Some command-line arguments should be selected from a restricted set of values. These can be handled by passing a container object as the `choices` keyword argument to `add_argument()`. When the command line is parsed, argument values will be checked, and an error message will be displayed if the argument was not one of the acceptable values :

```
>>> parser = argparse.ArgumentParser(prog='game.py')
>>> parser.add_argument('move', choices=['rock', 'paper', 'scissors'])
>>> parser.parse_args(['rock'])
Namespace(move='rock')
>>> parser.parse_args(['fire'])
usage: game.py [-h] {rock,paper,scissors}
game.py: error: argument move: invalid choice: 'fire' (choose from 'rock',
'paper', 'scissors')
```

Note that inclusion in the *choices* container is checked after any *type* conversions have been performed, so the type of the objects in the *choices* container should match the *type* specified :

```
>>> parser = argparse.ArgumentParser(prog='doors.py')
>>> parser.add_argument('door', type=int, choices=range(1, 4))
>>> print(parser.parse_args(['3']))
Namespace(door=3)
>>> parser.parse_args(['4'])
usage: doors.py [-h] {1,2,3}
doors.py: error: argument door: invalid choice: 4 (choose from 1, 2, 3)
```

Any object that supports the *in* operator can be passed as the *choices* value, so *dict* objects, *set* objects, custom containers, etc. are all supported.

### required

In general, the *argparse* module assumes that flags like *-f* and *--bar* indicate *optional* arguments, which can always be omitted at the command line. To make an option *required*, *True* can be specified for the *required=* keyword argument to *add\_argument()* :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', required=True)
>>> parser.parse_args(['--foo', 'BAR'])
Namespace(foo='BAR')
>>> parser.parse_args([])
usage: argparse.py [-h] [--foo FOO]
argparse.py: error: option --foo is required
```

As the example shows, if an option is marked as *required*, *parse\_args()* will report an error if that option is not present at the command line.

**Note :** Required options are generally considered bad form because users expect *options* to be *optional*, and thus they should be avoided when possible.

### help

The *help* value is a string containing a brief description of the argument. When a user requests help (usually by using *-h* or *--help* at the command line), these *help* descriptions will be displayed with each argument :

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', action='store_true',
...                     help='foo the bars before frobbling')
>>> parser.add_argument('bar', nargs='+',
```

(suite sur la page suivante)

(suite de la page précédente)

```
...             help='one of the bars to be frobbled')
>>> parser.parse_args(['-h'])
usage: frobble [-h] [--foo] bar [bar ...]

positional arguments:
  bar      one of the bars to be frobbled

optional arguments:
  -h, --help  show this help message and exit
  --foo      foo the bars before frobbling
```

The `help` strings can include various format specifiers to avoid repetition of things like the program name or the argument *default*. The available specifiers include the program name, `%(prog)s` and most keyword arguments to `add_argument()`, e.g. `%(default)s`, `%(type)s`, etc. :

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('bar', nargs='?', type=int, default=42,
...                     help='the bar to %(prog)s (default: %(default)s)')
>>> parser.print_help()
usage: frobble [-h] [bar]

positional arguments:
  bar      the bar to frobble (default: 42)

optional arguments:
  -h, --help  show this help message and exit
```

`argparse` supports silencing the help entry for certain options, by setting the `help` value to `argparse.SUPPRESS` :

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', help=argparse.SUPPRESS)
>>> parser.print_help()
usage: frobble [-h]

optional arguments:
  -h, --help  show this help message and exit
```

## metavar

When `ArgumentParser` generates help messages, it needs some way to refer to each expected argument. By default, `ArgumentParser` objects use the *dest* value as the « name » of each object. By default, for positional argument actions, the *dest* value is used directly, and for optional argument actions, the *dest* value is uppercased. So, a single positional argument with `dest='bar'` will be referred to as `bar`. A single optional argument `--foo` that should be followed by a single command-line argument will be referred to as `F00`. An example :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> parser.print_help()
usage: [-h] [--foo F00] bar

positional arguments:
  bar

optional arguments:
  -h, --help  show this help message and exit
  --foo F00
```

An alternative name can be specified with `metavar` :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', metavar='YYY')
>>> parser.add_argument('bar', metavar='XXX')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage: [-h] [--foo YYY] XXX

positional arguments:
  XXX

optional arguments:
  -h, --help  show this help message and exit
  --foo YYY
```

Note that `metavar` only changes the *displayed* name - the name of the attribute on the `parse_args()` object is still determined by the `dest` value.

Different values of `nargs` may cause the metavar to be used multiple times. Providing a tuple to `metavar` specifies a different display for each of the arguments :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', nargs=2)
>>> parser.add_argument('--foo', nargs=2, metavar=('bar', 'baz'))
>>> parser.print_help()
usage: PROG [-h] [-x X X] [--foo bar baz]

optional arguments:
  -h, --help  show this help message and exit
  -x X X
  --foo bar baz
```

## dest

Most `ArgumentParser` actions add some value as an attribute of the object returned by `parse_args()`. The name of this attribute is determined by the `dest` keyword argument of `add_argument()`. For positional argument actions, `dest` is normally supplied as the first argument to `add_argument()` :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar')
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> parser.parse_args(['XXX'])
Namespace(bar='XXX')
```

For optional argument actions, the value of `dest` is normally inferred from the option strings. `ArgumentParser` generates the value of `dest` by taking the first long option string and stripping away the initial `--` string. If no long option strings were supplied, `dest` will be derived from the first short option string by stripping the initial `-` character. Any internal `-` characters will be converted to `_` characters to make sure the string is a valid attribute name. The examples below illustrate this behavior :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('-f', '--foo-bar', '--foo')
>>> parser.add_argument('-x', '-y')
>>> parser.parse_args('-f 1 -x 2'.split())
Namespace(foo_bar='1', x='2')
>>> parser.parse_args('--foo 1 -y 2'.split())
Namespace(foo_bar='1', x='2')
```

`dest` allows a custom attribute name to be provided :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', dest='bar')
>>> parser.parse_args('--foo XXX'.split())
Namespace(bar='XXX')
```

## Classes Action

Action classes implement the Action API, a callable which returns a callable which processes arguments from the command-line. Any object which follows this API may be passed as the `action` parameter to `add_argument()`.

```
class argparse.Action(option_strings, dest, nargs=None, const=None, default=None, type=None,
                      choices=None, required=False, help=None, metavar=None)
```

Action objects are used by an `ArgumentParser` to represent the information needed to parse a single argument from one or more strings from the command line. The Action class must accept the two positional arguments plus any keyword arguments passed to `ArgumentParser.add_argument()` except for the `action` itself.

Instances of Action (or return value of any callable to the `action` parameter) should have attributes « `dest` », « `option_strings` », « `default` », « `type` », « `required` », « `help` », etc. defined. The easiest way to ensure these attributes are defined is to call `Action.__init__`.

Action instances should be callable, so subclasses must override the `__call__` method, which should accept four parameters :

- `parser` - The `ArgumentParser` object which contains this action.
- `namespace` - The `Namespace` object that will be returned by `parse_args()`. Most actions add an attribute to this object using `setattr()`.
- `values` - The associated command-line arguments, with any type conversions applied. Type conversions are specified with the `type` keyword argument to `add_argument()`.
- `option_string` - The option string that was used to invoke this action. The `option_string` argument is optional, and will be absent if the action is associated with a positional argument.

The `__call__` method may perform arbitrary actions, but will typically set attributes on the `namespace` based on `dest` and `values`.

### 15.4.4 La méthode `parse_args()`

`ArgumentParser.parse_args(args=None, namespace=None)`

Convert argument strings to objects and assign them as attributes of the namespace. Return the populated namespace.

Previous calls to `add_argument()` determine exactly what objects are created and how they are assigned. See the documentation for `add_argument()` for details.

- `args` - List of strings to parse. The default is taken from `sys.argv`.
- `namespace` - An object to take the attributes. The default is a new empty `Namespace` object.

#### Option value syntax

The `parse_args()` method supports several ways of specifying the value of an option (if it takes one). In the simplest case, the option and its value are passed as two separate arguments :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('--foo')
>>> parser.parse_args(['-x', 'X'])
Namespace(foo=None, x='X')
>>> parser.parse_args(['--foo', 'FOO'])
Namespace(foo='FOO', x=None)
```

For long options (options with names longer than a single character), the option and value can also be passed as a single command-line argument, using `=` to separate them :

```
>>> parser.parse_args(['--foo=FOO'])
Namespace(foo='FOO', x=None)
```

For short options (options only one character long), the option and its value can be concatenated :

```
>>> parser.parse_args(['-xX'])
Namespace(foo=None, x='X')
```

Several short options can be joined together, using only a single `-` prefix, as long as only the last option (or none of them) requires a value :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', action='store_true')
>>> parser.add_argument('-y', action='store_true')
>>> parser.add_argument('-z')
>>> parser.parse_args(['-xyzZ'])
Namespace(x=True, y=True, z='Z')
```

#### Arguments invalides

While parsing the command line, `parse_args()` checks for a variety of errors, including ambiguous options, invalid types, invalid options, wrong number of positional arguments, etc. When it encounters such an error, it exits and prints the error along with a usage message :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', nargs='?')

>>> # invalid type
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> parser.parse_args(['--foo', 'spam'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: argument --foo: invalid int value: 'spam'

>>> # invalid option
>>> parser.parse_args(['--bar'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: no such option: --bar

>>> # wrong number of arguments
>>> parser.parse_args(['spam', 'badger'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: extra arguments found: badger
```

### Arguments contenant -

The `parse_args()` method attempts to give errors whenever the user has clearly made a mistake, but some situations are inherently ambiguous. For example, the command-line argument `-1` could either be an attempt to specify an option or an attempt to provide a positional argument. The `parse_args()` method is cautious here : positional arguments may only begin with `-` if they look like negative numbers and there are no options in the parser that look like negative numbers :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('foo', nargs='?')

>>> # no negative number options, so -1 is a positional argument
>>> parser.parse_args(['-x', '-1'])
Namespace(foo=None, x='-1')

>>> # no negative number options, so -1 and -5 are positional arguments
>>> parser.parse_args(['-x', '-1', '-5'])
Namespace(foo='-5', x='-1')

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-1', dest='one')
>>> parser.add_argument('foo', nargs='?')

>>> # negative number options present, so -1 is an option
>>> parser.parse_args(['-1', 'X'])
Namespace(foo=None, one='X')

>>> # negative number options present, so -2 is an option
>>> parser.parse_args(['-2'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: no such option: -2

>>> # negative number options present, so both -1s are options
>>> parser.parse_args(['-1', '-1'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: argument -1: expected one argument
```

If you have positional arguments that must begin with `-` and don't look like negative numbers, you can insert

the pseudo-argument `--` which tells `parse_args()` that everything after that is a positional argument :

```
>>> parser.parse_args(['--', '-f'])
Namespace(foo='-f', one=None)
```

### Arguments abrégés (Part comparaison de leur préfixes)

The `parse_args()` method allows long options to be abbreviated to a prefix, if the abbreviation is unambiguous (the prefix matches a unique option) :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-bacon')
>>> parser.add_argument('-badger')
>>> parser.parse_args(['-bac MMM'].split())
Namespace(bacon='MMM', badger=None)
>>> parser.parse_args(['-bad WOOD'].split())
Namespace(bacon=None, badger='WOOD')
>>> parser.parse_args(['-ba BA'].split())
usage: PROG [-h] [-bacon BACON] [-badger BADGER]
PROG: error: ambiguous option: -ba could match -badger, -bacon
```

An error is produced for arguments that could produce more than one options.

### Au delà de `sys.argv`

Sometimes it may be useful to have an `ArgumentParser` parse arguments other than those of `sys.argv`. This can be accomplished by passing a list of strings to `parse_args()`. This is useful for testing at the interactive prompt :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument(
...     'integers', metavar='int', type=int, choices=xrange(10),
...     nargs='+', help='an integer in the range 0..9')
>>> parser.add_argument(
...     '--sum', dest='accumulate', action='store_const', const=sum,
...     default=max, help='sum the integers (default: find the max)')
>>> parser.parse_args(['1', '2', '3', '4'])
Namespace(accumulate=<built-in function max>, integers=[1, 2, 3, 4])
>>> parser.parse_args(['1', '2', '3', '4', '--sum'])
Namespace(accumulate=<built-in function sum>, integers=[1, 2, 3, 4])
```

### L'objet namespace

#### `class argparse.Namespace`

Simple class used by default by `parse_args()` to create an object holding attributes and return it.

This class is deliberately simple, just an *object* subclass with a readable string representation. If you prefer to have dict-like view of the attributes, you can use the standard Python idiom, `vars()` :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> args = parser.parse_args(['--foo', 'BAR'])
>>> vars(args)
{'foo': 'BAR'}
```

It may also be useful to have an *ArgumentParser* assign attributes to an already existing object, rather than a new *Namespace* object. This can be achieved by specifying the `namespace=` keyword argument :

```
>>> class C(object):
...     pass
...
>>> c = C()
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args(args=['--foo', 'BAR'], namespace=c)
>>> c.foo
'BAR'
```

## 15.4.5 Autres outils

### Sous commandes

`ArgumentParser.add_subparsers([title][, description][, prog][, parser_class][, action][, option_string][, dest][, help][, metavar])`

Many programs split up their functionality into a number of sub-commands, for example, the `svn` program can invoke sub-commands like `svn checkout`, `svn update`, and `svn commit`. Splitting up functionality this way can be a particularly good idea when a program performs several different functions which require different kinds of command-line arguments. *ArgumentParser* supports the creation of such sub-commands with the `add_subparsers()` method. The `add_subparsers()` method is normally called with no arguments and returns a special action object. This object has a single method, `add_parser()`, which takes a command name and any *ArgumentParser* constructor arguments, and returns an *ArgumentParser* object that can be modified as usual.

Description des paramètres

- `title` - title for the sub-parser group in help output ; by default « subcommands » if description is provided, otherwise uses title for positional arguments
- `description` - description for the sub-parser group in help output, by default `None`
- `prog` - usage information that will be displayed with sub-command help, by default the name of the program and any positional arguments before the subparser argument
- `parser_class` - class which will be used to create sub-parser instances, by default the class of the current parser (e.g. *ArgumentParser*)
- `action` - the basic type of action to be taken when this argument is encountered at the command line
- `dest` - name of the attribute under which sub-command name will be stored ; by default `None` and no value is stored
- `help` - help for sub-parser group in help output, by default `None`
- `metavar` - string presenting available sub-commands in help ; by default it is `None` and presents sub-commands in form {cmd1, cmd2, ..}

Quelques exemples d'utilisation :

```
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', action='store_true', help='foo help')
>>> subparsers = parser.add_subparsers(help='sub-command help')
>>>
>>> # create the parser for the "a" command
>>> parser_a = subparsers.add_parser('a', help='a help')
>>> parser_a.add_argument('bar', type=int, help='bar help')
>>>
```

(suite sur la page suivante)

(suite de la page précédente)

```

>>> # create the parser for the "b" command
>>> parser_b = subparsers.add_parser('b', help='b help')
>>> parser_b.add_argument('--baz', choices='XYZ', help='baz help')
>>>
>>> # parse some argument lists
>>> parser.parse_args(['a', '12'])
Namespace(bar=12, foo=False)
>>> parser.parse_args(['--foo', 'b', '--baz', 'Z'])
Namespace(baz='Z', foo=True)

```

Note that the object returned by `parse_args()` will only contain attributes for the main parser and the subparser that was selected by the command line (and not any other subparsers). So in the example above, when the `a` command is specified, only the `foo` and `bar` attributes are present, and when the `b` command is specified, only the `foo` and `baz` attributes are present.

Similarly, when a help message is requested from a subparser, only the help for that particular parser will be printed. The help message will not include parent parser or sibling parser messages. (A help message for each subparser command, however, can be given by supplying the `help=` argument to `add_parser()` as above.)

```

>>> parser.parse_args(['--help'])
usage: PROG [-h] [--foo] {a,b} ...

positional arguments:
  {a,b}    sub-command help
  a        a help
  b        b help

optional arguments:
  -h, --help  show this help message and exit
  --foo       foo help

>>> parser.parse_args(['a', '--help'])
usage: PROG a [-h] bar

positional arguments:
  bar        bar help

optional arguments:
  -h, --help  show this help message and exit

>>> parser.parse_args(['b', '--help'])
usage: PROG b [-h] [--baz {X,Y,Z}]

optional arguments:
  -h, --help      show this help message and exit
  --baz {X,Y,Z}  baz help

```

The `add_subparsers()` method also supports `title` and `description` keyword arguments. When either is present, the subparser's commands will appear in their own group in the help output. For example :

```

>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(title='subcommands',

```

(suite sur la page suivante)

(suite de la page précédente)

```

...                                     description='valid subcommands',
...                                     help='additional help')
>>> subparsers.add_parser('foo')
>>> subparsers.add_parser('bar')
>>> parser.parse_args(['-h'])
usage: [-h] {foo,bar} ...

optional arguments:
  -h, --help  show this help message and exit

subcommands:
  valid subcommands

{foo,bar}  additional help

```

One particularly effective way of handling sub-commands is to combine the use of the `add_subparsers()` method with calls to `set_defaults()` so that each subparser knows which Python function it should execute. For example :

```

>>> # sub-command functions
>>> def foo(args):
...     print args.x * args.y
...
>>> def bar(args):
...     print '(%s)' % args.z
...
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>>
>>> # create the parser for the "foo" command
>>> parser_foo = subparsers.add_parser('foo')
>>> parser_foo.add_argument('-x', type=int, default=1)
>>> parser_foo.add_argument('y', type=float)
>>> parser_foo.set_defaults(func=foo)
>>>
>>> # create the parser for the "bar" command
>>> parser_bar = subparsers.add_parser('bar')
>>> parser_bar.add_argument('z')
>>> parser_bar.set_defaults(func=bar)
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('foo 1 -x 2'.split())
>>> args.func(args)
2.0
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('bar XYZYX'.split())
>>> args.func(args)
((XYZYX))

```

This way, you can let `parse_args()` do the job of calling the appropriate function after argument parsing is complete. Associating functions with actions like this is typically the easiest way to handle the different actions for each of your subparsers. However, if it is necessary to check the name of the

subparser that was invoked, the `dest` keyword argument to the `add_subparsers()` call will work :

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(dest='subparser_name')
>>> subparser1 = subparsers.add_parser('1')
>>> subparser1.add_argument('-x')
>>> subparser2 = subparsers.add_parser('2')
>>> subparser2.add_argument('y')
>>> parser.parse_args(['2', 'frobble'])
Namespace(subparser_name='2', y='frobble')
```

## Objets FileType

`class argparse.FileType(mode='r', bufsize=None)`

The `FileType` factory creates objects that can be passed to the type argument of `ArgumentParser.add_argument()`. Arguments that have `FileType` objects as their type will open command-line arguments as files with the requested modes and buffer sizes :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--output', type=argparse.FileType('wb', 0))
>>> parser.parse_args(['--output', 'out'])
Namespace(output=<open file 'out', mode 'wb' at 0x...>)
```

`FileType` objects understand the pseudo-argument `-` and automatically convert this into `sys.stdin` for readable `FileType` objects and `sys.stdout` for writable `FileType` objects :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', type=argparse.FileType('r'))
>>> parser.parse_args(['-'])
Namespace(infile=<open file '<stdin>', mode 'r' at 0x...>)
```

## Groupes d'arguments

`ArgumentParser.add_argument_group(title=None, description=None)`

By default, `ArgumentParser` groups command-line arguments into « positional arguments » and « optional arguments » when displaying help messages. When there is a better conceptual grouping of arguments than this default one, appropriate groups can be created using the `add_argument_group()` method :

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group = parser.add_argument_group('group')
>>> group.add_argument('--foo', help='foo help')
>>> group.add_argument('bar', help='bar help')
>>> parser.print_help()
usage: PROG [--foo F00] bar

group:
  bar      bar help
  --foo F00  foo help
```

The `add_argument_group()` method returns an argument group object which has an `add_argument()` method just like a regular `ArgumentParser`. When an argument is added to the group, the parser treats it just like a normal argument, but displays the argument in a separate group for help messages. The `add_argument_group()` method accepts `title` and `description` arguments which can be used to customize this display :

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group1 = parser.add_argument_group('group1', 'group1 description')
>>> group1.add_argument('foo', help='foo help')
>>> group2 = parser.add_argument_group('group2', 'group2 description')
>>> group2.add_argument('--bar', help='bar help')
>>> parser.print_help()
usage: PROG [--bar BAR] foo

group1:
  group1 description

  foo    foo help

group2:
  group2 description

  --bar BAR  bar help
```

Note that any arguments not in your user-defined groups will end up back in the usual « positional arguments » and « optional arguments » sections.

### Exclusion mutuelle

`ArgumentParser.add_mutually_exclusive_group(required=False)`

Create a mutually exclusive group. `argparse` will make sure that only one of the arguments in the mutually exclusive group was present on the command line :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group()
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args(['--foo'])
Namespace(bar=True, foo=True)
>>> parser.parse_args(['--bar'])
Namespace(bar=False, foo=False)
>>> parser.parse_args(['--foo', '--bar'])
usage: PROG [-h] [--foo | --bar]
PROG: error: argument --bar: not allowed with argument --foo
```

The `add_mutually_exclusive_group()` method also accepts a `required` argument, to indicate that at least one of the mutually exclusive arguments is required :

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group(required=True)
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args([])
usage: PROG [-h] (--foo | --bar)
PROG: error: one of the arguments --foo --bar is required
```

Note that currently mutually exclusive argument groups do not support the `title` and `description` arguments of `add_argument_group()`.

## Valeurs par défaut de l'analyseur

`ArgumentParser.set_defaults(**kwargs)`

Most of the time, the attributes of the object returned by `parse_args()` will be fully determined by inspecting the command-line arguments and the argument actions. `set_defaults()` allows some additional attributes that are determined without any inspection of the command line to be added :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.set_defaults(bar=42, baz='badger')
>>> parser.parse_args(['736'])
Namespace(bar=42, baz='badger', foo=736)
```

Note that parser-level defaults always override argument-level defaults :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='bar')
>>> parser.set_defaults(foo='spam')
>>> parser.parse_args([])
Namespace(foo='spam')
```

Parser-level defaults can be particularly useful when working with multiple parsers. See the `add_subparsers()` method for an example of this type.

`ArgumentParser.get_default(dest)`

Get the default value for a namespace attribute, as set by either `add_argument()` or by `set_defaults()` :

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='badger')
>>> parser.get_default('foo')
'badger'
```

## Afficher l'aide

In most typical applications, `parse_args()` will take care of formatting and printing any usage or error messages. However, several formatting methods are available :

`ArgumentParser.print_usage(file=None)`

Print a brief description of how the `ArgumentParser` should be invoked on the command line. If `file` is `None`, `sys.stdout` is assumed.

`ArgumentParser.print_help(file=None)`

Print a help message, including the program usage and information about the arguments registered with the `ArgumentParser`. If `file` is `None`, `sys.stdout` is assumed.

There are also variants of these methods that simply return a string instead of printing it :

`ArgumentParser.format_usage()`

Return a string containing a brief description of how the `ArgumentParser` should be invoked on the command line.

`ArgumentParser.format_help()`

Return a string containing a help message, including the program usage and information about the arguments registered with the `ArgumentParser`.

## Parsing partiel

`ArgumentParser.parse_known_args(args=None, namespace=None)`

Sometimes a script may only parse a few of the command-line arguments, passing the remaining arguments on to another script or program. In these cases, the `parse_known_args()` method can be useful. It works much like `parse_args()` except that it does not produce an error when extra arguments are present. Instead, it returns a two item tuple containing the populated namespace and the list of remaining argument strings.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('bar')
>>> parser.parse_known_args(['--foo', '--badger', 'BAR', 'spam'])
(Namespace(bar='BAR', foo=True), ['--badger', 'spam'])
```

**Avertissement :** *Prefix matching* rules apply to `parse_known_args()`. The parser may consume an option even if it's just a prefix of one of its known options, instead of leaving it in the remaining arguments list.

### Personnaliser le parsing de fichiers

`ArgumentParser.convert_arg_line_to_args(arg_line)`

Arguments that are read from a file (see the `fromfile_prefix_chars` keyword argument to the `ArgumentParser` constructor) are read one argument per line. `convert_arg_line_to_args()` can be overridden for fancier reading.

This method takes a single argument `arg_line` which is a string read from the argument file. It returns a list of arguments parsed from this string. The method is called once per line read from the argument file, in order.

A useful override of this method is one that treats each space-separated word as an argument :

```
def convert_arg_line_to_args(self, arg_line):
    return arg_line.split()
```

### Exiting methods

`ArgumentParser.exit(status=0, message=None)`

This method terminates the program, exiting with the specified `status` and, if given, it prints a `message` before that.

`ArgumentParser.error(message)`

This method prints a usage message including the `message` to the standard error and terminates the program with a status code of 2.

## 15.4.6 Mettre à jour du code optparse

Originally, the `argparse` module had attempted to maintain compatibility with `optparse`. However, `optparse` was difficult to extend transparently, particularly with the changes required to support the new `nargs=` specifiers and better usage messages. When most everything in `optparse` had either been copy-pasted over or monkey-patched, it no longer seemed practical to try to maintain the backwards compatibility.

The `argparse` module improves on the standard library `optparse` module in a number of ways including :

- Gérer les arguments positionnels.
- Gérer les sous commandes.
- Allowing alternative option prefixes like `+` and `/`.
- Handling zero-or-more and one-or-more style arguments.
- Fournir des message d'aide plus complets.
- Providing a much simpler interface for custom `type` and `action`.

A partial upgrade path from `optparse` to `argparse` :

- Replace all `optparse.OptionParser.add_option()` calls with `ArgumentParser.add_argument()` calls.
- Replace `(options, args) = parser.parse_args()` with `args = parser.parse_args()` and add additional `ArgumentParser.add_argument()` calls for the positional arguments. Keep in mind that what was previously called `options`, now in the `argparse` context is called `args`.
- Replace `optparse.OptionParser.disable_interspersed_args()` by setting `nargs` of a positional argument to `argparse.REMAINDER`, or use `parse_known_args()` to collect unparsed argument strings in a separate list.
- Replace callback actions and the `callback_*` keyword arguments with `type` or `action` arguments.
- Replace string names for `type` keyword arguments with the corresponding type objects (e.g. `int`, `float`, `complex`, etc).
- Replace `optparse.Values` with `Namespace` and `optparse.OptionError` and `optparse.OptionValueError` with `ArgumentError`.
- Replace strings with implicit arguments such as `%default` or `%prog` with the standard Python syntax to use dictionaries to format strings, that is, `%(default)s` and `%(prog)s`.
- Replace the `OptionParser` constructor `version` argument with a call to `parser.add_argument('--version', action='version', version='<the version>')`.

## 15.5 optparse — Parser for command line options

Nouveau dans la version 2.3.

Obsolète depuis la version 2.7 : The `optparse` module is deprecated and will not be developed further ; development will continue with the `argparse` module.

**Code source :** [Lib/optparse.py](#)

`optparse` is a more convenient, flexible, and powerful library for parsing command-line options than the old `getopt` module. `optparse` uses a more declarative style of command-line parsing : you create an instance of `OptionParser`, populate it with options, and parse the command line. `optparse` allows users to specify options in the conventional GNU/POSIX syntax, and additionally generates usage and help messages for you.

Here's an example of using `optparse` in a simple script :

```
from optparse import OptionParser
...
parser = OptionParser()
parser.add_option("-f", "--file", dest="filename",
                  help="write report to FILE", metavar="FILE")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose", default=True,
                  help="don't print status messages to stdout")

(options, args) = parser.parse_args()
```

With these few lines of code, users of your script can now do the « usual thing » on the command-line, for example :

```
<yourscript> --file=outfile -q
```

As it parses the command line, `optparse` sets attributes of the `options` object returned by `parse_args()` based on user-supplied command-line values. When `parse_args()` returns from parsing this command line, `options.filename` will be `"outfile"` and `options.verbose` will be `False`. `optparse` supports both long

and short options, allows short options to be merged together, and allows options to be associated with their arguments in a variety of ways. Thus, the following command lines are all equivalent to the above example :

```
<yourscript> -f outfile --quiet
<yourscript> --quiet --file outfile
<yourscript> -q -foutfile
<yourscript> -qfoutfile
```

Additionally, users can run one of

```
<yourscript> -h
<yourscript> --help
```

and *optparse* will print out a brief summary of your script's options :

```
Usage: <yourscript> [options]

Options:
  -h, --help            show this help message and exit
  -f FILE, --file=FILE  write report to FILE
  -q, --quiet           don't print status messages to stdout
```

where the value of *yourscript* is determined at runtime (normally from `sys.argv[0]`).

### 15.5.1 Background

*optparse* was explicitly designed to encourage the creation of programs with straightforward, conventional command-line interfaces. To that end, it supports only the most common command-line syntax and semantics conventionally used under Unix. If you are unfamiliar with these conventions, read this section to acquaint yourself with them.

#### Terminology

**argument** a string entered on the command-line, and passed by the shell to `exec1()` or `execv()`. In Python, arguments are elements of `sys.argv[1:]` (`sys.argv[0]` is the name of the program being executed). Unix shells also use the term « word ».

It is occasionally desirable to substitute an argument list other than `sys.argv[1:]`, so you should read « argument » as « an element of `sys.argv[1:]`, or of some other list provided as a substitute for `sys.argv[1:]` ».

**option** an argument used to supply extra information to guide or customize the execution of a program. There are many different syntaxes for options ; the traditional Unix syntax is a hyphen (« -« ) followed by a single letter, e.g. `-x` or `-F`. Also, traditional Unix syntax allows multiple options to be merged into a single argument, e.g. `-x -F` is equivalent to `-xF`. The GNU project introduced `--` followed by a series of hyphen-separated words, e.g. `--file` or `--dry-run`. These are the only two option syntaxes provided by *optparse*.

Some other option syntaxes that the world has seen include :

- a hyphen followed by a few letters, e.g. `-pf` (this is *not* the same as multiple options merged into a single argument)
- a hyphen followed by a whole word, e.g. `-file` (this is technically equivalent to the previous syntax, but they aren't usually seen in the same program)
- a plus sign followed by a single letter, or a few letters, or a word, e.g. `+f`, `+rgb`
- a slash followed by a letter, or a few letters, or a word, e.g. `/f`, `/file`

These option syntaxes are not supported by *optparse*, and they never will be. This is deliberate : the first three are non-standard on any environment, and the last only makes sense if you're exclusively targeting VMS, MS-DOS, and/or Windows.

**option argument** an argument that follows an option, is closely associated with that option, and is consumed from the argument list when that option is. With *optparse*, option arguments may either be in a separate argument from their option :

```
-f foo
--file foo
```

or included in the same argument :

```
-ffoo
--file=foo
```

Typically, a given option either takes an argument or it doesn't. Lots of people want an « optional option arguments » feature, meaning that some options will take an argument if they see it, and won't if they don't. This is somewhat controversial, because it makes parsing ambiguous : if **-a** takes an optional argument and **-b** is another option entirely, how do we interpret **-ab**? Because of this ambiguity, *optparse* does not support this feature.

**argument positionnel** something leftover in the argument list after options have been parsed, i.e. after options and their arguments have been parsed and removed from the argument list.

**required option** an option that must be supplied on the command-line ; note that the phrase « required option » is self-contradictory in English. *optparse* doesn't prevent you from implementing required options, but doesn't give you much help at it either.

For example, consider this hypothetical command-line :

```
prog -v --report report.txt foo bar
```

**-v** and **--report** are both options. Assuming that **--report** takes one argument, **report.txt** is an option argument. **foo** and **bar** are positional arguments.

### What are options for ?

Options are used to provide extra information to tune or customize the execution of a program. In case it wasn't clear, options are usually *optional*. A program should be able to run just fine with no options whatsoever. (Pick a random program from the Unix or GNU toolsets. Can it run without any options at all and still make sense? The main exceptions are **find**, **tar**, and **dd**—all of which are mutant oddballs that have been rightly criticized for their non-standard syntax and confusing interfaces.)

Lots of people want their programs to have « required options ». Think about it. If it's required, then it's *not optional*! If there is a piece of information that your program absolutely requires in order to run successfully, that's what positional arguments are for.

As an example of good command-line interface design, consider the humble **cp** utility, for copying files. It doesn't make much sense to try to copy files without supplying a destination and at least one source. Hence, **cp** fails if you run it with no arguments. However, it has a flexible, useful syntax that does not require any options at all :

```
cp SOURCE DEST
cp SOURCE ... DEST-DIR
```

You can get pretty far with just that. Most **cp** implementations provide a bunch of options to tweak exactly how the files are copied : you can preserve mode and modification time, avoid following symlinks, ask before clobbering existing files, etc. But none of this distracts from the core mission of **cp**, which is to copy either one file to another, or several files to another directory.

### What are positional arguments for ?

Positional arguments are for those pieces of information that your program absolutely, positively requires to run.

A good user interface should have as few absolute requirements as possible. If your program requires 17 distinct pieces of information in order to run successfully, it doesn't much matter *how* you get that information from the user—most people will give up and walk away before they successfully run the program. This applies whether the user interface is a command-line, a configuration file, or a GUI : if you make that many demands on your users, most of them will simply give up.

In short, try to minimize the amount of information that users are absolutely required to supply—use sensible defaults whenever possible. Of course, you also want to make your programs reasonably flexible. That's what options are for. Again, it doesn't matter if they are entries in a config file, widgets in the « Preferences » dialog of a GUI, or command-line options—the more options you implement, the more flexible your program is, and the more complicated its implementation becomes. Too much flexibility has drawbacks as well, of course ; too many options can overwhelm users and make your code much harder to maintain.

## 15.5.2 Tutoriel

While *optparse* is quite flexible and powerful, it's also straightforward to use in most cases. This section covers the code patterns that are common to any *optparse*-based program.

First, you need to import the `OptionParser` class ; then, early in the main program, create an `OptionParser` instance :

```
from optparse import OptionParser
...
parser = OptionParser()
```

Then you can start defining options. The basic syntax is :

```
parser.add_option(opt_str, ...,
                  attr=value, ...)
```

Each option has one or more option strings, such as `-f` or `--file`, and several option attributes that tell *optparse* what to expect and what to do when it encounters that option on the command line.

Typically, each option will have one short option string and one long option string, e.g. :

```
parser.add_option("-f", "--file", ...)
```

You're free to define as many short option strings and as many long option strings as you like (including zero), as long as there is at least one option string overall.

The option strings passed to `OptionParser.add_option()` are effectively labels for the option defined by that call. For brevity, we will frequently refer to *encountering an option* on the command line ; in reality, *optparse* encounters *option strings* and looks up options from them.

Once all of your options are defined, instruct *optparse* to parse your program's command line :

```
(options, args) = parser.parse_args()
```

(If you like, you can pass a custom argument list to `parse_args()`, but that's rarely necessary : by default it uses `sys.argv[1:]`.)

`parse_args()` returns two values :

- `options`, an object containing values for all of your options—e.g. if `--file` takes a single string argument, then `options.file` will be the filename supplied by the user, or `None` if the user did not supply that option
- `args`, the list of positional arguments leftover after parsing options

This tutorial section only covers the four most important option attributes : *action*, *type*, *dest* (destination), and *help*. Of these, *action* is the most fundamental.

### Understanding option actions

Actions tell *optparse* what to do when it encounters an option on the command line. There is a fixed set of actions hard-coded into *optparse*; adding new actions is an advanced topic covered in section *Extending optparse*. Most actions tell *optparse* to store a value in some variable—for example, take a string from the command line and store it in an attribute of `options`.

If you don't specify an option action, *optparse* defaults to `store`.

### The store action

The most common option action is `store`, which tells *optparse* to take the next argument (or the remainder of the current argument), ensure that it is of the correct type, and store it to your chosen destination.

Par exemple :

```
parser.add_option("-f", "--file",
                  action="store", type="string", dest="filename")
```

Now let's make up a fake command line and ask *optparse* to parse it :

```
args = ["-f", "foo.txt"]
(options, args) = parser.parse_args(args)
```

When *optparse* sees the option string `-f`, it consumes the next argument, `foo.txt`, and stores it in `options.filename`. So, after this call to `parse_args()`, `options.filename` is `"foo.txt"`.

Some other option types supported by *optparse* are `int` and `float`. Here's an option that expects an integer argument :

```
parser.add_option("-n", type="int", dest="num")
```

Note that this option has no long option string, which is perfectly acceptable. Also, there's no explicit action, since the default is `store`.

Let's parse another fake command-line. This time, we'll jam the option argument right up against the option : since `-n42` (one argument) is equivalent to `-n 42` (two arguments), the code

```
(options, args) = parser.parse_args(["-n42"])
print options.num
```

affichera 42.

If you don't specify a type, *optparse* assumes `string`. Combined with the fact that the default action is `store`, that means our first example can be a lot shorter :

```
parser.add_option("-f", "--file", dest="filename")
```

If you don't supply a destination, *optparse* figures out a sensible default from the option strings : if the first long option string is `--foo-bar`, then the default destination is `foo_bar`. If there are no long option strings, *optparse* looks at the first short option string : the default destination for `-f` is `f`.

*optparse* also includes built-in long and complex types. Adding types is covered in section [Extending optparse](#).

### Handling boolean (flag) options

Flag options—set a variable to true or false when a particular option is seen—are quite common. *optparse* supports them with two separate actions, `store_true` and `store_false`. For example, you might have a `verbose` flag that is turned on with `-v` and off with `-q` :

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose")
```

Here we have two different options with the same destination, which is perfectly OK. (It just means you have to be a bit careful when setting default values—see below.)

When *optparse* encounters `-v` on the command line, it sets `options.verbose` to `True` ; when it encounters `-q`, `options.verbose` is set to `False`.

### Other actions

Some other actions supported by *optparse* are :

- `"store_const"` store a constant value
- `"append"` append this option's argument to a list
- `"count"` increment a counter by one
- `"callback"` call a specified function

These are covered in section [Reference Guide](#), Reference Guide and section [Option Callbacks](#).

### Valeurs par défaut

All of the above examples involve setting some variable (the « destination ») when certain command-line options are seen. What happens if those options are never seen? Since we didn't supply any defaults, they are all set to `None`. This is usually fine, but sometimes you want more control. *optparse* lets you supply a default value for each destination, which is assigned before the command line is parsed.

First, consider the `verbose/quiet` example. If we want *optparse* to set `verbose` to `True` unless `-q` is seen, then we can do this :

```
parser.add_option("-v", action="store_true", dest="verbose", default=True)
parser.add_option("-q", action="store_false", dest="verbose")
```

Since default values apply to the *destination* rather than to any particular option, and these two options happen to have the same destination, this is exactly equivalent :

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose", default=True)
```

Consider this :

```
parser.add_option("-v", action="store_true", dest="verbose", default=False)
parser.add_option("-q", action="store_false", dest="verbose", default=True)
```

Again, the default value for `verbose` will be `True` : the last default value supplied for any particular destination is the one that counts.

A clearer way to specify default values is the `set_defaults()` method of `OptionParser`, which you can call at any time before calling `parse_args()` :

```
parser.set_defaults(verbose=True)
parser.add_option(...)
(options, args) = parser.parse_args()
```

As before, the last value specified for a given option destination is the one that counts. For clarity, try to use one method or the other of setting default values, not both.

## Generating help

*optparse*'s ability to generate help and usage text automatically is useful for creating user-friendly command-line interfaces. All you have to do is supply a *help* value for each option, and optionally a short usage message for your whole program. Here's an *OptionParser* populated with user-friendly (documented) options :

```
usage = "usage: %prog [options] arg1 arg2"
parser = OptionParser(usage=usage)
parser.add_option("-v", "--verbose",
                  action="store_true", dest="verbose", default=True,
                  help="make lots of noise [default]")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose",
                  help="be vewwy quiet (I'm hunting wabbits)")
parser.add_option("-f", "--filename",
                  metavar="FILE", help="write output to FILE")
parser.add_option("-m", "--mode",
                  default="intermediate",
                  help="interaction mode: novice, intermediate, "
                       "or expert [default: %default]")
```

If *optparse* encounters either `-h` or `--help` on the command-line, or if you just call `parser.print_help()`, it prints the following to standard output :

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose          make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or
                        expert [default: intermediate]
```

(If the help output is triggered by a help option, *optparse* exits after printing the help text.)

There's a lot going on here to help *optparse* generate the best possible help message :

- the script defines its own usage message :

```
usage = "usage: %prog [options] arg1 arg2"
```

*optparse* expands `%prog` in the usage string to the name of the current program, i.e. `os.path.basename(sys.argv[0])`. The expanded string is then printed before the detailed option help.

If you don't supply a usage string, *optparse* uses a bland but sensible default : `"Usage: %prog [options]"`, which is fine if your script doesn't take any positional arguments.

- every option defines a help string, and doesn't worry about line-wrapping— *optparse* takes care of wrapping lines and making the help output look good.

- options that take a value indicate this fact in their automatically-generated help message, e.g. for the « mode » option :

```
-m MODE, --mode=MODE
```

Here, « MODE » is called the meta-variable : it stands for the argument that the user is expected to supply to `-m/--mode`. By default, `optparse` converts the destination variable name to uppercase and uses that for the meta-variable. Sometimes, that's not what you want—for example, the `--filename` option explicitly sets `metavar="FILE"`, resulting in this automatically-generated option description :

```
-f FILE, --filename=FILE
```

This is important for more than just saving space, though : the manually written help text uses the meta-variable `FILE` to clue the user in that there's a connection between the semi-formal syntax `-f FILE` and the informal semantic description « write output to `FILE` ». This is a simple but effective way to make your help text a lot clearer and more useful for end users.

Nouveau dans la version 2.4 : Options that have a default value can include `%default` in the help string—`optparse` will replace it with `str()` of the option's default value. If an option has no default value (or the default value is `None`), `%default` expands to `none`.

## Grouping Options

When dealing with many options, it is convenient to group these options for better help output. An `OptionParser` can contain several option groups, each of which can contain several options.

An option group is obtained using the class `OptionGroup` :

```
class optparse.OptionGroup(parser, title, description=None)
    where
    — parser is the OptionParser instance the group will be insterted in to
    — title is the group title
    — description, optional, is a long description of the group
```

`OptionGroup` inherits from `OptionContainer` (like `OptionParser`) and so the `add_option()` method can be used to add an option to the group.

Once all the options are declared, using the `OptionParser` method `add_option_group()` the group is added to the previously defined parser.

Continuing with the parser defined in the previous section, adding an `OptionGroup` to a parser is easy :

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your own risk. "
                    "It is believed that some of them bite.")
group.add_option("-g", action="store_true", help="Group option.")
parser.add_option_group(group)
```

This would result in the following help output :

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose          make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
```

(suite sur la page suivante)

(suite de la page précédente)

```
-m MODE, --mode=MODE  interaction mode: novice, intermediate, or
                        expert [default: intermediate]
```

**Dangerous Options:**

Caution: use these options at your own risk. It is believed that some of them bite.

```
-g                      Group option.
```

A bit more complete example might involve using more than one group : still extending the previous example :

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your own risk. "
                    "It is believed that some of them bite.")
group.add_option("-g", action="store_true", help="Group option.")
parser.add_option_group(group)

group = OptionGroup(parser, "Debug Options")
group.add_option("-d", "--debug", action="store_true",
                help="Print debug information")
group.add_option("-s", "--sql", action="store_true",
                help="Print all SQL statements executed")
group.add_option("-e", action="store_true", help="Print every action done")
parser.add_option_group(group)
```

that results in the following output :

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose          make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or expert
                        [default: intermediate]

Dangerous Options:
  Caution: use these options at your own risk. It is believed that some
  of them bite.

  -g                      Group option.

Debug Options:
  -d, --debug            Print debug information
  -s, --sql             Print all SQL statements executed
  -e                    Print every action done
```

Another interesting method, in particular when working programmatically with option groups is :

`OptionParser.get_option_group(opt_str)`

Return the *OptionGroup* to which the short or long option string *opt\_str* (e.g. '-o' or '--option') belongs. If there's no such *OptionGroup*, return `None`.

### Printing a version string

Similar to the brief usage string, *optparse* can also print a version string for your program. You have to supply the string as the `version` argument to `OptionParser` :

```
parser = OptionParser(usage="%prog [-f] [-q]", version="%prog 1.0")
```

`%prog` is expanded just like it is in `usage`. Apart from that, `version` can contain anything you like. When you supply it, *optparse* automatically adds a `--version` option to your parser. If it encounters this option on the command line, it expands your `version` string (by replacing `%prog`), prints it to `stdout`, and exits.

For example, if your script is called `/usr/bin/foo` :

```
$ /usr/bin/foo --version
foo 1.0
```

The following two methods can be used to print and get the `version` string :

`OptionParser.print_version(file=None)`

Print the version message for the current program (`self.version`) to `file` (default `stdout`). As with `print_usage()`, any occurrence of `%prog` in `self.version` is replaced with the name of the current program. Does nothing if `self.version` is empty or undefined.

`OptionParser.get_version()`

Same as `print_version()` but returns the version string instead of printing it.

### How *optparse* handles errors

There are two broad classes of errors that *optparse* has to worry about : programmer errors and user errors. Programmer errors are usually erroneous calls to `OptionParser.add_option()`, e.g. invalid option strings, unknown option attributes, missing option attributes, etc. These are dealt with in the usual way : raise an exception (either `optparse.OptionError` or `TypeError`) and let the program crash.

Handling user errors is much more important, since they are guaranteed to happen no matter how stable your code is. *optparse* can automatically detect some user errors, such as bad option arguments (passing `-n 4x` where `-n` takes an integer argument), missing arguments (`-n` at the end of the command line, where `-n` takes an argument of any type). Also, you can call `OptionParser.error()` to signal an application-defined error condition :

```
(options, args) = parser.parse_args()
...
if options.a and options.b:
    parser.error("options -a and -b are mutually exclusive")
```

In either case, *optparse* handles the error the same way : it prints the program's usage message and an error message to standard error and exits with error status 2.

Consider the first example above, where the user passes `4x` to an option that takes an integer :

```
$ /usr/bin/foo -n 4x
Usage: foo [options]

foo: error: option -n: invalid integer value: '4x'
```

Or, where the user fails to pass a value at all :

```
$ /usr/bin/foo -n
Usage: foo [options]

foo: error: -n option requires an argument
```

*optparse*-generated error messages take care always to mention the option involved in the error; be sure to do the same when calling `OptionParser.error()` from your application code.

If *optparse*'s default error-handling behaviour does not suit your needs, you'll need to subclass `OptionParser` and override its `exit()` and/or `error()` methods.

### Putting it all together

Here's what *optparse*-based scripts usually look like :

```
from optparse import OptionParser
...
def main():
    usage = "usage: %prog [options] arg"
    parser = OptionParser(usage)
    parser.add_option("-f", "--file", dest="filename",
                      help="read data from FILENAME")
    parser.add_option("-v", "--verbose",
                      action="store_true", dest="verbose")
    parser.add_option("-q", "--quiet",
                      action="store_false", dest="verbose")
    ...
    (options, args) = parser.parse_args()
    if len(args) != 1:
        parser.error("incorrect number of arguments")
    if options.verbose:
        print "reading %s..." % options.filename
    ...

if __name__ == "__main__":
    main()
```

## 15.5.3 Reference Guide

### Creating the parser

The first step in using *optparse* is to create an `OptionParser` instance.

**class** `optparse.OptionParser(...)`

The `OptionParser` constructor has no required arguments, but a number of optional keyword arguments. You should always pass them as keyword arguments, i.e. do not rely on the order in which the arguments are declared.

**usage** (default : `"%prog [options]"`) The usage summary to print when your program is run incorrectly or with a help option. When *optparse* prints the usage string, it expands `%prog` to `os.path.basename(sys.argv[0])` (or to `prog` if you passed that keyword argument). To suppress a usage message, pass the special value `optparse.SUPPRESS_USAGE`.

**option\_list** (default : `[]`) A list of `Option` objects to populate the parser with. The options in `option_list` are added after any options in `standard_option_list` (a class attribute that may be set by `OptionParser` subclasses), but before any version or help options. Deprecated; use `add_option()` after creating the parser instead.

**option\_class** (default : `optparse.Option`) Class to use when adding options to the parser in `add_option()`.

**version** (default : `None`) A version string to print when the user supplies a version option. If you supply a true value for **version**, `optparse` automatically adds a version option with the single option string `--version`. The substring `%prog` is expanded the same as for **usage**.

**conflict\_handler** (default : `"error"`) Specifies what to do when options with conflicting option strings are added to the parser; see section *Conflicts between options*.

**description** (default : `None`) A paragraph of text giving a brief overview of your program. `optparse` reformats this paragraph to fit the current terminal width and prints it when the user requests help (after **usage**, but before the list of options).

**formatter** (default : a new `IndentedHelpFormatter`) An instance of `optparse.HelpFormatter` that will be used for printing help text. `optparse` provides two concrete classes for this purpose : `IndentedHelpFormatter` and `TitledHelpFormatter`.

**add\_help\_option** (default : `True`) If true, `optparse` will add a help option (with option strings `-h` and `--help`) to the parser.

**prog** The string to use when expanding `%prog` in **usage** and **version** instead of `os.path.basename(sys.argv[0])`.

**epilog** (default : `None`) A paragraph of help text to print after the option help.

### Populating the parser

There are several ways to populate the parser with options. The preferred way is by using `OptionParser.add_option()`, as shown in section *Tutorial*. `add_option()` can be called in one of two ways :

- pass it an `Option` instance (as returned by `make_option()`)
- pass it any combination of positional and keyword arguments that are acceptable to `make_option()` (i.e., to the `Option` constructor), and it will create the `Option` instance for you

The other alternative is to pass a list of pre-constructed `Option` instances to the `OptionParser` constructor, as in :

```
option_list = [
    make_option("-f", "--filename",
                action="store", type="string", dest="filename"),
    make_option("-q", "--quiet",
                action="store_false", dest="verbose"),
]
parser = OptionParser(option_list=option_list)
```

(`make_option()` is a factory function for creating `Option` instances; currently it is an alias for the `Option` constructor. A future version of `optparse` may split `Option` into several classes, and `make_option()` will pick the right class to instantiate. Do not instantiate `Option` directly.)

### Defining options

Each `Option` instance represents a set of synonymous command-line option strings, e.g. `-f` and `--file`. You can specify any number of short or long option strings, but you must specify at least one overall option string.

The canonical way to create an `Option` instance is with the `add_option()` method of `OptionParser`.

`OptionParser.add_option(option)`

`OptionParser.add_option(*opt_str, attr=value, ...)`

To define an option with only a short option string :

```
parser.add_option("-f", attr=value, ...)
```

And to define an option with only a long option string :

```
parser.add_option("--foo", attr=value, ...)
```

The keyword arguments define attributes of the new Option object. The most important option attribute is *action*, and it largely determines which other attributes are relevant or required. If you pass irrelevant option attributes, or fail to pass required ones, *optparse* raises an *OptionError* exception explaining your mistake.

An option's *action* determines what *optparse* does when it encounters this option on the command-line. The standard option actions hard-coded into *optparse* are :

"store" store this option's argument (default)

"store\_const" store a constant value

"store\_true" store a true value

"store\_false" store a false value

"append" append this option's argument to a list

"append\_const" append a constant value to a list

"count" increment a counter by one

"callback" call a specified function

"help" print a usage message including all options and the documentation for them

(If you don't supply an action, the default is "store". For this action, you may also supply *type* and *dest* option attributes; see *Standard option actions*.)

As you can see, most actions involve storing or updating a value somewhere. *optparse* always creates a special object for this, conventionally called *options* (it happens to be an instance of *optparse.Values*). Option arguments (and various other values) are stored as attributes of this object, according to the *dest* (destination) option attribute.

For example, when you call

```
parser.parse_args()
```

one of the first things *optparse* does is create the *options* object :

```
options = Values()
```

If one of the options in this parser is defined with

```
parser.add_option("-f", "--file", action="store", type="string", dest="filename")
```

and the command-line being parsed includes any of the following :

```
-ffoo
-f foo
--file=foo
--file foo
```

then *optparse*, on seeing this option, will do the equivalent of

```
options.filename = "foo"
```

The *type* and *dest* option attributes are almost as important as *action*, but *action* is the only one that makes sense for *all* options.

## Option attributes

The following option attributes may be passed as keyword arguments to `OptionParser.add_option()`. If you pass an option attribute that is not relevant to a particular option, or fail to pass a required option attribute, `optparse` raises `OptionError`.

### `Option.action`

(default : "store")

Determines `optparse`'s behaviour when this option is seen on the command line ; the available options are documented [here](#).

### `Option.type`

(default : "string")

The argument type expected by this option (e.g., "string" or "int"); the available option types are documented [here](#).

### `Option.dest`

(default : derived from option strings)

If the option's action implies writing or modifying a value somewhere, this tells `optparse` where to write it : `dest` names an attribute of the `options` object that `optparse` builds as it parses the command line.

### `Option.default`

The value to use for this option's destination if the option is not seen on the command line. See also `OptionParser.set_defaults()`.

### `Option.nargs`

(default : 1)

How many arguments of type `type` should be consumed when this option is seen. If  $> 1$ , `optparse` will store a tuple of values to `dest`.

### `Option.const`

For actions that store a constant value, the constant value to store.

### `Option.choices`

For options of type "choice", the list of strings the user may choose from.

### `Option.callback`

For options with action "callback", the callable to call when this option is seen. See section [Option Callbacks](#) for detail on the arguments passed to the callable.

### `Option.callback_args`

### `Option.callback_kwargs`

Additional positional and keyword arguments to pass to `callback` after the four standard callback arguments.

### `Option.help`

Help text to print for this option when listing all available options after the user supplies a `help` option (such as `--help`). If no help text is supplied, the option will be listed without help text. To hide this option, use the special value `optparse.SUPPRESS_HELP`.

### `Option.metavar`

(default : derived from option strings)

Stand-in for the option argument(s) to use when printing help text. See section [Tutoriel](#) for an example.

## Standard option actions

The various option actions all have slightly different requirements and effects. Most actions have several relevant option attributes which you may specify to guide `optparse`'s behaviour ; a few have required attributes, which you must specify for any option using that action.

- "store" [relevant : *type*, *dest*, *nargs*, *choices*]

The option must be followed by an argument, which is converted to a value according to *type* and stored in *dest*. If *nargs* > 1, multiple arguments will be consumed from the command line; all will be converted according to *type* and stored to *dest* as a tuple. See the *Standard option types* section. If *choices* is supplied (a list or tuple of strings), the type defaults to "choice".

If *type* is not supplied, it defaults to "string".

If *dest* is not supplied, *optparse* derives a destination from the first long option string (e.g., --foo-bar implies foo\_bar). If there are no long option strings, *optparse* derives a destination from the first short option string (e.g., -f implies f).

Example :

```
parser.add_option("-f")
parser.add_option("-p", type="float", nargs=3, dest="point")
```

As it parses the command line

```
-f foo.txt -p 1 -3.5 4 -fbar.txt
```

*optparse* will set

```
options.f = "foo.txt"
options.point = (1.0, -3.5, 4.0)
options.f = "bar.txt"
```

- "store\_const" [required : *const*; relevant : *dest*]

The value *const* is stored in *dest*.

Example :

```
parser.add_option("-q", "--quiet",
                  action="store_const", const=0, dest="verbose")
parser.add_option("-v", "--verbose",
                  action="store_const", const=1, dest="verbose")
parser.add_option("--noisy",
                  action="store_const", const=2, dest="verbose")
```

If --noisy is seen, *optparse* will set

```
options.verbose = 2
```

- "store\_true" [relevant : *dest*]
- A special case of "store\_const" that stores a true value to *dest*.
- "store\_false" [relevant : *dest*]
- Like "store\_true", but stores a false value.

Example :

```
parser.add_option("--clobber", action="store_true", dest="clobber")
parser.add_option("--no-clobber", action="store_false", dest="clobber")
```

- "append" [relevant : *type*, *dest*, *nargs*, *choices*]

The option must be followed by an argument, which is appended to the list in *dest*. If no default value for *dest* is supplied, an empty list is automatically created when *optparse* first encounters this option on the command-line. If *nargs* > 1, multiple arguments are consumed, and a tuple of length *nargs* is appended to *dest*.

The defaults for *type* and *dest* are the same as for the "store" action.

Example :

```
parser.add_option("-t", "--tracks", action="append", type="int")
```

If -t3 is seen on the command-line, *optparse* does the equivalent of :

```
options.tracks = []
options.tracks.append(int("3"))
```

If, a little later on, `--tracks=4` is seen, it does :

```
options.tracks.append(int("4"))
```

The `append` action calls the `append` method on the current value of the option. This means that any default value specified must have an `append` method. It also means that if the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values :

```
>>> parser.add_option("--files", action="append", default=['~/mypkg/defaults'])
>>> opts, args = parser.parse_args(['--files', 'overrides.mypkg'])
>>> opts.files
['~/mypkg/defaults', 'overrides.mypkg']
```

- `"append_const"` [required : *const*; relevant : *dest*]  
Like `"store_const"`, but the value *const* is appended to *dest*; as with `"append"`, *dest* defaults to `None`, and an empty list is automatically created the first time the option is encountered.
- `"count"` [relevant : *dest*]  
Increment the integer stored at *dest*. If no default value is supplied, *dest* is set to zero before being incremented the first time.  
Exemple :

```
parser.add_option("-v", action="count", dest="verbosity")
```

The first time `-v` is seen on the command line, *optparse* does the equivalent of :

```
options.verbosity = 0
options.verbosity += 1
```

Every subsequent occurrence of `-v` results in

```
options.verbosity += 1
```

- `"callback"` [required : *callback*; relevant : *type*, *nargs*, *callback\_args*, *callback\_kwargs*]  
Call the function specified by *callback*, which is called as

```
func(option, opt_str, value, parser, *args, **kwargs)
```

See section *Option Callbacks* for more detail.

- `"help"`  
Prints a complete help message for all the options in the current option parser. The help message is constructed from the *usage* string passed to `OptionParser`'s constructor and the *help* string passed to every option.  
If no *help* string is supplied for an option, it will still be listed in the help message. To omit an option entirely, use the special value `optparse.SUPPRESS_HELP`.  
*optparse* automatically adds a *help* option to all `OptionParsers`, so you do not normally need to create one.  
Exemple :

```
from optparse import OptionParser, SUPPRESS_HELP

# usually, a help option is added automatically, but that can
# be suppressed using the add_help_option argument
parser = OptionParser(add_help_option=False)
```

(suite sur la page suivante)

(suite de la page précédente)

```

parser.add_option("-h", "--help", action="help")
parser.add_option("-v", action="store_true", dest="verbose",
                  help="Be moderately verbose")
parser.add_option("--file", dest="filename",
                  help="Input file to read data from")
parser.add_option("--secret", help=SUPPRESS_HELP)

```

If *optparse* sees either `-h` or `--help` on the command line, it will print something like the following help message to stdout (assuming `sys.argv[0]` is `"foo.py"`) :

```

Usage: foo.py [options]

Options:
  -h, --help          Show this help message and exit
  -v                  Be moderately verbose
  --file=FILENAME     Input file to read data from

```

After printing the help message, *optparse* terminates your process with `sys.exit(0)`.

— **"version"**

Prints the version number supplied to the `OptionParser` to stdout and exits. The version number is actually formatted and printed by the `print_version()` method of `OptionParser`. Generally only relevant if the `version` argument is supplied to the `OptionParser` constructor. As with *help* options, you will rarely create `version` options, since *optparse* automatically adds them when needed.

## Standard option types

*optparse* has six built-in option types : `"string"`, `"int"`, `"long"`, `"choice"`, `"float"` and `"complex"`. If you need to add new option types, see section *Extending optparse*.

Arguments to string options are not checked or converted in any way : the text on the command line is stored in the destination (or passed to the callback) as-is.

Integer arguments (type `"int"` or `"long"`) are parsed as follows :

- if the number starts with `0x`, it is parsed as a hexadecimal number
- if the number starts with `0`, it is parsed as an octal number
- if the number starts with `0b`, it is parsed as a binary number
- otherwise, the number is parsed as a decimal number

The conversion is done by calling either `int()` or `long()` with the appropriate base (2, 8, 10, or 16). If this fails, so will *optparse*, although with a more useful error message.

`"float"` and `"complex"` option arguments are converted directly with `float()` and `complex()`, with similar error-handling.

`"choice"` options are a subtype of `"string"` options. The *choices* option attribute (a sequence of strings) defines the set of allowed option arguments. `optparse.check_choice()` compares user-supplied option arguments against this master list and raises `OptionValueError` if an invalid string is given.

## Analyse des arguments

The whole point of creating and populating an `OptionParser` is to call its `parse_args()` method :

```
(options, args) = parser.parse_args(args=None, values=None)
```

where the input parameters are

**args** the list of arguments to process (default : `sys.argv[1:]`)

**values** an `optparse.Values` object to store option arguments in (default : a new instance of `Values`) – if you give an existing object, the option defaults will not be initialized on it  
and the return values are

**options** the same object that was passed in as **values**, or the `optparse.Values` instance created by `optparse`

**args** the leftover positional arguments after all options have been processed

The most common usage is to supply neither keyword argument. If you supply **values**, it will be modified with repeated `setattr()` calls (roughly one for every option argument stored to an option destination) and returned by `parse_args()`.

If `parse_args()` encounters any errors in the argument list, it calls the `OptionParser`'s `error()` method with an appropriate end-user error message. This ultimately terminates your process with an exit status of 2 (the traditional Unix exit status for command-line errors).

### Querying and manipulating your option parser

The default behavior of the option parser can be customized slightly, and you can also poke around your option parser and see what's there. `OptionParser` provides several methods to help you out :

`OptionParser.disable_interspersed_args()`

Set parsing to stop on the first non-option. For example, if `-a` and `-b` are both simple options that take no arguments, `optparse` normally accepts this syntax :

```
prog -a arg1 -b arg2
```

and treats it as equivalent to

```
prog -a -b arg1 arg2
```

To disable this feature, call `disable_interspersed_args()`. This restores traditional Unix syntax, where option parsing stops with the first non-option argument.

Use this if you have a command processor which runs another command which has options of its own and you want to make sure these options don't get confused. For example, each command might have a different set of options.

`OptionParser.enable_interspersed_args()`

Set parsing to not stop on the first non-option, allowing interspersing switches with command arguments. This is the default behavior.

`OptionParser.get_option(opt_str)`

Returns the `Option` instance with the option string `opt_str`, or `None` if no options have that option string.

`OptionParser.has_option(opt_str)`

Return true if the `OptionParser` has an option with option string `opt_str` (e.g., `-q` or `--verbose`).

`OptionParser.remove_option(opt_str)`

If the `OptionParser` has an option corresponding to `opt_str`, that option is removed. If that option provided any other option strings, all of those option strings become invalid. If `opt_str` does not occur in any option belonging to this `OptionParser`, raises `ValueError`.

### Conflicts between options

If you're not careful, it's easy to define options with conflicting option strings :

```
parser.add_option("-n", "--dry-run", ...)
...
parser.add_option("-n", "--noisy", ...)
```

(This is particularly true if you've defined your own `OptionParser` subclass with some standard options.)

Every time you add an option, *optparse* checks for conflicts with existing options. If it finds any, it invokes the current conflict-handling mechanism. You can set the conflict-handling mechanism either in the constructor :

```
parser = OptionParser(..., conflict_handler=handler)
```

or with a separate call :

```
parser.set_conflict_handler(handler)
```

The available conflict handlers are :

**"error"** (default) assume option conflicts are a programming error and raise `OptionConflictError`

**"resolve"** resolve option conflicts intelligently (see below)

As an example, let's define an *OptionParser* that resolves conflicts intelligently and add conflicting options to it :

```
parser = OptionParser(conflict_handler="resolve")
parser.add_option("-n", "--dry-run", ..., help="do no harm")
parser.add_option("-n", "--noisy", ..., help="be noisy")
```

At this point, *optparse* detects that a previously-added option is already using the `-n` option string. Since `conflict_handler` is `"resolve"`, it resolves the situation by removing `-n` from the earlier option's list of option strings. Now `--dry-run` is the only way for the user to activate that option. If the user asks for help, the help message will reflect that :

```
Options:
  --dry-run      do no harm
  ...
  -n, --noisy    be noisy
```

It's possible to whittle away the option strings for a previously-added option until there are none left, and the user has no way of invoking that option from the command-line. In that case, *optparse* removes that option completely, so it doesn't show up in help text or anywhere else. Carrying on with our existing `OptionParser` :

```
parser.add_option("--dry-run", ..., help="new dry-run option")
```

At this point, the original `-n/--dry-run` option is no longer accessible, so *optparse* removes it, leaving this help text :

```
Options:
  ...
  -n, --noisy    be noisy
  --dry-run      new dry-run option
```

## Cleanup

`OptionParser` instances have several cyclic references. This should not be a problem for Python's garbage collector, but you may wish to break the cyclic references explicitly by calling `destroy()` on your `OptionParser` once you are done with it. This is particularly useful in long-running applications where large object graphs are reachable from your `OptionParser`.

## Other methods

OptionParser supports several other public methods :

`OptionParser.set_usage(usage)`

Set the usage string according to the rules described above for the `usage` constructor keyword argument. Passing `None` sets the default usage string; use `optparse.SUPPRESS_USAGE` to suppress a usage message.

`OptionParser.print_usage(file=None)`

Print the usage message for the current program (`self.usage`) to `file` (default `stdout`). Any occurrence of the string `%prog` in `self.usage` is replaced with the name of the current program. Does nothing if `self.usage` is empty or not defined.

`OptionParser.get_usage()`

Same as `print_usage()` but returns the usage string instead of printing it.

`OptionParser.set_defaults(dest=value, ...)`

Set default values for several option destinations at once. Using `set_defaults()` is the preferred way to set default values for options, since multiple options can share the same destination. For example, if several « `mode` » options all set the same destination, any one of them can set the default, and the last one wins :

```
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced",
                  default="novice")    # overridden below
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice",
                  default="advanced")  # overrides above setting
```

To avoid this confusion, use `set_defaults()` :

```
parser.set_defaults(mode="advanced")
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced")
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice")
```

## 15.5.4 Option Callbacks

When `optparse`'s built-in actions and types aren't quite enough for your needs, you have two choices : extend `optparse` or define a callback option. Extending `optparse` is more general, but overkill for a lot of simple cases. Quite often a simple callback is all you need.

There are two steps to defining a callback option :

- define the option itself using the "callback" action
- write the callback; this is a function (or method) that takes at least four arguments, as described below

### Defining a callback option

As always, the easiest way to define a callback option is by using the `OptionParser.add_option()` method. Apart from `action`, the only option attribute you must specify is `callback`, the function to call :

```
parser.add_option("-c", action="callback", callback=my_callback)
```

`callback` is a function (or other callable object), so you must have already defined `my_callback()` when you create this callback option. In this simple case, `optparse` doesn't even know if `-c` takes any arguments, which usually means that the option takes no arguments—the mere presence of `-c` on the command-line is

all it needs to know. In some circumstances, though, you might want your callback to consume an arbitrary number of command-line arguments. This is where writing callbacks gets tricky; it's covered later in this section.

`optparse` always passes four particular arguments to your callback, and it will only pass additional arguments if you specify them via `callback_args` and `callback_kwargs`. Thus, the minimal callback function signature is :

```
def my_callback(option, opt, value, parser):
```

The four arguments to a callback are described below.

There are several other option attributes that you can supply when you define a callback option :

`type` has its usual meaning : as with the "store" or "append" actions, it instructs `optparse` to consume one argument and convert it to `type`. Rather than storing the converted value(s) anywhere, though, `optparse` passes it to your callback function.

`nargs` also has its usual meaning : if it is supplied and  $> 1$ , `optparse` will consume `nargs` arguments, each of which must be convertible to `type`. It then passes a tuple of converted values to your callback.

`callback_args` a tuple of extra positional arguments to pass to the callback

`callback_kwargs` a dictionary of extra keyword arguments to pass to the callback

### How callbacks are called

All callbacks are called as follows :

```
func(option, opt_str, value, parser, *args, **kwargs)
```

where

**option** is the Option instance that's calling the callback

**opt\_str** is the option string seen on the command-line that's triggering the callback. (If an abbreviated long option was used, **opt\_str** will be the full, canonical option string—e.g. if the user puts `--foo` on the command-line as an abbreviation for `--foobar`, then **opt\_str** will be `--foobar`.)

**value** is the argument to this option seen on the command-line. `optparse` will only expect an argument if `type` is set; the type of **value** will be the type implied by the option's type. If `type` for this option is `None` (no argument expected), then **value** will be `None`. If `nargs`  $> 1$ , **value** will be a tuple of values of the appropriate type.

**parser** is the OptionParser instance driving the whole thing, mainly useful because you can access some other interesting data through its instance attributes :

**parser.largs** the current list of leftover arguments, ie. arguments that have been consumed but are neither options nor option arguments. Feel free to modify **parser.largs**, e.g. by adding more arguments to it. (This list will become **args**, the second return value of `parse_args()`.)

**parser.rargs** the current list of remaining arguments, ie. with **opt\_str** and **value** (if applicable) removed, and only the arguments following them still there. Feel free to modify **parser.rargs**, e.g. by consuming more arguments.

**parser.values** the object where option values are by default stored (an instance of `optparse.OptionValues`). This lets callbacks use the same mechanism as the rest of `optparse` for storing option values; you don't need to mess around with globals or closures. You can also access or modify the value(s) of any options already encountered on the command-line.

**args** is a tuple of arbitrary positional arguments supplied via the `callback_args` option attribute.

**kwargs** is a dictionary of arbitrary keyword arguments supplied via `callback_kwargs`.

### Raising errors in a callback

The callback function should raise `OptionValueError` if there are any problems with the option or its argument(s). `optparse` catches this and terminates the program, printing the error message you supply to `stderr`. Your message should be clear, concise, accurate, and mention the option at fault. Otherwise, the user will have a hard time figuring out what they did wrong.

### Callback example 1 : trivial callback

Here's an example of a callback option that takes no arguments, and simply records that the option was seen :

```
def record_foo_seen(option, opt_str, value, parser):
    parser.values.saw_foo = True

parser.add_option("--foo", action="callback", callback=record_foo_seen)
```

Of course, you could do that with the "store\_true" action.

### Callback example 2 : check option order

Here's a slightly more interesting example : record the fact that `-a` is seen, but blow up if it comes after `-b` in the command-line.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use -a after -b")
    parser.values.a = 1
...
parser.add_option("-a", action="callback", callback=check_order)
parser.add_option("-b", action="store_true", dest="b")
```

### Callback example 3 : check option order (generalized)

If you want to re-use this callback for several similar options (set a flag, but blow up if `-b` has already been seen), it needs a bit of work : the error message and the flag that it sets must be generalized.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use %s after -b" % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("-a", action="callback", callback=check_order, dest='a')
parser.add_option("-b", action="store_true", dest="b")
parser.add_option("-c", action="callback", callback=check_order, dest='c')
```

### Callback example 4 : check arbitrary condition

Of course, you could put any condition in there—you're not limited to checking the values of already-defined options. For example, if you have options that should not be called when the moon is full, all you have to do is this :

```
def check_moon(option, opt_str, value, parser):
    if is_moon_full():
        raise OptionValueError("%s option invalid when moon is full"
```

(suite sur la page suivante)

(suite de la page précédente)

```

                                % opt_str)
    setattr(parser.values, option.dest, 1)
    ...
    parser.add_option("--foo",
                      action="callback", callback=check_moon, dest="foo")

```

(The definition of `is_moon_full()` is left as an exercise for the reader.)

### Callback example 5 : fixed arguments

Things get slightly more interesting when you define callback options that take a fixed number of arguments. Specifying that a callback option takes arguments is similar to defining a "store" or "append" option : if you define *type*, then the option takes one argument that must be convertible to that type ; if you further define *nargs*, then the option takes *nargs* arguments.

Here's an example that just emulates the standard "store" action :

```

def store_value(option, opt_str, value, parser):
    setattr(parser.values, option.dest, value)
    ...
    parser.add_option("--foo",
                      action="callback", callback=store_value,
                      type="int", nargs=3, dest="foo")

```

Note that *optparse* takes care of consuming 3 arguments and converting them to integers for you ; all you have to do is store them. (Or whatever ; obviously you don't need a callback for this example.)

### Callback example 6 : variable arguments

Things get hairy when you want an option to take a variable number of arguments. For this case, you must write a callback, as *optparse* doesn't provide any built-in capabilities for it. And you have to deal with certain intricacies of conventional Unix command-line parsing that *optparse* normally handles for you. In particular, callbacks should implement the conventional rules for bare `--` and `-` arguments :

- either `--` or `-` can be option arguments
- bare `--` (if not the argument to some option) : halt command-line processing and discard the `--`
- bare `-` (if not the argument to some option) : halt command-line processing but keep the `-` (append it to `parser.largs`)

If you want an option that takes a variable number of arguments, there are several subtle, tricky issues to worry about. The exact implementation you choose will be based on which trade-offs you're willing to make for your application (which is why *optparse* doesn't support this sort of thing directly).

Nevertheless, here's a stab at a callback for an option with variable arguments :

```

def vararg_callback(option, opt_str, value, parser):
    assert value is None
    value = []

    def floatable(str):
        try:
            float(str)
            return True
        except ValueError:
            return False

```

(suite sur la page suivante)

(suite de la page précédente)

```

for arg in parser.rargs:
    # stop on --foo like options
    if arg[:2] == "--" and len(arg) > 2:
        break
    # stop on -a, but not on -3 or -3.0
    if arg[:1] == "-" and len(arg) > 1 and not floatable(arg):
        break
    value.append(arg)

del parser.rargs[:len(value)]
setattr(parser.values, option.dest, value)

...
parser.add_option("-c", "--callback", dest="vararg_attr",
                  action="callback", callback=vararg_callback)

```

### 15.5.5 Extending optparse

Since the two major controlling factors in how *optparse* interprets command-line options are the action and type of each option, the most likely direction of extension is to add new actions and new types.

#### Adding new types

To add new types, you need to define your own subclass of *optparse*'s `Option` class. This class has a couple of attributes that define *optparse*'s types : *TYPES* and *TYPE\_CHECKER*.

##### `Option.TYPES`

A tuple of type names; in your subclass, simply define a new tuple *TYPES* that builds on the standard one.

##### `Option.TYPE_CHECKER`

A dictionary mapping type names to type-checking functions. A type-checking function has the following signature :

```
def check_mytype(option, opt, value)
```

where *option* is an `Option` instance, *opt* is an option string (e.g., `-f`), and *value* is the string from the command line that must be checked and converted to your desired type. `check_mytype()` should return an object of the hypothetical type *mytype*. The value returned by a type-checking function will wind up in the `OptionValues` instance returned by `OptionParser.parse_args()`, or be passed to a callback as the *value* parameter.

Your type-checking function should raise `OptionValueError` if it encounters any problems. `OptionValueError` takes a single string argument, which is passed as-is to *OptionParser*'s `error()` method, which in turn prepends the program name and the string `"error:"` and prints everything to `stderr` before terminating the process.

Here's a silly example that demonstrates adding a `"complex"` option type to parse Python-style complex numbers on the command line. (This is even sillier than it used to be, because *optparse* 1.3 added built-in support for complex numbers, but never mind.)

First, the necessary imports :

```

from copy import copy
from optparse import Option, OptionValueError

```

You need to define your type-checker first, since it's referred to later (in the `TYPE_CHECKER` class attribute of your Option subclass) :

```
def check_complex(option, opt, value):
    try:
        return complex(value)
    except ValueError:
        raise OptionValueError(
            "option %s: invalid complex value: %r" % (opt, value))
```

Finally, the Option subclass :

```
class MyOption (Option):
    TYPES = Option.TYPES + ("complex",)
    TYPE_CHECKER = copy(Option.TYPE_CHECKER)
    TYPE_CHECKER["complex"] = check_complex
```

(If we didn't make a `copy()` of `Option.TYPE_CHECKER`, we would end up modifying the `TYPE_CHECKER` attribute of `optparse`'s Option class. This being Python, nothing stops you from doing that except good manners and common sense.)

That's it! Now you can write a script that uses the new option type just like any other `optparse`-based script, except you have to instruct your OptionParser to use MyOption instead of Option :

```
parser = OptionParser(option_class=MyOption)
parser.add_option("-c", type="complex")
```

Alternately, you can build your own option list and pass it to OptionParser; if you don't use `add_option()` in the above way, you don't need to tell OptionParser which option class to use :

```
option_list = [MyOption("-c", action="store", type="complex", dest="c")]
parser = OptionParser(option_list=option_list)
```

### Adding new actions

Adding new actions is a bit trickier, because you have to understand that `optparse` has a couple of classifications for actions :

- « **store** » **actions** actions that result in `optparse` storing a value to an attribute of the current OptionValues instance; these options require a `dest` attribute to be supplied to the Option constructor.
- « **typed** » **actions** actions that take a value from the command line and expect it to be of a certain type; or rather, a string that can be converted to a certain type. These options require a `type` attribute to the Option constructor.

These are overlapping sets : some default « store » actions are "store", "store\_const", "append", and "count", while the default « typed » actions are "store", "append", and "callback".

When you add an action, you need to categorize it by listing it in at least one of the following class attributes of Option (all are lists of strings) :

#### Option.ACTIONS

All actions must be listed in ACTIONS.

#### Option.STORE\_ACTIONS

« store » actions are additionally listed here.

#### Option.TYPED\_ACTIONS

« typed » actions are additionally listed here.

**Option.ALWAYS\_TYPED\_ACTIONS**

Actions that always take a type (i.e. whose options always take a value) are additionally listed here. The only effect of this is that *optparse* assigns the default type, "string", to options with no explicit type whose action is listed in *ALWAYS\_TYPED\_ACTIONS*.

In order to actually implement your new action, you must override Option's `take_action()` method and add a case that recognizes your action.

For example, let's add an "extend" action. This is similar to the standard "append" action, but instead of taking a single value from the command-line and appending it to an existing list, "extend" will take multiple values in a single comma-delimited string, and extend an existing list with them. That is, if `--names` is an "extend" option of type "string", the command line

```
--names=foo,bar --names blah --names ding,dong
```

would result in a list

```
["foo", "bar", "blah", "ding", "dong"]
```

Again we define a subclass of Option :

```
class MyOption(Option):

    ACTIONS = Option.ACTIONS + ("extend",)
    STORE_ACTIONS = Option.STORE_ACTIONS + ("extend",)
    TYPED_ACTIONS = Option.TYPED_ACTIONS + ("extend",)
    ALWAYS_TYPED_ACTIONS = Option.ALWAYS_TYPED_ACTIONS + ("extend",)

    def take_action(self, action, dest, opt, value, values, parser):
        if action == "extend":
            lvalue = value.split(",")
            values.ensure_value(dest, []).extend(lvalue)
        else:
            Option.take_action(
                self, action, dest, opt, value, values, parser)
```

Features of note :

- "extend" both expects a value on the command-line and stores that value somewhere, so it goes in both *STORE\_ACTIONS* and *TYPED\_ACTIONS*.
- to ensure that *optparse* assigns the default type of "string" to "extend" actions, we put the "extend" action in *ALWAYS\_TYPED\_ACTIONS* as well.
- `MyOption.take_action()` implements just this one new action, and passes control back to `Option.take_action()` for the standard *optparse* actions.
- `values` is an instance of the `optparse_parser.Values` class, which provides the very useful `ensure_value()` method. `ensure_value()` is essentially *getattr()* with a safety valve; it is called as

```
values.ensure_value(attr, value)
```

If the `attr` attribute of `values` doesn't exist or is `None`, then `ensure_value()` first sets it to `value`, and then returns "value. This is very handy for actions like "extend", "append", and "count", all of which accumulate data in a variable and expect that variable to be of a certain type (a list for the first two, an integer for the latter). Using `ensure_value()` means that scripts using your action don't have to worry about setting a default value for the option destinations in question; they can just leave the default as `None` and `ensure_value()` will take care of getting it right when it's needed.

## 15.6 getopt — C-style parser for command line options

Code source : [Lib/getopt.py](#)

---

**Note :** The `getopt` module is a parser for command line options whose API is designed to be familiar to users of the C `getopt()` function. Users who are unfamiliar with the C `getopt()` function or who would like to write less code and get better help and error messages should consider using the `argparse` module instead.

---

This module helps scripts to parse the command line arguments in `sys.argv`. It supports the same conventions as the Unix `getopt()` function (including the special meanings of arguments of the form “-” and “--”). Long options similar to those supported by GNU software may be used as well via an optional third argument.

This module provides two functions and an exception :

**getopt.getopt**(*args*, *options*[, *long\_options*])

Parses command line options and parameter list. *args* is the argument list to be parsed, without the leading reference to the running program. Typically, this means `sys.argv[1:]`. *options* is the string of option letters that the script wants to recognize, with options that require an argument followed by a colon (':'); i.e., the same format that Unix `getopt()` uses).

---

**Note :** Unlike GNU `getopt()`, after a non-option argument, all further arguments are considered also non-options. This is similar to the way non-GNU Unix systems work.

---

*long\_options*, if specified, must be a list of strings with the names of the long options which should be supported. The leading ‘--’ characters should not be included in the option name. Long options which require an argument should be followed by an equal sign (=). Optional arguments are not supported. To accept only long options, *options* should be an empty string. Long options on the command line can be recognized so long as they provide a prefix of the option name that matches exactly one of the accepted options. For example, if *long\_options* is ['foo', 'frob'], the option --fo will match as --foo, but --f will not match uniquely, so `GetoptError` will be raised.

The return value consists of two elements : the first is a list of (**option**, **value**) pairs ; the second is the list of program arguments left after the option list was stripped (this is a trailing slice of *args*). Each option-and-value pair returned has the option as its first element, prefixed with a hyphen for short options (e.g., '-x') or two hyphens for long options (e.g., '--long-option'), and the option argument as its second element, or an empty string if the option has no argument. The options occur in the list in the same order in which they were found, thus allowing multiple occurrences. Long and short options may be mixed.

**getopt.gnu\_getopt**(*args*, *options*[, *long\_options*])

This function works like `getopt()`, except that GNU style scanning mode is used by default. This means that option and non-option arguments may be intermixed. The `getopt()` function stops processing options as soon as a non-option argument is encountered.

If the first character of the option string is '+', or if the environment variable `POSIXLY_CORRECT` is set, then option processing stops as soon as a non-option argument is encountered.

Nouveau dans la version 2.3.

**exception getopt.GetoptError**

This is raised when an unrecognized option is found in the argument list or when an option requiring an argument is given none. The argument to the exception is a string indicating the cause of the error. For long options, an argument given to an option which does not require one will also cause this

exception to be raised. The attributes `msg` and `opt` give the error message and related option; if there is no specific option to which the exception relates, `opt` is an empty string.

Modifié dans la version 1.6 : Introduced *GetoptError* as a synonym for *error*.

**exception** `getopt.error`

Alias for *GetoptError*; for backward compatibility.

An example using only Unix style options :

```
>>> import getopt
>>> args = '-a -b -cfoo -d bar a1 a2'.split()
>>> args
['-a', '-b', '-cfoo', '-d', 'bar', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'abc:d:')
>>> optlist
[('-a', ''), ('-b', ''), ('-c', 'foo'), ('-d', 'bar')]
>>> args
['a1', 'a2']
```

Using long option names is equally easy :

```
>>> s = '--condition=foo --testing --output-file abc.def -x a1 a2'
>>> args = s.split()
>>> args
['--condition=foo', '--testing', '--output-file', 'abc.def', '-x', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'x', [
...     'condition=', 'output-file=', 'testing'])
>>> optlist
[('--condition', 'foo'), ('--testing', ''), ('--output-file', 'abc.def'), ('-x', '')]
>>> args
['a1', 'a2']
```

In a script, typical usage is something like this :

```
import getopt, sys

def main():
    try:
        opts, args = getopt.getopt(sys.argv[1:], "ho:v", ["help", "output="])
    except getopt.GetoptError as err:
        # print help information and exit:
        print str(err) # will print something like "option -a not recognized"
        usage()
        sys.exit(2)
    output = None
    verbose = False
    for o, a in opts:
        if o == "-v":
            verbose = True
        elif o in ("-h", "--help"):
            usage()
            sys.exit()
        elif o in ("-o", "--output"):
            output = a
        else:
            usage()
```

(suite sur la page suivante)

(suite de la page précédente)

```

        assert False, "unhandled option"

    # ...

if __name__ == "__main__":
    main()

```

Note that an equivalent command line interface could be produced with less code and more informative help and error messages by using the *argparse* module :

```

import argparse

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument('-o', '--output')
    parser.add_argument('-v', dest='verbose', action='store_true')
    args = parser.parse_args()
    # ... do something with args.output ...
    # ... do something with args.verbose ..

```

## 15.7 logging — Logging facility for Python

### Important

This page contains the API reference information. For tutorial information and discussion of more advanced topics, see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

**Source code :** `Lib/logging/__init__.py`

Nouveau dans la version 2.3.

This module defines functions and classes which implement a flexible event logging system for applications and libraries.

The key benefit of having the logging API provided by a standard library module is that all Python modules can participate in logging, so your application log can include your own messages integrated with messages from third-party modules.

The module provides a lot of functionality and flexibility. If you are unfamiliar with logging, the best way to get to grips with it is to see the tutorials (see the links on the right).

The basic classes defined by the module, together with their functions, are listed below.

- Loggers expose the interface that application code directly uses.
- Handlers send the log records (created by loggers) to the appropriate destination.
- Filters provide a finer grained facility for determining which log records to output.
- Formatters specify the layout of log records in the final output.

### 15.7.1 Logger Objects

Loggers have the following attributes and methods. Note that Loggers are never instantiated directly, but always through the module-level function `logging.getLogger(name)`. Multiple calls to `getLogger()` with the same name will always return a reference to the same Logger object.

The `name` is potentially a period-separated hierarchical value, like `foo.bar.baz` (though it could also be just plain `foo`, for example). Loggers that are further down in the hierarchical list are children of loggers higher up in the list. For example, given a logger with a name of `foo`, loggers with names of `foo.bar`, `foo.bar.baz`, and `foo.bam` are all descendants of `foo`. The logger name hierarchy is analogous to the Python package hierarchy, and identical to it if you organise your loggers on a per-module basis using the recommended construction `logging.getLogger(__name__)`. That's because in a module, `__name__` is the module's name in the Python package namespace.

**class** `logging.Logger`

**Logger.propagate**

If this evaluates to true, events logged to this logger will be passed to the handlers of higher level (ancestor) loggers, in addition to any handlers attached to this logger. Messages are passed directly to the ancestor loggers' handlers - neither the level nor filters of the ancestor loggers in question are considered.

If this evaluates to false, logging messages are not passed to the handlers of ancestor loggers.

The constructor sets this attribute to **True**.

---

**Note :** If you attach a handler to a logger *and* one or more of its ancestors, it may emit the same record multiple times. In general, you should not need to attach a handler to more than one logger - if you just attach it to the appropriate logger which is highest in the logger hierarchy, then it will see all events logged by all descendant loggers, provided that their propagate setting is left set to **True**. A common scenario is to attach handlers only to the root logger, and to let propagation take care of the rest.

---

**Logger.setLevel(level)**

Sets the threshold for this logger to *level*. Logging messages which are less severe than *level* will be ignored. When a logger is created, the level is set to **NOTSET** (which causes all messages to be processed when the logger is the root logger, or delegation to the parent when the logger is a non-root logger). Note that the root logger is created with level **WARNING**.

The term "delegation to the parent" means that if a logger has a level of **NOTSET**, its chain of ancestor loggers is traversed until either an ancestor with a level other than **NOTSET** is found, or the root is reached.

If an ancestor is found with a level other than **NOTSET**, then that ancestor's level is treated as the effective level of the logger where the ancestor search began, and is used to determine how a logging event is handled.

If the root is reached, and it has a level of **NOTSET**, then all messages will be processed. Otherwise, the root's level will be used as the effective level.

See *Logging Levels* for a list of levels.

**Logger.isEnabledFor(lvl)**

Indicates if a message of severity *lvl* would be processed by this logger. This method checks first the module-level level set by `logging.disable(lvl)` and then the logger's effective level as determined by `getEffectiveLevel()`.

**Logger.getEffectiveLevel()**

Indicates the effective level for this logger. If a value other than **NOTSET** has been set using `setLevel()`, it is returned. Otherwise, the hierarchy is traversed towards the root until a value other than **NOTSET** is found, and that value is returned. The value returned is an integer, typically one of `logging.DEBUG`, `logging.INFO` etc.

`Logger.getChild(suffix)`

Returns a logger which is a descendant to this logger, as determined by the suffix. Thus, `logging.getLogger('abc').getChild('def.ghi')` would return the same logger as would be returned by `logging.getLogger('abc.def.ghi')`. This is a convenience method, useful when the parent logger is named using e.g. `__name__` rather than a literal string.

Nouveau dans la version 2.7.

`Logger.debug(msg, *args, **kwargs)`

Logs a message with level `DEBUG` on this logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are two keyword arguments in *kwargs* which are inspected : `exc_info` which, if it does not evaluate as false, causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) is provided, it is used ; otherwise, `sys.exc_info()` is called to get the exception information.

The second keyword argument is *extra* which can be used to pass a dictionary which is used to populate the `__dict__` of the `LogRecord` created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example :

```
FORMAT = '%(asctime)-15s %(clientip)s %(user)-8s %(message)s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logger = logging.getLogger('tcpserver')
logger.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs Protocol problem: connection reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the *Formatter* documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the *Formatter* has been set up with a format string which expects “clientip” and “user” in the attribute dictionary of the `LogRecord`. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized *Formatters* would be used with particular *Handlers*.

`Logger.info(msg, *args, **kwargs)`

Logs a message with level `INFO` on this logger. The arguments are interpreted as for `debug()`.

`Logger.warning(msg, *args, **kwargs)`

Logs a message with level `WARNING` on this logger. The arguments are interpreted as for `debug()`.

`Logger.error(msg, *args, **kwargs)`

Logs a message with level `ERROR` on this logger. The arguments are interpreted as for `debug()`.

`Logger.critical(msg, *args, **kwargs)`

Logs a message with level `CRITICAL` on this logger. The arguments are interpreted as for `debug()`.

`Logger.log(lvl, msg, *args, **kwargs)`

Logs a message with integer level *lvl* on this logger. The other arguments are interpreted as for `debug()`.

`Logger.exception(msg, *args, **kwargs)`

Logs a message with level **ERROR** on this logger. The arguments are interpreted as for `debug()`, except that any passed `exc_info` is not inspected. Exception info is always added to the logging message. This method should only be called from an exception handler.

`Logger.addFilter(filter)`

Adds the specified filter *filter* to this logger.

`Logger.removeFilter(filter)`

Removes the specified filter *filter* from this logger.

`Logger.filter(record)`

Applies this logger's filters to the record and returns a true value if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be processed (passed to handlers). If one returns a false value, no further processing of the record occurs.

`Logger.addHandler(hdlr)`

Adds the specified handler *hdlr* to this logger.

`Logger.removeHandler(hdlr)`

Removes the specified handler *hdlr* from this logger.

`Logger.findCaller()`

Finds the caller's source filename and line number. Returns the filename, line number and function name as a 3-element tuple.

Modifié dans la version 2.4 : The function name was added. In earlier versions, the filename and line number were returned as a 2-element tuple.

`Logger.handle(record)`

Handles a record by passing it to all handlers associated with this logger and its ancestors (until a false value of *propagate* is found). This method is used for unpickled records received from a socket, as well as those created locally. Logger-level filtering is applied using `filter()`.

`Logger.makeRecord(name, lvl, fn, lno, msg, args, exc_info, func=None, extra=None)`

This is a factory method which can be overridden in subclasses to create specialized *LogRecord* instances.

Modifié dans la version 2.5 : *func* and *extra* were added.

## 15.7.2 Logging Levels

The numeric values of logging levels are given in the following table. These are primarily of interest if you want to define your own levels, and need them to have specific values relative to the predefined levels. If you define a level with the same numeric value, it overwrites the predefined value ; the predefined name is lost.

Level	Numeric value
CRITICAL	50
ERROR	40
WARNING	30
INFO	20
DEBUG	10
NOTSET	0

## 15.7.3 Handler Objects

Handlers have the following attributes and methods. Note that **Handler** is never instantiated directly ; this class acts as a base for more useful subclasses. However, the `__init__()` method in subclasses needs to call

*Handler.\_\_init\_\_()*.

**Handler.\_\_init\_\_(level=NOTSET)**

Initializes the **Handler** instance by setting its level, setting the list of filters to the empty list and creating a lock (using *createLock()*) for serializing access to an I/O mechanism.

**Handler.createLock()**

Initializes a thread lock which can be used to serialize access to underlying I/O functionality which may not be threadsafe.

**Handler.acquire()**

Acquires the thread lock created with *createLock()*.

**Handler.release()**

Releases the thread lock acquired with *acquire()*.

**Handler.setLevel(level)**

Sets the threshold for this handler to *level*. Logging messages which are less severe than *level* will be ignored. When a handler is created, the level is set to NOTSET (which causes all messages to be processed).

See *Logging Levels* for a list of levels.

**Handler.setFormatter(fmt)**

Sets the *Formatter* for this handler to *fmt*.

**Handler.addFilter(filter)**

Adds the specified filter *filter* to this handler.

**Handler.removeFilter(filter)**

Removes the specified filter *filter* from this handler.

**Handler.filter(record)**

Applies this handler's filters to the record and returns a true value if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be emitted. If one returns a false value, the handler will not emit the record.

**Handler.flush()**

Ensure all logging output has been flushed. This version does nothing and is intended to be implemented by subclasses.

**Handler.close()**

Tidy up any resources used by the handler. This version does no output but removes the handler from an internal list of handlers which is closed when *shutdown()* is called. Subclasses should ensure that this gets called from overridden *close()* methods.

**Handler.handle(record)**

Conditionally emits the specified logging record, depending on filters which may have been added to the handler. Wraps the actual emission of the record with acquisition/release of the I/O thread lock.

**Handler.handleError(record)**

This method should be called from handlers when an exception is encountered during an *emit()* call. If the module-level attribute **raiseExceptions** is **False**, exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors. You could, however, replace this with a custom handler if you wish. The specified record is the one which was being processed when the exception occurred. (The default value of **raiseExceptions** is **True**, as that is more useful during development).

**Handler.format(record)**

Do formatting for a record - if a formatter is set, use it. Otherwise, use the default formatter for the module.

`Handler.emit(record)`

Do whatever it takes to actually log the specified logging record. This version is intended to be implemented by subclasses and so raises a *NotImplementedError*.

For a list of handlers included as standard, see *logging.handlers*.

### 15.7.4 Formatter Objects

*Formatter* objects have the following attributes and methods. They are responsible for converting a *LogRecord* to (usually) a string which can be interpreted by either a human or an external system. The base *Formatter* allows a formatting string to be specified. If none is supplied, the default value of `'%(message)s'` is used, which just includes the message in the logging call. To have additional items of information in the formatted output (such as a timestamp), keep reading.

A *Formatter* can be initialized with a format string which makes use of knowledge of the *LogRecord* attributes - such as the default value mentioned above making use of the fact that the user's message and arguments are pre-formatted into a *LogRecord*'s *message* attribute. This format string contains standard Python %-style mapping keys. See section *String Formatting Operations* for more information on string formatting.

The useful mapping keys in a *LogRecord* are given in the section on *LogRecord attributes*.

**class** `logging.Formatter`(*fmt=None*, *datefmt=None*)

Returns a new instance of the *Formatter* class. The instance is initialized with a format string for the message as a whole, as well as a format string for the date/time portion of a message. If no *fmt* is specified, `'%(message)s'` is used. If no *datefmt* is specified, the ISO8601 date format is used.

**format**(*record*)

The record's attribute dictionary is used as the operand to a string formatting operation. Returns the resulting string. Before formatting the dictionary, a couple of preparatory steps are carried out. The *message* attribute of the record is computed using *msg % args*. If the formatting string contains `'(asctime)'`, *formatTime()* is called to format the event time. If there is exception information, it is formatted using *formatException()* and appended to the message. Note that the formatted exception information is cached in attribute *exc\_text*. This is useful because the exception information can be pickled and sent across the wire, but you should be careful if you have more than one *Formatter* subclass which customizes the formatting of exception information. In this case, you will have to clear the cached value after a formatter has done its formatting, so that the next formatter to handle the event doesn't use the cached value but recalculates it afresh.

**formatTime**(*record*, *datefmt=None*)

This method should be called from *format()* by a formatter which wants to make use of a formatted time. This method can be overridden in formatters to provide for any specific requirement, but the basic behavior is as follows : if *datefmt* (a string) is specified, it is used with *time.strftime()* to format the creation time of the record. Otherwise, the ISO8601 format is used. The resulting string is returned.

This function uses a user-configurable function to convert the creation time to a tuple. By default, *time.localtime()* is used ; to change this for a particular formatter instance, set the *converter* attribute to a function with the same signature as *time.localtime()* or *time.gmtime()*. To change it for all formatters, for example if you want all logging times to be shown in GMT, set the *converter* attribute in the *Formatter* class.

**formatException**(*exc\_info*)

Formats the specified exception information (a standard exception tuple as returned by *sys.exc\_info()*) as a string. This default implementation just uses *traceback.print\_exception()*. The resulting string is returned.

### 15.7.5 Filter Objects

*Filters* can be used by *Handlers* and *Loggers* for more sophisticated filtering than is provided by levels. The base filter class only allows events which are below a certain point in the logger hierarchy. For example,

a filter initialized with “A.B” will allow events logged by loggers “A.B”, “A.B.C”, “A.B.C.D”, “A.B.D” etc. but not “A.BB”, “B.A.B” etc. If initialized with the empty string, all events are passed.

```
class logging.Filter(name="")
```

Returns an instance of the `Filter` class. If *name* is specified, it names a logger which, together with its children, will have its events allowed through the filter. If *name* is the empty string, allows every event.

```
filter(record)
```

Is the specified record to be logged? Returns zero for no, nonzero for yes. If deemed appropriate, the record may be modified in-place by this method.

Note that filters attached to handlers are consulted before an event is emitted by the handler, whereas filters attached to loggers are consulted whenever an event is logged (using `debug()`, `info()`, etc.), before sending an event to handlers. This means that events which have been generated by descendant loggers will not be filtered by a logger’s filter setting, unless the filter has also been applied to those descendant loggers.

You don’t actually need to subclass `Filter` : you can pass any instance which has a `filter` method with the same semantics.

Although filters are used primarily to filter records based on more sophisticated criteria than levels, they get to see every record which is processed by the handler or logger they’re attached to : this can be useful if you want to do things like counting how many records were processed by a particular logger or handler, or adding, changing or removing attributes in the `LogRecord` being processed. Obviously changing the `LogRecord` needs to be done with some care, but it does allow the injection of contextual information into logs (see `filters-contextual`).

### 15.7.6 LogRecord Objects

`LogRecord` instances are created automatically by the `Logger` every time something is logged, and can be created manually via `makeLogRecord()` (for example, from a pickled event received over the wire).

```
class logging.LogRecord(name, level, pathname, lineno, msg, args, exc_info, func=None)
```

Contains all the information pertinent to the event being logged.

The primary information is passed in *msg* and *args*, which are combined using `msg % args` to create the `message` field of the record.

#### Paramètres

- **name** – The name of the logger used to log the event represented by this `LogRecord`. Note that this name will always have this value, even though it may be emitted by a handler attached to a different (ancestor) logger.
- **level** – The numeric level of the logging event (one of `DEBUG`, `INFO` etc.) Note that this is converted to *two* attributes of the `LogRecord` : `levelname` for the numeric value and `levelname` for the corresponding level name.
- **pathname** – The full pathname of the source file where the logging call was made.
- **lineno** – The line number in the source file where the logging call was made.
- **msg** – The event description message, possibly a format string with placeholders for variable data.
- **args** – Variable data to merge into the *msg* argument to obtain the event description.
- **exc\_info** – An exception tuple with the current exception information, or `None` if no exception information is available.
- **func** – The name of the function or method from which the logging call was invoked.

Modifié dans la version 2.5 : *func* was added.

```
getMessage()
```

Returns the message for this `LogRecord` instance after merging any user-supplied arguments with the message. If the user-supplied message argument to the logging call is not a string, `str()` is called on it to convert it to a string. This allows use of user-defined classes as messages, whose `__str__` method can return the actual format string to be used.

### 15.7.7 LogRecord attributes

The `LogRecord` has a number of attributes, most of which are derived from the parameters to the constructor. (Note that the names do not always correspond exactly between the `LogRecord` constructor parameters and the `LogRecord` attributes.) These attributes can be used to merge data from the record into the format string. The following table lists (in alphabetical order) the attribute names, their meanings and the corresponding placeholder in a %-style format string.

Attribute name	Format	Description
<code>args</code>	You shouldn't need to format this yourself.	The tuple of arguments merged into <code>msg</code> to produce <code>message</code> , or a dict whose values are used for the merge (when there is only one argument, and it is a dictionary).
<code>asctime</code>	<code>%(asctime)s</code>	Human-readable time when the <i>LogRecord</i> was created. By default this is of the form "2003-07-08 16 :49 :45,896" (the numbers after the comma are millisecond portion of the time).
<code>created</code>	<code>%(created)f</code>	Time when the <i>LogRecord</i> was created (as returned by <code>time.time()</code> ).
<code>exc_info</code>	You shouldn't need to format this yourself.	Exception tuple (à la <code>sys.exc_info</code> ) or, if no exception has occurred, <code>None</code> .
<code>filename</code>	<code>%(filename)s</code>	Filename portion of <code>pathname</code> .
<code>funcName</code>	<code>%(funcName)s</code>	Name of function containing the logging call.
<code>levelname</code>	<code>%(levelname)s</code>	Text logging level for the message ('DEBUG', 'INFO', 'WARNING', 'ERROR', 'CRITICAL').
<code>levelno</code>	<code>%(levelno)s</code>	Numeric logging level for the message (DEBUG, INFO, WARNING, ERROR, CRITICAL).
<code>lineno</code>	<code>%(lineno)d</code>	Source line number where the logging call was issued (if available).
<code>module</code>	<code>%(module)s</code>	Module (name portion of <code>filename</code> ).
<code>msecs</code>	<code>%(msecs)d</code>	Millisecond portion of the time when the <i>LogRecord</i> was created.
<code>message</code>	<code>%(message)s</code>	The logged message, computed as <code>msg % args</code> . This is set when <i>Formatter.format()</i> is invoked.
<code>msg</code>	You shouldn't need to format this yourself.	The format string passed in the original logging call. Merged with <code>args</code> to produce <code>message</code> , or an arbitrary object (see arbitrary-object-messages).
<code>name</code>	<code>%(name)s</code>	Name of the logger used to log the call.
<code>pathname</code>	<code>%(pathname)s</code>	Full pathname of the source file where the logging call was issued (if available).
<code>process</code>	<code>%(process)d</code>	Process ID (if available).
<code>processName</code>	<code>%(processName)s</code>	Process name (if available).
<code>relativeCreated</code>	<code>%(relativeCreated)d</code>	Time in milliseconds when the <i>LogRecord</i> was created, relative to the time the logging module was loaded.
<code>thread</code>	<code>%(thread)d</code>	Thread ID (if available).
<code>threadName</code>	<code>%(threadName)s</code>	Thread name (if available).

Modifié dans la version 2.5 : *funcName* was added.

Modifié dans la version 2.6 : *processName* was added.

### 15.7.8 LoggerAdapter Objects

*LoggerAdapter* instances are used to conveniently pass contextual information into logging calls. For a usage example, see the section on adding contextual information to your logging output.

Nouveau dans la version 2.6.

**class** `logging.LoggerAdapter(logger, extra)`

Returns an instance of *LoggerAdapter* initialized with an underlying *Logger* instance and a dict-like object.

**process**(*msg, kwargs*)

Modifies the message and/or keyword arguments passed to a logging call in order to insert contextual information. This implementation takes the object passed as *extra* to the constructor and adds it to *kwargs* using key “extra”. The return value is a (*msg, kwargs*) tuple which has the (possibly modified) versions of the arguments passed in.

In addition to the above, *LoggerAdapter* supports the following methods of *Logger* : *debug()*, *info()*, *warning()*, *error()*, *exception()*, *critical()*, *log()* and *isEnabledFor()*. These methods have the same signatures as their counterparts in *Logger*, so you can use the two types of instances interchangeably for these calls.

Modifié dans la version 2.7 : The *isEnabledFor()* method was added to *LoggerAdapter*. This method delegates to the underlying logger.

### 15.7.9 Thread Safety

The logging module is intended to be thread-safe without any special work needing to be done by its clients. It achieves this though using threading locks; there is one lock to serialize access to the module’s shared data, and each handler also creates a lock to serialize access to its underlying I/O.

If you are implementing asynchronous signal handlers using the *signal* module, you may not be able to use logging from within such handlers. This is because lock implementations in the *threading* module are not always re-entrant, and so cannot be invoked from such signal handlers.

### 15.7.10 Fonctions de niveau module

In addition to the classes described above, there are a number of module- level functions.

**logging.getLogger**(*[name]*)

Return a logger with the specified name or, if no name is specified, return a logger which is the root logger of the hierarchy. If specified, the name is typically a dot-separated hierarchical name like « *a* », « *a.b* » or « *a.b.c.d* ». Choice of these names is entirely up to the developer who is using logging.

All calls to this function with a given name return the same logger instance. This means that logger instances never need to be passed between different parts of an application.

**logging.getLoggerClass**()

Return either the standard *Logger* class, or the last class passed to *setLoggerClass()*. This function may be called from within a new class definition, to ensure that installing a customized *Logger* class will not undo customizations already applied by other code. For example :

```
class MyLogger(logging.getLoggerClass()):
    # ... override behaviour here
```

```
logging.debug(msg[, *args[, **kwargs]])
```

Logs a message with level **DEBUG** on the root logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are two keyword arguments in *kwargs* which are inspected : *exc\_info* which, if it does not evaluate as false, causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) is provided, it is used ; otherwise, `sys.exc_info()` is called to get the exception information.

The other optional keyword argument is *extra* which can be used to pass a dictionary which is used to populate the `__dict__` of the LogRecord created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example :

```
FORMAT = "%(asctime)-15s %(clientip)s %(user)-8s %(message)s"
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logging.warning("Protocol problem: %s", "connection reset", extra=d)
```

would print something like :

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs Protocol problem: connection reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the *Formatter* documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the *Formatter* has been set up with a format string which expects “clientip” and “user” in the attribute dictionary of the LogRecord. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized *Formatters* would be used with particular *Handlers*.

Modifié dans la version 2.5 : *extra* was added.

```
logging.info(msg[, *args[, **kwargs]])
```

Logs a message with level **INFO** on the root logger. The arguments are interpreted as for `debug()`.

```
logging.warning(msg[, *args[, **kwargs]])
```

Logs a message with level **WARNING** on the root logger. The arguments are interpreted as for `debug()`.

```
logging.error(msg[, *args[, **kwargs]])
```

Logs a message with level **ERROR** on the root logger. The arguments are interpreted as for `debug()`.

```
logging.critical(msg[, *args[, **kwargs]])
```

Logs a message with level **CRITICAL** on the root logger. The arguments are interpreted as for `debug()`.

```
logging.exception(msg[, *args[, **kwargs]])
```

Logs a message with level **ERROR** on the root logger. The arguments are interpreted as for `debug()`, except that any passed *exc\_info* is not inspected. Exception info is always added to the logging message. This function should only be called from an exception handler.

```
logging.log(level, msg[, *args[, **kwargs]])
```

Logs a message with level *level* on the root logger. The other arguments are interpreted as for `debug()`.

---

**Note :** The above module-level convenience functions, which delegate to the root logger, call `basicConfig()` to ensure that at least one handler is available. Because of this, they should *not* be used in threads, in versions of Python earlier than 2.7.1 and 3.2, unless at least one handler has been added to the root logger *before* the threads are started. In earlier versions of Python, due to a thread safety shortcoming in `basicConfig()`, this can (under rare circumstances) lead to handlers being added multiple times to the root logger, which can in turn lead to multiple messages for the same event.

---

#### `logging.disable(lvl)`

Provides an overriding level *lvl* for all loggers which takes precedence over the logger's own level. When the need arises to temporarily throttle logging output down across the whole application, this function can be useful. Its effect is to disable all logging calls of severity *lvl* and below, so that if you call it with a value of INFO, then all INFO and DEBUG events would be discarded, whereas those of severity WARNING and above would be processed according to the logger's effective level. If `logging.disable(logging.NOTSET)` is called, it effectively removes this overriding level, so that logging output again depends on the effective levels of individual loggers.

#### `logging.addLevelName(lvl, levelName)`

Associates level *lvl* with text *levelName* in an internal dictionary, which is used to map numeric levels to a textual representation, for example when a `Formatter` formats a message. This function can also be used to define your own levels. The only constraints are that all levels used must be registered using this function, levels should be positive integers and they should increase in increasing order of severity.

---

**Note :** If you are thinking of defining your own levels, please see the section on custom-levels.

---

#### `logging.getLevelName(lvl)`

Returns the textual representation of logging level *lvl*. If the level is one of the predefined levels CRITICAL, ERROR, WARNING, INFO or DEBUG then you get the corresponding string. If you have associated levels with names using `addLevelName()` then the name you have associated with *lvl* is returned. If a numeric value corresponding to one of the defined levels is passed in, the corresponding string representation is returned. Otherwise, the string « Level %s » % lvl is returned.

---

**Note :** Integer levels should be used when e.g. setting levels on instances of `Logger` and handlers. This function is used to convert between an integer level and the level name displayed in the formatted log output by means of the `%(levelname)s` format specifier (see `LogRecord attributes`).

---

#### `logging.makeLogRecord(attrdict)`

Creates and returns a new `LogRecord` instance whose attributes are defined by *attrdict*. This function is useful for taking a pickled `LogRecord` attribute dictionary, sent over a socket, and reconstituting it as a `LogRecord` instance at the receiving end.

#### `logging.basicConfig(**kwargs)`

Does basic configuration for the logging system by creating a `StreamHandler` with a default `Formatter` and adding it to the root logger. The functions `debug()`, `info()`, `warning()`, `error()` and `critical()` will call `basicConfig()` automatically if no handlers are defined for the root logger.

This function does nothing if the root logger already has handlers configured for it.

Modifié dans la version 2.4 : Formerly, `basicConfig()` did not take any keyword arguments.

---

**Note :** This function should be called from the main thread before other threads are started. In versions of Python prior to 2.7.1 and 3.2, if this function is called from multiple threads, it is possible (in rare circumstances) that a handler will be added to the root logger more than once, leading to

unexpected results such as messages being duplicated in the log.

The following keyword arguments are supported.

Format	Description
<i>filename</i>	Specifies that a <code>FileHandler</code> be created, using the specified filename, rather than a <code>StreamHandler</code> .
<i>filemode</i>	If <i>filename</i> is specified, open the file in this mode. Defaults to 'a'.
<i>format</i>	Use the specified format string for the handler.
<i>datefmt</i>	Use the specified date/time format, as accepted by <code>time.strftime()</code> .
<i>level</i>	Set the root logger level to the specified <i>level</i> .
<i>stream</i>	Use the specified stream to initialize the <code>StreamHandler</code> . Note that this argument is incompatible with <i>filename</i> - if both are present, <i>stream</i> is ignored.

#### `logging.shutdown()`

Informs the logging system to perform an orderly shutdown by flushing and closing all handlers. This should be called at application exit and no further use of the logging system should be made after this call.

#### `logging.setLoggerClass(klass)`

Tells the logging system to use the class *klass* when instantiating a logger. The class should define `__init__()` such that only a name argument is required, and the `__init__()` should call `Logger.__init__()`. This function is typically called before any loggers are instantiated by applications which need to use custom logger behavior.

### 15.7.11 Integration with the warnings module

The `captureWarnings()` function can be used to integrate `logging` with the `warnings` module.

#### `logging.captureWarnings(capture)`

This function is used to turn the capture of warnings by logging on and off.

If *capture* is `True`, warnings issued by the `warnings` module will be redirected to the logging system. Specifically, a warning will be formatted using `warnings.formatwarning()` and the resulting string logged to a logger named 'py.warnings' with a severity of `WARNING`.

If *capture* is `False`, the redirection of warnings to the logging system will stop, and warnings will be redirected to their original destinations (i.e. those in effect before `captureWarnings(True)` was called).

**Original Python logging package** This is the original source for the `logging` package. The version of the package available from this site is suitable for use with Python 1.5.2, 2.1.x and 2.2.x, which do not include the `logging` package in the standard library.

## 15.8 logging.config — Logging configuration

### Important

This page contains only reference information. For tutorials, please see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

Source code : [Lib/logging/config.py](#)

This section describes the API for configuring the logging module.

### 15.8.1 Configuration functions

The following functions configure the logging module. They are located in the `logging.config` module. Their use is optional — you can configure the logging module using these functions or by making calls to the main API (defined in `logging` itself) and defining handlers which are declared either in `logging` or `logging.handlers`.

`logging.config.dictConfig(config)`

Takes the logging configuration from a dictionary. The contents of this dictionary are described in *Configuration dictionary schema* below.

If an error is encountered during configuration, this function will raise a `ValueError`, `TypeError`, `AttributeError` or `ImportError` with a suitably descriptive message. The following is a (possibly incomplete) list of conditions which will raise an error :

- A `level` which is not a string or which is a string not corresponding to an actual logging level.
- A `propagate` value which is not a boolean.
- An id which does not have a corresponding destination.
- A non-existent handler id found during an incremental call.
- An invalid logger name.
- Inability to resolve to an internal or external object.

Parsing is performed by the `DictConfigurator` class, whose constructor is passed the dictionary used for configuration, and has a `configure()` method. The `logging.config` module has a callable attribute `dictConfigClass` which is initially set to `DictConfigurator`. You can replace the value of `dictConfigClass` with a suitable implementation of your own.

`dictConfig()` calls `dictConfigClass` passing the specified dictionary, and then calls the `configure()` method on the returned object to put the configuration into effect :

```
def dictConfig(config):
    dictConfigClass(config).configure()
```

For example, a subclass of `DictConfigurator` could call `DictConfigurator.__init__()` in its own `__init__()`, then set up custom prefixes which would be usable in the subsequent `configure()` call. `dictConfigClass` would be bound to this new subclass, and then `dictConfig()` could be called exactly as in the default, uncustomized state.

Nouveau dans la version 2.7.

`logging.config.fileConfig(fname, defaults=None, disable_existing_loggers=True)`

Reads the logging configuration from a `configparser`-format file named `fname`. The format of the file should be as described in *Configuration file format*. This function can be called several times from an application, allowing an end user to select from various pre-canned configurations (if the developer provides a mechanism to present the choices and load the chosen configuration).

#### Paramètres

- **defaults** – Defaults to be passed to the `ConfigParser` can be specified in this argument.

- **disable\_existing\_loggers** – If specified as `False`, loggers which exist when this call is made are left enabled. The default is `True` because this enables old behaviour in a backward-compatible way. This behaviour is to disable any existing loggers unless they or their ancestors are explicitly named in the logging configuration.

Modifié dans la version 2.6 : The `disable_existing_loggers` keyword argument was added. Previously, existing loggers were *always* disabled.

`logging.config.listen(port=DEFAULT_LOGGING_CONFIG_PORT)`

Starts up a socket server on the specified port, and listens for new configurations. If no port is specified, the module's default `DEFAULT_LOGGING_CONFIG_PORT` is used. Logging configurations will be sent as a file suitable for processing by `fileConfig()`. Returns a `Thread` instance on which you can call `start()` to start the server, and which you can `join()` when appropriate. To stop the server, call `stopListening()`.

To send a configuration to the socket, read in the configuration file and send it to the socket as a string of bytes preceded by a four-byte length string packed in binary using `struct.pack('>L', n)`.

---

**Note :** Because portions of the configuration are passed through `eval()`, use of this function may open its users to a security risk. While the function only binds to a socket on `localhost`, and so does not accept connections from remote machines, there are scenarios where untrusted code could be run under the account of the process which calls `listen()`. Specifically, if the process calling `listen()` runs on a multi-user machine where users cannot trust each other, then a malicious user could arrange to run essentially arbitrary code in a victim user's process, simply by connecting to the victim's `listen()` socket and sending a configuration which runs whatever code the attacker wants to have executed in the victim's process. This is especially easy to do if the default port is used, but not hard even if a different port is used).

---

`logging.config.stopListening()`

Stops the listening server which was created with a call to `listen()`. This is typically called before calling `join()` on the return value from `listen()`.

## 15.8.2 Configuration dictionary schema

Describing a logging configuration requires listing the various objects to create and the connections between them; for example, you may create a handler named “console” and then say that the logger named “startup” will send its messages to the “console” handler. These objects aren't limited to those provided by the `logging` module because you might write your own formatter or handler class. The parameters to these classes may also need to include external objects such as `sys.stderr`. The syntax for describing these objects and connections is defined in *Object connections* below.

### Dictionary Schema Details

The dictionary passed to `dictConfig()` must contain the following keys :

- *version* - to be set to an integer value representing the schema version. The only valid value at present is 1, but having this key allows the schema to evolve while still preserving backwards compatibility. All other keys are optional, but if present they will be interpreted as described below. In all cases below where a “configuring dict” is mentioned, it will be checked for the special '()' key to see if a custom instantiation is required. If so, the mechanism described in *User-defined objects* below is used to create an instance; otherwise, the context is used to determine what to instantiate.
- *formatters* - the corresponding value will be a dict in which each key is a formatter id and each value is a dict describing how to configure the corresponding `Formatter` instance. The configuring dict is searched for keys `format` and `datefmt` (with defaults of `None`) and these are used to construct a `Formatter` instance.
- *filters* - the corresponding value will be a dict in which each key is a filter id and each value is a dict describing how to configure the corresponding `Filter` instance.

The configuring dict is searched for the key `name` (defaulting to the empty string) and this is used to construct a `logging.Filter` instance.

- `handlers` - the corresponding value will be a dict in which each key is a handler id and each value is a dict describing how to configure the corresponding Handler instance.

The configuring dict is searched for the following keys :

- `class` (mandatory). This is the fully qualified name of the handler class.
- `level` (optional). The level of the handler.
- `formatter` (optional). The id of the formatter for this handler.
- `filters` (optional). A list of ids of the filters for this handler.

All *other* keys are passed through as keyword arguments to the handler's constructor. For example, given the snippet :

```
handlers:
  console:
    class : logging.StreamHandler
    formatter: brief
    level  : INFO
    filters: [allow_foo]
    stream : ext://sys.stdout
  file:
    class : logging.handlers.RotatingFileHandler
    formatter: precise
    filename: logconfig.log
    maxBytes: 1024
    backupCount: 3
```

the handler with id `console` is instantiated as a `logging.StreamHandler`, using `sys.stdout` as the underlying stream. The handler with id `file` is instantiated as a `logging.handlers.RotatingFileHandler` with the keyword arguments `filename='logconfig.log'`, `maxBytes=1024`, `backupCount=3`.

- `loggers` - the corresponding value will be a dict in which each key is a logger name and each value is a dict describing how to configure the corresponding Logger instance.

The configuring dict is searched for the following keys :

- `level` (optional). The level of the logger.
- `propagate` (optional). The propagation setting of the logger.
- `filters` (optional). A list of ids of the filters for this logger.
- `handlers` (optional). A list of ids of the handlers for this logger.

The specified loggers will be configured according to the level, propagation, filters and handlers specified.

- `root` - this will be the configuration for the root logger. Processing of the configuration will be as for any logger, except that the `propagate` setting will not be applicable.
- `incremental` - whether the configuration is to be interpreted as incremental to the existing configuration. This value defaults to `False`, which means that the specified configuration replaces the existing configuration with the same semantics as used by the existing `fileConfig()` API.

If the specified value is `True`, the configuration is processed as described in the section on *Incremental Configuration*.

- `disable_existing_loggers` - whether any existing loggers are to be disabled. This setting mirrors the parameter of the same name in `fileConfig()`. If absent, this parameter defaults to `True`. This value is ignored if `incremental` is `True`.

## Incremental Configuration

It is difficult to provide complete flexibility for incremental configuration. For example, because objects such as filters and formatters are anonymous, once a configuration is set up, it is not possible to refer to such anonymous objects when augmenting a configuration.

Furthermore, there is not a compelling case for arbitrarily altering the object graph of loggers, handlers, filters, formatters at run-time, once a configuration is set up; the verbosity of loggers and handlers can be controlled just by setting levels (and, in the case of loggers, propagation flags). Changing the object graph arbitrarily in a safe way is problematic in a multi-threaded environment; while not impossible, the benefits are not worth the complexity it adds to the implementation.

Thus, when the `incremental` key of a configuration dict is present and is `True`, the system will completely ignore any `formatters` and `filters` entries, and process only the `level` settings in the `handlers` entries, and the `level` and `propagate` settings in the `loggers` and `root` entries.

Using a value in the configuration dict lets configurations to be sent over the wire as pickled dicts to a socket listener. Thus, the logging verbosity of a long-running application can be altered over time with no need to stop and restart the application.

### Object connections

The schema describes a set of logging objects - loggers, handlers, formatters, filters - which are connected to each other in an object graph. Thus, the schema needs to represent connections between the objects. For example, say that, once configured, a particular logger has attached to it a particular handler. For the purposes of this discussion, we can say that the logger represents the source, and the handler the destination, of a connection between the two. Of course in the configured objects this is represented by the logger holding a reference to the handler. In the configuration dict, this is done by giving each destination object an id which identifies it unambiguously, and then using the id in the source object's configuration to indicate that a connection exists between the source and the destination object with that id.

So, for example, consider the following YAML snippet :

```
formatters:
  brief:
    # configuration for formatter with id 'brief' goes here
  precise:
    # configuration for formatter with id 'precise' goes here
handlers:
  h1: #This is an id
    # configuration of handler with id 'h1' goes here
    formatter: brief
  h2: #This is another id
    # configuration of handler with id 'h2' goes here
    formatter: precise
loggers:
  foo.bar.baz:
    # other configuration for logger 'foo.bar.baz'
    handlers: [h1, h2]
```

(Note : YAML used here because it's a little more readable than the equivalent Python source form for the dictionary.)

The ids for loggers are the logger names which would be used programmatically to obtain a reference to those loggers, e.g. `foo.bar.baz`. The ids for Formatters and Filters can be any string value (such as `brief`, `precise` above) and they are transient, in that they are only meaningful for processing the configuration dictionary and used to determine connections between objects, and are not persisted anywhere when the configuration call is complete.

The above snippet indicates that logger named `foo.bar.baz` should have two handlers attached to it, which are described by the handler ids `h1` and `h2`. The formatter for `h1` is that described by id `brief`, and the formatter for `h2` is that described by id `precise`.

## User-defined objects

The schema supports user-defined objects for handlers, filters and formatters. (Loggers do not need to have different types for different instances, so there is no support in this configuration schema for user-defined logger classes.)

Objects to be configured are described by dictionaries which detail their configuration. In some places, the logging system will be able to infer from the context how an object is to be instantiated, but when a user-defined object is to be instantiated, the system will not know how to do this. In order to provide complete flexibility for user-defined object instantiation, the user needs to provide a “factory” - a callable which is called with a configuration dictionary and which returns the instantiated object. This is signalled by an absolute import path to the factory being made available under the special key '()''. Here’s a concrete example :

```
formatters:
  brief:
    format: '%(message)s'
  default:
    format: '%(asctime)s %(levelname)-8s %(name)-15s %(message)s'
    datefmt: '%Y-%m-%d %H:%M:%S'
  custom:
    (): my.package.customFormatterFactory
    bar: baz
    spam: 99.9
    answer: 42
```

The above YAML snippet defines three formatters. The first, with id `brief`, is a standard `logging.Formatter` instance with the specified format string. The second, with id `default`, has a longer format and also defines the time format explicitly, and will result in a `logging.Formatter` initialized with those two format strings. Shown in Python source form, the `brief` and `default` formatters have configuration sub-dictionaries :

```
{
  'format' : '%(message)s'
}
```

et :

```
{
  'format' : '%(asctime)s %(levelname)-8s %(name)-15s %(message)s',
  'datefmt' : '%Y-%m-%d %H:%M:%S'
}
```

respectively, and as these dictionaries do not contain the special key '()', the instantiation is inferred from the context : as a result, standard `logging.Formatter` instances are created. The configuration sub-dictionary for the third formatter, with id `custom`, is :

```
{
  '()' : 'my.package.customFormatterFactory',
  'bar' : 'baz',
  'spam' : 99.9,
  'answer' : 42
}
```

and this contains the special key '()', which means that user-defined instantiation is wanted. In this case, the specified factory callable will be used. If it is an actual callable it will be used directly - otherwise, if you

specify a string (as in the example) the actual callable will be located using normal import mechanisms. The callable will be called with the **remaining** items in the configuration sub-dictionary as keyword arguments. In the above example, the formatter with id `custom` will be assumed to be returned by the call :

```
my.package.customFormatterFactory(bar='baz', spam=99.9, answer=42)
```

The key '()' has been used as the special key because it is not a valid keyword parameter name, and so will not clash with the names of the keyword arguments used in the call. The '()' also serves as a mnemonic that the corresponding value is a callable.

### Access to external objects

There are times where a configuration needs to refer to objects external to the configuration, for example `sys.stderr`. If the configuration dict is constructed using Python code, this is straightforward, but a problem arises when the configuration is provided via a text file (e.g. JSON, YAML). In a text file, there is no standard way to distinguish `sys.stderr` from the literal string `'sys.stderr'`. To facilitate this distinction, the configuration system looks for certain special prefixes in string values and treat them specially. For example, if the literal string `'ext://sys.stderr'` is provided as a value in the configuration, then the `ext://` will be stripped off and the remainder of the value processed using normal import mechanisms.

The handling of such prefixes is done in a way analogous to protocol handling : there is a generic mechanism to look for prefixes which match the regular expression `^(?P<prefix>[a-z]+)://(?P<suffix>.*)$` whereby, if the `prefix` is recognised, the `suffix` is processed in a prefix-dependent manner and the result of the processing replaces the string value. If the prefix is not recognised, then the string value will be left as-is.

### Access to internal objects

As well as external objects, there is sometimes also a need to refer to objects in the configuration. This will be done implicitly by the configuration system for things that it knows about. For example, the string value `'DEBUG'` for a `level` in a logger or handler will automatically be converted to the value `logging.DEBUG`, and the `handlers`, `filters` and `formatter` entries will take an object id and resolve to the appropriate destination object.

However, a more generic mechanism is needed for user-defined objects which are not known to the `logging` module. For example, consider `logging.handlers.MemoryHandler`, which takes a `target` argument which is another handler to delegate to. Since the system already knows about this class, then in the configuration, the given `target` just needs to be the object id of the relevant target handler, and the system will resolve to the handler from the id. If, however, a user defines a `my.package.MyHandler` which has an `alternate` handler, the configuration system would not know that the `alternate` referred to a handler. To cater for this, a generic resolution system allows the user to specify :

```
handlers:
  file:
    # configuration of file handler goes here

  custom:
    (): my.package.MyHandler
    alternate: cfg://handlers.file
```

The literal string `'cfg://handlers.file'` will be resolved in an analogous way to strings with the `ext://` prefix, but looking in the configuration itself rather than the import namespace. The mechanism allows access by dot or by index, in a similar way to that provided by `str.format`. Thus, given the following snippet :

```
handlers:
  email:
```

(suite sur la page suivante)

(suite de la page précédente)

```
class: logging.handlers.SMTPHandler
mailhost: localhost
fromaddr: my_app@domain.tld
toaddrs:
    - support_team@domain.tld
    - dev_team@domain.tld
subject: Houston, we have a problem.
```

in the configuration, the string `'cfg://handlers'` would resolve to the dict with key `handlers`, the string `'cfg://handlers.email'` would resolve to the dict with key `email` in the `handlers` dict, and so on. The string `'cfg://handlers.email.toaddrs[1]'` would resolve to `'dev_team.domain.tld'` and the string `'cfg://handlers.email.toaddrs[0]'` would resolve to the value `'support_team@domain.tld'`. The `subject` value could be accessed using either `'cfg://handlers.email.subject'` or, equivalently, `'cfg://handlers.email[subject]'`. The latter form only needs to be used if the key contains spaces or non-alphanumeric characters. If an index value consists only of decimal digits, access will be attempted using the corresponding integer value, falling back to the string value if needed.

Given a string `cfg://handlers.myhandler.mykey.123`, this will resolve to `config_dict['handlers']['myhandler']['mykey']['123']`. If the string is specified as `cfg://handlers.myhandler.mykey[123]`, the system will attempt to retrieve the value from `config_dict['handlers']['myhandler']['mykey'][123]`, and fall back to `config_dict['handlers']['myhandler']['mykey']['123']` if that fails.

### Import resolution and custom importers

Import resolution, by default, uses the builtin `__import__()` function to do its importing. You may want to replace this with your own importing mechanism : if so, you can replace the `importer` attribute of the `DictConfigurator` or its superclass, the `BaseConfigurator` class. However, you need to be careful because of the way functions are accessed from classes via descriptors. If you are using a Python callable to do your imports, and you want to define it at class level rather than instance level, you need to wrap it with `staticmethod()`. For example :

```
from importlib import import_module
from logging.config import BaseConfigurator

BaseConfigurator.importer = staticmethod(import_module)
```

You don't need to wrap with `staticmethod()` if you're setting the import callable on a configurator *instance*.

### 15.8.3 Configuration file format

The configuration file format understood by `fileConfig()` is based on `configparser` functionality. The file must contain sections called `[loggers]`, `[handlers]` and `[formatters]` which identify by name the entities of each type which are defined in the file. For each such entity, there is a separate section which identifies how that entity is configured. Thus, for a logger named `log01` in the `[loggers]` section, the relevant configuration details are held in a section `[logger_log01]`. Similarly, a handler called `hand01` in the `[handlers]` section will have its configuration held in a section called `[handler_hand01]`, while a formatter called `form01` in the `[formatters]` section will have its configuration specified in a section called `[formatter_form01]`. The root logger configuration must be specified in a section called `[logger_root]`.

**Note :** The `fileConfig()` API is older than the `dictConfig()` API and does not provide functionality to cover certain aspects of logging. For example, you cannot configure `Filter` objects, which provide for filtering of messages beyond simple integer levels, using `fileConfig()`. If you need to have instances of

*Filter* in your logging configuration, you will need to use *dictConfig()*. Note that future enhancements to configuration functionality will be added to *dictConfig()*, so it's worth considering transitioning to this newer API when it's convenient to do so.

---

Examples of these sections in the file are given below.

```
[loggers]
keys=root,log02,log03,log04,log05,log06,log07

[handlers]
keys=hand01,hand02,hand03,hand04,hand05,hand06,hand07,hand08,hand09

[formatters]
keys=form01,form02,form03,form04,form05,form06,form07,form08,form09
```

The root logger must specify a level and a list of handlers. An example of a root logger section is given below.

```
[logger_root]
level=NOTSET
handlers=hand01
```

The `level` entry can be one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL` or `NOTSET`. For the root logger only, `NOTSET` means that all messages will be logged. Level values are *eval()*uated in the context of the `logging` package's namespace.

The `handlers` entry is a comma-separated list of handler names, which must appear in the `[handlers]` section. These names must appear in the `[handlers]` section and have corresponding sections in the configuration file.

For loggers other than the root logger, some additional information is required. This is illustrated by the following example.

```
[logger_parser]
level=DEBUG
handlers=hand01
propagate=1
qualname=compiler.parser
```

The `level` and `handlers` entries are interpreted as for the root logger, except that if a non-root logger's level is specified as `NOTSET`, the system consults loggers higher up the hierarchy to determine the effective level of the logger. The `propagate` entry is set to 1 to indicate that messages must propagate to handlers higher up the logger hierarchy from this logger, or 0 to indicate that messages are **not** propagated to handlers up the hierarchy. The `qualname` entry is the hierarchical channel name of the logger, that is to say the name used by the application to get the logger.

Sections which specify handler configuration are exemplified by the following.

```
[handler_hand01]
class=StreamHandler
level=NOTSET
formatter=form01
args=(sys.stdout,)
```

The `class` entry indicates the handler's class (as determined by *eval()* in the `logging` package's namespace). The `level` is interpreted as for loggers, and `NOTSET` is taken to mean "log everything".

Modifié dans la version 2.6 : Added support for resolving the handler's class as a dotted module and class name.

The **formatter** entry indicates the key name of the formatter for this handler. If blank, a default formatter (`logging.defaultFormatter`) is used. If a name is specified, it must appear in the **[formatters]** section and have a corresponding section in the configuration file.

The **args** entry, when *eval()*uated in the context of the `logging` package's namespace, is the list of arguments to the constructor for the handler class. Refer to the constructors for the relevant handlers, or to the examples below, to see how typical entries are constructed.

```
[handler_hand02]
class=FileHandler
level=DEBUG
formatter=form02
args=('python.log', 'w')

[handler_hand03]
class=handlers.SocketHandler
level=INFO
formatter=form03
args=('localhost', handlers.DEFAULT_TCP_LOGGING_PORT)

[handler_hand04]
class=handlers.DatagramHandler
level=WARN
formatter=form04
args=('localhost', handlers.DEFAULT_UDP_LOGGING_PORT)

[handler_hand05]
class=handlers.SysLogHandler
level=ERROR
formatter=form05
args= (('localhost', handlers.SYSLOG_UDP_PORT), handlers.SysLogHandler.LOG_USER)

[handler_hand06]
class=handlers.NTEventLogHandler
level=CRITICAL
formatter=form06
args=('Python Application', '', 'Application')

[handler_hand07]
class=handlers.SMTPHandler
level=WARN
formatter=form07
args=('localhost', 'from@abc', ['user1@abc', 'user2@xyz'], 'Logger Subject')

[handler_hand08]
class=handlers.MemoryHandler
level=NOTSET
formatter=form08
target=
args=(10, ERROR)
```

(suite sur la page suivante)

(suite de la page précédente)

```
[handler_hand09]
class=handlers.HTTPHandler
level=NOTSET
formatter=form09
args=('localhost:9022', '/log', 'GET')
```

Sections which specify formatter configuration are typified by the following.

```
[formatter_form01]
format=F1 %(asctime)s %(levelname)s %(message)s
datefmt=
class=logging.Formatter
```

The `format` entry is the overall format string, and the `datefmt` entry is the `strftime()`-compatible date/time format string. If empty, the package substitutes ISO8601 format date/times, which is almost equivalent to specifying the date format string `'%Y-%m-%d %H:%M:%S'`. The ISO8601 format also specifies milliseconds, which are appended to the result of using the above format string, with a comma separator. An example time in ISO8601 format is 2003-01-23 00:29:50,411.

The `class` entry is optional. It indicates the name of the formatter's class (as a dotted module and class name.) This option is useful for instantiating a *Formatter* subclass. Subclasses of *Formatter* can present exception tracebacks in an expanded or condensed format.

---

**Note :** Due to the use of `eval()` as described above, there are potential security risks which result from using the `listen()` to send and receive configurations via sockets. The risks are limited to where multiple users with no mutual trust run code on the same machine; see the `listen()` documentation for more information.

## 15.9 logging.handlers — Logging handlers

### Important

This page contains only reference information. For tutorials, please see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

**Source code :** `Lib/logging/handlers.py`

---

The following useful handlers are provided in the package. Note that three of the handlers (*StreamHandler*, *FileHandler* and *NullHandler*) are actually defined in the `logging` module itself, but have been documented here along with the other handlers.

### 15.9.1 StreamHandler

The *StreamHandler* class, located in the core *logging* package, sends logging output to streams such as *sys.stdout*, *sys.stderr* or any file-like object (or, more precisely, any object which supports *write()* and *flush()* methods).

**class** *logging.StreamHandler*(*stream=None*)

Returns a new instance of the *StreamHandler* class. If *stream* is specified, the instance will use it for logging output; otherwise, *sys.stderr* will be used.

**emit**(*record*)

If a formatter is specified, it is used to format the record. The record is then written to the stream with a newline terminator. If exception information is present, it is formatted using *traceback.print\_exception()* and appended to the stream.

**flush**()

Flushes the stream by calling its *flush()* method. Note that the *close()* method is inherited from *Handler* and so does no output, so an explicit *flush()* call may be needed at times.

### 15.9.2 FileHandler

The *FileHandler* class, located in the core *logging* package, sends logging output to a disk file. It inherits the output functionality from *StreamHandler*.

**class** *logging.FileHandler*(*filename*, *mode='a'*, *encoding=None*, *delay=False*)

Returns a new instance of the *FileHandler* class. The specified file is opened and used as the stream for logging. If *mode* is not specified, 'a' is used. If *encoding* is not *None*, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to *emit()*. By default, the file grows indefinitely.

Modifié dans la version 2.6 : *delay* was added.

**close**()

Closes the file.

**emit**(*record*)

Outputs the record to the file.

### 15.9.3 NullHandler

Nouveau dans la version 2.7.

The *NullHandler* class, located in the core *logging* package, does not do any formatting or output. It is essentially a “no-op” handler for use by library developers.

**class** *logging.NullHandler*

Returns a new instance of the *NullHandler* class.

**emit**(*record*)

This method does nothing.

**handle**(*record*)

This method does nothing.

**createLock**()

This method returns *None* for the lock, since there is no underlying I/O to which access needs to be serialized.

See library-config for more information on how to use *NullHandler*.

### 15.9.4 WatchedFileHandler

Nouveau dans la version 2.6.

The `WatchedFileHandler` class, located in the `logging.handlers` module, is a `FileHandler` which watches the file it is logging to. If the file changes, it is closed and reopened using the file name.

A file change can happen because of usage of programs such as `newsyslog` and `logrotate` which perform log file rotation. This handler, intended for use under Unix/Linux, watches the file to see if it has changed since the last emit. (A file is deemed to have changed if its device or inode have changed.) If the file has changed, the old file stream is closed, and the file opened to get a new stream.

This handler is not appropriate for use under Windows, because under Windows open log files cannot be moved or renamed - logging opens the files with exclusive locks - and so there is no need for such a handler. Furthermore, `ST_INO` is not supported under Windows; `stat()` always returns zero for this value.

```
class logging.handlers.WatchedFileHandler(filename[, mode[, encoding[, delay]]])
```

Returns a new instance of the `WatchedFileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, 'a' is used. If `encoding` is not `None`, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely.

```
emit(record)
```

Outputs the record to the file, but first checks to see if the file has changed. If it has, the existing stream is flushed and closed and the file opened again, before outputting the record to the file.

### 15.9.5 RotatingFileHandler

The `RotatingFileHandler` class, located in the `logging.handlers` module, supports rotation of disk log files.

```
class logging.handlers.RotatingFileHandler(filename, mode='a', maxBytes=0, backupCount=0,
                                           encoding=None, delay=0)
```

Returns a new instance of the `RotatingFileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, 'a' is used. If `encoding` is not `None`, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely.

You can use the `maxBytes` and `backupCount` values to allow the file to *rollover* at a predetermined size. When the size is about to be exceeded, the file is closed and a new file is silently opened for output. Rollover occurs whenever the current log file is nearly `maxBytes` in length; if either of `maxBytes` or `backupCount` is zero, rollover never occurs. If `backupCount` is non-zero, the system will save old log files by appending the extensions ".1", ".2" etc., to the filename. For example, with a `backupCount` of 5 and a base file name of `app.log`, you would get `app.log`, `app.log.1`, `app.log.2`, up to `app.log.5`. The file being written to is always `app.log`. When this file is filled, it is closed and renamed to `app.log.1`, and if files `app.log.1`, `app.log.2`, etc. exist, then they are renamed to `app.log.2`, `app.log.3` etc. respectively.

Modifié dans la version 2.6 : `delay` was added.

```
doRollover()
```

Does a rollover, as described above.

```
emit(record)
```

Outputs the record to the file, catering for rollover as described previously.

### 15.9.6 TimedRotatingFileHandler

The `TimedRotatingFileHandler` class, located in the `logging.handlers` module, supports rotation of disk log files at certain timed intervals.

```
class logging.handlers.TimedRotatingFileHandler(filename, when='h', interval=1, backup-
                                                Count=0, encoding=None, delay=False,
                                                utc=False)
```

Returns a new instance of the `TimedRotatingFileHandler` class. The specified file is opened and used

as the stream for logging. On rotating it also sets the filename suffix. Rotating happens based on the product of *when* and *interval*.

You can use the *when* to specify the type of *interval*. The list of possible values is below. Note that they are not case sensitive.

Valeur	Type of interval
'S'	Seconds
'M'	Minutes
'H'	Hours
'D'	Days
'W0'-'W6'	Weekday (0=Monday)
'midnight'	Roll over at midnight

When using weekday-based rotation, specify “W0” for Monday, “W1” for Tuesday, and so on up to “W6” for Sunday. In this case, the value passed for *interval* isn’t used.

The system will save old log files by appending extensions to the filename. The extensions are date-and-time based, using the strftime format `%Y-%m-%d_%H-%M-%S` or a leading portion thereof, depending on the rollover interval.

When computing the next rollover time for the first time (when the handler is created), the last modification time of an existing log file, or else the current time, is used to compute when the next rotation will occur.

If the *utc* argument is true, times in UTC will be used; otherwise local time is used.

If *backupCount* is nonzero, at most *backupCount* files will be kept, and if more would be created when rollover occurs, the oldest one is deleted. The deletion logic uses the interval to determine which files to delete, so changing the interval may leave old files lying around.

If *delay* is true, then file opening is deferred until the first call to *emit()*.

Modifié dans la version 2.6 : *delay* and *utc* were added.

**doRollover()**

Does a rollover, as described above.

**emit(record)**

Outputs the record to the file, catering for rollover as described above.

### 15.9.7 SocketHandler

The *SocketHandler* class, located in the *logging.handlers* module, sends logging output to a network socket. The base class uses a TCP socket.

**class logging.handlers.SocketHandler(host, port)**

Returns a new instance of the *SocketHandler* class intended to communicate with a remote machine whose address is given by *host* and *port*.

**close()**

Closes the socket.

**emit()**

Pickles the record’s attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. If the connection was previously lost, re-establishes the connection. To unpickle the record at the receiving end into a *LogRecord*, use the *makeLogRecord()* function.

**handleError()**

Handles an error which has occurred during *emit()*. The most likely cause is a lost connection. Closes the socket so that we can retry on the next event.

**makeSocket()**

This is a factory method which allows subclasses to define the precise type of socket they want. The default implementation creates a TCP socket (*socket.SOCK\_STREAM*).

**makePickle(record)**

Pickles the record's attribute dictionary in binary format with a length prefix, and returns it ready for transmission across the socket.

Note that pickles aren't completely secure. If you are concerned about security, you may want to override this method to implement a more secure mechanism. For example, you can sign pickles using HMAC and then verify them on the receiving end, or alternatively you can disable unpickling of global objects on the receiving end.

**send(packet)**

Send a pickled string *packet* to the socket. This function allows for partial sends which can happen when the network is busy.

**createSocket()**

Tries to create a socket ; on failure, uses an exponential back-off algorithm. On initial failure, the handler will drop the message it was trying to send. When subsequent messages are handled by the same instance, it will not try connecting until some time has passed. The default parameters are such that the initial delay is one second, and if after that delay the connection still can't be made, the handler will double the delay each time up to a maximum of 30 seconds.

This behaviour is controlled by the following handler attributes :

- **retryStart** (initial delay, defaulting to 1.0 seconds).
- **retryFactor** (multiplier, defaulting to 2.0).
- **retryMax** (maximum delay, defaulting to 30.0 seconds).

This means that if the remote listener starts up *after* the handler has been used, you could lose messages (since the handler won't even attempt a connection until the delay has elapsed, but just silently drop messages during the delay period).

## 15.9.8 DatagramHandler

The *DatagramHandler* class, located in the *logging.handlers* module, inherits from *SocketHandler* to support sending logging messages over UDP sockets.

**class logging.handlers.DatagramHandler(host, port)**

Returns a new instance of the *DatagramHandler* class intended to communicate with a remote machine whose address is given by *host* and *port*.

**emit()**

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. To unpickle the record at the receiving end into a *LogRecord*, use the *makeLogRecord()* function.

**makeSocket()**

The factory method of *SocketHandler* is here overridden to create a UDP socket (*socket.SOCK\_DGRAM*).

**send(s)**

Send a pickled string to a socket.

## 15.9.9 SysLogHandler

The *SysLogHandler* class, located in the *logging.handlers* module, supports sending logging messages to a remote or local Unix syslog.

**class logging.handlers.SysLogHandler(address=('localhost', SYSLOG\_UDP\_PORT), facility=LOG\_USER, socktype=socket.SOCK\_DGRAM)**

Returns a new instance of the *SysLogHandler* class intended to communicate with a remote Unix machine whose address is given by *address* in the form of a (*host*, *port*) tuple. If *address* is not specified, ('localhost', 514) is used. The address is used to open a socket. An alternative to providing a (*host*, *port*) tuple is providing an address as a string, for example "/dev/log". In this case, a Unix domain socket is used to send the message to the syslog. If *facility* is not specified, LOG\_USER is used. The type of socket opened depends on the *socktype* argument, which defaults to *socket.SOCK\_DGRAM*.

and thus opens a UDP socket. To open a TCP socket (for use with the newer syslog daemons such as rsyslog), specify a value of `socket.SOCK_STREAM`.

Note that if your server is not listening on UDP port 514, `SysLogHandler` may appear not to work. In that case, check what address you should be using for a domain socket - it's system dependent. For example, on Linux it's usually `"/dev/log"` but on OS/X it's `"/var/run/syslog"`. You'll need to check your platform and use the appropriate address (you may need to do this check at runtime if your application needs to run on several platforms). On Windows, you pretty much have to use the UDP option.

Modifié dans la version 2.7 : `socktype` was added.

**close()**

Closes the socket to the remote host.

**emit(record)**

The record is formatted, and then sent to the syslog server. If exception information is present, it is *not* sent to the server.

**encodePriority(facility, priority)**

Encodes the facility and priority into an integer. You can pass in strings or integers - if strings are passed, internal mapping dictionaries are used to convert them to integers.

The symbolic `LOG_` values are defined in `SysLogHandler` and mirror the values defined in the `sys/syslog.h` header file.

#### Priorities

Name (string)	Symbolic value
alert	LOG_ALERT
crit ou critical	LOG_CRIT
debug	LOG_DEBUG
emerg ou panic	LOG_EMERG
err ou error	LOG_ERR
info	LOG_INFO
notice	LOG_NOTICE
warn ou warning	LOG_WARNING

#### Facilities

Name (string)	Symbolic value
auth	LOG_AUTH
authpriv	LOG_AUTHPRIV
cron	LOG_CRON
daemon	LOG_DAEMON
ftp	LOG_FTP
kern	LOG_KERN
lpr	LOG_LPR
mail	LOG_MAIL
news	LOG_NEWS
syslog	LOG_SYSLOG
user	LOG_USER
uucp	LOG_UUCP
local0	LOG_LOCAL0
local1	LOG_LOCAL1
local2	LOG_LOCAL2
local3	LOG_LOCAL3
local4	LOG_LOCAL4
local5	LOG_LOCAL5
local6	LOG_LOCAL6
local7	LOG_LOCAL7

**mapPriority(*levelname*)**

Maps a logging level name to a syslog priority name. You may need to override this if you are using custom levels, or if the default algorithm is not suitable for your needs. The default algorithm maps `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL` to the equivalent syslog names, and all other level names to “warning”.

### 15.9.10 NTEventLogHandler

The *NTEventLogHandler* class, located in the *logging.handlers* module, supports sending logging messages to a local Windows NT, Windows 2000 or Windows XP event log. Before you can use it, you need Mark Hammond’s Win32 extensions for Python installed.

**class** *logging.handlers.NTEventLogHandler*(*appname*, *dllname=None*, *logtype='Application'*)

Returns a new instance of the *NTEventLogHandler* class. The *appname* is used to define the application name as it appears in the event log. An appropriate registry entry is created using this name. The *dllname* should give the fully qualified pathname of a .dll or .exe which contains message definitions to hold in the log (if not specified, 'win32service.pyd' is used - this is installed with the Win32 extensions and contains some basic placeholder message definitions. Note that use of these placeholders will make your event logs big, as the entire message source is held in the log. If you want slimmer logs, you have to pass in the name of your own .dll or .exe which contains the message definitions you want to use in the event log). The *logtype* is one of 'Application', 'System' or 'Security', and defaults to 'Application'.

**close()**

At this point, you can remove the application name from the registry as a source of event log entries. However, if you do this, you will not be able to see the events as you intended in the Event Log Viewer - it needs to be able to access the registry to get the .dll name. The current version does not do this.

**emit(*record*)**

Determines the message ID, event category and event type, and then logs the message in the NT event log.

**getEventCategory(record)**

Returns the event category for the record. Override this if you want to specify your own categories. This version returns 0.

**getEventType(record)**

Returns the event type for the record. Override this if you want to specify your own types. This version does a mapping using the handler's `typemap` attribute, which is set up in `__init__()` to a dictionary which contains mappings for `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL`. If you are using your own levels, you will either need to override this method or place a suitable dictionary in the handler's `typemap` attribute.

**getMessageID(record)**

Returns the message ID for the record. If you are using your own messages, you could do this by having the `msg` passed to the logger being an ID rather than a format string. Then, in here, you could use a dictionary lookup to get the message ID. This version returns 1, which is the base message ID in `win32service.pyd`.

### 15.9.11 SMTPHandler

The `SMTPHandler` class, located in the `logging.handlers` module, supports sending logging messages to an email address via SMTP.

**class** `logging.handlers.SMTPHandler(mailhost, fromaddr, toaddrs, subject, credentials=None, secure=None)`

Returns a new instance of the `SMTPHandler` class. The instance is initialized with the from and to addresses and subject line of the email. The `toaddrs` should be a list of strings. To specify a non-standard SMTP port, use the (host, port) tuple format for the `mailhost` argument. If you use a string, the standard SMTP port is used. If your SMTP server requires authentication, you can specify a (username, password) tuple for the `credentials` argument.

To specify the use of a secure protocol (TLS), pass in a tuple to the `secure` argument. This will only be used when authentication credentials are supplied. The tuple should be either an empty tuple, or a single-value tuple with the name of a keyfile, or a 2-value tuple with the names of the keyfile and certificate file. (This tuple is passed to the `smtplib.SMTP.starttls()` method.)

Modifié dans la version 2.6 : `credentials` was added.

Modifié dans la version 2.7 : `secure` was added.

**emit(record)**

Formats the record and sends it to the specified addressees.

**getSubject(record)**

If you want to specify a subject line which is record-dependent, override this method.

### 15.9.12 MemoryHandler

The `MemoryHandler` class, located in the `logging.handlers` module, supports buffering of logging records in memory, periodically flushing them to a `target` handler. Flushing occurs whenever the buffer is full, or when an event of a certain severity or greater is seen.

`MemoryHandler` is a subclass of the more general `BufferingHandler`, which is an abstract class. This buffers logging records in memory. Whenever each record is added to the buffer, a check is made by calling `shouldFlush()` to see if the buffer should be flushed. If it should, then `flush()` is expected to do the flushing.

**class** `logging.handlers.BufferingHandler(capacity)`

Initializes the handler with a buffer of the specified capacity.

**emit(record)**

Appends the record to the buffer. If `shouldFlush()` returns true, calls `flush()` to process the buffer.

**flush()**

You can override this to implement custom flushing behavior. This version just zaps the buffer to empty.

**shouldFlush(record)**

Returns true if the buffer is up to capacity. This method can be overridden to implement custom flushing strategies.

**class logging.handlers.MemoryHandler(capacity, flushLevel=ERROR, target=None)**

Returns a new instance of the *MemoryHandler* class. The instance is initialized with a buffer size of *capacity*. If *flushLevel* is not specified, *ERROR* is used. If no *target* is specified, the target will need to be set using *setTarget()* before this handler does anything useful.

**close()**

Calls *flush()*, sets the target to *None* and clears the buffer.

**flush()**

For a *MemoryHandler*, flushing means just sending the buffered records to the target, if there is one. The buffer is also cleared when this happens. Override if you want different behavior.

**setTarget(target)**

Sets the target handler for this handler.

**shouldFlush(record)**

Checks for buffer full or a record at the *flushLevel* or higher.

### 15.9.13 HTTPHandler

The *HTTPHandler* class, located in the *logging.handlers* module, supports sending logging messages to a Web server, using either GET or POST semantics.

**class logging.handlers.HTTPHandler(host, url, method='GET')**

Returns a new instance of the *HTTPHandler* class. The *host* can be of the form *host:port*, should you need to use a specific port number.

**mapLogRecord(record)**

Provides a dictionary, based on *record*, which is to be URL-encoded and sent to the web server. The default implementation just returns *record.\_\_dict\_\_*. This method can be overridden if e.g. only a subset of *LogRecord* is to be sent to the web server, or if more specific customization of what's sent to the server is required.

**emit(record)**

Sends the record to the Web server as a URL-encoded dictionary. The *mapLogRecord()* method is used to convert the record to the dictionary to be sent.

---

**Note :** Since preparing a record for sending it to a Web server is not the same as a generic formatting operation, using *setFormatter()* to specify a *Formatter* for a *HTTPHandler* has no effect. Instead of calling *format()*, this handler calls *mapLogRecord()* and then *urllib.urlencode()* to encode the dictionary in a form suitable for sending to a Web server.

Module *logging.config* Configuration API for the logging module.

## 15.10 Saisie de mot de passe portable

Le module *getpass* fournit 2 fonctions :

---

```
getpass.getpass([prompt[, stream]])
```

Prompt the user for a password without echoing. The user is prompted using the string *prompt*, which defaults to 'Password: '. On Unix, the prompt is written to the file-like object *stream*. *stream* defaults to the controlling terminal (/dev/tty) or if that is unavailable to `sys.stderr` (this argument is ignored on Windows).

Si aucune saisie en mode sans affichage n'est disponible, `getpass()` se résoudra à afficher un message d'avertissement vers *stream*, puis lire l'entrée depuis `sys.stdin`, en levant une *GetPassWarning*.

Modifié dans la version 2.5 : The *stream* parameter was added.

Modifié dans la version 2.6 : On Unix it defaults to using /dev/tty before falling back to `sys.stdin` and `sys.stderr`.

---

**Note :** Si vous appelez *getpass* depuis IDLE, la saisie peut être faite dans le terminal depuis lequel IDLE a été lancé, plutôt que dans la fenêtre d'IDLE.

---

**exception** `getpass.GetPassWarning`

Une sous classe d'exception *UserWarning* est levée quand le mot de passe saisi pourrait être affiché.

`getpass.getuser()`

Renvoie le *login name* de l'utilisateur.

Cette fonction examine les variables d'environnement LOGNAME, USER, LNAME et USERNAME, dans cet ordre, et renvoie la valeur de la première qui a comme valeur une string non vide. Si aucune des variables n'est renseignée, dans le cas de systèmes qui prennent en charge le module *pwd*, le *login name* de la base de données des mots de passes est renvoyé, pour les autres systèmes une exception est levée.

## 15.11 curses — Terminal handling for character-cell displays

Modifié dans la version 1.6 : Added support for the `ncurses` library and converted to a package.

The *curses* module provides an interface to the curses library, the de-facto standard for portable advanced terminal handling.

While curses is most widely used in the Unix environment, versions are available for DOS, OS/2, and possibly other systems as well. This extension module is designed to match the API of ncurses, an open-source curses library hosted on Linux and the BSD variants of Unix.

---

**Note :** Since version 5.4, the ncurses library decides how to interpret non-ASCII data using the `nl_langinfo` function. That means that you have to call `locale.setlocale()` in the application and encode Unicode strings using one of the system's available encodings. This example uses the system's default encoding :

```
import locale
locale.setlocale(locale.LC_ALL, '')
code = locale.getpreferredencoding()
```

Then use *code* as the encoding for *str.encode()* calls.

The `Demo/curses/` directory in the Python source distribution contains some example programs using the curses bindings provided by this module.

### 15.11.1 Fonctions

The module `curses` defines the following exception :

**exception `curses.error`**

Exception raised when a curses library function returns an error.

---

**Note :** Whenever *x* or *y* arguments to a function or a method are optional, they default to the current cursor location. Whenever *attr* is optional, it defaults to `A_NORMAL`.

---

The module `curses` defines the following functions :

**`curses.baudrate()`**

Return the output speed of the terminal in bits per second. On software terminal emulators it will have a fixed high value. Included for historical reasons; in former times, it was used to write output loops for time delays and occasionally to change interfaces depending on the line speed.

**`curses.beep()`**

Emit a short attention sound.

**`curses.can_change_color()`**

Return `True` or `False`, depending on whether the programmer can change the colors displayed by the terminal.

**`curses.cbreak()`**

Enter cbreak mode. In cbreak mode (sometimes called « rare » mode) normal tty line buffering is turned off and characters are available to be read one by one. However, unlike raw mode, special characters (interrupt, quit, suspend, and flow control) retain their effects on the tty driver and calling program. Calling first `raw()` then `cbreak()` leaves the terminal in cbreak mode.

**`curses.color_content(color_number)`**

Return the intensity of the red, green, and blue (RGB) components in the color *color\_number*, which must be between 0 and `COLORS`. A 3-tuple is returned, containing the R,G,B values for the given color, which will be between 0 (no component) and 1000 (maximum amount of component).

**`curses.color_pair(color_number)`**

Return the attribute value for displaying text in the specified color. This attribute value can be combined with `A_STANDOUT`, `A_REVERSE`, and the other `A_*` attributes. `pair_number()` is the counterpart to this function.

**`curses.curs_set(visibility)`**

Set the cursor state. *visibility* can be set to 0, 1, or 2, for invisible, normal, or very visible. If the terminal supports the visibility requested, the previous cursor state is returned; otherwise, an exception is raised. On many terminals, the « visible » mode is an underline cursor and the « very visible » mode is a block cursor.

**`curses.def_prog_mode()`**

Save the current terminal mode as the « program » mode, the mode when the running program is using curses. (Its counterpart is the « shell » mode, for when the program is not in curses.) Subsequent calls to `reset_prog_mode()` will restore this mode.

**`curses.def_shell_mode()`**

Save the current terminal mode as the « shell » mode, the mode when the running program is not using curses. (Its counterpart is the « program » mode, when the program is using curses capabilities.) Subsequent calls to `reset_shell_mode()` will restore this mode.

`curses.delay_output(ms)`

Insert an *ms* millisecond pause in output.

`curses.doupdate()`

Update the physical screen. The curses library keeps two data structures, one representing the current physical screen contents and a virtual screen representing the desired next state. The `doupdate()` ground updates the physical screen to match the virtual screen.

The virtual screen may be updated by a `noutrefresh()` call after write operations such as `addstr()` have been performed on a window. The normal `refresh()` call is simply `noutrefresh()` followed by `doupdate()`; if you have to update multiple windows, you can speed performance and perhaps reduce screen flicker by issuing `noutrefresh()` calls on all windows, followed by a single `doupdate()`.

`curses.echo()`

Enter echo mode. In echo mode, each character input is echoed to the screen as it is entered.

`curses.endwin()`

De-initialize the library, and return terminal to normal status.

`curses.erasechar()`

Return the user's current erase character. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

`curses.filter()`

The `filter()` routine, if used, must be called before `initscr()` is called. The effect is that, during those calls, `LINES` is set to 1; the capabilities `clear`, `cup`, `cud`, `cud1`, `cuu1`, `cuu`, `vpa` are disabled; and the home string is set to the value of `cr`. The effect is that the cursor is confined to the current line, and so are screen updates. This may be used for enabling character-at-a-time line editing without touching the rest of the screen.

`curses.flash()`

Flash the screen. That is, change it to reverse-video and then change it back in a short interval. Some people prefer such as “visible bell” to the audible attention signal produced by `beep()`.

`curses.flushinp()`

Flush all input buffers. This throws away any typeahead that has been typed by the user and has not yet been processed by the program.

`curses.getmouse()`

After `getch()` returns `KEY_MOUSE` to signal a mouse event, this method should be call to retrieve the queued mouse event, represented as a 5-tuple (`id`, `x`, `y`, `z`, `bstate`). `id` is an ID value used to distinguish multiple devices, and `x`, `y`, `z` are the event's coordinates. (`z` is currently unused.) `bstate` is an integer value whose bits will be set to indicate the type of event, and will be the bitwise OR of one or more of the following constants, where `n` is the button number from 1 to 4 : `BUTTONn_PRESSED`, `BUTTONn_RELEASED`, `BUTTONn_CLICKED`, `BUTTONn_DOUBLE_CLICKED`, `BUTTONn_TRIPLE_CLICKED`, `BUTTON_SHIFT`, `BUTTON_CTRL`, `BUTTON_ALT`.

`curses.getsyx()`

Return the current coordinates of the virtual screen cursor in `y` and `x`. If `leaveok` is currently true, then -1,-1 is returned.

`curses.getwin(file)`

Read window related data stored in the file by an earlier `putwin()` call. The routine then creates and initializes a new window using that data, returning the new window object.

`curses.has_colors()`

Return `True` if the terminal can display colors; otherwise, return `False`.

`curses.has_ic()`

Return `True` if the terminal has insert- and delete-character capabilities. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.has_il()`

Return **True** if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.has_key(ch)`

Take a key value *ch*, and return **True** if the current terminal type recognizes a key with that value.

`curses.halfdelay(tenths)`

Used for half-delay mode, which is similar to `cbreak` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, an exception is raised if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

`curses.init_color(color_number, r, g, b)`

Change the definition of a color, taking the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of *color\_number* must be between 0 and `COLORS`. Each of *r*, *g*, *b*, must be a value between 0 and 1000. When `init_color()` is used, all occurrences of that color on the screen immediately change to the new definition. This function is a no-op on most terminals; it is active only if `can_change_color()` returns 1.

`curses.init_pair(pair_number, fg, bg)`

Change the definition of a color-pair. It takes three arguments : the number of the color-pair to be changed, the foreground color number, and the background color number. The value of *pair\_number* must be between 1 and `COLOR_PAIRS - 1` (the 0 color pair is wired to white on black and cannot be changed). The value of *fg* and *bg* arguments must be between 0 and `COLORS`. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair are changed to the new definition.

`curses.initscr()`

Initialize the library. Return a `WindowObject` which represents the whole screen.

---

**Note :** If there is an error opening the terminal, the underlying curses library may cause the interpreter to exit.

---

`curses.is_term_resized(nlines, ncols)`

Return **True** if `resize_term()` would modify the window structure, **False** otherwise.

`curses.isendwin()`

Return **True** if `endwin()` has been called (that is, the curses library has been deinitialized).

`curses.keyname(k)`

Return the name of the key numbered *k*. The name of a key generating printable ASCII character is the key's character. The name of a control-key combination is a two-character string consisting of a caret followed by the corresponding printable ASCII character. The name of an alt-key combination (128–255) is a string consisting of the prefix “M-“ followed by the name of the corresponding ASCII character.

`curses.killchar()`

Return the user's current line kill character. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

`curses.longname()`

Return a string containing the terminfo long name field describing the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to `initscr()`.

`curses.meta(yes)`

If *yes* is 1, allow 8-bit characters to be input. If *yes* is 0, allow only 7-bit chars.

`curses.mouseinterval(interval)`

Set the maximum time in milliseconds that can elapse between press and release events in order for them to be recognized as a click, and return the previous interval value. The default value is 200 msec, or one fifth of a second.

`curses.mousemask(mousemask)`

Set the mouse events to be reported, and return a tuple (*availmask*, *oldmask*). *availmask* indicates which of the specified mouse events can be reported; on complete failure it returns 0. *oldmask* is the previous value of the given window's mouse event mask. If this function is never called, no mouse events are ever reported.

`curses.napms(ms)`

Sleep for *ms* milliseconds.

`curses.newpad(nlines, ncols)`

Create and return a pointer to a new pad data structure with the given number of lines and columns. A pad is returned as a window object.

A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (such as from scrolling or echoing of input) do not occur. The `refresh()` and `noutrefresh()` methods of a pad require 6 arguments to specify the part of the pad to be displayed and the location on the screen to be used for the display. The arguments are *pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*; the *p* arguments refer to the upper left corner of the pad region to be displayed and the *s* arguments define a clipping box on the screen within which the pad region is to be displayed.

`curses.newwin(nlines, ncols)`

`curses.newwin(nlines, ncols, begin_y, begin_x)`

Return a new window, whose left-upper corner is at (*begin\_y*, *begin\_x*), and whose height/width is *nlines/ncols*.

By default, the window will extend from the specified position to the lower right corner of the screen.

`curses.nl()`

Enter newline mode. This mode translates the return key into newline on input, and translates newline into return and line-feed on output. Newline mode is initially on.

`curses.nocbreak()`

Leave cbreak mode. Return to normal « cooked » mode with line buffering.

`curses.noecho()`

Leave echo mode. Echoing of input characters is turned off.

`curses.nonl()`

Leave newline mode. Disable translation of return into newline on input, and disable low-level translation of newline into newline/return on output (but this does not change the behavior of `addch('\n')`, which always does the equivalent of return and line feed on the virtual screen). With translation off, curses can sometimes speed up vertical motion a little; also, it will be able to detect the return key on input.

`curses.noqiflush()`

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the INTR, QUIT and SUSP characters will not be done. You may want to call `noqiflush()` in a signal handler if you want output to continue as though the interrupt had not occurred, after the handler exits.

`curses.noraw()`

Leave raw mode. Return to normal « cooked » mode with line buffering.

`curses.pair_content(pair_number)`

Return a tuple (fg, bg) containing the colors for the requested color pair. The value of *pair\_number* must be between 1 and COLOR\_PAIRS - 1.

`curses.pair_number(attr)`

Return the number of the color-pair set by the attribute value *attr*. *color\_pair()* is the counterpart to this function.

`curses.putp(string)`

Equivalent to `tputs(str, 1, putchar)`; emit the value of a specified terminfo capability for the current terminal. Note that the output of *putp()* always goes to standard output.

`curses.qiflush([flag])`

If *flag* is False, the effect is the same as calling *noqiflush()*. If *flag* is True, or no argument is provided, the queues will be flushed when these control characters are read.

`curses.raw()`

Enter raw mode. In raw mode, normal line buffering and processing of interrupt, quit, suspend, and flow control keys are turned off; characters are presented to curses input functions one by one.

`curses.reset_prog_mode()`

Restore the terminal to « program » mode, as previously saved by *def\_prog\_mode()*.

`curses.reset_shell_mode()`

Restore the terminal to « shell » mode, as previously saved by *def\_shell\_mode()*.

`curses.resetty()`

Restore the state of the terminal modes to what it was at the last call to *savetty()*.

`curses.resize_term(nlines, ncols)`

Backend function used by *resizeterm()*, performing most of the work; when resizing the windows, *resize\_term()* blank-fills the areas that are extended. The calling application should fill in these areas with appropriate data. The *resize\_term()* function attempts to resize all windows. However, due to the calling convention of pads, it is not possible to resize these without additional interaction with the application.

`curses.resizeterm(nlines, ncols)`

Resize the standard and current windows to the specified dimensions, and adjusts other bookkeeping data used by the curses library that record the window dimensions (in particular the SIGWINCH handler).

`curses.savetty()`

Save the current state of the terminal modes in a buffer, usable by *resetty()*.

`curses.setsyx(y, x)`

Set the virtual screen cursor to *y*, *x*. If *y* and *x* are both -1, then leaveok is set.

`curses.setupterm([termstr, fd])`

Initialize the terminal. *termstr* is a string giving the terminal name; if omitted, the value of the TERM environment variable will be used. *fd* is the file descriptor to which any initialization sequences will be sent; if not supplied, the file descriptor for `sys.stdout` will be used.

`curses.start_color()`

Must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after *initscr()*.

*start\_color()* initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables in the *curses* module, COLOR\_S and COLOR\_PAIRS, containing the maximum number of colors and color-pairs the terminal can support. It also restores the colors on the terminal to the values they had when the terminal was just turned on.

`curses.termattrs()`

Return a logical OR of all video attributes supported by the terminal. This information is useful when a curses program needs complete control over the appearance of the screen.

`curses.termname()`

Return the value of the environment variable `TERM`, truncated to 14 characters.

`curses.tigetflag(capname)`

Return the value of the Boolean capability corresponding to the terminfo capability name *capname*. The value `-1` is returned if *capname* is not a Boolean capability, or `0` if it is canceled or absent from the terminal description.

`curses.tigetnum(capname)`

Return the value of the numeric capability corresponding to the terminfo capability name *capname*. The value `-2` is returned if *capname* is not a numeric capability, or `-1` if it is canceled or absent from the terminal description.

`curses.tigetstr(capname)`

Return the value of the string capability corresponding to the terminfo capability name *capname*. `None` is returned if *capname* is not a string capability, or is canceled or absent from the terminal description.

`curses.tparm(str[, ...])`

Instantiate the string *str* with the supplied parameters, where *str* should be a parameterized string obtained from the terminfo database. E.g. `tparm(tigetstr("cup"), 5, 3)` could result in `'\033[6;4H'`, the exact result depending on terminal type.

`curses.typeahead(fd)`

Specify that the file descriptor *fd* be used for typeahead checking. If *fd* is `-1`, then no typeahead checking is done.

The curses library does « line-breakout optimization » by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a `tty`, the current update is postponed until `refresh` or `doupdate` is called again, allowing faster response to commands typed in advance. This function allows specifying a different file descriptor for typeahead checking.

`curses.unctrl(ch)`

Return a string which is a printable representation of the character *ch*. Control characters are displayed as a caret followed by the character, for example as `^C`. Printing characters are left as they are.

`curses.ungetch(ch)`

Push *ch* so the next `getch()` will return it.

---

**Note :** Only one *ch* can be pushed before `getch()` is called.

---

`curses.ungetmouse(id, x, y, z, bstate)`

Push a `KEY_MOUSE` event onto the input queue, associating the given state data with it.

`curses.use_env(flag)`

If used, this function should be called before `initscr()` or `newterm` are called. When *flag* is `False`, the values of lines and columns specified in the terminfo database will be used, even if environment variables `LINES` and `COLUMNS` (used by default) are set, or if curses is running in a window (in which case default behavior would be to use the window size if `LINES` and `COLUMNS` are not set).

`curses.use_default_colors()`

Allow use of default values for colors on terminals supporting this feature. Use this to support transparency in your application. The default color is assigned to the color number `-1`. After calling this function, `init_pair(x, curses.COLOR_RED, -1)` initializes, for instance, color pair *x* to a red foreground color on the default background.

`curses.wrapper(func, ...)`

Initialize curses and call another callable object, *func*, which should be the rest of your curses-using application. If the application raises an exception, this function will restore the terminal to a sane state before re-raising the exception and generating a traceback. The callable object *func* is then passed the main window “stdscr” as its first argument, followed by any other arguments passed to `wrapper()`. Before calling *func*, `wrapper()` turns on cbreak mode, turns off echo, enables the terminal keypad, and initializes colors if the terminal has color support. On exit (whether normally or by exception) it restores cooked mode, turns on echo, and disables the terminal keypad.

### 15.11.2 Window Objects

Window objects, as returned by `initscr()` and `newwin()` above, have the following methods :

`window.addch(ch[, attr])`

`window.addch(y, x, ch[, attr])`

---

**Note :** A *character* means a C character (an ASCII code), rather than a Python character (a string of length 1). (This note is true whenever the documentation mentions a character.) The built-in `ord()` is handy for conveying strings to codes.

---

Paint character *ch* at (*y*, *x*) with attributes *attr*, overwriting any character previously painter at that location. By default, the character position and attributes are the current settings for the window object.

---

**Note :** Writing outside the window, subwindow, or pad raises a `curses.error`. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the character is printed.

---

`window.addnstr(str, n[, attr])`

`window.addnstr(y, x, str, n[, attr])`

Paint at most *n* characters of the string *str* at (*y*, *x*) with attributes *attr*, overwriting anything previously on the display.

`window.addstr(str[, attr])`

`window.addstr(y, x, str[, attr])`

Paint the string *str* at (*y*, *x*) with attributes *attr*, overwriting anything previously on the display.

---

**Note :** Writing outside the window, subwindow, or pad raises `curses.error`. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the string is printed.

---

`window.attroff(attr)`

Remove attribute *attr* from the « background » set applied to all writes to the current window.

`window.atron(attr)`

Add attribute *attr* from the « background » set applied to all writes to the current window.

`window.attrset(attr)`

Set the « background » set of attributes to *attr*. This set is initially 0 (no attributes).

`window.bkgd(ch[, attr])`

Set the background property of the window to the character *ch*, with attributes *attr*. The change is then applied to every character position in that window :

- The attribute of every character in the window is changed to the new background attribute.
- Wherever the former background character appears, it is changed to the new background character.

`window.bkgdset(ch[, attr])`

Set the window's background. A window's background consists of a character and any combination of attributes. The attribute part of the background is combined (OR'ed) with all non-blank characters that are written into the window. Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations.

`window.border([ls[, rs[, ts[, bs[, tl[, tr[, bl[, br]]]]]]])`

Draw a border around the edges of the window. Each parameter specifies the character to use for a specific part of the border; see the table below for more details. The characters can be specified as integers or as one-character strings.

---

**Note :** A 0 value for any parameter will cause the default character to be used for that parameter. Keyword parameters can *not* be used. The defaults are listed in this table :

---

Paramètre	Description	Valeur par défaut
<i>ls</i>	Left side	ACS_VLINE
<i>rs</i>	Right side	ACS_VLINE
<i>ts</i>	Top	ACS_HLINE
<i>bs</i>	Bottom	ACS_HLINE
<i>tl</i>	Upper-left corner	ACS_ULCORNER
<i>tr</i>	Upper-right corner	ACS_URCORNER
<i>bl</i>	Bottom-left corner	ACS_LLCORNER
<i>br</i>	Bottom-right corner	ACS_LRCORNER

`window.box([vertch, horch])`

Similar to `border()`, but both *ls* and *rs* are *vertch* and both *ts* and *bs* are *horch*. The default corner characters are always used by this function.

`window.chgat(attr)`

`window.chgat(num, attr)`

`window.chgat(y, x, attr)`

`window.chgat(y, x, num, attr)`

Set the attributes of *num* characters at the current cursor position, or at position (*y*, *x*) if supplied. If *num* is not given or is -1, the attribute will be set on all the characters to the end of the line. This function moves cursor to position (*y*, *x*) if supplied. The changed line will be touched using the `touchline()` method so that the contents will be redisplayed by the next window refresh.

`window.clear()`

Like `erase()`, but also cause the whole window to be repainted upon next call to `refresh()`.

`window.clearok(yes)`

If *yes* is 1, the next call to `refresh()` will clear the window completely.

`window.clrtoeol()`

Erase from cursor to the end of the window : all lines below the cursor are deleted, and then the equivalent of `clrtoeol()` is performed.

`window.clrtoeol()`

Erase from cursor to the end of the line.

`window.cursyncup()`

Update the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

`window.delch([y, x])`

Delete any character at (y, x).

`window.deleteln()`

Delete the line under the cursor. All following lines are moved up by one line.

`window.derwin(begin_y, begin_x)`

`window.derwin(nlines, ncols, begin_y, begin_x)`

An abbreviation for « derive window », `derwin()` is the same as calling `subwin()`, except that `begin_y` and `begin_x` are relative to the origin of the window, rather than relative to the entire screen. Return a window object for the derived window.

`window.echochar(ch[, attr])`

Add character `ch` with attribute `attr`, and immediately call `refresh()` on the window.

`window.enclose(y, x)`

Test whether the given pair of screen-relative character-cell coordinates are enclosed by the given window, returning `True` or `False`. It is useful for determining what subset of the screen windows enclose the location of a mouse event.

`window.erase()`

Clear the window.

`window.getbegyx()`

Return a tuple (y, x) of co-ordinates of upper-left corner.

`window.getbkgd()`

Return the given window's current background character/attribute pair.

`window.getch([y, x])`

Get a character. Note that the integer returned does *not* have to be in ASCII range : function keys, keypad keys and so on return numbers higher than 256. In no-delay mode, -1 is returned if there is no input, else `getch()` waits until a key is pressed.

`window.getkey([y, x])`

Get a character, returning a string instead of an integer, as `getch()` does. Function keys, keypad keys and so on return a multibyte string containing the key name. In no-delay mode, an exception is raised if there is no input.

`window.getmaxyx()`

Return a tuple (y, x) of the height and width of the window.

`window.getparyx()`

Return the beginning coordinates of this window relative to its parent window into two integer variables y and x. Return -1, -1 if this window has no parent.

`window.getstr([y, x])`

Read a string from the user, with primitive line editing capacity.

`window.getyx()`

Return a tuple (y, x) of current cursor position relative to the window's upper-left corner.

`window.hline(ch, n)`

`window.hline(y, x, ch, n)`

Display a horizontal line starting at (y, x) with length `n` consisting of the character `ch`.

`window.idcok(flag)`

If `flag` is `False`, curses no longer considers using the hardware insert/delete character feature of the terminal; if `flag` is `True`, use of character insertion and deletion is enabled. When curses is first initialized, use of character insert/delete is enabled by default.

`window.idlok(yes)`

If called with *yes* equal to 1, *curses* will try and use hardware line editing facilities. Otherwise, line insertion/deletion are disabled.

`window.immedok(flag)`

If *flag* is `True`, any change in the window image automatically causes the window to be refreshed; you no longer have to call *refresh()* yourself. However, it may degrade performance considerably, due to repeated calls to *wrefresh*. This option is disabled by default.

`window.inch([y, x])`

Return the character at the given position in the window. The bottom 8 bits are the character proper, and upper bits are the attributes.

`window.insch(ch, [attr])`

`window.insch(y, x, ch, [attr])`

Paint character *ch* at (*y*, *x*) with attributes *attr*, moving the line from position *x* right by one character.

`window.insdelln(nlines)`

Insert *nlines* lines into the specified window above the current line. The *nlines* bottom lines are lost. For negative *nlines*, delete *nlines* lines starting with the one under the cursor, and move the remaining lines up. The bottom *nlines* lines are cleared. The current cursor position remains the same.

`window.insertln()`

Insert a blank line under the cursor. All following lines are moved down by one line.

`window.insnstr(str, [n, [attr]])`

`window.insnstr(y, x, str, [n, [attr]])`

Insert a character string (as many characters as will fit on the line) before the character under the cursor, up to *n* characters. If *n* is zero or negative, the entire string is inserted. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

`window.insstr(str, [attr])`

`window.insstr(y, x, str, [attr])`

Insert a character string (as many characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

`window.instr([n])`

`window.instr(y, x, [n])`

Return a string of characters, extracted from the window starting at the current cursor position, or at *y*, *x* if specified. Attributes are stripped from the characters. If *n* is specified, *instr()* returns a string at most *n* characters long (exclusive of the trailing NUL).

`window.is_linetouched(line)`

Return `True` if the specified line was modified since the last call to *refresh()*; otherwise return `False`. Raise a *curses.error* exception if *line* is not valid for the given window.

`window.is_wintouched()`

Return `True` if the specified window was modified since the last call to *refresh()*; otherwise return `False`.

`window.keypad(yes)`

If *yes* is 1, escape sequences generated by some keys (keypad, function keys) will be interpreted by *curses*. If *yes* is 0, escape sequences will be left as is in the input stream.

`window.leaveok(yes)`

If *yes* is 1, cursor is left where it is on update, instead of being at « cursor position. » This reduces

cursor movement where possible. If possible the cursor will be made invisible.

If *yes* is 0, cursor will always be at « cursor position » after an update.

`window.move(new_y, new_x)`

Move cursor to (*new\_y*, *new\_x*).

`window.mvderwin(y, x)`

Move the window inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

`window.mvwin(new_y, new_x)`

Move the window so its upper-left corner is at (*new\_y*, *new\_x*).

`window.nodelay(yes)`

If *yes* is 1, *getch()* will be non-blocking.

`window.notimeout(yes)`

If *yes* is 1, escape sequences will not be timed out.

If *yes* is 0, after a few milliseconds, an escape sequence will not be interpreted, and will be left in the input stream as is.

`window.noutrefresh()`

Mark for refresh but wait. This function updates the data structure representing the desired state of the window, but does not force an update of the physical screen. To accomplish that, call *doupdate()*.

`window.overlay(destwin[, sminrow, smincol, dminrow, dmincol, dmaxrow, dmaxcol])`

Overlay the window on top of *destwin*. The windows need not be the same size, only the overlapping region is copied. This copy is non-destructive, which means that the current background character does not overwrite the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of *overlay()* can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, and the other variables mark a rectangle in the destination window.

`window.overwrite(destwin[, sminrow, smincol, dminrow, dmincol, dmaxrow, dmaxcol])`

Overwrite the window on top of *destwin*. The windows need not be the same size, in which case only the overlapping region is copied. This copy is destructive, which means that the current background character overwrites the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of *overwrite()* can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, the other variables mark a rectangle in the destination window.

`window.putwin(file)`

Write all data associated with the window into the provided file object. This information can be later retrieved using the *getwin()* function.

`window.redrawln(beg, num)`

Indicate that the *num* screen lines, starting at line *beg*, are corrupted and should be completely redrawn on the next *refresh()* call.

`window.redrawwin()`

Touch the entire window, causing it to be completely redrawn on the next *refresh()* call.

`window.refresh([pminrow, pmincol, sminrow, smincol, smaxrow, smaxcol])`

Update the display immediately (sync actual screen with previous drawing/deleting methods).

The 6 optional arguments can only be specified when the window is a pad created with *newpad()*. The additional parameters are needed to indicate what part of the pad and screen are involved. *pminrow* and *pmincol* specify the upper left-hand corner of the rectangle to be displayed in the pad. *sminrow*, *smincol*, *smaxrow*, and *smaxcol* specify the edges of the rectangle to be displayed on the screen. The

lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of *pminrow*, *pmincol*, *sminrow*, or *smincol* are treated as if they were zero.

**window.resize(*nlines*, *ncols*)**

Reallocate storage for a curses window to adjust its dimensions to the specified values. If either dimension is larger than the current values, the window's data is filled with blanks that have the current background rendition (as set by *bkgdset()*) merged into them.

**window.scroll([*lines*=1])**

Scroll the screen or scrolling region upward by *lines* lines.

**window.scrollok(*flag*)**

Control what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If *flag* is false, the cursor is left on the bottom line. If *flag* is true, the window is scrolled up one line. Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call *idlok()*.

**window.setscrreg(*top*, *bottom*)**

Set the scrolling region from line *top* to line *bottom*. All scrolling actions will take place in this region.

**window.standend()**

Turn off the standout attribute. On some terminals this has the side effect of turning off all attributes.

**window.standout()**

Turn on attribute *A\_STANDOUT*.

**window.subpad(*begin\_y*, *begin\_x*)**

**window.subpad(*nlines*, *ncols*, *begin\_y*, *begin\_x*)**

Return a sub-window, whose upper-left corner is at (*begin\_y*, *begin\_x*), and whose width/height is *ncols/nlines*.

**window.subwin(*begin\_y*, *begin\_x*)**

**window.subwin(*nlines*, *ncols*, *begin\_y*, *begin\_x*)**

Return a sub-window, whose upper-left corner is at (*begin\_y*, *begin\_x*), and whose width/height is *ncols/nlines*.

By default, the sub-window will extend from the specified position to the lower right corner of the window.

**window.syncdown()**

Touch each location in the window that has been touched in any of its ancestor windows. This routine is called by *refresh()*, so it should almost never be necessary to call it manually.

**window.syncok(*flag*)**

If called with *flag* set to *True*, then *syncup()* is called automatically whenever there is a change in the window.

**window.syncup()**

Touch all locations in ancestors of the window that have been changed in the window.

**window.timeout(*delay*)**

Set blocking or non-blocking read behavior for the window. If *delay* is negative, blocking read is used (which will wait indefinitely for input). If *delay* is zero, then non-blocking read is used, and -1 will be returned by *getch()* if no input is waiting. If *delay* is positive, then *getch()* will block for *delay* milliseconds, and return -1 if there is still no input at the end of that time.

**window.touchline(*start*, *count*[, *changed*])**

Pretend *count* lines have been changed, starting with line *start*. If *changed* is supplied, it specifies

whether the affected lines are marked as having been changed (*changed*=1) or unchanged (*changed*=0).

`window.touchwin()`

Pretend the whole window has been changed, for purposes of drawing optimizations.

`window.untouchwin()`

Mark all lines in the window as unchanged since the last call to *refresh()*.

`window.vline(ch, n)`

`window.vline(y, x, ch, n)`

Display a vertical line starting at (y, x) with length *n* consisting of the character *ch*.

### 15.11.3 Constantes

The *curses* module defines the following data members :

`curses.ERR`

Some curses routines that return an integer, such as *getch()*, return *ERR* upon failure.

`curses.OK`

Some curses routines that return an integer, such as *napms()*, return *OK* upon success.

`curses.version`

A string representing the current version of the module. Also available as `__version__`.

Some constants are available to specify character cell attributes. The exact constants available are system dependent.

Attribut	Signification
A_ALTCHARSET	Alternate character set mode
A_BLINK	Blink mode
A_BOLD	Bold mode
A_DIM	Dim mode
A_INVIS	Invisible or blank mode
A_NORMAL	Normal attribute
A_PROTECT	Protected mode
A_REVERSE	Reverse background and foreground colors
A_STANDOUT	Standout mode
A_UNDERLINE	Underline mode
A_HORIZONTAL	Horizontal highlight
A_LEFT	Left highlight
A_LOW	Low highlight
A_RIGHT	Right highlight
A_TOP	Top highlight
A_VERTICAL	Vertical highlight
A_CHARTEXT	Bit-mask to extract a character

Several constants are available to extract corresponding attributes returned by some methods.

Bit-mask	Signification
A_ATTRIBUTES	Bit-mask to extract attributes
A_CHARTEXT	Bit-mask to extract a character
A_COLOR	Bit-mask to extract color-pair field information

Keys are referred to by integer constants with names starting with `KEY_`. The exact keycaps available are system dependent.

Key constant	Key
KEY_MIN	Minimum key value
KEY_BREAK	Break key (unreliable)
KEY_DOWN	Down-arrow
KEY_UP	Up-arrow
KEY_LEFT	Left-arrow
KEY_RIGHT	Right-arrow
KEY_HOME	Home key (upward+left arrow)
KEY_BACKSPACE	Backspace (unreliable)
KEY_F0	Function keys. Up to 64 function keys are supported.
KEY_Fn	Value of function key <i>n</i>
KEY_DL	Delete line
KEY_IL	Insert line
KEY_DC	Delete character
KEY_IC	Insert char or enter insert mode
KEY_EIC	Exit insert char mode
KEY_CLEAR	Clear screen
KEY_EOS	Clear to end of screen
KEY_EOL	Clear to end of line
KEY_SF	Scroll 1 line forward
KEY_SR	Scroll 1 line backward (reverse)
KEY_NPAGE	Next page
KEY_PPAGE	Previous page
KEY_STAB	Set tab
KEY_CTAB	Clear tab
KEY_CATAB	Clear all tabs
KEY_ENTER	Enter or send (unreliable)
KEY_SRESET	Soft (partial) reset (unreliable)
KEY_RESET	Reset or hard reset (unreliable)
KEY_PRINT	Print
KEY_LL	Home down or bottom (lower left)
KEY_A1	Upper left of keypad
KEY_A3	Upper right of keypad
KEY_B2	Center of keypad
KEY_C1	Lower left of keypad
KEY_C3	Lower right of keypad
KEY_BTAB	Back tab
KEY_BEG	Beg (beginning)
KEY_CANCEL	Cancel
KEY_CLOSE	Close
KEY_COMMAND	Cmd (command)
KEY_COPY	Copy
KEY_CREATE	Create
KEY_END	End
KEY_EXIT	Exit
KEY_FIND	Find
KEY_HELP	Help
KEY_MARK	Mark
KEY_MESSAGE	Message
KEY_MOVE	Move

Suite sur la page suivante

Tableau 1 – suite de la page précédente

Key constant	Key
KEY_NEXT	Next
KEY_OPEN	Open
KEY_OPTIONS	Options
KEY_PREVIOUS	Prev (previous)
KEY_REDO	Redo
KEY_REFERENCE	Ref (reference)
KEY_REFRESH	Refresh
KEY_REPLACE	Replace
KEY_RESTART	Restart
KEY_RESUME	Resume
KEY_SAVE	Save
KEY_SBEG	Shifted Beg (beginning)
KEY_SCANCEL	Shifted Cancel
KEY_SCOMMAND	Shifted Command
KEY_SCOPY	Shifted Copy
KEY_SCREATE	Shifted Create
KEY_SDC	Shifted Delete char
KEY_SDL	Shifted Delete line
KEY_SELECT	Select
KEY_SEND	Shifted End
KEY_SEOL	Shifted Clear line
KEY_SEXIT	Shifted Exit
KEY_SFIND	Shifted Find
KEY_SHELP	Shifted Help
KEY_SHOME	Shifted Home
KEY_SIC	Shifted Input
KEY_SLEFT	Shifted Left arrow
KEY_SMESSAGE	Shifted Message
KEY_SMOVE	Shifted Move
KEY_SNEXT	Shifted Next
KEY_SOPTIONS	Shifted Options
KEY_SPREVIOUS	Shifted Prev
KEY_SPRINT	Shifted Print
KEY_SREDO	Shifted Redo
KEY_SREPLACE	Shifted Replace
KEY_SRIGHT	Shifted Right arrow
KEY_SRSUME	Shifted Resume
KEY_SSAVE	Shifted Save
KEY_SSUSPEND	Shifted Suspend
KEY_SUNDO	Shifted Undo
KEY_SUSPEND	Suspend
KEY_UNDO	Undo
KEY_MOUSE	Mouse event has occurred
KEY_RESIZE	Terminal resize event
KEY_MAX	Maximum key value

On VT100s and their software emulations, such as X terminal emulators, there are normally at least four function keys (`KEY_F1`, `KEY_F2`, `KEY_F3`, `KEY_F4`) available, and the arrow keys mapped to `KEY_UP`, `KEY_DOWN`, `KEY_LEFT` and `KEY_RIGHT` in the obvious way. If your machine has a PC keyboard, it is safe to expect arrow keys and twelve function keys (older PC keyboards may have only ten function keys); also, the following

keypad mappings are standard :

Keycap	Constante
Insert	KEY_IC
Delete	KEY_DC
Home	KEY_HOME
End	KEY_END
Page Up	KEY_PPAGE
Page Down	KEY_NPAGE

The following table lists characters from the alternate character set. These are inherited from the VT100 terminal, and will generally be available on software emulations such as X terminals. When there is no graphic available, curses falls back on a crude printable ASCII approximation.

---

**Note :** These are available only after `initscr()` has been called.

---

ACS code	Signification
ACS_BBSS	alternate name for upper right corner
ACS_BLOCK	solid square block
ACS_BOARD	board of squares
ACS_BSBS	alternate name for horizontal line
ACS_BSSB	alternate name for upper left corner
ACS_BSSS	alternate name for top tee
ACS_BTEE	bottom tee
ACS_BULLET	bullet
ACS_CKBOARD	checker board (stipple)
ACS_DARROW	arrow pointing down
ACS_DEGREE	degree symbol
ACS_DIAMOND	diamond
ACS_GEQUAL	greater-than-or-equal-to
ACS_HLINE	horizontal line
ACS_LANTERN	lantern symbol
ACS_LARROW	left arrow
ACS_LEQUAL	less-than-or-equal-to
ACS_LLCORNER	lower left-hand corner
ACS_LRCORNER	lower right-hand corner
ACS_LTEE	left tee
ACS_NEQUAL	not-equal sign
ACS_PI	letter pi
ACS_PLMINUS	plus-or-minus sign
ACS_PLUS	big plus sign
ACS_RARROW	right arrow
ACS_RTEE	right tee
ACS_S1	scan line 1
ACS_S3	scan line 3
ACS_S7	scan line 7
ACS_S9	scan line 9
ACS_SBBS	alternate name for lower right corner
ACS_SBSB	alternate name for vertical line

ACS_URCORNER	upper right corner
ACS_VLINE	vertical line

The following table lists the predefined colors :

Constante	Color
COLOR_BLACK	Black
COLOR_BLUE	Blue
COLOR_CYAN	Cyan (light greenish blue)
COLOR_GREEN	Green
COLOR_MAGENTA	Magenta (purplish red)
COLOR_RED	Red
COLOR_WHITE	White
COLOR_YELLOW	Yellow

## 15.12 `curses.textpad` — Text input widget for curses programs

Nouveau dans la version 1.6.

The `curses.textpad` module provides a `Textbox` class that handles elementary text editing in a curses window, supporting a set of keybindings resembling those of Emacs (thus, also of Netscape Navigator, BBedit 6.x, FrameMaker, and many other programs). The module also provides a rectangle-drawing function useful for framing text boxes or for other purposes.

The module `curses.textpad` defines the following function :

`curses.textpad.rectangle(win, uly, ulx, lry, lrx)`

Draw a rectangle. The first argument must be a window object; the remaining arguments are coordinates relative to that window. The second and third arguments are the y and x coordinates of the upper left hand corner of the rectangle to be drawn; the fourth and fifth arguments are the y and x coordinates of the lower right hand corner. The rectangle will be drawn using VT100/IBM PC forms characters on terminals that make this possible (including xterm and most other software terminal emulators). Otherwise it will be drawn with ASCII dashes, vertical bars, and plus signs.

### 15.12.1 Textbox objects

You can instantiate a `Textbox` object as follows :

`class curses.textpad.Textbox(win)`

Return a textbox widget object. The `win` argument should be a curses `WindowObject` in which the textbox is to be contained. The edit cursor of the textbox is initially located at the upper left hand corner of the containing window, with coordinates (0, 0). The instance's `stripspaces` flag is initially on.

*Textbox* objects have the following methods :

**edit**(*validator*)

This is the entry point you will normally use. It accepts editing keystrokes until one of the termination keystrokes is entered. If *validator* is supplied, it must be a function. It will be called for each keystroke entered with the keystroke as a parameter; command dispatch is done on the result. This method returns the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* attribute.

**do\_command**(*ch*)

Process a single command keystroke. Here are the supported special keystrokes :

Keystroke	Action
Control-A	Go to left edge of window.
Control-B	Cursor left, wrapping to previous line if appropriate.
Control-D	Delete character under cursor.
Control-E	Go to right edge (stripspaces off) or end of line (stripspaces on).
Control-F	Cursor right, wrapping to next line when appropriate.
Control-G	Terminate, returning the window contents.
Control-H	Delete character backward.
Control-J	Terminate if the window is 1 line, otherwise insert newline.
Control-K	If line is blank, delete it, otherwise clear to end of line.
Control-L	Refresh screen.
Control-N	Cursor down; move down one line.
Control-O	Insert a blank line at cursor location.
Control-P	Cursor up; move up one line.

Move operations do nothing if the cursor is at an edge where the movement is not possible. The following synonyms are supported where possible :

Constante	Keystroke
KEY_LEFT	Control-B
KEY_RIGHT	Control-F
KEY_UP	Control-P
KEY_DOWN	Control-N
KEY_BACKSPACE	Control-h

All other keystrokes are treated as a command to insert the given character and move right (with line wrapping).

**gather**()

Return the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* member.

**stripspaces**

This attribute is a flag which controls the interpretation of blanks in the window. When it is on, trailing blanks on each line are ignored; any cursor motion that would land the cursor on a trailing blank goes to the end of that line instead, and trailing blanks are stripped when the window contents are gathered.

## 15.13 curses.ascii — Utilities for ASCII characters

Nouveau dans la version 1.6.

The *curses.ascii* module supplies name constants for ASCII characters and functions to test membership in various ASCII character classes. The constants supplied are names for control characters as follows :

Nom	Signification
NUL	
SOH	Start of heading, console interrupt
STX	Start of text
ETX	End of text
EOT	End of transmission
ENQ	Enquiry, goes with ACK flow control
ACK	Acknowledgement
BEL	Bell
BS	Backspace
TAB	Tab
HT	Alias for TAB : « Horizontal tab »
LF	Line feed
NL	Alias for LF : « New line »
VT	Vertical tab
FF	Form feed
CR	Retour chariot
SO	Shift-out, begin alternate character set
SI	Shift-in, resume default character set
DLE	Data-link escape
DC1	XON, for flow control
DC2	Device control 2, block-mode flow control
DC3	XOFF, for flow control
DC4	Device control 4
NAK	Negative acknowledgement
SYN	Synchronous idle
ETB	End transmission block
CAN	Cancel
EM	End of medium
SUB	Substitute
ESC	Escape
FS	Séparateur de fichiers
GS	Séparateur de groupe
RS	Record separator, block-mode terminator
US	Unit separator
SP	Space
DEL	Delete

Note that many of these have little practical significance in modern usage. The mnemonics derive from teleprinter conventions that predate digital computers.

The module supplies the following functions, patterned on those in the standard C library :

`curses.ascii.isalnum(c)`

Checks for an ASCII alphanumeric character; it is equivalent to `isalpha(c)` or `isdigit(c)`.

`curses.ascii.isalpha(c)`

Checks for an ASCII alphabetic character; it is equivalent to `isupper(c)` or `islower(c)`.

`curses.ascii.isascii(c)`

Checks for a character value that fits in the 7-bit ASCII set.

`curses.ascii.isblank(c)`

Checks for an ASCII whitespace character; space or horizontal tab.

`curses.ascii.iscntrl(c)`

Checks for an ASCII control character (in the range 0x00 to 0x1f or 0x7f).

`curses.ascii.isdigit(c)`

Checks for an ASCII decimal digit, '0' through '9'. This is equivalent to `c in string.digits`.

`curses.ascii.isgraph(c)`

Checks for ASCII any printable character except space.

`curses.ascii.islower(c)`

Checks for an ASCII lower-case character.

`curses.ascii.isprint(c)`

Checks for any ASCII printable character including space.

`curses.ascii.ispunct(c)`

Checks for any printable ASCII character which is not a space or an alphanumeric character.

`curses.ascii.isspace(c)`

Checks for ASCII white-space characters; space, line feed, carriage return, form feed, horizontal tab, vertical tab.

`curses.ascii.isupper(c)`

Checks for an ASCII uppercase letter.

`curses.ascii.isxdigit(c)`

Checks for an ASCII hexadecimal digit. This is equivalent to `c in string.hexdigits`.

`curses.ascii.isctrl(c)`

Checks for an ASCII control character (ordinal values 0 to 31).

`curses.ascii.ismeta(c)`

Checks for a non-ASCII character (ordinal values 0x80 and above).

These functions accept either integers or strings; when the argument is a string, it is first converted using the built-in function `ord()`.

Note that all these functions check ordinal bit values derived from the first character of the string you pass in; they do not actually know anything about the host machine's character encoding. For functions that know about the character encoding (and handle internationalization properly) see the `string` module.

The following two functions take either a single-character string or integer byte value; they return a value of the same type.

`curses.ascii.ascii(c)`

Return the ASCII value corresponding to the low 7 bits of *c*.

`curses.ascii.ctrl(c)`

Return the control character corresponding to the given character (the character bit value is bitwise-anded with 0x1f).

`curses.ascii.alt(c)`

Return the 8-bit character corresponding to the given ASCII character (the character bit value is bitwise-ored with 0x80).

The following function takes either a single-character string or integer value; it returns a string.

`curses.ascii.unctrl(c)`

Return a string representation of the ASCII character *c*. If *c* is printable, this string is the character itself. If the character is a control character (0x00–0x1f) the string consists of a caret ('^') followed by the corresponding uppercase letter. If the character is an ASCII delete (0x7f) the string is '^?'. If the character has its meta bit (0x80) set, the meta bit is stripped, the preceding rules applied, and '!' prepended to the result.

`curses.ascii.controlnames`

A 33-element string array that contains the ASCII mnemonics for the thirty-two ASCII control characters from 0 (NUL) to 0x1f (US), in order, plus the mnemonic SP for the space character.

## 15.14 `curses.panel` — A panel stack extension for `curses`

Panels are windows with the added feature of depth, so they can be stacked on top of each other, and only the visible portions of each window will be displayed. Panels can be added, moved up or down in the stack, and removed.

### 15.14.1 Fonctions

The module `curses.panel` defines the following functions :

`curses.panel.bottom_panel()`

Returns the bottom panel in the panel stack.

`curses.panel.new_panel(win)`

Returns a panel object, associating it with the given window *win*. Be aware that you need to keep the returned panel object referenced explicitly. If you don't, the panel object is garbage collected and removed from the panel stack.

`curses.panel.top_panel()`

Returns the top panel in the panel stack.

`curses.panel.update_panels()`

Updates the virtual screen after changes in the panel stack. This does not call `curses.doupdate()`, so you'll have to do this yourself.

### 15.14.2 Panel Objects

Panel objects, as returned by `new_panel()` above, are windows with a stacking order. There's always a window associated with a panel which determines the content, while the panel methods are responsible for the window's depth in the panel stack.

Panel objects have the following methods :

`Panel.above()`

Returns the panel above the current panel.

`Panel.below()`

Returns the panel below the current panel.

`Panel.bottom()`

Push the panel to the bottom of the stack.

`Panel.hidden()`

Returns true if the panel is hidden (not visible), false otherwise.

`Panel.hide()`

Hide the panel. This does not delete the object, it just makes the window on screen invisible.

`Panel.move(y, x)`

Move the panel to the screen coordinates (y, x).

`Panel.replace(win)`

Change the window associated with the panel to the window *win*.

`Panel.set_userptr(obj)`

Set the panel's user pointer to *obj*. This is used to associate an arbitrary piece of data with the panel, and can be any Python object.

`Panel.show()`

Display the panel (which might have been hidden).

`Panel.top()`

Push panel to the top of the stack.

`Panel.userptr()`

Returns the user pointer for the panel. This might be any Python object.

`Panel.window()`

Returns the window object associated with the panel.

## 15.15 platform — Access to underlying platform's identifying data

Nouveau dans la version 2.3.

**Code source :** [Lib/platform.py](#)

---

---

**Note :** Specific platforms listed alphabetically, with Linux included in the Unix section.

---

### 15.15.1 Cross Platform

`platform.architecture(executable=sys.executable, bits="", linkage="")`

Queries the given executable (defaults to the Python interpreter binary) for various architecture information.

Returns a tuple (**bits**, **linkage**) which contain information about the bit architecture and the linkage format used for the executable. Both values are returned as strings.

Values that cannot be determined are returned as given by the parameter presets. If bits is given as '', the `sizeof(pointer)` (or `sizeof(long)` on Python version < 1.5.2) is used as indicator for the supported pointer size.

The function relies on the system's `file` command to do the actual work. This is available on most if not all Unix platforms and some non-Unix platforms and then only if the executable points to the Python interpreter. Reasonable defaults are used when the above needs are not met.

---

**Note :** On Mac OS X (and perhaps other platforms), executable files may be universal files containing multiple architectures.

To get at the « 64-bitness » of the current interpreter, it is more reliable to query the `sys.maxsize` attribute :

```
is_64bits = sys.maxsize > 2**32
```

---

`platform.machine()`

Returns the machine type, e.g. 'i386'. An empty string is returned if the value cannot be determined.

`platform.node()`

Returns the computer's network name (may not be fully qualified!). An empty string is returned if the value cannot be determined.

`platform.platform(aliased=0, terse=0)`

Returns a single string identifying the underlying platform with as much useful information as possible. The output is intended to be *human readable* rather than machine parseable. It may look different on different platforms and this is intended.

If *aliased* is true, the function will use aliases for various platforms that report system names which differ from their common names, for example SunOS will be reported as Solaris. The `system_alias()` function is used to implement this.

Setting *terse* to true causes the function to return only the absolute minimum information needed to identify the platform.

`platform.processor()`

Returns the (real) processor name, e.g. 'amd64'.

An empty string is returned if the value cannot be determined. Note that many platforms do not provide this information or simply return the same value as for `machine()`. NetBSD does this.

`platform.python_build()`

Returns a tuple (buildno, builddate) stating the Python build number and date as strings.

`platform.python_compiler()`

Returns a string identifying the compiler used for compiling Python.

`platform.python_branch()`

Returns a string identifying the Python implementation SCM branch.

Nouveau dans la version 2.6.

`platform.python_implementation()`

Returns a string identifying the Python implementation. Possible return values are : "CPython", "Iron-Python", "Jython", "PyPy".

Nouveau dans la version 2.6.

`platform.python_revision()`

Returns a string identifying the Python implementation SCM revision.

Nouveau dans la version 2.6.

`platform.python_version()`

Returns the Python version as string 'major.minor.patchlevel'.

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to 0).

`platform.python_version_tuple()`

Returns the Python version as tuple (major, minor, patchlevel) of strings.

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to '0').

`platform.release()`

Returns the system's release, e.g. '2.2.0' or 'NT'. An empty string is returned if the value cannot be determined.

`platform.system()`

Returns the system/OS name, e.g. 'Linux', 'Windows', or 'Java'. An empty string is returned if the value cannot be determined.

`platform.system_alias(system, release, version)`

Returns (system, release, version) aliased to common marketing names used for some systems. It also does some reordering of the information in some cases where it would otherwise cause confusion.

`platform.version()`

Returns the system's release version, e.g. '#3 on degas'. An empty string is returned if the value cannot be determined.

`platform.uname()`

Fairly portable uname interface. Returns a tuple of strings (`system`, `node`, `release`, `version`, `machine`, `processor`) identifying the underlying platform.

Note that unlike the `os.uname()` function this also returns possible processor information as additional tuple entry.

Entries which cannot be determined are set to ''.

### 15.15.2 Java Platform

`platform.java_ver(release="", vendor="", vminfo=("", "", ""), osinfo=("", "", ""))`

Version interface for Jython.

Returns a tuple (`release`, `vendor`, `vminfo`, `osinfo`) with `vminfo` being a tuple (`vm_name`, `vm_release`, `vm_vendor`) and `osinfo` being a tuple (`os_name`, `os_version`, `os_arch`). Values which cannot be determined are set to the defaults given as parameters (which all default to '').

### 15.15.3 Windows Platform

`platform.win32_ver(release="", version="", csd="", ptype="")`

Get additional version information from the Windows Registry and return a tuple (`release`, `version`, `csd`, `ptype`) referring to OS release, version number, CSD level (service pack) and OS type (multi/single processor).

As a hint : `ptype` is 'Uniprocessor Free' on single processor NT machines and 'Multiprocessor Free' on multi processor machines. The "Free" refers to the OS version being free of debugging code. It could also state "Checked" which means the OS version uses debugging code, i.e. code that checks arguments, ranges, etc.

---

**Note :** This function works best with Mark Hammond's `win32all` package installed, but also on Python 2.3 and later (support for this was added in Python 2.6). It obviously only runs on Win32 compatible platforms.

---

#### Win95/98 specific

`platform.popen(cmd, mode='r', bufsize=None)`

Portable `popen()` interface. Find a working popen implementation preferring `win32pipe.popen()`. On Windows NT, `win32pipe.popen()` should work; on Windows 9x it hangs due to bugs in the MS C library.

### 15.15.4 Mac OS Platform

`platform.mac_ver(release="", versioninfo=("", "", ""), machine="")`

Get Mac OS version information and return it as tuple (`release`, `versioninfo`, `machine`) with `versioninfo` being a tuple (`version`, `dev_stage`, `non_release_version`).

Entries which cannot be determined are set to ''. All tuple entries are strings.

### 15.15.5 Unix Platforms

`platform.dist(distname="", version="", id="", supported_dists=('SuSE', 'debian', 'redhat', 'mandrake', ...))`

This is an old version of the functionality now provided by `linux_distribution()`. For new code, please use the `linux_distribution()`.

The only difference between the two is that `dist()` always returns the short name of the distribution taken from the `supported_dists` parameter.

Obsolète depuis la version 2.6.

`platform.linux_distribution(distname="", version="", id="", supported_dists=('SuSE', 'debian', 'redhat', 'mandrake', ...), full_distribution_name=1)`

Tries to determine the name of the Linux OS distribution name.

`supported_dists` may be given to define the set of Linux distributions to look for. It defaults to a list of currently supported Linux distributions identified by their release file name.

If `full_distribution_name` is true (default), the full distribution read from the OS is returned. Otherwise the short name taken from `supported_dists` is used.

Returns a tuple (`distname`, `version`, `id`) which defaults to the args given as parameters. `id` is the item in parentheses after the version number. It is usually the version codename.

---

**Note :** This function is deprecated since Python 3.5 and removed in Python 3.8. See alternative like the [distro](#) package.

---

Nouveau dans la version 2.6.

`platform.libc_ver(executable=sys.executable, lib="", version="", chunksize=2048)`

Tries to determine the libc version against which the file executable (defaults to the Python interpreter) is linked. Returns a tuple of strings (`lib`, `version`) which default to the given parameters in case the lookup fails.

Note that this function has intimate knowledge of how different libc versions add symbols to the executable is probably only usable for executables compiled using `gcc`.

The file is read and scanned in chunks of `chunksize` bytes.

## 15.16 `errno` — Standard `errno` system symbols

This module makes available standard `errno` system symbols. The value of each symbol is the corresponding integer value. The names and descriptions are borrowed from `linux/include/errno.h`, which should be pretty all-inclusive.

### `errno.errorcode`

Dictionary providing a mapping from the `errno` value to the string name in the underlying system. For instance, `errno.errorcode[errno.EPERM]` maps to `'EPERM'`.

To translate a numeric error code to an error message, use `os.strerror()`.

Of the following list, symbols that are not used on the current platform are not defined by the module. The specific list of defined symbols is available as `errno.errorcode.keys()`. Symbols available can include :

#### `errno.EPERM`

Operation not permitted

#### `errno.ENOENT`

No such file or directory

#### `errno.ESRCH`

No such process

#### `errno.EINTR`

Interrupted system call

#### `errno.EIO`

I/O error

#### `errno.ENXIO`

No such device or address

#### `errno.E2BIG`

Arg list too long

`errno.ENOEXEC`  
Exec format error

`errno.EBADF`  
Bad file number

`errno.ECHILD`  
No child processes

`errno.EAGAIN`  
Try again

`errno.ENOMEM`  
Out of memory

`errno.EACCES`  
Permission denied

`errno.EFAULT`  
Bad address

`errno.ENOTBLK`  
Block device required

`errno.EBUSY`  
Device or resource busy

`errno.EEXIST`  
File exists

`errno.EXDEV`  
Cross-device link

`errno.ENODEV`  
No such device

`errno.ENOTDIR`  
Not a directory

`errno.EISDIR`  
Is a directory

`errno.EINVAL`  
Argument invalide

`errno.ENFILE`  
File table overflow

`errno.EMFILE`  
Too many open files

`errno.ENOTTY`  
Not a typewriter

`errno.ETXTBSY`  
Text file busy

`errno.EFBIG`  
File too large

`errno.ENOSPC`  
No space left on device

**errno.ESPIPE**  
Illegal seek

**errno.EROFS**  
Read-only file system

**errno.EMLINK**  
Too many links

**errno.EPIPE**  
Broken pipe

**errno.EDOM**  
Math argument out of domain of func

**errno.ERANGE**  
Math result not representable

**errno.EDEADLK**  
Resource deadlock would occur

**errno.ENAMETOOLONG**  
File name too long

**errno.ENOLCK**  
No record locks available

**errno.ENOSYS**  
Function not implemented

**errno.ENOTEMPTY**  
Directory not empty

**errno.ELOOP**  
Too many symbolic links encountered

**errno.EWOULDBLOCK**  
Operation would block

**errno.ENOMSG**  
No message of desired type

**errno.EIDRM**  
Identifier removed

**errno.ECHRNG**  
Channel number out of range

**errno.EL2NSYNC**  
Level 2 not synchronized

**errno.EL3HLT**  
Level 3 halted

**errno.EL3RST**  
Level 3 reset

**errno.ELNRNG**  
Link number out of range

**errno.EUNATCH**  
Protocol driver not attached

**errno.ENOCSI**  
No CSI structure available

**errno.EL2HLT**  
Level 2 halted

**errno.EBADE**  
Invalid exchange

**errno.EBADR**  
Invalid request descriptor

**errno.EXFULL**  
Exchange full

**errno.ENOANO**  
No anode

**errno.EBADRQC**  
Invalid request code

**errno.EBADSLT**  
Invalid slot

**errno.EDEADLOCK**  
File locking deadlock error

**errno.EBFONT**  
Bad font file format

**errno.ENOSTR**  
Device not a stream

**errno.ENODATA**  
No data available

**errno.ETIME**  
Timer expired

**errno.ENOSR**  
Out of streams resources

**errno.ENONET**  
Machine is not on the network

**errno.ENOPKG**  
Package not installed

**errno.EREMOTE**  
Object is remote

**errno.ENOLINK**  
Link has been severed

**errno.EADV**  
Advertise error

**errno.ESRMNT**  
Srmount error

**errno.ECOMM**  
Communication error on send

**errno.EPROTO**  
Protocol error

**errno.EMULTIHOP**  
Multihop attempted

**errno.EDOTDOT**  
RFS specific error

**errno.EBADMSG**  
Not a data message

**errno.EOVERFLOW**  
Value too large for defined data type

**errno.ENOTUNIQ**  
Name not unique on network

**errno.EBADFD**  
File descriptor in bad state

**errno.EREMCHG**  
Remote address changed

**errno.ELIBACC**  
Can not access a needed shared library

**errno.ELIBBAD**  
Accessing a corrupted shared library

**errno.ELIBSCN**  
.lib section in a.out corrupted

**errno.ELIBMAX**  
Attempting to link in too many shared libraries

**errno.ELIBEXEC**  
Cannot exec a shared library directly

**errno.EILSEQ**  
Illegal byte sequence

**errno.ERESTART**  
Interrupted system call should be restarted

**errno.ESTRPIPE**  
Streams pipe error

**errno.EUSERS**  
Too many users

**errno.ENOTSOCK**  
Socket operation on non-socket

**errno.EDESTADDRREQ**  
Destination address required

**errno.EMSGSIZE**  
Message too long

**errno.EPROTOTYPE**  
Protocol wrong type for socket

`errno.ENOPROTOOPT`  
Protocol not available

`errno.EPROTONOSUPPORT`  
Protocol not supported

`errno.ESOCKTNOSUPPORT`  
Socket type not supported

`errno.EOPNOTSUPP`  
Operation not supported on transport endpoint

`errno.EPFNOSUPPORT`  
Protocol family not supported

`errno.EAFNOSUPPORT`  
Address family not supported by protocol

`errno.EADDRINUSE`  
Address already in use

`errno.EADDRNOTAVAIL`  
Cannot assign requested address

`errno.ENETDOWN`  
Network is down

`errno.ENETUNREACH`  
Network is unreachable

`errno.ENETRESET`  
Network dropped connection because of reset

`errno.ECONNABORTED`  
Software caused connection abort

`errno.ECONNRESET`  
Connection reset by peer

`errno.ENOBUFS`  
No buffer space available

`errno.EISCONN`  
Transport endpoint is already connected

`errno.ENOTCONN`  
Transport endpoint is not connected

`errno.ESHUTDOWN`  
Cannot send after transport endpoint shutdown

`errno.ETOOMANYREFS`  
Too many references : cannot splice

`errno.ETIMEDOUT`  
Connection timed out

`errno.ECONNREFUSED`  
Connection refused

`errno.EHOSTDOWN`  
Host is down

`errno.EHOSTUNREACH`  
No route to host

`errno.EALREADY`  
Operation already in progress

`errno.EINPROGRESS`  
Operation now in progress

`errno.ESTALE`  
Stale NFS file handle

`errno.EUCLEAN`  
Structure needs cleaning

`errno.ENOTNAM`  
Not a XENIX named type file

`errno.ENAVAIL`  
No XENIX semaphores available

`errno.EISNAM`  
Is a named type file

`errno.EREMOTEIO`  
Remote I/O error

`errno.EDQUOT`  
Quota exceeded

## 15.17 ctypes — A foreign function library for Python

Nouveau dans la version 2.5.

*ctypes* is a foreign function library for Python. It provides C compatible data types, and allows calling functions in DLLs or shared libraries. It can be used to wrap these libraries in pure Python.

### 15.17.1 ctypes tutorial

Note : The code samples in this tutorial use *doctest* to make sure that they actually work. Since some code samples behave differently under Linux, Windows, or Mac OS X, they contain doctest directives in comments.

Note : Some code samples reference the ctypes *c\_int* type. This type is an alias for the *c\_long* type on 32-bit systems. So, you should not be confused if *c\_long* is printed if you would expect *c\_int* — they are actually the same type.

#### Loading dynamic link libraries

*ctypes* exports the *cdll*, and on Windows *windll* and *oledll* objects, for loading dynamic link libraries.

You load libraries by accessing them as attributes of these objects. *cdll* loads libraries which export functions using the standard *cdecl* calling convention, while *windll* libraries call functions using the *stdcall* calling convention. *oledll* also uses the *stdcall* calling convention, and assumes the functions return a Windows *HRESULT* error code. The error code is used to automatically raise a *WindowsError* exception when the function call fails.

Here are some examples for Windows. Note that *msvcrt* is the MS standard C library containing most standard C functions, and uses the *cdecl* calling convention :

```
>>> from ctypes import *
>>> print windll.kernel32
<WinDLL 'kernel32', handle ... at ...>
>>> print cdll.msvcrt
<CDLL 'msvcrt', handle ... at ...>
>>> libc = cdll.msvcrt
>>>
```

Windows appends the usual `.dll` file suffix automatically.

On Linux, it is required to specify the filename *including* the extension to load a library, so attribute access can not be used to load libraries. Either the `LoadLibrary()` method of the dll loaders should be used, or you should load the library by creating an instance of `CDLL` by calling the constructor :

```
>>> cdll.LoadLibrary("libc.so.6")
<CDLL 'libc.so.6', handle ... at ...>
>>> libc = CDLL("libc.so.6")
>>> libc
<CDLL 'libc.so.6', handle ... at ...>
>>>
```

### Accessing functions from loaded dlls

Functions are accessed as attributes of dll objects :

```
>>> from ctypes import *
>>> libc.printf
<_FuncPtr object at 0x...>
>>> print windll.kernel32.GetModuleHandleA
<_FuncPtr object at 0x...>
>>> print windll.kernel32.MyOwnFunction
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 239, in __getattr__
    func = _StdcallFuncPtr(name, self)
AttributeError: function 'MyOwnFunction' not found
>>>
```

Note that win32 system dlls like `kernel32` and `user32` often export ANSI as well as UNICODE versions of a function. The UNICODE version is exported with an `W` appended to the name, while the ANSI version is exported with an `A` appended to the name. The win32 `GetModuleHandle` function, which returns a *module handle* for a given module name, has the following C prototype, and a macro is used to expose one of them as `GetModuleHandle` depending on whether UNICODE is defined or not :

```
/* ANSI version */
HMODULE GetModuleHandleA(LPCSTR lpModuleName);
/* UNICODE version */
HMODULE GetModuleHandleW(LPCWSTR lpModuleName);
```

`windll` does not try to select one of them by magic, you must access the version you need by specifying `GetModuleHandleA` or `GetModuleHandleW` explicitly, and then call it with strings or unicode strings respectively.

Sometimes, dlls export functions with names which aren't valid Python identifiers, like `???2@YAPAXI@Z`. In this case you have to use `getattr()` to retrieve the function :

```
>>> getattr(cdll.msvcrt, "??2@YAPAXI@Z")
<_FuncPtr object at 0x...>
>>>
```

On Windows, some dlls export functions not by name but by ordinal. These functions can be accessed by indexing the dll object with the ordinal number :

```
>>> cdll.kernel32[1]
<_FuncPtr object at 0x...>
>>> cdll.kernel32[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 310, in __getitem__
    func = _StdcallFuncPtr(name, self)
AttributeError: function ordinal 0 not found
>>>
```

### Calling functions

You can call these functions like any other Python callable. This example uses the `time()` function, which returns system time in seconds since the Unix epoch, and the `GetModuleHandleA()` function, which returns a win32 module handle.

This example calls both functions with a NULL pointer (`None` should be used as the NULL pointer) :

```
>>> print libc.time(None)
1150640792
>>> print hex(windll.kernel32.GetModuleHandleA(None))
0x1d000000
>>>
```

`ctypes` tries to protect you from calling functions with the wrong number of arguments or the wrong calling convention. Unfortunately this only works on Windows. It does this by examining the stack after the function returns, so although an error is raised the function *has* been called :

```
>>> windll.kernel32.GetModuleHandleA()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with not enough arguments (4 bytes missing)
>>> windll.kernel32.GetModuleHandleA(0, 0)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with too many arguments (4 bytes in excess)
>>>
```

The same exception is raised when you call an `stdcall` function with the `cdecl` calling convention, or vice versa :

```
>>> cdll.kernel32.GetModuleHandleA(None)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with not enough arguments (4 bytes missing)
>>>
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> windll.msvcrt.printf("spam")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with too many arguments (4 bytes in excess)
>>>
```

To find out the correct calling convention you have to look into the C header file or the documentation for the function you want to call.

On Windows, `ctypes` uses win32 structured exception handling to prevent crashes from general protection faults when functions are called with invalid argument values :

```
>>> windll.kernel32.GetModuleHandleA(32)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
WindowsError: exception: access violation reading 0x00000020
>>>
```

There are, however, enough ways to crash Python with `ctypes`, so you should be careful anyway.

`None`, integers, longs, byte strings and unicode strings are the only native Python objects that can directly be used as parameters in these function calls. `None` is passed as a C `NULL` pointer, byte strings and unicode strings are passed as pointer to the memory block that contains their data (`char *` or `wchar_t *`). Python integers and Python longs are passed as the platforms default C `int` type, their value is masked to fit into the C type.

Before we move on calling functions with other parameter types, we have to learn more about `ctypes` data types.

## Fundamental data types

`ctypes` defines a number of primitive C compatible data types :

Type <i>ctype</i>	Type C	Type Python
<code>c_bool</code>	<code>_Bool</code>	<code>bool</code> (1)
<code>c_char</code>	<code>char</code>	1-character string
<code>c_wchar</code>	<code>wchar_t</code>	1-character unicode string
<code>c_byte</code>	<code>char</code>	<code>int/long</code>
<code>c_ubyte</code>	<code>unsigned char</code>	<code>int/long</code>
<code>c_short</code>	<code>short</code>	<code>int/long</code>
<code>c_ushort</code>	<code>unsigned short</code>	<code>int/long</code>
<code>c_int</code>	<code>int</code>	<code>int/long</code>
<code>c_uint</code>	<code>unsigned int</code>	<code>int/long</code>
<code>c_long</code>	<code>long</code>	<code>int/long</code>
<code>c_ulong</code>	<code>unsigned long</code>	<code>int/long</code>
<code>c_longlong</code>	<code>__int64</code> ou <code>long long</code>	<code>int/long</code>
<code>c_ulonglong</code>	<code>unsigned __int64</code> or <code>unsigned long long</code>	<code>int/long</code>
<code>c_float</code>	<code>float</code>	<code>float</code>
<code>c_double</code>	<code>double</code>	<code>float</code>
<code>c_longdouble</code>	<code>long double</code>	<code>float</code>
<code>c_char_p</code>	<code>char *</code> (NUL terminated)	string ou <code>None</code>
<code>c_wchar_p</code>	<code>wchar_t *</code> (Terminé par NUL)	unicode or <code>None</code>
<code>c_void_p</code>	<code>void *</code>	<code>int/long</code> or <code>None</code>

- (1) The constructor accepts any object with a truth value.

All these types can be created by calling them with an optional initializer of the correct type and value :

```
>>> c_int()
c_long(0)
>>> c_char_p("Hello, World")
c_char_p('Hello, World')
>>> c_ushort(-3)
c_ushort(65533)
>>>
```

Since these types are mutable, their value can also be changed afterwards :

```
>>> i = c_int(42)
>>> print i
c_long(42)
>>> print i.value
42
>>> i.value = -99
>>> print i.value
-99
>>>
```

Assigning a new value to instances of the pointer types `c_char_p`, `c_wchar_p`, and `c_void_p` changes the *memory location* they point to, *not the contents* of the memory block (of course not, because Python strings are immutable) :

```
>>> s = "Hello, World"
>>> c_s = c_char_p(s)
>>> print c_s
c_char_p('Hello, World')
>>> c_s.value = "Hi, there"
>>> print c_s
c_char_p('Hi, there')
>>> print s                                # first string is unchanged
Hello, World
>>>
```

You should be careful, however, not to pass them to functions expecting pointers to mutable memory. If you need mutable memory blocks, ctypes has a `create_string_buffer()` function which creates these in various ways. The current memory block contents can be accessed (or changed) with the `raw` property; if you want to access it as NUL terminated string, use the `value` property :

```
>>> from ctypes import *
>>> p = create_string_buffer(3)          # create a 3 byte buffer, initialized to NUL bytes
>>> print sizeof(p), repr(p.raw)
3 '\x00\x00\x00'
>>> p = create_string_buffer("Hello")    # create a buffer containing a NUL terminated
↪ string
>>> print sizeof(p), repr(p.raw)
6 'Hello\x00'
>>> print repr(p.value)
'Hello'
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> p = create_string_buffer("Hello", 10) # create a 10 byte buffer
>>> print sizeof(p), repr(p.raw)
10 'Hello\x00\x00\x00\x00\x00'
>>> p.value = "Hi"
>>> print sizeof(p), repr(p.raw)
10 'Hi\x00lo\x00\x00\x00\x00'
>>>
```

The `create_string_buffer()` function replaces the `c_buffer()` function (which is still available as an alias), as well as the `c_string()` function from earlier ctypes releases. To create a mutable memory block containing unicode characters of the C type `wchar_t` use the `create_unicode_buffer()` function.

### Calling functions, continued

Note that `printf` prints to the real standard output channel, *not* to `sys.stdout`, so these examples will only work at the console prompt, not from within *IDLE* or *PythonWin* :

```
>>> printf = libc.printf
>>> printf("Hello, %s\n", "World!")
Hello, World!
14
>>> printf("Hello, %S\n", u"World!")
Hello, World!
14
>>> printf("%d bottles of beer\n", 42)
42 bottles of beer
19
>>> printf("%f bottles of beer\n", 42.5)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: Don't know how to convert parameter 2
>>>
```

As has been mentioned before, all Python types except integers, strings, and unicode strings have to be wrapped in their corresponding *ctypes* type, so that they can be converted to the required C data type :

```
>>> printf("An int %d, a double %f\n", 1234, c_double(3.14))
An int 1234, a double 3.140000
31
>>>
```

### Calling functions with your own custom data types

You can also customize *ctypes* argument conversion to allow instances of your own classes be used as function arguments. *ctypes* looks for an `_as_parameter_` attribute and uses this as the function argument. Of course, it must be one of integer, string, or unicode :

```
>>> class Bottles(object):
...     def __init__(self, number):
...         self._as_parameter_ = number
...
>>> bottles = Bottles(42)
>>> printf("%d bottles of beer\n", bottles)
```

(suite sur la page suivante)

(suite de la page précédente)

```
42 bottles of beer
19
>>>
```

If you don't want to store the instance's data in the `_as_parameter_` instance variable, you could define a *property()* which makes the data available.

### Specifying the required argument types (function prototypes)

It is possible to specify the required argument types of functions exported from DLLs by setting the `argtypes` attribute.

`argtypes` must be a sequence of C data types (the `printf` function is probably not a good example here, because it takes a variable number and different types of parameters depending on the format string, on the other hand this is quite handy to experiment with this feature) :

```
>>> printf.argtypes = [c_char_p, c_char_p, c_int, c_double]
>>> printf("String '%s', Int %d, Double %f\n", "Hi", 10, 2.2)
String 'Hi', Int 10, Double 2.200000
37
>>>
```

Specifying a format protects against incompatible argument types (just as a prototype for a C function), and tries to convert the arguments to valid types :

```
>>> printf("%d %d %d", 1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: wrong type
>>> printf("%s %d %f\n", "X", 2, 3)
X 2 3.000000
13
>>>
```

If you have defined your own classes which you pass to function calls, you have to implement a `from_param()` class method for them to be able to use them in the `argtypes` sequence. The `from_param()` class method receives the Python object passed to the function call, it should do a typecheck or whatever is needed to make sure this object is acceptable, and then return the object itself, its `_as_parameter_` attribute, or whatever you want to pass as the C function argument in this case. Again, the result should be an integer, string, unicode, a *ctypes* instance, or an object with an `_as_parameter_` attribute.

### Return types

By default functions are assumed to return the C `int` type. Other return types can be specified by setting the `restype` attribute of the function object.

Here is a more advanced example, it uses the `strchr` function, which expects a string pointer and a char, and returns a pointer to a string :

```
>>> strchr = libc.strchr
>>> strchr("abcdef", ord("d"))
8059983
>>> strchr.restype = c_char_p    # c_char_p is a pointer to a string
>>> strchr("abcdef", ord("d"))
```

(suite sur la page suivante)

(suite de la page précédente)

```
'def'
>>> print strchr("abcdef", ord("x"))
None
>>>
```

If you want to avoid the `ord("x")` calls above, you can set the `argtypes` attribute, and the second argument will be converted from a single character Python string into a C char :

```
>>> strchr.restype = c_char_p
>>> strchr.argtypes = [c_char_p, c_char]
>>> strchr("abcdef", "d")
'def'
>>> strchr("abcdef", "def")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: one character string expected
>>> print strchr("abcdef", "x")
None
>>> strchr("abcdef", "d")
'def'
>>>
```

You can also use a callable Python object (a function or a class for example) as the `restype` attribute, if the foreign function returns an integer. The callable will be called with the *integer* the C function returns, and the result of this call will be used as the result of your function call. This is useful to check for error return values and automatically raise an exception :

```
>>> GetModuleHandle = windll.kernel32.GetModuleHandleA
>>> def ValidHandle(value):
...     if value == 0:
...         raise WinError()
...     return value
...
>>>
>>> GetModuleHandle.restype = ValidHandle
>>> GetModuleHandle(None)
486539264
>>> GetModuleHandle("something silly")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 3, in ValidHandle
WindowsError: [Errno 126] The specified module could not be found.
>>>
```

`WinError` is a function which will call Windows `FormatMessage()` api to get the string representation of an error code, and *returns* an exception. `WinError` takes an optional error code parameter, if no one is used, it calls `GetLastError()` to retrieve it.

Please note that a much more powerful error checking mechanism is available through the `errcheck` attribute ; see the reference manual for details.

### Passing pointers (or : passing parameters by reference)

Sometimes a C api function expects a *pointer* to a data type as parameter, probably to write into the corresponding location, or if the data is too large to be passed by value. This is also known as *passing parameters by reference*.

`ctypes` exports the `byref()` function which is used to pass parameters by reference. The same effect can be achieved with the `pointer()` function, although `pointer()` does a lot more work since it constructs a real pointer object, so it is faster to use `byref()` if you don't need the pointer object in Python itself :

```
>>> i = c_int()
>>> f = c_float()
>>> s = create_string_buffer('\000' * 32)
>>> print i.value, f.value, repr(s.value)
0 0.0 ''
>>> libc.sscanf("1 3.14 Hello", "%d %f %s",
...             byref(i), byref(f), s)
3
>>> print i.value, f.value, repr(s.value)
1 3.1400001049 'Hello'
>>>
```

### Structures and unions

Structures and unions must derive from the `Structure` and `Union` base classes which are defined in the `ctypes` module. Each subclass must define a `_fields_` attribute. `_fields_` must be a list of *2-tuples*, containing a *field name* and a *field type*.

The field type must be a `ctypes` type like `c_int`, or any other derived `ctypes` type : structure, union, array, pointer.

Here is a simple example of a POINT structure, which contains two integers named *x* and *y*, and also shows how to initialize a structure in the constructor :

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = [("x", c_int),
...                 ("y", c_int)]
...
>>> point = POINT(10, 20)
>>> print point.x, point.y
10 20
>>> point = POINT(y=5)
>>> print point.x, point.y
0 5
>>> POINT(1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: too many initializers
>>>
```

You can, however, build much more complicated structures. A structure can itself contain other structures by using a structure as a field type.

Here is a RECT structure which contains two POINTs named *upperleft* and *lowerright* :

```
>>> class RECT(Structure):
...     _fields_ = [("upperleft", POINT),
...                 ("lowerright", POINT)]
...
>>> rc = RECT(point)
>>> print rc.upperleft.x, rc.upperleft.y
0 5
>>> print rc.lowerright.x, rc.lowerright.y
0 0
>>>
```

Nested structures can also be initialized in the constructor in several ways :

```
>>> r = RECT(POINT(1, 2), POINT(3, 4))
>>> r = RECT((1, 2), (3, 4))
```

Field *descriptors* can be retrieved from the *class*, they are useful for debugging because they can provide useful information :

```
>>> print POINT.x
<Field type=c_long, ofs=0, size=4>
>>> print POINT.y
<Field type=c_long, ofs=4, size=4>
>>>
```

**Avertissement :** *ctypes* does not support passing unions or structures with bit-fields to functions by value. While this may work on 32-bit x86, it's not guaranteed by the library to work in the general case. Unions and structures with bit-fields should always be passed to functions by pointer.

### Structure/union alignment and byte order

By default, Structure and Union fields are aligned in the same way the C compiler does it. It is possible to override this behavior by specifying a `_pack_` class attribute in the subclass definition. This must be set to a positive integer and specifies the maximum alignment for the fields. This is what `#pragma pack(n)` also does in MSVC.

*ctypes* uses the native byte order for Structures and Unions. To build structures with non-native byte order, you can use one of the *BigEndianStructure*, *LittleEndianStructure*, *BigEndianUnion*, and *LittleEndianUnion* base classes. These classes cannot contain pointer fields.

### Bit fields in structures and unions

It is possible to create structures and unions containing bit fields. Bit fields are only possible for integer fields, the bit width is specified as the third item in the `_fields_` tuples :

```
>>> class Int(Structure):
...     _fields_ = [("first_16", c_int, 16),
...                 ("second_16", c_int, 16)]
...
>>> print Int.first_16
<Field type=c_long, ofs=0:0, bits=16>
>>> print Int.second_16
```

(suite sur la page suivante)

(suite de la page précédente)

```
<Field type=c_long, ofs=0:16, bits=16>
>>>
```

## Arrays

Arrays are sequences, containing a fixed number of instances of the same type.

The recommended way to create array types is by multiplying a data type with a positive integer :

```
TenPointsArrayType = POINT * 10
```

Here is an example of a somewhat artificial data type, a structure containing 4 POINTs among other stuff :

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class MyStruct(Structure):
...     _fields_ = [("a", c_int),
...                 ("b", c_float),
...                 ("point_array", POINT * 4)]
>>>
>>> print len(MyStruct().point_array)
4
>>>
```

Instances are created in the usual way, by calling the class :

```
arr = TenPointsArrayType()
for pt in arr:
    print pt.x, pt.y
```

The above code print a series of 0 0 lines, because the array contents is initialized to zeros.

Initializers of the correct type can also be specified :

```
>>> from ctypes import *
>>> TenIntegers = c_int * 10
>>> ii = TenIntegers(1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
>>> print ii
<c_long_Array_10 object at 0x...>
>>> for i in ii: print i,
...
1 2 3 4 5 6 7 8 9 10
>>>
```

## Pointers

Pointer instances are created by calling the *pointer()* function on a *ctypes* type :

```
>>> from ctypes import *
>>> i = c_int(42)
>>> pi = pointer(i)
>>>
```

Pointer instances have a `contents` attribute which returns the object to which the pointer points, the `i` object above :

```
>>> pi.contents
c_long(42)
>>>
```

Note that `ctypes` does not have OOR (original object return), it constructs a new, equivalent object each time you retrieve an attribute :

```
>>> pi.contents is i
False
>>> pi.contents is pi.contents
False
>>>
```

Assigning another `c_int` instance to the pointer's `contents` attribute would cause the pointer to point to the memory location where this is stored :

```
>>> i = c_int(99)
>>> pi.contents = i
>>> pi.contents
c_long(99)
>>>
```

Pointer instances can also be indexed with integers :

```
>>> pi[0]
99
>>>
```

Assigning to an integer index changes the pointed to value :

```
>>> print i
c_long(99)
>>> pi[0] = 22
>>> print i
c_long(22)
>>>
```

It is also possible to use indexes different from 0, but you must know what you're doing, just as in C : You can access or change arbitrary memory locations. Generally you only use this feature if you receive a pointer from a C function, and you *know* that the pointer actually points to an array instead of a single item.

Behind the scenes, the `pointer()` function does more than simply create pointer instances, it has to create pointer *types* first. This is done with the `POINTER()` function, which accepts any `ctypes` type, and returns a new type :

```
>>> PI = POINTER(c_int)
>>> PI
<class 'ctypes.LP_c_int'>
>>> PI(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: expected c_int instead of int
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> PI(c_int(42))
<ctypes.LP_c_long object at 0x...>
>>>
```

Calling the pointer type without an argument creates a **NULL** pointer. **NULL** pointers have a **False** boolean value :

```
>>> null_ptr = POINTER(c_int)()
>>> print bool(null_ptr)
False
>>>
```

*ctypes* checks for **NULL** when dereferencing pointers (but dereferencing invalid non-**NULL** pointers would crash Python) :

```
>>> null_ptr[0]
Traceback (most recent call last):
....
ValueError: NULL pointer access
>>>

>>> null_ptr[0] = 1234
Traceback (most recent call last):
....
ValueError: NULL pointer access
>>>
```

### Type conversions

Usually, *ctypes* does strict type checking. This means, if you have `POINTER(c_int)` in the `argtypes` list of a function or as the type of a member field in a structure definition, only instances of exactly the same type are accepted. There are some exceptions to this rule, where *ctypes* accepts other objects. For example, you can pass compatible array instances instead of pointer types. So, for `POINTER(c_int)`, *ctypes* accepts an array of `c_int` :

```
>>> class Bar(Structure):
...     _fields_ = [("count", c_int), ("values", POINTER(c_int))]
...
>>> bar = Bar()
>>> bar.values = (c_int * 3)(1, 2, 3)
>>> bar.count = 3
>>> for i in range(bar.count):
...     print bar.values[i]
...
1
2
3
>>>
```

In addition, if a function argument is explicitly declared to be a pointer type (such as `POINTER(c_int)`) in `argtypes`, an object of the pointed type (`c_int` in this case) can be passed to the function. *ctypes* will apply the required *byref()* conversion in this case automatically.

To set a `POINTER` type field to **NULL**, you can assign `None` :

```
>>> bar.values = None
>>>
```

Sometimes you have instances of incompatible types. In C, you can cast one type into another type. *ctypes* provides a *cast()* function which can be used in the same way. The *Bar* structure defined above accepts *POINTER(c\_int)* pointers or *c\_int* arrays for its *values* field, but not instances of other types :

```
>>> bar.values = (c_byte * 4)()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: incompatible types, c_byte_Array_4 instance instead of LP_c_long instance
>>>
```

For these cases, the *cast()* function is handy.

The *cast()* function can be used to cast a *ctypes* instance into a pointer to a different *ctypes* data type. *cast()* takes two parameters, a *ctypes* object that is or can be converted to a pointer of some kind, and a *ctypes* pointer type. It returns an instance of the second argument, which references the same memory block as the first argument :

```
>>> a = (c_byte * 4)()
>>> cast(a, POINTER(c_int))
<ctypes.LP_c_long object at ...>
>>>
```

So, *cast()* can be used to assign to the *values* field of *Bar* the structure :

```
>>> bar = Bar()
>>> bar.values = cast((c_byte * 4)(), POINTER(c_int))
>>> print bar.values[0]
0
>>>
```

## Incomplete Types

*Incomplete Types* are structures, unions or arrays whose members are not yet specified. In C, they are specified by forward declarations, which are defined later :

```
struct cell; /* forward declaration */

struct cell {
    char *name;
    struct cell *next;
};
```

The straightforward translation into *ctypes* code would be this, but it does not work :

```
>>> class cell(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("next", POINTER(cell))]
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in cell
```

(suite sur la page suivante)

(suite de la page précédente)

```
NameError: name 'cell' is not defined
>>>
```

because the new class `cell` is not available in the class statement itself. In *ctypes*, we can define the `cell` class and set the `_fields_` attribute later, after the class statement :

```
>>> from ctypes import *
>>> class cell(Structure):
...     pass
...
>>> cell._fields_ = [("name", c_char_p),
...                  ("next", POINTER(cell))]
>>>
```

Lets try it. We create two instances of `cell`, and let them point to each other, and finally follow the pointer chain a few times :

```
>>> c1 = cell()
>>> c1.name = "foo"
>>> c2 = cell()
>>> c2.name = "bar"
>>> c1.next = pointer(c2)
>>> c2.next = pointer(c1)
>>> p = c1
>>> for i in range(8):
...     print p.name,
...     p = p.next[0]
...
foo bar foo bar foo bar foo bar
>>>
```

## Callback functions

*ctypes* allows creating C callable function pointers from Python callables. These are sometimes called *callback functions*.

First, you must create a class for the callback function, the class knows the calling convention, the return type, and the number and types of arguments this function will receive.

The `CFUNCTYPE` factory function creates types for callback functions using the normal `cdecl` calling convention, and, on Windows, the `WINFUNCTYPE` factory function creates types for callback functions using the `stdcall` calling convention.

Both of these factory functions are called with the result type as first argument, and the callback functions expected argument types as the remaining arguments.

I will present an example here which uses the standard C library's `qsort()` function, this is used to sort items with the help of a callback function. `qsort()` will be used to sort an array of integers :

```
>>> IntArray5 = c_int * 5
>>> ia = IntArray5(5, 1, 7, 33, 99)
>>> qsort = libc.qsort
>>> qsort.restype = None
>>>
```

`qsort()` must be called with a pointer to the data to sort, the number of items in the data array, the size of one item, and a pointer to the comparison function, the callback. The callback will then be called with two pointers to items, and it must return a negative integer if the first item is smaller than the second, a zero if they are equal, and a positive integer else.

So our callback function receives pointers to integers, and must return an integer. First we create the `type` for the callback function :

```
>>> CMPFUNC = CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
>>>
```

For the first implementation of the callback function, we simply print the arguments we get, and return 0 (incremental development ;-):

```
>>> def py_cmp_func(a, b):
...     print "py_cmp_func", a, b
...     return 0
...
>>>
```

Create the C callable callback :

```
>>> cmp_func = CMPFUNC(py_cmp_func)
>>>
```

And we're ready to go :

```
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
>>>
```

We know how to access the contents of a pointer, so let's redefine our callback :

```
>>> def py_cmp_func(a, b):
...     print "py_cmp_func", a[0], b[0]
...     return 0
...
>>> cmp_func = CMPFUNC(py_cmp_func)
>>>
```

Here is what we get on Windows :

```
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func 7 1
py_cmp_func 33 1
py_cmp_func 99 1
```

(suite sur la page suivante)

(suite de la page précédente)

```
py_cmp_func 5 1
py_cmp_func 7 5
py_cmp_func 33 5
py_cmp_func 99 5
py_cmp_func 7 99
py_cmp_func 33 99
py_cmp_func 7 33
>>>
```

It is funny to see that on linux the sort function seems to work much more efficiently, it is doing less comparisons :

```
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 5 7
py_cmp_func 1 7
>>>
```

Ah, we're nearly done! The last step is to actually compare the two items and return a useful result :

```
>>> def py_cmp_func(a, b):
...     print "py_cmp_func", a[0], b[0]
...     return a[0] - b[0]
...
>>>
```

Final run on Windows :

```
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_func))
py_cmp_func 33 7
py_cmp_func 99 33
py_cmp_func 5 99
py_cmp_func 1 99
py_cmp_func 33 7
py_cmp_func 1 33
py_cmp_func 5 33
py_cmp_func 5 7
py_cmp_func 1 7
py_cmp_func 5 1
>>>
```

and on Linux :

```
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_func))
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>
```

It is quite interesting to see that the Windows `qsort()` function needs more comparisons than the linux version!

As we can easily check, our array is sorted now :

```
>>> for i in ia: print i,
...
1 5 7 33 99
>>>
```

**Note :** Make sure you keep references to `CFUNCTYPE()` objects as long as they are used from C code. `ctypes` doesn't, and if you don't, they may be garbage collected, crashing your program when a callback is made.

Also, note that if the callback function is called in a thread created outside of Python's control (e.g. by the foreign code that calls the callback), `ctypes` creates a new dummy Python thread on every invocation. This behavior is correct for most purposes, but it means that values stored with `threading.local` will *not* survive across different callbacks, even when those calls are made from the same C thread.

### Accessing values exported from dlls

Some shared libraries not only export functions, they also export variables. An example in the Python library itself is the `Py_OptimizeFlag`, an integer set to 0, 1, or 2, depending on the `-O` or `-OO` flag given on startup.

`ctypes` can access values like this with the `in_dll()` class methods of the type. `pythonapi` is a predefined symbol giving access to the Python C api :

```
>>> opt_flag = c_int.in_dll(pythonapi, "Py_OptimizeFlag")
>>> print opt_flag
c_long(0)
>>>
```

If the interpreter would have been started with `-O`, the sample would have printed `c_long(1)`, or `c_long(2)` if `-OO` would have been specified.

An extended example which also demonstrates the use of pointers accesses the `PyImport_FrozenModules` pointer exported by Python.

Quoting the Python docs : *This pointer is initialized to point to an array of « struct \_\_frozen » records, terminated by one whose members are all NULL or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.*

So manipulating this pointer could even prove useful. To restrict the example size, we show only how this table can be read with `ctypes` :

```
>>> from ctypes import *
>>>
>>> class struct_frozen(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("code", POINTER(c_ubyte)),
...                 ("size", c_int)]
...
>>>
```

We have defined the `struct __frozen` data type, so we can get the pointer to the table :

```
>>> FrozenTable = POINTER(struct_frozen)
>>> table = FrozenTable.in_dll(pythonsapi, "PyImport_FrozenModules")
>>>
```

Since `table` is a pointer to the array of `struct_frozen` records, we can iterate over it, but we just have to make sure that our loop terminates, because pointers have no size. Sooner or later it would probably crash with an access violation or whatever, so it's better to break out of the loop when we hit the NULL entry :

```
>>> for item in table:
...     print item.name, item.size
...     if item.name is None:
...         break
...
__hello__ 104
__phello__ -104
__phello__.spam 104
None 0
>>>
```

The fact that standard Python has a frozen module and a frozen package (indicated by the negative size member) is not well known, it is only used for testing. Try it out with `import __hello__` for example.

### Surprises

There are some edge cases in `ctypes` where you might expect something other than what actually happens. Consider the following example :

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class RECT(Structure):
...     _fields_ = ("a", POINT), ("b", POINT)
...
>>> p1 = POINT(1, 2)
>>> p2 = POINT(3, 4)
>>> rc = RECT(p1, p2)
>>> print rc.a.x, rc.a.y, rc.b.x, rc.b.y
1 2 3 4
>>> # now swap the two points
>>> rc.a, rc.b = rc.b, rc.a
>>> print rc.a.x, rc.a.y, rc.b.x, rc.b.y
3 4 3 4
>>>
```

Hm. We certainly expected the last statement to print 3 4 1 2. What happened? Here are the steps of the `rc.a, rc.b = rc.b, rc.a` line above :

```
>>> temp0, temp1 = rc.b, rc.a
>>> rc.a = temp0
>>> rc.b = temp1
>>>
```

Note that `temp0` and `temp1` are objects still using the internal buffer of the `rc` object above. So executing `rc.a = temp0` copies the buffer contents of `temp0` into `rc`’s buffer. This, in turn, changes the contents of `temp1`. So, the last assignment `rc.b = temp1`, doesn’t have the expected effect.

Keep in mind that retrieving sub-objects from Structure, Unions, and Arrays doesn’t *copy* the sub-object, instead it retrieves a wrapper object accessing the root-object’s underlying buffer.

Another example that may behave different from what one would expect is this :

```
>>> s = c_char_p()
>>> s.value = "abc def ghi"
>>> s.value
'abc def ghi'
>>> s.value is s.value
False
>>>
```

Why is it printing **False**? `ctypes` instances are objects containing a memory block plus some *descriptors* accessing the contents of the memory. Storing a Python object in the memory block does not store the object itself, instead the **contents** of the object is stored. Accessing the contents again constructs a new Python object each time!

### Variable-sized data types

`ctypes` provides some support for variable-sized arrays and structures.

The `resize()` function can be used to resize the memory buffer of an existing `ctypes` object. The function takes the object as first argument, and the requested size in bytes as the second argument. The memory block cannot be made smaller than the natural memory block specified by the objects type, a `ValueError` is raised if this is tried :

```
>>> short_array = (c_short * 4)()
>>> print sizeof(short_array)
8
>>> resize(short_array, 4)
Traceback (most recent call last):
...
ValueError: minimum size is 8
>>> resize(short_array, 32)
>>> sizeof(short_array)
32
>>> sizeof(type(short_array))
8
>>>
```

This is nice and fine, but how would one access the additional elements contained in this array? Since the type still only knows about 4 elements, we get errors accessing other elements :

```
>>> short_array[:]
[0, 0, 0, 0]
>>> short_array[7]
Traceback (most recent call last):
...
IndexError: invalid index
>>>
```

Another way to use variable-sized data types with *ctypes* is to use the dynamic nature of Python, and (re-)define the data type after the required size is already known, on a case by case basis.

## 15.17.2 ctypes reference

### Finding shared libraries

When programming in a compiled language, shared libraries are accessed when compiling/linking a program, and when the program is run.

The purpose of the `find_library()` function is to locate a library in a way similar to what the compiler does (on platforms with several versions of a shared library the most recent should be loaded), while the *ctypes* library loaders act like when a program is run, and call the runtime loader directly.

The `ctypes.util` module provides a function which can help to determine the library to load.

`ctypes.util.find_library(name)`

Try to find a library and return a pathname. *name* is the library name without any prefix like *lib*, suffix like *.so*, *.dylib* or version number (this is the form used for the posix linker option *-l*). If no library can be found, returns `None`.

The exact functionality is system dependent.

On Linux, `find_library()` tries to run external programs (`/sbin/ldconfig`, `gcc`, and `objdump`) to find the library file. It returns the filename of the library file. Here are some examples :

```
>>> from ctypes.util import find_library
>>> find_library("m")
'libm.so.6'
>>> find_library("c")
'libc.so.6'
>>> find_library("bz2")
'libbz2.so.1.0'
>>>
```

On OS X, `find_library()` tries several predefined naming schemes and paths to locate the library, and returns a full pathname if successful :

```
>>> from ctypes.util import find_library
>>> find_library("c")
'/usr/lib/libc.dylib'
>>> find_library("m")
'/usr/lib/libm.dylib'
>>> find_library("bz2")
'/usr/lib/libbz2.dylib'
>>> find_library("AGL")
'/System/Library/Frameworks/AGL.framework/AGL'
>>>
```

On Windows, `find_library()` searches along the system search path, and returns the full pathname, but since there is no predefined naming scheme a call like `find_library("c")` will fail and return `None`.

If wrapping a shared library with *ctypes*, it *may* be better to determine the shared library name at development time, and hardcode that into the wrapper module instead of using `find_library()` to locate the library at runtime.

## Loading shared libraries

There are several ways to load shared libraries into the Python process. One way is to instantiate one of the following classes :

```
class ctypes.CDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False,
                  use_last_error=False)
```

Instances of this class represent loaded shared libraries. Functions in these libraries use the standard C calling convention, and are assumed to return `int`.

```
class ctypes.OleDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False,
                   use_last_error=False)
```

Windows only : Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return the windows specific `HRESULT` code. `HRESULT` values contain information specifying whether the function call failed or succeeded, together with additional error code. If the return value signals a failure, an `WindowsError` is automatically raised.

```
class ctypes.WinDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False,
                   use_last_error=False)
```

Windows only : Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return `int` by default.

On Windows CE only the standard calling convention is used, for convenience the `WinDLL` and `OleDLL` use the standard calling convention on this platform.

The Python *global interpreter lock* is released before calling any function exported by these libraries, and reacquired afterwards.

```
class ctypes.PyDLL(name, mode=DEFAULT_MODE, handle=None)
```

Instances of this class behave like `CDLL` instances, except that the Python GIL is *not* released during the function call, and after the function execution the Python error flag is checked. If the error flag is set, a Python exception is raised.

Thus, this is only useful to call Python C api functions directly.

All these classes can be instantiated by calling them with at least one argument, the pathname of the shared library. If you have an existing handle to an already loaded shared library, it can be passed as the `handle` named parameter, otherwise the underlying platforms `dlopen` or `LoadLibrary` function is used to load the library into the process, and to get a handle to it.

The `mode` parameter can be used to specify how the library is loaded. For details, consult the `dlopen(3)` manpage. On Windows, `mode` is ignored. On posix systems, `RTLD_NOW` is always added, and is not configurable.

The `use_errno` parameter, when set to true, enables a ctypes mechanism that allows accessing the system `errno` error number in a safe way. ctypes maintains a thread-local copy of the systems `errno` variable; if you call foreign functions created with `use_errno=True` then the `errno` value before the function call is swapped with the ctypes private copy, the same happens immediately after the function call.

The function `ctypes.get_errno()` returns the value of the ctypes private copy, and the function `ctypes.set_errno()` changes the ctypes private copy to a new value and returns the former value.

The `use_last_error` parameter, when set to true, enables the same mechanism for the Windows error code which is managed by the `GetLastError()` and `SetLastError()` Windows API functions; `ctypes.get_last_error()` and `ctypes.set_last_error()` are used to request and change the ctypes private copy of the windows error code.

Nouveau dans la version 2.6 : The `use_last_error` and `use_errno` optional parameters were added.

```
ctypes.RTLD_GLOBAL
```

Flag to use as `mode` parameter. On platforms where this flag is not available, it is defined as the integer zero.

**ctypes.RTLD\_LOCAL**

Flag to use as *mode* parameter. On platforms where this is not available, it is the same as *RTLD\_GLOBAL*.

**ctypes.DEFAULT\_MODE**

The default mode which is used to load shared libraries. On OSX 10.3, this is *RTLD\_GLOBAL*, otherwise it is the same as *RTLD\_LOCAL*.

Instances of these classes have no public methods. Functions exported by the shared library can be accessed as attributes or by index. Please note that accessing the function through an attribute caches the result and therefore accessing it repeatedly returns the same object each time. On the other hand, accessing it through an index returns a new object each time :

```
>>> libc.time == libc.time
True
>>> libc['time'] == libc['time']
False
```

The following public attributes are available, their name starts with an underscore to not clash with exported function names :

**PyDLL.\_handle**

The system handle used to access the library.

**PyDLL.\_name**

The name of the library passed in the constructor.

Shared libraries can also be loaded by using one of the prefabricated objects, which are instances of the *LibraryLoader* class, either by calling the *LoadLibrary()* method, or by retrieving the library as attribute of the loader instance.

**class ctypes.LibraryLoader(*dlltype*)**

Class which loads shared libraries. *dlltype* should be one of the *CDLL*, *PyDLL*, *WinDLL*, or *OleDLL* types. *\_\_getattr\_\_()* has special behavior : It allows loading a shared library by accessing it as attribute of a library loader instance. The result is cached, so repeated attribute accesses return the same library each time.

**LoadLibrary(*name*)**

Load a shared library into the process and return it. This method always returns a new instance of the library.

These prefabricated library loaders are available :

**ctypes.cdll**

Creates *CDLL* instances.

**ctypes.windll**

Windows only : Creates *WinDLL* instances.

**ctypes.ole32**

Windows only : Creates *OleDLL* instances.

**ctypes.pydll**

Creates *PyDLL* instances.

For accessing the C Python api directly, a ready-to-use Python shared library object is available :

**ctypes.pythonapi**

An instance of *PyDLL* that exposes Python C API functions as attributes. Note that all these functions are assumed to return C *int*, which is of course not always the truth, so you have to assign the correct *restype* attribute to use these functions.

## Foreign functions

As explained in the previous section, foreign functions can be accessed as attributes of loaded shared libraries. The function objects created in this way by default accept any number of arguments, accept any ctypes data instances as arguments, and return the default result type specified by the library loader. They are instances of a private class :

**class** ctypes.\_FuncPtr

Base class for C callable foreign functions.

Instances of foreign functions are also C compatible data types ; they represent C function pointers.

This behavior can be customized by assigning to special attributes of the foreign function object.

**restype**

Assign a ctypes type to specify the result type of the foreign function. Use `None` for `void`, a function not returning anything.

It is possible to assign a callable Python object that is not a ctypes type, in this case the function is assumed to return a C `int`, and the callable will be called with this integer, allowing further processing or error checking. Using this is deprecated, for more flexible post processing or error checking use a ctypes data type as *restype* and assign a callable to the *errcheck* attribute.

**argtypes**

Assign a tuple of ctypes types to specify the argument types that the function accepts. Functions using the `stdcall` calling convention can only be called with the same number of arguments as the length of this tuple ; functions using the C calling convention accept additional, unspecified arguments as well.

When a foreign function is called, each actual argument is passed to the `from_param()` class method of the items in the *argtypes* tuple, this method allows adapting the actual argument to an object that the foreign function accepts. For example, a `c_char_p` item in the *argtypes* tuple will convert a unicode string passed as argument into a byte string using ctypes conversion rules.

New : It is now possible to put items in *argtypes* which are not ctypes types, but each item must have a `from_param()` method which returns a value usable as argument (integer, string, ctypes instance). This allows defining adapters that can adapt custom objects as function parameters.

**errcheck**

Assign a Python function or another callable to this attribute. The callable will be called with three or more arguments :

**callable**(*result*, *func*, *arguments*)

*result* is what the foreign function returns, as specified by the *restype* attribute.

*func* is the foreign function object itself, this allows reusing the same callable object to check or post process the results of several functions.

*arguments* is a tuple containing the parameters originally passed to the function call, this allows specializing the behavior on the arguments used.

The object that this function returns will be returned from the foreign function call, but it can also check the result value and raise an exception if the foreign function call failed.

**exception** ctypes.ArgumentError

This exception is raised when a foreign function call cannot convert one of the passed arguments.

## Function prototypes

Foreign functions can also be created by instantiating function prototypes. Function prototypes are similar to function prototypes in C ; they describe a function (return type, argument types, calling convention) without defining an implementation. The factory functions must be called with the desired result type and the argument types of the function.

**ctypes.CFUNCTYPE**(*restype*, \**argtypes*, *use\_errno=False*, *use\_last\_error=False*)

The returned function prototype creates functions that use the standard C calling convention. The function will release the GIL during the call. If *use\_errno* is set to true, the ctypes private copy of the

system `errno` variable is exchanged with the real `errno` value before and after the call; `use_last_error` does the same for the Windows error code.

Modifié dans la version 2.6 : The optional `use_errno` and `use_last_error` parameters were added.

`ctypes.WINFUNCTYPE(restype, *argtypes, use_errno=False, use_last_error=False)`

Windows only : The returned function prototype creates functions that use the `stdcall` calling convention, except on Windows CE where `WINFUNCTYPE()` is the same as `CFUNCTYPE()`. The function will release the GIL during the call. `use_errno` and `use_last_error` have the same meaning as above.

`ctypes.PYFUNCTYPE(restype, *argtypes)`

The returned function prototype creates functions that use the Python calling convention. The function will *not* release the GIL during the call.

Function prototypes created by these factory functions can be instantiated in different ways, depending on the type and number of the parameters in the call :

`prototype(address)`

Returns a foreign function at the specified address which must be an integer.

`prototype(callable)`

Create a C callable function (a callback function) from a Python *callable*.

`prototype(func_spec[, paramflags])`

Returns a foreign function exported by a shared library. *func\_spec* must be a 2-tuple (`name_or_ordinal`, `library`). The first item is the name of the exported function as string, or the ordinal of the exported function as small integer. The second item is the shared library instance.

`prototype(vtbl_index, name[, paramflags[, iid]])`

Returns a foreign function that will call a COM method. *vtbl\_index* is the index into the virtual function table, a small non-negative integer. *name* is name of the COM method. *iid* is an optional pointer to the interface identifier which is used in extended error reporting.

COM methods use a special calling convention : They require a pointer to the COM interface as first argument, in addition to those parameters that are specified in the `argtypes` tuple.

The optional *paramflags* parameter creates foreign function wrappers with much more functionality than the features described above.

*paramflags* must be a tuple of the same length as `argtypes`.

Each item in this tuple contains further information about a parameter, it must be a tuple containing one, two, or three items.

The first item is an integer containing a combination of direction flags for the parameter :

- 1 Specifies an input parameter to the function.
- 2 Output parameter. The foreign function fills in a value.
- 4 Input parameter which defaults to the integer zero.

The optional second item is the parameter name as string. If this is specified, the foreign function can be called with named parameters.

The optional third item is the default value for this parameter.

This example demonstrates how to wrap the Windows `MessageBoxA` function so that it supports default parameters and named arguments. The C declaration from the windows header file is this :

```
WINUSERAPI int WINAPI
MessageBoxA(
    HWND hWnd,
    LPCSTR lpText,
    LPCSTR lpCaption,
    UINT uType);
```

Here is the wrapping with *ctypes* :

```
>>> from ctypes import c_int, WINFUNCTYPE, windll
>>> from ctypes.wintypes import HWND, LPCSTR, UINT
>>> prototype = WINFUNCTYPE(c_int, HWND, LPCSTR, LPCSTR, UINT)
>>> paramflags = (1, "hwnd", 0), (1, "text", "Hi"), (1, "caption", None), (1, "flags", 0)
>>> MessageBox = prototype(("MessageBoxA", windll.user32), paramflags)
>>>
```

The `MessageBox` foreign function can now be called in these ways :

```
>>> MessageBox()
>>> MessageBox(text="Spam, spam, spam")
>>> MessageBox(flags=2, text="foo bar")
>>>
```

A second example demonstrates output parameters. The win32 `GetWindowRect` function retrieves the dimensions of a specified window by copying them into `RECT` structure that the caller has to supply. Here is the C declaration :

```
WINUSERAPI BOOL WINAPI
GetWindowRect(
    HWND hWnd,
    LPRECT lpRect);
```

Here is the wrapping with `ctypes` :

```
>>> from ctypes import POINTER, WINFUNCTYPE, windll, WinError
>>> from ctypes.wintypes import BOOL, HWND, RECT
>>> prototype = WINFUNCTYPE(BOOL, HWND, POINTER(RECT))
>>> paramflags = (1, "hwnd"), (2, "lprect")
>>> GetWindowRect = prototype(("GetWindowRect", windll.user32), paramflags)
>>>
```

Functions with output parameters will automatically return the output parameter value if there is a single one, or a tuple containing the output parameter values when there are more than one, so the `GetWindowRect` function now returns a `RECT` instance, when called.

Output parameters can be combined with the `errcheck` protocol to do further output processing and error checking. The win32 `GetWindowRect` api function returns a `BOOL` to signal success or failure, so this function could do the error checking, and raises an exception when the api call failed :

```
>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     return args
...
>>> GetWindowRect.errcheck = errcheck
>>>
```

If the `errcheck` function returns the argument tuple it receives unchanged, `ctypes` continues the normal processing it does on the output parameters. If you want to return a tuple of window coordinates instead of a `RECT` instance, you can retrieve the fields in the function and return them instead, the normal processing will no longer take place :

```
>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     rc = args[1]
...     return rc.left, rc.top, rc.bottom, rc.right
...
>>> GetWindowRect.errcheck = errcheck
>>>
```

## Utility functions

**ctypes.addressof(*obj*)**

Returns the address of the memory buffer as integer. *obj* must be an instance of a ctypes type.

**ctypes.alignment(*obj\_or\_type*)**

Returns the alignment requirements of a ctypes type. *obj\_or\_type* must be a ctypes type or instance.

**ctypes.byref(*obj*[, *offset*])**

Returns a light-weight pointer to *obj*, which must be an instance of a ctypes type. *offset* defaults to zero, and must be an integer that will be added to the internal pointer value.

**byref(*obj*, *offset*)** corresponds to this C code :

```
((char *)&obj) + offset)
```

The returned object can only be used as a foreign function call parameter. It behaves similar to **pointer(*obj*)**, but the construction is a lot faster.

Nouveau dans la version 2.6 : The *offset* optional argument was added.

**ctypes.cast(*obj*, *type*)**

This function is similar to the cast operator in C. It returns a new instance of *type* which points to the same memory block as *obj*. *type* must be a pointer type, and *obj* must be an object that can be interpreted as a pointer.

**ctypes.create\_string\_buffer(*init\_or\_size*[, *size*])**

This function creates a mutable character buffer. The returned object is a ctypes array of *c\_char*.

*init\_or\_size* must be an integer which specifies the size of the array, or a string which will be used to initialize the array items.

If a string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the string should not be used.

If the first parameter is a unicode string, it is converted into an 8-bit string according to ctypes conversion rules.

**ctypes.create\_unicode\_buffer(*init\_or\_size*[, *size*])**

This function creates a mutable unicode character buffer. The returned object is a ctypes array of *c\_wchar*.

*init\_or\_size* must be an integer which specifies the size of the array, or a unicode string which will be used to initialize the array items.

If a unicode string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the string should not be used.

If the first parameter is an 8-bit string, it is converted into a unicode string according to ctypes conversion rules.

**ctypes.DllCanUnloadNow()**

Windows only : This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the DllCanUnloadNow function that the `_ctypes` extension dll exports.

**ctypes.DllGetClassObject()**

Windows only : This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the DllGetClassObject function that the `_ctypes` extension dll exports.

**ctypes.util.find\_library(*name*)**

Try to find a library and return a pathname. *name* is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

Modifié dans la version 2.6 : Windows only : `find_library("m")` or `find_library("c")` return the result of a call to `find_msvcrt()`.

**ctypes.util.find\_msvcrt()**

Windows only : return the filename of the VC runtime library used by Python, and by the extension modules. If the name of the library cannot be determined, `None` is returned.

If you need to free memory, for example, allocated by an extension module with a call to the `free(void *)`, it is important that you use the function in the same library that allocated the memory.

Nouveau dans la version 2.6.

**ctypes.FormatError(*code*)**

Windows only : Returns a textual description of the error code *code*. If no error code is specified, the last error code is used by calling the Windows api function `GetLastError`.

**ctypes.GetLastError()**

Windows only : Returns the last error code set by Windows in the calling thread. This function calls the Windows `GetLastError()` function directly, it does not return the ctypes-private copy of the error code.

**ctypes.get\_errno()**

Returns the current value of the ctypes-private copy of the system `errno` variable in the calling thread.

Nouveau dans la version 2.6.

**ctypes.get\_last\_error()**

Windows only : returns the current value of the ctypes-private copy of the system `LastError` variable in the calling thread.

Nouveau dans la version 2.6.

**ctypes.memmove(*dst*, *src*, *count*)**

Same as the standard C `memmove` library function : copies *count* bytes from *src* to *dst*. *dst* and *src* must be integers or ctypes instances that can be converted to pointers.

**ctypes.memset(*dst*, *c*, *count*)**

Same as the standard C `memset` library function : fills the memory block at address *dst* with *count* bytes of value *c*. *dst* must be an integer specifying an address, or a ctypes instance.

**ctypes.POINTER(*type*)**

This factory function creates and returns a new ctypes pointer type. Pointer types are cached and reused internally, so calling this function repeatedly is cheap. *type* must be a ctypes type.

**ctypes.pointer(*obj*)**

This function creates a new pointer instance, pointing to *obj*. The returned object is of the type `POINTER(type(obj))`.

Note : If you just want to pass a pointer to an object to a foreign function call, you should use `byref(obj)` which is much faster.

`ctypes.resize(obj, size)`

This function resizes the internal memory buffer of *obj*, which must be an instance of a ctypes type. It is not possible to make the buffer smaller than the native size of the objects type, as given by `sizeof(type(obj))`, but it is possible to enlarge the buffer.

`ctypes.set_conversion_mode(encoding, errors)`

This function sets the rules that ctypes objects use when converting between 8-bit strings and unicode strings. *encoding* must be a string specifying an encoding, like 'utf-8' or 'mbcs', *errors* must be a string specifying the error handling on encoding/decoding errors. Examples of possible values are "strict", "replace", or "ignore".

`set_conversion_mode()` returns a 2-tuple containing the previous conversion rules. On windows, the initial conversion rules are ('mbcs', 'ignore'), on other systems ('ascii', 'strict').

`ctypes.set_errno(value)`

Set the current value of the ctypes-private copy of the system *errno* variable in the calling thread to *value* and return the previous value.

Nouveau dans la version 2.6.

`ctypes.set_last_error(value)`

Windows only : set the current value of the ctypes-private copy of the system `LastError` variable in the calling thread to *value* and return the previous value.

Nouveau dans la version 2.6.

`ctypes.sizeof(obj_or_type)`

Returns the size in bytes of a ctypes type or instance memory buffer. Does the same as the C `sizeof` operator.

`ctypes.string_at(address[, size])`

This function returns the string starting at memory address *address*. If *size* is specified, it is used as *size*, otherwise the string is assumed to be zero-terminated.

`ctypes.WinError(code=None, descr=None)`

Windows only : this function is probably the worst-named thing in ctypes. It creates an instance of `WindowsError`. If *code* is not specified, `GetLastError` is called to determine the error code. If *descr* is not specified, `FormatError()` is called to get a textual description of the error.

`ctypes.wstring_at(address[, size])`

This function returns the wide character string starting at memory address *address* as unicode string. If *size* is specified, it is used as the number of characters of the string, otherwise the string is assumed to be zero-terminated.

## Types de données

`class ctypes._CData`

This non-public class is the common base class of all ctypes data types. Among other things, all ctypes type instances contain a memory block that hold C compatible data ; the address of the memory block is returned by the `addressof()` helper function. Another instance variable is exposed as `_objects` ; this contains other Python objects that need to be kept alive in case the memory block contains pointers. Common methods of ctypes data types, these are all class methods (to be exact, they are methods of the *metaclass*) :

`from_buffer(source[, offset])`

This method returns a ctypes instance that shares the buffer of the *source* object. The *source* object must support the writeable buffer interface. The optional *offset* parameter specifies an offset into the source buffer in bytes ; the default is zero. If the source buffer is not large enough a *ValueError* is raised.

Nouveau dans la version 2.6.

**from\_buffer\_copy**(*source*[, *offset*])

This method creates a ctypes instance, copying the buffer from the *source* object buffer which must be readable. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a *ValueError* is raised.

Nouveau dans la version 2.6.

**from\_address**(*address*)

This method returns a ctypes type instance using the memory specified by *address* which must be an integer.

**from\_param**(*obj*)

This method adapts *obj* to a ctypes type. It is called with the actual object used in a foreign function call when the type is present in the foreign function's **argtypes** tuple; it must return an object that can be used as a function call parameter.

All ctypes data types have a default implementation of this classmethod that normally returns *obj* if that is an instance of the type. Some types accept other objects as well.

**in\_dll**(*library*, *name*)

This method returns a ctypes type instance exported by a shared library. *name* is the name of the symbol that exports the data, *library* is the loaded shared library.

Common instance variables of ctypes data types :

**\_b\_base\_**

Sometimes ctypes data instances do not own the memory block they contain, instead they share part of the memory block of a base object. The **\_b\_base\_** read-only member is the root ctypes object that owns the memory block.

**\_b\_needsfree\_**

This read-only variable is true when the ctypes data instance has allocated the memory block itself, false otherwise.

**\_objects**

This member is either *None* or a dictionary containing Python objects that need to be kept alive so that the memory block contents is kept valid. This object is only exposed for debugging; never modify the contents of this dictionary.

## Fundamental data types

**class** ctypes.\_SimpleCData

This non-public class is the base class of all fundamental ctypes data types. It is mentioned here because it contains the common attributes of the fundamental ctypes data types. *\_SimpleCData* is a subclass of *\_CData*, so it inherits their methods and attributes.

Modifié dans la version 2.6 : ctypes data types that are not and do not contain pointers can now be pickled.

Instances have a single attribute :

**value**

This attribute contains the actual value of the instance. For integer and pointer types, it is an integer, for character types, it is a single character string, for character pointer types it is a Python string or unicode string.

When the **value** attribute is retrieved from a ctypes instance, usually a new object is returned each time. *ctypes* does *not* implement original object return, always a new object is constructed. The same is true for all other ctypes object instances.

Fundamental data types, when returned as foreign function call results, or, for example, by retrieving structure field members or array items, are transparently converted to native Python types. In other words, if a foreign function has a **restype** of *c\_char\_p*, you will always receive a Python string, *not* a *c\_char\_p* instance.

Subclasses of fundamental data types do *not* inherit this behavior. So, if a foreign functions **restype** is a subclass of *c\_void\_p*, you will receive an instance of this subclass from the function call. Of course, you can

get the value of the pointer by accessing the `value` attribute.

These are the fundamental ctypes data types :

**class ctypes.c\_byte**

Represents the C `signed char` datatype, and interprets the value as small integer. The constructor accepts an optional integer initializer ; no overflow checking is done.

**class ctypes.c\_char**

Represents the C `char` datatype, and interprets the value as a single character. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

**class ctypes.c\_char\_p**

Represents the C `char *` datatype when it points to a zero-terminated string. For a general character pointer that may also point to binary data, `POINTER(c_char)` must be used. The constructor accepts an integer address, or a string.

**class ctypes.c\_double**

Represents the C `double` datatype. The constructor accepts an optional float initializer.

**class ctypes.c\_longdouble**

Represents the C `long double` datatype. The constructor accepts an optional float initializer. On platforms where `sizeof(long double) == sizeof(double)` it is an alias to `c_double`.

Nouveau dans la version 2.6.

**class ctypes.c\_float**

Represents the C `float` datatype. The constructor accepts an optional float initializer.

**class ctypes.c\_int**

Represents the C `signed int` datatype. The constructor accepts an optional integer initializer ; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias to `c_long`.

**class ctypes.c\_int8**

Represents the C 8-bit `signed int` datatype. Usually an alias for `c_byte`.

**class ctypes.c\_int16**

Represents the C 16-bit `signed int` datatype. Usually an alias for `c_short`.

**class ctypes.c\_int32**

Represents the C 32-bit `signed int` datatype. Usually an alias for `c_int`.

**class ctypes.c\_int64**

Represents the C 64-bit `signed int` datatype. Usually an alias for `c_longlong`.

**class ctypes.c\_long**

Represents the C `signed long` datatype. The constructor accepts an optional integer initializer ; no overflow checking is done.

**class ctypes.c\_longlong**

Represents the C `signed long long` datatype. The constructor accepts an optional integer initializer ; no overflow checking is done.

**class ctypes.c\_short**

Represents the C `signed short` datatype. The constructor accepts an optional integer initializer ; no overflow checking is done.

**class ctypes.c\_size\_t**

Represents the C `size_t` datatype.

**class ctypes.c\_ssize\_t**

Represents the C `ssize_t` datatype.

Nouveau dans la version 2.7.

**class ctypes.c\_ubyte**

Represents the C `unsigned char` datatype, it interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

**class ctypes.c\_uint**

Represents the C `unsigned int` datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias for `c_ulong`.

**class ctypes.c\_uint8**

Represents the C 8-bit `unsigned int` datatype. Usually an alias for `c_ubyte`.

**class ctypes.c\_uint16**

Represents the C 16-bit `unsigned int` datatype. Usually an alias for `c_ushort`.

**class ctypes.c\_uint32**

Represents the C 32-bit `unsigned int` datatype. Usually an alias for `c_uint`.

**class ctypes.c\_uint64**

Represents the C 64-bit `unsigned int` datatype. Usually an alias for `c_ulonglong`.

**class ctypes.c\_ulong**

Represents the C `unsigned long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

**class ctypes.c\_ulonglong**

Represents the C `unsigned long long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

**class ctypes.c\_ushort**

Represents the C `unsigned short` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

**class ctypes.c\_void\_p**

Represents the C `void *` type. The value is represented as integer. The constructor accepts an optional integer initializer.

**class ctypes.c\_wchar**

Represents the C `wchar_t` datatype, and interprets the value as a single character unicode string. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

**class ctypes.c\_wchar\_p**

Represents the C `wchar_t *` datatype, which must be a pointer to a zero-terminated wide character string. The constructor accepts an integer address, or a string.

**class ctypes.c\_bool**

Represent the C `bool` datatype (more accurately, `_Bool` from C99). Its value can be `True` or `False`, and the constructor accepts any object that has a truth value.

Nouveau dans la version 2.6.

**class ctypes.HRESULT**

Windows only : Represents a `HRESULT` value, which contains success or error information for a function or method call.

**class ctypes.py\_object**

Represents the C `PyObject *` datatype. Calling this without an argument creates a `NULL PyObject *` pointer.

The `ctypes.wintypes` module provides quite some other Windows specific data types, for example `HWND`, `WPARAM`, or `DWORD`. Some useful structures like `MSG` or `RECT` are also defined.

## Structured data types

```
class ctypes.Union(*args, **kw)
```

Abstract base class for unions in native byte order.

```
class ctypes.BigEndianStructure(*args, **kw)
```

Abstract base class for structures in *big endian* byte order.

```
class ctypes.LittleEndianStructure(*args, **kw)
```

Abstract base class for structures in *little endian* byte order.

Structures with non-native byte order cannot contain pointer type fields, or any other data types containing pointer type fields.

```
class ctypes.Structure(*args, **kw)
```

Abstract base class for structures in *native* byte order.

Concrete structure and union types must be created by subclassing one of these types, and at least define a `_fields_` class variable. `ctypes` will create *descriptors* which allow reading and writing the fields by direct attribute accesses. These are the

### `_fields_`

A sequence defining the structure fields. The items must be 2-tuples or 3-tuples. The first item is the name of the field, the second item specifies the type of the field; it can be any `ctypes` data type.

For integer type fields like `c_int`, a third optional item can be given. It must be a small positive integer defining the bit width of the field.

Field names must be unique within one structure or union. This is not checked, only one field can be accessed when names are repeated.

It is possible to define the `_fields_` class variable *after* the class statement that defines the Structure subclass, this allows creating data types that directly or indirectly reference themselves :

```
class List(Structure):
    pass
List._fields_ = [("pNext", POINTER(List)),
                 ...
                 ]
```

The `_fields_` class variable must, however, be defined before the type is first used (an instance is created, `sizeof()` is called on it, and so on). Later assignments to the `_fields_` class variable will raise an `AttributeError`.

It is possible to defined sub-subclasses of structure types, they inherit the fields of the base class plus the `_fields_` defined in the sub-subclass, if any.

### `_pack_`

An optional small integer that allows overriding the alignment of structure fields in the instance. `_pack_` must already be defined when `_fields_` is assigned, otherwise it will have no effect.

### `_anonymous_`

An optional sequence that lists the names of unnamed (anonymous) fields. `_anonymous_` must be already defined when `_fields_` is assigned, otherwise it will have no effect.

The fields listed in this variable must be structure or union type fields. `ctypes` will create descriptors in the structure type that allow accessing the nested fields directly, without the need to create the structure or union field.

Here is an example type (Windows) :

```
class _U(Union):
    _fields_ = [("lptdesc", POINTER(TYPEDESC)),
                ("lpadesc", POINTER(ARRAYDESC)),
```

(suite sur la page suivante)

(suite de la page précédente)

```

        ("hreftype", HREFTYPE)]

class TYPEDESC(Structure):
    _anonymous_ = ("u",)
    _fields_ = [("u", _U),
                ("vt", VARTYPE)]

```

The TYPEDESC structure describes a COM data type, the `vt` field specifies which one of the union fields is valid. Since the `u` field is defined as anonymous field, it is now possible to access the members directly off the TYPEDESC instance. `td.lptdesc` and `td.u.lptdesc` are equivalent, but the former is faster since it does not need to create a temporary union instance :

```

td = TYPEDESC()
td.vt = VT_PTR
td.lptdesc = POINTER(some_type)
td.u.lptdesc = POINTER(some_type)

```

It is possible to defined sub-subclasses of structures, they inherit the fields of the base class. If the subclass definition has a separate `_fields_` variable, the fields specified in this are appended to the fields of the base class.

Structure and union constructors accept both positional and keyword arguments. Positional arguments are used to initialize member fields in the same order as they are appear in `_fields_`. Keyword arguments in the constructor are interpreted as attribute assignments, so they will initialize `_fields_` with the same name, or create new attributes for names not present in `_fields_`.

## Arrays and pointers

**class** `ctypes.Array(*args)`

Classe de base abstraite pour les *arrays*.

The recommended way to create concrete array types is by multiplying any *ctypes* data type with a positive integer. Alternatively, you can subclass this type and define `_length_` and `_type_` class variables. Array elements can be read and written using standard subscript and slice accesses ; for slice reads, the resulting object is *not* itself an *Array*.

**\_length\_**

A positive integer specifying the number of elements in the array. Out-of-range subscripts result in an *IndexError*. Will be returned by `len()`.

**\_type\_**

Spécifie le type de chaque élément de l'*array*.

Array subclass constructors accept positional arguments, used to initialize the elements in order.

**class** `ctypes._Pointer`

Private, abstract base class for pointers.

Concrete pointer types are created by calling `POINTER()` with the type that will be pointed to ; this is done automatically by `pointer()`.

If a pointer points to an array, its elements can be read and written using standard subscript and slice accesses. Pointer objects have no size, so `len()` will raise *TypeError*. Negative subscripts will read from the memory *before* the pointer (as in C), and out-of-range subscripts will probably crash with an access violation (if you're lucky).

**\_type\_**

Specifies the type pointed to.

**contents**

Returns the object to which to pointer points. Assigning to this attribute changes the pointer to point to the assigned object.

---

Optional Operating System Services

---

The modules described in this chapter provide interfaces to operating system features that are available on selected operating systems only. The interfaces are generally modeled after the Unix or C interfaces but they are available on some other systems as well (e.g. Windows or NT). Here's an overview :

## 16.1 `select` — Waiting for I/O completion

This module provides access to the `select()` and `poll()` functions available in most operating systems, `epoll()` available on Linux 2.5+ and `kqueue()` available on most BSD. Note that on Windows, it only works for sockets; on other operating systems, it also works for other file types (in particular, on Unix, it works on pipes). It cannot be used on regular files to determine whether a file has grown since it was last read.

Le module définit :

**exception `select.error`**

The exception raised when an error occurs. The accompanying value is a pair containing the numeric error code from `errno` and the corresponding string, as would be printed by the C function `perror()`.

**`select.epoll([sizehint=-1])`**

(Only supported on Linux 2.5.44 and newer.) Returns an edge polling object, which can be used as Edge or Level Triggered interface for I/O events; see section *Edge and Level Trigger Polling (epoll) Objects* below for the methods supported by epolling objects.

Nouveau dans la version 2.6.

**`select.poll()`**

(Not supported by all operating systems.) Returns a polling object, which supports registering and unregistering file descriptors, and then polling them for I/O events; see section *Polling Objects* below for the methods supported by polling objects.

**`select.kqueue()`**

(Only supported on BSD.) Returns a kernel queue object; see section *Kqueue Objects* below for the methods supported by kqueue objects.

Nouveau dans la version 2.6.

`select.kevent(ident, filter=KQ_FILTER_READ, flags=KQ_EV_ADD, fflags=0, data=0, udata=0)`

(Only supported on BSD.) Returns a kernel event object; see section [Kevent Objects](#) below for the methods supported by kevent objects.

Nouveau dans la version 2.6.

`select.select(rlist, wlist, xlist[, timeout])`

This is a straightforward interface to the Unix `select()` system call. The first three arguments are sequences of “waitable objects”: either integers representing file descriptors or objects with a parameterless method named `fileno()` returning such an integer:

- `rlist`: wait until ready for reading
- `wlist`: wait until ready for writing
- `xlist`: wait for an « exceptional condition » (see the manual page for what your system considers such a condition)

Empty sequences are allowed, but acceptance of three empty sequences is platform-dependent. (It is known to work on Unix but not on Windows.) The optional `timeout` argument specifies a time-out as a floating point number in seconds. When the `timeout` argument is omitted the function blocks until at least one file descriptor is ready. A time-out value of zero specifies a poll and never blocks.

The return value is a triple of lists of objects that are ready: subsets of the first three arguments. When the time-out is reached without a file descriptor becoming ready, three empty lists are returned.

Among the acceptable object types in the sequences are Python file objects (e.g. `sys.stdin`, or objects returned by `open()` or `os.popen()`), socket objects returned by `socket.socket()`. You may also define a `wrapper` class yourself, as long as it has an appropriate `fileno()` method (that really returns a file descriptor, not just a random integer).

---

**Note :** File objects on Windows are not acceptable, but sockets are. On Windows, the underlying `select()` function is provided by the WinSock library, and does not handle file descriptors that don’t originate from WinSock.

---

`select.PIPE_BUF`

Files reported as ready for writing by `select()`, `poll()` or similar interfaces in this module are guaranteed to not block on a write of up to `PIPE_BUF` bytes. This value is guaranteed by POSIX to be at least 512. Availability: Unix.

Nouveau dans la version 2.7.

### 16.1.1 Edge and Level Trigger Polling (epoll) Objects

<http://linux.die.net/man/4/epoll>

*eventmask*

Constante	Signification
EPOLLIN	Available for read
EPOLLOUT	Available for write
EPOLLPRI	Urgent data for read
EPOLLERR	Error condition happened on the assoc. fd
EPOLLHUP	Hang up happened on the assoc. fd
EPOLLET	Set Edge Trigger behavior, the default is Level Trigger behavior
EPOLLONESHOT	Set one-shot behavior. After one event is pulled out, the fd is internally disabled
EPOLLRDNORM	Equivalent to EPOLLIN
EPOLLRDBAND	Priority data band can be read.
EPOLLWRNORM	Equivalent to EPOLLOUT
EPOLLWRBAND	Priority data may be written.
EPOLLMSG	Ignored.

`epoll.close()`  
Close the control file descriptor of the `epoll` object.

`epoll.fileno()`  
Return the file descriptor number of the control fd.

`epoll.fromfd(fd)`  
Create an `epoll` object from a given file descriptor.

`epoll.register(fd[, eventmask])`  
Register a fd descriptor with the `epoll` object.

---

**Note :** Registering a file descriptor that's already registered raises an `IOError` – contrary to *Polling Objects's* register.

---

`epoll.modify(fd, eventmask)`  
Modify a register file descriptor.

`epoll.unregister(fd)`  
Remove a registered file descriptor from the `epoll` object.

`epoll.poll([timeout=-1[, maxevents=-1]])`  
Wait for events. timeout in seconds (float)

### 16.1.2 Polling Objects

The `poll()` system call, supported on most Unix systems, provides better scalability for network servers that service many, many clients at the same time. `poll()` scales better because the system call only requires listing the file descriptors of interest, while `select()` builds a bitmap, turns on bits for the fds of interest, and then afterward the whole bitmap has to be linearly scanned again. `select()` is  $O(\text{highest file descriptor})$ , while `poll()` is  $O(\text{number of file descriptors})$ .

`poll.register(fd[, eventmask])`  
Register a file descriptor with the polling object. Future calls to the `poll()` method will then check whether the file descriptor has any pending I/O events. `fd` can be either an integer, or an object with a `fileno()` method that returns an integer. File objects implement `fileno()`, so they can also be used as the argument.

`eventmask` is an optional bitmask describing the type of events you want to check for, and can be a combination of the constants `POLLIN`, `POLLPRI`, and `POLLOUT`, described in the table below. If not specified, the default value used will check for all 3 types of events.

Constante	Signification
<code>POLLIN</code>	There is data to read
<code>POLLPRI</code>	There is urgent data to read
<code>POLLOUT</code>	Ready for output : writing will not block
<code>POLLERR</code>	Error condition of some sort
<code>POLLHUP</code>	Hung up
<code>POLLNVAL</code>	Invalid request : descriptor not open

Registering a file descriptor that's already registered is not an error, and has the same effect as registering the descriptor exactly once.

`poll.modify(fd, eventmask)`  
Modifies an already registered fd. This has the same effect as `register(fd, eventmask)`. Attempting to modify a file descriptor that was never registered causes an `IOError` exception with `errno ENOENT` to be raised.

Nouveau dans la version 2.6.

`poll.unregister(fd)`

Remove a file descriptor being tracked by a polling object. Just like the `register()` method, *fd* can be an integer or an object with a `fileno()` method that returns an integer.

Attempting to remove a file descriptor that was never registered causes a `KeyError` exception to be raised.

`poll.poll([timeout])`

Polls the set of registered file descriptors, and returns a possibly-empty list containing (*fd*, *event*) 2-tuples for the descriptors that have events or errors to report. *fd* is the file descriptor, and *event* is a bitmask with bits set for the reported events for that descriptor — `POLLIN` for waiting input, `POLLOUT` to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If *timeout* is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If *timeout* is omitted, negative, or `None`, the call will block until there is an event for this poll object.

### 16.1.3 Kqueue Objects

`kqueue.close()`

Close the control file descriptor of the kqueue object.

`kqueue.fileno()`

Return the file descriptor number of the control fd.

`kqueue.fromfd(fd)`

Create a kqueue object from a given file descriptor.

`kqueue.control(changelist, max_events[, timeout=None])` → eventlist

Low level interface to kevent

— *changelist* must be an iterable of kevent object or `None`

— *max\_events* must be 0 or a positive integer

— *timeout* in seconds (floats possible)

### 16.1.4 Kevent Objects

<https://www.freebsd.org/cgi/man.cgi?query=kqueue&sektion=2>

`kevent.ident`

Value used to identify the event. The interpretation depends on the filter but it's usually the file descriptor. In the constructor *ident* can either be an int or an object with a `fileno()` function. `kevent` stores the integer internally.

`kevent.filter`

Name of the kernel filter.

Constante	Signification
<code>KQ_FILTER_READ</code>	Takes a descriptor and returns whenever there is data available to read
<code>KQ_FILTER_WRITE</code>	Takes a descriptor and returns whenever there is data available to write
<code>KQ_FILTER_AIO</code>	AIO requests
<code>KQ_FILTER_VNODE</code>	Returns when one or more of the requested events watched in <i>fflag</i> occurs
<code>KQ_FILTER_PROC</code>	Watch for events on a process id
<code>KQ_FILTER_NETDEV</code>	Watch for events on a network device [not available on Mac OS X]
<code>KQ_FILTER_SIGNAL</code>	Returns whenever the watched signal is delivered to the process
<code>KQ_FILTER_TIMER</code>	Establishes an arbitrary timer

`kevent.flags`

Filter action.

Constante	Signification
KQ_EV_ADD	Adds or modifies an event
KQ_EV_DELETE	Removes an event from the queue
KQ_EV_ENABLE	Permits <code>control()</code> to return the event
KQ_EV_DISABLE	Disables event
KQ_EV_ONESHOT	Removes event after first occurrence
KQ_EV_CLEAR	Reset the state after an event is retrieved
KQ_EV_SYSFLAGS	internal event
KQ_EV_FLAG1	internal event
KQ_EV_EOF	Filter specific EOF condition
KQ_EV_ERROR	See return values

**kevent.fflags**

Filter specific flags.

KQ\_FILTER\_READ and KQ\_FILTER\_WRITE filter flags :

Constante	Signification
KQ_NOTE_LOWAT	low water mark of a socket buffer

KQ\_FILTER\_VNODE filter flags :

Constante	Signification
KQ_NOTE_DELETE	<i>unlink()</i> was called
KQ_NOTE_WRITE	a write occurred
KQ_NOTE_EXTEND	the file was extended
KQ_NOTE_ATTRIB	an attribute was changed
KQ_NOTE_LINK	the link count has changed
KQ_NOTE_RENAME	the file was renamed
KQ_NOTE_REVOKE	access to the file was revoked

KQ\_FILTER\_PROC filter flags :

Constante	Signification
KQ_NOTE_EXIT	the process has exited
KQ_NOTE_FORK	the process has called <i>fork()</i>
KQ_NOTE_EXEC	the process has executed a new process
KQ_NOTE_PCTRLMASK	internal filter flag
KQ_NOTE_PDATAMASK	internal filter flag
KQ_NOTE_TRACK	follow a process across <i>fork()</i>
KQ_NOTE_CHILD	returned on the child process for <i>NOTE_TRACK</i>
KQ_NOTE_TRACKERR	unable to attach to a child

KQ\_FILTER\_NETDEV filter flags (not available on Mac OS X) :

Constante	Signification
KQ_NOTE_LINKUP	link is up
KQ_NOTE_LINKDOWN	link is down
KQ_NOTE_LINKINV	link state is invalid

**kevent.data**

Filter specific data.

**kevent.udata**

User defined value.

## 16.2 threading — Higher-level threading interface

Code source : [Lib/threading.py](#)

---

This module constructs higher-level threading interfaces on top of the lower level *thread* module. See also the *mutex* and *Queue* modules.

The *dummy\_threading* module is provided for situations where *threading* cannot be used because *thread* is missing.

---

**Note :** Starting with Python 2.6, this module provides **PEP 8** compliant aliases and properties to replace the `camelCase` names that were inspired by Java's threading API. This updated API is compatible with that of the *multiprocessing* module. However, no schedule has been set for the deprecation of the `camelCase` names and they remain fully supported in both Python 2.x and 3.x.

---

---

**Note :** Starting with Python 2.5, several Thread methods raise *RuntimeError* instead of *AssertionError* if called erroneously.

---

**CPython implementation detail :** In CPython, due to the *Global Interpreter Lock*, only one thread can execute Python code at once (even though certain performance-oriented libraries might overcome this limitation). If you want your application to make better use of the computational resources of multi-core machines, you are advised to use *multiprocessing*. However, threading is still an appropriate model if you want to run multiple I/O-bound tasks simultaneously.

This module defines the following functions and objects :

`threading.active_count()`

`threading.activeCount()`

Return the number of *Thread* objects currently alive. The returned count is equal to the length of the list returned by *enumerate()*.

Modifié dans la version 2.6 : Added `active_count()` spelling.

`threading.Condition()`

A factory function that returns a new condition variable object. A condition variable allows one or more threads to wait until they are notified by another thread.

See *Condition Objects*.

`threading.current_thread()`

`threading.currentThread()`

Return the current *Thread* object, corresponding to the caller's thread of control. If the caller's thread of control was not created through the *threading* module, a dummy thread object with limited functionality is returned.

Modifié dans la version 2.6 : Added `current_thread()` spelling.

`threading.enumerate()`

Return a list of all *Thread* objects currently alive. The list includes daemon threads, dummy thread objects created by *current\_thread()*, and the main thread. It excludes terminated threads and threads that have not yet been started.

`threading.Event()`

A factory function that returns a new event object. An event manages a flag that can be set to true with the *set()* method and reset to false with the *clear()* method. The *wait()* method blocks until the flag is true.

See *Event Objects*.

**class `threading.local`**

A class that represents thread-local data. Thread-local data are data whose values are thread specific. To manage thread-local data, just create an instance of `local` (or a subclass) and store attributes on it :

```
mydata = threading.local()
mydata.x = 1
```

The instance's values will be different for separate threads.

For more details and extensive examples, see the documentation string of the `_threading_local` module.

Nouveau dans la version 2.4.

**`threading.Lock()`**

A factory function that returns a new primitive lock object. Once a thread has acquired it, subsequent attempts to acquire it block, until it is released; any thread may release it.

See *Lock Objects*.

**`threading.RLock()`**

A factory function that returns a new reentrant lock object. A reentrant lock must be released by the thread that acquired it. Once a thread has acquired a reentrant lock, the same thread may acquire it again without blocking; the thread must release it once for each time it has acquired it.

See *RLock Objects*.

**`threading.Semaphore([value])`**

A factory function that returns a new semaphore object. A semaphore manages a counter representing the number of `release()` calls minus the number of `acquire()` calls, plus an initial value. The `acquire()` method blocks if necessary until it can return without making the counter negative. If not given, *value* defaults to 1.

See *Semaphore Objects*.

**`threading.BoundedSemaphore([value])`**

A factory function that returns a new bounded semaphore object. A bounded semaphore checks to make sure its current value doesn't exceed its initial value. If it does, `ValueError` is raised. In most situations semaphores are used to guard resources with limited capacity. If the semaphore is released too many times it's a sign of a bug. If not given, *value* defaults to 1.

**class `threading.Thread`**

A class that represents a thread of control. This class can be safely subclassed in a limited fashion.

See *Thread Objects*.

**class `threading.Timer`**

A thread that executes a function after a specified interval has passed.

See *Timer Objects*.

**`threading.settrace(func)`**

Set a trace function for all threads started from the `threading` module. The *func* will be passed to `sys.settrace()` for each thread, before its `run()` method is called.

Nouveau dans la version 2.3.

**`threading.setprofile(func)`**

Set a profile function for all threads started from the `threading` module. The *func* will be passed to `sys.setprofile()` for each thread, before its `run()` method is called.

Nouveau dans la version 2.3.

**`threading.stack_size([size])`**

Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured

default) or a positive integer value of at least 32,768 (32 KiB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, a *ThreadError* is raised. If the specified stack size is invalid, a *ValueError* is raised and the stack size is unmodified. 32kB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32kB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4kB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability : Windows, systems with POSIX threads.

Nouveau dans la version 2.5.

#### exception `threading.ThreadError`

Raised for various threading-related errors as described below. Note that many interfaces use *RuntimeError* instead of *ThreadError*.

Detailed interfaces for the objects are documented below.

The design of this module is loosely based on Java's threading model. However, where Java makes locks and condition variables basic behavior of every object, they are separate objects in Python. Python's *Thread* class supports a subset of the behavior of Java's Thread class; currently, there are no priorities, no thread groups, and threads cannot be destroyed, stopped, suspended, resumed, or interrupted. The static methods of Java's Thread class, when implemented, are mapped to module-level functions.

All of the methods described below are executed atomically.

### 16.2.1 Thread Objects

This class represents an activity that is run in a separate thread of control. There are two ways to specify the activity : by passing a callable object to the constructor, or by overriding the `run()` method in a subclass. No other methods (except for the constructor) should be overridden in a subclass. In other words, *only* override the `__init__()` and `run()` methods of this class.

Once a thread object is created, its activity must be started by calling the thread's `start()` method. This invokes the `run()` method in a separate thread of control.

Once the thread's activity is started, the thread is considered "alive". It stops being alive when its `run()` method terminates – either normally, or by raising an unhandled exception. The `is_alive()` method tests whether the thread is alive.

Other threads can call a thread's `join()` method. This blocks the calling thread until the thread whose `join()` method is called is terminated.

A thread has a name. The name can be passed to the constructor, and read or changed through the `name` attribute.

A thread can be flagged as a « daemon thread ». The significance of this flag is that the entire Python program exits when only daemon threads are left. The initial value is inherited from the creating thread. The flag can be set through the `daemon` property.

---

**Note :** Daemon threads are abruptly stopped at shutdown. Their resources (such as open files, database transactions, etc.) may not be released properly. If you want your threads to stop gracefully, make them non-daemonic and use a suitable signalling mechanism such as an *Event*.

---

There is a « main thread » object; this corresponds to the initial thread of control in the Python program. It is not a daemon thread.

There is the possibility that « dummy thread objects » are created. These are thread objects corresponding to « alien threads », which are threads of control started outside the threading module, such as directly from

C code. Dummy thread objects have limited functionality; they are always considered alive and daemonic, and cannot be `join()`ed. They are never deleted, since it is impossible to detect the termination of alien threads.

**class** `threading.Thread`(*group=None*, *target=None*, *name=None*, *args=()*, *kwargs={}*)

This constructor should always be called with keyword arguments. Arguments are :

*group* should be `None`; reserved for future extension when a `ThreadGroup` class is implemented.

*target* is the callable object to be invoked by the `run()` method. Defaults to `None`, meaning nothing is called.

*name* is the thread name. By default, a unique name is constructed of the form « Thread-*N* » where *N* is a small decimal number.

*args* is the argument tuple for the target invocation. Defaults to `()`.

*kwargs* is a dictionary of keyword arguments for the target invocation. Defaults to `{}`.

If the subclass overrides the constructor, it must make sure to invoke the base class constructor (`Thread.__init__()`) before doing anything else to the thread.

**start()**

Start the thread's activity.

It must be called at most once per thread object. It arranges for the object's `run()` method to be invoked in a separate thread of control.

This method will raise a `RuntimeError` if called more than once on the same thread object.

**run()**

Method representing the thread's activity.

You may override this method in a subclass. The standard `run()` method invokes the callable object passed to the object's constructor as the *target* argument, if any, with sequential and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

**join**([*timeout*])

Wait until the thread terminates. This blocks the calling thread until the thread whose `join()` method is called terminates – either normally or through an unhandled exception – or until the optional timeout occurs.

When the *timeout* argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof). As `join()` always returns `None`, you must call `isAlive()` after `join()` to decide whether a timeout happened – if the thread is still alive, the `join()` call timed out.

When the *timeout* argument is not present or `None`, the operation will block until the thread terminates.

A thread can be `join()`ed many times.

`join()` raises a `RuntimeError` if an attempt is made to join the current thread as that would cause a deadlock. It is also an error to `join()` a thread before it has been started and attempts to do so raises the same exception.

**name**

A string used for identification purposes only. It has no semantics. Multiple threads may be given the same name. The initial name is set by the constructor.

Nouveau dans la version 2.6.

**getName()**

**setName()**

Pre-2.6 API for *name*.

**ident**

The “thread identifier” of this thread or `None` if the thread has not been started. This is a nonzero integer. See the `thread.get_ident()` function. Thread identifiers may be recycled when a thread exits and another thread is created. The identifier is available even after the thread has exited.

Nouveau dans la version 2.6.

**is\_alive()**

**isAlive()**

Return whether the thread is alive.

This method returns **True** just before the `run()` method starts until just after the `run()` method terminates. The module function `enumerate()` returns a list of all alive threads.

Modifié dans la version 2.6 : Added `is_alive()` spelling.

**daemon**

A boolean value indicating whether this thread is a daemon thread (**True**) or not (**False**). This must be set before `start()` is called, otherwise `RuntimeError` is raised. Its initial value is inherited from the creating thread ; the main thread is not a daemon thread and therefore all threads created in the main thread default to `daemon = False`.

The entire Python program exits when no alive non-daemon threads are left.

Nouveau dans la version 2.6.

**isDaemon()****setDaemon()**

Pre-2.6 API for `daemon`.

## 16.2.2 Lock Objects

A primitive lock is a synchronization primitive that is not owned by a particular thread when locked. In Python, it is currently the lowest level synchronization primitive available, implemented directly by the `thread` extension module.

A primitive lock is in one of two states, « locked » or « unlocked ». It is created in the unlocked state. It has two basic methods, `acquire()` and `release()`. When the state is unlocked, `acquire()` changes the state to locked and returns immediately. When the state is locked, `acquire()` blocks until a call to `release()` in another thread changes it to unlocked, then the `acquire()` call resets it to locked and returns. The `release()` method should only be called in the locked state ; it changes the state to unlocked and returns immediately. If an attempt is made to release an unlocked lock, a `ThreadError` will be raised.

When more than one thread is blocked in `acquire()` waiting for the state to turn to unlocked, only one thread proceeds when a `release()` call resets the state to unlocked ; which one of the waiting threads proceeds is not defined, and may vary across implementations.

All methods are executed atomically.

**Lock.acquire(*[blocking]*)**

Acquire a lock, blocking or non-blocking.

When invoked with the *blocking* argument set to **True** (the default), block until the lock is unlocked, then set it to locked and return **True**.

When invoked with the *blocking* argument set to **False**, do not block. If a call with *blocking* set to **True** would block, return **False** immediately ; otherwise, set the lock to locked and return **True**.

**Lock.release()**

Libère un verrou.

When the lock is locked, reset it to unlocked, and return. If any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a `ThreadError` is raised.

Il n'y a pas de valeur de retour.

## 16.2.3 RLock Objects

A reentrant lock is a synchronization primitive that may be acquired multiple times by the same thread. Internally, it uses the concepts of « owning thread » and « recursion level » in addition to the locked/unlocked state used by primitive locks. In the locked state, some thread owns the lock ; in the unlocked state, no thread owns it.

To lock the lock, a thread calls its `acquire()` method ; this returns once the thread owns the lock. To unlock the lock, a thread calls its `release()` method. `acquire()/release()` call pairs may be nested ; only the final `release()` (the `release()` of the outermost pair) resets the lock to unlocked and allows another thread blocked in `acquire()` to proceed.

`RLock.acquire([blocking=1])`

Acquire a lock, blocking or non-blocking.

When invoked without arguments : if this thread already owns the lock, increment the recursion level by one, and return immediately. Otherwise, if another thread owns the lock, block until the lock is unlocked. Once the lock is unlocked (not owned by any thread), then grab ownership, set the recursion level to one, and return. If more than one thread is blocked waiting until the lock is unlocked, only one at a time will be able to grab ownership of the lock. There is no return value in this case.

When invoked with the *blocking* argument set to true, do the same thing as when called without arguments, and return true.

When invoked with the *blocking* argument set to false, do not block. If a call without an argument would block, return false immediately ; otherwise, do the same thing as when called without arguments, and return true.

`RLock.release()`

Release a lock, decrementing the recursion level. If after the decrement it is zero, reset the lock to unlocked (not owned by any thread), and if any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling thread.

Only call this method when the calling thread owns the lock. A *RuntimeError* is raised if this method is called when the lock is unlocked.

Il n'y a pas de valeur de retour.

## 16.2.4 Condition Objects

A condition variable is always associated with some kind of lock ; this can be passed in or one will be created by default. (Passing one in is useful when several condition variables must share the same lock.)

A condition variable has `acquire()` and `release()` methods that call the corresponding methods of the associated lock. It also has a `wait()` method, and `notify()` and `notifyAll()` methods. These three must only be called when the calling thread has acquired the lock, otherwise a *RuntimeError* is raised.

The `wait()` method releases the lock, and then blocks until it is awakened by a `notify()` or `notifyAll()` call for the same condition variable in another thread. Once awakened, it re-acquires the lock and returns. It is also possible to specify a timeout.

The `notify()` method wakes up one of the threads waiting for the condition variable, if any are waiting. The `notifyAll()` method wakes up all threads waiting for the condition variable.

Note : the `notify()` and `notifyAll()` methods don't release the lock ; this means that the thread or threads awakened will not return from their `wait()` call immediately, but only when the thread that called `notify()` or `notifyAll()` finally relinquishes ownership of the lock.

Tip : the typical programming style using condition variables uses the lock to synchronize access to some shared state ; threads that are interested in a particular change of state call `wait()` repeatedly until they see the desired state, while threads that modify the state call `notify()` or `notifyAll()` when they change the state in such a way that it could possibly be a desired state for one of the waiters. For example, the following code is a generic producer-consumer situation with unlimited buffer capacity :

```
# Consume one item
cv.acquire()
while not an_item_is_available():
```

(suite sur la page suivante)

(suite de la page précédente)

```

    cv.wait()
get_an_available_item()
cv.release()

# Produce one item
cv.acquire()
make_an_item_available()
cv.notify()
cv.release()

```

To choose between `notify()` and `notifyAll()`, consider whether one state change can be interesting for only one or several waiting threads. E.g. in a typical producer-consumer situation, adding one item to the buffer only needs to wake up one consumer thread.

**class** `threading.Condition([lock])`

If the *lock* argument is given and not `None`, it must be a *Lock* or *RLock* object, and it is used as the underlying lock. Otherwise, a new *RLock* object is created and used as the underlying lock.

**acquire**(*\*args*)

Acquire the underlying lock. This method calls the corresponding method on the underlying lock; the return value is whatever that method returns.

**release**()

Release the underlying lock. This method calls the corresponding method on the underlying lock; there is no return value.

**wait**([*timeout*])

Wait until notified or until a timeout occurs. If the calling thread has not acquired the lock when this method is called, a *RuntimeError* is raised.

This method releases the underlying lock, and then blocks until it is awakened by a *notify()* or *notifyAll()* call for the same condition variable in another thread, or until the optional timeout occurs. Once awakened or timed out, it re-acquires the lock and returns.

When the *timeout* argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

When the underlying lock is an *RLock*, it is not released using its *release()* method, since this may not actually unlock the lock when it was acquired multiple times recursively. Instead, an internal interface of the *RLock* class is used, which really unlocks it even when it has been recursively acquired several times. Another internal interface is then used to restore the recursion level when the lock is reacquired.

**notify**(*n=1*)

By default, wake up one thread waiting on this condition, if any. If the calling thread has not acquired the lock when this method is called, a *RuntimeError* is raised.

This method wakes up at most *n* of the threads waiting for the condition variable; it is a no-op if no threads are waiting.

The current implementation wakes up exactly *n* threads, if at least *n* threads are waiting. However, it's not safe to rely on this behavior. A future, optimized implementation may occasionally wake up more than *n* threads.

Note : an awakened thread does not actually return from its *wait()* call until it can reacquire the lock. Since *notify()* does not release the lock, its caller should.

**notify\_all**()

**notifyAll**()

Wake up all threads waiting on this condition. This method acts like *notify()*, but wakes up all waiting threads instead of one. If the calling thread has not acquired the lock when this method is called, a *RuntimeError* is raised.

Modifié dans la version 2.6 : Added *notify\_all()* spelling.

### 16.2.5 Semaphore Objects

This is one of the oldest synchronization primitives in the history of computer science, invented by the early Dutch computer scientist Edsger W. Dijkstra (he used `P()` and `V()` instead of `acquire()` and `release()`).

A semaphore manages an internal counter which is decremented by each `acquire()` call and incremented by each `release()` call. The counter can never go below zero; when `acquire()` finds that it is zero, it blocks, waiting until some other thread calls `release()`.

**class** `threading.Semaphore`(`[value]`)

The optional argument gives the initial *value* for the internal counter; it defaults to 1. If the *value* given is less than 0, `ValueError` is raised.

**acquire**(`[blocking]`)

Acquire a semaphore.

When invoked without arguments : if the internal counter is larger than zero on entry, decrement it by one and return immediately. If it is zero on entry, block, waiting until some other thread has called `release()` to make it larger than zero. This is done with proper interlocking so that if multiple `acquire()` calls are blocked, `release()` will wake exactly one of them up. The implementation may pick one at random, so the order in which blocked threads are awakened should not be relied on. There is no return value in this case.

When invoked with *blocking* set to true, do the same thing as when called without arguments, and return true.

When invoked with *blocking* set to false, do not block. If a call without an argument would block, return false immediately; otherwise, do the same thing as when called without arguments, and return true.

**release**()

Release a semaphore, incrementing the internal counter by one. When it was zero on entry and another thread is waiting for it to become larger than zero again, wake up that thread.

#### Semaphore Example

Semaphores are often used to guard resources with limited capacity, for example, a database server. In any situation where the size of the resource is fixed, you should use a bounded semaphore. Before spawning any worker threads, your main thread would initialize the semaphore :

```
maxconnections = 5
...
pool_sema = BoundedSemaphore(value=maxconnections)
```

Once spawned, worker threads call the semaphore's `acquire` and `release` methods when they need to connect to the server :

```
pool_sema.acquire()
conn = connectdb()
... use connection ...
conn.close()
pool_sema.release()
```

The use of a bounded semaphore reduces the chance that a programming error which causes the semaphore to be released more than it's acquired will go undetected.

### 16.2.6 Event Objects

This is one of the simplest mechanisms for communication between threads : one thread signals an event and other threads wait for it.

An event object manages an internal flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true.

**class threading.Event**

The internal flag is initially false.

**is\_set()****isSet()**

Return true if and only if the internal flag is true.

Modifié dans la version 2.6 : Added `is_set()` spelling.

**set()**

Set the internal flag to true. All threads waiting for it to become true are awakened. Threads that call `wait()` once the flag is true will not block at all.

**clear()**

Reset the internal flag to false. Subsequently, threads calling `wait()` will block until `set()` is called to set the internal flag to true again.

**wait([*timeout*])**

Block until the internal flag is true. If the internal flag is true on entry, return immediately. Otherwise, block until another thread calls `set()` to set the flag to true, or until the optional timeout occurs.

When the timeout argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

This method returns the internal flag on exit, so it will always return `True` except if a timeout is given and the operation times out.

Modifié dans la version 2.7 : Previously, the method always returned `None`.

## 16.2.7 Timer Objects

This class represents an action that should be run only after a certain amount of time has passed — a timer. `Timer` is a subclass of `Thread` and as such also functions as an example of creating custom threads.

Timers are started, as with threads, by calling their `start()` method. The timer can be stopped (before its action has begun) by calling the `cancel()` method. The interval the timer will wait before executing its action may not be exactly the same as the interval specified by the user.

Par exemple :

```
def hello():
    print "hello, world"

t = Timer(30.0, hello)
t.start()  # after 30 seconds, "hello, world" will be printed
```

**class threading.Timer(interval, function, args=[], kwargs={})**

Create a timer that will run *function* with arguments *args* and keyword arguments *kwargs*, after *interval* seconds have passed.

**cancel()**

Stop the timer, and cancel the execution of the timer's action. This will only work if the timer is still in its waiting stage.

## 16.2.8 Using locks, conditions, and semaphores in the with statement

All of the objects provided by this module that have `acquire()` and `release()` methods can be used as context managers for a `with` statement. The `acquire()` method will be called when the block is entered, and `release()` will be called when the block is exited.

Currently, *Lock*, *RLock*, *Condition*, *Semaphore*, and *BoundedSemaphore* objects may be used as `with` statement context managers. For example :

```
import threading

some_rlock = threading.RLock()

with some_rlock:
    print "some_rlock is locked while this executes"
```

### 16.2.9 Importing in threaded code

While the import machinery is thread-safe, there are two key restrictions on threaded imports due to inherent limitations in the way that thread-safety is provided :

- Firstly, other than in the main module, an import should not have the side effect of spawning a new thread and then waiting for that thread in any way. Failing to abide by this restriction can lead to a deadlock if the spawned thread directly or indirectly attempts to import a module.
- Secondly, all import attempts must be completed before the interpreter starts shutting itself down. This can be most easily achieved by only performing imports from non-daemon threads created through the threading module. Daemon threads and threads created directly with the thread module will require some other form of synchronization to ensure they do not attempt imports after system shutdown has commenced. Failure to abide by this restriction will lead to intermittent exceptions and crashes during interpreter shutdown (as the late imports attempt to access machinery which is no longer in a valid state).

## 16.3 thread — Multiple threads of control

---

**Note :** The *thread* module has been renamed to *\_thread* in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3 ; however, you should consider using the high-level *threading* module instead.

---

This module provides low-level primitives for working with multiple threads (also called *light-weight processes* or *tasks*) — multiple threads of control sharing their global data space. For synchronization, simple locks (also called *mutexes* or *binary semaphores*) are provided. The *threading* module provides an easier to use and higher-level threading API built on top of this module.

The module is optional. It is supported on Windows, Linux, SGI IRIX, Solaris 2.x, as well as on systems that have a POSIX thread (a.k.a. « pthread ») implementation. For systems lacking the *thread* module, the *dummy\_thread* module is available. It duplicates this module's interface and can be used as a drop-in replacement.

It defines the following constant and functions :

**exception** *thread.error*

Levée lors d'erreur spécifique aux fils d'exécution.

**thread.LockType**

C'est le type des verrous.

**thread.start\_new\_thread**(*function*, *args*[, *kwargs*])

Start a new thread and return its identifier. The thread executes the function *function* with the argument list *args* (which must be a tuple). The optional *kwargs* argument specifies a dictionary of keyword arguments. When the function returns, the thread silently exits. When the function terminates with

an unhandled exception, a stack trace is printed and then the thread exits (but other threads continue to run).

`thread.interrupt_main()`

Raise a `KeyboardInterrupt` exception in the main thread. A subthread can use this function to interrupt the main thread.

Nouveau dans la version 2.3.

`thread.exit()`

Raise the `SystemExit` exception. When not caught, this will cause the thread to exit silently.

`thread.allocate_lock()`

Renvoie un nouvel objet `lock`. Les méthodes de l'objet `lock` sont décrites ci-après. Le `lock` est initialement déverrouillé.

`thread.get_ident()`

Return the “thread identifier” of the current thread. This is a nonzero integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

`thread.stack_size([size])`

Return the thread stack size used when creating new threads. The optional `size` argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32kB). If `size` is not specified, 0 is used. If changing the thread stack size is unsupported, the `error` exception is raised. If the specified stack size is invalid, a `ValueError` is raised and the stack size is unmodified. 32kB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32kB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4kB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability : Windows, systems with POSIX threads.

Nouveau dans la version 2.5.

Les verrous (*lock objects*) ont les méthodes suivantes :

`lock.acquire([waitflag])`

Without the optional argument, this method acquires the lock unconditionally, if necessary waiting until it is released by another thread (only one thread at a time can acquire a lock — that’s their reason for existence). If the integer `waitflag` argument is present, the action depends on its value : if it is zero, the lock is only acquired if it can be acquired immediately without waiting, while if it is nonzero, the lock is acquired unconditionally as before. The return value is `True` if the lock is acquired successfully, `False` if not.

`lock.release()`

Releases the lock. The lock must have been acquired earlier, but not necessarily by the same thread.

`lock.locked()`

Return the status of the lock : `True` if it has been acquired by some thread, `False` if not.

In addition to these methods, lock objects can also be used via the `with` statement, e.g. :

```
import thread

a_lock = thread.allocate_lock()

with a_lock:
    print "a_lock is locked while this executes"
```

**Avertissements :**

- Threads interact strangely with interrupts : the `KeyboardInterrupt` exception will be received by an arbitrary thread. (When the `signal` module is available, interrupts always go to the main thread.)
- Calling `sys.exit()` or raising the `SystemExit` exception is equivalent to calling `thread.exit()`.
- It is not possible to interrupt the `acquire()` method on a lock — the `KeyboardInterrupt` exception will happen after the lock has been acquired.
- When the main thread exits, it is system defined whether the other threads survive. On SGI IRIX using the native thread implementation, they survive. On most other systems, they are killed without executing `try ... finally` clauses or executing object destructors.
- When the main thread exits, it does not do any of its usual cleanup (except that `try ... finally` clauses are honored), and the standard I/O files are not flushed.

## 16.4 dummy\_threading — Module de substitution au module threading

Code source : [Lib/dummy\\_threading.py](#)

This module provides a duplicate interface to the `threading` module. It is meant to be imported when the `thread` module is not provided on a platform.

Utilisation suggérée :

```
try:
    import threading as _threading
except ImportError:
    import dummy_threading as _threading
```

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.

## 16.5 dummy\_thread — Drop-in replacement for the thread module

**Note :** The `dummy_thread` module has been renamed to `_dummy_thread` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3; however, you should consider using the high-level `dummy_threading` module instead.

Source code : [Lib/dummy\\_thread.py](#)

This module provides a duplicate interface to the `thread` module. It is meant to be imported when the `thread` module is not provided on a platform.

Utilisation suggérée :

```
try:
    import thread as _thread
except ImportError:
    import dummy_thread as _thread
```

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.

## 16.6 multiprocessing — Process-based « threading » interface

Nouveau dans la version 2.6.

### 16.6.1 Introduction

*multiprocessing* is a package that supports spawning processes using an API similar to the *threading* module. The *multiprocessing* package offers both local and remote concurrency, effectively side-stepping the *Global Interpreter Lock* by using subprocesses instead of threads. Due to this, the *multiprocessing* module allows the programmer to fully leverage multiple processors on a given machine. It runs on both Unix and Windows.

The *multiprocessing* module also introduces APIs which do not have analogs in the *threading* module. A prime example of this is the *Pool* object which offers a convenient means of parallelizing the execution of a function across multiple input values, distributing the input data across processes (data parallelism). The following example demonstrates the common practice of defining such functions in a module so that child processes can successfully import that module. This basic example of data parallelism using *Pool*,

```
from multiprocessing import Pool

def f(x):
    return x*x

if __name__ == '__main__':
    p = Pool(5)
    print(p.map(f, [1, 2, 3]))
```

will print to standard output

```
[1, 4, 9]
```

### The Process class

In *multiprocessing*, processes are spawned by creating a *Process* object and then calling its *start()* method. *Process* follows the API of *threading.Thread*. A trivial example of a multiprocess program is

```
from multiprocessing import Process

def f(name):
    print 'hello', name

if __name__ == '__main__':
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

To show the individual process IDs involved, here is an expanded example :

```
from multiprocessing import Process
import os

def info(title):
    print title
    print 'module name:', __name__
```

(suite sur la page suivante)

(suite de la page précédente)

```

if hasattr(os, 'getppid'): # only available on Unix
    print 'parent process:', os.getppid()
print 'process id:', os.getpid()

def f(name):
    info('function f')
    print 'hello', name

if __name__ == '__main__':
    info('main line')
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()

```

For an explanation of why (on Windows) the `if __name__ == '__main__':` part is necessary, see *Programming guidelines*.

### Exchanging objects between processes

*multiprocessing* supports two types of communication channel between processes :

#### Queues

The *Queue* class is a near clone of *Queue.Queue*. For example :

```

from multiprocessing import Process, Queue

def f(q):
    q.put([42, None, 'hello'])

if __name__ == '__main__':
    q = Queue()
    p = Process(target=f, args=(q,))
    p.start()
    print q.get()    # prints "[42, None, 'hello']"
    p.join()

```

Queues are thread and process safe.

#### Pipes

The *Pipe()* function returns a pair of connection objects connected by a pipe which by default is duplex (two-way). For example :

```

from multiprocessing import Process, Pipe

def f(conn):
    conn.send([42, None, 'hello'])
    conn.close()

if __name__ == '__main__':
    parent_conn, child_conn = Pipe()
    p = Process(target=f, args=(child_conn,))
    p.start()
    print parent_conn.recv()    # prints "[42, None, 'hello']"
    p.join()

```

The two connection objects returned by `Pipe()` represent the two ends of the pipe. Each connection object has `send()` and `recv()` methods (among others). Note that data in a pipe may become corrupted if two processes (or threads) try to read from or write to the *same* end of the pipe at the same time. Of course there is no risk of corruption from processes using different ends of the pipe at the same time.

### Synchronization between processes

`multiprocessing` contains equivalents of all the synchronization primitives from `threading`. For instance one can use a lock to ensure that only one process prints to standard output at a time :

```
from multiprocessing import Process, Lock

def f(l, i):
    l.acquire()
    print 'hello world', i
    l.release()

if __name__ == '__main__':
    lock = Lock()

    for num in range(10):
        Process(target=f, args=(lock, num)).start()
```

Without using the lock output from the different processes is liable to get all mixed up.

### Sharing state between processes

As mentioned above, when doing concurrent programming it is usually best to avoid using shared state as far as possible. This is particularly true when using multiple processes.

However, if you really do need to use some shared data then `multiprocessing` provides a couple of ways of doing so.

#### Shared memory

Data can be stored in a shared memory map using `Value` or `Array`. For example, the following code

```
from multiprocessing import Process, Value, Array

def f(n, a):
    n.value = 3.1415927
    for i in range(len(a)):
        a[i] = -a[i]

if __name__ == '__main__':
    num = Value('d', 0.0)
    arr = Array('i', range(10))

    p = Process(target=f, args=(num, arr))
    p.start()
    p.join()

    print num.value
    print arr[:]
```

will print

```
3.1415927
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
```

The 'd' and 'i' arguments used when creating `num` and `arr` are typecodes of the kind used by the `array` module : 'd' indicates a double precision float and 'i' indicates a signed integer. These shared objects will be process and thread-safe.

For more flexibility in using shared memory one can use the `multiprocessing.sharedctypes` module which supports the creation of arbitrary ctypes objects allocated from shared memory.

### Server process

A manager object returned by `Manager()` controls a server process which holds Python objects and allows other processes to manipulate them using proxies.

A manager returned by `Manager()` will support types `list`, `dict`, `Namespace`, `Lock`, `RLock`, `Semaphore`, `BoundedSemaphore`, `Condition`, `Event`, `Queue`, `Value` and `Array`. For example,

```
from multiprocessing import Process, Manager

def f(d, l):
    d[1] = '1'
    d['2'] = 2
    d[0.25] = None
    l.reverse()

if __name__ == '__main__':
    manager = Manager()

    d = manager.dict()
    l = manager.list(range(10))

    p = Process(target=f, args=(d, l))
    p.start()
    p.join()

    print d
    print l
```

will print

```
{0.25: None, 1: '1', '2': 2}
[9, 8, 7, 6, 5, 4, 3, 2, 1, 0]
```

Server process managers are more flexible than using shared memory objects because they can be made to support arbitrary object types. Also, a single manager can be shared by processes on different computers over a network. They are, however, slower than using shared memory.

### Using a pool of workers

The `Pool` class represents a pool of worker processes. It has methods which allows tasks to be offloaded to the worker processes in a few different ways.

Par exemple :

```
from multiprocessing import Pool, TimeoutError
import time
```

(suite sur la page suivante)

(suite de la page précédente)

```

import os

def f(x):
    return x*x

if __name__ == '__main__':
    pool = Pool(processes=4)           # start 4 worker processes

    # print "[0, 1, 4,..., 81]"
    print pool.map(f, range(10))

    # print same numbers in arbitrary order
    for i in pool.imap_unordered(f, range(10)):
        print i

    # evaluate "f(20)" asynchronously
    res = pool.apply_async(f, (20,))   # runs in *only* one process
    print res.get(timeout=1)           # prints "400"

    # evaluate "os.getpid()" asynchronously
    res = pool.apply_async(os.getpid, ()) # runs in *only* one process
    print res.get(timeout=1)           # prints the PID of that process

    # launching multiple evaluations asynchronously *may* use more processes
    multiple_results = [pool.apply_async(os.getpid, ()) for i in range(4)]
    print [res.get(timeout=1) for res in multiple_results]

    # make a single worker sleep for 10 secs
    res = pool.apply_async(time.sleep, (10,))
    try:
        print res.get(timeout=1)
    except TimeoutError:
        print "We lacked patience and got a multiprocessing.TimeoutError"

```

Note that the methods of a pool should only ever be used by the process which created it.

**Note :** Functionality within this package requires that the `__main__` module be importable by the children. This is covered in *Programming guidelines* however it is worth pointing out here. This means that some examples, such as the Pool examples will not work in the interactive interpreter. For example :

```

>>> from multiprocessing import Pool
>>> p = Pool(5)
>>> def f(x):
...     return x*x
...
>>> p.map(f, [1,2,3])
Process PoolWorker-1:
Process PoolWorker-2:
Process PoolWorker-3:
Traceback (most recent call last):
AttributeError: 'module' object has no attribute 'f'

```

(suite sur la page suivante)

(suite de la page précédente)

```

AttributeError: 'module' object has no attribute 'f'
AttributeError: 'module' object has no attribute 'f'

```

(If you try this it will actually output three full tracebacks interleaved in a semi-random fashion, and then you may have to stop the master process somehow.)

## 16.6.2 Reference

The *multiprocessing* package mostly replicates the API of the *threading* module.

### Process and exceptions

**class multiprocessing.Process**(*group=None*, *target=None*, *name=None*, *args=()*, *kwargs={}*)

Process objects represent activity that is run in a separate process. The *Process* class has equivalents of all the methods of *threading.Thread*.

The constructor should always be called with keyword arguments. *group* should always be *None*; it exists solely for compatibility with *threading.Thread*. *target* is the callable object to be invoked by the *run()* method. It defaults to *None*, meaning nothing is called. *name* is the process name. By default, a unique name is constructed of the form “Process-*N*<sub>1</sub>:*N*<sub>2</sub> :... :*N*<sub>*k*</sub>” where *N*<sub>1</sub>,*N*<sub>2</sub>,...,*N*<sub>*k*</sub> is a sequence of integers whose length is determined by the *generation* of the process. *args* is the argument tuple for the target invocation. *kwargs* is a dictionary of keyword arguments for the target invocation. By default, no arguments are passed to *target*.

If a subclass overrides the constructor, it must make sure it invokes the base class constructor (*Process.\_\_init\_\_()*) before doing anything else to the process.

**run()**

Method representing the process’s activity.

You may override this method in a subclass. The standard *run()* method invokes the callable object passed to the object’s constructor as the target argument, if any, with sequential and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

**start()**

Start the process’s activity.

This must be called at most once per process object. It arranges for the object’s *run()* method to be invoked in a separate process.

**join**([*timeout*])

Block the calling thread until the process whose *join()* method is called terminates or until the optional timeout occurs.

If *timeout* is *None* then there is no timeout.

A process can be joined many times.

A process cannot join itself because this would cause a deadlock. It is an error to attempt to join a process before it has been started.

**name**

The process’s name.

The name is a string used for identification purposes only. It has no semantics. Multiple processes may be given the same name. The initial name is set by the constructor.

**is\_alive()**

Return whether the process is alive.

Roughly, a process object is alive from the moment the *start()* method returns until the child process terminates.

**daemon**

The process’s daemon flag, a Boolean value. This must be set before *start()* is called.

The initial value is inherited from the creating process.

When a process exits, it attempts to terminate all of its daemon child processes.

Note that a daemon process is not allowed to create child processes. Otherwise a daemon process would leave its children orphaned if it gets terminated when its parent process exits. Additionally, these are **not** Unix daemons or services, they are normal processes that will be terminated (and not joined) if non-daemon processes have exited.

In addition to the `threading.Thread` API, `Process` objects also support the following attributes and methods :

**pid**

Return the process ID. Before the process is spawned, this will be `None`.

**exitcode**

The child's exit code. This will be `None` if the process has not yet terminated. A negative value `-N` indicates that the child was terminated by signal `N`.

**authkey**

The process's authentication key (a byte string).

When `multiprocessing` is initialized the main process is assigned a random string using `os.urandom()`.

When a `Process` object is created, it will inherit the authentication key of its parent process, although this may be changed by setting `authkey` to another byte string.

See *Authentication keys*.

**terminate()**

Terminate the process. On Unix this is done using the `SIGTERM` signal; on Windows `TerminateProcess()` is used. Note that exit handlers and finally clauses, etc., will not be executed.

Note that descendant processes of the process will *not* be terminated – they will simply become orphaned.

**Avertissement :** If this method is used when the associated process is using a pipe or queue then the pipe or queue is liable to become corrupted and may become unusable by other process. Similarly, if the process has acquired a lock or semaphore etc. then terminating it is liable to cause other processes to deadlock.

Note that the `start()`, `join()`, `is_alive()`, `terminate()` and `exitcode` methods should only be called by the process that created the process object.

Example usage of some of the methods of `Process` :

```
>>> import multiprocessing, time, signal
>>> p = multiprocessing.Process(target=time.sleep, args=(1000,))
>>> print p, p.is_alive()
<Process(Process-1, initial)> False
>>> p.start()
>>> print p, p.is_alive()
<Process(Process-1, started)> True
>>> p.terminate()
>>> time.sleep(0.1)
>>> print p, p.is_alive()
<Process(Process-1, stopped[SIGTERM])> False
>>> p.exitcode == -signal.SIGTERM
True
```

**exception** `multiprocessing.BufferTooShort`

Exception raised by `Connection.recv_bytes_into()` when the supplied buffer object is too small for the message read.

If `e` is an instance of `BufferTooShort` then `e.args[0]` will give the message as a byte string.

## Pipes and Queues

When using multiple processes, one generally uses message passing for communication between processes and avoids having to use any synchronization primitives like locks.

For passing messages one can use `Pipe()` (for a connection between two processes) or a queue (which allows multiple producers and consumers).

The `Queue`, `multiprocessing.queues.SimpleQueue` and `JoinableQueue` types are multi-producer, multi-consumer FIFO queues modelled on the `Queue.Queue` class in the standard library. They differ in that `Queue` lacks the `task_done()` and `join()` methods introduced into Python 2.5's `Queue.Queue` class.

If you use `JoinableQueue` then you **must** call `JoinableQueue.task_done()` for each task removed from the queue or else the semaphore used to count the number of unfinished tasks may eventually overflow, raising an exception.

Note that one can also create a shared queue by using a manager object – see *Managers*.

---

**Note :** `multiprocessing` uses the usual `Queue.Empty` and `Queue.Full` exceptions to signal a timeout. They are not available in the `multiprocessing` namespace so you need to import them from `Queue`.

---

---

**Note :** When an object is put on a queue, the object is pickled and a background thread later flushes the pickled data to an underlying pipe. This has some consequences which are a little surprising, but should not cause any practical difficulties – if they really bother you then you can instead use a queue created with a *manager*.

- (1) After putting an object on an empty queue there may be an infinitesimal delay before the queue's `empty()` method returns `False` and `get_nowait()` can return without raising `Queue.Empty`.
  - (2) If multiple processes are enqueueing objects, it is possible for the objects to be received at the other end out-of-order. However, objects enqueueued by the same process will always be in the expected order with respect to each other.
- 

**Avertissement :** If a process is killed using `Process.terminate()` or `os.kill()` while it is trying to use a `Queue`, then the data in the queue is likely to become corrupted. This may cause any other process to get an exception when it tries to use the queue later on.

**Avertissement :** As mentioned above, if a child process has put items on a queue (and it has not used `JoinableQueue.cancel_join_thread()`), then that process will not terminate until all buffered items have been flushed to the pipe.

This means that if you try joining that process you may get a deadlock unless you are sure that all items which have been put on the queue have been consumed. Similarly, if the child process is non-daemonic then the parent process may hang on exit when it tries to join all its non-daemonic children.

Note that a queue created using a manager does not have this issue. See *Programming guidelines*.

For an example of the usage of queues for interprocess communication see *Examples*.

`multiprocessing.Pipe([duplex])`

Returns a pair (`conn1`, `conn2`) of `Connection` objects representing the ends of a pipe.

If *duplex* is **True** (the default) then the pipe is bidirectional. If *duplex* is **False** then the pipe is unidirectional : *conn1* can only be used for receiving messages and *conn2* can only be used for sending messages.

**class multiprocessing.Queue**([*maxsize*])

Returns a process shared queue implemented using a pipe and a few locks/semaphores. When a process first puts an item on the queue a feeder thread is started which transfers objects from a buffer into the pipe.

The usual *Queue.Empty* and *Queue.Full* exceptions from the standard library's *Queue* module are raised to signal timeouts.

*Queue* implements all the methods of *Queue.Queue* except for *task\_done()* and *join()*.

**qsize()**

Return the approximate size of the queue. Because of multithreading/multiprocessing semantics, this number is not reliable.

Note that this may raise *NotImplementedError* on Unix platforms like Mac OS X where *sem\_getvalue()* is not implemented.

**empty()**

Return **True** if the queue is empty, **False** otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

**full()**

Return **True** if the queue is full, **False** otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

**put**(*obj*[, *block*[, *timeout*]])

Put *obj* into the queue. If the optional argument *block* is **True** (the default) and *timeout* is **None** (the default), block if necessary until a free slot is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the *Queue.Full* exception if no free slot was available within that time. Otherwise (*block* is **False**), put an item on the queue if a free slot is immediately available, else raise the *Queue.Full* exception (*timeout* is ignored in that case).

**put\_nowait**(*obj*)

Equivalent to *put*(*obj*, **False**).

**get**([*block*[, *timeout*]])

Remove and return an item from the queue. If optional args *block* is **True** (the default) and *timeout* is **None** (the default), block if necessary until an item is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the *Queue.Empty* exception if no item was available within that time. Otherwise (*block* is **False**), return an item if one is immediately available, else raise the *Queue.Empty* exception (*timeout* is ignored in that case).

**get\_nowait()**

Équivalent à *get*(**False**).

*Queue* has a few additional methods not found in *Queue.Queue*. These methods are usually unnecessary for most code :

**close()**

Indicate that no more data will be put on this queue by the current process. The background thread will quit once it has flushed all buffered data to the pipe. This is called automatically when the queue is garbage collected.

**join\_thread()**

Join the background thread. This can only be used after *close()* has been called. It blocks until the background thread exits, ensuring that all data in the buffer has been flushed to the pipe.

By default if a process is not the creator of the queue then on exit it will attempt to join the queue's background thread. The process can call *cancel\_join\_thread()* to make *join\_thread()* do nothing.

**cancel\_join\_thread()**

Prevent *join\_thread()* from blocking. In particular, this prevents the background thread from being joined automatically when the process exits – see *join\_thread()*.

A better name for this method might be `allow_exit_without_flush()`. It is likely to cause enqueued data to be lost, and you almost certainly will not need to use it. It is really only there if you need the current process to exit immediately without waiting to flush enqueued data to the underlying pipe, and you don't care about lost data.

---

**Note :** This class's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the functionality in this class will be disabled, and attempts to instantiate a *Queue* will result in an *ImportError*. See [bpo-3770](#) for additional information. The same holds true for any of the specialized queue types listed below.

---

`class multiprocessing.queues.SimpleQueue`

It is a simplified *Queue* type, very close to a locked *Pipe*.

`empty()`

Return `True` if the queue is empty, `False` otherwise.

`get()`

Supprime et donne un élément de la queue.

`put(item)`

Put *item* into the queue.

`class multiprocessing.JoinableQueue([maxsize])`

*JoinableQueue*, a *Queue* subclass, is a queue which additionally has *task\_done()* and *join()* methods.

`task_done()`

Indicate that a formerly enqueued task is complete. Used by queue consumer threads. For each *get()* used to fetch a task, a subsequent call to *task\_done()* tells the queue that the processing on the task is complete.

If a *join()* is currently blocking, it will resume when all items have been processed (meaning that a *task\_done()* call was received for every item that had been *put()* into the queue).

Lève une exception *ValueError* si appelée plus de fois qu'il y avait d'éléments dans la file.

`join()`

Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls *task\_done()* to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, *join()* unblocks.

## Miscellaneous

`multiprocessing.active_children()`

Return list of all live children of the current process.

Calling this has the side effect of « joining » any processes which have already finished.

`multiprocessing.cpu_count()`

Return the number of CPUs in the system. May raise *NotImplementedError*.

`multiprocessing.current_process()`

Return the *Process* object corresponding to the current process.

An analogue of *threading.current\_thread()*.

`multiprocessing.freeze_support()`

Add support for when a program which uses *multiprocessing* has been frozen to produce a Windows executable. (Has been tested with *py2exe*, *PyInstaller* and *cx\_Freeze*.)

One needs to call this function straight after the `if __name__ == '__main__':` line of the main module. For example :

```
from multiprocessing import Process, freeze_support

def f():
    print 'hello world!'

if __name__ == '__main__':
    freeze_support()
    Process(target=f).start()
```

If the `freeze_support()` line is omitted then trying to run the frozen executable will raise *RuntimeError*.

Calling `freeze_support()` has no effect when invoked on any operating system other than Windows. In addition, if the module is being run normally by the Python interpreter on Windows (the program has not been frozen), then `freeze_support()` has no effect.

`multiprocessing.set_executable()`

Sets the path of the Python interpreter to use when starting a child process. (By default `sys.executable` is used). Embedders will probably need to do some thing like

```
set_executable(os.path.join(sys.exec_prefix, 'pythonw.exe'))
```

before they can create child processes. (Windows only)

---

**Note :** `multiprocessing` contains no analogues of `threading.active_count()`, `threading.enumerate()`, `threading.settrace()`, `threading.setprofile()`, `threading.Timer`, or `threading.local`.

---

## Connection Objects

Connection objects allow the sending and receiving of picklable objects or strings. They can be thought of as message oriented connected sockets.

Connection objects are usually created using *Pipe* – see also *Listeners and Clients*.

**class Connection**

**send(obj)**

Send an object to the other end of the connection which should be read using `recv()`.

The object must be picklable. Very large pickles (approximately 32 MB+, though it depends on the OS) may raise a *ValueError* exception.

**recv()**

Return an object sent from the other end of the connection using `send()`. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end was closed.

**fileno()**

Return the file descriptor or handle used by the connection.

**close()**

Close the connection.

This is called automatically when the connection is garbage collected.

**poll([timeout])**

Return whether there is any data available to be read.

If *timeout* is not specified then it will return immediately. If *timeout* is a number then this specifies the maximum time in seconds to block. If *timeout* is `None` then an infinite timeout is used.

`send_bytes(buffer[, offset[, size]])`

Send byte data from an object supporting the buffer interface as a complete message.

If *offset* is given then data is read from that position in *buffer*. If *size* is given then that many bytes will be read from buffer. Very large buffers (approximately 32 MB+, though it depends on the OS) may raise a *ValueError* exception

`recv_bytes([maxlength])`

Return a complete message of byte data sent from the other end of the connection as a string. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end has closed.

If *maxlength* is specified and the message is longer than *maxlength* then *IOError* is raised and the connection will no longer be readable.

`recv_bytes_into(buffer[, offset])`

Read into *buffer* a complete message of byte data sent from the other end of the connection and return the number of bytes in the message. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end was closed.

*buffer* must be an object satisfying the writable buffer interface. If *offset* is given then the message will be written into the buffer from that position. Offset must be a non-negative integer less than the length of *buffer* (in bytes).

If the buffer is too short then a *BufferTooShort* exception is raised and the complete message is available as `e.args[0]` where *e* is the exception instance.

Par exemple :

```
>>> from multiprocessing import Pipe
>>> a, b = Pipe()
>>> a.send([1, 'hello', None])
>>> b.recv()
[1, 'hello', None]
>>> b.send_bytes('thank you')
>>> a.recv_bytes()
'thank you'
>>> import array
>>> arr1 = array.array('i', range(5))
>>> arr2 = array.array('i', [0] * 10)
>>> a.send_bytes(arr1)
>>> count = b.recv_bytes_into(arr2)
>>> assert count == len(arr1) * arr1.itemsize
>>> arr2
array('i', [0, 1, 2, 3, 4, 0, 0, 0, 0, 0])
```

**Avertissement :** The `Connection.recv()` method automatically unpickles the data it receives, which can be a security risk unless you can trust the process which sent the message.

Therefore, unless the connection object was produced using `Pipe()` you should only use the `recv()` and `send()` methods after performing some sort of authentication. See *Authentication keys*.

**Avertissement :** If a process is killed while it is trying to read or write to a pipe then the data in the pipe is likely to become corrupted, because it may become impossible to be sure where the message boundaries lie.

## Synchronization primitives

Generally synchronization primitives are not as necessary in a multiprocess program as they are in a multi-threaded program. See the documentation for [\*threading\*](#) module.

Note that one can also create synchronization primitives by using a manager object – see [\*Managers\*](#).

**class** multiprocessing.BoundedSemaphore(*[value]*)

A bounded semaphore object : a close analog of [\*threading.BoundedSemaphore\*](#).

A solitary difference from its close analog exists : its **acquire** method's first argument is named *block* and it supports an optional second argument *timeout*, as is consistent with [\*Lock.acquire\(\)\*](#).

---

**Note :** On Mac OS X, this is indistinguishable from [\*Semaphore\*](#) because **sem\_getvalue()** is not implemented on that platform.

---

**class** multiprocessing.Condition(*[lock]*)

A condition variable : a clone of [\*threading.Condition\*](#).

If *lock* is specified then it should be a [\*Lock\*](#) or [\*RLock\*](#) object from [\*multiprocessing\*](#).

**class** multiprocessing.Event

A clone of [\*threading.Event\*](#). This method returns the state of the internal semaphore on exit, so it will always return **True** except if a timeout is given and the operation times out.

Modifié dans la version 2.7 : Previously, the method always returned **None**.

**class** multiprocessing.Lock

A non-recursive lock object : a close analog of [\*threading.Lock\*](#). Once a process or thread has acquired a lock, subsequent attempts to acquire it from any process or thread will block until it is released ; any process or thread may release it. The concepts and behaviors of [\*threading.Lock\*](#) as it applies to threads are replicated here in [\*multiprocessing.Lock\*](#) as it applies to either processes or threads, except as noted.

Note that [\*Lock\*](#) is actually a factory function which returns an instance of [\*multiprocessing.synchronize.Lock\*](#) initialized with a default context.

[\*Lock\*](#) supports the [\*context manager\*](#) protocol and thus may be used in **with** statements.

**acquire**(*block=True, timeout=None*)

Acquire a lock, blocking or non-blocking.

With the *block* argument set to **True** (the default), the method call will block until the lock is in an unlocked state, then set it to locked and return **True**. Note that the name of this first argument differs from that in [\*threading.Lock.acquire\(\)\*](#).

With the *block* argument set to **False**, the method call does not block. If the lock is currently in a locked state, return **False** ; otherwise set the lock to a locked state and return **True**.

When invoked with a positive, floating-point value for *timeout*, block for at most the number of seconds specified by *timeout* as long as the lock can not be acquired. Invocations with a negative value for *timeout* are equivalent to a *timeout* of zero. Invocations with a *timeout* value of **None** (the default) set the timeout period to infinite. The *timeout* argument has no practical implications if the *block* argument is set to **False** and is thus ignored. Returns **True** if the lock has been acquired or **False** if the timeout period has elapsed. Note that the *timeout* argument does not exist in this method's analog, [\*threading.Lock.acquire\(\)\*](#).

**release()**

Release a lock. This can be called from any process or thread, not only the process or thread which originally acquired the lock.

Behavior is the same as in [\*threading.Lock.release\(\)\*](#) except that when invoked on an unlocked lock, a [\*ValueError\*](#) is raised.

**class** multiprocessing.RLock

A recursive lock object : a close analog of [\*threading.RLock\*](#). A recursive lock must be released by the

process or thread that acquired it. Once a process or thread has acquired a recursive lock, the same process or thread may acquire it again without blocking; that process or thread must release it once for each time it has been acquired.

Note that `RLock` is actually a factory function which returns an instance of `multiprocessing.synchronize.RLock` initialized with a default context.

`RLock` supports the *context manager* protocol and thus may be used in `with` statements.

**acquire**(*block=True, timeout=None*)

Acquire a lock, blocking or non-blocking.

When invoked with the *block* argument set to `True`, block until the lock is in an unlocked state (not owned by any process or thread) unless the lock is already owned by the current process or thread. The current process or thread then takes ownership of the lock (if it does not already have ownership) and the recursion level inside the lock increments by one, resulting in a return value of `True`. Note that there are several differences in this first argument's behavior compared to the implementation of `threading.RLock.acquire()`, starting with the name of the argument itself.

When invoked with the *block* argument set to `False`, do not block. If the lock has already been acquired (and thus is owned) by another process or thread, the current process or thread does not take ownership and the recursion level within the lock is not changed, resulting in a return value of `False`. If the lock is in an unlocked state, the current process or thread takes ownership and the recursion level is incremented, resulting in a return value of `True`.

Use and behaviors of the *timeout* argument are the same as in `Lock.acquire()`. Note that the *timeout* argument does not exist in this method's analog, `threading.RLock.acquire()`.

**release()**

Release a lock, decrementing the recursion level. If after the decrement the recursion level is zero, reset the lock to unlocked (not owned by any process or thread) and if any other processes or threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling process or thread.

Only call this method when the calling process or thread owns the lock. An `AssertionError` is raised if this method is called by a process or thread other than the owner or if the lock is in an unlocked (unowned) state. Note that the type of exception raised in this situation differs from the implemented behavior in `threading.RLock.release()`.

**class** `multiprocessing.Semaphore`(*[value]*)

A semaphore object : a close analog of `threading.Semaphore`.

A solitary difference from its close analog exists : its `acquire` method's first argument is named *block* and it supports an optional second argument *timeout*, as is consistent with `Lock.acquire()`.

---

**Note :** The `acquire()` method of `BoundedSemaphore`, `Lock`, `RLock` and `Semaphore` has a *timeout* parameter not supported by the equivalents in `threading`. The signature is `acquire(block=True, timeout=None)` with keyword parameters being acceptable. If *block* is `True` and *timeout* is not `None` then it specifies a timeout in seconds. If *block* is `False` then *timeout* is ignored.

On Mac OS X, `sem_timedwait` is unsupported, so calling `acquire()` with a *timeout* will emulate that function's behavior using a sleeping loop.

---

---

**Note :** If the SIGINT signal generated by Ctrl-C arrives while the main thread is blocked by a call to `BoundedSemaphore.acquire()`, `Lock.acquire()`, `RLock.acquire()`, `Semaphore.acquire()`, `Condition.acquire()` or `Condition.wait()` then the call will be immediately interrupted and `KeyboardInterrupt` will be raised.

This differs from the behaviour of `threading` where SIGINT will be ignored while the equivalent blocking calls are in progress.

---

---

**Note :** Some of this package’s functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the `multiprocessing.synchronize` module will be disabled, and attempts to import it will result in an `ImportError`. See [bpo-3770](#) for additional information.

---

## Shared ctypes Objects

It is possible to create shared objects using shared memory which can be inherited by child processes.

`multiprocessing.Value(typecode_or_type, *args[, lock])`

Return a `ctypes` object allocated from shared memory. By default the return value is actually a synchronized wrapper for the object.

`typecode_or_type` determines the type of the returned object : it is either a `ctypes` type or a one character typecode of the kind used by the `array` module. `*args` is passed on to the constructor for the type.

If `lock` is `True` (the default) then a new recursive lock object is created to synchronize access to the value. If `lock` is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If `lock` is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be « process-safe ».

Operations like `+=` which involve a read and write are not atomic. So if, for instance, you want to atomically increment a shared value it is insufficient to just do

```
counter.value += 1
```

Assuming the associated lock is recursive (which it is by default) you can instead do

```
with counter.get_lock():
    counter.value += 1
```

Note that `lock` is a keyword-only argument.

`multiprocessing.Array(typecode_or_type, size_or_initializer, *, lock=True)`

Return a `ctypes` array allocated from shared memory. By default the return value is actually a synchronized wrapper for the array.

`typecode_or_type` determines the type of the elements of the returned array : it is either a `ctypes` type or a one character typecode of the kind used by the `array` module. If `size_or_initializer` is an integer, then it determines the length of the array, and the array will be initially zeroed. Otherwise, `size_or_initializer` is a sequence which is used to initialize the array and whose length determines the length of the array.

If `lock` is `True` (the default) then a new lock object is created to synchronize access to the value. If `lock` is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If `lock` is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be « process-safe ».

Note that `lock` is a keyword only argument.

Note that an array of `ctypes.c_char` has `value` and `raw` attributes which allow one to use it to store and retrieve strings.

## The multiprocessing.sharedctypes module

The `multiprocessing.sharedctypes` module provides functions for allocating `ctypes` objects from shared memory which can be inherited by child processes.

---

**Note :** Although it is possible to store a pointer in shared memory remember that this will refer to a location in the address space of a specific process. However, the pointer is quite likely to be invalid in the

context of a second process and trying to dereference the pointer from the second process may cause a crash.

`multiprocessing.sharedctypes.RawArray(typecode_or_type, size_or_initializer)`

Return a ctypes array allocated from shared memory.

*typecode\_or\_type* determines the type of the elements of the returned array : it is either a ctypes type or a one character typecode of the kind used by the `array` module. If *size\_or\_initializer* is an integer then it determines the length of the array, and the array will be initially zeroed. Otherwise *size\_or\_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

Note that setting and getting an element is potentially non-atomic – use `Array()` instead to make sure that access is automatically synchronized using a lock.

`multiprocessing.sharedctypes.RawValue(typecode_or_type, *args)`

Return a ctypes object allocated from shared memory.

*typecode\_or\_type* determines the type of the returned object : it is either a ctypes type or a one character typecode of the kind used by the `array` module. *\*args* is passed on to the constructor for the type.

Note that setting and getting the value is potentially non-atomic – use `Value()` instead to make sure that access is automatically synchronized using a lock.

Note that an array of `ctypes.c_char` has `value` and `raw` attributes which allow one to use it to store and retrieve strings – see documentation for `ctypes`.

`multiprocessing.sharedctypes.Array(typecode_or_type, size_or_initializer, *args[, lock])`

The same as `RawArray()` except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw ctypes array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be « process-safe ».

Note that *lock* is a keyword-only argument.

`multiprocessing.sharedctypes.Value(typecode_or_type, *args[, lock])`

The same as `RawValue()` except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw ctypes object.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be « process-safe ».

Note that *lock* is a keyword-only argument.

`multiprocessing.sharedctypes.copy(obj)`

Return a ctypes object allocated from shared memory which is a copy of the ctypes object *obj*.

`multiprocessing.sharedctypes.synchronized(obj[, lock])`

Return a process-safe wrapper object for a ctypes object which uses *lock* to synchronize access. If *lock* is `None` (the default) then a `multiprocessing.RLock` object is created automatically.

A synchronized wrapper will have two methods in addition to those of the object it wraps : `get_obj()` returns the wrapped object and `get_lock()` returns the lock object used for synchronization.

Note that accessing the ctypes object through the wrapper can be a lot slower than accessing the raw ctypes object.

The table below compares the syntax for creating shared ctypes objects from shared memory with the normal ctypes syntax. (In the table `MyStruct` is some subclass of `ctypes.Structure`.)

ctypes	sharedctypes using type	sharedctypes using typecode
c_double(2.4)	RawValue(c_double, 2.4)	RawValue("d", 2.4)
MyStruct(4, 6)	RawValue(MyStruct, 4, 6)	
(c_short * 7)()	RawArray(c_short, 7)	RawArray("h", 7)
(c_int * 3)(9, 2, 8)	RawArray(c_int, (9, 2, 8))	RawArray("i", (9, 2, 8))

Below is an example where a number of ctypes objects are modified by a child process :

```
from multiprocessing import Process, Lock
from multiprocessing.sharedctypes import Value, Array
from ctypes import Structure, c_double

class Point(Structure):
    _fields_ = [('x', c_double), ('y', c_double)]

def modify(n, x, s, A):
    n.value **= 2
    x.value **= 2
    s.value = s.value.upper()
    for a in A:
        a.x **= 2
        a.y **= 2

if __name__ == '__main__':
    lock = Lock()

    n = Value('i', 7)
    x = Value(c_double, 1.0/3.0, lock=False)
    s = Array('c', 'hello world', lock=lock)
    A = Array(Point, [(1.875,-6.25), (-5.75,2.0), (2.375,9.5)], lock=lock)

    p = Process(target=modify, args=(n, x, s, A))
    p.start()
    p.join()

    print n.value
    print x.value
    print s.value
    print [(a.x, a.y) for a in A]
```

The results printed are

```
49
0.1111111111111111
HELLO WORLD
[(3.515625, 39.0625), (33.0625, 4.0), (5.640625, 90.25)]
```

## Managers

Managers provide a way to create data which can be shared between different processes. A manager object controls a server process which manages *shared objects*. Other processes can access the shared objects by using proxies.

`multiprocessing.Manager()`

Returns a started *SyncManager* object which can be used for sharing objects between processes. The returned manager object corresponds to a spawned child process and has methods which will create shared objects and return corresponding proxies.

Manager processes will be shutdown as soon as they are garbage collected or their parent process exits. The manager classes are defined in the *multiprocessing.managers* module :

**class** `multiprocessing.managers.BaseManager`(`[address[, authkey]]`)

Create a BaseManager object.

Once created one should call *start()* or *get\_server().serve\_forever()* to ensure that the manager object refers to a started manager process.

*address* is the address on which the manager process listens for new connections. If *address* is *None* then an arbitrary one is chosen.

*authkey* is the authentication key which will be used to check the validity of incoming connections to the server process. If *authkey* is *None* then *current\_process().authkey*. Otherwise *authkey* is used and it must be a string.

**start**(`[initializer[, initargs]]`)

Start a subprocess to start the manager. If *initializer* is not *None* then the subprocess will call *initializer(\*initargs)* when it starts.

**get\_server**()

Returns a *Server* object which represents the actual server under the control of the Manager. The *Server* object supports the *serve\_forever()* method :

```
>>> from multiprocessing.managers import BaseManager
>>> manager = BaseManager(address=(' ', 50000), authkey='abc')
>>> server = manager.get_server()
>>> server.serve_forever()
```

Server additionally has an *address* attribute.

**connect**()

Connect a local manager object to a remote manager process :

```
>>> from multiprocessing.managers import BaseManager
>>> m = BaseManager(address=('127.0.0.1', 5000), authkey='abc')
>>> m.connect()
```

**shutdown**()

Stop the process used by the manager. This is only available if *start()* has been used to start the server process.

This can be called multiple times.

**register**(`[typeid[, callable[, proxytype[, exposed[, method_to_typeid[, create_method]]]]]]`)

A classmethod which can be used for registering a type or callable with the manager class.

*typeid* is a « type identifier » which is used to identify a particular type of shared object. This must be a string.

*callable* is a callable used for creating objects for this type identifier. If a manager instance will be created using the *from\_address()* classmethod or if the *create\_method* argument is *False* then this can be left as *None*.

*proxytype* is a subclass of *BaseProxy* which is used to create proxies for shared objects with this *typeid*. If *None* then a proxy class is created automatically.

*exposed* is used to specify a sequence of method names which proxies for this typeid should be allowed to access using *BaseProxy.\_callmethod()*. (If *exposed* is *None* then *proxytype.\_exposed\_* is used instead if it exists.) In the case where no exposed list is specified, all « public methods » of the shared object will be accessible. (Here a « public method » means any attribute which has a *\_\_call\_\_()* method and whose name does not begin with *'\_'*.)

*method\_to\_typeid* is a mapping used to specify the return type of those exposed methods which should return a proxy. It maps method names to typeid strings. (If *method\_to\_typeid* is `None` then `proxytype._method_to_typeid_` is used instead if it exists.) If a method's name is not a key of this mapping or if the mapping is `None` then the object returned by the method will be copied by value.

*create\_method* determines whether a method should be created with name *typeid* which can be used to tell the server process to create a new shared object and return a proxy for it. By default it is `True`.

*BaseManager* instances also have one read-only property :

**address**

The address used by the manager.

**class multiprocessing.managers.SyncManager**

A subclass of *BaseManager* which can be used for the synchronization of processes. Objects of this type are returned by `multiprocessing.Manager()`.

It also supports creation of shared lists and dictionaries.

**BoundedSemaphore**(*[value]*)

Create a shared *threading.BoundedSemaphore* object and return a proxy for it.

**Condition**(*[lock]*)

Create a shared *threading.Condition* object and return a proxy for it.

If *lock* is supplied then it should be a proxy for a *threading.Lock* or *threading.RLock* object.

**Event**()

Create a shared *threading.Event* object and return a proxy for it.

**Lock**()

Create a shared *threading.Lock* object and return a proxy for it.

**Namespace**()

Create a shared *Namespace* object and return a proxy for it.

**Queue**(*[maxsize]*)

Create a shared *Queue.Queue* object and return a proxy for it.

**RLock**()

Create a shared *threading.RLock* object and return a proxy for it.

**Semaphore**(*[value]*)

Create a shared *threading.Semaphore* object and return a proxy for it.

**Array**(*typecode, sequence*)

Create an array and return a proxy for it.

**Value**(*typecode, value*)

Create an object with a writable *value* attribute and return a proxy for it.

**dict**()

**dict**(*mapping*)

**dict**(*sequence*)

Create a shared dict object and return a proxy for it.

**list**()

**list**(*sequence*)

Create a shared list object and return a proxy for it.

---

**Note :** Modifications to mutable values or items in dict and list proxies will not be propagated through the manager, because the proxy has no way of knowing when its values or items are modified. To modify such an item, you can re-assign the modified object to the container proxy :

```
# create a list proxy and append a mutable object (a dictionary)
lproxy = manager.list()
```

(suite sur la page suivante)

(suite de la page précédente)

```

lproxy.append({})
# now mutate the dictionary
d = lproxy[0]
d['a'] = 1
d['b'] = 2
# at this point, the changes to d are not yet synced, but by
# reassigning the dictionary, the proxy is notified of the change
lproxy[0] = d

```

**class multiprocessing.managers.Namespace**

A type that can register with *SyncManager*.

A namespace object has no public methods, but does have writable attributes. Its representation shows the values of its attributes.

However, when using a proxy for a namespace object, an attribute beginning with '\_' will be an attribute of the proxy and not an attribute of the referent :

```

>>> manager = multiprocessing.Manager()
>>> Global = manager.Namespace()
>>> Global.x = 10
>>> Global.y = 'hello'
>>> Global._z = 12.3    # this is an attribute of the proxy
>>> print Global
Namespace(x=10, y='hello')

```

**Customized managers**

To create one's own manager, one creates a subclass of *BaseManager* and uses the *register()* classmethod to register new types or callables with the manager class. For example :

```

from multiprocessing.managers import BaseManager

class MathsClass(object):
    def add(self, x, y):
        return x + y
    def mul(self, x, y):
        return x * y

class MyManager(BaseManager):
    pass

MyManager.register('Maths', MathsClass)

if __name__ == '__main__':
    manager = MyManager()
    manager.start()
    maths = manager.Maths()
    print maths.add(4, 3)      # prints 7
    print maths.mul(7, 8)     # prints 56

```

### Using a remote manager

It is possible to run a manager server on one machine and have clients use it from other machines (assuming that the firewalls involved allow it).

Running the following commands creates a server for a single shared queue which remote clients can access :

```
>>> from multiprocessing.managers import BaseManager
>>> import Queue
>>> queue = Queue.Queue()
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=(' ', 50000), authkey='abracadabra')
>>> s = m.get_server()
>>> s.serve_forever()
```

One client can access the server as follows :

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey='abracadabra')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.put('hello')
```

Another client can also use it :

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey='abracadabra')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.get()
'hello'
```

Local processes can also access that queue, using the code from above on the client to access it remotely :

```
>>> from multiprocessing import Process, Queue
>>> from multiprocessing.managers import BaseManager
>>> class Worker(Process):
...     def __init__(self, q):
...         self.q = q
...         super(Worker, self).__init__()
...     def run(self):
...         self.q.put('local hello')
...
>>> queue = Queue()
>>> w = Worker(queue)
>>> w.start()
>>> class QueueManager(BaseManager): pass
...
>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=(' ', 50000), authkey='abracadabra')
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> s = m.get_server()
>>> s.serve_forever()
```

## Proxy Objects

A proxy is an object which *refers* to a shared object which lives (presumably) in a different process. The shared object is said to be the *referent* of the proxy. Multiple proxy objects may have the same referent.

A proxy object has methods which invoke corresponding methods of its referent (although not every method of the referent will necessarily be available through the proxy). A proxy can usually be used in most of the same ways that its referent can :

```
>>> from multiprocessing import Manager
>>> manager = Manager()
>>> l = manager.list([i*i for i in range(10)])
>>> print l
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
>>> print repr(l)
<ListProxy object, typeid 'list' at 0x...>
>>> l[4]
16
>>> l[2:5]
[4, 9, 16]
```

Notice that applying `str()` to a proxy will return the representation of the referent, whereas applying `repr()` will return the representation of the proxy.

An important feature of proxy objects is that they are picklable so they can be passed between processes. Note, however, that if a proxy is sent to the corresponding manager's process then unpickling it will produce the referent itself. This means, for example, that one shared object can contain a second :

```
>>> a = manager.list()
>>> b = manager.list()
>>> a.append(b)           # referent of a now contains referent of b
>>> print a, b
[[]] []
>>> b.append('hello')
>>> print a, b
[['hello']] ['hello']
```

**Note :** The proxy types in `multiprocessing` do nothing to support comparisons by value. So, for instance, we have :

```
>>> manager.list([1,2,3]) == [1,2,3]
False
```

One should just use a copy of the referent instead when making comparisons.

```
class multiprocessing.managers.BaseProxy
    Proxy objects are instances of subclasses of BaseProxy.
    _callmethod(methodname[, args[, kwds]])
        Call and return the result of a method of the proxy's referent.
```

If `proxy` is a proxy whose referent is `obj` then the expression

```
proxy._callmethod(methodname, args, kwds)
```

will evaluate the expression

```
getattr(obj, methodname)(*args, **kwds)
```

in the manager's process.

The returned value will be a copy of the result of the call or a proxy to a new shared object – see documentation for the `method_to_typeid` argument of `BaseManager.register()`.

If an exception is raised by the call, then is re-raised by `_callmethod()`. If some other exception is raised in the manager's process then this is converted into a `RemoteError` exception and is raised by `_callmethod()`.

Note in particular that an exception will be raised if `methodname` has not been *exposed*.

An example of the usage of `_callmethod()` :

```
>>> l = manager.list(range(10))
>>> l._callmethod('__len__')
10
>>> l._callmethod('__getslice__', (2, 7))    # equiv to `l[2:7]`
[2, 3, 4, 5, 6]
>>> l._callmethod('__getitem__', (20,))      # equiv to `l[20]`
Traceback (most recent call last):
...
IndexError: list index out of range
```

`_getvalue()`

Return a copy of the referent.

If the referent is unpicklable then this will raise an exception.

`--repr--()`

Return a representation of the proxy object.

`--str--()`

Return the representation of the referent.

## Cleanup

A proxy object uses a weakref callback so that when it gets garbage collected it deregisters itself from the manager which owns its referent.

A shared object gets deleted from the manager process when there are no longer any proxies referring to it.

## Process Pools

One can create a pool of processes which will carry out tasks submitted to it with the `Pool` class.

```
class multiprocessing.Pool([processes[, initializer[, initargs[, maxtasksperchild]]])
```

A process pool object which controls a pool of worker processes to which jobs can be submitted. It supports asynchronous results with timeouts and callbacks and has a parallel map implementation.

`processes` is the number of worker processes to use. If `processes` is `None` then the number returned by `cpu_count()` is used. If `initializer` is not `None` then each worker process will call `initializer(*initargs)` when it starts.

Note that the methods of the pool object should only be called by the process which created the pool. Nouveau dans la version 2.7 : `maxtasksperchild` is the number of tasks a worker process can complete before it will exit and be replaced with a fresh worker process, to enable unused resources to be freed. The default `maxtasksperchild` is `None`, which means worker processes will live as long as the pool.

---

**Note :** Worker processes within a `Pool` typically live for the complete duration of the `Pool`'s work queue. A frequent pattern found in other systems (such as Apache, `mod_wsgi`, etc) to free resources held by workers is to allow a worker within a pool to complete only a set amount of work before being exiting, being cleaned up and a new process spawned to replace the old one. The `maxtasksperchild` argument to the `Pool` exposes this ability to the end user.

---

**apply**(*func*[, *args*[, *kwds*]])

Equivalent of the `apply()` built-in function. It blocks until the result is ready, so `apply_async()` is better suited for performing work in parallel. Additionally, *func* is only executed in one of the workers of the pool.

**apply\_async**(*func*[, *args*[, *kwds*[, *callback*]]])

A variant of the `apply()` method which returns a result object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it (unless the call failed). *callback* should complete immediately since otherwise the thread which handles the results will get blocked.

**map**(*func*, *iterable*[, *chunksize*])

A parallel equivalent of the `map()` built-in function (it supports only one *iterable* argument though). It blocks until the result is ready.

This method chops the iterable into a number of chunks which it submits to the process pool as separate tasks. The (approximate) size of these chunks can be specified by setting *chunksize* to a positive integer.

**map\_async**(*func*, *iterable*[, *chunksize*[, *callback*]]])

A variant of the `map()` method which returns a result object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it (unless the call failed). *callback* should complete immediately since otherwise the thread which handles the results will get blocked.

**imap**(*func*, *iterable*[, *chunksize*])

An equivalent of `itertools.imap()`.

The *chunksize* argument is the same as the one used by the `map()` method. For very long iterables using a large value for *chunksize* can make the job complete **much** faster than using the default value of 1.

Also if *chunksize* is 1 then the `next()` method of the iterator returned by the `imap()` method has an optional *timeout* parameter : `next(timeout)` will raise `multiprocessing.TimeoutError` if the result cannot be returned within *timeout* seconds.

**imap\_unordered**(*func*, *iterable*[, *chunksize*])

The same as `imap()` except that the ordering of the results from the returned iterator should be considered arbitrary. (Only when there is only one worker process is the order guaranteed to be « correct ».)

**close()**

Prevents any more tasks from being submitted to the pool. Once all the tasks have been completed the worker processes will exit.

**terminate()**

Stops the worker processes immediately without completing outstanding work. When the pool object is garbage collected `terminate()` will be called immediately.

**join()**

Wait for the worker processes to exit. One must call `close()` or `terminate()` before using `join()`.

**class multiprocessing.pool.AsyncResult**

The class of the result returned by `Pool.apply_async()` and `Pool.map_async()`.

**get**([*timeout*])

Return the result when it arrives. If *timeout* is not `None` and the result does not arrive within

*timeout* seconds then `multiprocessing.TimeoutError` is raised. If the remote call raised an exception then that exception will be reraised by `get()`.

`wait([timeout])`  
Wait until the result is available or until *timeout* seconds pass.

`ready()`  
Return whether the call has completed.

`successful()`  
Return whether the call completed without raising an exception. Will raise `AssertionError` if the result is not ready.

The following example demonstrates the use of a pool :

```
from multiprocessing import Pool
import time

def f(x):
    return x*x

if __name__ == '__main__':
    pool = Pool(processes=4)           # start 4 worker processes

    result = pool.apply_async(f, (10,)) # evaluate "f(10)" asynchronously in a single
    ↪ process
    print result.get(timeout=1)         # prints "100" unless your computer is *very*
    ↪ slow

    print pool.map(f, range(10))       # prints "[0, 1, 4, ..., 81]"

    it = pool.imap(f, range(10))
    print it.next()                    # prints "0"
    print it.next()                    # prints "1"
    print it.next(timeout=1)           # prints "4" unless your computer is *very*
    ↪ slow

    result = pool.apply_async(time.sleep, (10,))
    print result.get(timeout=1)        # raises multiprocessing.TimeoutError
```

## Listeners and Clients

Usually message passing between processes is done using queues or by using `Connection` objects returned by `Pipe()`.

However, the `multiprocessing.connection` module allows some extra flexibility. It basically gives a high level message oriented API for dealing with sockets or Windows named pipes, and also has support for *digest authentication* using the `hmac` module.

`multiprocessing.connection.deliver_challenge(connection, authkey)`

Send a randomly generated message to the other end of the connection and wait for a reply.

If the reply matches the digest of the message using *authkey* as the key then a welcome message is sent to the other end of the connection. Otherwise `AuthenticationError` is raised.

`multiprocessing.connection.answer_challenge(connection, authkey)`

Receive a message, calculate the digest of the message using *authkey* as the key, and then send the digest back.

If a welcome message is not received, then `AuthenticationError` is raised.

`multiprocessing.connection.Client(address[, family[, authenticate[, authkey]]])`

Attempt to set up a connection to the listener which is using address *address*, returning a *Connection*.

The type of the connection is determined by *family* argument, but this can generally be omitted since it can usually be inferred from the format of *address*. (See *Address Formats*)

If *authenticate* is `True` or *authkey* is a string then digest authentication is used. The key used for authentication will be either *authkey* or `current_process().authkey` if *authkey* is `None`. If authentication fails then *AuthenticationError* is raised. See *Authentication keys*.

`class multiprocessing.connection.Listener([address[, family[, backlog[, authenticate[, authkey]]]])`

A wrapper for a bound socket or Windows named pipe which is “listening” for connections.

*address* is the address to be used by the bound socket or named pipe of the listener object.

---

**Note :** If an address of “0.0.0.0” is used, the address will not be a connectable end point on Windows. If you require a connectable end-point, you should use “127.0.0.1”.

---

*family* is the type of socket (or named pipe) to use. This can be one of the strings 'AF\_INET' (for a TCP socket), 'AF\_UNIX' (for a Unix domain socket) or 'AF\_PIPE' (for a Windows named pipe). Of these only the first is guaranteed to be available. If *family* is `None` then the family is inferred from the format of *address*. If *address* is also `None` then a default is chosen. This default is the family which is assumed to be the fastest available. See *Address Formats*. Note that if *family* is 'AF\_UNIX' and *address* is `None` then the socket will be created in a private temporary directory created using *tempfile.mkstemp()*.

If the listener object uses a socket then *backlog* (1 by default) is passed to the *listen()* method of the socket once it has been bound.

If *authenticate* is `True` (`False` by default) or *authkey* is not `None` then digest authentication is used.

If *authkey* is a string then it will be used as the authentication key; otherwise it must be `None`.

If *authkey* is `None` and *authenticate* is `True` then `current_process().authkey` is used as the authentication key. If *authkey* is `None` and *authenticate* is `False` then no authentication is done. If authentication fails then *AuthenticationError* is raised. See *Authentication keys*.

**accept()**

Accept a connection on the bound socket or named pipe of the listener object and return a *Connection* object. If authentication is attempted and fails, then *AuthenticationError* is raised.

**close()**

Close the bound socket or named pipe of the listener object. This is called automatically when the listener is garbage collected. However it is advisable to call it explicitly.

Listener objects have the following read-only properties :

**address**

The address which is being used by the Listener object.

**last\_accepted**

The address from which the last accepted connection came. If this is unavailable then it is `None`.

The module defines the following exceptions :

**exception multiprocessing.connection.ProcessError**

The base class of all *multiprocessing* exceptions.

**exception multiprocessing.connection.BufferTooShort**

Exception raised by *Connection.recv\_bytes\_into()* when the supplied buffer object is too small for the message read.

**exception multiprocessing.connection.AuthenticationError**

Raised when there is an authentication error.

**exception multiprocessing.connection.TimeoutError**

Raised by methods with a timeout when the timeout expires.

## Examples

The following server code creates a listener which uses 'secret password' as an authentication key. It then waits for a connection and sends some data to the client :

```
from multiprocessing.connection import Listener
from array import array

address = ('localhost', 6000)      # family is deduced to be 'AF_INET'
listener = Listener(address, authkey='secret password')

conn = listener.accept()
print 'connection accepted from', listener.last_accepted

conn.send([2.25, None, 'junk', float])

conn.send_bytes('hello')

conn.send_bytes(array('i', [42, 1729]))

conn.close()
listener.close()
```

The following code connects to the server and receives some data from the server :

```
from multiprocessing.connection import Client
from array import array

address = ('localhost', 6000)
conn = Client(address, authkey='secret password')

print conn.recv()                # => [2.25, None, 'junk', float]

print conn.recv_bytes()          # => 'hello'

arr = array('i', [0, 0, 0, 0, 0])
print conn.recv_bytes_into(arr)  # => 8
print arr                        # => array('i', [42, 1729, 0, 0, 0])

conn.close()
```

## Address Formats

- An 'AF\_INET' address is a tuple of the form (hostname, port) where *hostname* is a string and *port* is an integer.
- An 'AF\_UNIX' address is a string representing a filename on the filesystem.
- An 'AF\_PIPE' address is a string of the form `r'\\.\pipe{PipeName}'`. To use `Client()` to connect to a named pipe on a remote computer called *ServerName* one should use an address of the form `r'\\ServerName\pipe{PipeName}'` instead.

Note that any string beginning with two backslashes is assumed by default to be an 'AF\_PIPE' address rather than an 'AF\_UNIX' address.

## Authentication keys

When one uses `Connection.recv()`, the data received is automatically unpickled. Unfortunately unpickling data from an untrusted source is a security risk. Therefore `Listener` and `Client()` use the `hmac` module to provide digest authentication.

An authentication key is a string which can be thought of as a password : once a connection is established both ends will demand proof that the other knows the authentication key. (Demonstrating that both ends are using the same key does **not** involve sending the key over the connection.)

If authentication is requested but no authentication key is specified then the return value of `current_process().authkey` is used (see `Process`). This value will be automatically inherited by any `Process` object that the current process creates. This means that (by default) all processes of a multi-process program will share a single authentication key which can be used when setting up connections between themselves.

Suitable authentication keys can also be generated by using `os.urandom()`.

## Journalisation

Some support for logging is available. Note, however, that the `logging` package does not use process shared locks so it is possible (depending on the handler type) for messages from different processes to get mixed up.

### `multiprocessing.get_logger()`

Returns the logger used by `multiprocessing`. If necessary, a new one will be created.

When first created the logger has level `logging.NOTSET` and no default handler. Messages sent to this logger will not by default propagate to the root logger.

Note that on Windows child processes will only inherit the level of the parent process's logger – any other customization of the logger will not be inherited.

### `multiprocessing.log_to_stderr()`

This function performs a call to `get_logger()` but in addition to returning the logger created by `get_logger`, it adds a handler which sends output to `sys.stderr` using format `'[% (levelname)s/ %(processName)s] %(message)s'`.

Below is an example session with logging turned on :

```
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
>>> logger.setLevel(logging.INFO)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
[INFO/SyncManager-...] child process calling self.run()
[INFO/SyncManager-...] created temp directory /.../pypm-...
[INFO/SyncManager-...] manager serving at '/.../listener-...'
>>> del m
[INFO/MainProcess] sending shutdown message to manager
[INFO/SyncManager-...] manager exiting with exitcode 0
```

In addition to having these two logging functions, the `multiprocessing` also exposes two additional logging level attributes. These are `SUBWARNING` and `SUBDEBUG`. The table below illustrates where these fit in the normal level hierarchy.

Level	Numeric value
<code>SUBWARNING</code>	25
<code>SUBDEBUG</code>	5

For a full table of logging levels, see the *logging* module.

These additional logging levels are used primarily for certain debug messages within the multiprocessing module. Below is the same example as above, except with SUBDEBUG enabled :

```
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
>>> logger.setLevel(multiprocessing.SUBDEBUG)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
[INFO/SyncManager-...] child process calling self.run()
[INFO/SyncManager-...] created temp directory /.../pypm-...
[INFO/SyncManager-...] manager serving at '/.../pypm-djGBXN/listener-...'
>>> del m
[SUBDEBUG/MainProcess] finalizer calling ...
[INFO/MainProcess] sending shutdown message to manager
[DEBUG/SyncManager-...] manager received shutdown message
[SUBDEBUG/SyncManager-...] calling <Finalize object, callback=unlink, ...
[SUBDEBUG/SyncManager-...] finalizer calling <built-in function unlink> ...
[SUBDEBUG/SyncManager-...] calling <Finalize object, dead>
[SUBDEBUG/SyncManager-...] finalizer calling <function rmtree at 0x5aa730> ...
[INFO/SyncManager-...] manager exiting with exitcode 0
```

### The multiprocessing.dummy module

*multiprocessing.dummy* replicates the API of *multiprocessing* but is no more than a wrapper around the *threading* module.

## 16.6.3 Programming guidelines

There are certain guidelines and idioms which should be adhered to when using *multiprocessing*.

### All platforms

Avoid shared state

As far as possible one should try to avoid shifting large amounts of data between processes.

It is probably best to stick to using queues or pipes for communication between processes rather than using the lower level synchronization primitives from the *threading* module.

Picklability

Ensure that the arguments to the methods of proxies are picklable.

Thread safety of proxies

Do not use a proxy object from more than one thread unless you protect it with a lock.

(There is never a problem with different processes using the *same* proxy.)

Joining zombie processes

On Unix when a process finishes but has not been joined it becomes a zombie. There should never be very many because each time a new process starts (or *active\_children()* is called) all completed processes which have not yet been joined will be joined. Also calling a finished process's *Process.is\_alive* will join the process. Even so it is probably good practice to explicitly join all the processes that you start.

Better to inherit than pickle/unpickle

On Windows many types from *multiprocessing* need to be picklable so that child processes can use them. However, one should generally avoid sending shared objects to other processes using pipes or queues. Instead you should arrange the program so that a process which needs access to a shared resource created elsewhere can inherit it from an ancestor process.

#### Avoid terminating processes

Using the *Process.terminate* method to stop a process is liable to cause any shared resources (such as locks, semaphores, pipes and queues) currently being used by the process to become broken or unavailable to other processes.

Therefore it is probably best to only consider using *Process.terminate* on processes which never use any shared resources.

#### Joining processes that use queues

Bear in mind that a process that has put items in a queue will wait before terminating until all the buffered items are fed by the « feeder » thread to the underlying pipe. (The child process can call the *cancel\_join\_thread()* method of the queue to avoid this behaviour.)

This means that whenever you use a queue you need to make sure that all items which have been put on the queue will eventually be removed before the process is joined. Otherwise you cannot be sure that processes which have put items on the queue will terminate. Remember also that non-daemonic processes will be joined automatically.

An example which will deadlock is the following :

```
from multiprocessing import Process, Queue

def f(q):
    q.put('X' * 1000000)

if __name__ == '__main__':
    queue = Queue()
    p = Process(target=f, args=(queue,))
    p.start()
    p.join()                # this deadlocks
    obj = queue.get()
```

A fix here would be to swap the last two lines (or simply remove the *p.join()* line).

#### Explicitly pass resources to child processes

On Unix a child process can make use of a shared resource created in a parent process using a global resource. However, it is better to pass the object as an argument to the constructor for the child process.

Apart from making the code (potentially) compatible with Windows this also ensures that as long as the child process is still alive the object will not be garbage collected in the parent process. This might be important if some resource is freed when the object is garbage collected in the parent process.

So for instance

```
from multiprocessing import Process, Lock

def f():
    ... do something using "lock" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f).start()
```

should be rewritten as

```
from multiprocessing import Process, Lock

def f(l):
    ... do something using "l" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f, args=(lock,)).start()
```

Beware of replacing `sys.stdin` with a « file like object »

`multiprocessing` originally unconditionally called :

```
os.close(sys.stdin.fileno())
```

in the `multiprocessing.Process._bootstrap()` method — this resulted in issues with processes-in-processes. This has been changed to :

```
sys.stdin.close()
sys.stdin = open(os.devnull)
```

Which solves the fundamental issue of processes colliding with each other resulting in a bad file descriptor error, but introduces a potential danger to applications which replace `sys.stdin()` with a « file-like object » with output buffering. This danger is that if multiple processes call `close()` on this file-like object, it could result in the same data being flushed to the object multiple times, resulting in corruption.

If you write a file-like object and implement your own caching, you can make it fork-safe by storing the pid whenever you append to the cache, and discarding the cache when the pid changes. For example :

```
@property
def cache(self):
    pid = os.getpid()
    if pid != self._pid:
        self._pid = pid
        self._cache = []
    return self._cache
```

For more information, see [bpo-5155](#), [bpo-5313](#) and [bpo-5331](#)

## Windows

Since Windows lacks `os.fork()` it has a few extra restrictions :

### More picklability

Ensure that all arguments to `Process.__init__()` are picklable. This means, in particular, that bound or unbound methods cannot be used directly as the `target` argument on Windows — just define a function and use that instead.

Also, if you subclass `Process` then make sure that instances will be picklable when the `Process.start` method is called.

### Global variables

Bear in mind that if code run in a child process tries to access a global variable, then the value it sees (if any) may not be the same as the value in the parent process at the time that `Process.start` was called.

However, global variables which are just module level constants cause no problems.

Safe importing of main module

Make sure that the main module can be safely imported by a new Python interpreter without causing unintended side effects (such as starting a new process).

For example, under Windows running the following module would fail with a *RuntimeError* :

```
from multiprocessing import Process

def foo():
    print 'hello'

p = Process(target=foo)
p.start()
```

Instead one should protect the « entry point » of the program by using `if __name__ == '__main__':` as follows :

```
from multiprocessing import Process, freeze_support

def foo():
    print 'hello'

if __name__ == '__main__':
    freeze_support()
    p = Process(target=foo)
    p.start()
```

(The `freeze_support()` line can be omitted if the program will be run normally instead of frozen.)

This allows the newly spawned Python interpreter to safely import the module and then run the module's `foo()` function.

Similar restrictions apply if a pool or manager is created in the main module.

## 16.6.4 Examples

Demonstration of how to create and use customized managers and proxies :

```
#
# This module shows how to use arbitrary callables with a subclass of
# `BaseManager`.
#
# Copyright (c) 2006-2008, R Oudkerk
# All rights reserved.
#

from multiprocessing import freeze_support
from multiprocessing.managers import BaseManager, BaseProxy
import operator

##

class Foo(object):
    def f(self):
        print 'you called Foo.f()'
```

(suite sur la page suivante)

(suite de la page précédente)

```

def g(self):
    print 'you called Foo.g()'
def _h(self):
    print 'you called Foo._h()'

# A simple generator function
def baz():
    for i in xrange(10):
        yield i*i

# Proxy type for generator objects
class GeneratorProxy(BaseProxy):
    _exposed_ = ('next', '__next__')
    def __iter__(self):
        return self
    def next(self):
        return self._callmethod('next')
    def __next__(self):
        return self._callmethod('__next__')

# Function to return the operator module
def get_operator_module():
    return operator

##

class MyManager(BaseManager):
    pass

# register the Foo class; make `f()` and `g()` accessible via proxy
MyManager.register('Foo1', Foo)

# register the Foo class; make `g()` and `_h()` accessible via proxy
MyManager.register('Foo2', Foo, exposed=('g', '_h'))

# register the generator function baz; use `GeneratorProxy` to make proxies
MyManager.register('baz', baz, proxytype=GeneratorProxy)

# register get_operator_module(); make public functions accessible via proxy
MyManager.register('operator', get_operator_module)

##

def test():
    manager = MyManager()
    manager.start()

    print '-' * 20

    f1 = manager.Foo1()
    f1.f()
    f1.g()

```

(suite sur la page suivante)

(suite de la page précédente)

```

assert not hasattr(f1, '_h')
assert sorted(f1._exposed_) == sorted(['f', 'g'])

print '-' * 20

f2 = manager.Foo2()
f2.g()
f2._h()
assert not hasattr(f2, 'f')
assert sorted(f2._exposed_) == sorted(['g', '_h'])

print '-' * 20

An example showing how to use queues to feed tasks to a collection of worker processes and collect the results :

```

#
# Simple example which uses a pool of workers to carry out some tasks.
#
# Notice that the results will probably not come out of the output
# queue in the same in the same order as the corresponding tasks were
# put on the input queue. If it is important to get the results back
# in the original order then consider using `Pool.map()` or
# `Pool.imap()` (which will save on the amount of code needed anyway).

    test()

```

## 16.7 mmap — Memory-mapped file support

Memory-mapped file objects behave like both strings and like file objects. Unlike normal string objects, however, these are mutable. You can use mmap objects in most places where strings are expected; for example, you can use the `re` module to search through a memory-mapped file. Since they're mutable, you can change a single character by doing `obj[index] = 'a'`, or change a substring by assigning to a slice : `obj[i1:i2] = '...'`. You can also read and write data starting at the current file position, and `seek()` through the file to different positions.

A memory-mapped file is created by the `mmap` constructor, which is different on Unix and on Windows. In either case you must provide a file descriptor for a file opened for update. If you wish to map an existing Python file object, use its `fileno()` method to obtain the correct value for the `fileno` parameter. Otherwise, you can open the file using the `os.open()` function, which returns a file descriptor directly (the file still needs to be closed when done).

---

**Note :** If you want to create a memory-mapping for a writable, buffered file, you should `flush()` the file first. This is necessary to ensure that local modifications to the buffers are actually available to the mapping.

---

For both the Unix and Windows versions of the constructor, `access` may be specified as an optional keyword parameter. `access` accepts one of three values : `ACCESS_READ`, `ACCESS_WRITE`, or `ACCESS_COPY` to specify read-only, write-through or copy-on-write memory respectively. `access` can be used on both Unix and Windows. If `access` is not specified, Windows mmap returns a write-through mapping. The initial memory values for all three access types are taken from the specified file. Assignment to an `ACCESS_READ` memory map raises a `TypeError` exception. Assignment to an `ACCESS_WRITE` memory map affects both memory and the underlying file. Assignment to an `ACCESS_COPY` memory map affects memory but does not update the underlying file.

Modifié dans la version 2.5 : To map anonymous memory, -1 should be passed as the `fileno` along with the `length`.

Modifié dans la version 2.6 : `mmap.mmap` has formerly been a factory function creating mmap objects. Now `mmap.mmap` is the class itself.

```
class mmap.mmap(fileno, length[, tagname[, access[, offset]]])
```

**(Windows version)** Maps `length` bytes from the file specified by the file handle `fileno`, and creates a mmap object. If `length` is larger than the current size of the file, the file is extended to contain `length` bytes. If `length` is 0, the maximum length of the map is the current size of the file, except that if the file is empty Windows raises an exception (you cannot create an empty mapping on Windows).

`tagname`, if specified and not `None`, is a string giving a tag name for the mapping. Windows allows you to have many different mappings against the same file. If you specify the name of an existing tag, that tag is opened, otherwise a new tag of this name is created. If this parameter is omitted or `None`, the mapping is created without a name. Avoiding the use of the tag parameter will assist in keeping your code portable between Unix and Windows.

`offset` may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. `offset` defaults to 0. `offset` must be a multiple of the `ALLOCATIONGRANULARITY`.

```
class mmap.mmap(fileno, length[, flags[, prot[, access[, offset]]]])
```

**(Unix version)** Maps `length` bytes from the file specified by the file descriptor `fileno`, and returns a mmap object. If `length` is 0, the maximum length of the map will be the current size of the file when `mmap` is called.

`flags` specifies the nature of the mapping. `MAP_PRIVATE` creates a private copy-on-write mapping, so changes to the contents of the mmap object will be private to this process, and `MAP_SHARED` creates a mapping that's shared with all other processes mapping the same areas of the file. The default value is `MAP_SHARED`.

*prot*, if specified, gives the desired memory protection; the two most useful values are `PROT_READ` and `PROT_WRITE`, to specify that the pages may be read or written. *prot* defaults to `PROT_READ | PROT_WRITE`.

*access* may be specified in lieu of *flags* and *prot* as an optional keyword parameter. It is an error to specify both *flags*, *prot* and *access*. See the description of *access* above for information on how to use this parameter.

*offset* may be specified as a non-negative integer offset. `mmap` references will be relative to the offset from the beginning of the file. *offset* defaults to 0. *offset* must be a multiple of `ALLOCATIONGRANULARITY` which is equal to `PAGESIZE` on Unix systems.

To ensure validity of the created memory mapping the file specified by the descriptor *fileno* is internally automatically synchronized with physical backing store on Mac OS X and OpenVMS.

This example shows a simple way of using `mmap` :

```
import mmap

# write a simple example file
with open("hello.txt", "wb") as f:
    f.write("Hello Python!\n")

with open("hello.txt", "r+b") as f:
    # memory-map the file, size 0 means whole file
    mm = mmap.mmap(f.fileno(), 0)
    # read content via standard file methods
    print mm.readline() # prints "Hello Python!"
    # read content via slice notation
    print mm[:5] # prints "Hello"
    # update content using slice notation;
    # note that new content must have same size
    mm[6:] = " world!\n"
    # ... and read again using standard file methods
    mm.seek(0)
    print mm.readline() # prints "Hello world!"
    # close the map
    mm.close()
```

The next example demonstrates how to create an anonymous map and exchange data between the parent and child processes :

```
import mmap
import os

mm = mmap.mmap(-1, 13)
mm.write("Hello world!")

pid = os.fork()

if pid == 0: # In a child process
    mm.seek(0)
    print mm.readline()

    mm.close()
```

Memory-mapped file objects support the following methods :

**close()**

Closes the `mmap`. Subsequent calls to other methods of the object will result in a `ValueError`

exception being raised. This will not close the open file.

**find**(*string*[, *start*[, *end*]])

Returns the lowest index in the object where the substring *string* is found, such that *string* is contained in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation. Returns -1 on failure.

**flush**([*offset*, *size*])

Flushes changes made to the in-memory copy of a file back to disk. Without use of this call there is no guarantee that changes are written back before the object is destroyed. If *offset* and *size* are specified, only changes to the given range of bytes will be flushed to disk; otherwise, the whole extent of the mapping is flushed. *offset* must be a multiple of the `PAGESIZE` or `ALLOCATIONGRANULARITY`.  
**(Windows version)** A nonzero value returned indicates success; zero indicates failure.  
**(Unix version)** A zero value is returned to indicate success. An exception is raised when the call failed.

**move**(*dest*, *src*, *count*)

Copy the *count* bytes starting at offset *src* to the destination index *dest*. If the mmap was created with `ACCESS_READ`, then calls to move will raise a *TypeError* exception.

**read**(*num*)

Return a string containing up to *num* bytes starting from the current file position; the file position is updated to point after the bytes that were returned.

**read\_byte**()

Returns a string of length 1 containing the character at the current file position, and advances the file position by 1.

**readline**()

Returns a single line, starting at the current file position and up to the next newline.

**resize**(*newsize*)

Resizes the map and the underlying file, if any. If the mmap was created with `ACCESS_READ` or `ACCESS_COPY`, resizing the map will raise a *TypeError* exception.

**rfind**(*string*[, *start*[, *end*]])

Returns the highest index in the object where the substring *string* is found, such that *string* is contained in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation. Returns -1 on failure.

**seek**(*pos*[, *whence*])

Set the file's current position. *whence* argument is optional and defaults to `os.SEEK_SET` or 0 (absolute file positioning); other values are `os.SEEK_CUR` or 1 (seek relative to the current position) and `os.SEEK_END` or 2 (seek relative to the file's end).

**size**()

Return the length of the file, which can be larger than the size of the memory-mapped area.

**tell**()

Returns the current position of the file pointer.

**write**(*string*)

Write the bytes in *string* into memory at the current position of the file pointer; the file position is updated to point after the bytes that were written. If the mmap was created with `ACCESS_READ`, then writing to it will raise a *TypeError* exception.

**write\_byte**(*byte*)

Write the single-character string *byte* into memory at the current position of the file pointer; the file position is advanced by 1. If the mmap was created with `ACCESS_READ`, then writing to it will raise a *TypeError* exception.

## 16.8 readline — interface pour GNU readline

The *readline* module defines a number of functions to facilitate completion and reading/writing of history files from the Python interpreter. This module can be used directly, or via the *rlcompleter* module, which

supports completion of Python identifiers at the interactive prompt. Settings made using this module affect the behaviour of both the interpreter's interactive prompt and the prompts offered by the `raw_input()` and `input()` built-in functions.

---

**Note :** The underlying Readline library API may be implemented by the `libedit` library instead of GNU readline. On MacOS X the `readline` module detects which library is being used at run time.

Le fichier de configuration pour *libedit* est différent de celui de *GNU readline*. Si, dans votre programme, vous chargez les chaînes de configuration vous pouvez valider le texte *libedit* dans `readline.__doc__` pour faire la différence entre *GNU readline* et *libedit*.

---

L'association de touches de *readline* peut être configurée via un fichier d'initialisation, typiquement nommé `.inputrc` dans votre répertoire utilisateur. Voir [Readline Init File](#) dans le manuel GNU pour *readline* pour des informations à propos du format et de la construction autorisée de ce fichier, ainsi que les possibilités de la bibliothèque *readline* en général.

### 16.8.1 Fichier d'initialisation

Les fonctions suivantes se rapportent au fichier d'initialisation et à la configuration utilisateur.

`readline.parse_and_bind(string)`

Exécute la ligne d'initialisation fournie dans l'argument *string*. Cela appelle la fonction `rl_parse_and_bind()` de la bibliothèque sous-jacente.

`readline.read_init_file([filename])`

Exécute un fichier d'initialisation *readline*. Le nom de fichier par défaut est le dernier nom de fichier utilisé. Cela appelle la fonction `rl_read_init_file()` de la bibliothèque sous-jacente.

### 16.8.2 Tampon de ligne

Les fonctions suivantes opèrent sur le tampon de ligne :

`readline.get_line_buffer()`

Renvoie le contenu courant du tampon de ligne (`rl_line_buffer` dans la bibliothèque sous-jacente).

`readline.insert_text(string)`

Insère du texte dans le tampon de ligne à la position du curseur. Cela appelle la fonction `rl_insert_text()` de la bibliothèque sous-jacente, mais ignore la valeur de retour.

`readline.redisplay()`

Change ce qui est affiché sur l'écran pour représenter le contenu courant de la ligne de tampon. Cela appelle la fonction `rl_redisplay()` dans la bibliothèque sous-jacente.

### 16.8.3 Fichier d'historique

les fonctions suivantes opèrent sur un fichier d'historique :

`readline.read_history_file([filename])`

Charge un fichier d'historique de *readline*, et l'ajoute à la liste d'historique. Le fichier par défaut est `~/.history`. Cela appelle la fonction `read_history()` de la bibliothèque sous-jacente.

`readline.write_history_file([filename])`

Enregistre la liste de l'historique dans un fichier d'historique de *readline*, en écrasant un éventuel fichier existant. Le nom de fichier par défaut est `~/.history`. Cela appelle la fonction `write_history()` de la bibliothèque sous-jacente.

`readline.get_history_length()`

`readline.set_history_length(length)`

Définit ou renvoie le nombre souhaité de lignes à enregistrer dans le fichier d'historique. La fonction `write_history_file()` utilise cette valeur pour tronquer le fichier d'historique, en appelant `history_truncate_file()` de la bibliothèque sous-jacente. Les valeurs négatives impliquent une taille de fichier d'historique illimitée.

### 16.8.4 Liste d'historique

Les fonctions suivantes opèrent sur une liste d'historique globale :

`readline.clear_history()`

Effacer l'historique courant. Cela appelle la fonction `clear_history()` de la bibliothèque sous-jacente. La fonction Python existe seulement si Python a été compilé pour une version de la bibliothèque qui le gère.

Nouveau dans la version 2.4.

`readline.get_current_history_length()`

Renvoie le nombre d'objets actuellement dans l'historique. (C'est différent de `get_history_length()`, qui renvoie le nombre maximum de lignes qui vont être écrites dans un fichier d'historique.)

Nouveau dans la version 2.3.

`readline.get_history_item(index)`

Renvoie le contenu courant de l'objet d'historique à *index*. L'index de l'objet commence à 1. Cela appelle `history_get()` de la bibliothèque sous-jacente.

Nouveau dans la version 2.3.

`readline.remove_history_item(pos)`

Supprime l'objet de l'historique défini par sa position depuis l'historique. L'index de la position commence à zéro. Cela appelle la fonction `remove_history()` de la bibliothèque sous-jacente.

Nouveau dans la version 2.4.

`readline.replace_history_item(pos, line)`

Remplace un objet de l'historique à la position définie par *line*. L'index de la position commence à zéro. Cela appelle `replace_history_entry()` de la bibliothèque sous-jacente.

Nouveau dans la version 2.4.

`readline.add_history(line)`

Ajoute *line* au tampon d'historique, comme si c'était la dernière ligne saisie. Cela appelle la fonction `add_history()` de la librairie sous-jacente.

### 16.8.5 Fonctions de rappel au démarrage

Nouveau dans la version 2.3.

`readline.set_startup_hook([function])`

Définit ou supprime la fonction invoquée par la fonction de retour `rl_startup_hook` de la bibliothèque sous-jacente. Si *function* est spécifié, il est utilisé en tant que nouvelle fonction de rappel ; si omis ou `None`, toute fonction déjà installée est supprimée. La fonction de rappel est appelée sans arguments juste avant que *readline* affiche la première invite de commande.

`readline.set_pre_input_hook([function])`

Définit ou supprime la fonction invoquée par la fonction de retour `rl_pre_input_hook` de la bibliothèque sous-jacente. Si *function* est spécifié, il sera utilisé par la nouvelle fonction de rappel ; si omis ou `None`, toute fonction déjà installée est supprimée. La fonction de rappel est appelée sans arguments après que la première invite de commande ait été affichée et juste avant que *readline* commence à lire les caractères saisis. Cette fonction existe seulement si Python a été compilé pour une version de la bibliothèque qui le gère.

## 16.8.6 Complétion

Les fonctions suivantes relatent comment implémenter une fonction de complétion d'un mot spécifique. C'est typiquement déclenché par la touche Tab, et peut suggérer et automatiquement compléter un mot en cours de saisie. Par défaut, Readline est configuré pour être utilisé par `rlcompleter` pour compléter les mots clefs de Python pour l'interpréteur interactif. Si le module `readline` doit être utilisé avec une complétion spécifique, un ensemble de mots délimiteurs doivent être définis.

`readline.set_completer([function])`

Définit ou supprime la fonction de complétion. Si *function* est spécifié, il sera utilisé en tant que nouvelle fonction de complétion ; si omis ou `None`, toute fonction de complétion déjà installé est supprimé. La fonction de complétion est appelée telle que `function(text, state)`, pour *state* valant 0, 1, 2, ..., jusqu'à ce qu'elle renvoie une valeur qui n'est pas une chaîne de caractères. Elle doit renvoyer les prochaines complétions possibles commençant par *text*.

La fonction de complétion installée est invoquée par la fonction de retour *entry\_func* passée à `rl_completion_matches()` de la bibliothèque sous-jacente. La chaîne de caractère *text* va du premier paramètres vers la fonction de retour `rl_attempted_completion_function` de la bibliothèque sous-jacente.

`readline.get_completer()`

Récupère la fonction de complétion, ou `None` si aucune fonction de complétion n'a été définie.

Nouveau dans la version 2.3.

`readline.get_completion_type()`

Récupère le type de complétion essayé. Cela renvoie la variable `rl_completion_type` dans la bibliothèque sous-jacente en tant qu'entier.

Nouveau dans la version 2.6.

`readline.get_begidx()`

`readline.get_endidx()`

Récupère l'indexe de début ou de fin d'un contexte de complétion. Ces indexes sont les arguments *start* et *end* passés à la fonction de retour `rl_attempted_completion_function` de la bibliothèque sous-jacente.

`readline.set_completer_delims(string)`

`readline.get_completer_delims()`

Définit ou récupère les mots délimitants pour la complétion. Ceux-ci déterminent le début du mot devant être considéré pour la complétion (le contexte de la complétion). Ces fonctions accèdent à la variable `rl_completer_word_break_characters` de la bibliothèque sous-jacente.

`readline.set_completion_display_matches_hook([function])`

Définit ou supprime la fonction d'affichage de la complétion. Si *function* est spécifié, il sera utilisé en tant que nouvelle fonction d'affichage de complétion ; si omis ou `None`, toute fonction de complétion déjà installée est supprimée. Cela définit ou supprime la fonction de retour `rl_completion_display_matches_hook` dans la bibliothèque sous-jacente. La fonction d'affichage de complétion est appelée telle que `function(substitution, [matches], longest_match_length)` une seule fois lorsque les correspondances doivent être affichées.

Nouveau dans la version 2.6.

## 16.8.7 Exemple

The following example demonstrates how to use the `readline` module's history reading and writing functions to automatically load and save a history file named `.pyhist` from the user's home directory. The code below would normally be executed automatically during interactive sessions from the user's `PYTHONSTARTUP` file.

```
import os
import readline
histfile = os.path.join(os.path.expanduser("~"), ".pyhist")
try:
    readline.read_history_file(histfile)
    # default history len is -1 (infinite), which may grow unruly
    readline.set_history_length(1000)
except IOError:
    pass
import atexit
atexit.register(readline.write_history_file, histfile)
del os, histfile
```

L'exemple suivant étend la classe `code.InteractiveConsole` pour gérer la sauvegarde/restauration de l'historique. :

```
import code
import readline
import atexit
import os

class HistoryConsole(code.InteractiveConsole):
    def __init__(self, locals=None, filename="<console>",
                 histfile=os.path.expanduser("~/console-history")):
        code.InteractiveConsole.__init__(self, locals, filename)
        self.init_history(histfile)

    def init_history(self, histfile):
        readline.parse_and_bind("tab: complete")
        if hasattr(readline, "read_history_file"):
            try:
                readline.read_history_file(histfile)
            except IOError:
                pass
        atexit.register(self.save_history, histfile)

    def save_history(self, histfile):
        readline.set_history_length(1000)
        readline.write_history_file(histfile)
```

## 16.9 rlcompleter — Fonction de complétion pour GNU readline

Code source : `Lib/rlcompleter.py`

Le module `rlcompleter` définit une fonction de complétion appropriée pour le module `readline` en complétant des identifiants et mots-clés Python valides.

Quand le module est importé dans une plate-forme Unix et la méthode `complete()` est configurée pour assurer la complétion de `readline`, une instance de classe `Completer` est automatiquement créée et la méthode est configurée au finisseur `complete()`

Exemple :

```
>>> import rlcompleter
>>> import readline
>>> readline.parse_and_bind("tab: complete")
>>> readline. <TAB PRESSED>
readline.__doc__      readline.get_line_buffer(  readline.read_init_file(
readline.__file__    readline.insert_text(      readline.set_completer(
readline.__name__    readline.parse_and_bind(
>>> readline.
```

The *rlcompleter* module is designed for use with Python's interactive mode. A user can add the following lines to his or her initialization file (identified by the PYTHONSTARTUP environment variable) to get automatic Tab completion :

```
try:
    import readline
except ImportError:
    print "Module readline not available."
else:
    import rlcompleter
    readline.parse_and_bind("tab: complete")
```

Sur les plate-formes sans *readline*, la classe *Completer* définie par ce module peut quand même être utilisée pour des fins personnalisées.

### 16.9.1 Objets pour la complétion (*Completer Objects*)

Les objets pour la complétion (*Completer objects* en anglais) disposent de la méthode suivante :

**Completer.complete(text, state)**

Renvoie la *state*-ième complétion pour *text*.

If called for *text* that doesn't include a period character ('.'), it will complete from names currently defined in *\_\_main\_\_*, *\_\_builtin\_\_* and keywords (as defined by the *keyword* module).

Quand elle est appelée pour un nom qui comporte un point, elle ne tente d'évaluer que ce qui n'a pas d'effet secondaire (les fonctions ne sont pas évaluées, mais elle peut faire des appels à *\_\_getattr\_\_()*), jusqu'à la dernière partie, et trouve des équivalents pour le reste via la fonction *dir()*. Toute exception levée durant l'évaluation de l'expression est interceptée, mise sous silence, et *None* est renvoyé.

---

## Communication et réseau entre processus

---

Les modules décrits dans ce chapitre fournissent différents mécanismes permettant à des processus de communiquer.

Some modules only work for two processes that are on the same machine, e.g. *signal* and *subprocess*. Other modules support networking protocols that two or more processes can use to communicate across machines.

La liste des modules documentés dans ce chapitre est :

### 17.1 subprocess — Gestion de sous-processus

Nouveau dans la version 2.4.

Le module *subprocess* vous permet de lancer de nouveaux processus, les connecter à des tubes d'entrée/sortie/erreur, et d'obtenir leurs codes de retour. Ce module a l'intention de remplacer plusieurs anciens modules et fonctions :

```
os.system
os.spawn*
os.popen*
popen2.*
commands.*
```

Information about how this module can be used to replace the older functions can be found in the *subprocess-replacements* section.

**Voir aussi :**

POSIX users (Linux, BSD, etc.) are strongly encouraged to install and use the much more recent *subprocess32* module instead of the version included with python 2.7. It is a drop in replacement with better behavior in many situations.

**PEP 324** – PEP proposant le module *subprocess*

### 17.1.1 Utiliser le module subprocess

The recommended way to launch subprocesses is to use the following convenience functions. For more advanced use cases when these do not meet your needs, use the underlying *Popen* interface.

`subprocess.call(args, *, stdin=None, stdout=None, stderr=None, shell=False)`

Run the command described by *args*. Wait for command to complete, then return the `returncode` attribute.

The arguments shown above are merely the most common ones, described below in *Arguments fréquemment utilisés* (hence the slightly odd notation in the abbreviated signature). The full function signature is the same as that of the *Popen* constructor - this functions passes all supplied arguments directly through to that interface.

Exemples :

```
>>> subprocess.call(["ls", "-l"])
0

>>> subprocess.call("exit 1", shell=True)
1
```

**Avertissement :** Using `shell=True` can be a security hazard. See the warning under *Arguments fréquemment utilisés* for details.

---

**Note :** Do not use `stdout=PIPE` or `stderr=PIPE` with this function as that can deadlock based on the child process output volume. Use *Popen* with the `communicate()` method when you need pipes.

---

`subprocess.check_call(args, *, stdin=None, stdout=None, stderr=None, shell=False)`

Lance la commande avec les arguments et attend qu'elle se termine. Se termine normalement si le code de retour est zéro, et lève une *CalledProcessError* autrement. L'objet *CalledProcessError* contiendra le code de retour dans son attribut `returncode`.

The arguments shown above are merely the most common ones, described below in *Arguments fréquemment utilisés* (hence the slightly odd notation in the abbreviated signature). The full function signature is the same as that of the *Popen* constructor - this functions passes all supplied arguments directly through to that interface.

Exemples :

```
>>> subprocess.check_call(["ls", "-l"])
0

>>> subprocess.check_call("exit 1", shell=True)
Traceback (most recent call last):
...
subprocess.CalledProcessError: Command 'exit 1' returned non-zero exit status 1
```

Nouveau dans la version 2.5.

**Avertissement :** Using `shell=True` can be a security hazard. See the warning under *Arguments fréquemment utilisés* for details.

---

**Note :** Do not use `stdout=PIPE` or `stderr=PIPE` with this function as that can deadlock based on

---

the child process output volume. Use [Popen](#) with the `communicate()` method when you need pipes.

`subprocess.check_output(args, *, stdin=None, stderr=None, shell=False, universal_newlines=False)`

Run command with arguments and return its output as a byte string.

Si le code de retour est non-nul, la fonction lève une [CalledProcessError](#). L'objet [CalledProcessError](#) contiendra le code de retour dans son attribut `returncode`, et la sortie du programme dans son attribut `output`.

The arguments shown above are merely the most common ones, described below in [Arguments fréquemment utilisés](#) (hence the slightly odd notation in the abbreviated signature). The full function signature is largely the same as that of the [Popen](#) constructor, except that `stdout` is not permitted as it is used internally. All other supplied arguments are passed directly through to the [Popen](#) constructor.

Exemples :

```
>>> subprocess.check_output(["echo", "Hello World!"])
'Hello World!\n'

>>> subprocess.check_output("exit 1", shell=True)
Traceback (most recent call last):
...
subprocess.CalledProcessError: Command 'exit 1' returned non-zero exit status 1
```

Pour capturer aussi la sortie d'erreur dans le résultat, utilisez `stderr=subprocess.STDOUT` :

```
>>> subprocess.check_output(
...     "ls non_existent_file; exit 0",
...     stderr=subprocess.STDOUT,
...     shell=True)
'ls: non_existent_file: No such file or directory\n'
```

Nouveau dans la version 2.7.

**Avertissement :** Using `shell=True` can be a security hazard. See the warning under [Arguments fréquemment utilisés](#) for details.

**Note :** Do not use `stderr=PIPE` with this function as that can deadlock based on the child process error volume. Use [Popen](#) with the `communicate()` method when you need a `stderr` pipe.

#### `subprocess.PIPE`

Special value that can be used as the `stdin`, `stdout` or `stderr` argument to [Popen](#) and indicates that a pipe to the standard stream should be opened.

#### `subprocess.STDOUT`

Valeur spéciale qui peut être utilisée pour l'argument `stderr` de [Popen](#) et qui indique que la sortie d'erreur doit être redirigée vers le même gestionnaire que la sortie standard.

#### exception `subprocess.CalledProcessError`

Exception raised when a process run by [check\\_call\(\)](#) or [check\\_output\(\)](#) returns a non-zero exit status.

##### `returncode`

Exit status of the child process.

##### `cmd`

La commande utilisée pour instancier le processus fils.

**output**

Output of the child process if this exception is raised by `check_output()`. Otherwise, `None`.

**Arguments fréquemment utilisés**

Pour supporter un large ensemble de cas, la constructeur de `Popen` (et les fonctions de convenance) acceptent de nombreux arguments optionnels. Pour les cas d'utilisation les plus typiques, beaucoup de ces arguments peuvent sans problème être laissés à leurs valeurs par défaut. Les arguments les plus communément nécessaires sont :

`args` est requis pour tous les appels et doit être une chaîne de caractères ou une séquence d'arguments du programme. Il est généralement préférable de fournir une séquence d'arguments, puisque cela permet au module de s'occuper des potentiels échappements ou guillemets autour des arguments (p. ex. pour permettre des espaces dans des noms de fichiers). Si l'argument est passé comme une simple chaîne, soit `shell` doit valoir `True` (voir ci-dessous) soit la chaîne doit simplement contenir le nom du programme à exécuter sans spécifier d'arguments supplémentaires. `stdin`, `stdout` and `stderr` specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are `PIPE`, an existing file descriptor (a positive integer), an existing file object, and `None`. `PIPE` indicates that a new pipe to the child should be created. With the default settings of `None`, no redirection will occur; the child's file handles will be inherited from the parent. Additionally, `stderr` can be `STDOUT`, which indicates that the stderr data from the child process should be captured into the same file handle as for stdout.

When `stdout` or `stderr` are pipes and `universal_newlines` is `True` then all line endings will be converted to `'\n'` as described for the `universal_newlines 'U'` mode argument to `open()`.

Si `shell` vaut `True`, la commande spécifiée sera exécutée à travers un `shell`. Cela peut être utile si vous utilisez Python pour le contrôle de flot qu'il propose par rapport à beaucoup de `shells` système et voulez tout de même profiter des autres fonctionnalités des `shells` telles que les tubes (`pipes`), les motifs de fichiers, l'expansion des variables d'environnement, et l'expansion du `~` vers le répertoire principal de l'utilisateur. Cependant, notez que Python lui-même propose l'implémentation de beaucoup de ces fonctionnalités (en particulier `glob`, `fnmatch`, `os.walk()`, `os.path.expandvars()`, `os.path.expanduser()` et `shutil`).

**Avertissement :** Executing shell commands that incorporate unsanitized input from an untrusted source makes a program vulnerable to [shell injection](#), a serious security flaw which can result in arbitrary command execution. For this reason, the use of `shell=True` is **strongly discouraged** in cases where the command string is constructed from external input :

```
>>> from subprocess import call
>>> filename = input("What file would you like to display?\n")
What file would you like to display?
non_existent; rm -rf / #
>>> call("cat " + filename, shell=True) # Uh-oh. This will end badly...
```

`shell=False` disables all shell based features, but does not suffer from this vulnerability; see the Note in the `Popen` constructor documentation for helpful hints in getting `shell=False` to work.

When using `shell=True`, `pipes.quote()` can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

Ces options, ainsi que toutes les autres, sont décrites plus en détails dans la documentation du constructeur de `Popen`.

## Constructeur de *Popen*

La création et la gestion sous-jacentes des processus est gérée par la classe *Popen*. Elle offre beaucoup de flexibilité de façon à ce que les développeurs soient capables de gérer les cas d'utilisation les moins communs, non couverts par les fonctions de convenance.

```
class subprocess.Popen(args, bufsize=0, executable=None, stdin=None, stdout=None, st-
                        derr=None, preexec_fn=None, close_fds=False, shell=False, cwd=None,
                        env=None, universal_newlines=False, startupinfo=None, creation-
                        flags=0)
```

Execute a child program in a new process. On Unix, the class uses *os.execvp()*-like behavior to execute the child program. On Windows, the class uses the Windows *CreateProcess()* function. The arguments to *Popen* are as follows.

*args* doit être une séquence d'arguments du programme ou une chaîne seule. Par défaut, le programme à exécuter est le premier élément de *args* si *args* est une séquence. Si *args* est une chaîne, l'interprétation dépend de la plateforme et est décrite plus bas. Voir les arguments *shell* et *executable* pour d'autres différences avec le comportement par défaut. Sans autre indication, il est recommandé de passer *args* comme une séquence.

On Unix, if *args* is a string, the string is interpreted as the name or path of the program to execute. However, this can only be done if not passing arguments to the program.

**Note :** *shlex.split()* peut être utilisée pour déterminer le découpage correct de *args*, spécifiquement dans les cas complexes :

```
>>> import shlex, subprocess
>>> command_line = raw_input()
/bin/vikings -input eggs.txt -output "spam spam.txt" -cmd "echo '$MONEY'"
>>> args = shlex.split(command_line)
>>> print args
['/bin/vikings', '-input', 'eggs.txt', '-output', 'spam spam.txt', '-cmd', 'echo '
↳ '$MONEY'"]
>>> p = subprocess.Popen(args) # Success!
```

Notez en particulier que les options (comme *-input*) et arguments (comme *eggs.txt*) qui sont séparés par des espaces dans le *shell* iront dans des éléments séparés de la liste, alors que les arguments qui nécessitent des guillemets et échappements quand utilisés dans le *shell* (comme les noms de fichiers contenant des espaces ou la commande *echo* montrée plus haut) forment des éléments uniques.

Sous Windows, si *args* est une séquence, elle sera convertie vers une chaîne de caractères de la manière décrite dans *Convertir une séquence d'arguments vers une chaîne de caractères sous Windows*. Cela fonctionne ainsi parce que la fonction *CreateProcess()* opère sur des chaînes.

L'argument *shell* (qui vaut *False* par défaut) spécifie s'il faut utiliser un *shell* comme programme à exécuter. Si *shell* vaut *True*, il est recommandé de passer *args* comme une chaîne de caractères plutôt qu'une séquence.

On Unix with *shell=True*, the shell defaults to */bin/sh*. If *args* is a string, the string specifies the command to execute through the shell. This means that the string must be formatted exactly as it would be when typed at the shell prompt. This includes, for example, quoting or backslash escaping filenames with spaces in them. If *args* is a sequence, the first item specifies the command string, and any additional items will be treated as additional arguments to the shell itself. That is to say, *Popen* does the equivalent of :

```
Popen(['/bin/sh', '-c', args[0], args[1], ...])
```

Sous Windows avec *shell=True*, la variable d'environnement *COMSPEC* spécifie le *shell* par défaut. La seule raison pour laquelle vous devriez spécifier *shell=True* sous Windows est quand la commande

que vous souhaitez exécuter est une *built-in* du *shell* (p. ex. `dir` ou `copy`). Vous n'avez pas besoin de `shell=True` pour lancer un fichier batch ou un exécutable console.

**Avertissement :** Passing `shell=True` can be a security hazard if combined with untrusted input. See the warning under *Arguments fréquemment utilisés* for details.

*bufsize*, if given, has the same meaning as the corresponding argument to the built-in `open()` function : 0 means unbuffered, 1 means line buffered, any other positive value means use a buffer of (approximately) that size. A negative *bufsize* means to use the system default, which usually means fully buffered. The default value for *bufsize* is 0 (unbuffered).

---

**Note :** If you experience performance issues, it is recommended that you try to enable buffering by setting *bufsize* to either -1 or a large enough positive value (such as 4096).

---

The *executable* argument specifies a replacement program to execute. It is very seldom needed. When `shell=False`, *executable* replaces the program to execute specified by *args*. However, the original *args* is still passed to the program. Most programs treat the program specified by *args* as the command name, which can then be different from the program actually executed. On Unix, the *args* name becomes the display name for the executable in utilities such as `ps`. If `shell=True`, on Unix the *executable* argument specifies a replacement shell for the default `/bin/sh`.

*stdin*, *stdout* and *stderr* specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are *PIPE*, an existing file descriptor (a positive integer), an existing file object, and `None`. *PIPE* indicates that a new pipe to the child should be created. With the default settings of `None`, no redirection will occur ; the child's file handles will be inherited from the parent. Additionally, *stderr* can be *STDOUT*, which indicates that the *stderr* data from the child process should be captured into the same file handle as for *stdout*.

If *preexec\_fn* is set to a callable object, this object will be called in the child process just before the child is executed. (Unix only)

If *close\_fds* is true, all file descriptors except 0, 1 and 2 will be closed before the child process is executed. (Unix only). Or, on Windows, if *close\_fds* is true then no handles will be inherited by the child process. Note that on Windows, you cannot set *close\_fds* to true and also redirect the standard handles by setting *stdin*, *stdout* or *stderr*.

If *cwd* is not `None`, the child's current directory will be changed to *cwd* before it is executed. Note that this directory is not considered when searching the executable, so you can't specify the program's path relative to *cwd*.

If *env* is not `None`, it must be a mapping that defines the environment variables for the new process ; these are used instead of inheriting the current process' environment, which is the default behavior.

---

**Note :** Si spécifié, *env* doit fournir chaque variable requise pour l'exécution du programme. Sous Windows, afin d'exécuter un *side-by-side assembly*, l'environnement *env* spécifié **doit** contenir une variable `SystemRoot` valide.

---

If *universal\_newlines* is `True`, the file objects *stdout* and *stderr* are opened as text files in *universal newlines* mode. Lines may be terminated by any of `'\n'`, the Unix end-of-line convention, `'\r'`, the old Macintosh convention or `'\r\n'`, the Windows convention. All of these external representations are seen as `'\n'` by the Python program.

---

**Note :** This feature is only available if Python is built with universal newline support (the default). Also, the *newlines* attribute of the file objects *stdout*, *stdin* and *stderr* are not updated by the `communicate()` method.

---

Si fourni, *startupinfo* sera un objet *STARTUPINFO*, qui sera passé à la fonction `CreateProcess` inhérente.

*creationflags*, si fourni, peut valoir `CREATE_NEW_CONSOLE` ou `CREATE_NEW_PROCESS_GROUP`. (Windows seulement)

## Exceptions

Les exceptions levées dans le processus fils, avant que le nouveau programme n'ait commencé son exécution, seront relayées dans le parent. Additionnellement, l'objet de l'exception aura un attribut supplémentaire appelé `child_traceback`, une chaîne de caractères contenant la trace de l'exception du point de vue du fils.

L'exception la plus communément levée est `OSError`. Elle survient, par exemple, si vous essayez d'exécuter un fichier inexistant. Les applications doivent se préparer à traiter des exceptions `OSError`.

Une `ValueError` sera levée si `Popen` est appelé avec des arguments invalides.

`check_call()` et `check_output()` lèveront une `CalledProcessError` si le processus appelé renvoie un code de retour non nul.

## Security

Unlike some other popen functions, this implementation will never call a system shell implicitly. This means that all characters, including shell metacharacters, can safely be passed to child processes. Obviously, if the shell is invoked explicitly, then it is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately.

### 17.1.2 Objets `Popen`

Les instances de la classe `Popen` possèdent les méthodes suivantes :

`Popen.poll()`

Vérifie que le processus enfant s'est terminé. Modifie l'attribut `returncode` et le renvoie.

`Popen.wait()`

Attend qu'un processus enfant se termine. Modifie l'attribut `returncode` et le renvoie.

**Avertissement :** This will deadlock when using `stdout=PIPE` and/or `stderr=PIPE` and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use `communicate()` to avoid that.

`Popen.communicate(input=None)`

Interact with process : Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate. The optional *input* argument should be a string to be sent to the child process, or `None`, if no data should be sent to the child.

`communicate()` returns a tuple (`stdoutdata`, `stderrdata`).

Notez que si vous souhaitez envoyer des données sur l'entrée standard du processus, vous devez créer l'objet `Popen` avec `stdin=PIPE`. Similairement, pour obtenir autre chose que `None` dans le *tuple* résultat, vous devez aussi préciser `stdout=PIPE` et/ou `stderr=PIPE`.

---

**Note :** Les données lues sont mises en cache en mémoire, donc n'utilisez pas cette méthode si la taille des données est importante voire illimitée.

---

`Popen.send_signal(signal)`

Envoie le signal *signal* au fils.

---

**Note :** Sous Windows, `SIGTERM` est un alias pour `terminate()`. `CTRL_C_EVENT` et

`CTRL_BREAK_EVENT` peuvent être envoyés aux processus démarrés avec un paramètre *creation-flags* incluant `CREATE_NEW_PROCESS_GROUP`.

---

Nouveau dans la version 2.6.

**Popen.terminate()**

Stoppe le processus fils. Sur les systèmes POSIX, la méthode envoie un signal `SIGTERM` au fils. Sous Windows, la fonction `TerminateProcess()` de l'API *Win32* est appelée pour arrêter le fils.

Nouveau dans la version 2.6.

**Popen.kill()**

Tue le processus fils. Sur les systèmes POSIX, la fonction envoie un signal `SIGKILL` au fils. Sous Windows, *kill()* est un alias pour *terminate()*.

Nouveau dans la version 2.6.

Les attributs suivants sont aussi disponibles :

**Avertissement :** Utilisez *communicate()* plutôt que *.stdin.write*, *.stdout.read* ou *.stderr.read* pour empêcher les *deadlocks* dus au remplissage des tampons des tubes de l'OS et bloquant le processus enfant.

**Popen.stdin**

If the *stdin* argument was *PIPE*, this attribute is a file object that provides input to the child process. Otherwise, it is `None`.

**Popen.stdout**

If the *stdout* argument was *PIPE*, this attribute is a file object that provides output from the child process. Otherwise, it is `None`.

**Popen.stderr**

If the *stderr* argument was *PIPE*, this attribute is a file object that provides error output from the child process. Otherwise, it is `None`.

**Popen.pid**

L'identifiant de processus du processus enfant.

Notez que si vous passez l'argument *shell* à `True`, il s'agit alors de l'identifiant du *shell* instancié.

**Popen.returncode**

Le code de retour de l'enfant, attribué par *poll()* et *wait()* (et indirectement par *communicate()*).

Une valeur `None` indique que le processus ne s'est pas encore terminé.

A negative value `-N` indicates that the child was terminated by signal `N` (Unix only).

### 17.1.3 Utilitaires *Popen* pour Windows

La classe *STARTUPINFO* et les constantes suivantes sont seulement disponibles sous Windows.

**class subprocess.STARTUPINFO**

Un support partiel de la structure *STARTUPINFO* de Windows est utilisé lors de la création d'un objet *Popen*.

**dwFlags**

Un champ de bits déterminant si certains attributs *STARTUPINFO* sont utilisés quand le processus crée une fenêtre :

```
si = subprocess.STARTUPINFO()
si.dwFlags = subprocess.STARTF_USESTDHANDLES | subprocess.STARTF_USESHOWWINDOW
```

**hStdInput**

Si *dwFlags* spécifie *STARTF\_USESTDHANDLES*, cet attribut est le gestionnaire d'entrée standard du processus. Si *STARTF\_USESTDHANDLES* n'est pas spécifié, l'entrée standard par défaut est le tampon du clavier.

**hStdOutput**

Si *dwFlags* spécifie *STARTF\_USESTDHANDLES*, cet attribut est le gestionnaire de sortie standard du processus. Autrement, l'attribut est ignoré et la sortie standard par défaut est le tampon de la console.

**hStdError**

Si *dwFlags* spécifie *STARTF\_USESTDHANDLES*, cet attribut est le gestionnaire de sortie d'erreur du processus. Autrement, l'attribut est ignoré et la sortie d'erreur par défaut est le tampon de la console.

**wShowWindow**

Si *dwFlags* spécifie *STARTF\_USESHOWWINDOW*, cet attribut peut-être n'importe quel attribut valide pour le paramètre *nCmdShow* de la fonction *ShowWindow*, à l'exception de *SW\_SHOWDEFAULT*. Autrement, cet attribut est ignoré.

*SW\_HIDE* est fourni pour cet attribut. Il est utilisé quand *Popen* est appelée avec *shell=True*.

**Constantes**

Le module *subprocess* expose les constantes suivantes.

**subprocess.STD\_INPUT\_HANDLE**

Le périphérique d'entrée standard. Initialement, il s'agit du tampon de la console d'entrée, *CONIN\$*.

**subprocess.STD\_OUTPUT\_HANDLE**

Le périphérique de sortie standard. Initialement, il s'agit du tampon de l'écran de console actif, *CONOUT\$*.

**subprocess.STD\_ERROR\_HANDLE**

Le périphérique de sortie d'erreur. Initialement, il s'agit du tampon de l'écran de console actif, *CONOUT\$*.

**subprocess.SW\_HIDE**

Cache la fenêtre. Une autre fenêtre sera activée.

**subprocess.STARTF\_USESTDHANDLES**

Spécifie que les attributs *STARTUPINFO.hStdInput*, *STARTUPINFO.hStdOutput* et *STARTUPINFO.hStdError* contiennent des informations additionnelles.

**subprocess.STARTF\_USESHOWWINDOW**

Spécifie que l'attribut *STARTUPINFO.wShowWindow* contient des informations additionnelles.

**subprocess.CREATE\_NEW\_CONSOLE**

Le nouveau processus instancie une nouvelle console, plutôt que d'hériter de celle de son père (par défaut).

This flag is always set when *Popen* is created with *shell=True*.

**subprocess.CREATE\_NEW\_PROCESS\_GROUP**

Un paramètre *creationflags* de *Popen* pour spécifier si un nouveau groupe de processus doit être créé. Cette option est nécessaire pour utiliser *os.kill()* sur le sous-processus.

L'option est ignorée si *CREATE\_NEW\_CONSOLE* est spécifié.

**17.1.4 Remplacer les fonctions plus anciennes par le module subprocess**

Dans cette section, « a devient b » signifie que b peut être utilisée en remplacement de a.

**Note :** Toutes les fonctions « a » dans cette section échouent (plus ou moins) silencieusement si le programme à exécuter ne peut être trouvé ; les fonctions « b » de remplacement lèvent à la place une *OSError*.

De plus, les remplacements utilisant `check_output()` échoueront avec une `CalledProcessError` si l'opération requise produit un code de retour non-nul. La sortie est toujours disponible par l'attribut `output` de l'exception levée.

---

Dans les exemples suivants, nous supposons que les fonctions utilisées ont déjà été importées depuis le module `subprocess`.

### Remplacement des *backquotes* des *shells* `/bin/sh`

```
output=`mycmd myarg`
```

devient :

```
output = check_output(["mycmd", "myarg"])
```

### Remplacer les *pipes* du *shell*

```
output=`dmesg | grep hda`
```

devient :

```
p1 = Popen(["dmesg"], stdout=PIPE)
p2 = Popen(["grep", "hda"], stdin=p1.stdout, stdout=PIPE)
p1.stdout.close() # Allow p1 to receive a SIGPIPE if p2 exits.
output = p2.communicate()[0]
```

L'appel à `p1.stdout.close()` après le démarrage de `p2` est important pour que `p1` reçoive un `SIGPIPE` si `p2` se termine avant lui.

Alternativement, pour des entrées fiables, le support des tubes du *shell* peut directement être utilisé :

```
output=`dmesg | grep hda`
```

devient :

```
output=check_output("dmesg | grep hda", shell=True)
```

### Remplacer `os.system()`

```
status = os.system("mycmd" + " myarg")
# becomes
status = subprocess.call("mycmd" + " myarg", shell=True)
```

Notes :

— Appeler le programme à travers un *shell* n'est habituellement pas requis.

Un exemple plus réaliste ressemblerait à cela :

```
try:
    retcode = call("mycmd" + " myarg", shell=True)
    if retcode < 0:
        print >>sys.stderr, "Child was terminated by signal", -retcode
    else:
        print >>sys.stderr, "Child returned", retcode
```

(suite sur la page suivante)

(suite de la page précédente)

```
except OSError as e:
    print >>sys.stderr, "Execution failed:", e
```

### Remplacer les fonctions de la famille `os.spawn`

Exemple avec `P_NOWAIT` :

```
pid = os.spawnlp(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg")
==>
pid = Popen(["/bin/mycmd", "myarg"]).pid
```

Exemple avec `P_WAIT` :

```
retcode = os.spawnlp(os.P_WAIT, "/bin/mycmd", "mycmd", "myarg")
==>
retcode = call(["/bin/mycmd", "myarg"])
```

Exemple avec un tableau :

```
os.spawnvp(os.P_NOWAIT, path, args)
==>
Popen([path] + args[1:])
```

Exemple en passant un environnement :

```
os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg", env)
==>
Popen(["/bin/mycmd", "myarg"], env={"PATH": "/usr/bin"})
```

### Remplacer `os.popen()`, `os.popen2()`, `os.popen3()` etc.

```
pipe = os.popen("cmd", 'r', bufsize)
==>
pipe = Popen("cmd", shell=True, bufsize=bufsize, stdout=PIPE).stdout
```

```
pipe = os.popen("cmd", 'w', bufsize)
==>
pipe = Popen("cmd", shell=True, bufsize=bufsize, stdin=PIPE).stdin
```

```
(child_stdin, child_stdout) = os.popen2("cmd", mode, bufsize)
==>
p = Popen("cmd", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdin, child_stdout) = (p.stdin, p.stdout)
```

```
(child_stdin,
 child_stdout,
 child_stderr) = os.popen3("cmd", mode, bufsize)
==>
p = Popen("cmd", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=PIPE, close_fds=True)
```

(suite sur la page suivante)

(suite de la page précédente)

```
(child_stdin,
 child_stdout,
 child_stderr) = (p.stdin, p.stdout, p.stderr)
```

```
(child_stdin, child_stdout_and_stderr) = os.popen4("cmd", mode,
                                                    bufsize)
==>
p = Popen("cmd", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=STDOUT, close_fds=True)
(child_stdin, child_stdout_and_stderr) = (p.stdin, p.stdout)
```

On Unix, `os.popen2`, `os.popen3` and `os.popen4` also accept a sequence as the command to execute, in which case arguments will be passed directly to the program without shell intervention. This usage can be replaced as follows :

```
(child_stdin, child_stdout) = os.popen2(["/bin/ls", "-l"], mode,
                                         bufsize)
==>
p = Popen(["/bin/ls", "-l"], bufsize=bufsize, stdin=PIPE, stdout=PIPE)
(child_stdin, child_stdout) = (p.stdin, p.stdout)
```

La gestion du code de retour se traduit comme suit :

```
pipe = os.popen("cmd", 'w')
...
rc = pipe.close()
if rc is not None and rc >> 8:
    print "There were some errors"
==>
process = Popen("cmd", shell=True, stdin=PIPE)
...
process.stdin.close()
if process.wait() != 0:
    print "There were some errors"
```

### Remplacer les fonctions du module `popen2`

```
(child_stdout, child_stdin) = popen2.popen2("somestring", bufsize, mode)
==>
p = Popen("somestring", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

On Unix, `popen2` also accepts a sequence as the command to execute, in which case arguments will be passed directly to the program without shell intervention. This usage can be replaced as follows :

```
(child_stdout, child_stdin) = popen2.popen2(["mycmd", "myarg"], bufsize,
                                             mode)
==>
p = Popen(["mycmd", "myarg"], bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

`popen2.Popen3` et `popen2.Popen4` fonctionnent basiquement comme `subprocess.Popen`, excepté que :

- `Popen` lève une exception si l'exécution échoue.
- L'argument `capturestderr` est remplacé par `stderr`.
- `stdin=PIPE` et `stdout=PIPE` doivent être spécifiés.
- `popen2` closes all file descriptors by default, but you have to specify `close_fds=True` with `Popen`.

## 17.1.5 Notes

### Convertir une séquence d'arguments vers une chaîne de caractères sous Windows

Sous Windows, une séquence *args* est convertie vers une chaîne qui peut être analysée avec les règles suivantes (qui correspondent aux règles utilisées par l'environnement *MS C*) :

1. Les arguments sont délimités par des espaces, qui peuvent être des espaces ou des tabulations.
2. Une chaîne entourée de double guillemets est interprétée comme un argument seul, qu'elle contienne ou non des espaces. Une chaîne entre guillemets peut être intégrée dans un argument.
3. Un guillemet double précédé d'un *backslash* est interprété comme un guillemet double littéral.
4. Les *backslashes* sont interprétés littéralement, à moins qu'ils précèdent immédiatement un guillemet double.
5. Si des *backslashes* précèdent directement un guillemet double, toute paire de *backslashes* est interprétée comme un *backslash* littéral. Si le nombre de *backslashes* est impair, le dernier *backslash* échappe le prochain guillemet double comme décrit en règle 3.

## 17.2 socket — Low-level networking interface

This module provides access to the BSD *socket* interface. It is available on all modern Unix systems, Windows, Mac OS X, BeOS, OS/2, and probably additional platforms.

---

**Note :** Some behavior may be platform dependent, since calls are made to the operating system socket APIs.

---

For an introduction to socket programming (in C), see the following papers : An Introductory 4.3BSD Interprocess Communication Tutorial, by Stuart Sechrest and An Advanced 4.3BSD Interprocess Communication Tutorial, by Samuel J. Leffler et al, both in the UNIX Programmer's Manual, Supplementary Documents 1 (sections PS1 :7 and PS1 :8). The platform-specific reference material for the various socket-related system calls are also a valuable source of information on the details of socket semantics. For Unix, refer to the manual pages; for Windows, see the WinSock (or Winsock 2) specification. For IPv6-ready APIs, readers may want to refer to **RFC 3493** titled Basic Socket Interface Extensions for IPv6.

The Python interface is a straightforward transliteration of the Unix system call and library interface for sockets to Python's object-oriented style : the `socket()` function returns a *socket object* whose methods implement the various socket system calls. Parameter types are somewhat higher-level than in the C interface : as with `read()` and `write()` operations on Python files, buffer allocation on receive operations is automatic, and buffer length is implicit on send operations.

Socket addresses are represented as follows : A single string is used for the `AF_UNIX` address family. A pair (*host*, *port*) is used for the `AF_INET` address family, where *host* is a string representing either a hostname in Internet domain notation like 'daring.cwi.nl' or an IPv4 address like '100.50.200.5', and *port* is an integer. For `AF_INET6` address family, a four-tuple (*host*, *port*, *flowinfo*, *scopeid*) is used, where *flowinfo* and *scopeid* represents `sin6_flowinfo` and `sin6_scope_id` member in `struct sockaddr_in6` in C. For `socket` module methods, *flowinfo* and *scopeid* can be omitted just for backward compatibility. Note, however, omission of *scopeid* can cause problems in manipulating scoped IPv6 addresses. Other address families are currently not supported. The address format required by a particular socket object is automatically selected based on the address family specified when the socket object was created.

For IPv4 addresses, two special forms are accepted instead of a host address : the empty string represents `INADDR_ANY`, and the string '`<broadcast>`' represents `INADDR_BROADCAST`. The behavior is not available for IPv6 for backward compatibility, therefore, you may want to avoid these if you intend to support IPv6 with your Python programs.

If you use a hostname in the *host* portion of IPv4/v6 socket address, the program may show a nondeterministic behavior, as Python uses the first address returned from the DNS resolution. The socket address will be resolved differently into an actual IPv4/v6 address, depending on the results from DNS resolution and/or the host configuration. For deterministic behavior use a numeric address in *host* portion.

Nouveau dans la version 2.5 : `AF_NETLINK` sockets are represented as pairs `pid, groups`.

Nouveau dans la version 2.6 : Linux-only support for TIPC is also available using the `AF_TIPC` address family. TIPC is an open, non-IP based networked protocol designed for use in clustered computer environments. Addresses are represented by a tuple, and the fields depend on the address type. The general tuple form is `(addr_type, v1, v2, v3 [, scope])`, where :

- *addr\_type* is one of `TIPC_ADDR_NAMESEQ`, `TIPC_ADDR_NAME`, or `TIPC_ADDR_ID`.
- *scope* is one of `TIPC_ZONE_SCOPE`, `TIPC_CLUSTER_SCOPE`, and `TIPC_NODE_SCOPE`.
- If *addr\_type* is `TIPC_ADDR_NAME`, then *v1* is the server type, *v2* is the port identifier, and *v3* should be 0.
  - If *addr\_type* is `TIPC_ADDR_NAMESEQ`, then *v1* is the server type, *v2* is the lower port number, and *v3* is the upper port number.
  - If *addr\_type* is `TIPC_ADDR_ID`, then *v1* is the node, *v2* is the reference, and *v3* should be set to 0.

All errors raise exceptions. The normal exceptions for invalid argument types and out-of-memory conditions can be raised ; errors related to socket or address semantics raise the error `socket.error`.

Non-blocking mode is supported through `setblocking()`. A generalization of this based on timeouts is supported through `settimeout()`.

The module `socket` exports the following constants and functions :

#### **exception `socket.error`**

This exception is raised for socket-related errors. The accompanying value is either a string telling what went wrong or a pair `(errno, string)` representing an error returned by a system call, similar to the value accompanying `os.error`. See the module `errno`, which contains names for the error codes defined by the underlying operating system.

Modifié dans la version 2.6 : `socket.error` is now a child class of `IOError`.

#### **exception `socket.herror`**

This exception is raised for address-related errors, i.e. for functions that use `h_errno` in the C API, including `gethostbyname_ex()` and `gethostbyaddr()`.

The accompanying value is a pair `(h_errno, string)` representing an error returned by a library call. *string* represents the description of `h_errno`, as returned by the `hstrerror()` C function.

#### **exception `socket.gaierror`**

This exception is raised for address-related errors, for `getaddrinfo()` and `getnameinfo()`. The accompanying value is a pair `(error, string)` representing an error returned by a library call. *string* represents the description of *error*, as returned by the `gai_strerror()` C function. The *error* value will match one of the `EAI_*` constants defined in this module.

#### **exception `socket.timeout`**

This exception is raised when a timeout occurs on a socket which has had timeouts enabled via a prior call to `settimeout()`. The accompanying value is a string whose value is currently always « timed out ».

Nouveau dans la version 2.3.

`socket.AF_UNIX`

`socket.AF_INET`

`socket.AF_INET6`

These constants represent the address (and protocol) families, used for the first argument to `socket()`. If the `AF_UNIX` constant is not defined then this protocol is unsupported.

`socket.SOCK_STREAM`

`socket.SOCK_DGRAM`

`socket.SOCK_RAW`

`socket.SOCK_RDM`

`socket.SOCK_SEQPACKET`

These constants represent the socket types, used for the second argument to `socket()`. (Only `SOCK_STREAM` and `SOCK_DGRAM` appear to be generally useful.)

`SO_*`

`socket.SOMAXCONN`

`MSG_*`

`SOL_*`

`IPPROTO_*`

`IPPORT_*`

`INADDR_*`

`IP_*`

`IPV6_*`

`EAI_*`

`AI_*`

`NI_*`

`TCP_*`

Many constants of these forms, documented in the Unix documentation on sockets and/or the IP protocol, are also defined in the socket module. They are generally used in arguments to the `setsockopt()` and `getsockopt()` methods of socket objects. In most cases, only those symbols that are defined in the Unix header files are defined; for a few symbols, default values are provided.

`SIO_*`

`RCVALL_*`

Constants for Windows' `WSAIoctl()`. The constants are used as arguments to the `ioctl()` method of socket objects.

Nouveau dans la version 2.6.

`TIPC_*`

TIPC related constants, matching the ones exported by the C socket API. See the TIPC documentation for more information.

Nouveau dans la version 2.6.

`socket.has_ipv6`

This constant contains a boolean value which indicates if IPv6 is supported on this platform.

Nouveau dans la version 2.3.

`socket.create_connection(address[, timeout[, source_address]])`

Connect to a TCP service listening on the Internet *address* (a 2-tuple (*host*, *port*)), and return the socket object. This is a higher-level function than `socket.connect()`: if *host* is a non-numeric hostname, it will try to resolve it for both `AF_INET` and `AF_INET6`, and then try to connect to all possible addresses in turn until a connection succeeds. This makes it easy to write clients that are compatible to both IPv4 and IPv6.

Passing the optional *timeout* parameter will set the timeout on the socket instance before attempting to connect. If no *timeout* is supplied, the global default timeout setting returned by `getdefaulttimeout()` is used.

If supplied, *source\_address* must be a 2-tuple (*host*, *port*) for the socket to bind to as its source address before connecting. If *host* or *port* are "" or 0 respectively the OS default behavior will be used.

Nouveau dans la version 2.6.

Modifié dans la version 2.7 : `source_address` was added.

`socket.getaddrinfo(host, port[, family[, socktype[, proto[, flags]]]])`

Translate the *host/port* argument into a sequence of 5-tuples that contain all the necessary arguments for creating a socket connected to that service. *host* is a domain name, a string representation of an IPv4/v6 address or `None`. *port* is a string service name such as `'http'`, a numeric port number or `None`. By passing `None` as the value of *host* and *port*, you can pass `NULL` to the underlying C API.

The *family*, *socktype* and *proto* arguments can be optionally specified in order to narrow the list of addresses returned. By default, their value is 0, meaning that the full range of results is selected. The *flags* argument can be one or several of the `AI_*` constants, and will influence how results are computed and returned. Its default value is 0. For example, `AI_NUMERICHOST` will disable domain name resolution and will raise an error if *host* is a domain name.

The function returns a list of 5-tuples with the following structure :

(family, socktype, proto, canonname, sockaddr)

In these tuples, *family*, *socktype*, *proto* are all integers and are meant to be passed to the `socket()` function. *canonname* will be a string representing the canonical name of the *host* if `AI_CANONNAME` is part of the *flags* argument; else *canonname* will be empty. *sockaddr* is a tuple describing a socket address, whose format depends on the returned *family* (a (address, port) 2-tuple for `AF_INET`, a (address, port, flow info, scope id) 4-tuple for `AF_INET6`), and is meant to be passed to the `socket.connect()` method.

The following example fetches address information for a hypothetical TCP connection to `example.org` on port 80 (results may differ on your system if IPv6 isn't enabled) :

```
>>> socket.getaddrinfo("example.org", 80, 0, 0, socket.IPPROTO_TCP)
[(10, 1, 6, '', ('2606:2800:220:1:248:1893:25c8:1946', 80, 0, 0)),
 (2, 1, 6, '', ('93.184.216.34', 80))]
```

Nouveau dans la version 2.2.

`socket.getfqdn([name])`

Return a fully qualified domain name for *name*. If *name* is omitted or empty, it is interpreted as the local host. To find the fully qualified name, the hostname returned by `gethostbyaddr()` is checked, followed by aliases for the host, if available. The first name which includes a period is selected. In case no fully qualified domain name is available, the hostname as returned by `gethostname()` is returned.

Nouveau dans la version 2.0.

`socket.gethostbyname(hostname)`

Translate a host name to IPv4 address format. The IPv4 address is returned as a string, such as `'100.50.200.5'`. If the host name is an IPv4 address itself it is returned unchanged. See `gethostbyname_ex()` for a more complete interface. `gethostbyname()` does not support IPv6 name resolution, and `getaddrinfo()` should be used instead for IPv4/v6 dual stack support.

`socket.gethostbyname_ex(hostname)`

Translate a host name to IPv4 address format, extended interface. Return a triple (*hostname*, *aliaslist*, *ipaddrlist*) where *hostname* is the primary host name responding to the given *ip\_address*, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4 addresses for the same interface on the same host (often but not always a single address). `gethostbyname_ex()` does not support IPv6 name resolution, and `getaddrinfo()` should be used instead for IPv4/v6 dual stack support.

`socket.gethostname()`

Return a string containing the hostname of the machine where the Python interpreter is currently executing.

If you want to know the current machine's IP address, you may want to use `gethostbyname(gethostname())`. This operation assumes that there is a valid address-to-host

mapping for the host, and the assumption does not always hold.

Note : `gethostname()` doesn't always return the fully qualified domain name; use `getfqdn()` (see above).

`socket.gethostbyaddr(ip_address)`

Return a triple (`hostname`, `aliaslist`, `ipaddrlist`) where *hostname* is the primary host name responding to the given *ip\_address*, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4/v6 addresses for the same interface on the same host (most likely containing only a single address). To find the fully qualified domain name, use the function `getfqdn()`. `gethostbyaddr()` supports both IPv4 and IPv6.

`socket.getnameinfo(sockaddr, flags)`

Translate a socket address *sockaddr* into a 2-tuple (`host`, `port`). Depending on the settings of *flags*, the result can contain a fully-qualified domain name or numeric address representation in *host*. Similarly, *port* can contain a string port name or a numeric port number.

Nouveau dans la version 2.2.

`socket.getprotobyname(protocolname)`

Translate an Internet protocol name (for example, 'icmp') to a constant suitable for passing as the (optional) third argument to the `socket()` function. This is usually only needed for sockets opened in « raw » mode (`SOCK_RAW`); for the normal socket modes, the correct protocol is chosen automatically if the protocol is omitted or zero.

`socket.getservbyname(servicename[, protocolname])`

Translate an Internet service name and protocol name to a port number for that service. The optional protocol name, if given, should be 'tcp' or 'udp', otherwise any protocol will match.

`socket.getservbyport(port[, protocolname])`

Translate an Internet port number and protocol name to a service name for that service. The optional protocol name, if given, should be 'tcp' or 'udp', otherwise any protocol will match.

`socket.socket([family[, type[, proto]]])`

Create a new socket using the given address family, socket type and protocol number. The address family should be `AF_INET` (the default), `AF_INET6` or `AF_UNIX`. The socket type should be `SOCK_STREAM` (the default), `SOCK_DGRAM` or perhaps one of the other `SOCK_` constants. The protocol number is usually zero and may be omitted in that case.

`socket.socketpair([family[, type[, proto]]])`

Build a pair of connected socket objects using the given address family, socket type, and protocol number. Address family, socket type, and protocol number are as for the `socket()` function above. The default family is `AF_UNIX` if defined on the platform; otherwise, the default is `AF_INET`. Availability : Unix.

Nouveau dans la version 2.4.

`socket.fromfd(fd, family, type[, proto])`

Duplicate the file descriptor *fd* (an integer as returned by a file object's `fileno()` method) and build a socket object from the result. Address family, socket type and protocol number are as for the `socket()` function above. The file descriptor should refer to a socket, but this is not checked — subsequent operations on the object may fail if the file descriptor is invalid. This function is rarely needed, but can be used to get or set socket options on a socket passed to a program as standard input or output (such as a server started by the Unix inet daemon). The socket is assumed to be in blocking mode. Availability : Unix.

`socket.ntohl(x)`

Convert 32-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

**socket.ntohs(*x*)**

Convert 16-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op ; otherwise, it performs a 2-byte swap operation.

**socket.htonl(*x*)**

Convert 32-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op ; otherwise, it performs a 4-byte swap operation.

**socket.htons(*x*)**

Convert 16-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op ; otherwise, it performs a 2-byte swap operation.

**socket.inet\_aton(*ip\_string*)**

Convert an IPv4 address from dotted-quad string format (for example, “123.45.67.89”) to 32-bit packed binary format, as a string four characters in length. This is useful when conversing with a program that uses the standard C library and needs objects of type `struct in_addr`, which is the C type for the 32-bit packed binary this function returns.

`inet_aton()` also accepts strings with less than three dots; see the Unix manual page `inet(3)` for details.

If the IPv4 address string passed to this function is invalid, `socket.error` will be raised. Note that exactly what is valid depends on the underlying C implementation of `inet_aton()`.

`inet_aton()` does not support IPv6, and `inet_pton()` should be used instead for IPv4/v6 dual stack support.

**socket.inet\_ntoa(*packed\_ip*)**

Convert a 32-bit packed IPv4 address (a string four characters in length) to its standard dotted-quad string representation (for example, “123.45.67.89”). This is useful when conversing with a program that uses the standard C library and needs objects of type `struct in_addr`, which is the C type for the 32-bit packed binary data this function takes as an argument.

If the string passed to this function is not exactly 4 bytes in length, `socket.error` will be raised.

`inet_ntoa()` does not support IPv6, and `inet_ntop()` should be used instead for IPv4/v6 dual stack support.

**socket.inet\_pton(*address\_family*, *ip\_string*)**

Convert an IP address from its family-specific string format to a packed, binary format. `inet_pton()` is useful when a library or network protocol calls for an object of type `struct in_addr` (similar to `inet_aton()`) or `struct in6_addr`.

Supported values for `address_family` are currently `AF_INET` and `AF_INET6`. If the IP address string `ip_string` is invalid, `socket.error` will be raised. Note that exactly what is valid depends on both the value of `address_family` and the underlying implementation of `inet_pton()`.

Availability : Unix (maybe not all platforms).

Nouveau dans la version 2.3.

**socket.inet\_ntop(*address\_family*, *packed\_ip*)**

Convert a packed IP address (a string of some number of characters) to its standard, family-specific string representation (for example, '7.10.0.5' or '5aef:2b::8') `inet_ntop()` is useful when a library or network protocol returns an object of type `struct in_addr` (similar to `inet_ntoa()`) or `struct in6_addr`.

Supported values for `address_family` are currently `AF_INET` and `AF_INET6`. If the string `packed_ip` is not the correct length for the specified address family, `ValueError` will be raised. A `socket.error` is raised for errors from the call to `inet_ntop()`.

Availability : Unix (maybe not all platforms).

Nouveau dans la version 2.3.

**socket.getdefaulttimeout()**

Return the default timeout in seconds (float) for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

Nouveau dans la version 2.3.

`socket.setdefaulttimeout(timeout)`

Set the default timeout in seconds (float) for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

Nouveau dans la version 2.3.

`socket.SocketType`

This is a Python type object that represents the socket object type. It is the same as `type(socket(...))`.

Voir aussi :

Module `SocketServer` Classes that simplify writing network servers.

Module `ssl` A TLS/SSL wrapper for socket objects.

### 17.2.1 Socket Objects

Socket objects have the following methods. Except for `makefile()` these correspond to Unix system calls applicable to sockets.

`socket.accept()`

Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair (`conn`, `address`) where `conn` is a new socket object usable to send and receive data on the connection, and `address` is the address bound to the socket on the other end of the connection.

`socket.bind(address)`

Bind the socket to `address`. The socket must not already be bound. (The format of `address` depends on the address family — see above.)

---

**Note :** This method has historically accepted a pair of parameters for `AF_INET` addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

---

`socket.close()`

Close the socket. All future operations on the socket object will fail. The remote end will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

---

**Note :** `close()` releases the resource associated with a connection but does not necessarily close the connection immediately. If you want to close the connection in a timely fashion, call `shutdown()` before `close()`.

---

`socket.connect(address)`

Connect to a remote socket at `address`. (The format of `address` depends on the address family — see above.)

---

**Note :** This method has historically accepted a pair of parameters for `AF_INET` addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

---

`socket.connect_ex(address)`

Like `connect(address)`, but return an error indicator instead of raising an exception for errors returned by the C-level `connect()` call (other problems, such as « host not found, » can still raise exceptions). The error indicator is 0 if the operation succeeded, otherwise the value of the `errno` variable. This is useful to support, for example, asynchronous connects.

---

**Note :** This method has historically accepted a pair of parameters for [AF\\_INET](#) addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

---

`socket.fileno()`

Return the socket's file descriptor (a small integer). This is useful with [select.select\(\)](#).

Under Windows the small integer returned by this method cannot be used where a file descriptor can be used (such as [os.fdopen\(\)](#)). Unix does not have this limitation.

`socket.getpeername()`

Return the remote address to which the socket is connected. This is useful to find out the port number of a remote IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.) On some systems this function is not supported.

`socket.getsockname()`

Return the socket's own address. This is useful to find out the port number of an IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.)

`socket.getsockopt(level, optname[, buflen])`

Return the value of the given socket option (see the Unix man page [getsockopt\(2\)](#)). The needed symbolic constants (`SO_*` etc.) are defined in this module. If *buflen* is absent, an integer option is assumed and its integer value is returned by the function. If *buflen* is present, it specifies the maximum length of the buffer used to receive the option in, and this buffer is returned as a string. It is up to the caller to decode the contents of the buffer (see the optional built-in module [struct](#) for a way to decode C structures encoded as strings).

`socket.ioctl(control, option)`

#### Platform Windows

The [ioctl\(\)](#) method is a limited interface to the `WSAIoctl` system interface. Please refer to the [Win32 documentation](#) for more information.

On other platforms, the generic [fcntl.fcntl\(\)](#) and [fcntl.ioctl\(\)](#) functions may be used; they accept a socket object as their first argument.

Nouveau dans la version 2.6.

`socket.listen(backlog)`

Listen for connections made to the socket. The *backlog* argument specifies the maximum number of queued connections and should be at least 0; the maximum value is system-dependent (usually 5), the minimum value is forced to 0.

`socket.makefile([mode[, bufsize]])`

Return a *file object* associated with the socket. (File objects are described in [Objets fichiers](#).) The file object does not close the socket explicitly when its [close\(\)](#) method is called, but only removes its reference to the socket object, so that the socket will be closed if it is not referenced from anywhere else.

The socket must be in blocking mode (it can not have a timeout). The optional *mode* and *bufsize* arguments are interpreted the same way as by the built-in [file\(\)](#) function.

---

**Note :** On Windows, the file-like object created by [makefile\(\)](#) cannot be used where a file object with a file descriptor is expected, such as the stream arguments of [subprocess.Popen\(\)](#).

---

`socket.recv(bufsize[, flags])`

Receive data from the socket. The return value is a string representing the data received. The maximum amount of data to be received at once is specified by *bufsize*. See the Unix manual page [recv\(2\)](#) for the meaning of the optional argument *flags*; it defaults to zero.

---

**Note :** For best match with hardware and network realities, the value of *bufsize* should be a relatively small power of 2, for example, 4096.

---

`socket.recvfrom(bufsize[, flags])`

Receive data from the socket. The return value is a pair (*string*, *address*) where *string* is a string representing the data received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.)

`socket.recvfrom_into(buffer[, nbytes[, flags]])`

Receive data from the socket, writing it into *buffer* instead of creating a new string. The return value is a pair (*nbytes*, *address*) where *nbytes* is the number of bytes received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.) Nouveau dans la version 2.5.

`socket.recv_into(buffer[, nbytes[, flags]])`

Receive up to *nbytes* bytes from the socket, storing the data into a buffer rather than creating a new string. If *nbytes* is not specified (or 0), receive up to the size available in the given buffer. Returns the number of bytes received. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero.

Nouveau dans la version 2.5.

`socket.send(string[, flags])`

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for *recv()* above. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data. For further information on this concept, consult the socket-howto.

`socket.sendall(string[, flags])`

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for *recv()* above. Unlike *send()*, this method continues to send data from *string* until either all data has been sent or an error occurs. *None* is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

`socket.sendto(string, address)`

`socket.sendto(string, flags, address)`

Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by *address*. The optional *flags* argument has the same meaning as for *recv()* above. Return the number of bytes sent. (The format of *address* depends on the address family — see above.)

`socket.setblocking(flag)`

Set blocking or non-blocking mode of the socket : if *flag* is 0, the socket is set to non-blocking, else to blocking mode. Initially all sockets are in blocking mode. In non-blocking mode, if a *recv()* call doesn't find any data, or if a *send()* call can't immediately dispose of the data, an *error* exception is raised; in blocking mode, the calls block until they can proceed. *s.setblocking(0)* is equivalent to *s.settimeout(0.0)*; *s.setblocking(1)* is equivalent to *s.settimeout(None)*.

`socket.settimeout(value)`

Set a timeout on blocking socket operations. The *value* argument can be a nonnegative float expressing seconds, or *None*. If a float is given, subsequent socket operations will raise a *timeout* exception if the timeout period *value* has elapsed before the operation has completed. Setting a timeout of *None* disables timeouts on socket operations. *s.settimeout(0.0)* is equivalent to *s.setblocking(0)*; *s.settimeout(None)* is equivalent to *s.setblocking(1)*.

Nouveau dans la version 2.3.

#### `socket.gettimeout()`

Return the timeout in seconds (float) associated with socket operations, or `None` if no timeout is set. This reflects the last call to `setblocking()` or `settimeout()`.

Nouveau dans la version 2.3.

Some notes on socket blocking and timeouts : A socket object can be in one of three modes : blocking, non-blocking, or timeout. Sockets are always created in blocking mode. In blocking mode, operations block until complete or the system returns an error (such as connection timed out). In non-blocking mode, operations fail (with an error that is unfortunately system-dependent) if they cannot be completed immediately. In timeout mode, operations fail if they cannot be completed within the timeout specified for the socket or if the system returns an error. The `setblocking()` method is simply a shorthand for certain `settimeout()` calls.

Timeout mode internally sets the socket in non-blocking mode. The blocking and timeout modes are shared between file descriptors and socket objects that refer to the same network endpoint. A consequence of this is that file objects returned by the `makefile()` method must only be used when the socket is in blocking mode ; in timeout or non-blocking mode file operations that cannot be completed immediately will fail.

Note that the `connect()` operation is subject to the timeout setting, and in general it is recommended to call `settimeout()` before calling `connect()` or pass a timeout parameter to `create_connection()`. The system network stack may return a connection timeout error of its own regardless of any Python socket timeout setting.

#### `socket.setsockopt(level, optname, value)`

Set the value of the given socket option (see the Unix manual page `setsockopt(2)`). The needed symbolic constants are defined in the `socket` module (`SO_*` etc.). The value can be an integer or a string representing a buffer. In the latter case it is up to the caller to ensure that the string contains the proper bits (see the optional built-in module `struct` for a way to encode C structures as strings).

#### `socket.shutdown(how)`

Shut down one or both halves of the connection. If `how` is `SHUT_RD`, further receives are disallowed. If `how` is `SHUT_WR`, further sends are disallowed. If `how` is `SHUT_RDWR`, further sends and receives are disallowed. Depending on the platform, shutting down one half of the connection can also close the opposite half (e.g. on Mac OS X, `shutdown(SHUT_WR)` does not allow further reads on the other end of the connection).

Note that there are no methods `read()` or `write()` ; use `recv()` and `send()` without `flags` argument instead.

Socket objects also have these (read-only) attributes that correspond to the values given to the `socket` constructor.

#### `socket.family`

The socket family.

Nouveau dans la version 2.5.

#### `socket.type`

The socket type.

Nouveau dans la version 2.5.

#### `socket.proto`

The socket protocol.

Nouveau dans la version 2.5.

## 17.2.2 Exemple

Here are four minimal example programs using the TCP/IP protocol : a server that echoes all data that it receives back (servicing only one client), and a client using it. Note that a server must perform the

sequence `socket()`, `bind()`, `listen()`, `accept()` (possibly repeating the `accept()` to service more than one client), while a client only needs the sequence `socket()`, `connect()`. Also note that the server does not `sendall()/recv()` on the socket it is listening on but on the new socket returned by `accept()`.

The first two examples support IPv4 only.

```
# Echo server program
import socket

HOST = ''          # Symbolic name meaning all available interfaces
PORT = 50007       # Arbitrary non-privileged port
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.bind((HOST, PORT))
s.listen(1)
conn, addr = s.accept()
print 'Connected by', addr
while 1:
    data = conn.recv(1024)
    if not data: break
    conn.sendall(data)
conn.close()
```

```
# Echo client program
import socket

HOST = 'daring.cwi.nl'    # The remote host
PORT = 50007              # The same port as used by the server
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.connect((HOST, PORT))
s.sendall('Hello, world')
data = s.recv(1024)
s.close()
print 'Received', repr(data)
```

The next two examples are identical to the above two, but support both IPv4 and IPv6. The server side will listen to the first address family available (it should listen to both instead). On most of IPv6-ready systems, IPv6 will take precedence and the server may not accept IPv4 traffic. The client side will try to connect to the all addresses returned as a result of the name resolution, and sends traffic to the first one connected successfully.

```
# Echo server program
import socket
import sys

HOST = None          # Symbolic name meaning all available interfaces
PORT = 50007         # Arbitrary non-privileged port
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC,
                              socket.SOCK_STREAM, 0, socket.AI_PASSIVE):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except socket.error as msg:
        s = None
```

(suite sur la page suivante)

(suite de la page précédente)

```

        continue
    try:
        s.bind(sa)
        s.listen(1)
    except socket.error as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print 'could not open socket'
    sys.exit(1)
conn, addr = s.accept()
print 'Connected by', addr
while 1:
    data = conn.recv(1024)
    if not data: break
    conn.send(data)
conn.close()

```

```

# Echo client program
import socket
import sys

HOST = 'daring.cwi.nl'      # The remote host
PORT = 50007                # The same port as used by the server
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC, socket.SOCK_STREAM):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except socket.error as msg:
        s = None
        continue
    try:
        s.connect(sa)
    except socket.error as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print 'could not open socket'
    sys.exit(1)
s.sendall('Hello, world')
data = s.recv(1024)
s.close()
print 'Received', repr(data)

```

The last example shows how to write a very simple network sniffer with raw sockets on Windows. The example requires administrator privileges to modify the interface :

```
import socket

# the public network interface
HOST = socket.gethostbyname(socket.gethostname())

# create a raw socket and bind it to the public interface
s = socket.socket(socket.AF_INET, socket.SOCK_RAW, socket.IPPROTO_IP)
s.bind((HOST, 0))

# Include IP headers
s.setsockopt(socket.IPPROTO_IP, socket.IP_HDRINCL, 1)

# receive all packages
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_ON)

# receive a package
print s.recvfrom(65565)

# disabled promiscuous mode
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_OFF)
```

Running an example several times with too small delay between executions, could lead to this error :

```
socket.error: [Errno 98] Address already in use
```

This is because the previous execution has left the socket in a `TIME_WAIT` state, and can't be immediately reused.

There is a `socket` flag to set, in order to prevent this, `socket.SO_REUSEADDR` :

```
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.setsockopt(socket.SOL_SOCKET, socket.SO_REUSEADDR, 1)
s.bind((HOST, PORT))
```

the `SO_REUSEADDR` flag tells the kernel to reuse a local socket in `TIME_WAIT` state, without waiting for its natural timeout to expire.

## 17.3 ssl — TLS/SSL wrapper for socket objects

Nouveau dans la version 2.6.

**Code source :** [Lib/ssl.py](#)

This module provides access to Transport Layer Security (often known as « Secure Sockets Layer ») encryption and peer authentication facilities for network sockets, both client-side and server-side. This module uses the OpenSSL library. It is available on all modern Unix systems, Windows, Mac OS X, and probably additional platforms, as long as OpenSSL is installed on that platform.

Modifié dans la version 2.7.13 : Updated to support linking with OpenSSL 1.1.0

**Note :** Some behavior may be platform dependent, since calls are made to the operating system socket APIs. The installed version of OpenSSL may also cause variations in behavior. For example, TLSv1.1 and TLSv1.2 come with openssl version 1.0.1.

**Avertissement :** Don't use this module without reading the *Security considerations*. Doing so may lead to a false sense of security, as the default settings of the `ssl` module are not necessarily appropriate for your application.

This section documents the objects and functions in the `ssl` module; for more general information about TLS, SSL, and certificates, the reader is referred to the documents in the « See Also » section at the bottom.

This module provides a class, `ssl.SSLSocket`, which is derived from the `socket.socket` type, and provides a socket-like wrapper that also encrypts and decrypts the data going over the socket with SSL. It supports additional methods such as `getpeercert()`, which retrieves the certificate of the other side of the connection, and `cipher()`, which retrieves the cipher being used for the secure connection.

For more sophisticated applications, the `ssl.SSLContext` class helps manage settings and certificates, which can then be inherited by SSL sockets created through the `SSLContext.wrap_socket()` method.

### 17.3.1 Functions, Constants, and Exceptions

#### **exception** `ssl.SSLError`

Raised to signal an error from the underlying SSL implementation (currently provided by the OpenSSL library). This signifies some problem in the higher-level encryption and authentication layer that's superimposed on the underlying network connection. This error is a subtype of `socket.error`, which in turn is a subtype of `IOError`. The error code and message of `SSLError` instances are provided by the OpenSSL library.

##### **library**

A string mnemonic designating the OpenSSL submodule in which the error occurred, such as `SSL`, `PEM` or `X509`. The range of possible values depends on the OpenSSL version.

Nouveau dans la version 2.7.9.

##### **reason**

A string mnemonic designating the reason this error occurred, for example `CERTIFICATE_VERIFY_FAILED`. The range of possible values depends on the OpenSSL version.

Nouveau dans la version 2.7.9.

#### **exception** `ssl.SSLZeroReturnError`

A subclass of `SSLError` raised when trying to read or write and the SSL connection has been closed cleanly. Note that this doesn't mean that the underlying transport (read TCP) has been closed.

Nouveau dans la version 2.7.9.

#### **exception** `ssl.SSLWantReadError`

A subclass of `SSLError` raised by a *non-blocking SSL socket* when trying to read or write data, but more data needs to be received on the underlying TCP transport before the request can be fulfilled.

Nouveau dans la version 2.7.9.

#### **exception** `ssl.SSLWantWriteError`

A subclass of `SSLError` raised by a *non-blocking SSL socket* when trying to read or write data, but more data needs to be sent on the underlying TCP transport before the request can be fulfilled.

Nouveau dans la version 2.7.9.

#### **exception** `ssl.SSLSyscallError`

A subclass of `SSLError` raised when a system error was encountered while trying to fulfill an operation on a SSL socket. Unfortunately, there is no easy way to inspect the original `errno` number.

Nouveau dans la version 2.7.9.

#### **exception** `ssl.SSLEOFError`

A subclass of `SSLError` raised when the SSL connection has been terminated abruptly. Generally, you shouldn't try to reuse the underlying transport when this error is encountered.

Nouveau dans la version 2.7.9.

**exception `ssl.CertificateError`**

Raised to signal an error with a certificate (such as mismatching hostname). Certificate errors detected by OpenSSL, though, raise an *SSL*[Error](#).

### Socket creation

The following function allows for standalone socket creation. Starting from Python 2.7.9, it can be more flexible to use *SSLContext.wrap\_socket()* instead.

**`ssl.wrap_socket(sock, keyfile=None, certfile=None, server_side=False, cert_reqs=CERT_NONE, ssl_version={see docs}, ca_certs=None, do_handshake_on_connect=True, suppress_ragged_eofs=True, ciphers=None)`**

Takes an instance `sock` of *socket.socket*, and returns an instance of *ssl.SSLSocket*, a subtype of *socket.socket*, which wraps the underlying socket in an SSL context. `sock` must be a *SOCK\_STREAM* socket; other socket types are unsupported.

For client-side sockets, the context construction is lazy; if the underlying socket isn't connected yet, the context construction will be performed after `connect()` is called on the socket. For server-side sockets, if the socket has no remote peer, it is assumed to be a listening socket, and the server-side SSL wrapping is automatically performed on client connections accepted via the `accept()` method. *wrap\_socket()* may raise *SSL*[Error](#).

The `keyfile` and `certfile` parameters specify optional files which contain a certificate to be used to identify the local side of the connection. See the discussion of *Certificates* for more information on how the certificate is stored in the `certfile`.

The parameter `server_side` is a boolean which identifies whether server-side or client-side behavior is desired from this socket.

The parameter `cert_reqs` specifies whether a certificate is required from the other side of the connection, and whether it will be validated if provided. It must be one of the three values *CERT\_NONE* (certificates ignored), *CERT\_OPTIONAL* (not required, but validated if provided), or *CERT\_REQUIRED* (required and validated). If the value of this parameter is not *CERT\_NONE*, then the `ca_certs` parameter must point to a file of CA certificates.

The `ca_certs` file contains a set of concatenated « certification authority » certificates, which are used to validate certificates passed from the other end of the connection. See the discussion of *Certificates* for more information about how to arrange the certificates in this file.

The parameter `ssl_version` specifies which version of the SSL protocol to use. Typically, the server chooses a particular protocol version, and the client must adapt to the server's choice. Most of the versions are not interoperable with the other versions. If not specified, the default is *PROTOCOL\_SSLv23*; it provides the most compatibility with other versions.

Here's a table showing which versions in a client (down the side) can connect to which versions in a server (along the top) :

<i>client</i> / <b>server</b>	<b>SSLv2</b>	<b>SSLv3</b>	<b>SSLv23</b>	<b>TLSv1</b>	<b>TLSv1.1</b>	<b>TLSv1.2</b>
<i>SSLv2</i>	oui	non	oui	non	non	non
<i>SSLv3</i>	non	oui	oui	non	non	non
<i>SSLv23</i> <sup>1</sup>	non	oui	oui	oui	oui	oui
<i>TLSv1</i>	non	non	oui	oui	non	non
<i>TLSv1.1</i>	non	non	oui	non	oui	non
<i>TLSv1.2</i>	non	non	oui	non	non	oui

1. TLS 1.3 protocol will be available with *PROTOCOL\_SSLv23* in OpenSSL >= 1.1.1. There is no dedicated *PROTOCOL* constant for just TLS 1.3.

---

**Note :** Which connections succeed will vary depending on the version of OpenSSL. For example, before OpenSSL 1.0.0, an SSLv23 client would always attempt SSLv2 connections.

---

The *ciphers* parameter sets the available ciphers for this SSL object. It should be a string in the OpenSSL cipher list format.

The parameter *do\_handshake\_on\_connect* specifies whether to do the SSL handshake automatically after doing a `socket.connect()`, or whether the application program will call it explicitly, by invoking the `SSLSocket.do_handshake()` method. Calling `SSLSocket.do_handshake()` explicitly gives the program control over the blocking behavior of the socket I/O involved in the handshake.

The parameter *suppress\_ragged\_eofs* specifies how the `SSLSocket.read()` method should signal unexpected EOF from the other end of the connection. If specified as *True* (the default), it returns a normal EOF (an empty bytes object) in response to unexpected EOF errors raised from the underlying socket; if *False*, it will raise the exceptions back to the caller.

Modifié dans la version 2.7 : New optional argument *ciphers*.

## Context creation

A convenience function helps create *SSLContext* objects for common purposes.

`ssl.create_default_context(purpose=Purpose.SERVER_AUTH, cafile=None, capath=None, ca-`  
`data=None)`

Return a new *SSLContext* object with default settings for the given *purpose*. The settings are chosen by the *ssl* module, and usually represent a higher security level than when calling the *SSLContext* constructor directly.

*cafile*, *capath*, *cadata* represent optional CA certificates to trust for certificate verification, as in *SSLContext.load\_verify\_locations()*. If all three are *None*, this function can choose to trust the system's default CA certificates instead.

The settings are : *PROTOCOL\_SSLv23*, *OP\_NO\_SSLv2*, and *OP\_NO\_SSLv3* with high encryption cipher suites without RC4 and without unauthenticated cipher suites. Passing *SERVER\_AUTH* as *purpose* sets *verify\_mode* to *CERT\_REQUIRED* and either loads CA certificates (when at least one of *cafile*, *capath* or *cadata* is given) or uses *SSLContext.load\_default\_certs()* to load default CA certificates.

---

**Note :** The protocol, options, cipher and other settings may change to more restrictive values anytime without prior deprecation. The values represent a fair balance between compatibility and security.

If your application needs specific settings, you should create a *SSLContext* and apply the settings yourself.

---

---

**Note :** If you find that when certain older clients or servers attempt to connect with a *SSLContext* created by this function that they get an error stating « Protocol or cipher suite mismatch », it may be that they only support SSL3.0 which this function excludes using the *OP\_NO\_SSLv3*. SSL3.0 is widely considered to be *completely broken*. If you still wish to continue to use this function but still allow SSL 3.0 connections you can re-enable them using :

```
ctx = ssl.create_default_context(Purpose.CLIENT_AUTH)
ctx.options &= ~ssl.OP_NO_SSLv3
```

---

Nouveau dans la version 2.7.9.

Modifié dans la version 2.7.10 : RC4 was dropped from the default cipher string.

Modifié dans la version 2.7.13 : ChaCha20/Poly1305 was added to the default cipher string.

3DES was dropped from the default cipher string.

Modifié dans la version 2.7.15 : TLS 1.3 cipher suites `TLS_AES_128_GCM_SHA256`, `TLS_AES_256_GCM_SHA384`, and `TLS_CHACHA20_POLY1305_SHA256` were added to the default cipher string.

`ssl._https_verify_certificates(enable=True)`

Specifies whether or not server certificates are verified when creating client HTTPS connections without specifying a particular SSL context.

Starting with Python 2.7.9, `httpplib` and modules which use it, such as `urllib2` and `xmllib`, default to verifying remote server certificates received when establishing client HTTPS connections. This default verification checks that the certificate is signed by a Certificate Authority in the system trust store and that the Common Name (or Subject Alternate Name) on the presented certificate matches the requested host.

Setting `enable` to `True` ensures this default behaviour is in effect.

Setting `enable` to `False` reverts the default HTTPS certificate handling to that of Python 2.7.8 and earlier, allowing connections to servers using self-signed certificates, servers using certificates signed by a Certificate Authority not present in the system trust store, and servers where the hostname does not match the presented server certificate.

The leading underscore on this function denotes that it intentionally does not exist in any implementation of Python 3 and may not be present in all Python 2.7 implementations. The portable approach to bypassing certificate checks or the system trust store when necessary is for tools to enable that on a case-by-case basis by explicitly passing in a suitably configured SSL context, rather than reverting the default behaviour of the standard library client modules.

Nouveau dans la version 2.7.12.

**Voir aussi :**

- [CVE-2014-9365](#) – HTTPS man-in-the-middle attack against Python clients using default settings
- [PEP 476](#) – Enabling certificate verification by default for HTTPS
- [PEP 493](#) – HTTPS verification migration tools for Python 2.7

## Random generation

Obsolète depuis la version 2.7.13 : OpenSSL has deprecated `ssl.RAND_pseudo_bytes()`, use `ssl.RAND_bytes()` instead.

`ssl.RAND_status()`

Return `True` if the SSL pseudo-random number generator has been seeded with “enough” randomness, and `False` otherwise. You can use `ssl.RAND_egd()` and `ssl.RAND_add()` to increase the randomness of the pseudo-random number generator.

`ssl.RAND_egd(path)`

If you are running an entropy-gathering daemon (EGD) somewhere, and `path` is the pathname of a socket connection open to it, this will read 256 bytes of randomness from the socket, and add it to the SSL pseudo-random number generator to increase the security of generated secret keys. This is typically only necessary on systems without better sources of randomness.

See <http://egd.sourceforge.net/> or <http://prngd.sourceforge.net/> for sources of entropy-gathering daemons.

Availability : not available with LibreSSL and OpenSSL > 1.1.0

`ssl.RAND_add(bytes, entropy)`

Mix the given `bytes` into the SSL pseudo-random number generator. The parameter `entropy` (a float) is a lower bound on the entropy contained in string (so you can always use 0.0). See [RFC 1750](#) for more information on sources of entropy.

## Certificate handling

`ssl.match_hostname(cert, hostname)`

Verify that `cert` (in decoded format as returned by `SSLSocket.getpeercert()`) matches the given

*hostname*. The rules applied are those for checking the identity of HTTPS servers as outlined in [RFC 2818](#) and [RFC 6125](#), except that IP addresses are not currently supported. In addition to HTTPS, this function should be suitable for checking the identity of servers in various SSL-based protocols such as FTPS, IMAPS, POPS and others.

*CertificateError* is raised on failure. On success, the function returns nothing :

```
>>> cert = {'subject': (((('commonName', 'example.com'),),),)}
>>> ssl.match_hostname(cert, "example.com")
>>> ssl.match_hostname(cert, "example.org")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/py3k/Lib/ssl.py", line 130, in match_hostname
ssl.CertificateError: hostname 'example.org' doesn't match 'example.com'
```

Nouveau dans la version 2.7.9.

`ssl.cert_time_to_seconds(cert_time)`

Return the time in seconds since the Epoch, given the *cert\_time* string representing the « notBefore » or « notAfter » date from a certificate in "%b %d %H:%M:%S %Y %Z" strptime format (C locale).

Here's an example :

```
>>> import ssl
>>> timestamp = ssl.cert_time_to_seconds("Jan  5 09:34:43 2018 GMT")
>>> timestamp
1515144883
>>> from datetime import datetime
>>> print(datetime.utcfromtimestamp(timestamp))
2018-01-05 09:34:43
```

« notBefore » or « notAfter » dates must use GMT ([RFC 5280](#)).

Modifié dans la version 2.7.9 : Interpret the input time as a time in UTC as specified by “GMT” timezone in the input string. Local timezone was used previously. Return an integer (no fractions of a second in the input format)

`ssl.get_server_certificate(addr, ssl_version=PROTOCOL_SSLv23, ca_certs=None)`

Given the address *addr* of an SSL-protected server, as a (*hostname*, *port-number*) pair, fetches the server's certificate, and returns it as a PEM-encoded string. If *ssl\_version* is specified, uses that version of the SSL protocol to attempt to connect to the server. If *ca\_certs* is specified, it should be a file containing a list of root certificates, the same format as used for the same parameter in *wrap\_socket()*. The call will attempt to validate the server certificate against that set of root certificates, and will fail if the validation attempt fails.

Modifié dans la version 2.7.9 : This function is now IPv6-compatible, and the default *ssl\_version* is changed from *PROTOCOL\_SSLv3* to *PROTOCOL\_SSLv23* for maximum compatibility with modern servers.

`ssl.DER_cert_to_PEM_cert(DER_cert_bytes)`

Given a certificate as a DER-encoded blob of bytes, returns a PEM-encoded string version of the same certificate.

`ssl.PEM_cert_to_DER_cert(PEM_cert_string)`

Given a certificate as an ASCII PEM string, returns a DER-encoded sequence of bytes for that same certificate.

`ssl.get_default_verify_paths()`

Returns a named tuple with paths to OpenSSL's default cafile and capath. The paths are the same as used by *SSLContext.set\_default\_verify\_paths()*. The return value is a *named tuple* *DefaultVerifyPaths* :

— *cafile* - resolved path to cafile or *None* if the file doesn't exist,

- `capath` - resolved path to `capath` or `None` if the directory doesn't exist,
- `openssl_cafile_env` - OpenSSL's environment key that points to a cafile,
- `openssl_cafile` - hard coded path to a cafile,
- `openssl_capath_env` - OpenSSL's environment key that points to a capath,
- `openssl_capath` - hard coded path to a capath directory

Availability : LibreSSL ignores the environment vars `openssl_cafile_env` and `openssl_capath_env`

Nouveau dans la version 2.7.9.

#### `ssl.enum_certificates(store_name)`

Retrieve certificates from Windows' system cert store. `store_name` may be one of `CA`, `ROOT` or `MY`. Windows may provide additional cert stores, too.

The function returns a list of (`cert_bytes`, `encoding_type`, `trust`) tuples. The `encoding_type` specifies the encoding of `cert_bytes`. It is either `x509_asn` for X.509 ASN.1 data or `pkcs_7_asn` for PKCS#7 ASN.1 data. `trust` specifies the purpose of the certificate as a set of OIDS or exactly `True` if the certificate is trustworthy for all purposes.

Exemple :

```
>>> ssl.enum_certificates("CA")
[(b'data...', 'x509_asn', {'1.3.6.1.5.5.7.3.1', '1.3.6.1.5.5.7.3.2'}),
 (b'data...', 'x509_asn', True)]
```

Disponibilité : Windows.

Nouveau dans la version 2.7.9.

#### `ssl.enum_crls(store_name)`

Retrieve CRLs from Windows' system cert store. `store_name` may be one of `CA`, `ROOT` or `MY`. Windows may provide additional cert stores, too.

The function returns a list of (`cert_bytes`, `encoding_type`, `trust`) tuples. The `encoding_type` specifies the encoding of `cert_bytes`. It is either `x509_asn` for X.509 ASN.1 data or `pkcs_7_asn` for PKCS#7 ASN.1 data.

Disponibilité : Windows.

Nouveau dans la version 2.7.9.

### Constantes

#### `ssl.CERT_NONE`

Possible value for `SSLContext.verify_mode`, or the `cert_reqs` parameter to `wrap_socket()`. In this mode (the default), no certificates will be required from the other side of the socket connection. If a certificate is received from the other end, no attempt to validate it is made.

See the discussion of *Security considerations* below.

#### `ssl.CERT_OPTIONAL`

Possible value for `SSLContext.verify_mode`, or the `cert_reqs` parameter to `wrap_socket()`. In this mode no certificates will be required from the other side of the socket connection; but if they are provided, validation will be attempted and an `SSLError` will be raised on failure.

Use of this setting requires a valid set of CA certificates to be passed, either to `SSLContext.load_verify_locations()` or as a value of the `ca_certs` parameter to `wrap_socket()`.

#### `ssl.CERT_REQUIRED`

Possible value for `SSLContext.verify_mode`, or the `cert_reqs` parameter to `wrap_socket()`. In this mode, certificates are required from the other side of the socket connection; an `SSLError` will be raised if no certificate is provided, or if its validation fails.

Use of this setting requires a valid set of CA certificates to be passed, either to `SSLContext.load_verify_locations()` or as a value of the `ca_certs` parameter to `wrap_socket()`.

`ssl.VERIFY_DEFAULT`

Possible value for `SSLContext.verify_flags`. In this mode, certificate revocation lists (CRLs) are not checked. By default OpenSSL does neither require nor verify CRLs.

Nouveau dans la version 2.7.9.

`ssl.VERIFY_CRL_CHECK_LEAF`

Possible value for `SSLContext.verify_flags`. In this mode, only the peer cert is check but non of the intermediate CA certificates. The mode requires a valid CRL that is signed by the peer cert's issuer (its direct ancestor CA). If no proper has been loaded `SSLContext.load_verify_locations`, validation will fail.

Nouveau dans la version 2.7.9.

`ssl.VERIFY_CRL_CHECK_CHAIN`

Possible value for `SSLContext.verify_flags`. In this mode, CRLs of all certificates in the peer cert chain are checked.

Nouveau dans la version 2.7.9.

`ssl.VERIFY_X509_STRICT`

Possible value for `SSLContext.verify_flags` to disable workarounds for broken X.509 certificates.

Nouveau dans la version 2.7.9.

`ssl.VERIFY_X509_TRUSTED_FIRST`

Possible value for `SSLContext.verify_flags`. It instructs OpenSSL to prefer trusted certificates when building the trust chain to validate a certificate. This flag is enabled by default.

Nouveau dans la version 2.7.10.

`ssl.PROTOCOL_TLS`

Selects the highest protocol version that both the client and server support. Despite the name, this option can select « TLS » protocols as well as « SSL ».

Nouveau dans la version 2.7.13.

`ssl.PROTOCOL_SSLv23`

Alias for `PROTOCOL_TLS`.

Obsolète depuis la version 2.7.13 : Use `PROTOCOL_TLS` instead.

`ssl.PROTOCOL_SSLv2`

Selects SSL version 2 as the channel encryption protocol.

This protocol is not available if OpenSSL is compiled with the `OPENSSL_NO_SSL2` flag.

**Avertissement :** SSL version 2 is insecure. Its use is highly discouraged.

Obsolète depuis la version 2.7.13 : OpenSSL has removed support for SSLv2.

`ssl.PROTOCOL_SSLv3`

Selects SSL version 3 as the channel encryption protocol.

This protocol is not be available if OpenSSL is compiled with the `OPENSSL_NO_SSLv3` flag.

**Avertissement :** SSL version 3 is insecure. Its use is highly discouraged.

Obsolète depuis la version 2.7.13 : OpenSSL has deprecated all version specific protocols. Use the default protocol with flags like `OP_NO_SSLv3` instead.

`ssl.PROTOCOL_TLSv1`

Selects TLS version 1.0 as the channel encryption protocol.

Obsolète depuis la version 2.7.13 : OpenSSL has deprecated all version specific protocols. Use the default protocol with flags like `OP_NO_SSLv3` instead.

**ssl.PROTOCOL\_TLSv1\_1**

Selects TLS version 1.1 as the channel encryption protocol. Available only with openssl version 1.0.1+.  
Nouveau dans la version 2.7.9.

Obsolète depuis la version 2.7.13 : OpenSSL has deprecated all version specific protocols. Use the default protocol with flags like `OP_NO_SSLv3` instead.

**ssl.PROTOCOL\_TLSv1\_2**

Selects TLS version 1.2 as the channel encryption protocol. This is the most modern version, and probably the best choice for maximum protection, if both sides can speak it. Available only with openssl version 1.0.1+.

Nouveau dans la version 2.7.9.

Obsolète depuis la version 2.7.13 : OpenSSL has deprecated all version specific protocols. Use the default protocol with flags like `OP_NO_SSLv3` instead.

**ssl.OP\_ALL**

Enables workarounds for various bugs present in other SSL implementations. This option is set by default. It does not necessarily set the same flags as OpenSSL's `SSL_OP_ALL` constant.

Nouveau dans la version 2.7.9.

**ssl.OP\_NO\_SSLv2**

Prevents an SSLv2 connection. This option is only applicable in conjunction with [PROTOCOL\\_SSLv23](#). It prevents the peers from choosing SSLv2 as the protocol version.

Nouveau dans la version 2.7.9.

**ssl.OP\_NO\_SSLv3**

Prevents an SSLv3 connection. This option is only applicable in conjunction with [PROTOCOL\\_SSLv23](#). It prevents the peers from choosing SSLv3 as the protocol version.

Nouveau dans la version 2.7.9.

**ssl.OP\_NO\_TLSv1**

Prevents a TLSv1 connection. This option is only applicable in conjunction with [PROTOCOL\\_SSLv23](#). It prevents the peers from choosing TLSv1 as the protocol version.

Nouveau dans la version 2.7.9.

**ssl.OP\_NO\_TLSv1\_1**

Prevents a TLSv1.1 connection. This option is only applicable in conjunction with [PROTOCOL\\_SSLv23](#). It prevents the peers from choosing TLSv1.1 as the protocol version. Available only with openssl version 1.0.1+.

Nouveau dans la version 2.7.9.

**ssl.OP\_NO\_TLSv1\_2**

Prevents a TLSv1.2 connection. This option is only applicable in conjunction with [PROTOCOL\\_SSLv23](#). It prevents the peers from choosing TLSv1.2 as the protocol version. Available only with openssl version 1.0.1+.

Nouveau dans la version 2.7.9.

**ssl.OP\_NO\_TLSv1\_3**

Prevents a TLSv1.3 connection. This option is only applicable in conjunction with [PROTOCOL\\_TLS](#). It prevents the peers from choosing TLSv1.3 as the protocol version. TLS 1.3 is available with OpenSSL 1.1.1 or later. When Python has been compiled against an older version of OpenSSL, the flag defaults to 0.

Nouveau dans la version 2.7.15.

**ssl.OP\_CIPHER\_SERVER\_PREFERENCE**

Use the server's cipher ordering preference, rather than the client's. This option has no effect on client sockets and SSLv2 server sockets.

Nouveau dans la version 2.7.9.

**ssl.OP\_SINGLE\_DH\_USE**

Prevents re-use of the same DH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

Nouveau dans la version 2.7.9.

**ssl.OP\_SINGLE\_ECDH\_USE**

Prevents re-use of the same ECDH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

Nouveau dans la version 2.7.9.

**ssl.OP\_NO\_COMPRESSION**

Disable compression on the SSL channel. This is useful if the application protocol supports its own compression scheme.

This option is only available with OpenSSL 1.0.0 and later.

Nouveau dans la version 2.7.9.

**ssl.HAS\_ALPN**

Whether the OpenSSL library has built-in support for the *Application-Layer Protocol Negotiation* TLS extension as described in [RFC 7301](#).

Nouveau dans la version 2.7.10.

**ssl.HAS\_ECDH**

Whether the OpenSSL library has built-in support for Elliptic Curve-based Diffie-Hellman key exchange. This should be true unless the feature was explicitly disabled by the distributor.

Nouveau dans la version 2.7.9.

**ssl.HAS\_SNI**

Whether the OpenSSL library has built-in support for the *Server Name Indication* extension (as defined in [RFC 4366](#)).

Nouveau dans la version 2.7.9.

**ssl.HAS\_NPN**

Whether the OpenSSL library has built-in support for *Next Protocol Negotiation* as described in the [NPN draft specification](#). When true, you can use the `SSLContext.set_npn_protocols()` method to advertise which protocols you want to support.

Nouveau dans la version 2.7.9.

**ssl.HAS\_TLSv1\_3**

Whether the OpenSSL library has built-in support for the TLS 1.3 protocol.

Nouveau dans la version 2.7.15.

**ssl.CHANNEL\_BINDING\_TYPES**

List of supported TLS channel binding types. Strings in this list can be used as arguments to `SSLSocket.get_channel_binding()`.

Nouveau dans la version 2.7.9.

**ssl.OPENSSL\_VERSION**

The version string of the OpenSSL library loaded by the interpreter :

```
>>> ssl.OPENSSL_VERSION
'OpenSSL 0.9.8k 25 Mar 2009'
```

Nouveau dans la version 2.7.

**ssl.OPENSSL\_VERSION\_INFO**

A tuple of five integers representing version information about the OpenSSL library :

```
>>> ssl.OPENSSL_VERSION_INFO
(0, 9, 8, 11, 15)
```

Nouveau dans la version 2.7.

`ssl.OPENSSL_VERSION_NUMBER`

The raw version number of the OpenSSL library, as a single integer :

```
>>> ssl.OPENSSL_VERSION_NUMBER
9470143L
>>> hex(ssl.OPENSSL_VERSION_NUMBER)
'0x9080bfL'
```

Nouveau dans la version 2.7.

`ssl.ALERT_DESCRIPTION_HANDSHAKE_FAILURE`

`ssl.ALERT_DESCRIPTION_INTERNAL_ERROR`

`ALERT_DESCRIPTION_*`

Alert Descriptions from [RFC 5246](#) and others. The [IANA TLS Alert Registry](#) contains this list and references to the RFCs where their meaning is defined.

Used as the return value of the callback function in `SSLContext.set_servername_callback()`.

Nouveau dans la version 2.7.9.

`Purpose.SERVER_AUTH`

Option for `create_default_context()` and `SSLContext.load_default_certs()`. This value indicates that the context may be used to authenticate Web servers (therefore, it will be used to create client-side sockets).

Nouveau dans la version 2.7.9.

`Purpose.CLIENT_AUTH`

Option for `create_default_context()` and `SSLContext.load_default_certs()`. This value indicates that the context may be used to authenticate Web clients (therefore, it will be used to create server-side sockets).

Nouveau dans la version 2.7.9.

### 17.3.2 SSL Sockets

SSL sockets provide the following methods of *Socket Objects* :

- `accept()`
- `bind()`
- `close()`
- `connect()`
- `fileno()`
- `getpeername()`, `getsockname()`
- `getsockopt()`, `setsockopt()`
- `gettimeout()`, `settimeout()`, `setblocking()`
- `listen()`
- `makefile()`
- `recv()`, `recv_into()` (but passing a non-zero `flags` argument is not allowed)
- `send()`, `sendall()` (with the same limitation)
- `shutdown()`

However, since the SSL (and TLS) protocol has its own framing atop of TCP, the SSL sockets abstraction can, in certain respects, diverge from the specification of normal, OS-level sockets. See especially the [notes on non-blocking sockets](#).

SSL sockets also have the following additional methods and attributes :

**SSLSocket.do\_handshake()**

Perform the SSL setup handshake.

Modifié dans la version 2.7.9 : The handshake method also performs `match_hostname()` when the `check_hostname` attribute of the socket's `context` is true.

**SSLSocket.getpeercert(binary\_form=False)**

If there is no certificate for the peer on the other end of the connection, return `None`. If the SSL handshake hasn't been done yet, raise `ValueError`.

If the `binary_form` parameter is `False`, and a certificate was received from the peer, this method returns a `dict` instance. If the certificate was not validated, the dict is empty. If the certificate was validated, it returns a dict with several keys, amongst them `subject` (the principal for which the certificate was issued) and `issuer` (the principal issuing the certificate). If a certificate contains an instance of the *Subject Alternative Name* extension (see [RFC 3280](#)), there will also be a `subjectAltName` key in the dictionary.

The `subject` and `issuer` fields are tuples containing the sequence of relative distinguished names (RDNs) given in the certificate's data structure for the respective fields, and each RDN is a sequence of name-value pairs. Here is a real-world example :

```
{'issuer': (((('countryName', 'IL'),),
              (('organizationName', 'StartCom Ltd.'),),
              (('organizationalUnitName',
                'Secure Digital Certificate Signing'),),
              (('commonName',
                'StartCom Class 2 Primary Intermediate Server CA'))),),
'notAfter': 'Nov 22 08:15:19 2013 GMT',
'notBefore': 'Nov 21 03:09:52 2011 GMT',
'serialNumber': '95F0',
'subject': (((('description', '571208-SLe257oHY9fVQ07Z'),),
              (('countryName', 'US'),),
              (('stateOrProvinceName', 'California'),),
              (('localityName', 'San Francisco'),),
              (('organizationName', 'Electronic Frontier Foundation, Inc.'),),
              (('commonName', '*.eff.org'),),
              (('emailAddress', 'hostmaster@eff.org'),)),),
'subjectAltName': (('DNS', '*.eff.org'), ('DNS', 'eff.org')),
'version': 3}
```

---

**Note :** To validate a certificate for a particular service, you can use the `match_hostname()` function.

---

If the `binary_form` parameter is `True`, and a certificate was provided, this method returns the DER-encoded form of the entire certificate as a sequence of bytes, or `None` if the peer did not provide a certificate. Whether the peer provides a certificate depends on the SSL socket's role :

- for a client SSL socket, the server will always provide a certificate, regardless of whether validation was required ;
- for a server SSL socket, the client will only provide a certificate when requested by the server ; therefore `getpeercert()` will return `None` if you used `CERT_NONE` (rather than `CERT_OPTIONAL` or `CERT_REQUIRED`).

Modifié dans la version 2.7.9 : The returned dictionary includes additional items such as `issuer` and `notBefore`. Additional `ValueError` is raised when the handshake isn't done. The returned dictionary includes additional X509v3 extension items such as `crldistributionPoints`, `caIssuers` and `OCSP` URIs.

**SSLSocket.cipher()**

Returns a three-value tuple containing the name of the cipher being used, the version of the SSL

protocol that defines its use, and the number of secret bits being used. If no connection has been established, returns `None`.

#### `SSLSocket.compression()`

Return the compression algorithm being used as a string, or `None` if the connection isn't compressed.

If the higher-level protocol supports its own compression mechanism, you can use `OP_NO_COMPRESSION` to disable SSL-level compression.

Nouveau dans la version 2.7.9.

#### `SSLSocket.get_channel_binding(cb_type="tls-unique")`

Get channel binding data for current connection, as a bytes object. Returns `None` if not connected or the handshake has not been completed.

The `cb_type` parameter allow selection of the desired channel binding type. Valid channel binding types are listed in the `CHANNEL_BINDING_TYPES` list. Currently only the "tls-unique" channel binding, defined by [RFC 5929](#), is supported. `ValueError` will be raised if an unsupported channel binding type is requested.

Nouveau dans la version 2.7.9.

#### `SSLSocket.selected_alpn_protocol()`

Return the protocol that was selected during the TLS handshake. If `SSLContext.set_alpn_protocols()` was not called, if the other party does not support ALPN, if this socket does not support any of the client's proposed protocols, or if the handshake has not happened yet, `None` is returned.

Nouveau dans la version 2.7.10.

#### `SSLSocket.selected_npn_protocol()`

Return the higher-level protocol that was selected during the TLS/SSL handshake. If `SSLContext.set_npn_protocols()` was not called, or if the other party does not support NPN, or if the handshake has not yet happened, this will return `None`.

Nouveau dans la version 2.7.9.

#### `SSLSocket.unwrap()`

Performs the SSL shutdown handshake, which removes the TLS layer from the underlying socket, and returns the underlying socket object. This can be used to go from encrypted operation over a connection to unencrypted. The returned socket should always be used for further communication with the other side of the connection, rather than the original socket.

#### `SSLSocket.version()`

Return the actual SSL protocol version negotiated by the connection as a string, or `None` if no secure connection is established. As of this writing, possible return values include "SSLv2", "SSLv3", "TLSv1", "TLSv1.1" and "TLSv1.2". Recent OpenSSL versions may define more return values.

Nouveau dans la version 2.7.9.

#### `SSLSocket.context`

The `SSLContext` object this SSL socket is tied to. If the SSL socket was created using the top-level `wrap_socket()` function (rather than `SSLContext.wrap_socket()`), this is a custom context object created for this SSL socket.

Nouveau dans la version 2.7.9.

### 17.3.3 SSL Contexts

Nouveau dans la version 2.7.9.

An SSL context holds various data longer-lived than single SSL connections, such as SSL configuration options, certificate(s) and private key(s). It also manages a cache of SSL sessions for server-side sockets, in order to speed up repeated connections from the same clients.

`class ssl.SSLContext(protocol)`

Create a new SSL context. You must pass *protocol* which must be one of the `PROTOCOL_*` constants defined in this module. `PROTOCOL_SSLv23` is currently recommended for maximum interoperability.

**Voir aussi :**

`create_default_context()` lets the `ssl` module choose security settings for a given purpose.

`SSLContext` objects have the following methods and attributes :

`SSLContext.cert_store_stats()`

Get statistics about quantities of loaded X.509 certificates, count of X.509 certificates flagged as CA certificates and certificate revocation lists as dictionary.

Example for a context with one CA cert and one other cert :

```
>>> context.cert_store_stats()
{'crl': 0, 'x509_ca': 1, 'x509': 2}
```

`SSLContext.load_cert_chain(certfile, keyfile=None, password=None)`

Load a private key and the corresponding certificate. The *certfile* string must be the path to a single file in PEM format containing the certificate as well as any number of CA certificates needed to establish the certificate's authenticity. The *keyfile* string, if present, must point to a file containing the private key in. Otherwise the private key will be taken from *certfile* as well. See the discussion of [Certificates](#) for more information on how the certificate is stored in the *certfile*.

The *password* argument may be a function to call to get the password for decrypting the private key. It will only be called if the private key is encrypted and a password is necessary. It will be called with no arguments, and it should return a string, bytes, or bytearray. If the return value is a string it will be encoded as UTF-8 before using it to decrypt the key. Alternatively a string, bytes, or bytearray value may be supplied directly as the *password* argument. It will be ignored if the private key is not encrypted and no password is needed.

If the *password* argument is not specified and a password is required, OpenSSL's built-in password prompting mechanism will be used to interactively prompt the user for a password.

An `SSLError` is raised if the private key doesn't match with the certificate.

`SSLContext.load_default_certs(purpose=Purpose.SERVER_AUTH)`

Load a set of default « certification authority » (CA) certificates from default locations. On Windows it loads CA certs from the CA and ROOT system stores. On other systems it calls `SSLContext.set_default_verify_paths()`. In the future the method may load CA certificates from other locations, too.

The *purpose* flag specifies what kind of CA certificates are loaded. The default settings `Purpose.SERVER_AUTH` loads certificates, that are flagged and trusted for TLS web server authentication (client side sockets). `Purpose.CLIENT_AUTH` loads CA certificates for client certificate verification on the server side.

`SSLContext.load_verify_locations(cafile=None, capath=None, cadata=None)`

Load a set of « certification authority » (CA) certificates used to validate other peers' certificates when *verify\_mode* is other than `CERT_NONE`. At least one of *cafile* or *capath* must be specified.

This method can also load certification revocation lists (CRLs) in PEM or DER format. In order to make use of CRLs, `SSLContext.verify_flags` must be configured properly.

The *cafile* string, if present, is the path to a file of concatenated CA certificates in PEM format. See the discussion of [Certificates](#) for more information about how to arrange the certificates in this file.

The *capath* string, if present, is the path to a directory containing several CA certificates in PEM format, following an [OpenSSL specific layout](#).

The *cadata* object, if present, is either an ASCII string of one or more PEM-encoded certificates or a bytes-like object of DER-encoded certificates. Like with *capath* extra lines around PEM-encoded certificates are ignored but at least one certificate must be present.

`SSLContext.get_ca_certs(binary_form=False)`

Get a list of loaded « certification authority » (CA) certificates. If the `binary_form` parameter is `False` each list entry is a dict like the output of `SSLSocket.getpeercert()`. Otherwise the method returns a list of DER-encoded certificates. The returned list does not contain certificates from `capath` unless a certificate was requested and loaded by a SSL connection.

---

**Note :** Certificates in a `capath` directory aren't loaded unless they have been used at least once.

---

`SSLContext.set_default_verify_paths()`

Load a set of default « certification authority » (CA) certificates from a filesystem path defined when building the OpenSSL library. Unfortunately, there's no easy way to know whether this method succeeds : no error is returned if no certificates are to be found. When the OpenSSL library is provided as part of the operating system, though, it is likely to be configured properly.

`SSLContext.set_ciphers(ciphers)`

Set the available ciphers for sockets created with this context. It should be a string in the [OpenSSL cipher list format](#). If no cipher can be selected (because compile-time options or other configuration forbids use of all the specified ciphers), an `SSLError` will be raised.

---

**Note :** when connected, the `SSLSocket.cipher()` method of SSL sockets will give the currently selected cipher.

---

`SSLContext.set_alpn_protocols(protocols)`

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of ASCII strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to [RFC 7301](#). After a successful handshake, the `SSLSocket.selected_alpn_protocol()` method will return the agreed-upon protocol.

This method will raise `NotImplementedError` if `HAS_ALPN` is False.

OpenSSL 1.1.0 to 1.1.0e will abort the handshake and raise `SSLError` when both sides support ALPN but cannot agree on a protocol. 1.1.0f+ behaves like 1.0.2, `SSLSocket.selected_alpn_protocol()` returns None.

Nouveau dans la version 2.7.10.

`SSLContext.set_npn_protocols(protocols)`

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to the [NPN draft specification](#). After a successful handshake, the `SSLSocket.selected_npn_protocol()` method will return the agreed-upon protocol.

This method will raise `NotImplementedError` if `HAS_NPN` is False.

`SSLContext.set_servername_callback(server_name_callback)`

Register a callback function that will be called after the TLS Client Hello handshake message has been received by the SSL/TLS server when the TLS client specifies a server name indication. The server name indication mechanism is specified in [RFC 6066](#) section 3 - Server Name Indication.

Only one callback can be set per `SSLContext`. If `server_name_callback` is `None` then the callback is disabled. Calling this function a subsequent time will disable the previously registered callback.

The callback function, `server_name_callback`, will be called with three arguments; the first being the `ssl.SSLSocket`, the second is a string that represents the server name that the client is intending to communicate (or `None` if the TLS Client Hello does not contain a server name) and the third argument is the original `SSLContext`. The server name argument is the IDNA decoded server name.

A typical use of this callback is to change the `ssl.SSLSocket`'s `SSLSocket.context` attribute to a new object of type `SSLContext` representing a certificate chain that matches the server name.

Due to the early negotiation phase of the TLS connection, only limited methods and attributes are usable like `SSLSocket.selected_alpn_protocol()` and `SSLSocket.context.SSLSocket.getpeercert()`, `SSLSocket.getpeercert()`, `SSLSocket.cipher()` and `SSLSocket.compress()` methods require that the TLS connection has progressed beyond the TLS Client Hello and therefore will not contain return meaningful values nor can they be called safely.

The `server_name_callback` function must return `None` to allow the TLS negotiation to continue. If a TLS failure is required, a constant `ALERT_DESCRIPTION_*` can be returned. Other return values will result in a TLS fatal error with `ALERT_DESCRIPTION_INTERNAL_ERROR`.

If there is an IDNA decoding error on the server name, the TLS connection will terminate with an `ALERT_DESCRIPTION_INTERNAL_ERROR` fatal TLS alert message to the client.

If an exception is raised from the `server_name_callback` function the TLS connection will terminate with a fatal TLS alert message `ALERT_DESCRIPTION_HANDSHAKE_FAILURE`.

This method will raise `NotImplementedError` if the OpenSSL library had `OPENSSL_NO_TLSEXT` defined when it was built.

#### `SSLContext.load_dh_params(dhfile)`

Load the key generation parameters for Diffie-Helman (DH) key exchange. Using DH key exchange improves forward secrecy at the expense of computational resources (both on the server and on the client). The `dhfile` parameter should be the path to a file containing DH parameters in PEM format.

This setting doesn't apply to client sockets. You can also use the `OP_SINGLE_DH_USE` option to further improve security.

#### `SSLContext.set_ecdh_curve(curve_name)`

Set the curve name for Elliptic Curve-based Diffie-Hellman (ECDH) key exchange. ECDH is significantly faster than regular DH while arguably as secure. The `curve_name` parameter should be a string describing a well-known elliptic curve, for example `prime256v1` for a widely supported curve.

This setting doesn't apply to client sockets. You can also use the `OP_SINGLE_ECDH_USE` option to further improve security.

This method is not available if `HAS_ECDH` is `False`.

**Voir aussi :**

**SSL/TLS & Perfect Forward Secrecy** Vincent Bernat.

#### `SSLContext.wrap_socket(sock, server_side=False, do_handshake_on_connect=True, suppress_ragged_eofs=True, server_hostname=None)`

Wrap an existing Python socket `sock` and return an `SSLSocket` object. `sock` must be a `SOCK_STREAM` socket; other socket types are unsupported.

The returned SSL socket is tied to the context, its settings and certificates. The parameters `server_side`, `do_handshake_on_connect` and `suppress_ragged_eofs` have the same meaning as in the top-level `wrap_socket()` function.

On client connections, the optional parameter `server_hostname` specifies the hostname of the service which we are connecting to. This allows a single server to host multiple SSL-based services with distinct certificates, quite similarly to HTTP virtual hosts. Specifying `server_hostname` will raise a `ValueError` if `server_side` is `true`.

Modifié dans la version 2.7.9 : Always allow a `server_hostname` to be passed, even if OpenSSL does not have SNI.

#### `SSLContext.session_stats()`

Get statistics about the SSL sessions created or managed by this context. A dictionary is returned which maps the names of each `piece of information` to their numeric values. For example, here is the total number of hits and misses in the session cache since the context was created :

```
>>> stats = context.session_stats()
>>> stats['hits'], stats['misses']
(0, 0)
```

**SSLContext.check\_hostname**

Whether to match the peer cert's hostname with `match_hostname()` in `SSLSocket.do_handshake()`. The context's `verify_mode` must be set to `CERT_OPTIONAL` or `CERT_REQUIRED`, and you must pass `server_hostname` to `wrap_socket()` in order to match the hostname.

Example :

```
import socket, ssl

context = ssl.SSLContext(ssl.PROTOCOL_TLS)
context.verify_mode = ssl.CERT_REQUIRED
context.check_hostname = True
context.load_default_certs()

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
ssl_sock = context.wrap_socket(s, server_hostname='www.verisign.com')
ssl_sock.connect(('www.verisign.com', 443))
```

---

**Note :** This feature requires OpenSSL 0.9.8f or newer.

---

**SSLContext.options**

An integer representing the set of SSL options enabled on this context. The default value is `OP_ALL`, but you can specify other options such as `OP_NO_SSLv2` by ORing them together.

---

**Note :** With versions of OpenSSL older than 0.9.8m, it is only possible to set options, not to clear them. Attempting to clear an option (by resetting the corresponding bits) will raise a `ValueError`.

---

**SSLContext.protocol**

The protocol version chosen when constructing the context. This attribute is read-only.

**SSLContext.verify\_flags**

The flags for certificate verification operations. You can set flags like `VERIFY_CRL_CHECK_LEAF` by ORing them together. By default OpenSSL does neither require nor verify certificate revocation lists (CRLs). Available only with openssl version 0.9.8+.

**SSLContext.verify\_mode**

Whether to try to verify other peers' certificates and how to behave if verification fails. This attribute must be one of `CERT_NONE`, `CERT_OPTIONAL` or `CERT_REQUIRED`.

## 17.3.4 Certificates

Certificates in general are part of a public-key / private-key system. In this system, each *principal*, (which may be a machine, or a person, or an organization) is assigned a unique two-part encryption key. One part of the key is public, and is called the *public key*; the other part is kept secret, and is called the *private key*. The two parts are related, in that if you encrypt a message with one of the parts, you can decrypt it with the other part, and **only** with the other part.

A certificate contains information about two principals. It contains the name of a *subject*, and the subject's public key. It also contains a statement by a second principal, the *issuer*, that the subject is who they claim to be, and that this is indeed the subject's public key. The issuer's statement is signed with the issuer's private key, which only the issuer knows. However, anyone can verify the issuer's statement by finding the issuer's public key, decrypting the statement with it, and comparing it to the other information in the certificate. The certificate also contains information about the time period over which it is valid. This is expressed as two fields, called « notBefore » and « notAfter ».

In the Python use of certificates, a client or server can use a certificate to prove who they are. The other side of a network connection can also be required to produce a certificate, and that certificate can be validated to the satisfaction of the client or server that requires such validation. The connection attempt can be set to raise an exception if the validation fails. Validation is done automatically, by the underlying OpenSSL framework; the application need not concern itself with its mechanics. But the application does usually need to provide sets of certificates to allow this process to take place.

Python uses files to contain certificates. They should be formatted as « PEM » (see [RFC 1422](#)), which is a base-64 encoded form wrapped with a header line and a footer line :

```
-----BEGIN CERTIFICATE-----  
... (certificate in base64 PEM encoding) ...  
-----END CERTIFICATE-----
```

### Certificate chains

The Python files which contain certificates can contain a sequence of certificates, sometimes called a *certificate chain*. This chain should start with the specific certificate for the principal who « is » the client or server, and then the certificate for the issuer of that certificate, and then the certificate for the issuer of *that* certificate, and so on up the chain till you get to a certificate which is *self-signed*, that is, a certificate which has the same subject and issuer, sometimes called a *root certificate*. The certificates should just be concatenated together in the certificate file. For example, suppose we had a three certificate chain, from our server certificate to the certificate of the certification authority that signed our server certificate, to the root certificate of the agency which issued the certification authority's certificate :

```
-----BEGIN CERTIFICATE-----  
... (certificate for your server)...  
-----END CERTIFICATE-----  
-----BEGIN CERTIFICATE-----  
... (the certificate for the CA)...  
-----END CERTIFICATE-----  
-----BEGIN CERTIFICATE-----  
... (the root certificate for the CA's issuer)...  
-----END CERTIFICATE-----
```

### CA certificates

If you are going to require validation of the other side of the connection's certificate, you need to provide a « CA certs » file, filled with the certificate chains for each issuer you are willing to trust. Again, this file just contains these chains concatenated together. For validation, Python will use the first chain it finds in the file which matches. The platform's certificates file can be used by calling `SSLContext.load_default_certs()`, this is done automatically with `create_default_context()`.

### Combined key and certificate

Often the private key is stored in the same file as the certificate; in this case, only the `certfile` parameter to `SSLContext.load_cert_chain()` and `wrap_socket()` needs to be passed. If the private key is stored with the certificate, it should come before the first certificate in the certificate chain :

```
-----BEGIN RSA PRIVATE KEY-----  
... (private key in base64 encoding) ...  
-----END RSA PRIVATE KEY-----  
-----BEGIN CERTIFICATE-----  
... (certificate in base64 PEM encoding) ...  
-----END CERTIFICATE-----
```

## Self-signed certificates

If you are going to create a server that provides SSL-encrypted connection services, you will need to acquire a certificate for that service. There are many ways of acquiring appropriate certificates, such as buying one from a certification authority. Another common practice is to generate a self-signed certificate. The simplest way to do this is with the OpenSSL package, using something like the following :

```
% openssl req -new -x509 -days 365 -nodes -out cert.pem -keyout cert.pem
Generating a 1024 bit RSA private key
.....++++++
.....++++++
writing new private key to 'cert.pem'
-----
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MyState
Locality Name (eg, city) []:Some City
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Organization, Inc.
Organizational Unit Name (eg, section) []:My Group
Common Name (eg, YOUR name) []:myserver.mygroup.myorganization.com
Email Address []:ops@myserver.mygroup.myorganization.com
%
```

The disadvantage of a self-signed certificate is that it is its own root certificate, and no one else will have it in their cache of known (and trusted) root certificates.

## 17.3.5 Examples

### Testing for SSL support

To test for the presence of SSL support in a Python installation, user code should use the following idiom :

```
try:
    import ssl
except ImportError:
    pass
else:
    ... # do something that requires SSL support
```

### Client-side operation

This example creates a SSL context with the recommended security settings for client sockets, including automatic certificate verification :

```
>>> context = ssl.create_default_context()
```

If you prefer to tune security settings yourself, you might create a context from scratch (but beware that you might not get the settings right) :

```
>>> context = ssl.SSLContext(ssl.PROTOCOL_TLS)
>>> context.verify_mode = ssl.CERT_REQUIRED
>>> context.check_hostname = True
>>> context.load_verify_locations("/etc/ssl/certs/ca-bundle.crt")
```

(this snippet assumes your operating system places a bundle of all CA certificates in `/etc/ssl/certs/ca-bundle.crt`; if not, you'll get an error and have to adjust the location)

When you use the context to connect to a server, `CERT_REQUIRED` validates the server certificate : it ensures that the server certificate was signed with one of the CA certificates, and checks the signature for correctness :

```
>>> conn = context.wrap_socket(socket.socket(socket.AF_INET),
...                             server_hostname="www.python.org")
>>> conn.connect(("www.python.org", 443))
```

You may then fetch the certificate :

```
>>> cert = conn.getpeercert()
```

Visual inspection shows that the certificate does identify the desired service (that is, the HTTPS host `www.python.org`) :

```
>>> pprint.pprint(cert)
{'OCSP': ('http://ocsp.digicert.com',),
 'caIssuers': ('http://cacerts.digicert.com/DigiCertSHA2ExtendedValidationServerCA.crt',
 →),
 'crlDistributionPoints': ('http://crl3.digicert.com/sha2-ev-server-g1.crl',
                           'http://crl4.digicert.com/sha2-ev-server-g1.crl'),
 'issuer': (((('countryName', 'US'),),
               (('organizationName', 'DigiCert Inc'),),
               (('organizationalUnitName', 'www.digicert.com'),),
               (('commonName', 'DigiCert SHA2 Extended Validation Server CA'),)),),
 'notAfter': 'Sep  9 12:00:00 2016 GMT',
 'notBefore': 'Sep  5 00:00:00 2014 GMT',
 'serialNumber': '01BB6F00122B177F36CAB49CEA8B6B26',
 'subject': (((('businessCategory', 'Private Organization'),),
                (('1.3.6.1.4.1.311.60.2.1.3', 'US'),),
                (('1.3.6.1.4.1.311.60.2.1.2', 'Delaware'),),
                (('serialNumber', '3359300'),),
                (('streetAddress', '16 Allen Rd'),),
                (('postalCode', '03894-4801'),),
                (('countryName', 'US'),),
                (('stateOrProvinceName', 'NH'),),
                (('localityName', 'Wolfeboro,'),),
                (('organizationName', 'Python Software Foundation'),),
                (('commonName', 'www.python.org'),)),),
 'subjectAltName': (('DNS', 'www.python.org'),
                    ('DNS', 'python.org'),
                    ('DNS', 'pypi.org'),
                    ('DNS', 'docs.python.org'),
                    ('DNS', 'testpypi.python.org'),
                    ('DNS', 'bugs.python.org'),
                    ('DNS', 'wiki.python.org'),
                    ('DNS', 'hg.python.org'),
```

(suite sur la page suivante)

(suite de la page précédente)

```

        ('DNS', 'mail.python.org'),
        ('DNS', 'packaging.python.org'),
        ('DNS', 'pythonhosted.org'),
        ('DNS', 'www.pythonhosted.org'),
        ('DNS', 'test.pythonhosted.org'),
        ('DNS', 'us.pycon.org'),
        ('DNS', 'id.python.org')),
    'version': 3}

```

Now the SSL channel is established and the certificate verified, you can proceed to talk with the server :

```

>>> conn.sendall(b"HEAD / HTTP/1.0\r\nHost: linuxfr.org\r\n\r\n")
>>> pprint.pprint(conn.recv(1024).split(b"\r\n"))
[b'HTTP/1.1 200 OK',
 b'Date: Sat, 18 Oct 2014 18:27:20 GMT',
 b'Server: nginx',
 b'Content-Type: text/html; charset=utf-8',
 b'X-Frame-Options: SAMEORIGIN',
 b'Content-Length: 45679',
 b'Accept-Ranges: bytes',
 b'Via: 1.1 varnish',
 b'Age: 2188',
 b'X-Served-By: cache-lcy1134-LCY',
 b'X-Cache: HIT',
 b'X-Cache-Hits: 11',
 b'Vary: Cookie',
 b'Strict-Transport-Security: max-age=63072000; includeSubDomains',
 b'Connection: close',
 b'',
 b'']

```

See the discussion of *Security considerations* below.

### Server-side operation

For server operation, typically you'll need to have a server certificate, and private key, each in a file. You'll first create a context holding the key and the certificate, so that clients can check your authenticity. Then you'll open a socket, bind it to a port, call `listen()` on it, and start waiting for clients to connect :

```

import socket, ssl

context = ssl.create_default_context(ssl.Purpose.CLIENT_AUTH)
context.load_cert_chain(certfile="mycertfile", keyfile="mykeyfile")

bindsocket = socket.socket()
bindsocket.bind(('myaddr.mydomain.com', 10023))
bindsocket.listen(5)

```

When a client connects, you'll call `accept()` on the socket to get the new socket from the other end, and use the context's `SSLContext.wrap_socket()` method to create a server-side SSL socket for the connection :

```

while True:
    newsocket, fromaddr = bindsocket.accept()

```

(suite sur la page suivante)

(suite de la page précédente)

```

connstream = context.wrap_socket(newsocket, server_side=True)
try:
    deal_with_client(connstream)
finally:
    connstream.shutdown(socket.SHUT_RDWR)
    connstream.close()

```

Then you'll read data from the `connstream` and do something with it till you are finished with the client (or the client is finished with you) :

```

def deal_with_client(connstream):
    data = connstream.read()
    # null data means the client is finished with us
    while data:
        if not do_something(connstream, data):
            # we'll assume do_something returns False
            # when we're finished with client
            break
        data = connstream.read()
    # finished with client

```

And go back to listening for new client connections (of course, a real server would probably handle each client connection in a separate thread, or put the sockets in non-blocking mode and use an event loop).

### 17.3.6 Notes on non-blocking sockets

When working with non-blocking sockets, there are several things you need to be aware of :

- Calling `select()` tells you that the OS-level socket can be read from (or written to), but it does not imply that there is sufficient data at the upper SSL layer. For example, only part of an SSL frame might have arrived. Therefore, you must be ready to handle `SSLSocket.recv()` and `SSLSocket.send()` failures, and retry after another call to `select()`.
- Conversely, since the SSL layer has its own framing, a SSL socket may still have data available for reading without `select()` being aware of it. Therefore, you should first call `SSLSocket.recv()` to drain any potentially available data, and then only block on a `select()` call if still necessary. (of course, similar provisions apply when using other primitives such as `poll()`, or those in the `selectors` module)
- The SSL handshake itself will be non-blocking : the `SSLSocket.do_handshake()` method has to be retried until it returns successfully. Here is a synopsis using `select()` to wait for the socket's readiness :

```

while True:
    try:
        sock.do_handshake()
        break
    except ssl.SSLWantReadError:
        select.select([sock], [], [])
    except ssl.SSLWantWriteError:
        select.select([], [sock], [])

```

### 17.3.7 Security considerations

## Best defaults

For **client use**, if you don't have any special requirements for your security policy, it is highly recommended that you use the `create_default_context()` function to create your SSL context. It will load the system's trusted CA certificates, enable certificate validation and hostname checking, and try to choose reasonably secure protocol and cipher settings.

If a client certificate is needed for the connection, it can be added with `SSLContext.load_cert_chain()`.

By contrast, if you create the SSL context by calling the `SSLContext` constructor yourself, it will not have certificate validation nor hostname checking enabled by default. If you do so, please read the paragraphs below to achieve a good security level.

## Manual settings

### Verifying certificates

When calling the `SSLContext` constructor directly, `CERT_NONE` is the default. Since it does not authenticate the other peer, it can be insecure, especially in client mode where most of the time you would like to ensure the authenticity of the server you're talking to. Therefore, when in client mode, it is highly recommended to use `CERT_REQUIRED`. However, it is in itself not sufficient; you also have to check that the server certificate, which can be obtained by calling `SSLSocket.getpeercert()`, matches the desired service. For many protocols and applications, the service can be identified by the hostname; in this case, the `match_hostname()` function can be used. This common check is automatically performed when `SSLContext.check_hostname` is enabled.

In server mode, if you want to authenticate your clients using the SSL layer (rather than using a higher-level authentication mechanism), you'll also have to specify `CERT_REQUIRED` and similarly check the client certificate.

---

**Note :** In client mode, `CERT_OPTIONAL` and `CERT_REQUIRED` are equivalent unless anonymous ciphers are enabled (they are disabled by default).

---

## Protocol versions

SSL versions 2 and 3 are considered insecure and are therefore dangerous to use. If you want maximum compatibility between clients and servers, it is recommended to use `PROTOCOL_SSLv23` as the protocol version and then disable SSLv2 and SSLv3 explicitly using the `SSLContext.options` attribute :

```
context = ssl.SSLContext(ssl.PROTOCOL_SSLv23)
context.options |= ssl.OP_NO_SSLv2
context.options |= ssl.OP_NO_SSLv3
```

The SSL context created above will only allow TLSv1 and later (if supported by your system) connections.

## Cipher selection

If you have advanced security requirements, fine-tuning of the ciphers enabled when negotiating a SSL session is possible through the `SSLContext.set_ciphers()` method. Starting from Python 2.7.9, the `ssl` module disables certain weak ciphers by default, but you may want to further restrict the cipher choice. Be sure to read OpenSSL's documentation about the [cipher list format](#). If you want to check which ciphers are enabled by a given cipher list, use the `openssl ciphers` command on your system.

## Multi-processing

If using this module as part of a multi-processed application (using, for example the `multiprocessing` or `concurrent.futures` modules), be aware that OpenSSL's internal random number generator does not

properly handle forked processes. Applications must change the PRNG state of the parent process if they use any SSL feature with `os.fork()`. Any successful call of `RAND_add()`, `RAND_bytes()` or `RAND_pseudo_bytes()` is sufficient.

### 17.3.8 LibreSSL support

LibreSSL is a fork of OpenSSL 1.0.1. The `ssl` module has limited support for LibreSSL. Some features are not available when the `ssl` module is compiled with LibreSSL.

- LibreSSL >= 2.6.1 no longer supports NPN. The methods `SSLContext.set_npn_protocols()` and `SSLSocket.selected_npn_protocol()` are not available.
- `SSLContext.set_default_verify_paths()` ignores the env vars `SSL_CERT_FILE` and `SSL_CERT_PATH` although `get_default_verify_paths()` still reports them.

## 17.4 signal — Set handlers for asynchronous events

This module provides mechanisms to use signal handlers in Python. Some general rules for working with signals and their handlers :

- A handler for a particular signal, once set, remains installed until it is explicitly reset (Python emulates the BSD style interface regardless of the underlying implementation), with the exception of the handler for `SIGCHLD`, which follows the underlying implementation.
- There is no way to « block » signals temporarily from critical sections (since this is not supported by all Unix flavors).
- Although Python signal handlers are called asynchronously as far as the Python user is concerned, they can only occur between the « atomic » instructions of the Python interpreter. This means that signals arriving during long calculations implemented purely in C (such as regular expression matches on large bodies of text) may be delayed for an arbitrary amount of time.
- When a signal arrives during an I/O operation, it is possible that the I/O operation raises an exception after the signal handler returns. This is dependent on the underlying Unix system's semantics regarding interrupted system calls.
- Because the C signal handler always returns, it makes little sense to catch synchronous errors like `SIGFPE` or `SIGSEGV`.
- Python installs a small number of signal handlers by default : `SIGPIPE` is ignored (so write errors on pipes and sockets can be reported as ordinary Python exceptions) and `SIGINT` is translated into a `KeyboardInterrupt` exception. All of these can be overridden.

- Some care must be taken if both signals and threads are used in the same program. The fundamental thing to remember in using signals and threads simultaneously is : always perform `signal()` operations in the main thread of execution. Any thread can perform an `alarm()`, `getsignal()`, `pause()`, `setitimer()` or `getitimer()`; only the main thread can set a new signal handler, and the main thread will be the only one to receive signals (this is enforced by the Python `signal` module, even if the underlying thread implementation supports sending signals to individual threads). This means that signals can't be used as a means of inter-thread communication. Use locks instead.

The variables defined in the `signal` module are :

#### `signal.SIG_DFL`

This is one of two standard signal handling options; it will simply perform the default function for the signal. For example, on most systems the default action for `SIGQUIT` is to dump core and exit, while the default action for `SIGCHLD` is to simply ignore it.

#### `signal.SIG_IGN`

This is another standard signal handler, which will simply ignore the given signal.

#### `SIG*`

All the signal numbers are defined symbolically. For example, the hangup signal is defined as `signal.SIGHUP`; the variable names are identical to the names used in C programs, as found in `<signal.h>`. The Unix man page for “`signal()`” lists the existing signals (on some systems this is `signal(2)`, on others the list is in `signal(7)`). Note that not all systems define the same set of signal names; only those names defined by the system are defined by this module.

#### `signal.CTRL_C_EVENT`

The signal corresponding to the `Ctrl+C` keystroke event. This signal can only be used with `os.kill()`.

Disponibilité : Windows.

Nouveau dans la version 2.7.

#### `signal.CTRL_BREAK_EVENT`

The signal corresponding to the `Ctrl+Break` keystroke event. This signal can only be used with `os.kill()`.

Disponibilité : Windows.

Nouveau dans la version 2.7.

#### `signal.NSIG`

One more than the number of the highest signal number.

#### `signal.ITIMER_REAL`

Decrements interval timer in real time, and delivers `SIGALRM` upon expiration.

#### `signal.ITIMER_VIRTUAL`

Decrements interval timer only when the process is executing, and delivers `SIGVTALRM` upon expiration.

#### `signal.ITIMER_PROF`

Decrements interval timer both when the process executes and when the system is executing on behalf of the process. Coupled with `ITIMER_VIRTUAL`, this timer is usually used to profile the time spent by the application in user and kernel space. `SIGPROF` is delivered upon expiration.

The `signal` module defines one exception :

#### **exception** `signal.ItimerError`

Raised to signal an error from the underlying `setitimer()` or `getitimer()` implementation. Expect this error if an invalid interval timer or a negative time is passed to `setitimer()`. This error is a subtype of `IOError`.

The `signal` module defines the following functions :

**signal.alarm(*time*)**

If *time* is non-zero, this function requests that a SIGALRM signal be sent to the process in *time* seconds. Any previously scheduled alarm is canceled (only one alarm can be scheduled at any time). The returned value is then the number of seconds before any previously set alarm was to have been delivered. If *time* is zero, no alarm is scheduled, and any scheduled alarm is canceled. If the return value is zero, no alarm is currently scheduled. (See the Unix man page *alarm(2)*.) Availability : Unix.

**signal.getsignal(*signalnum*)**

Return the current signal handler for the signal *signalnum*. The returned value may be a callable Python object, or one of the special values *signal.SIG\_IGN*, *signal.SIG\_DFL* or *None*. Here, *signal.SIG\_IGN* means that the signal was previously ignored, *signal.SIG\_DFL* means that the default way of handling the signal was previously in use, and *None* means that the previous signal handler was not installed from Python.

**signal.pause()**

Cause the process to sleep until a signal is received ; the appropriate handler will then be called. Returns nothing. Not on Windows. (See the Unix man page *signal(2)*.)

**signal.setitimer(*which*, *seconds*[, *interval*])**

Sets given interval timer (one of *signal.ITIMER\_REAL*, *signal.ITIMER\_VIRTUAL* or *signal.ITIMER\_PROF*) specified by *which* to fire after *seconds* (float is accepted, different from *alarm()*) and after that every *interval* seconds. The interval timer specified by *which* can be cleared by setting *seconds* to zero.

When an interval timer fires, a signal is sent to the process. The signal sent is dependent on the timer being used ; *signal.ITIMER\_REAL* will deliver SIGALRM, *signal.ITIMER\_VIRTUAL* sends SIGVTALRM, and *signal.ITIMER\_PROF* will deliver SIGPROF.

The old values are returned as a tuple : (delay, interval).

Attempting to pass an invalid interval timer will cause an *ItimerError*. Availability : Unix.

Nouveau dans la version 2.6.

**signal.getitimer(*which*)**

Returns current value of a given interval timer specified by *which*. Availability : Unix.

Nouveau dans la version 2.6.

**signal.set\_wakeup\_fd(*fd*)**

Set the wakeup fd to *fd*. When a signal is received, a '\0' byte is written to the fd. This can be used by a library to wakeup a poll or select call, allowing the signal to be fully processed.

The old wakeup fd is returned (or -1 if file descriptor wakeup was not enabled). If *fd* is -1, file descriptor wakeup is disabled. If not -1, *fd* must be non-blocking. It is up to the library to remove any bytes from *fd* before calling poll or select again.

When threads are enabled, this function can only be called from the main thread ; attempting to call it from other threads will cause a *ValueError* exception to be raised.

Nouveau dans la version 2.6.

**signal.siginterrupt(*signalnum*, *flag*)**

Change system call restart behaviour : if *flag* is *False*, system calls will be restarted when interrupted by signal *signalnum*, otherwise system calls will be interrupted. Returns nothing. Availability : Unix (see the man page *siginterrupt(3)* for further information).

Note that installing a signal handler with *signal()* will reset the restart behaviour to interruptible by implicitly calling *siginterrupt()* with a true *flag* value for the given signal.

Nouveau dans la version 2.6.

**signal.signal(*signalnum*, *handler*)**

Set the handler for signal *signalnum* to the function *handler*. *handler* can be a callable Python object taking two arguments (see below), or one of the special values *signal.SIG\_IGN* or *signal.SIG\_DFL*.

The previous signal handler will be returned (see the description of `getsignal()` above). (See the Unix man page `signal(2)`.)

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

The *handler* is called with two arguments : the signal number and the current stack frame (`None` or a frame object; for a description of frame objects, see the description in the type hierarchy or see the attribute descriptions in the `inspect` module).

On Windows, `signal()` can only be called with `SIGABRT`, `SIGFPE`, `SIGILL`, `SIGINT`, `SIGSEGV`, or `SIGTERM`. A `ValueError` will be raised in any other case.

### 17.4.1 Example

Here is a minimal example program. It uses the `alarm()` function to limit the time spent waiting to open a file; this is useful if the file is for a serial device that may not be turned on, which would normally cause the `os.open()` to hang indefinitely. The solution is to set a 5-second alarm before opening the file; if the operation takes too long, the alarm signal will be sent, and the handler raises an exception.

```
import signal, os

def handler(signum, frame):
    print 'Signal handler called with signal', signum
    raise IOError("Couldn't open device!")

# Set the signal handler and a 5-second alarm
signal.signal(signal.SIGALRM, handler)
signal.alarm(5)

# This open() may hang indefinitely
fd = os.open('/dev/ttyS0', os.O_RDWR)

signal.alarm(0)          # Disable the alarm
```

## 17.5 popen2 — Subprocesses with accessible I/O streams

Obsolète depuis la version 2.6 : This module is obsolete. Use the `subprocess` module. Check especially the *Remplacer les fonctions plus anciennes par le module subprocess* section.

This module allows you to spawn processes and connect to their input/output/error pipes and obtain their return codes under Unix and Windows.

The `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results. Using the `subprocess` module is preferable to using the `popen2` module.

The primary interface offered by this module is a trio of factory functions. For each of these, if *bufsize* is specified, it specifies the buffer size for the I/O pipes. *mode*, if provided, should be the string `'b'` or `'t'`; on Windows this is needed to determine whether the file objects should be opened in binary or text mode. The default value for *mode* is `'t'`.

On Unix, *cmd* may be a sequence, in which case arguments will be passed directly to the program without shell intervention (as with `os.spawnv()`). If *cmd* is a string it will be passed to the shell (as with `os.system()`).

The only way to retrieve the return codes for the child processes is by using the `poll()` or `wait()` methods on the `Popen3` and `Popen4` classes; these are only available on Unix. This information is not available when using the `popen2()`, `popen3()`, and `popen4()` functions, or the equivalent functions in the `os` module. (Note

that the tuples returned by the `os` module's functions are in a different order from the ones returned by the `popen2` module.)

`popen2.popen2(cmd[, bufsize[, mode]])`

Executes `cmd` as a sub-process. Returns the file objects (`child_stdout`, `child_stdin`).

`popen2.popen3(cmd[, bufsize[, mode]])`

Executes `cmd` as a sub-process. Returns the file objects (`child_stdout`, `child_stdin`, `child_stderr`).

`popen2.popen4(cmd[, bufsize[, mode]])`

Executes `cmd` as a sub-process. Returns the file objects (`child_stdout_and_stderr`, `child_stdin`).  
Nouveau dans la version 2.0.

On Unix, a class defining the objects returned by the factory functions is also available. These are not used for the Windows implementation, and are not available on that platform.

`class popen2.Popen3(cmd[, capturestderr[, bufsize]])`

This class represents a child process. Normally, `Popen3` instances are created using the `popen2()` and `popen3()` factory functions described above.

If not using one of the helper functions to create `Popen3` objects, the parameter `cmd` is the shell command to execute in a sub-process. The `capturestderr` flag, if true, specifies that the object should capture standard error output of the child process. The default is false. If the `bufsize` parameter is specified, it specifies the size of the I/O buffers to/from the child process.

`class popen2.Popen4(cmd[, bufsize])`

Similar to `Popen3`, but always captures standard error into the same file object as standard output. These are typically created using `popen4()`.

Nouveau dans la version 2.0.

### 17.5.1 Popen3 and Popen4 Objects

Instances of the `Popen3` and `Popen4` classes have the following methods :

`Popen3.poll()`

Returns -1 if child process hasn't completed yet, or its status code (see `wait()`) otherwise.

`Popen3.wait()`

Waits for and returns the status code of the child process. The status code encodes both the return code of the process and information about whether it exited using the `exit()` system call or died due to a signal. Functions to help interpret the status code are defined in the `os` module; see section *Gestion des processus* for the `W*`() family of functions.

Les attributs suivants sont aussi disponibles :

`Popen3.fromchild`

A file object that provides output from the child process. For `Popen4` instances, this will provide both the standard output and standard error streams.

`Popen3.tochild`

A file object that provides input to the child process.

`Popen3.childerr`

A file object that provides error output from the child process, if `capturestderr` was true for the constructor, otherwise `None`. This will always be `None` for `Popen4` instances.

`Popen3.pid`

L'identifiant de processus du processus enfant.

### 17.5.2 Flow Control Issues

Any time you are working with any form of inter-process communication, control flow needs to be carefully thought out. This remains the case with the file objects provided by this module (or the `os` module equivalents).

When reading output from a child process that writes a lot of data to standard error while the parent is reading from the child's standard output, a deadlock can occur. A similar situation can occur with other combinations of reads and writes. The essential factors are that more than `_PC_PIPE_BUF` bytes are being written by one process in a blocking fashion, while the other process is reading from the first process, also in a blocking fashion.

There are several ways to deal with this situation.

The simplest application change, in many cases, will be to follow this model in the parent process :

```
import popen2

r, w, e = popen2.popen3('python slave.py')
e.readlines()
r.readlines()
r.close()
e.close()
w.close()
```

with code like this in the child :

```
import os
import sys

# note that each of these print statements
# writes a single long string

print >>sys.stderr, 400 * 'this is a test\n'
os.close(sys.stderr.fileno())
print >>sys.stdout, 400 * 'this is another test\n'
```

In particular, note that `sys.stderr` must be closed after writing all data, or `readlines()` won't return. Also note that `os.close()` must be used, as `sys.stderr.close()` won't close `stderr` (otherwise assigning to `sys.stderr` will silently close it, so no further errors can be printed).

Applications which need to support a more general approach should integrate I/O over pipes with their `select()` loops, or use separate threads to read each of the individual files provided by whichever `popen*()` function or `Popen*` class was used.

Module `subprocess` Module for spawning and managing subprocesses.

## 17.6 asyncore — Gestionnaire de socket asynchrone

Code source : [Lib/asyncore.py](#)

This module provides the basic infrastructure for writing asynchronous socket service clients and servers.

There are only two ways to have a program on a single processor do « more than one thing at a time. » Multi-threaded programming is the simplest and most popular way to do it, but there is another very different technique, that lets you have nearly all the advantages of multi-threading, without actually using multiple threads. It's really only practical if your program is largely I/O bound. If your program is processor bound, then pre-emptive scheduled threads are probably what you really need. Network servers are rarely processor bound, however.

If your operating system supports the `select()` system call in its I/O library (and nearly all do), then you can use it to juggle multiple communication channels at once ; doing other work while your I/O is taking place in the « background. » Although this strategy can seem strange and complex, especially at first, it is in many ways easier to understand and control than multi-threaded programming. The `asyncore` module solves many of the difficult problems for you, making the task of building sophisticated high-performance network servers and clients a snap. For « conversational » applications and protocols the companion `asynchat` module is invaluable.

The basic idea behind both modules is to create one or more network *channels*, instances of class `asyncore.dispatcher` and `asynchat.async_chat`. Creating the channels adds them to a global map, used by the `loop()` function if you do not provide it with your own *map*.

Once the initial channel(s) is(are) created, calling the `loop()` function activates channel service, which continues until the last channel (including any that have been added to the map during asynchronous service) is closed.

```
asyncore.loop([timeout[, use_poll[, map[, count]]]])
```

Enter a polling loop that terminates after count passes or all open channels have been closed. All arguments are optional. The *count* parameter defaults to `None`, resulting in the loop terminating only when all channels have been closed. The *timeout* argument sets the timeout parameter for the appropriate `select()` or `poll()` call, measured in seconds ; the default is 30 seconds. The *use\_poll* parameter, if true, indicates that `poll()` should be used in preference to `select()` (the default is `False`).

The *map* parameter is a dictionary whose items are the channels to watch. As channels are closed they are deleted from their map. If *map* is omitted, a global map is used. Channels (instances of `asyncore.dispatcher`, `asynchat.async_chat` and subclasses thereof) can freely be mixed in the map.

#### **class** `asyncore.dispatcher`

The `dispatcher` class is a thin wrapper around a low-level socket object. To make it more useful, it has a few methods for event-handling which are called from the asynchronous loop. Otherwise, it can be treated as a normal non-blocking socket object.

The firing of low-level events at certain times or in certain connection states tells the asynchronous loop that certain higher-level events have taken place. For example, if we have asked for a socket to connect to another host, we know that the connection has been made when the socket becomes writable for the first time (at this point you know that you may write to it with the expectation of success). The implied higher-level events are :

Event	Description
<code>handle_connect()</code>	Implied by the first read or write event
<code>handle_close()</code>	Implied by a read event with no data available
<code>handle_accept()</code>	Implied by a read event on a listening socket

During asynchronous processing, each mapped channel's `readable()` and `writable()` methods are used to determine whether the channel's socket should be added to the list of channels `select()`ed or `poll()`ed for read and write events.

Thus, the set of channel events is larger than the basic socket events. The full set of methods that can be overridden in your subclass follows :

#### **handle\_read()**

Called when the asynchronous loop detects that a `read()` call on the channel's socket will succeed.

**handle\_write()**

Called when the asynchronous loop detects that a writable socket can be written. Often this method will implement the necessary buffering for performance. For example :

```
def handle_write(self):
    sent = self.send(self.buffer)
    self.buffer = self.buffer[sent:]
```

**handle\_expt()**

Called when there is out of band (OOB) data for a socket connection. This will almost never happen, as OOB is tenuously supported and rarely used.

**handle\_connect()**

Called when the active opener's socket actually makes a connection. Might send a « welcome » banner, or initiate a protocol negotiation with the remote endpoint, for example.

**handle\_close()**

Appelé lorsque la socket est fermée.

**handle\_error()**

Called when an exception is raised and not otherwise handled. The default version prints a condensed traceback.

**handle\_accept()**

Called on listening channels (passive openers) when a connection can be established with a new remote endpoint that has issued a `connect()` call for the local endpoint.

**readable()**

Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which read events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in read events.

**writable()**

Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which write events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in write events.

In addition, each channel delegates or extends many of the socket methods. Most of these are nearly identical to their socket partners.

**create\_socket(family, type)**

This is identical to the creation of a normal socket, and will use the same options for creation. Refer to the `socket` documentation for information on creating sockets.

**connect(address)**

As with the normal socket object, *address* is a tuple with the first element the host to connect to, and the second the port number.

**send(data)**

Envoie *data* à l'autre bout de la socket.

**recv(buffer\_size)**

Read at most *buffer\_size* bytes from the socket's remote end-point. An empty string implies that the channel has been closed from the other end.

Note that `recv()` may raise `socket.error` with `EAGAIN` or `EWOULDBLOCK`, even though `select.select()` or `select.poll()` has reported the socket ready for reading.

**listen(backlog)**

Listen for connections made to the socket. The *backlog* argument specifies the maximum number of queued connections and should be at least 1 ; the maximum value is system-dependent (usually 5).

**bind(address)**

Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family — refer to the `socket` documentation for more information.) To mark the socket as re-usable (setting the `SO_REUSEADDR` option), call the `dispatcher` object's `set_reuse_addr()` method.

**accept()**

Accept a connection. The socket must be bound to an address and listening for connections. The return value can be either `None` or a pair (`conn`, `address`) where *conn* is a *new* socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection. When `None` is returned it means the connection didn't take place, in which case the server should just ignore this event and keep listening for further incoming connections.

**close()**

Close the socket. All future operations on the socket object will fail. The remote end-point will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

**class `asyncore.dispatcher_with_send`**

A *dispatcher* subclass which adds simple buffered output capability, useful for simple clients. For more sophisticated usage use *asynchat.async\_chat*.

**class `asyncore.file_dispatcher`**

A *file\_dispatcher* takes a file descriptor or file object along with an optional map argument and wraps it for use with the `poll()` or `loop()` functions. If provided a file object or anything with a `fileno()` method, that method will be called and passed to the *file\_wrapper* constructor. Availability : UNIX.

**class `asyncore.file_wrapper`**

A *file\_wrapper* takes an integer file descriptor and calls *os.dup()* to duplicate the handle so that the original handle may be closed independently of the *file\_wrapper*. This class implements sufficient methods to emulate a socket for use by the *file\_dispatcher* class. Availability : UNIX.

### 17.6.1 Exemple de client HTTP basique avec `asyncore`

Here is a very basic HTTP client that uses the *dispatcher* class to implement its socket handling :

```
import asyncore, socket

class HTTPClient(asyncore.dispatcher):

    def __init__(self, host, path):
        asyncore.dispatcher.__init__(self)
        self.create_socket(socket.AF_INET, socket.SOCK_STREAM)
        self.connect( (host, 80) )
        self.buffer = 'GET %s HTTP/1.0\r\n\r\n' % path

    def handle_connect(self):
        pass

    def handle_close(self):
        self.close()

    def handle_read(self):
        print self.recv(8192)

    def writable(self):
        return (len(self.buffer) > 0)

    def handle_write(self):
        sent = self.send(self.buffer)
        self.buffer = self.buffer[sent:]
```

(suite sur la page suivante)

(suite de la page précédente)

```
client = HTTPClient('www.python.org', '/')
asyncore.loop()
```

### 17.6.2 Serveur *echo* basique avec *asyncore*

Here is a basic echo server that uses the *dispatcher* class to accept connections and dispatches the incoming connections to a handler :

```
import asyncore
import socket

class EchoHandler(asyncore.dispatcher_with_send):

    def handle_read(self):
        data = self.recv(8192)
        if data:
            self.send(data)

class EchoServer(asyncore.dispatcher):

    def __init__(self, host, port):
        asyncore.dispatcher.__init__(self)
        self.create_socket(socket.AF_INET, socket.SOCK_STREAM)
        self.set_reuse_addr()
        self.bind((host, port))
        self.listen(5)

    def handle_accept(self):
        pair = self.accept()
        if pair is not None:
            sock, addr = pair
            print 'Incoming connection from %s' % repr(addr)
            handler = EchoHandler(sock)

server = EchoServer('localhost', 8080)
asyncore.loop()
```

## 17.7 *asynchat* — Gestionnaire d'interfaces de connexion (*socket*) commande/réponse asynchrones

Code source : *\* Lib/asynchat.py*

Ce module s'appuie sur l'infrastructure de *asyncore*, en simplifiant les clients et serveurs asynchrones et en rendant plus facile la gestion de protocoles dont les éléments finissent par une chaîne arbitraire, ou sont de longueur variable. *asynchat* définit une classe abstraite *async\_chat* dont vous héritez, et qui fournit des implémentations des méthodes *collect\_incoming\_data()* et *found\_terminator()*. Il utilise la même boucle asynchrone que *asyncore*, et deux types de canaux, *asyncore.dispatcher* et *asynchat.async\_chat*, qui peuvent être librement mélangés dans la carte des canaux. Habituellement, un canal de

serveur `asyncore.dispatcher` génère de nouveaux canaux d'objets `asynchat.async_chat` à la réception de requêtes de connexion.

#### `class asynchat.async_chat`

Cette classe est une sous-classe abstraite de `asyncore.dispatcher`. Pour en faire un usage pratique, vous devez créer une classe héritant de `async_chat`, et implémentant des méthodes `collect_incoming_data()` et `found_terminator()` sensées. Les méthodes de `asyncore.dispatcher` peuvent être utilisées, même si toutes n'ont pas de sens dans un contexte de messages/réponse.

Comme `asyncore.dispatcher`, `async_chat` définit un ensemble d'événements générés par une analyse de l'état des interfaces de connexion (*socket* en anglais) après un appel à `select()`. Une fois que la boucle de scrutation (*polling* en anglais) a été lancée, les méthodes des objets `async_chat` sont appelées par le *framework* de traitement d'événements sans que le programmeur n'ait à le spécifier.

Deux attributs de classe peuvent être modifiés, pour améliorer la performance, ou potentiellement pour économiser de la mémoire.

##### `ac_in_buffer_size`

La taille du tampon d'entrées asynchrones (4096 par défaut).

##### `ac_out_buffer_size`

La taille du tampon de sorties asynchrones (4096 par défaut).

Unlike `asyncore.dispatcher`, `async_chat` allows you to define a first-in-first-out queue (fifo) of *producers*. A producer need have only one method, `more()`, which should return data to be transmitted on the channel. The producer indicates exhaustion (*i.e.* that it contains no more data) by having its `more()` method return the empty string. At this point the `async_chat` object removes the producer from the fifo and starts using the next producer, if any. When the producer fifo is empty the `handle_write()` method does nothing. You use the channel object's `set_terminator()` method to describe how to recognize the end of, or an important breakpoint in, an incoming transmission from the remote endpoint.

Pour construire une sous classe fonctionnelle de `async_chat` pour vos méthodes d'entrées `collect_incoming_data()` et `found_terminator()` doivent gérer la donnée que le canal reçoit de manière asynchrone. Ces méthodes sont décrites ci-dessous.

#### `async_chat.close_when_done()`

Pushes a `None` on to the producer fifo. When this producer is popped off the fifo it causes the channel to be closed.

#### `async_chat.collect_incoming_data(data)`

Appelé avec `data` contenant une quantité arbitraire de données. La méthode par défaut, qui doit être écrasée, lève une `NotImplementedError`.

#### `async_chat.discard_buffers()`

In emergencies this method will discard any data held in the input and/or output buffers and the producer fifo.

#### `async_chat.found_terminator()`

Appelée quand le flux de donné correspond à la condition de fin décrite par `set_terminator()`. La méthode par défaut, qui doit être écrasée, lève une `NotImplementedError`. Les données entrantes mise en tampon devraient être disponible via un attribut de l'instance.

#### `async_chat.get_terminator()`

Renvoie le terminateur courant pour le canal.

#### `async_chat.push(data)`

Pushes data on to the channel's fifo to ensure its transmission. This is all you need to do to have the channel write the data out to the network, although it is possible to use your own producers in more complex schemes to implement encryption and chunking, for example.

#### `async_chat.push_with_producer(producer)`

Takes a producer object and adds it to the producer fifo associated with the channel. When all currently-

pushed producers have been exhausted the channel will consume this producer's data by calling its `more()` method and send the data to the remote endpoint.

`async_chat.set_terminator(term)`

Définit le marqueur de fin que le canal doit reconnaître. `term` peut être n'importe lequel des trois types de valeurs, correspondant aux trois différentes manières de gérer les données entrantes.

<i>term</i>	Description
<i>string</i>	Appellera <code>found_terminator()</code> quand la chaîne est trouvée dans le flux d'entrée
<i>integer</i>	Appellera <code>found_terminator()</code> quand le nombre de caractère indiqué à été reçu
<code>None</code>	Le canal continue de collecter des informations indéfiniment

Notez que toute donnée située après le marqueur de fin sera accessible en lecture par le canal après que `found_terminator()` ai été appelé.

### 17.7.1 `asyncchat` - Auxiliary Classes

`class asyncchat.fifo([list=None])`

A *fifo* holding data which has been pushed by the application but not yet popped for writing to the channel. A *fifo* is a list used to hold data and/or producers until they are required. If the *list* argument is provided then it should contain producers or data items to be written to the channel.

`is_empty()`

Returns `True` if and only if the fifo is empty.

`first()`

Returns the least-recently *push()*ed item from the fifo.

`push(data)`

Adds the given data (which may be a string or a producer object) to the producer fifo.

`pop()`

If the fifo is not empty, returns `True`, `first()`, deleting the popped item. Returns `False`, `None` for an empty fifo.

### 17.7.2 Exemple `asyncchat`

L'exemple partiel suivant montre comment des requêtes HTTP peuvent être lues avec `async_chat`. Un serveur web pourrait créer un objet `http_request_handler` pour chaque connections lient entrantes. Notez que initialement, le marqueur de fin du canal est défini pour reconnaître les lignes vides à la fin des entêtes HTTP, et une option indique que les entêtes sont en train d'être lues.

Une fois que les entêtes ont été lues, si la requête est de type *POST* (ce qui indique que davantage de données sont présent dans dans le flux entrant) alors l'entête **Content-Length**: est utilisé pour définir un marqueur de fin numérique pour lire la bonne quantité de donné depuis le canal.

La méthode `handle_request()` est appelée une fois que toutes les données pertinentes ont été rassemblées, après avoir défini le marqueur de fin à `None` pour s'assurer que toute données étrangères envoyées par le client web sont ignorées.

```
class http_request_handler(asyncchat.async_chat):

    def __init__(self, sock, addr, sessions, log):
        asyncchat.async_chat.__init__(self, sock=sock)
        self.addr = addr
        self.sessions = sessions
        self.ibuffer = []
        self.obuffer = ""
```

(suite sur la page suivante)

(suite de la page précédente)

```
self.set_terminator("\r\n\r\n")
self.reading_headers = True
self.handling = False
self.cgi_data = None
self.log = log

def collect_incoming_data(self, data):
    """Buffer the data"""
    self.ibuffer.append(data)

def found_terminator(self):
    if self.reading_headers:
        self.reading_headers = False
        self.parse_headers("".join(self.ibuffer))
        self.ibuffer = []
        if self.op.upper() == "POST":
            clen = self.headers.getheader("content-length")
            self.set_terminator(int(clen))
        else:
            self.handling = True
            self.set_terminator(None)
            self.handle_request()
    elif not self.handling:
        self.set_terminator(None) # browsers sometimes over-send
        self.cgi_data = parse(self.headers, "".join(self.ibuffer))
        self.handling = True
        self.ibuffer = []
        self.handle_request()
```

---

## Traitement des données provenant d'Internet

---

Ce chapitre décrit les modules qui prennent en charge le traitement des formats de données couramment utilisés sur Internet.

### 18.1 `email` — An email and MIME handling package

Nouveau dans la version 2.2.

The `email` package is a library for managing email messages, including MIME and other [RFC 2822](#)-based message documents. It subsumes most of the functionality in several older standard modules such as `rfc822`, `mimetools`, `multifile`, and other non-standard packages such as `mimecntl`. It is specifically *not* designed to do any sending of email messages to SMTP ([RFC 2821](#)), NNTP, or other servers; those are functions of modules such as `smtplib` and `nntplib`. The `email` package attempts to be as RFC-compliant as possible, supporting in addition to [RFC 2822](#), such MIME-related RFCs as [RFC 2045](#), [RFC 2046](#), [RFC 2047](#), and [RFC 2231](#).

The primary distinguishing feature of the `email` package is that it splits the parsing and generating of email messages from the internal *object model* representation of email. Applications using the `email` package deal primarily with objects; you can add sub-objects to messages, remove sub-objects from messages, completely re-arrange the contents, etc. There is a separate parser and a separate generator which handles the transformation from flat text to the object model, and then back to flat text again. There are also handy subclasses for some common MIME object types, and a few miscellaneous utilities that help with such common tasks as extracting and parsing message field values, creating RFC-compliant dates, etc.

The following sections describe the functionality of the `email` package. The ordering follows a progression that should be common in applications: an email message is read as flat text from a file or other source, the text is parsed to produce the object structure of the email message, this structure is manipulated, and finally, the object tree is rendered back into flat text.

It is perfectly feasible to create the object structure out of whole cloth — i.e. completely from scratch. From there, a similar progression can be taken as above.

Also included are detailed specifications of all the classes and modules that the `email` package provides, the exception classes you might encounter while using the `email` package, some auxiliary utilities, and a few

examples. For users of the older `mimelib` package, or previous versions of the `email` package, a section on differences and porting is provided.

Contents of the `email` package documentation :

### 18.1.1 `email.message` : Representing an email message

The central class in the `email` package is the `Message` class, imported from the `email.message` module. It is the base class for the `email` object model. `Message` provides the core functionality for setting and querying header fields, and for accessing message bodies.

Conceptually, a `Message` object consists of *headers* and *payloads*. Headers are **RFC 2822** style field names and values where the field name and value are separated by a colon. The colon is not part of either the field name or the field value.

Headers are stored and returned in case-preserving form but are matched case-insensitively. There may also be a single envelope header, also known as the *Unix-From* header or the `From_` header. The payload is either a string in the case of simple message objects or a list of `Message` objects for MIME container documents (e.g. `multipart/*` and `message/rfc822`).

`Message` objects provide a mapping style interface for accessing the message headers, and an explicit interface for accessing both the headers and the payload. It provides convenience methods for generating a flat text representation of the message object tree, for accessing commonly used header parameters, and for recursively walking over the object tree.

Here are the methods of the `Message` class :

**class** `email.message.Message`

The constructor takes no arguments.

**as\_string**(`[unixfrom]`)

Return the entire message flattened as a string. When optional `unixfrom` is `True`, the envelope header is included in the returned string. `unixfrom` defaults to `False`. Flattening the message may trigger changes to the `Message` if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it mangles lines that begin with `From`. For more flexibility, instantiate a `Generator` instance and use its `flatten()` method directly. For example :

```
from cStringIO import StringIO
from email.generator import Generator
fp = StringIO()
g = Generator(fp, mangle_from_=False, maxheaderlen=60)
g.flatten(msg)
text = fp.getvalue()
```

**\_\_str\_\_**()

Equivalent to `as_string(unixfrom=True)`.

**is\_multipart**()

Return `True` if the message's payload is a list of sub-`Message` objects, otherwise return `False`. When `is_multipart()` returns `False`, the payload should be a string object.

**set\_unixfrom**(`unixfrom`)

Set the message's envelope header to `unixfrom`, which should be a string.

**get\_unixfrom**()

Return the message's envelope header. Defaults to `None` if the envelope header was never set.

**attach**(`payload`)

Add the given `payload` to the current payload, which must be `None` or a list of `Message` objects

before the call. After the call, the payload will always be a list of *Message* objects. If you want to set the payload to a scalar object (e.g. a string), use *set\_payload()* instead.

**get\_payload**(*i*[, *decode*])

Return the current payload, which will be a list of *Message* objects when *is\_multipart()* is *True*, or a string when *is\_multipart()* is *False*. If the payload is a list and you mutate the list object, you modify the message's payload in place.

With optional argument *i*, *get\_payload()* will return the *i*-th element of the payload, counting from zero, if *is\_multipart()* is *True*. An *IndexError* will be raised if *i* is less than 0 or greater than or equal to the number of items in the payload. If the payload is a string (i.e. *is\_multipart()* is *False*) and *i* is given, a *TypeError* is raised.

Optional *decode* is a flag indicating whether the payload should be decoded or not, according to the *Content-Transfer-Encoding* header. When *True* and the message is not a multipart, the payload will be decoded if this header's value is *quoted-printable* or *base64*. If some other encoding is used, or *Content-Transfer-Encoding* header is missing, or if the payload has bogus base64 data, the payload is returned as-is (undecoded). If the message is a multipart and the *decode* flag is *True*, then *None* is returned. The default for *decode* is *False*.

**set\_payload**(*payload*[, *charset*])

Set the entire message object's payload to *payload*. It is the client's responsibility to ensure the payload invariants. Optional *charset* sets the message's default character set; see *set\_charset()* for details.

Modifié dans la version 2.2.2 : *charset* argument added.

**set\_charset**(*charset*)

Set the character set of the payload to *charset*, which can either be a *Charset* instance (see *email.charset*), a string naming a character set, or *None*. If it is a string, it will be converted to a *Charset* instance. If *charset* is *None*, the *charset* parameter will be removed from the *Content-Type* header (the message will not be otherwise modified). Anything else will generate a *TypeError*.

If there is no existing *MIME-Version* header one will be added. If there is no existing *Content-Type* header, one will be added with a value of *text/plain*. Whether the *Content-Type* header already exists or not, its *charset* parameter will be set to *charset.output\_charset*. If *charset.input\_charset* and *charset.output\_charset* differ, the payload will be re-encoded to the *output\_charset*. If there is no existing *Content-Transfer-Encoding* header, then the payload will be transfer-encoded, if needed, using the specified *Charset*, and a header with the appropriate value will be added. If a *Content-Transfer-Encoding* header already exists, the payload is assumed to already be correctly encoded using that *Content-Transfer-Encoding* and is not modified.

The message will be assumed to be of type *text/\**, with the payload either in unicode or encoded with *charset.input\_charset*. It will be encoded or converted to *charset.output\_charset* and transfer encoded properly, if needed, when generating the plain text representation of the message. MIME headers (*MIME-Version*, *Content-Type*, *Content-Transfer-Encoding*) will be added as needed.

Nouveau dans la version 2.2.2.

**get\_charset**()

Return the *Charset* instance associated with the message's payload.

Nouveau dans la version 2.2.2.

The following methods implement a mapping-like interface for accessing the message's **RFC 2822** headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by *keys()*, but in a *Message* object, headers are always returned in the order they appeared in the original message, or were added to the message later. Any header deleted and then re-added are always appended to the end of the header list.

These semantic differences are intentional and are biased toward maximal convenience.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

**`__len__()`**

Return the total number of headers, including duplicates.

**`__contains__(name)`**

Return true if the message object has a field named *name*. Matching is done case-insensitively and *name* should not include the trailing colon. Used for the `in` operator, e.g. :

```
if 'message-id' in myMessage:
    print 'Message-ID:', myMessage['message-id']
```

**`__getitem__(name)`**

Return the value of the named header field. *name* should not include the colon field separator. If the header is missing, `None` is returned; a `KeyError` is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field values will be returned is undefined. Use the `get_all()` method to get the values of all the extant named headers.

**`__setitem__(name, val)`**

Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message's existing fields.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g. :

```
del msg['subject']
msg['subject'] = 'Python roolz!'
```

**`__delitem__(name)`**

Delete all occurrences of the field with name *name* from the message's headers. No exception is raised if the named field isn't present in the headers.

**`has_key(name)`**

Return true if the message contains a header field named *name*, otherwise return false.

**`keys()`**

Return a list of all the message's header field names.

**`values()`**

Return a list of all the message's field values.

**`items()`**

Return a list of 2-tuples containing all the message's field headers and values.

**`get(name[, failobj])`**

Return the value of the named header field. This is identical to `__getitem__()` except that optional *failobj* is returned if the named header is missing (defaults to `None`).

Here are some additional useful methods :

**`get_all(name[, failobj])`**

Return a list of all the values for the field named *name*. If there are no such named headers in the message, *failobj* is returned (defaults to `None`).

**`add_header(_name, _value, **_params)`**

Extended header setting. This method is similar to `__setitem__()` except that additional header parameters can be provided as keyword arguments. *\_name* is the header field to add and *\_value* is the *primary* value for the header.

For each item in the keyword argument dictionary *\_params*, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as `key="value"` unless the value is `None`, in which case only the key will be added. If the value contains non-ASCII characters, it must be specified as a three tuple in the format (CHARSET, LANGUAGE, VALUE), where CHARSET is a string naming the charset to be used to encode the value, LANGUAGE can usually be set to `None` or the empty string (see [RFC 2231](#) for other possibilities), and VALUE is the string value containing non-ASCII code points.

Here's an example :

```
msg.add_header('Content-Disposition', 'attachment', filename='bud.gif')
```

This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.gif"
```

An example with non-ASCII characters :

```
msg.add_header('Content-Disposition', 'attachment',
               filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

Which produces

```
Content-Disposition: attachment; filename*="iso-8859-1'Fu%DFballer.ppt"
```

**replace\_header**(*\_name*, *\_value*)

Replace a header. Replace the first header found in the message that matches *\_name*, retaining header order and field name case. If no matching header was found, a *KeyError* is raised.

Nouveau dans la version 2.2.2.

**get\_content\_type**()

Return the message's content type. The returned string is coerced to lower case of the form *maintype/subtype*. If there was no *Content-Type* header in the message the default type as given by *get\_default\_type()* will be returned. Since according to [RFC 2045](#), messages always have a default type, *get\_content\_type()* will always return a value.

[RFC 2045](#) defines a message's default type to be *text/plain* unless it appears inside a *multipart/digest* container, in which case it would be *message/rfc822*. If the *Content-Type* header has an invalid type specification, [RFC 2045](#) mandates that the default type be *text/plain*.

Nouveau dans la version 2.2.2.

**get\_content\_maintype**()

Return the message's main content type. This is the *maintype* part of the string returned by *get\_content\_type()*.

Nouveau dans la version 2.2.2.

**get\_content\_subtype**()

Return the message's sub-content type. This is the *subtype* part of the string returned by *get\_content\_type()*.

Nouveau dans la version 2.2.2.

**get\_default\_type**()

Return the default content type. Most messages have a default content type of *text/plain*, except for messages that are subparts of *multipart/digest* containers. Such subparts have a default content type of *message/rfc822*.

Nouveau dans la version 2.2.2.

**set\_default\_type**(*ctype*)

Set the default content type. *ctype* should either be *text/plain* or *message/rfc822*, although this is not enforced. The default content type is not stored in the *Content-Type* header.

Nouveau dans la version 2.2.2.

**get\_params**(*[failobj, header[, unquote]]*)

Return the message's *Content-Type* parameters, as a list. The elements of the returned list are 2-tuples of key/value pairs, as split on the '=' sign. The left hand side of the '=' is the key, while the right hand side is the value. If there is no '=' sign in the parameter the value is the empty string, otherwise the value is as described in *get\_param()* and is unquoted if optional *unquote* is True (the default).

Optional *failobj* is the object to return if there is no *Content-Type* header. Optional *header* is the header to search instead of *Content-Type*.

Modifié dans la version 2.2.2 : *unquote* argument added.

**get\_param**(*param*[, *failobj*[, *header*[, *unquote*]]])

Return the value of the *Content-Type* header's parameter *param* as a string. If the message has no *Content-Type* header or if there is no such parameter, then *failobj* is returned (defaults to *None*).

Optional *header* if given, specifies the message header to use instead of *Content-Type*.

Parameter keys are always compared case insensitively. The return value can either be a string, or a 3-tuple if the parameter was [RFC 2231](#) encoded. When it's a 3-tuple, the elements of the value are of the form (CHARSET, LANGUAGE, VALUE). Note that both CHARSET and LANGUAGE can be *None*, in which case you should consider VALUE to be encoded in the *us-ascii* charset. You can usually ignore LANGUAGE.

If your application doesn't care whether the parameter was encoded as in [RFC 2231](#), you can collapse the parameter value by calling `email.utils.collapse_rfc2231_value()`, passing in the return value from `get_param()`. This will return a suitably decoded Unicode string when the value is a tuple, or the original string unquoted if it isn't. For example :

```
rawparam = msg.get_param('foo')
param = email.utils.collapse_rfc2231_value(rawparam)
```

In any case, the parameter value (either the returned string, or the VALUE item in the 3-tuple) is always unquoted, unless *unquote* is set to *False*.

Modifié dans la version 2.2.2 : *unquote* argument added, and 3-tuple return value possible.

**set\_param**(*param*, *value*[, *header*[, *quote*[, *charset*[, *language*]]]])

Set a parameter in the *Content-Type* header. If the parameter already exists in the header, its value will be replaced with *value*. If the *Content-Type* header has not yet been defined for this message, it will be set to *text/plain* and the new parameter value will be appended as per [RFC 2045](#).

Optional *header* specifies an alternative header to *Content-Type*, and all parameters will be quoted as necessary unless optional *quote* is *False* (the default is *True*).

If optional *charset* is specified, the parameter will be encoded according to [RFC 2231](#). Optional *language* specifies the RFC 2231 language, defaulting to the empty string. Both *charset* and *language* should be strings.

Nouveau dans la version 2.2.2.

**del\_param**(*param*[, *header*[, *quote*]])

Remove the given parameter completely from the *Content-Type* header. The header will be rewritten in place without the parameter or its value. All values will be quoted as necessary unless *quote* is *False* (the default is *True*). Optional *header* specifies an alternative to *Content-Type*.

Nouveau dans la version 2.2.2.

**set\_type**(*type*[, *header*[, *quote*]])

Set the main type and subtype for the *Content-Type* header. *type* must be a string in the form *maintype/subtype*, otherwise a *ValueError* is raised.

This method replaces the *Content-Type* header, keeping all the parameters in place. If *quote* is *False*, this leaves the existing header's quoting as is, otherwise the parameters will be quoted (the default).

An alternative header can be specified in the *header* argument. When the *Content-Type* header is set a *MIME-Version* header is also added.

Nouveau dans la version 2.2.2.

**get\_filename**(*failobj*)

Return the value of the *filename* parameter of the *Content-Disposition* header of the message. If the header does not have a *filename* parameter, this method falls back to looking for the *name*

parameter on the *Content-Type* header. If neither is found, or the header is missing, then *failobj* is returned. The returned string will always be unquoted as per `email.utils.unquote()`.

**get\_boundary**(*[failobj]*)

Return the value of the *boundary* parameter of the *Content-Type* header of the message, or *failobj* if either the header is missing, or has no *boundary* parameter. The returned string will always be unquoted as per `email.utils.unquote()`.

**set\_boundary**(*boundary*)

Set the *boundary* parameter of the *Content-Type* header to *boundary*. `set_boundary()` will always quote *boundary* if necessary. A `HeaderParseError` is raised if the message object has no *Content-Type* header.

Note that using this method is subtly different than deleting the old *Content-Type* header and adding a new one with the new boundary via `add_header()`, because `set_boundary()` preserves the order of the *Content-Type* header in the list of headers. However, it does *not* preserve any continuation lines which may have been present in the original *Content-Type* header.

**get\_content\_charset**(*[failobj]*)

Return the *charset* parameter of the *Content-Type* header, coerced to lower case. If there is no *Content-Type* header, or if that header has no *charset* parameter, *failobj* is returned.

Note that this method differs from `get_charset()` which returns the *Charset* instance for the default encoding of the message body.

Nouveau dans la version 2.2.2.

**get\_charsets**(*[failobj]*)

Return a list containing the character set names in the message. If the message is a *multipart*, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the *charset* parameter in the *Content-Type* header for the represented subpart. However, if the subpart has no *Content-Type* header, no *charset* parameter, or is not of the *text* main MIME type, then that item in the returned list will be *failobj*.

**walk()**

The `walk()` method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use `walk()` as the iterator in a `for` loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure :

```
>>> for part in msg.walk():
...     print part.get_content_type()
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
```

Modifié dans la version 2.5 : The previously deprecated methods `get_type()`, `get_main_type()`, and `get_subtype()` were removed.

*Message* objects can also optionally contain two instance attributes, which can be used when generating the plain text of a MIME message.

**preamble**

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the *Parser* discovers some text after the headers but before the first boundary string, it assigns this text to the message's *preamble* attribute. When the *Generator* is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See *email.parser* and *email.generator* for details.

Note that if the message object has no preamble, the *preamble* attribute will be *None*.

#### epilogue

The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message.

Modifié dans la version 2.5 : You do not need to set the epilogue to the empty string in order for the *Generator* to print a newline at the end of the file.

#### defects

The *defects* attribute contains a list of all the problems found when parsing this message. See *email.errors* for a detailed description of the possible parsing defects.

Nouveau dans la version 2.4.

### 18.1.2 email.parser : Parsing email messages

Message object structures can be created in one of two ways : they can be created from whole cloth by instantiating *Message* objects and stringing them together via *attach()* and *set\_payload()* calls, or they can be created by parsing a flat text representation of the email message.

The *email* package provides a standard parser that understands most email document structures, including MIME documents. You can pass the parser a string or a file object, and the parser will return to you the root *Message* instance of the object structure. For simple, non-MIME messages the payload of this root object will likely be a string containing the text of the message. For MIME messages, the root object will return *True* from its *is\_multipart()* method, and the subparts can be accessed via the *get\_payload()* and *walk()* methods.

There are actually two parser interfaces available for use, the classic *Parser* API and the incremental *FeedParser* API. The classic *Parser* API is fine if you have the entire text of the message in memory as a string, or if the entire message lives in a file on the file system. *FeedParser* is more appropriate for when you're reading the message from a stream which might block waiting for more input (e.g. reading an email message from a socket). The *FeedParser* can consume and parse the message incrementally, and only returns the root object when you close the parser<sup>1</sup>.

Note that the parser can be extended in limited ways, and of course you can implement your own parser completely from scratch. There is no magical connection between the *email* package's bundled parser and the *Message* class, so your custom parser can create message object trees any way it finds necessary.

#### FeedParser API

Nouveau dans la version 2.4.

The *FeedParser*, imported from the *email.feedparser* module, provides an API that is conducive to incremental parsing of email messages, such as would be necessary when reading the text of an email message from a source that can block (e.g. a socket). The *FeedParser* can of course be used to parse an email message fully contained in a string or a file, but the classic *Parser* API may be more convenient for such use cases. The semantics and results of the two parser APIs are identical.

The *FeedParser*'s API is simple ; you create an instance, feed it a bunch of text until there's no more to feed it, then close the parser to retrieve the root message object. The *FeedParser* is extremely accurate when parsing standards-compliant messages, and it does a very good job of parsing non-compliant messages,

---

1. As of email package version 3.0, introduced in Python 2.4, the classic *Parser* was re-implemented in terms of the *FeedParser*, so the semantics and results are identical between the two parsers.

providing information about how a message was deemed broken. It will populate a message object's *defects* attribute with a list of any problems it found in a message. See the `email.errors` module for the list of defects that it can find.

Here is the API for the `FeedParser` :

```
class email.parser.FeedParser([__factory])
```

Create a `FeedParser` instance. Optional `__factory` is a no-argument callable that will be called whenever a new message object is needed. It defaults to the `email.message.Message` class.

```
feed(data)
```

Feed the `FeedParser` some more data. `data` should be a string containing one or more lines. The lines can be partial and the `FeedParser` will stitch such partial lines together properly. The lines in the string can have any of the common three line endings, carriage return, newline, or carriage return and newline (they can even be mixed).

```
close()
```

Closing a `FeedParser` completes the parsing of all previously fed data, and returns the root message object. It is undefined what happens if you feed more data to a closed `FeedParser`.

### Parser class API

The `Parser` class, imported from the `email.parser` module, provides an API that can be used to parse a message when the complete contents of the message are available in a string or file. The `email.parser` module also provides a second class, called `HeaderParser` which can be used if you're only interested in the headers of the message. `HeaderParser` can be much faster in these situations, since it does not attempt to parse the message body, instead setting the payload to the raw body as a string. `HeaderParser` has the same API as the `Parser` class.

```
class email.parser.Parser([__class])
```

The constructor for the `Parser` class takes an optional argument `__class`. This must be a callable factory (such as a function or a class), and it is used whenever a sub-message object needs to be created. It defaults to `Message` (see `email.message`). The factory will be called without arguments.

The optional `strict` flag is ignored.

Obsolète depuis la version 2.4 : Because the `Parser` class is a backward compatible API wrapper around the new-in-Python 2.4 `FeedParser`, all parsing is effectively non-strict. You should simply stop passing a `strict` flag to the `Parser` constructor.

Modifié dans la version 2.2.2 : The `strict` flag was added.

Modifié dans la version 2.4 : The `strict` flag was deprecated.

The other public `Parser` methods are :

```
parse(fp[, headersonly])
```

Read all the data from the file-like object `fp`, parse the resulting text, and return the root message object. `fp` must support both the `readline()` and the `read()` methods on file-like objects.

The text contained in `fp` must be formatted as a block of **RFC 2822** style headers and header continuation lines, optionally preceded by an envelope header. The header block is terminated either by the end of the data or by a blank line. Following the header block is the body of the message (which may contain MIME-encoded subparts).

Optional `headersonly` is a flag specifying whether to stop parsing after reading the headers or not. The default is `False`, meaning it parses the entire contents of the file.

Modifié dans la version 2.2.2 : The `headersonly` flag was added.

```
parsestr(text[, headersonly])
```

Similar to the `parse()` method, except it takes a string object instead of a file-like object. Calling this method on a string is exactly equivalent to wrapping `text` in a `StringIO` instance first and calling `parse()`.

Optional `headersonly` is as with the `parse()` method.

Modifié dans la version 2.2.2 : The `headersonly` flag was added.

Since creating a message object structure from a string or a file object is such a common task, two functions are provided as a convenience. They are available in the top-level *email* package namespace.

`email.message_from_string(s[, _class[, strict]])`

Return a message object structure from a string. This is exactly equivalent to `Parser().parsestr(s)`.

Optional `_class` and `strict` are interpreted as with the *Parser* class constructor.

Modifié dans la version 2.2.2 : The *strict* flag was added.

`email.message_from_file(fp[, _class[, strict]])`

Return a message object structure tree from an open file object. This is exactly equivalent to `Parser().`

`parse(fp)`. Optional `_class` and `strict` are interpreted as with the *Parser* class constructor.

Modifié dans la version 2.2.2 : The *strict* flag was added.

Here's an example of how you might use this at an interactive Python prompt :

```
>>> import email
>>> msg = email.message_from_string(myString)
```

### Additional notes

Here are some notes on the parsing semantics :

- Most non-*multipart* type messages are parsed as a single message object with a string payload. These objects will return `False` for `is_multipart()`. Their `get_payload()` method will return a string object.
- All *multipart* type messages will be parsed as a container message object with a list of sub-message objects for their payload. The outer container message will return `True` for `is_multipart()` and their `get_payload()` method will return the list of *Message* subparts.
- Most messages with a content type of *message/\** (e.g. *message/delivery-status* and *message/rfc822*) will also be parsed as container object containing a list payload of length 1. Their `is_multipart()` method will return `True`. The single element in the list payload will be a sub-message object.
- Some non-standards compliant messages may not be internally consistent about their *multipart*-edness. Such messages may have a *Content-Type* header of type *multipart*, but their `is_multipart()` method may return `False`. If such messages were parsed with the *FeedParser*, they will have an instance of the `MultipartInvariantViolationDefect` class in their `defects` attribute list. See *email.errors* for details.

### Notes

#### 18.1.3 email.generator : Generating MIME documents

One of the most common tasks is to generate the flat text of the email message represented by a message object structure. You will need to do this if you want to send your message via the *smtplib* module or the *ntplib* module, or print the message on the console. Taking a message object structure and producing a flat text document is the job of the *Generator* class.

Again, as with the *email.parser* module, you aren't limited to the functionality of the bundled generator ; you could write one from scratch yourself. However the bundled generator knows how to generate most email in a standards-compliant way, should handle MIME and non-MIME email messages just fine, and is designed so that the transformation from flat text, to a message structure via the *Parser* class, and back to flat text, is idempotent (the input is identical to the output)<sup>1</sup>. On the other hand, using the *Generator* on a *Message* constructed by program may result in changes to the *Message* object as defaults are filled in.

Here are the public methods of the *Generator* class, imported from the *email.generator* module :

---

1. This statement assumes that you use the appropriate setting for the `unixfrom` argument, and that you set `maxheaderlen=0` (which will preserve whatever the input line lengths were). It is also not strictly true, since in many cases runs of whitespace in headers are collapsed into single blanks. The latter is a bug that will eventually be fixed.

```
class email.generator.Generator(outfp[, mangle_from[, maxheaderlen]])
```

The constructor for the *Generator* class takes a file-like object called *outfp* for an argument. *outfp* must support the *write()* method and be usable as the output file in a Python extended print statement.

Optional *mangle\_from* is a flag that, when *True*, puts a > character in front of any line in the body that starts exactly as *From*, i.e. *From* followed by a space at the beginning of the line. This is the only guaranteed portable way to avoid having such lines be mistaken for a Unix mailbox format envelope header separator (see [WHY THE CONTENT-LENGTH FORMAT IS BAD](#) for details). *mangle\_from* defaults to *True*, but you might want to set this to *False* if you are not writing Unix mailbox format files.

Optional *maxheaderlen* specifies the longest length for a non-continued header. When a header line is longer than *maxheaderlen* (in characters, with tabs expanded to 8 spaces), the header will be split as defined in the *Header* class. Set to zero to disable header wrapping. The default is 78, as recommended (but not required) by [RFC 2822](#).

The other public *Generator* methods are :

```
flatten(msg[, unixfrom])
```

Print the textual representation of the message object structure rooted at *msg* to the output file specified when the *Generator* instance was created. Subparts are visited depth-first and the resulting text will be properly MIME encoded.

Optional *unixfrom* is a flag that forces the printing of the envelope header delimiter before the first [RFC 2822](#) header of the root message object. If the root object has no envelope header, a standard one is crafted. By default, this is set to *False* to inhibit the printing of the envelope delimiter.

Note that for subparts, no envelope header is ever printed.

Nouveau dans la version 2.2.2.

```
clone(fp)
```

Return an independent clone of this *Generator* instance with the exact same options.

Nouveau dans la version 2.2.2.

```
write(s)
```

Write the string *s* to the underlying file object, i.e. *outfp* passed to *Generator*'s constructor. This provides just enough file-like API for *Generator* instances to be used in extended print statements.

As a convenience, see the methods *Message.as\_string()* and *str(aMessage)*, a.k.a. *Message.\_\_str\_\_()*, which simplify the generation of a formatted string representation of a message object. For more detail, see [email.message](#).

The *email.generator* module also provides a derived class, called *DecodedGenerator* which is like the *Generator* base class, except that non-*text* parts are substituted with a format string representing the part.

```
class email.generator.DecodedGenerator(outfp[, mangle_from[, maxheaderlen[, fmt]])
```

This class, derived from *Generator* walks through all the subparts of a message. If the subpart is of main type *text*, then it prints the decoded payload of the subpart. Optional *mangle\_from* and *maxheaderlen* are as with the *Generator* base class.

If the subpart is not of main type *text*, optional *fmt* is a format string that is used instead of the message payload. *fmt* is expanded with the following keywords, *%(keyword)s* format :

- *type* – Full MIME type of the non-*text* part
- *maintype* – Main MIME type of the non-*text* part
- *subtype* – Sub-MIME type of the non-*text* part
- *filename* – Filename of the non-*text* part
- *description* – Description associated with the non-*text* part
- *encoding* – Content transfer encoding of the non-*text* part

The default value for *fmt* is *None*, meaning

`[Non-text %(type)s part of message omitted, filename %(filename)s]`

Nouveau dans la version 2.2.2.

Modifié dans la version 2.5 : The previously deprecated method `__call__()` was removed.

## Notes

### 18.1.4 `email.mime` : Creating email and MIME objects from scratch

Ordinarily, you get a message object structure by passing a file or some text to a parser, which parses the text and returns the root message object. However you can also build a complete message structure from scratch, or even individual *Message* objects by hand. In fact, you can also take an existing structure and add new *Message* objects, move them around, etc. This makes a very convenient interface for slicing-and-dicing MIME messages.

You can create a new object structure by creating *Message* instances, adding attachments and all the appropriate headers manually. For MIME messages though, the *email* package provides some convenient subclasses to make things easier.

Here are the classes :

```
class email.mime.base.MIMEBase(__maintype, __subtype, **__params)
```

Module : `email.mime.base`

This is the base class for all the MIME-specific subclasses of *Message*. Ordinarily you won't create instances specifically of *MIMEBase*, although you could. *MIMEBase* is provided primarily as a convenient base class for more specific MIME-aware subclasses.

`__maintype` is the *Content-Type* major type (e.g. *text* or *image*), and `__subtype` is the *Content-Type* minor type (e.g. *plain* or *gif*). `__params` is a parameter key/value dictionary and is passed directly to *Message.add\_header*.

The *MIMEBase* class always adds a *Content-Type* header (based on `__maintype`, `__subtype`, and `__params`), and a *MIME-Version* header (always set to 1.0).

```
class email.mime.nonmultipart.MIMENonMultipart
```

Module : `email.mime.nonmultipart`

A subclass of *MIMEBase*, this is an intermediate base class for MIME messages that are not *multipart*. The primary purpose of this class is to prevent the use of the *attach()* method, which only makes sense for *multipart* messages. If *attach()* is called, a *MultipartConversionError* exception is raised.

Nouveau dans la version 2.2.2.

```
class email.mime.multipart.MIMEMultipart([__subtype[, boundary[, __subparts[, __params]]]])
```

Module : `email.mime.multipart`

A subclass of *MIMEBase*, this is an intermediate base class for MIME messages that are *multipart*. Optional `__subtype` defaults to *mixed*, but can be used to specify the subtype of the message. A *Content-Type* header of *multipart/\_subtype* will be added to the message object. A *MIME-Version* header will also be added.

Optional *boundary* is the multipart boundary string. When *None* (the default), the boundary is calculated when needed (for example, when the message is serialized).

`__subparts` is a sequence of initial subparts for the payload. It must be possible to convert this sequence to a list. You can always attach new subparts to the message by using the *Message.attach* method.

Additional parameters for the *Content-Type* header are taken from the keyword arguments, or passed into the `__params` argument, which is a keyword dictionary.

Nouveau dans la version 2.2.2.

```
class email.mime.application.MIMEApplication(__data[, __subtype[, __encoder[, **__params]]])
```

Module : `email.mime.application`

A subclass of *MIMENonMultipart*, the *MIMEApplication* class is used to represent MIME message objects of major type *application*. *\_\_data* is a string containing the raw byte data. Optional *\_\_subtype* specifies the MIME subtype and defaults to *octet-stream*.

Optional *\_\_encoder* is a callable (i.e. function) which will perform the actual encoding of the data for transport. This callable takes one argument, which is the *MIMEApplication* instance. It should use *get\_payload()* and *set\_payload()* to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the *email.encoders* module for a list of the built-in encoders.

*\_\_params* are passed straight through to the base class constructor.

Nouveau dans la version 2.5.

```
class email.mime.audio.MIMEAudio(__audiodata[, __subtype[, __encoder[, **__params]]])
Module : email.mime.audio
```

A subclass of *MIMENonMultipart*, the *MIMEAudio* class is used to create MIME message objects of major type *audio*. *\_\_audiodata* is a string containing the raw audio data. If this data can be decoded by the standard Python module *sndhdr*, then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the audio subtype via the *\_\_subtype* parameter. If the minor type could not be guessed and *\_\_subtype* was not given, then *TypeError* is raised.

Optional *\_\_encoder* is a callable (i.e. function) which will perform the actual encoding of the audio data for transport. This callable takes one argument, which is the *MIMEAudio* instance. It should use *get\_payload()* and *set\_payload()* to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the *email.encoders* module for a list of the built-in encoders.

*\_\_params* are passed straight through to the base class constructor.

```
class email.mime.image.MIMEImage(__imagedata[, __subtype[, __encoder[, **__params]]])
Module : email.mime.image
```

A subclass of *MIMENonMultipart*, the *MIMEImage* class is used to create MIME message objects of major type *image*. *\_\_imagedata* is a string containing the raw image data. If this data can be decoded by the standard Python module *imghdr*, then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the image subtype via the *\_\_subtype* parameter. If the minor type could not be guessed and *\_\_subtype* was not given, then *TypeError* is raised.
