Optional *\_\_encoder* is a callable (i.e. function) which will perform the actual encoding of the image data for transport. This callable takes one argument, which is the *MIMEImage* instance. It should use *get\_payload()* and *set\_payload()* to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the *email.encoders* module for a list of the built-in encoders.

*\_\_params* are passed straight through to the *MIMEBase* constructor.

```
class email.mime.message.MIMEMessage(__msg[, __subtype])
Module : email.mime.message
```

A subclass of *MIMENonMultipart*, the *MIMEMessage* class is used to create MIME objects of main type *message*. *\_\_msg* is used as the payload, and must be an instance of class *Message* (or a subclass thereof), otherwise a *TypeError* is raised.

Optional *\_\_subtype* sets the subtype of the message; it defaults to *rfc822*.

```
class email.mime.text.MIMEText(__text[, __subtype[, __charset]])
Module : email.mime.text
```

A subclass of *MIMENonMultipart*, the *MIMEText* class is used to create MIME objects of major type *text*. *\_\_text* is the string for the payload. *\_\_subtype* is the minor type and defaults to *plain*. *\_\_charset* is the character set of the text and is passed as a parameter to the *MIMENonMultipart* constructor; it defaults to *us-ascii*. If *\_\_text* is unicode, it is encoded using the *output\_charset* of *\_\_charset*, otherwise it is used as-is.

Modifié dans la version 2.4 : The previously deprecated `_encoding` argument has been removed. Content Transfer Encoding now happens implicitly based on the `_charset` argument.

Unless the `_charset` parameter is explicitly set to `None`, the `MIMEText` object created will have both a *Content-Type* header with a `charset` parameter, and a *Content-Transfer-Encoding* header. This means that a subsequent `set_payload` call will not result in an encoded payload, even if a charset is passed in the `set_payload` command. You can « reset » this behavior by deleting the *Content-Transfer-Encoding* header, after which a `set_payload` call will automatically encode the new payload (and add a new *Content-Transfer-Encoding* header).

### 18.1.5 `email.header` : Internationalized headers

**RFC 2822** is the base standard that describes the format of email messages. It derives from the older **RFC 822** standard which came into widespread use at a time when most email was composed of ASCII characters only. **RFC 2822** is a specification written assuming email contains only 7-bit ASCII characters.

Of course, as email has been deployed worldwide, it has become internationalized, such that language specific character sets can now be used in email messages. The base standard still requires email messages to be transferred using only 7-bit ASCII characters, so a slew of RFCs have been written describing how to encode email containing non-ASCII characters into **RFC 2822**-compliant format. These RFCs include **RFC 2045**, **RFC 2046**, **RFC 2047**, and **RFC 2231**. The `email` package supports these standards in its `email.header` and `email.charset` modules.

If you want to include non-ASCII characters in your email headers, say in the *Subject* or *To* fields, you should use the `Header` class and assign the field in the `Message` object to an instance of `Header` instead of using a string for the header value. Import the `Header` class from the `email.header` module. For example :

```
>>> from email.message import Message
>>> from email.header import Header
>>> msg = Message()
>>> h = Header('p\xf6stal', 'iso-8859-1')
>>> msg['Subject'] = h
>>> print msg.as_string()
Subject: =?iso-8859-1?q?p=F6stal?=
```

Notice here how we wanted the *Subject* field to contain a non-ASCII character? We did this by creating a `Header` instance and passing in the character set that the byte string was encoded in. When the subsequent `Message` instance was flattened, the *Subject* field was properly **RFC 2047** encoded. MIME-aware mail readers would show this header using the embedded ISO-8859-1 character.

Nouveau dans la version 2.2.2.

Here is the `Header` class description :

```
class email.header.Header([s[, charset[, maxlinelen[, header_name[, continuation_ws[, errors]]]]])
```

Create a MIME-compliant header that can contain strings in different character sets.

Optional `s` is the initial header value. If `None` (the default), the initial header value is not set. You can later append to the header with `append()` method calls. `s` may be a byte string or a Unicode string, but see the `append()` documentation for semantics.

Optional `charset` serves two purposes : it has the same meaning as the `charset` argument to the `append()` method. It also sets the default character set for all subsequent `append()` calls that omit the `charset` argument. If `charset` is not provided in the constructor (the default), the `us-ascii` character set is used both as `s`'s initial charset and as the default for subsequent `append()` calls.

The maximum line length can be specified explicitly via `maxlinelen`. For splitting the first line to a shorter value (to account for the field header which isn't included in `s`, e.g. *Subject*) pass in the name

of the field in *header\_name*. The default *maxlinelen* is 76, and the default value for *header\_name* is *None*, meaning it is not taken into account for the first line of a long, split header.

Optional *continuation\_ws* must be [RFC 2822](#)-compliant folding whitespace, and is usually either a space or a hard tab character. This character will be prepended to continuation lines. *continuation\_ws* defaults to a single space character ( « » ).

Optional *errors* is passed straight through to the [append\(\)](#) method.

**append**(*s*[, *charset*[, *errors*]])

Append the string *s* to the MIME header.

Optional *charset*, if given, should be a [Charset](#) instance (see [email.charset](#)) or the name of a character set, which will be converted to a [Charset](#) instance. A value of *None* (the default) means that the *charset* given in the constructor is used.

*s* may be a byte string or a Unicode string. If it is a byte string (i.e. `isinstance(s, str)` is true), then *charset* is the encoding of that byte string, and a [UnicodeError](#) will be raised if the string cannot be decoded with that character set.

If *s* is a Unicode string, then *charset* is a hint specifying the character set of the characters in the string. In this case, when producing an [RFC 2822](#)-compliant header using [RFC 2047](#) rules, the Unicode string will be encoded using the following charsets in order : *us-ascii*, the *charset* hint, *utf-8*. The first character set to not provoke a [UnicodeError](#) is used.

Optional *errors* is passed through to any [unicode\(\)](#) or `unicode.encode()` call, and defaults to « strict ».

**encode**([*splitchars*])

Encode a message header into an RFC-compliant format, possibly wrapping long lines and encapsulating non-ASCII parts in base64 or quoted-printable encodings. Optional *splitchars* is a string containing characters to split long ASCII lines on, in rough support of [RFC 2822](#)'s *highest level syntactic breaks*. This doesn't affect [RFC 2047](#) encoded lines.

The [Header](#) class also provides a number of methods to support standard operators and built-in functions.

**\_\_str\_\_**()

A synonym for [Header.encode\(\)](#). Useful for `str(aHeader)`.

**\_\_unicode\_\_**()

A helper for the built-in [unicode\(\)](#) function. Returns the header as a Unicode string.

**\_\_eq\_\_**(*other*)

This method allows you to compare two [Header](#) instances for equality.

**\_\_ne\_\_**(*other*)

This method allows you to compare two [Header](#) instances for inequality.

The [email.header](#) module also provides the following convenient functions.

**email.header.decode\_header**(*header*)

Decode a message header value without converting the character set. The header value is in *header*.

This function returns a list of (*decoded\_string*, *charset*) pairs containing each of the decoded parts of the header. *charset* is *None* for non-encoded parts of the header, otherwise a lower case string containing the name of the character set specified in the encoded string.

Here's an example :

```
>>> from email.header import decode_header
>>> decode_header('=?iso-8859-1?q?p=F6stal?='')
[('p\xF6stal', 'iso-8859-1')]
```

**email.header.make\_header**(*decoded\_seq*[, *maxlinelen*[, *header\_name*[, *continuation\_ws*]]])

Create a [Header](#) instance from a sequence of pairs as returned by [decode\\_header\(\)](#).

[decode\\_header\(\)](#) takes a header value string and returns a sequence of pairs of the format (*decoded\_string*, *charset*) where *charset* is the name of the character set.

This function takes one of those sequence of pairs and returns a *Header* instance. Optional *maxlinelen*, *header\_name*, and *continuation\_ws* are as in the *Header* constructor.

### 18.1.6 email.charset : Representing character sets

This module provides a class *Charset* for representing character sets and character set conversions in email messages, as well as a character set registry and several convenience methods for manipulating this registry. Instances of *Charset* are used in several other modules within the *email* package.

Import this class from the *email.charset* module.

Nouveau dans la version 2.2.2.

```
class email.charset.Charset([input_charset])
```

Map character sets to their email properties.

This class provides information about the requirements imposed on email for a specific character set. It also provides convenience routines for converting between character sets, given the availability of the applicable codecs. Given a character set, it will do its best to provide information on how to use that character set in an email message in an RFC-compliant way.

Certain character sets must be encoded with quoted-printable or base64 when used in email headers or bodies. Certain character sets must be converted outright, and are not allowed in email.

Optional *input\_charset* is as described below; it is always coerced to lower case. After being alias normalized it is also used as a lookup into the registry of character sets to find out the header encoding, body encoding, and output conversion codec to be used for the character set. For example, if *input\_charset* is *iso-8859-1*, then headers and bodies will be encoded using quoted-printable and no output conversion codec is necessary. If *input\_charset* is *euc-jp*, then headers will be encoded with base64, bodies will not be encoded, but output text will be converted from the *euc-jp* character set to the *iso-2022-jp* character set.

*Charset* instances have the following data attributes :

**input\_charset**

The initial character set specified. Common aliases are converted to their *official* email names (e.g. *latin\_1* is converted to *iso-8859-1*). Defaults to 7-bit *us-ascii*.

**header\_encoding**

If the character set must be encoded before it can be used in an email header, this attribute will be set to *Charset.QP* (for quoted-printable), *Charset.BASE64* (for base64 encoding), or *Charset.SHORTEST* for the shortest of QP or BASE64 encoding. Otherwise, it will be *None*.

**body\_encoding**

Same as *header\_encoding*, but describes the encoding for the mail message's body, which indeed may be different than the header encoding. *Charset.SHORTEST* is not allowed for *body\_encoding*.

**output\_charset**

Some character sets must be converted before they can be used in email headers or bodies. If the *input\_charset* is one of them, this attribute will contain the name of the character set output will be converted to. Otherwise, it will be *None*.

**input\_codec**

The name of the Python codec used to convert the *input\_charset* to Unicode. If no conversion codec is necessary, this attribute will be *None*.

**output\_codec**

The name of the Python codec used to convert Unicode to the *output\_charset*. If no conversion codec is necessary, this attribute will have the same value as the *input\_codec*.

*Charset* instances also have the following methods :

**get\_body\_encoding()**

Return the content transfer encoding used for body encoding.

This is either the string *quoted-printable* or *base64* depending on the encoding used, or it is a function, in which case you should call the function with a single argument, the Message object

being encoded. The function should then set the *Content-Transfer-Encoding* header itself to whatever is appropriate.

Returns the string `quoted-printable` if *body\_encoding* is `QP`, returns the string `base64` if *body\_encoding* is `BASE64`, and returns the string `7bit` otherwise.

**convert(*s*)**

Convert the string *s* from the *input\_codec* to the *output\_codec*.

**to\_splittable(*s*)**

Convert a possibly multibyte string to a safely splittable format. *s* is the string to split.

Uses the *input\_codec* to try and convert the string to Unicode, so it can be safely split on character boundaries (even for multibyte characters).

Returns the string as-is if it isn't known how to convert *s* to Unicode with the *input\_charset*.

Characters that could not be converted to Unicode will be replaced with the Unicode replacement character 'U+FFFD'.

**from\_splittable(*ustr*, *to\_output*)**

Convert a splittable string back into an encoded string. *ustr* is a Unicode string to « unsplit ».

This method uses the proper codec to try and convert the string from Unicode back into an encoded format. Return the string as-is if it is not Unicode, or if it could not be converted from Unicode.

Characters that could not be converted from Unicode will be replaced with an appropriate character (usually '?').

If *to\_output* is `True` (the default), uses *output\_codec* to convert to an encoded format. If *to\_output* is `False`, it uses *input\_codec*.

**get\_output\_charset()**

Return the output character set.

This is the *output\_charset* attribute if that is not `None`, otherwise it is *input\_charset*.

**encoded\_header\_len()**

Return the length of the encoded header string, properly calculating for quoted-printable or base64 encoding.

**header\_encode(*s*, *convert*)**

Header-encode the string *s*.

If *convert* is `True`, the string will be converted from the input charset to the output charset automatically. This is not useful for multibyte character sets, which have line length issues (multibyte characters must be split on a character, not a byte boundary); use the higher-level *Header* class to deal with these issues (see *email.header*). *convert* defaults to `False`.

The type of encoding (base64 or quoted-printable) will be based on the *header\_encoding* attribute.

**body\_encode(*s*, *convert*)**

Body-encode the string *s*.

If *convert* is `True` (the default), the string will be converted from the input charset to output charset automatically. Unlike *header\_encode()*, there are no issues with byte boundaries and multibyte charsets in email bodies, so this is usually pretty safe.

The type of encoding (base64 or quoted-printable) will be based on the *body\_encoding* attribute.

The *Charset* class also provides a number of methods to support standard operations and built-in functions.

**\_\_str\_\_()**

Returns *input\_charset* as a string coerced to lower case. *\_\_repr\_\_()* is an alias for *\_\_str\_\_()*.

**\_\_eq\_\_(*other*)**

This method allows you to compare two *Charset* instances for equality.

**\_\_ne\_\_(*other*)**

This method allows you to compare two *Charset* instances for inequality.

The *email.charset* module also provides the following functions for adding new entries to the global character set, alias, and codec registries :

```
email.charset.add_charset(charset[, header_enc[, body_enc[, output_charset]]])
```

Add character properties to the global registry.

*charset* is the input character set, and must be the canonical name of a character set.

Optional *header\_enc* and *body\_enc* is either `Charset.QP` for quoted-printable, `Charset.BASE64` for base64 encoding, `Charset.SHORTEST` for the shortest of quoted-printable or base64 encoding, or `None` for no encoding. `SHORTEST` is only valid for *header\_enc*. The default is `None` for no encoding.

Optional *output\_charset* is the character set that the output should be in. Conversions will proceed from input charset, to Unicode, to the output charset when the method `Charset.convert()` is called. The default is to output in the same character set as the input.

Both *input\_charset* and *output\_charset* must have Unicode codec entries in the module's character set-to-codec mapping; use `add_codec()` to add codecs the module does not know about. See the `codecs` module's documentation for more information.

The global character set registry is kept in the module global dictionary `CHARSETS`.

```
email.charset.add_alias(alias, canonical)
```

Add a character set alias. *alias* is the alias name, e.g. `latin-1`. *canonical* is the character set's canonical name, e.g. `iso-8859-1`.

The global charset alias registry is kept in the module global dictionary `ALIASES`.

```
email.charset.add_codec(charset, codecname)
```

Add a codec that map characters in the given character set to and from Unicode.

*charset* is the canonical name of a character set. *codecname* is the name of a Python codec, as appropriate for the second argument to the `unicode()` built-in, or to the `encode()` method of a Unicode string.

### 18.1.7 email.encoders : Encodeurs

Au moment de la création d'objets `Message` à la main, il est souvent nécessaire d'encoder les charges utiles pour le transport à travers des serveurs mail conformes. C'est particulièrement vrai pour les messages de type `image/*` et `text/*` contenant des données binaires.

Le paquet `email` fournit quelques encodeurs pratiques dans son module `encoders`. Ces encodeurs sont d'ailleurs utilisés par les constructeurs des classes `MIMEAudio` et `MIMEImage` afin de fournir des encodages par défaut. Toutes les fonctions d'encodage prennent exactement un argument, l'objet message à encoder. Généralement, elles extraient la charge utile, l'encodent, puis changent la charge utile pour la nouvelle valeur encodée. Elles devraient également assigner l'en-tête `Content-Transfer-Encoding` si besoin.

À noter que ces fonctions n'ont pas de sens dans le cadre d'un message en plusieurs parties. Elles doivent à la place être appliquées aux sous-parties individuelles, et lèvent `TypeError` si on leur passe un message en plusieurs parties.

Voici les fonctions d'encodages fournies :

```
email.encoders.encode_quopri(msg)
```

Encode la charge utile au format Quoted-Printable, et assigne `quoted-printable`<sup>1</sup> à l'en-tête `Content-Transfer-Encoding`. C'est un bon encodage à utiliser quand la majorité de la charge utile contient essentiellement des données imprimables, à l'exception de quelques caractères.

```
email.encoders.encode_base64(msg)
```

Encode la charge utile au format `base64`, et assigne `base64` à l'en-tête `Content-Transfer-Encoding`. C'est un bon encodage à utiliser quand la majorité de la charge utile est non imprimable puisque c'est une forme plus compacte que `quoted-printable`.

```
email.encoders.encode_7or8bit(msg)
```

Ceci ne modifie pas effectivement la charge utile du message, mais va bien en revanche assigner la valeur `7bit` ou `8bit` à l'en-tête `Content-Transfer-Encoding` selon la nature de la charge utile.

---

1. À noter que l'encodage avec `encode_quopri()` encode également tous les caractères tabulation et espace.

`email.encoders.encode_noop(msg)`

Ceci ne fait rien ; et ne va même pas changer la valeur de l'en-tête *Content-Transfer-Encoding*.

## Notes

### 18.1.8 email.errors : Exception and Defect classes

The following exception classes are defined in the `email.errors` module :

#### **exception email.errors.MessageError**

This is the base class for all exceptions that the `email` package can raise. It is derived from the standard `Exception` class and defines no additional methods.

#### **exception email.errors.MessageParseError**

This is the base class for exceptions raised by the `Parser` class. It is derived from `MessageError`.

#### **exception email.errors.HeaderParseError**

Raised under some error conditions when parsing the **RFC 2822** headers of a message, this class is derived from `MessageParseError`. It can be raised from the `Parser.parse` or `Parser.parsestr` methods.

Situations where it can be raised include finding an envelope header after the first **RFC 2822** header of the message, finding a continuation line before the first **RFC 2822** header is found, or finding a line in the headers which is neither a header or a continuation line.

#### **exception email.errors.BoundaryError**

Raised under some error conditions when parsing the **RFC 2822** headers of a message, this class is derived from `MessageParseError`. It can be raised from the `Parser.parse` or `Parser.parsestr` methods.

Situations where it can be raised include not being able to find the starting or terminating boundary in a *multipart/\** message when strict parsing is used.

#### **exception email.errors.MultipartConversionError**

Raised when a payload is added to a `Message` object using `add_payload()`, but the payload is already a scalar and the message's *Content-Type* main type is not either *multipart* or missing. `MultipartConversionError` multiply inherits from `MessageError` and the built-in `TypeError`.

Since `Message.add_payload()` is deprecated, this exception is rarely raised in practice. However the exception may also be raised if the `attach()` method is called on an instance of a class derived from `MIMENonMultipart` (e.g. `MIMEImage`).

Here's the list of the defects that the `FeedParser` can find while parsing messages. Note that the defects are added to the message where the problem was found, so for example, if a message nested inside a *multipart/alternative* had a malformed header, that nested message object would have a defect, but the containing messages would not.

All defect classes are subclassed from `email.errors.MessageDefect`, but this class is *not* an exception !

Nouveau dans la version 2.4 : All the defect classes were added.

- `NoBoundaryInMultipartDefect` – A message claimed to be a multipart, but had no *boundary* parameter.
- `StartBoundaryNotFoundDefect` – The start boundary claimed in the *Content-Type* header was never found.
- `FirstHeaderLineIsContinuationDefect` – The message had a continuation line as its first header line.
- `MisplacedEnvelopeHeaderDefect` – A « Unix From » header was found in the middle of a header block.
- `MalformedHeaderDefect` – A header was found that was missing a colon, or was otherwise malformed.

- `MultipartInvariantViolationDefect` – A message claimed to be a *multipart*, but no subparts were found. Note that when a message has this defect, its `is_multipart()` method may return false even though its content type claims to be *multipart*.

### 18.1.9 `email.utils` : Miscellaneous utilities

There are several useful utilities provided in the `email.utils` module :

`email.utils.quote(str)`

Return a new string with backslashes in *str* replaced by two backslashes, and double quotes replaced by backslash-double quote.

`email.utils.unquote(str)`

Return a new string which is an *unquoted* version of *str*. If *str* ends and begins with double quotes, they are stripped off. Likewise if *str* ends and begins with angle brackets, they are stripped off.

`email.utils.parseaddr(address)`

Parse address – which should be the value of some address-containing field such as *To* or *Cc* – into its constituent *realname* and *email address* parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple of ('', '') is returned.

`email.utils.formataddr(pair)`

The inverse of `parseaddr()`, this takes a 2-tuple of the form (*realname*, *email\_address*) and returns the string value suitable for a *To* or *Cc* header. If the first element of *pair* is false, then the second element is returned unmodified.

`email.utils.getaddresses(fieldvalues)`

This method returns a list of 2-tuples of the form returned by `parseaddr()`. *fieldvalues* is a sequence of header field values as might be returned by `Message.get_all`. Here's a simple example that gets all the recipients of a message :

```
from email.utils import getaddresses

tos = msg.get_all('to', [])
ccs = msg.get_all('cc', [])
resent_tos = msg.get_all('resent-to', [])
resent_ccs = msg.get_all('resent-cc', [])
all_recipients = getaddresses(tos + ccs + resent_tos + resent_ccs)
```

`email.utils.parsedate(date)`

Attempts to parse a date according to the rules in **RFC 2822**. however, some mailers don't follow that format as specified, so `parsedate()` tries to guess correctly in such cases. *date* is a string containing an **RFC 2822** date, such as "Mon, 20 Nov 1995 19:12:08 -0500". If it succeeds in parsing the date, `parsedate()` returns a 9-tuple that can be passed directly to `time.mktime()`; otherwise `None` will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

`email.utils.parsedate_tz(date)`

Performs the same function as `parsedate()`, but returns either `None` or a 10-tuple; the first 9 elements make up a tuple that can be passed directly to `time.mktime()`, and the tenth is the offset of the date's timezone from UTC (which is the official term for Greenwich Mean Time)<sup>1</sup>. If the input string has no timezone, the last element of the tuple returned is `None`. Note that indexes 6, 7, and 8 of the result tuple are not usable.

`email.utils.mktime_tz(tuple)`

Turn a 10-tuple as returned by `parsedate_tz()` into a UTC timestamp (seconds since the Epoch). If the timezone item in the tuple is `None`, assume local time.

---

1. Note that the sign of the timezone offset is the opposite of the sign of the `time.timezone` variable for the same timezone; the latter variable follows the POSIX standard while this module follows **RFC 2822**.

`email.utils.formatdate([timeval[, localtime[, usegmt]])`

Returns a date string as per [RFC 2822](#), e.g. :

```
Fri, 09 Nov 2001 01:08:47 -0000
```

Optional *timeval* if given is a floating point time value as accepted by `time.gmtime()` and `time.localtime()`, otherwise the current time is used.

Optional *localtime* is a flag that when `True`, interprets *timeval*, and returns a date relative to the local timezone instead of UTC, properly taking daylight savings time into account. The default is `False` meaning UTC is used.

Optional *usegmt* is a flag that when `True`, outputs a date string with the timezone as an ascii string GMT, rather than a numeric -0000. This is needed for some protocols (such as HTTP). This only applies when *localtime* is `False`. The default is `False`.

Nouveau dans la version 2.4.

`email.utils.make_msgid([idstring])`

Returns a string suitable for an [RFC 2822](#)-compliant *Message-ID* header. Optional *idstring* if given, is a string used to strengthen the uniqueness of the message id.

`email.utils.decode_rfc2231(s)`

Decode the string *s* according to [RFC 2231](#).

`email.utils.encode_rfc2231(s[, charset[, language]])`

Encode the string *s* according to [RFC 2231](#). Optional *charset* and *language*, if given is the character set name and language name to use. If neither is given, *s* is returned as-is. If *charset* is given but *language* is not, the string is encoded using the empty string for *language*.

`email.utils.collapse_rfc2231_value(value[, errors[, fallback_charset]])`

When a header parameter is encoded in [RFC 2231](#) format, `Message.get_param` may return a 3-tuple containing the character set, language, and value. `collapse_rfc2231_value()` turns this into a unicode string. Optional *errors* is passed to the *errors* argument of the built-in `unicode()` function; it defaults to `replace`. Optional *fallback\_charset* specifies the character set to use if the one in the [RFC 2231](#) header is not known by Python; it defaults to `us-ascii`.

For convenience, if the *value* passed to `collapse_rfc2231_value()` is not a tuple, it should be a string and it is returned unquoted.

`email.utils.decode_params(params)`

Decode parameters list according to [RFC 2231](#). *params* is a sequence of 2-tuples containing elements of the form (content-type, string-value).

Modifié dans la version 2.4 : The `dump_address_pair()` function has been removed; use `formataddr()` instead.

Modifié dans la version 2.4 : The `decode()` function has been removed; use the `Header.decode_header` method instead.

Modifié dans la version 2.4 : The `encode()` function has been removed; use the `Header.encode` method instead.

### 18.1.10 email.iterators : Itérateurs

Itérer sur l'arborescence d'un objet message est plutôt simple avec la méthode `Message.walk`. Le module `email.iterators` fournit des fonctionnalités d'itérations de plus haut niveau sur les arbres d'objets messages.

`email.iterators.body_line_iterator(msg[, decode])`

Cette fonction permet d'itérer sur tous les contenus de tous les éléments de *msg*, en retournant les contenus sous forme de chaînes de caractères ligne par ligne. Il saute les entêtes des sous éléments, et

tous les sous éléments dont le contenu n'est pas une chaîne de caractères Python. C'est en quelque sorte équivalent à une lecture plate d'une représentation textuelle du message à partir d'un fichier en utilisant `readline()`, et en sautant toutes les entêtes intermédiaires.

Le paramètre optionnel `decode` est transmis à la méthode `Message.get_payload`.

`email.iterators.typed_subpart_iterator(msg[, maintype[, subtype]])`

Cette fonction permet d'itérer sur tous les sous éléments de `msg`, en retournant seulement les sous éléments qui correspondent au type MIME spécifié par `maintype` et `subtype`.

Notez que le paramètre `subtype` est optionnel ; s'il n'est pas présent, alors le type MIME du sous élément est seulement composé du type principal. `maintype` est également optionnel ; sa valeur par défaut est `text`.

En conséquence, par défaut, `typed_subpart_iterator()` retourne chaque sous élément qui a un type MIME de type `text/*`.

La fonction suivante a été ajoutée en tant qu'un outil de débogage. Elle *ne devrait pas* être considérée comme une interface publique supportée pour ce paquet.

`email.iterators._structure(msg[, fp[, level]])`

Prints an indented representation of the content types of the message object structure. For example :

```
>>> msg = email.message_from_file(somefile)
>>> _structure(msg)
multipart/mixed
  text/plain
  text/plain
  multipart/digest

```

Optional `fp` is a file-like object to print the output to. It must be suitable for Python's extended print statement. `level` is used internally.

### 18.1.11 email : Exemples

Cette page contient quelques exemples de l'utilisation du package `email` pour lire, écrire, et envoyer de simples messages mail, ainsi que des messages MIME plus complexes.

First, let's see how to create and send a simple text message :

```
# Import smtplib for the actual sending function
import smtplib

# Import the email modules we'll need
from email.mime.text import MIMEText

# Open a plain text file for reading. For this example, assume that
```

(suite sur la page suivante)

(suite de la page précédente)

```
# the text file contains only ASCII characters.
fp = open(textfile, 'rb')
# Create a text/plain message
msg = MIMEText(fp.read())
fp.close()

# me == the sender's email address
# you == the recipient's email address
msg['Subject'] = 'The contents of %s' % textfile
msg['From'] = me
msg['To'] = you

# Send the message via our own SMTP server, but don't include the
# envelope header.
s = smtplib.SMTP('localhost')
s.sendmail(me, [you], msg.as_string())
s.quit()
```

And parsing RFC822 headers can easily be done by the `parse(filename)` or `parsestr(message_as_string)` methods of the `Parser()` class :

```
# Import the email modules we'll need
from email.parser import Parser

# If the e-mail headers are in a file, uncomment this line:
#headers = Parser().parse(open(messagefile, 'r'))

# Or for parsing headers in a string, use:
headers = Parser().parsestr('From: <user@example.com>\n'
    'To: <someone_else@example.com>\n'
    'Subject: Test message\n'
    '\n'
    'Body would go here\n')

# Now the header items can be accessed as a dictionary:
print 'To: %s' % headers['to']
print 'From: %s' % headers['from']
print 'Subject: %s' % headers['subject']
```

Voici un exemple de l'envoi d'un message MIME contenant une série de photos de famille qui sont stockés ensemble dans un dossier :

```
# Import smtplib for the actual sending function
import smtplib

# Here are the email package modules we'll need
from email.mime.image import MIMEImage
from email.mime.multipart import MIMEMultipart

COMMASPACE = ', '

# Create the container (outer) email message.
```

(suite sur la page suivante)

(suite de la page précédente)

```

msg = MIMEMultipart()
msg['Subject'] = 'Our family reunion'
# me == the sender's email address
# family = the list of all recipients' email addresses
msg['From'] = me
msg['To'] = COMMASPACE.join(family)
msg.preamble = 'Our family reunion'

# Assume we know that the image files are all in PNG format
for file in pngfiles:
    # Open the files in binary mode. Let the MIMEImage class automatically
    # guess the specific image type.
    fp = open(file, 'rb')
    img = MIMEImage(fp.read())
    fp.close()
    msg.attach(img)

# Send the email via our own SMTP server.
s = smtplib.SMTP('localhost')
s.sendmail(me, family, msg.as_string())
s.quit()

```

Voici un exemple d'envoi du contenu d'un dossier entier en tant que message mail :<sup>1</sup>

```

#!/usr/bin/env python

"""Send the contents of a directory as a MIME message."""

import os
import sys
import smtplib
# For guessing MIME type based on file name extension
import mimetypes

from optparse import OptionParser

from email import encoders
from email.message import Message
from email.mime.audio import MIMEAudio
from email.mime.base import MIMEBase
from email.mime.image import MIMEImage
from email.mime.multipart import MIMEMultipart
from email.mime.text import MIMEText

COMMASPACE = ', '

def main():
    parser = OptionParser(usage="""\
Send the contents of a directory as a MIME message.

```

(suite sur la page suivante)

1. Merci à Matthew Dixon Cowles pour l'inspiration originale et les exemples.

(suite de la page précédente)

Usage: %prog [options]

Unless the -o option is given, the email is sent by forwarding to your local SMTP server, which then does the normal delivery process. Your local machine must be running an SMTP server.

```

"""
    parser.add_option('-d', '--directory',
                      type='string', action='store',
                      help="""Mail the contents of the specified directory,
                      otherwise use the current directory. Only the regular
                      files in the directory are sent, and we don't recurse to
                      subdirectories.""")
    parser.add_option('-o', '--output',
                      type='string', action='store', metavar='FILE',
                      help="""Print the composed message to FILE instead of
                      sending the message to the SMTP server.""")
    parser.add_option('-s', '--sender',
                      type='string', action='store', metavar='SENDER',
                      help='The value of the From: header (required)')
    parser.add_option('-r', '--recipient',
                      type='string', action='append', metavar='RECIPIENT',
                      default=[], dest='recipients',
                      help='A To: header value (at least one required)')

    opts, args = parser.parse_args()
    if not opts.sender or not opts.recipients:
        parser.print_help()
        sys.exit(1)
    directory = opts.directory
    if not directory:
        directory = '.'
    # Create the enclosing (outer) message
    outer = MIMEMultipart()
    outer['Subject'] = 'Contents of directory %s' % os.path.abspath(directory)
    outer['To'] = COMMASPACE.join(opts.recipients)
    outer['From'] = opts.sender
    outer.preamble = 'You will not see this in a MIME-aware mail reader.\n'

    for filename in os.listdir(directory):
        path = os.path.join(directory, filename)
        if not os.path.isfile(path):
            continue
        # Guess the content type based on the file's extension. Encoding
        # will be ignored, although we should check for simple things like
        # gzip'd or compressed files.
        ctype, encoding = mimetypes.guess_type(path)
        if ctype is None or encoding is not None:
            # No guess could be made, or the file is encoded (compressed), so
            # use a generic bag-of-bits type.
            ctype = 'application/octet-stream'
        maintype, subtype = ctype.split('/', 1)
        if maintype == 'text':
            fp = open(path)

```

(suite sur la page suivante)

(suite de la page précédente)

```

    # Note: we should handle calculating the charset
    msg = MIMEText(fp.read(), _subtype=subtype)
    fp.close()

    msg = MIMEAudio(fp.read(), _subtype=subtype)
    fp.close()
else:
    fp = open(path, 'rb')
    msg = MIMEBase(maintype, subtype)
    msg.set_payload(fp.read())
    fp.close()
    # Encode the payload using Base64
    encoders.encode_base64(msg)
    # Set the filename parameter
    msg.add_header('Content-Disposition', 'attachment', filename=filename)
    outer.attach(msg)
# Now send or store the message
    composed = outer.as_string()
    if opts.output:
        fp = open(opts.output, 'w')
        fp.write(composed)
        fp.close()
    else:
        s = smtplib.SMTP('localhost')
        s.sendmail(opts.sender, opts.recipients, composed)
        s.quit()

if __name__ == '__main__':
    main()

```

Voici un message de comment décomposer un message MIME comme celui ci dessus en tant que fichiers dans un dossier :

```

#!/usr/bin/env python

"""Unpack a MIME message into a directory of files."""

import os
import sys
import email
import errno
import mimetypes

from optparse import OptionParser

```

(suite sur la page suivante)

(suite de la page précédente)

```

def main():
    parser = OptionParser(usage="""\
Unpack a MIME message into a directory of files.

Usage: %prog [options] msgfile
""")
    parser.add_option('-d', '--directory',
                      type='string', action='store',
                      help="""Unpack the MIME message into the named
                              directory, which will be created if it doesn't already
                              exist.""")
    opts, args = parser.parse_args()
    if not opts.directory:
        parser.print_help()
        sys.exit(1)

    try:
        msgfile = args[0]
    except IndexError:
        parser.print_help()
        sys.exit(1)

    try:
        os.mkdir(opts.directory)
    except OSError as e:
        # Ignore directory exists error
        if e.errno != errno.EEXIST:
            raise

    fp = open(msgfile)
    msg = email.message_from_file(fp)
    fp.close()

    counter = 1
    for part in msg.walk():
        # multipart/* are just containers
        if part.get_content_maintype() == 'multipart':
            continue
        # Applications should really sanitize the given filename so that an
        # email message can't be used to overwrite important files
        filename = part.get_filename()
        if not filename:
            ext = mimetypes.guess_extension(part.get_content_type())
            if not ext:
                # Use a generic bag-of-bits extension
                ext = '.bin'
            filename = 'part-%03d%s' % (counter, ext)
        counter += 1
        fp = open(os.path.join(opts.directory, filename), 'wb')
        fp.write(part.get_payload(decode=True))
        fp.close()

```

(suite sur la page suivante)

(suite de la page précédente)

```
if __name__ == '__main__':  
    main()
```

Here's an example of how to create an HTML message with an alternative plain text version :<sup>2</sup>

```
#!/usr/bin/env python  
  
import smtplib  
  
from email.mime.multipart import MIMEMultipart  
from email.mime.text import MIMEText  
  
# me == my email address  
# you == recipient's email address  
me = "my@email.com"  
you = "your@email.com"  
  
# Create message container - the correct MIME type is multipart/alternative.  
msg = MIMEMultipart('alternative')  
msg['Subject'] = "Link"  
msg['From'] = me  
msg['To'] = you  
  
# Create the body of the message (a plain-text and an HTML version).  
text = "Hi!\nHow are you?\nHere is the link you wanted:\nhttps://www.python.org"  
html = """\  
<html>  
  <head></head>  
  <body>  
    <p>Hi!<br>  
      How are you?<br>  
      Here is the <a href="https://www.python.org">link</a> you wanted.  
    </p>  
  </body>  
</html>  
"""  
  
# Record the MIME types of both parts - text/plain and text/html.  
part1 = MIMEText(text, 'plain')  
part2 = MIMEText(html, 'html')  
  
# Attach parts into message container.  
# According to RFC 2046, the last part of a multipart message, in this case  
# the HTML message, is best and preferred.  
msg.attach(part1)  
msg.attach(part2)  
  
# Send the message via local SMTP server.  
s = smtplib.SMTP('localhost')  
# sendmail function takes 3 arguments: sender's address, recipient's address
```

(suite sur la page suivante)

## 18.1.12 Package History

This table describes the release history of the email package, corresponding to the version of Python that the package was released with. For purposes of this document, when you see a note about change or added versions, these refer to the Python version the change was made in, *not* the email package version. This table also describes the Python compatibility of each version of the package.

email version	distributed with	compatible with
1.x	Python 2.2.0 à Python 2.2.1	<i>no longer supported</i>
2.5	Python 2.2.2+ et Python 2.3	Python 2.1 à 2.5
3.0	Python 2.4	Python 2.3 to 2.5
4.0	Python 2.5	Python 2.3 to 2.5

Here are the major differences between `email` version 4 and version 3 :

- All modules have been renamed according to [PEP 8](#) standards. For example, the version 3 module `email.Message` was renamed to `email.message` in version 4.
- A new subpackage `email.mime` was added and all the version 3 `email.MIME*` modules were renamed and situated into the `email.mime` subpackage. For example, the version 3 module `email.MIMEText` was renamed to `email.mime.text`.  
*Note that the version 3 names will continue to work until Python 2.6.*
- The `email.mime.application` module was added, which contains the `MIMEApplication` class.
- Methods that were deprecated in version 3 have been removed. These include `Generator.__call__()`, `Message.get_type()`, `Message.get_main_type()`, `Message.get_subtype()`.
- Fixes have been added for [RFC 2231](#) support which can change some of the return types for `Message.get_param` and friends. Under some circumstances, values which used to return a 3-tuple now return simple strings (specifically, if all extended parameter segments were unencoded, there is no language and charset designation expected, so the return type is now a simple string). Also, %-decoding used to be done for both encoded and unencoded segments; this decoding is now done only for encoded segments.

Here are the major differences between `email` version 3 and version 2 :

- The `FeedParser` class was introduced, and the `Parser` class was implemented in terms of the `FeedParser`. All parsing therefore is non-strict, and parsing will make a best effort never to raise an exception. Problems found while parsing messages are stored in the message's `defect` attribute.
- All aspects of the API which raised `DeprecationWarnings` in version 2 have been removed. These include the `__encoder` argument to the `MIMEText` constructor, the `Message.add_payload()` method, the `Utils.dump_address_pair()` function, and the functions `Utils.decode()` and `Utils.encode()`.
- New `DeprecationWarnings` have been added to : `Generator.__call__()`, `Message.get_type()`, `Message.get_main_type()`, `Message.get_subtype()`, and the `strict` argument to the `Parser` class. These are expected to be removed in future versions.
- Support for Pythons earlier than 2.3 has been removed.

Here are the differences between `email` version 2 and version 1 :

- The `email.Header` and `email.Charset` modules have been added.
- The pickle format for `Message` instances has changed. Since this was never (and still isn't) formally defined, this isn't considered a backward incompatibility. However if your application pickles and unpickles `Message` instances, be aware that in `email` version 2, `Message` instances now have private variables `__charset` and `__default_type`.
- Several methods in the `Message` class have been deprecated, or their signatures changed. Also, many new methods have been added. See the documentation for the `Message` class for details. The changes should be completely backward compatible.
- The object structure has changed in the face of `message/rfc822` content types. In `email` version 1, such a type would be represented by a scalar payload, i.e. the container message's `is_multipart()` returned false, `get_payload()` was not a list object, but a single `Message` instance. This structure was inconsistent with the rest of the package, so the object representation for `message/rfc822` content types was changed. In `email` version 2, the container *does* return True from `is_multipart()`, and `get_payload()` returns a list containing a single `Message` item. Note that this is one place that backward compatibility could not be completely maintained. However, if you're already testing the return type of `get_payload()`, you should be fine. You just need to make sure your code doesn't do a `set_payload()` with a `Message` instance on a container with a content type of `message/rfc822`.
- The `Parser` constructor's `strict` argument was added, and its `parse()` and `parsestr()` methods grew a `headersonly` argument. The `strict` flag was also added to functions `email.message_from_file()` and `email.message_from_string()`.
- `Generator.__call__()` is deprecated; use `Generator.flatten` instead. The `Generator` class has also grown the `clone()` method.
- The `DecodedGenerator` class in the `email.generator` module was added.
- The intermediate base classes `MIMENonMultipart` and `MIMEMultipart` have been added, and interposed in the class hierarchy for most of the other MIME-related derived classes.
- The `__encoder` argument to the `MIMEText` constructor has been deprecated. Encoding now happens implicitly based on the `__charset` argument.
- The following functions in the `email.Utils` module have been deprecated : `dump_address_pairs()`, `decode()`, and `encode()`. The following functions have been added to the module : `make_msgid()`, `decode_rfc2231()`, `encode_rfc2231()`, and `decode_params()`.
- The non-public function `email.Iterators._structure()` was added.

### 18.1.13 Differences from `mimelib`

The `email` package was originally prototyped as a separate library called `mimelib`. Changes have been made so that method names are more consistent, and some methods or modules have either been added or removed. The semantics of some of the methods have also changed. For the most part, any functionality available in `mimelib` is still available in the `email` package, albeit often in a different way. Backward compatibility between the `mimelib` package and the `email` package was not a priority.

Here is a brief description of the differences between the `mimelib` and the `email` packages, along with hints on how to port your applications.

Of course, the most visible difference between the two packages is that the package name has been changed to `email`. In addition, the top-level package has the following differences :

- `messageFromString()` has been renamed to `message_from_string()`.
- `messageFromFile()` has been renamed to `message_from_file()`.

The `Message` class has the following differences :

- The method `asString()` was renamed to `as_string()`.
- The method `ismultipart()` was renamed to `is_multipart()`.
- The `get_payload()` method has grown a `decode` optional argument.
- The method `getall()` was renamed to `get_all()`.
- The method `addheader()` was renamed to `add_header()`.
- The method `gettype()` was renamed to `get_type()`.

- The method `getmaintype()` was renamed to `get_main_type()`.
- The method `getsubtype()` was renamed to `get_subtype()`.
- The method `getparams()` was renamed to `get_params()`. Also, whereas `getparams()` returned a list of strings, `get_params()` returns a list of 2-tuples, effectively the key/value pairs of the parameters, split on the '=' sign.
- The method `getparam()` was renamed to `get_param()`.
- The method `getcharsets()` was renamed to `get_charsets()`.
- The method `getfilename()` was renamed to `get_filename()`.
- The method `getboundary()` was renamed to `get_boundary()`.
- The method `setboundary()` was renamed to `set_boundary()`.
- The method `getdecodedpayload()` was removed. To get similar functionality, pass the value 1 to the `decode` flag of the `get_payload()` method.
- The method `getpayloadastext()` was removed. Similar functionality is supported by the `DecodedGenerator` class in the `email.generator` module.
- The method `getbodyastext()` was removed. You can get similar functionality by creating an iterator with `typed_subpart_iterator()` in the `email.iterators` module.

The `Parser` class has no differences in its public interface. It does have some additional smarts to recognize `message/delivery-status` type messages, which it represents as a `Message` instance containing separate `Message` subparts for each header block in the delivery status notification<sup>1</sup>.

The `Generator` class has no differences in its public interface. There is a new class in the `email.generator` module though, called `DecodedGenerator` which provides most of the functionality previously available in the `Message.getpayloadastext()` method.

The following modules and classes have been changed :

- The `MIMEBase` class constructor arguments `__major` and `__minor` have changed to `__maintype` and `__subtype` respectively.
- The `Image` class/module has been renamed to `MIMEImage`. The `__minor` argument has been renamed to `__subtype`.
- The `Text` class/module has been renamed to `MIMEText`. The `__minor` argument has been renamed to `__subtype`.
- The `MessageRFC822` class/module has been renamed to `MIMEMessage`. Note that an earlier version of `mimelib` called this class/module `RFC822`, but that clashed with the Python standard library module `rfc822` on some case-insensitive file systems.  
Also, the `MIMEMessage` class now represents any kind of MIME message with main type `message`. It takes an optional argument `__subtype` which is used to set the MIME subtype. `__subtype` defaults to `rfc822`.

`mimelib` provided some utility functions in its `address` and `date` modules. All of these functions have been moved to the `email.utils` module.

The `MsgReader` class/module has been removed. Its functionality is most closely supported in the `body_line_iterator()` function in the `email.iterators` module.

## Notes

## 18.2 json — Encodage et décodage JSON

Nouveau dans la version 2.6.

JSON (JavaScript Object Notation), spécifié par la **RFC 7159** (qui rend la **RFC 4627** obsolète) et par le standard **ECMA-404**, est une interface légère d'échange de données inspirée par la syntaxe des objets littéraux JavaScript (bien que ce ne soit pas un sous-ensemble strict de Javascript<sup>1</sup>).

1. Delivery Status Notifications (DSN) are defined in **RFC 1894**.

1. Comme noté dans l'errata de la **RFC 7159**, JSON autorise les caractères littéraux U+2028 (*LINE SEPARATOR*) et U+2029 (*PARAGRAPH SEPARATOR*) dans les chaînes de caractères, alors que Javascript (selon le standard ECMA Script édition 5.1) ne le permet pas.

*json* expose une API familière aux utilisateurs des modules de la bibliothèque standard *marshal* et *pickle*.

Encodage d'objets Python basiques :

```
>>> import json
>>> json.dumps(['foo', {'bar': ('baz', None, 1.0, 2)}})
'["foo", {"bar": ["baz", null, 1.0, 2]}]'
>>> print json.dumps("\"foo\\bar\"")
\"foo\\bar\"
>>> print json.dumps(u'\\u1234')
\"\\u1234\"
>>> print json.dumps('\\\\')
\"\\\\\"
>>> print json.dumps({'c': 0, "b": 0, "a": 0}, sort_keys=True)
{"a": 0, "b": 0, "c": 0}
>>> from StringIO import StringIO
>>> io = StringIO()
>>> json.dump(['streaming API'], io)
>>> io.getvalue()
'["streaming API"]'
```

Encodage compact :

```
>>> import json
>>> json.dumps([1,2,3,{ '4': 5, '6': 7}], separators=(',', ':'))
'[1,2,3,{"4":5,"6":7}]'
```

Affichage élégant :

```
>>> import json
>>> print json.dumps({'4': 5, '6': 7}, sort_keys=True,
...                  indent=4, separators=(',', ': '))
{
    "4": 5,
    "6": 7
}
```

Décodage JSON :

```
>>> import json
>>> json.loads('["foo", {"bar":["baz", null, 1.0, 2]}]')
[u'foo', {'bar': [u'baz', None, 1.0, 2]}]
>>> json.loads('\"\\\"foo\\bar\"')
u'foo\\x08ar'
>>> from StringIO import StringIO
>>> io = StringIO('["streaming API"]')
>>> json.load(io)
[u'streaming API']
```

Spécialisation du décodage JSON pour un objet :

```
>>> import json
>>> def as_complex(dct):
...     if '__complex__' in dct:
...         return complex(dct['real'], dct['imag'])
```

(suite sur la page suivante)

(suite de la page précédente)

```

...     return dct
...
>>> json.loads('{"__complex__": true, "real": 1, "imag": 2}',
...     object_hook=as_complex)
(1+2j)
>>> import decimal
>>> json.loads('1.1', parse_float=decimal.Decimal)
Decimal('1.1')

```

Étendre la classe `JSONEncoder` :

```

>>> import json
>>> class ComplexEncoder(json.JSONEncoder):
...     def default(self, obj):
...         if isinstance(obj, complex):
...             return [obj.real, obj.imag]
...         # Let the base class default method raise the TypeError
...         return json.JSONEncoder.default(self, obj)
...
>>> json.dumps(2 + 1j, cls=ComplexEncoder)
'[2.0, 1.0]'
>>> ComplexEncoder().encode(2 + 1j)
'[2.0, 1.0]'
>>> list(ComplexEncoder().iterencode(2 + 1j))
['[', '2.0', ',', '1.0', ']']

```

Utiliser `json.tool` depuis la *shell* pour valider et afficher élégamment :

```

$ echo '{"json":"obj"}' | python -m json.tool
{
  "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json.tool
Expecting property name enclosed in double quotes: line 1 column 2 (char 1)

```

**Note :** JSON est un sous-ensemble de [YAML 1.2](#). Le JSON produit par les paramètres par défaut de ce module (en particulier, la valeur par défaut de *separators*) est aussi un sous ensemble de [YAML 1.0](#) et [1.1](#). Ce module peut alors aussi être utilisé comme sérialiseur [YAML](#).

### 18.2.1 Utilisation basique

```

json.dump(obj, fp, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True,
          cls=None, indent=None, separators=None, encoding="utf-8", default=None,
          sort_keys=False, **kw)

```

Sérialise *obj* comme un flux JSON formaté vers *fp* (un *file-like object* gérant `.write()`) utilisant cette *table de conversion*.

If *skipkeys* is true (default : `False`), then dict keys that are not of a basic type (*str*, *unicode*, *int*, *long*, *float*, *bool*, `None`) will be skipped instead of raising a *TypeError*.

If *ensure\_ascii* is true (the default), all non-ASCII characters in the output are escaped with `\uXXXX` sequences, and the result is a *str* instance consisting of ASCII characters only. If *ensure\_ascii* is false, some chunks written to *fp* may be *unicode* instances. This usually happens because the input contains

unicode strings or the *encoding* parameter is used. Unless `fp.write()` explicitly understands *unicode* (as in `codecs.getwriter()`) this is likely to cause an error.

Si *check\_circular* est faux (vrai par défaut), la vérification des références circulaires pour les conteneurs sera ignorée, et une référence circulaire résultera en une *OverflowError* (ou pire).

Si *allow\_nan* est faux (vrai par défaut), une *ValueError* sera levée lors de la sérialisation de valeurs *float* extérieures aux bornes (*nan*, *inf*, *-inf*), en respect strict de la spécification JSON. Si *allow\_nan* est vrai, leurs équivalents JavaScript (*NaN*, *Infinity*, *-Infinity*) seront utilisés.

If *indent* is a non-negative integer, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, or negative, will only insert newlines. *None* (the default) selects the most compact representation.

---

**Note :** Since the default item separator is `' '`, the output might include trailing whitespace when *indent* is specified. You can use `separators=(',', ':')` to avoid this.

---

If specified, *separators* should be an (*item\_separator*, *key\_separator*) tuple. By default, `(' ', ':')` are used. To get the most compact JSON representation, you should specify `(' ', ':')` to eliminate whitespace.

*encoding* is the character encoding for str instances, default is UTF-8.

Si spécifié, *default* doit être une fonction qui sera appelée pour les objets qui ne peuvent être sérialisés autrement. Elle doit renvoyer une représentation de l'objet sérialisable en JSON ou lever une *TypeError*. Si non spécifié, une *TypeError* sera levée pour les types non sérialisables.

Si *sort\_keys* est vrai (faux par défaut), les dictionnaires seront retranscrits triés selon leurs clés.

Pour utiliser une sous-classe *JSONEncoder* personnalisée (p. ex. une qui redéfinit la méthode `default()` pour sérialiser des types additionnels), spécifiez-la avec le paramètre nommé *cls* ; autrement, *JSONEncoder* est utilisée.

---

**Note :** Unlike *pickle* and *marshal*, JSON is not a framed protocol so trying to serialize more objects with repeated calls to `dump()` and the same *fp* will result in an invalid JSON file.

---

```
json.dumps(obj, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True,
           cls=None, indent=None, separators=None, encoding="utf-8", default=None,
           sort_keys=False, **kw)
```

Serialize *obj* to a JSON formatted *str* using this *conversion table*. If *ensure\_ascii* is false, the result may contain non-ASCII characters and the return value may be a *unicode* instance.

The arguments have the same meaning as in `dump()`.

---

**Note :** Les clés dans les couples JSON clé/valeur sont toujours de type *str*. Quand un dictionnaire est converti en JSON, toutes les clés du dictionnaire sont transformées en chaînes de caractères. Ce qui fait que si un dictionnaire est converti en JSON et reconverti en dictionnaire, le résultat peut ne pas être égal à l'original. Ainsi, `loads(dumps(x)) != x` si *x* contient des clés qui ne sont pas des chaînes.

---

```
json.load(fp[, encoding[, cls[, object_hook[, parse_float[, parse_int[, parse_constant[, ob-
           ject_pairs_hook[, **kw]]]]]]]])
```

Désérialise *fp* (un *file-like object* supportant `.read()`, contenant un document JSON) vers un objet Python en utilisant cette *table de conversion*.

If the contents of *fp* are encoded with an ASCII based encoding other than UTF-8 (e.g. latin-1), then an appropriate *encoding* name must be specified. Encodings that are not ASCII based (such as UCS-2) are not allowed, and should be wrapped with `codecs.getreader(encoding)(fp)`, or simply decoded to a *unicode* object and passed to `loads()`.

*object\_hook* est une fonction optionnelle qui sera appelée avec le résultat de chaque objet littéral décodé (chaque *dict*). La valeur de retour de *object\_hook* sera utilisée à la place du *dict*. Cette fonctionnalité peut être utilisée pour implémenter des décodeurs personnalisés (p. ex. les *class hinting* de *JSON-RPC*).

*object\_pairs\_hook* est une fonction optionnelle qui sera appelé pour chaque objet littéral décodé, avec une liste ordonnée de couples. La valeur de retour de *object\_pairs\_hook* sera utilisée à la place du *dict*. Cette fonctionnalité peut être utilisée pour implémenter des décodeurs personnalisés qui s'appuient sur l'ordre dans lequel les couples clé/valeur sont décodés (par exemple, *collections.OrderedDict()* mémorise l'ordre d'insertion). *object\_pairs\_hook* prend la priorité sur *object\_hook*, si cette dernière est aussi définie.

Modifié dans la version 2.7 : Ajout du support de *object\_pairs\_hook*.

*parse\_float*, si spécifiée, sera appelée pour chaque nombre réel JSON à décoder sous forme d'une chaîne de caractères. Par défaut, elle est équivalente à *float(num\_str)*. Cela peut servir à utiliser un autre type de données ou un autre analyseur pour les nombres réels JSON (p. ex. *decimal.Decimal*).

*parse\_int*, si spécifiée, sera appelée pour chaque nombre entier JSON à décoder sous forme d'une chaîne de caractères. Par défaut, elle est équivalente à *int(num\_str)*. Cela peut servir à utiliser un autre type de données ou un autre analyseur pour les nombres entiers JSON (p. ex. *float*).

*parse\_constant*, si spécifiée, sera appelée avec l'une des chaînes de caractères suivantes : *'-Infinity'*, *'Infinity'* ou *'NaN'*. Cela peut servir à lever une exception si des nombres JSON invalides sont rencontrés.

Modifié dans la version 2.7 : *parse\_constant* n'est plus appelée pour *null*, *true* ou *false*.

Pour utiliser une sous-classe *JSONDecoder* personnalisée, spécifiez-la avec l'argument nommé *cls* ; autrement, *JSONDecoder* est utilisée. Les arguments nommés additionnels seront passés au constructeur de cette classe.

```
json.loads(s[, encoding[, cls[, object_hook[, parse_float[, parse_int[, parse_constant[, ob-
ject_pairs_hook[, **kw]]]]]]]])
```

Deserialize *s* (a *str* or *unicode* instance containing a JSON document) to a Python object using this *conversion table*.

If *s* is a *str* instance and is encoded with an ASCII based encoding other than UTF-8 (e.g. latin-1), then an appropriate *encoding* name must be specified. Encodings that are not ASCII based (such as UCS-2) are not allowed and should be decoded to *unicode* first.

The other arguments have the same meaning as in *load()*.

## 18.2.2 Encodeurs et décodeurs

```
class json.JSONDecoder([encoding[, object_hook[, parse_float[, parse_int[, parse_constant[,
strict[, object_pairs_hook]]]]]])
```

Décodeur simple JSON.

Applique par défaut les conversions suivantes en décodant :

JSON	Python
objet	<i>dict</i>
<i>array</i>	<i>list</i>
<i>string</i>	unicode
<i>number</i> (nombre entier)	int, long
<i>number</i> (nombre réel)	<i>float</i>
<i>true</i>	<i>True</i>
<i>false</i>	<i>False</i>
<i>null</i>	<i>None</i>

Les valeurs NaN, Infinity et -Infinity sont aussi comprises comme leurs valeurs *float* correspondantes, bien que ne faisant pas partie de la spécification JSON.

*encoding* determines the encoding used to interpret any *str* objects decoded by this instance (UTF-8 by default). It has no effect when decoding *unicode* objects.

Note that currently only encodings that are a superset of ASCII work, strings of other encodings should be passed in as *unicode*.

*object\_hook*, si spécifiée, sera appelée avec le résultat de chaque objet JSON décodé et sa valeur de retour sera utilisée à la place du *dict* donné. Cela peut être utilisé pour apporter des désérialisations personnalisées (p. ex. pour supporter les *class hinting* de JSON-RPC).

*object\_pairs\_hook*, si spécifiée, sera appelée avec le résultat de chaque objet JSON décodé avec une liste ordonnée de couples. Sa valeur de retour sera utilisée à la place du *dict*. Cette fonctionnalité peut être utilisée pour implémenter des décodeurs personnalisés se basant sur l'ordre dans lequel les couples clé/valeur sont décodés (par exemple, *collections.OrderedDict()* mémoriserait l'ordre d'insertion). *object\_pairs\_hook* prend la priorité sur *object\_hook*, si cette dernière est aussi définie.

Modifié dans la version 2.7 : Ajout du support de *object\_pairs\_hook*.

*parse\_float*, si spécifiée, sera appelée pour chaque nombre réel JSON à décoder sous forme d'une chaîne de caractères. Par défaut, elle est équivalente à *float(num\_str)*. Cela peut servir à utiliser un autre type de données ou un autre analyseur pour les nombres réels JSON (p. ex. *decimal.Decimal*).

*parse\_int*, si spécifiée, sera appelée pour chaque nombre entier JSON à décoder sous forme d'une chaîne de caractères. Par défaut, elle est équivalente à *int(num\_str)*. Cela peut servir à utiliser un autre type de données ou un autre analyseur pour les nombres entiers JSON (p. ex. *float*).

*parse\_constant*, si spécifiée, sera appelée avec l'une des chaînes de caractères suivantes : *'-Infinity'*, *'Infinity'* ou *'NaN'*. Cela peut servir à lever une exception si des nombres JSON invalides sont rencontrés.

If *strict* is false (*True* is the default), then control characters will be allowed inside strings. Control characters in this context are those with character codes in the 0–31 range, including *'\t'* (tab), *'\n'*, *'\r'* and *'\0'*.

If the data being deserialized is not a valid JSON document, a *ValueError* will be raised.

**decode(s)**

Return the Python representation of *s* (a *str* or *unicode* instance containing a JSON document).

**raw\_decode(s)**

Decode a JSON document from *s* (a *str* or *unicode* beginning with a JSON document) and return a 2-tuple of the Python representation and the index in *s* where the document ended.

Elle peut être utilisée pour décoder un document JSON depuis une chaîne qui peut contenir des données supplémentaires à la fin.

```
class json.JSONEncoder([skipkeys[, ensure_ascii[, check_circular[, allow_nan[, sort_keys[,
                        indent[, separators[, encoding[, default]]]]]]]])
```

Encodeur JSON extensible pour les structures de données Python.

Supporte par défaut les objets et types suivants :

Python	JSON
<i>dict</i>	objet
<i>list, tuple</i>	<i>array</i>
<i>str, unicode</i>	<i>string</i>
<i>int, long, float</i>	<i>number</i>
<i>True</i>	<i>true</i>
<i>False</i>	<i>false</i>
<i>None</i>	<i>null</i>

Pour l'étendre afin de reconnaître d'autres types d'objets, il suffit d'en créer une sous-classe et d'implémenter une nouvelle méthode *default()* qui renverrait si possible un objet sérialisable pour o, ou ferait appel à l'implémentation de la classe mère (qui lèverait une *TypeError*).

If *skipkeys* is false (the default), then it is a *TypeError* to attempt encoding of keys that are not *str*, *int*, *long*, *float* or *None*. If *skipkeys* is true, such items are simply skipped.

If *ensure\_ascii* is true (the default), all non-ASCII characters in the output are escaped with *\uXXXX* sequences, and the results are *str* instances consisting of ASCII characters only. If *ensure\_ascii* is false, a result may be a *unicode* instance. This usually happens if the input contains unicode strings or the *encoding* parameter is used.

Si `check_circular` est vrai (par défaut), une vérification aura lieu sur les listes, dictionnaires et objets personnalisés, afin de détecter les références circulaires et éviter les récursions infinies (qui causeraient une *OverflowError*). Autrement, la vérification n'a pas lieu.

Si `allow_nan` est vrai (par défaut), alors NaN, Infinity et -Infinity seront encodés comme tels. Ce comportement ne respecte pas la spécification JSON, mais est cohérent avec le majorité des encodeurs/décodeurs JavaScript. Autrement, une *ValueError* sera levée pour de telles valeurs.

Si `sort_keys` est vrai (**False** par défaut), alors les dictionnaires seront triés par clés en sortie ; cela est utile lors de tests de régression pour pouvoir comparer les sérialisations JSON au jour le jour.

If `indent` is a non-negative integer (it is **None** by default), then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0 will only insert newlines. **None** is the most compact representation.

---

**Note :** Since the default item separator is `' '`, the output might include trailing whitespace when `indent` is specified. You can use `separators=(',', ':')` to avoid this.

---

If specified, `separators` should be an (`item_separator`, `key_separator`) tuple. By default, `(' ', ': ')` are used. To get the most compact JSON representation, you should specify `(' ', ':')` to eliminate whitespace.

Si spécifié, `default` doit être une fonction qui sera appelée pour les objets qui ne peuvent être sérialisés autrement. Elle doit renvoyer une représentation de l'objet sérialisable en JSON ou lever une *TypeError*. Si non spécifié, une *TypeError* sera levée pour les types non sérialisables.

If `encoding` is not **None**, then all input strings will be transformed into unicode using that encoding prior to JSON-encoding. The default is UTF-8.

#### `default(o)`

Implémentez cette méthode dans une sous-classe afin qu'elle renvoie un objet sérialisable pour `o`, ou appelle l'implémentation de base (qui lèvera une *TypeError*).

Par exemple, pour supporter des itérateurs arbitraires, vous pourriez implémenter `default` comme cela :

```
def default(self, o):
    try:
        iterable = iter(o)
    except TypeError:
        pass
    else:
        return list(iterable)
    # Let the base class default method raise the TypeError
    return JSONEncoder.default(self, o)
```

#### `encode(o)`

Renvoie une chaîne JSON représentant la structure de données Python `o`. Par exemple :

```
>>> JSONEncoder().encode({"foo": ["bar", "baz"]})
'{"foo": ["bar", "baz"]}'
```

#### `iterencode(o)`

Encode l'objet `o` donné, et produit chaque chaîne représentant l'objet selon disponibilité. Par exemple :

```
for chunk in JSONEncoder().iterencode(bigobject):
    mysocket.write(chunk)
```

### 18.2.3 Conformité au standard et Interopérabilité

Le format JSON est spécifié par la [RFC 7159](#) et le standard [ECMA-404](#). Cette section détaille la conformité à la RFC au niveau du module. Pour faire simple, les sous-classes de *JSONEncoder* et *JSONDecoder*, et les paramètres autres que ceux explicitement mentionnés ne sont pas considérés.

Ce module ne se conforme pas strictement à la RFC, implémentant quelques extensions qui sont valides en JavaScript mais pas en JSON. En particulier :

- Les nombres infinis et *NaN* sont acceptés et retranscrits ;
- Les noms répétés au sein d'un objet sont acceptés, seule la valeur du dernier couple nom/valeur sera utilisée.

Comme la RFC permet aux analyseurs conformes d'accepter des textes en entrée non conformes, le désérialiseur de ce module avec ses paramètres par défaut est techniquement conforme à la RFC.

#### Encodage des caractères

The RFC requires that JSON be represented using either UTF-8, UTF-16, or UTF-32, with UTF-8 being the recommended default for maximum interoperability. Accordingly, this module uses UTF-8 as the default for its *encoding* parameter.

This module's deserializer only directly works with ASCII-compatible encodings; UTF-16, UTF-32, and other ASCII-incompatible encodings require the use of workarounds described in the documentation for the deserializer's *encoding* parameter.

Comme cela est permis par la RFC, bien que non requis, le sérialiseur du module active *ensure\_ascii=True* par défaut, échappant ainsi la sortie de façon à ce que les chaînes résultants ne contiennent que des caractères ASCII.

La RFC interdit d'ajouter un *byte* marqueur d'ordre (BOM) au début du texte JSON, et le sérialiseur de ce module n'ajoute pas de tel BOM. La RFC permet, mais ne requiert pas, que les désérialiseurs JSON ignorent ces BOM. Le désérialiseur de ce module lève une *ValueError* quand un BOM est présent au début du fichier.

La RFC n'interdit pas explicitement les chaînes JSON contenant des séquences de *bytes* ne correspondant à aucun caractère Unicode valide (p. ex. les *surrogates* UTF-16 sans correspondance), mais précise que cela peut causer des problèmes d'interopérabilité. Par défaut, ce module accepte et retranscrit (quand présents dans la *str* originale) les *code points* de telles séquences.

#### Valeurs numériques infinies et NaN

La RFC ne permet pas la représentation des nombres infinis ou des *NaN*. Néanmoins, par défaut, ce module accepte et retranscrit *Infinity*, *-Infinity* et *NaN* comme s'ils étaient des valeurs numériques littérales JSON valides :

```
>>> # Neither of these calls raises an exception, but the results are not valid JSON
>>> json.dumps(float('-inf'))
'-Infinity'
>>> json.dumps(float('nan'))
'NaN'
>>> # Same when deserializing
>>> json.loads('-Infinity')
-inf
>>> json.loads('NaN')
nan
```

Dans le sérialiseur, le paramètre *allow\_nan* peut être utilisé pour altérer ce comportement. Dans le désérialiseur, le paramètre *parse\_constant* peut être utilisé pour altérer ce comportement.

### Noms répétés au sein d'un objet

La RFC spécifie que les noms au sein d'un objet JSON doivent être uniques, mais ne décrit pas comment les noms répétés doivent être gérés. Par défaut, ce module ne lève pas d'exception ; à la place, il ignore tous les couples nom/valeur sauf le dernier pour un nom donné :

```
>>> weird_json = '{"x": 1, "x": 2, "x": 3}'
>>> json.loads(weird_json)
{'u'x': 3}
```

Le paramètre `object_pairs_hook` peut être utilisé pour altérer ce comportement.

### Valeurs de plus haut niveau autres qu'objets ou tableaux

L'ancienne version de JSON spécifiée par l'obsolète [RFC 4627](#) demandait à ce que la valeur de plus haut niveau du texte JSON soit un objet ou un tableau JSON (*dict* ou *list* Python), et ne soit pas *null*, un nombre, ou une chaîne de caractères. La [RFC 7159](#) a supprimé cette restriction, jamais implémentée par ce module, que ce soit dans le sérialiseur ou le désérialiseur.

Cependant, pour une interopérabilité maximale, vous pourriez volontairement souhaiter adhérer à cette restriction par vous-même.

### Limitations de l'implémentation

Certaines implémentations de désérialiseurs JSON peuvent avoir des limites sur :

- la taille des textes JSON acceptés ;
- le niveau maximum d'objets et tableaux JSON imbriqués ;
- l'intervalle et la précision des nombres JSON ;
- le contenu et la longueur maximale des chaînes JSON.

Ce module n'impose pas de telles limites si ce n'est celles inhérentes aux types de données Python ou à l'interpréteur.

Lors d'une sérialisation JSON, faites attention à ces limitations dans les applications qui utiliseraient votre JSON. En particulier, il est commun pour les nombres JSON d'être désérialisés vers des nombres IEEE 754 à précision double, et donc sujets à l'intervalle et aux limitations sur la précision de cette représentation. Cela est d'autant plus important lors de la sérialisation de valeurs *int* Python de forte magnitude, ou d'instances de types numériques « exotiques » comme *decimal.Decimal*.

### Notes

## 18.3 mailcap — Manipulation de fichiers Mailcap

Code source : [Lib/mailcap.py](#)

Les fichiers *mailcap* sont utilisés pour configurer la façon dont les applications compatibles avec MIME, comme les clients mails ou les navigateurs, réagissent aux différents fichiers de types MIME. (Le nom *mailcap* est une contraction de l'expression « *mail capability* ».) Par exemple, un fichier *mailcap* peut contenir une ligne de type `video/mpeg; xmpeg %s`. Ensuite, si l'utilisateur récupère un message mail ou un document web avec un type MIME `video/mpeg`, `%s` est remplacé par un nom de fichier (généralement celui d'un fichier temporaire) et le programme `xmpeg` peut automatiquement débiter la lecture de ce dernier.

Le format *mailcap* est documenté dans la [RFC 1524](#) « A User Agent Configuration Mechanism For Multimedia Mail Format Information », mais n'est pas un standard Internet. Cependant, la plupart des systèmes Unix savent gérer les fichiers *mailcap*.

```
mailcap.findmatch(caps, MIMEtype[, key[, filename[, plist]]])
```

Renvoie un tuple à deux éléments ; le premier élément est une chaîne de caractères (string) contenant la ligne de commande à exécuter (qui peut être passée à `os.system()`), et le second élément est l'entrée *mailcap* pour un type de MIME donné. Si le type MIME n'est pas identifié, (`None`, `None`) est renvoyé. *key* est le nom de champ souhaité, qui représente le type d'action à exécuter ; la valeur par défaut est 'view', puisque dans la majorité des cas le besoin consiste juste à lire le corps (body) de la donnée de type MIME. Les autres valeurs possibles peuvent être 'compose' et 'edit', si le besoin consiste à créer un nouveau corps de données (body) ou modifier celui existant. Voir la [RFC 1524](#) pour une liste complète des champs.

*filename* est le nom de fichier à remplacer pour %s en ligne de commande ; la valeur par défaut est '/dev/null' qui n'est certainement pas celle que vous attendez. Donc la plupart du temps, le nom de fichier doit être indiqué.

*plist* peut être une liste contenant des noms de paramètres ; la valeur par défaut est une simple liste vide. Chaque entrée dans la liste doit être une chaîne de caractères contenant le nom du paramètre, un signe égal ('='), ainsi que la valeur du paramètre. Les entrées *mailcap* peuvent contenir des noms de paramètres tels que %foo, remplacé par la valeur du paramètre nommé *foo*. Par exemple, si la ligne de commande `showpartial %id %number %total` est un fichier *mailcap*, et *plist* configuré à ['id=1', 'number=2', 'total=3'], la ligne de commande qui en résulte est 'showpartial 1 2 3'. Dans un fichier *mailcap*, le champ « test » peut être renseigné de façon optionnelle afin de tester certaines conditions externes (comme l'architecture machine, ou le gestionnaire de fenêtre utilisé) afin de déterminer si la ligne *mailcap* est pertinente ou non. `findmatch()` vérifie automatiquement ces conditions et ignore l'entrée si la vérification échoue.

```
mailcap.getcaps()
```

Renvoie un dictionnaire qui associe les types MIME à une liste d'entrées de fichier *mailcap*. Ce dictionnaire doit être transmis à la fonction `findmatch()`. Une entrée est enregistrée en tant qu'une liste de dictionnaires, mais il n'est pas nécessaire de connaître les détails de cette représentation.

L'information provient de tous les fichiers *mailcap* trouvés dans le système. Les configurations réalisées dans le fichier *mailcap* du répertoire utilisateur \$HOME/.mailcap outrepasse les configurations systèmes des fichiers *mailcap* /etc/mailcap, /usr/etc/mailcap, et /usr/local/etc/mailcap.

Un exemple d'utilisation :

```
>>> import mailcap
>>> d = mailcap.getcaps()
>>> mailcap.findmatch(d, 'video/mpeg', filename='tmp1223')
('xmpeg tmp1223', {'view': 'xmpeg %s'})
```

## 18.4 mailbox — Manipulate mailboxes in various formats

This module defines two classes, *Mailbox* and *Message*, for accessing and manipulating on-disk mailboxes and the messages they contain. *Mailbox* offers a dictionary-like mapping from keys to messages. *Message* extends the *email.message* module's *Message* class with format-specific state and behavior. Supported mailbox formats are Maildir, mbox, MH, Babyl, and MMDF.

Voir aussi :

Module *email* Represent and manipulate messages.

### 18.4.1 Mailbox objects

```
class mailbox.Mailbox
```

A mailbox, which may be inspected and modified.

The `Mailbox` class defines an interface and is not intended to be instantiated. Instead, format-specific subclasses should inherit from `Mailbox` and your code should instantiate a particular subclass.

The `Mailbox` interface is dictionary-like, with small keys corresponding to messages. Keys are issued by the `Mailbox` instance with which they will be used and are only meaningful to that `Mailbox` instance. A key continues to identify a message even if the corresponding message is modified, such as by replacing it with another message.

Messages may be added to a `Mailbox` instance using the set-like method `add()` and removed using a `del` statement or the set-like methods `remove()` and `discard()`.

`Mailbox` interface semantics differ from dictionary semantics in some noteworthy ways. Each time a message is requested, a new representation (typically a `Message` instance) is generated based upon the current state of the mailbox. Similarly, when a message is added to a `Mailbox` instance, the provided message representation's contents are copied. In neither case is a reference to the message representation kept by the `Mailbox` instance.

The default `Mailbox` iterator iterates over message representations, not keys as the default dictionary iterator does. Moreover, modification of a mailbox during iteration is safe and well-defined. Messages added to the mailbox after an iterator is created will not be seen by the iterator. Messages removed from the mailbox before the iterator yields them will be silently skipped, though using a key from an iterator may result in a `KeyError` exception if the corresponding message is subsequently removed.

**Avertissement :** Be very cautious when modifying mailboxes that might be simultaneously changed by some other process. The safest mailbox format to use for such tasks is Maildir ; try to avoid using single-file formats such as mbox for concurrent writing. If you're modifying a mailbox, you *must* lock it by calling the `lock()` and `unlock()` methods *before* reading any messages in the file or making any changes by adding or deleting a message. Failing to lock the mailbox runs the risk of losing messages or corrupting the entire mailbox.

`Mailbox` instances have the following methods :

`add(message)`

Add *message* to the mailbox and return the key that has been assigned to it.

Parameter *message* may be a `Message` instance, an `email.message.Message` instance, a string, or a file-like object (which should be open in text mode). If *message* is an instance of the appropriate format-specific `Message` subclass (e.g., if it's an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, reasonable defaults for format-specific information are used.

`remove(key)`

`__delitem__(key)`

`discard(key)`

Delete the message corresponding to *key* from the mailbox.

If no such message exists, a `KeyError` exception is raised if the method was called as `remove()` or `__delitem__()` but no exception is raised if the method was called as `discard()`. The behavior of `discard()` may be preferred if the underlying mailbox format supports concurrent modification by other processes.

`__setitem__(key, message)`

Replace the message corresponding to *key* with *message*. Raise a `KeyError` exception if no message already corresponds to *key*.

As with `add()`, parameter *message* may be a `Message` instance, an `email.message.Message` instance, a string, or a file-like object (which should be open in text mode). If *message* is an instance of the appropriate format-specific `Message` subclass (e.g., if it's an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, the format-specific information of the message that currently corresponds to *key* is left unchanged.

`iterkeys()`

`keys()`

Return an iterator over all keys if called as `iterkeys()` or return a list of keys if called as `keys()`.

`itervalues()`  
`__iter__()`  
`values()`

Return an iterator over representations of all messages if called as `itervalues()` or `__iter__()` or return a list of such representations if called as `values()`. The messages are represented as instances of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

---

**Note :** The behavior of `__iter__()` is unlike that of dictionaries, which iterate over keys.

---

`iteritems()`  
`items()`

Return an iterator over *(key, message)* pairs, where *key* is a key and *message* is a message representation, if called as `iteritems()` or return a list of such pairs if called as `items()`. The messages are represented as instances of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

`get(key, default=None)`  
`__getitem__(key)`

Return a representation of the message corresponding to *key*. If no such message exists, *default* is returned if the method was called as `get()` and a `KeyError` exception is raised if the method was called as `__getitem__()`. The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

`get_message(key)`

Return a representation of the message corresponding to *key* as an instance of the appropriate format-specific `Message` subclass, or raise a `KeyError` exception if no such message exists.

`get_string(key)`

Return a string representation of the message corresponding to *key*, or raise a `KeyError` exception if no such message exists.

`get_file(key)`

Return a file-like representation of the message corresponding to *key*, or raise a `KeyError` exception if no such message exists. The file-like object behaves as if open in binary mode. This file should be closed once it is no longer needed.

---

**Note :** Unlike other representations of messages, file-like representations are not necessarily independent of the `Mailbox` instance that created them or of the underlying mailbox. More specific documentation is provided by each subclass.

---

`has_key(key)`

`__contains__(key)`

Return `True` if *key* corresponds to a message, `False` otherwise.

`__len__()`

Return a count of messages in the mailbox.

`clear()`

Delete all messages from the mailbox.

`pop(key[, default])`

Return a representation of the message corresponding to *key* and delete the message. If no such message exists, return *default* if it was supplied or else raise a `KeyError` exception. The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

`popitem()`

Return an arbitrary *(key, message)* pair, where *key* is a key and *message* is a message representation, and delete the corresponding message. If the mailbox is empty, raise a `KeyError` exception.

The message is represented as an instance of the appropriate format-specific *Message* subclass unless a custom message factory was specified when the *Mailbox* instance was initialized.

#### **update(*arg*)**

Parameter *arg* should be a *key-to-message* mapping or an iterable of (*key*, *message*) pairs. Updates the mailbox so that, for each given *key* and *message*, the message corresponding to *key* is set to *message* as if by using `__setitem__()`. As with `__setitem__()`, each *key* must already correspond to a message in the mailbox or else a *KeyError* exception will be raised, so in general it is incorrect for *arg* to be a *Mailbox* instance.

---

**Note :** Unlike with dictionaries, keyword arguments are not supported.

---

#### **flush()**

Write any pending changes to the filesystem. For some *Mailbox* subclasses, changes are always written immediately and *flush()* does nothing, but you should still make a habit of calling this method.

#### **lock()**

Acquire an exclusive advisory lock on the mailbox so that other processes know not to modify it. An *ExternalClashError* is raised if the lock is not available. The particular locking mechanisms used depend upon the mailbox format. You should *always* lock the mailbox before making any modifications to its contents.

#### **unlock()**

Release the lock on the mailbox, if any.

#### **close()**

Flush the mailbox, unlock it if necessary, and close any open files. For some *Mailbox* subclasses, this method does nothing.

### **Maildir**

**class mailbox.Maildir(*dirname*, *factory*=rfc822.Message, *create*=True)**

A subclass of *Mailbox* for mailboxes in Maildir format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is *None*, *MaildirMessage* is used as the default message representation. If *create* is *True*, the mailbox is created if it does not exist.

It is for historical reasons that *factory* defaults to *rfc822.Message* and that *dirname* is named as such rather than *path*. For a *Maildir* instance that behaves like instances of other *Mailbox* subclasses, set *factory* to *None*.

Maildir is a directory-based mailbox format invented for the qmail mail transfer agent and now widely supported by other programs. Messages in a Maildir mailbox are stored in separate files within a common directory structure. This design allows Maildir mailboxes to be accessed and modified by multiple unrelated programs without data corruption, so file locking is unnecessary.

Maildir mailboxes contain three subdirectories, namely : **tmp**, **new**, and **cur**. Messages are created momentarily in the **tmp** subdirectory and then moved to the **new** subdirectory to finalize delivery. A mail user agent may subsequently move the message to the **cur** subdirectory and store information about the state of the message in a special « info » section appended to its file name.

Folders of the style introduced by the Courier mail transfer agent are also supported. Any subdirectory of the main mailbox is considered a folder if '.' is the first character in its name. Folder names are represented by *Maildir* without the leading '.'. Each folder is itself a Maildir mailbox but should not contain other folders. Instead, a logical nesting is indicated using '.' to delimit levels, e.g., « Archived.2005.07 ».

---

**Note :** The Maildir specification requires the use of a colon (':') in certain message file names. However, some operating systems do not permit this character in file names, If you wish to use a

---

Maildir-like format on such an operating system, you should specify another character to use instead. The exclamation point ('!') is a popular choice. For example :

```
import mailbox
mailbox.Maildir.colon = '!'
```

The `colon` attribute may also be set on a per-instance basis.

---

*Maildir* instances have all of the methods of *Mailbox* in addition to the following :

**list\_folders()**

Return a list of the names of all folders.

**get\_folder(folder)**

Return a *Maildir* instance representing the folder whose name is *folder*. A *NoSuchMailboxError* exception is raised if the folder does not exist.

**add\_folder(folder)**

Create a folder whose name is *folder* and return a *Maildir* instance representing it.

**remove\_folder(folder)**

Delete the folder whose name is *folder*. If the folder contains any messages, a *NotEmptyError* exception will be raised and the folder will not be deleted.

**clean()**

Delete temporary files from the mailbox that have not been accessed in the last 36 hours. The Maildir specification says that mail-reading programs should do this occasionally.

Some *Mailbox* methods implemented by *Maildir* deserve special remarks :

**add(message)**

**\_\_setitem\_\_(key, message)**

**update(arg)**

**Avertissement :** These methods generate unique file names based upon the current process ID. When using multiple threads, undetected name clashes may occur and cause corruption of the mailbox unless threads are coordinated to avoid using these methods to manipulate the same mailbox simultaneously.

**flush()**

All changes to Maildir mailboxes are immediately applied, so this method does nothing.

**lock()**

**unlock()**

Maildir mailboxes do not support (or require) locking, so these methods do nothing.

**close()**

*Maildir* instances do not keep any open files and the underlying mailboxes do not support locking, so this method does nothing.

**get\_file(key)**

Depending upon the host platform, it may not be possible to modify or remove the underlying message while the returned file remains open.

**Voir aussi :**

**Using maildir format** Notes on Maildir by its inventor. Includes an updated name-creation scheme and details on « info » semantics.

**maildir man page from Courier** Another specification of the format. Describes a common extension for supporting folders.

**mbox**

```
class mailbox.mbox(path, factory=None, create=True)
```

A subclass of *Mailbox* for mailboxes in mbox format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is *None*, *mboxMessage* is used as the default message representation. If *create* is *True*, the mailbox is created if it does not exist.

The mbox format is the classic format for storing mail on Unix systems. All messages in an mbox mailbox are stored in a single file with the beginning of each message indicated by a line whose first five characters are « From ».

Several variations of the mbox format exist to address perceived shortcomings in the original. In the interest of compatibility, *mbox* implements the original format, which is sometimes referred to as *mboxo*. This means that the *Content-Length* header, if present, is ignored and that any occurrences of « From » at the beginning of a line in a message body are transformed to « >From » when storing the message, although occurrences of « >From » are not transformed to « From » when reading the message.

Some *Mailbox* methods implemented by *mbox* deserve special remarks :

```
get_file(key)
```

Using the file after calling *flush()* or *close()* on the *mbox* instance may yield unpredictable results or raise an exception.

```
lock()
```

```
unlock()
```

Three locking mechanisms are used—dot locking and, if available, the *flock()* and *lockf()* system calls.

**Configuring Netscape Mail on Unix : Why The Content-Length Format is Bad** An argument for using the original mbox format rather than a variation.

« **mbox** » is a family of several mutually incompatible mailbox formats A history of mbox variations.

**MH**

```
class mailbox.MH(path, factory=None, create=True)
```

A subclass of *Mailbox* for mailboxes in MH format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is *None*, *MHMessage* is used as the default message representation. If *create* is *True*, the mailbox is created if it does not exist.

MH is a directory-based mailbox format invented for the MH Message Handling System, a mail user agent. Each message in an MH mailbox resides in its own file. An MH mailbox may contain other MH mailboxes (called *folders*) in addition to messages. Folders may be nested indefinitely. MH mailboxes also support *sequences*, which are named lists used to logically group messages without moving them to sub-folders. Sequences are defined in a file called *.mh\_sequences* in each folder.

The *MH* class manipulates MH mailboxes, but it does not attempt to emulate all of *mh*'s behaviors. In particular, it does not modify and is not affected by the *context* or *.mh\_profile* files that are used by *mh* to store its state and configuration.

*MH* instances have all of the methods of *Mailbox* in addition to the following :

```
list_folders()
```

Return a list of the names of all folders.

`get_folder(folder)`

Return an *MH* instance representing the folder whose name is *folder*. A *NoSuchMailboxError* exception is raised if the folder does not exist.

`add_folder(folder)`

Create a folder whose name is *folder* and return an *MH* instance representing it.

`remove_folder(folder)`

Delete the folder whose name is *folder*. If the folder contains any messages, a *NotEmptyError* exception will be raised and the folder will not be deleted.

`get_sequences()`

Return a dictionary of sequence names mapped to key lists. If there are no sequences, the empty dictionary is returned.

`set_sequences(sequences)`

Re-define the sequences that exist in the mailbox based upon *sequences*, a dictionary of names mapped to key lists, like returned by *get\_sequences()*.

`pack()`

Rename messages in the mailbox as necessary to eliminate gaps in numbering. Entries in the sequences list are updated correspondingly.

---

**Note :** Already-issued keys are invalidated by this operation and should not be subsequently used.

---

Some *Mailbox* methods implemented by *MH* deserve special remarks :

`remove(key)`

`__delitem__(key)`

`discard(key)`

These methods immediately delete the message. The *MH* convention of marking a message for deletion by prepending a comma to its name is not used.

`lock()`

`unlock()`

Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls. For *MH* mailboxes, locking the mailbox means locking the `.mh_sequences` file and, only for the duration of any operations that affect them, locking individual message files.

`get_file(key)`

Depending upon the host platform, it may not be possible to remove the underlying message while the returned file remains open.

`flush()`

All changes to *MH* mailboxes are immediately applied, so this method does nothing.

`close()`

*MH* instances do not keep any open files, so this method is equivalent to *unlock()*.

## Babyl

`class mailbox.Babyl(path, factory=None, create=True)`

A subclass of *Mailbox* for mailboxes in Babyl format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is *None*, *BabylMessage* is used as the default message representation. If *create* is *True*, the mailbox is created if it does not exist.

Babyl is a single-file mailbox format used by the Rmail mail user agent included with Emacs. The beginning of a message is indicated by a line containing the two characters Control-Underscore (`'\037'`) and Control-L (`'\014'`). The end of a message is indicated by the start of the next message or, in the case of the last message, a line containing a Control-Underscore (`'\037'`) character.

Messages in a Babyl mailbox have two sets of headers, original headers and so-called visible headers. Visible headers are typically a subset of the original headers that have been reformatted or abridged to be more attractive. Each message in a Babyl mailbox also has an accompanying list of *labels*, or short strings that record extra information about the message, and a list of all user-defined labels found in the mailbox is kept in the Babyl options section.

*Babyl* instances have all of the methods of *Mailbox* in addition to the following :

**get\_labels()**

Return a list of the names of all user-defined labels used in the mailbox.

---

**Note :** The actual messages are inspected to determine which labels exist in the mailbox rather than consulting the list of labels in the Babyl options section, but the Babyl section is updated whenever the mailbox is modified.

---

Some *Mailbox* methods implemented by *Babyl* deserve special remarks :

**get\_file(key)**

In Babyl mailboxes, the headers of a message are not stored contiguously with the body of the message. To generate a file-like representation, the headers and body are copied together into a *StringIO* instance (from the *StringIO* module), which has an API identical to that of a file. As a result, the file-like object is truly independent of the underlying mailbox but does not save memory compared to a string representation.

**lock()**

**unlock()**

Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls.

**Voir aussi :**

**Format of Version 5 Babyl Files** A specification of the Babyl format.

**Reading Mail with Rmail** The Rmail manual, with some information on Babyl semantics.

## MMDF

**class mailbox.MMDF(path, factory=None, create=True)**

A subclass of *Mailbox* for mailboxes in MMDF format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, *MMDFMessage* is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

MMDF is a single-file mailbox format invented for the Multichannel Memorandum Distribution Facility, a mail transfer agent. Each message is in the same form as an mbox message but is bracketed before and after by lines containing four Control-A (`'\001'`) characters. As with the mbox format, the beginning of each message is indicated by a line whose first five characters are « From », but additional occurrences of « From » are not transformed to « >From » when storing messages because the extra message separator lines prevent mistaking such occurrences for the starts of subsequent messages.

Some *Mailbox* methods implemented by *MMDF* deserve special remarks :

**get\_file(key)**

Using the file after calling `flush()` or `close()` on the *MMDF* instance may yield unpredictable results or raise an exception.

**lock()**

`unlock()`

Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls.

Voir aussi :

**mmdf man page from tin** A specification of MMDF format from the documentation of tin, a news-reader.

**MMDF** A Wikipedia article describing the Multichannel Memorandum Distribution Facility.

## 18.4.2 Message objects

`class mailbox.Message([message])`

A subclass of the `email.message` module's `Message`. Subclasses of `mailbox.Message` add mailbox-format-specific state and behavior.

If `message` is omitted, the new instance is created in a default, empty state. If `message` is an `email.message.Message` instance, its contents are copied; furthermore, any format-specific information is converted insofar as possible if `message` is a `Message` instance. If `message` is a string or a file, it should contain an **RFC 2822**-compliant message, which is read and parsed.

The format-specific state and behaviors offered by subclasses vary, but in general it is only the properties that are not specific to a particular mailbox that are supported (although presumably the properties are specific to a particular mailbox format). For example, file offsets for single-file mailbox formats and file names for directory-based mailbox formats are not retained, because they are only applicable to the original mailbox. But state such as whether a message has been read by the user or marked as important is retained, because it applies to the message itself.

There is no requirement that `Message` instances be used to represent messages retrieved using `Mailbox` instances. In some situations, the time and memory required to generate `Message` representations might not be acceptable. For such situations, `Mailbox` instances also offer string and file-like representations, and a custom message factory may be specified when a `Mailbox` instance is initialized.

### `MaidirMessage`

`class mailbox.MaidirMessage([message])`

A message with Maildir-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

Typically, a mail user agent application moves all of the messages in the `new` subdirectory to the `cur` subdirectory after the first time the user opens and closes the mailbox, recording that the messages are old whether or not they've actually been read. Each message in `cur` has an « info » section added to its file name to store information about its state. (Some mail readers may also add an « info » section to messages in `new`.) The « info » section may take one of two forms : it may contain « 2, » followed by a list of standardized flags (e.g., « 2,FR ») or it may contain « 1, » followed by so-called experimental information. Standard flags for Maildir messages are as follows :

Option	Signification	Explication
D	Draft	Under composition
F	Flagged	Marked as important
P	Passed	Forwarded, resent, or bounced
R	Replied	Replied to
S	Seen	Read
T	Trashed	Marked for subsequent deletion

`MaidirMessage` instances offer the following methods :

**get\_subdir()**

Return either « new » (if the message should be stored in the **new** subdirectory) or « cur » (if the message should be stored in the **cur** subdirectory).

---

**Note :** A message is typically moved from **new** to **cur** after its mailbox has been accessed, whether or not the message is has been read. A message **msg** has been read if "S" in **msg.get\_flags()** is **True**.

---

**set\_subdir(subdir)**

Set the subdirectory the message should be stored in. Parameter *subdir* must be either « new » or « cur ».

**get\_flags()**

Return a string specifying the flags that are currently set. If the message complies with the standard Maildir format, the result is the concatenation in alphabetical order of zero or one occurrence of each of 'D', 'F', 'P', 'R', 'S', and 'T'. The empty string is returned if no flags are set or if « info » contains experimental semantics.

**set\_flags(flags)**

Set the flags specified by *flags* and unset all others.

**add\_flag(flag)**

Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character. The current « info » is overwritten whether or not it contains experimental information rather than flags.

**remove\_flag(flag)**

Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character. If « info » contains experimental information rather than flags, the current « info » is not modified.

**get\_date()**

Return the delivery date of the message as a floating-point number representing seconds since the epoch.

**set\_date(date)**

Set the delivery date of the message to *date*, a floating-point number representing seconds since the epoch.

**get\_info()**

Return a string containing the « info » for a message. This is useful for accessing and modifying « info » that is experimental (i.e., not a list of flags).

**set\_info(info)**

Set « info » to *info*, which should be a string.

When a *MaildirMessage* instance is created based upon an *mboxMessage* or *MMDFMessage* instance, the *Status* and *X-Status* headers are omitted and the following conversions take place :

Resulting state	<i>mboxMessage</i> or <i>MMDFMessage</i> state
« cur » subdirectory	O flag
F flag	F flag
R flag	A flag
S flag	R flag
T flag	D flag

When a *MaildirMessage* instance is created based upon an *MHMessage* instance, the following conversions take place :

Resulting state	<i>MHMessage</i> state
« cur » subdirectory	« unseen » sequence
« cur » subdirectory and S flag	no « unseen » sequence
F flag	« flagged » sequence
R flag	« replied » sequence

When a *MaildirMessage* instance is created based upon a *BabylMessage* instance, the following conversions take place :

Resulting state	<i>BabylMessage</i> state
« cur » subdirectory	« unseen » label
« cur » subdirectory and S flag	no « unseen » label
P flag	« forwarded » or « resent » label
R flag	« answered » label
T flag	« deleted » label

### **mbxMessage**

**class mailbox.mbxMessage**(*[message]*)

A message with mbx-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

Messages in an mbx mailbox are stored together in a single file. The sender's envelope address and the time of delivery are typically stored in a line beginning with « From » that is used to indicate the start of a message, though there is considerable variation in the exact format of this data among mbx implementations. Flags that indicate the state of the message, such as whether it has been read or marked as important, are typically stored in *Status* and *X-Status* headers.

Conventional flags for mbx messages are as follows :

Option	Signification	Explication
R	Read	Read
O	Old	Previously detected by MUA
D	Deleted	Marked for subsequent deletion
F	Flagged	Marked as important
A	Answered	Replied to

The « R » and « O » flags are stored in the *Status* header, and the « D », « F », and « A » flags are stored in the *X-Status* header. The flags and headers typically appear in the order mentioned.

*mbxMessage* instances offer the following methods :

**get\_from()**

Return a string representing the « From » line that marks the start of the message in an mbx mailbox. The leading « From » and the trailing newline are excluded.

**set\_from**(*from\_*, *time\_*=None)

Set the « From » line to *from\_*, which should be specified without a leading « From » or trailing newline. For convenience, *time\_* may be specified and will be formatted appropriately and appended to *from\_*. If *time\_* is specified, it should be a *time.struct\_time* instance, a tuple suitable for passing to *time.strftime()*, or True (to use *time.gmtime()*).

**get\_flags()**

Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of 'R', 'O', 'D', 'F', and 'A'.

**set\_flags(flags)**

Set the flags specified by *flags* and unset all others. Parameter *flags* should be the concatenation in any order of zero or more occurrences of each of 'R', 'O', 'D', 'F', and 'A'.

**add\_flag(flag)**

Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character.

**remove\_flag(flag)**

Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* may be a string of more than one character.

When an *mailboxMessage* instance is created based upon a *MaiIdirMessage* instance, a « From » line is generated based upon the *MaiIdirMessage* instance's delivery date, and the following conversions take place :

Resulting state	<i>MaiIdirMessage</i> state
R flag	S flag
O flag	« cur » subdirectory
D flag	T flag
F flag	F flag
A flag	R flag

When an *mailboxMessage* instance is created based upon an *MHMessage* instance, the following conversions take place :

Resulting state	<i>MHMessage</i> state
R flag and O flag	no « unseen » sequence
O flag	« unseen » sequence
F flag	« flagged » sequence
A flag	« replied » sequence

When an *mailboxMessage* instance is created based upon a *BabylMessage* instance, the following conversions take place :

Resulting state	<i>BabylMessage</i> state
R flag and O flag	no « unseen » label
O flag	« unseen » label
D flag	« deleted » label
A flag	« answered » label

When a *Message* instance is created based upon an *MMDFMessage* instance, the « From » line is copied and all flags directly correspond :

Resulting state	<i>MMDFMessage</i> state
R flag	R flag
O flag	O flag
D flag	D flag
F flag	F flag
A flag	A flag

## MHMessage

```
class mailbox.MHMessage([message])
```

A message with MH-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

MH messages do not support marks or flags in the traditional sense, but they do support sequences, which are logical groupings of arbitrary messages. Some mail reading programs (although not the standard **mh** and **nmh**) use sequences in much the same way flags are used with other formats, as follows :

Sequence	Explication
unseen	Not read, but previously detected by MUA
replied	Replied to
flagged	Marked as important

*MHMessage* instances offer the following methods :

**get\_sequences()**

Return a list of the names of sequences that include this message.

**set\_sequences(sequences)**

Set the list of sequences that include this message.

**add\_sequence(sequence)**

Add *sequence* to the list of sequences that include this message.

**remove\_sequence(sequence)**

Remove *sequence* from the list of sequences that include this message.

When an *MHMessage* instance is created based upon a *MaildirMessage* instance, the following conversions take place :

Resulting state	<i>MaildirMessage</i> state
« unseen » sequence	no S flag
« replied » sequence	R flag
« flagged » sequence	F flag

When an *MHMessage* instance is created based upon an *mboxMessage* or *MMDFMessage* instance, the *Status* and *X-Status* headers are omitted and the following conversions take place :

Resulting state	<i>mboxMessage</i> or <i>MMDFMessage</i> state
« unseen » sequence	no R flag
« replied » sequence	A flag
« flagged » sequence	F flag

When an *MHMessage* instance is created based upon a *BabylMessage* instance, the following conversions take place :

Resulting state	<i>BabylMessage</i> state
« unseen » sequence	« unseen » label
« replied » sequence	« answered » label

## BabylMessage

```
class mailbox.BabylMessage([message])
```

A message with Babyl-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

Certain message labels, called *attributes*, are defined by convention to have special meanings. The attributes are as follows :

Label	Explication
unseen	Not read, but previously detected by MUA
deleted	Marked for subsequent deletion
filed	Copied to another file or mailbox
answered	Replied to
forwarded	Forwarded
edited	Modified by the user
resent	Resent

By default, Rmail displays only visible headers. The *BabylMessage* class, though, uses the original headers because they are more complete. Visible headers may be accessed explicitly if desired.

*BabylMessage* instances offer the following methods :

**get\_labels()**

Return a list of labels on the message.

**set\_labels(labels)**

Set the list of labels on the message to *labels*.

**add\_label(label)**

Add *label* to the list of labels on the message.

**remove\_label(label)**

Remove *label* from the list of labels on the message.

**get\_visible()**

Return an *Message* instance whose headers are the message's visible headers and whose body is empty.

**set\_visible(visible)**

Set the message's visible headers to be the same as the headers in *message*. Parameter *visible* should be a *Message* instance, an *email.message.Message* instance, a string, or a file-like object (which should be open in text mode).

**update\_visible()**

When a *BabylMessage* instance's original headers are modified, the visible headers are not automatically modified to correspond. This method updates the visible headers as follows : each visible header with a corresponding original header is set to the value of the original header, each visible header without a corresponding original header is removed, and any of *Date*, *From*, *Reply-To*, *To*, *CC*, and *Subject* that are present in the original headers but not the visible headers are added to the visible headers.

When a *BabylMessage* instance is created based upon a *MaildirMessage* instance, the following conversions take place :

Resulting state	<i>MaildirMessage</i> state
« unseen » label	no S flag
« deleted » label	T flag
« answered » label	R flag
« forwarded » label	P flag

When a *BabylMessage* instance is created based upon an *mboxMessage* or *MMDFMessage* instance, the *Status* and *X-Status* headers are omitted and the following conversions take place :

Resulting state	<i>mboxMessage</i> or <i>MMDFMessage</i> state
« unseen » label	no R flag
« deleted » label	D flag
« answered » label	A flag

When a *BabylMessage* instance is created based upon an *MHMessage* instance, the following conversions take place :

Resulting state	<i>MHMessage</i> state
« unseen » label	« unseen » sequence
« answered » label	« replied » sequence

### MMDFMessage

**class mailbox.MMDFMessage**(*[message]*)

A message with MMDF-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

As with message in an mbox mailbox, MMDF messages are stored with the sender's address and the delivery date in an initial line beginning with « From ». Likewise, flags that indicate the state of the message are typically stored in *Status* and *X-Status* headers.

Conventional flags for MMDF messages are identical to those of mbox message and are as follows :

Option	Signification	Explication
R	Read	Read
O	Old	Previously detected by MUA
D	Deleted	Marked for subsequent deletion
F	Flagged	Marked as important
A	Answered	Replied to

The « R » and « O » flags are stored in the *Status* header, and the « D », « F », and « A » flags are stored in the *X-Status* header. The flags and headers typically appear in the order mentioned.

*MMDFMessage* instances offer the following methods, which are identical to those offered by *mboxMessage* :

**get\_from()**

Return a string representing the « From » line that marks the start of the message in an mbox mailbox. The leading « From » and the trailing newline are excluded.

**set\_from**(*from\_*, *time\_=None*)

Set the « From » line to *from\_*, which should be specified without a leading « From » or trailing newline. For convenience, *time\_* may be specified and will be formatted appropriately and appended to *from\_*. If *time\_* is specified, it should be a *time.struct\_time* instance, a tuple suitable for passing to *time.strftime()*, or *True* (to use *time.gmtime()*).

**get\_flags()**

Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of 'R', 'O', 'D', 'F', and 'A'.

**set\_flags**(*flags*)

Set the flags specified by *flags* and unset all others. Parameter *flags* should be the concatenation in any order of zero or more occurrences of each of 'R', 'O', 'D', 'F', and 'A'.

**add\_flag**(*flag*)

Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character.

**remove\_flag(flag)**

Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character.

When an *MMDFMessage* instance is created based upon a *MaiDirMessage* instance, a « From » line is generated based upon the *MaiDirMessage* instance's delivery date, and the following conversions take place :

Resulting state	<i>MaiDirMessage</i> state
R flag	S flag
O flag	« cur » subdirectory
D flag	T flag
F flag	F flag
A flag	R flag

When an *MMDFMessage* instance is created based upon an *MHMessage* instance, the following conversions take place :

Resulting state	<i>MHMessage</i> state
R flag and O flag	no « unseen » sequence
O flag	« unseen » sequence
F flag	« flagged » sequence
A flag	« replied » sequence

When an *MMDFMessage* instance is created based upon a *BabylMessage* instance, the following conversions take place :

Resulting state	<i>BabylMessage</i> state
R flag and O flag	no « unseen » label
O flag	« unseen » label
D flag	« deleted » label
A flag	« answered » label

When an *MMDFMessage* instance is created based upon an *mboxMessage* instance, the « From » line is copied and all flags directly correspond :

Resulting state	<i>mboxMessage</i> state
R flag	R flag
O flag	O flag
D flag	D flag
F flag	F flag
A flag	A flag

### 18.4.3 Exceptions

The following exception classes are defined in the *mailbox* module :

**exception mailbox.Error**

The based class for all other module-specific exceptions.

**exception mailbox.NoSuchMailboxError**

Raised when a mailbox is expected but is not found, such as when instantiating a *Mailbox* subclass

with a path that does not exist (and with the *create* parameter set to **False**), or when opening a folder that does not exist.

**exception mailbox.NotEmptyError**

Raised when a mailbox is not empty but is expected to be, such as when deleting a folder that contains messages.

**exception mailbox.ExternalClashError**

Raised when some mailbox-related condition beyond the control of the program causes it to be unable to proceed, such as when failing to acquire a lock that another program already holds a lock, or when a uniquely-generated file name already exists.

**exception mailbox.FormatError**

Raised when the data in a file cannot be parsed, such as when an *MH* instance attempts to read a corrupted *.mh\_sequences* file.

### 18.4.4 Deprecatcd classes and methods

Obsolète depuis la version 2.6.

Older versions of the *mailbox* module do not support modification of mailboxes, such as adding or removing message, and do not provide classes to represent format-specific message properties. For backward compatibility, the older mailbox classes are still available, but the newer classes should be used in preference to them. The old classes have been removed in Python 3.

Older mailbox objects support only iteration and provide a single public method :

**oldmailbox.next()**

Return the next message in the mailbox, created with the optional *factory* argument passed into the mailbox object's constructor. By default this is an *rfc822.Message* object (see the *rfc822* module). Depending on the mailbox implementation the *fp* attribute of this object may be a true file object or a class instance simulating a file object, taking care of things like message boundaries if multiple mail messages are contained in a single file, etc. If no more messages are available, this method returns **None**.

Most of the older mailbox classes have names that differ from the current mailbox class names, except for *MaiIdir*. For this reason, the new *MaiIdir* class defines a **next()** method and its constructor differs slightly from those of the other new mailbox classes.

The older mailbox classes whose names are not the same as their newer counterparts are as follows :

**class mailbox.UnixMailbox(*fp*[, *factory*])**

Access to a classic Unix-style mailbox, where all messages are contained in a single file and separated by **From** (a.k.a. **From\_**) lines. The file object *fp* points to the mailbox file. The optional *factory* parameter is a callable that should create new message objects. *factory* is called with one argument, *fp* by the **next()** method of the mailbox object. The default is the *rfc822.Message* class (see the *rfc822* module – and the note below).

---

**Note :** For reasons of this module's internal implementation, you will probably want to open the *fp* object in binary mode. This is especially important on Windows.

---

For maximum portability, messages in a Unix-style mailbox are separated by any line that begins exactly with the string **'From '** (note the trailing space) if preceded by exactly two newlines. Because of the wide-range of variations in practice, nothing else on the **From\_** line should be considered. However, the current implementation doesn't check for the leading two newlines. This is usually fine for most applications.

The *UnixMailbox* class implements a more strict version of **From\_** line checking, using a regular expression that usually correctly matched **From\_** delimiters. It considers delimiter line to be separated by

From name time lines. For maximum portability, use the *PortableUnixMailbox* class instead. This class is identical to *UnixMailbox* except that individual messages are separated by only From lines.

```
class mailbox.PortableUnixMailbox(fp[, factory])
```

A less-strict version of *UnixMailbox*, which considers only the From at the beginning of the line separating messages. The « name time » portion of the From line is ignored, to protect against some variations that are observed in practice. This works since lines in the message which begin with 'From ' are quoted by mail handling software at delivery-time.

```
class mailbox.MmdfMailbox(fp[, factory])
```

Access an MMDF-style mailbox, where all messages are contained in a single file and separated by lines consisting of 4 control-A characters. The file object *fp* points to the mailbox file. Optional *factory* is as with the *UnixMailbox* class.

```
class mailbox.MHMailbox(dirname[, factory])
```

Access an MH mailbox, a directory with each message in a separate file with a numeric name. The name of the mailbox directory is passed in *dirname*. *factory* is as with the *UnixMailbox* class.

```
class mailbox.BabylMailbox(fp[, factory])
```

Access a Babyl mailbox, which is similar to an MMDF mailbox. In Babyl format, each message has two sets of headers, the *original* headers and the *visible* headers. The original headers appear before a line containing only '\*\*\* EOOH \*\*\*' (End-Of-Original-Headers) and the visible headers appear after the EOOH line. Babyl-compliant mail readers will show you only the visible headers, and *BabylMailbox* objects will return messages containing only the visible headers. You'll have to do your own parsing of the mailbox file to get at the original headers. Mail messages start with the EOOH line and end with a line containing only '\037\014'. *factory* is as with the *UnixMailbox* class.

If you wish to use the older mailbox classes with the *email* module rather than the deprecated *rfc822* module, you can do so as follows :

```
import email
import email.Errors
import mailbox

def msgfactory(fp):
    try:
        return email.message_from_file(fp)
    except email.Errors.MessageParseError:
        # Don't return None since that will
        # stop the mailbox iterator
        return ''

mbox = mailbox.UnixMailbox(fp, msgfactory)
```

Alternatively, if you know your mailbox contains only well-formed MIME messages, you can simplify this to :

```
import email
import mailbox

mbox = mailbox.UnixMailbox(fp, email.message_from_file)
```

## 18.4.5 Examples

A simple example of printing the subjects of all messages in a mailbox that seem interesting :

```
import mailbox
for message in mailbox.mbox('~/.mbox'):
    subject = message['subject']          # Could possibly be None.
    if subject and 'python' in subject.lower():
        print subject
```

To copy all mail from a Babyl mailbox to an MH mailbox, converting all of the format-specific information that can be converted :

```
import mailbox
destination = mailbox.MH('~/.Mail')
destination.lock()
for message in mailbox.Babyl('~/.RMAIL'):
    destination.add(mailbox.MHMessage(message))
destination.flush()
destination.unlock()
```

This example sorts mail from several mailing lists into different mailboxes, being careful to avoid mail corruption due to concurrent modification by other programs, mail loss due to interruption of the program, or premature termination due to malformed messages in the mailbox :

```
import mailbox
import email.errors

list_names = ('python-list', 'python-dev', 'python-bugs')

boxes = dict((name, mailbox.mbox('~/.email/%s' % name)) for name in list_names)
inbox = mailbox.Maildir('~/.Maildir', factory=None)

for key in inbox.iterkeys():
    try:
        message = inbox[key]
    except email.errors.MessageParseError:
        continue          # The message is malformed. Just leave it.

    for name in list_names:
        list_id = message['list-id']
        if list_id and name in list_id:
            # Get mailbox to use
            box = boxes[name]

            # Write copy to disk before removing original.
            # If there's a crash, you might duplicate a message, but
            # that's better than losing a message completely.
            box.lock()
            box.add(message)
            box.flush()
            box.unlock()

            # Remove original message
            inbox.lock()
            inbox.discard(key)
            inbox.flush()
```

(suite sur la page suivante)

(suite de la page précédente)

```

        inbox.unlock()
        break                # Found destination, so stop looking.

for box in boxes.itervalues():
    box.close()

```

## 18.5 mhtmlib — Access to MH mailboxes

Obsolète depuis la version 2.6 : The *mhtmlib* module has been removed in Python 3. Use the *mailbox* instead.

The *mhtmlib* module provides a Python interface to MH folders and their contents.

The module contains three basic classes, *MH*, which represents a particular collection of folders, *Folder*, which represents a single folder, and *Message*, which represents a single message.

```
class mhtmlib.MH([path[, profile]])
```

*MH* represents a collection of MH folders.

```
class mhtmlib.Folder(mh, name)
```

The *Folder* class represents a single folder and its messages.

```
class mhtmlib.Message(folder, number[, name])
```

*Message* objects represent individual messages in a folder. The *Message* class is derived from *mimetools.Message*.

### 18.5.1 MH Objects

*MH* instances have the following methods :

```
MH.error(format[, ...])
```

Print an error message – can be overridden.

```
MH.getprofile(key)
```

Return a profile entry (*None* if not set).

```
MH.getpath()
```

Return the mailbox pathname.

```
MH.getcontext()
```

Return the current folder name.

```
MH.setcontext(name)
```

Set the current folder name.

```
MH.listfolders()
```

Return a list of top-level folders.

```
MH.listallfolders()
```

Return a list of all folders.

```
MH.listsubfolders(name)
```

Return a list of direct subfolders of the given folder.

```
MH.listallsubfolders(name)
```

Return a list of all subfolders of the given folder.

```
MH.makefolder(name)
```

Create a new folder.

**MH.deletefolder**(*name*)

Delete a folder – must have no subfolders.

**MH.openfolder**(*name*)

Return a new open folder object.

## 18.5.2 Folder Objects

*Folder* instances represent open folders and have the following methods :

**Folder.error**(*format*[, ...])

Print an error message – can be overridden.

**Folder.getfullname**()

Return the folder's full pathname.

**Folder.getsequencesfilename**()

Return the full pathname of the folder's sequences file.

**Folder.getmessagefilename**(*n*)

Return the full pathname of message *n* of the folder.

**Folder.listmessages**()

Return a list of messages in the folder (as numbers).

**Folder.getcurrent**()

Return the current message number.

**Folder.setcurrent**(*n*)

Set the current message number to *n*.

**Folder.parsesequence**(*seq*)

Parse msgs syntax into list of messages.

**Folder.getlast**()

Get last message, or 0 if no messages are in the folder.

**Folder.setlast**(*n*)

Set last message (internal use only).

**Folder.getsequences**()

Return dictionary of sequences in folder. The sequence names are used as keys, and the values are the lists of message numbers in the sequences.

**Folder.putsequences**(*dict*)

Return dictionary of sequences in folder name : list.

**Folder.removemessages**(*list*)

Remove messages in list from folder.

**Folder.refilemessages**(*list*, *tofolder*)

Move messages in list to other folder.

**Folder.movemessage**(*n*, *tofolder*, *ton*)

Move one message to a given destination in another folder.

**Folder.copymessage**(*n*, *tofolder*, *ton*)

Copy one message to a given destination in another folder.

## 18.5.3 Message Objects

The *Message* class adds one method to those of *mimertools.Message* :

`Message.openmessage(n)`

Return a new open message object (costs a file descriptor).

## 18.6 `mimertools` — Tools for parsing MIME messages

Obsolète depuis la version 2.3 : The `email` package should be used in preference to the `mimertools` module. This module is present only to maintain backward compatibility, and it has been removed in 3.x.

This module defines a subclass of the `rfc822` module's `Message` class and a number of utility functions that are useful for the manipulation for MIME multipart or encoded message.

It defines the following items :

`class mimertools.Message(fp, seekable)`

Return a new instance of the `Message` class. This is a subclass of the `rfc822.Message` class, with some additional methods (see below). The *seekable* argument has the same meaning as for `rfc822.Message`.

`mimertools.choose_boundary()`

Return a unique string that has a high likelihood of being usable as a part boundary. The string has the form 'hostipaddr.uid.pid.timestamp.random'.

`mimertools.decode(input, output, encoding)`

Read data encoded using the allowed MIME *encoding* from open file object *input* and write the decoded data to open file object *output*. Valid values for *encoding* include 'base64', 'quoted-printable', 'uuencode', 'x-uuencode', 'uue', 'x-uue', '7bit', and '8bit'. Decoding messages encoded in '7bit' or '8bit' has no effect. The input is simply copied to the output.

`mimertools.encode(input, output, encoding)`

Read data from open file object *input* and write it encoded using the allowed MIME *encoding* to open file object *output*. Valid values for *encoding* are the same as for `decode()`.

`mimertools.copyliteral(input, output)`

Read lines from open file *input* until EOF and write them to open file *output*.

`mimertools.copybinary(input, output)`

Read blocks until EOF from open file *input* and write them to open file *output*. The block size is currently fixed at 8192.

Voir aussi :

**Module `email`** Comprehensive email handling package; supersedes the `mimertools` module.

**Module `rfc822`** Provides the base class for `mimertools.Message`.

**Module `multifile`** Support for reading files which contain distinct parts, such as MIME data.

<http://faqs.cs.uu.nl/na-dir/mail/mime-faq/.html> The MIME Frequently Asked Questions document. For an overview of MIME, see the answer to question 1.1 in Part 1 of this document.

### 18.6.1 Additional Methods of Message Objects

The `Message` class defines the following methods in addition to the `rfc822.Message` methods :

`Message.getplist()`

Return the parameter list of the *Content-Type* header. This is a list of strings. For parameters of the form *key=value*, *key* is converted to lower case but *value* is not. For example, if the message contains the header *Content-type: text/html; spam=1; Spam=2; Spam* then `getplist()` will return the Python list ['spam=1', 'spam=2', 'Spam'].

`Message.getparam(name)`

Return the *value* of the first parameter (as returned by `getplist()`) of the form *name=value* for the given *name*. If *value* is surrounded by quotes of the form “<...>” or “...””, these are removed.

`Message.getencoding()`

Return the encoding specified in the *Content-Transfer-Encoding* message header. If no such header exists, return `'7bit'`. The encoding is converted to lower case.

`Message.gettype()`

Return the message type (of the form *type/subtype*) as specified in the *Content-Type* header. If no such header exists, return `'text/plain'`. The type is converted to lower case.

`Message.getmaintype()`

Return the main type as specified in the *Content-Type* header. If no such header exists, return `'text'`. The main type is converted to lower case.

`Message.getsubtype()`

Return the subtype as specified in the *Content-Type* header. If no such header exists, return `'plain'`. The subtype is converted to lower case.

## 18.7 mimetypes — Map filenames to MIME types

Source code : [Lib/mimetypes.py](#)

---

The *mimetypes* module converts between a filename or URL and the MIME type associated with the filename extension. Conversions are provided from filename to MIME type and from MIME type to filename extension; encodings are not supported for the latter conversion.

The module provides one class and a number of convenience functions. The functions are the normal interface to this module, but some applications may be interested in the class as well.

The functions described below provide the primary interface for this module. If the module has not been initialized, they will call `init()` if they rely on the information `init()` sets up.

`mimetypes.guess_type(url, strict=True)`

Guess the type of a file based on its filename or URL, given by *url*. The return value is a tuple (*type*, *encoding*) where *type* is `None` if the type can't be guessed (missing or unknown suffix) or a string of the form *'type/subtype'*, usable for a MIME *content-type* header.

*encoding* is `None` for no encoding or the name of the program used to encode (e.g. `compress` or `gzip`). The encoding is suitable for use as a *Content-Encoding* header, **not** as a *Content-Transfer-Encoding* header. The mappings are table driven. Encoding suffixes are case sensitive; type suffixes are first tried case sensitively, then case insensitively.

The optional *strict* argument is a flag specifying whether the list of known MIME types is limited to only the official types registered with IANA. When *strict* is `True` (the default), only the IANA types are supported; when *strict* is `False`, some additional non-standard but commonly used MIME types are also recognized.

`mimetypes.guess_all_extensions(type, strict=True)`

Guess the extensions for a file based on its MIME type, given by *type*. The return value is a list of strings giving all possible filename extensions, including the leading dot (`'.'`). The extensions are not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type *type* by `guess_type()`.

The optional *strict* argument has the same meaning as with the `guess_type()` function.

`mimetypes.guess_extension(type, strict=True)`

Guess the extension for a file based on its MIME type, given by *type*. The return value is a string

giving a filename extension, including the leading dot ('.'). The extension is not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type *type* by *guess\_type()*. If no extension can be guessed for *type*, *None* is returned.

The optional *strict* argument has the same meaning as with the *guess\_type()* function.

Some additional functions and data items are available for controlling the behavior of the module.

**mimetypes.init(files=None)**

Initialize the internal data structures. If given, *files* must be a sequence of file names which should be used to augment the default type map. If omitted, the file names to use are taken from *knownfiles*; on Windows, the current registry settings are loaded. Each file named in *files* or *knownfiles* takes precedence over those named before it. Calling *init()* repeatedly is allowed.

Specifying an empty list for *files* will prevent the system defaults from being applied : only the well-known values will be present from a built-in list.

Modifié dans la version 2.7 : Previously, Windows registry settings were ignored.

**mimetypes.read\_mime\_types(filename)**

Load the type map given in the file *filename*, if it exists. The type map is returned as a dictionary mapping filename extensions, including the leading dot ('.'), to strings of the form 'type/subtype'. If the file *filename* does not exist or cannot be read, *None* is returned.

**mimetypes.add\_type(type, ext, strict=True)**

Add a mapping from the MIME type *type* to the extension *ext*. When the extension is already known, the new type will replace the old one. When the type is already known the extension will be added to the list of known extensions.

When *strict* is *True* (the default), the mapping will be added to the official MIME types, otherwise to the non-standard ones.

**mimetypes.inited**

Flag indicating whether or not the global data structures have been initialized. This is set to *True* by *init()*.

**mimetypes.knownfiles**

List of type map file names commonly installed. These files are typically named *mime.types* and are installed in different locations by different packages.

**mimetypes.suffix\_map**

Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the *.tgz* extension is mapped to *.tar.gz* to allow the encoding and type to be recognized separately.

**mimetypes.encodings\_map**

Dictionary mapping filename extensions to encoding types.

**mimetypes.types\_map**

Dictionary mapping filename extensions to MIME types.

**mimetypes.common\_types**

Dictionary mapping filename extensions to non-standard, but commonly found MIME types.

Un exemple d'utilisation du module :

```
>>> import mimetypes
>>> mimetypes.init()
>>> mimetypes.knownfiles
['/etc/mime.types', '/etc/httpd/mime.types', ... ]
>>> mimetypes.suffix_map['.tgz']
'.tar.gz'
```

(suite sur la page suivante)

```
>>> mimetypes.encodings_map['.gz']
'gzip'
>>> mimetypes.types_map['.tgz']
'application/x-tar-gz'
```

### 18.7.1 MimeTypes Objects

The *MimeTypes* class may be useful for applications which may want more than one MIME-type database ; it provides an interface similar to the one of the *mimetypes* module.

**class** *mimetypes.MimeTypes*(*filenames=()*, *strict=True*)

This class represents a MIME-types database. By default, it provides access to the same database as the rest of this module. The initial database is a copy of that provided by the module, and may be extended by loading additional *mime.types*-style files into the database using the *read()* or *readfp()* methods. The mapping dictionaries may also be cleared before loading additional data if the default data is not desired.

The optional *filenames* parameter can be used to cause additional files to be loaded « on top » of the default database.

**suffix\_map**

Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the *.tgz* extension is mapped to *.tar.gz* to allow the encoding and type to be recognized separately. This is initially a copy of the global *suffix\_map* defined in the module.

**encodings\_map**

Dictionary mapping filename extensions to encoding types. This is initially a copy of the global *encodings\_map* defined in the module.

**types\_map**

Tuple containing two dictionaries, mapping filename extensions to MIME types : the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by *common\_types* and *types\_map*.

**types\_map\_inv**

Tuple containing two dictionaries, mapping MIME types to a list of filename extensions : the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by *common\_types* and *types\_map*.

**guess\_extension**(*type*, *strict=True*)

Similar to the *guess\_extension()* function, using the tables stored as part of the object.

**guess\_type**(*url*, *strict=True*)

Similar to the *guess\_type()* function, using the tables stored as part of the object.

**guess\_all\_extensions**(*type*, *strict=True*)

Similar to the *guess\_all\_extensions()* function, using the tables stored as part of the object.

**read**(*filename*, *strict=True*)

Load MIME information from a file named *filename*. This uses *readfp()* to parse the file.

If *strict* is *True*, information will be added to list of standard types, else to the list of non-standard types.

**readfp**(*fp*, *strict=True*)

Load MIME type information from an open file *fp*. The file must have the format of the standard *mime.types* files.

If *strict* is *True*, information will be added to the list of standard types, else to the list of non-standard types.

**read\_windows\_registry**(*strict=True*)

Load MIME type information from the Windows registry. Availability : Windows.

If *strict* is **True**, information will be added to the list of standard types, else to the list of non-standard types.

Nouveau dans la version 2.7.

## 18.8 MimeWriter — Generic MIME file writer

Obsolète depuis la version 2.3 : The *email* package should be used in preference to the *MimeWriter* module. This module is present only to maintain backward compatibility.

This module defines the class *MimeWriter*. The *MimeWriter* class implements a basic formatter for creating MIME multi-part files. It doesn't seek around the output file nor does it use large amounts of buffer space. You must write the parts out in the order that they should occur in the final file. *MimeWriter* does buffer the headers you add, allowing you to rearrange their order.

**class** *MimeWriter.MimeWriter*(*fp*)

Return a new instance of the *MimeWriter* class. The only argument passed, *fp*, is a file object to be used for writing. Note that a *StringIO* object could also be used.

### 18.8.1 MimeWriter Objects

*MimeWriter* instances have the following methods :

*MimeWriter.addheader*(*key*, *value*[, *prefix*])

Add a header line to the MIME message. The *key* is the name of the header, where the *value* obviously provides the value of the header. The optional argument *prefix* determines where the header is inserted ; 0 means append at the end, 1 is insert at the start. The default is to append.

*MimeWriter.flushheaders*()

Causes all headers accumulated so far to be written out (and forgotten). This is useful if you don't need a body part at all, e.g. for a subpart of type *message/rfc822* that's (mis)used to store some header-like information.

*MimeWriter.startbody*(*ctype*[, *plist*[, *prefix*]])

Returns a file-like object which can be used to write to the body of the message. The content-type is set to the provided *ctype*, and the optional parameter *plist* provides additional parameters for the content-type declaration. *prefix* functions as in *addheader()* except that the default is to insert at the start.

*MimeWriter.startmultipartbody*(*subtype*[, *boundary*[, *plist*[, *prefix*]]])

Returns a file-like object which can be used to write to the body of the message. Additionally, this method initializes the multi-part code, where *subtype* provides the multipart subtype, *boundary* may provide a user-defined boundary specification, and *plist* provides optional parameters for the subtype. *prefix* functions as in *startbody()*. Subparts should be created using *nextpart()*.

*MimeWriter.nextpart*()

Returns a new instance of *MimeWriter* which represents an individual part in a multipart message. This may be used to write the part as well as used for creating recursively complex multipart messages. The message must first be initialized with *startmultipartbody()* before using *nextpart()*.

*MimeWriter.lastpart*()

This is used to designate the last part of a multipart message, and should *always* be used when writing multipart messages.

## 18.9 mimify — MIME processing of mail messages

Obsolète depuis la version 2.3 : The *email* package should be used in preference to the *mimify* module. This module is present only to maintain backward compatibility.

The *mimify* module defines two functions to convert mail messages to and from MIME format. The mail message can be either a simple message or a so-called multipart message. Each part is treated separately. Mimifying (a part of) a message entails encoding the message as quoted-printable if it contains any characters that cannot be represented using 7-bit ASCII. Unmimifying (a part of) a message entails undoing the quoted-printable encoding. Mimify and unmimify are especially useful when a message has to be edited before being sent. Typical use would be :

```
unmimify message
edit message
mimify message
send message
```

The modules defines the following user-callable functions and user-settable variables :

**mimify.mimify(*infile*, *outfile*)**

Copy the message in *infile* to *outfile*, converting parts to quoted-printable and adding MIME mail headers when necessary. *infile* and *outfile* can be file objects (actually, any object that has a *readline()* method (for *infile*) or a *write()* method (for *outfile*)) or strings naming the files. If *infile* and *outfile* are both strings, they may have the same value.

**mimify.unmimify(*infile*, *outfile*[, *decode\_base64*])**

Copy the message in *infile* to *outfile*, decoding all quoted-printable parts. *infile* and *outfile* can be file objects (actually, any object that has a *readline()* method (for *infile*) or a *write()* method (for *outfile*)) or strings naming the files. If *infile* and *outfile* are both strings, they may have the same value. If the *decode\_base64* argument is provided and tests true, any parts that are coded in the base64 encoding are decoded as well.

**mimify.mime\_decode\_header(*line*)**

Return a decoded version of the encoded header line in *line*. This only supports the ISO 8859-1 charset (Latin-1).

**mimify.mime\_encode\_header(*line*)**

Return a MIME-encoded version of the header line in *line*.

**mimify.MAXLEN**

By default, a part will be encoded as quoted-printable when it contains any non-ASCII characters (characters with the 8th bit set), or if there are any lines longer than *MAXLEN* characters (default value 200).

**mimify.CHARSET**

When not specified in the mail headers, a character set must be filled in. The string used is stored in *CHARSET*, and the default value is ISO-8859-1 (also known as Latin1 (latin-one)).

This module can also be used from the command line. Usage is as follows :

```
mimify.py -e [-l length] [infile [outfile]]
mimify.py -d [-b] [infile [outfile]]
```

to encode (mimify) and decode (unmimify) respectively. *infile* defaults to standard input, *outfile* defaults to standard output. The same file can be specified for input and output.

If the **-l** option is given when encoding, if there are any lines longer than the specified *length*, the containing part will be encoded.

If the **-b** option is given when decoding, any base64 parts will be decoded as well.

**Voir aussi :**

Module *quopri* Encode and decode MIME quoted-printable files.

## 18.10 multifile — Support for files containing distinct parts

Obsolète depuis la version 2.5 : The *email* package should be used in preference to the *multifile* module. This module is present only to maintain backward compatibility.

The *MultiFile* object enables you to treat sections of a text file as file-like input objects, with `''` being returned by *readline()* when a given delimiter pattern is encountered. The defaults of this class are designed to make it useful for parsing MIME multipart messages, but by subclassing it and overriding methods it can be easily adapted for more general use.

**class multifile.MultiFile(*fp*[, *seekable*])**

Create a multi-file. You must instantiate this class with an input object argument for the *MultiFile* instance to get lines from, such as a file object returned by *open()*.

*MultiFile* only ever looks at the input object's *readline()*, *seek()* and *tell()* methods, and the latter two are only needed if you want random access to the individual MIME parts. To use *MultiFile* on a non-seekable stream object, set the optional *seekable* argument to false; this will prevent using the input object's *seek()* and *tell()* methods.

It will be useful to know that in *MultiFile*'s view of the world, text is composed of three kinds of lines : data, section-dividers, and end-markers. *MultiFile* is designed to support parsing of messages that may have multiple nested message parts, each with its own pattern for section-divider and end-marker lines.

**Voir aussi :**

Module *email* Comprehensive email handling package; supersedes the *multifile* module.

### 18.10.1 MultiFile Objects

A *MultiFile* instance has the following methods :

**MultiFile.readline(*str*)**

Read a line. If the line is data (not a section-divider or end-marker or real EOF) return it. If the line matches the most-recently-stacked boundary, return `''` and set *self.last* to 1 or 0 according as the match is or is not an end-marker. If the line matches any other stacked boundary, raise an error. On encountering end-of-file on the underlying stream object, the method raises **Error** unless all boundaries have been popped.

**MultiFile.readlines(*str*)**

Return all lines remaining in this part as a list of strings.

**MultiFile.read()**

Read all lines, up to the next section. Return them as a single (multiline) string. Note that this doesn't take a size argument!

**MultiFile.seek(*pos*[, *whence*])**

Seek. Seek indices are relative to the start of the current section. The *pos* and *whence* arguments are interpreted as for a file seek.

**MultiFile.tell()**

Return the file position relative to the start of the current section.

**MultiFile.next()**

Skip lines to the next section (that is, read lines until a section-divider or end-marker has been consumed). Return true if there is such a section, false if an end-marker is seen. Re-enable the most-recently-pushed boundary.

**MultiFile.is\_data(*str*)**

Return true if *str* is data and false if it might be a section boundary. As written, it tests for a prefix

other than '--' at start of line (which all MIME boundaries have) but it is declared so it can be overridden in derived classes.

Note that this test is used intended as a fast guard for the real boundary tests; if it always returns false it will merely slow processing, not cause it to fail.

#### `MultiFile.push(str)`

Push a boundary string. When a decorated version of this boundary is found as an input line, it will be interpreted as a section-divider or end-marker (depending on the decoration, see [RFC 2045](#)). All subsequent reads will return the empty string to indicate end-of-file, until a call to `pop()` removes the boundary a or `next()` call reenables it.

It is possible to push more than one boundary. Encountering the most-recently-pushed boundary will return EOF; encountering any other boundary will raise an error.

#### `MultiFile.pop()`

Pop a section boundary. This boundary will no longer be interpreted as EOF.

#### `MultiFile.section_divider(str)`

Turn a boundary into a section-divider line. By default, this method prepends '--' (which MIME section boundaries have) but it is declared so it can be overridden in derived classes. This method need not append LF or CR-LF, as comparison with the result ignores trailing whitespace.

#### `MultiFile.end_marker(str)`

Turn a boundary string into an end-marker line. By default, this method prepends '--' and appends '--' (like a MIME-multipart end-of-message marker) but it is declared so it can be overridden in derived classes. This method need not append LF or CR-LF, as comparison with the result ignores trailing whitespace.

Finally, `MultiFile` instances have two public instance variables :

#### `MultiFile.level`

Nesting depth of the current part.

#### `MultiFile.last`

True if the last end-of-file was for an end-of-message marker.

## 18.10.2 MultiFile Example

```
import mimetools
import multifile
import StringIO

def extract_mime_part_matching(stream, mimetype):
    """Return the first element in a multipart MIME message on stream
    matching mimetype."""

    msg = mimetools.Message(stream)
    msgtype = msg.gettype()
    params = msg.getplist()

    data = StringIO.StringIO()
    if msgtype[:10] == "multipart/":

        file = multifile.MultiFile(stream)
        file.push(msg.getparam("boundary"))
        while file.next():
            submsg = mimetools.Message(file)
```

(suite sur la page suivante)

(suite de la page précédente)

```

try:
    data = StringIO.StringIO()
    mimetools.decode(file, data, submsg.getencoding())
except ValueError:
    continue
if submsg.gettype() == mimetype:
    break
file.pop()
return data.getvalue()

```

## 18.11 rfc822 — Parse RFC 2822 mail headers

Obsolète depuis la version 2.3 : The *email* package should be used in preference to the *rfc822* module. This module is present only to maintain backward compatibility, and has been removed in Python 3.

This module defines a class, *Message*, which represents an « email message » as defined by the Internet standard **RFC 2822**.<sup>1</sup> Such messages consist of a collection of message headers, and a message body. This module also defines a helper class *AddressList* for parsing **RFC 2822** addresses. Please refer to the RFC for information on the specific syntax of **RFC 2822** messages.

The *mailbox* module provides classes to read mailboxes produced by various end-user mail programs.

**class** `rfc822.Message(file[, seekable])`

A *Message* instance is instantiated with an input object as parameter. Message relies only on the input object having a *readline()* method; in particular, ordinary file objects qualify. Instantiation reads headers from the input object up to a delimiter line (normally a blank line) and stores them in the instance. The message body, following the headers, is not consumed.

This class can work with any input object that supports a *readline()* method. If the input object has seek and tell capability, the *rewindbody()* method will work; also, illegal lines will be pushed back onto the input stream. If the input object lacks seek but has an *unread()* method that can push back a line of input, *Message* will use that to push back illegal lines. Thus this class can be used to parse messages coming from a buffered stream.

The optional *seekable* argument is provided as a workaround for certain stdio libraries in which *tell()* discards buffered data before discovering that the *lseek()* system call doesn't work. For maximum portability, you should set the *seekable* argument to zero to prevent that initial *tell()* when passing in an unseekable object such as a file object created from a socket object.

Input lines as read from the file may either be terminated by CR-LF or by a single linefeed; a terminating CR-LF is replaced by a single linefeed before the line is stored.

All header matching is done independent of upper or lower case; e.g. `m['From']`, `m['from']` and `m['FROM']` all yield the same result.

**class** `rfc822.AddressList(field)`

You may instantiate the *AddressList* helper class using a single string parameter, a comma-separated list of **RFC 2822** addresses to be parsed. (The parameter `None` yields an empty list.)

**rfc822.quote(str)**

Return a new string with backslashes in *str* replaced by two backslashes and double quotes replaced by backslash-double quote.

1. This module originally conformed to **RFC 822**, hence the name. Since then, **RFC 2822** has been released as an update to **RFC 822**. This module should be considered **RFC 2822**-conformant, especially in cases where the syntax or semantics have changed since **RFC 822**.

`rfc822.unquote(str)`

Return a new string which is an *unquoted* version of *str*. If *str* ends and begins with double quotes, they are stripped off. Likewise if *str* ends and begins with angle brackets, they are stripped off.

`rfc822.parseaddr(address)`

Parse *address*, which should be the value of some address-containing field such as *To* or *Cc*, into its constituent « realname » and « email address » parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple (`None`, `None`) is returned.

`rfc822.dump_address_pair(pair)`

The inverse of `parseaddr()`, this takes a 2-tuple of the form (`realname`, `email_address`) and returns the string value suitable for a *To* or *Cc* header. If the first element of *pair* is false, then the second element is returned unmodified.

`rfc822.parsedate(date)`

Attempts to parse a date according to the rules in [RFC 2822](#). however, some mailers don't follow that format as specified, so `parsedate()` tries to guess correctly in such cases. *date* is a string containing an [RFC 2822](#) date, such as 'Mon, 20 Nov 1995 19:12:08 -0500'. If it succeeds in parsing the date, `parsedate()` returns a 9-tuple that can be passed directly to `time.mktime()`; otherwise `None` will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

`rfc822.parsedate_tz(date)`

Performs the same function as `parsedate()`, but returns either `None` or a 10-tuple; the first 9 elements make up a tuple that can be passed directly to `time.mktime()`, and the tenth is the offset of the date's timezone from UTC (which is the official term for Greenwich Mean Time). (Note that the sign of the timezone offset is the opposite of the sign of the `time.timezone` variable for the same timezone; the latter variable follows the POSIX standard while this module follows [RFC 2822](#).) If the input string has no timezone, the last element of the tuple returned is `None`. Note that indexes 6, 7, and 8 of the result tuple are not usable.

`rfc822.mktime_tz(tuple)`

Turn a 10-tuple as returned by `parsedate_tz()` into a UTC timestamp. If the timezone item in the tuple is `None`, assume local time. Minor deficiency : this first interprets the first 8 elements as a local time and then compensates for the timezone difference; this may yield a slight error around daylight savings time switch dates. Not enough to worry about for common use.

**Voir aussi :**

**Module `email`** Comprehensive email handling package; supersedes the `rfc822` module.

**Module `mailbox`** Classes to read various mailbox formats produced by end-user mail programs.

**Module `mimetools`** Subclass of `rfc822.Message` that handles MIME encoded messages.

### 18.11.1 Message Objects

A `Message` instance has the following methods :

`Message.rewindbody()`

Seek to the start of the message body. This only works if the file object is seekable.

`Message.isheader(line)`

Returns a line's canonicalized fieldname (the dictionary key that will be used to index it) if the line is a legal [RFC 2822](#) header; otherwise returns `None` (implying that parsing should stop here and the line be pushed back on the input stream). It is sometimes useful to override this method in a subclass.

`Message.islast(line)`

Return true if the given line is a delimiter on which Message should stop. The delimiter line is consumed, and the file object's read location positioned immediately after it. By default this method just checks that the line is blank, but you can override it in a subclass.

`Message.iscomment(line)`

Return `True` if the given line should be ignored entirely, just skipped. By default this is a stub that always returns `False`, but you can override it in a subclass.

`Message.getallmatchingheaders(name)`

Return a list of lines consisting of all headers matching *name*, if any. Each physical line, whether it is a continuation line or not, is a separate list item. Return the empty list if no header matches *name*.

`Message.getfirstmatchingheader(name)`

Return a list of lines comprising the first header matching *name*, and its continuation line(s), if any. Return `None` if there is no header matching *name*.

`Message.getrawheader(name)`

Return a single string consisting of the text after the colon in the first header matching *name*. This includes leading whitespace, the trailing linefeed, and internal linefeeds and whitespace if there any continuation line(s) were present. Return `None` if there is no header matching *name*.

`Message.getheader(name[, default])`

Return a single string consisting of the last header matching *name*, but strip leading and trailing whitespace. Internal whitespace is not stripped. The optional *default* argument can be used to specify a different default to be returned when there is no header matching *name*; it defaults to `None`. This is the preferred way to get parsed headers.

`Message.get(name[, default])`

An alias for `getheader()`, to make the interface more compatible with regular dictionaries.

`Message.getaddr(name)`

Return a pair (**full name**, **email address**) parsed from the string returned by `getheader(name)`. If no header matching *name* exists, return `(None, None)`; otherwise both the full name and the address are (possibly empty) strings.

Example : If *m*'s first *From* header contains the string `'jack@cwil.nl (Jack Jansen)'`, then `m.getaddr('From')` will yield the pair `('Jack Jansen', 'jack@cwil.nl')`. If the header contained `'Jack Jansen <jack@cwil.nl>'` instead, it would yield the exact same result.

`Message.getaddrlist(name)`

This is similar to `getaddr(list)`, but parses a header containing a list of email addresses (e.g. a *To* header) and returns a list of (**full name**, **email address**) pairs (even if there was only one address in the header). If there is no header matching *name*, return an empty list.

If multiple headers exist that match the named header (e.g. if there are several *Cc* headers), all are parsed for addresses. Any continuation lines the named headers contain are also parsed.

`Message.getdate(name)`

Retrieve a header using `getheader()` and parse it into a 9-tuple compatible with `time.mktime()`; note that fields 6, 7, and 8 are not usable. If there is no header matching *name*, or it is unparsable, return `None`.

Date parsing appears to be a black art, and not all mailers adhere to the standard. While it has been tested and found correct on a large collection of email from many sources, it is still possible that this function may occasionally yield an incorrect result.

`Message.getdate_tz(name)`

Retrieve a header using `getheader()` and parse it into a 10-tuple; the first 9 elements will make a tuple compatible with `time.mktime()`, and the 10th is a number giving the offset of the date's timezone from UTC. Note that fields 6, 7, and 8 are not usable. Similarly to `getdate()`, if there is no header matching *name*, or it is unparsable, return `None`.

*Message* instances also support a limited mapping interface. In particular : `m[name]` is like `m.getheader(name)` but raises `KeyError` if there is no matching header; and `len(m)`, `m.get(name[, default])`, `name in m`, `m.keys()`, `m.values()` `m.items()`, and `m.setdefault(name[, default])` act as

expected, with the one difference that `setdefault()` uses an empty string as the default value. *Message* instances also support the mapping writable interface `m[name] = value` and `del m[name]`. *Message* objects do not support the `clear()`, `copy()`, `popitem()`, or `update()` methods of the mapping interface. (Support for `get()` and `setdefault()` was only added in Python 2.2.)

Finally, *Message* instances have some public instance variables :

**Message.headers**

A list containing the entire set of header lines, in the order in which they were read (except that `setitem` calls may disturb this order). Each line contains a trailing newline. The blank line terminating the headers is not contained in the list.

**Message.fp**

The file or file-like object passed at instantiation time. This can be used to read the message content.

**Message.unixfrom**

The Unix **From** line, if the message had one, or an empty string. This is needed to regenerate the message in some contexts, such as an **mbox**-style mailbox file.

## 18.11.2 AddressList Objects

An *AddressList* instance has the following methods :

**AddressList.\_\_len\_\_()**

Return the number of addresses in the address list.

**AddressList.\_\_str\_\_()**

Return a canonicalized string representation of the address list. Addresses are rendered in « name » <host@domain> form, comma-separated.

**AddressList.\_\_add\_\_(alist)**

Return a new *AddressList* instance that contains all addresses in both *AddressList* operands, with duplicates removed (set union).

**AddressList.\_\_iadd\_\_(alist)**

In-place version of `__add__()`; turns this *AddressList* instance into the union of itself and the right-hand instance, *alist*.

**AddressList.\_\_sub\_\_(alist)**

Return a new *AddressList* instance that contains every address in the left-hand *AddressList* operand that is not present in the right-hand address operand (set difference).

**AddressList.\_\_isub\_\_(alist)**

In-place version of `__sub__()`, removing addresses in this list which are also in *alist*.

Finally, *AddressList* instances have one public instance variable :

**AddressList.addresslist**

A list of tuple string pairs, one per address. In each member, the first is the canonicalized name part, the second is the actual route-address ('@'-separated username-host.domain pair).

### Notes

## 18.12 base64 — RFC 3548 : Base16, Base32, Base64 Data Encodings

This module provides data encoding and decoding as specified in [RFC 3548](#). This standard defines the Base16, Base32, and Base64 algorithms for encoding and decoding arbitrary binary strings into text strings that can be safely sent by email, used as parts of URLs, or included as part of an HTTP POST request. The encoding algorithm is not the same as the **uuencode** program.

There are two interfaces provided by this module. The modern interface supports encoding and decoding string objects using both base-64 alphabets defined in [RFC 3548](#) (normal, and URL- and filesystem-safe). The legacy interface provides for encoding and decoding to and from file-like objects as well as strings, but only using the Base64 standard alphabet.

The modern interface, which was introduced in Python 2.4, provides :

`base64.b64encode(s[, altchars])`

Encode a string using Base64.

*s* is the string to encode. Optional *altchars* must be a string of at least length 2 (additional characters are ignored) which specifies an alternative alphabet for the + and / characters. This allows an application to e.g. generate URL or filesystem safe Base64 strings. The default is `None`, for which the standard Base64 alphabet is used.

The encoded string is returned.

`base64.b64decode(s[, altchars])`

Decode a Base64 encoded string.

*s* is the string to decode. Optional *altchars* must be a string of at least length 2 (additional characters are ignored) which specifies the alternative alphabet used instead of the + and / characters.

The decoded string is returned. A `TypeError` is raised if *s* is incorrectly padded. Characters that are neither in the normal base-64 alphabet nor the alternative alphabet are discarded prior to the padding check.

`base64.standard_b64encode(s)`

Encode string *s* using the standard Base64 alphabet.

`base64.standard_b64decode(s)`

Decode string *s* using the standard Base64 alphabet.

`base64.urlsafe_b64encode(s)`

Encode string *s* using the URL- and filesystem-safe alphabet, which substitutes - instead of + and \_ instead of / in the standard Base64 alphabet. The result can still contain =.

`base64.urlsafe_b64decode(s)`

Decode string *s* using the URL- and filesystem-safe alphabet, which substitutes - instead of + and \_ instead of / in the standard Base64 alphabet.

`base64.b32encode(s)`

Encode a string using Base32. *s* is the string to encode. The encoded string is returned.

`base64.b32decode(s[, casefold[, map01]])`

Decode a Base32 encoded string.

*s* is the string to decode. Optional *casefold* is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is `False`.

[RFC 3548](#) allows for optional mapping of the digit 0 (zero) to the letter O (oh), and for optional mapping of the digit 1 (one) to either the letter I (eye) or letter L (el). The optional argument *map01* when not `None`, specifies which letter the digit 1 should be mapped to (when *map01* is not `None`, the digit 0 is always mapped to the letter O). For security purposes the default is `None`, so that 0 and 1 are not allowed in the input.

The decoded string is returned. A `TypeError` is raised if *s* is incorrectly padded or if there are non-alphabet characters present in the string.

`base64.b16encode(s)`

Encode a string using Base16.

*s* is the string to encode. The encoded string is returned.

`base64.b16decode(s[, casefold])`

Decode a Base16 encoded string.

*s* is the string to decode. Optional *casefold* is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is `False`.

The decoded string is returned. A `TypeError` is raised if *s* were incorrectly padded or if there are non-alphabet characters present in the string.

L'interface historique :

`base64.decode(input, output)`

Decode the contents of the *input* file and write the resulting binary data to the *output* file. *input* and *output* must either be file objects or objects that mimic the file object interface. *input* will be read until `input.read()` returns an empty string.

`base64.decodestring(s)`

Decode the string *s*, which must contain one or more lines of base64 encoded data, and return a string containing the resulting binary data.

`base64.encode(input, output)`

Encode the contents of the *input* file and write the resulting base64 encoded data to the *output* file. *input* and *output* must either be file objects or objects that mimic the file object interface. *input* will be read until `input.read()` returns an empty string. `encode()` returns the encoded data plus a trailing newline character (`'\n'`).

`base64.encodestring(s)`

Encode the string *s*, which can contain arbitrary binary data, and return a string containing one or more lines of base64-encoded data. `encodestring()` returns a string containing one or more lines of base64-encoded data always including an extra trailing newline (`'\n'`).

Un exemple d'utilisation du module :

```
>>> import base64
>>> encoded = base64.b64encode('data to be encoded')
>>> encoded
'ZGFOYSB0byBiZSB1bmNvZGVk'
>>> data = base64.b64decode(encoded)
>>> data
'data to be encoded'
```

Voir aussi :

Module `binascii` Module secondaire contenant les conversions ASCII vers binaire et binaire vers ASCII.

**RFC 1521 - MIME (Multipurpose Internet Mail Extensions) Part One : Mechanisms for Specifying and**  
Section 5.2, « Base64 Content-Transfer-Encoding, » provides the definition of the base64 encoding.

## 18.13 binhex — Encode et décode les fichiers *binhex4*

This module encodes and decodes files in binhex4 format, a format allowing representation of Macintosh files in ASCII. On the Macintosh, both forks of a file and the finder information are encoded (or decoded), on other platforms only the data fork is handled.

---

**Note :** In Python 3.x, special Macintosh support has been removed.

---

Le module `binhex` définit les fonctions suivantes :

`binhex.binhex(input, output)`

Convertit un fichier binaire avec comme nom *input* en fichier *binhex output*. Le paramètre *output* peut

être soit un nom de fichier, soit un objet s'apparentant à un fichier (tout objet supportant les méthodes `write()` et `close()`).

`binhex.hexbin(input[, output])`

Decode a binhex file *input*. *input* may be a filename or a file-like object supporting `read()` and `close()` methods. The resulting file is written to a file named *output*, unless the argument is omitted in which case the output filename is read from the binhex file.

L'exception suivante est aussi définie :

**exception** `binhex.Error`

Exception levée quand quelque chose ne peut être encodé en utilisant le format *binhex* (par exemple, un nom de fichier trop long pour rentrer dans le champ *filename*) ou quand les données d'entrée ne sont pas encodées correctement en *binhex*.

**Voir aussi :**

**Module** `binascii` Module secondaire contenant les conversions ASCII vers binaire et binaire vers ASCII.

### 18.13.1 Notes

Il y a une alternative, une interface plus puissante pour le codeur et décodeur, voir les sources pour les détails.

Si vous codez ou décidez sur des plateformes autres que Macintosh, elles utiliseront l'ancienne convention Macintosh pour les retours à la ligne (retour-chariot comme fin de ligne).

As of this writing, `hexbin()` appears to not work in all cases.

## 18.14 binascii — Convert between binary and ASCII

The `binascii` module contains a number of methods to convert between binary and various ASCII-encoded binary representations. Normally, you will not use these functions directly but use wrapper modules like `uu`, `base64`, or `binhex` instead. The `binascii` module contains low-level functions written in C for greater speed that are used by the higher-level modules.

The `binascii` module defines the following functions :

`binascii.a2b_uu(string)`

Convert a single line of uuencoded data back to binary and return the binary data. Lines normally contain 45 (binary) bytes, except for the last line. Line data may be followed by whitespace.

`binascii.b2a_uu(data)`

Convert binary data to a line of ASCII characters, the return value is the converted line, including a newline char. The length of *data* should be at most 45.

`binascii.a2b_base64(string)`

Convert a block of base64 data back to binary and return the binary data. More than one line may be passed at a time.

`binascii.b2a_base64(data)`

Convert binary data to a line of ASCII characters in base64 coding. The return value is the converted line, including a newline char. The newline is added because the original use case for this function was to feed it a series of 57 byte input lines to get output lines that conform to the MIME-base64 standard. Otherwise the output conforms to [RFC 3548](#).

`binascii.a2b_qp(string[, header])`

Convert a block of quoted-printable data back to binary and return the binary data. More than one

line may be passed at a time. If the optional argument *header* is present and true, underscores will be decoded as spaces.

`binascii.b2a_qp(data[, quotetabs, istext, header])`

Convert binary data to a line(s) of ASCII characters in quoted-printable encoding. The return value is the converted line(s). If the optional argument *quotetabs* is present and true, all tabs and spaces will be encoded. If the optional argument *istext* is present and true, newlines are not encoded but trailing whitespace will be encoded. If the optional argument *header* is present and true, spaces will be encoded as underscores per RFC1522. If the optional argument *header* is present and false, newline characters will be encoded as well; otherwise linefeed conversion might corrupt the binary data stream.

`binascii.a2b_hqx(string)`

Convert binhex4 formatted ASCII data to binary, without doing RLE-decompression. The string should contain a complete number of binary bytes, or (in case of the last portion of the binhex4 data) have the remaining bits zero.

`binascii.rledecode_hqx(data)`

Perform RLE-decompression on the data, as per the binhex4 standard. The algorithm uses 0x90 after a byte as a repeat indicator, followed by a count. A count of 0 specifies a byte value of 0x90. The routine returns the decompressed data, unless data input data ends in an orphaned repeat indicator, in which case the *Incomplete* exception is raised.

`binascii.rlecode_hqx(data)`

Perform binhex4 style RLE-compression on *data* and return the result.

`binascii.b2a_hqx(data)`

Perform hexbin4 binary-to-ASCII translation and return the resulting string. The argument should already be RLE-coded, and have a length divisible by 3 (except possibly the last fragment).

`binascii.crc_hqx(data, crc)`

Compute a 16-bit CRC value of *data*, starting with an initial *crc* and returning the result. This uses the CRC-CCITT polynomial  $x^{16} + x^{12} + x^5 + 1$ , often represented as 0x1021. This CRC is used in the binhex4 format.

`binascii.crc32(data[, crc])`

Compute CRC-32, the 32-bit checksum of data, starting with an initial *crc*. This is consistent with the ZIP file checksum. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm. Use as follows :

```
print binascii.crc32("hello world")
# Or, in two pieces:
crc = binascii.crc32("hello")
crc = binascii.crc32(" world", crc) & 0xffffffff
print 'crc32 = 0x%08x' % crc
```

---

**Note :** To generate the same numeric value across all Python versions and platforms use `crc32(data) & 0xffffffff`. If you are only using the checksum in packed binary format this is not necessary as the return value is the correct 32bit binary representation regardless of sign.

---

Modifié dans la version 2.6 : The return value is in the range `[-2**31, 2**31-1]` regardless of platform. In the past the value would be signed on some platforms and unsigned on others. Use `& 0xffffffff` on the value if you want it to match Python 3 behavior.

Modifié dans la version 3.0 : The return value is unsigned and in the range `[0, 2**32-1]` regardless of platform.

`binascii.b2a_hex(data)`

`binascii.hexlify(data)`

Return the hexadecimal representation of the binary *data*. Every byte of *data* is converted into the corresponding 2-digit hex representation. The resulting string is therefore twice as long as the length of *data*.

`binascii.a2b_hex(hexstr)`

`binascii.unhexlify(hexstr)`

Return the binary data represented by the hexadecimal string *hexstr*. This function is the inverse of `b2a_hex()`. *hexstr* must contain an even number of hexadecimal digits (which can be upper or lower case), otherwise a `TypeError` is raised.

**exception** `binascii.Error`

Exception raised on errors. These are usually programming errors.

**exception** `binascii.Incomplete`

Exception raised on incomplete data. These are usually not programming errors, but may be handled by reading a little more data and trying again.

Voir aussi :

Module `base64` Support for RFC compliant base64-style encoding in base 16, 32, and 64.

Module `binhex` Support for the binhex format used on the Macintosh.

Module `uu` Gestion de l'encodage UU utilisé sur Unix.

Module `quopri` Support for quoted-printable encoding used in MIME email messages.

## 18.15 quopri — Encode et décode des données *MIME quoted-printable*

Code source : [Lib/quopri.py](#)

Ce module effectue des encodages et décodages de transport *quoted-printable*, tel que définis dans la [RFC 1521](#) : « *MIME (Multipurpose Internet Mail Extensions) Part One Mechanisms for Specifying and Describing the Format of Internet Message Bodies* ». L'encodage *quoted-printable* est adapté aux données dans lesquelles peu de données ne sont pas affichables. L'encodage *base64* disponible dans le module `base64` est plus compact dans les cas où ces caractères sont nombreux, typiquement pour encoder des images.

`quopri.decode(input, output[, header])`

Decode the contents of the *input* file and write the resulting decoded binary data to the *output* file. *input* and *output* must either be file objects or objects that mimic the file object interface. *input* will be read until `input.readline()` returns an empty string. If the optional argument *header* is present and true, underscore will be decoded as space. This is used to decode « Q »-encoded headers as described in [RFC 1522](#) : « *MIME (Multipurpose Internet Mail Extensions) Part Two : Message Header Extensions for Non-ASCII Text* ».

`quopri.encode(input, output, quotetabs)`

Encode the contents of the *input* file and write the resulting quoted-printable data to the *output* file. *input* and *output* must either be file objects or objects that mimic the file object interface. *input* will be read until `input.readline()` returns an empty string. *quotetabs* is a flag which controls whether to encode embedded spaces and tabs; when true it encodes such embedded whitespace, and when false it leaves them unencoded. Note that spaces and tabs appearing at the end of lines are always encoded, as per [RFC 1521](#).

`quopri.decodestring(s[, header])`

Like `decode()`, except that it accepts a source string and returns the corresponding decoded string.

```
quopri.encodestring(s[, quotetabs])
```

Like `encode()`, except that it accepts a source string and returns the corresponding encoded string. `quotetabs` is optional (defaulting to 0), and is passed straight through to `encode()`.

Module `base64` Encode et décode des données MIME en *base64*

## 18.16 uu — Encode et décode les fichiers *uuencode*

Code source : `Lib/uu.py`

---

Ce module encode et décode les fichiers au format *uuencode*, permettant à des données binaires d'être transférées lors de connexion ASCII. Pour tous les arguments où un fichier est attendu, les fonctions acceptent un « objet fichier-compatible ». Pour des raisons de compatibilité avec les anciennes versions de Python, une chaîne de caractères contenant un chemin est aussi acceptée, et le fichier correspondant sera ouvert en lecture et écriture ; le chemin '-' est considéré comme l'entrée ou la sortie standard. Cependant cette interface est obsolète ; il vaut mieux que l'appelant ouvre le fichier lui-même, en s'assurant si nécessaire que le mode d'ouverture soit 'rb' ou 'wb' sur Windows.

Ce code provient d'une contribution de Lance Ellinghouse et a été modifié par Jack Jansen.

Le module `uu` définit les fonctions suivantes :

```
uu.encode(in_file, out_file[, name[, mode]])
```

Uuencode file *in\_file* into file *out\_file*. The uuencoded file will have the header specifying *name* and *mode* as the defaults for the results of decoding the file. The default defaults are taken from *in\_file*, or '-' and 0666 respectively.

```
uu.decode(in_file[, out_file[, mode[, quiet]]])
```

Décode le fichier *in\_file* et écrit le résultat dans *out\_file*. Si *out\_file* est un chemin, *mode* est utilisé pour les permissions du fichier lors de sa création. Les valeurs par défaut pour *out\_file* et *mode* sont récupérées des entêtes *uuencode*. Cependant, si le fichier spécifié par les entêtes est déjà existant, une exception `uu.Error` est levée.

La fonction `decode()` écrit un avertissement sur la sortie d'erreur si l'entrée contient des erreurs mais que Python a pu s'en sortir. Mettre *quiet* à *True* empêche l'écriture de cet avertissement.

**exception** `uu.Error`

Classe fille d'*Exception*, elle peut être levée par `uu.decode()` dans différentes situations, tel que décrit plus haut, mais aussi en cas d'entête mal formatée ou d'entrée tronquée.

Module `binascii` Module secondaire contenant les conversions ASCII vers binaire et binaire vers ASCII.

---

Outils de traitement de balises structurées

---

Python intègre une variété de modules pour fonctionner avec différentes formes de données structurées et balisées, comme le SGML (*Standard Generalized Markup Language*), le HTML (*Hypert Markup Language*), et quelques interfaces pour travailler avec du XML (*eXtensible Markup Language*).

It is important to note that modules in the `xml` package require that there be at least one SAX-compliant XML parser available. Starting with Python 2.3, the Expat parser is included with Python, so the `xml.parsers.expat` module will always be available. You may still want to be aware of the PyXML add-on package; that package provides an extended set of XML libraries for Python.

La documentation des *bindings* des interfaces DOM et SAX se trouve dans `xml.dom` et `xml.sax`.

## 19.1 HTMLParser — Simple HTML and XHTML parser

---

**Note :** The `HTMLParser` module has been renamed to `html.parser` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

---

Nouveau dans la version 2.2.

**Source code :** [Lib/HTMLParser.py](#)

---

This module defines a class `HTMLParser` which serves as the basis for parsing text files formatted in HTML (HyperText Mark-up Language) and XHTML. Unlike the parser in `html.lib`, this parser is not based on the SGML parser in `sgml.lib`.

### **class** HTMLParser.HTMLParser

An `HTMLParser` instance is fed HTML data and calls handler methods when start tags, end tags, text, comments, and other markup elements are encountered. The user should subclass `HTMLParser` and override its methods to implement the desired behavior.

The `HTMLParser` class is instantiated without arguments.

Unlike the parser in `html.lib`, this parser does not check that end tags match start tags or call the end-tag handler for elements which are closed implicitly by closing an outer element.

An exception is defined as well :

**exception** `HTMLParser.HTMLParseError`

*HTMLParser* is able to handle broken markup, but in some cases it might raise this exception when it encounters an error while parsing. This exception provides three attributes : `msg` is a brief message explaining the error, `lineno` is the number of the line on which the broken construct was detected, and `offset` is the number of characters into the line at which the construct starts.

### 19.1.1 Example HTML Parser Application

As a basic example, below is a simple HTML parser that uses the *HTMLParser* class to print out start tags, end tags and data as they are encountered :

```
from HTMLParser import HTMLParser

# create a subclass and override the handler methods
class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print "Encountered a start tag:", tag

    def handle_endtag(self, tag):
        print "Encountered an end tag :", tag

    def handle_data(self, data):
        print "Encountered some data  :", data

# instantiate the parser and fed it some HTML
parser = MyHTMLParser()
parser.feed('<html><head><title>Test</title></head>'
          '<body><h1>Parse me!</h1></body></html>')
```

The output will then be :

```
Encountered a start tag: html
Encountered a start tag: head
Encountered a start tag: title
Encountered some data  : Test
Encountered an end tag : title
Encountered an end tag : head
Encountered a start tag: body
Encountered a start tag: h1
Encountered some data  : Parse me!
Encountered an end tag : h1
Encountered an end tag : body
Encountered an end tag : html
```

### 19.1.2 HTMLParser Methods

*HTMLParser* instances have the following methods :

`HTMLParser.feed(data)`

Feed some text to the parser. It is processed insofar as it consists of complete elements ; incomplete data is buffered until more data is fed or *close()* is called. *data* can be either *unicode* or *str*, but passing *unicode* is advised.

**HTMLParser.close()**

Force processing of all buffered data as if it were followed by an end-of-file mark. This method may be redefined by a derived class to define additional processing at the end of the input, but the redefined version should always call the *HTMLParser* base class method *close()*.

**HTMLParser.reset()**

Reset the instance. Loses all unprocessed data. This is called implicitly at instantiation time.

**HTMLParser.getpos()**

Return current line number and offset.

**HTMLParser.get\_starttag\_text()**

Return the text of the most recently opened start tag. This should not normally be needed for structured processing, but may be useful in dealing with HTML « as deployed » or for re-generating input with minimal changes (whitespace between attributes can be preserved, etc.).

The following methods are called when data or markup elements are encountered and they are meant to be overridden in a subclass. The base class implementations do nothing (except for *handle\_startendtag()*) :

**HTMLParser.handle\_starttag(tag, attrs)**

This method is called to handle the start of a tag (e.g. `<div id="main">`).

The *tag* argument is the name of the tag converted to lower case. The *attrs* argument is a list of (*name*, *value*) pairs containing the attributes found inside the tag's `<>` brackets. The *name* will be translated to lower case, and quotes in the *value* have been removed, and character and entity references have been replaced.

For instance, for the tag `<A HREF="https://www.cwi.nl/">`, this method would be called as *handle\_starttag('a', [('href', 'https://www.cwi.nl/')])*.

Modifié dans la version 2.6 : All entity references from *htmlentitydefs* are now replaced in the attribute values.

**HTMLParser.handle\_endtag(tag)**

This method is called to handle the end tag of an element (e.g. `</div>`).

The *tag* argument is the name of the tag converted to lower case.

**HTMLParser.handle\_startendtag(tag, attrs)**

Similar to *handle\_starttag()*, but called when the parser encounters an XHTML-style empty tag (`<img ... />`). This method may be overridden by subclasses which require this particular lexical information; the default implementation simply calls *handle\_starttag()* and *handle\_endtag()*.

**HTMLParser.handle\_data(data)**

This method is called to process arbitrary data (e.g. text nodes and the content of `<script>...</script>` and `<style>...</style>`).

**HTMLParser.handle\_entityref(name)**

This method is called to process a named character reference of the form `&name;` (e.g. `&gt;`), where *name* is a general entity reference (e.g. `'gt'`).

**HTMLParser.handle\_charref(name)**

This method is called to process decimal and hexadecimal numeric character references of the form `&#NNN;` and `&#xNNN;`. For example, the decimal equivalent for `&gt;` is `&#62;`, whereas the hexadecimal is `&#x3E;`; in this case the method will receive `'62'` or `'x3E'`.

**HTMLParser.handle\_comment(data)**

This method is called when a comment is encountered (e.g. `<!--comment-->`).

For example, the comment `<!-- comment -->` will cause this method to be called with the argument `' comment '`.

The content of Internet Explorer conditional comments (condcoms) will also be sent to this method, so, for `<!--[if IE 9]>IE9-specific content<![endif]-->`, this method will receive `'[if IE 9]>IE9-specific content<![endif]'`.

`HTMLParser.handle_decl(decl)`

This method is called to handle an HTML doctype declaration (e.g. `<!DOCTYPE html>`).

The *decl* parameter will be the entire contents of the declaration inside the `<![...]>` markup (e.g. `'DOCTYPE html'`).

`HTMLParser.handle_pi(data)`

This method is called when a processing instruction is encountered. The *data* parameter will contain the entire processing instruction. For example, for the processing instruction `<?proc color='red'>`, this method would be called as `handle_pi("proc color='red'")`.

---

**Note :** The *HTMLParser* class uses the SGML syntactic rules for processing instructions. An XHTML processing instruction using the trailing `'?'` will cause the `'?'` to be included in *data*.

---

`HTMLParser.unknown_decl(data)`

This method is called when an unrecognized declaration is read by the parser.

The *data* parameter will be the entire contents of the declaration inside the `<![...]>` markup. It is sometimes useful to be overridden by a derived class.

### 19.1.3 Exemples

The following class implements a parser that will be used to illustrate more examples :

```
from HTMLParser import HTMLParser
from htmlentitydefs import name2codepoint

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print "Start tag:", tag
        for attr in attrs:
            print "    attr:", attr

    def handle_endtag(self, tag):
        print "End tag  :", tag

    def handle_data(self, data):
        print "Data      :", data

    def handle_comment(self, data):
        print "Comment  :", data

    def handle_entityref(self, name):
        c = unichr(name2codepoint[name])
        print "Named ent:", c

    def handle_charref(self, name):
        if name.startswith('x'):
            c = unichr(int(name[1:], 16))
        else:
            c = unichr(int(name))
        print "Num ent  :", c

    def handle_decl(self, data):
        print "Decl      :", data
```

(suite sur la page suivante)

(suite de la page précédente)

```
parser = MyHTMLParser()
```

Parsing a doctype :

```
>>> parser.feed('<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" '
...           '"http://www.w3.org/TR/html4/strict.dtd">')
Decl      : DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" "http://www.w3.org/TR/html4/
↳strict.dtd"
```

Parsing an element with a few attributes and a title :

```
>>> parser.feed('')
Start tag: img
  attr: ('src', 'python-logo.png')
  attr: ('alt', 'The Python logo')
>>>
>>> parser.feed('<h1>Python</h1>')
Start tag: h1
Data      : Python
End tag   : h1
```

The content of `script` and `style` elements is returned as is, without further parsing :

```
>>> parser.feed('<style type="text/css">#python { color: green }</style>')
Start tag: style
  attr: ('type', 'text/css')
Data      : #python { color: green }
End tag   : style

>>> parser.feed('<script type="text/javascript">'
...           'alert("<strong>hello!</strong>");</script>')
Start tag: script
  attr: ('type', 'text/javascript')
Data      : alert("<strong>hello!</strong>");
End tag   : script
```

Parsing comments :

```
>>> parser.feed('<!-- a comment -->'
...           '<!--[if IE 9]>IE-specific content<![endif]-->')
Comment   : a comment
Comment   : [if IE 9]>IE-specific content<![endif]
```

Parsing named and numeric character references and converting them to the correct char (note : these 3 references are all equivalent to '>') :

```
>>> parser.feed('&gt;&#62;&#x3E;')
Named ent: >
Num ent   : >
Num ent   : >
```

Feeding incomplete chunks to `feed()` works, but `handle_data()` might be called more than once :

```
>>> for chunk in ['<sp', 'an>buff', 'ered ', 'text</s', 'pan>']:
...     parser.feed(chunk)
...
Start tag: span
Data      : buff
Data      : ered
Data      : text
End tag   : span
```

Parsing invalid HTML (e.g. unquoted attributes) also works :

```
>>> parser.feed('<p><a class=link href=#main>tag soup</p ></a>')
Start tag: p
Start tag: a
      attr: ('class', 'link')
      attr: ('href', '#main')
Data      : tag soup
End tag   : p
End tag   : a
```

## 19.2 sgmllib — Simple SGML parser

Obsolète depuis la version 2.6 : The *sgmllib* module has been removed in Python 3.

This module defines a class *SGMLParser* which serves as the basis for parsing text files formatted in SGML (Standard Generalized Mark-up Language). In fact, it does not provide a full SGML parser — it only parses SGML insofar as it is used by HTML, and the module only exists as a base for the *htmlib* module. Another HTML parser which supports XHTML and offers a somewhat different interface is available in the *HTMLParser* module.

### **class** sgmlib.SGMLParser

The *SGMLParser* class is instantiated without arguments. The parser is hardcoded to recognize the following constructs :

- Opening and closing tags of the form `<tag attr="value" ...>` and `</tag>`, respectively.
- Numeric character references of the form `&#name;`.
- Entity references of the form `&name;`.
- SGML comments of the form `<!--text-->`. Note that spaces, tabs, and newlines are allowed between the trailing `>` and the immediately preceding `--`.

A single exception is defined as well :

### **exception** sgmlib.SGMLParseError

Exception raised by the *SGMLParser* class when it encounters an error while parsing.

Nouveau dans la version 2.1.

*SGMLParser* instances have the following methods :

### **SGMLParser.reset()**

Reset the instance. Loses all unprocessed data. This is called implicitly at instantiation time.

### **SGMLParser.setnomoretags()**

Stop processing tags. Treat all following input as literal input (CDATA). (This is only provided so the HTML tag `<PLAINTEXT>` can be implemented.)

### **SGMLParser.setliteral()**

Enter literal mode (CDATA mode).

**SGMLParser.feed(*data*)**

Feed some text to the parser. It is processed insofar as it consists of complete elements; incomplete data is buffered until more data is fed or `close()` is called.

**SGMLParser.close()**

Force processing of all buffered data as if it were followed by an end-of-file mark. This method may be redefined by a derived class to define additional processing at the end of the input, but the redefined version should always call `close()`.

**SGMLParser.get\_starttag\_text()**

Return the text of the most recently opened start tag. This should not normally be needed for structured processing, but may be useful in dealing with HTML « as deployed » or for re-generating input with minimal changes (whitespace between attributes can be preserved, etc.).

**SGMLParser.handle\_starttag(*tag*, *method*, *attributes*)**

This method is called to handle start tags for which either a `start_tag()` or `do_tag()` method has been defined. The *tag* argument is the name of the tag converted to lower case, and the *method* argument is the bound method which should be used to support semantic interpretation of the start tag. The *attributes* argument is a list of (*name*, *value*) pairs containing the attributes found inside the tag's <> brackets.

The *name* has been translated to lower case. Double quotes and backslashes in the *value* have been interpreted, as well as known character references and known entity references terminated by a semi-colon (normally, entity references can be terminated by any non-alphanumeric character, but this would break the very common case of <A HREF="url?spam=1&eggs=2"> when *eggs* is a valid entity name).

For instance, for the tag <A HREF="http://www.cwi.nl/">, this method would be called as `unknown_starttag('a', [('href', 'http://www.cwi.nl/')])`. The base implementation simply calls *method* with *attributes* as the only argument.

Nouveau dans la version 2.5 : Handling of entity and character references within attribute values.

**SGMLParser.handle\_endtag(*tag*, *method*)**

This method is called to handle endtags for which an `end_tag()` method has been defined. The *tag* argument is the name of the tag converted to lower case, and the *method* argument is the bound method which should be used to support semantic interpretation of the end tag. If no `end_tag()` method is defined for the closing element, this handler is not called. The base implementation simply calls *method*.

**SGMLParser.handle\_data(*data*)**

This method is called to process arbitrary data. It is intended to be overridden by a derived class; the base class implementation does nothing.

**SGMLParser.handle\_charref(*ref*)**

This method is called to process a character reference of the form `&#ref;`. The base implementation uses `convert_charref()` to convert the reference to a string. If that method returns a string, it is passed to `handle_data()`, otherwise `unknown_charref(ref)` is called to handle the error.

Modifié dans la version 2.5 : Use `convert_charref()` instead of hard-coding the conversion.

**SGMLParser.convert\_charref(*ref*)**

Convert a character reference to a string, or `None`. *ref* is the reference passed in as a string. In the base implementation, *ref* must be a decimal number in the range 0–255. It converts the code point found using the `convert_codepoint()` method. If *ref* is invalid or out of range, this method returns `None`. This method is called by the default `handle_charref()` implementation and by the attribute value parser.

Nouveau dans la version 2.5.

**SGMLParser.convert\_codepoint(*codepoint*)**

Convert a code point to a `str` value. Encodings can be handled here if appropriate, though the rest of `sgmlib` is oblivious on this matter.

Nouveau dans la version 2.5.

**SGMLParser.handle\_entityref(*ref*)**

This method is called to process a general entity reference of the form `&ref;` where *ref* is a general entity reference. It converts *ref* by passing it to `convert_entityref()`. If a translation is returned, it calls the method `handle_data()` with the translation; otherwise, it calls the method `unknown_entityref(ref)`. The default `entitydefs` defines translations for `&amp;`, `&apos;`, `&gt;`, `&lt;`, and `&quot;`.

Modifié dans la version 2.5 : Use `convert_entityref()` instead of hard-coding the conversion.

**SGMLParser.convert\_entityref(*ref*)**

Convert a named entity reference to a `str` value, or `None`. The resulting value will not be parsed. *ref* will be only the name of the entity. The default implementation looks for *ref* in the instance (or class) variable `entitydefs` which should be a mapping from entity names to corresponding translations. If no translation is available for *ref*, this method returns `None`. This method is called by the default `handle_entityref()` implementation and by the attribute value parser.

Nouveau dans la version 2.5.

**SGMLParser.handle\_comment(*comment*)**

This method is called when a comment is encountered. The *comment* argument is a string containing the text between the `<!--` and `-->` delimiters, but not the delimiters themselves. For example, the comment `<!--text-->` will cause this method to be called with the argument `'text'`. The default method does nothing.

**SGMLParser.handle\_decl(*data*)**

Method called when an SGML declaration is read by the parser. In practice, the DOCTYPE declaration is the only thing observed in HTML, but the parser does not discriminate among different (or broken) declarations. Internal subsets in a DOCTYPE declaration are not supported. The *data* parameter will be the entire contents of the declaration inside the `<!...>` markup. The default implementation does nothing.

**SGMLParser.report\_unbalanced(*tag*)**

This method is called when an end tag is found which does not correspond to any open element.

**SGMLParser.unknown\_starttag(*tag*, *attributes*)**

This method is called to process an unknown start tag. It is intended to be overridden by a derived class; the base class implementation does nothing.

**SGMLParser.unknown\_endtag(*tag*)**

This method is called to process an unknown end tag. It is intended to be overridden by a derived class; the base class implementation does nothing.

**SGMLParser.unknown\_charref(*ref*)**

This method is called to process unresolvable numeric character references. Refer to `handle_charref()` to determine what is handled by default. It is intended to be overridden by a derived class; the base class implementation does nothing.

**SGMLParser.unknown\_entityref(*ref*)**

This method is called to process an unknown entity reference. It is intended to be overridden by a derived class; the base class implementation does nothing.

Apart from overriding or extending the methods listed above, derived classes may also define methods of the following form to define processing of specific tags. Tag names in the input stream are case independent; the *tag* occurring in method names must be in lower case :

**SGMLParser.start\_tag(*attributes*)**

This method is called to process an opening tag *tag*. It has preference over `do_tag()`. The *attributes* argument has the same meaning as described for `handle_starttag()` above.

`SGMLParser.do_tag(attributes)`

This method is called to process an opening tag *tag* for which no `start_tag()` method is defined. The *attributes* argument has the same meaning as described for `handle_starttag()` above.

`SGMLParser.end_tag()`

This method is called to process a closing tag *tag*.

Note that the parser maintains a stack of open elements for which no end tag has been found yet. Only tags processed by `start_tag()` are pushed on this stack. Definition of an `end_tag()` method is optional for these tags. For tags processed by `do_tag()` or by `unknown_tag()`, no `end_tag()` method must be defined; if defined, it will not be used. If both `start_tag()` and `do_tag()` methods exist for a tag, the `start_tag()` method takes precedence.

## 19.3 `htmllib` — A parser for HTML documents

Obsolète depuis la version 2.6 : The `htmllib` module has been removed in Python 3. Use `HTMLParser` instead in Python 2, and the equivalent, `html.parser`, in Python 3.

This module defines a class which can serve as a base for parsing text files formatted in the HyperText Markup Language (HTML). The class is not directly concerned with I/O — it must be provided with input in string form via a method, and makes calls to methods of a « formatter » object in order to produce output. The `HTMLParser` class is designed to be used as a base class for other classes in order to add functionality, and allows most of its methods to be extended or overridden. In turn, this class is derived from and extends the `SGMLParser` class defined in module `sgmlib`. The `HTMLParser` implementation supports the HTML 2.0 language as described in [RFC 1866](#). Two implementations of formatter objects are provided in the `formatter` module; refer to the documentation for that module for information on the formatter interface.

The following is a summary of the interface defined by `sgmlib.SGMLParser` :

- The interface to feed data to an instance is through the `feed()` method, which takes a string argument. This can be called with as little or as much text at a time as desired; `p.feed(a)`; `p.feed(b)` has the same effect as `p.feed(a+b)`. When the data contains complete HTML markup constructs, these are processed immediately; incomplete constructs are saved in a buffer. To force processing of all unprocessed data, call the `close()` method.  
For example, to parse the entire contents of a file, use :

```
parser.feed(open('myfile.html').read())
parser.close()
```

- The interface to define semantics for HTML tags is very simple : derive a class and define methods called `start_tag()`, `end_tag()`, or `do_tag()`. The parser will call these at appropriate moments : `start_tag()` or `do_tag()` is called when an opening tag of the form `<tag ...>` is encountered; `end_tag()` is called when a closing tag of the form `</tag>` is encountered. If an opening tag requires a corresponding closing tag, like `<H1> ... </H1>`, the class should define the `start_tag()` method; if a tag requires no closing tag, like `<P>`, the class should define the `do_tag()` method.

The module defines a parser class and an exception :

`class htmllib.HTMLParser(formatter)`

This is the basic HTML parser class. It supports all entity names required by the XHTML 1.0 Recommendation (<https://www.w3.org/TR/xhtml1>). It also defines handlers for all HTML 2.0 and many HTML 3.0 and 3.2 elements.

`exception htmllib.HTMLParseError`

Exception raised by the `HTMLParser` class when it encounters an error while parsing.

Nouveau dans la version 2.4.

Voir aussi :

**Module `formatter`** Interface definition for transforming an abstract flow of formatting events into specific output events on writer objects.

**Module `HTMLParser`** Alternate HTML parser that offers a slightly lower-level view of the input, but is designed to work with XHTML, and does not implement some of the SGML syntax not used in « HTML as deployed » and which isn't legal for XHTML.

**Module `htmlentitydefs`** Definition of replacement text for XHTML 1.0 entities.

**Module `sgmllib`** Base class for `HTMLParser`.

### 19.3.1 HTMLParser Objects

In addition to tag methods, the `HTMLParser` class provides some additional methods and instance variables for use within tag methods.

`HTMLParser.formatter`

This is the formatter instance associated with the parser.

`HTMLParser.nofill`

Boolean flag which should be true when whitespace should not be collapsed, or false when it should be. In general, this should only be true when character data is to be treated as « preformatted » text, as within a `<PRE>` element. The default value is false. This affects the operation of `handle_data()` and `save_end()`.

`HTMLParser.anchor_bgn(href, name, type)`

This method is called at the start of an anchor region. The arguments correspond to the attributes of the `<A>` tag with the same names. The default implementation maintains a list of hyperlinks (defined by the `HREF` attribute for `<A>` tags) within the document. The list of hyperlinks is available as the data attribute `anchorlist`.

`HTMLParser.anchor_end()`

This method is called at the end of an anchor region. The default implementation adds a textual footnote marker using an index into the list of hyperlinks created by `anchor_bgn()`.

`HTMLParser.handle_image(source, alt[, ismap[, align[, width[, height]]]])`

This method is called to handle images. The default implementation simply passes the `alt` value to the `handle_data()` method.

`HTMLParser.save_bgn()`

Begins saving character data in a buffer instead of sending it to the formatter object. Retrieve the stored data via `save_end()`. Use of the `save_bgn()` / `save_end()` pair may not be nested.

`HTMLParser.save_end()`

Ends buffering character data and returns all data saved since the preceding call to `save_bgn()`. If the `nofill` flag is false, whitespace is collapsed to single spaces. A call to this method without a preceding call to `save_bgn()` will raise a `TypeError` exception.

## 19.4 htmlentitydefs — Definitions of HTML general entities

---

**Note :** The `htmlentitydefs` module has been renamed to `html.entities` in Python 3. The `2to3` tool will automatically adapt imports when converting your sources to Python 3.

---

**Source code :** [Lib/htmlentitydefs.py](#)

---

This module defines three dictionaries, `name2codepoint`, `codepoint2name`, and `entitydefs`. `entitydefs` is used by the `html` module to provide the `entitydefs` attribute of the `HTMLParser` class. The definition

provided here contains all the entities defined by XHTML 1.0 that can be handled using simple textual substitution in the Latin-1 character set (ISO-8859-1).

#### `htmlentitydefs.entitydefs`

Un dictionnaire qui fait correspondre les définitions d'entités XHTML 1.0 avec leur remplacement en ISO Latin-1.

#### `htmlentitydefs.name2codepoint`

Un dictionnaire qui fait correspondre les noms d'entités HTML avec les points de code Unicode.  
Nouveau dans la version 2.3.

#### `htmlentitydefs.codepoint2name`

Un dictionnaire qui fait correspondre les points de code Unicode avec les noms d'entités HTML.  
Nouveau dans la version 2.3.

## 19.5 Modules de traitement XML

Les interfaces de Python de traitement de XML sont regroupées dans le paquet `xml`.

**Avertissement :** The XML modules are not secure against erroneous or maliciously constructed data. If you need to parse untrusted or unauthenticated data see [Vulnérabilités XML](#).

Il est important de noter que les modules dans le paquet `xml` nécessitent qu'au moins un analyseur compatible SAX soit disponible. L'analyseur Expat est inclus dans Python, ainsi le module `xml.parsers.expat` est toujours disponible.

La documentation des *bindings* des interfaces DOM et SAX se trouve dans `xml.dom` et `xml.sax`.

Les sous-modules de traitement XML sont :

- `xml.etree.ElementTree` : l'API ElementTree, un processeur simple et léger
- `xml.dom` : la définition de l'API DOM
- `xml.dom.minidom` : une implémentation minimale de DOM
- `xml.dom.pulldom` : gestion de la construction partiel des arbres DOM
- `xml.sax` : classes de bases SAX2 base et fonctions utilitaires
- `xml.parsers.expat` : le *binding* de l'analyseur Expat

## 19.6 Vulnérabilités XML

The XML processing modules are not secure against maliciously constructed data. An attacker can abuse vulnerabilities for e.g. denial of service attacks, to access local files, to generate network connections to other machines, or to circumvent firewalls. The attacks on XML abuse unfamiliar features like inline DTD (document type definition) with entities.

The following table gives an overview of the known attacks and if the various modules are vulnerable to them.

type	sax	etree	minidom	pulldom	xmlrpc
<i>billion laughs</i>	<b>Vulnérable</b>	<b>Vulnérable</b>	<b>Vulnérable</b>	<b>Vulnérable</b>	<b>Vulnérable</b>
<i>quadratic blowup</i>	<b>Vulnérable</b>	<b>Vulnérable</b>	<b>Vulnérable</b>	<b>Vulnérable</b>	<b>Vulnérable</b>
<i>external entity expansion</i>	<b>Vulnérable</b>	Sûr (1)	Sûr (2)	<b>Vulnérable</b>	Sûr (3)
Récupération de DTD	<b>Vulnérable</b>	Sûr	Sûr	<b>Vulnérable</b>	Sûr
<i>decompression bomb</i>	Sûr	Sûr	Sûr	Sûr	<b>Vulnérable</b>

1. `xml.etree.ElementTree` doesn't expand external entities and raises a `ParserError` when an entity occurs.
2. `xml.dom.minidom` n'étend pas les entités externe et renvoie simplement le verbatim de l'entité non étendu.
3. `xmlrpclib` n'étend pas les entités externes et les omet.

**billion laughs / exponential entity expansion** The [Billion Laughs](#) attack – also known as exponential entity expansion – uses multiple levels of nested entities. Each entity refers to another entity several times, the final entity definition contains a small string. Eventually the small string is expanded to several gigabytes. The exponential expansion consumes lots of CPU time, too.

**quadratic blowup entity expansion** A quadratic blowup attack is similar to a [Billion Laughs](#) attack ; it abuses entity expansion, too. Instead of nested entities it repeats one large entity with a couple of thousand chars over and over again. The attack isn't as efficient as the exponential case but it avoids triggering countermeasures of parsers against heavily nested entities.

**external entity expansion** Entity declarations can contain more than just text for replacement. They can also point to external resources by public identifiers or system identifiers. System identifiers are standard URIs or can refer to local files. The XML parser retrieves the resource with e.g. HTTP or FTP requests and embeds the content into the XML document.

**Récupération de DTD** Certaines bibliothèques XML comme `xml.dom.pulldom` de Python récupère les documents de définitions de types (DTD) depuis des emplacements distants ou locaux. La fonctionnalité a des implications similaires que le problème d'extension d'entités externes.

**decompression bomb** The issue of decompression bombs (aka [ZIP bomb](#)) apply to all XML libraries that can parse compressed XML stream like gzipped HTTP streams or LZMA-ed files. For an attacker it can reduce the amount of transmitted data by three magnitudes or more.

The documentation of [defusedxml](#) on PyPI has further information about all known attack vectors with examples and references.

### 19.6.1 defused packages

These external packages are recommended for any code that parses untrusted XML data.

[defusedxml](#) is a pure Python package with modified subclasses of all stdlib XML parsers that prevent any potentially malicious operation. The package also ships with example exploits and extended documentation on more XML exploits like xpath injection.

[defusedexpat](#) provides a modified libexpat and patched replacement `pyexpat` extension module with countermeasures against entity expansion DoS attacks. Defusedexpat still allows a sane and configurable amount of entity expansions. The modifications will be merged into future releases of Python.

The workarounds and modifications are not included in patch releases as they break backward compatibility. After all inline DTD and entity expansion are well-defined XML features.

## 19.7 `xml.etree.ElementTree` — The `ElementTree` XML API

Nouveau dans la version 2.5.

**Source code :** [Lib/xml/etree/ElementTree.py](#)

---

The `Element` type is a flexible container object, designed to store hierarchical data structures in memory. The type can be described as a cross between a list and a dictionary.

**Avertissement :** The `xml.etree.ElementTree` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see *Vulnérabilités XML*.

Each element has a number of properties associated with it :

- a tag which is a string identifying what kind of data this element represents (the element type, in other words).
- a number of attributes, stored in a Python dictionary.
- a text string.
- an optional tail string.
- a number of child elements, stored in a Python sequence

To create an element instance, use the `Element` constructor or the `SubElement()` factory function.

The `ElementTree` class can be used to wrap an element structure, and convert it from and to XML.

A C implementation of this API is available as `xml.etree.cElementTree`.

See <http://effbot.org/zone/element-index.htm> for tutorials and links to other docs. Fredrik Lundh's page is also the location of the development version of the `xml.etree.ElementTree`.

Modifié dans la version 2.7 : The `ElementTree` API is updated to 1.3. For more information, see [Introducing ElementTree 1.3](#).

### 19.7.1 Tutoriel

This is a short tutorial for using `xml.etree.ElementTree` (ET in short). The goal is to demonstrate some of the building blocks and basic concepts of the module.

#### XML tree and elements

XML is an inherently hierarchical data format, and the most natural way to represent it is with a tree. ET has two classes for this purpose - `ElementTree` represents the whole XML document as a tree, and `Element` represents a single node in this tree. Interactions with the whole document (reading and writing to/from files) are usually done on the `ElementTree` level. Interactions with a single XML element and its sub-elements are done on the `Element` level.

#### Parsing XML

We'll be using the following XML document as the sample data for this section :

```
<?xml version="1.0"?>
<data>
  <country name="Liechtenstein">
    <rank>1</rank>
    <year>2008</year>
    <gdppc>141100</gdppc>
    <neighbor name="Austria" direction="E"/>
    <neighbor name="Switzerland" direction="W"/>
  </country>
  <country name="Singapore">
    <rank>4</rank>
    <year>2011</year>
    <gdppc>59900</gdppc>
    <neighbor name="Malaysia" direction="N"/>
  </country>
  <country name="Panama">
```

(suite sur la page suivante)

(suite de la page précédente)

```

    <rank>68</rank>
    <year>2011</year>
    <gdppc>13600</gdppc>
    <neighbor name="Costa Rica" direction="W"/>
    <neighbor name="Colombia" direction="E"/>
  </country>
</data>

```

We have a number of ways to import the data. Reading the file from disk :

```

import xml.etree.ElementTree as ET
tree = ET.parse('country_data.xml')
root = tree.getroot()

```

Reading the data from a string :

```

root = ET.fromstring(country_data_as_string)

```

*fromstring()* parses XML from a string directly into an *Element*, which is the root element of the parsed tree. Other parsing functions may create an *ElementTree*. Check the documentation to be sure.

As an *Element*, root has a tag and a dictionary of attributes :

```

>>> root.tag
'data'
>>> root.attrib
{}

```

It also has children nodes over which we can iterate :

```

>>> for child in root:
...     print child.tag, child.attrib
...
country {'name': 'Liechtenstein'}
country {'name': 'Singapore'}
country {'name': 'Panama'}

```

Children are nested, and we can access specific child nodes by index :

```

>>> root[0][1].text
'2008'

```

### Finding interesting elements

*Element* has some useful methods that help iterate recursively over all the sub-tree below it (its children, their children, and so on). For example, *Element.iter()* :

```

>>> for neighbor in root.iter('neighbor'):
...     print neighbor.attrib
...
{'name': 'Austria', 'direction': 'E'}
{'name': 'Switzerland', 'direction': 'W'}
{'name': 'Malaysia', 'direction': 'N'}

```

(suite sur la page suivante)

(suite de la page précédente)

```
{'name': 'Costa Rica', 'direction': 'W'}
{'name': 'Colombia', 'direction': 'E'}
```

*Element.findall()* finds only elements with a tag which are direct children of the current element. *Element.find()* finds the *first* child with a particular tag, and *Element.text* accesses the element's text content. *Element.get()* accesses the element's attributes :

```
>>> for country in root.findall('country'):
...     rank = country.find('rank').text
...     name = country.get('name')
...     print name, rank
...
Liechtenstein 1
Singapore 4
Panama 68
```

More sophisticated specification of which elements to look for is possible by using *XPath*.

### Modifying an XML File

*ElementTree* provides a simple way to build XML documents and write them to files. The *ElementTree.write()* method serves this purpose.

Once created, an *Element* object may be manipulated by directly changing its fields (such as *Element.text*), adding and modifying attributes (*Element.set()* method), as well as adding new children (for example with *Element.append()*).

Let's say we want to add one to each country's rank, and add an *updated* attribute to the rank element :

```
>>> for rank in root.iter('rank'):
...     new_rank = int(rank.text) + 1
...     rank.text = str(new_rank)
...     rank.set('updated', 'yes')
...
>>> tree.write('output.xml')
```

Our XML now looks like this :

```
<?xml version="1.0"?>
<data>
  <country name="Liechtenstein">
    <rank updated="yes">2</rank>
    <year>2008</year>
    <gdppc>141100</gdppc>
    <neighbor name="Austria" direction="E"/>
    <neighbor name="Switzerland" direction="W"/>
  </country>
  <country name="Singapore">
    <rank updated="yes">5</rank>
    <year>2011</year>
    <gdppc>59900</gdppc>
    <neighbor name="Malaysia" direction="N"/>
  </country>
  <country name="Panama">
```

(suite sur la page suivante)

(suite de la page précédente)

```

    <rank updated="yes">69</rank>
    <year>2011</year>
    <gdppc>13600</gdppc>
    <neighbor name="Costa Rica" direction="W"/>
    <neighbor name="Colombia" direction="E"/>
  </country>
</data>

```

We can remove elements using `Element.remove()`. Let's say we want to remove all countries with a rank higher than 50 :

```

>>> for country in root.findall('country'):
...     rank = int(country.find('rank').text)
...     if rank > 50:
...         root.remove(country)
...
>>> tree.write('output.xml')

```

Our XML now looks like this :

```

<?xml version="1.0"?>
<data>
  <country name="Liechtenstein">
    <rank updated="yes">2</rank>
    <year>2008</year>
    <gdppc>141100</gdppc>
    <neighbor name="Austria" direction="E"/>
    <neighbor name="Switzerland" direction="W"/>
  </country>
  <country name="Singapore">
    <rank updated="yes">5</rank>
    <year>2011</year>
    <gdppc>59900</gdppc>
    <neighbor name="Malaysia" direction="N"/>
  </country>
</data>

```

## Building XML documents

The `SubElement()` function also provides a convenient way to create new sub-elements for a given element :

```

>>> a = ET.Element('a')
>>> b = ET.SubElement(a, 'b')
>>> c = ET.SubElement(a, 'c')
>>> d = ET.SubElement(c, 'd')
>>> ET.dump(a)
<a><b /><c><d /></c></a>

```

## Parsing XML with Namespaces

If the XML input has `namespaces`, tags and attributes with prefixes in the form `prefix:sometag` get expanded to `{uri}sometag` where the *prefix* is replaced by the full *URI*. Also, if there is a `default namespace`, that full URI gets prepended to all of the non-prefixed tags.

Here is an XML example that incorporates two namespaces, one with the prefix « fictional » and the other serving as the default namespace :

```
<?xml version="1.0"?>
<actors xmlns:fictional="http://characters.example.com"
        xmlns="http://people.example.com">
  <actor>
    <name>John Cleese</name>
    <fictional:character>Lancelot</fictional:character>
    <fictional:character>Archie Leach</fictional:character>
  </actor>
  <actor>
    <name>Eric Idle</name>
    <fictional:character>Sir Robin</fictional:character>
    <fictional:character>Gunther</fictional:character>
    <fictional:character>Commander Clement</fictional:character>
  </actor>
</actors>
```

One way to search and explore this XML example is to manually add the URI to every tag or attribute in the xpath of a *find()* or *findall()* :

```
root = fromstring(xml_text)
for actor in root.findall('{http://people.example.com}actor'):
    name = actor.find('{http://people.example.com}name')
    print name.text
    for char in actor.findall('{http://characters.example.com}character'):
        print ' |-->', char.text
```

A better way to search the namespaced XML example is to create a dictionary with your own prefixes and use those in the search functions :

```
ns = {'real_person': 'http://people.example.com',
      'role': 'http://characters.example.com'}

for actor in root.findall('real_person:actor', ns):
    name = actor.find('real_person:name', ns)
    print name.text
    for char in actor.findall('role:character', ns):
        print ' |-->', char.text
```

These two approaches both output :

```
John Cleese
 |--> Lancelot
 |--> Archie Leach
Eric Idle
 |--> Sir Robin
 |--> Gunther
 |--> Commander Clement
```

### Additional resources

See <http://effbot.org/zone/element-index.htm> for tutorials and links to other docs.

### 19.7.2 XPath support

This module provides limited support for [XPath expressions](#) for locating elements in a tree. The goal is to support a small subset of the abbreviated syntax; a full XPath engine is outside the scope of the module.

#### Exemple

Here's an example that demonstrates some of the XPath capabilities of the module. We'll be using the `countrydata` XML document from the *Parsing XML* section :

```
import xml.etree.ElementTree as ET

root = ET.fromstring(countrydata)

# Top-level elements
root.findall(".")

# All 'neighbor' grand-children of 'country' children of the top-level
# elements
root.findall("./country/neighbor")

# Nodes with name='Singapore' that have a 'year' child
root.findall("./year/..[@name='Singapore']")

# 'year' nodes that are children of nodes with name='Singapore'
root.findall("./*[@name='Singapore']/year")

# All 'neighbor' nodes that are the second child of their parent
root.findall("./neighbor[2]")
```

#### Supported XPath syntax

Syntax	Signification
<code>tag</code>	Selects all child elements with the given tag. For example, <code>spam</code> selects all child elements named <code>spam</code> , and <code>spam/egg</code> selects all grandchildren named <code>egg</code> in all children named <code>spam</code> .
<code>*</code>	Selects all child elements. For example, <code>*/egg</code> selects all grandchildren named <code>egg</code> .
<code>.</code>	Selects the current node. This is mostly useful at the beginning of the path, to indicate that it's a relative path.
<code>//</code>	Selects all subelements, on all levels beneath the current element. For example, <code>./egg</code> selects all <code>egg</code> elements in the entire tree.
<code>..</code>	Selects the parent element.
<code>[@attrib]</code>	Selects all elements that have the given attribute.
<code>[@attrib='value']</code>	Selects all elements for which the given attribute has the given value. The value cannot contain quotes.
<code>[tag]</code>	Selects all elements that have a child named <code>tag</code> . Only immediate children are supported.
<code>[tag='text']</code>	Selects all elements that have a child named <code>tag</code> whose complete text content, including descendants, equals the given <code>text</code> .
<code>[position]</code>	Selects all elements that are located at the given position. The position can be either an integer (1 is the first position), the expression <code>last()</code> (for the last position), or a position relative to the last position (e.g. <code>last()-1</code> ).

Predicates (expressions within square brackets) must be preceded by a tag name, an asterisk, or another predicate. `position` predicates must be preceded by a tag name.

### 19.7.3 Reference

#### Fonctions

`xml.etree.ElementTree.Comment(text=None)`

Comment element factory. This factory function creates a special element that will be serialized as an XML comment by the standard serializer. The comment string can be either a bytestring or a Unicode string. *text* is a string containing the comment string. Returns an element instance representing a comment.

`xml.etree.ElementTree.dump(elem)`

Writes an element tree or element structure to `sys.stdout`. This function should be used for debugging only.

The exact output format is implementation dependent. In this version, it's written as an ordinary XML file.

*elem* is an element tree or an individual element.

`xml.etree.ElementTree.fromstring(text)`

Parses an XML section from a string constant. Same as `XML()`. *text* is a string containing XML data. Returns an *Element* instance.

`xml.etree.ElementTree.fromstringlist(sequence, parser=None)`

Parses an XML document from a sequence of string fragments. *sequence* is a list or other sequence containing XML data fragments. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *Element* instance.

Nouveau dans la version 2.7.

`xml.etree.ElementTree.iselement(element)`

Checks if an object appears to be a valid element object. *element* is an element instance. Returns a true value if this is an element object.

`xml.etree.ElementTree.iterparse(source, events=None, parser=None)`

Parses an XML section into an element tree incrementally, and reports what's going on to the user. *source* is a filename or file object containing XML data. *events* is a list of events to report back. If omitted, only « end » events are reported. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. *parser* is not supported by *cElementTree*. Returns an *iterator* providing (*event*, *elem*) pairs.

---

**Note :** *iterparse()* only guarantees that it has seen the « > » character of a starting tag when it emits a « start » event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present. If you need a fully populated element, look for « end » events instead.

---

`xml.etree.ElementTree.parse(source, parser=None)`

Parses an XML section into an element tree. *source* is a filename or file object containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *ElementTree* instance.

`xml.etree.ElementTree.ProcessingInstruction(target, text=None)`

PI element factory. This factory function creates a special element that will be serialized as an XML processing instruction. *target* is a string containing the PI target. *text* is a string containing the PI contents, if given. Returns an element instance, representing a processing instruction.

`xml.etree.ElementTree.register_namespace(prefix, uri)`

Registers a namespace prefix. The registry is global, and any existing mapping for either the given prefix or the namespace URI will be removed. *prefix* is a namespace prefix. *uri* is a namespace uri. Tags and attributes in this namespace will be serialized with the given prefix, if at all possible.

Nouveau dans la version 2.7.

`xml.etree.ElementTree.SubElement(parent, tag, attrib={}, **extra)`

Subelement factory. This function creates an element instance, and appends it to an existing element. The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *parent* is the parent element. *tag* is the subelement name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments. Returns an element instance.

`xml.etree.ElementTree.tostring(element, encoding="us-ascii", method="xml")`

Generates a string representation of an XML element, including all subelements. *element* is an *Element* instance. *encoding*<sup>1</sup> is the output encoding (default is US-ASCII). *method* is either "xml", "html" or "text" (default is "xml"). Returns an encoded string containing the XML data.

`xml.etree.ElementTree.tostringlist(element, encoding="us-ascii", method="xml")`

Generates a string representation of an XML element, including all subelements. *element* is an *Element* instance. *encoding*<sup>1</sup> is the output encoding (default is US-ASCII). *method* is either "xml", "html" or "text" (default is "xml"). Returns a list of encoded strings containing the XML data. It does not guarantee any specific sequence, except that `"".join(tostringlist(element)) == tostring(element)`.

Nouveau dans la version 2.7.

`xml.etree.ElementTree.XML(text, parser=None)`

Parses an XML section from a string constant. This function can be used to embed « XML literals » in Python code. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *Element* instance.

`xml.etree.ElementTree.XMLID(text, parser=None)`

Parses an XML section from a string constant, and also returns a dictionary which maps from element id :s to elements. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns a tuple containing an *Element* instance and a dictionary.

## Objets Elements

`class xml.etree.ElementTree.Element(tag, attrib={}, **extra)`

Element class. This class defines the Element interface, and provides a reference implementation of this interface.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *tag* is the element name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments.

**tag**

A string identifying what kind of data this element represents (the element type, in other words).

**text**

**tail**

These attributes can be used to hold additional data associated with the element. Their values are usually strings but may be any application-specific object. If the element is created from an XML file, the *text* attribute holds either the text between the element's start tag and its first child

---

1. The encoding string included in XML output should conform to the appropriate standards. For example, « UTF-8 » is valid, but « UTF8 » is not. See <https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl> and <https://www.iana.org/assignments/character-sets/character-sets.xhtml>.

or end tag, or `None`, and the *tail* attribute holds either the text between the element's end tag and the next tag, or `None`. For the XML data

```
<a><b>1<c>2<d/>3</c></b>4</a>
```

the *a* element has `None` for both *text* and *tail* attributes, the *b* element has *text* "1" and *tail* "4", the *c* element has *text* "2" and *tail* `None`, and the *d* element has *text* `None` and *tail* "3".

To collect the inner text of an element, see `itertext()`, for example `".join(element.itertext())`.

Applications may store arbitrary objects in these attributes.

#### **attrib**

A dictionary containing the element's attributes. Note that while the *attrib* value is always a real mutable Python dictionary, an `ElementTree` implementation may choose to use another internal representation, and create the dictionary only if someone asks for it. To take advantage of such implementations, use the dictionary methods below whenever possible.

The following dictionary-like methods work on the element attributes.

#### **clear()**

Resets an element. This function removes all subelements, clears all attributes, and sets the text and tail attributes to `None`.

#### **get(key, default=None)**

Gets the element attribute named *key*.

Returns the attribute value, or *default* if the attribute was not found.

#### **items()**

Returns the element attributes as a sequence of (name, value) pairs. The attributes are returned in an arbitrary order.

#### **keys()**

Returns the elements attribute names as a list. The names are returned in an arbitrary order.

#### **set(key, value)**

Set the attribute *key* on the element to *value*.

The following methods work on the element's children (subelements).

#### **append(subelement)**

Adds the element *subelement* to the end of this elements internal list of subelements.

#### **extend(subelements)**

Appends *subelements* from a sequence object with zero or more elements. Raises `AssertionError` if a subelement is not a valid object.

Nouveau dans la version 2.7.

#### **find(match)**

Finds the first subelement matching *match*. *match* may be a tag name or path. Returns an element instance or `None`.

#### **findall(match)**

Finds all matching subelements, by tag name or path. Returns a list containing all matching elements in document order.

#### **findtext(match, default=None)**

Finds text for the first subelement matching *match*. *match* may be a tag name or path. Returns the text content of the first matching element, or *default* if no element was found. Note that if the matching element has no text content an empty string is returned.

#### **getchildren()**

Obsolète depuis la version 2.7 : Use `list(elem)` or iteration.

#### **getiterator(tag=None)**

Obsolète depuis la version 2.7 : Use method `Element.iter()` instead.

#### **insert(index, element)**

Inserts a subelement at the given position in this element.

**iter**(tag=None)

Creates a tree *iterator* with the current element as the root. The iterator iterates over this element and all elements below it, in document (depth first) order. If *tag* is not `None` or `'*'`, only elements whose tag equals *tag* are returned from the iterator. If the tree structure is modified during iteration, the result is undefined.

Nouveau dans la version 2.7.

**iterfind**(match)

Finds all matching subelements, by tag name or path. Returns an iterable yielding all matching elements in document order.

Nouveau dans la version 2.7.

**itertext**()

Creates a text iterator. The iterator loops over this element and all subelements, in document order, and returns all inner text.

Nouveau dans la version 2.7.

**makeelement**(tag, attrib)

Creates a new element object of the same type as this element. Do not call this method, use the *SubElement()* factory function instead.

**remove**(subelement)

Removes *subelement* from the element. Unlike the *find\** methods this method compares elements based on the instance identity, not on tag value or contents.

*Element* objects also support the following sequence type methods for working with subelements : *\_\_delitem\_\_()*, *\_\_getitem\_\_()*, *\_\_setitem\_\_()*, *\_\_len\_\_()*.

Caution : Elements with no subelements will test as `False`. This behavior will change in future versions. Use specific `len(elem)` or `elem is None` test instead.

```
element = root.find('foo')

if not element: # careful!
    print "element not found, or element has no subelements"

if element is None:
    print "element not found"
```

## ElementTree Objects

**class xml.etree.ElementTree.ElementTree**(element=None, file=None)

ElementTree wrapper class. This class represents an entire element hierarchy, and adds some extra support for serialization to and from standard XML.

*element* is the root element. The tree is initialized with the contents of the XML *file* if given.

**\_setroot**(element)

Replaces the root element for this tree. This discards the current contents of the tree, and replaces it with the given element. Use with care. *element* is an element instance.

**find**(match)

Same as *Element.find()*, starting at the root of the tree.

**findall**(match)

Same as *Element.findall()*, starting at the root of the tree.

**findtext**(match, default=None)

Same as *Element.findtext()*, starting at the root of the tree.

**getiterator**(tag=None)

Obsolète depuis la version 2.7 : Use method *ElementTree.iter()* instead.

**getroot**()

Returns the root element for this tree.

**iter**(tag=None)

Creates and returns a tree iterator for the root element. The iterator loops over all elements in this tree, in section order. *tag* is the tag to look for (default is to return all elements).

**iterfind**(match)

Finds all matching subelements, by tag name or path. Same as `getroot().iterfind(match)`. Returns an iterable yielding all matching elements in document order.

Nouveau dans la version 2.7.

**parse**(source, parser=None)

Loads an external XML section into this element tree. *source* is a file name or file object. *parser* is an optional parser instance. If not given, the standard XMLParser parser is used. Returns the section root element.

**write**(file, encoding="us-ascii", xml\_declaration=None, default\_namespace=None, method="xml")

Writes the element tree to a file, as XML. *file* is a file name, or a file object opened for writing. *encoding*<sup>1</sup> is the output encoding (default is US-ASCII). *xml\_declaration* controls if an XML declaration should be added to the file. Use **False** for never, **True** for always, **None** for only if not US-ASCII or UTF-8 (default is **None**). *default\_namespace* sets the default XML namespace (for « xmlns »). *method* is either "xml", "html" or "text" (default is "xml"). Returns an encoded string.

This is the XML file that is going to be manipulated :

```
<html>
  <head>
    <title>Example page</title>
  </head>
  <body>
    <p>Moved to <a href="http://example.org/">example.org</a>
    or <a href="http://example.com/">example.com</a>.</p>
  </body>
</html>
```

Example of changing the attribute « target » of every link in first paragraph :

```
>>> from xml.etree.ElementTree import ElementTree
>>> tree = ElementTree()
>>> tree.parse("index.xhtml")
<Element 'html' at 0xb77e6fac>
>>> p = tree.find("body/p")      # Finds first occurrence of tag p in body
>>> p
<Element 'p' at 0xb77ec26c>
>>> links = list(p.iter("a"))    # Returns list of all links
>>> links
[<Element 'a' at 0xb77ec2ac>, <Element 'a' at 0xb77ec1cc>]
>>> for i in links:              # Iterates through all found links
...     i.attrib["target"] = "blank"
...
>>> tree.write("output.xhtml")
```

## QName Objects

**class xml.etree.ElementTree.QName**(text\_or\_uri, tag=None)

QName wrapper. This can be used to wrap a QName attribute value, in order to get proper namespace handling on output. *text\_or\_uri* is a string containing the QName value, in the form {uri}local, or, if

the `tag` argument is given, the URI part of a QName. If `tag` is given, the first argument is interpreted as a URI, and this argument is interpreted as a local name. *QName* instances are opaque.

### TreeBuilder Objects

**class** `xml.etree.ElementTree.TreeBuilder`(*element\_factory=None*)

Generic element structure builder. This builder converts a sequence of start, data, and end method calls to a well-formed element structure. You can use this class to build an element structure using a custom XML parser, or a parser for some other XML-like format. The *element\_factory* is called to create new *Element* instances when given.

**close**()

Flushes the builder buffers, and returns the toplevel document element. Returns an *Element* instance.

**data**(*data*)

Adds text to the current element. *data* is a string. This should be either a bytestring, or a Unicode string.

**end**(*tag*)

Closes the current element. *tag* is the element name. Returns the closed element.

**start**(*tag, attrs*)

Opens a new element. *tag* is the element name. *attrs* is a dictionary containing element attributes. Returns the opened element.

In addition, a custom *TreeBuilder* object can provide the following method :

**doctype**(*name, pubid, system*)

Handles a doctype declaration. *name* is the doctype name. *pubid* is the public identifier. *system* is the system identifier. This method does not exist on the default *TreeBuilder* class.

Nouveau dans la version 2.7.

### XMLParser Objects

**class** `xml.etree.ElementTree.XMLParser`(*html=0, target=None, encoding=None*)

*Element* structure builder for XML source data, based on the expat parser. *html* are predefined HTML entities. This flag is not supported by the current implementation. *target* is the target object. If omitted, the builder uses an instance of the standard *TreeBuilder* class. *encoding*<sup>1</sup> is optional. If given, the value overrides the encoding specified in the XML file.

**close**()

Finishes feeding data to the parser. Returns an element structure.

**doctype**(*name, pubid, system*)

Obsolète depuis la version 2.7 : Define the *TreeBuilder.doctype()* method on a custom *TreeBuilder* target.

**feed**(*data*)

Feeds data to the parser. *data* is encoded data.

*XMLParser.feed()* calls *target*'s *start()* method for each opening tag, its *end()* method for each closing tag, and data is processed by method *data()*. *XMLParser.close()* calls *target*'s method *close()*. *XMLParser* can be used not only for building a tree structure. This is an example of counting the maximum depth of an XML file :

```
>>> from xml.etree.ElementTree import XMLParser
>>> class MaxDepth:                                # The target object of the parser
...     maxDepth = 0
...     depth = 0
...     def start(self, tag, attrib):               # Called for each opening tag.
...         self.depth += 1
```

(suite sur la page suivante)

(suite de la page précédente)

```

...         if self.depth > self.maxDepth:
...             self.maxDepth = self.depth
...     def end(self, tag):                # Called for each closing tag.
...         self.depth -= 1
...     def data(self, data):
...         pass                          # We do not need to do anything with data.
...     def close(self):                  # Called when all data has been parsed.
...         return self.maxDepth
...
>>> target = MaxDepth()
>>> parser = XMLParser(target=target)
>>> exampleXml = """
... <a>
...   <b>
...   </b>
...   <b>
...     <c>
...     <d>
...     </d>
...     </c>
...   </b>
... </a>"""
>>> parser.feed(exampleXml)
>>> parser.close()
4

```

## Notes

## 19.8 xml.dom — L'API Document Object Model

Nouveau dans la version 2.0.

Le Document Object Model, ou « DOM, » est une API inter-langage du World Wide Web Consortium (*W3C*) pour accéder et modifier les documents XML. Une implémentation DOM présente le document XML comme un arbre ou autorise le code client à construire une telle structure depuis zéro. Il permet alors d'accéder à la structure à l'aide d'un ensemble d'objet qui fournissent des interfaces bien connues.

Le DOM est extrêmement utile pour les applications à accès aléatoire. SAX ne vous permet de visualiser qu'un seul morceau du document à la fois. Si vous regardez un élément SAX, vous n'avez pas accès à un autre. Si vous regardez un nœud de texte, vous n'avez pas accès à un élément parent. Lorsque vous écrivez une application SAX, vous devez suivre la position de votre programme dans le document quelque part dans votre propre code. SAX ne le fait pas pour vous. De plus, si vous devez examiner un nœud plus loin dans le document XML, vous n'avez pas de chance.

Il est tout simplement impossible d'implémenter certains algorithmes avec un modèle événementiel, sans un accès à un arbre. Bien sûr, vous pourriez construire vous même un arbre à partir des événements SAX mais DOM vous permet d'éviter d'écrire ce code. Le DOM est représentation standard en arbre pour des données XML.

Le DOM (Document Object Model) est défini par le *W3C* en étapes ou « *levels* » (niveaux) selon leur terminologie. Le couplage de l'API de Python est essentiellement basée sur la recommandation DOM Level 2.

Typiquement, les applications DOM commencent par analyser du XML dans du DOM. Comment cela doit

être exposé n'est absolument pas décrit par DOM Level 1 et Level 2 ne fournit que des améliorations limitées. Il existe une classe `DOMImplementation` qui fournit un accès à des méthodes de création de `Document` mais il n'y a pas de moyen d'accéder à un lecteur/analyseur/constructeur de *document* de façon indépendante de l'implémentation. Il n'est pas également très bien définis comment accéder à ces méthodes sans un objet `Document`. En Python, chaque implémentation fournira une fonction `getDOMImplementation()`. DOM Level 3 ajoute une spécification *Load/Store* (charge/stocke) qui définit une interface pour le lecteur mais qui n'est pas disponible dans la bibliothèque standard de Python.

Une fois que vous avez un objet document DOM, vous pouvez accéder aux parties de votre document XML à travers ses méthodes et propriétés. Ces propriétés sont définies dans les spécifications DOM ; cette portion du manuel de références décrit l'interprétation de ces spécifications en Python.

Les spécifications fournies par le *W3C* définissent les API DOM pour Java, ECMAScript, et OMG IDL. Les correspondances de Python définies ici sont basées pour une grande part sur la version IDL de la spécification mais une conformité stricte n'est pas requise (bien que ces implémentations soient libre d'implémenter le support strict des correspondances de IDL). Voir la section *Conformité* pour une discussion détaillée des pré-requis des correspondances.

**Voir aussi :**

**Spécification Level 2 Document Object Model (DOM)** La recommandation *W3C* sur laquelle l'API DOM de Python est basée.

**Spécification Level 1 Document Object Model (DOM)** La recommandation du *W3C* pour le DOM supporté par `xml.dom.minidom`.

**Python Language Mapping Specification** Ceci spécifie les correspondances depuis OMG IDL vers Python.

### 19.8.1 Contenu du module

Le `xml.dom` contient les fonctions suivantes :

`xml.dom.registerDOMImplementation(name, factory)`

Enregistre la fonction *factory* avec le nom *name*. La fonction *factory* doit renvoyer un objet qui implémente l'interface de `DOMImplementation`. La fonction *factory* peut renvoyer le même objet à chaque fois ou un nouveau à chaque appel en accord avec les spécificités de l'implémentation (Par exemple si l'implémentation supporte certaines personnalisations).

`xml.dom.getDOMImplementation([name[, features]])`

Renvoie une implémentation DOM appropriée. Le *name* est soit connu, soit le nom du module d'une implémentation DOM, soit `None`. Si ce n'est pas `None`, le module correspondant est importé et retourne un objet `DOMImplementation` si l'import réussit. Si Aucun *name* n'est donné et que la variable d'environnement `PYTHON_DOM` est positionnée, cette variable est utilisée pour trouver l'implémentation. Si *name* n'est pas donné, la fonction examine les implémentations disponibles pour en trouver une avec l'ensemble des fonctionnalités requises. Si aucune implémentation n'est trouvée, une *ImportError* est levée. La liste de fonctionnalité doit être une séquence de paires (*feature*, *version*) qui est passée à la méthode `hasFeature()` disponible dans les objets `DOMImplementation`.

Quelques constantes pratiques sont également fournies :

`xml.dom.EMPTY_NAMESPACE`

La valeur utilisée pour indiquer qu'aucun espace de nom n'est associé à un nœud dans le DOM. Typiquement, ceci est trouvé comme `namespaceURI` dans un nœud ou utilisé comme le paramètre *namespaceURI* dans une méthode spécifique aux espaces de nom. Nouveau dans la version 2.2.

`xml.dom.XML_NAMESPACE`

L'URI de l'espace de nom associé avec le préfixe réservé `xml` comme défini par *Namespaces in XML* (section 4).

Nouveau dans la version 2.2.

#### `xml.dom.XMLNS_NAMESPACE`

L'URI de l'espace de nom pour la déclaration des espaces de noms, tel que défini par [Document Object Model \(DOM\) Level 2 Core Specification](#) (section 1.1.8).

Nouveau dans la version 2.2.

#### `xml.dom.XHTML_NAMESPACE`

L'URI de l'espace de nom XHTML tel que défini par [XHTML 1.0 : The Extensible HyperText Markup Language](#) (section 3.1.1).

Nouveau dans la version 2.2.

Par ailleurs, `xml.dom` contient une classe de base `Node` et les exceptions de DOM. La classe `Node` fournie par ce module n'implémente aucune des méthodes ou des attributs définis par les spécifications DOM ; les implémentations concrètes des DOM doivent fournir les informations suivantes. La classe `Node` fournie part ce modules fournit les constantes utilisées pour l'attribut `nodeType` pour des objets concrets `Node` ; ils sont situés dans les classes plutôt qu'au niveau du module en accord avec les spécifications DOM.

## 19.8.2 Objets dans le DOM

La documentation finale pour le DOM est la spécification DOM du *W3C*.

Notez que les attributs DOM peuvent également être manipulés comme des nœuds au lieu de simples chaînes. Il est relativement rare que vous ayez besoin de faire cela, cependant, cet usage n'est pas encore documenté.

Interface	Section	Objectif
<code>DOMImplementation</code>	<i>Objets DOMImplementation</i>	Interface de l'implémentation sous-jacente.
<code>Node</code>	<i>Objets nœuds</i>	Interface de base pour la majorité des objets dans un document.
<code>NodeList</code>	<i>Objet NodeList</i>	Interface pour une séquence de nœuds.
<code>DocumentType</code>	<i>Objets DocumentType</i>	Informations sur les déclarations nécessaires au traitement d'un document.
<code>Document</code>	<i>Objets Document</i>	Objet représentant un document entier.
<code>Element</code>	<i>Objets Elements</i>	Nœuds éléments dans la hiérarchie d'un document.
<code>Attr</code>	<i>Objets Attr</i>	Valeur des nœuds attributs sur dans des nœuds éléments.
<code>Comment</code>	<i>Objets Comment</i>	Représentation des commentaires dans le fichier source du document.
<code>Text</code>	<i>Objets Text et CDATASection</i>	Nœud contenant un contenu texte du document.
<code>ProcessingInstruction</code>	<i>Objets ProcessingInstruction</i>	Représentation des <i>Processing Instructions</i> .

Une Section additionnelle décrit les exceptions définis pour travailler avec le DOM en Python.

### Objets `DOMImplementation`

L'interface `DOMImplementation` fournit un moyen pour les applications de déterminer la disponibilité de fonctionnalités particulières dans le DOM qu'elles utilisent. *DOM Level 2* ajoute la capacité de créer des nouveaux objets `Document` et `DocumentType` utilisant également `DOMImplementation`.

`DOMImplementation.hasFeature(feature, version)`

Renvoie vrai si la fonctionnalité identifiée par une paire de chaîne *feature* et *version* est implémentée.

`DOMImplementation.createDocument(namespaceUri, qualifiedName, doctype)`

Renvoie un nouvel objet `Document` (la racine du DOM), avec un objet fils `Element` ayant les *namespaceUri* et *qualifiedName* passés en paramètre. Le *doctype* doit être un objet `DocumentType` créé par

`createDocumentType()` ou `None`. Dans l'API DOM de Python, les deux premiers arguments peuvent également être à `None` de manière à indiquer qu'aucun enfant `Element` ne soit créé.

`DOMImplementation.createDocumentType(qualifiedName, publicId, systemId)`

Renvoie un nouvel objet `DocumentType` qui encapsule les chaînes *qualifiedName*, *publicId*, et *systemId* passées en paramètre représentant les informations contenues dans la déclaration du document XML.

## Objets nœuds

Tous les composants d'un document XML sont des sous-classes de `Node`.

### `Node.nodeType`

Un entier représentant le type de nœud. Pour l'objet `Node`, les constantes symboliques pour les types sont `ELEMENT_NODE`, `ATTRIBUTE_NODE`, `TEXT_NODE`, `CDATA_SECTION_NODE`, `ENTITY_NODE`, `PROCESSING_INSTRUCTION_NODE`, `COMMENT_NODE`, `DOCUMENT_NODE`, `DOCUMENT_TYPE_NODE`, `NOTATION_NODE`. Ceci est un attribut en lecture seule.

### `Node.parentNode`

Le parent du nœud courant ou `None` dans le cas du nœud document. La valeur est toujours un objet `Node` ou `None`. Pour les nœuds `Element`, ce sera le parent de l'élément sauf si l'élément est la racine, dans ce cas ce sera l'objet `Document`. Pour les nœuds `Attr`, cela sera toujours `None`. Ceci est un attribut en lecture seule.

### `Node.attributes`

Un objet `NamedNodeMap` d'objet attributs. Seulement les éléments ayant des valeurs seront listés, les autres renverront `None` pour cet attribut. Cet attribut est en lecture seule.

### `Node.previousSibling`

Le nœud avec le même parent qui précède immédiatement le nœud courant. Par exemple, l'élément avec la balise fermentée qui est juste avant la balise ouvrante de l'élément *self*. Naturellement, les documents XML sont fait de plus que juste des éléments; donc le *previous sibling* peut être du texte, un commentaire ou autre chose. Si le nœud courant est le premier fils du parent, cet attribut vaudra `None`. Cet attribut est en lecture seule.

### `Node.nextSibling`

Le nœud qui suit immédiatement le nœud courant dans le même parent. Voir également *previousSibling*. Si ce nœud est le dernier de son parent, alors l'attribut sera `None`. Cet attribut est en lecture seule.

### `Node.childNodes`

Une liste de nœuds contenu dans le nœud courant. Cet attribut est en lecture seule.

### `Node.firstChild`

S'il y a des fils, premier fils du nœud courant, sinon `None`. Cet attribut est en lecture seule.

### `Node.lastChild`

S'il y a des fils, le dernier nœud fils du nœud courant. Sinon `None`. Cet attribut est en lecture seule.

### `Node.localName`

S'il y a un `:`, contient la partie suivante de `tagName` ce `:` sinon la valeur complète de `tagName`. Cette valeur est une chaîne.

### `Node.prefix`

La partie de `tagName` précédant le `:` s'il y en a un. sinon une chaîne vide. La valeur est une chaîne ou `None`.

### `Node.namespaceURI`

L'espace de nom associé (*namespace*) au nom de l'élément. Cette valeur sera une chaîne ou `None`. Cet attribut est en lecture seule.

**Node.nodeName**

L'attribut a un sens différent pour chaque type de nœud ; se reporter à la spécification DOM pour les détails. Vous obtiendrez toujours l'information que vous obtiendrez à l'aide d'une autre propriété comme **tagName** pour les éléments ou **name** pour les attributs. Pour tous les types de nœuds, la valeur sera soit une chaîne soit **None**. Cet attribut est en lecture seule.

**Node.nodeValue**

L'attribut a un sens différent pour chaque type de nœud ; se reporter à la spécification DOM pour les détails. La situation est similaire à *nodeName*. La valeur est une chaîne ou **None**.

**Node.hasAttributes()**

Renvoie vrai si le nœud a des attributs.

**Node.hasChildNodes()**

Renvoie vrai si le nœud a des nœuds fils.

**Node.isSameNode(*other*)**

Renvoie vrai si *other* fait référence au même nœud que le nœud courant. Ceci est particulièrement pratique pour implémentation de DOM qui utilise une architecture proxy (car plus d'un objet peut se référer au même nœud).

---

**Note :** Ceci est basé sur l'API proposé par \* DOM Level 3\* qui est toujours à l'étape « *working draft* » mais cette interface particulière ne paraît pas controversée. Les changements du *W3C* n'affecteront pas nécessairement cette méthode dans l'interface DOM de Python. (bien que toute nouvelle API *W3C* à cet effet soit également supportée).

---

**Node.appendChild(*newChild*)**

Ajoute un nouveau nœud fils à ce nœud à la fin de la liste des fils renvoyant *newChild*. Si ce nœud est déjà dans l'arbre, il sera d'abord retiré.

**Node.insertBefore(*newChild*, *refChild*)**

Insère un nouveau nœud fils avant un fils existant. Il est impératif que *refChild* soit un fils du nœud, sinon *ValueError* sera levée. *newChild* est renvoyé. Si *refChild* est **None**, *newChild* est inséré à la fin de la liste des fils.

**Node.removeChild(*oldChild*)**

Retire un nœud fils. *oldChild* doit être un fils de ce nœud ; sinon *ValueError* sera levée. En cas de succès, *oldChild* est renvoyé. Si *oldChild* n'est plus utilisé, sa méthode **unlink()** doit être appelée.

**Node.replaceChild(*newChild*, *oldChild*)**

Remplace un nœud existant avec un nouveau. *oldChild* doit être un fils de ce nœud ; sinon *ValueError* sera levée.

**Node.normalize()**

Jointe les nœuds texte adjacents de manière à ce que tous les segments de texte soient stockés dans une seule instance de **Text**. Ceci simplifie le traitement du texte d'un arbre DOM pour de nombreuses applications.

Nouveau dans la version 2.1.

**Node.cloneNode(*deep*)**

Clone ce nœud. Positionner *deep* signifie que tous les nœuds fils seront également clonés. La méthode renvoie le clone.

**Objet NodeList**

**NodeList** représente une séquence de nœuds. Ces objets sont utilisés de deux manières dans la recommandation Dom Core : un objet **Element** fournit en fournissant liste des nœuds fils et les méthodes

`getElementsByTagName()` et `getElementsByTagNameNS()` de `Node` renvoient des objet avec cette interface pour représenter les résultats des requêtes.

La recommandation DOM Level 2 définit un attribut et une méthode pour ces objets :

**`NodeList.item(i)`**

Renvoie le *i*\*ème élément de la séquence s'il existe ou *“None”*. L'index *\*i* ne peut pas être inférieur à 0 ou supérieur ou égale à la longueur de la séquence.

**`NodeList.length`**

Le nombre d'éléments dans la séquence.

En plus, l'interface DOM de Python requiert quelques ajouts supplémentaires pour permettre que les objet `NodeList` puissent être utilisés comme des séquences Python. Toutes les implémentations de `NodeList` doivent inclure le support de `__len__()` et de `__getitem__()` ; ceci permet l'itération sur `NodeList` avec l'instruction `for` et un support de la fonction native `len()`.

Si une implémentation de DOM support les modifications du document, l'implémentation de `NodeList` doit également supporter les méthodes `__setitem__()` et `__delitem__()` .

## Objets DocumentType

Les objets de type `DocumentType` fournissent des informations sur les notations et les entités déclarées par un document (incluant les données externes si l'analyseur les utilise et peut les fournir). Le `DocumentType` d'un `Document` est accessible via l'attribut `doctype`. Si le document ne déclare pas de `DOCTYPE`, l'attribut `doctype` vaudra `None` plutôt qu'une instance de cette interface.

`DocumentType` est une spécialisation de `Node` et ajoute les attributs suivants :

**`DocumentType.publicId`**

L'identifiant publique pour un sous ensemble de la définition type de document (*DTD*). Cela sera une chaîne ou `None`.

**`DocumentType.systemId`**

L'identifiant système pour un sous ensemble du document de définition type (*DTD*). Cela sera une URI sous la forme d'une chaîne ou `None`.

**`DocumentType.internalSubset`**

Un chaîne donnant le sous ensemble complet du document. Ceci n'inclut pas les chevrons qui englobe le sous ensemble. Si le document n'a pas de sous ensemble, cela devrait être `None`.

**`DocumentType.name`**

Le nom de l'élément racine donné dans la déclaration `DOCTYPE` si présente.

**`DocumentType.entities`**

Ceci est un `NamedNodeMap` donnant les définitions des entités externes. Pour les entités définies plusieurs fois seule la première définition est fournie (les suivantes sont ignorées comme requis par la recommandation XML). Ceci peut retourner `None` si l'information n'est pas fournie à l'analyseur ou si aucune entités n'est définis.

**`DocumentType.notations`**

Ceci est un `NamedNodeMap` donnant la définition des notations. Pour les notations définies plus d'une fois, seule la première est fournie (les suivante sont ignorées comme requis par la recommandation XML). Ceci peut retourner `None` si l'information n'est pas fournie à l'analyseur ou si aucune entités n'est définis.

## Objets Document

Un `Document` représente un document XML en son entier, incluant les éléments qui le constitue, les attributs, les *processing instructions*, commentaires, etc. Rappelez vous qu'il hérite des propriété de `Node`.

**Document.documentElement**

Le seul et unique élément racine du document.

**Document.createElement(*tagName*)**

Créé et renvoi un nouveau nœud élément. Ce n'est pas inséré dans le document quand il est créé. Vous avez besoin de l'insérer explicitement avec l'une des autres méthodes comme `insertBefore()` ou `appendChild()`.

**Document.createElementNS(*namespaceURI*, *tagName*)**

Créé et renvoi un nouvel élément avec un *namespace*. Le *tagName* peut avoir un préfixe. L'élément ne sera pas inséré dans le document quand il est créé. Vous avez besoin de l'insérer explicitement avec l'une des autres méthodes comme `insertBefore()` ou `appendChild()`.

**Document.createTextNode(*data*)**

Créé et renvoi un nœud texte contenant les *data* passées en paramètre. Comme pour les autres méthodes de création, la méthode n'insère pas le nœud dans l'arbre.

**Document.createComment(*data*)**

Créé et renvoi un nœud commentaire contenant les *data* passé en commentaire. Comme pour les autres méthodes de création, la méthode n'insère pas le nœud dans l'arbre.

**Document.createProcessingInstruction(*target*, *data*)**

Créé et retourne un nœud *processing instruction* contenant les *target* et *data* passés en paramètres. Comme pour les autres méthodes de création, la méthode n'insère pas le nœud dans l'arbre.

**Document.createAttribute(*name*)**

Créé et renvoi un nœud attribut. Cette méthode n'associe le nœud attribut aucun nœud en particulier. Vous devez utiliser la méthode `setAttributeNode()` sur un objet `Element` approprié pour utiliser une instance d'attribut nouvellement créé.

**Document.createAttributeNS(*namespaceURI*, *qualifiedName*)**

Créé et renvoi un nœud attribut avec un *namespace*. Le *tagName* peut avoir un préfixe. Cette méthode n'associe le nœud attribut à aucun nœud en particulier. Vous devez utiliser la méthode `setAttributeNode()` sur un objet `Element` approprié pour utiliser une instance d'attribut nouvellement créé.

**Document.getElementsByTagName(*tagName*)**

Cherche tout les descendants (fils directs, fils de fils, etc.) avec un nom de balise particulier.

**Document.getElementsByTagNameNS(*namespaceURI*, *localName*)**

Cherche tous les descendants (fils directs, fils de fils, etc.) avec un *namespace URI* particulier et un *localName*. Le *localName* fait parti du *namespace* après le préfixe.

## Objets Elements

`Element` est une sous classe de `Node` et donc hérite de tout les éléments de cette classe.

**Element.tagName**

Le nom de l'élément type. Dans un document utilisant des *namespace*, il pourrait y avoir des : dedans. La valeur est une chaîne.

**Element.getElementsByTagName(*tagName*)**

Identique à la méthode équivalente de la classe `Document`.

**Element.getElementsByTagNameNS(*namespaceURI*, *localName*)**

Identique à la méthode équivalente de la classe `Document`.

**Element.hasAttribute(*name*)**

Renvoi vrai si l'élément a un attribut nommé *name*.

`Element.hasAttributeNS(namespaceURI, localName)`

Renvoie vrai si l'élément a un nommée par *namespaceURI* et *localName*.

`Element.getAttribute(name)`

Retourne la valeur de l'attribut nommé par *name* comme une chaîne. Si un tel attribut n'existe pas, une chaîne vide est retournée comme si l'attribut n'avait aucune valeur.

`Element.getAttributeNode(attrname)`

Retourne le nœud `Attr` pour l'attribut nommé par *attrname*.

`Element.getAttributeNS(namespaceURI, localName)`

Renvoie la valeur de l'attribut nommé par *namespaceURI* et *localName* comme une chaîne. Si un tel attribut n'existe pas, une chaîne vide est retournée comme si l'attribut n'avait aucune valeur.

`Element.getAttributeNodeNS(namespaceURI, localName)`

Renvoie la valeur de l'attribut comme un nœud étant donné *namespaceURI* et *localName*.

`Element.removeAttribute(name)`

Retire un attribut nommé *name*. S'il n'y a aucun attribut correspondant une `NotFoundError` est levée.

`Element.removeAttributeNode(oldAttr)`

Supprime et renvoie *oldAttr* de la liste des attributs si présent. Si *oldAttr* n'est pas présent, `NotFoundError` est levée.

`Element.removeAttributeNS(namespaceURI, localName)`

Retire un attribut selon son nom. Notez qu'il utilise un *localName* et non un *qname*. Aucune exception n'est levée s'il n'y a pas d'attribut correspondant.

`Element.setAttribute(name, value)`

Assigne la valeur à un attribut pour la chaîne.

`Element.setAttributeNode(newAttr)`

Ajoute un nouveau nœud attribut à l'élément, remplaçant un attribut existant si nécessaire si *name* correspond à un attribut. Si l'attribut en remplace un précédent, l'ancien attribut sera retourné. Si *newAttr* est déjà utilisé, `InuseAttributeError` sera levée.

`Element.setAttributeNodeNS(newAttr)`

Ajoute un nouveau nœud attribut, remplaçant un attribut existant si *namespaceURI* et *localName* correspond à un attribut. S'il y a remplacement, l'ancien nœud sera renvoyé. Si *newAttr* est déjà utilisé, `InuseAttributeError` sera levée.

`Element.setAttributeNS(namespaceURI, qname, value)`

Assigne la valeur d'un attribut depuis une chaîne étant donnée un *namespaceURI* et un *qname*. Notez que *qname* est le nom de l'attribut en entier. Ceci est différent d'au dessus.

## Objets `Attr`

`Attr` hérite `Node` et donc hérite de tout ces attributs.

`Attr.name`

Le nom de l'attribut. Dans un document utilisant des *namespaces*, il pourra inclure un `:`.

`Attr.localName`

La partie du nom suivant le `:` s'il y en a un ou le nom entier sinon. Ceci est un attribut en lecture seule.

`Attr.prefix`

La partie du nom précédent le `:` s'il y en a un ou une chaîne vide.

`Attr.value`

La valeur texte de l'attribut. C'est un synonyme de l'attribut `nodeValue`.

## Objets `NameNodeMap`

`NamedNodeMap` n'hérite pas de `Node`.

`NamedNodeMap.length`

La longueur de la liste d'attributs.

`NamedNodeMap.item(index)`

Renvoie un attribut à un index particulier. L'ordre des attributs est arbitraire mais sera constant durant toute la vie du DOM. Chacun des items sera un nœud attribut. Obtenez sa valeur avec `value` de l'attribut.

Il y existe également des méthodes expérimentales qui donnent à cette classe un comportement plus *mappable*. Vous pouvez les utiliser ou utiliser la famille de méthodes standardisées `getAttribute*()` des objets `Element`.

## Objets `Comment`

`Comment` représente un commentaire dans le document XML. C'est une sous-classe `Node` mais n'a aucune nœuds fils.

`Comment.data`

Le contenu du commentaire comme une chaîne. L'attribut contient tous les caractères entre `<!--` et `-->` mais ne les inclut pas.

## Objets `Text` et `CDATASection`

L'interface `Text` représente le texte dans un document XML. Si l'analyseur et l'implémentation DOM supportent les extensions XML du DOM, les portions de texte encapsulées dans des sections marquées `CDATA` seront stockées dans des objets `CDATASection`. Ces deux interfaces sont identiques mais fournissent des valeurs différentes pour l'attribut `nodeType`.

Ces interfaces étendent l'interface `Node`. Elles ne peuvent pas avoir de nœuds fils.

`Text.data`

Le contenu du nœud texte comme une chaîne.

---

**Note :** L'utilisation d'un nœud `CDATASection` n'indique pas que le nœud représente une section complète marquée `CDATA`, seulement que le contenu du nœud est le contenu d'une section `CDATA`. Une seule section `CDATA` peut représenter plus d'un nœud dans l'arbre du document. Il n'y a aucun moyen de déterminer si deux nœuds `CDATASection` adjacents représentent différentes sections `CDATA`.

---

## Objets `ProcessingInstruction`

Représente une *processing instruction* dans un document XML. Hérite de l'interface `Node` et ne peut avoir aucun nœud fils.

`ProcessingInstruction.target`

Le contenu de la *processing instruction* jusqu'au premier caractère blanc. Cet attribut est en lecture seule.

`ProcessingInstruction.data`

Le contenu de la *processing instruction* après le premier caractère blanc.

## Exceptions

Nouveau dans la version 2.1.

La recommandation *DOM Level 2* définit une seule exception `DOMException` et un nombre de constantes qui permettent aux applications à déterminer quelle type d'erreur s'est produit. Les instances de `DOMException` ont un attribut `code` qui fournit une valeur appropriée pour une exception spécifique.

L'interface DOM de Python fournit des constantes mais étend également un ensemble d'exception pour qu'il existe une exception spécifique pour chaque code d'exception défini par le DOM. L'implémentation doit lever l'exception spécifique appropriée. Chacune ayant la valeur appropriée pour l'attribut `code`.

**exception `xml.dom.DOMException`**

Exception de base utilisée pour toutes les exceptions spécifiques du DOM. Cette classe ne peut pas être instanciée directement.

**exception `xml.dom.DomstringSizeErr`**

Levée quand un intervalle spécifique de texte ne rentre pas dans une chaîne. Cette exception n'est pas réputée être utilisée par les implémentations DOM de Python mais elle peut être levée par des implémentations de DOM qui ne sont pas écrites en Python.

**exception `xml.dom.HierarchyRequestErr`**

Levée quand l'insertion d'un nœud est tentée dans un type de nœud incompatible.

**exception `xml.dom.IndexSizeErr`**

Levée quand un index ou la taille d'un paramètre d'une méthode est négatif ou excède les valeurs autorisées.

**exception `xml.dom.InuseAttributeErr`**

Levée quand l'insertion d'un nœud `Attr` est tentée alors que ce nœud est déjà présent ailleurs dans le document.

**exception `xml.dom.InvalidAccessErr`**

Levée si un paramètre ou une opération n'est pas supporté par l'objet sous-jacent.

**exception `xml.dom.InvalidCharacterErr`**

Cette exception est levée quand un paramètre chaîne contient un caractère qui n'est pas autorisé dans le contexte utilisé par la recommandation XML 1.0. Par exemple, lors la tentative de création d'un nœud `Element` avec un espace dans le nom de l'élément.

**exception `xml.dom.InvalidModificationErr`**

Levée lors de la tentative de modifier le type de nœud.

**exception `xml.dom.InvalidStateErr`**

Levée quand une tentative est faite d'utiliser un objet non défini ou qui ne sont plus utilisables.

**exception `xml.dom.NamespaceErr`**

Si une tentative est faite de changer un objet d'une manière qui n'est pas autorisée selon la recommandation *Namespaces in XML*, cette exception est levée.

**exception `xml.dom.NotFoundErr`**

Exception quand un nœud n'existe pas dans le contexte référencé. Par exemple, `NamedNodeMap.removeNamedItem()` lèvera cette exception si le nœud passé n'appartient pas à la séquence.

**exception `xml.dom.NotSupportedErr`**

Levée si l'implémentation ne supporte pas le type d'objet requis ou l'opération.

**exception `xml.dom.NoDataAllowedErr`**

Levée si la donnée spécifiée pour un nœud n'est pas supportée.

**exception `xml.dom.NoModificationAllowedErr`**

Levée lors de la tentative de modification sur objet où les modifications ne sont pas autorisées (tels que les nœuds en lecture seule).

**exception `xml.dom.SyntaxErr`**

Levée quand une chaîne invalide ou illégale est spécifiée.

**exception `xml.dom.WrongDocumentErr`**

Levée quand un nœud est inséré dans un document différent de celui auquel il appartient et que l'implémentation ne supporte pas la migration d'un document à un autre.

Les codes d'exceptions définis par la recommandation DOM avec leurs correspondances décrites si dessous selon ce tableau :

Constante	Exception
<code>DOMSTRING_SIZE_ERR</code>	<i>DomstringSizeErr</i>
<code>HIERARCHY_REQUEST_ERR</code>	<i>HierarchyRequestErr</i>
<code>INDEX_SIZE_ERR</code>	<i>IndexSizeErr</i>
<code>INUSE_ATTRIBUTE_ERR</code>	<i>InuseAttributeErr</i>
<code>INVALID_ACCESS_ERR</code>	<i>InvalidAccessErr</i>
<code>INVALID_CHARACTER_ERR</code>	<i>InvalidCharacterErr</i>
<code>INVALID_MODIFICATION_ERR</code>	<i>InvalidModificationErr</i>
<code>INVALID_STATE_ERR</code>	<i>InvalidStateErr</i>
<code>NAMESPACE_ERR</code>	<i>NamespaceErr</i>
<code>NOT_FOUND_ERR</code>	<i>NotFoundErr</i>
<code>NOT_SUPPORTED_ERR</code>	<i>NotSupportedErr</i>
<code>NO_DATA_ALLOWED_ERR</code>	<i>NoDataAllowedErr</i>
<code>NO_MODIFICATION_ALLOWED_ERR</code>	<i>NoModificationAllowedErr</i>
<code>SYNTAX_ERR</code>	<i>SyntaxErr</i>
<code>WRONG_DOCUMENT_ERR</code>	<i>WrongDocumentErr</i>

### 19.8.3 Conformité

Cette section décrit la conformité des pré requis et des relations entre l'API DOM de Python, les recommandations *W3C* DOM et les correspondances *OMG IDL* pour Python.

#### Correspondance des types

The primitive IDL types used in the DOM specification are mapped to Python types according to the following table.

Type IDL	Type Python
<code>boolean</code>	<code>IntegerType</code> (with a value of 0 or 1)
<code>int</code>	<code>IntegerType</code>
<code>long int</code>	<code>IntegerType</code>
<code>unsigned int</code>	<code>IntegerType</code>

Additionally, the `DOMString` defined in the recommendation is mapped to a Python string or Unicode string. Applications should be able to handle Unicode whenever a string is returned from the DOM.

The IDL `null` value is mapped to `None`, which may be accepted or provided by the implementation whenever `null` is allowed by the API.

#### Méthodes d'accès

Les correspondance de *OMG IDL* vers Python définissent des fonction d'accès pour les déclarations `attribut` d'IDL à la manière dont Java le fait. Correspondance des déclarations IDL

```
readonly attribute string someValue;
    attribute string anotherValue;
```

Donne trois fonctions d'accès : une méthode *get* pour `someValue` (`_get_someValue()`) et des méthodes *get* et *set* pour `anotherValue` (`_get_anotherValue()` et `_set_anotherValue()`). Le *mapping*, en particulier, ne requiert pas que les attributs IDL soient accessible comme des attributs Python normaux : `object.someValue` n'est *pas* requis de fonctionner et peut lever une *AttributeError*.

Cependant, l'API DOM de Python *impose* que les accès par attributs classiques fonctionnent. Par conséquent, les substituts générés par le compilateur IDL de Python ne fonctionneront probablement pas, et des objets façade pourraient être nécessaires côté client si les objets DOM sont manipulés via CORBA. Bien qu'utiliser un client DOM CORBA nécessite une bonne réflexion, les développeurs habitués et expérimentés à l'utilisation de CORBA ne considèrent pas que c'est un problème. Les attributs déclarés `readonly` pourraient ne pas voir leur accès en écriture restreint dans toutes les implémentations du DOM.

Dans l'API DOM de Python, les fonctions d'accès ne sont pas requises. Si elles sont fournies, elles doivent prendre la forme définie par le *mapping* de Python IDL, mais ces méthodes sont considérées inutiles car les attributs sont directement accessible depuis Python. Les fonctions d'accès « Set » ne devraient jamais être fournies pour les attributs `readonly` (en lecture seule).

Les définitions IDL n'embarquent pas entièrement les pré-requis de l'API de DOM API telle que la notion de objets ou que la valeur de retour de `getElementsByTagName()` est dynamique. L'API DOM de Python ne requiert pas des implémentations d'avoir de tel pré-requis.

## 19.9 xml.dom.minidom — Minimal DOM implementation

Nouveau dans la version 2.0.

**Source code :** `Lib/xml/dom/minidom.py`

---

`xml.dom.minidom` is a minimal implementation of the Document Object Model interface, with an API similar to that in other languages. It is intended to be simpler than the full DOM and also significantly smaller. Users who are not already proficient with the DOM should consider using the `xml.etree.ElementTree` module for their XML processing instead.

**Avertissement :** The `xml.dom.minidom` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see *Vulnérabilités XML*.

DOM applications typically start by parsing some XML into a DOM. With `xml.dom.minidom`, this is done through the parse functions :

```
from xml.dom.minidom import parse, parseString

dom1 = parse('c:\\temp\\mydata.xml') # parse an XML file by name

datasource = open('c:\\temp\\mydata.xml')
dom2 = parse(datasource) # parse an open file

dom3 = parseString('<myxml>Some data<empty/> some more data</myxml>')
```

The `parse()` function can take either a filename or an open file object.

`xml.dom.minidom.parse(filename_or_file[, parser[, bufsize]])`

Return a *Document* from the given input. *filename\_or\_file* may be either a file name, or a file-like object. *parser*, if given, must be a SAX2 parser object. This function will change the document handler of the parser and activate namespace support ; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the `parseString()` function instead :

```
xml.dom.minidom.parseString(string[, parser])
```

Return a `Document` that represents the *string*. This method creates a *StringIO* object for the string and passes that on to `parse()`.

Both functions return a `Document` object representing the content of the document.

What the `parse()` and `parseString()` functions do is connect an XML parser with a « DOM builder » that can accept parse events from any SAX parser and convert them into a DOM tree. The name of the functions are perhaps misleading, but are easy to grasp when learning the interfaces. The parsing of the document will be completed before these functions return ; it's simply that these functions do not provide a parser implementation themselves.

You can also create a `Document` by calling a method on a « DOM Implementation » object. You can get this object either by calling the `getDOMImplementation()` function in the `xml.dom` package or the `xml.dom.minidom` module. Using the implementation from the `xml.dom.minidom` module will always return a `Document` instance from the minidom implementation, while the version from `xml.dom` may provide an alternate implementation (this is likely if you have the `PyXML` package installed). Once you have a `Document`, you can add child nodes to it to populate the DOM :

```
from xml.dom.minidom import getDOMImplementation

impl = getDOMImplementation()

newdoc = impl.createDocument(None, "some_tag", None)
top_element = newdoc.documentElement
text = newdoc.createTextNode('Some textual content.')
top_element.appendChild(text)
```

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification. The main property of the document object is the `documentElement` property. It gives you the main element in the XML document : the one that holds all others. Here is an example program :

```
dom3 = parseString("<myxml>Some data</myxml>")
assert dom3.documentElement.tagName == "myxml"
```

When you are finished with a DOM tree, you may optionally call the `unlink()` method to encourage early cleanup of the now-unneeded objects. `unlink()` is an `xml.dom.minidom`-specific extension to the DOM API that renders the node and its descendants are essentially useless. Otherwise, Python's garbage collector will eventually take care of the objects in the tree.

**Voir aussi :**

**Spécification Level 1 Document Object Model (DOM)** La recommandation du *W3C* pour le DOM supporté par `xml.dom.minidom`.

### 19.9.1 DOM Objects

The definition of the DOM API for Python is given as part of the `xml.dom` module documentation. This section lists the differences between the API and `xml.dom.minidom`.

**Node.unlink()**

Break internal references within the DOM so that it will be garbage collected on versions of Python without cyclic GC. Even when cyclic GC is available, using this can make large amounts of memory available sooner, so calling this on DOM objects as soon as they are no longer needed is good practice.

This only needs to be called on the `Document` object, but may be called on child nodes to discard children of that node.

`Node.writexml(writer, indent="", addindent="", newl="")`

Write XML to the writer object. The writer should have a `write()` method which matches that of the file object interface. The *indent* parameter is the indentation of the current node. The *addindent* parameter is the incremental indentation to use for subnodes of the current one. The *newl* parameter specifies the string to use to terminate newlines.

For the `Document` node, an additional keyword argument *encoding* can be used to specify the encoding field of the XML header.

Modifié dans la version 2.1 : The optional keyword parameters *indent*, *addindent*, and *newl* were added to support pretty output.

Modifié dans la version 2.3 : For the `Document` node, an additional keyword argument *encoding* can be used to specify the encoding field of the XML header.

`Node.toxml([encoding])`

Return the XML that the DOM represents as a string.

With no argument, the XML header does not specify an encoding, and the result is Unicode string if the default encoding cannot represent all characters in the document. Encoding this string in an encoding other than UTF-8 is likely incorrect, since UTF-8 is the default encoding of XML.

With an explicit *encoding*<sup>1</sup> argument, the result is a byte string in the specified encoding. It is recommended that this argument is always specified. To avoid `UnicodeError` exceptions in case of unrepresentable text data, the encoding argument should be specified as « utf-8 ».

Modifié dans la version 2.3 : the *encoding* argument was introduced ; see `writexml()`.

`Node.toprettyxml(indent="t", newl="\n", encoding=None)`

Return a pretty-printed version of the document. *indent* specifies the indentation string and defaults to a tabulator ; *newl* specifies the string emitted at the end of each line and defaults to `\n`.

Nouveau dans la version 2.1.

Modifié dans la version 2.3 : the encoding argument was introduced ; see `writexml()`.

The following standard DOM methods have special considerations with `xml.dom.minidom` :

`Node.cloneNode(deep)`

Although this method was present in the version of `xml.dom.minidom` packaged with Python 2.0, it was seriously broken. This has been corrected for subsequent releases.

## 19.9.2 DOM Example

This example program is a fairly realistic example of a simple program. In this particular case, we do not take much advantage of the flexibility of the DOM.

```
import xml.dom.minidom

document = """\
<slideshow>
<title>Demo slideshow</title>
<slide><title>Slide title</title>
<point>This is a demo</point>
<point>Of a program for processing slides</point>
</slide>
```

(suite sur la page suivante)

---

1. The encoding string included in XML output should conform to the appropriate standards. For example, « UTF-8 » is valid, but « UTF8 » is not. See <https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl> and <https://www.iana.org/assignments/character-sets/character-sets.xhtml>.

(suite de la page précédente)

```

<slide><title>Another demo slide</title>
<point>It is important</point>
<point>To have more than</point>
<point>one slide</point>
</slide>
</slideshow>
"""

dom = xml.dom.minidom.parseString(document)

def getText(nodelist):
    rc = []
    for node in nodelist:
        if node.nodeType == node.TEXT_NODE:
            rc.append(node.data)
    return ''.join(rc)

def handleSlideshow(slideshow):
    print "<html>"
    handleSlideshowTitle(slideshow.getElementsByTagName("title")[0])
    slides = slideshow.getElementsByTagName("slide")
    handleToc(slides)
    handleSlides(slides)
    print "</html>"

def handleSlides(slides):
    for slide in slides:
        handleSlide(slide)

def handleSlide(slide):
    handleSlideTitle(slide.getElementsByTagName("title")[0])
    handlePoints(slide.getElementsByTagName("point"))

def handleSlideshowTitle(title):
    print "<title>%s</title>" % getText(title.childNodes)

def handleSlideTitle(title):
    print "<h2>%s</h2>" % getText(title.childNodes)

def handlePoints(points):
    print "<ul>"
    for point in points:
        handlePoint(point)
    print "</ul>"

def handlePoint(point):
    print "<li>%s</li>" % getText(point.childNodes)

def handleToc(slides):
    for slide in slides:
        title = slide.getElementsByTagName("title")[0]
        print "<p>%s</p>" % getText(title.childNodes)

```

(suite sur la page suivante)

```
handleSlideshow(dom)
```

### 19.9.3 minidom and the DOM standard

The `xml.dom.minidom` module is essentially a DOM 1.0-compatible DOM with some DOM 2 features (primarily namespace features).

Usage of the DOM interface in Python is straight-forward. The following mapping rules apply :

- Interfaces are accessed through instance objects. Applications should not instantiate the classes themselves; they should use the creator functions available on the `Document` object. Derived interfaces support all operations (and attributes) from the base interfaces, plus any new operations.
- Operations are used as methods. Since the DOM uses only `in` parameters, the arguments are passed in normal order (from left to right). There are no optional arguments. `void` operations return `None`.
- IDL attributes map to instance attributes. For compatibility with the OMG IDL language mapping for Python, an attribute `foo` can also be accessed through accessor methods `_get_foo()` and `_set_foo()`. `readonly` attributes must not be changed; this is not enforced at runtime.
- The types `short int`, `unsigned int`, `unsigned long long`, and `boolean` all map to Python integer objects.
- The type `DOMString` maps to Python strings. `xml.dom.minidom` supports either byte or Unicode strings, but will normally produce Unicode strings. Values of type `DOMString` may also be `None` where allowed to have the IDL `null` value by the DOM specification from the W3C.
- `const` declarations map to variables in their respective scope (e.g. `xml.dom.minidom.Node.PROCESSING_INSTRUCTION_NODE`); they must not be changed.
- `DOMException` is currently not supported in `xml.dom.minidom`. Instead, `xml.dom.minidom` uses standard Python exceptions such as `TypeError` and `AttributeError`.
- `NodeList` objects are implemented using Python's built-in list type. Starting with Python 2.2, these objects provide the interface defined in the DOM specification, but with earlier versions of Python they do not support the official API. They are, however, much more « Pythonic » than the interface defined in the W3C recommendations.

The following interfaces have no implementation in `xml.dom.minidom` :

- `DOMTimeStamp`
- `DocumentType` (added in Python 2.1)
- `DOMImplementation` (added in Python 2.1)
- `CharacterData`
- `CDATASection`
- `Notation`
- `Entity`
- `EntityReference`
- `DocumentFragment`

Most of these reflect information in the XML document that is not of general utility to most DOM users.

#### Notes

## 19.10 xml.dom.pulldom — Support for building partial DOM trees

Nouveau dans la version 2.0.

**Source code :** `Lib/xml/dom/pulldom.py`

`xml.dom.pulldom` allows building only selected portions of a Document Object Model representation of a document from SAX events.

**Avertissement :** The `xml.dom.pulldom` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [Vulnérabilités XML](#).

```
class xml.dom.pulldom.PullDOM([documentFactory])
    xml.sax.handler.ContentHandler implementation that ...

class xml.dom.pulldom.DOMEvtStream(stream, parser, bufsize)
    ...

class xml.dom.pulldom.SAX2DOM([documentFactory])
    xml.sax.handler.ContentHandler implementation that ...

xml.dom.pulldom.parse(stream_or_string[, parser[, bufsize]])
    ...

xml.dom.pulldom.parseString(string[, parser])
    ...

xml.dom.pulldom.default_bufsize
    Default value for the bufsize parameter to parse().
    Modifié dans la version 2.1 : The value of this variable can be changed before calling parse() and the
    new value will take effect.
```

### 19.10.1 DOMEvtStream Objects

```
DOMEvtStream.getEvent()
    ...

DOMEvtStream.expandNode(node)
    ...

DOMEvtStream.reset()
    ...
```

## 19.11 xml.sax — Prise en charge des analyseurs SAX2

Nouveau dans la version 2.0.

Le paquet `xml.sax` fournit des modules qui implémentent l'interface *Simple API for XML (SAX)* pour Python. Le paquet en lui même fournit les exceptions SAX et les fonctions les plus utiles qui seront le plus utilisées par les utilisateurs de SAX API.

**Avertissement :** Le module `xml.sax` n'est pas sécurisé contre les données construites de façon malveillante. Si vous avez besoin d'analyser des données non sécurisées ou non authentifiées, voir [Vulnérabilités XML](#).

Les fonctions les plus utiles sont :

```
xml.sax.make_parser([parser_list])
    Create and return a SAX XMLReader object. The first parser found will be used. If parser_list is
    provided, it must be a list of strings which name modules that have a function named create_parser().
    Modules listed in parser_list will be used before modules in the default list of parsers.
```

```
xml.sax.parse(filename_or_stream, handler[, error_handler])
```

Crée un analyseur SAX et l'utilise pour analyser un document. Le document transmis comme *filename\_or\_stream*, peut être un nom de fichier ou un objet fichier. Le paramètre *handler* doit être une instance SAX [ContentHandler](#). Si un *error\_handler* est donné, il doit être un SAX [ErrorHandler](#); si omis, [SAXParseException](#) sera levé sur toutes les erreurs. Il n'y a pas de valeur de retour, tout le travail doit être fait par le *handler* transmis.

```
xml.sax.parseString(string, handler[, error_handler])
```

Similar to [parse\(\)](#), but parses from a buffer *string* received as a parameter.

Une application SAX typique utilise trois types d'objets : les *readers*, les *handlers* et les sources d'entrée. « Reader » dans ce contexte est un autre terme pour le analyseur, c'est-à-dire un morceau de code qui lit les octets ou les caractères de la source d'entrée et qui produit une séquence d'événements. Les événements sont ensuite distribués aux objets du *handler*, c'est-à-dire que le lecteur appelle une méthode sur le *handler*. L'application doit donc obtenir un objet *reader*, créer ou ouvrir les sources d'entrée, créer les *handlers* et connecter ces objets tous ensemble. La dernière étape de la préparation, le *reader* est appelé à analyser l'entrée. Pendant l'analyse, les méthodes sur les objets du *handler* sont appelées en fonction d'événements structurels et syntaxiques à partir des données d'entrée.

Pour ces objets, seules les interfaces sont pertinentes ; elles ne sont pas normalement instanciées par l'application elle-même. Puisque Python n'a pas de notion explicite d'interface, elles sont formellement introduites en tant que classes, mais les applications peuvent utiliser des implémentations qui n'héritent pas des classes fournies. Les interfaces [InputSource](#), [Locator](#), [Attributes](#), [AttributesNS](#), et [XMLReader](#) sont définies dans le module [xml.sax.xmlreader](#). Les interfaces du *handler* sont définies dans [xml.sax.handler](#). Pour plus de commodité, [xml.sax.xmlreader.InputSource](#) (qui est souvent instancié directement) et les classes du *handler* sont également disponibles à partir de [xml.sax](#). Ces interfaces sont décrites ci-dessous.

En plus de ces classes, [xml.sax](#) fournit les classes d'exceptions suivantes.

```
exception xml.sax.SAXException(msg[, exception])
```

Encapsule une erreur ou un avertissement XML. Cette classe peut contenir une erreur de base ou une information d'avertissement soit du analyseur XML ou de l'application : elle peut être sous-classée pour fournir des fonctionnalités supplémentaires ou pour ajouter une localisation. Noter que même si les *handlers* définis dans l'interface [ErrorHandler](#) reçoivent des instances de cette exception, ce n'est pas nécessaire de lever l'exception — il est également utile en tant que conteneur pour l'information. Quand instancié, *msg* devrait être une description lisible par l'homme de l'erreur. Le paramètre optionnel *exception*, s'il est donné, devrait être `None` ou une exception qui a été interceptée par le code d'analyse et qui est transmise comme information.

Ceci est la classe de base pour les autres classes d'exception SAX.

```
exception xml.sax.SAXParseException(msg, exception, locator)
```

Sous-classe de [SAXException](#) élevée sur les erreurs d'analyse. Les instances de cette classe sont passées aux méthodes de l'interface SAX [ErrorHandler](#) pour fournir des informations sur l'erreur d'analyse. Cette classe supporte aussi l'interface SAX [Locator](#) comme l'interface [SAXException](#).

```
exception xml.sax.SAXNotRecognizedException(msg[, exception])
```

Sous-classe de [SAXException](#) levée quand un SAX [XMLReader](#) est confronté à une caractéristique ou à une propriété non reconnue. Les applications et les extensions SAX peuvent utiliser cette classe à des fins similaires.

```
exception xml.sax.SAXNotSupportedException(msg[, exception])
```

Sous-classe de [SAXException](#) levée quand un SAX [XMLReader](#) est demandé pour activer une fonctionnalité qui n'est pas supportée, ou pour définir une propriété à une valeur que l'implémentation ne prend pas en charge. Les applications et les extensions SAX peuvent utiliser cette classe à des fins similaires.

### 19.11.1 Les objets `SAXException`

La classe d'exception `SAXException` supporte les méthodes suivantes :

`SAXException.getMessage()`

Renvoyer un message lisible par l'homme décrivant la condition d'erreur.

`SAXException.getException()`

Renvoie un objet d'exception encapsulé, ou "None".

## 19.12 `xml.sax.handler` — Base classes for SAX handlers

Nouveau dans la version 2.0.

The SAX API defines four kinds of handlers : content handlers, DTD handlers, error handlers, and entity resolvers. Applications normally only need to implement those interfaces whose events they are interested in ; they can implement the interfaces in a single object or in multiple objects. Handler implementations should inherit from the base classes provided in the module `xml.sax.handler`, so that all methods get default implementations.

**`class xml.sax.handler.ContentHandler`**

This is the main callback interface in SAX, and the one most important to applications. The order of events in this interface mirrors the order of the information in the document.

**`class xml.sax.handler.DTDHandler`**

Handle DTD events.

This interface specifies only those DTD events required for basic parsing (unparsed entities and attributes).

**`class xml.sax.handler.EntityResolver`**

Basic interface for resolving entities. If you create an object implementing this interface, then register the object with your Parser, the parser will call the method in your object to resolve all external entities.

**`class xml.sax.handler.ErrorHandler`**

Interface used by the parser to present error and warning messages to the application. The methods of this object control whether errors are immediately converted to exceptions or are handled in some other way.

In addition to these classes, `xml.sax.handler` provides symbolic constants for the feature and property names.

**`xml.sax.handler.feature_namespaces`**

value : "http://xml.org/sax/features/namespaces"

true : Perform Namespace processing.

false : Optionally do not perform Namespace processing (implies namespace-prefixes ; default).

access : (parsing) read-only ; (not parsing) read/write

**xml.sax.handler.feature\_namespace\_prefixes**

value : "http://xml.org/sax/features/namespace-prefixes"  
true : Report the original prefixed names and attributes used for Namespace declarations.  
false : Do not report attributes used for Namespace declarations, and optionally do not report original prefixed names (default).  
access : (parsing) read-only ; (not parsing) read/write

**xml.sax.handler.feature\_string\_interning**

value : "http://xml.org/sax/features/string-interning"  
true : All element names, prefixes, attribute names, Namespace URIs, and local names are interned using the built-in intern function.  
false : Names are not necessarily interned, although they may be (default).  
access : (parsing) read-only ; (not parsing) read/write

**xml.sax.handler.feature\_validation**

value : "http://xml.org/sax/features/validation"  
true : Report all validation errors (implies external-general-entities and external-parameter-entities).  
false : Do not report validation errors.  
access : (parsing) read-only ; (not parsing) read/write

**xml.sax.handler.feature\_external\_ges**

value : "http://xml.org/sax/features/external-general-entities"  
true : Include all external general (text) entities.  
false : Do not include external general entities.  
access : (parsing) read-only ; (not parsing) read/write

**xml.sax.handler.feature\_external\_pes**

value : "http://xml.org/sax/features/external-parameter-entities"  
true : Include all external parameter entities, including the external DTD subset.  
false : Do not include any external parameter entities, even the external DTD subset.  
access : (parsing) read-only ; (not parsing) read/write

**xml.sax.handler.all\_features**

List of all features.

**xml.sax.handler.property\_lexical\_handler**

value : "http://xml.org/sax/properties/lexical-handler"  
data type : xml.sax.sax2lib.LexicalHandler (not supported in Python 2)  
description : An optional extension handler for lexical events like comments.  
access : read/write

**xml.sax.handler.property\_declaration\_handler**

value : "http://xml.org/sax/properties/declaration-handler"  
data type : xml.sax.sax2lib.DeclHandler (not supported in Python 2)  
description : An optional extension handler for DTD-related events other than notations and unparsed entities.

access : read/write

#### `xml.sax.handler.property_dom_node`

value : "http://xml.org/sax/properties/dom-node"

data type : `org.w3c.dom.Node` (not supported in Python 2)

description : When parsing, the current DOM node being visited if this is a DOM iterator; when not parsing, the root DOM node for iteration.

access : (parsing) read-only; (not parsing) read/write

#### `xml.sax.handler.property_xml_string`

value : "http://xml.org/sax/properties/xml-string"

data type : `String`

description : The literal string of characters that was the source for the current event.

access : read-only

#### `xml.sax.handler.all_properties`

List of all known property names.

### 19.12.1 ContentHandler Objects

Users are expected to subclass *ContentHandler* to support their application. The following methods are called by the parser on the appropriate events in the input document :

#### `ContentHandler.setDocumentLocator(locator)`

Called by the parser to give the application a locator for locating the origin of document events.

SAX parsers are strongly encouraged (though not absolutely required) to supply a locator : if it does so, it must supply the locator to the application by invoking this method before invoking any of the other methods in the DocumentHandler interface.

The locator allows the application to determine the end position of any document-related event, even if the parser is not reporting an error. Typically, the application will use this information for reporting its own errors (such as character content that does not match an application's business rules). The information returned by the locator is probably not sufficient for use with a search engine.

Note that the locator will return correct information only during the invocation of the events in this interface. The application should not attempt to use it at any other time.

#### `ContentHandler.startDocument()`

Receive notification of the beginning of a document.

The SAX parser will invoke this method only once, before any other methods in this interface or in *DTDHandler* (except for *setDocumentLocator()*).

#### `ContentHandler.endDocument()`

Receive notification of the end of a document.

The SAX parser will invoke this method only once, and it will be the last method invoked during the parse. The parser shall not invoke this method until it has either abandoned parsing (because of an unrecoverable error) or reached the end of input.

#### `ContentHandler.startPrefixMapping(prefix, uri)`

Begin the scope of a prefix-URI Namespace mapping.

The information from this event is not necessary for normal Namespace processing : the SAX XML reader will automatically replace prefixes for element and attribute names when the `feature_namespaces` feature is enabled (the default).

There are cases, however, when applications need to use prefixes in character data or in attribute values, where they cannot safely be expanded automatically; the *startPrefixMapping()* and

*endPrefixMapping()* events supply the information to the application to expand prefixes in those contexts itself, if necessary.

Note that *startPrefixMapping()* and *endPrefixMapping()* events are not guaranteed to be properly nested relative to each-other : all *startPrefixMapping()* events will occur before the corresponding *startElement()* event, and all *endPrefixMapping()* events will occur after the corresponding *endElement()* event, but their order is not guaranteed.

**ContentHandler.endPrefixMapping(*prefix*)**

End the scope of a prefix-URI mapping.

See *startPrefixMapping()* for details. This event will always occur after the corresponding *endElement()* event, but the order of *endPrefixMapping()* events is not otherwise guaranteed.

**ContentHandler.startElement(*name*, *attrs*)**

Signals the start of an element in non-namespace mode.

The *name* parameter contains the raw XML 1.0 name of the element type as a string and the *attrs* parameter holds an object of the **Attributes** interface (see *The Attributes Interface*) containing the attributes of the element. The object passed as *attrs* may be re-used by the parser ; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the *copy()* method of the *attrs* object.

**ContentHandler.endElement(*name*)**

Signals the end of an element in non-namespace mode.

The *name* parameter contains the name of the element type, just as with the *startElement()* event.

**ContentHandler.startElementNS(*name*, *qname*, *attrs*)**

Signals the start of an element in namespace mode.

The *name* parameter contains the name of the element type as a (*uri*, *localname*) tuple, the *qname* parameter contains the raw XML 1.0 name used in the source document, and the *attrs* parameter holds an instance of the **AttributesNS** interface (see *The AttributesNS Interface*) containing the attributes of the element. If no namespace is associated with the element, the *uri* component of *name* will be **None**. The object passed as *attrs* may be re-used by the parser ; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the *copy()* method of the *attrs* object.

Parsers may set the *qname* parameter to **None**, unless the *feature\_namespace\_prefixes* feature is activated.

**ContentHandler.endElementNS(*name*, *qname*)**

Signals the end of an element in namespace mode.

The *name* parameter contains the name of the element type, just as with the *startElementNS()* method, likewise the *qname* parameter.

**ContentHandler.characters(*content*)**

Receive notification of character data.

The Parser will call this method to report each chunk of character data. SAX parsers may return all contiguous character data in a single chunk, or they may split it into several chunks ; however, all of the characters in any single event must come from the same external entity so that the Locator provides useful information.

*content* may be a Unicode string or a byte string ; the *expat* reader module produces always Unicode strings.

---

**Note :** The earlier SAX 1 interface provided by the Python XML Special Interest Group used a more Java-like interface for this method. Since most parsers used from Python did not take advantage of the older interface, the simpler signature was chosen to replace it. To convert old code to the new interface, use *content* instead of slicing content with the old *offset* and *length* parameters.

---

**ContentHandler.ignorableWhitespace(*whitespace*)**

Receive notification of ignorable whitespace in element content.

Validating Parsers must use this method to report each chunk of ignorable whitespace (see the W3C XML 1.0 recommendation, section 2.10) : non-validating parsers may also use this method if they are capable of parsing and using content models.

SAX parsers may return all contiguous whitespace in a single chunk, or they may split it into several chunks ; however, all of the characters in any single event must come from the same external entity, so that the Locator provides useful information.

**ContentHandler.processingInstruction(*target*, *data*)**

Receive notification of a processing instruction.

The Parser will invoke this method once for each processing instruction found : note that processing instructions may occur before or after the main document element.

A SAX parser should never report an XML declaration (XML 1.0, section 2.8) or a text declaration (XML 1.0, section 4.3.1) using this method.

**ContentHandler.skippedEntity(*name*)**

Receive notification of a skipped entity.

The Parser will invoke this method once for each entity skipped. Non-validating processors may skip entities if they have not seen the declarations (because, for example, the entity was declared in an external DTD subset). All processors may skip external entities, depending on the values of the `feature_external_ges` and the `feature_external_pes` properties.

## 19.12.2 DTDHandler Objects

*DTDHandler* instances provide the following methods :

**DTDHandler.notationDecl(*name*, *publicId*, *systemId*)**

Handle a notation declaration event.

**DTDHandler.unparsedEntityDecl(*name*, *publicId*, *systemId*, *ndata*)**

Handle an unparsed entity declaration event.

## 19.12.3 EntityResolver Objects

**EntityResolver.resolveEntity(*publicId*, *systemId*)**

Resolve the system identifier of an entity and return either the system identifier to read from as a string, or an `InputSource` to read from. The default implementation returns *systemId*.

## 19.12.4 ErrorHandler Objects

Objects with this interface are used to receive error and warning information from the *XMLReader*. If you create an object that implements this interface, then register the object with your *XMLReader*, the parser will call the methods in your object to report all warnings and errors. There are three levels of errors available : warnings, (possibly) recoverable errors, and unrecoverable errors. All methods take a `SAXParseException` as the only parameter. Errors and warnings may be converted to an exception by raising the passed-in exception object.

**ErrorHandler.error(*exception*)**

Called when the parser encounters a recoverable error. If this method does not raise an exception, parsing may continue, but further document information should not be expected by the application. Allowing the parser to continue may allow additional errors to be discovered in the input document.

**ErrorHandler.fatalError(*exception*)**

Called when the parser encounters an error it cannot recover from ; parsing is expected to terminate when this method returns.

`ErrorHandler.warning(exception)`

Called when the parser presents minor warning information to the application. Parsing is expected to continue when this method returns, and document information will continue to be passed to the application. Raising an exception in this method will cause parsing to end.

## 19.13 `xml.sax.saxutils` — SAX Utilities

Nouveau dans la version 2.0.

The module `xml.sax.saxutils` contains a number of classes and functions that are commonly useful when creating SAX applications, either in direct use, or as base classes.

`xml.sax.saxutils.escape(data[, entities])`

Escape '&', '<', and '>' in a string of data.

You can escape other strings of data by passing a dictionary as the optional *entities* parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. The characters '&', '<' and '>' are always escaped, even if *entities* is provided.

`xml.sax.saxutils.unescape(data[, entities])`

Unescape '&amp;', '&lt;', and '&gt;' in a string of data.

You can unescape other strings of data by passing a dictionary as the optional *entities* parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. '&amp;', '&lt;', and '&gt;' are always unescaped, even if *entities* is provided.

Nouveau dans la version 2.3.

`xml.sax.saxutils.quoteattr(data[, entities])`

Similar to *escape()*, but also prepares *data* to be used as an attribute value. The return value is a quoted version of *data* with any additional required replacements. *quoteattr()* will select a quote character based on the content of *data*, attempting to avoid encoding any quote characters in the string. If both single- and double-quote characters are already in *data*, the double-quote characters will be encoded and *data* will be wrapped in double-quotes. The resulting string can be used directly as an attribute value :

```
>>> print "<element attr=%s>" % quoteattr("ab ' cd \" ef")
<element attr="ab ' cd &quot; ef">
```

This function is useful when generating attribute values for HTML or any SGML using the reference concrete syntax.

Nouveau dans la version 2.2.

`class xml.sax.saxutils.XMLGenerator([out[, encoding]])`

This class implements the *ContentHandler* interface by writing SAX events back into an XML document. In other words, using an *XMLGenerator* as the content handler will reproduce the original document being parsed. *out* should be a file-like object which will default to *sys.stdout*. *encoding* is the encoding of the output stream which defaults to 'iso-8859-1'.

`class xml.sax.saxutils.XMLFilterBase(base)`

This class is designed to sit between an *XMLReader* and the client application's event handlers. By default, it does nothing but pass requests up to the reader and events on to the handlers unmodified, but subclasses can override specific methods to modify the event stream or the configuration requests as they pass through.

`xml.sax.saxutils.prepare_input_source(source[, base])`

This function takes an input source and an optional base URL and returns a fully resolved *InputSource* object ready for reading. The input source can be given as a string, a file-like object, or an *InputSource* object; parsers will use this function to implement the polymorphic *source* argument to their *parse()* method.

## 19.14 xml.sax.xmlreader — Interface for XML parsers

Nouveau dans la version 2.0.

SAX parsers implement the *XMLReader* interface. They are implemented in a Python module, which must provide a function `create_parser()`. This function is invoked by `xml.sax.make_parser()` with no arguments to create a new parser object.

**class xml.sax.xmlreader.XMLReader**

Base class which can be inherited by SAX parsers.

**class xml.sax.xmlreader.IncrementalParser**

In some cases, it is desirable not to parse an input source at once, but to feed chunks of the document as they get available. Note that the reader will normally not read the entire file, but read it in chunks as well; still `parse()` won't return until the entire document is processed. So these interfaces should be used if the blocking behaviour of `parse()` is not desirable.

When the parser is instantiated it is ready to begin accepting data from the feed method immediately. After parsing has been finished with a call to close the reset method must be called to make the parser ready to accept new data, either from feed or using the parse method.

Note that these methods must *not* be called during parsing, that is, after `parse` has been called and before it returns.

By default, the class also implements the parse method of the XMLReader interface using the feed, close and reset methods of the IncrementalParser interface as a convenience to SAX 2.0 driver writers.

**class xml.sax.xmlreader.Locator**

Interface for associating a SAX event with a document location. A locator object will return valid results only during calls to DocumentHandler methods; at any other time, the results are unpredictable. If information is not available, methods may return `None`.

**class xml.sax.xmlreader.InputSource([systemId])**

Encapsulation of the information needed by the *XMLReader* to read entities.

This class may include information about the public identifier, system identifier, byte stream (possibly with character encoding information) and/or the character stream of an entity.

Applications will create objects of this class for use in the *XMLReader.parse()* method and for returning from `EntityResolver.resolveEntity`.

An *InputSource* belongs to the application, the *XMLReader* is not allowed to modify *InputSource* objects passed to it from the application, although it may make copies and modify those.

**class xml.sax.xmlreader.AttributesImpl(attrs)**

This is an implementation of the *Attributes* interface (see section *The Attributes Interface*). This is a dictionary-like object which represents the element attributes in a `startElement()` call. In addition to the most useful dictionary operations, it supports a number of other methods as described by the interface. Objects of this class should be instantiated by readers; *attrs* must be a dictionary-like object containing a mapping from attribute names to attribute values.

**class xml.sax.xmlreader.AttributesNSImpl(attrs, qnames)**

Namespace-aware variant of *AttributesImpl*, which will be passed to `startElementNS()`. It is derived from *AttributesImpl*, but understands attribute names as two-tuples of *namespaceURI* and *localname*. In addition, it provides a number of methods expecting qualified names as they appear in the original document. This class implements the *AttributesNS* interface (see section *The AttributesNS Interface*).

### 19.14.1 XMLReader Objects

The *XMLReader* interface supports the following methods :

**XMLReader.parse(source)**

Process an input source, producing SAX events. The *source* object can be a system identifier (a string

identifying the input source – typically a file name or a URL), a file-like object, or an *InputSource* object. When *parse()* returns, the input is completely processed, and the parser object can be discarded or reset. As a limitation, the current implementation only accepts byte streams; processing of character streams is for further study.

`XMLReader.getContentHandler()`

Return the current *ContentHandler*.

`XMLReader.setContentHandler(handler)`

Set the current *ContentHandler*. If no *ContentHandler* is set, content events will be discarded.

`XMLReader.getDTDHandler()`

Return the current *DTDHandler*.

`XMLReader.setDTDHandler(handler)`

Set the current *DTDHandler*. If no *DTDHandler* is set, DTD events will be discarded.

`XMLReader.getEntityResolver()`

Return the current *EntityResolver*.

`XMLReader.setEntityResolver(handler)`

Set the current *EntityResolver*. If no *EntityResolver* is set, attempts to resolve an external entity will result in opening the system identifier for the entity, and fail if it is not available.

`XMLReader.getErrorHandler()`

Return the current *ErrorHandler*.

`XMLReader.setErrorHandler(handler)`

Set the current error handler. If no *ErrorHandler* is set, errors will be raised as exceptions, and warnings will be printed.

`XMLReader.setLocale(locale)`

Allow an application to set the locale for errors and warnings.

SAX parsers are not required to provide localization for errors and warnings; if they cannot support the requested locale, however, they must raise a SAX exception. Applications may request a locale change in the middle of a parse.

`XMLReader.getFeature(featurename)`

Return the current setting for feature *featurename*. If the feature is not recognized, *SAXNotRecognizedException* is raised. The well-known featurenames are listed in the module *xml.sax.handler*.

`XMLReader.setFeature(featurename, value)`

Set the *featurename* to *value*. If the feature is not recognized, *SAXNotRecognizedException* is raised. If the feature or its setting is not supported by the parser, *SAXNotSupportedException* is raised.

`XMLReader.getProperty(propertyname)`

Return the current setting for property *propertyname*. If the property is not recognized, a *SAXNotRecognizedException* is raised. The well-known propertynames are listed in the module *xml.sax.handler*.

`XMLReader.setProperty(propertyname, value)`

Set the *propertyname* to *value*. If the property is not recognized, *SAXNotRecognizedException* is raised. If the property or its setting is not supported by the parser, *SAXNotSupportedException* is raised.

## 19.14.2 IncrementalParser Objects

Instances of *IncrementalParser* offer the following additional methods :

`IncrementalParser.feed(data)`

Process a chunk of *data*.

`IncrementalParser.close()`

Assume the end of the document. That will check well-formedness conditions that can be checked only at the end, invoke handlers, and may clean up resources allocated during parsing.

`IncrementalParser.reset()`

This method is called after `close` has been called to reset the parser so that it is ready to parse new documents. The results of calling `parse` or `feed` after `close` without calling `reset` are undefined.

### 19.14.3 Locator Objects

Instances of *Locator* provide these methods :

`Locator.getColumnNumber()`

Return the column number where the current event begins.

`Locator.getLineNumber()`

Return the line number where the current event begins.

`Locator.getPublicId()`

Return the public identifier for the current event.

`Locator.getSystemId()`

Return the system identifier for the current event.

### 19.14.4 InputSource Objects

`InputSource.setPublicId(id)`

Sets the public identifier of this *InputSource*.

`InputSource.getPublicId()`

Returns the public identifier of this *InputSource*.

`InputSource.setSystemId(id)`

Sets the system identifier of this *InputSource*.

`InputSource.getSystemId()`

Returns the system identifier of this *InputSource*.

`InputSource.setEncoding(encoding)`

Sets the character encoding of this *InputSource*.

The encoding must be a string acceptable for an XML encoding declaration (see section 4.3.3 of the XML recommendation).

The encoding attribute of the *InputSource* is ignored if the *InputSource* also contains a character stream.

`InputSource.getEncoding()`

Get the character encoding of this *InputSource*.

`InputSource.setByteStream(bytefile)`

Set the byte stream (a Python file-like object which does not perform byte-to-character conversion) for this input source.

The SAX parser will ignore this if there is also a character stream specified, but it will use a byte stream in preference to opening a URI connection itself.

If the application knows the character encoding of the byte stream, it should set it with the `setEncoding` method.

`InputSource.getByteStream()`

Get the byte stream for this input source.

The `getEncoding` method will return the character encoding for this byte stream, or `None` if unknown.

`InputSource.setCharacterStream(charfile)`

Set the character stream for this input source. (The stream must be a Python 1.6 Unicode-wrapped file-like that performs conversion to Unicode strings.)

If there is a character stream specified, the SAX parser will ignore any byte stream and will not attempt to open a URI connection to the system identifier.

`InputSource.getCharacterStream()`

Get the character stream for this input source.

### 19.14.5 The Attributes Interface

`Attributes` objects implement a portion of the mapping protocol, including the methods `copy()`, `get()`, `has_key()`, `items()`, `keys()`, and `values()`. The following methods are also provided :

`Attributes.getLength()`

Return the number of attributes.

`Attributes.getNames()`

Return the names of the attributes.

`Attributes.getType(name)`

Returns the type of the attribute *name*, which is normally 'CDATA'.

`Attributes.getValue(name)`

Return the value of attribute *name*.

### 19.14.6 The AttributesNS Interface

This interface is a subtype of the `Attributes` interface (see section *The Attributes Interface*). All methods supported by that interface are also available on `AttributesNS` objects.

The following methods are also available :

`AttributesNS.getValueByQName(name)`

Return the value for a qualified name.

`AttributesNS.getNameByQName(name)`

Return the (namespace, localname) pair for a qualified *name*.

`AttributesNS.getQNameByName(name)`

Return the qualified name for a (namespace, localname) pair.

`AttributesNS.getQNames()`

Return the qualified names of all attributes.

## 19.15 `xml.parsers.expat` — Fast XML parsing using Expat

**Avertissement :** The `pyexpat` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see *Vulnérabilités XML*.

Nouveau dans la version 2.0.

The `xml.parsers.expat` module is a Python interface to the Expat non-validating XML parser. The module provides a single extension type, `xmlparser`, that represents the current state of an XML parser. After an `xmlparser` object has been created, various attributes of the object can be set to handler functions. When an XML document is then fed to the parser, the handler functions are called for the character data and markup in the XML document.

This module uses the `pyexpat` module to provide access to the Expat parser. Direct use of the `pyexpat` module is deprecated.

This module provides one exception and one type object :

**exception** `xml.parsers.expat.ExpatError`

The exception raised when Expat reports an error. See section [ExpatError Exceptions](#) for more information on interpreting Expat errors.

**exception** `xml.parsers.expat.error`

Alias for [ExpatError](#).

**xml.parsers.expat.XMLParserType**

The type of the return values from the [ParserCreate\(\)](#) function.

The `xml.parsers.expat` module contains two functions :

**xml.parsers.expat.ErrorString(errno)**

Returns an explanatory string for a given error number *errno*.

**xml.parsers.expat.ParserCreate([*encoding*, *namespace\_separator*])**

Creates and returns a new `xmlparser` object. *encoding*, if specified, must be a string naming the encoding used by the XML data. Expat doesn't support as many encodings as Python does, and its repertoire of encodings can't be extended; it supports UTF-8, UTF-16, ISO-8859-1 (Latin1), and ASCII. If *encoding*<sup>1</sup> is given it will override the implicit or explicit encoding of the document.

Expat can optionally do XML namespace processing for you, enabled by providing a value for *namespace\_separator*. The value must be a one-character string; a [ValueError](#) will be raised if the string has an illegal length (`None` is considered the same as omission). When namespace processing is enabled, element type names and attribute names that belong to a namespace will be expanded. The element name passed to the element handlers `StartElementHandler` and `EndElementHandler` will be the concatenation of the namespace URI, the namespace separator character, and the local part of the name. If the namespace separator is a zero byte (`chr(0)`) then the namespace URI and the local part will be concatenated without any separator.

For example, if *namespace\_separator* is set to a space character (' ') and the following document is parsed :

```
<?xml version="1.0"?>
<root xmlns      = "http://default-namespace.org/"
      xmlns:py   = "http://www.python.org/ns/">
  <py:elem1 />
  <elem2 xmlns="" />
</root>
```

`StartElementHandler` will receive the following strings for each element :

```
http://default-namespace.org/ root
http://www.python.org/ns/ elem1
elem2
```

Due to limitations in the Expat library used by `pyexpat`, the `xmlparser` instance returned can only be used to parse a single XML document. Call `ParserCreate` for each document to provide unique parser instances.

**Voilà aussi :**

**The Expat XML Parser** Home page of the Expat project.

1. The encoding string included in XML output should conform to the appropriate standards. For example, « UTF-8 » is valid, but « UTF8 » is not. See <https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl> and <https://www.iana.org/assignments/character-sets/character-sets.xhtml>.

### 19.15.1 XMLParser Objects

`xmlparser` objects have the following methods :

`xmlparser.Parse(data[, isfinal])`

Parses the contents of the string *data*, calling the appropriate handler functions to process the parsed data. *isfinal* must be true on the final call to this method; it allows the parsing of a single file in fragments, not the submission of multiple files. *data* can be the empty string at any time.

`xmlparser.ParseFile(file)`

Parse XML data reading from the object *file*. *file* only needs to provide the `read(nbytes)` method, returning the empty string when there's no more data.

`xmlparser.SetBase(base)`

Sets the base to be used for resolving relative URIs in system identifiers in declarations. Resolving relative identifiers is left to the application : this value will be passed through as the *base* argument to the `ExternalEntityRefHandler()`, `NotationDeclHandler()`, and `UnparsedEntityDeclHandler()` functions.

`xmlparser.GetBase()`

Returns a string containing the base set by a previous call to `SetBase()`, or `None` if `SetBase()` hasn't been called.

`xmlparser.GetInputContext()`

Returns the input data that generated the current event as a string. The data is in the encoding of the entity which contains the text. When called while an event handler is not active, the return value is `None`.

Nouveau dans la version 2.1.

`xmlparser.ExternalEntityParserCreate(context[, encoding])`

Create a « child » parser which can be used to parse an external parsed entity referred to by content parsed by the parent parser. The *context* parameter should be the string passed to the `ExternalEntityRefHandler()` handler function, described below. The child parser is created with the *ordered\_attributes*, *returns\_unicode* and *specified\_attributes* set to the values of this parser.

`xmlparser.SetParamEntityParsing(flag)`

Control parsing of parameter entities (including the external DTD subset). Possible *flag* values are `XML_PARAM_ENTITY_PARSING_NEVER`, `XML_PARAM_ENTITY_PARSING_UNLESS_STANDALONE` and `XML_PARAM_ENTITY_PARSING_ALWAYS`. Return true if setting the flag was successful.

`xmlparser.UseForeignDTD([flag])`

Calling this with a true value for *flag* (the default) will cause Expat to call the `ExternalEntityRefHandler` with `None` for all arguments to allow an alternate DTD to be loaded. If the document does not contain a document type declaration, the `ExternalEntityRefHandler` will still be called, but the `StartDoctypeDeclHandler` and `EndDoctypeDeclHandler` will not be called.

Passing a false value for *flag* will cancel a previous call that passed a true value, but otherwise has no effect.

This method can only be called before the `Parse()` or `ParseFile()` methods are called; calling it after either of those have been called causes `ExpatError` to be raised with the *code* attribute set to `errors.XML_ERROR_CANT_CHANGE_FEATURE_ONCE_PARSING`.

Nouveau dans la version 2.3.

`xmlparser` objects have the following attributes :

`xmlparser.buffer_size`

The size of the buffer used when *buffer\_text* is true. A new buffer size can be set by assigning a new integer value to this attribute. When the size is changed, the buffer will be flushed.

Nouveau dans la version 2.3.

Modifié dans la version 2.6 : The buffer size can now be changed.

#### `xmlparser.buffer_text`

Setting this to true causes the `xmlparser` object to buffer textual content returned by Expat to avoid multiple calls to the `CharacterDataHandler()` callback whenever possible. This can improve performance substantially since Expat normally breaks character data into chunks at every line ending. This attribute is false by default, and may be changed at any time.

Nouveau dans la version 2.3.

#### `xmlparser.buffer_used`

If `buffer_text` is enabled, the number of bytes stored in the buffer. These bytes represent UTF-8 encoded text. This attribute has no meaningful interpretation when `buffer_text` is false.

Nouveau dans la version 2.3.

#### `xmlparser.ordered_attributes`

Setting this attribute to a non-zero integer causes the attributes to be reported as a list rather than a dictionary. The attributes are presented in the order found in the document text. For each attribute, two list entries are presented : the attribute name and the attribute value. (Older versions of this module also used this format.) By default, this attribute is false ; it may be changed at any time.

Nouveau dans la version 2.1.

#### `xmlparser.returns_unicode`

If this attribute is set to a non-zero integer, the handler functions will be passed Unicode strings. If `returns_unicode` is *False*, 8-bit strings containing UTF-8 encoded data will be passed to the handlers. This is *True* by default when Python is built with Unicode support.

Modifié dans la version 1.6 : Can be changed at any time to affect the result type.

#### `xmlparser.specified_attributes`

If set to a non-zero integer, the parser will report only those attributes which were specified in the document instance and not those which were derived from attribute declarations. Applications which set this need to be especially careful to use what additional information is available from the declarations as needed to comply with the standards for the behavior of XML processors. By default, this attribute is false ; it may be changed at any time.

Nouveau dans la version 2.1.

The following attributes contain values relating to the most recent error encountered by an `xmlparser` object, and will only have correct values once a call to `Parse()` or `ParseFile()` has raised an `xml.parsers.expat.ExpatError` exception.

#### `xmlparser.ErrorByteIndex`

Byte index at which an error occurred.

#### `xmlparser.ErrorCode`

Numeric code specifying the problem. This value can be passed to the `ErrorString()` function, or compared to one of the constants defined in the `errors` object.

#### `xmlparser.ErrorColumnNumber`

Column number at which an error occurred.

#### `xmlparser.ErrorLineNumber`

Line number at which an error occurred.

The following attributes contain values relating to the current parse location in an `xmlparser` object. During a callback reporting a parse event they indicate the location of the first of the sequence of characters that generated the event. When called outside of a callback, the position indicated will be just past the last parse event (regardless of whether there was an associated callback).

Nouveau dans la version 2.4.

`xmlparser.CurrentByteIndex`

Current byte index in the parser input.

`xmlparser.CurrentColumnNumber`

Current column number in the parser input.

`xmlparser.CurrentLineNumber`

Current line number in the parser input.

Here is the list of handlers that can be set. To set a handler on an `xmlparser` object *o*, use `o.handlername = func`. *handlername* must be taken from the following list, and *func* must be a callable object accepting the correct number of arguments. The arguments are all strings, unless otherwise stated.

`xmlparser.XmlDeclHandler(version, encoding, standalone)`

Called when the XML declaration is parsed. The XML declaration is the (optional) declaration of the applicable version of the XML recommendation, the encoding of the document text, and an optional « standalone » declaration. *version* and *encoding* will be strings of the type dictated by the `returns_unicode` attribute, and *standalone* will be 1 if the document is declared standalone, 0 if it is declared not to be standalone, or -1 if the standalone clause was omitted. This is only available with Expat version 1.95.0 or newer.

Nouveau dans la version 2.1.

`xmlparser.StartDoctypeDeclHandler(doctypeName, systemId, publicId, has_internal_subset)`

Called when Expat begins parsing the document type declaration (`<!DOCTYPE ...`). The *doctypeName* is provided exactly as presented. The *systemId* and *publicId* parameters give the system and public identifiers if specified, or `None` if omitted. *has\_internal\_subset* will be true if the document contains and internal document declaration subset. This requires Expat version 1.2 or newer.

`xmlparser.EndDoctypeDeclHandler()`

Called when Expat is done parsing the document type declaration. This requires Expat version 1.2 or newer.

`xmlparser.ElementDeclHandler(name, model)`

Called once for each element type declaration. *name* is the name of the element type, and *model* is a representation of the content model.

`xmlparser.AttnlistDeclHandler(ename, attname, type, default, required)`

Called for each declared attribute for an element type. If an attribute list declaration declares three attributes, this handler is called three times, once for each attribute. *ename* is the name of the element to which the declaration applies and *attname* is the name of the attribute declared. The attribute type is a string passed as *type*; the possible values are 'CDATA', 'ID', 'IDREF', ... *default* gives the default value for the attribute used when the attribute is not specified by the document instance, or `None` if there is no default value (#IMPLIED values). If the attribute is required to be given in the document instance, *required* will be true. This requires Expat version 1.95.0 or newer.

`xmlparser.StartElementHandler(name, attributes)`

Called for the start of every element. *name* is a string containing the element name, and *attributes* is a dictionary mapping attribute names to their values.

`xmlparser.EndElementHandler(name)`

Called for the end of every element.

`xmlparser.ProcessingInstructionHandler(target, data)`

Called for every processing instruction.

`xmlparser.CharacterDataHandler(data)`

Called for character data. This will be called for normal character data, CDATA marked content, and ignorable whitespace. Applications which must distinguish these cases can use the `StartCdataSectionHandler`, `EndCdataSectionHandler`, and `ElementDeclHandler` callbacks to collect the required information.

`xmlparser.UnparsedEntityDeclHandler(entityName, base, systemId, publicId, notationName)`

Called for unparsed (NDATA) entity declarations. This is only present for version 1.2 of the Expat library; for more recent versions, use [EntityDeclHandler](#) instead. (The underlying function in the Expat library has been declared obsolete.)

`xmlparser.EntityDeclHandler(entityName, is_parameter_entity, value, base, systemId, publicId, notationName)`

Called for all entity declarations. For parameter and internal entities, *value* will be a string giving the declared contents of the entity; this will be `None` for external entities. The *notationName* parameter will be `None` for parsed entities, and the name of the notation for unparsed entities. *is\_parameter\_entity* will be true if the entity is a parameter entity or false for general entities (most applications only need to be concerned with general entities). This is only available starting with version 1.95.0 of the Expat library.

Nouveau dans la version 2.1.

`xmlparser.NotationDeclHandler(notationName, base, systemId, publicId)`

Called for notation declarations. *notationName*, *base*, and *systemId*, and *publicId* are strings if given. If the public identifier is omitted, *publicId* will be `None`.

`xmlparser.StartNamespaceDeclHandler(prefix, uri)`

Called when an element contains a namespace declaration. Namespace declarations are processed before the [StartElementHandler](#) is called for the element on which declarations are placed.

`xmlparser.EndNamespaceDeclHandler(prefix)`

Called when the closing tag is reached for an element that contained a namespace declaration. This is called once for each namespace declaration on the element in the reverse of the order for which the [StartNamespaceDeclHandler](#) was called to indicate the start of each namespace declaration's scope. Calls to this handler are made after the corresponding [EndElementHandler](#) for the end of the element.

`xmlparser.CommentHandler(data)`

Called for comments. *data* is the text of the comment, excluding the leading '`<!--`' and trailing '`-->`'.

`xmlparser.StartCdataSectionHandler()`

Called at the start of a CDATA section. This and [EndCdataSectionHandler](#) are needed to be able to identify the syntactical start and end for CDATA sections.

`xmlparser.EndCdataSectionHandler()`

Called at the end of a CDATA section.

`xmlparser.DefaultHandler(data)`

Called for any characters in the XML document for which no applicable handler has been specified. This means characters that are part of a construct which could be reported, but for which no handler has been supplied.

`xmlparser.DefaultHandlerExpand(data)`

This is the same as the [DefaultHandler\(\)](#), but doesn't inhibit expansion of internal entities. The entity reference will not be passed to the default handler.

`xmlparser.NotStandaloneHandler()`

Called if the XML document hasn't been declared as being a standalone document. This happens when there is an external subset or a reference to a parameter entity, but the XML declaration does not set standalone to `yes` in an XML declaration. If this handler returns 0, then the parser will raise an `XML_ERROR_NOT_STANDALONE` error. If this handler is not set, no exception is raised by the parser for this condition.

`xmlparser.ExternalEntityRefHandler(context, base, systemId, publicId)`

Called for references to external entities. *base* is the current base, as set by a previous call to [SetBase\(\)](#). The public and system identifiers, *systemId* and *publicId*, are strings if given; if the public identifier is not given, *publicId* will be `None`. The *context* value is opaque and should only be used as described below.

For external entities to be parsed, this handler must be implemented. It is responsible for creating the sub-parser using `ExternalEntityParserCreate(context)`, initializing it with the appropriate callbacks, and parsing the entity. This handler should return an integer; if it returns 0, the parser will raise an `XML_ERROR_EXTERNAL_ENTITY_HANDLING` error, otherwise parsing will continue.

If this handler is not provided, external entities are reported by the *DefaultHandler* callback, if provided.

### 19.15.2 ExpatError Exceptions

*ExpatError* exceptions have a number of interesting attributes :

**ExpatError.code**

Expat's internal error number for the specific error. This will match one of the constants defined in the `errors` object from this module.

Nouveau dans la version 2.1.

**ExpatError.lineno**

Line number on which the error was detected. The first line is numbered 1.

Nouveau dans la version 2.1.

**ExpatError.offset**

Character offset into the line where the error occurred. The first column is numbered 0.

Nouveau dans la version 2.1.

### 19.15.3 Exemple

The following program defines three handlers that just print out their arguments.

```
import xml.parsers.expat

# 3 handler functions
def start_element(name, attrs):
    print 'Start element:', name, attrs
def end_element(name):
    print 'End element:', name
def char_data(data):
    print 'Character data:', repr(data)

p = xml.parsers.expat.ParserCreate()

p.StartElementHandler = start_element
p.EndElementHandler = end_element
p.CharacterDataHandler = char_data

p.Parse("""<?xml version="1.0"?>
<parent id="top"><child1 name="paul">Text goes here</child1>
<child2 name="fred">More text</child2>
</parent>""", 1)
```

The output from this program is :

```
Start element: parent {'id': 'top'}
Start element: child1 {'name': 'paul'}
Character data: 'Text goes here'
End element: child1
```

(suite sur la page suivante)

(suite de la page précédente)

```

Character data: '\n'
Start element: child2 {'name': 'fred'}
Character data: 'More text'
End element: child2
Character data: '\n'
End element: parent

```

### 19.15.4 Content Model Descriptions

Content models are described using nested tuples. Each tuple contains four values : the type, the quantifier, the name, and a tuple of children. Children are simply additional content model descriptions.

The values of the first two fields are constants defined in the `model` object of the `xml.parsers.expat` module. These constants can be collected in two groups : the model type group and the quantifier group.

The constants in the model type group are :

`xml.parsers.expat.XML_CTYPE_ANY`

The element named by the model name was declared to have a content model of `ANY`.

`xml.parsers.expat.XML_CTYPE_CHOICE`

The named element allows a choice from a number of options ; this is used for content models such as (A | B | C).

`xml.parsers.expat.XML_CTYPE_EMPTY`

Elements which are declared to be `EMPTY` have this model type.

`xml.parsers.expat.XML_CTYPE_MIXED`

`xml.parsers.expat.XML_CTYPE_NAME`

`xml.parsers.expat.XML_CTYPE_SEQ`

Models which represent a series of models which follow one after the other are indicated with this model type. This is used for models such as (A, B, C).

The constants in the quantifier group are :

`xml.parsers.expat.XML_CQUANT_NONE`

No modifier is given, so it can appear exactly once, as for A.

`xml.parsers.expat.XML_CQUANT_OPT`

The model is optional : it can appear once or not at all, as for A?

`xml.parsers.expat.XML_CQUANT_PLUS`

The model must occur one or more times (like A+).

`xml.parsers.expat.XML_CQUANT_REP`

The model must occur zero or more times, as for A\*.

### 19.15.5 Expat error constants

The following constants are provided in the `errors` object of the `xml.parsers.expat` module. These constants are useful in interpreting some of the attributes of the `ExpatError` exception objects raised when an error has occurred.

The `errors` object has the following attributes :

`xml.parsers.expat.XML_ERROR_ASYNC_ENTITY`

`xml.parsers.expat.XML_ERROR_ATTRIBUTE_EXTERNAL_ENTITY_REF`

An entity reference in an attribute value referred to an external entity instead of an internal entity.

`xml.parsers.expat.XML_ERROR_BAD_CHAR_REF`

A character reference referred to a character which is illegal in XML (for example, character 0, or “&#0;”).

`xml.parsers.expat.XML_ERROR_BINARY_ENTITY_REF`

An entity reference referred to an entity which was declared with a notation, so cannot be parsed.

`xml.parsers.expat.XML_ERROR_DUPLICATE_ATTRIBUTE`

An attribute was used more than once in a start tag.

`xml.parsers.expat.XML_ERROR_INCORRECT_ENCODING`

`xml.parsers.expat.XML_ERROR_INVALID_TOKEN`

Raised when an input byte could not properly be assigned to a character; for example, a NUL byte (value 0) in a UTF-8 input stream.

`xml.parsers.expat.XML_ERROR_JUNK_AFTER_DOC_ELEMENT`

Something other than whitespace occurred after the document element.

`xml.parsers.expat.XML_ERROR_MISPLACED_XML_PI`

An XML declaration was found somewhere other than the start of the input data.

`xml.parsers.expat.XML_ERROR_NO_ELEMENTS`

The document contains no elements (XML requires all documents to contain exactly one top-level element)..

`xml.parsers.expat.XML_ERROR_NO_MEMORY`

Expat was not able to allocate memory internally.

`xml.parsers.expat.XML_ERROR_PARAM_ENTITY_REF`

A parameter entity reference was found where it was not allowed.

`xml.parsers.expat.XML_ERROR_PARTIAL_CHAR`

An incomplete character was found in the input.

`xml.parsers.expat.XML_ERROR_RECURSIVE_ENTITY_REF`

An entity reference contained another reference to the same entity; possibly via a different name, and possibly indirectly.

`xml.parsers.expat.XML_ERROR_SYNTAX`

Some unspecified syntax error was encountered.

`xml.parsers.expat.XML_ERROR_TAG_MISMATCH`

An end tag did not match the innermost open start tag.

`xml.parsers.expat.XML_ERROR_UNCLOSED_TOKEN`

Some token (such as a start tag) was not closed before the end of the stream or the next token was encountered.

`xml.parsers.expat.XML_ERROR_UNDEFINED_ENTITY`

A reference was made to an entity which was not defined.

`xml.parsers.expat.XML_ERROR_UNKNOWN_ENCODING`

The document encoding is not supported by Expat.

`xml.parsers.expat.XML_ERROR_UNCLOSED_CDATA_SECTION`

A CDATA marked section was not closed.

`xml.parsers.expat.XML_ERROR_EXTERNAL_ENTITY_HANDLING`

`xml.parsers.expat.XML_ERROR_NOT_STANDALONE`

The parser determined that the document was not « standalone » though it declared itself to be in the XML declaration, and the `NotStandaloneHandler` was set and returned 0.

`xml.parsers.expat.XML_ERROR_UNEXPECTED_STATE`

`xml.parsers.expat.XML_ERROR_ENTITY_DECLARED_IN_PE`

`xml.parsers.expat.XML_ERROR_FEATURE_REQUIRES_XML_DTD`

An operation was requested that requires DTD support to be compiled in, but Expat was configured without DTD support. This should never be reported by a standard build of the `xml.parsers.expat` module.

`xml.parsers.expat.XML_ERROR_CANT_CHANGE_FEATURE_ONCE_PARSING`

A behavioral change was requested after parsing started that can only be changed before parsing has started. This is (currently) only raised by `UseForeignDTD()`.

`xml.parsers.expat.XML_ERROR_UNBOUND_PREFIX`

An undeclared prefix was found when namespace processing was enabled.

`xml.parsers.expat.XML_ERROR_UNDECLARING_PREFIX`

The document attempted to remove the namespace declaration associated with a prefix.

`xml.parsers.expat.XML_ERROR_INCOMPLETE_PE`

A parameter entity contained incomplete markup.

`xml.parsers.expat.XML_ERROR_XML_DECL`

The document contained no document element at all.

`xml.parsers.expat.XML_ERROR_TEXT_DECL`

There was an error parsing a text declaration in an external entity.

`xml.parsers.expat.XML_ERROR_PUBLICID`

Characters were found in the public id that are not allowed.

`xml.parsers.expat.XML_ERROR_SUSPENDED`

The requested operation was made on a suspended parser, but isn't allowed. This includes attempts to provide additional input or to stop the parser.

`xml.parsers.expat.XML_ERROR_NOT_SUSPENDED`

An attempt to resume the parser was made when the parser had not been suspended.

`xml.parsers.expat.XML_ERROR_ABORTED`

This should not be reported to Python applications.

`xml.parsers.expat.XML_ERROR_FINISHED`

The requested operation was made on a parser which was finished parsing input, but isn't allowed. This includes attempts to provide additional input or to stop the parser.

`xml.parsers.expat.XML_ERROR_SUSPEND_PE`

## Notes

Les modules documentés dans ce chapitre implémentent des protocoles relatifs à Internet et à ses technologies relatives. Ils sont tous implémentés en Python. La majorité de ces modules nécessitent la présence du module *socket* lui-même dépendant du système, mais fourni sur la plupart des plateformes populaires. Voici une vue d'ensemble :

## 20.1 webbrowser — Convenient Web-browser controller

Source code : [Lib/webbrowser.py](#)

---

The *webbrowser* module provides a high-level interface to allow displaying Web-based documents to users. Under most circumstances, simply calling the *open()* function from this module will do the right thing.

Under Unix, graphical browsers are preferred under X11, but text-mode browsers will be used if graphical browsers are not available or an X11 display isn't available. If text-mode browsers are used, the calling process will block until the user exits the browser.

If the environment variable **BROWSER** exists, it is interpreted to override the platform default list of browsers, as an *os.pathsep*-separated list of browsers to try in order. When the value of a list part contains the string *%s*, then it is interpreted as a literal browser command line to be used with the argument URL substituted for *%s*; if the part does not contain *%s*, it is simply interpreted as the name of the browser to launch.<sup>1</sup>

For non-Unix platforms, or when a remote browser is available on Unix, the controlling process will not wait for the user to finish with the browser, but allow the remote browser to maintain its own windows on the display. If remote browsers are not available on Unix, the controlling process will launch a new browser and wait.

The script **webbrowser** can be used as a command-line interface for the module. It accepts a URL as the argument. It accepts the following optional parameters : **-n** opens the URL in a new browser window, if possible ; **-t** opens the URL in a new browser page (« tab »). The options are, naturally, mutually exclusive. Usage example :

---

1. Executables named here without a full path will be searched in the directories given in the **PATH** environment variable.

```
python -m webbrowser -t "http://www.python.org"
```

L'exception suivante est définie :

**exception webbrowser.Error**

Exception raised when a browser control error occurs.

The following functions are defined :

**webbrowser.open(url, new=0, autoraise=True)**

Display *url* using the default browser. If *new* is 0, the *url* is opened in the same browser window if possible. If *new* is 1, a new browser window is opened if possible. If *new* is 2, a new browser page (« tab ») is opened if possible. If *autoraise* is **True**, the window is raised if possible (note that under many window managers this will occur regardless of the setting of this variable).

Note that on some platforms, trying to open a filename using this function, may work and start the operating system's associated program. However, this is neither supported nor portable.

Modifié dans la version 2.5 : *new* can now be 2.

**webbrowser.open\_new(url)**

Open *url* in a new window of the default browser, if possible, otherwise, open *url* in the only browser window.

**webbrowser.open\_new\_tab(url)**

Open *url* in a new page (« tab ») of the default browser, if possible, otherwise equivalent to [\*open\\_new\(\)\*](#).

Nouveau dans la version 2.5.

**webbrowser.get([name])**

Return a controller object for the browser type *name*. If *name* is empty, return a controller for a default browser appropriate to the caller's environment.

**webbrowser.register(name, constructor[, instance])**

Register the browser type *name*. Once a browser type is registered, the [\*get\(\)\*](#) function can return a controller for that browser type. If *instance* is not provided, or is **None**, *constructor* will be called without parameters to create an instance when needed. If *instance* is provided, *constructor* will never be called, and may be **None**.

This entry point is only useful if you plan to either set the **BROWSER** variable or call [\*get\(\)\*](#) with a nonempty argument matching the name of a handler you declare.

A number of browser types are predefined. This table gives the type names that may be passed to the [\*get\(\)\*](#) function and the corresponding instantiations for the controller classes, all defined in this module.

Type Name	Class Name	Notes
'mozilla'	Mozilla('mozilla')	
'firefox'	Mozilla('mozilla')	
'netscape'	Mozilla('netscape')	
'galeon'	Galeon('galeon')	
'epiphany'	Galeon('epiphany')	
'skipstone'	BackgroundBrowser('skipstone')	
'kfmclient'	Konqueror()	(1)
'konqueror'	Konqueror()	(1)
'kfm'	Konqueror()	(1)
'mosaic'	BackgroundBrowser('mosaic')	
'opera'	Opera()	
'grail'	Grail()	
'links'	GenericBrowser('links')	
'elinks'	Elinks('elinks')	
'lynx'	GenericBrowser('lynx')	
'w3m'	GenericBrowser('w3m')	
'windows-default'	WindowsDefault	(2)
'macosx'	MacOSX('default')	(3)
'safari'	MacOSX('safari')	(3)
'google-chrome'	Chrome('google-chrome')	(4)
'chrome'	Chrome('chrome')	(4)
'chromium'	Chromium('chromium')	(4)
'chromium-browser'	Chromium('chromium-browser')	(4)

Notes :

- (1) « Konqueror » is the file manager for the KDE desktop environment for Unix, and only makes sense to use if KDE is running. Some way of reliably detecting KDE would be nice; the KDEDIR variable is not sufficient. Note also that the name « kfm » is used even when using the **konqueror** command with KDE 2 — the implementation selects the best strategy for running Konqueror.
- (2) Only on Windows platforms.
- (3) Only on Mac OS X platform.
- (4) Support for Chrome/Chromium has been added in version 2.7.5.

Here are some simple examples :

```
url = 'http://www.python.org/'

# Open URL in a new tab, if a browser window is already open.
webbrowser.open_new_tab(url + 'doc/')

# Open URL in new window, raising the window if possible.
webbrowser.open_new(url)
```

### 20.1.1 Browser Controller Objects

Browser controllers provide these methods which parallel three of the module-level convenience functions :

`controller.open(url, new=0, autoraise=True)`

Display *url* using the browser handled by this controller. If *new* is 1, a new browser window is opened if possible. If *new* is 2, a new browser page (« tab ») is opened if possible.

`controller.open_new(url)`

Open *url* in a new window of the browser handled by this controller, if possible, otherwise, open *url* in the only browser window. Alias *open\_new()*.

`controller.open_new_tab(url)`

Open *url* in a new page (« tab ») of the browser handled by this controller, if possible, otherwise equivalent to *open\_new()*.

Nouveau dans la version 2.5.

## Notes

## 20.2 cgi — Common Gateway Interface support

Code source : [Lib/cgi.py](#)

---

Support module for Common Gateway Interface (CGI) scripts.

This module defines a number of utilities for use by CGI scripts written in Python.

### 20.2.1 Introduction

A CGI script is invoked by an HTTP server, usually to process user input submitted through an HTML `<FORM>` or `<ISINDEX>` element.

Most often, CGI scripts live in the server's special `cgi-bin` directory. The HTTP server places all sorts of information about the request (such as the client's hostname, the requested URL, the query string, and lots of other goodies) in the script's shell environment, executes the script, and sends the script's output back to the client.

The script's input is connected to the client too, and sometimes the form data is read this way; at other times the form data is passed via the « query string » part of the URL. This module is intended to take care of the different cases and provide a simpler interface to the Python script. It also provides a number of utilities that help in debugging scripts, and the latest addition is support for file uploads from a form (if your browser supports it).

The output of a CGI script should consist of two sections, separated by a blank line. The first section contains a number of headers, telling the client what kind of data is following. Python code to generate a minimal header section looks like this :

```
print "Content-Type: text/html"      # HTML is following
print                               # blank line, end of headers
```

The second section is usually HTML, which allows the client software to display nicely formatted text with header, in-line images, etc. Here's Python code that prints a simple piece of HTML :

```
print "<TITLE>CGI script output</TITLE>"
print "<H1>This is my first CGI script</H1>"
print "Hello, world!"
```

### 20.2.2 Using the cgi module

Begin by writing `import cgi`. Do not use `from cgi import *` — the module defines all sorts of names for its own use or for backward compatibility that you don't want in your namespace.

When you write a new script, consider adding these lines :

```
import cgitb
cgitb.enable()
```

This activates a special exception handler that will display detailed reports in the Web browser if any errors occur. If you'd rather not show the guts of your program to users of your script, you can have the reports saved to files instead, with code like this :

```
import cgitb
cgitb.enable(display=0, logdir="/path/to/logdir")
```

It's very helpful to use this feature during script development. The reports produced by `cgitb` provide information that can save you a lot of time in tracking down bugs. You can always remove the `cgitb` line later when you have tested your script and are confident that it works correctly.

To get at submitted form data, it's best to use the `FieldStorage` class. The other classes defined in this module are provided mostly for backward compatibility. Instantiate it exactly once, without arguments. This reads the form contents from standard input or the environment (depending on the value of various environment variables set according to the CGI standard). Since it may consume standard input, it should be instantiated only once.

The `FieldStorage` instance can be indexed like a Python dictionary. It allows membership testing with the `in` operator, and also supports the standard dictionary method `keys()` and the built-in function `len()`. Form fields containing empty strings are ignored and do not appear in the dictionary; to keep such values, provide a true value for the optional `keep_blank_values` keyword parameter when creating the `FieldStorage` instance.

For instance, the following code (which assumes that the *Content-Type* header and blank line have already been printed) checks that the fields `name` and `addr` are both set to a non-empty string :

```
form = cgi.FieldStorage()
if "name" not in form or "addr" not in form:
    print "<H1>Error</H1>"
    print "Please fill in the name and addr fields."
    return
print "<p>name:", form["name"].value
print "<p>addr:", form["addr"].value
...further form processing here...
```

Here the fields, accessed through `form[key]`, are themselves instances of `FieldStorage` (or `MiniFieldStorage`, depending on the form encoding). The `value` attribute of the instance yields the string value of the field. The `getvalue()` method returns this string value directly; it also accepts an optional second argument as a default to return if the requested key is not present.

If the submitted form data contains more than one field with the same name, the object retrieved by `form[key]` is not a `FieldStorage` or `MiniFieldStorage` instance but a list of such instances. Similarly, in this situation, `form.getvalue(key)` would return a list of strings. If you expect this possibility (when your HTML form contains multiple fields with the same name), use the `getlist()` method, which always returns a list of values (so that you do not need to special-case the single item case). For example, this code concatenates any number of username fields, separated by commas :

```
value = form.getlist("username")
usernames = ",".join(value)
```

If a field represents an uploaded file, accessing the value via the `value` attribute or the `getvalue()` method reads the entire file in memory as a string. This may not be what you want. You can test for an uploaded

file by testing either the `filename` attribute or the `file` attribute. You can then read the data at leisure from the `file` attribute :

```
fileitem = form["userfile"]
if fileitem.file:
    # It's an uploaded file; count lines
    linecount = 0
    while 1:
        line = fileitem.file.readline()
        if not line: break
        linecount = linecount + 1
```

If an error is encountered when obtaining the contents of an uploaded file (for example, when the user interrupts the form submission by clicking on a Back or Cancel button) the `done` attribute of the object for the field will be set to the value -1.

The file upload draft standard entertains the possibility of uploading multiple files from one field (using a recursive *multipart/\** encoding). When this occurs, the item will be a dictionary-like `FieldStorage` item. This can be determined by testing its `type` attribute, which should be *multipart/form-data* (or perhaps another MIME type matching *multipart/\**). In this case, it can be iterated over recursively just like the top-level form object.

When a form is submitted in the « old » format (as the query string or as a single data part of type *application/x-www-form-urlencoded*), the items will actually be instances of the class `MiniFieldStorage`. In this case, the `list`, `file`, and `filename` attributes are always `None`.

A form submitted via POST that also has a query string will contain both `FieldStorage` and `MiniFieldStorage` items.

### 20.2.3 Higher Level Interface

Nouveau dans la version 2.2.

The previous section explains how to read CGI form data using the `FieldStorage` class. This section describes a higher level interface which was added to this class to allow one to do it in a more readable and intuitive way. The interface doesn't make the techniques described in previous sections obsolete — they are still useful to process file uploads efficiently, for example.

The interface consists of two simple methods. Using the methods you can process form data in a generic way, without the need to worry whether only one or more values were posted under one name.

In the previous section, you learned to write following code anytime you expected a user to post more than one value under one name :

```
item = form.getvalue("item")
if isinstance(item, list):
    # The user is requesting more than one item.
else:
    # The user is requesting only one item.
```

This situation is common for example when a form contains a group of multiple checkboxes with the same name :

```
<input type="checkbox" name="item" value="1" />
<input type="checkbox" name="item" value="2" />
```

In most situations, however, there's only one form control with a particular name in a form and then you expect and need only one value associated with this name. So you write a script containing for example this

code :

```
user = form.getvalue("user").upper()
```

The problem with the code is that you should never expect that a client will provide valid input to your scripts. For example, if a curious user appends another `user=foo` pair to the query string, then the script would crash, because in this situation the `getvalue("user")` method call returns a list instead of a string. Calling the `upper()` method on a list is not valid (since lists do not have a method of this name) and results in an `AttributeError` exception.

Therefore, the appropriate way to read form data values was to always use the code which checks whether the obtained value is a single value or a list of values. That's annoying and leads to less readable scripts.

A more convenient approach is to use the methods `getfirst()` and `getlist()` provided by this higher level interface.

`FieldStorage.getfirst(name[, default])`

This method always returns only one value associated with form field *name*. The method returns only the first value in case that more values were posted under such name. Please note that the order in which the values are received may vary from browser to browser and should not be counted on.<sup>1</sup> If no such form field or value exists then the method returns the value specified by the optional parameter *default*. This parameter defaults to `None` if not specified.

`FieldStorage.getlist(name)`

This method always returns a list of values associated with form field *name*. The method returns an empty list if no such form field or value exists for *name*. It returns a list consisting of one item if only one such value exists.

Using these methods you can write nice compact code :

```
import cgi
form = cgi.FieldStorage()
user = form.getfirst("user", "").upper()    # This way it's safe.
for item in form.getlist("item"):
    do_something(item)
```

## 20.2.4 Old classes

Obsolète depuis la version 2.6 : These classes, present in earlier versions of the `cgi` module, are still supported for backward compatibility. New applications should use the `FieldStorage` class.

`SvFormContentDict` stores single value form content as dictionary ; it assumes each field name occurs in the form only once.

`FormContentDict` stores multiple value form content as a dictionary (the form items are lists of values). Useful if your form contains multiple fields with the same name.

Other classes (`FormContent`, `InterpFormContentDict`) are present for backwards compatibility with really old applications only.

## 20.2.5 Fonctions

These are useful if you want more control, or if you want to employ some of the algorithms implemented in this module in other circumstances.

1. Note that some recent versions of the HTML specification do state what order the field values should be supplied in, but knowing whether a request was received from a conforming browser, or even from a browser at all, is tedious and error-prone.

`cgi.parse(fp[, environ[, keep_blank_values[, strict_parsing]]])`

Parse a query in the environment or from a file (the file defaults to `sys.stdin` and environment defaults to `os.environ`). The `keep_blank_values` and `strict_parsing` parameters are passed to `urlparse.parse_qs()` unchanged.

`cgi.parse_qs(qs[, keep_blank_values[, strict_parsing[, max_num_fields]]])`

This function is deprecated in this module. Use `urlparse.parse_qs()` instead. It is maintained here only for backward compatibility.

`cgi.parse_qsl(qs[, keep_blank_values[, strict_parsing[, max_num_fields]]])`

This function is deprecated in this module. Use `urlparse.parse_qsl()` instead. It is maintained here only for backward compatibility.

`cgi.parse_multipart(fp, pdict)`

Parse input of type *multipart/form-data* (for file uploads). Arguments are `fp` for the input file and `pdict` for a dictionary containing other parameters in the *Content-Type* header.

Returns a dictionary just like `urlparse.parse_qs()` keys are the field names, each value is a list of values for that field. This is easy to use but not much good if you are expecting megabytes to be uploaded — in that case, use the `FieldStorage` class instead which is much more flexible.

Note that this does not parse nested multipart parts — use `FieldStorage` for that.

`cgi.parse_header(string)`

Parse a MIME header (such as *Content-Type*) into a main value and a dictionary of parameters.

`cgi.test()`

Robust test CGI script, usable as main program. Writes minimal HTTP headers and formats all information provided to the script in HTML form.

`cgi.print_environ()`

Format the shell environment in HTML.

`cgi.print_form(form)`

Format a form in HTML.

`cgi.print_directory()`

Format the current directory in HTML.

`cgi.print_environ_usage()`

Print a list of useful (used by CGI) environment variables in HTML.

`cgi.escape(s[, quote])`

Convert the characters '&', '<' and '>' in string `s` to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag `quote` is true, the quotation mark character (") is also translated; this helps for inclusion in an HTML attribute value delimited by double quotes, as in `<a href="...">`. Note that single quotes are never translated.

If the value to be quoted might include single- or double-quote characters, or both, consider using the `quoteattr()` function in the `xml.sax.saxutils` module instead.

## 20.2.6 Caring about security

There's one important rule : if you invoke an external program (via the `os.system()` or `os.popen()` functions, or others with similar functionality), make very sure you don't pass arbitrary strings received from the client to the shell. This is a well-known security hole whereby clever hackers anywhere on the Web can exploit a gullible CGI script to invoke arbitrary shell commands. Even parts of the URL or field names cannot be trusted, since the request doesn't have to come from your form!

To be on the safe side, if you must pass a string gotten from a form to a shell command, you should make sure the string contains only alphanumeric characters, dashes, underscores, and periods.

## 20.2.7 Installing your CGI script on a Unix system

Read the documentation for your HTTP server and check with your local system administrator to find the directory where CGI scripts should be installed; usually this is in a directory `cgi-bin` in the server tree.

Make sure that your script is readable and executable by « others »; the Unix file mode should be 0755 octal (use `chmod 0755 filename`). Make sure that the first line of the script contains `#!` starting in column 1 followed by the pathname of the Python interpreter, for instance :

```
#!/usr/local/bin/python
```

Make sure the Python interpreter exists and is executable by « others ».

Make sure that any files your script needs to read or write are readable or writable, respectively, by « others » — their mode should be 0644 for readable and 0666 for writable. This is because, for security reasons, the HTTP server executes your script as user « nobody », without any special privileges. It can only read (write, execute) files that everybody can read (write, execute). The current directory at execution time is also different (it is usually the server's `cgi-bin` directory) and the set of environment variables is also different from what you get when you log in. In particular, don't count on the shell's search path for executables (`PATH`) or the Python module search path (`PYTHONPATH`) to be set to anything interesting.

If you need to load modules from a directory which is not on Python's default module search path, you can change the path in your script, before importing other modules. For example :

```
import sys
sys.path.insert(0, "/usr/home/joe/lib/python")
sys.path.insert(0, "/usr/local/lib/python")
```

(This way, the directory inserted last will be searched first!)

Instructions for non-Unix systems will vary; check your HTTP server's documentation (it will usually have a section on CGI scripts).

## 20.2.8 Testing your CGI script

Unfortunately, a CGI script will generally not run when you try it from the command line, and a script that works perfectly from the command line may fail mysteriously when run from the server. There's one reason why you should still test your script from the command line : if it contains a syntax error, the Python interpreter won't execute it at all, and the HTTP server will most likely send a cryptic error to the client.

Assuming your script has no syntax errors, yet it does not work, you have no choice but to read the next section.

## 20.2.9 Debugging CGI scripts

First of all, check for trivial installation errors — reading the section above on installing your CGI script carefully can save you a lot of time. If you wonder whether you have understood the installation procedure correctly, try installing a copy of this module file (`cgi.py`) as a CGI script. When invoked as a script, the file will dump its environment and the contents of the form in HTML form. Give it the right mode etc, and send it a request. If it's installed in the standard `cgi-bin` directory, it should be possible to send it a request by entering a URL into your browser of the form :

```
http://yourhostname/cgi-bin/cgi.py?name=Joe+Blow&addr=At+Home
```

If this gives an error of type 404, the server cannot find the script — perhaps you need to install it in a different directory. If it gives another error, there's an installation problem that you should fix before trying to go any further. If you get a nicely formatted listing of the environment and form content (in this example, the fields should be listed as « `addr` » with value « `At Home` » and « `name` » with value « `Joe Blow` »),

the `cgi.py` script has been installed correctly. If you follow the same procedure for your own script, you should now be able to debug it.

The next step could be to call the `cgi` module's `test()` function from your script : replace its main code with the single statement

```
cgi.test()
```

This should produce the same results as those gotten from installing the `cgi.py` file itself.

When an ordinary Python script raises an unhandled exception (for whatever reason : of a typo in a module name, a file that can't be opened, etc.), the Python interpreter prints a nice traceback and exits. While the Python interpreter will still do this when your CGI script raises an exception, most likely the traceback will end up in one of the HTTP server's log files, or be discarded altogether.

Fortunately, once you have managed to get your script to execute *some* code, you can easily send tracebacks to the Web browser using the `cgitb` module. If you haven't done so already, just add the lines :

```
import cgitb
cgitb.enable()
```

to the top of your script. Then try running it again ; when a problem occurs, you should see a detailed report that will likely make apparent the cause of the crash.

If you suspect that there may be a problem in importing the `cgitb` module, you can use an even more robust approach (which only uses built-in modules) :

```
import sys
sys.stderr = sys.stdout
print "Content-Type: text/plain"
print
...your code here...
```

This relies on the Python interpreter to print the traceback. The content type of the output is set to plain text, which disables all HTML processing. If your script works, the raw HTML will be displayed by your client. If it raises an exception, most likely after the first two lines have been printed, a traceback will be displayed. Because no HTML interpretation is going on, the traceback will be readable.

### 20.2.10 Common problems and solutions

- Most HTTP servers buffer the output from CGI scripts until the script is completed. This means that it is not possible to display a progress report on the client's display while the script is running.
- Check the installation instructions above.
- Check the HTTP server's log files. (`tail -f logfile` in a separate window may be useful!)
- Always check a script for syntax errors first, by doing something like `python script.py`.
- If your script does not have any syntax errors, try adding `import cgitb; cgitb.enable()` to the top of the script.
- When invoking external programs, make sure they can be found. Usually, this means using absolute path names — `PATH` is usually not set to a very useful value in a CGI script.
- When reading or writing external files, make sure they can be read or written by the `userid` under which your CGI script will be running : this is typically the `userid` under which the web server is running, or some explicitly specified `userid` for a web server's `suexec` feature.
- Don't try to give a CGI script a `set-uid` mode. This doesn't work on most systems, and is a security liability as well.

## Notes

## 20.3 `cgitb` — Gestionnaire d'exceptions pour les scripts CGI

Nouveau dans la version 2.2.

Le module `cgitb` fournit un gestionnaire d'exceptions spécifique pour les scripts Python. (Son nom est trompeur : Il a été conçu à l'origine pour afficher des pile d'appels en HTML pour les scripts CGI, puis a été généralisé par la suite pour afficher cette information en texte brut.) Une fois ce module activé, si une exception remonte jusqu'à l'interpréteur, un rapport détaillé sera affiché. Le rapport affiche la pile d'appels, montrant des extraits de code pour chaque niveau, ainsi que les arguments et les variables locales des fonctions appelantes pour vous aider à résoudre le problème. Il est aussi possible de sauvegarder cette information dans un fichier plutôt que de l'envoyer dans le navigateur.

Pour activer cette fonctionnalité, ajoutez simplement ceci au début de votre script CGI :

```
import cgitb
cgitb.enable()
```

Les paramètres optionnels de la fonction `enable()` permettent de choisir si le rapport est envoyé au navigateur ou si le rapport est écrit dans un fichier pour analyse ultérieure.

```
cgitb.enable([display[, logdir[, context[, format]]]])
```

Appeler cette fonction remplace le gestionnaire d'exceptions par défaut de l'interpréteur par celui du module `cgitb`, en configurant `sys.excepthook`.

Le paramètre optionnel `display` vaut 1 par défaut, et peut être mis à 0 pour désactiver l'envoi des piles d'appels au navigateur. Si l'argument `logdir` est donné les piles d'appels seront écrites dans des fichiers placés dans le dossier `logdir`. L'argument optionnel `context` est le nombre de lignes de code à afficher autour de la ligne courante dans le code source à chaque niveau de la pile d'appel, il vaut 5 par défaut. Si l'argument optionnel `format` est "html", le rapport sera rédigé en HTML. Le rapport sera écrit en texte brut pour toute autre valeur. La valeur par défaut est "html".

```
cgitb.handler([info])
```

Cette fonction gère les exceptions en utilisant la configuration par défaut (c'est à dire envoyer un rapport HTML au navigateur sans l'enregistrer dans un fichier). Il peut être utilisé lorsque vous avez attrapé une exception et que vous en voulez un rapport généré par `cgitb`. L'argument optionnel `info` doit être un *tuple* de trois éléments contenant le type de l'exception, l'exception, et la pile d'appels, tel que le *tuple* renvoyé par `sys.exc_info()`. Si l'argument `info` n'est pas donné, l'exception courante est obtenue via `sys.exc_info()`.

## 20.4 `wsgiref` — WSGI Utilities and Reference Implementation

Nouveau dans la version 2.5.

The Web Server Gateway Interface (WSGI) is a standard interface between web server software and web applications written in Python. Having a standard interface makes it easy to use an application that supports WSGI with a number of different web servers.

Only authors of web servers and programming frameworks need to know every detail and corner case of the WSGI design. You don't need to understand every detail of WSGI just to install a WSGI application or to write a web application using an existing framework.

`wsgiref` is a reference implementation of the WSGI specification that can be used to add WSGI support to a web server or framework. It provides utilities for manipulating WSGI environment variables and response headers, base classes for implementing WSGI servers, a demo HTTP server that serves WSGI applications, and a validation tool that checks WSGI servers and applications for conformance to the WSGI specification ([PEP 333](#)).

See <https://wsgi.readthedocs.org/> for more information about WSGI, and links to tutorials and other resources.

### 20.4.1 wsgiref.util – WSGI environment utilities

This module provides a variety of utility functions for working with WSGI environments. A WSGI environment is a dictionary containing HTTP request variables as described in [PEP 333](#). All of the functions taking an *environ* parameter expect a WSGI-compliant dictionary to be supplied; please see [PEP 333](#) for a detailed specification.

`wsgiref.util.guess_scheme(environ)`

Return a guess for whether `wsgi.url_scheme` should be « `http` » or « `https` », by checking for a `HTTPS` environment variable in the *environ* dictionary. The return value is a string.

This function is useful when creating a gateway that wraps CGI or a CGI-like protocol such as FastCGI. Typically, servers providing such protocols will include a `HTTPS` variable with a value of « `1` » « `yes` », or « `on` » when a request is received via SSL. So, this function returns « `https` » if such a value is found, and « `http` » otherwise.

`wsgiref.util.request_uri(environ, include_query=1)`

Return the full request URI, optionally including the query string, using the algorithm found in the « `URL Reconstruction` » section of [PEP 333](#). If *include\_query* is false, the query string is not included in the resulting URI.

`wsgiref.util.application_uri(environ)`

Similar to `request_uri()`, except that the `PATH_INFO` and `QUERY_STRING` variables are ignored. The result is the base URI of the application object addressed by the request.

`wsgiref.util.shift_path_info(environ)`

Shift a single name from `PATH_INFO` to `SCRIPT_NAME` and return the name. The *environ* dictionary is *modified* in-place; use a copy if you need to keep the original `PATH_INFO` or `SCRIPT_NAME` intact.

If there are no remaining path segments in `PATH_INFO`, `None` is returned.

Typically, this routine is used to process each portion of a request URI path, for example to treat the path as a series of dictionary keys. This routine modifies the passed-in environment to make it suitable for invoking another WSGI application that is located at the target URI. For example, if there is a WSGI application at `/foo`, and the request URI path is `/foo/bar/baz`, and the WSGI application at `/foo` calls `shift_path_info()`, it will receive the string « `bar` », and the environment will be updated to be suitable for passing to a WSGI application at `/foo/bar`. That is, `SCRIPT_NAME` will change from `/foo` to `/foo/bar`, and `PATH_INFO` will change from `/bar/baz` to `/baz`.

When `PATH_INFO` is just a « `/` », this routine returns an empty string and appends a trailing slash to `SCRIPT_NAME`, even though empty path segments are normally ignored, and `SCRIPT_NAME` doesn't normally end in a slash. This is intentional behavior, to ensure that an application can tell the difference between URIs ending in `/x` from ones ending in `/x/` when using this routine to do object traversal.

`wsgiref.util.setup_testing_defaults(environ)`

Update *environ* with trivial defaults for testing purposes.

This routine adds various parameters required for WSGI, including `HTTP_HOST`, `SERVER_NAME`, `SERVER_PORT`, `REQUEST_METHOD`, `SCRIPT_NAME`, `PATH_INFO`, and all of the [PEP 333](#)-defined `wsgi.*` variables. It only supplies default values, and does not replace any existing settings for these variables.

This routine is intended to make it easier for unit tests of WSGI servers and applications to set up dummy environments. It should NOT be used by actual WSGI servers or applications, since the data is fake!

Example usage :

```
from wsgiref.util import setup_testing_defaults
from wsgiref.simple_server import make_server
```

(suite sur la page suivante)

(suite de la page précédente)

```

# A relatively simple WSGI application. It's going to print out the
# environment dictionary after being updated by setup_testing_defaults
def simple_app(environ, start_response):
    setup_testing_defaults(environ)

    status = '200 OK'
    headers = [('Content-type', 'text/plain')]

    start_response(status, headers)

    ret = ["%s: %s\n" % (key, value)
            for key, value in environ.iteritems()]
    return ret

httpd = make_server('', 8000, simple_app)
print "Serving on port 8000..."
httpd.serve_forever()

```

In addition to the environment functions above, the `wsgiref.util` module also provides these miscellaneous utilities :

`wsgiref.util.is_hop_by_hop(header_name)`

Return true if “header\_name” is an HTTP/1.1 « Hop-by-Hop » header, as defined by [RFC 2616](#).

`class wsgiref.util.FileWrapper(filelike, blksize=8192)`

A wrapper to convert a file-like object to an *iterator*. The resulting objects support both `__getitem__()` and `__iter__()` iteration styles, for compatibility with Python 2.1 and Jython. As the object is iterated over, the optional `blksize` parameter will be repeatedly passed to the *filelike* object’s `read()` method to obtain strings to yield. When `read()` returns an empty string, iteration is ended and is not resumable. If *filelike* has a `close()` method, the returned object will also have a `close()` method, and it will invoke the *filelike* object’s `close()` method when called.

Example usage :

```

from StringIO import StringIO
from wsgiref.util import FileWrapper

# We're using a StringIO-buffer for as the file-like object
filelike = StringIO("This is an example file-like object"*10)
wrapper = FileWrapper(filelike, blksize=5)

for chunk in wrapper:
    print chunk

```

## 20.4.2 wsgiref.headers – WSGI response header tools

This module provides a single class, `Headers`, for convenient manipulation of WSGI response headers using a mapping-like interface.

`class wsgiref.headers.Headers(headers)`

Create a mapping-like object wrapping *headers*, which must be a list of header name/value tuples as described in [PEP 333](#). Any changes made to the new `Headers` object will directly update the *headers* list it was created with.

*Headers* objects support typical mapping operations including `__getitem__()`, `get()`, `__setitem__()`, `setdefault()`, `__delitem__()`, `__contains__()` and `has_key()`. For each of these methods, the key is the header name (treated case-insensitively), and the value is the first value associated with that header name. Setting a header deletes any existing values for that header, then adds a new value at the end of the wrapped header list. Headers' existing order is generally maintained, with new headers added to the end of the wrapped list.

Unlike a dictionary, *Headers* objects do not raise an error when you try to get or delete a key that isn't in the wrapped header list. Getting a nonexistent header just returns `None`, and deleting a nonexistent header does nothing.

*Headers* objects also support `keys()`, `values()`, and `items()` methods. The lists returned by `keys()` and `items()` can include the same key more than once if there is a multi-valued header. The `len()` of a *Headers* object is the same as the length of its `items()`, which is the same as the length of the wrapped header list. In fact, the `items()` method just returns a copy of the wrapped header list.

Calling `str()` on a *Headers* object returns a formatted string suitable for transmission as HTTP response headers. Each header is placed on a line with its value, separated by a colon and a space. Each line is terminated by a carriage return and line feed, and the string is terminated with a blank line.

In addition to their mapping interface and formatting features, *Headers* objects also have the following methods for querying and adding multi-valued headers, and for adding headers with MIME parameters :

**get\_all(name)**

Return a list of all the values for the named header.

The returned list will be sorted in the order they appeared in the original header list or were added to this instance, and may contain duplicates. Any fields deleted and re-inserted are always appended to the header list. If no fields exist with the given name, returns an empty list.

**add\_header(name, value, \*\*\_params)**

Add a (possibly multi-valued) header, with optional MIME parameters specified via keyword arguments.

*name* is the header field to add. Keyword arguments can be used to set MIME parameters for the header field. Each parameter must be a string or `None`. Underscores in parameter names are converted to dashes, since dashes are illegal in Python identifiers, but many MIME parameter names include dashes. If the parameter value is a string, it is added to the header value parameters in the form `name="value"`. If it is `None`, only the parameter name is added. (This is used for MIME parameters without a value.) Example usage :

```
h.add_header('content-disposition', 'attachment', filename='bud.gif')
```

The above will add a header that looks like this :

```
Content-Disposition: attachment; filename="bud.gif"
```

### 20.4.3 wsgiref.simple\_server – a simple WSGI HTTP server

This module implements a simple HTTP server (based on *BaseHTTPServer*) that serves WSGI applications. Each server instance serves a single WSGI application on a given host and port. If you want to serve multiple applications on a single host and port, you should create a WSGI application that parses `PATH_INFO` to select which application to invoke for each request. (E.g., using the `shift_path_info()` function from *wsgiref.util*.)

`wsgiref.simple_server.make_server(host, port, app, server_class=WSGIServer, handler_class=WSGIRequestHandler)`

Create a new WSGI server listening on *host* and *port*, accepting connections for *app*. The return value is an instance of the supplied *server\_class*, and will process requests using the specified *handler\_class*. *app* must be a WSGI application object, as defined by [PEP 333](#).

Example usage :

```
from wsgiref.simple_server import make_server, demo_app

httpd = make_server('', 8000, demo_app)
print "Serving HTTP on port 8000..."

# Respond to requests until process is killed
httpd.serve_forever()

# Alternative: serve one request, then exit
httpd.handle_request()
```

`wsgiref.simple_server.demo_app(environ, start_response)`

This function is a small but complete WSGI application that returns a text page containing the message « Hello world! » and a list of the key/value pairs provided in the *environ* parameter. It's useful for verifying that a WSGI server (such as *wsgiref.simple\_server*) is able to run a simple WSGI application correctly.

`class wsgiref.simple_server.WSGIServer(server_address, RequestHandlerClass)`

Create a *WSGIServer* instance. *server\_address* should be a (host,port) tuple, and *RequestHandlerClass* should be the subclass of *BaseHTTPServer.BaseHTTPRequestHandler* that will be used to process requests.

You do not normally need to call this constructor, as the *make\_server()* function can handle all the details for you.

*WSGIServer* is a subclass of *BaseHTTPServer.HTTPServer*, so all of its methods (such as *serve\_forever()* and *handle\_request()*) are available. *WSGIServer* also provides these WSGI-specific methods :

`set_app(application)`

Sets the callable *application* as the WSGI application that will receive requests.

`get_app()`

Returns the currently-set application callable.

Normally, however, you do not need to use these additional methods, as *set\_app()* is normally called by *make\_server()*, and the *get\_app()* exists mainly for the benefit of request handler instances.

`class wsgiref.simple_server.WSGIRequestHandler(request, client_address, server)`

Create an HTTP handler for the given *request* (i.e. a socket), *client\_address* (a (host,port) tuple), and *server* (*WSGIServer* instance).

You do not need to create instances of this class directly; they are automatically created as needed by *WSGIServer* objects. You can, however, subclass this class and supply it as a *handler\_class* to the *make\_server()* function. Some possibly relevant methods for overriding in subclasses :

`get_environ()`

Returns a dictionary containing the WSGI environment for a request. The default implementation copies the contents of the *WSGIServer* object's *base\_environ* dictionary attribute and then adds various headers derived from the HTTP request. Each call to this method should return a new dictionary containing all of the relevant CGI environment variables as specified in **PEP 333**.

`get_stderr()`

Return the object that should be used as the *wsgi.errors* stream. The default implementation just returns *sys.stderr*.

`handle()`

Process the HTTP request. The default implementation creates a handler instance using a *wsgiref.handlers* class to implement the actual WSGI application interface.

#### 20.4.4 `wsgiref.validate` — WSGI conformance checker

When creating new WSGI application objects, frameworks, servers, or middleware, it can be useful to validate the new code's conformance using `wsgiref.validate`. This module provides a function that creates WSGI application objects that validate communications between a WSGI server or gateway and a WSGI application object, to check both sides for protocol conformance.

Note that this utility does not guarantee complete **PEP 333** compliance; an absence of errors from this module does not necessarily mean that errors do not exist. However, if this module does produce an error, then it is virtually certain that either the server or application is not 100% compliant.

This module is based on the `paste.lint` module from Ian Bicking's « Python Paste » library.

`wsgiref.validate.validator(application)`

Wrap *application* and return a new WSGI application object. The returned application will forward all requests to the original *application*, and will check that both the *application* and the server invoking it are conforming to the WSGI specification and to RFC 2616.

Any detected nonconformance results in an `AssertionError` being raised; note, however, that how these errors are handled is server-dependent. For example, `wsgiref.simple_server` and other servers based on `wsgiref.handlers` (that don't override the error handling methods to do something else) will simply output a message that an error has occurred, and dump the traceback to `sys.stderr` or some other error stream.

This wrapper may also generate output using the `warnings` module to indicate behaviors that are questionable but which may not actually be prohibited by **PEP 333**. Unless they are suppressed using Python command-line options or the `warnings` API, any such warnings will be written to `sys.stderr` (not `wsgi.errors`, unless they happen to be the same object).

Example usage :

```
from wsgiref.validate import validator
from wsgiref.simple_server import make_server

# Our callable object which is intentionally not compliant to the
# standard, so the validator is going to break
def simple_app(environ, start_response):
    status = '200 OK' # HTTP Status
    headers = [('Content-type', 'text/plain')] # HTTP Headers
    start_response(status, headers)

    # This is going to break because we need to return a list, and
    # the validator is going to inform us
    return "Hello World"

# This is the application wrapped in a validator
validator_app = validator(simple_app)

httpd = make_server('', 8000, validator_app)
print "Listening on port 8000..."
httpd.serve_forever()
```

#### 20.4.5 `wsgiref.handlers` – server/gateway base classes

This module provides base handler classes for implementing WSGI servers and gateways. These base classes handle most of the work of communicating with a WSGI application, as long as they are given a CGI-like environment, along with input, output, and error streams.

`class wsgiref.handlers.CGIHandler`

CGI-based invocation via `sys.stdin`, `sys.stdout`, `sys.stderr` and `os.environ`. This is useful when you have a WSGI application and want to run it as a CGI script. Simply invoke `CGIHandler().run(app)`, where `app` is the WSGI application object you wish to invoke.

This class is a subclass of `BaseCGIHandler` that sets `wsgi.run_once` to true, `wsgi.multithread` to false, and `wsgi.multiprocess` to true, and always uses `sys` and `os` to obtain the necessary CGI streams and environment.

```
class wsgiref.handlers.BaseCGIHandler(stdin, stdout, stderr, environ, multithread=True, multiprocess=False)
```

Similar to `CGIHandler`, but instead of using the `sys` and `os` modules, the CGI environment and I/O streams are specified explicitly. The `multithread` and `multiprocess` values are used to set the `wsgi.multithread` and `wsgi.multiprocess` flags for any applications run by the handler instance.

This class is a subclass of `SimpleHandler` intended for use with software other than HTTP « origin servers ». If you are writing a gateway protocol implementation (such as CGI, FastCGI, SCGI, etc.) that uses a `Status`: header to send an HTTP status, you probably want to subclass this instead of `SimpleHandler`.

```
class wsgiref.handlers.SimpleHandler(stdin, stdout, stderr, environ, multithread=True, multiprocess=False)
```

Similar to `BaseCGIHandler`, but designed for use with HTTP origin servers. If you are writing an HTTP server implementation, you will probably want to subclass this instead of `BaseCGIHandler`.

This class is a subclass of `BaseHandler`. It overrides the `__init__()`, `get_stdin()`, `get_stderr()`, `add_cgi_vars()`, `_write()`, and `_flush()` methods to support explicitly setting the environment and streams via the constructor. The supplied environment and streams are stored in the `stdin`, `stdout`, `stderr`, and `environ` attributes.

```
class wsgiref.handlers.BaseHandler
```

This is an abstract base class for running WSGI applications. Each instance will handle a single HTTP request, although in principle you could create a subclass that was reusable for multiple requests.

`BaseHandler` instances have only one method intended for external use :

```
run(app)
```

Run the specified WSGI application, `app`.

All of the other `BaseHandler` methods are invoked by this method in the process of running the application, and thus exist primarily to allow customizing the process.

The following methods MUST be overridden in a subclass :

```
_write(data)
```

Buffer the string `data` for transmission to the client. It's okay if this method actually transmits the data; `BaseHandler` just separates write and flush operations for greater efficiency when the underlying system actually has such a distinction.

```
_flush()
```

Force buffered data to be transmitted to the client. It's okay if this method is a no-op (i.e., if `_write()` actually sends the data).

```
get_stdin()
```

Return an input stream object suitable for use as the `wsgi.input` of the request currently being processed.

```
get_stderr()
```

Return an output stream object suitable for use as the `wsgi.errors` of the request currently being processed.

```
add_cgi_vars()
```

Insert CGI variables for the current request into the `environ` attribute.

Here are some other methods and attributes you may wish to override. This list is only a summary, however, and does not include every method that can be overridden. You should consult the docstrings and source code for additional information before attempting to create a customized `BaseHandler` subclass.

Attributes and methods for customizing the WSGI environment :

**wsgi\_multithread**

The value to be used for the `wsgi.multithread` environment variable. It defaults to true in *BaseHandler*, but may have a different default (or be set by the constructor) in the other subclasses.

**wsgi\_multiprocess**

The value to be used for the `wsgi.multiprocess` environment variable. It defaults to true in *BaseHandler*, but may have a different default (or be set by the constructor) in the other subclasses.

**wsgi\_run\_once**

The value to be used for the `wsgi.run_once` environment variable. It defaults to false in *BaseHandler*, but *CGIHandler* sets it to true by default.

**os\_environ**

The default environment variables to be included in every request's WSGI environment. By default, this is a copy of `os.environ` at the time that *wsgiref.handlers* was imported, but subclasses can either create their own at the class or instance level. Note that the dictionary should be considered read-only, since the default value is shared between multiple classes and instances.

**server\_software**

If the *origin\_server* attribute is set, this attribute's value is used to set the default `SERVER_SOFTWARE` WSGI environment variable, and also to set a default `Server:` header in HTTP responses. It is ignored for handlers (such as *BaseCGIHandler* and *CGIHandler*) that are not HTTP origin servers.

**get\_scheme()**

Return the URL scheme being used for the current request. The default implementation uses the `guess_scheme()` function from *wsgiref.util* to guess whether the scheme should be « http » or « https », based on the current request's `environ` variables.

**setup\_environ()**

Set the `environ` attribute to a fully-populated WSGI environment. The default implementation uses all of the above methods and attributes, plus the `get_stdin()`, `get_stderr()`, and `add_cgi_vars()` methods and the *wsgi\_file\_wrapper* attribute. It also inserts a `SERVER_SOFTWARE` key if not present, as long as the *origin\_server* attribute is a true value and the *server\_software* attribute is set.

Methods and attributes for customizing exception handling :

**log\_exception(exc\_info)**

Log the *exc\_info* tuple in the server log. *exc\_info* is a (type, value, traceback) tuple. The default implementation simply writes the traceback to the request's `wsgi.errors` stream and flushes it. Subclasses can override this method to change the format or retarget the output, mail the traceback to an administrator, or whatever other action may be deemed suitable.

**traceback\_limit**

The maximum number of frames to include in tracebacks output by the default *log\_exception()* method. If `None`, all frames are included.

**error\_output(environ, start\_response)**

This method is a WSGI application to generate an error page for the user. It is only invoked if an error occurs before headers are sent to the client.

This method can access the current error information using `sys.exc_info()`, and should pass that information to *start\_response* when calling it (as described in the « Error Handling » section of [PEP 333](#)).

The default implementation just uses the *error\_status*, *error\_headers*, and *error\_body* attributes to generate an output page. Subclasses can override this to produce more dynamic error output.

Note, however, that it's not recommended from a security perspective to spit out diagnostics to any old user ; ideally, you should have to do something special to enable diagnostic output, which is why the default implementation doesn't include any.

**error\_status**

The HTTP status used for error responses. This should be a status string as defined in [PEP 333](#); it defaults to a 500 code and message.

**error\_headers**

The HTTP headers used for error responses. This should be a list of WSGI response headers ((name, value) tuples), as described in [PEP 333](#). The default list just sets the content type to text/plain.

**error\_body**

The error response body. This should be an HTTP response body string. It defaults to the plain text, « A server error occurred. Please contact the administrator. »

Methods and attributes for [PEP 333](#)'s « Optional Platform-Specific File Handling » feature :

**wsgi\_file\_wrapper**

A `wsgi.file_wrapper` factory, or None. The default value of this attribute is the `FileWrapper` class from `wsgiref.util`.

**sendfile()**

Override to implement platform-specific file transmission. This method is called only if the application's return value is an instance of the class specified by the `wsgi_file_wrapper` attribute. It should return a true value if it was able to successfully transmit the file, so that the default transmission code will not be executed. The default implementation of this method just returns a false value.

Miscellaneous methods and attributes :

**origin\_server**

This attribute should be set to a true value if the handler's `_write()` and `_flush()` are being used to communicate directly to the client, rather than via a CGI-like gateway protocol that wants the HTTP status in a special `Status:` header.

This attribute's default value is true in `BaseHandler`, but false in `BaseCGIHandler` and `CGIHandler`.

**http\_version**

If `origin_server` is true, this string attribute is used to set the HTTP version of the response set to the client. It defaults to "1.0".

## 20.4.6 Examples

This is a working « Hello World » WSGI application :

```
from wsgiref.simple_server import make_server

# Every WSGI application must have an application object - a callable
# object that accepts two arguments. For that purpose, we're going to
# use a function (note that you're not limited to a function, you can
# use a class for example). The first argument passed to the function
# is a dictionary containing CGI-style environment variables and the
# second variable is the callable object (see PEP 333).
def hello_world_app(environ, start_response):
    status = '200 OK' # HTTP Status
    headers = [('Content-type', 'text/plain')] # HTTP Headers
    start_response(status, headers)

    # The returned object is going to be printed
    return ["Hello World"]

httpd = make_server('', 8000, hello_world_app)
```

(suite sur la page suivante)

(suite de la page précédente)

```
print "Serving on port 8000..."

# Serve until process is killed
httpd.serve_forever()
```

## 20.5 urllib — Open arbitrary resources by URL

**Note :** The `urllib` module has been split into parts and renamed in Python 3 to `urllib.request`, `urllib.parse`, and `urllib.error`. The *2to3* tool will automatically adapt imports when converting your sources to Python 3. Also note that the `urllib.request.urlopen()` function in Python 3 is equivalent to `urllib2.urlopen()` and that `urllib.urlopen()` has been removed.

This module provides a high-level interface for fetching data across the World Wide Web. In particular, the `urlopen()` function is similar to the built-in function `open()`, but accepts Universal Resource Locators (URLs) instead of filenames. Some restrictions apply — it can only open URLs for reading, and no seek operations are available.

### Voir aussi :

The `Requests` package is recommended for a higher-level HTTP client interface.

Modifié dans la version 2.7.9 : For HTTPS URIs, `urllib` performs all the necessary certificate and hostname checks by default.

**Avertissement :** For Python versions earlier than 2.7.9, `urllib` does not attempt to validate the server certificates of HTTPS URIs. Use at your own risk!

### 20.5.1 High-level interface

`urllib.urlopen(uri[, data[, proxies[, context]]])`

Open a network object denoted by a URL for reading. If the URL does not have a scheme identifier, or if it has `file:` as its scheme identifier, this opens a local file (without *universal newlines*) ; otherwise it opens a socket to a server somewhere on the network. If the connection cannot be made the `IOError` exception is raised. If all went well, a file-like object is returned. This supports the following methods : `read()`, `readline()`, `readlines()`, `fileno()`, `close()`, `info()`, `getcode()` and `geturl()`. It also has proper support for the *iterator* protocol. One caveat : the `read()` method, if the size argument is omitted or negative, may not read until the end of the data stream ; there is no good way to determine that the entire stream from a socket has been read in the general case.

Except for the `info()`, `getcode()` and `geturl()` methods, these methods have the same interface as for file objects — see section *Objets fichiers* in this manual. (It is not a built-in file object, however, so it can't be used at those few places where a true built-in file object is required.)

The `info()` method returns an instance of the class `mimetypes.Message` containing meta-information associated with the URL. When the method is HTTP, these headers are those returned by the server at the head of the retrieved HTML page (including Content-Length and Content-Type). When the method is FTP, a Content-Length header will be present if (as is now usual) the server passed back a file length in response to the FTP retrieval request. A Content-Type header will be present if the MIME type can be guessed. When the method is local-file, returned headers will include a Date representing the file's last-modified time, a Content-Length giving file size, and a Content-Type containing a guess at the file's type. See also the description of the `mimetypes` module.

The `geturl()` method returns the real URL of the page. In some cases, the HTTP server redirects a client to another URL. The `urlopen()` function handles this transparently, but in some cases the caller needs to know which URL the client was redirected to. The `geturl()` method can be used to get at this redirected URL.

The `getcode()` method returns the HTTP status code that was sent with the response, or `None` if the URL is no HTTP URL.

If the *url* uses the `http:` scheme identifier, the optional *data* argument may be given to specify a POST request (normally the request type is GET). The *data* argument must be in standard *application/x-www-form-urlencoded* format; see the `urlencode()` function below.

The `urlopen()` function works transparently with proxies which do not require authentication. In a Unix or Windows environment, set the `http_proxy`, or `ftp_proxy` environment variables to a URL that identifies the proxy server before starting the Python interpreter. For example (the `'%'` is the command prompt) :

```
% http_proxy="http://www.someproxy.com:3128"
% export http_proxy
% python
...
```

The `no_proxy` environment variable can be used to specify hosts which shouldn't be reached via proxy; if set, it should be a comma-separated list of hostname suffixes, optionally with `:port` appended, for example `cern.ch,ncsa.uiuc.edu,some.host:8080`.

In a Windows environment, if no proxy environment variables are set, proxy settings are obtained from the registry's Internet Settings section.

In a Mac OS X environment, `urlopen()` will retrieve proxy information from the OS X System Configuration Framework, which can be managed with Network System Preferences panel.

Alternatively, the optional *proxies* argument may be used to explicitly specify proxies. It must be a dictionary mapping scheme names to proxy URLs, where an empty dictionary causes no proxies to be used, and `None` (the default value) causes environmental proxy settings to be used as discussed above. For example :

```
# Use http://www.someproxy.com:3128 for HTTP proxying
proxies = {'http': 'http://www.someproxy.com:3128'}
filehandle = urllib.urlopen(some_url, proxies=proxies)
# Don't use any proxies
filehandle = urllib.urlopen(some_url, proxies={})
# Use proxies from environment - both versions are equivalent
filehandle = urllib.urlopen(some_url, proxies=None)
filehandle = urllib.urlopen(some_url)
```

Proxies which require authentication for use are not currently supported; this is considered an implementation limitation.

The *context* parameter may be set to a `ssl.SSLContext` instance to configure the SSL settings that are used if `urlopen()` makes a HTTPS connection.

Modifié dans la version 2.3 : Added the *proxies* support.

Modifié dans la version 2.6 : Added `getcode()` to returned object and support for the `no_proxy` environment variable.

Modifié dans la version 2.7.9 : The *context* parameter was added. All the necessary certificate and hostname checks are done by default.

Obsolète depuis la version 2.6 : The `urlopen()` function has been removed in Python 3 in favor of `urllib2.urlopen()`.

`urllib.urlretrieve(url[, filename[, reporthook[, data[, context]]]])`

Copy a network object denoted by a URL to a local file, if necessary. If the URL points to a local file, or

a valid cached copy of the object exists, the object is not copied. Return a tuple (`filename`, `headers`) where *filename* is the local file name under which the object can be found, and *headers* is whatever the `info()` method of the object returned by `urlopen()` returned (for a remote object, possibly cached). Exceptions are the same as for `urlopen()`.

The second argument, if present, specifies the file location to copy to (if absent, the location will be a tempfile with a generated name). The third argument, if present, is a callable that will be called once on establishment of the network connection and once after each block read thereafter. The callable will be passed three arguments; a count of blocks transferred so far, a block size in bytes, and the total size of the file. The third argument may be `-1` on older FTP servers which do not return a file size in response to a retrieval request.

If the *url* uses the `http:` scheme identifier, the optional *data* argument may be given to specify a POST request (normally the request type is GET). The *data* argument must in standard *application/x-www-form-urlencoded* format; see the `urlencode()` function below.

The *context* parameter may be set to a `ssl.SSLContext` instance to configure the SSL settings that are used if `urlretrieve()` makes a HTTPS connection.

Modifié dans la version 2.5 : `urlretrieve()` will raise `ContentTooShortError` when it detects that the amount of data available was less than the expected amount (which is the size reported by a *Content-Length* header). This can occur, for example, when the download is interrupted.

The *Content-Length* is treated as a lower bound : if there's more data to read, `urlretrieve()` reads more data, but if less data is available, it raises the exception.

You can still retrieve the downloaded data in this case, it is stored in the `content` attribute of the exception instance.

If no *Content-Length* header was supplied, `urlretrieve()` can not check the size of the data it has downloaded, and just returns it. In this case you just have to assume that the download was successful.

Modifié dans la version 2.7.9 : The *context* parameter was added. All the necessary certificate and hostname checks are done by default.

#### `urllib._urlopener`

The public functions `urlopen()` and `urlretrieve()` create an instance of the *FancyURLopener* class and use it to perform their requested actions. To override this functionality, programmers can create a subclass of *URLopener* or *FancyURLopener*, then assign an instance of that class to the `urllib._urlopener` variable before calling the desired function. For example, applications may want to specify a different *User-Agent* header than *URLopener* defines. This can be accomplished with the following code :

```
import urllib

class AppURLopener(urllib.FancyURLopener):
    version = "App/1.7"

urllib._urlopener = AppURLopener()
```

#### `urllib.urlcleanup()`

Clear the cache that may have been built up by previous calls to `urlretrieve()`.

### 20.5.2 Utility functions

#### `urllib.quote(string[, safe])`

Replace special characters in *string* using the `%xx` escape. Letters, digits, and the characters `'_.'` are never quoted. By default, this function is intended for quoting the path section of the URL. The optional *safe* parameter specifies additional characters that should not be quoted — its default value is `('/')`.

Example : `quote('/~connolly/')` yields `/%7econnolly/`.

`urllib.quote_plus(string[, safe])`

Like `quote()`, but also replaces spaces by plus signs, as required for quoting HTML form values when building up a query string to go into a URL. Plus signs in the original string are escaped unless they are included in *safe*. It also does not have *safe* default to `'/'`.

`urllib.unquote(string)`

Replace `%xx` escapes by their single-character equivalent.

Example : `unquote('%7Econnolly/')` yields `'/~connolly/'`.

`urllib.unquote_plus(string)`

Like `unquote()`, but also replaces plus signs by spaces, as required for unquoting HTML form values.

`urllib.urlencode(query[, doseq])`

Convert a mapping object or a sequence of two-element tuples to a « percent-encoded » string, suitable to pass to `urlopen()` above as the optional *data* argument. This is useful to pass a dictionary of form fields to a POST request. The resulting string is a series of `key=value` pairs separated by `'&'` characters, where both *key* and *value* are quoted using `quote_plus()` above. When a sequence of two-element tuples is used as the *query* argument, the first element of each tuple is a key and the second is a value. The value element in itself can be a sequence and in that case, if the optional parameter *doseq* is evaluates to `True`, individual `key=value` pairs separated by `'&'` are generated for each element of the value sequence for the key. The order of parameters in the encoded string will match the order of parameter tuples in the sequence. The `urlparse` module provides the functions `parse_qs()` and `parse_qsl()` which are used to parse query strings into Python data structures.

`urllib.pathname2url(path)`

Convert the pathname *path* from the local syntax for a path to the form used in the path component of a URL. This does not produce a complete URL. The return value will already be quoted using the `quote()` function.

`urllib.url2pathname(path)`

Convert the path component *path* from a percent-encoded URL to the local syntax for a path. This does not accept a complete URL. This function uses `unquote()` to decode *path*.

`urllib.getproxies()`

This helper function returns a dictionary of scheme to proxy server URL mappings. It scans the environment for variables named `<scheme>_proxy`, in case insensitive way, for all operating systems first, and when it cannot find it, looks for proxy information from Mac OSX System Configuration for Mac OS X and Windows Systems Registry for Windows. If both lowercase and uppercase environment variables exist (and disagree), lowercase is preferred.

---

**Note :** If the environment variable `REQUEST_METHOD` is set, which usually indicates your script is running in a CGI environment, the environment variable `HTTP_PROXY` (uppercase `_PROXY`) will be ignored. This is because that variable can be injected by a client using the « Proxy : » HTTP header. If you need to use an HTTP proxy in a CGI environment, either use `ProxyHandler` explicitly, or make sure the variable name is in lowercase (or at least the `_proxy` suffix).

---

---

**Note :** `urllib` also exposes certain utility functions like `splitttype`, `splithost` and others parsing URL into various components. But it is recommended to use `urlparse` for parsing URLs rather than using these functions directly. Python 3 does not expose these helper functions from `urllib.parse` module.

---

### 20.5.3 URL Opener objects

`class urllib.URLopener([proxies[, context[, **x509]])]`

Base class for opening and reading URLs. Unless you need to support opening objects using schemes

other than `http:`, `ftp:`, or `file:`, you probably want to use *FancyURLopener*.

By default, the *URLopener* class sends a *User-Agent* header of `urllib/VVV`, where *VVV* is the *urllib* version number. Applications can define their own *User-Agent* header by subclassing *URLopener* or *FancyURLopener* and setting the class attribute *version* to an appropriate string value in the subclass definition.

The optional *proxies* parameter should be a dictionary mapping scheme names to proxy URLs, where an empty dictionary turns proxies off completely. Its default value is `None`, in which case environmental proxy settings will be used if present, as discussed in the definition of *urlopen()*, above.

The *context* parameter may be a *ssl.SSLContext* instance. If given, it defines the SSL settings the opener uses to make HTTPS connections.

Additional keyword parameters, collected in *x509*, may be used for authentication of the client when using the `https:` scheme. The keywords *key\_file* and *cert\_file* are supported to provide an SSL key and certificate; both are needed to support client authentication.

*URLopener* objects will raise an *IOError* exception if the server returns an error code.

Modifié dans la version 2.7.9 : The *context* parameter was added. All the necessary certificate and hostname checks are done by default.

**open**(*fullurl*[, *data*])

Open *fullurl* using the appropriate protocol. This method sets up cache and proxy information, then calls the appropriate open method with its input arguments. If the scheme is not recognized, *open\_unknown()* is called. The *data* argument has the same meaning as the *data* argument of *urlopen()*.

**open\_unknown**(*fullurl*[, *data*])

Overridable interface to open unknown URL types.

**retrieve**(*url*[, *filename*[, *repthook*[, *data*]]])

Retrieves the contents of *url* and places it in *filename*. The return value is a tuple consisting of a local filename and either a *mimertools.Message* object containing the response headers (for remote URLs) or `None` (for local URLs). The caller must then open and read the contents of *filename*. If *filename* is not given and the URL refers to a local file, the input filename is returned. If the URL is non-local and *filename* is not given, the filename is the output of *tempfile.mktemp()* with a suffix that matches the suffix of the last path component of the input URL. If *repthook* is given, it must be a function accepting three numeric parameters. It will be called after each chunk of data is read from the network. *repthook* is ignored for local URLs.

If the *url* uses the `http:` scheme identifier, the optional *data* argument may be given to specify a POST request (normally the request type is GET). The *data* argument must in standard *application/x-www-form-urlencoded* format; see the *urlencode()* function below.

**version**

Variable that specifies the user agent of the opener object. To get *urllib* to tell servers that it is a particular user agent, set this in a subclass as a class variable or in the constructor before calling the base constructor.

**class** `urllib.FancyURLopener(...)`

*FancyURLopener* subclasses *URLopener* providing default handling for the following HTTP response codes : 301, 302, 303, 307 and 401. For the 30x response codes listed above, the *Location* header is used to fetch the actual URL. For 401 response codes (authentication required), basic HTTP authentication is performed. For the 30x response codes, recursion is bounded by the value of the *maxtries* attribute, which defaults to 10.

For all other response codes, the method *http\_error\_default()* is called which you can override in subclasses to handle the error appropriately.

---

**Note :** According to the letter of **RFC 2616**, 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and *urllib* reproduces this behaviour.

---

The parameters to the constructor are the same as those for *URLopener*.

**Note :** When performing basic authentication, a *FancyURLopener* instance calls its *prompt\_user\_passwd()* method. The default implementation asks the users for the required information on the controlling terminal. A subclass may override this method to support more appropriate behavior if needed.

The *FancyURLopener* class offers one additional method that should be overloaded to provide the appropriate behavior :

**prompt\_user\_passwd**(*host, realm*)

Return information needed to authenticate the user at the given host in the specified security realm. The return value should be a tuple, (**user**, **password**), which can be used for basic authentication.

The implementation prompts for this information on the terminal ; an application should override this method to use an appropriate interaction model in the local environment.

**exception urllib.ContentTooShortError**(*msg*[, *content*])

This exception is raised when the *urlretrieve()* function detects that the amount of the downloaded data is less than the expected amount (given by the *Content-Length* header). The **content** attribute stores the downloaded (and supposedly truncated) data.

Nouveau dans la version 2.5.

## 20.5.4 urllib Restrictions

- Currently, only the following protocols are supported : HTTP, (versions 0.9 and 1.0), FTP, and local files.
- The caching feature of *urlretrieve()* has been disabled until I find the time to hack proper processing of Expiration time headers.
- There should be a function to query whether a particular URL is in the cache.
- For backward compatibility, if a URL appears to point to a local file but the file can't be opened, the URL is re-interpreted using the FTP protocol. This can sometimes cause confusing error messages.
- The *urlopen()* and *urlretrieve()* functions can cause arbitrarily long delays while waiting for a network connection to be set up. This means that it is difficult to build an interactive Web client using these functions without using threads.
- The data returned by *urlopen()* or *urlretrieve()* is the raw data returned by the server. This may be binary data (such as an image), plain text or (for example) HTML. The HTTP protocol provides type information in the reply header, which can be inspected by looking at the *Content-Type* header. If the returned data is HTML, you can use the module *htmllib* to parse it.
- The code handling the FTP protocol cannot differentiate between a file and a directory. This can lead to unexpected behavior when attempting to read a URL that points to a file that is not accessible. If the URL ends in a /, it is assumed to refer to a directory and will be handled accordingly. But if an attempt to read a file leads to a 550 error (meaning the URL cannot be found or is not accessible, often for permission reasons), then the path is treated as a directory in order to handle the case when a directory is specified by a URL but the trailing / has been left off. This can cause misleading results when you try to fetch a file whose read permissions make it inaccessible ; the FTP code will try to read it, fail with a 550 error, and then perform a directory listing for the unreadable file. If fine-grained control is needed, consider using the *ftplib* module, subclassing *FancyURLopener*, or changing *\_urlopener* to meet your needs.
- This module does not support the use of proxies which require authentication. This may be implemented in the future.
- Although the *urllib* module contains (undocumented) routines to parse and unparse URL strings, the recommended interface for URL manipulation is in module *urlparse*.

### 20.5.5 Examples

Here is an example session that uses the GET method to retrieve a URL containing parameters :

```
>>> import urllib
>>> params = urllib.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0})
>>> f = urllib.urlopen("http://www.musi-cal.com/cgi-bin/query?" + params)
>>> print f.read()
```

The following example uses the POST method instead :

```
>>> import urllib
>>> params = urllib.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0})
>>> f = urllib.urlopen("http://www.musi-cal.com/cgi-bin/query", params)
>>> print f.read()
```

The following example uses an explicitly specified HTTP proxy, overriding environment settings :

```
>>> import urllib
>>> proxies = {'http': 'http://proxy.example.com:8080/'}
>>> opener = urllib.FancyURLopener(proxies)
>>> f = opener.open("http://www.python.org")
>>> f.read()
```

The following example uses no proxies at all, overriding environment settings :

```
>>> import urllib
>>> opener = urllib.FancyURLopener({})
>>> f = opener.open("http://www.python.org/")
>>> f.read()
```

## 20.6 urllib2 — extensible library for opening URLs

---

**Note :** The `urllib2` module has been split across several modules in Python 3 named `urllib.request` and `urllib.error`. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

The `urllib2` module defines functions and classes which help in opening URLs (mostly HTTP) in a complex world — basic and digest authentication, redirections, cookies and more.

**Voir aussi :**

The `Requests` package is recommended for a higher-level HTTP client interface.

The `urllib2` module defines the following functions :

`urllib2.urlopen(url[, data[, timeout[, cafile[, capath[, cadefault[, context]]]])`

Open the URL *url*, which can be either a string or a `Request` object.

*data* may be a string specifying additional data to send to the server, or `None` if no such data is needed. Currently HTTP requests are the only ones that use *data*; the HTTP request will be a POST instead of a GET when the *data* parameter is provided. *data* should be a buffer in the standard *application/x-www-form-urlencoded* format. The `urllib.urlencode()` function takes a mapping or sequence of 2-tuples and returns a string in this format. `urllib2` module sends HTTP/1.1 requests with `Connection:close` header included.

The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). This actually only works for HTTP, HTTPS and FTP connections.

If *context* is specified, it must be a `ssl.SSLContext` instance describing the various SSL options. See `HTTPConnection` for more details.

The optional *cafile* and *capath* parameters specify a set of trusted CA certificates for HTTPS requests. *cafile* should point to a single file containing a bundle of CA certificates, whereas *capath* should point to a directory of hashed certificate files. More information can be found in `ssl.SSLContext.load_verify_locations()`.

The *cadefault* parameter is ignored.

This function returns a file-like object with three additional methods :

- `geturl()` — return the URL of the resource retrieved, commonly used to determine if a redirect was followed
- `info()` — return the meta-information of the page, such as headers, in the form of an `mimetypes.Message` instance (see Quick Reference to HTTP Headers)
- `getcode()` — return the HTTP status code of the response.

Raises `URLError` on errors.

Note that `None` may be returned if no handler handles the request (though the default installed global `OpenerDirector` uses `UnknownHandler` to ensure this never happens).

In addition, if proxy settings are detected (for example, when a `*_proxy` environment variable like `http_proxy` is set), `ProxyHandler` is default installed and makes sure the requests are handled through the proxy.

Modifié dans la version 2.6 : Ajout de *timeout*.

Modifié dans la version 2.7.9 : *cafile*, *capath*, *cadefault*, and *context* were added.

#### `urllib2.install_opener(opener)`

Install an `OpenerDirector` instance as the default global opener. Installing an opener is only necessary if you want `urlopen` to use that opener; otherwise, simply call `OpenerDirector.open()` instead of `urlopen()`. The code does not check for a real `OpenerDirector`, and any class with the appropriate interface will work.

#### `urllib2.build_opener([handler, ...])`

Return an `OpenerDirector` instance, which chains the handlers in the order given. *handlers* can be either instances of `BaseHandler`, or subclasses of `BaseHandler` (in which case it must be possible to call the constructor without any parameters). Instances of the following classes will be in front of the *handlers*, unless the *handlers* contain them, instances of them or subclasses of them : `ProxyHandler` (if proxy settings are detected), `UnknownHandler`, `HTTPHandler`, `HTTPDefaultErrorHandler`, `HTTPRedirectHandler`, `FTPHandler`, `FileHandler`, `HTTPErrorProcessor`.

If the Python installation has SSL support (i.e., if the `ssl` module can be imported), `HTTPSHandler` will also be added.

Beginning in Python 2.3, a `BaseHandler` subclass may also change its `handler_order` attribute to modify its position in the handlers list.

The following exceptions are raised as appropriate :

#### **exception** `urllib2.URLError`

The handlers raise this exception (or derived exceptions) when they run into a problem. It is a subclass of `IOError`.

##### **reason**

The reason for this error. It can be a message string or another exception instance (`socket.error` for remote URLs, `OSError` for local URLs).

#### **exception** `urllib2.HTTPError`

Though being an exception (a subclass of `URLError`), an `HTTPError` can also function as a non-exceptional file-like return value (the same thing that `urlopen()` returns). This is useful when handling exotic HTTP errors, such as requests for authentication.

**code**

An HTTP status code as defined in [RFC 2616](#). This numeric value corresponds to a value found in the dictionary of codes as found in `BaseHTTPServer.BaseHTTPRequestHandler.responses`.

**reason**

La raison de cette erreur. Il peut s'agir d'un message textuel ou d'une autre instance d'exception.

The following classes are provided :

```
class urllib2.Request(url[, data][, headers][, origin_req_host][, unverifiable])
```

This class is an abstraction of a URL request.

*url* should be a string containing a valid URL.

*data* may be a string specifying additional data to send to the server, or `None` if no such data is needed. Currently HTTP requests are the only ones that use *data*; the HTTP request will be a POST instead of a GET when the *data* parameter is provided. *data* should be a buffer in the standard *application/x-www-form-urlencoded* format. The `urllib.urlencode()` function takes a mapping or sequence of 2-tuples and returns a string in this format.

*headers* should be a dictionary, and will be treated as if `add_header()` was called with each key and value as arguments. This is often used to « spoof » the *User-Agent* header value, which is used by a browser to identify itself – some HTTP servers only allow requests coming from common browsers as opposed to scripts. For example, Mozilla Firefox may identify itself as "Mozilla/5.0 (X11; U; Linux i686) Gecko/20071127 Firefox/2.0.0.11", while `urllib2`'s default user agent string is "Python-urllib/2.6" (on Python 2.6).

The final two arguments are only of interest for correct handling of third-party HTTP cookies :

*origin\_req\_host* should be the request-host of the origin transaction, as defined by [RFC 2965](#). It defaults to `cookielib.request_host(self)`. This is the host name or IP address of the original request that was initiated by the user. For example, if the request is for an image in an HTML document, this should be the request-host of the request for the page containing the image.

*unverifiable* should indicate whether the request is unverifiable, as defined by RFC 2965. It defaults to `False`. An unverifiable request is one whose URL the user did not have the option to approve. For example, if the request is for an image in an HTML document, and the user had no option to approve the automatic fetching of the image, this should be true.

```
class urllib2.OpenerDirector
```

The *OpenerDirector* class opens URLs via *BaseHandlers* chained together. It manages the chaining of handlers, and recovery from errors.

```
class urllib2.BaseHandler
```

This is the base class for all registered handlers — and handles only the simple mechanics of registration.

```
class urllib2.HTTPDefaultErrorHandler
```

A class which defines a default handler for HTTP error responses; all responses are turned into *HTTPError* exceptions.

```
class urllib2.HTTPRedirectHandler
```

A class to handle redirections.

```
class urllib2.HTTPCookieProcessor([cookiejar])
```

A class to handle HTTP Cookies.

```
class urllib2.ProxyHandler([proxies])
```

Cause requests to go through a proxy. If *proxies* is given, it must be a dictionary mapping protocol names to URLs of proxies. The default is to read the list of proxies from the environment variables `<protocol>_proxy`. If no proxy environment variables are set, then in a Windows environment proxy settings are obtained from the registry's Internet Settings section, and in a Mac OS X environment proxy information is retrieved from the OS X System Configuration Framework.

To disable autodetected proxy pass an empty dictionary.

---

**Note :** HTTP\_PROXY will be ignored if a variable REQUEST\_METHOD is set ; see the documentation on [getproxies\(\)](#).

---

**class urllib2.HTTPPasswordMgr**

Keep a database of (realm, uri) -> (user, password) mappings.

**class urllib2.HTTPPasswordMgrWithDefaultRealm**

Keep a database of (realm, uri) -> (user, password) mappings. A realm of None is considered a catch-all realm, which is searched if no other realm fits.

**class urllib2.AbstractBasicAuthHandler**([password\_mgr])

This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. *password\_mgr*, if given, should be something that is compatible with [HTTPPasswordMgr](#) ; refer to section [HTTPPasswordMgr Objects](#) for information on the interface that must be supported.

**class urllib2.HTTPBasicAuthHandler**([password\_mgr])

Handle authentication with the remote host. *password\_mgr*, if given, should be something that is compatible with [HTTPPasswordMgr](#) ; refer to section [HTTPPasswordMgr Objects](#) for information on the interface that must be supported.

**class urllib2.ProxyBasicAuthHandler**([password\_mgr])

Handle authentication with the proxy. *password\_mgr*, if given, should be something that is compatible with [HTTPPasswordMgr](#) ; refer to section [HTTPPasswordMgr Objects](#) for information on the interface that must be supported.

**class urllib2.AbstractDigestAuthHandler**([password\_mgr])

This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. *password\_mgr*, if given, should be something that is compatible with [HTTPPasswordMgr](#) ; refer to section [HTTPPasswordMgr Objects](#) for information on the interface that must be supported.

**class urllib2.HTTPDigestAuthHandler**([password\_mgr])

Handle authentication with the remote host. *password\_mgr*, if given, should be something that is compatible with [HTTPPasswordMgr](#) ; refer to section [HTTPPasswordMgr Objects](#) for information on the interface that must be supported.

**class urllib2.ProxyDigestAuthHandler**([password\_mgr])

Handle authentication with the proxy. *password\_mgr*, if given, should be something that is compatible with [HTTPPasswordMgr](#) ; refer to section [HTTPPasswordMgr Objects](#) for information on the interface that must be supported.

**class urllib2.HTTPHandler**

A class to handle opening of HTTP URLs.

**class urllib2.HTTPSHandler**([debuglevel[, context]])

A class to handle opening of HTTPS URLs. *context* has the same meaning as for [httplib.HTTPSConnection](#).

Modifié dans la version 2.7.9 : *context* added.

**class urllib2.FileHandler**

Open local files.

**class urllib2.FTPHandler**

Open FTP URLs.

**class urllib2.CacheFTPHandler**

Open FTP URLs, keeping a cache of open FTP connections to minimize delays.

`class urllib2.UnknownHandler`  
A catch-all class to handle unknown URLs.

`class urllib2.HTTPErrorProcessor`  
Process HTTP error responses.

## 20.6.1 Request Objects

The following methods describe all of *Request*'s public interface, and so all must be overridden in subclasses.

`Request.add_data(data)`  
Set the *Request* data to *data*. This is ignored by all handlers except HTTP handlers — and there it should be a byte string, and will change the request to be POST rather than GET.

`Request.get_method()`  
Return a string indicating the HTTP request method. This is only meaningful for HTTP requests, and currently always returns 'GET' or 'POST'.

`Request.has_data()`  
Return whether the instance has a non-None data.

`Request.get_data()`  
Return the instance's data.

`Request.add_header(key, val)`  
Add another header to the request. Headers are currently ignored by all handlers except HTTP handlers, where they are added to the list of headers sent to the server. Note that there cannot be more than one header with the same name, and later calls will overwrite previous calls in case the *key* collides. Currently, this is no loss of HTTP functionality, since all headers which have meaning when used more than once have a (header-specific) way of gaining the same functionality using only one header.

`Request.add_unredirected_header(key, header)`  
Add a header that will not be added to a redirected request.  
Nouveau dans la version 2.4.

`Request.has_header(header)`  
Return whether the instance has the named header (checks both regular and unredirected).  
Nouveau dans la version 2.4.

`Request.get_full_url()`  
Return the URL given in the constructor.

`Request.get_type()`  
Return the type of the URL — also known as the scheme.

`Request.get_host()`  
Return the host to which a connection will be made.

`Request.get_selector()`  
Return the selector — the part of the URL that is sent to the server.

`Request.get_header(header_name, default=None)`  
Return the value of the given header. If the header is not present, return the default value.

`Request.header_items()`  
Return a list of tuples (header\_name, header\_value) of the Request headers.

`Request.set_proxy(host, type)`  
Prepare the request by connecting to a proxy server. The *host* and *type* will replace those of the instance, and the instance's selector will be the original URL given in the constructor.

`Request.get_origin_req_host()`

Return the request-host of the origin transaction, as defined by [RFC 2965](#). See the documentation for the *Request* constructor.

`Request.is_unverifiable()`

Return whether the request is unverifiable, as defined by RFC 2965. See the documentation for the *Request* constructor.

## 20.6.2 OpenerDirector Objects

*OpenerDirector* instances have the following methods :

`OpenerDirector.add_handler(handler)`

*handler* should be an instance of *BaseHandler*. The following methods are searched, and added to the possible chains (note that HTTP errors are a special case).

- *protocol\_open* — signal that the handler knows how to open *protocol* URLs.
- *http\_error\_type* — signal that the handler knows how to handle HTTP errors with HTTP error code *type*.
- *protocol\_error* — signal that the handler knows how to handle errors from (non-*http*) *protocol*.
- *protocol\_request* — signal that the handler knows how to pre-process *protocol* requests.
- *protocol\_response* — signal that the handler knows how to post-process *protocol* responses.

`OpenerDirector.open(url[, data][, timeout])`

Open the given *url* (which can be a request object or a string), optionally passing the given *data*. Arguments, return values and exceptions raised are the same as those of *urlopen()* (which simply calls the *open()* method on the currently installed global *OpenerDirector*). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). The timeout feature actually works only for HTTP, HTTPS and FTP connections).

Modifié dans la version 2.6 : Ajout de *timeout*.

`OpenerDirector.error(proto[, arg[, ...]])`

Handle an error of the given protocol. This will call the registered error handlers for the given protocol with the given arguments (which are protocol specific). The HTTP protocol is a special case which uses the HTTP response code to determine the specific error handler; refer to the *http\_error\_\*()* methods of the handler classes.

Return values and exceptions raised are the same as those of *urlopen()*.

*OpenerDirector* objects open URLs in three stages :

The order in which these methods are called within each stage is determined by sorting the handler instances.

1. Every handler with a method named like *protocol\_request* has that method called to pre-process the request.
2. Handlers with a method named like *protocol\_open* are called to handle the request. This stage ends when a handler either returns a non-*None* value (ie. a response), or raises an exception (usually *URLError*). Exceptions are allowed to propagate.

In fact, the above algorithm is first tried for methods named *default\_open()*. If all such methods return *None*, the algorithm is repeated for methods named like *protocol\_open*. If all such methods return *None*, the algorithm is repeated for methods named *unknown\_open()*.

Note that the implementation of these methods may involve calls of the parent *OpenerDirector* instance's *open()* and *error()* methods.

3. Every handler with a method named like *protocol\_response* has that method called to post-process the response.

### 20.6.3 BaseHandler Objects

*BaseHandler* objects provide a couple of methods that are directly useful, and others that are meant to be used by derived classes. These are intended for direct use :

`BaseHandler.add_parent(director)`  
Add a director as parent.

`BaseHandler.close()`  
Remove any parents.

The following attributes and methods should only be used by classes derived from *BaseHandler*.

---

**Note :** The convention has been adopted that subclasses defining `protocol_request()` or `protocol_response()` methods are named *\*Processor* ; all others are named *\*Handler*.

---

`BaseHandler.parent`  
A valid *OpenerDirector*, which can be used to open using a different protocol, or handle errors.

`BaseHandler.default_open(req)`  
This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to catch all URLs.  
This method, if implemented, will be called by the parent *OpenerDirector*. It should return a file-like object as described in the return value of the `open()` of *OpenerDirector*, or `None`. It should raise *URLError*, unless a truly exceptional thing happens (for example, *MemoryError* should not be mapped to *URLError*).  
This method will be called before any protocol-specific open method.

`BaseHandler.protocol_open(req)`  
(« protocol » is to be replaced by the protocol name.)  
This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to handle URLs with the given *protocol*.  
This method, if defined, will be called by the parent *OpenerDirector*. Return values should be the same as for `default_open()`.

`BaseHandler.unknown_open(req)`  
This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to catch all URLs with no specific registered handler to open it.  
This method, if implemented, will be called by the *parent OpenerDirector*. Return values should be the same as for `default_open()`.

`BaseHandler.http_error_default(req, fp, code, msg, hdrs)`  
This method is *not* defined in *BaseHandler*, but subclasses should override it if they intend to provide a catch-all for otherwise unhandled HTTP errors. It will be called automatically by the *OpenerDirector* getting the error, and should not normally be called in other circumstances.  
*req* will be a *Request* object, *fp* will be a file-like object with the HTTP error body, *code* will be the three-digit code of the error, *msg* will be the user-visible explanation of the code and *hdrs* will be a mapping object with the headers of the error.  
Return values and exceptions raised should be the same as those of `urlopen()`.

`BaseHandler.http_error_nnn(req, fp, code, msg, hdrs)`  
*nnn* should be a three-digit HTTP error code. This method is also not defined in *BaseHandler*, but will be called, if it exists, on an instance of a subclass, when an HTTP error with code *nnn* occurs.  
Subclasses should override this method to handle specific HTTP errors.  
Arguments, return values and exceptions raised should be the same as for `http_error_default()`.

`BaseHandler.protocol_request(req)`

(« protocol » is to be replaced by the protocol name.)

This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to pre-process requests of the given *protocol*.

This method, if defined, will be called by the parent *OpenerDirector*. *req* will be a *Request* object. The return value should be a *Request* object.

`BaseHandler.protocol_response(req, response)`

(« protocol » is to be replaced by the protocol name.)

This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to post-process responses of the given *protocol*.

This method, if defined, will be called by the parent *OpenerDirector*. *req* will be a *Request* object. *response* will be an object implementing the same interface as the return value of *urlopen()*. The return value should implement the same interface as the return value of *urlopen()*.

## 20.6.4 HTTPRedirectHandler Objects

---

**Note :** Some HTTP redirections require action from this module’s client code. If this is the case, *HTTPError* is raised. See [RFC 2616](#) for details of the precise meanings of the various redirection codes.

---

`HTTPRedirectHandler.redirect_request(req, fp, code, msg, hdrs, newurl)`

Return a *Request* or *None* in response to a redirect. This is called by the default implementations of the `http_error_30*`() methods when a redirection is received from the server. If a redirection should take place, return a new *Request* to allow `http_error_30*`() to perform the redirect to *newurl*. Otherwise, raise *HTTPError* if no other handler should try to handle this URL, or return *None* if you can’t but another handler might.

---

**Note :** The default implementation of this method does not strictly follow [RFC 2616](#), which says that 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and the default implementation reproduces this behavior.

---

`HTTPRedirectHandler.http_error_301(req, fp, code, msg, hdrs)`

Redirect to the Location: or URI: URL. This method is called by the parent *OpenerDirector* when getting an HTTP “moved permanently” response.

`HTTPRedirectHandler.http_error_302(req, fp, code, msg, hdrs)`

The same as `http_error_301()`, but called for the “found” response.

`HTTPRedirectHandler.http_error_303(req, fp, code, msg, hdrs)`

The same as `http_error_301()`, but called for the “see other” response.

`HTTPRedirectHandler.http_error_307(req, fp, code, msg, hdrs)`

The same as `http_error_301()`, but called for the “temporary redirect” response.

## 20.6.5 HTTPCookieProcessor Objects

Nouveau dans la version 2.4.

*HTTPCookieProcessor* instances have one attribute :

`HTTPCookieProcessor.cookiejar`

The *cookielib.CookieJar* in which cookies are stored.

## 20.6.6 ProxyHandler Objects

`ProxyHandler.protocol_open(request)`

(« protocol » is to be replaced by the protocol name.)

The *ProxyHandler* will have a method `protocol_open` for every *protocol* which has a proxy in the *proxies* dictionary given in the constructor. The method will modify requests to go through the proxy, by calling `request.set_proxy()`, and call the next handler in the chain to actually execute the protocol.

## 20.6.7 HTTPPasswordMgr Objects

These methods are available on *HTTPPasswordMgr* and *HTTPPasswordMgrWithDefaultRealm* objects.

`HTTPPasswordMgr.add_password(realm, uri, user, passwd)`

*uri* can be either a single URI, or a sequence of URIs. *realm*, *user* and *passwd* must be strings. This causes (*user*, *passwd*) to be used as authentication tokens when authentication for *realm* and a super-URI of any of the given URIs is given.

`HTTPPasswordMgr.find_user_password(realm, authuri)`

Get user/password for given realm and URI, if any. This method will return (*None*, *None*) if there is no matching user/password.

For *HTTPPasswordMgrWithDefaultRealm* objects, the realm *None* will be searched if the given *realm* has no matching user/password.

## 20.6.8 AbstractBasicAuthHandler Objects

`AbstractBasicAuthHandler.http_error_auth_requed(authreq, host, req, headers)`

Handle an authentication request by getting a user/password pair, and re-trying the request. *authreq* should be the name of the header where the information about the realm is included in the request, *host* specifies the URL and path to authenticate for, *req* should be the (failed) *Request* object, and *headers* should be the error headers.

*host* is either an authority (e.g. "python.org") or a URL containing an authority component (e.g. "http://python.org/"). In either case, the authority must not contain a userinfo component (so, "python.org" and "python.org:80" are fine, "joe:password@python.org" is not).

## 20.6.9 HTTPBasicAuthHandler Objects

`HTTPBasicAuthHandler.http_error_401(req, fp, code, msg, hdrs)`

Retry the request with authentication information, if available.

## 20.6.10 ProxyBasicAuthHandler Objects

`ProxyBasicAuthHandler.http_error_407(req, fp, code, msg, hdrs)`

Retry the request with authentication information, if available.

## 20.6.11 AbstractDigestAuthHandler Objects

`AbstractDigestAuthHandler.http_error_auth_requed(authreq, host, req, headers)`

*authreq* should be the name of the header where the information about the realm is included in the request, *host* should be the host to authenticate to, *req* should be the (failed) *Request* object, and *headers* should be the error headers.

## 20.6.12 HTTPDigestAuthHandler Objects

`HTTPDigestAuthHandler.http_error_401(req, fp, code, msg, hdrs)`

Retry the request with authentication information, if available.

### 20.6.13 ProxyDigestAuthHandler Objects

`ProxyDigestAuthHandler.http_error_407(req, fp, code, msg, hdrs)`  
 Retry the request with authentication information, if available.

### 20.6.14 HTTPHandler Objects

`HTTPHandler.http_open(req)`  
 Send an HTTP request, which can be either GET or POST, depending on `req.has_data()`.

### 20.6.15 HTTPSHandler Objects

`HTTPSHandler.https_open(req)`  
 Send an HTTPS request, which can be either GET or POST, depending on `req.has_data()`.

### 20.6.16 FileHandler Objects

`FileHandler.file_open(req)`  
 Open the file locally, if there is no host name, or the host name is 'localhost'. Change the protocol to ftp otherwise, and retry opening it using `parent`.

### 20.6.17 FTPHandler Objects

`FTPHandler.ftp_open(req)`  
 Open the FTP file indicated by `req`. The login is always done with empty username and password.

### 20.6.18 CacheFTPHandler Objects

*CacheFTPHandler* objects are *FTPHandler* objects with the following additional methods :

`CacheFTPHandler.setTimeout(t)`  
 Set timeout of connections to *t* seconds.

`CacheFTPHandler.setMaxConns(m)`  
 Set maximum number of cached connections to *m*.

### 20.6.19 UnknownHandler Objects

`UnknownHandler.unknown_open()`  
 Raise a *URLError* exception.

### 20.6.20 HTTPErrorProcessor Objects

Nouveau dans la version 2.4.

`HTTPErrorProcessor.http_response()`  
 Process HTTP error responses.  
 For 200 error codes, the response object is returned immediately.  
 For non-200 error codes, this simply passes the job on to the *protocol\_error\_code* handler methods, via *OpenerDirector.error()*. Eventually, *urllib2.HTTPDefaultErrorHandler* will raise an *HTTPError* if no other handler handles the error.

`HTTPErrorProcessor.https_response()`  
 Process HTTPS error responses.  
 The behavior is same as *http\_response()*.

### 20.6.21 Examples

In addition to the examples below, more examples are given in `urllib-howto`.

This example gets the `python.org` main page and displays the first 100 bytes of it :

```
>>> import urllib2
>>> f = urllib2.urlopen('http://www.python.org/')
>>> print f.read(100)
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN">
<?xml-styleeet href="./css/ht2html
```

Here we are sending a data-stream to the stdin of a CGI and reading the data it returns to us. Note that this example will only work when the Python installation supports SSL.

```
>>> import urllib2
>>> req = urllib2.Request(url='https://localhost/cgi-bin/test.cgi',
...                        data='This data is passed to stdin of the CGI')
>>> f = urllib2.urlopen(req)
>>> print f.read()
Got Data: "This data is passed to stdin of the CGI"
```

The code for the sample CGI used in the above example is :

```
#!/usr/bin/env python
import sys
data = sys.stdin.read()
print 'Content-type: text-plain\n\nGot Data: "%s"' % data
```

Use of Basic HTTP Authentication :

```
import urllib2
# Create an OpenerDirector with support for Basic HTTP Authentication...
auth_handler = urllib2.HTTPBasicAuthHandler()
auth_handler.add_password(realm='PDQ Application',
                          uri='https://mahler:8092/site-updates.py',
                          user='klem',
                          passwd='kadidd!ehopper')
opener = urllib2.build_opener(auth_handler)
# ...and install it globally so it can be used with urlopen.
urllib2.install_opener(opener)
urllib2.urlopen('http://www.example.com/login.html')
```

`build_opener()` provides many handlers by default, including a `ProxyHandler`. By default, `ProxyHandler` uses the environment variables named `<scheme>_proxy`, where `<scheme>` is the URL scheme involved. For example, the `http_proxy` environment variable is read to obtain the HTTP proxy's URL.

This example replaces the default `ProxyHandler` with one that uses programmatically-supplied proxy URLs, and adds proxy authorization support with `ProxyBasicAuthHandler`.

```
proxy_handler = urllib2.ProxyHandler({'http': 'http://www.example.com:3128/'})
proxy_auth_handler = urllib2.ProxyBasicAuthHandler()
proxy_auth_handler.add_password('realm', 'host', 'username', 'password')

opener = urllib2.build_opener(proxy_handler, proxy_auth_handler)
```

(suite sur la page suivante)

(suite de la page précédente)

```
# This time, rather than install the OpenerDirector, we use it directly:
opener.open('http://www.example.com/login.html')
```

Adding HTTP headers :

Use the *headers* argument to the *Request* constructor, or :

```
import urllib2
req = urllib2.Request('http://www.example.com/')
req.add_header('Referer', 'http://www.python.org/')
# Customize the default User-Agent header value:
req.add_header('User-Agent', 'urllib-example/0.1 (Contact: . . .)')
r = urllib2.urlopen(req)
```

*OpenerDirector* automatically adds a *User-Agent* header to every *Request*. To change this :

```
import urllib2
opener = urllib2.build_opener()
opener.addheaders = [('User-agent', 'Mozilla/5.0')]
opener.open('http://www.example.com/')
```

Also, remember that a few standard headers (*Content-Length*, *Content-Type* and *Host*) are added when the *Request* is passed to *urlopen()* (or *OpenerDirector.open()*).

## 20.7 httplib — HTTP protocol client

**Note :** The *httplib* module has been renamed to *http.client* in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

**Source code :** [Lib/httplib.py](#)

This module defines classes which implement the client side of the HTTP and HTTPS protocols. It is normally not used directly — the module *urllib* uses it to handle URLs that use HTTP and HTTPS.

**Voir aussi :**

The *Requests* package is recommended for a higher-level HTTP client interface.

**Note :** HTTPS support is only available if the *socket* module was compiled with SSL support.

**Note :** The public interface for this module changed substantially in Python 2.0. The *HTTP* class is retained only for backward compatibility with 1.5.2. It should not be used in new code. Refer to the online docstrings for usage.

The module provides the following classes :

```
class httplib.HTTPConnection(host[, port[, strict[, timeout[, source_address]]]])
    An HTTPConnection instance represents one transaction with an HTTP server. It should be instantiated passing it a host and optional port number. If no port number is passed, the port is extracted from
```

the host string if it has the form `host:port`, else the default HTTP port (80) is used. When true, the optional parameter *strict* (which defaults to a false value) causes `BadStatusLine` to be raised if the status line can't be parsed as a valid HTTP/1.0 or 1.1 status line. If the optional *timeout* parameter is given, blocking operations (like connection attempts) will timeout after that many seconds (if it is not given, the global default timeout setting is used). The optional *source\_address* parameter may be a tuple of a (host, port) to use as the source address the HTTP connection is made from.

For example, the following calls all create instances that connect to the server at the same host and port :

```
>>> h1 = urllib.HTTPConnection('www.cwi.nl')
>>> h2 = urllib.HTTPConnection('www.cwi.nl:80')
>>> h3 = urllib.HTTPConnection('www.cwi.nl', 80)
>>> h3 = urllib.HTTPConnection('www.cwi.nl', 80, timeout=10)
```

Nouveau dans la version 2.0.

Modifié dans la version 2.6 : Ajout de *timeout*.

Modifié dans la version 2.7 : *source\_address* was added.

```
class urllib.HTTPSConnection(host[, port[, key_file[, cert_file[, strict[, timeout[,
                                source_address[, context]]]]]]])
```

A subclass of `HTTPConnection` that uses SSL for communication with secure servers. Default port is 443. If *context* is specified, it must be a `ssl.SSLContext` instance describing the various SSL options. *key\_file* and *cert\_file* are deprecated, please use `ssl.SSLContext.load_cert_chain()` instead, or let `ssl.create_default_context()` select the system's trusted CA certificates for you.

Please read *Security considerations* for more information on best practices.

Nouveau dans la version 2.0.

Modifié dans la version 2.6 : Ajout de *timeout*.

Modifié dans la version 2.7 : *source\_address* was added.

Modifié dans la version 2.7.9 : *context* was added.

This class now performs all the necessary certificate and hostname checks by default. To revert to the previous, unverified, behavior `ssl._create_unverified_context()` can be passed to the *context* parameter.

```
class urllib.HTTPResponse(sock, debuglevel=0, strict=0)
```

Class whose instances are returned upon successful connection. Not instantiated directly by user.

Nouveau dans la version 2.0.

```
class urllib.HTTPMessage
```

An `HTTPMessage` instance is used to hold the headers from an HTTP response. It is implemented using the `mimetypes.Message` class and provides utility functions to deal with HTTP Headers. It is not directly instantiated by the users.

The following exceptions are raised as appropriate :

```
exception urllib.HTTPException
```

The base class of the other exceptions in this module. It is a subclass of `Exception`.

Nouveau dans la version 2.0.

```
exception urllib.NotConnected
```

A subclass of `HTTPException`.

Nouveau dans la version 2.0.

```
exception urllib.InvalidURL
```

A subclass of `HTTPException`, raised if a port is given and is either non-numeric or empty.

Nouveau dans la version 2.3.

**exception** `httplib.UnknownProtocol`

A subclass of [HTTPException](#).

Nouveau dans la version 2.0.

**exception** `httplib.UnknownTransferEncoding`

A subclass of [HTTPException](#).

Nouveau dans la version 2.0.

**exception** `httplib.UnimplementedFileMode`

A subclass of [HTTPException](#).

Nouveau dans la version 2.0.

**exception** `httplib.IncompleteRead`

A subclass of [HTTPException](#).

Nouveau dans la version 2.0.

**exception** `httplib.ImproperConnectionState`

A subclass of [HTTPException](#).

Nouveau dans la version 2.0.

**exception** `httplib.CannotSendRequest`

A subclass of [ImproperConnectionState](#).

Nouveau dans la version 2.0.

**exception** `httplib.CannotSendHeader`

A subclass of [ImproperConnectionState](#).

Nouveau dans la version 2.0.

**exception** `httplib.ResponseNotReady`

A subclass of [ImproperConnectionState](#).

Nouveau dans la version 2.0.

**exception** `httplib.BadStatusLine`

A subclass of [HTTPException](#). Raised if a server responds with a HTTP status code that we don't understand.

Nouveau dans la version 2.0.

Les constantes définies dans ce module sont :

**httplib.HTTP\_PORT**

The default port for the HTTP protocol (always 80).

**httplib.HTTPS\_PORT**

The default port for the HTTPS protocol (always 443).

and also the following constants for integer status codes :

Constante	Valeur	Définition

**httplib.responses**

This dictionary maps the HTTP 1.1 status codes to the W3C names.

Exemple : `httplib.responses[httplib.NOT_FOUND]` is 'Not Found'.

Nouveau dans la version 2.5.

**20.7.1 HTTPConnection Objects**

*HTTPConnection* instances have the following methods :

`HTTPConnection.request(method, url[, body[, headers]])`

This will send a request to the server using the HTTP request method *method* and the selector *url*. If the *body* argument is present, it should be a string of data to send after the headers are finished. Alternatively, it may be an open file object, in which case the contents of the file is sent ; this file object should support `fileno()` and `read()` methods. The *headers* argument should be a mapping of extra HTTP headers to send with the request.

If one is not provided in *headers*, a **Content-Length** header is added automatically for all methods if the length of the body can be determined, either from the length of the `str` representation, or from the reported size of the file on disk. If *body* is `None` the header is not set except for methods that expect a body (PUT, POST, and PATCH) in which case it is set to 0.

Modifié dans la version 2.6 : *body* can be a file object.

#### `HTTPConnection.getresponse()`

Should be called after a request is sent to get the response from the server. Returns an *HTTPResponse* instance.

---

**Note :** Note that you must have read the whole response before you can send a new request to the server.

---

#### `HTTPConnection.set_debuglevel(level)`

Set the debugging level (the amount of debugging output printed). The default debug level is 0, meaning no debugging output is printed.

#### `HTTPConnection.set_tunnel(host, port=None, headers=None)`

Set the host and the port for HTTP Connect Tunnelling. Normally used when it is required to do HTTPS Connection through a proxy server.

The headers argument should be a mapping of extra HTTP headers to send with the CONNECT request.

Nouveau dans la version 2.7.

#### `HTTPConnection.connect()`

Connect to the server specified when the object was created.

#### `HTTPConnection.close()`

Close the connection to the server.

As an alternative to using the `request()` method described above, you can also send your request step by step, by using the four functions below.

#### `HTTPConnection.putrequest(request, selector[, skip_host[, skip_accept_encoding]])`

This should be the first call after the connection to the server has been made. It sends a line to the server consisting of the *request* string, the *selector* string, and the HTTP version (HTTP/1.1). To disable automatic sending of **Host:** or **Accept-Encoding:** headers (for example to accept additional content encodings), specify *skip\_host* or *skip\_accept\_encoding* with non-False values.

Modifié dans la version 2.4 : *skip\_accept\_encoding* argument added.

#### `HTTPConnection.putheader(header, argument[, ...])`

Send an **RFC 822**-style header to the server. It sends a line to the server consisting of the header, a colon and a space, and the first argument. If more arguments are given, continuation lines are sent, each consisting of a tab and an argument.

#### `HTTPConnection.endheaders(message_body=None)`

Send a blank line to the server, signalling the end of the headers. The optional *message\_body* argument can be used to pass a message body associated with the request. The message body will be sent in the same packet as the message headers if it is string, otherwise it is sent in a separate packet.

Modifié dans la version 2.7 : *message\_body* was added.

`HTTPConnection.send(data)`

Send data to the server. This should be used directly only after the `endheaders()` method has been called and before `getresponse()` is called.

## 20.7.2 HTTPResponse Objects

`HTTPResponse` instances have the following methods and attributes :

`HTTPResponse.read([amt])`

Reads and returns the response body, or up to the next *amt* bytes.

`HTTPResponse.getheader(name[, default])`

Get the contents of the header *name*, or *default* if there is no matching header.

`HTTPResponse.getheaders()`

Return a list of (header, value) tuples.

Nouveau dans la version 2.4.

`HTTPResponse.fileno()`

Returns the `fileno` of the underlying socket.

`HTTPResponse.msg`

A `mimetools.Message` instance containing the response headers.

`HTTPResponse.version`

HTTP protocol version used by server. 10 for HTTP/1.0, 11 for HTTP/1.1.

`HTTPResponse.status`

Status code returned by server.

`HTTPResponse.reason`

Reason phrase returned by server.

## 20.7.3 Exemples

Here is an example session that uses the GET method :

```
>>> import httpplib
>>> conn = httpplib.HTTPSConnection("www.python.org")
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> print r1.status, r1.reason
200 OK
>>> data1 = r1.read()
>>> conn.request("GET", "/")
>>> r2 = conn.getresponse()
>>> print r2.status, r2.reason
404 Not Found
>>> data2 = r2.read()
>>> conn.close()
```

Here is an example session that uses the HEAD method. Note that the HEAD method never returns any data.

```
>>> import httpplib
>>> conn = httpplib.HTTPSConnection("www.python.org")
>>> conn.request("HEAD", "/")
>>> res = conn.getresponse()
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> print res.status, res.reason
200 OK
>>> data = res.read()
>>> print len(data)
0
>>> data == ''
True
```

Here is an example session that shows how to POST requests :

```
>>> import urllib, urllib
>>> params = urllib.urlencode({'@number': 12524, '@type': 'issue', '@action': 'show'})
>>> headers = {"Content-type": "application/x-www-form-urlencoded",
...           "Accept": "text/plain"}
>>> conn = urllib.HTTPConnection("bugs.python.org")
>>> conn.request("POST", "", params, headers)
>>> response = conn.getresponse()
>>> print response.status, response.reason
302 Found
>>> data = response.read()
>>> data
'Redirecting to <a href="http://bugs.python.org/issue12524">http://bugs.python.org/
↪issue12524</a>'
>>> conn.close()
```

Client side HTTP PUT requests are very similar to POST requests. The difference lies only the server side where HTTP server will allow resources to be created via PUT request. Here is an example session that shows how to do PUT request using urllib :

```
>>> # This creates an HTTP message
>>> # with the content of BODY as the enclosed representation
>>> # for the resource http://localhost:8080/foobar
...
>>> import urllib
>>> BODY = "****filecontents****"
>>> conn = urllib.HTTPConnection("localhost", 8080)
>>> conn.request("PUT", "/file", BODY)
>>> response = conn.getresponse()
>>> print response.status, response.reason
200, OK
```

## 20.8 ftplib — FTP protocol client

Code source : [Lib/ftplib.py](#)

This module defines the class *FTP* and a few related items. The *FTP* class implements the client side of the FTP protocol. You can use this to write Python programs that perform a variety of automated FTP jobs, such as mirroring other FTP servers. It is also used by the module *urllib* to handle URLs that use FTP. For more information on FTP (File Transfer Protocol), see Internet [RFC 959](#).

Here's a sample session using the *ftplib* module :

```

>>> from ftplib import FTP
>>> ftp = FTP('ftp.debian.org')      # connect to host, default port
>>> ftp.login()                      # user anonymous, passwd anonymous@
'230 Login successful.'
>>> ftp.cwd('debian')                # change into "debian" directory
>>> ftp.retrlines('LIST')            # list directory contents
-rw-rw-r-- 1 1176      1176      1063 Jun 15 10:18 README
...

'226 Directory send OK.'
>>> ftp.retrbinary('RETR README', open('README', 'wb').write)
'226 Transfer complete.'
>>> ftp.quit()

```

Le module définit les éléments suivants :

```
class ftplib.FTP([host[, user[, passwd[, acct[, timeout]]]]])
```

Return a new instance of the `FTP` class. When `host` is given, the method call `connect(host)` is made. When `user` is given, additionally the method call `login(user, passwd, acct)` is made (where `passwd` and `acct` default to the empty string when not given). The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if is not specified, the global default timeout setting will be used).

Modifié dans la version 2.6 : Ajout de `timeout`.

```
class ftplib.FTP_TLS([host[, user[, passwd[, acct[, keyfile[, certfile[, context[, timeout]]]]]]]])
```

A `FTP` subclass which adds TLS support to FTP as described in [RFC 4217](#). Connect as usual to port 21 implicitly securing the FTP control connection before authenticating. Securing the data connection requires the user to explicitly ask for it by calling the `prot_p()` method. `context` is a `ssl.SSLContext` object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read *Security considerations* for best practices.

`keyfile` and `certfile` are a legacy alternative to `context` – they can point to PEM-formatted private key and certificate chain files (respectively) for the SSL connection.

Nouveau dans la version 2.7.

Modifié dans la version 2.7.10 : The `context` parameter was added.

Here's a sample session using the `FTP_TLS` class :

```

>>> from ftplib import FTP_TLS
>>> ftps = FTP_TLS('ftp.python.org')
>>> ftps.login()                    # login anonymously before securing control channel
>>> ftps.prot_p()                   # switch to secure data connection
>>> ftps.retrlines('LIST')          # list directory content securely
total 9

(suite de la page précédente)

```
'226 Transfer complete.'
>>> ftps.quit()
>>>
```

**exception `ftplib.error_reply`**

Exception raised when an unexpected reply is received from the server.

**exception `ftplib.error_temp`**

Exception raised when an error code signifying a temporary error (response codes in the range 400–499) is received.

**exception `ftplib.error_perm`**

Exception raised when an error code signifying a permanent error (response codes in the range 500–599) is received.

**exception `ftplib.error_proto`**

Exception raised when a reply is received from the server that does not fit the response specifications of the File Transfer Protocol, i.e. begin with a digit in the range 1–5.

**`ftplib.all_errors`**

The set of all exceptions (as a tuple) that methods of *FTP* instances may raise as a result of problems with the FTP connection (as opposed to programming errors made by the caller). This set includes the four exceptions listed above as well as *socket.error* and *IOError*.

**Voir aussi :**

Module *netrc* Parser for the *.netrc* file format. The file *.netrc* is typically used by FTP clients to load user authentication information before prompting the user.

The file `Tools/scripts/ftpmirror.py` in the Python source distribution is a script that can mirror FTP sites, or portions thereof, using the *ftplib* module. It can be used as an extended example that applies this module.

## 20.8.1 FTP Objects

Several methods are available in two flavors : one for handling text files and another for binary files. These are named for the command which is used followed by **lines** for the text version or **binary** for the binary version.

*FTP* instances have the following methods :

**`FTP.set_debuglevel(level)`**

Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

**`FTP.connect(host[, port[, timeout]])`**

Connect to the given host and port. The default port number is 21, as specified by the FTP protocol specification. It is rarely needed to specify a different port number. This function should be called only once for each instance ; it should not be called at all if a host was given when the instance was created. All other methods can only be used after a connection has been made.

The optional *timeout* parameter specifies a timeout in seconds for the connection attempt. If no *timeout* is passed, the global default timeout setting will be used.

Modifié dans la version 2.6 : Ajout de *timeout*.

**FTP.getwelcome()**

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

**FTP.login([user[, passwd[, acct]]])**

Log in as the given *user*. The *passwd* and *acct* parameters are optional and default to the empty string. If no *user* is specified, it defaults to 'anonymous'. If *user* is 'anonymous', the default *passwd* is 'anonymous@'. This function should be called only once for each instance, after a connection has been established; it should not be called at all if a host and user were given when the instance was created. Most FTP commands are only allowed after the client has logged in. The *acct* parameter supplies « accounting information »; few systems implement this.

**FTP.abort()**

Abort a file transfer that is in progress. Using this does not always work, but it's worth a try.

**FTP.sendcmd(command)**

Send a simple command string to the server and return the response string.

**FTP.voidcmd(command)**

Send a simple command string to the server and handle the response. Return nothing if a response code corresponding to success (codes in the range 200–299) is received. Raise *error\_reply* otherwise.

**FTP.retrbinary(command, callback[, maxblocksize[, rest]])**

Retrieve a file in binary transfer mode. *command* should be an appropriate RETR command : 'RETR filename'. The *callback* function is called for each block of data received, with a single string argument giving the data block. The optional *maxblocksize* argument specifies the maximum chunk size to read on the low-level socket object created to do the actual transfer (which will also be the largest size of the data blocks passed to *callback*). A reasonable default is chosen. *rest* means the same thing as in the *transfercmd()* method.

**FTP.retrlines(command[, callback])**

Retrieve a file or directory listing in ASCII transfer mode. *command* should be an appropriate RETR command (see *retrbinary()*) or a command such as LIST, NLST or MLSD (usually just the string 'LIST'). LIST retrieves a list of files and information about those files. NLST retrieves a list of file names. On some servers, MLSD retrieves a machine readable list of files and information about those files. The *callback* function is called for each line with a string argument containing the line with the trailing CRLF stripped. The default *callback* prints the line to *sys.stdout*.

**FTP.set\_pasv(val)**

Enable « passive » mode if *val* is true, otherwise disable passive mode. (In Python 2.0 and before, passive mode was off by default; in Python 2.1 and later, it is on by default.)

**FTP.storbinary(command, fp[, blocksize, callback, rest])**

Store a file in binary transfer mode. *command* should be an appropriate STOR command : "STOR filename". *fp* is an open file object which is read until EOF using its *read()* method in blocks of size *blocksize* to provide the data to be stored. The *blocksize* argument defaults to 8192. *callback* is an optional single parameter callable that is called on each block of data after it is sent. *rest* means the same thing as in the *transfercmd()* method.

Modifié dans la version 2.1 : default for *blocksize* added.

Modifié dans la version 2.6 : *callback* parameter added.

Modifié dans la version 2.7 : *rest* parameter added.

**FTP.storlines(command, fp[, callback])**

Store a file in ASCII transfer mode. *command* should be an appropriate STOR command (see *storbinary()*). Lines are read until EOF from the open file object *fp* using its *readline()* method to provide the data to be stored. *callback* is an optional single parameter callable that is called on each line after it is sent.

Modifié dans la version 2.6 : *callback* parameter added.

**FTP.transfercmd(*cmd*[, *rest*])**

Initiate a transfer over the data connection. If the transfer is active, send an EPRT or PORT command and the transfer command specified by *cmd*, and accept the connection. If the server is passive, send an EPSV or PASV command, connect to it, and start the transfer command. Either way, return the socket for the connection.

If optional *rest* is given, a REST command is sent to the server, passing *rest* as an argument. *rest* is usually a byte offset into the requested file, telling the server to restart sending the file's bytes at the requested offset, skipping over the initial bytes. Note however that RFC 959 requires only that *rest* be a string containing characters in the printable range from ASCII code 33 to ASCII code 126. The *transfercmd()* method, therefore, converts *rest* to a string, but no check is performed on the string's contents. If the server does not recognize the REST command, an *error\_reply* exception will be raised. If this happens, simply call *transfercmd()* without a *rest* argument.

**FTP.ntransfercmd(*cmd*[, *rest*])**

Like *transfercmd()*, but returns a tuple of the data connection and the expected size of the data. If the expected size could not be computed, *None* will be returned as the expected size. *cmd* and *rest* means the same thing as in *transfercmd()*.

**FTP.nlst(*argument*[, ...])**

Return a list of file names as returned by the NLST command. The optional *argument* is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the NLST command.

**FTP.dir(*argument*[, ...])**

Produce a directory listing as returned by the LIST command, printing it to standard output. The optional *argument* is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the LIST command. If the last argument is a function, it is used as a *callback* function as for *retrlines()*; the default prints to *sys.stdout*. This method returns *None*.

**FTP.rename(*fromname*, *toname*)**

Rename file *fromname* on the server to *toname*.

**FTP.delete(*filename*)**

Remove the file named *filename* from the server. If successful, returns the text of the response, otherwise raises *error\_perm* on permission errors or *error\_reply* on other errors.

**FTP.cwd(*pathname*)**

Set the current directory on the server.

**FTP.mkd(*pathname*)**

Create a new directory on the server.

**FTP.pwd()**

Return the pathname of the current directory on the server.

**FTP.rmd(*dirname*)**

Remove the directory named *dirname* on the server.

**FTP.size(*filename*)**

Request the size of the file named *filename* on the server. On success, the size of the file is returned as an integer, otherwise *None* is returned. Note that the SIZE command is not standardized, but is supported by many common server implementations.

**FTP.quit()**

Send a QUIT command to the server and close the connection. This is the « polite » way to close a connection, but it may raise an exception if the server responds with an error to the QUIT command.

This implies a call to the `close()` method which renders the `FTP` instance useless for subsequent calls (see below).

**FTP.close()**

Close the connection unilaterally. This should not be applied to an already closed connection such as after a successful call to `quit()`. After this call the `FTP` instance should not be used any more (after a call to `close()` or `quit()` you cannot reopen the connection by issuing another `login()` method).

## 20.8.2 FTP\_TLS Objects

`FTP_TLS` class inherits from `FTP`, defining these additional objects :

**FTP\_TLS.ssl\_version**

The SSL version to use (defaults to `ssl.PROTOCOL_SSLv23`).

**FTP\_TLS.auth()**

Set up secure control connection by using TLS or SSL, depending on what specified in `ssl_version()` attribute.

**FTP\_TLS.prot\_p()**

Set up secure data connection.

**FTP\_TLS.prot\_c()**

Set up clear text data connection.

## 20.9 poplib — POP3 protocol client

Code source : [Lib/poplib.py](#)

---

This module defines a class, `POP3`, which encapsulates a connection to a POP3 server and implements the protocol as defined in [RFC 1725](#). The `POP3` class supports both the minimal and optional command sets. Additionally, this module provides a class `POP3_SSL`, which provides support for connecting to POP3 servers that use SSL as an underlying protocol layer.

Note that POP3, though widely supported, is obsolescent. The implementation quality of POP3 servers varies widely, and too many are quite poor. If your mailserver supports IMAP, you would be better off using the `imaplib.IMAP4` class, as IMAP servers tend to be better implemented.

The `poplib` module provides two classes :

```
class poplib.POP3(host[, port[, timeout]])
```

This class implements the actual POP3 protocol. The connection is created when the instance is initialized. If `port` is omitted, the standard POP3 port (110) is used. The optional `timeout` parameter specifies a timeout in seconds for the connection attempt (if not specified, the global default timeout setting will be used).

Modifié dans la version 2.6 : Ajout de `timeout`.

```
class poplib.POP3_SSL(host[, port[, keyfile[, certfile]]])
```

This is a subclass of `POP3` that connects to the server over an SSL encrypted socket. If `port` is not specified, 995, the standard POP3-over-SSL port is used. `keyfile` and `certfile` are also optional - they can contain a PEM formatted private key and certificate chain file for the SSL connection.

Nouveau dans la version 2.4.

One exception is defined as an attribute of the `poplib` module :

**exception poplib.error\_proto**

Exception raised on any errors from this module (errors from `socket` module are not caught). The reason for the exception is passed to the constructor as a string.

Voir aussi :

**Module `imaplib`** The standard Python IMAP module.

**Frequently Asked Questions About Fetchmail** The FAQ for the `fetchmail` POP/IMAP client collects information on POP3 server variations and RFC noncompliance that may be useful if you need to write an application based on the POP protocol.

### 20.9.1 POP3 Objects

All POP3 commands are represented by methods of the same name, in lower-case; most return the response text sent by the server.

An `POP3` instance has the following methods :

`POP3.set_debuglevel(level)`

Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

`POP3.getwelcome()`

Returns the greeting string sent by the POP3 server.

`POP3.user(username)`

Send user command, response should indicate that a password is required.

`POP3.pass_(password)`

Send password, response includes message count and mailbox size. Note : the mailbox on the server is locked until `quit()` is called.

`POP3.apop(user, secret)`

Use the more secure APOP authentication to log into the POP3 server.

`POP3.rpop(user)`

Use RPOP authentication (similar to UNIX r-commands) to log into POP3 server.

`POP3.stat()`

Get mailbox status. The result is a tuple of 2 integers : (message count, mailbox size).

`POP3.list([which])`

Request message list, result is in the form (response, ['mesg\_num octets', ...], octets). If *which* is set, it is the message to list.

`POP3.retr(which)`

Retrieve whole message number *which*, and set its seen flag. Result is in form (response, ['line', ...], octets).

`POP3.delete(which)`

Flag message number *which* for deletion. On most servers deletions are not actually performed until QUIT (the major exception is Eudora QPOP, which deliberately violates the RFCs by doing pending deletes on any disconnect).

`POP3.rset()`

Remove any deletion marks for the mailbox.

`POP3.noop()`

Do nothing. Might be used as a keep-alive.

`POP3.quit()`

Signoff : commit changes, unlock mailbox, drop connection.

`POP3.top(which, howmuch)`

Retrieves the message header plus *howmuch* lines of the message after the header of message number *which*. Result is in form (`response`, `['line', ...]`, octets).

The POP3 TOP command this method uses, unlike the RETR command, doesn't set the message's seen flag; unfortunately, TOP is poorly specified in the RFCs and is frequently broken in off-brand servers. Test this method by hand against the POP3 servers you will use before trusting it.

`POP3.uidl([which])`

Return message digest (unique id) list. If *which* is specified, result contains the unique id for that message in the form '`response mesgnum uid`', otherwise result is list (`response`, `['mesgnum uid', ...]`, octets).

Instances of `POP3_SSL` have no additional methods. The interface of this subclass is identical to its parent.

## 20.9.2 POP3 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages :

```
import getpass, poplib

M = poplib.POP3('localhost')
M.user(getpass.getuser())
M.pass_(getpass.getpass())
numMessages = len(M.list()[1])
for i in range(numMessages):
    for j in M.retr(i+1)[1]:
        print j
```

At the end of the module, there is a test section that contains a more extensive example of usage.

## 20.10 imaplib — IMAP4 protocol client

Code source : [Lib/imaplib.py](#)

---

This module defines three classes, `IMAP4`, `IMAP4_SSL` and `IMAP4_stream`, which encapsulate a connection to an IMAP4 server and implement a large subset of the IMAP4rev1 client protocol as defined in [RFC 2060](#). It is backward compatible with IMAP4 ([RFC 1730](#)) servers, but note that the `STATUS` command is not supported in IMAP4.

Three classes are provided by the `imaplib` module, `IMAP4` is the base class :

`class imaplib.IMAP4([host[, port]])`

This class implements the actual IMAP4 protocol. The connection is created and protocol version (IMAP4 or IMAP4rev1) is determined when the instance is initialized. If *host* is not specified, '' (the local host) is used. If *port* is omitted, the standard IMAP4 port (143) is used.

Three exceptions are defined as attributes of the `IMAP4` class :

`exception IMAP4.error`

Exception raised on any errors. The reason for the exception is passed to the constructor as a string.

`exception IMAP4.abort`

IMAP4 server errors cause this exception to be raised. This is a sub-class of `IMAP4.error`. Note that closing the instance and instantiating a new one will usually allow recovery from this exception.

**exception IMAP4.readonly**

This exception is raised when a writable mailbox has its status changed by the server. This is a subclass of *IMAP4.error*. Some other client now has write permission, and the mailbox will need to be re-opened to re-obtain write permission.

There's also a subclass for secure connections :

```
class imaplib.IMAP4_SSL(host[, port[, keyfile[, certfile]]])
```

This is a subclass derived from *IMAP4* that connects over an SSL encrypted socket (to use this class you need a socket module that was compiled with SSL support). If *host* is not specified, '' (the local host) is used. If *port* is omitted, the standard IMAP4-over-SSL port (993) is used. *keyfile* and *certfile* are also optional - they can contain a PEM formatted private key and certificate chain file for the SSL connection.

The second subclass allows for connections created by a child process :

```
class imaplib.IMAP4_stream(command)
```

This is a subclass derived from *IMAP4* that connects to the *stdin/stdout* file descriptors created by passing *command* to *os.popen2()*.

Nouveau dans la version 2.3.

The following utility functions are defined :

```
imaplib.Internaldate2tuple(datestr)
```

Parse an IMAP4 INTERNALDATE string and return corresponding local time. The return value is a *time.struct\_time* instance or *None* if the string has wrong format.

```
imaplib.Int2AP(num)
```

Converts an integer into a string representation using characters from the set [A .. P].

```
imaplib.ParseFlags(flagstr)
```

Converts an IMAP4 FLAGS response to a tuple of individual flags.

```
imaplib.Time2Internaldate(date_time)
```

Convert *date\_time* to an IMAP4 INTERNALDATE representation. The return value is a string in the form : "DD-Mmm-YYYY HH:MM:SS +HHMM" (including double-quotes). The *date\_time* argument can be a number (int or float) representing seconds since epoch (as returned by *time.time()*), a 9-tuple representing local time (as returned by *time.localtime()*), or a double-quoted string. In the last case, it is assumed to already be in the correct format.

Note that IMAP4 message numbers change as the mailbox changes ; in particular, after an **EXPUNGE** command performs deletions the remaining messages are renumbered. So it is highly advisable to use UIDs instead, with the UID command.

At the end of the module, there is a test section that contains a more extensive example of usage.

**Voir aussi :**

Documents describing the protocol, and sources and binaries for servers implementing it, can all be found at the University of Washington's *IMAP Information Center* (<https://www.washington.edu/imap/>).

## 20.10.1 IMAP4 Objects

All IMAP4rev1 commands are represented by methods of the same name, either upper-case or lower-case.

All arguments to commands are converted to strings, except for **AUTHENTICATE**, and the last argument to **APPEND** which is passed as an IMAP4 literal. If necessary (the string contains IMAP4 protocol-sensitive characters and isn't enclosed with either parentheses or double quotes) each string is quoted. However, the *password* argument to the **LOGIN** command is always quoted. If you want to avoid having an argument string quoted (eg : the *flags* argument to **STORE**) then enclose the string in parentheses (eg : *r'(\Deleted)'*).

Each command returns a tuple : (type, [data, ...]) where *type* is usually 'OK' or 'NO', and *data* is either the text from the command response, or mandated results from the command. Each *data* is either a string, or a tuple. If a tuple, then the first part is the header of the response, and the second part contains the data (ie : “literal” value).

The *message\_set* options to commands below is a string specifying one or more messages to be acted upon. It may be a simple message number ('1'), a range of message numbers ('2:4'), or a group of non-contiguous ranges separated by commas ('1:3,6:9'). A range can contain an asterisk to indicate an infinite upper bound ('3:\*').

An *IMAP4* instance has the following methods :

**IMAP4.append**(*mailbox*, *flags*, *date\_time*, *message*)

Append *message* to named mailbox.

**IMAP4.authenticate**(*mechanism*, *authobject*)

Authenticate command — requires response processing.

*mechanism* specifies which authentication mechanism is to be used - it should appear in the instance variable *capabilities* in the form AUTH=*mechanism*.

*authobject* must be a callable object :

```
data = authobject(response)
```

It will be called to process server continuation responses. It should return **data** that will be encoded and sent to server. It should return **None** if the client abort response \* should be sent instead.

**IMAP4.check**()

Checkpoint mailbox on server.

**IMAP4.close**()

Close currently selected mailbox. Deleted messages are removed from writable mailbox. This is the recommended command before LOGOUT.

**IMAP4.copy**(*message\_set*, *new\_mailbox*)

Copy *message\_set* messages onto end of *new\_mailbox*.

**IMAP4.create**(*mailbox*)

Create new mailbox named *mailbox*.

**IMAP4.delete**(*mailbox*)

Delete old mailbox named *mailbox*.

**IMAP4.deleteacl**(*mailbox*, *who*)

Delete the ACLs (remove any rights) set for *who* on mailbox.

Nouveau dans la version 2.4.

**IMAP4.expunge**()

Permanently remove deleted items from selected mailbox. Generates an EXPUNGE response for each deleted message. Returned data contains a list of EXPUNGE message numbers in order received.

**IMAP4.fetch**(*message\_set*, *message\_parts*)

Fetch (parts of) messages. *message\_parts* should be a string of message part names enclosed within parentheses, eg : "(UID BODY[TEXT])". Returned data are tuples of message part envelope and data.

**IMAP4.getacl**(*mailbox*)

Get the ACLs for *mailbox*. The method is non-standard, but is supported by the Cyrus server.

**IMAP4.getannotation**(*mailbox*, *entry*, *attribute*)

Retrieve the specified ANNOTATIONS for *mailbox*. The method is non-standard, but is supported by the Cyrus server.

Nouveau dans la version 2.5.

**IMAP4.getquota(*root*)**

Get the **quota** *root*'s resource usage and limits. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

Nouveau dans la version 2.3.

**IMAP4.getquotaroot(*mailbox*)**

Get the list of **quota roots** for the named *mailbox*. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

Nouveau dans la version 2.3.

**IMAP4.list(*[directory[, pattern]]*)**

List mailbox names in *directory* matching *pattern*. *directory* defaults to the top-level mail folder, and *pattern* defaults to match anything. Returned data contains a list of LIST responses.

**IMAP4.login(*user, password*)**

Identify the client using a plaintext password. The *password* will be quoted.

**IMAP4.login\_cram\_md5(*user, password*)**

Force use of CRAM-MD5 authentication when identifying the client to protect the password. Will only work if the server **CAPABILITY** response includes the phrase **AUTH=CRAM-MD5**.

Nouveau dans la version 2.3.

**IMAP4.logout()**

Shutdown connection to server. Returns server BYE response.

**IMAP4.lsub(*[directory[, pattern]]*)**

List subscribed mailbox names in directory matching pattern. *directory* defaults to the top level directory and *pattern* defaults to match any mailbox. Returned data are tuples of message part envelope and data.

**IMAP4.myrights(*mailbox*)**

Show my ACLs for a mailbox (i.e. the rights that I have on mailbox).

Nouveau dans la version 2.4.

**IMAP4.namespace()**

Returns IMAP namespaces as defined in RFC2342.

Nouveau dans la version 2.3.

**IMAP4.noop()**

Send NOOP to server.

**IMAP4.open(*host, port*)**

Opens socket to *port* at *host*. This method is implicitly called by the *IMAP4* constructor. The connection objects established by this method will be used in the *IMAP4.read()*, *IMAP4.readline()*, *IMAP4.send()*, and *IMAP4.shutdown()* methods. You may override this method.

**IMAP4.partial(*message\_num, message\_part, start, length*)**

Fetch truncated part of a message. Returned data is a tuple of message part envelope and data.

**IMAP4.proxyauth(*user*)**

Assume authentication as *user*. Allows an authorised administrator to proxy into any user's mailbox.

Nouveau dans la version 2.3.

**IMAP4.read(*size*)**

Reads *size* bytes from the remote server. You may override this method.

**IMAP4.readline()**

Reads one line from the remote server. You may override this method.

**IMAP4.recent()**

Prompt server for an update. Returned data is **None** if no new messages, else value of RECENT response.

**IMAP4.rename**(*oldmailbox*, *newmailbox*)  
Rename mailbox named *oldmailbox* to *newmailbox*.

**IMAP4.response**(*code*)  
Return data for response *code* if received, or **None**. Returns the given code, instead of the usual type.

**IMAP4.search**(*charset*, *criterion*[, ...])  
Search mailbox for matching messages. *charset* may be **None**, in which case no **CHARSET** will be specified in the request to the server. The IMAP protocol requires that at least one criterion be specified; an exception will be raised when the server returns an error.  
Exemple :

```
# M is a connected IMAP4 instance...
typ, msgnums = M.search(None, 'FROM', '"LDJ"')

# or:
typ, msgnums = M.search(None, '(FROM "LDJ")')
```

**IMAP4.select**([*mailbox*[, *readonly*]])  
Select a mailbox. Returned data is the count of messages in *mailbox* (**EXISTS** response). The default *mailbox* is **'INBOX'**. If the *readonly* flag is set, modifications to the mailbox are not allowed.

**IMAP4.send**(*data*)  
Sends *data* to the remote server. You may override this method.

**IMAP4.setacl**(*mailbox*, *who*, *what*)  
Set an ACL for *mailbox*. The method is non-standard, but is supported by the Cyrus server.

**IMAP4.setannotation**(*mailbox*, *entry*, *attribute*[, ...])  
Set **ANNOTATIONS** for *mailbox*. The method is non-standard, but is supported by the Cyrus server.  
Nouveau dans la version 2.5.

**IMAP4.setquota**(*root*, *limits*)  
Set the **quota** *root*'s resource *limits*. This method is part of the IMAP4 QUOTA extension defined in rfc2087.  
Nouveau dans la version 2.3.

**IMAP4.shutdown**()  
Close connection established in **open**. This method is implicitly called by *IMAP4.logout()*. You may override this method.

**IMAP4.socket**()  
Returns socket instance used to connect to server.

**IMAP4.sort**(*sort\_criteria*, *charset*, *search\_criterion*[, ...])  
The **sort** command is a variant of **search** with sorting semantics for the results. Returned data contains a space separated list of matching message numbers.  
Sort has two arguments before the *search\_criterion* argument(s); a parenthesized list of *sort\_criteria*, and the searching *charset*. Note that unlike **search**, the searching *charset* argument is mandatory. There is also a **uid sort** command which corresponds to **sort** the way that **uid search** corresponds to **search**. The **sort** command first searches the mailbox for messages that match the given searching criteria using the *charset* argument for the interpretation of strings in the searching criteria. It then returns the numbers of matching messages.  
This is an **IMAP4rev1** extension command.

**IMAP4.status**(*mailbox*, *names*)  
Request named status conditions for *mailbox*.

**IMAP4.store**(*message\_set*, *command*, *flag\_list*)

Alters flag dispositions for messages in mailbox. *command* is specified by section 6.4.6 of [RFC 2060](#) as being one of « **FLAGS** », « **+FLAGS** », or « **-FLAGS** », optionally with a suffix of « **.SILENT** ». For example, to set the delete flag on all messages :

```
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    M.store(num, '+FLAGS', '\\Deleted')
M.expunge()
```

**IMAP4.subscribe**(*mailbox*)

Subscribe to new mailbox.

**IMAP4.thread**(*threading\_algorithm*, *charset*, *search\_criterion*[, ...])

The **thread** command is a variant of **search** with threading semantics for the results. Returned data contains a space separated list of thread members.

Thread members consist of zero or more messages numbers, delimited by spaces, indicating successive parent and child.

Thread has two arguments before the *search\_criterion* argument(s) ; a *threading\_algorithm*, and the searching *charset*. Note that unlike **search**, the searching *charset* argument is mandatory. There is also a **uid thread** command which corresponds to **thread** the way that **uid search** corresponds to **search**. The **thread** command first searches the mailbox for messages that match the given searching criteria using the *charset* argument for the interpretation of strings in the searching criteria. It then returns the matching messages threaded according to the specified threading algorithm.

This is an IMAP4rev1 extension command.

Nouveau dans la version 2.4.

**IMAP4.uid**(*command*, *arg*[, ...])

Execute command args with messages identified by UID, rather than message number. Returns response appropriate to command. At least one argument must be supplied ; if none are provided, the server will return an error and an exception will be raised.

**IMAP4.unsubscribe**(*mailbox*)

Unsubscribe from old mailbox.

**IMAP4.xatom**(*name*[, *arg*[, ...]])

Allow simple extension commands notified by server in **CAPABILITY** response.

Instances of *IMAP4\_SSL* have just one additional method :

**IMAP4\_SSL.ssl**()

Returns SSLObject instance used for the secure connection with the server.

The following attributes are defined on instances of *IMAP4* :

**IMAP4.PROTOCOL\_VERSION**

The most recent supported protocol in the **CAPABILITY** response from the server.

**IMAP4.debug**

Integer value to control debugging output. The initialize value is taken from the module variable **Debug**. Values greater than three trace each command.

## 20.10.2 IMAP4 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages :

```
import getpass, imaplib

M = imaplib.IMAP4()
M.login(getpass.getuser(), getpass.getpass())
M.select()
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    typ, data = M.fetch(num, '(RFC822)')
    print 'Message %s\n%s\n' % (num, data[0][1])
M.close()
M.logout()
```

## 20.11 nntplib — NNTP protocol client

Code source : [Lib/nntplib.py](#)

---

This module defines the class *NNTP* which implements the client side of the NNTP protocol. It can be used to implement a news reader or poster, or automated news processors. For more information on NNTP (Network News Transfer Protocol), see Internet [RFC 977](#).

Here are two small examples of how it can be used. To list some statistics about a newsgroup and print the subjects of the last 10 articles :

```
>>> s = NNTP('news.gmane.org')
>>> resp, count, first, last, name = s.group('gmane.comp.python.committers')
>>> print 'Group', name, 'has', count, 'articles, range', first, 'to', last
Group gmane.comp.python.committers has 1071 articles, range 1 to 1071
>>> resp, subs = s.xhdr('subject', first + '-' + last)
>>> for id, sub in subs[-10:]: print id, sub
...
1062 Re: Mercurial Status?
1063 Re: [python-committers] (Windows) buildbots on 3.x
1064 Re: Mercurial Status?
1065 Re: Mercurial Status?
1066 Python 2.6.6 status
1067 Commit Privileges for Ask Solem
1068 Re: Commit Privileges for Ask Solem
1069 Re: Commit Privileges for Ask Solem
1070 Re: Commit Privileges for Ask Solem
1071 2.6.6 rc 2
>>> s.quit()
'205 Bye!'
```

To post an article from a file (this assumes that the article has valid headers, and that you have right to post on the particular newsgroup) :

```
>>> s = NNTP('news.gmane.org')
>>> f = open('articlefile')
>>> s.post(f)
'240 Article posted successfully.'
>>> s.quit()
'205 Bye!'
```

The module itself defines the following items :

**class** `ntplib.NNTP(host[, port[, user[, password[, readermode][, usenetrc]]])`

Return a new instance of the *NNTP* class, representing a connection to the NNTP server running on host *host*, listening at port *port*. The default *port* is 119. If the optional *user* and *password* are provided, or if suitable credentials are present in *.netrc* and the optional flag *usenetcrc* is true (the default), the *AUTHINFO USER* and *AUTHINFO PASS* commands are used to identify and authenticate the user to the server. If the optional flag *readermode* is true, then a *mode reader* command is sent before authentication is performed. Reader mode is sometimes necessary if you are connecting to an NNTP server on the local machine and intend to call reader-specific commands, such as *group*. If you get unexpected *NNTPPermanentErrors*, you might need to set *readermode*. *readermode* defaults to *None*. *usenetcrc* defaults to *True*.

Modifié dans la version 2.4 : *usenetcrc* argument added.

**exception** `ntplib.NNTPError`

Derived from the standard exception *Exception*, this is the base class for all exceptions raised by the *ntplib* module.

**exception** `ntplib.NNTPReplyError`

Exception raised when an unexpected reply is received from the server. For backwards compatibility, the exception *error\_reply* is equivalent to this class.

**exception** `ntplib.NNTPTemporaryError`

Exception raised when an error code in the range 400–499 is received. For backwards compatibility, the exception *error\_temp* is equivalent to this class.

**exception** `ntplib.NNTPPermanentError`

Exception raised when an error code in the range 500–599 is received. For backwards compatibility, the exception *error\_perm* is equivalent to this class.

**exception** `ntplib.NNTPProtocolError`

Exception raised when a reply is received from the server that does not begin with a digit in the range 1–5. For backwards compatibility, the exception *error\_proto* is equivalent to this class.

**exception** `ntplib.NNTPDataError`

Exception raised when there is some error in the response data. For backwards compatibility, the exception *error\_data* is equivalent to this class.

### 20.11.1 NNTP Objects

NNTP instances have the following methods. The *response* that is returned as the first item in the return tuple of almost all methods is the server's response : a string beginning with a three-digit code. If the server's response indicates an error, the method raises one of the above exceptions.

**NNTP.getwelcome()**

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

**NNTP.set\_debuglevel(*level*)**

Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request or response. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the connection (including message text).

**NNTP.newgroups(*date*, *time*[, *file*])**

Send a *NEWGROUPS* command. The *date* argument should be a string of the form '*yymmdd*' indicating the date, and *time* should be a string of the form '*hhmmss*' indicating the time. Return a pair (*response*, *groups*) where *groups* is a list of group names that are new since the given date and time. If the *file* parameter is supplied, then the output of the *NEWGROUPS* command is stored in a file. If *file* is a string,

then the method will open a file object with that name, write to it then close it. If *file* is a file object, then it will start calling `write()` on it to store the lines of the command output. If *file* is supplied, then the returned *list* is an empty list.

`NNTP.newnews(group, date, time[, file])`

Send a NEWNEWS command. Here, *group* is a group name or '\*', and *date* and *time* have the same meaning as for `newgroups()`. Return a pair (`response`, `articles`) where *articles* is a list of message ids. If the *file* parameter is supplied, then the output of the NEWNEWS command is stored in a file. If *file* is a string, then the method will open a file object with that name, write to it then close it. If *file* is a file object, then it will start calling `write()` on it to store the lines of the command output. If *file* is supplied, then the returned *list* is an empty list.

`NNTP.list([file])`

Send a LIST command. Return a pair (`response`, `list`) where *list* is a list of tuples. Each tuple has the form (`group`, `last`, `first`, `flag`), where *group* is a group name, *last* and *first* are the last and first article numbers (as strings), and *flag* is 'y' if posting is allowed, 'n' if not, and 'm' if the newsgroup is moderated. (Note the ordering : *last*, *first*.) If the *file* parameter is supplied, then the output of the LIST command is stored in a file. If *file* is a string, then the method will open a file object with that name, write to it then close it. If *file* is a file object, then it will start calling `write()` on it to store the lines of the command output. If *file* is supplied, then the returned *list* is an empty list.

`NNTP.descriptions(grouppattern)`

Send a LIST NEWSGROUPS command, where *grouppattern* is a wildmat string as specified in RFC2980 (it's essentially the same as DOS or UNIX shell wildcard strings). Return a pair (`response`, `list`), where *list* is a list of tuples containing (`name`, `title`).

Nouveau dans la version 2.4.

`NNTP.description(group)`

Get a description for a single group *group*. If more than one group matches (if "group" is a real wildmat string), return the first match. If no group matches, return an empty string.

This elides the response code from the server. If the response code is needed, use `descriptions()`.

Nouveau dans la version 2.4.

`NNTP.group(name)`

Send a GROUP command, where *name* is the group name. Return a tuple (`response`, `count`, `first`, `last`, `name`) where *count* is the (estimated) number of articles in the group, *first* is the first article number in the group, *last* is the last article number in the group, and *name* is the group name. The numbers are returned as strings.

`NNTP.help([file])`

Send a HELP command. Return a pair (`response`, `list`) where *list* is a list of help strings. If the *file* parameter is supplied, then the output of the HELP command is stored in a file. If *file* is a string, then the method will open a file object with that name, write to it then close it. If *file* is a file object, then it will start calling `write()` on it to store the lines of the command output. If *file* is supplied, then the returned *list* is an empty list.

`NNTP.stat(id)`

Send a STAT command, where *id* is the message id (enclosed in '<' and '>') or an article number (as a string). Return a triple (`response`, `number`, `id`) where *number* is the article number (as a string) and *id* is the message id (enclosed in '<' and '>').

`NNTP.next()`

Send a NEXT command. Return as for `stat()`.

`NNTP.last()`

Send a LAST command. Return as for `stat()`.

**NNTP.head(*id*)**

Send a HEAD command, where *id* has the same meaning as for *stat()*. Return a tuple (**response**, **number**, **id**, **list**) where the first three are the same as for *stat()*, and *list* is a list of the article's headers (an uninterpreted list of lines, without trailing newlines).

**NNTP.body(*id*[, *file*])**

Send a BODY command, where *id* has the same meaning as for *stat()*. If the *file* parameter is supplied, then the body is stored in a file. If *file* is a string, then the method will open a file object with that name, write to it then close it. If *file* is a file object, then it will start calling *write()* on it to store the lines of the body. Return as for *head()*. If *file* is supplied, then the returned *list* is an empty list.

**NNTP.article(*id*)**

Send an ARTICLE command, where *id* has the same meaning as for *stat()*. Return as for *head()*.

**NNTP.slave()**

Send a SLAVE command. Return the server's *response*.

**NNTP.xhdr(*header*, *string*[, *file*])**

Send an XHDR command. This command is not defined in the RFC but is a common extension. The *header* argument is a header keyword, e.g. 'subject'. The *string* argument should have the form 'first-last' where *first* and *last* are the first and last article numbers to search. Return a pair (**response**, **list**), where *list* is a list of pairs (**id**, **text**), where *id* is an article number (as a string) and *text* is the text of the requested header for that article. If the *file* parameter is supplied, then the output of the XHDR command is stored in a file. If *file* is a string, then the method will open a file object with that name, write to it then close it. If *file* is a file object, then it will start calling *write()* on it to store the lines of the command output. If *file* is supplied, then the returned *list* is an empty list.

**NNTP.post(*file*)**

Post an article using the POST command. The *file* argument is an open file object which is read until EOF using its *readline()* method. It should be a well-formed news article, including the required headers. The *post()* method automatically escapes lines beginning with ..

**NNTP.ihave(*id*, *file*)**

Send an IHAVE command. *id* is a message id (enclosed in '<' and '>'). If the response is not an error, treat *file* exactly as for the *post()* method.

**NNTP.date()**

Return a triple (**response**, **date**, **time**), containing the current date and time in a form suitable for the *newnews()* and *newgroups()* methods. This is an optional NNTP extension, and may not be supported by all servers.

**NNTP.xgtitle(*name*[, *file*])**

Process an XGTITLE command, returning a pair (**response**, **list**), where *list* is a list of tuples containing (**name**, **title**). If the *file* parameter is supplied, then the output of the XGTITLE command is stored in a file. If *file* is a string, then the method will open a file object with that name, write to it then close it. If *file* is a file object, then it will start calling *write()* on it to store the lines of the command output. If *file* is supplied, then the returned *list* is an empty list. This is an optional NNTP extension, and may not be supported by all servers.

RFC2980 says « It is suggested that this extension be deprecated ». Use *descriptions()* or *description()* instead.

**NNTP.xover(*start*, *end*[, *file*])**

Return a pair (**resp**, **list**). *list* is a list of tuples, one for each article in the range delimited by the *start* and *end* article numbers. Each tuple is of the form (**article number**, **subject**, **poster**, **date**, **id**, **references**, **size**, **lines**). If the *file* parameter is supplied, then the output of the XOVER command is stored in a file. If *file* is a string, then the method will open a file object with that name, write to it then close it. If *file* is a file object, then it will start calling *write()* on it to store the lines

of the command output. If *file* is supplied, then the returned *list* is an empty list. This is an optional NNTP extension, and may not be supported by all servers.

**NNTP.xpath(*id*)**

Return a pair (**resp**, **path**), where *path* is the directory path to the article with message ID *id*. This is an optional NNTP extension, and may not be supported by all servers.

**NNTP.quit()**

Send a QUIT command and close the connection. Once this method has been called, no other methods of the NNTP object should be called.

## 20.12 smtplib — SMTP protocol client

Code source : [Lib/smtplib.py](#)

---

The *smtplib* module defines an SMTP client session object that can be used to send mail to any Internet machine with an SMTP or ESMTP listener daemon. For details of SMTP and ESMTP operation, consult [RFC 821](#) (Simple Mail Transfer Protocol) and [RFC 1869](#) (SMTP Service Extensions).

**class smtplib.SMTP([*host*[, *port*[, *local\_hostname*[, *timeout*]]]])**

An *SMTP* instance encapsulates an SMTP connection. It has methods that support a full repertoire of SMTP and ESMTP operations. If the optional *host* and *port* parameters are given, the *SMTP.connect()* method is called with those parameters during initialization. If specified, *local\_hostname* is used as the FQDN of the local host in the HELO/EHLO command. Otherwise, the local hostname is found using *socket.getfqdn()*. If the *connect()* call returns anything other than a success code, an *SMTPConnectError* is raised. The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). If the timeout expires, *socket.timeout* is raised.

For normal use, you should only require the initialization/connect, *sendmail()*, and *SMTP.quit()* methods. An example is included below.

Modifié dans la version 2.6 : Ajout de *timeout*.

**class smtplib.SMTP\_SSL([*host*[, *port*[, *local\_hostname*[, *keyfile*[, *certfile*[, *timeout*]]]]]])**

An *SMTP\_SSL* instance behaves exactly the same as instances of *SMTP*. *SMTP\_SSL* should be used for situations where SSL is required from the beginning of the connection and using *starttls()* is not appropriate. If *host* is not specified, the local host is used. If *port* is omitted, the standard SMTP-over-SSL port (465) is used. *local\_hostname* has the same meaning as it does for the *SMTP* class. *keyfile* and *certfile* are also optional, and can contain a PEM formatted private key and certificate chain file for the SSL connection. The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). If the timeout expires, *socket.timeout* is raised.

Nouveau dans la version 2.6.

**class smtplib.LMTP([*host*[, *port*[, *local\_hostname*]]])**

The LMTP protocol, which is very similar to ESMTP, is heavily based on the standard SMTP client. It's common to use Unix sockets for LMTP, so our *connect()* method must support that as well as a regular host :port server. *local\_hostname* has the same meaning as it does for the *SMTP* class. To specify a Unix socket, you must use an absolute path for *host*, starting with a "/".

Authentication is supported, using the regular SMTP mechanism. When using a Unix socket, LMTP generally don't support or require any authentication, but your mileage might vary.

Nouveau dans la version 2.6.

A nice selection of exceptions is defined as well :

**exception `smtplib.SMTPException`**

The base exception class for all the other exceptions provided by this module.

**exception `smtplib.SMTPServerDisconnected`**

This exception is raised when the server unexpectedly disconnects, or when an attempt is made to use the *SMTP* instance before connecting it to a server.

**exception `smtplib.SMTPResponseException`**

Base class for all exceptions that include an SMTP error code. These exceptions are generated in some instances when the SMTP server returns an error code. The error code is stored in the `smtp_code` attribute of the error, and the `smtp_error` attribute is set to the error message.

**exception `smtplib.SMTPSenderRefused`**

Sender address refused. In addition to the attributes set by on all *SMTPResponseException* exceptions, this sets “sender” to the string that the SMTP server refused.

**exception `smtplib.SMTPRecipientsRefused`**

All recipient addresses refused. The errors for each recipient are accessible through the attribute `recipients`, which is a dictionary of exactly the same sort as *SMTP.sendmail()* returns.

**exception `smtplib.SMTPDataError`**

The SMTP server refused to accept the message data.

**exception `smtplib.SMTPConnectError`**

Error occurred during establishment of a connection with the server.

**exception `smtplib.SMTPHeloError`**

The server refused our HELO message.

**exception `smtplib.SMTPAuthenticationError`**

SMTP authentication went wrong. Most probably the server didn’t accept the username/password combination provided.

Voir aussi :

**RFC 821 - Simple Mail Transfer Protocol** Protocol definition for SMTP. This document covers the model, operating procedure, and protocol details for SMTP.

**RFC 1869 - SMTP Service Extensions** Definition of the ESMTP extensions for SMTP. This describes a framework for extending SMTP with new commands, supporting dynamic discovery of the commands provided by the server, and defines a few additional commands.

## 20.12.1 SMTP Objects

An *SMTP* instance has the following methods :

**`SMTP.set_debuglevel(level)`**

Set the debug output level. A true value for *level* results in debug messages for connection and for all messages sent to and received from the server.

**`SMTP.docmd(cmd[, argstring])`**

Send a command *cmd* to the server. The optional argument *argstring* is simply concatenated to the command, separated by a space.

This returns a 2-tuple composed of a numeric response code and the actual response line (multiline responses are joined into one long line.)

In normal operation it should not be necessary to call this method explicitly. It is used to implement other methods and may be useful for testing private extensions.

If the connection to the server is lost while waiting for the reply, *SMTPServerDisconnected* will be raised.

`SMTP.connect([host[, port]])`

Connect to a host on a given port. The defaults are to connect to the local host at the standard SMTP port (25). If the hostname ends with a colon (':') followed by a number, that suffix will be stripped off and the number interpreted as the port number to use. This method is automatically invoked by the constructor if a host is specified during instantiation. Returns a 2-tuple of the response code and message sent by the server in its connection response.

`SMTP.helo([hostname])`

Identify yourself to the SMTP server using HELO. The hostname argument defaults to the fully qualified domain name of the local host. The message returned by the server is stored as the `helo_resp` attribute of the object.

In normal operation it should not be necessary to call this method explicitly. It will be implicitly called by the `sendmail()` when necessary.

`SMTP.ehlo([hostname])`

Identify yourself to an ESMTP server using EHLO. The hostname argument defaults to the fully qualified domain name of the local host. Examine the response for ESMTP option and store them for use by `has_extn()`. Also sets several informational attributes : the message returned by the server is stored as the `ehlo_resp` attribute, `does_esmtp` is set to true or false depending on whether the server supports ESMTP, and `esmtp_features` will be a dictionary containing the names of the SMTP service extensions this server supports, and their parameters (if any).

Unless you wish to use `has_extn()` before sending mail, it should not be necessary to call this method explicitly. It will be implicitly called by `sendmail()` when necessary.

`SMTP.ehlo_or_helo_if_needed()`

This method call `ehlo()` and or `helo()` if there has been no previous EHLO or HELO command this session. It tries ESMTP EHLO first.

**SMTPHeloError** The server didn't reply properly to the HELO greeting.

Nouveau dans la version 2.6.

`SMTP.has_extn(name)`

Return `True` if `name` is in the set of SMTP service extensions returned by the server, `False` otherwise. Case is ignored.

`SMTP.verify(address)`

Check the validity of an address on this server using SMTP VRFY. Returns a tuple consisting of code 250 and a full **RFC 822** address (including human name) if the user address is valid. Otherwise returns an SMTP error code of 400 or greater and an error string.

---

**Note :** Many sites disable SMTP VRFY in order to foil spammers.

---

`SMTP.login(user, password)`

Log in on an SMTP server that requires authentication. The arguments are the username and the password to authenticate with. If there has been no previous EHLO or HELO command this session, this method tries ESMTP EHLO first. This method will return normally if the authentication was successful, or may raise the following exceptions :

**SMTPHeloError** The server didn't reply properly to the HELO greeting.

**SMTPAuthenticationError** The server didn't accept the username/password combination.

**SMTPException** No suitable authentication method was found.

`SMTP.starttls([keyfile[, certfile]])`

Put the SMTP connection in TLS (Transport Layer Security) mode. All SMTP commands that follow will be encrypted. You should then call `ehlo()` again.

If `keyfile` and `certfile` are provided, these are passed to the `socket` module's `ssl()` function.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first. Modifié dans la version 2.6.

**`SMTPHeloError`** The server didn't reply properly to the `HELO` greeting.

**`SMTPException`** The server does not support the `STARTTLS` extension.

Modifié dans la version 2.6.

**`RuntimeError`** SSL/TLS support is not available to your Python interpreter.

**`SMTP.sendmail`**(*from\_addr*, *to\_addrs*, *msg*[, *mail\_options*, *rcpt\_options*])

Send mail. The required arguments are an **RFC 822** from-address string, a list of **RFC 822** to-address strings (a bare string will be treated as a list with 1 address), and a message string. The caller may pass a list of ESMTP options (such as `8bitmime`) to be used in `MAIL FROM` commands as *mail\_options*. ESMTP options (such as `DSN` commands) that should be used with all `RCPT` commands can be passed as *rcpt\_options*. (If you need to use different ESMTP options to different recipients you have to use the low-level methods such as `mail()`, `rcpt()` and `data()` to send the message.)

---

**Note :** The *from\_addr* and *to\_addrs* parameters are used to construct the message envelope used by the transport agents. The **`SMTP`** does not modify the message headers in any way.

---

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first. If the server does ESMTP, message size and each of the specified options will be passed to it (if the option is in the feature set the server advertises). If `EHLO` fails, `HELO` will be tried and ESMTP options suppressed.

This method will return normally if the mail is accepted for at least one recipient. Otherwise it will raise an exception. That is, if this method does not raise an exception, then someone should get your mail. If this method does not raise an exception, it returns a dictionary, with one entry for each recipient that was refused. Each entry contains a tuple of the SMTP error code and the accompanying error message sent by the server.

This method may raise the following exceptions :

**`SMTPRecipientsRefused`** All recipients were refused. Nobody got the mail. The `recipients` attribute of the exception object is a dictionary with information about the refused recipients (like the one returned when at least one recipient was accepted).

**`SMTPHeloError`** The server didn't reply properly to the `HELO` greeting.

**`SMTPSenderRefused`** The server didn't accept the *from\_addr*.

**`SMTPDataError`** The server replied with an unexpected error code (other than a refusal of a recipient).

Unless otherwise noted, the connection will be open even after an exception is raised.

**`SMTP.quit`**()

Terminate the SMTP session and close the connection. Return the result of the SMTP `QUIT` command.

Modifié dans la version 2.6 : Return a value.

Low-level methods corresponding to the standard SMTP/ESMTP commands `HELP`, `RSET`, `NOOP`, `MAIL`, `RCPT`, and `DATA` are also supported. Normally these do not need to be called directly, so they are not documented here. For details, consult the module code.

## 20.12.2 SMTP Example

This example prompts the user for addresses needed in the message envelope ("To" and "From" addresses), and the message to be delivered. Note that the headers to be included with the message must be included in the message as entered ; this example doesn't do any processing of the **RFC 822** headers. In particular, the "To" and "From" addresses must be included in the message headers explicitly.

```
import smtplib

def prompt(prompt):
    return raw_input(prompt).strip()

fromaddr = prompt("From: ")
toaddrs = prompt("To: ").split()
print "Enter message, end with ^D (Unix) or ^Z (Windows):"

# Add the From: and To: headers at the start!
msg = ("From: %s\r\nTo: %s\r\n\r\n"
       % (fromaddr, ", ".join(toaddrs)))
while 1:
    try:
        line = raw_input()
    except EOFError:
        break
    if not line:
        break
    msg = msg + line

print "Message length is " + repr(len(msg))

server = smtplib.SMTP('localhost')
server.set_debuglevel(1)
server.sendmail(fromaddr, toaddrs, msg)
server.quit()
```

---

**Note :** In general, you will want to use the [email](#) package's features to construct an email message, which you can then convert to a string and send via `sendmail()`; see [email : Examples](#).

---

## 20.13 smtpd — SMTP Server

Code source : [Lib/smtpd.py](#)

---

This module offers several classes to implement SMTP servers. One is a generic do-nothing implementation, which can be overridden, while the other two offer specific mail-sending strategies.

### 20.13.1 SMTPServer Objects

`class smtpd.SMTPServer(localaddr, remoteaddr)`

Create a new *SMTPServer* object, which binds to local address *localaddr*. It will treat *remoteaddr* as an upstream SMTP relay. Both *localaddr* and *remoteaddr* should be a *(host, port)* tuple. The object inherits from *asyncore.dispatcher*, and so will insert itself into *asyncore*'s event loop on instantiation.

`process_message(peer, mailfrom, rcpttos, data)`

Raise *NotImplementedError* exception. Override this in subclasses to do something useful with this message. Whatever was passed in the constructor as *remoteaddr* will be available as the `_remoteaddr` attribute. *peer* is the remote host's address, *mailfrom* is the envelope originator,

*rcpttos* are the envelope recipients and *data* is a string containing the contents of the e-mail (which should be in [RFC 2822](#) format).

### 20.13.2 DebuggingServer Objects

**class** smtpd.DebuggingServer(*localaddr*, *remoteaddr*)

Create a new debugging server. Arguments are as per [SMTPServer](#). Messages will be discarded, and printed on stdout.

### 20.13.3 PureProxy Objects

**class** smtpd.PureProxy(*localaddr*, *remoteaddr*)

Create a new pure proxy server. Arguments are as per [SMTPServer](#). Everything will be relayed to *remoteaddr*. Note that running this has a good chance to make you into an open relay, so please be careful.

### 20.13.4 MailmanProxy Objects

**class** smtpd.MailmanProxy(*localaddr*, *remoteaddr*)

Create a new pure proxy server. Arguments are as per [SMTPServer](#). Everything will be relayed to *remoteaddr*, unless local mailman configurations knows about an address, in which case it will be handled via mailman. Note that running this has a good chance to make you into an open relay, so please be careful.

## 20.14 telnetlib — Telnet client

Code source : [Lib/telnetlib.py](#)

The [telnetlib](#) module provides a [Telnet](#) class that implements the Telnet protocol. See [RFC 854](#) for details about the protocol. In addition, it provides symbolic constants for the protocol characters (see below), and for the telnet options. The symbolic names of the telnet options follow the definitions in [arpa/telnet.h](#), with the leading `TELOPT_` removed. For symbolic names of options which are traditionally not included in [arpa/telnet.h](#), see the module source itself.

The symbolic constants for the telnet commands are : IAC, DONT, DO, WONT, WILL, SE (Subnegotiation End), NOP (No Operation), DM (Data Mark), BRK (Break), IP (Interrupt process), AO (Abort output), AYT (Are You There), EC (Erase Character), EL (Erase Line), GA (Go Ahead), SB (Subnegotiation Begin).

**class** telnetlib.Telnet(*[host[, port[, timeout]]]*)

[Telnet](#) represents a connection to a Telnet server. The instance is initially not connected by default ; the [open\(\)](#) method must be used to establish a connection. Alternatively, the host name and optional port number can be passed to the constructor, to, in which case the connection to the server will be established before the constructor returns. The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not reopen an already connected instance.

This class has many `read_*()` methods. Note that some of them raise [EOFError](#) when the end of the connection is read, because they can return an empty string for other reasons. See the individual descriptions below.

Modifié dans la version 2.6 : Ajout de *timeout*.

Voir aussi :

[RFC 854 - Telnet Protocol Specification](#) Definition of the Telnet protocol.

### 20.14.1 Telnet Objects

*Telnet* instances have the following methods :

`Telnet.read_until(expected[, timeout])`

Read until a given string, *expected*, is encountered or until *timeout* seconds have passed.

When no match is found, return whatever is available instead, possibly the empty string. Raise *EOFError* if the connection is closed and no cooked data is available.

`Telnet.read_all()`

Read all data until EOF ; block until connection closed.

`Telnet.read_some()`

Read at least one byte of cooked data unless EOF is hit. Return '' if EOF is hit. Block if no data is immediately available.

`Telnet.read_very_eager()`

Read everything that can be without blocking in I/O (eager).

Raise *EOFError* if connection closed and no cooked data available. Return '' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

`Telnet.read_eager()`

Read readily available data.

Raise *EOFError* if connection closed and no cooked data available. Return '' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

`Telnet.read_lazy()`

Process and return data already in the queues (lazy).

Raise *EOFError* if connection closed and no data available. Return '' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

`Telnet.read_very_lazy()`

Return any data available in the cooked queue (very lazy).

Raise *EOFError* if connection closed and no data available. Return '' if no cooked data available otherwise. This method never blocks.

`Telnet.read_sb_data()`

Return the data collected between a SB/SE pair (suboption begin/end). The callback should access these data when it was invoked with a SE command. This method never blocks.

Nouveau dans la version 2.3.

`Telnet.open(host[, port[, timeout]])`

Connect to a host. The optional second argument is the port number, which defaults to the standard Telnet port (23). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not try to reopen an already connected instance.

Modifié dans la version 2.6 : Ajout de *timeout*.

`Telnet.msg(msg[, *args])`

Print a debug message when the debug level is > 0. If extra arguments are present, they are substituted in the message using the standard string formatting operator.

`Telnet.set_debuglevel(debuglevel)`

Set the debug level. The higher the value of *debuglevel*, the more debug output you get (on `sys.stdout`).

`Telnet.close()`

Close the connection.

`Telnet.get_socket()`

Return the socket object used internally.

`Telnet.fileno()`

Return the file descriptor of the socket object used internally.

`Telnet.write(buffer)`

Write a string to the socket, doubling any IAC characters. This can block if the connection is blocked. May raise `socket.error` if the connection is closed.

`Telnet.interact()`

Interaction function, emulates a very dumb Telnet client.

`Telnet.mt_interact()`

Multithreaded version of `interact()`.

`Telnet.expect(list[, timeout])`

Read until one from a list of a regular expressions matches.

The first argument is a list of regular expressions, either compiled (**regex objects**) or uncompiled (strings). The optional second argument is a timeout, in seconds; the default is to block indefinitely.

Return a tuple of three items : the index in the list of the first regular expression that matches; the match object returned; and the text read up till and including the match.

If end of file is found and no text was read, raise `EOFError`. Otherwise, when nothing matches, return `(-1, None, text)` where `text` is the text received so far (may be the empty string if a timeout happened).

If a regular expression ends with a greedy match (such as `.*`) or if more than one expression can match the same input, the results are non-deterministic, and may depend on the I/O timing.

`Telnet.set_option_negotiation_callback(callback)`

Each time a telnet option is read on the input flow, this `callback` (if set) is called with the following parameters : `callback(telnet socket, command (DO/DONT/WILL/WONT), option)`. No other action is done afterwards by `telnetlib`.

## 20.14.2 Telnet Example

A simple example illustrating typical use :

```
import getpass
import sys
import telnetlib

HOST = "localhost"
user = raw_input("Enter your remote account: ")
password = getpass.getpass()

tn = telnetlib.Telnet(HOST)

tn.read_until("login: ")
tn.write(user + "\n")
if password:
    tn.read_until("Password: ")
    tn.write(password + "\n")

tn.write("ls\n")
tn.write("exit\n")

print tn.read_all()
```

## 20.15 uuid — UUID objects according to RFC 4122

Nouveau dans la version 2.5.

This module provides immutable *UUID* objects (the *UUID* class) and the functions *uuid1()*, *uuid3()*, *uuid4()*, *uuid5()* for generating version 1, 3, 4, and 5 UUIDs as specified in [RFC 4122](#).

If all you want is a unique ID, you should probably call *uuid1()* or *uuid4()*. Note that *uuid1()* may compromise privacy since it creates a UUID containing the computer's network address. *uuid4()* creates a random UUID.

```
class uuid.UUID([hex[, bytes[, bytes_le[, fields[, int[, version]]]]])
```

Create a UUID from either a string of 32 hexadecimal digits, a string of 16 bytes in big-endian order as the *bytes* argument, a string of 16 bytes in little-endian order as the *bytes\_le* argument, a tuple of six integers (32-bit *time\_low*, 16-bit *time\_mid*, 16-bit *time\_hi\_version*, 8-bit *clock\_seq\_hi\_variant*, 8-bit *clock\_seq\_low*, 48-bit *node*) as the *fields* argument, or a single 128-bit integer as the *int* argument. When a string of hex digits is given, curly braces, hyphens, and a URN prefix are all optional. For example, these expressions all yield the same UUID :

```
UUID('{12345678-1234-5678-1234-567812345678}')
UUID('12345678123456781234567812345678')
UUID('urn:uuid:12345678-1234-5678-1234-567812345678')
UUID(bytes='\x12\x34\x56\x78'*4)
UUID(bytes_le='\x78\x56\x34\x12\x34\x12\x78\x56' +
              '\x12\x34\x56\x78\x12\x34\x56\x78')
UUID(fields=(0x12345678, 0x1234, 0x5678, 0x12, 0x34, 0x567812345678))
UUID(int=0x12345678123456781234567812345678)
```

Exactly one of *hex*, *bytes*, *bytes\_le*, *fields*, or *int* must be given. The *version* argument is optional; if given, the resulting UUID will have its variant and version number set according to RFC 4122, overriding bits in the given *hex*, *bytes*, *bytes\_le*, *fields*, or *int*.

*UUID* instances have these read-only attributes :

**UUID.bytes**

The UUID as a 16-byte string (containing the six integer fields in big-endian byte order).

**UUID.bytes\_le**

The UUID as a 16-byte string (with *time\_low*, *time\_mid*, and *time\_hi\_version* in little-endian byte order).

**UUID.fields**

A tuple of the six integer fields of the UUID, which are also available as six individual attributes and two derived attributes :

Field	Signification
<code>time_low</code>	the first 32 bits of the UUID
<code>time_mid</code>	the next 16 bits of the UUID
<code>time_hi_version</code>	the next 16 bits of the UUID
<code>clock_seq_hi_variant</code>	the next 8 bits of the UUID
<code>clock_seq_low</code>	the next 8 bits of the UUID
<code>node</code>	the last 48 bits of the UUID
<code>time</code>	the 60-bit timestamp
<code>clock_seq</code>	the 14-bit sequence number

**UUID.hex**

The UUID as a 32-character hexadecimal string.

**UUID.int**

The UUID as a 128-bit integer.

**UUID.urn**

The UUID as a URN as specified in RFC 4122.

**UUID.variant**

The UUID variant, which determines the internal layout of the UUID. This will be one of the constants [RESERVED\\_NCS](#), [RFC\\_4122](#), [RESERVED\\_MICROSOFT](#), or [RESERVED\\_FUTURE](#).

**UUID.version**

The UUID version number (1 through 5, meaningful only when the variant is [RFC\\_4122](#)).

The [uuid](#) module defines the following functions :

**uuid.getnode()**

Get the hardware address as a 48-bit positive integer. The first time this runs, it may launch a separate program, which could be quite slow. If all attempts to obtain the hardware address fail, we choose a random 48-bit number with its eighth bit set to 1 as recommended in RFC 4122. « Hardware address » means the MAC address of a network interface, and on a machine with multiple network interfaces the MAC address of any one of them may be returned.

**uuid.uuid1([node[, clock\_seq]])**

Generate a UUID from a host ID, sequence number, and the current time. If *node* is not given, [getnode\(\)](#) is used to obtain the hardware address. If *clock\_seq* is given, it is used as the sequence number ; otherwise a random 14-bit sequence number is chosen.

**uuid.uuid3(namespace, name)**

Generate a UUID based on the MD5 hash of a namespace identifier (which is a UUID) and a name (which is a string).

**uuid.uuid4()**

Generate a random UUID.

**uuid.uuid5(namespace, name)**

Generate a UUID based on the SHA-1 hash of a namespace identifier (which is a UUID) and a name (which is a string).

The [uuid](#) module defines the following namespace identifiers for use with [uuid3\(\)](#) or [uuid5\(\)](#).

**uuid.NAMESPACE\_DNS**

When this namespace is specified, the *name* string is a fully-qualified domain name.

**uuid.NAMESPACE\_URL**

When this namespace is specified, the *name* string is a URL.

**uuid.NAMESPACE\_OID**

When this namespace is specified, the *name* string is an ISO OID.

**uuid.NAMESPACE\_X500**

When this namespace is specified, the *name* string is an X.500 DN in DER or a text output format.

The [uuid](#) module defines the following constants for the possible values of the **variant** attribute :

**uuid.RESERVED\_NCS**

Reserved for NCS compatibility.

**uuid.RFC\_4122**

Specifies the UUID layout given in [RFC 4122](#).

**uuid.RESERVED\_MICROSOFT**

Reserved for Microsoft compatibility.

`uuid.RESERVED_FUTURE`

Reserved for future definition.

Voir aussi :

**RFC 4122 - A Universally Unique IDentifier (UUID) URN Namespace** This specification defines a Uniform Resource Name namespace for UUIDs, the internal format of UUIDs, and methods of generating UUIDs.

### 20.15.1 Exemple

Here are some examples of typical usage of the `uuid` module :

```
>>> import uuid

>>> # make a UUID based on the host ID and current time
>>> uuid.uuid1()
UUID('a8098c1a-f86e-11da-bd1a-00112444be1e')

>>> # make a UUID using an MD5 hash of a namespace UUID and a name
>>> uuid.uuid3(uuid.NAMESPACE_DNS, 'python.org')
UUID('6fa459ea-ee8a-3ca4-894e-db77e160355e')

>>> # make a random UUID
>>> uuid.uuid4()
UUID('16fd2706-8baf-433b-82eb-8c7fada847da')

>>> # make a UUID using a SHA-1 hash of a namespace UUID and a name
>>> uuid.uuid5(uuid.NAMESPACE_DNS, 'python.org')
UUID('886313e1-3b8a-5372-9b90-0c9aee199e5d')

>>> # make a UUID from a string of hex digits (braces and hyphens ignored)
>>> x = uuid.UUID('{00010203-0405-0607-0809-0a0b0c0d0e0f}')

>>> # convert a UUID to a string of hex digits in standard form
>>> str(x)
'00010203-0405-0607-0809-0a0b0c0d0e0f'

>>> # get the raw 16 bytes of the UUID
>>> x.bytes
'\x00\x01\x02\x03\x04\x05\x06\x07\x08\t\n\x0b\x0c\r\x0e\x0f'

>>> # make a UUID from a 16-byte string
>>> uuid.UUID(bytes=x.bytes)
UUID('00010203-0405-0607-0809-0a0b0c0d0e0f')
```

## 20.16 urlparse — Parse URLs into components

---

**Note :** The `urlparse` module is renamed to `urllib.parse` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

**Source code :** `Lib/urlparse.py`

This module defines a standard interface to break Uniform Resource Locator (URL) strings up in components (addressing scheme, network location, path etc.), to combine the components back into a URL string, and to convert a « relative URL » to an absolute URL given a « base URL. »

The module has been designed to match the Internet RFC on Relative Uniform Resource Locators. It supports the following URL schemes : `file`, `ftp`, `gopher`, `hdl`, `http`, `https`, `imap`, `mailto`, `mms`, `news`, `nntp`, `prospero`, `rsync`, `rtsp`, `rtspu`, `sftp`, `shttp`, `sip`, `sips`, `snews`, `svn`, `svn+ssh`, `telnet`, `wais`.

Nouveau dans la version 2.5 : Support for the `sftp` and `sips` schemes.

The `urlparse` module defines the following functions :

`urlparse.urlparse(urlstring[, scheme[, allow_fragments]])`

Parse a URL into six components, returning a 6-tuple. This corresponds to the general structure of a URL : `scheme://netloc/path;parameters?query#fragment`. Each tuple item is a string, possibly empty. The components are not broken up in smaller parts (for example, the network location is a single string), and % escapes are not expanded. The delimiters as shown above are not part of the result, except for a leading slash in the *path* component, which is retained if present. For example :

```
>>> from urlparse import urlparse
>>> o = urlparse('http://www.cwi.nl:80/%7Eguido/Python.html')
>>> o      # doctest: +NORMALIZE_WHITESPACE
ParseResult(scheme='http', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> o.scheme
'http'
>>> o.port
80
>>> o.geturl()
'http://www.cwi.nl:80/%7Eguido/Python.html'
```

Following the syntax specifications in [RFC 1808](#), `urlparse` recognizes a netloc only if it is properly introduced by “//”. Otherwise the input is presumed to be a relative URL and thus to start with a path component.

```
>>> from urlparse import urlparse
>>> urlparse('//www.cwi.nl:80/%7Eguido/Python.html')
ParseResult(scheme='', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> urlparse('www.cwi.nl/%7Eguido/Python.html')
ParseResult(scheme='', netloc='', path='www.cwi.nl/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> urlparse('help/Python.html')
ParseResult(scheme='', netloc='', path='help/Python.html', params='',
            query='', fragment='')
```

If the *scheme* argument is specified, it gives the default addressing scheme, to be used only if the URL does not specify one. The default value for this argument is the empty string.

If the *allow\_fragments* argument is false, fragment identifiers are not recognized and parsed as part of the preceding component, even if the URL’s addressing scheme normally does support them. The default value for this argument is `True`.

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes :

Attribut	Index	Valeur	Value if not present
<code>scheme</code>	0	URL scheme specifier	<i>scheme</i> parameter
<code>netloc</code>	1	Network location part	empty string
<code>path</code>	2	Hierarchical path	empty string
<code>params</code>	3	Parameters for last path element	empty string
<code>query</code>	4	Query component	empty string
<code>fragment</code>	5	Fragment identifier	empty string
<code>username</code>		User name	<i>None</i>
<code>password</code>		Password	<i>None</i>
<code>hostname</code>		Host name (lower case)	<i>None</i>
<code>port</code>		Port number as integer, if present	<i>None</i>

See section [Results of `urlparse\(\)` and `urlsplit\(\)`](#) for more information on the result object.

Modifié dans la version 2.5 : Added attributes to return value.

Modifié dans la version 2.7 : Added IPv6 URL parsing capabilities.

`urlparse.parse_qs(qs[, keep_blank_values[, strict_parsing[, max_num_fields]])]`

Parse a query string given as a string argument (data of type *application/x-www-form-urlencoded*). Data are returned as a dictionary. The dictionary keys are the unique query variable names and the values are lists of values for each name.

The optional argument *keep\_blank\_values* is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument *strict\_parsing* is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a *ValueError* exception.

The optional argument *max\_num\_fields* is the maximum number of fields to read. If set, then throws a *ValueError* if there are more than *max\_num\_fields* fields read.

Use the [`urllib.urlencode\(\)`](#) function to convert such dictionaries into query strings.

Nouveau dans la version 2.6 : Copied from the *cgi* module.

Modifié dans la version 2.7.16 : Added *max\_num\_fields* parameter.

`urlparse.parse_qsl(qs[, keep_blank_values[, strict_parsing[, max_num_fields]])]`

Parse a query string given as a string argument (data of type *application/x-www-form-urlencoded*). Data are returned as a list of name, value pairs.

The optional argument *keep\_blank\_values* is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument *strict\_parsing* is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a *ValueError* exception.

The optional argument *max\_num\_fields* is the maximum number of fields to read. If set, then throws a *ValueError* if there are more than *max\_num\_fields* fields read.

Use the [`urllib.urlencode\(\)`](#) function to convert such lists of pairs into query strings.

Nouveau dans la version 2.6 : Copied from the *cgi* module.

Modifié dans la version 2.7.16 : Added *max\_num\_fields* parameter.

`urlparse.urlunparse(parts)`

Construct a URL from a tuple as returned by `urlparse()`. The *parts* argument can be any six-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

`urlparse.urlsplit(urlstring[, scheme[, allow_fragments]])`

This is similar to `urlparse()`, but does not split the params from the URL. This should generally be used instead of `urlparse()` if the more recent URL syntax allowing parameters to be applied to each segment of the *path* portion of the URL (see [RFC 2396](#)) is wanted. A separate function is needed to separate the path segments and parameters. This function returns a 5-tuple : (addressing scheme, network location, path, query, fragment identifier).

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes :

Attribut	Index	Valeur	Value if not present
<code>scheme</code>	0	URL scheme specifier	<i>scheme</i> parameter
<code>netloc</code>	1	Network location part	empty string
<code>path</code>	2	Hierarchical path	empty string
<code>query</code>	3	Query component	empty string
<code>fragment</code>	4	Fragment identifier	empty string
<code>username</code>		User name	<i>None</i>
<code>password</code>		Password	<i>None</i>
<code>hostname</code>		Host name (lower case)	<i>None</i>
<code>port</code>		Port number as integer, if present	<i>None</i>

See section *Results of urlparse() and urlsplit()* for more information on the result object.

Nouveau dans la version 2.2.

Modifié dans la version 2.5 : Added attributes to return value.

`urlparse.urlunsplit(parts)`

Combine the elements of a tuple as returned by `urlsplit()` into a complete URL as a string. The *parts* argument can be any five-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query ; the RFC states that these are equivalent).

Nouveau dans la version 2.2.

`urlparse.urljoin(base, url[, allow_fragments])`

Construct a full (« absolute ») URL by combining a « base URL » (*base*) with another URL (*url*). Informally, this uses components of the base URL, in particular the addressing scheme, the network location and (part of) the path, to provide missing components in the relative URL. For example :

```
>>> from urlparse import urljoin
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', 'FAQ.html')
'http://www.cwi.nl/%7Eguido/FAQ.html'
```

The *allow\_fragments* argument has the same meaning and default as for `urlparse()`.

**Note :** If *url* is an absolute URL (that is, starting with `//` or `scheme://`), the *url*'s host name and/or scheme will be present in the result. For example :

```
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html',
...         '//www.python.org/%7Eguido')
'http://www.python.org/%7Eguido'
```

If you do not want that behavior, preprocess the *url* with `urlsplit()` and `urlunsplit()`, removing possible *scheme* and *netloc* parts.

`urlparse.urldefrag(url)`

If *url* contains a fragment identifier, returns a modified version of *url* with no fragment identifier,

and the fragment identifier as a separate string. If there is no fragment identifier in *url*, returns *url* unmodified and an empty string.

Voir aussi :

**RFC 3986 - Uniform Resource Identifiers** This is the current standard (STD66). Any changes to `urlparse` module should conform to this. Certain deviations could be observed, which are mostly for backward compatibility purposes and for certain de-facto parsing requirements as commonly observed in major browsers.

**RFC 2732 - Format for Literal IPv6 Addresses in URL's.** This specifies the parsing requirements of IPv6 URLs.

**RFC 2396 - Uniform Resource Identifiers (URI) : Generic Syntax** Document describing the generic syntactic requirements for both Uniform Resource Names (URNs) and Uniform Resource Locators (URLs).

**RFC 2368 - The mailto URL scheme.** Parsing requirements for mailto URL schemes.

**RFC 1808 - Relative Uniform Resource Locators** This Request For Comments includes the rules for joining an absolute and a relative URL, including a fair number of « Abnormal Examples » which govern the treatment of border cases.

**RFC 1738 - Uniform Resource Locators (URL)** This specifies the formal syntax and semantics of absolute URLs.

### 20.16.1 Results of `urlparse()` and `urlsplit()`

The result objects from the `urlparse()` and `urlsplit()` functions are subclasses of the `tuple` type. These subclasses add the attributes described in those functions, as well as provide an additional method :

`ParseResult.geturl()`

Return the re-combined version of the original URL as a string. This may differ from the original URL in that the scheme will always be normalized to lower case and empty components may be dropped. Specifically, empty parameters, queries, and fragment identifiers will be removed.

The result of this method is a fixpoint if passed back through the original parsing function :

```
>>> import urlparse
>>> url = 'HTTP://www.Python.org/doc/#'
```

```
>>> r1 = urlparse.urlsplit(url)
>>> r1.geturl()
'http://www.Python.org/doc/'
```

```
>>> r2 = urlparse.urlsplit(r1.geturl())
>>> r2.geturl()
'http://www.Python.org/doc/'
```

Nouveau dans la version 2.5.

The following classes provide the implementations of the parse results :

**`class urlparse.ParseResult(scheme, netloc, path, params, query, fragment)`**  
Concrete class for `urlparse()` results.

**`class urlparse.SplitResult(scheme, netloc, path, query, fragment)`**  
Concrete class for `urlsplit()` results.

## 20.17 SocketServer — A framework for network servers

**Note :** The *SocketServer* module has been renamed to `socketserver` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

**Source code :** `Lib/SocketServer.py`

The *SocketServer* module simplifies the task of writing network servers.

There are four basic concrete server classes :

**class** `SocketServer.TCPServer(server_address, RequestHandlerClass, bind_and_activate=True)`  
 This uses the Internet TCP protocol, which provides for continuous streams of data between the client and server. If *bind\_and\_activate* is true, the constructor automatically attempts to invoke *server\_bind()* and *server\_activate()*. The other parameters are passed to the *BaseServer* base class.

**class** `SocketServer.UDPServer(server_address, RequestHandlerClass, bind_and_activate=True)`  
 This uses datagrams, which are discrete packets of information that may arrive out of order or be lost while in transit. The parameters are the same as for *TCPServer*.

**class** `SocketServer.UnixStreamServer(server_address, RequestHandlerClass, bind_and_activate=True)`

**class** `SocketServer.UnixDatagramServer(server_address, RequestHandlerClass, bind_and_activate=True)`

These more infrequently used classes are similar to the TCP and UDP classes, but use Unix domain sockets; they're not available on non-Unix platforms. The parameters are the same as for *TCPServer*.

These four classes process requests *synchronously*; each request must be completed before the next request can be started. This isn't suitable if each request takes a long time to complete, because it requires a lot of computation, or because it returns a lot of data which the client is slow to process. The solution is to create a separate process or thread to handle each request; the *ForkingMixIn* and *ThreadingMixIn* mix-in classes can be used to support asynchronous behaviour.

Creating a server requires several steps. First, you must create a request handler class by subclassing the *BaseRequestHandler* class and overriding its *handle()* method; this method will process incoming requests. Second, you must instantiate one of the server classes, passing it the server's address and the request handler class. Then call the *handle\_request()* or *serve\_forever()* method of the server object to process one or many requests. Finally, call *server\_close()* to close the socket.

When inheriting from *ThreadingMixIn* for threaded connection behavior, you should explicitly declare how you want your threads to behave on an abrupt shutdown. The *ThreadingMixIn* class defines an attribute *daemon\_threads*, which indicates whether or not the server should wait for thread termination. You should set the flag explicitly if you would like threads to behave autonomously; the default is *False*, meaning that Python will not exit until all threads created by *ThreadingMixIn* have exited.

Server classes have the same external methods and attributes, no matter what network protocol they use.

### 20.17.1 Server Creation Notes

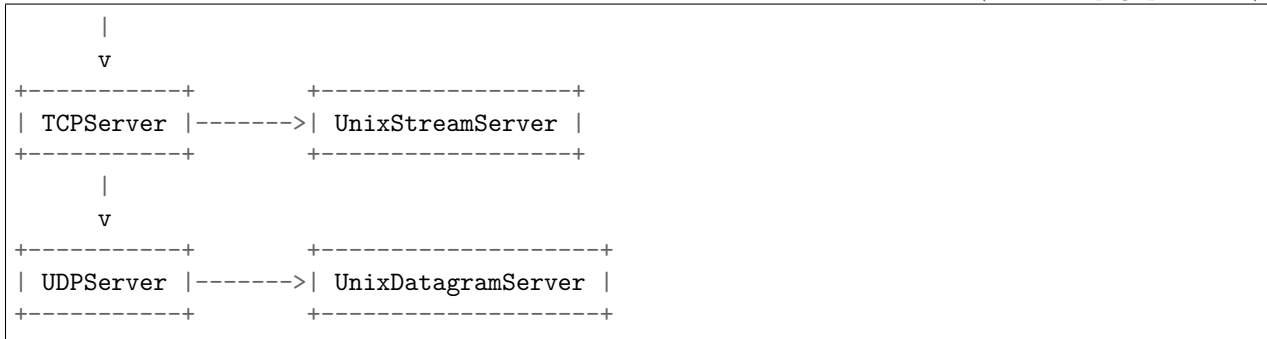

There are five classes in an inheritance diagram, four of which represent synchronous servers of four types :

```
+-----+
| BaseServer |
+-----+
```

(suite sur la page suivante)

(suite de la page précédente)

Note that *UnixDatagramServer* derives from *UDPServer*, not from *UnixStreamServer* — the only difference between an IP and a Unix stream server is the address family, which is simply repeated in both Unix server classes.

```
class SocketServer.ForkingMixIn
class SocketServer.ThreadingMixIn
```

Forking and threading versions of each type of server can be created using these mix-in classes. For instance, *ThreadingUDPServer* is created as follows :

```
class ThreadingUDPServer(ThreadingMixIn, UDPServer):
    pass
```

The mix-in class comes first, since it overrides a method defined in *UDPServer*. Setting the various attributes also changes the behavior of the underlying server mechanism.

*ForkingMixIn* and the Forking classes mentioned below are only available on POSIX platforms that support *fork()*.

```
class SocketServer.ForkingTCPServer
class SocketServer.ForkingUDPServer
class SocketServer.ThreadingTCPServer
class SocketServer.ThreadingUDPServer
```

These classes are pre-defined using the mix-in classes.

To implement a service, you must derive a class from *BaseRequestHandler* and redefine its *handle()* method. You can then run various versions of the service by combining one of the server classes with your request handler class. The request handler class must be different for datagram or stream services. This can be hidden by using the handler subclasses *StreamRequestHandler* or *DatagramRequestHandler*.

Of course, you still have to use your head! For instance, it makes no sense to use a forking server if the service contains state in memory that can be modified by different requests, since the modifications in the child process would never reach the initial state kept in the parent process and passed to each child. In this case, you can use a threading server, but you will probably have to use locks to protect the integrity of the shared data.

On the other hand, if you are building an HTTP server where all data is stored externally (for instance, in the file system), a synchronous class will essentially render the service « deaf » while one request is being handled – which may be for a very long time if a client is slow to receive all the data it has requested. Here a threading or forking server is appropriate.

In some cases, it may be appropriate to process part of a request synchronously, but to finish processing in a forked child depending on the request data. This can be implemented by using a synchronous server and doing an explicit fork in the request handler class *handle()* method.

Another approach to handling multiple simultaneous requests in an environment that supports neither threads nor *fork()* (or where these are too expensive or inappropriate for the service) is to maintain an explicit table of partially finished requests and to use *select()* to decide which request to work on next (or

whether to handle a new incoming request). This is particularly important for stream services where each client can potentially be connected for a long time (if threads or subprocesses cannot be used). See [asyncore](#) for another way to manage this.

## 20.17.2 Server Objects

**class** `SocketServer.BaseServer(server_address, RequestHandlerClass)`

This is the superclass of all Server objects in the module. It defines the interface, given below, but does not implement most of the methods, which is done in subclasses. The two parameters are stored in the respective `server_address` and `RequestHandlerClass` attributes.

**fileno()**

Return an integer file descriptor for the socket on which the server is listening. This function is most commonly passed to `select.select()`, to allow monitoring multiple servers in the same process.

**handle\_request()**

Process a single request. This function calls the following methods in order : `get_request()`, `verify_request()`, and `process_request()`. If the user-provided `handle()` method of the handler class raises an exception, the server's `handle_error()` method will be called. If no request is received within `timeout` seconds, `handle_timeout()` will be called and `handle_request()` will return.

**serve\_forever(poll\_interval=0.5)**

Handle requests until an explicit `shutdown()` request. Poll for shutdown every `poll_interval` seconds. Ignores the `timeout` attribute. If you need to do periodic tasks, do them in another thread.

**shutdown()**

Tell the `serve_forever()` loop to stop and wait until it does.

Nouveau dans la version 2.6.

**server\_close()**

Clean up the server. May be overridden.

Nouveau dans la version 2.6.

**address\_family**

The family of protocols to which the server's socket belongs. Common examples are `socket.AF_INET` and `socket.AF_UNIX`.

**RequestHandlerClass**

The user-provided request handler class ; an instance of this class is created for each request.

**server\_address**

The address on which the server is listening. The format of addresses varies depending on the protocol family ; see the documentation for the `socket` module for details. For Internet protocols, this is a tuple containing a string giving the address, and an integer port number : `('127.0.0.1', 80)`, for example.

**socket**

The socket object on which the server will listen for incoming requests.

The server classes support the following class variables :

**allow\_reuse\_address**

Whether the server will allow the reuse of an address. This defaults to `False`, and can be set in subclasses to change the policy.

**request\_queue\_size**

The size of the request queue. If it takes a long time to process a single request, any requests that arrive while the server is busy are placed into a queue, up to `request_queue_size` requests. Once the queue is full, further requests from clients will get a « Connection denied » error. The default value is usually 5, but this can be overridden by subclasses.

**socket\_type**

The type of socket used by the server ; `socket.SOCK_STREAM` and `socket.SOCK_DGRAM` are two common values.

**timeout**

Timeout duration, measured in seconds, or *None* if no timeout is desired. If *handle\_request()* receives no incoming requests within the timeout period, the *handle\_timeout()* method is called.

There are various server methods that can be overridden by subclasses of base server classes like *TCPServer*; these methods aren't useful to external users of the server object.

**finish\_request(request, client\_address)**

Actually processes the request by instantiating *RequestHandlerClass* and calling its *handle()* method.

**get\_request()**

Must accept a request from the socket, and return a 2-tuple containing the *new* socket object to be used to communicate with the client, and the client's address.

**handle\_error(request, client\_address)**

This function is called if the *handle()* method of a *RequestHandlerClass* instance raises an exception. The default action is to print the traceback to standard output and continue handling further requests.

**handle\_timeout()**

This function is called when the *timeout* attribute has been set to a value other than *None* and the timeout period has passed with no requests being received. The default action for forking servers is to collect the status of any child processes that have exited, while in threading servers this method does nothing.

**process\_request(request, client\_address)**

Calls *finish\_request()* to create an instance of the *RequestHandlerClass*. If desired, this function can create a new process or thread to handle the request; the *ForkingMixIn* and *ThreadingMixIn* classes do this.

**server\_activate()**

Called by the server's constructor to activate the server. The default behavior for a TCP server just invokes *listen()* on the server's socket. May be overridden.

**server\_bind()**

Called by the server's constructor to bind the socket to the desired address. May be overridden.

**verify\_request(request, client\_address)**

Must return a Boolean value; if the value is *True*, the request will be processed, and if it's *False*, the request will be denied. This function can be overridden to implement access controls for a server. The default implementation always returns *True*.

## 20.17.3 Request Handler Objects

**class SocketServer.BaseRequestHandler**

This is the superclass of all request handler objects. It defines the interface, given below. A concrete request handler subclass must define a new *handle()* method, and can override any of the other methods. A new instance of the subclass is created for each request.

**setup()**

Called before the *handle()* method to perform any initialization actions required. The default implementation does nothing.

**handle()**

This function must do all the work required to service a request. The default implementation does nothing. Several instance attributes are available to it; the request is available as *self.request*; the client address as *self.client\_address*; and the server instance as *self.server*, in case it needs access to per-server information.

The type of *self.request* is different for datagram or stream services. For stream services, *self.request* is a socket object; for datagram services, *self.request* is a pair of string and socket.

**finish()**

Called after the *handle()* method to perform any clean-up actions required. The default implementation does nothing. If *setup()* raises an exception, this function will not be called.

```
class SocketServer.StreamRequestHandler
class SocketServer.DatagramRequestHandler
```

These *BaseRequestHandler* subclasses override the *setup()* and *finish()* methods, and provide *self.rfile* and *self.wfile* attributes. The *self.rfile* and *self.wfile* attributes can be read or written, respectively, to get the request data or return data to the client.

## 20.17.4 Examples

### SocketServer.TCPServer Example

This is the server side :

```
import SocketServer

class MyTCPHandler(SocketServer.BaseRequestHandler):
    """
    The request handler class for our server.

    It is instantiated once per connection to the server, and must
    override the handle() method to implement communication to the
    client.
    """

    def handle(self):
        # self.request is the TCP socket connected to the client
        self.data = self.request.recv(1024).strip()
        print "{} wrote:".format(self.client_address[0])
        print self.data
        # just send back the same data, but upper-cased
        self.request.sendall(self.data.upper())

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999

    # Create the server, binding to localhost on port 9999
    server = SocketServer.TCPServer((HOST, PORT), MyTCPHandler)

    # Activate the server; this will keep running until you
    # interrupt the program with Ctrl-C
    server.serve_forever()
```

An alternative request handler class that makes use of streams (file-like objects that simplify communication by providing the standard file interface) :

```
class MyTCPHandler(SocketServer.StreamRequestHandler):

    def handle(self):
        # self.rfile is a file-like object created by the handler;
        # we can now use e.g. readline() instead of raw recv() calls
        self.data = self.rfile.readline().strip()
        print "{} wrote:".format(self.client_address[0])
        print self.data
        # Likewise, self.wfile is a file-like object used to write back
        # to the client
```

(suite sur la page suivante)

(suite de la page précédente)

```
self.wfile.write(self.data.upper())
```

The difference is that the `readline()` call in the second handler will call `recv()` multiple times until it encounters a newline character, while the single `recv()` call in the first handler will just return what has been sent from the client in one `sendall()` call.

This is the client side :

```
import socket
import sys

HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:])

# Create a socket (SOCK_STREAM means a TCP socket)
sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM)

try:
    # Connect to server and send data
    sock.connect((HOST, PORT))
    sock.sendall(data + "\n")

    # Receive data from the server and shut down
    received = sock.recv(1024)
finally:
    sock.close()

print "Sent:      {}".format(data)
print "Received: {}".format(received)
```

The output of the example should look something like this :

Serveur :

```
$ python TCPServer.py
127.0.0.1 wrote:
hello world with TCP
127.0.0.1 wrote:
python is nice
```

Client :

```
$ python TCPClient.py hello world with TCP
Sent:      hello world with TCP
Received: HELLO WORLD WITH TCP
$ python TCPClient.py python is nice
Sent:      python is nice
Received: PYTHON IS NICE
```

### SocketServer.UDPServer Example

This is the server side :

```

import SocketServer

class MyUDPHandler(SocketServer.BaseRequestHandler):
    """
    This class works similar to the TCP handler class, except that
    self.request consists of a pair of data and client socket, and since
    there is no connection the client address must be given explicitly
    when sending data back via sendto().
    """

    def handle(self):
        data = self.request[0].strip()
        socket = self.request[1]
        print "{} wrote:".format(self.client_address[0])
        print data
        socket.sendto(data.upper(), self.client_address)

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999
    server = SocketServer.UDPServer((HOST, PORT), MyUDPHandler)
    server.serve_forever()

```

This is the client side :

```

import socket
import sys

HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:])

# SOCK_DGRAM is the socket type to use for UDP sockets
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)

# As you can see, there is no connect() call; UDP has no connections.
# Instead, data is directly sent to the recipient via sendto().
sock.sendto(data + "\n", (HOST, PORT))
received = sock.recv(1024)

print "Sent:      {}".format(data)
print "Received: {}".format(received)

```

The output of the example should look exactly like for the TCP server example.

### Asynchronous Mixins

To build asynchronous handlers, use the *ThreadingMixIn* and *ForkingMixIn* classes.

An example for the *ThreadingMixIn* class :

```

import socket
import threading
import SocketServer

class ThreadedTCPRequestHandler(SocketServer.BaseRequestHandler):

```

(suite sur la page suivante)

(suite de la page précédente)

```

def handle(self):
    data = self.request.recv(1024)
    cur_thread = threading.current_thread()
    response = "{}: {}".format(cur_thread.name, data)
    self.request.sendall(response)

class ThreadedTCPServer(SocketServer.ThreadingMixIn, SocketServer.TCPServer):
    pass

def client(ip, port, message):
    sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
    sock.connect((ip, port))
    try:
        sock.sendall(message)
        response = sock.recv(1024)
        print "Received: {}".format(response)
    finally:
        sock.close()

if __name__ == "__main__":
    # Port 0 means to select an arbitrary unused port
    HOST, PORT = "localhost", 0

    server = ThreadedTCPServer((HOST, PORT), ThreadedTCPRequestHandler)
    ip, port = server.server_address

    # Start a thread with the server -- that thread will then start one
    # more thread for each request
    server_thread = threading.Thread(target=server.serve_forever)
    # Exit the server thread when the main thread terminates
    server_thread.daemon = True
    server_thread.start()
    print "Server loop running in thread:", server_thread.name

    client(ip, port, "Hello World 1")
    client(ip, port, "Hello World 2")
    client(ip, port, "Hello World 3")

    server.shutdown()
    server.server_close()

```

The output of the example should look something like this :

```

$ python ThreadedTCPServer.py
Server loop running in thread: Thread-1
Received: Thread-2: Hello World 1
Received: Thread-3: Hello World 2
Received: Thread-4: Hello World 3

```

The *ForkingMixIn* class is used in the same way, except that the server will spawn a new process for each request. Available only on POSIX platforms that support *fork()*.

## 20.18 BaseHTTPServer — Basic HTTP server

**Note :** The *BaseHTTPServer* module has been merged into `http.server` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

**Source code :** `Lib/BaseHTTPServer.py`

This module defines two classes for implementing HTTP servers (Web servers). Usually, this module isn't used directly, but is used as a basis for building functioning Web servers. See the *SimpleHTTPServer* and *CGIHTTPServer* modules.

The first class, *HTTPServer*, is a *SocketServer.TCPServer* subclass, and therefore implements the *SocketServer.BaseServer* interface. It creates and listens at the HTTP socket, dispatching the requests to a handler. Code to create and run the server looks like this :

```
def run(server_class=BaseHTTPServer.HTTPServer,
        handler_class=BaseHTTPServer.BaseHTTPRequestHandler):
    server_address = ('', 8000)
    httpd = server_class(server_address, handler_class)
    httpd.serve_forever()
```

**class** `BaseHTTPServer.HTTPServer(server_address, RequestHandlerClass)`

This class builds on the *TCPServer* class by storing the server address as instance variables named `server_name` and `server_port`. The server is accessible by the handler, typically through the handler's `server` instance variable.

**class** `BaseHTTPServer.BaseHTTPRequestHandler(request, client_address, server)`

This class is used to handle the HTTP requests that arrive at the server. By itself, it cannot respond to any actual HTTP requests; it must be subclassed to handle each request method (e.g. GET or POST). *BaseHTTPRequestHandler* provides a number of class and instance variables, and methods for use by subclasses.

The handler will parse the request and the headers, then call a method specific to the request type. The method name is constructed from the request. For example, for the request method SPAM, the `do_SPAM()` method will be called with no arguments. All of the relevant information is stored in instance variables of the handler. Subclasses should not need to override or extend the `__init__()` method.

*BaseHTTPRequestHandler* has the following instance variables :

**client\_address**

Contains a tuple of the form (host, port) referring to the client's address.

**server**

Contains the server instance.

**command**

Contains the command (request type). For example, 'GET'.

**path**

Contains the request path.

**request\_version**

Contains the version string from the request. For example, 'HTTP/1.0'.

**headers**

Holds an instance of the class specified by the *MessageClass* class variable. This instance parses and manages the headers in the HTTP request.

**rfile**

Contains an input stream, positioned at the start of the optional input data.

**wfile**

Contains the output stream for writing a response back to the client. Proper adherence to the HTTP protocol must be used when writing to this stream.

*BaseHTTPRequestHandler* has the following class variables :

**server\_version**

Specifies the server software version. You may want to override this. The format is multiple whitespace-separated strings, where each string is of the form *name[/version]*. For example, 'BaseHTTP/0.2'.

**sys\_version**

Contains the Python system version, in a form usable by the *version\_string* method and the *server\_version* class variable. For example, 'Python/1.4'.

**error\_message\_format**

Specifies a format string for building an error response to the client. It uses parenthesized, keyed format specifiers, so the format operand must be a dictionary. The *code* key should be an integer, specifying the numeric HTTP error code value. *message* should be a string containing a (detailed) error message of what occurred, and *explain* should be an explanation of the error code number. Default *message* and *explain* values can found in the *responses* class variable.

**error\_content\_type**

Specifies the Content-Type HTTP header of error responses sent to the client. The default value is 'text/html'.

Nouveau dans la version 2.6 : Previously, the content type was always 'text/html'.

**protocol\_version**

This specifies the HTTP protocol version used in responses. If set to 'HTTP/1.1', the server will permit HTTP persistent connections; however, your server *must* then include an accurate Content-Length header (using *send\_header()*) in all of its responses to clients. For backwards compatibility, the setting defaults to 'HTTP/1.0'.

**MessageClass**

Specifies a *rfc822.Message*-like class to parse HTTP headers. Typically, this is not overridden, and it defaults to *mimetools.Message*.

**responses**

This variable contains a mapping of error code integers to two-element tuples containing a short and long message. For example, {*code*: (*shortmessage*, *longmessage*)}. The *shortmessage* is usually used as the *message* key in an error response, and *longmessage* as the *explain* key (see the *error\_message\_format* class variable).

A *BaseHTTPRequestHandler* instance has the following methods :

**handle()**

Calls *handle\_one\_request()* once (or, if persistent connections are enabled, multiple times) to handle incoming HTTP requests. You should never need to override it; instead, implement appropriate *do\_\**() methods.

**handle\_one\_request()**

This method will parse and dispatch the request to the appropriate *do\_\**() method. You should never need to override it.

**send\_error(*code*[, *message*])**

Sends and logs a complete error reply to the client. The numeric *code* specifies the HTTP error code, with *message* as optional, more specific text. A complete set of headers is sent, followed by text composed using the *error\_message\_format* class variable. The body will be empty if the method is HEAD or the response code is one of the following : 1xx, 204 No Content, 205 Reset Content, 304 Not Modified.

**send\_response(*code*[, *message*])**

Sends a response header and logs the accepted request. The HTTP response line is sent, followed by *Server* and *Date* headers. The values for these two headers are picked up from the *version\_string()* and *date\_time\_string()* methods, respectively.

**send\_header**(*keyword*, *value*)  
Writes a specific HTTP header to the output stream. *keyword* should specify the header keyword, with *value* specifying its value.

**end\_headers**()  
Sends a blank line, indicating the end of the HTTP headers in the response.

**log\_request**([*code*, *size*])  
Logs an accepted (successful) request. *code* should specify the numeric HTTP code associated with the response. If a size of the response is available, then it should be passed as the *size* parameter.

**log\_error**(...)  
Logs an error when a request cannot be fulfilled. By default, it passes the message to *log\_message()*, so it takes the same arguments (*format* and additional values).

**log\_message**(*format*, ...)  
Logs an arbitrary message to `sys.stderr`. This is typically overridden to create custom error logging mechanisms. The *format* argument is a standard printf-style format string, where the additional arguments to *log\_message()* are applied as inputs to the formatting. The client ip address and current date and time are prefixed to every message logged.

**version\_string**()  
Returns the server software's version string. This is a combination of the *server\_version* and *sys\_version* class variables.

**date\_time\_string**([*timestamp*])  
Returns the date and time given by *timestamp* (which must be in the format returned by *time.time()*), formatted for a message header. If *timestamp* is omitted, it uses the current date and time.  
The result looks like 'Sun, 06 Nov 1994 08:49:37 GMT'.  
Nouveau dans la version 2.5 : The *timestamp* parameter.

**log\_date\_time\_string**()  
Returns the current date and time, formatted for logging.

**address\_string**()  
Returns the client address, formatted for logging. A name lookup is performed on the client's IP address.

### 20.18.1 More examples

To create a server that doesn't run forever, but until some condition is fulfilled :

```
def run_while_true(server_class=BaseHTTPServer.HTTPServer,
                  handler_class=BaseHTTPServer.BaseHTTPRequestHandler):
    """
    This assumes that keep_running() is a function of no arguments which
    is tested initially and after each request. If its return value
    is true, the server continues.
    """
    server_address = ('', 8000)
    httpd = server_class(server_address, handler_class)
    while keep_running():
        httpd.handle_request()
```

Module *CGIHTTPServer* Extended request handler that supports CGI scripts.

Module *SimpleHTTPServer* Basic request handler that limits response to files actually under the document root.

## 20.19 SimpleHTTPServer — Simple HTTP request handler

---

**Note :** The *SimpleHTTPServer* module has been merged into `http.server` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

**Avertissement :** `mod :SimpleHTTPServer` is not recommended for production. It only implements basic security checks.

The *SimpleHTTPServer* module defines a single class, *SimpleHTTPRequestHandler*, which is interface-compatible with *BaseHTTPServer.BaseHTTPRequestHandler*.

The *SimpleHTTPServer* module defines the following class :

**class** SimpleHTTPServer.SimpleHTTPRequestHandler(request, client\_address, server)

This class serves files from the current directory and below, directly mapping the directory structure to HTTP requests.

A lot of the work, such as parsing the request, is done by the base class *BaseHTTPServer.BaseHTTPRequestHandler*. This class implements the *do\_GET()* and *do\_HEAD()* functions.

The following are defined as class-level attributes of *SimpleHTTPRequestHandler* :

**server\_version**

This will be "SimpleHTTP/" + `__version__`, where `__version__` is defined at the module level.

**extensions\_map**

A dictionary mapping suffixes into MIME types. The default is signified by an empty string, and is considered to be `application/octet-stream`. The mapping is used case-insensitively, and so should contain only lower-cased keys.

The *SimpleHTTPRequestHandler* class defines the following methods :

**do\_HEAD()**

This method serves the 'HEAD' request type : it sends the headers it would send for the equivalent GET request. See the *do\_GET()* method for a more complete explanation of the possible headers.

**do\_GET()**

The request is mapped to a local file by interpreting the request as a path relative to the current working directory.

If the request was mapped to a directory, the directory is checked for a file named `index.html` or `index.htm` (in that order). If found, the file's contents are returned ; otherwise a directory listing is generated by calling the `list_directory()` method. This method uses `os.listdir()` to scan the directory, and returns a 404 error response if the `listdir()` fails.

If the request was mapped to a file, it is opened and the contents are returned. Any *IOError* exception in opening the requested file is mapped to a 404, 'File not found' error. Otherwise, the content type is guessed by calling the `guess_type()` method, which in turn uses the `extensions_map` variable.

A 'Content-type:' header with the guessed content type is output, followed by a 'Content-Length:' header with the file's size and a 'Last-Modified:' header with the file's modification time.

Then follows a blank line signifying the end of the headers, and then the contents of the file are output. If the file's MIME type starts with `text/` the file is opened in text mode ; otherwise binary mode is used.

The *test()* function in the *SimpleHTTPServer* module is an example which creates a server using the *SimpleHTTPRequestHandler* as the Handler.

Nouveau dans la version 2.5 : The 'Last-Modified' header.

The *SimpleHTTPServer* module can be used in the following manner in order to set up a very basic web server serving files relative to the current directory.

```
import SimpleHTTPServer
import SocketServer

PORT = 8000

Handler = SimpleHTTPServer.SimpleHTTPRequestHandler

httpd = SocketServer.TCPServer(("", PORT), Handler)

print "serving at port", PORT
httpd.serve_forever()
```

The *SimpleHTTPServer* module can also be invoked directly using the `-m` switch of the interpreter with a `port number` argument. Similar to the previous example, this serves the files relative to the current directory.

```
python -m SimpleHTTPServer 8000
```

## 20.20 CGIHTTPServer — CGI-capable HTTP request handler

**Note :** The *CGIHTTPServer* module has been merged into `http.server` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

The *CGIHTTPServer* module defines a request-handler class, interface compatible with *BaseHTTPServer.BaseHTTPRequestHandler* and inherits behavior from *SimpleHTTPServer.SimpleHTTPRequestHandler* but can also run CGI scripts.

**Note :** This module can run CGI scripts on Unix and Windows systems.

**Note :** CGI scripts run by the *CGIHTTPRequestHandler* class cannot execute redirects (HTTP code 302), because code 200 (script output follows) is sent prior to execution of the CGI script. This pre-empts the status code.

The *CGIHTTPServer* module defines the following class :

```
class CGIHTTPServer.CGIHTTPRequestHandler(request, client_address, server)
```

This class is used to serve either files or output of CGI scripts from the current directory and below. Note that mapping HTTP hierarchic structure to local directory structure is exactly as in *SimpleHTTPServer.SimpleHTTPRequestHandler*.

The class will however, run the CGI script, instead of serving it as a file, if it guesses it to be a CGI script. Only directory-based CGI are used — the other common server configuration is to treat special extensions as denoting CGI scripts.

The `do_GET()` and `do_HEAD()` functions are modified to run CGI scripts and serve the output, instead of serving files, if the request leads to somewhere below the `cgi_directories` path.

The *CGIHTTPRequestHandler* defines the following data member :

**cgi\_directories**

This defaults to `['/cgi-bin', '/htbin']` and describes directories to treat as containing CGI scripts.

The *CGIHTTPRequestHandler* defines the following methods :

**do\_POST()**

This method serves the 'POST' request type, only allowed for CGI scripts. Error 501, « Can only POST to CGI scripts », is output when trying to POST to a non-CGI url.

Note that CGI scripts will be run with UID of user nobody, for security reasons. Problems with the CGI script will be translated to error 403.

For example usage, see the implementation of the *test()* function.

Module *BaseHTTPServer* Base class implementation for Web server and request handler.

## 20.21 cookielib — Cookie handling for HTTP clients

---

**Note :** The *cookielib* module has been renamed to `http.cookiejar` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

Nouveau dans la version 2.4.

**Source code :** [Lib/cookie.py](#)

---

The *cookielib* module defines classes for automatic handling of HTTP cookies. It is useful for accessing web sites that require small pieces of data – *cookies* – to be set on the client machine by an HTTP response from a web server, and then returned to the server in later HTTP requests.

Both the regular Netscape cookie protocol and the protocol defined by **RFC 2965** are handled. RFC 2965 handling is switched off by default. **RFC 2109** cookies are parsed as Netscape cookies and subsequently treated either as Netscape or RFC 2965 cookies according to the “policy” in effect. Note that the great majority of cookies on the Internet are Netscape cookies. *cookielib* attempts to follow the de-facto Netscape cookie protocol (which differs substantially from that set out in the original Netscape specification), including taking note of the `max-age` and `port` cookie-attributes introduced with RFC 2965.

---

**Note :** The various named parameters found in *Set-Cookie* and *Set-Cookie2* headers (eg. `domain` and `expires`) are conventionally referred to as *attributes*. To distinguish them from Python attributes, the documentation for this module uses the term *cookie-attribute* instead.

---

The module defines the following exception :

**exception** `cookielib.LoadError`

Instances of *FileCookieJar* raise this exception on failure to load cookies from a file.

---

**Note :** For backwards-compatibility with Python 2.4 (which raised an *IOError*), *LoadError* is a subclass of *IOError*.

---

The following classes are provided :

```
class cookielib.CookieJar(policy=None)
```

*policy* is an object implementing the *CookiePolicy* interface.

The *CookieJar* class stores HTTP cookies. It extracts cookies from HTTP requests, and returns them in HTTP responses. *CookieJar* instances automatically expire contained cookies when necessary. Subclasses are also responsible for storing and retrieving cookies from a file or database.

```
class cookielib.FileCookieJar(filename, delayload=None, policy=None)
```

*policy* is an object implementing the *CookiePolicy* interface. For the other arguments, see the documentation for the corresponding attributes.

A *CookieJar* which can load cookies from, and perhaps save cookies to, a file on disk. Cookies are **NOT** loaded from the named file until either the *load()* or *revert()* method is called. Subclasses of this class are documented in section *FileCookieJar subclasses and co-operation with web browsers*.

```
class cookielib.CookiePolicy
```

This class is responsible for deciding whether each cookie should be accepted from / returned to the server.

```
class cookielib.DefaultCookiePolicy(blocked_domains=None, allowed_domains=None, netscape=True, rfc2965=False, rfc2109_as_netscape=None, hide_cookie2=False, strict_domain=False, strict_rfc2965_unverifiable=True, strict_ns_unverifiable=False, strict_ns_domain=DefaultCookiePolicy.DomainLiberal, strict_ns_set_initial_dollar=False, strict_ns_set_path=False)
```

Constructor arguments should be passed as keyword arguments only. *blocked\_domains* is a sequence of domain names that we never accept cookies from, nor return cookies to. *allowed\_domains* if not *None*, this is a sequence of the only domains for which we accept and return cookies. For all other arguments, see the documentation for *CookiePolicy* and *DefaultCookiePolicy* objects.

*DefaultCookiePolicy* implements the standard accept / reject rules for Netscape and RFC 2965 cookies. By default, RFC 2109 cookies (ie. cookies received in a *Set-Cookie* header with a version cookie-attribute of 1) are treated according to the RFC 2965 rules. However, if RFC 2965 handling is turned off or *rfc2109\_as\_netscape* is *True*, RFC 2109 cookies are “downgraded” by the *CookieJar* instance to Netscape cookies, by setting the *version* attribute of the *Cookie* instance to 0. *DefaultCookiePolicy* also provides some parameters to allow some fine-tuning of policy.

```
class cookielib.Cookie
```

This class represents Netscape, RFC 2109 and RFC 2965 cookies. It is not expected that users of *cookielib* construct their own *Cookie* instances. Instead, if necessary, call *make\_cookies()* on a *CookieJar* instance.

Voir aussi :

**Module** *urllib2* URL opening with automatic cookie handling.

**Module** *Cookie* HTTP cookie classes, principally useful for server-side code. The *cookielib* and *Cookie* modules do not depend on each other.

[https://curl.haxx.se/rfc/cookie\\_spec.html](https://curl.haxx.se/rfc/cookie_spec.html) The specification of the original Netscape cookie protocol. Though this is still the dominant protocol, the “Netscape cookie protocol” implemented by all the major browsers (and *cookielib*) only bears a passing resemblance to the one sketched out in *cookie\_spec.html*.

**RFC 2109 - HTTP State Management Mechanism** Obsoleted by RFC 2965. Uses *Set-Cookie* with *version=1*.

**RFC 2965 - HTTP State Management Mechanism** The Netscape protocol with the bugs fixed. Uses *Set-Cookie2* in place of *Set-Cookie*. Not widely used.

<http://kristol.org/cookie/errata.html> Unfinished errata to RFC 2965.

## RFC 2964 - Use of HTTP State Management

### 20.21.1 CookieJar and FileCookieJar Objects

*CookieJar* objects support the *iterator* protocol for iterating over contained *Cookie* objects.

*CookieJar* has the following methods :

**CookieJar.add\_cookie\_header(request)**

Add correct *Cookie* header to *request*.

If policy allows (ie. the `rfc2965` and `hide_cookie2` attributes of the *CookieJar*'s *CookiePolicy* instance are true and false respectively), the *Cookie2* header is also added when appropriate.

The *request* object (usually a *urllib2.Request* instance) must support the methods `get_full_url()`, `get_host()`, `get_type()`, `unverifiable()`, `get_origin_req_host()`, `has_header()`, `get_header()`, `header_items()`, and `add_unredirected_header()`, as documented by *urllib2*.

**CookieJar.extract\_cookies(response, request)**

Extract cookies from HTTP *response* and store them in the *CookieJar*, where allowed by policy.

The *CookieJar* will look for allowable *Set-Cookie* and *Set-Cookie2* headers in the *response* argument, and store cookies as appropriate (subject to the *CookiePolicy.set\_ok()* method's approval).

The *response* object (usually the result of a call to *urllib2.urlopen()*, or similar) should support an `info()` method, which returns an object with a `getallmatchingheaders()` method (usually a *mimetools.Message* instance).

The *request* object (usually a *urllib2.Request* instance) must support the methods `get_full_url()`, `get_host()`, `unverifiable()`, and `get_origin_req_host()`, as documented by *urllib2*. The request is used to set default values for cookie-attributes as well as for checking that the cookie is allowed to be set.

**CookieJar.set\_policy(policy)**

Set the *CookiePolicy* instance to be used.

**CookieJar.make\_cookies(response, request)**

Return sequence of *Cookie* objects extracted from *response* object.

See the documentation for *extract\_cookies()* for the interfaces required of the *response* and *request* arguments.

**CookieJar.set\_cookie\_if\_ok(cookie, request)**

Set a *Cookie* if policy says it's OK to do so.

**CookieJar.set\_cookie(cookie)**

Set a *Cookie*, without checking with policy to see whether or not it should be set.

**CookieJar.clear([domain[, path[, name]])]**

Clear some cookies.

If invoked without arguments, clear all cookies. If given a single argument, only cookies belonging to that *domain* will be removed. If given two arguments, cookies belonging to the specified *domain* and URL *path* are removed. If given three arguments, then the cookie with the specified *domain*, *path* and *name* is removed.

Raises *KeyError* if no matching cookie exists.

**CookieJar.clear\_session\_cookies()**

Discard all session cookies.

Discards all contained cookies that have a true `discard` attribute (usually because they had either no `max-age` or `expires` cookie-attribute, or an explicit `discard` cookie-attribute). For interactive browsers, the end of a session usually corresponds to closing the browser window.

Note that the `save()` method won't save session cookies anyway, unless you ask otherwise by passing a true *ignore\_discard* argument.

*FileCookieJar* implements the following additional methods :

**FileCookieJar.save**(*filename=None, ignore\_discard=False, ignore\_expires=False*)

Save cookies to a file.

This base class raises *NotImplementedError*. Subclasses may leave this method unimplemented.

*filename* is the name of file in which to save cookies. If *filename* is not specified, *self.filename* is used (whose default is the value passed to the constructor, if any); if *self.filename* is *None*, *ValueError* is raised.

*ignore\_discard* : save even cookies set to be discarded. *ignore\_expires* : save even cookies that have expired

The file is overwritten if it already exists, thus wiping all the cookies it contains. Saved cookies can be restored later using the *load()* or *revert()* methods.

**FileCookieJar.load**(*filename=None, ignore\_discard=False, ignore\_expires=False*)

Load cookies from a file.

Old cookies are kept unless overwritten by newly loaded ones.

Arguments are as for *save()*.

The named file must be in the format understood by the class, or *LoadError* will be raised. Also, *IOError* may be raised, for example if the file does not exist.

---

**Note :** For backwards-compatibility with Python 2.4 (which raised an *IOError*), *LoadError* is a subclass of *IOError*.

---

**FileCookieJar.revert**(*filename=None, ignore\_discard=False, ignore\_expires=False*)

Clear all cookies and reload cookies from a saved file.

*revert()* can raise the same exceptions as *load()*. If there is a failure, the object's state will not be altered.

*FileCookieJar* instances have the following public attributes :

**FileCookieJar.filename**

Filename of default file in which to keep cookies. This attribute may be assigned to.

**FileCookieJar.delayload**

If true, load cookies lazily from disk. This attribute should not be assigned to. This is only a hint, since this only affects performance, not behaviour (unless the cookies on disk are changing). A *CookieJar* object may ignore it. None of the *FileCookieJar* classes included in the standard library lazily loads cookies.

### 20.21.2 FileCookieJar subclasses and co-operation with web browsers

The following *CookieJar* subclasses are provided for reading and writing.

**class** *cookieilib.MozillaCookieJar*(*filename, delayload=None, policy=None*)

A *FileCookieJar* that can load from and save cookies to disk in the Mozilla *cookies.txt* file format (which is also used by the Lynx and Netscape browsers).

---

**Note :** Version 3 of the Firefox web browser no longer writes cookies in the *cookies.txt* file format.

---

---

**Note :** This loses information about RFC 2965 cookies, and also about newer or non-standard cookie-attributes such as *port*.

---

**Avertissement :** Back up your cookies before saving if you have cookies whose loss / corruption would be inconvenient (there are some subtleties which may lead to slight changes in the file over a load / save round-trip).

Also note that cookies saved while Mozilla is running will get clobbered by Mozilla.

`class cookielib.LWPCookieJar(filename, delayload=None, policy=None)`

A *FileCookieJar* that can load from and save cookies to disk in format compatible with the libwww-perl library's Set-Cookie3 file format. This is convenient if you want to store cookies in a human-readable file.

### 20.21.3 CookiePolicy Objects

Objects implementing the *CookiePolicy* interface have the following methods :

`CookiePolicy.set_ok(cookie, request)`

Return boolean value indicating whether cookie should be accepted from server.

*cookie* is a *cookielib.Cookie* instance. *request* is an object implementing the interface defined by the documentation for *CookieJar.extract\_cookies()*.

`CookiePolicy.return_ok(cookie, request)`

Return boolean value indicating whether cookie should be returned to server.

*cookie* is a *cookielib.Cookie* instance. *request* is an object implementing the interface defined by the documentation for *CookieJar.add\_cookie\_header()*.

`CookiePolicy.domain_return_ok(domain, request)`

Return false if cookies should not be returned, given cookie domain.

This method is an optimization. It removes the need for checking every cookie with a particular domain (which might involve reading many files). Returning true from *domain\_return\_ok()* and *path\_return\_ok()* leaves all the work to *return\_ok()*.

If *domain\_return\_ok()* returns true for the cookie domain, *path\_return\_ok()* is called for the cookie path. Otherwise, *path\_return\_ok()* and *return\_ok()* are never called for that cookie domain. If *path\_return\_ok()* returns true, *return\_ok()* is called with the *Cookie* object itself for a full check. Otherwise, *return\_ok()* is never called for that cookie path.

Note that *domain\_return\_ok()* is called for every *cookie* domain, not just for the *request* domain. For example, the function might be called with both ".example.com" and "www.example.com" if the request domain is "www.example.com". The same goes for *path\_return\_ok()*.

The *request* argument is as documented for *return\_ok()*.

`CookiePolicy.path_return_ok(path, request)`

Return false if cookies should not be returned, given cookie path.

See the documentation for *domain\_return\_ok()*.

In addition to implementing the methods above, implementations of the *CookiePolicy* interface must also supply the following attributes, indicating which protocols should be used, and how. All of these attributes may be assigned to.

`CookiePolicy.netscape`

Implement Netscape protocol.

`CookiePolicy.rfc2965`

Implement RFC 2965 protocol.

`CookiePolicy.hide_cookie2`

Don't add *Cookie2* header to requests (the presence of this header indicates to the server that we understand RFC 2965 cookies).

The most useful way to define a *CookiePolicy* class is by subclassing from *DefaultCookiePolicy* and overriding some or all of the methods above. *CookiePolicy* itself may be used as a “null policy” to allow setting and receiving any and all cookies (this is unlikely to be useful).

### 20.21.4 DefaultCookiePolicy Objects

Implements the standard rules for accepting and returning cookies.

Both RFC 2965 and Netscape cookies are covered. RFC 2965 handling is switched off by default.

The easiest way to provide your own policy is to override this class and call its methods in your overridden implementations before adding your own additional checks :

```
import cookielib
class MyCookiePolicy(cockielib.DefaultCookiePolicy):
    def set_ok(self, cookie, request):
        if not cookielib.DefaultCookiePolicy.set_ok(self, cookie, request):
            return False
        if i_dont_want_to_store_this_cookie(cookie):
            return False
        return True
```

In addition to the features required to implement the *CookiePolicy* interface, this class allows you to block and allow domains from setting and receiving cookies. There are also some strictness switches that allow you to tighten up the rather loose Netscape protocol rules a little bit (at the cost of blocking some benign cookies).

A domain blacklist and whitelist is provided (both off by default). Only domains not in the blacklist and present in the whitelist (if the whitelist is active) participate in cookie setting and returning. Use the *blocked\_domains* constructor argument, and *blocked\_domains()* and *set\_blocked\_domains()* methods (and the corresponding argument and methods for *allowed\_domains*). If you set a whitelist, you can turn it off again by setting it to *None*.

Domains in block or allow lists that do not start with a dot must equal the cookie domain to be matched. For example, "example.com" matches a blacklist entry of "example.com", but "www.example.com" does not. Domains that do start with a dot are matched by more specific domains too. For example, both "www.example.com" and "www.coyote.example.com" match ".example.com" (but "example.com" itself does not). IP addresses are an exception, and must match exactly. For example, if *blocked\_domains* contains "192.168.1.2" and ".168.1.2", 192.168.1.2 is blocked, but 193.168.1.2 is not.

*DefaultCookiePolicy* implements the following additional methods :

*DefaultCookiePolicy.blocked\_domains()*

Return the sequence of blocked domains (as a tuple).

*DefaultCookiePolicy.set\_blocked\_domains(blocked\_domains)*

Set the sequence of blocked domains.

*DefaultCookiePolicy.is\_blocked(domain)*

Return whether *domain* is on the blacklist for setting or receiving cookies.

*DefaultCookiePolicy.allowed\_domains()*

Return *None*, or the sequence of allowed domains (as a tuple).

*DefaultCookiePolicy.set\_allowed\_domains(allowed\_domains)*

Set the sequence of allowed domains, or *None*.

*DefaultCookiePolicy.is\_not\_allowed(domain)*

Return whether *domain* is not on the whitelist for setting or receiving cookies.

*DefaultCookiePolicy* instances have the following attributes, which are all initialised from the constructor arguments of the same name, and which may all be assigned to.

**DefaultCookiePolicy.rfc2109\_as\_netscape**

If true, request that the *CookieJar* instance downgrade RFC 2109 cookies (ie. cookies received in a *Set-Cookie* header with a version cookie-attribute of 1) to Netscape cookies by setting the version attribute of the *Cookie* instance to 0. The default value is *None*, in which case RFC 2109 cookies are downgraded if and only if RFC 2965 handling is turned off. Therefore, RFC 2109 cookies are downgraded by default.

Nouveau dans la version 2.5.

General strictness switches :

**DefaultCookiePolicy.strict\_domain**

Don't allow sites to set two-component domains with country-code top-level domains like *.co.uk*, *.gov.uk*, *.co.nz*.etc. This is far from perfect and isn't guaranteed to work!

RFC 2965 protocol strictness switches :

**DefaultCookiePolicy.strict\_rfc2965\_unverifiable**

Follow RFC 2965 rules on unverifiable transactions (usually, an unverifiable transaction is one resulting from a redirect or a request for an image hosted on another site). If this is false, cookies are *never* blocked on the basis of verifiability

Netscape protocol strictness switches :

**DefaultCookiePolicy.strict\_ns\_unverifiable**

Apply RFC 2965 rules on unverifiable transactions even to Netscape cookies.

**DefaultCookiePolicy.strict\_ns\_domain**

Flags indicating how strict to be with domain-matching rules for Netscape cookies. See below for acceptable values.

**DefaultCookiePolicy.strict\_ns\_set\_initial\_dollar**

Ignore cookies in Set-Cookie : headers that have names starting with '\$'.

**DefaultCookiePolicy.strict\_ns\_set\_path**

Don't allow setting cookies whose path doesn't path-match request URI.

*strict\_ns\_domain* is a collection of flags. Its value is constructed by or-ing together (for example, *DomainStrictNoDots|DomainStrictNonDomain* means both flags are set).

**DefaultCookiePolicy.DomainStrictNoDots**

When setting cookies, the "host prefix" must not contain a dot (eg. *www.foo.bar.com* can't set a cookie for *.bar.com*, because *www.foo* contains a dot).

**DefaultCookiePolicy.DomainStrictNonDomain**

Cookies that did not explicitly specify a *domain* cookie-attribute can only be returned to a domain equal to the domain that set the cookie (eg. *spam.example.com* won't be returned cookies from *example.com* that had no *domain* cookie-attribute).

**DefaultCookiePolicy.DomainRFC2965Match**

When setting cookies, require a full RFC 2965 domain-match.

The following attributes are provided for convenience, and are the most useful combinations of the above flags :

**DefaultCookiePolicy.DomainLiberal**

Equivalent to 0 (ie. all of the above Netscape domain strictness flags switched off).

**DefaultCookiePolicy.DomainStrict**

Equivalent to *DomainStrictNoDots|DomainStrictNonDomain*.

## 20.21.5 Cookie Objects

*Cookie* instances have Python attributes roughly corresponding to the standard cookie-attributes specified in the various cookie standards. The correspondence is not one-to-one, because there are complicated rules for assigning default values, because the `max-age` and `expires` cookie-attributes contain equivalent information, and because RFC 2109 cookies may be “downgraded” by *cookielib* from version 1 to version 0 (Netscape) cookies.

Assignment to these attributes should not be necessary other than in rare circumstances in a *CookiePolicy* method. The class does not enforce internal consistency, so you should know what you’re doing if you do that.

### `Cookie.version`

Integer or *None*. Netscape cookies have *version* 0. RFC 2965 and RFC 2109 cookies have a *version* cookie-attribute of 1. However, note that *cookielib* may “downgrade” RFC 2109 cookies to Netscape cookies, in which case *version* is 0.

### `Cookie.name`

Cookie name (a string).

### `Cookie.value`

Cookie value (a string), or *None*.

### `Cookie.port`

String representing a port or a set of ports (eg. “80”, or “80,8080”), or *None*.

### `Cookie.path`

Cookie path (a string, eg.  `'/acme/rocket_launchers'`).

### `Cookie.secure`

*True* if cookie should only be returned over a secure connection.

### `Cookie.expires`

Integer expiry date in seconds since epoch, or *None*. See also the *is\_expired()* method.

### `Cookie.discard`

*True* if this is a session cookie.

### `Cookie.comment`

String comment from the server explaining the function of this cookie, or *None*.

### `Cookie.comment_url`

URL linking to a comment from the server explaining the function of this cookie, or *None*.

### `Cookie.rfc2109`

*True* if this cookie was received as an RFC 2109 cookie (ie. the cookie arrived in a *Set-Cookie* header, and the value of the Version cookie-attribute in that header was 1). This attribute is provided because *cookielib* may “downgrade” RFC 2109 cookies to Netscape cookies, in which case *version* is 0. Nouveau dans la version 2.5.

### `Cookie.port_specified`

*True* if a port or set of ports was explicitly specified by the server (in the *Set-Cookie* / *Set-Cookie2* header).

### `Cookie.domain_specified`

*True* if a domain was explicitly specified by the server.

### `Cookie.domain_initial_dot`

*True* if the domain explicitly specified by the server began with a dot (`'.'`).

Cookies may have additional non-standard cookie-attributes. These may be accessed using the following methods :

`Cookie.has_nonstandard_attr(name)`  
Return true if cookie has the named cookie-attribute.

`Cookie.get_nonstandard_attr(name, default=None)`  
If cookie has the named cookie-attribute, return its value. Otherwise, return *default*.

`Cookie.set_nonstandard_attr(name, value)`  
Set the value of the named cookie-attribute.

The *Cookie* class also defines the following method :

`Cookie.is_expired([now=None])`  
True if cookie has passed the time at which the server requested it should expire. If *now* is given (in seconds since the epoch), return whether the cookie has expired at the specified time.

## 20.21.6 Examples

The first example shows the most common usage of *cookielib* :

```
import cookielib, urllib2
cj = cookielib.CookieJar()
opener = urllib2.build_opener(urllib2.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```

This example illustrates how to open a URL using your Netscape, Mozilla, or Lynx cookies (assumes Unix/Netscape convention for location of the cookies file) :

```
import os, cookielib, urllib2
cj = cookielib.MozillaCookieJar()
cj.load(os.path.join(os.path.expanduser("~"), ".netscape", "cookies.txt"))
opener = urllib2.build_opener(urllib2.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```

The next example illustrates the use of *DefaultCookiePolicy*. Turn on RFC 2965 cookies, be more strict about domains when setting and returning Netscape cookies, and block some domains from setting cookies or having them returned :

```
import urllib2
from cookielib import CookieJar, DefaultCookiePolicy
policy = DefaultCookiePolicy(
    rfc2965=True, strict_ns_domain=DefaultCookiePolicy.DomainStrict,
    blocked_domains=["ads.net", ".ads.net"])
cj = CookieJar(policy)
opener = urllib2.build_opener(urllib2.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```

## 20.22 Cookie — HTTP state management

---

**Note :** The *Cookie* module has been renamed to `http.cookies` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

Source code : [Lib/Cookie.py](#)

---

The `Cookie` module defines classes for abstracting the concept of cookies, an HTTP state management mechanism. It supports both simple string-only cookies, and provides an abstraction for having any serializable data-type as cookie value.

The module formerly strictly applied the parsing rules described in the [RFC 2109](#) and [RFC 2068](#) specifications. It has since been discovered that MSIE 3.0x doesn't follow the character rules outlined in those specs and also many current day browsers and servers have relaxed parsing rules when comes to Cookie handling. As a result, the parsing rules used are a bit less strict.

The character set, `string.ascii_letters`, `string.digits` and `!#$%&'*+-.^_`|~` denote the set of valid characters allowed by this module in Cookie name (as *key*).

---

**Note :** On encountering an invalid cookie, `CookieError` is raised, so if your cookie data comes from a browser you should always prepare for invalid data and catch `CookieError` on parsing.

---

**exception** `Cookie.CookieError`

Exception failing because of [RFC 2109](#) invalidity : incorrect attributes, incorrect *Set-Cookie* header, etc.

**class** `Cookie.BaseCookie([input])`

This class is a dictionary-like object whose keys are strings and whose values are *Morsel* instances. Note that upon setting a key to a value, the value is first converted to a *Morsel* containing the key and the value.

If *input* is given, it is passed to the `load()` method.

**class** `Cookie.SimpleCookie([input])`

This class derives from *BaseCookie* and overrides `value_decode()` and `value_encode()` to be the identity and `str()` respectively.

**class** `Cookie.SerialCookie([input])`

This class derives from *BaseCookie* and overrides `value_decode()` and `value_encode()` to be the `pickle.loads()` and `pickle.dumps()`.

Obsolète depuis la version 2.3 : Reading pickled values from untrusted cookie data is a huge security hole, as pickle strings can be crafted to cause arbitrary code to execute on your server. It is supported for backwards compatibility only, and may eventually go away.

**class** `Cookie.SmartCookie([input])`

This class derives from *BaseCookie*. It overrides `value_decode()` to be `pickle.loads()` if it is a valid pickle, and otherwise the value itself. It overrides `value_encode()` to be `pickle.dumps()` unless it is a string, in which case it returns the value itself.

Obsolète depuis la version 2.3 : The same security warning from *SerialCookie* applies here.

A further security note is warranted. For backwards compatibility, the `Cookie` module exports a class named `Cookie` which is just an alias for *SmartCookie*. This is probably a mistake and will likely be removed in a future version. You should not use the `Cookie` class in your applications, for the same reason why you should not use the *SerialCookie* class.

**Voir aussi :**

**Module** `cookielib` HTTP cookie handling for web *clients*. The `cookielib` and `Cookie` modules do not depend on each other.

**RFC 2109 - HTTP State Management Mechanism** This is the state management specification implemented by this module.

### 20.22.1 Cookie Objects

`BaseCookie.value_decode(val)`

Return a decoded value from a string representation. Return value can be any type. This method does nothing in *BaseCookie* — it exists so it can be overridden.

`BaseCookie.value_encode(val)`

Return an encoded value. *val* can be any type, but return value must be a string. This method does nothing in *BaseCookie* — it exists so it can be overridden.

In general, it should be the case that *value\_encode()* and *value\_decode()* are inverses on the range of *value\_decode*.

`BaseCookie.output([attrs[, header[, sep]]])`

Return a string representation suitable to be sent as HTTP headers. *attrs* and *header* are sent to each *Morsel*'s *output()* method. *sep* is used to join the headers together, and is by default the combination `'\r\n'` (CRLF).

Modifié dans la version 2.5 : The default separator has been changed from `'\n'` to match the cookie specification.

`BaseCookie.js_output([attrs])`

Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP headers was sent.

The meaning for *attrs* is the same as in *output()*.

`BaseCookie.load(rawdata)`

If *rawdata* is a string, parse it as an HTTP\_COOKIE and add the values found there as *Morsels*. If it is a dictionary, it is equivalent to :

```
for k, v in rawdata.items():
    cookie[k] = v
```

### 20.22.2 Morsel Objects

`class Cookie.Morsel`

Abstract a key/value pair, which has some **RFC 2109** attributes.

Morsels are dictionary-like objects, whose set of keys is constant — the valid **RFC 2109** attributes, which are

- `expires`
- `path`
- `comment`
- `domain`
- `max-age`
- `secure`
- `version`
- `httponly`

The attribute `httponly` specifies that the cookie is only transferred in HTTP requests, and is not accessible through JavaScript. This is intended to mitigate some forms of cross-site scripting.

The keys are case-insensitive.

Nouveau dans la version 2.6 : The `httponly` attribute was added.

`Morsel.value`

The value of the cookie.

`Morsel.coded_value`

The encoded value of the cookie — this is what should be sent.

`Morsel.key`

The name of the cookie.

`Morsel.set(key, value, coded_value)`

Set the *key*, *value* and *coded\_value* attributes.

`Morsel.isReservedKey(K)`

Whether *K* is a member of the set of keys of a *Morsel*.

`Morsel.output([attrs[, header]])`

Return a string representation of the Morsel, suitable to be sent as an HTTP header. By default, all the attributes are included, unless *attrs* is given, in which case it should be a list of attributes to use. *header* is by default "Set-Cookie:".

`Morsel.js_output([attrs])`

Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP header was sent.

The meaning for *attrs* is the same as in `output()`.

`Morsel.OutputString([attrs])`

Return a string representing the Morsel, without any surrounding HTTP or JavaScript.

The meaning for *attrs* is the same as in `output()`.

### 20.22.3 Exemple

The following example demonstrates how to use the *Cookie* module.

```
>>> import Cookie
>>> C = Cookie.SimpleCookie()
>>> C["fig"] = "newton"
>>> C["sugar"] = "wafer"
>>> print C # generate HTTP headers
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> print C.output() # same thing
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> C = Cookie.SimpleCookie()
>>> C["rocky"] = "road"
>>> C["rocky"]["path"] = "/cookie"
>>> print C.output(header="Cookie:")
Cookie: rocky=road; Path=/cookie
>>> print C.output(attrs=[], header="Cookie:")
Cookie: rocky=road
>>> C = Cookie.SimpleCookie()
>>> C.load("chips=ahoy; vienna=finger") # load from a string (HTTP header)
>>> print C
Set-Cookie: chips=ahoy
Set-Cookie: vienna=finger
>>> C = Cookie.SimpleCookie()
>>> C.load('keebler="E=everybody; L=\\\"Loves\\\"; fudge=\\\"012;\";')
>>> print C
Set-Cookie: keebler="E=everybody; L=\\\"Loves\\\"; fudge=\\\"012;"
>>> C = Cookie.SimpleCookie()
>>> C["oreo"] = "doublestuff"
```

(suite sur la page suivante)

(suite de la page précédente)

```

>>> C["oreo"]["path"] = "/"
>>> print C
Set-Cookie: oreo=doublestuff; Path=/
>>> C["twix"] = "none for you"
>>> C["twix"].value
'none for you'
>>> C = Cookie.SimpleCookie()
>>> C["number"] = 7 # equivalent to C["number"] = str(7)
>>> C["string"] = "seven"
>>> C["number"].value
'7'
>>> C["string"].value
'seven'
>>> print C
Set-Cookie: number=7
Set-Cookie: string=seven
>>> # SerialCookie and SmartCookie are deprecated
>>> # using it can cause security loopholes in your code.
>>> C = Cookie.SerialCookie()
>>> C["number"] = 7
>>> C["string"] = "seven"
>>> C["number"].value
7
>>> C["string"].value
'seven'
>>> print C
Set-Cookie: number="I7\012."
Set-Cookie: string="S'seven'\012p1\012."
>>> C = Cookie.SmartCookie()
>>> C["number"] = 7
>>> C["string"] = "seven"
>>> C["number"].value
7
>>> C["string"].value
'seven'
>>> print C
Set-Cookie: number="I7\012."
Set-Cookie: string=seven

```

## 20.23 xmlrpclib — XML-RPC client access

**Note :** The *xmlrpclib* module has been renamed to `xmlrpc.client` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

Nouveau dans la version 2.2.

**Source code :** `Lib/xmlrpclib.py`

XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP(S) as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get

back structured data. This module supports writing XML-RPC client code; it handles all the details of translating between conformable Python objects and XML on the wire.

**Avertissement :** The `xmlrpclib` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see *Vulnérabilités XML*.

Modifié dans la version 2.7.9 : For HTTPS URIs, `xmlrpclib` now performs all the necessary certificate and hostname checks by default.

```
class xmlrpclib.ServerProxy(uri[, transport[, encoding[, verbose[, allow_none[, use_datetime[,
                                context]]]]]])
```

A `ServerProxy` instance is an object that manages communication with a remote XML-RPC server. The required first argument is a URI (Uniform Resource Indicator), and will normally be the URL of the server. The optional second argument is a transport factory instance; by default it is an internal `SafeTransport` instance for https : URLs and an internal `HTTP Transport` instance otherwise. The optional third argument is an encoding, by default UTF-8. The optional fourth argument is a debugging flag.

The following parameters govern the use of the returned proxy instance. If `allow_none` is true, the Python constant `None` will be translated into XML; the default behaviour is for `None` to raise a `TypeError`. This is a commonly-used extension to the XML-RPC specification, but isn't supported by all clients and servers; see <http://ontosys.com/xml-rpc/extensions.php> for a description. The `use_datetime` flag can be used to cause date/time values to be presented as `datetime.datetime` objects; this is false by default. `datetime.datetime` objects may be passed to calls.

Both the HTTP and HTTPS transports support the URL syntax extension for HTTP Basic Authentication : `http://user:pass@host:port/path`. The `user:pass` portion will be base64-encoded as an HTTP "Authorization" header, and sent to the remote server as part of the connection process when invoking an XML-RPC method. You only need to use this if the remote server requires a Basic Authentication user and password. If an HTTPS URL is provided, `context` may be `ssl.SSLContext` and configures the SSL settings of the underlying HTTPS connection.

The returned instance is a proxy object with methods that can be used to invoke corresponding RPC calls on the remote server. If the remote server supports the introspection API, the proxy can also be used to query the remote server for the methods it supports (service discovery) and fetch other server-associated metadata.

Types that are conformable (e.g. that can be marshalled through XML), include the following (and except where noted, they are unmarshalled as the same Python type) :

XML-RPC type	Type Python
boolean	<code>bool</code>
int or i4	<code>int</code> or <code>long</code> in range from -2147483648 to 2147483647.
double	<code>float</code>
string	<code>str</code> or <code>unicode</code>
array	list or <code>tuple</code> containing conformable elements. Arrays are returned as lists.
struct	<code>dict</code> . Keys must be strings, values may be any conformable type. Objects of user-defined classes can be passed in; only their <code>__dict__</code> attribute is transmitted.
dateTime.iso8601	<code>DateTime</code> or <code>datetime.datetime</code> . Returned type depends on values of the <code>use_datetime</code> flags.
base64	<code>Binary</code>
nil	The <code>None</code> constant. Passing is allowed only if <code>allow_none</code> is true.

This is the full set of data types supported by XML-RPC. Method calls may also raise a special `Fault` instance, used to signal XML-RPC server errors, or `ProtocolError` used to signal an error in

the HTTP/HTTPS transport layer. Both *Fault* and *ProtocolError* derive from a base class called *Error*. Note that even though starting with Python 2.2 you can subclass built-in types, the *xmlrpclib* module currently does not marshal instances of such subclasses.

When passing strings, characters special to XML such as `<`, `>`, and `&` will be automatically escaped. However, it's the caller's responsibility to ensure that the string is free of characters that aren't allowed in XML, such as the control characters with ASCII values between 0 and 31 (except, of course, tab, newline and carriage return); failing to do this will result in an XML-RPC request that isn't well-formed XML. If you have to pass arbitrary strings via XML-RPC, use the *Binary* wrapper class described below.

*Server* is retained as an alias for *ServerProxy* for backwards compatibility. New code should use *ServerProxy*.

Modifié dans la version 2.5 : The *use\_datetime* flag was added.

Modifié dans la version 2.6 : Instances of *new-style classes* can be passed in if they have an *\_\_dict\_\_* attribute and don't have a base class that is marshalled in a special way.

Modifié dans la version 2.7.9 : Added the *context* argument.

**Voir aussi :**

**XML-RPC HOWTO** A good description of XML-RPC operation and client software in several languages. Contains pretty much everything an XML-RPC client developer needs to know.

**XML-RPC Introspection** Describes the XML-RPC protocol extension for introspection.

**XML-RPC Specification** The official specification.

**Unofficial XML-RPC Errata** Fredrik Lundh's « unofficial errata, intended to clarify certain details in the XML-RPC specification, as well as hint at “best practices” to use when designing your own XML-RPC implementations. »

### 20.23.1 ServerProxy Objects

A *ServerProxy* instance has a method corresponding to each remote procedure call accepted by the XML-RPC server. Calling the method performs an RPC, dispatched by both name and argument signature (e.g. the same method name can be overloaded with multiple argument signatures). The RPC finishes by returning a value, which may be either returned data in a conformant type or a *Fault* or *ProtocolError* object indicating an error.

Servers that support the XML introspection API support some common methods grouped under the reserved *system* attribute :

*ServerProxy.system.listMethods()*

This method returns a list of strings, one for each (non-system) method supported by the XML-RPC server.

*ServerProxy.system.methodSignature(name)*

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns an array of possible signatures for this method. A signature is an array of types. The first of these types is the return type of the method, the rest are parameters.

Because multiple signatures (ie. overloading) is permitted, this method returns a list of signatures rather than a singleton.

Signatures themselves are restricted to the top level parameters expected by a method. For instance if a method expects one array of structs as a parameter, and it returns a string, its signature is simply « string, array ». If it expects three integers and returns a string, its signature is « string, int, int, int ».

If no signature is defined for the method, a non-array value is returned. In Python this means that the type of the returned value will be something other than list.

`ServerProxy.system.methodHelp(name)`

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns a documentation string describing the use of that method. If no such string is available, an empty string is returned. The documentation string may contain HTML markup.

### 20.23.2 Les objets booléens

This class may be initialized from any Python value; the instance returned depends only on its truth value. It supports various Python operators through `__cmp__()`, `__repr__()`, `__int__()`, and `__nonzero__()` methods, all implemented in the obvious ways.

It also has the following method, supported mainly for internal use by the unmarshalling code :

`Boolean.encode(out)`

Write the XML-RPC encoding of this Boolean item to the out stream object.

A working example follows. The server code :

```
import xmlrpclib
from SimpleXMLRPCServer import SimpleXMLRPCServer

def is_even(n):
    return n % 2 == 0

server = SimpleXMLRPCServer(("localhost", 8000))
print "Listening on port 8000..."
server.register_function(is_even, "is_even")
server.serve_forever()
```

The client code for the preceding server :

```
import xmlrpclib

proxy = xmlrpclib.ServerProxy("http://localhost:8000/")
print "3 is even: %s" % str(proxy.is_even(3))
print "100 is even: %s" % str(proxy.is_even(100))
```

### 20.23.3 Objets DateTime

`class xmlrpclib.DateTime`

This class may be initialized with seconds since the epoch, a time tuple, an ISO 8601 time/date string, or a `datetime.datetime` instance. It has the following methods, supported mainly for internal use by the marshalling/unmarshalling code :

`decode(string)`

Accept a string as the instance's new time value.

`encode(out)`

Write the XML-RPC encoding of this `DateTime` item to the *out* stream object.

It also supports certain of Python's built-in operators through `__cmp__()` and `__repr__()` methods.

A working example follows. The server code :

```
import datetime
from SimpleXMLRPCServer import SimpleXMLRPCServer
import xmlrpclib
```

(suite sur la page suivante)

(suite de la page précédente)

```
def today():
    today = datetime.datetime.today()
    return xmlrpclib.DateTime(today)

server = SimpleXMLRPCServer(("localhost", 8000))
print "Listening on port 8000..."
server.register_function(today, "today")
server.serve_forever()
```

The client code for the preceding server :

```
import xmlrpclib
import datetime

proxy = xmlrpclib.ServerProxy("http://localhost:8000/")

today = proxy.today()
# convert the ISO8601 string to a datetime object
converted = datetime.datetime.strptime(today.value, "%Y%m%dT%H:%M:%S")
print "Today: %s" % converted.strftime("%d.%m.%Y, %H:%M")
```

## 20.23.4 Binary Objects

**class** `xmlrpclib.Binary`

This class may be initialized from string data (which may include NULs). The primary access to the content of a *Binary* object is provided by an attribute :

**data**

The binary data encapsulated by the *Binary* instance. The data is provided as an 8-bit string. *Binary* objects have the following methods, supported mainly for internal use by the marshaling/unmarshaling code :

**decode**(*string*)

Accept a base64 string and decode it as the instance's new data.

**encode**(*out*)

Write the XML-RPC base 64 encoding of this binary item to the *out* stream object.

The encoded data will have newlines every 76 characters as per RFC 2045 section 6.8, which was the de facto standard base64 specification when the XML-RPC spec was written.

It also supports certain of Python's built-in operators through a `__cmp__()` method.

Example usage of the binary objects. We're going to transfer an image over XMLRPC :

```
from SimpleXMLRPCServer import SimpleXMLRPCServer
import xmlrpclib

def python_logo():
    with open("python_logo.jpg", "rb") as handle:
        return xmlrpclib.Binary(handle.read())

server = SimpleXMLRPCServer(("localhost", 8000))
print "Listening on port 8000..."
server.register_function(python_logo, 'python_logo')

server.serve_forever()
```

The client gets the image and saves it to a file :

```
import xmlrpclib

proxy = xmlrpclib.ServerProxy("http://localhost:8000/")
with open("fetched_python_logo.jpg", "wb") as handle:
    handle.write(proxy.python_logo().data)
```

### 20.23.5 Fault Objects

`class xmlrpclib.Fault`

A *Fault* object encapsulates the content of an XML-RPC fault tag. Fault objects have the following attributes :

**faultCode**

A string indicating the fault type.

**faultString**

A string containing a diagnostic message associated with the fault.

In the following example we’re going to intentionally cause a *Fault* by returning a complex type object. The server code :

```
from SimpleXMLRPCServer import SimpleXMLRPCServer

# A marshalling error is going to occur because we're returning a
# complex number
def add(x, y):
    return x+y+0j

server = SimpleXMLRPCServer(("localhost", 8000))
print "Listening on port 8000..."
server.register_function(add, 'add')

server.serve_forever()
```

The client code for the preceding server :

```
import xmlrpclib

proxy = xmlrpclib.ServerProxy("http://localhost:8000/")
try:
    proxy.add(2, 5)
except xmlrpclib.Fault as err:
    print "A fault occurred"
    print "Fault code: %d" % err.faultCode
    print "Fault string: %s" % err.faultString
```

### 20.23.6 ProtocolError Objects

`class xmlrpclib.ProtocolError`

A *ProtocolError* object describes a protocol error in the underlying transport layer (such as a 404 “not found” error if the server named by the URI does not exist). It has the following attributes :

**url**

The URI or URL that triggered the error.

**errcode**

The error code.

**errmsg**

The error message or diagnostic string.

**headers**

A string containing the headers of the HTTP/HTTPS request that triggered the error.

In the following example we're going to intentionally cause a *ProtocolError* by providing a URI that doesn't point to an XMLRPC server :

```
import xmlrpclib

# create a ServerProxy with a URI that doesn't respond to XMLRPC requests
proxy = xmlrpclib.ServerProxy("http://www.google.com/")

try:
    proxy.some_method()
except xmlrpclib.ProtocolError as err:
    print "A protocol error occurred"
    print "URL: %s" % err.url
    print "HTTP/HTTPS headers: %s" % err.headers
    print "Error code: %d" % err.errcode
    print "Error message: %s" % err.errmsg
```

## 20.23.7 MultiCall Objects

Nouveau dans la version 2.4.

The *MultiCall* object provides a way to encapsulate multiple calls to a remote server into a single request <sup>1</sup>.

**class xmlrpclib.MultiCall(server)**

Create an object used to boxcar method calls. *server* is the eventual target of the call. Calls can be made to the result object, but they will immediately return *None*, and only store the call name and parameters in the *MultiCall* object. Calling the object itself causes all stored calls to be transmitted as a single *system.multicall* request. The result of this call is a *generator*; iterating over this generator yields the individual results.

A usage example of this class follows. The server code

```
from SimpleXMLRPCServer import SimpleXMLRPCServer

def add(x,y):
    return x+y

def subtract(x, y):
    return x-y

def multiply(x, y):
    return x*y

def divide(x, y):
    return x/y
```

(suite sur la page suivante)

---

1. This approach has been first presented in a [discussion on xmlrpc.com](#).

(suite de la page précédente)

```
# A simple server with simple arithmetic functions
server = SimpleXMLRPCServer(("localhost", 8000))
print "Listening on port 8000..."
server.register_multicall_functions()
server.register_function(add, 'add')
server.register_function(subtract, 'subtract')
server.register_function(multiply, 'multiply')
server.register_function(divide, 'divide')
server.serve_forever()
```

The client code for the preceding server :

```
import xmlrpclib

proxy = xmlrpclib.ServerProxy("http://localhost:8000/")
multicall = xmlrpclib.MultiCall(proxy)
multicall.add(7,3)
multicall.subtract(7,3)
multicall.multiply(7,3)
multicall.divide(7,3)
result = multicall()

print "7+3=%d, 7-3=%d, 7*3=%d, 7/3=%d" % tuple(result)
```

### 20.23.8 Convenience Functions

`xmlrpclib.boolean(value)`

Convert any Python value to one of the XML-RPC Boolean constants, `True` or `False`.

`xmlrpclib.dumps(params[, methodname[, methodresponse[, encoding[, allow_none]]])`

Convert *params* into an XML-RPC request. or into a response if *methodresponse* is true. *params* can be either a tuple of arguments or an instance of the `Fault` exception class. If *methodresponse* is true, only a single value can be returned, meaning that *params* must be of length 1. *encoding*, if supplied, is the encoding to use in the generated XML; the default is UTF-8. Python's `None` value cannot be used in standard XML-RPC; to allow using it via an extension, provide a true value for *allow\_none*.

`xmlrpclib.loads(data[, use_datetime])`

Convert an XML-RPC request or response into Python objects, a `(params, methodname)`. *params* is a tuple of argument; *methodname* is a string, or `None` if no method name is present in the packet. If the XML-RPC packet represents a fault condition, this function will raise a `Fault` exception. The *use\_datetime* flag can be used to cause date/time values to be presented as `datetime.datetime` objects; this is false by default.

Modifié dans la version 2.5 : The *use\_datetime* flag was added.

### 20.23.9 Example of Client Usage

```
# simple test program (from the XML-RPC specification)
from xmlrpclib import ServerProxy, Error

# server = ServerProxy("http://localhost:8000") # local server
server = ServerProxy("http://betty.userland.com")
```

(suite sur la page suivante)

(suite de la page précédente)

```
print server

try:
    print server.examples.getStateName(41)
except Error as v:
    print "ERROR", v
```

To access an XML-RPC server through a HTTP proxy, you need to define a custom transport. The following example shows how :

```
import xmlrpclib, httplib

class ProxiedTransport(xmlrpclib.Transport):
    def set_proxy(self, proxy):
        self.proxy = proxy

    def make_connection(self, host):
        self.realhost = host
        h = httplib.HTTPConnection(self.proxy)
        return h

    def send_request(self, connection, handler, request_body):
        connection.putrequest("POST", 'http://%s%s' % (self.realhost, handler))

    def send_host(self, connection, host):
        connection.putheader('Host', self.realhost)

p = ProxiedTransport()
p.set_proxy('proxy-server:8080')
server = xmlrpclib.ServerProxy('http://time.xmlrpc.com/RPC2', transport=p)
print server.currentTime.getCurrentTime()
```

### 20.23.10 Example of Client and Server Usage

See *SimpleXMLRPCServer Example*.

#### Notes

## 20.24 SimpleXMLRPCServer — Basic XML-RPC server

---

**Note :** The *SimpleXMLRPCServer* module has been merged into `xmlrpc.server` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

Nouveau dans la version 2.2.

**Source code :** `Lib/SimpleXMLRPCServer.py`

---

The *SimpleXMLRPCServer* module provides a basic server framework for XML-RPC servers written in Python. Servers can either be free standing, using *SimpleXMLRPCServer*, or embedded in a CGI environment, using *CGIXMLRPCRequestHandler*.

```
class SimpleXMLRPCServer.SimpleXMLRPCServer(addr[, requestHandler[, logRequests[, allow_none[, encoding[, bind_and_activate]]]])
```

Create a new server instance. This class provides methods for registration of functions that can be called by the XML-RPC protocol. The *requestHandler* parameter should be a factory for request handler instances; it defaults to *SimpleXMLRPCRequestHandler*. The *addr* and *requestHandler* parameters are passed to the *SocketServer.TCPServer* constructor. If *logRequests* is true (the default), requests will be logged; setting this parameter to false will turn off logging. The *allow\_none* and *encoding* parameters are passed on to *xmrlplib* and control the XML-RPC responses that will be returned from the server. The *bind\_and\_activate* parameter controls whether *server\_bind()* and *server\_activate()* are called immediately by the constructor; it defaults to true. Setting it to false allows code to manipulate the *allow\_reuse\_address* class variable before the address is bound.

Modifié dans la version 2.5 : The *allow\_none* and *encoding* parameters were added.

Modifié dans la version 2.6 : The *bind\_and\_activate* parameter was added.

```
class SimpleXMLRPCServer.CGIXMLRPCRequestHandler([allow_none[, encoding]])
```

Create a new instance to handle XML-RPC requests in a CGI environment. The *allow\_none* and *encoding* parameters are passed on to *xmrlplib* and control the XML-RPC responses that will be returned from the server.

Nouveau dans la version 2.3.

Modifié dans la version 2.5 : The *allow\_none* and *encoding* parameters were added.

```
class SimpleXMLRPCServer.SimpleXMLRPCRequestHandler
```

Create a new request handler instance. This request handler supports POST requests and modifies logging so that the *logRequests* parameter to the *SimpleXMLRPCServer* constructor parameter is honored.

### 20.24.1 SimpleXMLRPCServer Objects

The *SimpleXMLRPCServer* class is based on *SocketServer.TCPServer* and provides a means of creating simple, stand alone XML-RPC servers.

```
SimpleXMLRPCServer.register_function(function[, name])
```

Register a function that can respond to XML-RPC requests. If *name* is given, it will be the method name associated with *function*, otherwise *function.\_\_name\_\_* will be used. *name* can be either a normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

```
SimpleXMLRPCServer.register_instance(instance[, allow_dotted_names])
```

Register an object which is used to expose method names which have not been registered using *register\_function()*. If *instance* contains a *\_dispatch()* method, it is called with the requested method name and the parameters from the request. Its API is *def \_dispatch(self, method, params)* (note that *params* does not represent a variable argument list). If it calls an underlying function to perform its task, that function is called as *func(\*params)*, expanding the parameter list. The return value from *\_dispatch()* is returned to the client as the result. If *instance* does not have a *\_dispatch()* method, it is searched for an attribute matching the name of the requested method.

If the optional *allow\_dotted\_names* argument is true and the instance does not have a *\_dispatch()* method, then if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

**Avertissement :** Enabling the *allow\_dotted\_names* option allows intruders to access your module's global variables and may allow intruders to execute arbitrary code on your machine. Only use this option on a secure, closed network.

Modifié dans la version 2.3.5, : 2.4.1 `allow_dotted_names` was added to plug a security hole; prior versions are insecure.

`SimpleXMLRPCServer.register_introspection_functions()`

Registers the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

Nouveau dans la version 2.3.

`SimpleXMLRPCServer.register_multicall_functions()`

Registers the XML-RPC multicall function `system.multicall`.

`SimpleXMLRPCRequestHandler.rpc_paths`

An attribute value that must be a tuple listing valid path portions of the URL for receiving XML-RPC requests. Requests posted to other paths will result in a 404 « no such page » HTTP error. If this tuple is empty, all paths will be considered valid. The default value is `('/', '/RPC2')`.

Nouveau dans la version 2.5.

`SimpleXMLRPCRequestHandler.encode_threshold`

If this attribute is not `None`, responses larger than this value will be encoded using the *gzip* transfer encoding, if permitted by the client. The default is 1400 which corresponds roughly to a single TCP packet.

Nouveau dans la version 2.7.

## SimpleXMLRPCServer Example

Server code :

```
from SimpleXMLRPCServer import SimpleXMLRPCServer
from SimpleXMLRPCServer import SimpleXMLRPCRequestHandler

# Restrict to a particular path.
class RequestHandler(SimpleXMLRPCRequestHandler):
    rpc_paths = ('/RPC2',)

# Create server
server = SimpleXMLRPCServer(("localhost", 8000),
                           requestHandler=RequestHandler)
server.register_introspection_functions()

# Register pow() function; this will use the value of
# pow.__name__ as the name, which is just 'pow'.
server.register_function(pow)

# Register a function under a different name
def adder_function(x,y):
    return x + y
server.register_function(adder_function, 'add')

# Register an instance; all the methods of the instance are
# published as XML-RPC methods (in this case, just 'div').
class MyFuncs:
    def div(self, x, y):
        return x // y

server.register_instance(MyFuncs())
```

(suite sur la page suivante)

(suite de la page précédente)

```
# Run the server's main loop
server.serve_forever()
```

The following client code will call the methods made available by the preceding server :

```
import xmlrpclib

s = xmlrpclib.ServerProxy('http://localhost:8000')
print s.pow(2,3) # Returns 2**3 = 8
print s.add(2,3) # Returns 5
print s.div(5,2) # Returns 5//2 = 2

# Print list of available methods
print s.system.listMethods()
```

The following *SimpleXMLRPCServer* example is included in the module *Lib/SimpleXMLRPCServer.py* :

```
server = SimpleXMLRPCServer(("localhost", 8000))
server.register_function(pow)
server.register_function(lambda x,y: x+y, 'add')
server.register_multicall_functions()
server.serve_forever()
```

This demo server can be run from the command line as :

```
python -m SimpleXMLRPCServer
```

Example client code which talks to the above server is included with *Lib/xmlrpclib.py* :

```
server = ServerProxy("http://localhost:8000")
print server
multi = MultiCall(server)
multi.pow(2, 9)
multi.add(5, 1)
multi.add(24, 11)
try:
    for response in multi():
        print response
except Error, v:
    print "ERROR", v
```

And the client can be invoked directly using the following command :

```
python -m xmlrpclib
```

## 20.24.2 CGIXMLRPCRequestHandler

The *CGIXMLRPCRequestHandler* class can be used to handle XML-RPC requests sent to Python CGI scripts.

**CGIXMLRPCRequestHandler.register\_function(function[, name])**

Register a function that can respond to XML-RPC requests. If *name* is given, it will be the method name associated with function, otherwise *function.\_\_name\_\_* will be used. *name* can be either a

normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

`CGIXMLRPCRequestHandler.register_instance(instance)`

Register an object which is used to expose method names which have not been registered using `register_function()`. If instance contains a `_dispatch()` method, it is called with the requested method name and the parameters from the request; the return value is returned to the client as the result. If instance does not have a `_dispatch()` method, it is searched for an attribute matching the name of the requested method; if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

`CGIXMLRPCRequestHandler.register_introspection_functions()`

Register the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

`CGIXMLRPCRequestHandler.register_multicall_functions()`

Register the XML-RPC multicall function `system.multicall`.

`CGIXMLRPCRequestHandler.handle_request([request_text = None])`

Handle an XML-RPC request. If `request_text` is given, it should be the POST data provided by the HTTP server, otherwise the contents of stdin will be used.

Exemple :

```
class MyFuncs:
    def div(self, x, y): return x // y

handler = CGIXMLRPCRequestHandler()
handler.register_function(pow)
handler.register_function(lambda x,y: x+y, 'add')
handler.register_introspection_functions()
handler.register_instance(MyFuncs())
handler.handle_request()
```

## 20.25 DocXMLRPCServer — Self-documenting XML-RPC server

---

**Note :** The `DocXMLRPCServer` module has been merged into `xmlrpc.server` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

Nouveau dans la version 2.3.

The `DocXMLRPCServer` module extends the classes found in `SimpleXMLRPCServer` to serve HTML documentation in response to HTTP GET requests. Servers can either be free standing, using `DocXMLRPCServer`, or embedded in a CGI environment, using `DocCGIXMLRPCRequestHandler`.

```
class DocXMLRPCServer.DocXMLRPCServer(addr[, requestHandler[, logRequests[, allow_none[, encoding[, bind_and_activate]]]]])
```

Create a new server instance. All parameters have the same meaning as for `SimpleXMLRPCServer`. `SimpleXMLRPCServer`; `requestHandler` defaults to `DocXMLRPCRequestHandler`.

```
class DocXMLRPCServer.DocCGIXMLRPCRequestHandler
```

Create a new instance to handle XML-RPC requests in a CGI environment.

**class DocXMLRPCServer.DocXMLRPCRequestHandler**

Create a new request handler instance. This request handler supports XML-RPC POST requests, documentation GET requests, and modifies logging so that the *logRequests* parameter to the *DocXMLRPCServer* constructor parameter is honored.

**20.25.1 DocXMLRPCServer Objects**

The *DocXMLRPCServer* class is derived from *SimpleXMLRPCServer.SimpleXMLRPCServer* and provides a means of creating self-documenting, stand alone XML-RPC servers. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

**DocXMLRPCServer.set\_server\_title(server\_title)**

Set the title used in the generated HTML documentation. This title will be used inside the HTML « title » element.

**DocXMLRPCServer.set\_server\_name(server\_name)**

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a « h1 » element.

**DocXMLRPCServer.set\_server\_documentation(server\_documentation)**

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.

**20.25.2 DocCGIXMLRPCRequestHandler**

The *DocCGIXMLRPCRequestHandler* class is derived from *SimpleXMLRPCServer.CGIXMLRPCRequestHandler* and provides a means of creating self-documenting, XML-RPC CGI scripts. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

**DocCGIXMLRPCRequestHandler.set\_server\_title(server\_title)**

Set the title used in the generated HTML documentation. This title will be used inside the HTML « title » element.

**DocCGIXMLRPCRequestHandler.set\_server\_name(server\_name)**

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a « h1 » element.

**DocCGIXMLRPCRequestHandler.set\_server\_documentation(server\_documentation)**

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.

Les modules documentés dans ce chapitre implémentent divers algorithmes ou interfaces principalement utiles pour les applications multimédia. Ils peuvent ne pas être disponibles sur votre installation. En voici un aperçu :

### 21.1 audioloop — Manipulation de données audio brutes

The *audioloop* module contains some useful operations on sound fragments. It operates on sound fragments consisting of signed integer samples 8, 16 or 32 bits wide, stored in Python strings. This is the same format as used by the *al* and *sunaudiodev* modules. All scalar items are integers, unless specified otherwise.

This module provides support for a-LAW, u-LAW and Intel/DVI ADPCM encodings.

A few of the more complicated operations only take 16-bit samples, otherwise the sample size (in bytes) is always a parameter of the operation.

The module defines the following variables and functions :

**exception `audioloop.error`**

This exception is raised on all errors, such as unknown number of bytes per sample, etc.

**`audioloop.add(fragment1, fragment2, width)`**

Return a fragment which is the addition of the two samples passed as parameters. *width* is the sample width in bytes, either 1, 2 or 4. Both fragments should have the same length. Samples are truncated in case of overflow.

**`audioloop.adpcm2lin(adpcmfragment, width, state)`**

Decode an Intel/DVI ADPCM coded fragment to a linear fragment. See the description of *lin2adpcm()* for details on ADPCM coding. Return a tuple (*sample*, *newstate*) where the sample has the width specified in *width*.

**`audioloop.alaw2lin(fragment, width)`**

Convert sound fragments in a-LAW encoding to linearly encoded sound fragments. a-LAW encoding always uses 8 bits samples, so *width* refers only to the sample width of the output fragment here.

Nouveau dans la version 2.5.

`audioop.avg(fragment, width)`

Return the average over all samples in the fragment.

`audioop.avgpp(fragment, width)`

Return the average peak-peak value over all samples in the fragment. No filtering is done, so the usefulness of this routine is questionable.

`audioop.bias(fragment, width, bias)`

Return a fragment that is the original fragment with a bias added to each sample. Samples wrap around in case of overflow.

`audioop.cross(fragment, width)`

Return the number of zero crossings in the fragment passed as an argument.

`audioop.findfactor(fragment, reference)`

Return a factor *F* such that `rms(add(fragment, mul(reference, -F)))` is minimal, i.e., return the factor with which you should multiply *reference* to make it match as well as possible to *fragment*. The fragments should both contain 2-byte samples.

The time taken by this routine is proportional to `len(fragment)`.

`audioop.findfit(fragment, reference)`

Try to match *reference* as well as possible to a portion of *fragment* (which should be the longer fragment). This is (conceptually) done by taking slices out of *fragment*, using `findfactor()` to compute the best match, and minimizing the result. The fragments should both contain 2-byte samples. Return a tuple (*offset*, *factor*) where *offset* is the (integer) offset into *fragment* where the optimal match started and *factor* is the (floating-point) factor as per `findfactor()`.

`audioop.findmax(fragment, length)`

Search *fragment* for a slice of length *length* samples (not bytes!) with maximum energy, i.e., return *i* for which `rms(fragment[i*2:(i+length)*2])` is maximal. The fragments should both contain 2-byte samples.

The routine takes time proportional to `len(fragment)`.

`audioop.getsample(fragment, width, index)`

Return the value of sample *index* from the fragment.

`audioop.lin2adpcm(fragment, width, state)`

Convert samples to 4 bit Intel/DVI ADPCM encoding. ADPCM coding is an adaptive coding scheme, whereby each 4 bit number is the difference between one sample and the next, divided by a (varying) step. The Intel/DVI ADPCM algorithm has been selected for use by the IMA, so it may well become a standard.

*state* is a tuple containing the state of the coder. The coder returns a tuple (*adpcmfrag*, *newstate*), and the *newstate* should be passed to the next call of `lin2adpcm()`. In the initial call, `None` can be passed as the state. *adpcmfrag* is the ADPCM coded fragment packed 2 4-bit values per byte.

`audioop.lin2alaw(fragment, width)`

Convert samples in the audio fragment to a-LAW encoding and return this as a Python string. a-LAW is an audio encoding format whereby you get a dynamic range of about 13 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

Nouveau dans la version 2.5.

`audioop.lin2lin(fragment, width, newwidth)`

Convert samples between 1-, 2- and 4-byte formats.

---

**Note :** In some audio formats, such as .WAV files, 16 and 32 bit samples are signed, but 8 bit samples are unsigned. So when converting to 8 bit wide samples for these formats, you need to also add 128 to the result :

```
new_frames = audioop.lin2lin(frames, old_width, 1)
new_frames = audioop.bias(new_frames, 1, 128)
```

The same, in reverse, has to be applied when converting from 8 to 16 or 32 bit width samples.

**audioop.lin2ulaw(fragment, width)**

Convert samples in the audio fragment to u-LAW encoding and return this as a Python string. u-LAW is an audio encoding format whereby you get a dynamic range of about 14 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

**audioop.max(fragment, width)**

Return the maximum of the *absolute value* of all samples in a fragment.

**audioop.maxpp(fragment, width)**

Return the maximum peak-peak value in the sound fragment.

**audioop.minmax(fragment, width)**

Return a tuple consisting of the minimum and maximum values of all samples in the sound fragment.

**audioop.mul(fragment, width, factor)**

Return a fragment that has all samples in the original fragment multiplied by the floating-point value *factor*. Samples are truncated in case of overflow.

**audioop.ratecv(fragment, width, nchannels, inrate, outrate, state[, weightA[, weightB]])**

Convert the frame rate of the input fragment.

*state* is a tuple containing the state of the converter. The converter returns a tuple (**newfragment**, **newstate**), and *newstate* should be passed to the next call of *ratecv()*. The initial call should pass **None** as the state.

The *weightA* and *weightB* arguments are parameters for a simple digital filter and default to 1 and 0 respectively.

**audioop.reverse(fragment, width)**

Reverse the samples in a fragment and returns the modified fragment.

**audioop.rms(fragment, width)**

Return the root-mean-square of the fragment, i.e.  $\sqrt{\text{sum}(S_i^2)/n}$ .

C'est une mesure de la puissance dans un signal audio.

**audioop.tomono(fragment, width, lfactor, rfactor)**

Convert a stereo fragment to a mono fragment. The left channel is multiplied by *lfactor* and the right channel by *rfactor* before adding the two channels to give a mono signal.

**audioop.tostereo(fragment, width, lfactor, rfactor)**

Generate a stereo fragment from a mono fragment. Each pair of samples in the stereo fragment are computed from the mono sample, whereby left channel samples are multiplied by *lfactor* and right channel samples by *rfactor*.

**audioop.ulaw2lin(fragment, width)**

Convert sound fragments in u-LAW encoding to linearly encoded sound fragments. u-LAW encoding always uses 8 bits samples, so *width* refers only to the sample width of the output fragment here.

Note that operations such as *mul()* or *max()* make no distinction between mono and stereo fragments, i.e. all samples are treated equal. If this is a problem the stereo fragment should be split into two mono fragments first and recombined later. Here is an example of how to do that :

```
def mul_stereo(sample, width, lfactor, rfactor):
    lsample = audioop.tomono(sample, width, 1, 0)
    rsample = audioop.tomono(sample, width, 0, 1)
```

(suite sur la page suivante)

(suite de la page précédente)

```

lsample = audioop.mul(lsample, width, lfactor)
rsample = audioop.mul(rsample, width, rfactor)
lsample = audioop.tostereo(lsample, width, 1, 0)
rsample = audioop.tostereo(rsample, width, 0, 1)
return audioop.add(lsample, rsample, width)

```

If you use the ADPCM coder to build network packets and you want your protocol to be stateless (i.e. to be able to tolerate packet loss) you should not only transmit the data but also the state. Note that you should send the *initial* state (the one you passed to `lin2adpcm()`) along to the decoder, not the final state (as returned by the coder). If you want to use `struct.Struct` to store the state in binary you can code the first element (the predicted value) in 16 bits and the second (the delta index) in 8.

The ADPCM coders have never been tried against other ADPCM coders, only against themselves. It could well be that I misinterpreted the standards in which case they will not be interoperable with the respective standards.

The `find*()` routines might look a bit funny at first sight. They are primarily meant to do echo cancellation. A reasonably fast way to do this is to pick the most energetic piece of the output sample, locate that in the input sample and subtract the whole output sample from the input sample :

```

def echocancel(outputdata, inputdata):
    pos = audioop.findmax(outputdata, 800)    # one tenth second
    out_test = outputdata[pos*2:]
    in_test = inputdata[pos*2:]
    ipos, factor = audioop.findfit(in_test, out_test)
    # Optional (for better cancellation):
    # factor = audioop.findfactor(in_test[ipos*2:ipos*2+len(out_test)],
    #                             out_test)
    prefill = '\0'*(pos+ipos)*2
    postfill = '\0'*(len(inputdata)-len(prefill)-len(outputdata))
    outputdata = prefill + audioop.mul(outputdata, 2, -factor) + postfill
    return audioop.add(inputdata, outputdata, 2)

```

## 21.2 imageop — Manipulate raw image data

Obsolète depuis la version 2.6 : The `imageop` module has been removed in Python 3.

The `imageop` module contains some useful operations on images. It operates on images consisting of 8 or 32 bit pixels stored in Python strings. This is the same format as used by `gl.rectwrite()` and the `imgfile` module.

The module defines the following variables and functions :

### exception `imageop.error`

This exception is raised on all errors, such as unknown number of bits per pixel, etc.

### `imageop.crop(image, psize, width, height, x0, y0, x1, y1)`

Return the selected part of `image`, which should be `width` by `height` in size and consist of pixels of `psize` bytes. `x0`, `y0`, `x1` and `y1` are like the `gl.rectread()` parameters, i.e. the boundary is included in the new image. The new boundaries need not be inside the picture. Pixels that fall outside the old image will have their value set to zero. If `x0` is bigger than `x1` the new image is mirrored. The same holds for the y coordinates.

### `imageop.scale(image, psize, width, height, newwidth, newheight)`

Return `image` scaled to size `newwidth` by `newheight`. No interpolation is done, scaling is done by simple-

minded pixel duplication or removal. Therefore, computer-generated images or dithered images will not look nice after scaling.

`imageop.tovideo(image, psize, width, height)`

Run a vertical low-pass filter over an image. It does so by computing each destination pixel as the average of two vertically-aligned source pixels. The main use of this routine is to forestall excessive flicker if the image is displayed on a video device that uses interlacing, hence the name.

`imageop.grey2mono(image, width, height, threshold)`

Convert an 8-bit deep greyscale image to a 1-bit deep image by thresholding all the pixels. The resulting image is tightly packed and is probably only useful as an argument to `mono2grey()`.

`imageop.dither2mono(image, width, height)`

Convert an 8-bit greyscale image to a 1-bit monochrome image using a (simple-minded) dithering algorithm.

`imageop.mono2grey(image, width, height, p0, p1)`

Convert a 1-bit monochrome image to an 8 bit greyscale or color image. All pixels that are zero-valued on input get value *p0* on output and all one-value input pixels get value *p1* on output. To convert a monochrome black-and-white image to greyscale pass the values 0 and 255 respectively.

`imageop.grey2grey4(image, width, height)`

Convert an 8-bit greyscale image to a 4-bit greyscale image without dithering.

`imageop.grey2grey2(image, width, height)`

Convert an 8-bit greyscale image to a 2-bit greyscale image without dithering.

`imageop.dither2grey2(image, width, height)`

Convert an 8-bit greyscale image to a 2-bit greyscale image with dithering. As for `dither2mono()`, the dithering algorithm is currently very simple.

`imageop.grey42grey(image, width, height)`

Convert a 4-bit greyscale image to an 8-bit greyscale image.

`imageop.grey22grey(image, width, height)`

Convert a 2-bit greyscale image to an 8-bit greyscale image.

`imageop.backward_compatible`

If set to 0, the functions in this module use a non-backward compatible way of representing multi-byte pixels on little-endian systems. The SGI for which this module was originally written is a big-endian system, so setting this variable will have no effect. However, the code wasn't originally intended to run on anything else, so it made assumptions about byte order which are not universal. Setting this variable to 0 will cause the byte order to be reversed on little-endian systems, so that it then is the same as on big-endian systems.

## 21.3 aifc — Lis et écrit dans les fichiers AIFF et AIFC

Code source : [Lib/aifc.py](#)

---

This module provides support for reading and writing AIFF and AIFF-C files. AIFF is Audio Interchange File Format, a format for storing digital audio samples in a file. AIFF-C is a newer version of the format that includes the ability to compress the audio data.

---

**Note :** Some operations may only work under IRIX; these will raise `ImportError` when attempting to import the `c1` module, which is only available on IRIX.

---

Audio files have a number of parameters that describe the audio data. The sampling rate or frame rate is the number of times per second the sound is sampled. The number of channels indicate if the audio is mono, stereo, or quadro. Each frame consists of one sample per channel. The sample size is the size in bytes of each sample. Thus a frame consists of  $nchannels * samplesize$  bytes, and a second's worth of audio consists of  $nchannels * samplesize * framerate$  bytes.

For example, CD quality audio has a sample size of two bytes (16 bits), uses two channels (stereo) and has a frame rate of 44,100 frames/second. This gives a frame size of 4 bytes ( $2 * 2$ ), and a second's worth occupies  $2 * 2 * 44100$  bytes (176,400 bytes).

Le module `aifc` définit les fonctions suivantes :

`aifc.open(file[, mode])`

Open an AIFF or AIFF-C file and return an object instance with methods that are described below. The argument *file* is either a string naming a file or a file object. *mode* must be 'r' or 'rb' when the file must be opened for reading, or 'w' or 'wb' when the file must be opened for writing. If omitted, `file.mode` is used if it exists, otherwise 'rb' is used. When used for writing, the file object should be seekable, unless you know ahead of time how many samples you are going to write in total and use `writeframesraw()` and `setnframes()`.

Objects returned by `open()` when a file is opened for reading have the following methods :

`aifc.getnchannels()`

Return the number of audio channels (1 for mono, 2 for stereo).

`aifc.getsampwidth()`

Donne la taille en octets des échantillons, individuellement.

`aifc.getframerate()`

Return the sampling rate (number of audio frames per second).

`aifc.getnframes()`

Donne le nombre de trames (*frames*) audio du fichier.

`aifc.getcomptype()`

Return a four-character string describing the type of compression used in the audio file. For AIFF files, the returned value is 'NONE'.

`aifc.getcompname()`

Return a human-readable description of the type of compression used in the audio file. For AIFF files, the returned value is 'not compressed'.

`aifc.getparams()`

Return a tuple consisting of all of the above values in the above order.

`aifc.getmarkers()`

Return a list of markers in the audio file. A marker consists of a tuple of three elements. The first is the mark ID (an integer), the second is the mark position in frames from the beginning of the data (an integer), the third is the name of the mark (a string).

`aifc.getmark(id)`

Return the tuple as described in `getmarkers()` for the mark with the given *id*.

`aifc.readframes(nframes)`

Read and return the next *nframes* frames from the audio file. The returned data is a string containing for each frame the uncompressed samples of all channels.

`aifc.rewind()`

Rewind the read pointer. The next `readframes()` will start from the beginning.

`aifc.setpos(pos)`

Va à la trame de numéro donné.

`aifc.tell()`

Donne le numéro de la trame courante.

`aifc.close()`

Close the AIFF file. After calling this method, the object can no longer be used.

Objects returned by `open()` when a file is opened for writing have all the above methods, except for `readframes()` and `setpos()`. In addition the following methods exist. The `get*()` methods can only be called after the corresponding `set*()` methods have been called. Before the first `writeframes()` or `writeframesraw()`, all parameters except for the number of frames must be filled in.

`aifc.aiff()`

Create an AIFF file. The default is that an AIFF-C file is created, unless the name of the file ends in `'.aiff'` in which case the default is an AIFF file.

`aifc.aifc()`

Create an AIFF-C file. The default is that an AIFF-C file is created, unless the name of the file ends in `'.aiff'` in which case the default is an AIFF file.

`aifc.setnchannels(nchannels)`

Définit le nombre de canaux du fichier audio.

`aifc.setsampwidth(width)`

Définit la taille en octets des échantillons audio.

`aifc.setframerate(rate)`

Specify the sampling frequency in frames per second.

`aifc.setnframes(nframes)`

Specify the number of frames that are to be written to the audio file. If this parameter is not set, or not set correctly, the file needs to support seeking.

`aifc.setcomptype(type, name)`

Specify the compression type. If not specified, the audio data will not be compressed. In AIFF files, compression is not possible. The name parameter should be a human-readable description of the compression type, the type parameter should be a four-character string. Currently the following compression types are supported : NONE, ULAW, ALAW, G722.

`aifc.setparams(nchannels, sampwidth, framerate, comptype, compname)`

Set all the above parameters at once. The argument is a tuple consisting of the various parameters. This means that it is possible to use the result of a `getparams()` call as argument to `setparams()`.

`aifc.setmark(id, pos, name)`

Add a mark with the given id (larger than 0), and the given name at the given position. This method can be called at any time before `close()`.

`aifc.tell()`

Return the current write position in the output file. Useful in combination with `setmark()`.

`aifc.writeframes(data)`

Write data to the output file. This method can only be called after the audio file parameters have been set.

`aifc.writeframesraw(data)`

Like `writeframes()`, except that the header of the audio file is not updated.

`aifc.close()`

Close the AIFF file. The header of the file is updated to reflect the actual size of the audio data. After calling this method, the object can no longer be used.

## 21.4 sunau — Read and write Sun AU files

Code source : [Lib/sunau.py](#)

---

The `sunau` module provides a convenient interface to the Sun AU sound format. Note that this module is interface-compatible with the modules `aifc` and `wave`.

An audio file consists of a header followed by the data. The fields of the header are :

Field	Sommaire
magic word	The four bytes <code>.snd</code> .
header size	Size of the header, including info, in bytes.
data size	Physical size of the data, in bytes.
encoding	Indicates how the audio samples are encoded.
sample rate	The sampling rate.
# of channels	The number of channels in the samples.
info	ASCII string giving a description of the audio file (padded with null bytes).

Apart from the info field, all header fields are 4 bytes in size. They are all 32-bit unsigned integers encoded in big-endian byte order.

The `sunau` module defines the following functions :

`sunau.open(file, mode)`

If *file* is a string, open the file by that name, otherwise treat it as a seekable file-like object. *mode* can be any of

'r' Read only mode.

'w' Write only mode.

Note that it does not allow read/write files.

A *mode* of 'r' returns an `AU_read` object, while a *mode* of 'w' or 'wb' returns an `AU_write` object.

`sunau.openfp(file, mode)`

A synonym for `open()`, maintained for backwards compatibility.

The `sunau` module defines the following exception :

**exception `sunau.Error`**

An error raised when something is impossible because of Sun AU specs or implementation deficiency.

The `sunau` module defines the following data items :

`sunau.AUDIO_FILE_MAGIC`

An integer every valid Sun AU file begins with, stored in big-endian form. This is the string `.snd` interpreted as an integer.

`sunau.AUDIO_FILE_ENCODING_MULAW_8`

`sunau.AUDIO_FILE_ENCODING_LINEAR_8`

`sunau.AUDIO_FILE_ENCODING_LINEAR_16`

`sunau.AUDIO_FILE_ENCODING_LINEAR_24`

`sunau.AUDIO_FILE_ENCODING_LINEAR_32`

`sunau.AUDIO_FILE_ENCODING_ALAW_8`

Values of the encoding field from the AU header which are supported by this module.

`sunau.AUDIO_FILE_ENCODING_FLOAT`

`sunau.AUDIO_FILE_ENCODING_DOUBLE`

`sunau.AUDIO_FILE_ENCODING_ADPCM_G721`

```

sunau.AUDIO_FILE_ENCODING_ADPCM_G722
sunau.AUDIO_FILE_ENCODING_ADPCM_G723_3
sunau.AUDIO_FILE_ENCODING_ADPCM_G723_5

```

Additional known values of the encoding field from the AU header, but which are not supported by this module.

### 21.4.1 AU\_read Objects

AU\_read objects, as returned by `open()` above, have the following methods :

`AU_read.close()`

Close the stream, and make the instance unusable. (This is called automatically on deletion.)

`AU_read.getnchannels()`

Returns number of audio channels (1 for mono, 2 for stereo).

`AU_read.getsampwidth()`

Returns sample width in bytes.

`AU_read.getframerate()`

Returns sampling frequency.

`AU_read.getnframes()`

Returns number of audio frames.

`AU_read.getcomptype()`

Returns compression type. Supported compression types are 'ULAW', 'ALAW' and 'NONE'.

`AU_read.getcompname()`

Human-readable version of `getcomptype()`. The supported types have the respective names 'CCITT G.711 u-law', 'CCITT G.711 A-law' and 'not compressed'.

`AU_read.getparams()`

Returns a tuple (nchannels, sampwidth, framerate, nframes, comptype, compname), equivalent to output of the `get*()` methods.

`AU_read.readframes(n)`

Reads and returns at most *n* frames of audio, as a string of bytes. The data will be returned in linear format. If the original data is in u-LAW format, it will be converted.

`AU_read.rewind()`

Rewind the file pointer to the beginning of the audio stream.

The following two methods define a term « position » which is compatible between them, and is otherwise implementation dependent.

`AU_read.setpos(pos)`

Set the file pointer to the specified position. Only values returned from `tell()` should be used for *pos*.

`AU_read.tell()`

Return current file pointer position. Note that the returned value has nothing to do with the actual position in the file.

The following two functions are defined for compatibility with the `aifc`, and don't do anything interesting.

`AU_read.getmarkers()`

Returns None.

`AU_read.getmark(id)`

Raise an error.

### 21.4.2 AU\_write Objects

AU\_write objects, as returned by *open()* above, have the following methods :

`AU_write.setnchannels(n)`

Set the number of channels.

`AU_write.setsampwidth(n)`

Set the sample width (in bytes.)

`AU_write.setframerate(n)`

Set the frame rate.

`AU_write.setnframes(n)`

Set the number of frames. This can be later changed, when and if more frames are written.

`AU_write.setcomptype(type, name)`

Set the compression type and description. Only 'NONE' and 'ULAW' are supported on output.

`AU_write.setparams(tuple)`

The *tuple* should be (*nchannels*, *sampwidth*, *framerate*, *nframes*, *comptype*, *compname*), with values valid for the *set\*()* methods. Set all parameters.

`AU_write.tell()`

Return current position in the file, with the same disclaimer for the *AU\_read.tell()* and *AU\_read.setpos()* methods.

`AU_write.writeframesraw(data)`

Write audio frames, without correcting *nframes*.

`AU_write.writeframes(data)`

Write audio frames and make sure *nframes* is correct.

`AU_write.close()`

Make sure *nframes* is correct, and close the file.

This method is called upon deletion.

Note that it is invalid to set any parameters after calling *writeframes()* or *writeframesraw()*.

## 21.5 wave — Read and write WAV files

Code source : [Lib/wave.py](#)

---

The *wave* module provides a convenient interface to the WAV sound format. It does not support compression/decompression, but it does support mono/stereo.

The *wave* module defines the following function and exception :

`wave.open(file[, mode])`

If *file* is a string, open the file by that name, otherwise treat it as a seekable file-like object. *mode* can be any of

'r', 'rb' Read only mode.

'w', 'wb' Write only mode.

Note that it does not allow read/write WAV files.

A *mode* of 'r' or 'rb' returns a *Wave\_read* object, while a *mode* of 'w' or 'wb' returns a *Wave\_write* object. If *mode* is omitted and a file-like object is passed as *file*, *file.mode* is used as the default value for *mode* (the 'b' flag is still added if necessary).

If you pass in a file-like object, the wave object will not close it when its *close()* method is called ; it is the caller's responsibility to close the file object.

`wave.openfp(file, mode)`

A synonym for `open()`, maintained for backwards compatibility.

**exception** `wave.Error`

An error raised when something is impossible because it violates the WAV specification or hits an implementation deficiency.

### 21.5.1 Wave\_read Objects

Wave\_read objects, as returned by `open()`, have the following methods :

`Wave_read.close()`

Close the stream if it was opened by `wave`, and make the instance unusable. This is called automatically on object collection.

`Wave_read.getnchannels()`

Returns number of audio channels (1 for mono, 2 for stereo).

`Wave_read.getsampwidth()`

Returns sample width in bytes.

`Wave_read.getframerate()`

Returns sampling frequency.

`Wave_read.getnframes()`

Returns number of audio frames.

`Wave_read.getcomptype()`

Returns compression type ('NONE' is the only supported type).

`Wave_read.getcompname()`

Human-readable version of `getcomptype()`. Usually 'not compressed' parallels 'NONE'.

`Wave_read.getparams()`

Returns a tuple (nchannels, sampwidth, framerate, nframes, comptype, compname), equivalent to output of the `get*()` methods.

`Wave_read.readframes(n)`

Reads and returns at most *n* frames of audio, as a string of bytes.

`Wave_read.rewind()`

Rewind the file pointer to the beginning of the audio stream.

The following two methods are defined for compatibility with the `aifc` module, and don't do anything interesting.

`Wave_read.getmarkers()`

Returns None.

`Wave_read.getmark(id)`

Raise an error.

The following two methods define a term « position » which is compatible between them, and is otherwise implementation dependent.

`Wave_read.setpos(pos)`

Set the file pointer to the specified position.

`Wave_read.tell()`

Return current file pointer position.

## 21.5.2 Wave\_write Objects

Wave\_write objects, as returned by `open()`, have the following methods :

`Wave_write.close()`

Make sure *nframes* is correct, and close the file if it was opened by *wave*. This method is called upon object collection.

`Wave_write.setnchannels(n)`

Set the number of channels.

`Wave_write.setsampwidth(n)`

Set the sample width to *n* bytes.

`Wave_write.setframerate(n)`

Set the frame rate to *n*.

`Wave_write.setnframes(n)`

Set the number of frames to *n*. This will be changed later if more frames are written.

`Wave_write.setcomptype(type, name)`

Set the compression type and description. At the moment, only compression type NONE is supported, meaning no compression.

`Wave_write.setparams(tuple)`

The *tuple* should be (*nchannels*, *sampwidth*, *framerate*, *nframes*, *comptype*, *compname*), with values valid for the `set*()` methods. Sets all parameters.

`Wave_write.tell()`

Return current position in the file, with the same disclaimer for the `Wave_read.tell()` and `Wave_read.setpos()` methods.

`Wave_write.writeframesraw(data)`

Write audio frames, without correcting *nframes*.

`Wave_write.writeframes(data)`

Write audio frames and make sure *nframes* is correct.

Note that it is invalid to set any parameters after calling `writeframes()` or `writeframesraw()`, and any attempt to do so will raise `wave.Error`.

## 21.6 chunk — Read IFF chunked data

This module provides an interface for reading files that use EA IFF 85 chunks.<sup>1</sup> This format is used in at least the Audio Interchange File Format (AIFF/AIFF-C) and the Real Media File Format (RMFF). The WAVE audio file format is closely related and can also be read using this module.

A chunk has the following structure :

Offset	Length	Sommaire
0	4	Chunk ID
4	4	Size of chunk in big-endian byte order, not including the header
8	<i>n</i>	Data bytes, where <i>n</i> is the size given in the preceding field
8 + <i>n</i>	0 or 1	Pad byte needed if <i>n</i> is odd and chunk alignment is used

The ID is a 4-byte string which identifies the type of chunk.

---

1. « EA IFF 85 » Standard for Interchange Format Files, Jerry Morrison, Electronic Arts, January 1985.

The size field (a 32-bit value, encoded using big-endian byte order) gives the size of the chunk data, not including the 8-byte header.

Usually an IFF-type file consists of one or more chunks. The proposed usage of the `Chunk` class defined here is to instantiate an instance at the start of each chunk and read from the instance until it reaches the end, after which a new instance can be instantiated. At the end of the file, creating a new instance will fail with an `EOFError` exception.

```
class chunk.Chunk(file[, align, bigendian, inclheader])
```

Class which represents a chunk. The `file` argument is expected to be a file-like object. An instance of this class is specifically allowed. The only method that is needed is `read()`. If the methods `seek()` and `tell()` are present and don't raise an exception, they are also used. If these methods are present and raise an exception, they are expected to not have altered the object. If the optional argument `align` is true, chunks are assumed to be aligned on 2-byte boundaries. If `align` is false, no alignment is assumed. The default value is true. If the optional argument `bigendian` is false, the chunk size is assumed to be in little-endian order. This is needed for WAVE audio files. The default value is true. If the optional argument `inclheader` is true, the size given in the chunk header includes the size of the header. The default value is false.

A `Chunk` object supports the following methods :

`getname()`

Returns the name (ID) of the chunk. This is the first 4 bytes of the chunk.

`getsize()`

Returns the size of the chunk.

`close()`

Close and skip to the end of the chunk. This does not close the underlying file.

The remaining methods will raise `IOError` if called after the `close()` method has been called.

`isatty()`

Returns `False`.

`seek(pos[, whence])`

Set the chunk's current position. The `whence` argument is optional and defaults to 0 (absolute file positioning); other values are 1 (seek relative to the current position) and 2 (seek relative to the file's end). There is no return value. If the underlying file does not allow seek, only forward seeks are allowed.

`tell()`

Return the current position into the chunk.

`read([size])`

Read at most `size` bytes from the chunk (less if the read hits the end of the chunk before obtaining `size` bytes). If the `size` argument is negative or omitted, read all data until the end of the chunk. The bytes are returned as a string object. An empty string is returned when the end of the chunk is encountered immediately.

`skip()`

Skip to the end of the chunk. All further calls to `read()` for the chunk will return ''. If you are not interested in the contents of the chunk, this method should be called so that the file points to the start of the next chunk.

## Notes

## 21.7 colorsys — Conversions entre les systèmes de couleurs

Code source : [Lib/colors.py](#)

Le module `colorsys` définit les conversions bidirectionnelles des valeurs de couleur entre les couleurs exprimées dans l'espace colorimétrique RVB (Rouge Vert Bleu) utilisé par les écrans d'ordinateur et trois autres

systèmes de coordonnées : YIQ, HLS (Hue Lightness Saturation) et HSV (Hue Saturation Value). Les coordonnées dans tous ces espaces colorimétriques sont des valeurs en virgule flottante. Dans l'espace YIQ, la coordonnée Y est comprise entre 0 et 1, mais les coordonnées I et Q peuvent être positives ou négatives. Dans tous les autres espaces, les coordonnées sont toutes comprises entre 0 et 1.

**Voir aussi :**

Consultez <http://www.poynton.com/ColorFAQ.html> et <https://www.cambridgeincolour.com/tutorials/color-spaces.htm> pour plus d'informations concernant les espaces colorimétriques.

Le module `colorsys` définit les fonctions suivantes :

`colorsys.rgb_to_yiq(r, g, b)`

Convertit la couleur des coordonnées RGB (RVB) vers les coordonnées YIQ.

`colorsys.yiq_to_rgb(y, i, q)`

Convertit la couleur des coordonnées YIQ vers les coordonnées RGB (RVB).

`colorsys.rgb_to_hls(r, g, b)`

Convertit la couleur des coordonnées RGB (RVB) vers les coordonnées HLS (TSV).

`colorsys.hls_to_rgb(h, l, s)`

Convertit la couleur des coordonnées HLS (TSV) vers les coordonnées RGB (RVB).

`colorsys.rgb_to_hsv(r, g, b)`

Convertit la couleur des coordonnées RGB (RVB) vers les coordonnées HSV (TSV).

`colorsys.hsv_to_rgb(h, s, v)`

Convertit la couleur des coordonnées HSV (TSV) vers les coordonnées RGB (RVB).

Exemple :

```
>>> import colorsys
>>> colorsys.rgb_to_hsv(0.2, 0.4, 0.4)
(0.5, 0.5, 0.4)
>>> colorsys.hsv_to_rgb(0.5, 0.5, 0.4)
(0.2, 0.4, 0.4)
```

## 21.8 `imghdr` — Determine the type of an image

Code source : [Lib/imghdr.py](#)

---

The `imghdr` module determines the type of image contained in a file or byte stream.

The `imghdr` module defines the following function :

`imghdr.what(filename[, h])`

Tests the image data contained in the file named by *filename*, and returns a string describing the image type. If optional *h* is provided, the *filename* is ignored and *h* is assumed to contain the byte stream to test.

The following image types are recognized, as listed below with the return value from `what()` :

Valeur	Image format
'rgb'	SGI ImgLib Files
'gif'	GIF 87a and 89a Files
'pbm'	Portable Bitmap Files
'pgm'	Portable Graymap Files
'ppm'	Portable Pixmap Files
'tiff'	TIFF Files
'rast'	Sun Raster Files
'xbm'	X Bitmap Files
'jpeg'	JPEG data in JFIF or Exif formats
'bmp'	BMP files
'png'	Portable Network Graphics

Nouveau dans la version 2.5 : Exif detection.

You can extend the list of file types *imghdr* can recognize by appending to this variable :

#### **imghdr.tests**

A list of functions performing the individual tests. Each function takes two arguments : the byte-stream and an open file-like object. When *what()* is called with a byte-stream, the file-like object will be *None*. The test function should return a string describing the image type if the test succeeded, or *None* if it failed.

Exemple :

```
>>> import imghdr
>>> imghdr.what('bass.gif')
'gif'
```

## 21.9 sndhdr — Détermine le type d'un fichier audio

Code source : [Lib/sndhdr.py](#)

The *sndhdr* provides utility functions which attempt to determine the type of sound data which is in a file. When these functions are able to determine what type of sound data is stored in a file, they return a tuple (*type*, *sampling\_rate*, *channels*, *frames*, *bits\_per\_sample*). The value for *type* indicates the data type and will be one of the strings 'aifc', 'aiff', 'au', 'hcom', 'sndr', 'sndt', 'voc', 'wav', '8svx', 'sb', 'ub', or 'ul'. The *sampling\_rate* will be either the actual value or 0 if unknown or difficult to decode. Similarly, *channels* will be either the number of channels or 0 if it cannot be determined or if the value is difficult to decode. The value for *frames* will be either the number of frames or -1. The last item in the tuple, *bits\_per\_sample*, will either be the sample size in bits or 'A' for A-LAW or 'U' for u-LAW.

#### **sndhdr.what(filename)**

Determines the type of sound data stored in the file *filename* using *whathdr()*. If it succeeds, returns a tuple as described above, otherwise *None* is returned.

#### **sndhdr.whathdr(filename)**

Determines the type of sound data stored in a file based on the file header. The name of the file is given by *filename*. This function returns a tuple as described above on success, or *None*.

## 21.10 ossaudiodev — Access to OSS-compatible audio devices

Nouveau dans la version 2.3.

This module allows you to access the OSS (Open Sound System) audio interface. OSS is available for a wide range of open-source and commercial Unices, and is the standard audio interface for Linux and recent versions of FreeBSD.

**Voir aussi :**

**Open Sound System Programmer's Guide** the official documentation for the OSS C API

The module defines a large number of constants supplied by the OSS device driver ; see `<sys/soundcard.h>` on either Linux or FreeBSD for a listing.

`ossaudiodev` defines the following variables and functions :

**exception** `ossaudiodev.OSSAudioError`

This exception is raised on certain errors. The argument is a string describing what went wrong.

(If `ossaudiodev` receives an error from a system call such as `open()`, `write()`, or `ioctl()`, it raises `IOError`. Errors detected directly by `ossaudiodev` result in `OSSAudioError`.)

(For backwards compatibility, the exception class is also available as `ossaudiodev.error`.)

`ossaudiodev.open(mode)`

`ossaudiodev.open(device, mode)`

Open an audio device and return an OSS audio device object. This object supports many file-like methods, such as `read()`, `write()`, and `fileno()` (although there are subtle differences between conventional Unix read/write semantics and those of OSS audio devices). It also supports a number of audio-specific methods ; see below for the complete list of methods.

*device* is the audio device filename to use. If it is not specified, this module first looks in the environment variable `AUDIODEV` for a device to use. If not found, it falls back to `/dev/dsp`.

*mode* is one of `'r'` for read-only (record) access, `'w'` for write-only (playback) access and `'rw'` for both. Since many sound cards only allow one process to have the recorder or player open at a time, it is a good idea to open the device only for the activity needed. Further, some sound cards are half-duplex : they can be opened for reading or writing, but not both at once.

Note the unusual calling syntax : the *first* argument is optional, and the second is required. This is a historical artifact for compatibility with the older `linuxaudiodev` module which `ossaudiodev` supersedes.

`ossaudiodev.openmixer([device])`

Open a mixer device and return an OSS mixer device object. *device* is the mixer device filename to use. If it is not specified, this module first looks in the environment variable `MIXERDEV` for a device to use. If not found, it falls back to `/dev/mixer`.

### 21.10.1 Audio Device Objects

Before you can write to or read from an audio device, you must call three methods in the correct order :

1. `setfmt()` to set the output format
2. `channels()` to set the number of channels
3. `speed()` to set the sample rate

Alternately, you can use the `setparameters()` method to set all three audio parameters at once. This is more convenient, but may not be as flexible in all cases.

The audio device objects returned by `open()` define the following methods and (read-only) attributes :

`oss_audio_device.close()`

Explicitly close the audio device. When you are done writing to or reading from an audio device, you should explicitly close it. A closed device cannot be used again.

`oss_audio_device.fileno()`

Return the file descriptor associated with the device.

`oss_audio_device.read(size)`

Read *size* bytes from the audio input and return them as a Python string. Unlike most Unix device drivers, OSS audio devices in blocking mode (the default) will block `read()` until the entire requested amount of data is available.

`oss_audio_device.write(data)`

Write the Python string *data* to the audio device and return the number of bytes written. If the audio device is in blocking mode (the default), the entire string is always written (again, this is different from usual Unix device semantics). If the device is in non-blocking mode, some data may not be written—see `writeall()`.

`oss_audio_device.writeall(data)`

Write the entire Python string *data* to the audio device : waits until the audio device is able to accept data, writes as much data as it will accept, and repeats until *data* has been completely written. If the device is in blocking mode (the default), this has the same effect as `write()`; `writeall()` is only useful in non-blocking mode. Has no return value, since the amount of data written is always equal to the amount of data supplied.

The following methods each map to exactly one `ioctl()` system call. The correspondence is obvious : for example, `setfmt()` corresponds to the `SNDCTL_DSP_SETFMT` `ioctl`, and `sync()` to `SNDCTL_DSP_SYNC` (this can be useful when consulting the OSS documentation). If the underlying `ioctl()` fails, they all raise `IOError`.

`oss_audio_device.nonblock()`

Put the device into non-blocking mode. Once in non-blocking mode, there is no way to return it to blocking mode.

`oss_audio_device.getfmts()`

Return a bitmask of the audio output formats supported by the soundcard. Some of the formats supported by OSS are :

Format	Description
AFMT_MU_LAW	a logarithmic encoding (used by Sun .au files and /dev/audio)
AFMT_A_LAW	a logarithmic encoding
AFMT_IMA_ADPCM	a 4 :1 compressed format defined by the Interactive Multimedia Association
AFMT_U8	Unsigned, 8-bit audio
AFMT_S16_LE	Signed, 16-bit audio, little-endian byte order (as used by Intel processors)
AFMT_S16_BE	Signed, 16-bit audio, big-endian byte order (as used by 68k, PowerPC, Sparc)
AFMT_S8	Signed, 8 bit audio
AFMT_U16_LE	Unsigned, 16-bit little-endian audio
AFMT_U16_BE	Unsigned, 16-bit big-endian audio

Consult the OSS documentation for a full list of audio formats, and note that most devices support only a subset of these formats. Some older devices only support `AFMT_U8`; the most common format used today is `AFMT_S16_LE`.

`oss_audio_device.setfmt(format)`

Try to set the current audio format to *format*—see `getfmts()` for a list. Returns the audio format that the device was set to, which may not be the requested format. May also be used to return the current audio format—do this by passing an « audio format » of `AFMT_QUERY`.

`oss_audio_device.channels(nchannels)`

Set the number of output channels to *nchannels*. A value of 1 indicates monophonic sound, 2 stereophonic. Some devices may have more than 2 channels, and some high-end devices may not support mono. Returns the number of channels the device was set to.

`oss_audio_device.speed(samplerate)`

Try to set the audio sampling rate to *samplerate* samples per second. Returns the rate actually set. Most sound devices don't support arbitrary sampling rates. Common rates are :

Rate	Description
8000	default rate for <code>/dev/audio</code>
11025	speech recording
22050	
44100	CD quality audio (at 16 bits/sample and 2 channels)
96000	DVD quality audio (at 24 bits/sample)

`oss_audio_device.sync()`

Wait until the sound device has played every byte in its buffer. (This happens implicitly when the device is closed.) The OSS documentation recommends closing and re-opening the device rather than using `sync()`.

`oss_audio_device.reset()`

Immediately stop playing or recording and return the device to a state where it can accept commands. The OSS documentation recommends closing and re-opening the device after calling `reset()`.

`oss_audio_device.post()`

Tell the driver that there is likely to be a pause in the output, making it possible for the device to handle the pause more intelligently. You might use this after playing a spot sound effect, before waiting for user input, or before doing disk I/O.

The following convenience methods combine several `ioctl`s, or one `ioctl` and some simple calculations.

`oss_audio_device.setparameters(format, nchannels, samplerate[, strict=False])`

Set the key audio sampling parameters—sample format, number of channels, and sampling rate—in one method call. *format*, *nchannels*, and *samplerate* should be as specified in the `setfmt()`, `channels()`, and `speed()` methods. If *strict* is true, `setparameters()` checks to see if each parameter was actually set to the requested value, and raises `OSSAudioError` if not. Returns a tuple (*format*, *nchannels*, *samplerate*) indicating the parameter values that were actually set by the device driver (i.e., the same as the return values of `setfmt()`, `channels()`, and `speed()`).

For example,

```
(fmt, channels, rate) = dsp.setparameters(fmt, channels, rate)
```

is equivalent to

```
fmt = dsp.setfmt(fmt)
channels = dsp.channels(channels)
rate = dsp.rate(rate)
```

`oss_audio_device.bufsize()`

Returns the size of the hardware buffer, in samples.

`oss_audio_device.obufcount()`

Returns the number of samples that are in the hardware buffer yet to be played.

`oss_audio_device.obuffree()`

Returns the number of samples that could be queued into the hardware buffer to be played without blocking.

Audio device objects also support several read-only attributes :

`oss_audio_device.closed`  
 Boolean indicating whether the device has been closed.

`oss_audio_device.name`  
 String containing the name of the device file.

`oss_audio_device.mode`  
 The I/O mode for the file, either "r", "rw", or "w".

## 21.10.2 Mixer Device Objects

The mixer object provides two file-like methods :

`oss_mixer_device.close()`  
 This method closes the open mixer device file. Any further attempts to use the mixer after this file is closed will raise an *IOError*.

`oss_mixer_device.fileno()`  
 Returns the file handle number of the open mixer device file.

The remaining methods are specific to audio mixing :

`oss_mixer_device.controls()`  
 This method returns a bitmask specifying the available mixer controls (« Control » being a specific mixable « channel », such as `SOUND_MIXER_PCM` or `SOUND_MIXER_SYNTH`). This bitmask indicates a subset of all available mixer controls—the `SOUND_MIXER_*` constants defined at module level. To determine if, for example, the current mixer object supports a PCM mixer, use the following Python code :

```
mixer=ossaudiodev.openmixer()
if mixer.controls() & (1 << ossaudiodev.SOUND_MIXER_PCM):
    # PCM is supported
    ... code ...
```

For most purposes, the `SOUND_MIXER_VOLUME` (master volume) and `SOUND_MIXER_PCM` controls should suffice—but code that uses the mixer should be flexible when it comes to choosing mixer controls. On the Gravis Ultrasound, for example, `SOUND_MIXER_VOLUME` does not exist.

`oss_mixer_device.stereocontrols()`  
 Returns a bitmask indicating stereo mixer controls. If a bit is set, the corresponding control is stereo ; if it is unset, the control is either monophonic or not supported by the mixer (use in combination with *controls()* to determine which).  
 See the code example for the *controls()* function for an example of getting data from a bitmask.

`oss_mixer_device.recontrols()`  
 Returns a bitmask specifying the mixer controls that may be used to record. See the code example for *controls()* for an example of reading from a bitmask.

`oss_mixer_device.get(control)`  
 Returns the volume of a given mixer control. The returned volume is a 2-tuple (`left_volume`, `right_volume`). Volumes are specified as numbers from 0 (silent) to 100 (full volume). If the control is monophonic, a 2-tuple is still returned, but both volumes are the same.  
 Raises *OSSAudioError* if an invalid control was specified, or *IOError* if an unsupported control is specified.

`oss_mixer_device.set(control, (left, right))`  
 Sets the volume for a given mixer control to (`left`, `right`). `left` and `right` must be ints and between 0 (silent) and 100 (full volume). On success, the new volume is returned as a 2-tuple. Note that this may

not be exactly the same as the volume specified, because of the limited resolution of some soundcard's mixers.

Raises *OSSAudioError* if an invalid mixer control was specified, or if the specified volumes were out-of-range.

`oss_mixer_device.get_recsrc()`

This method returns a bitmask indicating which control(s) are currently being used as a recording source.

`oss_mixer_device.set_recsrc(bitmask)`

Call this function to specify a recording source. Returns a bitmask indicating the new recording source (or sources) if successful; raises *IOError* if an invalid source was specified. To set the current recording source to the microphone input :

```
mixer.setrecsrc (1 << ossaudiodev.SOUND_MIXER_MIC)
```

Les modules décrits dans ce chapitre vous aident à rédiger des programmes indépendants des langues et des cultures en fournissant des mécanismes pour sélectionner une langue à utiliser dans les messages, ou en adaptant la sortie aux conventions culturelles.

La liste des modules documentés dans ce chapitre est :

## 22.1 gettext — Services d'internationalisation multilingue

Code source : [Lib/gettext.py](#)

---

Le module `gettext` fournit un service d'internationalisation (*I18N*) et de localisation linguistique (*L10N*) pour vos modules et applications Python. Il est compatible avec l'API du catalogue de messages GNU `gettext` et à un plus haut niveau, avec l'API basée sur les classes qui serait peut-être plus adaptée aux fichiers Python. L'interface décrite ci-dessous vous permet d'écrire les textes de vos modules et applications dans une langue naturelle, puis de fournir un catalogue de traductions pour les lancer ensuite dans d'autres langues naturelles.

Quelques astuces sur la localisation de vos modules et applications Python sont également données.

### 22.1.1 API GNU gettext

Le module `gettext` définit l'API suivante, qui est très proche de l'API de GNU `gettext`. Si vous utilisez cette API, cela affectera la traduction de toute votre application. C'est souvent le comportement attendu si votre application est monolingue, avec le choix de la langue qui dépend des paramètres linguistiques de l'utilisateur. Si vous localisez un module Python ou si votre application a besoin de changer de langue à la volée, il est plus judicieux d'utiliser l'API basée sur des classes.

```
gettext.bindtextdomain(domain[, localedir])
```

Lie `domain` au répertoire `localedir` des localisations. Plus spécifiquement, `gettext` va chercher les fichiers binaires `.mo` pour un domaine donné, en utilisant le chemin suivant (sous Unix) : `localedir/language/LC_MESSAGES/domain.mo`, où `language` est contenu respectivement dans l'une des variables d'environnement suivantes : `LANGUAGE`, `LC_ALL`, `LC_MESSAGES` et `LANG`.

Si *localedir* n'est pas renseigné ou vaut `None`, alors le lien actuel de *domain* est renvoyé.<sup>1</sup>

`gettext.bind_textdomain_codeset(domain[, codeset])`

Bind the *domain* to *codeset*, changing the encoding of strings returned by the *gettext()* family of functions. If *codeset* is omitted, then the current binding is returned.

Nouveau dans la version 2.4.

`gettext.textdomain([domain])`

Change ou interroge le domaine global actuel. Si *domain* vaut `None`, alors le domaine global actuel est renvoyé. Sinon, le domaine global est positionné à *domain*, puis renvoyé.

`gettext.gettext(message)`

Renvoie la traduction localisée de *message*, en se basant sur le domaine global actuel, la langue et le répertoire des localisations. Cette fonction est typiquement renommée `_()` dans le namespace courant (voir les exemples ci-dessous).

`gettext.lgettext(message)`

Equivalent to *gettext()*, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with *bind\_textdomain\_codeset()*.

Nouveau dans la version 2.4.

`gettext.dgettext(domain, message)`

Like *gettext()*, but look the message up in the specified *domain*.

`gettext.ldgettext(domain, message)`

Equivalent to *dgettext()*, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with *bind\_textdomain\_codeset()*.

Nouveau dans la version 2.4.

`gettext.ngettext(singular, plural, n)`

Like *gettext()*, but consider plural forms. If a translation is found, apply the plural formula to *n*, and return the resulting message (some languages have more than two plural forms). If no translation is found, return *singular* if *n* is 1; return *plural* otherwise.

The Plural formula is taken from the catalog header. It is a C or Python expression that has a free variable *n*; the expression evaluates to the index of the plural in the catalog. See the GNU gettext documentation for the precise syntax to be used in *.po* files and the formulas for a variety of languages.

Nouveau dans la version 2.3.

`gettext.lngettext(singular, plural, n)`

Equivalent to *lngettext()*, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with *bind\_textdomain\_codeset()*.

Nouveau dans la version 2.4.

`gettext.dngettext(domain, singular, plural, n)`

Comme *lngettext()*, mais cherche le message dans le domaine spécifié.

Nouveau dans la version 2.3.

`gettext.ldngettext(domain, singular, plural, n)`

Equivalent to *dngettext()*, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with *bind\_textdomain\_codeset()*.

Nouveau dans la version 2.4.

Notez que GNU **gettext** a aussi une méthode *dcgettext()*, mais elle a été considérée comme inutile et donc actuellement marquée comme non implémentée.

---

1. Le dossier par défaut pour les localisations dépend du système : par exemple, sur RedHat c'est `/usr/share/locale`, mais sur Solaris c'est `/usr/lib/locale`. Le module *gettext* n'essaie pas de prendre en charge ce paramètre système, mais utilise le dossier `sys.prefix/share/locale`. C'est pour cette raison qu'il est toujours préférable d'appeler *bindtextdomain()* en donnant explicitement un chemin absolu au début de votre application.

Voici un exemple classique d'utilisation de cette API :

```
import gettext
gettext.bindtextdomain('myapplication', '/path/to/my/language/directory')
gettext.textdomain('myapplication')
_ = gettext.gettext
# ...
print _('This is a translatable string.')
```

### 22.1.2 API basée sur les classes

The class-based API of the `gettext` module gives you more flexibility and greater convenience than the GNU `gettext` API. It is the recommended way of localizing your Python applications and modules. `gettext` defines a « translations » class which implements the parsing of GNU `.mo` format files, and has methods for returning either standard 8-bit strings or Unicode strings. Instances of this « translations » class can also install themselves in the built-in namespace as the function `_()`.

`gettext.find(domain[, localedir[, languages[, all]]])`

Cette fonction implémente l'algorithme standard de recherche de fichier `.mo`. Il prend en entrée un *domain*, tout comme la fonction `textdomain()`. Le paramètre optionnel *localedir* est le même que celui de `bindtextdomain()`. Le paramètre optionnel *languages* est une liste de chaînes de caractères correspondants au code d'une langue.

Si *localedir* n'est pas renseigné, alors le répertoire de la locale par défaut du système est utilisé.<sup>2</sup> Si *languages* n'est pas renseigné, alors les variables d'environnement suivantes sont utilisées : `LANGUAGE`, `LC_ALL`, `LC_MESSAGES` et `LANG`. La première à renvoyer une valeur non vide est alors utilisée pour *languages*. Ces variables d'environnement doivent contenir une liste de langues, séparées par des deux-points, qui sera utilisée pour générer la liste des codes de langues attendue.

Recherche avec `find()`, découvre et normalise les langues, puis itère sur la liste obtenue afin de trouver un fichier de traduction existant et correspondant :

`localedir/language/LC_MESSAGES/domain.mo`

Le premier nom de fichier trouvé est renvoyé par `find()`. Si aucun fichier n'a été trouvé, alors `None` est renvoyé. Si *all* est vrai, est renvoyée la liste de tous les noms de fichiers, dans l'ordre dans lequel ils apparaissent dans *languages* ou dans les variables d'environnement.

`gettext.translation(domain[, localedir[, languages[, class_[, fallback[, codeset]]]])`

Return a `Translations` instance based on the *domain*, *localedir*, and *languages*, which are first passed to `find()` to get a list of the associated `.mo` file paths. Instances with identical `.mo` file names are cached. The actual class instantiated is either *class\_* if provided, otherwise `GNUTranslations`. The class's constructor must take a single file object argument. If provided, *codeset* will change the charset used to encode translated strings.

Si plusieurs fichiers ont été trouvés, les derniers sont utilisés comme substitut des premiers. Pour rendre possible cette substitution, `copy.copy()` est utilisé pour copier chaque objet traduit depuis le cache ; les vraies données de l'instance étant toujours recopiées dans le cache.

If no `.mo` file is found, this function raises `IOError` if *fallback* is false (which is the default), and returns a `NullTranslations` instance if *fallback* is true.

Modifié dans la version 2.4 : Added the *codeset* parameter.

`gettext.install(domain[, localedir[, unicode[, codeset[, names]]])`

This installs the function `_()` in Python's builtins namespace, based on *domain*, *localedir*, and *codeset* which are passed to the function `translation()`. The *unicode* flag is passed to the resulting translation object's `install()` method.

Concernant le paramètre *names*, se référer à la description de la méthode `install()`.

2. Voir la note de `bindtextdomain()` ci-dessus.

Habituellement, la fonction `_()` est appliquée aux chaînes de caractères qui doivent être traduites comme suit :

```
print _('This string will be translated.')
```

Pour plus de confort, il vaut mieux positionner la fonction `_()` dans l'espace de noms natif à Python pour la rendre plus accessible dans tous les modules de votre application.

Modifié dans la version 2.4 : Added the *codeset* parameter.

Modifié dans la version 2.5 : Added the *names* parameter.

### La classe `NullTranslations`

Translation classes are what actually implement the translation of original source file message strings to translated message strings. The base class used by all translation classes is *NullTranslations*; this provides the basic interface you can use to write your own specialized translation classes. Here are the methods of `NullTranslations` :

**`class gettext.NullTranslations([fp])`**

Takes an optional file object *fp*, which is ignored by the base class. Initializes « protected » instance variables `__info` and `__charset` which are set by derived classes, as well as `__fallback`, which is set through `add_fallback()`. It then calls `self._parse(fp)` if *fp* is not `None`.

**`_parse(fp)`**

Cette méthode, non exécutée dans la classe de base, prend en paramètre un objet fichier *fp* et lit les données de ce dernier. Si vous avez un catalogue de messages dont le format n'est pas pris en charge, vous devriez surcharger cette méthode pour analyser votre format.

**`add_fallback(fallback)`**

Ajoute *fallback* comme objet de substitution pour l'objet de traduction courant. Un objet de traduction devrait interroger cet objet de substitution s'il ne peut fournir une traduction pour un message donné.

**`gettext(message)`**

If a fallback has been set, forward `gettext()` to the fallback. Otherwise, return the translated message. Overridden in derived classes.

**`lgettext(message)`**

If a fallback has been set, forward `lgettext()` to the fallback. Otherwise, return the translated message. Overridden in derived classes.

Nouveau dans la version 2.4.

**`ugettext(message)`**

If a fallback has been set, forward `ugettext()` to the fallback. Otherwise, return the translated message as a Unicode string. Overridden in derived classes.

**`ngettext(singular, plural, n)`**

If a fallback has been set, forward `ngettext()` to the fallback. Otherwise, return the translated message. Overridden in derived classes.

Nouveau dans la version 2.3.

**`lngettext(singular, plural, n)`**

If a fallback has been set, forward `lngettext()` to the fallback. Otherwise, return the translated message. Overridden in derived classes.

Nouveau dans la version 2.4.

**`ungettext(singular, plural, n)`**

If a fallback has been set, forward `ungettext()` to the fallback. Otherwise, return the translated message as a Unicode string. Overridden in derived classes.

Nouveau dans la version 2.3.

**`info()`**

Renvoie la variable « protégée » `__info`.

**charset()**

Return the « protected » `_charset` variable.

**output\_charset()**

Return the « protected » `_output_charset` variable, which defines the encoding used to return translated messages.

Nouveau dans la version 2.4.

**set\_output\_charset(charset)**

Change the « protected » `_output_charset` variable, which defines the encoding used to return translated messages.

Nouveau dans la version 2.4.

**install([unicode[, names]])**

If the `unicode` flag is false, this method installs `self.gettext()` into the built-in namespace, binding it to `_`. If `unicode` is true, it binds `self.ugettext()` instead. By default, `unicode` is false. If the `names` parameter is given, it must be a sequence containing the names of functions you want to install in the builtins namespace in addition to `_()`. Supported names are 'gettext' (bound to `self.gettext()` or `self.ugettext()` according to the `unicode` flag), 'ngettext' (bound to `self.ngettext()` or `self.ungettext()` according to the `unicode` flag), 'lgettext' and 'lngettext'.

Notez que ce n'est là qu'un moyen parmi d'autres, quoique le plus pratique, pour rendre la fonction `_()` accessible à votre application. Puisque cela affecte toute l'application, et plus particulièrement l'espace de noms natif, les modules localisés ne devraient jamais y positionner `_()`. Au lieu de cela, ces derniers doivent plutôt utiliser le code suivant pour rendre `_()` accessible par leurs modules :

```
import gettext
t = gettext.translation('mymodule', ...)
_ = t.gettext
```

Cela met `_()` dans l'espace de noms global du module uniquement et donc n'affectera ses appels que dans ce module.

Modifié dans la version 2.5 : Added the `names` parameter.

**La classe GNUTranslations**

The `gettext` module provides one additional class derived from `NullTranslations` : `GNUTranslations`. This class overrides `_parse()` to enable reading GNU `gettext` format `.mo` files in both big-endian and little-endian format. It also coerces both message ids and message strings to Unicode.

`GNUTranslations` parses optional meta-data out of the translation catalog. It is convention with GNU `gettext` to include meta-data as the translation for the empty string. This meta-data is in [RFC 822](#)-style `key: value` pairs, and should contain the `Project-Id-Version` key. If the key `Content-Type` is found, then the `charset` property is used to initialize the « protected » `_charset` instance variable, defaulting to `None` if not found. If the charset encoding is specified, then all message ids and message strings read from the catalog are converted to Unicode using this encoding. The `ugettext()` method always returns a Unicode, while the `gettext()` returns an encoded 8-bit string. For the message id arguments of both methods, either Unicode strings or 8-bit strings containing only US-ASCII characters are acceptable. Note that the Unicode version of the methods (i.e. `ugettext()` and `ungettext()`) are the recommended interface to use for internationalized Python programs.

La totalité des paires clef / valeur est insérée dans un dictionnaire et représente la variable d'instance « protégée » `_info`.

If the `.mo` file's magic number is invalid, or if other problems occur while reading the file, instantiating a `GNUTranslations` class can raise `IOError`.

Les méthodes suivantes, provenant de l'implémentation de la classe de base, ont été surchargées :

**GNUTranslations.gettext(message)**

Look up the *message* id in the catalog and return the corresponding message string, as an 8-bit string encoded with the catalog's charset encoding, if known. If there is no entry in the catalog for the *message* id, and a fallback has been set, the look up is forwarded to the fallback's *gettext()* method. Otherwise, the *message* id is returned.

**GNUTranslations.lgettext(message)**

Equivalent to *gettext()*, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with *set\_output\_charset()*.

Nouveau dans la version 2.4.

**GNUTranslations.uggettext(message)**

Look up the *message* id in the catalog and return the corresponding message string, as a Unicode string. If there is no entry in the catalog for the *message* id, and a fallback has been set, the look up is forwarded to the fallback's *uggettext()* method. Otherwise, the *message* id is returned.

**GNUTranslations.ngettext(singular, plural, n)**

Do a plural-forms lookup of a message id. *singular* is used as the message id for purposes of lookup in the catalog, while *n* is used to determine which plural form to use. The returned message string is an 8-bit string encoded with the catalog's charset encoding, if known.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback's *ngettext()* method. Otherwise, when *n* is 1 *singular* is returned, and *plural* is returned in all other cases.

Nouveau dans la version 2.3.

**GNUTranslations.lngettext(singular, plural, n)**

Equivalent to *gettext()*, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with *set\_output\_charset()*.

Nouveau dans la version 2.4.

**GNUTranslations.ungettext(singular, plural, n)**

Effectue une recherche sur les formes plurielles de l'identifiant d'un message. *singular* est utilisé pour la recherche de l'identifiant dans le catalogue, alors que *n* permet de savoir quelle forme plurielle utiliser. La chaîne de caractère du message renvoyée est une chaîne Unicode.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback's *ungettext()* method. Otherwise, when *n* is 1 *singular* is returned, and *plural* is returned in all other cases.

Voici un exemple :

```
n = len(os.listdir('.'))
cat = GNUTranslations(somefile)
message = cat.ungettext(
    'There is %(num)d file in this directory',
    'There are %(num)d files in this directory',
    n) % {'num': n}
```

Nouveau dans la version 2.3.

## Support du catalogue de message de Solaris

Le système d'exploitation Solaris possède son propre format de fichier binaire *.mo*, mais pour l'heure, puisqu'on ne peut trouver de documentation sur ce format, il n'est pas géré.

## Le constructeur *Catalog*

GNOME utilise une version du module *gettext* de James Henstridge, mais qui a une API légèrement différente. D'après la documentation, elle s'utilise ainsi :

```
import gettext
cat = gettext.Catalog(domain, localedir)
_ = cat.gettext
print _('hello world')
```

Pour des raisons de compatibilité avec cet ancien module, la fonction `Catalog()` est un alias de la fonction `translation()` décrite ci-dessous.

Une différence entre ce module et celui de Henstridge : les objets de son catalogue étaient accessibles depuis un schéma de l'API, mais cela semblait ne pas être utilisé et donc n'est pas pris en charge.

### 22.1.3 Internationaliser vos programmes et modules

L'internationalisation (*I18N*) consiste à permettre à un programme de recevoir des traductions dans plusieurs langues. La localisation (*L10N*) consiste à adapter un programme à la langue et aux habitudes culturelles locales, une fois celui-ci internationalisé. Afin de fournir du texte multilingue à votre programme Python, les étapes suivantes sont nécessaires :

1. préparer votre programme ou module en marquant spécifiquement les chaînes à traduire
2. lancer une suite d'outils sur les fichiers contenant des chaînes à traduire pour générer des catalogues de messages brut
3. créer les traductions spécifiques à une langue des catalogues de messages
4. utiliser le module `gettext` pour que les chaînes de caractères soient bien traduites

Afin de préparer votre code à être traduit (*I18N*), vous devrez rechercher toutes les chaînes de caractères de vos fichiers. À chaque chaîne de caractères à traduire doit être appliqué le marqueur `_('...')` — c'est-à-dire en appelant la fonction `_()`. Par exemple :

```
filename = 'mylog.txt'
message = _('writing a log message')
fp = open(filename, 'w')
fp.write(message)
fp.close()
```

Dans cet exemple, la chaîne `'writing a log message'` est maquée comme traduite, contrairement aux chaînes `'mylog.txt'` et `'w'`.

The Python distribution comes with two tools which help you generate the message catalogs once you've prepared your source code. These may or may not be available from a binary distribution, but they can be found in a source distribution, in the `Tools/i18n` directory.

The `pygettext`<sup>3</sup> program scans all your Python source code looking for the strings you previously marked as translatable. It is similar to the GNU `gettext` program except that it understands all the intricacies of Python source code, but knows nothing about C or C++ source code. You don't need GNU `gettext` unless you're also going to be translating C code (such as C extension modules).

`pygettext` generates textual Uniform-style human readable message catalog `.pot` files, essentially structured human readable files which contain every marked string in the source code, along with a placeholder for the translation strings. `pygettext` is a command line script that supports a similar command line interface as `xgettext`; for details on its use, run :

```
pygettext.py --help
```

Copies of these `.pot` files are then handed over to the individual human translators who write language-specific versions for every supported natural language. They send you back the filled in language-specific

3. François Pinard has written a program called `xpot` which does a similar job. It is available as part of his `po-utils` package.

versions as a `.po` file. Using the `msgfmt.py`<sup>4</sup> program (in the `Tools/i18n` directory), you take the `.po` files from your translators and generate the machine-readable `.mo` binary catalog files. The `.mo` files are what the `gettext` module uses for the actual translation processing during run-time.

La façon dont vous utilisez le module `gettext` dans votre code dépend de si vous internationalisez un seul module ou l'ensemble de votre application. Les deux sections suivantes traitent chacune des cas.

### Localiser votre module

Si vous localisez votre module, veillez à ne pas faire de changements globaux, e.g. dans l'espace de nom natif. Vous ne devriez pas utiliser l'API GNU `gettext` mais plutôt celle basée sur les classes.

Disons que votre module s'appelle « spam » et que les fichiers `.mo` de traduction dans les différentes langues naturelles soient dans `/usr/share/locale` au format GNU `gettext`. Voici ce que vous pouvez alors mettre en haut de votre module :

```
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.lgettext
```

If your translators were providing you with Unicode strings in their `.po` files, you'd instead do :

```
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.ugettext
```

### Localiser votre application

Si vous localisez votre application, vous pouvez positionner la fonction `_()` de manière globale dans l'espace de noms natif, généralement dans le fichier principal de votre application. Cela permettra à tous les fichiers de votre application de n'utiliser que `_('...')` sans devoir le redéfinir explicitement dans chaque fichier.

Dans ce cas, vous n'aurez à ajouter que le bout de code suivant au fichier principal de votre application :

```
import gettext
gettext.install('myapplication')
```

If you need to set the locale directory or the `unicode` flag, you can pass these into the `install()` function :

```
import gettext
gettext.install('myapplication', '/usr/share/locale', unicode=1)
```

### Changer de langue à la volée

Si votre programme a besoin de prendre en charge plusieurs langues en même temps, vous pouvez créer plusieurs instances de traduction, puis basculer entre elles de façon explicite, comme ceci :

```
import gettext

lang1 = gettext.translation('myapplication', languages=['en'])
lang2 = gettext.translation('myapplication', languages=['fr'])
lang3 = gettext.translation('myapplication', languages=['de'])
```

(suite sur la page suivante)

---

4. `msgfmt.py` is binary compatible with GNU `msgfmt` except that it provides a simpler, all-Python implementation. With this and `pygettext.py`, you generally won't need to install the GNU `gettext` package to internationalize your Python applications.

(suite de la page précédente)

```
# start by using language1
lang1.install()

# ... time goes by, user selects language 2
lang2.install()

# ... more time goes by, user selects language 3
lang3.install()
```

### Traductions différées

Dans la plupart des cas, en programmation, les chaînes de caractères sont traduites à l'endroit où on les écrit. Cependant, il peut arriver que vous ayez besoin de traduire une chaîne de caractères un peu plus loin. Un exemple classique est :

```
animals = ['mollusk',
           'albatross',
           'rat',
           'penguin',
           'python', ]

# ...
for a in animals:
    print a
```

Ici, vous voulez marquer les chaînes de caractères de la liste `animals` comme étant traduisibles, mais ne les traduire qu'au moment de les afficher.

Voici un moyen de gérer ce cas :

```
def _(message): return message

animals = [_('mollusk'),
           _('albatross'),
           _('rat'),
           _('penguin'),
           _('python'), ]

del _

# ...
for a in animals:
    print _(a)
```

Cela fonctionne car la définition factice de `_()` renvoie simplement la chaîne de caractères passée en entrée. Et cette définition factice va temporairement outrepasser toute autre définition de `_()` dans l'espace de noms natif (jusqu'à l'utilisation de la commande `del`). Attention toutefois si vous avez déjà une autre définition de `_()` dans l'espace de noms local.

Note that the second use of `_()` will not identify « a » as being translatable to the `pygettext` program, since it is not a string.

Voici une autre solution :

```
def N_(message): return message

animals = [N_('mollusk'),
           N_('albatross'),
           N_('rat'),
           N_('penguin'),
           N_('python'), ]

# ...
for a in animals:
    print _(a)
```

In this case, you are marking translatable strings with the function `N_()`,<sup>5</sup> which won't conflict with any definition of `_()`. However, you will need to teach your message extraction program to look for translatable strings marked with `N_()`. `pygettext` and `xpot` both support this through the use of command line switches.

#### `gettext()` vs. `lgettext()`

In Python 2.4 the `lgettext()` family of functions were introduced. The intention of these functions is to provide an alternative which is more compliant with the current implementation of GNU `gettext`. Unlike `gettext()`, which returns strings encoded with the same codeset used in the translation file, `lgettext()` will return strings encoded with the preferred system encoding, as returned by `locale.getpreferredencoding()`. Also notice that Python 2.4 introduces new functions to explicitly choose the codeset used in translated strings. If a codeset is explicitly set, even `lgettext()` will return translated strings in the requested codeset, as would be expected in the GNU `gettext` implementation.

### 22.1.4 Remerciements

Les personnes suivantes ont contribué au code, ont fait des retours, ont participé aux suggestions de conception et aux implémentations précédentes, et ont partagé leur expérience précieuse pour la création de ce module :

- Peter Funk

#### Notes

## 22.2 `locale` — Internationalization services

The `locale` module opens access to the POSIX locale database and functionality. The POSIX locale mechanism allows programmers to deal with certain cultural issues in an application, without requiring the programmer to know all the specifics of each country where the software is executed.

The `locale` module is implemented on top of the `_locale` module, which in turn uses an ANSI C locale implementation if available.

The `locale` module defines the following exception and functions :

---

5. The choice of `N_()` here is totally arbitrary ; it could have just as easily been `MarkThisStringForTranslation()`.

**exception `locale.Error`**

Exception raised when the locale passed to `setlocale()` is not recognized.

**`locale.setlocale(category[, locale])`**

If *locale* is given and not `None`, `setlocale()` modifies the locale setting for the *category*. The available categories are listed in the data description below. *locale* may be a string, or an iterable of two strings (language code and encoding). If it's an iterable, it's converted to a locale name using the locale aliasing engine. An empty string specifies the user's default settings. If the modification of the locale fails, the exception `Error` is raised. If successful, the new locale setting is returned.

If *locale* is omitted or `None`, the current setting for *category* is returned.

`setlocale()` is not thread-safe on most systems. Applications typically start with a call of

```
import locale
locale.setlocale(locale.LC_ALL, '')
```

This sets the locale for all categories to the user's default setting (typically specified in the `LANG` environment variable). If the locale is not changed thereafter, using multithreading should not cause problems.

Modifié dans la version 2.0 : Added support for iterable values of the *locale* parameter.

**`locale.localeconv()`**

Returns the database of the local conventions as a dictionary. This dictionary has the following strings as keys :

Category	Key	Signification
<i>LC_NUMERIC</i>	'decimal_point'	Decimal point character.
	'grouping'	Sequence of numbers specifying which relative positions the 'thousands_sep' is expected. If the sequence is terminated with <i>CHAR_MAX</i> , no further grouping is performed. If the sequence terminates with a 0, the last group size is repeatedly used.
	'thousands_sep'	Character used between groups.
<i>LC_MONETARY</i>	'int_curr_symbol'	International currency symbol.
	'currency_symbol'	Local currency symbol.
	'p_cs_precedes/n_cs_precedes'	Whether the currency symbol precedes the value (for positive resp. negative values).
	'p_sep_by_space/n_sep_by_space'	Whether the currency symbol is separated from the value by a space (for positive resp. negative values).
	'mon_decimal_point'	Decimal point used for monetary values.
	'frac_digits'	Number of fractional digits used in local formatting of monetary values.
	'int_frac_digits'	Number of fractional digits used in international formatting of monetary values.
	'mon_thousands_sep'	Group separator used for monetary values.
	'mon_grouping'	Equivalent to 'grouping', used for monetary values.
	'positive_sign'	Symbol used to annotate a positive monetary value.
	'negative_sign'	Symbol used to annotate a negative monetary value.
	'p_sign_posn/n_sign_posn'	The position of the sign (for positive resp. negative values), see below.

All numeric values can be set to *CHAR\_MAX* to indicate that there is no value specified in this locale. The possible values for 'p\_sign\_posn' and 'n\_sign\_posn' are given below.

Valeur	Explication
0	Currency and value are surrounded by parentheses.
1	The sign should precede the value and currency symbol.
2	The sign should follow the value and currency symbol.
3	The sign should immediately precede the value.
4	The sign should immediately follow the value.
<i>CHAR_MAX</i>	Nothing is specified in this locale.

#### `locale.nl_langinfo(option)`

Return some locale-specific information as a string. This function is not available on all systems, and the set of possible options might also vary across platforms. The possible argument values are numbers, for which symbolic constants are available in the locale module.

The `nl_langinfo()` function accepts one of the following keys. Most descriptions are taken from the corresponding description in the GNU C library.

**locale.CODESET**

Get a string with the name of the character encoding used in the selected locale.

**locale.D\_T\_FMT**

Get a string that can be used as a format string for *time.strftime()* to represent date and time in a locale-specific way.

**locale.D\_FMT**

Get a string that can be used as a format string for *time.strftime()* to represent a date in a locale-specific way.

**locale.T\_FMT**

Get a string that can be used as a format string for *time.strftime()* to represent a time in a locale-specific way.

**locale.T\_FMT\_AMPM**

Get a format string for *time.strftime()* to represent time in the am/pm format.

**DAY\_1 ... DAY\_7**

Get the name of the n-th day of the week.

---

**Note :** This follows the US convention of **DAY\_1** being Sunday, not the international convention (ISO 8601) that Monday is the first day of the week.

---

**ABDAY\_1 ... ABDAY\_7**

Get the abbreviated name of the n-th day of the week.

**MON\_1 ... MON\_12**

Get the name of the n-th month.

**ABMON\_1 ... ABMON\_12**

Get the abbreviated name of the n-th month.

**locale.RADIXCHAR**

Get the radix character (decimal dot, decimal comma, etc.).

**locale.THOUSEP**

Get the separator character for thousands (groups of three digits).

**locale.YESEXPR**

Get a regular expression that can be used with the *regex* function to recognize a positive response to a yes/no question.

---

**Note :** The expression is in the syntax suitable for the *regex()* function from the C library, which might differ from the syntax used in *re*.

---

**locale.NOEXPR**

Get a regular expression that can be used with the *regex(3)* function to recognize a negative response to a yes/no question.

**locale.CRNCYSTR**

Get the currency symbol, preceded by « - » if the symbol should appear before the value, « + » if the symbol should appear after the value, or « . » if the symbol should replace the radix character.

**locale.ERA**

Get a string that represents the era used in the current locale.

Most locales do not define this value. An example of a locale which does define this value is the Japanese one. In Japan, the traditional representation of dates includes the name of the era corresponding to the then-emperor's reign.

Normally it should not be necessary to use this value directly. Specifying the E modifier in their format strings causes the *time.strftime()* function to use this information. The format of the returned string is not specified, and therefore you should not assume knowledge of it on different systems.

`locale.ERA_D_T_FMT`

Get a format string for `time.strftime()` to represent date and time in a locale-specific era-based way.

`locale.ERA_D_FMT`

Get a format string for `time.strftime()` to represent a date in a locale-specific era-based way.

`locale.ERA_T_FMT`

Get a format string for `time.strftime()` to represent a time in a locale-specific era-based way.

`locale.ALT_DIGITS`

Get a representation of up to 100 values used to represent the values 0 to 99.

`locale.getdefaultlocale([envvars])`

Tries to determine the default locale settings and returns them as a tuple of the form (language code, encoding).

According to POSIX, a program which has not called `setlocale(LC_ALL, '')` runs using the portable 'C' locale. Calling `setlocale(LC_ALL, '')` lets it use the default locale as defined by the LANG variable. Since we do not want to interfere with the current locale setting we thus emulate the behavior in the way described above.

To maintain compatibility with other platforms, not only the LANG variable is tested, but a list of variables given as envvars parameter. The first found to be defined will be used. *envvars* defaults to the search path used in GNU gettext; it must always contain the variable name LANG. The GNU gettext search path contains 'LANGUAGE', 'LC\_ALL', 'LC\_CTYPE', and 'LANG', in that order.

Except for the code 'C', the language code corresponds to [RFC 1766](#). *language code* and *encoding* may be `None` if their values cannot be determined.

Nouveau dans la version 2.0.

`locale.getlocale([category])`

Returns the current setting for the given locale category as sequence containing *language code*, *encoding*. *category* may be one of the LC\_\* values except `LC_ALL`. It defaults to `LC_CTYPE`.

Except for the code 'C', the language code corresponds to [RFC 1766](#). *language code* and *encoding* may be `None` if their values cannot be determined.

Nouveau dans la version 2.0.

`locale.getpreferredencoding([do_setlocale])`

Return the encoding used for text data, according to user preferences. User preferences are expressed differently on different systems, and might not be available programmatically on some systems, so this function only returns a guess.

On some systems, it is necessary to invoke `setlocale()` to obtain the user preferences, so this function is not thread-safe. If invoking `setlocale` is not necessary or desired, *do\_setlocale* should be set to `False`.

Nouveau dans la version 2.3.

`locale.normalize(localename)`

Returns a normalized locale code for the given locale name. The returned locale code is formatted for use with `setlocale()`. If normalization fails, the original name is returned unchanged.

If the given encoding is not known, the function defaults to the default encoding for the locale code just like `setlocale()`.

Nouveau dans la version 2.0.

`locale.resetlocale([category])`

Sets the locale for *category* to the default setting.

The default setting is determined by calling `getdefaultlocale()`. *category* defaults to `LC_ALL`.

Nouveau dans la version 2.0.

`locale.strcoll(string1, string2)`

Compares two strings according to the current `LC_COLLATE` setting. As any other compare function, returns a negative, or a positive value, or 0, depending on whether *string1* collates before or after *string2* or is equal to it.

`locale.strxfrm(string)`

Transforms a string to one that can be used for the built-in function `cmp()`, and still returns locale-aware results. This function can be used when the same string is compared repeatedly, e.g. when collating a sequence of strings.

`locale.format(format, val[, grouping[, monetary]])`

Formats a number *val* according to the current `LC_NUMERIC` setting. The format follows the conventions of the `%` operator. For floating point values, the decimal point is modified if appropriate. If *grouping* is true, also takes the grouping into account.

If *monetary* is true, the conversion uses monetary thousands separator and grouping strings.

Please note that this function will only work for exactly one `%char` specifier. For whole format strings, use `format_string()`.

Modifié dans la version 2.5 : Added the *monetary* parameter.

`locale.format_string(format, val[, grouping])`

Processes formatting specifiers as in `format % val`, but takes the current locale settings into account.

Nouveau dans la version 2.5.

`locale.currency(val[, symbol[, grouping[, international]]])`

Formats a number *val* according to the current `LC_MONETARY` settings.

The returned string includes the currency symbol if *symbol* is true, which is the default. If *grouping* is true (which is not the default), grouping is done with the value. If *international* is true (which is not the default), the international currency symbol is used.

Note that this function will not work with the “C” locale, so you have to set a locale via `setlocale()` first.

Nouveau dans la version 2.5.

`locale.str(float)`

Formats a floating point number using the same format as the built-in function `str(float)`, but takes the decimal point into account.

`locale.atof(string)`

Converts a string to a floating point number, following the `LC_NUMERIC` settings.

`locale.atoi(string)`

Converts a string to an integer, following the `LC_NUMERIC` conventions.

`locale.LC_CTYPE`

Locale category for the character type functions. Depending on the settings of this category, the functions of module `string` dealing with case change their behaviour.

`locale.LC_COLLATE`

Locale category for sorting strings. The functions `strcoll()` and `strxfrm()` of the `locale` module are affected.

`locale.LC_TIME`

Locale category for the formatting of time. The function `time.strftime()` follows these conventions.

`locale.LC_MONETARY`

Locale category for formatting of monetary values. The available options are available from the `localeconv()` function.

`locale.LC_MESSAGES`

Locale category for message display. Python currently does not support application specific locale-aware messages. Messages displayed by the operating system, like those returned by `os.strerror()` might be affected by this category.

**locale.LC\_NUMERIC**

Locale category for formatting numbers. The functions *format()*, *atoi()*, *atof()* and *str()* of the *locale* module are affected by that category. All other numeric formatting operations are not affected.

**locale.LC\_ALL**

Combination of all locale settings. If this flag is used when the locale is changed, setting the locale for all categories is attempted. If that fails for any category, no category is changed at all. When the locale is retrieved using this flag, a string indicating the setting for all categories is returned. This string can be later used to restore the settings.

**locale.CHAR\_MAX**

This is a symbolic constant used for different values returned by *localeconv()*.

Example :

```
>>> import locale
>>> loc = locale.getlocale() # get current locale
# use German locale; name might vary with platform
>>> locale.setlocale(locale.LC_ALL, 'de_DE')
>>> locale.strcoll('f\xee4n', 'foo') # compare a string containing an umlaut
>>> locale.setlocale(locale.LC_ALL, '') # use user's preferred locale
>>> locale.setlocale(locale.LC_ALL, 'C') # use default (C) locale
>>> locale.setlocale(locale.LC_ALL, loc) # restore saved locale
```

### 22.2.1 Background, details, hints, tips and caveats

The C standard defines the locale as a program-wide property that may be relatively expensive to change. On top of that, some implementation are broken in such a way that frequent locale changes may cause core dumps. This makes the locale somewhat painful to use correctly.

Initially, when a program is started, the locale is the C locale, no matter what the user's preferred locale is. The program must explicitly say that it wants the user's preferred locale settings by calling *setlocale(LC\_ALL, '')*.

It is generally a bad idea to call *setlocale()* in some library routine, since as a side effect it affects the entire program. Saving and restoring it is almost as bad : it is expensive and affects other threads that happen to run before the settings have been restored.

If, when coding a module for general use, you need a locale independent version of an operation that is affected by the locale (such as *string.lower()*, or certain formats used with *time.strftime()*), you will have to find a way to do it without using the standard library routine. Even better is convincing yourself that using locale settings is okay. Only as a last resort should you document that your module is not compatible with non-C locale settings.

The case conversion functions in the *string* module are affected by the locale settings. When a call to the *setlocale()* function changes the *LC\_CTYPE* settings, the variables *string.lowercase*, *string.uppercase* and *string.letters* are recalculated. Note that code that uses these variable through "from ... import ...", e.g. *from string import letters*, is not affected by subsequent *setlocale()* calls.

The only way to perform numeric operations according to the locale is to use the special functions defined by this module : *atof()*, *atoi()*, *format()*, *str()*.

### 22.2.2 For extension writers and programs that embed Python

Extension modules should never call *setlocale()*, except to find out what the current locale is. But since the return value can only be used portably to restore it, that is not very useful (except perhaps to find out whether or not the locale is C).

When Python code uses the `locale` module to change the locale, this also affects the embedding application. If the embedding application doesn't want this to happen, it should remove the `_locale` extension module (which does all the work) from the table of built-in modules in the `config.c` file, and make sure that the `_locale` module is not accessible as a shared library.

### 22.2.3 Access to message catalogs

```
locale.gettext(msg)
```

```
locale.dgettext(domain, msg)
```

```
locale.dcgettext(domain, msg, category)
```

```
locale.textdomain(domain)
```

```
locale.bindtextdomain(domain, dir)
```

The `locale` module exposes the C library's `gettext` interface on systems that provide this interface. It consists of the functions `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, `bindtextdomain()`, and `bind_textdomain_codeset()`. These are similar to the same functions in the `gettext` module, but use the C library's binary format for message catalogs, and the C library's search algorithms for locating message catalogs.

Python applications should normally find no need to invoke these functions, and should use `gettext` instead. A known exception to this rule are applications that link with additional C libraries which internally invoke `gettext()` or `dcgettext()`. For these applications, it may be necessary to bind the text domain, so that the libraries can properly locate their message catalogs.

Les modules décrits dans ce chapitre sont des *frameworks* qui encadreront la structure de vos programmes. Actuellement tous les modules décrits ici sont destinés à écrire des interfaces en ligne de commande.

La liste complète des modules décrits dans ce chapitre est :

## 23.1 cmd — Interpréteurs en ligne de commande.

Code source : [Lib/cmd.py](#)

---

La *Cmd* fournit une base simple permettant d'écrire des interpréteurs en ligne de commande. Ceux-ci sont souvent utiles pour piloter des tests, pour des outils administratifs, et pour des prototypes destinés à être intégrés à une interface plus sophistiquée.

```
class cmd.Cmd([completekey[, stdin[, stdout]]])
```

Une instance de *Cmd* ou d'une classe en héritant est un *framework* orienté ligne de commande. Il n'y a pas de bonne raison d'instancier *Cmd* directement. Elle est plutôt utile en tant que classe mère d'une classe-interprète que vous définirez afin d'hériter des méthodes de *Cmd* et d'encapsuler les opérations.

L'argument facultatif *completekey* est le nom *readline* d'une touche de complétion. Si *completekey* ne vaut pas *None* et que *readline* est disponible, la complétion de commandes est faite automatiquement.

Les arguments facultatifs *stdin* et *stdout* spécifient les objets-fichiers de lecture et d'écriture que l'instance de *Cmd* ou d'une classe fille utilisera comme entrée et sortie. Si ces arguments ne sont pas spécifiés, ils prendront comme valeur par défaut *sys.stdin* et *sys.stdout*.

Si vous souhaitez qu'un *stdin* donné soit utilisé, assurez-vous que l'attribut *use\_rawinput* de l'instance vaille *False*, faute de quoi *stdin* sera ignoré.

Modifié dans la version 2.3 : The *stdin* and *stdout* parameters were added.

### 23.1.1 Objets Cmd

Une instance de *Cmd* possède les méthodes suivantes :

`Cmd.cmdloop([intro])`

Affiche une invite de commande de manière répétée, accepte une entrée, soustrait un préfixe initial de l'entrée reçue et envoie aux méthodes d'opération la partie restante de l'entrée reçue.

L'argument facultatif est une bannière ou chaîne de caractères d'introduction à afficher avant la première invite de commande (il redéfinit l'attribut de classe *intro*).

Si le module *readline* est chargé, l'entrée héritera automatiquement d'une édition d'historique similaire à **bash** (Par exemple, **Control-P** reviendra à la dernière commande, **Control-N** avancera à la suivante, **Control-F** déplace le curseur vers la droite, **Control-B** déplace le curseur vers la gauche, etc...).

Une caractère de fin de fichier est transmis via la chaîne de caractères 'EOF'.

Une instance d'un interpréteur reconnaîtra un nom de commande `foo` si et seulement si celle-ci possède une méthode `do_foo()`. Les lignes commençant par le caractère '?' sont un cas particulier : elles sont envoyées à la méthode `do_help()`. Les lignes commençant par le caractère '!' sont également un cas particulier : elles sont envoyées à la méthode `do_shell()` (si une telle méthode est définie).

Cette méthode ne s'arrêtera que lorsque `postcmd()` renverra une valeur vraie. L'argument *stop* de `postcmd()` est la valeur de retour de la méthode `do_*`() correspondant à la commande.

Si la complétion est activée, la complétion de commandes sera faite automatiquement ; et la complétion d'arguments sera faite en appelant `complete_foo()` avec les arguments *text*, *line*, *begidx*, et *endidx*. *text* est le préfixe que nous cherchons à faire coïncider : toutes les valeurs renvoyées doivent commencer par ce préfixe. *line* est la ligne d'entrée actuelle sans les espaces blancs de début. *begidx* et *endidx* sont les index de début et de fin du préfixe, ils pourraient être utilisés pour fournir différentes complétions en fonction de la position de l'argument.

Toutes les classes filles de *Cmd* héritent d'une méthode `do_help()` prédéfinie. Cette méthode appellera la méthode `help_bar()` lorsqu'elle est appelée avec un argument 'bar'. Si celle-ci n'est pas définie, elle affichera la *docstring* de `do_bar()`, (si elle a une *docstring*). Sans argument, `do_help()` listera tous les sujets d'aide (c'est à dire, toutes les commandes avec une méthode `help_*`() correspondante ou commande ayant une *docstring*, elle lisera aussi les commandes non documentées.

`Cmd.onecmd(str)`

Interprète l'argument comme si il avait été entré en réponse à l'invite de commande. Cette méthode peut être surchargée, mais ne devrait normalement pas avoir besoin de l'être ; voir les méthodes `precmd()` et `postcmd()` pour altérer l'exécution d'une commande. La valeur de retour est un *flag* indiquant si l'interprétation de commandes par l'interpréteur devrait arrêter. S'il existe une méthode `do_*`() pour la commande *str*, la valeur de retour de cette méthode est renvoyée. Dans le cas contraire, la valeur de retour de la méthode `default()` est renvoyée.

`Cmd.emptyline()`

Méthode appelée quand une ligne vide est entrée en réponse à l'invite de commande. Si cette méthode n'est pas surchargée, elle répète la dernière commande non-vide entrée.

`Cmd.default(line)`

Méthode appelée lorsque le préfixe de commande d'une ligne entrée n'est pas reconnu. Si cette méthode n'est pas surchargée, elle affiche un message d'erreur et s'arrête.

`Cmd.completedefault(text, line, begidx, endidx)`

Méthode appelée pour compléter une ligne entrée quand aucune méthode `complete_*`() spécifique à la commande n'est disponible. Par défaut, elle renvoie une liste vide.

`Cmd.precmd(line)`

Méthode de rappel exécutée juste avant que la ligne de commande *line* ne soit interprétée, mais après que l'invite de commande ait été généré et affiché. Cette méthode existe afin d'être surchargée par des classes filles de *Cmd*. La valeur de retour est utilisée comme la commande qui sera exécutée par la méthode `onecmd()`. L'implémentation de `precmd()` peut réécrire la commande ou simplement renvoyer *line* sans modification.

`Cmd.postcmd(stop, line)`

Méthode de rappel exécutée juste après qu'une commande ait été exécutée. Cette méthode existe afin

d'être surchargée par des classes filles de `Cmd`. *line* est la ligne de commande ayant été exécutée et *\*stop* est un *flag* indiquant si l'exécution sera terminée après un appel à `postcmd()`. *stop* sera la valeur de retour de `onecmd()`. La valeur de retour de cette méthode sera utilisée comme nouvelle valeur pour le *flag* interne correspondant à *stop*. Renvoyer `False` permettra à l'interprétation de continuer.

**Cmd.preloop()**

Méthode de rappel exécutée une fois lorsque `cmdloop()` est appelée. Cette méthode existe afin d'être surchargée par des classes filles de `Cmd`.

**Cmd.postloop()**

Méthode de rappel exécutée une fois lorsque `cmdloop()` va s'arrêter. Cette méthode existe afin d'être surchargée par des classes filles de `Cmd`.

Les instances de classes filles de `Cmd` possèdent des variables d'instance publiques :

**Cmd.prompt**

L'invite de commande affiché pour solliciter une entrée.

**Cmd.identchars**

La chaîne de caractères acceptée en tant que préfixe de commande.

**Cmd.lastcmd**

Le dernier préfixe de commande non-vide vu.

**Cmd.cmdqueue**

Une liste de lignes entrées en file. La liste `cmdqueue` est vérifiée dans `cmdloop()` lorsqu'une nouvelle entrée est nécessitée ; si elle n'est pas vide, ses éléments seront traités dans l'ordre, comme si ils avaient entrés dans l'invite de commande.

**Cmd.intro**

Une chaîne de caractères à afficher en introduction ou bannière. Peut être surchargée en passant un argument à la méthode `cmdloop()`.

**Cmd.doc\_header**

L'en-tête à afficher si la sortie de l'aide possède une section pour les commandes documentées.

**Cmd.misc\_header**

L'en-tête à afficher si la sortie de l'aide possède une section pour divers sujets (c'est-à-dire qu'il existe des méthodes `help_*`() sans méthodes `do_*`() correspondantes).

**Cmd.undoc\_header**

L'en-tête à afficher si la sortie de l'aide possède une section pour les commandes non documentées (c'est-à-dire qu'il existe des méthodes `dop_*`() sans méthodes `help_*`() correspondantes).

**Cmd.ruler**

Le caractère utilisé pour afficher des lignes de séparation sous les en-têtes de messages d'aide. Si il est vide, aucune ligne de séparation n'est affichée. Par défaut, ce caractère vaut '='.

**Cmd.use\_rawinput**

A flag, defaulting to true. If true, `cmdloop()` uses `raw_input()` to display a prompt and read the next command ; if false, `sys.stdout.write()` and `sys.stdin.readline()` are used. (This means that by importing `readline`, on systems that support it, the interpreter will automatically support **Emacs**-like line editing and command-history keystrokes.)

## 23.2 shlex — Simple lexical analysis

Nouveau dans la version 1.5.2.

Code source : [Lib/shlex.py](#)

The `shlex` class makes it easy to write lexical analyzers for simple syntaxes resembling that of the Unix shell. This will often be useful for writing minilanguages, (for example, in run control files for Python applications) or for parsing quoted strings.

Prior to Python 2.7.3, this module did not support Unicode input.

The `shlex` module defines the following functions :

`shlex.split(s[, comments[, posix]])`

Split the string `s` using shell-like syntax. If `comments` is `False` (the default), the parsing of comments in the given string will be disabled (setting the `commenters` attribute of the `shlex` instance to the empty string). This function operates in POSIX mode by default, but uses non-POSIX mode if the `posix` argument is false.

Nouveau dans la version 2.3.

Modifié dans la version 2.6 : Added the `posix` parameter.

---

**Note :** Since the `split()` function instantiates a `shlex` instance, passing `None` for `s` will read the string to split from standard input.

---

The `shlex` module defines the following class :

`class shlex.shlex([instream[, infile[, posix]]])`

A `shlex` instance or subclass instance is a lexical analyzer object. The initialization argument, if present, specifies where to read characters from. It must be a file-/stream-like object with `read()` and `readline()` methods, or a string (strings are accepted since Python 2.3). If no argument is given, input will be taken from `sys.stdin`. The second optional argument is a filename string, which sets the initial value of the `infile` attribute. If the `instream` argument is omitted or equal to `sys.stdin`, this second argument defaults to « `stdin` ». The `posix` argument was introduced in Python 2.3, and defines the operational mode. When `posix` is not true (default), the `shlex` instance will operate in compatibility mode. When operating in POSIX mode, `shlex` will try to be as close as possible to the POSIX shell parsing rules.

Voir aussi :

Module `ConfigParser` Parser for configuration files similar to the Windows `.ini` files.

### 23.2.1 shlex Objects

A `shlex` instance has the following methods :

`shlex.get_token()`

Return a token. If tokens have been stacked using `push_token()`, pop a token off the stack. Otherwise, read one from the input stream. If reading encounters an immediate end-of-file, `eof` is returned (the empty string `('')` in non-POSIX mode, and `None` in POSIX mode).

`shlex.push_token(str)`

Push the argument onto the token stack.

`shlex.read_token()`

Read a raw token. Ignore the pushback stack, and do not interpret source requests. (This is not ordinarily a useful entry point, and is documented here only for the sake of completeness.)

`shlex.sourcehook(filename)`

When `shlex` detects a source request (see `source` below) this method is given the following token as argument, and expected to return a tuple consisting of a filename and an open file-like object.

Normally, this method first strips any quotes off the argument. If the result is an absolute pathname, or there was no previous source request in effect, or the previous source was a stream (such as `sys.stdin`),

the result is left alone. Otherwise, if the result is a relative pathname, the directory part of the name of the file immediately before it on the source inclusion stack is prepended (this behavior is like the way the C preprocessor handles `#include "file.h"`).

The result of the manipulations is treated as a filename, and returned as the first component of the tuple, with `open()` called on it to yield the second component. (Note : this is the reverse of the order of arguments in instance initialization!)

This hook is exposed so that you can use it to implement directory search paths, addition of file extensions, and other namespace hacks. There is no corresponding “close” hook, but a `shlex` instance will call the `close()` method of the sourced input stream when it returns EOF.

For more explicit control of source stacking, use the `push_source()` and `pop_source()` methods.

`shlex.push_source(stream[, filename])`

Push an input source stream onto the input stack. If the filename argument is specified it will later be available for use in error messages. This is the same method used internally by the `sourcehook()` method.

Nouveau dans la version 2.1.

`shlex.pop_source()`

Pop the last-pushed input source from the input stack. This is the same method used internally when the lexer reaches EOF on a stacked input stream.

Nouveau dans la version 2.1.

`shlex.error_leader([file[, line]])`

This method generates an error message leader in the format of a Unix C compiler error label; the format is `"%s", line %d: '`, where the `%s` is replaced with the name of the current source file and the `%d` with the current input line number (the optional arguments can be used to override these).

This convenience is provided to encourage `shlex` users to generate error messages in the standard, parseable format understood by Emacs and other Unix tools.

Instances of `shlex` subclasses have some public instance variables which either control lexical analysis or can be used for debugging :

`shlex.commenters`

The string of characters that are recognized as comment beginners. All characters from the comment beginner to end of line are ignored. Includes just `'#'` by default.

`shlex.wordchars`

The string of characters that will accumulate into multi-character tokens. By default, includes all ASCII alphanumerics and underscore.

`shlex.whitespace`

Characters that will be considered whitespace and skipped. Whitespace bounds tokens. By default, includes space, tab, linefeed and carriage-return.

`shlex.escape`

Characters that will be considered as escape. This will be only used in POSIX mode, and includes just `'\'` by default.

Nouveau dans la version 2.3.

`shlex.quotes`

Characters that will be considered string quotes. The token accumulates until the same quote is encountered again (thus, different quote types protect each other as in the shell.) By default, includes ASCII single and double quotes.

`shlex.escapedquotes`

Characters in `quotes` that will interpret escape characters defined in `escape`. This is only used in POSIX mode, and includes just `'\"'` by default.

Nouveau dans la version 2.3.

**shlex.whitespace\_split**

If `True`, tokens will only be split in whitespaces. This is useful, for example, for parsing command lines with *shlex*, getting tokens in a similar way to shell arguments.

Nouveau dans la version 2.3.

**shlex.infile**

The name of the current input file, as initially set at class instantiation time or stacked by later source requests. It may be useful to examine this when constructing error messages.

**shlex.instream**

The input stream from which this *shlex* instance is reading characters.

**shlex.source**

This attribute is `None` by default. If you assign a string to it, that string will be recognized as a lexical-level inclusion request similar to the `source` keyword in various shells. That is, the immediately following token will be opened as a filename and input will be taken from that stream until EOF, at which point the `close()` method of that stream will be called and the input source will again become the original input stream. Source requests may be stacked any number of levels deep.

**shlex.debug**

If this attribute is numeric and 1 or more, a *shlex* instance will print verbose progress output on its behavior. If you need to use this, you can read the module source code to learn the details.

**shlex.lineno**

Source line number (count of newlines seen so far plus one).

**shlex.token**

The token buffer. It may be useful to examine this when catching exceptions.

**shlex.eof**

Token used to determine end of file. This will be set to the empty string (`''`), in non-POSIX mode, and to `None` in POSIX mode.

Nouveau dans la version 2.3.

## 23.2.2 Parsing Rules

When operating in non-POSIX mode, *shlex* will try to obey to the following rules.

- Quote characters are not recognized within words (`Do"Not"Separate` is parsed as the single word `Do"Not"Separate`);
- Escape characters are not recognized;
- Enclosing characters in quotes preserve the literal value of all characters within the quotes;
- Closing quotes separate words (`"Do"Separate` is parsed as `"Do"` and `Separate`);
- If *whitespace\_split* is `False`, any character not declared to be a word character, whitespace, or a quote will be returned as a single-character token. If it is `True`, *shlex* will only split words in whitespaces;
- EOF is signaled with an empty string (`''`);
- It's not possible to parse empty strings, even if quoted.

When operating in POSIX mode, *shlex* will try to obey to the following parsing rules.

- Quotes are stripped out, and do not separate words (`"Do"Not"Separate"` is parsed as the single word `DoNotSeparate`);
- Non-quoted escape characters (e.g. `'\'`) preserve the literal value of the next character that follows;
- Enclosing characters in quotes which are not part of *escapedquotes* (e.g. `""`) preserve the literal value of all characters within the quotes;
- Enclosing characters in quotes which are part of *escapedquotes* (e.g. `'''`) preserves the literal value of all characters within the quotes, with the exception of the characters mentioned in *escape*. The escape characters retain its special meaning only when followed by the quote in use, or the escape character itself. Otherwise the escape character will be considered a normal character.

- EOF is signaled with a *None* value;
- Quoted empty strings ( `' '` ) are allowed;

---

## Interfaces Utilisateur Graphiques avec Tk

---

Tk/Tcl has long been an integral part of Python. It provides a robust and platform independent windowing toolkit, that is available to Python programmers using the *Tkinter* module, and its extensions, the *Tix* and the *ttk* modules.

The *Tkinter* module is a thin object-oriented layer on top of Tcl/Tk. To use *Tkinter*, you don't need to write Tcl code, but you will need to consult the Tk documentation, and occasionally the Tcl documentation. *Tkinter* is a set of wrappers that implement the Tk widgets as Python classes. In addition, the internal module `_tkinter` provides a threadsafe mechanism which allows Python and Tcl to interact.

*Tkinter*'s chief virtues are that it is fast, and that it usually comes bundled with Python. Although its standard documentation is weak, good material is available, which includes : references, tutorials, a book and others. *Tkinter* is also famous for having an outdated look and feel, which has been vastly improved in Tk 8.5. Nevertheless, there are many other GUI libraries that you could be interested in. For more information about alternatives, see the *Autres paquets d'interface graphique utilisateur* section.

### 24.1 Tkinter — Python interface to Tcl/Tk

The *Tkinter* module (« Tk interface ») is the standard Python interface to the Tk GUI toolkit. Both Tk and *Tkinter* are available on most Unix platforms, as well as on Windows systems. (Tk itself is not part of Python; it is maintained at ActiveState.)

Running `python -m Tkinter` from the command line should open a window demonstrating a simple Tk interface, letting you know that *Tkinter* is properly installed on your system, and also showing what version of Tcl/Tk is installed, so you can read the Tcl/Tk documentation specific to that version.

---

**Note :** *Tkinter* has been renamed to `tkinter` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

**TKDocs** Extensive tutorial plus friendlier widget pages for some of the widgets.

**Tkinter reference : a GUI for Python** On-line reference material.

**Tkinter docs from effbot** Online reference for tkinter supported by effbot.org.

**Programming Python** Book by Mark Lutz, has excellent coverage of Tkinter.

**Modern Tkinter for Busy Python Developers** Book by Mark Rozerman about building attractive and modern graphical user interfaces with Python and Tkinter.

**Python and Tkinter Programming** Book by John Grayson (ISBN 1-884777-81-3).

Tcl/Tk documentation :

**Tk commands** Most commands are available as *Tkinter* or `Tkinter.ttk` classes. Change “8.6” to match the version of your Tcl/Tk installation.

**Tcl/Tk recent man pages** Recent Tcl/Tk manuals on [www.tcl.tk](http://www.tcl.tk).

**ActiveState Tcl Home Page** The Tk/Tcl development is largely taking place at ActiveState.

**Tcl and the Tk Toolkit** Book by John Ousterhout, the inventor of Tcl.

**Practical Programming in Tcl and Tk** Brent Welch’s encyclopedic book.

### 24.1.1 Tkinter Modules

Most of the time, the *Tkinter* module is all you really need, but a number of additional modules are available as well. The Tk interface is located in a binary module named `_tkinter`. This module contains the low-level interface to Tk, and should never be used directly by application programmers. It is usually a shared library (or DLL), but might in some cases be statically linked with the Python interpreter.

In addition to the Tk interface module, *Tkinter* includes a number of Python modules. The two most important modules are the *Tkinter* module itself, and a module called `Tkconstants`. The former automatically imports the latter, so to use Tkinter, all you need to do is to import one module :

```
import Tkinter
```

Or, more often :

```
from Tkinter import *
```

```
class Tkinter.Tk(screenName=None, baseName=None, className='Tk', useTk=1)
```

The *Tk* class is instantiated without arguments. This creates a toplevel widget of Tk which usually is the main window of an application. Each instance has its own associated Tcl interpreter.

Modifié dans la version 2.4 : The *useTk* parameter was added.

```
Tkinter.Tcl(screenName=None, baseName=None, className='Tk', useTk=0)
```

The *Tcl()* function is a factory function which creates an object much like that created by the *Tk* class, except that it does not initialize the Tk subsystem. This is most often useful when driving the Tcl interpreter in an environment where one doesn’t want to create extraneous toplevel windows, or where one cannot (such as Unix/Linux systems without an X server). An object created by the *Tcl()* object can have a Toplevel window created (and the Tk subsystem initialized) by calling its `loadtk()` method.

Nouveau dans la version 2.4.

Other modules that provide Tk support include :

*ScrolledText* Text widget with a vertical scroll bar built in.

`tkColorChooser` Dialog to let the user choose a color.

`tkCommonDialog` Base class for the dialogs defined in the other modules listed here.

**tkFileDialog** Common dialogs to allow the user to specify a file to open or save.

**tkFont** Utilities to help work with fonts.

**tkMessageBox** Access to standard Tk dialog boxes.

**tkSimpleDialog** Basic dialogs and convenience functions.

**Tkdnd** Drag-and-drop support for *Tkinter*. This is experimental and should become deprecated when it is replaced with the Tk DND.

**turtle** Turtle graphics in a Tk window.

These have been renamed as well in Python 3; they were all made submodules of the new **tkinter** package.

### 24.1.2 Tkinter Life Preserver

This section is not designed to be an exhaustive tutorial on either Tk or Tkinter. Rather, it is intended as a stop gap, providing some introductory orientation on the system.

Credits :

- Tkinter was written by Steen Lumholt and Guido van Rossum.
- Tk was written by John Ousterhout while at Berkeley.
- This Life Preserver was written by Matt Conway at the University of Virginia.
- The html rendering, and some liberal editing, was produced from a FrameMaker version by Ken Manheimer.
- Fredrik Lundh elaborated and revised the class interface descriptions, to get them current with Tk 4.2.
- Mike Clarkson converted the documentation to LaTeX, and compiled the User Interface chapter of the reference manual.

#### How To Use This Section

This section is designed in two parts : the first half (roughly) covers background material, while the second half can be taken to the keyboard as a handy reference.

When trying to answer questions of the form « how do I do blah », it is often best to find out how to do « blah » in straight Tk, and then convert this back into the corresponding *Tkinter* call. Python programmers can often guess at the correct Python command by looking at the Tk documentation. This means that in order to use Tkinter, you will have to know a little bit about Tk. This document can't fulfill that role, so the best we can do is point you to the best documentation that exists. Here are some hints :

- The authors strongly suggest getting a copy of the Tk man pages. Specifically, the man pages in the **mann** directory are most useful. The **man3** man pages describe the C interface to the Tk library and thus are not especially helpful for script writers.
- Addison-Wesley publishes a book called Tcl and the Tk Toolkit by John Ousterhout (ISBN 0-201-63337-X) which is a good introduction to Tcl and Tk for the novice. The book is not exhaustive, and for many details it defers to the man pages.
- **Tkinter.py** is a last resort for most, but can be a good place to go when nothing else makes sense.

#### A Simple Hello World Program

```
from Tkinter import *

class Application(Frame):
    def say_hi(self):
        print "hi there, everyone!"

    def createWidgets(self):
        self.QUIT = Button(self)
```

(suite sur la page suivante)

(suite de la page précédente)

```

self.QUIT["text"] = "QUIT"
self.QUIT["fg"]   = "red"
self.QUIT["command"] = self.quit

self.QUIT.pack({"side": "left"})

self.hi_there = Button(self)
self.hi_there["text"] = "Hello",
self.hi_there["command"] = self.say_hi

self.hi_there.pack({"side": "left"})

def __init__(self, master=None):
    Frame.__init__(self, master)
    self.pack()
    self.createWidgets()

root = Tk()
app = Application(master=root)
app.mainloop()
root.destroy()

```

### 24.1.3 A (Very) Quick Look at Tcl/Tk

The class hierarchy looks complicated, but in actual practice, application programmers almost always refer to the classes at the very bottom of the hierarchy.

Notes :

- These classes are provided for the purposes of organizing certain functions under one namespace. They aren't meant to be instantiated independently.
- The *Tk* class is meant to be instantiated only once in an application. Application programmers need not instantiate one explicitly, the system creates one whenever any of the other classes are instantiated.
- The *Widget* class is not meant to be instantiated, it is meant only for subclassing to make « real » widgets (in C++, this is called an “abstract class”).

To make use of this reference material, there will be times when you will need to know how to read short passages of Tk and how to identify the various parts of a Tk command. (See section *Mapping Basic Tk into Tkinter* for the *Tkinter* equivalents of what's below.)

Tk scripts are Tcl programs. Like all Tcl programs, Tk scripts are just lists of tokens separated by spaces. A Tk widget is just its *class*, the *options* that help configure it, and the *actions* that make it do useful things.

To make a widget in Tk, the command is always of the form :

```
classCommand newPathname options
```

*classCommand* denotes which kind of widget to make (a button, a label, a menu...)

*newPathname* is the new name for this widget. All names in Tk must be unique. To help enforce this, widgets in Tk are named with *pathnames*, just like files in a file system. The top level widget, the *root*, is called . (period) and children are delimited by more periods. For example, *.myApp.controlPanel.okButton* might be the name of a widget.

*options* configure the widget's appearance and in some cases, its behavior. The options come in the form of a list of flags and values. Flags are preceded by a “-“, like Unix shell command flags, and values are put in quotes if they are more than one word.

Par exemple :

```
button .fred -fg red -text "hi there"
  ^      ^      \-----/
  |      |      |
class  new      options
command widget (-opt val -opt val ...)
```

Once created, the pathname to the widget becomes a new command. This new *widget command* is the programmer's handle for getting the new widget to perform some *action*. In C, you'd express this as `someAction(fred, someOptions)`, in C++, you would express this as `fred.someAction(someOptions)`, and in Tk, you say :

```
.fred someAction someOptions
```

Note that the object name, `.fred`, starts with a dot.

As you'd expect, the legal values for *someAction* will depend on the widget's class : `.fred disable` works if fred is a button (fred gets greyed out), but does not work if fred is a label (disabling of labels is not supported in Tk).

The legal values of *someOptions* is action dependent. Some actions, like `disable`, require no arguments, others, like a text-entry box's `delete` command, would need arguments to specify what range of text to delete.

#### 24.1.4 Mapping Basic Tk into Tkinter

Class commands in Tk correspond to class constructors in Tkinter.

```
button .fred          =====> fred = Button()
```

The master of an object is implicit in the new name given to it at creation time. In Tkinter, masters are specified explicitly.

```
button .panel.fred    =====> fred = Button(panel)
```

The configuration options in Tk are given in lists of hyphenated tags followed by values. In Tkinter, options are specified as keyword-arguments in the instance constructor, and keyword-args for `configure` calls or as instance indices, in dictionary style, for established instances. See section [Setting Options](#) on setting options.

```
button .fred -fg red   =====> fred = Button(panel, fg = "red")
.fred configure -fg red =====> fred["fg"] = red
OR ==> fred.config(fg = "red")
```

In Tk, to perform an action on a widget, use the widget name as a command, and follow it with an action name, possibly with arguments (options). In Tkinter, you call methods on the class instance to invoke actions on the widget. The actions (methods) that a given widget can perform are listed in the `Tkinter.py` module.

```
.fred invoke          =====> fred.invoke()
```

To give a widget to the packer (geometry manager), you call `pack` with optional arguments. In Tkinter, the `Pack` class holds all this functionality, and the various forms of the `pack` command are implemented as methods. All widgets in *Tkinter* are subclassed from the `Packer`, and so inherit all the packing methods. See the [Tix](#) module documentation for additional information on the Form geometry manager.

```
pack .fred -side left      =====>  fred.pack(side = "left")
```

### 24.1.5 How Tk and Tkinter are Related

From the top down :

**Your App Here (Python)** A Python application makes a *Tkinter* call.

**Tkinter (Python Module)** This call (say, for example, creating a button widget), is implemented in the *Tkinter* module, which is written in Python. This Python function will parse the commands and the arguments and convert them into a form that makes them look as if they had come from a Tk script instead of a Python script.

**tkinter (C)** These commands and their arguments will be passed to a C function in the *tkinter* - note the lowercase - extension module.

**Tk Widgets (C and Tcl)** This C function is able to make calls into other C modules, including the C functions that make up the Tk library. Tk is implemented in C and some Tcl. The Tcl part of the Tk widgets is used to bind certain default behaviors to widgets, and is executed once at the point where the Python *Tkinter* module is imported. (The user never sees this stage).

**Tk (C)** The Tk part of the Tk Widgets implement the final mapping to ...

**Xlib (C)** the Xlib library to draw graphics on the screen.

### 24.1.6 Handy Reference

#### Setting Options

Options control things like the color and border width of a widget. Options can be set in three ways :

**At object creation time, using keyword arguments**

```
fred = Button(self, fg = "red", bg = "blue")
```

**After object creation, treating the option name like a dictionary index**

```
fred["fg"] = "red"
fred["bg"] = "blue"
```

**Use the `config()` method to update multiple attrs subsequent to object creation**

```
fred.config(fg = "red", bg = "blue")
```

For a complete explanation of a given option and its behavior, see the Tk man pages for the widget in question.

Note that the man pages list « STANDARD OPTIONS » and « WIDGET SPECIFIC OPTIONS » for each widget. The former is a list of options that are common to many widgets, the latter are the options that are idiosyncratic to that particular widget. The Standard Options are documented on the *options(3)* man page.

No distinction between standard and widget-specific options is made in this document. Some options don't apply to some kinds of widgets. Whether a given widget responds to a particular option depends on the class of the widget; buttons have a `command` option, labels do not.

The options supported by a given widget are listed in that widget's man page, or can be queried at runtime by calling the `config()` method without arguments, or by calling the `keys()` method on that widget. The return value of these calls is a dictionary whose key is the name of the option as a string (for example, `'relief'`) and whose values are 5-tuples.

Some options, like `bg` are synonyms for common options with long names (`bg` is shorthand for « background »). Passing the `config()` method the name of a shorthand option will return a 2-tuple, not 5-tuple. The 2-tuple passed back will contain the name of the synonym and the « real » option (such as `('bg', 'background')`).

Index	Signification	Exemple
0	option name	'relief'
1	option name for database lookup	'relief'
2	option class for database lookup	'Relief'
3	Valeur par défaut	'raised'
4	current value	'groove'

Exemple :

```
>>> print fred.config()
{'relief': ('relief', 'relief', 'Relief', 'raised', 'groove')}
```

Of course, the dictionary printed will include all the options available and their values. This is meant only as an example.

## The Packer

The packer is one of Tk's geometry-management mechanisms. Geometry managers are used to specify the relative positioning of the positioning of widgets within their container - their mutual *master*. In contrast to the more cumbersome *placer* (which is used less commonly, and we do not cover here), the packer takes qualitative relationship specification - *above*, *to the left of*, *filling*, etc - and works everything out to determine the exact placement coordinates for you.

The size of any *master* widget is determined by the size of the « slave widgets » inside. The packer is used to control where slave widgets appear inside the master into which they are packed. You can pack widgets into frames, and frames into other frames, in order to achieve the kind of layout you desire. Additionally, the arrangement is dynamically adjusted to accommodate incremental changes to the configuration, once it is packed.

Note that widgets do not appear until they have had their geometry specified with a geometry manager. It's a common early mistake to leave out the geometry specification, and then be surprised when the widget is created but nothing appears. A widget will appear only after it has had, for example, the packer's `pack()` method applied to it.

The `pack()` method can be called with keyword-option/value pairs that control where the widget is to appear within its container, and how it is to behave when the main application window is resized. Here are some examples :

```
fred.pack()                                # defaults to side = "top"
fred.pack(side = "left")
fred.pack(expand = 1)
```

## Packer Options

For more extensive information on the packer and the options that it can take, see the man pages and page 183 of John Ousterhout's book.

**anchor** Anchor type. Denotes where the packer is to place each slave in its parcel.

**expand** Boolean, 0 or 1.

**fill** Legal values : 'x', 'y', 'both', 'none'.

**ipadx and ipady** A distance - designating internal padding on each side of the slave widget.

**padx and pady** A distance - designating external padding on each side of the slave widget.

**side** Legal values are : 'left', 'right', 'top', 'bottom'.

### Coupling Widget Variables

The current-value setting of some widgets (like text entry widgets) can be connected directly to application variables by using special options. These options are **variable**, **textvariable**, **onvalue**, **offvalue**, and **value**. This connection works both ways : if the variable changes for any reason, the widget it's connected to will be updated to reflect the new value.

Unfortunately, in the current implementation of *Tkinter* it is not possible to hand over an arbitrary Python variable to a widget through a **variable** or **textvariable** option. The only kinds of variables for which this works are variables that are subclassed from a class called **Variable**, defined in the *Tkinter* module.

There are many useful subclasses of **Variable** already defined : **StringVar**, **IntVar**, **DoubleVar**, and **BooleanVar**. To read the current value of such a variable, call the **get()** method on it, and to change its value you call the **set()** method. If you follow this protocol, the widget will always track the value of the variable, with no further intervention on your part.

Par exemple :

```
class App(Frame):
    def __init__(self, master=None):
        Frame.__init__(self, master)
        self.pack()

        self.entrythingy = Entry()
        self.entrythingy.pack()

        # here is the application variable
        self.contents = StringVar()
        # set it to some value
        self.contents.set("this is a variable")
        # tell the entry widget to watch this variable
        self.entrythingy["textvariable"] = self.contents

        # and here we get a callback when the user hits return.
        # we will have the program print out the value of the
        # application variable when the user hits return
        self.entrythingy.bind('<Key-Return>',
                               self.print_contents)

    def print_contents(self, event):
        print "hi. contents of entry is now ---->", \
              self.contents.get()
```

### The Window Manager

In Tk, there is a utility command, **wm**, for interacting with the window manager. Options to the **wm** command allow you to control things like titles, placement, icon bitmaps, and the like. In *Tkinter*, these commands have been implemented as methods on the **Wm** class. Toplevel widgets are subclassed from the **Wm** class, and so can call the **Wm** methods directly.

To get at the toplevel window that contains a given widget, you can often just refer to the widget's master. Of course if the widget has been packed inside of a frame, the master won't represent a toplevel window.

To get at the toplevel window that contains an arbitrary widget, you can call the `_root()` method. This method begins with an underscore to denote the fact that this function is part of the implementation, and not an interface to Tk functionality.

Here are some examples of typical usage :

```
from Tkinter import *
class App(Frame):
    def __init__(self, master=None):
        Frame.__init__(self, master)
        self.pack()

# create the application
myapp = App()

#
# here are method calls to the window manager class
#
myapp.master.title("My Do-Nothing Application")
myapp.master.maxsize(1000, 400)

# start the program
myapp.mainloop()
```

## Tk Option Data Types

**anchor** Legal values are points of the compass : "n", "ne", "e", "se", "s", "sw", "w", "nw", and also "center".

**bitmap** There are eight built-in, named bitmaps : 'error', 'gray25', 'gray50', 'hourglass', 'info', 'questhead', 'question', 'warning'. To specify an X bitmap filename, give the full path to the file, preceded with an @, as in "@/usr/contrib/bitmap/gumby.bit".

**boolean** You can pass integers 0 or 1 or the strings "yes" or "no".

**callback** This is any Python function that takes no arguments. For example :

```
def print_it():
    print "hi there"
fred["command"] = print_it
```

**color** Colors can be given as the names of X colors in the rgb.txt file, or as strings representing RGB values in 4 bit : "#RGB", 8 bit : "#RRGGBB", 12 bit » "#RRRGGBBB", or 16 bit "#RRRRGGGGBBBB" ranges, where R,G,B here represent any legal hex digit. See page 160 of Ousterhout's book for details.

**cursor** The standard X cursor names from `cursorfont.h` can be used, without the `XC_` prefix. For example to get a hand cursor (`XC_hand2`), use the string "hand2". You can also specify a bitmap and mask file of your own. See page 179 of Ousterhout's book.

**distance** Screen distances can be specified in either pixels or absolute distances. Pixels are given as numbers and absolute distances as strings, with the trailing character denoting units : c for centimetres, i for inches, m for millimetres, p for printer's points. For example, 3.5 inches is expressed as "3.5i".

**font** Tk uses a list font name format, such as {courier 10 bold}. Font sizes with positive numbers are measured in points; sizes with negative numbers are measured in pixels.

**geometry** This is a string of the form `widthxheight`, where width and height are measured in pixels for most widgets (in characters for widgets displaying text). For example : `fred["geometry"] = "200x100"`.

**justify** Legal values are the strings : "left", "center", "right", and "fill".

**region** This is a string with four space-delimited elements, each of which is a legal distance (see above). For example : "2 3 4 5" and "3i 2i 4.5i 2i" and "3c 2c 4c 10.43c" are all legal regions.

**relief** Determines what the border style of a widget will be. Legal values are : "raised", "sunken", "flat", "groove", and "ridge".

**scrollcommand** This is almost always the `set()` method of some scrollbar widget, but can be any widget method that takes a single argument. Refer to the file `Demo/tkinter/matt/canvas-with-scrollbars.py` in the Python source distribution for an example.

**wrap** : Must be one of : "none", "char", or "word".

## Bindings and Events

The `bind` method from the widget command allows you to watch for certain events and to have a callback function trigger when that event type occurs. The form of the `bind` method is :

```
def bind(self, sequence, func, add='')
```

where :

**sequence** is a string that denotes the target kind of event. (See the `bind` man page and page 201 of John Ousterhout's book for details).

**func** is a Python function, taking one argument, to be invoked when the event occurs. An `Event` instance will be passed as the argument. (Functions deployed this way are commonly known as *callbacks*.)

**add** is optional, either '' or '+'. Passing an empty string denotes that this binding is to replace any other bindings that this event is associated with. Passing a '+' means that this function is to be added to the list of functions bound to this event type.

Par exemple :

```
def turnRed(self, event):
    event.widget["activeforeground"] = "red"

self.button.bind("<Enter>", self.turnRed)
```

Notice how the `widget` field of the event is being accessed in the `turnRed()` callback. This field contains the widget that caught the X event. The following table lists the other event fields you can access, and how they are denoted in Tk, which can be useful when referring to the Tk man pages.

Tk	Tkinter Event Field	Tk	Tkinter Event Field
--	-----	--	-----
%f	focus	%A	char
%h	height	%E	send_event
%k	keycode	%K	keysym
%s	state	%N	keysym_num
%t	time	%T	type
%w	width	%W	widget
%x	x	%X	x_root
%y	y	%Y	y_root

## The index Parameter

A number of widgets require »index« parameters to be passed. These are used to point at a specific place in a `Text` widget, or to particular characters in an `Entry` widget, or to particular menu items in a `Menu` widget.

**Entry widget indexes (index, view index, etc.)** Entry widgets have options that refer to character positions in the text being displayed. You can use these *Tkinter* functions to access these special points in text widgets :

**AtEnd()** refers to the last position in the text

**AtInsert()** refers to the point where the text cursor is

**AtSelFirst()** indicates the beginning point of the selected text

**AtSelLast()** denotes the last point of the selected text and finally

**At(x[, y])** refers to the character at pixel location *x*, *y* (with *y* not used in the case of a text entry widget, which contains a single line of text).

**Text widget indexes** The index notation for Text widgets is very rich and is best described in the Tk man pages.

**Menu indexes (menu.invoke(), menu.entryconfig(), etc.)** Some options and methods for menus manipulate specific menu entries. Anytime a menu index is needed for an option or a parameter, you may pass in :

- an integer which refers to the numeric position of the entry in the widget, counted from the top, starting with 0;
- the string 'active', which refers to the menu position that is currently under the cursor;
- the string "last" which refers to the last menu item;
- An integer preceded by @, as in @6, where the integer is interpreted as a y pixel coordinate in the menu's coordinate system;
- the string "none", which indicates no menu entry at all, most often used with menu.activate() to deactivate all entries, and finally,
- a text string that is pattern matched against the label of the menu entry, as scanned from the top of the menu to the bottom. Note that this index type is considered after all the others, which means that matches for menu items labelled last, active, or none may be interpreted as the above literals, instead.

## Images

Images of different formats can be created through the corresponding subclass of `Tkinter.Image` :

- `BitmapImage` for images in XBM format.
- `PhotoImage` for images in PGM, PPM, GIF and PNG formats. The latter is supported starting with Tk 8.6.

Either type of image is created through either the `file` or the `data` option (other options are available as well).

The image object can then be used wherever an `image` option is supported by some widget (e.g. labels, buttons, menus). In these cases, Tk will not keep a reference to the image. When the last Python reference to the image object is deleted, the image data is deleted as well, and Tk will display an empty box wherever the image was used.

**Voir aussi :**

The *Pillow* package adds support for formats such as BMP, JPEG, TIFF, and WebP, among others.

### 24.1.7 File Handlers

Tk allows you to register and unregister a callback function which will be called from the Tk mainloop when I/O is possible on a file descriptor. Only one handler may be registered per file descriptor. Example code :

```
import Tkinter
widget = Tkinter.Tk()
mask = Tkinter.READABLE | Tkinter.WRITABLE
```

(suite sur la page suivante)

(suite de la page précédente)

```
widget.tk.createfilehandler(file, mask, callback)
...
widget.tk.deletefilehandler(file)
```

This feature is not available on Windows.

Since you don't know how many bytes are available for reading, you may not want to use the *BufferedIOBase* or *TextIOBase* *read()* or *readline()* methods, since these will insist on reading a predefined number of bytes. For sockets, the *recv()* or *recvfrom()* methods will work fine; for other files, use raw reads or *os.read(file.fileno(), maxbytecount)*.

**Widget.tk.createfilehandler**(*file*, *mask*, *func*)

Registers the file handler callback function *func*. The *file* argument may either be an object with a *fileno()* method (such as a file or socket object), or an integer file descriptor. The *mask* argument is an ORed combination of any of the three constants below. The callback is called as follows :

```
callback(file, mask)
```

**Widget.tk.deletefilehandler**(*file*)

Unregisters a file handler.

**Tkinter.READABLE**

**Tkinter.WRITABLE**

**Tkinter.EXCEPTION**

Constants used in the *mask* arguments.

## 24.2 ttk — Tk themed widgets

The *ttk* module provides access to the Tk themed widget set, which has been introduced in Tk 8.5. If Python is not compiled against Tk 8.5 code may still use this module as long as Tile is installed. However, some features provided by the new Tk, like anti-aliased font rendering under X11, window transparency (on X11 you will need a composition window manager) will be missing.

The basic idea of *ttk* is to separate, to the extent possible, the code implementing a widget's behavior from the code implementing its appearance.

**Voir aussi :**

**Tk Widget Styling Support** The document which brought up theming support for Tk

### 24.2.1 Using Ttk

To start using Ttk, import its module :

```
import ttk
```

But code like this :

```
from Tkinter import *
```

may optionally want to use this :

```
from Tkinter import *
from ttk import *
```

And then several *ttk* widgets (`Button`, `Checkbutton`, `Entry`, `Frame`, `Label`, `LabelFrame`, `Menubutton`, `PanedWindow`, `Radiobutton`, `Scale` and `Scrollbar`) will automatically substitute for the Tk widgets.

This has the direct benefit of using the new widgets, giving better look & feel across platforms, but be aware that they are not totally compatible. The main difference is that widget options such as « `fg` », « `bg` » and others related to widget styling are no longer present in Ttk widgets. Use *ttk.Style* to achieve the same (or better) styling.

**Voir aussi :**

**Converting existing applications to use the Tile widgets** A text which talks in Tcl terms about differences typically found when converting applications to use the new widgets.

### 24.2.2 Ttk Widgets

Ttk comes with 17 widgets, 11 of which already exist in Tkinter : `Button`, `Checkbutton`, `Entry`, `Frame`, `Label`, `LabelFrame`, `Menubutton`, `PanedWindow`, `Radiobutton`, `Scale` and `Scrollbar`. The 6 new widget classes are : *Combobox*, *Notebook*, *Progressbar*, `Separator`, `Sizegrip` and *Treeview*. All of these classes are subclasses of *Widget*.

As said previously, you will notice changes in look-and-feel as well in the styling code. To demonstrate the latter, a very simple example is shown below.

Tk code :

```
l1 = Tkinter.Label(text="Test", fg="black", bg="white")
l2 = Tkinter.Label(text="Test", fg="black", bg="white")
```

Corresponding Ttk code :

```
style = ttk.Style()
style.configure("BW.TLabel", foreground="black", background="white")

l1 = ttk.Label(text="Test", style="BW.TLabel")
l2 = ttk.Label(text="Test", style="BW.TLabel")
```

For more information about *TtkStyling* read the *Style* class documentation.

### 24.2.3 Widget

*ttk.Widget* defines standard options and methods supported by Tk themed widgets and is not supposed to be directly instantiated.

#### Standard Options

All the *ttk* widgets accept the following options :

Op- tion	Description
class	Specifies the window class. The class is used when querying the option database for the window's other options, to determine the default bindtags for the window, and to select the widget's default layout and style. This is a read-only option which may only be specified when the window is created.
cursor	Specifies the mouse cursor to be used for the widget. If set to the empty string (the default), the cursor is inherited from the parent widget.
take- fo- cus	Determines whether the window accepts the focus during keyboard traversal. 0, 1 or an empty string is returned. If 0, the window should be skipped entirely during keyboard traversal. If 1, the window should receive the input focus as long as it is viewable. An empty string means that the traversal scripts make the decision about whether or not to focus on the window.
style	May be used to specify a custom widget style.

### Scrollable Widget Options

The following options are supported by widgets that are controlled by a scrollbar.

op- tion	description
xs- croll- com- mand	Used to communicate with horizontal scrollbars. When the view in the widget's window changes, the widget will generate a Tcl command based on the scrollcommand. Usually this option consists of the <code>Scrollbar.set()</code> method of some scrollbar. This will cause the scrollbar to be updated whenever the view in the window changes.
ys- croll- com- mand	Used to communicate with vertical scrollbars. For more information, see above.

### Label Options

The following options are supported by labels, buttons and other button-like widgets.

option	description
text	Specifies a text string to be displayed inside the widget.
textvariable	Specifies a name whose value will be used in place of the text option resource.
underline	If set, specifies the index (0-based) of a character to underline in the text string. The underline character is used for mnemonic activation.
image	Specifies an image to display. This is a list of 1 or more elements. The first element is the default image name. The rest of the list is a sequence of statespec/value pairs as defined by <i>Style.map()</i> , specifying different images to use when the widget is in a particular state or a combination of states. All images in the list should have the same size.
compound	Specifies how to display the image relative to the text, in the case both text and image options are present. Valid values are : <ul style="list-style-type: none"> <li>— text : display text only</li> <li>— image : display image only</li> <li>— top, bottom, left, right : display image above, below, left of, or right of the text, respectively.</li> <li>— none : the default. display the image if present, otherwise the text.</li> </ul>
width	If greater than zero, specifies how much space, in character widths, to allocate for the text label ; if less than zero, specifies a minimum width. If zero or unspecified, the natural width of the text label is used.

### Compatibility Options

option	description
state	May be set to « normal » or « disabled » to control the « disabled » state bit. This is a write-only option : setting it changes the widget state, but the <i>Widget.state()</i> method does not affect this option.

### Widget States

The widget state is a bitmap of independent state flags.

option	description
active	The mouse cursor is over the widget and pressing a mouse button will cause some action to occur.
disabled	Widget is disabled under program control.
focus	Widget has keyboard focus.
pressed	Widget is being pressed.
selected	« On », « true », or « current » for things like Checkbuttons and radiobuttons.
background	Windows and Mac have a notion of an « active » or foreground window. The <i>background</i> state is set for widgets in a background window, and cleared for those in the foreground window.
readonly	Widget should not allow user modification.
alternate	A widget-specific alternate display format.
invalid	The widget's value is invalid.

A state specification is a sequence of state names, optionally prefixed with an exclamation point indicating that the bit is off.

### ttk.Widget

Besides the methods described below, the `ttk.Widget` class supports the `Tkinter.Widget.cget()` and `Tkinter.Widget.configure()` methods.

**class** `ttk.Widget`

**identify**(*x*, *y*)

Returns the name of the element at position *x y*, or the empty string if the point does not lie within any element.

*x* and *y* are pixel coordinates relative to the widget.

**instate**(*statespec*, *callback*=None, *\*args*, *\*\*kw*)

Test the widget's state. If a callback is not specified, returns **True** if the widget state matches *statespec* and **False** otherwise. If callback is specified then it is called with *args* if widget state matches *statespec*.

**state**([*statespec*=None])

Modify or read widget state. If *statespec* is specified, sets the widget state accordingly and returns a new *statespec* indicating which flags were changed. If *statespec* is not specified, returns the currently-enabled state flags.

*statespec* will usually be a list or a tuple.

### 24.2.4 Combobox

The `ttk.Combobox` widget combines a text field with a pop-down list of values. This widget is a subclass of `Entry`.

Besides the methods inherited from `Widget` (`Widget.cget()`, `Widget.configure()`, `Widget.identify()`, `Widget.instate()` and `Widget.state()`) and those inherited from `Entry` (`Entry.bbox()`, `Entry.delete()`,

`Entry.icursor()`, `Entry.index()`, `Entry.insert()`, `Entry.selection()`, `Entry.xview()`), this class has some other methods, described at [`ttk.Combobox`](#).

## Options

This widget accepts the following options :

option	description
export-selection	Boolean value. If set, the widget selection is linked to the Window Manager selection (which can be returned by invoking <code>Misc.selection_get()</code> , for example).
justify	Specifies how the text is aligned within the widget. One of « left », « center », or « right ».
height	Specifies the height of the pop-down listbox, in rows.
post-command	A script (possibly registered with <code>Misc.register()</code> ) that is called immediately before displaying the values. It may specify which values to display.
state	One of « normal », « readonly », or « disabled ». In the « readonly » state, the value may not be edited directly, and the user can only select one of the values from the dropdown list. In the « normal » state, the text field is directly editable. In the « disabled » state, no interaction is possible.
text-variable	Specifies a name whose value is linked to the widget value. Whenever the value associated with that name changes, the widget value is updated, and vice versa. See <code>Tkinter.StringVar</code> .
values	Specifies the list of values to display in the drop-down listbox.
width	Specifies an integer value indicating the desired width of the entry window, in average-size characters of the widget's font.

## Virtual events

The combobox widget generates a `<<ComboboxSelected>>` virtual event when the user selects an element from the list of values.

## `ttk.Combobox`

```
class ttk.Combobox
```

```
current([newindex=None])
```

If *newindex* is specified, sets the combobox value to the element position *newindex*. Otherwise, returns the index of the current value or -1 if the current value is not in the values list.

```
get()
```

Returns the current value of the combobox.

```
set(value)
```

Sets the value of the combobox to *value*.

## 24.2.5 Notebook

The Ttk Notebook widget manages a collection of windows and displays a single one at a time. Each child window is associated with a tab, which the user may select to change the currently-displayed window.

## Options

This widget accepts the following specific options :

option	description
height	If present and greater than zero, specifies the desired height of the pane area (not including internal padding or tabs). Otherwise, the maximum height of all panes is used.
padding	Specifies the amount of extra space to add around the outside of the notebook. The padding is a list of up to four length specifications : left top right bottom. If fewer than four elements are specified, bottom defaults to top, right defaults to left, and top defaults to left.
width	If present and greater than zero, specifies the desired width of the pane area (not including internal padding). Otherwise, the maximum width of all panes is used.

## Tab Options

There are also specific options for tabs :

option	description
state	Either « normal », « disabled » or « hidden ». If « disabled », then the tab is not selectable. If « hidden », then the tab is not shown.
sticky	Specifies how the child window is positioned within the pane area. Value is a string containing zero or more of the characters « n », « s », « e » or « w ». Each letter refers to a side (north, south, east or west) that the child window will stick to, as per the <code>grid()</code> geometry manager.
padding	Specifies the amount of extra space to add between the notebook and this pane. Syntax is the same as for the option padding used by this widget.
text	Specifies a text to be displayed in the tab.
image	Specifies an image to display in the tab. See the option image described in <i>Widget</i> .
compound	Specifies how to display the image relative to the text, in the case both text and image options are present. See <i>Label Options</i> for legal values.
underline	Specifies the index (0-based) of a character to underline in the text string. The underlined character is used for mnemonic activation if <code>Notebook.enable_traversal()</code> is called.

## Tab Identifiers

The `tab_id` present in several methods of `ttk.Notebook` may take any of the following forms :

- An integer between zero and the number of tabs.
- The name of a child window.
- A positional specification of the form « @x,y », which identifies the tab.
- The literal string « current », which identifies the currently-selected tab.
- The literal string « end », which returns the number of tabs (only valid for `Notebook.index()`).

## Virtual Events

This widget generates a `<<NotebookTabChanged>>` virtual event after a new tab is selected.

**ttk.Notebook**

```
class ttk.Notebook
```

```
    add(child, **kw)
```

Adds a new tab to the notebook.

If window is currently managed by the notebook but hidden, it is restored to its previous position.

See [Tab Options](#) for the list of available options.

```
    forget(tab_id)
```

Removes the tab specified by *tab\_id*, unmaps and unmanages the associated window.

```
    hide(tab_id)
```

Hides the tab specified by *tab\_id*.

The tab will not be displayed, but the associated window remains managed by the notebook and its configuration remembered. Hidden tabs may be restored with the [add\(\)](#) command.

```
    identify(x, y)
```

Returns the name of the tab element at position *x*, *y*, or the empty string if none.

```
    index(tab_id)
```

Returns the numeric index of the tab specified by *tab\_id*, or the total number of tabs if *tab\_id* is the string « end ».

```
    insert(pos, child, **kw)
```

Inserts a pane at the specified position.

*pos* is either the string « end », an integer index, or the name of a managed child. If *child* is already managed by the notebook, moves it to the specified position.

See [Tab Options](#) for the list of available options.

```
    select([tab_id])
```

Selects the specified *tab\_id*.

The associated child window will be displayed, and the previously-selected window (if different) is unmapped. If *tab\_id* is omitted, returns the widget name of the currently selected pane.

```
    tab(tab_id, option=None, **kw)
```

Query or modify the options of the specific *tab\_id*.

If *kw* is not given, returns a dictionary of the tab option values. If *option* is specified, returns the value of that *option*. Otherwise, sets the options to the corresponding values.

```
    tabs()
```

Returns a list of windows managed by the notebook.

```
    enable_traversal()
```

Enable keyboard traversal for a toplevel window containing this notebook.

This will extend the bindings for the toplevel window containing the notebook as follows :

- **Control-Tab** : selects the tab following the currently selected one.
- **Shift-Control-Tab** : selects the tab preceding the currently selected one.
- **Alt-K** : where *K* is the mnemonic (underlined) character of any tab, will select that tab.

Multiple notebooks in a single toplevel may be enabled for traversal, including nested notebooks. However, notebook traversal only works properly if all panes have the notebook they are in as master.

**24.2.6 Progressbar**

The [ttk.Progressbar](#) widget shows the status of a long-running operation. It can operate in two modes : determinate mode shows the amount completed relative to the total amount of work to be done, and indeterminate mode provides an animated display to let the user know that something is happening.

**Options**

This widget accepts the following specific options :

option	description
orient	One of « horizontal » or « vertical ». Specifies the orientation of the progress bar.
length	Specifies the length of the long axis of the progress bar (width if horizontal, height if vertical).
mode	One of « determinate » or « indeterminate ».
maximum	A number specifying the maximum value. Defaults to 100.
value	The current value of the progress bar. In « determinate » mode, this represents the amount of work completed. In « indeterminate » mode, it is interpreted as modulo <i>maximum</i> ; that is, the progress bar completes one « cycle » when its value increases by <i>maximum</i> .
variable	A name which is linked to the option value. If specified, the value of the progress bar is automatically set to the value of this name whenever the latter is modified.
phase	Read-only option. The widget periodically increments the value of this option whenever its value is greater than 0 and, in determinate mode, less than maximum. This option may be used by the current theme to provide additional animation effects.

### ttk.Progressbar

**class** `ttk.Progressbar`

**start**(`[interval]`)  
Begin autoincrement mode : schedules a recurring timer event that calls `Progressbar.step()` every `interval` milliseconds. If omitted, `interval` defaults to 50 milliseconds.

**step**(`[amount]`)  
Increments the progress bar's value by `amount`.  
`amount` defaults to 1.0 if omitted.

**stop**()  
Stop autoincrement mode : cancels any recurring timer event initiated by `Progressbar.start()` for this progress bar.

### 24.2.7 Separator

The `ttk.Separator` widget displays a horizontal or vertical separator bar.

It has no other methods besides the ones inherited from `ttk.Widget`.

#### Options

This widget accepts the following specific option :

option	description
orient	One of « horizontal » or « vertical ». Specifies the orientation of the separator.

### 24.2.8 Sizegrip

The `ttk.Sizegrip` widget (also known as a grow box) allows the user to resize the containing toplevel window by pressing and dragging the grip.

This widget has neither specific options nor specific methods, besides the ones inherited from `ttk.Widget`.

### Platform-specific notes

- On Mac OS X, toplevel windows automatically include a built-in size grip by default. Adding a `Sizegrip` is harmless, since the built-in grip will just mask the widget.

### Bugs

- If the containing toplevel's position was specified relative to the right or bottom of the screen (e.g. ....), the `Sizegrip` widget will not resize the window.
- This widget supports only « southeast » resizing.

## 24.2.9 Treeview

The `ttk.Treeview` widget displays a hierarchical collection of items. Each item has a textual label, an optional image, and an optional list of data values. The data values are displayed in successive columns after the tree label.

The order in which data values are displayed may be controlled by setting the widget option `displaycolumns`. The tree widget can also display column headings. Columns may be accessed by number or symbolic names listed in the widget option `columns`. See *Column Identifiers*.

Each item is identified by a unique name. The widget will generate item IDs if they are not supplied by the caller. There is a distinguished root item, named `{}`. The root item itself is not displayed; its children appear at the top level of the hierarchy.

Each item also has a list of tags, which can be used to associate event bindings with individual items and control the appearance of the item.

The Treeview widget supports horizontal and vertical scrolling, according to the options described in *Scrollable Widget Options* and the methods `Treeview.xview()` and `Treeview.yview()`.

### Options

This widget accepts the following specific options :

option	description
columns	A list of column identifiers, specifying the number of columns and their names.
displaycolumns	A list of column identifiers (either symbolic or integer indices) specifying which data columns are displayed and the order in which they appear, or the string « #all ».
height	Specifies the number of rows which should be visible. Note : the requested width is determined from the sum of the column widths.
padding	Specifies the internal padding for the widget. The padding is a list of up to four length specifications.
selectmode	Controls how the built-in class bindings manage the selection. One of « extended », « browse » or « none ». If set to « extended » (the default), multiple items may be selected. If « browse », only a single item will be selected at a time. If « none », the selection will not be changed. Note that the application code and tag bindings can set the selection however they wish, regardless of the value of this option.
show	A list containing zero or more of the following values, specifying which elements of the tree to display. — tree : display tree labels in column #0. — headings : display the heading row. The default is « tree headings », i.e., show all elements. <b>Note</b> : Column #0 always refers to the tree column, even if show= »tree » is not specified.

### Item Options

The following item options may be specified for items in the insert and item widget commands.

option	description
text	The textual label to display for the item.
image	A Tk Image, displayed to the left of the label.
values	The list of values associated with the item. Each item should have the same number of values as the widget option columns. If there are fewer values than columns, the remaining values are assumed empty. If there are more values than columns, the extra values are ignored.
open	True/False value indicating whether the item's children should be displayed or hidden.
tags	A list of tags associated with this item.

### Tag Options

The following options may be specified on tags :

option	description
foreground	Specifies the text foreground color.
background	Specifies the cell or item background color.
font	Specifies the font to use when drawing text.
image	Specifies the item image, in case the item's image option is empty.

### Column Identifiers

Column identifiers take any of the following forms :

- A symbolic name from the list of columns option.

- An integer *n*, specifying the *n*th data column.
- A string of the form *#n*, where *n* is an integer, specifying the *n*th display column.

Notes :

- Item's option values may be displayed in a different order than the order in which they are stored.
- Column *#0* always refers to the tree column, even if *show= »tree »* is not specified.

A data column number is an index into an item's option values list ; a display column number is the column number in the tree where the values are displayed. Tree labels are displayed in column *#0*. If option display-columns is not set, then data column *n* is displayed in column *#n+1*. Again, **column *#0* always refers to the tree column.**

## Virtual Events

The Treeview widget generates the following virtual events.

event	description
<<TreeviewSelect>>	Generated whenever the selection changes.
<<TreeviewOpen>>	Generated just before settings the focus item to <i>open=True</i> .
<<TreeviewClose>>	Generated just after setting the focus item to <i>open=False</i> .

The *Treeview.focus()* and *Treeview.selection()* methods can be used to determine the affected item or items.

## ttk.Treeview

**class** `ttk.Treeview`

**bbox**(*item*, *column=None*)

Returns the bounding box (relative to the treeview widget's window) of the specified *item* in the form (x, y, width, height).

If *column* is specified, returns the bounding box of that cell. If the *item* is not visible (i.e., if it is a descendant of a closed item or is scrolled offscreen), returns an empty string.

**get\_children**([*item*])

Returns the list of children belonging to *item*.

If *item* is not specified, returns root children.

**set\_children**(*item*, *\*newchildren*)

Replaces *item*'s child with *newchildren*.

Children present in *item* that are not present in *newchildren* are detached from the tree. No items in *newchildren* may be an ancestor of *item*. Note that not specifying *newchildren* results in detaching *item*'s children.

**column**(*column*, *option=None*, *\*\*kw*)

Query or modify the options for the specified *column*.

If *kw* is not given, returns a dict of the column option values. If *option* is specified then the value for that *option* is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are :

- **id** Returns the column name. This is a read-only option.
- **anchor : One of the standard Tk anchor values.** Specifies how the text in this column should be aligned with respect to the cell.
- **minwidth : width** The minimum width of the column in pixels. The treeview widget will not make the column any smaller than specified by this option when the widget is resized or the user drags a column.
- **stretch : True/False** Specifies whether the column's width should be adjusted when the widget is resized.
- **width : width** The width of the column in pixels.

To configure the tree column, call this with `column = « #0 »`

**delete**(\**items*)  
Delete all specified *items* and all their descendants.  
The root item may not be deleted.

**detach**(\**items*)  
Unlinks all of the specified *items* from the tree.  
The items and all of their descendants are still present, and may be reinserted at another point in the tree, but will not be displayed.  
The root item may not be detached.

**exists**(*item*)  
Returns **True** if the specified *item* is present in the tree.

**focus**([*item=None*])  
If *item* is specified, sets the focus item to *item*. Otherwise, returns the current focus item, or “” if there is none.

**heading**(*column*, *option=None*, *\*\*kw*)  
Query or modify the heading options for the specified *column*.  
If *kw* is not given, returns a dict of the heading option values. If *option* is specified then the value for that *option* is returned. Otherwise, sets the options to the corresponding values.  
The valid options/values are :  
— **text : text** The text to display in the column heading.  
— **image : imageName** Specifies an image to display to the right of the column heading.  
— **anchor : anchor** Specifies how the heading text should be aligned. One of the standard Tk anchor values.  
— **command : callback** A callback to be invoked when the heading label is pressed.  
To configure the tree column heading, call this with `column = « #0 »`.

**identify**(*component*, *x*, *y*)  
Returns a description of the specified *component* under the point given by *x* and *y*, or the empty string if no such *component* is present at that position.

**identify\_row**(*y*)  
Returns the item ID of the item at position *y*.

**identify\_column**(*x*)  
Returns the data column identifier of the cell at position *x*.  
The tree column has ID `#0`.

**identify\_region**(*x*, *y*)  
Returns one of :

region	meaning
heading	Tree heading area.
separator	Space between two columns headings.
tree	The tree area.
cell	A data cell.

Availability : Tk 8.6.

**identify\_element**(*x*, *y*)  
Returns the element at position *x*, *y*.  
Availability : Tk 8.6.

**index**(*item*)  
Returns the integer index of *item* within its parent’s list of children.

**insert**(*parent*, *index*, *iid=None*, *\*\*kw*)  
Creates a new item and returns the item identifier of the newly created item.  
*parent* is the item ID of the parent item, or the empty string to create a new top-level item. *index* is an integer, or the value « end », specifying where in the list of parent’s children to insert the

new item. If *index* is less than or equal to zero, the new node is inserted at the beginning; if *index* is greater than or equal to the current number of children, it is inserted at the end. If *iid* is specified, it is used as the item identifier; *iid* must not already exist in the tree. Otherwise, a new unique identifier is generated.

See [Item Options](#) for the list of available points.

**item**(*item*[, *option*[, *\*\*kw*]])

Query or modify the options for the specified *item*.

If no options are given, a dict with options/values for the item is returned. If *option* is specified then the value for that option is returned. Otherwise, sets the options to the corresponding values as given by *kw*.

**move**(*item*, *parent*, *index*)

Moves *item* to position *index* in *parent*'s list of children.

It is illegal to move an item under one of its descendants. If *index* is less than or equal to zero, *item* is moved to the beginning; if greater than or equal to the number of children, it is moved to the end. If *item* was detached it is reattached.

**next**(*item*)

Returns the identifier of *item*'s next sibling, or "" if *item* is the last child of its parent.

**parent**(*item*)

Returns the ID of the parent of *item*, or "" if *item* is at the top level of the hierarchy.

**prev**(*item*)

Returns the identifier of *item*'s previous sibling, or "" if *item* is the first child of its parent.

**reattach**(*item*, *parent*, *index*)

An alias for [Treeview.move\(\)](#).

**see**(*item*)

Ensure that *item* is visible.

Sets all of *item*'s ancestors open option to **True**, and scrolls the widget if necessary so that *item* is within the visible portion of the tree.

**selection**([*selop*=None[, *items*=None]])

If *selop* is not specified, returns selected items. Otherwise, it will act according to the following selection methods.

**selection\_set**(*items*)

*items* becomes the new selection.

**selection\_add**(*items*)

Add *items* to the selection.

**selection\_remove**(*items*)

Remove *items* from the selection.

**selection\_toggle**(*items*)

Toggle the selection state of each item in *items*.

**set**(*item*, *column*=None, *value*=None)

With one argument, returns a dictionary of column/value pairs for the specified *item*. With two arguments, returns the current value of the specified *column*. With three arguments, sets the value of given *column* in given *item* to the specified *value*.

**tag\_bind**(*tagname*, *sequence*=None, *callback*=None)

Bind a callback for the given event *sequence* to the tag *tagname*. When an event is delivered to an item, the callbacks for each of the item's tags option are called.

**tag\_configure**(*tagname*, *option*=None, *\*\*kw*)

Query or modify the options for the specified *tagname*.

If *kw* is not given, returns a dict of the option settings for *tagname*. If *option* is specified, returns the value for that *option* for the specified *tagname*. Otherwise, sets the options to the corresponding values for the given *tagname*.

`tag_has(tagname[, item])`

If *item* is specified, returns 1 or 0 depending on whether the specified *item* has the given *tagname*. Otherwise, returns a list of all items that have the specified tag.

Availability : Tk 8.6

`xview(*args)`

Query or modify horizontal position of the treeview.

`yview(*args)`

Query or modify vertical position of the treeview.

### 24.2.10 Ttk Styling

Each widget in *ttk* is assigned a style, which specifies the set of elements making up the widget and how they are arranged, along with dynamic and default settings for element options. By default the style name is the same as the widget's class name, but it may be overridden by the widget's style option. If the class name of a widget is unknown, use the method `Misc.winfo_class()` (`somewidget.winfo_class()`).

Voir aussi :

**Tcl'2004 conference presentation** This document explains how the theme engine works

`class ttk.Style`

This class is used to manipulate the style database.

`configure(style, query_opt=None, **kw)`

Query or set the default value of the specified option(s) in *style*.

Each key in *kw* is an option and each value is a string identifying the value for that option.

For example, to change every default button to be a flat button with some padding and a different background color do :

```
import ttk
import Tkinter

root = Tkinter.Tk()

ttk.Style().configure("TButton", padding=6, relief="flat",
                     background="#ccc")

btn = ttk.Button(text="Sample")
btn.pack()

root.mainloop()
```

`map(style, query_opt=None, **kw)`

Query or sets dynamic values of the specified option(s) in *style*.

Each key in *kw* is an option and each value should be a list or a tuple (usually) containing statespecs grouped in tuples, lists, or something else of your preference. A statespec is a compound of one or more states and then a value.

Un exemple :

```
import Tkinter
import ttk

root = Tkinter.Tk()

style = ttk.Style()
```

(suite sur la page suivante)

(suite de la page précédente)

```

style.map("C.TButton",
    foreground=[('pressed', 'red'), ('active', 'blue')],
    background=[('pressed', '!disabled', 'black'), ('active', 'white')]
)

colored_btn = ttk.Button(text="Test", style="C.TButton").pack()

root.mainloop()

```

Note that the order of the (states, value) sequences for an option matters. In the previous example, if you change the order to [('active', 'blue'), ('pressed', 'red')] in the foreground option, for example, you would get a blue foreground when the widget is in the active or pressed states.

**lookup**(*style*, *option*, *state*=None, *default*=None)

Returns the value specified for *option* in *style*.

If *state* is specified, it is expected to be a sequence of one or more states. If the *default* argument is set, it is used as a fallback value in case no specification for option is found.

To check what font a Button uses by default, do :

```

import ttk

print ttk.Style().lookup("TButton", "font")

```

**layout**(*style*, *layoutspect*=None)

Define the widget layout for given *style*. If *layoutspect* is omitted, return the layout specification for given style.

*layoutspect*, if specified, is expected to be a list or some other sequence type (excluding strings), where each item should be a tuple and the first item is the layout name and the second item should have the format described in [Layouts](#).

To understand the format, see the following example (it is not intended to do anything useful) :

```

import ttk
import Tkinter

root = Tkinter.Tk()

style = ttk.Style()
style.layout("TMenubutton", [
    ("Menubutton.background", None),
    ("Menubutton.button", {"children":
        [("Menubutton.focus", {"children":
            [("Menubutton.padding", {"children":
                [("Menubutton.label", {"side": "left", "expand": 1})]
            })]
        })]
    })],
])

mbtn = ttk.Menubutton(text='Text')
mbtn.pack()
root.mainloop()

```

**element\_create**(*elementname*, *etype*, \**args*, \*\**kw*)

Create a new element in the current theme, of the given *etype* which is expected to be either

« image », « from » or « vsapi ». The latter is only available in Tk 8.6a for Windows XP and Vista and is not described here.

If « image » is used, *args* should contain the default image name followed by statespec/value pairs (this is the imagespec), and *kw* may have the following options :

- **border=padding** padding is a list of up to four integers, specifying the left, top, right, and bottom borders, respectively.
- **height=height** Specifies a minimum height for the element. If less than zero, the base image's height is used as a default.
- **padding=padding** Specifies the element's interior padding. Defaults to border's value if not specified.
- **sticky=spec** Specifies how the image is placed within the final parcel. spec contains zero or more characters « n », « s », « w », or « e ».
- **width=width** Specifies a minimum width for the element. If less than zero, the base image's width is used as a default.

If « from » is used as the value of *etype*, *element\_create()* will clone an existing element. *args* is expected to contain a themename, from which the element will be cloned, and optionally an element to clone from. If this element to clone from is not specified, an empty element will be used. *kw* is discarded.

**element\_names()**

Returns the list of elements defined in the current theme.

**element\_options(*elementname*)**

Returns the list of *elementname*'s options.

**theme\_create(*themename*, *parent=None*, *settings=None*)**

Create a new theme.

It is an error if *themename* already exists. If *parent* is specified, the new theme will inherit styles, elements and layouts from the parent theme. If *settings* are present they are expected to have the same syntax used for *theme\_settings()*.

**theme\_settings(*themename*, *settings*)**

Temporarily sets the current theme to *themename*, apply specified *settings* and then restore the previous theme.

Each key in *settings* is a style and each value may contain the keys “configure”, “map”, “layout” and “element create” and they are expected to have the same format as specified by the methods *Style.configure()*, *Style.map()*, *Style.layout()* and *Style.element\_create()* respectively. As an example, let's change the Combobox for the default theme a bit :

```
import ttk
import Tkinter

root = Tkinter.Tk()

style = ttk.Style()
style.theme_settings("default", {
    "TCombobox": {
        "configure": {"padding": 5},
        "map": {
            "background": [("active", "green2"),
                           ("!disabled", "green4")],
            "fieldbackground": [("!disabled", "green3")],
            "foreground": [("focus", "OliveDrab1"),
                           ("!disabled", "OliveDrab2")]
        }
    }
})
```

(suite sur la page suivante)

(suite de la page précédente)

```

}))

combo = ttk.Combobox().pack()

root.mainloop()

```

**theme\_names()**

Returns a list of all known themes.

**theme\_use([*themename*])**If *themename* is not given, returns the theme in use. Otherwise, sets the current theme to *themename*, refreshes all widgets and emits a <<ThemeChanged>> event.

## Layouts

A layout can be just `None`, if it takes no options, or a dict of options specifying how to arrange the element. The layout mechanism uses a simplified version of the pack geometry manager : given an initial cavity, each element is allocated a parcel. Valid options/values are :

- **side : whichside** Specifies which side of the cavity to place the element ; one of top, right, bottom or left. If omitted, the element occupies the entire cavity.
- **sticky : nswe** Specifies where the element is placed inside its allocated parcel.
- **unit : 0 or 1** If set to 1, causes the element and all of its descendants to be treated as a single element for the purposes of *Widget.identify()* et al. It's used for things like scrollbar thumbs with grips.
- **children : [sublayout... ]** Specifies a list of elements to place inside the element. Each element is a tuple (or other sequence type) where the first item is the layout name, and the other is a *Layout*.

## 24.3 Tix — Extension widgets for Tk

The *Tix* (Tk Interface Extension) module provides an additional rich set of widgets. Although the standard Tk library has many useful widgets, they are far from complete. The *Tix* library provides most of the commonly needed widgets that are missing from standard Tk : *HList*, *ComboBox*, *Control* (a.k.a. *SpinBox*) and an assortment of scrollable widgets. *Tix* also includes many more widgets that are generally useful in a wide range of applications : *NoteBook*, *FileEntry*, *PanedWindow*, etc ; there are more than 40 of them.

With all these new widgets, you can introduce new interaction techniques into applications, creating more useful and more intuitive user interfaces. You can design your application by choosing the most appropriate widgets to match the special needs of your application and users.

---

**Note :** *Tix* has been renamed to `tkinter.tix` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

Voir aussi :

**Tix Homepage** The home page for *Tix*. This includes links to additional documentation and downloads.

**Tix Man Pages** On-line version of the man pages and reference material.

**Tix Programming Guide** On-line version of the programmer's reference material.

**Tix Development Applications** Tix applications for development of Tix and Tkinter programs. Tide applications work under Tk or Tkinter, and include **TixInspect**, an inspector to remotely modify and debug Tix/Tk/Tkinter applications.

### 24.3.1 Using Tix

**class** `Tix.Tix`(*screenName*[, *baseName*[, *className*]])

Toplevel widget of Tix which represents mostly the main window of an application. It has an associated Tcl interpreter.

Classes in the *Tix* module subclasses the classes in the *Tkinter* module. The former imports the latter, so to use *Tix* with Tkinter, all you need to do is to import one module. In general, you can just import *Tix*, and replace the toplevel call to *Tkinter.Tk* with *Tix.Tk* :

```
import Tix
from Tkconstants import *
root = Tix.Tk()
```

To use *Tix*, you must have the *Tix* widgets installed, usually alongside your installation of the Tk widgets. To test your installation, try the following :

```
import Tix
root = Tix.Tk()
root.tk.eval('package require Tix')
```

If this fails, you have a Tk installation problem which must be resolved before proceeding. Use the environment variable `TIX_LIBRARY` to point to the installed *Tix* library directory, and make sure you have the dynamic object library (`tix8183.dll` or `libtix8183.so`) in the same directory that contains your Tk dynamic object library (`tk8183.dll` or `libtk8183.so`). The directory with the dynamic object library should also have a file called `pkgIndex.tcl` (case sensitive), which contains the line :

```
package ifneeded Tix 8.1 [list load "[file join $dir tix8183.dll]" Tix]
```

### 24.3.2 Tix Widgets

*Tix* introduces over 40 widget classes to the *Tkinter* repertoire. There is a demo of all the *Tix* widgets in the `Demo/tix` directory of the standard distribution.

#### Basic Widgets

**class** `Tix.Balloon`

A *Balloon* that pops up over a widget to provide help. When the user moves the cursor inside a widget to which a *Balloon* widget has been bound, a small pop-up window with a descriptive message will be shown on the screen.

**class** `Tix.ButtonBox`

The *ButtonBox* widget creates a box of buttons, such as is commonly used for `Ok Cancel`.

**class** `Tix.ComboBox`

The *ComboBox* widget is similar to the combo box control in MS Windows. The user can select a choice by either typing in the entry subwidget or selecting from the listbox subwidget.

**class** `Tix.Control`

The *Control* widget is also known as the *SpinBox* widget. The user can adjust the value by pressing the two arrow buttons or by entering the value directly into the entry. The new value will be checked against the user-defined upper and lower limits.

**class** `Tix.LabelEntry`

The *LabelEntry* widget packages an entry widget and a label into one mega widget. It can be used to simplify the creation of « entry-form » type of interface.

**class Tix.LabelFrame**

The [LabelFrame](#) widget packages a frame widget and a label into one mega widget. To create widgets inside a LabelFrame widget, one creates the new widgets relative to the **frame** subwidget and manage them inside the **frame** subwidget.

**class Tix.Meter**

The [Meter](#) widget can be used to show the progress of a background job which may take a long time to execute.

**class Tix.OptionMenu**

The [OptionMenu](#) creates a menu button of options.

**class Tix.PopupMenu**

The [PopupMenu](#) widget can be used as a replacement of the `tk_popup` command. The advantage of the *Tix PopupMenu* widget is it requires less application code to manipulate.

**class Tix.Select**

The [Select](#) widget is a container of button subwidgets. It can be used to provide radio-box or check-box style of selection options for the user.

**class Tix.StdButtonBox**

The [StdButtonBox](#) widget is a group of standard buttons for Motif-like dialog boxes.

**File Selectors****class Tix.DirList**

The [DirList](#) widget displays a list view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

**class Tix.DirTree**

The [DirTree](#) widget displays a tree view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

**class Tix.DirSelectDialog**

The [DirSelectDialog](#) widget presents the directories in the file system in a dialog window. The user can use this dialog window to navigate through the file system to select the desired directory.

**class Tix.DirSelectBox**

The *DirSelectBox* is similar to the standard Motif(TM) directory-selection box. It is generally used for the user to choose a directory. DirSelectBox stores the directories mostly recently selected into a [ComboBox](#) widget so that they can be quickly selected again.

**class Tix.ExFileSelectBox**

The [ExFileSelectBox](#) widget is usually embedded in a `tixExFileSelectDialog` widget. It provides a convenient method for the user to select files. The style of the *ExFileSelectBox* widget is very similar to the standard file dialog on MS Windows 3.1.

**class Tix.FileSelectBox**

The [FileSelectBox](#) is similar to the standard Motif(TM) file-selection box. It is generally used for the user to choose a file. FileSelectBox stores the files mostly recently selected into a *ComboBox* widget so that they can be quickly selected again.

**class Tix.FileEntry**

The [FileEntry](#) widget can be used to input a filename. The user can type in the filename manually. Alternatively, the user can press the button widget that sits next to the entry, which will bring up a file selection dialog.

### Hierarchical ListBox

#### `class Tix.HList`

The `HList` widget can be used to display any data that have a hierarchical structure, for example, file system directory trees. The list entries are indented and connected by branch lines according to their places in the hierarchy.

#### `class Tix.CheckList`

The `CheckList` widget displays a list of items to be selected by the user. `CheckList` acts similarly to the Tk `checkboxbutton` or `radiobutton` widgets, except it is capable of handling many more items than `checkboxbuttons` or `radiobuttons`.

#### `class Tix.Tree`

The `Tree` widget can be used to display hierarchical data in a tree form. The user can adjust the view of the tree by opening or closing parts of the tree.

### Tabular ListBox

#### `class Tix.TList`

The `TList` widget can be used to display data in a tabular format. The list entries of a `TList` widget are similar to the entries in the Tk `listbox` widget. The main differences are (1) the `TList` widget can display the list entries in a two dimensional format and (2) you can use graphical images as well as multiple colors and fonts for the list entries.

### Manager Widgets

#### `class Tix.PanedWindow`

The `PanedWindow` widget allows the user to interactively manipulate the sizes of several panes. The panes can be arranged either vertically or horizontally. The user changes the sizes of the panes by dragging the resize handle between two panes.

#### `class Tix.ListNoteBook`

The `ListNoteBook` widget is very similar to the `TixNoteBook` widget : it can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages (windows). At one time only one of these pages can be shown. The user can navigate through these pages by choosing the name of the desired page in the `hlist` subwidget.

#### `class Tix.NoteBook`

The `NoteBook` widget can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages. At one time only one of these pages can be shown. The user can navigate through these pages by choosing the visual « tabs » at the top of the `NoteBook` widget.

### Image Types

The `Tix` module adds :

- `pixmap` capabilities to all `Tix` and `Tkinter` widgets to create color images from XPM files.
- `Compound` image types can be used to create images that consists of multiple horizontal lines ; each line is composed of a series of items (texts, bitmaps, images or spaces) arranged from left to right. For example, a compound image can be used to display a bitmap and a text string simultaneously in a Tk `Button` widget.

### Miscellaneous Widgets

#### `class Tix.InputOnly`

The `InputOnly` widgets are to accept inputs from the user, which can be done with the `bind` command (Unix only).

## Form Geometry Manager

In addition, *Tix* augments *Tkinter* by providing :

`class Tix.Form`

The *Form* geometry manager based on attachment rules for all Tk widgets.

### 24.3.3 Tix Commands

`class Tix.tixCommand`

The *tix commands* provide access to miscellaneous elements of *Tix*'s internal state and the *Tix* application context. Most of the information manipulated by these methods pertains to the application as a whole, or to a screen or display, rather than to a particular window.

To view the current settings, the common usage is :

```
import Tix
root = Tix.Tk()
print root.tix_configure()
```

`tixCommand.tix_configure(cnf=None **kw)`

Query or modify the configuration options of the Tix application context. If no option is specified, returns a dictionary all of the available options. If option is specified with no value, then the method returns a list describing the one named option (this list will be identical to the corresponding sublist of the value returned if no option is specified). If one or more option-value pairs are specified, then the method modifies the given option(s) to have the given value(s); in this case the method returns an empty string. Option may be any of the configuration options.

`tixCommand.tix_cget(option)`

Returns the current value of the configuration option given by *option*. Option may be any of the configuration options.

`tixCommand.tix_getbitmap(name)`

Locates a bitmap file of the name *name.xpm* or *name* in one of the bitmap directories (see the *tix\_addbitmapdir()* method). By using *tix\_getbitmap()*, you can avoid hard coding the pathnames of the bitmap files in your application. When successful, it returns the complete pathname of the bitmap file, prefixed with the character `@`. The returned value can be used to configure the *bitmap* option of the Tk and Tix widgets.

`tixCommand.tix_addbitmapdir(directory)`

Tix maintains a list of directories under which the *tix\_getimage()* and *tix\_getbitmap()* methods will search for image files. The standard bitmap directory is `$TIX_LIBRARY/bitmaps`. The *tix\_addbitmapdir()* method adds *directory* into this list. By using this method, the image files of an applications can also be located using the *tix\_getimage()* or *tix\_getbitmap()* method.

`tixCommand.tix_filedialog([dlgclass])`

Returns the file selection dialog that may be shared among different calls from this application. This method will create a file selection dialog widget when it is called the first time. This dialog will be returned by all subsequent calls to *tix\_filedialog()*. An optional *dlgclass* parameter can be passed as a string to specified what type of file selection dialog widget is desired. Possible options are *tix*, *FileSelectDialog* or *tixExFileSelectDialog*.

`tixCommand.tix_getimage(self, name)`

Locates an image file of the name *name.xpm*, *name.xbm* or *name.ppm* in one of the bitmap directories (see the *tix\_addbitmapdir()* method above). If more than one file with the same name (but different extensions) exist, then the image type is chosen according to the depth of the X display : *xbm* images are chosen on monochrome displays and color images are chosen on color displays. By using *tix\_getimage()*, you can avoid hard coding the pathnames of the image files in your application.

When successful, this method returns the name of the newly created image, which can be used to configure the `image` option of the Tk and Tix widgets.

`tixCommand.tix_option_get(name)`

Gets the options maintained by the Tix scheme mechanism.

`tixCommand.tix_resetoptions(newScheme, newFontSet[, newScmPrio])`

Resets the scheme and fontset of the Tix application to *newScheme* and *newFontSet*, respectively. This affects only those widgets created after this call. Therefore, it is best to call the `resetoptions` method before the creation of any widgets in a Tix application.

The optional parameter *newScmPrio* can be given to reset the priority level of the Tk options set by the Tix schemes.

Because of the way Tk handles the X option database, after Tix has been imported and initied, it is not possible to reset the color schemes and font sets using the `tix_config()` method. Instead, the `tix_resetoptions()` method must be used.

## 24.4 ScrolledText — Scrolled Text Widget

The *ScrolledText* module provides a class of the same name which implements a basic text widget which has a vertical scroll bar configured to do the « right thing. » Using the `ScrolledText` class is a lot easier than setting up a text widget and scroll bar directly. The constructor is the same as that of the `Tkinter.Text` class.

---

**Note :** *ScrolledText* has been renamed to `tkinter.scrolledtext` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

The text widget and scrollbar are packed together in a `Frame`, and the methods of the `Grid` and `Pack` geometry managers are acquired from the `Frame` object. This allows the `ScrolledText` widget to be used directly to achieve most normal geometry management behavior.

Si un contrôle plus fin est nécessaire, les attributs suivants sont disponibles :

`ScrolledText.frame`

Le cadre (objet *Frame*) qui englobe le gadget texte et le gadget de la barre de défilement.

`ScrolledText.vbar`

Le gadget de la barre de défilement.

## 24.5 turtle — Turtle graphics for Tk

### 24.5.1 Introduction

Turtle graphics is a popular way for introducing programming to kids. It was part of the original Logo programming language developed by Wally Feurzig and Seymour Papert in 1966.

Imagine a robotic turtle starting at (0, 0) in the x-y plane. After an `import turtle`, give it the command `turtle.forward(15)`, and it moves (on-screen!) 15 pixels in the direction it is facing, drawing a line as it moves. Give it the command `turtle.right(25)`, and it rotates in-place 25 degrees clockwise.

By combining together these and similar commands, intricate shapes and pictures can easily be drawn.

The *turtle* module is an extended reimplementaion of the same-named module from the Python standard distribution up to version Python 2.5.

It tries to keep the merits of the old turtle module and to be (nearly) 100% compatible with it. This means in the first place to enable the learning programmer to use all the commands, classes and methods interactively when using the module from within IDLE run with the `-n` switch.

The turtle module provides turtle graphics primitives, in both object-oriented and procedure-oriented ways. Because it uses *Tkinter* for the underlying graphics, it needs a version of Python installed with Tk support.

The object-oriented interface uses essentially two+two classes :

1. The *TurtleScreen* class defines graphics windows as a playground for the drawing turtles. Its constructor needs a *Tkinter.Canvas* or a *ScrolledCanvas* as argument. It should be used when *turtle* is used as part of some application.

The function *Screen()* returns a singleton object of a *TurtleScreen* subclass. This function should be used when *turtle* is used as a standalone tool for doing graphics. As a singleton object, inheriting from its class is not possible.

All methods of *TurtleScreen*/*Screen* also exist as functions, i.e. as part of the procedure-oriented interface.

2. *RawTurtle* (alias : *RawPen*) defines Turtle objects which draw on a *TurtleScreen*. Its constructor needs a *Canvas*, *ScrolledCanvas* or *TurtleScreen* as argument, so the *RawTurtle* objects know where to draw.

Derived from *RawTurtle* is the subclass *Turtle* (alias : *Pen*), which draws on « the » *Screen* - instance which is automatically created, if not already present.

All methods of *RawTurtle*/*Turtle* also exist as functions, i.e. part of the procedure-oriented interface.

The procedural interface provides functions which are derived from the methods of the classes *Screen* and *Turtle*. They have the same names as the corresponding methods. A screen object is automatically created whenever a function derived from a *Screen* method is called. An (unnamed) turtle object is automatically created whenever any of the functions derived from a *Turtle* method is called.

To use multiple turtles on a screen one has to use the object-oriented interface.

---

**Note :** In the following documentation the argument list for functions is given. Methods, of course, have the additional first argument *self* which is omitted here.

---

## 24.5.2 Overview over available Turtle and Screen methods

### Turtle methods

#### Turtle motion

##### Move and draw

```
forward() | fd()
backward() | bk() | back()
right() | rt()
left() | lt()
goto() | setpos() | setposition()
setx()
sety()
setheading() | seth()
home()
circle()
dot()
stamp()
clearstamp()
```

*clearstamps()*

*undo()*

*speed()*

#### **Tell Turtle's state**

*position()* | *pos()*

*towards()*

*xcor()*

*ycor()*

*heading()*

*distance()*

#### **Setting and measurement**

*degrees()*

*radians()*

#### **Pen control**

##### **Drawing state**

*pendown()* | *pd()* | *down()*

*penup()* | *pu()* | *up()*

*pensize()* | *width()*

*pen()*

*isdown()*

##### **Color control**

*color()*

*pencolor()*

*fillcolor()*

##### **Filling**

*fill()*

*begin\_fill()*

*end\_fill()*

##### **More drawing control**

*reset()*

*clear()*

*write()*

#### **Turtle state**

##### **Visibility**

*showturtle()* | *st()*

*hideturtle()* | *ht()*

*isvisible()*

##### **Appearance**

*shape()*

*resizemode()*

*shapeseize()* | *turtlesize()*

*settiltangle()*

*tiltangle()*

*tilt()*

#### **Using events**

*onclick()*

```
onrelease()  
ondrag()  
mainloop() | done()
```

### Special Turtle methods

```
begin_poly()  
end_poly()  
get_poly()  
clone()  
getturtle() | getpen()  
getscreen()  
setundobuffer()  
undobufferentries()  
tracer()  
window_width()  
window_height()
```

## Methods of TurtleScreen/Screen

### Window control

```
bgcolor()  
bgpic()  
clear() | clearscreen()  
reset() | resetscreen()  
screensize()  
setworldcoordinates()
```

### Animation control

```
delay()  
tracer()  
update()
```

### Using screen events

```
listen()  
onkey()  
onclick() | onscreenclick()  
ontimer()
```

### Settings and special methods

```
mode()  
colormode()  
getcanvas()  
getshapes()  
register_shape() | addshape()  
turtles()  
window_height()  
window_width()
```

### Methods specific to Screen

```
bye()  
exitonclick()  
setup()  
title()
```

### 24.5.3 Methods of RawTurtle/Turtle and corresponding functions

Most of the examples in this section refer to a Turtle instance called `turtle`.

#### Turtle motion

`turtle.forward(distance)`

`turtle.fd(distance)`

**Paramètres** `distance` – a number (integer or float)

Move the turtle forward by the specified *distance*, in the direction the turtle is headed.

```
>>> turtle.position()
(0.00,0.00)
>>> turtle.forward(25)
>>> turtle.position()
(25.00,0.00)
>>> turtle.forward(-75)
>>> turtle.position()
(-50.00,0.00)
```

`turtle.back(distance)`

`turtle.bk(distance)`

`turtle.backward(distance)`

**Paramètres** `distance` – a number

Move the turtle backward by *distance*, opposite to the direction the turtle is headed. Do not change the turtle's heading.

```
>>> turtle.position()
(0.00,0.00)
>>> turtle.backward(30)
>>> turtle.position()
(-30.00,0.00)
```

`turtle.right(angle)`

`turtle.rt(angle)`

**Paramètres** `angle` – a number (integer or float)

Turn turtle right by *angle* units. (Units are by default degrees, but can be set via the `degrees()` and `radians()` functions.) Angle orientation depends on the turtle mode, see `mode()`.

```
>>> turtle.heading()
22.0
>>> turtle.right(45)
>>> turtle.heading()
337.0
```

`turtle.left(angle)`

`turtle.lt(angle)`

**Paramètres** `angle` – a number (integer or float)

Turn turtle left by *angle* units. (Units are by default degrees, but can be set via the `degrees()` and `radians()` functions.) Angle orientation depends on the turtle mode, see `mode()`.

```
>>> turtle.heading()
22.0
>>> turtle.left(45)
>>> turtle.heading()
67.0
```

```
turtle.goto(x, y=None)
turtle.setpos(x, y=None)
turtle.setposition(x, y=None)
```

**Paramètres**

- **x** – a number or a pair/vector of numbers
- **y** – a number or None

If *y* is None, *x* must be a pair of coordinates or a *Vec2D* (e.g. as returned by *pos()*).

Move turtle to an absolute position. If the pen is down, draw line. Do not change the turtle's orientation.

```
>>> tp = turtle.pos()
>>> tp
(0.00,0.00)
>>> turtle.setpos(60,30)
>>> turtle.pos()
(60.00,30.00)
>>> turtle.setpos((20,80))
>>> turtle.pos()
(20.00,80.00)
>>> turtle.setpos(tp)
>>> turtle.pos()
(0.00,0.00)
```

```
turtle.setx(x)
```

**Paramètres** **x** – a number (integer or float)

Set the turtle's first coordinate to *x*, leave second coordinate unchanged.

```
>>> turtle.position()
(0.00,240.00)
>>> turtle.setx(10)
>>> turtle.position()
(10.00,240.00)
```

```
turtle.sety(y)
```

**Paramètres** **y** – a number (integer or float)

Set the turtle's second coordinate to *y*, leave first coordinate unchanged.

```
>>> turtle.position()
(0.00,40.00)
>>> turtle.sety(-10)
>>> turtle.position()
(0.00,-10.00)
```

```
turtle.setheading(to_angle)
```

```
turtle.seth(to_angle)
```

**Paramètres** **to\_angle** – a number (integer or float)

Set the orientation of the turtle to *to\_angle*. Here are some common directions in degrees :

standard mode	logo mode
0 - east	0 - north
90 - north	90 - east
180 - west	180 - south
270 - south	270 - west

```
>>> turtle.setheading(90)
>>> turtle.heading()
90.0
```

**turtle.home()**

Move turtle to the origin – coordinates (0,0) – and set its heading to its start-orientation (which depends on the mode, see *mode()*).

```
>>> turtle.heading()
90.0
>>> turtle.position()
(0.00,-10.00)
>>> turtle.home()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
```

**turtle.circle(*radius*, *extent*=None, *steps*=None)**

**Paramètres**

- **radius** – a number
- **extent** – a number (or None)
- **steps** – an integer (or None)

Draw a circle with given *radius*. The center is *radius* units left of the turtle; *extent* – an angle – determines which part of the circle is drawn. If *extent* is not given, draw the entire circle. If *extent* is not a full circle, one endpoint of the arc is the current pen position. Draw the arc in counterclockwise direction if *radius* is positive, otherwise in clockwise direction. Finally the direction of the turtle is changed by the amount of *extent*.

As the circle is approximated by an inscribed regular polygon, *steps* determines the number of steps to use. If not given, it will be calculated automatically. May be used to draw regular polygons.

```
>>> turtle.home()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
>>> turtle.circle(50)
>>> turtle.position()
(-0.00,0.00)
>>> turtle.heading()
0.0
>>> turtle.circle(120, 180) # draw a semicircle
>>> turtle.position()
(0.00,240.00)
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> turtle.heading()
180.0
```

`turtle.dot(size=None, *color)`

**Paramètres**

- **size** – an integer  $\geq 1$  (if given)
- **color** – a colorstring or a numeric color tuple

Draw a circular dot with diameter *size*, using *color*. If *size* is not given, the maximum of pensize+4 and 2\*pensize is used.

```
>>> turtle.home()
>>> turtle.dot()
>>> turtle.fd(50); turtle.dot(20, "blue"); turtle.fd(50)
>>> turtle.position()
(100.00,-0.00)
>>> turtle.heading()
0.0
```

`turtle.stamp()`

Stamp a copy of the turtle shape onto the canvas at the current turtle position. Return a `stamp_id` for that stamp, which can be used to delete it by calling `clearstamp(stamp_id)`.

```
>>> turtle.color("blue")
>>> turtle.stamp()
11
>>> turtle.fd(50)
```

`turtle.clearstamp(stampid)`

**Paramètres** `stampid` – an integer, must be return value of previous `stamp()` call

Delete stamp with given *stampid*.

```
>>> turtle.position()
(150.00,-0.00)
>>> turtle.color("blue")
>>> astamp = turtle.stamp()
>>> turtle.fd(50)
>>> turtle.position()
(200.00,-0.00)
>>> turtle.clearstamp(astamp)
>>> turtle.position()
(200.00,-0.00)
```

`turtle.clearstamps(n=None)`

**Paramètres** `n` – an integer (or None)

Delete all or first/last *n* of turtle's stamps. If *n* is None, delete all stamps, if  $n > 0$  delete first *n* stamps, else if  $n < 0$  delete last *n* stamps.

```
>>> for i in range(8):
...     turtle.stamp(); turtle.fd(30)
13
14
```

(suite sur la page suivante)

(suite de la page précédente)

```
15
16
17
18
19
20
>>> turtle.clearstamps(2)
>>> turtle.clearstamps(-2)
>>> turtle.clearstamps()
```

**turtle.undo()**

Undo (repeatedly) the last turtle action(s). Number of available undo actions is determined by the size of the undobuffer.

```
>>> for i in range(4):
...     turtle.fd(50); turtle.lt(80)
...
>>> for i in range(8):
...     turtle.undo()
```

**turtle.speed(*speed=None*)**

**Paramètres** **speed** – an integer in the range 0..10 or a speedstring (see below)

Set the turtle's speed to an integer value in the range 0..10. If no argument is given, return current speed.

If input is a number greater than 10 or smaller than 0.5, speed is set to 0. Speedstrings are mapped to speedvalues as follows :

- « fastest » : 0
- « fast » : 10
- « normal » : 6
- « slow » : 3
- « slowest » : 1

Speeds from 1 to 10 enforce increasingly faster animation of line drawing and turtle turning.

Attention : *speed* = 0 means that *no* animation takes place. forward/back makes turtle jump and likewise left/right make the turtle turn instantly.

```
>>> turtle.speed()
3
>>> turtle.speed('normal')
>>> turtle.speed()
6
>>> turtle.speed(9)
>>> turtle.speed()
9
```

### Tell Turtle's state

**turtle.position()****turtle.pos()**

Return the turtle's current location (x,y) (as a *Vec2D* vector).

```
>>> turtle.pos()
(440.00,-0.00)
```

`turtle.towards(x, y=None)`

**Paramètres**

- **x** – a number or a pair/vector of numbers or a turtle instance
- **y** – a number if *x* is a number, else `None`

Return the angle between the line from turtle position to position specified by (x,y), the vector or the other turtle. This depends on the turtle's start orientation which depends on the mode - « standard »/ « world » or « logo »).

```
>>> turtle.goto(10, 10)
>>> turtle.towards(0,0)
225.0
```

`turtle.xcor()`

Return the turtle's x coordinate.

```
>>> turtle.home()
>>> turtle.left(50)
>>> turtle.forward(100)
>>> turtle.pos()
(64.28,76.60)
>>> print turtle.xcor()
64.2787609687
```

`turtle.ycor()`

Return the turtle's y coordinate.

```
>>> turtle.home()
>>> turtle.left(60)
>>> turtle.forward(100)
>>> print turtle.pos()
(50.00,86.60)
>>> print turtle.ycor()
86.6025403784
```

`turtle.heading()`

Return the turtle's current heading (value depends on the turtle mode, see [mode\(\)](#)).

```
>>> turtle.home()
>>> turtle.left(67)
>>> turtle.heading()
67.0
```

`turtle.distance(x, y=None)`

**Paramètres**

- **x** – a number or a pair/vector of numbers or a turtle instance
- **y** – a number if *x* is a number, else `None`

Return the distance from the turtle to (x,y), the given vector, or the given other turtle, in turtle step units.

```
>>> turtle.home()
>>> turtle.distance(30,40)
50.0
>>> turtle.distance((30,40))
```

(suite sur la page suivante)

(suite de la page précédente)

```
50.0
>>> joe = Turtle()
>>> joe.forward(77)
>>> turtle.distance(joe)
77.0
```

### Settings for measurement

`turtle.degrees(fullcircle=360.0)`

**Paramètres** `fullcircle` – a number

Set angle measurement units, i.e. set number of « degrees » for a full circle. Default value is 360 degrees.

```
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0
```

Change angle measurement unit to grad (also known as gon, grade, or gradian and equals 1/100-th of the right angle.)

```
>>> turtle.degrees(400.0)
>>> turtle.heading()
100.0
>>> turtle.degrees(360)
>>> turtle.heading()
90.0
```

`turtle.radians()`

Set the angle measurement units to radians. Equivalent to `degrees(2*math.pi)`.

```
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0
>>> turtle.radians()
>>> turtle.heading()
1.5707963267948966
```

### Pen control

#### Drawing state

`turtle.pendown()`  
`turtle.pd()`  
`turtle.down()`

Pull the pen down – drawing when moving.

`turtle.penup()`  
`turtle.pu()`  
`turtle.up()`

Pull the pen up – no drawing when moving.

`turtle.pensize(width=None)`

`turtle.width(width=None)`

**Paramètres** `width` – a positive number

Set the line thickness to *width* or return it. If `resizemode` is set to « auto » and `turtleshape` is a polygon, that polygon is drawn with the same line thickness. If no argument is given, the current pensize is returned.

```
>>> turtle.pensize()
1
>>> turtle.pensize(10)    # from here on lines of width 10 are drawn
```

`turtle.pen(pen=None, **pendict)`

**Paramètres**

- `pen` – a dictionary with some or all of the below listed keys
- `pendict` – one or more keyword-arguments with the below listed keys as keywords

Return or set the pen's attributes in a « pen-dictionary » with the following key/value pairs :

- « shown » : True/False
- « pendown » : True/False
- « pencolor » : color-string or color-tuple
- « fillcolor » : color-string or color-tuple
- « pensize » : positive number
- « speed » : number in range 0..10
- « resizingmode » : « auto » or « user » or « noresize »
- « stretchfactor » : (positive number, positive number)
- « outline » : positive number
- « tilt » : number

This dictionary can be used as argument for a subsequent call to `pen()` to restore the former pen-state. Moreover one or more of these attributes can be provided as keyword-arguments. This can be used to set several pen attributes in one statement.

```
>>> turtle.pen(fillcolor="black", pencolor="red", pensize=10)
>>> sorted(turtle.pen().items())
[('fillcolor', 'black'), ('outline', 1), ('pencolor', 'red'),
 ('pendown', True), ('pensize', 10), ('resizingmode', 'noresize'),
 ('shown', True), ('speed', 9), ('stretchfactor', (1, 1)), ('tilt', 0)]
>>> penstate=turtle.pen()
>>> turtle.color("yellow", "")
>>> turtle.penup()
>>> sorted(turtle.pen().items())
[('fillcolor', ''), ('outline', 1), ('pencolor', 'yellow'),
 ('pendown', False), ('pensize', 10), ('resizingmode', 'noresize'),
 ('shown', True), ('speed', 9), ('stretchfactor', (1, 1)), ('tilt', 0)]
>>> turtle.pen(penstate, fillcolor="green")
>>> sorted(turtle.pen().items())
[('fillcolor', 'green'), ('outline', 1), ('pencolor', 'red'),
 ('pendown', True), ('pensize', 10), ('resizingmode', 'noresize'),
 ('shown', True), ('speed', 9), ('stretchfactor', (1, 1)), ('tilt', 0)]
```

`turtle.isdown()`

Return True if pen is down, False if it's up.

```
>>> turtle.penup()
>>> turtle.isdown()
False
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> turtle.pendown()
>>> turtle.isdown()
True
```

## Color control

**turtle.pencolor(\*args)**

Return or set the pencolor.

Four input formats are allowed :

**pencolor()** Return the current pencolor as color specification string or as a tuple (see example). May be used as input to another color/pencolor/fillcolor call.

**pencolor(colorstring)** Set pencolor to *colorstring*, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

**pencolor((r, g, b))** Set pencolor to the RGB color represented by the tuple of *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode, where colormode is either 1.0 or 255 (see [colormode\(\)](#)).

**pencolor(r, g, b)**

Set pencolor to the RGB color represented by *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode.

If turtleshape is a polygon, the outline of that polygon is drawn with the newly set pencolor.

```
>>> colormode()
1.0
>>> turtle.pencolor()
'red'
>>> turtle.pencolor("brown")
>>> turtle.pencolor()
'brown'
>>> tup = (0.2, 0.8, 0.55)
>>> turtle.pencolor(tup)
>>> turtle.pencolor()
(0.2, 0.8, 0.5490196078431373)
>>> colormode(255)
>>> turtle.pencolor()
(51, 204, 140)
>>> turtle.pencolor('#32c18f')
>>> turtle.pencolor()
(50, 193, 143)
```

**turtle.fillcolor(\*args)**

Return or set the fillcolor.

Four input formats are allowed :

**fillcolor()** Return the current fillcolor as color specification string, possibly in tuple format (see example). May be used as input to another color/pencolor/fillcolor call.

**fillcolor(colorstring)** Set fillcolor to *colorstring*, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

**fillcolor((r, g, b))** Set fillcolor to the RGB color represented by the tuple of *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode, where colormode is either 1.0 or 255 (see [colormode\(\)](#)).

**fillcolor(r, g, b)**

Set fillcolor to the RGB color represented by *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode.

If `turtleshape` is a polygon, the interior of that polygon is drawn with the newly set `fillcolor`.

```
>>> turtle.fillcolor("violet")
>>> turtle.fillcolor()
'violet'
>>> col = turtle.pencolor()
>>> col
(50, 193, 143)
>>> turtle.fillcolor(col)
>>> turtle.fillcolor()
(50, 193, 143)
>>> turtle.fillcolor('#ffffff')
>>> turtle.fillcolor()
(255, 255, 255)
```

`turtle.color(*args)`

Return or set `pencolor` and `fillcolor`.

Several input formats are allowed. They use 0 to 3 arguments as follows :

`color()` Return the current `pencolor` and the current `fillcolor` as a pair of color specification strings or tuples as returned by `pencolor()` and `fillcolor()`.

`color(colorstring)`, `color((r,g,b))`, `color(r,g,b)` Inputs as in `pencolor()`, set both, `fillcolor` and `pencolor`, to the given value.

`color(colorstring1, colorstring2)`, `color((r1,g1,b1), (r2,g2,b2))`

Equivalent to `pencolor(colorstring1)` and `fillcolor(colorstring2)` and analogously if the other input format is used.

If `turtleshape` is a polygon, outline and interior of that polygon is drawn with the newly set colors.

```
>>> turtle.color("red", "green")
>>> turtle.color()
('red', 'green')
>>> color("#285078", "#a0c8f0")
>>> color()
((40, 80, 120), (160, 200, 240))
```

See also : Screen method `colormode()`.

## Filling

`turtle.fill(flag)`

**Paramètres** `flag` – True/False (or 1/0 respectively)

Call `fill(True)` before drawing the shape you want to fill, and `fill(False)` when done. When used without argument : return `fillstate` (True if filling, False else).

```
>>> turtle.fill(True)
>>> for _ in range(3):
...     turtle.forward(100)
...     turtle.left(120)
...
>>> turtle.fill(False)
```

`turtle.begin_fill()`

Call just before drawing a shape to be filled. Equivalent to `fill(True)`.

`turtle.end_fill()`

Fill the shape drawn after the last call to `begin_fill()`. Equivalent to `fill(False)`.

```
>>> turtle.color("black", "red")
>>> turtle.begin_fill()
>>> turtle.circle(80)
>>> turtle.end_fill()
```

## More drawing control

`turtle.reset()`

Delete the turtle's drawings from the screen, re-center the turtle and set variables to the default values.

```
>>> turtle.goto(0,-22)
>>> turtle.left(100)
>>> turtle.position()
(0.00,-22.00)
>>> turtle.heading()
100.0
>>> turtle.reset()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
```

`turtle.clear()`

Delete the turtle's drawings from the screen. Do not move turtle. State and position of the turtle as well as drawings of other turtles are not affected.

`turtle.write(arg, move=False, align="left", font=("Arial", 8, "normal"))`

### Paramètres

- **arg** – object to be written to the TurtleScreen
- **move** – True/False
- **align** – one of the strings « left », « center » or right »
- **font** – a triple (fontname, fontsize, fonttype)

Write text - the string representation of *arg* - at the current turtle position according to *align* (« left », « center » or right ») and with the given font. If *move* is true, the pen is moved to the bottom-right corner of the text. By default, *move* is **False**.

```
>>> turtle.write("Home = ", True, align="center")
>>> turtle.write((0,0), True)
```

## Turtle state

### Visibility

`turtle.hideturtle()`

`turtle.ht()`

Make the turtle invisible. It's a good idea to do this while you're in the middle of doing some complex drawing, because hiding the turtle speeds up the drawing observably.

```
>>> turtle.hideturtle()
```

`turtle.showturtle()`

`turtle.st()`

Make the turtle visible.

```
>>> turtle.showturtle()
```

`turtle.isvisible()`

Return `True` if the Turtle is shown, `False` if it's hidden.

```
>>> turtle.hideturtle()
>>> turtle.isvisible()
False
>>> turtle.showturtle()
>>> turtle.isvisible()
True
```

## Appearance

`turtle.shape(name=None)`

**Paramètres** `name` – a string which is a valid shapename

Set turtle shape to shape with given `name` or, if name is not given, return name of current shape. Shape with `name` must exist in the TurtleScreen's shape dictionary. Initially there are the following polygon shapes : « arrow », « turtle », « circle », « square », « triangle », « classic ». To learn about how to deal with shapes see Screen method [register\\_shape\(\)](#).

```
>>> turtle.shape()
'classic'
>>> turtle.shape("turtle")
>>> turtle.shape()
'turtle'
```

`turtle.resizemode(rmode=None)`

**Paramètres** `rmode` – one of the strings « auto », « user », « noresize »

Set `resizemode` to one of the values : « auto », « user », « noresize ». If `rmode` is not given, return current `resizemode`. Different `resizemodes` have the following effects :

- « auto » : adapts the appearance of the turtle corresponding to the value of `pensize`.
  - « user » : adapts the appearance of the turtle according to the values of `stretchfactor` and `outline-width` (outline), which are set by [shapsize\(\)](#).
  - « noresize » : no adaption of the turtle's appearance takes place.
- `resizemode`(« user ») is called by [shapsize\(\)](#) when used with arguments.

```
>>> turtle.resizemode()
'noresize'
>>> turtle.resizemode("auto")
>>> turtle.resizemode()
'auto'
```

`turtle.shapesize(stretch_wid=None, stretch_len=None, outline=None)`

`turtle.turtlesize(stretch_wid=None, stretch_len=None, outline=None)`

**Paramètres**

- `stretch_wid` – positive number
- `stretch_len` – positive number
- `outline` – positive number

Return or set the pen's attributes x/y-stretchfactors and/or outline. Set `resizemode` to « user ». If and only if `resizemode` is set to « user », the turtle will be displayed stretched according to its stretchfactors : *stretch\_wid* is stretchfactor perpendicular to its orientation, *stretch\_len* is stretchfactor in direction of its orientation, *outline* determines the width of the shapes's outline.

```
>>> turtle.shapesize()
(1, 1, 1)
>>> turtle.resizemode("user")
>>> turtle.shapesize(5, 5, 12)
>>> turtle.shapesize()
(5, 5, 12)
>>> turtle.shapesize(outline=8)
>>> turtle.shapesize()
(5, 5, 8)
```

`turtle.tilt(angle)`

**Paramètres** *angle* – a number

Rotate the turtleshape by *angle* from its current tilt-angle, but do *not* change the turtle's heading (direction of movement).

```
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(30)
>>> turtle.fd(50)
>>> turtle.tilt(30)
>>> turtle.fd(50)
```

`turtle.settiltangle(angle)`

**Paramètres** *angle* – a number

Rotate the turtleshape to point in the direction specified by *angle*, regardless of its current tilt-angle. *Do not* change the turtle's heading (direction of movement).

```
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.settiltangle(45)
>>> turtle.fd(50)
>>> turtle.settiltangle(-45)
>>> turtle.fd(50)
```

`turtle.tiltangle()`

Return the current tilt-angle, i.e. the angle between the orientation of the turtleshape and the heading of the turtle (its direction of movement).

```
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(45)
>>> turtle.tiltangle()
45.0
```

## Using events

`turtle.onclick(fun, btn=1, add=None)`

### Paramètres

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – **True** or **False** – if **True**, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-click events on this turtle. If *fun* is **None**, existing bindings are removed. Example for the anonymous turtle, i.e. the procedural way :

```
>>> def turn(x, y):
...     left(180)
...
>>> onclick(turn)  # Now clicking into the turtle will turn it.
>>> onclick(None)  # event-binding will be removed
```

`turtle.onrelease(fun, btn=1, add=None)`

### Paramètres

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – **True** or **False** – if **True**, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-button-release events on this turtle. If *fun* is **None**, existing bindings are removed.

```
>>> class MyTurtle(Turtle):
...     def glow(self,x,y):
...         self.fillcolor("red")
...     def unglow(self,x,y):
...         self.fillcolor("")
...
>>> turtle = MyTurtle()
>>> turtle.onclick(turtle.glow)      # clicking on turtle turns fillcolor red,
>>> turtle.onrelease(turtle.unglow)  # releasing turns it to transparent.
```

`turtle.ondrag(fun, btn=1, add=None)`

### Paramètres

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – **True** or **False** – if **True**, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-move events on this turtle. If *fun* is **None**, existing bindings are removed.

Remark : Every sequence of mouse-move-events on a turtle is preceded by a mouse-click event on that turtle.

```
>>> turtle.ondrag(turtle.goto)
```

Subsequently, clicking and dragging the Turtle will move it across the screen thereby producing hand-drawings (if pen is down).

`turtle.mainloop()`

`turtle.done()`

Starts event loop - calling Tkinter's mainloop function. Must be the last statement in a turtle graphics program.

```
>>> turtle.mainloop()
```

### Special Turtle methods

`turtle.begin_poly()`

Start recording the vertices of a polygon. Current turtle position is first vertex of polygon.

`turtle.end_poly()`

Stop recording the vertices of a polygon. Current turtle position is last vertex of polygon. This will be connected with the first vertex.

`turtle.get_poly()`

Return the last recorded polygon.

```
>>> turtle.home()
>>> turtle.begin_poly()
>>> turtle.fd(100)
>>> turtle.left(20)
>>> turtle.fd(30)
>>> turtle.left(60)
>>> turtle.fd(50)
>>> turtle.end_poly()
>>> p = turtle.get_poly()
>>> register_shape("myFavouriteShape", p)
```

`turtle.clone()`

Create and return a clone of the turtle with same position, heading and turtle properties.

```
>>> mick = Turtle()
>>> joe = mick.clone()
```

`turtle.getturtle()`

`turtle.getpen()`

Return the Turtle object itself. Only reasonable use : as a function to return the « anonymous turtle » :

```
>>> pet = getturtle()
>>> pet.fd(50)
>>> pet
<turtle.Turtle object at 0x...>
```

`turtle.getscreen()`

Return the *TurtleScreen* object the turtle is drawing on. TurtleScreen methods can then be called for that object.

```
>>> ts = turtle.getscreen()
>>> ts
<turtle._Screen object at 0x...>
>>> ts.bgcolor("pink")
```

`turtle.setundobuffer(size)`

Paramètres **size** – an integer or None

Set or disable undobuffer. If *size* is an integer an empty undobuffer of given size is installed. *size* gives the maximum number of turtle actions that can be undone by the `undo()` method/function. If *size* is `None`, the undobuffer is disabled.

```
>>> turtle.setundobuffer(42)
```

`turtle.undobufferentries()`

Return number of entries in the undobuffer.

```
>>> while undobufferentries():
...     undo()
```

`turtle.tracer(flag=None, delay=None)`

A replica of the corresponding TurtleScreen method.

Obsolète depuis la version 2.6.

`turtle.window_width()`

`turtle.window_height()`

Both are replicas of the corresponding TurtleScreen methods.

Obsolète depuis la version 2.6.

### Excursus about the use of compound shapes

To use compound turtle shapes, which consist of several polygons of different color, you must use the helper class *Shape* explicitly as described below :

1. Create an empty Shape object of type « compound ».
2. Add as many components to this object as desired, using the `addcomponent()` method.

Par exemple :

```
>>> s = Shape("compound")
>>> poly1 = ((0,0),(10,-5),(0,10),(-10,-5))
>>> s.addcomponent(poly1, "red", "blue")
>>> poly2 = ((0,0),(10,-5),(-10,-5))
>>> s.addcomponent(poly2, "blue", "red")
```

3. Now add the Shape to the Screen's shapelist and use it :

```
>>> register_shape("myshape", s)
>>> shape("myshape")
```

**Note :** The *Shape* class is used internally by the `register_shape()` method in different ways. The application programmer has to deal with the Shape class *only* when using compound shapes like shown above !

## 24.5.4 Methods of TurtleScreen/Screen and corresponding functions

Most of the examples in this section refer to a TurtleScreen instance called `screen`.

### Window control

`turtle.bgcolor(*args)`

**Paramètres `args`** – a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers

Set or return background color of the TurtleScreen.

```
>>> screen.bgcolor("orange")
>>> screen.bgcolor()
'orange'
>>> screen.bgcolor("#800080")
>>> screen.bgcolor()
(128, 0, 128)
```

`turtle.bgpic(picname=None)`

**Paramètres** `picname` – a string, name of a gif-file or "nopic", or None

Set background image or return name of current backgroundimage. If *picname* is a filename, set the corresponding image as background. If *picname* is "nopic", delete background image, if present. If *picname* is None, return the filename of the current backgroundimage.

```
>>> screen.bgpic()
'nopic'
>>> screen.bgpic("landscape.gif")
>>> screen.bgpic()
"landscape.gif"
```

`turtle.clear()`

`turtle.clearscreen()`

Delete all drawings and all turtles from the TurtleScreen. Reset the now empty TurtleScreen to its initial state : white background, no background image, no event bindings and tracing on.

---

**Note :** This TurtleScreen method is available as a global function only under the name `clearscreen`. The global function `clear` is another one derived from the Turtle method `clear`.

---

`turtle.reset()`

`turtle.resetscreen()`

Reset all Turtles on the Screen to their initial state.

---

**Note :** This TurtleScreen method is available as a global function only under the name `resetscreen`. The global function `reset` is another one derived from the Turtle method `reset`.

---

`turtle.screensize(canvwidth=None, canvheight=None, bg=None)`

**Paramètres**

- **canvwidth** – positive integer, new width of canvas in pixels
- **canvheight** – positive integer, new height of canvas in pixels
- **bg** – colorstring or color-tuple, new background color

If no arguments are given, return current (canvaswidth, canvasheight). Else resize the canvas the turtles are drawing on. Do not alter the drawing window. To observe hidden parts of the canvas, use the scrollbars. With this method, one can make visible those parts of a drawing which were outside the canvas before.

```
>>> screen.screensize()
(400, 300)
>>> screen.screensize(2000,1500)
>>> screen.screensize()
(2000, 1500)
```

e.g. to search for an erroneously escaped turtle;-)

`turtle.setworldcoordinates(llx, lly, urx, ury)`

**Paramètres**

- **llx** – a number, x-coordinate of lower left corner of canvas
- **lly** – a number, y-coordinate of lower left corner of canvas
- **urx** – a number, x-coordinate of upper right corner of canvas
- **ury** – a number, y-coordinate of upper right corner of canvas

Set up user-defined coordinate system and switch to mode « world » if necessary. This performs a `screen.reset()`. If mode « world » is already active, all drawings are redrawn according to the new coordinates.

**ATTENTION** : in user-defined coordinate systems angles may appear distorted.

```
>>> screen.reset()
>>> screen.setworldcoordinates(-50,-7.5,50,7.5)
>>> for _ in range(72):
...     left(10)
...
>>> for _ in range(8):
...     left(45); fd(2)    # a regular octagon
```

**Animation control**

`turtle.delay(delay=None)`

**Paramètres** **delay** – positive integer

Set or return the drawing *delay* in milliseconds. (This is approximately the time interval between two consecutive canvas updates.) The longer the drawing delay, the slower the animation.

Optional argument :

```
>>> screen.delay()
10
>>> screen.delay(5)
>>> screen.delay()
5
```

`turtle.tracer(n=None, delay=None)`

**Paramètres**

- **n** – nonnegative integer
- **delay** – nonnegative integer

Turn turtle animation on/off and set delay for update drawings. If *n* is given, only each *n*-th regular screen update is really performed. (Can be used to accelerate the drawing of complex graphics.) Second argument sets delay value (see `delay()`).

```
>>> screen.tracer(8, 25)
>>> dist = 2
>>> for i in range(200):
...     fd(dist)
...     rt(90)
...     dist += 2
```

`turtle.update()`

Perform a TurtleScreen update. To be used when tracer is turned off.

See also the RawTurtle/Turtle method `speed()`.

### Using screen events

`turtle.listen(xdummy=None, ydummy=None)`

Set focus on TurtleScreen (in order to collect key-events). Dummy arguments are provided in order to be able to pass `listen()` to the onclick method.

`turtle.onkey(fun, key)`

#### Paramètres

- **fun** – a function with no arguments or **None**
- **key** – a string : key (e.g. « a ») or key-symbol (e.g. « space »)

Bind *fun* to key-release event of key. If *fun* is **None**, event bindings are removed. Remark : in order to be able to register key-events, TurtleScreen must have the focus. (See method `listen()`.)

```
>>> def f():
...     fd(50)
...     lt(60)
...
>>> screen.onkey(f, "Up")
>>> screen.listen()
```

`turtle.onclick(fun, btn=1, add=None)`

`turtle.onscreenclick(fun, btn=1, add=None)`

#### Paramètres

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – True or False – if **True**, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-click events on this screen. If *fun* is **None**, existing bindings are removed.

Example for a TurtleScreen instance named **screen** and a Turtle instance named **turtle** :

```
>>> screen.onclick(turtle.goto) # Subsequently clicking into the TurtleScreen will
>>>                               # make the turtle move to the clicked point.
>>> screen.onclick(None)        # remove event binding again
```

---

**Note :** This TurtleScreen method is available as a global function only under the name **onscreenclick**. The global function **onclick** is another one derived from the Turtle method **onclick**.

---

`turtle.ontimer(fun, t=0)`

#### Paramètres

- **fun** – a function with no arguments
- **t** – a number  $\geq 0$

Install a timer that calls *fun* after *t* milliseconds.

```
>>> running = True
>>> def f():
...     if running:
...         fd(50)
...         lt(60)
...         screen.ontimer(f, 250)
>>> f()    ### makes the turtle march around
>>> running = False
```

## Settings and special methods

`turtle.mode(mode=None)`

**Paramètres** `mode` – one of the strings « standard », « logo » or « world »

Set turtle mode (« standard », « logo » or « world ») and perform reset. If mode is not given, current mode is returned.

Mode « standard » is compatible with old *turtle*. Mode « logo » is compatible with most Logo turtle graphics. Mode « world » uses user-defined « world coordinates ». **Attention** : in this mode angles appear distorted if x/y unit-ratio doesn't equal 1.

Mode	Initial turtle heading	positive angles
« standard »	to the right (east)	counterclockwise
« logo »	upward (north)	clockwise

```
>>> mode("logo")    # resets turtle heading to north
>>> mode()
'logo'
```

`turtle.colormode(cmode=None)`

**Paramètres** `cmode` – one of the values 1.0 or 255

Return the colormode or set it to 1.0 or 255. Subsequently *r*, *g*, *b* values of color triples have to be in the range 0..*cmode*.

```
>>> screen.colormode(1)
>>> turtle.pencolor(240, 160, 80)
Traceback (most recent call last):
...
TurtleGraphicsError: bad color sequence: (240, 160, 80)
>>> screen.colormode()
1.0
>>> screen.colormode(255)
>>> screen.colormode()
255
>>> turtle.pencolor(240,160,80)
```

`turtle.getcanvas()`

Return the Canvas of this TurtleScreen. Useful for insiders who know what to do with a Tkinter Canvas.

```
>>> cv = screen.getcanvas()
>>> cv
<turtle.ScrolledCanvas instance at 0x...>
```

`turtle.getshapes()`

Return a list of names of all currently available turtle shapes.

```
>>> screen.getshapes()
['arrow', 'blank', 'circle', ..., 'turtle']
```

`turtle.register_shape(name, shape=None)`

`turtle.addshape(name, shape=None)`

There are three different ways to call this function :

- (1) *name* is the name of a gif-file and *shape* is `None` : Install the corresponding image shape.

```
>>> screen.register_shape("turtle.gif")
```

**Note :** Image shapes *do not* rotate when turning the turtle, so they do not display the heading of the turtle!

- (2) *name* is an arbitrary string and *shape* is a tuple of pairs of coordinates : Install the corresponding polygon shape.

```
>>> screen.register_shape("triangle", ((5,-3), (0,5), (-5,-3)))
```

- (3) *name* is an arbitrary string and *shape* is a (compound) *Shape* object : Install the corresponding compound shape.

Add a turtle shape to TurtleScreen's shapelist. Only thusly registered shapes can be used by issuing the command `shape(shapename)`.

`turtle.turtles()`

Return the list of turtles on the screen.

```
>>> for turtle in screen.turtles():  
...     turtle.color("red")
```

`turtle.window_height()`

Return the height of the turtle window.

```
>>> screen.window_height()  
480
```

`turtle.window_width()`

Return the width of the turtle window.

```
>>> screen.window_width()  
640
```

### Methods specific to Screen, not inherited from TurtleScreen

`turtle.bye()`

Shut the turtlegraphics window.

`turtle.exitonclick()`

Bind `bye()` method to mouse clicks on the Screen.

If the value « `using_IDLE` » in the configuration dictionary is **False** (default value), also enter main-loop. Remark : If IDLE with the `-n` switch (no subprocess) is used, this value should be set to **True** in `turtle.cfg`. In this case IDLE's own mainloop is active also for the client script.

`turtle.setup(width=_CFG["width"], height=_CFG["height"], startx=_CFG["leftright"], starty=_CFG["topbottom"])`

Set the size and position of the main window. Default values of arguments are stored in the configuration dictionary and can be changed via a `turtle.cfg` file.

#### Paramètres

- **width** – if an integer, a size in pixels, if a float, a fraction of the screen ; default is 50% of screen
- **height** – if an integer, the height in pixels, if a float, a fraction of the screen ; default is 75% of screen
- **startx** – if positive, starting position in pixels from the left edge of the screen, if negative from the right edge, if **None**, center window horizontally

- **starty** – if positive, starting position in pixels from the top edge of the screen, if negative from the bottom edge, if `None`, center window vertically

```
>>> screen.setup (width=200, height=200, startx=0, starty=0)
>>>           # sets window to 200x200 pixels, in upper left of screen
>>> screen.setup(width=.75, height=0.5, startx=None, starty=None)
>>>           # sets window to 75% of screen by 50% of screen and centers
```

`turtle.title(titlestring)`

**Paramètres** `titlestring` – a string that is shown in the titlebar of the turtle graphics window

Set title of turtle window to *titlestring*.

```
>>> screen.title("Welcome to the turtle zoo!")
```

### 24.5.5 The public classes of the module turtle

`class turtle.RawTurtle(canvas)`

`class turtle.RawPen(canvas)`

**Paramètres** `canvas` – a `Tkinter.Canvas`, a *ScrolledCanvas* or a *TurtleScreen*

Create a turtle. The turtle has all methods described above as « methods of Turtle/RawTurtle ».

`class turtle.Turtle`

Subclass of `RawTurtle`, has the same interface but draws on a default *Screen* object created automatically when needed for the first time.

`class turtle.TurtleScreen(cv)`

**Paramètres** `cv` – a `Tkinter.Canvas`

Provides screen oriented methods like `setbg()` etc. that are described above.

`class turtle.Screen`

Subclass of `TurtleScreen`, with *four methods added*.

`class turtle.ScrolledCanvas(master)`

**Paramètres** `master` – some `Tkinter` widget to contain the `ScrolledCanvas`, i.e. a `Tkinter`-canvas with scrollbars added

Used by class `Screen`, which thus automatically provides a `ScrolledCanvas` as playground for the turtles.

`class turtle.Shape(type_, data)`

**Paramètres** `type_` – one of the strings « `polygon` », « `image` », « `compound` »

Data structure modeling shapes. The pair (`type_`, `data`) must follow this specification :

<i>type_</i>	<i>data</i>
« <code>polygon</code> »	a polygon-tuple, i.e. a tuple of pairs of coordinates
« <code>image</code> »	an image (in this form only used internally!)
« <code>compound</code> »	<code>None</code> (a compound shape has to be constructed using the <i><code>addcomponent()</code></i> method)

`addcomponent(poly, fill, outline=None)`

**Paramètres**

- **poly** – a polygon, i.e. a tuple of pairs of numbers
- **fill** – a color the *poly* will be filled with
- **outline** – a color for the poly's outline (if given)

Exemple :

```
>>> poly = ((0,0),(10,-5),(0,10),(-10,-5))
>>> s = Shape("compound")
>>> s.addcomponent(poly, "red", "blue")
>>> # ... add more components and then use register_shape()
```

See *Excursus about the use of compound shapes*.

**class** turtle.**Vec2D**(*x, y*)

A two-dimensional vector class, used as a helper class for implementing turtle graphics. May be useful for turtle graphics programs too. Derived from tuple, so a vector is a tuple!

Provides (for *a, b* vectors, *k* number) :

- *a* + *b* vector addition
- *a* - *b* vector subtraction
- *a* \* *b* inner product
- *k* \* *a* and *a* \* *k* multiplication with scalar
- **abs**(*a*) absolute value of *a*
- *a*.**rotate**(*angle*) rotation

## 24.5.6 Help and configuration

### How to use help

The public methods of the Screen and Turtle classes are documented extensively via docstrings. So these can be used as online-help via the Python help facilities :

- When using IDLE, tooltips show the signatures and first lines of the docstrings of typed in function-/method calls.
- Calling *help()* on methods or functions displays the docstrings :

```
>>> help(Screen.bgcolor)
Help on method bgcolor in module turtle:

bgcolor(self, *args) unbound turtle.Screen method
    Set or return backgroundcolor of the TurtleScreen.

    Arguments (if given): a color string or three numbers
    in the range 0..colormode or a 3-tuple of such numbers.

    >>> screen.bgcolor("orange")
    >>> screen.bgcolor()
    "orange"
    >>> screen.bgcolor(0.5,0,0.5)
    >>> screen.bgcolor()
    "#800080"

>>> help(Turtle.penup)
Help on method penup in module turtle:

penup(self) unbound turtle.Turtle method
    Pull the pen up -- no drawing when moving.

    Aliases: penup | pu | up
```

(suite sur la page suivante)

(suite de la page précédente)

No argument

```
>>> turtle.penup()
```

- The docstrings of the functions which are derived from methods have a modified form :

```
>>> help(bgcolor)
Help on function bgcolor in module turtle:

bgcolor(*args)
    Set or return backgroundcolor of the TurtleScreen.

    Arguments (if given): a color string or three numbers
    in the range 0..colormode or a 3-tuple of such numbers.

    Example::

    >>> bgcolor("orange")
    >>> bgcolor()
    "orange"
    >>> bgcolor(0.5,0,0.5)
    >>> bgcolor()
    "#800080"

>>> help(penup)
Help on function penup in module turtle:

penup()
    Pull the pen up -- no drawing when moving.

    Aliases: penup | pu | up

    No argument

    Example:
    >>> penup()
```

These modified docstrings are created automatically together with the function definitions that are derived from the methods at import time.

### Translation of docstrings into different languages

There is a utility to create a dictionary the keys of which are the method names and the values of which are the docstrings of the public methods of the classes Screen and Turtle.

```
turtle.write_docstringdict(filename="turtle_docstringdict")
```

**Paramètres filename** – a string, used as filename

Create and write docstring-dictionary to a Python script with the given filename. This function has to be called explicitly (it is not used by the turtle graphics classes). The docstring dictionary will be written to the Python script *filename.py*. It is intended to serve as a template for translation of the docstrings into different languages.

If you (or your students) want to use *turtle* with online help in your native language, you have to translate the docstrings and save the resulting file as e.g. *turtle\_docstringdict\_german.py*.

If you have an appropriate entry in your `turtle.cfg` file this dictionary will be read in at import time and will replace the original English docstrings.

At the time of this writing there are docstring dictionaries in German and in Italian. (Requests please to [glingsl@aon.at](mailto:glingsl@aon.at).)

### How to configure Screen and Turtles

The built-in default configuration mimics the appearance and behaviour of the old turtle module in order to retain best possible compatibility with it.

If you want to use a different configuration which better reflects the features of this module or which better fits to your needs, e.g. for use in a classroom, you can prepare a configuration file `turtle.cfg` which will be read at import time and modify the configuration according to its settings.

The built in configuration would correspond to the following `turtle.cfg` :

```
width = 0.5
height = 0.75
leftright = None
topbottom = None
canvwidth = 400
canvheight = 300
mode = standard
colormode = 1.0
delay = 10
undobuffersize = 1000
shape = classic
pencolor = black
fillcolor = black
resizemode = noresize
visible = True
language = english
exampleturtle = turtle
examplescreen = screen
title = Python Turtle Graphics
using_IDLE = False
```

Short explanation of selected entries :

- The first four lines correspond to the arguments of the `Screen.setup()` method.
- Line 5 and 6 correspond to the arguments of the method `Screen.screensize()`.
- `shape` can be any of the built-in shapes, e.g. : `arrow`, `turtle`, etc. For more info try `help(shape)`.
- If you want to use no fillcolor (i.e. make the turtle transparent), you have to write `fillcolor = ""` (but all nonempty strings must not have quotes in the `cfg`-file).
- If you want to reflect the turtle its state, you have to use `resizemode = auto`.
- If you set e.g. `language = italian` the docstringdict `turtle_docstringdict_italian.py` will be loaded at import time (if present on the import path, e.g. in the same directory as `turtle`).
- The entries `exampleturtle` and `examplescreen` define the names of these objects as they occur in the docstrings. The transformation of method-docstrings to function-docstrings will delete these names from the docstrings.
- `using_IDLE` : Set this to `True` if you regularly work with IDLE and its `-n` switch (« no subprocess »). This will prevent `exitonclick()` to enter the mainloop.

There can be a `turtle.cfg` file in the directory where `turtle` is stored and an additional one in the current working directory. The latter will override the settings of the first one.

The `Demo/turtle` directory contains a `turtle.cfg` file. You can study it as an example and see its effects when running the demos (preferably not from within the demo-viewer).

## 24.5.7 Demo scripts

There is a set of demo scripts in the `turtledemo` directory located in the `Demo/turtle` directory in the source distribution.

It contains :

- a set of 15 demo scripts demonstrating different features of the new module `turtle`
- a demo viewer `turtleDemo.py` which can be used to view the sourcecode of the scripts and run them at the same time. 14 of the examples can be accessed via the Examples menu ; all of them can also be run standalone.
- The example `turtledemo_two_cavases.py` demonstrates the simultaneous use of two canvases with the turtle module. Therefore it only can be run standalone.
- There is a `turtle.cfg` file in this directory, which also serves as an example for how to write and use such files.

The demoscripts are :

Nom	Description	Features
bytedesign	complex classical turtlegraphics pattern	<code>tracer()</code> , delay, <code>update()</code>
chaos	graphs Verhulst dynamics, shows that computer's computations can generate results sometimes against the common sense expectations	world coordinates
clock	analog clock showing time of your computer	turtles as clock's hands, ontimer
colormixer	experiment with r, g, b	<code>ondrag()</code>
fractalcurves	Hilbert & Koch curves	recursion
lindenmayer	ethnomathematics (indian kolams)	L-System
minimal_hanoi	Towers of Hanoi	Rectangular Turtles as Hanoi discs (shape, shapeseize)
paint	super minimalistic drawing program	<code>onclick()</code>
peace	elementary	turtle : appearance and animation
penrose	aperiodic tiling with kites and darts	<code>stamp()</code>
planet_and_moon	simulation of gravitational system	compound shapes, <code>Vec2D</code>
tree	a (graphical) breadth first tree (using generators)	<code>clone()</code>
wikipedia	a pattern from the wikipedia article on turtle graphics	<code>clone()</code> , <code>undo()</code>
yinyang	another elementary example	<code>circle()</code>

Have fun !

## 24.6 IDLE

IDLE is Python's Integrated Development and Learning Environment.

IDLE has the following features :

- coded in 100% pure Python, using the `tkinter` GUI toolkit
- cross-platform : works mostly the same on Windows, Unix, and Mac OS X
- Python shell window (interactive interpreter) with colorizing of code input, output, and error messages
- multi-window text editor with multiple undo, Python colorizing, smart indent, call tips, auto completion, and other features
- search within any window, replace within editor windows, and search through multiple files (grep)
- debugger with persistent breakpoints, stepping, and viewing of global and local namespaces

— configuration, browsers, and other dialogs

### 24.6.1 Menus

IDLE has two main window types, the Shell window and the Editor window. It is possible to have multiple editor windows simultaneously. Output windows, such as used for Edit / Find in Files, are a subtype of edit window. They currently have the same top menu as Editor windows but a different default title and context menu.

IDLE's menus dynamically change based on which window is currently selected. Each menu documented below indicates which window type it is associated with.

#### File menu (Shell and Editor)

**New File** Create a new file editing window.

**Open...** Open an existing file with an Open dialog.

**Recent Files** Open a list of recent files. Click one to open it.

**Open Module...** Open an existing module (searches sys.path).

**Class Browser** Show functions, classes, and methods in the current Editor file in a tree structure. In the shell, open a module first.

**Path Browser** Show sys.path directories, modules, functions, classes and methods in a tree structure.

**Save** Save the current window to the associated file, if there is one. Windows that have been changed since being opened or last saved have a \* before and after the window title. If there is no associated file, do Save As instead.

**Save As...** Save the current window with a Save As dialog. The file saved becomes the new associated file for the window.

**Save Copy As...** Save the current window to different file without changing the associated file.

**Print Window** Print the current window to the default printer.

**Close** Close the current window (ask to save if unsaved).

**Exit** Close all windows and quit IDLE (ask to save unsaved windows).

#### Edit menu (Shell and Editor)

**Undo** Undo the last change to the current window. A maximum of 1000 changes may be undone.

**Redo** Redo the last undone change to the current window.

**Cut** Copy selection into the system-wide clipboard; then delete the selection.

**Copy** Copy selection into the system-wide clipboard.

**Paste** Insert contents of the system-wide clipboard into the current window.

The clipboard functions are also available in context menus.

**Select All** Select the entire contents of the current window.

**Find...** Open a search dialog with many options

**Find Again** Repeat the last search, if there is one.

**Find Selection** Search for the currently selected string, if there is one.

**Find in Files...** Open a file search dialog. Put results in a new output window.

**Replace...** Open a search-and-replace dialog.

**Go to Line** Move cursor to the line number requested and make that line visible.

**Show Completions** Open a scrollable list allowing selection of keywords and attributes. See Completions in the Tips sections below.

**Expand Word** Expand a prefix you have typed to match a full word in the same window; repeat to get a different expansion.

**Show call tip** After an unclosed parenthesis for a function, open a small window with function parameter hints.

**Show surrounding parens** Highlight the surrounding parenthesis.

#### Format menu (Editor window only)

**Indent Region** Shift selected lines right by the indent width (default 4 spaces).

**Dedent Region** Shift selected lines left by the indent width (default 4 spaces).

**Comment Out Region** Insert `##` in front of selected lines.

**Uncomment Region** Remove leading `#` or `##` from selected lines.

**Tabify Region** Turn *leading* stretches of spaces into tabs. (Note : We recommend using 4 space blocks to indent Python code.)

**Untabify Region** Turn *all* tabs into the correct number of spaces.

**Toggle Tabs** Open a dialog to switch between indenting with spaces and tabs.

**New Indent Width** Open a dialog to change indent width. The accepted default by the Python community is 4 spaces.

**Format Paragraph** Reformat the current blank-line-delimited paragraph in comment block or multiline string or selected line in a string. All lines in the paragraph will be formatted to less than N columns, where N defaults to 72.

**Strip trailing whitespace** Remove any space characters after the last non-space character of a line.

#### Run menu (Editor window only)

**Python Shell** Open or wake up the Python Shell window.

**Check Module** Check the syntax of the module currently open in the Editor window. If the module has not been saved IDLE will either prompt the user to save or autosave, as selected in the General tab of the Idle Settings dialog. If there is a syntax error, the approximate location is indicated in the Editor window.

**Run Module** Do Check Module (above). If no error, restart the shell to clean the environment, then execute the module. Output is displayed in the Shell window. Note that output requires use of `print` or `write`. When execution is complete, the Shell retains focus and displays a prompt. At this point, one may interactively explore the result of execution. This is similar to executing a file with `python -i file` at a command line.

#### Shell menu (Shell window only)

**View Last Restart** Scroll the shell window to the last Shell restart.

**Restart Shell** Restart the shell to clean the environment.

**Interrupt Execution** Stop a running program.

#### Debug menu (Shell window only)

**Go to File/Line** Look on the current line, with the cursor, and the line above for a filename and line number. If found, open the file if not already open, and show the line. Use this to view source lines referenced in an exception traceback and lines found by Find in Files. Also available in the context menu of the Shell window and Output windows.

**Debugger (toggle)** When activated, code entered in the Shell or run from an Editor will run under the debugger. In the Editor, breakpoints can be set with the context menu. This feature is still incomplete and somewhat experimental.

**Stack Viewer** Show the stack traceback of the last exception in a tree widget, with access to locals and globals.

**Auto-open Stack Viewer** Toggle automatically opening the stack viewer on an unhandled exception.

### Options menu (Shell and Editor)

**Configure IDLE** Open a configuration dialog and change preferences for the following : fonts, indentation, keybindings, text color themes, startup windows and size, additional help sources, and extensions (see below). On OS X, open the configuration dialog by selecting Preferences in the application menu. To use a new built-in color theme (IDLE Dark) with older IDLEs, save it as a new custom theme.

Non-default user settings are saved in a .idlerc directory in the user's home directory. Problems caused by bad user configuration files are solved by editing or deleting one or more of the files in .idlerc.

**Code Context (toggle)(Editor Window only)** Open a pane at the top of the edit window which shows the block context of the code which has scrolled above the top of the window.

### Window menu (Shell and Editor)

**Zoom Height** Toggles the window between normal size and maximum height. The initial size defaults to 40 lines by 80 chars unless changed on the General tab of the Configure IDLE dialog.

The rest of this menu lists the names of all open windows ; select one to bring it to the foreground (deiconifying it if necessary).

### Help menu (Shell and Editor)

**About IDLE** Display version, copyright, license, credits, and more.

**IDLE Help** Display a help file for IDLE detailing the menu options, basic editing and navigation, and other tips.

**Python Docs** Access local Python documentation, if installed, or start a web browser and open docs.python.org showing the latest Python documentation.

**Turtle Demo** Run the turtledemo module with example python code and turtle drawings.

Additional help sources may be added here with the Configure IDLE dialog under the General tab.

### Context Menus

Open a context menu by right-clicking in a window (Control-click on OS X). Context menus have the standard clipboard functions also on the Edit menu.

**Cut** Copy selection into the system-wide clipboard ; then delete the selection.

**Copy** Copy selection into the system-wide clipboard.

**Paste** Insert contents of the system-wide clipboard into the current window.

Editor windows also have breakpoint functions. Lines with a breakpoint set are specially marked. Breakpoints only have an effect when running under the debugger. Breakpoints for a file are saved in the user's .idlerc directory.

**Set Breakpoint** Set a breakpoint on the current line.

**Clear Breakpoint** Clear the breakpoint on that line.

Shell and Output windows have the following.

**Go to file/line** Same as in Debug menu.

## 24.6.2 Editing and navigation

In this section, “C” refers to the **Control** key on Windows and Unix and the **Command** key on Mac OSX.

- **Backspace** deletes to the left ; **Del** deletes to the right
- **C-Backspace** delete word left ; **C-Del** delete word to the right
- Arrow keys and **Page Up**/**Page Down** to move around
- **C-LeftArrow** and **C-RightArrow** moves by words
- **Home**/**End** go to begin/end of line
- **C-Home**/**C-End** go to begin/end of file
- Some useful Emacs bindings are inherited from Tcl/Tk :
  - **C-a** beginning of line
  - **C-e** end of line
  - **C-k** kill line (but doesn't put it in clipboard)
  - **C-l** center window around the insertion point
  - **C-b** go backward one character without deleting (usually you can also use the cursor key for this)
  - **C-f** go forward one character without deleting (usually you can also use the cursor key for this)
  - **C-p** go up one line (usually you can also use the cursor key for this)
  - **C-d** delete next character

Standard keybindings (like **C-c** to copy and **C-v** to paste) may work. Keybindings are selected in the Configure IDLE dialog.

### Automatic indentation

After a block-opening statement, the next line is indented by 4 spaces (in the Python Shell window by one tab). After certain keywords (break, return etc.) the next line is dedented. In leading indentation, **Backspace** deletes up to 4 spaces if they are there. **Tab** inserts spaces (in the Python Shell window one tab), number depends on Indent width. Currently, tabs are restricted to four spaces due to Tcl/Tk limitations.

See also the indent/dedent region commands in the edit menu.

### Completions

Completions are supplied for functions, classes, and attributes of classes, both built-in and user-defined. Completions are also provided for filenames.

The `AutoCompleteWindow` (ACW) will open after a predefined delay (default is two seconds) after a “.” or (in a string) an `os.sep` is typed. If after one of those characters (plus zero or more other characters) a tab is typed the ACW will open immediately if a possible continuation is found.

If there is only one possible completion for the characters entered, a **Tab** will supply that completion without opening the ACW.

“Show Completions” will force open a completions window, by default the **C-space** will open a completions window. In an empty string, this will contain the files in the current directory. On a blank line, it will contain the built-in and user-defined functions and classes in the current namespaces, plus any modules imported. If some characters have been entered, the ACW will attempt to be more specific.

If a string of characters is typed, the ACW selection will jump to the entry most closely matching those characters. Entering a **tab** will cause the longest non-ambiguous match to be entered in the Editor window or Shell. Two **tab** in a row will supply the current ACW selection, as will return or a double click. Cursor keys, **Page Up**/**Page Down**, mouse selection, and the scroll wheel all operate on the ACW.

« Hidden » attributes can be accessed by typing the beginning of hidden name after a “.”, e.g. “.”. This allows access to modules with `__all__` set, or to class-private attributes.

Completions and the “Expand Word” facility can save a lot of typing!

Completions are currently limited to those in the namespaces. Names in an Editor window which are not via `__main__` and `sys.modules` will not be found. Run the module once with your imports to correct this

situation. Note that IDLE itself places quite a few modules in `sys.modules`, so much can be found by default, e.g. the `re` module.

If you don't like the ACW popping up unbidden, simply make the delay longer or disable the extension.

### Calltips

A calltip is shown when one types `(` after the name of an *accessible* function. A name expression may include dots and subscripts. A calltip remains until it is clicked, the cursor is moved out of the argument area, or `)` is typed. When the cursor is in the argument part of a definition, the menu or shortcut display a calltip.

A calltip consists of the function signature and the first line of the docstring. For builtins without an accessible signature, the calltip consists of all lines up the fifth line or the first blank line. These details may change.

The set of *accessible* functions depends on what modules have been imported into the user process, including those imported by Idle itself, and what definitions have been run, all since the last restart.

For example, restart the Shell and enter `itertools.count()`. A calltip appears because Idle imports `itertools` into the user process for its own use. (This could change.) Enter `turtle.write()` and nothing appears. Idle does not import `turtle`. The menu or shortcut do nothing either. Enter `import turtle` and then `turtle.write()` will work.

In an editor, import statements have no effect until one runs the file. One might want to run a file after writing the import statements at the top, or immediately run an existing file before editing.

### Python Shell window

- **C-c** interrupts executing command
- **C-d** sends end-of-file; closes window if typed at a `>>>` prompt
- **Alt-/** (Expand word) is also useful to reduce typing
- Command history
  - **Alt-p** retrieves previous command matching what you have typed. On OS X use **C-p**.
  - **Alt-n** retrieves next. On OS X use **C-n**.
- **Return** while on any previous command retrieves that command

### Text colors

Idle defaults to black on white text, but colors text with special meanings. For the shell, these are shell output, shell error, user output, and user error. For Python code, at the shell prompt or in an editor, these are keywords, builtin class and function names, names following `class` and `def`, strings, and comments. For any text window, these are the cursor (when present), found text (when possible), and selected text.

Text coloring is done in the background, so uncolored text is occasionally visible. To change the color scheme, use the Configure IDLE dialog Highlighting tab. The marking of debugger breakpoint lines in the editor and text in popups and dialogs is not user-configurable.

## 24.6.3 Startup and code execution

Upon startup with the `-s` option, IDLE will execute the file referenced by the environment variables `IDLESTARTUP` or `PYTHONSTARTUP`. IDLE first checks for `IDLESTARTUP`; if `IDLESTARTUP` is present the file referenced is run. If `IDLESTARTUP` is not present, IDLE checks for `PYTHONSTARTUP`. Files referenced by these environment variables are convenient places to store functions that are used frequently from the IDLE shell, or for executing import statements to import common modules.

In addition, Tk also loads a startup file if it is present. Note that the Tk file is loaded unconditionally. This additional file is `.Idle.py` and is looked for in the user's home directory. Statements in this file will be executed in the Tk namespace, so this file is not useful for importing functions to be used from IDLE's Python shell.

## Command line usage

```
idle.py [-c command] [-d] [-e] [-h] [-i] [-r file] [-s] [-t title] [-] [arg] ...

-c command  run command in the shell window
-d          enable debugger and open shell window
-e          open editor window
-h          print help message with legal combinations and exit
-i          open shell window
-r file     run file in shell window
-s          run $IDLESTARTUP or $PYTHONSTARTUP first, in shell window
-t title    set title of shell window
-          run stdin in shell (- must be last option before args)
```

If there are arguments :

- If `-`, `-c`, or `r` is used, all arguments are placed in `sys.argv[1:...]` and `sys.argv[0]` is set to `'`, `'-c'`, or `'-r'`. No editor window is opened, even if that is the default set in the Options dialog.
- Otherwise, arguments are files opened for editing and `sys.argv` reflects the arguments passed to IDLE itself.

## IDLE-console differences

As much as possible, the result of executing Python code with IDLE is the same as executing the same code in a console window. However, the different interface and operation occasionally affect visible results. For instance, `sys.modules` starts with more entries.

IDLE also replaces `sys.stdin`, `sys.stdout`, and `sys.stderr` with objects that get input from and send output to the Shell window. When this window has the focus, it controls the keyboard and screen. This is normally transparent, but functions that directly access the keyboard and screen will not work. If `sys` is reset with `reload(sys)`, IDLE's changes are lost and things like `input`, `raw_input`, and `print` will not work correctly.

With IDLE's Shell, one enters, edits, and recalls complete statements. Some consoles only work with a single physical line at a time. IDLE uses `exec` to run each statement. As a result, `'__builtins__'` is always defined for each statement.

## Running without a subprocess

By default, IDLE executes user code in a separate subprocess via a socket, which uses the internal loopback interface. This connection is not externally visible and no data is sent to or received from the Internet. If firewall software complains anyway, you can ignore it.

If the attempt to make the socket connection fails, Idle will notify you. Such failures are sometimes transient, but if persistent, the problem may be either a firewall blocking the connection or misconfiguration of a particular system. Until the problem is fixed, one can run Idle with the `-n` command line switch.

If IDLE is started with the `-n` command line switch it will run in a single process and will not create the subprocess which runs the RPC Python execution server. This can be useful if Python cannot create the subprocess or the RPC socket interface on your platform. However, in this mode user code is not isolated from IDLE itself. Also, the environment is not restarted when Run/Run Module (F5) is selected. If your code has been modified, you must `reload()` the affected modules and re-import any specific items (e.g. from `foo import baz`) if the changes are to take effect. For these reasons, it is preferable to run IDLE with the default subprocess if at all possible.

Obsolète depuis la version 3.4.

## 24.6.4 Help and preferences

### Additional help sources

IDLE includes a help menu entry called « Python Docs » that will open the extensive sources of help, including tutorials, available at [docs.python.org](http://docs.python.org). Selected URLs can be added or removed from the help menu at any time using the Configure IDLE dialog. See the IDLE help option in the help menu of IDLE for more information.

### Setting preferences

The font preferences, highlighting, keys, and general preferences can be changed via Configure IDLE on the Option menu. Keys can be user defined ; IDLE ships with four built-in key sets. In addition, a user can create a custom key set in the Configure IDLE dialog under the keys tab.

### Extensions

IDLE contains an extension facility. Preferences for extensions can be changed with Configure Extensions. See the beginning of `config-extensions.def` in the `idlelib` directory for further information. The default extensions are currently :

- `FormatParagraph`
- `AutoExpand`
- `ZoomHeight`
- `ScriptBinding`
- `CallTips`
- `ParenMatch`
- `AutoComplete`
- `CodeContext`
- `RstripExtension`

## 24.7 Autres paquets d'interface graphique utilisateur

Des boîtes à outils multiplateformes (Windows, Mac OS X ou Unix et assimilé) majeures sont disponibles pour Python :

**Voir aussi :**

**PyGTK** is a set of bindings for the **GTK** widget set. It provides an object oriented interface that is slightly higher level than the C one. It comes with many more widgets than Tkinter provides, and has good Python-specific reference documentation. There are also bindings to **GNOME**. An online [tutorial](#) is available.

**PyQt** PyQt is a **sip**-wrapped binding to the Qt toolkit. Qt is an extensive C++ GUI application development framework that is available for Unix, Windows and Mac OS X. **sip** is a tool for generating bindings for C++ libraries as Python classes, and is specifically designed for Python. The *PyQt3* bindings have a book, [GUI Programming with Python : QT Edition](#) by Boudewijn Rempt. The *PyQt4* bindings also have a book, [Rapid GUI Programming with Python and Qt](#), by Mark Summerfield.

**wxPython** wxPython is a cross-platform GUI toolkit for Python that is built around the popular **wxWidgets** (formerly **wxWindows**) C++ toolkit. It provides a native look and feel for applications on Windows, Mac OS X, and Unix systems by using each platform's native widgets where ever possible, (GTK+ on Unix-like systems). In addition to an extensive set of widgets, wxPython provides classes for online documentation and context sensitive help, printing, HTML viewing, low-level device context drawing, drag and drop, system clipboard access, an XML-based resource format and more, including an ever growing library of user-contributed modules. wxPython has a book, [wxPython in Action](#), by Noel Rappin and Robin Dunn.

*PyGTK*, *PyQt*, et *wxPython* fournissent tous un aspect et une expérience moderne ainsi que plus de composants graphiques que Tkinter. De plus, il y a de nombreuses autres boîtes à outils pour Python, que ce soit multiplateformes ou spécifiques à une plateforme. Consultez la page sur la [programmation d'interface graphique](#) du Wiki Python pour une liste bien plus complète, ainsi que des liens vers des documents où les différentes boîtes à outils graphiques sont comparées.

Les modules décrits dans ce chapitre vous aident à écrire des logiciels. Par exemple, le module *pydoc* prend un module et génère de la documentation basée sur son contenu. Les modules *doctest* et *unittest* contiennent des cadres applicatifs pour écrire des tests unitaires qui permettent de valider automatiquement le code en vérifiant que chaque résultat attendu est produit. Le programme **2to3** peut traduire du code Python 2.x en Python 3.x.

La liste des modules documentés dans ce chapitre est :

## 25.1 pydoc — Générateur de documentation et système d'aide en ligne

Nouveau dans la version 2.1.

**Code source :** [Lib/pydoc.py](#)

---

Le module *pydoc* génère automatiquement de la documentation à partir de modules Python. La documentation peut se présenter sous forme de pages de texte dans la console, rendue dans un navigateur web, ou sauvegardée dans des fichiers HTML.

Pour les modules, classes, fonctions et méthodes, la documentation affichée est tirée de la *docstring* (c.à.d de l'attribut `__doc__`) de l'objet et ce, de manière récursive pour les membres qui peuvent être documentés. S'il n'y a pas de *docstring*, *pydoc* essaie d'obtenir une description à partir du bloc de commentaires juste au-dessus de la définition de la classe, fonction ou méthode du fichier source, ou en haut du module (voir *inspect.getcomments()*).

La fonction intégrée *help()* appelle le système d'aide en ligne dans l'interpréteur Python qui utilise *pydoc* pour générer sa documentation sous forme textuelle dans la console. Cette même documentation peut aussi être consultée à l'extérieur de l'interpréteur Python en lançant **pydoc** dans le terminal du système d'exploitation. Par exemple en lançant :

```
pydoc sys
```

dans un terminal, cela affiche la documentation du module `sys` dans un style similaire à la commande Unix `man`. On peut passer comme argument à `pydoc` le nom d'une fonction, d'un module, d'un paquet, ou une référence pointant vers une classe, une méthode, ou une fonction dans un module ou dans un paquet. Si l'argument passé à `pydoc` est un chemin (c.à.d qu'il contient des séparateurs de chemin tels que la barre oblique / dans Unix), et fait référence à un fichier source Python existant, alors la documentation est générée pour ce fichier.

---

**Note :** Afin de trouver des objets et leur documentation, `pydoc` importe le ou les modules à documenter. Par conséquent tout code au niveau du module sera exécuté à cette occasion. Utiliser `if __name__ == '__main__':` évite d'exécuter du code lorsqu'un fichier est appelé directement et non pas importé.

---

Lorsque l'on affiche une sortie sur la console, `pydoc` essaye de créer une pagination pour faciliter la lecture. Si la variable d'environnement `PAGER` est configurée, `pydoc` utilise sa valeur comme programme de pagination.

Ajouter une option `-w` avant l'argument entraîne l'enregistrement de la documentation HTML générée dans un fichier du répertoire courant au lieu de l'afficher dans la console.

Ajouter une option `-w` avant l'argument cherche les lignes de résumé de tous les modules disponibles pour le mot clé donné comme argument, ceci à la manière de la commande Unix `man`. Les lignes de résumé d'un module sont les premières lignes de sa *docstring*.

You can also use `pydoc` to start an HTTP server on the local machine that will serve documentation to visiting Web browsers. `pydoc -p 1234` will start a HTTP server on port 1234, allowing you to browse the documentation at `http://localhost:1234/` in your preferred Web browser. `pydoc -g` will start the server and additionally bring up a small *Tkinter*-based graphical interface to help you search for documentation pages.

Quand `pydoc` génère de la documentation, il utilise l'environnement et le chemin courant pour localiser les modules. Ainsi, en invoquant les documents `pydoc spam` en précisant la version du module, vous obtenez le même résultat qu'en lançant l'interpréteur Python et en tapant la commande `import spam`.

Module docs for core modules are assumed to reside in <https://docs.python.org/library/>. This can be overridden by setting the `PYTHONDOS` environment variable to a different URL or to a local directory containing the Library Reference Manual pages.

## 25.2 doctest — Test interactive Python examples

The *doctest* module searches for pieces of text that look like interactive Python sessions, and then executes those sessions to verify that they work exactly as shown. There are several common ways to use doctest :

- To check that a module's docstrings are up-to-date by verifying that all interactive examples still work as documented.
- To perform regression testing by verifying that interactive examples from a test file or a test object work as expected.
- To write tutorial documentation for a package, liberally illustrated with input-output examples. Depending on whether the examples or the expository text are emphasized, this has the flavor of « *literate testing* » or « *executable documentation* ».

Here's a complete but small example module :

```
"""
This is the "example" module.

The example module supplies one function, factorial(). For example,

>>> factorial(5)
```

(suite sur la page suivante)

(suite de la page précédente)

```

120
"""

def factorial(n):
    """Return the factorial of n, an exact integer >= 0.

    If the result is small enough to fit in an int, return an int.
    Else return a long.

    >>> [factorial(n) for n in range(6)]
    [1, 1, 2, 6, 24, 120]
    >>> [factorial(long(n)) for n in range(6)]
    [1, 1, 2, 6, 24, 120]
    >>> factorial(30)
    2652528598121910586363084800000000L
    >>> factorial(30L)
    2652528598121910586363084800000000L
    >>> factorial(-1)
    Traceback (most recent call last):
    ...
    ValueError: n must be >= 0

    Factorials of floats are OK, but the float must be an exact integer:
    >>> factorial(30.1)
    Traceback (most recent call last):
    ...
    ValueError: n must be exact integer
    >>> factorial(30.0)
    2652528598121910586363084800000000L

    It must also not be ridiculously large:
    >>> factorial(1e100)
    Traceback (most recent call last):
    ...
    OverflowError: n too large
    """

import math
if not n >= 0:
    raise ValueError("n must be >= 0")
if math.floor(n) != n:
    raise ValueError("n must be exact integer")
if n+1 == n: # catch a value like 1e300
    raise OverflowError("n too large")
result = 1
factor = 2
while factor <= n:
    result *= factor
    factor += 1
return result

```

(suite sur la page suivante)

(suite de la page précédente)

```
if __name__ == "__main__":
    import doctest
    doctest.testmod()
```

If you run `example.py` directly from the command line, `doctest` works its magic :

```
$ python example.py
$
```

There's no output ! That's normal, and it means all the examples worked. Pass `-v` to the script, and `doctest` prints a detailed log of what it's trying, and prints a summary at the end :

```
$ python example.py -v
Trying:
    factorial(5)
Expecting:
    120
ok
Trying:
    [factorial(n) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
Trying:
    [factorial(long(n)) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
```

And so on, eventually ending with :

```
Trying:
    factorial(1e100)
Expecting:
    Traceback (most recent call last):
      ...
    OverflowError: n too large
ok
2 items passed all tests:
  1 tests in __main__
  8 tests in __main__.factorial
9 tests in 2 items.
9 passed and 0 failed.
Test passed.
$
```

That's all you need to know to start making productive use of `doctest`! Jump in. The following sections provide full details. Note that there are many examples of doctests in the standard Python test suite and libraries. Especially useful examples can be found in the standard test file `Lib/test/test_doctest.py`.

### 25.2.1 Simple Usage : Checking Examples in Docstrings

The simplest way to start using `doctest` (but not necessarily the way you'll continue to do it) is to end each module `M` with :

```
if __name__ == "__main__":
    import doctest
    doctest.testmod()
```

`doctest` then examines docstrings in module `M`.

Running the module as a script causes the examples in the docstrings to get executed and verified :

```
python M.py
```

This won't display anything unless an example fails, in which case the failing example(s) and the cause(s) of the failure(s) are printed to stdout, and the final line of output is **\*\*\*Test Failed\*\*\* N failures.**, where *N* is the number of examples that failed.

Run it with the `-v` switch instead :

```
python M.py -v
```

and a detailed report of all examples tried is printed to standard output, along with assorted summaries at the end.

You can force verbose mode by passing `verbose=True` to `testmod()`, or prohibit it by passing `verbose=False`. In either of those cases, `sys.argv` is not examined by `testmod()` (so passing `-v` or not has no effect).

Since Python 2.6, there is also a command line shortcut for running `testmod()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the module name(s) on the command line :

```
python -m doctest -v example.py
```

This will import `example.py` as a standalone module and run `testmod()` on it. Note that this may not work correctly if the file is part of a package and imports other submodules from that package.

For more information on `testmod()`, see section *Basic API*.

### 25.2.2 Simple Usage : Checking Examples in a Text File

Another simple application of doctest is testing interactive examples in a text file. This can be done with the `testfile()` function :

```
import doctest
doctest.testfile("example.txt")
```

That short script executes and verifies any interactive Python examples contained in the file `example.txt`. The file content is treated as if it were a single giant docstring; the file doesn't need to contain a Python program! For example, perhaps `example.txt` contains this :

```
The ``example`` module
=====

Using ``factorial``
-----

This is an example text file in reStructuredText format. First import
``factorial`` from the ``example`` module:
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> from example import factorial

Now use it:

>>> factorial(6)
120
```

Running `doctest.testfile("example.txt")` then finds the error in this documentation :

```
File "./example.txt", line 14, in example.txt
Failed example:
    factorial(6)
Expected:
    120
Got:
    720
```

As with `testmod()`, `testfile()` won't display anything unless an example fails. If an example does fail, then the failing example(s) and the cause(s) of the failure(s) are printed to stdout, using the same format as `testmod()`.

By default, `testfile()` looks for files in the calling module's directory. See section [Basic API](#) for a description of the optional arguments that can be used to tell it to look for files in other locations.

Like `testmod()`, `testfile()`'s verbosity can be set with the `-v` command-line switch or with the optional keyword argument `verbose`.

Since Python 2.6, there is also a command line shortcut for running `testfile()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the file name(s) on the command line :

```
python -m doctest -v example.txt
```

Because the file name does not end with `.py`, `doctest` infers that it must be run with `testfile()`, not `testmod()`.

For more information on `testfile()`, see section [Basic API](#).

### 25.2.3 How It Works

This section examines in detail how doctest works : which docstrings it looks at, how it finds interactive examples, what execution context it uses, how it handles exceptions, and how option flags can be used to control its behavior. This is the information that you need to know to write doctest examples ; for information about actually running doctest on these examples, see the following sections.

#### Which Docstrings Are Examined ?

The module docstring, and all function, class and method docstrings are searched. Objects imported into the module are not searched.

In addition, if `M.__test__` exists and « is true », it must be a dict, and each entry maps a (string) name to a function object, class object, or string. Function and class object docstrings found from `M.__test__` are searched, and strings are treated as if they were docstrings. In output, a key `K` in `M.__test__` appears with name

```
<name of M>.__test__.K
```

Any classes found are recursively searched similarly, to test docstrings in their contained methods and nested classes.

Modifié dans la version 2.4 : A « private name » concept is deprecated and no longer documented.

### How are Docstring Examples Recognized ?

In most cases a copy-and-paste of an interactive console session works fine, but doctest isn't trying to do an exact emulation of any specific Python shell.

```
>>> # comments are ignored
>>> x = 12
>>> x
12
>>> if x == 13:
...     print "yes"
... else:
...     print "no"
...     print "NO"
...     print "NO!!!"
...
no
NO
NO!!!
>>>
```

Any expected output must immediately follow the final '>>> ' or '...' line containing the code, and the expected output (if any) extends to the next '>>> ' or all-whitespace line.

The fine print :

- Expected output cannot contain an all-whitespace line, since such a line is taken to signal the end of expected output. If expected output does contain a blank line, put `<BLANKLINE>` in your doctest example each place a blank line is expected.

Nouveau dans la version 2.4 : `<BLANKLINE>` was added; there was no way to use expected output containing empty lines in previous versions.

- All hard tab characters are expanded to spaces, using 8-column tab stops. Tabs in output generated by the tested code are not modified. Because any hard tabs in the sample output *are* expanded, this means that if the code output includes hard tabs, the only way the doctest can pass is if the `NORMALIZE_WHITESPACE` option or *directive* is in effect. Alternatively, the test can be rewritten to capture the output and compare it to an expected value as part of the test. This handling of tabs in the source was arrived at through trial and error, and has proven to be the least error prone way of handling them. It is possible to use a different algorithm for handling tabs by writing a custom `DocTestParser` class.

Modifié dans la version 2.4 : Expanding tabs to spaces is new; previous versions tried to preserve hard tabs, with confusing results.

- Output to stdout is captured, but not output to stderr (exception tracebacks are captured via a different means).
- If you continue a line via backslashing in an interactive session, or for any other reason use a backslash, you should use a raw docstring, which will preserve your backslashes exactly as you type them :

```
>>> def f(x):
...     r'''Backslashes in a raw docstring: m\n'''
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> print f.__doc__
Backslashes in a raw docstring: m\n
```

Otherwise, the backslash will be interpreted as part of the string. For example, the `\n` above would be interpreted as a newline character. Alternatively, you can double each backslash in the doctest version (and not use a raw string) :

```
>>> def f(x):
...     '''Backslashes in a raw docstring: m\\n'''
>>> print f.__doc__
Backslashes in a raw docstring: m\n
```

— The starting column doesn't matter :

```
>>> assert "Easy!"
>>> import math
>>> math.floor(1.9)
1.0
```

and as many leading whitespace characters are stripped from the expected output as appeared in the initial `'>>> '` line that started the example.

### What's the Execution Context ?

By default, each time *doctest* finds a docstring to test, it uses a *shallow copy* of M's globals, so that running tests doesn't change the module's real globals, and so that one test in M can't leave behind crumbs that accidentally allow another test to work. This means examples can freely use any names defined at top-level in M, and names defined earlier in the docstring being run. Examples cannot see names defined in other docstrings.

You can force use of your own dict as the execution context by passing `globals=your_dict` to *testmod()* or *testfile()* instead.

### What About Exceptions ?

No problem, provided that the traceback is the only output produced by the example : just paste in the traceback.<sup>1</sup> Since tracebacks contain details that are likely to change rapidly (for example, exact file paths and line numbers), this is one case where doctest works hard to be flexible in what it accepts.

Simple example :

```
>>> [1, 2, 3].remove(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: list.remove(x): x not in list
```

That doctest succeeds if *ValueError* is raised, with the `list.remove(x): x not in list` detail as shown.

The expected output for an exception must start with a traceback header, which may be either of the following two lines, indented the same as the first line of the example :

```
Traceback (most recent call last):
Traceback (innermost last):
```

1. Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.

The traceback header is followed by an optional traceback stack, whose contents are ignored by doctest. The traceback stack is typically omitted, or copied verbatim from an interactive session.

The traceback stack is followed by the most interesting part : the line(s) containing the exception type and detail. This is usually the last line of a traceback, but can extend across multiple lines if the exception has a multi-line detail :

```
>>> raise ValueError('multi\n    line\ndetail')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: multi
    line
detail
```

The last three lines (starting with *ValueError*) are compared against the exception's type and detail, and the rest are ignored.

Modifié dans la version 2.4 : Previous versions were unable to handle multi-line exception details.

Best practice is to omit the traceback stack, unless it adds significant documentation value to the example. So the last example is probably better as :

```
>>> raise ValueError('multi\n    line\ndetail')
Traceback (most recent call last):
...
ValueError: multi
    line
detail
```

Note that tracebacks are treated very specially. In particular, in the rewritten example, the use of ... is independent of doctest's *ELLIPSIS* option. The ellipsis in that example could be left out, or could just as well be three (or three hundred) commas or digits, or an indented transcript of a Monty Python skit.

Some details you should read once, but won't need to remember :

- Doctest can't guess whether your expected output came from an exception traceback or from ordinary printing. So, e.g., an example that expects *ValueError: 42 is prime* will pass whether *ValueError* is actually raised or if the example merely prints that traceback text. In practice, ordinary output rarely begins with a traceback header line, so this doesn't create real problems.
- Each line of the traceback stack (if present) must be indented further than the first line of the example, *or* start with a non-alphanumeric character. The first line following the traceback header indented the same and starting with an alphanumeric is taken to be the start of the exception detail. Of course this does the right thing for genuine tracebacks.
- When the *IGNORE\_EXCEPTION\_DETAIL* doctest option is specified, everything following the leftmost colon and any module information in the exception name is ignored.
- The interactive shell omits the traceback header line for some *SyntaxErrors*. But doctest uses the traceback header line to distinguish exceptions from non-exceptions. So in the rare case where you need to test a *SyntaxError* that omits the traceback header, you will need to manually add the traceback header line to your test example.
- For some *SyntaxErrors*, Python displays the character position of the syntax error, using a ^ marker :

```
>>> 1 1
    File "<stdin>", line 1
      1 1
      ^
SyntaxError: invalid syntax
```

Since the lines showing the position of the error come before the exception type and detail, they are not checked by doctest. For example, the following test would pass, even though it puts the `^` marker in the wrong location :

```
>>> 1 1
      File "<stdin>", line 1
        1 1
        ^
SyntaxError: invalid syntax
```

## Option Flags

A number of option flags control various aspects of doctest's behavior. Symbolic names for the flags are supplied as module constants, which can be bitwise ORed together and passed to various functions. The names can also be used in *doctest directives*.

The first group of options define test semantics, controlling aspects of how doctest decides whether actual output matches an example's expected output :

### `doctest.DONT_ACCEPT_TRUE_FOR_1`

By default, if an expected output block contains just 1, an actual output block containing just 1 or just `True` is considered to be a match, and similarly for 0 versus `False`. When `DONT_ACCEPT_TRUE_FOR_1` is specified, neither substitution is allowed. The default behavior caters to that Python changed the return type of many functions from integer to boolean; doctests expecting « little integer » output still work in these cases. This option will probably go away, but not for several years.

### `doctest.DONT_ACCEPT_BLANKLINE`

By default, if an expected output block contains a line containing only the string `<BLANKLINE>`, then that line will match a blank line in the actual output. Because a genuinely blank line delimits the expected output, this is the only way to communicate that a blank line is expected. When `DONT_ACCEPT_BLANKLINE` is specified, this substitution is not allowed.

### `doctest.NORMALIZE_WHITESPACE`

When specified, all sequences of whitespace (blanks and newlines) are treated as equal. Any sequence of whitespace within the expected output will match any sequence of whitespace within the actual output. By default, whitespace must match exactly. `NORMALIZE_WHITESPACE` is especially useful when a line of expected output is very long, and you want to wrap it across multiple lines in your source.

### `doctest.ELLIPSIS`

When specified, an ellipsis marker (`...`) in the expected output can match any substring in the actual output. This includes substrings that span line boundaries, and empty substrings, so it's best to keep usage of this simple. Complicated uses can lead to the same kinds of « oops, it matched too much! » surprises that `.*` is prone to in regular expressions.

### `doctest.IGNORE_EXCEPTION_DETAIL`

When specified, an example that expects an exception passes if an exception of the expected type is raised, even if the exception detail does not match. For example, an example expecting `ValueError: 42` will pass if the actual exception raised is `ValueError: 3*14`, but will fail, e.g., if `TypeError` is raised.

It will also ignore the module name used in Python 3 doctest reports. Hence both of these variations will work with the flag specified, regardless of whether the test is run under Python 2.7 or Python 3.2 (or later versions) :

```
>>> raise CustomError('message')
Traceback (most recent call last):
CustomError: message
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> raise CustomError('message')
Traceback (most recent call last):
my_module.CustomError: message
```

Note that *ELLIPSIS* can also be used to ignore the details of the exception message, but such a test may still fail based on whether or not the module details are printed as part of the exception name. Using *IGNORE\_EXCEPTION\_DETAIL* and the details from Python 2.3 is also the only clear way to write a doctest that doesn't care about the exception detail yet continues to pass under Python 2.3 or earlier (those releases do not support *doctest directives* and ignore them as irrelevant comments). For example :

```
>>> (1, 2)[3] = 'moo'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: object doesn't support item assignment
```

passes under Python 2.3 and later Python versions with the flag specified, even though the detail changed in Python 2.4 to say « does not » instead of « doesn't ».

Modifié dans la version 2.7 : *IGNORE\_EXCEPTION\_DETAIL* now also ignores any information relating to the module containing the exception under test

#### doctest.SKIP

When specified, do not run the example at all. This can be useful in contexts where doctest examples serve as both documentation and test cases, and an example should be included for documentation purposes, but should not be checked. E.g., the example's output might be random; or the example might depend on resources which would be unavailable to the test driver.

The SKIP flag can also be used for temporarily « commenting out » examples.

Nouveau dans la version 2.5.

#### doctest.COMPARISON\_FLAGS

A bitmask or'ing together all the comparison flags above.

The second group of options controls how test failures are reported :

#### doctest.REPORT\_UDIFF

When specified, failures that involve multi-line expected and actual outputs are displayed using a unified diff.

#### doctest.REPORT\_CDIFF

When specified, failures that involve multi-line expected and actual outputs will be displayed using a context diff.

#### doctest.REPORT\_NDIFF

When specified, differences are computed by `difflib.Differ`, using the same algorithm as the popular `ndiff.py` utility. This is the only method that marks differences within lines as well as across lines. For example, if a line of expected output contains digit 1 where actual output contains letter l, a line is inserted with a caret marking the mismatching column positions.

#### doctest.REPORT\_ONLY\_FIRST\_FAILURE

When specified, display the first failing example in each doctest, but suppress output for all remaining examples. This will prevent doctest from reporting correct examples that break because of earlier failures; but it might also hide incorrect examples that fail independently of the first failure. When *REPORT\_ONLY\_FIRST\_FAILURE* is specified, the remaining examples are still run, and still count towards the total number of failures reported; only the output is suppressed.

#### doctest.REPORTING\_FLAGS

A bitmask or'ing together all the reporting flags above.

Nouveau dans la version 2.4 : The constants `DONT_ACCEPT_BLANKLINE`, `NORMALIZE_WHITESPACE`, `ELLIPSIS`, `IGNORE_EXCEPTION_DETAIL`, `REPORT_UDIFF`, `REPORT_CDIFF`, `REPORT_NDIFF`, `REPORT_ONLY_FIRST_FAILURE`, `COMPARISON_FLAGS` and `REPORTING_FLAGS` were added.

There's also a way to register new option flag names, although this isn't useful unless you intend to extend `doctest` internals via subclassing :

`doctest.register_optionflag(name)`

Create a new option flag with a given name, and return the new flag's integer value. `register_optionflag()` can be used when subclassing `OutputChecker` or `DocTestRunner` to create new options that are supported by your subclasses. `register_optionflag()` should always be called using the following idiom :

```
MY_FLAG = register_optionflag('MY_FLAG')
```

Nouveau dans la version 2.4.

## Directives

Doctest directives may be used to modify the *option flags* for an individual example. Doctest directives are special Python comments following an example's source code :

```
directive          ::=  "#" "doctest:" directive_options
directive_options  ::=  directive_option ("," directive_option)\*
directive_option   ::=  on_or_off directive_option_name
on_or_off          ::=  "+" \| "-"
directive_option_name ::=  "DONT_ACCEPT_BLANKLINE" \| "NORMALIZE_WHITESPACE" \| ...
```

Whitespace is not allowed between the + or - and the directive option name. The directive option name can be any of the option flag names explained above.

An example's doctest directives modify doctest's behavior for that single example. Use + to enable the named behavior, or - to disable it.

For example, this test passes :

```
>>> print range(20)
[0,  1,  2,  3,  4,  5,  6,  7,  8,  9,
10, 11, 12, 13, 14, 15, 16, 17, 18, 19]
```

Without the directive it would fail, both because the actual output doesn't have two blanks before the single-digit list elements, and because the actual output is on a single line. This test also passes, and also requires a directive to do so :

```
>>> print range(20)
[0, 1, ..., 18, 19]
```

Multiple directives can be used on a single physical line, separated by commas :

```
>>> print range(20)
[0,  1, ...,  18,  19]
```

If multiple directive comments are used for a single example, then they are combined :

```
>>> print range(20)
...
```

(suite sur la page suivante)

(suite de la page précédente)

```
[0,      1, ...,   18,   19]
```

As the previous example shows, you can add ... lines to your example containing only directives. This can be useful when an example is too long for a directive to comfortably fit on the same line :

```
>>> print range(5) + range(10,20) + range(30,40) + range(50,60)
...
[0, ..., 4, 10, ..., 19, 30, ..., 39, 50, ..., 59]
```

Note that since all options are disabled by default, and directives apply only to the example they appear in, enabling options (via + in a directive) is usually the only meaningful choice. However, option flags can also be passed to functions that run doctests, establishing different defaults. In such cases, disabling an option via - in a directive can be useful.

Nouveau dans la version 2.4 : Support for doctest directives was added.

### Avertissements

`doctest` is serious about requiring exact matches in expected output. If even a single character doesn't match, the test fails. This will probably surprise you a few times, as you learn exactly what Python does and doesn't guarantee about output. For example, when printing a dict, Python doesn't guarantee that the key-value pairs will be printed in any particular order, so a test like

```
>>> foo()
{"Hermione": "hippogryph", "Harry": "broomstick"}
```

is vulnerable! One workaround is to do

```
>>> foo() == {"Hermione": "hippogryph", "Harry": "broomstick"}
True
```

instead. Another is to do

```
>>> d = foo().items()
>>> d.sort()
>>> d
[('Harry', 'broomstick'), ('Hermione', 'hippogryph')]
```

There are others, but you get the idea.

Another bad idea is to print things that embed an object address, like

```
>>> id(1.0) # certain to fail some of the time
7948648
>>> class C: pass
>>> C()    # the default repr() for instances embeds an address
<__main__.C instance at 0x00AC18F0>
```

The *ELLIPSIS* directive gives a nice approach for the last example :

```
>>> C()
<__main__.C instance at 0x...>
```

Floating-point numbers are also subject to small output variations across platforms, because Python defers to the platform C library for float formatting, and C libraries vary widely in quality here.

```
>>> 1./7 # risky
0.14285714285714285
>>> print 1./7 # safer
0.142857142857
>>> print round(1./7, 6) # much safer
0.142857
```

Numbers of the form `I/2.**J` are safe across all platforms, and I often contrive doctest examples to produce numbers of that form :

```
>>> 3./4 # utterly safe
0.75
```

Simple fractions are also easier for people to understand, and that makes for better documentation.

### 25.2.4 Basic API

The functions `testmod()` and `testfile()` provide a simple interface to doctest that should be sufficient for most basic uses. For a less formal introduction to these two functions, see sections *Simple Usage : Checking Examples in Docstrings* and *Simple Usage : Checking Examples in a Text File*.

`doctest.testfile(filename[, module_relative[, name[, package[, globs[, verbose[, report[, option-flags[, extraglobs[, raise_on_error[, parser[, encoding]]]]]]]]])`

All arguments except `filename` are optional, and should be specified in keyword form.

Test examples in the file named `filename`. Return `(failure_count, test_count)`.

Optional argument `module_relative` specifies how the filename should be interpreted :

- If `module_relative` is `True` (the default), then `filename` specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory ; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, `filename` should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then `filename` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument `name` gives the name of the test; by default, or if `None`, `os.path.basename(filename)` is used.

Optional argument `package` is a Python package or the name of a Python package whose directory should be used as the base directory for a module-relative filename. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify `package` if `module_relative` is `False`.

Optional argument `globs` gives a dict to be used as the globals when executing examples. A new shallow copy of this dict is created for the doctest, so its examples start with a clean slate. By default, or if `None`, a new empty dict is used.

Optional argument `extraglobs` gives a dict merged into the globals used to execute examples. This works like `dict.update()` : if `globs` and `extraglobs` have a common key, the associated value in `extraglobs` appears in the combined dict. By default, or if `None`, no extra globals are used. This is an advanced feature that allows parameterization of doctests. For example, a doctest can be written for a base class, using a generic name for the class, then reused to test any number of subclasses by passing an `extraglobs` dict mapping the generic name to the subclass to be tested.

Optional argument `verbose` prints lots of stuff if true, and prints only failures if false ; by default, or if `None`, it's true if and only if `'-v'` is in `sys.argv`.

Optional argument `report` prints a summary at the end when true, else prints nothing at the end. In verbose mode, the summary is detailed, else the summary is very brief (in fact, empty if all tests passed).

Optional argument *optionflags* or's together option flags. See section [Option Flags](#).

Optional argument *raise\_on\_error* defaults to false. If true, an exception is raised upon the first failure or unexpected exception in an example. This allows failures to be post-mortem debugged. Default behavior is to continue running examples.

Optional argument *parser* specifies a [DocTestParser](#) (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode. Nouveau dans la version 2.4.

Modifié dans la version 2.5 : The parameter *encoding* was added.

```
doctest.testmod([m]/, name]/, globs]/, verbose]/, report]/, optionflags]/, extraglobs]/, raise_on_error]/,
                exclude_empty)
```

All arguments are optional, and all except for *m* should be specified in keyword form.

Test examples in docstrings in functions and classes reachable from module *m* (or module `__main__` if *m* is not supplied or is `None`), starting with `m.__doc__`.

Also test examples reachable from dict `m.__test__`, if it exists and is not `None`. `m.__test__` maps names (strings) to functions, classes and strings; function and class docstrings are searched for examples; strings are searched directly, as if they were docstrings.

Only docstrings attached to objects belonging to module *m* are searched.

Return (`failure_count`, `test_count`).

Optional argument *name* gives the name of the module; by default, or if `None`, `m.__name__` is used.

Optional argument *exclude\_empty* defaults to false. If true, objects for which no doctests are found are excluded from consideration. The default is a backward compatibility hack, so that code still using `doctest.master.summarize()` in conjunction with `testmod()` continues to get output for objects with no tests. The *exclude\_empty* argument to the newer [DocTestFinder](#) constructor defaults to true.

Optional arguments *extraglobs*, *verbose*, *report*, *optionflags*, *raise\_on\_error*, and *globs* are the same as for function `testfile()` above, except that *globs* defaults to `m.__dict__`.

Modifié dans la version 2.3 : The parameter *optionflags* was added.

Modifié dans la version 2.4 : The parameters *extraglobs*, *raise\_on\_error* and *exclude\_empty* were added.

Modifié dans la version 2.5 : The optional argument *isprivate*, deprecated in 2.4, was removed.

```
doctest.run_docstring_examples(f, globs[, verbose]/, name]/, compileflags]/, optionflags)
```

Test examples associated with object *f*; for example, *f* may be a string, a module, a function, or a class object.

A shallow copy of dictionary argument *globs* is used for the execution context.

Optional argument *name* is used in failure messages, and defaults to "NoName".

If optional argument *verbose* is true, output is generated even if there are no failures. By default, output is generated only in case of an example failure.

Optional argument *compileflags* gives the set of flags that should be used by the Python compiler when running the examples. By default, or if `None`, flags are deduced corresponding to the set of future features found in *globs*.

Optional argument *optionflags* works as for function `testfile()` above.

### 25.2.5 unittest API

As your collection of doctest'ed modules grows, you'll want a way to run all their doctests systematically. Prior to Python 2.4, `doctest` had a barely documented `Tester` class that supplied a rudimentary way to combine doctests from multiple modules. `Tester` was feeble, and in practice most serious Python testing frameworks build on the `unittest` module, which supplies many flexible ways to combine tests from multiple sources. So, in Python 2.4, `doctest`'s `Tester` class is deprecated, and `doctest` provides two functions that can be used to create `unittest` test suites from modules and text files containing doctests. To integrate with `unittest` test discovery, include a `load_tests()` function in your test module :

```
import unittest
import doctest
import my_module_with_doctests

def load_tests(loader, tests, ignore):
    tests.addTests(doctest.DocTestSuite(my_module_with_doctests))
    return tests
```

There are two main functions for creating `unittest.TestSuite` instances from text files and modules with doctests :

`doctest.DocFileSuite(*paths, [module_relative][, package][, setUp][, tearDown][, globs][, optionflags][, parser][, encoding])`

Convert doctest tests from one or more text files to a `unittest.TestSuite`.

The returned `unittest.TestSuite` is to be run by the unittest framework and runs the interactive examples in each file. If an example in any file fails, then the synthesized unit test fails, and a `failureException` exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Pass one or more paths (as strings) to text files to be examined.

Options may be provided as keyword arguments :

Optional argument `module_relative` specifies how the filenames in `paths` should be interpreted :

- If `module_relative` is `True` (the default), then each filename in `paths` specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory ; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, each filename should use / characters to separate path segments, and may not be an absolute path (i.e., it may not begin with /).
- If `module_relative` is `False`, then each filename in `paths` specifies an OS-specific path. The path may be absolute or relative ; relative paths are resolved with respect to the current working directory.

Optional argument `package` is a Python package or the name of a Python package whose directory should be used as the base directory for module-relative filenames in `paths`. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify `package` if `module_relative` is `False`.

Optional argument `setUp` specifies a set-up function for the test suite. This is called before running the tests in each file. The `setUp` function will be passed a `DocTest` object. The `setUp` function can access the test globals as the `globs` attribute of the test passed.

Optional argument `tearDown` specifies a tear-down function for the test suite. This is called after running the tests in each file. The `tearDown` function will be passed a `DocTest` object. The `setUp` function can access the test globals as the `globs` attribute of the test passed.

Optional argument `globs` is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, `globs` is a new empty dictionary.

Optional argument `optionflags` specifies the default doctest options for the tests, created by or-ing together individual option flags. See section *Option Flags*. See function `set_unittest_reportflags()` below for a better way to set reporting options.

Optional argument `parser` specifies a `DocTestParser` (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument `encoding` specifies an encoding that should be used to convert the file to unicode. Nouveau dans la version 2.4.

Modifié dans la version 2.5 : The global `__file__` was added to the globals provided to doctests loaded from a text file using `DocFileSuite()`.

Modifié dans la version 2.5 : The parameter `encoding` was added.

---

**Note :** Unlike `testmod()` and `DocTestFinder`, this function raises a `ValueError` if `module` contains

no docstrings. You can prevent this error by passing a *DocTestFinder* instance as the *test\_finder* argument with its *exclude\_empty* keyword argument set to *False* :

```
>>> finder = doctest.DocTestFinder(exclude_empty=False)
>>> suite = doctest.DocTestSuite(test_finder=finder)
```

**doctest.DocTestSuite([module][, globs][, extraglobs][, test\_finder][, setUp][, tearDown][, checker])**

Convert doctest tests for a module to a *unittest.TestSuite*.

The returned *unittest.TestSuite* is to be run by the unittest framework and runs each doctest in the module. If any of the doctests fail, then the synthesized unit test fails, and a *failureException* exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Optional argument *module* provides the module to be tested. It can be a module object or a (possibly dotted) module name. If not specified, the module calling this function is used.

Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *extraglobs* specifies an extra set of global variables, which is merged into *globs*. By default, no extra globals are used.

Optional argument *test\_finder* is the *DocTestFinder* object (or a drop-in replacement) that is used to extract doctests from the module.

Optional arguments *setUp*, *tearDown*, and *optionflags* are the same as for function *DocFileSuite()* above.

Nouveau dans la version 2.3.

Modifié dans la version 2.4 : The parameters *globs*, *extraglobs*, *test\_finder*, *setUp*, *tearDown*, and *optionflags* were added ; this function now uses the same search technique as *testmod()*.

Under the covers, *DocTestSuite()* creates a *unittest.TestSuite* out of *doctest.DocTestCase* instances, and *DocTestCase* is a subclass of *unittest.TestCase*. *DocTestCase* isn't documented here (it's an internal detail), but studying its code can answer questions about the exact details of *unittest* integration.

Similarly, *DocFileSuite()* creates a *unittest.TestSuite* out of *doctest.DocFileCase* instances, and *DocFileCase* is a subclass of *DocTestCase*.

So both ways of creating a *unittest.TestSuite* run instances of *DocTestCase*. This is important for a subtle reason : when you run *doctest* functions yourself, you can control the *doctest* options in use directly, by passing option flags to *doctest* functions. However, if you're writing a *unittest* framework, *unittest* ultimately controls when and how tests get run. The framework author typically wants to control *doctest* reporting options (perhaps, e.g., specified by command line options), but there's no way to pass options through *unittest* to *doctest* test runners.

For this reason, *doctest* also supports a notion of *doctest* reporting flags specific to *unittest* support, via this function :

**doctest.set\_unittest\_reportflags(flags)**

Set the *doctest* reporting flags to use.

Argument *flags* or's together option flags. See section *Option Flags*. Only « reporting flags » can be used.

This is a module-global setting, and affects all future doctests run by module *unittest* : the *runTest()* method of *DocTestCase* looks at the option flags specified for the test case when the *DocTestCase* instance was constructed. If no reporting flags were specified (which is the typical and expected case), *doctest's* *unittest* reporting flags are bitwise ORed into the option flags, and the option flags so augmented are passed to the *DocTestRunner* instance created to run the doctest. If any reporting flags were specified when the *DocTestCase* instance was constructed, *doctest's* *unittest* reporting flags are ignored.

The value of the `unittest` reporting flags in effect before the function was called is returned by the function.

Nouveau dans la version 2.4.

## 25.2.6 Advanced API

The basic API is a simple wrapper that's intended to make doctest easy to use. It is fairly flexible, and should meet most users' needs; however, if you require more fine-grained control over testing, or wish to extend doctest's capabilities, then you should use the advanced API.

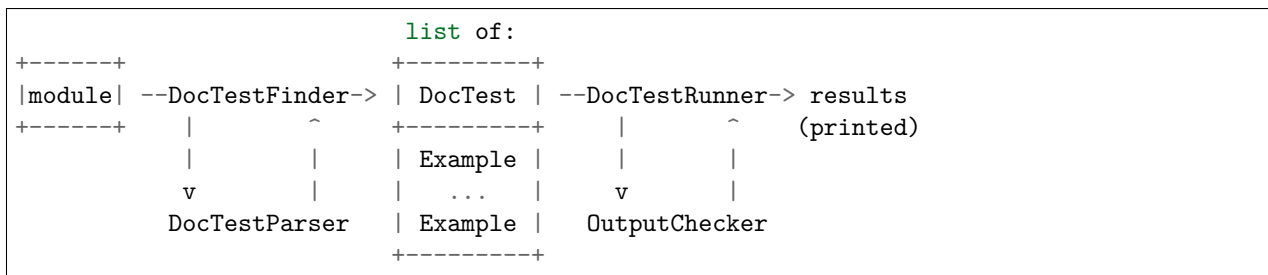

The advanced API revolves around two container classes, which are used to store the interactive examples extracted from doctest cases :

- *Example* : A single Python *statement*, paired with its expected output.
- *DocTest* : A collection of *Examples*, typically extracted from a single docstring or text file.

Additional processing classes are defined to find, parse, and run, and check doctest examples :

- *DocTestFinder* : Finds all docstrings in a given module, and uses a *DocTestParser* to create a *DocTest* from every docstring that contains interactive examples.
- *DocTestParser* : Creates a *DocTest* object from a string (such as an object's docstring).
- *DocTestRunner* : Executes the examples in a *DocTest*, and uses an *OutputChecker* to verify their output.
- *OutputChecker* : Compares the actual output from a doctest example with the expected output, and decides whether they match.

The relationships among these processing classes are summarized in the following diagram :

## DocTest Objects

**class** `doctest.DocTest(examples, globs, name, filename, lineno, docstring)`

A collection of doctest examples that should be run in a single namespace. The constructor arguments are used to initialize the attributes of the same names.

Nouveau dans la version 2.4.

*DocTest* defines the following attributes. They are initialized by the constructor, and should not be modified directly.

### examples

A list of *Example* objects encoding the individual interactive Python examples that should be run by this test.

### globs

The namespace (aka globals) that the examples should be run in. This is a dictionary mapping names to values. Any changes to the namespace made by the examples (such as binding new variables) will be reflected in *globs* after the test is run.

### name

A string name identifying the *DocTest*. Typically, this is the name of the object or file that the test was extracted from.

### filename

The name of the file that this *DocTest* was extracted from; or `None` if the filename is unknown, or if the *DocTest* was not extracted from a file.

**lineno**

The line number within *filename* where this *DocTest* begins, or *None* if the line number is unavailable. This line number is zero-based with respect to the beginning of the file.

**docstring**

The string that the test was extracted from, or *None* if the string is unavailable, or if the test was not extracted from a string.

**Example Objects**

**class** `doctest.Example(source, want[, exc_msg][, lineno][, indent][, options])`

A single interactive example, consisting of a Python statement and its expected output. The constructor arguments are used to initialize the attributes of the same names.

Nouveau dans la version 2.4.

*Example* defines the following attributes. They are initialized by the constructor, and should not be modified directly.

**source**

A string containing the example's source code. This source code consists of a single Python statement, and always ends with a newline; the constructor adds a newline when necessary.

**want**

The expected output from running the example's source code (either from stdout, or a traceback in case of exception). *want* ends with a newline unless no output is expected, in which case it's an empty string. The constructor adds a newline when necessary.

**exc\_msg**

The exception message generated by the example, if the example is expected to generate an exception; or *None* if it is not expected to generate an exception. This exception message is compared against the return value of `traceback.format_exception_only()`. *exc\_msg* ends with a newline unless it's *None*. The constructor adds a newline if needed.

**lineno**

The line number within the string containing this example where the example begins. This line number is zero-based with respect to the beginning of the containing string.

**indent**

The example's indentation in the containing string, i.e., the number of space characters that precede the example's first prompt.

**options**

A dictionary mapping from option flags to *True* or *False*, which is used to override default options for this example. Any option flags not contained in this dictionary are left at their default value (as specified by the *DocTestRunner*'s *optionflags*). By default, no options are set.

**DocTestFinder objects**

**class** `doctest.DocTestFinder([verbose][, parser][, recurse][, exclude_empty])`

A processing class used to extract the *DocTests* that are relevant to a given object, from its docstring and the docstrings of its contained objects. *DocTests* can currently be extracted from the following object types : modules, functions, classes, methods, staticmethods, classmethods, and properties.

The optional argument *verbose* can be used to display the objects searched by the finder. It defaults to *False* (no output).

The optional argument *parser* specifies the *DocTestParser* object (or a drop-in replacement) that is used to extract doctests from docstrings.

If the optional argument *recurse* is false, then *DocTestFinder.find()* will only examine the given object, and not any contained objects.

If the optional argument *exclude\_empty* is false, then *DocTestFinder.find()* will include tests for objects with empty docstrings.

Nouveau dans la version 2.4.

*DocTestFinder* defines the following method :

**find**(*obj*[, *name*][, *module*][, *globs*][, *extraglobs*])

Return a list of the *DocTests* that are defined by *obj*'s docstring, or by any of its contained objects' docstrings.

The optional argument *name* specifies the object's name; this name will be used to construct names for the returned *DocTests*. If *name* is not specified, then *obj.\_\_name\_\_* is used.

The optional parameter *module* is the module that contains the given object. If the module is not specified or is *None*, then the test finder will attempt to automatically determine the correct module. The object's module is used :

- As a default namespace, if *globs* is not specified.
- To prevent the *DocTestFinder* from extracting *DocTests* from objects that are imported from other modules. (Contained objects with modules other than *module* are ignored.)
- To find the name of the file containing the object.
- To help find the line number of the object within its file.

If *module* is *False*, no attempt to find the module will be made. This is obscure, of use mostly in testing doctest itself : if *module* is *False*, or is *None* but cannot be found automatically, then all objects are considered to belong to the (non-existent) module, so all contained objects will (recursively) be searched for doctests.

The globals for each *DocTest* is formed by combining *globs* and *extraglobs* (bindings in *extraglobs* override bindings in *globs*). A new shallow copy of the globals dictionary is created for each *DocTest*. If *globs* is not specified, then it defaults to the module's *\_\_dict\_\_*, if specified, or *{}* otherwise. If *extraglobs* is not specified, then it defaults to *{}*.

## DocTestParser objects

**class doctest.DocTestParser**

A processing class used to extract interactive examples from a string, and use them to create a *DocTest* object.

Nouveau dans la version 2.4.

*DocTestParser* defines the following methods :

**get\_doctest**(*string*, *globs*, *name*, *filename*, *lineno*)

Extract all doctest examples from the given string, and collect them into a *DocTest* object.

*globs*, *name*, *filename*, and *lineno* are attributes for the new *DocTest* object. See the documentation for *DocTest* for more information.

**get\_examples**(*string*[, *name*])

Extract all doctest examples from the given string, and return them as a list of *Example* objects. Line numbers are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

**parse**(*string*[, *name*])

Divide the given string into examples and intervening text, and return them as a list of alternating *Examples* and strings. Line numbers for the *Examples* are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

## DocTestRunner objects

**class doctest.DocTestRunner**(*[checker]*[, *verbose*][, *optionflags*])

A processing class used to execute and verify the interactive examples in a *DocTest*.

The comparison between expected outputs and actual outputs is done by an *OutputChecker*. This comparison may be customized with a number of option flags; see section *Option Flags* for more information. If the option flags are insufficient, then the comparison may also be customized by passing a subclass of *OutputChecker* to the constructor.

The test runner's display output can be controlled in two ways. First, an output function can be passed to *TestRunner.run()*; this function will be called with strings that should be displayed.

It defaults to `sys.stdout.write`. If capturing the output is not sufficient, then the display output can be also customized by subclassing `DocTestRunner`, and overriding the methods `report_start()`, `report_success()`, `report_unexpected_exception()`, and `report_failure()`.

The optional keyword argument `checker` specifies the `OutputChecker` object (or drop-in replacement) that should be used to compare the expected outputs to the actual outputs of doctest examples.

The optional keyword argument `verbose` controls the `DocTestRunner`'s verbosity. If `verbose` is `True`, then information is printed about each example, as it is run. If `verbose` is `False`, then only failures are printed. If `verbose` is unspecified, or `None`, then verbose output is used iff the command-line switch `-v` is used.

The optional keyword argument `optionflags` can be used to control how the test runner compares expected output to actual output, and how it displays failures. For more information, see section [Option Flags](#).

Nouveau dans la version 2.4.

`DocTestParser` defines the following methods :

**report\_start**(*out*, *test*, *example*)

Report that the test runner is about to process the given example. This method is provided to allow subclasses of `DocTestRunner` to customize their output ; it should not be called directly.

*example* is the example about to be processed. *test* is the test containing *example*. *out* is the output function that was passed to `DocTestRunner.run()`.

**report\_success**(*out*, *test*, *example*, *got*)

Report that the given example ran successfully. This method is provided to allow subclasses of `DocTestRunner` to customize their output ; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to `DocTestRunner.run()`.

**report\_failure**(*out*, *test*, *example*, *got*)

Report that the given example failed. This method is provided to allow subclasses of `DocTestRunner` to customize their output ; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to `DocTestRunner.run()`.

**report\_unexpected\_exception**(*out*, *test*, *example*, *exc\_info*)

Report that the given example raised an unexpected exception. This method is provided to allow subclasses of `DocTestRunner` to customize their output ; it should not be called directly.

*example* is the example about to be processed. *exc\_info* is a tuple containing information about the unexpected exception (as returned by `sys.exc_info()`). *test* is the test containing *example*. *out* is the output function that was passed to `DocTestRunner.run()`.

**run**(*test*[, *compileflags*][, *out*][, *clear\_globs*])

Run the examples in *test* (a `DocTest` object), and display the results using the writer function *out*.

The examples are run in the namespace `test.globs`. If *clear\_globs* is true (the default), then this namespace will be cleared after the test runs, to help with garbage collection. If you would like to examine the namespace after the test completes, then use *clear\_globs=False*.

*compileflags* gives the set of flags that should be used by the Python compiler when running the examples. If not specified, then it will default to the set of future-import flags that apply to *globs*.

The output of each example is checked using the `DocTestRunner`'s output checker, and the results are formatted by the `DocTestRunner.report_*` methods.

**summarize**([*verbose*])

Print a summary of all the test cases that have been run by this `DocTestRunner`, and return a *named tuple* `TestResults(failed, attempted)`.

The optional *verbose* argument controls how detailed the summary is. If the verbosity is not specified, then the `DocTestRunner`'s verbosity is used.

Modifié dans la version 2.6 : Use a named tuple.

## OutputChecker objects

### class doctest.OutputChecker

A class used to check the whether the actual output from a doctest example matches the expected output. *OutputChecker* defines two methods : *check\_output()*, which compares a given pair of outputs, and returns true if they match; and *output\_difference()*, which returns a string describing the differences between two outputs.

Nouveau dans la version 2.4.

*OutputChecker* defines the following methods :

#### check\_output(want, got, optionflags)

Return True iff the actual output from an example (*got*) matches the expected output (*want*). These strings are always considered to match if they are identical; but depending on what option flags the test runner is using, several non-exact match types are also possible. See section *Option Flags* for more information about option flags.

#### output\_difference(example, got, optionflags)

Return a string describing the differences between the expected output for a given example (*example*) and the actual output (*got*). *optionflags* is the set of option flags used to compare *want* and *got*.

## 25.2.7 Debugging

Doctest provides several mechanisms for debugging doctest examples :

- Several functions convert doctests to executable Python programs, which can be run under the Python debugger, *pdb*.
- The *DebugRunner* class is a subclass of *DocTestRunner* that raises an exception for the first failing example, containing information about that example. This information can be used to perform post-mortem debugging on the example.
- The *unittest* cases generated by *DocTestSuite()* support the *debug()* method defined by *unittest.TestCase*.
- You can add a call to *pdb.set\_trace()* in a doctest example, and you'll drop into the Python debugger when that line is executed. Then you can inspect current values of variables, and so on. For example, suppose *a.py* contains just this module docstring :

```
"""
>>> def f(x):
...     g(x*2)
>>> def g(x):
...     print x+3
...     import pdb; pdb.set_trace()
>>> f(3)
9
"""
```

Then an interactive Python session may look like this :

```
>>> import a, doctest
>>> doctest.testmod(a)
--Return--
> <doctest a[1]>(3)g()->None
-> import pdb; pdb.set_trace()
(Pdb) list
1      def g(x):
2          print x+3
3  ->      import pdb; pdb.set_trace()
```

(suite sur la page suivante)

(suite de la page précédente)

```
[EOF]
(Pdb) print x
6
(Pdb) step
--Return--
> <doctest a[0]>(2)f()->None
-> g(x*2)
(Pdb) list
1      def f(x):
2  ->    g(x*2)
[EOF]
(Pdb) print x
3
(Pdb) step
--Return--
> <doctest a[2]>(1)?()->None
-> f(3)
(Pdb) cont
(0, 3)
>>>
```

Modifié dans la version 2.4 : The ability to use `pdb.set_trace()` usefully inside doctests was added. Functions that convert doctests to Python code, and possibly run the synthesized code under the debugger :

#### `doctest.script_from_examples(s)`

Convert text with examples to a script.

Argument *s* is a string containing doctest examples. The string is converted to a Python script, where doctest examples in *s* are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```
import doctest
print doctest.script_from_examples(r"""
    Set x and y to 1 and 2.
    >>> x, y = 1, 2

    Print their sum:
    >>> print x+y
    3
""")
```

displays :

```
# Set x and y to 1 and 2.
x, y = 1, 2
#
# Print their sum:
print x+y
# Expected:
## 3
```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.

Nouveau dans la version 2.4.

`doctest.testsource(module, name)`

Convert the doctest for an object to a script.

Argument *module* is a module object, or dotted name of a module, containing the object whose doctests are of interest. Argument *name* is the name (within the module) of the object with the doctests of interest. The result is a string, containing the object's docstring converted to a Python script, as described for [script\\_from\\_examples\(\)](#) above. For example, if module `a.py` contains a top-level function `f()`, then

```
import a, doctest
print doctest.testsource(a, "a.f")
```

prints a script version of function `f()`'s docstring, with doctests converted to code, and the rest placed in comments.

Nouveau dans la version 2.3.

`doctest.debug(module, name[, pm])`

Debug the doctests for an object.

The *module* and *name* arguments are the same as for function [testsource\(\)](#) above. The synthesized Python script for the named object's docstring is written to a temporary file, and then that file is run under the control of the Python debugger, [pdb](#).

A shallow copy of `module.__dict__` is used for both local and global execution context.

Optional argument *pm* controls whether post-mortem debugging is used. If *pm* has a true value, the script file is run directly, and the debugger gets involved only if the script terminates via raising an unhandled exception. If it does, then post-mortem debugging is invoked, via [pdb.post\\_mortem\(\)](#), passing the traceback object from the unhandled exception. If *pm* is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate [execfile\(\)](#) call to [pdb.run\(\)](#).

Nouveau dans la version 2.3.

Modifié dans la version 2.4 : The *pm* argument was added.

`doctest.debug_src(src[, pm][, globs])`

Debug the doctests in a string.

This is like function [debug\(\)](#) above, except that a string containing doctest examples is specified directly, via the *src* argument.

Optional argument *pm* has the same meaning as in function [debug\(\)](#) above.

Optional argument *globs* gives a dictionary to use as both local and global execution context. If not specified, or `None`, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

Nouveau dans la version 2.4.

The [DebugRunner](#) class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially [DebugRunner](#)'s docstring (which is a doctest !) for more details :

`class doctest.DebugRunner([checker][, verbose][, optionflags])`

A subclass of [DocTestRunner](#) that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an [UnexpectedException](#) exception is raised, containing the test, the example, and the original exception. If the output doesn't match, then a [DocTestFailure](#) exception is raised, containing the test, the example, and the actual output.

For information about the constructor parameters and methods, see the documentation for [DocTestRunner](#) in section [Advanced API](#).

There are two exceptions that may be raised by [DebugRunner](#) instances :

**exception** `doctest.DocTestFailure(test, example, got)`

An exception raised by [DocTestRunner](#) to signal that a doctest example's actual output did not match its expected output. The constructor arguments are used to initialize the attributes of the same names.

[DocTestFailure](#) defines the following attributes :

`DocTestFailure.test`

The *DocTest* object that was being run when the example failed.

`DocTestFailure.example`

The *Example* that failed.

`DocTestFailure.got`

The example's actual output.

**exception** `doctest.UnexpectedException(test, example, exc_info)`

An exception raised by *DocTestRunner* to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the attributes of the same names.

*UnexpectedException* defines the following attributes :

`UnexpectedException.test`

The *DocTest* object that was being run when the example failed.

`UnexpectedException.example`

The *Example* that failed.

`UnexpectedException.exc_info`

A tuple containing information about the unexpected exception, as returned by *sys.exc\_info()*.

## 25.2.8 Soapbox

As mentioned in the introduction, *doctest* has grown to have three primary uses :

1. Checking examples in docstrings.
2. Regression testing.
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned—it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my *doctest* examples stops working after a « harmless » change.

Doctest also makes an excellent tool for regression testing, especially if you don't skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what's actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It's true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper than just that : the natural attitude when writing a doctest-based test is that you want to explain the fine points of your software, and illustrate them with examples. This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It's a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests :

- Write text files containing test cases as interactive examples, and test the files using *testfile()* or *DocFileSuite()*. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.

- Define functions named `_regtest_topic` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a `__test__` dictionary mapping from regression test topics to docstrings containing test cases.

When you have placed your tests in a module, the module can itself be the test runner. When a test fails, you can arrange for your test runner to re-run only the failing doctest while you debug the problem. Here is a minimal example of such a test runner :

```
if __name__ == '__main__':
    import doctest
    flags = doctest.REPORT_NDIFF|doctest.REPORT_ONLY_FIRST_FAILURE
    if len(sys.argv) > 1:
        name = sys.argv[1]
        if name in globals():
            obj = globals()[name]
        else:
            obj = __test__[name]
        doctest.run_docstring_examples(obj, globals(), name=name,
                                      optionflags=flags)
    else:
        fail, total = doctest.testmod(optionflags=flags)
        print("{} failures out of {} tests".format(fail, total))
```

## Notes

## 25.3 unittest — *Framework de tests unitaires*

Nouveau dans la version 2.1.

(Si vous êtes déjà familier des concepts de base concernant les tests, vous pouvez souhaiter passer à *la liste des méthodes*.)

The Python unit testing framework, sometimes referred to as « PyUnit, » is a Python language version of JUnit, by Kent Beck and Erich Gamma. JUnit is, in turn, a Java version of Kent's Smalltalk testing framework. Each is the de facto standard unit testing framework for its respective language.

`unittest` supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework. The `unittest` module provides classes that make it easy to support these qualities for a set of tests.

To achieve this, `unittest` supports some important concepts :

**aménagement de test (*fixture*)** Un *aménagement de test* (*\*fixture\**) désigne la préparation nécessaire au déroulement d'un ou plusieurs tests, et toutes les actions de nettoyage associées. Cela peut concerner, par exemple, la création de bases de données temporaires ou mandataires, de répertoires, ou le démarrage d'un processus serveur.

**scénario de test** A *test case* is the smallest unit of testing. It checks for a specific response to a particular set of inputs. `unittest` provides a base class, `TestCase`, which may be used to create new test cases.

**suite de tests** Une *suite de tests* est une collection de scénarios de test, de suites de tests ou les deux. Cela sert à regrouper les tests qui devraient être exécutés ensemble.

**lanceur de tests** Un *lanceur de tests* est un composant qui orchestre l'exécution des tests et fournit le résultat pour l'utilisateur. Le lanceur peut utiliser une interface graphique, une interface textuelle, ou renvoie une valeur spéciale pour indiquer les résultats de l'exécution des tests.

The test case and test fixture concepts are supported through the `TestCase` and `FunctionTestCase` classes ; the former should be used when creating new tests, and the latter can be used when integrating existing

test code with a *unittest*-driven framework. When building test fixtures using *TestCase*, the *setUp()* and *tearDown()* methods can be overridden to provide initialization and cleanup for the fixture. With *FunctionTestCase*, existing functions can be passed to the constructor for these purposes. When the test is run, the fixture initialization is run first; if it succeeds, the cleanup method is run after the test has been executed, regardless of the outcome of the test. Each instance of the *TestCase* will only be used to run a single test method, so a new fixture is created for each test.

Test suites are implemented by the *TestSuite* class. This class allows individual tests and test suites to be aggregated; when the suite is executed, all tests added directly to the suite and in « child » test suites are run.

A test runner is an object that provides a single method, *run()*, which accepts a *TestCase* or *TestSuite* object as a parameter, and returns a result object. The class *TestResult* is provided for use as the result object. *unittest* provides the *TextTestRunner* as an example test runner which reports test results on the standard error stream by default. Alternate runners can be implemented for other environments (such as graphical environments) without any need to derive from a specific class.

**Testing in Python Mailing List** un groupe de discussion dédié aux tests, et outils de test, en Python.

### 25.3.1 Exemple basique

Le module *unittest* fournit un riche ensemble d'outils pour construire et lancer des tests. Cette section montre qu'une petite partie des outils suffit pour satisfaire les besoins de la plupart des utilisateurs.

Voici un court script pour tester trois méthodes de *string* :

```
import unittest

class TestStringMethods(unittest.TestCase):

    def test_upper(self):
        self.assertEqual('foo'.upper(), 'FOO')

    def test_isupper(self):
        self.assertTrue('FOO'.isupper())
        self.assertFalse('Foo'.isupper())

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', 'world'])
        # check that s.split fails when the separator is not a string
        with self.assertRaises(TypeError):
```

(suite sur la page suivante)

(suite de la page précédente)

```
s.split(2)

if __name__ == '__main__':
    unittest.main()
```

Un scénario de test est créé comme classe-fille de `unittest.TestCase`. Les trois tests individuels sont définis par des méthodes dont les noms commencent par les lettres **test**. Cette convention de nommage signale au lanceur de tests quelles méthodes sont des tests.

Le cœur de chaque test est un appel à `assertEqual()` pour vérifier un résultat attendu ; `assertTrue()` ou `assertFalse()` pour vérifier une condition ; ou `assertRaises()` pour vérifier qu'une exception particulière est levée. Ces méthodes sont utilisées à la place du mot-clé **assert** pour que le lanceur de tests puisse récupérer les résultats de tous les tests et produire un rapport.

Les méthodes `setUp()` et `tearDown()` vous autorisent à définir des instructions qui seront exécutées avant et après chaque méthode test. Elles sont davantage détaillées dans la section *Organizing test code*.

Le bloc final montre une manière simple de lancer les tests. `unittest.main()` fournit une interface en ligne de commande pour le script de test. Lorsqu'il est lancé en ligne de commande, le script ci-dessus produit une sortie qui ressemble à ceci :

```
...
-----
Ran 3 tests in 0.000s

OK
```

Instead of `unittest.main()`, there are other ways to run the tests with a finer level of control, less terse output, and no requirement to be run from the command line. For example, the last two lines may be replaced with :

```
suite = unittest.TestLoader().loadTestsFromTestCase(TestStringMethods)
unittest.TextTestRunner(verbosity=2).run(suite)
```

Running the revised script from the interpreter or another script produces the following output :

```
test_isupper (__main__.TestStringMethods) ... ok
test_split (__main__.TestStringMethods) ... ok
test_upper (__main__.TestStringMethods) ... ok

-----
Ran 3 tests in 0.001s

OK
```

Les exemples ci-dessus montrent les fonctionnalités d'`unittest` les plus communément utilisées et qui sont suffisantes pour couvrir les besoins courants en matière de test. Le reste de la documentation explore l'ensemble complet des fonctionnalités depuis les premiers principes.

### 25.3.2 Command-Line Interface

The `unittest` module can be used from the command line to run tests from modules, classes or even individual test methods :

```
python -m unittest test_module1 test_module2
python -m unittest test_module.TestClass
python -m unittest test_module.TestClass.test_method
```

You can pass in a list with any combination of module names, and fully qualified class or method names.

You can run tests with more detail (higher verbosity) by passing in the `-v` flag :

```
python -m unittest -v test_module
```

For a list of all the command-line options :

```
python -m unittest -h
```

Modifié dans la version 2.7 : In earlier versions it was only possible to run individual test methods and not modules or classes.

### Command-line options

`unittest` supports these command-line options :

**-b, --buffer**

The standard output and standard error streams are buffered during the test run. Output during a passing test is discarded. Output is echoed normally on test fail or error and is added to the failure messages.

**-c, --catch**

**Control-C** during the test run waits for the current test to end and then reports all the results so far. A second **Control-C** raises the normal *KeyboardInterrupt* exception. See *Signal Handling* for the functions that provide this functionality.

**-f, --failfast**

Stop the test run on the first error or failure.

Nouveau dans la version 2.7 : The command-line options `-b`, `-c` and `-f` were added.

The command line can also be used for test discovery, for running all of the tests in a project or just a subset.

### 25.3.3 Test Discovery

Nouveau dans la version 2.7.

Unittest supports simple test discovery. In order to be compatible with test discovery, all of the test files must be modules or packages importable from the top-level directory of the project (this means that their filenames must be valid identifiers).

Test discovery is implemented in *TestLoader.discover()*, but can also be used from the command line. The basic command-line usage is :

```
cd project_directory
python -m unittest discover
```

The `discover` sub-command has the following options :

**-v, --verbose**

Verbose output

**-s, --start-directory directory**

Directory to start discovery (. default)

**-p, --pattern pattern**  
Pattern to match test files (`test*.py` default)

**-t, --top-level-directory directory**  
Top level directory of project (defaults to start directory)

The `-s`, `-p`, and `-t` options can be passed in as positional arguments in that order. The following two command lines are equivalent :

```
python -m unittest discover -s project_directory -p "*_test.py"
python -m unittest discover project_directory "*_test.py"
```

As well as being a path it is possible to pass a package name, for example `myproject.subpackage.test`, as the start directory. The package name you supply will then be imported and its location on the filesystem will be used as the start directory.

**Prudence :** Test discovery loads tests by importing them. Once test discovery has found all the test files from the start directory you specify it turns the paths into package names to import. For example `foo/bar/baz.py` will be imported as `foo.bar.baz`.

If you have a package installed globally and attempt test discovery on a different copy of the package then the import *could* happen from the wrong place. If this happens test discovery will warn you and exit.

If you supply the start directory as a package name rather than a path to a directory then discover assumes that whichever location it imports from is the location you intended, so you will not get the warning.

Test modules and packages can customize test loading and discovery by through the *load\_tests protocol*.

### 25.3.4 Organizing test code

The basic building blocks of unit testing are *test cases* — single scenarios that must be set up and checked for correctness. In *unittest*, test cases are represented by instances of *unittest*'s *TestCase* class. To make your own test cases you must write subclasses of *TestCase*, or use *FunctionTestCase*.

An instance of a *TestCase*-derived class is an object that can completely run a single test method, together with optional set-up and tidy-up code.

The testing code of a *TestCase* instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest *TestCase* subclass will simply override the `runTest()` method in order to perform specific testing code :

```
import unittest

class DefaultWidgetSizeTestCase(unittest.TestCase):
    def runTest(self):
        widget = Widget('The widget')
        self.assertEqual(widget.size(), (50, 50), 'incorrect default size')
```

Note that in order to test something, we use one of the `assert*()` methods provided by the *TestCase* base class. If the test fails, an exception will be raised, and *unittest* will identify the test case as a *failure*. Any other exceptions will be treated as *errors*. This helps you identify where the problem is : *failures* are caused by incorrect results - a 5 where you expected a 6. *Errors* are caused by incorrect code - e.g., a *TypeError* caused by an incorrect function call.

The way to run a test case will be described later. For now, note that to construct an instance of such a test case, we call its constructor without arguments :

```
testCase = DefaultWidgetSizeTestCase()
```

Now, such test cases can be numerous, and their set-up can be repetitive. In the above case, constructing a `Widget` in each of 100 `Widget` test case subclasses would mean unsightly duplication.

Luckily, we can factor out such set-up code by implementing a method called `setUp()`, which the testing framework will automatically call for us when we run the test :

```
import unittest

class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

class DefaultWidgetSizeTestCase(SimpleWidgetTestCase):
    def runTest(self):
        self.assertEqual(self.widget.size(), (50,50),
                         'incorrect default size')

class WidgetResizeTestCase(SimpleWidgetTestCase):
    def runTest(self):
        self.widget.resize(100,150)
        self.assertEqual(self.widget.size(), (100,150),
                         'wrong size after resize')
```

If the `setUp()` method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the `runTest()` method will not be executed.

Similarly, we can provide a `tearDown()` method that tidies up after the `runTest()` method has been run :

```
import unittest

class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def tearDown(self):
        self.widget.dispose()
        self.widget = None
```

If `setUp()` succeeded, the `tearDown()` method will be run whether `runTest()` succeeded or not.

Such a working environment for the testing code is called a *fixture*.

Often, many small test cases will use the same fixture. In this case, we would end up subclassing `SimpleWidgetTestCase` into many small one-method classes such as `DefaultWidgetSizeTestCase`. This is time-consuming and discouraging, so in the same vein as JUnit, `unittest` provides a simpler mechanism :

```
import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')
```

(suite sur la page suivante)

(suite de la page précédente)

```

def tearDown(self):
    self.widget.dispose()
    self.widget = None

def test_default_size(self):
    self.assertEqual(self.widget.size(), (50,50),
                     'incorrect default size')

def test_resize(self):
    self.widget.resize(100,150)
    self.assertEqual(self.widget.size(), (100,150),
                     'wrong size after resize')

```

Here we have not provided a `runTest()` method, but have instead provided two different test methods. Class instances will now each run one of the `test_*`() methods, with `self.widget` created and destroyed separately for each instance. When creating an instance we must specify the test method it is to run. We do this by passing the method name in the constructor :

```

defaultSizeTestCase = WidgetTestCase('test_default_size')
resizeTestCase = WidgetTestCase('test_resize')

```

Test case instances are grouped together according to the features they test. *unittest* provides a mechanism for this : the *test suite*, represented by *unittest*'s *TestSuite* class :

```

widgetTestSuite = unittest.TestSuite()
widgetTestSuite.addTest(WidgetTestCase('test_default_size'))
widgetTestSuite.addTest(WidgetTestCase('test_resize'))

```

For the ease of running tests, as we will see later, it is a good idea to provide in each test module a callable object that returns a pre-built test suite :

```

def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_size'))
    suite.addTest(WidgetTestCase('test_resize'))
    return suite

```

or even :

```

def suite():
    tests = ['test_default_size', 'test_resize']

    return unittest.TestSuite(map(WidgetTestCase, tests))

```

Since it is a common pattern to create a *TestCase* subclass with many similarly named test functions, *unittest* provides a *TestLoader* class that can be used to automate the process of creating a test suite and populating it with individual tests. For example,

```

suite = unittest.TestLoader().loadTestsFromTestCase(WidgetTestCase)

```

will create a test suite that will run `WidgetTestCase.test_default_size()` and `WidgetTestCase.test_resize`. *TestLoader* uses the 'test' method name prefix to identify test methods automatically.

Note that the order in which the various test cases will be run is determined by sorting the test function names with respect to the built-in ordering for strings.

Often it is desirable to group suites of test cases together, so as to run tests for the whole system at once. This is easy, since `TestSuite` instances can be added to a `TestSuite` just as `TestCase` instances can be added to a `TestSuite`:

```
suite1 = module1.TheTestSuite()
suite2 = module2.TheTestSuite()
alltests = unittest.TestSuite([suite1, suite2])
```

You can place the definitions of test cases and test suites in the same modules as the code they are to test (such as `widget.py`), but there are several advantages to placing the test code in a separate module, such as `test_widget.py`:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it tests without a good reason.
- Test code should be modified much less frequently than the code it tests.
- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules anyway, so why not be consistent?
- If the testing strategy changes, there is no need to change the source code.

### 25.3.5 Re-using old test code

Some users will find that they have existing test code that they would like to run from `unittest`, without converting every old test function to a `TestCase` subclass.

For this reason, `unittest` provides a `FunctionTestCase` class. This subclass of `TestCase` can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```
def testSomething():
    something = makeSomething()
    assert something.name is not None
    # ...
```

one can create an equivalent test case instance as follows:

```
testcase = unittest.FunctionTestCase(testSomething)
```

If there are additional set-up and tear-down methods that should be called as part of the test case's operation, they can also be provided like so:

```
testcase = unittest.FunctionTestCase(testSomething,
                                     setUp=makeSomethingDB,
                                     tearDown=deleteSomethingDB)
```

To make migrating existing test suites easier, `unittest` supports tests raising `AssertionError` to indicate test failure. However, it is recommended that you use the explicit `TestCase.fail*()` and `TestCase.assert*()` methods instead, as future versions of `unittest` may treat `AssertionError` differently.

**Note :** Even though `FunctionTestCase` can be used to quickly convert an existing test base over to a `unittest`-based system, this approach is not recommended. Taking the time to set up proper `TestCase` subclasses will make future test refactorings infinitely easier.

In some cases, the existing tests may have been written using the `doctest` module. If so, `doctest` provides a `DocTestSuite` class that can automatically build `unittest.TestSuite` instances from the existing `doctest`-based tests.

### 25.3.6 Skipping tests and expected failures

Nouveau dans la version 2.7.

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as an « expected failure, » a test that is broken and will fail, but shouldn't be counted as a failure on a `TestResult`.

Skipping a test is simply a matter of using the `skip()` decorator or one of its conditional variants.

Basic skipping looks like this :

```
class MyTestCase(unittest.TestCase):

    @unittest.skip("demonstrating skipping")
    def test_nothing(self):
        self.fail("shouldn't happen")

    @unittest.skipIf(mylib.__version__ < (1, 3),
                     "not supported in this library version")
    def test_format(self):
        # Tests that work for only a certain version of the library.
        pass

    @unittest.skipUnless(sys.platform.startswith("win"), "requires Windows")
    def test_windows_support(self):
        # windows specific testing code
        pass
```

This is the output of running the example above in verbose mode :

```
test_format (__main__.MyTestCase) ... skipped 'not supported in this library version'
test_nothing (__main__.MyTestCase) ... skipped 'demonstrating skipping'
test_windows_support (__main__.MyTestCase) ... skipped 'requires Windows'
```

```
-----
Ran 3 tests in 0.005s
```

```
OK (skipped=3)
```

Classes can be skipped just like methods :

```
@unittest.skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass
```

`TestCase.setUp()` can also skip the test. This is useful when a resource that needs to be set up is not available.

Expected failures use the `expectedFailure()` decorator.

```
class ExpectedFailureTestCase(unittest.TestCase):
    @unittest.expectedFailure
    def test_fail(self):
        self.assertEqual(1, 0, "broken")
```

It's easy to roll your own skipping decorators by making a decorator that calls `skip()` on the test when it wants it to be skipped. This decorator skips the test unless the passed object has a certain attribute :

```
def skipUnlessHasattr(obj, attr):
    if hasattr(obj, attr):
        return lambda func: func
    return unittest.skip("{} doesn't have {}".format(obj, attr))
```

The following decorators implement test skipping and expected failures :

`unittest.skip(reason)`

Unconditionally skip the decorated test. *reason* should describe why the test is being skipped.

`unittest.skipIf(condition, reason)`

Skip the decorated test if *condition* is true.

`unittest.skipUnless(condition, reason)`

Skip the decorated test unless *condition* is true.

`unittest.expectedFailure()`

Mark the test as an expected failure. If the test fails when run, the test is not counted as a failure.

`exception unittest.SkipTest(reason)`

This exception is raised to skip a test.

Usually you can use `TestCase.skipTest()` or one of the skipping decorators instead of raising this directly.

Skipped tests will not have `setUp()` or `tearDown()` run around them. Skipped classes will not have `setUpClass()` or `tearDownClass()` run.

### 25.3.7 Classes and functions

This section describes in depth the API of `unittest`.

#### Test cases

`class unittest.TestCase(methodName='runTest')`

Instances of the `TestCase` class represent the smallest testable units in the `unittest` universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the test, and methods that the test code can use to check for and report various kinds of failure.

Each instance of `TestCase` will run a single test method : the method named *methodName*. If you remember, we had an earlier example that went something like this :

```
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_size'))
    suite.addTest(WidgetTestCase('test_resize'))
    return suite
```

Here, we create two instances of `WidgetTestCase`, each of which runs a single test.

*methodName* defaults to `runTest()`.

*TestCase* instances provide three groups of methods : one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.

Methods in the first group (running the test) are :

**setUp()**

Method called to prepare the test fixture. This is called immediately before calling the test method; other than *AssertionError* or *SkipTest*, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

**tearDown()**

Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than *AssertionError* or *SkipTest*, raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the *setUp()* succeeds, regardless of the outcome of the test method. The default implementation does nothing.

**setUpClass()**

A class method called before tests in an individual class are run. *setUpClass* is called with the class as the only argument and must be decorated as a *classmethod()* :

```
@classmethod
def setUpClass(cls):
    ...
```

See *Class and Module Fixtures* for more details.

Nouveau dans la version 2.7.

**tearDownClass()**

A class method called after tests in an individual class have run. *tearDownClass* is called with the class as the only argument and must be decorated as a *classmethod()* :

```
@classmethod
def tearDownClass(cls):
    ...
```

See *Class and Module Fixtures* for more details.

Nouveau dans la version 2.7.

**run(result=None)**

Run the test, collecting the result into the test result object passed as *result*. If *result* is omitted or *None*, a temporary result object is created (by calling the *defaultTestResult()* method) and used. The result object is not returned to *run()*'s caller.

The same effect may be had by simply calling the *TestCase* instance.

**skipTest(reason)**

Calling this during a test method or *setUp()* skips the current test. See *Skipping tests and expected failures* for more information.

Nouveau dans la version 2.7.

**debug()**

Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the caller, and can be used to support running tests under a debugger.

The *TestCase* class provides several assert methods to check for and report failures. The following table lists the most commonly used methods (see the tables below for more assert methods) :

Méthode	Checks that	New in
<code>assertEqual(a, b)</code>	<code>a == b</code>	
<code>assertNotEqual(a, b)</code>	<code>a != b</code>	
<code>assertTrue(x)</code>	<code>bool(x)</code> is True	
<code>assertFalse(x)</code>	<code>bool(x)</code> is False	
<code>assertIs(a, b)</code>	<code>a is b</code>	2.7
<code>assertIsNot(a, b)</code>	<code>a is not b</code>	2.7
<code>assertIsNone(x)</code>	<code>x is None</code>	2.7
<code>assertIsNotNone(x)</code>	<code>x is not None</code>	2.7
<code>assertIn(a, b)</code>	<code>a in b</code>	2.7
<code>assertNotIn(a, b)</code>	<code>a not in b</code>	2.7
<code>assertIsInstance(a, b)</code>	<code>isinstance(a, b)</code>	2.7
<code>assertNotIsInstance(a, b)</code>	<code>not isinstance(a, b)</code>	2.7

All the assert methods (except `assertRaises()`, `assertRaisesRegex()`) accept a `msg` argument that, if specified, is used as the error message on failure (see also `longMessage`).

**assertEqual**(*first*, *second*, *msg=None*)

Test that *first* and *second* are equal. If the values do not compare equal, the test will fail.

In addition, if *first* and *second* are the exact same type and one of list, tuple, dict, set, frozenset or unicode or any type that a subclass registers with `addTypeEqualityFunc()` the type-specific equality function will be called in order to generate a more useful default error message (see also the *list of type-specific methods*).

Modifié dans la version 2.7 : Added the automatic calling of type-specific equality function.

**assertNotEqual**(*first*, *second*, *msg=None*)

Test that *first* and *second* are not equal. If the values do compare equal, the test will fail.

**assertTrue**(*expr*, *msg=None*)

**assertFalse**(*expr*, *msg=None*)

Test that *expr* is true (or false).

Note that this is equivalent to `bool(expr) is True` and not to `expr is True` (use `assertIs(expr, True)` for the latter). This method should also be avoided when more specific methods are available (e.g. `assertEqual(a, b)` instead of `assertTrue(a == b)`), because they provide a better error message in case of failure.

**assertIs**(*first*, *second*, *msg=None*)

**assertIsNot**(*first*, *second*, *msg=None*)

Test that *first* and *second* evaluate (or don't evaluate) to the same object.

Nouveau dans la version 2.7.

**assertIsNone**(*expr*, *msg=None*)

**assertIsNotNone**(*expr*, *msg=None*)

Test that *expr* is (or is not) None.

Nouveau dans la version 2.7.

**assertIn**(*first*, *second*, *msg=None*)

**assertNotIn**(*first*, *second*, *msg=None*)

Test that *first* is (or is not) in *second*.

Nouveau dans la version 2.7.

**assertIsInstance**(*obj*, *cls*, *msg=None*)

**assertNotIsInstance**(*obj*, *cls*, *msg=None*)

Test that *obj* is (or is not) an instance of *cls* (which can be a class or a tuple of classes, as supported by `isinstance()`). To check for the exact type, use `assertIs(type(obj), cls)`.

Nouveau dans la version 2.7.

It is also possible to check that exceptions and warnings are raised using the following methods :

Méthode	Checks that	New in
<code>assertRaises(exc, fun, *args, **kwargs)</code>	<code>fun(*args, **kwargs)</code> raises <i>exc</i>	
<code>assertRaisesRegexp(exc, r, fun, *args, **kwargs)</code>	<code>fun(*args, **kwargs)</code> raises <i>exc</i> and the message matches regex <i>r</i>	2.7

**assertRaises**(*exception*, *callable*, \**args*, \*\**kwargs*)

**assertRaises**(*exception*)

Test that an exception is raised when *callable* is called with any positional or keyword arguments that are also passed to `assertRaises()`. The test passes if *exception* is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as *exception*.

If only the *exception* argument is given, returns a context manager so that the code under test can be written inline rather than as a function :

```
with self.assertRaises(SomeException):
    do_something()
```

The context manager will store the caught exception object in its `exception` attribute. This can be useful if the intention is to perform additional checks on the exception raised :

```
with self.assertRaises(SomeException) as cm:
    do_something()

the_exception = cm.exception
self.assertEqual(the_exception.error_code, 3)
```

Modifié dans la version 2.7 : Added the ability to use `assertRaises()` as a context manager.

**assertRaisesRegexp**(*exception*, *regexp*, *callable*, \**args*, \*\**kwargs*)

**assertRaisesRegexp**(*exception*, *regexp*)

Like `assertRaises()` but also tests that *regexp* matches on the string representation of the raised exception. *regexp* may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`. Examples :

```
self.assertRaises(ValueError, "invalid literal for.*XYZ'",
                  int, 'XYZ')
```

ou :

```
with self.assertRaisesRegexp(ValueError, 'literal'):
    int('XYZ')
```

Nouveau dans la version 2.7.

There are also other methods used to perform more specific checks, such as :

Méthode	Checks that	New in
<code>assertAlmostEqual(a, b)</code>	<code>round(a-b, 7) == 0</code>	
<code>assertNotAlmostEqual(a, b)</code>	<code>round(a-b, 7) != 0</code>	
<code>assertGreater(a, b)</code>	<code>a &gt; b</code>	2.7
<code>assertGreaterEqual(a, b)</code>	<code>a &gt;= b</code>	2.7
<code>assertLess(a, b)</code>	<code>a &lt; b</code>	2.7
<code>assertLessEqual(a, b)</code>	<code>a &lt;= b</code>	2.7
<code>assertRegexpMatches(s, r)</code>	<code>r.search(s)</code>	2.7
<code>assertNotRegexpMatches(s, r)</code>	<code>not r.search(s)</code>	2.7
<code>assertItemsEqual(a, b)</code>	<code>sorted(a) == sorted(b)</code> and works with unhashable objs	2.7
<code>assertDictContainsSubset(a, b)</code>	all the key/value pairs in <i>a</i> exist in <i>b</i>	2.7

**assertAlmostEqual**(*first*, *second*, *places*=7, *msg*=None, *delta*=None)

**assertNotAlmostEqual**(*first*, *second*, *places*=7, *msg*=None, *delta*=None)

Test that *first* and *second* are approximately (or not approximately) equal by computing the difference, rounding to the given number of decimal *places* (default 7), and comparing to zero. Note that these methods round the values to the given number of *decimal places* (i.e. like the `round()` function) and not *significant digits*.

If *delta* is supplied instead of *places* then the difference between *first* and *second* must be less or equal to (or greater than) *delta*.

Supplying both *delta* and *places* raises a `TypeError`.

Modifié dans la version 2.7 : `assertAlmostEqual()` automatically considers almost equal objects that compare equal. `assertNotAlmostEqual()` automatically fails if the objects compare equal.

Added the *delta* keyword argument.

**assertGreater**(*first*, *second*, *msg*=None)

**assertGreaterEqual**(*first*, *second*, *msg*=None)

**assertLess**(*first*, *second*, *msg*=None)

**assertLessEqual**(*first*, *second*, *msg*=None)

Test that *first* is respectively `>`, `>=`, `<` or `<=` than *second* depending on the method name. If not, the test will fail :

```
>>> self.assertGreaterEqual(3, 4)
AssertionError: "3" unexpectedly not greater than or equal to "4"
```

Nouveau dans la version 2.7.

**assertRegexpMatches**(*text*, *regexp*, *msg*=None)

Test that a *regexp* search matches *text*. In case of failure, the error message will include the pattern and the *text* (or the pattern and the part of *text* that unexpectedly matched). *regexp* may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`.

Nouveau dans la version 2.7.

**assertNotRegexpMatches**(*text*, *regexp*, *msg*=None)

Verifies that a *regexp* search does not match *text*. Fails with an error message including the pattern and the part of *text* that matches. *regexp* may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`.

Nouveau dans la version 2.7.

**assertItemsEqual**(*actual*, *expected*, *msg*=None)

Test that sequence *expected* contains the same elements as *actual*, regardless of their order. When they don't, an error message listing the differences between the sequences will be generated.

Duplicate elements are *not* ignored when comparing *actual* and *expected*. It verifies if each element has the same count in both sequences. It is the equivalent of `assertEqual(sorted(expected), sorted(actual))` but it works with sequences of unhashable objects as well.

In Python 3, this method is named `assertCountEqual`.

Nouveau dans la version 2.7.

**`assertDictContainsSubset(expected, actual, msg=None)`**

Tests whether the key/value pairs in dictionary *actual* are a superset of those in *expected*. If not, an error message listing the missing keys and mismatched values is generated.

Nouveau dans la version 2.7.

Obsolète depuis la version 3.2.

The `assertEqual()` method dispatches the equality check for objects of the same type to different type-specific methods. These methods are already implemented for most of the built-in types, but it's also possible to register new methods using `addTypeEqualityFunc()` :

**`addTypeEqualityFunc(typeobj, function)`**

Registers a type-specific method called by `assertEqual()` to check if two objects of exactly the same *typeobj* (not subclasses) compare equal. *function* must take two positional arguments and a third `msg=None` keyword argument just as `assertEqual()` does. It must raise `self.failureException(msg)` when inequality between the first two parameters is detected – possibly providing useful information and explaining the inequalities in details in the error message.

Nouveau dans la version 2.7.

The list of type-specific methods automatically used by `assertEqual()` are summarized in the following table. Note that it's usually not necessary to invoke these methods directly.

Méthode	Used to compare	New in
<code>assertMultiLineEqual(a, b)</code>	chaînes	2.7
<code>assertSequenceEqual(a, b)</code>	séquences	2.7
<code>assertListEqual(a, b)</code>	lists	2.7
<code>assertTupleEqual(a, b)</code>	tuples	2.7
<code>assertSetEqual(a, b)</code>	sets or frozensets	2.7
<code>assertDictEqual(a, b)</code>	dicts	2.7

**`assertMultiLineEqual(first, second, msg=None)`**

Test that the multiline string *first* is equal to the string *second*. When not equal a diff of the two strings highlighting the differences will be included in the error message. This method is used by default when comparing Unicode strings with `assertEqual()`.

Nouveau dans la version 2.7.

**`assertSequenceEqual(seq1, seq2, msg=None, seq_type=None)`**

Tests that two sequences are equal. If a *seq\_type* is supplied, both *seq1* and *seq2* must be instances of *seq\_type* or a failure will be raised. If the sequences are different an error message is constructed that shows the difference between the two.

This method is not called directly by `assertEqual()`, but it's used to implement `assertListEqual()` and `assertTupleEqual()`.

Nouveau dans la version 2.7.

**`assertListEqual(list1, list2, msg=None)`**

**`assertTupleEqual(tuple1, tuple2, msg=None)`**

Tests that two lists or tuples are equal. If not, an error message is constructed that shows only the differences between the two. An error is also raised if either of the parameters are of the wrong type. These methods are used by default when comparing lists or tuples with `assertEqual()`.

Nouveau dans la version 2.7.

**`assertSetEqual(set1, set2, msg=None)`**

Tests that two sets are equal. If not, an error message is constructed that lists the differences between the sets. This method is used by default when comparing sets or frozensets with `assertEqual()`.

Fails if either of *set1* or *set2* does not have a `set.difference()` method.

Nouveau dans la version 2.7.

**assertDictEqual**(*expected*, *actual*, *msg=None*)

Test that two dictionaries are equal. If not, an error message is constructed that shows the differences in the dictionaries. This method will be used by default to compare dictionaries in calls to `assertEqual()`.

Nouveau dans la version 2.7.

Finally the `TestCase` provides the following methods and attributes :

**fail**(*msg=None*)

Signals a test failure unconditionally, with *msg* or `None` for the error message.

**failureException**

This class attribute gives the exception raised by the test method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to « play fair » with the framework. The initial value of this attribute is `AssertionError`.

**longMessage**

If set to `True` then any explicit failure message you pass in to the *assert methods* will be appended to the end of the normal failure message. The normal messages contain useful information about the objects involved, for example the message from `assertEqual` shows you the repr of the two unequal objects. Setting this attribute to `True` allows you to have a custom error message in addition to the normal one.

This attribute defaults to `False`, meaning that a custom message passed to an assert method will silence the normal message.

The class setting can be overridden in individual tests by assigning an instance attribute to `True` or `False` before calling the assert methods.

Nouveau dans la version 2.7.

**maxDiff**

This attribute controls the maximum length of diffs output by assert methods that report diffs on failure. It defaults to 80\*8 characters. Assert methods affected by this attribute are `assertSequenceEqual()` (including all the sequence comparison methods that delegate to it), `assertDictEqual()` and `assertMultiLineEqual()`.

Setting `maxDiff` to `None` means that there is no maximum length of diffs.

Nouveau dans la version 2.7.

Testing frameworks can use the following methods to collect information on the test :

**countTestCases()**

Return the number of tests represented by this test object. For `TestCase` instances, this will always be 1.

**defaultTestResult()**

Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the `run()` method).

For `TestCase` instances, this will always be an instance of `TestResult`; subclasses of `TestCase` should override this as necessary.

**id()**

Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.

**shortDescription()**

Returns a description of the test, or `None` if no description has been provided. The default implementation of this method returns the first line of the test method's docstring, if available, or `None`.

**addCleanup**(*function*, *\*args*, *\*\*kwargs*)

Add a function to be called after `tearDown()` to cleanup resources used during the test. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into `addCleanup()` when they are added.

If `setUp()` fails, meaning that `tearDown()` is not called, then any cleanup functions added will still be called.

Nouveau dans la version 2.7.

#### `doCleanups()`

This method is called unconditionally after `tearDown()`, or after `setUp()` if `setUp()` raises an exception.

It is responsible for calling all the cleanup functions added by `addCleanup()`. If you need cleanup functions to be called *prior* to `tearDown()` then you can call `doCleanups()` yourself.

`doCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

Nouveau dans la version 2.7.

**class** `unittest.FunctionTestCase`(*testFunc*, *setUp=None*, *tearDown=None*, *description=None*)

This class implements the portion of the `TestCase` interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to be integrated into a `unittest`-based test framework.

### Deprecated aliases

For historical reasons, some of the `TestCase` methods had one or more aliases that are now deprecated. The following table lists the correct names along with their deprecated aliases :

Nom de méthode	Deprecated alias(es)
<code>assertEqual()</code>	<code>failUnlessEqual</code> , <code>assertEquals</code>
<code>assertNotEqual()</code>	<code>failIfEqual</code>
<code>assertTrue()</code>	<code>failUnless</code> , <code>assert__</code>
<code>assertFalse()</code>	<code>failIf</code>
<code>assertRaises()</code>	<code>failUnlessRaises</code>
<code>assertAlmostEqual()</code>	<code>failUnlessAlmostEqual</code>
<code>assertNotAlmostEqual()</code>	<code>failIfAlmostEqual</code>

Obsolète depuis la version 2.7 : the aliases listed in the second column

### Grouping tests

**class** `unittest.TestSuite`(*tests=()*)

This class represents an aggregation of individual test cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a `TestSuite` instance is the same as iterating over the suite, running each test individually.

If *tests* is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

`TestSuite` objects behave much like `TestCase` objects, except they do not actually implement a test. Instead, they are used to aggregate tests into groups of tests that should be run together. Some additional methods are available to add tests to `TestSuite` instances :

#### `addTest(test)`

Add a `TestCase` or `TestSuite` to the suite.

#### `addTests(tests)`

Add all the tests from an iterable of `TestCase` and `TestSuite` instances to this test suite.

This is equivalent to iterating over *tests*, calling `addTest()` for each element.

`TestSuite` shares the following methods with `TestCase` :

**run(*result*)**

Run the tests associated with this suite, collecting the result into the test result object passed as *result*. Note that unlike *TestCase.run()*, *TestSuite.run()* requires the result object to be passed in.

**debug()**

Run the tests associated with this suite without collecting the result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

**countTestCases()**

Return the number of tests represented by this test object, including all individual tests and sub-suites.

**\_\_iter\_\_()**

Tests grouped by a *TestSuite* are always accessed by iteration. Subclasses can lazily provide tests by overriding *\_\_iter\_\_()*. Note that this method maybe called several times on a single suite (for example when counting tests or comparing for equality) so the tests returned must be the same for repeated iterations.

Modifié dans la version 2.7 : In earlier versions the *TestSuite* accessed tests directly rather than through iteration, so overriding *\_\_iter\_\_()* wasn't sufficient for providing tests.

In the typical usage of a *TestSuite* object, the *run()* method is invoked by a *TestRunner* rather than by the end-user test harness.

## Loading and running tests

**class unittest.TestLoader**

The *TestLoader* class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the *unittest* module provides an instance that can be shared as *unittest.defaultTestLoader*. Using a subclass or instance, however, allows customization of some configurable properties.

*TestLoader* objects have the following methods :

**loadTestsFromTestCase(*testCaseClass*)**

Return a suite of all test cases contained in the *TestCase*-derived *testCaseClass*.

**loadTestsFromModule(*module*)**

Return a suite of all test cases contained in the given module. This method searches *module* for classes derived from *TestCase* and creates an instance of the class for each test method defined for the class.

---

**Note :** While using a hierarchy of *TestCase*-derived classes can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures are different and defined in subclasses.

---

If a module provides a *load\_tests* function it will be called to load the tests. This allows modules to customize test loading. This is the *load\_tests protocol*.

Modifié dans la version 2.7 : Support for *load\_tests* added.

**loadTestsFromName(*name*, *module=None*)**

Return a suite of all test cases given a string specifier.

The specifier *name* is a « dotted name » that may resolve either to a module, a test case class, a test method within a test case class, a *TestSuite* instance, or a callable object which returns a *TestCase* or *TestSuite* instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as « a test method within a test case class », rather than « a callable object ».

For example, if you have a module *SampleTests* containing a *TestCase*-derived class *SampleTestCase* with three test methods (*test\_one()*, *test\_two()*, and *test\_three()*), the

specifier `'SampleTests.SampleTestCase'` would cause this method to return a suite which will run all three test methods. Using the specifier `'SampleTests.SampleTestCase.test_two'` would cause it to return a test suite which will run only the `test_two()` test method. The specifier can refer to modules and packages which have not been imported; they will be imported as a side-effect.

The method optionally resolves *name* relative to the given *module*.

**loadTestsFromNames**(*names*, *module=None*)

Similar to `loadTestsFromName()`, but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

**getTestCaseNames**(*testCaseClass*)

Return a sorted sequence of method names found within *testCaseClass*; this should be a subclass of `TestCase`.

**discover**(*start\_dir*, *pattern='test\*.py'*, *top\_level\_dir=None*)

Find all the test modules by recursing into subdirectories from the specified start directory, and return a `TestSuite` object containing them. Only test files that match *pattern* will be loaded. (Using shell style pattern matching.) Only module names that are importable (i.e. are valid Python identifiers) will be loaded.

All test modules must be importable from the top level of the project. If the start directory is not the top level directory then the top level directory must be specified separately.

If importing a module fails, for example due to a syntax error, then this will be recorded as a single error and discovery will continue.

If a test package name (directory with `__init__.py`) matches the pattern then the package will be checked for a `load_tests` function. If this exists then it will be called with *loader*, *tests*, *pattern*. If `load_tests` exists then discovery does *not* recurse into the package, `load_tests` is responsible for loading all tests in the package.

The pattern is deliberately not stored as a loader attribute so that packages can continue discovery themselves. *top\_level\_dir* is stored so `load_tests` does not need to pass this argument in to `loader.discover()`.

*start\_dir* can be a dotted module name as well as a directory.

Nouveau dans la version 2.7.

The following attributes of a `TestLoader` can be configured either by subclassing or assignment on an instance :

**testMethodPrefix**

String giving the prefix of method names which will be interpreted as test methods. The default value is `'test'`.

This affects `getTestCaseNames()` and all the `loadTestsFrom*()` methods.

**sortTestMethodsUsing**

Function to be used to compare method names when sorting them in `getTestCaseNames()` and all the `loadTestsFrom*()` methods. The default value is the built-in `cmp()` function; the attribute can also be set to `None` to disable the sort.

**suiteClass**

Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the `TestSuite` class.

This affects all the `loadTestsFrom*()` methods.

**class unittest.TestResult**

This class is used to compile information about which tests have succeeded and which have failed.

A `TestResult` object stores the results of a set of tests. The `TestCase` and `TestSuite` classes ensure that results are properly recorded; test authors do not need to worry about recording the outcome of tests.

Testing frameworks built on top of `unittest` may want access to the `TestResult` object generated by running a set of tests for reporting purposes; a `TestResult` instance is returned by the `TestRunner.run()` method for this purpose.

*TestResult* instances have the following attributes that will be of interest when inspecting the results of running a set of tests :

**errors**

A list containing 2-tuples of *TestCase* instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

Modifié dans la version 2.2 : Contains formatted tracebacks instead of *sys.exc\_info()* results.

**failures**

A list containing 2-tuples of *TestCase* instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the *TestCase.assert\*()* methods.

Modifié dans la version 2.2 : Contains formatted tracebacks instead of *sys.exc\_info()* results.

**skipped**

A list containing 2-tuples of *TestCase* instances and strings holding the reason for skipping the test.

Nouveau dans la version 2.7.

**expectedFailures**

A list containing 2-tuples of *TestCase* instances and strings holding formatted tracebacks. Each tuple represents an expected failure of the test case.

**unexpectedSuccesses**

A list containing *TestCase* instances that were marked as expected failures, but succeeded.

**shouldStop**

Set to *True* when the execution of tests should stop by *stop()*.

**testsRun**

The total number of tests run so far.

**buffer**

If set to *true*, *sys.stdout* and *sys.stderr* will be buffered in between *startTest()* and *stopTest()* being called. Collected output will only be echoed onto the real *sys.stdout* and *sys.stderr* if the test fails or errors. Any output is also attached to the failure / error message.

Nouveau dans la version 2.7.

**failfast**

If set to *true* *stop()* will be called on the first failure or error, halting the test run.

Nouveau dans la version 2.7.

**wasSuccessful()**

Return *True* if all tests run so far have passed, otherwise returns *False*.

**stop()**

This method can be called to signal that the set of tests being run should be aborted by setting the *shouldStop* attribute to *True*. *TestRunner* objects should respect this flag and return without running any additional tests.

For example, this feature is used by the *TextTestRunner* class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide *TestRunner* implementations can use this in a similar manner.

The following methods of the *TestResult* class are used to maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

**startTest(test)**

Called when the test case *test* is about to be run.

**stopTest(test)**

Called after the test case *test* has been executed, regardless of the outcome.

**startTestRun()**

Called once before any tests are executed.

Nouveau dans la version 2.7.

**stopTestRun()**

Called once after all tests are executed.

Nouveau dans la version 2.7.

**addError(test, err)**

Called when the test case *test* raises an unexpected exception. *err* is a tuple of the form returned by `sys.exc_info()`: (type, value, traceback).

The default implementation appends a tuple (test, formatted\_err) to the instance's *errors* attribute, where *formatted\_err* is a formatted traceback derived from *err*.

**addFailure(test, err)**

Called when the test case *test* signals a failure. *err* is a tuple of the form returned by `sys.exc_info()`: (type, value, traceback).

The default implementation appends a tuple (test, formatted\_err) to the instance's *failures* attribute, where *formatted\_err* is a formatted traceback derived from *err*.

**addSuccess(test)**

Called when the test case *test* succeeds.

The default implementation does nothing.

**addSkip(test, reason)**

Called when the test case *test* is skipped. *reason* is the reason the test gave for skipping.

The default implementation appends a tuple (test, reason) to the instance's *skipped* attribute.

**addExpectedFailure(test, err)**

Called when the test case *test* fails, but was marked with the `expectedFailure()` decorator.

The default implementation appends a tuple (test, formatted\_err) to the instance's *expectedFailures* attribute, where *formatted\_err* is a formatted traceback derived from *err*.

**addUnexpectedSuccess(test)**

Called when the test case *test* was marked with the `expectedFailure()` decorator, but succeeded.

The default implementation appends the test to the instance's *unexpectedSuccesses* attribute.

**class unittest.TextTestResult(stream, descriptions, verbosity)**

A concrete implementation of *TestResult* used by the *TextTestRunner*.

Nouveau dans la version 2.7 : This class was previously named `_TextTestResult`. The old name still exists as an alias but is deprecated.

**unittest.defaultTestLoader**

Instance of the *TestLoader* class intended to be shared. If no customization of the *TestLoader* is needed, this instance can be used instead of repeatedly creating new instances.

**class unittest.TextTestRunner(stream=sys.stderr, descriptions=True, verbosity=1, failfast=False, buffer=False, resultclass=None)**

A basic test runner implementation which prints results on standard error. It has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations.

**\_makeResult()**

This method returns the instance of *TestResult* used by `run()`. It is not intended to be called directly, but can be overridden in subclasses to provide a custom *TestResult*.

`_makeResult()` instantiates the class or callable passed in the *TextTestRunner* constructor as the *resultclass* argument. It defaults to *TextTestResult* if no *resultclass* is provided. The result class is instantiated with the following arguments :

`stream, descriptions, verbosity`

```
unittest.main([module[, defaultTest[, argv[, testRunner[, testLoader[, exit[, verbosity[, failfast[,  
catchbreak[, buffer]]]]]]]]]])
```

A command-line program that loads a set of tests from *module* and runs them; this is primarily for

making test modules conveniently executable. The simplest use for this function is to include the following line at the end of a test script :

```
if __name__ == '__main__':
    unittest.main()
```

You can run tests with more detailed information by passing in the verbosity argument :

```
if __name__ == '__main__':
    unittest.main(verbosity=2)
```

The *defaultTest* argument is the name of the test to run if no test names are specified via *argv*. If not specified or *None* and no test names are provided via *argv*, all tests found in *module* are run.

The *argv* argument can be a list of options passed to the program, with the first element being the program name. If not specified or *None*, the values of *sys.argv* are used.

The *testRunner* argument can either be a test runner class or an already created instance of it. By default *main* calls *sys.exit()* with an exit code indicating success or failure of the tests run.

The *testLoader* argument has to be a *TestLoader* instance, and defaults to *defaultTestLoader*.

*main* supports being used from the interactive interpreter by passing in the argument *exit=False*. This displays the result on standard output without calling *sys.exit()* :

```
>>> from unittest import main
>>> main(module='test_module', exit=False)
```

The *failfast*, *catchbreak* and *buffer* parameters have the same effect as the same-name *command-line options*.

Calling *main* actually returns an instance of the *TestProgram* class. This stores the result of the tests run as the *result* attribute.

Modifié dans la version 2.7 : The *exit*, *verbosity*, *failfast*, *catchbreak* and *buffer* parameters were added.

## load\_tests Protocol

Nouveau dans la version 2.7.

Modules or packages can customize how tests are loaded from them during normal test runs or test discovery by implementing a function called *load\_tests*.

If a test module defines *load\_tests* it will be called by *TestLoader.loadTestsFromModule()* with the following arguments :

```
load_tests(loader, standard_tests, None)
```

It should return a *TestSuite*.

*loader* is the instance of *TestLoader* doing the loading. *standard\_tests* are the tests that would be loaded by default from the module. It is common for test modules to only want to add or remove tests from the standard set of tests. The third argument is used when loading packages as part of test discovery.

A typical *load\_tests* function that loads tests from a specific set of *TestCase* classes may look like :

```
test_cases = (TestCase1, TestCase2, TestCase3)

def load_tests(loader, tests, pattern):
    suite = TestSuite()
    for test_class in test_cases:
        tests = loader.loadTestsFromTestCase(test_class)
```

(suite sur la page suivante)

(suite de la page précédente)

```
suite.addTests(tests)
return suite
```

If discovery is started, either from the command line or by calling `TestLoader.discover()`, with a pattern that matches a package name then the package `__init__.py` will be checked for `load_tests`.

**Note :** The default pattern is `'test*.py'`. This matches all Python files that start with `'test'` but *won't* match any test directories.

A pattern like `'test*'` will match test packages as well as modules.

If the package `__init__.py` defines `load_tests` then it will be called and discovery not continued into the package. `load_tests` is called with the following arguments :

```
load_tests(loader, standard_tests, pattern)
```

This should return a `TestSuite` representing all the tests from the package. (`standard_tests` will only contain tests collected from `__init__.py`.)

Because the pattern is passed into `load_tests` the package is free to continue (and potentially modify) test discovery. A “do nothing” `load_tests` function for a test package would look like :

```
def load_tests(loader, standard_tests, pattern):
    # top level directory cached on loader instance
    this_dir = os.path.dirname(__file__)
    package_tests = loader.discover(start_dir=this_dir, pattern=pattern)
    standard_tests.addTests(package_tests)
    return standard_tests
```

### 25.3.8 Class and Module Fixtures

Class and module level fixtures are implemented in `TestSuite`. When the test suite encounters a test from a new class then `tearDownClass()` from the previous class (if there is one) is called, followed by `setUpClass()` from the new class.

Similarly if a test is from a different module from the previous test then `tearDownModule` from the previous module is run, followed by `setUpModule` from the new module.

After all the tests have run the final `tearDownClass` and `tearDownModule` are run.

Note that shared fixtures do not play well with [potential] features like test parallelization and they break test isolation. They should be used with care.

The default ordering of tests created by the unittest test loaders is to group all tests from the same modules and classes together. This will lead to `setUpClass` / `setUpModule` (etc) being called exactly once per class and module. If you randomize the order, so that tests from different modules and classes are adjacent to each other, then these shared fixture functions may be called multiple times in a single test run.

Shared fixtures are not intended to work with suites with non-standard ordering. A `BaseTestSuite` still exists for frameworks that don't want to support shared fixtures.

If there are any exceptions raised during one of the shared fixture functions the test is reported as an error. Because there is no corresponding test instance an `_ErrorHolder` object (that has the same interface as a `TestCase`) is created to represent the error. If you are just using the standard unittest test runner then this detail doesn't matter, but if you are a framework author it may be relevant.

### setUpClass and tearDownClass

These must be implemented as class methods :

```
import unittest

class Test(unittest.TestCase):
    @classmethod
    def setUpClass(cls):
        cls._connection = createExpensiveConnectionObject()

    @classmethod
    def tearDownClass(cls):
        cls._connection.destroy()
```

If you want the `setUpClass` and `tearDownClass` on base classes called then you must call up to them yourself. The implementations in `TestCase` are empty.

If an exception is raised during a `setUpClass` then the tests in the class are not run and the `tearDownClass` is not run. Skipped classes will not have `setUpClass` or `tearDownClass` run. If the exception is a `SkipTest` exception then the class will be reported as having been skipped instead of as an error.

### setUpModule and tearDownModule

These should be implemented as functions :

```
def setUpModule():
    createConnection()

def tearDownModule():
    closeConnection()
```

If an exception is raised in a `setUpModule` then none of the tests in the module will be run and the `tearDownModule` will not be run. If the exception is a `SkipTest` exception then the module will be reported as having been skipped instead of as an error.

## 25.3.9 Signal Handling

The `-c/--catch` command-line option to `unittest`, along with the `catchbreak` parameter to `unittest.main()`, provide more friendly handling of control-C during a test run. With catch break behavior enabled control-C will allow the currently running test to complete, and the test run will then end and report all the results so far. A second control-c will raise a `KeyboardInterrupt` in the usual way.

The control-c handling signal handler attempts to remain compatible with code or tests that install their own `signal.SIGINT` handler. If the `unittest` handler is called but *isn't* the installed `signal.SIGINT` handler, i.e. it has been replaced by the system under test and delegated to, then it calls the default handler. This will normally be the expected behavior by code that replaces an installed handler and delegates to it. For individual tests that need `unittest` control-c handling disabled the `removeHandler()` decorator can be used.

There are a few utility functions for framework authors to enable control-c handling functionality within test frameworks.

#### `unittest.installHandler()`

Install the control-c handler. When a `signal.SIGINT` is received (usually in response to the user pressing control-c) all registered results have `stop()` called.

Nouveau dans la version 2.7.

`unittest.registerResult(result)`

Register a `TestResult` object for control-c handling. Registering a result stores a weak reference to it, so it doesn't prevent the result from being garbage collected.

Registering a `TestResult` object has no side-effects if control-c handling is not enabled, so test frameworks can unconditionally register all results they create independently of whether or not handling is enabled.

Nouveau dans la version 2.7.

`unittest.removeResult(result)`

Remove a registered result. Once a result has been removed then `stop()` will no longer be called on that result object in response to a control-c.

Nouveau dans la version 2.7.

`unittest.removeHandler(function=None)`

When called without arguments this function removes the control-c handler if it has been installed. This function can also be used as a test decorator to temporarily remove the handler while the test is being executed :

```
@unittest.removeHandler
def test_signal_handling(self):
    ...
```

Nouveau dans la version 2.7.

## 25.4 *2to3* — Traduction automatique de code en Python 2 vers Python 3

*2to3* est un programme Python qui lit du code source en Python 2.x et applique une suite de correcteurs pour le transformer en code Python 3.x valide. La bibliothèque standard contient un ensemble riche de correcteurs qui gèreront quasiment tout le code. La bibliothèque *lib2to3* utilisée par *2to3* est cependant une bibliothèque flexible et générique, il est donc possible d'écrire vos propres correcteurs pour *2to3*. *lib2to3* pourrait aussi être adaptée à des applications personnalisées dans lesquelles le code Python doit être édité automatiquement.

### 25.4.1 Utilisation de *2to3*

*2to3* sera généralement installé avec l'interpréteur Python en tant que script. Il est également situé dans le dossier `Tools/scripts` à racine de Python.

Les arguments de base de *2to3* sont une liste de fichiers et de répertoires à transformer. Les répertoires sont parcourus récursivement pour trouver les sources Python.

Voici un exemple de fichier source Python 2.x, `example.py` :

```
def greet(name):
    print "Hello, {0}!".format(name)
print "What's your name?"
name = raw_input()
greet(name)
```

Il peut être converti en code Python 3.x par *2to3* en ligne de commande :

```
$ 2to3 example.py
```

A diff against the original source file is printed. 2to3 can also write the needed modifications right back to the source file. (A backup of the original file is made unless `-n` is also given.) Writing the changes back is enabled with the `-w` flag :

```
$ 2to3 -w example.py
```

Après transformation, `example.py` ressemble à :

```
def greet(name):
    print("Hello, {0}!".format(name))
print("What's your name?")
name = input()
greet(name)
```

Les commentaires et les retraits sont préservés tout au long du processus de traduction.

By default, 2to3 runs a set of *predefined fixers*. The `-l` flag lists all available fixers. An explicit set of fixers to run can be given with `-f`. Likewise the `-x` explicitly disables a fixer. The following example runs only the imports and has\_key fixers :

```
$ 2to3 -f imports -f has_key example.py
```

Cette commande exécute tous les correcteurs, sauf le correcteurs `apply` :

```
$ 2to3 -x apply example.py
```

Certains correcteurs sont *explicités*, ce qui signifie qu'ils ne sont pas exécutés par défaut et doivent être énumérés sur la ligne de commande à exécuter. Ici, en plus des correcteurs par défaut, le correcteur `idioms` est exécuté :

```
$ 2to3 -f all -f idioms example.py
```

Notez que passer `all` active tous les correcteurs par défaut.

Parfois, 2to3 trouvera un endroit dans votre code source qui doit être changé, mais qu'il ne peut pas résoudre automatiquement. Dans ce cas, 2to3 affiche un avertissement sous la comparaison d'un fichier. Vous devez traiter l'avertissement afin d'avoir un code conforme à Python 3.x.

2to3 peut également réusiner les *doctests*. Pour activer ce mode, utilisez `-d`. Notez que *seul* les *doctests* seront réusins. Cela ne nécessite pas que le module soit du Python valide. Par exemple, des *doctests* tels que des exemples dans un document *reST* peuvent également être réusins avec cette option.

L'option `-v` augmente la quantité de messages générés par le processus de traduction.

Since some print statements can be parsed as function calls or statements, 2to3 cannot always read files containing the print function. When 2to3 detects the presence of the `from __future__ import print_function` compiler directive, it modifies its internal grammar to interpret `print()` as a function. This change can also be enabled manually with the `-p` flag. Use `-p` to run fixers on code that already has had its print statements converted.

The `-o` or `--output-dir` option allows specification of an alternate directory for processed output files to be written to. The `-n` flag is required when using this as backup files do not make sense when not overwriting the input files.

Nouveau dans la version 2.7.3 : The `-o` option was added.

The `-W` or `--write-unchanged-files` flag tells 2to3 to always write output files even if no changes were required to the file. This is most useful with `-o` so that an entire Python source tree is copied with translation from one directory to another. This option implies the `-w` flag as it would not make sense otherwise.

Nouveau dans la version 2.7.3 : L'option `-W` a été ajoutée.

The `--add-suffix` option specifies a string to append to all output filenames. The `-n` flag is required when specifying this as backups are not necessary when writing to different filenames. Example :

```
$ 2to3 -n -W --add-suffix=3 example.py
```

Écrit un fichier converti nommé `example.py3`.

Nouveau dans la version 2.7.3 : The `--add-suffix` option was added.

Pour traduire un projet entier d'une arborescence de répertoires à une autre, utilisez :

```
$ 2to3 --output-dir=python3-version/mycode -W -n python2-version/mycode
```

## 25.4.2 Correcteurs

Chaque étape de la transformation du code est encapsulée dans un correcteur. La commande `2to3 -l` les énumère. Comme *documenté ci-dessus*, chacun peut être activé ou désactivé individuellement. Ils sont décrits plus en détails ici.

### **apply**

Supprime l'usage d'*apply()*. Par exemple, `apply(function, *args, **kwargs)` est converti en `function(*args, **kwargs)`.

### **asserts**

Remplace les noms de méthodes obsolètes du module *unittest* par les bons.

De	À
<code>failUnlessEqual(a, b)</code>	<code>assertEqual(a, b)</code>
<code>assertEquals(a, b)</code>	<code>assertEqual(a, b)</code>
<code>failIfEqual(a, b)</code>	<code>assertNotEqual(a, b)</code>
<code>assertNotEquals(a, b)</code>	<code>assertNotEqual(a, b)</code>
<code>failUnless(a)</code>	<code>assertTrue(a)</code>
<code>assert_(a)</code>	<code>assertTrue(a)</code>
<code>failIf(a)</code>	<code>assertFalse(a)</code>
<code>failUnlessRaises(exc, cal)</code>	<code>assertRaises(exc, cal)</code>
<code>failUnlessAlmostEqual(a, b)</code>	<code>assertAlmostEqual(a, b)</code>
<code>assertAlmostEquals(a, b)</code>	<code>assertAlmostEqual(a, b)</code>
<code>failIfAlmostEqual(a, b)</code>	<code>assertNotAlmostEqual(a, b)</code>
<code>assertNotAlmostEquals(a, b)</code>	<code>assertNotAlmostEqual(a, b)</code>

### **basestring**

Convertit une *basestring* en *str*.

### **buffer**

Convertit un *buffer* en *memoryview*. Ce correcteur est optionnel car l'API *memoryview* est similaire mais pas exactement pareil que celle de *buffer*.

### **dict**

Fixe les méthodes d'itération sur les dictionnaires. *dict.iteritems()* est converti en *dict.items()*, *dict.iterkeys()* en *dict.keys()* et *dict.itervalues()* en *dict.values()*. Similarly, *dict.viewitems()*, *dict.viewkeys()* et *dict.viewvalues()* sont convertis respectivement en *dict.items()*, *dict.keys()* et *dict.values()*. Il encapsule également les usages existants de *dict.items()*, *dict.keys()* et *dict.values()* dans un appel à *list*.

### **except**

Convertit `except X, T` en `except X as T`.

**exec**

Converts the `exec` statement to the `exec()` function.

**execfile**

Supprime l'usage de `execfile()`. L'argument de `execfile()` est encapsulé dans des appels à `open()`, `compile()` et `exec()`.

**exitfunc**

Change l'affectation de `sys.exitfunc` pour utiliser le module `atexit`.

**filter**

Encapsule l'usage de `filter()` dans un appel à `list`.

**funcattrs**

Fixe les attributs de fonction ayant été renommés. Par exemple, `my_function.func_closure` est converti en `my_function.__closure__`.

**future**

Supprime les instructions `from __future__ import new_feature`.

**getcwdu**

Renomme `os.getcwdu()` en `os.getcwd()`.

**has\_key**

Change `dict.has_key(key)` en `key in dict`.

**idioms**

Ce correcteur optionnel effectue plusieurs transformations rendant le code Python plus idiomatique. Les comparaisons de types telles que `type(x) is SomeClass` et `type(x) == SomeClass` sont converties en `isinstance(x, SomeClass)`. `while 1` devient `while True`. Ce correcteur essaye aussi d'utiliser `sorted()` aux endroits appropriés. Par exemple, ce bloc

```
L = list(some_iterable)
L.sort()
```

est transformé en :

```
L = sorted(some_iterable)
```

**import**

Détecte les imports voisins et les convertis en imports relatifs.

**imports**

Gère les renommages de modules dans la bibliothèque standard.

**imports2**

Gères d'autres renommages de modules dans la bibliothèque standard. Il est distinct de `imports` seulement en raison de limitations techniques.

**input**

Convertit `input(prompt)` en `eval(input(prompt))`.

**intern**

Convertit `intern()` en `sys.intern()`.

**isinstance**

Fixes duplicate types in the second argument of `isinstance()`. For example, `isinstance(x, (int, int))` is converted to `isinstance(x, (int))`.

**itertools\_imports**

Supprime les imports de `itertools.ifilter()`, `itertools.izip()` et `itertools.imap()`. Les imports de `itertools.ifilterfalse()` sont aussi changés en `itertools.filterfalse()`.

**itertools**

Change l'usage de *itertools.ifilter()*, *itertools.izip()* et *itertools.imap()* en leurs équivalents intégrés. *itertools.ifilterfalse()* est changé en *itertools.filterfalse()*.

**long**

Renomme *long* en *int*.

**map**

Encapsule *map()* dans un appel à *list*. Change aussi *map(None, x)* en *list(x)*. L'usage de *from future\_builtins import map* désactive ce correcteur.

**metaclass**

Convertit l'ancienne syntaxe de métaclass (*\_\_metaclass\_\_ = Meta* dans le corps de la classe) à la nouvelle (*class X(metaclass=Meta)*).

**methodattrs**

Fixe les anciens noms d'attributs de méthodes. Par exemple, *meth.im\_func* est converti en *meth.\_\_func\_\_*.

**ne**

Convertit l'ancienne syntaxe d'inégalité, *<>*, en *!=*.

**next**

Converts the use of iterator's *next()* methods to the *next()* function. It also renames *next()* methods to *\_\_next\_\_()*.

**nonzero**

Renomme *\_\_nonzero\_\_()* en *\_\_bool\_\_()*.

**numliterals**

Convertit les nombres écrits littéralement en octal dans leur nouvelle syntaxe.

**paren**

Ajoute des parenthèses supplémentaires lorsqu'elles sont nécessaires dans les listes en compréhension. Par exemple, *[x for x in 1, 2]* devient *[x for x in (1, 2)]*.

**print**

Converts the *print* statement to the *print()* function.

**raise**

Converts *raise E, V* to *raise E(V)*, and *raise E, V, T* to *raise E(V).with\_traceback(T)*. If *E* is a tuple, the translation will be incorrect because substituting tuples for exceptions has been removed in Python 3.

**raw\_input**

Convertit *raw\_input()* en *input()*.

**reduce**

Gère le déplacement de *reduce()* à *functools.reduce()*.

**renames**

Change *sys.maxint* en *sys.maxsize*.

**repr**

Remplace les accents graves utilisés comme *repr* par des appels à *repr()*.

**set\_literal**

Remplace l'usage du constructeur de *set* par les ensembles littéraux. Ce correcteur est optionnel.

**standarderror**

Renomme *StandardError* en *Exception*.

**sys\_exc**

Change les `sys.exc_value`, `sys.exc_type`, `sys.exc_traceback` dépréciés en `sys.exc_info()`.

**throw**

Fixe le changement de l'API dans la méthode `throw()` du générateur.

**tuple\_params**

Supprime la décompression implicite des paramètres d'un tuple. Ce correcteur ajoute des variables temporaires.

**types**

Fixe le code cassé par la suppression de certains membres du module `types`.

**unicode**

Renomme `unicode` en `str`.

**urllib**

Gère le renommage des paquets `urllib` et `urllib2` en `urllib`.

**ws\_comma**

Supprime l'espace excédentaire des éléments séparés par des virgules. Ce correcteur est optionnel.

**xrange**

Renomme la fonction `xrange()` en `range()` et encapsule les appels à la fonction `range()` avec des appels à `list`.

**xreadlines**

Change `for x in file.xreadlines()` en `for x in file`.

**zip**

Encapsule l'usage de `zip()` dans un appel à `list`. Ceci est désactivé lorsque `from future_builtins import zip` apparaît.

### 25.4.3 lib2to3 — la bibliothèque de 2to3

---

**Note :** L'API de `lib2to3` devrait être considérée instable et peut changer drastiquement dans le futur.

---

## 25.5 test — Regression tests package for Python

---

**Note :** The `test` package is meant for internal use by Python only. It is documented for the benefit of the core developers of Python. Any use of this package outside of Python's standard library is discouraged as code mentioned here can change or be removed without notice between releases of Python.

---

The `test` package contains all regression tests for Python as well as the modules `test.support` and `test.regrtest`. `test.support` is used to enhance your tests while `test.regrtest` drives the testing suite.

Each module in the `test` package whose name starts with `test_` is a testing suite for a specific module or feature. All new tests should be written using the `unittest` or `doctest` module. Some older tests are written using a « traditional » testing style that compares output printed to `sys.stdout`; this style of test is considered deprecated.

**Voir aussi :**

Module `unittest` Writing PyUnit regression tests.

Module `doctest` Tests embedded in documentation strings.

### 25.5.1 Writing Unit Tests for the test package

It is preferred that tests that use the `unittest` module follow a few guidelines. One is to name the test module by starting it with `test_` and end it with the name of the module being tested. The test methods in the test module should start with `test_` and end with a description of what the method is testing. This is needed so that the methods are recognized by the test driver as test methods. Also, no documentation string for the method should be included. A comment (such as `# Tests function returns only True or False`) should be used to provide documentation for test methods. This is done because documentation strings get printed out if they exist and thus what test is being run is not stated.

A basic boilerplate is often used :

```
import unittest
from test import support

class MyTestCase1(unittest.TestCase):

    # Only use setUp() and tearDown() if necessary

    def setUp(self):
        ... code to execute in preparation for tests ...

    def tearDown(self):
        ... code to execute to clean up after tests ...

    def test_feature_one(self):
        # Test feature one.
        ... testing code ...

    def test_feature_two(self):
        # Test feature two.
        ... testing code ...

    ... more test methods ...

class MyTestCase2(unittest.TestCase):
    ... same structure as MyTestCase1 ...

... more test classes ...

def test_main():
    support.run_unittest(MyTestCase1,
                        MyTestCase2,
                        ... list other tests ...
                        )

if __name__ == '__main__':
    test_main()
```

This boilerplate code allows the testing suite to be run by `test.regrtest` as well as on its own as a script.

The goal for regression testing is to try to break code. This leads to a few guidelines to be followed :

- The testing suite should exercise all classes, functions, and constants. This includes not just the external API that is to be presented to the outside world but also « private » code.
- Whitebox testing (examining the code being tested when the tests are being written) is preferred. Blackbox testing (testing only the published user interface) is not complete enough to make sure all

- boundary and edge cases are tested.
- Make sure all possible values are tested including invalid ones. This makes sure that not only all valid values are acceptable but also that improper values are handled correctly.
- Exhaust as many code paths as possible. Test where branching occurs and thus tailor input to make sure as many different paths through the code are taken.
- Add an explicit test for any bugs discovered for the tested code. This will make sure that the error does not crop up again if the code is changed in the future.
- Make sure to clean up after your tests (such as close and remove all temporary files).
- If a test is dependent on a specific condition of the operating system then verify the condition already exists before attempting the test.
- Import as few modules as possible and do it as soon as possible. This minimizes external dependencies of tests and also minimizes possible anomalous behavior from side-effects of importing a module.
- Try to maximize code reuse. On occasion, tests will vary by something as small as what type of input is used. Minimize code duplication by subclassing a basic test class with a class that specifies the input :

```
class TestFuncAcceptsSequences(unittest.TestCase):

    func = mySuperWhammyFunction

    def test_func(self):
        self.func(self.arg)

class AcceptLists(TestFuncAcceptsSequences):
    arg = [1, 2, 3]

class AcceptStrings(TestFuncAcceptsSequences):
    arg = 'abc'

class AcceptTuples(TestFuncAcceptsSequences):
    arg = (1, 2, 3)
```

Voir aussi :

**Test Driven Development** A book by Kent Beck on writing tests before code.

### 25.5.2 Running tests using the command-line interface

The `test.regrtest` module can be run as a script to drive Python's regression test suite, thanks to the `-m` option : `python -m test.regrtest`. Running the script by itself automatically starts running all regression tests in the `test` package. It does this by finding all modules in the package whose name starts with `test_`, importing them, and executing the function `test_main()` if present. The names of tests to execute may also be passed to the script. Specifying a single regression test (`python -m test.regrtest test_spam`) will minimize output and only print whether the test passed or failed and thus minimize output.

Running `test.regrtest` directly allows what resources are available for tests to use to be set. You do this by using the `-u` command-line option. Specifying `all` as the value for the `-u` option enables all possible resources : `python -m test.regrtest -uall`. If all but one resource is desired (a more common case), a comma-separated list of resources that are not desired may be listed after `all`. The command `python -m test.regrtest -uall,-audio,-largefile` will run `test.regrtest` with all resources except the `audio` and `largefile` resources. For a list of all resources and more command-line options, run `python -m test.regrtest -h`.

Some other ways to execute the regression tests depend on what platform the tests are being executed on. On Unix, you can run `make test` at the top-level directory where Python was built. On Windows, executing `rt.bat` from your PCBuild directory will run all regression tests.

Modifié dans la version 2.7.14 : The `test` package can be run as a script : `python -m test`. This works the same as running the `test.regrtest` module.

## 25.6 `test.support` — Utility functions for tests

---

**Note :** The `test.test_support` module has been renamed to `test.support` in Python 3.x and 2.7.14. The name `test.test_support` has been retained as an alias in 2.7.

---

The `test.support` module provides support for Python's regression tests.

This module defines the following exceptions :

**exception `test.support.TestFailed`**

Exception to be raised when a test fails. This is deprecated in favor of `unittest`-based tests and `unittest.TestCase`'s assertion methods.

**exception `test.support.ResourceDenied`**

Subclass of `unittest.SkipTest`. Raised when a resource (such as a network connection) is not available. Raised by the `requires()` function.

The `test.support` module defines the following constants :

**`test.support.verbose`**

`True` when verbose output is enabled. Should be checked when more detailed information is desired about a running test. `verbose` is set by `test.regrtest`.

**`test.support.have_unicode`**

`True` when Unicode support is available.

**`test.support.is_jython`**

`True` if the running interpreter is Jython.

**`test.support.TESTFN`**

Set to a name that is safe to use as the name of a temporary file. Any temporary file that is created should be closed and unlinked (removed).

The `test.support` module defines the following functions :

**`test.support.forget(module_name)`**

Remove the module named `module_name` from `sys.modules` and delete any byte-compiled files of the module.

**`test.support.is_resource_enabled(resource)`**

Return `True` if `resource` is enabled and available. The list of available resources is only set when `test.regrtest` is executing the tests.

**`test.support.requires(resource[, msg])`**

Raise `ResourceDenied` if `resource` is not available. `msg` is the argument to `ResourceDenied` if it is raised. Always returns `True` if called by a function whose `__name__` is `'__main__'`. Used when tests are executed by `test.regrtest`.

**`test.support.findfile(filename)`**

Return the path to the file named `filename`. If no match is found `filename` is returned. This does not equal a failure since it could be the path to the file.

**`test.support.run_unittest(*classes)`**

Execute `unittest.TestCase` subclasses passed to the function. The function scans the classes for methods starting with the prefix `test_` and executes the tests individually.

It is also legal to pass strings as parameters; these should be keys in `sys.modules`. Each associated module will be scanned by `unittest.TestLoader.loadTestsFromModule()`. This is usually seen in the following `test_main()` function :

```
def test_main():
    support.run_unittest(__name__)
```

This will run all tests defined in the named module.

`test.support.check_warnings(*filters, quiet=True)`

A convenience wrapper for `warnings.catch_warnings()` that makes it easier to test that a warning was correctly raised. It is approximately equivalent to calling `warnings.catch_warnings(record=True)` with `warnings.simplefilter()` set to `always` and with the option to automatically validate the results that are recorded.

`check_warnings` accepts 2-tuples of the form ("message regexp", `WarningCategory`) as positional arguments. If one or more *filters* are provided, or if the optional keyword argument *quiet* is `False`, it checks to make sure the warnings are as expected : each specified filter must match at least one of the warnings raised by the enclosed code or the test fails, and if any warnings are raised that do not match any of the specified filters the test fails. To disable the first of these checks, set *quiet* to `True`.

If no arguments are specified, it defaults to :

```
check_warnings(("", Warning), quiet=True)
```

In this case all warnings are caught and no errors are raised.

On entry to the context manager, a `WarningRecorder` instance is returned. The underlying warnings list from `catch_warnings()` is available via the recorder object's `warnings` attribute. As a convenience, the attributes of the object representing the most recent warning can also be accessed directly through the recorder object (see example below). If no warning has been raised, then any of the attributes that would otherwise be expected on an object representing a warning will return `None`.

The recorder object also has a `reset()` method, which clears the warnings list.

The context manager is designed to be used like this :

```
with check_warnings(("assertion is always true", SyntaxWarning),
                    ("", UserWarning)):
    exec('assert(False, "Hey!")')
    warnings.warn(UserWarning("Hide me!"))
```

In this case if either warning was not raised, or some other warning was raised, `check_warnings()` would raise an error.

When a test needs to look more deeply into the warnings, rather than just checking whether or not they occurred, code like this can be used :

```
with check_warnings(quiet=True) as w:
    warnings.warn("foo")
    assert str(w.args[0]) == "foo"
    warnings.warn("bar")
    assert str(w.args[0]) == "bar"
    assert str(w.warnings[0].args[0]) == "foo"
    assert str(w.warnings[1].args[0]) == "bar"
    w.reset()
    assert len(w.warnings) == 0
```

Here all warnings will be caught, and the test code tests the captured warnings directly.

Nouveau dans la version 2.6.

Modifié dans la version 2.7 : New optional arguments *filters* and *quiet*.

`test.support.check_py3k_warnings(*filters, quiet=False)`

Similar to `check_warnings()`, but for Python 3 compatibility warnings. If `sys.py3kwarning == 1`, it checks if the warning is effectively raised. If `sys.py3kwarning == 0`, it checks that no warning is raised. It accepts 2-tuples of the form `("message regexp", WarningCategory)` as positional arguments. When the optional keyword argument `quiet` is `True`, it does not fail if a filter catches nothing. Without arguments, it defaults to :

```
check_py3k_warnings((" ", DeprecationWarning), quiet=False)
```

Nouveau dans la version 2.7.

`test.support.captured_stdout()`

This is a context manager that runs the `with` statement body using a `StringIO.StringIO` object as `sys.stdout`. That object can be retrieved using the `as` clause of the `with` statement.

Example use :

```
with captured_stdout() as s:
    print "hello"
assert s.getvalue() == "hello\n"
```

Nouveau dans la version 2.6.

`test.support.import_module(name, deprecated=False)`

This function imports and returns the named module. Unlike a normal import, this function raises `unittest.SkipTest` if the module cannot be imported.

Module and package deprecation messages are suppressed during this import if `deprecated` is `True`.

Nouveau dans la version 2.7.

`test.support.import_fresh_module(name, fresh=(), blocked=(), deprecated=False)`

This function imports and returns a fresh copy of the named Python module by removing the named module from `sys.modules` before doing the import. Note that unlike `reload()`, the original module is not affected by this operation.

`fresh` is an iterable of additional module names that are also removed from the `sys.modules` cache before doing the import.

`blocked` is an iterable of module names that are replaced with 0 in the module cache during the import to ensure that attempts to import them raise `ImportError`.

The named module and any modules named in the `fresh` and `blocked` parameters are saved before starting the import and then reinserted into `sys.modules` when the fresh import is complete.

Module and package deprecation messages are suppressed during this import if `deprecated` is `True`.

This function will raise `unittest.SkipTest` if the named module cannot be imported.

Example use :

```
# Get copies of the warnings module for testing without
# affecting the version being used by the rest of the test suite
# One copy uses the C implementation, the other is forced to use
# the pure Python fallback implementation
py_warnings = import_fresh_module('warnings', blocked=['_warnings'])
c_warnings = import_fresh_module('warnings', fresh=['_warnings'])
```

Nouveau dans la version 2.7.

The `test.support` module defines the following classes :

`class test.support.TransientResource(exc[, **kwargs])`

Instances are a context manager that raises `ResourceDenied` if the specified exception type is raised.

Any keyword arguments are treated as attribute/value pairs to be compared against any exception

raised within the `with` statement. Only if all pairs match properly against attributes on the exception is *ResourceDenied* raised.

Nouveau dans la version 2.6.

**class test.support.EnvironmentVarGuard**

Class used to temporarily set or unset environment variables. Instances can be used as a context manager and have a complete dictionary interface for querying/modifying the underlying `os.environ`. After exit from the context manager all changes to environment variables done through this instance will be rolled back.

Nouveau dans la version 2.6.

Modifié dans la version 2.7 : Added dictionary interface.

**EnvironmentVarGuard.set(envvar, value)**

Temporarily set the environment variable `envvar` to the value of `value`.

**EnvironmentVarGuard.unset(envvar)**

Temporarily unset the environment variable `envvar`.

**class test.support.WarningsRecorder**

Class used to record warnings for unit tests. See documentation of *check\_warnings()* above for more details.

Nouveau dans la version 2.6.

Ces bibliothèques sont là pour vous aider lors du développement en Python : Le débogueur vous permet d'avancer pas à pas dans le code, d'analyser la pile d'appel, de placer des points d'arrêts, ... Les outils d'instrumentation exécutent du code et vous donnent un rapport détaillé du temps d'exécution, vous permettant d'identifier les goulots d'étranglement dans vos programmes.

## 26.1 bdb — Framework de débogage

Code source : [Lib/bdb.py](#)

---

The `bdb` module handles basic debugger functions, like setting breakpoints or managing execution via the debugger.

L'exception suivante est définie :

```
exception bdb.BdbQuit
    Exception raised by the Bdb class for quitting the debugger.
```

Le module `bdb` définit deux classes :

```
class bdb.Breakpoint(self, file, line, temporary=0, cond=None, funcname=None)
    This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

    Breakpoints are indexed by number through a list called bdbynumber and by (file, line) pairs through bplist. The former points to a single instance of class Breakpoint. The latter points to a list of such instances since there may be more than one breakpoint per line.

    When creating a breakpoint, its associated filename should be in canonical form. If a funcname is defined, a breakpoint hit will be counted when the first line of that function is executed. A conditional breakpoint always counts a hit.

    Breakpoint instances have the following methods :

    deleteMe()
        Delete the breakpoint from the list associated to a file/line. If it is the last breakpoint in that position, it also deletes the entry for the file/line.
```

**enable()**

Active le point d'arrêt.

**disable()**

Désactive le point d'arrêt.

**pprint([out])**

Print all the information about the breakpoint :

- Le numéro du point d'arrêt.
- S'il est temporaire ou non.
- Its file,line position.
- The condition that causes a break.
- If it must be ignored the next N times.
- The breakpoint hit count.

**class bdb.Bdb(skip=None)**

The *Bdb* class acts as a generic Python debugger base class.

This class takes care of the details of the trace facility ; a derived class should implement user interaction.

The standard debugger class (*pdb.Pdb*) is an example.

The *skip* argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

Nouveau dans la version 2.7 : L'argument *skip*.

The following methods of *Bdb* normally don't need to be overridden.

**canonic(filename)**

Auxiliary method for getting a filename in a canonical form, that is, as a case-normalized (on case-insensitive filesystems) absolute path, stripped of surrounding angle brackets.

**reset()**

Set the `botframe`, `stopframe`, `returnframe` and `quitting` attributes with values ready to start debugging.

**trace\_dispatch(frame, event, arg)**

This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. *event* can be one of the following :

- "line" : A new line of code is going to be executed.
- "call" : A function is about to be called, or another code block entered.
- "return" : A function or other code block is about to return.
- "exception" : Une exception est survenue.
- "c\_call" : Une fonction C est sur le point d'être appelée.
- "c\_return" : Une fonction C s'est terminée.
- "c\_exception" : A C function has raised an exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

Le paramètre *arg* dépend de l'événement précédent.

See the documentation for *sys.settrace()* for more information on the trace function. For more information on code and frame objects, refer to types.

**dispatch\_line(frame)**

If the debugger should stop on the current line, invoke the *user\_line()* method (which should be overridden in subclasses). Raise a *BdbQuit* exception if the `Bdb.quitting` flag is set (which can be set from *user\_line()*). Return a reference to the *trace\_dispatch()* method for further tracing in that scope.

**dispatch\_call(frame, arg)**

If the debugger should stop on this function call, invoke the *user\_call()* method (which should be overridden in subclasses). Raise a *BdbQuit* exception if the `Bdb.quitting` flag is set (which

can be set from `user_call()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch\_return**(*frame*, *arg*)

If the debugger should stop on this function return, invoke the `user_return()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_return()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch\_exception**(*frame*, *arg*)

If the debugger should stop at this exception, invokes the `user_exception()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_exception()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

Normally derived classes don't override the following methods, but they may if they want to redefine the definition of stopping and breakpoints.

**stop\_here**(*frame*)

This method checks if the *frame* is somewhere below `botframe` in the call stack. `botframe` is the frame in which debugging started.

**break\_here**(*frame*)

This method checks if there is a breakpoint in the filename and line belonging to *frame* or, at least, in the current function. If the breakpoint is a temporary one, this method deletes it.

**break\_anywhere**(*frame*)

This method checks if there is a breakpoint in the filename of the current frame.

Derived classes should override these methods to gain control over debugger operation.

**user\_call**(*frame*, *argument\_list*)

This method is called from `dispatch_call()` when there is the possibility that a break might be necessary anywhere inside the called function.

**user\_line**(*frame*)

This method is called from `dispatch_line()` when either `stop_here()` or `break_here()` yields True.

**user\_return**(*frame*, *return\_value*)

This method is called from `dispatch_return()` when `stop_here()` yields True.

**user\_exception**(*frame*, *exc\_info*)

This method is called from `dispatch_exception()` when `stop_here()` yields True.

**do\_clear**(*arg*)

Handle how a breakpoint must be removed when it is a temporary one.

This method must be implemented by derived classes.

Derived classes and clients can call the following methods to affect the stepping state.

**set\_step**()

Arrête après une ligne de code.

**set\_next**(*frame*)

Stop on the next line in or below the given frame.

**set\_return**(*frame*)

Stop when returning from the given frame.

**set\_until**(*frame*)

Stop when the line with the line no greater than the current one is reached or when returning from current frame.

**set\_trace**([*frame*])

Start debugging from *frame*. If *frame* is not specified, debugging starts from caller's frame.

**set\_continue**()

Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to None.

**set\_quit()**

Set the `quitting` attribute to `True`. This raises `BdbQuit` in the next call to one of the `dispatch_*`() methods.

Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or `None` if all is well.

**set\_break(filename, lineno, temporary=0, cond=None, funcname=None)**

Set a new breakpoint. If the `lineno` line doesn't exist for the `filename` passed as argument, return an error message. The `filename` should be in canonical form, as described in the `canonic()` method.

**clear\_break(filename, lineno)**

Delete the breakpoints in `filename` and `lineno`. If none were set, an error message is returned.

**clear\_bpbynumber(arg)**

Delete the breakpoint which has the index `arg` in the `Breakpoint.bpbynumber`. If `arg` is not numeric or out of range, return an error message.

**clear\_all\_file\_breaks(filename)**

Delete all breakpoints in `filename`. If none were set, an error message is returned.

**clear\_all\_breaks()**

Supprime tous les points d'arrêt définis.

**get\_break(filename, lineno)**

Check if there is a breakpoint for `lineno` of `filename`.

**get\_breaks(filename, lineno)**

Return all breakpoints for `lineno` in `filename`, or an empty list if none are set.

**get\_file\_breaks(filename)**

Return all breakpoints in `filename`, or an empty list if none are set.

**get\_all\_breaks()**

Donne tous les points d'arrêt définis.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

**get\_stack(f, t)**

Get a list of records for a frame and all higher (calling) and lower frames, and the size of the higher part.

**format\_stack\_entry(frame\_lineno[, lprefix=' : '])**

Return a string with information about a stack entry, identified by a `(frame, lineno)` tuple :

- The canonical form of the filename which contains the frame.
- Le nom de la fonction, ou "`<lambda>`".
- Les arguments donnés.
- Le résultat.
- La ligne de code (si elle existe).

The following two methods can be called by clients to use a debugger to debug a `statement`, given as a string.

**run(cmd[, globals[, locals]])**

Debug a statement executed via the `exec` statement. `globals` defaults to `__main__.__dict__`, `locals` defaults to `globals`.

**runeval(expr[, globals[, locals]])**

Debug an expression executed via the `eval()` function. `globals` and `locals` have the same meaning as in `run()`.

**runctx(cmd, globals, locals)**

For backwards compatibility. Calls the `run()` method.

**runcall(func, \*args, \*\*kws)**

Debug a single function call, and return its result.

Finally, the module defines the following functions :

`bdb.checkfuncname(b, frame)`

Check whether we should break here, depending on the way the breakpoint *b* was set.

If it was set via line number, it checks if `b.line` is the same as the one in the frame also passed as argument. If the breakpoint was set via function name, we have to check we are in the right frame (the right function) and if we are in its first executable line.

`bdb.effective(file, line, frame)`

Determine if there is an effective (active) breakpoint at this line of code. Return a tuple of the breakpoint and a boolean that indicates if it is ok to delete a temporary breakpoint. Return `(None, None)` if there is no matching breakpoint.

`bdb.set_trace()`

Start debugging with a *Bdb* instance from caller's frame.

## 26.2 pdb — Le débogueur Python

Code source : [Lib/pdb.py](#)

Le module *pdb* définit un débogueur de code source interactif pour les programmes Python. Il supporte le paramétrage (conditionnel) de points d'arrêt et l'exécution du code source ligne par ligne, l'inspection des *frames* de la pile, la liste du code source, et l'évaluation arbitraire de code Python dans le contexte de n'importe quelle *frame* de la pile. Il supporte aussi le débogage post-mortem et peut être contrôlé depuis un programme.

The debugger is extensible — it is actually defined as the class *Pdb*. This is currently undocumented but easily understood by reading the source. The extension interface uses the modules *bdb* and *cmd*.

L'invite du débogueur est `(Pdb)`. L'usage typique pour exécuter un programme sous le contrôle du débogueur est :

```
>>> import pdb
>>> import mymodule
>>> pdb.run('mymodule.test()')
> <string>(0)?()
(Pdb) continue
> <string>(1)?()
(Pdb) continue
NameError: 'spam'
> <string>(1)?()
(Pdb)
```

Le fichier *pdb.py* peut aussi être invoqué comme un script pour déboguer d'autres scripts. Par exemple :

```
python -m pdb myscript.py
```

When invoked as a script, *pdb* will automatically enter post-mortem debugging if the program being debugged exits abnormally. After post-mortem debugging (or after normal exit of the program), *pdb* will restart the program. Automatic restarting preserves *pdb*'s state (such as breakpoints) and in most cases is more useful than quitting the debugger upon program's exit.

Nouveau dans la version 2.4 : Restarting post-mortem behavior added.

L'usage typique pour forcer le débogueur depuis un programme s'exécutant est d'insérer :

```
import pdb; pdb.set_trace()
```

at the location you want to break into the debugger. You can then step through the code following this statement, and continue running without the debugger using the `c` command.

L'usage typique pour inspecter un programme planté :

```
>>> import pdb
>>> import mymodule
>>> mymodule.test()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "./mymodule.py", line 4, in test
    test2()
  File "./mymodule.py", line 3, in test2
    print spam
NameError: spam
>>> pdb.pm()
> ./mymodule.py(3)test2()
-> print spam
(Pdb)
```

Le module définit les fonctions suivantes; chacune entre dans le débogueur d'une manière légèrement différente :

`pdb.run(statement[, globals[, locals]])`

Execute the *statement* (given as a string) under debugger control. The debugger prompt appears before any code is executed; you can set breakpoints and type `continue`, or you can step through the statement using `step` or `next` (all these commands are explained below). The optional *globals* and *locals* arguments specify the environment in which the code is executed; by default the dictionary of the module `__main__` is used. (See the explanation of the `exec` statement or the `eval()` built-in function.)

`pdb.runeval(expression[, globals[, locals]])`

Evaluate the *expression* (given as a string) under debugger control. When `runeval()` returns, it returns the value of the expression. Otherwise this function is similar to `run()`.

`pdb.runcall(function[, argument, ...])`

Appelle la *function* (une fonction ou une méthode, pas une chaîne de caractères) avec les arguments donnés. Quand `runcall()` revient, il retourne ce que l'appel de fonction a renvoyé. L'invite de débogage apparaît dès que la fonction est entrée.

`pdb.set_trace()`

Entre le débogueur dans la *frame* de la pile d'appel. Ceci est utile pour coder en dur un point d'arrêt dans un programme, même si le code n'est pas autrement débogué (par exemple, quand une assertion échoue).

`pdb.post_mortem([traceback])`

Entre le débogage post-mortem de l'objet *traceback* donné. Si aucun *traceback* n'est donné, il utilise celui de l'exception en cours de traitement (une exception doit être gérée si la valeur par défaut doit être utilisée).

`pdb.pm()`

Entre le débogage post-mortem de la trace trouvée dans `sys.last_traceback`.

Les fonctions `run*` et `set_trace()` sont des alias pour instancier la classe `Pdb` et appeler la méthode du même nom. Si vous souhaitez accéder à d'autres fonctionnalités, vous devez le faire vous-même :

`class pdb.Pdb(completekey='tab', stdin=None, stdout=None, skip=None)`

Le classe du débogueur est la classe `Pdb`.

Les arguments `completekey`, `stdin` et `stdout` sont transmis à la classe sous-jacente `cmd.Cmd`; voir la description ici.

L'argument `skip`, s'il est donné, doit être un itérable des noms de modules de style *glob*. Le débogueur n'entrera pas dans les *frames* qui proviennent d'un module qui correspond à l'un de ces motifs.<sup>1</sup>

Exemple d'appel pour activer le traçage avec `skip` :

```
import pdb; pdb.Pdb(skip=['django.*']).set_trace()
```

Nouveau dans la version 2.7 : L'argument `skip`.

```
run(statement[, globals[, locals]])
runeval(expression[, globals[, locals]])
runcall(function[, argument, ...])
set_trace()
```

Voir la documentation pour les fonctions expliquées ci-dessus.

## 26.3 Commande du débogueur

The debugger recognizes the following commands. Most commands can be abbreviated to one or two letters ; e.g. `h(elp)` means that either `h` or `help` can be used to enter the help command (but not `he` or `hel`, nor `H` or `Help` or `HELP`). Arguments to commands must be separated by whitespace (spaces or tabs). Optional arguments are enclosed in square brackets (`[]`) in the command syntax; the square brackets must not be typed. Alternatives in the command syntax are separated by a vertical bar (`|`).

Entering a blank line repeats the last command entered. Exception : if the last command was a `list` command, the next 11 lines are listed.

Les commandes que le débogueur ne reconnaît pas sont supposées être des instructions Python et sont exécutées dans le contexte du programme en cours de débogage. Les instructions Python peuvent également être préfixées avec un point d'exclamation (`!`). C'est une façon puissante d'inspecter le programme en cours de débogage; il est même possible de changer une variable ou d'appeler une fonction. Lorsqu'une exception se produit dans une telle instruction, le nom de l'exception est affiché mais l'état du débogueur n'est pas modifié.

Multiple commands may be entered on a single line, separated by `;;`. (A single `;` is not used as it is the separator for multiple commands in a line that is passed to the Python parser.) No intelligence is applied to separating the commands; the input is split at the first `;;` pair, even if it is in the middle of a quoted string.

The debugger supports aliases. Aliases can have parameters which allows one a certain level of adaptability to the context under examination.

If a file `.pdbrc` exists in the user's home directory or in the current directory, it is read in and executed as if it had been typed at the debugger prompt. This is particularly useful for aliases. If both files exist, the one in the home directory is read first and aliases defined there can be overridden by the local file.

**h(elp)** [*command*] Without argument, print the list of available commands. With a *command* as argument, print help about that command. `help pdb` displays the full documentation file; if the environment variable `PAGER` is defined, the file is piped through that command instead. Since the *command* argument must be an identifier, `help exec` must be entered to get help on the `!` command.

**w(here)** Affiche une trace de pile, avec la *frame* le plus récent en bas. Une flèche indique le *frame* courant, qui détermine le contexte de la plupart des commandes.

**d(own)** Move the current frame one level down in the stack trace (to a newer frame).

1. La question de savoir si une *frame* est considérée comme provenant d'un certain module est déterminée par le `__name__` dans les globales de la *frame*.

**u(p)** Move the current frame one level up in the stack trace (to an older frame).

**b(reak)** `[[filename:]lineno | function[, condition]]` With a *lineno* argument, set a break there in the current file. With a *function* argument, set a break at the first executable statement within that function. The line number may be prefixed with a filename and a colon, to specify a breakpoint in another file (probably one that hasn't been loaded yet). The file is searched on `sys.path`. Note that each breakpoint is assigned a number to which all the other breakpoint commands refer.

Si un second argument est présent, c'est une expression qui doit évaluer à *True* avant que le point d'arrêt ne soit honoré.

Sans argument, liste tous les arrêts, incluant pour chaque point d'arrêt, le nombre de fois qu'un point d'arrêt a été atteint, le nombre de ignore, et la condition associée le cas échéant.

**tbreak** `[[filename:]lineno | function[, condition]]` Temporary breakpoint, which is removed automatically when it is first hit. The arguments are the same as break.

**cl(ear)** `[filename:lineno | bnumber [bnumber ...]]` Avec un argument *filename:lineno*, efface tous les points d'arrêt sur cette ligne. Avec une liste de numéros de points d'arrêt séparés par un espace, efface ces points d'arrêt. Sans argument, efface tous les points d'arrêt (mais demande d'abord confirmation).

**disable** `[bnumber [bnumber ...]]` Disables the breakpoints given as a space separated list of breakpoint numbers. Disabling a breakpoint means it cannot cause the program to stop execution, but unlike clearing a breakpoint, it remains in the list of breakpoints and can be (re-)enabled.

**enable** `[bnumber [bnumber ...]]` Enables the breakpoints specified.

**ignore** *bnumber* `[count]` Sets the ignore count for the given breakpoint number. If count is omitted, the ignore count is set to 0. A breakpoint becomes active when the ignore count is zero. When non-zero, the count is decremented each time the breakpoint is reached and the breakpoint is not disabled and any associated condition evaluates to true.

**condition** *bnumber* `[condition]` Condition is an expression which must evaluate to true before the breakpoint is honored. If condition is absent, any existing condition is removed; i.e., the breakpoint is made unconditional.

**commands** `[bnumber]` Specify a list of commands for breakpoint number *bnumber*. The commands themselves appear on the following lines. Type a line containing just "end" to terminate the commands. An example :

```
(Pdb) commands 1
(com) print some_variable
(com) end
(Pdb)
```

To remove all commands from a breakpoint, type commands and follow it immediately with end; that is, give no commands.

Sans argument *bnumber*, les commandes se réfèrent au dernier point d'arrêt défini.

You can use breakpoint commands to start your program up again. Simply use the continue command, or step, or any other command that resumes execution.

Specifying any command resuming execution (currently continue, step, next, return, jump, quit and their abbreviations) terminates the command list (as if that command was immediately followed by end). This is because any time you resume execution (even with a simple next or step), you may encounter another breakpoint—which could have its own command list, leading to ambiguities about which list to execute.

Si vous utilisez la commande "silence" dans la liste des commandes, le message habituel concernant l'arrêt à un point d'arrêt n'est pas affiché. Ceci peut être souhaitable pour les points d'arrêt qui doivent afficher un message spécifique et ensuite continuer. Si aucune des autres commandes n'affiche quoi que ce soit, vous ne voyez aucun signe indiquant que le point de rupture a été atteint.

Nouveau dans la version 2.5.

- s(step)** Exécute la ligne en cours, s'arrête à la première occasion possible (soit dans une fonction qui est appelée, soit sur la ligne suivante de la fonction courante).
- n(ext)** Continue execution until the next line in the current function is reached or it returns. (The difference between **next** and **step** is that **step** stops inside a called function, while **next** executes called functions at (nearly) full speed, only stopping at the next line in the current function.)
- unt(il)** Continue execution until the line with the line number greater than the current one is reached or when returning from current frame.  
Nouveau dans la version 2.6.
- r(eturn)** Continue l'exécution jusqu'au retour de la fonction courante.
- c(ont(inue))** Continue l'exécution, seulement s'arrête quand un point d'arrêt est rencontré.
- j(ump) lineno** Définit la prochaine ligne qui sera exécutée. Uniquement disponible dans la *frame* inférieur. Cela vous permet de revenir en arrière et d'exécuter à nouveau le code, ou de passer en avant pour sauter le code que vous ne voulez pas exécuter.  
It should be noted that not all jumps are allowed — for instance it is not possible to jump into the middle of a **for** loop or out of a **finally** clause.
- l(ist) [first[, last]]** List source code for the current file. Without arguments, list 11 lines around the current line or continue the previous listing. With one argument, list 11 lines around at that line. With two arguments, list the given range ; if the second argument is less than the first, it is interpreted as a count.
- a(rgs)** Affiche la liste d'arguments de la fonction courante.
- p expression** Évalue l'*expression* dans le contexte courant et affiche sa valeur.

---

**Note :** `print` can also be used, but is not a debugger command — this executes the Python `print` statement.

---

**pp expression** Like the `p` command, except the value of the expression is pretty-printed using the *pprint* module.

**alias [name [command]]** Creates an alias called *name* that executes *command*. The command must *not* be enclosed in quotes. Replaceable parameters can be indicated by `%1`, `%2`, and so on, while `/*` is replaced by all the parameters. If no command is given, the current alias for *name* is shown. If no arguments are given, all aliases are listed.

Aliases may be nested and can contain anything that can be legally typed at the `pdb` prompt. Note that internal `pdb` commands *can* be overridden by aliases. Such a command is then hidden until the alias is removed. Aliasing is recursively applied to the first word of the command line ; all other words in the line are left alone.

Comme un exemple, voici deux alias utiles (spécialement quand il est placé dans le fichier `.pdbrc`) :

```
#Print instance variables (usage "pi classInst")
alias pi for k in %1.__dict__.keys(): print "%1.",k,"=",%1.__dict__[k]
#Print instance variables in self
alias ps pi self
```

**unalias name** Deletes the specified alias.

**[!]statement** Execute the (one-line) *statement* in the context of the current stack frame. The exclamation point can be omitted unless the first word of the statement resembles a debugger command. To set a global variable, you can prefix the assignment command with a `global` command on the same line, e.g. :

```
(Pdb) global list_options; list_options = ['-l']
(Pdb)
```

**run** [*args* ...] Restart the debugged Python program. If an argument is supplied, it is split with « shlex » and the result is used as the new sys.argv. History, breakpoints, actions and debugger options are preserved. « restart » is an alias for « run ».

Nouveau dans la version 2.6.

**q(uit)** Quit from the debugger. The program being executed is aborted.

## Notes

## 26.4 The Python Profilers

Source code : `Lib/profile.py` and `Lib/pstats.py`

---

### 26.4.1 Introduction to the profilers

`cProfile` and `profile` provide *deterministic profiling* of Python programs. A *profile* is a set of statistics that describes how often and for how long various parts of the program executed. These statistics can be formatted into reports via the `pstats` module.

The Python standard library provides three different implementations of the same profiling interface :

1. `cProfile` is recommended for most users ; it's a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on `lsprof`, contributed by Brett Rosen and Ted Czotter.

Nouveau dans la version 2.5.

2. `profile`, a pure Python module whose interface is imitated by `cProfile`, but which adds significant overhead to profiled programs. If you're trying to extend the profiler in some way, the task might be easier with this module. Originally designed and written by Jim Roskind.

Modifié dans la version 2.4 : Now also reports the time spent in calls to built-in functions and methods.

3. `hotshot` was an experimental C module that focused on minimizing the overhead of profiling, at the expense of longer data post-processing times. It is no longer maintained and may be dropped in a future version of Python.

Modifié dans la version 2.5 : The results should be more meaningful than in the past : the timing core contained a critical bug.

The `profile` and `cProfile` modules export the same interface, so they are mostly interchangeable ; `cProfile` has a much lower overhead but is newer and might not be available on all systems. `cProfile` is really a compatibility layer on top of the internal `_lsprof` module. The `hotshot` module is reserved for specialized usage.

---

**Note :** The profiler modules are designed to provide an execution profile for a given program, not for benchmarking purposes (for that, there is `timeit` for reasonably accurate results). This particularly applies to benchmarking Python code against C code : the profilers introduce overhead for Python code, but not for C-level functions, and so the C code would seem faster than any Python one.

---

### 26.4.2 Instant User's Manual

This section is provided for users that « don't want to read the manual. » It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile a function that takes a single argument, you can do :

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")')
```

(Use *profile* instead of *cProfile* if the latter is not available on your system.)

The above action would run *re.compile()* and print profile results like the following :

```
197 function calls (192 primitive calls) in 0.002 seconds

Ordered by: standard name
```

ncalls	tottime	percall	cumtime	percall	filename:lineno(function)
1	0.000	0.000	0.001	0.001	<string>:1(<module>)
1	0.000	0.000	0.001	0.001	re.py:212(compile)
1	0.000	0.000	0.001	0.001	re.py:268(_compile)
1	0.000	0.000	0.000	0.000	sre_compile.py:172(_compile_charset)
1	0.000	0.000	0.000	0.000	sre_compile.py:201(_optimize_charset)
4	0.000	0.000	0.000	0.000	sre_compile.py:25(_identityfunction)
3/1	0.000	0.000	0.000	0.000	sre_compile.py:33(_compile)

The first line indicates that 197 calls were monitored. Of those calls, 192 were *primitive*, meaning that the call was not induced via recursion. The next line : **Ordered by: standard name**, indicates that the text string in the far right column was used to sort the output. The column headings include :

**ncalls** for the number of calls,

**tottime** for the total time spent in the given function (and excluding time made in calls to sub-functions)

**percall** is the quotient of **tottime** divided by **ncalls**

**cumtime** is the cumulative time spent in this and all subfunctions (from invocation till exit). This figure is accurate *even* for recursive functions.

**percall** is the quotient of **cumtime** divided by primitive calls

**filename :lineno(function)** provides the respective data of each function

When there are two numbers in the first column (for example 3/1), it means that the function recursed. The second value is the number of primitive calls and the former is the total number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

Instead of printing the output at the end of the profile run, you can save the results to a file by specifying a filename to the **run()** function :

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")', 'restats')
```

The *pstats.Stats* class reads profile results from a file and formats them in various ways.

The file *cProfile* can also be invoked as a script to profile another script. For example :

```
python -m cProfile [-o output_file] [-s sort_order] myscript.py
```

**-o** writes the profile results to a file instead of to stdout

**-s** specifies one of the *sort\_stats()* sort values to sort the output by. This only applies when **-o** is not supplied.

The *pstats* module's *Stats* class has a variety of methods for manipulating and printing the data saved into a profile results file :

```
import pstats
p = pstats.Stats('restats')
p.strip_dirs().sort_stats(-1).print_stats()
```

The `strip_dirs()` method removed the extraneous path from all the module names. The `sort_stats()` method sorted all the entries according to the standard module/line/name string that is printed. The `print_stats()` method printed out all the statistics. You might try the following sort calls :

```
p.sort_stats('name')
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls to experiment with :

```
p.sort_stats('cumulative').print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.

If you were looking to see what functions were looping a lot, and taking a lot of time, you would do :

```
p.sort_stats('time').print_stats(10)
```

to sort according to time spent within each function, and then print the statistics for the top ten functions.

You might also try :

```
p.sort_stats('file').print_stats('__init__')
```

This will sort all the statistics by file name, and then print out statistics for only the class init methods (since they are spelled with `__init__` in them). As one final example, you could try :

```
p.sort_stats('time', 'cum').print_stats(.5, 'init')
```

This line sorts statistics with a primary key of time, and a secondary key of cumulative time, and then prints out some of the statistics. To be specific, the list is first culled down to 50% (re : `.5`) of its original size, then only lines containing `init` are maintained, and that sub-sub-list is printed.

If you wondered what functions called the above functions, you could now (`p` is still sorted according to the last criteria) do :

```
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you're going to have to read the manual, or guess what the following functions do :

```
p.print_callees()
p.add('restats')
```

Invoked as a script, the `pstats` module is a statistics browser for reading and examining profile dumps. It has a simple line-oriented interface (implemented using `cma`) and interactive help.

### 26.4.3 profile and cProfile Module Reference

Both the `profile` and `cProfile` modules provide the following functions :

`profile.run(command, filename=None, sort=-1)`

This function takes a single argument that can be passed to the `exec()` function, and an optional file name. In all cases this routine executes :

```
exec(command, __main__.__dict__, __main__.__dict__)
```

and gathers profiling statistics from the execution. If no file name is present, then this function automatically creates a `Stats` instance and prints a simple profiling report. If the sort value is specified it is passed to this `Stats` instance to control how the results are sorted.

`profile.runtcx(command, globals, locals, filename=None)`

This function is similar to `run()`, with added arguments to supply the globals and locals dictionaries for the `command` string. This routine executes :

```
exec(command, globals, locals)
```

and gathers profiling statistics as in the `run()` function above.

`class profile.Profile(timer=None, timeunit=0.0, subcalls=True, builtins=True)`

This class is normally only used if more precise control over profiling is needed than what the `cProfile.run()` function provides.

A custom timer can be supplied for measuring how long code takes to run via the `timer` argument. This must be a function that returns a single number representing the current time. If the number is an integer, the `timeunit` specifies a multiplier that specifies the duration of each unit of time. For example, if the timer returns times measured in thousands of seconds, the time unit would be `.001`.

Directly using the `Profile` class allows formatting profile results without writing the profile data to a file :

```
import cProfile, pstats, StringIO
pr = cProfile.Profile()
pr.enable()
# ... do something ...
pr.disable()
s = StringIO.StringIO()
sortby = 'cumulative'
ps = pstats.Stats(pr, stream=s).sort_stats(sortby)
ps.print_stats()
print s.getvalue()
```

`enable()`

Start collecting profiling data.

`disable()`

Stop collecting profiling data.

`create_stats()`

Stop collecting profiling data and record the results internally as the current profile.

`print_stats(sort=-1)`

Create a `Stats` object based on the current profile and print the results to stdout.

`dump_stats(filename)`

Write the results of the current profile to `filename`.

`run(cmd)`

Profile the `cmd` via `exec()`.

`runtcx(cmd, globals, locals)`

Profile the `cmd` via `exec()` with the specified global and local environment.

`runcall(func, *args, **kwargs)`

Profile `func(*args, **kwargs)`

## 26.4.4 The Stats Class

Analysis of the profiler data is done using the *Stats* class.

**class** *pstats.Stats*(\**filenames* or *profile*, *stream=sys.stdout*)

This class constructor creates an instance of a « statistics object » from a *filename* (or list of filenames) or from a *Profile* instance. Output will be printed to the stream specified by *stream*.

The file selected by the above constructor must have been created by the corresponding version of *profile* or *cProfile*. To be specific, there is *no* file compatibility guaranteed with future versions of this profiler, and there is no compatibility with files produced by other profilers, or the same profiler run on a different operating system. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be combined with data in an existing *Stats* object, the *add()* method can be used.

Instead of reading the profile data from a file, a *cProfile.Profile* or *profile.Profile* object can be used as the profile data source.

*Stats* objects have the following methods :

**strip\_dirs()**

This method for the *Stats* class removes all leading path information from file names. It is very useful in reducing the size of the printout to fit within (close to) 80 columns. This method modifies the object, and the stripped information is lost. After performing a strip operation, the object is considered to have its entries in a « random » order, as it was just after object initialization and loading. If *strip\_dirs()* causes two function names to be indistinguishable (they are on the same line of the same filename, and have the same function name), then the statistics for these two entries are accumulated into a single entry.

**add**(\**filenames*)

This method of the *Stats* class accumulates additional profiling information into the current profiling object. Its arguments should refer to filenames created by the corresponding version of *profile.run()* or *cProfile.run()*. Statistics for identically named (re : file, line, name) functions are automatically accumulated into single function statistics.

**dump\_stats**(*filename*)

Save the data loaded into the *Stats* object to a file named *filename*. The file is created if it does not exist, and is overwritten if it already exists. This is equivalent to the method of the same name on the *profile.Profile* and *cProfile.Profile* classes.

Nouveau dans la version 2.3.

**sort\_stats**(\**keys*)

This method modifies the *Stats* object by sorting it according to the supplied criteria. The argument is typically a string identifying the basis of a sort (example : 'time' or 'name').

When more than one key is provided, then additional keys are used as secondary criteria when there is equality in all keys selected before them. For example, *sort\_stats('name', 'file')* will sort all the entries according to their function name, and resolve all ties (identical function names) by sorting by file name.

Abbreviations can be used for any key names, as long as the abbreviation is unambiguous. The following are the keys currently defined :

Valid Arg	Signification
'calls'	call count
'cumulative'	cumulative time
'cumtime'	cumulative time
'file'	file name
'filename'	file name
'module'	file name
'ncalls'	call count
'pcalls'	primitive call count
'line'	line number
'name'	function name
'nfl'	name/file/line
'stdname'	standard name
'time'	internal time
'tottime'	internal time

Note that all sorts on statistics are in descending order (placing most time consuming items first), where as name, file, and line number searches are in ascending order (alphabetical). The subtle distinction between 'nfl' and 'stdname' is that the standard name is a sort of the name as printed, which means that the embedded line numbers get compared in an odd way. For example, lines 3, 20, and 40 would (if the file names were the same) appear in the string order 20, 3 and 40. In contrast, 'nfl' does a numeric compare of the line numbers. In fact, `sort_stats('nfl')` is the same as `sort_stats('name', 'file', 'line')`.

For backward-compatibility reasons, the numeric arguments -1, 0, 1, and 2 are permitted. They are interpreted as 'stdname', 'calls', 'time', and 'cumulative' respectively. If this old style format (numeric) is used, only one sort key (the numeric key) will be used, and additional arguments will be silently ignored.

#### `reverse_order()`

This method for the `Stats` class reverses the ordering of the basic list within the object. Note that by default ascending vs descending order is properly selected based on the sort key of choice.

#### `print_stats(*restrictions)`

This method for the `Stats` class prints out a report as described in the `profile.run()` definition. The order of the printing is based on the last `sort_stats()` operation done on the object (subject to caveats in `add()` and `strip_dirs()`).

The arguments provided (if any) can be used to limit the list down to the significant entries. Initially, the list is taken to be the complete set of profiled functions. Each restriction is either an integer (to select a count of lines), or a decimal fraction between 0.0 and 1.0 inclusive (to select a percentage of lines), or a regular expression (to pattern match the standard name that is printed. If several restrictions are provided, then they are applied sequentially. For example :

```
print_stats(.1, 'foo:')
```

would first limit the printing to first 10% of list, and then only print functions that were part of filename `.*foo:.` In contrast, the command :

```
print_stats('foo:', .1)
```

would limit the list to all functions having file names `.*foo:.`, and then proceed to only print the first 10% of them.

#### `print_callers(*restrictions)`

This method for the `Stats` class prints a list of all functions that called each function in the profiled database. The ordering is identical to that provided by `print_stats()`, and the definition of the restricting argument is also identical. Each caller is reported on its own line. The format differs slightly depending on the profiler that produced the stats :

- With `profile`, a number is shown in parentheses after each caller to show how many times this specific call was made. For convenience, a second non-parenthesized number repeats the cumulative time spent in the function at the right.
- With `cProfile`, each caller is preceded by three numbers : the number of times this specific call was made, and the total and cumulative times spent in the current function while it was invoked by this specific caller.

`print_callees(*restrictions)`

This method for the `Stats` class prints a list of all function that were called by the indicated function. Aside from this reversal of direction of calls (re : called vs was called by), the arguments and ordering are identical to the `print_callers()` method.

### 26.4.5 What Is Deterministic Profiling ?

*Deterministic profiling* is meant to reflect the fact that all *function call*, *function return*, and *exception* events are monitored, and precise timings are made for the intervals between these events (during which time the user's code is executing). In contrast, *statistical profiling* (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required to do deterministic profiling. Python automatically provides a *hook* (optional callback) for each event. In addition, the interpreted nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify « hot loops » that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.

### 26.4.6 Limitations

One limitation has to do with accuracy of timing information. There is a fundamental problem with deterministic profilers involving accuracy. The most obvious restriction is that the underlying « clock » is only ticking at a rate (typically) of about .001 seconds. Hence no measurements will be more accurate than the underlying clock. If enough measurements are taken, then the « error » will tend to average out. Unfortunately, removing this first error induces a second source of error.

The second problem is that it « takes a while » from when an event is dispatched until the profiler's call to get the time actually *gets* the state of the clock. Similarly, there is a certain lag when exiting the profiler event handler from the time that the clock's value was obtained (and then squirreled away), until the user's code is once again executing. As a result, functions that are called many times, or call many functions, will typically accumulate this error. The error that accumulates in this fashion is typically less than the accuracy of the clock (less than one clock tick), but it *can* accumulate and become very significant.

The problem is more important with `profile` than with the lower-overhead `cProfile`. For this reason, `profile` provides a means of calibrating itself for a given platform so that this error can be probabilistically (on the average) removed. After the profiler is calibrated, it will be more accurate (in a least square sense), but it will sometimes produce negative numbers (when call counts are exceptionally low, and the gods of probability work against you :-). ) Do *not* be alarmed by negative numbers in the profile. They should *only* appear if you have calibrated your profiler, and the results are actually better than without calibration.

### 26.4.7 Calibration

The profiler of the `profile` module subtracts a constant from each event handling time to compensate for the overhead of calling the time function, and socking away the results. By default, the constant is 0. The following procedure can be used to obtain a better constant for a given platform (see *Limitations*).

```
import profile
pr = profile.Profile()
for i in range(5):
    print pr.calibrate(10000)
```

The method executes the number of Python calls given by the argument, directly and again under the profiler, measuring the time for both. It then computes the hidden overhead per profiler event, and returns that as a float. For example, on a 1.8Ghz Intel Core i5 running Mac OS X, and using Python's `time.clock()` as the timer, the magical number is about 4.04e-6.

The object of this exercise is to get a fairly consistent result. If your computer is *very* fast, or your timer function has poor resolution, you might have to pass 100000, or even 1000000, to get consistent results.

When you have a consistent answer, there are three ways you can use it :<sup>1</sup>

```
import profile

# 1. Apply computed bias to all Profile instances created hereafter.
profile.Profile.bias = your_computed_bias

# 2. Apply computed bias to a specific Profile instance.
pr = profile.Profile()
pr.bias = your_computed_bias

# 3. Specify computed bias in instance constructor.
pr = profile.Profile(bias=your_computed_bias)
```

If you have a choice, you are better off choosing a smaller constant, and then your results will « less often » show up as negative in profile statistics.

### 26.4.8 Using a custom timer

If you want to change how current time is determined (for example, to force use of wall-clock time or elapsed process time), pass the timing function you want to the `Profile` class constructor :

```
pr = profile.Profile(your_time_func)
```

The resulting profiler will then call `your_time_func`. Depending on whether you are using `profile.Profile` or `cProfile.Profile`, `your_time_func`'s return value will be interpreted differently :

`profile.Profile` `your_time_func` should return a single number, or a list of numbers whose sum is the current time (like what `os.times()` returns). If the function returns a single time number, or the list of returned numbers has length 2, then you will get an especially fast version of the dispatch routine. Be warned that you should calibrate the profiler class for the timer function that you choose (see *Calibration*). For most machines, a timer that returns a lone integer value will provide the best results in terms of low overhead during profiling. (`os.times()` is *pretty* bad, as it returns a tuple of floating point values). If you want to substitute a better timer in the cleanest fashion, derive a class and hardwire a replacement dispatch method that best handles your timer call, along with the appropriate calibration constant.

1. Prior to Python 2.2, it was necessary to edit the profiler source code to embed the bias as a literal number. You still can, but that method is no longer described, because no longer needed.

`cProfile.Profile` your\_time\_func should return a single number. If it returns integers, you can also invoke the class constructor with a second argument specifying the real duration of one unit of time. For example, if `your_integer_time_func` returns times measured in thousands of seconds, you would construct the `Profile` instance as follows :

```
pr = cProfile.Profile(your_integer_time_func, 0.001)
```

As the `cProfile.Profile` class cannot be calibrated, custom timer functions should be used with care and should be as fast as possible. For the best results with a custom timer, it might be necessary to hard-code it in the C source of the internal `_lsprof` module.

## Notes

## 26.5 hotshot — High performance logging profiler

Nouveau dans la version 2.2.

This module provides a nicer interface to the `_hotshot` C module. Hotshot is a replacement for the existing `profile` module. As it's written mostly in C, it should result in a much smaller performance impact than the existing `profile` module.

---

**Note :** The `hotshot` module focuses on minimizing the overhead while profiling, at the expense of long data post-processing times. For common usage it is recommended to use `cProfile` instead. `hotshot` is not maintained and might be removed from the standard library in the future.

---

Modifié dans la version 2.5 : The results should be more meaningful than in the past : the timing core contained a critical bug.

---

**Note :** The `hotshot` profiler does not yet work well with threads. It is useful to use an unthreaded script to run the profiler over the code you're interested in measuring if at all possible.

---

```
class hotshot.Profile(logfile[, lineevents[, linetimings]])
```

The profiler object. The argument `logfile` is the name of a log file to use for logged profile data. The argument `lineevents` specifies whether to generate events for every source line, or just on function call/return. It defaults to 0 (only log function call/return). The argument `linetimings` specifies whether to record timing information. It defaults to 1 (store timing information).

### 26.5.1 Profile Objects

Profile objects have the following methods :

`Profile.addinfo(key, value)`

Add an arbitrary labelled value to the profile output.

`Profile.close()`

Close the logfile and terminate the profiler.

`Profile.fileno()`

Return the file descriptor of the profiler's log file.

`Profile.run(cmd)`

Profile an `exec`-compatible string in the script environment. The globals from the `__main__` module are used as both the globals and locals for the script.

`Profile.runcall(func, *args, **keywords)`

Profile a single call of a callable. Additional positional and keyword arguments may be passed along ;

the result of the call is returned, and exceptions are allowed to propagate cleanly, while ensuring that profiling is disabled on the way out.

`Profile.runctx(cmd, globals, locals)`

Evaluate an `exec`-compatible string in a specific environment. The string is compiled before profiling begins.

`Profile.start()`

Start the profiler.

`Profile.stop()`

Stop the profiler.

## 26.5.2 Using hotshot data

Nouveau dans la version 2.2.

This module loads hotshot profiling data into the standard `pstats` Stats objects.

`hotshot.stats.load(filename)`

Load hotshot data from *filename*. Returns an instance of the `pstats.Stats` class.

Voir aussi :

Module `profile` The `profile` module's Stats class

## 26.5.3 Example Usage

Note that this example runs the Python « benchmark » `pystones`. It can take some time to run, and will produce large output files.

```
>>> import hotshot, hotshot.stats, test.pystone
>>> prof = hotshot.Profile("stones.prof")
>>> benchtime, stones = prof.runcall(test.pystone.pystones)
>>> prof.close()
>>> stats = hotshot.stats.load("stones.prof")
>>> stats.strip_dirs()
>>> stats.sort_stats('time', 'calls')
>>> stats.print_stats(20)
      850004 function calls in 10.090 CPU seconds

Ordered by: internal time, call count

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
      1    3.295    3.295    10.090    10.090 pystone.py:79(Proc0)
150000    1.315    0.000     1.315     0.000 pystone.py:203(Proc7)
 50000    1.313    0.000     1.463     0.000 pystone.py:229(Func2)
.
.
.
```

## 26.6 timeit — Measure execution time of small code snippets

Nouveau dans la version 2.3.

Code source : [Lib/timeit.py](#)

This module provides a simple way to time small bits of Python code. It has both a *Command-Line Interface* as well as a *callable* one. It avoids a number of common traps for measuring execution times. See also Tim Peters' introduction to the « Algorithms » chapter in the *Python Cookbook*, published by O'Reilly.

### 26.6.1 Basic Examples

The following example shows how the *Command-Line Interface* can be used to compare three different expressions :

```
$ python -m timeit '"-".join(str(n) for n in range(100))'
10000 loops, best of 3: 40.3 usec per loop
$ python -m timeit '"-".join([str(n) for n in range(100)])'
10000 loops, best of 3: 33.4 usec per loop
$ python -m timeit '"-".join(map(str, range(100)))'
10000 loops, best of 3: 25.2 usec per loop
```

This can be achieved from the *Python Interface* with :

```
>>> import timeit
>>> timeit.timeit('"-".join(str(n) for n in range(100))', number=10000)
0.8187260627746582
>>> timeit.timeit('"-".join([str(n) for n in range(100)])', number=10000)
0.7288308143615723
>>> timeit.timeit('"-".join(map(str, range(100)))', number=10000)
0.5858950614929199
```

Note however that *timeit* will automatically determine the number of repetitions only when the command-line interface is used. In the *Examples* section you can find more advanced examples.

### 26.6.2 Python Interface

The module defines three convenience functions and a public class :

**timeit.timeit**(*stmt*='pass', *setup*='pass', *timer*=<default timer>, *number*=1000000)

Create a *Timer* instance with the given statement, *setup* code and *timer* function and run its *timeit()* method with *number* executions.

Nouveau dans la version 2.6.

**timeit.repeat**(*stmt*='pass', *setup*='pass', *timer*=<default timer>, *repeat*=3, *number*=1000000)

Create a *Timer* instance with the given statement, *setup* code and *timer* function and run its *repeat()* method with the given *repeat* count and *number* executions.

Nouveau dans la version 2.6.

**timeit.default\_timer()**

Define a default timer, in a platform-specific manner. On Windows, *time.clock()* has microsecond granularity, but *time.time()*'s granularity is 1/60th of a second. On Unix, *time.clock()* has 1/100th of a second granularity, and *time.time()* is much more precise. On either platform, *default\_timer()* measures wall clock time, not the CPU time. This means that other processes running on the same computer may interfere with the timing.

**class timeit.Timer**(*stmt*='pass', *setup*='pass', *timer*=<timer function>)

Class for timing execution speed of small code snippets.

The constructor takes a statement to be timed, an additional statement used for setup, and a timer function. Both statements default to 'pass' ; the timer function is platform-dependent (see the module doc string). *stmt* and *setup* may also contain multiple statements separated by ; or newlines, as long as they don't contain multi-line string literals.

To measure the execution time of the first statement, use the `timeit()` method. The `repeat()` method is a convenience to call `timeit()` multiple times and return a list of results.

Modifié dans la version 2.6 : The `stmt` and `setup` parameters can now also take objects that are callable without arguments. This will embed calls to them in a timer function that will then be executed by `timeit()`. Note that the timing overhead is a little larger in this case because of the extra function calls.

**timeit**(*number*=1000000)

Time *number* executions of the main statement. This executes the setup statement once, and then returns the time it takes to execute the main statement a number of times, measured in seconds as a float. The argument is the number of times through the loop, defaulting to one million. The main statement, the setup statement and the timer function to be used are passed to the constructor.

**Note :** By default, `timeit()` temporarily turns off *garbage collection* during the timing. The advantage of this approach is that it makes independent timings more comparable. This disadvantage is that GC may be an important component of the performance of the function being measured. If so, GC can be re-enabled as the first statement in the `setup` string. For example :

```
timeit.Timer('for i in xrange(10): oct(i)', 'gc.enable()').timeit()
```

**repeat**(*repeat*=3, *number*=1000000)

Call `timeit()` a few times.

This is a convenience function that calls the `timeit()` repeatedly, returning a list of results. The first argument specifies how many times to call `timeit()`. The second argument specifies the *number* argument for `timeit()`.

**Note :** It's tempting to calculate mean and standard deviation from the result vector and report these. However, this is not very useful. In a typical case, the lowest value gives a lower bound for how fast your machine can run the given code snippet; higher values in the result vector are typically not caused by variability in Python's speed, but by other processes interfering with your timing accuracy. So the `min()` of the result is probably the only number you should be interested in. After that, you should look at the entire vector and apply common sense rather than statistics.

**print\_exc**(*file*=None)

Helper to print a traceback from the timed code.

Typical use :

```
t = Timer(...)          # outside the try/except
try:
    t.timeit(...)        # or t.repeat(...)
except:
    t.print_exc()
```

The advantage over the standard traceback is that source lines in the compiled template will be displayed. The optional *file* argument directs where the traceback is sent; it defaults to `sys.stderr`.

### 26.6.3 Command-Line Interface

When called as a program from the command line, the following form is used :

```
python -m timeit [-n N] [-r N] [-s S] [-t] [-c] [-h] [statement ...]
```

Where the following options are understood :

`-n N, --number=N`  
how many times to execute “statement”

`-r N, --repeat=N`  
how many times to repeat the timer (default 3)

`-s S, --setup=S`  
statement to be executed once initially (default `pass`)

`-t, --time`  
use `time.time()` (default on all platforms but Windows)

`-c, --clock`  
use `time.clock()` (default on Windows)

`-v, --verbose`  
print raw timing results; repeat for more digits precision

`-h, --help`  
print a short usage message and exit

A multi-line statement may be given by specifying each line as a separate statement argument; indented lines are possible by enclosing an argument in quotes and using leading spaces. Multiple `-s` options are treated similarly.

If `-n` is not given, a suitable number of loops is calculated by trying successive powers of 10 until the total time is at least 0.2 seconds.

`default_timer()` measurements can be affected by other programs running on the same machine, so the best thing to do when accurate timing is necessary is to repeat the timing a few times and use the best time. The `-r` option is good for this; the default of 3 repetitions is probably enough in most cases. On Unix, you can use `time.clock()` to measure CPU time.

---

**Note :** There is a certain baseline overhead associated with executing a `pass` statement. The code here doesn't try to hide it, but you should be aware of it. The baseline overhead can be measured by invoking the program without arguments, and it might differ between Python versions. Also, to fairly compare older Python versions to Python 2.3, you may want to use Python's `-O` option (see Optimizations) for the older versions to avoid timing `SET_LINENO` instructions.

---

## 26.6.4 Examples

It is possible to provide a setup statement that is executed only once at the beginning :

```
$ python -m timeit -s 'text = "sample string"; char = "g"' 'char in text'
1000000 loops, best of 3: 0.0877 usec per loop
$ python -m timeit -s 'text = "sample string"; char = "g"' 'text.find(char)'
1000000 loops, best of 3: 0.342 usec per loop
```

```
>>> import timeit
>>> timeit.timeit('char in text', setup='text = "sample string"; char = "g"')
0.41440500499993504
>>> timeit.timeit('text.find(char)', setup='text = "sample string"; char = "g"')
1.7246671520006203
```

The same can be done using the `Timer` class and its methods :

```
>>> import timeit
>>> t = timeit.Timer('char in text', setup='text = "sample string"; char = "g"')
>>> t.timeit()
0.3955516149999312
>>> t.repeat()
[0.40193588800002544, 0.3960157959998014, 0.39594301399984033]
```

The following examples show how to time expressions that contain multiple lines. Here we compare the cost of using `hasattr()` vs. `try/except` to test for missing and present object attributes :

```
$ python -m timeit 'try: ' ' str.__nonzero__ 'except AttributeError: ' ' pass'
100000 loops, best of 3: 15.7 usec per loop
$ python -m timeit 'if hasattr(str, "__nonzero__"): pass'
100000 loops, best of 3: 4.26 usec per loop

$ python -m timeit 'try: ' ' int.__nonzero__ 'except AttributeError: ' ' pass'
1000000 loops, best of 3: 1.43 usec per loop
$ python -m timeit 'if hasattr(int, "__nonzero__"): pass'
100000 loops, best of 3: 2.23 usec per loop
```

```
>>> import timeit
>>> # attribute is missing
>>> s = """\
... try:
...     str.__nonzero__
... except AttributeError:
...     pass
... """
>>> timeit.timeit(stmt=s, number=100000)
0.9138244460009446
>>> s = "if hasattr(str, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.5829014980008651
>>>
>>> # attribute is present
>>> s = """\
... try:
...     int.__nonzero__
... except AttributeError:
...     pass
... """
>>> timeit.timeit(stmt=s, number=100000)
0.04215312199994514
>>> s = "if hasattr(int, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.08588060699912603
```

To give the `timeit` module access to functions you define, you can pass a `setup` parameter which contains an import statement :

```
def test():
    """Stupid test function"""
    L = []
```

(suite sur la page suivante)

(suite de la page précédente)

```
for i in range(100):
    L.append(i)

if __name__ == '__main__':
    import timeit
    print(timeit.timeit("test()", setup="from __main__ import test"))
```

## 26.7 trace — Trace or track Python statement execution

Code source : [Lib/abc.py](#)

---

The *trace* module allows you to trace program execution, generate annotated statement coverage listings, print caller/callee relationships and list functions executed during a program run. It can be used in another program or from the command line.

### 26.7.1 Utilisation en ligne de commande.

The *trace* module can be invoked from the command line. It can be as simple as

```
python -m trace --count -C . somefile.py ...
```

The above will execute `somefile.py` and generate annotated listings of all Python modules imported during the execution into the current directory.

#### **--help**

Display usage and exit.

#### **--version**

Display the version of the module and exit.

### Main options

At least one of the following options must be specified when invoking *trace*. The *--listfuncs* option is mutually exclusive with the *--trace* and *--count* options. When *--listfuncs* is provided, neither *--count* nor *--trace* are accepted, and vice versa.

#### **-c, --count**

Produce a set of annotated listing files upon program completion that shows how many times each statement was executed. See also *--coverdir*, *--file* and *--no-report* below.

#### **-t, --trace**

Display lines as they are executed.

#### **-l, --listfuncs**

Display the functions executed by running the program.

#### **-r, --report**

Produce an annotated list from an earlier program run that used the *--count* and *--file* option. This does not execute any code.

#### **-T, --trackcalls**

Display the calling relationships exposed by running the program.

## Modifiers

- f, --file=<file>**  
Name of a file to accumulate counts over several tracing runs. Should be used with the `--count` option.
- C, --coverdir=<dir>**  
Directory where the report files go. The coverage report for `package.module` is written to file `dir/package/module.cover`.
- m, --missing**  
When generating annotated listings, mark lines which were not executed with `>>>>>`.
- s, --summary**  
When using `--count` or `--report`, write a brief summary to stdout for each file processed.
- R, --no-report**  
Do not generate annotated listings. This is useful if you intend to make several runs with `--count`, and then produce a single set of annotated listings at the end.
- g, --timing**  
Prefix each line with the time since the program started. Only used while tracing.

## Filters

These options may be repeated multiple times.

- ignore-module=<mod>**  
Ignore each of the given module names and its submodules (if it is a package). The argument can be a list of names separated by a comma.
- ignore-dir=<dir>**  
Ignore all modules and packages in the named directory and subdirectories. The argument can be a list of directories separated by `os.pathsep`.

## 26.7.2 Programmatic Interface

```
class trace.Trace([count=1[, trace=1[, countfuncs=0[, countcallers=0[, ignoremods=()[, ignore-
                    dirs=()[, infile=None[, outfile=None[, timing=False]]]]]]]])
```

Create an object to trace execution of a single statement or expression. All parameters are optional. `count` enables counting of line numbers. `trace` enables line execution tracing. `countfuncs` enables listing of the functions called during the run. `countcallers` enables call relationship tracking. `ignoremods` is a list of modules or packages to ignore. `ignoredirs` is a list of directories whose modules or packages should be ignored. `infile` is the name of the file from which to read stored count information. `outfile` is the name of the file in which to write updated count information. `timing` enables a timestamp relative to when tracing was started to be displayed.

**run(cmd)**

Execute the command and gather statistics from the execution with the current tracing parameters. `cmd` must be a string or code object, suitable for passing into `exec()`.

**runctx(cmd, globals=None, locals=None)**

Execute the command and gather statistics from the execution with the current tracing parameters, in the defined global and local environments. If not defined, `globals` and `locals` default to empty dictionaries.

**runfunc(func, \*args, \*\*kws)**

Call `func` with the given arguments under control of the `Trace` object with the current tracing parameters.

**results()**

Return a `CoverageResults` object that contains the cumulative results of all previous

calls to `run`, `runctx` and `runfunc` for the given *Trace* instance. Does not reset the accumulated trace results.

**class `trace.CoverageResults`**

A container for coverage results, created by *Trace.results()*. Should not be created directly by the user.

**`update(other)`**

Merge in data from another *CoverageResults* object.

**`write_results([show_missing=True[, summary=False[, coverdir=None]])`**

Write coverage results. Set *show\_missing* to show lines that had no hits. Set *summary* to include in the output the coverage summary per module. *coverdir* specifies the directory into which the coverage result files will be output. If *None*, the results for each source file are placed in its directory.

A simple example demonstrating the use of the programmatic interface :

```
import sys
import trace

# create a Trace object, telling it what to ignore, and whether to
# do tracing or line-counting or both.
tracer = trace.Trace(
    ignoredirs=[sys.prefix, sys.exec_prefix],
    trace=0,
    count=1)

# run the new command using the given tracer
tracer.run('main()')

# make a report, placing output in the current directory
r = tracer.results()
r.write_results(show_missing=True, coverdir=".")
```

---

## Paquets et distribution de paquets logiciels

---

These libraries help you with publishing and installing Python software. While these modules are designed to work in conjunction with the [Python Package Index](#), they can also be used with a local index server, or without any index server at all.

### 27.1 `distutils` — Création et installation des modules Python

Le package `distutils` fournit le support pour la création et l'installation de modules supplémentaires dans une installation Python. Les nouveaux modules peuvent être soit en Python pur à 100%, soit des modules d'extension écrits en C, soit des collections de paquets Python qui incluent des modules codés en C et en Python.

La plupart des utilisateurs de Python ne voudront *pas* utiliser ce module directement, mais plutôt les outils cross-version maintenus par la *Python Packaging Authority*. En particulier, `setuptools` est une alternative améliorée à `distutils` qui fournit :

- support pour la déclaration des dépendances de projets
- mécanismes supplémentaires pour configurer quels fichiers inclure dans les distributions source (y compris les extensions pour l'intégration avec les systèmes de contrôle de version)
- la possibilité de déclarer les « points d'entrée » du projet, qui peuvent être utilisés comme base pour les systèmes d'extensions
- la possibilité de générer automatiquement des exécutables en ligne de commande Windows au moment de l'installation plutôt que de devoir les pré-construire
- comportement cohérent entre toutes les versions Python supportées

Le programme d'installation recommandé `pip` exécute tous les scripts `setup.py` avec `setuptools`, même si le script lui-même n'importe que `distutils`. Pour plus d'informations, reportez-vous au [Python Packaging User Guide](#).

À destination des auteurs et utilisateurs d'outils d'empaquetage cherchant une compréhension plus approfondie des détails du système actuel de création de paquets et de leur distribution, la documentation utilisateur historique de `distutils` la référence de son API restent disponibles :

- `install-index`
- `distutils-index`

## 27.2 ensurepip — Bootstrapping the pip installer

Nouveau dans la version 2.7.9.

The *ensurepip* package provides support for bootstrapping the `pip` installer into an existing Python installation or virtual environment. This bootstrapping approach reflects the fact that `pip` is an independent project with its own release cycle, and the latest available stable version is bundled with maintenance and feature releases of the CPython reference interpreter.

In most cases, end users of Python shouldn't need to invoke this module directly (as `pip` should be bootstrapped by default), but it may be needed if installing `pip` was skipped when installing Python (or when creating a virtual environment) or after explicitly uninstalling `pip`.

---

**Note :** This module *does not* access the internet. All of the components needed to bootstrap `pip` are included as internal parts of the package.

---

Voir aussi :

**installing-index** The end user guide for installing Python packages

**PEP 453 : Explicit bootstrapping of pip in Python installations** The original rationale and specification for this module.

**PEP 477 : Backport ensurepip (PEP 453) to Python 2.7** The rationale and specification for backporting PEP 453 to Python 2.7.

### 27.2.1 Command line interface

The command line interface is invoked using the interpreter's `-m` switch.

The simplest possible invocation is :

```
python -m ensurepip
```

This invocation will install `pip` if it is not already installed, but otherwise does nothing. To ensure the installed version of `pip` is at least as recent as the one bundled with `ensurepip`, pass the `--upgrade` option :

```
python -m ensurepip --upgrade
```

By default, `pip` is installed into the current virtual environment (if one is active) or into the system site packages (if there is no active virtual environment). The installation location can be controlled through two additional command line options :

- `--root <dir>` : Installs `pip` relative to the given root directory rather than the root of the currently active virtual environment (if any) or the default root for the current Python installation.
- `--user` : Installs `pip` into the user site packages directory rather than globally for the current Python installation (this option is not permitted inside an active virtual environment).

By default, the scripts `pip`, `pipX`, and `pipX.Y` will be installed (where `X.Y` stands for the version of Python used to invoke `ensurepip`). The scripts installed can be controlled through two additional command line options :

- `--altinstall` : if an alternate installation is requested, the `pip` and `pipX` script will *not* be installed.
- `--no-default-pip` : if a non-default installation is request, the `pip` script will *not* be installed.

Modifié dans la version 2.7.15 : The exit status is non-zero if the command fails.

### 27.2.2 Module API

*ensurepip* exposes two functions for programmatic use :

`ensurepip.version()`

Returns a string specifying the bundled version of `pip` that will be installed when bootstrapping an environment.

`ensurepip.bootstrap(root=None, upgrade=False, user=False, altinstall=False, default_pip=True, verbosity=0)`

Bootstraps `pip` into the current or designated environment.

*root* specifies an alternative root directory to install relative to. If *root* is `None`, then installation uses the default install location for the current environment.

*upgrade* indicates whether or not to upgrade an existing installation of an earlier version of `pip` to the bundled version.

*user* indicates whether to use the user scheme rather than installing globally.

By default, the scripts `pip`, `pipX`, and `pipX.Y` will be installed (where `X.Y` stands for the current version of Python).

If *altinstall* is set, then `pip` and `pipX` will *not* be installed.

If *default\_pip* is set to `False`, then `pip` will *not* be installed.

Setting both *altinstall* and *default\_pip* will trigger `ValueError`.

*verbosity* controls the level of output to `sys.stdout` from the bootstrapping operation.

---

**Note :** The bootstrapping process has side effects on both `sys.path` and `os.environ`. Invoking the command line interface in a subprocess instead allows these side effects to be avoided.

---

---

**Note :** The bootstrapping process may install additional modules required by `pip`, but other software should not assume those dependencies will always be present by default (as the dependencies may be removed in a future version of `pip`).

---

---

Environnement d'exécution Python

---

Les modules décrits dans ce chapitre fournissent une large collection de services relatifs à l'interpréteur Python et son interaction avec son environnement. En voici un survol :

## 28.1 sys — Paramètres et fonctions propres à des systèmes

Ce module fournit un accès à certaines variables utilisées et maintenues par l'interpréteur, et à des fonctions interagissant fortement avec ce dernier. Ce module est toujours disponible.

### **sys.argv**

La liste des arguments de la ligne de commande passés à un script Python. `argv[0]` est le nom du script (chemin complet, ou non, en fonction du système d'exploitation). Si la commande a été exécutée avec l'option `-c` de l'interpréteur, `argv[0]` vaut la chaîne `'-c'`. Si aucun nom de script n'a été donné à l'interpréteur Python, `argv[0]` sera une chaîne vide.

Pour boucler sur l'entrée standard, ou la liste des fichiers donnés sur la ligne de commande, utilisez le module *fileinput*.

### **sys.byteorder**

Un indicateur de l'ordre natif des octets. Vaudra `'big'` sur les plateformes gros-boutistes (octet le plus significatif en premier), et `'little'` sur les plateformes petit-boutiste (octet le moins significatif en premier).

Nouveau dans la version 2.0.

### **sys.builtin\_module\_names**

Un *tuple* de chaînes de caractères donnant les noms de tous les modules compilés dans l'interpréteur Python. (Cette information n'est pas disponible autrement — `modules.keys()` liste seulement les modules importés.)

### **sys.call\_tracing(func, args)**

Appelle `func(*args)`, avec le traçage activé. L'état du traçage est sauvegardé et restauré après l'appel. Ceci est destiné à être appelé depuis un débogueur à partir d'un point de contrôle, pour déboguer récursivement un autre code.

### **sys.copyright**

Une chaîne contenant le copyright relatif à l'interpréteur Python.

**sys.\_clear\_type\_cache()**

Vide le cache interne de types. Le cache de types est utilisé pour accélérer les recherches d'attributs et de méthodes. N'utilisez cette fonction *que* pour libérer des références inutiles durant le débogage de fuite de référence.

Cette fonction ne devrait être utilisée que pour un usage interne et spécialisé.

Nouveau dans la version 2.6.

**sys.\_current\_frames()**

Renvoie un dictionnaire faisant correspondre chaque identifiant de fil d'exécution à la *stack frame* actuellement active pour ces fils d'exécution au moment où la fonction est appelée. Notez que les fonctions du module *traceback* peuvent construire une *call stack* à partir d'une telle *frame*.

N'ayant pas besoin de la coopération des fils d'exécution bloqués, cette fonction est très utile pour déboguer un *deadlock*. Aussi, les *call stack* de ces fils d'exécution ne changeront pas tant qu'ils seront bloqués. La *frame* renvoyée pour un fil d'exécution non bloqué peut ne plus être liée à l'activité courante du fil d'exécution au moment où le code appelant examine la *frame*.

Cette fonction ne devrait être utilisée que pour un usage interne et spécialisé.

Nouveau dans la version 2.5.

**sys.dllhandle**

Nombre entier spécifiant le descripteur de la DLL Python. Disponibilité : Windows.

**sys.displayhook(value)**

If *value* is not *None*, this function prints it to *sys.stdout*, and saves it in *\_\_builtin\_\_*.

*sys.displayhook* est appelé avec le résultat de l'évaluation d'une *expression* entrée dans une session Python interactive. L'affichage de ces valeurs peut être personnalisé en assignant une autre fonction d'un argument à *sys.displayhook*.

**sys.dont\_write\_bytecode**

If this is true, Python won't try to write *.pyc* or *.pyo* files on the import of source modules. This value is initially set to *True* or *False* depending on the *-B* command line option and the *PYTHONDONTWRITEBYTECODE* environment variable, but you can set it yourself to control bytecode file generation.

Nouveau dans la version 2.6.

**sys.excepthook(type, value, traceback)**

Cette fonction affiche la *traceback* et l'exception donnée sur *sys.stderr*.

Lorsqu'une exception est levée et n'est pas attrapée, l'interpréteur appelle *sys.excepthook* avec trois arguments, la classe de l'exception, l'instance de l'exception, et un objet *traceback*. Dans une session interactive, cela se produit juste avant que le que l'invite soit rendue. Dans un programme Python, cela se produit juste avant que le programme quitte. La gestion de ces exceptions peut être personnalisé en affectant une autre fonction de trois arguments à *sys.excepthook*.

**sys.\_\_displayhook\_\_****sys.\_\_excepthook\_\_**

Ces objets contiennent les valeurs originales de *displayhook* et *excepthook* au début du programme. Elles sont sauvegardées de façon à ce que *displayhook* et *excepthook* puisse être restaurées au cas où elles seraient remplacées par des objets cassés.

**sys.exc\_info()**

This function returns a tuple of three values that give information about the exception that is currently being handled. The information returned is specific both to the current thread and to the current stack frame. If the current stack frame is not handling an exception, the information is taken from the calling stack frame, or its caller, and so on until a stack frame is found that is handling an exception. Here, « handling an exception » is defined as « executing or having executed an except clause. » For any stack frame, only information about the most recently handled exception is accessible.

If no exception is being handled anywhere on the stack, a tuple containing three *None* values is returned. Otherwise, the values returned are (*type*, *value*, *traceback*). Their meaning is : *type* gets the

exception type of the exception being handled (a class object); *value* gets the exception parameter (its *associated value* or the second argument to `raise`, which is always a class instance if the exception type is a class object); *traceback* gets a traceback object (see the Reference Manual) which encapsulates the call stack at the point where the exception originally occurred.

If `exc_clear()` is called, this function will return three `None` values until either another exception is raised in the current thread or the execution stack returns to a frame where another exception is being handled.

**Avertissement :** Assigning the *traceback* return value to a local variable in a function that is handling an exception will cause a circular reference. This will prevent anything referenced by a local variable in the same function or by the traceback from being garbage collected. Since most functions don't need access to the traceback, the best solution is to use something like `exc_type, value = sys.exc_info()[:2]` to extract only the exception type and value. If you do need the traceback, make sure to delete it after use (best done with a `try ... finally` statement) or to call `exc_info()` in a function that does not itself handle an exception.

**Note :** Beginning with Python 2.2, such cycles are automatically reclaimed when garbage collection is enabled and they become unreachable, but it remains more efficient to avoid creating cycles.

#### `sys.exc_clear()`

This function clears all information relating to the current or last exception that occurred in the current thread. After calling this function, `exc_info()` will return three `None` values until another exception is raised in the current thread or the execution stack returns to a frame where another exception is being handled.

This function is only needed in only a few obscure situations. These include logging and error handling systems that report information on the last or current exception. This function can also be used to try to free resources and trigger object finalization, though no guarantee is made as to what objects will be freed, if any.

Nouveau dans la version 2.3.

#### `sys.exc_type`

#### `sys.exc_value`

#### `sys.exc_traceback`

Obsolète depuis la version 1.5 : Use `exc_info()` instead.

Since they are global variables, they are not specific to the current thread, so their use is not safe in a multi-threaded program. When no exception is being handled, `exc_type` is set to `None` and the other two are undefined.

#### `sys.exec_prefix`

A string giving the site-specific directory prefix where the platform-dependent Python files are installed; by default, this is also `'/usr/local'`. This can be set at build time with the `--exec-prefix` argument to the `configure` script. Specifically, all configuration files (e.g. the `pyconfig.h` header file) are installed in the directory `exec_prefix/lib/pythonX.Y/config`, and shared library modules are installed in `exec_prefix/lib/pythonX.Y/lib-dynload`, where `X.Y` is the version number of Python, for example 2.7.

#### `sys.executable`

Une chaîne donnant le chemin absolu vers l'interpréteur Python, un fichier binaire exécutable, sur les systèmes sur lesquels ça a du sens. Si Python n'est pas capable de récupérer le chemin réel de son exécutable, `sys.executable` sera une chaîne vide ou `None`.

#### `sys.exit([arg])`

Quitte Python. C'est implémenté en levant l'exception `SystemExit`, afin que toutes les actions de

nettoyage spécifiées par des clauses *finally* des instructions `try` soient correctement exécutées. Il est aussi possible d'intercepter la tentative de sortie à un niveau au dessus.

The optional argument *arg* can be an integer giving the exit status (defaulting to zero), or another type of object. If it is an integer, zero is considered « successful termination » and any nonzero value is considered « abnormal termination » by shells and the like. Most systems require it to be in the range 0–127, and produce undefined results otherwise. Some systems have a convention for assigning specific meanings to specific exit codes, but these are generally underdeveloped ; Unix programs generally use 2 for command line syntax errors and 1 for all other kind of errors. If another type of object is passed, `None` is equivalent to passing zero, and any other object is printed to *stderr* and results in an exit code of 1. In particular, `sys.exit("some error message")` is a quick way to exit a program when an error occurs.

Puisque la fonction `exit()` ne fait « que » lever une exception, elle ne fera quitter le processus que si elle est appelée depuis le fil d'exécution principal, et que l'exception n'est pas interceptée.

#### `sys.exitfunc`

This value is not actually defined by the module, but can be set by the user (or by a program) to specify a clean-up action at program exit. When set, it should be a parameterless function. This function will be called when the interpreter exits. Only one function may be installed in this way ; to allow multiple functions which will be called at termination, use the *atexit* module.

---

**Note :** The exit function is not called when the program is killed by a signal, when a Python fatal internal error is detected, or when `os._exit()` is called.

---

Obsolète depuis la version 2.4 : Use *atexit* instead.

#### `sys.flags`

The struct sequence *flags* exposes the status of command line flags. The attributes are read only.

attribut	option
<code>debug</code>	<code>-d</code>
<code>py3k_warning</code>	<code>-3</code>
<code>division_warning</code>	<code>-Q</code>
<code>division_new</code>	<code>-Qnew</code>
<i>inspect</i>	<code>-i</code>
<code>interactive</code>	<code>-i</code>
<code>optimize</code>	<code>-O</code> or <code>-OO</code>
<i>dont_write_bytecode</i>	<code>-B</code>
<code>no_user_site</code>	<code>-s</code>
<code>no_site</code>	<code>-S</code>
<code>ignore_environment</code>	<code>-E</code>
<code>tabcheck</code>	<code>-t</code> or <code>-tt</code>
<code>verbose</code>	<code>-v</code>
<i>unicode</i>	<code>-U</code>
<code>bytes_warning</code>	<code>-b</code>
<code>hash_randomization</code>	<code>-R</code>

Nouveau dans la version 2.6.

Nouveau dans la version 2.7.3 : L'attribut `hash_randomization`.

#### `sys.float_info`

A structseq holding information about the float type. It contains low level information about the precision and internal representation. The values correspond to the various floating-point constants defined in the standard header file `float.h` for the “C” programming language ; see section 5.2.4.2.2 of the 1999 ISO/IEC C standard [C99], “Characteristics of floating types”, for details.

attribut	macro <i>float.h</i>	explication
<code>epsilon</code>	<code>DBL_EPSILON</code>	différence entre 1 et la plus petite valeur plus grande que 1 représentable en <i>float</i>
<code>dig</code>	<code>DBL_DIG</code>	nombre maximum de décimales pouvant être représentées fidèlement dans un <i>float</i> (voir ci-dessous)
<code>mant_dig</code>	<code>DBL_MANT_DIG</code>	précision : nombre de <i>base-radix</i> chiffres dans la mantisse du <i>float</i>
<i>max</i>	<code>DBL_MAX</code>	plus grand <i>float</i> fini représentable
<code>max_exp</code>	<code>DBL_MAX_EXP</code>	plus grand nombre entier <i>e</i> tel que <code>radix**(e-1)</code> soit représentable sous forme de <i>float</i> fini
<code>max_10_exp</code>	<code>DBL_MAX_10_EXP</code>	plus grand nombre entier <i>e</i> tel que <code>10**e</code> est dans l'intervalle des nombre flottants finis
<i>min</i>	<code>DBL_MIN</code>	plus petit nombre à virgule flottante positif normalisé
<code>min_exp</code>	<code>DBL_MIN_EXP</code>	plus petit entier <i>e</i> tel que <code>radix**(e-1)</code> est un <i>float</i> normalisé
<code>min_10_exp</code>	<code>DBL_MIN_10_EXP</code>	plus petit nombre entier <i>e</i> tel que <code>10**e</code> est un nombre à virgule flottante normalisé
<code>radix</code>	<code>FLT_RADIX</code>	base de la représentation de l'exposant
<code>rounds</code>	<code>FLT_ROUNDS</code>	constante, nombre entier représentant le mode d'arrondi utilisé pour les opérations arithmétiques. Elle reflète la valeur de la macro système <code>FLT_ROUNDS</code> au moment du démarrage de l'interpréteur. Voir section 5.2.4.4.2.2 de la norme C99 pour une explication des valeurs possibles et de leurs significations.

L'attribut `sys.float_info.dig` nécessite plus d'explications : Si *s* est une chaîne représentant un nombre décimal avec au plus `sys.float_info.dig` chiffres significatifs, alors, convertir *s* en un nombre à virgule flottante puis à nouveau en chaîne redonnera la même valeur :

```
>>> import sys
>>> sys.float_info.dig
15
>>> s = '3.14159265358979'      # decimal string with 15 significant digits
>>> format(float(s), '.15g')    # convert to float and back -> same value
'3.14159265358979'
```

Cependant, pour les chaînes avec plus de `sys.float_info.dig` chiffres significatifs, ce n'est pas toujours vrai :

```
>>> s = '9876543211234567'     # 16 significant digits is too many!
>>> format(float(s), '.16g')    # conversion changes value
'9876543211234568'
```

Nouveau dans la version 2.6.

#### `sys.float_repr_style`

A string indicating how the `repr()` function behaves for floats. If the string has value `'short'` then for a finite float *x*, `repr(x)` aims to produce a short string with the property that `float(repr(x)) == x`. This is the usual behaviour in Python 2.7 and later. Otherwise, `float_repr_style` has value `'legacy'` and `repr(x)` behaves in the same way as it did in versions of Python prior to 2.7.

Nouveau dans la version 2.7.

#### `sys.getcheckinterval()`

Renvoie le *check interval* de l'interpréteur, voir `setcheckinterval()`.

Nouveau dans la version 2.3.

`sys.getdefaultencoding()`

Renvoie le nom du codage par défaut actuellement utilisé par l'implémentation *Unicode* pour coder les chaînes.

Nouveau dans la version 2.0.

`sys.getdlopenflags()`

Return the current value of the flags that are used for `dlopen()` calls. The flag constants are defined in the *dl* and *DLFCN* modules. Availability : Unix.

Nouveau dans la version 2.2.

`sys.getfilesystemencoding()`

Return the name of the encoding used to convert Unicode filenames into system file names, or `None` if the system default encoding is used. The result value depends on the operating system :

- Sur Mac OS X, l'encodage est `'utf-8'`.
- On Unix, the encoding is the user's preference according to the result of `nl_langinfo(CODESET)`, or `None` if the `nl_langinfo(CODESET)` failed.
- On Windows NT+, file names are Unicode natively, so no conversion is performed. `getfilesystemencoding()` still returns `'mbcs'`, as this is the encoding that applications should use when they explicitly want to convert Unicode strings to byte strings that are equivalent when used as file names.
- On Windows 9x, the encoding is `'mbcs'`.

Nouveau dans la version 2.3.

`sys.getrefcount(object)`

Donne le nombre de référence de l'objet *object*. Le nombre renvoyé est généralement d'une référence de plus qu'attendu, puisqu'il compte la référence (temporaire) de l'argument à `getrefcount()`.

`sys.getrecursionlimit()`

Donne la limite actuelle de la limite de récursion, la profondeur maximum de la pile de l'interpréteur. Cette limite empêche Python de planter lors d'une récursion infinie à cause d'un débordement de la pile. Elle peut être modifiée par `setrecursionlimit()`.

`sys.getsizeof(object[, default])`

Donne la taille d'un objet en octets. L'objet peut être de n'importe quel type. Le résultat sera correct pour tous les objets natifs, mais le résultat peut ne pas être toujours vrai pour les extensions, la valeur étant dépendante de l'implémentation.

S'il est fourni, *default* sera renvoyé si l'objet ne fournit aucun moyen de récupérer sa taille. Sinon, une exception *TypeError* sera levée.

`getsizeof()` appelle la méthode `__sizeof__` de l'objet, et s'il est géré par lui, ajoute le surcoût du ramasse-miettes.

Nouveau dans la version 2.6.

`sys._getframe([depth])`

Renvoie une *frame* de la pile d'appels. Si le nombre entier optionnel *depth* est donné, la *frame* donnée sera de *depth* appels depuis le haut de la pile. Si c'est plus profond que la hauteur de la pile, une exception *ValueError* est levée. La profondeur par défaut est zéro, donnant ainsi la *frame* du dessus de la pile.

Cette fonction ne devrait être utilisée que pour une utilisation interne et spécifique. Il n'est pas garanti qu'elle existe dans toutes les implémentations de Python.

`sys.getprofile()`

Renvoie la fonction de profilage tel que défini par `setprofile()`.

Nouveau dans la version 2.6.

`sys.gettrace()`

Renvoie la fonction de traçage tel que définie par `settrace()`.

La fonction `gettrace()` ne sert que pour implémenter des débogueurs, des *profilers*, outils d'analyse de couverture, etc.... Son comportement dépend de l'implémentation et non du langage, elle n'est donc pas forcément disponible dans toutes les implémentations de Python.

Nouveau dans la version 2.6.

#### `sys.getwindowsversion()`

Return a named tuple describing the Windows version currently running. The named elements are *major*, *minor*, *build*, *platform*, *service\_pack*, *service\_pack\_minor*, *service\_pack\_major*, *suite\_mask*, and *product\_type*. *service\_pack* contains a string while all other values are integers. The components can also be accessed by name, so `sys.getwindowsversion()[0]` is equivalent to `sys.getwindowsversion().major`. For compatibility with prior versions, only the first 5 elements are retrievable by indexing.

*platform* may be one of the following values :

Constante	Plateforme
0 (VER_PLATFORM_WIN32s)	Win32s on Windows 3.1
1 (VER_PLATFORM_WIN32_WINDOWS)	Windows 95/98/ME
2 (VER_PLATFORM_WIN32_NT)	Windows NT/2000/XP/x64
3 (VER_PLATFORM_WIN32_CE)	Windows CE

*product\_type* peut être une des valeurs suivantes :

Constante	Signification
1 (VER_NT_WORKSTATION)	Le système une station de travail.
2 (VER_NT_DOMAIN_CONTROLLER)	Le système est un contrôleur de domaine.
3 (VER_NT_SERVER)	Le système est un serveur, mais pas un contrôleur de domaine.

Cette fonction enveloppe la fonction Win32 `GetVersionEx()`. Voir la documentation de Microsoft sur `OSVERSIONINFOEX()` pour plus d'informations sur ces champs.

Disponibilité : Windows.

Nouveau dans la version 2.3.

Modifié dans la version 2.7 : Changé en un *tuple* nommé, et ajout de *service\_pack\_minor*, *service\_pack\_major*, *suite\_mask*, et *product\_type*.

#### `sys.hexversion`

Le numéro de version codé sous forme d'un seul nombre entier. Ce numéro augmente avec chaque version, y compris pour les versions hors production. Par exemple, pour vérifier que l'interpréteur Python est au moins la version 1.5, utilisez :

```
if sys.hexversion >= 0x010502F0:
    # use some advanced feature
    ...
else:
    # use an alternative implementation or warn the user
    ...
```

This is called `hexversion` since it only really looks meaningful when viewed as the result of passing it to the built-in `hex()` function. The `version_info` value may be used for a more human-friendly encoding of the same information.

The `hexversion` is a 32-bit number with the following layout :

Bits (ordre gross-boutiste)	Signification
1-8	PY_MAJOR_VERSION (the 2 in 2.1.0a3)
9-16	PY_MINOR_VERSION (the 1 in 2.1.0a3)
17-24	PY_MICRO_VERSION (the 0 in 2.1.0a3)
25-28	PY_RELEASE_LEVEL (0xA for alpha, 0xB for beta, 0xC for release candidate and 0xF for final)
29-32	PY_RELEASE_SERIAL (the 3 in 2.1.0a3, zero for final releases)

Thus 2.1.0a3 is hexversion 0x020100a3.

Nouveau dans la version 1.5.2.

#### `sys.long_info`

A struct sequence that holds information about Python's internal representation of integers. The attributes are read only.

Attribut	Explication
<code>bits_per_digit</code>	number of bits held in each digit. Python integers are stored internally in base <code>2**long_info.bits_per_digit</code>
<code>sizeof_digit</code>	taille en octets du type C utilisé pour représenter un chiffre

Nouveau dans la version 2.7.

#### `sys.last_type`

#### `sys.last_value`

#### `sys.last_traceback`

These three variables are not always defined; they are set when an exception is not handled and the interpreter prints an error message and a stack traceback. Their intended use is to allow an interactive user to import a debugger module and engage in post-mortem debugging without having to re-execute the command that caused the error. (Typical use is `import pdb; pdb.pm()` to enter the post-mortem debugger; see chapter [pdb — Le débogueur Python](#) for more information.)

The meaning of the variables is the same as that of the return values from `exc_info()` above. (Since there is only one interactive thread, thread-safety is not a concern for these variables, unlike for `exc_type` etc.)

#### `sys.maxint`

The largest positive integer supported by Python's regular integer type. This is at least `2**31-1`. The largest negative integer is `-maxint-1` — the asymmetry results from the use of 2's complement binary arithmetic.

#### `sys.maxsize`

The largest positive integer supported by the platform's `Py_ssize_t` type, and thus the maximum size lists, strings, dicts, and many other containers can have.

#### `sys.maxunicode`

An integer giving the largest supported code point for a Unicode character. The value of this depends on the configuration option that specifies whether Unicode characters are stored as UCS-2 or UCS-4.

#### `sys.meta_path`

A list of *finder* objects that have their `find_module()` methods called to see if one of the objects can find the module to be imported. The `find_module()` method is called at least with the absolute name of the module being imported. If the module to be imported is contained in package then the parent package's `__path__` attribute is passed in as a second argument. The method returns `None` if the module cannot be found, else returns a *loader*.

`sys.meta_path` is searched before any implicit default finders or `sys.path`.

See [PEP 302](#) for the original specification.

**sys.modules**

This is a dictionary that maps module names to modules which have already been loaded. This can be manipulated to force reloading of modules and other tricks. Note that removing a module from this dictionary is *not* the same as calling `reload()` on the corresponding module object.

**sys.path**

Une liste de chaînes de caractères spécifiant les chemins de recherche des modules, initialisée à partir de la variable d'environnement `PYTHONPATH` et d'une valeur par défaut dépendante de l'installation.

Puisqu'il est initialisé au démarrage du programme, le premier élément de cette liste, `path[0]`, est le dossier contenant le script qui a été utilisé pour invoquer l'interpréteur Python. Si le dossier du script n'est pas disponible (typiquement, si l'interpréteur est invoqué interactivement ou si le script est lu à partir d'une entrée standard), `path[0]` sera une chaîne vide, qui indiquera à Python de chercher des modules dans le dossier actuel. Notez que le dossier du script est inséré *avant* les dossiers de `PYTHONPATH`.

A program is free to modify this list for its own purposes.

Modifié dans la version 2.3 : Unicode strings are no longer ignored.

**Voir aussi :**

Le module *site* décrit comment utiliser les fichiers *.pth* pour étendre *sys.path*.

**sys.path\_hooks**

Une liste d'appelables d'un argument, *path*, pour essayer de créer un *finder* pour ce chemin. Si un *finder* peut être créé, il doit être renvoyé par l'appelable, sinon une *ImportError* doit être levée.

Précisé à l'origine dans la **PEP 302**.

**sys.path\_importer\_cache**

A dictionary acting as a cache for *finder* objects. The keys are paths that have been passed to *sys.path\_hooks* and the values are the finders that are found. If a path is a valid file system path but no explicit finder is found on *sys.path\_hooks* then `None` is stored to represent the implicit default finder should be used. If the path is not an existing path then *imp.NullImporter* is set.

Précisé à l'origine dans la **PEP 302**.

**sys.platform**

Cette chaîne contient un identificateur de plateforme qui peut être typiquement utilisé pour ajouter des composants spécifiques à *sys.path*.

For most Unix systems, this is the lowercased OS name as returned by `uname -s` with the first part of the version as returned by `uname -r` appended, e.g. 'sunos5', *at the time when Python was built*. Unless you want to test for a specific system version, it is therefore recommended to use the following idiom :

```
if sys.platform.startswith('freebsd'):
    # FreeBSD-specific code here...
elif sys.platform.startswith('linux'):
    # Linux-specific code here...
```

Modifié dans la version 2.7.3 : Since lots of code check for `sys.platform == 'linux2'`, and there is no essential change between Linux 2.x and 3.x, `sys.platform` is always set to 'linux2', even on Linux 3.x. In Python 3.3 and later, the value will always be set to 'linux', so it is recommended to always use the `startswith` idiom presented above.

Pour les autres systèmes, les valeurs sont :

Système	<i>platform</i> value
Linux (2.x and 3.x)	'linux2'
Windows	'win32'
Windows/Cygwin	'cygwin'
Mac OS X	'darwin'
OS/2	'os2'
OS/2 EMX	'os2emx'
RiscOS	'riscos'
AtheOS	'atheos'

**Voir aussi :**

*os.name* a une granularité plus grossière. *os.uname()* donne des informations sur la version dépendantes du système.

Le module *platform* fournit des vérifications détaillées pour l'identité du système.

**sys.prefix**

A string giving the site-specific directory prefix where the platform independent Python files are installed; by default, this is the string `'/usr/local'`. This can be set at build time with the `--prefix` argument to the `configure` script. The main collection of Python library modules is installed in the directory *prefix*/lib/python*X.Y* while the platform independent header files (all except `pyconfig.h`) are stored in *prefix*/include/python*X.Y*, where *X.Y* is the version number of Python, for example 2.7.

**sys.ps1****sys.ps2**

Chaînes spécifiant l'invite primaire et secondaire de l'interpréteur. Celles-ci ne sont définies que si l'interpréteur est en mode interactif. Dans ce cas, leurs valeurs initiales sont `'>>>'` et `'...'`. Si un objet qui n'est pas une chaîne est assigné à l'une ou l'autre variable, sa méthode *str()* sera appelée à chaque fois que l'interpréteur se prépare à lire une nouvelle commande interactive, c'est donc utilisable pour implémenter une invite dynamique.

**sys.py3kwarning**

Bool containing the status of the Python 3 warning flag. It's `True` when Python is started with the `-3` option. (This should be considered read-only; setting it to a different value doesn't have an effect on Python 3 warnings.)

Nouveau dans la version 2.6.

**sys.setcheckinterval(interval)**

Défini l'« intervalle de vérification » de l'interpréteur. Ce nombre entier détermine la fréquence à laquelle l'interpréteur effectue des tâches périodiques tels que la commutation de fil d'exécution et la gestion de signaux. La valeur par défaut est 100, ce qui signifie que le contrôle est effectué toutes les 100 instructions virtuelles Python. L'augmenter peut améliorer les performances des programmes utilisant des fils d'exécution. Le paramétrer à une valeur inférieure ou égale à zéro permet d'effectuer ces tâches à chaque instruction virtuelle, maximisant ainsi la réactivité mais aussi son surcoût.

**sys.setdefaultencoding(name)**

Set the current default string encoding used by the Unicode implementation. If *name* does not match any available encoding, *LookupError* is raised. This function is only intended to be used by the *site* module implementation and, where needed, by *sitecustomize*. Once used by the *site* module, it is removed from the *sys* module's namespace.

Nouveau dans la version 2.0.

**sys.setdlopenflags(n)**

Set the flags used by the interpreter for `dlopen()` calls, such as when the interpreter loads extension modules. Among other things, this will enable a lazy resolving of symbols when importing a module, if called as `sys.setdlopenflags(0)`. To share symbols across extension modules, call as

`sys.setdlopenflags(dl.RTLD_NOW | dl.RTLD_GLOBAL)`. Symbolic names for the flag modules can be either found in the `dl` module, or in the `DLFCN` module. If `DLFCN` is not available, it can be generated from `/usr/include/dlfcn.h` using the `h2py` script. Availability : Unix.

Nouveau dans la version 2.2.

#### `sys.setprofile(profilefunc)`

Set the system's profile function, which allows you to implement a Python source code profiler in Python. See chapter *The Python Profilers* for more information on the Python profiler. The system's profile function is called similarly to the system's trace function (see `settrace()`), but it is called with different events, for example it isn't called for each executed line of code (only on call and return, but the return event is reported even when an exception has been set). The function is thread-specific, but there is no way for the profiler to know about context switches between threads, so it does not make sense to use this in the presence of multiple threads. Also, its return value is not used, so it can simply return `None`.

Profile functions should have three arguments : *frame*, *event*, and *arg*. *frame* is the current stack frame. *event* is a string : 'call', 'return', 'c\_call', 'c\_return', or 'c\_exception'. *arg* depends on the event type.

Les événements ont la signification suivante :

'call' A function is called (or some other code block entered). The profile function is called ; *arg* is `None`.

'return' A function (or other code block) is about to return. The profile function is called ; *arg* is the value that will be returned, or `None` if the event is caused by an exception being raised.

'c\_call' Une fonction C est sur le point d'être appelée. C'est soit une fonction d'extension ou une fonction native. *arg* représente la fonction C.

'c\_return' Une fonction C a renvoyé une valeur. *arg* représente la fonction C.

'c\_exception' Une fonction C a levé une exception. *arg* représente la fonction C.

#### `sys.setrecursionlimit(limit)`

Définit la profondeur maximale de la pile de l'interpréteur Python à *limit*. Cette limite empêche une récursion infinie de provoquer un débordement de la pile C et ainsi un crash de Python.

The highest possible limit is platform-dependent. A user may need to set the limit higher when she has a program that requires deep recursion and a platform that supports a higher limit. This should be done with care, because a too-high limit can lead to a crash.

#### `sys.settrace(tracefunc)`

Définit la fonction de traçage du système, qui vous permet d'implémenter un débogueur de code source Python en Python. Cette fonction est locale au fil d'exécution courant. Pour qu'un débogueur puisse gérer plusieurs fils d'exécution, il doit enregistrer sa fonction en appelant `settrace()` pour chaque fil d'exécution qu'il souhaite surveiller.

Trace functions should have three arguments : *frame*, *event*, and *arg*. *frame* is the current stack frame. *event* is a string : 'call', 'line', 'return' or 'exception'. *arg* depends on the event type.

La fonction de traçage est appelée (avec *event* à 'call') à chaque fois que l'interpréteur entre dans un nouveau *scope*. Elle doit renvoyer une référence à une fonction de traçage locale à utiliser pour ce *scope*, ou `None` si le *Scope* ne doit pas être tracé.

La fonction de traçage doit renvoyer une référence à elle-même (ou à une autre fonction de traçage pour un traçage ultérieur dans cette portée), ou `None` pour désactiver le traçage dans cette portée.

Les événements ont la signification suivante :

'call' Une fonction est appelée (un un bloc de code). La fonction de traçage globale est appelée, *arg* est `None`, la valeur renvoyée donne la fonction de traçage locale.

'line' L'interpréteur est sur le point d'exécuter une nouvelle ligne de code ou de ré-exécuter la condition d'une boucle. La fonction de traçage locale est appelée, *arg* vaut `None`, et la valeur de retour donne la nouvelle fonction de traçage locale. Voir `Objects/lnotab_notes.txt` pour une explication détaillée de ce mécanisme.

**'return'** La fonction (ou un autre type de bloc) est sur le point de se terminer. La fonction de traçage locale est appelée, *arg* est la valeur qui sera renvoyée, ou **None** si l'événement est causé par la levée d'une exception. La valeur renvoyée par la fonction de traçage est ignorée.

**'exception'** Une exception est survenue. La fonction de traçage locale est appelée, *arg* est le *tuple* (exception, valeur, traceback), la valeur renvoyée spécifie la nouvelle fonction de traçage locale.

Remarquez que, comme une exception se propage au travers de toute chaîne d'appelants, un événement **'exception'** est généré à chaque niveau.

Pour plus d'informations sur les objets code et objets représentant une *frame* de la pile, consultez `types`. La fonction `settrace()` est destinée uniquement à l'implémentation de débogueurs, de profileurs, d'outils d'analyse de couverture et d'autres outils similaires. Son comportement fait partie de l'implémentation, plutôt que de la définition du langage, et peut donc ne pas être disponible dans toutes les implémentations de Python.

`sys.settsdump(on_flag)`

Active dumping of VM measurements using the Pentium timestamp counter, if *on\_flag* is true. Deactivate these dumps if *on\_flag* is off. The function is available only if Python was compiled with `--with-tsc`. To understand the output of this dump, read `Python/ceval.c` in the Python sources.

Nouveau dans la version 2.4.

**CPython implementation detail :** This function is intimately bound to CPython implementation details and thus not likely to be implemented elsewhere.

`sys.stdin`

`sys.stdout`

`sys.stderr`

File objects corresponding to the interpreter's standard input, output and error streams. `stdin` is used for all interpreter input except for scripts but including calls to `input()` and `raw_input()`. `stdout` is used for the output of `print` and `expression` statements and for the prompts of `input()` and `raw_input()`. The interpreter's own prompts and (almost all of) its error messages go to `stderr`. `stdout` and `stderr` needn't be built-in file objects : any object is acceptable as long as it has a `write()` method that takes a string argument. (Changing these objects doesn't affect the standard I/O streams of processes executed by `os.popen()`, `os.system()` or the `exec*()` family of functions in the `os` module.)

`sys.__stdin__`

`sys.__stdout__`

`sys.__stderr__`

Ces objets contiennent les valeurs d'origine de `stdin`, `stderr` et `stdout` tel que présentes au début du programme. Ils sont utilisés pendant la finalisation, et peuvent être utiles pour écrire dans le vrai flux standard, peu importe si l'objet `sys.std*` a été redirigé.

Ils peuvent également être utilisés pour restaurer les entrées / sorties d'origine, au cas où ils auraient été écrasés par des objets cassés, cependant la bonne façon de faire serait de sauvegarder explicitement les flux avant de les remplacer et ainsi pouvoir les restaurer.

`sys.subversion`

A triple (repo, branch, version) representing the Subversion information of the Python interpreter. *repo* is the name of the repository, 'CPython'. *branch* is a string of one of the forms 'trunk', 'branches/name' or 'tags/name'. *version* is the output of `svnversion`, if the interpreter was built from a Subversion checkout ; it contains the revision number (range) and possibly a trailing "M" if there were local modifications. If the tree was exported (or `svnversion` was not available), it is the revision of `Include/patchlevel.h` if the branch is a tag. Otherwise, it is **None**.

Nouveau dans la version 2.5.

---

**Note :** Python is now `developed` using Mercurial. In recent Python 2.7 bugfix releases, `subversion`

therefore contains placeholder information. It is removed in Python 3.3.

#### `sys.tracebacklimit`

Lorsque cette variable contient un nombre entier, elle détermine la profondeur maximum de la pile d'appels affichée lorsqu'une exception non gérée se produit. La valeur par défaut est 1000, lorsque cette valeur est égale ou inférieure à 0, la pile d'appels n'est pas affichée, seul le type et la valeur de l'exception sont les sont.

#### `sys.version`

Une chaîne contenant le numéro de version de l'interpréteur Python, ainsi que d'autres informations comme le numéro de compilation et le compilateur utilisé. Cette chaîne est affichée lorsque l'interpréteur est démarré en mode interactif. N'essayez pas d'en extraire des informations de version, utilisez plutôt `version_info` et les fonctions fournies par le module `platform`.

#### `sys.api_version`

La version de l'API C pour cet interpréteur. Les développeurs peuvent trouver cette information utile en déboguant des conflits de versions entre Python et des modules d'extension.  
Nouveau dans la version 2.3.

#### `sys.version_info`

Un *tuple* contenant les cinq composants du numéro de version : *major*, *minor*, *micro*, *releaselevel* et *serial*. Toutes les valeurs sauf *releaselevel* sont des nombres entiers. *releaselevel* peut valoir 'alpha', 'beta', 'candidate', ou 'final'. La valeur de `version_info` pour Python 2.0 est (2, 0, 0, 'final', 0). Ces attributs sont aussi accessibles par leur nom, ainsi `sys.version_info[0]` est équivalent à `sys.version_info.major`, et ainsi de suite.

Nouveau dans la version 2.0.

Modifié dans la version 2.7 : Added named component attributes

#### `sys.warnoptions`

C'est une spécificité de l'implémentation de la gestion des avertissements. Ne modifiez pas cette valeur. Reportez-vous au module `warnings` pour plus d'informations sur le gestionnaire d'avertissements.

#### `sys.winver`

Le numéro de version utilisé pour construire les clefs de registre sous Windows. Elle est stockée en tant que *string resource* 1000 dans la DLL Python. Cette valeur équivaut typiquement aux trois premiers caractères de `version`. Elle est fournie par le module `sys` à titre d'information, et la modifier n'a aucun effet sur les clés de registre utilisées par Python. Disponibilité : Windows.

## Citations

## 28.2 sysconfig — Provide access to Python's configuration information

Nouveau dans la version 2.7.

**Source code :** [Lib/sysconfig.py](#)

The `sysconfig` module provides access to Python's configuration information like the list of installation paths and the configuration variables relevant for the current platform.

### 28.2.1 Configuration variables

A Python distribution contains a `Makefile` and a `pyconfig.h` header file that are necessary to build both the Python binary itself and third-party C extensions compiled using `distutils`.

`sysconfig` puts all variables found in these files in a dictionary that can be accessed using `get_config_vars()` or `get_config_var()`.

Notice that on Windows, it's a much smaller set.

`sysconfig.get_config_vars(*args)`

With no arguments, return a dictionary of all configuration variables relevant for the current platform.

With arguments, return a list of values that result from looking up each argument in the configuration variable dictionary.

For each argument, if the value is not found, return `None`.

`sysconfig.get_config_var(name)`

Return the value of a single variable *name*. Equivalent to `get_config_vars().get(name)`.

If *name* is not found, return `None`.

Example of usage :

```
>>> import sysconfig
>>> sysconfig.get_config_var('Py_ENABLE_SHARED')
0
>>> sysconfig.get_config_var('LIBDIR')
'/usr/local/lib'
>>> sysconfig.get_config_vars('AR', 'CXX')
['ar', 'g++']
```

## 28.2.2 Installation paths

Python uses an installation scheme that differs depending on the platform and on the installation options. These schemes are stored in `sysconfig` under unique identifiers based on the value returned by `os.name`.

Every new component that is installed using `distutils` or a Distutils-based system will follow the same scheme to copy its file in the right places.

Python currently supports seven schemes :

- `posix_prefix` : scheme for Posix platforms like Linux or Mac OS X. This is the default scheme used when Python or a component is installed.
- `posix_home` : scheme for Posix platforms used when a *home* option is used upon installation. This scheme is used when a component is installed through Distutils with a specific home prefix.
- `posix_user` : scheme for Posix platforms used when a component is installed through Distutils and the *user* option is used. This scheme defines paths located under the user home directory.
- `nt` : scheme for NT platforms like Windows.
- `nt_user` : scheme for NT platforms, when the *user* option is used.
- `os2` : scheme for OS/2 platforms.
- `os2_home` : scheme for OS/2 platforms, when the *user* option is used.

Each scheme is itself composed of a series of paths and each path has a unique identifier. Python currently uses eight paths :

- `stdlib` : directory containing the standard Python library files that are not platform-specific.
- `platstdlib` : directory containing the standard Python library files that are platform-specific.
- `platlib` : directory for site-specific, platform-specific files.
- `purelib` : directory for site-specific, non-platform-specific files.
- `include` : directory for non-platform-specific header files.
- `platinclude` : directory for platform-specific header files.
- `scripts` : directory for script files.
- `data` : directory for data files.

`sysconfig` provides some functions to determine these paths.

`sysconfig.get_scheme_names()`

Return a tuple containing all schemes currently supported in `sysconfig`.

`sysconfig.get_path_names()`

Return a tuple containing all path names currently supported in *sysconfig*.

`sysconfig.get_path(name[, scheme[, vars[, expand]]])`

Return an installation path corresponding to the path *name*, from the install scheme named *scheme*.

*name* has to be a value from the list returned by *get\_path\_names()*.

*sysconfig* stores installation paths corresponding to each path name, for each platform, with variables to be expanded. For instance the *stdlib* path for the *nt* scheme is : `{base}/Lib`.

*get\_path()* will use the variables returned by *get\_config\_vars()* to expand the path. All variables have default values for each platform so one may call this function and get the default value.

If *scheme* is provided, it must be a value from the list returned by *get\_scheme\_names()*. Otherwise, the default scheme for the current platform is used.

If *vars* is provided, it must be a dictionary of variables that will update the dictionary return by *get\_config\_vars()*.

If *expand* is set to `False`, the path will not be expanded using the variables.

If *name* is not found, return `None`.

`sysconfig.get_paths([scheme[, vars[, expand]]])`

Return a dictionary containing all installation paths corresponding to an installation scheme. See *get\_path()* for more information.

If *scheme* is not provided, will use the default scheme for the current platform.

If *vars* is provided, it must be a dictionary of variables that will update the dictionary used to expand the paths.

If *expand* is set to `false`, the paths will not be expanded.

If *scheme* is not an existing scheme, *get\_paths()* will raise a *KeyError*.

### 28.2.3 Other functions

`sysconfig.get_python_version()`

Return the MAJOR.MINOR Python version number as a string. Similar to `sys.version[:3]`.

`sysconfig.get_platform()`

Return a string that identifies the current platform.

This is used mainly to distinguish platform-specific build directories and platform-specific built distributions. Typically includes the OS name and version and the architecture (as supplied by *os.uname()*), although the exact information included depends on the OS ; e.g. for IRIX the architecture isn't particularly important (IRIX only runs on SGI hardware), but for Linux the kernel version isn't particularly important.

Examples of returned values :

- linux-i586
- linux-alpha (?)
- solaris-2.6-sun4u
- irix-5.3
- irix64-6.2

Windows will return one of :

- win-amd64 (64bit Windows on AMD64, aka x86\_64, Intel64, and EM64T)
- win-ia64 (64bit Windows on Itanium)
- win32 (all others - specifically, `sys.platform` is returned)

Mac OS X can return :

- macosx-10.6-ppc
- macosx-10.4-ppc64
- macosx-10.3-i386
- macosx-10.4-fat

For other non-POSIX platforms, currently just returns *sys.platform*.

`sysconfig.is_python_build()`

Return True if the current Python installation was built from source.

`sysconfig.parse_config_h(fp[, vars])`

Parse a `config.h`-style file.

`fp` is a file-like object pointing to the `config.h`-like file.

A dictionary containing name/value pairs is returned. If an optional dictionary is passed in as the second argument, it is used instead of a new dictionary, and updated with the values read in the file.

`sysconfig.get_config_h_filename()`

Return the path of `pyconfig.h`.

`sysconfig.get_makefile_filename()`

Return the path of Makefile.

## 28.3 `__builtin__` — Objets natifs

Ce module fournit un accès direct aux identifiants “natifs” de Python ; par exemple, `__builtin__.open` est le nom complet pour la fonction native `open()`. Voir *Fonctions natives* et *Constantes natives* pour plus de documentation.

Ce module n’est normalement pas accédé explicitement par la plupart des applications, mais peut être utile dans des modules qui exposent des objets de même nom qu’une valeur native, mais pour qui le natif de même nom est aussi nécessaire. Par exemple, dans un module qui voudrait implémenter une fonction `open()` autour de la fonction native `open()`, ce module peut être utilisé directement :

```
import __builtin__

def open(path):
    f = __builtin__.open(path, 'r')
    return UpperCaser(f)

class UpperCaser:
    '''Wrapper around a file that converts output to upper-case.'''

    def __init__(self, f):
        self._f = f

    def read(self, count=-1):
        return self._f.read(count).upper()

    # ...
```

**CPython implementation detail :** Most modules have the name `__builtins__` (note the 's') made available as part of their globals. The value of `__builtins__` is normally either this module or the value of this module’s `__dict__` attribute. Since this is an implementation detail, it may not be used by alternate implementations of Python.

## 28.4 `future_builtins` — Python 3 builtins

Nouveau dans la version 2.6.

This module provides functions that exist in 2.x, but have different behavior in Python 3, so they cannot be put into the 2.x builtins namespace.

Instead, if you want to write code compatible with Python 3 builtins, import them from this module, like this :

```
from future_builtins import map, filter

... code using Python 3-style map and filter ...
```

The *2to3* tool that ports Python 2 code to Python 3 will recognize this usage and leave the new builtins alone.

**Note :** The Python 3 *print()* function is already in the builtins, but cannot be accessed from Python 2 code unless you use the appropriate future statement :

```
from __future__ import print_function
```

Available builtins are :

`future_builtins.ascii(object)`

Returns the same as *repr()*. In Python 3, *repr()* will return printable Unicode characters unescaped, while *ascii()* will always backslash-escape them. Using *future\_builtins.ascii()* instead of *repr()* in 2.6 code makes it clear that you need a pure ASCII return value.

`future_builtins.filter(function, iterable)`

Works like *itertools.ifilter()*.

`future_builtins.hex(object)`

Works like the built-in *hex()*, but instead of *\_\_hex\_\_()* it will use the *\_\_index\_\_()* method on its argument to get an integer that is then converted to hexadecimal.

`future_builtins.map(function, iterable, ...)`

Works like *itertools.imap()*.

---

**Note :** In Python 3, *map()* does not accept *None* for the function argument.

---

`future_builtins.oct(object)`

Works like the built-in *oct()*, but instead of *\_\_oct\_\_()* it will use the *\_\_index\_\_()* method on its argument to get an integer that is then converted to octal.

`future_builtins.zip(*iterables)`

Works like *itertools.izip()*.

## 28.5 \_\_main\_\_ — Point d'entrée des scripts

This module represents the (otherwise anonymous) scope in which the interpreter's main program executes — commands read either from standard input, from a script file, or from an interactive prompt. It is this environment in which the idiomatic « conditional script » stanza causes a script to run :

```
if __name__ == "__main__":
    main()
```

## 28.6 warnings — Warning control

Nouveau dans la version 2.1.

Code source : [Lib/warnings.py](#)

---

Warning messages are typically issued in situations where it is useful to alert the user of some condition in a program, where that condition (normally) doesn't warrant raising an exception and terminating the program. For example, one might want to issue a warning when a program uses an obsolete module.

Python programmers issue warnings by calling the `warn()` function defined in this module. (C programmers use `PyErr_WarnEx()` ; see exceptionhandling for details).

Warning messages are normally written to `sys.stderr`, but their disposition can be changed flexibly, from ignoring all warnings to turning them into exceptions. The disposition of warnings can vary based on the warning category (see below), the text of the warning message, and the source location where it is issued. Repetitions of a particular warning for the same source location are typically suppressed.

There are two stages in warning control : first, each time a warning is issued, a determination is made whether a message should be issued or not ; next, if a message is to be issued, it is formatted and printed using a user-settable hook.

The determination whether to issue a warning message is controlled by the warning filter, which is a sequence of matching rules and actions. Rules can be added to the filter by calling `filterwarnings()` and reset to its default state by calling `resetwarnings()`.

The printing of warning messages is done by calling `showwarning()`, which may be overridden ; the default implementation of this function formats the message by calling `formatwarning()`, which is also available for use by custom implementations.

**Voir aussi :**

`logging.captureWarnings()` allows you to handle all warnings with the standard logging infrastructure.

### 28.6.1 Warning Categories

There are a number of built-in exceptions that represent warning categories. This categorization is useful to be able to filter out groups of warnings. The following warnings category classes are currently defined :

Class	Description
<i>Warning</i>	This is the base class of all warning category classes. It is a subclass of <i>Exception</i> .
<i>UserWarning</i>	The default category for <code>warn()</code> .
<i>DeprecationWarning</i>	Base category for warnings about deprecated features (ignored by default).
<i>SyntaxWarning</i>	Base category for warnings about dubious syntactic features.
<i>RuntimeWarning</i>	Base category for warnings about dubious runtime features.
<i>FutureWarning</i>	Base category for warnings about constructs that will change semantically in the future.
<i>PendingDeprecationWarning</i>	Base category for warnings about features that will be deprecated in the future (ignored by default).
<i>ImportWarning</i>	Base category for warnings triggered during the process of importing a module (ignored by default).
<i>UnicodeWarning</i>	Base category for warnings related to Unicode.

While these are technically built-in exceptions, they are documented here, because conceptually they belong to the warnings mechanism.

User code can define additional warning categories by subclassing one of the standard warning categories. A warning category must always be a subclass of the *Warning* class.

Modifié dans la version 2.7 : *DeprecationWarning* is ignored by default.

### 28.6.2 The Warnings Filter

The warnings filter controls whether warnings are ignored, displayed, or turned into errors (raising an exception).

Conceptually, the warnings filter maintains an ordered list of filter specifications; any specific warning is matched against each filter specification in the list in turn until a match is found; the match determines the disposition of the match. Each entry is a tuple of the form (*action*, *message*, *category*, *module*, *lineno*), where :

- *action* is one of the following strings :

Valeur	Disposition
"error"	turn matching warnings into exceptions
"ignore"	never print matching warnings
"always"	always print matching warnings
"default"	print the first occurrence of matching warnings for each location where the warning is issued
"module"	print the first occurrence of matching warnings for each module where the warning is issued
"once"	print only the first occurrence of matching warnings, regardless of location

- *message* is a string containing a regular expression that the start of the warning message must match. The expression is compiled to always be case-insensitive.
- *category* is a class (a subclass of *Warning*) of which the warning category must be a subclass in order to match.
- *module* is a string containing a regular expression that the module name must match. The expression is compiled to be case-sensitive.
- *lineno* is an integer that the line number where the warning occurred must match, or 0 to match all line numbers.

Since the *Warning* class is derived from the built-in *Exception* class, to turn a warning into an error we simply raise `category(message)`.

The warnings filter is initialized by `-W` options passed to the Python interpreter command line. The interpreter saves the arguments for all `-W` options without interpretation in `sys.warnoptions`; the *warnings* module parses these when it is first imported (invalid options are ignored, after printing a message to `sys.stderr`).

#### Default Warning Filters

By default, Python installs several warning filters, which can be overridden by the command-line options passed to `-W` and calls to *filterwarnings()*.

- *DeprecationWarning* and *PendingDeprecationWarning*, and *ImportWarning* are ignored.
- *BytesWarning* is ignored unless the `-b` option is given once or twice; in this case this warning is either printed (`-b`) or turned into an exception (`-bb`).

### 28.6.3 Temporarily Suppressing Warnings

If you are using code that you know will raise a warning, such as a deprecated function, but do not want to see the warning, then it is possible to suppress the warning using the *catch\_warnings* context manager :

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)
```

(suite sur la page suivante)

(suite de la page précédente)

```
with warnings.catch_warnings():
    warnings.simplefilter("ignore")
    fxn()
```

While within the context manager all warnings will simply be ignored. This allows you to use known-deprecated code without having to see the warning while not suppressing the warning for other code that might not be aware of its use of deprecated code. Note : this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

### 28.6.4 Testing Warnings

To test warnings raised by code, use the `catch_warnings` context manager. With it you can temporarily mutate the warnings filter to facilitate your testing. For instance, do the following to capture all raised warnings to check :

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings(record=True) as w:
    # Cause all warnings to always be triggered.
    warnings.simplefilter("always")
    # Trigger a warning.
    fxn()
    # Verify some things
    assert len(w) == 1
    assert isinstance(w[-1].category, DeprecationWarning)
    assert "deprecated" in str(w[-1].message)
```

One can also cause all warnings to be exceptions by using `error` instead of `always`. One thing to be aware of is that if a warning has already been raised because of a `once/default` rule, then no matter what filters are set the warning will not be seen again unless the warnings registry related to the warning has been cleared.

Once the context manager exits, the warnings filter is restored to its state when the context was entered. This prevents tests from changing the warnings filter in unexpected ways between tests and leading to indeterminate test results. The `showwarning()` function in the module is also restored to its original value. Note : this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

When testing multiple operations that raise the same kind of warning, it is important to test them in a manner that confirms each operation is raising a new warning (e.g. set warnings to be raised as exceptions and check the operations raise exceptions, check that the length of the warning list continues to increase after each operation, or else delete the previous entries from the warnings list before each new operation).

### 28.6.5 Updating Code For New Versions of Python

Warnings that are only of interest to the developer are ignored by default. As such you should make sure to test your code with typically ignored warnings made visible. You can do this from the command-line by passing `-Wd` to the interpreter (this is shorthand for `-W default`). This enables default handling for all warnings, including those that are ignored by default. To change what action is taken for encountered

warnings you simply change what argument is passed to `-W`, e.g. `-W error`. See the `-W` flag for more details on what is possible.

To programmatically do the same as `-Wd`, use :

```
warnings.simplefilter('default')
```

Make sure to execute this code as soon as possible. This prevents the registering of what warnings have been raised from unexpectedly influencing how future warnings are treated.

Having certain warnings ignored by default is done to prevent a user from seeing warnings that are only of interest to the developer. As you do not necessarily have control over what interpreter a user uses to run their code, it is possible that a new version of Python will be released between your release cycles. The new interpreter release could trigger new warnings in your code that were not there in an older interpreter, e.g. `DeprecationWarning` for a module that you are using. While you as a developer want to be notified that your code is using a deprecated module, to a user this information is essentially noise and provides no benefit to them.

## 28.6.6 Available Functions

```
warnings.warn(message[, category[, stacklevel]])
```

Issue a warning, or maybe ignore it or raise an exception. The *category* argument, if given, must be a warning category class (see above); it defaults to `UserWarning`. Alternatively *message* can be a `Warning` instance, in which case *category* will be ignored and `message.__class__` will be used. In this case the message text will be `str(message)`. This function raises an exception if the particular warning issued is changed into an error by the warnings filter see above. The *stacklevel* argument can be used by wrapper functions written in Python, like this :

```
def deprecation(message):
    warnings.warn(message, DeprecationWarning, stacklevel=2)
```

This makes the warning refer to `deprecation()`'s caller, rather than to the source of `deprecation()` itself (since the latter would defeat the purpose of the warning message).

```
warnings.warn_explicit(message, category, filename, lineno[, module[, registry[, module_globals]]])
```

This is a low-level interface to the functionality of `warn()`, passing in explicitly the message, category, filename and line number, and optionally the module name and the registry (which should be the `__warningregistry__` dictionary of the module). The module name defaults to the filename with `.py` stripped; if no registry is passed, the warning is never suppressed. *message* must be a string and *category* a subclass of `Warning` or *message* may be a `Warning` instance, in which case *category* will be ignored.

*module\_globals*, if supplied, should be the global namespace in use by the code for which the warning is issued. (This argument is used to support displaying source for modules found in zipfiles or other non-filesystem import sources).

Modifié dans la version 2.5 : Added the *module\_globals* parameter.

```
warnings.warnpy3k(message[, category[, stacklevel]])
```

Issue a warning related to Python 3.x deprecation. Warnings are only shown when Python is started with the `-3` option. Like `warn()` *message* must be a string and *category* a subclass of `Warning`. `warnpy3k()` is using `DeprecationWarning` as default warning class.

Nouveau dans la version 2.6.

```
warnings.showwarning(message, category, filename, lineno[, file[, line]])
```

Write a warning to a file. The default implementation calls `formatwarning(message, category, filename, lineno, line)` and writes the resulting string to *file*, which defaults to `sys.stderr`. You

may replace this function with an alternative implementation by assigning to `warnings.showwarning`. *line* is a line of source code to be included in the warning message; if *line* is not supplied, `showwarning()` will try to read the line specified by *filename* and *lineno*.

Modifié dans la version 2.7 : The *line* argument is required to be supported.

`warnings.formatwarning(message, category, filename, lineno[, line])`

Format a warning the standard way. This returns a string which may contain embedded newlines and ends in a newline. *line* is a line of source code to be included in the warning message; if *line* is not supplied, `formatwarning()` will try to read the line specified by *filename* and *lineno*.

Modifié dans la version 2.6 : Added the *line* argument.

`warnings.filterwarnings(action[, message[, category[, module[, lineno[, append]]]])`

Insert an entry into the list of *warnings filter specifications*. The entry is inserted at the front by default; if *append* is true, it is inserted at the end. This checks the types of the arguments, compiles the *message* and *module* regular expressions, and inserts them as a tuple in the list of warnings filters. Entries closer to the front of the list override entries later in the list, if both match a particular warning. Omitted arguments default to a value that matches everything.

`warnings.simplefilter(action[, category[, lineno[, append]]])`

Insert a simple entry into the list of *warnings filter specifications*. The meaning of the function parameters is as for `filterwarnings()`, but regular expressions are not needed as the filter inserted always matches any message in any module as long as the category and line number match.

`warnings.resetwarnings()`

Reset the warnings filter. This discards the effect of all previous calls to `filterwarnings()`, including that of the `-W` command line options and calls to `simplefilter()`.

### 28.6.7 Available Context Managers

`class warnings.catch_warnings(*, record=False, module=None)`

A context manager that copies and, upon exit, restores the warnings filter and the `showwarning()` function. If the *record* argument is *False* (the default) the context manager returns *None* on entry. If *record* is *True*, a list is returned that is progressively populated with objects as seen by a custom `showwarning()` function (which also suppresses output to `sys.stdout`). Each object in the list has attributes with the same names as the arguments to `showwarning()`.

The *module* argument takes a module that will be used instead of the module returned when you import `warnings` whose filter will be protected. This argument exists primarily for testing the `warnings` module itself.

---

**Note :** The `catch_warnings` manager works by replacing and then later restoring the module's `showwarning()` function and internal list of filter specifications. This means the context manager is modifying global state and therefore is not thread-safe.

---

---

**Note :** In Python 3, the arguments to the constructor for `catch_warnings` are keyword-only arguments.

---

Nouveau dans la version 2.6.

## 28.7 contextlib — Utilities for with-statement contexts

Nouveau dans la version 2.5.

Code source : [Lib/contextlib.py](#)

This module provides utilities for common tasks involving the `with` statement. For more information see also *Le type gestionnaire de contexte* and `context-managers`.

Functions provided :

`contextlib.contextmanager(func)`

This function is a *decorator* that can be used to define a factory function for `with` statement context managers, without needing to create a class or separate `__enter__()` and `__exit__()` methods.

While many objects natively support use in `with` statements, sometimes a resource needs to be managed that isn't a context manager in its own right, and doesn't implement a `close()` method for use with `contextlib.closing`

An abstract example would be the following to ensure correct resource management :

```
from contextlib import contextmanager

@contextmanager
def managed_resource(*args, **kwargs):
    # Code to acquire resource, e.g.:
    resource = acquire_resource(*args, **kwargs)
    try:
        yield resource
    finally:
        # Code to release resource, e.g.:
        release_resource(resource)

>>> with managed_resource(timeout=3600) as resource:
...     # Resource is released at the end of this block,
...     # even if code in the block raises an exception
```

The function being decorated must return a *generator*-iterator when called. This iterator must yield exactly one value, which will be bound to the targets in the `with` statement's `as` clause, if any.

At the point where the generator yields, the block nested in the `with` statement is executed. The generator is then resumed after the block is exited. If an unhandled exception occurs in the block, it is reraised inside the generator at the point where the `yield` occurred. Thus, you can use a `try...except...finally` statement to trap the error (if any), or ensure that some cleanup takes place. If an exception is trapped merely in order to log it or to perform some action (rather than to suppress it entirely), the generator must reraise that exception. Otherwise the generator context manager will indicate to the `with` statement that the exception has been handled, and execution will resume with the statement immediately following the `with` statement.

`contextlib.nested(mgr1[, mgr2[, ...]])`

Combine multiple context managers into a single nested context manager.

This function has been deprecated in favour of the multiple manager form of the `with` statement.

The one advantage of this function over the multiple manager form of the `with` statement is that argument unpacking allows it to be used with a variable number of context managers as follows :

```
from contextlib import nested

with nested(*managers):
    do_something()
```

Note that if the `__exit__()` method of one of the nested context managers indicates an exception should be suppressed, no exception information will be passed to any remaining outer context managers. Similarly, if the `__exit__()` method of one of the nested managers raises an exception, any previous

exception state will be lost; the new exception will be passed to the `__exit__()` methods of any remaining outer context managers. In general, `__exit__()` methods should avoid raising exceptions, and in particular they should not re-raise a passed-in exception.

This function has two major quirks that have led to it being deprecated. Firstly, as the context managers are all constructed before the function is invoked, the `__new__()` and `__init__()` methods of the inner context managers are not actually covered by the scope of the outer context managers. That means, for example, that using `nested()` to open two files is a programming error as the first file will not be closed promptly if an exception is thrown when opening the second file.

Secondly, if the `__enter__()` method of one of the inner context managers raises an exception that is caught and suppressed by the `__exit__()` method of one of the outer context managers, this construct will raise `RuntimeError` rather than skipping the body of the `with` statement.

Developers that need to support nesting of a variable number of context managers can either use the `warnings` module to suppress the `DeprecationWarning` raised by this function or else use this function as a model for an application specific implementation.

Obsolète depuis la version 2.7 : The with-statement now supports this functionality directly (without the confusing error prone quirks).

`contextlib.closing(thing)`

Return a context manager that closes *thing* upon completion of the block. This is basically equivalent to :

```
from contextlib import contextmanager

@contextmanager
def closing(thing):
    try:
        yield thing
    finally:
        thing.close()
```

And lets you write code like this :

```
from contextlib import closing
import urllib

with closing(urllib.urlopen('http://www.python.org')) as page:
    for line in page:
        print line
```

without needing to explicitly close `page`. Even if an error occurs, `page.close()` will be called when the `with` block is exited.

## 28.8 abc — Classes de Base Abstraites

Nouveau dans la version 2.6.

Code source : [Lib/abc.py](#)

---

Le module fournit l'infrastructure pour définir les *classes de bases abstraites* (*Abstract Base Class* ou *ABC* en anglais) en Python, tel qu'indiqué dans la **PEP 3119** ; voir la PEP pour la raison de son ajout à Python.

(Voir également la [PEP 3141](#) et le module `numbers` pour ce qui concerne la hiérarchie de types pour les nombres basés sur les classes de base abstraites). Par la suite nous utiliserons l'abréviation ABC (*Abstract Base Class*) pour désigner une classe de base abstraite.

The `collections` module has some concrete classes that derive from ABCs; these can, of course, be further derived. In addition, the `collections` module has some ABCs that can be used to test whether a class or instance provides a particular interface, for example, if it is hashable or if it is a mapping.

This module provides the following class :

**class** `abc.ABCMeta`

Métaclasse pour définir des classes de base abstraites (ABC).

Utilisez cette métaclasse pour créer une ABC. Il est possible d'hériter d'une ABC directement, cette classe de base abstraite fonctionne alors comme une classe *mixin*. Vous pouvez également enregistrer une classe concrète sans lien (même une classe native) et des ABC comme « sous-classes virtuelles » – celles-ci et leur descendantes seront considérées comme des sous-classes de la classe de base abstraite par la fonction native `issubclass()`, mais les ABC enregistrées n'apparaîtront pas dans leur ordre de résolution des méthodes (*MRO* pour *Method Resolution Order* en anglais). Les implémentations de méthodes définies par l'ABC ne seront pas appelable (pas même via `super()`).<sup>1</sup>

Les classes dont la métaclasse est `ABCMeta` possèdent les méthodes suivantes :

**register**(*subclass*)

Enregistrer *subclass* en tant que sous-classe virtuelle de cette ABC. Par exemple :

```
from abc import ABCMeta

class MyABC:
    __metaclass__ = ABCMeta

MyABC.register(tuple)

assert issubclass(tuple, MyABC)
assert isinstance(), MyABC
```

Vous pouvez également redéfinir cette méthode dans une ABC :

**\_\_subclasshook\_\_**(*subclass*)

(Doit être définie en tant que méthode de classe.)

Vérifie si *subclass* est considérée comme une sous-classe de cette ABC. Cela signifie que vous pouvez personnaliser le comportement de `issubclass` sans nécessiter d'appeler `register()` pour chacune des classes que vous souhaitez considérer comme sous-classe de l'ABC. (Cette méthode de classe est appelée par la méthode `__subclasscheck__()` de la classe de base abstraite).

Cette méthode doit renvoyer `True`, `False` ou `NotImplemented`. Si elle renvoie `True`, *subclass* est considérée comme sous-classe de cette ABC. Si elle renvoie `False`, la *subclass* n'est pas considérée une sous-classe de cette ABC même si elle l'aurait été en temps normal. Si elle renvoie `NotImplemented`, la vérification d'appartenance à la sous-classe continue via le mécanisme habituel.

Pour une illustration de ces concepts, voir cet exemple de définition de ABC :

```
class Foo(object):
    def __getitem__(self, index):
        ...
    def __len__(self):
        ...
```

(suite sur la page suivante)

1. Les développeurs C++ noteront que le concept Python de classe de base virtuelle (*virtual base class*) n'est pas le même que celui de C++.

(suite de la page précédente)

```

def get_iterator(self):
    return iter(self)

class MyIterable:
    __metaclass__ = ABCMeta

    @abstractmethod
    def __iter__(self):
        while False:
            yield None

    def get_iterator(self):
        return self.__iter__()

    @classmethod
    def __subclasshook__(cls, C):
        if cls is MyIterable:
            if any("__iter__" in B.__dict__ for B in C.__mro__):
                return True
            return NotImplemented

MyIterable.register(Foo)

```

L'ABC `MyIterable` définit la méthode d'itération `__iter__()` comme méthode abstraite. L'implémentation qui lui est donnée ici peut être appelée depuis les sous-classes. La méthode `get_iterator()` fait également partie de la classe de base abstraite `MyIterable`, mais elle n'a pas à être redéfinie dans les classes dérivées non-abstraites.

La méthode de classe `__subclasshook__()` définie ici dit que toute classe qui possède la méthode `__iter__()` dans son `__dict__` (ou dans une de ses classes de base, accédée via la liste `__mro__`) est considérée également comme un `MyIterable`.

Enfin, la dernière ligne fait de `Foo` une sous-classe virtuelle de `MyIterable`, même si cette classe ne définit pas de méthode `__iter__()` (elle utilise l'ancien protocole d'itération qui se définit en termes de `__len__()` et `__getitem__()`). À noter que cela ne rendra pas le `get_iterator` de `MyIterable` disponible comme une méthode de `Foo`, `get_iterator` est donc implémenté séparément.

It also provides the following decorators :

`abc.abstractmethod(function)`

Un décorateur marquant les méthodes comme abstraites.

Using this decorator requires that the class's metaclass is `ABCMeta` or is derived from it. A class that has a metaclass derived from `ABCMeta` cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract methods can be called using any of the normal “super” call mechanisms.

Python ne gère pas l'ajout dynamique de méthodes abstraites à une classe, il n'est pas non plus possible de modifier l'état d'abstraction d'une méthode ou d'une classe une fois celle-ci créée. `abstractmethod()` n'affecte que les sous-classes dérivées utilisant l'héritage classique. Les « sous-classes virtuelles » enregistrées avec la méthode `register()` de l'ABC ne sont pas affectées.

Utilisation :

```

class C:
    __metaclass__ = ABCMeta
    @abstractmethod
    def my_abstract_method(self, ...):

```

(suite sur la page suivante)

(suite de la page précédente)

...

**Note :** Contrairement aux méthodes abstraites Java, ces méthodes abstraites peuvent être implémentées. Cette implémentation peut être appelée via le mécanisme `super()` depuis la classe qui la redéfinit. C’est typiquement utile pour y appeler `super` et ainsi coopérer correctement dans un environnement utilisant de l’héritage multiple.

abc.`abstractproperty`(`[fget[, fset[, fdel[, doc]]]]`)

Sous-classe de `property()`, qui indique une propriété abstraite.

Using this function requires that the class’s metaclass is `ABCMeta` or is derived from it. A class that has a metaclass derived from `ABCMeta` cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract properties can be called using any of the normal “super” call mechanisms.

Utilisation :

```
class C:
    __metaclass__ = ABCMeta
    @abstractproperty
    def my_abstract_property(self):
        ...
```

This defines a read-only property ; you can also define a read-write abstract property using the “long” form of property declaration :

```
class C:
    __metaclass__ = ABCMeta
    def getx(self): ...
    def setx(self, value): ...
    x = abstractproperty(getx, setx)
```

## Notes

## 28.9 atexit — Gestionnaire de fin de programme

Nouveau dans la version 2.0.

**Source code :** `Lib/atexit.py`

The `atexit` module defines a single function to register cleanup functions. Functions thus registered are automatically executed upon normal interpreter termination. `atexit` runs these functions in the *reverse* order in which they were registered ; if you register A, B, and C, at interpreter termination time they will be run in the order C, B, A.

**Note :** Les fonctions inscrites via ce module ne sont pas appelées quand le programme est tué par un signal non géré par Python, quand une erreur fatale interne de Python est détectée, ou quand `os._exit()` est appelé.

This is an alternate interface to the functionality provided by the `sys.exitfunc()` variable.

Note : This module is unlikely to work correctly when used with other code that sets `sys.exitfunc`. In particular, other core Python modules are free to use `atexit` without the programmer’s knowledge. Authors who use `sys.exitfunc` should convert their code to use `atexit` instead. The simplest way to convert code

that sets `sys.exitfunc` is to import `atexit` and register the function that had been bound to `sys.exitfunc`.

```
atexit.register(func[, *args[, **kwargs]])
```

Inscrit *func* comme une fonction à exécuter au moment de l'arrêt de l'interpréteur. Tout argument optionnel qui doit être passé à *func* doit être passé comme argument à `register()`. Il est possible d'inscrire les mêmes fonctions et arguments plus d'une fois.

At normal program termination (for instance, if `sys.exit()` is called or the main module's execution completes), all functions registered are called in last in, first out order. The assumption is that lower level modules will normally be imported before higher level modules and thus must be cleaned up later.

Si une exception est levée durant l'exécution du gestionnaire de fin de programme, une trace d'appels est affichée (à moins que `SystemExit` ait été levée) et les informations de l'exception sont sauvegardées. Une fois que tous les gestionnaires de fin de programme ont eu une chance de s'exécuter, la dernière exception à avoir été levée l'est de nouveau.

Modifié dans la version 2.6 : This function now returns *func*, which makes it possible to use it as a decorator.

Voir aussi :

Module `readline` Un exemple utile de l'usage de `atexit` pour lire et écrire des fichiers d'historique `readline`.

### 28.9.1 Exemple avec atexit

Le simple exemple suivant démontre comment un module peut initialiser un compteur depuis un fichier quand il est importé, et sauver la valeur mise à jour du compteur automatiquement quand le programme se termine, sans avoir besoin que l'application fasse un appel explicite dans ce module au moment de l'arrêt de l'interpréteur.

```
try:
    _count = int(open("counter").read())
except IOError:
    _count = 0

def incrcounter(n):
    global _count
    _count = _count + n

def savecounter():
    open("counter", "w").write("%d" % _count)

import atexit
atexit.register(savecounter)
```

Les arguments positionnels et par mot-clé peuvent aussi être passés à `register()` afin d'être repassés à la fonction inscrite lors de son appel :

```
def goodbye(name, adjective):
    print 'Goodbye, %s, it was %s to meet you.' % (name, adjective)

import atexit
atexit.register(goodbye, 'Donny', 'nice')

# or:
atexit.register(goodbye, adjective='nice', name='Donny')
```

Utilisation en tant que *décorateur* :

```
import atexit

@atexit.register
def goodbye():
    print "You are now leaving the Python sector."
```

Ceci fonctionne uniquement avec des fonctions qui peuvent être appelées sans argument.

## 28.10 traceback — Print or retrieve a stack traceback

This module provides a standard interface to extract, format and print stack traces of Python programs. It exactly mimics the behavior of the Python interpreter when it prints a stack trace. This is useful when you want to print stack traces under program control, such as in a « wrapper » around the interpreter.

The module uses traceback objects — this is the object type that is stored in the variables `sys.exc_traceback` (deprecated) and `sys.last_traceback` and returned as the third item from `sys.exc_info()`.

Le module définit les fonctions suivantes :

`traceback.print_tb(tb[, limit[, file]])`

Print up to *limit* stack trace entries from the traceback object *tb*. If *limit* is omitted or `None`, all entries are printed. If *file* is omitted or `None`, the output goes to `sys.stderr`; otherwise it should be an open file or file-like object to receive the output.

`traceback.print_exception(etype, value, tb[, limit[, file]])`

Print exception information and up to *limit* stack trace entries from the traceback *tb* to *file*. This differs from `print_tb()` in the following ways : (1) if *tb* is not `None`, it prints a header `Traceback (most recent call last):`; (2) it prints the exception *etype* and *value* after the stack trace; (3) if *etype* is `SyntaxError` and *value* has the appropriate format, it prints the line where the syntax error occurred with a caret indicating the approximate position of the error.

`traceback.print_exc([limit[, file]])`

This is a shorthand for `print_exception(sys.exc_type, sys.exc_value, sys.exc_traceback, limit, file)`. (In fact, it uses `sys.exc_info()` to retrieve the same information in a thread-safe way instead of using the deprecated variables.)

`traceback.format_exc([limit])`

This is like `print_exc(limit)` but returns a string instead of printing to a file.  
Nouveau dans la version 2.4.

`traceback.print_last([limit[, file]])`

This is a shorthand for `print_exception(sys.last_type, sys.last_value, sys.last_traceback, limit, file)`. In general it will work only after an exception has reached an interactive prompt (see `sys.last_type`).

`traceback.print_stack([f[, limit[, file]]])`

This function prints a stack trace from its invocation point. The optional *f* argument can be used to specify an alternate stack frame to start. The optional *limit* and *file* arguments have the same meaning as for `print_exception()`.

`traceback.extract_tb(tb[, limit])`

Return a list of up to *limit* « pre-processed » stack trace entries extracted from the traceback object *tb*. It is useful for alternate formatting of stack traces. If *limit* is omitted or `None`, all entries are extracted. A « pre-processed » stack trace entry is a 4-tuple (*filename*, *line number*, *function name*\*,

*text*) representing the information that is usually printed for a stack trace. The *text* is a string with leading and trailing whitespace stripped; if the source is not available it is `None`.

`traceback.extract_stack([f[, limit]])`

Extract the raw traceback from the current stack frame. The return value has the same format as for `extract_tb()`. The optional *f* and *limit* arguments have the same meaning as for `print_stack()`.

`traceback.format_list(extracted_list)`

Given a list of tuples as returned by `extract_tb()` or `extract_stack()`, return a list of strings ready for printing. Each string in the resulting list corresponds to the item with the same index in the argument list. Each string ends in a newline; the strings may contain internal newlines as well, for those items whose source text line is not `None`.

`traceback.format_exception(etype, value)`

Format the exception part of a traceback. The arguments are the exception type, *etype* and *value* such as given by `sys.last_type` and `sys.last_value`. The return value is a list of strings, each ending in a newline. Normally, the list contains a single string; however, for `SyntaxError` exceptions, it contains several lines that (when printed) display detailed information about where the syntax error occurred. The message indicating which exception occurred is the always last string in the list.

`traceback.format_exception(etype, value, tb[, limit])`

Format a stack trace and the exception information. The arguments have the same meaning as the corresponding arguments to `print_exception()`. The return value is a list of strings, each ending in a newline and some containing internal newlines. When these lines are concatenated and printed, exactly the same text is printed as does `print_exception()`.

`traceback.format_tb(tb[, limit])`

A shorthand for `format_list(extract_tb(tb, limit))`.

`traceback.format_stack([f[, limit]])`

A shorthand for `format_list(extract_stack(f, limit))`.

`traceback.tb_lineno(tb)`

This function returns the current line number set in the traceback object. This function was necessary because in versions of Python prior to 2.3 when the `-O` flag was passed to Python the `tb.tb_lineno` was not updated correctly. This function has no use in versions past 2.3.

### 28.10.1 Traceback Examples

This simple example implements a basic read-eval-print loop, similar to (but less useful than) the standard Python interactive interpreter loop. For a more complete implementation of the interpreter loop, refer to the `code` module.

```
import sys, traceback

def run_user_code(envdir):
    source = raw_input(">>> ")
    try:
        exec source in envdir
    except:
        print "Exception in user code:"
        print '-'*60
        traceback.print_exc(file=sys.stdout)
        print '-'*60

envdir = {}
```

(suite sur la page suivante)

(suite de la page précédente)

```
while 1:
    run_user_code(envdir)
```

The following example demonstrates the different ways to print and format the exception and traceback :

```
import sys, traceback

def lumberjack():
    bright_side_of_death()

def bright_side_of_death():
    return tuple()[0]

try:
    lumberjack()
except IndexError:
    exc_type, exc_value, exc_traceback = sys.exc_info()
    print "*** print_tb:"
    traceback.print_tb(exc_traceback, limit=1, file=sys.stdout)
    print "*** print_exception:"
    traceback.print_exception(exc_type, exc_value, exc_traceback,
                             limit=2, file=sys.stdout)

    print "*** print_exc:"
    traceback.print_exc()
    print "*** format_exc, first and last line:"
    formatted_lines = traceback.format_exc().splitlines()
    print formatted_lines[0]
    print formatted_lines[-1]
    print "*** format_exception:"
    print repr(traceback.format_exception(exc_type, exc_value,
                                         exc_traceback))

    print "*** extract_tb:"
    print repr(traceback.extract_tb(exc_traceback))
    print "*** format_tb:"
    print repr(traceback.format_tb(exc_traceback))
    print "*** tb_lineno:", exc_traceback.tb_lineno
```

The output for the example would look similar to this :

```
*** print_tb:
  File "<doctest...>", line 10, in <module>
    lumberjack()
*** print_exception:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
    lumberjack()
  File "<doctest...>", line 4, in lumberjack
    bright_side_of_death()
IndexError: tuple index out of range
*** print_exc:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
```

(suite sur la page suivante)

(suite de la page précédente)

```

    lumberjack()
File "<doctest...>", line 4, in lumberjack
    bright_side_of_death()
IndexError: tuple index out of range
*** format_exc, first and last line:
Traceback (most recent call last):
IndexError: tuple index out of range
*** format_exception:
['Traceback (most recent call last):\n',
 '  File "<doctest...>", line 10, in <module>\n    lumberjack()\n',
 '  File "<doctest...>", line 4, in lumberjack\n    bright_side_of_death()\n',
 '  File "<doctest...>", line 7, in bright_side_of_death\n    return tuple()[0]\n',
 'IndexError: tuple index out of range\n']
*** extract_tb:
[('<doctest...>', 10, '<module>', 'lumberjack()'),
 ('<doctest...>', 4, 'lumberjack', 'bright_side_of_death()'),
 ('<doctest...>', 7, 'bright_side_of_death', 'return tuple()[0]')]
*** format_tb:
['  File "<doctest...>", line 10, in <module>\n    lumberjack()\n',
 '  File "<doctest...>", line 4, in lumberjack\n    bright_side_of_death()\n',
 '  File "<doctest...>", line 7, in bright_side_of_death\n    return tuple()[0]\n']
*** tb_lineno: 10

```

The following example shows the different ways to print and format the stack :

```

>>> import traceback
>>> def another_function():
...     lumberstack()
...
>>> def lumberstack():
...     traceback.print_stack()
...     print repr(traceback.extract_stack())
...     print repr(traceback.format_stack())
...
>>> another_function()
File "<doctest>", line 10, in <module>
    another_function()
File "<doctest>", line 3, in another_function
    lumberstack()
File "<doctest>", line 6, in lumberstack
    traceback.print_stack()
[('<doctest>', 10, '<module>', 'another_function()'),
 ('<doctest>', 3, 'another_function', 'lumberstack()'),
 ('<doctest>', 7, 'lumberstack', 'print repr(traceback.extract_stack())')]
['  File "<doctest>", line 10, in <module>\n    another_function()\n',
 '  File "<doctest>", line 3, in another_function\n    lumberstack()\n',
 '  File "<doctest>", line 8, in lumberstack\n    print repr(traceback.format_stack())\n'
↪']

```

This last example demonstrates the final few formatting functions :

```
>>> import traceback
```

(suite sur la page suivante)

(suite de la page précédente)

```
>>> traceback.format_list([('spam.py', 3, '<module>', 'spam.eggs()'),
...                        ('eggs.py', 42, 'eggs', 'return "bacon"')])
['  File "spam.py", line 3, in <module>\n    spam.eggs()\n',
 '  File "eggs.py", line 42, in eggs\n    return "bacon"\n']
>>> an_error = IndexError('tuple index out of range')
>>> traceback.format_exception_only(type(an_error), an_error)
['IndexError: tuple index out of range\n']
```

## 28.11 `__future__` — Définitions des futurs

Source code : `Lib/_future_.py`

`__future__` is a real module, and serves three purposes :

- To avoid confusing existing tools that analyze import statements and expect to find the modules they're importing.
- To ensure that future statements run under releases prior to 2.1 at least yield runtime exceptions (the import of `__future__` will fail, because there was no module of that name prior to 2.1).
- To document when incompatible changes were introduced, and when they will be — or were — made mandatory. This is a form of executable documentation, and can be inspected programmatically via importing `__future__` and examining its contents.

Each statement in `__future__.py` is of the form :

```
FeatureName = _Feature(OptionalRelease, MandatoryRelease,
                        CompilerFlag)
```

where, normally, *OptionalRelease* is less than *MandatoryRelease*, and both are 5-tuples of the same form as `sys.version_info` :

```
(PY_MAJOR_VERSION, # the 2 in 2.1.0a3; an int
 PY_MINOR_VERSION, # the 1; an int
 PY_MICRO_VERSION, # the 0; an int
 PY_RELEASE_LEVEL, # "alpha", "beta", "candidate" or "final"; string
 PY_RELEASE_SERIAL # the 3; an int
)
```

*OptionalRelease* records the first release in which the feature was accepted.

In the case of a *MandatoryRelease* that has not yet occurred, *MandatoryRelease* predicts the release in which the feature will become part of the language.

Else *MandatoryRelease* records when the feature became part of the language; in releases at or after that, modules no longer need a future statement to use the feature in question, but may continue to use such imports.

*MandatoryRelease* may also be `None`, meaning that a planned feature got dropped.

Instances of class `_Feature` have two corresponding methods, `getOptionalRelease()` and `getMandatoryRelease()`.

*CompilerFlag* is the (bitfield) flag that should be passed in the fourth argument to the built-in function `compile()` to enable the feature in dynamically compiled code. This flag is stored in the `compiler_flag` attribute on `_Feature` instances.

Aucune fonctionnalité ne sera jamais supprimée de `__future__`. Depuis son introduction dans Python 2.1, les fonctionnalités suivantes ont trouvé leur places dans le langage utilisant ce mécanisme :

fonctionnalité	optionnel dans	obligatoire dans	effet
nested_scopes	2.1.0b1	2.2	<b>PEP 227</b> : <i>Statically Nested Scopes</i>
générateurs	2.2.0a1	2.3	<b>PEP 255</b> : <i>Générateurs simples</i>
division	2.2.0a2	3.0	<b>PEP 328</b> : <i>Changer l'opérateur de division</i>
absolute_import	2.5.0a1	3.0	<b>PEP 328</b> : <i>Imports : Multi-Line and Absolute/Relative</i>
with_statement	2.5.0a1	2.6	<b>PEP 343</b> : <i>L'instruction « with »</i>
print_function	2.6.0a2	3.0	<b>PEP 3105</b> : <i>Make print a function</i>
unicode_literals	2.6.0a2	3.0	<b>PEP 3112</b> : <i>Obtets littéraux en Python 3000</i>

**future** Comment le compilateur gère les imports du futur.

## 28.12 gc — Garbage Collector interface

This module provides an interface to the optional garbage collector. It provides the ability to disable the collector, tune the collection frequency, and set debugging options. It also provides access to unreachable objects that the collector found but cannot free. Since the collector supplements the reference counting already used in Python, you can disable the collector if you are sure your program does not create reference cycles. Automatic collection can be disabled by calling `gc.disable()`. To debug a leaking program call `gc.set_debug(gc.DEBUG_LEAK)`. Notice that this includes `gc.DEBUG_SAVEALL`, causing garbage-collected objects to be saved in `gc.garbage` for inspection.

The `gc` module provides the following functions :

**gc.enable()**

Enable automatic garbage collection.

**gc.disable()**

Disable automatic garbage collection.

**gc.isenabled()**

Returns true if automatic collection is enabled.

**gc.collect([*generation*])**

With no arguments, run a full collection. The optional argument *generation* may be an integer specifying which generation to collect (from 0 to 2). A *ValueError* is raised if the generation number is invalid. The number of unreachable objects found is returned.

Modifié dans la version 2.5 : The optional *generation* argument was added.

Modifié dans la version 2.6 : The free lists maintained for a number of built-in types are cleared whenever a full collection or collection of the highest generation (2) is run. Not all items in some free lists may be freed due to the particular implementation, in particular *int* and *float*.

**gc.set\_debug(flags)**

Set the garbage collection debugging flags. Debugging information will be written to `sys.stderr`. See below for a list of debugging flags which can be combined using bit operations to control debugging.

`gc.get_debug()`

Return the debugging flags currently set.

`gc.get_objects()`

Returns a list of all objects tracked by the collector, excluding the list returned.

Nouveau dans la version 2.2.

`gc.set_threshold(threshold0[, threshold1[, threshold2]])`

Set the garbage collection thresholds (the collection frequency). Setting *threshold0* to zero disables collection.

The GC classifies objects into three generations depending on how many collection sweeps they have survived. New objects are placed in the youngest generation (generation 0). If an object survives a collection it is moved into the next older generation. Since generation 2 is the oldest generation, objects in that generation remain there after a collection. In order to decide when to run, the collector keeps track of the number object allocations and deallocations since the last collection. When the number of allocations minus the number of deallocations exceeds *threshold0*, collection starts. Initially only generation 0 is examined. If generation 0 has been examined more than *threshold1* times since generation 1 has been examined, then generation 1 is examined as well. Similarly, *threshold2* controls the number of collections of generation 1 before collecting generation 2.

`gc.get_count()`

Return the current collection counts as a tuple of (*count0*, *count1*, *count2*).

Nouveau dans la version 2.5.

`gc.get_threshold()`

Return the current collection thresholds as a tuple of (*threshold0*, *threshold1*, *threshold2*).

`gc.get_referrers(*objs)`

Return the list of objects that directly refer to any of *objs*. This function will only locate those containers which support garbage collection; extension types which do refer to other objects but do not support garbage collection will not be found.

Note that objects which have already been dereferenced, but which live in cycles and have not yet been collected by the garbage collector can be listed among the resulting referrers. To get only currently live objects, call `collect()` before calling `get_referrers()`.

Care must be taken when using objects returned by `get_referrers()` because some of them could still be under construction and hence in a temporarily invalid state. Avoid using `get_referrers()` for any purpose other than debugging.

Nouveau dans la version 2.2.

`gc.get_referents(*objs)`

Return a list of objects directly referred to by any of the arguments. The referents returned are those objects visited by the arguments' C-level `tp_traverse` methods (if any), and may not be all objects actually directly reachable. `tp_traverse` methods are supported only by objects that support garbage collection, and are only required to visit objects that may be involved in a cycle. So, for example, if an integer is directly reachable from an argument, that integer object may or may not appear in the result list.

Nouveau dans la version 2.3.

`gc.is_tracked(obj)`

Returns `True` if the object is currently tracked by the garbage collector, `False` otherwise. As a general rule, instances of atomic types aren't tracked and instances of non-atomic types (containers, user-defined objects...) are. However, some type-specific optimizations can be present in order to suppress the garbage collector footprint of simple instances (e.g. dicts containing only atomic keys and values) :

```
>>> gc.is_tracked(0)
False
```

(suite sur la page suivante)

(suite de la page précédente)

```

>>> gc.is_tracked("a")
False
>>> gc.is_tracked([])
True
>>> gc.is_tracked({})
False
>>> gc.is_tracked({"a": 1})
False
>>> gc.is_tracked({"a": []})
True

```

Nouveau dans la version 2.7.

The following variable is provided for read-only access (you can mutate its value but should not rebind it) :

#### `gc.garbage`

A list of objects which the collector found to be unreachable but could not be freed (uncollectable objects). By default, this list contains only objects with `__del__()` methods.<sup>1</sup> Objects that have `__del__()` methods and are part of a reference cycle cause the entire reference cycle to be uncollectable, including objects not necessarily in the cycle but reachable only from it. Python doesn't collect such cycles automatically because, in general, it isn't possible for Python to guess a safe order in which to run the `__del__()` methods. If you know a safe order, you can force the issue by examining the *garbage* list, and explicitly breaking cycles due to your objects within the list. Note that these objects are kept alive even so by virtue of being in the *garbage* list, so they should be removed from *garbage* too. For example, after breaking cycles, do `del gc.garbage[:]` to empty the list. It's generally better to avoid the issue by not creating cycles containing objects with `__del__()` methods, and *garbage* can be examined in that case to verify that no such cycles are being created.

If `DEBUG_SAVEALL` is set, then all unreachable objects will be added to this list rather than freed.

The following constants are provided for use with `set_debug()` :

#### `gc.DEBUG_STATS`

Print statistics during collection. This information can be useful when tuning the collection frequency.

#### `gc.DEBUG_COLLECTABLE`

Print information on collectable objects found.

#### `gc.DEBUG_UNCOLLECTABLE`

Print information of uncollectable objects found (objects which are not reachable but cannot be freed by the collector). These objects will be added to the *garbage* list.

#### `gc.DEBUG_INSTANCES`

When `DEBUG_COLLECTABLE` or `DEBUG_UNCOLLECTABLE` is set, print information about instance objects found.

#### `gc.DEBUG_OBJECTS`

When `DEBUG_COLLECTABLE` or `DEBUG_UNCOLLECTABLE` is set, print information about objects other than instance objects found.

#### `gc.DEBUG_SAVEALL`

When set, all unreachable objects found will be appended to *garbage* rather than being freed. This can be useful for debugging a leaking program.

#### `gc.DEBUG_LEAK`

The debugging flags necessary for the collector to print information about a leaking program (equal to `DEBUG_COLLECTABLE | DEBUG_UNCOLLECTABLE | DEBUG_INSTANCES | DEBUG_OBJECTS | DEBUG_SAVEALL`).

1. Prior to Python 2.2, the list contained all instance objects in unreachable cycles, not only those with `__del__()` methods.

## Notes

## 28.13 inspect — Inspect live objects

Nouveau dans la version 2.1.

**Code source :** [Lib/inspect.py](#)

The *inspect* module provides several useful functions to help get information about live objects such as modules, classes, methods, functions, tracebacks, frame objects, and code objects. For example, it can help you examine the contents of a class, retrieve the source code of a method, extract and format the argument list for a function, or get all the information you need to display a detailed traceback.

There are four main kinds of services provided by this module : type checking, getting source code, inspecting classes and functions, and examining the interpreter stack.

### 28.13.1 Types and members

The *getmembers()* function retrieves the members of an object such as a class or module. The sixteen functions whose names begin with « *is* » are mainly provided as convenient choices for the second argument to *getmembers()*. They also help you determine when you can expect to find the following special attributes :

Type	Attribut	Description
module	<code>__doc__</code>	documentation string
	<code>__file__</code>	filename (missing for built-in modules)
classe	<code>__doc__</code>	documentation string
	<code>__module__</code>	name of module in which this class was defined
méthode	<code>__doc__</code>	documentation string
	<code>__name__</code>	name with which this method was defined
	<code>im_class</code>	class object that asked for this method
fonction	<code>im_func</code> or <code>__func__</code>	function object containing implementation of method
	<code>im_self</code> or <code>__self__</code>	instance to which this method is bound, or <code>None</code>
	<code>__doc__</code>	documentation string
	<code>__name__</code>	name with which this function was defined
générateur	<code>func_code</code>	code object containing compiled function <i>bytecode</i>
	<code>func_defaults</code>	tuple of any default values for arguments
	<code>func_doc</code>	(same as <code>__doc__</code> )
	<code>func_globals</code>	global namespace in which this function was defined
	<code>func_name</code>	(same as <code>__name__</code> )
	<code>__iter__</code>	defined to support iteration over container
	<code>close</code>	raises new <code>GeneratorExit</code> exception inside the generator to terminate the iteration
	<code>gi_code</code>	code object
	<code>gi_frame</code>	frame object or possibly <code>None</code> once the generator has been exhausted
	<code>gi_running</code>	set to 1 when generator is executing, 0 otherwise
traceback	<code>next</code>	return the next item from the container
	<code>send</code>	resumes the generator and « sends » a value that becomes the result of the current iteration
	<code>throw</code>	used to raise an exception inside the generator
	<code>tb_frame</code>	frame object at this level
	<code>tb_lasti</code>	index of last attempted instruction in bytecode
frame	<code>tb_lineno</code>	current line number in Python source code
	<code>tb_next</code>	next inner traceback object (called by this level)
	<code>f_back</code>	next outer frame object (this frame's caller)

Tableau 1 – suite de la page précédente

Type	Attribut	Description
	<code>f_builtins</code>	builtins namespace seen by this frame
	<code>f_code</code>	code object being executed in this frame
	<code>f_exc_traceback</code>	traceback if raised in this frame, or <code>None</code>
	<code>f_exc_type</code>	exception type if raised in this frame, or <code>None</code>
	<code>f_exc_value</code>	exception value if raised in this frame, or <code>None</code>
	<code>f_globals</code>	global namespace seen by this frame
	<code>f_lasti</code>	index of last attempted instruction in bytecode
	<code>f_lineno</code>	current line number in Python source code
	<code>f_locals</code>	local namespace seen by this frame
	<code>f_restricted</code>	0 or 1 if frame is in restricted execution mode
	<code>f_trace</code>	tracing function for this frame, or <code>None</code>
code	<code>co_argcount</code>	number of arguments (not including <code>*</code> or <code>**</code> args)
	<code>co_code</code>	string of raw compiled bytecode
	<code>co_consts</code>	tuple of constants used in the bytecode
	<code>co_filename</code>	name of file in which this code object was created
	<code>co_firstlineno</code>	number of first line in Python source code
	<code>co_flags</code>	bitmap : 1=optimized   2=newlocals   4= <code>*arg</code>   8= <code>**arg</code>
	<code>co_lnotab</code>	encoded mapping of line numbers to bytecode indices
	<code>co_name</code>	name with which this code object was defined
	<code>co_names</code>	tuple of names of local variables
	<code>co_nlocals</code>	number of local variables
	<code>co_stacksize</code>	virtual machine stack space required
	<code>co_varnames</code>	tuple of names of arguments and local variables
builtin	<code>__doc__</code>	documentation string
	<code>__name__</code>	original name of this function or method
	<code>__self__</code>	instance to which a method is bound, or <code>None</code>

Note :

- (1) Modifié dans la version 2.2 : `im_class` used to refer to the class that defined the method.

`inspect.getmembers(object[, predicate])`

Return all the members of an object in a list of (name, value) pairs sorted by name. If the optional *predicate* argument is supplied, only members for which the predicate returns a true value are included.

**Note :** `getmembers()` does not return metaclass attributes when the argument is a class (this behavior is inherited from the `dir()` function).

`inspect.getmoduleinfo(path)`

Return a tuple of values that describe how Python will interpret the file identified by *path* if it is a module, or `None` if it would not be identified as a module. The return tuple is (*name*, *suffix*, *mode*, *module\_type*), where *name* is the name of the module without the name of any enclosing package, *suffix* is the trailing part of the file name (which may not be a dot-delimited extension), *mode* is the `open()` mode that would be used ('r' or 'rb'), and *module\_type* is an integer giving the type of the module. *module\_type* will have a value which can be compared to the constants defined in the `imp` module; see the documentation for that module for more information on module types.

Modifié dans la version 2.6 : Returns a *named tuple* `ModuleInfo(name, suffix, mode, module_type)`.

`inspect.getmodulename(path)`

Return the name of the module named by the file *path*, without including the names of enclosing

packages. This uses the same algorithm as the interpreter uses when searching for modules. If the name cannot be matched according to the interpreter's rules, `None` is returned.

`inspect.ismodule(object)`

Return true if the object is a module.

`inspect.isclass(object)`

Return true if the object is a class, whether built-in or created in Python code.

`inspect.ismethod(object)`

Return true if the object is a bound or unbound method written in Python.

`inspect.isfunction(object)`

Return true if the object is a Python function, which includes functions created by a *lambda* expression.

`inspect.isgeneratorfunction(object)`

Return true if the object is a Python generator function.

Nouveau dans la version 2.6.

`inspect.isgenerator(object)`

Return true if the object is a generator.

Nouveau dans la version 2.6.

`inspect.istraceback(object)`

Return true if the object is a traceback.

`inspect.isframe(object)`

Return true if the object is a frame.

`inspect.iscode(object)`

Return true if the object is a code.

`inspect.isbuiltin(object)`

Return true if the object is a built-in function or a bound built-in method.

`inspect.isroutine(object)`

Return true if the object is a user-defined or built-in function or method.

`inspect.isabstract(object)`

Return true if the object is an abstract base class.

Nouveau dans la version 2.6.

`inspect.ismethoddescriptor(object)`

Return true if the object is a method descriptor, but not if *ismethod()*, *isclass()*, *isfunction()* or *isbuiltin()* are true.

This is new as of Python 2.2, and, for example, is true of `int.__add__`. An object passing this test has a `__get__()` method but not a `__set__()` method, but beyond that the set of attributes varies. A `__name__` attribute is usually sensible, and `__doc__` often is.

Methods implemented via descriptors that also pass one of the other tests return false from the *ismethoddescriptor()* test, simply because the other tests promise more – you can, e.g., count on having the `im_func` attribute (etc) when an object passes *ismethod()*.

`inspect.isdatadescriptor(object)`

Return true if the object is a data descriptor.

Data descriptors have both a `__get__` and a `__set__` method. Examples are properties (defined in Python), getsets, and members. The latter two are defined in C and there are more specific tests available for those types, which is robust across Python implementations. Typically, data descriptors will also have `__name__` and `__doc__` attributes (properties, getsets, and members have both of these attributes), but this is not guaranteed.

Nouveau dans la version 2.3.

`inspect.isgetsetdescriptor(object)`

Return true if the object is a getset descriptor.

**CPython implementation detail :** getsets are attributes defined in extension modules via `PyGetSetDef` structures. For Python implementations without such types, this method will always return `False`.

Nouveau dans la version 2.5.

`inspect.ismemberdescriptor(object)`

Return true if the object is a member descriptor.

**CPython implementation detail :** Member descriptors are attributes defined in extension modules via `PyMemberDef` structures. For Python implementations without such types, this method will always return `False`.

Nouveau dans la version 2.5.

### 28.13.2 Retrieving source code

`inspect.getdoc(object)`

Get the documentation string for an object, cleaned up with `cleandoc()`.

`inspect.getcomments(object)`

Return in a single string any lines of comments immediately preceding the object's source code (for a class, function, or method), or at the top of the Python source file (if the object is a module).

`inspect.getfile(object)`

Return the name of the (text or binary) file in which an object was defined. This will fail with a `TypeError` if the object is a built-in module, class, or function.

`inspect.getmodule(object)`

Try to guess which module an object was defined in.

`inspect.getsourcefile(object)`

Return the name of the Python source file in which an object was defined. This will fail with a `TypeError` if the object is a built-in module, class, or function.

`inspect.getsourcelines(object)`

Return a list of source lines and starting line number for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a list of the lines corresponding to the object and the line number indicates where in the original source file the first line of code was found. An `IOError` is raised if the source code cannot be retrieved.

`inspect.getsource(object)`

Return the text of the source code for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a single string. An `IOError` is raised if the source code cannot be retrieved.

`inspect.cleandoc(doc)`

Clean up indentation from docstrings that are indented to line up with blocks of code.

All leading whitespace is removed from the first line. Any leading whitespace that can be uniformly removed from the second line onwards is removed. Empty lines at the beginning and end are subsequently removed. Also, all tabs are expanded to spaces.

Nouveau dans la version 2.6.

### 28.13.3 Classes and functions

`inspect.getclasstree(classes[, unique])`

Arrange the given list of classes into a hierarchy of nested lists. Where a nested list appears, it contains classes derived from the class whose entry immediately precedes the list. Each entry is a 2-tuple

containing a class and a tuple of its base classes. If the *unique* argument is true, exactly one entry appears in the returned structure for each class in the given list. Otherwise, classes using multiple inheritance and their descendants will appear multiple times.

`inspect.getargspec(func)`

Get the names and default values of a Python function's arguments. A tuple of four things is returned : (*args*, *varargs*, *keywords*, *defaults*). *args* is a list of the argument names (it may contain nested lists). *varargs* and *keywords* are the names of the \* and \*\* arguments or None. *defaults* is a tuple of default argument values or None if there are no default arguments ; if this tuple has *n* elements, they correspond to the last *n* elements listed in *args*.

Modifié dans la version 2.6 : Returns a *named tuple* `ArgSpec(args, varargs, keywords, defaults)`.

`inspect.getargvalues(frame)`

Get information about arguments passed into a particular frame. A tuple of four things is returned : (*args*, *varargs*, *keywords*, *locals*). *args* is a list of the argument names (it may contain nested lists). *varargs* and *keywords* are the names of the \* and \*\* arguments or None. *locals* is the locals dictionary of the given frame.

Modifié dans la version 2.6 : Returns a *named tuple* `ArgInfo(args, varargs, keywords, locals)`.

`inspect.formatargspec(args[, varargs, varkw, defaults, formatarg, formatvarargs, formatvarkw, formatvalue, join])`

Format a pretty argument spec from the four values returned by `getargspec()`. The format\* arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

`inspect.formatargvalues(args[, varargs, varkw, locals, formatarg, formatvarargs, formatvarkw, formatvalue, join])`

Format a pretty argument spec from the four values returned by `getargvalues()`. The format\* arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

`inspect.getmro(cls)`

Return a tuple of class *cls*'s base classes, including *cls*, in method resolution order. No class appears more than once in this tuple. Note that the method resolution order depends on *cls*'s type. Unless a very peculiar user-defined metatype is in use, *cls* will be the first element of the tuple.

`inspect.getcallargs(func[, *args][, **kwargs])`

Bind the *args* and *kws* to the argument names of the Python function or method *func*, as if it was called with them. For bound methods, bind also the first argument (typically named *self*) to the associated instance. A dict is returned, mapping the argument names (including the names of the \* and \*\* arguments, if any) to their values from *args* and *kws*. In case of invoking *func* incorrectly, i.e. whenever `func(*args, **kwargs)` would raise an exception because of incompatible signature, an exception of the same type and the same or similar message is raised. For example :

```
>>> from inspect import getcallargs
>>> def f(a, b=1, *pos, **named):
...     pass
>>> getcallargs(f, 1, 2, 3)
{'a': 1, 'named': {}, 'b': 2, 'pos': (3,)}
>>> getcallargs(f, a=2, x=4)
{'a': 2, 'named': {'x': 4}, 'b': 1, 'pos': ()}
>>> getcallargs(f)
Traceback (most recent call last):
...
TypeError: f() takes at least 1 argument (0 given)
```

Nouveau dans la version 2.7.

### 28.13.4 The interpreter stack

When the following functions return « frame records, » each record is a tuple of six items : the frame object, the filename, the line number of the current line, the function name, a list of lines of context from the source code, and the index of the current line within that list.

---

**Note :** Keeping references to frame objects, as found in the first element of the frame records these functions return, can cause your program to create reference cycles. Once a reference cycle has been created, the lifespan of all objects which can be accessed from the objects which form the cycle can become much longer even if Python's optional cycle detector is enabled. If such cycles must be created, it is important to ensure they are explicitly broken to avoid the delayed destruction of objects and increased memory consumption which occurs.

Though the cycle detector will catch these, destruction of the frames (and local variables) can be made deterministic by removing the cycle in a **finally** clause. This is also important if the cycle detector was disabled when Python was compiled or using `gc.disable()`. For example :

```
def handle_stackframe_without_leak():
    frame = inspect.currentframe()
    try:
        # do something with the frame
    finally:
        del frame
```

---

The optional *context* argument supported by most of these functions specifies the number of lines of context to return, which are centered around the current line.

`inspect.getframeinfo(frame[, context])`

Get information about a frame or traceback object. A 5-tuple is returned, the last five elements of the frame's frame record.

Modifié dans la version 2.6 : Returns a *named tuple* `Traceback(filename, lineno, function, code_context, index)`.

`inspect.getouterframes(frame[, context])`

Get a list of frame records for a frame and all outer frames. These frames represent the calls that lead to the creation of *frame*. The first entry in the returned list represents *frame*; the last entry represents the outermost call on *frame*'s stack.

`inspect.getinnerframes(traceback[, context])`

Get a list of frame records for a traceback's frame and all inner frames. These frames represent calls made as a consequence of *frame*. The first entry in the list represents *traceback*; the last entry represents where the exception was raised.

`inspect.currentframe()`

Return the frame object for the caller's stack frame.

**CPython implementation detail :** This function relies on Python stack frame support in the interpreter, which isn't guaranteed to exist in all implementations of Python. If running in an implementation without Python stack frame support this function returns `None`.

`inspect.stack([context])`

Return a list of frame records for the caller's stack. The first entry in the returned list represents the caller; the last entry represents the outermost call on the stack.

```
inspect.trace([context])
```

Return a list of frame records for the stack between the current frame and the frame in which an exception currently being handled was raised in. The first entry in the list represents the caller; the last entry represents where the exception was raised.

## 28.14 site — Site-specific configuration hook

Code source : [Lib/site.py](#)

**This module is automatically imported during initialization.** The automatic import can be suppressed using the interpreter's `-S` option.

Importing this module will append site-specific paths to the module search path and add a few builtins.

It starts by constructing up to four directories from a head and a tail part. For the head part, it uses `sys.prefix` and `sys.exec_prefix`; empty heads are skipped. For the tail part, it uses the empty string and then `lib/site-packages` (on Windows) or `lib/pythonX.Y/site-packages` and then `lib/site-python` (on Unix and Macintosh). For each of the distinct head-tail combinations, it sees if it refers to an existing directory, and if so, adds it to `sys.path` and also inspects the newly added path for configuration files.

A path configuration file is a file whose name has the form `name.pth` and exists in one of the four directories mentioned above; its contents are additional items (one per line) to be added to `sys.path`. Non-existing items are never added to `sys.path`, and no check is made that the item refers to a directory rather than a file. No item is added to `sys.path` more than once. Blank lines and lines beginning with `#` are skipped. Lines starting with `import` (followed by space or tab) are executed.

Modifié dans la version 2.6 : A space or tab is now required after the import keyword.

For example, suppose `sys.prefix` and `sys.exec_prefix` are set to `/usr/local`. The Python X.Y library is then installed in `/usr/local/lib/pythonX.Y`. Suppose this has a subdirectory `/usr/local/lib/pythonX.Y/site-packages` with three subsubdirectories, `foo`, `bar` and `spam`, and two path configuration files, `foo.pth` and `bar.pth`. Assume `foo.pth` contains the following :

```
# foo package configuration

foo
bar
bletch
```

and `bar.pth` contains :

```
# bar package configuration

bar
```

Then the following version-specific directories are added to `sys.path`, in this order :

```
/usr/local/lib/pythonX.Y/site-packages/bar
/usr/local/lib/pythonX.Y/site-packages/foo
```

Note that `bletch` is omitted because it doesn't exist; the `bar` directory precedes the `foo` directory because `bar.pth` comes alphabetically before `foo.pth`; and `spam` is omitted because it is not mentioned in either path configuration file.

After these path manipulations, an attempt is made to import a module named `sitecustomize`, which can perform arbitrary site-specific customizations. It is typically created by a system administrator in the

site-packages directory. If this import fails with an `ImportError` exception, it is silently ignored. If Python is started without output streams available, as with `pythonw.exe` on Windows (which is used by default to start IDLE), attempted output from `sitecustomize` is ignored. Any exception other than `ImportError` causes a silent and perhaps mysterious failure of the process.

After this, an attempt is made to import a module named `usercustomize`, which can perform arbitrary user-specific customizations, if `ENABLE_USER_SITE` is true. This file is intended to be created in the user site-packages directory (see below), which is part of `sys.path` unless disabled by `-s`. An `ImportError` will be silently ignored.

Note that for some non-Unix systems, `sys.prefix` and `sys.exec_prefix` are empty, and the path manipulations are skipped; however the import of `sitecustomize` and `usercustomize` is still attempted.

#### `site.PREFIXES`

A list of prefixes for site-packages directories.

Nouveau dans la version 2.6.

#### `site.ENABLE_USER_SITE`

Flag showing the status of the user site-packages directory. `True` means that it is enabled and was added to `sys.path`. `False` means that it was disabled by user request (with `-s` or `PYTHONNOUSERSITE`). `None` means it was disabled for security reasons (mismatch between user or group id and effective id) or by an administrator.

Nouveau dans la version 2.6.

#### `site.USER_SITE`

Path to the user site-packages for the running Python. Can be `None` if `getusersitepackages()` hasn't been called yet. Default value is `~/.local/lib/pythonX.Y/site-packages` for UNIX and non-framework Mac OS X builds, `~/Library/Python/X.Y/lib/python/site-packages` for Mac framework builds, and `%APPDATA%\Python\PythonXY\site-packages` on Windows. This directory is a site directory, which means that `.pth` files in it will be processed.

Nouveau dans la version 2.6.

#### `site.USER_BASE`

Path to the base directory for the user site-packages. Can be `None` if `getuserbase()` hasn't been called yet. Default value is `~/.local` for UNIX and Mac OS X non-framework builds, `~/Library/Python/X.Y` for Mac framework builds, and `%APPDATA%\Python` for Windows. This value is used by Distutils to compute the installation directories for scripts, data files, Python modules, etc. for the user installation scheme. See also `PYTHONUSERBASE`.

Nouveau dans la version 2.6.

#### `site.addsitedir(sitedir, known_paths=None)`

Add a directory to `sys.path` and process its `.pth` files. Typically used in `sitecustomize` or `usercustomize` (see above).

#### `site.getsitepackages()`

Return a list containing all global site-packages directories (and possibly site-python).

Nouveau dans la version 2.7.

#### `site.getuserbase()`

Return the path of the user base directory, `USER_BASE`. If it is not initialized yet, this function will also set it, respecting `PYTHONUSERBASE`.

Nouveau dans la version 2.7.

#### `site.getusersitepackages()`

Return the path of the user-specific site-packages directory, `USER_SITE`. If it is not initialized yet, this function will also set it, respecting `PYTHONNOUSERSITE` and `USER_BASE`.

Nouveau dans la version 2.7.

The `site` module also provides a way to get the user directories from the command line :

```
$ python -m site --user-site
/home/user/.local/lib/python2.7/site-packages
```

If it is called without arguments, it will print the contents of `sys.path` on the standard output, followed by the value of `USER_BASE` and whether the directory exists, then the same thing for `USER_SITE`, and finally the value of `ENABLE_USER_SITE`.

#### **--user-base**

Print the path to the user base directory.

#### **--user-site**

Print the path to the user site-packages directory.

If both options are given, user base and user site will be printed (always in this order), separated by `os.pathsep`.

If any option is given, the script will exit with one of these values : 0 if the user site-packages directory is enabled, 1 if it was disabled by the user, 2 if it is disabled for security reasons or by an administrator, and a value greater than 2 if there is an error.

**PEP 370** – Répertoire site-packages propre à l'utilisateur.

## 28.15 user — User-specific configuration hook

Obsolète depuis la version 2.6 : The `user` module has been removed in Python 3.

As a policy, Python doesn't run user-specified code on startup of Python programs. (Only interactive sessions execute the script specified in the `PYTHONSTARTUP` environment variable if it exists).

However, some programs or sites may find it convenient to allow users to have a standard customization file, which gets run when a program requests it. This module implements such a mechanism. A program that wishes to use the mechanism must execute the statement

```
import user
```

The `user` module looks for a file `.pythonrc.py` in the user's home directory and if it can be opened, executes it (using `execfile()`) in its own (the module `user`'s) global namespace. Errors during this phase are not caught; that's up to the program that imports the `user` module, if it wishes. The home directory is assumed to be named by the `HOME` environment variable; if this is not set, the current directory is used.

The user's `.pythonrc.py` could conceivably test for `sys.version` if it wishes to do different things depending on the Python version.

A warning to users : be very conservative in what you place in your `.pythonrc.py` file. Since you don't know which programs will use it, changing the behavior of standard modules or functions is generally not a good idea.

A suggestion for programmers who wish to use this mechanism : a simple way to let users specify options for your package is to have them define variables in their `.pythonrc.py` file that you test in your module. For example, a module `spam` that has a verbosity level can look for a variable `user.spam_verbose`, as follows :

```
import user

verbose = bool(getattr(user, "spam_verbose", 0))
```

(The three-argument form of `getattr()` is used in case the user has not defined `spam_verbose` in their `.pythonrc.py` file.)

Programs with extensive customization needs are better off reading a program-specific customization file.

Programs with security or privacy concerns should *not* import this module; a user can easily break into a program by placing arbitrary code in the `.pythonrc.py` file.

Modules for general use should *not* import this module; it may interfere with the operation of the importing program.

Module `site` Site-wide customization mechanism.

## 28.16 `fpectl` — Floating point exception control

---

**Note :** The `fpectl` module is not built by default, and its usage is discouraged and may be dangerous except in the hands of experts. See also the section *Limitations and other considerations* on limitations for more details.

---

Most computers carry out floating point operations in conformance with the so-called IEEE-754 standard. On any real computer, some floating point operations produce results that cannot be expressed as a normal floating point value. For example, try

```
>>> import math
>>> math.exp(1000)
inf
>>> math.exp(1000) / math.exp(1000)
nan
```

(The example above will work on many platforms. DEC Alpha may be one exception.) « Inf » is a special, non-numeric value in IEEE-754 that stands for « infinity », and « nan » means « not a number. » Note that, other than the non-numeric results, nothing special happened when you asked Python to carry out those calculations. That is in fact the default behaviour prescribed in the IEEE-754 standard, and if it works for you, stop reading now.

In some circumstances, it would be better to raise an exception and stop processing at the point where the faulty operation was attempted. The `fpectl` module is for use in that situation. It provides control over floating point units from several hardware manufacturers, allowing the user to turn on the generation of SIGFPE whenever any of the IEEE-754 exceptions Division by Zero, Overflow, or Invalid Operation occurs. In tandem with a pair of wrapper macros that are inserted into the C code comprising your python system, SIGFPE is trapped and converted into the Python `FloatingPointError` exception.

The `fpectl` module defines the following functions and may raise the given exception :

`fpectl.turnon_sigfpe()`

Turn on the generation of SIGFPE, and set up an appropriate signal handler.

`fpectl.turnoff_sigfpe()`

Reset default handling of floating point exceptions.

exception `fpectl.FloatingPointError`

After `turnon_sigfpe()` has been executed, a floating point operation that raises one of the IEEE-754 exceptions Division by Zero, Overflow, or Invalid operation will in turn raise this standard Python exception.

### 28.16.1 Exemple

The following example demonstrates how to start up and test operation of the *fpectl* module.

```
>>> import fpectl
>>> import fpetest
>>> fpectl.turnon_sigfpe()
>>> fpetest.test()
overflow          PASS
FloatingPointError: Overflow

div by 0          PASS
FloatingPointError: Division by zero
[ more output from test elided ]
>>> import math
>>> math.exp(1000)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
FloatingPointError: in math_1
```

### 28.16.2 Limitations and other considerations

Setting up a given processor to trap IEEE-754 floating point errors currently requires custom code on a per-architecture basis. You may have to modify *fpectl* to control your particular hardware.

Conversion of an IEEE-754 exception to a Python exception requires that the wrapper macros `PyFPE_START_PROTECT` and `PyFPE_END_PROTECT` be inserted into your code in an appropriate fashion. Python itself has been modified to support the *fpectl* module, but many other codes of interest to numerical analysts have not.

The *fpectl* module is not thread-safe.

#### Voir aussi :

Some files in the source distribution may be interesting in learning more about how this module operates. The include file [Include/pyfpe.h](#) discusses the implementation of this module at some length. [Modules/fpetestmodule.c](#) gives several examples of use. Many additional examples can be found in [Objects/floatobject.c](#).

## Interpréteurs Python personnalisés

Les modules décrits dans ce chapitre permettent d'écrire des interfaces similaires à l'interpréteur interactif de Python. Si vous voulez un interpréteur Python qui gère quelques fonctionnalités supplémentaires, vous devriez regarder le module `code`. (Le module `codeop` est un module de plus bas niveau permettant de compiler des morceaux, pas forcément complets, de Python.)

La liste complète des modules décrits dans ce chapitre est :

## 29.1 `code` — Interpreter base classes

The `code` module provides facilities to implement read-eval-print loops in Python. Two classes and convenience functions are included which can be used to build applications which provide an interactive interpreter prompt.

```
class code.InteractiveInterpreter([locals])
```

This class deals with parsing and interpreter state (the user's namespace); it does not deal with input buffering or prompting or input file naming (the filename is always passed in explicitly). The optional *locals* argument specifies the dictionary in which code will be executed; it defaults to a newly created dictionary with key `'__name__'` set to `'__console__'` and key `'__doc__'` set to `None`.

```
class code.InteractiveConsole([locals[, filename]])
```

Closely emulate the behavior of the interactive Python interpreter. This class builds on *InteractiveInterpreter* and adds prompting using the familiar `sys.ps1` and `sys.ps2`, and input buffering.

```
code.interact([banner[, readfunc[, local]])
```

Convenience function to run a read-eval-print loop. This creates a new instance of *InteractiveConsole* and sets *readfunc* to be used as the *InteractiveConsole.raw\_input()* method, if provided. If *local* is provided, it is passed to the *InteractiveConsole* constructor for use as the default namespace for the interpreter loop. The *interact()* method of the instance is then run with *banner* passed as the banner to use, if provided. The console object is discarded after use.

```
code.compile_command(source[, filename[, symbol]])
```

This function is useful for programs that want to emulate Python's interpreter main loop (a.k.a. the

read-eval-print loop). The tricky part is to determine when the user has entered an incomplete command that can be completed by entering more text (as opposed to a complete command or a syntax error). This function *almost* always makes the same decision as the real interpreter main loop.

*source* is the source string; *filename* is the optional filename from which source was read, defaulting to '<input>'; and *symbol* is the optional grammar start symbol, which should be either 'single' (the default) or 'eval'.

Returns a code object (the same as `compile(source, filename, symbol)`) if the command is complete and valid; `None` if the command is incomplete; raises `SyntaxError` if the command is complete and contains a syntax error, or raises `OverflowError` or `ValueError` if the command contains an invalid literal.

### 29.1.1 Interactive Interpreter Objects

`InteractiveInterpreter.runsource(source[, filename[, symbol]])`

Compile and run some source in the interpreter. Arguments are the same as for `compile_command()`; the default for *filename* is '<input>', and for *symbol* is 'single'. One several things can happen :

- The input is incorrect; `compile_command()` raised an exception (`SyntaxError` or `OverflowError`). A syntax traceback will be printed by calling the `showsyntaxerror()` method. `runsource()` returns `False`.
- The input is incomplete, and more input is required; `compile_command()` returned `None`. `runsource()` returns `True`.
- The input is complete; `compile_command()` returned a code object. The code is executed by calling the `runcode()` (which also handles run-time exceptions, except for `SystemExit`). `runsource()` returns `False`.

The return value can be used to decide whether to use `sys.ps1` or `sys.ps2` to prompt the next line.

`InteractiveInterpreter.runcode(code)`

Execute a code object. When an exception occurs, `showtraceback()` is called to display a traceback. All exceptions are caught except `SystemExit`, which is allowed to propagate.

A note about `KeyboardInterrupt` : this exception may occur elsewhere in this code, and may not always be caught. The caller should be prepared to deal with it.

`InteractiveInterpreter.showsyntaxerror([filename])`

Display the syntax error that just occurred. This does not display a stack trace because there isn't one for syntax errors. If *filename* is given, it is stuffed into the exception instead of the default filename provided by Python's parser, because it always uses '<string>' when reading from a string. The output is written by the `write()` method.

`InteractiveInterpreter.showtraceback()`

Display the exception that just occurred. We remove the first stack item because it is within the interpreter object implementation. The output is written by the `write()` method.

`InteractiveInterpreter.write(data)`

Write a string to the standard error stream (`sys.stderr`). Derived classes should override this to provide the appropriate output handling as needed.

### 29.1.2 Interactive Console Objects

The `InteractiveConsole` class is a subclass of `InteractiveInterpreter`, and so offers all the methods of the interpreter objects as well as the following additions.

`InteractiveConsole.interact([banner])`

Closely emulate the interactive Python console. The optional banner argument specify the banner to print before the first interaction; by default it prints a banner similar to the one printed by the standard Python interpreter, followed by the class name of the console object in parentheses (so as not to confuse this with the real interpreter – since it's so close!).

`InteractiveConsole.push(line)`

Push a line of source text to the interpreter. The line should not have a trailing newline; it may have internal newlines. The line is appended to a buffer and the interpreter's `runsource()` method is called with the concatenated contents of the buffer as source. If this indicates that the command was executed or invalid, the buffer is reset; otherwise, the command is incomplete, and the buffer is left as it was after the line was appended. The return value is `True` if more input is required, `False` if the line was dealt with in some way (this is the same as `runsource()`).

`InteractiveConsole.resetbuffer()`

Remove any unhandled source text from the input buffer.

`InteractiveConsole.raw_input([prompt])`

Write a prompt and read a line. The returned line does not include the trailing newline. When the user enters the EOF key sequence, `EOFError` is raised. The base implementation uses the built-in function `raw_input()`; a subclass may replace this with a different implementation.

## 29.2 codeop — Compile Python code

The `codeop` module provides utilities upon which the Python read-eval-print loop can be emulated, as is done in the `code` module. As a result, you probably don't want to use the module directly; if you want to include such a loop in your program you probably want to use the `code` module instead.

There are two parts to this job :

1. Being able to tell if a line of input completes a Python statement : in short, telling whether to print “>>>” or “...” next.
2. Remembering which future statements the user has entered, so subsequent input can be compiled with these in effect.

The `codeop` module provides a way of doing each of these things, and a way of doing them both.

To do just the former :

`codeop.compile_command(source[, filename[, symbol]])`

Tries to compile *source*, which should be a string of Python code and return a code object if *source* is valid Python code. In that case, the filename attribute of the code object will be *filename*, which defaults to '<input>'. Returns `None` if *source* is *not* valid Python code, but is a prefix of valid Python code.

If there is a problem with *source*, an exception will be raised. `SyntaxError` is raised if there is invalid Python syntax, and `OverflowError` or `ValueError` if there is an invalid literal.

The *symbol* argument determines whether *source* is compiled as a statement ('single', the default) or as an *expression* ('eval'). Any other value will cause `ValueError` to be raised.

---

**Note :** It is possible (but not likely) that the parser stops parsing with a successful outcome before reaching the end of the source; in this case, trailing symbols may be ignored instead of causing an error. For example, a backslash followed by two newlines may be followed by arbitrary garbage. This will be fixed once the API for the parser is better.

---

`class codeop.Compile`

Instances of this class have `__call__()` methods identical in signature to the built-in function `compile()`, but with the difference that if the instance compiles program text containing a `__future__` statement, the instance “remembers” and compiles all subsequent program texts with the statement in force.

`class codeop.CommandCompiler`

Instances of this class have `__call__()` methods identical in signature to `compile_command()`; the

difference is that if the instance compiles program text containing a `__future__` statement, the instance “remembers” and compiles all subsequent program texts with the statement in force.

A note on version compatibility : the `Compile` and `CommandCompiler` are new in Python 2.2. If you want to enable the future-tracking features of 2.2 but also retain compatibility with 2.1 and earlier versions of Python you can either write

```
try:
    from codeop import CommandCompiler
    compile_command = CommandCompiler()
    del CommandCompiler
except ImportError:
    from codeop import compile_command
```

which is a low-impact change, but introduces possibly unwanted global state into your program, or you can write :

```
try:
    from codeop import CommandCompiler
except ImportError:
    def CommandCompiler():
        from codeop import compile_command
        return compile_command
```

and then call `CommandCompiler` every time you need a fresh compiler object.

---

Restricted Execution

---

**Avertissement :** In Python 2.3 these modules have been disabled due to various known and not readily fixable security holes. The modules are still documented here to help in reading old code that uses the *rexec* and *Bastion* modules.

*Restricted execution* is the basic framework in Python that allows for the segregation of trusted and untrusted code. The framework is based on the notion that trusted Python code (a *supervisor*) can create a « padded cell » (or environment) with limited permissions, and run the untrusted code within this cell. The untrusted code cannot break out of its cell, and can only interact with sensitive system resources through interfaces defined and managed by the trusted code. The term « restricted execution » is favored over « safe-Python » since true safety is hard to define, and is determined by the way the restricted environment is created. Note that the restricted environments can be nested, with inner cells creating subcells of lesser, but never greater, privilege.

An interesting aspect of Python's restricted execution model is that the interfaces presented to untrusted code usually have the same names as those presented to trusted code. Therefore no special interfaces need to be learned to write code designed to run in a restricted environment. And because the exact nature of the padded cell is determined by the supervisor, different restrictions can be imposed, depending on the application. For example, it might be deemed « safe » for untrusted code to read any file within a specified directory, but never to write a file. In this case, the supervisor may redefine the built-in *open()* function so that it raises an exception whenever the *mode* parameter is 'w'. It might also perform a *chroot()*-like operation on the *filename* parameter, such that root is always relative to some safe « sandbox » area of the filesystem. In this case, the untrusted code would still see a built-in *open()* function in its environment, with the same calling interface. The semantics would be identical too, with *IOErrors* being raised when the supervisor determined that an unallowable parameter is being used.

The Python run-time determines whether a particular code block is executing in restricted execution mode based on the identity of the `__builtins__` object in its global variables : if this is (the dictionary of) the standard `__builtin__` module, the code is deemed to be unrestricted, else it is deemed to be restricted.

Python code executing in restricted mode faces a number of limitations that are designed to prevent it from escaping from the padded cell. For instance, the function object attribute `func_globals` and the class and instance object attribute `__dict__` are unavailable.

Two modules provide the framework for setting up restricted execution environments :

## 30.1 `rexec` — Restricted execution framework

Obsolète depuis la version 2.6 : The `rexec` module has been removed in Python 3.

Modifié dans la version 2.3 : Disabled module.

**Avertissement :** The documentation has been left in place to help in reading old code that uses the module.

This module contains the `RExec` class, which supports `r_eval()`, `r_execfile()`, `r_exec()`, and `r_import()` methods, which are restricted versions of the standard Python functions `eval()`, `execfile()` and the `exec` and `import` statements. Code executed in this restricted environment will only have access to modules and functions that are deemed safe; you can subclass `RExec` to add or remove capabilities as desired.

**Avertissement :** While the `rexec` module is designed to perform as described below, it does have a few known vulnerabilities which could be exploited by carefully written code. Thus it should not be relied upon in situations requiring « production ready » security. In such situations, execution via sub-processes or very careful « cleansing » of both code and data to be processed may be necessary. Alternatively, help in patching known `rexec` vulnerabilities would be welcomed.

---

**Note :** The `RExec` class can prevent code from performing unsafe operations like reading or writing disk files, or using TCP/IP sockets. However, it does not protect against code using extremely large amounts of memory or processor time.

---

```
class rexec.RExec([hooks[, verbose]])
```

Returns an instance of the `RExec` class.

`hooks` is an instance of the `RHooks` class or a subclass of it. If it is omitted or `None`, the default `RHooks` class is instantiated. Whenever the `rexec` module searches for a module (even a built-in one) or reads a module's code, it doesn't actually go out to the file system itself. Rather, it calls methods of an `RHooks` instance that was passed to or created by its constructor. (Actually, the `RExec` object doesn't make these calls — they are made by a module loader object that's part of the `RExec` object. This allows another level of flexibility, which can be useful when changing the mechanics of `import` within the restricted environment.)

By providing an alternate `RHooks` object, we can control the file system accesses made to import a module, without changing the actual algorithm that controls the order in which those accesses are made. For instance, we could substitute an `RHooks` object that passes all filesystem requests to a file server elsewhere, via some RPC mechanism such as ILU. Grail's applet loader uses this to support importing applets from a URL for a directory.

If `verbose` is true, additional debugging output may be sent to standard output.

It is important to be aware that code running in a restricted environment can still call the `sys.exit()` function. To disallow restricted code from exiting the interpreter, always protect calls that cause restricted code to run with a `try/except` statement that catches the `SystemExit` exception. Removing the `sys.exit()` function from the restricted environment is not sufficient — the restricted code could still use `raise SystemExit`. Removing `SystemExit` is not a reasonable option; some library code makes use of this and would break were it not available.

**Voir aussi :**

**Grail Home Page** Grail is a Web browser written entirely in Python. It uses the `rexec` module as a foundation for supporting Python applets, and can be used as an example usage of this module.

### 30.1.1 RExec Objects

`RExec` instances support the following methods :

`RExec.r_eval(code)`

`code` must either be a string containing a Python expression, or a compiled code object, which will be evaluated in the restricted environment's `__main__` module. The value of the expression or code object will be returned.

`RExec.r_exec(code)`

`code` must either be a string containing one or more lines of Python code, or a compiled code object, which will be executed in the restricted environment's `__main__` module.

`RExec.r_execfile(filename)`

Execute the Python code contained in the file `filename` in the restricted environment's `__main__` module.

Methods whose names begin with `s_` are similar to the functions beginning with `r_`, but the code will be granted access to restricted versions of the standard I/O streams `sys.stdin`, `sys.stderr`, and `sys.stdout`.

`RExec.s_eval(code)`

`code` must be a string containing a Python expression, which will be evaluated in the restricted environment.

`RExec.s_exec(code)`

`code` must be a string containing one or more lines of Python code, which will be executed in the restricted environment.

`RExec.s_execfile(filename)`

Execute the Python code contained in the file `filename` in the restricted environment.

`RExec` objects must also support various methods which will be implicitly called by code executing in the restricted environment. Overriding these methods in a subclass is used to change the policies enforced by a restricted environment.

`RExec.r_import(modulename[, globals[, locals[, fromlist]]])`

Import the module `modulename`, raising an `ImportError` exception if the module is considered unsafe.

`RExec.r_open(filename[, mode[, bufsize]])`

Method called when `open()` is called in the restricted environment. The arguments are identical to those of `open()`, and a file object (or a class instance compatible with file objects) should be returned. `RExec`'s default behaviour is allow opening any file for reading, but forbidding any attempt to write a file. See the example below for an implementation of a less restrictive `r_open()`.

`RExec.r_reload(module)`

Reload the module object `module`, re-parsing and re-initializing it.

`RExec.r_unload(module)`

Unload the module object `module` (remove it from the restricted environment's `sys.modules` dictionary).

And their equivalents with access to restricted standard I/O streams :

`RExec.s_import(modulename[, globals[, locals[, fromlist]]])`

Import the module `modulename`, raising an `ImportError` exception if the module is considered unsafe.

`RExec.s_reload(module)`

Reload the module object *module*, re-parsing and re-initializing it.

`RExec.s_unload(module)`

Unload the module object *module*.

### 30.1.2 Defining restricted environments

The `RExec` class has the following class attributes, which are used by the `__init__()` method. Changing them on an existing instance won't have any effect; instead, create a subclass of `RExec` and assign them new values in the class definition. Instances of the new class will then use those new values. All these attributes are tuples of strings.

`RExec.nok_builtin_names`

Contains the names of built-in functions which will *not* be available to programs running in the restricted environment. The value for `RExec` is ('open', 'reload', '\_\_import\_\_'). (This gives the exceptions, because by far the majority of built-in functions are harmless. A subclass that wants to override this variable should probably start with the value from the base class and concatenate additional forbidden functions — when new dangerous built-in functions are added to Python, they will also be added to this module.)

`RExec.ok_builtin_modules`

Contains the names of built-in modules which can be safely imported. The value for `RExec` is ('audioop', 'array', 'binascii', 'cmath', 'errno', 'imageop', 'marshal', 'math', 'md5', 'operator', 'parser', 'regex', 'select', 'sha', '\_sre', 'strop', 'struct', 'time'). A similar remark about overriding this variable applies — use the value from the base class as a starting point.

`RExec.ok_path`

Contains the directories which will be searched when an `import` is performed in the restricted environment. The value for `RExec` is the same as `sys.path` (at the time the module is loaded) for unrestricted code.

`RExec.ok_posix_names`

Contains the names of the functions in the `os` module which will be available to programs running in the restricted environment. The value for `RExec` is ('error', 'fstat', 'listdir', 'lstat', 'readlink', 'stat', 'times', 'uname', 'getpid', 'getppid', 'getcwd', 'getuid', 'getgid', 'geteuid', 'getegid').

`RExec.ok_sys_names`

Contains the names of the functions and variables in the `sys` module which will be available to programs running in the restricted environment. The value for `RExec` is ('ps1', 'ps2', 'copyright', 'version', 'platform', 'exit', 'maxint').

`RExec.ok_file_types`

Contains the file types from which modules are allowed to be loaded. Each file type is an integer constant defined in the `imp` module. The meaningful values are `PY_SOURCE`, `PY_COMPILED`, and `C_EXTENSION`. The value for `RExec` is (`C_EXTENSION`, `PY_SOURCE`). Adding `PY_COMPILED` in subclasses is not recommended; an attacker could exit the restricted execution mode by putting a forged byte-compiled file (`.pyc`) anywhere in your file system, for example by writing it to `/tmp` or uploading it to the `/incoming` directory of your public FTP server.

### 30.1.3 An example

Let us say that we want a slightly more relaxed policy than the standard `RExec` class. For example, if we're willing to allow files in `/tmp` to be written, we can subclass the `RExec` class :

```

class TmpWriterRExec(rexec.RExec):
    def r_open(self, file, mode='r', buf=-1):
        if mode in ('r', 'rb'):
            pass
        elif mode in ('w', 'wb', 'a', 'ab'):
            # check filename: must begin with /tmp/
            if file[:5] != '/tmp/':
                raise IOError("can't write outside /tmp")
            elif (string.find(file, '/../') >= 0 or
                  file[:3] == '../' or file[-3:] == '/../'):
                raise IOError("'..' in filename forbidden")
            else: raise IOError("Illegal open() mode")
        return open(file, mode, buf)

```

Notice that the above code will occasionally forbid a perfectly valid filename; for example, code in the restricted environment won't be able to open a file called `/tmp/foo/../bar`. To fix this, the `r_open()` method would have to simplify the filename to `/tmp/bar`, which would require splitting apart the filename and performing various operations on it. In cases where security is at stake, it may be preferable to write simple code which is sometimes overly restrictive, instead of more general code that is also more complex and may harbor a subtle security hole.

## 30.2 Bastion — Restricting access to objects

Obsolète depuis la version 2.6 : The *Bastion* module has been removed in Python 3.

Modifié dans la version 2.3 : Disabled module.

---

**Note :** The documentation has been left in place to help in reading old code that uses the module.

---

According to the dictionary, a bastion is « a fortified area or position », or « something that is considered a stronghold. » It's a suitable name for this module, which provides a way to forbid access to certain attributes of an object. It must always be used with the *rexec* module, in order to allow restricted-mode programs access to certain safe attributes of an object, while denying access to other, unsafe attributes.

**Bastion.Bastion**(*object*[, *filter*[, *name*[, *class*]]])

Protect the object *object*, returning a bastion for the object. Any attempt to access one of the object's attributes will have to be approved by the *filter* function; if the access is denied an *AttributeError* exception will be raised.

If present, *filter* must be a function that accepts a string containing an attribute name, and returns true if access to that attribute will be permitted; if *filter* returns false, the access is denied. The default filter denies access to any function beginning with an underscore ('\_'). The bastion's string representation will be `<Bastion for name>` if a value for *name* is provided; otherwise, `repr(object)` will be used.

*class*, if present, should be a subclass of *BastionClass*; see the code in `bastion.py` for the details. Overriding the default *BastionClass* will rarely be required.

**class Bastion.BastionClass**(*getfunc*, *name*)

Class which actually implements bastion objects. This is the default class used by *Bastion()*. The *getfunc* parameter is a function which returns the value of an attribute which should be exposed to the restricted execution environment when called with the name of the attribute as the only parameter. *name* is used to construct the *repr()* of the *BastionClass* instance.

Importer des modules

---

Les modules décrits dans ce chapitre fournissent de nouveaux moyens d'importer d'autres modules Python, et des *hooks* pour personnaliser le processus d'importation.

La liste complète des modules décrits dans ce chapitre est :

### 31.1 `imp` — Access the `import` internals

This module provides an interface to the mechanisms used to implement the `import` statement. It defines the following constants and functions :

`imp.get_magic()`

Return the magic string value used to recognize byte-compiled code files (`.pyc` files). (This value may be different for each Python version.)

`imp.get_suffixes()`

Return a list of 3-element tuples, each describing a particular type of module. Each triple has the form `(suffix, mode, type)`, where *suffix* is a string to be appended to the module name to form the filename to search for, *mode* is the mode string to pass to the built-in `open()` function to open the file (this can be `'r'` for text files or `'rb'` for binary files), and *type* is the file type, which has one of the values `PY_SOURCE`, `PY_COMPILED`, or `C_EXTENSION`, described below.

`imp.find_module(name[, path])`

Try to find the module *name*. If *path* is omitted or `None`, the list of directory names given by `sys.path` is searched, but first a few special places are searched : the function tries to find a built-in module with the given name (`C_BUILTIN`), then a frozen module (`PY_FROZEN`), and on some systems some other places are looked in as well (on Windows, it looks in the registry which may point to a specific file).

Otherwise, *path* must be a list of directory names; each directory is searched for files with any of the suffixes returned by `get_suffixes()` above. Invalid names in the list are silently ignored (but all list items must be strings).

If search is successful, the return value is a 3-element tuple `(file, pathname, description)` :

*file* is an open file object positioned at the beginning, *pathname* is the pathname of the file found, and *description* is a 3-element tuple as contained in the list returned by `get_suffixes()` describing the kind of module found.

If the module does not live in a file, the returned *file* is `None`, *pathname* is the empty string, and the *description* tuple contains empty strings for its suffix and mode; the module type is indicated as given in parentheses above. If the search is unsuccessful, `ImportError` is raised. Other exceptions indicate problems with the arguments or environment.

If the module is a package, *file* is `None`, *pathname* is the package path and the last item in the *description* tuple is `PKG_DIRECTORY`.

This function does not handle hierarchical module names (names containing dots). In order to find *P.M*, that is, submodule *M* of package *P*, use `find_module()` and `load_module()` to find and load package *P*, and then use `find_module()` with the *path* argument set to `P.__path__`. When *P* itself has a dotted name, apply this recipe recursively.

`imp.load_module(name, file, pathname, description)`

Load a module that was previously found by `find_module()` (or by an otherwise conducted search yielding compatible results). This function does more than importing the module : if the module was already imported, it is equivalent to a `reload()`! The *name* argument indicates the full module name (including the package name, if this is a submodule of a package). The *file* argument is an open file, and *pathname* is the corresponding file name; these can be `None` and `''`, respectively, when the module is a package or not being loaded from a file. The *description* argument is a tuple, as would be returned by `get_suffixes()`, describing what kind of module must be loaded.

If the load is successful, the return value is the module object; otherwise, an exception (usually `ImportError`) is raised.

**Important :** the caller is responsible for closing the *file* argument, if it was not `None`, even when an exception is raised. This is best done using a `try ... finally` statement.

`imp.new_module(name)`

Return a new empty module object called *name*. This object is *not* inserted in `sys.modules`.

`imp.lock_held()`

Return `True` if the import lock is currently held, else `False`. On platforms without threads, always return `False`.

On platforms with threads, a thread executing an import holds an internal lock until the import is complete. This lock blocks other threads from doing an import until the original import completes, which in turn prevents other threads from seeing incomplete module objects constructed by the original thread while in the process of completing its import (and the imports, if any, triggered by that).

`imp.acquire_lock()`

Acquire the interpreter's import lock for the current thread. This lock should be used by import hooks to ensure thread-safety when importing modules.

Once a thread has acquired the import lock, the same thread may acquire it again without blocking; the thread must release it once for each time it has acquired it.

On platforms without threads, this function does nothing.

Nouveau dans la version 2.3.

`imp.release_lock()`

Release the interpreter's import lock. On platforms without threads, this function does nothing.

Nouveau dans la version 2.3.

The following constants with integer values, defined in this module, are used to indicate the search result of `find_module()`.

`imp.PY_SOURCE`

The module was found as a source file.

`imp.PY_COMPILED`

The module was found as a compiled code object file.

`imp.C_EXTENSION`

The module was found as dynamically loadable shared library.

`imp.PKG_DIRECTORY`

The module was found as a package directory.

`imp.C_BUILTIN`

The module was found as a built-in module.

`imp.PY_FROZEN`

The module was found as a frozen module (see `init_frozen()`).

The following constant and functions are obsolete; their functionality is available through `find_module()` or `load_module()`. They are kept around for backward compatibility :

`imp.SEARCH_ERROR`

Unused.

`imp.init_builtin(name)`

Initialize the built-in module called *name* and return its module object along with storing it in `sys.modules`. If the module was already initialized, it will be initialized *again*. Re-initialization involves the copying of the built-in module's `__dict__` from the cached module over the module's entry in `sys.modules`. If there is no built-in module called *name*, `None` is returned.

`imp.init_frozen(name)`

Initialize the frozen module called *name* and return its module object. If the module was already initialized, it will be initialized *again*. If there is no frozen module called *name*, `None` is returned. (Frozen modules are modules written in Python whose compiled byte-code object is incorporated into a custom-built Python interpreter by Python's **freeze** utility. See `Tools/freeze/` for now.)

`imp.is_builtin(name)`

Return 1 if there is a built-in module called *name* which can be initialized again. Return -1 if there is a built-in module called *name* which cannot be initialized again (see `init_builtin()`). Return 0 if there is no built-in module called *name*.

`imp.is_frozen(name)`

Return `True` if there is a frozen module (see `init_frozen()`) called *name*, or `False` if there is no such module.

`imp.load_compiled(name, pathname[, file])`

Load and initialize a module implemented as a byte-compiled code file and return its module object. If the module was already initialized, it will be initialized *again*. The *name* argument is used to create or access a module object. The *pathname* argument points to the byte-compiled code file. The *file* argument is the byte-compiled code file, open for reading in binary mode, from the beginning. It must currently be a real file object, not a user-defined class emulating a file.

`imp.load_dynamic(name, pathname[, file])`

Load and initialize a module implemented as a dynamically loadable shared library and return its module object. If the module was already initialized, it will be initialized *again*. Re-initialization involves copying the `__dict__` attribute of the cached instance of the module over the value used in the module cached in `sys.modules`. The *pathname* argument must point to the shared library. The *name* argument is used to construct the name of the initialization function : an external C function called `initname()` in the shared library is called. The optional *file* argument is ignored. (Note : using shared libraries is highly system dependent, and not all systems support it.)

**CPython implementation detail :** The import internals identify extension modules by filename, so doing `foo = load_dynamic("foo", "mod.so")` and `bar = load_dynamic("bar", "mod.so")` will result in both `foo` and `bar` referring to the same module, regardless of whether or not `mod.so` exports an `initbar` function. On systems which support them, symlinks can be used to import multiple modules from the same shared library, as each reference to the module will use a different file name.

`imp.load_source(name, pathname[, file])`

Load and initialize a module implemented as a Python source file and return its module object. If the

module was already initialized, it will be initialized *again*. The *name* argument is used to create or access a module object. The *pathname* argument points to the source file. The *file* argument is the source file, open for reading as text, from the beginning. It must currently be a real file object, not a user-defined class emulating a file. Note that if a properly matching byte-compiled file (with suffix `.pyc` or `.pyo`) exists, it will be used instead of parsing the given source file.

`class imp.NullImporter(path_string)`

The *NullImporter* type is a **PEP 302** import hook that handles non-directory path strings by failing to find any modules. Calling this type with an existing directory or empty string raises *ImportError*. Otherwise, a *NullImporter* instance is returned.

Python adds instances of this type to `sys.path_importer_cache` for any path entries that are not directories and are not handled by any other path hooks on `sys.path_hooks`. Instances have only one method :

`find_module(fullname[, path])`

This method always returns `None`, indicating that the requested module could not be found.

Nouveau dans la version 2.5.

### 31.1.1 Exemples

The following function emulates what was the standard import statement up to Python 1.4 (no hierarchical module names). (This *implementation* wouldn't work in that version, since *find\_module()* has been extended and *load\_module()* has been added in 1.4.)

```
import imp
import sys

def __import__(name, globals=None, locals=None, fromlist=None):
    # Fast path: see if the module has already been imported.
    try:
        return sys.modules[name]
    except KeyError:
        pass

    # If any of the following calls raises an exception,
    # there's a problem we can't handle -- let the caller handle it.

    fp, pathname, description = imp.find_module(name)

    try:
        return imp.load_module(name, fp, pathname, description)
    finally:
        # Since we may exit via an exception, close fp explicitly.
        if fp:
            fp.close()
```

A more complete example that implements hierarchical module names and includes a *reload()* function can be found in the module `knee`. The `knee` module can be found in `Demo/imputil/` in the Python source distribution.

## 31.2 importlib — Convenience wrappers for `__import__()`

Nouveau dans la version 2.7.

This module is a minor subset of what is available in the more full-featured package of the same name from

Python 3.1 that provides a complete implementation of `import`. What is here has been provided to help ease in transitioning from 2.7 to 3.1.

`importlib.import_module(name, package=None)`

Import a module. The *name* argument specifies what module to import in absolute or relative terms (e.g. either `pkg.mod` or `..mod`). If the name is specified in relative terms, then the *package* argument must be specified to the package which is to act as the anchor for resolving the package name (e.g. `import_module('..mod', 'pkg.subpkg')` will import `pkg.mod`). The specified module will be inserted into `sys.modules` and returned.

## 31.3 `importlib` — Import utilities

Obsolète depuis la version 2.6 : The `importlib` module has been removed in Python 3.

This module provides a very handy and useful mechanism for custom `import` hooks. Compared to the older `ihooks` module, `importlib` takes a dramatically simpler and more straight-forward approach to custom `import` functions.

`class importlib.ImportManager([fs_imp])`

Manage the import process.

`install([namespace])`

Install this ImportManager into the specified namespace.

`uninstall()`

Restore the previous import mechanism.

`add_suffix(suffix, importFunc)`

Undocumented.

`class importlib.Importer`

Base class for replacing standard import functions.

`import_top(name)`

Import a top-level module.

`get_code(parent, modname, fqname)`

Find and retrieve the code for the given module.

*parent* specifies a parent module to define a context for importing. It may be `None`, indicating no particular context for the search.

*modname* specifies a single module (not dotted) within the parent.

*fqname* specifies the fully-qualified module name. This is a (potentially) dotted name from the « root » of the module namespace down to the *modname*.

If there is no parent, then *modname*==*fqname*.

This method should return `None`, or a 3-tuple.

— If the module was not found, then `None` should be returned.

— The first item of the 2- or 3-tuple should be the integer 0 or 1, specifying whether the module that was found is a package or not.

— The second item is the code object for the module (it will be executed within the new module's namespace). This item can also be a fully-loaded module object (e.g. loaded from a shared lib).

— The third item is a dictionary of name/value pairs that will be inserted into new module before the code object is executed. This is provided in case the module's code expects certain values (such as where the module was found). When the second item is a module object, then these names/values will be inserted *after* the module has been loaded/initialized.

`class importlib.BuiltinImporter`

Emulate the import mechanism for built-in and frozen modules. This is a sub-class of the `Importer` class.

```
get_code(parent, modname, fname)
    Undocumented.
```

```
imputil.py_suffix_importer(filename, finfo, fname)
    Undocumented.
```

```
class imputil.DynLoadSuffixImporter([desc])
    Undocumented.
    import_file(filename, finfo, fname)
        Undocumented.
```

### 31.3.1 Exemples

This is a re-implementation of hierarchical module import.

This code is intended to be read, not executed. However, it does work – all you need to do to enable it is « import knee ».

(The name is a pun on the clunkier predecessor of this module, « ni ».)

```
import sys, imp, __builtin__

# Replacement for __import__()
def import_hook(name, globals=None, locals=None, fromlist=None):
    parent = determine_parent(globals)
    q, tail = find_head_package(parent, name)
    m = load_tail(q, tail)
    if not fromlist:
        return q
    if hasattr(m, "__path__"):
        ensure_fromlist(m, fromlist)
    return m

def determine_parent(globals):
    if not globals or not globals.has_key("__name__"):
        return None
    pname = globals['__name__']
    if globals.has_key("__path__"):
        parent = sys.modules[pname]
        assert globals is parent.__dict__
        return parent
    if '.' in pname:
        i = pname.rfind('.')
        pname = pname[:i]
        parent = sys.modules[pname]
        assert parent.__name__ == pname
        return parent
    return None

def find_head_package(parent, name):
    if '.' in name:
        i = name.find('.')
        head = name[:i]
        tail = name[i+1:]
    else:
```

(suite sur la page suivante)

(suite de la page précédente)

```

        head = name
        tail = ""
    if parent:
        qname = "%s.%s" % (parent.__name__, head)
    else:
        qname = head
    q = import_module(head, qname, parent)
    if q: return q, tail
    if parent:
        qname = head
        parent = None
        q = import_module(head, qname, parent)
        if q: return q, tail
    raise ImportError("No module named " + qname)

def load_tail(q, tail):
    m = q
    while tail:
        i = tail.find('.')
        if i < 0: i = len(tail)
        head, tail = tail[:i], tail[i+1:]
        mname = "%s.%s" % (m.__name__, head)
        m = import_module(head, mname, m)
        if not m:
            raise ImportError("No module named " + mname)
    return m

def ensure_fromlist(m, fromlist, recursive=0):
    for sub in fromlist:
        if sub == "*":
            if not recursive:
                try:
                    all = m.__all__
                except AttributeError:
                    pass
            else:
                ensure_fromlist(m, all, 1)
            continue
        if sub != "*" and not hasattr(m, sub):
            subname = "%s.%s" % (m.__name__, sub)
            submod = import_module(sub, subname, m)
            if not submod:
                raise ImportError("No module named " + subname)

def import_module(partname, fqname, parent):
    try:
        return sys.modules[fqname]
    except KeyError:
        pass
    try:
        fp, pathname, stuff = imp.find_module(partname,
                                                parent and parent.__path__)

```

(suite sur la page suivante)

(suite de la page précédente)

```

except ImportError:
    return None
try:
    m = imp.load_module(fqname, fp, pathname, stuff)
finally:
    if fp: fp.close()
if parent:
    setattr(parent, partname, m)
return m

# Replacement for reload()
def reload_hook(module):
    name = module.__name__
    if '.' not in name:
        return import_module(name, name, None)
    i = name.rfind('.')
    pname = name[:i]
    parent = sys.modules[pname]
    return import_module(name[i+1:], name, parent)

# Save the original hooks
original_import = __builtin__.__import__
original_reload = __builtin__.reload

# Now install our hooks
__builtin__.__import__ = import_hook
__builtin__.reload = reload_hook

```

Also see the `importers` module (which can be found in `Demo/imputil/` in the Python source distribution) for additional examples.

## 31.4 zipimport — Import modules from Zip archives

Nouveau dans la version 2.3.

This module adds the ability to import Python modules (`*.py`, `*.py[co]`) and packages from ZIP-format archives. It is usually not needed to use the `zipimport` module explicitly; it is automatically used by the built-in `import` mechanism for `sys.path` items that are paths to ZIP archives.

Typically, `sys.path` is a list of directory names as strings. This module also allows an item of `sys.path` to be a string naming a ZIP file archive. The ZIP archive can contain a subdirectory structure to support package imports, and a path within the archive can be specified to only import from a subdirectory. For example, the path `example.zip/lib/` would only import from the `lib/` subdirectory within the archive.

Any files may be present in the ZIP archive, but only files `.py` and `.py[co]` are available for import. ZIP import of dynamic modules (`.pyd`, `.so`) is disallowed. Note that if an archive only contains `.py` files, Python will not attempt to modify the archive by adding the corresponding `.pyc` or `.pyo` file, meaning that if a ZIP archive doesn't contain `.pyc` files, importing may be rather slow.

Using the built-in `reload()` function will fail if called on a module loaded from a ZIP archive; it is unlikely that `reload()` would be needed, since this would imply that the ZIP has been altered during runtime.

ZIP archives with an archive comment are currently not supported.

**PKZIP Application Note** Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

**PEP 273 - Import Modules from Zip Archives** Written by James C. Ahlstrom, who also provided an implementation. Python 2.3 follows the specification in PEP 273, but uses an implementation written by Just van Rossum that uses the import hooks described in PEP 302.

**PEP 302 - New Import Hooks** The PEP to add the import hooks that help this module work.

This module defines an exception :

**exception `zipimport.ZipImportError`**

Exception raised by `zipimporter` objects. It's a subclass of `ImportError`, so it can be caught as `ImportError`, too.

### 31.4.1 `zipimporter` Objects

`zipimporter` is the class for importing ZIP files.

**class `zipimport.zipimporter(archivepath)`**

Create a new `zipimporter` instance. *archivepath* must be a path to a ZIP file, or to a specific path within a ZIP file. For example, an *archivepath* of `foo/bar.zip/lib` will look for modules in the `lib` directory inside the ZIP file `foo/bar.zip` (provided that it exists).

`ZipImportError` is raised if *archivepath* doesn't point to a valid ZIP archive.

**`find_module(fullname[, path])`**

Search for a module specified by *fullname*. *fullname* must be the fully qualified (dotted) module name. It returns the `zipimporter` instance itself if the module was found, or `None` if it wasn't. The optional *path* argument is ignored—it's there for compatibility with the importer protocol.

**`get_code(fullname)`**

Return the code object for the specified module. Raise `ZipImportError` if the module couldn't be found.

**`get_data(pathname)`**

Return the data associated with *pathname*. Raise `IOError` if the file wasn't found.

**`get_filename(fullname)`**

Return the value `__file__` would be set to if the specified module was imported. Raise `ZipImportError` if the module couldn't be found.

Nouveau dans la version 2.7.

**`get_source(fullname)`**

Return the source code for the specified module. Raise `ZipImportError` if the module couldn't be found, return `None` if the archive does contain the module, but has no source for it.

**`is_package(fullname)`**

Return `True` if the module specified by *fullname* is a package. Raise `ZipImportError` if the module couldn't be found.

**`load_module(fullname)`**

Load the module specified by *fullname*. *fullname* must be the fully qualified (dotted) module name. It returns the imported module, or raises `ZipImportError` if it wasn't found.

**`archive`**

The file name of the importer's associated ZIP file, without a possible subpath.

**`prefix`**

The subpath within the ZIP file where modules are searched. This is the empty string for `zipimporter` objects which point to the root of the ZIP file.

The *archive* and *prefix* attributes, when combined with a slash, equal the original *archivepath* argument given to the `zipimporter` constructor.

### 31.4.2 Examples

Here is an example that imports a module from a ZIP archive - note that the `zipimport` module is not explicitly used.

```
$ unzip -l example.zip
Archive:  example.zip
  Length      Date    Time    Name
-----
      8467   11-26-02  22:30   jwzthreading.py
-----
      8467
              1 file
$ ./python
Python 2.3 (#1, Aug 1 2003, 19:54:32)
>>> import sys
>>> sys.path.insert(0, 'example.zip')  # Add .zip file to front of path
>>> import jwzthreading
>>> jwzthreading.__file__
'example.zip/jwzthreading.py'
```

## 31.5 pkgutil — Package extension utility

Nouveau dans la version 2.3.

Code source : [Lib/pkgutil.py](#)

---

This module provides utilities for the import system, in particular package support.

`pkgutil.extend_path(path, name)`

Extend the search path for the modules which comprise a package. Intended use is to place the following code in a package's `__init__.py` :

```
from pkgutil import extend_path
__path__ = extend_path(__path__, __name__)
```

This will add to the package's `__path__` all subdirectories of directories on `sys.path` named after the package. This is useful if one wants to distribute different parts of a single logical package as multiple directories.

It also looks for `*.pkg` files beginning where `*` matches the `name` argument. This feature is similar to `*.pth` files (see the [site](#) module for more information), except that it doesn't special-case lines starting with `import`. A `*.pkg` file is trusted at face value : apart from checking for duplicates, all entries found in a `*.pkg` file are added to the path, regardless of whether they exist on the filesystem. (This is a feature.)

If the input path is not a list (as is the case for frozen packages) it is returned unchanged. The input path is not modified ; an extended copy is returned. Items are only appended to the copy at the end.

It is assumed that `sys.path` is a sequence. Items of `sys.path` that are not (Unicode or 8-bit) strings referring to existing directories are ignored. Unicode items on `sys.path` that cause errors when used as filenames may cause this function to raise an exception (in line with `os.path.isdir()` behavior).

`class pkgutil.ImpImporter(dirname=None)`

**PEP 302** Importer that wraps Python's « classic » import algorithm.

If `dirname` is a string, a **PEP 302** importer is created that searches that directory. If `dirname` is `None`, a **PEP 302** importer is created that searches the current `sys.path`, plus any modules that are frozen or built-in.

Note that *ImpImporter* does not currently support being used by placement on *sys.meta\_path*.

**class** pkgutil.ImpLoader(*fullname*, *file*, *filename*, *etc*)

**PEP 302** Loader that wraps Python's « classic » import algorithm.

**pkgutil.find\_loader**(*fullname*)

Find a **PEP 302** « loader » object for *fullname*.

If *fullname* contains dots, path must be the containing package's *\_\_path\_\_*. Returns *None* if the module cannot be found or imported. This function uses *iter\_importers()*, and is thus subject to the same limitations regarding platform-specific special import locations such as the Windows registry.

**pkgutil.get\_importer**(*path\_item*)

Retrieve a **PEP 302** importer for the given *path\_item*.

The returned importer is cached in *sys.path\_importer\_cache* if it was newly created by a path hook.

If there is no importer, a wrapper around the basic import machinery is returned. This wrapper is never inserted into the importer cache (*None* is inserted instead).

The cache (or part of it) can be cleared manually if a rescan of *sys.path\_hooks* is necessary.

**pkgutil.get\_loader**(*module\_or\_name*)

Get a **PEP 302** « loader » object for *module\_or\_name*.

If the module or package is accessible via the normal import mechanism, a wrapper around the relevant part of that machinery is returned. Returns *None* if the module cannot be found or imported. If the named module is not already imported, its containing package (if any) is imported, in order to establish the package *\_\_path\_\_*.

This function uses *iter\_importers()*, and is thus subject to the same limitations regarding platform-specific special import locations such as the Windows registry.

**pkgutil.iter\_importers**(*fullname=""*)

Yield **PEP 302** importers for the given module name.

If *fullname* contains a ".", the importers will be for the package containing *fullname*, otherwise they will be importers for *sys.meta\_path*, *sys.path*, and Python's « classic » import machinery, in that order. If the named module is in a package, that package is imported as a side effect of invoking this function.

Non-**PEP 302** mechanisms (e.g. the Windows registry) used by the standard import machinery to find files in alternative locations are partially supported, but are searched *after* *sys.path*. Normally, these locations are searched *before* *sys.path*, preventing *sys.path* entries from shadowing them.

For this to cause a visible difference in behaviour, there must be a module or package name that is accessible via both *sys.path* and one of the non-**PEP 302** file system mechanisms. In this case, the emulation will find the former version, while the builtin import mechanism will find the latter.

Items of the following types can be affected by this discrepancy : *imp.C\_EXTENSION*, *imp.PY\_SOURCE*, *imp.PY\_COMPILED*, *imp.PKG\_DIRECTORY*.

**pkgutil.iter\_modules**(*path=None*, *prefix=""*)

Yields (*module\_loader*, *name*, *ispkg*) for all submodules on *path*, or, if *path* is *None*, all top-level modules on *sys.path*.

*path* should be either *None* or a list of paths to look for modules in.

*prefix* is a string to output on the front of every module name on output.

**pkgutil.walk\_packages**(*path=None*, *prefix=""*, *onerror=None*)

Yields (*module\_loader*, *name*, *ispkg*) for all modules recursively on *path*, or, if *path* is *None*, all accessible modules.

*path* should be either *None* or a list of paths to look for modules in.

*prefix* is a string to output on the front of every module name on output.

Note that this function must import all *packages* (not all modules!) on the given *path*, in order to access the *\_\_path\_\_* attribute to find submodules.

*onerror* is a function which gets called with one argument (the name of the package which was being imported) if any exception occurs while trying to import a package. If no *onerror* function is supplied, *ImportErrors* are caught and ignored, while all other exceptions are propagated, terminating the search.

Exemples :

```
# list all modules python can access
walk_packages()

# list all submodules of ctypes
walk_packages(ctypes.__path__, ctypes.__name__ + '.')
```

`pkgutil.get_data(package, resource)`

Get a resource from a package.

This is a wrapper for the [PEP 302](#) loader *get\_data()* API. The *package* argument should be the name of a package, in standard module format (`foo.bar`). The *resource* argument should be in the form of a relative filename, using `/` as the path separator. The parent directory name `..` is not allowed, and nor is a rooted name (starting with a `/`).

The function returns a binary string that is the contents of the specified resource.

For packages located in the filesystem, which have already been imported, this is the rough equivalent of :

```
d = os.path.dirname(sys.modules[package].__file__)
data = open(os.path.join(d, resource), 'rb').read()
```

If the package cannot be located or loaded, or it uses a [PEP 302](#) loader which does not support *get\_data()*, then `None` is returned.

Nouveau dans la version 2.6.

## 31.6 modulefinder — Identifie les modules utilisés par un script

Nouveau dans la version 2.3.

**Code source :** [Lib/modulefinder.py](#)

---

Ce module fournit une classe *ModuleFinder* qui peut être utilisée pour déterminer la liste des modules importés par un script. `modulefinder.py` peut aussi être utilisé en tant que script, en passant le nom du fichier Python en argument, ce qui affichera un rapport sur les modules importés.

`modulefinder.AddPackagePath(pkg_name, path)`

Enregistre que le paquet *pkg\_name* peut être trouvé au chemin *path* spécifié.

`modulefinder.ReplacePackage(oldname, newname)`

Allows specifying that the module named *oldname* is in fact the package named *newname*. The most common usage would be to handle how the `_xmlplus` package replaces the `xml` package.

`class modulefinder.ModuleFinder([path=None, debug=0, excludes=[], replace_paths=[]])`

This class provides *run\_script()* and *report()* methods to determine the set of modules imported by a script. *path* can be a list of directories to search for modules ; if not specified, `sys.path` is used. *debug* sets the debugging level; higher values make the class print debugging messages about what it's doing. *excludes* is a list of module names to exclude from the analysis. *replace\_paths* is a list of (*oldpath*, *newpath*) tuples that will be replaced in module paths.

*report()*

Affiche un rapport sur la sortie standard qui liste les modules importés par le script et leurs chemins, ainsi que les modules manquants ou qui n'ont pas été trouvés.

`run_script(pathname)`

Analyse le contenu du fichier *pathname*, qui doit contenir du code Python.

`modules`

Un dictionnaire de correspondance entre nom de modules et modules. Voir *Exemples d'utilisation de la classe ModuleFinder*.

### 31.6.1 Exemples d'utilisation de la classe ModuleFinder

Le script qui sera analysé (*bacon.py*) :

```
import re, itertools

try:
    import baconhameggs
except ImportError:
    pass

try:
    import guido.python.ham
except ImportError:
    pass
```

Le script qui va afficher le rapport de *bacon.py* :

```
from modulefinder import ModuleFinder

finder = ModuleFinder()
finder.run_script('bacon.py')

print 'Loaded modules:'
for name, mod in finder.modules.iteritems():
    print '%s: ' % name,
    print ','.join(mod.globalnames.keys()[:3])

print '-'*50
print 'Modules not imported:'
print '\n'.join(finder.badmodules.iterkeys())
```

Exemple de sortie (peut varier en fonction de l'architecture) :

```
Loaded modules:
_types:
copy_reg:  _inverted_registry, _slotnames, __all__
sre_compile:  isstring, _sre, _optimize_unicode
_sre:
sre_constants:  REPEAT_ONE, makedict, AT_END_LINE
sys:
re:  __module__, finditer, _expand
itertools:
__main__:  re, itertools, baconhameggs
sre_parse:  __getslice__, _PATTERNENDERS, SRE_FLAG_UNICODE
array:
types:  __module__, IntType, TypeType
-----
```

(suite sur la page suivante)

```
Modules not imported:
guido.python.ham
baconhameggs
```

## 31.7 runpy — Locating and executing Python modules

Nouveau dans la version 2.5.

Code source : [Lib/runpy.py](#)

The *runpy* module is used to locate and run Python modules without importing them first. Its main use is to implement the `-m` command line switch that allows scripts to be located using the Python module namespace rather than the filesystem.

The *runpy* module provides two functions :

**runpy.run\_module(mod\_name, init\_globals=None, run\_name=None, alter\_sys=False)**

Execute the code of the specified module and return the resulting module globals dictionary. The module's code is first located using the standard import mechanism (refer to [PEP 302](#) for details) and then executed in a fresh module namespace.

If the supplied module name refers to a package rather than a normal module, then that package is imported and the `__main__` submodule within that package is then executed and the resulting module globals dictionary returned.

The optional dictionary argument *init\_globals* may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by *run\_module()*.

The special global variables `__name__`, `__file__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

`__name__` is set to *run\_name* if this optional argument is not *None*, to *mod\_name* + `'.__main__'` if the named module is a package and to the *mod\_name* argument otherwise.

`__file__` is set to the name provided by the module loader. If the loader does not make filename information available, this variable is set to *None*.

`__loader__` is set to the [PEP 302](#) module loader used to retrieve the code for the module (This loader may be a wrapper around the standard import mechanism).

`__package__` is set to *mod\_name* if the named module is a package and to *mod\_name.rpartition('.')[0]* otherwise.

If the argument *alter\_sys* is supplied and evaluates to *True*, then `sys.argv[0]` is updated with the value of `__file__` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. Both `sys.argv[0]` and `sys.modules[__name__]` are restored to their original values before the function returns.

Note that this manipulation of *sys* is not thread-safe. Other threads may see the partially initialised module, as well as the altered list of arguments. It is recommended that the *sys* module be left alone when invoking this function from threaded code.

**Voir aussi :**

The `-m` option offering equivalent functionality from the command line.

Modifié dans la version 2.7 : Added ability to execute packages by looking for a `__main__` submodule

**runpy.run\_path(file\_path, init\_globals=None, run\_name=None)**

Execute the code at the named filesystem location and return the resulting module globals dictionary.

As with a script name supplied to the CPython command line, the supplied path may refer to a Python source file, a compiled bytecode file or a valid `sys.path` entry containing a `__main__` module (e.g. a zipfile containing a top-level `__main__.py` file).

For a simple script, the specified code is simply executed in a fresh module namespace. For a valid `sys.path` entry (typically a zipfile or directory), the entry is first added to the beginning of `sys.path`. The function then looks for and executes a `__main__` module using the updated path. Note that there is no special protection against invoking an existing `__main__` entry located elsewhere on `sys.path` if there is no such module at the specified location.

The optional dictionary argument `init_globals` may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by `run_path()`.

The special global variables `__name__`, `__file__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

`__name__` is set to `run_name` if this optional argument is not `None` and to `'<run_path>'` otherwise.

`__file__` is set to the name provided by the module loader. If the loader does not make filename information available, this variable is set to `None`. For a simple script, this will be set to `file_path`.

`__loader__` is set to the [PEP 302](#) module loader used to retrieve the code for the module (This loader may be a wrapper around the standard import mechanism). For a simple script, this will be set to `None`.

`__package__` is set to `__name__.rpartition('.')[0]`.

A number of alterations are also made to the `sys` module. Firstly, `sys.path` may be altered as described above. `sys.argv[0]` is updated with the value of `file_path` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. All modifications to items in `sys` are reverted before the function returns.

Note that, unlike `run_module()`, the alterations made to `sys` are not optional in this function as these adjustments are essential to allowing the execution of `sys.path` entries. As the thread-safety limitations still apply, use of this function in threaded code should be either serialised with the import lock or delegated to a separate process.

---

Services du Langage Python

---

Python fournit quelques modules pour vous aider à travailler avec le langage Python lui-même. Ces modules gèrent entre autres l'analyse lexicale, l'analyse syntaxique, et le désassemblage de *bytecode*.

Ces modules sont :

### 32.1 parser — Access Python parse trees

The *parser* module provides an interface to Python's internal parser and byte-code compiler. The primary purpose for this interface is to allow Python code to edit the parse tree of a Python expression and create executable code from this. This is better than trying to parse and modify an arbitrary Python code fragment as a string because parsing is performed in a manner identical to the code forming the application. It is also faster.

---

**Note :** From Python 2.5 onward, it's much more convenient to cut in at the Abstract Syntax Tree (AST) generation and compilation stage, using the *ast* module.

The *parser* module exports the names documented here also with « st » replaced by « ast »; this is a legacy from the time when there was no other AST and has nothing to do with the AST found in Python 2.5. This is also the reason for the functions' keyword arguments being called *ast*, not *st*. The « ast » functions have been removed in Python 3.

---

There are a few things to note about this module which are important to making use of the data structures created. This is not a tutorial on editing the parse trees for Python code, but some examples of using the *parser* module are presented.

Most importantly, a good understanding of the Python grammar processed by the internal parser is required. For full information on the language syntax, refer to reference-index. The parser itself is created from a grammar specification defined in the file **Grammar/Grammar** in the standard Python distribution. The parse trees stored in the ST objects created by this module are the actual output from the internal parser when created by the *expr()* or *suite()* functions, described below. The ST objects created by *sequence2st()* faithfully simulate those structures. Be aware that the values of the sequences which are considered « correct » will vary from one version of Python to another as the formal grammar for the language is revised. However,

transporting code from one Python version to another as source text will always allow correct parse trees to be created in the target version, with the only restriction being that migrating to an older version of the interpreter will not support more recent language constructs. The parse trees are not typically compatible from one version to another, whereas source code has always been forward-compatible.

Each element of the sequences returned by `st2list()` or `st2tuple()` has a simple form. Sequences representing non-terminal elements in the grammar always have a length greater than one. The first element is an integer which identifies a production in the grammar. These integers are given symbolic names in the C header file `Include/graminit.h` and the Python module `symbol`. Each additional element of the sequence represents a component of the production as recognized in the input string : these are always sequences which have the same form as the parent. An important aspect of this structure which should be noted is that keywords used to identify the parent node type, such as the keyword `if` in an `if_stmt`, are included in the node tree without any special treatment. For example, the `if` keyword is represented by the tuple `(1, 'if')`, where `1` is the numeric value associated with all `NAME` tokens, including variable and function names defined by the user. In an alternate form returned when line number information is requested, the same token might be represented as `(1, 'if', 12)`, where the `12` represents the line number at which the terminal symbol was found.

Terminal elements are represented in much the same way, but without any child elements and the addition of the source text which was identified. The example of the `if` keyword above is representative. The various types of terminal symbols are defined in the C header file `Include/token.h` and the Python module `token`.

The ST objects are not required to support the functionality of this module, but are provided for three purposes : to allow an application to amortize the cost of processing complex parse trees, to provide a parse tree representation which conserves memory space when compared to the Python list or tuple representation, and to ease the creation of additional modules in C which manipulate parse trees. A simple « wrapper » class may be created in Python to hide the use of ST objects.

The `parser` module defines functions for a few distinct purposes. The most important purposes are to create ST objects and to convert ST objects to other representations such as parse trees and compiled code objects, but there are also functions which serve to query the type of parse tree represented by an ST object.

**Voir aussi :**

**Module `symbol`** Useful constants representing internal nodes of the parse tree.

**Module `token`** Useful constants representing leaf nodes of the parse tree and functions for testing node values.

### 32.1.1 Creating ST Objects

ST objects may be created from source code or from a parse tree. When creating an ST object from source, different functions are used to create the `'eval'` and `'exec'` forms.

`parser.expr(source)`

The `expr()` function parses the parameter `source` as if it were an input to `compile(source, 'file.py', 'eval')`. If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is raised.

`parser.suite(source)`

The `suite()` function parses the parameter `source` as if it were an input to `compile(source, 'file.py', 'exec')`. If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is raised.

`parser.sequence2st(sequence)`

This function accepts a parse tree represented as a sequence and builds an internal representation if possible. If it can validate that the tree conforms to the Python grammar and all nodes are valid node types in the host version of Python, an ST object is created from the internal representation and returned to the caller. If there is a problem creating the internal representation, or if the tree cannot be

validated, a *ParserError* exception is raised. An ST object created this way should not be assumed to compile correctly; normal exceptions raised by compilation may still be initiated when the ST object is passed to *compilest()*. This may indicate problems not related to syntax (such as a *MemoryError* exception), but may also be due to constructs such as the result of parsing `del f(0)`, which escapes the Python parser but is checked by the bytecode compiler.

Sequences representing terminal tokens may be represented as either two-element lists of the form `(1, 'name')` or as three-element lists of the form `(1, 'name', 56)`. If the third element is present, it is assumed to be a valid line number. The line number may be specified for any subset of the terminal symbols in the input tree.

`parser.tuple2st(sequence)`

This is the same function as *sequence2st()*. This entry point is maintained for backward compatibility.

### 32.1.2 Converting ST Objects

ST objects, regardless of the input used to create them, may be converted to parse trees represented as list- or tuple- trees, or may be compiled into executable code objects. Parse trees may be extracted with or without line numbering information.

`parser.st2list(ast[, line_info])`

This function accepts an ST object from the caller in *ast* and returns a Python list representing the equivalent parse tree. The resulting list representation can be used for inspection or the creation of a new parse tree in list form. This function does not fail so long as memory is available to build the list representation. If the parse tree will only be used for inspection, *st2tuple()* should be used instead to reduce memory consumption and fragmentation. When the list representation is required, this function is significantly faster than retrieving a tuple representation and converting that to nested lists.

If *line\_info* is true, line number information will be included for all terminal tokens as a third element of the list representing the token. Note that the line number provided specifies the line on which the token *ends*. This information is omitted if the flag is false or omitted.

`parser.st2tuple(ast[, line_info])`

This function accepts an ST object from the caller in *ast* and returns a Python tuple representing the equivalent parse tree. Other than returning a tuple instead of a list, this function is identical to *st2list()*.

If *line\_info* is true, line number information will be included for all terminal tokens as a third element of the list representing the token. This information is omitted if the flag is false or omitted.

`parser.compilest(ast, filename='<syntax-tree>')`

The Python byte compiler can be invoked on an ST object to produce code objects which can be used as part of an `exec` statement or a call to the built-in *eval()* function. This function provides the interface to the compiler, passing the internal parse tree from *ast* to the parser, using the source file name specified by the *filename* parameter. The default value supplied for *filename* indicates that the source was an ST object.

Compiling an ST object may result in exceptions related to compilation; an example would be a *SyntaxError* caused by the parse tree for `del f(0)`: this statement is considered legal within the formal grammar for Python but is not a legal language construct. The *SyntaxError* raised for this condition is actually generated by the Python byte-compiler normally, which is why it can be raised at this point by the *parser* module. Most causes of compilation failure can be diagnosed programmatically by inspection of the parse tree.

### 32.1.3 Queries on ST Objects

Two functions are provided which allow an application to determine if an ST was created as an expression or a suite. Neither of these functions can be used to determine if an ST was created from source code via *expr()* or *suite()* or from a parse tree via *sequence2st()*.

`parser.isexpr(ast)`

When *ast* represents an 'eval' form, this function returns true, otherwise it returns false. This is useful, since code objects normally cannot be queried for this information using existing built-in functions. Note that the code objects created by `compilest()` cannot be queried like this either, and are identical to those created by the built-in `compile()` function.

`parser.issuite(ast)`

This function mirrors `isexpr()` in that it reports whether an ST object represents an 'exec' form, commonly known as a « suite. » It is not safe to assume that this function is equivalent to `not isexpr(ast)`, as additional syntactic fragments may be supported in the future.

### 32.1.4 Exceptions and Error Handling

The parser module defines a single exception, but may also pass other built-in exceptions from other portions of the Python runtime environment. See each function for information about the exceptions it can raise.

**exception** `parser.ParserError`

Exception raised when a failure occurs within the parser module. This is generally produced for validation failures rather than the built-in `SyntaxError` raised during normal parsing. The exception argument is either a string describing the reason of the failure or a tuple containing a sequence causing the failure from a parse tree passed to `sequence2st()` and an explanatory string. Calls to `sequence2st()` need to be able to handle either type of exception, while calls to other functions in the module will only need to be aware of the simple string values.

Note that the functions `compilest()`, `expr()`, and `suite()` may raise exceptions which are normally raised by the parsing and compilation process. These include the built in exceptions `MemoryError`, `OverflowError`, `SyntaxError`, and `SystemError`. In these cases, these exceptions carry all the meaning normally associated with them. Refer to the descriptions of each function for detailed information.

### 32.1.5 ST Objects

Ordered and equality comparisons are supported between ST objects. Pickling of ST objects (using the `pickle` module) is also supported.

`parser.STType`

The type of the objects returned by `expr()`, `suite()` and `sequence2st()`.

ST objects have the following methods :

`ST.compile([filename])`

Same as `compilest(st, filename)`.

`ST.isexpr()`

Same as `isexpr(st)`.

`ST.issuite()`

Same as `issuite(st)`.

`ST.tolist([line_info])`

Same as `st2list(st, line_info)`.

`ST.totuple([line_info])`

Same as `st2tuple(st, line_info)`.

### 32.1.6 Example : Emulation of `compile()`

While many useful operations may take place between parsing and bytecode generation, the simplest operation is to do nothing. For this purpose, using the `parser` module to produce an intermediate data structure is equivalent to the code

```
>>> code = compile('a + 5', 'file.py', 'eval')
>>> a = 5
>>> eval(code)
10
```

The equivalent operation using the `parser` module is somewhat longer, and allows the intermediate internal parse tree to be retained as an ST object :

```
>>> import parser
>>> st = parser.expr('a + 5')
>>> code = st.compile('file.py')
>>> a = 5
>>> eval(code)
10
```

An application which needs both ST and code objects can package this code into readily available functions :

```
import parser

def load_suite(source_string):
    st = parser.suite(source_string)
    return st, st.compile()

def load_expression(source_string):
    st = parser.expr(source_string)
    return st, st.compile()
```

## 32.2 ast — Arbres Syntaxiques Abstraits

Nouveau dans la version 2.5 : The low-level `_ast` module containing only the node classes.

Nouveau dans la version 2.6 : The high-level `ast` module containing all helpers.

**Code source :** [Lib/ast.py](#)

Le module `ast` permet aux applications Python de traiter la grammaire abstraite de l'arbre syntaxique Python. La grammaire abstraite Python elle-même est susceptible d'être modifiée à chaque nouvelle version de Python ; ce module permet de trouver à quoi la grammaire actuelle ressemble.

Un arbre syntaxique abstrait peut être généré en passant l'option `ast.PyCF_ONLY_AST` à la fonction native `compile()`, ou en utilisant la fonction de facilité `parse()` fournie par le module. Le résultat est un arbre composé d'objets dont les classes héritent toutes de `ast.AST`. Un arbre syntaxique abstrait peut être compilé en code objet Python en utilisant la fonction native `compile()`.

### 32.2.1 Les classes nœud

**class** `ast.AST`

C'est la classe de base de toute classe nœud de l'AST. Les classes nœud courantes sont dérivées du fichier `Parser/Python.asdl`, qui est reproduit *ci-dessous*. Ils sont définis dans le module `C_ast` et ré-exportés dans le module `ast`.

Il y a une classe définie pour chacun des symboles présents à gauche dans la grammaire abstraite (par exemple, `ast.stmt` ou `ast.expr`). En plus de cela, il y a une classe définie pour chacun des constructeurs présentés à droite ; ces classes héritent des classes situées à gauche dans l'arbre. Par exemple, la classe

`ast.BinOp` hérite de la classe `ast.expr`. Pour les règles de réécriture avec alternatives (comme *sums*), la partie gauche est abstraite : seules les instances des constructeurs spécifiques aux nœuds sont créés.

#### `_fields`

Chaque classe concrète possède un attribut `_fields` donnant les noms de tous les nœuds enfants. Chaque instance d'une classe concrète possède un attribut pour chaque nœud enfant, du type défini par la grammaire. Par exemple, les instances `ast.BinOp` possèdent un attribut `left` de type `ast.expr`.

Si ces attributs sont marqués comme optionnels dans la grammaire (en utilisant un point d'interrogation ?), la valeur peut être `None`. Si les attributs peuvent avoir zéro ou plus valeurs (marqués avec un astérisque \*), les valeurs sont représentées par des listes Python. Tous les attributs possibles doivent être présents et avoir une valeur valide pour compiler un AST avec `compile()`.

#### `lineno`

#### `col_offset`

Les instances des sous-classes `ast.expr` et `ast.stmt` possèdent les attributs `lineno` et `col_offset`. L'attribut `lineno` est le numéro de ligne dans le code source (indexé à partir de 1 tel que la première ligne est la ligne 1) et l'attribut `col_offset` qui représente le décalage UTF-8 en byte du premier jeton qui a généré le nœud. Le décalage UTF-8 est enregistré parce que l'analyseur syntaxique utilise l'UTF-8 en interne.

Le constructeur d'une classe `ast.T` analyse ses arguments comme suit :

- S'il y a des arguments positionnels, il doit y avoir autant de termes dans `T._fields` ; ils sont assignés comme attributs portant ces noms.
  - S'il y a des arguments nommés, ils définissent les attributs de mêmes noms avec les valeurs données.
- Par exemple, pour créer et peupler un nœud `ast.UnaryOp`, on peut utiliser :

```
node = ast.UnaryOp()
node.op = ast.USub()
node.operand = ast.Num()
node.operand.n = 5
node.operand.lineno = 0
node.operand.col_offset = 0
node.lineno = 0
node.col_offset = 0
```

ou, plus compact :

```
node = ast.UnaryOp(ast.USub(), ast.Num(5, lineno=0, col_offset=0),
                  lineno=0, col_offset=0)
```

Nouveau dans la version 2.6 : The constructor as explained above was added. In Python 2.5 nodes had to be created by calling the class constructor without arguments and setting the attributes afterwards.

### 32.2.2 Grammaire abstraite

The module defines a string constant `__version__` which is the decimal Subversion revision number of the file shown below.

La grammaire abstraite est actuellement définie comme suit :

```
-- ASDL's five builtin types are identifier, int, string, object, bool

module Python version "$Revision$"
{
    mod = Module(stmt* body)
        | Interactive(stmt* body)
        | Expression(expr body)
```

(suite sur la page suivante)

(suite de la page précédente)

```

-- not really an actual node but useful in Jython's typesystem.
| Suite(stmt* body)

stmt = FunctionDef(identifier name, arguments args,
                    stmt* body, expr* decorator_list)
| ClassDef(identifier name, expr* bases, stmt* body, expr* decorator_list)
| Return(expr? value)

| Delete(expr* targets)
| Assign(expr* targets, expr value)
| AugAssign(expr target, operator op, expr value)

-- not sure if bool is allowed, can always use int
| Print(expr? dest, expr* values, bool nl)

-- use 'orelse' because else is a keyword in target languages
| For(expr target, expr iter, stmt* body, stmt* orelse)
| While(expr test, stmt* body, stmt* orelse)
| If(expr test, stmt* body, stmt* orelse)
| With(expr context_expr, expr? optional_vars, stmt* body)

-- 'type' is a bad name
| Raise(expr? type, expr? inst, expr? tback)
| TryExcept(stmt* body, excepthandler* handlers, stmt* orelse)
| TryFinally(stmt* body, stmt* finalbody)
| Assert(expr test, expr? msg)

| Import(alias* names)
| ImportFrom(identifier? module, alias* names, int? level)

-- Doesn't capture requirement that locals must be
-- defined if globals is
-- still supports use as a function!
| Exec(expr body, expr? globals, expr? locals)

| Global(identifier* names)
| Expr(expr value)
| Pass | Break | Continue

-- XXX Jython will be different
-- col_offset is the byte offset in the utf8 string the parser uses
attributes (int lineno, int col_offset)

-- BoolOp() can use left & right?
expr = BoolOp(boolop op, expr* values)
| BinOp(expr left, operator op, expr right)
| UnaryOp(unaryop op, expr operand)
| Lambda(arguments args, expr body)

### 32.2.3 Outils du module `ast`

Nouveau dans la version 2.6.

Apart from the node classes, `ast` module defines these utility functions and classes for traversing abstract syntax trees :

`ast.parse(source, filename='<unknown>', mode='exec')`

Analyse le code source en un nœud AST. Équivalent à `compile(source, filename, mode, ast.PyCF_ONLY_AST)`.

`ast.literal_eval(node_or_string)`

Safely evaluate an expression node or a Unicode or *Latin-1* encoded string containing a Python literal or container display. The string or node provided may only consist of the following Python literal structures : strings, numbers, tuples, lists, dicts, booleans, and `None`.

Cela peut être utilisé pour évaluer de manière sûre la chaîne de caractères contenant des valeurs Python de sources non fiable sans avoir besoin d'analyser les valeurs elles-mêmes. Cette fonction n'est pas capable d'évaluer des expressions complexes arbitraires, par exemple impliquant des opérateurs ou de l'indexation.

`ast.get_docstring(node, clean=True)`

Return the docstring of the given *node* (which must be a `FunctionDef`, `ClassDef` or `Module` node), or `None` if it has no docstring. If *clean* is true, clean up the docstring's indentation with `inspect.cleandoc()`.

`ast.fix_missing_locations(node)`

Lorsque l'on compile un arbre avec `compile()`, le compilateur attend les attributs `lineno` et `col_offset` pour tous les nœuds qui les supportent. Il est fastidieux de les remplir pour les nœuds générés, cette fonction utilitaire ajoute ces attributs de manière récursive là où ils ne sont pas déjà définis, en les définissant comme les valeurs du nœud parent. Elle fonctionne récursivement en démarrant de *node*.

`ast.increment_lineno(node, n=1)`

Incrémente de *n* le numéro de ligne de chaque nœud dans l'arbre en commençant par le nœud *node*. C'est utile pour « déplacer du code » à un endroit différent dans un fichier.

`ast.copy_location(new_node, old_node)`

Copie le code source (`lineno` et `col_offset`) de l'ancien nœud *old\_node* vers le nouveau nœud *new\_node* si possible, et renvoie *new\_node*.

`ast.iter_fields(node)`

Produit un n-uplet de (`fieldname`, `value`) pour chaque champ de `node._fields` qui est présent dans *node*.

`ast.iter_child_nodes(node)`

Produit tous les nœuds enfants directs de *node*, c'est à dire, tous les champs qui sont des nœuds et tous les éléments des champs qui sont des listes de nœuds.

`ast.walk(node)`

Produit récursivement tous les nœuds enfants dans l'arbre en commençant par *node* (*node* lui-même est inclus), sans ordre spécifique. C'est utile lorsque l'on souhaite modifier les nœuds sur place sans prêter attention au contexte.

**class ast.NodeVisitor**

Classe de base pour un visiteur de nœud, qui parcourt l'arbre syntaxique abstrait et appelle une fonction de visite pour chacun des nœuds trouvés. Cette fonction peut renvoyer une valeur qui est transmise par la méthode `visit()`.

Cette classe est faite pour être dérivée, en ajoutant des méthodes de visite à la sous-classe.

**visit(*node*)**

Visite un nœud. L'implémentation par défaut appelle la méthode `self.visit_classname` où *classname* représente le nom de la classe du nœud, ou `generic_visit()` si cette méthode n'existe pas.

**generic\_visit(*node*)**

Le visiteur appelle la méthode `visit()` de tous les enfants du nœud.

Notons que les nœuds enfants qui possèdent une méthode de visite spéciale ne seront pas visités à moins que le visiteur n'appelle la méthode `generic_visit()` ou ne les visite lui-même.

N'utilisez pas `NodeVisitor` si vous souhaitez appliquer des changements sur les nœuds lors du parcours.

Pour cela, un visiteur spécial existe (`NodeTransformer`) qui permet les modifications.

**class ast.NodeTransformer**

Une sous-classe `NodeVisitor` qui traverse l'arbre syntaxique abstrait et permet les modifications des nœuds.

Le `NodeTransformer` traverse l'AST et utilise la valeur renvoyée par les méthodes du visiteur pour remplacer ou supprimer l'ancien nœud. Si la valeur renvoyée par la méthode du visiteur est `None`, le nœud est supprimé de sa position, sinon il est remplacé par la valeur de retour. La valeur de retour peut être le nœud original et dans ce cas, il n'y a pas de remplacement.

Voici un exemple du *transformer* qui réécrit les occurrences du dictionnaire (`foo`) en `data['foo']` :

```
class RewriteName(NodeTransformer):

    def visit_Name(self, node):
        return copy_location(Subscript(
            value=Name(id='data', ctx=Load()),
            slice=Index(value=Str(s=node.id)),
            ctx=node.ctx
        ), node)
```

Gardez en tête que si un nœud sur lequel vous travaillez a des nœuds enfants, vous devez transformer également ces nœuds enfant vous-même ou appeler d'abord la méthode `generic_visit()` sur le nœud.

Pour les nœuds qui font partie d'une collection d'instructions (cela s'applique à tous les nœuds instruction), le visiteur peut aussi renvoyer la liste des nœuds plutôt qu'un seul nœud.

Utilisation typique du *transformer* :

```
node = YourTransformer().visit(node)
```

**ast.dump(*node*, *annotate\_fields=True*, *include\_attributes=False*)**

Renvoie un *dump* formaté de l'arbre dans *node*. C'est principalement utile à des fins de débogage. La chaîne de caractères renvoyée présente les noms et valeurs des champs. Cela rend le code impossible à évaluer, si l'on souhaite évaluer ce code, l'option `annotate_fields` doit être définie comme `False`. Les attributs comme les numéros de ligne et les décalages de colonne ne sont pas récupérés par défaut. Si l'on souhaite les récupérer, l'option `include_attributes` peut être définie comme `True`.

## 32.3 symtable — Access to the compiler's symbol tables

Code source : [Lib/symtable.py](#)

Symbol tables are generated by the compiler from AST just before bytecode is generated. The symbol table is responsible for calculating the scope of every identifier in the code. *symtable* provides an interface to examine these tables.

### 32.3.1 Generating Symbol Tables

`symtable.symtable(code, filename, compile_type)`

Return the toplevel *SymbolTable* for the Python source *code*. *filename* is the name of the file containing the code. *compile\_type* is like the *mode* argument to *compile()*.

### 32.3.2 Examining Symbol Tables

`class symtable.SymbolTable`

A namespace table for a block. The constructor is not public.

`get_type()`

Return the type of the symbol table. Possible values are 'class', 'module', and 'function'.

`get_id()`

Return the table's identifier.

`get_name()`

Return the table's name. This is the name of the class if the table is for a class, the name of the function if the table is for a function, or 'top' if the table is global (*get\_type()* returns 'module').

`get_lineno()`

Return the number of the first line in the block this table represents.

`is_optimized()`

Return True if the locals in this table can be optimized.

`is_nested()`

Return True if the block is a nested class or function.

`has_children()`

Return True if the block has nested namespaces within it. These can be obtained with *get\_children()*.

`has_exec()`

Return True if the block uses `exec`.

`has_import_star()`

Return True if the block uses a starred from-import.

`get_identifiers()`

Return a list of names of symbols in this table.

`lookup(name)`

Lookup *name* in the table and return a *Symbol* instance.

`get_symbols()`

Return a list of *Symbol* instances for names in the table.

`get_children()`

Return a list of the nested symbol tables.

`class symtable.Function`

A namespace for a function or method. This class inherits *SymbolTable*.

`get_parameters()`

Return a tuple containing names of parameters to this function.

`get_locals()`

Return a tuple containing names of locals in this function.

`get_globals()`

Return a tuple containing names of globals in this function.

`get_frees()`  
Return a tuple containing names of free variables in this function.

`class symtable.Class`  
A namespace of a class. This class inherits *SymbolTable*.

`get_methods()`  
Return a tuple containing the names of methods declared in the class.

`class symtable.Symbol`  
An entry in a *SymbolTable* corresponding to an identifier in the source. The constructor is not public.

`get_name()`  
Return the symbol's name.

`is_referenced()`  
Return `True` if the symbol is used in its block.

`is_imported()`  
Return `True` if the symbol is created from an import statement.

`is_parameter()`  
Return `True` if the symbol is a parameter.

`is_global()`  
Return `True` if the symbol is global.

`is_declared_global()`  
Return `True` if the symbol is declared global with a global statement.

`is_local()`  
Return `True` if the symbol is local to its block.

`is_free()`  
Return `True` if the symbol is referenced in its block, but not assigned to.

`is_assigned()`  
Return `True` if the symbol is assigned to in its block.

`is_namespace()`  
Return `True` if name binding introduces new namespace.  
If the name is used as the target of a function or class statement, this will be true.  
Par exemple :

```
>>> table = symtable.symtable("def some_func(): pass", "string", "exec")
>>> table.lookup("some_func").is_namespace()
True
```

Note that a single name can be bound to multiple objects. If the result is `True`, the name may also be bound to other objects, like an int or list, that does not introduce a new namespace.

`get_namespaces()`  
Return a list of namespaces bound to this name.

`get_namespace()`  
Return the namespace bound to this name. If more than one namespace is bound, a *ValueError* is raised.

## 32.4 symbol — Constantes utilisées dans les Arbres Syntaxiques

Code source : [Lib/symbol.py](#)

---

Ce module fournit des constantes représentant les valeurs numériques des nœuds internes de l'analyseur. Contrairement à la plupart des constantes en Python, celles-ci utilisent des noms en minuscules. Référez-vous au fichier `Grammar/Grammar` dans la distribution de Python pour les définitions de ces noms dans le

contexte de la grammaire du langage. La valeur numérique correspondant au nom peut changer d'une version de Python à l'autre.

Ce module fournit aussi ces objets :

`symbol.sym_name`

Dictionnaire faisant correspondre les valeurs numériques des constantes définies dans ce module à leurs noms, permettant de générer une représentation plus humaine des arbres syntaxiques.

## 32.5 token — Constantes utilisées avec les arbres d'analyse Python (*parse trees*)

Code source : [Lib/token.py](#)

---

Ce module fournit des constantes qui représentent les valeurs numériques des nœuds enfants du *parse tree* (les jetons « terminaux »). Voir le fichier `Grammar/Grammar` dans la distribution Python pour la définitions des noms dans le contexte de la grammaire. Les valeurs numériques correspondant aux noms sont susceptibles de changer entre deux versions de Python.

Le module fournit également une correspondance entre les codes numériques et les noms et certaines fonctions. Les fonctions reflètent les définitions des fichiers d'en-tête C de Python.

`token.tok_name`

Dictionnaire faisant correspondre les valeurs numériques des constantes définies dans ce module à leurs noms, permettant de générer une représentation plus humaine des arbres syntaxiques.

`token.ISTERMINAL(x)`

Renvoie `True` pour les valeurs des jetons terminaux.

`token.ISNONTERMINAL(x)`

Renvoie `True` pour les valeurs des jetons non terminaux.

`token.ISEOF(x)`

Renvoie `True` si `x` est le marqueur indiquant la fin de la source.

Les constantes associées aux jetons sont :

`token.ENDMARKER`

`token.NAME`

`token.NUMBER`

`token.STRING`

`token.NEWLINE`

`token.INDENT`

`token.DEDENT`

`token.LPAR`

`token.RPAR`

`token.LSQB`

`token.RSQB`

`token.COLON`

`token.COMMA`

`token.SEMI`

`token.PLUS`

`token.MINUS`

`token.STAR`

`token.SLASH`

`token.VBAR`

```
token.AMPER
token.LESS
token.GREATER
token.EQUAL
token.DOT
token.PERCENT
token.BACKQUOTE
token.LBRACE
token.RBRACE
token.EQUAL
token.NOTEQUAL
token.LESSEQUAL
token.GREATEREQUAL
token.TILDE
token.CIRCUMFLEX
token.LEFTSHIFT
token.RIGHTSHIFT
token.DOUBLESTAR
token.PLUSEQUAL
token.MINEQUAL
token.STAREQUAL
token.SLASHEQUAL
token.PERCENTEQUAL
token.AMPEREQUAL
token.VBAREQUAL
token.CIRCUMFLEXEQUAL
token.LEFTSHIFTEQUAL
token.RIGHTSHIFTEQUAL
token.DOUBLESTAREQUAL
token.DOUBLES LASH
token.DOUBLES LASH EQUAL
token.AT
token.OP
token.ERRORTOKEN
token.N_TOKENS
token.NT_OFFSET
```

Voir aussi :

Module *parser* The second example for the *parser* module shows how to use the *symbol* module.

## 32.6 keyword — Tester si des chaînes sont des mot-clés Python

Code source : [Lib/keyword.py](#)

---

Ce module permet à un programme Python de déterminer si une chaîne représente un mot-clé.

`keyword.iskeyword(s)`

Renvoie vrai si *s* est un mot-clé Python.

`keyword.kwlist`

Séquence contenant tous les mots-clés définis par l'interpréteur. Si certains mots-clés sont définis pour être actifs seulement si des instructions `__future__` particulières sont effectives, ils seront tout de même inclus.

## 32.7 tokenize — Analyseur lexical de Python

Code source : [Lib/tokenize.py](#)

Le module `tokenize` fournit un analyseur lexical pour Python, implémenté en Python. L'analyseur de ce module renvoie les commentaires sous forme de *token*, ce qui le rend intéressant pour implémenter des *pretty-printers*, typiquement pour faire de la coloration syntaxique.

To simplify token stream handling, all operators and delimiters tokens are returned using the generic *token.OP* token type. The exact type can be determined by checking the second field (containing the actual token string matched) of the tuple returned from `tokenize.generate_tokens()` for the character sequence that identifies a specific operator token.

Le point d'entrée principal est un *générateur* :

`tokenize.generate_tokens(readline)`

The `generate_tokens()` generator requires one argument, *readline*, which must be a callable object which provides the same interface as the `readline()` method of built-in file objects (see section *Objets fichiers*). Each call to the function should return one line of input as a string. Alternately, *readline* may be a callable object that signals completion by raising *StopIteration*.

The generator produces 5-tuples with these members : the token type; the token string; a 2-tuple (*srow*, *scol*) of ints specifying the row and column where the token begins in the source; a 2-tuple (*erow*, *ecol*) of ints specifying the row and column where the token ends in the source; and the line on which the token was found. The line passed (the last tuple item) is the *logical* line; continuation lines are included.

Nouveau dans la version 2.2.

An older entry point is retained for backward compatibility :

`tokenize.tokenize(readline[, tokeneater])`

The `tokenize()` function accepts two parameters : one representing the input stream, and one providing an output mechanism for `tokenize()`.

The first parameter, *readline*, must be a callable object which provides the same interface as the `readline()` method of built-in file objects (see section *Objets fichiers*). Each call to the function should return one line of input as a string. Alternately, *readline* may be a callable object that signals completion by raising *StopIteration*.

Modifié dans la version 2.5 : Added *StopIteration* support.

The second parameter, *tokeneater*, must also be a callable object. It is called once for each token, with five arguments, corresponding to the tuples generated by `generate_tokens()`.

All constants from the `token` module are also exported from `tokenize`, as are two additional token type values that might be passed to the *tokeneater* function by `tokenize()` :

`tokenize.COMMENT`

Valeur du jeton utilisée pour indiquer un commentaire.

`tokenize.NL`

Token value used to indicate a non-terminating newline. The NEWLINE token indicates the end of a logical line of Python code; NL tokens are generated when a logical line of code is continued over multiple physical lines.

Une autre fonction est fournie pour inverser le processus de tokenisation. Ceci est utile pour créer des outils permettant de codifier un script, de modifier le flux de jetons et de réécrire le script modifié.

`tokenize.untokenize(iterable)`

Converts tokens back into Python source code. The *iterable* must return sequences with at least two elements, the token type and the token string. Any additional sequence elements are ignored.

Le script reconstruit est renvoyé sous la forme d'une chaîne unique. Le résultat est garanti pour que le jeton corresponde à l'entrée afin que la conversion soit sans perte et que les allers et retours soient assurés. La garantie ne s'applique qu'au type de jeton et à la chaîne de jetons car l'espacement entre les jetons (positions des colonnes) peut changer.

Nouveau dans la version 2.5.

**exception tokenize.TokenError**

Déclenché lorsque soit une *docstring* soit une expression qui pourrait être divisée sur plusieurs lignes n'est pas complété dans le fichier, par exemple :

```
"""Beginning of
docstring
```

ou :

```
[1,
2,
3
```

Note that unclosed single-quoted strings do not cause an error to be raised. They are tokenized as **ERRORTOKEN**, followed by the tokenization of their contents.

Example of a script re-writer that transforms float literals into Decimal objects :

```
def decistmt(s):
    """Substitute Decimals for floats in a string of statements.

    >>> from decimal import Decimal
    >>> s = 'print +21.3e-5*-.1234/81.7'
    >>> decistmt(s)
    "print +Decimal ('21.3e-5')*-Decimal ('.1234')/Decimal ('81.7')"

    >>> exec(s)
    -3.21716034272e-007
    >>> exec(decistmt(s))
    -3.217160342717258261933904529E-7

    """
    result = []
    g = generate_tokens(StringIO(s).readline)    # tokenize the string
    for toknum, tokval, _, _, _ in g:
        if toknum == NUMBER and '.' in tokval:    # replace NUMBER tokens
            result.extend([
                (NAME, 'Decimal'),
                (OP, '('),
                (STRING, repr(tokval)),
                (OP, ')')
            ])
        else:
            result.append((toknum, tokval))
    return untokenize(result)
```

## 32.8 tabnanny — Détection d'indentation ambiguë

Code source : [Lib/tabnanny.py](#)

Pour l'instant ce module est destiné à être appelé comme un script. Toutefois, il est possible de l'importer dans un IDE et d'utiliser la fonction `check()` décrite ci-dessous.

---

**Note :** L'API fournie par ce module est susceptible de changer dans les versions futures ; ces modifications peuvent ne pas être rétro-compatibles.

---

`tabnanny.check(file_or_dir)`

If `file_or_dir` is a directory and not a symbolic link, then recursively descend the directory tree named by `file_or_dir`, checking all `.py` files along the way. If `file_or_dir` is an ordinary Python source file, it is checked for whitespace related problems. The diagnostic messages are written to standard output using the print statement.

`tabnanny.verbose`

Option indiquant s'il faut afficher des messages détaillés. Cela est incrémenté par l'option `-v` s'il est appelé comme un script.

`tabnanny.filename_only`

Option indiquant s'il faut afficher uniquement les noms de fichiers contenant des problèmes liés aux espaces blancs. Est défini à `True` par l'option `-q` s'il est appelé comme un script.

**exception** `tabnanny.NannyNag`

Raised by `process_tokens()` if detecting an ambiguous indent. Captured and handled in `check()`.

`tabnanny.process_tokens(tokens)`

This function is used by `check()` to process tokens generated by the `tokenize` module.

**Voir aussi :**

Module `tokenize` Analyseur lexical pour le code source Python.

## 32.9 pycldr — Python class browser support

**Code source :** [Lib/pycldr.py](#)

---

The `pycldr` module can be used to determine some limited information about the classes, methods and top-level functions defined in a module. The information provided is sufficient to implement a traditional three-pane class browser. The information is extracted from the source code rather than by importing the module, so this module is safe to use with untrusted code. This restriction makes it impossible to use this module with modules not implemented in Python, including all standard and optional extension modules.

`pycldr.readmodule(module, path=None)`

Read a module and return a dictionary mapping class names to class descriptor objects. The parameter `module` should be the name of a module as a string ; it may be the name of a module within a package. The `path` parameter should be a sequence, and is used to augment the value of `sys.path`, which is used to locate module source code.

`pycldr.readmodule_ex(module, path=None)`

Like `readmodule()`, but the returned dictionary, in addition to mapping class names to class descriptor objects, also maps top-level function names to function descriptor objects. Moreover, if the module being read is a package, the key `'__path__'` in the returned dictionary has as its value a list which contains the package search path.

### 32.9.1 Objets classes

The `Class` objects used as values in the dictionary returned by `readmodule()` and `readmodule_ex()` provide the following data attributes :

**Class.module**

The name of the module defining the class described by the class descriptor.

**Class.name**

The name of the class.

**Class.super**

A list of `Class` objects which describe the immediate base classes of the class being described. Classes which are named as superclasses but which are not discoverable by `readmodule()` are listed as a string with the class name instead of as `Class` objects.

**Class.methods**

A dictionary mapping method names to line numbers.

**Class.file**

Name of the file containing the `class` statement defining the class.

**Class.lineno**

The line number of the `class` statement within the file named by *file*.

### 32.9.2 Objets fonctions

The `Function` objects used as values in the dictionary returned by `readmodule_ex()` provide the following attributes :

**Function.module**

The name of the module defining the function described by the function descriptor.

**Function.name**

The name of the function.

**Function.file**

Name of the file containing the `def` statement defining the function.

**Function.lineno**

The line number of the `def` statement within the file named by *file*.

## 32.10 py\_compile — Compile Python source files

**Code source :** `Lib/py_compile.py`

---

The `py_compile` module provides a function to generate a byte-code file from a source file, and another function used when the module source file is invoked as a script.

Though not often needed, this function can be useful when installing modules for shared use, especially if some of the users may not have permission to write the byte-code cache files in the directory containing the source code.

**exception py\_compile.PyCompileError**

Exception raised when an error occurs while attempting to compile the file.

`py_compile.compile(file[, cfile[, dfile[, doraise]]])`

Compile a source file to byte-code and write out the byte-code cache file. The source code is loaded from the file named *file*. The byte-code is written to *cfile*, which defaults to *file* + '.c' ('.o' if optimization is

enabled in the current interpreter). If *dfile* is specified, it is used as the name of the source file in error messages instead of *file*. If *doraise* is true, a *PyCompileError* is raised when an error is encountered while compiling *file*. If *doraise* is false (the default), an error string is written to `sys.stderr`, but no exception is raised.

```
py_compile.main([args])
```

Compile several source files. The files named in *args* (or on the command line, if *args* is not specified) are compiled and the resulting bytecode is cached in the normal manner. This function does not search a directory structure to locate source files; it only compiles files named explicitly. If '-' is the only parameter in *args*, the list of files is taken from standard input.

Modifié dans la version 2.7 : Added support for '-'.

When this module is run as a script, the *main()* is used to compile all the files named on the command line. The exit status is nonzero if one of the files could not be compiled.

Modifié dans la version 2.6 : Added the nonzero exit status when module is run as a script.

**Voir aussi :**

Module *compileall* Utilities to compile all Python source files in a directory tree.

## 32.11 compileall — Byte-compile Python libraries

**Code source :** [Lib/compileall.py](#)

---

This module provides some utility functions to support installing Python libraries. These functions compile Python source files in a directory tree. This module can be used to create the cached byte-code files at library installation time, which makes them available for use even by users who don't have write permission to the library directories.

### 32.11.1 Command-line use

This module can work as a script (using `python -m compileall`) to compile Python sources.

**directory ...**

**file ...**

Positional arguments are files to compile or directories that contain source files, traversed recursively. If no argument is given, behave as if the command line was `-l <directories from sys.path>`.

**-l**

Do not recurse into subdirectories, only compile source code files directly contained in the named or implied directories.

**-f**

Force rebuild even if timestamps are up-to-date.

**-q**

Do not print the list of files compiled, print only error messages.

**-d destdir**

Directory prepended to the path to each file being compiled. This will appear in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

**-x regex**

regex is used to search the full path to each file considered for compilation, and if the regex produces a match, the file is skipped.

`-i list`

Read the file `list` and add each line that it contains to the list of files and directories to compile. If `list` is `-`, read lines from `stdin`.

Modifié dans la version 2.7 : Added the `-i` option.

### 32.11.2 Public functions

`compileall.compile_dir(dir[, maxlevels[, ddir[, force[, rx[, quiet]]]])`

Recursively descend the directory tree named by `dir`, compiling all `.py` files along the way.

The `maxlevels` parameter is used to limit the depth of the recursion; it defaults to 10.

If `ddir` is given, it is prepended to the path to each file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If `force` is true, modules are re-compiled even if the timestamps are up to date.

If `rx` is given, its search method is called on the complete path to each file considered for compilation, and if it returns a true value, the file is skipped.

If `quiet` is true, nothing is printed to the standard output unless errors occur.

`compileall.compile_file(fullname[, ddir[, force[, rx[, quiet]]]])`

Compile the file with path `fullname`.

If `ddir` is given, it is prepended to the path to the file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If `rx` is given, its search method is passed the full path name to the file being compiled, and if it returns a true value, the file is not compiled and `True` is returned.

If `quiet` is true, nothing is printed to the standard output unless errors occur.

Nouveau dans la version 2.7.

`compileall.compile_path([skip_curdir[, maxlevels[, force]])`

Byte-compile all the `.py` files found along `sys.path`. If `skip_curdir` is true (the default), the current directory is not included in the search. All other parameters are passed to the `compile_dir()` function.

Note that unlike the other compile functions, `maxlevels` defaults to 0.

To force a recompile of all the `.py` files in the `Lib/` subdirectory and all its subdirectories :

```
import compileall

compileall.compile_dir('Lib/', force=True)

# Perform same compilation, excluding files in .svn directories.
import re
compileall.compile_dir('Lib/', rx=re.compile(r'[/\\][.]svn'), force=True)
```

Voir aussi :

Module `py_compile` Byte-compile a single source file.

## 32.12 dis — Disassembler for Python bytecode

Code source : `Lib/dis.py`

---

The `dis` module supports the analysis of CPython *bytecode* by disassembling it. The CPython bytecode which this module takes as an input is defined in the file `Include/opcode.h` and used by the compiler and the interpreter.

**CPython implementation detail :** Bytecode is an implementation detail of the CPython interpreter! No guarantees are made that bytecode will not be added, removed, or changed between versions of Python. Use of this module should not be considered to work across Python VMs or Python releases.

Example : Given the function `myfunc()` :

```
def myfunc(alist):
    return len(alist)
```

the following command can be used to get the disassembly of `myfunc()` :

```
>>> dis.dis(myfunc)
2          0 LOAD_GLOBAL              0 (len)
          3 LOAD_FAST                   0 (alist)
          6 CALL_FUNCTION               1
          9 RETURN_VALUE
```

(The « 2 » is a line number).

The `dis` module defines the following functions and constants :

`dis.dis([bytesource])`

Disassemble the *bytesource* object. *bytesource* can denote either a module, a class, a method, a function, or a code object. For a module, it disassembles all functions. For a class, it disassembles all methods. For a single code sequence, it prints one line per bytecode instruction. If no object is provided, it disassembles the last traceback.

`dis.distb([tb])`

Disassembles the top-of-stack function of a traceback, using the last traceback if none was passed. The instruction causing the exception is indicated.

`dis.disassemble(code[, lasti])`

Disassembles a code object, indicating the last instruction if *lasti* was provided. The output is divided in the following columns :

1. the line number, for the first instruction of each line
2. the current instruction, indicated as -->,
3. a labelled instruction, indicated with >>.,
4. the address of the instruction,
5. the operation code name,
6. operation parameters, and
7. interpretation of the parameters in parentheses.

The parameter interpretation recognizes local and global variable names, constant values, branch targets, and compare operators.

`dis.disco(code[, lasti])`

A synonym for `disassemble()`. It is more convenient to type, and kept for compatibility with earlier Python releases.

`dis.findlinestarts(code)`

This generator function uses the `co_firstlineno` and `co_lnotab` attributes of the code object *code* to find the offsets which are starts of lines in the source code. They are generated as (`offset`, `lineno`) pairs.

`dis.findlabels(code)`  
Detect all offsets in the code object *code* which are jump targets, and return a list of these offsets.

`dis.opname`  
Sequence of operation names, indexable using the bytecode.

`dis.opmap`  
Dictionary mapping operation names to bytecodes.

`dis.cmp_op`  
Sequence of all compare operation names.

`dis.hasconst`  
Sequence of bytecodes that access a constant.

`dis.hasfree`  
Sequence of bytecodes that access a free variable.

`dis.hasname`  
Sequence of bytecodes that access an attribute by name.

`dis.hasjrel`  
Sequence of bytecodes that have a relative jump target.

`dis.hasjabs`  
Sequence of bytecodes that have an absolute jump target.

`dis.haslocal`  
Sequence of bytecodes that access a local variable.

`dis.hascompare`  
Sequence of bytecodes of Boolean operations.

### 32.12.1 Python Bytecode Instructions

The Python compiler currently generates the following bytecode instructions.

**STOP\_CODE()**  
Indicates end-of-code to the compiler, not used by the interpreter.

**NOP()**  
Do nothing code. Used as a placeholder by the bytecode optimizer.

**POP\_TOP()**  
Removes the top-of-stack (TOS) item.

**ROT\_TWO()**  
Swaps the two top-most stack items.

**ROT\_THREE()**  
Lifts second and third stack item one position up, moves top down to position three.

**ROT\_FOUR()**  
Lifts second, third and forth stack item one position up, moves top down to position four.

**DUP\_TOP()**  
Duplicates the reference on top of the stack.

Unary Operations take the top of the stack, apply the operation, and push the result back on the stack.

**UNARY\_POSITIVE()**  
Implements `TOS = +TOS`.

**UNARY\_NEGATIVE()**  
Implements `TOS = -TOS`.

**UNARY\_NOT()**  
Implements `TOS = not TOS`.

**UNARY\_CONVERT()**  
Implements `TOS = `TOS``.

**UNARY\_INVERT()**  
Implements `TOS = ~TOS`.

**GET\_ITER()**  
Implements `TOS = iter(TOS)`.

Binary operations remove the top of the stack (TOS) and the second top-most stack item (TOS1) from the stack. They perform the operation, and put the result back on the stack.

**BINARY\_POWER()**  
Implements `TOS = TOS1 ** TOS`.

**BINARY\_MULTIPLY()**  
Implements `TOS = TOS1 * TOS`.

**BINARY\_DIVIDE()**  
Implements `TOS = TOS1 / TOS` when from `__future__` import `division` is not in effect.

**BINARY\_FLOOR\_DIVIDE()**  
Implements `TOS = TOS1 // TOS`.

**BINARY\_TRUE\_DIVIDE()**  
Implements `TOS = TOS1 / TOS` when from `__future__` import `division` is in effect.

**BINARY\_MODULO()**  
Implements `TOS = TOS1 % TOS`.

**BINARY\_ADD()**  
Implements `TOS = TOS1 + TOS`.

**BINARY\_SUBTRACT()**  
Implements `TOS = TOS1 - TOS`.

**BINARY\_SUBSCR()**  
Implements `TOS = TOS1[TOS]`.

**BINARY\_LSHIFT()**  
Implements `TOS = TOS1 << TOS`.

**BINARY\_RSHIFT()**  
Implements `TOS = TOS1 >> TOS`.

**BINARY\_AND()**  
Implements `TOS = TOS1 & TOS`.

**BINARY\_XOR()**  
Implements `TOS = TOS1 ^ TOS`.

**BINARY\_OR()**  
Implements `TOS = TOS1 | TOS`.

In-place operations are like binary operations, in that they remove TOS and TOS1, and push the result back on the stack, but the operation is done in-place when TOS1 supports it, and the resulting TOS may be (but does not have to be) the original TOS1.

**INPLACE\_POWER()**

Implements in-place  $TOS = TOS1 ** TOS$ .

**INPLACE\_MULTIPLY()**

Implements in-place  $TOS = TOS1 * TOS$ .

**INPLACE\_DIVIDE()**

Implements in-place  $TOS = TOS1 / TOS$  when from `__future__` import `division` is not in effect.

**INPLACE\_FLOOR\_DIVIDE()**

Implements in-place  $TOS = TOS1 // TOS$ .

**INPLACE\_TRUE\_DIVIDE()**

Implements in-place  $TOS = TOS1 / TOS$  when from `__future__` import `division` is in effect.

**INPLACE\_MODULO()**

Implements in-place  $TOS = TOS1 \% TOS$ .

**INPLACE\_ADD()**

Implements in-place  $TOS = TOS1 + TOS$ .

**INPLACE\_SUBTRACT()**

Implements in-place  $TOS = TOS1 - TOS$ .

**INPLACE\_LSHIFT()**

Implements in-place  $TOS = TOS1 << TOS$ .

**INPLACE\_RSHIFT()**

Implements in-place  $TOS = TOS1 >> TOS$ .

**INPLACE\_AND()**

Implements in-place  $TOS = TOS1 \& TOS$ .

**INPLACE\_XOR()**

Implements in-place  $TOS = TOS1 \wedge TOS$ .

**INPLACE\_OR()**

Implements in-place  $TOS = TOS1 | TOS$ .

The slice opcodes take up to three parameters.

**SLICE+0()**

Implements  $TOS = TOS[:]$ .

**SLICE+1()**

Implements  $TOS = TOS1[TOS:]$ .

**SLICE+2()**

Implements  $TOS = TOS1[:TOS]$ .

**SLICE+3()**

Implements  $TOS = TOS2[TOS1:TOS]$ .

Slice assignment needs even an additional parameter. As any statement, they put nothing on the stack.

**STORE\_SLICE+0()**

Implements  $TOS[:] = TOS1$ .

**STORE\_SLICE+1()**

Implements  $TOS1[TOS:] = TOS2$ .

**STORE\_SLICE+2()**

Implements  $TOS1[:TOS] = TOS2$ .

**STORE\_SLICE+3()**  
Implements `TOS2[TOS1:TOS] = TOS3`.

**DELETE\_SLICE+0()**  
Implements `del TOS[:]`.

**DELETE\_SLICE+1()**  
Implements `del TOS1[TOS:]`.

**DELETE\_SLICE+2()**  
Implements `del TOS1[:TOS]`.

**DELETE\_SLICE+3()**  
Implements `del TOS2[TOS1:TOS]`.

**STORE\_SUBSCR()**  
Implements `TOS1[TOS] = TOS2`.

**DELETE\_SUBSCR()**  
Implements `del TOS1[TOS]`.

Miscellaneous opcodes.

**PRINT\_EXPR()**  
Implements the expression statement for the interactive mode. TOS is removed from the stack and printed. In non-interactive mode, an expression statement is terminated with [POP\\_TOP](#).

**PRINT\_ITEM()**  
Prints TOS to the file-like object bound to `sys.stdout`. There is one such instruction for each item in the `print` statement.

**PRINT\_ITEM\_TO()**  
Like `PRINT_ITEM`, but prints the item second from TOS to the file-like object at TOS. This is used by the extended print statement.

**PRINT\_NEWLINE()**  
Prints a new line on `sys.stdout`. This is generated as the last operation of a `print` statement, unless the statement ends with a comma.

**PRINT\_NEWLINE\_TO()**  
Like `PRINT_NEWLINE`, but prints the new line on the file-like object on the TOS. This is used by the extended print statement.

**BREAK\_LOOP()**  
Terminates a loop due to a `break` statement.

**CONTINUE\_LOOP(*target*)**  
Continues a loop due to a `continue` statement. *target* is the address to jump to (which should be a [FOR\\_ITER](#) instruction).

**LIST\_APPEND(*i*)**  
Calls `list.append(TOS[-i], TOS)`. Used to implement list comprehensions. While the appended value is popped off, the list object remains on the stack so that it is available for further iterations of the loop.

**LOAD\_LOCALS()**  
Pushes a reference to the locals of the current scope on the stack. This is used in the code for a class definition : After the class body is evaluated, the locals are passed to the class definition.

**RETURN\_VALUE()**  
Returns with TOS to the caller of the function.

**YIELD\_VALUE()**

Pops TOS and yields it from a *generator*.

**IMPORT\_STAR()**

Loads all symbols not starting with `'_'` directly from the module TOS to the local namespace. The module is popped after loading all names. This opcode implements `from module import *`.

**EXEC\_STMT()**

Implements `exec TOS2, TOS1, TOS`. The compiler fills missing optional parameters with `None`.

**POP\_BLOCK()**

Removes one block from the block stack. Per frame, there is a stack of blocks, denoting nested loops, try statements, and such.

**END\_FINALLY()**

Terminates a `finally` clause. The interpreter recalls whether the exception has to be re-raised, or whether the function returns, and continues with the outer-next block.

**BUILD\_CLASS()**

Creates a new class object. TOS is the methods dictionary, TOS1 the tuple of the names of the base classes, and TOS2 the class name.

**SETUP\_WITH(*delta*)**

This opcode performs several operations before a `with` block starts. First, it loads `__exit__()` from the context manager and pushes it onto the stack for later use by *WITH\_CLEANUP*. Then, `__enter__()` is called, and a finally block pointing to *delta* is pushed. Finally, the result of calling the enter method is pushed onto the stack. The next opcode will either ignore it (*POP\_TOP*), or store it in (a) variable(s) (*STORE\_FAST*, *STORE\_NAME*, or *UNPACK\_SEQUENCE*).

**WITH\_CLEANUP()**

Cleans up the stack when a `with` statement block exits. On top of the stack are 1–3 values indicating how/why the finally clause was entered :

- TOP = `None`
- (TOP, SECOND) = (`WHY_{RETURN,CONTINUE}`), `retval`
- TOP = `WHY_*`; no `retval` below it
- (TOP, SECOND, THIRD) = `exc_info()`

Under them is `EXIT`, the context manager's `__exit__()` bound method.

In the last case, `EXIT(TOP, SECOND, THIRD)` is called, otherwise `EXIT(None, None, None)`.

`EXIT` is removed from the stack, leaving the values above it in the same order. In addition, if the stack represents an exception, *and* the function call returns a “true” value, this information is « zapped », to prevent `END_FINALLY` from re-raising the exception. (But non-local `gotos` should still be resumed.)

All of the following opcodes expect arguments. An argument is two bytes, with the more significant byte last.

**STORE\_NAME(*namei*)**

Implements `name = TOS`. *namei* is the index of *name* in the attribute `co_names` of the code object. The compiler tries to use *STORE\_FAST* or *STORE\_GLOBAL* if possible.

**DELETE\_NAME(*namei*)**

Implements `del name`, where *namei* is the index into `co_names` attribute of the code object.

**UNPACK\_SEQUENCE(*count*)**

Unpacks TOS into *count* individual values, which are put onto the stack right-to-left.

**DUP\_TOPX(*count*)**

Duplicate *count* items, keeping them in the same order. Due to implementation limits, *count* should be between 1 and 5 inclusive.

**STORE\_ATTR**(*namei*)  
 Implements `TOS.name = TOS1`, where *namei* is the index of name in `co_names`.

**DELETE\_ATTR**(*namei*)  
 Implements `del TOS.name`, using *namei* as index into `co_names`.

**STORE\_GLOBAL**(*namei*)  
 Works as **STORE\_NAME**, but stores the name as a global.

**DELETE\_GLOBAL**(*namei*)  
 Works as **DELETE\_NAME**, but deletes a global name.

**LOAD\_CONST**(*consti*)  
 Pushes `co_consts[consti]` onto the stack.

**LOAD\_NAME**(*namei*)  
 Pushes the value associated with `co_names[namei]` onto the stack.

**BUILD\_TUPLE**(*count*)  
 Creates a tuple consuming *count* items from the stack, and pushes the resulting tuple onto the stack.

**BUILD\_LIST**(*count*)  
 Works as **BUILD\_TUPLE**, but creates a list.

**BUILD\_SET**(*count*)  
 Works as **BUILD\_TUPLE**, but creates a set.  
 Nouveau dans la version 2.7.

**BUILD\_MAP**(*count*)  
 Pushes a new dictionary object onto the stack. The dictionary is pre-sized to hold *count* entries.

**LOAD\_ATTR**(*namei*)  
 Replaces TOS with `getattr(TOS, co_names[namei])`.

**COMPARE\_OP**(*opname*)  
 Performs a Boolean operation. The operation name can be found in `cmp_op[opname]`.

**IMPORT\_NAME**(*namei*)  
 Imports the module `co_names[namei]`. TOS and TOS1 are popped and provide the *fromlist* and *level* arguments of `__import__()`. The module object is pushed onto the stack. The current namespace is not affected : for a proper import statement, a subsequent **STORE\_FAST** instruction modifies the namespace.

**IMPORT\_FROM**(*namei*)  
 Loads the attribute `co_names[namei]` from the module found in TOS. The resulting object is pushed onto the stack, to be subsequently stored by a **STORE\_FAST** instruction.

**JUMP\_FORWARD**(*delta*)  
 Increments bytecode counter by *delta*.

**POP\_JUMP\_IF\_TRUE**(*target*)  
 If TOS is true, sets the bytecode counter to *target*. TOS is popped.

**POP\_JUMP\_IF\_FALSE**(*target*)  
 If TOS is false, sets the bytecode counter to *target*. TOS is popped.

**JUMP\_IF\_TRUE\_OR\_POP**(*target*)  
 If TOS is true, sets the bytecode counter to *target* and leaves TOS on the stack. Otherwise (TOS is false), TOS is popped.

**JUMP\_IF\_FALSE\_OR\_POP**(*target*)  
 If TOS is false, sets the bytecode counter to *target* and leaves TOS on the stack. Otherwise (TOS is true), TOS is popped.

**JUMP\_ABSOLUTE**(*target*)

Set bytecode counter to *target*.

**FOR\_ITER**(*delta*)

TOS is an *iterator*. Call its `next()` method. If this yields a new value, push it on the stack (leaving the iterator below it). If the iterator indicates it is exhausted TOS is popped, and the bytecode counter is incremented by *delta*.

**LOAD\_GLOBAL**(*namei*)

Loads the global named `co_names[namei]` onto the stack.

**SETUP\_LOOP**(*delta*)

Pushes a block for a loop onto the block stack. The block spans from the current instruction with a size of *delta* bytes.

**SETUP\_EXCEPT**(*delta*)

Pushes a try block from a try-except clause onto the block stack. *delta* points to the first except block.

**SETUP\_FINALLY**(*delta*)

Pushes a try block from a try-except clause onto the block stack. *delta* points to the finally block.

**STORE\_MAP**()

Store a key and value pair in a dictionary. Pops the key and value while leaving the dictionary on the stack.

**LOAD\_FAST**(*var\_num*)

Pushes a reference to the local `co_varnames[var_num]` onto the stack.

**STORE\_FAST**(*var\_num*)

Stores TOS into the local `co_varnames[var_num]`.

**DELETE\_FAST**(*var\_num*)

Deletes local `co_varnames[var_num]`.

**LOAD\_CLOSURE**(*i*)

Pushes a reference to the cell contained in slot *i* of the cell and free variable storage. The name of the variable is `co_cellvars[i]` if *i* is less than the length of `co_cellvars`. Otherwise it is `co_freevars[i - len(co_cellvars)]`.

**LOAD\_DEREF**(*i*)

Loads the cell contained in slot *i* of the cell and free variable storage. Pushes a reference to the object the cell contains on the stack.

**STORE\_DEREF**(*i*)

Stores TOS into the cell contained in slot *i* of the cell and free variable storage.

**SET\_LINENO**(*lineno*)

This opcode is obsolete.

**RAISE\_VARARGS**(*argc*)

Raises an exception. *argc* indicates the number of arguments to the raise statement, ranging from 0 to 3. The handler will find the traceback as TOS2, the parameter as TOS1, and the exception as TOS.

**CALL\_FUNCTION**(*argc*)

Calls a callable object. The low byte of *argc* indicates the number of positional arguments, the high byte the number of keyword arguments. The stack contains keyword arguments on top (if any), then the positional arguments below that (if any), then the callable object to call below that. Each keyword argument is represented with two values on the stack : the argument's name, and its value, with the argument's value above the name on the stack. The positional arguments are pushed in the order that they are passed in to the callable object, with the right-most positional argument on top.

`CALL_FUNCTION` pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

**MAKE\_FUNCTION(*argc*)**

Pushes a new function object on the stack. TOS is the code associated with the function. The function object is defined to have *argc* default parameters, which are found below TOS.

**MAKE\_CLOSURE(*argc*)**

Creates a new function object, sets its *func\_closure* slot, and pushes it on the stack. TOS is the code associated with the function, TOS1 the tuple containing cells for the closure's free variables. The function also has *argc* default parameters, which are found below the cells.

**BUILD\_SLICE(*argc*)**

Pushes a slice object on the stack. *argc* must be 2 or 3. If it is 2, `slice(TOS1, TOS)` is pushed; if it is 3, `slice(TOS2, TOS1, TOS)` is pushed. See the `slice()` built-in function for more information.

**EXTENDED\_ARG(*ext*)**

Prefixes any opcode which has an argument too big to fit into the default two bytes. *ext* holds two additional bytes which, taken together with the subsequent opcode's argument, comprise a four-byte argument, *ext* being the two most-significant bytes.

**CALL\_FUNCTION\_VAR(*argc*)**

Calls a callable object, similarly to `CALL_FUNCTION`. *argc* represents the number of keyword and positional arguments, identically to `CALL_FUNCTION`. The top of the stack contains an iterable object containing additional positional arguments. Below that are keyword arguments (if any), positional arguments (if any) and a callable object, identically to `CALL_FUNCTION`. Before the callable object is called, the iterable object is « unpacked » and its contents are appended to the positional arguments passed in. The iterable object is ignored when computing the value of *argc*.

**CALL\_FUNCTION\_KW(*argc*)**

Calls a callable object, similarly to `CALL_FUNCTION`. *argc* represents the number of keyword and positional arguments, identically to `CALL_FUNCTION`. The top of the stack contains a mapping object containing additional keyword arguments. Below that are keyword arguments (if any), positional arguments (if any) and a callable object, identically to `CALL_FUNCTION`. Before the callable is called, the mapping object at the top of the stack is « unpacked » and its contents are appended to the keyword arguments passed in. The mapping object at the top of the stack is ignored when computing the value of *argc*.

**CALL\_FUNCTION\_VAR\_KW(*argc*)**

Calls a callable object, similarly to `CALL_FUNCTION_VAR` and `CALL_FUNCTION_KW`. *argc* represents the number of keyword and positional arguments, identically to `CALL_FUNCTION`. The top of the stack contains a mapping object, as per `CALL_FUNCTION_KW`. Below that is an iterable object, as per `CALL_FUNCTION_VAR`. Below that are keyword arguments (if any), positional arguments (if any) and a callable object, identically to `CALL_FUNCTION`. Before the callable is called, the mapping object and iterable object are each « unpacked » and their contents passed in as keyword and positional arguments respectively, identically to `CALL_FUNCTION_VAR` and `CALL_FUNCTION_KW`. The mapping object and iterable object are both ignored when computing the value of *argc*.

**HAVE\_ARGUMENT()**

This is not really an opcode. It identifies the dividing line between opcodes which don't take arguments < HAVE\_ARGUMENT and those which do >= HAVE\_ARGUMENT.

## 32.13 pickletools — Tools for pickle developers

Nouveau dans la version 2.3.

Source code : [Lib/pickletools.py](#)

This module contains various constants relating to the intimate details of the `pickle` module, some lengthy comments about the implementation, and a few useful functions for analyzing pickled data. The contents of this module are useful for Python core developers who are working on the `pickle` and `cPickle` implementations; ordinary users of the `pickle` module probably won't find the `pickletools` module relevant.

`pickletools.dis(pickle, out=None, memo=None, indentlevel=4)`

Outputs a symbolic disassembly of the pickle to the file-like object `out`, defaulting to `sys.stdout`. `pickle` can be a string or a file-like object. `memo` can be a Python dictionary that will be used as the pickle's memo; it can be used to perform disassemblies across multiple pickles created by the same pickler. Successive levels, indicated by `MARK` opcodes in the stream, are indented by `indentlevel` spaces.

`pickletools.genops(pickle)`

Provides an *iterator* over all of the opcodes in a pickle, returning a sequence of (`opcode`, `arg`, `pos`) triples. `opcode` is an instance of an `OpcodeInfo` class; `arg` is the decoded value, as a Python object, of the opcode's argument; `pos` is the position at which this opcode is located. `pickle` can be a string or a file-like object.

`pickletools.optimize(picklestring)`

Returns a new equivalent pickle string after eliminating unused `PUT` opcodes. The optimized pickle is shorter, takes less transmission time, requires less storage space, and unpickles more efficiently.

Nouveau dans la version 2.6.

---

## Python compiler package

---

Obsolète depuis la version 2.6 : The *compiler* package has been removed in Python 3.

The Python compiler package is a tool for analyzing Python source code and generating Python bytecode. The compiler contains libraries to generate an abstract syntax tree from Python source code and to generate Python *bytecode* from the tree.

The *compiler* package is a Python source to bytecode translator written in Python. It uses the built-in parser and standard *parser* module to generate a concrete syntax tree. This tree is used to generate an abstract syntax tree (AST) and then Python bytecode.

The full functionality of the package duplicates the built-in compiler provided with the Python interpreter. It is intended to match its behavior almost exactly. Why implement another compiler that does the same thing? The package is useful for a variety of purposes. It can be modified more easily than the built-in compiler. The AST it generates is useful for analyzing Python source code.

This chapter explains how the various components of the *compiler* package work. It blends reference material with a tutorial.

### 33.1 The basic interface

The top-level of the package defines four functions. If you import *compiler*, you will get these functions and a collection of modules contained in the package.

`compiler.parse(buf)`

Returns an abstract syntax tree for the Python source code in *buf*. The function raises *SyntaxError* if there is an error in the source code. The return value is a `compiler.ast.Module` instance that contains the tree.

`compiler.parseFile(path)`

Return an abstract syntax tree for the Python source code in the file specified by *path*. It is equivalent to `parse(open(path).read())`.

`compiler.walk(ast, visitor[, verbose])`

Do a pre-order walk over the abstract syntax tree *ast*. Call the appropriate method on the *visitor* instance for each node encountered.

`compiler.compile(source, filename, mode, flags=None, dont_inherit=None)`

Compile the string *source*, a Python module, statement or expression, into a code object that can be executed by the `exec` statement or `eval()`. This function is a replacement for the built-in `compile()` function.

The *filename* will be used for run-time error messages.

The *mode* must be “exec” to compile a module, “single” to compile a single (interactive) statement, or “eval” to compile an expression.

The *flags* and *dont\_inherit* arguments affect future-related statements, but are not supported yet.

`compiler.compileFile(source)`

Compiles the file *source* and generates a .pyc file.

The `compiler` package contains the following modules : `ast`, `consts`, `future`, `misc`, `pyassem`, `pycodegen`, `symbols`, `transformer`, and `visitor`.

## 33.2 Limitations

There are some problems with the error checking of the compiler package. The interpreter detects syntax errors in two distinct phases. One set of errors is detected by the interpreter’s parser, the other set by the compiler. The compiler package relies on the interpreter’s parser, so it get the first phases of error checking for free. It implements the second phase itself, and that implementation is incomplete. For example, the compiler package does not raise an error if a name appears more than once in an argument list : `def f(x, x): ...`

A future version of the compiler should fix these problems.

## 33.3 Python Abstract Syntax

The `compiler.ast` module defines an abstract syntax for Python. In the abstract syntax tree, each node represents a syntactic construct. The root of the tree is `Module` object.

The abstract syntax offers a higher level interface to parsed Python source code. The `parser` module and the compiler written in C for the Python interpreter use a concrete syntax tree. The concrete syntax is tied closely to the grammar description used for the Python parser. Instead of a single node for a construct, there are often several levels of nested nodes that are introduced by Python’s precedence rules.

The abstract syntax tree is created by the `compiler.transformer` module. The transformer relies on the built-in Python parser to generate a concrete syntax tree. It generates an abstract syntax tree from the concrete tree.

The `transformer` module was created by Greg Stein and Bill Tutt for an experimental Python-to-C compiler. The current version contains a number of modifications and improvements, but the basic form of the abstract syntax and of the transformer are due to Stein and Tutt.

### 33.3.1 AST Nodes

The `compiler.ast` module is generated from a text file that describes each node type and its elements. Each node type is represented as a class that inherits from the abstract base class `compiler.ast.Node` and defines a set of named attributes for child nodes.

`class compiler.ast.Node`

The `Node` instances are created automatically by the parser generator. The recommended interface for specific `Node` instances is to use the public attributes to access child nodes. A public attribute may be bound to a single node or to a sequence of nodes, depending on the `Node` type. For example, the `bases` attribute of the `Class` node, is bound to a list of base class nodes, and the `doc` attribute is bound to a single node.

Each *Node* instance has a *lineno* attribute which may be *None*. XXX Not sure what the rules are for which nodes will have a useful *lineno*.

All *Node* objects offer the following methods :

**getChildren()**

Returns a flattened list of the child nodes and objects in the order they occur. Specifically, the order of the nodes is the order in which they appear in the Python grammar. Not all of the children are *Node* instances. The names of functions and classes, for example, are plain strings.

**getChildNodes()**

Returns a flattened list of the child nodes in the order they occur. This method is like *getChildren()*, except that it only returns those children that are *Node* instances.

Two examples illustrate the general structure of *Node* classes. The *while* statement is defined by the following grammar production :

```
while_stmt:      "while" expression ":" suite
                ["else" ":" suite]
```

The *While* node has three attributes : *test*, *body*, and *else\_*. (If the natural name for an attribute is also a Python reserved word, it can't be used as an attribute name. An underscore is appended to the word to make it a legal identifier, hence *else\_* instead of *else*.)

The *if* statement is more complicated because it can include several tests.

```
if_stmt: 'if' test ':' suite ('elif' test ':' suite)* ['else' ':' suite]
```

The *If* node only defines two attributes : *tests* and *else\_*. The *tests* attribute is a sequence of test expression, consequent body pairs. There is one pair for each *if/elif* clause. The first element of the pair is the test expression. The second elements is a *Stmt* node that contains the code to execute if the test is true.

The *getChildren()* method of *If* returns a flat list of child nodes. If there are three *if/elif* clauses and no *else* clause, then *getChildren()* will return a list of six elements : the first test expression, the first *Stmt*, the second test expression, etc.

The following table lists each of the *Node* subclasses defined in *compiler.ast* and each of the public attributes available on their instances. The values of most of the attributes are themselves *Node* instances or sequences of instances. When the value is something other than an instance, the type is noted in the comment. The attributes are listed in the order in which they are returned by *getChildren()* and *getChildNodes()*.

Node type	Attribut	Valeur
Add	left	left operand
	right	right operand
And	nodes	list of operands

### 33.3.2 Assignment nodes

There is a collection of nodes used to represent assignments. Each assignment statement in the source code becomes a single **Assign** node in the AST. The **nodes** attribute is a list that contains a node for each assignment target. This is necessary because assignment can be chained, e.g. `a = b = 2`. Each *Node* in the list will be one of the following classes : **AssAttr**, **AssList**, **AssName**, or **AssTuple**.

Each target assignment node will describe the kind of object being assigned to : **AssName** for a simple name, e.g. `a = 1`. **AssAttr** for an attribute assigned, e.g. `a.x = 1`. **AssList** and **AssTuple** for list and tuple expansion respectively, e.g. `a, b, c = a_tuple`.

The target assignment nodes also have a **flags** attribute that indicates whether the node is being used for assignment or in a delete statement. The **AssName** is also used to represent a delete statement, e.g. `del x`.

When an expression contains several attribute references, an assignment or delete statement will contain only one **AssAttr** node – for the final attribute reference. The other attribute references will be represented as **Getattr** nodes in the **expr** attribute of the **AssAttr** instance.

### 33.3.3 Examples

This section shows several simple examples of ASTs for Python source code. The examples demonstrate how to use the **parse()** function, what the repr of an AST looks like, and how to access attributes of an AST node.

The first module defines a single function. Assume it is stored in `doublelib.py`.

```
"""This is an example module.
```

(suite sur la page suivante)

(suite de la page précédente)

```

This is the docstring.
"""

def double(x):
    "Return twice the argument"
    return x * 2

```

In the interactive interpreter session below, I have reformatted the long AST reprs for readability. The AST reprs use unqualified class names. If you want to create an instance from a repr, you must import the class names from the `compiler.ast` module.

```

>>> import compiler
>>> mod = compiler.parseFile("doublelib.py")
>>> mod
Module('This is an example module.\n\nThis is the docstring.\n',
      Stmt([Function(None, 'double', ['x'], [], 0,
                    'Return twice the argument',
                    Stmt([Return(Mul((Name('x'), Const(2))))]))]))
>>> from compiler.ast import *
>>> Module('This is an example module.\n\nThis is the docstring.\n',
...      Stmt([Function(None, 'double', ['x'], [], 0,
...                    'Return twice the argument',
...                    Stmt([Return(Mul((Name('x'), Const(2))))]))]))
Module('This is an example module.\n\nThis is the docstring.\n',
      Stmt([Function(None, 'double', ['x'], [], 0,
                    'Return twice the argument',
                    Stmt([Return(Mul((Name('x'), Const(2))))]))]))
>>> mod.doc
'This is an example module.\n\nThis is the docstring.\n'
>>> for node in mod.node.nodes:
...     print node
...
Function(None, 'double', ['x'], [], 0, 'Return twice the argument',
      Stmt([Return(Mul((Name('x'), Const(2))))]))
>>> func = mod.node.nodes[0]
>>> func.code
Stmt([Return(Mul((Name('x'), Const(2))))])

```

## 33.4 Using Visitors to Walk ASTs

The visitor pattern is ... The `compiler` package uses a variant on the visitor pattern that takes advantage of Python's introspection features to eliminate the need for much of the visitor's infrastructure.

The classes being visited do not need to be programmed to accept visitors. The visitor need only define visit methods for classes it is specifically interested in; a default visit method can handle the rest.

XXX The magic `visit()` method for visitors.

```
compiler.visitor.walk(tree, visitor[, verbose])
```

```
class compiler.visitor.ASTVisitor
```

The `ASTVisitor` is responsible for walking over the tree in the correct order. A walk begins with a call to `preorder()`. For each node, it checks the `visitor` argument to `preorder()` for a method

named “visitNodeType,” where NodeType is the name of the node’s class, e.g. for a `While` node a `visitWhile()` would be called. If the method exists, it is called with the node as its first argument.

The visitor method for a particular node type can control how child nodes are visited during the walk. The *ASTVisitor* modifies the visitor argument by adding a visit method to the visitor; this method can be used to visit a particular child node. If no visitor is found for a particular node type, the *default()* method is called.

*ASTVisitor* objects have the following methods :

XXX describe extra arguments

`default(node[, ...])`

`dispatch(node[, ...])`

`preorder(tree, visitor)`

## 33.5 Bytecode Generation

The code generator is a visitor that emits bytecodes. Each visit method can call the `emit()` method to emit a new bytecode. The basic code generator is specialized for modules, classes, and functions. An assembler converts that emitted instructions to the low-level bytecode format. It handles things like generation of constant lists of code objects and calculation of jump offsets.

Les modules documentés dans ce chapitre fournissent différents services disponibles dans toutes les version de Python. En voici un aperçu :

## 34.1 `formatter` — Generic output formatting

This module supports two interface definitions, each with multiple implementations. The *formatter* interface is used by the *HTMLParser* class of the *html* module, and the *writer* interface is required by the *formatter* interface.

Formatter objects transform an abstract flow of formatting events into specific output events on writer objects. Formatters manage several stack structures to allow various properties of a writer object to be changed and restored ; writers need not be able to handle relative changes nor any sort of « change back » operation. Specific writer properties which may be controlled via formatter objects are horizontal alignment, font, and left margin indentations. A mechanism is provided which supports providing arbitrary, non-exclusive style settings to a writer as well. Additional interfaces facilitate formatting events which are not reversible, such as paragraph separation.

Writer objects encapsulate device interfaces. Abstract devices, such as file formats, are supported as well as physical devices. The provided implementations all work with abstract devices. The interface makes available mechanisms for setting the properties which formatter objects manage and inserting data into the output.

### 34.1.1 The Formatter Interface

Interfaces to create formatters are dependent on the specific formatter class being instantiated. The interfaces described below are the required interfaces which all formatters must support once initialized.

One data element is defined at the module level :

`formatter.AS_IS`

Value which can be used in the font specification passed to the `push_font()` method described below, or as the new value to any other `push_property()` method. Pushing the `AS_IS` value allows the corresponding `pop_property()` method to be called without having to track whether the property was changed.

The following attributes are defined for formatter instance objects :

**formatter.writer**

The writer instance with which the formatter interacts.

**formatter.end\_paragraph(*blanklines*)**

Close any open paragraphs and insert at least *blanklines* before the next paragraph.

**formatter.add\_line\_break()**

Add a hard line break if one does not already exist. This does not break the logical paragraph.

**formatter.add\_hor\_rule(\**args*, \*\**kw*)**

Insert a horizontal rule in the output. A hard break is inserted if there is data in the current paragraph, but the logical paragraph is not broken. The arguments and keywords are passed on to the writer's `send_line_break()` method.

**formatter.add\_flowning\_data(*data*)**

Provide data which should be formatted with collapsed whitespace. Whitespace from preceding and successive calls to `add_flowning_data()` is considered as well when the whitespace collapse is performed. The data which is passed to this method is expected to be word-wrapped by the output device. Note that any word-wrapping still must be performed by the writer object due to the need to rely on device and font information.

**formatter.add\_literal\_data(*data*)**

Provide data which should be passed to the writer unchanged. Whitespace, including newline and tab characters, are considered legal in the value of *data*.

**formatter.add\_label\_data(*format*, *counter*)**

Insert a label which should be placed to the left of the current left margin. This should be used for constructing bulleted or numbered lists. If the *format* value is a string, it is interpreted as a format specification for *counter*, which should be an integer. The result of this formatting becomes the value of the label; if *format* is not a string it is used as the label value directly. The label value is passed as the only argument to the writer's `send_label_data()` method. Interpretation of non-string label values is dependent on the associated writer.

Format specifications are strings which, in combination with a counter value, are used to compute label values. Each character in the format string is copied to the label value, with some characters recognized to indicate a transform on the counter value. Specifically, the character '1' represents the counter value formatter as an Arabic number, the characters 'A' and 'a' represent alphabetic representations of the counter value in upper and lower case, respectively, and 'I' and 'i' represent the counter value in Roman numerals, in upper and lower case. Note that the alphabetic and roman transforms require that the counter value be greater than zero.

**formatter.flush\_softspace()**

Send any pending whitespace buffered from a previous call to `add_flowning_data()` to the associated writer object. This should be called before any direct manipulation of the writer object.

**formatter.push\_alignment(*align*)**

Push a new alignment setting onto the alignment stack. This may be `AS_IS` if no change is desired. If the alignment value is changed from the previous setting, the writer's `new_alignment()` method is called with the *align* value.

**formatter.pop\_alignment()**

Restore the previous alignment.

**formatter.push\_font(*(size, italic, bold, teletype)*)**

Change some or all font properties of the writer object. Properties which are not set to `AS_IS` are set to the values passed in while others are maintained at their current settings. The writer's `new_font()` method is called with the fully resolved font specification.

`formatter.pop_font()`

Restore the previous font.

`formatter.push_margin(margin)`

Increase the number of left margin indentations by one, associating the logical tag *margin* with the new indentation. The initial margin level is 0. Changed values of the logical tag must be true values; false values other than *AS\_IS* are not sufficient to change the margin.

`formatter.pop_margin()`

Restore the previous margin.

`formatter.push_style(*styles)`

Push any number of arbitrary style specifications. All styles are pushed onto the styles stack in order. A tuple representing the entire stack, including *AS\_IS* values, is passed to the writer's `new_styles()` method.

`formatter.pop_style(n=1)`

Pop the last *n* style specifications passed to `push_style()`. A tuple representing the revised stack, including *AS\_IS* values, is passed to the writer's `new_styles()` method.

`formatter.set_spacing(spacing)`

Set the spacing style for the writer.

`formatter.assert_line_data(flag=1)`

Inform the formatter that data has been added to the current paragraph out-of-band. This should be used when the writer has been manipulated directly. The optional *flag* argument can be set to false if the writer manipulations produced a hard line break at the end of the output.

### 34.1.2 Formatter Implementations

Two implementations of formatter objects are provided by this module. Most applications may use one of these classes without modification or subclassing.

`class formatter.NullFormatter(writer)`

A formatter which does nothing. If *writer* is omitted, a *NullWriter* instance is created. No methods of the writer are called by *NullFormatter* instances. Implementations should inherit from this class if implementing a writer interface but don't need to inherit any implementation.

`class formatter.AbstractFormatter(writer)`

The standard formatter. This implementation has demonstrated wide applicability to many writers, and may be used directly in most circumstances. It has been used to implement a full-featured World Wide Web browser.

### 34.1.3 The Writer Interface

Interfaces to create writers are dependent on the specific writer class being instantiated. The interfaces described below are the required interfaces which all writers must support once initialized. Note that while most applications can use the *AbstractFormatter* class as a formatter, the writer must typically be provided by the application.

`writer.flush()`

Flush any buffered output or device control events.

`writer.new_alignment(align)`

Set the alignment style. The *align* value can be any object, but by convention is a string or *None*, where *None* indicates that the writer's « preferred » alignment should be used. Conventional *align* values are 'left', 'center', 'right', and 'justify'.

`writer.new_font(font)`

Set the font style. The value of *font* will be `None`, indicating that the device's default font should be used, or a tuple of the form (*size*, *italic*, *bold*, *teletype*). *Size* will be a string indicating the size of font that should be used; specific strings and their interpretation must be defined by the application. The *italic*, *bold*, and *teletype* values are Boolean values specifying which of those font attributes should be used.

`writer.new_margin(margin, level)`

Set the margin level to the integer *level* and the logical tag to *margin*. Interpretation of the logical tag is at the writer's discretion; the only restriction on the value of the logical tag is that it not be a false value for non-zero values of *level*.

`writer.new_spacing(spacing)`

Set the spacing style to *spacing*.

`writer.new_styles(styles)`

Set additional styles. The *styles* value is a tuple of arbitrary values; the value `AS_IS` should be ignored. The *styles* tuple may be interpreted either as a set or as a stack depending on the requirements of the application and writer implementation.

`writer.send_line_break()`

Break the current line.

`writer.send_paragraph(blankline)`

Produce a paragraph separation of at least *blankline* blank lines, or the equivalent. The *blankline* value will be an integer. Note that the implementation will receive a call to `send_line_break()` before this call if a line break is needed; this method should not include ending the last line of the paragraph. It is only responsible for vertical spacing between paragraphs.

`writer.send_hor_rule(*args, **kw)`

Display a horizontal rule on the output device. The arguments to this method are entirely application- and writer-specific, and should be interpreted with care. The method implementation may assume that a line break has already been issued via `send_line_break()`.

`writer.send_flowling_data(data)`

Output character data which may be word-wrapped and re-flowed as needed. Within any sequence of calls to this method, the writer may assume that spans of multiple whitespace characters have been collapsed to single space characters.

`writer.send_literal_data(data)`

Output character data which has already been formatted for display. Generally, this should be interpreted to mean that line breaks indicated by newline characters should be preserved and no new line breaks should be introduced. The data may contain embedded newline and tab characters, unlike data provided to the `send_formatted_data()` interface.

`writer.send_label_data(data)`

Set *data* to the left of the current left margin, if possible. The value of *data* is not restricted; treatment of non-string values is entirely application- and writer-dependent. This method will only be called at the beginning of a line.

### 34.1.4 Writer Implementations

Three implementations of the writer object interface are provided as examples by this module. Most applications will need to derive new writer classes from the `NullWriter` class.

`class formatter.NullWriter`

A writer which only provides the interface definition; no actions are taken on any methods. This should be the base class for all writers which do not need to inherit any implementation methods.

**class** `formatter.AbstractWriter`

A writer which can be used in debugging formatters, but not much else. Each method simply announces itself by printing its name and arguments on standard output.

**class** `formatter.DumbWriter`(*file=None*, *maxcol=72*)

Simple writer class which writes output on the file object passed in as *file* or, if *file* is `None`, on standard output. The output is simply word-wrapped to the number of columns specified by *maxcol*. This class is suitable for reflowing a sequence of paragraphs.

---

Services spécifiques à MS Windows

---

Ce chapitre documente les modules qui ne sont disponibles que sous MS Windows.

## 35.1 msilib — Read and write Microsoft Installer files

Nouveau dans la version 2.5.

The *msilib* supports the creation of Microsoft Installer (.msi) files. Because these files often contain an embedded « cabinet » file (.cab), it also exposes an API to create CAB files. Support for reading .cab files is currently not implemented; read support for the .msi database is possible.

This package aims to provide complete access to all tables in an .msi file, therefore, it is a fairly low-level API. Two primary applications of this package are the *distutils* command `bdist_msi`, and the creation of Python installer package itself (although that currently uses a different version of *msilib*).

The package contents can be roughly split into four parts : low-level CAB routines, low-level MSI routines, higher-level MSI routines, and standard table structures.

**msilib.FCICreate**(*cabname*, *files*)

Create a new CAB file named *cabname*. *files* must be a list of tuples, each containing the name of the file on disk, and the name of the file inside the CAB file.

The files are added to the CAB file in the order they appear in the list. All files are added into a single CAB file, using the MSZIP compression algorithm.

Callbacks to Python for the various steps of MSI creation are currently not exposed.

**msilib.UuidCreate**()

Return the string representation of a new unique identifier. This wraps the Windows API functions `UuidCreate()` and `UuidToString()`.

**msilib.OpenDatabase**(*path*, *persist*)

Return a new database object by calling `MsiOpenDatabase`. *path* is the file name of the MSI file; *persist* can be one of the constants `MSIDBOPEN_CREATEDIRECT`, `MSIDBOPEN_CREATE`, `MSIDBOPEN_DIRECT`, `MSIDBOPEN_READONLY`, or `MSIDBOPEN_TRANSACT`, and may include the flag `MSIDBOPEN_PATCHFILE`. See the Microsoft documentation for the meaning of these flags; depending on the flags, an existing database is opened, or a new one created.

`msilib.CreateRecord(count)`

Return a new record object by calling `MSICreateRecord()`. *count* is the number of fields of the record.

`msilib.init_database(name, schema, ProductName, ProductCode, ProductVersion, Manufacturer)`

Create and return a new database *name*, initialize it with *schema*, and set the properties *ProductName*, *ProductCode*, *ProductVersion*, and *Manufacturer*.

*schema* must be a module object containing `tables` and `_Validation_records` attributes; typically, `msilib.schema` should be used.

The database will contain just the schema and the validation records when this function returns.

`msilib.add_data(database, table, records)`

Add all *records* to the table named *table* in *database*.

The *table* argument must be one of the predefined tables in the MSI schema, e.g. 'Feature', 'File', 'Component', 'Dialog', 'Control', etc.

*records* should be a list of tuples, each one containing all fields of a record according to the schema of the table. For optional fields, `None` can be passed.

Field values can be int or long numbers, strings, or instances of the Binary class.

`class msilib.Binary(filename)`

Represents entries in the Binary table; inserting such an object using `add_data()` reads the file named *filename* into the table.

`msilib.add_tables(database, module)`

Add all table content from *module* to *database*. *module* must contain an attribute *tables* listing all tables for which content should be added, and one attribute per table that has the actual content.

This is typically used to install the sequence tables.

`msilib.add_stream(database, name, path)`

Add the file *path* into the `_Stream` table of *database*, with the stream name *name*.

`msilib.gen_uuid()`

Return a new UUID, in the format that MSI typically requires (i.e. in curly braces, and with all hexdigits in upper-case).

**Voir aussi :**

[FCICreateFile](#) [UuidCreate](#) [UuidToString](#)

### 35.1.1 Database Objects

`Database.OpenView(sql)`

Return a view object, by calling `MSIDatabaseOpenView()`. *sql* is the SQL statement to execute.

`Database.Commit()`

Commit the changes pending in the current transaction, by calling `MSIDatabaseCommit()`.

`Database.GetSummaryInformation(count)`

Return a new summary information object, by calling `MsiGetSummaryInformation()`. *count* is the maximum number of updated values.

**Voir aussi :**

[MSIDatabaseOpenView](#) [MSIDatabaseCommit](#) [MsiGetSummaryInformation](#)

### 35.1.2 View Objects

`View.Execute(params)`

Execute the SQL query of the view, through `MSIViewExecute()`. If *params* is not `None`, it is a record describing actual values of the parameter tokens in the query.

`View.GetColumnInfo(kind)`

Return a record describing the columns of the view, through calling `MsiViewGetColumnInfo()`. *kind* can be either `MSICOLINFO_NAMES` or `MSICOLINFO_TYPES`.

`View.Fetch()`

Return a result record of the query, through calling `MsiViewFetch()`.

`View.Modify(kind, data)`

Modify the view, by calling `MsiViewModify()`. *kind* can be one of `MSIMODIFY_SEEK`, `MSIMODIFY_REFRESH`, `MSIMODIFY_INSERT`, `MSIMODIFY_UPDATE`, `MSIMODIFY_ASSIGN`, `MSIMODIFY_REPLACE`, `MSIMODIFY_MERGE`, `MSIMODIFY_DELETE`, `MSIMODIFY_INSERT_TEMPORARY`, `MSIMODIFY_VALIDATE`, `MSIMODIFY_VALIDATE_NEW`, `MSIMODIFY_VALIDATE_FIELD`, or `MSIMODIFY_VALIDATE_DELETE`.

*data* must be a record describing the new data.

`View.Close()`

Close the view, through `MsiViewClose()`.

**Voir aussi :**

`MsiViewExecute` `MsiViewGetColumnInfo` `MsiViewFetch` `MsiViewModify` `MsiViewClose`

### 35.1.3 Summary Information Objects

`SummaryInformation.GetProperty(field)`

Return a property of the summary, through `MsiSummaryInfoGetProperty()`. *field* is the name of the property, and can be one of the constants `PID_CODEPAGE`, `PID_TITLE`, `PID_SUBJECT`, `PID_AUTHOR`, `PID_KEYWORDS`, `PID_COMMENTS`, `PID_TEMPLATE`, `PID_LASTAUTHOR`, `PID_REVNUMBER`, `PID_LASTPRINTED`, `PID_CREATE_DTM`, `PID_LASTSAVE_DTM`, `PID_PAGECOUNT`, `PID_WORDCOUNT`, `PID_CHARCOUNT`, `PID_APPNAME`, or `PID_SECURITY`.

`SummaryInformation.GetPropertyCount()`

Return the number of summary properties, through `MsiSummaryInfoGetPropertyCount()`.

`SummaryInformation.SetProperty(field, value)`

Set a property through `MsiSummaryInfoSetProperty()`. *field* can have the same values as in `GetProperty()`, *value* is the new value of the property. Possible value types are integer and string.

`SummaryInformation.Persist()`

Write the modified properties to the summary information stream, using `MsiSummaryInfoPersist()`.

**Voir aussi :**

`MsiSummaryInfoGetProperty` `MsiSummaryInfoGetPropertyCount` `MsiSummaryInfoSetProperty` `MsiSummaryInfoPersist`

### 35.1.4 Record Objects

`Record.GetFieldCount()`

Return the number of fields of the record, through `MsiRecordGetFieldCount()`.

`Record.GetInteger(field)`

Return the value of *field* as an integer where possible. *field* must be an integer.

`Record.GetString(field)`

Return the value of *field* as a string where possible. *field* must be an integer.

`Record.SetString(field, value)`

Set *field* to *value* through `MsiRecordSetString()`. *field* must be an integer; *value* a string.

**Record.SetStream(*field*, *value*)**

Set *field* to the contents of the file named *value*, through `MsiRecordSetStream()`. *field* must be an integer; *value* a string.

**Record.SetInteger(*field*, *value*)**

Set *field* to *value* through `MsiRecordSetInteger()`. Both *field* and *value* must be an integer.

**Record.ClearData()**

Set all fields of the record to 0, through `MsiRecordClearData()`.

**Voir aussi :**

[MsiRecordGetFieldCount](#) [MsiRecordSetString](#) [MsiRecordSetStream](#) [MsiRecordSetInteger](#) [MsiRecordClear](#)

### 35.1.5 Errors

All wrappers around MSI functions raise `MSIError`; the string inside the exception will contain more detail.

### 35.1.6 CAB Objects

**class msilib.CAB(*name*)**

The class `CAB` represents a CAB file. During MSI construction, files will be added simultaneously to the `Files` table, and to a CAB file. Then, when all files have been added, the CAB file can be written, then added to the MSI file.

*name* is the name of the CAB file in the MSI file.

**append(*full*, *file*, *logical*)**

Add the file with the pathname *full* to the CAB file, under the name *logical*. If there is already a file named *logical*, a new file name is created.

Return the index of the file in the CAB file, and the new name of the file inside the CAB file.

**commit(*database*)**

Generate a CAB file, add it as a stream to the MSI file, put it into the `Media` table, and remove the generated file from the disk.

### 35.1.7 Directory Objects

**class msilib.Directory(*database*, *cab*, *basedir*, *physical*, *logical*, *default*[, *componentflags*])**

Create a new directory in the Directory table. There is a current component at each point in time for the directory, which is either explicitly created through `start_component()`, or implicitly when files are added for the first time. Files are added into the current component, and into the cab file. To create a directory, a base directory object needs to be specified (can be `None`), the path to the physical directory, and a logical directory name. *default* specifies the DefaultDir slot in the directory table. *componentflags* specifies the default flags that new components get.

**start\_component([*component*[, *feature*[, *flags*[, *keyfile*[, *uuid*]]]])**

Add an entry to the Component table, and make this component the current component for this directory. If no component name is given, the directory name is used. If no *feature* is given, the current feature is used. If no *flags* are given, the directory's default flags are used. If no *keyfile* is given, the KeyPath is left null in the Component table.

**add\_file(*file*[, *src*[, *version*[, *language*]])**

Add a file to the current component of the directory, starting a new one if there is no current component. By default, the file name in the source and the file table will be identical. If the *src* file is specified, it is interpreted relative to the current directory. Optionally, a *version* and a *language* can be specified for the entry in the File table.

**glob(*pattern*[, *exclude*])**

Add a list of files to the current component as specified in the glob pattern. Individual files can be excluded in the *exclude* list.

```
remove_pyc()
    Remove .pyc/.pyo files on uninstall.
```

Voir aussi :

[Directory Table](#) [File Table](#) [Component Table](#) [FeatureComponents Table](#)

### 35.1.8 Features

```
class msilib.Feature(database, id, title, desc, display[, level=1[, parent[, directory[, attributes=0]
    ]]])
```

Add a new record to the **Feature** table, using the values *id*, *parent.id*, *title*, *desc*, *display*, *level*, *directory*, and *attributes*. The resulting feature object can be passed to the **start\_component()** method of *Directory*.

```
set_current()
    Make this feature the current feature of msilib. New components are automatically added to the
    default feature, unless a feature is explicitly specified.
```

Voir aussi :

[Feature Table](#)

### 35.1.9 GUI classes

*msilib* provides several classes that wrap the GUI tables in an MSI database. However, no standard user interface is provided; use **bdist\_msi** to create MSI files with a user-interface for installing Python packages.

```
class msilib.Control(dlg, name)
    Base class of the dialog controls. dlg is the dialog object the control belongs to, and name is the control's
    name.
    event(event, argument[, condition=1[, ordering]])
        Make an entry into the ControlEvents table for this control.
    mapping(event, attribute)
        Make an entry into the EventMapping table for this control.
    condition(action, condition)
        Make an entry into the ControlCondition table for this control.

class msilib.RadioButtonGroup(dlg, name, property)
    Create a radio button control named name. property is the installer property that gets set when a radio
    button is selected.
    add(name, x, y, width, height, text[, value])
        Add a radio button named name to the group, at the coordinates x, y, width, height, and with the
        label text. If value is omitted, it defaults to name.

class msilib.Dialog(db, name, x, y, w, h, attr, title, first, default, cancel)
    Return a new Dialog object. An entry in the Dialog table is made, with the specified coordinates,
    dialog attributes, title, name of the first, default, and cancel controls.
    control(name, type, x, y, width, height, attributes, property, text, control_next, help)
        Return a new Control object. An entry in the Control table is made with the specified parameters.
        This is a generic method; for specific types, specialized methods are provided.
    text(name, x, y, width, height, attributes, text)
        Add and return a Text control.
    bitmap(name, x, y, width, height, text)
        Add and return a Bitmap control.
```

`line(name, x, y, width, height)`  
Add and return a `Line` control.

`pushbutton(name, x, y, width, height, attributes, text, next_control)`  
Add and return a `PushButton` control.

`radiogroup(name, x, y, width, height, attributes, property, text, next_control)`  
Add and return a `RadioButtonGroup` control.

`checkbox(name, x, y, width, height, attributes, property, text, next_control)`  
Add and return a `CheckBox` control.

[RadioButton](#) [Table](#)

### 35.1.10 Precomputed tables

`msilib` provides a few subpackages that contain only schema and table definitions. Currently, these definitions are based on MSI version 2.0.

#### `msilib.schema`

This is the standard MSI schema for MSI 2.0, with the `tables` variable providing a list of table definitions, and `__Validation_records` providing the data for MSI validation.

#### `msilib.sequence`

This module contains table contents for the standard sequence tables : *AdminExecuteSequence*, *AdminUISequence*, *AdvtExecuteSequence*, *InstallExecuteSequence*, and *InstallUISequence*.

#### `msilib.text`

This module contains definitions for the `UIText` and `ActionText` tables, for the standard installer actions.

## 35.2 msvcrt — Useful routines from the MS VC++ runtime

These functions provide access to some useful capabilities on Windows platforms. Some higher-level modules use these functions to build the Windows implementations of their services. For example, the `getpass` module uses this in the implementation of the `getpass()` function.

Further documentation on these functions can be found in the Platform API documentation.

The module implements both the normal and wide char variants of the console I/O api. The normal API deals only with ASCII characters and is of limited use for internationalized applications. The wide char API should be used where ever possible.

### 35.2.1 File Operations

#### `msvcrt.locking(fd, mode, nbytes)`

Lock part of a file based on file descriptor `fd` from the C runtime. Raises *IOError* on failure. The locked region of the file extends from the current file position for `nbytes` bytes, and may continue beyond the end of the file. `mode` must be one of the `LK_*` constants listed below. Multiple regions in a file may be locked at the same time, but may not overlap. Adjacent regions are not merged ; they must be unlocked individually.

#### `msvcrt.LK_LOCK`

#### `msvcrt.LK_RLOCK`

Locks the specified bytes. If the bytes cannot be locked, the program immediately tries again after 1 second. If, after 10 attempts, the bytes cannot be locked, *IOError* is raised.

#### `msvcrt.LK_NBLCK`

`msvcrt.LK_NBRLCK`

Locks the specified bytes. If the bytes cannot be locked, *IOError* is raised.

`msvcrt.LK_UNLCK`

Unlocks the specified bytes, which must have been previously locked.

`msvcrt.setmode(fd, flags)`

Set the line-end translation mode for the file descriptor *fd*. To set it to text mode, *flags* should be *os.O\_TEXT*; for binary, it should be *os.O\_BINARY*.

`msvcrt.open_osfhandle(handle, flags)`

Create a C runtime file descriptor from the file handle *handle*. The *flags* parameter should be a bitwise OR of *os.O\_APPEND*, *os.O\_RDONLY*, and *os.O\_TEXT*. The returned file descriptor may be used as a parameter to *os.fdopen()* to create a file object.

`msvcrt.get_osfhandle(fd)`

Return the file handle for the file descriptor *fd*. Raises *IOError* if *fd* is not recognized.

### 35.2.2 Console I/O

`msvcrt.kbhit()`

Return true if a keypress is waiting to be read.

`msvcrt.getch()`

Read a keypress and return the resulting character. Nothing is echoed to the console. This call will block if a keypress is not already available, but will not wait for **Enter** to be pressed. If the pressed key was a special function key, this will return '\000' or '\xe0'; the next call will return the keycode. The **Control-C** keypress cannot be read with this function.

`msvcrt.getwch()`

Wide char variant of *getch()*, returning a Unicode value.

Nouveau dans la version 2.6.

`msvcrt.getche()`

Similar to *getch()*, but the keypress will be echoed if it represents a printable character.

`msvcrt.getwche()`

Wide char variant of *getche()*, returning a Unicode value.

Nouveau dans la version 2.6.

`msvcrt.putch(char)`

Print the character *char* to the console without buffering.

`msvcrt.putwch(unicode_char)`

Wide char variant of *putch()*, accepting a Unicode value.

Nouveau dans la version 2.6.

`msvcrt.ungetch(char)`

Cause the character *char* to be « pushed back » into the console buffer; it will be the next character read by *getch()* or *getche()*.

`msvcrt.ungetwch(unicode_char)`

Wide char variant of *ungetch()*, accepting a Unicode value.

Nouveau dans la version 2.6.

### 35.2.3 Other Functions

`msvcrt.heapmin()`

Force the *malloc()* heap to clean itself up and return unused blocks to the operating system. On failure, this raises *IOError*.

## 35.3 \_winreg — Windows registry access

---

**Note :** The `_winreg` module has been renamed to `winreg` in Python 3. The *2to3* tool will automatically adapt imports when converting your sources to Python 3.

---

Nouveau dans la version 2.0.

These functions expose the Windows registry API to Python. Instead of using an integer as the registry handle, a *handle object* is used to ensure that the handles are closed correctly, even if the programmer neglects to explicitly close them.

This module offers the following functions :

`_winreg.CloseKey(hkey)`

Closes a previously opened registry key. The *hkey* argument specifies a previously opened key.

---

**Note :** If *hkey* is not closed using this method (or via *hkey.Close()*), it is closed when the *hkey* object is destroyed by Python.

---

`_winreg.ConnectRegistry(computer_name, key)`

Establishes a connection to a predefined registry handle on another computer, and returns a *handle object*.

*computer\_name* is the name of the remote computer, of the form `r"\\computername"`. If `None`, the local computer is used.

*key* is the predefined handle to connect to.

The return value is the handle of the opened key. If the function fails, a *WindowsError* exception is raised.

`_winreg.CreateKey(key, sub_key)`

Creates or opens the specified key, returning a *handle object*.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*sub\_key* is a string that names the key this method opens or creates.

If *key* is one of the predefined keys, *sub\_key* may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, a *WindowsError* exception is raised.

`_winreg.CreateKeyEx(key, sub_key[, res[, sam]])`

Creates or opens the specified key, returning a *handle object*.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*sub\_key* is a string that names the key this method opens or creates.

*res* is a reserved integer, and must be zero. The default is zero.

*sam* is an integer that specifies an access mask that describes the desired security access for the key. Default is *KEY\_ALL\_ACCESS*. See *Access Rights* for other allowed values.

If *key* is one of the predefined keys, *sub\_key* may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, a *WindowsError* exception is raised.

Nouveau dans la version 2.7.

`_winreg.DeleteKey(key, sub_key)`

Deletes the specified key.

*key* is an already open key, or any one of the predefined *HKEY\_\* constants*.

*sub\_key* is a string that must be a subkey of the key identified by the *key* parameter. This value must not be `None`, and the key may not have subkeys.

*This method can not delete keys with subkeys.*

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, a *WindowsError* exception is raised.

`_winreg.DeleteKeyEx(key, sub_key[, sam[, res]])`

Deletes the specified key.

---

**Note :** The *DeleteKeyEx()* function is implemented with the *RegDeleteKeyEx* Windows API function, which is specific to 64-bit versions of Windows. See the *RegDeleteKeyEx documentation*.

---

*key* is an already open key, or any one of the predefined *HKEY\_\* constants*.

*sub\_key* is a string that must be a subkey of the key identified by the *key* parameter. This value must not be `None`, and the key may not have subkeys.

*res* is a reserved integer, and must be zero. The default is zero.

*sam* is an integer that specifies an access mask that describes the desired security access for the key. Default is *KEY\_WOW64\_64KEY*. See *Access Rights* for other allowed values.

*This method can not delete keys with subkeys.*

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, a *WindowsError* exception is raised.

On unsupported Windows versions, *NotImplementedError* is raised.

Nouveau dans la version 2.7.

`_winreg.DeleteValue(key, value)`

Removes a named value from a registry key.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*value* is a string that identifies the value to remove.

`_winreg.EnumKey(key, index)`

Enumerates subkeys of an open registry key, returning a string.

*key* is an already open key, or any one of the predefined *HKEY\_\* constants*.

*index* is an integer that identifies the index of the key to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly until a *WindowsError* exception is raised, indicating, no more values are available.

`_winreg.EnumValue(key, index)`

Enumerates values of an open registry key, returning a tuple.

*key* is an already open key, or any one of the predefined *HKEY\_\* constants*.

*index* is an integer that identifies the index of the value to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly, until a *WindowsError* exception is raised, indicating no more values.

The result is a tuple of 3 items :

In- dex	Signification
0	A string that identifies the value name
1	An object that holds the value data, and whose type depends on the underlying registry type
2	An integer that identifies the type of the value data (see table in docs for <i>SetValueEx()</i> )

`_winreg.ExpandEnvironmentStrings(unicode)`

Expands environment variable placeholders %NAME% in unicode strings like [REG\\_EXPAND\\_SZ](#) :

```
>>> ExpandEnvironmentStrings(u"%windir%")
u"C:\\Windows"
```

Nouveau dans la version 2.6.

`_winreg.FlushKey(key)`

Writes all the attributes of a key to the registry.

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

It is not necessary to call [FlushKey\(\)](#) to change a key. Registry changes are flushed to disk by the registry using its lazy flusher. Registry changes are also flushed to disk at system shutdown. Unlike [CloseKey\(\)](#), the [FlushKey\(\)](#) method returns only when all the data has been written to the registry. An application should only call [FlushKey\(\)](#) if it requires absolute certainty that registry changes are on disk.

---

**Note :** If you don't know whether a [FlushKey\(\)](#) call is required, it probably isn't.

---

`_winreg.LoadKey(key, sub_key, file_name)`

Creates a subkey under the specified key and stores registration information from a specified file into that subkey.

*key* is a handle returned by [ConnectRegistry\(\)](#) or one of the constants [HKEY\\_USERS](#) or [HKEY\\_LOCAL\\_MACHINE](#).

*sub\_key* is a string that identifies the subkey to load.

*file\_name* is the name of the file to load registry data from. This file must have been created with the [SaveKey\(\)](#) function. Under the file allocation table (FAT) file system, the filename may not have an extension.

A call to [LoadKey\(\)](#) fails if the calling process does not have the SE\_RESTORE\_PRIVILEGE privilege. Note that privileges are different from permissions – see the [RegLoadKey documentation](#) for more details.

If *key* is a handle returned by [ConnectRegistry\(\)](#), then the path specified in *file\_name* is relative to the remote computer.

`_winreg.OpenKey(key, sub_key[, res[, sam]])`

Opens the specified key, returning a *handle object*.

*key* is an already open key, or any one of the predefined [HKEY\\_\\* constants](#).

*sub\_key* is a string that identifies the sub\_key to open.

*res* is a reserved integer, and must be zero. The default is zero.

*sam* is an integer that specifies an access mask that describes the desired security access for the key. Default is [KEY\\_READ](#). See [Access Rights](#) for other allowed values.

The result is a new handle to the specified key.

If the function fails, [WindowsError](#) is raised.

`_winreg.OpenKeyEx()`

The functionality of [OpenKeyEx\(\)](#) is provided via [OpenKey\(\)](#), by the use of default arguments.

`_winreg.QueryInfoKey(key)`

Returns information about a key, as a tuple.

*key* is an already open key, or one of the predefined [HKEY\\_\\* constants](#).

The result is a tuple of 3 items :

In- dex	Signification
0	An integer giving the number of sub keys this key has.
1	An integer giving the number of values this key has.
2	A long integer giving when the key was last modified (if available) as 100's of nanoseconds since Jan 1, 1601.

**`_winreg.QueryValue(key, sub_key)`**

Retrieves the unnamed value for a key, as a string.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*sub\_key* is a string that holds the name of the subkey with which the value is associated. If this parameter is `None` or empty, the function retrieves the value set by the *SetValue()* method for the key identified by *key*.

Values in the registry have name, type, and data components. This method retrieves the data for a key's first value that has a NULL name. But the underlying API call doesn't return the type, so always use *QueryValueEx()* if possible.

**`_winreg.QueryValueEx(key, value_name)`**

Retrieves the type and data for a specified value name associated with an open registry key.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*value\_name* is a string indicating the value to query.

The result is a tuple of 2 items :

Index	Signification
0	The value of the registry item.
1	An integer giving the registry type for this value (see table in docs for <i>SetValueEx()</i> )

**`_winreg.SaveKey(key, file_name)`**

Saves the specified key, and all its subkeys to the specified file.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*file\_name* is the name of the file to save registry data to. This file cannot already exist. If this filename includes an extension, it cannot be used on file allocation table (FAT) file systems by the *LoadKey()* method.

If *key* represents a key on a remote computer, the path described by *file\_name* is relative to the remote computer. The caller of this method must possess the *SeBackupPrivilege* security privilege. Note that privileges are different than permissions – see the [Conflicts Between User Rights and Permissions documentation](#) for more details.

This function passes `NULL` for *security\_attributes* to the API.

**`_winreg.SetValue(key, sub_key, type, value)`**

Associates a value with a specified key.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*sub\_key* is a string that names the subkey with which the value is associated.

*type* is an integer that specifies the type of the data. Currently this must be *REG\_SZ*, meaning only strings are supported. Use the *SetValueEx()* function for support for other data types.

*value* is a string that specifies the new value.

If the key specified by the *sub\_key* parameter does not exist, the *SetValue* function creates it.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

The key identified by the *key* parameter must have been opened with *KEY\_SET\_VALUE* access.

**`_winreg.SetValueEx(key, value_name, reserved, type, value)`**

Stores data in the value field of an open registry key.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*value\_name* is a string that names the subkey with which the value is associated.

*type* is an integer that specifies the type of the data. See *Value Types* for the available types.

*reserved* can be anything – zero is always passed to the API.

*value* is a string that specifies the new value.

This method can also set additional value and type information for the specified key. The key identified by the key parameter must have been opened with *KEY\_SET\_VALUE* access.

To open the key, use the *CreateKey()* or *OpenKey()* methods.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

#### **`_winreg.DisableReflectionKey(key)`**

Disables registry reflection for 32-bit processes running on a 64-bit operating system.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

Will generally raise *NotImplemented* if executed on a 32-bit operating system.

If the key is not on the reflection list, the function succeeds but has no effect. Disabling reflection for a key does not affect reflection of any subkeys.

#### **`_winreg.EnableReflectionKey(key)`**

Restores registry reflection for the specified disabled key.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

Will generally raise *NotImplemented* if executed on a 32-bit operating system.

Restoring reflection for a key does not affect reflection of any subkeys.

#### **`_winreg.QueryReflectionKey(key)`**

Determines the reflection state for the specified key.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

Returns *True* if reflection is disabled.

Will generally raise *NotImplemented* if executed on a 32-bit operating system.

### **35.3.1 Constantes**

The following constants are defined for use in many *\_winreg* functions.

#### ***HKEY\_\* Constants***

##### **`_winreg.HKEY_CLASSES_ROOT`**

Registry entries subordinate to this key define types (or classes) of documents and the properties associated with those types. Shell and COM applications use the information stored under this key.

##### **`_winreg.HKEY_CURRENT_USER`**

Registry entries subordinate to this key define the preferences of the current user. These preferences include the settings of environment variables, data about program groups, colors, printers, network connections, and application preferences.

##### **`_winreg.HKEY_LOCAL_MACHINE`**

Registry entries subordinate to this key define the physical state of the computer, including data about the bus type, system memory, and installed hardware and software.

##### **`_winreg.HKEY_USERS`**

Registry entries subordinate to this key define the default user configuration for new users on the local computer and the user configuration for the current user.

##### **`_winreg.HKEY_PERFORMANCE_DATA`**

Registry entries subordinate to this key allow you to access performance data. The data is not actually stored in the registry; the registry functions cause the system to collect the data from its source.

`_winreg.HKEY_CURRENT_CONFIG`

Contains information about the current hardware profile of the local computer system.

`_winreg.HKEY_DYN_DATA`

This key is not used in versions of Windows after 98.

### Access Rights

For more information, see [Registry Key Security and Access](#).

`_winreg.KEY_ALL_ACCESS`

Combines the `STANDARD_RIGHTS_REQUIRED`, `KEY_QUERY_VALUE`, `KEY_SET_VALUE`, `KEY_CREATE_SUB_KEY`, `KEY_ENUMERATE_SUB_KEYS`, `KEY_NOTIFY`, and `KEY_CREATE_LINK` access rights.

`_winreg.KEY_WRITE`

Combines the `STANDARD_RIGHTS_WRITE`, `KEY_SET_VALUE`, and `KEY_CREATE_SUB_KEY` access rights.

`_winreg.KEY_READ`

Combines the `STANDARD_RIGHTS_READ`, `KEY_QUERY_VALUE`, `KEY_ENUMERATE_SUB_KEYS`, and `KEY_NOTIFY` values.

`_winreg.KEY_EXECUTE`

Equivalent to `KEY_READ`.

`_winreg.KEY_QUERY_VALUE`

Required to query the values of a registry key.

`_winreg.KEY_SET_VALUE`

Required to create, delete, or set a registry value.

`_winreg.KEY_CREATE_SUB_KEY`

Required to create a subkey of a registry key.

`_winreg.KEY_ENUMERATE_SUB_KEYS`

Required to enumerate the subkeys of a registry key.

`_winreg.KEY_NOTIFY`

Required to request change notifications for a registry key or for subkeys of a registry key.

`_winreg.KEY_CREATE_LINK`

Reserved for system use.

### 64-bit Specific

For more information, see [Accessing an Alternate Registry View](#).

`_winreg.KEY_WOW64_64KEY`

Indicates that an application on 64-bit Windows should operate on the 64-bit registry view.

`_winreg.KEY_WOW64_32KEY`

Indicates that an application on 64-bit Windows should operate on the 32-bit registry view.

### Value Types

For more information, see [Registry Value Types](#).

`_winreg.REG_BINARY`

Binary data in any form.

`_winreg.REG_DWORD`  
32-bit number.

`_winreg.REG_DWORD_LITTLE_ENDIAN`  
A 32-bit number in little-endian format.

`_winreg.REG_DWORD_BIG_ENDIAN`  
A 32-bit number in big-endian format.

`_winreg.REG_EXPAND_SZ`  
Null-terminated string containing references to environment variables (%PATH%).

`_winreg.REG_LINK`  
A Unicode symbolic link.

`_winreg.REG_MULTI_SZ`  
A sequence of null-terminated strings, terminated by two null characters. (Python handles this termination automatically.)

`_winreg.REG_NONE`  
No defined value type.

`_winreg.REG_RESOURCE_LIST`  
A device-driver resource list.

`_winreg.REG_FULL_RESOURCE_DESCRIPTOR`  
A hardware setting.

`_winreg.REG_RESOURCE_REQUIREMENTS_LIST`  
A hardware resource list.

`_winreg.REG_SZ`  
A null-terminated string.

### 35.3.2 Registry Handle Objects

This object wraps a Windows HKEY object, automatically closing it when the object is destroyed. To guarantee cleanup, you can call either the `Close()` method on the object, or the `CloseKey()` function.

All registry functions in this module return one of these objects.

All registry functions in this module which accept a handle object also accept an integer, however, use of the handle object is encouraged.

Handle objects provide semantics for `__nonzero__()` – thus :

```
if handle:
    print "Yes"
```

will print **Yes** if the handle is currently valid (has not been closed or detached).

The object also support comparison semantics, so handle objects will compare true if they both reference the same underlying Windows handle value.

Handle objects can be converted to an integer (e.g., using the built-in `int()` function), in which case the underlying Windows handle value is returned. You can also use the `Detach()` method to return the integer handle, and also disconnect the Windows handle from the handle object.

**PyHKEY.Close()**  
Closes the underlying Windows handle.  
If the handle is already closed, no error is raised.

**PyHKEY.Detach()**

Detaches the Windows handle from the handle object.

The result is an integer (or long on 64 bit Windows) that holds the value of the handle before it is detached. If the handle is already detached or closed, this will return zero.

After calling this function, the handle is effectively invalidated, but the handle is not closed. You would call this function when you need the underlying Win32 handle to exist beyond the lifetime of the handle object.

**PyHKEY.\_\_enter\_\_()****PyHKEY.\_\_exit\_\_(\*exc\_info)**

The HKEY object implements `__enter__()` and `__exit__()` and thus supports the context protocol for the `with` statement :

```
with OpenKey(HKEY_LOCAL_MACHINE, "foo") as key:
    ... # work with key
```

will automatically close *key* when control leaves the `with` block.

Nouveau dans la version 2.6.

## 35.4 winsound — Sound-playing interface for Windows

Nouveau dans la version 1.5.2.

The *winsound* module provides access to the basic sound-playing machinery provided by Windows platforms. It includes functions and several constants.

**winsound.Beep(*frequency*, *duration*)**

Beep the PC's speaker. The *frequency* parameter specifies frequency, in hertz, of the sound, and must be in the range 37 through 32,767. The *duration* parameter specifies the number of milliseconds the sound should last. If the system is not able to beep the speaker, *RuntimeError* is raised.

Nouveau dans la version 1.6.

**winsound.PlaySound(*sound*, *flags*)**

Call the underlying `PlaySound()` function from the Platform API. The *sound* parameter may be a filename, audio data as a string, or `None`. Its interpretation depends on the value of *flags*, which can be a bitwise ORed combination of the constants described below. If the *sound* parameter is `None`, any currently playing waveform sound is stopped. If the system indicates an error, *RuntimeError* is raised.

**winsound.MessageBeep([*type*=MB\_OK])**

Call the underlying `MessageBeep()` function from the Platform API. This plays a sound as specified in the registry. The *type* argument specifies which sound to play ; possible values are -1, `MB_ICONASTERISK`, `MB_ICONEXCLAMATION`, `MB_ICONHAND`, `MB_ICONQUESTION`, and `MB_OK`, all described below. The value -1 produces a « simple beep » ; this is the final fallback if a sound cannot be played otherwise.

Nouveau dans la version 2.3.

**winsound.SND\_FILENAME**

The *sound* parameter is the name of a WAV file. Do not use with *SND\_ALIAS*.

**winsound.SND\_ALIAS**

The *sound* parameter is a sound association name from the registry. If the registry contains no such name, play the system default sound unless *SND\_NODEFAULT* is also specified. If no default sound is registered, raise *RuntimeError*. Do not use with *SND\_FILENAME*.

All Win32 systems support at least the following ; most systems support many more :

<i>PlaySound()</i> name	Corresponding Control Panel Sound name
'SystemAsterisk'	Asterisk
'SystemExclamation'	Exclamation
'SystemExit'	Exit Windows
'SystemHand'	Critical Stop
'SystemQuestion'	Question

Par exemple :

```
import winsound
# Play Windows exit sound.
winsound.PlaySound("SystemExit", winsound.SND_ALIAS)

# Probably play Windows default sound, if any is registered (because
# "*" probably isn't the registered name of any sound).
winsound.PlaySound("*", winsound.SND_ALIAS)
```

`winsound.SND_LOOP`

Play the sound repeatedly. The *SND\_ASYNC* flag must also be used to avoid blocking. Cannot be used with *SND\_MEMORY*.

`winsound.SND_MEMORY`

The *sound* parameter to *PlaySound()* is a memory image of a WAV file, as a string.

---

**Note :** This module does not support playing from a memory image asynchronously, so a combination of this flag and *SND\_ASYNC* will raise *RuntimeError*.

---

`winsound.SND_PURGE`

Stop playing all instances of the specified sound.

---

**Note :** This flag is not supported on modern Windows platforms.

---

`winsound.SND_ASYNC`

Return immediately, allowing sounds to play asynchronously.

`winsound.SND_NODEFAULT`

If the specified sound cannot be found, do not play the system default sound.

`winsound.SND_NOSTOP`

Do not interrupt sounds currently playing.

`winsound.SND_NOWAIT`

Return immediately if the sound driver is busy.

---

**Note :** This flag is not supported on modern Windows platforms.

---

`winsound.MB_ICONASTERISK`

Play the `SystemDefault` sound.

`winsound.MB_ICONEXCLAMATION`

Play the `SystemExclamation` sound.

`winsound.MB_ICONHAND`

Play the `SystemHand` sound.

`winsound.MB_ICONQUESTION`

Play the `SystemQuestion` sound.

`winsound.MB_OK`

Play the `SystemDefault` sound.

---

Services spécifiques à Unix

---

Les modules décrits dans ce chapitre fournissent des interfaces aux fonctionnalités propres au système d'exploitation Unix ou, dans certains cas, à certaines de ses variantes, en voici un aperçu :

## 36.1 `posix` — Les appels système POSIX les plus courants

Ce module permet d'accéder aux fonctionnalités du système d'exploitation normalisés par le Standard C et le Standard POSIX (une interface Unix habilement déguisée).

**Ne pas importer ce module directement.** À la place, importer le module `os`, qui fournit une version *portable* de cette interface. Sous Unix, le module `os` fournit un sur-ensemble de l'interface `posix`. Sous les systèmes d'exploitation non Unix le module `posix` n'est pas disponible, mais un sous ensemble est toujours disponible via l'interface `os`. Une fois que `os` est importé, il n'y a aucune perte de performance à l'utiliser à la place de `posix`. De plus, `os` fournit des fonctionnalités supplémentaires, telles que l'appel automatique de `putenv()` lorsqu'une entrée dans `os.environ` est modifiée.

Les erreurs sont signalées comme des exceptions ; les exceptions habituelles sont données pour les erreurs de type, tandis que les erreurs signalées par les appels système lèvent une erreur `OSError`.

### 36.1.1 Prise en charge de gros fichiers

Several operating systems (including AIX, HP-UX, Irix and Solaris) provide support for files that are larger than 2 GB from a C programming model where `int` and `long` are 32-bit values. This is typically accomplished by defining the relevant size and offset types as 64-bit values. Such files are sometimes referred to as *large files*.

Large file support is enabled in Python when the size of an `off_t` is larger than a `long` and the `long long` type is available and is at least as large as an `off_t`. Python longs are then used to represent file sizes, offsets and other values that can exceed the range of a Python int. It may be necessary to configure and compile Python with certain compiler flags to enable this mode. For example, it is enabled by default with recent versions of Irix, but with Solaris 2.6 and 2.7 you need to do something like :

```
CFLAGS="-getconf LFS_CFLAGS" OPT="-g -O2 $CFLAGS" \  
./configure
```

Sur les systèmes Linux capable de supporter les fichiers volumineux, cela pourrait fonctionner :

```
CFLAGS='-D_LARGEFILE64_SOURCE -D_FILE_OFFSET_BITS=64' OPT="-g -O2 $CFLAGS" \  
./configure
```

### 36.1.2 Contenu du Module

En plus des nombreuses fonctions décrites dans la documentation du module *os*, *posix* possède les éléments suivants :

#### `posix.envIRON`

A dictionary representing the string environment at the time the interpreter was started. For example, `environ['HOME']` is the pathname of your home directory, equivalent to `getenv("HOME")` in C.

Modifier ce dictionnaire n'affecte pas les variables d'environnements fournis par *execv()*, *popen()* ou *system()* ; Si vous avez besoin de changer l'environnement, passer le paramètre `environ` à *execve()* ou ajouter les assignations de variables et les *export* à la commande à exécuter via *system()* ou *popen()*.

---

**Note :** The *os* module provides an alternate implementation of `environ` which updates the environment on modification. Note also that updating `os.environ` will render this dictionary obsolete. Use of the *os* module version of this is recommended over direct access to the *posix* module.

---

## 36.2 pwd — The password database

This module provides access to the Unix user account and password database. It is available on all Unix versions.

Password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `passwd` structure (Attribute field below, see `<pwd.h>`) :

Index	Attribut	Signification
0	<code>pw_name</code>	Login name
1	<code>pw_passwd</code>	Optional encrypted password
2	<code>pw_uid</code>	Numerical user ID
3	<code>pw_gid</code>	Numerical group ID
4	<code>pw_gecos</code>	User name or comment field
5	<code>pw_dir</code>	User home directory
6	<code>pw_shell</code>	User command interpreter

The uid and gid items are integers, all others are strings. *KeyError* is raised if the entry asked for cannot be found.

---

**Note :** In traditional Unix the field `pw_passwd` usually contains a password encrypted with a DES derived algorithm (see module *crypt*). However most modern unices use a so-called *shadow password* system. On those unices the `pw_passwd` field only contains an asterisk ('\*') or the letter 'x' where the encrypted password is stored in a file `/etc/shadow` which is not world readable. Whether the `pw_passwd` field contains anything useful is system-dependent. If available, the *spwd* module should be used where access to the encrypted password is required.

---

It defines the following items :

#### `pwd.getpwuid(uid)`

Return the password database entry for the given numeric user ID.

`pwd.getpwnam(name)`

Return the password database entry for the given user name.

`pwd.getpwall()`

Return a list of all available password database entries, in arbitrary order.

**Voir aussi :**

**Module `grp`** An interface to the group database, similar to this.

**Module `spwd`** An interface to the shadow password database, similar to this.

## 36.3 spwd — The shadow password database

Nouveau dans la version 2.5.

This module provides access to the Unix shadow password database. It is available on various Unix versions.

You must have enough privileges to access the shadow password database (this usually means you have to be root).

Shadow password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `spwd` structure (Attribute field below, see `<shadow.h>`) :

Index	Attribut	Signification
0	<code>sp_nam</code>	Login name
1	<code>sp_pwd</code>	Encrypted password
2	<code>sp_lstchg</code>	Date of last change
3	<code>sp_min</code>	Minimal number of days between changes
4	<code>sp_max</code>	Maximum number of days between changes
5	<code>sp_warn</code>	Number of days before password expires to warn user about it
6	<code>sp_inact</code>	Number of days after password expires until account is blocked
7	<code>sp_expire</code>	Number of days since 1970-01-01 until account is disabled
8	<code>sp_flag</code>	Réservé

The `sp_nam` and `sp_pwd` items are strings, all others are integers. `KeyError` is raised if the entry asked for cannot be found.

It defines the following items :

`spwd.getspnam(name)`

Return the shadow password database entry for the given user name.

`spwd.getspall()`

Return a list of all available shadow password database entries, in arbitrary order.

**Voir aussi :**

**Module `grp`** An interface to the group database, similar to this.

**Module `pwd`** An interface to the normal password database, similar to this.

## 36.4 grp — The group database

This module provides access to the Unix group database. It is available on all Unix versions.

Group database entries are reported as a tuple-like object, whose attributes correspond to the members of the `group` structure (Attribute field below, see `<pwd.h>`) :

Index	Attribut	Signification
0	gr_name	the name of the group
1	gr_passwd	the (encrypted) group password; often empty
2	gr_gid	the numerical group ID
3	gr_mem	all the group member's user names

The gid is an integer, name and password are strings, and the member list is a list of strings. (Note that most users are not explicitly listed as members of the group they are in according to the password database. Check both databases to get complete membership information. Also note that a `gr_name` that starts with a `+` or `-` is likely to be a YP/NIS reference and may not be accessible via `getgrnam()` or `getgrgid()`.)

It defines the following items :

`grp.getgrgid(gid)`

Return the group database entry for the given numeric group ID. `KeyError` is raised if the entry asked for cannot be found.

`grp.getgrnam(name)`

Return the group database entry for the given group name. `KeyError` is raised if the entry asked for cannot be found.

`grp.getgrall()`

Return a list of all available group entries, in arbitrary order.

Voir aussi :

Module `pwd` An interface to the user database, similar to this.

Module `spwd` An interface to the shadow password database, similar to this.

## 36.5 crypt — Function to check Unix passwords

This module implements an interface to the `crypt(3)` routine, which is a one-way hash function based upon a modified DES algorithm; see the Unix man page for further details. Possible uses include allowing Python scripts to accept typed passwords from the user, or attempting to crack Unix passwords with a dictionary.

Notice that the behavior of this module depends on the actual implementation of the `crypt(3)` routine in the running system. Therefore, any extensions available on the current implementation will also be available on this module.

`crypt.crypt(word, salt)`

`word` will usually be a user's password as typed at a prompt or in a graphical interface. `salt` is usually a random two-character string which will be used to perturb the DES algorithm in one of 4096 ways. The characters in `salt` must be in the set `[/a-zA-Z0-9]`. Returns the hashed password as a string, which will be composed of characters from the same alphabet as the salt (the first two characters represent the salt itself).

Since a few `crypt(3)` extensions allow different values, with different sizes in the `salt`, it is recommended to use the full crypted password as salt when checking for a password.

A simple example illustrating typical use :

```
import crypt, getpass, pwd

def login():
    username = raw_input('Python login:')
    cryptpasswd = pwd.getpwnam(username)[1]
```

(suite sur la page suivante)

(suite de la page précédente)

```

if cryptedpasswd:
    if cryptedpasswd == 'x' or cryptedpasswd == '*':
        raise NotImplementedError(
            "Sorry, currently no support for shadow passwords")
    cleartext = getpass.getpass()
    return crypt.crypt(cleartext, cryptedpasswd) == cryptedpasswd
else:
    return 1

```

## 36.6 dl — Call C functions in shared objects

Obsolète depuis la version 2.6 : The `dl` module has been removed in Python 3. Use the `ctypes` module instead.

The `dl` module defines an interface to the `dlopen()` function, which is the most common interface on Unix platforms for handling dynamically linked libraries. It allows the program to call arbitrary functions in such a library.

**Avertissement :** The `dl` module bypasses the Python type system and error handling. If used incorrectly it may cause segmentation faults, crashes or other incorrect behaviour.

**Note :** This module will not work unless `sizeof(int) == sizeof(long) == sizeof(char *)`. If this is not the case, `SystemError` will be raised on import.

The `dl` module defines the following function :

`dl.open(name[, mode=RTLD_LAZY])`  
 Open a shared object file, and return a handle. Mode signifies late binding (`RTLD_LAZY`) or immediate binding (`RTLD_NOW`). Default is `RTLD_LAZY`. Note that some systems do not support `RTLD_NOW`.  
 Return value is a `dlobj`ect.

The `dl` module defines the following constants :

`dl.RTLD_LAZY`  
 Useful as an argument to `open()`.

`dl.RTLD_NOW`  
 Useful as an argument to `open()`. Note that on systems which do not support immediate binding, this constant will not appear in the module. For maximum portability, use `hasattr()` to determine if the system supports immediate binding.

The `dl` module defines the following exception :

**exception `dl.error`**  
 Exception raised when an error has occurred inside the dynamic loading and linking routines.

Exemple :

```

>>> import dl, time
>>> a=dl.open('/lib/libc.so.6')
>>> a.call('time'), time.time()
(929723914, 929723914.498)

```

This example was tried on a Debian GNU/Linux system, and is a good example of the fact that using this module is usually a bad alternative.

### 36.6.1 Dl Objects

Dl objects, as returned by `open()` above, have the following methods :

`dl.close()`

Free all resources, except the memory.

`dl.sym(name)`

Return the pointer for the function named *name*, as a number, if it exists in the referenced shared object, otherwise `None`. This is useful in code like :

```
>>> if a.sym('time'):
...     a.call('time')
... else:
...     time.time()
```

(Note that this function will return a non-zero number, as zero is the *NULL* pointer)

`dl.call(name[, arg1[, arg2...]])`

Call the function named *name* in the referenced shared object. The arguments must be either Python integers, which will be passed as is, Python strings, to which a pointer will be passed, or `None`, which will be passed as *NULL*. Note that strings should only be passed to functions as `const char*`, as Python will not like its string mutated.

There must be at most 10 arguments, and arguments not given will be treated as `None`. The function's return value must be a C long, which is a Python integer.

## 36.7 termios — Le style POSIX le contrôle TTY

This module provides an interface to the POSIX calls for tty I/O control. For a complete description of these calls, see *termios(2)* Unix manual page. It is only available for those Unix versions that support POSIX *termios* style tty I/O control configured during installation.

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or a file object, such as `sys.stdin` itself.

Ce module définit aussi toutes les constantes nécessaires pour travailler avec les fonctions fournies ici ; elles ont les mêmes noms que leurs équivalents en C. Pour plus d'informations sur l'utilisation de ces terminaux, veuillez vous référer à votre documentation système.

Le module définit les fonctions suivantes :

`termios.tcgetattr(fd)`

Retourne une liste contenant les attributs TTY pour le descripteur de fichier *fd*, tel que : `[iflag, oflag, cflag, lflag, ispeed, ospeed, cc]` où *cc* est une liste de caractères spéciaux TTY (chacun est une chaîne de caractère de longueur 1, à l'exception des éléments ayant les indices *VMIN* et *VTIME*, ceux-ci sont alors des entiers quand ces champs sont définis). L'interprétation des options (*flags* en anglais) et des vitesses ainsi que l'indexation dans le tableau *cc* doit être fait en utilisant les constantes symboliques définies dans le module *termios*.

`termios.tcsetattr(fd, when, attributes)`

Définit les attributs TTY pour le descripteur de fichiers *fd* à partir des *attributes*, qui est une liste comme celle retournée par `tcgetattr()`. L'argument *when* détermine quand les attributs sont changés : *TCSANOW* pour un changement immédiat, *TCSADRAIN* pour un changement après la transmission de toute sortie en file d'attente, ou *TCSAFLUSH* pour un changement après avoir transmis toute sortie en file d'attente et rejeté toutes entrées en file d'attente.

`termios.tcsendbreak(fd, duration)`

Envoie une pause sur le descripteur de fichier *fd*. Une *duration* à zéro envoie une pause de 0.25 —0.5 seconde ; Une *duration* différente de zéro a une définition spécifique pour chaque système.

`termios.tcdrain(fd)`

Attends que toutes les sorties écrites dans le descripteur de fichier *fd* soient transmises.

`termios.tcflush(fd, queue)`

Vide la queue de données du descripteur de fichier *fd*. Le sélecteur *queue* précise la queue : TCIFLUSH pour la queue des entrées, TCOFLUSH pour la queue des sorties, ou TCIOFLUSH pour les deux queues.

`termios.tcflow(fd, action)`

Suspend ou reprends l'entrée ou la sortie du descripteur de fichier *fd*. L'argument *action* peut être TCOOFF pour suspendre la sortie, TCOON pour relancer la sortie, TCIOFF pour suspendre l'entrée, ou TCION pour relancer l'entrée.

Voir aussi :

Le module `tty` Fonctions utiles pour les opérations de contrôle communes dans le terminal.

### 36.7.1 Exemple

Voici une fonction qui demande à l'utilisateur d'entrer un mot de passe sans l'afficher. Remarquez la technique qui consiste à séparer un appel à `tcgetattr()` et une instruction `try... finally` pour s'assurer que les anciens attributs `tty` soient restaurés tels quels quoi qu'il arrive :

```
def getpass(prompt="Password: "):
    import termios, sys
    fd = sys.stdin.fileno()
    old = termios.tcgetattr(fd)
    new = termios.tcgetattr(fd)
    new[3] = new[3] & ~termios.ECHO          # lflags
    try:
        termios.tcsetattr(fd, termios.TCSADRAIN, new)
        passwd = raw_input(prompt)
    finally:
        termios.tcsetattr(fd, termios.TCSADRAIN, old)
    return passwd
```

## 36.8 tty — Fonctions de gestion du terminal

Le module `tty` expose des fonctions permettant de mettre le `tty` en mode *cbreak* ou *raw*.

Puisqu'il a besoin du module `termios`, il ne fonctionnera que sur Unix.

Le module `tty` définit les fonctions suivantes :

`tty.setraw(fd[, when])`

Définit le mode du descripteur de fichier *fd* à *raw*. Par défaut, *when* vaut `termios.TCSAFLUSH`, et est passé à `termios.tcsetattr()`.

`tty.setcbreak(fd[, when])`

Définit le mode du descripteur de fichier *fd* à *cbreak*. *when* vaut `termios.TCSAFLUSH` par défaut, et est passé à `termios.tcsetattr()`.

Voir aussi :

Module `termios` Interface bas niveau de gestion du terminal.

## 36.9 pty — Outils de manipulation de pseudo-terminals

Le module *pty* expose des fonctions de manipulation de pseudo-terminals, il permet d'écrire un programme capable de démarrer un autre processus, d'écrire et de lire depuis son terminal.

La gestion de pseudo-terminals étant très dépendante de la plateforme, ce code ne gère que Linux. (Code supposé fonctionner sur d'autres plateformes, mais sans avoir été testé).

Le module *pty* expose les fonctions suivantes :

`pty.fork()`

*Fork*. Connecte le terminal contrôlé par le fils à un pseudo-terminal. La valeur renvoyée est (*pid*, *fd*). Notez que le fils obtient 0 comme *pid* et un *fd* non valide. Le parent obtient le *pid* du fils, et *fd* un descripteur de fichier connecté à un terminal contrôlé par le fils (et donc à l'entrée et la sortie standard du fils).

`pty.openpty()`

Ouvre une nouvelle paire de pseudo-terminals, en utilisant si possible *os.openpty()*, ou du code émulant la fonctionnalité pour des systèmes Unix génériques. Renvoie une paire de descripteurs de fichier (*master*, *slave*), pour le maître et pour l'esclave respectivement.

`pty.spawn(argv[, master_read[, stdin_read]])`

Crée un nouveau processus et connecte son terminal aux entrées/sorties standard du processus courant. C'est typiquement utilisé pour duper les programmes insistant sur le fait de lire depuis leur terminal. Les fonctions *master\_read* et *stdin\_read* doivent être des fonctions lisant sur un descripteur de fichier. Par défaut elles lisent 1024 octets à chaque fois qu'elles sont appelées.

## 36.10 fcntl — The fcntl and ioctl system calls

This module performs file control and I/O control on file descriptors. It is an interface to the *fcntl()* and *ioctl()* Unix routines. For a complete description of these calls, see *fcntl(2)* and *ioctl(2)* Unix manual pages.

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by *sys.stdin.fileno()*, or a file object, such as *sys.stdin* itself, which provides a *fileno()* which returns a genuine file descriptor.

Le module définit les fonctions suivantes :

`fcntl.fcntl(fd, op[, arg])`

Perform the operation *op* on file descriptor *fd* (file objects providing a *fileno()* method are accepted as well). The values used for *op* are operating system dependent, and are available as constants in the *fcntl* module, using the same names as used in the relevant C header files. The argument *arg* is optional, and defaults to the integer value 0. When present, it can either be an integer value, or a string. With the argument missing or an integer value, the return value of this function is the integer return value of the C *fcntl()* call. When the argument is a string it represents a binary structure, e.g. created by *struct.pack()*. The binary data is copied to a buffer whose address is passed to the C *fcntl()* call. The return value after a successful call is the contents of the buffer, converted to a string object. The length of the returned string will be the same as the length of the *arg* argument. This is limited to 1024 bytes. If the information returned in the buffer by the operating system is larger than 1024 bytes, this is most likely to result in a segmentation violation or a more subtle data corruption. If the *fcntl()* fails, an *IOError* is raised.

`fcntl.ioctl(fd, op[, arg[, mutate_flag]])`

This function is identical to the *fcntl()* function, except that the operations are typically defined in the library module *termios* and the argument handling is even more complicated.

The *op* parameter is limited to values that can fit in 32-bits. Additional constants of interest for use as the *op* argument can be found in the `termios` module, under the same names as used in the relevant C header files.

The parameter *arg* can be one of an integer, absent (treated identically to the integer 0), an object supporting the read-only buffer interface (most likely a plain Python string) or an object supporting the read-write buffer interface.

In all but the last case, behaviour is as for the `fcntl()` function.

If a mutable buffer is passed, then the behaviour is determined by the value of the `mutate_flag` parameter.

If it is false, the buffer's mutability is ignored and behaviour is as for a read-only buffer, except that the 1024 byte limit mentioned above is avoided – so long as the buffer you pass is at least as long as what the operating system wants to put there, things should work.

If `mutate_flag` is true, then the buffer is (in effect) passed to the underlying `ioctl()` system call, the latter's return code is passed back to the calling Python, and the buffer's new contents reflect the action of the `ioctl()`. This is a slight simplification, because if the supplied buffer is less than 1024 bytes long it is first copied into a static buffer 1024 bytes long which is then passed to `ioctl()` and copied back into the supplied buffer.

If `mutate_flag` is not supplied, then from Python 2.5 it defaults to true, which is a change from versions 2.3 and 2.4. Supply the argument explicitly if version portability is a priority.

If the `ioctl()` fails, an `IOError` exception is raised.

Un exemple :

```
>>> import array, fcntl, struct, termios, os
>>> os.getpgrp()
13341
>>> struct.unpack('h', fcntl.ioctl(0, termios.TIOCGPGRP, "  "))[0]
13341
>>> buf = array.array('h', [0])
>>> fcntl.ioctl(0, termios.TIOCGPGRP, buf, 1)
0
>>> buf
array('h', [13341])
```

#### `fcntl.flock(fd, op)`

Perform the lock operation *op* on file descriptor *fd* (file objects providing a `fileno()` method are accepted as well). See the Unix manual `flock(2)` for details. (On some systems, this function is emulated using `fcntl()`.)

If the `flock()` fails, an `IOError` exception is raised.

#### `fcntl.lockf(fd, operation[, length[, start[, whence]]])`

This is essentially a wrapper around the `fcntl()` locking calls. *fd* is the file descriptor of the file to lock or unlock, and *operation* is one of the following values :

- `LOCK_UN` – unlock
- `LOCK_SH` – acquire a shared lock
- `LOCK_EX` – acquire an exclusive lock

When *operation* is `LOCK_SH` or `LOCK_EX`, it can also be bitwise ORed with `LOCK_NB` to avoid blocking on lock acquisition. If `LOCK_NB` is used and the lock cannot be acquired, an `IOError` will be raised and the exception will have an `errno` attribute set to `EACCES` or `EAGAIN` (depending on the operating system; for portability, check for both values). On at least some systems, `LOCK_EX` can only be used if the file descriptor refers to a file opened for writing.

*length* is the number of bytes to lock, *start* is the byte offset at which the lock starts, relative to *whence*, and *whence* is as with `io.IOBase.seek()`, specifically :

- 0 – relative to the start of the file (`os.SEEK_SET`)

- 1 – relative to the current buffer position (*os.SEEK\_CUR*)
- 2 – relative to the end of the file (*os.SEEK\_END*)

The default for *start* is 0, which means to start at the beginning of the file. The default for *length* is 0 which means to lock to the end of the file. The default for *whence* is also 0.

Examples (all on a SVR4 compliant system) :

```
import struct, fcntl, os

f = open(...)
rv = fcntl.fcntl(f, fcntl.F_SETFL, os.O_NDELAY)

lockdata = struct.pack('hhllhh', fcntl.F_WRLCK, 0, 0, 0, 0, 0)
rv = fcntl.fcntl(f, fcntl.F_SETLKW, lockdata)
```

Note that in the first example the return value variable *rv* will hold an integer value; in the second example it will hold a string value. The structure lay-out for the *lockdata* variable is system dependent — therefore using the *flock()* call may be better.

Voir aussi :

**Module *os*** If the locking flags *O\_SHLOCK* and *O\_EXLOCK* are present in the *os* module (on BSD only), the *os.open()* function provides an alternative to the *lockf()* and *flock()* functions.

## 36.11 pipes — Interface au *pipelines* shell

Code source : [Lib/pipes.py](#)

---

Le module *pipes* définit une classe permettant d'abstraire le concept de *pipeline* — une séquence de convertisseurs d'un fichier vers un autre.

Du fait que le module utilise les lignes de commandes */bin/sh*, un shell POSIX ou compatible est requis pour *os.system()* et *os.popen()*.

**class *pipes.Template***  
Une abstraction d'un *pipeline*.

Exemple :

```
>>> import pipes
>>> t = pipes.Template()
>>> t.append('tr a-z A-Z', '--')
>>> f = t.open('pipefile', 'w')
>>> f.write('hello world')
>>> f.close()
>>> open('pipefile').read()
'HELLO WORLD'
```

***pipes.quote(s)***

Obsolète depuis la version 2.7 : Prior to Python 2.7, this function was not publicly documented. It is finally exposed publicly in Python 3.3 as the *quote* function in the *shlex* module.

Return a shell-escaped version of the string *s*. The returned value is a string that can safely be used as one token in a shell command line, for cases where you cannot use a list.

This idiom would be unsafe :

```
>>> filename = 'somefile; rm -rf ~'
>>> command = 'ls -l {}'.format(filename)
>>> print command # executed by a shell: boom!
ls -l somefile; rm -rf ~
```

`quote()` lets you plug the security hole :

```
>>> command = 'ls -l {}'.format(quote(filename))
>>> print command
ls -l 'somefile; rm -rf ~'
>>> remote_command = 'ssh home {}'.format(quote(command))
>>> print remote_command
ssh home 'ls -l \''somefile; rm -rf ~\''
```

The quoting is compatible with UNIX shells and with `shlex.split()` :

```
>>> remote_command = shlex.split(remote_command)
>>> remote_command
['ssh', 'home', 'ls -l 'somefile; rm -rf ~']
>>> command = shlex.split(remote_command[-1])
>>> command
['ls', '-l', 'somefile; rm -rf ~']
```

### 36.11.1 L'Objet *Template*

Les méthodes de l'objet *Template* :

**Template.reset()**

Réinitialise un modèle de *pipeline* à son état initial.

**Template.clone()**

Renvoie un nouveau modèle de *pipeline*, équivalent.

**Template.debug(flag)**

Si *flag* est vrai, active le débogage. Sinon, le désactive. Quand le débogage est actif, les commandes à exécuter seront affichées et le shell est pourvu de la commande `set -x` afin d'être plus verbeux.

**Template.append(cmd, kind)**

Ajoute une nouvelle action à la fin. La variable *cmd* doit être une commande *bourne shell* valide. La variable *kind* est composée de deux lettres.

La première lettre peut soit être '-' (qui signifie que la commande lit sa sortie standard), soit 'f' (qui signifie que la commande lit un fichier donné par la ligne de commande), soit '.' (qui signifie que la commande ne lit pas d'entrée, et donc doit être la première.)

De même, la seconde lettre peut soit être '-' (qui signifie que la commande écrit sur la sortie standard), soit 'f' (qui signifie que la commande écrit sur un fichier donné par la ligne de commande), soit '.' (qui signifie que la commande n'écrit rien, et donc doit être la dernière.)

**Template.prepend(cmd, kind)**

Ajoute une nouvelle action au début. Voir `append()` pour plus d'explications sur les arguments.

**Template.open(file, mode)**

Renvoie un objet *file-like*, ouvert à *file*, mais permettant d'écrire vers le *pipeline* ou de lire depuis celui-ci. À noter que seulement un des deux ("r" ou "w") peut être donné.

**Template.copy(infile, outfile)**

Copie *infile* vers *outfile* au travers du *pipe*.

## 36.12 posixfile — File-like objects with locking support

Obsolète depuis la version 1.5 : The locking operation that this module provides is done better and more portably by the `fcntl.lockf()` call.

This module implements some additional functionality over the built-in file objects. In particular, it implements file locking, control over the file flags, and an easy interface to duplicate the file object. The module defines a new file object, the `posixfile` object. It has all the standard file object methods and adds the methods described below. This module only works for certain flavors of Unix, since it uses `fcntl.fcntl()` for file locking.

To instantiate a `posixfile` object, use the `posixfile.open()` function. The resulting object looks and feels roughly the same as a standard file object.

The `posixfile` module defines the following constants :

`posixfile.SEEK_SET`

Offset is calculated from the start of the file.

`posixfile.SEEK_CUR`

Offset is calculated from the current position in the file.

`posixfile.SEEK_END`

Offset is calculated from the end of the file.

The `posixfile` module defines the following functions :

`posixfile.open(filename[, mode[, bufsize]])`

Create a new `posixfile` object with the given filename and mode. The *filename*, *mode* and *bufsize* arguments are interpreted the same way as by the built-in `open()` function.

`posixfile.fileopen(fileobject)`

Create a new `posixfile` object with the given standard file object. The resulting object has the same filename and mode as the original file object.

The `posixfile` object defines the following additional methods :

`posixfile.lock(fmt[, len[, start[, whence]]])`

Lock the specified section of the file that the file object is referring to. The format is explained below in a table. The *len* argument specifies the length of the section that should be locked. The default is 0. *start* specifies the starting offset of the section, where the default is 0. The *whence* argument specifies where the offset is relative to. It accepts one of the constants `SEEK_SET`, `SEEK_CUR` or `SEEK_END`. The default is `SEEK_SET`. For more information about the arguments refer to the `fcntl(2)` manual page on your system.

`posixfile.flags([flags])`

Set the specified flags for the file that the file object is referring to. The new flags are ORed with the old flags, unless specified otherwise. The format is explained below in a table. Without the *flags* argument a string indicating the current flags is returned (this is the same as the `?` modifier). For more information about the flags refer to the `fcntl(2)` manual page on your system.

`posixfile.dup()`

Duplicate the file object and the underlying file pointer and file descriptor. The resulting object behaves as if it were newly opened.

`posixfile.dup2(fd)`

Duplicate the file object and the underlying file pointer and file descriptor. The new object will have the given file descriptor. Otherwise the resulting object behaves as if it were newly opened.

`posixfile.file()`

Return the standard file object that the `posixfile` object is based on. This is sometimes necessary for functions that insist on a standard file object.

All methods raise *`IOError`* when the request fails.

Format characters for the `lock()` method have the following meaning :

Format	Signification
<b>u</b>	unlock the specified region
<b>r</b>	request a read lock for the specified section
<b>w</b>	request a write lock for the specified section

In addition the following modifiers can be added to the format :

Modifier	Signification	Notes
<b>l</b>	wait until the lock has been granted	
<b>?</b>	return the first lock conflicting with the requested lock, or <code>None</code> if there is no conflict.	(1)

Note :

- (1) The lock returned is in the format (`mode`, `len`, `start`, `whence`, `pid`) where *mode* is a character representing the type of lock (“r” or “w”). This modifier prevents a request from being granted ; it is for query purposes only.

Format characters for the `flags()` method have the following meanings :

Format	Signification
<b>a</b>	append only flag
<b>c</b>	close on exec flag
<b>n</b>	no delay flag (also called non-blocking flag)
<b>s</b>	synchronization flag

In addition the following modifiers can be added to the format :

Modifier	Signification	Notes
<b>!</b>	turn the specified flags “off”, instead of the default “on”	(1)
<b>=</b>	replace the flags, instead of the default “OR” operation	(1)
<b>?</b>	return a string in which the characters represent the flags that are set.	(2)

Notes :

- (1) The `!` and `=` modifiers are mutually exclusive.
- (2) This string represents the flags after they may have been altered by the same call.

Exemples :

```
import posixfile

file = posixfile.open('testfile', 'w')
file.lock('w|')
...
file.lock('u')
file.close()
```

## 36.13 resource — Resource usage information

This module provides basic mechanisms for measuring and controlling system resources utilized by a program.

Symbolic constants are used to specify particular system resources and to request usage information about either the current process or its children.

A single exception is defined for errors :

### **exception resource.error**

The functions described below may raise this error if the underlying system call failures unexpectedly.

### 36.13.1 Resource Limits

Resources usage can be limited using the `setrlimit()` function described below. Each resource is controlled by a pair of limits : a soft limit and a hard limit. The soft limit is the current limit, and may be lowered or raised by a process over time. The soft limit can never exceed the hard limit. The hard limit can be lowered to any value greater than the soft limit, but not raised. (Only processes with the effective UID of the super-user can raise a hard limit.)

The specific resources that can be limited are system dependent. They are described in the `getrlimit(2)` man page. The resources listed below are supported when the underlying operating system supports them ; resources which cannot be checked or controlled by the operating system are not defined in this module for those platforms.

#### **resource.RLIM\_INFINITY**

Constant used to represent the limit for an unlimited resource.

#### **resource.getrlimit(resource)**

Returns a tuple (**soft**, **hard**) with the current soft and hard limits of *resource*. Raises `ValueError` if an invalid resource is specified, or `error` if the underlying system call fails unexpectedly.

#### **resource.setrlimit(resource, limits)**

Sets new limits of consumption of *resource*. The *limits* argument must be a tuple (**soft**, **hard**) of two integers describing the new limits. A value of `RLIM_INFINITY` can be used to request a limit that is unlimited.

Raises `ValueError` if an invalid resource is specified, if the new soft limit exceeds the hard limit, or if a process tries to raise its hard limit. Specifying a limit of `RLIM_INFINITY` when the hard or system limit for that resource is not unlimited will result in a `ValueError`. A process with the effective UID of super-user can request any valid limit value, including unlimited, but `ValueError` will still be raised if the requested limit exceeds the system imposed limit.

`setrlimit` may also raise `error` if the underlying system call fails.

These symbols define resources whose consumption can be controlled using the `setrlimit()` and `getrlimit()` functions described below. The values of these symbols are exactly the constants used by C programs.

The Unix man page for `getrlimit(2)` lists the available resources. Note that not all systems use the same symbol or same value to denote the same resource. This module does not attempt to mask platform differences — symbols not defined for a platform will not be available from this module on that platform.

#### **resource.RLIMIT\_CORE**

The maximum size (in bytes) of a core file that the current process can create. This may result in the creation of a partial core file if a larger core would be required to contain the entire process image.

#### **resource.RLIMIT\_CPU**

The maximum amount of processor time (in seconds) that a process can use. If this limit is exceeded, a `SIGXCPU` signal is sent to the process. (See the `signal` module documentation for information about how to catch this signal and do something useful, e.g. flush open files to disk.)

`resource.RLIMIT_FSIZE`

The maximum size of a file which the process may create.

`resource.RLIMIT_DATA`

The maximum size (in bytes) of the process's heap.

`resource.RLIMIT_STACK`

The maximum size (in bytes) of the call stack for the current process. This only affects the stack of the main thread in a multi-threaded process.

`resource.RLIMIT_RSS`

The maximum resident set size that should be made available to the process.

`resource.RLIMIT_NPROC`

The maximum number of processes the current process may create.

`resource.RLIMIT_NOFILE`

The maximum number of open file descriptors for the current process.

`resource.RLIMIT_OFILE`

The BSD name for [\*RLIMIT\\_NOFILE\*](#).

`resource.RLIMIT_MEMLOCK`

The maximum address space which may be locked in memory.

`resource.RLIMIT_VMEM`

The largest area of mapped memory which the process may occupy.

`resource.RLIMIT_AS`

The maximum area (in bytes) of address space which may be taken by the process.

### 36.13.2 Resource Usage

These functions are used to retrieve resource usage information :

`resource.getrusage(who)`

This function returns an object that describes the resources consumed by either the current process or its children, as specified by the *who* parameter. The *who* parameter should be specified using one of the `RUSAGE_*` constants described below.

The fields of the return value each describe how a particular system resource has been used, e.g. amount of time spent running in user mode or number of times the process was swapped out of main memory. Some values are dependent on the clock tick interval, e.g. the amount of memory the process is using. For backward compatibility, the return value is also accessible as a tuple of 16 elements.

The fields `ru_utime` and `ru_stime` of the return value are floating point values representing the amount of time spent executing in user mode and the amount of time spent executing in system mode, respectively. The remaining values are integers. Consult the [\*getrusage\(2\)\*](#) man page for detailed information about these values. A brief summary is presented here :

Index	Field	Resource
0	<code>ru_utime</code>	time in user mode (float)
1	<code>ru_stime</code>	time in system mode (float)
2	<code>ru_maxrss</code>	maximum resident set size
3	<code>ru_ixrss</code>	shared memory size
4	<code>ru_idrss</code>	unshared memory size
5	<code>ru_isrss</code>	unshared stack size
6	<code>ru_minflt</code>	page faults not requiring I/O
7	<code>ru_majflt</code>	page faults requiring I/O
8	<code>ru_nswap</code>	number of swap outs
9	<code>ru_inblock</code>	block input operations
10	<code>ru_oublock</code>	block output operations
11	<code>ru_msgsnd</code>	messages sent
12	<code>ru_msgrcv</code>	messages received
13	<code>ru_nsignals</code>	signals received
14	<code>ru_nvcsw</code>	voluntary context switches
15	<code>ru_nivcsw</code>	involuntary context switches

This function will raise a *ValueError* if an invalid *who* parameter is specified. It may also raise *error* exception in unusual circumstances.

Modifié dans la version 2.3 : Added access to values as attributes of the returned object.

`resource.getpagesize()`

Returns the number of bytes in a system page. (This need not be the same as the hardware page size.)

The following `RUSAGE_*` symbols are passed to the *getrusage()* function to specify which processes information should be provided for.

`resource.RUSAGE_SELF`

*RUSAGE\_SELF* should be used to request information pertaining only to the process itself.

`resource.RUSAGE_CHILDREN`

Pass to *getrusage()* to request resource information for child processes of the calling process.

`resource.RUSAGE_BOTH`

Pass to *getrusage()* to request resources consumed by both the current process and child processes. May not be available on all systems.

## 36.14 nis — Interface à Sun's NIS (pages jaunes)

Le module *nis* est une simple abstraction de la librairie NIS, utile pour l'administration centralisée de plusieurs hôtes.

Du fait que NIS existe seulement sur les systèmes Unix, ce module est seulement disponible pour Unix.

Le module *nis* définit les instructions suivantes :

`nis.match(key, mapname[, domain=default_domain])`

Renvoie la valeur correspondante à *key* dans carte *mapname*, ou lève une erreur (*nis.error*) s'il n'y en a pas. Toutes les deux doivent être des chaînes, *key* doit être une chaîne ASCII. La valeur renvoyée est un dictionnaire arbitraire d'octets (pourrait contenir NULL et autres joyeusetés).

Notez que *mapname* est vérifié la première fois si c'est un alias d'un autre nom.

Modifié dans la version 2.5 : L'argument *domain* permet de passer outre le domaine NIS utilisé pour les recherches. Lorsqu'il n'est pas spécifié, recherche est dans le domaine NIS défaut.

`nis.cat(mapname[, domain=default_domain])`

Renvoie un dictionnaire qui associe *key* à *value* tel que `match(key, mapname)==value`. Notez que les clés comme les valeurs peuvent contenir des séquences arbitraires d'octets.

Notez que *mapname* est vérifié la première fois si c'est un alias d'un autre nom.

Modifié dans la version 2.5 : L'argument *domain* permet de passer outre le domaine NIS utilisé pour les recherches. Lorsqu'il n'est pas spécifié, recherche est dans le domaine NIS défaut.

`nis.maps([domain=default_domain])`

Renvoie la liste de toutes les correspondances valides.

Modifié dans la version 2.5 : L'argument *domain* permet de passer outre le domaine NIS utilisé pour les recherches. Lorsqu'il n'est pas spécifié, recherche est dans le domaine NIS défaut.

`nis.get_default_domain()`

Renvoie le domaine NIS par défaut du système.

Nouveau dans la version 2.5.

Le module *nis* définit les exceptions suivantes :

**exception `nis.error`**

Une erreur apparaît quand une fonction NIS renvoie un code d'erreur.

## 36.15 syslog — Unix syslog library routines

This module provides an interface to the Unix **syslog** library routines. Refer to the Unix manual pages for a detailed description of the **syslog** facility.

This module wraps the system **syslog** family of routines. A pure Python library that can speak to a syslog server is available in the *logging.handlers* module as **SysLogHandler**.

Le module définit les fonctions suivantes :

`syslog.syslog(message)`

`syslog.syslog(priority, message)`

Send the string *message* to the system logger. A trailing newline is added if necessary. Each message is tagged with a priority composed of a *facility* and a *level*. The optional *priority* argument, which defaults to `LOG_INFO`, determines the message priority. If the facility is not encoded in *priority* using logical-or (`LOG_INFO | LOG_USER`), the value given in the *openlog()* call is used.

If *openlog()* has not been called prior to the call to *syslog()*, *openlog()* will be called with no arguments.

`syslog.openlog([ident[, logoption[, facility]]])`

Logging options of subsequent *syslog()* calls can be set by calling *openlog()*. *syslog()* will call *openlog()* with no arguments if the log is not currently open.

The optional *ident* keyword argument is a string which is prepended to every message, and defaults to `sys.argv[0]` with leading path components stripped. The optional *logoption* keyword argument (default is 0) is a bit field – see below for possible values to combine. The optional *facility* keyword argument (default is `LOG_USER`) sets the default facility for messages which do not have a facility explicitly encoded.

`syslog.closelog()`

Reset the syslog module values and call the system library *closelog()*.

This causes the module to behave as it does when initially imported. For example, *openlog()* will be called on the first *syslog()* call (if *openlog()* hasn't already been called), and *ident* and other *openlog()* parameters are reset to defaults.

`syslog.setlogmask(maskpri)`

Set the priority mask to *maskpri* and return the previous mask value. Calls to *syslog()* with a priority

level not set in *maskpri* are ignored. The default is to log all priorities. The function `LOG_MASK(pri)` calculates the mask for the individual priority *pri*. The function `LOG_UPTO(pri)` calculates the mask for all priorities up to and including *pri*.

The module defines the following constants :

**Priority levels (high to low) :** `LOG_EMERG`, `LOG_ALERT`, `LOG_CRIT`, `LOG_ERR`, `LOG_WARNING`, `LOG_NOTICE`, `LOG_INFO`, `LOG_DEBUG`.

**Facilities :** `LOG_KERN`, `LOG_USER`, `LOG_MAIL`, `LOG_DAEMON`, `LOG_AUTH`, `LOG_LPR`, `LOG_NEWS`, `LOG_UUCP`, `LOG_CRON`, `LOG_SYSLOG` and `LOG_LOCAL0` to `LOG_LOCAL7`.

**Log options :** `LOG_PID`, `LOG_CONS`, `LOG_NDELAY`, `LOG_NOWAIT` and `LOG_PERROR` if defined in `<syslog.h>`.

## 36.15.1 Exemples

### Simple example

A simple set of examples :

```
import syslog

syslog.syslog('Processing started')
if error:
    syslog.syslog(syslog.LOG_ERR, 'Processing started')
```

An example of setting some log options, these would include the process ID in logged messages, and write the messages to the destination facility used for mail logging :

```
syslog.openlog(logoption=syslog.LOG_PID, facility=syslog.LOG_MAIL)
syslog.syslog('E-mail processing initiated...')
```

## 36.16 commands — Utilities for running commands

Obsolète depuis la version 2.6 : The *commands* module has been removed in Python 3. Use the *subprocess* module instead.

The *commands* module contains wrapper functions for *os.popen()* which take a system command as a string and return any output generated by the command and, optionally, the exit status.

The *subprocess* module provides more powerful facilities for spawning new processes and retrieving their results. Using the *subprocess* module is preferable to using the *commands* module.

---

**Note :** In Python 3.x, *getstatus()* and two undocumented functions (*mk2arg()* and *mkarg()*) have been removed. Also, *getstatusoutput()* and *getoutput()* have been moved to the *subprocess* module.

---

The *commands* module defines the following functions :

`commands.getstatusoutput(cmd)`

Execute the string *cmd* in a shell with *os.popen()* and return a 2-tuple (*status*, *output*). *cmd* is actually run as { *cmd* ; } 2>&1, so that the returned output will contain output or error messages. A trailing newline is stripped from the output. The exit status for the command can be interpreted according to the rules for the C function *wait()*.

`commands.getoutput(cmd)`

Like *getstatusoutput()*, except the exit status is ignored and the return value is a string containing the command's output.

`commands.getstatus(file)`

Return the output of `ls -ld file` as a string. This function uses the `getoutput()` function, and properly escapes backslashes and dollar signs in the argument.

Obsolète depuis la version 2.6 : This function is nonobvious and useless. The name is also misleading in the presence of `getstatusoutput()`.

Exemple :

```
>>> import commands
>>> commands.getstatusoutput('ls /bin/ls')
(0, '/bin/ls')
>>> commands.getstatusoutput('cat /bin/junk')
(256, 'cat: /bin/junk: No such file or directory')
>>> commands.getstatusoutput('/bin/junk')
(256, 'sh: /bin/junk: not found')
>>> commands.getoutput('ls /bin/ls')
'/bin/ls'
>>> commands.getstatus('/bin/ls')
'-rwxr-xr-x  1 root          13352 Oct 14  1994 /bin/ls'
```

Voir aussi :

Module `subprocess` Module for spawning and managing subprocesses.

---

Mac OS X specific services

---

This chapter describes modules that are only available on the Mac OS X platform.

See the chapters *MacPython OSA Modules* and *Undocumented Mac OS modules* for more modules, and the HOWTO using-on-mac for a general introduction to Mac-specific Python programming.

---

**Note :** Most of the OS X APIs that these modules use are deprecated or removed in recent versions of OS X. Many are not available when Python is executing in 64-bit mode. These modules have been removed in Python 3. You should avoid using them in Python 2.

---

## 37.1 `ic` — Access to the Mac OS X Internet Config

This module provides access to various internet-related preferences set through **System Preferences** or the **Finder**.

---

**Note :** This module has been removed in Python 3.x.

---

There is a low-level companion module `icglue` which provides the basic Internet Config access functionality. This low-level module is not documented, but the docstrings of the routines document the parameters and the routine names are the same as for the Pascal or C API to Internet Config, so the standard IC programmers' documentation can be used if this module is needed.

The `ic` module defines the `error` exception and symbolic names for all error codes Internet Config can produce; see the source for details.

**exception `ic.error`**

Exception raised on errors in the `ic` module.

The `ic` module defines the following class and function :

```
class ic.IC([signature[, ic]])
```

Create an Internet Config object. The signature is a 4-character creator code of the current application

(default 'Pyth') which may influence some of ICs settings. The optional *ic* argument is a low-level `icglue.icinstance` created beforehand, this may be useful if you want to get preferences from a different config file, etc.

```
ic.launchurl(url[, hint])
ic.parseurl(data[, start[, end[, hint]]])
ic.mapfile(file)
ic.maptypescreator(type, creator[, filename])
ic.settypescreator(file)
```

These functions are « shortcuts » to the methods of the same name, described below.

### 37.1.1 IC Objects

*IC* objects have a mapping interface, hence to obtain the mail address you simply get `ic['MailAddress']`. Assignment also works, and changes the option in the configuration file.

The module knows about various datatypes, and converts the internal IC representation to a « logical » Python data structure. Running the *ic* module standalone will run a test program that lists all keys and values in your IC database, this will have to serve as documentation.

If the module does not know how to represent the data it returns an instance of the `ICOpaqueData` type, with the raw data in its `data` attribute. Objects of this type are also acceptable values for assignment.

Besides the dictionary interface, *IC* objects have the following methods :

**IC.launchurl**(url[, hint])

Parse the given URL, launch the correct application and pass it the URL. The optional *hint* can be a scheme name such as 'mailto:', in which case incomplete URLs are completed with this scheme. If *hint* is not provided, incomplete URLs are invalid.

**IC.parseurl**(data[, start[, end[, hint]]])

Find a URL somewhere in *data* and return start position, end position and the URL. The optional *start* and *end* can be used to limit the search, so for instance if a user clicks in a long text field you can pass the whole text field and the click-position in *start* and this routine will return the whole URL in which the user clicked. As above, *hint* is an optional scheme used to complete incomplete URLs.

**IC.mapfile**(file)

Return the mapping entry for the given *file*, which can be passed as either a filename or an `FSSpec()` result, and which need not exist.

The mapping entry is returned as a tuple (*version*, *type*, *creator*, *postcreator*, *flags*, *extension*, *appname*, *postappname*, *mimetype*, *entryname*), where *version* is the entry version number, *type* is the 4-character filetype, *creator* is the 4-character creator type, *postcreator* is the 4-character creator code of an optional application to post-process the file after downloading, *flags* are various bits specifying whether to transfer in binary or ascii and such, *extension* is the filename extension for this file type, *appname* is the printable name of the application to which this file belongs, *postappname* is the name of the postprocessing application, *mimetype* is the MIME type of this file and *entryname* is the name of this entry.

**IC.maptypescreator**(type, creator[, filename])

Return the mapping entry for files with given 4-character *type* and *creator* codes. The optional *filename* may be specified to further help finding the correct entry (if the creator code is '????', for instance).

The mapping entry is returned in the same format as for *mapfile*.

**IC.settypescreator**(file)

Given an existing *file*, specified either as a filename or as an `FSSpec()` result, set its creator and type correctly based on its extension. The finder is told about the change, so the finder icon will be updated quickly.

## 37.2 MacOS — Access to Mac OS interpreter features

This module provides access to MacOS specific functionality in the Python interpreter, such as how the interpreter eventloop functions and the like. Use with care.

---

**Note :** This module has been removed in Python 3.x.

---

Note the capitalization of the module name; this is a historical artifact.

### `MacOS.runtimeModel`

Always 'macho', from Python 2.4 on. In earlier versions of Python the value could also be 'ppc' for the classic Mac OS 8 runtime model or 'carbon' for the Mac OS 9 runtime model.

### `MacOS.linkModel`

The way the interpreter has been linked. As extension modules may be incompatible between linking models, packages could use this information to give more decent error messages. The value is one of 'static' for a statically linked Python, 'framework' for Python in a Mac OS X framework, 'shared' for Python in a standard Unix shared library. Older Pythons could also have the value 'cfm' for Mac OS 9-compatible Python.

### `exception MacOS.Error`

This exception is raised on MacOS generated errors, either from functions in this module or from other mac-specific modules like the toolbox interfaces. The arguments are the integer error code (the `OSErr` value) and a textual description of the error code. Symbolic names for all known error codes are defined in the standard module `macerrors`.

### `MacOS.GetErrorString(errno)`

Return the textual description of MacOS error code *errno*.

### `MacOS.DebugStr(message[, object])`

On Mac OS X the string is simply printed to stderr (on older Mac OS systems more elaborate functionality was available), but it provides a convenient location to attach a breakpoint in a low-level debugger like `gdb`.

---

**Note :** Not available in 64-bit mode.

---

### `MacOS.SysBeep()`

Ring the bell.

---

**Note :** Not available in 64-bit mode.

---

### `MacOS.GetTicks()`

Get the number of clock ticks (1/60th of a second) since system boot.

### `MacOS.GetCreatorAndType(file)`

Return the file creator and file type as two four-character strings. The *file* parameter can be a pathname or an `FSSpec` or `FSRef` object.

---

**Note :** It is not possible to use an `FSSpec` in 64-bit mode.

---

### `MacOS.SetCreatorAndType(file, creator, type)`

Set the file creator and file type. The *file* parameter can be a pathname or an `FSSpec` or `FSRef` object. *creator* and *type* must be four character strings.

---

**Note :** It is not possible to use an `FSSpec` in 64-bit mode.

---

`MacOS.openrf(name[, mode])`

Open the resource fork of a file. Arguments are the same as for the built-in function `open()`. The object returned has file-like semantics, but it is not a Python file object, so there may be subtle differences.

`MacOS.WMAvailable()`

Checks whether the current process has access to the window manager. The method will return `False` if the window manager is not available, for instance when running on Mac OS X Server or when logged in via ssh, or when the current interpreter is not running from a fullblown application bundle. A script runs from an application bundle either when it has been started with `pythonw` instead of `python` or when running as an applet.

`MacOS.splash([resourceid])`

Opens a splash screen by resource id. Use resourceid 0 to close the splash screen.

---

**Note :** Not available in 64-bit mode.

---

## 37.3 macostools — Convenience routines for file manipulation

This module contains some convenience routines for file-manipulation on the Macintosh. All file parameters can be specified as pathnames, `FSRef` or `FSSpec` objects. This module expects a filesystem which supports forked files, so it should not be used on UFS partitions.

---

**Note :** This module has been removed in Python 3.

---

The `macostools` module defines the following functions :

`macostools.copy(src, dst[, createpath[, copytimes]])`

Copy file `src` to `dst`. If `createpath` is non-zero the folders leading to `dst` are created if necessary. The method copies data and resource fork and some finder information (creator, type, flags) and optionally the creation, modification and backup times (default is to copy them). Custom icons, comments and icon position are not copied.

---

**Note :** This function does not work in 64-bit code because it uses APIs that are not available in 64-bit mode.

---

`macostools.copypath(src, dst)`

Recursively copy a file tree from `src` to `dst`, creating folders as needed. `src` and `dst` should be specified as pathnames.

---

**Note :** This function does not work in 64-bit code because it uses APIs that are not available in 64-bit mode.

---

`macostools.mkalias(src, dst)`

Create a finder alias `dst` pointing to `src`.

---

**Note :** This function does not work in 64-bit code because it uses APIs that are not available in 64-bit mode.

---

`macostools.touched(dst)`

Tell the finder that some bits of finder-information such as creator or type for file *dst* has changed. The file can be specified by pathname or fsspec. This call should tell the finder to redraw the files icon.

Obsolète depuis la version 2.6 : The function is a no-op on OS X.

`macostools.BUFSIZ`

The buffer size for `copy`, default 1 megabyte.

Note that the process of creating finder aliases is not specified in the Apple documentation. Hence, aliases created with `mkalias()` could conceivably have incompatible behaviour in some cases.

## 37.4 findertools — The finder's Apple Events interface

This module contains routines that give Python programs access to some functionality provided by the finder. They are implemented as wrappers around the AppleEvent interface to the finder.

All file and folder parameters can be specified either as full pathnames, or as `FSRef` or `FSSpec` objects.

The `findertools` module defines the following functions :

`findertools.launch(file)`

Tell the finder to launch *file*. What launching means depends on the file : applications are started, folders are opened and documents are opened in the correct application.

`findertools.Print(file)`

Tell the finder to print a file. The behaviour is identical to selecting the file and using the print command in the finder's file menu.

`findertools.copy(file, destdir)`

Tell the finder to copy a file or folder *file* to folder *destdir*. The function returns an `Alias` object pointing to the new file.

`findertools.move(file, destdir)`

Tell the finder to move a file or folder *file* to folder *destdir*. The function returns an `Alias` object pointing to the new file.

`findertools.sleep()`

Tell the finder to put the Macintosh to sleep, if your machine supports it.

`findertools.restart()`

Tell the finder to perform an orderly restart of the machine.

`findertools.shutdown()`

Tell the finder to perform an orderly shutdown of the machine.

## 37.5 EasyDialogs — Basic Macintosh dialogs

The `EasyDialogs` module contains some simple dialogs for the Macintosh. The dialogs get launched in a separate application which appears in the dock and must be clicked on for the dialogs be displayed. All routines take an optional resource ID parameter *id* with which one can override the `DLOG` resource used for the dialog, provided that the dialog items correspond (both type and item number) to those in the default `DLOG` resource. See source code for details.

---

**Note :** This module has been removed in Python 3.x.

---

The `EasyDialogs` module defines the following functions :

`EasyDialogs.Message(str[, id[, ok]])`

Displays a modal dialog with the message text *str*, which should be at most 255 characters long. The button text defaults to « OK », but is set to the string argument *ok* if the latter is supplied. Control is returned when the user clicks the « OK » button.

`EasyDialogs.AskString(prompt[, default[, id[, ok[, cancel]]]])`

Asks the user to input a string value via a modal dialog. *prompt* is the prompt message, and the optional *default* supplies the initial value for the string (otherwise "" is used). The text of the « OK » and « Cancel » buttons can be changed with the *ok* and *cancel* arguments. All strings can be at most 255 bytes long. *AskString()* returns the string entered or *None* in case the user cancelled.

`EasyDialogs.AskPassword(prompt[, default[, id[, ok[, cancel]]]])`

Asks the user to input a string value via a modal dialog. Like *AskString()*, but with the text shown as bullets. The arguments have the same meaning as for *AskString()*.

`EasyDialogs.AskYesNoCancel(question[, default[, yes[, no[, cancel[, id]]]])`

Presents a dialog with prompt *question* and three buttons labelled « Yes », « No », and « Cancel ». Returns 1 for « Yes », 0 for « No » and -1 for « Cancel ». The value of *default* (or 0 if *default* is not supplied) is returned when the RETURN key is pressed. The text of the buttons can be changed with the *yes*, *no*, and *cancel* arguments; to prevent a button from appearing, supply "" for the corresponding argument.

`EasyDialogs.ProgressBar([title[, maxval[, label[, id]]]])`

Displays a modeless progress-bar dialog. This is the constructor for the *ProgressBar* class described below. *title* is the text string displayed (default « Working... »), *maxval* is the value at which progress is complete (default 0, indicating that an indeterminate amount of work remains to be done), and *label* is the text that is displayed above the progress bar itself.

`EasyDialogs.GetArgv([optionlist/ commandlist[, addoldfile[, addnewfile[, addfolder[, id]]]])`

Displays a dialog which aids the user in constructing a command-line argument list. Returns the list in `sys.argv` format, suitable for passing as an argument to *getopt.getopt()*. *addoldfile*, *addnewfile*, and *addfolder* are boolean arguments. When nonzero, they enable the user to insert into the command line paths to an existing file, a (possibly) not-yet-existent file, and a folder, respectively. (Note : Option arguments must appear in the command line before file and folder arguments in order to be recognized by *getopt.getopt()*.) Arguments containing spaces can be specified by enclosing them within single or double quotes. A *SystemExit* exception is raised if the user presses the « Cancel » button.

*optionlist* is a list that determines a popup menu from which the allowed options are selected. Its items can take one of two forms : *optstr* or (*optstr*, *descr*). When present, *descr* is a short descriptive string that is displayed in the dialog while this option is selected in the popup menu. The correspondence between *optstrs* and command-line arguments is :

<i>optstr</i> format	Command-line format
<b>x</b>	-x (short option)
<b>x:</b> or <b>x=</b>	-x (short option with value)
<b>xyz</b>	--xyz (long option)
<b>xyz:</b> or <b>xyz=</b>	--xyz (long option with value)

*commandlist* is a list of items of the form *cmdstr* or (*cmdstr*, *descr*), where *descr* is as above. The *cmdstrs* will appear in a popup menu. When chosen, the text of *cmdstr* will be appended to the command line as is, except that a trailing ':' or '=' (if present) will be trimmed off.

Nouveau dans la version 2.0.

`EasyDialogs.AskFileForOpen([message] [, typeList] [, defaultLocation] [, defaultOptionFlags] [, location] [, clientName] [, windowTitle] [, actionButtonLabel] [, cancelButtonLabel] [, preferenceKey] [, popupExtension] [, eventProc] [, previewProc] [, filterProc] [, wanted] )`

Post a dialog asking the user for a file to open, and return the file selected or *None* if the user cancelled.

*message* is a text message to display, *typeList* is a list of 4-char filetypes allowable, *defaultLocation* is the pathname, *FSSpec* or *FSRef* of the folder to show initially, *location* is the (x, y) position on the screen where the dialog is shown, *actionButtonLabel* is a string to show instead of « Open » in the OK button, *cancelButtonLabel* is a string to show instead of « Cancel » in the cancel button, *wanted* is the type of value wanted as a return : *str*, *unicode*, *FSSpec*, *FSRef* and subtypes thereof are acceptable.

For a description of the other arguments please see the Apple Navigation Services documentation and the *EasyDialogs* source code.

```
EasyDialogs.AskFileForSave([message] [, savedFileName] [, defaultLocation] [, defaultOptionFlags]
                           [, location] [, clientName] [, windowTitle] [, actionButtonLabel] [, can-
                           celButtonLabel] [, preferenceKey] [, popupExtension] [, fileType] [, fi-
                           leCreator] [, eventProc] [, wanted] )
```

Post a dialog asking the user for a file to save to, and return the file selected or *None* if the user cancelled. *savedFileName* is the default for the file name to save to (the return value). See *AskFileForOpen()* for a description of the other arguments.

```
EasyDialogs.AskFolder([message] [, defaultLocation] [, defaultOptionFlags] [, location] [, clientName]
                      [, windowTitle] [, actionButtonLabel] [, cancelButtonLabel] [, preferenceKey]
                      [, popupExtension] [, eventProc] [, filterProc] [, wanted] )
```

Post a dialog asking the user to select a folder, and return the folder selected or *None* if the user cancelled. See *AskFileForOpen()* for a description of the arguments.

**Navigation Services Reference** Programmer's reference documentation for the Navigation Services, a part of the Carbon framework.

### 37.5.1 ProgressBar Objects

*ProgressBar* objects provide support for modeless progress-bar dialogs. Both determinate (thermometer style) and indeterminate (barber-pole style) progress bars are supported. The bar will be determinate if its maximum value is greater than zero; otherwise it will be indeterminate.

Modifié dans la version 2.2 : Support for indeterminate-style progress bars was added.

The dialog is displayed immediately after creation. If the dialog's « Cancel » button is pressed, or if Cmd- or ESC is typed, the dialog window is hidden and *KeyboardInterrupt* is raised (but note that this response does not occur until the progress bar is next updated, typically via a call to *inc()* or *set()*). Otherwise, the bar remains visible until the *ProgressBar* object is discarded.

*ProgressBar* objects possess the following attributes and methods :

**ProgressBar.curval**

The current value (of type integer or long integer) of the progress bar. The normal access methods coerce *curval* between 0 and *maxval*. This attribute should not be altered directly.

**ProgressBar.maxval**

The maximum value (of type integer or long integer) of the progress bar; the progress bar (thermometer style) is full when *curval* equals *maxval*. If *maxval* is 0, the bar will be indeterminate (barber-pole). This attribute should not be altered directly.

**ProgressBar.title([newstr])**

Sets the text in the title bar of the progress dialog to *newstr*.

**ProgressBar.label([newstr])**

Sets the text in the progress box of the progress dialog to *newstr*.

**ProgressBar.set(value[, max])**

Sets the progress bar's *curval* to *value*, and also *maxval* to *max* if the latter is provided. *value* is first

coerced between 0 and *maxval*. The thermometer bar is updated to reflect the changes, including a change from indeterminate to determinate or vice versa.

`ProgressBar.inc(n)`

Increments the progress bar's *curval* by *n*, or by 1 if *n* is not provided. (Note that *n* may be negative, in which case the effect is a decrement.) The progress bar is updated to reflect the change. If the bar is indeterminate, this causes one « spin » of the barber pole. The resulting *curval* is coerced between 0 and *maxval* if incrementing causes it to fall outside this range.

## 37.6 Framework — Interactive application framework

The *Framework* module contains classes that together provide a framework for an interactive Macintosh application. The programmer builds an application by creating subclasses that override various methods of the bases classes, thereby implementing the functionality wanted. Overriding functionality can often be done on various different levels, i.e. to handle clicks in a single dialog window in a non-standard way it is not necessary to override the complete event handling.

---

**Note :** This module has been removed in Python 3.x.

---

Work on the *Framework* has pretty much stopped, now that PyObjC is available for full Cocoa access from Python, and the documentation describes only the most important functionality, and not in the most logical manner at that. Examine the source or the examples for more details. The following are some comments posted on the MacPython newsgroup about the strengths and limitations of *Framework* :

The strong point of *Framework* is that it allows you to break into the control-flow at many different places. *W*, for instance, uses a different way to enable/disable menus and that plugs right in leaving the rest intact. The weak points of *Framework* are that it has no abstract command interface (but that shouldn't be difficult), that its dialog support is minimal and that its control/toolbar support is non-existent.

The *Framework* module defines the following functions :

`Framework.Application()`

An object representing the complete application. See below for a description of the methods. The default `__init__()` routine creates an empty window dictionary and a menu bar with an apple menu.

`Framework.MenuBar()`

An object representing the menubar. This object is usually not created by the user.

`Framework.Menu(bar, title[, after])`

An object representing a menu. Upon creation you pass the `MenuBar` the menu appears in, the *title* string and a position (1-based) *after* where the menu should appear (default : at the end).

`Framework.MenuItem(menu, title[, shortcut, callback])`

Create a menu item object. The arguments are the menu to create, the item title string and optionally the keyboard shortcut and a callback routine. The callback is called with the arguments menu-id, item number within menu (1-based), current front window and the event record.

Instead of a callable object the callback can also be a string. In this case menu selection causes the lookup of a method in the topmost window and the application. The method name is the callback string with 'domenu\_' prepended.

Calling the `MenuBar fixmenudimstate()` method sets the correct dimming for all menu items based on the current front window.

`Framework.Separator(menu)`

Add a separator to the end of a menu.

`FrameWork.SubMenu(menu, label)`

Create a submenu named *label* under menu *menu*. The menu object is returned.

`FrameWork.Window(parent)`

Creates a (modeless) window. *Parent* is the application object to which the window belongs. The window is not displayed until later.

`FrameWork.DialogWindow(parent)`

Creates a modeless dialog window.

`FrameWork.windowbounds(width, height)`

Return a (left, top, right, bottom) tuple suitable for creation of a window of given width and height. The window will be staggered with respect to previous windows, and an attempt is made to keep the whole window on-screen. However, the window will however always be the exact size given, so parts may be offscreen.

`FrameWork.setwatchcursor()`

Set the mouse cursor to a watch.

`FrameWork.setarrowcursor()`

Set the mouse cursor to an arrow.

### 37.6.1 Application Objects

Application objects have the following methods, among others :

`Application.makeusermenus()`

Override this method if you need menus in your application. Append the menus to the attribute `menubar`.

`Application.getabouttext()`

Override this method to return a text string describing your application. Alternatively, override the `do_about()` method for more elaborate « about » messages.

`Application.mainloop([mask[, wait]])`

This routine is the main event loop, call it to set your application rolling. *Mask* is the mask of events you want to handle, *wait* is the number of ticks you want to leave to other concurrent application (default 0, which is probably not a good idea). While raising *self* to exit the mainloop is still supported it is not recommended : call `self._quit()` instead.

The event loop is split into many small parts, each of which can be overridden. The default methods take care of dispatching events to windows and dialogs, handling drags and resizes, Apple Events, events for non-FrameWork windows, etc.

In general, all event handlers should return 1 if the event is fully handled and 0 otherwise (because the front window was not a FrameWork window, for instance). This is needed so that update events and such can be passed on to other windows like the Sioux console window. Calling `MacOS.HandleEvent()` is not allowed within *our\_dispatch* or its callees, since this may result in an infinite loop if the code is called through the Python inner-loop event handler.

`Application.asynccevents(onoff)`

Call this method with a nonzero parameter to enable asynchronous event handling. This will tell the inner interpreter loop to call the application event handler *async\_dispatch* whenever events are available. This will cause FrameWork window updates and the user interface to remain working during long computations, but will slow the interpreter down and may cause surprising results in non-reentrant code (such as FrameWork itself). By default *async\_dispatch* will immediately call *our\_dispatch* but you may override this to handle only certain events asynchronously. Events you do not handle will be passed to Sioux and such.

The old on/off value is returned.

`Application._quit()`

Terminate the running *mainloop()* call at the next convenient moment.

`Application.do_char(c, event)`

The user typed character *c*. The complete details of the event can be found in the *event* structure. This method can also be provided in a `Window` object, which overrides the application-wide handler if the window is frontmost.

`Application.do_dialogevent(event)`

Called early in the event loop to handle modeless dialog events. The default method simply dispatches the event to the relevant dialog (not through the `DialogWindow` object involved). Override if you need special handling of dialog events (keyboard shortcuts, etc).

`Application.idle(event)`

Called by the main event loop when no events are available. The null-event is passed (so you can look at mouse position, etc).

## 37.6.2 Window Objects

Window objects have the following methods, among others :

`Window.open()`

Override this method to open a window. Store the Mac OS window-id in `self.wid` and call the `do_postopen()` method to register the window with the parent application.

`Window.close()`

Override this method to do any special processing on window close. Call the `do_postclose()` method to cleanup the parent state.

`Window.do_postresize(width, height, macoswindowid)`

Called after the window is resized. Override if more needs to be done than calling `InvalRect`.

`Window.do_contentclick(local, modifiers, event)`

The user clicked in the content part of a window. The arguments are the coordinates (window-relative), the key modifiers and the raw event.

`Window.do_update(macoswindowid, event)`

An update event for the window was received. Redraw the window.

`Window.do_activate(activate, event)`

The window was activated (`activate == 1`) or deactivated (`activate == 0`). Handle things like focus highlighting, etc.

## 37.6.3 ControlsWindow Object

ControlsWindow objects have the following methods besides those of `Window` objects :

`ControlsWindow.do_controlhit(window, control, pcode, event)`

Part *pcode* of control *control* was hit by the user. Tracking and such has already been taken care of.

## 37.6.4 ScrolledWindow Object

ScrolledWindow objects are ControlsWindow objects with the following extra methods :

`ScrolledWindow.scrollbars([wantx[, wanty]])`

Create (or destroy) horizontal and vertical scrollbars. The arguments specify which you want (default : both). The scrollbars always have minimum 0 and maximum 32767.

`ScrolledWindow.getscrollbarvalues()`

You must supply this method. It should return a tuple (*x*, *y*) giving the current position of the

scrollbars (between 0 and 32767). You can return `None` for either to indicate the whole document is visible in that direction.

`ScrolledWindow.updatescrollbars()`

Call this method when the document has changed. It will call `getscrollbarvalues()` and update the scrollbars.

`ScrolledWindow.scrollbar_callback(which, what, value)`

Supplied by you and called after user interaction. *which* will be 'x' or 'y', *what* will be '-', '--', 'set', '++' or '+'. For 'set', *value* will contain the new scrollbar position.

`ScrolledWindow.scalebarvalues(absmin, absmax, curmin, curmax)`

Auxiliary method to help you calculate values to return from `getscrollbarvalues()`. You pass document minimum and maximum value and topmost (leftmost) and bottommost (rightmost) visible values and it returns the correct number or `None`.

`ScrolledWindow.do_activate(onoff, event)`

Takes care of dimming/highlighting scrollbars when a window becomes frontmost. If you override this method, call this one at the end of your method.

`ScrolledWindow.do_postresize(width, height, window)`

Moves scrollbars to the correct position. Call this method initially if you override it.

`ScrolledWindow.do_controlhit(window, control, pcode, event)`

Handles scrollbar interaction. If you override it call this method first, a nonzero return value indicates the hit was in the scrollbars and has been handled.

### 37.6.5 DialogWindow Objects

DialogWindow objects have the following methods besides those of Window objects :

`DialogWindow.open(resid)`

Create the dialog window, from the DLOG resource with id *resid*. The dialog object is stored in `self.wid`.

`DialogWindow.do_itemhit(item, event)`

Item number *item* was hit. You are responsible for redrawing toggle buttons, etc.

## 37.7 autoGIL — Global Interpreter Lock handling in event loops

The `autoGIL` module provides a function `installAutoGIL()` that automatically locks and unlocks Python's *Global Interpreter Lock* when running an event loop.

---

**Note :** This module has been removed in Python 3.x.

---

**exception** `autoGIL.AutoGILError`

Raised if the observer callback cannot be installed, for example because the current thread does not have a run loop.

`autoGIL.installAutoGIL()`

Install an observer callback in the event loop (CFRunLoop) for the current thread, that will lock and unlock the Global Interpreter Lock (GIL) at appropriate times, allowing other Python threads to run while the event loop is idle.

Availability : OSX 10.1 or later.

## 37.8 Mac OS Toolbox Modules

These are a set of modules that provide interfaces to various legacy Mac OS toolboxes. If applicable the module will define a number of Python objects for the various structures declared by the toolbox, and operations will be implemented as methods of the object. Other operations will be implemented as functions in the module. Not all operations possible in C will also be possible in Python (callbacks are often a problem), and parameters will occasionally be different in Python (input and output buffers, especially). All methods and functions have a `__doc__` string describing their arguments and return values, and for additional description you are referred to [Inside Macintosh](#) or similar works.

These modules all live in a package called `Carbon`. Despite that name they are not all part of the Carbon framework : CF is really in the CoreFoundation framework and Qt is in the QuickTime framework. The normal use pattern is

```
from Carbon import AE
```

---

**Note :** Most of the OS X APIs that these modules use are deprecated or removed in recent versions of OS X. Many are not available when Python is executing in 64-bit mode. The Carbon modules have been removed in Python 3. You should avoid using them in Python 2.

---

### 37.8.1 `Carbon.AE` — Apple Events

### 37.8.2 `Carbon.AH` — Apple Help

### 37.8.3 `Carbon.App` — Appearance Manager

### 37.8.4 `Carbon.Appearance` — Appearance Manager constants

### 37.8.5 `Carbon.CF` — Core Foundation

The `CFBase`, `CFArray`, `CFData`, `CFDictionary`, `CFString` and `CFURL` objects are supported, some only partially.

- 37.8.6 `Carbon.CG` — **Core Graphics**
- 37.8.7 `Carbon.CarbonEvt` — **Carbon Event Manager**
- 37.8.8 `Carbon.CarbonEvents` — **Carbon Event Manager constants**
- 37.8.9 `Carbon.Cm` — **Component Manager**
- 37.8.10 `Carbon.Components` — **Component Manager constants**
- 37.8.11 `Carbon.ControlAccessor` — **Control Manager accssors**
- 37.8.12 `Carbon.Controls` — **Control Manager constants**
- 37.8.13 `Carbon.CoreFounation` — **CoreFounation constants**
- 37.8.14 `Carbon.CoreGraphics` — **CoreGraphics constants**
- 37.8.15 `Carbon.Ctl` — **Control Manager**
- 37.8.16 `Carbon.Dialogs` — **Dialog Manager constants**
- 37.8.17 `Carbon.Dlg` — **Dialog Manager**
- 37.8.18 `Carbon.Drag` — **Drag and Drop Manager**
- 37.8.19 `Carbon.Dragconst` — **Drag and Drop Manager constants**
- 37.8.20 `Carbon.Events` — **Event Manager constants**
- 37.8.21 `Carbon.Evt` — **Event Manager**
- 37.8.22 `Carbon.File` — **File Manager**
- 37.8.23 `Carbon.Files` — **File Manager constants**
- 37.8.24 `Carbon.Fm` — **Font Manager**
- 37.8.25 `Carbon.Folder` — **Folder Manager**
- 37.8.26 `Carbon.Folders` — **Folder Manager constants**
- 37.8.27 `Carbon.Fonts` — **Font Manager constants**
- 37.8.28 `Carbon.Help` — **Help Manager**
- 37.8.29 `Carbon.IBCarbon` — **Carbon InterfaceBuilder**
- 37.8.30 `Carbon.IBCarbonRuntime` — **Carbon InterfaceBuilder constants**
- 37.8.31 `Carbon.Icn` — **Carbon Icon Manager**
- 37.8.32 `Carbon.Icons` — **Carbon Icon Manager constants**
- 37.8.33 `Carbon.Launch` — **Carbon Launch Services**
- 37.8.34 `Carbon.LaunchServices` — **Carbon Launch Services constants**
- 37.8.35 `Carbon.List` — **List Manager**
- 37.8.36 `Carbon.Lists` — **List Manager constants**
- 37.8.37 `Carbon.MacHelp` — **Help Manager constants**
- 37.8.38 `Carbon.MediaDescr` — **Parsers and generators for Quicktime Media descriptors**
- 37.8.39 `Carbon.Menu` — **Menu Manager**
- 37.8.40 `Carbon.Menus` — **Menu Manager constants**
- 37.8.41 `Carbon.Mlto` — **Multilingual Text Editor**

The Scrap Manager supports the simplest form of cut & paste operations on the Macintosh. It can be use for both inter- and intra-application clipboard operations.

The `Scrap` module provides low-level access to the functions of the Scrap Manager. It contains the following functions :

`Carbon.Scrap.InfoScrap()`

Return current information about the scrap. The information is encoded as a tuple containing the fields (`size`, `handle`, `count`, `state`, `path`).

Field	Signification
<i>size</i>	Size of the scrap in bytes.
<i>handle</i>	Resource object representing the scrap.
<i>count</i>	Serial number of the scrap contents.
<i>state</i>	Integer ; positive if in memory, 0 if on disk, negative if uninitialized.
<i>path</i>	Filename of the scrap when stored on disk.

Voir aussi :

**Scrap Manager** Apple's documentation for the Scrap Manager gives a lot of useful information about using the Scrap Manager in applications.

### 37.8.53 `Carbon.Snd` — Sound Manager

### 37.8.54 `Carbon.Sound` — Sound Manager constants

### 37.8.55 `Carbon.TE` — TextEdit

### 37.8.56 `Carbon.TextEdit` — TextEdit constants

### 37.8.57 `Carbon.Win` — Window Manager

### 37.8.58 `Carbon.Windows` — Window Manager constants

## 37.9 `ColorPicker` — Color selection dialog

The `ColorPicker` module provides access to the standard color picker dialog.

---

**Note :** This module has been removed in Python 3.x.

---

`ColorPicker.GetColor(prompt, rgb)`

Show a standard color selection dialog and allow the user to select a color. The user is given instruction by the *prompt* string, and the default color is set to *rgb*. *rgb* must be a tuple giving the red, green, and blue components of the color. `GetColor()` returns a tuple giving the user's selected color and a flag indicating whether they accepted the selection of cancelled.

---

MacPython OSA Modules

---

This chapter describes the current implementation of the Open Scripting Architecture (OSA, also commonly referred to as AppleScript) for Python, allowing you to control scriptable applications from your Python program, and with a fairly pythonic interface. Development on this set of modules has stopped.

For a description of the various components of AppleScript and OSA, and to get an understanding of the architecture and terminology, you should read Apple's documentation. The « Applescript Language Guide » explains the conceptual model and the terminology, and documents the standard suite. The « Open Scripting Architecture » document explains how to use OSA from an application programmers point of view. In the Apple Help Viewer these books are located in the Developer Documentation, Core Technologies section.

As an example of scripting an application, the following piece of AppleScript will get the name of the frontmost **Finder** window and print it :

```
tell application "Finder"
    get name of window 1
end tell
```

In Python, the following code fragment will do the same :

```
import Finder

f = Finder.Finder()
print f.get(f.window(1).name)
```

As distributed the Python library includes packages that implement the standard suites, plus packages that interface to a small number of common applications.

To send AppleEvents to an application you must first create the Python package interfacing to the terminology of the application (what **Script Editor** calls the « Dictionary »). This can be done from within the **PythonIDE** or by running the `gensuitemodule.py` module as a standalone program from the command line.

The generated output is a package with a number of modules, one for every suite used in the program plus an `__init__` module to glue it all together. The Python inheritance graph follows the AppleScript inheritance graph, so if a program's dictionary specifies that it includes support for the Standard Suite, but extends one or two verbs with extra arguments then the output suite will contain a module `Standard_Suite`

that imports and re-exports everything from `StdSuites.Standard_Suite` but overrides the methods that have extra functionality. The output of *gensuitemodule* is pretty readable, and contains the documentation that was in the original AppleScript dictionary in Python docstrings, so reading it is a good source of documentation.

The output package implements a main class with the same name as the package which contains all the AppleScript verbs as methods, with the direct object as the first argument and all optional parameters as keyword arguments. AppleScript classes are also implemented as Python classes, as are comparisons and all the other thingies.

The main Python class implementing the verbs also allows access to the properties and elements declared in the AppleScript class « application ». In the current release that is as far as the object orientation goes, so in the example above we need to use `f.get(f.window(1).name)` instead of the more Pythonic `f.window(1).name.get()`.

If an AppleScript identifier is not a Python identifier the name is mangled according to a small number of rules :

- spaces are replaced with underscores
- other non-alphanumeric characters are replaced with `_xx_` where `xx` is the hexadecimal character value
- any Python reserved word gets an underscore appended

Python also has support for creating scriptable applications in Python, but The following modules are relevant to MacPython AppleScript support :

## 38.1 gensuitemodule — Generate OSA stub packages

The *gensuitemodule* module creates a Python package implementing stub code for the AppleScript suites that are implemented by a specific application, according to its AppleScript dictionary.

It is usually invoked by the user through the **PythonIDE**, but it can also be run as a script from the command line (pass `--help` for help on the options) or imported from Python code. For an example of its use see `Mac/scripts/genallsuites.py` in a source distribution, which generates the stub packages that are included in the standard library.

It defines the following public functions :

`gensuitemodule.is_scriptable(application)`

Returns true if `application`, which should be passed as a pathname, appears to be scriptable. Take the return value with a grain of salt : **Internet Explorer** appears not to be scriptable but definitely is.

`gensuitemodule.processfile(application[, output, basepkgname, edit_modnames, creatorsignature, dump, verbose])`

Create a stub package for `application`, which should be passed as a full pathname. For a `.app` bundle this is the pathname to the bundle, not to the executable inside the bundle ; for an unbundled CFM application you pass the filename of the application binary.

This function asks the application for its OSA terminology resources, decodes these resources and uses the resultant data to create the Python code for the package implementing the client stubs.

`output` is the pathname where the resulting package is stored, if not specified a standard « save file as » dialog is presented to the user. `basepkgname` is the base package on which this package will build, and defaults to `StdSuites`. Only when generating `StdSuites` itself do you need to specify this. `edit_modnames` is a dictionary that can be used to change modulenames that are too ugly after name mangling. `creator_signature` can be used to override the 4-char creator code, which is normally obtained from the `PkgInfo` file in the package or from the CFM file creator signature. When `dump` is given it should refer to a file object, and `processfile` will stop after decoding the resources and

dump the Python representation of the terminology resources to this file. **verbose** should also be a file object, and specifying it will cause **processfile** to tell you what it is doing.

```
gensuitemodule.processfile_fromresource(application[, output, basepkgname, edit_modnames,
                                         creatorsignature, dump, verbose])
```

This function does the same as **processfile**, except that it uses a different method to get the terminology resources. It opens **application** as a resource file and reads all "aete" and "aet" resources from this file.

## 38.2 aetools — OSA client support

The *aetools* module contains the basic functionality on which Python AppleScript client support is built. It also imports and re-exports the core functionality of the *aetypes* and *aepack* modules. The stub packages generated by *gensuitemodule* import the relevant portions of *aetools*, so usually you do not need to import it yourself. The exception to this is when you cannot use a generated suite package and need lower-level access to scripting.

The *aetools* module itself uses the AppleEvent support provided by the *Carbon.AE* module. This has one drawback : you need access to the window manager, see section osx-gui-scripts for details. This restriction may be lifted in future releases.

---

**Note :** This module has been removed in Python 3.x.

---

The *aetools* module defines the following functions :

**aetools.packevent**(*ae*, *parameters*, *attributes*)

Stores parameters and attributes in a pre-created *Carbon.AE.AEDesc* object. **parameters** and **attributes** are dictionaries mapping 4-character OSA parameter keys to Python objects. The objects are packed using *aepack.pack()*.

**aetools.unpackevent**(*ae*[, *formodulename*])

Recursively unpacks a *Carbon.AE.AEDesc* event to Python objects. The function returns the parameter dictionary and the attribute dictionary. The **formodulename** argument is used by generated stub packages to control where AppleScript classes are looked up.

**aetools.keysubst**(*arguments*, *keydict*)

Converts a Python keyword argument dictionary **arguments** to the format required by **packevent** by replacing the keys, which are Python identifiers, by the four-character OSA keys according to the mapping specified in **keydict**. Used by the generated suite packages.

**aetools.enumsubst**(*arguments*, *key*, *edict*)

If the **arguments** dictionary contains an entry for **key** convert the value for that entry according to dictionary **edict**. This converts human-readable Python enumeration names to the OSA 4-character codes. Used by the generated suite packages.

The *aetools* module defines the following class :

```
class aetools.TalkTo([signature=None, start=0, timeout=0])
```

Base class for the proxy used to talk to an application. **signature** overrides the class attribute **\_signature** (which is usually set by subclasses) and is the 4-char creator code defining the application to talk to. **start** can be set to true to enable running the application on class instantiation. **timeout** can be specified to change the default timeout used while waiting for an AppleEvent reply.

**TalkTo.\_start()**

Test whether the application is running, and attempt to start it if not.

`TalkTo.send(code, subcode[, parameters, attributes])`

Create the AppleEvent `Carbon.AE.AEDesc` for the verb with the OSA designation `code`, `subcode` (which are the usual 4-character strings), pack the `parameters` and `attributes` into it, send it to the target application, wait for the reply, unpack the reply with `unpackevent` and return the reply appleevent, the unpacked return values as a dictionary and the return attributes.

## 38.3 aepack — Conversion between Python variables and AppleEvent data containers

The `aepack` module defines functions for converting (packing) Python variables to AppleEvent descriptors and back (unpacking). Within Python the AppleEvent descriptor is handled by Python objects of built-in type `AEDesc`, defined in module `Carbon.AE`.

---

**Note :** This module has been removed in Python 3.x.

---

The `aepack` module defines the following functions :

`aepack.pack(x[, forcetype])`

Returns an `AEDesc` object containing a conversion of Python value `x`. If `forcetype` is provided it specifies the descriptor type of the result. Otherwise, a default mapping of Python types to Apple Event descriptor types is used, as follows :

Type Python	descriptor type
<code>FSSpec</code>	<code>typeFSS</code>
<code>FSRef</code>	<code>typeFSRef</code>
<code>Alias</code>	<code>typeAlias</code>
<code>integer</code>	<code>typeLong</code> (32 bit integer)
<code>float</code>	<code>typeFloat</code> (64 bit floating point)
<code>string</code>	<code>typeText</code>
<code>unicode</code>	<code>typeUnicodeText</code>
<code>list</code>	<code>typeAEList</code>
<code>dictionnaire</code>	<code>typeAERecord</code>
<code>instance</code>	<i>see below</i>

If `x` is a Python instance then this function attempts to call an `__aepack__()` method. This method should return an `AEDesc` object.

If the conversion `x` is not defined above, this function returns the Python string representation of a value (the `repr()` function) encoded as a text descriptor.

`aepack.unpack(x[, formodulename])`

`x` must be an object of type `AEDesc`. This function returns a Python object representation of the data in the Apple Event descriptor `x`. Simple AppleEvent data types (integer, text, float) are returned as their obvious Python counterparts. Apple Event lists are returned as Python lists, and the list elements are recursively unpacked. Object references (ex. [line 3 of document 1](#)) are returned as instances of `aetypes.ObjectSpecifier`, unless `formodulename` is specified. AppleEvent descriptors with descriptor type `typeFSS` are returned as `FSSpec` objects. AppleEvent record descriptors are returned as Python dictionaries, with 4-character string keys and elements recursively unpacked.

The optional `formodulename` argument is used by the stub packages generated by `gensuitemodule`, and ensures that the OSA classes for object specifiers are looked up in the correct module. This ensures that if, say, the Finder returns an object specifier for a window you get an instance of `Finder.Window` and not a generic `aetypes.Window`. The former knows about all the properties and elements a window has in the Finder, while the latter knows no such things.

Voir aussi :

Module `Carbon.AE` Built-in access to Apple Event Manager routines.

Module `aetypes` Python definitions of codes for Apple Event descriptor types.

## 38.4 aetypes — AppleEvent objects

The `aetypes` defines classes used to represent Apple Event data descriptors and Apple Event object specifiers.

Apple Event data is contained in descriptors, and these descriptors are typed. For many descriptors the Python representation is simply the corresponding Python type : `typeText` in OSA is a Python string, `typeFloat` is a float, etc. For OSA types that have no direct Python counterpart this module declares classes. Packing and unpacking instances of these classes is handled automatically by `aepack`.

An object specifier is essentially an address of an object implemented in an Apple Event server. An Apple Event specifier is used as the direct object for an Apple Event or as the argument of an optional parameter. The `aetypes` module contains the base classes for OSA classes and properties, which are used by the packages generated by `gensuitemodule` to populate the classes and properties in a given suite.

For reasons of backward compatibility, and for cases where you need to script an application for which you have not generated the stub package this module also contains object specifiers for a number of common OSA classes such as `Document`, `Window`, `Character`, etc.

---

**Note :** This module has been removed in Python 3.x.

---

The `AEObjects` module defines the following classes to represent Apple Event descriptor data :

**class** `aetypes.Unknown(type, data)`

The representation of OSA descriptor data for which the `aepack` and `aetypes` modules have no support, i.e. anything that is not represented by the other classes here and that is not equivalent to a simple Python value.

**class** `aetypes.Enum(enum)`

An enumeration value with the given 4-character string value.

**class** `aetypes.InsertionLoc(of, pos)`

Position `pos` in object `of`.

**class** `aetypes.Boolean(bool)`

A boolean.

**class** `aetypes.StyledText(style, text)`

Text with style information (font, face, etc) included.

**class** `aetypes.AEText(script, style, text)`

Text with script system and style information included.

**class** `aetypes.IntlText(script, language, text)`

Text with script system and language information included.

**class** `aetypes.IntlWritingCode(script, language)`

Script system and language information.

**class** `aetypes.QDPoint(v, h)`

A quickdraw point.

**class** `aetypes.QDRectangle(v0, h0, v1, h1)`

A quickdraw rectangle.

```
class aetypes.RGBColor(r, g, b)
    A color.
```

```
class aetypes.Type(type)
    An OSA type value with the given 4-character name.
```

```
class aetypes.Keyword(name)
    An OSA keyword with the given 4-character name.
```

```
class aetypes.Range(start, stop)
    A range.
```

```
class aetypes.Ordinal(abso)
    Non-numeric absolute positions, such as "firs", first, or "midd", middle.
```

```
class aetypes.Logical(logc, term)
    The logical expression of applying operator logc to term.
```

```
class aetypes.Comparison(obj1, relo, obj2)
    The comparison relo of obj1 to obj2.
```

The following classes are used as base classes by the generated stub packages to represent AppleScript classes and properties in Python :

```
class aetypes.ComponentItem(which[, fr])
    Abstract baseclass for an OSA class. The subclass should set the class attribute want to the 4-character OSA class code. Instances of subclasses of this class are equivalent to AppleScript Object Specifiers. Upon instantiation you should pass a selector in which, and optionally a parent object in fr.
```

```
class aetypes.NProperty(fr)
    Abstract baseclass for an OSA property. The subclass should set the class attributes want and which to designate which property we are talking about. Instances of subclasses of this class are Object Specifiers.
```

```
class aetypes.ObjectSpecifier(want, form, seld[, fr])
    Base class of ComponentItem and NProperty, a general OSA Object Specifier. See the Apple Open Scripting Architecture documentation for the parameters. Note that this class is not abstract.
```

## 38.5 MiniAEFrame — Open Scripting Architecture server support

The module *MiniAEFrame* provides a framework for an application that can function as an Open Scripting Architecture (OSA) server, i.e. receive and process AppleEvents. It can be used in conjunction with *FrameWork* or standalone. As an example, it is used in *PythonCGISlave*.

The *MiniAEFrame* module defines the following classes :

```
class MiniAEFrame.AEServer
    A class that handles AppleEvent dispatch. Your application should subclass this class together with either MiniApplication or FrameWork.Application. Your __init__() method should call the __init__() method for both classes.
```

```
class MiniAEFrame.MinApplication
    A class that is more or less compatible with FrameWork.Application but with less functionality. Its event loop supports the apple menu, command-dot and AppleEvents; other events are passed on to the Python interpreter and/or Sioux. Useful if your application wants to use AEServer but does not provide its own windows, etc.
```

### 38.5.1 AEServer Objects

`AEServer.installaehandler(classe, type, callback)`

Installs an AppleEvent handler. *classe* and *type* are the four-character OSA Class and Type designators, '\*\*\*\*' wildcards are allowed. When a matching AppleEvent is received the parameters are decoded and your callback is invoked.

`AEServer.callback(_object, **kwargs)`

Your callback is called with the OSA Direct Object as first positional parameter. The other parameters are passed as keyword arguments, with the 4-character designator as name. Three extra keyword parameters are passed : `_class` and `_type` are the Class and Type designators and `_attributes` is a dictionary with the AppleEvent attributes.

The return value of your method is packed with `aetools.packevent()` and sent as reply.

Note that there are some serious problems with the current design. AppleEvents which have non-identifier 4-character designators for arguments are not implementable, and it is not possible to return an error to the originator. This will be addressed in a future release.

In addition, support modules have been pre-generated for Finder, Terminal, Explorer, Netscape, CodeWarrior, SystemEvents and StdSuites.

---

SGI IRIX Specific Services

---

The modules described in this chapter provide interfaces to features that are unique to SGI's IRIX operating system (versions 4 and 5).

### 39.1 `al` — Audio functions on the SGI

Obsolète depuis la version 2.6 : The `al` module has been removed in Python 3.

This module provides access to the audio facilities of the SGI Indy and Indigo workstations. See section 3A of the IRIX man pages for details. You'll need to read those man pages to understand what these functions do! Some of the functions are not available in IRIX releases before 4.0.5. Again, see the manual to check whether a specific function is available on your platform.

All functions and methods defined in this module are equivalent to the C functions with `AL` prefixed to their name.

Symbolic constants from the C header file `<audio.h>` are defined in the standard module `AL`, see below.

**Avertissement :** The current version of the audio library may dump core when bad argument values are passed rather than returning an error status. Unfortunately, since the precise circumstances under which this may happen are undocumented and hard to check, the Python interface can provide no protection against this kind of problems. (One example is specifying an excessive queue size — there is no documented upper limit.)

Le module définit les fonctions suivantes :

`al.openport(name, direction[, config])`

The name and direction arguments are strings. The optional *config* argument is a configuration object as returned by `newconfig()`. The return value is an *audio port object*; methods of audio port objects are described below.

`al.newconfig()`

The return value is a new *audio configuration object*; methods of audio configuration objects are described below.

`al.queryparams(device)`

The *device* argument is an integer. The return value is a list of integers containing the data returned by `ALqueryparams()`.

`al.getparams(device, list)`

The *device* argument is an integer. The *list* argument is a list such as returned by `queryparams()`; it is modified in place (!).

`al.setparams(device, list)`

The *device* argument is an integer. The *list* argument is a list such as returned by `queryparams()`.

### 39.1.1 Configuration Objects

Configuration objects returned by `newconfig()` have the following methods :

`audio configuration.getqueuesize()`

Return the queue size.

`audio configuration.setqueuesize(size)`

Set the queue size.

`audio configuration.getwidth()`

Get the sample width.

`audio configuration.setwidth(width)`

Set the sample width.

`audio configuration.getchannels()`

Get the channel count.

`audio configuration.setchannels(nchannels)`

Set the channel count.

`audio configuration.getsampfmt()`

Get the sample format.

`audio configuration.setsampfmt(sampfmt)`

Set the sample format.

`audio configuration.getfloatmax()`

Get the maximum value for floating sample formats.

`audio configuration.setfloatmax(floatmax)`

Set the maximum value for floating sample formats.

### 39.1.2 Port Objects

Port objects, as returned by `openport()`, have the following methods :

`audio port.closeport()`

Close the port.

`audio port.getfd()`

Return the file descriptor as an int.

`audio port.getfilled()`

Return the number of filled samples.

`audio port.getfillable()`

Return the number of fillable samples.

`audio port.readsamps(nsamples)`

Read a number of samples from the queue, blocking if necessary. Return the data as a string containing the raw data, (e.g., 2 bytes per sample in big-endian byte order (high byte, low byte) if you have set the sample width to 2 bytes).

`audio port.writesamps(samples)`

Write samples into the queue, blocking if necessary. The samples are encoded as described for the `readsamps()` return value.

`audio port.getfillpoint()`

Return the “fill point”.

`audio port.setfillpoint(fillpoint)`

Set the “fill point”.

`audio port.getconfig()`

Return a configuration object containing the current configuration of the port.

`audio port.setconfig(config)`

Set the configuration from the argument, a configuration object.

`audio port.getstatus(list)`

Get status information on last error.

## 39.2 AL — Constants used with the `al` module

Obsolète depuis la version 2.6 : The `AL` module has been removed in Python 3.

This module defines symbolic constants needed to use the built-in module `al` (see above) ; they are equivalent to those defined in the C header file `<audio.h>` except that the name prefix `AL_` is omitted. Read the module source for a complete list of the defined names. Suggested use :

```
import al
from AL import *
```

## 39.3 `cd` — CD-ROM access on SGI systems

Obsolète depuis la version 2.6 : The `cd` module has been removed in Python 3.

This module provides an interface to the Silicon Graphics CD library. It is available only on Silicon Graphics systems.

The way the library works is as follows. A program opens the CD-ROM device with `open()` and creates a parser to parse the data from the CD with `createparser()`. The object returned by `open()` can be used to read data from the CD, but also to get status information for the CD-ROM device, and to get information about the CD, such as the table of contents. Data from the CD is passed to the parser, which parses the frames, and calls any callback functions that have previously been added.

An audio CD is divided into *tracks* or *programs* (the terms are used interchangeably). Tracks can be subdivided into *indices*. An audio CD contains a *table of contents* which gives the starts of the tracks on the CD. Index 0 is usually the pause before the start of a track. The start of the track as given by the table of contents is normally the start of index 1.

Positions on a CD can be represented in two ways. Either a frame number or a tuple of three values, minutes, seconds and frames. Most functions use the latter representation. Positions can be both relative to the beginning of the CD, and to the beginning of the track.

Module `cd` defines the following functions and constants :

`cd.createparser()`

Create and return an opaque parser object. The methods of the parser object are described below.

`cd.msftoframe(minutes, seconds, frames)`

Converts a (*minutes*, *seconds*, *frames*) triple representing time in absolute time code into the corresponding CD frame number.

`cd.open([device[, mode]])`

Open the CD-ROM device. The return value is an opaque player object ; methods of the player object are described below. The device is the name of the SCSI device file, e.g. `'/dev/scsi/sc0d410'`, or `None`. If omitted or `None`, the hardware inventory is consulted to locate a CD-ROM drive. The *mode*, if not omitted, should be the string `'r'`.

The module defines the following variables :

**exception `cd.error`**

Exception raised on various errors.

**`cd.DATASIZE`**

The size of one frame's worth of audio data. This is the size of the audio data as passed to the callback of type `audio`.

**`cd.BLOCKSIZE`**

The size of one uninterpreted frame of audio data.

The following variables are states as returned by `getstatus()` :

**`cd.READY`**

The drive is ready for operation loaded with an audio CD.

**`cd.NODISC`**

The drive does not have a CD loaded.

**`cd.CDROM`**

The drive is loaded with a CD-ROM. Subsequent play or read operations will return I/O errors.

**`cd.ERROR`**

An error occurred while trying to read the disc or its table of contents.

**`cd.PLAYING`**

The drive is in CD player mode playing an audio CD through its audio jacks.

**`cd.PAUSED`**

The drive is in CD layer mode with play paused.

**`cd.STILL`**

The equivalent of *PAUSED* on older (non 3301) model Toshiba CD-ROM drives. Such drives have never been shipped by SGI.

**`cd.audio`**

**`cd.pnum`**

**`cd.index`**

**`cd.ptime`**

**`cd.ptime`**

**`cd.catalog`**

**`cd.ident`**

**`cd.control`**

Integer constants describing the various types of parser callbacks that can be set by the `addcallback()` method of CD parser objects (see below).

### 39.3.1 Player Objects

Player objects (returned by `open()`) have the following methods :

**CD `player.allowremoval()`**

Unlocks the eject button on the CD-ROM drive permitting the user to eject the caddy if desired.

**CD `player.bestreadsize()`**

Returns the best value to use for the `num_frames` parameter of the `reada()` method. Best is defined as the value that permits a continuous flow of data from the CD-ROM drive.

**CD `player.close()`**

Frees the resources associated with the player object. After calling `close()`, the methods of the object should no longer be used.

**CD `player.eject()`**

Ejects the caddy from the CD-ROM drive.

**CD `player.getstatus()`**

Returns information pertaining to the current state of the CD-ROM drive. The returned information is a tuple with the following values : `state`, `track`, `rtime`, `atime`, `ttime`, `first`, `last`, `scsi_audio`, `cur_block`. `rtime` is the time relative to the start of the current track ; `atime` is the time relative to the beginning of the disc ; `ttime` is the total time on the disc. For more information on the meaning of the values, see the man page `CDgetstatus(3dm)`. The value of `state` is one of the following : `ERROR`, `NODISC`, `READY`, `PLAYING`, `PAUSED`, `STILL`, or `CDROM`.

**CD `player.gettrackinfo(track)`**

Returns information about the specified track. The returned information is a tuple consisting of two elements, the start time of the track and the duration of the track.

**CD `player.msftoblock(min, sec, frame)`**

Converts a minutes, seconds, frames triple representing a time in absolute time code into the corresponding logical block number for the given CD-ROM drive. You should use `msftoframe()` rather than `msftoblock()` for comparing times. The logical block number differs from the frame number by an offset required by certain CD-ROM drives.

**CD `player.play(start, play)`**

Starts playback of an audio CD in the CD-ROM drive at the specified track. The audio output appears on the CD-ROM drive's headphone and audio jacks (if fitted). Play stops at the end of the disc. `start` is the number of the track at which to start playing the CD ; if `play` is 0, the CD will be set to an initial paused state. The method `togglepause()` can then be used to commence play.

**CD `player.playabs(minutes, seconds, frames, play)`**

Like `play()`, except that the start is given in minutes, seconds, and frames instead of a track number.

**CD `player.playtrack(start, play)`**

Like `play()`, except that playing stops at the end of the track.

**CD `player.playtrackabs(track, minutes, seconds, frames, play)`**

Like `play()`, except that playing begins at the specified absolute time and ends at the end of the specified track.

**CD `player.preventremoval()`**

Locks the eject button on the CD-ROM drive thus preventing the user from arbitrarily ejecting the caddy.

**CD `player.reada(num_frames)`**

Reads the specified number of frames from an audio CD mounted in the CD-ROM drive. The return value is a string representing the audio frames. This string can be passed unaltered to the `parseframe()` method of the parser object.

**CD `player.seek(minutes, seconds, frames)`**

Sets the pointer that indicates the starting point of the next read of digital audio data from a CD-ROM. The pointer is set to an absolute time code location specified in *minutes*, *seconds*, and *frames*. The return value is the logical block number to which the pointer has been set.

**CD `player.seekblock(block)`**

Sets the pointer that indicates the starting point of the next read of digital audio data from a CD-ROM. The pointer is set to the specified logical block number. The return value is the logical block number to which the pointer has been set.

**CD `player.seektrack(track)`**

Sets the pointer that indicates the starting point of the next read of digital audio data from a CD-ROM. The pointer is set to the specified track. The return value is the logical block number to which the pointer has been set.

**CD `player.stop()`**

Stops the current playing operation.

**CD `player.togglepause()`**

Pauses the CD if it is playing, and makes it play if it is paused.

### 39.3.2 Parser Objects

Parser objects (returned by `createparser()`) have the following methods :

**CD `parser.addcallback(type, func, arg)`**

Adds a callback for the parser. The parser has callbacks for eight different types of data in the digital audio data stream. Constants for these types are defined at the `cd` module level (see above). The callback is called as follows : `func(arg, type, data)`, where *arg* is the user supplied argument, *type* is the particular type of callback, and *data* is the data returned for this *type* of callback. The type of the data depends on the *type* of callback as follows :

Type	Valeur
<code>audio</code>	String which can be passed unmodified to <code>al.writesamps()</code> .
<code>pnum</code>	Integer giving the program (track) number.
<code>index</code>	Integer giving the index number.
<code>ptime</code>	Tuple consisting of the program time in minutes, seconds, and frames.
<code>atime</code>	Tuple consisting of the absolute time in minutes, seconds, and frames.
<code>catalog</code>	String of 13 characters, giving the catalog number of the CD.
<code>ident</code>	String of 12 characters, giving the ISRC identification number of the recording. The string consists of two characters country code, three characters owner code, two characters giving the year, and five characters giving a serial number.
<code>control</code>	Integer giving the control bits from the CD subcode data

**CD `parser.deleteparser()`**

Deletes the parser and frees the memory it was using. The object should not be used after this call. This call is done automatically when the last reference to the object is removed.

**CD `parser.parseframe(frame)`**

Parses one or more frames of digital audio data from a CD such as returned by `readdda()`. It determines which subcodes are present in the data. If these subcodes have changed since the last frame, then `parseframe()` executes a callback of the appropriate type passing to it the subcode data found in the frame. Unlike the C function, more than one frame of digital audio data can be passed to this method.

**CD `parser.removecallback(type)`**

Removes the callback for the given *type*.

**CD `parser.resetparser()`**

Resets the fields of the parser used for tracking subcodes to an initial state. `resetparser()` should be called after the disc has been changed.

## 39.4 `fl` — FORMS library for graphical user interfaces

Obsolète depuis la version 2.6 : The `fl` module has been removed in Python 3.

This module provides an interface to the FORMS Library by Mark Overmars. The source for the library can be retrieved by anonymous FTP from host `ftp.cs.ruu.nl`, directory `SGI/FORMS`. It was last tested with version 2.0b.

Most functions are literal translations of their C equivalents, dropping the initial `fl_` from their name. Constants used by the library are defined in module `FL` described below.

The creation of objects is a little different in Python than in C : instead of the “current form” maintained by the library to which new FORMS objects are added, all functions that add a FORMS object to a form are methods of the Python object representing the form. Consequently, there are no Python equivalents for the C functions `fl_addto_form()` and `fl_end_form()`, and the equivalent of `fl_bgn_form()` is called `fl.make_form()`.

Watch out for the somewhat confusing terminology : FORMS uses the word *object* for the buttons, sliders etc. that you can place in a form. In Python, “object” means any value. The Python interface to FORMS introduces two new Python object types : form objects (representing an entire form) and FORMS objects (representing one button, slider etc.). Hopefully this isn’t too confusing.

There are no “free objects” in the Python interface to FORMS, nor is there an easy way to add object classes written in Python. The FORMS interface to GL event handling is available, though, so you can mix FORMS with pure GL windows.

**Please note :** importing `fl` implies a call to the GL function `foreground()` and to the FORMS routine `fl_init()`.

### 39.4.1 Functions Defined in Module `fl`

Module `fl` defines the following functions. For more information about what they do, see the description of the equivalent C function in the FORMS documentation :

**`fl.make_form(type, width, height)`**

Create a form with given type, width and height. This returns a *form* object, whose methods are described below.

**`fl.do_forms()`**

The standard FORMS main loop. Returns a Python object representing the FORMS object needing interaction, or the special value `FL.EVENT`.

**`fl.check_forms()`**

Check for FORMS events. Returns what `do_forms()` above returns, or `None` if there is no event that immediately needs interaction.

**`fl.set_event_callback(function)`**

Set the event callback function.

**`fl.set_graphics_mode(rgbmode, doublebuffering)`**

Set the graphics modes.

**`fl.get_rgbmode()`**

Return the current rgb mode. This is the value of the C global variable `fl_rgbmode`.

`fl.show_message(str1, str2, str3)`

Show a dialog box with a three-line message and an OK button.

`fl.show_question(str1, str2, str3)`

Show a dialog box with a three-line message and YES and NO buttons. It returns 1 if the user pressed YES, 0 if NO.

`fl.show_choice(str1, str2, str3, but1[, but2[, but3]])`

Show a dialog box with a three-line message and up to three buttons. It returns the number of the button clicked by the user (1, 2 or 3).

`fl.show_input(prompt, default)`

Show a dialog box with a one-line prompt message and text field in which the user can enter a string. The second argument is the default input string. It returns the string value as edited by the user.

`fl.show_file_selector(message, directory, pattern, default)`

Show a dialog box in which the user can select a file. It returns the absolute filename selected by the user, or None if the user presses Cancel.

`fl.get_directory()`

`fl.get_pattern()`

`fl.get_filename()`

These functions return the directory, pattern and filename (the tail part only) selected by the user in the last `show_file_selector()` call.

`fl.qdevice(dev)`

`fl.unqdevice(dev)`

`fl.isqueued(dev)`

`fl.qtest()`

`fl.qread()`

`fl.qreset()`

`fl.qenter(dev, val)`

`fl.get_mouse()`

`fl.tie(button, valuator1, valuator2)`

These functions are the FORMS interfaces to the corresponding GL functions. Use these if you want to handle some GL events yourself when using `fl.do_events()`. When a GL event is detected that FORMS cannot handle, `fl.do_forms()` returns the special value `FL.EVENT` and you should call `fl.qread()` to read the event from the queue. Don't use the equivalent GL functions!

`fl.color()`

`fl.mapcolor()`

`fl.getmcolor()`

See the description in the FORMS documentation of `fl_color()`, `fl_mapcolor()` and `fl_getmcolor()`.

### 39.4.2 Form Objects

Form objects (returned by `make_form()` above) have the following methods. Each method corresponds to a C function whose name is prefixed with `fl_`; and whose first argument is a form pointer; please refer to the official FORMS documentation for descriptions.

All the `add_*()` methods return a Python object representing the FORMS object. Methods of FORMS objects are described below. Most kinds of FORMS object also have some methods specific to that kind; these methods are listed here.

`form.show_form(placement, bordertype, name)`

Show the form.

---

```

form.hide_form()
    Hide the form.

form.redraw_form()
    Redraw the form.

form.set_form_position(x, y)
    Set the form's position.

form.freeze_form()
    Freeze the form.

form.unfreeze_form()
    Unfreeze the form.

form.activate_form()
    Activate the form.

form.deactivate_form()
    Deactivate the form.

form.bgn_group()
    Begin a new group of objects; return a group object.

form.end_group()
    End the current group of objects.

form.find_first()
    Find the first object in the form.

form.find_last()
    Find the last object in the form.

form.add_box(type, x, y, w, h, name)
    Add a box object to the form. No extra methods.

form.add_text(type, x, y, w, h, name)
    Add a text object to the form. No extra methods.

form.add_clock(type, x, y, w, h, name)
    Add a clock object to the form. — Method : get_clock().

form.add_button(type, x, y, w, h, name)
    Add a button object to the form. — Methods : get_button(), set_button().

form.add_lightbutton(type, x, y, w, h, name)
    Add a lightbutton object to the form. — Methods : get_button(), set_button().

form.add_roundbutton(type, x, y, w, h, name)
    Add a roundbutton object to the form. — Methods : get_button(), set_button().

form.add_slider(type, x, y, w, h, name)
    Add a slider object to the form. — Methods : set_slider_value(), get_slider_value(),
    set_slider_bounds(), get_slider_bounds(), set_slider_return(), set_slider_size(),
    set_slider_precision(), set_slider_step().

form.add_valslider(type, x, y, w, h, name)
    Add a valslider object to the form. — Methods : set_slider_value(), get_slider_value(),
    set_slider_bounds(), get_slider_bounds(), set_slider_return(), set_slider_size(),
    set_slider_precision(), set_slider_step().

```

`form.add_dial(type, x, y, w, h, name)`  
Add a dial object to the form. — Methods : `set_dial_value()`, `get_dial_value()`, `set_dial_bounds()`, `get_dial_bounds()`.

`form.add_positioner(type, x, y, w, h, name)`  
Add a positioner object to the form. — Methods : `set_positioner_xvalue()`, `set_positioner_yvalue()`, `set_positioner_xbounds()`, `set_positioner_ybounds()`, `get_positioner_xvalue()`, `get_positioner_yvalue()`, `get_positioner_xbounds()`, `get_positioner_ybounds()`.

`form.add_counter(type, x, y, w, h, name)`  
Add a counter object to the form. — Methods : `set_counter_value()`, `get_counter_value()`, `set_counter_bounds()`, `set_counter_step()`, `set_counter_precision()`, `set_counter_return()`.

`form.add_input(type, x, y, w, h, name)`  
Add an input object to the form. — Methods : `set_input()`, `get_input()`, `set_input_color()`, `set_input_return()`.

`form.add_menu(type, x, y, w, h, name)`  
Add a menu object to the form. — Methods : `set_menu()`, `get_menu()`, `addto_menu()`.

`form.add_choice(type, x, y, w, h, name)`  
Add a choice object to the form. — Methods : `set_choice()`, `get_choice()`, `clear_choice()`, `addto_choice()`, `replace_choice()`, `delete_choice()`, `get_choice_text()`, `set_choice_fontsize()`, `set_choice_fontstyle()`.

`form.add_browser(type, x, y, w, h, name)`  
Add a browser object to the form. — Methods : `set_browser_topline()`, `clear_browser()`, `add_browser_line()`, `addto_browser()`, `insert_browser_line()`, `delete_browser_line()`, `replace_browser_line()`, `get_browser_line()`, `load_browser()`, `get_browser_maxline()`, `select_browser_line()`, `deselect_browser_line()`, `deselect_browser()`, `isselected_browser_line()`, `get_browser()`, `set_browser_fontsize()`, `set_browser_fontstyle()`, `set_browser_specialkey()`.

`form.add_timer(type, x, y, w, h, name)`  
Add a timer object to the form. — Methods : `set_timer()`, `get_timer()`.

Form objects have the following data attributes; see the FORMS documentation :

Nom	Type C	Signification
<b>window</b>	int (read-only)	GL window id
<b>w</b>	<i>float</i>	form width
<b>h</b>	<i>float</i>	form height
<b>x</b>	<i>float</i>	form x origin
<b>y</b>	<i>float</i>	form y origin
<b>deactivated</b>	<i>int</i>	nonzero if form is deactivated
<b>visible</b>	<i>int</i>	nonzero if form is visible
<b>frozen</b>	<i>int</i>	nonzero if form is frozen
<b>doublebuf</b>	<i>int</i>	nonzero if double buffering on

### 39.4.3 FORMS Objects

Besides methods specific to particular kinds of FORMS objects, all FORMS objects also have the following methods :

**FORMS object.set\_call\_back(*function*, *argument*)**

Set the object's callback function and argument. When the object needs interaction, the callback function will be called with two arguments : the object, and the callback argument. (FORMS objects

without a callback function are returned by `fl.do_forms()` or `fl.check_forms()` when they need interaction.) Call this method without arguments to remove the callback function.

**FORMS** `object.delete_object()`

Delete the object.

**FORMS** `object.show_object()`

Show the object.

**FORMS** `object.hide_object()`

Hide the object.

**FORMS** `object.redraw_object()`

Redraw the object.

**FORMS** `object.freeze_object()`

Freeze the object.

**FORMS** `object.unfreeze_object()`

Unfreeze the object.

FORMS objects have these data attributes; see the FORMS documentation :

Nom	Type C	Signification
<code>objclass</code>	int (read-only)	object class
<code>type</code>	int (read-only)	object type
<code>boxtype</code>	<i>int</i>	box type
<code>x</code>	<i>float</i>	x origin
<code>y</code>	<i>float</i>	y origin
<code>w</code>	<i>float</i>	width
<code>h</code>	<i>float</i>	height
<code>col1</code>	<i>int</i>	primary color
<code>col2</code>	<i>int</i>	secondary color
<code>align</code>	<i>int</i>	alignment
<code>lcol</code>	<i>int</i>	label color
<code>lsize</code>	<i>float</i>	label font size
<code>label</code>	<i>string</i>	label string
<code>lstyle</code>	<i>int</i>	label style
<code>pushed</code>	int (read-only)	(see FORMS docs)
<code>focus</code>	int (read-only)	(see FORMS docs)
<code>belowmouse</code>	int (read-only)	(see FORMS docs)
<code>frozen</code>	int (read-only)	(see FORMS docs)
<code>active</code>	int (read-only)	(see FORMS docs)
<code>input</code>	int (read-only)	(see FORMS docs)
<code>visible</code>	int (read-only)	(see FORMS docs)
<code>radio</code>	int (read-only)	(see FORMS docs)
<code>automatic</code>	int (read-only)	(see FORMS docs)

## 39.5 FL — Constants used with the fl module

Obsolète depuis la version 2.6 : The *FL* module has been removed in Python 3.

This module defines symbolic constants needed to use the built-in module *fl* (see above) ; they are equivalent to those defined in the C header file `<forms.h>` except that the name prefix `FL_` is omitted. Read the module source for a complete list of the defined names. Suggested use :

```
import fl
from FL import *
```

## 39.6 flp — Functions for loading stored FORMS designs

Obsolète depuis la version 2.6 : The *flp* module has been removed in Python 3.

This module defines functions that can read form definitions created by the “form designer” (*fdesign*) program that comes with the FORMS library (see module *fl* above).

For now, see the file *flp.doc* in the Python library source directory for a description.

XXX A complete description should be inserted here !

## 39.7 fm — Font Manager interface

Obsolète depuis la version 2.6 : The *fm* module has been removed in Python 3.

This module provides access to the IRIS *Font Manager* library. It is available only on Silicon Graphics machines. See also : *4Sight User's Guide*, section 1, chapter 5 : « Using the IRIS Font Manager. »

This is not yet a full interface to the IRIS Font Manager. Among the unsupported features are : matrix operations ; cache operations ; character operations (use string operations instead) ; some details of font info ; individual glyph metrics ; and printer matching.

It supports the following operations :

**fm.init()**

Initialization function. Calls *fminit()*. It is normally not necessary to call this function, since it is called automatically the first time the *fm* module is imported.

**fm.findfont(fontname)**

Return a font handle object. Calls *fmfindfont(fontname)*.

**fm.enumerate()**

Returns a list of available font names. This is an interface to *fmenumerate()*.

**fm.prstr(string)**

Render a string using the current font (see the *setfont()* font handle method below). Calls *fmprstr(string)*.

**fm.setpath(string)**

Sets the font search path. Calls *fmsetpath(string)*. (XXX Does not work!?!)

**fm.fontpath()**

Returns the current font search path.

Font handle objects support the following operations :

**font handle.scalefont(factor)**

Returns a handle for a scaled version of this font. Calls *fmscalefont(fh, factor)*.

**font handle.setfont()**

Makes this font the current font. Note : the effect is undone silently when the font handle object is deleted. Calls *fmsetfont(fh)*.

**font handle.getfontname()**

Returns this font's name. Calls *fmgetfontname(fh)*.

**font** `handle.getcomment()`  
 Returns the comment string associated with this font. Raises an exception if there is none. Calls `fmgetcomment(fh)`.

**font** `handle.getfontinfo()`  
 Returns a tuple giving some pertinent data about this font. This is an interface to `fmgetfontinfo()`. The returned tuple contains the following numbers : (`printermatched`, `fixed_width`, `xorig`, `yorig`, `xsize`, `ysize`, `height`, `nglyphs`).

**font** `handle.getstrwidth(string)`  
 Returns the width, in pixels, of *string* when drawn in this font. Calls `fmgetstrwidth(fh, string)`.

## 39.8 gl — Graphics Library interface

Obsolète depuis la version 2.6 : The *gl* module has been removed in Python 3.

This module provides access to the Silicon Graphics *Graphics Library*. It is available only on Silicon Graphics machines.

**Avertissement :** Some illegal calls to the GL library cause the Python interpreter to dump core. In particular, the use of most GL calls is unsafe before the first window is opened.

The module is too large to document here in its entirety, but the following should help you to get started. The parameter conventions for the C functions are translated to Python as follows :

- All (short, long, unsigned) int values are represented by Python integers.
- All float and double values are represented by Python floating point numbers. In most cases, Python integers are also allowed.
- All arrays are represented by one-dimensional Python lists. In most cases, tuples are also allowed.
- All string and character arguments are represented by Python strings, for instance, `winopen('Hi There!')` and `rotate(900, 'z')`.
- All (short, long, unsigned) integer arguments or return values that are only used to specify the length of an array argument are omitted. For example, the C call

```
lmdef(deftype, index, np, props)
```

is translated to Python as

```
lmdef(deftype, index, props)
```

- Output arguments are omitted from the argument list ; they are transmitted as function return values instead. If more than one value must be returned, the return value is a tuple. If the C function has both a regular return value (that is not omitted because of the previous rule) and an output argument, the return value comes first in the tuple. Examples : the C call

```
getmcolor(i, &red, &green, &blue)
```

is translated to Python as

```
red, green, blue = getmcolor(i)
```

The following functions are non-standard or have special argument conventions :

**gl.varray**(*argument*)

Equivalent to but faster than a number of `v3d()` calls. The *argument* is a list (or tuple) of points. Each point must be a tuple of coordinates (`x`, `y`, `z`) or (`x`, `y`). The points may be 2- or 3-dimensional but must all have the same dimension. Float and int values may be mixed however. The points are always

converted to 3D double precision points by assuming  $z = 0.0$  if necessary (as indicated in the man page), and for each point `v3d()` is called.

`gl.nvarray()`

Equivalent to but faster than a number of `n3f` and `v3f` calls. The argument is an array (list or tuple) of pairs of normals and points. Each pair is a tuple of a point and a normal for that point. Each point or normal must be a tuple of coordinates ( $x$ ,  $y$ ,  $z$ ). Three coordinates must be given. Float and int values may be mixed. For each pair, `n3f()` is called for the normal, and then `v3f()` is called for the point.

`gl.vnarray()`

Similar to `nvarray()` but the pairs have the point first and the normal second.

`gl.nurbssurface(s_k, t_k, ctl, s_ord, t_ord, type)`

Defines a nurbs surface. The dimensions of `ctl[][]` are computed as follows : `[len(s_k) - s_ord]`, `[len(t_k) - t_ord]`.

`gl.nurbscurve(knots, ctlpoints, order, type)`

Defines a nurbs curve. The length of `ctlpoints` is `len(knots) - order`.

`gl.pwlcurve(points, type)`

Defines a piecewise-linear curve. *points* is a list of points. *type* must be `N_ST`.

`gl.pick(n)`

`gl.select(n)`

The only argument to these functions specifies the desired size of the pick or select buffer.

`gl.endpick()`

`gl.endselect()`

These functions have no arguments. They return a list of integers representing the used part of the pick/select buffer. No method is provided to detect buffer overrun.

Here is a tiny but complete example GL program in Python :

```
import gl, GL, time

def main():
    gl.foreground()
    gl.prefposition(500, 900, 500, 900)
    w = gl.winopen('CrissCross')
    gl.ortho2(0.0, 400.0, 0.0, 400.0)
    gl.color(GL.WHITE)
    gl.clear()
    gl.color(GL.RED)
    gl.bgnline()
    gl.v2f(0.0, 0.0)
    gl.v2f(400.0, 400.0)
    gl.endline()
    gl.bgnline()
    gl.v2f(400.0, 0.0)
    gl.v2f(0.0, 400.0)
    gl.endline()
    time.sleep(5)

main()
```

Voir aussi :

**PyOpenGL : The Python OpenGL Binding** An interface to OpenGL is also available; see information about the **PyOpenGL** project online at <http://pyopengl.sourceforge.net/>. This may be a better option if support for SGI hardware from before about 1996 is not required.

## 39.9 DEVICE — Constants used with the gl module

Obsolète depuis la version 2.6 : The *DEVICE* module has been removed in Python 3.

This modules defines the constants used by the Silicon Graphics *Graphics Library* that C programmers find in the header file `<gl/device.h>`. Read the module source file for details.

## 39.10 GL — Constants used with the gl module

Obsolète depuis la version 2.6 : The *GL* module has been removed in Python 3.

This module contains constants used by the Silicon Graphics *Graphics Library* from the C header file `<gl/gl.h>`. Read the module source file for details.

## 39.11 imgfile — Support for SGI imglib files

Obsolète depuis la version 2.6 : The *imgfile* module has been removed in Python 3.

The *imgfile* module allows Python programs to access SGI imglib image files (also known as `.rgb` files). The module is far from complete, but is provided anyway since the functionality that there is enough in some cases. Currently, colormap files are not supported.

The module defines the following variables and functions :

**exception `imgfile.error`**

This exception is raised on all errors, such as unsupported file type, etc.

**`imgfile.getsizes(file)`**

This function returns a tuple `(x, y, z)` where *x* and *y* are the size of the image in pixels and *z* is the number of bytes per pixel. Only 3 byte RGB pixels and 1 byte greyscale pixels are currently supported.

**`imgfile.read(file)`**

This function reads and decodes the image on the specified file, and returns it as a Python string. The string has either 1 byte greyscale pixels or 4 byte RGBA pixels. The bottom left pixel is the first in the string. This format is suitable to pass to `gl.rectwrite()`, for instance.

**`imgfile.readscaled(file, x, y, filter[, blur])`**

This function is identical to `read` but it returns an image that is scaled to the given *x* and *y* sizes. If the *filter* and *blur* parameters are omitted scaling is done by simply dropping or duplicating pixels, so the result will be less than perfect, especially for computer-generated images.

Alternatively, you can specify a filter to use to smooth the image after scaling. The filter forms supported are `'impulse'`, `'box'`, `'triangle'`, `'quadratic'` and `'gaussian'`. If a filter is specified *blur* is an optional parameter specifying the blurriness of the filter. It defaults to `1.0`.

*`readscaled()`* makes no attempt to keep the aspect ratio correct, so that is the users' responsibility.

**`imgfile.ttob(flag)`**

This function sets a global flag which defines whether the scan lines of the image are read or written from bottom to top (flag is zero, compatible with SGI GL) or from top to bottom(flag is one, compatible with X). The default is zero.

**`imgfile.write(file, data, x, y, z)`**

This function writes the RGB or greyscale data in *data* to image file *file*. *x* and *y* give the size of the

image, *z* is 1 for 1 byte greyscale images or 3 for RGB images (which are stored as 4 byte values of which only the lower three bytes are used). These are the formats returned by `gl.lrectread()`.

## 39.12 jpeg — Read and write JPEG files

Obsolète depuis la version 2.6 : The `jpeg` module has been removed in Python 3.

The module `jpeg` provides access to the jpeg compressor and decompressor written by the Independent JPEG Group (IJG). JPEG is a standard for compressing pictures; it is defined in ISO 10918. For details on JPEG or the Independent JPEG Group software refer to the JPEG standard or the documentation provided with the software.

A portable interface to JPEG image files is available with the Python Imaging Library (PIL) by Fredrik Lundh. Information on PIL is available at <http://www.pythonware.com/products/pil/>.

The `jpeg` module defines an exception and some functions.

### exception `jpeg.error`

Exception raised by `compress()` and `decompress()` in case of errors.

### `jpeg.compress(data, w, h, b)`

Treat data as a pixmap of width *w* and height *h*, with *b* bytes per pixel. The data is in SGI GL order, so the first pixel is in the lower-left corner. This means that `gl.lrectread()` return data can immediately be passed to `compress()`. Currently only 1 byte and 4 byte pixels are allowed, the former being treated as greyscale and the latter as RGB color. `compress()` returns a string that contains the compressed picture, in JFIF format.

### `jpeg.decompress(data)`

Data is a string containing a picture in JFIF format. It returns a tuple (`data`, `width`, `height`, `bytesperpixel`). Again, the data is suitable to pass to `gl.lrectwrite()`.

### `jpeg.setoption(name, value)`

Set various options. Subsequent `compress()` and `decompress()` calls will use these options. The following options are available :

Option	Effect
'forcegray'	Force output to be grayscale, even if input is RGB.
'quality'	Set the quality of the compressed image to a value between 0 and 100 (default is 75). This only affects compression.
'optimize'	Perform Huffman table optimization. Takes longer, but results in smaller compressed image. This only affects compression.
'smooth'	Perform inter-block smoothing on uncompressed image. Only useful for low- quality images. This only affects decompression.

Voir aussi :

**JPEG Still Image Data Compression Standard** The canonical reference for the JPEG image format, by Pennebaker and Mitchell.

**Information Technology - Digital Compression and Coding of Continuous-tone Still Images - Requirements and Test Methods**

The ISO standard for JPEG is also published as ITU T.81. This is available online in PDF form.

The modules described in this chapter provide interfaces to features that are unique to SunOS 5 (also known as Solaris version 2).

### 40.1 sunaudiodev — Access to Sun audio hardware

Obsolète depuis la version 2.6 : The *sunaudiodev* module has been removed in Python 3.

This module allows you to access the Sun audio interface. The Sun audio hardware is capable of recording and playing back audio data in u-LAW format with a sample rate of 8K per second. A full description can be found in the *audio(7I)* manual page.

The module *SUNAUDIODEV* defines constants which may be used with this module.

This module defines the following variables and functions :

**exception *sunaudiodev.error***

This exception is raised on all errors. The argument is a string describing what went wrong.

***sunaudiodev.open(mode)***

This function opens the audio device and returns a Sun audio device object. This object can then be used to do I/O on. The *mode* parameter is one of 'r' for record-only access, 'w' for play-only access, 'rw' for both and 'control' for access to the control device. Since only one process is allowed to have the recorder or player open at the same time it is a good idea to open the device only for the activity needed. See *audio(7I)* for details.

As per the manpage, this module first looks in the environment variable *AUDIODEV* for the base audio device filename. If not found, it falls back to */dev/audio*. The control device is calculated by appending « *ctl* » to the base audio device.

#### 40.1.1 Audio Device Objects

The audio device objects are returned by *open()* define the following methods (except *control* objects which only provide *getinfo()*, *setinfo()*, *fileno()*, and *drain()*) :

**audio device.close()**

This method explicitly closes the device. It is useful in situations where deleting the object does not immediately close it since there are other references to it. A closed device should not be used again.

**audio device.fileno()**

Returns the file descriptor associated with the device. This can be used to set up SIGPOLL notification, as described below.

**audio device.drain()**

This method waits until all pending output is processed and then returns. Calling this method is often not necessary : destroying the object will automatically close the audio device and this will do an implicit drain.

**audio device.flush()**

This method discards all pending output. It can be used avoid the slow response to a user's stop request (due to buffering of up to one second of sound).

**audio device.getinfo()**

This method retrieves status information like input and output volume, etc. and returns it in the form of an audio status object. This object has no methods but it contains a number of attributes describing the current device status. The names and meanings of the attributes are described in <sun/audioio.h> and in the *audio(7I)* manual page. Member names are slightly different from their C counterparts : a status object is only a single structure. Members of the **play** substructure have **o\_** prepended to their name and members of the **record** structure have **i\_**. So, the C member **play.sample\_rate** is accessed as **o\_sample\_rate**, **record.gain** as **i\_gain** and **monitor\_gain** plainly as **monitor\_gain**.

**audio device.ibufcount()**

This method returns the number of samples that are buffered on the recording side, i.e. the program will not block on a **read()** call of so many samples.

**audio device.obufcount()**

This method returns the number of samples buffered on the playback side. Unfortunately, this number cannot be used to determine a number of samples that can be written without blocking since the kernel output queue length seems to be variable.

**audio device.read(size)**

This method reads *size* samples from the audio input and returns them as a Python string. The function blocks until enough data is available.

**audio device.setinfo(status)**

This method sets the audio device status parameters. The *status* parameter is a device status object as returned by **getinfo()** and possibly modified by the program.

**audio device.write(samples)**

Write is passed a Python string containing audio samples to be played. If there is enough buffer space free it will immediately return, otherwise it will block.

The audio device supports asynchronous notification of various events, through the SIGPOLL signal. Here's an example of how you might enable this in Python :

```
def handle_sigpoll(signum, frame):
    print 'I got a SIGPOLL update'

import fcntl, signal, STROPTS

signal.signal(signal.SIGPOLL, handle_sigpoll)
fcntl.ioctl(audio_obj.fileno(), STROPTS.I_SETSIG, STROPTS.S_MSG)
```

## 40.2 SUNAUDIODEV — Constants used with sunaudiodev

Obsolète depuis la version 2.6 : The *SUNAUDIODEV* module has been removed in Python 3.

This is a companion module to *sunaudiodev* which defines useful symbolic constants like `MIN_GAIN`, `MAX_GAIN`, `SPEAKER`, etc. The names of the constants are the same names as used in the C include file `<sun/audioio.h>`, with the leading string `AUDIO_` stripped.

---

Modules non Documentés

---

Voici un rapide survol des modules actuellement non documentés, mais qui devraient l'être. N'hésitez pas à contribuer à leur documentation ! (En anglais, par mail, à [docs@python.org](mailto:docs@python.org).)

L'idée de lister les modules à documenter vient d'un message de Fredrik Lundh. Depuis, le contenu de ce chapitre à pu être mis à jour.

### 41.1 Miscellaneous useful utilities

Some of these are very old and/or not very robust ; marked with « *hmm.* »

**ihooks** — Import hook support (for *rexec*; may become obsolete). Removed in Python 3.x.

### 41.2 Modules spécifiques à une plateforme

Ces modules sont utilisés pour implémenter le module *os.path*, et n'ont pas plus de documentation. Le besoin de les documenter ne se fait pas réellement sentir.

**ntpath** — Implementation of *os.path* on Win32, Win64, WinCE, and OS/2 platforms.

**posixpath** — Implementation du module *os.path* pour les systèmes POSIX.

**bsddb185** — Backwards compatibility module for systems which still use the Berkeley DB 1.85 module. It is normally only available on certain BSD Unix-based systems. It should never be used directly.

### 41.3 Multimedia

**audiodev** — Platform-independent API for playing audio data. Removed in Python 3.x.

**linuxaudiodev** — Play audio data on the Linux audio device. Replaced in Python 2.3 by the *ossaudiodev* module. Removed in Python 3.x.

**sunaudio** — Interpret Sun audio headers (may become obsolete or a tool/demo). Removed in Python 3.x.

**toaiff** — Convert « arbitrary » sound files to AIFF files ; should probably become a tool or demo. Requires the external program **sox**. Removed in Python 3.x.

## 41.4 Undocumented Mac OS modules

### 41.4.1 applesingle — AppleSingle decoder

Obsolète depuis la version 2.6.

### 41.4.2 buildtools — Helper module for BuildApplet and Friends

Obsolète depuis la version 2.4.

### 41.4.3 cfmfile — Code Fragment Resource module

*cfmfile* is a module that understands Code Fragments and the accompanying « cfrg » resources. It can parse them and merge them, and is used by BuildApplication to combine all plugin modules to a single executable.

Obsolète depuis la version 2.4.

### 41.4.4 icopen — Internet Config replacement for open()

Importing *icopen* will replace the built-in *open()* with a version that uses Internet Config to set file type and creator for new files.

Obsolète depuis la version 2.6.

### 41.4.5 macerrors — Mac OS Errors

*macerrors* contains constant definitions for many Mac OS error codes.

Obsolète depuis la version 2.6.

### 41.4.6 macresource — Locate script resources

*macresource* helps scripts finding their resources, such as dialogs and menus, without requiring special case code for when the script is run under MacPython, as a MacPython applet or under OSX Python.

Obsolète depuis la version 2.6.

### 41.4.7 Nav — NavServices calls

A low-level interface to Navigation Services.

Obsolète depuis la version 2.6.

### 41.4.8 PixmapWrapper — Wrapper for Pixmap objects

*PixmapWrapper* wraps a Pixmap object with a Python object that allows access to the fields by name. It also has methods to convert to and from PIL images.

Obsolète depuis la version 2.6.

### 41.4.9 videoreader — Read QuickTime movies

*videoreader* reads and decodes QuickTime movies and passes a stream of images to your program. It also provides some support for audio tracks.

Obsolète depuis la version 2.6.

#### 41.4.10 **W** — Widgets built on **FrameWork**

The *W* widgets are used extensively in the **IDE**.

Obsolète depuis la version 2.6.

### 41.5 **Obsolete**

These modules are not normally available for import ; additional work must be done to make them available.

These extension modules written in C are not built by default. Under Unix, these must be enabled by uncommenting the appropriate lines in **Modules/Setup** in the build tree and either rebuilding Python if the modules are statically linked, or building and installing the shared object if using dynamically-loaded extensions.

**timing** — Measure time intervals to high resolution (use `time.clock()` instead). Removed in Python 3.x.

### 41.6 **SGI-specific Extension modules**

The following are SGI specific, and may be out of touch with the current version of reality.

**c1** — Interface to the SGI compression library.

**sv** — Interface to the « simple video » board on SGI Indigo (obsolete hardware). Removed in Python 3.x.

>>> L'invite de commande utilisée par défaut dans l'interpréteur interactif. On la voit souvent dans des exemples de code qui peuvent être exécutés interactivement dans l'interpréteur.

... The default Python prompt of the interactive shell when entering code for an indented code block, when within a pair of matching left and right delimiters (parentheses, square brackets, curly braces or triple quotes), or after specifying a decorator.

**2to3** Outil qui essaie de convertir du code pour Python 2.x en code pour Python 3.x en gérant la plupart des incompatibilités qui peuvent être détectées en analysant la source et parcourant son arbre syntaxique.

*2to3* est disponible dans la bibliothèque standard sous le nom de `lib2to3`; un point d'entrée indépendant est fourni via `Tools/scripts/2to3`. Cf. *2to3 — Traduction automatique de code en Python 2 vers Python 3*.

**classe de base abstraite** Les classes de base abstraites (ABC, suivant l'abréviation anglaise *Abstract Base Class*) complètent le *duck-typing* en fournissant un moyen de définir des interfaces pour les cas où d'autres techniques comme `hasattr()` seraient inélégantes, ou subitement fausses (par exemple avec les méthodes magiques). Les ABC introduisent des sous-classes virtuelles, qui n'héritent pas d'une classe mais qui sont quand même reconnues par `isinstance()` ou `issubclass()` (Voir la documentation du module `abc`). Python contient de nombreuses ABC pour les structures de données (dans le module `collections`), les nombres (dans le module `numbers`), les flux (dans le module `io`). Vous pouvez créer vos propres ABC avec le module `abc`.

**argument** Une valeur, donnée à une *fonction* ou à une *méthode* lors de son appel. Il existe deux types d'arguments :

- *argument nommé* : un argument précédé d'un identifiant (comme `name=`) ou un dictionnaire précédé de `**`, lors d'un appel de fonction. Par exemple, 3 et 5 sont tous les deux des arguments nommés dans l'appel à `complex()` ici :

```
complex(real=3, imag=5)
complex(**{'real': 3, 'imag': 5})
```

- *argument positionnel* : Un argument qui n'est pas nommé. Les arguments positionnels apparaissent au début de la liste des arguments, ou donnés sous forme d'un *itérable* précédé par `*`. Par exemple, 3 et 5 sont tous les deux des arguments positionnels dans les appels suivants :

```
complex(3, 5)
complex(*(3, 5))
```

Les arguments se retrouvent dans le corps de la fonction appelée parmi les variables locales. Voir la section [calls](#) à propos des règles dictant cette affectation. Syntaxiquement, toute expression est acceptée comme argument, et c'est la valeur résultante de l'expression qui sera affectée à la variable locale.

Voir aussi [parameter](#) dans le glossaire, et la question dans la FAQ à propos de la différence entre argument et paramètre.

**attribut** Valeur associée à un objet et désignée par son nom via une notation utilisant des points. Par exemple, si un objet *o* possède un attribut *a*, il sera référencé par *o.a*.

**BDFL** Dictateur bienveillant à vie (*Benevolent Dictator For Life* en anglais). Pseudonyme de [Guido van Rossum](#), le créateur de Python.

**Objet bytes-compatible** Un objet gérant le `bufferobjects`, comme les classes [str](#), [bytearray](#), ou [memoryview](#). Les objets bytes-compatibles peuvent manipuler des données binaires et ainsi servir à leur compression, sauvegarde, ou envoi sur une socket. Certaines actions nécessitent que la donnée binaire soit modifiable, ce qui n'est pas possible avec tous les objets byte-compatibles.

**code intermédiaire (*bytecode*)** Le code source, en Python, est compilé en un `bytecode`, la représentation interne à CPython d'un programme Python. Le `bytecode` est stocké dans un fichier nommé `.pyc` ou `.pyo`. Ces caches permettent de charger les fichiers plus rapidement lors de la deuxième exécution (en évitant ainsi de recommencer la compilation en `bytecode`). On dit que ce *langage intermédiaire* est exécuté sur une *machine virtuelle* qui exécute des instructions machine pour chaque instruction du `bytecode`. Notez que le `bytecode` n'a pas vocation à fonctionner entre différentes machines virtuelle Python, encore moins entre différentes version de Python.

La documentation du [module dis](#) fournit une liste des instructions du code intermédiaire.

**classe** Modèle pour créer des objets définis par l'utilisateur. Une définition de classe (*class*) contient normalement des définitions de méthodes qui agissent sur les instances de la classe.

**classic class** Any class which does not inherit from [object](#). See [new-style class](#). Classic classes have been removed in Python 3.

**coercition** The implicit conversion of an instance of one type to another during an operation which involves two arguments of the same type. For example, `int(3.15)` converts the floating point number to the integer 3, but in `3+4.5`, each argument is of a different type (one int, one float), and both must be converted to the same type before they can be added or it will raise a `TypeError`. Coercion between two operands can be performed with the `coerce` built-in function; thus, `3+4.5` is equivalent to calling `operator.add(*coerce(3, 4.5))` and results in `operator.add(3.0, 4.5)`. Without coercion, all arguments of even compatible types would have to be normalized to the same value by the programmer, e.g., `float(3)+4.5` rather than just `3+4.5`.

**nombre complexe** Extension des nombres réels familiers, dans laquelle tous les nombres sont exprimés sous la forme d'une somme d'une partie réelle et d'une partie imaginaire. Les nombres imaginaires sont les nombres réels multipliés par l'unité imaginaire (la racine carrée de  $-1$ , souvent écrite *i* en mathématiques ou *j* par les ingénieurs). Python comprend nativement les nombres complexes, écrits avec cette dernière notation : la partie imaginaire est écrite avec un suffixe *j*, exemple, `3+1j`. Pour utiliser les équivalents complexes de [math](#), utilisez [cmath](#). Les nombres complexes sont un concept assez avancé en mathématiques. Si vous ne connaissez pas ce concept, vous pouvez tranquillement les ignorer.

**gestionnaire de contexte** Objet contrôlant l'environnement à l'intérieur d'un bloc `with` en définissant les méthodes `__enter__()` et `__exit__()`. Consultez la [PEP 343](#).

**CPython** L'implémentation canonique du langage de programmation Python, tel que distribué sur [python.org](#). Le terme « CPython » est utilisé dans certains contextes lorsqu'il est nécessaire de distinguer cette implémentation des autres comme *Jython* ou *IronPython*.

**décorateur** Fonction dont la valeur de retour est une autre fonction. Un décorateur est habituellement utilisé pour transformer une fonction via la syntaxe `@wrapper`, dont les exemples typiques sont : `classmethod()` et `staticmethod()`.

La syntaxe des décorateurs est simplement du sucre syntaxique, les définitions des deux fonctions suivantes sont sémantiquement équivalentes :

```
def f(...):
    ...
f = staticmethod(f)

@staticmethod
def f(...):
    ...
```

Quoique moins fréquemment utilisé, le même concept existe pour les classes. Consultez la documentation définitions de fonctions et définitions de classes pour en savoir plus sur les décorateurs.

**descripteur** Any *new-style* object which defines the methods `__get__()`, `__set__()`, or `__delete__()`. When a class attribute is a descriptor, its special binding behavior is triggered upon attribute lookup. Normally, using `a.b` to get, set or delete an attribute looks up the object named `b` in the class dictionary for `a`, but if `b` is a descriptor, the respective descriptor method gets called. Understanding descriptors is a key to a deep understanding of Python because they are the basis for many features including functions, methods, properties, class methods, static methods, and reference to super classes.

Pour plus d'informations sur les méthodes des descripteurs, consultez `descriptors`.

**dictionnaire** An associative array, where arbitrary keys are mapped to values. The keys can be any object with `__hash__()` and `__eq__()` methods. Called a hash in Perl.

**vue de dictionnaire** The objects returned from `dict.viewkeys()`, `dict.viewvalues()`, and `dict.viewitems()` are called dictionary views. They provide a dynamic view on the dictionary's entries, which means that when the dictionary changes, the view reflects these changes. To force the dictionary view to become a full list use `list(dictview)`. See *Les vues de dictionnaires*.

**docstring** Première chaîne littérale qui apparaît dans l'expression d'une classe, fonction, ou module. Bien qu'ignorée à l'exécution, elle est reconnue par le compilateur et placée dans l'attribut `__doc__` de la classe, de la fonction ou du module. Comme cette chaîne est disponible par introspection, c'est l'endroit idéal pour documenter l'objet.

**duck-typing** Style de programmation qui ne prend pas en compte le type d'un objet pour déterminer s'il respecte une interface, mais qui appelle simplement la méthode ou l'attribut (*Si ça a un bec et que ça cancanne, ça doit être un canard*, *duck* signifie canard en anglais). En se concentrant sur les interfaces plutôt que les types, du code bien construit améliore sa flexibilité en autorisant des substitutions polymorphiques. Le *duck-typing* évite de vérifier les types via `type()` ou `isinstance()`. Notez cependant que le *duck-typing* peut travailler de pair avec les *classes de base abstraites*. À la place, le *duck-typing* utilise plutôt `hasattr()` ou la programmation *EAFP*.

**EAFP** Il est plus simple de demander pardon que demander la permission (*Easier to Ask for Forgiveness than Permission* en anglais). Ce style de développement Python fait l'hypothèse que le code est valide et traite les exceptions si cette hypothèse s'avère fausse. Ce style, propre et efficace, est caractérisé par la présence de beaucoup de mots clés `try` et `except`. Cette technique de programmation contraste avec le style *LBYL* utilisé couramment dans les langages tels que C.

**expression** A piece of syntax which can be evaluated to some value. In other words, an expression is an accumulation of expression elements like literals, names, attribute access, operators or function calls which all return a value. In contrast to many other languages, not all language constructs are expressions. There are also *statements* which cannot be used as expressions, such as `print` or `if`. Assignments are also statements, not expressions.

**module d'extension** Module écrit en C ou C++, utilisant l'API C de Python pour interagir avec Python et le code de l'utilisateur.

**objet fichier** Objet exposant une ressource via une API orientée fichier (avec les méthodes `read()` ou `write()`). En fonction de la manière dont il a été créé, un objet fichier peut interfacer l'accès à un fichier sur le disque ou à un autre type de stockage ou de communication (typiquement l'entrée standard, la sortie standard, un tampon en mémoire, une socket réseau, ...). Les objets fichiers sont aussi appelés *file-like-objects* ou *streams*.

There are actually three categories of file objects : raw binary files, buffered binary files and text files. Their interfaces are defined in the `io` module. The canonical way to create a file object is by using the `open()` function.

**objet fichier-compatible** Synonyme de *objet fichier*.

**chercheur** An object that tries to find the *loader* for a module. It must implement a method named `find_module()`. See [PEP 302](#) for details.

**division entière** Division mathématique arrondissant à l'entier inférieur. L'opérateur de la division entière est `//`. Par exemple l'expression `11 // 4` vaut 2, contrairement à `11 / 4` qui vaut 2.75. Notez que `(-11) // 4` vaut -3 car l'arrondi se fait à l'entier inférieur. Voir la [PEP 328](#).

**fonction** Suite d'instructions qui renvoie une valeur à son appelant. On peut lui passer des *arguments* qui pourront être utilisés dans le corps de la fonction. Voir aussi *paramètre*, *méthode* et *fonction*.

**\_\_future\_\_** A pseudo-module which programmers can use to enable new language features which are not compatible with the current interpreter. For example, the expression `11/4` currently evaluates to 2. If the module in which it is executed had enabled *true division* by executing :

```
from __future__ import division
```

the expression `11/4` would evaluate to 2.75. By importing the `__future__` module and evaluating its variables, you can see when a new feature was first added to the language and when it will become the default :

```
>>> import __future__
>>> __future__.division
_Feature((2, 2, 0, 'alpha', 2), (3, 0, 0, 'alpha', 0), 8192)
```

**ramasse-miettes** (*garbage collection*) Le mécanisme permettant de libérer de la mémoire lorsqu'elle n'est plus utilisée. Python utilise un ramasse-miettes par comptage de référence, et un ramasse-miettes cyclique capable de détecter et casser les références circulaires.

**générateur** A function which returns an iterator. It looks like a normal function except that it contains `yield` statements for producing a series of values usable in a for-loop or that can be retrieved one at a time with the `next()` function. Each `yield` temporarily suspends processing, remembering the location execution state (including local variables and pending try-statements). When the generator resumes, it picks up where it left off (in contrast to functions which start fresh on every invocation).

**expression génératrice** Expression qui donne un itérateur. Elle ressemble à une expression normale, suivie d'une expression `for` définissant une variable de boucle, un intervalle et une expression `if` optionnelle. Toute cette expression génère des valeurs pour la fonction qui l'entoure :

```
>>> sum(i*i for i in range(10))           # sum of squares 0, 1, 4, ... 81
285
```

**GIL** Voir *global interpreter lock*.

**verrou global de l'interpréteur** (*global interpreter lock* en anglais) Mécanisme utilisé par l'interpréteur *CPython* pour s'assurer qu'un seul fil d'exécution (*thread* en anglais) n'exécute le *bytecode* à la fois. Cela simplifie l'implémentation de *CPython* en rendant le modèle objet (incluant des parties critiques comme la classe native *dict*) implicitement protégé contre les accès concourants. Verrouiller l'interpréteur entier rend plus facile l'implémentation de multiples fils d'exécution (*multi-thread* en anglais), au détriment malheureusement de beaucoup du parallélisme possible sur les machines ayant plusieurs processeurs.

Cependant, certains modules d'extension, standards ou non, sont conçus de manière à libérer le GIL lorsqu'ils effectuent des tâches lourdes tel que la compression ou le hachage. De la même manière, le GIL est toujours libéré lors des entrées / sorties.

Les tentatives précédentes d'implémenter un interpréteur Python avec une granularité de verrouillage plus fine ont toutes échouées, à cause de leurs mauvaises performances dans le cas d'un processeur unique. Il est admis que corriger ce problème de performance induit mènerait à une implémentation beaucoup plus compliquée et donc plus coûteuse à maintenir.

**hachable** An object is *hashable* if it has a hash value which never changes during its lifetime (it needs a `__hash__()` method), and can be compared to other objects (it needs an `__eq__()` or `__cmp__()` method). Hashable objects which compare equal must have the same hash value.

La hachabilité permet à un objet d'être utilisé comme clé de dictionnaire ou en tant que membre d'un ensemble (type *set*), car ces structures de données utilisent ce *hash*.

Tous les types immuables fournis par Python sont hachables, et aucun type mutable (comme les listes ou les dictionnaires) ne l'est. Toutes les instances de classes définies par les utilisateurs sont hachables par défaut, elles sont toutes différentes selon `__eq__`, sauf comparées à elles mêmes, et leur empreinte (*hash*) est calculée à partir de leur *id()*.

**IDLE** Environnement de développement intégré pour Python. IDLE est un éditeur basique et un interpréteur livré avec la distribution standard de Python.

**immuable** Objet dont la valeur ne change pas. Les nombres, les chaînes et les n-uplets sont immuables. Ils ne peuvent être modifiés. Un nouvel objet doit être créé si une valeur différente doit être stockée. Ils jouent un rôle important quand une valeur de *hash* constante est requise, typiquement en clé de dictionnaire.

**integer division** Mathematical division discarding any remainder. For example, the expression `11/4` currently evaluates to 2 in contrast to the 2.75 returned by float division. Also called *floor division*. When dividing two integers the outcome will always be another integer (having the floor function applied to it). However, if one of the operands is another numeric type (such as a *float*), the result will be coerced (see *coercion*) to a common type. For example, an integer divided by a float will result in a float value, possibly with a decimal fraction. Integer division can be forced by using the `//` operator instead of the `/` operator. See also *future*.

**importer** Processus rendant le code Python d'un module disponible dans un autre.

**importateur** Objet qui trouve et charge un module, en même temps un *chercheur* et un *chargeur*.

**interactif** Python a un interpréteur interactif, ce qui signifie que vous pouvez écrire des expressions et des instructions à l'invite de l'interpréteur. L'interpréteur Python va les exécuter immédiatement et vous en présenter le résultat. Démarrez juste `python` (probablement depuis le menu principal de votre ordinateur). C'est un moyen puissant pour tester de nouvelles idées ou étudier de nouveaux modules (souvenez-vous de `help(x)`).

**interprété** Python est un langage interprété, en opposition aux langages compilés, bien que la frontière soit floue en raison de la présence d'un compilateur en code intermédiaire. Cela signifie que les fichiers sources peuvent être exécutés directement, sans avoir à compiler un fichier exécutable intermédiaire. Les langages interprétés ont généralement un cycle de développement / débogage plus court que les langages compilés. Cependant, ils s'exécutent généralement plus lentement. Voir aussi *interactif*.

**itérable** An object capable of returning its members one at a time. Examples of iterables include all sequence types (such as `list`, *str*, and *tuple*) and some non-sequence types like *dict* and *file* and objects of any classes you define with an `__iter__()` or `__getitem__()` method. Iterables can be used in a `for` loop and in many other places where a sequence is needed (`zip()`, `map()`, ...). When an iterable object is passed as an argument to the built-in function *iter()*, it returns an iterator for the object. This iterator is good for one pass over the set of values. When using iterables, it is usually not necessary to call *iter()* or deal with iterator objects yourself. The `for` statement does that automatically for you, creating a temporary unnamed variable to hold the iterator for the duration of the loop. See also *iterator*, *sequence*, and *generator*.

**itérateur** An object representing a stream of data. Repeated calls to the iterator's `next()` method return successive items in the stream. When no more data are available a *StopIteration* exception

is raised instead. At this point, the iterator object is exhausted and any further calls to its `next()` method just raise `StopIteration` again. Iterators are required to have an `__iter__()` method that returns the iterator object itself so every iterator is also iterable and may be used in most places where other iterables are accepted. One notable exception is code which attempts multiple iteration passes. A container object (such as a `list`) produces a fresh new iterator each time you pass it to the `iter()` function or use it in a `for` loop. Attempting this with an iterator will just return the same exhausted iterator object used in the previous iteration pass, making it appear like an empty container.

Vous trouverez davantage d'informations dans *Les types itérateurs*.

**fonction clé** Une fonction clé est un objet callable qui renvoie une valeur à fins de tri ou de classement. Par exemple, la fonction `locale.strxfrm()` est utilisée pour générer une clé de classement prenant en compte les conventions de classement spécifiques aux paramètres régionaux courants.

Plusieurs outils dans Python acceptent des fonctions clé pour maîtriser comment les éléments sont triés ou groupés. Typiquement les fonctions `min()`, `max()`, `sorted()`, `list.sort()`, `heapq.nsmallest()`, `heapq.nlargest()`, et `itertools.groupby()`.

La méthode `str.lower()` peut servir en fonction clé pour effectuer des recherches insensibles à la casse. Aussi, il est possible de créer des fonctions clé au besoin avec des expressions `lambda`, comme `lambda r: (r[0], r[2])`. Finalement le module `operator` fournit des constructeurs de fonctions clé : `attrgetter()`, `itemgetter()`, et `methodcaller()`. Voir Comment Trier pour avoir des exemples de création et d'utilisation de fonctions clés.

**argument nommé** Voir *argument*.

**lambda** An anonymous inline function consisting of a single *expression* which is evaluated when the function is called. The syntax to create a lambda function is `lambda [parameters]: expression`

**LBYL** Regarde avant de tomber, (*Look before you leap* en anglais). Ce style de programmation consiste à vérifier des conditions avant d'effectuer des appels ou des accès. Ce style contraste avec le style *EAFP* et se caractérise par la présence de beaucoup d'instructions `if`.

Dans un environnement avec plusieurs fils d'exécution (*multi-threaded* en anglais), le style *LBYL* peut engendrer un séquençement critique (*race condition* en anglais) entre le « regarde » et le « tomber ». Par exemple, le code `if key in mapping: return mapping[key]` peut échouer si un autre fil d'exécution supprime la clé `key` du `mapping` après le test mais avant l'accès. Ce problème peut être résolu avec des verrous (*locks*) ou avec l'approche *EAFP*.

**list** A built-in Python *sequence*. Despite its name it is more akin to an array in other languages than to a linked list since access to elements is  $O(1)$ .

**liste en compréhension (ou liste en intension)** A compact way to process all or part of the elements in a sequence and return a list with the results. `result = ["0x%02x" % x for x in range(256) if x % 2 == 0]` generates a list of strings containing even hex numbers (0x..) in the range from 0 to 255. The `if` clause is optional. If omitted, all elements in `range(256)` are processed.

**chargeur** An object that loads a module. It must define a method named `load_module()`. A loader is typically returned by a *finder*. See [PEP 302](#) for details.

**Tableau de correspondances** Un conteneur permettant d'accéder à des éléments par clé et implémente les méthodes spécifiées dans *Mapping* ou `~collections.MutableMapping` :ref:`classes de base abstraites`. Les classes suivantes sont des exemples de mapping : *dict*, *collections.defaultdict*, *collections.OrderedDict*, et *collections.Counter*.

**métaclasses** Classe d'une classe. Les définitions de classe créent un nom pour la classe, un dictionnaire de classe et une liste de classes parentes. La métaclasses a pour rôle de réunir ces trois paramètres pour construire la classe. La plupart des langages orientés objet fournissent une implémentation par défaut. La particularité de Python est la possibilité de créer des métaclasses personnalisées. La plupart des utilisateurs n'aura jamais besoin de cet outil, mais lorsque le besoin survient, les métaclasses offrent des solutions élégantes et puissantes. Elles sont utilisées pour journaliser les accès à des propriétés, rendre sûr les environnements *multi-threads*, suivre la création d'objets, implémenter des singletons et bien d'autres tâches.

Plus d'informations sont disponibles dans : *metaclasses*.

**méthode** Fonction définie à l'intérieur d'une classe. Lorsqu'elle est appelée comme un attribut d'une instance de cette classe, la méthode reçoit l'instance en premier *argument* (qui, par convention, est habituellement nommé *self*). Voir *function* et *nested scope*.

**ordre de résolution des méthodes** L'ordre de résolution des méthodes (*MRO* pour *Method Resolution Order* en anglais) est, lors de la recherche d'un attribut dans les classes parentes, la façon dont l'interpréteur Python classe ces classes parentes. Voir [The Python 2.3 Method Resolution Order](#) pour plus de détails sur l'algorithme utilisé par l'interpréteur Python depuis la version 2.3.

**module** Objet utilisé pour organiser une portion unitaire de code en Python. Les modules ont un espace de noms et peuvent contenir n'importe quels objets Python. Charger des modules est appelé *importer*. Voir aussi *paquet*.

**MRO** Voir *ordre de résolution des méthodes*.

**muable** Un objet muable peut changer de valeur tout en gardant le même *id()*. Voir aussi *immuable*.

**n-uplet nommé** (*named-tuple* en anglais) Classe qui, comme un *n-uplet* (*tuple* en anglais), a ses éléments accessibles par leur indice. Et en plus, les éléments sont accessibles par leur nom. Par exemple, *time.localtime()* donne un objet ressemblant à un *n-uplet*, dont *year* est accessible par son indice : *t[0]* ou par son nom : *t.tm\_year*).

Un *n-uplet nommé* peut être un type natif tel que *time.struct\_time* ou il peut être construit comme une simple classe. Un *n-uplet nommé* complet peut aussi être créé via la fonction *collections.namedtuple()*. Cette dernière approche fournit automatiquement des fonctionnalités supplémentaires, tel qu'une représentation lisible comme *Employee(name='jones', title='programmer')*.

**espace de noms** The place where a variable is stored. Namespaces are implemented as dictionaries. There are the local, global and built-in namespaces as well as nested namespaces in objects (in methods). Namespaces support modularity by preventing naming conflicts. For instance, the functions *\_\_builtin\_\_.open()* and *os.open()* are distinguished by their namespaces. Namespaces also aid readability and maintainability by making it clear which module implements a function. For instance, writing *random.seed()* or *itertools.izip()* makes it clear that those functions are implemented by the *random* and *itertools* modules, respectively.

**portée imbriquée** The ability to refer to a variable in an enclosing definition. For instance, a function defined inside another function can refer to variables in the outer function. Note that nested scopes work only for reference and not for assignment which will always write to the innermost scope. In contrast, local variables both read and write in the innermost scope. Likewise, global variables read and write to the global namespace.

**nouvelle classe** Any class which inherits from *object*. This includes all built-in types like *list* and *dict*. Only new-style classes can use Python's newer, versatile features like *\_\_slots\_\_*, descriptors, properties, and *\_\_getattr\_\_()*.

More information can be found in newstyle.

**objet** N'importe quelle donnée comportant des états (sous forme d'attributs ou d'une valeur) et un comportement (des méthodes). C'est aussi (*object*) l'ancêtre commun à absolument toutes les *nouvelles classes*.

**paquet** *module* Python qui peut contenir des sous-modules ou des sous-paquets. Techniquement, un paquet est un module qui possède un attribut *\_\_path\_\_*.

**paramètre** A named entity in a *function* (or method) definition that specifies an *argument* (or in some cases, arguments) that the function can accept. There are four types of parameters :

- *positional-or-keyword* : l'argument peut être passé soit par sa *position*, soit en tant que *argument nommé*. C'est le type de paramètre par défaut. Par exemple, *foo* et *bar* dans l'exemple suivant :

```
def func(foo, bar=None): ...
```

- *positional-only* : l'argument ne peut être donné que par sa position. Python n'a pas de syntaxe pour déclarer de tels paramètres, cependant des fonctions natives, comme *abs()*, en utilisent.

- *var-positional* : une séquence d'arguments positionnels peut être fournie (en plus de tous les arguments positionnels déjà acceptés par d'autres paramètres). Un tel paramètre peut être défini en préfixant son nom par une \*. Par exemple *args* ci-après :

```
def func(*args, **kwargs): ...
```

- *var-keyword* : une quantité arbitraire d'arguments peut être passée, chacun étant nommé (en plus de tous les arguments nommés déjà acceptés par d'autres paramètres). Un tel paramètre est défini en préfixant le nom du paramètre par \*\*. Par exemple, *kwargs* ci-dessus.

Les paramètres peuvent spécifier des arguments obligatoires ou optionnels, ainsi que des valeurs par défaut pour les arguments optionnels.

See also the [argument](#) glossary entry, the FAQ question on the difference between arguments and parameters, and the function section.

**PEP** Python Enhancement Proposal. A PEP is a design document providing information to the Python community, or describing a new feature for Python or its processes or environment. PEPs should provide a concise technical specification and a rationale for proposed features.

PEPs are intended to be the primary mechanisms for proposing major new features, for collecting community input on an issue, and for documenting the design decisions that have gone into Python. The PEP author is responsible for building consensus within the community and documenting dissenting opinions.

See [PEP 1](#).

**argument positionnel** Voir [argument](#).

**Python 3000** Surnom donné à la série des Python 3.x (très vieux surnom donné à l'époque où Python 3 représentait un futur lointain). Aussi abrégé *Py3k*.

**Pythonique** Idée, ou bout de code, qui colle aux idiomes de Python plutôt qu'aux concepts communs rencontrés dans d'autres langages. Par exemple, il est idiomatique en Python de parcourir les éléments d'un itérable en utilisant `for`. Beaucoup d'autres langages n'ont pas cette possibilité, donc les gens qui ne sont pas habitués à Python utilisent parfois un compteur numérique à la place :

```
for i in range(len(food)):
    print food[i]
```

Plutôt qu'utiliser la méthode, plus propre et élégante, donc *Pythonique* :

```
for piece in food:
    print piece
```

**nombre de références** Nombre de références à un objet. Lorsque le nombre de références à un objet descend à zéro, l'objet est désalloué. Le comptage de référence n'est généralement pas visible dans le code Python, mais c'est un élément clé de l'implémentation *CPython*. Le module `sys` définit une fonction `getrefcount()` que les développeurs peuvent utiliser pour obtenir le nombre de références à un objet donné.

**\_\_slots\_\_** A declaration inside a *new-style class* that saves memory by pre-declaring space for instance attributes and eliminating instance dictionaries. Though popular, the technique is somewhat tricky to get right and is best reserved for rare cases where there are large numbers of instances in a memory-critical application.

**séquence** An *iterable* which supports efficient element access using integer indices via the `__getitem__()` special method and defines a `len()` method that returns the length of the sequence. Some built-in sequence types are `list`, `str`, `tuple`, and `unicode`. Note that `dict` also supports `__getitem__()` and `__len__()`, but is considered a mapping rather than a sequence because the lookups use arbitrary *immutable* keys rather than integers.

**tranche** An object usually containing a portion of a *sequence*. A slice is created using the subscript notation, `[]` with colons between numbers when several are given, such as in `variable_name[1:3:5]`.

The bracket (subscript) notation uses *slice* objects internally (or in older versions, `__getslice__()` and `__setslice__()`).

**méthode spéciale** (*special method* en anglais) Méthode appelée implicitement par Python pour exécuter une opération sur un type, comme une addition. De telles méthodes ont des noms commençant et terminant par des doubles tirets bas. Les méthodes spéciales sont documentées dans `specialnames`.

**instruction** Une instruction (*statement* en anglais) est un composant d'un « bloc » de code. Une instruction est soit une *expression*, soit une ou plusieurs constructions basées sur un mot-clé, comme `if`, `while` ou `for`.

**struct sequence** A tuple with named elements. Struct sequences expose an interface similar to *named tuple* in that elements can be accessed either by index or as an attribute. However, they do not have any of the named tuple methods like `_make()` or `_asdict()`. Examples of struct sequences include `sys.float_info` and the return value of `os.stat()`.

**chaîne entre triple guillemets** Chaîne qui est délimitée par trois guillemets simples (') ou trois guillemets doubles ("). Bien qu'elle ne fournisse aucune fonctionnalité qui ne soit pas disponible avec une chaîne entre guillemets, elle est utile pour de nombreuses raisons. Elle vous autorise à insérer des guillemets simples et doubles dans une chaîne sans avoir à les protéger et elle peut s'étendre sur plusieurs lignes sans avoir à terminer chaque ligne par un \. Elle est ainsi particulièrement utile pour les chaînes de documentation (*docstrings*).

**type** Le type d'un objet Python détermine quel genre d'objet c'est. Tous les objets ont un type. Le type d'un objet peut être obtenu via son attribut `__class__` ou via `type(obj)`.

**retours à la ligne universels** A manner of interpreting text streams in which all of the following are recognized as ending a line : the Unix end-of-line convention '\n', the Windows convention '\r\n', and the old Macintosh convention '\r'. See [PEP 278](#) and [PEP 3116](#), as well as `str.splitlines()` for an additional use.

**environnement virtuel** Environnement d'exécution isolé (en mode coopératif) qui permet aux utilisateurs de Python et aux applications d'installer et de mettre à jour des paquets sans interférer avec d'autres applications Python fonctionnant sur le même système.

**machine virtuelle** Ordinateur défini entièrement par du logiciel. La machine virtuelle (*virtual machine*) de Python exécute le *bytecode* produit par le compilateur de *bytecode*.

**Le zen de Python** Liste de principes et de préceptes utiles pour comprendre et utiliser le langage. Cette liste peut être obtenue en tapant « `import this` » dans une invite Python interactive.

---

### À propos de ces documents

---

Ces documents sont générés à partir de sources en [reStructuredText](#) par [Sphinx](#), un analyseur de documents spécialement conçu pour la documentation Python.

Le développement de la documentation et de ses outils est entièrement basé sur le volontariat, tout comme Python. Si vous voulez contribuer, allez voir la page [reporting-bugs](#) qui contient des informations pour vous y aider. Les nouveaux volontaires sont toujours les bienvenus !

Merci beaucoup à :

- Fred L. Drake, Jr., créateur des outils originaux de la documentation Python et rédacteur de la plupart de son contenu ;
- le projet [Docutils](#) pour avoir créé *reStructuredText* et la suite d'outils *Docutils* ;
- Fredrik Lundh pour son projet [Alternative Python Reference](#), dont Sphinx a pris beaucoup de bonnes idées.

### B.1 Contributeurs de la documentation Python

De nombreuses personnes ont contribué au langage Python, à sa bibliothèque standard et à sa documentation. Consultez [Misc/ACKS](#) dans les sources de la distribution Python pour avoir une liste partielle des contributeurs.

Ce n'est que grâce aux suggestions et contributions de la communauté Python que Python a une documentation si merveilleuse – Merci !

---

Histoire et licence

---

## C.1 Histoire du logiciel

Python a été créé au début des années 1990 par Guido van Rossum, au Stichting Mathematisch Centrum (CWI, voir <https://www.cwi.nl/>) au Pays-Bas en tant que successeur d'un langage appelé ABC. Guido est l'auteur principal de Python, bien qu'il inclut de nombreuses contributions de la part d'autres personnes.

En 1995, Guido continua son travail sur Python au Corporation for National Research Initiatives (CNRI, voir <https://www.cnri.reston.va.us/>) de Reston, en Virginie, d'où il diffusa plusieurs versions du logiciel.

En mai 2000, Guido et l'équipe de développement centrale de Python sont parti vers BeOpen.com pour former l'équipe BeOpen PythonLabs. En octobre de la même année, l'équipe de PythonLabs est partie vers Digital Creations (désormais Zope Corporation ; voir <http://www.zope.com/>). En 2001, la Python Software Foundation (PSF, voir <http://www.python.org/psf/>) voit le jour. Il s'agit d'une organisation à but non lucratif détenant les droits de propriété intellectuelle de Python. Zope Corporation en est un sponsor.

Toutes les versions de Python sont Open Source (voir <https://www.opensource.org/> pour la définition d'Open Source). Historiquement, la plupart, mais pas toutes, des versions de Python ont également été compatible avec la GPL, le tableau ci-dessous résume les différentes versions.

Version	Dérivé de	Année	Propriétaire	Compatible avec la GPL ?
0.9.0 à 1.2	n/a	1991-1995	CWI	oui
1.3 à 1.5.2	1.2	1995-1999	CNRI	oui
1.6	1.5.2	2000	CNRI	non
2.0	1.6	2000	BeOpen.com	non
1.6.1	1.6	2001	CNRI	non
2.1	2.0+1.6.1	2001	PSF	non
2.0.1	2.0+1.6.1	2001	PSF	oui
2.1.1	2.1+2.0.1	2001	PSF	oui
2.1.2	2.1.1	2002	PSF	oui
2.1.3	2.1.2	2002	PSF	oui
2.2 et supérieur	2.1.1	2001-maintenant	PSF	oui

---

**Note :** Compatible GPL ne signifie pas que nous distribuons Python sous licence GPL. Toutes les licences Python, excepté la licence GPL, vous permettent la distribution d'une version modifiée sans rendre open source ces changements. La licence « compatible GPL » rend possible la diffusion de Python avec un autre logiciel qui est lui, diffusé sous la licence GPL ; les licences « non compatible GPL » ne le peuvent pas.

---

Merci aux nombreux bénévoles qui ont travaillé sous la direction de Guido pour rendre ces versions possibles.

## C.2 Conditions générales pour accéder à, ou utiliser, Python

### C.2.1 PSF LICENSE AGREEMENT FOR PYTHON 2.7.15

1. This LICENSE AGREEMENT is between the Python Software Foundation ("PSF"), and the Individual or Organization ("Licensee") accessing and otherwise using Python 2.7.15 software in source or binary form and its associated documentation.
2. Subject to the terms and conditions of this License Agreement, PSF hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python 2.7.15 alone or in any derivative version, provided, however, that PSF's License Agreement and PSF's notice of copyright, i.e., "Copyright © 2001-2019 Python Software Foundation; All Rights Reserved" are retained in Python 2.7.15 alone or in any derivative version prepared by Licensee.
3. In the event Licensee prepares a derivative work that is based on or incorporates Python 2.7.15 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python 2.7.15.
4. PSF is making Python 2.7.15 available to Licensee on an "AS IS" basis. PSF MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, PSF MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON 2.7.15 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
5. PSF SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 2.7.15 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 2.7.15, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.
6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
7. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between PSF and Licensee. This License Agreement does not grant permission to use PSF trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.
8. By copying, installing or otherwise using Python 2.7.15, Licensee agrees to be bound by the terms and conditions of this License Agreement.

## C.2.2 LICENCE D'UTILISATION BEOPEN.COM POUR PYTHON 2.0

### LICENCE D'UTILISATION LIBRE BEOPEN PYTHON VERSION 1

1. This LICENSE AGREEMENT is between BeOpen.com ("BeOpen"), having an office at 160 Saratoga Avenue, Santa Clara, CA 95051, and the Individual or Organization ("Licensee") accessing and otherwise using this software in source or binary form and its associated documentation ("the Software").
2. Subject to the terms and conditions of this BeOpen Python License Agreement, BeOpen hereby grants Licensee a non-exclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use the Software alone or in any derivative version, provided, however, that the BeOpen Python License is retained in the Software, alone or in any derivative version prepared by Licensee.
3. BeOpen is making the Software available to Licensee on an "AS IS" basis. BEOPEN MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, BEOPEN MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF THE SOFTWARE WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
4. BEOPEN SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF THE SOFTWARE FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF USING, MODIFYING OR DISTRIBUTING THE SOFTWARE, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.
5. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
6. This License Agreement shall be governed by and interpreted in all respects by the law of the State of California, excluding conflict of law provisions. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between BeOpen and Licensee. This License Agreement does not grant permission to use BeOpen trademarks or trade names in a trademark sense to endorse or promote products or services of Licensee, or any third party. As an exception, the "BeOpen Python" logos available at <http://www.pythonlabs.com/logos.html> may be used according to the permissions granted on that web page.
7. By copying, installing or otherwise using the software, Licensee agrees to be bound by the terms and conditions of this License Agreement.

## C.2.3 LICENCE D'UTILISATION CNRI POUR PYTHON 1.6.1

1. This LICENSE AGREEMENT is between the Corporation for National Research Initiatives, having an office at 1895 Preston White Drive, Reston, VA 20191 ("CNRI"), and the Individual or Organization ("Licensee") accessing and otherwise using Python 1.6.1 software in source or binary form and its associated documentation.
2. Subject to the terms and conditions of this License Agreement, CNRI hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce,

(suite sur la page suivante)

(suite de la page précédente)

analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python 1.6.1 alone or in any derivative version, provided, however, that CNRI's License Agreement and CNRI's notice of copyright, i.e., "Copyright © 1995-2001 Corporation for National Research Initiatives; All Rights Reserved" are retained in Python 1.6.1 alone or in any derivative version prepared by Licensee. Alternately, in lieu of CNRI's License Agreement, Licensee may substitute the following text (omitting the quotes): "Python 1.6.1 is made available subject to the terms and conditions in CNRI's License Agreement. This Agreement together with Python 1.6.1 may be located on the Internet using the following unique, persistent identifier (known as a handle): 1895.22/1013. This Agreement may also be obtained from a proxy server on the Internet using the following URL: <http://hdl.handle.net/1895.22/1013>."

3. In the event Licensee prepares a derivative work that is based on or incorporates Python 1.6.1 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python 1.6.1.
4. CNRI is making Python 1.6.1 available to Licensee on an "AS IS" basis. CNRI MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, CNRI MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON 1.6.1 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
5. CNRI SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 1.6.1 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 1.6.1, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.
6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
7. This License Agreement shall be governed by the federal intellectual property law of the United States, including without limitation the federal copyright law, and, to the extent such U.S. federal law does not apply, by the law of the Commonwealth of Virginia, excluding Virginia's conflict of law provisions. Notwithstanding the foregoing, with regard to derivative works based on Python 1.6.1 that incorporate non-separable material that was previously distributed under the GNU General Public License (GPL), the law of the Commonwealth of Virginia shall govern this License Agreement only as to issues arising under or with respect to Paragraphs 4, 5, and 7 of this License Agreement. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between CNRI and Licensee. This License Agreement does not grant permission to use CNRI trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.
8. By clicking on the "ACCEPT" button where indicated, or by copying, installing or otherwise using Python 1.6.1, Licensee agrees to be bound by the terms and conditions of this License Agreement.

## C.2.4 LICENCE D'UTILISATION CWI POUR PYTHON 0.9.0 à 1.2

Copyright © 1991 - 1995, Stichting Mathematisch Centrum Amsterdam, The Netherlands. All rights reserved.

Permission to use, copy, modify, and distribute this software and its documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Stichting Mathematisch Centrum or CWI not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

STICHTING MATHEMATISCH CENTRUM DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS, IN NO EVENT SHALL STICHTING MATHEMATISCH CENTRUM BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

## C.3 Licences et Remerciements pour les logiciels inclus

Cette section est une liste incomplète mais grandissante de licences et remerciements pour les logiciels tiers incorporés dans la distribution de Python.

### C.3.1 Mersenne twister

Le module `_random` inclut du code construit à partir d'un téléchargement depuis <http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/MT2002/emt19937ar.html>. Voici mot pour mot les commentaires du code original :

A C-program for MT19937, with initialization improved 2002/1/26.  
Coded by Takuji Nishimura and Makoto Matsumoto.

Before using, initialize the state by using `init_genrand(seed)`  
or `init_by_array(init_key, key_length)`.

Copyright (C) 1997 - 2002, Makoto Matsumoto and Takuji Nishimura,  
All rights reserved.

Redistribution and use in source and binary forms, with or without  
modification, are permitted provided that the following conditions  
are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.

(suite sur la page suivante)

(suite de la page précédente)

3. The names of its contributors may not be used to endorse or promote products derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

Any feedback is very welcome.

<http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html>

email: m-mat @ math.sci.hiroshima-u.ac.jp (remove space)

### C.3.2 Interfaces de connexion (*sockets*)

Le module *socket* utilise les fonctions `getaddrinfo()` et `getnameinfo()` codées dans des fichiers source séparés et provenant du projet WIDE : <http://www.wide.ad.jp/>.

Copyright (C) 1995, 1996, 1997, and 1998 WIDE Project.  
All rights reserved.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
3. Neither the name of the project nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED BY THE PROJECT AND CONTRIBUTORS ``AS IS'' AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE PROJECT OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

### C.3.3 Virgule flottante et contrôle d'exception

Le code source pour le module *fpectl* inclut la note suivante :

```

-----
/                               Copyright (c) 1996.                               \

-----

```

### C.3.4 MD5 message digest algorithm

The source code for the *md5* module contains the following notice :

```

Copyright (C) 1999, 2002 Aladdin Enterprises.  All rights reserved.

This software is provided 'as-is', without any express or implied
warranty.  In no event will the authors be held liable for any damages
arising from the use of this software.

Permission is granted to anyone to use this software for any purpose,
including commercial applications, and to alter it and redistribute it
freely, subject to the following restrictions:

```

(suite sur la page suivante)

(suite de la page précédente)

1. The origin of this software must not be misrepresented; you must not claim that you wrote the original software. If you use this software in a product, an acknowledgment in the product documentation would be appreciated but is not required.
2. Altered source versions must be plainly marked as such, and must not be misrepresented as being the original software.
3. This notice may not be removed or altered from any source distribution.

L. Peter Deutsch  
ghost@aladdin.com

Independent implementation of MD5 (RFC 1321).

This code implements the MD5 Algorithm defined in RFC 1321, whose text is available at

<http://www.ietf.org/rfc/rfc1321.txt>

The code is derived from the text of the RFC, including the test suite (section A.5) but excluding the rest of Appendix A. It does not include any code or documentation that is identified in the RFC as being copyrighted.

The original and principal author of md5.h is L. Peter Deutsch <ghost@aladdin.com>. Other authors are noted in the change history that follows (in reverse chronological order):

2002-04-13 lpd Removed support for non-ANSI compilers; removed references to Ghostscript; clarified derivation from RFC 1321; now handles byte order either statically or dynamically.  
1999-11-04 lpd Edited comments slightly for automatic TOC extraction.  
1999-10-18 lpd Fixed typo in header comment (ansi2knr rather than md5); added conditionalization for C++ compilation from Martin Purschke <purschke@bnl.gov>.  
1999-05-03 lpd Original version.

### C.3.5 Interfaces de connexion asynchrones

Les modules *asynchat* et *asyncore* contiennent la note suivante :

Copyright 1996 by Sam Rushing

All Rights Reserved

Permission to use, copy, modify, and distribute this software and its documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Sam Rushing not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

SAM RUSHING DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE,

```

(suite sur la page suivante)

(suite de la page précédente)

Copyright 1991-1995, Stichting Mathematisch Centrum, all rights reserved.

Permission to use, copy, modify, and distribute this Python software and its associated documentation for any purpose without fee is hereby granted, provided that the above copyright notice appears in all copies, and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of neither Automatrix, Bioreason or Mojam Media be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

### C.3.8 Les fonctions UUencode et UUdecode

Le module `uu` contient la note suivante :

Copyright 1994 by Lance Ellinghouse  
Cathedral City, California Republic, United States of America.

All Rights Reserved

Permission to use, copy, modify, and distribute this software and its documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Lance Ellinghouse not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

LANCE ELLINGHOUSE DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS, IN NO EVENT SHALL LANCE ELLINGHOUSE CENTRUM BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

Modified by Jack Jansen, CWI, July 1995:

- Use `binascii` module to do the actual line-by-line conversion between `ascii` and `binary`. This results in a 1000-fold speedup. The C version is still 5 times faster, though.
- Arguments more compliant with Python standard

### C.3.9 Appel de procédures distantes en XML (*RPC*, pour *Remote Procedure Call*)

The `xmlrpc.lib` module contains the following notice :

The XML-RPC client interface is

Copyright (c) 1999-2002 by Secret Labs AB  
Copyright (c) 1999-2002 by Fredrik Lundh

By obtaining, using, and/or copying this software and/or its associated documentation, you agree that you have read, understood, and will comply with the following terms and conditions:

(suite sur la page suivante)

(suite de la page précédente)

Permission to use, copy, modify, and distribute this software and its associated documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appears in all copies, and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Secret Labs AB or the author not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

SECRET LABS AB AND THE AUTHOR DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS. */

```

### C.3.14 expat

Le module `pyexpat` est compilé avec une copie des sources d'*expat*, sauf si la compilation est configurée avec `--with-system-expat` :

```

Copyright (c) 1998, 1999, 2000 Thai Open Source Software Center Ltd
and Clark Cooper

Permission is hereby granted, free of charge, to any person obtaining
a copy of this software and associated documentation files (the
"Software"), to deal in the Software without restriction, including
without limitation the rights to use, copy, modify, merge, publish,
distribute, sublicense, and/or sell copies of the Software, and to
permit persons to whom the Software is furnished to do so, subject to
the following conditions:

The above copyright notice and this permission notice shall be included
in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND,
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF
MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT.
IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY
CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT,
TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE
SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

```

### C.3.15 libffi

Le module `_ctypes` est compilé en utilisant une copie des sources de la *libffi*, sauf si la compilation est configurée avec `--with-system-libffi` :

```
Copyright (c) 1996-2008 Red Hat, Inc and others.
```

```
Permission is hereby granted, free of charge, to any person obtaining
a copy of this software and associated documentation files (the
``Software''), to deal in the Software without restriction, including
without limitation the rights to use, copy, modify, merge, publish,
distribute, sublicense, and/or sell copies of the Software, and to
permit persons to whom the Software is furnished to do so, subject to
the following conditions:
```

```
The above copyright notice and this permission notice shall be included
in all copies or substantial portions of the Software.
```

```
THE SOFTWARE IS PROVIDED ``AS IS'', WITHOUT WARRANTY OF ANY KIND,
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF
MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND
NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT
HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY,
WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM,
OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER
DEALINGS IN THE SOFTWARE.
```

### C.3.16 zlib

Le module `zlib` est compilé en utilisant une copie du code source de *zlib* si la version de *zlib* trouvée sur le système est trop vieille pour être utilisée :

```
Copyright (C) 1995-2010 Jean-loup Gailly and Mark Adler
```

```
This software is provided 'as-is', without any express or implied
warranty. In no event will the authors be held liable for any damages
arising from the use of this software.
```

```
Permission is granted to anyone to use this software for any purpose,
including commercial applications, and to alter it and redistribute it
freely, subject to the following restrictions:
```

1. The origin of this software must not be misrepresented; you must not claim that you wrote the original software. If you use this software in a product, an acknowledgment in the product documentation would be appreciated but is not required.
2. Altered source versions must be plainly marked as such, and must not be misrepresented as being the original software.
3. This notice may not be removed or altered from any source distribution.

```
