Upon startup with the `-s` option, IDLE will execute the file referenced by the environment variables `IDLESTARTUP` or `PYTHONSTARTUP`. IDLE first checks for `IDLESTARTUP`; if `IDLESTARTUP` is present the file referenced is run. If `IDLESTARTUP` is not present, IDLE checks for `PYTHONSTARTUP`. Files referenced by these environment variables are convenient places to store functions that are used frequently from the IDLE shell, or for executing import statements to import common modules.

In addition, `Tk` also loads a startup file if it is present. Note that the `Tk` file is loaded unconditionally. This additional file is `.Idle.py` and is looked for in the user's home directory. Statements in this file will be executed in the `Tk` namespace, so this file is not useful for importing functions to be used from IDLE's Python shell.

### Command line usage

```
idle.py [-c command] [-d] [-e] [-h] [-i] [-r file] [-s] [-t title] [-] [arg] ...

-c command    run command in the shell window
-d            enable debugger and open shell window
-e            open editor window
-h            print help message with legal combinations and exit
-i            open shell window
-r file       run file in shell window
-s            run $IDLESTARTUP or $PYTHONSTARTUP first, in shell window
-t title      set title of shell window
-            run stdin in shell (- must be last option before args)
```

If there are arguments:

- If `-`, `-c`, or `r` is used, all arguments are placed in `sys.argv[1:..]` and `sys.argv[0]` is set to `'', '-c'`, or `'-r'`. No editor window is opened, even if that is the default set in the Options dialog.
- Otherwise, arguments are files opened for editing and `sys.argv` reflects the arguments passed to IDLE itself.

### Startup failure

IDLE uses a socket to communicate between the IDLE GUI process and the user code execution process. A connection must be established whenever the Shell starts or restarts. (The latter is indicated by a divider line that says 'RESTART'). If the user process fails to connect to the GUI process, it usually displays a Tk error box with a 'cannot connect' message that directs the user here. It then exits.

One specific connection failure on Unix systems results from misconfigured masquerading rules somewhere in a system's network setup. When IDLE is started from a terminal, one will see a message starting with `** Invalid host:.` The valid value is `127.0.0.1` (`idlelib.rpc.LOCALHOST`). One can diagnose with `tcpconnect -irv 127.0.0.1 6543` in one terminal window and `tcplisten <same args>` in another.

A common cause of failure is a user-written file with the same name as a standard library module, such as *random.py* and *tkinter.py*. When such a file is located in the same directory as a file that is about to be run, IDLE cannot import the stdlib file. The current fix is to rename the user file.

Though less common than in the past, an antivirus or firewall program may stop the connection. If the program cannot be taught to allow the connection, then it must be turned off for IDLE to work. It is safe to allow this internal connection because no data is visible on external ports. A similar problem is a network mis-configuration that blocks connections.

Python installation issues occasionally stop IDLE: multiple versions can clash, or a single installation might need admin access. If one undo the clash, or cannot or does not want to run as admin, it might be easiest to completely remove Python and start over.

A zombie pythonw.exe process could be a problem. On Windows, use Task Manager to check for one and stop it if there is. Sometimes a restart initiated by a program crash or Keyboard Interrupt (control-C) may fail to connect. Dismissing the error box or using Restart Shell on the Shell menu may fix a temporary problem.

When IDLE first starts, it attempts to read user configuration files in `~/ .idlerc/` (`~` is one's home directory). If there is a problem, an error message should be displayed. Leaving aside random disk glitches, this can be prevented by never editing the files by hand. Instead, use the configuration dialog, under Options. Once there is an error in a user configuration file, the best solution may be to delete it and start over with the settings dialog.

If IDLE quits with no message, and it was not started from a console, try starting it from a console or terminal (`python -m idlelib`) and see if this results in an error message.

On Unix-based systems with tcl/tk older than 8.6.11 (see `About IDLE`) certain characters of certain fonts can cause a tk failure with a message to the terminal. This can happen either if one starts IDLE to edit a file with such a character or later when entering such a character. If one cannot upgrade tcl/tk, then re-configure IDLE to use a font that works better.

## Running user code

With rare exceptions, the result of executing Python code with IDLE is intended to be the same as executing the same code by the default method, directly with Python in a text-mode system console or terminal window. However, the different interface and operation occasionally affect visible results. For instance, `sys.modules` starts with more entries, and `threading.active_count()` returns 2 instead of 1.

By default, IDLE runs user code in a separate OS process rather than in the user interface process that runs the shell and editor. In the execution process, it replaces `sys.stdin`, `sys.stdout`, and `sys.stderr` with objects that get input from and send output to the Shell window. The original values stored in `sys.__stdin__`, `sys.__stdout__`, and `sys.__stderr__` are not touched, but may be `None`.

Sending print output from one process to a text widget in another is slower than printing to a system terminal in the same process. This has the most effect when printing multiple arguments, as the string for each argument, each separator, the newline are sent separately. For development, this is usually not a problem, but if one wants to print faster in IDLE, format and join together everything one wants displayed together and then print a single string. Both format strings and `str.join()` can help combine fields and lines.

IDLE's standard stream replacements are not inherited by subprocesses created in the execution process, whether directly by user code or by modules such as multiprocessing. If such subprocess use `input` from `sys.stdin` or `print` or `write` to `sys.stdout` or `sys.stderr`, IDLE should be started in a command line window. The secondary subprocess will then be attached to that window for input and output.

If `sys` is reset by user code, such as with `importlib.reload(sys)`, IDLE's changes are lost and input from the keyboard and output to the screen will not work correctly.

When Shell has the focus, it controls the keyboard and screen. This is normally transparent, but functions that directly access the keyboard and screen will not work. These include system-specific functions that determine whether a key has been pressed and if so, which.

The IDLE code running in the execution process adds frames to the call stack that would not be there otherwise. IDLE wraps `sys.getrecursionlimit` and `sys.setrecursionlimit` to reduce the effect of the additional stack frames.

When user code raises `SystemExit` either directly or by calling `sys.exit`, IDLE returns to a Shell prompt instead of exiting.

## User output in Shell

When a program outputs text, the result is determined by the corresponding output device. When IDLE executes user code, `sys.stdout` and `sys.stderr` are connected to the display area of IDLE's Shell. Some of its features are inherited from the underlying Tk Text widget. Others are programmed additions. Where it matters, Shell is designed for development rather than production runs.

For instance, Shell never throws away output. A program that sends unlimited output to Shell will eventually fill memory, resulting in a memory error. In contrast, some system text windows only keep the last *n* lines of output. A Windows console, for instance, keeps a user-settable 1 to 9999 lines, with 300 the default.

A Tk Text widget, and hence IDLE's Shell, displays characters (codepoints) in the BMP (Basic Multilingual Plane) subset of Unicode. Which characters are displayed with a proper glyph and which with a replacement box depends on the operating system and installed fonts. Tab characters cause the following text to begin after the next tab stop. (They occur every 8 'characters'). Newline characters cause following text to appear on a new line. Other control characters are ignored or displayed as a space, box, or something else, depending on the operating system and font. (Moving the text cursor through such output with arrow keys may exhibit some surprising spacing behavior.)

```
>>> s = 'a\tb\aa<\x02><\r>\bc\nd' # Enter 22 chars.
>>> len(s)
14
>>> s # Display repr(s)
'a\tb\x07<\x02><\r>\x08c\nd'
>>> print(s, end='') # Display s as is.
# Result varies by OS and font. Try it.
```

The `repr` function is used for interactive echo of expression values. It returns an altered version of the input string in which control codes, some BMP codepoints, and all non-BMP codepoints are replaced with escape codes. As demonstrated above, it allows one to identify the characters in a string, regardless of how they are displayed.

Normal and error output are generally kept separate (on separate lines) from code input and each other. They each get different highlight colors.

For `SyntaxError` tracebacks, the normal '^' marking where the error was detected is replaced by coloring the text with an error highlight. When code run from a file causes other exceptions, one may right click on a traceback line to jump to the corresponding line in an IDLE editor. The file will be opened if necessary.

Shell has a special facility for squeezing output lines down to a 'Squeezed text' label. This is done automatically for output over N lines (N = 50 by default). N can be changed in the PyShell section of the General page of the Settings dialog. Output with fewer lines can be squeezed by right clicking on the output. This can be useful lines long enough to slow down scrolling.

Squeezed output is expanded in place by double-clicking the label. It can also be sent to the clipboard or a separate view window by right-clicking the label.

### Developing tkinter applications

IDLE is intentionally different from standard Python in order to facilitate development of tkinter programs. Enter `import tkinter as tk; root = tk.Tk()` in standard Python and nothing appears. Enter the same in IDLE and a tk window appears. In standard Python, one must also enter `root.update()` to see the window. IDLE does the equivalent in the background, about 20 times a second, which is about every 50 milliseconds. Next enter `b = tk.Button(root, text='button');` `b.pack()`. Again, nothing visibly changes in standard Python until one enters `root.update()`.

Most tkinter programs run `root.mainloop()`, which usually does not return until the tk app is destroyed. If the program is run with `python -i` or from an IDLE editor, a `>>>` shell prompt does not appear until `mainloop()` returns, at which time there is nothing left to interact with.

When running a tkinter program from an IDLE editor, one can comment out the `mainloop` call. One then gets a shell prompt immediately and can interact with the live application. One just has to remember to re-enable the `mainloop` call when running in standard Python.

### Running without a subprocess

By default, IDLE executes user code in a separate subprocess via a socket, which uses the internal loopback interface. This connection is not externally visible and no data is sent to or received from the Internet. If firewall software complains anyway, you can ignore it.

If the attempt to make the socket connection fails, Idle will notify you. Such failures are sometimes transient, but if persistent, the problem may be either a firewall blocking the connection or misconfiguration of a particular system. Until the problem is fixed, one can run Idle with the `-n` command line switch.

If IDLE is started with the `-n` command line switch it will run in a single process and will not create the subprocess which runs the RPC Python execution server. This can be useful if Python cannot create the subprocess or the RPC socket

interface on your platform. However, in this mode user code is not isolated from IDLE itself. Also, the environment is not restarted when Run/Run Module (F5) is selected. If your code has been modified, you must `reload()` the affected modules and re-import any specific items (e.g. `from foo import baz`) if the changes are to take effect. For these reasons, it is preferable to run IDLE with the default subprocess if at all possible.

Ditinggalkan sejak versi 3.4.

## 25.5.4 Help and preferences

### Help sources

Help menu entry "IDLE Help" displays a formatted html version of the IDLE chapter of the Library Reference. The result, in a read-only tkinter text window, is close to what one sees in a web browser. Navigate through the text with a mousewheel, the scrollbar, or up and down arrow keys held down. Or click the TOC (Table of Contents) button and select a section header in the opened box.

Help menu entry "Python Docs" opens the extensive sources of help, including tutorials, available at `docs.python.org/x.y`, where 'x.y' is the currently running Python version. If your system has an off-line copy of the docs (this may be an installation option), that will be opened instead.

Selected URLs can be added or removed from the help menu at any time using the General tab of the Configure IDLE dialog.

### Setting preferences

The font preferences, highlighting, keys, and general preferences can be changed via Configure IDLE on the Option menu. Non-default user settings are saved in a `.idlerc` directory in the user's home directory. Problems caused by bad user configuration files are solved by editing or deleting one or more of the files in `.idlerc`.

On the Font tab, see the text sample for the effect of font face and size on multiple characters in multiple languages. Edit the sample to add other characters of personal interest. Use the sample to select monospaced fonts. If particular characters have problems in Shell or an editor, add them to the top of the sample and try changing first size and then font.

On the Highlights and Keys tab, select a built-in or custom color theme and key set. To use a newer built-in color theme or key set with older IDLEs, save it as a new custom theme or key set and it will be accessible to older IDLEs.

### IDLE on macOS

Under System Preferences: Dock, one can set "Prefer tabs when opening documents" to "Always". This setting is not compatible with the tk/tkinter GUI framework used by IDLE, and it breaks a few IDLE features.

### Extensions

IDLE contains an extension facility. Preferences for extensions can be changed with the Extensions tab of the preferences dialog. See the beginning of `config-extensions.def` in the `idlelib` directory for further information. The only current default extension is `zzdummy`, an example also used for testing.

## 25.6 Other Graphical User Interface Packages

Major cross-platform (Windows, Mac OS X, Unix-like) GUI toolkits are available for Python:

**Lihat juga:**

**PyGObject** PyGObject provides introspection bindings for C libraries using [GObject](#). One of these libraries is the [GTK+ 3](#) widget set. GTK+ comes with many more widgets than Tkinter provides. An online [Python GTK+ 3 Tutorial](#) is available.

**PyGTK** PyGTK provides bindings for an older version of the library, GTK+ 2. It provides an object oriented interface that is slightly higher level than the C one. There are also bindings to [GNOME](#). An online [tutorial](#) is available.

**PyQt** PyQt is a **sip**-wrapped binding to the Qt toolkit. Qt is an extensive C++ GUI application development framework that is available for Unix, Windows and Mac OS X. **sip** is a tool for generating bindings for C++ libraries as Python classes, and is specifically designed for Python.

**PySide2** Also known as the Qt for Python project, PySide2 is a newer binding to the Qt toolkit. It is provided by The Qt Company and aims to provide a complete port of PySide to Qt 5. Compared to PyQt, its licensing scheme is friendlier to non-open source applications.

**wxPython** wxPython is a cross-platform GUI toolkit for Python that is built around the popular [wxWidgets](#) (formerly wxWindows) C++ toolkit. It provides a native look and feel for applications on Windows, Mac OS X, and Unix systems by using each platform's native widgets where ever possible, (GTK+ on Unix-like systems). In addition to an extensive set of widgets, wxPython provides classes for online documentation and context sensitive help, printing, HTML viewing, low-level device context drawing, drag and drop, system clipboard access, an XML-based resource format and more, including an ever growing library of user-contributed modules.

PyGTK, PyQt, PySide2, and wxPython, all have a modern look and feel and more widgets than Tkinter. In addition, there are many other GUI toolkits for Python, both cross-platform, and platform-specific. See the [GUI Programming](#) page in the Python Wiki for a much more complete list, and also for links to documents where the different GUI toolkits are compared.

---

## Alat Pengembangan

---

Modul yang dijelaskan dalam bab ini membantu Anda menulis perangkat lunak. Sebagai contoh, modul *pydoc* mengambil modul dan menghasilkan dokumentasi berdasarkan isi modul. Modul *doctest* dan *unittest* berisi kerangka kerja untuk penulisan unit test yang secara otomatis menjalankan kode dan memverifikasi bahwa output yang diharapkan dihasilkan. **2to3** dapat menerjemahkan kode Python 2.x menjadi kode Python 3.x yang valid.

Daftar modul yang dijelaskan di dalam bab ini adalah:

### 26.1 *typing* --- Support for type hints

Baru pada versi 3.5.

**Source code:** [Lib/typing.py](#)

---

**Catatan:** The Python runtime does not enforce function and variable type annotations. They can be used by third party tools such as type checkers, IDEs, linters, etc.

---

This module provides runtime support for type hints as specified by **PEP 484**, **PEP 526**, **PEP 544**, **PEP 586**, **PEP 589**, and **PEP 591**. The most fundamental support consists of the types *Any*, *Union*, *Tuple*, *Callable*, *TypeVar*, and *Generic*. For full specification please see **PEP 484**. For a simplified introduction to type hints see **PEP 483**.

The function below takes and returns a string and is annotated as follows:

```
def greeting(name: str) -> str:
    return 'Hello ' + name
```

In the function `greeting`, the argument `name` is expected to be of type `str` and the return type `str`. Subtypes are accepted as arguments.

### 26.1.1 Type aliases

A type alias is defined by assigning the type to the alias. In this example, `Vector` and `List[float]` will be treated as interchangeable synonyms:

```
from typing import List
Vector = List[float]

def scale(scalar: float, vector: Vector) -> Vector:
    return [scalar * num for num in vector]

# typechecks; a list of floats qualifies as a Vector.
new_vector = scale(2.0, [1.0, -4.2, 5.4])
```

Type aliases are useful for simplifying complex type signatures. For example:

```
from typing import Dict, Tuple, Sequence

ConnectionOptions = Dict[str, str]
Address = Tuple[str, int]
Server = Tuple[Address, ConnectionOptions]

def broadcast_message(message: str, servers: Sequence[Server]) -> None:
    ...

# The static type checker will treat the previous type signature as
# being exactly equivalent to this one.
def broadcast_message(
    message: str,
    servers: Sequence[Tuple[Tuple[str, int], Dict[str, str]]]) -> None:
    ...
```

Note that `None` as a type hint is a special case and is replaced by `type(None)`.

### 26.1.2 NewType

Use the `NewType()` helper function to create distinct types:

```
from typing import NewType

UserId = NewType('UserId', int)
some_id = UserId(524313)
```

The static type checker will treat the new type as if it were a subclass of the original type. This is useful in helping catch logical errors:

```
def get_user_name(user_id: UserId) -> str:
    ...

# typechecks
user_a = get_user_name(UserId(42351))

# does not typecheck; an int is not a UserId
user_b = get_user_name(-1)
```

You may still perform all `int` operations on a variable of type `UserId`, but the result will always be of type `int`. This lets you pass in a `UserId` wherever an `int` might be expected, but will prevent you from accidentally creating a

UserId in an invalid way:

```
# 'output' is of type 'int', not 'UserId'
output = UserId(23413) + UserId(54341)
```

Note that these checks are enforced only by the static type checker. At runtime, the statement `Derived = NewType('Derived', Base)` will make `Derived` a function that immediately returns whatever parameter you pass it. That means the expression `Derived(some_value)` does not create a new class or introduce any overhead beyond that of a regular function call.

More precisely, the expression `some_value is Derived(some_value)` is always true at runtime.

This also means that it is not possible to create a subtype of `Derived` since it is an identity function at runtime, not an actual type:

```
from typing import NewType

UserId = NewType('UserId', int)

# Fails at runtime and does not typecheck
class AdminUserId(UserId): pass
```

However, it is possible to create a `NewType()` based on a 'derived' `NewType`:

```
from typing import NewType

UserId = NewType('UserId', int)

ProUserId = NewType('ProUserId', UserId)
```

and typechecking for `ProUserId` will work as expected.

See [PEP 484](#) for more details.

---

**Catatan:** Recall that the use of a type alias declares two types to be *equivalent* to one another. Doing `Alias = Original` will make the static type checker treat `Alias` as being *exactly equivalent* to `Original` in all cases. This is useful when you want to simplify complex type signatures.

In contrast, `NewType` declares one type to be a *subtype* of another. Doing `Derived = NewType('Derived', Original)` will make the static type checker treat `Derived` as a *subclass* of `Original`, which means a value of type `Original` cannot be used in places where a value of type `Derived` is expected. This is useful when you want to prevent logic errors with minimal runtime cost.

---

Baru pada versi 3.5.2.

### 26.1.3 Callable

Frameworks expecting callback functions of specific signatures might be type hinted using `Callable[[Arg1Type, Arg2Type], ReturnTypes]`.

Sebagai contoh:

```
from typing import Callable

def feeder(get_next_item: Callable[[], str]) -> None:
    # Body
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
def async_query(on_success: Callable[[int], None],
               on_error: Callable[[int, Exception], None]) -> None:
    # Body
```

It is possible to declare the return type of a callable without specifying the call signature by substituting a literal ellipsis for the list of arguments in the type hint: `Callable[..., ReturnType]`.

## 26.1.4 Generics

Since type information about objects kept in containers cannot be statically inferred in a generic way, abstract base classes have been extended to support subscription to denote expected types for container elements.

```
from typing import Mapping, Sequence

def notify_by_email(employees: Sequence[Employee],
                  overrides: Mapping[str, str]) -> None: ...
```

Generics can be parameterized by using a new factory available in typing called *TypeVar*.

```
from typing import Sequence, TypeVar

T = TypeVar('T')          # Declare type variable

def first(l: Sequence[T]) -> T:    # Generic function
    return l[0]
```

## 26.1.5 User-defined generic types

A user-defined class can be defined as a generic class.

```
from typing import TypeVar, Generic
from logging import Logger

T = TypeVar('T')

class LoggedVar(Generic[T]):
    def __init__(self, value: T, name: str, logger: Logger) -> None:
        self.name = name
        self.logger = logger
        self.value = value

    def set(self, new: T) -> None:
        self.log('Set ' + repr(self.value))
        self.value = new

    def get(self) -> T:
        self.log('Get ' + repr(self.value))
        return self.value

    def log(self, message: str) -> None:
        self.logger.info('%s: %s', self.name, message)
```

`Generic[T]` as a base class defines that the class `LoggedVar` takes a single type parameter `T`. This also makes `T` valid as a type within the class body.

The *Generic* base class defines `__class_getitem__()` so that `LoggedVar[t]` is valid as a type:

```
from typing import Iterable

def zero_all_vars(vars: Iterable[LoggedVar[int]]) -> None:
    for var in vars:
        var.set(0)
```

A generic type can have any number of type variables, and type variables may be constrained:

```
from typing import TypeVar, Generic
...

T = TypeVar('T')
S = TypeVar('S', int, str)

class StrangePair(Generic[T, S]):
    ...
```

Each type variable argument to *Generic* must be distinct. This is thus invalid:

```
from typing import TypeVar, Generic
...

T = TypeVar('T')

class Pair(Generic[T, T]):    # INVALID
    ...
```

You can use multiple inheritance with *Generic*:

```
from typing import TypeVar, Generic, Sized

T = TypeVar('T')

class LinkedList(Sized, Generic[T]):
    ...
```

When inheriting from generic classes, some type variables could be fixed:

```
from typing import TypeVar, Mapping

T = TypeVar('T')

class MyDict(Mapping[str, T]):
    ...
```

In this case `MyDict` has a single parameter, `T`.

Using a generic class without specifying type parameters assumes *Any* for each position. In the following example, `MyIterable` is not generic but implicitly inherits from `Iterable[Any]`:

```
from typing import Iterable

class MyIterable(Iterable): # Same as Iterable[Any]
```

User defined generic type aliases are also supported. Examples:

```
from typing import TypeVar, Iterable, Tuple, Union
S = TypeVar('S')
Response = Union[Iterable[S], int]

# Return type here is same as Union[Iterable[str], int]
def response(query: str) -> Response[str]:
    ...

T = TypeVar('T', int, float, complex)
Vec = Iterable[Tuple[T, T]]

def inproduct(v: Vec[T]) -> T: # Same as Iterable[Tuple[T, T]]
    return sum(x*y for x, y in v)
```

Berubah pada versi 3.7: *Generic* no longer has a custom metaclass.

A user-defined generic class can have ABCs as base classes without a metaclass conflict. Generic metaclasses are not supported. The outcome of parameterizing generics is cached, and most types in the typing module are hashable and comparable for equality.

### 26.1.6 The Any type

A special kind of type is *Any*. A static type checker will treat every type as being compatible with *Any* and *Any* as being compatible with every type.

This means that it is possible to perform any operation or method call on a value of type *Any* and assign it to any variable:

```
from typing import Any

a = None      # type: Any
a = []        # OK
a = 2         # OK

s = ''        # type: str
s = a         # OK

def foo(item: Any) -> int:
    # Typechecks; 'item' could be any type,
    # and that type might have a 'bar' method
    item.bar()
    ...
```

Notice that no typechecking is performed when assigning a value of type *Any* to a more precise type. For example, the static type checker did not report an error when assigning *a* to *s* even though *s* was declared to be of type *str* and receives an *int* value at runtime!

Furthermore, all functions without a return type or parameter types will implicitly default to using *Any*:

```
def legacy_parser(text):
    ...
    return data

# A static type checker will treat the above
# as having the same signature as:
def legacy_parser(text: Any) -> Any:
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
...
return data
```

This behavior allows *Any* to be used as an *escape hatch* when you need to mix dynamically and statically typed code.

Contrast the behavior of *Any* with the behavior of *object*. Similar to *Any*, every type is a subtype of *object*. However, unlike *Any*, the reverse is not true: *object* is *not* a subtype of every other type.

That means when the type of a value is *object*, a type checker will reject almost all operations on it, and assigning it to a variable (or using it as a return value) of a more specialized type is a type error. For example:

```
def hash_a(item: object) -> int:
    # Fails; an object does not have a 'magic' method.
    item.magic()
    ...

def hash_b(item: Any) -> int:
    # Typechecks
    item.magic()
    ...

# Typechecks, since ints and strs are subclasses of object
hash_a(42)
hash_a("foo")

# Typechecks, since Any is compatible with all types
hash_b(42)
hash_b("foo")
```

Use *object* to indicate that a value could be any type in a typesafe manner. Use *Any* to indicate that a value is dynamically typed.

## 26.1.7 Nominal vs structural subtyping

Initially **PEP 484** defined Python static type system as using *nominal subtyping*. This means that a class A is allowed where a class B is expected if and only if A is a subclass of B.

This requirement previously also applied to abstract base classes, such as *Iterable*. The problem with this approach is that a class had to be explicitly marked to support them, which is unpythonic and unlike what one would normally do in idiomatic dynamically typed Python code. For example, this conforms to **PEP 484**:

```
from typing import Sized, Iterable, Iterator

class Bucket(Sized, Iterable[int]):
    ...
    def __len__(self) -> int: ...
    def __iter__(self) -> Iterator[int]: ...
```

**PEP 544** allows to solve this problem by allowing users to write the above code without explicit base classes in the class definition, allowing *Bucket* to be implicitly considered a subtype of both *Sized* and *Iterable[int]* by static type checkers. This is known as *structural subtyping* (or static duck-typing):

```
from typing import Iterator, Iterable

class Bucket: # Note: no base classes
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
...
def __len__(self) -> int: ...
def __iter__(self) -> Iterator[int]: ...

def collect(items: Iterable[int]) -> int: ...
result = collect(Bucket()) # Passes type check
```

Moreover, by subclassing a special class *Protocol*, a user can define new custom protocols to fully enjoy structural subtyping (see examples below).

## 26.1.8 Classes, functions, and decorators

The module defines the following classes, functions and decorators:

**class** `typing.TypeVar`

Type variable.

Penggunaan:

```
T = TypeVar('T') # Can be anything
A = TypeVar('A', str, bytes) # Must be str or bytes
```

Type variables exist primarily for the benefit of static type checkers. They serve as the parameters for generic types as well as for generic function definitions. See class *Generic* for more information on generic types. Generic functions work as follows:

```
def repeat(x: T, n: int) -> Sequence[T]:
    """Return a list containing n references to x."""
    return [x]*n

def longest(x: A, y: A) -> A:
    """Return the longest of two strings."""
    return x if len(x) >= len(y) else y
```

The latter example's signature is essentially the overloading of `(str, str) -> str` and `(bytes, bytes) -> bytes`. Also note that if the arguments are instances of some subclass of *str*, the return type is still plain *str*.

At runtime, `isinstance(x, T)` will raise *TypeError*. In general, `isinstance()` and `issubclass()` should not be used with types.

Type variables may be marked covariant or contravariant by passing `covariant=True` or `contravariant=True`. See [PEP 484](#) for more details. By default type variables are invariant. Alternatively, a type variable may specify an upper bound using `bound=<type>`. This means that an actual type substituted (explicitly or implicitly) for the type variable must be a subclass of the boundary type, see [PEP 484](#).

**class** `typing.Generic`

Abstract base class for generic types.

A generic type is typically declared by inheriting from an instantiation of this class with one or more type variables. For example, a generic mapping type might be defined as:

```
class Mapping(Generic[KT, VT]):
    def __getitem__(self, key: KT) -> VT:
        ...
        # Etc.
```

This class can then be used as follows:

```
X = TypeVar('X')
Y = TypeVar('Y')

def lookup_name(mapping: Mapping[X, Y], key: X, default: Y) -> Y:
    try:
        return mapping[key]
    except KeyError:
        return default
```

**class** `typing.Protocol` (*Generic*)

Base class for protocol classes. Protocol classes are defined like this:

```
class Proto(Protocol):
    def meth(self) -> int:
        ...
```

Such classes are primarily used with static type checkers that recognize structural subtyping (static duck-typing), for example:

```
class C:
    def meth(self) -> int:
        return 0

def func(x: Proto) -> int:
    return x.meth()

func(C()) # Passes static type check
```

See [PEP 544](#) for details. Protocol classes decorated with `runtime_checkable()` (described later) act as simple-minded runtime protocols that check only the presence of given attributes, ignoring their type signatures.

Protocol classes can be generic, for example:

```
class GenProto(Protocol[T]):
    def meth(self) -> T:
        ...
```

Baru pada versi 3.8.

**class** `typing.Type` (*Generic*[*CT\_co*])

A variable annotated with `C` may accept a value of type `C`. In contrast, a variable annotated with `Type[C]` may accept values that are classes themselves -- specifically, it will accept the *class object* of `C`. For example:

```
a = 3 # Has type 'int'
b = int # Has type 'Type[int]'
c = type(a) # Also has type 'Type[int]'
```

Note that `Type[C]` is covariant:

```
class User: ...
class BasicUser(User): ...
class ProUser(User): ...
class TeamUser(User): ...

# Accepts User, BasicUser, ProUser, TeamUser, ...
def make_new_user(user_class: Type[User]) -> User:
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
# ...  
return user_class()
```

The fact that `Type[C]` is covariant implies that all subclasses of `C` should implement the same constructor signature and class method signatures as `C`. The type checker should flag violations of this, but should also allow constructor calls in subclasses that match the constructor calls in the indicated base class. How the type checker is required to handle this particular case may change in future revisions of [PEP 484](#).

The only legal parameters for `Type` are classes, *Any*, *type variables*, and unions of any of these types. For example:

```
def new_non_team_user(user_class: Type[Union[BasicUser, ProUser]]): ...
```

`Type[Any]` is equivalent to `Type` which in turn is equivalent to `type`, which is the root of Python's metaclass hierarchy.

Baru pada versi 3.5.2.

```
class typing.Iterable(Generic[T_co])  
    A generic version of collections.abc.Iterable.  
  
class typing.Iterator(Iterable[T_co])  
    A generic version of collections.abc.Iterator.  
  
class typing.Reversible(Iterable[T_co])  
    A generic version of collections.abc.Reversible.  
  
class typing.SupportsInt  
    An ABC with one abstract method __int__.  
  
class typing.SupportsFloat  
    An ABC with one abstract method __float__.  
  
class typing.SupportsComplex  
    An ABC with one abstract method __complex__.  
  
class typing.SupportsBytes  
    An ABC with one abstract method __bytes__.  
  
class typing.SupportsIndex  
    An ABC with one abstract method __index__.
```

Baru pada versi 3.8.

```
class typing.SupportsAbs  
    An ABC with one abstract method __abs__ that is covariant in its return type.  
  
class typing.SupportsRound  
    An ABC with one abstract method __round__ that is covariant in its return type.  
  
class typing.Container(Generic[T_co])  
    A generic version of collections.abc.Container.  
  
class typing.Hashable  
    An alias to collections.abc.Hashable  
  
class typing.Sized  
    An alias to collections.abc.Sized  
  
class typing.Collection(Sized, Iterable[T_co], Container[T_co])  
    A generic version of collections.abc.Collection
```

Baru pada versi 3.6.0.

**class** `typing.AbstractSet` (*Sized*, *Collection*[*T\_co*])

A generic version of `collections.abc.Set`.

**class** `typing.MutableSet` (*AbstractSet*[*T*])

A generic version of `collections.abc.MutableSet`.

**class** `typing.Mapping` (*Sized*, *Collection*[*KT*], *Generic*[*VT\_co*])

A generic version of `collections.abc.Mapping`. This type can be used as follows:

```
def get_position_in_index(word_list: Mapping[str, int], word: str) -> int:
    return word_list[word]
```

**class** `typing.MutableMapping` (*Mapping*[*KT*, *VT*])

A generic version of `collections.abc.MutableMapping`.

**class** `typing.Sequence` (*Reversible*[*T\_co*], *Collection*[*T\_co*])

A generic version of `collections.abc.Sequence`.

**class** `typing.MutableSequence` (*Sequence*[*T*])

A generic version of `collections.abc.MutableSequence`.

**class** `typing.ByteString` (*Sequence*[*int*])

A generic version of `collections.abc.ByteString`.

This type represents the types `bytes`, `bytearray`, and `memoryview` of byte sequences.

As a shorthand for this type, `bytes` can be used to annotate arguments of any of the types mentioned above.

**class** `typing.Deque` (*deque*, *MutableSequence*[*T*])

A generic version of `collections.deque`.

Baru pada versi 3.5.4.

Baru pada versi 3.6.1.

**class** `typing.List` (*list*, *MutableSequence*[*T*])

Generic version of `list`. Useful for annotating return types. To annotate arguments it is preferred to use an abstract collection type such as `Sequence` or `Iterable`.

This type may be used as follows:

```
T = TypeVar('T', int, float)

def vec2(x: T, y: T) -> List[T]:
    return [x, y]

def keep_positives(vector: Sequence[T]) -> List[T]:
    return [item for item in vector if item > 0]
```

**class** `typing.Set` (*set*, *MutableSet*[*T*])

A generic version of `builtins.set`. Useful for annotating return types. To annotate arguments it is preferred to use an abstract collection type such as `AbstractSet`.

**class** `typing.FrozenSet` (*frozenset*, *AbstractSet*[*T\_co*])

A generic version of `builtins.frozenset`.

**class** `typing.MappingView` (*Sized*, *Iterable*[*T\_co*])

A generic version of `collections.abc.MappingView`.

**class** `typing.KeysView` (*MappingView*[*KT\_co*], *AbstractSet*[*KT\_co*])

A generic version of `collections.abc.KeysView`.

**class** `typing.ItemsView` (*MappingView*, *Generic*[*KT\_co*, *VT\_co*])  
A generic version of `collections.abc.ItemsView`.

**class** `typing.ValuesView` (*MappingView*[*VT\_co*])  
A generic version of `collections.abc.ValuesView`.

**class** `typing.Awaitable` (*Generic*[*T\_co*])  
A generic version of `collections.abc.Awaitable`.

Baru pada versi 3.5.2.

**class** `typing.Coroutine` (*Awaitable*[*V\_co*], *Generic*[*T\_co*, *T\_contra*, *V\_co*])  
A generic version of `collections.abc.Coroutine`. The variance and order of type variables correspond to those of `Generator`, for example:

```
from typing import List, Coroutine
c = None # type: Coroutine[List[str], str, int]
...
x = c.send('hi') # type: List[str]
async def bar() -> None:
    x = await c # type: int
```

Baru pada versi 3.5.3.

**class** `typing.AsyncIterable` (*Generic*[*T\_co*])  
A generic version of `collections.abc.AsyncIterable`.

Baru pada versi 3.5.2.

**class** `typing.AsyncIterator` (*AsyncIterable*[*T\_co*])  
A generic version of `collections.abc.AsyncIterator`.

Baru pada versi 3.5.2.

**class** `typing.ContextManager` (*Generic*[*T\_co*])  
A generic version of `contextlib.AbstractContextManager`.

Baru pada versi 3.5.4.

Baru pada versi 3.6.0.

**class** `typing.AsyncContextManager` (*Generic*[*T\_co*])  
A generic version of `contextlib.AbstractAsyncContextManager`.

Baru pada versi 3.5.4.

Baru pada versi 3.6.2.

**class** `typing.Dict` (*dict*, *MutableMapping*[*KT*, *VT*])  
A generic version of `dict`. Useful for annotating return types. To annotate arguments it is preferred to use an abstract collection type such as `Mapping`.

This type can be used as follows:

```
def count_words(text: str) -> Dict[str, int]:
    ...
```

**class** `typing.DefaultDict` (*collections.defaultdict*, *MutableMapping*[*KT*, *VT*])  
A generic version of `collections.defaultdict`.

Baru pada versi 3.5.2.

**class** `typing.OrderedDict` (*collections.OrderedDict*, *MutableMapping*[*KT*, *VT*])  
A generic version of `collections.OrderedDict`.

Baru pada versi 3.7.2.

**class** `typing.Counter` (`collections.Counter`, `Dict[T, int]`)  
 A generic version of `collections.Counter`.

Baru pada versi 3.5.4.

Baru pada versi 3.6.1.

**class** `typing.ChainMap` (`collections.ChainMap`, `MutableMapping[KT, VT]`)  
 A generic version of `collections.ChainMap`.

Baru pada versi 3.5.4.

Baru pada versi 3.6.1.

**class** `typing.Generator` (`Iterator[T_co]`, `Generic[T_co, T_contra, V_co]`)  
 A generator can be annotated by the generic type `Generator[YieldType, SendType, ReturnType]`.  
 For example:

```
def echo_round() -> Generator[int, float, str]:
    sent = yield 0
    while sent >= 0:
        sent = yield round(sent)
    return 'Done'
```

Note that unlike many other generics in the typing module, the `SendType` of `Generator` behaves contravariantly, not covariantly or invariantly.

If your generator will only yield values, set the `SendType` and `ReturnType` to `None`:

```
def infinite_stream(start: int) -> Generator[int, None, None]:
    while True:
        yield start
        start += 1
```

Alternatively, annotate your generator as having a return type of either `Iterable[YieldType]` or `Iterator[YieldType]`:

```
def infinite_stream(start: int) -> Iterator[int]:
    while True:
        yield start
        start += 1
```

**class** `typing.AsyncGenerator` (`AsyncIterator[T_co]`, `Generic[T_co, T_contra]`)

An async generator can be annotated by the generic type `AsyncGenerator[YieldType, SendType]`.  
 For example:

```
async def echo_round() -> AsyncGenerator[int, float]:
    sent = yield 0
    while sent >= 0.0:
        rounded = await round(sent)
        sent = yield rounded
```

Unlike normal generators, async generators cannot return a value, so there is no `ReturnType` type parameter. As with `Generator`, the `SendType` behaves contravariantly.

If your generator will only yield values, set the `SendType` to `None`:

```
async def infinite_stream(start: int) -> AsyncGenerator[int, None]:
    while True:
        yield start
        start = await increment(start)
```

Alternatively, annotate your generator as having a return type of either `AsyncIterable[YieldType]` or `AsyncIterator[YieldType]`:

```
async def infinite_stream(start: int) -> AsyncIterator[int]:
    while True:
        yield start
        start = await increment(start)
```

Baru pada versi 3.6.1.

### **class** `typing.Text`

`Text` is an alias for `str`. It is provided to supply a forward compatible path for Python 2 code: in Python 2, `Text` is an alias for `unicode`.

Use `Text` to indicate that a value must contain a unicode string in a manner that is compatible with both Python 2 and Python 3:

```
def add_unicode_checkmark(text: Text) -> Text:
    return text + u' \u2713'
```

Baru pada versi 3.5.2.

### **class** `typing.IO`

### **class** `typing.TextIO`

### **class** `typing.BinaryIO`

Generic type `IO[AnyStr]` and its subclasses `TextIO(IO[str])` and `BinaryIO(IO[bytes])` represent the types of I/O streams such as returned by `open()`.

### **class** `typing.Pattern`

### **class** `typing.Match`

These type aliases correspond to the return types from `re.compile()` and `re.match()`. These types (and the corresponding functions) are generic in `AnyStr` and can be made specific by writing `Pattern[str]`, `Pattern[bytes]`, `Match[str]`, or `Match[bytes]`.

### **class** `typing.NamedTuple`

Typed version of `collections.namedtuple()`.

Penggunaan:

```
class Employee(NamedTuple):
    name: str
    id: int
```

Ini setara dengan:

```
Employee = collections.namedtuple('Employee', ['name', 'id'])
```

To give a field a default value, you can assign to it in the class body:

```
class Employee(NamedTuple):
    name: str
    id: int = 3
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
employee = Employee('Guido')
assert employee.id == 3
```

Fields with a default value must come after any fields without a default.

The resulting class has an extra attribute `__annotations__` giving a dict that maps the field names to the field types. (The field names are in the `_fields` attribute and the default values are in the `_field_defaults` attribute both of which are part of the namedtuple API.)

NamedTuple subclasses can also have docstrings and methods:

```
class Employee(NamedTuple):
    """Represents an employee."""
    name: str
    id: int = 3

    def __repr__(self) -> str:
        return f'<Employee {self.name}, id={self.id}>'
```

Backward-compatible usage:

```
Employee = NamedTuple('Employee', [('name', str), ('id', int)])
```

Berubah pada versi 3.6: Added support for [PEP 526](#) variable annotation syntax.

Berubah pada versi 3.6.1: Added support for default values, methods, and docstrings.

Deprecated since version 3.8, will be removed in version 3.9: Deprecated the `_field_types` attribute in favor of the more standard `__annotations__` attribute which has the same information.

Berubah pada versi 3.8: The `_field_types` and `__annotations__` attributes are now regular dictionaries instead of instances of `OrderedDict`.

### **class** `typing.TypedDict` (*dict*)

A simple typed namespace. At runtime it is equivalent to a plain *dict*.

`TypedDict` creates a dictionary type that expects all of its instances to have a certain set of keys, where each key is associated with a value of a consistent type. This expectation is not checked at runtime but is only enforced by type checkers. Usage:

```
class Point2D(TypedDict):
    x: int
    y: int
    label: str

a: Point2D = {'x': 1, 'y': 2, 'label': 'good'} # OK
b: Point2D = {'z': 3, 'label': 'bad'}          # Fails type check

assert Point2D(x=1, y=2, label='first') == dict(x=1, y=2, label='first')
```

The type info for introspection can be accessed via `Point2D.__annotations__` and `Point2D.__total__`. To allow using this feature with older versions of Python that do not support [PEP 526](#), `TypedDict` supports two additional equivalent syntactic forms:

```
Point2D = TypedDict('Point2D', x=int, y=int, label=str)
Point2D = TypedDict('Point2D', {'x': int, 'y': int, 'label': str})
```

By default, all keys must be present in a `TypedDict`. It is possible to override this by specifying totality. Usage:

```
class point2D(TypedDict, total=False):
    x: int
    y: int
```

This means that a point2D TypedDict can have any of the keys omitted. A type checker is only expected to support a literal False or True as the value of the total argument. True is the default, and makes all items defined in the class body be required.

See [PEP 589](#) for more examples and detailed rules of using TypedDict.

Baru pada versi 3.8.

#### **class** typing.**ForwardRef**

A class used for internal typing representation of string forward references. For example, `List["SomeClass"]` is implicitly transformed into `List[ForwardRef("SomeClass")]`. This class should not be instantiated by a user, but may be used by introspection tools.

Baru pada versi 3.7.4.

#### typing.**NewType** (*name*, *tp*)

A helper function to indicate a distinct type to a typechecker, see [NewType](#). At runtime it returns a function that returns its argument. Usage:

```
UserId = NewType('UserId', int)
first_user = UserId(1)
```

Baru pada versi 3.5.2.

#### typing.**cast** (*typ*, *val*)

Cast a value to a type.

This returns the value unchanged. To the type checker this signals that the return value has the designated type, but at runtime we intentionally don't check anything (we want this to be as fast as possible).

#### typing.**get\_type\_hints** (*obj*[, *globals*[, *locals*]])

Return a dictionary containing type hints for a function, method, module or class object.

This is often the same as `obj.__annotations__`. In addition, forward references encoded as string literals are handled by evaluating them in `globals` and `locals` namespaces. If necessary, `Optional[t]` is added for function and method annotations if a default value equal to `None` is set. For a class `C`, return a dictionary constructed by merging all the `__annotations__` along `C.__mro__` in reverse order.

#### typing.**get\_origin** (*tp*)

#### typing.**get\_args** (*tp*)

Provide basic introspection for generic types and special typing forms.

For a typing object of the form `X[Y, Z, ...]` these functions return `X` and `(Y, Z, ...)`. If `X` is a generic alias for a builtin or [collections](#) class, it gets normalized to the original class. For unsupported objects return `None` and `()` correspondingly. Examples:

```
assert get_origin(Dict[str, int]) is dict
assert get_args(Dict[int, str]) == (int, str)

assert get_origin(Union[int, str]) is Union
assert get_args(Union[int, str]) == (int, str)
```

Baru pada versi 3.8.

**@typing.overload**

The `@overload` decorator allows describing functions and methods that support multiple different combinations of argument types. A series of `@overload`-decorated definitions must be followed by exactly one non-`@overload`-decorated definition (for the same function/method). The `@overload`-decorated definitions are for the benefit of the type checker only, since they will be overwritten by the non-`@overload`-decorated definition, while the latter is used at runtime but should be ignored by a type checker. At runtime, calling a `@overload`-decorated function directly will raise `NotImplementedError`. An example of overload that gives a more precise type than can be expressed using a union or a type variable:

```
@overload
def process(response: None) -> None:
    ...
@overload
def process(response: int) -> Tuple[int, str]:
    ...
@overload
def process(response: bytes) -> str:
    ...
def process(response):
    <actual implementation>
```

See [PEP 484](#) for details and comparison with other typing semantics.

**@typing.final**

A decorator to indicate to type checkers that the decorated method cannot be overridden, and the decorated class cannot be subclassed. For example:

```
class Base:
    @final
    def done(self) -> None:
        ...
class Sub(Base):
    def done(self) -> None: # Error reported by type checker
        ...

@final
class Leaf:
    ...
class Other(Leaf): # Error reported by type checker
    ...
```

There is no runtime checking of these properties. See [PEP 591](#) for more details.

Baru pada versi 3.8.

**@typing.no\_type\_check**

Decorator to indicate that annotations are not type hints.

This works as class or function *decorator*. With a class, it applies recursively to all methods defined in that class (but not to methods defined in its superclasses or subclasses).

This mutates the function(s) in place.

**@typing.no\_type\_check\_decorator**

Decorator to give another decorator the `no_type_check()` effect.

This wraps the decorator with something that wraps the decorated function in `no_type_check()`.

**@typing.type\_check\_only**

Decorator to mark a class or function to be unavailable at runtime.

This decorator is itself not available at runtime. It is mainly intended to mark classes that are defined in type stub files if an implementation returns an instance of a private class:

```
@type_check_only
class Response: # private or not available at runtime
    code: int
    def get_header(self, name: str) -> str: ...

def fetch_response() -> Response: ...
```

Note that returning instances of private classes is not recommended. It is usually preferable to make such classes public.

#### `typing.runtime_checkable`

Mark a protocol class as a runtime protocol.

Such a protocol can be used with `isinstance()` and `issubclass()`. This raises `TypeError` when applied to a non-protocol class. This allows a simple-minded structural check, very similar to “one trick ponies” in `collections.abc` such as `Iterable`. For example:

```
@runtime_checkable
class Closable(Protocol):
    def close(self): ...

assert isinstance(open('/some/file'), Closable)
```

**Warning:** this will check only the presence of the required methods, not their type signatures!

Baru pada versi 3.8.

#### `typing.Any`

Special type indicating an unconstrained type.

- Every type is compatible with `Any`.
- `Any` is compatible with every type.

#### `typing.NoReturn`

Special type indicating that a function never returns. For example:

```
from typing import NoReturn

def stop() -> NoReturn:
    raise RuntimeError('no way')
```

Baru pada versi 3.5.4.

Baru pada versi 3.6.2.

#### `typing.Union`

Union type; `Union[X, Y]` means either X or Y.

To define a union, use e.g. `Union[int, str]`. Details:

- The arguments must be types and there must be at least one.
- Unions of unions are flattened, e.g.:

```
Union[Union[int, str], float] == Union[int, str, float]
```

- Unions of a single argument vanish, e.g.:

```
Union[int] == int # The constructor actually returns int
```

- Redundant arguments are skipped, e.g.:

```
Union[int, str, int] == Union[int, str]
```

- When comparing unions, the argument order is ignored, e.g.:

```
Union[int, str] == Union[str, int]
```

- You cannot subclass or instantiate a union.
- You cannot write `Union[X][Y]`.
- You can use `Optional[X]` as a shorthand for `Union[X, None]`.

Berubah pada versi 3.7: Don't remove explicit subclasses from unions at runtime.

### typing.Optional

Optional type.

`Optional[X]` is equivalent to `Union[X, None]`.

Note that this is not the same concept as an optional argument, which is one that has a default. An optional argument with a default does not require the `Optional` qualifier on its type annotation just because it is optional. For example:

```
def foo(arg: int = 0) -> None:
    ...
```

On the other hand, if an explicit value of `None` is allowed, the use of `Optional` is appropriate, whether the argument is optional or not. For example:

```
def foo(arg: Optional[int] = None) -> None:
    ...
```

### typing.Tuple

Tuple type; `Tuple[X, Y]` is the type of a tuple of two items with the first item of type `X` and the second of type `Y`. The type of the empty tuple can be written as `Tuple[()]`.

Example: `Tuple[T1, T2]` is a tuple of two elements corresponding to type variables `T1` and `T2`. `Tuple[int, float, str]` is a tuple of an int, a float and a string.

To specify a variable-length tuple of homogeneous type, use literal ellipsis, e.g. `Tuple[int, ...]`. A plain `Tuple` is equivalent to `Tuple[Any, ...]`, and in turn to `tuple`.

### typing.Callable

Callable type; `Callable[[int], str]` is a function of `(int) -> str`.

The subscription syntax must always be used with exactly two values: the argument list and the return type. The argument list must be a list of types or an ellipsis; the return type must be a single type.

There is no syntax to indicate optional or keyword arguments; such function types are rarely used as callback types. `Callable[..., ReturnType]` (literal ellipsis) can be used to type hint a callable taking any number of arguments and returning `ReturnType`. A plain `Callable` is equivalent to `Callable[..., Any]`, and in turn to `collections.abc.Callable`.

### typing.Literal

A type that can be used to indicate to type checkers that the corresponding variable or function parameter has a value equivalent to the provided literal (or one of several literals). For example:

```
def validate_simple(data: Any) -> Literal[True]: # always returns True
    ...

MODE = Literal['r', 'rb', 'w', 'wb']
def open_helper(file: str, mode: MODE) -> str:
    ...

open_helper('/some/path', 'r') # Passes type check
open_helper('/other/path', 'typo') # Error in type checker
```

`Literal[...]` cannot be subclassed. At runtime, an arbitrary value is allowed as type argument to `Literal[...]`, but type checkers may impose restrictions. See [PEP 586](#) for more details about literal types.

Baru pada versi 3.8.

### typing.**ClassVar**

Special type construct to mark class variables.

As introduced in [PEP 526](#), a variable annotation wrapped in `ClassVar` indicates that a given attribute is intended to be used as a class variable and should not be set on instances of that class. Usage:

```
class Starship:
    stats: ClassVar[Dict[str, int]] = {} # class variable
    damage: int = 10 # instance variable
```

`ClassVar` accepts only types and cannot be further subscribed.

`ClassVar` is not a class itself, and should not be used with `isinstance()` or `issubclass()`. `ClassVar` does not change Python runtime behavior, but it can be used by third-party type checkers. For example, a type checker might flag the following code as an error:

```
enterprise_d = Starship(3000)
enterprise_d.stats = {} # Error, setting class variable on instance
Starship.stats = {} # This is OK
```

Baru pada versi 3.5.3.

### typing.**Final**

A special typing construct to indicate to type checkers that a name cannot be re-assigned or overridden in a subclass. For example:

```
MAX_SIZE: Final = 9000
MAX_SIZE += 1 # Error reported by type checker

class Connection:
    TIMEOUT: Final[int] = 10

class FastConnector(Connection):
    TIMEOUT = 1 # Error reported by type checker
```

There is no runtime checking of these properties. See [PEP 591](#) for more details.

Baru pada versi 3.8.

### typing.**AnyStr**

`AnyStr` is a type variable defined as `AnyStr = TypeVar('AnyStr', str, bytes)`.

It is meant to be used for functions that may accept any kind of string without allowing different kinds of strings to mix. For example:

```
def concat(a: AnyStr, b: AnyStr) -> AnyStr:
    return a + b

concat(u"foo", u"bar")  # Ok, output has type 'unicode'
concat(b"foo", b"bar")  # Ok, output has type 'bytes'
concat(u"foo", b"bar")  # Error, cannot mix unicode and bytes
```

**typing.TYPE\_CHECKING**

A special constant that is assumed to be `True` by 3rd party static type checkers. It is `False` at runtime. Usage:

```
if TYPE_CHECKING:
    import expensive_mod

def fun(arg: 'expensive_mod.SomeType') -> None:
    local_var: expensive_mod.AnotherType = other_fun()
```

Note that the first type annotation must be enclosed in quotes, making it a “forward reference”, to hide the `expensive_mod` reference from the interpreter runtime. Type annotations for local variables are not evaluated, so the second annotation does not need to be enclosed in quotes.

Baru pada versi 3.5.2.

## 26.2 pydoc --- Documentation generator and online help system

Source code: [Lib/pydoc.py](#)

The `pydoc` module automatically generates documentation from Python modules. The documentation can be presented as pages of text on the console, served to a Web browser, or saved to HTML files.

For modules, classes, functions and methods, the displayed documentation is derived from the docstring (i.e. the `__doc__` attribute) of the object, and recursively of its documentable members. If there is no docstring, `pydoc` tries to obtain a description from the block of comment lines just above the definition of the class, function or method in the source file, or at the top of the module (see `inspect.getcomments()`).

The built-in function `help()` invokes the online help system in the interactive interpreter, which uses `pydoc` to generate its documentation as text on the console. The same text documentation can also be viewed from outside the Python interpreter by running `pydoc` as a script at the operating system’s command prompt. For example, running

```
pydoc sys
```

at a shell prompt will display documentation on the `sys` module, in a style similar to the manual pages shown by the Unix `man` command. The argument to `pydoc` can be the name of a function, module, or package, or a dotted reference to a class, method, or function within a module or module in a package. If the argument to `pydoc` looks like a path (that is, it contains the path separator for your operating system, such as a slash in Unix), and refers to an existing Python source file, then documentation is produced for that file.

**Catatan:** In order to find objects and their documentation, `pydoc` imports the module(s) to be documented. Therefore, any code on module level will be executed on that occasion. Use an `if __name__ == '__main__':` guard to only execute code when a file is invoked as a script and not just imported.

When printing output to the console, `pydoc` attempts to paginate the output for easier reading. If the `PAGER` environment variable is set, `pydoc` will use its value as a pagination program.

Specifying a `-w` flag before the argument will cause HTML documentation to be written out to a file in the current directory, instead of displaying text on the console.

Specifying a `-k` flag before the argument will search the synopsis lines of all available modules for the keyword given as the argument, again in a manner similar to the Unix `man` command. The synopsis line of a module is the first line of its documentation string.

You can also use `pydoc` to start an HTTP server on the local machine that will serve documentation to visiting Web browsers. `pydoc -p 1234` will start a HTTP server on port 1234, allowing you to browse the documentation at `http://localhost:1234/` in your preferred Web browser. Specifying 0 as the port number will select an arbitrary unused port.

`pydoc -n <hostname>` will start the server listening at the given hostname. By default the hostname is 'localhost' but if you want the server to be reached from other machines, you may want to change the host name that the server responds to. During development this is especially useful if you want to run `pydoc` from within a container.

`pydoc -b` will start the server and additionally open a web browser to a module index page. Each served page has a navigation bar at the top where you can *Get* help on an individual item, *Search* all modules with a keyword in their synopsis line, and go to the *Module index*, *Topics* and *Keywords* pages.

When `pydoc` generates documentation, it uses the current environment and path to locate modules. Thus, invoking `pydoc spam` documents precisely the version of the module you would get if you started the Python interpreter and typed `import spam`.

Module docs for core modules are assumed to reside in `https://docs.python.org/X.Y/library/` where X and Y are the major and minor version numbers of the Python interpreter. This can be overridden by setting the `PYTHONDOS` environment variable to a different URL or to a local directory containing the Library Reference Manual pages.

Berubah pada versi 3.2: Added the `-b` option.

Berubah pada versi 3.3: The `-g` command line option was removed.

Berubah pada versi 3.4: `pydoc` now uses `inspect.signature()` rather than `inspect.getfullargspec()` to extract signature information from callables.

Berubah pada versi 3.7: Added the `-n` option.

## 26.3 doctest --- Contoh uji interaktif Python

**Kode sumber:** `Lib/doctest.py`

---

The `doctest` module searches for pieces of text that look like interactive Python sessions, and then executes those sessions to verify that they work exactly as shown. There are several common ways to use `doctest`:

- To check that a module's docstrings are up-to-date by verifying that all interactive examples still work as documented.
- To perform regression testing by verifying that interactive examples from a test file or a test object work as expected.
- To write tutorial documentation for a package, liberally illustrated with input-output examples. Depending on whether the examples or the expository text are emphasized, this has the flavor of "literate testing" or "executable documentation".

Berikut modul contoh lengkap tapi sederhana:

```

"""
This is the "example" module.

The example module supplies one function, factorial().  For example,

>>> factorial(5)
120
"""

def factorial(n):
    """Return the factorial of n, an exact integer >= 0.

    >>> [factorial(n) for n in range(6)]
    [1, 1, 2, 6, 24, 120]
    >>> factorial(30)
    2652528598121910586363084800000000
    >>> factorial(-1)
    Traceback (most recent call last):
        ...
    ValueError: n must be >= 0

    Factorials of floats are OK, but the float must be an exact integer:
    >>> factorial(30.1)
    Traceback (most recent call last):
        ...
    ValueError: n must be exact integer
    >>> factorial(30.0)
    2652528598121910586363084800000000

    It must also not be ridiculously large:
    >>> factorial(1e100)
    Traceback (most recent call last):
        ...
    OverflowError: n too large
    """

    import math
    if not n >= 0:
        raise ValueError("n must be >= 0")
    if math.floor(n) != n:
        raise ValueError("n must be exact integer")
    if n+1 == n: # catch a value like 1e300
        raise OverflowError("n too large")
    result = 1
    factor = 2
    while factor <= n:
        result *= factor
        factor += 1
    return result

if __name__ == "__main__":
    import doctest
    doctest.testmod()

```

If you run `example.py` directly from the command line, `doctest` works its magic:

```
$ python example.py
$
```

There's no output! That's normal, and it means all the examples worked. Pass `-v` to the script, and `doctest` prints a detailed log of what it's trying, and prints a summary at the end:

```
$ python example.py -v
Trying:
    factorial(5)
Expecting:
    120
ok
Trying:
    [factorial(n) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
```

Dan seterusnya, akhirnya diakhiri dengan:

```
Trying:
    factorial(1e100)
Expecting:
    Traceback (most recent call last):
      ...
    OverflowError: n too large
ok
2 items passed all tests:
  1 tests in __main__
  8 tests in __main__.factorial
9 tests in 2 items.
9 passed and 0 failed.
Test passed.
$
```

That's all you need to know to start making productive use of `doctest`! Jump in. The following sections provide full details. Note that there are many examples of doctests in the standard Python test suite and libraries. Especially useful examples can be found in the standard test file `Lib/test/test_doctest.py`.

### 26.3.1 Simple Usage: Checking Examples in Docstrings

The simplest way to start using `doctest` (but not necessarily the way you'll continue to do it) is to end each module `M` with:

```
if __name__ == "__main__":
    import doctest
    doctest.testmod()
```

`doctest` then examines docstrings in module `M`.

Running the module as a script causes the examples in the docstrings to get executed and verified:

```
python M.py
```

This won't display anything unless an example fails, in which case the failing example(s) and the cause(s) of the failure(s) are printed to stdout, and the final line of output is `***Test Failed*** N failures.`, where `N` is the number of examples that failed.

Operasikan dengan opsi `-v` sebagai gantinya:

```
python M.py -v
```

and a detailed report of all examples tried is printed to standard output, along with assorted summaries at the end.

You can force verbose mode by passing `verbose=True` to `testmod()`, or prohibit it by passing `verbose=False`. In either of those cases, `sys.argv` is not examined by `testmod()` (so passing `-v` or not has no effect).

There is also a command line shortcut for running `testmod()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the module name(s) on the command line:

```
python -m doctest -v example.py
```

This will import `example.py` as a standalone module and run `testmod()` on it. Note that this may not work correctly if the file is part of a package and imports other submodules from that package.

For more information on `testmod()`, see section *Basic API*.

## 26.3.2 Penggunaan Sederhana: Memeriksa Contoh di Berkas Teks

Another simple application of doctest is testing interactive examples in a text file. This can be done with the `testfile()` function:

```
import doctest
doctest.testfile("example.txt")
```

That short script executes and verifies any interactive Python examples contained in the file `example.txt`. The file content is treated as if it were a single giant docstring; the file doesn't need to contain a Python program! For example, perhaps `example.txt` contains this:

```
The ``example`` module
=====

Using ``factorial``
-----

This is an example text file in reStructuredText format. First import
``factorial`` from the ``example`` module:

    >>> from example import factorial

Now use it:

    >>> factorial(6)
    120
```

Running `doctest.testfile("example.txt")` then finds the error in this documentation:

```
File "./example.txt", line 14, in example.txt
Failed example:
    factorial(6)
Expected:
    120
Got:
    720
```

As with `testmod()`, `testfile()` won't display anything unless an example fails. If an example does fail, then the failing example(s) and the cause(s) of the failure(s) are printed to stdout, using the same format as `testmod()`.

By default, `testfile()` looks for files in the calling module's directory. See section [Basic API](#) for a description of the optional arguments that can be used to tell it to look for files in other locations.

Like `testmod()`, `testfile()`'s verbosity can be set with the `-v` command-line switch or with the optional keyword argument `verbose`.

There is also a command line shortcut for running `testfile()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the file name(s) on the command line:

```
python -m doctest -v example.txt
```

Because the file name does not end with `.py`, `doctest` infers that it must be run with `testfile()`, not `testmod()`.

For more information on `testfile()`, see section [Basic API](#).

### 26.3.3 Bagaimana Itu Bekerja

This section examines in detail how doctest works: which docstrings it looks at, how it finds interactive examples, what execution context it uses, how it handles exceptions, and how option flags can be used to control its behavior. This is the information that you need to know to write doctest examples; for information about actually running doctest on these examples, see the following sections.

#### Docstrings Mana yang Diperiksa?

The module docstring, and all function, class and method docstrings are searched. Objects imported into the module are not searched.

In addition, if `M.__test__` exists and "is true", it must be a dict, and each entry maps a (string) name to a function object, class object, or string. Function and class object docstrings found from `M.__test__` are searched, and strings are treated as if they were docstrings. In output, a key `K` in `M.__test__` appears with name

```
<name of M>.__test__.K
```

Any classes found are recursively searched similarly, to test docstrings in their contained methods and nested classes.

**CPython implementation detail:** Prior to version 3.4, extension modules written in C were not fully searched by doctest.

#### Bagaimana Contoh Docstring Dikenali?

In most cases a copy-and-paste of an interactive console session works fine, but doctest isn't trying to do an exact emulation of any specific Python shell.

```
>>> # comments are ignored
>>> x = 12
>>> x
12
>>> if x == 13:
...     print("yes")
... else:
...     print("no")
...     print("NO")
...     print("NO!!!")
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
...
no
NO
NO!!!
>>>
```

Any expected output must immediately follow the final '>>>' or '...' line containing the code, and the expected output (if any) extends to the next '>>>' or all-whitespace line.

Tulisan halus:

- Expected output cannot contain an all-whitespace line, since such a line is taken to signal the end of expected output. If expected output does contain a blank line, put `<BLANKLINE>` in your doctest example each place a blank line is expected.
- All hard tab characters are expanded to spaces, using 8-column tab stops. Tabs in output generated by the tested code are not modified. Because any hard tabs in the sample output *are* expanded, this means that if the code output includes hard tabs, the only way the doctest can pass is if the `NORMALIZE_WHITESPACE` option or *directive* is in effect. Alternatively, the test can be rewritten to capture the output and compare it to an expected value as part of the test. This handling of tabs in the source was arrived at through trial and error, and has proven to be the least error prone way of handling them. It is possible to use a different algorithm for handling tabs by writing a custom `DocTestParser` class.
- Output to stdout is captured, but not output to stderr (exception tracebacks are captured via a different means).
- If you continue a line via backslashing in an interactive session, or for any other reason use a backslash, you should use a raw docstring, which will preserve your backslashes exactly as you type them:

```
>>> def f(x):
...     r'''Backslashes in a raw docstring: m\n'''
>>> print(f.__doc__)
Backslashes in a raw docstring: m\n
```

Otherwise, the backslash will be interpreted as part of the string. For example, the `\n` above would be interpreted as a newline character. Alternatively, you can double each backslash in the doctest version (and not use a raw string):

```
>>> def f(x):
...     '''Backslashes in a raw docstring: m\\n'''
>>> print(f.__doc__)
Backslashes in a raw docstring: m\n
```

- Kolom awal tidak masalah:

```
>>> assert "Easy!"
>>> import math
>>> math.floor(1.9)
1
```

and as many leading whitespace characters are stripped from the expected output as appeared in the initial '>>>' line that started the example.

## Apa itu Konteks Eksekusi?

By default, each time `doctest` finds a docstring to test, it uses a *shallow copy* of `M`'s globals, so that running tests doesn't change the module's real globals, and so that one test in `M` can't leave behind crumbs that accidentally allow another test to work. This means examples can freely use any names defined at top-level in `M`, and names defined earlier in the docstring being run. Examples cannot see names defined in other docstrings.

You can force use of your own dict as the execution context by passing `globals=your_dict` to `testmod()` or `testfile()` instead.

## Bagaimana dengan Pengecualian?

No problem, provided that the traceback is the only output produced by the example: just paste in the traceback.<sup>1</sup> Since tracebacks contain details that are likely to change rapidly (for example, exact file paths and line numbers), this is one case where `doctest` works hard to be flexible in what it accepts.

Contoh sederhana:

```
>>> [1, 2, 3].remove(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: list.remove(x): x not in list
```

That `doctest` succeeds if `ValueError` is raised, with the `list.remove(x): x not in list` detail as shown.

The expected output for an exception must start with a traceback header, which may be either of the following two lines, indented the same as the first line of the example:

```
Traceback (most recent call last):
Traceback (innermost last):
```

The traceback header is followed by an optional traceback stack, whose contents are ignored by `doctest`. The traceback stack is typically omitted, or copied verbatim from an interactive session.

The traceback stack is followed by the most interesting part: the line(s) containing the exception type and detail. This is usually the last line of a traceback, but can extend across multiple lines if the exception has a multi-line detail:

```
>>> raise ValueError('multi\n    line\ndetail')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: multi
    line
detail
```

The last three lines (starting with `ValueError`) are compared against the exception's type and detail, and the rest are ignored.

Best practice is to omit the traceback stack, unless it adds significant documentation value to the example. So the last example is probably better as:

```
>>> raise ValueError('multi\n    line\ndetail')
Traceback (most recent call last):
...
ValueError: multi
```

(berlanjut ke halaman berikutnya)

---

<sup>1</sup> Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.

(lanjutan dari halaman sebelumnya)

```
line
detail
```

Note that tracebacks are treated very specially. In particular, in the rewritten example, the use of `...` is independent of doctest's *ELLIPSIS* option. The ellipsis in that example could be left out, or could just as well be three (or three hundred) commas or digits, or an indented transcript of a Monty Python skit.

Some details you should read once, but won't need to remember:

- Doctest can't guess whether your expected output came from an exception traceback or from ordinary printing. So, e.g., an example that expects `ValueError: 42 is prime` will pass whether `ValueError` is actually raised or if the example merely prints that traceback text. In practice, ordinary output rarely begins with a traceback header line, so this doesn't create real problems.
- Each line of the traceback stack (if present) must be indented further than the first line of the example, *or* start with a non-alphanumeric character. The first line following the traceback header indented the same and starting with an alphanumeric is taken to be the start of the exception detail. Of course this does the right thing for genuine tracebacks.
- When the *IGNORE\_EXCEPTION\_DETAIL* doctest option is specified, everything following the leftmost colon and any module information in the exception name is ignored.
- The interactive shell omits the traceback header line for some *SyntaxErrors*. But doctest uses the traceback header line to distinguish exceptions from non-exceptions. So in the rare case where you need to test a *SyntaxError* that omits the traceback header, you will need to manually add the traceback header line to your test example.
- For some *SyntaxErrors*, Python displays the character position of the syntax error, using a `^` marker:

```
>>> 1 1
      File "<stdin>", line 1
        1 1
         ^
SyntaxError: invalid syntax
```

Since the lines showing the position of the error come before the exception type and detail, they are not checked by doctest. For example, the following test would pass, even though it puts the `^` marker in the wrong location:

```
>>> 1 1
Traceback (most recent call last):
  File "<stdin>", line 1
    1 1
     ^
SyntaxError: invalid syntax
```

## Penanda Opsi

A number of option flags control various aspects of doctest's behavior. Symbolic names for the flags are supplied as module constants, which can be bitwise ORed together and passed to various functions. The names can also be used in *doctest directives*, and may be passed to the doctest command line interface via the `-o` option.

Baru pada versi 3.4: Opsi baris perintah `-o`.

The first group of options define test semantics, controlling aspects of how doctest decides whether actual output matches an example's expected output:

**doctest.DONT\_ACCEPT\_TRUE\_FOR\_1**

By default, if an expected output block contains just 1, an actual output block containing just 1 or just True is considered to be a match, and similarly for 0 versus False. When `DONT_ACCEPT_TRUE_FOR_1` is specified, neither substitution is allowed. The default behavior caters to that Python changed the return type of many functions from integer to boolean; doctests expecting "little integer" output still work in these cases. This option will probably go away, but not for several years.

**doctest.DONT\_ACCEPT\_BLANKLINE**

By default, if an expected output block contains a line containing only the string `<BLANKLINE>`, then that line will match a blank line in the actual output. Because a genuinely blank line delimits the expected output, this is the only way to communicate that a blank line is expected. When `DONT_ACCEPT_BLANKLINE` is specified, this substitution is not allowed.

**doctest.NORMALIZE\_WHITESPACE**

When specified, all sequences of whitespace (blanks and newlines) are treated as equal. Any sequence of whitespace within the expected output will match any sequence of whitespace within the actual output. By default, whitespace must match exactly. `NORMALIZE_WHITESPACE` is especially useful when a line of expected output is very long, and you want to wrap it across multiple lines in your source.

**doctest.ELLIPSIS**

When specified, an ellipsis marker (`. . .`) in the expected output can match any substring in the actual output. This includes substrings that span line boundaries, and empty substrings, so it's best to keep usage of this simple. Complicated uses can lead to the same kinds of "oops, it matched too much!" surprises that `. *` is prone to in regular expressions.

**doctest.IGNORE\_EXCEPTION\_DETAIL**

When specified, an example that expects an exception passes if an exception of the expected type is raised, even if the exception detail does not match. For example, an example expecting `ValueError: 42` will pass if the actual exception raised is `ValueError: 3*14`, but will fail, e.g., if `TypeError` is raised.

It will also ignore the module name used in Python 3 doctest reports. Hence both of these variations will work with the flag specified, regardless of whether the test is run under Python 2.7 or Python 3.2 (or later versions):

```
>>> raise CustomError('message')
Traceback (most recent call last):
CustomError: message

>>> raise CustomError('message')
Traceback (most recent call last):
my_module.CustomError: message
```

Note that `ELLIPSIS` can also be used to ignore the details of the exception message, but such a test may still fail based on whether or not the module details are printed as part of the exception name. Using `IGNORE_EXCEPTION_DETAIL` and the details from Python 2.3 is also the only clear way to write a doctest that doesn't care about the exception detail yet continues to pass under Python 2.3 or earlier (those releases do not support *doctest directives* and ignore them as irrelevant comments). For example:

```
>>> (1, 2)[3] = 'moo'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: object doesn't support item assignment
```

passes under Python 2.3 and later Python versions with the flag specified, even though the detail changed in Python 2.4 to say "does not" instead of "doesn't".

Berubah pada versi 3.2: `IGNORE_EXCEPTION_DETAIL` now also ignores any information relating to the module containing the exception under test.

**doctest.SKIP**

When specified, do not run the example at all. This can be useful in contexts where doctest examples serve as both documentation and test cases, and an example should be included for documentation purposes, but should not be checked. E.g., the example's output might be random; or the example might depend on resources which would be unavailable to the test driver.

The SKIP flag can also be used for temporarily "commenting out" examples.

**doctest.COMPARISON\_FLAGS**

Menggabungkan bitmask OR semua tanda perbandingan di atas.

The second group of options controls how test failures are reported:

**doctest.REPORT\_UDIFF**

When specified, failures that involve multi-line expected and actual outputs are displayed using a unified diff.

**doctest.REPORT\_CDIFF**

When specified, failures that involve multi-line expected and actual outputs will be displayed using a context diff.

**doctest.REPORT\_NDIFF**

When specified, differences are computed by `diff.lib.Differ`, using the same algorithm as the popular `ndiff.py` utility. This is the only method that marks differences within lines as well as across lines. For example, if a line of expected output contains digit 1 where actual output contains letter l, a line is inserted with a caret marking the mismatching column positions.

**doctest.REPORT\_ONLY\_FIRST\_FAILURE**

When specified, display the first failing example in each doctest, but suppress output for all remaining examples. This will prevent doctest from reporting correct examples that break because of earlier failures; but it might also hide incorrect examples that fail independently of the first failure. When `REPORT_ONLY_FIRST_FAILURE` is specified, the remaining examples are still run, and still count towards the total number of failures reported; only the output is suppressed.

**doctest.FAIL\_FAST**

When specified, exit after the first failing example and don't attempt to run the remaining examples. Thus, the number of failures reported will be at most 1. This flag may be useful during debugging, since examples after the first failure won't even produce debugging output.

The doctest command line accepts the option `-f` as a shorthand for `-o FAIL_FAST`.

Baru pada versi 3.4.

**doctest.REPORTING\_FLAGS**

Menggabungkan bitmask OR semua tanda pelaporan di atas.

There is also a way to register new option flag names, though this isn't useful unless you intend to extend `doctest` internals via subclassing:

**doctest.register\_optionflag(name)**

Create a new option flag with a given name, and return the new flag's integer value. `register_optionflag()` can be used when subclassing `OutputChecker` or `DocTestRunner` to create new options that are supported by your subclasses. `register_optionflag()` should always be called using the following idiom:

```
MY_FLAG = register_optionflag('MY_FLAG')
```

## Petunjuk

Doctest directives may be used to modify the *option flags* for an individual example. Doctest directives are special Python comments following an example's source code:

```
directive          ::=  "#" "doctest:" directive_options
directive_options  ::=  directive_option ("," directive_option)*
directive_option   ::=  on_or_off directive_option_name
on_or_off          ::=  "+" \| "-"
directive_option_name ::=  "DONT_ACCEPT_BLANKLINE" \| "NORMALIZE_WHITESPACE" \| ...
```

Whitespace is not allowed between the + or - and the directive option name. The directive option name can be any of the option flag names explained above.

An example's doctest directives modify doctest's behavior for that single example. Use + to enable the named behavior, or - to disable it.

Misalnya, tes ini lolos:

```
>>> print(list(range(20)))
[0,  1,  2,  3,  4,  5,  6,  7,  8,  9,
10, 11, 12, 13, 14, 15, 16, 17, 18, 19]
```

Without the directive it would fail, both because the actual output doesn't have two blanks before the single-digit list elements, and because the actual output is on a single line. This test also passes, and also requires a directive to do so:

```
>>> print(list(range(20)))
[0, 1, ..., 18, 19]
```

Multiple directives can be used on a single physical line, separated by commas:

```
>>> print(list(range(20)))
[0,  1,  ...,  18,  19]
```

If multiple directive comments are used for a single example, then they are combined:

```
>>> print(list(range(20)))
...
[0,  1,  ...,  18,  19]
```

As the previous example shows, you can add ... lines to your example containing only directives. This can be useful when an example is too long for a directive to comfortably fit on the same line:

```
>>> print(list(range(5)) + list(range(10, 20)) + list(range(30, 40)))
...
[0, ..., 4, 10, ..., 19, 30, ..., 39]
```

Note that since all options are disabled by default, and directives apply only to the example they appear in, enabling options (via + in a directive) is usually the only meaningful choice. However, option flags can also be passed to functions that run doctests, establishing different defaults. In such cases, disabling an option via - in a directive can be useful.

## Peringatan

`doctest` is serious about requiring exact matches in expected output. If even a single character doesn't match, the test fails. This will probably surprise you a few times, as you learn exactly what Python does and doesn't guarantee about output. For example, when printing a set, Python doesn't guarantee that the element is printed in any particular order, so a test like

```
>>> foo()
{"Hermione", "Harry"}
```

rentan! Salah satu solusinya adalah dengan melakukan

```
>>> foo() == {"Hermione", "Harry"}
True
```

sebagai gantinya. Yang lainnya adalah melakukan

```
>>> d = sorted(foo())
>>> d
['Harry', 'Hermione']
```

---

**Catatan:** Before Python 3.6, when printing a dict, Python did not guarantee that the key-value pairs was printed in any particular order.

---

There are others, but you get the idea.

Another bad idea is to print things that embed an object address, like

```
>>> id(1.0) # certain to fail some of the time
7948648
>>> class C: pass
>>> C() # the default repr() for instances embeds an address
<__main__.C instance at 0x00AC18F0>
```

The *ELLIPSIS* directive gives a nice approach for the last example:

```
>>> C()
<__main__.C instance at 0x...>
```

Floating-point numbers are also subject to small output variations across platforms, because Python defers to the platform C library for float formatting, and C libraries vary widely in quality here.

```
>>> 1./7 # risky
0.14285714285714285
>>> print(1./7) # safer
0.142857142857
>>> print(round(1./7, 6)) # much safer
0.142857
```

Numbers of the form  $I/2 \cdot **J$  are safe across all platforms, and I often contrive doctest examples to produce numbers of that form:

```
>>> 3./4 # utterly safe
0.75
```

Simple fractions are also easier for people to understand, and that makes for better documentation.

### 26.3.4 Basic API

The functions `testmod()` and `testfile()` provide a simple interface to doctest that should be sufficient for most basic uses. For a less formal introduction to these two functions, see sections *Simple Usage: Checking Examples in Docstrings* and *Penggunaan Sederhana: Memeriksa Contoh di Berkas Teks*.

```
doctest.testfile(filename, module_relative=True, name=None, package=None, globs=None, verbose=None, report=True, optionflags=0, extraglobs=None, raise_on_error=False, parser=DocTestParser(), encoding=None)
```

All arguments except `filename` are optional, and should be specified in keyword form.

Test examples in the file named `filename`. Return `(failure_count, test_count)`.

Optional argument `module_relative` specifies how the filename should be interpreted:

- If `module_relative` is `True` (the default), then `filename` specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, `filename` should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then `filename` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument `name` gives the name of the test; by default, or if `None`, `os.path.basename(filename)` is used.

Optional argument `package` is a Python package or the name of a Python package whose directory should be used as the base directory for a module-relative filename. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify `package` if `module_relative` is `False`.

Optional argument `globs` gives a dict to be used as the globals when executing examples. A new shallow copy of this dict is created for the doctest, so its examples start with a clean slate. By default, or if `None`, a new empty dict is used.

Optional argument `extraglobs` gives a dict merged into the globals used to execute examples. This works like `dict.update()`: if `globs` and `extraglobs` have a common key, the associated value in `extraglobs` appears in the combined dict. By default, or if `None`, no extra globals are used. This is an advanced feature that allows parameterization of doctests. For example, a doctest can be written for a base class, using a generic name for the class, then reused to test any number of subclasses by passing an `extraglobs` dict mapping the generic name to the subclass to be tested.

Optional argument `verbose` prints lots of stuff if true, and prints only failures if false; by default, or if `None`, it's true if and only if `'-v'` is in `sys.argv`.

Optional argument `report` prints a summary at the end when true, else prints nothing at the end. In verbose mode, the summary is detailed, else the summary is very brief (in fact, empty if all tests passed).

Optional argument `optionflags` (default value 0) takes the bitwise OR of option flags. See section *Penanda Opsi*.

Optional argument `raise_on_error` defaults to false. If true, an exception is raised upon the first failure or unexpected exception in an example. This allows failures to be post-mortem debugged. Default behavior is to continue running examples.

Optional argument `parser` specifies a `DocTestParser` (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument `encoding` specifies an encoding that should be used to convert the file to unicode.

```
doctest.testmod(m=None, name=None, globs=None, verbose=None, report=True, optionflags=0, extraglobs=None, raise_on_error=False, exclude_empty=False)
```

All arguments are optional, and all except for `m` should be specified in keyword form.

Test examples in docstrings in functions and classes reachable from module *m* (or module `__main__` if *m* is not supplied or is `None`), starting with `m.__doc__`.

Also test examples reachable from dict `m.__test__`, if it exists and is not `None`. `m.__test__` maps names (strings) to functions, classes and strings; function and class docstrings are searched for examples; strings are searched directly, as if they were docstrings.

Only docstrings attached to objects belonging to module *m* are searched.

Return (failure\_count, test\_count).

Optional argument *name* gives the name of the module; by default, or if `None`, `m.__name__` is used.

Optional argument *exclude\_empty* defaults to `false`. If `true`, objects for which no doctests are found are excluded from consideration. The default is a backward compatibility hack, so that code still using `doctest.master.summarize()` in conjunction with `testmod()` continues to get output for objects with no tests. The *exclude\_empty* argument to the newer `DocTestFinder` constructor defaults to `true`.

Optional arguments *extraglobs*, *verbose*, *report*, *optionflags*, *raise\_on\_error*, and *globs* are the same as for function `testfile()` above, except that *globs* defaults to `m.__dict__`.

`doctest.run_docstring_examples(f, globs, verbose=False, name="NoName", compileflags=None, optionflags=0)`

Test examples associated with object *f*; for example, *f* may be a string, a module, a function, or a class object.

A shallow copy of dictionary argument *globs* is used for the execution context.

Optional argument *name* is used in failure messages, and defaults to `"NoName"`.

If optional argument *verbose* is `true`, output is generated even if there are no failures. By default, output is generated only in case of an example failure.

Optional argument *compileflags* gives the set of flags that should be used by the Python compiler when running the examples. By default, or if `None`, flags are deduced corresponding to the set of future features found in *globs*.

Optional argument *optionflags* works as for function `testfile()` above.

### 26.3.5 unittest API

As your collection of doctest'ed modules grows, you'll want a way to run all their doctests systematically. `doctest` provides two functions that can be used to create `unittest` test suites from modules and text files containing doctests. To integrate with `unittest` test discovery, include a `load_tests()` function in your test module:

```
import unittest
import doctest
import my_module_with_doctests

def load_tests(loader, tests, ignore):
    tests.addTests(doctest.DocTestSuite(my_module_with_doctests))
    return tests
```

There are two main functions for creating `unittest.TestSuite` instances from text files and modules with doctests:

`doctest.DocFileSuite(*paths, module_relative=True, package=None, setUp=None, tearDown=None, globs=None, optionflags=0, parser=DocTestParser(), encoding=None)`

Convert doctest tests from one or more text files to a `unittest.TestSuite`.

The returned `unittest.TestSuite` is to be run by the `unittest` framework and runs the interactive examples in each file. If an example in any file fails, then the synthesized unit test fails, and a `failureException` exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Pass one or more paths (as strings) to text files to be examined.

Options may be provided as keyword arguments:

Optional argument *module\_relative* specifies how the filenames in *paths* should be interpreted:

- If *module\_relative* is `True` (the default), then each filename in *paths* specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory; but if the *package* argument is specified, then it is relative to that package. To ensure OS-independence, each filename should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If *module\_relative* is `False`, then each filename in *paths* specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for module-relative filenames in *paths*. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify *package* if *module\_relative* is `False`.

Optional argument *setUp* specifies a set-up function for the test suite. This is called before running the tests in each file. The *setUp* function will be passed a *DocTest* object. The *setUp* function can access the test globals as the *globals* attribute of the test passed.

Optional argument *tearDown* specifies a tear-down function for the test suite. This is called after running the tests in each file. The *tearDown* function will be passed a *DocTest* object. The *setUp* function can access the test globals as the *globals* attribute of the test passed.

Optional argument *globals* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globals* is a new empty dictionary.

Optional argument *optionflags* specifies the default doctest options for the tests, created by or-ing together individual option flags. See section *Penanda Opsi*. See function *set\_unittest\_reportflags()* below for a better way to set reporting options.

Optional argument *parser* specifies a *DocTestParser* (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., *DocTestParser()*).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

The global `__file__` is added to the globals provided to doctests loaded from a text file using *DocFileSuite()*.

```
doctest.DocTestSuite (module=None, globals=None, extraglobs=None, test_finder=None, setUp=None, tearDown=None, checker=None)
```

Convert doctest tests for a module to a *unittest.TestSuite*.

The returned *unittest.TestSuite* is to be run by the unittest framework and runs each doctest in the module. If any of the doctests fail, then the synthesized unit test fails, and a *failureException* exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Optional argument *module* provides the module to be tested. It can be a module object or a (possibly dotted) module name. If not specified, the module calling this function is used.

Optional argument *globals* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globals* is a new empty dictionary.

Optional argument *extraglobs* specifies an extra set of global variables, which is merged into *globals*. By default, no extra globals are used.

Optional argument *test\_finder* is the *DocTestFinder* object (or a drop-in replacement) that is used to extract doctests from the module.

Optional arguments *setUp*, *tearDown*, and *optionflags* are the same as for function *DocFileSuite()* above.

This function uses the same search technique as `testmod()`.

Berubah pada versi 3.5: `DocTestSuite()` returns an empty `unittest.TestSuite` if `module` contains no docstrings instead of raising `ValueError`.

Under the covers, `DocTestSuite()` creates a `unittest.TestSuite` out of `doctest.DocTestCase` instances, and `DocTestCase` is a subclass of `unittest.TestCase`. `DocTestCase` isn't documented here (it's an internal detail), but studying its code can answer questions about the exact details of `unittest` integration.

Similarly, `DocFileSuite()` creates a `unittest.TestSuite` out of `doctest.DocFileCase` instances, and `DocFileCase` is a subclass of `DocTestCase`.

So both ways of creating a `unittest.TestSuite` run instances of `DocTestCase`. This is important for a subtle reason: when you run `doctest` functions yourself, you can control the `doctest` options in use directly, by passing option flags to `doctest` functions. However, if you're writing a `unittest` framework, `unittest` ultimately controls when and how tests get run. The framework author typically wants to control `doctest` reporting options (perhaps, e.g., specified by command line options), but there's no way to pass options through `unittest` to `doctest` test runners.

For this reason, `doctest` also supports a notion of `doctest` reporting flags specific to `unittest` support, via this function:

```
doctest.set_unittest_reportflags(flags)
    Set the doctest reporting flags to use.
```

Argument `flags` takes the bitwise OR of option flags. See section *Penanda Opsi*. Only "reporting flags" can be used.

This is a module-global setting, and affects all future doctests run by module `unittest`: the `runTest()` method of `DocTestCase` looks at the option flags specified for the test case when the `DocTestCase` instance was constructed. If no reporting flags were specified (which is the typical and expected case), `doctest`'s `unittest` reporting flags are bitwise ORed into the option flags, and the option flags so augmented are passed to the `DocTestRunner` instance created to run the doctest. If any reporting flags were specified when the `DocTestCase` instance was constructed, `doctest`'s `unittest` reporting flags are ignored.

The value of the `unittest` reporting flags in effect before the function was called is returned by the function.

### 26.3.6 Advanced API

The basic API is a simple wrapper that's intended to make `doctest` easy to use. It is fairly flexible, and should meet most users' needs; however, if you require more fine-grained control over testing, or wish to extend `doctest`'s capabilities, then you should use the advanced API.

The advanced API revolves around two container classes, which are used to store the interactive examples extracted from `doctest` cases:

- *Example*: A single Python *statement*, paired with its expected output.
- *DocTest*: A collection of *Examples*, typically extracted from a single docstring or text file.

Additional processing classes are defined to find, parse, and run, and check `doctest` examples:

- *DocTestFinder*: Finds all docstrings in a given module, and uses a *DocTestParser* to create a *DocTest* from every docstring that contains interactive examples.
- *DocTestParser*: Creates a *DocTest* object from a string (such as an object's docstring).
- *DocTestRunner*: Executes the examples in a *DocTest*, and uses an *OutputChecker* to verify their output.
- *OutputChecker*: Compares the actual output from a `doctest` example with the expected output, and decides whether they match.

The relationships among these processing classes are summarized in the following diagram:

```

list of:
+-----+
|module| --DocTestFinder-> | DocTest | --DocTestRunner-> results
+-----+                +-----+                (printed)
                        |           |
                        | Example |           |
                        |   ...   |           |
                        | Example |           |
                        |         |           |
                        +-----+
DocTestParser
OutputChecker

```

## DocTest Objects

**class** `doctest.DocTest` (*examples, globs, name, filename, lineno, docstring*)

A collection of doctest examples that should be run in a single namespace. The constructor arguments are used to initialize the attributes of the same names.

*DocTest* defines the following attributes. They are initialized by the constructor, and should not be modified directly.

### examples

A list of *Example* objects encoding the individual interactive Python examples that should be run by this test.

### globs

The namespace (aka globals) that the examples should be run in. This is a dictionary mapping names to values. Any changes to the namespace made by the examples (such as binding new variables) will be reflected in *globs* after the test is run.

### name

A string name identifying the *DocTest*. Typically, this is the name of the object or file that the test was extracted from.

### filename

The name of the file that this *DocTest* was extracted from; or *None* if the filename is unknown, or if the *DocTest* was not extracted from a file.

### lineno

The line number within *filename* where this *DocTest* begins, or *None* if the line number is unavailable. This line number is zero-based with respect to the beginning of the file.

### docstring

The string that the test was extracted from, or *None* if the string is unavailable, or if the test was not extracted from a string.

## Example Objects

**class** `doctest.Example` (*source, want, exc\_msg=None, lineno=0, indent=0, options=None*)

A single interactive example, consisting of a Python statement and its expected output. The constructor arguments are used to initialize the attributes of the same names.

*Example* defines the following attributes. They are initialized by the constructor, and should not be modified directly.

### source

A string containing the example's source code. This source code consists of a single Python statement, and always ends with a newline; the constructor adds a newline when necessary.

**want**

The expected output from running the example's source code (either from stdout, or a traceback in case of exception). *want* ends with a newline unless no output is expected, in which case it's an empty string. The constructor adds a newline when necessary.

**exc\_msg**

The exception message generated by the example, if the example is expected to generate an exception; or `None` if it is not expected to generate an exception. This exception message is compared against the return value of `traceback.format_exception_only()`. *exc\_msg* ends with a newline unless it's `None`. The constructor adds a newline if needed.

**lineno**

The line number within the string containing this example where the example begins. This line number is zero-based with respect to the beginning of the containing string.

**indent**

The example's indentation in the containing string, i.e., the number of space characters that precede the example's first prompt.

**options**

A dictionary mapping from option flags to `True` or `False`, which is used to override default options for this example. Any option flags not contained in this dictionary are left at their default value (as specified by the `DocTestRunner`'s `optionflags`). By default, no options are set.

## DocTestFinder objects

**class** `doctest.DocTestFinder` (*verbose=False*, *parser=DocTestParser()*, *recurse=True*, *exclude\_empty=True*)

A processing class used to extract the *DocTests* that are relevant to a given object, from its docstring and the docstrings of its contained objects. *DocTests* can be extracted from modules, classes, functions, methods, staticmethods, classmethods, and properties.

The optional argument *verbose* can be used to display the objects searched by the finder. It defaults to `False` (no output).

The optional argument *parser* specifies the *DocTestParser* object (or a drop-in replacement) that is used to extract doctests from docstrings.

If the optional argument *recurse* is false, then `DocTestFinder.find()` will only examine the given object, and not any contained objects.

If the optional argument *exclude\_empty* is false, then `DocTestFinder.find()` will include tests for objects with empty docstrings.

*DocTestFinder* defines the following method:

**find** (*obj*, [*name*], [*module*], [*globs*], [*extraglobs*])

Return a list of the *DocTests* that are defined by *obj*'s docstring, or by any of its contained objects' docstrings.

The optional argument *name* specifies the object's name; this name will be used to construct names for the returned *DocTests*. If *name* is not specified, then `obj.__name__` is used.

The optional parameter *module* is the module that contains the given object. If the module is not specified or is `None`, then the test finder will attempt to automatically determine the correct module. The object's module is used:

- As a default namespace, if *globs* is not specified.
- To prevent the `DocTestFinder` from extracting *DocTests* from objects that are imported from other modules. (Contained objects with modules other than *module* are ignored.)

- To find the name of the file containing the object.
- To help find the line number of the object within its file.

If `module` is `False`, no attempt to find the module will be made. This is obscure, of use mostly in testing doctest itself: if `module` is `False`, or is `None` but cannot be found automatically, then all objects are considered to belong to the (non-existent) module, so all contained objects will (recursively) be searched for doctests.

The globals for each `DocTest` is formed by combining `globs` and `extraglobs` (bindings in `extraglobs` override bindings in `globs`). A new shallow copy of the globals dictionary is created for each `DocTest`. If `globs` is not specified, then it defaults to the module's `__dict__`, if specified, or `{ }` otherwise. If `extraglobs` is not specified, then it defaults to `{ }`.

## DocTestParser objects

**class** `doctest.DocTestParser`

A processing class used to extract interactive examples from a string, and use them to create a `DocTest` object.

`DocTestParser` defines the following methods:

**get\_doctest** (*string*, *globs*, *name*, *filename*, *lineno*)

Extract all doctest examples from the given string, and collect them into a `DocTest` object.

*globs*, *name*, *filename*, and *lineno* are attributes for the new `DocTest` object. See the documentation for `DocTest` for more information.

**get\_examples** (*string*, *name*='<string>')

Extract all doctest examples from the given string, and return them as a list of `Example` objects. Line numbers are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

**parse** (*string*, *name*='<string>')

Divide the given string into examples and intervening text, and return them as a list of alternating `Examples` and strings. Line numbers for the `Examples` are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

## DocTestRunner objects

**class** `doctest.DocTestRunner` (*checker*=`None`, *verbose*=`None`, *optionflags*=0)

A processing class used to execute and verify the interactive examples in a `DocTest`.

The comparison between expected outputs and actual outputs is done by an `OutputChecker`. This comparison may be customized with a number of option flags; see section *Penanda Opsi* for more information. If the option flags are insufficient, then the comparison may also be customized by passing a subclass of `OutputChecker` to the constructor.

The test runner's display output can be controlled in two ways. First, an output function can be passed to `TestRunner.run()`; this function will be called with strings that should be displayed. It defaults to `sys.stdout.write`. If capturing the output is not sufficient, then the display output can be also customized by subclassing `DocTestRunner`, and overriding the methods `report_start()`, `report_success()`, `report_unexpected_exception()`, and `report_failure()`.

The optional keyword argument *checker* specifies the `OutputChecker` object (or drop-in replacement) that should be used to compare the expected outputs to the actual outputs of doctest examples.

The optional keyword argument *verbose* controls the *DocTestRunner*'s verbosity. If *verbose* is *True*, then information is printed about each example, as it is run. If *verbose* is *False*, then only failures are printed. If *verbose* is unspecified, or *None*, then verbose output is used iff the command-line switch *-v* is used.

The optional keyword argument *optionflags* can be used to control how the test runner compares expected output to actual output, and how it displays failures. For more information, see section *Penanda Opsi*.

*DocTestParser* defines the following methods:

**report\_start** (*out*, *test*, *example*)

Report that the test runner is about to process the given example. This method is provided to allow subclasses of *DocTestRunner* to customize their output; it should not be called directly.

*example* is the example about to be processed. *test* is the test containing *example*. *out* is the output function that was passed to *DocTestRunner.run()*.

**report\_success** (*out*, *test*, *example*, *got*)

Report that the given example ran successfully. This method is provided to allow subclasses of *DocTestRunner* to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to *DocTestRunner.run()*.

**report\_failure** (*out*, *test*, *example*, *got*)

Report that the given example failed. This method is provided to allow subclasses of *DocTestRunner* to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to *DocTestRunner.run()*.

**report\_unexpected\_exception** (*out*, *test*, *example*, *exc\_info*)

Report that the given example raised an unexpected exception. This method is provided to allow subclasses of *DocTestRunner* to customize their output; it should not be called directly.

*example* is the example about to be processed. *exc\_info* is a tuple containing information about the unexpected exception (as returned by *sys.exc\_info()*). *test* is the test containing *example*. *out* is the output function that was passed to *DocTestRunner.run()*.

**run** (*test*, *compileflags=None*, *out=None*, *clear\_globs=True*)

Run the examples in *test* (a *DocTest* object), and display the results using the writer function *out*.

The examples are run in the namespace *test.globs*. If *clear\_globs* is true (the default), then this namespace will be cleared after the test runs, to help with garbage collection. If you would like to examine the namespace after the test completes, then use *clear\_globs=False*.

*compileflags* gives the set of flags that should be used by the Python compiler when running the examples. If not specified, then it will default to the set of future-import flags that apply to *globs*.

The output of each example is checked using the *DocTestRunner*'s output checker, and the results are formatted by the *DocTestRunner.report\_\**() methods.

**summarize** (*verbose=None*)

Print a summary of all the test cases that have been run by this *DocTestRunner*, and return a *named tuple* *TestResults(failed, attempted)*.

The optional *verbose* argument controls how detailed the summary is. If the verbosity is not specified, then the *DocTestRunner*'s verbosity is used.

## OutputChecker objects

### **class** `doctest.OutputChecker`

A class used to check the whether the actual output from a doctest example matches the expected output. *OutputChecker* defines two methods: *check\_output()*, which compares a given pair of outputs, and returns `True` if they match; and *output\_difference()*, which returns a string describing the differences between two outputs.

*OutputChecker* defines the following methods:

#### **check\_output** (*want*, *got*, *optionflags*)

Return `True` iff the actual output from an example (*got*) matches the expected output (*want*). These strings are always considered to match if they are identical; but depending on what option flags the test runner is using, several non-exact match types are also possible. See section *Penanda Opsi* for more information about option flags.

#### **output\_difference** (*example*, *got*, *optionflags*)

Return a string describing the differences between the expected output for a given example (*example*) and the actual output (*got*). *optionflags* is the set of option flags used to compare *want* and *got*.

## 26.3.7 Debugging

Doctest provides several mechanisms for debugging doctest examples:

- Several functions convert doctests to executable Python programs, which can be run under the Python debugger, *pdb*.
- The *DebugRunner* class is a subclass of *DocTestRunner* that raises an exception for the first failing example, containing information about that example. This information can be used to perform post-mortem debugging on the example.
- The *unittest* cases generated by *DocTestSuite()* support the *debug()* method defined by *unittest.TestCase*.
- You can add a call to *pdb.set\_trace()* in a doctest example, and you'll drop into the Python debugger when that line is executed. Then you can inspect current values of variables, and so on. For example, suppose *a.py* contains just this module docstring:

```
"""
>>> def f(x):
...     g(x*2)
>>> def g(x):
...     print(x+3)
...     import pdb; pdb.set_trace()
>>> f(3)
9
"""
```

Then an interactive Python session may look like this:

```
>>> import a, doctest
>>> doctest.testmod(a)
--Return--
> <doctest a[1]>(3)g()->None
-> import pdb; pdb.set_trace()
(Pdb) list
1      def g(x):
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

2         print(x+3)
3  ->      import pdb; pdb.set_trace()
[EOF]
(Pdb) p x
6
(Pdb) step
--Return--
> <doctest a[0]>(2) f()->None
-> g(x*2)
(Pdb) list
1         def f(x):
2  ->      g(x*2)
[EOF]
(Pdb) p x
3
(Pdb) step
--Return--
> <doctest a[2]>(1)?()->None
-> f(3)
(Pdb) cont
(0, 3)
>>>

```

Functions that convert doctests to Python code, and possibly run the synthesized code under the debugger:

`doctest.script_from_examples(s)`

Convert text with examples to a script.

Argument *s* is a string containing doctest examples. The string is converted to a Python script, where doctest examples in *s* are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```

import doctest
print(doctest.script_from_examples(r"""
    Set x and y to 1 and 2.
    >>> x, y = 1, 2

    Print their sum:
    >>> print(x+y)
    3
"""))

```

displays:

```

# Set x and y to 1 and 2.
x, y = 1, 2
#
# Print their sum:
print(x+y)
# Expected:
## 3

```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.

`doctest.testsource(module, name)`

Convert the doctest for an object to a script.

Argument *module* is a module object, or dotted name of a module, containing the object whose doctests are of interest. Argument *name* is the name (within the module) of the object with the doctests of interest. The result is a string, containing the object's docstring converted to a Python script, as described for `script_from_examples()` above. For example, if module `a.py` contains a top-level function `f()`, then

```
import a, doctest
print(doctest.testsource(a, "a.f"))
```

prints a script version of function `f()`'s docstring, with doctests converted to code, and the rest placed in comments.

`doctest.debug(module, name, pm=False)`

Debug the doctests for an object.

The *module* and *name* arguments are the same as for function `testsource()` above. The synthesized Python script for the named object's docstring is written to a temporary file, and then that file is run under the control of the Python debugger, `pdb`.

A shallow copy of `module.__dict__` is used for both local and global execution context.

Optional argument *pm* controls whether post-mortem debugging is used. If *pm* has a true value, the script file is run directly, and the debugger gets involved only if the script terminates via raising an unhandled exception. If it does, then post-mortem debugging is invoked, via `pdb.post_mortem()`, passing the traceback object from the unhandled exception. If *pm* is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate `exec()` call to `pdb.run()`.

`doctest.debug_src(src, pm=False, globs=None)`

Debug the doctests in a string.

This is like function `debug()` above, except that a string containing doctest examples is specified directly, via the *src* argument.

Optional argument *pm* has the same meaning as in function `debug()` above.

Optional argument *globs* gives a dictionary to use as both local and global execution context. If not specified, or None, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

The `DebugRunner` class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially `DebugRunner`'s docstring (which is a doctest!) for more details:

**class** `doctest.DebugRunner` (*checker=None, verbose=None, optionflags=0*)

A subclass of `DocTestRunner` that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an `UnexpectedException` exception is raised, containing the test, the example, and the original exception. If the output doesn't match, then a `DocTestFailure` exception is raised, containing the test, the example, and the actual output.

For information about the constructor parameters and methods, see the documentation for `DocTestRunner` in section [Advanced API](#).

There are two exceptions that may be raised by `DebugRunner` instances:

**exception** `doctest.DocTestFailure` (*test, example, got*)

An exception raised by `DocTestRunner` to signal that a doctest example's actual output did not match its expected output. The constructor arguments are used to initialize the attributes of the same names.

`DocTestFailure` defines the following attributes:

`DocTestFailure.test`

The `DocTest` object that was being run when the example failed.

`DocTestFailure.example`

The `Example` that failed.

`DocTestFailure.got`

The example's actual output.

**exception** `doctest.UnexpectedException` (*test*, *example*, *exc\_info*)

An exception raised by `DocTestRunner` to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the attributes of the same names.

`UnexpectedException` defines the following attributes:

`UnexpectedException.test`

The `DocTest` object that was being run when the example failed.

`UnexpectedException.example`

The `Example` that failed.

`UnexpectedException.exc_info`

A tuple containing information about the unexpected exception, as returned by `sys.exc_info()`.

## 26.3.8 Soapbox

As mentioned in the introduction, `doctest` has grown to have three primary uses:

1. Checking examples in docstrings.
2. Regression testing.
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned---it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my `doctest` examples stops working after a "harmless" change.

Doctest also makes an excellent tool for regression testing, especially if you don't skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what's actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It's true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper than just that: the natural attitude when writing a doctest-based test is that you want to explain the fine points of your software, and illustrate them with examples. This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It's a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests:

- Write text files containing test cases as interactive examples, and test the files using `testfile()` or `DocFileSuite()`. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.
- Define functions named `_regtest_topic` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a `__test__` dictionary mapping from regression test topics to docstrings containing test cases.

When you have placed your tests in a module, the module can itself be the test runner. When a test fails, you can arrange for your test runner to re-run only the failing doctest while you debug the problem. Here is a minimal example of such a test runner:

```
if __name__ == '__main__':
    import doctest
    flags = doctest.REPORT_NDIFF|doctest.FAIL_FAST
    if len(sys.argv) > 1:
        name = sys.argv[1]
        if name in globals():
            obj = globals()[name]
        else:
            obj = __test__[name]
        doctest.run_docstring_examples(obj, globals(), name=name,
                                      optionflags=flags)
    else:
        fail, total = doctest.testmod(optionflags=flags)
        print("{} failures out of {} tests".format(fail, total))
```

## 26.4 unittest --- Unit testing framework

Source code: `Lib/unittest/__init__.py`

---

(If you are already familiar with the basic concepts of testing, you might want to skip to [the list of assert methods](#).)

The `unittest` unit testing framework was originally inspired by JUnit and has a similar flavor as major unit testing frameworks in other languages. It supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework.

To achieve this, `unittest` supports some important concepts in an object-oriented way:

**test fixture** A *test fixture* represents the preparation needed to perform one or more tests, and any associated cleanup actions. This may involve, for example, creating temporary or proxy databases, directories, or starting a server process.

**test case** A *test case* is the individual unit of testing. It checks for a specific response to a particular set of inputs. `unittest` provides a base class, `TestCase`, which may be used to create new test cases.

**test suite** A *test suite* is a collection of test cases, test suites, or both. It is used to aggregate tests that should be executed together.

**test runner** A *test runner* is a component which orchestrates the execution of tests and provides the outcome to the user. The runner may use a graphical interface, a textual interface, or return a special value to indicate the results of executing the tests.

**Lihat juga:**

**Modul `doctest`** Another test-support module with a very different flavor.

**Simple Smalltalk Testing: With Patterns** Kent Beck's original paper on testing frameworks using the pattern shared by `unittest`.

**pytest** Third-party unittest framework with a lighter-weight syntax for writing tests. For example, `assert func(10) == 42`.

**The Python Testing Tools Taxonomy** An extensive list of Python testing tools including functional testing frameworks and mock object libraries.

**Testing in Python Mailing List** A special-interest-group for discussion of testing, and testing tools, in Python.

The script `Tools/unittestgui/unittestgui.py` in the Python source distribution is a GUI tool for test discovery and execution. This is intended largely for ease of use for those new to unit testing. For production environments it is recommended that tests be driven by a continuous integration system such as [Buildbot](#), [Jenkins](#) or [Travis-CI](#), or [AppVeyor](#).

### 26.4.1 Contoh dasar

The `unittest` module provides a rich set of tools for constructing and running tests. This section demonstrates that a small subset of the tools suffice to meet the needs of most users.

Here is a short script to test three string methods:

```
import unittest

class TestStringMethods(unittest.TestCase):

    def test_upper(self):
        self.assertEqual('foo'.upper(), 'FOO')

    def test_isupper(self):
        self.assertTrue('FOO'.isupper())
        self.assertFalse('Foo'.isupper())

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', 'world'])
        # check that s.split fails when the separator is not a string
        with self.assertRaises(TypeError):
            s.split(2)

if __name__ == '__main__':
    unittest.main()
```

A testcase is created by subclassing `unittest.TestCase`. The three individual tests are defined with methods whose names start with the letters `test`. This naming convention informs the test runner about which methods represent tests.

The crux of each test is a call to `assertEqual()` to check for an expected result; `assertTrue()` or `assertFalse()` to verify a condition; or `assertRaises()` to verify that a specific exception gets raised. These methods are used instead of the `assert` statement so the test runner can accumulate all test results and produce a report.

The `setUp()` and `tearDown()` methods allow you to define instructions that will be executed before and after each test method. They are covered in more detail in the section [Organizing test code](#).

The final block shows a simple way to run the tests. `unittest.main()` provides a command-line interface to the test script. When run from the command line, the above script produces an output that looks like this:

```
...
-----
Ran 3 tests in 0.000s

OK
```

Passing the `-v` option to your test script will instruct `unittest.main()` to enable a higher level of verbosity, and produce the following output:

```
test_isupper (__main__.TestStringMethods) ... ok
test_split (__main__.TestStringMethods) ... ok
test_upper (__main__.TestStringMethods) ... ok
```

```
-----
Ran 3 tests in 0.001s
```

```
OK
```

The above examples show the most commonly used `unittest` features which are sufficient to meet many everyday testing needs. The remainder of the documentation explores the full feature set from first principles.

### 26.4.2 Command-Line Interface

The `unittest` module can be used from the command line to run tests from modules, classes or even individual test methods:

```
python -m unittest test_module1 test_module2
python -m unittest test_module.TestClass
python -m unittest test_module.TestClass.test_method
```

You can pass in a list with any combination of module names, and fully qualified class or method names.

Test modules can be specified by file path as well:

```
python -m unittest tests/test_something.py
```

This allows you to use the shell filename completion to specify the test module. The file specified must still be importable as a module. The path is converted to a module name by removing the `.py` and converting path separators into `.'`. If you want to execute a test file that isn't importable as a module you should execute the file directly instead.

You can run tests with more detail (higher verbosity) by passing in the `-v` flag:

```
python -m unittest -v test_module
```

When executed without arguments *Test Discovery* is started:

```
python -m unittest
```

For a list of all the command-line options:

```
python -m unittest -h
```

Berubah pada versi 3.2: In earlier versions it was only possible to run individual test methods and not modules or classes.

### Command-line options

`unittest` supports these command-line options:

#### **-b, --buffer**

The standard output and standard error streams are buffered during the test run. Output during a passing test is discarded. Output is echoed normally on test fail or error and is added to the failure messages.

#### **-c, --catch**

Control-C during the test run waits for the current test to end and then reports all the results so far. A second Control-C raises the normal *KeyboardInterrupt* exception.

See *Signal Handling* for the functions that provide this functionality.

**-f, --failfast**

Stop the test run on the first error or failure.

**-k**

Only run test methods and classes that match the pattern or substring. This option may be used multiple times, in which case all test cases that match of the given patterns are included.

Patterns that contain a wildcard character (\*) are matched against the test name using `fnmatch.fnmatchcase()`; otherwise simple case-sensitive substring matching is used.

Patterns are matched against the fully qualified test method name as imported by the test loader.

For example, `-k foo` matches `foo_tests.SomeTest.test_something`, `bar_tests.SomeTest.test_foo`, but not `bar_tests.FooTest.test_something`.

**--locals**

Show local variables in tracebacks.

Baru pada versi 3.2: The command-line options `-b`, `-c` and `-f` were added.

Baru pada versi 3.5: The command-line option `--locals`.

Baru pada versi 3.7: The command-line option `-k`.

The command line can also be used for test discovery, for running all of the tests in a project or just a subset.

### 26.4.3 Test Discovery

Baru pada versi 3.2.

Unittest supports simple test discovery. In order to be compatible with test discovery, all of the test files must be modules or packages (including *namespace packages*) importable from the top-level directory of the project (this means that their filenames must be valid identifiers).

Test discovery is implemented in `TestLoader.discover()`, but can also be used from the command line. The basic command-line usage is:

```
cd project_directory
python -m unittest discover
```

**Catatan:** As a shortcut, `python -m unittest` is the equivalent of `python -m unittest discover`. If you want to pass arguments to test discovery the `discover` sub-command must be used explicitly.

The `discover` sub-command has the following options:

**-v, --verbose**

Verbose output

**-s, --start-directory** directory

Directory to start discovery (. default)

**-p, --pattern** pattern

Pattern to match test files (test\*.py default)

**-t, --top-level-directory** directory

Top level directory of project (defaults to start directory)

The `-s`, `-p`, and `-t` options can be passed in as positional arguments in that order. The following two command lines are equivalent:

```
python -m unittest discover -s project_directory -p "*_test.py"
python -m unittest discover project_directory "*_test.py"
```

As well as being a path it is possible to pass a package name, for example `myproject.subpackage.test`, as the start directory. The package name you supply will then be imported and its location on the filesystem will be used as the start directory.

**Hati-hati:** Test discovery loads tests by importing them. Once test discovery has found all the test files from the start directory you specify it turns the paths into package names to import. For example `foo/bar/baz.py` will be imported as `foo.bar.baz`.

If you have a package installed globally and attempt test discovery on a different copy of the package then the import *could* happen from the wrong place. If this happens test discovery will warn you and exit.

If you supply the start directory as a package name rather than a path to a directory then discover assumes that whichever location it imports from is the location you intended, so you will not get the warning.

Test modules and packages can customize test loading and discovery by through the *load\_tests protocol*.

Berubah pada versi 3.4: Test discovery supports *namespace packages* for start directory. Note that you need to the top level directory too. (e.g. `python -m unittest discover -s root/namespace -t root`).

## 26.4.4 Organizing test code

The basic building blocks of unit testing are *test cases* --- single scenarios that must be set up and checked for correctness. In *unittest*, test cases are represented by *unittest.TestCase* instances. To make your own test cases you must write subclasses of *TestCase* or use *FunctionTestCase*.

The testing code of a *TestCase* instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest *TestCase* subclass will simply implement a test method (i.e. a method whose name starts with `test`) in order to perform specific testing code:

```
import unittest

class DefaultWidgetSizeTestCase(unittest.TestCase):
    def test_default_widget_size(self):
        widget = Widget('The widget')
        self.assertEqual(widget.size(), (50, 50))
```

Note that in order to test something, we use one of the `assert*()` methods provided by the *TestCase* base class. If the test fails, an exception will be raised with an explanatory message, and *unittest* will identify the test case as a *failure*. Any other exceptions will be treated as *errors*.

Tests can be numerous, and their set-up can be repetitive. Luckily, we can factor out set-up code by implementing a method called `setUp()`, which the testing framework will automatically call for every single test we run:

```
import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def test_default_widget_size(self):
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

self.assertEqual(self.widget.size(), (50,50),
                  'incorrect default size')

def test_widget_resize(self):
    self.widget.resize(100,150)
    self.assertEqual(self.widget.size(), (100,150),
                      'wrong size after resize')

```

**Catatan:** The order in which the various tests will be run is determined by sorting the test method names with respect to the built-in ordering for strings.

If the `setUp()` method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the test method will not be executed.

Similarly, we can provide a `tearDown()` method that tidies up after the test method has been run:

```

import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def tearDown(self):
        self.widget.dispose()

```

If `setUp()` succeeded, `tearDown()` will be run whether the test method succeeded or not.

Such a working environment for the testing code is called a *test fixture*. A new `TestCase` instance is created as a unique test fixture used to execute each individual test method. Thus `setUp()`, `tearDown()`, and `__init__()` will be called once per test.

It is recommended that you use `TestCase` implementations to group tests together according to the features they test. `unittest` provides a mechanism for this: the *test suite*, represented by `unittest`'s `TestSuite` class. In most cases, calling `unittest.main()` will do the right thing and collect all the module's test cases for you and execute them.

However, should you want to customize the building of your test suite, you can do it yourself:

```

def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_widget_size'))
    suite.addTest(WidgetTestCase('test_widget_resize'))
    return suite

if __name__ == '__main__':
    runner = unittest.TextTestRunner()
    runner.run(suite())

```

You can place the definitions of test cases and test suites in the same modules as the code they are to test (such as `widget.py`), but there are several advantages to placing the test code in a separate module, such as `test_widget.py`:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it tests without a good reason.
- Test code should be modified much less frequently than the code it tests.

- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules anyway, so why not be consistent?
- If the testing strategy changes, there is no need to change the source code.

### 26.4.5 Re-using old test code

Some users will find that they have existing test code that they would like to run from `unittest`, without converting every old test function to a `TestCase` subclass.

For this reason, `unittest` provides a `FunctionTestCase` class. This subclass of `TestCase` can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```
def testSomething():
    something = makeSomething()
    assert something.name is not None
    # ...
```

one can create an equivalent test case instance as follows, with optional set-up and tear-down methods:

```
testcase = unittest.FunctionTestCase(testSomething,
                                     setUp=makeSomethingDB,
                                     tearDown=deleteSomethingDB)
```

---

**Catatan:** Even though `FunctionTestCase` can be used to quickly convert an existing test base over to a `unittest`-based system, this approach is not recommended. Taking the time to set up proper `TestCase` subclasses will make future test refactorings infinitely easier.

---

In some cases, the existing tests may have been written using the `doctest` module. If so, `doctest` provides a `DocTestSuite` class that can automatically build `unittest.TestSuite` instances from the existing `doctest`-based tests.

### 26.4.6 Skipping tests and expected failures

Baru pada versi 3.1.

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as an "expected failure," a test that is broken and will fail, but shouldn't be counted as a failure on a `TestResult`.

Skipping a test is simply a matter of using the `skip() decorator` or one of its conditional variants, calling `TestCase.skipTest()` within a `setUp()` or test method, or raising `SkipTest` directly.

Basic skipping looks like this:

```
class MyTestCase(unittest.TestCase):

    @unittest.skip("demonstrating skipping")
    def test_nothing(self):
        self.fail("shouldn't happen")

    @unittest.skipIf(mylib.__version__ < (1, 3),
                    "not supported in this library version")
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
def test_format(self):
    # Tests that work for only a certain version of the library.
    pass

@unittest.skipUnless(sys.platform.startswith("win"), "requires Windows")
def test_windows_support(self):
    # windows specific testing code
    pass

def test_maybe_skipped(self):
    if not external_resource_available():
        self.skipTest("external resource not available")
    # test code that depends on the external resource
    pass
```

This is the output of running the example above in verbose mode:

```
test_format (__main__.MyTestCase) ... skipped 'not supported in this library version'
test_nothing (__main__.MyTestCase) ... skipped 'demonstrating skipping'
test_maybe_skipped (__main__.MyTestCase) ... skipped 'external resource not available'
test_windows_support (__main__.MyTestCase) ... skipped 'requires Windows'

-----
Ran 4 tests in 0.005s

OK (skipped=4)
```

Classes can be skipped just like methods:

```
@unittest.skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass
```

`TestCase.setUp()` can also skip the test. This is useful when a resource that needs to be set up is not available.

Expected failures use the `expectedFailure()` decorator.

```
class ExpectedFailureTestCase(unittest.TestCase):
    @unittest.expectedFailure
    def test_fail(self):
        self.assertEqual(1, 0, "broken")
```

It's easy to roll your own skipping decorators by making a decorator that calls `skip()` on the test when it wants it to be skipped. This decorator skips the test unless the passed object has a certain attribute:

```
def skipUnlessHasattr(obj, attr):
    if hasattr(obj, attr):
        return lambda func: func
    return unittest.skip("{!r} doesn't have {!r}".format(obj, attr))
```

The following decorators and exception implement test skipping and expected failures:

`@unittest.skip(reason)`

Unconditionally skip the decorated test. *reason* should describe why the test is being skipped.

`@unittest.skipIf(condition, reason)`

Skip the decorated test if *condition* is true.

`@unittest.skipUnless` (*condition*, *reason*)

Skip the decorated test unless *condition* is true.

`@unittest.expectedFailure`

Mark the test as an expected failure or error. If the test fails or errors it will be considered a success. If the test passes, it will be considered a failure.

**exception** `unittest.SkipTest` (*reason*)

This exception is raised to skip a test.

Usually you can use `TestCase.skipTest()` or one of the skipping decorators instead of raising this directly.

Skipped tests will not have `setUp()` or `tearDown()` run around them. Skipped classes will not have `setUpClass()` or `tearDownClass()` run. Skipped modules will not have `setUpModule()` or `tearDownModule()` run.

## 26.4.7 Distinguishing test iterations using subtests

Baru pada versi 3.4.

When there are very small differences among your tests, for instance some parameters, unittest allows you to distinguish them inside the body of a test method using the `subTest()` context manager.

For example, the following test:

```
class NumbersTest(unittest.TestCase):

    def test_even(self):
        """
        Test that numbers between 0 and 5 are all even.
        """
        for i in range(0, 6):
            with self.subTest(i=i):
                self.assertEqual(i % 2, 0)
```

will produce the following output:

```
=====
FAIL: test_even (__main__.NumbersTest) (i=1)
-----
Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0

=====
FAIL: test_even (__main__.NumbersTest) (i=3)
-----
Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0

=====
FAIL: test_even (__main__.NumbersTest) (i=5)
-----
Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
self.assertEqual(i % 2, 0)
AssertionError: 1 != 0
```

Without using a subtest, execution would stop after the first failure, and the error would be less easy to diagnose because the value of `i` wouldn't be displayed:

```
=====
FAIL: test_even (__main__.NumbersTest)
-----
Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0
```

## 26.4.8 Classes and functions

This section describes in depth the API of `unittest`.

### Kasus pengujian

**class** `unittest.TestCase` (*methodName='runTest'*)

Instances of the `TestCase` class represent the logical test units in the `unittest` universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the tests, and methods that the test code can use to check for and report various kinds of failure.

Each instance of `TestCase` will run a single base method: the method named *methodName*. In most uses of `TestCase`, you will neither change the *methodName* nor reimplement the default `runTest()` method.

Berubah pada versi 3.2: `TestCase` can be instantiated successfully without providing a *methodName*. This makes it easier to experiment with `TestCase` from the interactive interpreter.

`TestCase` instances provide three groups of methods: one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.

Methods in the first group (running the test) are:

**setUp()**

Method called to prepare the test fixture. This is called immediately before calling the test method; other than `AssertionError` or `SkipTest`, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

**tearDown()**

Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than `AssertionError` or `SkipTest`, raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the `setUp()` succeeds, regardless of the outcome of the test method. The default implementation does nothing.

**setUpClass()**

A class method called before tests in an individual class are run. `setUpClass` is called with the class as the only argument and must be decorated as a `classmethod()`:

```
@classmethod
def setUpClass(cls):
    ...
```

See *Class and Module Fixtures* for more details.

Baru pada versi 3.2.

#### **tearDownClass()**

A class method called after tests in an individual class have run. `tearDownClass` is called with the class as the only argument and must be decorated as a `classmethod()`:

```
@classmethod
def tearDownClass(cls):
    ...
```

See *Class and Module Fixtures* for more details.

Baru pada versi 3.2.

#### **run(result=None)**

Run the test, collecting the result into the `TestResult` object passed as *result*. If *result* is omitted or `None`, a temporary result object is created (by calling the `defaultTestResult()` method) and used. The result object is returned to `run()`'s caller.

The same effect may be had by simply calling the `TestCase` instance.

Berubah pada versi 3.3: Previous versions of `run` did not return the result. Neither did calling an instance.

#### **skipTest(reason)**

Calling this during a test method or `setUp()` skips the current test. See *Skipping tests and expected failures* for more information.

Baru pada versi 3.1.

#### **subTest(msg=None, \*\*params)**

Return a context manager which executes the enclosed code block as a subtest. *msg* and *params* are optional, arbitrary values which are displayed whenever a subtest fails, allowing you to identify them clearly.

A test case can contain any number of subtest declarations, and they can be arbitrarily nested.

See *Distinguishing test iterations using subtests* for more information.

Baru pada versi 3.4.

#### **debug()**

Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the caller, and can be used to support running tests under a debugger.

The `TestCase` class provides several assert methods to check for and report failures. The following table lists the most commonly used methods (see the tables below for more assert methods):

| Metode                                 | Checks that                       | Baru di |
|----------------------------------------|-----------------------------------|---------|
| <code>assertEqual(a, b)</code>         | <code>a == b</code>               |         |
| <code>assertNotEqual(a, b)</code>      | <code>a != b</code>               |         |
| <code>assertTrue(x)</code>             | <code>bool(x) is True</code>      |         |
| <code>assertFalse(x)</code>            | <code>bool(x) is False</code>     |         |
| <code>assertIs(a, b)</code>            | <code>a is b</code>               | 3.1     |
| <code>assertIsNot(a, b)</code>         | <code>a is not b</code>           | 3.1     |
| <code>assertIsNone(x)</code>           | <code>x is None</code>            | 3.1     |
| <code>assertIsNotNone(x)</code>        | <code>x is not None</code>        | 3.1     |
| <code>assertIn(a, b)</code>            | <code>a in b</code>               | 3.1     |
| <code>assertNotIn(a, b)</code>         | <code>a not in b</code>           | 3.1     |
| <code>assertIsInstance(a, b)</code>    | <code>isinstance(a, b)</code>     | 3.2     |
| <code>assertNotIsInstance(a, b)</code> | <code>not isinstance(a, b)</code> | 3.2     |

All the assert methods accept a *msg* argument that, if specified, is used as the error message on failure (see also *longMessage*). Note that the *msg* keyword argument can be passed to `assertRaises()`, `assertRaisesRegex()`, `assertWarns()`, `assertWarnsRegex()` only when they are used as a context manager.

**assertEqual** (*first, second, msg=None*)

Test that *first* and *second* are equal. If the values do not compare equal, the test will fail.

In addition, if *first* and *second* are the exact same type and one of list, tuple, dict, set, frozenset or str or any type that a subclass registers with `addTypeEqualityFunc()` the type-specific equality function will be called in order to generate a more useful default error message (see also the *list of type-specific methods*).

Berubah pada versi 3.1: Added the automatic calling of type-specific equality function.

Berubah pada versi 3.2: `assertMultiLineEqual()` added as the default type equality function for comparing strings.

**assertNotEqual** (*first, second, msg=None*)

Test that *first* and *second* are not equal. If the values do compare equal, the test will fail.

**assertTrue** (*expr, msg=None*)

**assertFalse** (*expr, msg=None*)

Test that *expr* is true (or false).

Note that this is equivalent to `bool(expr) is True` and not to `expr is True` (use `assertIs(expr, True)` for the latter). This method should also be avoided when more specific methods are available (e.g. `assertEqual(a, b)` instead of `assertTrue(a == b)`), because they provide a better error message in case of failure.

**assertIs** (*first, second, msg=None*)

**assertIsNot** (*first, second, msg=None*)

Test that *first* and *second* are (or are not) the same object.

Baru pada versi 3.1.

**assertIsNone** (*expr, msg=None*)

**assertIsNotNone** (*expr, msg=None*)

Test that *expr* is (or is not) None.

Baru pada versi 3.1.

**assertIn** (*member, container, msg=None*)

**assertNotIn** (*member, container, msg=None*)

Test that *member* is (or is not) in *container*.

Baru pada versi 3.1.

**assertIsInstance** (*obj, cls, msg=None*)

**assertNotIsInstance** (*obj, cls, msg=None*)

Test that *obj* is (or is not) an instance of *cls* (which can be a class or a tuple of classes, as supported by *isinstance()*). To check for the exact type, use *assertIs(type(obj), cls)*.

Baru pada versi 3.2.

It is also possible to check the production of exceptions, warnings, and log messages using the following methods:

| Metode                                                 | Checks that                                                                           | Baru di |
|--------------------------------------------------------|---------------------------------------------------------------------------------------|---------|
| <i>assertRaises(exc, fun, *args, **kwargs)</i>         | <i>fun(*args, **kwargs)</i> raises <i>exc</i>                                         |         |
| <i>assertRaisesRegex(exc, r, fun, *args, **kwargs)</i> | <i>fun(*args, **kwargs)</i> raises <i>exc</i> and the message matches regex <i>r</i>  | 3.1     |
| <i>assertWarns(warn, fun, *args, **kwargs)</i>         | <i>fun(*args, **kwargs)</i> raises <i>warn</i>                                        | 3.2     |
| <i>assertWarnsRegex(warn, r, fun, *args, **kwargs)</i> | <i>fun(*args, **kwargs)</i> raises <i>warn</i> and the message matches regex <i>r</i> | 3.2     |
| <i>assertLogs(logger, level)</i>                       | The <i>with</i> block logs on <i>logger</i> with minimum <i>level</i>                 | 3.4     |

**assertRaises** (*exception, callable, \*args, \*\*kwargs*)

**assertRaises** (*exception, \*, msg=None*)

Test that an exception is raised when *callable* is called with any positional or keyword arguments that are also passed to *assertRaises()*. The test passes if *exception* is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as *exception*.

If only the *exception* and possibly the *msg* arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```
with self.assertRaises(SomeException):
    do_something()
```

When used as a context manager, *assertRaises()* accepts the additional keyword argument *msg*.

The context manager will store the caught exception object in its *exception* attribute. This can be useful if the intention is to perform additional checks on the exception raised:

```
with self.assertRaises(SomeException) as cm:
    do_something()

the_exception = cm.exception
self.assertEqual(the_exception.error_code, 3)
```

Berubah pada versi 3.1: Added the ability to use *assertRaises()* as a context manager.

Berubah pada versi 3.2: Added the *exception* attribute.

Berubah pada versi 3.3: Added the *msg* keyword argument when used as a context manager.

**assertRaisesRegex** (*exception, regex, callable, \*args, \*\*kwargs*)

**assertRaisesRegex** (*exception, regex, \*, msg=None*)

Like *assertRaises()* but also tests that *regex* matches on the string representation of the raised exception. *regex* may be a regular expression object or a string containing a regular expression suitable for use by *re.search()*. Examples:

```
self.assertRaisesRegex(ValueError, "invalid literal for.*XYZ'",
                        int, 'XYZ')
```

atau:

```
with self.assertRaisesRegex(ValueError, 'literal'):
    int('XYZ')
```

Baru pada versi 3.1: Added under the name `assertRaisesRegexp`.

Berubah pada versi 3.2: Renamed to `assertRaisesRegex()`.

Berubah pada versi 3.3: Added the `msg` keyword argument when used as a context manager.

**assertWarns** (*warning*, *callable*, \**args*, \*\**kwargs*)

**assertWarns** (*warning*, \*, *msg*=None)

Test that a warning is triggered when *callable* is called with any positional or keyword arguments that are also passed to `assertWarns()`. The test passes if *warning* is triggered and fails if it isn't. Any exception is an error. To catch any of a group of warnings, a tuple containing the warning classes may be passed as *warnings*.

If only the *warning* and possibly the *msg* arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```
with self.assertWarns(SomeWarning):
    do_something()
```

When used as a context manager, `assertWarns()` accepts the additional keyword argument *msg*.

The context manager will store the caught warning object in its *warning* attribute, and the source line which triggered the warnings in the *filename* and *lineno* attributes. This can be useful if the intention is to perform additional checks on the warning caught:

```
with self.assertWarns(SomeWarning) as cm:
    do_something()

self.assertIn('myfile.py', cm.filename)
self.assertEqual(320, cm.lineno)
```

This method works regardless of the warning filters in place when it is called.

Baru pada versi 3.2.

Berubah pada versi 3.3: Added the *msg* keyword argument when used as a context manager.

**assertWarnsRegex** (*warning*, *regex*, *callable*, \**args*, \*\**kwargs*)

**assertWarnsRegex** (*warning*, *regex*, \*, *msg*=None)

Like `assertWarns()` but also tests that *regex* matches on the message of the triggered warning. *regex* may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`. Example:

```
self.assertWarnsRegex(DeprecationWarning,
                      r'legacy_function\(\) is deprecated',
                      legacy_function, 'XYZ')
```

atau:

```
with self.assertWarnsRegex(RuntimeWarning, 'unsafe frobnicating'):
    frobnicate('/etc/passwd')
```

Baru pada versi 3.2.

Berubah pada versi 3.3: Added the *msg* keyword argument when used as a context manager.

**assertLogs** (*logger=None, level=None*)

A context manager to test that at least one message is logged on the *logger* or one of its children, with at least the given *level*.

If given, *logger* should be a *logging.Logger* object or a *str* giving the name of a logger. The default is the root logger, which will catch all messages that were not blocked by a non-propagating descendent logger.

If given, *level* should be either a numeric logging level or its string equivalent (for example either "ERROR" or *logging.ERROR*). The default is *logging.INFO*.

The test passes if at least one message emitted inside the *with* block matches the *logger* and *level* conditions, otherwise it fails.

The object returned by the context manager is a recording helper which keeps tracks of the matching log messages. It has two attributes:

**records**

A list of *logging.LogRecord* objects of the matching log messages.

**output**

A list of *str* objects with the formatted output of matching messages.

Contoh:

```
with self.assertLogs('foo', level='INFO') as cm:
    logging.getLogger('foo').info('first message')
    logging.getLogger('foo.bar').error('second message')
self.assertEqual(cm.output, ['INFO:foo:first message',
                             'ERROR:foo.bar:second message'])
```

Baru pada versi 3.4.

There are also other methods used to perform more specific checks, such as:

| Metode                                  | Checks that                                                                                 | Baru di |
|-----------------------------------------|---------------------------------------------------------------------------------------------|---------|
| <code>assertAlmostEqual(a, b)</code>    | <code>round(a-b, 7) == 0</code>                                                             |         |
| <code>assertNotAlmostEqual(a, b)</code> | <code>round(a-b, 7) != 0</code>                                                             |         |
| <code>assertGreater(a, b)</code>        | <code>a &gt; b</code>                                                                       | 3.1     |
| <code>assertGreaterEqual(a, b)</code>   | <code>a &gt;= b</code>                                                                      | 3.1     |
| <code>assertLess(a, b)</code>           | <code>a &lt; b</code>                                                                       | 3.1     |
| <code>assertLessEqual(a, b)</code>      | <code>a &lt;= b</code>                                                                      | 3.1     |
| <code>assertRegex(s, r)</code>          | <code>r.search(s)</code>                                                                    | 3.1     |
| <code>assertNotRegex(s, r)</code>       | <code>not r.search(s)</code>                                                                | 3.2     |
| <code>assertCountEqual(a, b)</code>     | <i>a</i> and <i>b</i> have the same elements in the same number, regardless of their order. | 3.2     |

**assertAlmostEqual** (*first, second, places=7, msg=None, delta=None*)

**assertNotAlmostEqual** (*first, second, places=7, msg=None, delta=None*)

Test that *first* and *second* are approximately (or not approximately) equal by computing the difference, rounding to the given number of decimal *places* (default 7), and comparing to zero. Note that these methods

round the values to the given number of *decimal places* (i.e. like the `round()` function) and not *significant digits*.

If *delta* is supplied instead of *places* then the difference between *first* and *second* must be less or equal to (or greater than) *delta*.

Supplying both *delta* and *places* raises a `TypeError`.

Berubah pada versi 3.2: `assertAlmostEqual()` automatically considers almost equal objects that compare equal. `assertNotAlmostEqual()` automatically fails if the objects compare equal. Added the *delta* keyword argument.

**assertGreater** (*first, second, msg=None*)

**assertGreaterEqual** (*first, second, msg=None*)

**assertLess** (*first, second, msg=None*)

**assertLessEqual** (*first, second, msg=None*)

Test that *first* is respectively `>`, `>=`, `<` or `<=` than *second* depending on the method name. If not, the test will fail:

```
>>> self.assertGreaterEqual(3, 4)
AssertionError: "3" unexpectedly not greater than or equal to "4"
```

Baru pada versi 3.1.

**assertRegex** (*text, regex, msg=None*)

**assertNotRegex** (*text, regex, msg=None*)

Test that a *regex* search matches (or does not match) *text*. In case of failure, the error message will include the pattern and the *text* (or the pattern and the part of *text* that unexpectedly matched). *regex* may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`.

Baru pada versi 3.1: Added under the name `assertRegexpMatches`.

Berubah pada versi 3.2: The method `assertRegexpMatches()` has been renamed to `assertRegex()`.

Baru pada versi 3.2: `assertNotRegex()`.

Baru pada versi 3.5: The name `assertNotRegexpMatches` is a deprecated alias for `assertNotRegex()`.

**assertCountEqual** (*first, second, msg=None*)

Test that sequence *first* contains the same elements as *second*, regardless of their order. When they don't, an error message listing the differences between the sequences will be generated.

Duplicate elements are *not* ignored when comparing *first* and *second*. It verifies whether each element has the same count in both sequences. Equivalent to: `assertEqual(Counter(list(first)), Counter(list(second)))` but works with sequences of unhashable objects as well.

Baru pada versi 3.2.

The `assertEqual()` method dispatches the equality check for objects of the same type to different type-specific methods. These methods are already implemented for most of the built-in types, but it's also possible to register new methods using `addTypeEqualityFunc()`:

**addTypeEqualityFunc** (*typeobj, function*)

Registers a type-specific method called by `assertEqual()` to check if two objects of exactly the same *typeobj* (not subclasses) compare equal. *function* must take two positional arguments and a third `msg=None` keyword argument just as `assertEqual()` does. It must raise `self.failureException(msg)` when inequality between the first two parameters is detected -- possibly providing useful information and explaining the inequalities in details in the error message.

Baru pada versi 3.1.

The list of type-specific methods automatically used by `assertEqual()` are summarized in the following table. Note that it's usually not necessary to invoke these methods directly.

| Metode                                  | Used to compare    | Baru di |
|-----------------------------------------|--------------------|---------|
| <code>assertMultiLineEqual(a, b)</code> | strings            | 3.1     |
| <code>assertSequenceEqual(a, b)</code>  | sequences          | 3.1     |
| <code>assertListEqual(a, b)</code>      | lists              | 3.1     |
| <code>assertTupleEqual(a, b)</code>     | tuples             | 3.1     |
| <code>assertSetEqual(a, b)</code>       | sets or frozensets | 3.1     |
| <code>assertDictEqual(a, b)</code>      | dicts              | 3.1     |

**`assertMultiLineEqual`** (*first, second, msg=None*)

Test that the multiline string *first* is equal to the string *second*. When not equal a diff of the two strings highlighting the differences will be included in the error message. This method is used by default when comparing strings with `assertEqual()`.

Baru pada versi 3.1.

**`assertSequenceEqual`** (*first, second, msg=None, seq\_type=None*)

Tests that two sequences are equal. If a *seq\_type* is supplied, both *first* and *second* must be instances of *seq\_type* or a failure will be raised. If the sequences are different an error message is constructed that shows the difference between the two.

This method is not called directly by `assertEqual()`, but it's used to implement `assertListEqual()` and `assertTupleEqual()`.

Baru pada versi 3.1.

**`assertListEqual`** (*first, second, msg=None*)

**`assertTupleEqual`** (*first, second, msg=None*)

Tests that two lists or tuples are equal. If not, an error message is constructed that shows only the differences between the two. An error is also raised if either of the parameters are of the wrong type. These methods are used by default when comparing lists or tuples with `assertEqual()`.

Baru pada versi 3.1.

**`assertSetEqual`** (*first, second, msg=None*)

Tests that two sets are equal. If not, an error message is constructed that lists the differences between the sets. This method is used by default when comparing sets or frozensets with `assertEqual()`.

Fails if either of *first* or *second* does not have a `set.difference()` method.

Baru pada versi 3.1.

**`assertDictEqual`** (*first, second, msg=None*)

Test that two dictionaries are equal. If not, an error message is constructed that shows the differences in the dictionaries. This method will be used by default to compare dictionaries in calls to `assertEqual()`.

Baru pada versi 3.1.

Finally the `TestCase` provides the following methods and attributes:

**`fail`** (*msg=None*)

Signals a test failure unconditionally, with *msg* or `None` for the error message.

**`failureException`**

This class attribute gives the exception raised by the test method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to "play fair" with the framework. The initial value of this attribute is `AssertionError`.

**longMessage**

This class attribute determines what happens when a custom failure message is passed as the `msg` argument to an `assertXXX` call that fails. `True` is the default value. In this case, the custom message is appended to the end of the standard failure message. When set to `False`, the custom message replaces the standard message.

The class setting can be overridden in individual test methods by assigning an instance attribute, `self.longMessage`, to `True` or `False` before calling the assert methods.

The class setting gets reset before each test call.

Baru pada versi 3.1.

**maxDiff**

This attribute controls the maximum length of diffs output by assert methods that report diffs on failure. It defaults to 80\*8 characters. Assert methods affected by this attribute are `assertSequenceEqual()` (including all the sequence comparison methods that delegate to it), `assertDictEqual()` and `assertMultiLineEqual()`.

Setting `maxDiff` to `None` means that there is no maximum length of diffs.

Baru pada versi 3.2.

Testing frameworks can use the following methods to collect information on the test:

**countTestCases()**

Return the number of tests represented by this test object. For `TestCase` instances, this will always be 1.

**defaultTestResult()**

Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the `run()` method).

For `TestCase` instances, this will always be an instance of `TestResult`; subclasses of `TestCase` should override this as necessary.

**id()**

Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.

**shortDescription()**

Returns a description of the test, or `None` if no description has been provided. The default implementation of this method returns the first line of the test method's docstring, if available, or `None`.

Berubah pada versi 3.1: In 3.1 this was changed to add the test name to the short description even in the presence of a docstring. This caused compatibility issues with unittest extensions and adding the test name was moved to the `TextTestResult` in Python 3.2.

**addCleanup(function, \*args, \*\*kwargs)**

Add a function to be called after `tearDown()` to cleanup resources used during the test. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into `addCleanup()` when they are added.

If `setUp()` fails, meaning that `tearDown()` is not called, then any cleanup functions added will still be called.

Baru pada versi 3.1.

**doCleanups()**

This method is called unconditionally after `tearDown()`, or after `setUp()` if `setUp()` raises an exception.

It is responsible for calling all the cleanup functions added by `addCleanup()`. If you need cleanup functions to be called *prior* to `tearDown()` then you can call `doCleanups()` yourself.

`doCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

Baru pada versi 3.1.

**classmethod** `addClassCleanup` (*function*, /, \**args*, \*\**kwargs*)

Add a function to be called after `tearDownClass()` to cleanup resources used during the test class. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into `addClassCleanup()` when they are added.

If `setUpClass()` fails, meaning that `tearDownClass()` is not called, then any cleanup functions added will still be called.

Baru pada versi 3.8.

**classmethod** `doClassCleanups()`

This method is called unconditionally after `tearDownClass()`, or after `setUpClass()` if `setUpClass()` raises an exception.

It is responsible for calling all the cleanup functions added by `addClassCleanup()`. If you need cleanup functions to be called *prior* to `tearDownClass()` then you can call `doClassCleanups()` yourself.

`doClassCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

Baru pada versi 3.8.

**class** `unittest.IsolatedAsyncioTestCase` (*methodName*=`'runTest'`)

This class provides an API similar to `TestCase` and also accepts coroutines as test functions.

Baru pada versi 3.8.

**coroutine** `asyncSetUp()`

Method called to prepare the test fixture. This is called after `setUp()`. This is called immediately before calling the test method; other than `AssertionError` or `SkipTest`, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

**coroutine** `asyncTearDown()`

Method called immediately after the test method has been called and the result recorded. This is called before `tearDown()`. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than `AssertionError` or `SkipTest`, raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the `asyncSetUp()` succeeds, regardless of the outcome of the test method. The default implementation does nothing.

**addAsyncCleanup** (*function*, /, \**args*, \*\**kwargs*)

This method accepts a coroutine that can be used as a cleanup function.

**run** (*result*=None)

Sets up a new event loop to run the test, collecting the result into the `TestResult` object passed as *result*. If *result* is omitted or None, a temporary result object is created (by calling the `defaultTestResult()` method) and used. The result object is returned to `run()`'s caller. At the end of the test all the tasks in the event loop are cancelled.

An example illustrating the order:

```
from unittest import IsolatedAsyncioTestCase

events = []
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
class Test(IsolatedAsyncioTestCase):

    def setUp(self):
        events.append("setUp")

    async def asyncSetUp(self):
        self._async_connection = await AsyncConnection()
        events.append("asyncSetUp")

    async def test_response(self):
        events.append("test_response")
        response = await self._async_connection.get("https://example.com")
        self.assertEqual(response.status_code, 200)
        self.addAsyncCleanup(self.on_cleanup)

    def tearDown(self):
        events.append("tearDown")

    async def asyncTearDown(self):
        await self._async_connection.close()
        events.append("asyncTearDown")

    async def on_cleanup(self):
        events.append("cleanup")

if __name__ == "__main__":
    unittest.main()
```

After running the test, events would contain ["setUp", "asyncSetUp", "test\_response", "asyncTearDown", "tearDown", "cleanup"].

**class** `unittest.FunctionTestCase` (*testFunc*, *setUp=None*, *tearDown=None*, *description=None*)  
This class implements the portion of the *TestCase* interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to be integrated into a *unittest*-based test framework.

Deprecated aliases

For historical reasons, some of the *TestCase* methods had one or more aliases that are now deprecated. The following table lists the correct names along with their deprecated aliases:

| Nama Metode                         | Deprecated alias                   | Deprecated alias                    |
|-------------------------------------|------------------------------------|-------------------------------------|
| <code>assertEqual()</code>          | <code>failUnlessEqual</code>       | <code>assertEquals</code>           |
| <code>assertNotEqual()</code>       | <code>failIfEqual</code>           | <code>assertNotEquals</code>        |
| <code>assertTrue()</code>           | <code>failUnless</code>            | <code>assert_</code>                |
| <code>assertFalse()</code>          | <code>failIf</code>                |                                     |
| <code>assertRaises()</code>         | <code>failUnlessRaises</code>      |                                     |
| <code>assertAlmostEqual()</code>    | <code>failUnlessAlmostEqual</code> | <code>assertAlmostEquals</code>     |
| <code>assertNotAlmostEqual()</code> | <code>failIfAlmostEqual</code>     | <code>assertNotAlmostEquals</code>  |
| <code>assertRegex()</code>          |                                    | <code>assertRegexpMatches</code>    |
| <code>assertNotRegex()</code>       |                                    | <code>assertNotRegexpMatches</code> |
| <code>assertRaisesRegex()</code>    |                                    | <code>assertRaisesRegexp</code>     |

Ditinggalkan sejak versi 3.1: The fail\* aliases listed in the second column have been deprecated.

Ditinggalkan sejak versi 3.2: The assert\* aliases listed in the third column have been deprecated.

Ditinggalkan sejak versi 3.2: `assertRegexpMatches` and `assertRaisesRegexp` have been renamed to `assertRegex()` and `assertRaisesRegex()`.

Ditinggalkan sejak versi 3.5: The `assertNotRegexpMatches` name is deprecated in favor of `assertNotRegex()`.

## Grouping tests

**class** `unittest.TestSuite` (*tests=()*)

This class represents an aggregation of individual test cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a `TestSuite` instance is the same as iterating over the suite, running each test individually.

If *tests* is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

`TestSuite` objects behave much like `TestCase` objects, except they do not actually implement a test. Instead, they are used to aggregate tests into groups of tests that should be run together. Some additional methods are available to add tests to `TestSuite` instances:

**addTest** (*test*)

Add a `TestCase` or `TestSuite` to the suite.

**addTests** (*tests*)

Add all the tests from an iterable of `TestCase` and `TestSuite` instances to this test suite.

This is equivalent to iterating over *tests*, calling `addTest()` for each element.

`TestSuite` shares the following methods with `TestCase`:

**run** (*result*)

Run the tests associated with this suite, collecting the result into the test result object passed as *result*. Note that unlike `TestCase.run()`, `TestSuite.run()` requires the result object to be passed in.

**debug** ()

Run the tests associated with this suite without collecting the result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

**countTestCases** ()

Return the number of tests represented by this test object, including all individual tests and sub-suites.

**\_\_iter\_\_** ()

Tests grouped by a `TestSuite` are always accessed by iteration. Subclasses can lazily provide tests by overriding `__iter__()`. Note that this method may be called several times on a single suite (for example when counting tests or comparing for equality) so the tests returned by repeated iterations before `TestSuite.run()` must be the same for each call iteration. After `TestSuite.run()`, callers should not rely on the tests returned by this method unless the caller uses a subclass that overrides `TestSuite._removeTestAtIndex()` to preserve test references.

Berubah pada versi 3.2: In earlier versions the `TestSuite` accessed tests directly rather than through iteration, so overriding `__iter__()` wasn't sufficient for providing tests.

Berubah pada versi 3.4: In earlier versions the `TestSuite` held references to each `TestCase` after `TestSuite.run()`. Subclasses can restore that behavior by overriding `TestSuite._removeTestAtIndex()`.

In the typical usage of a `TestSuite` object, the `run()` method is invoked by a `TestRunner` rather than by the end-user test harness.

## Loading and running tests

### `class unittest.TestLoader`

The `TestLoader` class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the `unittest` module provides an instance that can be shared as `unittest.defaultTestLoader`. Using a subclass or instance, however, allows customization of some configurable properties.

`TestLoader` objects have the following attributes:

#### **errors**

A list of the non-fatal errors encountered while loading tests. Not reset by the loader at any point. Fatal errors are signalled by the relevant a method raising an exception to the caller. Non-fatal errors are also indicated by a synthetic test that will raise the original error when run.

Baru pada versi 3.5.

`TestLoader` objects have the following methods:

#### **loadTestsFromTestCase** (*testCaseClass*)

Return a suite of all test cases contained in the `TestCase`-derived `testCaseClass`.

A test case instance is created for each method named by `getTestCaseNames()`. By default these are the method names beginning with `test`. If `getTestCaseNames()` returns no methods, but the `runTest()` method is implemented, a single test case is created for that method instead.

#### **loadTestsFromModule** (*module*, *pattern=None*)

Return a suite of all test cases contained in the given module. This method searches *module* for classes derived from `TestCase` and creates an instance of the class for each test method defined for the class.

---

**Catatan:** While using a hierarchy of `TestCase`-derived classes can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures are different and defined in subclasses.

---

If a module provides a `load_tests` function it will be called to load the tests. This allows modules to customize test loading. This is the *load\_tests protocol*. The *pattern* argument is passed as the third argument to `load_tests`.

Berubah pada versi 3.2: Support for `load_tests` added.

Berubah pada versi 3.5: The undocumented and unofficial *use\_load\_tests* default argument is deprecated and ignored, although it is still accepted for backward compatibility. The method also now accepts a keyword-only argument *pattern* which is passed to `load_tests` as the third argument.

#### **loadTestsFromName** (*name*, *module=None*)

Return a suite of all test cases given a string specifier.

The specifier *name* is a "dotted name" that may resolve either to a module, a test case class, a test method within a test case class, a `TestSuite` instance, or a callable object which returns a `TestCase` or `TestSuite` instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as "a test method within a test case class", rather than "a callable object".

For example, if you have a module `SampleTests` containing a `TestCase`-derived class `SampleTestCase` with three test methods (`test_one()`, `test_two()`, and `test_three()`), the

specifier `'SampleTests.SampleTestCase'` would cause this method to return a suite which will run all three test methods. Using the specifier `'SampleTests.SampleTestCase.test_two'` would cause it to return a test suite which will run only the `test_two()` test method. The specifier can refer to modules and packages which have not been imported; they will be imported as a side-effect.

The method optionally resolves *name* relative to the given *module*.

Berubah pada versi 3.5: If an `ImportError` or `AttributeError` occurs while traversing *name* then a synthetic test that raises that error when run will be returned. These errors are included in the errors accumulated by `self.errors`.

**loadTestsFromNames** (*names*, *module=None*)

Similar to `loadTestsFromName()`, but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

**getTestCaseNames** (*testCaseClass*)

Return a sorted sequence of method names found within *testCaseClass*; this should be a subclass of `TestCase`.

**discover** (*start\_dir*, *pattern='test\*.py'*, *top\_level\_dir=None*)

Find all the test modules by recursing into subdirectories from the specified start directory, and return a `TestSuite` object containing them. Only test files that match *pattern* will be loaded. (Using shell style pattern matching.) Only module names that are importable (i.e. are valid Python identifiers) will be loaded.

All test modules must be importable from the top level of the project. If the start directory is not the top level directory then the top level directory must be specified separately.

If importing a module fails, for example due to a syntax error, then this will be recorded as a single error and discovery will continue. If the import failure is due to `SkipTest` being raised, it will be recorded as a skip instead of an error.

If a package (a directory containing a file named `__init__.py`) is found, the package will be checked for a `load_tests` function. If this exists then it will be called `package.load_tests(loader, tests, pattern)`. Test discovery takes care to ensure that a package is only checked for tests once during an invocation, even if the `load_tests` function itself calls `loader.discover`.

If `load_tests` exists then discovery does *not* recurse into the package, `load_tests` is responsible for loading all tests in the package.

The pattern is deliberately not stored as a loader attribute so that packages can continue discovery themselves. *top\_level\_dir* is stored so `load_tests` does not need to pass this argument in to `loader.discover()`.

*start\_dir* can be a dotted module name as well as a directory.

Baru pada versi 3.2.

Berubah pada versi 3.4: Modules that raise `SkipTest` on import are recorded as skips, not errors.

Berubah pada versi 3.4: *start\_dir* can be a *namespace packages*.

Berubah pada versi 3.4: Paths are sorted before being imported so that execution order is the same even if the underlying file system's ordering is not dependent on file name.

Berubah pada versi 3.5: Found packages are now checked for `load_tests` regardless of whether their path matches *pattern*, because it is impossible for a package name to match the default pattern.

The following attributes of a `TestLoader` can be configured either by subclassing or assignment on an instance:

**testMethodPrefix**

String giving the prefix of method names which will be interpreted as test methods. The default value is `'test'`.

This affects `getTestCaseNames()` and all the `loadTestsFrom*` methods.

#### **sortTestMethodsUsing**

Function to be used to compare method names when sorting them in `getTestCaseNames()` and all the `loadTestsFrom*` methods.

#### **suiteClass**

Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the `TestSuite` class.

This affects all the `loadTestsFrom*` methods.

#### **testNamePatterns**

List of Unix shell-style wildcard test name patterns that test methods have to match to be included in test suites (see `-v` option).

If this attribute is not `None` (the default), all test methods to be included in test suites must match one of the patterns in this list. Note that matches are always performed using `fnmatch.fnmatchcase()`, so unlike patterns passed to the `-v` option, simple substring patterns will have to be converted using `*` wildcards.

This affects all the `loadTestsFrom*` methods.

Baru pada versi 3.7.

### **class unittest.TestResult**

This class is used to compile information about which tests have succeeded and which have failed.

A `TestResult` object stores the results of a set of tests. The `TestCase` and `TestSuite` classes ensure that results are properly recorded; test authors do not need to worry about recording the outcome of tests.

Testing frameworks built on top of `unittest` may want access to the `TestResult` object generated by running a set of tests for reporting purposes; a `TestResult` instance is returned by the `TestRunner.run()` method for this purpose.

`TestResult` instances have the following attributes that will be of interest when inspecting the results of running a set of tests:

#### **errors**

A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

#### **failures**

A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the `TestCase.assert*` methods.

#### **skipped**

A list containing 2-tuples of `TestCase` instances and strings holding the reason for skipping the test.

Baru pada versi 3.1.

#### **expectedFailures**

A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents an expected failure or error of the test case.

#### **unexpectedSuccesses**

A list containing `TestCase` instances that were marked as expected failures, but succeeded.

#### **shouldStop**

Set to `True` when the execution of tests should stop by `stop()`.

#### **testsRun**

The total number of tests run so far.

**buffer**

If set to true, `sys.stdout` and `sys.stderr` will be buffered in between `startTest()` and `stopTest()` being called. Collected output will only be echoed onto the real `sys.stdout` and `sys.stderr` if the test fails or errors. Any output is also attached to the failure / error message.

Baru pada versi 3.2.

**failfast**

If set to true `stop()` will be called on the first failure or error, halting the test run.

Baru pada versi 3.2.

**tb\_locals**

If set to true then local variables will be shown in tracebacks.

Baru pada versi 3.5.

**wasSuccessful()**

Return True if all tests run so far have passed, otherwise returns False.

Berubah pada versi 3.4: Returns False if there were any `unexpectedSuccesses` from tests marked with the `expectedFailure()` decorator.

**stop()**

This method can be called to signal that the set of tests being run should be aborted by setting the `shouldStop` attribute to True. `TestRunner` objects should respect this flag and return without running any additional tests.

For example, this feature is used by the `TextTestRunner` class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide `TestRunner` implementations can use this in a similar manner.

The following methods of the `TestResult` class are used to maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

**startTest(test)**

Called when the test case `test` is about to be run.

**stopTest(test)**

Called after the test case `test` has been executed, regardless of the outcome.

**startTestRun()**

Called once before any tests are executed.

Baru pada versi 3.1.

**stopTestRun()**

Called once after all tests are executed.

Baru pada versi 3.1.

**addError(test, err)**

Called when the test case `test` raises an unexpected exception. `err` is a tuple of the form returned by `sys.exc_info(): (type, value, traceback)`.

The default implementation appends a tuple (`test`, `formatted_err`) to the instance's `errors` attribute, where `formatted_err` is a formatted traceback derived from `err`.

**addFailure(test, err)**

Called when the test case `test` signals a failure. `err` is a tuple of the form returned by `sys.exc_info(): (type, value, traceback)`.

The default implementation appends a tuple (*test*, *formatted\_err*) to the instance's *failures* attribute, where *formatted\_err* is a formatted traceback derived from *err*.

**addSuccess** (*test*)

Called when the test case *test* succeeds.

The default implementation does nothing.

**addSkip** (*test*, *reason*)

Called when the test case *test* is skipped. *reason* is the reason the test gave for skipping.

The default implementation appends a tuple (*test*, *reason*) to the instance's *skipped* attribute.

**addExpectedFailure** (*test*, *err*)

Called when the test case *test* fails or errors, but was marked with the *expectedFailure()* decorator.

The default implementation appends a tuple (*test*, *formatted\_err*) to the instance's *expectedFailures* attribute, where *formatted\_err* is a formatted traceback derived from *err*.

**addUnexpectedSuccess** (*test*)

Called when the test case *test* was marked with the *expectedFailure()* decorator, but succeeded.

The default implementation appends the test to the instance's *unexpectedSuccesses* attribute.

**addSubTest** (*test*, *subtest*, *outcome*)

Called when a subtest finishes. *test* is the test case corresponding to the test method. *subtest* is a custom *TestCase* instance describing the subtest.

If *outcome* is *None*, the subtest succeeded. Otherwise, it failed with an exception where *outcome* is a tuple of the form returned by *sys.exc\_info()*: (*type*, *value*, *traceback*).

The default implementation does nothing when the outcome is a success, and records subtest failures as normal failures.

Baru pada versi 3.4.

**class** `unittest.TextTestResult` (*stream*, *descriptions*, *verbosity*)

A concrete implementation of *TestResult* used by the *TextTestRunner*.

Baru pada versi 3.2: This class was previously named `_TextTestResult`. The old name still exists as an alias but is deprecated.

`unittest.defaultTestLoader`

Instance of the *TestLoader* class intended to be shared. If no customization of the *TestLoader* is needed, this instance can be used instead of repeatedly creating new instances.

**class** `unittest.TextTestRunner` (*stream=None*, *descriptions=True*, *verbosity=1*, *failfast=False*, *buffer=False*, *resultclass=None*, *warnings=None*, \*, *tb\_locals=False*)

A basic test runner implementation that outputs results to a stream. If *stream* is *None*, the default, *sys.stderr* is used as the output stream. This class has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations. Such implementations should accept *\*\*kwargs* as the interface to construct runners changes when features are added to *unittest*.

By default this runner shows *DeprecationWarning*, *PendingDeprecationWarning*, *ResourceWarning* and *ImportWarning* even if they are *ignored by default*. Deprecation warnings caused by *deprecated unittest methods* are also special-cased and, when the warning filters are 'default' or 'always', they will appear only once per-module, in order to avoid too many warning messages. This behavior can be overridden using Python's *-Wd* or *-Wa* options (see Warning control) and leaving *warnings* to *None*.

Berubah pada versi 3.2: Added the *warnings* argument.

Berubah pada versi 3.2: The default stream is set to *sys.stderr* at instantiation time rather than import time.

Berubah pada versi 3.5: Added the *tb\_locals* parameter.

**`_makeResult()`**

This method returns the instance of `TestResult` used by `run()`. It is not intended to be called directly, but can be overridden in subclasses to provide a custom `TestResult`.

`_makeResult()` instantiates the class or callable passed in the `TextTestRunner` constructor as the `resultclass` argument. It defaults to `TextTestResult` if no `resultclass` is provided. The result class is instantiated with the following arguments:

```
stream, descriptions, verbosity
```

**`run(test)`**

This method is the main public interface to the `TextTestRunner`. This method takes a `TestSuite` or `TestCase` instance. A `TestResult` is created by calling `_makeResult()` and the test(s) are run and the results printed to stdout.

```
unittest.main(module='__main__', defaultTest=None, argv=None, testRunner=None, testLoader=unittest.defaultTestLoader, exit=True, verbosity=1, failfast=None, catchbreak=None, buffer=None, warnings=None)
```

A command-line program that loads a set of tests from *module* and runs them; this is primarily for making test modules conveniently executable. The simplest use for this function is to include the following line at the end of a test script:

```
if __name__ == '__main__':
    unittest.main()
```

You can run tests with more detailed information by passing in the verbosity argument:

```
if __name__ == '__main__':
    unittest.main(verbosity=2)
```

The *defaultTest* argument is either the name of a single test or an iterable of test names to run if no test names are specified via *argv*. If not specified or `None` and no test names are provided via *argv*, all tests found in *module* are run.

The *argv* argument can be a list of options passed to the program, with the first element being the program name. If not specified or `None`, the values of `sys.argv` are used.

The *testRunner* argument can either be a test runner class or an already created instance of it. By default `main` calls `sys.exit()` with an exit code indicating success or failure of the tests run.

The *testLoader* argument has to be a `TestLoader` instance, and defaults to `defaultTestLoader`.

`main` supports being used from the interactive interpreter by passing in the argument `exit=False`. This displays the result on standard output without calling `sys.exit()`:

```
>>> from unittest import main
>>> main(module='test_module', exit=False)
```

The *failfast*, *catchbreak* and *buffer* parameters have the same effect as the same-name *command-line options*.

The *warnings* argument specifies the *warning filter* that should be used while running the tests. If it's not specified, it will remain `None` if a `-W` option is passed to **python** (see Warning control), otherwise it will be set to `'default'`.

Calling `main` actually returns an instance of the `TestProgram` class. This stores the result of the tests run as the `result` attribute.

Berubah pada versi 3.1: The *exit* parameter was added.

Berubah pada versi 3.2: The *verbosity*, *failfast*, *catchbreak*, *buffer* and *warnings* parameters were added.

Berubah pada versi 3.4: The *defaultTest* parameter was changed to also accept an iterable of test names.

## load\_tests Protocol

Baru pada versi 3.2.

Modules or packages can customize how tests are loaded from them during normal test runs or test discovery by implementing a function called `load_tests`.

If a test module defines `load_tests` it will be called by `TestLoader.loadTestsFromModule()` with the following arguments:

```
load_tests(loader, standard_tests, pattern)
```

where *pattern* is passed straight through from `loadTestsFromModule`. It defaults to `None`.

It should return a *TestSuite*.

*loader* is the instance of *TestLoader* doing the loading. *standard\_tests* are the tests that would be loaded by default from the module. It is common for test modules to only want to add or remove tests from the standard set of tests. The third argument is used when loading packages as part of test discovery.

A typical `load_tests` function that loads tests from a specific set of *TestCase* classes may look like:

```
test_cases = (TestCase1, TestCase2, TestCase3)

def load_tests(loader, tests, pattern):
    suite = TestSuite()
    for test_class in test_cases:
        tests = loader.loadTestsFromTestCase(test_class)
        suite.addTests(tests)
    return suite
```

If discovery is started in a directory containing a package, either from the command line or by calling *TestLoader.discover()*, then the package `__init__.py` will be checked for `load_tests`. If that function does not exist, discovery will recurse into the package as though it were just another directory. Otherwise, discovery of the package's tests will be left up to `load_tests` which is called with the following arguments:

```
load_tests(loader, standard_tests, pattern)
```

This should return a *TestSuite* representing all the tests from the package. (*standard\_tests* will only contain tests collected from `__init__.py`.)

Because the *pattern* is passed into `load_tests` the package is free to continue (and potentially modify) test discovery. A 'do nothing' `load_tests` function for a test package would look like:

```
def load_tests(loader, standard_tests, pattern):
    # top level directory cached on loader instance
    this_dir = os.path.dirname(__file__)
    package_tests = loader.discover(start_dir=this_dir, pattern=pattern)
    standard_tests.addTests(package_tests)
    return standard_tests
```

Berubah pada versi 3.5: Discovery no longer checks package names for matching *pattern* due to the impossibility of package names matching the default pattern.

## 26.4.9 Class and Module Fixtures

Class and module level fixtures are implemented in *TestSuite*. When the test suite encounters a test from a new class then `tearDownClass()` from the previous class (if there is one) is called, followed by `setUpClass()` from the new class.

Similarly if a test is from a different module from the previous test then `tearDownModule` from the previous module is run, followed by `setUpModule` from the new module.

After all the tests have run the final `tearDownClass` and `tearDownModule` are run.

Note that shared fixtures do not play well with [potential] features like test parallelization and they break test isolation. They should be used with care.

The default ordering of tests created by the unittest test loaders is to group all tests from the same modules and classes together. This will lead to `setUpClass` / `setUpModule` (etc) being called exactly once per class and module. If you randomize the order, so that tests from different modules and classes are adjacent to each other, then these shared fixture functions may be called multiple times in a single test run.

Shared fixtures are not intended to work with suites with non-standard ordering. A *BaseTestSuite* still exists for frameworks that don't want to support shared fixtures.

If there are any exceptions raised during one of the shared fixture functions the test is reported as an error. Because there is no corresponding test instance an `_ErrorHolder` object (that has the same interface as a *TestCase*) is created to represent the error. If you are just using the standard unittest test runner then this detail doesn't matter, but if you are a framework author it may be relevant.

### `setUpClass` and `tearDownClass`

These must be implemented as class methods:

```
import unittest

class Test(unittest.TestCase):
    @classmethod
    def setUpClass(cls):
        cls._connection = createExpensiveConnectionObject()

    @classmethod
    def tearDownClass(cls):
        cls._connection.destroy()
```

If you want the `setUpClass` and `tearDownClass` on base classes called then you must call up to them yourself. The implementations in *TestCase* are empty.

If an exception is raised during a `setUpClass` then the tests in the class are not run and the `tearDownClass` is not run. Skipped classes will not have `setUpClass` or `tearDownClass` run. If the exception is a *SkipTest* exception then the class will be reported as having been skipped instead of as an error.

## setUpModule and tearDownModule

These should be implemented as functions:

```
def setUpModule():
    createConnection()

def tearDownModule():
    closeConnection()
```

If an exception is raised in a `setUpModule` then none of the tests in the module will be run and the `tearDownModule` will not be run. If the exception is a `SkipTest` exception then the module will be reported as having been skipped instead of as an error.

To add cleanup code that must be run even in the case of an exception, use `addModuleCleanup`:

`unittest.addModuleCleanup(function, /, *args, **kwargs)`

Add a function to be called after `tearDownModule()` to cleanup resources used during the test class. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into `addModuleCleanup()` when they are added.

If `setUpModule()` fails, meaning that `tearDownModule()` is not called, then any cleanup functions added will still be called.

Baru pada versi 3.8.

`unittest.doModuleCleanups()`

This function is called unconditionally after `tearDownModule()`, or after `setUpModule()` if `setUpModule()` raises an exception.

It is responsible for calling all the cleanup functions added by `addCleanupModule()`. If you need cleanup functions to be called *prior* to `tearDownModule()` then you can call `doModuleCleanups()` yourself.

`doModuleCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

Baru pada versi 3.8.

## 26.4.10 Penanganan Sinyal *Signal*

Baru pada versi 3.2.

The `-c/--catch` command-line option to `unittest`, along with the `catchbreak` parameter to `unittest.main()`, provide more friendly handling of control-C during a test run. With catch break behavior enabled control-C will allow the currently running test to complete, and the test run will then end and report all the results so far. A second control-c will raise a `KeyboardInterrupt` in the usual way.

The control-c handling signal handler attempts to remain compatible with code or tests that install their own `signal.SIGINT` handler. If the `unittest` handler is called but *isn't* the installed `signal.SIGINT` handler, i.e. it has been replaced by the system under test and delegated to, then it calls the default handler. This will normally be the expected behavior by code that replaces an installed handler and delegates to it. For individual tests that need `unittest` control-c handling disabled the `removeHandler()` decorator can be used.

There are a few utility functions for framework authors to enable control-c handling functionality within test frameworks.

`unittest.installHandler()`

Install the control-c handler. When a `signal.SIGINT` is received (usually in response to the user pressing control-c) all registered results have `stop()` called.

`unittest.registerResult(result)`

Register a *TestResult* object for control-c handling. Registering a result stores a weak reference to it, so it doesn't prevent the result from being garbage collected.

Registering a *TestResult* object has no side-effects if control-c handling is not enabled, so test frameworks can unconditionally register all results they create independently of whether or not handling is enabled.

`unittest.removeResult(result)`

Remove a registered result. Once a result has been removed then `stop()` will no longer be called on that result object in response to a control-c.

`unittest.removeHandler(function=None)`

When called without arguments this function removes the control-c handler if it has been installed. This function can also be used as a test decorator to temporarily remove the handler while the test is being executed:

```
@unittest.removeHandler
def test_signal_handling(self):
    ...
```

## 26.5 unittest.mock --- mock object library

Baru pada versi 3.3.

**Source code:** [Lib/unittest/mock.py](#)

---

`unittest.mock` is a library for testing in Python. It allows you to replace parts of your system under test with mock objects and make assertions about how they have been used.

`unittest.mock` provides a core *Mock* class removing the need to create a host of stubs throughout your test suite. After performing an action, you can make assertions about which methods / attributes were used and arguments they were called with. You can also specify return values and set needed attributes in the normal way.

Additionally, mock provides a `patch()` decorator that handles patching module and class level attributes within the scope of a test, along with *sentinel* for creating unique objects. See the *quick guide* for some examples of how to use *Mock*, *MagicMock* and `patch()`.

Mock is very easy to use and is designed for use with `unittest`. Mock is based on the 'action -> assertion' pattern instead of 'record -> replay' used by many mocking frameworks.

There is a backport of `unittest.mock` for earlier versions of Python, available as [mock on PyPI](#).

### 26.5.1 Quick Guide

*Mock* and *MagicMock* objects create all attributes and methods as you access them and store details of how they have been used. You can configure them, to specify return values or limit what attributes are available, and then make assertions about how they have been used:

```
>>> from unittest.mock import MagicMock
>>> thing = ProductionClass()
>>> thing.method = MagicMock(return_value=3)
>>> thing.method(3, 4, 5, key='value')
3
>>> thing.method.assert_called_with(3, 4, 5, key='value')
```

`side_effect` allows you to perform side effects, including raising an exception when a mock is called:

```
>>> mock = Mock(side_effect=KeyError('foo'))
>>> mock()
Traceback (most recent call last):
...
KeyError: 'foo'
```

```
>>> values = {'a': 1, 'b': 2, 'c': 3}
>>> def side_effect(arg):
...     return values[arg]
...
>>> mock.side_effect = side_effect
>>> mock('a'), mock('b'), mock('c')
(1, 2, 3)
>>> mock.side_effect = [5, 4, 3, 2, 1]
>>> mock(), mock(), mock()
(5, 4, 3)
```

Mock has many other ways you can configure it and control its behaviour. For example the *spec* argument configures the mock to take its specification from another object. Attempting to access attributes or methods on the mock that don't exist on the spec will fail with an *AttributeError*.

The *patch()* decorator / context manager makes it easy to mock classes or objects in a module under test. The object you specify will be replaced with a mock (or other object) during the test and restored when the test ends:

```
>>> from unittest.mock import patch
>>> @patch('module.ClassName2')
... @patch('module.ClassName1')
... def test(MockClass1, MockClass2):
...     module.ClassName1()
...     module.ClassName2()
...     assert MockClass1 is module.ClassName1
...     assert MockClass2 is module.ClassName2
...     assert MockClass1.called
...     assert MockClass2.called
...
>>> test()
```

**Catatan:** When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal *Python* order that decorators are applied). This means from the bottom up, so in the example above the mock for *module.ClassName1* is passed in first.

With *patch()* it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read *where to patch*.

As well as a decorator *patch()* can be used as a context manager in a with statement:

```
>>> with patch.object(ProductionClass, 'method', return_value=None) as mock_method:
...     thing = ProductionClass()
...     thing.method(1, 2, 3)
...
>>> mock_method.assert_called_once_with(1, 2, 3)
```

There is also *patch.dict()* for setting values in a dictionary just during a scope and restoring the dictionary to its original state when the test ends:

```
>>> foo = {'key': 'value'}
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=True):
...     assert foo == {'newkey': 'newvalue'}
...
>>> assert foo == original
```

Mock supports the mocking of Python *magic methods*. The easiest way of using magic methods is with the *MagicMock* class. It allows you to do things like:

```
>>> mock = MagicMock()
>>> mock.__str__.return_value = 'foobarbaz'
>>> str(mock)
'foobarbaz'
>>> mock.__str__.assert_called_with()
```

Mock allows you to assign functions (or other Mock instances) to magic methods and they will be called appropriately. The *MagicMock* class is just a Mock variant that has all of the magic methods pre-created for you (well, all the useful ones anyway).

The following is an example of using magic methods with the ordinary Mock class:

```
>>> mock = Mock()
>>> mock.__str__ = Mock(return_value='whewheewheew')
>>> str(mock)
'whewheewheew'
```

For ensuring that the mock objects in your tests have the same api as the objects they are replacing, you can use *auto-specing*. Auto-specing can be done through the *autospec* argument to patch, or the *create\_autospec()* function. Auto-specing creates mock objects that have the same attributes and methods as the objects they are replacing, and any functions and methods (including constructors) have the same call signature as the real object.

This ensures that your mocks will fail in the same way as your production code if they are used incorrectly:

```
>>> from unittest.mock import create_autospec
>>> def function(a, b, c):
...     pass
...
>>> mock_function = create_autospec(function, return_value='fishy')
>>> mock_function(1, 2, 3)
'fishy'
>>> mock_function.assert_called_once_with(1, 2, 3)
>>> mock_function('wrong arguments')
Traceback (most recent call last):
...
TypeError: <lambda>() takes exactly 3 arguments (1 given)
```

*create\_autospec()* can also be used on classes, where it copies the signature of the *\_\_init\_\_* method, and on callable objects where it copies the signature of the *\_\_call\_\_* method.

## 26.5.2 The Mock Class

*Mock* is a flexible mock object intended to replace the use of stubs and test doubles throughout your code. Mocks are callable and create attributes as new mocks when you access them<sup>1</sup>. Accessing the same attribute will always return the same mock. Mocks record how you use them, allowing you to make assertions about what your code has done to them.

*MagicMock* is a subclass of *Mock* with all the magic methods pre-created and ready to use. There are also non-callable variants, useful when you are mocking out objects that aren't callable: *NonCallableMock* and *NonCallableMagicMock*

The *patch()* decorator makes it easy to temporarily replace classes in a particular module with a *Mock* object. By default *patch()* will create a *MagicMock* for you. You can specify an alternative class of *Mock* using the *new\_callable* argument to *patch()*.

**class** unittest.mock.**Mock** (*spec=None, side\_effect=None, return\_value=DEFAULT, wraps=None, name=None, spec\_set=None, unsafe=False, \*\*kwargs*)

Create a new *Mock* object. *Mock* takes several optional arguments that specify the behaviour of the Mock object:

- *spec*: This can be either a list of strings or an existing object (a class or instance) that acts as the specification for the mock object. If you pass in an object then a list of strings is formed by calling *dir* on the object (excluding unsupported magic attributes and methods). Accessing any attribute not in this list will raise an *AttributeError*.

If *spec* is an object (rather than a list of strings) then *\_\_class\_\_* returns the class of the spec object. This allows mocks to pass *isinstance()* tests.

- *spec\_set*: A stricter variant of *spec*. If used, attempting to *set* or *get* an attribute on the mock that isn't on the object passed as *spec\_set* will raise an *AttributeError*.
- *side\_effect*: A function to be called whenever the Mock is called. See the *side\_effect* attribute. Useful for raising exceptions or dynamically changing return values. The function is called with the same arguments as the mock, and unless it returns *DEFAULT*, the return value of this function is used as the return value.

Alternatively *side\_effect* can be an exception class or instance. In this case the exception will be raised when the mock is called.

If *side\_effect* is an iterable then each call to the mock will return the next value from the iterable.

A *side\_effect* can be cleared by setting it to *None*.

- *return\_value*: The value returned when the mock is called. By default this is a new Mock (created on first access). See the *return\_value* attribute.
- *unsafe*: By default if any attribute starts with *assert* or *assert* will raise an *AttributeError*. Passing *unsafe=True* will allow access to these attributes.

Baru pada versi 3.5.

- *wraps*: Item for the mock object to wrap. If *wraps* is not *None* then calling the Mock will pass the call through to the wrapped object (returning the real result). Attribute access on the mock will return a Mock object that wraps the corresponding attribute of the wrapped object (so attempting to access an attribute that doesn't exist will raise an *AttributeError*).

If the mock has an explicit *return\_value* set then calls are not passed to the wrapped object and the *return\_value* is returned instead.

- *name*: If the mock has a name then it will be used in the repr of the mock. This can be useful for debugging. The name is propagated to child mocks.

<sup>1</sup> The only exceptions are magic methods and attributes (those that have leading and trailing double underscores). Mock doesn't create these but instead raises an *AttributeError*. This is because the interpreter will often implicitly request these methods, and gets very confused to get a new Mock object when it expects a magic method. If you need magic method support see *magic methods*.

Mocks can also be called with arbitrary keyword arguments. These will be used to set attributes on the mock after it is created. See the `configure_mock()` method for details.

**assert\_called()**

Assert that the mock was called at least once.

```
>>> mock = Mock()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called()
```

Baru pada versi 3.6.

**assert\_called\_once()**

Assert that the mock was called exactly once.

```
>>> mock = Mock()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called_once()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called_once()
Traceback (most recent call last):
...
AssertionError: Expected 'method' to have been called once. Called 2 times.
```

Baru pada versi 3.6.

**assert\_called\_with(\*args, \*\*kwargs)**

This method is a convenient way of asserting that the last call has been made in a particular way:

```
>>> mock = Mock()
>>> mock.method(1, 2, 3, test='wow')
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called_with(1, 2, 3, test='wow')
```

**assert\_called\_once\_with(\*args, \*\*kwargs)**

Assert that the mock was called exactly once and that that call was with the specified arguments.

```
>>> mock = Mock(return_value=None)
>>> mock('foo', bar='baz')
>>> mock.assert_called_once_with('foo', bar='baz')
>>> mock('other', bar='values')
>>> mock.assert_called_once_with('other', bar='values')
Traceback (most recent call last):
...
AssertionError: Expected 'mock' to be called once. Called 2 times.
```

**assert\_any\_call(\*args, \*\*kwargs)**

assert the mock has been called with the specified arguments.

The assert passes if the mock has *ever* been called, unlike `assert_called_with()` and `assert_called_once_with()` that only pass if the call is the most recent one, and in the case of `assert_called_once_with()` it must also be the only call.

```
>>> mock = Mock(return_value=None)
>>> mock(1, 2, arg='thing')
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> mock('some', 'thing', 'else')
>>> mock.assert_any_call(1, 2, arg='thing')
```

**assert\_has\_calls** (*calls*, *any\_order=False*)

assert the mock has been called with the specified calls. The *mock\_calls* list is checked for the calls.

If *any\_order* is false then the calls must be sequential. There can be extra calls before or after the specified calls.

If *any\_order* is true then the calls can be in any order, but they must all appear in *mock\_calls*.

```
>>> mock = Mock(return_value=None)
>>> mock(1)
>>> mock(2)
>>> mock(3)
>>> mock(4)
>>> calls = [call(2), call(3)]
>>> mock.assert_has_calls(calls)
>>> calls = [call(4), call(2), call(3)]
>>> mock.assert_has_calls(calls, any_order=True)
```

**assert\_not\_called** ()

Assert the mock was never called.

```
>>> m = Mock()
>>> m.hello.assert_not_called()
>>> obj = m.hello()
>>> m.hello.assert_not_called()
Traceback (most recent call last):
...
AssertionError: Expected 'hello' to not have been called. Called 1 times.
```

Baru pada versi 3.5.

**reset\_mock** (\*, *return\_value=False*, *side\_effect=False*)

The *reset\_mock* method resets all the call attributes on a mock object:

```
>>> mock = Mock(return_value=None)
>>> mock('hello')
>>> mock.called
True
>>> mock.reset_mock()
>>> mock.called
False
```

Berubah pada versi 3.6: Added two keyword only argument to the *reset\_mock* function.

This can be useful where you want to make a series of assertions that reuse the same object. Note that *reset\_mock()* *doesn't* clear the return value, *side\_effect* or any child attributes you have set using normal assignment by default. In case you want to reset *return\_value* or *side\_effect*, then pass the corresponding parameter as *True*. Child mocks and the return value mock (if any) are reset as well.

---

**Catatan:** *return\_value*, and *side\_effect* are keyword only argument.

---

**mock\_add\_spec** (*spec*, *spec\_set=False*)

Add a spec to a mock. *spec* can either be an object or a list of strings. Only attributes on the *spec* can be fetched as attributes from the mock.

If `spec_set` is true then only attributes on the spec can be set.

**attach\_mock** (*mock*, *attribute*)

Attach a mock as an attribute of this one, replacing its name and parent. Calls to the attached mock will be recorded in the `method_calls` and `mock_calls` attributes of this one.

**configure\_mock** (\*\**kwargs*)

Set attributes on the mock through keyword arguments.

Attributes plus return values and side effects can be set on child mocks using standard dot notation and unpacking a dictionary in the method call:

```
>>> mock = Mock()
>>> attrs = {'method.return_value': 3, 'other.side_effect': KeyError}
>>> mock.configure_mock(**attrs)
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
...
KeyError
```

The same thing can be achieved in the constructor call to mocks:

```
>>> attrs = {'method.return_value': 3, 'other.side_effect': KeyError}
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute
'eggs'
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
...
KeyError
```

`configure_mock()` exists to make it easier to do configuration after the mock has been created.

**\_\_dir\_\_** ()

`Mock` objects limit the results of `dir(some_mock)` to useful results. For mocks with a *spec* this includes all the permitted attributes for the mock.

See [FILTER\\_DIR](#) for what this filtering does, and how to switch it off.

**\_get\_child\_mock** (\*\**kw*)

Create the child mocks for attributes and return value. By default child mocks will be the same type as the parent. Subclasses of `Mock` may want to override this to customize the way child mocks are made.

For non-callable mocks the callable variant will be used (rather than any custom subclass).

**called**

A boolean representing whether or not the mock object has been called:

```
>>> mock = Mock(return_value=None)
>>> mock.called
False
>>> mock()
>>> mock.called
True
```

**call\_count**

An integer telling you how many times the mock object has been called:

```
>>> mock = Mock(return_value=None)
>>> mock.call_count
0
>>> mock()
>>> mock()
>>> mock.call_count
2
```

**return\_value**

Set this to configure the value returned by calling the mock:

```
>>> mock = Mock()
>>> mock.return_value = 'fish'
>>> mock()
'fish'
```

The default return value is a mock object and you can configure it in the normal way:

```
>>> mock = Mock()
>>> mock.return_value.attribute = sentinel.Attribute
>>> mock.return_value()
<Mock name='mock()' id='...'>
>>> mock.return_value.assert_called_with()
```

*return\_value* can also be set in the constructor:

```
>>> mock = Mock(return_value=3)
>>> mock.return_value
3
>>> mock()
3
```

**side\_effect**

This can either be a function to be called when the mock is called, an iterable or an exception (class or instance) to be raised.

If you pass in a function it will be called with same arguments as the mock and unless the function returns the *DEFAULT* singleton the call to the mock will then return whatever the function returns. If the function returns *DEFAULT* then the mock will return its normal value (from the *return\_value*).

If you pass in an iterable, it is used to retrieve an iterator which must yield a value on every call. This value can either be an exception instance to be raised, or a value to be returned from the call to the mock (*DEFAULT* handling is identical to the function case).

An example of a mock that raises an exception (to test exception handling of an API):

```
>>> mock = Mock()
>>> mock.side_effect = Exception('Boom!')
>>> mock()
Traceback (most recent call last):
...
Exception: Boom!
```

Using *side\_effect* to return a sequence of values:

```
>>> mock = Mock()
>>> mock.side_effect = [3, 2, 1]
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> mock(), mock(), mock()
(3, 2, 1)
```

Using a callable:

```
>>> mock = Mock(return_value=3)
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
...
>>> mock.side_effect = side_effect
>>> mock()
3
```

`side_effect` can be set in the constructor. Here's an example that adds one to the value the mock is called with and returns it:

```
>>> side_effect = lambda value: value + 1
>>> mock = Mock(side_effect=side_effect)
>>> mock(3)
4
>>> mock(-8)
-7
```

Setting `side_effect` to `None` clears it:

```
>>> m = Mock(side_effect=KeyError, return_value=3)
>>> m()
Traceback (most recent call last):
...
KeyError
>>> m.side_effect = None
>>> m()
3
```

### **call\_args**

This is either `None` (if the mock hasn't been called), or the arguments that the mock was last called with. This will be in the form of a tuple: the first member, which can also be accessed through the `args` property, is any ordered arguments the mock was called with (or an empty tuple) and the second member, which can also be accessed through the `kwargs` property, is any keyword arguments (or an empty dictionary).

```
>>> mock = Mock(return_value=None)
>>> print(mock.call_args)
None
>>> mock()
>>> mock.call_args
call()
>>> mock.call_args == ()
True
>>> mock(3, 4)
>>> mock.call_args
call(3, 4)
>>> mock.call_args == ((3, 4),)
True
>>> mock.call_args.args
(3, 4)
>>> mock.call_args.kwargs
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
{}
```

```
>>> mock(3, 4, 5, key='fish', next='w00t!')
```

```
>>> mock.call_args
```

```
call(3, 4, 5, key='fish', next='w00t!')
```

```
>>> mock.call_args.args
```

```
(3, 4, 5)
```

```
>>> mock.call_args.kwargs
```

```
{'key': 'fish', 'next': 'w00t!'}
```

`call_args`, along with members of the lists `call_args_list`, `method_calls` and `mock_calls` are `call` objects. These are tuples, so they can be unpacked to get at the individual arguments and make more complex assertions. See *[calls as tuples](#)*.

Berubah pada versi 3.8: Added args and kwargs properties.

### `call_args_list`

This is a list of all the calls made to the mock object in sequence (so the length of the list is the number of times it has been called). Before any calls have been made it is an empty list. The `call` object can be used for conveniently constructing lists of calls to compare with `call_args_list`.

```
>>> mock = Mock(return_value=None)
```

```
>>> mock()
```

```
>>> mock(3, 4)
```

```
>>> mock(key='fish', next='w00t!')
```

```
>>> mock.call_args_list
```

```
[call(), call(3, 4), call(key='fish', next='w00t!')]
```

```
>>> expected = [(), ((3, 4),), ({'key': 'fish', 'next': 'w00t!'},)]
```

```
>>> mock.call_args_list == expected
```

```
True
```

Members of `call_args_list` are `call` objects. These can be unpacked as tuples to get at the individual arguments. See *[calls as tuples](#)*.

### `method_calls`

As well as tracking calls to themselves, mocks also track calls to methods and attributes, and *their* methods and attributes:

```
>>> mock = Mock()
```

```
>>> mock.method()
```

```
<Mock name='mock.method()' id='...'>
```

```
>>> mock.property.method.attribute()
```

```
<Mock name='mock.property.method.attribute()' id='...'>
```

```
>>> mock.method_calls
```

```
[call.method(), call.property.method.attribute()]
```

Members of `method_calls` are `call` objects. These can be unpacked as tuples to get at the individual arguments. See *[calls as tuples](#)*.

### `mock_calls`

`mock_calls` records *all* calls to the mock object, its methods, magic methods *and* return value mocks.

```
>>> mock = MagicMock()
```

```
>>> result = mock(1, 2, 3)
```

```
>>> mock.first(a=3)
```

```
<MagicMock name='mock.first()' id='...'>
```

```
>>> mock.second()
```

```
<MagicMock name='mock.second()' id='...'>
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> int(mock)
1
>>> result(1)
<MagicMock name='mock()' id='... '>
>>> expected = [call(1, 2, 3), call.first(a=3), call.second(),
... call.__int__(), call()(1)]
>>> mock.mock_calls == expected
True
```

Members of `mock_calls` are `call` objects. These can be unpacked as tuples to get at the individual arguments. See [calls as tuples](#).

**Catatan:** The way `mock_calls` are recorded means that where nested calls are made, the parameters of ancestor calls are not recorded and so will always compare equal:

```
>>> mock = MagicMock()
>>> mock.top(a=3).bottom()
<MagicMock name='mock.top().bottom()' id='... '>
>>> mock.mock_calls
[call.top(a=3), call.top().bottom()]
>>> mock.mock_calls[-1] == call.top(a=-1).bottom()
True
```

### `__class__`

Normally the `__class__` attribute of an object will return its type. For a mock object with a spec, `__class__` returns the spec class instead. This allows mock objects to pass `isinstance()` tests for the object they are replacing / masquerading as:

```
>>> mock = Mock(spec=3)
>>> isinstance(mock, int)
True
```

`__class__` is assignable to, this allows a mock to pass an `isinstance()` check without forcing you to use a spec:

```
>>> mock = Mock()
>>> mock.__class__ = dict
>>> isinstance(mock, dict)
True
```

**class** `unittest.mock.NonCallableMock` (*spec=None, wraps=None, name=None, spec\_set=None, \*\*kwargs*)

A non-callable version of `Mock`. The constructor parameters have the same meaning of `Mock`, with the exception of `return_value` and `side_effect` which have no meaning on a non-callable mock.

Mock objects that use a class or an instance as a spec or spec\_set are able to pass `isinstance()` tests:

```
>>> mock = Mock(spec=SomeClass)
>>> isinstance(mock, SomeClass)
True
>>> mock = Mock(spec_set=SomeClass())
>>> isinstance(mock, SomeClass)
True
```

The `Mock` classes have support for mocking magic methods. See [magic methods](#) for the full details.

The mock classes and the `patch()` decorators all take arbitrary keyword arguments for configuration. For the `patch()` decorators the keywords are passed to the constructor of the mock being created. The keyword arguments are for configuring attributes of the mock:

```
>>> m = MagicMock(attribute=3, other='fish')
>>> m.attribute
3
>>> m.other
'fish'
```

The return value and side effect of child mocks can be set in the same way, using dotted notation. As you can't use dotted names directly in a call you have to create a dictionary and unpack it using `**`:

```
>>> attrs = {'method.return_value': 3, 'other.side_effect': KeyError}
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute
'eggs'
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
...
KeyError
```

A callable mock which was created with a *spec* (or a *spec\_set*) will introspect the specification object's signature when matching calls to the mock. Therefore, it can match the actual call's arguments regardless of whether they were passed positionally or by name:

```
>>> def f(a, b, c): pass
...
>>> mock = Mock(spec=f)
>>> mock(1, 2, c=3)
<Mock name='mock()' id='140161580456576'>
>>> mock.assert_called_with(1, 2, 3)
>>> mock.assert_called_with(a=1, b=2, c=3)
```

This applies to `assert_called_with()`, `assert_called_once_with()`, `assert_has_calls()` and `assert_any_call()`. When *Autospeccing*, it will also apply to method calls on the mock object.

Berubah pada versi 3.4: Added signature introspection on specced and autospecced mock objects.

**class** `unittest.mock.PropertyMock` (\*args, \*\*kwargs)

A mock intended to be used as a property, or other descriptor, on a class. *PropertyMock* provides `__get__()` and `__set__()` methods so you can specify a return value when it is fetched.

Fetching a *PropertyMock* instance from an object calls the mock, with no args. Setting it calls the mock with the value being set.

```
>>> class Foo:
...     @property
...     def foo(self):
...         return 'something'
...     @foo.setter
...     def foo(self, value):
...         pass
...
>>> with patch('__main__.Foo.foo', new_callable=PropertyMock) as mock_foo:
...     mock_foo.return_value = 'mockity-mock'
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

...     this_foo = Foo()
...     print(this_foo.foo)
...     this_foo.foo = 6
...
mockity-mock
>>> mock_foo.mock_calls
[call(), call(6)]

```

Because of the way mock attributes are stored you can't directly attach a *PropertyMock* to a mock object. Instead you can attach it to the mock type object:

```

>>> m = MagicMock()
>>> p = PropertyMock(return_value=3)
>>> type(m).foo = p
>>> m.foo
3
>>> p.assert_called_once_with()

```

**class** `unittest.mock.AsyncMock` (*spec=None, side\_effect=None, return\_value=DEFAULT, wraps=None, name=None, spec\_set=None, unsafe=False, \*\*kwargs*)

An asynchronous version of *Mock*. The *AsyncMock* object will behave so the object is recognized as an async function, and the result of a call is an awaitable.

```

>>> mock = AsyncMock()
>>> asyncio.iscoroutinefunction(mock)
True
>>> inspect.isawaitable(mock())
True

```

The result of `mock()` is an async function which will have the outcome of *side\_effect* or *return\_value* after it has been awaited:

- if *side\_effect* is a function, the async function will return the result of that function,
- if *side\_effect* is an exception, the async function will raise the exception,
- if *side\_effect* is an iterable, the async function will return the next value of the iterable, however, if the sequence of result is exhausted, *StopAsyncIteration* is raised immediately,
- if *side\_effect* is not defined, the async function will return the value defined by *return\_value*, hence, by default, the async function returns a new *AsyncMock* object.

Setting the *spec* of a *Mock* or *MagicMock* to an async function will result in a coroutine object being returned after calling.

```

>>> async def async_func(): pass
...
>>> mock = MagicMock(async_func)
>>> mock
<MagicMock spec='function' id='...'>
>>> mock()
<coroutine object AsyncMockMixin._mock_call at ...>

```

Setting the *spec* of a *Mock*, *MagicMock*, or *AsyncMock* to a class with asynchronous and synchronous functions will automatically detect the synchronous functions and set them as *MagicMock* (if the parent mock is *AsyncMock* or *MagicMock*) or *Mock* (if the parent mock is *Mock*). All asynchronous functions will be *AsyncMock*.

```

>>> class ExampleClass:
...     def sync_foo():
...         pass
...     async def async_foo():
...         pass
...
>>> a_mock = AsyncMock(ExampleClass)
>>> a_mock.sync_foo
<MagicMock name='mock.sync_foo' id='...'>
>>> a_mock.async_foo
<AsyncMock name='mock.async_foo' id='...'>
>>> mock = Mock(ExampleClass)
>>> mock.sync_foo
<Mock name='mock.sync_foo' id='...'>
>>> mock.async_foo
<AsyncMock name='mock.async_foo' id='...'>

```

Baru pada versi 3.8.

#### **assert\_awaited()**

Assert that the mock was awaited at least once. Note that this is separate from the object having been called, the `await` keyword must be used:

```

>>> mock = AsyncMock()
>>> async def main(coroutine_mock):
...     await coroutine_mock
...
>>> coroutine_mock = mock()
>>> mock.called
True
>>> mock.assert_awaited()
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awaited.
>>> asyncio.run(main(coroutine_mock))
>>> mock.assert_awaited()

```

#### **assert\_awaited\_once()**

Assert that the mock was awaited exactly once.

```

>>> mock = AsyncMock()
>>> async def main():
...     await mock()
...
>>> asyncio.run(main())
>>> mock.assert_awaited_once()
>>> asyncio.run(main())
>>> mock.method.assert_awaited_once()
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awaited once. Awaited 2 times.

```

#### **assert\_awaited\_with(\*args, \*\*kwargs)**

Assert that the last await was with the specified arguments.

```

>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):

```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_with('foo', bar='bar')
>>> mock.assert_awaited_with('other')
Traceback (most recent call last):
...
AssertionError: expected call not found.
Expected: mock('other')
Actual: mock('foo', bar='bar')
```

**assert\_awaited\_once\_with** (\*args, \*\*kwargs)

Assert that the mock was awaited exactly once and with the specified arguments.

```
>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_once_with('foo', bar='bar')
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_once_with('foo', bar='bar')
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awaited once. Awaited 2 times.
```

**assert\_any\_await** (\*args, \*\*kwargs)

Assert the mock has ever been awaited with the specified arguments.

```
>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> asyncio.run(main('hello'))
>>> mock.assert_any_await('foo', bar='bar')
>>> mock.assert_any_await('other')
Traceback (most recent call last):
...
AssertionError: mock('other') await not found
```

**assert\_has\_awaits** (calls, any\_order=False)Assert the mock has been awaited with the specified calls. The *await\_args\_list* list is checked for the awaits.If *any\_order* is false then the awaits must be sequential. There can be extra calls before or after the specified awaits.If *any\_order* is true then the awaits can be in any order, but they must all appear in *await\_args\_list*.

```
>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> calls = [call("foo"), call("bar")]
>>> mock.assert_has_awaits(calls)
Traceback (most recent call last):
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

...
AssertionError: Awaits not found.
Expected: [call('foo'), call('bar')]
Actual: []
>>> asyncio.run(main('foo'))
>>> asyncio.run(main('bar'))
>>> mock.assert_has_awaits(calls)

```

**assert\_not\_awaited()**

Assert that the mock was never awaited.

```

>>> mock = AsyncMock()
>>> mock.assert_not_awaited()

```

**reset\_mock(\*args, \*\*kwargs)**

See *Mock.reset\_mock()*. Also sets *await\_count* to 0, *await\_args* to None, and clears the *await\_args\_list*.

**await\_count**

An integer keeping track of how many times the mock object has been awaited.

```

>>> mock = AsyncMock()
>>> async def main():
...     await mock()
...
>>> asyncio.run(main())
>>> mock.await_count
1
>>> asyncio.run(main())
>>> mock.await_count
2

```

**await\_args**

This is either None (if the mock hasn't been awaited), or the arguments that the mock was last awaited with. Functions the same as *Mock.call\_args*.

```

>>> mock = AsyncMock()
>>> async def main(*args):
...     await mock(*args)
...
>>> mock.await_args
>>> asyncio.run(main('foo'))
>>> mock.await_args
call('foo')
>>> asyncio.run(main('bar'))
>>> mock.await_args
call('bar')

```

**await\_args\_list**

This is a list of all the awaits made to the mock object in sequence (so the length of the list is the number of times it has been awaited). Before any awaits have been made it is an empty list.

```

>>> mock = AsyncMock()
>>> async def main(*args):
...     await mock(*args)
...

```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

>>> mock.await_args_list
[]
>>> asyncio.run(main('foo'))
>>> mock.await_args_list
[call('foo')]
>>> asyncio.run(main('bar'))
>>> mock.await_args_list
[call('foo'), call('bar')]

```

## Calling

Mock objects are callable. The call will return the value set as the `return_value` attribute. The default return value is a new Mock object; it is created the first time the return value is accessed (either explicitly or by calling the Mock) - but it is stored and the same one returned each time.

Calls made to the object will be recorded in the attributes like `call_args` and `call_args_list`.

If `side_effect` is set then it will be called after the call has been recorded, so if `side_effect` raises an exception the call is still recorded.

The simplest way to make a mock raise an exception when called is to make `side_effect` an exception class or instance:

```

>>> m = MagicMock(side_effect=IndexError)
>>> m(1, 2, 3)
Traceback (most recent call last):
...
IndexError
>>> m.mock_calls
[call(1, 2, 3)]
>>> m.side_effect = KeyError('Bang!')
>>> m('two', 'three', 'four')
Traceback (most recent call last):
...
KeyError: 'Bang!'
>>> m.mock_calls
[call(1, 2, 3), call('two', 'three', 'four')]

```

If `side_effect` is a function then whatever that function returns is what calls to the mock return. The `side_effect` function is called with the same arguments as the mock. This allows you to vary the return value of the call dynamically, based on the input:

```

>>> def side_effect(value):
...     return value + 1
...
>>> m = MagicMock(side_effect=side_effect)
>>> m(1)
2
>>> m(2)
3
>>> m.mock_calls
[call(1), call(2)]

```

If you want the mock to still return the default return value (a new mock), or any set return value, then there are two ways of doing this. Either return `mock.return_value` from inside `side_effect`, or return `DEFAULT`:

```

>>> m = MagicMock()
>>> def side_effect(*args, **kwargs):
...     return m.return_value
...
>>> m.side_effect = side_effect
>>> m.return_value = 3
>>> m()
3
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
...
>>> m.side_effect = side_effect
>>> m()
3

```

To remove a `side_effect`, and return to the default behaviour, set the `side_effect` to `None`:

```

>>> m = MagicMock(return_value=6)
>>> def side_effect(*args, **kwargs):
...     return 3
...
>>> m.side_effect = side_effect
>>> m()
3
>>> m.side_effect = None
>>> m()
6

```

The `side_effect` can also be any iterable object. Repeated calls to the mock will return values from the iterable (until the iterable is exhausted and a *StopIteration* is raised):

```

>>> m = MagicMock(side_effect=[1, 2, 3])
>>> m()
1
>>> m()
2
>>> m()
3
>>> m()
Traceback (most recent call last):
...
StopIteration

```

If any members of the iterable are exceptions they will be raised instead of returned:

```

>>> iterable = (33, ValueError, 66)
>>> m = MagicMock(side_effect=iterable)
>>> m()
33
>>> m()
Traceback (most recent call last):
...
ValueError
>>> m()
66

```

### Deleting Attributes

Mock objects create attributes on demand. This allows them to pretend to be objects of any type.

You may want a mock object to return `False` to a `hasattr()` call, or raise an `AttributeError` when an attribute is fetched. You can do this by providing an object as a `spec` for a mock, but that isn't always convenient.

You "block" attributes by deleting them. Once deleted, accessing an attribute will raise an `AttributeError`.

```
>>> mock = MagicMock()
>>> hasattr(mock, 'm')
True
>>> del mock.m
>>> hasattr(mock, 'm')
False
>>> del mock.f
>>> mock.f
Traceback (most recent call last):
...
AttributeError: f
```

### Mock names and the name attribute

Since "name" is an argument to the `Mock` constructor, if you want your mock object to have a "name" attribute you can't just pass it in at creation time. There are two alternatives. One option is to use `configure_mock()`:

```
>>> mock = MagicMock()
>>> mock.configure_mock(name='my_name')
>>> mock.name
'my_name'
```

A simpler option is to simply set the "name" attribute after mock creation:

```
>>> mock = MagicMock()
>>> mock.name = "foo"
```

### Attaching Mocks as Attributes

When you attach a mock as an attribute of another mock (or as the return value) it becomes a "child" of that mock. Calls to the child are recorded in the `method_calls` and `mock_calls` attributes of the parent. This is useful for configuring child mocks and then attaching them to the parent, or for attaching mocks to a parent that records all calls to the children and allows you to make assertions about the order of calls between mocks:

```
>>> parent = MagicMock()
>>> child1 = MagicMock(return_value=None)
>>> child2 = MagicMock(return_value=None)
>>> parent.child1 = child1
>>> parent.child2 = child2
>>> child1(1)
>>> child2(2)
>>> parent.mock_calls
[call.child1(1), call.child2(2)]
```

The exception to this is if the mock has a name. This allows you to prevent the "parenting" if for some reason you don't want it to happen.

```
>>> mock = MagicMock()
>>> not_a_child = MagicMock(name='not-a-child')
>>> mock.attribute = not_a_child
>>> mock.attribute()
<MagicMock name='not-a-child()' id='...'>
>>> mock.mock_calls
[]
```

Mocks created for you by `patch()` are automatically given names. To attach mocks that have names to a parent you use the `attach_mock()` method:

```
>>> thing1 = object()
>>> thing2 = object()
>>> parent = MagicMock()
>>> with patch('__main__.thing1', return_value=None) as child1:
...     with patch('__main__.thing2', return_value=None) as child2:
...         parent.attach_mock(child1, 'child1')
...         parent.attach_mock(child2, 'child2')
...         child1('one')
...         child2('two')
...
>>> parent.mock_calls
[call.child1('one'), call.child2('two')]
```

### 26.5.3 The patchers

The patch decorators are used for patching objects only within the scope of the function they decorate. They automatically handle the unpatching for you, even if exceptions are raised. All of these functions can also be used in with statements or as class decorators.

#### patch

---

**Catatan:** `patch()` is straightforward to use. The key is to do the patching in the right namespace. See the section *where to patch*.

---

`unittest.mock.patch(target, new=DEFAULT, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)`

`patch()` acts as a function decorator, class decorator or a context manager. Inside the body of the function or with statement, the `target` is patched with a `new` object. When the function/with statement exits the patch is undone.

If `new` is omitted, then the target is replaced with an `AsyncMock` if the patched object is an async function or a `MagicMock` otherwise. If `patch()` is used as a decorator and `new` is omitted, the created mock is passed in as an extra argument to the decorated function. If `patch()` is used as a context manager the created mock is returned by the context manager.

`target` should be a string in the form `'package.module.ClassName'`. The `target` is imported and the specified object replaced with the `new` object, so the `target` must be importable from the environment you are calling `patch()` from. The target is imported when the decorated function is executed, not at decoration time.

The `spec` and `spec_set` keyword arguments are passed to the `MagicMock` if patch is creating one for you.

In addition you can pass `spec=True` or `spec_set=True`, which causes patch to pass in the object being mocked as the `spec/spec_set` object.

*new\_callable* allows you to specify a different class, or callable object, that will be called to create the *new* object. By default *AsyncMock* is used for async functions and *MagicMock* for the rest.

A more powerful form of *spec* is *autospec*. If you set `autospec=True` then the mock will be created with a spec from the object being replaced. All attributes of the mock will also have the spec of the corresponding attribute of the object being replaced. Methods and functions being mocked will have their arguments checked and will raise a *TypeError* if they are called with the wrong signature. For mocks replacing a class, their return value (the 'instance') will have the same spec as the class. See the *create\_autospec()* function and *Autospeccing*.

Instead of `autospec=True` you can pass `autospec=some_object` to use an arbitrary object as the spec instead of the one being replaced.

By default *patch()* will fail to replace attributes that don't exist. If you pass in `create=True`, and the attribute doesn't exist, patch will create the attribute for you when the patched function is called, and delete it again after the patched function has exited. This is useful for writing tests against attributes that your production code creates at runtime. It is off by default because it can be dangerous. With it switched on you can write passing tests against APIs that don't actually exist!

---

**Catatan:** Berubah pada versi 3.5: If you are patching builtins in a module then you don't need to pass `create=True`, it will be added by default.

---

Patch can be used as a *TestCase* class decorator. It works by decorating each test method in the class. This reduces the boilerplate code when your test methods share a common patchings set. *patch()* finds tests by looking for method names that start with `patch.TEST_PREFIX`. By default this is 'test', which matches the way *unittest* finds tests. You can specify an alternative prefix by setting `patch.TEST_PREFIX`.

Patch can be used as a context manager, with the *with* statement. Here the patching applies to the indented block after the *with* statement. If you use "as" then the patched object will be bound to the name after the "as"; very useful if *patch()* is creating a mock object for you.

*patch()* takes arbitrary keyword arguments. These will be passed to the *Mock* (or *new\_callable*) on construction.

`patch.dict(...)`, `patch.multiple(...)` and `patch.object(...)` are available for alternate use-cases.

*patch()* as function decorator, creating the mock for you and passing it into the decorated function:

```
>>> @patch('__main__.SomeClass')
... def function(normal_argument, mock_class):
...     print(mock_class is SomeClass)
...
>>> function(None)
True
```

Patching a class replaces the class with a *MagicMock instance*. If the class is instantiated in the code under test then it will be the *return\_value* of the mock that will be used.

If the class is instantiated multiple times you could use *side\_effect* to return a new mock each time. Alternatively you can set the *return\_value* to be anything you want.

To configure return values on methods of *instances* on the patched class you must do this on the *return\_value*. For example:

```
>>> class Class:
...     def method(self):
...         pass
...
>>> with patch('__main__.Class') as MockClass:
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

...     instance = MockClass.return_value
...     instance.method.return_value = 'foo'
...     assert Class() is instance
...     assert Class().method() == 'foo'
...

```

If you use *spec* or *spec\_set* and *patch()* is replacing a *class*, then the return value of the created mock will have the same spec.

```

>>> Original = Class
>>> patcher = patch('__main__.Class', spec=True)
>>> MockClass = patcher.start()
>>> instance = MockClass()
>>> assert isinstance(instance, Original)
>>> patcher.stop()

```

The *new\_callable* argument is useful where you want to use an alternative class to the default *MagicMock* for the created mock. For example, if you wanted a *NonCallableMock* to be used:

```

>>> thing = object()
>>> with patch('__main__.thing', new_callable=NonCallableMock) as mock_thing:
...     assert thing is mock_thing
...     thing()
...
Traceback (most recent call last):
...
TypeError: 'NonCallableMock' object is not callable

```

Another use case might be to replace an object with an *io.StringIO* instance:

```

>>> from io import StringIO
>>> def foo():
...     print('Something')
...
>>> @patch('sys.stdout', new_callable=StringIO)
... def test(mock_stdout):
...     foo()
...     assert mock_stdout.getvalue() == 'Something\n'
...
>>> test()

```

When *patch()* is creating a mock for you, it is common that the first thing you need to do is to configure the mock. Some of that configuration can be done in the call to *patch*. Any arbitrary keywords you pass into the call will be used to set attributes on the created mock:

```

>>> patcher = patch('__main__.thing', first='one', second='two')
>>> mock_thing = patcher.start()
>>> mock_thing.first
'one'
>>> mock_thing.second
'two'

```

As well as attributes on the created mock attributes, like the *return\_value* and *side\_effect*, of child mocks can also be configured. These aren't syntactically valid to pass in directly as keyword arguments, but a dictionary with these as keys can still be expanded into a *patch()* call using *\*\**:

```
>>> config = {'method.return_value': 3, 'other.side_effect': KeyError}
>>> patcher = patch('__main__.thing', **config)
>>> mock_thing = patcher.start()
>>> mock_thing.method()
3
>>> mock_thing.other()
Traceback (most recent call last):
...
KeyError
```

By default, attempting to patch a function in a module (or a method or an attribute in a class) that does not exist will fail with `AttributeError`:

```
>>> @patch('sys.non_existing_attribute', 42)
... def test():
...     assert sys.non_existing_attribute == 42
...
>>> test()
Traceback (most recent call last):
...
AttributeError: <module 'sys' (built-in)> does not have the attribute 'non_existing'
```

but adding `create=True` in the call to `patch()` will make the previous example work as expected:

```
>>> @patch('sys.non_existing_attribute', 42, create=True)
... def test(mock_stdout):
...     assert sys.non_existing_attribute == 42
...
>>> test()
```

Berubah pada versi 3.8: `patch()` now returns an `AsyncMock` if the target is an async function.

## patch.object

`patch.object(target, attribute, new=DEFAULT, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)`  
patch the named member (*attribute*) on an object (*target*) with a mock object.

`patch.object()` can be used as a decorator, class decorator or a context manager. Arguments *new*, *spec*, *create*, *spec\_set*, *autospec* and *new\_callable* have the same meaning as for `patch()`. Like `patch()`, `patch.object()` takes arbitrary keyword arguments for configuring the mock object it creates.

When used as a class decorator `patch.object()` honours `patch.TEST_PREFIX` for choosing which methods to wrap.

You can either call `patch.object()` with three arguments or two arguments. The three argument form takes the object to be patched, the attribute name and the object to replace the attribute with.

When calling with the two argument form you omit the replacement object, and a mock is created for you and passed in as an extra argument to the decorated function:

```
>>> @patch.object(SomeClass, 'class_method')
... def test(mock_method):
...     SomeClass.class_method(3)
...     mock_method.assert_called_with(3)
...
>>> test()
```

*spec*, *create* and the other arguments to `patch.object()` have the same meaning as they do for `patch()`.

## patch.dict

`patch.dict(in_dict, values=(), clear=False, **kwargs)`

Patch a dictionary, or dictionary like object, and restore the dictionary to its original state after the test.

*in\_dict* can be a dictionary or a mapping like container. If it is a mapping then it must at least support getting, setting and deleting items plus iterating over keys.

*in\_dict* can also be a string specifying the name of the dictionary, which will then be fetched by importing it.

*values* can be a dictionary of values to set in the dictionary. *values* can also be an iterable of (key, value) pairs.

If *clear* is true then the dictionary will be cleared before the new values are set.

`patch.dict()` can also be called with arbitrary keyword arguments to set values in the dictionary.

Berubah pada versi 3.8: `patch.dict()` now returns the patched dictionary when used as a context manager.

`patch.dict()` can be used as a context manager, decorator or class decorator:

```
>>> foo = {}
>>> @patch.dict(foo, {'newkey': 'newvalue'})
... def test():
...     assert foo == {'newkey': 'newvalue'}
>>> test()
>>> assert foo == {}
```

When used as a class decorator `patch.dict()` honours `patch.TEST_PREFIX` (default to 'test') for choosing which methods to wrap:

```
>>> import os
>>> import unittest
>>> from unittest.mock import patch
>>> @patch.dict('os.environ', {'newkey': 'newvalue'})
... class TestSample(unittest.TestCase):
...     def test_sample(self):
...         self.assertEqual(os.environ['newkey'], 'newvalue')
```

If you want to use a different prefix for your test, you can inform the patchers of the different prefix by setting `patch.TEST_PREFIX`. For more details about how to change the value of see [TEST\\_PREFIX](#).

`patch.dict()` can be used to add members to a dictionary, or simply let a test change a dictionary, and ensure the dictionary is restored when the test ends.

```
>>> foo = {}
>>> with patch.dict(foo, {'newkey': 'newvalue'}) as patched_foo:
...     assert foo == {'newkey': 'newvalue'}
...     assert patched_foo == {'newkey': 'newvalue'}
...     # You can add, update or delete keys of foo (or patched_foo, it's the same_
    ↪dict)
...     patched_foo['spam'] = 'eggs'
...
>>> assert foo == {}
>>> assert patched_foo == {}
```

```
>>> import os
>>> with patch.dict('os.environ', {'newkey': 'newvalue'}):
...     print(os.environ['newkey'])
...
newvalue
>>> assert 'newkey' not in os.environ
```

Keywords can be used in the `patch.dict()` call to set values in the dictionary:

```
>>> mymodule = MagicMock()
>>> mymodule.function.return_value = 'fish'
>>> with patch.dict('sys.modules', mymodule=mymodule):
...     import mymodule
...     mymodule.function('some', 'args')
...
'fish'
```

`patch.dict()` can be used with dictionary like objects that aren't actually dictionaries. At the very minimum they must support item getting, setting, deleting and either iteration or membership test. This corresponds to the magic methods `__getitem__()`, `__setitem__()`, `__delitem__()` and either `__iter__()` or `__contains__()`.

```
>>> class Container:
...     def __init__(self):
...         self.values = {}
...     def __getitem__(self, name):
...         return self.values[name]
...     def __setitem__(self, name, value):
...         self.values[name] = value
...     def __delitem__(self, name):
...         del self.values[name]
...     def __iter__(self):
...         return iter(self.values)
...
>>> thing = Container()
>>> thing['one'] = 1
>>> with patch.dict(thing, one=2, two=3):
...     assert thing['one'] == 2
...     assert thing['two'] == 3
...
>>> assert thing['one'] == 1
>>> assert list(thing) == ['one']
```

## patch.multiple

`patch.multiple(target, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)`

Perform multiple patches in a single call. It takes the object to be patched (either as an object or a string to fetch the object by importing) and keyword arguments for the patches:

```
with patch.multiple(settings, FIRST_PATCH='one', SECOND_PATCH='two'):
    ...
```

Use `DEFAULT` as the value if you want `patch.multiple()` to create mocks for you. In this case the created mocks are passed into a decorated function by keyword, and a dictionary is returned when `patch.multiple()` is used as a context manager.

`patch.multiple()` can be used as a decorator, class decorator or a context manager. The arguments *spec*, *spec\_set*, *create*, *autospec* and *new\_callable* have the same meaning as for `patch()`. These arguments will be applied to *all* patches done by `patch.multiple()`.

When used as a class decorator `patch.multiple()` honours `patch.TEST_PREFIX` for choosing which methods to wrap.

If you want `patch.multiple()` to create mocks for you, then you can use `DEFAULT` as the value. If you use `patch.multiple()` as a decorator then the created mocks are passed into the decorated function by keyword.

```
>>> thing = object()
>>> other = object()

>>> @patch.multiple('__main__', thing=DEFAULT, other=DEFAULT)
... def test_function(thing, other):
...     assert isinstance(thing, MagicMock)
...     assert isinstance(other, MagicMock)
...
>>> test_function()
```

`patch.multiple()` can be nested with other patch decorators, but put arguments passed by keyword *after* any of the standard arguments created by `patch()`:

```
>>> @patch('sys.exit')
... @patch.multiple('__main__', thing=DEFAULT, other=DEFAULT)
... def test_function(mock_exit, other, thing):
...     assert 'other' in repr(other)
...     assert 'thing' in repr(thing)
...     assert 'exit' in repr(mock_exit)
...
>>> test_function()
```

If `patch.multiple()` is used as a context manager, the value returned by the context manager is a dictionary where created mocks are keyed by name:

```
>>> with patch.multiple('__main__', thing=DEFAULT, other=DEFAULT) as values:
...     assert 'other' in repr(values['other'])
...     assert 'thing' in repr(values['thing'])
...     assert values['thing'] is thing
...     assert values['other'] is other
...
>>>
```

## patch methods: start and stop

All the patchers have `start()` and `stop()` methods. These make it simpler to do patching in `setUp` methods or where you want to do multiple patches without nesting decorators or with statements.

To use them call `patch()`, `patch.object()` or `patch.dict()` as normal and keep a reference to the returned patcher object. You can then call `start()` to put the patch in place and `stop()` to undo it.

If you are using `patch()` to create a mock for you then it will be returned by the call to `patcher.start`.

```
>>> patcher = patch('package.module.ClassName')
>>> from package import module
>>> original = module.ClassName
>>> new_mock = patcher.start()
>>> assert module.ClassName is not original
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> assert module.ClassName is new_mock
>>> patcher.stop()
>>> assert module.ClassName is original
>>> assert module.ClassName is not new_mock
```

A typical use case for this might be for doing multiple patches in the `setUp` method of a `TestCase`:

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         self.patcher1 = patch('package.module.Class1')
...         self.patcher2 = patch('package.module.Class2')
...         self.MockClass1 = self.patcher1.start()
...         self.MockClass2 = self.patcher2.start()
...
...     def tearDown(self):
...         self.patcher1.stop()
...         self.patcher2.stop()
...
...     def test_something(self):
...         assert package.module.Class1 is self.MockClass1
...         assert package.module.Class2 is self.MockClass2
...
>>> MyTest('test_something').run()
```

**Hati-hati:** If you use this technique you must ensure that the patching is "undone" by calling `stop`. This can be fiddlier than you might think, because if an exception is raised in the `setUp` then `tearDown` is not called. `unittest.TestCase.addCleanup()` makes this easier:

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         patcher = patch('package.module.Class')
...         self.MockClass = patcher.start()
...         self.addCleanup(patcher.stop)
...
...     def test_something(self):
...         assert package.module.Class is self.MockClass
...
... 
```

As an added bonus you no longer need to keep a reference to the patcher object.

It is also possible to stop all patches which have been started by using `patch.stopall()`.

`patch.stopall()`

Stop all active patches. Only stops patches started with `start`.

## patch builtins

You can patch any builtins within a module. The following example patches builtin `ord()`:

```
>>> @patch('__main__.ord')
... def test(mock_ord):
...     mock_ord.return_value = 101
...     print(ord('c'))
...
>>> test()
101
```

## TEST\_PREFIX

All of the patchers can be used as class decorators. When used in this way they wrap every test method on the class. The patchers recognise methods that start with 'test' as being test methods. This is the same way that the `unittest.TestLoader` finds test methods by default.

It is possible that you want to use a different prefix for your tests. You can inform the patchers of the different prefix by setting `patch.TEST_PREFIX`:

```
>>> patch.TEST_PREFIX = 'foo'
>>> value = 3
>>>
>>> @patch('__main__.value', 'not three')
... class Thing:
...     def foo_one(self):
...         print(value)
...     def foo_two(self):
...         print(value)
...
>>>
>>> Thing().foo_one()
not three
>>> Thing().foo_two()
not three
>>> value
3
```

## Nesting Patch Decorators

If you want to perform multiple patches then you can simply stack up the decorators.

You can stack up multiple patch decorators using this pattern:

```
>>> @patch.object(SomeClass, 'class_method')
... @patch.object(SomeClass, 'static_method')
... def test(mock1, mock2):
...     assert SomeClass.static_method is mock1
...     assert SomeClass.class_method is mock2
...     SomeClass.static_method('foo')
...     SomeClass.class_method('bar')
...     return mock1, mock2
...
>>> mock1, mock2 = test()
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> mock1.assert_called_once_with('foo')
>>> mock2.assert_called_once_with('bar')
```

Note that the decorators are applied from the bottom upwards. This is the standard way that Python applies decorators. The order of the created mocks passed into your test function matches this order.

### Where to patch

`patch()` works by (temporarily) changing the object that a *name* points to with another one. There can be many names pointing to any individual object, so for patching to work you must ensure that you patch the name used by the system under test.

The basic principle is that you patch where an object is *looked up*, which is not necessarily the same place as where it is defined. A couple of examples will help to clarify this.

Imagine we have a project that we want to test with the following structure:

```
a.py
    -> Defines SomeClass

b.py
    -> from a import SomeClass
    -> some_function instantiates SomeClass
```

Now we want to test `some_function` but we want to mock out `SomeClass` using `patch()`. The problem is that when we import module `b`, which we will have to do then it imports `SomeClass` from module `a`. If we use `patch()` to mock out `a.SomeClass` then it will have no effect on our test; module `b` already has a reference to the *real* `SomeClass` and it looks like our patching had no effect.

The key is to patch out `SomeClass` where it is used (or where it is looked up). In this case `some_function` will actually look up `SomeClass` in module `b`, where we have imported it. The patching should look like:

```
@patch('b.SomeClass')
```

However, consider the alternative scenario where instead of `from a import SomeClass` module `b` does `import a` and `some_function` uses `a.SomeClass`. Both of these import forms are common. In this case the class we want to patch is being looked up in the module and so we have to patch `a.SomeClass` instead:

```
@patch('a.SomeClass')
```

### Patching Descriptors and Proxy Objects

Both `patch` and `patch.object` correctly patch and restore descriptors: class methods, static methods and properties. You should patch these on the *class* rather than an instance. They also work with *some* objects that proxy attribute access, like the `django settings` object.

## 26.5.4 MagicMock and magic method support

### Mocking Magic Methods

*Mock* supports mocking the Python protocol methods, also known as “magic methods”. This allows mock objects to replace containers or other objects that implement Python protocols.

Because magic methods are looked up differently from normal methods<sup>2</sup>, this support has been specially implemented. This means that only specific magic methods are supported. The supported list includes *almost* all of them. If there are any missing that you need please let us know.

You mock magic methods by setting the method you are interested in to a function or a mock instance. If you are using a function then it *must* take `self` as the first argument<sup>3</sup>.

```
>>> def __str__(self):
...     return 'fooble'
...
>>> mock = Mock()
>>> mock.__str__ = __str__
>>> str(mock)
'fooble'
```

```
>>> mock = Mock()
>>> mock.__str__ = Mock()
>>> mock.__str__.return_value = 'fooble'
>>> str(mock)
'fooble'
```

```
>>> mock = Mock()
>>> mock.__iter__ = Mock(return_value=iter([]))
>>> list(mock)
[]
```

One use case for this is for mocking objects used as context managers in a `with` statement:

```
>>> mock = Mock()
>>> mock.__enter__ = Mock(return_value='foo')
>>> mock.__exit__ = Mock(return_value=False)
>>> with mock as m:
...     assert m == 'foo'
...
>>> mock.__enter__.assert_called_with()
>>> mock.__exit__.assert_called_with(None, None, None)
```

Calls to magic methods do not appear in *method\_calls*, but they are recorded in *mock\_calls*.

---

**Catatan:** If you use the *spec* keyword argument to create a mock then attempting to set a magic method that isn’t in the spec will raise an *AttributeError*.

---

The full list of supported magic methods is:

- `__hash__`, `__sizeof__`, `__repr__` and `__str__`

---

<sup>2</sup> Magic methods *should* be looked up on the class rather than the instance. Different versions of Python are inconsistent about applying this rule. The supported protocol methods should work with all supported versions of Python.

<sup>3</sup> The function is basically hooked up to the class, but each `Mock` instance is kept isolated from the others.

- `__dir__`, `__format__` and `__subclasses__`
- `__round__`, `__floor__`, `__trunc__` and `__ceil__`
- Comparisons: `__lt__`, `__gt__`, `__le__`, `__ge__`, `__eq__` and `__ne__`
- Container methods: `__getitem__`, `__setitem__`, `__delitem__`, `__contains__`, `__len__`, `__iter__`, `__reversed__` and `__missing__`
- Context manager: `__enter__`, `__exit__`, `__aenter__` and `__aexit__`
- Unary numeric methods: `__neg__`, `__pos__` and `__invert__`
- The numeric methods (including right hand and in-place variants): `__add__`, `__sub__`, `__mul__`, `__matmul__`, `__div__`, `__truediv__`, `__floordiv__`, `__mod__`, `__divmod__`, `__lshift__`, `__rshift__`, `__and__`, `__xor__`, `__or__`, and `__pow__`
- Numeric conversion methods: `__complex__`, `__int__`, `__float__` and `__index__`
- Descriptor methods: `__get__`, `__set__` and `__delete__`
- Pickling: `__reduce__`, `__reduce_ex__`, `__getinitargs__`, `__getnewargs__`, `__getstate__` and `__setstate__`
- File system path representation: `__fspath__`
- Asynchronous iteration methods: `__aiter__` and `__anext__`

Berubah pada versi 3.8: Added support for `os.PathLike.__fspath__()`.

Berubah pada versi 3.8: Added support for `__aenter__`, `__aexit__`, `__aiter__` and `__anext__`.

The following methods exist but are *not* supported as they are either in use by mock, can't be set dynamically, or can cause problems:

- `__getattr__`, `__setattr__`, `__init__` and `__new__`
- `__prepare__`, `__instancecheck__`, `__subclasscheck__`, `__del__`

## Magic Mock

There are two MagicMock variants: *MagicMock* and *NonCallableMagicMock*.

**class** `unittest.mock.MagicMock(*args, **kw)`

MagicMock is a subclass of *Mock* with default implementations of most of the magic methods. You can use MagicMock without having to configure the magic methods yourself.

The constructor parameters have the same meaning as for *Mock*.

If you use the *spec* or *spec\_set* arguments then *only* magic methods that exist in the spec will be created.

**class** `unittest.mock.NonCallableMagicMock(*args, **kw)`

A non-callable version of *MagicMock*.

The constructor parameters have the same meaning as for *MagicMock*, with the exception of *return\_value* and *side\_effect* which have no meaning on a non-callable mock.

The magic methods are setup with *MagicMock* objects, so you can configure them and use them in the usual way:

```
>>> mock = MagicMock()
>>> mock[3] = 'fish'
>>> mock.__setitem__.assert_called_with(3, 'fish')
>>> mock.__getitem__.return_value = 'result'
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> mock[2]
'result'
```

By default many of the protocol methods are required to return objects of a specific type. These methods are preconfigured with a default return value, so that they can be used without you having to do anything if you aren't interested in the return value. You can still *set* the return value manually if you want to change the default.

Methods and their defaults:

- `__lt__`: `NotImplemented`
- `__gt__`: `NotImplemented`
- `__le__`: `NotImplemented`
- `__ge__`: `NotImplemented`
- `__int__`: `1`
- `__contains__`: `False`
- `__len__`: `0`
- `__iter__`: `iter([])`
- `__exit__`: `False`
- `__aexit__`: `False`
- `__complex__`: `1j`
- `__float__`: `1.0`
- `__bool__`: `True`
- `__index__`: `1`
- `__hash__`: default hash for the mock
- `__str__`: default str for the mock
- `__sizeof__`: default sizeof for the mock

Sebagai contoh:

```
>>> mock = MagicMock()
>>> int(mock)
1
>>> len(mock)
0
>>> list(mock)
[]
>>> object() in mock
False
```

The two equality methods, `__eq__()` and `__ne__()`, are special. They do the default equality comparison on identity, using the *side\_effect* attribute, unless you change their return value to return something else:

```
>>> MagicMock() == 3
False
>>> MagicMock() != 3
True
>>> mock = MagicMock()
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> mock.__eq__.return_value = True
>>> mock == 3
True
```

The return value of `MagicMock.__iter__()` can be any iterable object and isn't required to be an iterator:

```
>>> mock = MagicMock()
>>> mock.__iter__.return_value = ['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
```

If the return value is an iterator, then iterating over it once will consume it and subsequent iterations will result in an empty list:

```
>>> mock.__iter__.return_value = iter(['a', 'b', 'c'])
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
[]
```

`MagicMock` has all of the supported magic methods configured except for some of the obscure and obsolete ones. You can still set these up if you want.

Magic methods that are supported but not setup by default in `MagicMock` are:

- `__subclasses__`
- `__dir__`
- `__format__`
- `__get__`, `__set__` and `__delete__`
- `__reversed__` and `__missing__`
- `__reduce__`, `__reduce_ex__`, `__getinitargs__`, `__getnewargs__`, `__getstate__` and `__setstate__`
- `__getformat__` and `__setformat__`

### 26.5.5 Helpers

#### sentinel

`unittest.mock.sentinel`

The `sentinel` object provides a convenient way of providing unique objects for your tests.

Attributes are created on demand when you access them by name. Accessing the same attribute will always return the same object. The objects returned have a sensible repr so that test failure messages are readable.

Berubah pada versi 3.7: The `sentinel` attributes now preserve their identity when they are *copied* or *pickled*.

Sometimes when testing you need to test that a specific object is passed as an argument to another method, or returned. It can be common to create named sentinel objects to test this. `sentinel` provides a convenient way of creating and testing the identity of objects like this.

In this example we monkey patch method to return `sentinel.some_object`:

```
>>> real = ProductionClass()
>>> real.method = Mock(name="method")
>>> real.method.return_value = sentinel.some_object
>>> result = real.method()
>>> assert result is sentinel.some_object
>>> sentinel.some_object
sentinel.some_object
```

## DEFAULT

`unittest.mock.DEFAULT`

The `DEFAULT` object is a pre-created sentinel (actually `sentinel.DEFAULT`). It can be used by `side_effect` functions to indicate that the normal return value should be used.

## call

`unittest.mock.call(*args, **kwargs)`

`call()` is a helper object for making simpler assertions, for comparing with `call_args`, `call_args_list`, `mock_calls` and `method_calls`. `call()` can also be used with `assert_has_calls()`.

```
>>> m = MagicMock(return_value=None)
>>> m(1, 2, a='foo', b='bar')
>>> m()
>>> m.call_args_list == [call(1, 2, a='foo', b='bar'), call()]
True
```

`call.call_list()`

For a call object that represents multiple calls, `call_list()` returns a list of all the intermediate calls as well as the final call.

`call_list` is particularly useful for making assertions on "chained calls". A chained call is multiple calls on a single line of code. This results in multiple entries in `mock_calls` on a mock. Manually constructing the sequence of calls can be tedious.

`call_list()` can construct the sequence of calls from the same chained call:

```
>>> m = MagicMock()
>>> m(1).method(arg='foo').other('bar')(2.0)
<MagicMock name='mock().method().other()' id='...'>
>>> kall = call(1).method(arg='foo').other('bar')(2.0)
>>> kall.call_list()
[call(1),
 call().method(arg='foo'),
 call().method().other('bar'),
 call().method().other()(2.0)]
>>> m.mock_calls == kall.call_list()
True
```

A `call` object is either a tuple of (positional args, keyword args) or (name, positional args, keyword args) depending on how it was constructed. When you construct them yourself this isn't particularly interesting, but the `call` objects that are in the `Mock.call_args`, `Mock.call_args_list` and `Mock.mock_calls` attributes can be introspected to get at the individual arguments they contain.

The `call` objects in `Mock.call_args` and `Mock.call_args_list` are two-tuples of (positional args, keyword args) whereas the `call` objects in `Mock.mock_calls`, along with ones you construct yourself, are three-tuples of (name, positional args, keyword args).

You can use their "tupleness" to pull out the individual arguments for more complex introspection and assertions. The positional arguments are a tuple (an empty tuple if there are no positional arguments) and the keyword arguments are a dictionary:

```
>>> m = MagicMock(return_value=None)
>>> m(1, 2, 3, arg='one', arg2='two')
>>> kall = m.call_args
>>> kall.args
(1, 2, 3)
>>> kall.kwargs
{'arg': 'one', 'arg2': 'two'}
>>> kall.args is kall[0]
True
>>> kall.kwargs is kall[1]
True
```

```
>>> m = MagicMock()
>>> m.foo(4, 5, 6, arg='two', arg2='three')
<MagicMock name='mock.foo()' id='...'>
>>> kall = m.mock_calls[0]
>>> name, args, kwargs = kall
>>> name
'foo'
>>> args
(4, 5, 6)
>>> kwargs
{'arg': 'two', 'arg2': 'three'}
>>> name is m.mock_calls[0][0]
True
```

### create\_autospec

`unittest.mock.create_autospec(spec, spec_set=False, instance=False, **kwargs)`

Create a mock object using another object as a spec. Attributes on the mock will use the corresponding attribute on the `spec` object as their spec.

Functions or methods being mocked will have their arguments checked to ensure that they are called with the correct signature.

If `spec_set` is `True` then attempting to set attributes that don't exist on the spec object will raise an `AttributeError`.

If a class is used as a spec then the return value of the mock (the instance of the class) will have the same spec. You can use a class as the spec for an instance object by passing `instance=True`. The returned mock will only be callable if instances of the mock are callable.

`create_autospec()` also takes arbitrary keyword arguments that are passed to the constructor of the created mock.

See *Autospeccing* for examples of how to use auto-speccing with `create_autospec()` and the `autospec` argument to `patch()`.

Berubah pada versi 3.8: `create_autospec()` now returns an `AsyncMock` if the target is an async function.

## ANY

`unittest.mock.ANY`

Sometimes you may need to make assertions about *some* of the arguments in a call to mock, but either not care about some of the arguments or want to pull them individually out of `call_args` and make more complex assertions on them.

To ignore certain arguments you can pass in objects that compare equal to *everything*. Calls to `assert_called_with()` and `assert_called_once_with()` will then succeed no matter what was passed in.

```

>>> mock = Mock(return_value=None)
>>> mock('foo', bar=object())
>>> mock.assert_called_once_with('foo', bar=ANY)

```

`ANY` can also be used in comparisons with call lists like `mock_calls`:

```

>>> m = MagicMock(return_value=None)
>>> m(1)
>>> m(1, 2)
>>> m(object())
>>> m.mock_calls == [call(1), call(1, 2), ANY]
True

```

## FILTER\_DIR

`unittest.mock.FILTER_DIR`

`FILTER_DIR` is a module level variable that controls the way mock objects respond to `dir()` (only for Python 2.6 or more recent). The default is `True`, which uses the filtering described below, to only show useful members. If you dislike this filtering, or need to switch it off for diagnostic purposes, then set `mock.FILTER_DIR = False`.

With filtering on, `dir(some_mock)` shows only useful attributes and will include any dynamically created attributes that wouldn't normally be shown. If the mock was created with a *spec* (or *autospec* of course) then all the attributes from the original are shown, even if they haven't been accessed yet:

```

>>> dir(Mock())
['assert_any_call',
 'assert_called',
 'assert_called_once',
 'assert_called_once_with',
 'assert_called_with',
 'assert_has_calls',
 'assert_not_called',
 'attach_mock',
 ...
>>> from urllib import request
>>> dir(Mock(spec=request))
['AbstractBasicAuthHandler',
 'AbstractDigestAuthHandler',
 'AbstractHTTPHandler',
 'BaseHandler',
 ...

```

Many of the not-very-useful (private to `Mock` rather than the thing being mocked) underscore and double underscore prefixed attributes have been filtered from the result of calling `dir()` on a `Mock`. If you dislike this behaviour you can switch it off by setting the module level switch `FILTER_DIR`:

```
>>> from unittest import mock
>>> mock.FILTER_DIR = False
>>> dir(mock.Mock())
['_NonCallableMock__get_return_value',
 '_NonCallableMock__get_side_effect',
 '_NonCallableMock__return_value_doc',
 '_NonCallableMock__set_return_value',
 '_NonCallableMock__set_side_effect',
 '__call__',
 '__class__',
 ...]
```

Alternatively you can just use `vars(my_mock)` (instance members) and `dir(type(my_mock))` (type members) to bypass the filtering irrespective of `mock.FILTER_DIR`.

## mock\_open

`unittest.mock.mock_open(mock=None, read_data=None)`

A helper function to create a mock to replace the use of `open()`. It works for `open()` called directly or used as a context manager.

The `mock` argument is the mock object to configure. If `None` (the default) then a *MagicMock* will be created for you, with the API limited to methods or attributes available on standard file handles.

`read_data` is a string for the `read()`, `readline()`, and `readlines()` methods of the file handle to return. Calls to those methods will take data from `read_data` until it is depleted. The mock of these methods is pretty simplistic: every time the `mock` is called, the `read_data` is rewound to the start. If you need more control over the data that you are feeding to the tested code you will need to customize this mock for yourself. When that is insufficient, one of the in-memory filesystem packages on [PyPI](#) can offer a realistic filesystem for testing.

Berubah pada versi 3.4: Added `readline()` and `readlines()` support. The mock of `read()` changed to consume `read_data` rather than returning it on each call.

Berubah pada versi 3.5: `read_data` is now reset on each call to the `mock`.

Berubah pada versi 3.8: Added `__iter__()` to implementation so that iteration (such as in for loops) correctly consumes `read_data`.

Using `open()` as a context manager is a great way to ensure your file handles are closed properly and is becoming common:

```
with open('/some/path', 'w') as f:
    f.write('something')
```

The issue is that even if you mock out the call to `open()` it is the *returned object* that is used as a context manager (and has `__enter__()` and `__exit__()` called).

Mocking context managers with a *MagicMock* is common enough and fiddly enough that a helper function is useful.

```
>>> m = mock_open()
>>> with patch('__main__.open', m):
...     with open('foo', 'w') as h:
...         h.write('some stuff')
...
>>> m.mock_calls
[call('foo', 'w'),
 call().__enter__(),
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

call().write('some stuff'),
call().__exit__(None, None, None)]
>>> m.assert_called_once_with('foo', 'w')
>>> handle = m()
>>> handle.write.assert_called_once_with('some stuff')

```

And for reading files:

```

>>> with patch('__main__.open', mock_open(read_data='bibble')) as m:
...     with open('foo') as h:
...         result = h.read()
...
>>> m.assert_called_once_with('foo')
>>> assert result == 'bibble'

```

## Autospeccing

Autospeccing is based on the existing `spec` feature of `mock`. It limits the api of mocks to the api of an original object (the spec), but it is recursive (implemented lazily) so that attributes of mocks only have the same api as the attributes of the spec. In addition mocked functions / methods have the same call signature as the original so they raise a `TypeError` if they are called incorrectly.

Before I explain how auto-speccing works, here's why it is needed.

`Mock` is a very powerful and flexible object, but it suffers from two flaws when used to mock out objects from a system under test. One of these flaws is specific to the `Mock` api and the other is a more general problem with using mock objects.

First the problem specific to `Mock`. `Mock` has two assert methods that are extremely handy: `assert_called_with()` and `assert_called_once_with()`.

```

>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(1, 2, 3)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(1, 2, 3)
Traceback (most recent call last):
...
AssertionError: Expected 'mock' to be called once. Called 2 times.

```

Because mocks auto-create attributes on demand, and allow you to call them with arbitrary arguments, if you misspell one of these assert methods then your assertion is gone:

```

>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assret_called_once_with(4, 5, 6)

```

Your tests can pass silently and incorrectly because of the typo.

The second issue is more general to mocking. If you refactor some of your code, rename members and so on, any tests for code that is still using the *old api* but uses mocks instead of the real objects will still pass. This means your tests can all pass even though your code is broken.

Note that this is another reason why you need integration tests as well as unit tests. Testing everything in isolation is all fine and dandy, but if you don't test how your units are "wired together" there is still lots of room for bugs that tests might have caught.

mock already provides a feature to help with this, called speccking. If you use a class or instance as the `spec` for a mock then you can only access attributes on the mock that exist on the real class:

```
>>> from urllib import request
>>> mock = Mock(spec=request.Request)
>>> mock.assert_called_with
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'assert_called_with'
```

The spec only applies to the mock itself, so we still have the same issue with any methods on the mock:

```
>>> mock.has_data()
<mock.Mock object at 0x...>
>>> mock.has_data.assert_called_with()
```

Auto-speccking solves this problem. You can either pass `autospec=True` to `patch()` / `patch.object()` or use the `create_autospec()` function to create a mock with a spec. If you use the `autospec=True` argument to `patch()` then the object that is being replaced will be used as the spec object. Because the speccking is done "lazily" (the spec is created as attributes on the mock are accessed) you can use it with very complex or deeply nested objects (like modules that import modules that import modules) without a big performance hit.

Here's an example of it in use:

```
>>> from urllib import request
>>> patcher = patch('__main__.request', autospec=True)
>>> mock_request = patcher.start()
>>> request is mock_request
True
>>> mock_request.Request
<MagicMock name='request.Request' spec='Request' id='... '>
```

You can see that `request.Request` has a spec. `request.Request` takes two arguments in the constructor (one of which is *self*). Here's what happens if we try to call it incorrectly:

```
>>> req = request.Request()
Traceback (most recent call last):
...
TypeError: <lambda>() takes at least 2 arguments (1 given)
```

The spec also applies to instantiated classes (i.e. the return value of speccked mocks):

```
>>> req = request.Request('foo')
>>> req
<NonCallableMagicMock name='request.Request()' spec='Request' id='... '>
```

`Request` objects are not callable, so the return value of instantiating our mocked out `request.Request` is a non-callable mock. With the spec in place any typos in our asserts will raise the correct error:

```
>>> req.add_header('spam', 'eggs')
<MagicMock name='request.Request().add_header()' id='... '>
>>> req.add_header.assert_called_with
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'assert_called_with'
>>> req.add_header.assert_called_with('spam', 'eggs')
```

In many cases you will just be able to add `autospec=True` to your existing `patch()` calls and then be protected against bugs due to typos and api changes.

As well as using *autospec* through `patch()` there is a `create_autospec()` for creating autospecced mocks directly:

```
>>> from urllib import request
>>> mock_request = create_autospec(request)
>>> mock_request.Request('foo', 'bar')
<NonCallableMagicMock name='mock.Request()' spec='Request' id='... '>
```

This isn't without caveats and limitations however, which is why it is not the default behaviour. In order to know what attributes are available on the spec object, *autospec* has to introspect (access attributes) the spec. As you traverse attributes on the mock a corresponding traversal of the original object is happening under the hood. If any of your specced objects have properties or descriptors that can trigger code execution then you may not be able to use *autospec*. On the other hand it is much better to design your objects so that introspection is safe<sup>4</sup>.

A more serious problem is that it is common for instance attributes to be created in the `__init__()` method and not to exist on the class at all. *autospec* can't know about any dynamically created attributes and restricts the api to visible attributes.

```
>>> class Something:
...     def __init__(self):
...         self.a = 33
...
>>> with patch('__main__.Something', autospec=True):
...     thing = Something()
...     thing.a
...
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'a'
```

There are a few different ways of resolving this problem. The easiest, but not necessarily the least annoying, way is to simply set the required attributes on the mock after creation. Just because *autospec* doesn't allow you to fetch attributes that don't exist on the spec it doesn't prevent you setting them:

```
>>> with patch('__main__.Something', autospec=True):
...     thing = Something()
...     thing.a = 33
...
...
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'a'
```

There is a more aggressive version of both *spec* and *autospec* that *does* prevent you setting non-existent attributes. This is useful if you want to ensure your code only *sets* valid attributes too, but obviously it prevents this particular scenario:

```
>>> with patch('__main__.Something', autospec=True, spec_set=True):
...     thing = Something()
...     thing.a = 33
...
...
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'a'
```

Probably the best way of solving the problem is to add class attributes as default values for instance members initialised in `__init__()`. Note that if you are only setting default attributes in `__init__()` then providing them via class attributes (shared between instances of course) is faster too. e.g.

<sup>4</sup> This only applies to classes or already instantiated objects. Calling a mocked class to create a mock instance *does not* create a real instance. It is only attribute lookups - along with calls to `dir()` - that are done.

```
class Something:
    a = 33
```

This brings up another issue. It is relatively common to provide a default value of `None` for members that will later be an object of a different type. `None` would be useless as a spec because it wouldn't let you access *any* attributes or methods on it. As `None` is *never* going to be useful as a spec, and probably indicates a member that will normally of some other type, `autospec` doesn't use a spec for members that are set to `None`. These will just be ordinary mocks (well - `MagicMocks`):

```
>>> class Something:
...     member = None
...
>>> mock = create_autospec(Something)
>>> mock.member.foo.bar.baz()
<MagicMock name='mock.member.foo.bar.baz()' id='...'>
```

If modifying your production classes to add defaults isn't to your liking then there are more options. One of these is simply to use an instance as the spec rather than the class. The other is to create a subclass of the production class and add the defaults to the subclass without affecting the production class. Both of these require you to use an alternative object as the spec. Thankfully `patch()` supports this - you can simply pass the alternative object as the *autospec* argument:

```
>>> class Something:
...     def __init__(self):
...         self.a = 33
...
>>> class SomethingForTest(Something):
...     a = 33
...
>>> p = patch('__main__.Something', autospec=SomethingForTest)
>>> mock = p.start()
>>> mock.a
<NonCallableMagicMock name='Something.a' spec='int' id='...'>
```

## Sealing mocks

`unittest.mock.seal(mock)`

Seal will disable the automatic creation of mocks when accessing an attribute of the mock being sealed or any of its attributes that are already mocks recursively.

If a mock instance with a name or a spec is assigned to an attribute it won't be considered in the sealing chain. This allows one to prevent seal from fixing part of the mock object.

```
>>> mock = Mock()
>>> mock.submock.attribute1 = 2
>>> mock.not_submock = mock.Mock(name="sample_name")
>>> seal(mock)
>>> mock.new_attribute # This will raise AttributeError.
>>> mock.submock.attribute2 # This will raise AttributeError.
>>> mock.not_submock.attribute2 # This won't raise.
```

## 26.6 unittest.mock --- getting started

Baru pada versi 3.3.

### 26.6.1 Using Mock

#### Mock Patching Methods

Common uses for *Mock* objects include:

- Patching methods
- Recording method calls on objects

You might want to replace a method on an object to check that it is called with the correct arguments by another part of the system:

```
>>> real = SomeClass()
>>> real.method = MagicMock(name='method')
>>> real.method(3, 4, 5, key='value')
<MagicMock name='method()' id='...'>
```

Once our mock has been used (`real.method` in this example) it has methods and attributes that allow you to make assertions about how it has been used.

---

**Catatan:** In most of these examples the *Mock* and *MagicMock* classes are interchangeable. As the *MagicMock* is the more capable class it makes a sensible one to use by default.

---

Once the mock has been called its *called* attribute is set to `True`. More importantly we can use the *assert\_called\_with()* or *assert\_called\_once\_with()* method to check that it was called with the correct arguments.

This example tests that calling `ProductionClass().method` results in a call to the `something` method:

```
>>> class ProductionClass:
...     def method(self):
...         self.something(1, 2, 3)
...     def something(self, a, b, c):
...         pass
...
>>> real = ProductionClass()
>>> real.something = MagicMock()
>>> real.method()
>>> real.something.assert_called_once_with(1, 2, 3)
```

## Mock for Method Calls on an Object

In the last example we patched a method directly on an object to check that it was called correctly. Another common use case is to pass an object into a method (or some part of the system under test) and then check that it is used in the correct way.

The simple `ProductionClass` below has a `closer` method. If it is called with an object then it calls `close` on it.

```
>>> class ProductionClass:
...     def closer(self, something):
...         something.close()
... 
```

So to test it we need to pass in an object with a `close` method and check that it was called correctly.

```
>>> real = ProductionClass()
>>> mock = Mock()
>>> real.closer(mock)
>>> mock.close.assert_called_with()
```

We don't have to do any work to provide the 'close' method on our mock. Accessing `close` creates it. So, if 'close' hasn't already been called then accessing it in the test will create it, but `assert_called_with()` will raise a failure exception.

## Mocking Classes

A common use case is to mock out classes instantiated by your code under test. When you patch a class, then that class is replaced with a mock. Instances are created by *calling the class*. This means you access the "mock instance" by looking at the return value of the mocked class.

In the example below we have a function `some_function` that instantiates `Foo` and calls a method on it. The call to `patch()` replaces the class `Foo` with a mock. The `Foo` instance is the result of calling the mock, so it is configured by modifying the mock `return_value`.

```
>>> def some_function():
...     instance = module.Foo()
...     return instance.method()
...
>>> with patch('module.Foo') as mock:
...     instance = mock.return_value
...     instance.method.return_value = 'the result'
...     result = some_function()
...     assert result == 'the result'
```

## Naming your mocks

It can be useful to give your mocks a name. The name is shown in the repr of the mock and can be helpful when the mock appears in test failure messages. The name is also propagated to attributes or methods of the mock:

```
>>> mock = MagicMock(name='foo')
>>> mock
<MagicMock name='foo' id='...'>
>>> mock.method
<MagicMock name='foo.method' id='...'>
```

## Tracking all Calls

Often you want to track more than a single call to a method. The `mock_calls` attribute records all calls to child attributes of the mock - and also to their children.

```
>>> mock = MagicMock()
>>> mock.method()
<MagicMock name='mock.method()' id='...'>
>>> mock.attribute.method(10, x=53)
<MagicMock name='mock.attribute.method()' id='...'>
>>> mock.mock_calls
[call.method(), call.attribute.method(10, x=53)]
```

If you make an assertion about `mock_calls` and any unexpected methods have been called, then the assertion will fail. This is useful because as well as asserting that the calls you expected have been made, you are also checking that they were made in the right order and with no additional calls:

You use the `call` object to construct lists for comparing with `mock_calls`:

```
>>> expected = [call.method(), call.attribute.method(10, x=53)]
>>> mock.mock_calls == expected
True
```

However, parameters to calls that return mocks are not recorded, which means it is not possible to track nested calls where the parameters used to create ancestors are important:

```
>>> m = Mock()
>>> m.factory(important=True).deliver()
<Mock name='mock.factory().deliver()' id='...'>
>>> m.mock_calls[-1] == call.factory(important=False).deliver()
True
```

## Setting Return Values and Attributes

Setting the return values on a mock object is trivially easy:

```
>>> mock = Mock()
>>> mock.return_value = 3
>>> mock()
3
```

Of course you can do the same for methods on the mock:

```
>>> mock = Mock()
>>> mock.method.return_value = 3
>>> mock.method()
3
```

The return value can also be set in the constructor:

```
>>> mock = Mock(return_value=3)
>>> mock()
3
```

If you need an attribute setting on your mock, just do it:

```
>>> mock = Mock()
>>> mock.x = 3
>>> mock.x
3
```

Sometimes you want to mock up a more complex situation, like for example `mock.connection.cursor().execute("SELECT 1")`. If we wanted this call to return a list, then we have to configure the result of the nested call.

We can use `call` to construct the set of calls in a “chained call” like this for easy assertion afterwards:

```
>>> mock = Mock()
>>> cursor = mock.connection.cursor.return_value
>>> cursor.execute.return_value = ['foo']
>>> mock.connection.cursor().execute("SELECT 1")
['foo']
>>> expected = call.connection.cursor().execute("SELECT 1").call_list()
>>> mock.mock_calls
[call.connection.cursor(), call.connection.cursor().execute('SELECT 1')]
>>> mock.mock_calls == expected
True
```

It is the call to `.call_list()` that turns our call object into a list of calls representing the chained calls.

### Raising exceptions with mocks

A useful attribute is `side_effect`. If you set this to an exception class or instance then the exception will be raised when the mock is called.

```
>>> mock = Mock(side_effect=Exception('Boom!'))
>>> mock()
Traceback (most recent call last):
...
Exception: Boom!
```

### Side effect functions and iterables

`side_effect` can also be set to a function or an iterable. The use case for `side_effect` as an iterable is where your mock is going to be called several times, and you want each call to return a different value. When you set `side_effect` to an iterable every call to the mock returns the next value from the iterable:

```
>>> mock = MagicMock(side_effect=[4, 5, 6])
>>> mock()
4
>>> mock()
5
>>> mock()
6
```

For more advanced use cases, like dynamically varying the return values depending on what the mock is called with, `side_effect` can be a function. The function will be called with the same arguments as the mock. Whatever the function returns is what the call returns:

```

>>> vals = {(1, 2): 1, (2, 3): 2}
>>> def side_effect(*args):
...     return vals[args]
...
>>> mock = MagicMock(side_effect=side_effect)
>>> mock(1, 2)
1
>>> mock(2, 3)
2

```

## Mocking asynchronous iterators

Since Python 3.8, AsyncMock and MagicMock have support to mock async-iterators through `__aiter__`. The `return_value` attribute of `__aiter__` can be used to set the return values to be used for iteration.

```

>>> mock = MagicMock() # AsyncMock also works here
>>> mock.__aiter__.return_value = [1, 2, 3]
>>> async def main():
...     return [i async for i in mock]
...
>>> asyncio.run(main())
[1, 2, 3]

```

## Mocking asynchronous context manager

Since Python 3.8, AsyncMock and MagicMock have support to mock async-context-managers through `__aenter__` and `__aexit__`. By default, `__aenter__` and `__aexit__` are AsyncMock instances that return an async function.

```

>>> class AsyncContextManager:
...     async def __aenter__(self):
...         return self
...     async def __aexit__(self, exc_type, exc, tb):
...         pass
...
>>> mock_instance = MagicMock(AsyncContextManager()) # AsyncMock also works here
>>> async def main():
...     async with mock_instance as result:
...         pass
...
>>> asyncio.run(main())
>>> mock_instance.__aenter__.assert_awaited_once()
>>> mock_instance.__aexit__.assert_awaited_once()

```

## Creating a Mock from an Existing Object

One problem with over use of mocking is that it couples your tests to the implementation of your mocks rather than your real code. Suppose you have a class that implements `some_method`. In a test for another class, you provide a mock of this object that *also* provides `some_method`. If later you refactor the first class, so that it no longer has `some_method` - then your tests will continue to pass even though your code is now broken!

`Mock` allows you to provide an object as a specification for the mock, using the `spec` keyword argument. Accessing methods / attributes on the mock that don't exist on your specification object will immediately raise an attribute error. If you change the implementation of your specification, then tests that use that class will start failing immediately without you having to instantiate the class in those tests.

```
>>> mock = Mock(spec=SomeClass)
>>> mock.old_method()
Traceback (most recent call last):
...
AttributeError: object has no attribute 'old_method'
```

Using a specification also enables a smarter matching of calls made to the mock, regardless of whether some parameters were passed as positional or named arguments:

```
>>> def f(a, b, c): pass
...
>>> mock = Mock(spec=f)
>>> mock(1, 2, 3)
<Mock name='mock()' id='140161580456576'>
>>> mock.assert_called_with(a=1, b=2, c=3)
```

If you want this smarter matching to also work with method calls on the mock, you can use *auto-specing*.

If you want a stronger form of specification that prevents the setting of arbitrary attributes as well as the getting of them then you can use `spec_set` instead of `spec`.

## 26.6.2 Patch Decorators

---

**Catatan:** With `patch()` it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read *where to patch*.

---

A common need in tests is to patch a class attribute or a module attribute, for example patching a builtin or patching a class in a module to test that it is instantiated. Modules and classes are effectively global, so patching on them has to be undone after the test or the patch will persist into other tests and cause hard to diagnose problems.

`mock` provides three convenient decorators for this: `patch()`, `patch.object()` and `patch.dict()`. `patch` takes a single string, of the form `package.module.Class.attribute` to specify the attribute you are patching. It also optionally takes a value that you want the attribute (or class or whatever) to be replaced with. `'patch.object'` takes an object and the name of the attribute you would like patched, plus optionally the value to patch it with.

`patch.object`:

```
>>> original = SomeClass.attribute
>>> @patch.object(SomeClass, 'attribute', sentinel.attribute)
... def test():
...     assert SomeClass.attribute == sentinel.attribute
...
>>> test()
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> assert SomeClass.attribute == original

>>> @patch('package.module.attribute', sentinel.attribute)
... def test():
...     from package.module import attribute
...     assert attribute is sentinel.attribute
...
>>> test()
```

If you are patching a module (including *builtins*) then use *patch()* instead of *patch.object()*:

```
>>> mock = MagicMock(return_value=sentinel.file_handle)
>>> with patch('builtins.open', mock):
...     handle = open('filename', 'r')
...
>>> mock.assert_called_with('filename', 'r')
>>> assert handle == sentinel.file_handle, "incorrect file handle returned"
```

The module name can be 'dotted', in the form *package.module* if needed:

```
>>> @patch('package.module.ClassName.attribute', sentinel.attribute)
... def test():
...     from package.module import ClassName
...     assert ClassName.attribute == sentinel.attribute
...
>>> test()
```

A nice pattern is to actually decorate test methods themselves:

```
>>> class MyTest(unittest.TestCase):
...     @patch.object(SomeClass, 'attribute', sentinel.attribute)
...     def test_something(self):
...         self.assertEqual(SomeClass.attribute, sentinel.attribute)
...
>>> original = SomeClass.attribute
>>> MyTest('test_something').test_something()
>>> assert SomeClass.attribute == original
```

If you want to patch with a Mock, you can use *patch()* with only one argument (or *patch.object()* with two arguments). The mock will be created for you and passed into the test function / method:

```
>>> class MyTest(unittest.TestCase):
...     @patch.object(SomeClass, 'static_method')
...     def test_something(self, mock_method):
...         SomeClass.static_method()
...         mock_method.assert_called_with()
...
>>> MyTest('test_something').test_something()
```

You can stack up multiple patch decorators using this pattern:

```
>>> class MyTest(unittest.TestCase):
...     @patch('package.module.ClassName1')
...     @patch('package.module.ClassName2')
...     def test_something(self, MockClass2, MockClass1):
...         self.assertIs(package.module.ClassName1, MockClass1)
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
...         self.assertIs(package.module.ClassName2, MockClass2)
...
>>> MyTest('test_something').test_something()
```

When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal *Python* order that decorators are applied). This means from the bottom up, so in the example above the mock for `test_module.ClassName2` is passed in first.

There is also `patch.dict()` for setting values in a dictionary just during a scope and restoring the dictionary to its original state when the test ends:

```
>>> foo = {'key': 'value'}
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=True):
...     assert foo == {'newkey': 'newvalue'}
...
>>> assert foo == original
```

`patch`, `patch.object` and `patch.dict` can all be used as context managers.

Where you use `patch()` to create a mock for you, you can get a reference to the mock using the “as” form of the with statement:

```
>>> class ProductionClass:
...     def method(self):
...         pass
...
>>> with patch.object(ProductionClass, 'method') as mock_method:
...     mock_method.return_value = None
...     real = ProductionClass()
...     real.method(1, 2, 3)
...
>>> mock_method.assert_called_with(1, 2, 3)
```

As an alternative `patch`, `patch.object` and `patch.dict` can be used as class decorators. When used in this way it is the same as applying the decorator individually to every method whose name starts with “test”.

## 26.6.3 Further Examples

Here are some more examples for some slightly more advanced scenarios.

### Mocking chained calls

Mocking chained calls is actually straightforward with mock once you understand the `return_value` attribute. When a mock is called for the first time, or you fetch its `return_value` before it has been called, a new *Mock* is created.

This means that you can see how the object returned from a call to a mocked object has been used by interrogating the `return_value` mock:

```
>>> mock = Mock()
>>> mock().foo(a=2, b=3)
<Mock name='mock().foo()' id='...'>
>>> mock.return_value.foo.assert_called_with(a=2, b=3)
```

From here it is a simple step to configure and then make assertions about chained calls. Of course another alternative is writing your code in a more testable way in the first place...

So, suppose we have some code that looks a little bit like this:

```
>>> class Something:
...     def __init__(self):
...         self.backend = BackendProvider()
...     def method(self):
...         response = self.backend.get_endpoint('foobar').create_call('spam', 'eggs
↳').start_call()
...         # more code
```

Assuming that `BackendProvider` is already well tested, how do we test `method()`? Specifically, we want to test that the code section `# more code` uses the response object in the correct way.

As this chain of calls is made from an instance attribute we can monkey patch the `backend` attribute on a `Something` instance. In this particular case we are only interested in the return value from the final call to `start_call` so we don't have much configuration to do. Let's assume the object it returns is 'file-like', so we'll ensure that our response object uses the builtin `open()` as its spec.

To do this we create a mock instance as our mock backend and create a mock response object for it. To set the response as the return value for that final `start_call` we could do this:

```
mock_backend.get_endpoint.return_value.create_call.return_value.start_call.return_
↳value = mock_response
```

We can do that in a slightly nicer way using the `configure_mock()` method to directly set the return value for us:

```
>>> something = Something()
>>> mock_response = Mock(spec=open)
>>> mock_backend = Mock()
>>> config = {'get_endpoint.return_value.create_call.return_value.start_call.return_
↳value': mock_response}
>>> mock_backend.configure_mock(**config)
```

With these we monkey patch the "mock backend" in place and can make the real call:

```
>>> something.backend = mock_backend
>>> something.method()
```

Using `mock_calls` we can check the chained call with a single assert. A chained call is several calls in one line of code, so there will be several entries in `mock_calls`. We can use `call.call_list()` to create this list of calls for us:

```
>>> chained = call.get_endpoint('foobar').create_call('spam', 'eggs').start_call()
>>> call_list = chained.call_list()
>>> assert mock_backend.mock_calls == call_list
```

## Partial mocking

In some tests I wanted to mock out a call to `datetime.date.today()` to return a known date, but I didn't want to prevent the code under test from creating new date objects. Unfortunately `datetime.date` is written in C, and so I couldn't just monkey-patch out the static `date.today()` method.

I found a simple way of doing this that involved effectively wrapping the date class with a mock, but passing through calls to the constructor to the real class (and returning real instances).

The `patch decorator` is used here to mock out the `date` class in the module under test. The `side_effect` attribute on the mock date class is then set to a lambda function that returns a real date. When the mock date class is called a real date will be constructed and returned by `side_effect`.

```
>>> from datetime import date
>>> with patch('mymodule.date') as mock_date:
...     mock_date.today.return_value = date(2010, 10, 8)
...     mock_date.side_effect = lambda *args, **kw: date(*args, **kw)
...
...     assert mymodule.date.today() == date(2010, 10, 8)
...     assert mymodule.date(2009, 6, 8) == date(2009, 6, 8)
```

Note that we don't patch `datetime.date` globally, we patch `date` in the module that *uses* it. See [where to patch](#).

When `date.today()` is called a known date is returned, but calls to the `date(...)` constructor still return normal dates. Without this you can find yourself having to calculate an expected result using exactly the same algorithm as the code under test, which is a classic testing anti-pattern.

Calls to the date constructor are recorded in the `mock_date` attributes (`call_count` and `friends`) which may also be useful for your tests.

An alternative way of dealing with mocking dates, or other builtin classes, is discussed in [this blog entry](#).

## Mocking a Generator Method

A Python generator is a function or method that uses the `yield` statement to return a series of values when iterated over<sup>1</sup>.

A generator method / function is called to return the generator object. It is the generator object that is then iterated over. The protocol method for iteration is `__iter__()`, so we can mock this using a `MagicMock`.

Here's an example class with an "iter" method implemented as a generator:

```
>>> class Foo:
...     def iter(self):
...         for i in [1, 2, 3]:
...             yield i
...
>>> foo = Foo()
>>> list(foo.iter())
[1, 2, 3]
```

How would we mock this class, and in particular its "iter" method?

To configure the values returned from the iteration (implicit in the call to `list`), we need to configure the object returned by the call to `foo.iter()`.

---

<sup>1</sup> There are also generator expressions and more [advanced uses](#) of generators, but we aren't concerned about them here. A very good introduction to generators and how powerful they are is: [Generator Tricks for Systems Programmers](#).

```
>>> mock_foo = MagicMock()
>>> mock_foo.iter.return_value = iter([1, 2, 3])
>>> list(mock_foo.iter())
[1, 2, 3]
```

### Applying the same patch to every test method

If you want several patches in place for multiple test methods the obvious way is to apply the patch decorators to every method. This can feel like unnecessary repetition. For Python 2.6 or more recent you can use `patch()` (in all its various forms) as a class decorator. This applies the patches to all test methods on the class. A test method is identified by methods whose names start with `test`:

```
>>> @patch('mymodule.SomeClass')
... class MyTest(unittest.TestCase):
...     def test_one(self, MockSomeClass):
...         self.assertIs(mymodule.SomeClass, MockSomeClass)
...     def test_two(self, MockSomeClass):
...         self.assertIs(mymodule.SomeClass, MockSomeClass)
...     def not_a_test(self):
...         return 'something'
...
>>> MyTest('test_one').test_one()
>>> MyTest('test_two').test_two()
>>> MyTest('test_two').not_a_test()
'something'
```

An alternative way of managing patches is to use the *patch methods: start and stop*. These allow you to move the patching into your `setUp` and `tearDown` methods.

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         self.patcher = patch('mymodule.foo')
...         self.mock_foo = self.patcher.start()
...     def test_foo(self):
...         self.assertIs(mymodule.foo, self.mock_foo)
...     def tearDown(self):
...         self.patcher.stop()
...
>>> MyTest('test_foo').run()
```

If you use this technique you must ensure that the patching is “undone” by calling `stop`. This can be fiddlier than you might think, because if an exception is raised in the `setUp` then `tearDown` is not called. `unittest.TestCase.addCleanup()` makes this easier:

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         patcher = patch('mymodule.foo')
...         self.addCleanup(patcher.stop)
...         self.mock_foo = patcher.start()
...     def test_foo(self):
...         self.assertIs(mymodule.foo, self.mock_foo)
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
...     def test_foo(self):
...         self.assertIs(mymodule.foo, self.mock_foo)
...
>>> MyTest('test_foo').run()
```

## Mocking Unbound Methods

Whilst writing tests today I needed to patch an *unbound method* (patching the method on the class rather than on the instance). I needed self to be passed in as the first argument because I want to make asserts about which objects were calling this particular method. The issue is that you can't patch with a mock for this, because if you replace an unbound method with a mock it doesn't become a bound method when fetched from the instance, and so it doesn't get self passed in. The workaround is to patch the unbound method with a real function instead. The `patch()` decorator makes it so simple to patch out methods with a mock that having to create a real function becomes a nuisance.

If you pass `autospec=True` to patch then it does the patching with a *real* function object. This function object has the same signature as the one it is replacing, but delegates to a mock under the hood. You still get your mock auto-created in exactly the same way as before. What it means though, is that if you use it to patch out an unbound method on a class the mocked function will be turned into a bound method if it is fetched from an instance. It will have `self` passed in as the first argument, which is exactly what I wanted:

```
>>> class Foo:
...     def foo(self):
...         pass
...
>>> with patch.object(Foo, 'foo', autospec=True) as mock_foo:
...     mock_foo.return_value = 'foo'
...     foo = Foo()
...     foo.foo()
...
'foo'
>>> mock_foo.assert_called_once_with(foo)
```

If we don't use `autospec=True` then the unbound method is patched out with a Mock instance instead, and isn't called with `self`.

## Checking multiple calls with mock

mock has a nice API for making assertions about how your mock objects are used.

```
>>> mock = Mock()
>>> mock.foo_bar.return_value = None
>>> mock.foo_bar('baz', spam='eggs')
>>> mock.foo_bar.assert_called_with('baz', spam='eggs')
```

If your mock is only being called once you can use the `assert_called_once_with()` method that also asserts that the `call_count` is one.

```
>>> mock.foo_bar.assert_called_once_with('baz', spam='eggs')
>>> mock.foo_bar()
>>> mock.foo_bar.assert_called_once_with('baz', spam='eggs')
Traceback (most recent call last):
...
AssertionError: Expected to be called once. Called 2 times.
```

Both `assert_called_with` and `assert_called_once_with` make assertions about the *most recent* call. If your mock is going to be called several times, and you want to make assertions about *all* those calls you can use `call_args_list`:

```
>>> mock = Mock(return_value=None)
>>> mock(1, 2, 3)
>>> mock(4, 5, 6)
>>> mock()
>>> mock.call_args_list
[call(1, 2, 3), call(4, 5, 6), call()]
```

The `call` helper makes it easy to make assertions about these calls. You can build up a list of expected calls and compare it to `call_args_list`. This looks remarkably similar to the repr of the `call_args_list`:

```
>>> expected = [call(1, 2, 3), call(4, 5, 6), call()]
>>> mock.call_args_list == expected
True
```

## Coping with mutable arguments

Another situation is rare, but can bite you, is when your mock is called with mutable arguments. `call_args` and `call_args_list` store *references* to the arguments. If the arguments are mutated by the code under test then you can no longer make assertions about what the values were when the mock was called.

Here's some example code that shows the problem. Imagine the following functions defined in 'mymodule':

```
def frob(val):
    pass

def grob(val):
    "First frob and then clear val"
    frob(val)
    val.clear()
```

When we try to test that `grob` calls `frob` with the correct argument look what happens:

```
>>> with patch('mymodule.frob') as mock_frob:
...     val = {6}
...     mymodule.grob(val)
...
>>> val
set()
>>> mock_frob.assert_called_with({6})
Traceback (most recent call last):
...
AssertionError: Expected: (({6},), {})
Called with: ((set(),), {})
```

One possibility would be for mock to copy the arguments you pass in. This could then cause problems if you do assertions that rely on object identity for equality.

Here's one solution that uses the `side_effect` functionality. If you provide a `side_effect` function for a mock then `side_effect` will be called with the same args as the mock. This gives us an opportunity to copy the arguments and store them for later assertions. In this example I'm using *another* mock to store the arguments so that I can use the mock methods for doing the assertion. Again a helper function sets this up for me.

```
>>> from copy import deepcopy
>>> from unittest.mock import Mock, patch, DEFAULT
>>> def copy_call_args(mock):
...     new_mock = Mock()
...     def side_effect(*args, **kwargs):
...         args = deepcopy(args)
...         kwargs = deepcopy(kwargs)
...         new_mock(*args, **kwargs)
...         return DEFAULT
...     mock.side_effect = side_effect
...     return new_mock
...
>>> with patch('mymodule.frob') as mock_frob:
...     new_mock = copy_call_args(mock_frob)
...     val = {6}
...     mymodule.grob(val)
...
>>> new_mock.assert_called_with({6})
>>> new_mock.call_args
call({6})
```

`copy_call_args` is called with the mock that will be called. It returns a new mock that we do the assertion on. The `side_effect` function makes a copy of the args and calls our `new_mock` with the copy.

---

**Catatan:** If your mock is only going to be used once there is an easier way of checking arguments at the point they are called. You can simply do the checking inside a `side_effect` function.

```
>>> def side_effect(arg):
...     assert arg == {6}
...
>>> mock = Mock(side_effect=side_effect)
>>> mock({6})
>>> mock(set())
Traceback (most recent call last):
...
AssertionError
```

---

An alternative approach is to create a subclass of `Mock` or `MagicMock` that copies (using `copy.deepcopy()`) the arguments. Here's an example implementation:

```
>>> from copy import deepcopy
>>> class CopyingMock(MagicMock):
...     def __call__(self, /, *args, **kwargs):
...         args = deepcopy(args)
...         kwargs = deepcopy(kwargs)
...         return super().__call__(*args, **kwargs)
...
>>> c = CopyingMock(return_value=None)
>>> arg = set()
>>> c(arg)
>>> arg.add(1)
>>> c.assert_called_with(set())
>>> c.assert_called_with(arg)
Traceback (most recent call last):
...
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

AssertionError: Expected call: mock({1})
Actual call: mock(set())
>>> c.foo
<CopyingMock name='mock.foo' id='... '>

```

When you subclass `Mock` or `MagicMock` all dynamically created attributes, and the `return_value` will use your subclass automatically. That means all children of a `CopyingMock` will also have the type `CopyingMock`.

## Nesting Patches

Using `patch` as a context manager is nice, but if you do multiple patches you can end up with nested `with` statements indenting further and further to the right:

```

>>> class MyTest(unittest.TestCase):
...     def test_foo(self):
...         with patch('mymodule.Foo') as mock_foo:
...             with patch('mymodule.Bar') as mock_bar:
...                 with patch('mymodule.Spam') as mock_spam:
...                     assert mymodule.Foo is mock_foo
...                     assert mymodule.Bar is mock_bar
...                     assert mymodule.Spam is mock_spam
...
>>> original = mymodule.Foo
>>> MyTest('test_foo').test_foo()
>>> assert mymodule.Foo is original

```

With `unittest` cleanup functions and the *patch methods: start and stop* we can achieve the same effect without the nested indentation. A simple helper method, `create_patch`, puts the patch in place and returns the created mock for us:

```

>>> class MyTest(unittest.TestCase):
...     def create_patch(self, name):
...         patcher = patch(name)
...         thing = patcher.start()
...         self.addCleanup(patcher.stop)
...         return thing
...
...     def test_foo(self):
...         mock_foo = self.create_patch('mymodule.Foo')
...         mock_bar = self.create_patch('mymodule.Bar')
...         mock_spam = self.create_patch('mymodule.Spam')
...
...         assert mymodule.Foo is mock_foo
...         assert mymodule.Bar is mock_bar
...         assert mymodule.Spam is mock_spam
...
>>> original = mymodule.Foo
>>> MyTest('test_foo').run()
>>> assert mymodule.Foo is original

```

## Mocking a dictionary with MagicMock

You may want to mock a dictionary, or other container object, recording all access to it whilst having it still behave like a dictionary.

We can do this with *MagicMock*, which will behave like a dictionary, and using *side\_effect* to delegate dictionary access to a real underlying dictionary that is under our control.

When the `__getitem__()` and `__setitem__()` methods of our *MagicMock* are called (normal dictionary access) then *side\_effect* is called with the key (and in the case of `__setitem__` the value too). We can also control what is returned.

After the *MagicMock* has been used we can use attributes like *call\_args\_list* to assert about how the dictionary was used:

```
>>> my_dict = {'a': 1, 'b': 2, 'c': 3}
>>> def getitem(name):
...     return my_dict[name]
...
>>> def setitem(name, val):
...     my_dict[name] = val
...
>>> mock = MagicMock()
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem
```

---

**Catatan:** An alternative to using *MagicMock* is to use *Mock* and *only* provide the magic methods you specifically want:

```
>>> mock = Mock()
>>> mock.__getitem__ = Mock(side_effect=getitem)
>>> mock.__setitem__ = Mock(side_effect=setitem)
```

A *third* option is to use *MagicMock* but passing in *dict* as the *spec* (or *spec\_set*) argument so that the *MagicMock* created only has dictionary magic methods available:

```
>>> mock = MagicMock(spec_set=dict)
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem
```

---

With these side effect functions in place, the *mock* will behave like a normal dictionary but recording the access. It even raises a *KeyError* if you try to access a key that doesn't exist.

```
>>> mock['a']
1
>>> mock['c']
3
>>> mock['d']
Traceback (most recent call last):
...
KeyError: 'd'
>>> mock['b'] = 'fish'
>>> mock['d'] = 'eggs'
>>> mock['b']
'fish'
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> mock['d']
'eggs'
```

After it has been used you can make assertions about the access using the normal mock methods and attributes:

```
>>> mock.__getitem__.call_args_list
[call('a'), call('c'), call('d'), call('b'), call('d')]
>>> mock.__setitem__.call_args_list
[call('b', 'fish'), call('d', 'eggs')]
>>> my_dict
{'a': 1, 'b': 'fish', 'c': 3, 'd': 'eggs'}
```

## Mock subclasses and their attributes

There are various reasons why you might want to subclass *Mock*. One reason might be to add helper methods. Here's a silly example:

```
>>> class MyMock(MagicMock):
...     def has_been_called(self):
...         return self.called
...
>>> mymock = MyMock(return_value=None)
>>> mymock
<MyMock id='...'>
>>> mymock.has_been_called()
False
>>> mymock()
>>> mymock.has_been_called()
True
```

The standard behaviour for *Mock* instances is that attributes and the return value mocks are of the same type as the mock they are accessed on. This ensures that *Mock* attributes are *Mocks* and *MagicMock* attributes are *MagicMocks*<sup>2</sup>. So if you're subclassing to add helper methods then they'll also be available on the attributes and return value mock of instances of your subclass.

```
>>> mymock.foo
<MyMock name='mock.foo' id='...'>
>>> mymock.foo.has_been_called()
False
>>> mymock.foo()
<MyMock name='mock.foo()' id='...'>
>>> mymock.foo.has_been_called()
True
```

Sometimes this is inconvenient. For example, [one user](#) is subclassing mock to created a *Twisted* adaptor. Having this applied to attributes too actually causes errors.

*Mock* (in all its flavours) uses a method called `_get_child_mock` to create these "sub-mocks" for attributes and return values. You can prevent your subclass being used for attributes by overriding this method. The signature is that it takes arbitrary keyword arguments (`**kwargs`) which are then passed onto the mock constructor:

<sup>2</sup> An exception to this rule are the non-callable mocks. Attributes use the callable variant because otherwise non-callable mocks couldn't have callable methods.

```
>>> class Subclass(MagicMock):
...     def _get_child_mock(self, /, **kwargs):
...         return MagicMock(**kwargs)
...
>>> mymock = Subclass()
>>> mymock.foo
<MagicMock name='mock.foo' id='...'>
>>> assert isinstance(mymock, Subclass)
>>> assert not isinstance(mymock.foo, Subclass)
>>> assert not isinstance(mymock(), Subclass)
```

## Mocking imports with patch.dict

One situation where mocking can be hard is where you have a local import inside a function. These are harder to mock because they aren't using an object from the module namespace that we can patch out.

Generally local imports are to be avoided. They are sometimes done to prevent circular dependencies, for which there is *usually* a much better way to solve the problem (refactor the code) or to prevent "up front costs" by delaying the import. This can also be solved in better ways than an unconditional local import (store the module as a class or module attribute and only do the import on first use).

That aside there is a way to use `mock` to affect the results of an import. Importing fetches an *object* from the `sys.modules` dictionary. Note that it fetches an *object*, which need not be a module. Importing a module for the first time results in a module object being put in `sys.modules`, so usually when you import something you get a module back. This need not be the case however.

This means you can use `patch.dict()` to *temporarily* put a mock in place in `sys.modules`. Any imports whilst this patch is active will fetch the mock. When the patch is complete (the decorated function exits, the with statement body is complete or `patcher.stop()` is called) then whatever was there previously will be restored safely.

Here's an example that mocks out the 'fooble' module.

```
>>> import sys
>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock}):
...     import fooble
...     fooble.blob()
...
<Mock name='mock.blob()' id='...'>
>>> assert 'fooble' not in sys.modules
>>> mock.blob.assert_called_once_with()
```

As you can see the `import fooble` succeeds, but on exit there is no 'fooble' left in `sys.modules`.

This also works for the `from module import name` form:

```
>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock}):
...     from fooble import blob
...     blob.blip()
...
<Mock name='mock.blob.blip()' id='...'>
>>> mock.blob.blip.assert_called_once_with()
```

With slightly more work you can also mock package imports:

```

>>> mock = Mock()
>>> modules = {'package': mock, 'package.module': mock.module}
>>> with patch.dict('sys.modules', modules):
...     from package.module import fooble
...     fooble()
...
<Mock name='mock.module.fooble()' id='...'>
>>> mock.module.fooble.assert_called_once_with()

```

### Tracking order of calls and less verbose call assertions

The `Mock` class allows you to track the *order* of method calls on your mock objects through the `method_calls` attribute. This doesn't allow you to track the order of calls between separate mock objects, however we can use `mock_calls` to achieve the same effect.

Because mocks track calls to child mocks in `mock_calls`, and accessing an arbitrary attribute of a mock creates a child mock, we can create our separate mocks from a parent one. Calls to those child mock will then all be recorded, in order, in the `mock_calls` of the parent:

```

>>> manager = Mock()
>>> mock_foo = manager.foo
>>> mock_bar = manager.bar

```

```

>>> mock_foo.something()
<Mock name='mock.foo.something()' id='...'>
>>> mock_bar.other.thing()
<Mock name='mock.bar.other.thing()' id='...'>

```

```

>>> manager.mock_calls
[call.foo.something(), call.bar.other.thing()]

```

We can then assert about the calls, including the order, by comparing with the `mock_calls` attribute on the manager mock:

```

>>> expected_calls = [call.foo.something(), call.bar.other.thing()]
>>> manager.mock_calls == expected_calls
True

```

If `patch` is creating, and putting in place, your mocks then you can attach them to a manager mock using the `attach_mock()` method. After attaching calls will be recorded in `mock_calls` of the manager.

```

>>> manager = MagicMock()
>>> with patch('mymodule.Class1') as MockClass1:
...     with patch('mymodule.Class2') as MockClass2:
...         manager.attach_mock(MockClass1, 'MockClass1')
...         manager.attach_mock(MockClass2, 'MockClass2')
...         MockClass1().foo()
...         MockClass2().bar()
<MagicMock name='mock.MockClass1().foo()' id='...'>
<MagicMock name='mock.MockClass2().bar()' id='...'>
>>> manager.mock_calls
[call.MockClass1(),
call.MockClass1().foo(),
call.MockClass2(),
call.MockClass2().bar()]

```

If many calls have been made, but you're only interested in a particular sequence of them then an alternative is to use the `assert_has_calls()` method. This takes a list of calls (constructed with the `call` object). If that sequence of calls are in `mock_calls` then the assert succeeds.

```
>>> m = MagicMock()
>>> m().foo().bar().baz()
<MagicMock name='mock().foo().bar().baz()' id='...'>
>>> m.one().two().three()
<MagicMock name='mock.one().two().three()' id='...'>
>>> calls = call.one().two().three().call_list()
>>> m.assert_has_calls(calls)
```

Even though the chained call `m.one().two().three()` aren't the only calls that have been made to the mock, the assert still succeeds.

Sometimes a mock may have several calls made to it, and you are only interested in asserting about *some* of those calls. You may not even care about the order. In this case you can pass `any_order=True` to `assert_has_calls`:

```
>>> m = MagicMock()
>>> m(1), m.two(2, 3), m.seven(7), m.fifty('50')
(...)
>>> calls = [call.fifty('50'), call(1), call.seven(7)]
>>> m.assert_has_calls(calls, any_order=True)
```

### More complex argument matching

Using the same basic concept as *ANY* we can implement matchers to do more complex assertions on objects used as arguments to mocks.

Suppose we expect some object to be passed to a mock that by default compares equal based on object identity (which is the Python default for user defined classes). To use `assert_called_with()` we would need to pass in the exact same object. If we are only interested in some of the attributes of this object then we can create a matcher that will check these attributes for us.

You can see in this example how a 'standard' call to `assert_called_with` isn't sufficient:

```
>>> class Foo:
...     def __init__(self, a, b):
...         self.a, self.b = a, b
...
>>> mock = Mock(return_value=None)
>>> mock(Foo(1, 2))
>>> mock.assert_called_with(Foo(1, 2))
Traceback (most recent call last):
...
AssertionError: Expected: call(<__main__.Foo object at 0x...>)
Actual call: call(<__main__.Foo object at 0x...>)
```

A comparison function for our `Foo` class might look something like this:

```
>>> def compare(self, other):
...     if not type(self) == type(other):
...         return False
...     if self.a != other.a:
...         return False
...     if self.b != other.b:
...         return False
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
...     return True
...
```

And a matcher object that can use comparison functions like this for its equality operation would look something like this:

```
>>> class Matcher:
...     def __init__(self, compare, some_obj):
...         self.compare = compare
...         self.some_obj = some_obj
...     def __eq__(self, other):
...         return self.compare(self.some_obj, other)
...
```

Putting all this together:

```
>>> match_foo = Matcher(compare, Foo(1, 2))
>>> mock.assert_called_with(match_foo)
```

The `Matcher` is instantiated with our `compare` function and the `Foo` object we want to compare against. In `assert_called_with` the `Matcher` equality method will be called, which compares the object the mock was called with against the one we created our matcher with. If they match then `assert_called_with` passes, and if they don't an `AssertionError` is raised:

```
>>> match_wrong = Matcher(compare, Foo(3, 4))
>>> mock.assert_called_with(match_wrong)
Traceback (most recent call last):
...
AssertionError: Expected: ((<Matcher object at 0x...>,), {})
Called with: ((<Foo object at 0x...>,), {})
```

With a bit of tweaking you could have the comparison function raise the `AssertionError` directly and provide a more useful failure message.

As of version 1.5, the Python testing library `PyHamcrest` provides similar functionality, that may be useful here, in the form of its equality matcher (`hamcrest.library.integration.match_equality`).

## 26.7 2to3 - Automated Python 2 to 3 code translation

2to3 is a Python program that reads Python 2.x source code and applies a series of *fixers* to transform it into valid Python 3.x code. The standard library contains a rich set of fixers that will handle almost all code. 2to3 supporting library `lib2to3` is, however, a flexible and generic library, so it is possible to write your own fixers for 2to3. `lib2to3` could also be adapted to custom applications in which Python code needs to be edited automatically.

## 26.7.1 Menggunakan 2to3

2to3 will usually be installed with the Python interpreter as a script. It is also located in the `Tools/scripts` directory of the Python root.

2to3's basic arguments are a list of files or directories to transform. The directories are recursively traversed for Python sources.

Here is a sample Python 2.x source file, `example.py`:

```
def greet(name):
    print "Hello, {0}!".format(name)
print "What's your name?"
name = raw_input()
greet(name)
```

It can be converted to Python 3.x code via 2to3 on the command line:

```
$ 2to3 example.py
```

A diff against the original source file is printed. 2to3 can also write the needed modifications right back to the source file. (A backup of the original file is made unless `-n` is also given.) Writing the changes back is enabled with the `-w` flag:

```
$ 2to3 -w example.py
```

After transformation, `example.py` looks like this:

```
def greet(name):
    print("Hello, {0}!".format(name))
print("What's your name?")
name = input()
greet(name)
```

Comments and exact indentation are preserved throughout the translation process.

By default, 2to3 runs a set of *predefined fixers*. The `-l` flag lists all available fixers. An explicit set of fixers to run can be given with `-f`. Likewise the `-x` explicitly disables a fixer. The following example runs only the `imports` and `has_key` fixers:

```
$ 2to3 -f imports -f has_key example.py
```

This command runs every fixer except the `apply` fixer:

```
$ 2to3 -x apply example.py
```

Some fixers are *explicit*, meaning they aren't run by default and must be listed on the command line to be run. Here, in addition to the default fixers, the `idioms` fixer is run:

```
$ 2to3 -f all -f idioms example.py
```

Notice how passing `all` enables all default fixers.

Sometimes 2to3 will find a place in your source code that needs to be changed, but 2to3 cannot fix automatically. In this case, 2to3 will print a warning beneath the diff for a file. You should address the warning in order to have compliant 3.x code.

2to3 can also refactor doctests. To enable this mode, use the `-d` flag. Note that *only* doctests will be refactored. This also doesn't require the module to be valid Python. For example, doctest like examples in a reST document could also be refactored with this option.

The `-v` option enables output of more information on the translation process.

Since some print statements can be parsed as function calls or statements, 2to3 cannot always read files containing the print function. When 2to3 detects the presence of the `from __future__ import print_function` compiler directive, it modifies its internal grammar to interpret `print()` as a function. This change can also be enabled manually with the `-p` flag. Use `-p` to run fixers on code that already has had its print statements converted.

The `-o` or `--output-dir` option allows specification of an alternate directory for processed output files to be written to. The `-n` flag is required when using this as backup files do not make sense when not overwriting the input files.

Baru pada versi 3.2.3: The `-o` option was added.

The `-W` or `--write-unchanged-files` flag tells 2to3 to always write output files even if no changes were required to the file. This is most useful with `-o` so that an entire Python source tree is copied with translation from one directory to another. This option implies the `-w` flag as it would not make sense otherwise.

Baru pada versi 3.2.3: The `-W` flag was added.

The `--add-suffix` option specifies a string to append to all output filenames. The `-n` flag is required when specifying this as backups are not necessary when writing to different filenames. Example:

```
$ 2to3 -n -W --add-suffix=3 example.py
```

Will cause a converted file named `example.py3` to be written.

Baru pada versi 3.2.3: The `--add-suffix` option was added.

To translate an entire project from one directory tree to another use:

```
$ 2to3 --output-dir=python3-version/mycode -W -n python2-version/mycode
```

## 26.7.2 Fixers

Each step of transforming code is encapsulated in a fixer. The command `2to3 -l` lists them. As *documented above*, each can be turned on and off individually. They are described here in more detail.

### apply

Removes usage of `apply()`. For example `apply(function, *args, **kwargs)` is converted to `function(*args, **kwargs)`.

### asserts

Replaces deprecated `unittest` method names with the correct ones.

| dari                                     | Ke                                      |
|------------------------------------------|-----------------------------------------|
| <code>failUnlessEqual(a, b)</code>       | <code>assertEqual(a, b)</code>          |
| <code>assertEquals(a, b)</code>          | <code>assertEqual(a, b)</code>          |
| <code>failIfEqual(a, b)</code>           | <code>assertNotEqual(a, b)</code>       |
| <code>assertNotEquals(a, b)</code>       | <code>assertNotEqual(a, b)</code>       |
| <code>failUnless(a)</code>               | <code>assertTrue(a)</code>              |
| <code>assert_(a)</code>                  | <code>assertTrue(a)</code>              |
| <code>failIf(a)</code>                   | <code>assertFalse(a)</code>             |
| <code>failUnlessRaises(exc, cal)</code>  | <code>assertRaises(exc, cal)</code>     |
| <code>failUnlessAlmostEqual(a, b)</code> | <code>assertAlmostEqual(a, b)</code>    |
| <code>assertAlmostEquals(a, b)</code>    | <code>assertAlmostEqual(a, b)</code>    |
| <code>failIfAlmostEqual(a, b)</code>     | <code>assertNotAlmostEqual(a, b)</code> |
| <code>assertNotAlmostEquals(a, b)</code> | <code>assertNotAlmostEqual(a, b)</code> |

### **basestring**

Converts basestring to *str*.

### **buffer**

Converts buffer to *memoryview*. This fixer is optional because the *memoryview* API is similar but not exactly the same as that of buffer.

### **dict**

Fixes dictionary iteration methods. `dict.iteritems()` is converted to *dict.items()*, `dict.iterkeys()` to *dict.keys()*, and `dict.itervalues()` to *dict.values()*. Similarly, `dict.viewitems()`, `dict.viewkeys()` and `dict.viewvalues()` are converted respectively to *dict.items()*, *dict.keys()* and *dict.values()*. It also wraps existing usages of *dict.items()*, *dict.keys()*, and *dict.values()* in a call to *list*.

### **except**

Converts `except X, T` to `except X as T`.

### **exec**

Converts the `exec` statement to the *exec()* function.

### **execfile**

Removes usage of `execfile()`. The argument to `execfile()` is wrapped in calls to *open()*, *compile()*, and *exec()*.

### **exitfunc**

Changes assignment of `sys.exitfunc` to use of the *atexit* module.

### **filter**

Wraps *filter()* usage in a *list* call.

### **funcattrs**

Fixes function attributes that have been renamed. For example, `my_function.func_closure` is converted to `my_function.__closure__`.

### **future**

Removes `from __future__ import new_feature` statements.

### **getcwdu**

Renames `os.getcwdu()` to *os.getcwd()*.

### **has\_key**

Changes `dict.has_key(key)` to `key in dict`.

### **idioms**

This optional fixer performs several transformations that make Python code more idiomatic. Type comparisons like `type(x) is SomeClass` and `type(x) == SomeClass` are converted to `isinstance(x, SomeClass)`. `while 1` becomes `while True`. This fixer also tries to make use of *sorted()* in appropriate places. For example, this block

```
L = list(some_iterable)
L.sort()
```

diubah jadi

```
L = sorted(some_iterable)
```

### **import**

Detects sibling imports and converts them to relative imports.

### **imports**

Handles module renames in the standard library.

**imports2**

Handles other modules renames in the standard library. It is separate from the *imports* fixer only because of technical limitations.

**input**

Converts `input(prompt)` to `eval(input(prompt))`.

**intern**

Converts `intern()` to `sys.intern()`.

**isinstance**

Fixes duplicate types in the second argument of *isinstance()*. For example, `isinstance(x, (int, int))` is converted to `isinstance(x, int)` and `isinstance(x, (int, float, int))` is converted to `isinstance(x, (int, float))`.

**itertools\_imports**

Removes imports of `itertools.filter()`, `itertools.izip()`, and `itertools.imap()`. Imports of `itertools.ifilterfalse()` are also changed to *itertools.filterfalse()*.

**itertools**

Changes usage of `itertools.filter()`, `itertools.izip()`, and `itertools.imap()` to their built-in equivalents. `itertools.ifilterfalse()` is changed to *itertools.filterfalse()*.

**long**

Renames `long` to *int*.

**map**

Wraps *map()* in a *list* call. It also changes `map(None, x)` to `list(x)`. Using `from future_builtins import map` disables this fixer.

**metaclass**

Converts the old metaclass syntax (`__metaclass__ = Meta` in the class body) to the new (`class X(metaclass=Meta)`).

**methodattrs**

Fixes old method attribute names. For example, `meth.im_func` is converted to `meth.__func__`.

**ne**

Converts the old not-equal syntax, `<>`, to `!=`.

**next**

Converts the use of iterator's `next()` methods to the *next()* function. It also renames *next()* methods to `__next__()`.

**nonzero**

Renames `__nonzero__()` to `__bool__()`.

**numliterals**

Converts octal literals into the new syntax.

**operator**

Converts calls to various functions in the *operator* module to other, but equivalent, function calls. When needed, the appropriate import statements are added, e.g. `import collections.abc`. The following mapping are made:

| dari                                        | Ke                                                     |
|---------------------------------------------|--------------------------------------------------------|
| <code>operator.isCallable(obj)</code>       | <code>callable(obj)</code>                             |
| <code>operator.sequenceIncludes(obj)</code> | <code>operator.contains(obj)</code>                    |
| <code>operator.isSequenceType(obj)</code>   | <code>isinstance(obj, collections.abc.Sequence)</code> |
| <code>operator.isMappingType(obj)</code>    | <code>isinstance(obj, collections.abc.Mapping)</code>  |
| <code>operator.isNumberType(obj)</code>     | <code>isinstance(obj, numbers.Number)</code>           |
| <code>operator.repeat(obj, n)</code>        | <code>operator.mul(obj, n)</code>                      |
| <code>operator.irepeat(obj, n)</code>       | <code>operator.imul(obj, n)</code>                     |

**paren**

Add extra parenthesis where they are required in list comprehensions. For example, `[x for x in 1, 2]` becomes `[x for x in (1, 2)]`.

**print**

Converts the print statement to the `print()` function.

**raise**

Converts `raise E, V` to `raise E(V)`, and `raise E, V, T` to `raise E(V).with_traceback(T)`. If `E` is a tuple, the translation will be incorrect because substituting tuples for exceptions has been removed in 3.0.

**raw\_input**

Converts `raw_input()` to `input()`.

**reduce**

Handles the move of `reduce()` to `functools.reduce()`.

**reload**

Converts `reload()` to `importlib.reload()`.

**renames**

Changes `sys.maxint` to `sys.maxsize`.

**repr**

Replaces backtick repr with the `repr()` function.

**set\_literal**

Replaces use of the `set` constructor with set literals. This fixer is optional.

**standarderror**

Renames `StandardError` to `Exception`.

**sys\_exc**

Changes the deprecated `sys.exc_value`, `sys.exc_type`, `sys.exc_traceback` to use `sys.exc_info()`.

**throw**

Fixes the API change in generator's `throw()` method.

**tuple\_params**

Removes implicit tuple parameter unpacking. This fixer inserts temporary variables.

**types**

Fixes code broken from the removal of some members in the `types` module.

**unicode**

Renames `unicode` to `str`.

**urllib**

Handles the rename of `urllib` and `urllib2` to the `urllib` package.

**ws\_comma**

Removes excess whitespace from comma separated items. This fixer is optional.

**xrange**

Renames `xrange()` to `range()` and wraps existing `range()` calls with `list`.

**xreadlines**

Changes for `x in file.xreadlines()` to `for x in file`.

**zip**

Wraps `zip()` usage in a `list` call. This is disabled when `from future_builtins import zip` appears.

### 26.7.3 lib2to3 - 2to3's library

Source code: [Lib/lib2to3/](#)

---

**Catatan:** The `lib2to3` API should be considered unstable and may change drastically in the future.

---

## 26.8 test --- Regression tests package for Python

---

**Catatan:** The `test` package is meant for internal use by Python only. It is documented for the benefit of the core developers of Python. Any use of this package outside of Python's standard library is discouraged as code mentioned here can change or be removed without notice between releases of Python.

---

The `test` package contains all regression tests for Python as well as the modules `test.support` and `test.regrtest`. `test.support` is used to enhance your tests while `test.regrtest` drives the testing suite.

Each module in the `test` package whose name starts with `test_` is a testing suite for a specific module or feature. All new tests should be written using the `unittest` or `doctest` module. Some older tests are written using a "traditional" testing style that compares output printed to `sys.stdout`; this style of test is considered deprecated.

**Lihat juga:**

**Module `unittest`** Writing PyUnit regression tests.

**Modul `doctest`** Tests embedded in documentation strings.

## 26.8.1 Writing Unit Tests for the `test` package

It is preferred that tests that use the `unittest` module follow a few guidelines. One is to name the test module by starting it with `test_` and end it with the name of the module being tested. The test methods in the test module should start with `test_` and end with a description of what the method is testing. This is needed so that the methods are recognized by the test driver as test methods. Also, no documentation string for the method should be included. A comment (such as `# Tests function returns only True or False`) should be used to provide documentation for test methods. This is done because documentation strings get printed out if they exist and thus what test is being run is not stated.

A basic boilerplate is often used:

```
import unittest
from test import support

class MyTestCase1(unittest.TestCase):

    # Only use setUp() and tearDown() if necessary

    def setUp(self):
        ... code to execute in preparation for tests ...

    def tearDown(self):
        ... code to execute to clean up after tests ...

    def test_feature_one(self):
        # Test feature one.
        ... testing code ...

    def test_feature_two(self):
        # Test feature two.
        ... testing code ...

    ... more test methods ...

class MyTestCase2(unittest.TestCase):
    ... same structure as MyTestCase1 ...

... more test classes ...

if __name__ == '__main__':
    unittest.main()
```

This code pattern allows the testing suite to be run by `test.regrtest`, on its own as a script that supports the `unittest` CLI, or via the `python -m unittest` CLI.

The goal for regression testing is to try to break code. This leads to a few guidelines to be followed:

- The testing suite should exercise all classes, functions, and constants. This includes not just the external API that is to be presented to the outside world but also “private” code.
- Whitebox testing (examining the code being tested when the tests are being written) is preferred. Blackbox testing (testing only the published user interface) is not complete enough to make sure all boundary and edge cases are tested.
- Make sure all possible values are tested including invalid ones. This makes sure that not only all valid values are acceptable but also that improper values are handled correctly.
- Exhaust as many code paths as possible. Test where branching occurs and thus tailor input to make sure as many different paths through the code are taken.

- Add an explicit test for any bugs discovered for the tested code. This will make sure that the error does not crop up again if the code is changed in the future.
- Make sure to clean up after your tests (such as close and remove all temporary files).
- If a test is dependent on a specific condition of the operating system then verify the condition already exists before attempting the test.
- Import as few modules as possible and do it as soon as possible. This minimizes external dependencies of tests and also minimizes possible anomalous behavior from side-effects of importing a module.
- Try to maximize code reuse. On occasion, tests will vary by something as small as what type of input is used. Minimize code duplication by subclassing a basic test class with a class that specifies the input:

```
class TestFuncAcceptsSequencesMixin:

    func = mySuperWhammyFunction

    def test_func(self):
        self.func(self.arg)

class AcceptLists(TestFuncAcceptsSequencesMixin, unittest.TestCase):
    arg = [1, 2, 3]

class AcceptStrings(TestFuncAcceptsSequencesMixin, unittest.TestCase):
    arg = 'abc'

class AcceptTuples(TestFuncAcceptsSequencesMixin, unittest.TestCase):
    arg = (1, 2, 3)
```

When using this pattern, remember that all classes that inherit from `unittest.TestCase` are run as tests. The Mixin class in the example above does not have any data and so can't be run by itself, thus it does not inherit from `unittest.TestCase`.

**Lihat juga:**

**Test Driven Development** A book by Kent Beck on writing tests before code.

## 26.8.2 Running tests using the command-line interface

The `test` package can be run as a script to drive Python's regression test suite, thanks to the `-m` option: **python -m test**. Under the hood, it uses `test.regrtest`; the call **python -m test.regrtest** used in previous Python versions still works. Running the script by itself automatically starts running all regression tests in the `test` package. It does this by finding all modules in the package whose name starts with `test_`, importing them, and executing the function `test_main()` if present or loading the tests via `unittest.TestLoader.loadTestsFromModule` if `test_main` does not exist. The names of tests to execute may also be passed to the script. Specifying a single regression test (**python -m test test\_spam**) will minimize output and only print whether the test passed or failed.

Running `test` directly allows what resources are available for tests to use to be set. You do this by using the `-u` command-line option. Specifying `all` as the value for the `-u` option enables all possible resources: **python -m test -uall**. If all but one resource is desired (a more common case), a comma-separated list of resources that are not desired may be listed after `all`. The command **python -m test -uall,-audio,-largefile** will run `test` with all resources except the `audio` and `largefile` resources. For a list of all resources and more command-line options, run **python -m test -h**.

Some other ways to execute the regression tests depend on what platform the tests are being executed on. On Unix, you can run **make test** at the top-level directory where Python was built. On Windows, executing **rt.bat** from your PCbuild directory will run all regression tests.

## 26.9 `test.support` --- Utilities for the Python test suite

The `test.support` module provides support for Python's regression test suite.

---

**Catatan:** `test.support` is not a public module. It is documented here to help Python developers write tests. The API of this module is subject to change without backwards compatibility concerns between releases.

---

This module defines the following exceptions:

**exception** `test.support.TestFailed`

Exception to be raised when a test fails. This is deprecated in favor of `unittest`-based tests and `unittest.TestCase`'s assertion methods.

**exception** `test.support.ResourceDenied`

Subclass of `unittest.SkipTest`. Raised when a resource (such as a network connection) is not available. Raised by the `requires()` function.

The `test.support` module defines the following constants:

`test.support.verbose`

True when verbose output is enabled. Should be checked when more detailed information is desired about a running test. `verbose` is set by `test.regrtest`.

`test.support.is_jython`

True if the running interpreter is Jython.

`test.support.is_android`

True if the system is Android.

`test.support.unix_shell`

Path for shell if not on Windows; otherwise None.

`test.support.FS_NONASCII`

A non-ASCII character encodable by `os.fsencode()`.

`test.support.TESTFN`

Set to a name that is safe to use as the name of a temporary file. Any temporary file that is created should be closed and unlinked (removed).

`test.support.TESTFN_UNICODE`

Set to a non-ASCII name for a temporary file.

`test.support.TESTFN_ENCODING`

Set to `sys.getfilesystemencoding()`.

`test.support.TESTFN_UNENCODABLE`

Set to a filename (str type) that should not be able to be encoded by file system encoding in strict mode. It may be None if it's not possible to generate such a filename.

`test.support.TESTFN_UNDECODABLE`

Set to a filename (bytes type) that should not be able to be decoded by file system encoding in strict mode. It may be None if it's not possible to generate such a filename.

`test.support.TESTFN_NONASCII`

Set to a filename containing the `FS_NONASCII` character.

`test.support.IPV6_ENABLED`

Set to True if IPV6 is enabled on this host, False otherwise.

`test.support.SAVEDCWD`  
Set to `os.getcwd()`.

`test.support.PGO`  
Set when tests can be skipped when they are not useful for PGO.

`test.support.PIPE_MAX_SIZE`  
A constant that is likely larger than the underlying OS pipe buffer size, to make writes blocking.

`test.support.SOCK_MAX_SIZE`  
A constant that is likely larger than the underlying OS socket buffer size, to make writes blocking.

`test.support.TEST_SUPPORT_DIR`  
Set to the top level directory that contains `test.support`.

`test.support.TEST_HOME_DIR`  
Set to the top level directory for the test package.

`test.support.TEST_DATA_DIR`  
Set to the data directory within the test package.

`test.support.MAX_Py_ssize_t`  
Set to `sys.maxsize` for big memory tests.

`test.support.max_memuse`  
Set by `set_memlimit()` as the memory limit for big memory tests. Limited by `MAX_Py_ssize_t`.

`test.support.real_max_memuse`  
Set by `set_memlimit()` as the memory limit for big memory tests. Not limited by `MAX_Py_ssize_t`.

`test.support.MISSING_C_DOCSTRINGS`  
Return True if running on CPython, not on Windows, and configuration not set with `WITH_DOC_STRINGS`.

`test.support.HAVE_DOCSTRINGS`  
Check for presence of docstrings.

`test.support.TEST_HTTP_URL`  
Define the URL of a dedicated HTTP server for the network tests.

`test.support.ALWAYS_EQ`  
Object that is equal to anything. Used to test mixed type comparison.

`test.support.LARGEST`  
Object that is greater than anything (except itself). Used to test mixed type comparison.

`test.support.SMALLEST`  
Object that is less than anything (except itself). Used to test mixed type comparison.

The `test.support` module defines the following functions:

`test.support.forget(module_name)`  
Remove the module named `module_name` from `sys.modules` and delete any byte-compiled files of the module.

`test.support.unload(name)`  
Delete `name` from `sys.modules`.

`test.support.unlink(filename)`  
Call `os.unlink()` on `filename`. On Windows platforms, this is wrapped with a wait loop that checks for the existence of the file.

`test.support.rmdir(filename)`  
Call `os.rmdir()` on `filename`. On Windows platforms, this is wrapped with a wait loop that checks for the existence of the file.

`test.support.rmtree(path)`

Call `shutil.rmtree()` on *path* or call `os.lstat()` and `os.rmdir()` to remove a path and its contents. On Windows platforms, this is wrapped with a wait loop that checks for the existence of the files.

`test.support.make_legacy_pyc(source)`

Move a [PEP 3147/PEP 488](#) pyc file to its legacy pyc location and return the file system path to the legacy pyc file. The *source* value is the file system path to the source file. It does not need to exist, however the PEP 3147/488 pyc file must exist.

`test.support.is_resource_enabled(resource)`

Return True if *resource* is enabled and available. The list of available resources is only set when `test.regrtest` is executing the tests.

`test.support.python_is_optimized()`

Return True if Python was not built with `-O0` or `-Og`.

`test.support.with_pymalloc()`

Return `_testcapi.WITH_PYMALLOC`.

`test.support.requires(resource, msg=None)`

Raise `ResourceDenied` if *resource* is not available. *msg* is the argument to `ResourceDenied` if it is raised. Always returns True if called by a function whose `__name__` is `'__main__'`. Used when tests are executed by `test.regrtest`.

`test.support.system_must_validate_cert(f)`

Raise `unittest.SkipTest` on TLS certification validation failures.

`test.support.sortedict(dict)`

Return a repr of *dict* with keys sorted.

`test.support.findfile(filename, subdir=None)`

Return the path to the file named *filename*. If no match is found *filename* is returned. This does not equal a failure since it could be the path to the file.

Setting *subdir* indicates a relative path to use to find the file rather than looking directly in the path directories.

`test.support.create_empty_file(filename)`

Create an empty file with *filename*. If it already exists, truncate it.

`test.support.fd_count()`

Count the number of open file descriptors.

`test.support.match_test(test)`

Match *test* to patterns set in `set_match_tests()`.

`test.support.set_match_tests(patterns)`

Define match test with regular expression *patterns*.

`test.support.run_unittest(*classes)`

Execute `unittest.TestCase` subclasses passed to the function. The function scans the classes for methods starting with the prefix `test_` and executes the tests individually.

It is also legal to pass strings as parameters; these should be keys in `sys.modules`. Each associated module will be scanned by `unittest.TestLoader.loadTestsFromModule()`. This is usually seen in the following `test_main()` function:

```
def test_main():
    support.run_unittest(__name__)
```

This will run all tests defined in the named module.

`test.support.run_doctest` (*module*, *verbosity=None*, *optionflags=0*)

Run `doctest.testmod()` on the given *module*. Return (*failure\_count*, *test\_count*).

If *verbosity* is `None`, `doctest.testmod()` is run with *verbosity* set to `verbose`. Otherwise, it is run with *verbosity* set to `None`. *optionflags* is passed as *optionflags* to `doctest.testmod()`.

`test.support.setswitchinterval` (*interval*)

Set the `sys.setswitchinterval()` to the given *interval*. Defines a minimum interval for Android systems to prevent the system from hanging.

`test.support.check_impl_detail` (*\*\*guards*)

Use this check to guard CPython's implementation-specific tests or to run them only on the implementations guarded by the arguments:

```
check_impl_detail()           # Only on CPython (default).
check_impl_detail(jython=True) # Only on Jython.
check_impl_detail(cpython=False) # Everywhere except CPython.
```

`test.support.check_warnings` (*\*filters*, *quiet=True*)

A convenience wrapper for `warnings.catch_warnings()` that makes it easier to test that a warning was correctly raised. It is approximately equivalent to calling `warnings.catch_warnings(record=True)` with `warnings.simplefilter()` set to `always` and with the option to automatically validate the results that are recorded.

`check_warnings` accepts 2-tuples of the form ("message regexp", `WarningCategory`) as positional arguments. If one or more *filters* are provided, or if the optional keyword argument *quiet* is `False`, it checks to make sure the warnings are as expected: each specified filter must match at least one of the warnings raised by the enclosed code or the test fails, and if any warnings are raised that do not match any of the specified filters the test fails. To disable the first of these checks, set *quiet* to `True`.

If no arguments are specified, it defaults to:

```
check_warnings(("", Warning), quiet=True)
```

In this case all warnings are caught and no errors are raised.

On entry to the context manager, a `WarningRecorder` instance is returned. The underlying warnings list from `catch_warnings()` is available via the recorder object's `warnings` attribute. As a convenience, the attributes of the object representing the most recent warning can also be accessed directly through the recorder object (see example below). If no warning has been raised, then any of the attributes that would otherwise be expected on an object representing a warning will return `None`.

The recorder object also has a `reset()` method, which clears the warnings list.

The context manager is designed to be used like this:

```
with check_warnings(("assertion is always true", SyntaxWarning),
                    ("", UserWarning)):
    exec('assert(False, "Hey!")')
    warnings.warn(UserWarning("Hide me!"))
```

In this case if either warning was not raised, or some other warning was raised, `check_warnings()` would raise an error.

When a test needs to look more deeply into the warnings, rather than just checking whether or not they occurred, code like this can be used:

```
with check_warnings(quiet=True) as w:
    warnings.warn("foo")
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

assert str(w.args[0]) == "foo"
warnings.warn("bar")
assert str(w.args[0]) == "bar"
assert str(w.warnings[0].args[0]) == "foo"
assert str(w.warnings[1].args[0]) == "bar"
w.reset()
assert len(w.warnings) == 0

```

Here all warnings will be caught, and the test code tests the captured warnings directly.

Berubah pada versi 3.2: New optional arguments *filters* and *quiet*.

`test.support.check_no_resource_warning(testcase)`

Context manager to check that no *ResourceWarning* was raised. You must remove the object which may emit *ResourceWarning* before the end of the context manager.

`test.support.set_memlimit(limit)`

Set the values for *max\_memuse* and *real\_max\_memuse* for big memory tests.

`test.support.record_original_stdout(stdout)`

Store the value from *stdout*. It is meant to hold the stdout at the time the regrtest began.

`test.support.get_original_stdout()`

Return the original stdout set by *record\_original\_stdout()* or `sys.stdout` if it's not set.

`test.support.strip_python_stderr(stderr)`

Strip the *stderr* of a Python process from potential debug output emitted by the interpreter. This will typically be run on the result of *subprocess.Popen.communicate()*.

`test.support.args_from_interpreter_flags()`

Return a list of command line arguments reproducing the current settings in `sys.flags` and `sys.warnoptions`.

`test.support.optim_args_from_interpreter_flags()`

Return a list of command line arguments reproducing the current optimization settings in `sys.flags`.

`test.support.captured_stdin()`

`test.support.captured_stdout()`

`test.support.captured_stderr()`

A context managers that temporarily replaces the named stream with *io.StringIO* object.

Example use with output streams:

```

with captured_stdout() as stdout, captured_stderr() as stderr:
    print("hello")
    print("error", file=sys.stderr)
assert stdout.getvalue() == "hello\n"
assert stderr.getvalue() == "error\n"

```

Example use with input stream:

```

with captured_stdin() as stdin:
    stdin.write('hello\n')
    stdin.seek(0)
    # call test code that consumes from sys.stdin
    captured = input()
self.assertEqual(captured, "hello")

```

`test.support.temp_dir(path=None, quiet=False)`

A context manager that creates a temporary directory at *path* and yields the directory.

If *path* is `None`, the temporary directory is created using `tempfile.mkdtemp()`. If *quiet* is `False`, the context manager raises an exception on error. Otherwise, if *path* is specified and cannot be created, only a warning is issued.

`test.support.change_cwd(path, quiet=False)`

A context manager that temporarily changes the current working directory to *path* and yields the directory.

If *quiet* is `False`, the context manager raises an exception on error. Otherwise, it issues only a warning and keeps the current working directory the same.

`test.support.temp_cwd(name='tempcwd', quiet=False)`

A context manager that temporarily creates a new directory and changes the current working directory (CWD).

The context manager creates a temporary directory in the current directory with name *name* before temporarily changing the current working directory. If *name* is `None`, the temporary directory is created using `tempfile.mkdtemp()`.

If *quiet* is `False` and it is not possible to create or change the CWD, an error is raised. Otherwise, only a warning is raised and the original CWD is used.

`test.support.temp_umask(umask)`

A context manager that temporarily sets the process umask.

`test.support.transient_internet(resource_name, *, timeout=30.0, errnos=())`

A context manager that raises `ResourceDenied` when various issues with the internet connection manifest themselves as exceptions.

`test.support.disable_faulthandler()`

A context manager that replaces `sys.stderr` with `sys.__stderr__`.

`test.support.gc_collect()`

Force as many objects as possible to be collected. This is needed because timely deallocation is not guaranteed by the garbage collector. This means that `__del__` methods may be called later than expected and weakrefs may remain alive for longer than expected.

`test.support.disable_gc()`

A context manager that disables the garbage collector upon entry and reenables it upon exit.

`test.support.swap_attr(obj, attr, new_val)`

Context manager to swap out an attribute with a new object.

Penggunaan:

```
with swap_attr(obj, "attr", 5):
    ...
```

This will set `obj.attr` to 5 for the duration of the `with` block, restoring the old value at the end of the block. If `attr` doesn't exist on `obj`, it will be created and then deleted at the end of the block.

The old value (or `None` if it doesn't exist) will be assigned to the target of the "as" clause, if there is one.

`test.support.swap_item(obj, attr, new_val)`

Context manager to swap out an item with a new object.

Penggunaan:

```
with swap_item(obj, "item", 5):
    ...
```

This will set `obj["item"]` to 5 for the duration of the `with` block, restoring the old value at the end of the block. If `item` doesn't exist on `obj`, it will be created and then deleted at the end of the block.

The old value (or `None` if it doesn't exist) will be assigned to the target of the "as" clause, if there is one.

`test.support.wait_threads_exit (timeout=60.0)`  
Context manager to wait until all threads created in the `with` statement exit.

`test.support.start_threads (threads, unlock=None)`  
Context manager to start *threads*. It attempts to join the threads upon exit.

`test.support.calcobjsize (fmt)`  
Return `struct.calcsize()` for `nP{fmt}0n` or, if `gettotalrefcount` exists, `2PnP{fmt}0P`.

`test.support.calcvobjsize (fmt)`  
Return `struct.calcsize()` for `nPn{fmt}0n` or, if `gettotalrefcount` exists, `2PnPn{fmt}0P`.

`test.support.checksizeof (test, o, size)`  
For testcase *test*, assert that the `sys.getsizeof` for *o* plus the GC header size equals *size*.

`test.support.can_symlink ()`  
Return True if the OS supports symbolic links, False otherwise.

`test.support.can_xattr ()`  
Return True if the OS supports xattr, False otherwise.

`@test.support.skip_unless_symlink`  
A decorator for running tests that require support for symbolic links.

`@test.support.skip_unless_xattr`  
A decorator for running tests that require support for xattr.

`@test.support.skip_unless_bind_unix_socket`  
A decorator for running tests that require a functional `bind()` for Unix sockets.

`@test.support.anticipate_failure (condition)`  
A decorator to conditionally mark tests with `unittest.expectedFailure()`. Any use of this decorator should have an associated comment identifying the relevant tracker issue.

`@test.support.run_with_locale (catstr, *locales)`  
A decorator for running a function in a different locale, correctly resetting it after it has finished. *catstr* is the locale category as a string (for example "LC\_ALL"). The *locales* passed will be tried sequentially, and the first valid locale will be used.

`@test.support.run_with_tz (tz)`  
A decorator for running a function in a specific timezone, correctly resetting it after it has finished.

`@test.support.requires_freebsd_version (*min_version)`  
Decorator for the minimum version when running test on FreeBSD. If the FreeBSD version is less than the minimum, raise `unittest.SkipTest`.

`@test.support.requires_linux_version (*min_version)`  
Decorator for the minimum version when running test on Linux. If the Linux version is less than the minimum, raise `unittest.SkipTest`.

`@test.support.requires_mac_version (*min_version)`  
Decorator for the minimum version when running test on Mac OS X. If the MAC OS X version is less than the minimum, raise `unittest.SkipTest`.

`@test.support.requires_IEEE_754`  
Decorator for skipping tests on non-IEEE 754 platforms.

`@test.support.requires_zlib`  
Decorator for skipping tests if *zlib* doesn't exist.

`@test.support.requires_gzip`  
Decorator for skipping tests if *gzip* doesn't exist.

`@test.support.requires_bz2`  
Decorator for skipping tests if `bz2` doesn't exist.

`@test.support.requires_lzma`  
Decorator for skipping tests if `lzma` doesn't exist.

`@test.support.requires_resource(resource)`  
Decorator for skipping tests if `resource` is not available.

`@test.support.requires_docstrings`  
Decorator for only running the test if `HAVE_DOCSTRINGS`.

`@test.support.cpython_only(test)`  
Decorator for tests only applicable to CPython.

`@test.support.impl_detail(msg=None, **guards)`  
Decorator for invoking `check_impl_detail()` on `guards`. If that returns `False`, then uses `msg` as the reason for skipping the test.

`@test.support.no_tracing(func)`  
Decorator to temporarily turn off tracing for the duration of the test.

`@test.support.refcount_test(test)`  
Decorator for tests which involve reference counting. The decorator does not run the test if it is not run by CPython. Any trace function is unset for the duration of the test to prevent unexpected refcounts caused by the trace function.

`@test.support.reap_threads(func)`  
Decorator to ensure the threads are cleaned up even if the test fails.

`@test.support.bigmemtest(size, memuse, dry_run=True)`  
Decorator for bigmem tests.

`size` is a requested size for the test (in arbitrary, test-interpreted units.) `memuse` is the number of bytes per unit for the test, or a good estimate of it. For example, a test that needs two byte buffers, of 4 GiB each, could be decorated with `@bigmemtest(size=_4G, memuse=2)`.

The `size` argument is normally passed to the decorated test method as an extra argument. If `dry_run` is `True`, the value passed to the test method may be less than the requested value. If `dry_run` is `False`, it means the test doesn't support dummy runs when `-M` is not specified.

`@test.support.bigaddrspace_test(f)`  
Decorator for tests that fill the address space. `f` is the function to wrap.

`test.support.make_bad_fd()`  
Create an invalid file descriptor by opening and closing a temporary file, and returning its descriptor.

`test.support.check_syntax_error(testcase, statement, errtext="*", lineno=None, offset=None)`  
Test for syntax errors in `statement` by attempting to compile `statement`. `testcase` is the `unittest` instance for the test. `errtext` is the regular expression which should match the string representation of the raised `SyntaxError`. If `lineno` is not `None`, compares to the line of the exception. If `offset` is not `None`, compares to the offset of the exception.

`test.support.check_syntax_warning(testcase, statement, errtext="*", lineno=1, offset=None)`  
Test for syntax warning in `statement` by attempting to compile `statement`. Test also that the `SyntaxWarning` is emitted only once, and that it will be converted to a `SyntaxError` when turned into error. `testcase` is the `unittest` instance for the test. `errtext` is the regular expression which should match the string representation of the emitted `SyntaxWarning` and raised `SyntaxError`. If `lineno` is not `None`, compares to the line of the warning and exception. If `offset` is not `None`, compares to the offset of the exception.

Baru pada versi 3.8.

`test.support.open_urlresource (url, *args, **kw)`

Open *url*. If open fails, raises *TestFailed*.

`test.support.import_module (name, deprecated=False, *, required_on())`

This function imports and returns the named module. Unlike a normal import, this function raises *unittest.SkipTest* if the module cannot be imported.

Module and package deprecation messages are suppressed during this import if *deprecated* is *True*. If a module is required on a platform but optional for others, set *required\_on* to an iterable of platform prefixes which will be compared against *sys.platform*.

Baru pada versi 3.1.

`test.support.import_fresh_module (name, fresh=(), blocked=(), deprecated=False)`

This function imports and returns a fresh copy of the named Python module by removing the named module from *sys.modules* before doing the import. Note that unlike *reload()*, the original module is not affected by this operation.

*fresh* is an iterable of additional module names that are also removed from the *sys.modules* cache before doing the import.

*blocked* is an iterable of module names that are replaced with *None* in the module cache during the import to ensure that attempts to import them raise *ImportError*.

The named module and any modules named in the *fresh* and *blocked* parameters are saved before starting the import and then reinserted into *sys.modules* when the fresh import is complete.

Module and package deprecation messages are suppressed during this import if *deprecated* is *True*.

This function will raise *ImportError* if the named module cannot be imported.

Example use:

```
# Get copies of the warnings module for testing without affecting the
# version being used by the rest of the test suite. One copy uses the
# C implementation, the other is forced to use the pure Python fallback
# implementation
py_warnings = import_fresh_module('warnings', blocked=['_warnings'])
c_warnings = import_fresh_module('warnings', fresh=['_warnings'])
```

Baru pada versi 3.1.

`test.support.modules_setup()`

Return a copy of *sys.modules*.

`test.support.modules_cleanup (oldmodules)`

Remove modules except for *oldmodules* and encodings in order to preserve internal cache.

`test.support.threading_setup()`

Return current thread count and copy of dangling threads.

`test.support.threading_cleanup (*original_values)`

Cleanup up threads not specified in *original\_values*. Designed to emit a warning if a test leaves running threads in the background.

`test.support.join_thread (thread, timeout=30.0)`

Join a *thread* within *timeout*. Raise an *AssertionError* if thread is still alive after *timeout* seconds.

`test.support.reap_children()`

Use this at the end of *test\_main* whenever sub-processes are started. This will help ensure that no extra children (zombies) stick around to hog resources and create problems when looking for *refleaks*.

`test.support.get_attribute(obj, name)`

Get an attribute, raising `unittest.SkipTest` if `AttributeError` is raised.

`test.support.bind_port(sock, host=HOST)`

Bind the socket to a free port and return the port number. Relies on ephemeral ports in order to ensure we are using an unbound port. This is important as many tests may be running simultaneously, especially in a buildbot environment. This method raises an exception if the `sock.family` is `AF_INET` and `sock.type` is `SOCK_STREAM`, and the socket has `SO_REUSEADDR` or `SO_REUSEPORT` set on it. Tests should never set these socket options for TCP/IP sockets. The only case for setting these options is testing multicasting via multiple UDP sockets.

Additionally, if the `SO_EXCLUSIVEADDRUSE` socket option is available (i.e. on Windows), it will be set on the socket. This will prevent anyone else from binding to our host/port for the duration of the test.

`test.support.bind_unix_socket(sock, addr)`

Bind a unix socket, raising `unittest.SkipTest` if `PermissionError` is raised.

`test.support.catch_threading_exception()`

Context manager catching `threading.Thread` exception using `threading.excepthook()`.

Attributes set when an exception is caught:

- `exc_type`
- `exc_value`
- `exc_traceback`
- `thread`

See `threading.excepthook()` documentation.

These attributes are deleted at the context manager exit.

Penggunaan:

```
with support.catch_threading_exception() as cm:
    # code spawning a thread which raises an exception
    ...

    # check the thread exception, use cm attributes:
    # exc_type, exc_value, exc_traceback, thread
    ...

# exc_type, exc_value, exc_traceback, thread attributes of cm no longer
# exists at this point
# (to avoid reference cycles)
```

Baru pada versi 3.8.

`test.support.catch_unraisable_exception()`

Context manager catching unraisable exception using `sys.unraisablehook()`.

Storing the exception value (`cm.unraisable.exc_value`) creates a reference cycle. The reference cycle is broken explicitly when the context manager exits.

Storing the object (`cm.unraisable.object`) can resurrect it if it is set to an object which is being finalized. Exiting the context manager clears the stored object.

Penggunaan:

```
with support.catch_unraisable_exception() as cm:
    # code creating an "unraisable exception"
    ...

    # check the unraisable exception: use cm.unraisable
    ...

# cm.unraisable attribute no longer exists at this point
# (to break a reference cycle)
```

Baru pada versi 3.8.

`test.support.find_unused_port(family=socket.AF_INET, socktype=socket.SOCK_STREAM)`

Returns an unused port that should be suitable for binding. This is achieved by creating a temporary socket with the same family and type as the `sock` parameter (default is `AF_INET`, `SOCK_STREAM`), and binding it to the specified host address (defaults to `0.0.0.0`) with the port set to 0, eliciting an unused ephemeral port from the OS. The temporary socket is then closed and deleted, and the ephemeral port is returned.

Either this method or `bind_port()` should be used for any tests where a server socket needs to be bound to a particular port for the duration of the test. Which one to use depends on whether the calling code is creating a Python socket, or if an unused port needs to be provided in a constructor or passed to an external program (i.e. the `-accept` argument to openssl's `s_server` mode). Always prefer `bind_port()` over `find_unused_port()` where possible. Using a hard coded port is discouraged since it can make multiple instances of the test impossible to run simultaneously, which is a problem for buildbots.

`test.support.load_package_tests(pkg_dir, loader, standard_tests, pattern)`

Generic implementation of the `unittest` `load_tests` protocol for use in test packages. `pkg_dir` is the root directory of the package; `loader`, `standard_tests`, and `pattern` are the arguments expected by `load_tests`. In simple cases, the test package's `__init__.py` can be the following:

```
import os
from test.support import load_package_tests

def load_tests(*args):
    return load_package_tests(os.path.dirname(__file__), *args)
```

`test.support.fs_is_case_insensitive(directory)`

Return True if the file system for `directory` is case-insensitive.

`test.support.detect_api_mismatch(ref_api, other_api, *, ignore=())`

Returns the set of attributes, functions or methods of `ref_api` not found on `other_api`, except for a defined list of items to be ignored in this check specified in `ignore`.

By default this skips private attributes beginning with `'_'` but includes all magic methods, i.e. those starting and ending in `'__'`.

Baru pada versi 3.5.

`test.support.patch(test_instance, object_to_patch, attr_name, new_value)`

Override `object_to_patch.attr_name` with `new_value`. Also add cleanup procedure to `test_instance` to restore `object_to_patch` for `attr_name`. The `attr_name` should be a valid attribute for `object_to_patch`.

`test.support.run_in_subinterp(code)`

Run `code` in subinterpreter. Raise `unittest.SkipTest` if `tracemalloc` is enabled.

`test.support.check_free_after_iterating(test, iter, cls, args=())`

Assert that `iter` is deallocated after iterating.

`test.support.missing_compiler_executable(cmd_names=[])`

Check for the existence of the compiler executables whose names are listed in `cmd_names` or all the compiler

executables when `cmd_names` is empty and return the first missing executable or `None` when none is found missing.

`test.support.check__all__` (*test\_case*, *module*, *name\_of\_module*=`None`, *extra*=(), *blacklist*=())

Assert that the `__all__` variable of *module* contains all public names.

The module's public names (its API) are detected automatically based on whether they match the public name convention and were defined in *module*.

The *name\_of\_module* argument can specify (as a string or tuple thereof) what module(s) an API could be defined in order to be detected as a public API. One case for this is when *module* imports part of its public API from other modules, possibly a C backend (like `csv` and its `_csv`).

The *extra* argument can be a set of names that wouldn't otherwise be automatically detected as "public", like objects without a proper `__module__` attribute. If provided, it will be added to the automatically detected ones.

The *blacklist* argument can be a set of names that must not be treated as part of the public API even though their names indicate otherwise.

Example use:

```
import bar
import foo
import unittest
from test import support

class MiscTestCase(unittest.TestCase):
    def test__all__(self):
        support.check__all__(self, foo)

class OtherTestCase(unittest.TestCase):
    def test__all__(self):
        extra = {'BAR_CONST', 'FOO_CONST'}
        blacklist = {'baz'} # Undocumented name.
        # bar imports part of its API from _bar.
        support.check__all__(self, bar, ('bar', '_bar'),
                               extra=extra, blacklist=blacklist)
```

Baru pada versi 3.6.

`test.support.adjust_int_max_str_digits` (*max\_digits*)

This function returns a context manager that will change the global `sys.set_int_max_str_digits()` setting for the duration of the context to allow execution of test code that needs a different limit on the number of digits when converting between an integer and string.

Baru pada versi 3.8.14.

The `test.support` module defines the following classes:

**class** `test.support.TransientResource` (*exc*, *\*\*kwargs*)

Instances are a context manager that raises `ResourceDenied` if the specified exception type is raised. Any keyword arguments are treated as attribute/value pairs to be compared against any exception raised within the `with` statement. Only if all pairs match properly against attributes on the exception is `ResourceDenied` raised.

**class** `test.support.EnvironmentVarGuard`

Class used to temporarily set or unset environment variables. Instances can be used as a context manager and have a complete dictionary interface for querying/modifying the underlying `os.environ`. After exit from the context manager all changes to environment variables done through this instance will be rolled back.

Berubah pada versi 3.1: Added dictionary interface.

`EnvironmentVarGuard.set` (*envvar*, *value*)

Temporarily set the environment variable *envvar* to the value of *value*.

`EnvironmentVarGuard.unset(envvar)`

Temporarily unset the environment variable `envvar`.

**class** `test.support.SuppressCrashReport`

A context manager used to try to prevent crash dialog popups on tests that are expected to crash a subprocess.

On Windows, it disables Windows Error Reporting dialogs using `SetErrorMode`.

On UNIX, `resource.setrlimit()` is used to set `resource.RLIMIT_CORE`'s soft limit to 0 to prevent coredump file creation.

On both platforms, the old value is restored by `__exit__()`.

**class** `test.support.CleanImport(*module_names)`

A context manager to force import to return a new module reference. This is useful for testing module-level behaviors, such as the emission of a `DeprecationWarning` on import. Example usage:

```
with CleanImport('foo'):
    importlib.import_module('foo') # New reference.
```

**class** `test.support.DirsOnSysPath(*paths)`

A context manager to temporarily add directories to `sys.path`.

This makes a copy of `sys.path`, appends any directories given as positional arguments, then reverts `sys.path` to the copied settings when the context ends.

Note that *all* `sys.path` modifications in the body of the context manager, including replacement of the object, will be reverted at the end of the block.

**class** `test.support.SaveSignals`

Class to save and restore signal handlers registered by the Python signal handler.

**class** `test.support.Matcher`

**matches** (*self*, *d*, *\*\*kwargs*)

Try to match a single dict with the supplied arguments.

**match\_value** (*self*, *k*, *dv*, *v*)

Try to match a single stored value (*dv*) with a supplied value (*v*).

**class** `test.support.WarningsRecorder`

Class used to record warnings for unit tests. See documentation of `check_warnings()` above for more details.

**class** `test.support.BasicTestRunner`

**run** (*test*)

Run *test* and return the result.

**class** `test.support.TestHandler(logging.handlers.BufferingHandler)`

Class for logging support.

**class** `test.support.FakePath(path)`

Simple *path-like object*. It implements the `__fspath__()` method which just returns the *path* argument. If *path* is an exception, it will be raised in `__fspath__()`.

## 26.10 `test.support.script_helper` --- Utilities for the Python execution tests

The `test.support.script_helper` module provides support for Python's script execution tests.

`test.support.script_helper.interpreter_requires_environment()`

Return True if `sys.executable` interpreter requires environment variables in order to be able to run at all.

This is designed to be used with `@unittest.skipIf()` to annotate tests that need to use an `assert_python*()` function to launch an isolated mode (`-I`) or no environment mode (`-E`) sub-interpreter process.

A normal build & test does not run into this situation but it can happen when trying to run the standard library test suite from an interpreter that doesn't have an obvious home with Python's current home finding logic.

Setting `PYTHONHOME` is one way to get most of the testsuite to run in that situation. `PYTHONPATH` or `PYTHONUSERSITE` are other common environment variables that might impact whether or not the interpreter can start.

`test.support.script_helper.run_python_until_end(*args, **env_vars)`

Set up the environment based on `env_vars` for running the interpreter in a subprocess. The values can include `__isolated`, `__cleanenv`, `__cwd`, and `TERM`.

`test.support.script_helper.assert_python_ok(*args, **env_vars)`

Assert that running the interpreter with `args` and optional environment variables `env_vars` succeeds (`rc == 0`) and return a (return code, stdout, stderr) tuple.

If the `__cleanenv` keyword is set, `env_vars` is used as a fresh environment.

Python is started in isolated mode (command line option `-I`), except if the `__isolated` keyword is set to False.

`test.support.script_helper.assert_python_failure(*args, **env_vars)`

Assert that running the interpreter with `args` and optional environment variables `env_vars` fails (`rc != 0`) and return a (return code, stdout, stderr) tuple.

See `assert_python_ok()` for more options.

`test.support.script_helper.spawn_python(*args, stdout=subprocess.PIPE, stderr=subprocess.STDOUT, **kw)`

Run a Python subprocess with the given arguments.

`kw` is extra keyword args to pass to `subprocess.Popen()`. Returns a `subprocess.Popen` object.

`test.support.script_helper.kill_python(p)`

Run the given `subprocess.Popen` process until completion and return stdout.

`test.support.script_helper.make_script(script_dir, script_basename, source, omit_suffix=False)`

Create script containing `source` in path `script_dir` and `script_basename`. If `omit_suffix` is False, append `.py` to the name. Return the full script path.

`test.support.script_helper.make_zip_script(zip_dir, zip_basename, script_name, name_in_zip=None)`

Create zip file at `zip_dir` and `zip_basename` with extension `zip` which contains the files in `script_name`. `name_in_zip` is the archive name. Return a tuple containing (full path, full path of archive name).

`test.support.script_helper.make_pkg(pkg_dir, init_source="")`

Create a directory named `pkg_dir` containing an `__init__` file with `init_source` as its contents.

`test.support.script_helper.make_zip_pkg(zip_dir, zip_basename, pkg_name, script_basename, source, depth=1, compiled=False)`

Create a zip package directory with a path of *zip\_dir* and *zip\_basename* containing an empty `__init__` file and a file *script\_basename* containing the *source*. If *compiled* is `True`, both source files will be compiled and added to the zip package. Return a tuple of the full zip path and the archive name for the zip file.

See also the Python development mode: the `-X dev` option and `PYTHONDEVMODE` environment variable.

---

## Debugging dan Profiling

---

Pustaka-pustaka ini membantu Anda dalam pengembangan Python: debugger memungkinkan Anda untuk menelusuri kode, menganalisis bingkai tumpukan (stack frames), dan mengatur breakpoints dll., Dan profiler menjalankan kode dan memberi Anda rincian waktu eksekusi, yang memungkinkan Anda untuk mengidentifikasi kemacetan (bottlenecks) dalam program Anda. Audit memberikan visibilitas ke dalam perilaku runtime yang seharusnya memerlukan debugging atau patch yang mengganggu.

### 27.1 Audit events table

This table contains all events raised by `sys.audit()` or `PySys_Audit()` calls throughout the CPython runtime and the standard library. These calls were added in 3.8.0 or later (see [PEP 578](#)).

See `sys.addaudithook()` and `PySys_AddAuditHook()` for information on handling these events.

**CPython implementation detail:** This table is generated from the CPython documentation, and may not represent events raised by other implementations. See your runtime specific documentation for actual events raised.

| Audit event                                   | Arguments                                                                            |
|-----------------------------------------------|--------------------------------------------------------------------------------------|
| <code>array.__new__</code>                    | <code>typecode, initializer</code>                                                   |
| <code>builtins.breakpoint</code>              | <code>breakpointhook</code>                                                          |
| <code>builtins.id</code>                      | <code>id</code>                                                                      |
| <code>builtins.input</code>                   | <code>prompt</code>                                                                  |
| <code>builtins.input/result</code>            | <code>result</code>                                                                  |
| <code>code.__new__</code>                     | <code>code, filename, name, argcount, posonlyargcount, kwonlyargcount, nlocal</code> |
| <code>compile</code>                          | <code>source, filename</code>                                                        |
| <code>cpython.PyInterpreterState_Clear</code> |                                                                                      |
| <code>cpython.PyInterpreterState_New</code>   |                                                                                      |
| <code>cpython._PySys_ClearAuditHooks</code>   |                                                                                      |
| <code>cpython.run_command</code>              | <code>command</code>                                                                 |
| <code>cpython.run_file</code>                 | <code>filename</code>                                                                |
| <code>cpython.run_interactivehook</code>      | <code>hook</code>                                                                    |

## 27.2 bdb --- Debugger framework

Source code: [Lib/bdb.py](#)

The *bdb* module handles basic debugger functions, like setting breakpoints or managing execution via the debugger.

The following exception is defined:

**exception** `bdb.BdbQuit`  
Exception raised by the *Bdb* class for quitting the debugger.

The *bdb* module also defines two classes:

**class** `bdb.Breakpoint` (*self*, *file*, *line*, *temporary*=0, *cond*=None, *funcname*=None)  
This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

Breakpoints are indexed by number through a list called `bppynumber` and by (*file*, *line*) pairs through `bplist`. The former points to a single instance of class *Breakpoint*. The latter points to a list of such instances since there may be more than one breakpoint per line.

When creating a breakpoint, its associated filename should be in canonical form. If a *funcname* is defined, a breakpoint hit will be counted when the first line of that function is executed. A conditional breakpoint always counts a hit.

*Breakpoint* instances have the following methods:

**deleteMe** ()  
Delete the breakpoint from the list associated to a file/line. If it is the last breakpoint in that position, it also deletes the entry for the file/line.

**enable** ()  
Mark the breakpoint as enabled.

**disable()**

Mark the breakpoint as disabled.

**bpformat()**

Return a string with all the information about the breakpoint, nicely formatted:

- The breakpoint number.
- If it is temporary or not.
- Its file, line position.
- The condition that causes a break.
- If it must be ignored the next N times.
- The breakpoint hit count.

Baru pada versi 3.2.

**bpprint(out=None)**

Print the output of `bpformat()` to the file *out*, or if it is `None`, to standard output.

**class bdb.Bdb(skip=None)**

The `Bdb` class acts as a generic Python debugger base class.

This class takes care of the details of the trace facility; a derived class should implement user interaction. The standard debugger class (`pdb.Pdb`) is an example.

The *skip* argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

Baru pada versi 3.1: The *skip* argument.

The following methods of `Bdb` normally don't need to be overridden.

**canonic(filename)**

Auxiliary method for getting a filename in a canonical form, that is, as a case-normalized (on case-insensitive filesystems) absolute path, stripped of surrounding angle brackets.

**reset()**

Set the `botframe`, `stopframe`, `returnframe` and `quitting` attributes with values ready to start debugging.

**trace\_dispatch(frame, event, arg)**

This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. *event* can be one of the following:

- "line": A new line of code is going to be executed.
- "call": A function is about to be called, or another code block entered.
- "return": A function or other code block is about to return.
- "exception": An exception has occurred.
- "c\_call": A C function is about to be called.
- "c\_return": A C function has returned.
- "c\_exception": A C function has raised an exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

The *arg* parameter depends on the previous event.

See the documentation for `sys.settrace()` for more information on the trace function. For more information on code and frame objects, refer to types.

#### **dispatch\_line** (*frame*)

If the debugger should stop on the current line, invoke the `user_line()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_line()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

#### **dispatch\_call** (*frame*, *arg*)

If the debugger should stop on this function call, invoke the `user_call()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_call()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

#### **dispatch\_return** (*frame*, *arg*)

If the debugger should stop on this function return, invoke the `user_return()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_return()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

#### **dispatch\_exception** (*frame*, *arg*)

If the debugger should stop at this exception, invokes the `user_exception()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_exception()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

Normally derived classes don't override the following methods, but they may if they want to redefine the definition of stopping and breakpoints.

#### **stop\_here** (*frame*)

This method checks if the *frame* is somewhere below `botframe` in the call stack. `botframe` is the frame in which debugging started.

#### **break\_here** (*frame*)

This method checks if there is a breakpoint in the filename and line belonging to *frame* or, at least, in the current function. If the breakpoint is a temporary one, this method deletes it.

#### **break\_anywhere** (*frame*)

This method checks if there is a breakpoint in the filename of the current frame.

Derived classes should override these methods to gain control over debugger operation.

#### **user\_call** (*frame*, *argument\_list*)

This method is called from `dispatch_call()` when there is the possibility that a break might be necessary anywhere inside the called function.

#### **user\_line** (*frame*)

This method is called from `dispatch_line()` when either `stop_here()` or `break_here()` yields True.

#### **user\_return** (*frame*, *return\_value*)

This method is called from `dispatch_return()` when `stop_here()` yields True.

#### **user\_exception** (*frame*, *exc\_info*)

This method is called from `dispatch_exception()` when `stop_here()` yields True.

**do\_clear** (*arg*)

Handle how a breakpoint must be removed when it is a temporary one.

This method must be implemented by derived classes.

Derived classes and clients can call the following methods to affect the stepping state.

**set\_step** ()

Stop after one line of code.

**set\_next** (*frame*)

Stop on the next line in or below the given frame.

**set\_return** (*frame*)

Stop when returning from the given frame.

**set\_until** (*frame*)

Stop when the line with the line no greater than the current one is reached or when returning from current frame.

**set\_trace** ([*frame*])

Start debugging from *frame*. If *frame* is not specified, debugging starts from caller's frame.

**set\_continue** ()

Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to `None`.

**set\_quit** ()

Set the `quitting` attribute to `True`. This raises `BdbQuit` in the next call to one of the `dispatch_*` () methods.

Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or `None` if all is well.

**set\_break** (*filename*, *lineno*, *temporary=0*, *cond*, *funcname*)

Set a new breakpoint. If the *lineno* line doesn't exist for the *filename* passed as argument, return an error message. The *filename* should be in canonical form, as described in the `canonic` () method.

**clear\_break** (*filename*, *lineno*)

Delete the breakpoints in *filename* and *lineno*. If none were set, an error message is returned.

**clear\_bpbynumber** (*arg*)

Delete the breakpoint which has the index *arg* in the `Breakpoint.bpbynumber`. If *arg* is not numeric or out of range, return an error message.

**clear\_all\_file\_breaks** (*filename*)

Delete all breakpoints in *filename*. If none were set, an error message is returned.

**clear\_all\_breaks** ()

Delete all existing breakpoints.

**get\_bpbynumber** (*arg*)

Return a breakpoint specified by the given number. If *arg* is a string, it will be converted to a number. If *arg* is a non-numeric string, if the given breakpoint never existed or has been deleted, a `ValueError` is raised.

Baru pada versi 3.2.

**get\_break** (*filename*, *lineno*)

Check if there is a breakpoint for *lineno* of *filename*.

**get\_breaks** (*filename*, *lineno*)

Return all breakpoints for *lineno* in *filename*, or an empty list if none are set.

**get\_file\_breaks** (*filename*)

Return all breakpoints in *filename*, or an empty list if none are set.

**get\_all\_breaks** ()

Return all breakpoints that are set.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

**get\_stack** (*f*, *t*)

Get a list of records for a frame and all higher (calling) and lower frames, and the size of the higher part.

**format\_stack\_entry** (*frame\_lineno*, *lprefix*=': ')

Return a string with information about a stack entry, identified by a (*frame*, *lineno*) tuple:

- The canonical form of the filename which contains the frame.
- The function name, or "<lambda>".
- The input arguments.
- The return value.
- The line of code (if it exists).

The following two methods can be called by clients to use a debugger to debug a *statement*, given as a string.

**run** (*cmd*, *globals*=None, *locals*=None)

Debug a statement executed via the *exec* () function. *globals* defaults to `__main__.__dict__`, *locals* defaults to *globals*.

**runeval** (*expr*, *globals*=None, *locals*=None)

Debug an expression executed via the *eval* () function. *globals* and *locals* have the same meaning as in *run* ().

**runctx** (*cmd*, *globals*, *locals*)

For backwards compatibility. Calls the *run* () method.

**runcall** (*func*, *\*args*, *\*\*kws*)

Debug a single function call, and return its result.

Finally, the module defines the following functions:

`bdb`.**checkfuncname** (*b*, *frame*)

Check whether we should break here, depending on the way the breakpoint *b* was set.

If it was set via line number, it checks if `b.line` is the same as the one in the frame also passed as argument. If the breakpoint was set via function name, we have to check we are in the right frame (the right function) and if we are in its first executable line.

`bdb`.**effective** (*file*, *line*, *frame*)

Determine if there is an effective (active) breakpoint at this line of code. Return a tuple of the breakpoint and a boolean that indicates if it is ok to delete a temporary breakpoint. Return (`None`, `None`) if there is no matching breakpoint.

`bdb`.**set\_trace** ()

Start debugging with a *Bdb* instance from caller's frame.

## 27.3 `faulthandler` --- Dump the Python traceback

Baru pada versi 3.3.

This module contains functions to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal. Call `faulthandler.enable()` to install fault handlers for the `SIGSEGV`, `SIGFPE`, `SIGABRT`, `SIGBUS`, and `SIGILL` signals. You can also enable them at startup by setting the `PYTHONFAULTHANDLER` environment variable or by using the `-X faulthandler` command line option.

The fault handler is compatible with system fault handlers like Apport or the Windows fault handler. The module uses an alternative stack for signal handlers if the `sigaltstack()` function is available. This allows it to dump the traceback even on a stack overflow.

The fault handler is called on catastrophic cases and therefore can only use signal-safe functions (e.g. it cannot allocate memory on the heap). Because of this limitation traceback dumping is minimal compared to normal Python tracebacks:

- Only ASCII is supported. The `backslashreplace` error handler is used on encoding.
- Each string is limited to 500 characters.
- Only the filename, the function name and the line number are displayed. (no source code)
- It is limited to 100 frames and 100 threads.
- The order is reversed: the most recent call is shown first.

By default, the Python traceback is written to `sys.stderr`. To see tracebacks, applications must be run in the terminal. A log file can alternatively be passed to `faulthandler.enable()`.

The module is implemented in C, so tracebacks can be dumped on a crash or when Python is deadlocked.

### 27.3.1 Dumping the traceback

`faulthandler.dump_traceback(file=sys.stderr, all_threads=True)`

Dump the tracebacks of all threads into *file*. If *all\_threads* is `False`, dump only the current thread.

Berubah pada versi 3.5: Added support for passing file descriptor to this function.

### 27.3.2 Fault handler state

`faulthandler.enable(file=sys.stderr, all_threads=True)`

Enable the fault handler: install handlers for the `SIGSEGV`, `SIGFPE`, `SIGABRT`, `SIGBUS` and `SIGILL` signals to dump the Python traceback. If *all\_threads* is `True`, produce tracebacks for every running thread. Otherwise, dump only the current thread.

The *file* must be kept open until the fault handler is disabled: see *issue with file descriptors*.

Berubah pada versi 3.5: Added support for passing file descriptor to this function.

Berubah pada versi 3.6: On Windows, a handler for Windows exception is also installed.

`faulthandler.disable()`

Disable the fault handler: uninstall the signal handlers installed by `enable()`.

`faulthandler.is_enabled()`

Check if the fault handler is enabled.

### 27.3.3 Dumping the tracebacks after a timeout

`faulthandler.dump_traceback_later` (*timeout*, *repeat=False*, *file=sys.stderr*, *exit=False*)

Dump the tracebacks of all threads, after a timeout of *timeout* seconds, or every *timeout* seconds if *repeat* is `True`. If *exit* is `True`, call `_exit()` with `status=1` after dumping the tracebacks. (Note `_exit()` exits the process immediately, which means it doesn't do any cleanup like flushing file buffers.) If the function is called twice, the new call replaces previous parameters and resets the timeout. The timer has a sub-second resolution.

The *file* must be kept open until the traceback is dumped or `cancel_dump_traceback_later()` is called: see [issue with file descriptors](#).

This function is implemented using a watchdog thread.

Berubah pada versi 3.7: This function is now always available.

Berubah pada versi 3.5: Added support for passing file descriptor to this function.

`faulthandler.cancel_dump_traceback_later()`

Cancel the last call to `dump_traceback_later()`.

### 27.3.4 Dumping the traceback on a user signal

`faulthandler.register` (*signum*, *file=sys.stderr*, *all\_threads=True*, *chain=False*)

Register a user signal: install a handler for the *signum* signal to dump the traceback of all threads, or of the current thread if *all\_threads* is `False`, into *file*. Call the previous handler if *chain* is `True`.

The *file* must be kept open until the signal is unregistered by `unregister()`: see [issue with file descriptors](#).

Not available on Windows.

Berubah pada versi 3.5: Added support for passing file descriptor to this function.

`faulthandler.unregister` (*signum*)

Unregister a user signal: uninstall the handler of the *signum* signal installed by `register()`. Return `True` if the signal was registered, `False` otherwise.

Not available on Windows.

### 27.3.5 Issue with file descriptors

`enable()`, `dump_traceback_later()` and `register()` keep the file descriptor of their *file* argument. If the file is closed and its file descriptor is reused by a new file, or if `os.dup2()` is used to replace the file descriptor, the traceback will be written into a different file. Call these functions again each time that the file is replaced.

### 27.3.6 Contoh

Example of a segmentation fault on Linux with and without enabling the fault handler:

```
$ python3 -c "import ctypes; ctypes.string_at(0)"
Segmentation fault

$ python3 -q -X faulthandler
>>> import ctypes
>>> ctypes.string_at(0)
Fatal Python error: Segmentation fault
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
Current thread 0x00007fb899f39700 (most recent call first):
  File "/home/python/cpython/Lib/ctypes/__init__.py", line 486 in string_at
  File "<stdin>", line 1 in <module>
Segmentation fault
```

## 27.4 pdb --- The Python Debugger

**Source code:** [Lib/pdb.py](#)

The module [pdb](#) defines an interactive source code debugger for Python programs. It supports setting (conditional) breakpoints and single stepping at the source line level, inspection of stack frames, source code listing, and evaluation of arbitrary Python code in the context of any stack frame. It also supports post-mortem debugging and can be called under program control.

The debugger is extensible -- it is actually defined as the class [Pdb](#). This is currently undocumented but easily understood by reading the source. The extension interface uses the modules [bdb](#) and [cmd](#).

The debugger's prompt is `(Pdb)`. Typical usage to run a program under control of the debugger is:

```
>>> import pdb
>>> import mymodule
>>> pdb.run('mymodule.test()')
> <string>(0)?()
(Pdb) continue
> <string>(1)?()
(Pdb) continue
NameError: 'spam'
> <string>(1)?()
(Pdb)
```

Berubah pada versi 3.3: Tab-completion via the [readline](#) module is available for commands and command arguments, e.g. the current global and local names are offered as arguments of the `p` command.

`pdb.py` can also be invoked as a script to debug other scripts. For example:

```
python3 -m pdb myscript.py
```

When invoked as a script, `pdb` will automatically enter post-mortem debugging if the program being debugged exits abnormally. After post-mortem debugging (or after normal exit of the program), `pdb` will restart the program. Automatic restarting preserves `pdb`'s state (such as breakpoints) and in most cases is more useful than quitting the debugger upon program's exit.

Baru pada versi 3.2: `pdb.py` now accepts a `-c` option that executes commands as if given in a `.pdbrc` file, see [Debugger Commands](#).

Baru pada versi 3.7: `pdb.py` now accepts a `-m` option that execute modules similar to the way `python3 -m` does. As with a script, the debugger will pause execution just before the first line of the module.

The typical usage to break into the debugger from a running program is to insert

```
import pdb; pdb.set_trace()
```

at the location you want to break into the debugger. You can then step through the code following this statement, and continue running without the debugger using the [continue](#) command.

Baru pada versi 3.7: The built-in `breakpoint()`, when called with defaults, can be used instead of `import pdb; pdb.set_trace()`.

The typical usage to inspect a crashed program is:

```
>>> import pdb
>>> import mymodule
>>> mymodule.test()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "./mymodule.py", line 4, in test
    test2()
  File "./mymodule.py", line 3, in test2
    print(spam)
NameError: spam
>>> pdb.pm()
> ./mymodule.py(3)test2()
-> print(spam)
(Pdb)
```

The module defines the following functions; each enters the debugger in a slightly different way:

`pdb.run(statement, globals=None, locals=None)`

Execute the *statement* (given as a string or a code object) under debugger control. The debugger prompt appears before any code is executed; you can set breakpoints and type `continue`, or you can step through the statement using `step` or `next` (all these commands are explained below). The optional *globals* and *locals* arguments specify the environment in which the code is executed; by default the dictionary of the module `__main__` is used. (See the explanation of the built-in `exec()` or `eval()` functions.)

`pdb.runeval(expression, globals=None, locals=None)`

Evaluate the *expression* (given as a string or a code object) under debugger control. When `runeval()` returns, it returns the value of the expression. Otherwise this function is similar to `run()`.

`pdb.runcall(function, *args, **kwargs)`

Call the *function* (a function or method object, not a string) with the given arguments. When `runcall()` returns, it returns whatever the function call returned. The debugger prompt appears as soon as the function is entered.

`pdb.set_trace(*, header=None)`

Enter the debugger at the calling stack frame. This is useful to hard-code a breakpoint at a given point in a program, even if the code is not otherwise being debugged (e.g. when an assertion fails). If given, *header* is printed to the console just before debugging begins.

Berubah pada versi 3.7: The keyword-only argument *header*.

`pdb.post_mortem(traceback=None)`

Enter post-mortem debugging of the given *traceback* object. If no *traceback* is given, it uses the one of the exception that is currently being handled (an exception must be being handled if the default is to be used).

`pdb.pm()`

Enter post-mortem debugging of the traceback found in `sys.last_traceback`.

The `run*` functions and `set_trace()` are aliases for instantiating the `Pdb` class and calling the method of the same name. If you want to access further features, you have to do this yourself:

**class** `pdb.Pdb` (*completekey='tab', stdin=None, stdout=None, skip=None, nosigint=False, readrc=True*)

*Pdb* is the debugger class.

The *completekey*, *stdin* and *stdout* arguments are passed to the underlying `cmd.Cmd` class; see the description there.

The *skip* argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step

into frames that originate in a module that matches one of these patterns.<sup>1</sup>

By default, Pdb sets a handler for the SIGINT signal (which is sent when the user presses Ctrl-C on the console) when you give a `continue` command. This allows you to break into the debugger again by pressing Ctrl-C. If you want Pdb not to touch the SIGINT handler, set `nosigint` to true.

The `readrc` argument defaults to true and controls whether Pdb will load `.pdbrc` files from the filesystem.

Example call to enable tracing with `skip`:

```
import pdb; pdb.Pdb(skip=['django.*']).set_trace()
```

Raises an *auditing event* `pdb.Pdb` with no arguments.

Baru pada versi 3.1: The `skip` argument.

Baru pada versi 3.2: The `nosigint` argument. Previously, a SIGINT handler was never set by Pdb.

Berubah pada versi 3.6: The `readrc` argument.

**run** (*statement*, *globals=None*, *locals=None*)

**runeval** (*expression*, *globals=None*, *locals=None*)

**runcall** (*function*, *\*args*, *\*\*kwargs*)

**set\_trace** ()

See the documentation for the functions explained above.

## 27.4.1 Debugger Commands

The commands recognized by the debugger are listed below. Most commands can be abbreviated to one or two letters as indicated; e.g. `h(elp)` means that either `h` or `help` can be used to enter the help command (but not `he` or `hel`, nor `H` or `Help` or `HELP`). Arguments to commands must be separated by whitespace (spaces or tabs). Optional arguments are enclosed in square brackets (`[]`) in the command syntax; the square brackets must not be typed. Alternatives in the command syntax are separated by a vertical bar (`|`).

Entering a blank line repeats the last command entered. Exception: if the last command was a `list` command, the next 11 lines are listed.

Commands that the debugger doesn't recognize are assumed to be Python statements and are executed in the context of the program being debugged. Python statements can also be prefixed with an exclamation point (`!`). This is a powerful way to inspect the program being debugged; it is even possible to change a variable or call a function. When an exception occurs in such a statement, the exception name is printed but the debugger's state is not changed.

The debugger supports *aliases*. Aliases can have parameters which allows one a certain level of adaptability to the context under examination.

Multiple commands may be entered on a single line, separated by `;;`. (A single `;` is not used as it is the separator for multiple commands in a line that is passed to the Python parser.) No intelligence is applied to separating the commands; the input is split at the first `;;` pair, even if it is in the middle of a quoted string.

If a file `.pdbrc` exists in the user's home directory or in the current directory, it is read in and executed as if it had been typed at the debugger prompt. This is particularly useful for aliases. If both files exist, the one in the home directory is read first and aliases defined there can be overridden by the local file.

Berubah pada versi 3.2: `.pdbrc` can now contain commands that continue debugging, such as `continue` or `next`. Previously, these commands had no effect.

**h(elp)** [*command*]

Without argument, print the list of available commands. With a *command* as argument, print help about that

---

<sup>1</sup> Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

command. `help pdb` displays the full documentation (the docstring of the `pdb` module). Since the *command* argument must be an identifier, `help exec` must be entered to get help on the `!` command.

**w(here)**

Print a stack trace, with the most recent frame at the bottom. An arrow indicates the current frame, which determines the context of most commands.

**d(own)** [*count*]

Move the current frame *count* (default one) levels down in the stack trace (to a newer frame).

**u(p)** [*count*]

Move the current frame *count* (default one) levels up in the stack trace (to an older frame).

**b(reak)** [[([*filename*:]*lineno* | *function*) [, *condition*]]

With a *lineno* argument, set a break there in the current file. With a *function* argument, set a break at the first executable statement within that function. The line number may be prefixed with a filename and a colon, to specify a breakpoint in another file (probably one that hasn't been loaded yet). The file is searched on `sys.path`. Note that each breakpoint is assigned a number to which all the other breakpoint commands refer.

If a second argument is present, it is an expression which must evaluate to true before the breakpoint is honored.

Without argument, list all breaks, including for each breakpoint, the number of times that breakpoint has been hit, the current ignore count, and the associated condition if any.

**tbreak** [[([*filename*:]*lineno* | *function*) [, *condition*]]

Temporary breakpoint, which is removed automatically when it is first hit. The arguments are the same as for *break*.

**cl(ear)** [*filename*:*lineno* | *bpnumber* [*bpnumber* ...]]

With a *filename:lineno* argument, clear all the breakpoints at this line. With a space separated list of breakpoint numbers, clear those breakpoints. Without argument, clear all breaks (but first ask confirmation).

**disable** [*bpnumber* [*bpnumber* ...]]

Disable the breakpoints given as a space separated list of breakpoint numbers. Disabling a breakpoint means it cannot cause the program to stop execution, but unlike clearing a breakpoint, it remains in the list of breakpoints and can be (re-)enabled.

**enable** [*bpnumber* [*bpnumber* ...]]

Enable the breakpoints specified.

**ignore** *bpnumber* [*count*]

Set the ignore count for the given breakpoint number. If *count* is omitted, the ignore count is set to 0. A breakpoint becomes active when the ignore count is zero. When non-zero, the count is decremented each time the breakpoint is reached and the breakpoint is not disabled and any associated condition evaluates to true.

**condition** *bpnumber* [*condition*]

Set a new *condition* for the breakpoint, an expression which must evaluate to true before the breakpoint is honored. If *condition* is absent, any existing condition is removed; i.e., the breakpoint is made unconditional.

**commands** [*bpnumber*]

Specify a list of commands for breakpoint number *bpnumber*. The commands themselves appear on the following lines. Type a line containing just `end` to terminate the commands. An example:

```
(Pdb) commands 1
(com) p some_variable
(com) end
(Pdb)
```

To remove all commands from a breakpoint, type `commands` and follow it immediately with `end`; that is, give no commands.

With no *bnumber* argument, `commands` refers to the last breakpoint set.

You can use breakpoint commands to start your program up again. Simply use the `continue` command, or `step`, or any other command that resumes execution.

Specifying any command resuming execution (currently `continue`, `step`, `next`, `return`, `jump`, `quit` and their abbreviations) terminates the command list (as if that command was immediately followed by `end`). This is because any time you resume execution (even with a simple `next` or `step`), you may encounter another breakpoint—which could have its own command list, leading to ambiguities about which list to execute.

If you use the 'silent' command in the command list, the usual message about stopping at a breakpoint is not printed. This may be desirable for breakpoints that are to print a specific message and then continue. If none of the other commands print anything, you see no sign that the breakpoint was reached.

### **s (step)**

Execute the current line, stop at the first possible occasion (either in a function that is called or on the next line in the current function).

### **n (ext)**

Continue execution until the next line in the current function is reached or it returns. (The difference between `next` and `step` is that `step` stops inside a called function, while `next` executes called functions at (nearly) full speed, only stopping at the next line in the current function.)

### **unt (il) [lineno]**

Without argument, continue execution until the line with a number greater than the current one is reached.

With a line number, continue execution until a line with a number greater or equal to that is reached. In both cases, also stop when the current frame returns.

Berubah pada versi 3.2: Allow giving an explicit line number.

### **r (eturn)**

Continue execution until the current function returns.

### **c (ontinue)**

Continue execution, only stop when a breakpoint is encountered.

### **j (ump) lineno**

Set the next line that will be executed. Only available in the bottom-most frame. This lets you jump back and execute code again, or jump forward to skip code that you don't want to run.

It should be noted that not all jumps are allowed -- for instance it is not possible to jump into the middle of a `for` loop or out of a `finally` clause.

### **l (ist) [first[, last]]**

List source code for the current file. Without arguments, list 11 lines around the current line or continue the previous listing. With `.` as argument, list 11 lines around the current line. With one argument, list 11 lines around at that line. With two arguments, list the given range; if the second argument is less than the first, it is interpreted as a count.

The current line in the current frame is indicated by `->`. If an exception is being debugged, the line where the exception was originally raised or propagated is indicated by `>>`, if it differs from the current line.

Baru pada versi 3.2: The `>>` marker.

### **ll | longlist**

List all source code for the current function or frame. Interesting lines are marked as for `list`.

Baru pada versi 3.2.

### **a (rgs)**

Print the argument list of the current function.

**p** *expression*Evaluate the *expression* in the current context and print its value.

---

**Catatan:** `print()` can also be used, but is not a debugger command --- this executes the Python `print()` function.

---

**pp** *expression*Like the `p` command, except the value of the expression is pretty-printed using the `pprint` module.**whatis** *expression*Print the type of the *expression*.**source** *expression*

Try to get source code for the given object and display it.

Baru pada versi 3.2.

**display** [*expression*]

Display the value of the expression if it changed, each time execution stops in the current frame.

Without expression, list all display expressions for the current frame.

Baru pada versi 3.2.

**undisplay** [*expression*]

Do not display the expression any more in the current frame. Without expression, clear all display expressions for the current frame.

Baru pada versi 3.2.

**interact**Start an interactive interpreter (using the `code` module) whose global namespace contains all the (global and local) names found in the current scope.

Baru pada versi 3.2.

**alias** [*name* [*command*]]Create an alias called *name* that executes *command*. The command must *not* be enclosed in quotes. Replaceable parameters can be indicated by %1, %2, and so on, while %\* is replaced by all the parameters. If no command is given, the current alias for *name* is shown. If no arguments are given, all aliases are listed.Aliases may be nested and can contain anything that can be legally typed at the pdb prompt. Note that internal pdb commands *can* be overridden by aliases. Such a command is then hidden until the alias is removed. Aliasing is recursively applied to the first word of the command line; all other words in the line are left alone.As an example, here are two useful aliases (especially when placed in the `.pdbrc` file):

```
# Print instance variables (usage "pi classInst")
alias pi for k in %1.__dict__.keys(): print("%1.", k, "=", %1.__dict__[k])
# Print instance variables in self
alias ps pi self
```

**unalias** *name*

Delete the specified alias.

**!** *statement*Execute the (one-line) *statement* in the context of the current stack frame. The exclamation point can be omitted unless the first word of the statement resembles a debugger command. To set a global variable, you can prefix the assignment command with a `global` statement on the same line, e.g.:

```
(Pdb) global list_options; list_options = ['-l']  
(Pdb)
```

**run** [args ...]

**restart** [args ...]

Restart the debugged Python program. If an argument is supplied, it is split with *shlex* and the result is used as the new *sys.argv*. History, breakpoints, actions and debugger options are preserved. *restart* is an alias for *run*.

**q(uit)**

Quit from the debugger. The program being executed is aborted.

**debug** code

Enter a recursive debugger that steps through the code argument (which is an arbitrary expression or statement to be executed in the current environment).

**retval**

Print the return value for the last return of a function.

## 27.5 The Python Profilers

**Source code:** [Lib/profile.py](#) and [Lib/pstats.py](#)

---

### 27.5.1 Introduction to the profilers

*cProfile* and *profile* provide *deterministic profiling* of Python programs. A *profile* is a set of statistics that describes how often and for how long various parts of the program executed. These statistics can be formatted into reports via the *pstats* module.

The Python standard library provides two different implementations of the same profiling interface:

1. *cProfile* is recommended for most users; it's a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on *lsprof*, contributed by Brett Rosen and Ted Czotter.
2. *profile*, a pure Python module whose interface is imitated by *cProfile*, but which adds significant overhead to profiled programs. If you're trying to extend the profiler in some way, the task might be easier with this module. Originally designed and written by Jim Roskind.

---

**Catatan:** The profiler modules are designed to provide an execution profile for a given program, not for benchmarking purposes (for that, there is *timeit* for reasonably accurate results). This particularly applies to benchmarking Python code against C code: the profilers introduce overhead for Python code, but not for C-level functions, and so the C code would seem faster than any Python one.

---

## 27.5.2 Instant User's Manual

This section is provided for users that "don't want to read the manual." It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile a function that takes a single argument, you can do:

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")')
```

(Use `profile` instead of `cProfile` if the latter is not available on your system.)

The above action would run `re.compile()` and print profile results like the following:

```
197 function calls (192 primitive calls) in 0.002 seconds

Ordered by: standard name
```

| ncalls | tottime | percall | cumtime | percall | filename:lineno(function)             |
|--------|---------|---------|---------|---------|---------------------------------------|
| 1      | 0.000   | 0.000   | 0.001   | 0.001   | <string>:1(<module>)                  |
| 1      | 0.000   | 0.000   | 0.001   | 0.001   | re.py:212(compile)                    |
| 1      | 0.000   | 0.000   | 0.001   | 0.001   | re.py:268(_compile)                   |
| 1      | 0.000   | 0.000   | 0.000   | 0.000   | sre_compile.py:172(_compile_charset)  |
| 1      | 0.000   | 0.000   | 0.000   | 0.000   | sre_compile.py:201(_optimize_charset) |
| 4      | 0.000   | 0.000   | 0.000   | 0.000   | sre_compile.py:25(_identityfunction)  |
| 3/1    | 0.000   | 0.000   | 0.000   | 0.000   | sre_compile.py:33(_compile)           |

The first line indicates that 197 calls were monitored. Of those calls, 192 were *primitive*, meaning that the call was not induced via recursion. The next line: Ordered by: standard name, indicates that the text string in the far right column was used to sort the output. The column headings include:

**ncalls** for the number of calls.

**tottime** for the total time spent in the given function (and excluding time made in calls to sub-functions)

**percall** is the quotient of `tottime` divided by `ncalls`

**cumtime** is the cumulative time spent in this and all subfunctions (from invocation till exit). This figure is accurate *even* for recursive functions.

**percall** is the quotient of `cumtime` divided by primitive calls

**filename:lineno(function)** provides the respective data of each function

When there are two numbers in the first column (for example 3/1), it means that the function recursed. The second value is the number of primitive calls and the former is the total number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

Instead of printing the output at the end of the profile run, you can save the results to a file by specifying a filename to the `run()` function:

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")', 'restats')
```

The `pstats.Stats` class reads profile results from a file and formats them in various ways.

The files `cProfile` and `profile` can also be invoked as a script to profile another script. For example:

```
python -m cProfile [-o output_file] [-s sort_order] (-m module | myscript.py)
```

- o writes the profile results to a file instead of to stdout
- s specifies one of the `sort_stats()` sort values to sort the output by. This only applies when -o is not supplied.
- m specifies that a module is being profiled instead of a script.

Baru pada versi 3.7: Added the -m option to `cProfile`.

Baru pada versi 3.8: Added the -m option to `profile`.

The `pstats` module's `Stats` class has a variety of methods for manipulating and printing the data saved into a profile results file:

```
import pstats
from pstats import SortKey
p = pstats.Stats('restats')
p.strip_dirs().sort_stats(-1).print_stats()
```

The `strip_dirs()` method removed the extraneous path from all the module names. The `sort_stats()` method sorted all the entries according to the standard module/line/name string that is printed. The `print_stats()` method printed out all the statistics. You might try the following sort calls:

```
p.sort_stats(SortKey.NAME)
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls to experiment with:

```
p.sort_stats(SortKey.CUMULATIVE).print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.

If you were looking to see what functions were looping a lot, and taking a lot of time, you would do:

```
p.sort_stats(SortKey.TIME).print_stats(10)
```

to sort according to time spent within each function, and then print the statistics for the top ten functions.

You might also try:

```
p.sort_stats(SortKey.FILENAME).print_stats('__init__')
```

This will sort all the statistics by file name, and then print out statistics for only the class init methods (since they are spelled with `__init__` in them). As one final example, you could try:

```
p.sort_stats(SortKey.TIME, SortKey.CUMULATIVE).print_stats(.5, 'init')
```

This line sorts statistics with a primary key of time, and a secondary key of cumulative time, and then prints out some of the statistics. To be specific, the list is first culled down to 50% (re: `.5`) of its original size, then only lines containing `init` are maintained, and that sub-sub-list is printed.

If you wondered what functions called the above functions, you could now (`p` is still sorted according to the last criteria) do:

```
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you're going to have to read the manual, or guess what the following functions do:

```
p.print_callees()
p.add('restats')
```

Invoked as a script, the `pstats` module is a statistics browser for reading and examining profile dumps. It has a simple line-oriented interface (implemented using `cmd`) and interactive help.

### 27.5.3 profile and cProfile Module Reference

Both the `profile` and `cProfile` modules provide the following functions:

`profile.run(command, filename=None, sort=-1)`

This function takes a single argument that can be passed to the `exec()` function, and an optional file name. In all cases this routine executes:

```
exec(command, __main__.__dict__, __main__.__dict__)
```

and gathers profiling statistics from the execution. If no file name is present, then this function automatically creates a `Stats` instance and prints a simple profiling report. If the sort value is specified, it is passed to this `Stats` instance to control how the results are sorted.

`profile.runctx(command, globals, locals, filename=None, sort=-1)`

This function is similar to `run()`, with added arguments to supply the globals and locals dictionaries for the `command` string. This routine executes:

```
exec(command, globals, locals)
```

and gathers profiling statistics as in the `run()` function above.

**class** `profile.Profile(timer=None, timeunit=0.0, subcalls=True, builtins=True)`

This class is normally only used if more precise control over profiling is needed than what the `cProfile.run()` function provides.

A custom timer can be supplied for measuring how long code takes to run via the `timer` argument. This must be a function that returns a single number representing the current time. If the number is an integer, the `timeunit` specifies a multiplier that specifies the duration of each unit of time. For example, if the timer returns times measured in thousands of seconds, the time unit would be `.001`.

Directly using the `Profile` class allows formatting profile results without writing the profile data to a file:

```
import cProfile, pstats, io
from pstats import SortKey
pr = cProfile.Profile()
pr.enable()
# ... do something ...
pr.disable()
s = io.StringIO()
sortby = SortKey.CUMULATIVE
ps = pstats.Stats(pr, stream=s).sort_stats(sortby)
ps.print_stats()
print(s.getvalue())
```

The `Profile` class can also be used as a context manager (supported only in `cProfile` module. see [Context Manager Types](#)):

```
import cProfile
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
with cProfile.Profile() as pr:
    # ... do something ...

pr.print_stats()
```

Berubah pada versi 3.8: Added context manager support.

**enable()**

Start collecting profiling data. Only in *cProfile*.

**disable()**

Stop collecting profiling data. Only in *cProfile*.

**create\_stats()**

Stop collecting profiling data and record the results internally as the current profile.

**print\_stats(sort=-1)**

Create a *Stats* object based on the current profile and print the results to stdout.

**dump\_stats(filename)**

Write the results of the current profile to *filename*.

**run(cmd)**

Profile the cmd via *exec()*.

**runctx(cmd, globals, locals)**

Profile the cmd via *exec()* with the specified global and local environment.

**runcall(func, \*args, \*\*kwargs)**

Profile *func(\*args, \*\*kwargs)*

Note that profiling will only work if the called command/function actually returns. If the interpreter is terminated (e.g. via a *sys.exit()* call during the called command/function execution) no profiling results will be printed.

## 27.5.4 The Stats Class

Analysis of the profiler data is done using the *Stats* class.

**class** *pstats.Stats* (\*filenames or profile, stream=sys.stdout)

This class constructor creates an instance of a "statistics object" from a *filename* (or list of filenames) or from a *Profile* instance. Output will be printed to the stream specified by *stream*.

The file selected by the above constructor must have been created by the corresponding version of *profile* or *cProfile*. To be specific, there is *no* file compatibility guaranteed with future versions of this profiler, and there is no compatibility with files produced by other profilers, or the same profiler run on a different operating system. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be combined with data in an existing *Stats* object, the *add()* method can be used.

Instead of reading the profile data from a file, a *cProfile.Profile* or *profile.Profile* object can be used as the profile data source.

*Stats* objects have the following methods:

**strip\_dirs()**

This method for the *Stats* class removes all leading path information from file names. It is very useful in reducing the size of the printout to fit within (close to) 80 columns. This method modifies the object, and the stripped information is lost. After performing a strip operation, the object is considered to have its entries in a "random" order, as it was just after object initialization and loading. If *strip\_dirs()* causes two

function names to be indistinguishable (they are on the same line of the same filename, and have the same function name), then the statistics for these two entries are accumulated into a single entry.

**add** (\**filenames*)

This method of the `Stats` class accumulates additional profiling information into the current profiling object. Its arguments should refer to filenames created by the corresponding version of `profile.run()` or `cProfile.run()`. Statistics for identically named (re: file, line, name) functions are automatically accumulated into single function statistics.

**dump\_stats** (*filename*)

Save the data loaded into the `Stats` object to a file named *filename*. The file is created if it does not exist, and is overwritten if it already exists. This is equivalent to the method of the same name on the `profile.Profile` and `cProfile.Profile` classes.

**sort\_stats** (\**keys*)

This method modifies the `Stats` object by sorting it according to the supplied criteria. The argument can be either a string or a `SortKey` enum identifying the basis of a sort (example: 'time', 'name', `SortKey.TIME` or `SortKey.NAME`). The `SortKey` enums argument have advantage over the string argument in that it is more robust and less error prone.

When more than one key is provided, then additional keys are used as secondary criteria when there is equality in all keys selected before them. For example, `sort_stats(SortKey.NAME, SortKey.FILE)` will sort all the entries according to their function name, and resolve all ties (identical function names) by sorting by file name.

For the string argument, abbreviations can be used for any key names, as long as the abbreviation is unambiguous.

The following are the valid string and `SortKey`:

| Valid String Arg | Valid enum Arg                  | Artinya              |
|------------------|---------------------------------|----------------------|
| 'calls'          | <code>SortKey.CALLS</code>      | call count           |
| 'cumulative'     | <code>SortKey.CUMULATIVE</code> | cumulative time      |
| 'cumtime'        | T/A                             | cumulative time      |
| 'file'           | T/A                             | file name            |
| 'filename'       | <code>SortKey.FILENAME</code>   | file name            |
| 'module'         | T/A                             | file name            |
| 'ncalls'         | T/A                             | call count           |
| 'pcalls'         | <code>SortKey.PCALLS</code>     | primitive call count |
| 'line'           | <code>SortKey.LINE</code>       | line number          |
| 'name'           | <code>SortKey.NAME</code>       | function name        |
| 'nfl'            | <code>SortKey.NFL</code>        | name/file/line       |
| 'stdname'        | <code>SortKey.STDNAME</code>    | standard name        |
| 'time'           | <code>SortKey.TIME</code>       | internal time        |
| 'tottime'        | T/A                             | internal time        |

Note that all sorts on statistics are in descending order (placing most time consuming items first), where as name, file, and line number searches are in ascending order (alphabetical). The subtle distinction between `SortKey.NFL` and `SortKey.STDNAME` is that the standard name is a sort of the name as printed, which means that the embedded line numbers get compared in an odd way. For example, lines 3, 20, and 40 would (if the file names were the same) appear in the string order 20, 3 and 40. In contrast, `SortKey.NFL` does a numeric compare of the line numbers. In fact, `sort_stats(SortKey.NFL)` is the same as `sort_stats(SortKey.NAME, SortKey.FILENAME, SortKey.LINE)`.

For backward-compatibility reasons, the numeric arguments -1, 0, 1, and 2 are permitted. They are interpreted as 'stdname', 'calls', 'time', and 'cumulative' respectively. If this old style format

(numeric) is used, only one sort key (the numeric key) will be used, and additional arguments will be silently ignored.

Baru pada versi 3.7: Added the `SortKey` enum.

### **`reverse_order()`**

This method for the `Stats` class reverses the ordering of the basic list within the object. Note that by default ascending vs descending order is properly selected based on the sort key of choice.

### **`print_stats(*restrictions)`**

This method for the `Stats` class prints out a report as described in the `profile.run()` definition.

The order of the printing is based on the last `sort_stats()` operation done on the object (subject to caveats in `add()` and `strip_dirs()`).

The arguments provided (if any) can be used to limit the list down to the significant entries. Initially, the list is taken to be the complete set of profiled functions. Each restriction is either an integer (to select a count of lines), or a decimal fraction between 0.0 and 1.0 inclusive (to select a percentage of lines), or a string that will be interpreted as a regular expression (to pattern match the standard name that is printed). If several restrictions are provided, then they are applied sequentially. For example:

```
print_stats(.1, 'foo:')
```

would first limit the printing to first 10% of list, and then only print functions that were part of filename `.foo:`. In contrast, the command:

```
print_stats('foo:', .1)
```

would limit the list to all functions having file names `.foo:`, and then proceed to only print the first 10% of them.

### **`print_callers(*restrictions)`**

This method for the `Stats` class prints a list of all functions that called each function in the profiled database. The ordering is identical to that provided by `print_stats()`, and the definition of the restricting argument is also identical. Each caller is reported on its own line. The format differs slightly depending on the profiler that produced the stats:

- With `profile`, a number is shown in parentheses after each caller to show how many times this specific call was made. For convenience, a second non-parenthesized number repeats the cumulative time spent in the function at the right.
- With `cProfile`, each caller is preceded by three numbers: the number of times this specific call was made, and the total and cumulative times spent in the current function while it was invoked by this specific caller.

### **`print_callees(*restrictions)`**

This method for the `Stats` class prints a list of all function that were called by the indicated function. Aside from this reversal of direction of calls (re: called vs was called by), the arguments and ordering are identical to the `print_callers()` method.

## 27.5.5 What Is Deterministic Profiling?

*Deterministic profiling* is meant to reflect the fact that all *function call*, *function return*, and *exception* events are monitored, and precise timings are made for the intervals between these events (during which time the user's code is executing). In contrast, *statistical profiling* (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required in order to do deterministic profiling. Python automatically provides a *hook* (optional callback) for each event. In addition, the interpreted nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify "hot loops" that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.

## 27.5.6 Limitations

One limitation has to do with accuracy of timing information. There is a fundamental problem with deterministic profilers involving accuracy. The most obvious restriction is that the underlying "clock" is only ticking at a rate (typically) of about .001 seconds. Hence no measurements will be more accurate than the underlying clock. If enough measurements are taken, then the "error" will tend to average out. Unfortunately, removing this first error induces a second source of error.

The second problem is that it "takes a while" from when an event is dispatched until the profiler's call to get the time actually *gets* the state of the clock. Similarly, there is a certain lag when exiting the profiler event handler from the time that the clock's value was obtained (and then squirreled away), until the user's code is once again executing. As a result, functions that are called many times, or call many functions, will typically accumulate this error. The error that accumulates in this fashion is typically less than the accuracy of the clock (less than one clock tick), but it *can* accumulate and become very significant.

The problem is more important with `profile` than with the lower-overhead `cProfile`. For this reason, `profile` provides a means of calibrating itself for a given platform so that this error can be probabilistically (on the average) removed. After the profiler is calibrated, it will be more accurate (in a least square sense), but it will sometimes produce negative numbers (when call counts are exceptionally low, and the gods of probability work against you :-). ) Do *not* be alarmed by negative numbers in the profile. They should *only* appear if you have calibrated your profiler, and the results are actually better than without calibration.

## 27.5.7 Calibration

The profiler of the `profile` module subtracts a constant from each event handling time to compensate for the overhead of calling the time function, and socking away the results. By default, the constant is 0. The following procedure can be used to obtain a better constant for a given platform (see [Limitations](#)).

```
import profile
pr = profile.Profile()
for i in range(5):
    print(pr.calibrate(10000))
```

The method executes the number of Python calls given by the argument, directly and again under the profiler, measuring the time for both. It then computes the hidden overhead per profiler event, and returns that as a float. For example, on

a 1.8Ghz Intel Core i5 running Mac OS X, and using Python's `time.process_time()` as the timer, the magical number is about 4.04e-6.

The object of this exercise is to get a fairly consistent result. If your computer is *very* fast, or your timer function has poor resolution, you might have to pass 100000, or even 1000000, to get consistent results.

When you have a consistent answer, there are three ways you can use it:

```
import profile

# 1. Apply computed bias to all Profile instances created hereafter.
profile.Profile.bias = your_computed_bias

# 2. Apply computed bias to a specific Profile instance.
pr = profile.Profile()
pr.bias = your_computed_bias

# 3. Specify computed bias in instance constructor.
pr = profile.Profile(bias=your_computed_bias)
```

If you have a choice, you are better off choosing a smaller constant, and then your results will "less often" show up as negative in profile statistics.

### 27.5.8 Using a custom timer

If you want to change how current time is determined (for example, to force use of wall-clock time or elapsed process time), pass the timing function you want to the `Profile` class constructor:

```
pr = profile.Profile(your_time_func)
```

The resulting profiler will then call `your_time_func`. Depending on whether you are using `profile.Profile` or `cProfile.Profile`, `your_time_func`'s return value will be interpreted differently:

**`profile.Profile`** `your_time_func` should return a single number, or a list of numbers whose sum is the current time (like what `os.times()` returns). If the function returns a single time number, or the list of returned numbers has length 2, then you will get an especially fast version of the dispatch routine.

Be warned that you should calibrate the profiler class for the timer function that you choose (see [Calibration](#)). For most machines, a timer that returns a lone integer value will provide the best results in terms of low overhead during profiling. (`os.times()` is *pretty* bad, as it returns a tuple of floating point values). If you want to substitute a better timer in the cleanest fashion, derive a class and hardwire a replacement dispatch method that best handles your timer call, along with the appropriate calibration constant.

**`cProfile.Profile`** `your_time_func` should return a single number. If it returns integers, you can also invoke the class constructor with a second argument specifying the real duration of one unit of time. For example, if `your_integer_time_func` returns times measured in thousands of seconds, you would construct the `Profile` instance as follows:

```
pr = cProfile.Profile(your_integer_time_func, 0.001)
```

As the `cProfile.Profile` class cannot be calibrated, custom timer functions should be used with care and should be as fast as possible. For the best results with a custom timer, it might be necessary to hard-code it in the C source of the internal `_lsprof` module.

Python 3.3 adds several new functions in `time` that can be used to make precise measurements of process or wall-clock time. For example, see `time.perf_counter()`.

## 27.6 `timeit` --- Measure execution time of small code snippets

Source code: [Lib/timeit.py](#)

This module provides a simple way to time small bits of Python code. It has both a *Command-Line Interface* as well as a *callable* one. It avoids a number of common traps for measuring execution times. See also Tim Peters' introduction to the "Algorithms" chapter in the *Python Cookbook*, published by O'Reilly.

### 27.6.1 Basic Examples

The following example shows how the *Command-Line Interface* can be used to compare three different expressions:

```
$ python3 -m timeit '"-".join(str(n) for n in range(100))'
10000 loops, best of 5: 30.2 usec per loop
$ python3 -m timeit '"-".join([str(n) for n in range(100)])'
10000 loops, best of 5: 27.5 usec per loop
$ python3 -m timeit '"-".join(map(str, range(100)))'
10000 loops, best of 5: 23.2 usec per loop
```

This can be achieved from the *Python Interface* with:

```
>>> import timeit
>>> timeit.timeit('"-".join(str(n) for n in range(100))', number=10000)
0.3018611848820001
>>> timeit.timeit('"-".join([str(n) for n in range(100)])', number=10000)
0.2727368790656328
>>> timeit.timeit('"-".join(map(str, range(100)))', number=10000)
0.23702679807320237
```

A callable can also be passed from the *Python Interface*:

```
>>> timeit.timeit(lambda: '"-".join(map(str, range(100)))', number=10000)
0.19665591977536678
```

Note however that `timeit()` will automatically determine the number of repetitions only when the command-line interface is used. In the *Contoh-contoh* section you can find more advanced examples.

### 27.6.2 Python Interface

The module defines three convenience functions and a public class:

`timeit.timeit` (*stmt*='pass', *setup*='pass', *timer*=<default timer>, *number*=1000000, *globals*=None)

Create a *Timer* instance with the given statement, *setup* code and *timer* function and run its `timeit()` method with *number* executions. The optional *globals* argument specifies a namespace in which to execute the code.

Berubah pada versi 3.5: The optional *globals* parameter was added.

`timeit.repeat` (*stmt*='pass', *setup*='pass', *timer*=<default timer>, *repeat*=5, *number*=1000000, *globals*=None)

Create a *Timer* instance with the given statement, *setup* code and *timer* function and run its `repeat()` method with the given *repeat* count and *number* executions. The optional *globals* argument specifies a namespace in which to execute the code.

Berubah pada versi 3.5: The optional *globals* parameter was added.

Berubah pada versi 3.7: Default value of *repeat* changed from 3 to 5.

`timeit.default_timer()`

The default timer, which is always `time.perf_counter()`.

Berubah pada versi 3.3: `time.perf_counter()` is now the default timer.

**class** `timeit.Timer` (*stmt*='pass', *setup*='pass', *timer*=<timer function>, *globals*=None)

Class for timing execution speed of small code snippets.

The constructor takes a statement to be timed, an additional statement used for setup, and a timer function. Both statements default to 'pass'; the timer function is platform-dependent (see the module doc string). *stmt* and *setup* may also contain multiple statements separated by ; or newlines, as long as they don't contain multi-line string literals. The statement will by default be executed within timeit's namespace; this behavior can be controlled by passing a namespace to *globals*.

To measure the execution time of the first statement, use the `timeit()` method. The `repeat()` and `autorange()` methods are convenience methods to call `timeit()` multiple times.

The execution time of *setup* is excluded from the overall timed execution run.

The *stmt* and *setup* parameters can also take objects that are callable without arguments. This will embed calls to them in a timer function that will then be executed by `timeit()`. Note that the timing overhead is a little larger in this case because of the extra function calls.

Berubah pada versi 3.5: The optional *globals* parameter was added.

**timeit** (*number*=1000000)

Time *number* executions of the main statement. This executes the setup statement once, and then returns the time it takes to execute the main statement a number of times, measured in seconds as a float. The argument is the number of times through the loop, defaulting to one million. The main statement, the setup statement and the timer function to be used are passed to the constructor.

---

**Catatan:** By default, `timeit()` temporarily turns off *garbage collection* during the timing. The advantage of this approach is that it makes independent timings more comparable. The disadvantage is that GC may be an important component of the performance of the function being measured. If so, GC can be re-enabled as the first statement in the *setup* string. For example:

```
timeit.Timer('for i in range(10): oct(i)', 'gc.enable()').timeit()
```

---

**autorange** (*callback*=None)

Automatically determine how many times to call `timeit()`.

This is a convenience function that calls `timeit()` repeatedly so that the total time  $\geq 0.2$  second, returning the eventual (number of loops, time taken for that number of loops). It calls `timeit()` with increasing numbers from the sequence 1, 2, 5, 10, 20, 50, ... until the time taken is at least 0.2 second.

If *callback* is given and is not None, it will be called after each trial with two arguments: `callback(number, time_taken)`.

Baru pada versi 3.6.

**repeat** (*repeat*=5, *number*=1000000)

Call `timeit()` a few times.

This is a convenience function that calls the `timeit()` repeatedly, returning a list of results. The first argument specifies how many times to call `timeit()`. The second argument specifies the *number* argument for `timeit()`.

**Catatan:** It's tempting to calculate mean and standard deviation from the result vector and report these. However, this is not very useful. In a typical case, the lowest value gives a lower bound for how fast your machine can run the given code snippet; higher values in the result vector are typically not caused by variability in Python's speed, but by other processes interfering with your timing accuracy. So the `min()` of the result is probably the only number you should be interested in. After that, you should look at the entire vector and apply common sense rather than statistics.

Berubah pada versi 3.7: Default value of *repeat* changed from 3 to 5.

**print\_exc** (*file=None*)

Helper to print a traceback from the timed code.

Typical use:

```
t = Timer(...)          # outside the try/except
try:
    t.timeit(...)        # or t.repeat(...)
except Exception:
    t.print_exc()
```

The advantage over the standard traceback is that source lines in the compiled template will be displayed. The optional *file* argument directs where the traceback is sent; it defaults to `sys.stderr`.

## 27.6.3 Command-Line Interface

When called as a program from the command line, the following form is used:

```
python -m timeit [-n N] [-r N] [-u U] [-s S] [-h] [statement ...]
```

Where the following options are understood:

- n N, --number=N**  
how many times to execute 'statement'
- r N, --repeat=N**  
how many times to repeat the timer (default 5)
- s S, --setup=S**  
statement to be executed once initially (default pass)
- p, --process**  
measure process time, not wallclock time, using `time.process_time()` instead of `time.perf_counter()`, which is the default  
Baru pada versi 3.3.
- u, --unit=U**  
specify a time unit for timer output; can select nsec, usec, msec, or sec  
Baru pada versi 3.5.
- v, --verbose**  
print raw timing results; repeat for more digits precision
- h, --help**  
print a short usage message and exit

A multi-line statement may be given by specifying each line as a separate statement argument; indented lines are possible by enclosing an argument in quotes and using leading spaces. Multiple `-s` options are treated similarly.

If `-n` is not given, a suitable number of loops is calculated by trying increasing numbers from the sequence 1, 2, 5, 10, 20, 50, ... until the total time is at least 0.2 seconds.

`default_timer()` measurements can be affected by other programs running on the same machine, so the best thing to do when accurate timing is necessary is to repeat the timing a few times and use the best time. The `-r` option is good for this; the default of 5 repetitions is probably enough in most cases. You can use `time.process_time()` to measure CPU time.

---

**Catatan:** There is a certain baseline overhead associated with executing a pass statement. The code here doesn't try to hide it, but you should be aware of it. The baseline overhead can be measured by invoking the program without arguments, and it might differ between Python versions.

---

### 27.6.4 Contoh-contoh

It is possible to provide a setup statement that is executed only once at the beginning:

```
$ python -m timeit -s 'text = "sample string"; char = "g"' 'char in text'
5000000 loops, best of 5: 0.0877 usec per loop
$ python -m timeit -s 'text = "sample string"; char = "g"' 'text.find(char)'
1000000 loops, best of 5: 0.342 usec per loop
```

```
>>> import timeit
>>> timeit.timeit('char in text', setup='text = "sample string"; char = "g"')
0.41440500499993504
>>> timeit.timeit('text.find(char)', setup='text = "sample string"; char = "g"')
1.7246671520006203
```

The same can be done using the `Timer` class and its methods:

```
>>> import timeit
>>> t = timeit.Timer('char in text', setup='text = "sample string"; char = "g"')
>>> t.timeit()
0.3955516149999312
>>> t.repeat()
[0.40183617287970225, 0.37027556854118704, 0.38344867356679524, 0.3712595970846668, 0.
↪ 37866875250654886]
```

The following examples show how to time expressions that contain multiple lines. Here we compare the cost of using `hasattr()` vs. `try/except` to test for missing and present object attributes:

```
$ python -m timeit 'try: ' ' str.__bool__' 'except AttributeError: ' ' pass'
20000 loops, best of 5: 15.7 usec per loop
$ python -m timeit 'if hasattr(str, "__bool__"): pass'
50000 loops, best of 5: 4.26 usec per loop

$ python -m timeit 'try: ' ' int.__bool__' 'except AttributeError: ' ' pass'
200000 loops, best of 5: 1.43 usec per loop
$ python -m timeit 'if hasattr(int, "__bool__"): pass'
100000 loops, best of 5: 2.23 usec per loop
```

```

>>> import timeit
>>> # attribute is missing
>>> s = """\
... try:
...     str.__bool__
... except AttributeError:
...     pass
... """
>>> timeit.timeit(stmt=s, number=100000)
0.9138244460009446
>>> s = "if hasattr(str, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.5829014980008651
>>>
>>> # attribute is present
>>> s = """\
... try:
...     int.__bool__
... except AttributeError:
...     pass
... """
>>> timeit.timeit(stmt=s, number=100000)
0.04215312199994514
>>> s = "if hasattr(int, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.08588060699912603

```

To give the *timeit* module access to functions you define, you can pass a *setup* parameter which contains an import statement:

```

def test():
    """Stupid test function"""
    L = [i for i in range(100)]

if __name__ == '__main__':
    import timeit
    print(timeit.timeit("test()", setup="from __main__ import test"))

```

Another option is to pass *globals()* to the *globals* parameter, which will cause the code to be executed within your current global namespace. This can be more convenient than individually specifying imports:

```

def f(x):
    return x**2
def g(x):
    return x**4
def h(x):
    return x**8

import timeit
print(timeit.timeit('[func(42) for func in (f,g,h)]', globals=globals()))

```

## 27.7 `trace` --- Trace or track Python statement execution

Source code: [Lib/trace.py](#)

---

The `trace` module allows you to trace program execution, generate annotated statement coverage listings, print caller/callee relationships and list functions executed during a program run. It can be used in another program or from the command line.

**Lihat juga:**

**Coverage.py** A popular third-party coverage tool that provides HTML output along with advanced features such as branch coverage.

### 27.7.1 Command-Line Usage

The `trace` module can be invoked from the command line. It can be as simple as

```
python -m trace --count -C . somefile.py ...
```

The above will execute `somefile.py` and generate annotated listings of all Python modules imported during the execution into the current directory.

**--help**

Display usage and exit.

**--version**

Display the version of the module and exit.

Baru pada versi 3.8: Added `--module` option that allows to run an executable module.

#### Main options

At least one of the following options must be specified when invoking `trace`. The `--listfuncs` option is mutually exclusive with the `--trace` and `--count` options. When `--listfuncs` is provided, neither `--count` nor `--trace` are accepted, and vice versa.

**-c, --count**

Produce a set of annotated listing files upon program completion that shows how many times each statement was executed. See also `--coverdir`, `--file` and `--no-report` below.

**-t, --trace**

Display lines as they are executed.

**-l, --listfuncs**

Display the functions executed by running the program.

**-r, --report**

Produce an annotated list from an earlier program run that used the `--count` and `--file` option. This does not execute any code.

**-T, --trackcalls**

Display the calling relationships exposed by running the program.

## Modifiers

- f, --file=<file>**  
Name of a file to accumulate counts over several tracing runs. Should be used with the `--count` option.
- C, --coverdir=<dir>**  
Directory where the report files go. The coverage report for `package.module` is written to file `dir/package/module.cover`.
- m, --missing**  
When generating annotated listings, mark lines which were not executed with `>>>>>>`.
- s, --summary**  
When using `--count` or `--report`, write a brief summary to stdout for each file processed.
- R, --no-report**  
Do not generate annotated listings. This is useful if you intend to make several runs with `--count`, and then produce a single set of annotated listings at the end.
- g, --timing**  
Prefix each line with the time since the program started. Only used while tracing.

## Filters

These options may be repeated multiple times.

- ignore-module=<mod>**  
Ignore each of the given module names and its submodules (if it is a package). The argument can be a list of names separated by a comma.
- ignore-dir=<dir>**  
Ignore all modules and packages in the named directory and subdirectories. The argument can be a list of directories separated by `os.pathsep`.

## 27.7.2 Programmatic Interface

**class** `trace.Trace` (*count=1, trace=1, countfuncs=0, countcallers=0, ignoremods=(), ignoredirs=(), infile=None, outfile=None, timing=False*)

Create an object to trace execution of a single statement or expression. All parameters are optional. *count* enables counting of line numbers. *trace* enables line execution tracing. *countfuncs* enables listing of the functions called during the run. *countcallers* enables call relationship tracking. *ignoremods* is a list of modules or packages to ignore. *ignoredirs* is a list of directories whose modules or packages should be ignored. *infile* is the name of the file from which to read stored count information. *outfile* is the name of the file in which to write updated count information. *timing* enables a timestamp relative to when tracing was started to be displayed.

**run** (*cmd*)

Execute the command and gather statistics from the execution with the current tracing parameters. *cmd* must be a string or code object, suitable for passing into `exec()`.

**runctx** (*cmd, globals=None, locals=None*)

Execute the command and gather statistics from the execution with the current tracing parameters, in the defined global and local environments. If not defined, *globals* and *locals* default to empty dictionaries.

**runfunc** (*func, \*args, \*\*kws*)

Call *func* with the given arguments under control of the `Trace` object with the current tracing parameters.

**results()**

Return a *CoverageResults* object that contains the cumulative results of all previous calls to *run*, *runcx* and *runfunc* for the given *Trace* instance. Does not reset the accumulated trace results.

**class** *trace.CoverageResults*

A container for coverage results, created by *Trace.results()*. Should not be created directly by the user.

**update** (*other*)

Merge in data from another *CoverageResults* object.

**write\_results** (*show\_missing=True, summary=False, coverdir=None*)

Write coverage results. Set *show\_missing* to show lines that had no hits. Set *summary* to include in the output the coverage summary per module. *coverdir* specifies the directory into which the coverage result files will be output. If *None*, the results for each source file are placed in its directory.

A simple example demonstrating the use of the programmatic interface:

```
import sys
import trace

# create a Trace object, telling it what to ignore, and whether to
# do tracing or line-counting or both.
tracer = trace.Trace(
    ignoredirs=[sys.prefix, sys.exec_prefix],
    trace=0,
    count=1)

# run the new command using the given tracer
tracer.run('main()')

# make a report, placing output in the current directory
r = tracer.results()
r.write_results(show_missing=True, coverdir=".")
```

## 27.8 tracemalloc --- Trace memory allocations

Baru pada versi 3.4.

**Source code:** [Lib/tracemalloc.py](#)

---

The *tracemalloc* module is a debug tool to trace memory blocks allocated by Python. It provides the following information:

- Traceback where an object was allocated
- Statistics on allocated memory blocks per filename and per line number: total size, number and average size of allocated memory blocks
- Compute the differences between two snapshots to detect memory leaks

To trace most memory blocks allocated by Python, the module should be started as early as possible by setting the *PYTHONTRACEMALLOC* environment variable to 1, or by using *-X tracemalloc* command line option. The *tracemalloc.start()* function can be called at runtime to start tracing Python memory allocations.

By default, a trace of an allocated memory block only stores the most recent frame (1 frame). To store 25 frames at startup: set the *PYTHONTRACEMALLOC* environment variable to 25, or use the *-X tracemalloc=25* command line option.

## 27.8.1 Contoh-contoh

### Display the top 10

Display the 10 files allocating the most memory:

```
import tracemalloc

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('lineno')

print("[ Top 10 ]")
for stat in top_stats[:10]:
    print(stat)
```

Example of output of the Python test suite:

```
[ Top 10 ]
<frozen importlib._bootstrap>:716: size=4855 KiB, count=39328, average=126 B
<frozen importlib._bootstrap>:284: size=521 KiB, count=3199, average=167 B
/usr/lib/python3.4/collections/__init__.py:368: size=244 KiB, count=2315, average=108.
↪B
/usr/lib/python3.4/unittest/case.py:381: size=185 KiB, count=779, average=243 B
/usr/lib/python3.4/unittest/case.py:402: size=154 KiB, count=378, average=416 B
/usr/lib/python3.4/abc.py:133: size=88.7 KiB, count=347, average=262 B
<frozen importlib._bootstrap>:1446: size=70.4 KiB, count=911, average=79 B
<frozen importlib._bootstrap>:1454: size=52.0 KiB, count=25, average=2131 B
<string>:5: size=49.7 KiB, count=148, average=344 B
/usr/lib/python3.4/sysconfig.py:411: size=48.0 KiB, count=1, average=48.0 KiB
```

We can see that Python loaded 4855 KiB data (bytecode and constants) from modules and that the *collections* module allocated 244 KiB to build *namedtuple* types.

See *Snapshot.statistics()* for more options.

### Compute differences

Take two snapshots and display the differences:

```
import tracemalloc
tracemalloc.start()
# ... start your application ...

snapshot1 = tracemalloc.take_snapshot()
# ... call the function leaking memory ...
snapshot2 = tracemalloc.take_snapshot()

top_stats = snapshot2.compare_to(snapshot1, 'lineno')

print("[ Top 10 differences ]")
for stat in top_stats[:10]:
    print(stat)
```

Example of output before/after running some tests of the Python test suite:

```
[ Top 10 differences ]
<frozen importlib._bootstrap>:716: size=8173 KiB (+4428 KiB), count=71332 (+39369), ↵
↪average=117 B
/usr/lib/python3.4/linecache.py:127: size=940 KiB (+940 KiB), count=8106 (+8106), ↵
↪average=119 B
/usr/lib/python3.4/unittest/case.py:571: size=298 KiB (+298 KiB), count=589 (+589), ↵
↪average=519 B
<frozen importlib._bootstrap>:284: size=1005 KiB (+166 KiB), count=7423 (+1526), ↵
↪average=139 B
/usr/lib/python3.4/mimetypes.py:217: size=112 KiB (+112 KiB), count=1334 (+1334), ↵
↪average=86 B
/usr/lib/python3.4/http/server.py:848: size=96.0 KiB (+96.0 KiB), count=1 (+1), ↵
↪average=96.0 KiB
/usr/lib/python3.4/inspect.py:1465: size=83.5 KiB (+83.5 KiB), count=109 (+109), ↵
↪average=784 B
/usr/lib/python3.4/unittest/mock.py:491: size=77.7 KiB (+77.7 KiB), count=143 (+143), ↵
↪average=557 B
/usr/lib/python3.4/urllib/parse.py:476: size=71.8 KiB (+71.8 KiB), count=969 (+969), ↵
↪average=76 B
/usr/lib/python3.4/contextlib.py:38: size=67.2 KiB (+67.2 KiB), count=126 (+126), ↵
↪average=546 B
```

We can see that Python has loaded 8173 KiB of module data (bytecode and constants), and that this is 4428 KiB more than had been loaded before the tests, when the previous snapshot was taken. Similarly, the *linecache* module has cached 940 KiB of Python source code to format tracebacks, all of it since the previous snapshot.

If the system has little free memory, snapshots can be written on disk using the *Snapshot.dump()* method to analyze the snapshot offline. Then use the *Snapshot.load()* method reload the snapshot.

### Get the traceback of a memory block

Code to display the traceback of the biggest memory block:

```
import tracemalloc

# Store 25 frames
tracemalloc.start(25)

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('traceback')

# pick the biggest memory block
stat = top_stats[0]
print("%s memory blocks: %.1f KiB" % (stat.count, stat.size / 1024))
for line in stat.traceback.format():
    print(line)
```

Example of output of the Python test suite (traceback limited to 25 frames):

```
903 memory blocks: 870.1 KiB
  File "<frozen importlib._bootstrap>", line 716
  File "<frozen importlib._bootstrap>", line 1036
  File "<frozen importlib._bootstrap>", line 934
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

File "<frozen importlib._bootstrap>", line 1068
File "<frozen importlib._bootstrap>", line 619
File "<frozen importlib._bootstrap>", line 1581
File "<frozen importlib._bootstrap>", line 1614
File "/usr/lib/python3.4/doctest.py", line 101
    import pdb
File "<frozen importlib._bootstrap>", line 284
File "<frozen importlib._bootstrap>", line 938
File "<frozen importlib._bootstrap>", line 1068
File "<frozen importlib._bootstrap>", line 619
File "<frozen importlib._bootstrap>", line 1581
File "<frozen importlib._bootstrap>", line 1614
File "/usr/lib/python3.4/test/support/__init__.py", line 1728
    import doctest
File "/usr/lib/python3.4/test/test_pickletools.py", line 21
    support.run_doctest(pickletools)
File "/usr/lib/python3.4/test/regrtest.py", line 1276
    test_runner()
File "/usr/lib/python3.4/test/regrtest.py", line 976
    display_failure=not verbose)
File "/usr/lib/python3.4/test/regrtest.py", line 761
    match_tests=ns.match_tests)
File "/usr/lib/python3.4/test/regrtest.py", line 1563
    main()
File "/usr/lib/python3.4/test/__main__.py", line 3
    regrtest.main_in_temp_cwd()
File "/usr/lib/python3.4/runpy.py", line 73
    exec(code, run_globals)
File "/usr/lib/python3.4/runpy.py", line 160
    "__main__", fname, loader, pkg_name)

```

We can see that the most memory was allocated in the `importlib` module to load data (bytecode and constants) from modules: 870.1 KiB. The traceback is where the `importlib` loaded data most recently: on the `import pdb` line of the `doctest` module. The traceback may change if a new module is loaded.

## Pretty top

Code to display the 10 lines allocating the most memory with a pretty output, ignoring `<frozen importlib._bootstrap>` and `<unknown>` files:

```

import linecache
import os
import tracemalloc

def display_top(snapshot, key_type='lineno', limit=10):
    snapshot = snapshot.filter_traces((
        tracemalloc.Filter(False, "<frozen importlib._bootstrap>"),
        tracemalloc.Filter(False, "<unknown>"),
    ))
    top_stats = snapshot.statistics(key_type)

    print("Top %s lines" % limit)
    for index, stat in enumerate(top_stats[:limit], 1):
        frame = stat.traceback[0]
        print("#%s: %s:%s: %.1f KiB"

```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

        % (index, frame.filename, frame.lineno, stat.size / 1024))
    line = linecache.getline(frame.filename, frame.lineno).strip()
    if line:
        print('    %s' % line)

    other = top_stats[limit:]
    if other:
        size = sum(stat.size for stat in other)
        print("%s other: %.1f KiB" % (len(other), size / 1024))
    total = sum(stat.size for stat in top_stats)
    print("Total allocated size: %.1f KiB" % (total / 1024))

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
display_top(snapshot)

```

Example of output of the Python test suite:

```

Top 10 lines
#1: Lib/base64.py:414: 419.8 KiB
    _b85chars2 = [(a + b) for a in _b85chars for b in _b85chars]
#2: Lib/base64.py:306: 419.8 KiB
    _a85chars2 = [(a + b) for a in _a85chars for b in _a85chars]
#3: collections/__init__.py:368: 293.6 KiB
    exec(class_definition, namespace)
#4: Lib/abc.py:133: 115.2 KiB
    cls = super().__new__(mcls, name, bases, namespace)
#5: unittest/case.py:574: 103.1 KiB
    testMethod()
#6: Lib/linecache.py:127: 95.4 KiB
    lines = fp.readlines()
#7: urllib/parse.py:476: 71.8 KiB
    for a in _hexdig for b in _hexdig}
#8: <string>:5: 62.0 KiB
#9: Lib/_weakrefset.py:37: 60.0 KiB
    self.data = set()
#10: Lib/base64.py:142: 59.8 KiB
    _b32tab2 = [a + b for a in _b32tab for b in _b32tab]
6220 other: 3602.8 KiB
Total allocated size: 5303.1 KiB

```

See `Snapshot.statistics()` for more options.

## 27.8.2 API

### Fungsi-Fungsi

`tracemalloc.clear_traces()`

Clear traces of memory blocks allocated by Python.

See also `stop()`.

`tracemalloc.get_object_traceback(obj)`

Get the traceback where the Python object *obj* was allocated. Return a `Traceback` instance, or `None` if the `tracemalloc` module is not tracing memory allocations or did not trace the allocation of the object.

See also `gc.get_referrers()` and `sys.getsizeof()` functions.

`tracemalloc.get_traceback_limit()`

Get the maximum number of frames stored in the traceback of a trace.

The `tracemalloc` module must be tracing memory allocations to get the limit, otherwise an exception is raised.

The limit is set by the `start()` function.

`tracemalloc.get_traced_memory()`

Get the current size and peak size of memory blocks traced by the `tracemalloc` module as a tuple: (current: int, peak: int).

`tracemalloc.get_tracemalloc_memory()`

Get the memory usage in bytes of the `tracemalloc` module used to store traces of memory blocks. Return an `int`.

`tracemalloc.is_tracing()`

True if the `tracemalloc` module is tracing Python memory allocations, False otherwise.

See also `start()` and `stop()` functions.

`tracemalloc.start(nframe: int=1)`

Start tracing Python memory allocations: install hooks on Python memory allocators. Collected tracebacks of traces will be limited to *nframe* frames. By default, a trace of a memory block only stores the most recent frame: the limit is 1. *nframe* must be greater or equal to 1.

Storing more than 1 frame is only useful to compute statistics grouped by 'traceback' or to compute cumulative statistics: see the `Snapshot.compare_to()` and `Snapshot.statistics()` methods.

Storing more frames increases the memory and CPU overhead of the `tracemalloc` module. Use the `get_tracemalloc_memory()` function to measure how much memory is used by the `tracemalloc` module.

The `PYTHONTRACEMALLOC` environment variable (`PYTHONTRACEMALLOC=NFRAME`) and the `-X tracemalloc=NFRAME` command line option can be used to start tracing at startup.

See also `stop()`, `is_tracing()` and `get_traceback_limit()` functions.

`tracemalloc.stop()`

Stop tracing Python memory allocations: uninstall hooks on Python memory allocators. Also clears all previously collected traces of memory blocks allocated by Python.

Call `take_snapshot()` function to take a snapshot of traces before clearing them.

See also `start()`, `is_tracing()` and `clear_traces()` functions.

`tracemalloc.take_snapshot()`

Take a snapshot of traces of memory blocks allocated by Python. Return a new `Snapshot` instance.

The snapshot does not include memory blocks allocated before the `tracemalloc` module started to trace memory allocations.

Tracebacks of traces are limited to `get_traceback_limit()` frames. Use the `nframe` parameter of the `start()` function to store more frames.

The `tracemalloc` module must be tracing memory allocations to take a snapshot, see the `start()` function.

See also the `get_object_traceback()` function.

### DomainFilter

**class** `tracemalloc.DomainFilter` (*inclusive: bool, domain: int*)

Filter traces of memory blocks by their address space (domain).

Baru pada versi 3.6.

#### **inclusive**

If *inclusive* is `True` (include), match memory blocks allocated in the address space *domain*.

If *inclusive* is `False` (exclude), match memory blocks not allocated in the address space *domain*.

#### **domain**

Address space of a memory block (`int`). Read-only property.

### Filter

**class** `tracemalloc.Filter` (*inclusive: bool, filename\_pattern: str, lineno: int=None, all\_frames: bool=False, domain: int=None*)

Filter on traces of memory blocks.

See the `fnmatch.fnmatch()` function for the syntax of *filename\_pattern*. The `'.pyc'` file extension is replaced with `'.py'`.

Contoh-contoh:

- `Filter(True, subprocess.__file__)` only includes traces of the `subprocess` module
- `Filter(False, tracemalloc.__file__)` excludes traces of the `tracemalloc` module
- `Filter(False, "<unknown>")` excludes empty tracebacks

Berubah pada versi 3.5: The `'.pyo'` file extension is no longer replaced with `'.py'`.

Berubah pada versi 3.6: Added the *domain* attribute.

#### **domain**

Address space of a memory block (`int` or `None`).

`tracemalloc` uses the domain 0 to trace memory allocations made by Python. C extensions can use other domains to trace other resources.

#### **inclusive**

If *inclusive* is `True` (include), only match memory blocks allocated in a file with a name matching *filename\_pattern* at line number *lineno*.

If *inclusive* is `False` (exclude), ignore memory blocks allocated in a file with a name matching *filename\_pattern* at line number *lineno*.

#### **lineno**

Line number (`int`) of the filter. If *lineno* is `None`, the filter matches any line number.

**filename\_pattern**

Filename pattern of the filter (`str`). Read-only property.

**all\_frames**

If `all_frames` is `True`, all frames of the traceback are checked. If `all_frames` is `False`, only the most recent frame is checked.

This attribute has no effect if the traceback limit is 1. See the `get_traceback_limit()` function and `Snapshot.traceback_limit` attribute.

**Frame****class** tracemalloc.**Frame**

Frame of a traceback.

The `Traceback` class is a sequence of `Frame` instances.

**filename**

Filename (`str`).

**lineno**

Line number (`int`).

**Snapshot****class** tracemalloc.**Snapshot**

Snapshot of traces of memory blocks allocated by Python.

The `take_snapshot()` function creates a snapshot instance.

**compare\_to** (*old\_snapshot: Snapshot, key\_type: str, cumulative: bool=False*)

Compute the differences with an old snapshot. Get statistics as a sorted list of `StatisticDiff` instances grouped by `key_type`.

See the `Snapshot.statistics()` method for `key_type` and `cumulative` parameters.

The result is sorted from the biggest to the smallest by: absolute value of `StatisticDiff.size_diff`, `StatisticDiff.size`, absolute value of `StatisticDiff.count_diff`, `Statistic.count` and then by `StatisticDiff.traceback`.

**dump** (*filename*)

Write the snapshot into a file.

Use `load()` to reload the snapshot.

**filter\_traces** (*filters*)

Create a new `Snapshot` instance with a filtered `traces` sequence, `filters` is a list of `DomainFilter` and `Filter` instances. If `filters` is an empty list, return a new `Snapshot` instance with a copy of the traces.

All inclusive filters are applied at once, a trace is ignored if no inclusive filters match it. A trace is ignored if at least one exclusive filter matches it.

Berubah pada versi 3.6: `DomainFilter` instances are now also accepted in `filters`.

**classmethod** **load** (*filename*)

Load a snapshot from a file.

See also `dump()`.

**statistics** (*key\_type*: str, *cumulative*: bool=False)

Get statistics as a sorted list of *Statistic* instances grouped by *key\_type*:

| key_type    | deskripsi                |
|-------------|--------------------------|
| 'filename'  | filename                 |
| 'lineno'    | filename and line number |
| 'traceback' | traceback                |

If *cumulative* is `True`, cumulate size and count of memory blocks of all frames of the traceback of a trace, not only the most recent frame. The cumulative mode can only be used with *key\_type* equals to 'filename' and 'lineno'.

The result is sorted from the biggest to the smallest by: *Statistic.size*, *Statistic.count* and then by *Statistic.traceback*.

**traceback\_limit**

Maximum number of frames stored in the traceback of *traces*: result of the *get\_traceback\_limit()* when the snapshot was taken.

**traces**

Traces of all memory blocks allocated by Python: sequence of *Trace* instances.

The sequence has an undefined order. Use the *Snapshot.statistics()* method to get a sorted list of statistics.

## Statistic

**class** tracemalloc.**Statistic**

Statistic on memory allocations.

*Snapshot.statistics()* returns a list of *Statistic* instances.

See also the *StatisticDiff* class.

**count**

Number of memory blocks (int).

**size**

Total size of memory blocks in bytes (int).

**traceback**

Traceback where the memory block was allocated, *Traceback* instance.

## StatisticDiff

**class** tracemalloc.**StatisticDiff**

Statistic difference on memory allocations between an old and a new *Snapshot* instance.

*Snapshot.compare\_to()* returns a list of *StatisticDiff* instances. See also the *Statistic* class.

**count**

Number of memory blocks in the new snapshot (int): 0 if the memory blocks have been released in the new snapshot.

**count\_diff**

Difference of number of memory blocks between the old and the new snapshots (int): 0 if the memory blocks have been allocated in the new snapshot.

**size**

Total size of memory blocks in bytes in the new snapshot (`int`): 0 if the memory blocks have been released in the new snapshot.

**size\_diff**

Difference of total size of memory blocks in bytes between the old and the new snapshots (`int`): 0 if the memory blocks have been allocated in the new snapshot.

**traceback**

Traceback where the memory blocks were allocated, *Traceback* instance.

**Trace****class** tracemalloc.Trace

Trace of a memory block.

The *Snapshot.traces* attribute is a sequence of *Trace* instances.

Berubah pada versi 3.6: Added the *domain* attribute.

**domain**

Address space of a memory block (`int`). Read-only property.

tracemalloc uses the domain 0 to trace memory allocations made by Python. C extensions can use other domains to trace other resources.

**size**

Size of the memory block in bytes (`int`).

**traceback**

Traceback where the memory block was allocated, *Traceback* instance.

**Traceback****class** tracemalloc.Traceback

Sequence of *Frame* instances sorted from the oldest frame to the most recent frame.

A traceback contains at least 1 frame. If the tracemalloc module failed to get a frame, the filename "<unknown>" at line number 0 is used.

When a snapshot is taken, tracebacks of traces are limited to *get\_traceback\_limit()* frames. See the *take\_snapshot()* function.

The *Trace.traceback* attribute is an instance of *Traceback* instance.

Berubah pada versi 3.7: Frames are now sorted from the oldest to the most recent, instead of most recent to oldest.

**format** (*limit=None, most\_recent\_first=False*)

Format the traceback as a list of lines with newlines. Use the *linecache* module to retrieve lines from the source code. If *limit* is set, format the *limit* most recent frames if *limit* is positive. Otherwise, format the `abs(limit)` oldest frames. If *most\_recent\_first* is `True`, the order of the formatted frames is reversed, returning the most recent frame first instead of last.

Similar to the *traceback.format\_tb()* function, except that *format()* does not include newlines.

Contoh:

```
print("Traceback (most recent call first):")
for line in traceback:
    print(line)
```

Output:

```
Traceback (most recent call first):
  File "test.py", line 9
    obj = Object()
  File "test.py", line 12
    tb = tracemalloc.get_object_traceback(f())
```

---

## Pengemasan dan Distribusi Perangkat Lunak

---

Pustaka ini membantu Anda dengan menerbitkan dan melakukan instalasi perangkat lunak Python. Sementara modul-modul ini dirancang untuk bekerja bersama dengan *Python Package Index* <<https://pypi.org>> \_\_, mereka juga dapat digunakan dengan server indeks lokal, atau tanpa server indeks sama sekali.

### 28.1 *distutils* --- Building and installing Python modules

---

The *distutils* package provides support for building and installing additional modules into a Python installation. The new modules may be either 100%-pure Python, or may be extension modules written in C, or may be collections of Python packages which include modules coded in both Python and C.

Most Python users will *not* want to use this module directly, but instead use the cross-version tools maintained by the Python Packaging Authority. In particular, *setuptools* is an enhanced alternative to *distutils* that provides:

- support for declaring project dependencies
- additional mechanisms for configuring which files to include in source releases (including plugins for integration with version control systems)
- the ability to declare project "entry points", which can be used as the basis for application plugin systems
- the ability to automatically generate Windows command line executables at installation time rather than needing to prebuild them
- consistent behaviour across all supported Python versions

The recommended *pip* installer runs all *setup.py* scripts with *setuptools*, even if the script itself only imports *distutils*. Refer to the [Python Packaging User Guide](#) for more information.

For the benefits of packaging tool authors and users seeking a deeper understanding of the details of the current packaging and distribution system, the legacy *distutils* based user documentation and API reference remain available:

- [install-index](#)
- [distutils-index](#)

## 28.2 ensurepip --- Bootstrapping the pip installer

Baru pada versi 3.4.

---

The `ensurepip` package provides support for bootstrapping the `pip` installer into an existing Python installation or virtual environment. This bootstrapping approach reflects the fact that `pip` is an independent project with its own release cycle, and the latest available stable version is bundled with maintenance and feature releases of the CPython reference interpreter.

In most cases, end users of Python shouldn't need to invoke this module directly (as `pip` should be bootstrapped by default), but it may be needed if installing `pip` was skipped when installing Python (or when creating a virtual environment) or after explicitly uninstalling `pip`.

---

**Catatan:** This module *does not* access the internet. All of the components needed to bootstrap `pip` are included as internal parts of the package.

---

### Lihat juga:

**installing-index** The end user guide for installing Python packages

**PEP 453: Explicit bootstrapping of pip in Python installations** The original rationale and specification for this module.

### 28.2.1 Command line interface

The command line interface is invoked using the interpreter's `-m` switch.

The simplest possible invocation is:

```
python -m ensurepip
```

This invocation will install `pip` if it is not already installed, but otherwise does nothing. To ensure the installed version of `pip` is at least as recent as the one bundled with `ensurepip`, pass the `--upgrade` option:

```
python -m ensurepip --upgrade
```

By default, `pip` is installed into the current virtual environment (if one is active) or into the system site packages (if there is no active virtual environment). The installation location can be controlled through two additional command line options:

- `--root <dir>`: Installs `pip` relative to the given root directory rather than the root of the currently active virtual environment (if any) or the default root for the current Python installation.
- `--user`: Installs `pip` into the user site packages directory rather than globally for the current Python installation (this option is not permitted inside an active virtual environment).

By default, the scripts `pipX` and `pipX.Y` will be installed (where `X.Y` stands for the version of Python used to invoke `ensurepip`). The scripts installed can be controlled through two additional command line options:

- `--altinstall`: if an alternate installation is requested, the `pipX` script will *not* be installed.
- `--default-pip`: if a "default `pip`" installation is requested, the `pip` script will be installed in addition to the two regular scripts.

Providing both of the script selection options will trigger an exception.

## 28.2.2 Module API

`ensurepip` exposes two functions for programmatic use:

`ensurepip.version()`

Returns a string specifying the bundled version of pip that will be installed when bootstrapping an environment.

`ensurepip.bootstrap(root=None, upgrade=False, user=False, altinstall=False, default_pip=False, verbosity=0)`

Bootstraps pip into the current or designated environment.

*root* specifies an alternative root directory to install relative to. If *root* is `None`, then installation uses the default install location for the current environment.

*upgrade* indicates whether or not to upgrade an existing installation of an earlier version of pip to the bundled version.

*user* indicates whether to use the user scheme rather than installing globally.

By default, the scripts `pipX` and `pipX.Y` will be installed (where `X.Y` stands for the current version of Python).

If *altinstall* is set, then `pipX` will *not* be installed.

If *default\_pip* is set, then `pip` will be installed in addition to the two regular scripts.

Setting both *altinstall* and *default\_pip* will trigger `ValueError`.

*verbosity* controls the level of output to `sys.stdout` from the bootstrapping operation.

Raises an *auditing event* `ensurepip.bootstrap` with argument *root*.

---

**Catatan:** The bootstrapping process has side effects on both `sys.path` and `os.environ`. Invoking the command line interface in a subprocess instead allows these side effects to be avoided.

---

---

**Catatan:** The bootstrapping process may install additional modules required by pip, but other software should not assume those dependencies will always be present by default (as the dependencies may be removed in a future version of pip).

---

## 28.3 venv --- Creation of virtual environments

Baru pada versi 3.3.

**Source code:** [Lib/venv/](#)

The `venv` module provides support for creating lightweight “virtual environments” with their own site directories, optionally isolated from system site directories. Each virtual environment has its own Python binary (which matches the version of the binary that was used to create this environment) and can have its own independent set of installed Python packages in its site directories.

See **PEP 405** for more information about Python virtual environments.

**Lihat juga:**

[Python Packaging User Guide: Creating and using virtual environments](#)

## 28.3.1 Creating virtual environments

Creation of *virtual environments* is done by executing the command `venv`:

```
python3 -m venv /path/to/new/virtual/environment
```

Running this command creates the target directory (creating any parent directories that don't exist already) and places a `pyvenv.cfg` file in it with a `home` key pointing to the Python installation from which the command was run (a common name for the target directory is `.venv`). It also creates a `bin` (or `Scripts` on Windows) subdirectory containing a copy/symlink of the Python binary/binaries (as appropriate for the platform or arguments used at environment creation time). It also creates an (initially empty) `lib/pythonX.Y/site-packages` subdirectory (on Windows, this is `Lib\site-packages`). If an existing directory is specified, it will be re-used.

Ditinggalkan sejak versi 3.6: `pyvenv` was the recommended tool for creating virtual environments for Python 3.3 and 3.4, and is [deprecated in Python 3.6](#).

Berubah pada versi 3.5: Penggunaan `venv` sekarang disarankan untuk membuat lingkungan virtual.

On Windows, invoke the `venv` command as follows:

```
c:\>c:\Python35\python -m venv c:\path\to\myenv
```

Alternatively, if you configured the `PATH` and `PATHEXT` variables for your Python installation:

```
c:\>python -m venv c:\path\to\myenv
```

The command, if run with `-h`, will show the available options:

```
usage: venv [-h] [--system-site-packages] [--symlinks | --copies] [--clear]
           [--upgrade] [--without-pip] [--prompt PROMPT]
           ENV_DIR [ENV_DIR ...]

Creates virtual Python environments in one or more target directories.

positional arguments:
  ENV_DIR                A directory to create the environment in.

optional arguments:
  -h, --help            show this help message and exit
  --system-site-packages
                        Give the virtual environment access to the system
                        site-packages dir.
  --symlinks            Try to use symlinks rather than copies, when symlinks
                        are not the default for the platform.
  --copies              Try to use copies rather than symlinks, even when
                        symlinks are the default for the platform.
  --clear               Delete the contents of the environment directory if it
                        already exists, before environment creation.
  --upgrade             Upgrade the environment directory to use this version
                        of Python, assuming Python has been upgraded in-place.
  --without-pip         Skips installing or upgrading pip in the virtual
                        environment (pip is bootstrapped by default)
  --prompt PROMPT      Provides an alternative prompt prefix for this
                        environment.
```

Once an environment has been created, you may wish to activate it, e.g. by sourcing an activate script in its `bin` directory.

Berubah pada versi 3.4: Installs `pip` by default, added the `--without-pip` and `--copies` options

Berubah pada versi 3.4: In earlier versions, if the target directory already existed, an error was raised, unless the `--clear` or `--upgrade` option was provided.

---

**Catatan:** While symlinks are supported on Windows, they are not recommended. Of particular note is that double-clicking `python.exe` in File Explorer will resolve the symlink eagerly and ignore the virtual environment.

---

---

**Catatan:** On Microsoft Windows, it may be required to enable the `Activate.ps1` script by setting the execution policy for the user. You can do this by issuing the following PowerShell command:

```
PS C:> Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope CurrentUser
```

See [About Execution Policies](#) for more information.

---

The created `pyvenv.cfg` file also includes the `include-system-site-packages` key, set to `true` if `venv` is run with the `--system-site-packages` option, `false` otherwise.

Unless the `--without-pip` option is given, `ensurepip` will be invoked to bootstrap `pip` into the virtual environment.

Multiple paths can be given to `venv`, in which case an identical virtual environment will be created, according to the given options, at each provided path.

Once a virtual environment has been created, it can be “activated” using a script in the virtual environment’s binary directory. The invocation of the script is platform-specific (`<venv>` must be replaced by the path of the directory containing the virtual environment):

| Platform | Shell           | Command to activate virtual environment                   |
|----------|-----------------|-----------------------------------------------------------|
| POSIX    | bash/zsh        | <code>\$ source &lt;venv&gt;/bin/activate</code>          |
|          | fish            | <code>\$ . &lt;venv&gt;/bin/activate.fish</code>          |
|          | csh/tcsh        | <code>\$ source &lt;venv&gt;/bin/activate.csh</code>      |
|          | PowerShell Core | <code>\$ &lt;venv&gt;/bin/Activate.ps1</code>             |
| Windows  | cmd.exe         | <code>C:\&gt; &lt;venv&gt;\Scripts\activate.bat</code>    |
|          | PowerShell      | <code>PS C:\&gt; &lt;venv&gt;\Scripts\Activate.ps1</code> |

When a virtual environment is active, the `VIRTUAL_ENV` environment variable is set to the path of the virtual environment. This can be used to check if one is running inside a virtual environment.

You don’t specifically *need* to activate an environment; activation just prepends the virtual environment’s binary directory to your path, so that “python” invokes the virtual environment’s Python interpreter and you can run installed scripts without having to use their full path. However, all scripts installed in a virtual environment should be runnable without activating it, and run with the virtual environment’s Python automatically.

You can deactivate a virtual environment by typing “deactivate” in your shell. The exact mechanism is platform-specific and is an internal implementation detail (typically a script or shell function will be used).

Baru pada versi 3.4: `fish` and `csh` activation scripts.

Baru pada versi 3.8: PowerShell activation scripts installed under POSIX for PowerShell Core support.

---

**Catatan:** A virtual environment is a Python environment such that the Python interpreter, libraries and scripts installed into it are isolated from those installed in other virtual environments, and (by default) any libraries installed in a “system” Python, i.e., one which is installed as part of your operating system.

A virtual environment is a directory tree which contains Python executable files and other files which indicate that it is a virtual environment.

Common installation tools such as `setuptools` and `pip` work as expected with virtual environments. In other words, when a virtual environment is active, they install Python packages into the virtual environment without needing to be told to do so explicitly.

When a virtual environment is active (i.e., the virtual environment's Python interpreter is running), the attributes `sys.prefix` and `sys.exec_prefix` point to the base directory of the virtual environment, whereas `sys.base_prefix` and `sys.base_exec_prefix` point to the non-virtual environment Python installation which was used to create the virtual environment. If a virtual environment is not active, then `sys.prefix` is the same as `sys.base_prefix` and `sys.exec_prefix` is the same as `sys.base_exec_prefix` (they all point to a non-virtual environment Python installation).

When a virtual environment is active, any options that change the installation path will be ignored from all `distutils` configuration files to prevent projects being inadvertently installed outside of the virtual environment.

When working in a command shell, users can make a virtual environment active by running an `activate` script in the virtual environment's executables directory (the precise filename and command to use the file is shell-dependent), which prepends the virtual environment's directory for executables to the `PATH` environment variable for the running shell. There should be no need in other circumstances to activate a virtual environment; scripts installed into virtual environments have a "shebang" line which points to the virtual environment's Python interpreter. This means that the script will run with that interpreter regardless of the value of `PATH`. On Windows, "shebang" line processing is supported if you have the Python Launcher for Windows installed (this was added to Python in 3.3 - see [PEP 397](#) for more details). Thus, double-clicking an installed script in a Windows Explorer window should run the script with the correct interpreter without there needing to be any reference to its virtual environment in `PATH`.

---

### 28.3.2 API

The high-level method described above makes use of a simple API which provides mechanisms for third-party virtual environment creators to customize environment creation according to their needs, the `EnvBuilder` class.

**class** `venv.EnvBuilder` (`system_site_packages=False`, `clear=False`, `symlinks=False`, `upgrade=False`, `with_pip=False`, `prompt=None`)

The `EnvBuilder` class accepts the following keyword arguments on instantiation:

- `system_site_packages` -- a Boolean value indicating that the system Python site-packages should be available to the environment (defaults to `False`).
- `clear` -- a Boolean value which, if true, will delete the contents of any existing target directory, before creating the environment.
- `symlinks` -- a Boolean value indicating whether to attempt to symlink the Python binary rather than copying.
- `upgrade` -- a Boolean value which, if true, will upgrade an existing environment with the running Python - for use when that Python has been upgraded in-place (defaults to `False`).
- `with_pip` -- a Boolean value which, if true, ensures `pip` is installed in the virtual environment. This uses `ensurepip` with the `--default-pip` option.
- `prompt` -- a String to be used after virtual environment is activated (defaults to `None` which means directory name of the environment would be used).

Berubah pada versi 3.4: Added the `with_pip` parameter

Baru pada versi 3.6: Added the `prompt` parameter

Creators of third-party virtual environment tools will be free to use the provided `EnvBuilder` class as a base class.

The returned env-builder is an object which has a method, `create`:

**create** (*env\_dir*)

Create a virtual environment by specifying the target directory (absolute or relative to the current directory) which is to contain the virtual environment. The `create` method will either create the environment in the specified directory, or raise an appropriate exception.

The `create` method of the `EnvBuilder` class illustrates the hooks available for subclass customization:

```
def create(self, env_dir):
    """
    Create a virtualized Python environment in a directory.
    env_dir is the target directory to create an environment in.
    """
    env_dir = os.path.abspath(env_dir)
    context = self.ensure_directories(env_dir)
    self.create_configuration(context)
    self.setup_python(context)
    self.setup_scripts(context)
    self.post_setup(context)
```

Each of the methods `ensure_directories()`, `create_configuration()`, `setup_python()`, `setup_scripts()` and `post_setup()` can be overridden.

**ensure\_directories** (*env\_dir*)

Creates the environment directory and all necessary directories, and returns a context object. This is just a holder for attributes (such as paths), for use by the other methods. The directories are allowed to exist already, as long as either `clear` or `upgrade` were specified to allow operating on an existing environment directory.

**create\_configuration** (*context*)

Creates the `pyvenv.cfg` configuration file in the environment.

**setup\_python** (*context*)

Creates a copy or symlink to the Python executable in the environment. On POSIX systems, if a specific executable `python3.x` was used, symlinks to `python` and `python3` will be created pointing to that executable, unless files with those names already exist.

**setup\_scripts** (*context*)

Installs activation scripts appropriate to the platform into the virtual environment.

**post\_setup** (*context*)

A placeholder method which can be overridden in third party implementations to pre-install packages in the virtual environment or perform other post-creation steps.

Berubah pada versi 3.7.2: Windows now uses redirector scripts for `python[w].exe` instead of copying the actual binaries. In 3.7.2 only `setup_python()` does nothing unless running from a build in the source tree.

Berubah pada versi 3.7.3: Windows copies the redirector scripts as part of `setup_python()` instead of `setup_scripts()`. This was not the case in 3.7.2. When using symlinks, the original executables will be linked.

In addition, `EnvBuilder` provides this utility method that can be called from `setup_scripts()` or `post_setup()` in subclasses to assist in installing custom scripts into the virtual environment.

**install\_scripts** (*context*, *path*)

*path* is the path to a directory that should contain subdirectories "common", "posix", "nt", each containing scripts destined for the bin directory in the environment. The contents of "common" and the directory corresponding to `os.name` are copied after some text replacement of placeholders:

- `__VENV_DIR__` is replaced with the absolute path of the environment directory.
- `__VENV_NAME__` is replaced with the environment name (final path segment of environment directory).

- `__VENV_PROMPT__` is replaced with the prompt (the environment name surrounded by parentheses and with a following space)
- `__VENV_BIN_NAME__` is replaced with the name of the bin directory (either `bin` or `Scripts`).
- `__VENV_PYTHON__` is replaced with the absolute path of the environment's executable.

The directories are allowed to exist (for when an existing environment is being upgraded).

There is also a module-level convenience function:

```
venv.create(env_dir, system_site_packages=False, clear=False, symlinks=False, with_pip=False,
            prompt=None)
```

Create an `EnvBuilder` with the given keyword arguments, and call its `create()` method with the `env_dir` argument.

Baru pada versi 3.3.

Berubah pada versi 3.4: Added the `with_pip` parameter

Berubah pada versi 3.6: Added the `prompt` parameter

### 28.3.3 An example of extending `EnvBuilder`

The following script shows how to extend `EnvBuilder` by implementing a subclass which installs `setuptools` and `pip` into a created virtual environment:

```
import os
import os.path
from subprocess import Popen, PIPE
import sys
from threading import Thread
from urllib.parse import urlparse
from urllib.request import urlretrieve
import venv

class ExtendedEnvBuilder(venv.EnvBuilder):
    """
    This builder installs setuptools and pip so that you can pip or
    easy_install other packages into the created virtual environment.

    :param nodist: If true, setuptools and pip are not installed into the
        created virtual environment.
    :param nopip: If true, pip is not installed into the created
        virtual environment.
    :param progress: If setuptools or pip are installed, the progress of the
        installation can be monitored by passing a progress
        callable. If specified, it is called with two
        arguments: a string indicating some progress, and a
        context indicating where the string is coming from.
        The context argument can have one of three values:
        'main', indicating that it is called from virtualize()
        itself, and 'stdout' and 'stderr', which are obtained
        by reading lines from the output streams of a subprocess
        which is used to install the app.

        If a callable is not specified, default progress
        information is output to sys.stderr.
    """
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

def __init__(self, *args, **kwargs):
    self.nodist = kwargs.pop('nodist', False)
    self.nopip = kwargs.pop('nopip', False)
    self.progress = kwargs.pop('progress', None)
    self.verbose = kwargs.pop('verbose', False)
    super().__init__(*args, **kwargs)

def post_setup(self, context):
    """
    Set up any packages which need to be pre-installed into the
    virtual environment being created.

    :param context: The information for the virtual environment
                    creation request being processed.
    """
    os.environ['VIRTUAL_ENV'] = context.env_dir
    if not self.nodist:
        self.install_setuptools(context)
    # Can't install pip without setuptools
    if not self.nopip and not self.nodist:
        self.install_pip(context)

def reader(self, stream, context):
    """
    Read lines from a subprocess' output stream and either pass to a progress
    callable (if specified) or write progress information to sys.stderr.
    """
    progress = self.progress
    while True:
        s = stream.readline()
        if not s:
            break
        if progress is not None:
            progress(s, context)
        else:
            if not self.verbose:
                sys.stderr.write('.')
            else:
                sys.stderr.write(s.decode('utf-8'))
            sys.stderr.flush()
    stream.close()

def install_script(self, context, name, url):
    _, _, path, _, _, _ = urlparse(url)
    fn = os.path.split(path)[-1]
    binpath = context.bin_path
    distpath = os.path.join(binpath, fn)
    # Download script into the virtual environment's binaries folder
    urlretrieve(url, distpath)
    progress = self.progress
    if self.verbose:
        term = '\n'
    else:
        term = ''
    if progress is not None:
        progress('Installing %s ...%s' % (name, term), 'main')

```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

    else:
        sys.stderr.write('Installing %s ...%s' % (name, term))
        sys.stderr.flush()
        # Install in the virtual environment
        args = [context.env_exe, fn]
        p = Popen(args, stdout=PIPE, stderr=PIPE, cwd=binpath)
        t1 = Thread(target=self.reader, args=(p.stdout, 'stdout'))
        t1.start()

## 28.4 zipapp --- Manage executable Python zip archives

Baru pada versi 3.5.

**Source code:** [Lib/zipapp.py](#)

---

This module provides tools to manage the creation of zip files containing Python code, which can be executed directly by the Python interpreter. The module provides both a *Command-Line Interface* and a *Python API*.

### 28.4.1 Basic Example

The following example shows how the *Command-Line Interface* can be used to create an executable archive from a directory containing Python code. When run, the archive will execute the `main` function from the module `myapp` in the archive.

```
$ python -m zipapp myapp -m "myapp:main"
$ python myapp.pyz
<output from myapp>
```

### 28.4.2 Command-Line Interface

When called as a program from the command line, the following form is used:

```
$ python -m zipapp source [options]
```

If *source* is a directory, this will create an archive from the contents of *source*. If *source* is a file, it should be an archive, and it will be copied to the target archive (or the contents of its shebang line will be displayed if the `--info` option is specified).

The following options are understood:

**-o <output>, --output=<output>**

Write the output to a file named *output*. If this option is not specified, the output filename will be the same as the input *source*, with the extension `.pyz` added. If an explicit filename is given, it is used as is (so a `.pyz` extension should be included if required).

An output filename must be specified if the *source* is an archive (and in that case, *output* must not be the same as *source*).

**-p** <interpreter>, **--python**=<interpreter>

Add a `#!` line to the archive specifying *interpreter* as the command to run. Also, on POSIX, make the archive executable. The default is to write no `#!` line, and not make the file executable.

**-m** <mainfn>, **--main**=<mainfn>

Write a `__main__.py` file to the archive that executes *mainfn*. The *mainfn* argument should have the form `"pkg.mod:fn"`, where `"pkg.mod"` is a package/module in the archive, and `"fn"` is a callable in the given module. The `__main__.py` file will execute that callable.

`--main` cannot be specified when copying an archive.

**-c**, **--compress**

Compress files with the deflate method, reducing the size of the output file. By default, files are stored uncompressed in the archive.

`--compress` has no effect when copying an archive.

Baru pada versi 3.7.

**--info**

Display the interpreter embedded in the archive, for diagnostic purposes. In this case, any other options are ignored and `SOURCE` must be an archive, not a directory.

**-h**, **--help**

Print a short usage message and exit.

### 28.4.3 Python API

The module defines two convenience functions:

`zipapp.create_archive(source, target=None, interpreter=None, main=None, filter=None, compressed=False)`

Create an application archive from *source*. The source can be any of the following:

- The name of a directory, or a *path-like object* referring to a directory, in which case a new application archive will be created from the content of that directory.
- The name of an existing application archive file, or a *path-like object* referring to such a file, in which case the file is copied to the target (modifying it to reflect the value given for the *interpreter* argument). The file name should include the `.pyz` extension, if required.
- A file object open for reading in bytes mode. The content of the file should be an application archive, and the file object is assumed to be positioned at the start of the archive.

The *target* argument determines where the resulting archive will be written:

- If it is the name of a file, or a *path-like object*, the archive will be written to that file.
- If it is an open file object, the archive will be written to that file object, which must be open for writing in bytes mode.
- If the target is omitted (or `None`), the source must be a directory and the target will be a file with the same name as the source, with a `.pyz` extension added.

The *interpreter* argument specifies the name of the Python interpreter with which the archive will be executed. It is written as a "shebang" line at the start of the archive. On POSIX, this will be interpreted by the OS, and on Windows it will be handled by the Python launcher. Omitting the *interpreter* results in no shebang line being written. If an interpreter is specified, and the target is a filename, the executable bit of the target file will be set.

The *main* argument specifies the name of a callable which will be used as the main program for the archive. It can only be specified if the source is a directory, and the source does not already contain a `__main__.py` file. The *main* argument should take the form `"pkg.module:callable"` and the archive will be run by importing `"pkg.module"`

and executing the given callable with no arguments. It is an error to omit *main* if the source is a directory and does not contain a `__main__.py` file, as otherwise the resulting archive would not be executable.

The optional *filter* argument specifies a callback function that is passed a `Path` object representing the path to the file being added (relative to the source directory). It should return `True` if the file is to be added.

The optional *compressed* argument determines whether files are compressed. If set to `True`, files in the archive are compressed with the deflate method; otherwise, files are stored uncompressed. This argument has no effect when copying an existing archive.

If a file object is specified for *source* or *target*, it is the caller's responsibility to close it after calling `create_archive`.

When copying an existing archive, file objects supplied only need `read` and `readline`, or `write` methods. When creating an archive from a directory, if the target is a file object it will be passed to the `zipfile.ZipFile` class, and must supply the methods needed by that class.

Baru pada versi 3.7: Added the *filter* and *compressed* arguments.

`zipapp.get_interpreter (archive)`

Return the interpreter specified in the `#!` line at the start of the archive. If there is no `#!` line, return `None`. The *archive* argument can be a filename or a file-like object open for reading in bytes mode. It is assumed to be at the start of the archive.

## 28.4.4 Contoh-contoh

Pack up a directory into an archive, and run it.

```
$ python -m zipapp myapp
$ python myapp.pyz
<output from myapp>
```

The same can be done using the `create_archive()` function:

```
>>> import zipapp
>>> zipapp.create_archive('myapp', 'myapp.pyz')
```

To make the application directly executable on POSIX, specify an interpreter to use.

```
$ python -m zipapp myapp -p "/usr/bin/env python"
$ ./myapp.pyz
<output from myapp>
```

To replace the shebang line on an existing archive, create a modified archive using the `create_archive()` function:

```
>>> import zipapp
>>> zipapp.create_archive('old_archive.pyz', 'new_archive.pyz', '/usr/bin/python3')
```

To update the file in place, do the replacement in memory using a `BytesIO` object, and then overwrite the source afterwards. Note that there is a risk when overwriting a file in place that an error will result in the loss of the original file. This code does not protect against such errors, but production code should do so. Also, this method will only work if the archive fits in memory:

```
>>> import zipapp
>>> import io
>>> temp = io.BytesIO()
>>> zipapp.create_archive('myapp.pyz', temp, '/usr/bin/python2')
>>> with open('myapp.pyz', 'wb') as f:
>>>     f.write(temp.getvalue())
```

## 28.4.5 Specifying the Interpreter

Note that if you specify an interpreter and then distribute your application archive, you need to ensure that the interpreter used is portable. The Python launcher for Windows supports most common forms of POSIX `#!` line, but there are other issues to consider:

- If you use `"/usr/bin/env python"` (or other forms of the `"python"` command, such as `"/usr/bin/python"`), you need to consider that your users may have either Python 2 or Python 3 as their default, and write your code to work under both versions.
- If you use an explicit version, for example `"/usr/bin/env python3"` your application will not work for users who do not have that version. (This may be what you want if you have not made your code Python 2 compatible).
- There is no way to say `"python X.Y or later"`, so be careful of using an exact version like `"/usr/bin/env python3.4"` as you will need to change your shebang line for users of Python 3.5, for example.

Typically, you should use an `"/usr/bin/env python2"` or `"/usr/bin/env python3"`, depending on whether your code is written for Python 2 or 3.

## 28.4.6 Creating Standalone Applications with zipapp

Using the `zipapp` module, it is possible to create self-contained Python programs, which can be distributed to end users who only need to have a suitable version of Python installed on their system. The key to doing this is to bundle all of the application's dependencies into the archive, along with the application code.

The steps to create a standalone archive are as follows:

1. Create your application in a directory as normal, so you have a `myapp` directory containing a `__main__.py` file, and any supporting application code.
2. Install all of your application's dependencies into the `myapp` directory, using `pip`:

```
$ python -m pip install -r requirements.txt --target myapp
```

(this assumes you have your project requirements in a `requirements.txt` file - if not, you can just list the dependencies manually on the `pip` command line).

3. Optionally, delete the `.dist-info` directories created by `pip` in the `myapp` directory. These hold metadata for `pip` to manage the packages, and as you won't be making any further use of `pip` they aren't required - although it won't do any harm if you leave them.
4. Package the application using:

```
$ python -m zipapp -p "interpreter" myapp
```

This will produce a standalone executable, which can be run on any machine with the appropriate interpreter available. See [Specifying the Interpreter](#) for details. It can be shipped to users as a single file.

On Unix, the `myapp.pyz` file is executable as it stands. You can rename the file to remove the `.pyz` extension if you prefer a "plain" command name. On Windows, the `myapp.pyz[w]` file is executable by virtue of the fact that the Python interpreter registers the `.pyz` and `.pyzw` file extensions when installed.

## Making a Windows executable

On Windows, registration of the `.pyz` extension is optional, and furthermore, there are certain places that don't recognise registered extensions "transparently" (the simplest example is that `subprocess.run(['myapp'])` won't find your application - you need to explicitly specify the extension).

On Windows, therefore, it is often preferable to create an executable from the zipapp. This is relatively easy, although it does require a C compiler. The basic approach relies on the fact that zipfiles can have arbitrary data prepended, and Windows exe files can have arbitrary data appended. So by creating a suitable launcher and tacking the `.pyz` file onto the end of it, you end up with a single-file executable that runs your application.

A suitable launcher can be as simple as the following:

```
#define Py_LIMITED_API 1
#include "Python.h"

#define WIN32_LEAN_AND_MEAN
#include <windows.h>

#ifdef WINDOWS
int WINAPI wWinMain(
    HINSTANCE hInstance,      /* handle to current instance */
    HINSTANCE hPrevInstance, /* handle to previous instance */
    LPWSTR lpCmdLine,         /* pointer to command line */
    int nCmdShow              /* show state of window */
)
#else
int wmain()
#endif
{
    wchar_t **myargv = _alloca((__argc + 1) * sizeof(wchar_t*));
    myargv[0] = __wargv[0];
    memcpy(myargv + 1, __wargv, __argc * sizeof(wchar_t *));
    return Py_Main(__argc+1, myargv);
}
```

If you define the `WINDOWS` preprocessor symbol, this will generate a GUI executable, and without it, a console executable.

To compile the executable, you can either just use the standard MSVC command line tools, or you can take advantage of the fact that `distutils` knows how to compile Python source:

```
>>> from distutils.ccompiler import new_compiler
>>> import distutils.sysconfig
>>> import sys
>>> import os
>>> from pathlib import Path

>>> def compile(src):
>>>     src = Path(src)
>>>     cc = new_compiler()
>>>     exe = src.stem
>>>     cc.add_include_dir(distutils.sysconfig.get_python_inc())
>>>     cc.add_library_dir(os.path.join(sys.base_exec_prefix, 'libs'))
>>>     # First the CLI executable
>>>     objs = cc.compile([str(src)])
>>>     cc.link_executable(objs, exe)
>>>     # Now the GUI executable
>>>     cc.define_macro('WINDOWS')
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

>>>     objs = cc.compile([str(src)])
>>>     cc.link_executable(objs, exe + 'w')

>>> if __name__ == "__main__":
>>>     compile("zastub.c")

```

The resulting launcher uses the "Limited ABI", so it will run unchanged with any version of Python 3.x. All it needs is for Python (`python3.dll`) to be on the user's `PATH`.

For a fully standalone distribution, you can distribute the launcher with your application appended, bundled with the Python "embedded" distribution. This will run on any PC with the appropriate architecture (32 bit or 64 bit).

## Caveats

There are some limitations to the process of bundling your application into a single file. In most, if not all, cases they can be addressed without needing major changes to your application.

1. If your application depends on a package that includes a C extension, that package cannot be run from a zip file (this is an OS limitation, as executable code must be present in the filesystem for the OS loader to load it). In this case, you can exclude that dependency from the zipfile, and either require your users to have it installed, or ship it alongside your zipfile and add code to your `__main__.py` to include the directory containing the unzipped module in `sys.path`. In this case, you will need to make sure to ship appropriate binaries for your target architecture(s) (and potentially pick the correct version to add to `sys.path` at runtime, based on the user's machine).
2. If you are shipping a Windows executable as described above, you either need to ensure that your users have `python3.dll` on their `PATH` (which is not the default behaviour of the installer) or you should bundle your application with the embedded distribution.
3. The suggested launcher above uses the Python embedding API. This means that in your application, `sys.executable` will be your application, and *not* a conventional Python interpreter. Your code and its dependencies need to be prepared for this possibility. For example, if your application uses the `multiprocessing` module, it will need to call `multiprocessing.set_executable()` to let the module know where to find the standard Python interpreter.

## 28.4.7 The Python Zip Application Archive Format

Python has been able to execute zip files which contain a `__main__.py` file since version 2.6. In order to be executed by Python, an application archive simply has to be a standard zip file containing a `__main__.py` file which will be run as the entry point for the application. As usual for any Python script, the parent of the script (in this case the zip file) will be placed on `sys.path` and thus further modules can be imported from the zip file.

The zip file format allows arbitrary data to be prepended to a zip file. The zip application format uses this ability to prepend a standard POSIX "shebang" line to the file (`#!/path/to/interpreter`).

Formally, the Python zip application format is therefore:

1. An optional shebang line, containing the characters `b'#!'` followed by an interpreter name, and then a newline (`b'\n'`) character. The interpreter name can be anything acceptable to the OS "shebang" processing, or the Python launcher on Windows. The interpreter should be encoded in UTF-8 on Windows, and in `sys.getfilesystemencoding()` on POSIX.
2. Standard zipfile data, as generated by the `zipfile` module. The zipfile content *must* include a file called `__main__.py` (which must be in the "root" of the zipfile - i.e., it cannot be in a subdirectory). The zipfile data can be compressed or uncompressed.

If an application archive has a shebang line, it may have the executable bit set on POSIX systems, to allow it to be executed directly.

There is no requirement that the tools in this module are used to create application archives - the module is a convenience, but archives in the above format created by any means are acceptable to Python.

---

## Layanan Runtime Python

---

Modul-modul yang dijelaskan dalam bab ini menyediakan berbagai layanan yang terkait dengan *interpreter* Python dan interaksi dengan lingkungannya. Berikut ini ikhtisar:

### 29.1 `sys` --- System-specific parameters and functions

---

This module provides access to some variables used or maintained by the interpreter and to functions that interact strongly with the interpreter. It is always available.

#### `sys.abiflags`

On POSIX systems where Python was built with the standard `configure` script, this contains the ABI flags as specified by [PEP 3149](#).

Berubah pada versi 3.8: Default flags became an empty string (m flag for pymalloc has been removed).

Baru pada versi 3.2.

#### `sys.addaudithook(hook)`

Append the callable *hook* to the list of active auditing hooks for the current (sub)interpreter.

When an auditing event is raised through the `sys.audit()` function, each hook will be called in the order it was added with the event name and the tuple of arguments. Native hooks added by `PySys_AddAuditHook()` are called first, followed by hooks added in the current (sub)interpreter. Hooks can then log the event, raise an exception to abort the operation, or terminate the process entirely.

Calling `sys.addaudithook()` will itself raise an auditing event named `sys.addaudithook` with no arguments. If any existing hooks raise an exception derived from `RuntimeError`, the new hook will not be added and the exception suppressed. As a result, callers cannot assume that their hook has been added unless they control all existing hooks.

See the [audit events table](#) for all events raised by CPython, and [PEP 578](#) for the original design discussion.

Baru pada versi 3.8.

Berubah pada versi 3.8.1: Exceptions derived from *Exception* but not *RuntimeError* are no longer suppressed.

**CPython implementation detail:** When tracing is enabled (see *settrace()*), Python hooks are only traced if the callable has a `__cantrace__` member that is set to a true value. Otherwise, trace functions will skip the hook.

### `sys.argv`

The list of command line arguments passed to a Python script. `argv[0]` is the script name (it is operating system dependent whether this is a full pathname or not). If the command was executed using the `-c` command line option to the interpreter, `argv[0]` is set to the string `'-c'`. If no script name was passed to the Python interpreter, `argv[0]` is the empty string.

To loop over the standard input, or the list of files given on the command line, see the *fileinput* module.

---

**Catatan:** On Unix, command line arguments are passed by bytes from OS. Python decodes them with file-system encoding and "surrogateescape" error handler. When you need original bytes, you can get it by `[os.fsencode(arg) for arg in sys.argv]`.

---

### `sys.audit(event, *args)`

Raise an auditing event and trigger any active auditing hooks. *event* is a string identifying the event, and *args* may contain optional arguments with more information about the event. The number and types of arguments for a given event are considered a public and stable API and should not be modified between releases.

For example, one auditing event is named `os.chdir`. This event has one argument called *path* that will contain the requested new working directory.

*sys.audit()* will call the existing auditing hooks, passing the event name and arguments, and will re-raise the first exception from any hook. In general, if an exception is raised, it should not be handled and the process should be terminated as quickly as possible. This allows hook implementations to decide how to respond to particular events: they can merely log the event or abort the operation by raising an exception.

Hooks are added using the *sys.addaudithook()* or `PySys_AddAuditHook()` functions.

The native equivalent of this function is `PySys_Audit()`. Using the native function is preferred when possible.

See the *audit events table* for all events raised by CPython.

Baru pada versi 3.8.

### `sys.base_exec_prefix`

Set during Python startup, before `site.py` is run, to the same value as *exec\_prefix*. If not running in a *virtual environment*, the values will stay the same; if `site.py` finds that a virtual environment is in use, the values of *prefix* and *exec\_prefix* will be changed to point to the virtual environment, whereas *base\_prefix* and *base\_exec\_prefix* will remain pointing to the base Python installation (the one which the virtual environment was created from).

Baru pada versi 3.3.

### `sys.base_prefix`

Set during Python startup, before `site.py` is run, to the same value as *prefix*. If not running in a *virtual environment*, the values will stay the same; if `site.py` finds that a virtual environment is in use, the values of *prefix* and *exec\_prefix* will be changed to point to the virtual environment, whereas *base\_prefix* and *base\_exec\_prefix* will remain pointing to the base Python installation (the one which the virtual environment was created from).

Baru pada versi 3.3.

**sys.byteorder**

An indicator of the native byte order. This will have the value 'big' on big-endian (most-significant byte first) platforms, and 'little' on little-endian (least-significant byte first) platforms.

**sys.builtin\_module\_names**

A tuple of strings giving the names of all modules that are compiled into this Python interpreter. (This information is not available in any other way --- `modules.keys()` only lists the imported modules.)

**sys.call\_tracing** (*func, args*)

Call `func(*args)`, while tracing is enabled. The tracing state is saved, and restored afterwards. This is intended to be called from a debugger from a checkpoint, to recursively debug some other code.

**sys.copyright**

A string containing the copyright pertaining to the Python interpreter.

**sys.\_clear\_type\_cache** ()

Clear the internal type cache. The type cache is used to speed up attribute and method lookups. Use the function *only* to drop unnecessary references during reference leak debugging.

This function should be used for internal and specialized purposes only.

**sys.\_current\_frames** ()

Return a dictionary mapping each thread's identifier to the topmost stack frame currently active in that thread at the time the function is called. Note that functions in the `traceback` module can build the call stack given such a frame.

This is most useful for debugging deadlock: this function does not require the deadlocked threads' cooperation, and such threads' call stacks are frozen for as long as they remain deadlocked. The frame returned for a non-deadlocked thread may bear no relationship to that thread's current activity by the time calling code examines the frame.

This function should be used for internal and specialized purposes only.

Raises an *auditing event* `sys._current_frames` with no arguments.

**sys.breakpointhook** ()

This hook function is called by built-in `breakpoint()`. By default, it drops you into the `pdb` debugger, but it can be set to any other function so that you can choose which debugger gets used.

The signature of this function is dependent on what it calls. For example, the default binding (e.g. `pdb.set_trace()`) expects no arguments, but you might bind it to a function that expects additional arguments (positional and/or keyword). The built-in `breakpoint()` function passes its `*args` and `**kws` straight through. Whatever `breakpointhooks()` returns is returned from `breakpoint()`.

The default implementation first consults the environment variable `PYTHONBREAKPOINT`. If that is set to "0" then this function returns immediately; i.e. it is a no-op. If the environment variable is not set, or is set to the empty string, `pdb.set_trace()` is called. Otherwise this variable should name a function to run, using Python's dotted-import nomenclature, e.g. `package.subpackage.module.function`. In this case, `package.subpackage.module` would be imported and the resulting module must have a callable named `function()`. This is run, passing in `*args` and `**kws`, and whatever `function()` returns, `sys.breakpointhook()` returns to the built-in `breakpoint()` function.

Note that if anything goes wrong while importing the callable named by `PYTHONBREAKPOINT`, a *RuntimeWarning* is reported and the breakpoint is ignored.

Also note that if `sys.breakpointhook()` is overridden programmatically, `PYTHONBREAKPOINT` is *not* consulted.

Baru pada versi 3.7.

**sys.\_debugmallocstats** ()

Print low-level information to stderr about the state of CPython's memory allocator.

If Python is configured `--with-pydebug`, it also performs some expensive internal consistency checks.

Baru pada versi 3.3.

**CPython implementation detail:** This function is specific to CPython. The exact output format is not defined here, and may change.

`sys.dllhandle`

Integer specifying the handle of the Python DLL.

*Availability:* Windows.

`sys.displayhook(value)`

If *value* is not `None`, this function prints `repr(value)` to `sys.stdout`, and saves *value* in `builtins._`. If `repr(value)` is not encodable to `sys.stdout.encoding` with `sys.stdout.errors` error handler (which is probably `'strict'`), encode it to `sys.stdout.encoding` with `'backslashreplace'` error handler.

`sys.displayhook` is called on the result of evaluating an *expression* entered in an interactive Python session. The display of these values can be customized by assigning another one-argument function to `sys.displayhook`.

Pseudo-code:

```
def displayhook(value):
    if value is None:
        return
    # Set '_' to None to avoid recursion
    builtins._ = None
    text = repr(value)
    try:
        sys.stdout.write(text)
    except UnicodeEncodeError:
        bytes = text.encode(sys.stdout.encoding, 'backslashreplace')
        if hasattr(sys.stdout, 'buffer'):
            sys.stdout.buffer.write(bytes)
        else:
            text = bytes.decode(sys.stdout.encoding, 'strict')
            sys.stdout.write(text)
    sys.stdout.write("\n")
    builtins._ = value
```

Berubah pada versi 3.2: Use `'backslashreplace'` error handler on `UnicodeEncodeError`.

`sys.dont_write_bytecode`

If this is true, Python won't try to write `.pyc` files on the import of source modules. This value is initially set to `True` or `False` depending on the `-B` command line option and the `PYTHONDONTWRITEBYTECODE` environment variable, but you can set it yourself to control bytecode file generation.

`sys.pycache_prefix`

If this is set (not `None`), Python will write bytecode-cache `.pyc` files to (and read them from) a parallel directory tree rooted at this directory, rather than from `__pycache__` directories in the source code tree. Any `__pycache__` directories in the source code tree will be ignored and new `.pyc` files written within the pycache prefix. Thus if you use `compileall` as a pre-build step, you must ensure you run it with the same pycache prefix (if any) that you will use at runtime.

A relative path is interpreted relative to the current working directory.

This value is initially set based on the value of the `-X pycache_prefix=PATH` command-line option or the `PYTHONPYCACHEPREFIX` environment variable (command-line takes precedence). If neither are set, it is `None`.

Baru pada versi 3.8.

`sys.excepthook` (*type, value, traceback*)

This function prints out a given traceback and exception to `sys.stderr`.

When an exception is raised and uncaught, the interpreter calls `sys.excepthook` with three arguments, the exception class, exception instance, and a traceback object. In an interactive session this happens just before control is returned to the prompt; in a Python program this happens just before the program exits. The handling of such top-level exceptions can be customized by assigning another three-argument function to `sys.excepthook`.

Raise an auditing event `sys.excepthook` with arguments `hook, type, value, traceback` when an uncaught exception occurs. If no hook has been set, `hook` may be `None`. If any hook raises an exception derived from `RuntimeError` the call to the hook will be suppressed. Otherwise, the audit hook exception will be reported as unraisable and `sys.excepthook` will be called.

**Lihat juga:**

The `sys.unraisablehook()` function handles unraisable exceptions and the `threading.excepthook()` function handles exception raised by `threading.Thread.run()`.

`sys.__breakpointhook__`

`sys.__displayhook__`

`sys.__excepthook__`

`sys.__unraisablehook__`

These objects contain the original values of `breakpointhook`, `displayhook`, `excepthook`, and `unraisablehook` at the start of the program. They are saved so that `breakpointhook`, `displayhook` and `excepthook`, `unraisablehook` can be restored in case they happen to get replaced with broken or alternative objects.

Baru pada versi 3.7: `__breakpointhook__`

Baru pada versi 3.8: `__unraisablehook__`

`sys.exc_info()`

This function returns a tuple of three values that give information about the exception that is currently being handled. The information returned is specific both to the current thread and to the current stack frame. If the current stack frame is not handling an exception, the information is taken from the calling stack frame, or its caller, and so on until a stack frame is found that is handling an exception. Here, "handling an exception" is defined as "executing an except clause." For any stack frame, only information about the exception being currently handled is accessible.

If no exception is being handled anywhere on the stack, a tuple containing three `None` values is returned. Otherwise, the values returned are (*type, value, traceback*). Their meaning is: *type* gets the type of the exception being handled (a subclass of `BaseException`); *value* gets the exception instance (an instance of the exception type); *traceback* gets a traceback object which encapsulates the call stack at the point where the exception originally occurred.

`sys.exec_prefix`

A string giving the site-specific directory prefix where the platform-dependent Python files are installed; by default, this is also `'/usr/local'`. This can be set at build time with the `--exec-prefix` argument to the **configure** script. Specifically, all configuration files (e.g. the `pyconfig.h` header file) are installed in the directory `exec_prefix/lib/pythonX.Y/config`, and shared library modules are installed in `exec_prefix/lib/pythonX.Y/lib-dynload`, where `X.Y` is the version number of Python, for example 3.2.

---

**Catatan:** If a *virtual environment* is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via `base_exec_prefix`.

---

`sys.executable`

A string giving the absolute path of the executable binary for the Python interpreter, on systems where this makes

sense. If Python is unable to retrieve the real path to its executable, `sys.executable` will be an empty string or `None`.

### `sys.exit([arg])`

Exit from Python. This is implemented by raising the `SystemExit` exception, so cleanup actions specified by finally clauses of `try` statements are honored, and it is possible to intercept the exit attempt at an outer level.

The optional argument `arg` can be an integer giving the exit status (defaulting to zero), or another type of object. If it is an integer, zero is considered "successful termination" and any nonzero value is considered "abnormal termination" by shells and the like. Most systems require it to be in the range 0--127, and produce undefined results otherwise. Some systems have a convention for assigning specific meanings to specific exit codes, but these are generally underdeveloped; Unix programs generally use 2 for command line syntax errors and 1 for all other kind of errors. If another type of object is passed, `None` is equivalent to passing zero, and any other object is printed to `stderr` and results in an exit code of 1. In particular, `sys.exit("some error message")` is a quick way to exit a program when an error occurs.

Since `exit()` ultimately "only" raises an exception, it will only exit the process when called from the main thread, and the exception is not intercepted.

Berubah pada versi 3.6: If an error occurs in the cleanup after the Python interpreter has caught `SystemExit` (such as an error flushing buffered data in the standard streams), the exit status is changed to 120.

### `sys.flags`

The *named tuple* `flags` exposes the status of command line flags. The attributes are read only.

| atribut                          | flag                                                                                      |
|----------------------------------|-------------------------------------------------------------------------------------------|
| <code>debug</code>               | <code>-d</code>                                                                           |
| <code>inspect</code>             | <code>-i</code>                                                                           |
| <code>interactive</code>         | <code>-i</code>                                                                           |
| <code>isolated</code>            | <code>-I</code>                                                                           |
| <code>optimize</code>            | <code>-O</code> or <code>-OO</code>                                                       |
| <code>dont_write_bytecode</code> | <code>-B</code>                                                                           |
| <code>no_user_site</code>        | <code>-s</code>                                                                           |
| <code>no_site</code>             | <code>-S</code>                                                                           |
| <code>ignore_environment</code>  | <code>-E</code>                                                                           |
| <code>verbose</code>             | <code>-v</code>                                                                           |
| <code>bytes_warning</code>       | <code>-b</code>                                                                           |
| <code>quiet</code>               | <code>-q</code>                                                                           |
| <code>hash_randomization</code>  | <code>-R</code>                                                                           |
| <code>dev_mode</code>            | <code>-X dev</code>                                                                       |
| <code>utf8_mode</code>           | <code>-X utf8</code>                                                                      |
| <code>int_max_str_digits</code>  | <code>-X int_max_str_digits</code> ( <i>integer string conversion length limitation</i> ) |

Berubah pada versi 3.2: Added `quiet` attribute for the new `-q` flag.

Baru pada versi 3.2.3: The `hash_randomization` attribute.

Berubah pada versi 3.3: Removed obsolete `division_warning` attribute.

Berubah pada versi 3.4: Added `isolated` attribute for `-I` isolated flag.

Berubah pada versi 3.7: Added `dev_mode` attribute for the new `-X dev` flag and `utf8_mode` attribute for the new `-X utf8` flag.

Berubah pada versi 3.8.14: Added the `int_max_str_digits` attribute.

### `sys.float_info`

A *named tuple* holding information about the float type. It contains low level information about the precision and

internal representation. The values correspond to the various floating-point constants defined in the standard header file `float.h` for the 'C' programming language; see section 5.2.4.2.2 of the 1999 ISO/IEC C standard [C99], 'Characteristics of floating types', for details.

| atribut                 | float.h macro               | explanation                                                                                                                                                                                                                                                                              |
|-------------------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>epsilon</code>    | <code>DBL_EPSILON</code>    | difference between 1.0 and the least value greater than 1.0 that is representable as a float                                                                                                                                                                                             |
| <code>dig</code>        | <code>DBL_DIG</code>        | maximum number of decimal digits that can be faithfully represented in a float; see below                                                                                                                                                                                                |
| <code>mant_dig</code>   | <code>DBL_MANT_DIG</code>   | float precision: the number of base-radix digits in the significand of a float                                                                                                                                                                                                           |
| <code>max</code>        | <code>DBL_MAX</code>        | maximum representable positive finite float                                                                                                                                                                                                                                              |
| <code>max_exp</code>    | <code>DBL_MAX_EXP</code>    | maximum integer $e$ such that <code>radix**(e-1)</code> is a representable finite float                                                                                                                                                                                                  |
| <code>max_10_exp</code> | <code>DBL_MAX_10_EXP</code> | maximum integer $e$ such that <code>10**e</code> is in the range of representable finite floats                                                                                                                                                                                          |
| <code>min</code>        | <code>DBL_MIN</code>        | minimum representable positive <i>normalized</i> float                                                                                                                                                                                                                                   |
| <code>min_exp</code>    | <code>DBL_MIN_EXP</code>    | minimum integer $e$ such that <code>radix**(e-1)</code> is a normalized float                                                                                                                                                                                                            |
| <code>min_10_exp</code> | <code>DBL_MIN_10_EXP</code> | minimum integer $e$ such that <code>10**e</code> is a normalized float                                                                                                                                                                                                                   |
| <code>radix</code>      | <code>FLT_RADIX</code>      | radix of exponent representation                                                                                                                                                                                                                                                         |
| <code>rounds</code>     | <code>FLT_ROUNDS</code>     | integer constant representing the rounding mode used for arithmetic operations. This reflects the value of the system <code>FLT_ROUNDS</code> macro at interpreter startup time. See section 5.2.4.2.2 of the C99 standard for an explanation of the possible values and their meanings. |

The attribute `sys.float_info.dig` needs further explanation. If `s` is any string representing a decimal number with at most `sys.float_info.dig` significant digits, then converting `s` to a float and back again will recover a string representing the same decimal value:

```
>>> import sys
>>> sys.float_info.dig
15
>>> s = '3.14159265358979'      # decimal string with 15 significant digits
>>> format(float(s), '.15g')    # convert to float and back -> same value
'3.14159265358979'
```

But for strings with more than `sys.float_info.dig` significant digits, this isn't always true:

```
>>> s = '9876543211234567'     # 16 significant digits is too many!
>>> format(float(s), '.16g')    # conversion changes value
'9876543211234568'
```

### `sys.float_repr_style`

A string indicating how the `repr()` function behaves for floats. If the string has value `'short'` then for a finite float `x`, `repr(x)` aims to produce a short string with the property that `float(repr(x)) == x`. This is the usual behaviour in Python 3.1 and later. Otherwise, `float_repr_style` has value `'legacy'` and `repr(x)` behaves in the same way as it did in versions of Python prior to 3.1.

Baru pada versi 3.1.

### `sys.getallocatedblocks()`

Return the number of memory blocks currently allocated by the interpreter, regardless of their size. This function is mainly useful for tracking and debugging memory leaks. Because of the interpreter's internal caches, the result

can vary from call to call; you may have to call `_clear_type_cache()` and `gc.collect()` to get more predictable results.

If a Python build or implementation cannot reasonably compute this information, `getallocatedblocks()` is allowed to return 0 instead.

Baru pada versi 3.4.

`sys.getandroidapilevel()`

Return the build time API version of Android as an integer.

*Availability:* Android.

Baru pada versi 3.7.

`sys.getcheckinterval()`

Return the interpreter's "check interval"; see `setcheckinterval()`.

Ditinggalkan sejak versi 3.2: Use `getswitchinterval()` instead.

`sys.getdefaultencoding()`

Return the name of the current default string encoding used by the Unicode implementation.

`sys.getdlopenflags()`

Return the current value of the flags that are used for `dlopen()` calls. Symbolic names for the flag values can be found in the `os` module (RTLD\_XXX constants, e.g. `os.RTLD_LAZY`).

*Availability:* Unix.

`sys.getfilesystemencoding()`

Return the name of the encoding used to convert between Unicode filenames and bytes filenames. For best compatibility, str should be used for filenames in all cases, although representing filenames as bytes is also supported. Functions accepting or returning filenames should support either str or bytes and internally convert to the system's preferred representation.

This encoding is always ASCII-compatible.

`os.fsencode()` and `os.fsdecode()` should be used to ensure that the correct encoding and errors mode are used.

- In the UTF-8 mode, the encoding is `utf-8` on any platform.
- On macOS, the encoding is `'utf-8'`.
- On Unix, the encoding is the locale encoding.
- On Windows, the encoding may be `'utf-8'` or `'mbcs'`, depending on user configuration.
- On Android, the encoding is `'utf-8'`.
- On VxWorks, the encoding is `'utf-8'`.

Berubah pada versi 3.2: `getfilesystemencoding()` result cannot be `None` anymore.

Berubah pada versi 3.6: Windows is no longer guaranteed to return `'mbcs'`. See [PEP 529](#) and `_enablelegacywindowsfsencoding()` for more information.

Berubah pada versi 3.7: Return `'utf-8'` in the UTF-8 mode.

`sys.getfilesystemcodeerrors()`

Return the name of the error mode used to convert between Unicode filenames and bytes filenames. The encoding name is returned from `getfilesystemencoding()`.

`os.fsencode()` and `os.fsdecode()` should be used to ensure that the correct encoding and errors mode are used.

Baru pada versi 3.6.

`sys.get_int_max_str_digits()`  
Returns the current value for the *integer string conversion length limitation*. See also *set\_int\_max\_str\_digits()*.

Baru pada versi 3.8.14.

`sys.getrefcount(object)`  
Return the reference count of the *object*. The count returned is generally one higher than you might expect, because it includes the (temporary) reference as an argument to *getrefcount()*.

`sys.getrecursionlimit()`  
Return the current value of the recursion limit, the maximum depth of the Python interpreter stack. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python. It can be set by *setrecursionlimit()*.

`sys.getsizeof(object[, default])`  
Return the size of an object in bytes. The object can be any type of object. All built-in objects will return correct results, but this does not have to hold true for third-party extensions as it is implementation specific.

Only the memory consumption directly attributed to the object is accounted for, not the memory consumption of objects it refers to.

If given, *default* will be returned if the object does not provide means to retrieve the size. Otherwise a *TypeError* will be raised.

*getsizeof()* calls the object's `__sizeof__` method and adds an additional garbage collector overhead if the object is managed by the garbage collector.

See *recursive sizeof recipe* for an example of using *getsizeof()* recursively to find the size of containers and all their contents.

`sys.getswitchinterval()`  
Return the interpreter's "thread switch interval"; see *setswitchinterval()*.

Baru pada versi 3.2.

`sys._getframe([depth])`  
Return a frame object from the call stack. If optional integer *depth* is given, return the frame object that many calls below the top of the stack. If that is deeper than the call stack, *ValueError* is raised. The default for *depth* is zero, returning the frame at the top of the call stack.

Raises an *auditing event* `sys._getframe` with no arguments.

**CPython implementation detail:** This function should be used for internal and specialized purposes only. It is not guaranteed to exist in all implementations of Python.

`sys.getprofile()`  
Get the profiler function as set by *setprofile()*.

`sys.gettrace()`  
Get the trace function as set by *settrace()*.

**CPython implementation detail:** The *gettrace()* function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

`sys.getwindowsversion()`  
Return a named tuple describing the Windows version currently running. The named elements are *major*, *minor*, *build*, *platform*, *service\_pack*, *service\_pack\_minor*, *service\_pack\_major*, *suite\_mask*, *product\_type* and *platform\_version*. *service\_pack* contains a string, *platform\_version* a 3-tuple and all other values are integers. The

components can also be accessed by name, so `sys.getwindowsversion()[0]` is equivalent to `sys.getwindowsversion().major`. For compatibility with prior versions, only the first 5 elements are retrievable by indexing.

*platform* will be 2 (`VER_PLATFORM_WIN32_NT`).

*product\_type* may be one of the following values:

| Konstanta                                   | Artinya                                              |
|---------------------------------------------|------------------------------------------------------|
| 1 ( <code>VER_NT_WORKSTATION</code> )       | The system is a workstation.                         |
| 2 ( <code>VER_NT_DOMAIN_CONTROLLER</code> ) | The system is a domain controller.                   |
| 3 ( <code>VER_NT_SERVER</code> )            | The system is a server, but not a domain controller. |

This function wraps the Win32 `GetVersionEx()` function; see the Microsoft documentation on `OSVERSIONINFOEX()` for more information about these fields.

*platform\_version* returns the major version, minor version and build number of the current operating system, rather than the version that is being emulated for the process. It is intended for use in logging rather than for feature detection.

---

**Catatan:** *platform\_version* derives the version from `kernel32.dll` which can be of a different version than the OS version. Please use *platform* module for achieving accurate OS version.

---

*Availability:* Windows.

Berubah pada versi 3.2: Changed to a named tuple and added *service\_pack\_minor*, *service\_pack\_major*, *suite\_mask*, and *product\_type*.

Berubah pada versi 3.6: Added *platform\_version*

`sys.get_asyncgen_hooks()`

Returns an *asyncgen\_hooks* object, which is similar to a *namedtuple* of the form (*firstiter*, *finalizer*), where *firstiter* and *finalizer* are expected to be either `None` or functions which take an *asynchronous generator iterator* as an argument, and are used to schedule finalization of an asynchronous generator by an event loop.

Baru pada versi 3.6: See [PEP 525](#) for more details.

---

**Catatan:** This function has been added on a provisional basis (see [PEP 411](#) for details.)

---

`sys.get_coroutine_origin_tracking_depth()`

Get the current coroutine origin tracking depth, as set by *set\_coroutine\_origin\_tracking\_depth()*.

Baru pada versi 3.7.

---

**Catatan:** This function has been added on a provisional basis (see [PEP 411](#) for details.) Use it only for debugging purposes.

---

`sys.hash_info`

A *named tuple* giving parameters of the numeric hash implementation. For more details about hashing of numeric types, see *Hashing of numeric types*.

| atribut   | explanation                                                     |
|-----------|-----------------------------------------------------------------|
| width     | width in bits used for hash values                              |
| modulus   | prime modulus P used for numeric hash scheme                    |
| inf       | hash value returned for a positive infinity                     |
| nan       | hash value returned for a nan                                   |
| imag      | multiplier used for the imaginary part of a complex number      |
| algorithm | name of the algorithm for hashing of str, bytes, and memoryview |
| hash_bits | internal output size of the hash algorithm                      |
| seed_bits | size of the seed key of the hash algorithm                      |

Baru pada versi 3.2.

Berubah pada versi 3.4: Added *algorithm*, *hash\_bits* and *seed\_bits*

#### `sys.hexversion`

The version number encoded as a single integer. This is guaranteed to increase with each version, including proper support for non-production releases. For example, to test that the Python interpreter is at least version 1.5.2, use:

```
if sys.hexversion >= 0x010502F0:
    # use some advanced feature
    ...
else:
    # use an alternative implementation or warn the user
    ...
```

This is called `hexversion` since it only really looks meaningful when viewed as the result of passing it to the built-in `hex()` function. The *named tuple* `sys.version_info` may be used for a more human-friendly encoding of the same information.

More details of `hexversion` can be found at `apiabiversion`.

#### `sys.implementation`

An object containing information about the implementation of the currently running Python interpreter. The following attributes are required to exist in all Python implementations.

*name* is the implementation's identifier, e.g. `'cpython'`. The actual string is defined by the Python implementation, but it is guaranteed to be lower case.

*version* is a named tuple, in the same format as `sys.version_info`. It represents the version of the Python *implementation*. This has a distinct meaning from the specific version of the Python *language* to which the currently running interpreter conforms, which `sys.version_info` represents. For example, for PyPy 1.8 `sys.implementation.version` might be `sys.version_info(1, 8, 0, 'final', 0)`, whereas `sys.version_info` would be `sys.version_info(2, 7, 2, 'final', 0)`. For CPython they are the same value, since it is the reference implementation.

*hexversion* is the implementation version in hexadecimal format, like `sys.hexversion`.

*cache\_tag* is the tag used by the import machinery in the filenames of cached modules. By convention, it would be a composite of the implementation's name and version, like `'cpython-33'`. However, a Python implementation may use some other value if appropriate. If *cache\_tag* is set to `None`, it indicates that module caching should be disabled.

`sys.implementation` may contain additional attributes specific to the Python implementation. These non-standard attributes must start with an underscore, and are not described here. Regardless of its contents, `sys.implementation` will not change during a run of the interpreter, nor between implementation versions. (It may change between Python language versions, however.) See [PEP 421](#) for more information.

Baru pada versi 3.3.

---

**Catatan:** The addition of new required attributes must go through the normal PEP process. See [PEP 421](#) for more information.

---

### `sys.int_info`

A *named tuple* that holds information about Python's internal representation of integers. The attributes are read only.

| Atribut                                 | Explanation                                                                                                                                         |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bits_per_digit</code>             | number of bits held in each digit. Python integers are stored internally in base $2^{**\text{int\_info.bits\_per\_digit}}$                          |
| <code>sizeof_digit</code>               | size in bytes of the C type used to represent a digit                                                                                               |
| <code>default_max_str_digits</code>     | default value for <code>sys.get_int_max_str_digits()</code> when it is not otherwise explicitly configured.                                         |
| <code>str_digits_check_threshold</code> | minimum non-zero value for <code>sys.set_int_max_str_digits()</code> , <code>PYTHONINTMAXSTRDIGITS</code> , or <code>-X int_max_str_digits</code> . |

Baru pada versi 3.1.

Berubah pada versi 3.8.14: Added `default_max_str_digits` and `str_digits_check_threshold`.

### `sys.__interactivehook__`

When this attribute exists, its value is automatically called (with no arguments) when the interpreter is launched in interactive mode. This is done after the `PYTHONSTARTUP` file is read, so that you can set this hook there. The *site* module *sets this*.

Raises an *auditing event* `cpython.run_interactivehook` with the hook object as the argument when the hook is called on startup.

Baru pada versi 3.4.

### `sys.intern(string)`

Enter *string* in the table of "interned" strings and return the interned string -- which is *string* itself or a copy. Interning strings is useful to gain a little performance on dictionary lookup -- if the keys in a dictionary are interned, and the lookup key is interned, the key comparisons (after hashing) can be done by a pointer compare instead of a string compare. Normally, the names used in Python programs are automatically interned, and the dictionaries used to hold module, class or instance attributes have interned keys.

Interned strings are not immortal; you must keep a reference to the return value of *intern()* around to benefit from it.

### `sys.is_finalizing()`

Return *True* if the Python interpreter is *shutting down*, *False* otherwise.

Baru pada versi 3.5.

### `sys.last_type`

### `sys.last_value`

### `sys.last_traceback`

These three variables are not always defined; they are set when an exception is not handled and the interpreter prints an error message and a stack traceback. Their intended use is to allow an interactive user to import a debugger module and engage in post-mortem debugging without having to re-execute the command that caused the error. (Typical use is `import pdb; pdb.pm()` to enter the post-mortem debugger; see *pdb* module for more information.)

The meaning of the variables is the same as that of the return values from *exc\_info()* above.

**sys.maxsize**

An integer giving the maximum value a variable of type `Py_ssize_t` can take. It's usually  $2^{31} - 1$  on a 32-bit platform and  $2^{63} - 1$  on a 64-bit platform.

**sys.maxunicode**

An integer giving the value of the largest Unicode code point, i.e. 1114111 (0x10FFFF in hexadecimal).

Berubah pada versi 3.3: Before **PEP 393**, `sys.maxunicode` used to be either 0xFFFF or 0x10FFFF, depending on the configuration option that specified whether Unicode characters were stored as UCS-2 or UCS-4.

**sys.meta\_path**

A list of *meta path finder* objects that have their `find_spec()` methods called to see if one of the objects can find the module to be imported. The `find_spec()` method is called with at least the absolute name of the module being imported. If the module to be imported is contained in a package, then the parent package's `__path__` attribute is passed in as a second argument. The method returns a *module spec*, or `None` if the module cannot be found.

**Lihat juga:**

`importlib.abc.MetaPathFinder` The abstract base class defining the interface of finder objects on `meta_path`.

`importlib.machinery.ModuleSpec` The concrete class which `find_spec()` should return instances of.

Berubah pada versi 3.4: *Module specs* were introduced in Python 3.4, by **PEP 451**. Earlier versions of Python looked for a method called `find_module()`. This is still called as a fallback if a `meta_path` entry doesn't have a `find_spec()` method.

**sys.modules**

This is a dictionary that maps module names to modules which have already been loaded. This can be manipulated to force reloading of modules and other tricks. However, replacing the dictionary will not necessarily work as expected and deleting essential items from the dictionary may cause Python to fail.

**sys.path**

A list of strings that specifies the search path for modules. Initialized from the environment variable `PYTHONPATH`, plus an installation-dependent default.

As initialized upon program startup, the first item of this list, `path[0]`, is the directory containing the script that was used to invoke the Python interpreter. If the script directory is not available (e.g. if the interpreter is invoked interactively or if the script is read from standard input), `path[0]` is the empty string, which directs Python to search modules in the current directory first. Notice that the script directory is inserted *before* the entries inserted as a result of `PYTHONPATH`.

A program is free to modify this list for its own purposes. Only strings and bytes should be added to `sys.path`; all other data types are ignored during import.

**Lihat juga:**

Module *site* This describes how to use `.pth` files to extend `sys.path`.

**sys.path\_hooks**

A list of callables that take a path argument to try to create a *finder* for the path. If a finder can be created, it is to be returned by the callable, else raise `ImportError`.

Originally specified in **PEP 302**.

**sys.path\_importer\_cache**

A dictionary acting as a cache for *finder* objects. The keys are paths that have been passed to `sys.path_hooks` and the values are the finders that are found. If a path is a valid file system path but no finder is found on `sys.path_hooks` then `None` is stored.

Originally specified in [PEP 302](#).

Berubah pada versi 3.3: `None` is stored instead of `imp.NullImporter` when no finder is found.

#### `sys.platform`

This string contains a platform identifier that can be used to append platform-specific components to `sys.path`, for instance.

For Unix systems, except on Linux and AIX, this is the lowercased OS name as returned by `uname -s` with the first part of the version as returned by `uname -r` appended, e.g. `'sunos5'` or `'freebsd8'`, *at the time when Python was built*. Unless you want to test for a specific system version, it is therefore recommended to use the following idiom:

```
if sys.platform.startswith('freebsd'):
    # FreeBSD-specific code here...
elif sys.platform.startswith('linux'):
    # Linux-specific code here...
elif sys.platform.startswith('aix'):
    # AIX-specific code here...
```

For other systems, the values are:

| System         | platform value |
|----------------|----------------|
| AIX            | 'aix'          |
| Linux          | 'linux'        |
| Windows        | 'win32'        |
| Windows/Cygwin | 'cygwin'       |
| macOS          | 'darwin'       |

Berubah pada versi 3.3: On Linux, `sys.platform` doesn't contain the major version anymore. It is always `'linux'`, instead of `'linux2'` or `'linux3'`. Since older Python versions include the version number, it is recommended to always use the `startswith` idiom presented above.

Berubah pada versi 3.8: On AIX, `sys.platform` doesn't contain the major version anymore. It is always `'aix'`, instead of `'aix5'` or `'aix7'`. Since older Python versions include the version number, it is recommended to always use the `startswith` idiom presented above.

#### Lihat juga:

`os.name` has a coarser granularity. `os.uname()` gives system-dependent version information.

The `platform` module provides detailed checks for the system's identity.

#### `sys.prefix`

A string giving the site-specific directory prefix where the platform independent Python files are installed; by default, this is the string `'/usr/local'`. This can be set at build time with the `--prefix` argument to the `configure` script. The main collection of Python library modules is installed in the directory `prefix/lib/pythonX.Y` while the platform independent header files (all except `pyconfig.h`) are stored in `prefix/include/pythonX.Y`, where `X.Y` is the version number of Python, for example `3.2`.

---

**Catatan:** If a *virtual environment* is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via `base_prefix`.

---

#### `sys.ps1`

#### `sys.ps2`

Strings specifying the primary and secondary prompt of the interpreter. These are only defined if the interpreter is in interactive mode. Their initial values in this case are `'>>> '` and `'... '`. If a non-string object is assigned

to either variable, its `str()` is re-evaluated each time the interpreter prepares to read a new interactive command; this can be used to implement a dynamic prompt.

`sys.setcheckinterval(interval)`

Set the interpreter's "check interval". This integer value determines how often the interpreter checks for periodic things such as thread switches and signal handlers. The default is 100, meaning the check is performed every 100 Python virtual instructions. Setting it to a larger value may increase performance for programs using threads. Setting it to a value  $\leq 0$  checks every virtual instruction, maximizing responsiveness as well as overhead.

Ditinggalkan sejak versi 3.2: This function doesn't have an effect anymore, as the internal logic for thread switching and asynchronous tasks has been rewritten. Use `setswitchinterval()` instead.

`sys.setdlopenflags(n)`

Set the flags used by the interpreter for `dlopen()` calls, such as when the interpreter loads extension modules. Among other things, this will enable a lazy resolving of symbols when importing a module, if called as `sys.setdlopenflags(0)`. To share symbols across extension modules, call as `sys.setdlopenflags(os.RTLD_GLOBAL)`. Symbolic names for the flag values can be found in the `os` module (`RTLD_XXX` constants, e.g. `os.RTLD_LAZY`).

Availability: Unix.

`sys.set_int_max_str_digits(n)`

Set the *integer string conversion length limitation* used by this interpreter. See also `get_int_max_str_digits()`.

Baru pada versi 3.8.14.

`sys.setprofile(profilefunc)`

Set the system's profile function, which allows you to implement a Python source code profiler in Python. See chapter *The Python Profilers* for more information on the Python profiler. The system's profile function is called similarly to the system's trace function (see `settrace()`), but it is called with different events, for example it isn't called for each executed line of code (only on call and return, but the return event is reported even when an exception has been set). The function is thread-specific, but there is no way for the profiler to know about context switches between threads, so it does not make sense to use this in the presence of multiple threads. Also, its return value is not used, so it can simply return `None`. Error in the profile function will cause itself unset.

Profile functions should have three arguments: *frame*, *event*, and *arg*. *frame* is the current stack frame. *event* is a string: 'call', 'return', 'c\_call', 'c\_return', or 'c\_exception'. *arg* depends on the event type.

Raises an *auditing event* `sys.setprofile` with no arguments.

The events have the following meaning:

'call' A function is called (or some other code block entered). The profile function is called; *arg* is `None`.

'return' A function (or other code block) is about to return. The profile function is called; *arg* is the value that will be returned, or `None` if the event is caused by an exception being raised.

'c\_call' A C function is about to be called. This may be an extension function or a built-in. *arg* is the C function object.

'c\_return' A C function has returned. *arg* is the C function object.

'c\_exception' A C function has raised an exception. *arg* is the C function object.

`sys.setrecursionlimit(limit)`

Set the maximum depth of the Python interpreter stack to *limit*. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python.

The highest possible limit is platform-dependent. A user may need to set the limit higher when they have a program that requires deep recursion and a platform that supports a higher limit. This should be done with care, because a

too-high limit can lead to a crash.

If the new limit is too low at the current recursion depth, a `RecursionError` exception is raised.

Berubah pada versi 3.5.1: A `RecursionError` exception is now raised if the new limit is too low at the current recursion depth.

`sys.setswitchinterval(interval)`

Set the interpreter's thread switch interval (in seconds). This floating-point value determines the ideal duration of the "timeslices" allocated to concurrently running Python threads. Please note that the actual value can be higher, especially if long-running internal functions or methods are used. Also, which thread becomes scheduled at the end of the interval is the operating system's decision. The interpreter doesn't have its own scheduler.

Baru pada versi 3.2.

`sys.settrace(tracefunc)`

Set the system's trace function, which allows you to implement a Python source code debugger in Python. The function is thread-specific; for a debugger to support multiple threads, it must register a trace function using `settrace()` for each thread being debugged or use `threading.settrace()`.

Trace functions should have three arguments: *frame*, *event*, and *arg*. *frame* is the current stack frame. *event* is a string: 'call', 'line', 'return', 'exception' or 'opcode'. *arg* depends on the event type.

The trace function is invoked (with *event* set to 'call') whenever a new local scope is entered; it should return a reference to a local trace function to be used for the new scope, or `None` if the scope shouldn't be traced.

The local trace function should return a reference to itself (or to another function for further tracing in that scope), or `None` to turn off tracing in that scope.

If there is any error occurred in the trace function, it will be unset, just like `settrace(None)` is called.

The events have the following meaning:

'call' A function is called (or some other code block entered). The global trace function is called; *arg* is `None`; the return value specifies the local trace function.

'line' The interpreter is about to execute a new line of code or re-execute the condition of a loop. The local trace function is called; *arg* is `None`; the return value specifies the new local trace function. See `Objects/lnotab_notes.txt` for a detailed explanation of how this works. Per-line events may be disabled for a frame by setting `f_trace_lines` to `False` on that frame.

'return' A function (or other code block) is about to return. The local trace function is called; *arg* is the value that will be returned, or `None` if the event is caused by an exception being raised. The trace function's return value is ignored.

'exception' An exception has occurred. The local trace function is called; *arg* is a tuple (`exception`, `value`, `traceback`); the return value specifies the new local trace function.

'opcode' The interpreter is about to execute a new opcode (see `dis` for opcode details). The local trace function is called; *arg* is `None`; the return value specifies the new local trace function. Per-opcode events are not emitted by default: they must be explicitly requested by setting `f_trace_opcodes` to `True` on the frame.

Note that as an exception is propagated down the chain of callers, an 'exception' event is generated at each level.

For more fine-grained usage, it's possible to set a trace function by assigning `frame.f_trace = tracefunc` explicitly, rather than relying on it being set indirectly via the return value from an already installed trace function. This is also required for activating the trace function on the current frame, which `settrace()` doesn't do. Note that in order for this to work, a global tracing function must have been installed with `settrace()` in order to enable the runtime tracing machinery, but it doesn't need to be the same tracing function (e.g. it could be a low overhead tracing function that simply returns `None` to disable itself immediately on each frame).

For more information on code and frame objects, refer to types.

Raises an *auditing event* `sys.settrace` with no arguments.

**CPython implementation detail:** The `settrace()` function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

Berubah pada versi 3.7: 'opcode' event type added; `f_trace_lines` and `f_trace_opcodes` attributes added to frames

`sys.set_asyncgen_hooks` (*firstiter*, *finalizer*)

Accepts two optional keyword arguments which are callables that accept an *asynchronous generator iterator* as an argument. The *firstiter* callable will be called when an asynchronous generator is iterated for the first time. The *finalizer* will be called when an asynchronous generator is about to be garbage collected.

Raises an *auditing event* `sys.set_asyncgen_hooks_firstiter` with no arguments.

Raises an *auditing event* `sys.set_asyncgen_hooks_finalizer` with no arguments.

Two auditing events are raised because the underlying API consists of two calls, each of which must raise its own event.

Baru pada versi 3.6: See **PEP 525** for more details, and for a reference example of a *finalizer* method see the implementation of `asyncio.Loop.shutdown_asyncgens` in [Lib/asyncio/base\\_events.py](#)

---

**Catatan:** This function has been added on a provisional basis (see **PEP 411** for details.)

---

`sys.set_coroutine_origin_tracking_depth` (*depth*)

Allows enabling or disabling coroutine origin tracking. When enabled, the `cr_origin` attribute on coroutine objects will contain a tuple of (filename, line number, function name) tuples describing the traceback where the coroutine object was created, with the most recent call first. When disabled, `cr_origin` will be `None`.

To enable, pass a *depth* value greater than zero; this sets the number of frames whose information will be captured. To disable, pass set *depth* to zero.

This setting is thread-specific.

Baru pada versi 3.7.

---

**Catatan:** This function has been added on a provisional basis (see **PEP 411** for details.) Use it only for debugging purposes.

---

`sys._enablelegacywindowsfsencoding` ()

Changes the default filesystem encoding and errors mode to 'mbcs' and 'replace' respectively, for consistency with versions of Python prior to 3.6.

This is equivalent to defining the `PYTHONLEGACYWINDOWSFSENCODING` environment variable before launching Python.

*Availability:* Windows.

Baru pada versi 3.6: Lihat **PEP 529** untuk lebih detail.

`sys.stdin`

`sys.stdout`

`sys.stderr`

*File objects* used by the interpreter for standard input, output and errors:

- `stdin` is used for all interactive input (including calls to `input()`);

- `stdout` is used for the output of `print()` and *expression* statements and for the prompts of `input()`;
- The interpreter's own prompts and its error messages go to `stderr`.

These streams are regular *text files* like those returned by the `open()` function. Their parameters are chosen as follows:

- The character encoding is platform-dependent. Non-Windows platforms use the locale encoding (see `locale.getpreferredencoding()`).

On Windows, UTF-8 is used for the console device. Non-character devices such as disk files and pipes use the system locale encoding (i.e. the ANSI codepage). Non-console character devices such as NUL (i.e. where `isatty()` returns `True`) use the value of the console input and output codepages at startup, respectively for `stdin` and `stdout/stderr`. This defaults to the system locale encoding if the process is not initially attached to a console.

The special behaviour of the console can be overridden by setting the environment variable `PYTHONLEGACYWINDOWSSTDIO` before starting Python. In that case, the console codepages are used as for any other character device.

Under all platforms, you can override the character encoding by setting the `PYTHONIOENCODING` environment variable before starting Python or by using the new `-X utf8` command line option and `PYTHONUTF8` environment variable. However, for the Windows console, this only applies when `PYTHONLEGACYWINDOWSSTDIO` is also set.

- When interactive, `stdout` and `stderr` streams are line-buffered. Otherwise, they are block-buffered like regular text files. You can override this value with the `-u` command-line option.

---

**Catatan:** To write or read binary data from/to the standard streams, use the underlying binary *buffer* object. For example, to write bytes to *stdout*, use `sys.stdout.buffer.write(b'abc')`.

However, if you are writing a library (and do not control in which context its code will be executed), be aware that the standard streams may be replaced with file-like objects like `io.StringIO` which do not support the `buffer` attribute.

---

```
sys.__stdin__
sys.__stdout__
sys.__stderr__
```

These objects contain the original values of `stdin`, `stderr` and `stdout` at the start of the program. They are used during finalization, and could be useful to print to the actual standard stream no matter if the `sys.std*` object has been redirected.

It can also be used to restore the actual files to known working file objects in case they have been overwritten with a broken object. However, the preferred way to do this is to explicitly save the previous stream before replacing it, and restore the saved object.

---

**Catatan:** Under some conditions `stdin`, `stdout` and `stderr` as well as the original values `__stdin__`, `__stdout__` and `__stderr__` can be `None`. It is usually the case for Windows GUI apps that aren't connected to a console and Python apps started with **pythonw**.

---

```
sys.thread_info
```

A *named tuple* holding information about the thread implementation.

| Atribut              | Explanation                                                                                                                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>    | Name of the thread implementation: <ul style="list-style-type: none"> <li>• <code>'nt'</code>: Windows threads</li> <li>• <code>'pthread'</code>: POSIX threads</li> <li>• <code>'solaris'</code>: Solaris threads</li> </ul>                                            |
| <code>lock</code>    | Name of the lock implementation: <ul style="list-style-type: none"> <li>• <code>'semaphore'</code>: a lock uses a semaphore</li> <li>• <code>'mutex+cond'</code>: a lock uses a mutex and a condition variable</li> <li>• None if this information is unknown</li> </ul> |
| <code>version</code> | Name and version of the thread library. It is a string, or None if this information is unknown.                                                                                                                                                                          |

Baru pada versi 3.3.

#### `sys.tracebacklimit`

When this variable is set to an integer value, it determines the maximum number of levels of traceback information printed when an unhandled exception occurs. The default is 1000. When set to 0 or less, all traceback information is suppressed and only the exception type and value are printed.

#### `sys.unraisablehook` (*unraisable*, /)

Handle an unraisable exception.

Called when an exception has occurred but there is no way for Python to handle it. For example, when a destructor raises an exception or during garbage collection (`gc.collect()`).

The *unraisable* argument has the following attributes:

- *exc\_type*: Exception type.
- *exc\_value*: Exception value, can be None.
- *exc\_traceback*: Exception traceback, can be None.
- *err\_msg*: Error message, can be None.
- *object*: Object causing the exception, can be None.

The default hook formats *err\_msg* and *object* as: `f'{err_msg}: {object!r}'`; use "Exception ignored in" error message if *err\_msg* is None.

`sys.unraisablehook()` can be overridden to control how unraisable exceptions are handled.

Storing *exc\_value* using a custom hook can create a reference cycle. It should be cleared explicitly to break the reference cycle when the exception is no longer needed.

Storing *object* using a custom hook can resurrect it if it is set to an object which is being finalized. Avoid storing *object* after the custom hook completes to avoid resurrecting objects.

See also `excepthook()` which handles uncaught exceptions.

Raise an auditing event `sys.unraisablehook` with arguments *hook*, *unraisable* when an exception that cannot be handled occurs. The *unraisable* object is the same as what will be passed to the hook. If no hook has been set, *hook* may be None.

Baru pada versi 3.8.

#### `sys.version`

A string containing the version number of the Python interpreter plus additional information on the build number

and compiler used. This string is displayed when the interactive interpreter is started. Do not extract version information out of it, rather, use `version_info` and the functions provided by the `platform` module.

**`sys.api_version`**

The C API version for this interpreter. Programmers may find this useful when debugging version conflicts between Python and extension modules.

**`sys.version_info`**

A tuple containing the five components of the version number: *major*, *minor*, *micro*, *releaselevel*, and *serial*. All values except *releaselevel* are integers; the release level is 'alpha', 'beta', 'candidate', or 'final'. The `version_info` value corresponding to the Python version 2.0 is (2, 0, 0, 'final', 0). The components can also be accessed by name, so `sys.version_info[0]` is equivalent to `sys.version_info.major` and so on.

Berubah pada versi 3.1: Added named component attributes.

**`sys.warnoptions`**

This is an implementation detail of the warnings framework; do not modify this value. Refer to the `warnings` module for more information on the warnings framework.

**`sys.winver`**

The version number used to form registry keys on Windows platforms. This is stored as string resource 1000 in the Python DLL. The value is normally the first three characters of `version`. It is provided in the `sys` module for informational purposes; modifying this value has no effect on the registry keys used by Python.

*Availability:* Windows.

**`sys._xoptions`**

A dictionary of the various implementation-specific flags passed through the `-X` command-line option. Option names are either mapped to their values, if given explicitly, or to `True`. Example:

```
$ ./python -Xa=b -Xc
Python 3.2a3+ (py3k, Oct 16 2010, 20:14:50)
[GCC 4.4.3] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import sys
>>> sys._xoptions
{'a': 'b', 'c': True}
```

**CPython implementation detail:** This is a CPython-specific way of accessing options passed through `-X`. Other implementations may export them through other means, or not at all.

## 29.2 `sysconfig` --- Provide access to Python's configuration information

Baru pada versi 3.2.

**Source code:** [Lib/sysconfig.py](#)

---

The `sysconfig` module provides access to Python's configuration information like the list of installation paths and the configuration variables relevant for the current platform.

### 29.2.1 Configuration variables

A Python distribution contains a `Makefile` and a `pyconfig.h` header file that are necessary to build both the Python binary itself and third-party C extensions compiled using *distutils*.

*sysconfig* puts all variables found in these files in a dictionary that can be accessed using `get_config_vars()` or `get_config_var()`.

Notice that on Windows, it's a much smaller set.

`sysconfig.get_config_vars(*args)`

With no arguments, return a dictionary of all configuration variables relevant for the current platform.

With arguments, return a list of values that result from looking up each argument in the configuration variable dictionary.

For each argument, if the value is not found, return `None`.

`sysconfig.get_config_var(name)`

Return the value of a single variable *name*. Equivalent to `get_config_vars().get(name)`.

If *name* is not found, return `None`.

Example of usage:

```
>>> import sysconfig
>>> sysconfig.get_config_var('Py_ENABLE_SHARED')
0
>>> sysconfig.get_config_var('LIBDIR')
'/usr/local/lib'
>>> sysconfig.get_config_vars('AR', 'CXX')
['ar', 'g++']
```

### 29.2.2 Installation paths

Python uses an installation scheme that differs depending on the platform and on the installation options. These schemes are stored in *sysconfig* under unique identifiers based on the value returned by `os.name`.

Every new component that is installed using *distutils* or a Distutils-based system will follow the same scheme to copy its file in the right places.

Python currently supports seven schemes:

- *posix\_prefix*: scheme for POSIX platforms like Linux or Mac OS X. This is the default scheme used when Python or a component is installed.
- *posix\_home*: scheme for POSIX platforms used when a *home* option is used upon installation. This scheme is used when a component is installed through Distutils with a specific home prefix.
- *posix\_user*: scheme for POSIX platforms used when a component is installed through Distutils and the *user* option is used. This scheme defines paths located under the user home directory.
- *nt*: scheme for NT platforms like Windows.
- *nt\_user*: scheme for NT platforms, when the *user* option is used.

Each scheme is itself composed of a series of paths and each path has a unique identifier. Python currently uses eight paths:

- *stdlib*: directory containing the standard Python library files that are not platform-specific.
- *platstdlib*: directory containing the standard Python library files that are platform-specific.

- *platlib*: directory for site-specific, platform-specific files.
- *purelib*: directory for site-specific, non-platform-specific files.
- *include*: directory for non-platform-specific header files.
- *platinclude*: directory for platform-specific header files.
- *scripts*: directory for script files.
- *data*: directory for data files.

*sysconfig* provides some functions to determine these paths.

`sysconfig.get_scheme_names()`

Return a tuple containing all schemes currently supported in *sysconfig*.

`sysconfig.get_path_names()`

Return a tuple containing all path names currently supported in *sysconfig*.

`sysconfig.get_path(name[, scheme[, vars[, expand]]])`

Return an installation path corresponding to the path *name*, from the install scheme named *scheme*.

*name* has to be a value from the list returned by *get\_path\_names()*.

*sysconfig* stores installation paths corresponding to each path name, for each platform, with variables to be expanded. For instance the *stdlib* path for the *nt* scheme is: {base}/Lib.

*get\_path()* will use the variables returned by *get\_config\_vars()* to expand the path. All variables have default values for each platform so one may call this function and get the default value.

If *scheme* is provided, it must be a value from the list returned by *get\_scheme\_names()*. Otherwise, the default scheme for the current platform is used.

If *vars* is provided, it must be a dictionary of variables that will update the dictionary return by *get\_config\_vars()*.

If *expand* is set to `False`, the path will not be expanded using the variables.

If *name* is not found, return `None`.

`sysconfig.get_paths([scheme[, vars[, expand]]])`

Return a dictionary containing all installation paths corresponding to an installation scheme. See *get\_path()* for more information.

If *scheme* is not provided, will use the default scheme for the current platform.

If *vars* is provided, it must be a dictionary of variables that will update the dictionary used to expand the paths.

If *expand* is set to `false`, the paths will not be expanded.

If *scheme* is not an existing scheme, *get\_paths()* will raise a *KeyError*.

### 29.2.3 Other functions

`sysconfig.get_python_version()`

Return the MAJOR.MINOR Python version number as a string. Similar to '%d.%d' % sys.version\_info[:2].

`sysconfig.get_platform()`

Return a string that identifies the current platform.

This is used mainly to distinguish platform-specific build directories and platform-specific built distributions. Typically includes the OS name and version and the architecture (as supplied by `'os.uname()'`), although the exact information included depends on the OS; e.g., on Linux, the kernel version isn't particularly important.

Examples of returned values:

- linux-i586
- linux-alpha (?)
- solaris-2.6-sun4u

Windows will return one of:

- win-amd64 (64bit Windows on AMD64, aka x86\_64, Intel64, and EM64T)
- win32 (all others - specifically, `sys.platform` is returned)

Mac OS X can return:

- macosx-10.6-ppc
- macosx-10.4-ppc64
- macosx-10.3-i386
- macosx-10.4-fat

For other non-POSIX platforms, currently just returns `sys.platform`.

`sysconfig.is_python_build()`

Return `True` if the running Python interpreter was built from source and is being run from its built location, and not from a location resulting from e.g. running `make install` or installing via a binary installer.

`sysconfig.parse_config_h(fp[, vars])`

Parse a `config.h`-style file.

`fp` is a file-like object pointing to the `config.h`-like file.

A dictionary containing name/value pairs is returned. If an optional dictionary is passed in as the second argument, it is used instead of a new dictionary, and updated with the values read in the file.

`sysconfig.get_config_h_filename()`

Return the path of `pyconfig.h`.

`sysconfig.get_makefile_filename()`

Return the path of `Makefile`.

## 29.2.4 Using `sysconfig` as a script

You can use `sysconfig` as a script with Python's `-m` option:

```
$ python -m sysconfig
Platform: "macosx-10.4-i386"
Python version: "3.2"
Current installation scheme: "posix_prefix"

Paths:
    data = "/usr/local"
    include = "/Users/tarek/Dev/svn.python.org/py3k/Include"
    platinclude = "."
    platlib = "/usr/local/lib/python3.2/site-packages"
    platstdlib = "/usr/local/lib/python3.2"
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
purelib = "/usr/local/lib/python3.2/site-packages"
scripts = "/usr/local/bin"
stdlib = "/usr/local/lib/python3.2"

Variables:
  AC_APPLE_UNIVERSAL_BUILD = "0"
  AIX_GENUINE_CPLUSPLUS = "0"
  AR = "ar"
  ARFLAGS = "rc"
  ...
```

This call will print in the standard output the information returned by `get_platform()`, `get_python_version()`, `get_path()` and `get_config_vars()`.

---

## 29.3 builtins --- Objek-objek bawaan

---

Modul ini menyediakan akses langsung ke semua pengidentifikasi 'bawaan' dari Python; misalnya, `builtins.open` adalah nama lengkap untuk fungsi bawaan `open()`. Lihat *Fungsi Bawaan* dan *Konstanta Bawaan* untuk dokumentasi.

Modul ini biasanya tidak diakses secara eksplisit oleh sebagian besar aplikasi, tetapi dapat berguna dalam modul yang menyediakan objek dengan nama yang sama dengan nilai bawaan, tetapi di dalamnya bawaan dari nama itu juga diperlukan. Sebagai contoh, dalam modul yang ingin mengimplementasikan fungsi `open()` yang membungkus bawaan `open()`, modul ini dapat digunakan secara langsung:

```
import builtins

def open(path):
    f = builtins.open(path, 'r')
    return UpperCaser(f)

class UpperCaser:
    '''Wrapper around a file that converts output to upper-case.'''

    def __init__(self, f):
        self._f = f

    def read(self, count=-1):
        return self._f.read(count).upper()

    # ...
```

Sebagai detail implementasi, sebagian besar modul memiliki nama `__builtins__` yang tersedia sebagai bagian dari globalnya. Nilai `__builtins__` biasanya berupa modul ini atau nilai dari modul ini atribut `__dict__`. Karena ini merupakan detail implementasi, ini mungkin tidak digunakan oleh implementasi alternatif Python.

## 29.4 `__main__` --- Lingkungan skrip tingkat atas

'`__main__`' adalah nama ruang lingkup di mana kode tingkat atas dijalankan. Sebuah modul `__name__` ditetapkan setara dengan '`__main__`' ketika dibaca dari standar input, skrip, atau dari prompt interaktif.

Sebuah modul dapat mengetahui apakah ia berjalan di ruang utama dengan memeriksa `__name__` miliknya sendiri, yang memungkinkan idiom umum untuk mengeksekusi kode secara kondisional dalam sebuah modul ketika dijalankan sebagai skrip atau dengan `python -m` tetapi tidak ketika diimpor:

```
if __name__ == "__main__":
    # execute only if run as a script
    main()
```

Untuk sebuah paket, efek yang sama dapat dicapai dengan memasukkan modul `__main__.py`, konten yang akan dijalankan saat modul dijalankan dengan `-m`.

## 29.5 `warnings` --- Warning control

**Source code:** [Lib/warnings.py](#)

Warning messages are typically issued in situations where it is useful to alert the user of some condition in a program, where that condition (normally) doesn't warrant raising an exception and terminating the program. For example, one might want to issue a warning when a program uses an obsolete module.

Python programmers issue warnings by calling the `warn()` function defined in this module. (C programmers use `PyErr_WarnEx()`; see exceptionhandling for details).

Warning messages are normally written to `sys.stderr`, but their disposition can be changed flexibly, from ignoring all warnings to turning them into exceptions. The disposition of warnings can vary based on the *warning category*, the text of the warning message, and the source location where it is issued. Repetitions of a particular warning for the same source location are typically suppressed.

There are two stages in warning control: first, each time a warning is issued, a determination is made whether a message should be issued or not; next, if a message is to be issued, it is formatted and printed using a user-settable hook.

The determination whether to issue a warning message is controlled by the *warning filter*, which is a sequence of matching rules and actions. Rules can be added to the filter by calling `filterwarnings()` and reset to its default state by calling `resetwarnings()`.

The printing of warning messages is done by calling `showwarning()`, which may be overridden; the default implementation of this function formats the message by calling `formatwarning()`, which is also available for use by custom implementations.

**Lihat juga:**

`logging.captureWarnings()` allows you to handle all warnings with the standard logging infrastructure.

## 29.5.1 Warning Categories

There are a number of built-in exceptions that represent warning categories. This categorization is useful to be able to filter out groups of warnings.

While these are technically *built-in exceptions*, they are documented here, because conceptually they belong to the warnings mechanism.

User code can define additional warning categories by subclassing one of the standard warning categories. A warning category must always be a subclass of the *Warning* class.

The following warnings category classes are currently defined:

| Class                            | Deskripsi                                                                                                                                                                                   |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Warning</i>                   | This is the base class of all warning category classes. It is a subclass of <i>Exception</i> .                                                                                              |
| <i>UserWarning</i>               | The default category for <i>warn()</i> .                                                                                                                                                    |
| <i>DeprecationWarning</i>        | Base category for warnings about deprecated features when those warnings are intended for other Python developers (ignored by default, unless triggered by code in <code>__main__</code> ). |
| <i>SyntaxWarning</i>             | Base category for warnings about dubious syntactic features.                                                                                                                                |
| <i>RuntimeWarning</i>            | Base category for warnings about dubious runtime features.                                                                                                                                  |
| <i>FutureWarning</i>             | Base category for warnings about deprecated features when those warnings are intended for end users of applications that are written in Python.                                             |
| <i>PendingDeprecationWarning</i> | Base category for warnings about features that will be deprecated in the future (ignored by default).                                                                                       |
| <i>ImportWarning</i>             | Base category for warnings triggered during the process of importing a module (ignored by default).                                                                                         |
| <i>UnicodeWarning</i>            | Base category for warnings related to Unicode.                                                                                                                                              |
| <i>BytesWarning</i>              | Base category for warnings related to <i>bytes</i> and <i>bytearray</i> .                                                                                                                   |
| <i>ResourceWarning</i>           | Base category for warnings related to resource usage.                                                                                                                                       |

Berubah pada versi 3.7: Previously *DeprecationWarning* and *FutureWarning* were distinguished based on whether a feature was being removed entirely or changing its behaviour. They are now distinguished based on their intended audience and the way they're handled by the default warnings filters.

## 29.5.2 The Warnings Filter

The warnings filter controls whether warnings are ignored, displayed, or turned into errors (raising an exception).

Conceptually, the warnings filter maintains an ordered list of filter specifications; any specific warning is matched against each filter specification in the list in turn until a match is found; the filter determines the disposition of the match. Each entry is a tuple of the form (*action*, *message*, *category*, *module*, *lineno*), where:

- *action* is one of the following strings:

| Nilai     | Disposition                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------|
| "default" | print the first occurrence of matching warnings for each location (module + line number) where the warning is issued    |
| "error"   | turn matching warnings into exceptions                                                                                  |
| "ignore"  | never print matching warnings                                                                                           |
| "always"  | always print matching warnings                                                                                          |
| "module"  | print the first occurrence of matching warnings for each module where the warning is issued (regardless of line number) |
| "once"    | print only the first occurrence of matching warnings, regardless of location                                            |

- *message* is a string containing a regular expression that the start of the warning message must match. The expression is compiled to always be case-insensitive.
- *category* is a class (a subclass of *Warning*) of which the warning category must be a subclass in order to match.
- *module* is a string containing a regular expression that the module name must match. The expression is compiled to be case-sensitive.
- *lineno* is an integer that the line number where the warning occurred must match, or 0 to match all line numbers.

Since the *Warning* class is derived from the built-in *Exception* class, to turn a warning into an error we simply raise *category* (*message*).

If a warning is reported and doesn't match any registered filter then the "default" action is applied (hence its name).

## Describing Warning Filters

The warnings filter is initialized by `-W` options passed to the Python interpreter command line and the `PYTHONWARNINGS` environment variable. The interpreter saves the arguments for all supplied entries without interpretation in `sys.warnoptions`; the `warnings` module parses these when it is first imported (invalid options are ignored, after printing a message to `sys.stderr`).

Individual warnings filters are specified as a sequence of fields separated by colons:

```
action:message:category:module:line
```

The meaning of each of these fields is as described in *The Warnings Filter*. When listing multiple filters on a single line (as for `PYTHONWARNINGS`), the individual filters are separated by commas and the filters listed later take precedence over those listed before them (as they're applied left-to-right, and the most recently applied filters take precedence over earlier ones).

Commonly used warning filters apply to either all warnings, warnings in a particular category, or warnings raised by particular modules or packages. Some examples:

```
default          # Show all warnings (even those ignored by default)
ignore           # Ignore all warnings
error            # Convert all warnings to errors
error::ResourceWarning # Treat ResourceWarning messages as errors
default::DeprecationWarning # Show DeprecationWarning messages
ignore,default::mymodule # Only report warnings triggered by "mymodule"
error::mymodule[.*]      # Convert warnings to errors in "mymodule"
                        # and any subpackages of "mymodule"
```

### Default Warning Filter

By default, Python installs several warning filters, which can be overridden by the `-W` command-line option, the `PYTHONWARNINGS` environment variable and calls to `filterwarnings()`.

In regular release builds, the default warning filter has the following entries (in order of precedence):

```
default::DeprecationWarning:__main__
ignore::DeprecationWarning
ignore::PendingDeprecationWarning
ignore::ImportWarning
ignore::ResourceWarning
```

In debug builds, the list of default warning filters is empty.

Berubah pada versi 3.2: `DeprecationWarning` is now ignored by default in addition to `PendingDeprecationWarning`.

Berubah pada versi 3.7: `DeprecationWarning` is once again shown by default when triggered directly by code in `__main__`.

Berubah pada versi 3.7: `BytesWarning` no longer appears in the default filter list and is instead configured via `sys.warnoptions` when `-b` is specified twice.

### Overriding the default filter

Developers of applications written in Python may wish to hide *all* Python level warnings from their users by default, and only display them when running tests or otherwise working on the application. The `sys.warnoptions` attribute used to pass filter configurations to the interpreter can be used as a marker to indicate whether or not warnings should be disabled:

```
import sys

if not sys.warnoptions:
    import warnings
    warnings.simplefilter("ignore")
```

Developers of test runners for Python code are advised to instead ensure that *all* warnings are displayed by default for the code under test, using code like:

```
import sys

if not sys.warnoptions:
    import os, warnings
    warnings.simplefilter("default") # Change the filter in this process
    os.environ["PYTHONWARNINGS"] = "default" # Also affect subprocesses
```

Finally, developers of interactive shells that run user code in a namespace other than `__main__` are advised to ensure that `DeprecationWarning` messages are made visible by default, using code like the following (where `user_ns` is the module used to execute code entered interactively):

```
import warnings
warnings.filterwarnings("default", category=DeprecationWarning,
                        module=user_ns.get("__name__"))
```

### 29.5.3 Temporarily Suppressing Warnings

If you are using code that you know will raise a warning, such as a deprecated function, but do not want to see the warning (even when warnings have been explicitly configured via the command line), then it is possible to suppress the warning using the `catch_warnings` context manager:

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings():
    warnings.simplefilter("ignore")
    fxn()
```

While within the context manager all warnings will simply be ignored. This allows you to use known-deprecated code without having to see the warning while not suppressing the warning for other code that might not be aware of its use of deprecated code. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

### 29.5.4 Testing Warnings

To test warnings raised by code, use the `catch_warnings` context manager. With it you can temporarily mutate the warnings filter to facilitate your testing. For instance, do the following to capture all raised warnings to check:

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings(record=True) as w:
    # Cause all warnings to always be triggered.
    warnings.simplefilter("always")
    # Trigger a warning.
    fxn()
    # Verify some things
    assert len(w) == 1
    assert isinstance(w[-1].category, DeprecationWarning)
    assert "deprecated" in str(w[-1].message)
```

One can also cause all warnings to be exceptions by using `error` instead of `always`. One thing to be aware of is that if a warning has already been raised because of a `once/default` rule, then no matter what filters are set the warning will not be seen again unless the warnings registry related to the warning has been cleared.

Once the context manager exits, the warnings filter is restored to its state when the context was entered. This prevents tests from changing the warnings filter in unexpected ways between tests and leading to indeterminate test results. The `showwarning()` function in the module is also restored to its original value. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

When testing multiple operations that raise the same kind of warning, it is important to test them in a manner that confirms each operation is raising a new warning (e.g. set warnings to be raised as exceptions and check the operations raise exceptions, check that the length of the warning list continues to increase after each operation, or else delete the previous entries from the warnings list before each new operation).

## 29.5.5 Updating Code For New Versions of Dependencies

Warning categories that are primarily of interest to Python developers (rather than end users of applications written in Python) are ignored by default.

Notably, this “ignored by default” list includes `DeprecationWarning` (for every module except `__main__`), which means developers should make sure to test their code with typically ignored warnings made visible in order to receive timely notifications of future breaking API changes (whether in the standard library or third party packages).

In the ideal case, the code will have a suitable test suite, and the test runner will take care of implicitly enabling all warnings when running tests (the test runner provided by the `unittest` module does this).

In less ideal cases, applications can be checked for use of deprecated interfaces by passing `-Wd` to the Python interpreter (this is shorthand for `-W default`) or setting `PYTHONWARNINGS=default` in the environment. This enables default handling for all warnings, including those that are ignored by default. To change what action is taken for encountered warnings you can change what argument is passed to `-W` (e.g. `-W error`). See the `-W` flag for more details on what is possible.

## 29.5.6 Available Functions

`warnings.warn(message, category=None, stacklevel=1, source=None)`

Issue a warning, or maybe ignore it or raise an exception. The `category` argument, if given, must be a [warning category class](#); it defaults to `UserWarning`. Alternatively, `message` can be a `Warning` instance, in which case `category` will be ignored and `message.__class__` will be used. In this case, the message text will be `str(message)`. This function raises an exception if the particular warning issued is changed into an error by the [warnings filter](#). The `stacklevel` argument can be used by wrapper functions written in Python, like this:

```
def deprecation(message):
    warnings.warn(message, DeprecationWarning, stacklevel=2)
```

This makes the warning refer to `deprecation()`’s caller, rather than to the source of `deprecation()` itself (since the latter would defeat the purpose of the warning message).

`source`, if supplied, is the destroyed object which emitted a [ResourceWarning](#).

Berubah pada versi 3.6: Added `source` parameter.

`warnings.warn_explicit(message, category, filename, lineno, module=None, registry=None, module_globals=None, source=None)`

This is a low-level interface to the functionality of `warn()`, passing in explicitly the message, category, filename and line number, and optionally the module name and the registry (which should be the `__warningregistry__` dictionary of the module). The module name defaults to the filename with `.py` stripped; if no registry is passed, the warning is never suppressed. `message` must be a string and `category` a subclass of `Warning` or `message` may be a `Warning` instance, in which case `category` will be ignored.

`module_globals`, if supplied, should be the global namespace in use by the code for which the warning is issued. (This argument is used to support displaying source for modules found in zipfiles or other non-filesystem import sources).

`source`, if supplied, is the destroyed object which emitted a [ResourceWarning](#).

Berubah pada versi 3.6: Add the `source` parameter.

`warnings.showwarning(message, category, filename, lineno, file=None, line=None)`

Write a warning to a file. The default implementation calls `formatwarning(message, category, filename, lineno, line)` and writes the resulting string to `file`, which defaults to `sys.stderr`. You may replace this function with any callable by assigning to `warnings.showwarning`. `line` is a line of source code to be included in the warning message; if `line` is not supplied, `showwarning()` will try to read the line specified by `filename` and `lineno`.

`warnings.formatwarning(message, category, filename, lineno, line=None)`

Format a warning the standard way. This returns a string which may contain embedded newlines and ends in a newline. *line* is a line of source code to be included in the warning message; if *line* is not supplied, `formatwarning()` will try to read the line specified by *filename* and *lineno*.

`warnings.filterwarnings(action, message="", category=Warning, module="", lineno=0, append=False)`

Insert an entry into the list of *warnings filter specifications*. The entry is inserted at the front by default; if *append* is true, it is inserted at the end. This checks the types of the arguments, compiles the *message* and *module* regular expressions, and inserts them as a tuple in the list of warnings filters. Entries closer to the front of the list override entries later in the list, if both match a particular warning. Omitted arguments default to a value that matches everything.

`warnings.simplefilter(action, category=Warnings, lineno=0, append=False)`

Insert a simple entry into the list of *warnings filter specifications*. The meaning of the function parameters is as for `filterwarnings()`, but regular expressions are not needed as the filter inserted always matches any message in any module as long as the category and line number match.

`warnings.resetwarnings()`

Reset the warnings filter. This discards the effect of all previous calls to `filterwarnings()`, including that of the `-W` command line options and calls to `simplefilter()`.

## 29.5.7 Available Context Managers

**class** `warnings.catch_warnings(*, record=False, module=None)`

A context manager that copies and, upon exit, restores the warnings filter and the `showwarning()` function. If the *record* argument is `False` (the default) the context manager returns `None` on entry. If *record* is `True`, a list is returned that is progressively populated with objects as seen by a custom `showwarning()` function (which also suppresses output to `sys.stdout`). Each object in the list has attributes with the same names as the arguments to `showwarning()`.

The *module* argument takes a module that will be used instead of the module returned when you import `warnings` whose filter will be protected. This argument exists primarily for testing the `warnings` module itself.

---

**Catatan:** The `catch_warnings` manager works by replacing and then later restoring the module's `showwarning()` function and internal list of filter specifications. This means the context manager is modifying global state and therefore is not thread-safe.

---

## 29.6 dataclasses --- Data Classes

**Source code:** `Lib/dataclasses.py`

This module provides a decorator and functions for automatically adding generated *special methods* such as `__init__()` and `__repr__()` to user-defined classes. It was originally described in [PEP 557](#).

The member variables to use in these generated methods are defined using [PEP 526](#) type annotations. For example this code:

```
from dataclasses import dataclass

@dataclass
class InventoryItem:
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

"""Class for keeping track of an item in inventory."""
name: str
unit_price: float
quantity_on_hand: int = 0

def total_cost(self) -> float:
    return self.unit_price * self.quantity_on_hand

```

Will add, among other things, a `__init__()` that looks like:

```

def __init__(self, name: str, unit_price: float, quantity_on_hand: int = 0):
    self.name = name
    self.unit_price = unit_price
    self.quantity_on_hand = quantity_on_hand

```

Note that this method is automatically added to the class: it is not directly specified in the `InventoryItem` definition shown above.

Baru pada versi 3.7.

## 29.6.1 Module-level decorators, classes, and functions

`@dataclasses.dataclass(*, init=True, repr=True, eq=True, order=False, unsafe_hash=False, frozen=False)`

This function is a *decorator* that is used to add generated *special methods* to classes, as described below.

The `dataclass()` decorator examines the class to find fields. A field is defined as class variable that has a *type annotation*. With two exceptions described below, nothing in `dataclass()` examines the type specified in the variable annotation.

The order of the fields in all of the generated methods is the order in which they appear in the class definition.

The `dataclass()` decorator will add various "dunder" methods to the class, described below. If any of the added methods already exist on the class, the behavior depends on the parameter, as documented below. The decorator returns the same class that is called on; no new class is created.

If `dataclass()` is used just as a simple decorator with no parameters, it acts as if it has the default values documented in this signature. That is, these three uses of `dataclass()` are equivalent:

```

@dataclass
class C:
    ...

@dataclass()
class C:
    ...

@dataclass(init=True, repr=True, eq=True, order=False, unsafe_hash=False, frozen=False)
class C:
    ...

```

The parameters to `dataclass()` are:

- `init`: If true (the default), a `__init__()` method will be generated.

If the class already defines `__init__()`, this parameter is ignored.

- `repr`: If true (the default), a `__repr__()` method will be generated. The generated repr string will have the class name and the name and repr of each field, in the order they are defined in the class. Fields that are marked as being excluded from the repr are not included. For example: `InventoryItem(name='widget', unit_price=3.0, quantity_on_hand=10)`.

If the class already defines `__repr__()`, this parameter is ignored.

- `eq`: If true (the default), an `__eq__()` method will be generated. This method compares the class as if it were a tuple of its fields, in order. Both instances in the comparison must be of the identical type.

If the class already defines `__eq__()`, this parameter is ignored.

- `order`: If true (the default is False), `__lt__()`, `__le__()`, `__gt__()`, and `__ge__()` methods will be generated. These compare the class as if it were a tuple of its fields, in order. Both instances in the comparison must be of the identical type. If `order` is true and `eq` is false, a `ValueError` is raised.

If the class already defines any of `__lt__()`, `__le__()`, `__gt__()`, or `__ge__()`, then `TypeError` is raised.

- `unsafe_hash`: If False (the default), a `__hash__()` method is generated according to how `eq` and `frozen` are set.

`__hash__()` is used by built-in `hash()`, and when objects are added to hashed collections such as dictionaries and sets. Having a `__hash__()` implies that instances of the class are immutable. Mutability is a complicated property that depends on the programmer's intent, the existence and behavior of `__eq__()`, and the values of the `eq` and `frozen` flags in the `dataclass()` decorator.

By default, `dataclass()` will not implicitly add a `__hash__()` method unless it is safe to do so. Neither will it add or change an existing explicitly defined `__hash__()` method. Setting the class attribute `__hash__ = None` has a specific meaning to Python, as described in the `__hash__()` documentation.

If `__hash__()` is not explicitly defined, or if it is set to `None`, then `dataclass()` may add an implicit `__hash__()` method. Although not recommended, you can force `dataclass()` to create a `__hash__()` method with `unsafe_hash=True`. This might be the case if your class is logically immutable but can nonetheless be mutated. This is a specialized use case and should be considered carefully.

Here are the rules governing implicit creation of a `__hash__()` method. Note that you cannot both have an explicit `__hash__()` method in your dataclass and set `unsafe_hash=True`; this will result in a `TypeError`.

If `eq` and `frozen` are both true, by default `dataclass()` will generate a `__hash__()` method for you. If `eq` is true and `frozen` is false, `__hash__()` will be set to `None`, marking it unhashable (which it is, since it is mutable). If `eq` is false, `__hash__()` will be left untouched meaning the `__hash__()` method of the superclass will be used (if the superclass is `object`, this means it will fall back to id-based hashing).

- `frozen`: If true (the default is False), assigning to fields will generate an exception. This emulates read-only frozen instances. If `__setattr__()` or `__delattr__()` is defined in the class, then `TypeError` is raised. See the discussion below.

fields may optionally specify a default value, using normal Python syntax:

```
@dataclass
class C:
    a: int          # 'a' has no default value
    b: int = 0       # assign a default value for 'b'
```

In this example, both `a` and `b` will be included in the added `__init__()` method, which will be defined as:

```
def __init__(self, a: int, b: int = 0):
```

`TypeError` will be raised if a field without a default value follows a field with a default value. This is true either when this occurs in a single class, or as a result of class inheritance.

`dataclasses.field(*, default=MISSING, default_factory=MISSING, repr=True, hash=None, init=True, compare=True, metadata=None)`

For common and simple use cases, no other functionality is required. There are, however, some dataclass features that require additional per-field information. To satisfy this need for additional information, you can replace the default field value with a call to the provided `field()` function. For example:

```
@dataclass
class C:
    mylist: List[int] = field(default_factory=list)

c = C()
c.mylist += [1, 2, 3]
```

As shown above, the `MISSING` value is a sentinel object used to detect if the `default` and `default_factory` parameters are provided. This sentinel is used because `None` is a valid value for `default`. No code should directly use the `MISSING` value.

The parameters to `field()` are:

- `default`: If provided, this will be the default value for this field. This is needed because the `field()` call itself replaces the normal position of the default value.
- `default_factory`: If provided, it must be a zero-argument callable that will be called when a default value is needed for this field. Among other purposes, this can be used to specify fields with mutable default values, as discussed below. It is an error to specify both `default` and `default_factory`.
- `init`: If true (the default), this field is included as a parameter to the generated `__init__()` method.
- `repr`: If true (the default), this field is included in the string returned by the generated `__repr__()` method.
- `compare`: If true (the default), this field is included in the generated equality and comparison methods (`__eq__()`, `__gt__()`, et al.).
- `hash`: This can be a bool or `None`. If true, this field is included in the generated `__hash__()` method. If `None` (the default), use the value of `compare`: this would normally be the expected behavior. A field should be considered in the hash if it's used for comparisons. Setting this value to anything other than `None` is discouraged.

One possible reason to set `hash=False` but `compare=True` would be if a field is expensive to compute a hash value for, that field is needed for equality testing, and there are other fields that contribute to the type's hash value. Even if a field is excluded from the hash, it will still be used for comparisons.

- `metadata`: This can be a mapping or `None`. `None` is treated as an empty dict. This value is wrapped in `MappingProxyType()` to make it read-only, and exposed on the `Field` object. It is not used at all by Data Classes, and is provided as a third-party extension mechanism. Multiple third-parties can each have their own key, to use as a namespace in the metadata.

If the default value of a field is specified by a call to `field()`, then the class attribute for this field will be replaced by the specified default value. If no `default` is provided, then the class attribute will be deleted. The intent is that after the `dataclass()` decorator runs, the class attributes will all contain the default values for the fields, just as if the default value itself were specified. For example, after:

```
@dataclass
class C:
    x: int
    y: int = field(repr=False)
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
z: int = field(repr=False, default=10)
t: int = 20
```

The class attribute `C.z` will be 10, the class attribute `C.t` will be 20, and the class attributes `C.x` and `C.y` will not be set.

### **class** `dataclasses.Field`

*Field* objects describe each defined field. These objects are created internally, and are returned by the *fields()* module-level method (see below). Users should never instantiate a *Field* object directly. Its documented attributes are:

- `name`: The name of the field.
- `type`: The type of the field.
- `default`, `default_factory`, `init`, `repr`, `hash`, `compare`, and `metadata` have the identical meaning and values as they do in the *field()* declaration.

Other attributes may exist, but they are private and must not be inspected or relied on.

### `dataclasses.fields` (*class\_or\_instance*)

Returns a tuple of *Field* objects that define the fields for this dataclass. Accepts either a dataclass, or an instance of a dataclass. Raises *TypeError* if not passed a dataclass or instance of one. Does not return pseudo-fields which are `ClassVar` or `InitVar`.

### `dataclasses.asdict` (*instance*, \*, *dict\_factory=dict*)

Converts the dataclass *instance* to a dict (by using the factory function *dict\_factory*). Each dataclass is converted to a dict of its fields, as `name: value` pairs. *dataclasses*, *dicts*, *lists*, and *tuples* are recursed into. For example:

```
@dataclass
class Point:
    x: int
    y: int

@dataclass
class C:
    mylist: List[Point]

p = Point(10, 20)
assert asdict(p) == {'x': 10, 'y': 20}

c = C([Point(0, 0), Point(10, 4)])
assert asdict(c) == {'mylist': [{ 'x': 0, 'y': 0 }, { 'x': 10, 'y': 4 }]}
```

Raises *TypeError* if *instance* is not a dataclass instance.

### `dataclasses.astuple` (*instance*, \*, *tuple\_factory=tuple*)

Converts the dataclass *instance* to a tuple (by using the factory function *tuple\_factory*). Each dataclass is converted to a tuple of its field values. *dataclasses*, *dicts*, *lists*, and *tuples* are recursed into.

Continuing from the previous example:

```
assert astuple(p) == (10, 20)
assert astuple(c) == ((0, 0), (10, 4)),)
```

Raises *TypeError* if *instance* is not a dataclass instance.

`dataclasses.make_dataclass` (*cls\_name*, *fields*, \*, *bases=()*, *namespace=None*, *init=True*, *repr=True*, *eq=True*, *order=False*, *unsafe\_hash=False*, *frozen=False*)

Creates a new dataclass with name `cls_name`, fields as defined in `fields`, base classes as given in `bases`, and initialized with a namespace as given in `namespace`. `fields` is an iterable whose elements are each either name, (name, type), or (name, type, Field). If just name is supplied, `typing.Any` is used for type. The values of `init`, `repr`, `eq`, `order`, `unsafe_hash`, and `frozen` have the same meaning as they do in `dataclass()`.

This function is not strictly required, because any Python mechanism for creating a new class with `__annotations__` can then apply the `dataclass()` function to convert that class to a dataclass. This function is provided as a convenience. For example:

```
C = make_dataclass('C',
                  [ ('x', int),
                    'y',
                    ('z', int, field(default=5)) ],
                  namespace={'add_one': lambda self: self.x + 1})
```

Is equivalent to:

```
@dataclass
class C:
    x: int
    y: 'typing.Any'
    z: int = 5

    def add_one(self):
        return self.x + 1
```

`dataclasses.replace` (*instance*, *\*\*changes*)

Creates a new object of the same type of `instance`, replacing fields with values from `changes`. If `instance` is not a Data Class, raises `TypeError`. If values in `changes` do not specify fields, raises `TypeError`.

The newly returned object is created by calling the `__init__()` method of the dataclass. This ensures that `__post_init__()`, if present, is also called.

Init-only variables without default values, if any exist, must be specified on the call to `replace()` so that they can be passed to `__init__()` and `__post_init__()`.

It is an error for `changes` to contain any fields that are defined as having `init=False`. A `ValueError` will be raised in this case.

Be forewarned about how `init=False` fields work during a call to `replace()`. They are not copied from the source object, but rather are initialized in `__post_init__()`, if they're initialized at all. It is expected that `init=False` fields will be rarely and judiciously used. If they are used, it might be wise to have alternate class constructors, or perhaps a custom `replace()` (or similarly named) method which handles instance copying.

`dataclasses.is_dataclass` (*class\_or\_instance*)

Return True if its parameter is a dataclass or an instance of one, otherwise return False.

If you need to know if a class is an instance of a dataclass (and not a dataclass itself), then add a further check for `not isinstance(obj, type)`:

```
def is_dataclass_instance(obj):
    return is_dataclass(obj) and not isinstance(obj, type)
```

## 29.6.2 Post-init processing

The generated `__init__()` code will call a method named `__post_init__()`, if `__post_init__()` is defined on the class. It will normally be called as `self.__post_init__()`. However, if any `InitVar` fields are defined, they will also be passed to `__post_init__()` in the order they were defined in the class. If no `__init__()` method is generated, then `__post_init__()` will not automatically be called.

Among other uses, this allows for initializing field values that depend on one or more other fields. For example:

```
@dataclass
class C:
    a: float
    b: float
    c: float = field(init=False)

    def __post_init__(self):
        self.c = self.a + self.b
```

See the section below on init-only variables for ways to pass parameters to `__post_init__()`. Also see the warning about how `replace()` handles `init=False` fields.

## 29.6.3 Class variables

One of two places where `dataclass()` actually inspects the type of a field is to determine if a field is a class variable as defined in [PEP 526](#). It does this by checking if the type of the field is `typing.ClassVar`. If a field is a `ClassVar`, it is excluded from consideration as a field and is ignored by the dataclass mechanisms. Such `ClassVar` pseudo-fields are not returned by the module-level `fields()` function.

## 29.6.4 Init-only variables

The other place where `dataclass()` inspects a type annotation is to determine if a field is an init-only variable. It does this by seeing if the type of a field is of type `dataclasses.InitVar`. If a field is an `InitVar`, it is considered a pseudo-field called an init-only field. As it is not a true field, it is not returned by the module-level `fields()` function. Init-only fields are added as parameters to the generated `__init__()` method, and are passed to the optional `__post_init__()` method. They are not otherwise used by dataclasses.

For example, suppose a field will be initialized from a database, if a value is not provided when creating the class:

```
@dataclass
class C:
    i: int
    j: int = None
    database: InitVar[DatabaseType] = None

    def __post_init__(self, database):
        if self.j is None and database is not None:
            self.j = database.lookup('j')

c = C(10, database=my_database)
```

In this case, `fields()` will return `Field` objects for `i` and `j`, but not for `database`.

### 29.6.5 Frozen instances

It is not possible to create truly immutable Python objects. However, by passing `frozen=True` to the `dataclass()` decorator you can emulate immutability. In that case, dataclasses will add `__setattr__()` and `__delattr__()` methods to the class. These methods will raise a `FrozenInstanceError` when invoked.

There is a tiny performance penalty when using `frozen=True`: `__init__()` cannot use simple assignment to initialize fields, and must use `object.__setattr__()`.

### 29.6.6 Pewarisan

When the dataclass is being created by the `dataclass()` decorator, it looks through all of the class's base classes in reverse MRO (that is, starting at `object`) and, for each dataclass that it finds, adds the fields from that base class to an ordered mapping of fields. After all of the base class fields are added, it adds its own fields to the ordered mapping. All of the generated methods will use this combined, calculated ordered mapping of fields. Because the fields are in insertion order, derived classes override base classes. An example:

```
@dataclass
class Base:
    x: Any = 15.0
    y: int = 0

@dataclass
class C(Base):
    z: int = 10
    x: int = 15
```

The final list of fields is, in order, `x`, `y`, `z`. The final type of `x` is `int`, as specified in class `C`.

The generated `__init__()` method for `C` will look like:

```
def __init__(self, x: int = 15, y: int = 0, z: int = 10):
```

### 29.6.7 Default factory functions

If a `field()` specifies a `default_factory`, it is called with zero arguments when a default value for the field is needed. For example, to create a new instance of a list, use:

```
mylist: list = field(default_factory=list)
```

If a field is excluded from `__init__()` (using `init=False`) and the field also specifies `default_factory`, then the default factory function will always be called from the generated `__init__()` function. This happens because there is no other way to give the field an initial value.

## 29.6.8 Mutable default values

Python stores default member variable values in class attributes. Consider this example, not using dataclasses:

```
class C:
    x = []
    def add(self, element):
        self.x.append(element)

o1 = C()
o2 = C()
o1.add(1)
o2.add(2)
assert o1.x == [1, 2]
assert o1.x is o2.x
```

Note that the two instances of class C share the same class variable x, as expected.

Using dataclasses, *if* this code was valid:

```
@dataclass
class D:
    x: List = []
    def add(self, element):
        self.x += element
```

it would generate code similar to:

```
class D:
    x = []
    def __init__(self, x=x):
        self.x = x
    def add(self, element):
        self.x += element

assert D().x is D().x
```

This has the same issue as the original example using class C. That is, two instances of class D that do not specify a value for x when creating a class instance will share the same copy of x. Because dataclasses just use normal Python class creation they also share this behavior. There is no general way for Data Classes to detect this condition. Instead, dataclasses will raise a `TypeError` if it detects a default parameter of type list, dict, or set. This is a partial solution, but it does protect against many common errors.

Using default factory functions is a way to create new instances of mutable types as default values for fields:

```
@dataclass
class D:
    x: list = field(default_factory=list)

assert D().x is not D().x
```

## 29.6.9 Pengecualian

**exception** `dataclasses.FrozenInstanceError`

Raised when an implicitly defined `__setattr__()` or `__delattr__()` is called on a dataclass which was defined with `frozen=True`. It is a subclass of `AttributeError`.

## 29.7 `contextlib` --- Utilities for with-statement contexts

**Source code:** [Lib/contextlib.py](#)

---

This module provides utilities for common tasks involving the `with` statement. For more information see also [Context Manager Types](#) and `context-managers`.

### 29.7.1 Utilitas

Functions and classes provided:

**class** `contextlib.AbstractContextManager`

An *abstract base class* for classes that implement `object.__enter__()` and `object.__exit__()`. A default implementation for `object.__enter__()` is provided which returns `self` while `object.__exit__()` is an abstract method which by default returns `None`. See also the definition of [Context Manager Types](#).

Baru pada versi 3.6.

**class** `contextlib.AbstractAsyncContextManager`

An *abstract base class* for classes that implement `object.__aenter__()` and `object.__aexit__()`. A default implementation for `object.__aenter__()` is provided which returns `self` while `object.__aexit__()` is an abstract method which by default returns `None`. See also the definition of `async-context-managers`.

Baru pada versi 3.7.

`@contextlib.contextmanager`

This function is a *decorator* that can be used to define a factory function for `with` statement context managers, without needing to create a class or separate `__enter__()` and `__exit__()` methods.

While many objects natively support use in `with` statements, sometimes a resource needs to be managed that isn't a context manager in its own right, and doesn't implement a `close()` method for use with `contextlib.closing`

An abstract example would be the following to ensure correct resource management:

```
from contextlib import contextmanager

@contextmanager
def managed_resource(*args, **kwargs):
    # Code to acquire resource, e.g.:
    resource = acquire_resource(*args, **kwargs)
    try:
        yield resource
    finally:
        # Code to release resource, e.g.:
        release_resource(resource)
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> with managed_resource(timeout=3600) as resource:
...     # Resource is released at the end of this block,
...     # even if code in the block raises an exception
```

The function being decorated must return a *generator*-iterator when called. This iterator must yield exactly one value, which will be bound to the targets in the `with` statement's `as` clause, if any.

At the point where the generator yields, the block nested in the `with` statement is executed. The generator is then resumed after the block is exited. If an unhandled exception occurs in the block, it is reraised inside the generator at the point where the yield occurred. Thus, you can use a `try...except...finally` statement to trap the error (if any), or ensure that some cleanup takes place. If an exception is trapped merely in order to log it or to perform some action (rather than to suppress it entirely), the generator must reraise that exception. Otherwise the generator context manager will indicate to the `with` statement that the exception has been handled, and execution will resume with the statement immediately following the `with` statement.

`contextmanager()` uses `ContextDecorator` so the context managers it creates can be used as decorators as well as in `with` statements. When used as a decorator, a new generator instance is implicitly created on each function call (this allows the otherwise "one-shot" context managers created by `contextmanager()` to meet the requirement that context managers support multiple invocations in order to be used as decorators).

Berubah pada versi 3.2: Use of `ContextDecorator`.

`@contextlib.asynccontextmanager`

Similar to `contextmanager()`, but creates an asynchronous context manager.

This function is a *decorator* that can be used to define a factory function for `async with` statement asynchronous context managers, without needing to create a class or separate `__aenter__()` and `__aexit__()` methods. It must be applied to an *asynchronous generator* function.

A simple example:

```
from contextlib import asynccontextmanager

@asynccontextmanager
async def get_connection():
    conn = await acquire_db_connection()
    try:
        yield conn
    finally:
        await release_db_connection(conn)

async def get_all_users():
    async with get_connection() as conn:
        return conn.query('SELECT ...')
```

Baru pada versi 3.7.

`contextlib.closing(thing)`

Return a context manager that closes *thing* upon completion of the block. This is basically equivalent to:

```
from contextlib import contextmanager

@contextmanager
def closing(thing):
    try:
        yield thing
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
finally:
    thing.close()
```

And lets you write code like this:

```
from contextlib import closing
from urllib.request import urlopen

with closing(urlopen('http://www.python.org')) as page:
    for line in page:
        print(line)
```

without needing to explicitly close page. Even if an error occurs, `page.close()` will be called when the `with` block is exited.

`contextlib.nullcontext` (*enter\_result=None*)

Return a context manager that returns *enter\_result* from `__enter__`, but otherwise does nothing. It is intended to be used as a stand-in for an optional context manager, for example:

```
def myfunction(arg, ignore_exceptions=False):
    if ignore_exceptions:
        # Use suppress to ignore all exceptions.
        cm = contextlib.suppress(Exception)
    else:
        # Do not ignore any exceptions, cm has no effect.
        cm = contextlib.nullcontext()
    with cm:
        # Do something
```

An example using *enter\_result*:

```
def process_file(file_or_path):
    if isinstance(file_or_path, str):
        # If string, open file
        cm = open(file_or_path)
    else:
        # Caller is responsible for closing file
        cm = nullcontext(file_or_path)

    with cm as file:
        # Perform processing on the file
```

Baru pada versi 3.7.

`contextlib.suppress` (*\*exceptions*)

Return a context manager that suppresses any of the specified exceptions if they occur in the body of a `with` statement and then resumes execution with the first statement following the end of the `with` statement.

As with any other mechanism that completely suppresses exceptions, this context manager should be used only to cover very specific errors where silently continuing with program execution is known to be the right thing to do.

Sebagai contoh:

```
from contextlib import suppress

with suppress(FileNotFoundError):
    os.remove('somefile.tmp')
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
with suppress(FileNotFoundError):
    os.remove('someotherfile.tmp')
```

This code is equivalent to:

```
try:
    os.remove('somefile.tmp')
except FileNotFoundError:
    pass

try:
    os.remove('someotherfile.tmp')
except FileNotFoundError:
    pass
```

This context manager is *reentrant*.

Baru pada versi 3.4.

`contextlib.redirect_stdout` (*new\_target*)

Context manager for temporarily redirecting `sys.stdout` to another file or file-like object.

This tool adds flexibility to existing functions or classes whose output is hardwired to stdout.

For example, the output of `help()` normally is sent to `sys.stdout`. You can capture that output in a string by redirecting the output to an `io.StringIO` object:

```
f = io.StringIO()
with redirect_stdout(f):
    help(pow)
s = f.getvalue()
```

To send the output of `help()` to a file on disk, redirect the output to a regular file:

```
with open('help.txt', 'w') as f:
    with redirect_stdout(f):
        help(pow)
```

To send the output of `help()` to `sys.stderr`:

```
with redirect_stdout(sys.stderr):
    help(pow)
```

Note that the global side effect on `sys.stdout` means that this context manager is not suitable for use in library code and most threaded applications. It also has no effect on the output of subprocesses. However, it is still a useful approach for many utility scripts.

This context manager is *reentrant*.

Baru pada versi 3.4.

`contextlib.redirect_stderr` (*new\_target*)

Similar to `redirect_stdout()` but redirecting `sys.stderr` to another file or file-like object.

This context manager is *reentrant*.

Baru pada versi 3.5.

**class** contextlib.ContextDecorator

A base class that enables a context manager to also be used as a decorator.

Context managers inheriting from ContextDecorator have to implement `__enter__` and `__exit__` as normal. `__exit__` retains its optional exception handling even when used as a decorator.

ContextDecorator is used by `contextmanager()`, so you get this functionality automatically.

Example of ContextDecorator:

```
from contextlib import ContextDecorator

class mycontext(ContextDecorator):
    def __enter__(self):
        print('Starting')
        return self

    def __exit__(self, *exc):
        print('Finishing')
        return False

>>> @mycontext()
... def function():
...     print('The bit in the middle')
...
>>> function()
Starting
The bit in the middle
Finishing

>>> with mycontext():
...     print('The bit in the middle')
...
Starting
The bit in the middle
Finishing
```

This change is just syntactic sugar for any construct of the following form:

```
def f():
    with cm():
        # Do stuff
```

ContextDecorator lets you instead write:

```
@cm()
def f():
    # Do stuff
```

It makes it clear that the `cm` applies to the whole function, rather than just a piece of it (and saving an indentation level is nice, too).

Existing context managers that already have a base class can be extended by using ContextDecorator as a mixin class:

```
from contextlib import ContextDecorator

class mycontext(ContextBaseClass, ContextDecorator):
    def __enter__(self):
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

    return self

def __exit__(self, *exc):
    return False

```

**Catatan:** As the decorated function must be able to be called multiple times, the underlying context manager must support use in multiple `with` statements. If this is not the case, then the original construct with the explicit `with` statement inside the function should be used.

Baru pada versi 3.2.

#### **class** `contextlib.ExitStack`

A context manager that is designed to make it easy to programmatically combine other context managers and cleanup functions, especially those that are optional or otherwise driven by input data.

For example, a set of files may easily be handled in a single `with` statement as follows:

```

with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for fname in filenames]
    # All opened files will automatically be closed at the end of
    # the with statement, even if attempts to open files later
    # in the list raise an exception

```

Each instance maintains a stack of registered callbacks that are called in reverse order when the instance is closed (either explicitly or implicitly at the end of a `with` statement). Note that callbacks are *not* invoked implicitly when the context stack instance is garbage collected.

This stack model is used so that context managers that acquire their resources in their `__init__` method (such as file objects) can be handled correctly.

Since registered callbacks are invoked in the reverse order of registration, this ends up behaving as if multiple nested `with` statements had been used with the registered set of callbacks. This even extends to exception handling - if an inner callback suppresses or replaces an exception, then outer callbacks will be passed arguments based on that updated state.

This is a relatively low level API that takes care of the details of correctly unwinding the stack of exit callbacks. It provides a suitable foundation for higher level context managers that manipulate the exit stack in application specific ways.

Baru pada versi 3.3.

#### **enter\_context** (*cm*)

Enters a new context manager and adds its `__exit__()` method to the callback stack. The return value is the result of the context manager's own `__enter__()` method.

These context managers may suppress exceptions just as they normally would if used directly as part of a `with` statement.

#### **push** (*exit*)

Adds a context manager's `__exit__()` method to the callback stack.

As `__enter__` is *not* invoked, this method can be used to cover part of an `__enter__()` implementation with a context manager's own `__exit__()` method.

If passed an object that is not a context manager, this method assumes it is a callback with the same signature as a context manager's `__exit__()` method and adds it directly to the callback stack.

By returning true values, these callbacks can suppress exceptions the same way context manager `__exit__()` methods can.

The passed in object is returned from the function, allowing this method to be used as a function decorator.

**callback** (*callback*, \*args, \*\*kws)

Accepts an arbitrary callback function and arguments and adds it to the callback stack.

Unlike the other methods, callbacks added this way cannot suppress exceptions (as they are never passed the exception details).

The passed in callback is returned from the function, allowing this method to be used as a function decorator.

**pop\_all** ()

Transfers the callback stack to a fresh `ExitStack` instance and returns it. No callbacks are invoked by this operation - instead, they will now be invoked when the new stack is closed (either explicitly or implicitly at the end of a `with` statement).

For example, a group of files can be opened as an "all or nothing" operation as follows:

```
with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for fname in filenames]
    # Hold onto the close method, but don't call it yet.
    close_files = stack.pop_all().close
    # If opening any file fails, all previously opened files will be
    # closed automatically. If all files are opened successfully,
    # they will remain open even after the with statement ends.
    # close_files() can then be invoked explicitly to close them all.
```

**close** ()

Immediately unwinds the callback stack, invoking callbacks in the reverse order of registration. For any context managers and exit callbacks registered, the arguments passed in will indicate that no exception occurred.

**class** `contextlib.AsyncExitStack`

An asynchronous context manager, similar to `ExitStack`, that supports combining both synchronous and asynchronous context managers, as well as having coroutines for cleanup logic.

The `close()` method is not implemented, `aclose()` must be used instead.

**enter\_async\_context** (*cm*)

Similar to `enter_context()` but expects an asynchronous context manager.

**push\_async\_exit** (*exit*)

Similar to `push()` but expects either an asynchronous context manager or a coroutine function.

**push\_async\_callback** (*callback*, \*args, \*\*kws)

Similar to `callback()` but expects a coroutine function.

**aclose** ()

Similar to `close()` but properly handles awaitables.

Continuing the example for `asynccontextmanager()`:

```
async with AsyncExitStack() as stack:
    connections = [await stack.enter_async_context(get_connection())
                    for i in range(5)]
    # All opened connections will automatically be released at the end of
    # the async with statement, even if attempts to open a connection
    # later in the list raise an exception.
```

Baru pada versi 3.7.

## 29.7.2 Examples and Recipes

This section describes some examples and recipes for making effective use of the tools provided by *contextlib*.

### Supporting a variable number of context managers

The primary use case for *ExitStack* is the one given in the class documentation: supporting a variable number of context managers and other cleanup operations in a single `with` statement. The variability may come from the number of context managers needed being driven by user input (such as opening a user specified collection of files), or from some of the context managers being optional:

```
with ExitStack() as stack:
    for resource in resources:
        stack.enter_context(resource)
    if need_special_resource():
        special = acquire_special_resource()
        stack.callback(release_special_resource, special)
    # Perform operations that use the acquired resources
```

As shown, *ExitStack* also makes it quite easy to use `with` statements to manage arbitrary resources that don't natively support the context management protocol.

### Catching exceptions from `__enter__` methods

It is occasionally desirable to catch exceptions from an `__enter__` method implementation, *without* inadvertently catching exceptions from the `with` statement body or the context manager's `__exit__` method. By using *ExitStack* the steps in the context management protocol can be separated slightly in order to allow this:

```
stack = ExitStack()
try:
    x = stack.enter_context(cm)
except Exception:
    # handle __enter__ exception
else:
    with stack:
        # Handle normal case
```

Actually needing to do this is likely to indicate that the underlying API should be providing a direct resource management interface for use with `try/except/finally` statements, but not all APIs are well designed in that regard. When a context manager is the only resource management API provided, then *ExitStack* can make it easier to handle various situations that can't be handled directly in a `with` statement.

### Cleaning up in an `__enter__` implementation

As noted in the documentation of *ExitStack.push()*, this method can be useful in cleaning up an already allocated resource if later steps in the `__enter__()` implementation fail.

Here's an example of doing this for a context manager that accepts resource acquisition and release functions, along with an optional validation function, and maps them to the context management protocol:

```
from contextlib import contextmanager, AbstractContextManager, ExitStack

class ResourceManager(AbstractContextManager):
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

def __init__(self, acquire_resource, release_resource, check_resource_ok=None):
    self.acquire_resource = acquire_resource
    self.release_resource = release_resource
    if check_resource_ok is None:
        def check_resource_ok(resource):
            return True
    self.check_resource_ok = check_resource_ok

@contextmanager
def _cleanup_on_error(self):
    with ExitStack() as stack:
        stack.push(self)
        yield
        # The validation check passed and didn't raise an exception
        # Accordingly, we want to keep the resource, and pass it
        # back to our caller
        stack.pop_all()

def __enter__(self):
    resource = self.acquire_resource()
    with self._cleanup_on_error():
        if not self.check_resource_ok(resource):
            msg = "Failed validation for {!r}"
            raise RuntimeError(msg.format(resource))
    return resource

def __exit__(self, *exc_details):
    # We don't need to duplicate any of our resource release logic
    self.release_resource()

```

## Replacing any use of try-finally and flag variables

A pattern you will sometimes see is a try-finally statement with a flag variable to indicate whether or not the body of the finally clause should be executed. In its simplest form (that can't already be handled just by using an except clause instead), it looks something like this:

```

cleanup_needed = True
try:
    result = perform_operation()
    if result:
        cleanup_needed = False
finally:
    if cleanup_needed:
        cleanup_resources()

```

As with any try statement based code, this can cause problems for development and review, because the setup code and the cleanup code can end up being separated by arbitrarily long sections of code.

`ExitStack` makes it possible to instead register a callback for execution at the end of a with statement, and then later decide to skip executing that callback:

```

from contextlib import ExitStack

with ExitStack() as stack:

```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

stack.callback(cleanup_resources)
result = perform_operation()
if result:
    stack.pop_all()

```

This allows the intended cleanup up behaviour to be made explicit up front, rather than requiring a separate flag variable.

If a particular application uses this pattern a lot, it can be simplified even further by means of a small helper class:

```

from contextlib import ExitStack

class Callback(ExitStack):
    def __init__(self, callback, /, *args, **kwargs):
        super().__init__()
        self.callback(callback, *args, **kwargs)

    def cancel(self):
        self.pop_all()

with Callback(cleanup_resources) as cb:
    result = perform_operation()
    if result:
        cb.cancel()

```

If the resource cleanup isn't already neatly bundled into a standalone function, then it is still possible to use the decorator form of `ExitStack.callback()` to declare the resource cleanup in advance:

```

from contextlib import ExitStack

with ExitStack() as stack:
    @stack.callback
    def cleanup_resources():
        ...
    result = perform_operation()
    if result:
        stack.pop_all()

```

Due to the way the decorator protocol works, a callback function declared this way cannot take any parameters. Instead, any resources to be released must be accessed as closure variables.

## Using a context manager as a function decorator

`ContextDecorator` makes it possible to use a context manager in both an ordinary `with` statement and also as a function decorator.

For example, it is sometimes useful to wrap functions or groups of statements with a logger that can track the time of entry and time of exit. Rather than writing both a function decorator and a context manager for the task, inheriting from `ContextDecorator` provides both capabilities in a single definition:

```

from contextlib import ContextDecorator
import logging

logging.basicConfig(level=logging.INFO)

class track_entry_and_exit(ContextDecorator):
    def __init__(self, name):

```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

        self.name = name

    def __enter__(self):
        logging.info('Entering: %s', self.name)

    def __exit__(self, exc_type, exc, exc_tb):
        logging.info('Exiting: %s', self.name)

```

Instances of this class can be used as both a context manager:

```

with track_entry_and_exit('widget loader'):
    print('Some time consuming activity goes here')
    load_widget()

```

And also as a function decorator:

```

@track_entry_and_exit('widget loader')
def activity():
    print('Some time consuming activity goes here')
    load_widget()

```

Note that there is one additional limitation when using context managers as function decorators: there's no way to access the return value of `__enter__()`. If that value is needed, then it is still necessary to use an explicit `with` statement.

**Lihat juga:**

**PEP 343 - The "with" statement** The specification, background, and examples for the Python `with` statement.

### 29.7.3 Single use, reusable and reentrant context managers

Most context managers are written in a way that means they can only be used effectively in a `with` statement once. These single use context managers must be created afresh each time they're used - attempting to use them a second time will trigger an exception or otherwise not work correctly.

This common limitation means that it is generally advisable to create context managers directly in the header of the `with` statement where they are used (as shown in all of the usage examples above).

Files are an example of effectively single use context managers, since the first `with` statement will close the file, preventing any further IO operations using that file object.

Context managers created using `contextmanager()` are also single use context managers, and will complain about the underlying generator failing to yield if an attempt is made to use them a second time:

```

>>> from contextlib import contextmanager
>>> @contextmanager
... def singleuse():
...     print("Before")
...     yield
...     print("After")
...
>>> cm = singleuse()
>>> with cm:
...     pass
...
Before
After

```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> with cm:
...     pass
...
Traceback (most recent call last):
...
RuntimeError: generator didn't yield
```

## Reentrant context managers

More sophisticated context managers may be “reentrant”. These context managers can not only be used in multiple `with` statements, but may also be used *inside* a `with` statement that is already using the same context manager.

`threading.RLock` is an example of a reentrant context manager, as are `suppress()` and `redirect_stdout()`. Here’s a very simple example of reentrant use:

```
>>> from contextlib import redirect_stdout
>>> from io import StringIO
>>> stream = StringIO()
>>> write_to_stream = redirect_stdout(stream)
>>> with write_to_stream:
...     print("This is written to the stream rather than stdout")
...     with write_to_stream:
...         print("This is also written to the stream")
...
>>> print("This is written directly to stdout")
This is written directly to stdout
>>> print(stream.getvalue())
This is written to the stream rather than stdout
This is also written to the stream
```

Real world examples of reentrancy are more likely to involve multiple functions calling each other and hence be far more complicated than this example.

Note also that being reentrant is *not* the same thing as being thread safe. `redirect_stdout()`, for example, is definitely not thread safe, as it makes a global modification to the system state by binding `sys.stdout` to a different stream.

## Reusable context managers

Distinct from both single use and reentrant context managers are “reusable” context managers (or, to be completely explicit, “reusable, but not reentrant” context managers, since reentrant context managers are also reusable). These context managers support being used multiple times, but will fail (or otherwise not work correctly) if the specific context manager instance has already been used in a containing `with` statement.

`threading.Lock` is an example of a reusable, but not reentrant, context manager (for a reentrant lock, it is necessary to use `threading.RLock` instead).

Another example of a reusable, but not reentrant, context manager is `ExitStack`, as it invokes *all* currently registered callbacks when leaving any `with` statement, regardless of where those callbacks were added:

```
>>> from contextlib import ExitStack
>>> stack = ExitStack()
>>> with stack:
...     stack.callback(print, "Callback: from first context")
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
...     print("Leaving first context")
...
Leaving first context
Callback: from first context
>>> with stack:
...     stack.callback(print, "Callback: from second context")
...     print("Leaving second context")
...
Leaving second context
Callback: from second context
>>> with stack:
...     stack.callback(print, "Callback: from outer context")
...     with stack:
...         stack.callback(print, "Callback: from inner context")
...         print("Leaving inner context")
...     print("Leaving outer context")
...
Leaving inner context
Callback: from inner context
Callback: from outer context
Leaving outer context
```

As the output from the example shows, reusing a single stack object across multiple with statements works correctly, but attempting to nest them will cause the stack to be cleared at the end of the innermost with statement, which is unlikely to be desirable behaviour.

Using separate `ExitStack` instances instead of reusing a single instance avoids that problem:

```
>>> from contextlib import ExitStack
>>> with ExitStack() as outer_stack:
...     outer_stack.callback(print, "Callback: from outer context")
...     with ExitStack() as inner_stack:
...         inner_stack.callback(print, "Callback: from inner context")
...         print("Leaving inner context")
...     print("Leaving outer context")
...
Leaving inner context
Callback: from inner context
Leaving outer context
Callback: from outer context
```

## 29.8 abc --- Abstract Base Classes

Source code: [Lib/abc.py](#)

---

This module provides the infrastructure for defining *abstract base classes* (ABCs) in Python, as outlined in [PEP 3119](#); see the PEP for why this was added to Python. (See also [PEP 3141](#) and the `numbers` module regarding a type hierarchy for numbers based on ABCs.)

The `collections` module has some concrete classes that derive from ABCs; these can, of course, be further derived. In addition, the `collections.abc` submodule has some ABCs that can be used to test whether a class or instance provides a particular interface, for example, if it is hashable or if it is a mapping.

This module provides the metaclass `ABCMeta` for defining ABCs and a helper class `ABC` to alternatively define ABCs through inheritance:

**class** `abc.ABC`

A helper class that has `ABCMeta` as its metaclass. With this class, an abstract base class can be created by simply deriving from `ABC` avoiding sometimes confusing metaclass usage, for example:

```
from abc import ABC

class MyABC(ABC):
    pass
```

Note that the type of `ABC` is still `ABCMeta`, therefore inheriting from `ABC` requires the usual precautions regarding metaclass usage, as multiple inheritance may lead to metaclass conflicts. One may also define an abstract base class by passing the metaclass keyword and using `ABCMeta` directly, for example:

```
from abc import ABCMeta

class MyABC(metaclass=ABCMeta):
    pass
```

Baru pada versi 3.4.

**class** `abc.ABCMeta`

Metaclass for defining Abstract Base Classes (ABCs).

Use this metaclass to create an ABC. An ABC can be subclassed directly, and then acts as a mix-in class. You can also register unrelated concrete classes (even built-in classes) and unrelated ABCs as "virtual subclasses" -- these and their descendants will be considered subclasses of the registering ABC by the built-in `issubclass()` function, but the registering ABC won't show up in their MRO (Method Resolution Order) nor will method implementations defined by the registering ABC be callable (not even via `super()`).<sup>1</sup>

Classes created with a metaclass of `ABCMeta` have the following method:

**register** (*subclass*)

Register *subclass* as a "virtual subclass" of this ABC. For example:

```
from abc import ABC

class MyABC(ABC):
    pass

MyABC.register(tuple)

assert issubclass(tuple, MyABC)
assert isinstance((), MyABC)
```

Berubah pada versi 3.3: Returns the registered subclass, to allow usage as a class decorator.

Berubah pada versi 3.4: To detect calls to `register()`, you can use the `get_cache_token()` function.

You can also override this method in an abstract base class:

**\_\_subclasshook\_\_** (*subclass*)

(Must be defined as a class method.)

Check whether *subclass* is considered a subclass of this ABC. This means that you can customize the behavior of `issubclass` further without the need to call `register()` on every class you want to consider a subclass of the ABC. (This class method is called from the `__subclasscheck__()` method of the ABC.)

<sup>1</sup> C++ programmers should note that Python's virtual base class concept is not the same as C++'s.

This method should return `True`, `False` or `NotImplemented`. If it returns `True`, the *subclass* is considered a subclass of this ABC. If it returns `False`, the *subclass* is not considered a subclass of this ABC, even if it would normally be one. If it returns `NotImplemented`, the subclass check is continued with the usual mechanism.

For a demonstration of these concepts, look at this example ABC definition:

```
class Foo:
    def __getitem__(self, index):
        ...
    def __len__(self):
        ...
    def get_iterator(self):
        return iter(self)

class MyIterable(ABC):

    @abstractmethod
    def __iter__(self):
        while False:
            yield None

    def get_iterator(self):
        return self.__iter__()

    @classmethod
    def __subclasshook__(cls, C):
        if cls is MyIterable:
            if any("__iter__" in B.__dict__ for B in C.__mro__):
                return True
            return NotImplemented

MyIterable.register(Foo)
```

The ABC `MyIterable` defines the standard iterable method, `__iter__()`, as an abstract method. The implementation given here can still be called from subclasses. The `get_iterator()` method is also part of the `MyIterable` abstract base class, but it does not have to be overridden in non-abstract derived classes.

The `__subclasshook__()` class method defined here says that any class that has an `__iter__()` method in its `__dict__` (or in that of one of its base classes, accessed via the `__mro__` list) is considered a `MyIterable` too.

Finally, the last line makes `Foo` a virtual subclass of `MyIterable`, even though it does not define an `__iter__()` method (it uses the old-style iterable protocol, defined in terms of `__len__()` and `__getitem__()`). Note that this will not make `get_iterator` available as a method of `Foo`, so it is provided separately.

The `abc` module also provides the following decorator:

`@abc.abstractmethod`

A decorator indicating abstract methods.

Using this decorator requires that the class's metaclass is `ABCMeta` or is derived from it. A class that has a metaclass derived from `ABCMeta` cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract methods can be called using any of the normal 'super' call mechanisms. `abstractmethod()` may be used to declare abstract methods for properties and descriptors.

Dynamically adding abstract methods to a class, or attempting to modify the abstraction status of a method or class once it is created, are not supported. The `abstractmethod()` only affects subclasses derived using regular inheritance; "virtual subclasses" registered with the ABC's `register()` method are not affected.

When `abstractmethod()` is applied in combination with other method descriptors, it should be applied as the innermost decorator, as shown in the following usage examples:

```
class C(ABC):
    @abstractmethod
    def my_abstract_method(self, ...):
        ...

    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, ...):
        ...

    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(...):
        ...

    @property
    @abstractmethod
    def my_abstract_property(self):
        ...

    @my_abstract_property.setter
    @abstractmethod
    def my_abstract_property(self, val):
        ...

    @abstractmethod
    def _get_x(self):
        ...

    @abstractmethod
    def _set_x(self, val):
        ...

    x = property(_get_x, _set_x)
```

In order to correctly interoperate with the abstract base class machinery, the descriptor must identify itself as abstract using `__isabstractmethod__`. In general, this attribute should be `True` if any of the methods used to compose the descriptor are abstract. For example, Python's built-in `property` does the equivalent of:

```
class Descriptor:
    ...
    @property
    def __isabstractmethod__(self):
        return any(getattr(f, '__isabstractmethod__', False) for
                    f in (self._fget, self._fset, self._fdel))
```

**Catatan:** Unlike Java abstract methods, these abstract methods may have an implementation. This implementation can be called via the `super()` mechanism from the class that overrides it. This could be useful as an end-point for a super-call in a framework that uses cooperative multiple-inheritance.

The `abc` module also supports the following legacy decorators:

`@abc.abstractmethod`

Baru pada versi 3.2.

Ditinggalkan sejak versi 3.3: It is now possible to use `classmethod` with `abstractmethod()`, making this decorator redundant.

A subclass of the built-in `classmethod()`, indicating an abstract classmethod. Otherwise it is similar to

*abstractmethod()*.

This special case is deprecated, as the *classmethod()* decorator is now correctly identified as abstract when applied to an abstract method:

```
class C(ABC):
    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, ...):
        ...
```

#### @abc.**abstractstaticmethod**

Baru pada versi 3.2.

Ditinggalkan sejak versi 3.3: It is now possible to use *staticmethod* with *abstractmethod()*, making this decorator redundant.

A subclass of the built-in *staticmethod()*, indicating an abstract staticmethod. Otherwise it is similar to *abstractmethod()*.

This special case is deprecated, as the *staticmethod()* decorator is now correctly identified as abstract when applied to an abstract method:

```
class C(ABC):
    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(...):
        ...
```

#### @abc.**abstractproperty**

Ditinggalkan sejak versi 3.3: It is now possible to use *property*, *property.getter()*, *property.setter()* and *property.deleter()* with *abstractmethod()*, making this decorator redundant.

A subclass of the built-in *property()*, indicating an abstract property.

This special case is deprecated, as the *property()* decorator is now correctly identified as abstract when applied to an abstract method:

```
class C(ABC):
    @property
    @abstractmethod
    def my_abstract_property(self):
        ...
```

The above example defines a read-only property; you can also define a read-write abstract property by appropriately marking one or more of the underlying methods as abstract:

```
class C(ABC):
    @property
    def x(self):
        ...

    @x.setter
    @abstractmethod
    def x(self, val):
        ...
```

If only some components are abstract, only those components need to be updated to create a concrete property in a subclass:

```
class D(C):
    @C.x.setter
    def x(self, val):
        ...
```

The `abc` module also provides the following functions:

`abc.get_cache_token()`

Returns the current abstract base class cache token.

The token is an opaque object (that supports equality testing) identifying the current version of the abstract base class cache for virtual subclasses. The token changes with every call to `ABCMeta.register()` on any ABC.

Baru pada versi 3.4.

## 29.9 atexit --- Exit handlers

The `atexit` module defines functions to register and unregister cleanup functions. Functions thus registered are automatically executed upon normal interpreter termination. `atexit` runs these functions in the *reverse* order in which they were registered; if you register A, B, and C, at interpreter termination time they will be run in the order C, B, A.

**Note:** The functions registered via this module are not called when the program is killed by a signal not handled by Python, when a Python fatal internal error is detected, or when `os._exit()` is called.

Berubah pada versi 3.7: When used with C-API subinterpreters, registered functions are local to the interpreter they were registered in.

`atexit.register(func, *args, **kwargs)`

Register *func* as a function to be executed at termination. Any optional arguments that are to be passed to *func* must be passed as arguments to `register()`. It is possible to register the same function and arguments more than once.

At normal program termination (for instance, if `sys.exit()` is called or the main module's execution completes), all functions registered are called in last in, first out order. The assumption is that lower level modules will normally be imported before higher level modules and thus must be cleaned up later.

If an exception is raised during execution of the exit handlers, a traceback is printed (unless `SystemExit` is raised) and the exception information is saved. After all exit handlers have had a chance to run the last exception to be raised is re-raised.

This function returns *func*, which makes it possible to use it as a decorator.

`atexit.unregister(func)`

Remove *func* from the list of functions to be run at interpreter shutdown. After calling `unregister()`, *func* is guaranteed not to be called when the interpreter shuts down, even if it was registered more than once. `unregister()` silently does nothing if *func* was not previously registered.

**Lihat juga:**

**Module `readline`** Useful example of `atexit` to read and write `readline` history files.

### 29.9.1 atexit Example

The following simple example demonstrates how a module can initialize a counter from a file when it is imported and save the counter's updated value automatically when the program terminates without relying on the application making an explicit call into this module at termination.

```
try:
    with open("counterfile") as infile:
        _count = int(infile.read())
except FileNotFoundError:
    _count = 0

def incrcounter(n):
    global _count
    _count = _count + n

def savecounter():
    with open("counterfile", "w") as outfile:
        outfile.write("%d" % _count)

import atexit
atexit.register(savecounter)
```

Positional and keyword arguments may also be passed to `register()` to be passed along to the registered function when it is called:

```
def goodbye(name, adjective):
    print('Goodbye, %s, it was %s to meet you.' % (name, adjective))

import atexit
atexit.register(goodbye, 'Donny', 'nice')

# or:
atexit.register(goodbye, adjective='nice', name='Donny')
```

Usage as a *decorator*:

```
import atexit

@atexit.register
def goodbye():
    print("You are now leaving the Python sector.")
```

This only works with functions that can be called without arguments.

## 29.10 traceback --- Print or retrieve a stack traceback

Source code: [Lib/traceback.py](#)

---

This module provides a standard interface to extract, format and print stack traces of Python programs. It exactly mimics the behavior of the Python interpreter when it prints a stack trace. This is useful when you want to print stack traces under program control, such as in a "wrapper" around the interpreter.

The module uses traceback objects --- this is the object type that is stored in the `sys.last_traceback` variable and returned as the third item from `sys.exc_info()`.

The module defines the following functions:

`traceback.print_tb(tb, limit=None, file=None)`

Print up to *limit* stack trace entries from traceback object *tb* (starting from the caller's frame) if *limit* is positive. Otherwise, print the last `abs(limit)` entries. If *limit* is omitted or `None`, all entries are printed. If *file* is omitted or `None`, the output goes to `sys.stderr`; otherwise it should be an open file or file-like object to receive the output.

Berubah pada versi 3.5: Added negative *limit* support.

`traceback.print_exception(etype, value, tb, limit=None, file=None, chain=True)`

Print exception information and stack trace entries from traceback object *tb* to *file*. This differs from `print_tb()` in the following ways:

- if *tb* is not `None`, it prints a header `Traceback (most recent call last):`
- it prints the exception *etype* and *value* after the stack trace
- if `type(value)` is `SyntaxError` and *value* has the appropriate format, it prints the line where the syntax error occurred with a caret indicating the approximate position of the error.

The optional *limit* argument has the same meaning as for `print_tb()`. If *chain* is true (the default), then chained exceptions (the `__cause__` or `__context__` attributes of the exception) will be printed as well, like the interpreter itself does when printing an unhandled exception.

Berubah pada versi 3.5: The *etype* argument is ignored and inferred from the type of *value*.

`traceback.print_exc(limit=None, file=None, chain=True)`

This is a shorthand for `print_exception(*sys.exc_info(), limit, file, chain)`.

`traceback.print_last(limit=None, file=None, chain=True)`

This is a shorthand for `print_exception(sys.last_type, sys.last_value, sys.last_traceback, limit, file, chain)`. In general it will work only after an exception has reached an interactive prompt (see `sys.last_type`).

`traceback.print_stack(f=None, limit=None, file=None)`

Print up to *limit* stack trace entries (starting from the invocation point) if *limit* is positive. Otherwise, print the last `abs(limit)` entries. If *limit* is omitted or `None`, all entries are printed. The optional *f* argument can be used to specify an alternate stack frame to start. The optional *file* argument has the same meaning as for `print_tb()`.

Berubah pada versi 3.5: Added negative *limit* support.

`traceback.extract_tb(tb, limit=None)`

Return a `StackSummary` object representing a list of "pre-processed" stack trace entries extracted from the traceback object *tb*. It is useful for alternate formatting of stack traces. The optional *limit* argument has the same meaning as for `print_tb()`. A "pre-processed" stack trace entry is a `FrameSummary` object containing attributes `filename`, `lineno`, `name`, and `line` representing the information that is usually printed for a stack trace. The `line` is a string with leading and trailing whitespace stripped; if the source is not available it is `None`.

`traceback.extract_stack(f=None, limit=None)`

Extract the raw traceback from the current stack frame. The return value has the same format as for `extract_tb()`. The optional *f* and *limit* arguments have the same meaning as for `print_stack()`.

`traceback.format_list(extracted_list)`

Given a list of tuples or `FrameSummary` objects as returned by `extract_tb()` or `extract_stack()`, return a list of strings ready for printing. Each string in the resulting list corresponds to the item with the same index in the argument list. Each string ends in a newline; the strings may contain internal newlines as well, for those items whose source text line is not `None`.

`traceback.format_exception_only(etype, value)`

Format the exception part of a traceback. The arguments are the exception type and value such as given by `sys.last_type` and `sys.last_value`. The return value is a list of strings, each ending in a newline. Normally, the list contains a single string; however, for `SyntaxError` exceptions, it contains several lines that (when printed) display detailed information about where the syntax error occurred. The message indicating which exception occurred is the always last string in the list.

`traceback.format_exception(etype, value, tb, limit=None, chain=True)`

Format a stack trace and the exception information. The arguments have the same meaning as the corresponding arguments to `print_exception()`. The return value is a list of strings, each ending in a newline and some containing internal newlines. When these lines are concatenated and printed, exactly the same text is printed as does `print_exception()`.

Berubah pada versi 3.5: The *etype* argument is ignored and inferred from the type of *value*.

`traceback.format_exc(limit=None, chain=True)`

This is like `print_exc(limit)` but returns a string instead of printing to a file.

`traceback.format_tb(tb, limit=None)`

A shorthand for `format_list(extract_tb(tb, limit))`.

`traceback.format_stack(f=None, limit=None)`

A shorthand for `format_list(extract_stack(f, limit))`.

`traceback.clear_frames(tb)`

Clears the local variables of all the stack frames in a traceback *tb* by calling the `clear()` method of each frame object.

Baru pada versi 3.4.

`traceback.walk_stack(f)`

Walk a stack following `f.f_back` from the given frame, yielding the frame and line number for each frame. If *f* is `None`, the current stack is used. This helper is used with `StackSummary.extract()`.

Baru pada versi 3.5.

`traceback.walk_tb(tb)`

Walk a traceback following `tb.next` yielding the frame and line number for each frame. This helper is used with `StackSummary.extract()`.

Baru pada versi 3.5.

The module also defines the following classes:

### 29.10.1 TracebackException Objects

Baru pada versi 3.5.

`TracebackException` objects are created from actual exceptions to capture data for later printing in a lightweight fashion.

**class** `traceback.TracebackException(exc_type, exc_value, exc_traceback, *, limit=None, lookup_lines=True, capture_locals=False)`

Capture an exception for later rendering. *limit*, *lookup\_lines* and *capture\_locals* are as for the `StackSummary` class.

Note that when locals are captured, they are also shown in the traceback.

**\_\_cause\_\_**

A `TracebackException` of the original `__cause__`.

**\_\_context\_\_**

A *TracebackException* of the original `__context__`.

**\_\_suppress\_context\_\_**

The `__suppress_context__` value from the original exception.

**stack**

A *StackSummary* representing the traceback.

**exc\_type**

The class of the original traceback.

**filename**

For syntax errors - the file name where the error occurred.

**lineno**

For syntax errors - the line number where the error occurred.

**text**

For syntax errors - the text where the error occurred.

**offset**

For syntax errors - the offset into the text where the error occurred.

**msg**

For syntax errors - the compiler error message.

**classmethod from\_exception** (*exc*, \*, *limit=None*, *lookup\_lines=True*, *capture\_locals=False*)

Capture an exception for later rendering. *limit*, *lookup\_lines* and *capture\_locals* are as for the *StackSummary* class.

Note that when locals are captured, they are also shown in the traceback.

**format** (\*, *chain=True*)

Format the exception.

If *chain* is not `True`, `__cause__` and `__context__` will not be formatted.

The return value is a generator of strings, each ending in a newline and some containing internal newlines. *print\_exception()* is a wrapper around this method which just prints the lines to a file.

The message indicating which exception occurred is always the last string in the output.

**format\_exception\_only** ()

Format the exception part of the traceback.

The return value is a generator of strings, each ending in a newline.

Normally, the generator emits a single string; however, for *SyntaxError* exceptions, it emits several lines that (when printed) display detailed information about where the syntax error occurred.

The message indicating which exception occurred is always the last string in the output.

## 29.10.2 StackSummary Objects

Baru pada versi 3.5.

*StackSummary* objects represent a call stack ready for formatting.

**class** `traceback.StackSummary`

**classmethod** `extract` (*frame\_gen*, \*, *limit=None*, *lookup\_lines=True*, *capture\_locals=False*)

Construct a *StackSummary* object from a frame generator (such as is returned by *walk\_stack()* or *walk\_tb()*).

If *limit* is supplied, only this many frames are taken from *frame\_gen*. If *lookup\_lines* is `False`, the returned *FrameSummary* objects will not have read their lines in yet, making the cost of creating the *StackSummary* cheaper (which may be valuable if it may not actually get formatted). If *capture\_locals* is `True` the local variables in each *FrameSummary* are captured as object representations.

**classmethod** `from_list` (*a\_list*)

Construct a *StackSummary* object from a supplied list of *FrameSummary* objects or old-style list of tuples. Each tuple should be a 4-tuple with filename, lineno, name, line as the elements.

**format** ()

Returns a list of strings ready for printing. Each string in the resulting list corresponds to a single frame from the stack. Each string ends in a newline; the strings may contain internal newlines as well, for those items with source text lines.

For long sequences of the same frame and line, the first few repetitions are shown, followed by a summary line stating the exact number of further repetitions.

Berubah pada versi 3.6: Long sequences of repeated frames are now abbreviated.

## 29.10.3 FrameSummary Objects

Baru pada versi 3.5.

*FrameSummary* objects represent a single frame in a traceback.

**class** `traceback.FrameSummary` (*filename*, *lineno*, *name*, *lookup\_line=True*, *locals=None*, *line=None*)

Represent a single frame in the traceback or stack that is being formatted or printed. It may optionally have a stringified version of the frames locals included in it. If *lookup\_line* is `False`, the source code is not looked up until the *FrameSummary* has the *line* attribute accessed (which also happens when casting it to a tuple). *line* may be directly provided, and will prevent line lookups happening at all. *locals* is an optional local variable dictionary, and if supplied the variable representations are stored in the summary for later display.

## 29.10.4 Traceback Examples

This simple example implements a basic read-eval-print loop, similar to (but less useful than) the standard Python interactive interpreter loop. For a more complete implementation of the interpreter loop, refer to the *code* module.

```
import sys, traceback

def run_user_code(envdir):
    source = input(">>> ")
    try:
        exec(source, envdir)
    except Exception:
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

    print("Exception in user code:")
    print("-"*60)
    traceback.print_exc(file=sys.stdout)
    print("-"*60)

envdir = {}
while True:
    run_user_code(envdir)

```

The following example demonstrates the different ways to print and format the exception and traceback:

```

import sys, traceback

def lumberjack():
    bright_side_of_death()

def bright_side_of_death():
    return tuple()[0]

try:
    lumberjack()
except IndexError:
    exc_type, exc_value, exc_traceback = sys.exc_info()
    print("*** print_tb:")
    traceback.print_tb(exc_traceback, limit=1, file=sys.stdout)
    print("*** print_exception:")
    # exc_type below is ignored on 3.5 and later
    traceback.print_exception(exc_type, exc_value, exc_traceback,
                             limit=2, file=sys.stdout)

    print("*** print_exc:")
    traceback.print_exc(limit=2, file=sys.stdout)
    print("*** format_exc, first and last line:")
    formatted_lines = traceback.format_exc().splitlines()
    print(formatted_lines[0])
    print(formatted_lines[-1])
    print("*** format_exception:")
    # exc_type below is ignored on 3.5 and later
    print(repr(traceback.format_exception(exc_type, exc_value,
                                         exc_traceback)))

    print("*** extract_tb:")
    print(repr(traceback.extract_tb(exc_traceback)))
    print("*** format_tb:")
    print(repr(traceback.format_tb(exc_traceback)))
    print("*** tb_lineno:", exc_traceback.tb_lineno)

```

The output for the example would look similar to this:

```

*** print_tb:
  File "<doctest...>", line 10, in <module>
    lumberjack()
*** print_exception:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
    lumberjack()
  File "<doctest...>", line 4, in lumberjack
    bright_side_of_death()
IndexError: tuple index out of range

```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

*** print_exc:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
    lumberjack()
  File "<doctest...>", line 4, in lumberjack
    bright_side_of_death()
IndexError: tuple index out of range
*** format_exc, first and last line:
Traceback (most recent call last):
IndexError: tuple index out of range
*** format_exception:
['Traceback (most recent call last):\n',
 '  File "<doctest...>", line 10, in <module>\n    lumberjack()\n',
 '  File "<doctest...>", line 4, in lumberjack\n    bright_side_of_death()\n',
 '  File "<doctest...>", line 7, in bright_side_of_death\n    return tuple()[0]\n',
 'IndexError: tuple index out of range\n']
*** extract_tb:
[<FrameSummary file <doctest...>, line 10 in <module>>,
 <FrameSummary file <doctest...>, line 4 in lumberjack>,
 <FrameSummary file <doctest...>, line 7 in bright_side_of_death>]
*** format_tb:
['  File "<doctest...>", line 10, in <module>\n    lumberjack()\n',
 '  File "<doctest...>", line 4, in lumberjack\n    bright_side_of_death()\n',
 '  File "<doctest...>", line 7, in bright_side_of_death\n    return tuple()[0]\n']
*** tb_lineno: 10

```

The following example shows the different ways to print and format the stack:

```

>>> import traceback
>>> def another_function():
...     lumberstack()
...
>>> def lumberstack():
...     traceback.print_stack()
...     print(repr(traceback.extract_stack()))
...     print(repr(traceback.format_stack()))
...
>>> another_function()
File "<doctest>", line 10, in <module>
  another_function()
File "<doctest>", line 3, in another_function
  lumberstack()
File "<doctest>", line 6, in lumberstack
  traceback.print_stack()
[('(<doctest>', 10, '<module>', 'another_function()'),
 ('(<doctest>', 3, 'another_function', 'lumberstack()'),
 ('(<doctest>', 7, 'lumberstack', 'print(repr(traceback.extract_stack()))')]
['  File "<doctest>", line 10, in <module>\n    another_function()\n',
 '  File "<doctest>", line 3, in another_function\n    lumberstack()\n',
 '  File "<doctest>", line 8, in lumberstack\n    print(repr(traceback.format_
↳ stack()))\n']

```

This last example demonstrates the final few formatting functions:

```

>>> import traceback
>>> traceback.format_list([('spam.py', 3, '<module>', 'spam.eggs()'),
...                       ('eggs.py', 42, 'eggs', 'return "bacon"')])

```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
[ ' File "spam.py", line 3, in <module>\n    spam.eggs()\n',
  ' File "eggs.py", line 42, in eggs\n    return "bacon"\n']
>>> an_error = IndexError('tuple index out of range')
>>> traceback.format_exception_only(type(an_error), an_error)
['IndexError: tuple index out of range\n']
```

## 29.11 `__future__` --- Future statement definitions

Source code: `Lib/_future_.py`

`__future__` is a real module, and serves three purposes:

- To avoid confusing existing tools that analyze import statements and expect to find the modules they're importing.
- To ensure that future statements run under releases prior to 2.1 at least yield runtime exceptions (the import of `__future__` will fail, because there was no module of that name prior to 2.1).
- To document when incompatible changes were introduced, and when they will be --- or were --- made mandatory. This is a form of executable documentation, and can be inspected programmatically via importing `__future__` and examining its contents.

Each statement in `__future__.py` is of the form:

```
FeatureName = _Feature(OptionalRelease, MandatoryRelease,
                        CompilerFlag)
```

where, normally, *OptionalRelease* is less than *MandatoryRelease*, and both are 5-tuples of the same form as `sys.version_info`:

```
(PY_MAJOR_VERSION, # the 2 in 2.1.0a3; an int
 PY_MINOR_VERSION, # the 1; an int
 PY_MICRO_VERSION, # the 0; an int
 PY_RELEASE_LEVEL, # "alpha", "beta", "candidate" or "final"; string
 PY_RELEASE_SERIAL # the 3; an int
)
```

*OptionalRelease* records the first release in which the feature was accepted.

In the case of a *MandatoryRelease* that has not yet occurred, *MandatoryRelease* predicts the release in which the feature will become part of the language.

Else *MandatoryRelease* records when the feature became part of the language; in releases at or after that, modules no longer need a future statement to use the feature in question, but may continue to use such imports.

*MandatoryRelease* may also be `None`, meaning that a planned feature got dropped.

Instances of class `_Feature` have two corresponding methods, `getOptionalRelease()` and `getMandatoryRelease()`.

*CompilerFlag* is the (bitfield) flag that should be passed in the fourth argument to the built-in function `compile()` to enable the feature in dynamically compiled code. This flag is stored in the `compiler_flag` attribute on `_Feature` instances.

No feature description will ever be deleted from `__future__`. Since its introduction in Python 2.1 the following features have found their way into the language using this mechanism:

| fitur            | optional in | mandatory in | efek                                                              |
|------------------|-------------|--------------|-------------------------------------------------------------------|
| nested_scopes    | 2.1.0b1     | 2.2          | <b>PEP 227</b> : <i>Statically Nested Scopes</i>                  |

## 29.12 gc --- Garbage Collector interface

---

This module provides an interface to the optional garbage collector. It provides the ability to disable the collector, tune the collection frequency, and set debugging options. It also provides access to unreachable objects that the collector found but cannot free. Since the collector supplements the reference counting already used in Python, you can disable the collector if you are sure your program does not create reference cycles. Automatic collection can be disabled by calling `gc.disable()`. To debug a leaking program call `gc.set_debug(gc.DEBUG_LEAK)`. Notice that this includes `gc.DEBUG_SAVEALL`, causing garbage-collected objects to be saved in `gc.garbage` for inspection.

The `gc` module provides the following functions:

`gc.enable()`

Enable automatic garbage collection.

`gc.disable()`

Disable automatic garbage collection.

`gc.isenabled()`

Return `True` if automatic collection is enabled.

`gc.collect(generation=2)`

With no arguments, run a full collection. The optional argument *generation* may be an integer specifying which generation to collect (from 0 to 2). A `ValueError` is raised if the generation number is invalid. The number of unreachable objects found is returned.

The free lists maintained for a number of built-in types are cleared whenever a full collection or collection of the highest generation (2) is run. Not all items in some free lists may be freed due to the particular implementation, in particular *float*.

`gc.set_debug(flags)`

Set the garbage collection debugging flags. Debugging information will be written to `sys.stderr`. See below for a list of debugging flags which can be combined using bit operations to control debugging.

`gc.get_debug()`

Return the debugging flags currently set.

`gc.get_objects(generation=None)`

Returns a list of all objects tracked by the collector, excluding the list returned. If *generation* is not `None`, return only the objects tracked by the collector that are in that generation.

Berubah pada versi 3.8: New *generation* parameter.

Raises an *auditing event* `gc.get_objects` with argument *generation*.

`gc.get_stats()`

Return a list of three per-generation dictionaries containing collection statistics since interpreter start. The number of keys may change in the future, but currently each dictionary will contain the following items:

- `collections` is the number of times this generation was collected;
- `collected` is the total number of objects collected inside this generation;
- `uncollectable` is the total number of objects which were found to be uncollectable (and were therefore moved to the *garbage* list) inside this generation.

Baru pada versi 3.4.

`gc.set_threshold(threshold0[, threshold1[, threshold2]])`

Set the garbage collection thresholds (the collection frequency). Setting *threshold0* to zero disables collection.

The GC classifies objects into three generations depending on how many collection sweeps they have survived. New objects are placed in the youngest generation (generation 0). If an object survives a collection it is moved into the next older generation. Since generation 2 is the oldest generation, objects in that generation remain there after a collection. In order to decide when to run, the collector keeps track of the number object allocations and deallocations since the last collection. When the number of allocations minus the number of deallocations exceeds *threshold0*, collection starts. Initially only generation 0 is examined. If generation 0 has been examined more than *threshold1* times since generation 1 has been examined, then generation 1 is examined as well. With the third generation, things are a bit more complicated, see [Collecting the oldest generation](#) for more information.

`gc.get_count()`

Return the current collection counts as a tuple of (`count0`, `count1`, `count2`).

`gc.get_threshold()`

Return the current collection thresholds as a tuple of (`threshold0`, `threshold1`, `threshold2`).

`gc.get_referrers(*objs)`

Return the list of objects that directly refer to any of *objs*. This function will only locate those containers which support garbage collection; extension types which do refer to other objects but do not support garbage collection will not be found.

Note that objects which have already been dereferenced, but which live in cycles and have not yet been collected by the garbage collector can be listed among the resulting referrers. To get only currently live objects, call `collect()` before calling `get_referrers()`.

**Peringatan:** Care must be taken when using objects returned by `get_referrers()` because some of them could still be under construction and hence in a temporarily invalid state. Avoid using `get_referrers()` for any purpose other than debugging.

Raises an *auditing event* `gc.get_referrers` with argument *objs*.

`gc.get_referents(*objs)`

Return a list of objects directly referred to by any of the arguments. The referents returned are those objects visited by the arguments' C-level `tp_traverse` methods (if any), and may not be all objects actually directly reachable.

`tp_traverse` methods are supported only by objects that support garbage collection, and are only required to visit objects that may be involved in a cycle. So, for example, if an integer is directly reachable from an argument, that integer object may or may not appear in the result list.

Raises an *auditing event* `gc.get_referents` with argument `objs`.

**`gc.is_tracked(obj)`**

Returns `True` if the object is currently tracked by the garbage collector, `False` otherwise. As a general rule, instances of atomic types aren't tracked and instances of non-atomic types (containers, user-defined objects...) are. However, some type-specific optimizations can be present in order to suppress the garbage collector footprint of simple instances (e.g. dicts containing only atomic keys and values):

```
>>> gc.is_tracked(0)
False
>>> gc.is_tracked("a")
False
>>> gc.is_tracked([])
True
>>> gc.is_tracked({})
False
>>> gc.is_tracked({"a": 1})
False
>>> gc.is_tracked({"a": []})
True
```

Baru pada versi 3.1.

**`gc.freeze()`**

Freeze all the objects tracked by `gc` - move them to a permanent generation and ignore all the future collections. This can be used before a `POSIX fork()` call to make the `gc` copy-on-write friendly or to speed up collection. Also collection before a `POSIX fork()` call may free pages for future allocation which can cause copy-on-write too so it's advised to disable `gc` in parent process and freeze before fork and enable `gc` in child process.

Baru pada versi 3.7.

**`gc.unfreeze()`**

Unfreeze the objects in the permanent generation, put them back into the oldest generation.

Baru pada versi 3.7.

**`gc.get_freeze_count()`**

Return the number of objects in the permanent generation.

Baru pada versi 3.7.

The following variables are provided for read-only access (you can mutate the values but should not rebind them):

**`gc.garbage`**

A list of objects which the collector found to be unreachable but could not be freed (uncollectable objects). Starting with Python 3.4, this list should be empty most of the time, except when using instances of C extension types with a non-NULL `tp_del` slot.

If `DEBUG_SAVEALL` is set, then all unreachable objects will be added to this list rather than freed.

Barubah pada versi 3.2: If this list is non-empty at *interpreter shutdown*, a *ResourceWarning* is emitted, which is silent by default. If `DEBUG_UNCOLLECTABLE` is set, in addition all uncollectable objects are printed.

Barubah pada versi 3.4: Following **PEP 442**, objects with a `__del__()` method don't end up in `gc.garbage` anymore.

**gc.callbacks**

A list of callbacks that will be invoked by the garbage collector before and after collection. The callbacks will be called with two arguments, *phase* and *info*.

*phase* can be one of two values:

”start”: The garbage collection is about to start.

”stop”: The garbage collection has finished.

*info* is a dict providing more information for the callback. The following keys are currently defined:

”generation”: The oldest generation being collected.

”collected”: When *phase* is ”stop”, the number of objects successfully collected.

”uncollectable”: When *phase* is ”stop”, the number of objects that could not be collected and were put in *garbage*.

Applications can add their own callbacks to this list. The primary use cases are:

Gathering statistics about garbage collection, such as how often various generations are collected, and how long the collection takes.

Allowing applications to identify and clear their own uncollectable types when they appear in *garbage*.

Baru pada versi 3.3.

The following constants are provided for use with `set_debug()`:

**gc.DEBUG\_STATS**

Print statistics during collection. This information can be useful when tuning the collection frequency.

**gc.DEBUG\_COLLECTABLE**

Print information on collectable objects found.

**gc.DEBUG\_UNCOLLECTABLE**

Print information of uncollectable objects found (objects which are not reachable but cannot be freed by the collector). These objects will be added to the *garbage* list.

Berubah pada versi 3.2: Also print the contents of the *garbage* list at *interpreter shutdown*, if it isn't empty.

**gc.DEBUG\_SAVEALL**

When set, all unreachable objects found will be appended to *garbage* rather than being freed. This can be useful for debugging a leaking program.

**gc.DEBUG\_LEAK**

The debugging flags necessary for the collector to print information about a leaking program (equal to `DEBUG_COLLECTABLE | DEBUG_UNCOLLECTABLE | DEBUG_SAVEALL`).

## 29.13 inspect --- Inspect live objects

Source code: [Lib/inspect.py](#)

The *inspect* module provides several useful functions to help get information about live objects such as modules, classes, methods, functions, tracebacks, frame objects, and code objects. For example, it can help you examine the contents of a class, retrieve the source code of a method, extract and format the argument list for a function, or get all the information you need to display a detailed traceback.

There are four main kinds of services provided by this module: type checking, getting source code, inspecting classes and functions, and examining the interpreter stack.

### 29.13.1 Types and members

The `getmembers()` function retrieves the members of an object such as a class or module. The functions whose names begin with "is" are mainly provided as convenient choices for the second argument to `getmembers()`. They also help you determine when you can expect to find the following special attributes:

| Type      | Atribut                         | Deskripsi                                                                                    |
|-----------|---------------------------------|----------------------------------------------------------------------------------------------|
| modul     | <code>__doc__</code>            | documentation string                                                                         |
|           | <code>__file__</code>           | filename (missing for built-in modules)                                                      |
|           | <code>__name__</code>           | name with which this class was defined                                                       |
| kelas     | <code>__doc__</code>            | documentation string                                                                         |
|           | <code>__qualname__</code>       | nama yang memenuhi syarat                                                                    |
|           | <code>__module__</code>         | name of module in which this class was defined                                               |
| method    | <code>__doc__</code>            | documentation string                                                                         |
|           | <code>__name__</code>           | name with which this method was defined                                                      |
|           | <code>__qualname__</code>       | nama yang memenuhi syarat                                                                    |
|           | <code>__func__</code>           | function object containing implementation of method                                          |
|           | <code>__self__</code>           | instance to which this method is bound, or <code>None</code>                                 |
|           | <code>__module__</code>         | name of module in which this method was defined                                              |
| fungsi    | <code>__doc__</code>            | documentation string                                                                         |
|           | <code>__name__</code>           | name with which this function was defined                                                    |
|           | <code>__qualname__</code>       | nama yang memenuhi syarat                                                                    |
|           | <code>__code__</code>           | code object containing compiled function <i>bytecode</i>                                     |
|           | <code>__defaults__</code>       | tuple of any default values for positional or keyword parameters                             |
|           | <code>__kwdefaults__</code>     | mapping of any default values for keyword-only parameters                                    |
|           | <code>__globals__</code>        | global namespace in which this function was defined                                          |
|           | <code>__annotations__</code>    | mapping of parameters names to annotations; "return" key is reserved for return annotations. |
| traceback | <code>__module__</code>         | name of module in which this function was defined                                            |
|           | <code>tb_frame</code>           | frame object at this level                                                                   |
|           | <code>tb_lasti</code>           | index of last attempted instruction in bytecode                                              |
|           | <code>tb_lineno</code>          | current line number in Python source code                                                    |
| frame     | <code>tb_next</code>            | next inner traceback object (called by this level)                                           |
|           | <code>f_back</code>             | next outer frame object (this frame's caller)                                                |
|           | <code>f_builtins</code>         | builtins namespace seen by this frame                                                        |
|           | <code>f_code</code>             | code object being executed in this frame                                                     |
|           | <code>f_globals</code>          | global namespace seen by this frame                                                          |
|           | <code>f_lasti</code>            | index of last attempted instruction in bytecode                                              |
|           | <code>f_lineno</code>           | current line number in Python source code                                                    |
|           | <code>f_locals</code>           | local namespace seen by this frame                                                           |
| code      | <code>f_trace</code>            | tracing function for this frame, or <code>None</code>                                        |
|           | <code>co_argcount</code>        | number of arguments (not including keyword only arguments, * or ** args)                     |
|           | <code>co_code</code>            | string of raw compiled bytecode                                                              |
|           | <code>co_cellvars</code>        | tuple of names of cell variables (referenced by containing scopes)                           |
|           | <code>co_consts</code>          | tuple of constants used in the bytecode                                                      |
|           | <code>co_filename</code>        | name of file in which this code object was created                                           |
|           | <code>co_firstlineno</code>     | number of first line in Python source code                                                   |
|           | <code>co_flags</code>           | bitmap of CO_* flags, read more <i>here</i>                                                  |
|           | <code>co_lnotab</code>          | encoded mapping of line numbers to bytecode indices                                          |
|           | <code>co_freevars</code>        | tuple of names of free variables (referenced via a function's closure)                       |
|           | <code>co_posonlyargcount</code> | number of positional only arguments                                                          |
|           | <code>co_kwonlyargcount</code>  | number of keyword only arguments (not including ** arg)                                      |

|            | <code>co_nlocals</code>   | number of local variables                                                                                         |
|            | <code>co_stacksize</code> | virtual machine stack space required                                                                              |
|            | <code>co_varnames</code>  | tuple of names of arguments and local variables                                                                   |
| pembangkit | <code>__name__</code>     | nama                                                                                                              |
|            | <code>__qualname__</code> | nama yang memenuhi syarat                                                                                         |
|            | <code>gi_frame</code>     | frame                                                                                                             |
|            | <code>gi_running</code>   | is the generator running?                                                                                         |
|            | <code>gi_code</code>      | code                                                                                                              |
|            | <code>gi_yieldfrom</code> | object being iterated by <code>yield from</code> , or <code>None</code>                                           |
| coroutine  | <code>__name__</code>     | nama                                                                                                              |
|            | <code>__qualname__</code> | nama yang memenuhi syarat                                                                                         |
|            | <code>cr_await</code>     | object being awaited on, or <code>None</code>                                                                     |
|            | <code>cr_frame</code>     | frame                                                                                                             |
|            | <code>cr_running</code>   | is the coroutine running?                                                                                         |
|            | <code>cr_code</code>      | code                                                                                                              |
|            | <code>cr_origin</code>    | where coroutine was created, or <code>None</code> . See <a href="#">sys.set_coroutine_origin_tracking_depth()</a> |
| builtin    | <code>__doc__</code>      | documentation string                                                                                              |
|            | <code>__name__</code>     | original name of this function or method                                                                          |
|            | <code>__qualname__</code> | nama yang memenuhi syarat                                                                                         |
|            | <code>__self__</code>     | instance to which a method is bound, or <code>None</code>                                                         |

Berubah pada versi 3.5: Add `__qualname__` and `gi_yieldfrom` attributes to generators.

The `__name__` attribute of generators is now set from the function name, instead of the code name, and it can now be modified.

Berubah pada versi 3.7: Add `cr_origin` attribute to coroutines.

`inspect.getmembers(object[, predicate])`

Return all the members of an object in a list of (name, value) pairs sorted by name. If the optional *predicate* argument—which will be called with the value object of each member—is supplied, only members for which the predicate returns a true value are included.

---

**Catatan:** `getmembers()` will only return class attributes defined in the metaclass when the argument is a class and those attributes have been listed in the metaclass' custom `__dir__()`.

---

`inspect.getmodule(path)`

Return the name of the module named by the file *path*, without including the names of enclosing packages. The file extension is checked against all of the entries in `importlib.machinery.all_suffixes()`. If it matches, the final path component is returned with the extension removed. Otherwise, `None` is returned.

Note that this function *only* returns a meaningful name for actual Python modules - paths that potentially refer to Python packages will still return `None`.

Berubah pada versi 3.3: The function is based directly on `importlib`.

`inspect.ismodule(object)`

Return `True` if the object is a module.

`inspect.isclass(object)`

Return `True` if the object is a class, whether built-in or created in Python code.

`inspect.ismethod(object)`

Return True if the object is a bound method written in Python.

`inspect.isfunction(object)`

Return True if the object is a Python function, which includes functions created by a *lambda* expression.

`inspect.isgeneratorfunction(object)`

Return True if the object is a Python generator function.

Berubah pada versi 3.8: Functions wrapped in `functools.partial()` now return True if the wrapped function is a Python generator function.

`inspect.isgenerator(object)`

Return True if the object is a generator.

`inspect.iscoroutinefunction(object)`

Return True if the object is a *coroutine function* (a function defined with an `async def` syntax).

Baru pada versi 3.5.

Berubah pada versi 3.8: Functions wrapped in `functools.partial()` now return True if the wrapped function is a *coroutine function*.

`inspect.iscoroutine(object)`

Return True if the object is a *coroutine* created by an `async def` function.

Baru pada versi 3.5.

`inspect.isawaitable(object)`

Return True if the object can be used in `await` expression.

Can also be used to distinguish generator-based coroutines from regular generators:

```
def gen():
    yield
@types.coroutine
def gen_coro():
    yield

assert not isawaitable(gen())
assert isawaitable(gen_coro())
```

Baru pada versi 3.5.

`inspect.isasyncgenfunction(object)`

Return True if the object is an *asynchronous generator* function, for example:

```
>>> async def agen():
...     yield 1
...
>>> inspect.isasyncgenfunction(agen)
True
```

Baru pada versi 3.6.

Berubah pada versi 3.8: Functions wrapped in `functools.partial()` now return True if the wrapped function is a *asynchronous generator* function.

`inspect.isasyncgen(object)`

Return True if the object is an *asynchronous generator iterator* created by an *asynchronous generator* function.

Baru pada versi 3.6.

`inspect.istraceback(object)`

Return True if the object is a traceback.

`inspect.isframe(object)`

Return True if the object is a frame.

`inspect.iscode(object)`

Return True if the object is a code.

`inspect.isbuiltin(object)`

Return True if the object is a built-in function or a bound built-in method.

`inspect.isroutine(object)`

Return True if the object is a user-defined or built-in function or method.

`inspect.isabstract(object)`

Return True if the object is an abstract base class.

`inspect.ismethoddescriptor(object)`

Return True if the object is a method descriptor, but not if `ismethod()`, `isclass()`, `isfunction()` or `isbuiltin()` are true.

This, for example, is true of `int.__add__`. An object passing this test has a `__get__()` method but not a `__set__()` method, but beyond that the set of attributes varies. A `__name__` attribute is usually sensible, and `__doc__` often is.

Methods implemented via descriptors that also pass one of the other tests return False from the `ismethoddescriptor()` test, simply because the other tests promise more -- you can, e.g., count on having the `__func__` attribute (etc) when an object passes `ismethod()`.

`inspect.isdatadescriptor(object)`

Return True if the object is a data descriptor.

Data descriptors have a `__set__` or a `__delete__` method. Examples are properties (defined in Python), getsets, and members. The latter two are defined in C and there are more specific tests available for those types, which is robust across Python implementations. Typically, data descriptors will also have `__name__` and `__doc__` attributes (properties, getsets, and members have both of these attributes), but this is not guaranteed.

`inspect.isgetsetdescriptor(object)`

Return True if the object is a getset descriptor.

**CPython implementation detail:** getsets are attributes defined in extension modules via `PyGetSetDef` structures. For Python implementations without such types, this method will always return False.

`inspect.ismemberdescriptor(object)`

Return True if the object is a member descriptor.

**CPython implementation detail:** Member descriptors are attributes defined in extension modules via `PyMemberDef` structures. For Python implementations without such types, this method will always return False.

### 29.13.2 Retrieving source code

`inspect.getdoc(object)`

Get the documentation string for an object, cleaned up with `cleandoc()`. If the documentation string for an object is not provided and the object is a class, a method, a property or a descriptor, retrieve the documentation string from the inheritance hierarchy.

Berubah pada versi 3.5: Documentation strings are now inherited if not overridden.

`inspect.getcomments(object)`

Return in a single string any lines of comments immediately preceding the object's source code (for a class, function, or method), or at the top of the Python source file (if the object is a module). If the object's source code is unavailable, return `None`. This could happen if the object has been defined in C or the interactive shell.

`inspect.getfile(object)`

Return the name of the (text or binary) file in which an object was defined. This will fail with a `TypeError` if the object is a built-in module, class, or function.

`inspect.getmodule(object)`

Try to guess which module an object was defined in.

`inspect.getsourcefile(object)`

Return the name of the Python source file in which an object was defined. This will fail with a `TypeError` if the object is a built-in module, class, or function.

`inspect.getsourcelines(object)`

Return a list of source lines and starting line number for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a list of the lines corresponding to the object and the line number indicates where in the original source file the first line of code was found. An `OSError` is raised if the source code cannot be retrieved.

Berubah pada versi 3.3: `OSError` is raised instead of `IOError`, now an alias of the former.

`inspect.getsource(object)`

Return the text of the source code for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a single string. An `OSError` is raised if the source code cannot be retrieved.

Berubah pada versi 3.3: `OSError` is raised instead of `IOError`, now an alias of the former.

`inspect.cleandoc(doc)`

Clean up indentation from docstrings that are indented to line up with blocks of code.

All leading whitespace is removed from the first line. Any leading whitespace that can be uniformly removed from the second line onwards is removed. Empty lines at the beginning and end are subsequently removed. Also, all tabs are expanded to spaces.

### 29.13.3 Introspecting callables with the Signature object

Baru pada versi 3.3.

The Signature object represents the call signature of a callable object and its return annotation. To retrieve a Signature object, use the `signature()` function.

`inspect.signature(callable, *, follow_wrapped=True)`

Return a `Signature` object for the given `callable`:

```

>>> from inspect import signature
>>> def foo(a, *, b:int, **kwargs):
...     pass

>>> sig = signature(foo)

>>> str(sig)
'(a, *, b:int, **kwargs)'

>>> str(sig.parameters['b'])
'b:int'

>>> sig.parameters['b'].annotation
<class 'int'>

```

Accepts a wide range of Python callables, from plain functions and classes to `functools.partial()` objects.

Raises `ValueError` if no signature can be provided, and `TypeError` if that type of object is not supported.

A slash(/) in the signature of a function denotes that the parameters prior to it are positional-only. For more info, see the FAQ entry on positional-only parameters.

Baru pada versi 3.5: `follow_wrapped` parameter. Pass `False` to get a signature of callable specifically (callable.`__wrapped__` will not be used to unwrap decorated callables.)

---

**Catatan:** Some callables may not be introspectable in certain implementations of Python. For example, in CPython, some built-in functions defined in C provide no metadata about their arguments.

---

**class** `inspect.Signature` (*parameters=None*, \*, *return\_annotation=Signature.empty*)

A `Signature` object represents the call signature of a function and its return annotation. For each parameter accepted by the function it stores a `Parameter` object in its `parameters` collection.

The optional `parameters` argument is a sequence of `Parameter` objects, which is validated to check that there are no parameters with duplicate names, and that the parameters are in the right order, i.e. positional-only first, then positional-or-keyword, and that parameters with defaults follow parameters without defaults.

The optional `return_annotation` argument, can be an arbitrary Python object, is the "return" annotation of the callable.

Signature objects are *immutable*. Use `Signature.replace()` to make a modified copy.

Berubah pada versi 3.5: Signature objects are picklable and hashable.

#### **empty**

A special class-level marker to specify absence of a return annotation.

#### **parameters**

An ordered mapping of parameters' names to the corresponding `Parameter` objects. Parameters appear in strict definition order, including keyword-only parameters.

Berubah pada versi 3.7: Python only explicitly guaranteed that it preserved the declaration order of keyword-only parameters as of version 3.7, although in practice this order had always been preserved in Python 3.

#### **return\_annotation**

The "return" annotation for the callable. If the callable has no "return" annotation, this attribute is set to `Signature.empty`.

#### **bind** (\*args, \*\*kwargs)

Create a mapping from positional and keyword arguments to parameters. Returns `BoundArguments` if

\*args and \*\*kwargs match the signature, or raises a `TypeError`.

**bind\_partial** (\*args, \*\*kwargs)

Works the same way as `Signature.bind()`, but allows the omission of some required arguments (mimics `functools.partial()` behavior.) Returns `BoundArguments`, or raises a `TypeError` if the passed arguments do not match the signature.

**replace** (\*[, parameters][, return\_annotation])

Create a new `Signature` instance based on the instance `replace` was invoked on. It is possible to pass different parameters and/or `return_annotation` to override the corresponding properties of the base signature. To remove `return_annotation` from the copied `Signature`, pass in `Signature.empty`.

```
>>> def test(a, b):
...     pass
>>> sig = signature(test)
>>> new_sig = sig.replace(return_annotation="new return anno")
>>> str(new_sig)
"(a, b) -> 'new return anno'"
```

**classmethod from\_callable** (obj, \*, follow\_wrapped=True)

Return a `Signature` (or its subclass) object for a given callable `obj`. Pass `follow_wrapped=False` to get a signature of `obj` without unwrapping its `__wrapped__` chain.

This method simplifies subclassing of `Signature`:

```
class MySignature(Signature):
    pass
sig = MySignature.from_callable(min)
assert isinstance(sig, MySignature)
```

Baru pada versi 3.5.

**class inspect.Parameter** (name, kind, \*, default=Parameter.empty, annotation=Parameter.empty)

Parameter objects are *immutable*. Instead of modifying a `Parameter` object, you can use `Parameter.replace()` to create a modified copy.

Berubah pada versi 3.5: `Parameter` objects are picklable and hashable.

**empty**

A special class-level marker to specify absence of default values and annotations.

**name**

The name of the parameter as a string. The name must be a valid Python identifier.

**CPython implementation detail:** CPython generates implicit parameter names of the form `.0` on the code objects used to implement comprehensions and generator expressions.

Berubah pada versi 3.6: These parameter names are exposed by this module as names like `implicit0`.

**default**

The default value for the parameter. If the parameter has no default value, this attribute is set to `Parameter.empty`.

**annotation**

The annotation for the parameter. If the parameter has no annotation, this attribute is set to `Parameter.empty`.

**kind**

Describes how argument values are bound to the parameter. Possible values (accessible via `Parameter`, like `Parameter.KEYWORD_ONLY`):

| Nama                         | Artinya                                                                                                                                                           |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>POSITIONAL_ONLY</i>       | Value must be supplied as a positional argument. Positional only parameters are those which appear before a / entry (if present) in a Python function definition. |
| <i>POSITIONAL_OR_KEYWORD</i> | Value may be supplied as either a keyword or positional argument (this is the standard binding behaviour for functions implemented in Python.)                    |
| <i>VAR_POSITIONAL</i>        | A tuple of positional arguments that aren't bound to any other parameter. This corresponds to a *args parameter in a Python function definition.                  |
| <i>KEYWORD_ONLY</i>          | Value must be supplied as a keyword argument. Keyword only parameters are those which appear after a * or *args entry in a Python function definition.            |
| <i>VAR_KEYWORD</i>           | A dict of keyword arguments that aren't bound to any other parameter. This corresponds to a **kwargs parameter in a Python function definition.                   |

Example: print all keyword-only arguments without default values:

```
>>> def foo(a, b, *, c, d=10):
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     if (param.kind == param.KEYWORD_ONLY and
...         param.default is param.empty):
...         print('Parameter:', param)
Parameter: c
```

**kind.description**

Describes a enum value of Parameter.kind.

Baru pada versi 3.8.

Example: print all descriptions of arguments:

```
>>> def foo(a, b, *, c, d=10):
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     print(param.kind.description)
positional or keyword
positional or keyword
keyword-only
keyword-only
```

**replace** (\*[, name][, kind][, default][, annotation])

Create a new Parameter instance based on the instance replaced was invoked on. To override a *Parameter* attribute, pass the corresponding argument. To remove a default value or/and an annotation from a Parameter, pass *Parameter.empty*.

```
>>> from inspect import Parameter
>>> param = Parameter('foo', Parameter.KEYWORD_ONLY, default=42)
>>> str(param)
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
'foo=42'

>>> str(param.replace()) # Will create a shallow copy of 'param'
'foo=42'

>>> str(param.replace(default=Parameter.empty, annotation='spam'))
"foo: 'spam'"
```

Berubah pada versi 3.4: In Python 3.3 Parameter objects were allowed to have name set to None if their kind was set to `POSITIONAL_ONLY`. This is no longer permitted.

### **class** `inspect.BoundArguments`

Result of a `Signature.bind()` or `Signature.bind_partial()` call. Holds the mapping of arguments to the function's parameters.

#### **arguments**

An ordered, mutable mapping (`collections.OrderedDict`) of parameters' names to arguments' values. Contains only explicitly bound arguments. Changes in `arguments` will reflect in `args` and `kwargs`.

Should be used in conjunction with `Signature.parameters` for any argument processing purposes.

---

**Catatan:** Arguments for which `Signature.bind()` or `Signature.bind_partial()` relied on a default value are skipped. However, if needed, use `BoundArguments.apply_defaults()` to add them.

---

#### **args**

A tuple of positional arguments values. Dynamically computed from the `arguments` attribute.

#### **kwargs**

A dict of keyword arguments values. Dynamically computed from the `arguments` attribute.

#### **signature**

A reference to the parent `Signature` object.

#### **apply\_defaults()**

Set default values for missing arguments.

For variable-positional arguments (`*args`) the default is an empty tuple.

For variable-keyword arguments (`**kwargs`) the default is an empty dict.

```
>>> def foo(a, b='ham', *args): pass
>>> ba = inspect.signature(foo).bind('spam')
>>> ba.apply_defaults()
>>> ba.arguments
OrderedDict([('a', 'spam'), ('b', 'ham'), ('args', ())])
```

Baru pada versi 3.5.

The `args` and `kwargs` properties can be used to invoke functions:

```
def test(a, *, b):
    ...

sig = signature(test)
ba = sig.bind(10, b=20)
test(*ba.args, **ba.kwargs)
```

Lihat juga:

**PEP 362 - Function Signature Object.** The detailed specification, implementation details and examples.

## 29.13.4 Classes and functions

`inspect.getclasstree(classes, unique=False)`

Arrange the given list of classes into a hierarchy of nested lists. Where a nested list appears, it contains classes derived from the class whose entry immediately precedes the list. Each entry is a 2-tuple containing a class and a tuple of its base classes. If the *unique* argument is true, exactly one entry appears in the returned structure for each class in the given list. Otherwise, classes using multiple inheritance and their descendants will appear multiple times.

`inspect.getargspec(func)`

Get the names and default values of a Python function's parameters. A *named tuple* `ArgSpec(args, varargs, keywords, defaults)` is returned. *args* is a list of the parameter names. *varargs* and *keywords* are the names of the \* and \*\* parameters or None. *defaults* is a tuple of default argument values or None if there are no default arguments; if this tuple has *n* elements, they correspond to the last *n* elements listed in *args*.

Ditinggalkan sejak versi 3.0: Use `getfullargspec()` for an updated API that is usually a drop-in replacement, but also correctly handles function annotations and keyword-only parameters.

Alternatively, use `signature()` and *Signature Object*, which provide a more structured introspection API for callables.

`inspect.getfullargspec(func)`

Get the names and default values of a Python function's parameters. A *named tuple* is returned:

```
FullArgSpec(args, varargs, varkw, defaults, kwonlyargs, kwonlydefaults,
            annotations)
```

*args* is a list of the positional parameter names. *varargs* is the name of the \* parameter or None if arbitrary positional arguments are not accepted. *varkw* is the name of the \*\* parameter or None if arbitrary keyword arguments are not accepted. *defaults* is an *n*-tuple of default argument values corresponding to the last *n* positional parameters, or None if there are no such defaults defined. *kwonlyargs* is a list of keyword-only parameter names in declaration order. *kwonlydefaults* is a dictionary mapping parameter names from *kwonlyargs* to the default values used if no argument is supplied. *annotations* is a dictionary mapping parameter names to annotations. The special key "return" is used to report the function return value annotation (if any).

Note that `signature()` and *Signature Object* provide the recommended API for callable introspection, and support additional behaviours (like positional-only arguments) that are sometimes encountered in extension module APIs. This function is retained primarily for use in code that needs to maintain compatibility with the Python 2 `inspect` module API.

Berubah pada versi 3.4: This function is now based on `signature()`, but still ignores `__wrapped__` attributes and includes the already bound first parameter in the signature output for bound methods.

Berubah pada versi 3.6: This method was previously documented as deprecated in favour of `signature()` in Python 3.5, but that decision has been reversed in order to restore a clearly supported standard interface for single-source Python 2/3 code migrating away from the legacy `getargspec()` API.

Berubah pada versi 3.7: Python only explicitly guaranteed that it preserved the declaration order of keyword-only parameters as of version 3.7, although in practice this order had always been preserved in Python 3.

`inspect.getargvalues(frame)`

Get information about arguments passed into a particular frame. A *named tuple* `ArgInfo(args, varargs, keywords, locals)` is returned. *args* is a list of the argument names. *varargs* and *keywords* are the names of the \* and \*\* arguments or None. *locals* is the locals dictionary of the given frame.

---

**Catatan:** This function was inadvertently marked as deprecated in Python 3.5.

---

`inspect.formatargspec` (*args*[, *varargs*, *varkw*, *defaults*, *kwoonlyargs*, *kwoonlydefaults*, *annotations*[, *formatarg*, *formatvarargs*, *formatvarkw*, *formatvalue*, *formatreturns*, *formatannotations*]])

Format a pretty argument spec from the values returned by `getfullargspec()`.

The first seven arguments are (*args*, *varargs*, *varkw*, *defaults*, *kwoonlyargs*, *kwoonlydefaults*, *annotations*).

The other six arguments are functions that are called to turn argument names, \* argument name, \*\* argument name, default values, return annotation and individual annotations into strings, respectively.

Sebagai contoh:

```
>>> from inspect import formatargspec, getfullargspec
>>> def f(a: int, b: float):
...     pass
...
>>> formatargspec(*getfullargspec(f))
'(a: int, b: float)'
```

Ditinggalkan sejak versi 3.5: Use `signature()` and *Signature Object*, which provide a better introspecting API for callables.

`inspect.formatargvalues` (*args*[, *varargs*, *varkw*, *locals*, *formatarg*, *formatvarargs*, *formatvarkw*, *formatvalue*])

Format a pretty argument spec from the four values returned by `getargvalues()`. The *format\** arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

---

**Catatan:** This function was inadvertently marked as deprecated in Python 3.5.

---

`inspect.getmro` (*cls*)

Return a tuple of class *cls*'s base classes, including *cls*, in method resolution order. No class appears more than once in this tuple. Note that the method resolution order depends on *cls*'s type. Unless a very peculiar user-defined metatype is in use, *cls* will be the first element of the tuple.

`inspect.getcallargs` (*func*, */*, *\*args*, *\*\*kwargs*)

Bind the *args* and *kwargs* to the argument names of the Python function or method *func*, as if it was called with them. For bound methods, bind also the first argument (typically named *self*) to the associated instance. A dict is returned, mapping the argument names (including the names of the \* and \*\* arguments, if any) to their values from *args* and *kwargs*. In case of invoking *func* incorrectly, i.e. whenever *func(\*args, \*\*kwargs)* would raise an exception because of incompatible signature, an exception of the same type and the same or similar message is raised. For example:

```
>>> from inspect import getcallargs
>>> def f(a, b=1, *pos, **named):
...     pass
...
>>> getcallargs(f, 1, 2, 3) == {'a': 1, 'named': {}, 'b': 2, 'pos': (3,)}
True
>>> getcallargs(f, a=2, x=4) == {'a': 2, 'named': {'x': 4}, 'b': 1, 'pos': ()}
True
>>> getcallargs(f)
Traceback (most recent call last):
...
TypeError: f() missing 1 required positional argument: 'a'
```

Baru pada versi 3.2.

Ditinggalkan sejak versi 3.5: Use `Signature.bind()` and `Signature.bind_partial()` instead.

`inspect.getclosurevars(func)`

Get the mapping of external name references in a Python function or method *func* to their current values. A *named tuple* `ClosureVars(nonlocals, globals, builtins, unbound)` is returned. *nonlocals* maps referenced names to lexical closure variables, *globals* to the function's module globals and *builtins* to the builtins visible from the function body. *unbound* is the set of names referenced in the function that could not be resolved at all given the current module globals and builtins.

`TypeError` is raised if *func* is not a Python function or method.

Baru pada versi 3.3.

`inspect.unwrap(func, *, stop=None)`

Get the object wrapped by *func*. It follows the chain of `__wrapped__` attributes returning the last object in the chain.

*stop* is an optional callback accepting an object in the wrapper chain as its sole argument that allows the unwrapping to be terminated early if the callback returns a true value. If the callback never returns a true value, the last object in the chain is returned as usual. For example, `signature()` uses this to stop unwrapping if any object in the chain has a `__signature__` attribute defined.

`ValueError` is raised if a cycle is encountered.

Baru pada versi 3.4.

### 29.13.5 The interpreter stack

When the following functions return "frame records," each record is a *named tuple* `FrameInfo(frame, filename, lineno, function, code_context, index)`. The tuple contains the frame object, the filename, the line number of the current line, the function name, a list of lines of context from the source code, and the index of the current line within that list.

Berubah pada versi 3.5: Return a named tuple instead of a tuple.

**Catatan:** Keeping references to frame objects, as found in the first element of the frame records these functions return, can cause your program to create reference cycles. Once a reference cycle has been created, the lifespan of all objects which can be accessed from the objects which form the cycle can become much longer even if Python's optional cycle detector is enabled. If such cycles must be created, it is important to ensure they are explicitly broken to avoid the delayed destruction of objects and increased memory consumption which occurs.

Though the cycle detector will catch these, destruction of the frames (and local variables) can be made deterministic by removing the cycle in a `finally` clause. This is also important if the cycle detector was disabled when Python was compiled or using `gc.disable()`. For example:

```
def handle_stackframe_without_leak():
    frame = inspect.currentframe()
    try:
        # do something with the frame
    finally:
        del frame
```

If you want to keep the frame around (for example to print a traceback later), you can also break reference cycles by using the `frame.clear()` method.

The optional *context* argument supported by most of these functions specifies the number of lines of context to return, which are centered around the current line.

`inspect.getframeinfo(frame, context=1)`

Get information about a frame or traceback object. A *named tuple* `Traceback(filename, lineno, function, code_context, index)` is returned.

`inspect.getouterframes(frame, context=1)`

Get a list of frame records for a frame and all outer frames. These frames represent the calls that lead to the creation of *frame*. The first entry in the returned list represents *frame*; the last entry represents the outermost call on *frame*'s stack.

Berubah pada versi 3.5: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

`inspect.getinnerframes(traceback, context=1)`

Get a list of frame records for a traceback's frame and all inner frames. These frames represent calls made as a consequence of *frame*. The first entry in the list represents *traceback*; the last entry represents where the exception was raised.

Berubah pada versi 3.5: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

`inspect.currentframe()`

Return the frame object for the caller's stack frame.

**CPython implementation detail:** This function relies on Python stack frame support in the interpreter, which isn't guaranteed to exist in all implementations of Python. If running in an implementation without Python stack frame support this function returns `None`.

`inspect.stack(context=1)`

Return a list of frame records for the caller's stack. The first entry in the returned list represents the caller; the last entry represents the outermost call on the stack.

Berubah pada versi 3.5: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

`inspect.trace(context=1)`

Return a list of frame records for the stack between the current frame and the frame in which an exception currently being handled was raised in. The first entry in the list represents the caller; the last entry represents where the exception was raised.

Berubah pada versi 3.5: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

### 29.13.6 Fetching attributes statically

Both `getattr()` and `hasattr()` can trigger code execution when fetching or checking for the existence of attributes. Descriptors, like properties, will be invoked and `__getattr__()` and `__getattribute__()` may be called.

For cases where you want passive introspection, like documentation tools, this can be inconvenient. `getattr_static()` has the same signature as `getattr()` but avoids executing code when it fetches attributes.

`inspect.getattr_static(obj, attr, default=None)`

Retrieve attributes without triggering dynamic lookup via the descriptor protocol, `__getattr__()` or `__getattribute__()`.

Note: this function may not be able to retrieve all attributes that `getattr` can fetch (like dynamically created attributes) and may find attributes that `getattr` can't (like descriptors that raise `AttributeError`). It can also return descriptors objects instead of instance members.

If the instance `__dict__` is shadowed by another member (for example a property) then this function will be unable to find instance members.

Baru pada versi 3.2.

`getattr_static()` does not resolve descriptors, for example slot descriptors or getset descriptors on objects implemented in C. The descriptor object is returned instead of the underlying attribute.

You can handle these with code like the following. Note that for arbitrary getset descriptors invoking these may trigger code execution:

```
# example code for resolving the builtin descriptor types
class _foo:
    __slots__ = ['foo']

slot_descriptor = type(_foo.foo)
getset_descriptor = type(type(open(__file__)).name)
wrapper_descriptor = type(str.__dict__['__add__'])
descriptor_types = (slot_descriptor, getset_descriptor, wrapper_descriptor)

result = getattr_static(some_object, 'foo')
if type(result) in descriptor_types:
    try:
        result = result.__get__()
    except AttributeError:
        # descriptors can raise AttributeError to
        # indicate there is no underlying value
        # in which case the descriptor itself will
        # have to do
        pass
```

## 29.13.7 Current State of Generators and Coroutines

When implementing coroutine schedulers and for other advanced uses of generators, it is useful to determine whether a generator is currently executing, is waiting to start or resume or execution, or has already terminated. `getgeneratorstate()` allows the current state of a generator to be determined easily.

`inspect.getgeneratorstate(generator)`

Get current state of a generator-iterator.

**Possible states are:**

- `GEN_CREATED`: Waiting to start execution.
- `GEN_RUNNING`: Currently being executed by the interpreter.
- `GEN_SUSPENDED`: Currently suspended at a yield expression.
- `GEN_CLOSED`: Execution has completed.

Baru pada versi 3.2.

`inspect.getcoroutinestate(coroutine)`

Get current state of a coroutine object. The function is intended to be used with coroutine objects created by `async def` functions, but will accept any coroutine-like object that has `cr_running` and `cr_frame` attributes.

**Possible states are:**

- `CORO_CREATED`: Waiting to start execution.
- `CORO_RUNNING`: Currently being executed by the interpreter.
- `CORO_SUSPENDED`: Currently suspended at an await expression.
- `CORO_CLOSED`: Execution has completed.

Baru pada versi 3.5.

The current internal state of the generator can also be queried. This is mostly useful for testing purposes, to ensure that internal state is being updated as expected:

`inspect.getgeneratorlocals(generator)`

Get the mapping of live local variables in *generator* to their current values. A dictionary is returned that maps from variable names to values. This is the equivalent of calling `locals()` in the body of the generator, and all the same caveats apply.

If *generator* is a *generator* with no currently associated frame, then an empty dictionary is returned. `TypeError` is raised if *generator* is not a Python generator object.

**CPython implementation detail:** This function relies on the generator exposing a Python stack frame for introspection, which isn't guaranteed to be the case in all implementations of Python. In such cases, this function will always return an empty dictionary.

Baru pada versi 3.3.

`inspect.getcoroutinelocals(coroutine)`

This function is analogous to `getgeneratorlocals()`, but works for coroutine objects created by `async def` functions.

Baru pada versi 3.5.

## 29.13.8 Code Objects Bit Flags

Python code objects have a `co_flags` attribute, which is a bitmap of the following flags:

`inspect.CO_OPTIMIZED`

The code object is optimized, using fast locals.

`inspect.CO_NEWLOCALS`

If set, a new dict will be created for the frame's `f_locals` when the code object is executed.

`inspect.CO_VARARGS`

The code object has a variable positional parameter (\*args-like).

`inspect.CO_VARKEYWORDS`

The code object has a variable keyword parameter (\*\*kwargs-like).

`inspect.CO_NESTED`

The flag is set when the code object is a nested function.

`inspect.CO_GENERATOR`

The flag is set when the code object is a generator function, i.e. a generator object is returned when the code object is executed.

`inspect.CO_NOFREE`

The flag is set if there are no free or cell variables.

`inspect.CO_COROUTINE`

The flag is set when the code object is a coroutine function. When the code object is executed it returns a coroutine object. See [PEP 492](#) for more details.

Baru pada versi 3.5.

`inspect.CO_ITERABLE_COROUTINE`

The flag is used to transform generators into generator-based coroutines. Generator objects with this flag can be used in `await` expression, and can `yield` from coroutine objects. See [PEP 492](#) for more details.

Baru pada versi 3.5.

`inspect.CO_ASYNC_GENERATOR`

The flag is set when the code object is an asynchronous generator function. When the code object is executed it returns an asynchronous generator object. See [PEP 525](#) for more details.

Baru pada versi 3.6.

---

**Catatan:** The flags are specific to CPython, and may not be defined in other Python implementations. Furthermore, the flags are an implementation detail, and can be removed or deprecated in future Python releases. It's recommended to use public APIs from the `inspect` module for any introspection needs.

---

### 29.13.9 Command Line Interface

The `inspect` module also provides a basic introspection capability from the command line.

By default, accepts the name of a module and prints the source of that module. A class or function within the module can be printed instead by appended a colon and the qualified name of the target object.

**--details**

Print information about the specified object rather than the source code

## 29.14 `site` --- Site-specific configuration hook

**Source code:** `Lib/site.py`

---

**This module is automatically imported during initialization.** The automatic import can be suppressed using the interpreter's `-S` option.

Importing this module will append site-specific paths to the module search path and add a few builtins, unless `-S` was used. In that case, this module can be safely imported with no automatic modifications to the module search path or additions to the builtins. To explicitly trigger the usual site-specific additions, call the `site.main()` function.

Berubah pada versi 3.3: Importing the module used to trigger paths manipulation even when using `-S`.

It starts by constructing up to four directories from a head and a tail part. For the head part, it uses `sys.prefix` and `sys.exec_prefix`; empty heads are skipped. For the tail part, it uses the empty string and then `lib/site-packages` (on Windows) or `lib/pythonX.Y/site-packages` (on Unix and Macintosh). For each of the distinct head-tail combinations, it sees if it refers to an existing directory, and if so, adds it to `sys.path` and also inspects the newly added path for configuration files.

Berubah pada versi 3.5: Support for the "site-python" directory has been removed.

If a file named "pyvenv.cfg" exists one directory above `sys.executable`, `sys.prefix` and `sys.exec_prefix` are set to that directory and it is also checked for site-packages (`sys.base_prefix` and `sys.base_exec_prefix` will always be the "real" prefixes of the Python installation). If "pyvenv.cfg" (a bootstrap configuration file) contains the key "include-system-site-packages" set to anything other than "true" (case-insensitive), the system-level prefixes will not be searched for site-packages; otherwise they will.

A path configuration file is a file whose name has the form `name.pth` and exists in one of the four directories mentioned above; its contents are additional items (one per line) to be added to `sys.path`. Non-existing items are never added to `sys.path`, and no check is made that the item refers to a directory rather than a file. No item is added to `sys.path` more than once. Blank lines and lines beginning with `#` are skipped. Lines starting with `import` (followed by space or tab) are executed.

---

**Catatan:** An executable line in a `.pth` file is run at every Python startup, regardless of whether a particular module is actually going to be used. Its impact should thus be kept to a minimum. The primary intended purpose of executable lines is to make the corresponding module(s) importable (load 3rd-party import hooks, adjust `PATH` etc). Any other initialization is supposed to be done upon a module's actual import, if and when it happens. Limiting a code chunk to a single line is a deliberate measure to discourage putting anything more complex here.

---

For example, suppose `sys.prefix` and `sys.exec_prefix` are set to `/usr/local`. The Python `X.Y` library is then installed in `/usr/local/lib/pythonX.Y`. Suppose this has a subdirectory `/usr/local/lib/pythonX.Y/site-packages` with three subsubdirectories, `foo`, `bar` and `spam`, and two path configuration files, `foo.pth` and `bar.pth`. Assume `foo.pth` contains the following:

```
# foo package configuration

foo
bar
bletch
```

and `bar.pth` contains:

```
# bar package configuration

bar
```

Then the following version-specific directories are added to `sys.path`, in this order:

```
/usr/local/lib/pythonX.Y/site-packages/bar
/usr/local/lib/pythonX.Y/site-packages/foo
```

Note that `bletch` is omitted because it doesn't exist; the `bar` directory precedes the `foo` directory because `bar.pth` comes alphabetically before `foo.pth`; and `spam` is omitted because it is not mentioned in either path configuration file.

After these path manipulations, an attempt is made to import a module named `sitecustomize`, which can perform arbitrary site-specific customizations. It is typically created by a system administrator in the `site-packages` directory. If this import fails with an `ImportError` or its subclass exception, and the exception's `name` attribute equals to `'sitecustomize'`, it is silently ignored. If Python is started without output streams available, as with `pythonw.exe` on Windows (which is used by default to start IDLE), attempted output from `sitecustomize` is ignored. Any other exception causes a silent and perhaps mysterious failure of the process.

After this, an attempt is made to import a module named `usercustomize`, which can perform arbitrary user-specific customizations, if `ENABLE_USER_SITE` is true. This file is intended to be created in the user `site-packages` directory (see below), which is part of `sys.path` unless disabled by `-s`. If this import fails with an `ImportError` or its subclass exception, and the exception's `name` attribute equals to `'usercustomize'`, it is silently ignored.

Note that for some non-Unix systems, `sys.prefix` and `sys.exec_prefix` are empty, and the path manipulations are skipped; however the import of `sitecustomize` and `usercustomize` is still attempted.

### 29.14.1 Readline configuration

On systems that support *readline*, this module will also import and configure the *rlcompleter* module, if Python is started in interactive mode and without the `-S` option. The default behavior is enable tab-completion and to use `~/.python_history` as the history save file. To disable it, delete (or override) the `sys.__interactivehook__` attribute in your `sitecustomize` or `usercustomize` module or your `PYTHONSTARTUP` file.

Berubah pada versi 3.4: Activation of *rlcompleter* and history was made automatic.

### 29.14.2 Module contents

#### `site.PREFIXES`

A list of prefixes for site-packages directories.

#### `site.ENABLE_USER_SITE`

Flag showing the status of the user site-packages directory. True means that it is enabled and was added to `sys.path`. False means that it was disabled by user request (with `-s` or `PYTHONNOUSERSITE`). None means it was disabled for security reasons (mismatch between user or group id and effective id) or by an administrator.

#### `site.USER_SITE`

Path to the user site-packages for the running Python. Can be None if `getusersitepackages()` hasn't been called yet. Default value is `~/.local/lib/pythonX.Y/site-packages` for UNIX and non-framework Mac OS X builds, `~/Library/Python/X.Y/lib/python/site-packages` for Mac framework builds, and `%APPDATA%\Python\PythonXY\site-packages` on Windows. This directory is a site directory, which means that `.pth` files in it will be processed.

#### `site.USER_BASE`

Path to the base directory for the user site-packages. Can be None if `getuserbase()` hasn't been called yet. Default value is `~/.local` for UNIX and Mac OS X non-framework builds, `~/Library/Python/X.Y` for Mac framework builds, and `%APPDATA%\Python` for Windows. This value is used by Distutils to compute the installation directories for scripts, data files, Python modules, etc. for the user installation scheme. See also `PYTHONUSERBASE`.

#### `site.main()`

Adds all the standard site-specific directories to the module search path. This function is called automatically when this module is imported, unless the Python interpreter was started with the `-S` flag.

Berubah pada versi 3.3: This function used to be called unconditionally.

#### `site.addsitedir(sitedir, known_paths=None)`

Add a directory to `sys.path` and process its `.pth` files. Typically used in `sitecustomize` or `usercustomize` (see above).

#### `site.getsitepackages()`

Return a list containing all global site-packages directories.

Baru pada versi 3.2.

#### `site.getuserbase()`

Return the path of the user base directory, `USER_BASE`. If it is not initialized yet, this function will also set it, respecting `PYTHONUSERBASE`.

Baru pada versi 3.2.

#### `site.getusersitepackages()`

Return the path of the user-specific site-packages directory, `USER_SITE`. If it is not initialized yet, this function will also set it, respecting `USER_BASE`. To determine if the user-specific site-packages was added to `sys.path` `ENABLE_USER_SITE` should be used.

Baru pada versi 3.2.

### 29.14.3 Command Line Interface

The `site` module also provides a way to get the user directories from the command line:

```
$ python3 -m site --user-site
/home/user/.local/lib/python3.3/site-packages
```

If it is called without arguments, it will print the contents of `sys.path` on the standard output, followed by the value of `USER_BASE` and whether the directory exists, then the same thing for `USER_SITE`, and finally the value of `ENABLE_USER_SITE`.

#### **--user-base**

Print the path to the user base directory.

#### **--user-site**

Print the path to the user site-packages directory.

If both options are given, user base and user site will be printed (always in this order), separated by `os.pathsep`.

If any option is given, the script will exit with one of these values: 0 if the user site-packages directory is enabled, 1 if it was disabled by the user, 2 if it is disabled for security reasons or by an administrator, and a value greater than 2 if there is an error.

#### **Lihat juga:**

**PEP 370** -- Per user site-packages directory

---

## Ubahsuaian Interpreter Python

---

Modul yang dijelaskan dalam bab ini memungkinkan antarmuka penulisan yang mirip dengan interpreter interaktif Python. Jika Anda menginginkan interpreter Python yang mendukung beberapa fitur khusus selain bahasa Python, Anda harus melihat pada modul `code`. (Modul `codeop` adalah level yang lebih rendah, digunakan untuk mendukung kompilasi sebagian kode Python yang mungkin tidak lengkap.)

Daftar lengkap modul yang dijelaskan dalam bab ini adalah:

### 30.1 `code` --- Interpreter base classes

Source code: [Lib/code.py](#)

---

The `code` module provides facilities to implement read-eval-print loops in Python. Two classes and convenience functions are included which can be used to build applications which provide an interactive interpreter prompt.

**class** `code.InteractiveInterpreter` (*locals=None*)

This class deals with parsing and interpreter state (the user's namespace); it does not deal with input buffering or prompting or input file naming (the filename is always passed in explicitly). The optional *locals* argument specifies the dictionary in which code will be executed; it defaults to a newly created dictionary with key '`__name__`' set to '`__console__`' and key '`__doc__`' set to `None`.

**class** `code.InteractiveConsole` (*locals=None, filename="<console>"*)

Closely emulate the behavior of the interactive Python interpreter. This class builds on `InteractiveInterpreter` and adds prompting using the familiar `sys.ps1` and `sys.ps2`, and input buffering.

`code.interact` (*banner=None, readfunc=None, local=None, exitmsg=None*)

Convenience function to run a read-eval-print loop. This creates a new instance of `InteractiveConsole` and sets *readfunc* to be used as the `InteractiveConsole.raw_input()` method, if provided. If *local* is provided, it is passed to the `InteractiveConsole` constructor for use as the default namespace for the interpreter loop. The `interact()` method of the instance is then run with *banner* and *exitmsg* passed as the banner and exit message to use, if provided. The console object is discarded after use.

Berubah pada versi 3.6: Added *exitmsg* parameter.

`code.compile_command(source, filename=<input>, symbol=<single>)`

This function is useful for programs that want to emulate Python's interpreter main loop (a.k.a. the read-eval-print loop). The tricky part is to determine when the user has entered an incomplete command that can be completed by entering more text (as opposed to a complete command or a syntax error). This function *almost* always makes the same decision as the real interpreter main loop.

*source* is the source string; *filename* is the optional filename from which source was read, defaulting to '<input>'; and *symbol* is the optional grammar start symbol, which should be 'single' (the default), 'eval' or 'exec'.

Returns a code object (the same as `compile(source, filename, symbol)`) if the command is complete and valid; None if the command is incomplete; raises *SyntaxError* if the command is complete and contains a syntax error, or raises *OverflowError* or *ValueError* if the command contains an invalid literal.

### 30.1.1 Interactive Interpreter Objects

`InteractiveInterpreter.runsource(source, filename=<input>, symbol=<single>)`

Compile and run some source in the interpreter. Arguments are the same as for `compile_command()`; the default for *filename* is '<input>', and for *symbol* is 'single'. One of several things can happen:

- The input is incorrect; `compile_command()` raised an exception (*SyntaxError* or *OverflowError*). A syntax traceback will be printed by calling the `showsyntaxerror()` method. `runsource()` returns False.
- The input is incomplete, and more input is required; `compile_command()` returned None. `runsource()` returns True.
- The input is complete; `compile_command()` returned a code object. The code is executed by calling the `runcode()` (which also handles run-time exceptions, except for *SystemExit*). `runsource()` returns False.

The return value can be used to decide whether to use `sys.ps1` or `sys.ps2` to prompt the next line.

`InteractiveInterpreter.runcode(code)`

Execute a code object. When an exception occurs, `showtraceback()` is called to display a traceback. All exceptions are caught except *SystemExit*, which is allowed to propagate.

A note about *KeyboardInterrupt*: this exception may occur elsewhere in this code, and may not always be caught. The caller should be prepared to deal with it.

`InteractiveInterpreter.showsyntaxerror(filename=None)`

Display the syntax error that just occurred. This does not display a stack trace because there isn't one for syntax errors. If *filename* is given, it is stuffed into the exception instead of the default filename provided by Python's parser, because it always uses '<string>' when reading from a string. The output is written by the `write()` method.

`InteractiveInterpreter.showtraceback()`

Display the exception that just occurred. We remove the first stack item because it is within the interpreter object implementation. The output is written by the `write()` method.

Berubah pada versi 3.5: The full chained traceback is displayed instead of just the primary traceback.

`InteractiveInterpreter.write(data)`

Write a string to the standard error stream (`sys.stderr`). Derived classes should override this to provide the appropriate output handling as needed.

### 30.1.2 Interactive Console Objects

The `InteractiveConsole` class is a subclass of `InteractiveInterpreter`, and so offers all the methods of the interpreter objects as well as the following additions.

`InteractiveConsole.interact` (*banner=None*, *exitmsg=None*)

Closely emulate the interactive Python console. The optional *banner* argument specifies the banner to print before the first interaction; by default it prints a banner similar to the one printed by the standard Python interpreter, followed by the class name of the console object in parentheses (so as not to confuse this with the real interpreter -- since it's so close!).

The optional *exitmsg* argument specifies an exit message printed when exiting. Pass the empty string to suppress the exit message. If *exitmsg* is not given or `None`, a default message is printed.

Berubah pada versi 3.4: To suppress printing any banner, pass an empty string.

Berubah pada versi 3.6: Print an exit message when exiting.

`InteractiveConsole.push` (*line*)

Push a line of source text to the interpreter. The line should not have a trailing newline; it may have internal newlines. The line is appended to a buffer and the interpreter's `runsource()` method is called with the concatenated contents of the buffer as source. If this indicates that the command was executed or invalid, the buffer is reset; otherwise, the command is incomplete, and the buffer is left as it was after the line was appended. The return value is `True` if more input is required, `False` if the line was dealt with in some way (this is the same as `runsource()`).

`InteractiveConsole.resetbuffer` ()

Remove any unhandled source text from the input buffer.

`InteractiveConsole.raw_input` (*prompt=""*)

Write a prompt and read a line. The returned line does not include the trailing newline. When the user enters the EOF key sequence, `EOFError` is raised. The base implementation reads from `sys.stdin`; a subclass may replace this with a different implementation.

## 30.2 codeop --- Compile Python code

Source code: `Lib/codeop.py`

The `codeop` module provides utilities upon which the Python read-eval-print loop can be emulated, as is done in the `code` module. As a result, you probably don't want to use the module directly; if you want to include such a loop in your program you probably want to use the `code` module instead.

There are two parts to this job:

1. Being able to tell if a line of input completes a Python statement: in short, telling whether to print `'>>>'` or `'...'` next.
2. Remembering which future statements the user has entered, so subsequent input can be compiled with these in effect.

The `codeop` module provides a way of doing each of these things, and a way of doing them both.

To do just the former:

`codeop.compile_command` (*source*, *filename="<input>"*, *symbol="single"*)

Tries to compile *source*, which should be a string of Python code and return a code object if *source* is valid Python code. In that case, the *filename* attribute of the code object will be *filename*, which defaults to `'<input>'`. Returns `None` if *source* is not valid Python code, but is a prefix of valid Python code.

If there is a problem with *source*, an exception will be raised. *SyntaxError* is raised if there is invalid Python syntax, and *OverflowError* or *ValueError* if there is an invalid literal.

The *symbol* argument determines whether *source* is compiled as a statement ('single', the default), as a sequence of statements ('exec') or as an *expression* ('eval'). Any other value will cause *ValueError* to be raised.

---

**Catatan:** It is possible (but not likely) that the parser stops parsing with a successful outcome before reaching the end of the source; in this case, trailing symbols may be ignored instead of causing an error. For example, a backslash followed by two newlines may be followed by arbitrary garbage. This will be fixed once the API for the parser is better.

---

### **class** codeop.Compile

Instances of this class have `__call__()` methods identical in signature to the built-in function `compile()`, but with the difference that if the instance compiles program text containing a `__future__` statement, the instance 'remembers' and compiles all subsequent program texts with the statement in force.

### **class** codeop.CommandCompiler

Instances of this class have `__call__()` methods identical in signature to `compile_command()`; the difference is that if the instance compiles program text containing a `__future__` statement, the instance 'remembers' and compiles all subsequent program texts with the statement in force.

---

Mengimpor Modul

---

Modul yang dijelaskan dalam bab ini memberikan cara baru untuk mengimpor modul Python dan kait lainnya untuk menyesuaikan proses impor.

Daftar lengkap modul yang dijelaskan dalam bab ini adalah:

## 31.1 `zipimport` --- Import modules from Zip archives

**Source code:** [Lib/zipimport.py](#)

---

This module adds the ability to import Python modules (`*.py`, `*.pyc`) and packages from ZIP-format archives. It is usually not needed to use the `zipimport` module explicitly; it is automatically used by the built-in `import` mechanism for `sys.path` items that are paths to ZIP archives.

Typically, `sys.path` is a list of directory names as strings. This module also allows an item of `sys.path` to be a string naming a ZIP file archive. The ZIP archive can contain a subdirectory structure to support package imports, and a path within the archive can be specified to only import from a subdirectory. For example, the path `example.zip/lib/` would only import from the `lib/` subdirectory within the archive.

Any files may be present in the ZIP archive, but only files `.py` and `.pyc` are available for import. ZIP import of dynamic modules (`.pyd`, `.so`) is disallowed. Note that if an archive only contains `.py` files, Python will not attempt to modify the archive by adding the corresponding `.pyc` file, meaning that if a ZIP archive doesn't contain `.pyc` files, importing may be rather slow.

Berubah pada versi 3.8: Previously, ZIP archives with an archive comment were not supported.

**Lihat juga:**

**PKZIP Application Note** Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

**PEP 273 - Import Modules from Zip Archives** Written by James C. Ahlstrom, who also provided an implementation. Python 2.3 follows the specification in **PEP 273**, but uses an implementation written by Just van Rossum that uses the import hooks described in **PEP 302**.

**PEP 302 - New Import Hooks** The PEP to add the import hooks that help this module work.

This module defines an exception:

**exception** `zipimport.ZipImportError`

Exception raised by zipimporter objects. It's a subclass of `ImportError`, so it can be caught as `ImportError`, too.

### 31.1.1 zipimporter Objects

`zipimporter` is the class for importing ZIP files.

**class** `zipimport.zipimporter` (*archivepath*)

Create a new zipimporter instance. *archivepath* must be a path to a ZIP file, or to a specific path within a ZIP file. For example, an *archivepath* of `foo/bar.zip/lib` will look for modules in the `lib` directory inside the ZIP file `foo/bar.zip` (provided that it exists).

`ZipImportError` is raised if *archivepath* doesn't point to a valid ZIP archive.

**find\_module** (*fullname* [, *path*])

Search for a module specified by *fullname*. *fullname* must be the fully qualified (dotted) module name. It returns the zipimporter instance itself if the module was found, or `None` if it wasn't. The optional *path* argument is ignored---it's there for compatibility with the importer protocol.

**get\_code** (*fullname*)

Return the code object for the specified module. Raise `ZipImportError` if the module couldn't be found.

**get\_data** (*pathname*)

Return the data associated with *pathname*. Raise `OSError` if the file wasn't found.

Berubah pada versi 3.3: `IOError` used to be raised instead of `OSError`.

**get\_filename** (*fullname*)

Return the value `__file__` would be set to if the specified module was imported. Raise `ZipImportError` if the module couldn't be found.

Baru pada versi 3.1.

**get\_source** (*fullname*)

Return the source code for the specified module. Raise `ZipImportError` if the module couldn't be found, return `None` if the archive does contain the module, but has no source for it.

**is\_package** (*fullname*)

Return True if the module specified by *fullname* is a package. Raise `ZipImportError` if the module couldn't be found.

**load\_module** (*fullname*)

Load the module specified by *fullname*. *fullname* must be the fully qualified (dotted) module name. It returns the imported module, or raises `ZipImportError` if it wasn't found.

**archive**

The file name of the importer's associated ZIP file, without a possible subpath.

**prefix**

The subpath within the ZIP file where modules are searched. This is the empty string for zipimporter objects which point to the root of the ZIP file.

The *archive* and *prefix* attributes, when combined with a slash, equal the original *archivepath* argument given to the `zipimporter` constructor.

### 31.1.2 Contoh-contoh

Here is an example that imports a module from a ZIP archive - note that the `zipimport` module is not explicitly used.

```
$ unzip -l example.zip
Archive:  example.zip
  Length      Date    Time    Name
-----
  8467      11-26-02  22:30    jwzthreading.py
-----
  8467
                  1 file
$ ./python
Python 2.3 (#1, Aug 1 2003, 19:54:32)
>>> import sys
>>> sys.path.insert(0, 'example.zip') # Add .zip file to front of path
>>> import jwzthreading
>>> jwzthreading.__file__
'example.zip/jwzthreading.py'
```

## 31.2 pkgutil --- Package extension utility

Source code: [Lib/pkgutil.py](#)

This module provides utilities for the import system, in particular package support.

**class** `pkgutil.ModuleInfo` (*module\_finder, name, ispkg*)  
A namedtuple that holds a brief summary of a module's info.

Baru pada versi 3.6.

`pkgutil.extend_path` (*path, name*)

Extend the search path for the modules which comprise a package. Intended use is to place the following code in a package's `__init__.py`:

```
from pkgutil import extend_path
__path__ = extend_path(__path__, __name__)
```

This will add to the package's `__path__` all subdirectories of directories on `sys.path` named after the package. This is useful if one wants to distribute different parts of a single logical package as multiple directories.

It also looks for `*.pkg` files beginning where `*` matches the *name* argument. This feature is similar to `*.pth` files (see the [site](#) module for more information), except that it doesn't special-case lines starting with `import`. A `*.pkg` file is trusted at face value: apart from checking for duplicates, all entries found in a `*.pkg` file are added to the path, regardless of whether they exist on the filesystem. (This is a feature.)

If the input path is not a list (as is the case for frozen packages) it is returned unchanged. The input path is not modified; an extended copy is returned. Items are only appended to the copy at the end.

It is assumed that `sys.path` is a sequence. Items of `sys.path` that are not strings referring to existing directories are ignored. Unicode items on `sys.path` that cause errors when used as filenames may cause this function to raise an exception (in line with `os.path.isdir()` behavior).

**class** `pkgutil.ImpImporter` (*dirname=None*)  
**PEP 302** Finder that wraps Python's "classic" import algorithm.

If *dirname* is a string, a **PEP 302** finder is created that searches that directory. If *dirname* is `None`, a **PEP 302** finder is created that searches the current `sys.path`, plus any modules that are frozen or built-in.

Note that `ImpImporter` does not currently support being used by placement on `sys.meta_path`.

Ditinggalkan sejak versi 3.3: This emulation is no longer needed, as the standard import mechanism is now fully **PEP 302** compliant and available in `importlib`.

**class** `pkgutil.ImpLoader` (*fullname*, *file*, *filename*, *etc*)  
*Loader* that wraps Python's "classic" import algorithm.

Ditinggalkan sejak versi 3.3: This emulation is no longer needed, as the standard import mechanism is now fully **PEP 302** compliant and available in `importlib`.

`pkgutil.find_loader` (*fullname*)  
Retrieve a module *loader* for the given *fullname*.

This is a backwards compatibility wrapper around `importlib.util.find_spec()` that converts most failures to `ImportError` and only returns the loader rather than the full `ModuleSpec`.

Berubah pada versi 3.3: Updated to be based directly on `importlib` rather than relying on the package internal **PEP 302** import emulation.

Berubah pada versi 3.4: Updated to be based on **PEP 451**

`pkgutil.get_importer` (*path\_item*)  
Retrieve a *finder* for the given *path\_item*.

The returned finder is cached in `sys.path_importer_cache` if it was newly created by a path hook.

The cache (or part of it) can be cleared manually if a rescan of `sys.path_hooks` is necessary.

Berubah pada versi 3.3: Updated to be based directly on `importlib` rather than relying on the package internal **PEP 302** import emulation.

`pkgutil.get_loader` (*module\_or\_name*)  
Get a *loader* object for *module\_or\_name*.

If the module or package is accessible via the normal import mechanism, a wrapper around the relevant part of that machinery is returned. Returns `None` if the module cannot be found or imported. If the named module is not already imported, its containing package (if any) is imported, in order to establish the package `__path__`.

Berubah pada versi 3.3: Updated to be based directly on `importlib` rather than relying on the package internal **PEP 302** import emulation.

Berubah pada versi 3.4: Updated to be based on **PEP 451**

`pkgutil.iter_importers` (*fullname*=")  
Yield *finder* objects for the given module name.

If *fullname* contains a `'.`, the finders will be for the package containing *fullname*, otherwise they will be all registered top level finders (i.e. those on both `sys.meta_path` and `sys.path_hooks`).

If the named module is in a package, that package is imported as a side effect of invoking this function.

If no module name is specified, all top level finders are produced.

Berubah pada versi 3.3: Updated to be based directly on `importlib` rather than relying on the package internal **PEP 302** import emulation.

`pkgutil.iter_modules` (*path*=`None`, *prefix*=")  
Yields *ModuleInfo* for all submodules on *path*, or, if *path* is `None`, all top-level modules on `sys.path`.

*path* should be either `None` or a list of paths to look for modules in.

*prefix* is a string to output on the front of every module name on output.

---

**Catatan:** Only works for a *finder* which defines an `iter_modules()` method. This interface is non-standard, so the module also provides implementations for `importlib.machinery.FileFinder` and `zipimport.zipimporter`.

---

Berubah pada versi 3.3: Updated to be based directly on `importlib` rather than relying on the package internal **PEP 302** import emulation.

`pkgutil.walk_packages(path=None, prefix="", onerror=None)`

Yields `ModuleInfo` for all modules recursively on `path`, or, if `path` is `None`, all accessible modules.

`path` should be either `None` or a list of paths to look for modules in.

`prefix` is a string to output on the front of every module name on output.

Note that this function must import all *packages* (not all modules!) on the given `path`, in order to access the `__path__` attribute to find submodules.

`onerror` is a function which gets called with one argument (the name of the package which was being imported) if any exception occurs while trying to import a package. If no `onerror` function is supplied, `ImportErrors` are caught and ignored, while all other exceptions are propagated, terminating the search.

Contoh:

```
# list all modules python can access
walk_packages()

# list all submodules of ctypes
walk_packages(ctypes.__path__, ctypes.__name__ + '.')

```

---

**Catatan:** Only works for a *finder* which defines an `iter_modules()` method. This interface is non-standard, so the module also provides implementations for `importlib.machinery.FileFinder` and `zipimport.zipimporter`.

---

Berubah pada versi 3.3: Updated to be based directly on `importlib` rather than relying on the package internal **PEP 302** import emulation.

`pkgutil.get_data(package, resource)`

Get a resource from a package.

This is a wrapper for the *loader* `get_data` API. The `package` argument should be the name of a package, in standard module format (`foo.bar`). The `resource` argument should be in the form of a relative filename, using `/` as the path separator. The parent directory name `..` is not allowed, and nor is a rooted name (starting with a `/`).

The function returns a binary string that is the contents of the specified resource.

For packages located in the filesystem, which have already been imported, this is the rough equivalent of:

```
d = os.path.dirname(sys.modules[package].__file__)
data = open(os.path.join(d, resource), 'rb').read()

```

If the package cannot be located or loaded, or it uses a *loader* which does not support `get_data`, then `None` is returned. In particular, the *loader* for *namespace packages* does not support `get_data`.

## 31.3 modulefinder --- Find modules used by a script

Source code: [Lib/modulefinder.py](#)

---

This module provides a `ModuleFinder` class that can be used to determine the set of modules imported by a script. `modulefinder.py` can also be run as a script, giving the filename of a Python script as its argument, after which a report of the imported modules will be printed.

`modulefinder.AddPackagePath(pkg_name, path)`

Record that the package named *pkg\_name* can be found in the specified *path*.

`modulefinder.ReplacePackage(oldname, newname)`

Allows specifying that the module named *oldname* is in fact the package named *newname*.

**class** `modulefinder.ModuleFinder` (*path=None, debug=0, excludes=[], replace\_paths=[]*)

This class provides `run_script()` and `report()` methods to determine the set of modules imported by a script. *path* can be a list of directories to search for modules; if not specified, `sys.path` is used. *debug* sets the debugging level; higher values make the class print debugging messages about what it's doing. *excludes* is a list of module names to exclude from the analysis. *replace\_paths* is a list of (*oldpath*, *newpath*) tuples that will be replaced in module paths.

**report** ()

Print a report to standard output that lists the modules imported by the script and their paths, as well as modules that are missing or seem to be missing.

**run\_script** (*pathname*)

Analyze the contents of the *pathname* file, which must contain Python code.

**modules**

A dictionary mapping module names to modules. See [Example usage of ModuleFinder](#).

### 31.3.1 Example usage of ModuleFinder

The script that is going to get analyzed later on (`bacon.py`):

```
import re, itertools

try:
    import baconhammeggs
except ImportError:
    pass

try:
    import guido.python.ham
except ImportError:
    pass
```

The script that will output the report of `bacon.py`:

```
from modulefinder import ModuleFinder

finder = ModuleFinder()
finder.run_script('bacon.py')

print('Loaded modules:')
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

for name, mod in finder.modules.items():
    print('%s: ' % name, end='')
    print(', '.join(list(mod.globalnames.keys())[:3]))

print('-'*50)
print('Modules not imported:')
print('\n'.join(finder.badmodules.keys()))

```

Sample output (may vary depending on the architecture):

```

Loaded modules:
_types:
copyreg:  _inverted_registry, _slotnames, __all__
sre_compile:  isstring, _sre, _optimize_unicode
_sre:
sre_constants:  REPEAT_ONE, makedict, AT_END_LINE
sys:
re:  __module__, finditer, _expand
itertools:
__main__:  re, itertools, baconhammeggs
sre_parse:  _PATTERNENDERS, SRE_FLAG_UNICODE
array:
types:  __module__, IntType, TypeType
-----
Modules not imported:
guido.python.ham
baconhammeggs

```

## 31.4 runpy --- Locating and executing Python modules

Source code: [Lib/runpy.py](#)

The `runpy` module is used to locate and run Python modules without importing them first. Its main use is to implement the `-m` command line switch that allows scripts to be located using the Python module namespace rather than the filesystem.

Note that this is *not* a sandbox module - all code is executed in the current process, and any side effects (such as cached imports of other modules) will remain in place after the functions have returned.

Furthermore, any functions and classes defined by the executed code are not guaranteed to work correctly after a `runpy` function has returned. If that limitation is not acceptable for a given use case, `importlib` is likely to be a more suitable choice than this module.

The `runpy` module provides two functions:

`runpy.run_module(mod_name, init_globals=None, run_name=None, alter_sys=False)`

Execute the code of the specified module and return the resulting module globals dictionary. The module's code is first located using the standard import mechanism (refer to [PEP 302](#) for details) and then executed in a fresh module namespace.

The `mod_name` argument should be an absolute module name. If the module name refers to a package rather than a normal module, then that package is imported and the `__main__` submodule within that package is then executed and the resulting module globals dictionary returned.

The optional dictionary argument `init_globals` may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by `run_module()`.

The special global variables `__name__`, `__spec__`, `__file__`, `__cached__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

`__name__` is set to `run_name` if this optional argument is not `None`, to `mod_name + '.__main__'` if the named module is a package and to the `mod_name` argument otherwise.

`__spec__` will be set appropriately for the *actually* imported module (that is, `__spec__.name` will always be `mod_name` or `mod_name + '.__main__'`, never `run_name`).

`__file__`, `__cached__`, `__loader__` and `__package__` are set as normal based on the module spec.

If the argument `alter_sys` is supplied and evaluates to `True`, then `sys.argv[0]` is updated with the value of `__file__` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. Both `sys.argv[0]` and `sys.modules[__name__]` are restored to their original values before the function returns.

Note that this manipulation of `sys` is not thread-safe. Other threads may see the partially initialised module, as well as the altered list of arguments. It is recommended that the `sys` module be left alone when invoking this function from threaded code.

#### Lihat juga:

The `-m` option offering equivalent functionality from the command line.

Berubah pada versi 3.1: Added ability to execute packages by looking for a `__main__` submodule.

Berubah pada versi 3.2: Added `__cached__` global variable (see [PEP 3147](#)).

Berubah pada versi 3.4: Updated to take advantage of the module spec feature added by [PEP 451](#). This allows `__cached__` to be set correctly for modules run this way, as well as ensuring the real module name is always accessible as `__spec__.name`.

`runpy.run_path(file_path, init_globals=None, run_name=None)`

Execute the code at the named filesystem location and return the resulting module globals dictionary. As with a script name supplied to the CPython command line, the supplied path may refer to a Python source file, a compiled bytecode file or a valid `sys.path` entry containing a `__main__` module (e.g. a zipfile containing a top-level `__main__.py` file).

For a simple script, the specified code is simply executed in a fresh module namespace. For a valid `sys.path` entry (typically a zipfile or directory), the entry is first added to the beginning of `sys.path`. The function then looks for and executes a `__main__` module using the updated path. Note that there is no special protection against invoking an existing `__main__` entry located elsewhere on `sys.path` if there is no such module at the specified location.

The optional dictionary argument `init_globals` may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by `run_path()`.

The special global variables `__name__`, `__spec__`, `__file__`, `__cached__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

`__name__` is set to `run_name` if this optional argument is not `None` and to `'<run_path>'` otherwise.

If the supplied path directly references a script file (whether as source or as precompiled byte code), then `__file__` will be set to the supplied path, and `__spec__`, `__cached__`, `__loader__` and `__package__` will all be set to `None`.

If the supplied path is a reference to a valid `sys.path` entry, then `__spec__` will be set appropriately for the imported `__main__` module (that is, `__spec__.name` will always be `__main__`). `__file__`, `__cached__`, `__loader__` and `__package__` will be set as normal based on the module spec.

A number of alterations are also made to the `sys` module. Firstly, `sys.path` may be altered as described above. `sys.argv[0]` is updated with the value of `file_path` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. All modifications to items in `sys` are reverted before the function returns.

Note that, unlike `run_module()`, the alterations made to `sys` are not optional in this function as these adjustments are essential to allowing the execution of `sys.path` entries. As the thread-safety limitations still apply, use of this function in threaded code should be either serialised with the import lock or delegated to a separate process.

using-on-general - CPython command line details

The `importlib.import_module()` function

## 31.5 importlib --- The implementation of import

Baru pada versi 3.1.

**Source code:** `Lib/importlib/__init__.py`

---

### 31.5.1 Pengenalan

The purpose of the `importlib` package is two-fold. One is to provide the implementation of the `import` statement (and thus, by extension, the `__import__()` function) in Python source code. This provides an implementation of `import` which is portable to any Python interpreter. This also provides an implementation which is easier to comprehend than one implemented in a programming language other than Python.

Two, the components to implement `import` are exposed in this package, making it easier for users to create their own custom objects (known generically as an *importer*) to participate in the import process.

**Lihat juga:**

**import** The language reference for the `import` statement.

**Packages specification** Original specification of packages. Some semantics have changed since the writing of this document (e.g. redirecting based on `None` in `sys.modules`).

**The `__import__()` function** The `import` statement is syntactic sugar for this function.

### 31.5.2 Fungsi-Fungsi

`importlib.__import__(name, globals=None, locals=None, fromlist=(), level=0)`  
An implementation of the built-in `__import__()` function.

---

**Catatan:** Programmatic importing of modules should use `import_module()` instead of this function.

---

`importlib.import_module(name, package=None)`  
Import a module. The *name* argument specifies what module to import in absolute or relative terms (e.g. either `pkg.mod` or `..mod`). If the name is specified in relative terms, then the *package* argument must be set to the name of the package which is to act as the anchor for resolving the package name (e.g. `import_module('..mod', 'pkg.subpkg')` will import `pkg.mod`).

The `import_module()` function acts as a simplifying wrapper around `importlib.__import__()`. This means all semantics of the function are derived from `importlib.__import__()`. The most important difference between these two functions is that `import_module()` returns the specified package or module (e.g. `pkg.mod`), while `__import__()` returns the top-level package or module (e.g. `pkg`).

If you are dynamically importing a module that was created since the interpreter began execution (e.g., created a Python source file), you may need to call `invalidate_caches()` in order for the new module to be noticed by the import system.

Berubah pada versi 3.3: Parent packages are automatically imported.

`importlib.find_loader(name, path=None)`  
Find the loader for a module, optionally within the specified *path*. If the module is in `sys.modules`, then `sys.modules[name].__loader__` is returned (unless the loader would be `None` or is not set, in which case `ValueError` is raised). Otherwise a search using `sys.meta_path` is done. `None` is returned if no loader is found.

A dotted name does not have its parents implicitly imported as that requires loading them and that may not be desired. To properly import a submodule you will need to import all parent packages of the submodule and use the correct argument to *path*.

Baru pada versi 3.3.

Berubah pada versi 3.4: If `__loader__` is not set, raise `ValueError`, just like when the attribute is set to `None`.

Ditinggalkan sejak versi 3.4: Use `importlib.util.find_spec()` instead.

`importlib.invalidate_caches()`

Invalidate the internal caches of finders stored at `sys.meta_path`. If a finder implements `invalidate_caches()` then it will be called to perform the invalidation. This function should be called if any modules are created/installed while your program is running to guarantee all finders will notice the new module's existence.

Baru pada versi 3.3.

`importlib.reload(module)`

Reload a previously imported *module*. The argument must be a module object, so it must have been successfully imported before. This is useful if you have edited the module source file using an external editor and want to try out the new version without leaving the Python interpreter. The return value is the module object (which can be different if re-importing causes a different object to be placed in `sys.modules`).

When `reload()` is executed:

- Python module's code is recompiled and the module-level code re-executed, defining a new set of objects which are bound to names in the module's dictionary by reusing the *loader* which originally loaded the module. The `init` function of extension modules is not called a second time.
- As with all other objects in Python the old objects are only reclaimed after their reference counts drop to zero.
- The names in the module namespace are updated to point to any new or changed objects.
- Other references to the old objects (such as names external to the module) are not rebound to refer to the new objects and must be updated in each namespace where they occur if that is desired.

There are a number of other caveats:

When a module is reloaded, its dictionary (containing the module's global variables) is retained. Redefinitions of names will override the old definitions, so this is generally not a problem. If the new version of a module does not define a name that was defined by the old version, the old definition remains. This feature can be used to the module's advantage if it maintains a global table or cache of objects --- with a `try` statement it can test for the table's presence and skip its initialization if desired:

```
try:
    cache
except NameError:
    cache = {}
```

It is generally not very useful to reload built-in or dynamically loaded modules. Reloading `sys`, `__main__`, `builtins` and other key modules is not recommended. In many cases extension modules are not designed to be initialized more than once, and may fail in arbitrary ways when reloaded.

If a module imports objects from another module using `from ... import ...`, calling `reload()` for the other module does not redefine the objects imported from it --- one way around this is to re-execute the `from` statement, another is to use `import` and qualified names (*module.name*) instead.

If a module instantiates instances of a class, reloading the module that defines the class does not affect the method definitions of the instances --- they continue to use the old class definition. The same is true for derived classes.

Baru pada versi 3.4.

Berubah pada versi 3.7: `ModuleNotFoundError` is raised when the module being reloaded lacks a `ModuleSpec`.

### 31.5.3 `importlib.abc` -- Abstract base classes related to import

Source code: [Lib/importlib/abc.py](#)

---

The `importlib.abc` module contains all of the core abstract base classes used by `import`. Some subclasses of the core abstract base classes are also provided to help in implementing the core ABCs.

ABC hierarchy:

```
object
+-- Finder (deprecated)
|   +-- MetaPathFinder
|   +-- PathEntryFinder
+-- Loader
    +-- ResourceLoader -----+
    +-- InspectLoader          |
        +-- ExecutionLoader --+
                                +-- FileLoader
                                +-- SourceLoader
```

**class** `importlib.abc.Finder`

An abstract base class representing a *finder*.

Ditinggalkan sejak versi 3.3: Use `MetaPathFinder` or `PathEntryFinder` instead.

**abstractmethod** `find_module` (*fullname*, *path=None*)

An abstract method for finding a *loader* for the specified module. Originally specified in **PEP 302**, this method was meant for use in `sys.meta_path` and in the path-based import subsystem.

Berubah pada versi 3.4: Returns `None` when called instead of raising `NotImplementedError`.

**class** `importlib.abc.MetaPathFinder`

An abstract base class representing a *meta path finder*. For compatibility, this is a subclass of `Finder`.

Baru pada versi 3.3.

**find\_spec** (*fullname*, *path*, *target=None*)

An abstract method for finding a *spec* for the specified module. If this is a top-level import, *path* will be `None`. Otherwise, this is a search for a subpackage or module and *path* will be the value of `__path__` from the parent package. If a spec cannot be found, `None` is returned. When passed in, *target* is a module object that the finder may use to make a more educated guess about what spec to return. `importlib.util.spec_from_loader()` may be useful for implementing concrete `MetaPathFinders`.

Baru pada versi 3.4.

**find\_module** (*fullname*, *path*)

A legacy method for finding a *loader* for the specified module. If this is a top-level import, *path* will be `None`. Otherwise, this is a search for a subpackage or module and *path* will be the value of `__path__` from the parent package. If a loader cannot be found, `None` is returned.

If `find_spec()` is defined, backwards-compatible functionality is provided.

Berubah pada versi 3.4: Returns `None` when called instead of raising `NotImplementedError`. Can use `find_spec()` to provide functionality.

Ditinggalkan sejak versi 3.4: Use `find_spec()` instead.

**invalidate\_caches** ()

An optional method which, when called, should invalidate any internal cache used by the finder. Used

by `importlib.invalidate_caches()` when invalidating the caches of all finders on `sys.meta_path`.

Berubah pada versi 3.4: Returns `None` when called instead of `NotImplemented`.

#### **class** `importlib.abc.PathEntryFinder`

An abstract base class representing a *path entry finder*. Though it bears some similarities to *MetaPathFinder*, `PathEntryFinder` is meant for use only within the path-based import subsystem provided by `PathFinder`. This ABC is a subclass of *Finder* for compatibility reasons only.

Baru pada versi 3.3.

#### **find\_spec** (*fullname*, *target=None*)

An abstract method for finding a *spec* for the specified module. The finder will search for the module only within the *path entry* to which it is assigned. If a spec cannot be found, `None` is returned. When passed in, *target* is a module object that the finder may use to make a more educated guess about what spec to return. `importlib.util.spec_from_loader()` may be useful for implementing concrete `PathEntryFinders`.

Baru pada versi 3.4.

#### **find\_loader** (*fullname*)

A legacy method for finding a *loader* for the specified module. Returns a 2-tuple of (*loader*, *portion*) where *portion* is a sequence of file system locations contributing to part of a namespace package. The loader may be `None` while specifying *portion* to signify the contribution of the file system locations to a namespace package. An empty list can be used for *portion* to signify the loader is not part of a namespace package. If loader is `None` and *portion* is the empty list then no loader or location for a namespace package were found (i.e. failure to find anything for the module).

If `find_spec()` is defined then backwards-compatible functionality is provided.

Berubah pada versi 3.4: Returns `(None, [])` instead of raising `NotImplementedError`. Uses `find_spec()` when available to provide functionality.

Ditinggalkan sejak versi 3.4: Use `find_spec()` instead.

#### **find\_module** (*fullname*)

A concrete implementation of `Finder.find_module()` which is equivalent to `self.find_loader(fullname)[0]`.

Ditinggalkan sejak versi 3.4: Use `find_spec()` instead.

#### **invalidate\_caches** ()

An optional method which, when called, should invalidate any internal cache used by the finder. Used by `PathFinder.invalidate_caches()` when invalidating the caches of all cached finders.

#### **class** `importlib.abc.Loader`

An abstract base class for a *loader*. See **PEP 302** for the exact definition for a loader.

Loaders that wish to support resource reading should implement a `get_resource_reader(fullname)` method as specified by `importlib.abc.ResourceReader`.

Berubah pada versi 3.7: Introduced the optional `get_resource_reader()` method.

#### **create\_module** (*spec*)

A method that returns the module object to use when importing a module. This method may return `None`, indicating that default module creation semantics should take place.

Baru pada versi 3.4.

Berubah pada versi 3.5: Starting in Python 3.6, this method will not be optional when `exec_module()` is defined.

**exec\_module (module)**

An abstract method that executes the module in its own namespace when a module is imported or reloaded. The module should already be initialized when `exec_module()` is called. When this method exists, `create_module()` must be defined.

Baru pada versi 3.4.

Berubah pada versi 3.6: `create_module()` must also be defined.

**load\_module (fullname)**

A legacy method for loading a module. If the module cannot be loaded, `ImportError` is raised, otherwise the loaded module is returned.

If the requested module already exists in `sys.modules`, that module should be used and reloaded. Otherwise the loader should create a new module and insert it into `sys.modules` before any loading begins, to prevent recursion from the import. If the loader inserted a module and the load fails, it must be removed by the loader from `sys.modules`; modules already in `sys.modules` before the loader began execution should be left alone (see `importlib.util.module_for_loader()`).

The loader should set several attributes on the module. (Note that some of these attributes can change when a module is reloaded):

- **\_\_name\_\_** The name of the module.
- **\_\_file\_\_** The path to where the module data is stored (not set for built-in modules).
- **\_\_cached\_\_** The path to where a compiled version of the module is/should be stored (not set when the attribute would be inappropriate).
- **\_\_path\_\_** A list of strings specifying the search path within a package. This attribute is not set on modules.
- **\_\_package\_\_** The fully-qualified name of the package under which the module was loaded as a submodule (or the empty string for top-level modules). For packages, it is the same as `__name__`. The `importlib.util.module_for_loader()` decorator can handle the details for `__package__`.
- **\_\_loader\_\_** The loader used to load the module. The `importlib.util.module_for_loader()` decorator can handle the details for `__package__`.

When `exec_module()` is available then backwards-compatible functionality is provided.

Berubah pada versi 3.4: Raise `ImportError` when called instead of `NotImplementedError`. Functionality provided when `exec_module()` is available.

Ditinggalkan sejak versi 3.4: The recommended API for loading a module is `exec_module()` (and `create_module()`). Loaders should implement it instead of `load_module()`. The import machinery takes care of all the other responsibilities of `load_module()` when `exec_module()` is implemented.

**module\_repr (module)**

A legacy method which when implemented calculates and returns the given module's repr, as a string. The module type's default `repr()` will use the result of this method as appropriate.

Baru pada versi 3.3.

Berubah pada versi 3.4: Made optional instead of an abstractmethod.

Ditinggalkan sejak versi 3.4: The import machinery now takes care of this automatically.

**class importlib.abc.ResourceReader**

An *abstract base class* to provide the ability to read *resources*.

From the perspective of this ABC, a *resource* is a binary artifact that is shipped within a package. Typically this is something like a data file that lives next to the `__init__.py` file of the package. The purpose of this class is

to help abstract out the accessing of such data files so that it does not matter if the package and its data file(s) are stored in a e.g. zip file versus on the file system.

For any of methods of this class, a *resource* argument is expected to be a *path-like object* which represents conceptually just a file name. This means that no subdirectory paths should be included in the *resource* argument. This is because the location of the package the reader is for, acts as the "directory". Hence the metaphor for directories and file names is packages and resources, respectively. This is also why instances of this class are expected to directly correlate to a specific package (instead of potentially representing multiple packages or a module).

Loaders that wish to support resource reading are expected to provide a method called `get_resource_reader(fullname)` which returns an object implementing this ABC's interface. If the module specified by `fullname` is not a package, this method should return `None`. An object compatible with this ABC should only be returned when the specified module is a package.

Baru pada versi 3.7.

**abstractmethod** `open_resource(resource)`

Returns an opened, *file-like object* for binary reading of the *resource*.

If the resource cannot be found, `FileNotFoundError` is raised.

**abstractmethod** `resource_path(resource)`

Returns the file system path to the *resource*.

If the resource does not concretely exist on the file system, raise `FileNotFoundError`.

**abstractmethod** `is_resource(name)`

Returns `True` if the named *name* is considered a resource. `FileNotFoundError` is raised if *name* does not exist.

**abstractmethod** `contents()`

Returns an *iterable* of strings over the contents of the package. Do note that it is not required that all names returned by the iterator be actual resources, e.g. it is acceptable to return names for which `is_resource()` would be false.

Allowing non-resource names to be returned is to allow for situations where how a package and its resources are stored are known a priori and the non-resource names would be useful. For instance, returning subdirectory names is allowed so that when it is known that the package and resources are stored on the file system then those subdirectory names can be used directly.

The abstract method returns an iterable of no items.

**class** `importlib.abc.ResourceLoader`

An abstract base class for a *loader* which implements the optional **PEP 302** protocol for loading arbitrary resources from the storage back-end.

Ditinggalkan sejak versi 3.7: This ABC is deprecated in favour of supporting resource loading through `importlib.abc.ResourceReader`.

**abstractmethod** `get_data(path)`

An abstract method to return the bytes for the data located at *path*. Loaders that have a file-like storage back-end that allows storing arbitrary data can implement this abstract method to give direct access to the data stored. `OSError` is to be raised if the *path* cannot be found. The *path* is expected to be constructed using a module's `__file__` attribute or an item from a package's `__path__`.

Berubah pada versi 3.4: Raises `OSError` instead of `NotImplementedError`.

**class** `importlib.abc.InspectLoader`

An abstract base class for a *loader* which implements the optional **PEP 302** protocol for loaders that inspect modules.

**get\_code** (*fullname*)

Return the code object for a module, or `None` if the module does not have a code object (as would be the case, for example, for a built-in module). Raise an `ImportError` if loader cannot find the requested module.

---

**Catatan:** While the method has a default implementation, it is suggested that it be overridden if possible for performance.

---

Berubah pada versi 3.4: No longer abstract and a concrete implementation is provided.

**abstractmethod get\_source** (*fullname*)

An abstract method to return the source of a module. It is returned as a text string using *universal newlines*, translating all recognized line separators into `'\n'` characters. Returns `None` if no source is available (e.g. a built-in module). Raises `ImportError` if the loader cannot find the module specified.

Berubah pada versi 3.4: Raises `ImportError` instead of `NotImplementedError`.

**is\_package** (*fullname*)

An abstract method to return a true value if the module is a package, a false value otherwise. `ImportError` is raised if the *loader* cannot find the module.

Berubah pada versi 3.4: Raises `ImportError` instead of `NotImplementedError`.

**static source\_to\_code** (*data*, *path*=`'<string>'`)

Create a code object from Python source.

The *data* argument can be whatever the `compile()` function supports (i.e. string or bytes). The *path* argument should be the "path" to where the source code originated from, which can be an abstract concept (e.g. location in a zip file).

With the subsequent code object one can execute it in a module by running `exec(code, module.__dict__)`.

Baru pada versi 3.4.

Berubah pada versi 3.5: Made the method static.

**exec\_module** (*module*)

Implementation of `Loader.exec_module()`.

Baru pada versi 3.4.

**load\_module** (*fullname*)

Implementation of `Loader.load_module()`.

Ditinggalkan sejak versi 3.4: use `exec_module()` instead.

**class** `importlib.abc.ExecutionLoader`

An abstract base class which inherits from `InspectLoader` that, when implemented, helps a module to be executed as a script. The ABC represents an optional **PEP 302** protocol.

**abstractmethod get\_filename** (*fullname*)

An abstract method that is to return the value of `__file__` for the specified module. If no path is available, `ImportError` is raised.

If source code is available, then the method should return the path to the source file, regardless of whether a bytecode was used to load the module.

Berubah pada versi 3.4: Raises `ImportError` instead of `NotImplementedError`.

**class** `importlib.abc.FileLoader` (*fullname*, *path*)

An abstract base class which inherits from `ResourceLoader` and `ExecutionLoader`, providing concrete implementations of `ResourceLoader.get_data()` and `ExecutionLoader.get_filename()`.

The *fullname* argument is a fully resolved name of the module the loader is to handle. The *path* argument is the path to the file for the module.

Baru pada versi 3.3.

**name**

The name of the module the loader can handle.

**path**

Path to the file of the module.

**load\_module** (*fullname*)

Calls super's `load_module()`.

Ditinggalkan sejak versi 3.4: Use `Loader.exec_module()` instead.

**abstractmethod** `get_filename` (*fullname*)

Returns *path*.

**abstractmethod** `get_data` (*path*)

Reads *path* as a binary file and returns the bytes from it.

**class** `importlib.abc.SourceLoader`

An abstract base class for implementing source (and optionally bytecode) file loading. The class inherits from both `ResourceLoader` and `ExecutionLoader`, requiring the implementation of:

- `ResourceLoader.get_data()`
- `ExecutionLoader.get_filename()` Should only return the path to the source file; sourceless loading is not supported.

The abstract methods defined by this class are to add optional bytecode file support. Not implementing these optional methods (or causing them to raise `NotImplementedError`) causes the loader to only work with source code. Implementing the methods allows the loader to work with source *and* bytecode files; it does not allow for *sourceless* loading where only bytecode is provided. Bytecode files are an optimization to speed up loading by removing the parsing step of Python's compiler, and so no bytecode-specific API is exposed.

**path\_stats** (*path*)

Optional abstract method which returns a *dict* containing metadata about the specified path. Supported dictionary keys are:

- 'mtime' (mandatory): an integer or floating-point number representing the modification time of the source code;
- 'size' (optional): the size in bytes of the source code.

Any other keys in the dictionary are ignored, to allow for future extensions. If the path cannot be handled, `OSError` is raised.

Baru pada versi 3.3.

Berubah pada versi 3.4: Raise `OSError` instead of `NotImplementedError`.

**path\_mtime** (*path*)

Optional abstract method which returns the modification time for the specified path.

Ditinggalkan sejak versi 3.3: This method is deprecated in favour of `path_stats()`. You don't have to implement it, but it is still available for compatibility purposes. Raise `OSError` if the path cannot be handled.

Berubah pada versi 3.4: Raise `OSError` instead of `NotImplementedError`.

**set\_data** (*path*, *data*)

Optional abstract method which writes the specified bytes to a file path. Any intermediate directories which do not exist are to be created automatically.

When writing to the path fails because the path is read-only (*errno.EACCES/PermissionError*), do not propagate the exception.

Berubah pada versi 3.4: No longer raises *NotImplementedError* when called.

**get\_code** (*fullname*)

Concrete implementation of *InspectLoader.get\_code()*.

**exec\_module** (*module*)

Concrete implementation of *Loader.exec\_module()*.

Baru pada versi 3.4.

**load\_module** (*fullname*)

Concrete implementation of *Loader.load\_module()*.

Ditinggalkan sejak versi 3.4: Use *exec\_module()* instead.

**get\_source** (*fullname*)

Concrete implementation of *InspectLoader.get\_source()*.

**is\_package** (*fullname*)

Concrete implementation of *InspectLoader.is\_package()*. A module is determined to be a package if its file path (as provided by *ExecutionLoader.get\_filename()*) is a file named `__init__` when the file extension is removed **and** the module name itself does not end in `__init__`.

## 31.5.4 `importlib.resources` -- Resources

Source code: [Lib/importlib/resources.py](#)

---

Baru pada versi 3.7.

This module leverages Python's import system to provide access to *resources* within *packages*. If you can import a package, you can access resources within that package. Resources can be opened or read, in either binary or text mode.

Resources are roughly akin to files inside directories, though it's important to keep in mind that this is just a metaphor. Resources and packages **do not** have to exist as physical files and directories on the file system.

---

**Catatan:** This module provides functionality similar to [pkg\\_resources Basic Resource Access](#) without the performance overhead of that package. This makes reading resources included in packages easier, with more stable and consistent semantics.

The standalone backport of this module provides more information on [using importlib.resources](#) and [migrating from pkg\\_resources to importlib.resources](#).

---

Loaders that wish to support resource reading should implement a `get_resource_reader(fullname)` method as specified by [importlib.abc.ResourceReader](#).

The following types are defined.

`importlib.resources.Package`

The `Package` type is defined as `Union[str, ModuleType]`. This means that where the function describes accepting a `Package`, you can pass in either a string or a module. Module objects must have a resolvable `__spec__.submodule_search_locations` that is not `None`.

`importlib.resources.Resource`

This type describes the resource names passed into the various functions in this package. This is defined as `Union[str, os.PathLike]`.

The following functions are available.

`importlib.resources.open_binary(package, resource)`

Open for binary reading the *resource* within *package*.

*package* is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory). This function returns a `typing.BinaryIO` instance, a binary I/O stream open for reading.

`importlib.resources.open_text(package, resource, encoding='utf-8', errors='strict')`

Open for text reading the *resource* within *package*. By default, the resource is opened for reading as UTF-8.

*package* is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory). *encoding* and *errors* have the same meaning as with built-in `open()`.

This function returns a `typing.TextIO` instance, a text I/O stream open for reading.

`importlib.resources.read_binary(package, resource)`

Read and return the contents of the *resource* within *package* as `bytes`.

*package* is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory). This function returns the contents of the resource as `bytes`.

`importlib.resources.read_text(package, resource, encoding='utf-8', errors='strict')`

Read and return the contents of *resource* within *package* as a `str`. By default, the contents are read as strict UTF-8.

*package* is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory). *encoding* and *errors* have the same meaning as with built-in `open()`. This function returns the contents of the resource as `str`.

`importlib.resources.path(package, resource)`

Return the path to the *resource* as an actual file system path. This function returns a context manager for use in a `with` statement. The context manager provides a `pathlib.Path` object.

Exiting the context manager cleans up any temporary file created when the resource needs to be extracted from e.g. a zip file.

*package* is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory).

`importlib.resources.is_resource(package, name)`

Return `True` if there is a resource named *name* in the package, otherwise `False`. Remember that directories are *not* resources! *package* is either a name or a module object which conforms to the `Package` requirements.

`importlib.resources.contents(package)`

Return an iterable over the named items within the package. The iterable returns `str` resources (e.g. files) and non-resources (e.g. directories). The iterable does not recurse into subdirectories.

*package* is either a name or a module object which conforms to the `Package` requirements.

### 31.5.5 `importlib.machinery` -- Importers and path hooks

Source code: [Lib/importlib/machinery.py](#)

---

This module contains the various objects that help `import` find and load modules.

`importlib.machinery.SOURCE_SUFFIXES`

A list of strings representing the recognized file suffixes for source modules.

Baru pada versi 3.3.

`importlib.machinery.DEBUG_BYTECODE_SUFFIXES`

A list of strings representing the file suffixes for non-optimized bytecode modules.

Baru pada versi 3.3.

Ditinggalkan sejak versi 3.5: Use `BYTECODE_SUFFIXES` instead.

`importlib.machinery.OPTIMIZED_BYTECODE_SUFFIXES`

A list of strings representing the file suffixes for optimized bytecode modules.

Baru pada versi 3.3.

Ditinggalkan sejak versi 3.5: Use `BYTECODE_SUFFIXES` instead.

`importlib.machinery.BYTECODE_SUFFIXES`

A list of strings representing the recognized file suffixes for bytecode modules (including the leading dot).

Baru pada versi 3.3.

Berubah pada versi 3.5: The value is no longer dependent on `__debug__`.

`importlib.machinery.EXTENSION_SUFFIXES`

A list of strings representing the recognized file suffixes for extension modules.

Baru pada versi 3.3.

`importlib.machinery.all_suffixes()`

Returns a combined list of strings representing all file suffixes for modules recognized by the standard import machinery. This is a helper for code which simply needs to know if a filesystem path potentially refers to a module without needing any details on the kind of module (for example, `inspect.getmodulename()`).

Baru pada versi 3.3.

**class** `importlib.machinery.BuiltinImporter`

An *importer* for built-in modules. All known built-in modules are listed in `sys.builtin_module_names`. This class implements the `importlib.abc.MetaPathFinder` and `importlib.abc.InspectLoader` ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

Berubah pada versi 3.5: As part of [PEP 489](#), the builtin importer now implements `Loader.create_module()` and `Loader.exec_module()`

**class** `importlib.machinery.FrozenImporter`

An *importer* for frozen modules. This class implements the `importlib.abc.MetaPathFinder` and `importlib.abc.InspectLoader` ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

Berubah pada versi 3.4: Gained `create_module()` and `exec_module()` methods.

**class** `importlib.machinery.WindowsRegistryFinder`

*Finder* for modules declared in the Windows registry. This class implements the `importlib.abc.MetaPathFinder` ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

Baru pada versi 3.3.

Ditinggalkan sejak versi 3.6: Use `site` configuration instead. Future versions of Python may not enable this finder by default.

**class** `importlib.machinery.PathFinder`

A *Finder* for `sys.path` and package `__path__` attributes. This class implements the `importlib.abc.MetaPathFinder` ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

**classmethod** `find_spec(fullname, path=None, target=None)`

Class method that attempts to find a *spec* for the module specified by *fullname* on `sys.path` or, if defined, on *path*. For each path entry that is searched, `sys.path_importer_cache` is checked. If a non-false object is found then it is used as the *path entry finder* to look for the module being searched for. If no entry is found in `sys.path_importer_cache`, then `sys.path_hooks` is searched for a finder for the path entry and, if found, is stored in `sys.path_importer_cache` along with being queried about the module. If no finder is ever found then `None` is both stored in the cache and returned.

Baru pada versi 3.4.

Berubah pada versi 3.5: If the current working directory -- represented by an empty string -- is no longer valid then `None` is returned but no value is cached in `sys.path_importer_cache`.

**classmethod** `find_module(fullname, path=None)`

A legacy wrapper around `find_spec()`.

Ditinggalkan sejak versi 3.4: Use `find_spec()` instead.

**classmethod** `invalidate_caches()`

Calls `importlib.abc.PathEntryFinder.invalidate_caches()` on all finders stored in `sys.path_importer_cache` that define the method. Otherwise entries in `sys.path_importer_cache` set to `None` are deleted.

Berubah pada versi 3.7: Entries of `None` in `sys.path_importer_cache` are deleted.

Berubah pada versi 3.4: Calls objects in `sys.path_hooks` with the current working directory for `' '` (i.e. the empty string).

**class** `importlib.machinery.FileFinder(path, *loader_details)`

A concrete implementation of `importlib.abc.PathEntryFinder` which caches results from the file system.

The *path* argument is the directory for which the finder is in charge of searching.

The *loader\_details* argument is a variable number of 2-item tuples each containing a loader and a sequence of file suffixes the loader recognizes. The loaders are expected to be callables which accept two arguments of the module's name and the path to the file found.

The finder will cache the directory contents as necessary, making stat calls for each module search to verify the cache is not outdated. Because cache staleness relies upon the granularity of the operating system's state information of the file system, there is a potential race condition of searching for a module, creating a new file, and then searching for the module the new file represents. If the operations happen fast enough to fit within the granularity of stat calls, then the module search will fail. To prevent this from happening, when you create a module dynamically, make sure to call `importlib.invalidate_caches()`.

Baru pada versi 3.3.

**path**

The path the finder will search in.

**find\_spec** (*fullname*, *target=None*)

Attempt to find the spec to handle *fullname* within *path*.

Baru pada versi 3.4.

**find\_loader** (*fullname*)

Attempt to find the loader to handle *fullname* within *path*.

**invalidate\_caches** ()

Clear out the internal cache.

**classmethod path\_hook** (\**loader\_details*)

A class method which returns a closure for use on `sys.path_hooks`. An instance of `FileFinder` is returned by the closure using the *path* argument given to the closure directly and *loader\_details* indirectly.

If the argument to the closure is not an existing directory, `ImportError` is raised.

**class** `importlib.machinery.SourceFileLoader` (*fullname*, *path*)

A concrete implementation of `importlib.abc.SourceLoader` by subclassing `importlib.abc.FileLoader` and providing some concrete implementations of other methods.

Baru pada versi 3.3.

**name**

The name of the module that this loader will handle.

**path**

The path to the source file.

**is\_package** (*fullname*)

Return True if *path* appears to be for a package.

**path\_stats** (*path*)

Concrete implementation of `importlib.abc.SourceLoader.path_stats()`.

**set\_data** (*path*, *data*)

Concrete implementation of `importlib.abc.SourceLoader.set_data()`.

**load\_module** (*name=None*)

Concrete implementation of `importlib.abc.Loader.load_module()` where specifying the name of the module to load is optional.

Ditinggalkan sejak versi 3.6: Use `importlib.abc.Loader.exec_module()` instead.

**class** `importlib.machinery.SourcelessFileLoader` (*fullname*, *path*)

A concrete implementation of `importlib.abc.FileLoader` which can import bytecode files (i.e. no source code files exist).

Please note that direct use of bytecode files (and thus not source code files) inhibits your modules from being usable by all Python implementations or new versions of Python which change the bytecode format.

Baru pada versi 3.3.

**name**

The name of the module the loader will handle.

**path**

The path to the bytecode file.

**is\_package** (*fullname*)

Determines if the module is a package based on *path*.

**get\_code** (*fullname*)

Returns the code object for *name* created from *path*.

**get\_source** (*fullname*)

Returns None as bytecode files have no source when this loader is used.

**load\_module** (*name=None*)

Concrete implementation of `importlib.abc.Loader.load_module()` where specifying the name of the module to load is optional.

Ditinggalkan sejak versi 3.6: Use `importlib.abc.Loader.exec_module()` instead.

**class** `importlib.machinery.ExtensionFileLoader` (*fullname, path*)

A concrete implementation of `importlib.abc.ExecutionLoader` for extension modules.

The *fullname* argument specifies the name of the module the loader is to support. The *path* argument is the path to the extension module's file.

Baru pada versi 3.3.

**name**

Name of the module the loader supports.

**path**

Path to the extension module.

**create\_module** (*spec*)

Creates the module object from the given specification in accordance with [PEP 489](#).

Baru pada versi 3.5.

**exec\_module** (*module*)

Initializes the given module object in accordance with [PEP 489](#).

Baru pada versi 3.5.

**is\_package** (*fullname*)

Returns True if the file path points to a package's `__init__` module based on `EXTENSION_SUFFIXES`.

**get\_code** (*fullname*)

Returns None as extension modules lack a code object.

**get\_source** (*fullname*)

Returns None as extension modules do not have source code.

**get\_filename** (*fullname*)

Returns *path*.

Baru pada versi 3.4.

**class** `importlib.machinery.ModuleSpec` (*name, loader, \*, origin=None, loader\_state=None, is\_package=None*)

A specification for a module's import-system-related state. This is typically exposed as the module's `__spec__` attribute. In the descriptions below, the names in parentheses give the corresponding attribute available directly on the module object. E.g. `module.__spec__.origin == module.__file__`. Note however that while the *values* are usually equivalent, they can differ since there is no synchronization between the two objects. Thus it is possible to update the module's `__path__` at runtime, and this will not be automatically reflected in `__spec__.submodule_search_locations`.

Baru pada versi 3.4.

**name**

`(__name__)`

A string for the fully-qualified name of the module.

**loader**

`(__loader__)`

The *Loader* that should be used when loading the module. *Finders* should always set this.

**origin**

`(__file__)`

Name of the place from which the module is loaded, e.g. "builtin" for built-in modules and the filename for modules loaded from source. Normally "origin" should be set, but it may be `None` (the default) which indicates it is unspecified (e.g. for namespace packages).

**submodule\_search\_locations**

`(__path__)`

List of strings for where to find submodules, if a package (`None` otherwise).

**loader\_state**

Container of extra module-specific data for use during loading (or `None`).

**cached**

`(__cached__)`

String for where the compiled module should be stored (or `None`).

**parent**

`(__package__)`

(Read-only) The fully-qualified name of the package under which the module should be loaded as a submodule (or the empty string for top-level modules). For packages, it is the same as `__name__`.

**has\_location**

Boolean indicating whether or not the module's "origin" attribute refers to a loadable location.

## 31.5.6 `importlib.util` -- Utility code for importers

Source code: [Lib/importlib/util.py](#)

---

This module contains the various objects that help in the construction of an *importer*.

`importlib.util.MAGIC_NUMBER`

The bytes which represent the bytecode version number. If you need help with loading/writing bytecode then consider `importlib.abc.SourceLoader`.

Baru pada versi 3.4.

`importlib.util.cache_from_source(path, debug_override=None, *, optimization=None)`

Return the [PEP 3147/PEP 488](#) path to the byte-compiled file associated with the source *path*. For example, if *path* is `/foo/bar/baz.py` the return value would be `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. The `cpython-32` string comes from the current magic tag (see `get_tag()`; if `sys.implementation.cache_tag` is not defined then `NotImplementedError` will be raised).

The *optimization* parameter is used to specify the optimization level of the bytecode file. An empty string represents no optimization, so `/foo/bar/baz.py` with an *optimization* of `' '` will result in a bytecode path of `/foo/bar/__pycache__/baz.cpython-32.pyc`. `None` causes the interpreter's optimization level to be used. Any other value's string representation is used, so `/foo/bar/baz.py` with an *optimization* of `2` will lead to the bytecode path of `/foo/bar/__pycache__/baz.cpython-32.opt-2.pyc`. The string representation of *optimization* can only be alphanumeric, else *ValueError* is raised.

The *debug\_override* parameter is deprecated and can be used to override the system's value for `__debug__`. A `True` value is the equivalent of setting *optimization* to the empty string. A `False` value is the same as setting *optimization* to `1`. If both *debug\_override* and *optimization* are not `None` then *TypeError* is raised.

Baru pada versi 3.4.

Berubah pada versi 3.5: The *optimization* parameter was added and the *debug\_override* parameter was deprecated.

Berubah pada versi 3.6: Menerima sebuah *path-like object*

`importlib.util.source_from_cache(path)`

Given the *path* to a [PEP 3147](#) file name, return the associated source code file path. For example, if *path* is `/foo/bar/__pycache__/baz.cpython-32.pyc` the returned path would be `/foo/bar/baz.py`. *path* need not exist, however if it does not conform to [PEP 3147](#) or [PEP 488](#) format, a *ValueError* is raised. If `sys.implementation.cache_tag` is not defined, *NotImplementedError* is raised.

Baru pada versi 3.4.

Berubah pada versi 3.6: Menerima sebuah *path-like object*

`importlib.util.decode_source(source_bytes)`

Decode the given bytes representing source code and return it as a string with universal newlines (as required by `importlib.abc.InspectLoader.get_source()`).

Baru pada versi 3.4.

`importlib.util.resolve_name(name, package)`

Resolve a relative module name to an absolute one.

If **name** has no leading dots, then **name** is simply returned. This allows for usage such as `importlib.util.resolve_name('sys', __spec__.parent)` without doing a check to see if the **package** argument is needed.

*ValueError* is raised if **name** is a relative module name but **package** is a false value (e.g. `None` or the empty string). *ValueError* is also raised a relative name would escape its containing package (e.g. requesting `..bacon` from within the `spam` package).

Baru pada versi 3.3.

`importlib.util.find_spec(name, package=None)`

Find the *spec* for a module, optionally relative to the specified **package** name. If the module is in `sys.modules`, then `sys.modules[name].__spec__` is returned (unless the *spec* would be `None` or is not set, in which case *ValueError* is raised). Otherwise a search using `sys.meta_path` is done. `None` is returned if no *spec* is found.

If **name** is for a submodule (contains a dot), the parent module is automatically imported.

**name** and **package** work the same as for `import_module()`.

Baru pada versi 3.4.

Berubah pada versi 3.7: Raises *ModuleNotFoundError* instead of *AttributeError* if **package** is in fact not a package (i.e. lacks a `__path__` attribute).

`importlib.util.module_from_spec(spec)`

Create a new module based on *spec* and `spec.loader.create_module`.

If `spec.loader.create_module` does not return `None`, then any pre-existing attributes will not be reset. Also, no `AttributeError` will be raised if triggered while accessing `spec` or setting an attribute on the module.

This function is preferred over using `types.ModuleType` to create a new module as `spec` is used to set as many import-controlled attributes on the module as possible.

Baru pada versi 3.5.

`@importlib.util.module_for_loader`

A *decorator* for `importlib.abc.Loader.load_module()` to handle selecting the proper module object to load with. The decorated method is expected to have a call signature taking two positional arguments (e.g. `load_module(self, module)`) for which the second argument will be the module **object** to be used by the loader. Note that the decorator will not work on static methods because of the assumption of two arguments.

The decorated method will take in the **name** of the module to be loaded as expected for a *loader*. If the module is not found in `sys.modules` then a new one is constructed. Regardless of where the module came from, `__loader__` set to **self** and `__package__` is set based on what `importlib.abc.InspectLoader.is_package()` returns (if available). These attributes are set unconditionally to support reloading.

If an exception is raised by the decorated method and a module was added to `sys.modules`, then the module will be removed to prevent a partially initialized module from being left in `sys.modules`. If the module was already in `sys.modules` then it is left alone.

Berubah pada versi 3.3: `__loader__` and `__package__` are automatically set (when possible).

Berubah pada versi 3.4: Set `__name__`, `__loader__` `__package__` unconditionally to support reloading.

Ditinggalkan sejak versi 3.4: The import machinery now directly performs all the functionality provided by this function.

`@importlib.util.set_loader`

A *decorator* for `importlib.abc.Loader.load_module()` to set the `__loader__` attribute on the returned module. If the attribute is already set the decorator does nothing. It is assumed that the first positional argument to the wrapped method (i.e. `self`) is what `__loader__` should be set to.

Berubah pada versi 3.4: Set `__loader__` if set to `None`, as if the attribute does not exist.

Ditinggalkan sejak versi 3.4: The import machinery takes care of this automatically.

`@importlib.util.set_package`

A *decorator* for `importlib.abc.Loader.load_module()` to set the `__package__` attribute on the returned module. If `__package__` is set and has a value other than `None` it will not be changed.

Ditinggalkan sejak versi 3.4: The import machinery takes care of this automatically.

`importlib.util.spec_from_loader(name, loader, *, origin=None, is_package=None)`

A factory function for creating a `ModuleSpec` instance based on a loader. The parameters have the same meaning as they do for `ModuleSpec`. The function uses available *loader* APIs, such as `InspectLoader.is_package()`, to fill in any missing information on the spec.

Baru pada versi 3.4.

`importlib.util.spec_from_file_location(name, location, *, loader=None, submodule_search_locations=None)`

A factory function for creating a `ModuleSpec` instance based on the path to a file. Missing information will be filled in on the spec by making use of loader APIs and by the implication that the module will be file-based.

Baru pada versi 3.4.

Berubah pada versi 3.6: Menerima sebuah *path-like object*

`importlib.util.source_hash(source_bytes)`

Return the hash of `source_bytes` as bytes. A hash-based `.pyc` file embeds the `source_hash()` of the corresponding source file's contents in its header.

Baru pada versi 3.7.

**class** `importlib.util.LazyLoader(loader)`

A class which postpones the execution of the loader of a module until the module has an attribute accessed.

This class **only** works with loaders that define `exec_module()` as control over what module type is used for the module is required. For those same reasons, the loader's `create_module()` method must return `None` or a type for which its `__class__` attribute can be mutated along with not using `slots`. Finally, modules which substitute the object placed into `sys.modules` will not work as there is no way to properly replace the module references throughout the interpreter safely; `ValueError` is raised if such a substitution is detected.

---

**Catatan:** For projects where startup time is critical, this class allows for potentially minimizing the cost of loading a module if it is never used. For projects where startup time is not essential then use of this class is **heavily** discouraged due to error messages created during loading being postponed and thus occurring out of context.

---

Baru pada versi 3.5.

Berubah pada versi 3.6: Began calling `create_module()`, removing the compatibility warning for `importlib.machinery.BuiltinImporter` and `importlib.machinery.ExtensionFileLoader`.

**classmethod** `factory(loader)`

A static method which returns a callable that creates a lazy loader. This is meant to be used in situations where the loader is passed by class instead of by instance.

```
suffixes = importlib.machinery.SOURCE_SUFFIXES
loader = importlib.machinery.SourceFileLoader
lazy_loader = importlib.util.LazyLoader.factory(loader)
finder = importlib.machinery.FileFinder(path, (lazy_loader, suffixes))
```

## 31.5.7 Contoh-contoh

### Importing programmatically

To programmatically import a module, use `importlib.import_module()`.

```
import importlib

itertools = importlib.import_module('itertools')
```

### Checking if a module can be imported

If you need to find out if a module can be imported without actually doing the import, then you should use `importlib.util.find_spec()`.

```
import importlib.util
import sys

# For illustrative purposes.
name = 'itertools'

if name in sys.modules:
    print(f"{name!r} already in sys.modules")
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
elif (spec := importlib.util.find_spec(name)) is not None:
    # If you chose to perform the actual import ...
    module = importlib.util.module_from_spec(spec)
    sys.modules[name] = module
    spec.loader.exec_module(module)
    print(f"{name!r} has been imported")
else:
    print(f"can't find the {name!r} module")
```

## Importing a source file directly

To import a Python source file directly, use the following recipe (Python 3.5 and newer only):

```
import importlib.util
import sys

# For illustrative purposes.
import tokenize
file_path = tokenize.__file__
module_name = tokenize.__name__

spec = importlib.util.spec_from_file_location(module_name, file_path)
module = importlib.util.module_from_spec(spec)
sys.modules[module_name] = module
spec.loader.exec_module(module)
```

## Setting up an importer

For deep customizations of import, you typically want to implement an *importer*. This means managing both the *finder* and *loader* side of things. For finders there are two flavours to choose from depending on your needs: a *meta path finder* or a *path entry finder*. The former is what you would put on `sys.meta_path` while the latter is what you create using a *path entry hook* on `sys.path_hooks` which works with `sys.path` entries to potentially create a finder. This example will show you how to register your own importers so that import will use them (for creating an importer for yourself, read the documentation for the appropriate classes defined within this package):

```
import importlib.machinery
import sys

# For illustrative purposes only.
SpamMetaPathFinder = importlib.machinery.PathFinder
SpamPathEntryFinder = importlib.machinery.FileFinder
loader_details = (importlib.machinery.SourceFileLoader,
                  importlib.machinery.SOURCE_SUFFIXES)

# Setting up a meta path finder.
# Make sure to put the finder in the proper location in the list in terms of
# priority.
sys.meta_path.append(SpamMetaPathFinder)

# Setting up a path entry finder.
# Make sure to put the path hook in the proper location in the list in terms
# of priority.
sys.path_hooks.append(SpamPathEntryFinder.path_hook(loader_details))
```

## Approximating `importlib.import_module()`

Import itself is implemented in Python code, making it possible to expose most of the import machinery through `importlib`. The following helps illustrate the various APIs that `importlib` exposes by providing an approximate implementation of `importlib.import_module()` (Python 3.4 and newer for the `importlib` usage, Python 3.6 and newer for other parts of the code).

```
import importlib.util
import sys

def import_module(name, package=None):

```

## 31.6 Using `importlib.metadata`

Baru pada versi 3.8.

Source code: [Lib/importlib/metadata.py](#)

---

**Catatan:** This functionality is provisional and may deviate from the usual version semantics of the standard library.

---

`importlib.metadata` is a library that provides for access to installed package metadata. Built in part on Python's import system, this library intends to replace similar functionality in the [entry point API](#) and [metadata API](#) of `pkg_resources`. Along with [importlib.resources](#) in Python 3.7 and newer (backported as [importlib\\_resources](#) for older versions of Python), this can eliminate the need to use the older and less efficient `pkg_resources` package.

By "installed package" we generally mean a third-party package installed into Python's `site-packages` directory via tools such as `pip`. Specifically, it means a package with either a discoverable `dist-info` or `egg-info` directory, and

metadata defined by [PEP 566](#) or its older specifications. By default, package metadata can live on the file system or in zip archives on `sys.path`. Through an extension mechanism, the metadata can live almost anywhere.

### 31.6.1 Overview

Let's say you wanted to get the version string for a package you've installed using `pip`. We start by creating a virtual environment and installing something into it:

```
$ python3 -m venv example
$ source example/bin/activate
(example) $ pip install wheel
```

You can get the version string for `wheel` by running the following:

```
(example) $ python
>>> from importlib.metadata import version
>>> version('wheel')
'0.32.3'
```

You can also get the set of entry points keyed by group, such as `console_scripts`, `distutils.commands` and others. Each group contains a sequence of [EntryPoint](#) objects.

You can get the *metadata for a distribution*:

```
>>> list(metadata('wheel'))
['Metadata-Version', 'Name', 'Version', 'Summary', 'Home-page', 'Author', 'Author-
↪email', 'Maintainer', 'Maintainer-email', 'License', 'Project-URL', 'Project-URL',
↪'Project-URL', 'Keywords', 'Platform', 'Classifier', 'Classifier', 'Classifier',
↪'Classifier', 'Classifier', 'Classifier', 'Classifier', 'Classifier', 'Classifier',
↪'Classifier', 'Classifier', 'Classifier', 'Requires-Python', 'Provides-Extra',
↪'Requires-Dist', 'Requires-Dist']
```

You can also get a *distribution's version number*, list its *constituent files*, and get a list of the distribution's *Distribution requirements*.

### 31.6.2 Functional API

This package provides the following functionality via its public API.

#### Entry points

The `entry_points()` function returns a dictionary of all entry points, keyed by group. Entry points are represented by `EntryPoint` instances; each `EntryPoint` has a `.name`, `.group`, and `.value` attributes and a `.load()` method to resolve the value.

```
>>> eps = entry_points()
>>> list(eps)
['console_scripts', 'distutils.commands', 'distutils.setup_keywords', 'egg_info.
↪writers', 'setuptools.installation']
>>> scripts = eps['console_scripts']
>>> wheel = [ep for ep in scripts if ep.name == 'wheel'][0]
>>> wheel
EntryPoint(name='wheel', value='wheel.cli:main', group='console_scripts')
>>> main = wheel.load()
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
>>> main
<function main at 0x103528488>
```

The `group` and `name` are arbitrary values defined by the package author and usually a client will wish to resolve all entry points for a particular group. Read [the `setuptools` docs](#) for more information on entrypoints, their definition, and usage.

## Distribution metadata

Every distribution includes some metadata, which you can extract using the `metadata()` function:

```
>>> wheel_metadata = metadata('wheel')
```

The keys of the returned data structure<sup>1</sup> name the metadata keywords, and their values are returned unparsed from the distribution metadata:

```
>>> wheel_metadata['Requires-Python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
```

## Distribution versions

The `version()` function is the quickest way to get a distribution's version number, as a string:

```
>>> version('wheel')
'0.32.3'
```

## Distribution files

You can also get the full set of files contained within a distribution. The `files()` function takes a distribution package name and returns all of the files installed by this distribution. Each file object returned is a `PackagePath`, a [pathlib.Path](#) derived object with additional `dist`, `size`, and `hash` properties as indicated by the metadata. For example:

```
>>> util = [p for p in files('wheel') if 'util.py' in str(p)][0]
>>> util
PackagePath('wheel/util.py')
>>> util.size
859
>>> util.dist
<importlib.metadata._hooks.PathDistribution object at 0x101e0cef0>
>>> util.hash
<FileHash mode: sha256 value: bYkw5oMccfazVCoYQwKkkemoVyMAFoR34mmKBx8R1NI>
```

Once you have the file, you can also read its contents:

```
>>> print(util.read_text())
import base64
import sys
...
def as_bytes(s):
    if isinstance(s, text_type):
```

(berlanjut ke halaman berikutnya)

<sup>1</sup> Technically, the returned distribution metadata object is an `email.message.EmailMessage` instance, but this is an implementation detail, and not part of the stable API. You should only use dictionary-like methods and syntax to access the metadata contents.

(lanjutan dari halaman sebelumnya)

```
    return s.encode('utf-8')
return s
```

In the case where the metadata file listing files (RECORD or SOURCES.txt) is missing, `files()` will return `None`. The caller may wish to wrap calls to `files()` in `always_iterable` or otherwise guard against this condition if the target distribution is not known to have the metadata present.

## Distribution requirements

To get the full set of requirements for a distribution, use the `requires()` function:

```
>>> requires('wheel')
["pytest (>=3.0.0) ; extra == 'test'", "pytest-cov ; extra == 'test'"]
```

### 31.6.3 Distributions

While the above API is the most common and convenient usage, you can get all of that information from the `Distribution` class. A `Distribution` is an abstract object that represents the metadata for a Python package. You can get the `Distribution` instance:

```
>>> from importlib.metadata import distribution
>>> dist = distribution('wheel')
```

Thus, an alternative way to get the version number is through the `Distribution` instance:

```
>>> dist.version
'0.32.3'
```

There are all kinds of additional metadata available on the `Distribution` instance:

```
>>> dist.metadata['Requires-Python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
>>> dist.metadata['License']
'MIT'
```

The full set of available metadata is not described here. See [PEP 566](#) for additional details.

### 31.6.4 Extending the search algorithm

Because package metadata is not available through `sys.path` searches, or package loaders directly, the metadata for a package is found through import system finders. To find a distribution package's metadata, `importlib.metadata` queries the list of *meta path finders* on `sys.meta_path`.

The default `PathFinder` for Python includes a hook that calls into `importlib.metadata.MetadataPathFinder` for finding distributions loaded from typical file-system-based paths.

The abstract class `importlib.abc.MetaPathFinder` defines the interface expected of finders by Python's import system. `importlib.metadata` extends this protocol by looking for an optional `find_distributions` callable on the finders from `sys.meta_path` and presents this extended interface as the `DistributionFinder` abstract base class, which defines this abstract method:

```
@abc.abstractmethod
def find_distributions(context=DistributionFinder.Context()):
    """Return an iterable of all Distribution instances capable of
    loading the metadata for packages for the indicated ``context``.
    """
```

The `DistributionFinder.Context` object provides `.path` and `.name` properties indicating the path to search and names to match and may supply other relevant context.

What this means in practice is that to support finding distribution package metadata in locations other than the file system, subclass `Distribution` and implement the abstract methods. Then from a custom finder, return instances of this derived `Distribution` in the `find_distributions()` method.

---

## Layanan Bahasa Python

---

Python menyediakan sejumlah modul untuk membantu bekerja dengan bahasa Python. Modul-modul ini mendukung tokenizing, parsing, analisis sintaks, bytecode disassembly, dan berbagai fasilitas lainnya.

Modul-modul ini termasuk:

### 32.1 `parser` --- Access Python parse trees

---

The `parser` module provides an interface to Python's internal parser and byte-code compiler. The primary purpose for this interface is to allow Python code to edit the parse tree of a Python expression and create executable code from this. This is better than trying to parse and modify an arbitrary Python code fragment as a string because parsing is performed in a manner identical to the code forming the application. It is also faster.

---

**Catatan:** From Python 2.5 onward, it's much more convenient to cut in at the Abstract Syntax Tree (AST) generation and compilation stage, using the `ast` module.

---

There are a few things to note about this module which are important to making use of the data structures created. This is not a tutorial on editing the parse trees for Python code, but some examples of using the `parser` module are presented.

Most importantly, a good understanding of the Python grammar processed by the internal parser is required. For full information on the language syntax, refer to reference-index. The parser itself is created from a grammar specification defined in the file `Grammar/Grammar` in the standard Python distribution. The parse trees stored in the ST objects created by this module are the actual output from the internal parser when created by the `expr()` or `suite()` functions, described below. The ST objects created by `sequence2st()` faithfully simulate those structures. Be aware that the values of the sequences which are considered "correct" will vary from one version of Python to another as the formal grammar for the language is revised. However, transporting code from one Python version to another as source text will always allow correct parse trees to be created in the target version, with the only restriction being that migrating to an older version of the interpreter will not support more recent language constructs. The parse trees are not typically compatible from one version to another, though source code has usually been forward-compatible within a major release series.

Each element of the sequences returned by `st2list()` or `st2tuple()` has a simple form. Sequences representing non-terminal elements in the grammar always have a length greater than one. The first element is an integer which identifies a production in the grammar. These integers are given symbolic names in the C header file `Include/graminit.h` and the Python module `symbol`. Each additional element of the sequence represents a component of the production as recognized in the input string: these are always sequences which have the same form as the parent. An important aspect of this structure which should be noted is that keywords used to identify the parent node type, such as the keyword `if` in an `if_stmt`, are included in the node tree without any special treatment. For example, the `if` keyword is represented by the tuple `(1, 'if')`, where `1` is the numeric value associated with all `NAME` tokens, including variable and function names defined by the user. In an alternate form returned when line number information is requested, the same token might be represented as `(1, 'if', 12)`, where the `12` represents the line number at which the terminal symbol was found.

Terminal elements are represented in much the same way, but without any child elements and the addition of the source text which was identified. The example of the `if` keyword above is representative. The various types of terminal symbols are defined in the C header file `Include/token.h` and the Python module `token`.

The ST objects are not required to support the functionality of this module, but are provided for three purposes: to allow an application to amortize the cost of processing complex parse trees, to provide a parse tree representation which conserves memory space when compared to the Python list or tuple representation, and to ease the creation of additional modules in C which manipulate parse trees. A simple "wrapper" class may be created in Python to hide the use of ST objects.

The `parser` module defines functions for a few distinct purposes. The most important purposes are to create ST objects and to convert ST objects to other representations such as parse trees and compiled code objects, but there are also functions which serve to query the type of parse tree represented by an ST object.

#### Lihat juga:

**Module `symbol`** Useful constants representing internal nodes of the parse tree.

**Module `token`** Useful constants representing leaf nodes of the parse tree and functions for testing node values.

### 32.1.1 Creating ST Objects

ST objects may be created from source code or from a parse tree. When creating an ST object from source, different functions are used to create the `'eval'` and `'exec'` forms.

`parser.expr(source)`

The `expr()` function parses the parameter `source` as if it were an input to `compile(source, 'file.py', 'eval')`. If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is raised.

`parser.suite(source)`

The `suite()` function parses the parameter `source` as if it were an input to `compile(source, 'file.py', 'exec')`. If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is raised.

`parser.sequence2st(sequence)`

This function accepts a parse tree represented as a sequence and builds an internal representation if possible. If it can validate that the tree conforms to the Python grammar and all nodes are valid node types in the host version of Python, an ST object is created from the internal representation and returned to the caller. If there is a problem creating the internal representation, or if the tree cannot be validated, a `ParserError` exception is raised. An ST object created this way should not be assumed to compile correctly; normal exceptions raised by compilation may still be initiated when the ST object is passed to `compilest()`. This may indicate problems not related to syntax (such as a `MemoryError` exception), but may also be due to constructs such as the result of parsing `del f(0)`, which escapes the Python parser but is checked by the bytecode compiler.

Sequences representing terminal tokens may be represented as either two-element lists of the form `(1, 'name')` or as three-element lists of the form `(1, 'name', 56)`. If the third element is present, it is assumed to be a

valid line number. The line number may be specified for any subset of the terminal symbols in the input tree.

`parser.tuple2st(sequence)`

This is the same function as `sequence2st()`. This entry point is maintained for backward compatibility.

### 32.1.2 Converting ST Objects

ST objects, regardless of the input used to create them, may be converted to parse trees represented as list- or tuple-trees, or may be compiled into executable code objects. Parse trees may be extracted with or without line numbering information.

`parser.st2list(st, line_info=False, col_info=False)`

This function accepts an ST object from the caller in `st` and returns a Python list representing the equivalent parse tree. The resulting list representation can be used for inspection or the creation of a new parse tree in list form. This function does not fail so long as memory is available to build the list representation. If the parse tree will only be used for inspection, `st2tuple()` should be used instead to reduce memory consumption and fragmentation. When the list representation is required, this function is significantly faster than retrieving a tuple representation and converting that to nested lists.

If `line_info` is true, line number information will be included for all terminal tokens as a third element of the list representing the token. Note that the line number provided specifies the line on which the token *ends*. This information is omitted if the flag is false or omitted.

`parser.st2tuple(st, line_info=False, col_info=False)`

This function accepts an ST object from the caller in `st` and returns a Python tuple representing the equivalent parse tree. Other than returning a tuple instead of a list, this function is identical to `st2list()`.

If `line_info` is true, line number information will be included for all terminal tokens as a third element of the list representing the token. This information is omitted if the flag is false or omitted.

`parser.compilest(st, filename='<syntax-tree>')`

The Python byte compiler can be invoked on an ST object to produce code objects which can be used as part of a call to the built-in `exec()` or `eval()` functions. This function provides the interface to the compiler, passing the internal parse tree from `st` to the parser, using the source file name specified by the `filename` parameter. The default value supplied for `filename` indicates that the source was an ST object.

Compiling an ST object may result in exceptions related to compilation; an example would be a `SyntaxError` caused by the parse tree for `del f(0):` this statement is considered legal within the formal grammar for Python but is not a legal language construct. The `SyntaxError` raised for this condition is actually generated by the Python byte-compiler normally, which is why it can be raised at this point by the `parser` module. Most causes of compilation failure can be diagnosed programmatically by inspection of the parse tree.

### 32.1.3 Queries on ST Objects

Two functions are provided which allow an application to determine if an ST was created as an expression or a suite. Neither of these functions can be used to determine if an ST was created from source code via `expr()` or `suite()` or from a parse tree via `sequence2st()`.

`parser.isexpr(st)`

When `st` represents an 'eval' form, this function returns `True`, otherwise it returns `False`. This is useful, since code objects normally cannot be queried for this information using existing built-in functions. Note that the code objects created by `compilest()` cannot be queried like this either, and are identical to those created by the built-in `compile()` function.

`parser.issuite(st)`

This function mirrors `isexpr()` in that it reports whether an ST object represents an 'exec' form, commonly

known as a "suite." It is not safe to assume that this function is equivalent to `not isexpr(st)`, as additional syntactic fragments may be supported in the future.

### 32.1.4 Exceptions and Error Handling

The parser module defines a single exception, but may also pass other built-in exceptions from other portions of the Python runtime environment. See each function for information about the exceptions it can raise.

**exception** `parser.ParserError`

Exception raised when a failure occurs within the parser module. This is generally produced for validation failures rather than the built-in `SyntaxError` raised during normal parsing. The exception argument is either a string describing the reason of the failure or a tuple containing a sequence causing the failure from a parse tree passed to `sequence2st()` and an explanatory string. Calls to `sequence2st()` need to be able to handle either type of exception, while calls to other functions in the module will only need to be aware of the simple string values.

Note that the functions `compilest()`, `expr()`, and `suite()` may raise exceptions which are normally raised by the parsing and compilation process. These include the built in exceptions `MemoryError`, `OverflowError`, `SyntaxError`, and `SystemError`. In these cases, these exceptions carry all the meaning normally associated with them. Refer to the descriptions of each function for detailed information.

### 32.1.5 ST Objects

Ordered and equality comparisons are supported between ST objects. Pickling of ST objects (using the `pickle` module) is also supported.

**parser.STType**

The type of the objects returned by `expr()`, `suite()` and `sequence2st()`.

ST objects have the following methods:

**ST.compile** (*filename*='<syntax-tree>')  
Same as `compilest(st, filename)`.

**ST.isexpr** ()  
Same as `isexpr(st)`.

**ST.issuite** ()  
Same as `issuite(st)`.

**ST.tolist** (*line\_info*=False, *col\_info*=False)  
Same as `st2list(st, line_info, col_info)`.

**ST.totuple** (*line\_info*=False, *col\_info*=False)  
Same as `st2tuple(st, line_info, col_info)`.

### 32.1.6 Example: Emulation of `compile()`

While many useful operations may take place between parsing and bytecode generation, the simplest operation is to do nothing. For this purpose, using the `parser` module to produce an intermediate data structure is equivalent to the code

```
>>> code = compile('a + 5', 'file.py', 'eval')
>>> a = 5
>>> eval(code)
10
```

The equivalent operation using the `parser` module is somewhat longer, and allows the intermediate internal parse tree to be retained as an ST object:

```
>>> import parser
>>> st = parser.expr('a + 5')
>>> code = st.compile('file.py')
>>> a = 5
>>> eval(code)
10
```

An application which needs both ST and code objects can package this code into readily available functions:

```
import parser

def load_suite(source_string):
    st = parser.suite(source_string)
    return st, st.compile()

def load_expression(source_string):
    st = parser.expr(source_string)
    return st, st.compile()
```

## 32.2 ast --- Abstract Syntax Trees

**Source code:** `Lib/ast.py`

The `ast` module helps Python applications to process trees of the Python abstract syntax grammar. The abstract syntax itself might change with each Python release; this module helps to find out programmatically what the current grammar looks like.

An abstract syntax tree can be generated by passing `ast.PyCF_ONLY_AST` as a flag to the `compile()` built-in function, or using the `parse()` helper provided in this module. The result will be a tree of objects whose classes all inherit from `ast.AST`. An abstract syntax tree can be compiled into a Python code object using the built-in `compile()` function.

### 32.2.1 Node classes

#### **class** `ast.AST`

This is the base of all AST node classes. The actual node classes are derived from the `Parser/Python.asdl` file, which is reproduced [below](#). They are defined in the `_ast` C module and re-exported in `ast`.

There is one class defined for each left-hand side symbol in the abstract grammar (for example, `ast.stmt` or `ast.expr`). In addition, there is one class defined for each constructor on the right-hand side; these classes inherit from the classes for the left-hand side trees. For example, `ast.BinOp` inherits from `ast.expr`. For production rules with alternatives (aka "sums"), the left-hand side class is abstract: only instances of specific constructor nodes are ever created.

#### **\_fields**

Each concrete class has an attribute `_fields` which gives the names of all child nodes.

Each instance of a concrete class has one attribute for each child node, of the type as defined in the grammar. For example, `ast.BinOp` instances have an attribute `left` of type `ast.expr`.

If these attributes are marked as optional in the grammar (using a question mark), the value might be `None`. If the attributes can have zero-or-more values (marked with an asterisk), the values are represented as Python lists. All possible attributes must be present and have valid values when compiling an AST with `compile()`.

```
lineno
col_offset
end_lineno
end_col_offset
```

Instances of `ast.expr` and `ast.stmt` subclasses have `lineno`, `col_offset`, `lineno`, and `col_offset` attributes. The `lineno` and `end_lineno` are the first and last line numbers of source text span (1-indexed so the first line is line 1) and the `col_offset` and `end_col_offset` are the corresponding UTF-8 byte offsets of the first and last tokens that generated the node. The UTF-8 offset is recorded because the parser uses UTF-8 internally.

Note that the end positions are not required by the compiler and are therefore optional. The end offset is *after* the last symbol, for example one can get the source segment of a one-line expression node using `source_line[node.col_offset : node.end_col_offset]`.

The constructor of a class `ast.T` parses its arguments as follows:

- If there are positional arguments, there must be as many as there are items in `T.__fields`; they will be assigned as attributes of these names.
- If there are keyword arguments, they will set the attributes of the same names to the given values.

For example, to create and populate an `ast.UnaryOp` node, you could use

```
node = ast.UnaryOp()
node.op = ast.USub()
node.operand = ast.Constant()
node.operand.value = 5
node.operand.lineno = 0
node.operand.col_offset = 0
node.lineno = 0
node.col_offset = 0
```

or the more compact

```
node = ast.UnaryOp(ast.USub(), ast.Constant(5, lineno=0, col_offset=0),
                  lineno=0, col_offset=0)
```

Berubah pada versi 3.8: Class `ast.Constant` is now used for all constants.

Ditinggalkan sejak versi 3.8: Old classes `ast.Num`, `ast.Str`, `ast.Bytes`, `ast.NameConstant` and `ast.Ellipsis` are still available, but they will be removed in future Python releases. In the meanwhile, instantiating them will return an instance of a different class.

## 32.2.2 Abstract Grammar

The abstract grammar is currently defined as follows:

```
-- ASDL's 5 builtin types are:
-- identifier, int, string, object, constant

module Python
{
    mod = Module(stmt* body, type_ignore *type_ignores)
        | Interactive(stmt* body)
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

| Expression(expr body)
| FunctionType(expr* argtypes, expr returns)

-- not really an actual node but useful in Jython's typesystem.
| Suite(stmt* body)

stmt = FunctionDef(identifier name, arguments args,
                    stmt* body, expr* decorator_list, expr? returns,
                    string? type_comment)
| AsyncFunctionDef(identifier name, arguments args,
                    stmt* body, expr* decorator_list, expr? returns,
                    string? type_comment)

| ClassDef(identifier name,
            expr* bases,
            keyword* keywords,
            stmt* body,
            expr* decorator_list)
| Return(expr? value)

| Delete(expr* targets)
| Assign(expr* targets, expr value, string? type_comment)
| AugAssign(expr target, operator op, expr value)
-- 'simple' indicates that we annotate simple name without parens
| AnnAssign(expr target, expr annotation, expr? value, int simple)

-- use 'orelse' because else is a keyword in target languages
| For(expr target, expr iter, stmt* body, stmt* orelse, string? type_
↪comment)
| AsyncFor(expr target, expr iter, stmt* body, stmt* orelse, string? type_

```

### 32.2.3 ast Helpers

Apart from the node classes, the `ast` module defines these utility functions and classes for traversing abstract syntax trees:

`ast.parse` (*source*, *filename*=<unknown>, *mode*='exec', \*, *type\_comments*=False, *feature\_version*=None)  
 Parse the source into an AST node. Equivalent to `compile(source, filename, mode, ast.PyCF_ONLY_AST)`.

If `type_comments=True` is given, the parser is modified to check and return type comments as specified by [PEP 484](#) and [PEP 526](#). This is equivalent to adding `ast.PyCF_TYPE_COMMENTS` to the flags passed to `compile()`. This will report syntax errors for misplaced type comments. Without this flag, type comments will be ignored, and the `type_comment` field on selected AST nodes will always be `None`. In addition, the locations of `# type: ignore` comments will be returned as the `type_ignores` attribute of `Module` (otherwise it is always an empty list).

In addition, if `mode` is `'func_type'`, the input syntax is modified to correspond to [PEP 484](#) "signature type comments", e.g. `(str, int) -> List[str]`.

Also, setting `feature_version` to a tuple (*major*, *minor*) will attempt to parse using that Python version's grammar. Currently *major* must equal to 3. For example, setting `feature_version=(3, 4)` will allow the use of `async` and `await` as variable names. The lowest supported version is `(3, 4)`; the highest is `sys.version_info[0:2]`.

**Peringatan:** It is possible to crash the Python interpreter with a sufficiently large/complex string due to stack depth limitations in Python's AST compiler.

Berubah pada versi 3.8: Added `type_comments`, `mode='func_type'` and `feature_version`.

`ast.literal_eval` (*node\_or\_string*)

Safely evaluate an expression node or a string containing a Python literal or container display. The string or node provided may only consist of the following Python literal structures: strings, bytes, numbers, tuples, lists, dicts, sets, booleans, and `None`.

This can be used for safely evaluating strings containing Python values from untrusted sources without the need to parse the values oneself. It is not capable of evaluating arbitrarily complex expressions, for example involving operators or indexing.

**Peringatan:** It is possible to crash the Python interpreter with a sufficiently large/complex string due to stack depth limitations in Python's AST compiler.

Berubah pada versi 3.2: Now allows bytes and set literals.

`ast.get_docstring(node, clean=True)`

Return the docstring of the given *node* (which must be a `FunctionDef`, `AsyncFunctionDef`, `ClassDef`, or `Module` node), or `None` if it has no docstring. If *clean* is true, clean up the docstring's indentation with `inspect.cleandoc()`.

Berubah pada versi 3.5: `AsyncFunctionDef` is now supported.

`ast.get_source_segment(source, node, *, padded=False)`

Get source code segment of the *source* that generated *node*. If some location information (`lineno`, `end_lineno`, `col_offset`, or `end_col_offset`) is missing, return `None`.

If *padded* is `True`, the first line of a multi-line statement will be padded with spaces to match its original position.

Baru pada versi 3.8.

`ast.fix_missing_locations(node)`

When you compile a node tree with `compile()`, the compiler expects `lineno` and `col_offset` attributes for every node that supports them. This is rather tedious to fill in for generated nodes, so this helper adds these attributes recursively where not already set, by setting them to the values of the parent node. It works recursively starting at *node*.

`ast.increment_lineno(node, n=1)`

Increment the line number and end line number of each node in the tree starting at *node* by *n*. This is useful to "move code" to a different location in a file.

`ast.copy_location(new_node, old_node)`

Copy source location (`lineno`, `col_offset`, `end_lineno`, and `end_col_offset`) from *old\_node* to *new\_node* if possible, and return *new\_node*.

`ast.iter_fields(node)`

Yield a tuple of (*fieldname*, *value*) for each field in `node._fields` that is present on *node*.

`ast.iter_child_nodes(node)`

Yield all direct child nodes of *node*, that is, all fields that are nodes and all items of fields that are lists of nodes.

`ast.walk(node)`

Recursively yield all descendant nodes in the tree starting at *node* (including *node* itself), in no specified order. This is useful if you only want to modify nodes in place and don't care about the context.

**class** `ast.NodeVisitor`

A node visitor base class that walks the abstract syntax tree and calls a visitor function for every node found. This function may return a value which is forwarded by the `visit()` method.

This class is meant to be subclassed, with the subclass adding visitor methods.

**visit** (*node*)

Visit a node. The default implementation calls the method called `self.visit_classname` where *classname* is the name of the node class, or `generic_visit()` if that method doesn't exist.

**generic\_visit** (*node*)

This visitor calls `visit()` on all children of the node.

Note that child nodes of nodes that have a custom visitor method won't be visited unless the visitor calls `generic_visit()` or visits them itself.

Don't use the `NodeVisitor` if you want to apply changes to nodes during traversal. For this a special visitor exists (`NodeTransformer`) that allows modifications.

Ditinggalkan sejak versi 3.8: Methods `visit_Num()`, `visit_Str()`, `visit_Bytes()`, `visit_NameConstant()` and `visit_Ellipsis()` are deprecated now and will not be called in future Python versions. Add the `visit_Constant()` method to handle all constant nodes.

#### **class** `ast.NodeTransformer`

A `NodeVisitor` subclass that walks the abstract syntax tree and allows modification of nodes.

The `NodeTransformer` will walk the AST and use the return value of the visitor methods to replace or remove the old node. If the return value of the visitor method is `None`, the node will be removed from its location, otherwise it is replaced with the return value. The return value may be the original node in which case no replacement takes place.

Here is an example transformer that rewrites all occurrences of name lookups (`foo`) to `data['foo']`:

```
class RewriteName(NodeTransformer):

    def visit_Name(self, node):
        return Subscript(
            value=Name(id='data', ctx=Load()),
            slice=Index(value=Constant(value=node.id)),
            ctx=node.ctx
        )
```

Keep in mind that if the node you're operating on has child nodes you must either transform the child nodes yourself or call the `generic_visit()` method for the node first.

For nodes that were part of a collection of statements (that applies to all statement nodes), the visitor may also return a list of nodes rather than just a single node.

If `NodeTransformer` introduces new nodes (that weren't part of original tree) without giving them location information (such as `lineno`), `fix_missing_locations()` should be called with the new sub-tree to recalculate the location information:

```
tree = ast.parse('foo', mode='eval')
new_tree = fix_missing_locations(RewriteName().visit(tree))
```

Usually you use the transformer like this:

```
node = YourTransformer().visit(node)
```

`ast.dump(node, annotate_fields=True, include_attributes=False)`

Return a formatted dump of the tree in `node`. This is mainly useful for debugging purposes. If `annotate_fields` is true (by default), the returned string will show the names and the values for fields. If `annotate_fields` is false, the result string will be more compact by omitting unambiguous field names. Attributes such as line numbers and column offsets are not dumped by default. If this is wanted, `include_attributes` can be set to true.

[Green Tree Snakes](#), an external documentation resource, has good details on working with Python ASTs.

[ASTTokens](#) annotates Python ASTs with the positions of tokens and text in the source code that generated them. This is helpful for tools that make source code transformations.

[leoAst.py](#) unifies the token-based and parse-tree-based views of python programs by inserting two-way links between tokens and ast nodes.

[LibCST](#) parses code as a Concrete Syntax Tree that looks like an ast tree and keeps all formatting details. It's useful for building automated refactoring (codemod) applications and linters.

[Parso](#) is a Python parser that supports error recovery and round-trip parsing for different Python versions (in multiple Python versions). Parso is also able to list multiple syntax errors in your python file.

## 32.3 `symtable` --- Access to the compiler's symbol tables

Source code: [Lib/symtable.py](#)

---

Symbol tables are generated by the compiler from AST just before bytecode is generated. The symbol table is responsible for calculating the scope of every identifier in the code. `symtable` provides an interface to examine these tables.

### 32.3.1 Generating Symbol Tables

`symtable.symtable (code, filename, compile_type)`

Return the toplevel `SymbolTable` for the Python source `code`. `filename` is the name of the file containing the code. `compile_type` is like the `mode` argument to `compile()`.

### 32.3.2 Examining Symbol Tables

**class** `symtable.SymbolTable`

A namespace table for a block. The constructor is not public.

`get_type()`

Return the type of the symbol table. Possible values are 'class', 'module', and 'function'.

`get_id()`

Return the table's identifier.

`get_name()`

Return the table's name. This is the name of the class if the table is for a class, the name of the function if the table is for a function, or 'top' if the table is global (`get_type()` returns 'module').

`get_lineno()`

Return the number of the first line in the block this table represents.

`is_optimized()`

Return True if the locals in this table can be optimized.

`is_nested()`

Return True if the block is a nested class or function.

`has_children()`

Return True if the block has nested namespaces within it. These can be obtained with `get_children()`.

`has_exec()`

Return True if the block uses `exec`.

`get_identifiers()`

Return a list of names of symbols in this table.

`lookup (name)`

Lookup `name` in the table and return a `Symbol` instance.

`get_symbols()`

Return a list of `Symbol` instances for names in the table.

**get\_children()**  
Return a list of the nested symbol tables.

**class** `symtable.Function`  
A namespace for a function or method. This class inherits *SymbolTable*.

**get\_parameters()**  
Return a tuple containing names of parameters to this function.

**get\_locals()**  
Return a tuple containing names of locals in this function.

**get\_globals()**  
Return a tuple containing names of globals in this function.

**get\_nonlocals()**  
Return a tuple containing names of nonlocals in this function.

**get\_frees()**  
Return a tuple containing names of free variables in this function.

**class** `symtable.Class`  
A namespace of a class. This class inherits *SymbolTable*.

**get\_methods()**  
Return a tuple containing the names of methods declared in the class.

**class** `symtable.Symbol`  
An entry in a *SymbolTable* corresponding to an identifier in the source. The constructor is not public.

**get\_name()**  
Return the symbol's name.

**is\_referenced()**  
Return True if the symbol is used in its block.

**is\_imported()**  
Return True if the symbol is created from an import statement.

**is\_parameter()**  
Return True if the symbol is a parameter.

**is\_global()**  
Return True if the symbol is global.

**is\_nonlocal()**  
Return True if the symbol is nonlocal.

**is\_declared\_global()**  
Return True if the symbol is declared global with a global statement.

**is\_local()**  
Return True if the symbol is local to its block.

**is\_annotated()**  
Return True if the symbol is annotated.  
  
Baru pada versi 3.6.

**is\_free()**  
Return True if the symbol is referenced in its block, but not assigned to.

**is\_assigned()**  
Return True if the symbol is assigned to in its block.

**is\_namespace()**

Return `True` if name binding introduces new namespace.

If the name is used as the target of a function or class statement, this will be true.

Sebagai contoh:

```
>>> table = symtable.symtable("def some_func(): pass", "string", "exec")
>>> table.lookup("some_func").is_namespace()
True
```

Note that a single name can be bound to multiple objects. If the result is `True`, the name may also be bound to other objects, like an int or list, that does not introduce a new namespace.

**get\_namespaces()**

Return a list of namespaces bound to this name.

**get\_namespace()**

Return the namespace bound to this name. If more than one namespace is bound, `ValueError` is raised.

## 32.4 symbol --- Constants used with Python parse trees

Source code: [Lib/symbol.py](#)

---

This module provides constants which represent the numeric values of internal nodes of the parse tree. Unlike most Python constants, these use lower-case names. Refer to the file `Grammar/Grammar` in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

This module also provides one additional data object:

**symbol.sym\_name**

Kamus memetakan nilai numerik dari konstanta yang didefinisikan dalam modul ini kembali ke string nama, yang memungkinkan dihasilkannya representasi pohon parse yang lebih dapat dibaca oleh manusia.

## 32.5 token --- Konstanta digunakan dengan pohon pengurai (parse tree) Python

Kode sumber: [Lib/token.py](#)

---

Modul ini menyediakan konstanta yang mewakili nilai numerik dari simpul daun pohon parse (token terminal). Merujuk pada berkas `Grammar/Grammar` dalam distribusi Python untuk definisi nama-nama dalam konteks tata bahasa bahasa. Nilai numerik tertentu yang dipetakan oleh nama-nama dapat berubah antar versi Python.

Modul ini juga menyediakan pemetaan dari kode numerik ke nama dan beberapa fungsi. Fungsi mencerminkan definisi pada file header Python C.

**token.tok\_name**

Kamus memetakan nilai numerik dari konstanta yang didefinisikan dalam modul ini kembali ke string nama, yang memungkinkan dihasilkannya representasi pohon parse yang lebih dapat dibaca oleh manusia.

**token.ISTERMINAL(x)**

Kembalikan `True` untuk nilai-nilai token terminal (akhir).

`token.ISNONTERMINAL` (*x*)

Kembalikan `True` untuk nilai-nilai token non-terminal.

`token.ISEOF` (*x*)

Kembalikan nilai `True` jika *x* adalah penanda yang menunjukkan akhir input.

Konstanta token antara lain:

`token.ENDMARKER`

`token.NAME`

`token.NUMBER`

`token.STRING`

`token.NEWLINE`

`token.INDENT`

`token.DEDENT`

`token.LPAR`

Nilai *token* untuk " ( ".

`token.RPAR`

Nilai *token* untuk " ) ".

`token.LSQB`

Nilai *token* untuk " [ ".

`token.RSQB`

Nilai *token* untuk " ] ".

`token.COLON`

Nilai *token* untuk " : ".

`token.COMMA`

Nilai *token* untuk " , ".

`token.SEMI`

Nilai *token* untuk " ; ".

`token.PLUS`

Nilai *token* untuk " + ".

`token.MINUS`

Nilai *token* untuk " - ".

`token.STAR`

Nilai *token* untuk " \* ".

`token.SLASH`

Nilai *token* untuk " / ".

`token.VBAR`

Nilai *token* untuk " | ".

`token.AMPER`

Nilai *token* untuk " & ".

`token.LESS`

Nilai *token* untuk " < ".

`token.GREATER`

Nilai *token* untuk " > " .

`token.EQUAL`  
Nilai *token* untuk `"="`.

`token.DOT`  
Nilai *token* untuk `"."`.

`token.PERCENT`  
Nilai *token* untuk `"%"`.

`token.LBRACE`  
Nilai *token* untuk `"{"`.

`token.RBRACE`  
Nilai *token* untuk `"}"`.

`token.EEQUAL`  
Nilai *token* untuk `"=="`.

`token.NOTEQUAL`  
Nilai *token* untuk `"!="`.

`token.LESSEQUAL`  
Nilai *token* untuk `"<="`.

`token.GREATEREQUAL`  
Nilai *token* untuk `">="`.

`token.TILDE`  
Nilai *token* untuk `"~"`.

`token.CIRCUMFLEX`  
Nilai *token* untuk `"^"`.

`token.LEFTSHIFT`  
Nilai *token* untuk `"<<"`.

`token.RIGHTSHIFT`  
Nilai *token* untuk `">>"`.

`token.DOUBLESTAR`  
Nilai *token* untuk `"**"`.

`token.PLUSEQUAL`  
Nilai *token* untuk `"+="`.

`token.MINEQUAL`  
Nilai *token* untuk `"-="`.

`token.STAREQUAL`  
Nilai *token* untuk `"*="`.

`token.SLASHEQUAL`  
Nilai *token* untuk `"/="`.

`token.PERCENTEQUAL`  
Nilai *token* untuk `"%="`.

`token.AMPEREQUAL`  
Nilai *token* untuk `"&="`.

`token.VBAREQUAL`  
Nilai *token* untuk `"|="`.

`token.CIRCUMFLEXEQUAL`

Nilai *token* untuk "^=".

`token.LEFTSHIFTEQUAL`

Nilai *token* untuk "<=".

`token.RIGHTSHIFTEQUAL`

Nilai *token* untuk ">=".

`token.DOUBLESTAREQUAL`

Nilai *token* untuk "\*\*=".

`token.DOUBLESASH`

Nilai *token* untuk "//".

`token.DOUBLESASHEQUAL`

Nilai *token* untuk "//=".

`token.AT`

Nilai *token* untuk "@".

`token.ATEQUAL`

Nilai *token* untuk "@=".

`token.RARROW`

Nilai *token* untuk "->".

`token.ELLIPSIS`

Nilai *token* untuk "...".

`token.COLONEQUAL`

Nilai *token* untuk " :=".

`token.OP`

`token.AWAIT`

`token.ASYNC`

`token.TYPE_IGNORE`

`token.TYPE_COMMENT`

`token.ERRORTOKEN`

`token.N_TOKENS`

`token.NT_OFFSET`

Nilai tipe token berikut tidak digunakan oleh penanda (tokenizer) C tetapi diperlukan untuk modul *tokenize*.

`token.COMMENT`

Nilai token digunakan untuk menunjukkan komentar.

`token.NL`

Nilai token digunakan untuk menunjukkan baris baru yang tidak berhenti. Token *NEWLINE* menunjukkan akhir baris logika kode Python; token *NL* dihasilkan ketika satu baris kode logis diteruskan melalui beberapa baris fisik.

`token.ENCODING`

Nilai token yang menunjukkan pengodean yang digunakan untuk mendekode sumber byte menjadi teks. Token pertama yang dikembalikan oleh *tokenize.tokenize()* akan selalu menjadi token *ENCODING*.

`token.TYPE_COMMENT`

Nilai token yang menunjukkan bahwa tipe komentar dikenali. Token tersebut hanya diproduksi ketika *ast.parse()* dipanggil dengan *type\_comments=True*.

Berubah pada versi 3.5: Menambahkan token `AWAIT` dan `ASYNC`.

Berubah pada versi 3.7: Menambahkan token `COMMENT`, `NL` dan `ENCODING`.

Berubah pada versi 3.7: Menghapus token `AWAIT` dan `ASYNC`. "async" dan "await" sekarang ditandai sebagai token `NAME`.

Berubah pada versi 3.8: Menambahkan `TYPE_COMMENT`, `TYPE_IGNORE`, `COLONEQUAL`. Menambahkan kembali `AWAIT` dan `ASYNC` (mereka diperlukan untuk mendukung parsing versi Python lama untuk `ast.parse()` dengan `feature_version` diatur ke 6 atau lebih rendah).

## 32.6 keyword --- Pengujian untuk kata kunci Python

**Kode sumber:** `Lib/keyword.py`

---

Modul ini memungkinkan sebuah program Python untuk menentukan jika sebuah string adalah sebuah keyword.

`keyword.iskeyword(s)`

Kembalikan `True` jika `s` adalah keyword Python.

`keyword.kwlist`

Sequence containing all the keywords defined for the interpreter. If any keywords are defined to only be active when particular `__future__` statements are in effect, these will be included as well.

## 32.7 tokenize --- Tokenizer for Python source

**Source code:** `Lib/tokenize.py`

---

The `tokenize` module provides a lexical scanner for Python source code, implemented in Python. The scanner in this module returns comments as tokens as well, making it useful for implementing "pretty-printers", including colorizers for on-screen displays.

To simplify token stream handling, all operator and delimiter tokens and `Ellipsis` are returned using the generic `OP` token type. The exact type can be determined by checking the `exact_type` property on the *named tuple* returned from `tokenize.tokenize()`.

### 32.7.1 Tokenizing Input

The primary entry point is a *generator*:

`tokenize.tokenize(readline)`

The `tokenize()` generator requires one argument, `readline`, which must be a callable object which provides the same interface as the `io.IOBase.readline()` method of file objects. Each call to the function should return one line of input as bytes.

The generator produces 5-tuples with these members: the token type; the token string; a 2-tuple (`srow`, `scol`) of ints specifying the row and column where the token begins in the source; a 2-tuple (`erow`, `ecol`) of ints specifying the row and column where the token ends in the source; and the line on which the token was found. The line passed (the last tuple item) is the *physical* line. The 5 tuple is returned as a *named tuple* with the field names: `type` `string` `start` `end` `line`.

The returned *named tuple* has an additional property named `exact_type` that contains the exact operator type for *OP* tokens. For all other token types `exact_type` equals the named tuple `type` field.

Berubah pada versi 3.1: Added support for named tuples.

Berubah pada versi 3.3: Added support for `exact_type`.

`tokenize()` determines the source encoding of the file by looking for a UTF-8 BOM or encoding cookie, according to [PEP 263](#).

`tokenize.generate_tokens(readline)`

Tokenize a source reading unicode strings instead of bytes.

Like `tokenize()`, the `readline` argument is a callable returning a single line of input. However, `generate_tokens()` expects `readline` to return a str object rather than bytes.

The result is an iterator yielding named tuples, exactly like `tokenize()`. It does not yield an *ENCODING* token.

All constants from the `token` module are also exported from `tokenize`.

Another function is provided to reverse the tokenization process. This is useful for creating tools that tokenize a script, modify the token stream, and write back the modified script.

`tokenize.untokenize(iterable)`

Converts tokens back into Python source code. The *iterable* must return sequences with at least two elements, the token type and the token string. Any additional sequence elements are ignored.

The reconstructed script is returned as a single string. The result is guaranteed to tokenize back to match the input so that the conversion is lossless and round-trips are assured. The guarantee applies only to the token type and token string as the spacing between tokens (column positions) may change.

It returns bytes, encoded using the *ENCODING* token, which is the first token sequence output by `tokenize()`. If there is no encoding token in the input, it returns a str instead.

`tokenize()` needs to detect the encoding of source files it tokenizes. The function it uses to do this is available:

`tokenize.detect_encoding(readline)`

The `detect_encoding()` function is used to detect the encoding that should be used to decode a Python source file. It requires one argument, `readline`, in the same way as the `tokenize()` generator.

It will call `readline` a maximum of twice, and return the encoding used (as a string) and a list of any lines (not decoded from bytes) it has read in.

It detects the encoding from the presence of a UTF-8 BOM or an encoding cookie as specified in [PEP 263](#). If both a BOM and a cookie are present, but disagree, a *SyntaxError* will be raised. Note that if the BOM is found, 'utf-8-sig' will be returned as an encoding.

If no encoding is specified, then the default of 'utf-8' will be returned.

Use `open()` to open Python source files: it uses `detect_encoding()` to detect the file encoding.

`tokenize.open(filename)`

Open a file in read only mode using the encoding detected by `detect_encoding()`.

Baru pada versi 3.2.

#### **exception** `tokenize.TokenError`

Raised when either a docstring or expression that may be split over several lines is not completed anywhere in the file, for example:

```
"""Beginning of
docstring
```

atau:

```
[1,  
2,  
3
```

Note that unclosed single-quoted strings do not cause an error to be raised. They are tokenized as `ERRORTOKEN`, followed by the tokenization of their contents.

## 32.7.2 Command-Line Usage

Baru pada versi 3.3.

The `tokenize` module can be executed as a script from the command line. It is as simple as:

```
python -m tokenize [-e] [filename.py]
```

The following options are accepted:

**-h, --help**  
show this help message and exit

**-e, --exact**  
display token names using the exact type

If `filename.py` is specified its contents are tokenized to stdout. Otherwise, tokenization is performed on stdin.

## 32.7.3 Contoh-contoh

Example of a script rewriter that transforms float literals into Decimal objects:

```
from tokenize import tokenize, untokenize, NUMBER, STRING, NAME, OP  
from io import BytesIO  
  
def decistmt(s):  
    """Substitute Decimals for floats in a string of statements.  
  
    >>> from decimal import Decimal  
    >>> s = 'print(+21.3e-5*-.1234/81.7)'  
    >>> decistmt(s)  
    "print (+Decimal ('21.3e-5')*-Decimal ('.1234')/Decimal ('81.7'))"  
  
    The format of the exponent is inherited from the platform C library.  
    Known cases are "e-007" (Windows) and "e-07" (not Windows). Since  
    we're only showing 12 digits, and the 13th isn't close to 5, the  
    rest of the output should be platform-independent.  
  
    >>> exec(s) #doctest: +ELLIPSIS  
    -3.21716034272e-0...7  
  
    Output from calculations with Decimal should be identical across all  
    platforms.  
  
    >>> exec(decistmt(s))  
    -3.217160342717258261933904529E-7  
    ""  
    result = []  
    g = tokenize(BytesIO(s.encode('utf-8')).readline) # tokenize the string
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

for toknum, tokval, _, _, _ in g:
    if toknum == NUMBER and '.' in tokval: # replace NUMBER tokens
        result.extend([
            (NAME, 'Decimal'),
            (OP, '('),
            (STRING, repr(tokval)),
            (OP, ')')
        ])
    else:
        result.append((toknum, tokval))
return untokenize(result).decode('utf-8')

```

Example of tokenizing from the command line. The script:

```

def say_hello():
    print("Hello, World!")

say_hello()

```

will be tokenized to the following output where the first column is the range of the line/column coordinates where the token is found, the second column is the name of the token, and the final column is the value of the token (if any)

```

$ python -m tokenize hello.py
0,0-0,0:      ENCODING      'utf-8'
1,0-1,3:      NAME          'def'
1,4-1,13:     NAME          'say_hello'
1,13-1,14:    OP            '('
1,14-1,15:    OP            ')'
1,15-1,16:    OP            ':'
1,16-1,17:    NEWLINE      '\n'
2,0-2,4:      INDENT       '    '
2,4-2,9:      NAME          'print'
2,9-2,10:     OP            '('
2,10-2,25:    STRING        '"Hello, World!"'
2,25-2,26:    OP            ')'
2,26-2,27:    NEWLINE      '\n'
3,0-3,1:      NL           '\n'
4,0-4,0:      DEDENT       ''
4,0-4,9:      NAME          'say_hello'
4,9-4,10:     OP            '('
4,10-4,11:    OP            ')'
4,11-4,12:    NEWLINE      '\n'
5,0-5,0:      ENDMARKER    ''

```

The exact token type names can be displayed using the `-e` option:

```

$ python -m tokenize -e hello.py
0,0-0,0:      ENCODING      'utf-8'
1,0-1,3:      NAME          'def'
1,4-1,13:     NAME          'say_hello'
1,13-1,14:    LPAR         '('
1,14-1,15:    RPAR         ')'
1,15-1,16:    COLON         ':'
1,16-1,17:    NEWLINE      '\n'
2,0-2,4:      INDENT       '    '
2,4-2,9:      NAME          'print'

```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

|            |           |                   |
|------------|-----------|-------------------|
| 2,9-2,10:  | LPAR      | ' ('              |
| 2,10-2,25: | STRING    | '"Hello, World!"' |
| 2,25-2,26: | RPAR      | ') '              |
| 2,26-2,27: | NEWLINE   | '\n'              |
| 3,0-3,1:   | NL        | '\n'              |
| 4,0-4,0:   | DEDENT    | ' '               |
| 4,0-4,9:   | NAME      | 'say_hello'       |
| 4,9-4,10:  | LPAR      | ' ('              |
| 4,10-4,11: | RPAR      | ') '              |
| 4,11-4,12: | NEWLINE   | '\n'              |
| 5,0-5,0:   | ENDMARKER | ' '               |

Example of tokenizing a file programmatically, reading unicode strings instead of bytes with `generate_tokens()`:

```
import tokenize

with tokenize.open('hello.py') as f:
    tokens = tokenize.generate_tokens(f.readline)
    for token in tokens:
        print(token)
```

Or reading bytes directly with `tokenize()`:

```
import tokenize

with open('hello.py', 'rb') as f:
    tokens = tokenize.tokenize(f.readline)
    for token in tokens:
        print(token)
```

## 32.8 mod:tabnanny --- Deteksi indentasi ambigu

**Kode sumber:** `Lib/tabnanny.py`

---

Untuk saat ini modul ini dimaksudkan untuk disebut sebagai script. Namun memungkinkan untuk mengimpornya ke IDE dan menggunakan fungsi `check()` yang dijelaskan di bawah ini.

---

**Catatan:** API yang disediakan oleh modul ini kemungkinan besar akan berubah dalam rilis mendatang; perubahan tersebut mungkin tidak kompatibel dengan versi sebelumnya.

---

`tabnanny.check(file_or_dir)`

Jika `file_or_dir` adalah direktori dan bukan tautan simbolis, maka secara rekursif turun pohon direktori yang dinamai oleh `file_or_dir`, memeriksa semua file `.py` di sepanjang jalan. Jika `file_or_dir` adalah file sumber Python biasa, akan diperiksa untuk masalah terkait spasi. Pesan diagnostik ditulis ke keluaran standar menggunakan fungsi `print()`.

`tabnanny.verbose`

Penanda yang menunjukkan apakah akan mencetak pesan verbose. Ini bertambah dengan opsi `-v` jika dipanggil sebagai skrip.

`tabnanny.filename_only`

Penanda yang menunjukkan apakah akan mencetak hanya nama file dari file yang berisi masalah terkait spasi. Ini disetel ke `true` oleh opsi `-q` jika dipanggil sebagai skrip.

**exception** `tabnanny.NannyNag`

Dibesarkan oleh `process_tokens()` jika mendeteksi indentasi yang ambigu. Diambil dan ditangani di `check()`.

`tabnanny.process_tokens(tokens)`

Fungsi ini digunakan oleh `check()` untuk memproses token yang dibuat oleh modul `tokenize`.

**Lihat juga:**

**Modul** `tokenize` Pemindai leksikal untuk kode sumber Python.

## 32.9 pyc1br --- Python module browser support

**Source code:** `Lib/pyc1br.py`

The `pyc1br` module provides limited information about the functions, classes, and methods defined in a Python-coded module. The information is sufficient to implement a module browser. The information is extracted from the Python source code rather than by importing the module, so this module is safe to use with untrusted code. This restriction makes it impossible to use this module with modules not implemented in Python, including all standard and optional extension modules.

`pyc1br.readmodule(module, path=None)`

Return a dictionary mapping module-level class names to class descriptors. If possible, descriptors for imported base classes are included. Parameter `module` is a string with the name of the module to read; it may be the name of a module within a package. If given, `path` is a sequence of directory paths prepended to `sys.path`, which is used to locate the module source code.

This function is the original interface and is only kept for back compatibility. It returns a filtered version of the following.

`pyc1br.readmodule_ex(module, path=None)`

Return a dictionary-based tree containing a function or class descriptors for each function and class defined in the module with a `def` or `class` statement. The returned dictionary maps module-level function and class names to their descriptors. Nested objects are entered into the children dictionary of their parent. As with `readmodule`, `module` names the module to be read and `path` is prepended to `sys.path`. If the module being read is a package, the returned dictionary has a key `'__path__'` whose value is a list containing the package search path.

Baru pada versi 3.7: Descriptors for nested definitions. They are accessed through the new `children` attribute. Each has a new `parent` attribute.

The descriptors returned by these functions are instances of `Function` and `Class` classes. Users are not expected to create instances of these classes.

### 32.9.1 Obyek Fungsi

Class `Function` instances describe functions defined by `def` statements. They have the following attributes:

`Function.file`

Name of the file in which the function is defined.

`Function.module`

The name of the module defining the function described.

`Function.name`

The name of the function.

`Function.lineno`

The line number in the file where the definition starts.

`Function.parent`

For top-level functions, `None`. For nested functions, the parent.

Baru pada versi 3.7.

`Function.children`

A dictionary mapping names to descriptors for nested functions and classes.

Baru pada versi 3.7.

### 32.9.2 Objek Kelas *Class Objects*

Class `Class` instances describe classes defined by `class` statements. They have the same attributes as Functions and two more.

`Class.file`

Name of the file in which the class is defined.

`Class.module`

The name of the module defining the class described.

`Class.name`

The name of the class.

`Class.lineno`

The line number in the file where the definition starts.

`Class.parent`

For top-level classes, `None`. For nested classes, the parent.

Baru pada versi 3.7.

`Class.children`

A dictionary mapping names to descriptors for nested functions and classes.

Baru pada versi 3.7.

`Class.super`

A list of `Class` objects which describe the immediate base classes of the class being described. Classes which are named as superclasses but which are not discoverable by `readmodule_ex()` are listed as a string with the class name instead of as `Class` objects.

`Class.methods`

A dictionary mapping method names to line numbers. This can be derived from the newer children dictionary, but remains for back-compatibility.

## 32.10 `py_compile` --- Compile Python source files

Source code: `Lib/py_compile.py`

The `py_compile` module provides a function to generate a byte-code file from a source file, and another function used when the module source file is invoked as a script.

Though not often needed, this function can be useful when installing modules for shared use, especially if some of the users may not have permission to write the byte-code cache files in the directory containing the source code.

### exception `py_compile.PyCompileError`

Exception raised when an error occurs while attempting to compile the file.

`py_compile.compile(file, cfile=None, dfile=None, doraise=False, optimize=-1, invalidation_mode=PycInvalidationMode.TIMESTAMP, quiet=0)`

Compile a source file to byte-code and write out the byte-code cache file. The source code is loaded from the file named `file`. The byte-code is written to `cfile`, which defaults to the [PEP 3147/PEP 488](#) path, ending in `.pyc`. For example, if `file` is `/foo/bar/baz.py` `cfile` will default to `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. If `dfile` is specified, it is used as the name of the source file in error messages instead of `file`. If `doraise` is true, a `PyCompileError` is raised when an error is encountered while compiling `file`. If `doraise` is false (the default), an error string is written to `sys.stderr`, but no exception is raised. This function returns the path to byte-compiled file, i.e. whatever `cfile` value was used.

The `doraise` and `quiet` arguments determine how errors are handled while compiling file. If `quiet` is 0 or 1, and `doraise` is false, the default behaviour is enabled: an error string is written to `sys.stderr`, and the function returns `None` instead of a path. If `doraise` is true, a `PyCompileError` is raised instead. However if `quiet` is 2, no message is written, and `doraise` has no effect.

If the path that `cfile` becomes (either explicitly specified or computed) is a symlink or non-regular file, `FileExistsError` will be raised. This is to act as a warning that import will turn those paths into regular files if it is allowed to write byte-compiled files to those paths. This is a side-effect of import using file renaming to place the final byte-compiled file into place to prevent concurrent file writing issues.

`optimize` controls the optimization level and is passed to the built-in `compile()` function. The default of `-1` selects the optimization level of the current interpreter.

`invalidation_mode` should be a member of the `PycInvalidationMode` enum and controls how the generated bytecode cache is invalidated at runtime. The default is `PycInvalidationMode.CHECKED_HASH` if the `SOURCE_DATE_EPOCH` environment variable is set, otherwise the default is `PycInvalidationMode.TIMESTAMP`.

Berubah pada versi 3.2: Changed default value of `cfile` to be [PEP 3147](#)-compliant. Previous default was `file + '.c'` (`'o'` if optimization was enabled). Also added the `optimize` parameter.

Berubah pada versi 3.4: Changed code to use `importlib` for the byte-code cache file writing. This means file creation/writing semantics now match what `importlib` does, e.g. permissions, write-and-move semantics, etc. Also added the caveat that `FileExistsError` is raised if `cfile` is a symlink or non-regular file.

Berubah pada versi 3.7: The `invalidation_mode` parameter was added as specified in [PEP 552](#). If the `SOURCE_DATE_EPOCH` environment variable is set, `invalidation_mode` will be forced to `PycInvalidationMode.CHECKED_HASH`.

Berubah pada versi 3.7.2: The `SOURCE_DATE_EPOCH` environment variable no longer overrides the value of the `invalidation_mode` argument, and determines its default value instead.

Berubah pada versi 3.8: The `quiet` parameter was added.

**class** `py_compile.PycInvalidationMode`

A enumeration of possible methods the interpreter can use to determine whether a bytecode file is up to date with a source file. The `.pyc` file indicates the desired invalidation mode in its header. See `pyc-invalidation` for more information on how Python invalidates `.pyc` files at runtime.

Baru pada versi 3.7.

**TIMESTAMP**

The `.pyc` file includes the timestamp and size of the source file, which Python will compare against the metadata of the source file at runtime to determine if the `.pyc` file needs to be regenerated.

**CHECKED\_HASH**

The `.pyc` file includes a hash of the source file content, which Python will compare against the source at runtime to determine if the `.pyc` file needs to be regenerated.

**UNCHECKED\_HASH**

Like `CHECKED_HASH`, the `.pyc` file includes a hash of the source file content. However, Python will at runtime assume the `.pyc` file is up to date and not validate the `.pyc` against the source file at all.

This option is useful when the `.pycs` are kept up to date by some system external to Python like a build system.

`py_compile.main` (*args=None*)

Compile several source files. The files named in *args* (or on the command line, if *args* is `None`) are compiled and the resulting byte-code is cached in the normal manner. This function does not search a directory structure to locate source files; it only compiles files named explicitly. If `'-'` is the only parameter in *args*, the list of files is taken from standard input.

Berubah pada versi 3.2: Added support for `'-'`.

When this module is run as a script, the `main()` is used to compile all the files named on the command line. The exit status is nonzero if one of the files could not be compiled.

**Lihat juga:**

Module `compileall` Utilities to compile all Python source files in a directory tree.

## 32.11 `compileall` --- Byte-compile Python libraries

**Source code:** [Lib/compileall.py](#)

---

This module provides some utility functions to support installing Python libraries. These functions compile Python source files in a directory tree. This module can be used to create the cached byte-code files at library installation time, which makes them available for use even by users who don't have write permission to the library directories.

### 32.11.1 Command-line use

This module can work as a script (using `python -m compileall`) to compile Python sources.

**directory** ...

**file** ...

Positional arguments are files to compile or directories that contain source files, traversed recursively. If no argument is given, behave as if the command line was `-l <directories from sys.path>`.

- l**  
Do not recurse into subdirectories, only compile source code files directly contained in the named or implied directories.
- f**  
Force rebuild even if timestamps are up-to-date.
- q**  
Do not print the list of files compiled. If passed once, error messages will still be printed. If passed twice (**-qq**), all output is suppressed.
- d** `destdir`  
Directory prepended to the path to each file being compiled. This will appear in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.
- x** `regex`  
`regex` is used to search the full path to each file considered for compilation, and if the regex produces a match, the file is skipped.
- i** `list`  
Read the file `list` and add each line that it contains to the list of files and directories to compile. If `list` is `-`, read lines from `stdin`.
- b**  
Write the byte-code files to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their [PEP 3147](#) locations and names, which allows byte-code files from multiple versions of Python to coexist.
- r**  
Control the maximum recursion level for subdirectories. If this is given, then **-l** option will not be taken into account. **python -m compileall <directory> -r 0** is equivalent to **python -m compileall <directory> -l**.
- j** `N`  
Use `N` workers to compile the files within the given directory. If 0 is used, then the result of `os.cpu_count()` will be used.
- invalidation-mode** [`timestamp|checked-hash|unchecked-hash`]  
Control how the generated byte-code files are invalidated at runtime. The `timestamp` value, means that `.pyc` files with the source timestamp and size embedded will be generated. The `checked-hash` and `unchecked-hash` values cause hash-based pycs to be generated. Hash-based pycs embed a hash of the source file contents rather than a timestamp. See [pyc-invalidation](#) for more information on how Python validates bytecode cache files at runtime. The default is `timestamp` if the `SOURCE_DATE_EPOCH` environment variable is not set, and `checked-hash` if the `SOURCE_DATE_EPOCH` environment variable is set.

Berubah pada versi 3.2: Added the **-i**, **-b** and **-h** options.

Berubah pada versi 3.5: Added the **-j**, **-r**, and **-qq** options. **-q** option was changed to a multilevel value. **-b** will always produce a byte-code file ending in `.pyc`, never `.pyo`.

Berubah pada versi 3.7: Added the **--invalidation-mode** option.

There is no command-line option to control the optimization level used by the `compile()` function, because the Python interpreter itself already provides the option: **python -O -m compileall**.

Similarly, the `compile()` function respects the `sys.pycache_prefix` setting. The generated bytecode cache will only be useful if `compile()` is run with the same `sys.pycache_prefix` (if any) that will be used at runtime.

### 32.11.2 Public functions

`compileall.compile_dir` (*dir*, *maxlevels*=10, *ddir*=None, *force*=False, *rx*=None, *quiet*=0, *legacy*=False, *optimize*=-1, *workers*=1, *invalidation\_mode*=None)

Recursively descend the directory tree named by *dir*, compiling all `.py` files along the way. Return a true value if all the files compiled successfully, and a false value otherwise.

The *maxlevels* parameter is used to limit the depth of the recursion; it defaults to 10.

If *ddir* is given, it is prepended to the path to each file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If *force* is true, modules are re-compiled even if the timestamps are up to date.

If *rx* is given, its search method is called on the complete path to each file considered for compilation, and if it returns a true value, the file is skipped.

If *quiet* is False or 0 (the default), the filenames and other information are printed to standard out. Set to 1, only errors are printed. Set to 2, all output is suppressed.

If *legacy* is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their [PEP 3147](#) locations and names, which allows byte-code files from multiple versions of Python to coexist.

*optimize* specifies the optimization level for the compiler. It is passed to the built-in `compile()` function.

The argument *workers* specifies how many workers are used to compile files in parallel. The default is to not use multiple workers. If the platform can't use multiple workers and *workers* argument is given, then sequential compilation will be used as a fallback. If *workers* is 0, the number of cores in the system is used. If *workers* is lower than 0, a `ValueError` will be raised.

*invalidation\_mode* should be a member of the `py_compile.PycInvalidationMode` enum and controls how the generated pycs are invalidated at runtime.

Berubah pada versi 3.2: Added the *legacy* and *optimize* parameter.

Berubah pada versi 3.5: Added the *workers* parameter.

Berubah pada versi 3.5: *quiet* parameter was changed to a multilevel value.

Berubah pada versi 3.5: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

Berubah pada versi 3.6: Menerima sebuah *path-like object*

Berubah pada versi 3.7: The *invalidation\_mode* parameter was added.

Berubah pada versi 3.7.2: The *invalidation\_mode* parameter's default value is updated to None.

Berubah pada versi 3.8: Setting *workers* to 0 now chooses the optimal number of cores.

`compileall.compile_file` (*fullname*, *ddir*=None, *force*=False, *rx*=None, *quiet*=0, *legacy*=False, *optimize*=-1, *invalidation\_mode*=None)

Compile the file with path *fullname*. Return a true value if the file compiled successfully, and a false value otherwise.

If *ddir* is given, it is prepended to the path to the file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If *rx* is given, its search method is passed the full path name to the file being compiled, and if it returns a true value, the file is not compiled and `True` is returned.

If *quiet* is False or 0 (the default), the filenames and other information are printed to standard out. Set to 1, only errors are printed. Set to 2, all output is suppressed.

If *legacy* is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their [PEP 3147](#) locations and names, which allows byte-code files from multiple versions of Python to coexist.

*optimize* specifies the optimization level for the compiler. It is passed to the built-in `compile()` function.

*invalidation\_mode* should be a member of the `py_compile.PycInvalidationMode` enum and controls how the generated pycs are invalidated at runtime.

Baru pada versi 3.2.

Berubah pada versi 3.5: *quiet* parameter was changed to a multilevel value.

Berubah pada versi 3.5: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

Berubah pada versi 3.7: The *invalidation\_mode* parameter was added.

Berubah pada versi 3.7.2: The *invalidation\_mode* parameter's default value is updated to None.

```
compileall.compile_path(skip_curdir=True, maxlevels=0, force=False, quiet=0, legacy=False,
                        optimize=-1, invalidation_mode=None)
```

Byte-compile all the `.py` files found along `sys.path`. Return a true value if all the files compiled successfully, and a false value otherwise.

If *skip\_curdir* is true (the default), the current directory is not included in the search. All other parameters are passed to the `compile_dir()` function. Note that unlike the other compile functions, *maxlevels* defaults to 0.

Berubah pada versi 3.2: Added the *legacy* and *optimize* parameter.

Berubah pada versi 3.5: *quiet* parameter was changed to a multilevel value.

Berubah pada versi 3.5: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

Berubah pada versi 3.7: The *invalidation\_mode* parameter was added.

Berubah pada versi 3.7.2: The *invalidation\_mode* parameter's default value is updated to None.

To force a recompile of all the `.py` files in the `Lib/` subdirectory and all its subdirectories:

```
import compileall

compileall.compile_dir('Lib/', force=True)

# Perform same compilation, excluding files in .svn directories.
import re
compileall.compile_dir('Lib/', rx=re.compile(r'[/\\][.]svn'), force=True)

# pathlib.Path objects can also be used.
import pathlib
compileall.compile_dir(pathlib.Path('Lib/'), force=True)
```

**Lihat juga:**

Module `py_compile` Byte-compile a single source file.

## 32.12 `dis` --- Disassembler for Python bytecode

Source code: [Lib/dis.py](#)

---

The `dis` module supports the analysis of CPython *bytecode* by disassembling it. The CPython bytecode which this module takes as an input is defined in the file `Include/opcode.h` and used by the compiler and the interpreter.

**CPython implementation detail:** Bytecode is an implementation detail of the CPython interpreter. No guarantees are made that bytecode will not be added, removed, or changed between versions of Python. Use of this module should not be considered to work across Python VMs or Python releases.

Berubah pada versi 3.6: Use 2 bytes for each instruction. Previously the number of bytes varied by instruction.

Example: Given the function `myfunc()`:

```
def myfunc(alist):  
    return len(alist)
```

the following command can be used to display the disassembly of `myfunc()`:

```
>>> dis.dis(myfunc)  
2          0 LOAD_GLOBAL              0 (len)  
          2 LOAD_FAST                0 (alist)  
          4 CALL_FUNCTION              1  
          6 RETURN_VALUE
```

(The "2" is a line number).

### 32.12.1 Bytecode analysis

Baru pada versi 3.4.

The bytecode analysis API allows pieces of Python code to be wrapped in a *Bytecode* object that provides easy access to details of the compiled code.

**class** `dis.Bytecode` (*x*, \*, *first\_line=None*, *current\_offset=None*)

Analyse the bytecode corresponding to a function, generator, asynchronous generator, coroutine, method, string of source code, or a code object (as returned by `compile()`).

This is a convenience wrapper around many of the functions listed below, most notably `get_instructions()`, as iterating over a *Bytecode* instance yields the bytecode operations as *Instruction* instances.

If *first\_line* is not `None`, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

If *current\_offset* is not `None`, it refers to an instruction offset in the disassembled code. Setting this means `dis()` will display a "current instruction" marker against the specified opcode.

**classmethod** `from_traceback` (*tb*)

Construct a *Bytecode* instance from the given traceback, setting *current\_offset* to the instruction responsible for the exception.

**codeobj**

The compiled code object.

**first\_line**

The first source line of the code object (if available)

**dis()**

Return a formatted view of the bytecode operations (the same as printed by `dis.dis()`, but returned as a multi-line string).

**info()**

Return a formatted multi-line string with detailed information about the code object, like `code_info()`.

Berubah pada versi 3.7: This can now handle coroutine and asynchronous generator objects.

Contoh:

```
>>> bytecode = dis.Bytecode(myfunc)
>>> for instr in bytecode:
...     print(instr.opname)
...
LOAD_GLOBAL
LOAD_FAST
CALL_FUNCTION
RETURN_VALUE
```

### 32.12.2 Analysis functions

The `dis` module also defines the following analysis functions that convert the input directly to the desired output. They can be useful if only a single operation is being performed, so the intermediate analysis object isn't useful:

**dis.code\_info(x)**

Return a formatted multi-line string with detailed code object information for the supplied function, generator, asynchronous generator, coroutine, method, source code string or code object.

Note that the exact contents of code info strings are highly implementation dependent and they may change arbitrarily across Python VMs or Python releases.

Baru pada versi 3.2.

Berubah pada versi 3.7: This can now handle coroutine and asynchronous generator objects.

**dis.show\_code(x, \*, file=None)**

Print detailed code object information for the supplied function, method, source code string or code object to `file` (or `sys.stdout` if `file` is not specified).

This is a convenient shorthand for `print(code_info(x), file=file)`, intended for interactive exploration at the interpreter prompt.

Baru pada versi 3.2.

Berubah pada versi 3.4: Added `file` parameter.

**dis.dis(x=None, \*, file=None, depth=None)**

Disassemble the `x` object. `x` can denote either a module, a class, a method, a function, a generator, an asynchronous generator, a coroutine, a code object, a string of source code or a byte sequence of raw bytecode. For a module, it disassembles all functions. For a class, it disassembles all methods (including class and static methods). For a code object or sequence of raw bytecode, it prints one line per bytecode instruction. It also recursively disassembles nested code objects (the code of comprehensions, generator expressions and nested functions, and the code used for building nested classes). Strings are first compiled to code objects with the `compile()` built-in function before being disassembled. If no object is provided, this function disassembles the last traceback.

The disassembly is written as text to the supplied `file` argument if provided and to `sys.stdout` otherwise.

The maximal depth of recursion is limited by `depth` unless it is `None`. `depth=0` means no recursion.

Berubah pada versi 3.4: Added `file` parameter.

Berubah pada versi 3.7: Implemented recursive disassembling and added *depth* parameter.

Berubah pada versi 3.7: This can now handle coroutine and asynchronous generator objects.

`dis.distb` (*tb=None*, \*, *file=None*)

Disassemble the top-of-stack function of a traceback, using the last traceback if none was passed. The instruction causing the exception is indicated.

The disassembly is written as text to the supplied *file* argument if provided and to `sys.stdout` otherwise.

Berubah pada versi 3.4: Added *file* parameter.

`dis.disassemble` (*code*, *lasti=-1*, \*, *file=None*)

`dis.disco` (*code*, *lasti=-1*, \*, *file=None*)

Disassemble a code object, indicating the last instruction if *lasti* was provided. The output is divided in the following columns:

1. the line number, for the first instruction of each line
2. the current instruction, indicated as `-->`,
3. a labelled instruction, indicated with `>>`,
4. the address of the instruction,
5. the operation code name,
6. operation parameters, and
7. interpretation of the parameters in parentheses.

The parameter interpretation recognizes local and global variable names, constant values, branch targets, and compare operators.

The disassembly is written as text to the supplied *file* argument if provided and to `sys.stdout` otherwise.

Berubah pada versi 3.4: Added *file* parameter.

`dis.get_instructions` (*x*, \*, *first\_line=None*)

Return an iterator over the instructions in the supplied function, method, source code string or code object.

The iterator generates a series of *Instruction* named tuples giving the details of each operation in the supplied code.

If *first\_line* is not `None`, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

Baru pada versi 3.4.

`dis.findlinestarts` (*code*)

This generator function uses the `co_firstlineno` and `co_notab` attributes of the code object *code* to find the offsets which are starts of lines in the source code. They are generated as (*offset*, *lineno*) pairs. See [Objects/notab\\_notes.txt](#) for the `co_notab` format and how to decode it.

Berubah pada versi 3.6: Line numbers can be decreasing. Before, they were always increasing.

`dis.findlabels` (*code*)

Detect all offsets in the raw compiled bytecode string *code* which are jump targets, and return a list of these offsets.

`dis.stack_effect` (*opcode*, *oparg=None*, \*, *jump=None*)

Compute the stack effect of *opcode* with argument *oparg*.

If the code has a jump target and *jump* is `True`, `stack_effect()` will return the stack effect of jumping. If *jump* is `False`, it will return the stack effect of not jumping. And if *jump* is `None` (default), it will return the maximal stack effect of both cases.

Baru pada versi 3.4.

Berubah pada versi 3.8: Added *jump* parameter.

### 32.12.3 Python Bytecode Instructions

The `get_instructions()` function and `Bytecode` class provide details of bytecode instructions as `Instruction` instances:

**class** `dis.Instruction`

Details for a bytecode operation

**opcode**

numeric code for operation, corresponding to the opcode values listed below and the bytecode values in the *Opcode collections*.

**opname**

human readable name for operation

**arg**

numeric argument to operation (if any), otherwise `None`

**argval**

resolved arg value (if known), otherwise same as arg

**argrepr**

human readable description of operation argument

**offset**

start index of operation within bytecode sequence

**starts\_line**

line started by this opcode (if any), otherwise `None`

**is\_jump\_target**

`True` if other code jumps to here, otherwise `False`

Baru pada versi 3.4.

The Python compiler currently generates the following bytecode instructions.

#### General instructions

**NOP**

Do nothing code. Used as a placeholder by the bytecode optimizer.

**POP\_TOP**

Removes the top-of-stack (TOS) item.

**ROT\_TWO**

Swaps the two top-most stack items.

**ROT\_THREE**

Lifts second and third stack item one position up, moves top down to position three.

**ROT\_FOUR**

Lifts second, third and fourth stack items one position up, moves top down to position four.

Baru pada versi 3.8.

**DUP\_TOP**

Duplicates the reference on top of the stack.

Baru pada versi 3.2.

### **DUP\_TOP\_TWO**

Duplicates the two references on top of the stack, leaving them in the same order.

Baru pada versi 3.2.

### **Unary operations**

Unary operations take the top of the stack, apply the operation, and push the result back on the stack.

#### **UNARY\_POSITIVE**

Implements `TOS = +TOS`.

#### **UNARY\_NEGATIVE**

Implements `TOS = -TOS`.

#### **UNARY\_NOT**

Implements `TOS = not TOS`.

#### **UNARY\_INVERT**

Implements `TOS = ~TOS`.

#### **GET\_ITER**

Implements `TOS = iter(TOS)`.

#### **GET\_YIELD\_FROM\_ITER**

If `TOS` is a *generator iterator* or *coroutine* object it is left as is. Otherwise, implements `TOS = iter(TOS)`.

Baru pada versi 3.5.

### **Binary operations**

Binary operations remove the top of the stack (`TOS`) and the second top-most stack item (`TOS1`) from the stack. They perform the operation, and put the result back on the stack.

#### **BINARY\_POWER**

Implements `TOS = TOS1 ** TOS`.

#### **BINARY\_MULTIPLY**

Implements `TOS = TOS1 * TOS`.

#### **BINARY\_MATRIX\_MULTIPLY**

Implements `TOS = TOS1 @ TOS`.

Baru pada versi 3.5.

#### **BINARY\_FLOOR\_DIVIDE**

Implements `TOS = TOS1 // TOS`.

#### **BINARY\_TRUE\_DIVIDE**

Implements `TOS = TOS1 / TOS`.

#### **BINARY\_MODULO**

Implements `TOS = TOS1 % TOS`.

#### **BINARY\_ADD**

Implements `TOS = TOS1 + TOS`.

#### **BINARY\_SUBTRACT**

Implements `TOS = TOS1 - TOS`.

#### **BINARY\_SUBSCR**

Implements `TOS = TOS1[TOS]`.

**BINARY\_LSHIFT**

Implements `TOS = TOS1 << TOS`.

**BINARY\_RSHIFT**

Implements `TOS = TOS1 >> TOS`.

**BINARY\_AND**

Implements `TOS = TOS1 & TOS`.

**BINARY\_XOR**

Implements `TOS = TOS1 ^ TOS`.

**BINARY\_OR**

Implements `TOS = TOS1 | TOS`.

**In-place operations**

In-place operations are like binary operations, in that they remove TOS and TOS1, and push the result back on the stack, but the operation is done in-place when TOS1 supports it, and the resulting TOS may be (but does not have to be) the original TOS1.

**INPLACE\_POWER**

Implements in-place `TOS = TOS1 ** TOS`.

**INPLACE\_MULTIPLY**

Implements in-place `TOS = TOS1 * TOS`.

**INPLACE\_MATRIX\_MULTIPLY**

Implements in-place `TOS = TOS1 @ TOS`.

Baru pada versi 3.5.

**INPLACE\_FLOOR\_DIVIDE**

Implements in-place `TOS = TOS1 // TOS`.

**INPLACE\_TRUE\_DIVIDE**

Implements in-place `TOS = TOS1 / TOS`.

**INPLACE\_MODULO**

Implements in-place `TOS = TOS1 % TOS`.

**INPLACE\_ADD**

Implements in-place `TOS = TOS1 + TOS`.

**INPLACE\_SUBTRACT**

Implements in-place `TOS = TOS1 - TOS`.

**INPLACE\_LSHIFT**

Implements in-place `TOS = TOS1 << TOS`.

**INPLACE\_RSHIFT**

Implements in-place `TOS = TOS1 >> TOS`.

**INPLACE\_AND**

Implements in-place `TOS = TOS1 & TOS`.

**INPLACE\_XOR**

Implements in-place `TOS = TOS1 ^ TOS`.

**INPLACE\_OR**

Implements in-place `TOS = TOS1 | TOS`.

**STORE\_SUBSCR**

Implements `TOS1[TOS] = TOS2`.

### **DELETE\_SUBSCR**

Implements `del TOS1[TOS]`.

### **Coroutine opcodes**

#### **GET\_AWAITABLE**

Implements `TOS = get_awaitable(TOS)`, where `get_awaitable(o)` returns `o` if `o` is a coroutine object or a generator object with the `CO_ITERABLE_COROUTINE` flag, or resolves `o.__await__`.

Baru pada versi 3.5.

#### **GET\_AITER**

Implements `TOS = TOS.__aiter__()`.

Baru pada versi 3.5.

Berubah pada versi 3.7: Returning awaitable objects from `__aiter__` is no longer supported.

#### **GET\_ANEXT**

Implements `PUSH(get_awaitable(TOS.__anext__()))`. See `GET_AWAITABLE` for details about `get_awaitable`.

Baru pada versi 3.5.

#### **END\_ASYNC\_FOR**

Terminates an `async for` loop. Handles an exception raised when awaiting a next item. If `TOS` is `StopAsyncIteration` pop 7 values from the stack and restore the exception state using the second three of them. Otherwise re-raise the exception using the three values from the stack. An exception handler block is removed from the block stack.

Baru pada versi 3.8.

#### **BEFORE\_ASYNC\_WITH**

Resolves `__aenter__` and `__aexit__` from the object on top of the stack. Pushes `__aexit__` and result of `__aenter__()` to the stack.

Baru pada versi 3.5.

#### **SETUP\_ASYNC\_WITH**

Creates a new frame object.

Baru pada versi 3.5.

### **Miscellaneous opcodes**

#### **PRINT\_EXPR**

Implements the expression statement for the interactive mode. `TOS` is removed from the stack and printed. In non-interactive mode, an expression statement is terminated with `POP_TOP`.

#### **SET\_ADD(i)**

Calls `set.add(TOS1[-i], TOS)`. Used to implement set comprehensions.

#### **LIST\_APPEND(i)**

Calls `list.append(TOS1[-i], TOS)`. Used to implement list comprehensions.

#### **MAP\_ADD(i)**

Calls `dict.__setitem__(TOS1[-i], TOS1, TOS)`. Used to implement dict comprehensions.

Baru pada versi 3.1.

Berubah pada versi 3.8: Map value is `TOS` and map key is `TOS1`. Before, those were reversed.

For all of the `SET_ADD`, `LIST_APPEND` and `MAP_ADD` instructions, while the added value or key/value pair is popped off, the container object remains on the stack so that it is available for further iterations of the loop.

**RETURN\_VALUE**

Returns with TOS to the caller of the function.

**YIELD\_VALUE**

Pops TOS and yields it from a *generator*.

**YIELD\_FROM**

Pops TOS and delegates to it as a subiterator from a *generator*.

Baru pada versi 3.3.

**SETUP\_ANNOTATIONS**

Checks whether `__annotations__` is defined in `locals()`, if not it is set up to an empty dict. This opcode is only emitted if a class or module body contains *variable annotations* statically.

Baru pada versi 3.6.

**IMPORT\_STAR**

Loads all symbols not starting with `'_'` directly from the module TOS to the local namespace. The module is popped after loading all names. This opcode implements `from module import *`.

**POP\_BLOCK**

Removes one block from the block stack. Per frame, there is a stack of blocks, denoting `try` statements, and such.

**POP\_EXCEPT**

Removes one block from the block stack. The popped block must be an exception handler block, as implicitly created when entering an except handler. In addition to popping extraneous values from the frame stack, the last three popped values are used to restore the exception state.

**POP\_FINALLY** (*preserve\_tos*)

Cleans up the value stack and the block stack. If *preserve\_tos* is not 0 TOS first is popped from the stack and pushed on the stack after performing other stack operations:

- If TOS is NULL or an integer (pushed by *BEGIN\_FINALLY* or *CALL\_FINALLY*) it is popped from the stack.
- If TOS is an exception type (pushed when an exception has been raised) 6 values are popped from the stack, the last three popped values are used to restore the exception state. An exception handler block is removed from the block stack.

It is similar to *END\_FINALLY*, but doesn't change the bytecode counter nor raise an exception. Used for implementing `break`, `continue` and `return` in the `finally` block.

Baru pada versi 3.8.

**BEGIN\_FINALLY**

Pushes NULL onto the stack for using it in *END\_FINALLY*, *POP\_FINALLY*, *WITH\_CLEANUP\_START* and *WITH\_CLEANUP\_FINISH*. Starts the `finally` block.

Baru pada versi 3.8.

**END\_FINALLY**

Terminates a `finally` clause. The interpreter recalls whether the exception has to be re-raised or execution has to be continued depending on the value of TOS.

- If TOS is NULL (pushed by *BEGIN\_FINALLY*) continue from the next instruction. TOS is popped.
- If TOS is an integer (pushed by *CALL\_FINALLY*), sets the bytecode counter to TOS. TOS is popped.
- If TOS is an exception type (pushed when an exception has been raised) 6 values are popped from the stack, the first three popped values are used to re-raise the exception and the last three popped values are used to restore the exception state. An exception handler block is removed from the block stack.

**LOAD\_BUILD\_CLASS**

Pushes `builtins.__build_class__()` onto the stack. It is later called by [CALL\\_FUNCTION](#) to construct a class.

**SETUP\_WITH** (*delta*)

This opcode performs several operations before a `with` block starts. First, it loads `__exit__()` from the context manager and pushes it onto the stack for later use by [WITH\\_CLEANUP\\_START](#). Then, `__enter__()` is called, and a finally block pointing to *delta* is pushed. Finally, the result of calling the `__enter__()` method is pushed onto the stack. The next opcode will either ignore it ([POP\\_TOP](#)), or store it in (a) variable(s) ([STORE\\_FAST](#), [STORE\\_NAME](#), or [UNPACK\\_SEQUENCE](#)).

Baru pada versi 3.2.

**WITH\_CLEANUP\_START**

Starts cleaning up the stack when a `with` statement block exits.

At the top of the stack are either `NULL` (pushed by [BEGIN\\_FINALLY](#)) or 6 values pushed if an exception has been raised in the `with` block. Below is the context manager's `__exit__()` or `__aexit__()` bound method.

If TOS is `NULL`, calls `SECOND (None, None, None)`, removes the function from the stack, leaving TOS, and pushes `None` to the stack. Otherwise calls `SEVENTH (TOP, SECOND, THIRD)`, shifts the bottom 3 values of the stack down, replaces the empty spot with `NULL` and pushes TOS. Finally pushes the result of the call.

**WITH\_CLEANUP\_FINISH**

Finishes cleaning up the stack when a `with` statement block exits.

TOS is result of `__exit__()` or `__aexit__()` function call pushed by [WITH\\_CLEANUP\\_START](#). `SECOND` is `None` or an exception type (pushed when an exception has been raised).

Pops two values from the stack. If `SECOND` is not `None` and TOS is true unwinds the `EXCEPT_HANDLER` block which was created when the exception was caught and pushes `NULL` to the stack.

All of the following opcodes use their arguments.

**STORE\_NAME** (*namei*)

Implements `name = TOS`. *namei* is the index of *name* in the attribute `co_names` of the code object. The compiler tries to use [STORE\\_FAST](#) or [STORE\\_GLOBAL](#) if possible.

**DELETE\_NAME** (*namei*)

Implements `del name`, where *namei* is the index into `co_names` attribute of the code object.

**UNPACK\_SEQUENCE** (*count*)

Unpacks TOS into *count* individual values, which are put onto the stack right-to-left.

**UNPACK\_EX** (*counts*)

Implements assignment with a starred target: Unpacks an iterable in TOS into individual values, where the total number of values can be smaller than the number of items in the iterable: one of the new values will be a list of all leftover items.

The low byte of *counts* is the number of values before the list value, the high byte of *counts* the number of values after it. The resulting values are put onto the stack right-to-left.

**STORE\_ATTR** (*namei*)

Implements `TOS.name = TOS1`, where *namei* is the index of *name* in `co_names`.

**DELETE\_ATTR** (*namei*)

Implements `del TOS.name`, using *namei* as index into `co_names`.

**STORE\_GLOBAL** (*namei*)

Works as [STORE\\_NAME](#), but stores the name as a global.

**DELETE\_GLOBAL** (*namei*)

Works as [DELETE\\_NAME](#), but deletes a global name.

**LOAD\_CONST** (*consti*)

Pushes `co_consts[consti]` onto the stack.

**LOAD\_NAME** (*namei*)

Pushes the value associated with `co_names[namei]` onto the stack.

**BUILD\_TUPLE** (*count*)

Creates a tuple consuming *count* items from the stack, and pushes the resulting tuple onto the stack.

**BUILD\_LIST** (*count*)

Works as [BUILD\\_TUPLE](#), but creates a list.

**BUILD\_SET** (*count*)

Works as [BUILD\\_TUPLE](#), but creates a set.

**BUILD\_MAP** (*count*)

Pushes a new dictionary object onto the stack. Pops 2 \* *count* items so that the dictionary holds *count* entries: `{..., TOS3: TOS2, TOS1: TOS}`.

Berubah pada versi 3.5: The dictionary is created from stack items instead of creating an empty dictionary pre-sized to hold *count* items.

**BUILD\_CONST\_KEY\_MAP** (*count*)

The version of [BUILD\\_MAP](#) specialized for constant keys. Pops the top element on the stack which contains a tuple of keys, then starting from `TOS1`, pops *count* values to form values in the built dictionary.

Baru pada versi 3.6.

**BUILD\_STRING** (*count*)

Concatenates *count* strings from the stack and pushes the resulting string onto the stack.

Baru pada versi 3.6.

**BUILD\_TUPLE\_UNPACK** (*count*)

Pops *count* iterables from the stack, joins them in a single tuple, and pushes the result. Implements iterable unpacking in tuple displays `(*x, *y, *z)`.

Baru pada versi 3.5.

**BUILD\_TUPLE\_UNPACK\_WITH\_CALL** (*count*)

This is similar to [BUILD\\_TUPLE\\_UNPACK](#), but is used for `f(*x, *y, *z)` call syntax. The stack item at position *count* + 1 should be the corresponding callable `f`.

Baru pada versi 3.6.

**BUILD\_LIST\_UNPACK** (*count*)

This is similar to [BUILD\\_TUPLE\\_UNPACK](#), but pushes a list instead of tuple. Implements iterable unpacking in list displays `[*x, *y, *z]`.

Baru pada versi 3.5.

**BUILD\_SET\_UNPACK** (*count*)

This is similar to [BUILD\\_TUPLE\\_UNPACK](#), but pushes a set instead of tuple. Implements iterable unpacking in set displays `{*x, *y, *z}`.

Baru pada versi 3.5.

**BUILD\_MAP\_UNPACK** (*count*)

Pops *count* mappings from the stack, merges them into a single dictionary, and pushes the result. Implements dictionary unpacking in dictionary displays `{**x, **y, **z}`.

Baru pada versi 3.5.

### **BUILD\_MAP\_UNPACK\_WITH\_CALL** (*count*)

This is similar to [BUILD\\_MAP\\_UNPACK](#), but is used for `f (**x, **y, **z)` call syntax. The stack item at position `count + 2` should be the corresponding callable `f`.

Baru pada versi 3.5.

Berubah pada versi 3.6: The position of the callable is determined by adding 2 to the opcode argument instead of encoding it in the second byte of the argument.

### **LOAD\_ATTR** (*namei*)

Replaces TOS with `getattr(TOS, co_names[namei])`.

### **COMPARE\_OP** (*opname*)

Performs a Boolean operation. The operation name can be found in `cmp_op[opname]`.

### **IMPORT\_NAME** (*namei*)

Imports the module `co_names[namei]`. TOS and TOS1 are popped and provide the *fromlist* and *level* arguments of `__import__()`. The module object is pushed onto the stack. The current namespace is not affected: for a proper import statement, a subsequent [STORE\\_FAST](#) instruction modifies the namespace.

### **IMPORT\_FROM** (*namei*)

Loads the attribute `co_names[namei]` from the module found in TOS. The resulting object is pushed onto the stack, to be subsequently stored by a [STORE\\_FAST](#) instruction.

### **JUMP\_FORWARD** (*delta*)

Increments bytecode counter by *delta*.

### **POP\_JUMP\_IF\_TRUE** (*target*)

If TOS is true, sets the bytecode counter to *target*. TOS is popped.

Baru pada versi 3.1.

### **POP\_JUMP\_IF\_FALSE** (*target*)

If TOS is false, sets the bytecode counter to *target*. TOS is popped.

Baru pada versi 3.1.

### **JUMP\_IF\_TRUE\_OR\_POP** (*target*)

If TOS is true, sets the bytecode counter to *target* and leaves TOS on the stack. Otherwise (TOS is false), TOS is popped.

Baru pada versi 3.1.

### **JUMP\_IF\_FALSE\_OR\_POP** (*target*)

If TOS is false, sets the bytecode counter to *target* and leaves TOS on the stack. Otherwise (TOS is true), TOS is popped.

Baru pada versi 3.1.

### **JUMP\_ABSOLUTE** (*target*)

Set bytecode counter to *target*.

### **FOR\_ITER** (*delta*)

TOS is an [iterator](#). Call its `__next__()` method. If this yields a new value, push it on the stack (leaving the iterator below it). If the iterator indicates it is exhausted TOS is popped, and the byte code counter is incremented by *delta*.

### **LOAD\_GLOBAL** (*namei*)

Loads the global named `co_names[namei]` onto the stack.

### **SETUP\_FINALLY** (*delta*)

Pushes a try block from a try-finally or try-except clause onto the block stack. *delta* points to the finally block or the first except block.

**CALL\_FINALLY** (*delta*)

Pushes the address of the next instruction onto the stack and increments bytecode counter by *delta*. Used for calling the finally block as a "subroutine".

Baru pada versi 3.8.

**LOAD\_FAST** (*var\_num*)

Pushes a reference to the local `co_varnames[var_num]` onto the stack.

**STORE\_FAST** (*var\_num*)

Stores TOS into the local `co_varnames[var_num]`.

**DELETE\_FAST** (*var\_num*)

Deletes local `co_varnames[var_num]`.

**LOAD\_CLOSURE** (*i*)

Pushes a reference to the cell contained in slot *i* of the cell and free variable storage. The name of the variable is `co_cellvars[i]` if *i* is less than the length of `co_cellvars`. Otherwise it is `co_freevars[i - len(co_cellvars)]`.

**LOAD\_DEREF** (*i*)

Loads the cell contained in slot *i* of the cell and free variable storage. Pushes a reference to the object the cell contains on the stack.

**LOAD\_CLASSDEREF** (*i*)

Much like [LOAD\\_DEREF](#) but first checks the locals dictionary before consulting the cell. This is used for loading free variables in class bodies.

Baru pada versi 3.4.

**STORE\_DEREF** (*i*)

Stores TOS into the cell contained in slot *i* of the cell and free variable storage.

**DELETE\_DEREF** (*i*)

Empties the cell contained in slot *i* of the cell and free variable storage. Used by the `del` statement.

Baru pada versi 3.2.

**RAISE\_VARARGS** (*argc*)

Raises an exception using one of the 3 forms of the `raise` statement, depending on the value of *argc*:

- 0: `raise` (re-raise previous exception)
- 1: `raise TOS` (raise exception instance or type at TOS)
- 2: `raise TOS1 from TOS` (raise exception instance or type at TOS1 with `__cause__` set to TOS)

**CALL\_FUNCTION** (*argc*)

Calls a callable object with positional arguments. *argc* indicates the number of positional arguments. The top of the stack contains positional arguments, with the right-most argument on top. Below the arguments is a callable object to call. `CALL_FUNCTION` pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

Berubah pada versi 3.6: This opcode is used only for calls with positional arguments.

**CALL\_FUNCTION\_KW** (*argc*)

Calls a callable object with positional (if any) and keyword arguments. *argc* indicates the total number of positional and keyword arguments. The top element on the stack contains a tuple of keyword argument names. Below that are keyword arguments in the order corresponding to the tuple. Below that are positional arguments, with the right-most parameter on top. Below the arguments is a callable object to call. `CALL_FUNCTION_KW` pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

Berubah pada versi 3.6: Keyword arguments are packed in a tuple instead of a dictionary, *argc* indicates the total number of arguments.

**CALL\_FUNCTION\_EX** (*flags*)

Calls a callable object with variable set of positional and keyword arguments. If the lowest bit of *flags* is set, the top of the stack contains a mapping object containing additional keyword arguments. Below that is an iterable object containing positional arguments and a callable object to call. [BUILD\\_MAP\\_UNPACK\\_WITH\\_CALL](#) and [BUILD\\_TUPLE\\_UNPACK\\_WITH\\_CALL](#) can be used for merging multiple mapping objects and iterables containing arguments. Before the callable is called, the mapping object and iterable object are each "unpacked" and their contents passed in as keyword and positional arguments respectively. **CALL\_FUNCTION\_EX** pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

Baru pada versi 3.6.

**LOAD\_METHOD** (*namei*)

Loads a method named `co_names[namei]` from the TOS object. TOS is popped. This bytecode distinguishes two cases: if TOS has a method with the correct name, the bytecode pushes the unbound method and TOS. TOS will be used as the first argument (*self*) by [CALL\\_METHOD](#) when calling the unbound method. Otherwise, `NULL` and the object return by the attribute lookup are pushed.

Baru pada versi 3.7.

**CALL\_METHOD** (*argc*)

Calls a method. *argc* is the number of positional arguments. Keyword arguments are not supported. This opcode is designed to be used with [LOAD\\_METHOD](#). Positional arguments are on top of the stack. Below them, the two items described in [LOAD\\_METHOD](#) are on the stack (either *self* and an unbound method object or `NULL` and an arbitrary callable). All of them are popped and the return value is pushed.

Baru pada versi 3.7.

**MAKE\_FUNCTION** (*flags*)

Pushes a new function object on the stack. From bottom to top, the consumed stack must consist of values if the argument carries a specified flag value

- 0x01 a tuple of default values for positional-only and positional-or-keyword parameters in positional order
- 0x02 a dictionary of keyword-only parameters' default values
- 0x04 an annotation dictionary
- 0x08 a tuple containing cells for free variables, making a closure
- the code associated with the function (at TOS1)
- the *qualified name* of the function (at TOS)

**BUILD\_SLICE** (*argc*)

Pushes a slice object on the stack. *argc* must be 2 or 3. If it is 2, `slice(TOS1, TOS)` is pushed; if it is 3, `slice(TOS2, TOS1, TOS)` is pushed. See the [slice\(\)](#) built-in function for more information.

**EXTENDED\_ARG** (*ext*)

Prefixes any opcode which has an argument too big to fit into the default one byte. *ext* holds an additional byte which act as higher bits in the argument. For each opcode, at most three prefixal **EXTENDED\_ARG** are allowed, forming an argument from two-byte to four-byte.

**FORMAT\_VALUE** (*flags*)

Used for implementing formatted literal strings (f-strings). Pops an optional *fmt\_spec* from the stack, then a required *value*. *flags* is interpreted as follows:

- (flags & 0x03) == 0x00: *value* is formatted as-is.
- (flags & 0x03) == 0x01: call [str\(\)](#) on *value* before formatting it.

- `(flags & 0x03) == 0x02`: call `repr()` on *value* before formatting it.
- `(flags & 0x03) == 0x03`: call `ascii()` on *value* before formatting it.
- `(flags & 0x04) == 0x04`: pop `fmt_spec` from the stack and use it, else use an empty `fmt_spec`.

Formatting is performed using `PyObject_Format()`. The result is pushed on the stack.

Baru pada versi 3.6.

#### **HAVE\_ARGUMENT**

This is not really an opcode. It identifies the dividing line between opcodes which don't use their argument and those that do (`< HAVE_ARGUMENT` and `>= HAVE_ARGUMENT`, respectively).

Berubah pada versi 3.6: Now every instruction has an argument, but opcodes `< HAVE_ARGUMENT` ignore it. Before, only opcodes `>= HAVE_ARGUMENT` had an argument.

### **32.12.4 Opcode collections**

These collections are provided for automatic introspection of bytecode instructions:

#### **`dis.opname`**

Sequence of operation names, indexable using the bytecode.

#### **`dis.opmap`**

Dictionary mapping operation names to bytecodes.

#### **`dis.cmp_op`**

Sequence of all compare operation names.

#### **`dis.hasconst`**

Sequence of bytecodes that access a constant.

#### **`dis.hasfree`**

Sequence of bytecodes that access a free variable (note that 'free' in this context refers to names in the current scope that are referenced by inner scopes or names in outer scopes that are referenced from this scope. It does *not* include references to global or builtin scopes).

#### **`dis.hasname`**

Sequence of bytecodes that access an attribute by name.

#### **`dis.hasjrel`**

Sequence of bytecodes that have a relative jump target.

#### **`dis.hasjabs`**

Sequence of bytecodes that have an absolute jump target.

#### **`dis.haslocal`**

Sequence of bytecodes that access a local variable.

#### **`dis.hascompare`**

Sequence of bytecodes of Boolean operations.

## 32.13 `pickletools` --- Tools for pickle developers

Source code: [Lib/pickletools.py](#)

---

This module contains various constants relating to the intimate details of the `pickle` module, some lengthy comments about the implementation, and a few useful functions for analyzing pickled data. The contents of this module are useful for Python core developers who are working on the `pickle`; ordinary users of the `pickle` module probably won't find the `pickletools` module relevant.

### 32.13.1 Command line usage

Baru pada versi 3.2.

When invoked from the command line, `python -m pickletools` will disassemble the contents of one or more pickle files. Note that if you want to see the Python object stored in the pickle rather than the details of pickle format, you may want to use `-m pickle` instead. However, when the pickle file that you want to examine comes from an untrusted source, `-m pickletools` is a safer option because it does not execute pickle bytecode.

For example, with a tuple `(1, 2)` pickled in file `x.pickle`:

```
$ python -m pickle x.pickle
(1, 2)

$ python -m pickletools x.pickle
0: \x80 PROTO      3
2: K    BININT1    1
4: K    BININT1    2
6: \x86 TUPLE2
7: q    BINPUT     0
9: .    STOP
highest protocol among opcodes = 2
```

#### Command line options

- a, --annotate**  
Annotate each line with a short opcode description.
- o, --output=<file>**  
Name of a file where the output should be written.
- l, --indentlevel=<num>**  
The number of blanks by which to indent a new MARK level.
- m, --memo**  
When multiple objects are disassembled, preserve memo between disassemblies.
- p, --preamble=<preamble>**  
When more than one pickle file are specified, print given preamble before each disassembly.

### 32.13.2 Programmatic Interface

`pickletools.dis` (*pickle*, *out=None*, *memo=None*, *indentlevel=4*, *annotate=0*)

Outputs a symbolic disassembly of the pickle to the file-like object *out*, defaulting to `sys.stdout`. *pickle* can be a string or a file-like object. *memo* can be a Python dictionary that will be used as the pickle's memo; it can be used to perform disassemblies across multiple pickles created by the same pickler. Successive levels, indicated by `MARK` opcodes in the stream, are indented by *indentlevel* spaces. If a nonzero value is given to *annotate*, each opcode in the output is annotated with a short description. The value of *annotate* is used as a hint for the column where annotation should start.

Baru pada versi 3.2: The *annotate* argument.

`pickletools.genops` (*pickle*)

Provides an *iterator* over all of the opcodes in a pickle, returning a sequence of (*opcode*, *arg*, *pos*) triples. *opcode* is an instance of an `OpcodeInfo` class; *arg* is the decoded value, as a Python object, of the opcode's argument; *pos* is the position at which this opcode is located. *pickle* can be a string or a file-like object.

`pickletools.optimize` (*picklestring*)

Returns a new equivalent pickle string after eliminating unused `PUT` opcodes. The optimized pickle is shorter, takes less transmission time, requires less storage space, and unpickles more efficiently.

---

## Layanan Miscellaneous

---

Modul yang dijelaskan dalam bab ini menyediakan layanan lain-lain yang tersedia di semua versi Python. Berikut gambarannya:

### 33.1 `formatter` --- Pemformatan umum output

Ditinggalkan sejak versi 3.4: Dikarenakan kurangnya penggunaan, modul `formatter` telah usang.

---

This module supports two interface definitions, each with multiple implementations: The *formatter* interface, and the *writer* interface which is required by the *formatter* interface.

Formatter objects transform an abstract flow of formatting events into specific output events on writer objects. Formatters manage several stack structures to allow various properties of a writer object to be changed and restored; writers need not be able to handle relative changes nor any sort of "change back" operation. Specific writer properties which may be controlled via formatter objects are horizontal alignment, font, and left margin indentations. A mechanism is provided which supports providing arbitrary, non-exclusive style settings to a writer as well. Additional interfaces facilitate formatting events which are not reversible, such as paragraph separation.

Writer objects encapsulate device interfaces. Abstract devices, such as file formats, are supported as well as physical devices. The provided implementations all work with abstract devices. The interface makes available mechanisms for setting the properties which formatter objects manage and inserting data into the output.

### 33.1.1 The Formatter Interface

Interfaces to create formatters are dependent on the specific formatter class being instantiated. The interfaces described below are the required interfaces which all formatters must support once initialized.

One data element is defined at the module level:

`formatter.AS_IS`

Value which can be used in the font specification passed to the `push_font()` method described below, or as the new value to any other `push_property()` method. Pushing the `AS_IS` value allows the corresponding `pop_property()` method to be called without having to track whether the property was changed.

The following attributes are defined for formatter instance objects:

`formatter.writer`

The writer instance with which the formatter interacts.

`formatter.end_paragraph(blanklines)`

Close any open paragraphs and insert at least *blanklines* before the next paragraph.

`formatter.add_line_break()`

Add a hard line break if one does not already exist. This does not break the logical paragraph.

`formatter.add_hor_rule(*args, **kw)`

Insert a horizontal rule in the output. A hard break is inserted if there is data in the current paragraph, but the logical paragraph is not broken. The arguments and keywords are passed on to the writer's `send_line_break()` method.

`formatter.add_flowning_data(data)`

Provide data which should be formatted with collapsed whitespace. Whitespace from preceding and successive calls to `add_flowning_data()` is considered as well when the whitespace collapse is performed. The data which is passed to this method is expected to be word-wrapped by the output device. Note that any word-wrapping still must be performed by the writer object due to the need to rely on device and font information.

`formatter.add_literal_data(data)`

Provide data which should be passed to the writer unchanged. Whitespace, including newline and tab characters, are considered legal in the value of *data*.

`formatter.add_label_data(format, counter)`

Insert a label which should be placed to the left of the current left margin. This should be used for constructing bulleted or numbered lists. If the *format* value is a string, it is interpreted as a format specification for *counter*, which should be an integer. The result of this formatting becomes the value of the label; if *format* is not a string it is used as the label value directly. The label value is passed as the only argument to the writer's `send_label_data()` method. Interpretation of non-string label values is dependent on the associated writer.

Format specifications are strings which, in combination with a counter value, are used to compute label values. Each character in the format string is copied to the label value, with some characters recognized to indicate a transform on the counter value. Specifically, the character '1' represents the counter value formatter as an Arabic number, the characters 'A' and 'a' represent alphabetic representations of the counter value in upper and lower case, respectively, and 'I' and 'i' represent the counter value in Roman numerals, in upper and lower case. Note that the alphabetic and roman transforms require that the counter value be greater than zero.

`formatter.flush_softspace()`

Send any pending whitespace buffered from a previous call to `add_flowning_data()` to the associated writer object. This should be called before any direct manipulation of the writer object.

`formatter.push_alignment(align)`

Push a new alignment setting onto the alignment stack. This may be `AS_IS` if no change is desired. If the alignment value is changed from the previous setting, the writer's `new_alignment()` method is called with the *align* value.

`formatter.pop_alignment()`

Restore the previous alignment.

`formatter.push_font((size, italic, bold, teletype))`

Change some or all font properties of the writer object. Properties which are not set to `AS_IS` are set to the values passed in while others are maintained at their current settings. The writer's `new_font()` method is called with the fully resolved font specification.

`formatter.pop_font()`

Restore the previous font.

`formatter.push_margin(margin)`

Increase the number of left margin indentations by one, associating the logical tag *margin* with the new indentation. The initial margin level is 0. Changed values of the logical tag must be true values; false values other than `AS_IS` are not sufficient to change the margin.

`formatter.pop_margin()`

Restore the previous margin.

`formatter.push_style(*styles)`

Push any number of arbitrary style specifications. All styles are pushed onto the styles stack in order. A tuple representing the entire stack, including `AS_IS` values, is passed to the writer's `new_styles()` method.

`formatter.pop_style(n=1)`

Pop the last *n* style specifications passed to `push_style()`. A tuple representing the revised stack, including `AS_IS` values, is passed to the writer's `new_styles()` method.

`formatter.set_spacing(spacing)`

Set the spacing style for the writer.

`formatter.assert_line_data(flag=1)`

Inform the formatter that data has been added to the current paragraph out-of-band. This should be used when the writer has been manipulated directly. The optional *flag* argument can be set to false if the writer manipulations produced a hard line break at the end of the output.

### 33.1.2 Formatter Implementations

Two implementations of formatter objects are provided by this module. Most applications may use one of these classes without modification or subclassing.

**class** `formatter.NullFormatter(writer=None)`

A formatter which does nothing. If *writer* is omitted, a `NullWriter` instance is created. No methods of the writer are called by `NullFormatter` instances. Implementations should inherit from this class if implementing a writer interface but don't need to inherit any implementation.

**class** `formatter.AbstractFormatter(writer)`

The standard formatter. This implementation has demonstrated wide applicability to many writers, and may be used directly in most circumstances. It has been used to implement a full-featured World Wide Web browser.

### 33.1.3 The Writer Interface

Interfaces to create writers are dependent on the specific writer class being instantiated. The interfaces described below are the required interfaces which all writers must support once initialized. Note that while most applications can use the `AbstractFormatter` class as a formatter, the writer must typically be provided by the application.

`writer.flush()`

Flush any buffered output or device control events.

`writer.new_alignment(align)`

Set the alignment style. The *align* value can be any object, but by convention is a string or `None`, where `None` indicates that the writer's "preferred" alignment should be used. Conventional *align* values are 'left', 'center', 'right', and 'justify'.

`writer.new_font(font)`

Set the font style. The value of *font* will be `None`, indicating that the device's default font should be used, or a tuple of the form (*size*, *italic*, *bold*, *teletype*). *Size* will be a string indicating the size of font that should be used; specific strings and their interpretation must be defined by the application. The *italic*, *bold*, and *teletype* values are Boolean values specifying which of those font attributes should be used.

`writer.new_margin(margin, level)`

Set the margin level to the integer *level* and the logical tag to *margin*. Interpretation of the logical tag is at the writer's discretion; the only restriction on the value of the logical tag is that it not be a false value for non-zero values of *level*.

`writer.new_spacing(spacing)`

Set the spacing style to *spacing*.

`writer.new_styles(styles)`

Set additional styles. The *styles* value is a tuple of arbitrary values; the value `AS_IS` should be ignored. The *styles* tuple may be interpreted either as a set or as a stack depending on the requirements of the application and writer implementation.

`writer.send_line_break()`

Break the current line.

`writer.send_paragraph(blankline)`

Produce a paragraph separation of at least *blankline* blank lines, or the equivalent. The *blankline* value will be an integer. Note that the implementation will receive a call to `send_line_break()` before this call if a line break is needed; this method should not include ending the last line of the paragraph. It is only responsible for vertical spacing between paragraphs.

`writer.send_hor_rule(*args, **kw)`

Display a horizontal rule on the output device. The arguments to this method are entirely application- and writer-specific, and should be interpreted with care. The method implementation may assume that a line break has already been issued via `send_line_break()`.

`writer.send_flowng_data(data)`

Output character data which may be word-wrapped and re-flowed as needed. Within any sequence of calls to this method, the writer may assume that spans of multiple whitespace characters have been collapsed to single space characters.

`writer.send_literal_data(data)`

Output character data which has already been formatted for display. Generally, this should be interpreted to mean that line breaks indicated by newline characters should be preserved and no new line breaks should be introduced. The data may contain embedded newline and tab characters, unlike data provided to the `send_formatted_data()` interface.

`writer.send_label_data(data)`

Set *data* to the left of the current left margin, if possible. The value of *data* is not restricted; treatment of non-string

values is entirely application- and writer-dependent. This method will only be called at the beginning of a line.

### 33.1.4 Writer Implementations

Three implementations of the writer object interface are provided as examples by this module. Most applications will need to derive new writer classes from the *NullWriter* class.

**class** `formatter.NullWriter`

A writer which only provides the interface definition; no actions are taken on any methods. This should be the base class for all writers which do not need to inherit any implementation methods.

**class** `formatter.AbstractWriter`

A writer which can be used in debugging formatters, but not much else. Each method simply announces itself by printing its name and arguments on standard output.

**class** `formatter.DumbWriter` (*file=None, maxcol=72*)

Simple writer class which writes output on the *file object* passed in as *file* or, if *file* is omitted, on standard output. The output is simply word-wrapped to the number of columns specified by *maxcol*. This class is suitable for reflowing a sequence of paragraphs.

---

## Layanan MS Windows Spesifik

---

Bab ini menjelaskan modul yang hanya tersedia pada platform MS Windows.

### 34.1 `msilib` --- Read and write Microsoft Installer files

**Source code:** `Lib/msilib/__init__.py`

---

The `msilib` supports the creation of Microsoft Installer (`.msi`) files. Because these files often contain an embedded "cabinet" file (`.cab`), it also exposes an API to create CAB files. Support for reading `.cab` files is currently not implemented; read support for the `.msi` database is possible.

This package aims to provide complete access to all tables in an `.msi` file, therefore, it is a fairly low-level API. Two primary applications of this package are the `distutils` command `bdist_msi`, and the creation of Python installer package itself (although that currently uses a different version of `msilib`).

The package contents can be roughly split into four parts: low-level CAB routines, low-level MSI routines, higher-level MSI routines, and standard table structures.

`msilib.FCICreate` (*cabname*, *files*)

Create a new CAB file named *cabname*. *files* must be a list of tuples, each containing the name of the file on disk, and the name of the file inside the CAB file.

The files are added to the CAB file in the order they appear in the list. All files are added into a single CAB file, using the MSZIP compression algorithm.

Callbacks to Python for the various steps of MSI creation are currently not exposed.

`msilib.UuidCreate` ()

Return the string representation of a new unique identifier. This wraps the Windows API functions `UuidCreate()` and `UuidToString()`.

`msilib.OpenDatabase` (*path*, *persist*)

Return a new database object by calling `MsiOpenDatabase`. *path* is the file name of the MSI file; *persist* can be one of the constants `MSIDBOPEN_CREATEDIRECT`, `MSIDBOPEN_CREATE`, `MSIDBOPEN_DIRECT`,

MSIDBOPEN\_READONLY, or MSIDBOPEN\_TRANSACT, and may include the flag MSIDBOPEN\_PATCHFILE. See the Microsoft documentation for the meaning of these flags; depending on the flags, an existing database is opened, or a new one created.

`msilib.CreateRecord(count)`

Return a new record object by calling `MSICreateRecord()`. *count* is the number of fields of the record.

`msilib.init_database(name, schema, ProductName, ProductCode, ProductVersion, Manufacturer)`

Create and return a new database *name*, initialize it with *schema*, and set the properties *ProductName*, *ProductCode*, *ProductVersion*, and *Manufacturer*.

*schema* must be a module object containing `tables` and `_Validation_records` attributes; typically, `msilib.schema` should be used.

The database will contain just the schema and the validation records when this function returns.

`msilib.add_data(database, table, records)`

Add all *records* to the table named *table* in *database*.

The *table* argument must be one of the predefined tables in the MSI schema, e.g. 'Feature', 'File', 'Component', 'Dialog', 'Control', etc.

*records* should be a list of tuples, each one containing all fields of a record according to the schema of the table. For optional fields, `None` can be passed.

Field values can be ints, strings, or instances of the Binary class.

**class** `msilib.Binary(filename)`

Represents entries in the Binary table; inserting such an object using `add_data()` reads the file named *filename* into the table.

`msilib.add_tables(database, module)`

Add all table content from *module* to *database*. *module* must contain an attribute *tables* listing all tables for which content should be added, and one attribute per table that has the actual content.

This is typically used to install the sequence tables.

`msilib.add_stream(database, name, path)`

Add the file *path* into the `_Stream` table of *database*, with the stream name *name*.

`msilib.gen_uuid()`

Return a new UUID, in the format that MSI typically requires (i.e. in curly braces, and with all hexdigits in upper-case).

### Lihat juga:

[FCICreate UuidCreate UuidToString](#)

## 34.1.1 Database Objects

`Database.OpenView(sql)`

Return a view object, by calling `MSIDatabaseOpenView()`. *sql* is the SQL statement to execute.

`Database.Commit()`

Commit the changes pending in the current transaction, by calling `MSIDatabaseCommit()`.

`Database.GetSummaryInformation(count)`

Return a new summary information object, by calling `MsiGetSummaryInformation()`. *count* is the maximum number of updated values.

`Database.Close()`  
 Close the database object, through `MsiCloseHandle()`.  
 Baru pada versi 3.7.

**Lihat juga:**

`MSIDatabaseOpenView` `MSIDatabaseCommit` `MSIGetSummaryInformation` `MsiCloseHandle`

### 34.1.2 View Objects

`View.Execute(params)`  
 Execute the SQL query of the view, through `MSIViewExecute()`. If *params* is not `None`, it is a record describing actual values of the parameter tokens in the query.

`View.GetColumnInfo(kind)`  
 Return a record describing the columns of the view, through calling `MsiViewGetColumnInfo()`. *kind* can be either `MSICOLINFO_NAMES` or `MSICOLINFO_TYPES`.

`View.Fetch()`  
 Return a result record of the query, through calling `MsiViewFetch()`.

`View.Modify(kind, data)`  
 Modify the view, by calling `MsiViewModify()`. *kind* can be one of `MSIMODIFY_SEEK`, `MSIMODIFY_REFRESH`, `MSIMODIFY_INSERT`, `MSIMODIFY_UPDATE`, `MSIMODIFY_ASSIGN`, `MSIMODIFY_REPLACE`, `MSIMODIFY_MERGE`, `MSIMODIFY_DELETE`, `MSIMODIFY_INSERT_TEMPORARY`, `MSIMODIFY_VALIDATE`, `MSIMODIFY_VALIDATE_NEW`, `MSIMODIFY_VALIDATE_FIELD`, or `MSIMODIFY_VALIDATE_DELETE`.  
*data* must be a record describing the new data.

`View.Close()`  
 Close the view, through `MsiViewClose()`.

**Lihat juga:**

`MsiViewExecute` `MSIViewGetColumnInfo` `MsiViewFetch` `MsiViewModify` `MsiViewClose`

### 34.1.3 Summary Information Objects

`SummaryInformation.GetProperty(field)`  
 Return a property of the summary, through `MsiSummaryInfoGetProperty()`. *field* is the name of the property, and can be one of the constants `PID_CODEPAGE`, `PID_TITLE`, `PID_SUBJECT`, `PID_AUTHOR`, `PID_KEYWORDS`, `PID_COMMENTS`, `PID_TEMPLATE`, `PID_LASTAUTHOR`, `PID_REVNUMBER`, `PID_LASTPRINTED`, `PID_CREATE_DTM`, `PID_LASTSAVE_DTM`, `PID_PAGECOUNT`, `PID_WORDCOUNT`, `PID_CHARCOUNT`, `PID_APPNAME`, or `PID_SECURITY`.

`SummaryInformation.GetPropertyCount()`  
 Return the number of summary properties, through `MsiSummaryInfoGetPropertyCount()`.

`SummaryInformation.SetProperty(field, value)`  
 Set a property through `MsiSummaryInfoSetProperty()`. *field* can have the same values as in `GetProperty()`, *value* is the new value of the property. Possible value types are integer and string.

`SummaryInformation.Persist()`  
 Write the modified properties to the summary information stream, using `MsiSummaryInfoPersist()`.

**Lihat juga:**

[MsiSummaryInfoGetProperty](#) [MsiSummaryInfoGetPropertyCount](#) [MsiSummaryInfoSetProperty](#) [MsiSummaryInfoPersist](#)

### 34.1.4 Record Objects

**Record.GetFieldCount()**

Return the number of fields of the record, through `MsiRecordGetFieldCount()`.

**Record.GetInteger(*field*)**

Return the value of *field* as an integer where possible. *field* must be an integer.

**Record.GetString(*field*)**

Return the value of *field* as a string where possible. *field* must be an integer.

**Record.SetString(*field*, *value*)**

Set *field* to *value* through `MsiRecordSetString()`. *field* must be an integer; *value* a string.

**Record.SetStream(*field*, *value*)**

Set *field* to the contents of the file named *value*, through `MsiRecordSetStream()`. *field* must be an integer; *value* a string.

**Record.SetInteger(*field*, *value*)**

Set *field* to *value* through `MsiRecordSetInteger()`. Both *field* and *value* must be an integer.

**Record.ClearData()**

Set all fields of the record to 0, through `MsiRecordClearData()`.

**Lihat juga:**

[MsiRecordGetFieldCount](#) [MsiRecordSetString](#) [MsiRecordSetStream](#) [MsiRecordSetInteger](#) [MsiRecordClearData](#)

### 34.1.5 Errors

All wrappers around MSI functions raise `MSIError`; the string inside the exception will contain more detail.

### 34.1.6 CAB Objects

**class** `msilib.CAB` (*name*)

The class `CAB` represents a CAB file. During MSI construction, files will be added simultaneously to the `Files` table, and to a CAB file. Then, when all files have been added, the CAB file can be written, then added to the MSI file.

*name* is the name of the CAB file in the MSI file.

**append** (*full*, *file*, *logical*)

Add the file with the pathname *full* to the CAB file, under the name *logical*. If there is already a file named *logical*, a new file name is created.

Return the index of the file in the CAB file, and the new name of the file inside the CAB file.

**commit** (*database*)

Generate a CAB file, add it as a stream to the MSI file, put it into the `Media` table, and remove the generated file from the disk.

### 34.1.7 Directory Objects

**class** `msilib.Directory` (*database, cab, basedir, physical, logical, default*[, *componentflags*])

Create a new directory in the Directory table. There is a current component at each point in time for the directory, which is either explicitly created through `start_component()`, or implicitly when files are added for the first time. Files are added into the current component, and into the cab file. To create a directory, a base directory object needs to be specified (can be `None`), the path to the physical directory, and a logical directory name. *default* specifies the DefaultDir slot in the directory table. *componentflags* specifies the default flags that new components get.

**start\_component** (*component=None, feature=None, flags=None, keyfile=None, uuid=None*)

Add an entry to the Component table, and make this component the current component for this directory. If no component name is given, the directory name is used. If no *feature* is given, the current feature is used. If no *flags* are given, the directory's default flags are used. If no *keyfile* is given, the KeyPath is left null in the Component table.

**add\_file** (*file, src=None, version=None, language=None*)

Add a file to the current component of the directory, starting a new one if there is no current component. By default, the file name in the source and the file table will be identical. If the *src* file is specified, it is interpreted relative to the current directory. Optionally, a *version* and a *language* can be specified for the entry in the File table.

**glob** (*pattern, exclude=None*)

Add a list of files to the current component as specified in the glob pattern. Individual files can be excluded in the *exclude* list.

**remove\_pyc** ()

Remove .pyc files on uninstall.

**Lihat juga:**

[Directory Table](#) [File Table](#) [Component Table](#) [FeatureComponents Table](#)

### 34.1.8 Features

**class** `msilib.Feature` (*db, id, title, desc, display, level=1, parent=None, directory=None, attributes=0*)

Add a new record to the Feature table, using the values *id*, *parent.id*, *title*, *desc*, *display*, *level*, *directory*, and *attributes*. The resulting feature object can be passed to the `start_component()` method of `Directory`.

**set\_current** ()

Make this feature the current feature of `msilib`. New components are automatically added to the default feature, unless a feature is explicitly specified.

**Lihat juga:**

[Feature Table](#)

### 34.1.9 GUI classes

*msilib* provides several classes that wrap the GUI tables in an MSI database. However, no standard user interface is provided; use *bdist\_msi* to create MSI files with a user-interface for installing Python packages.

**class** *msilib.Control* (*dlg, name*)

Base class of the dialog controls. *dlg* is the dialog object the control belongs to, and *name* is the control's name.

**event** (*event, argument, condition=1, ordering=None*)

Make an entry into the *ControlEvent* table for this control.

**mapping** (*event, attribute*)

Make an entry into the *EventMapping* table for this control.

**condition** (*action, condition*)

Make an entry into the *ControlCondition* table for this control.

**class** *msilib.RadioButtonGroup* (*dlg, name, property*)

Create a radio button control named *name*. *property* is the installer property that gets set when a radio button is selected.

**add** (*name, x, y, width, height, text, value=None*)

Add a radio button named *name* to the group, at the coordinates *x, y, width, height*, and with the label *text*. If *value* is *None*, it defaults to *name*.

**class** *msilib.Dialog* (*db, name, x, y, w, h, attr, title, first, default, cancel*)

Return a new *Dialog* object. An entry in the *Dialog* table is made, with the specified coordinates, dialog attributes, title, name of the first, default, and cancel controls.

**control** (*name, type, x, y, width, height, attributes, property, text, control\_next, help*)

Return a new *Control* object. An entry in the *Control* table is made with the specified parameters.

This is a generic method; for specific types, specialized methods are provided.

**text** (*name, x, y, width, height, attributes, text*)

Add and return a *Text* control.

**bitmap** (*name, x, y, width, height, text*)

Add and return a *Bitmap* control.

**line** (*name, x, y, width, height*)

Add and return a *Line* control.

**pushbutton** (*name, x, y, width, height, attributes, text, next\_control*)

Add and return a *PushButton* control.

**radiogroup** (*name, x, y, width, height, attributes, property, text, next\_control*)

Add and return a *RadioButtonGroup* control.

**checkbox** (*name, x, y, width, height, attributes, property, text, next\_control*)

Add and return a *CheckBox* control.

**Lihat juga:**

### 34.1.10 Precomputed tables

`msilib` provides a few subpackages that contain only schema and table definitions. Currently, these definitions are based on MSI version 2.0.

#### `msilib.schema`

This is the standard MSI schema for MSI 2.0, with the `tables` variable providing a list of table definitions, and `_Validation_records` providing the data for MSI validation.

#### `msilib.sequence`

This module contains table contents for the standard sequence tables: *AdminExecuteSequence*, *AdminUISequence*, *AdvExecuteSequence*, *InstallExecuteSequence*, and *InstallUISequence*.

#### `msilib.text`

This module contains definitions for the `UIText` and `ActionText` tables, for the standard installer actions.

## 34.2 `msvcrt` --- Useful routines from the MS VC++ runtime

These functions provide access to some useful capabilities on Windows platforms. Some higher-level modules use these functions to build the Windows implementations of their services. For example, the `getpass` module uses this in the implementation of the `getpass()` function.

Further documentation on these functions can be found in the Platform API documentation.

The module implements both the normal and wide char variants of the console I/O api. The normal API deals only with ASCII characters and is of limited use for internationalized applications. The wide char API should be used where ever possible.

Berubah pada versi 3.3: Operations in this module now raise `OSError` where `IOError` was raised.

### 34.2.1 File Operations

#### `msvcrt.locking(f, mode, nbytes)`

Lock part of a file based on file descriptor `fd` from the C runtime. Raises `OSError` on failure. The locked region of the file extends from the current file position for `nbytes` bytes, and may continue beyond the end of the file. `mode` must be one of the `LK_*` constants listed below. Multiple regions in a file may be locked at the same time, but may not overlap. Adjacent regions are not merged; they must be unlocked individually.

Raises an *auditing event* `msvcrt.locking` with arguments `fd, mode, nbytes`.

#### `msvcrt.LK_LOCK`

#### `msvcrt.LK_RLCK`

Locks the specified bytes. If the bytes cannot be locked, the program immediately tries again after 1 second. If, after 10 attempts, the bytes cannot be locked, `OSError` is raised.

#### `msvcrt.LK_NBLCK`

#### `msvcrt.LK_NBLCK`

Locks the specified bytes. If the bytes cannot be locked, `OSError` is raised.

#### `msvcrt.LK_UNLCK`

Unlocks the specified bytes, which must have been previously locked.

#### `msvcrt.setmode(f, flags)`

Set the line-end translation mode for the file descriptor `fd`. To set it to text mode, `flags` should be `os.O_TEXT`; for binary, it should be `os.O_BINARY`.

`msvcrt.open_osfhandle (handle, flags)`

Create a C runtime file descriptor from the file handle *handle*. The *flags* parameter should be a bitwise OR of `os.O_APPEND`, `os.O_RDONLY`, and `os.O_TEXT`. The returned file descriptor may be used as a parameter to `os.fdopen()` to create a file object.

Raises an *auditing event* `msvcrt.open_osfhandle` with arguments `handle`, `flags`.

`msvcrt.get_osfhandle (fd)`

Return the file handle for the file descriptor *fd*. Raises *OSError* if *fd* is not recognized.

Raises an *auditing event* `msvcrt.get_osfhandle` with argument `fd`.

## 34.2.2 Console I/O

`msvcrt.kbhit ()`

Return `True` if a keypress is waiting to be read.

`msvcrt.getch ()`

Read a keypress and return the resulting character as a byte string. Nothing is echoed to the console. This call will block if a keypress is not already available, but will not wait for `Enter` to be pressed. If the pressed key was a special function key, this will return `'\000'` or `'\xe0'`; the next call will return the keycode. The `Control-C` keypress cannot be read with this function.

`msvcrt.getwch ()`

Wide char variant of `getch()`, returning a Unicode value.

`msvcrt.getche ()`

Similar to `getch()`, but the keypress will be echoed if it represents a printable character.

`msvcrt.getwche ()`

Wide char variant of `getche()`, returning a Unicode value.

`msvcrt.putch (char)`

Print the byte string *char* to the console without buffering.

`msvcrt.putwch (unicode_char)`

Wide char variant of `putch()`, accepting a Unicode value.

`msvcrt.ungetch (char)`

Cause the byte string *char* to be "pushed back" into the console buffer; it will be the next character read by `getch()` or `getche()`.

`msvcrt.ungetwch (unicode_char)`

Wide char variant of `ungetch()`, accepting a Unicode value.

## 34.2.3 Other Functions

`msvcrt.heapmin ()`

Force the `malloc()` heap to clean itself up and return unused blocks to the operating system. On failure, this raises *OSError*.

## 34.3 winreg --- Windows registry access

These functions expose the Windows registry API to Python. Instead of using an integer as the registry handle, a *handle object* is used to ensure that the handles are closed correctly, even if the programmer neglects to explicitly close them.

Berubah pada versi 3.3: Several functions in this module used to raise a *WindowsError*, which is now an alias of *OSError*.

### 34.3.1 Fungsi-Fungsi

This module offers the following functions:

`winreg.CloseKey(hkey)`

Closes a previously opened registry key. The *hkey* argument specifies a previously opened key.

---

**Catatan:** If *hkey* is not closed using this method (or via *hkey.Close()*), it is closed when the *hkey* object is destroyed by Python.

---

`winreg.ConnectRegistry(computer_name, key)`

Establishes a connection to a predefined registry handle on another computer, and returns a *handle object*.

*computer\_name* is the name of the remote computer, of the form `r"\\computername"`. If `None`, the local computer is used.

*key* is the predefined handle to connect to.

The return value is the handle of the opened key. If the function fails, an *OSError* exception is raised.

Raises an *auditing event* `winreg.ConnectRegistry` with arguments *computer\_name*, *key*.

Berubah pada versi 3.3: See *above*.

`winreg.CreateKey(key, sub_key)`

Creates or opens the specified key, returning a *handle object*.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta *HKEY\_\**.

*sub\_key* is a string that names the key this method opens or creates.

If *key* is one of the predefined keys, *sub\_key* may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an *OSError* exception is raised.

Raises an *auditing event* `winreg.CreateKey` with arguments *key*, *sub\_key*, *access*.

Raises an *auditing event* `winreg.OpenKey/result` with argument *key*.

Berubah pada versi 3.3: See *above*.

`winreg.CreateKeyEx(key, sub_key, reserved=0, access=KEY_WRITE)`

Creates or opens the specified key, returning a *handle object*.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta *HKEY\_\**.

*sub\_key* is a string that names the key this method opens or creates.

*reserved* is a reserved integer, and must be zero. The default is zero.

*access* is an integer that specifies an access mask that describes the desired security access for the key. Default is `KEY_WRITE`. See [Access Rights](#) for other allowed values.

If *key* is one of the predefined keys, *sub\_key* may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an `OSError` exception is raised.

Raises an [auditing event](#) `winreg.CreateKey` with arguments `key`, `sub_key`, `access`.

Raises an [auditing event](#) `winreg.OpenKey/result` with argument `key`.

Baru pada versi 3.2.

Berubah pada versi 3.3: See [above](#).

`winreg.DeleteKey(key, sub_key)`

Deletes the specified key.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

*sub\_key* is a string that must be a subkey of the key identified by the *key* parameter. This value must not be `None`, and the key may not have subkeys.

*This method can not delete keys with subkeys.*

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an `OSError` exception is raised.

Raises an [auditing event](#) `winreg.DeleteKey` with arguments `key`, `sub_key`, `access`.

Berubah pada versi 3.3: See [above](#).

`winreg.DeleteKeyEx(key, sub_key, access=KEY_WOW64_64KEY, reserved=0)`

Deletes the specified key.

---

**Catatan:** The `DeleteKeyEx()` function is implemented with the `RegDeleteKeyEx` Windows API function, which is specific to 64-bit versions of Windows. See the [RegDeleteKeyEx documentation](#).

---

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

*sub\_key* is a string that must be a subkey of the key identified by the *key* parameter. This value must not be `None`, and the key may not have subkeys.

*reserved* is a reserved integer, and must be zero. The default is zero.

*access* is an integer that specifies an access mask that describes the desired security access for the key. Default is `KEY_WOW64_64KEY`. See [Access Rights](#) for other allowed values.

*This method can not delete keys with subkeys.*

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an `OSError` exception is raised.

On unsupported Windows versions, `NotImplementedError` is raised.

Raises an [auditing event](#) `winreg.DeleteKey` with arguments `key`, `sub_key`, `access`.

Baru pada versi 3.2.

Berubah pada versi 3.3: See [above](#).

`winreg.DeleteValue(key, value)`

Removes a named value from a registry key.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

*value* is a string that identifies the value to remove.

Raises an *auditing event* `winreg.DeleteValue` with arguments *key*, *value*.

`winreg.EnumKey(key, index)`

Enumerates subkeys of an open registry key, returning a string.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

*index* is an integer that identifies the index of the key to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly until an *OSError* exception is raised, indicating, no more values are available.

Raises an *auditing event* `winreg.EnumKey` with arguments *key*, *index*.

Berubah pada versi 3.3: See *above*.

`winreg.EnumValue(key, index)`

Enumerates values of an open registry key, returning a tuple.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

*index* is an integer that identifies the index of the value to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly, until an *OSError* exception is raised, indicating no more values.

The result is a tuple of 3 items:

| Indeks | Artinya                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------|
| 0      | A string that identifies the value name                                                                  |
| 1      | An object that holds the value data, and whose type depends on the underlying registry type              |
| 2      | An integer that identifies the type of the value data (see table in docs for <code>SetValueEx()</code> ) |

Raises an *auditing event* `winreg.EnumValue` with arguments *key*, *index*.

Berubah pada versi 3.3: See *above*.

`winreg.ExpandEnvironmentStrings(str)`

Expands environment variable placeholders `%NAME%` in strings like `REG_EXPAND_SZ`:

```
>>> ExpandEnvironmentStrings('%windir%')
'C:\\Windows'
```

Raises an *auditing event* `winreg.ExpandEnvironmentStrings` with argument *str*.

`winreg.FlushKey(key)`

Writes all the attributes of a key to the registry.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

It is not necessary to call `FlushKey()` to change a key. Registry changes are flushed to disk by the registry using its lazy flusher. Registry changes are also flushed to disk at system shutdown. Unlike `CloseKey()`, the `FlushKey()` method returns only when all the data has been written to the registry. An application should only call `FlushKey()` if it requires absolute certainty that registry changes are on disk.

---

**Catatan:** If you don't know whether a `FlushKey()` call is required, it probably isn't.

---

`winreg.LoadKey(key, sub_key, file_name)`

Creates a subkey under the specified key and stores registration information from a specified file into that subkey.

`key` is a handle returned by `ConnectRegistry()` or one of the constants `HKEY_USERS` or `HKEY_LOCAL_MACHINE`.

`sub_key` is a string that identifies the subkey to load.

`file_name` is the name of the file to load registry data from. This file must have been created with the `SaveKey()` function. Under the file allocation table (FAT) file system, the filename may not have an extension.

A call to `LoadKey()` fails if the calling process does not have the `SE_RESTORE_PRIVILEGE` privilege. Note that privileges are different from permissions -- see the [RegLoadKey documentation](#) for more details.

If `key` is a handle returned by `ConnectRegistry()`, then the path specified in `file_name` is relative to the remote computer.

Raises an *auditing event* `winreg.LoadKey` with arguments `key`, `sub_key`, `file_name`.

`winreg.OpenKey(key, sub_key, reserved=0, access=KEY_READ)`

`winreg.OpenKeyEx(key, sub_key, reserved=0, access=KEY_READ)`

Opens the specified key, returning a *handle object*.

`key` adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

`sub_key` is a string that identifies the sub\_key to open.

`reserved` is a reserved integer, and must be zero. The default is zero.

`access` is an integer that specifies an access mask that describes the desired security access for the key. Default is `KEY_READ`. See [Access Rights](#) for other allowed values.

The result is a new handle to the specified key.

If the function fails, `OSError` is raised.

Raises an *auditing event* `winreg.OpenKey` with arguments `key`, `sub_key`, `access`.

Raises an *auditing event* `winreg.OpenKey/result` with argument `key`.

Berubah pada versi 3.2: Allow the use of named arguments.

Berubah pada versi 3.3: See [above](#).

`winreg.QueryInfoKey(key)`

Returns information about a key, as a tuple.

`key` adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

The result is a tuple of 3 items:

| In-deks | Artinya                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------|
| 0       | An integer giving the number of sub keys this key has.                                                     |
| 1       | An integer giving the number of values this key has.                                                       |
| 2       | An integer giving when the key was last modified (if available) as 100's of nanoseconds since Jan 1, 1601. |

Raises an *auditing event* `winreg.QueryInfoKey` with argument `key`.

`winreg.QueryValue(key, sub_key)`

Retrieves the unnamed value for a key, as a string.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

*sub\_key* is a string that holds the name of the subkey with which the value is associated. If this parameter is `None` or empty, the function retrieves the value set by the `SetValue()` method for the key identified by *key*.

Values in the registry have name, type, and data components. This method retrieves the data for a key's first value that has a `NULL` name. But the underlying API call doesn't return the type, so always use `QueryValueEx()` if possible.

Raises an *auditing event* `winreg.QueryValue` with arguments *key*, *sub\_key*, *value\_name*.

`winreg.QueryValueEx(key, value_name)`

Retrieves the type and data for a specified value name associated with an open registry key.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

*value\_name* is a string indicating the value to query.

The result is a tuple of 2 items:

| Indeks | Artinya                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------|
| 0      | The value of the registry item.                                                                       |
| 1      | An integer giving the registry type for this value (see table in docs for <code>SetValueEx()</code> ) |

Raises an *auditing event* `winreg.QueryValue` with arguments *key*, *sub\_key*, *value\_name*.

`winreg.SaveKey(key, file_name)`

Saves the specified key, and all its subkeys to the specified file.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

*file\_name* is the name of the file to save registry data to. This file cannot already exist. If this filename includes an extension, it cannot be used on file allocation table (FAT) file systems by the `LoadKey()` method.

If *key* represents a key on a remote computer, the path described by *file\_name* is relative to the remote computer. The caller of this method must possess the `SeBackupPrivilege` security privilege. Note that privileges are different than permissions -- see the [Conflicts Between User Rights and Permissions](#) documentation for more details.

This function passes `NULL` for *security\_attributes* to the API.

Raises an *auditing event* `winreg.SaveKey` with arguments *key*, *file\_name*.

`winreg.SetValue(key, sub_key, type, value)`

Associates a value with a specified key.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta `HKEY_*`.

*sub\_key* is a string that names the subkey with which the value is associated.

*type* is an integer that specifies the type of the data. Currently this must be `REG_SZ`, meaning only strings are supported. Use the `SetValueEx()` function for support for other data types.

*value* is a string that specifies the new value.

If the key specified by the *sub\_key* parameter does not exist, the `SetValue` function creates it.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

The key identified by the *key* parameter must have been opened with `KEY_SET_VALUE` access.

Raises an *auditing event* `winreg.SetValue` with arguments *key*, *sub\_key*, *type*, *value*.

`winreg.SetValueEx(key, value_name, reserved, type, value)`

Stores data in the value field of an open registry key.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta *HKEY\_\**.

*value\_name* is a string that names the subkey with which the value is associated.

*reserved* can be anything -- zero is always passed to the API.

*type* is an integer that specifies the type of the data. See *Value Types* for the available types.

*value* is a string that specifies the new value.

This method can also set additional value and type information for the specified key. The key identified by the *key* parameter must have been opened with *KEY\_SET\_VALUE* access.

To open the key, use the *CreateKey()* or *OpenKey()* methods.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

Raises an *auditing event* `winreg.SetValue` with arguments *key*, *sub\_key*, *type*, *value*.

`winreg.DisableReflectionKey(key)`

Disables registry reflection for 32-bit processes running on a 64-bit operating system.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta *HKEY\_\**.

Will generally raise *NotImplementedError* if executed on a 32-bit operating system.

If the key is not on the reflection list, the function succeeds but has no effect. Disabling reflection for a key does not affect reflection of any subkeys.

Raises an *auditing event* `winreg.DisableReflectionKey` with argument *key*.

`winreg.EnableReflectionKey(key)`

Restores registry reflection for the specified disabled key.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta *HKEY\_\**.

Will generally raise *NotImplementedError* if executed on a 32-bit operating system.

Restoring reflection for a key does not affect reflection of any subkeys.

Raises an *auditing event* `winreg.EnableReflectionKey` with argument *key*.

`winreg.QueryReflectionKey(key)`

Determines the reflection state for the specified key.

*key* adalah sebuah kunci yang sudah terbuka, atau kunci yang sudah didefinisikan di konstanta *HKEY\_\**.

Returns *True* if reflection is disabled.

Will generally raise *NotImplementedError* if executed on a 32-bit operating system.

Raises an *auditing event* `winreg.QueryReflectionKey` with argument *key*.

### 34.3.2 Konstanta

The following constants are defined for use in many `_winreg` functions.

#### HKEY\_\* Constants

`winreg.HKEY_CLASSES_ROOT`

Registry entries subordinate to this key define types (or classes) of documents and the properties associated with those types. Shell and COM applications use the information stored under this key.

`winreg.HKEY_CURRENT_USER`

Registry entries subordinate to this key define the preferences of the current user. These preferences include the settings of environment variables, data about program groups, colors, printers, network connections, and application preferences.

`winreg.HKEY_LOCAL_MACHINE`

Registry entries subordinate to this key define the physical state of the computer, including data about the bus type, system memory, and installed hardware and software.

`winreg.HKEY_USERS`

Registry entries subordinate to this key define the default user configuration for new users on the local computer and the user configuration for the current user.

`winreg.HKEY_PERFORMANCE_DATA`

Registry entries subordinate to this key allow you to access performance data. The data is not actually stored in the registry; the registry functions cause the system to collect the data from its source.

`winreg.HKEY_CURRENT_CONFIG`

Contains information about the current hardware profile of the local computer system.

`winreg.HKEY_DYN_DATA`

This key is not used in versions of Windows after 98.

#### Access Rights

For more information, see [Registry Key Security and Access](#).

`winreg.KEY_ALL_ACCESS`

Combines the `STANDARD_RIGHTS_REQUIRED`, `KEY_QUERY_VALUE`, `KEY_SET_VALUE`, `KEY_CREATE_SUB_KEY`, `KEY_ENUMERATE_SUB_KEYS`, `KEY_NOTIFY`, and `KEY_CREATE_LINK` access rights.

`winreg.KEY_WRITE`

Combines the `STANDARD_RIGHTS_WRITE`, `KEY_SET_VALUE`, and `KEY_CREATE_SUB_KEY` access rights.

`winreg.KEY_READ`

Combines the `STANDARD_RIGHTS_READ`, `KEY_QUERY_VALUE`, `KEY_ENUMERATE_SUB_KEYS`, and `KEY_NOTIFY` values.

`winreg.KEY_EXECUTE`

Equivalent to `KEY_READ`.

`winreg.KEY_QUERY_VALUE`

Required to query the values of a registry key.

`winreg.KEY_SET_VALUE`

Required to create, delete, or set a registry value.

`winreg.KEY_CREATE_SUB_KEY`

Required to create a subkey of a registry key.

`winreg.KEY_ENUMERATE_SUB_KEYS`

Required to enumerate the subkeys of a registry key.

`winreg.KEY_NOTIFY`

Required to request change notifications for a registry key or for subkeys of a registry key.

`winreg.KEY_CREATE_LINK`

Reserved for system use.

### 64-bit Specific

For more information, see [Accessing an Alternate Registry View](#).

`winreg.KEY_WOW64_64KEY`

Indicates that an application on 64-bit Windows should operate on the 64-bit registry view.

`winreg.KEY_WOW64_32KEY`

Indicates that an application on 64-bit Windows should operate on the 32-bit registry view.

### Value Types

For more information, see [Registry Value Types](#).

`winreg.REG_BINARY`

Binary data in any form.

`winreg.REG_DWORD`

32-bit number.

`winreg.REG_DWORD_LITTLE_ENDIAN`

A 32-bit number in little-endian format. Equivalent to `REG_DWORD`.

`winreg.REG_DWORD_BIG_ENDIAN`

A 32-bit number in big-endian format.

`winreg.REG_EXPAND_SZ`

Null-terminated string containing references to environment variables (%PATH%).

`winreg.REG_LINK`

A Unicode symbolic link.

`winreg.REG_MULTI_SZ`

A sequence of null-terminated strings, terminated by two null characters. (Python handles this termination automatically.)

`winreg.REG_NONE`

No defined value type.

`winreg.REG_QWORD`

A 64-bit number.

Baru pada versi 3.6.

`winreg.REG_QWORD_LITTLE_ENDIAN`

A 64-bit number in little-endian format. Equivalent to `REG_QWORD`.

Baru pada versi 3.6.

`winreg.REG_RESOURCE_LIST`  
A device-driver resource list.

`winreg.REG_FULL_RESOURCE_DESCRIPTOR`  
A hardware setting.

`winreg.REG_RESOURCE_REQUIREMENTS_LIST`  
A hardware resource list.

`winreg.REG_SZ`  
A null-terminated string.

### 34.3.3 Registry Handle Objects

This object wraps a Windows HKEY object, automatically closing it when the object is destroyed. To guarantee cleanup, you can call either the `Close()` method on the object, or the `CloseKey()` function.

All registry functions in this module return one of these objects.

All registry functions in this module which accept a handle object also accept an integer, however, use of the handle object is encouraged.

Handle objects provide semantics for `__bool__()` -- thus

```
if handle:
    print("Yes")
```

will print `Yes` if the handle is currently valid (has not been closed or detached).

The object also support comparison semantics, so handle objects will compare true if they both reference the same underlying Windows handle value.

Handle objects can be converted to an integer (e.g., using the built-in `int()` function), in which case the underlying Windows handle value is returned. You can also use the `Detach()` method to return the integer handle, and also disconnect the Windows handle from the handle object.

`PyHKEY.Close()`  
Closes the underlying Windows handle.  
If the handle is already closed, no error is raised.

`PyHKEY.Detach()`  
Detaches the Windows handle from the handle object.

The result is an integer that holds the value of the handle before it is detached. If the handle is already detached or closed, this will return zero.

After calling this function, the handle is effectively invalidated, but the handle is not closed. You would call this function when you need the underlying Win32 handle to exist beyond the lifetime of the handle object.

Raises an *auditing event* `winreg.PyHKEY.Detach` with argument `key`.

`PyHKEY.__enter__()`  
`PyHKEY.__exit__(*exc_info)`  
The HKEY object implements `__enter__()` and `__exit__()` and thus supports the context protocol for the `with` statement:

```
with OpenKey(HKEY_LOCAL_MACHINE, "foo") as key:
    ... # work with key
```

will automatically close `key` when control leaves the `with` block.

## 34.4 winsound --- Sound-playing interface for Windows

The `winsound` module provides access to the basic sound-playing machinery provided by Windows platforms. It includes functions and several constants.

`winsound.Beep` (*frequency*, *duration*)

Beep the PC's speaker. The *frequency* parameter specifies frequency, in hertz, of the sound, and must be in the range 37 through 32,767. The *duration* parameter specifies the number of milliseconds the sound should last. If the system is not able to beep the speaker, `RuntimeError` is raised.

`winsound.PlaySound` (*sound*, *flags*)

Call the underlying `PlaySound()` function from the Platform API. The *sound* parameter may be a filename, a system sound alias, audio data as a *bytes-like object*, or `None`. Its interpretation depends on the value of *flags*, which can be a bitwise ORed combination of the constants described below. If the *sound* parameter is `None`, any currently playing waveform sound is stopped. If the system indicates an error, `RuntimeError` is raised.

`winsound.MessageBeep` (*type=MB\_OK*)

Call the underlying `MessageBeep()` function from the Platform API. This plays a sound as specified in the registry. The *type* argument specifies which sound to play; possible values are `-1`, `MB_ICONASTERISK`, `MB_ICONEXCLAMATION`, `MB_ICONHAND`, `MB_ICONQUESTION`, and `MB_OK`, all described below. The value `-1` produces a "simple beep"; this is the final fallback if a sound cannot be played otherwise. If the system indicates an error, `RuntimeError` is raised.

`winsound.SND_FILENAME`

The *sound* parameter is the name of a WAV file. Do not use with `SND_ALIAS`.

`winsound.SND_ALIAS`

The *sound* parameter is a sound association name from the registry. If the registry contains no such name, play the system default sound unless `SND_NODEFAULT` is also specified. If no default sound is registered, raise `RuntimeError`. Do not use with `SND_FILENAME`.

All Win32 systems support at least the following; most systems support many more:

| <code>PlaySound()</code> <i>name</i> | Corresponding Control Panel Sound name |
|--------------------------------------|----------------------------------------|
| 'SystemAsterisk'                     | Asterisk                               |
| 'SystemExclamation'                  | Exclamation                            |
| 'SystemExit'                         | Exit Windows                           |
| 'SystemHand'                         | Critical Stop                          |
| 'SystemQuestion'                     | Question                               |

Sebagai contoh:

```
import winsound
# Play Windows exit sound.
winsound.PlaySound("SystemExit", winsound.SND_ALIAS)

# Probably play Windows default sound, if any is registered (because
# "" probably isn't the registered name of any sound).
winsound.PlaySound("", winsound.SND_ALIAS)
```

`winsound.SND_LOOP`

Play the sound repeatedly. The `SND_ASYNC` flag must also be used to avoid blocking. Cannot be used with `SND_MEMORY`.

`winsound.SND_MEMORY`

The *sound* parameter to `PlaySound()` is a memory image of a WAV file, as a *bytes-like object*.

---

**Catatan:** This module does not support playing from a memory image asynchronously, so a combination of this flag and `SND_ASYNC` will raise `RuntimeError`.

---

`winsound.SND_PURGE`

Stop playing all instances of the specified sound.

---

**Catatan:** This flag is not supported on modern Windows platforms.

---

`winsound.SND_ASYNC`

Return immediately, allowing sounds to play asynchronously.

`winsound.SND_NODEFAULT`

If the specified sound cannot be found, do not play the system default sound.

`winsound.SND_NOSTOP`

Do not interrupt sounds currently playing.

`winsound.SND_NOWAIT`

Return immediately if the sound driver is busy.

---

**Catatan:** This flag is not supported on modern Windows platforms.

---

`winsound.MB_ICONASTERISK`

Play the `SystemDefault` sound.

`winsound.MB_ICONEXCLAMATION`

Play the `SystemExclamation` sound.

`winsound.MB_ICONHAND`

Play the `SystemHand` sound.

`winsound.MB_ICONQUESTION`

Play the `SystemQuestion` sound.

`winsound.MB_OK`

Play the `SystemDefault` sound.

Modul yang dijelaskan dalam bab ini memberikan antarmuka ke fitur-fitur yang unik untuk sistem operasi Unix, atau dalam beberapa kasus untuk sebagian atau banyak variannya. Berikut ini ikhtisar:

## 35.1 `posix` --- The most common POSIX system calls

---

This module provides access to operating system functionality that is standardized by the C Standard and the POSIX standard (a thinly disguised Unix interface).

**Do not import this module directly.** Instead, import the module `os`, which provides a *portable* version of this interface. On Unix, the `os` module provides a superset of the `posix` interface. On non-Unix operating systems the `posix` module is not available, but a subset is always available through the `os` interface. Once `os` is imported, there is *no* performance penalty in using it instead of `posix`. In addition, `os` provides some additional functionality, such as automatically calling `putenv()` when an entry in `os.environ` is changed.

Errors are reported as exceptions; the usual exceptions are given for type errors, while errors reported by the system calls raise `OSError`.

### 35.1.1 Large File Support

Several operating systems (including AIX, HP-UX, Irix and Solaris) provide support for files that are larger than 2 GiB from a C programming model where `int` and `long` are 32-bit values. This is typically accomplished by defining the relevant size and offset types as 64-bit values. Such files are sometimes referred to as *large files*.

Large file support is enabled in Python when the size of an `off_t` is larger than a `long` and the `long long` is at least as large as an `off_t`. It may be necessary to configure and compile Python with certain compiler flags to enable this mode. For example, it is enabled by default with recent versions of Irix, but with Solaris 2.6 and 2.7 you need to do something like:

```
CFLAGS="`getconf LFS_CFLAGS`" OPT="-g -O2 $CFLAGS" \  
./configure
```

On large-file-capable Linux systems, this might work:

```
CFLAGS='-D_LARGEFILE64_SOURCE -D_FILE_OFFSET_BITS=64' OPT="-g -O2 $CFLAGS" \  
./configure
```

### 35.1.2 Notable Module Contents

In addition to many functions described in the [os](#) module documentation, [posix](#) defines the following data item:

#### `posix.envIRON`

A dictionary representing the string environment at the time the interpreter was started. Keys and values are bytes on Unix and str on Windows. For example, `environ[b'HOME']` (`environ['HOME']` on Windows) is the pathname of your home directory, equivalent to `getenv("HOME")` in C.

Modifying this dictionary does not affect the string environment passed on by `execv()`, `popen()` or `system()`; if you need to change the environment, pass `environ` to `execve()` or add variable assignments and export statements to the command string for `system()` or `popen()`.

Berubah pada versi 3.2: On Unix, keys and values are bytes.

---

**Catatan:** The [os](#) module provides an alternate implementation of `environ` which updates the environment on modification. Note also that updating `os.environ` will render this dictionary obsolete. Use of the [os](#) module version of this is recommended over direct access to the [posix](#) module.

---

## 35.2 pwd --- The password database

---

This module provides access to the Unix user account and password database. It is available on all Unix versions.

Password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `passwd` structure (Attribute field below, see `<pwd.h>`):

| Indeks | Atribut                | Artinya                     |
|--------|------------------------|-----------------------------|
| 0      | <code>pw_name</code>   | Nama <i>login</i>           |
| 1      | <code>pw_passwd</code> | Optional encrypted password |
| 2      | <code>pw_uid</code>    | Numerical user ID           |
| 3      | <code>pw_gid</code>    | Numerical group ID          |
| 4      | <code>pw_gecos</code>  | User name or comment field  |
| 5      | <code>pw_dir</code>    | User home directory         |
| 6      | <code>pw_shell</code>  | User command interpreter    |

The uid and gid items are integers, all others are strings. [KeyError](#) is raised if the entry asked for cannot be found.

---

**Catatan:** In traditional Unix the field `pw_passwd` usually contains a password encrypted with a DES derived algorithm (see module [crypt](#)). However most modern unices use a so-called *shadow password* system. On those unices the

`pw_passwd` field only contains an asterisk ('\*') or the letter 'x' where the encrypted password is stored in a file `/etc/shadow` which is not world readable. Whether the `pw_passwd` field contains anything useful is system-dependent. If available, the `spwd` module should be used where access to the encrypted password is required.

It defines the following items:

`pwd.getpwuid(uid)`

Return the password database entry for the given numeric user ID.

`pwd.getpwnam(name)`

Return the password database entry for the given user name.

`pwd.getpwall()`

Return a list of all available password database entries, in arbitrary order.

**Lihat juga:**

**Modul `grp`** An interface to the group database, similar to this.

**Module `spwd`** An interface to the shadow password database, similar to this.

## 35.3 spwd --- The shadow password database

This module provides access to the Unix shadow password database. It is available on various Unix versions.

You must have enough privileges to access the shadow password database (this usually means you have to be root).

Shadow password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `spwd` structure (Attribute field below, see `<shadow.h>`):

| Indeks | Atribut                | Artinya                                                         |
|--------|------------------------|-----------------------------------------------------------------|
| 0      | <code>sp_namp</code>   | Nama <i>login</i>                                               |
| 1      | <code>sp_pwdp</code>   | Password terenkripsi                                            |
| 2      | <code>sp_lstchg</code> | Tanggal perubahan terakhir                                      |
| 3      | <code>sp_min</code>    | Minimal number of days between changes                          |
| 4      | <code>sp_max</code>    | Maximum number of days between changes                          |
| 5      | <code>sp_warn</code>   | Number of days before password expires to warn user about it    |
| 6      | <code>sp_inact</code>  | Number of days after password expires until account is disabled |
| 7      | <code>sp_expire</code> | Number of days since 1970-01-01 when account expires            |
| 8      | <code>sp_flag</code>   | Cadangan                                                        |

The `sp_namp` and `sp_pwdp` items are strings, all others are integers. `KeyError` is raised if the entry asked for cannot be found.

The following functions are defined:

`spwd.getspnam(name)`

Return the shadow password database entry for the given user name.

Berubah pada versi 3.6: Raises a `PermissionError` instead of `KeyError` if the user doesn't have privileges.

`spwd.getspall()`

Return a list of all available shadow password database entries, in arbitrary order.

**Lihat juga:**

**Modul *grp*** An interface to the group database, similar to this.

**Modul *pwd*** An interface to the normal password database, similar to this.

## 35.4 *grp* --- The group database

---

This module provides access to the Unix group database. It is available on all Unix versions.

Group database entries are reported as a tuple-like object, whose attributes correspond to the members of the group structure (Attribute field below, see `<pwd.h>`):

| Indeks | Atribut                | Artinya                                     |
|--------|------------------------|---------------------------------------------|
| 0      | <code>gr_name</code>   | the name of the group                       |
| 1      | <code>gr_passwd</code> | the (encrypted) group password; often empty |
| 2      | <code>gr_gid</code>    | the numerical group ID                      |
| 3      | <code>gr_mem</code>    | all the group member's user names           |

The gid is an integer, name and password are strings, and the member list is a list of strings. (Note that most users are not explicitly listed as members of the group they are in according to the password database. Check both databases to get complete membership information. Also note that a `gr_name` that starts with a + or - is likely to be a YP/NIS reference and may not be accessible via `getgrnam()` or `getgrgid().`)

It defines the following items:

`grp.getgrgid(gid)`

Return the group database entry for the given numeric group ID. `KeyError` is raised if the entry asked for cannot be found.

Ditinggalkan sejak versi 3.6: Since Python 3.6 the support of non-integer arguments like floats or strings in `getgrgid()` is deprecated.

`grp.getgrnam(name)`

Return the group database entry for the given group name. `KeyError` is raised if the entry asked for cannot be found.

`grp.getgrall()`

Return a list of all available group entries, in arbitrary order.

**Lihat juga:**

**Modul *pwd*** An interface to the user database, similar to this.

**Module *spwd*** An interface to the shadow password database, similar to this.

## 35.5 *crypt* --- Function to check Unix passwords

**Source code:** [Lib/crypt.py](#)

---

This module implements an interface to the `crypt(3)` routine, which is a one-way hash function based upon a modified DES algorithm; see the Unix man page for further details. Possible uses include storing hashed passwords so you can check passwords without storing the actual password, or attempting to crack Unix passwords with a dictionary.

Notice that the behavior of this module depends on the actual implementation of the `crypt(3)` routine in the running system. Therefore, any extensions available on the current implementation will also be available on this module.

*Availability:* Unix. Not available on VxWorks.

### 35.5.1 Hashing Methods

Baru pada versi 3.3.

The `crypt` module defines the list of hashing methods (not all methods are available on all platforms):

`crypt.METHOD_SHA512`

A Modular Crypt Format method with 16 character salt and 86 character hash based on the SHA-512 hash function. This is the strongest method.

`crypt.METHOD_SHA256`

Another Modular Crypt Format method with 16 character salt and 43 character hash based on the SHA-256 hash function.

`crypt.METHOD_BLOWFISH`

Another Modular Crypt Format method with 22 character salt and 31 character hash based on the Blowfish cipher.

Baru pada versi 3.7.

`crypt.METHOD_MD5`

Another Modular Crypt Format method with 8 character salt and 22 character hash based on the MD5 hash function.

`crypt.METHOD_CRYPT`

The traditional method with a 2 character salt and 13 characters of hash. This is the weakest method.

### 35.5.2 Module Attributes

Baru pada versi 3.3.

`crypt.methods`

A list of available password hashing algorithms, as `crypt.METHOD_*` objects. This list is sorted from strongest to weakest.

### 35.5.3 Module Functions

The `crypt` module defines the following functions:

`crypt.crypt(word, salt=None)`

`word` will usually be a user's password as typed at a prompt or in a graphical interface. The optional `salt` is either a string as returned from `mk salt()`, one of the `crypt.METHOD_*` values (though not all may be available on all platforms), or a full encrypted password including salt, as returned by this function. If `salt` is not provided, the strongest method will be used (as returned by `methods()`).

Checking a password is usually done by passing the plain-text password as `word` and the full results of a previous `crypt()` call, which should be the same as the results of this call.

`salt` (either a random 2 or 16 character string, possibly prefixed with `$digit$` to indicate the method) which will be used to perturb the encryption algorithm. The characters in `salt` must be in the set `[./a-zA-Z0-9]`, with the exception of Modular Crypt Format which prefixes a `$digit$`.

Returns the hashed password as a string, which will be composed of characters from the same alphabet as the salt.

Since a few `crypt (3)` extensions allow different values, with different sizes in the *salt*, it is recommended to use the full crypt password as salt when checking for a password.

Berubah pada versi 3.3: Accept `crypt.METHOD_*` values in addition to strings for *salt*.

`crypt.mksalt (method=None, *, rounds=None)`

Return a randomly generated salt of the specified method. If no *method* is given, the strongest method available as returned by `methods ()` is used.

The return value is a string suitable for passing as the *salt* argument to `crypt ()`.

*rounds* specifies the number of rounds for `METHOD_SHA256`, `METHOD_SHA512` and `METHOD_BLOWFISH`. For `METHOD_SHA256` and `METHOD_SHA512` it must be an integer between 1000 and 999\_999\_999, the default is 5000. For `METHOD_BLOWFISH` it must be a power of two between 16 ( $2^4$ ) and 2\_147\_483\_648 ( $2^{31}$ ), the default is 4096 ( $2^{12}$ ).

Baru pada versi 3.3.

Berubah pada versi 3.7: Added the *rounds* parameter.

## 35.5.4 Contoh-contoh

A simple example illustrating typical use (a constant-time comparison operation is needed to limit exposure to timing attacks. `hmac.compare_digest ()` is suitable for this purpose):

```
import pwd
import crypt
import getpass
from hmac import compare_digest as compare_hash

def login():
    username = input('Python login: ')
    cryptpasswd = pwd.getpwnam(username)[1]
    if cryptpasswd:
        if cryptpasswd == 'x' or cryptpasswd == '*':
            raise ValueError('no support for shadow passwords')
        cleartext = getpass.getpass()
        return compare_hash(crypt.crypt(cleartext, cryptpasswd), cryptpasswd)
    else:
        return True
```

To generate a hash of a password using the strongest available method and check it against the original:

```
import crypt
from hmac import compare_digest as compare_hash

hashed = crypt.crypt(plaintext)
if not compare_hash(hashed, crypt.crypt(plaintext, hashed)):
    raise ValueError("hashed version doesn't validate against original")
```

## 35.6 `termios` --- POSIX style tty control

This module provides an interface to the POSIX calls for tty I/O control. For a complete description of these calls, see *termios(3)* Unix manual page. It is only available for those Unix versions that support POSIX *termios* style tty I/O control configured during installation.

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or a *file object*, such as `sys.stdin` itself.

This module also defines all the constants needed to work with the functions provided here; these have the same name as their counterparts in C. Please refer to your system documentation for more information on using these terminal control interfaces.

The module defines the following functions:

`termios.tcgetattr(fd)`

Return a list containing the tty attributes for file descriptor *fd*, as follows: [*iflag*, *oflag*, *cflag*, *lflag*, *ispeed*, *ospeed*, *cc*] where *cc* is a list of the tty special characters (each a string of length 1, except the items with indices `VMIN` and `VTIME`, which are integers when these fields are defined). The interpretation of the flags and the speeds as well as the indexing in the *cc* array must be done using the symbolic constants defined in the *termios* module.

`termios.tcsetattr(fd, when, attributes)`

Set the tty attributes for file descriptor *fd* from the *attributes*, which is a list like the one returned by `tcgetattr()`. The *when* argument determines when the attributes are changed: `TCSANOW` to change immediately, `TCSADRAIN` to change after transmitting all queued output, or `TCSAFLUSH` to change after transmitting all queued output and discarding all queued input.

`termios.tcsendbreak(fd, duration)`

Send a break on file descriptor *fd*. A zero *duration* sends a break for 0.25--0.5 seconds; a nonzero *duration* has a system dependent meaning.

`termios.tcdrain(fd)`

Wait until all output written to file descriptor *fd* has been transmitted.

`termios.tcflush(fd, queue)`

Discard queued data on file descriptor *fd*. The *queue* selector specifies which queue: `TCIFLUSH` for the input queue, `TCOFLUSH` for the output queue, or `TCIOFLUSH` for both queues.

`termios.tcflow(fd, action)`

Suspend or resume input or output on file descriptor *fd*. The *action* argument can be `TCOOFF` to suspend output, `TCOON` to restart output, `TCIOFF` to suspend input, or `TCION` to restart input.

**Lihat juga:**

**Module `tty`** Convenience functions for common terminal control operations.

### 35.6.1 Contoh

Here's a function that prompts for a password with echoing turned off. Note the technique using a separate `tcgetattr()` call and a `try ... finally` statement to ensure that the old tty attributes are restored exactly no matter what happens:

```
def getpass(prompt="Password: "):
    import termios, sys
    fd = sys.stdin.fileno()
    old = termios.tcgetattr(fd)
    new = termios.tcgetattr(fd)
    new[3] = new[3] & ~termios.ECHO          # lflags
    try:
        termios.tcsetattr(fd, termios.TCSADRAIN, new)
        passwd = input(prompt)
    finally:
        termios.tcsetattr(fd, termios.TCSADRAIN, old)
    return passwd
```

## 35.7 tty --- Terminal control functions

Source code: `Lib/tty.py`

---

The `tty` module defines functions for putting the tty into cbreak and raw modes.

Because it requires the `termios` module, it will work only on Unix.

The `tty` module defines the following functions:

`tty.setraw(fd, when=termios.TCSAFLUSH)`

Change the mode of the file descriptor `fd` to raw. If `when` is omitted, it defaults to `termios.TCSAFLUSH`, and is passed to `termios.tcsetattr()`.

`tty.setcbreak(fd, when=termios.TCSAFLUSH)`

Change the mode of file descriptor `fd` to cbreak. If `when` is omitted, it defaults to `termios.TCSAFLUSH`, and is passed to `termios.tcsetattr()`.

**Lihat juga:**

Module `termios` Low-level terminal control interface.

## 35.8 pty --- Pseudo-terminal utilities

Source code: `Lib/pty.py`

---

The `pty` module defines operations for handling the pseudo-terminal concept: starting another process and being able to write to and read from its controlling terminal programmatically.

Because pseudo-terminal handling is highly platform dependent, there is code to do it only for Linux. (The Linux code is supposed to work on other platforms, but hasn't been tested yet.)

The `pty` module defines the following functions:

`pty.fork()`

Fork. Connect the child's controlling terminal to a pseudo-terminal. Return value is `(pid, fd)`. Note that the child gets `pid` 0, and the `fd` is *invalid*. The parent's return value is the `pid` of the child, and `fd` is a file descriptor connected to the child's controlling terminal (and also to the child's standard input and output).

`pty.openpty()`

Open a new pseudo-terminal pair, using `os.openpty()` if possible, or emulation code for generic Unix systems. Return a pair of file descriptors `(master, slave)`, for the master and the slave end, respectively.

`pty.spawn(argv[, master_read[, stdin_read]])`

Spawn a process, and connect its controlling terminal with the current process's standard io. This is often used to baffle programs which insist on reading from the controlling terminal. It is expected that the process spawned behind the `pty` will eventually terminate, and when it does `spawn` will return.

The functions `master_read` and `stdin_read` are passed a file descriptor which they should read from, and they should always return a byte string. In order to force `spawn` to return before the child process exits an `OSError` should be thrown.

The default implementation for both functions will read and return up to 1024 bytes each time the function is called. The `master_read` callback is passed the pseudoterminal's master file descriptor to read output from the child process, and `stdin_read` is passed file descriptor 0, to read from the parent process's standard input.

Returning an empty byte string from either callback is interpreted as an end-of-file (EOF) condition, and that callback will not be called after that. If `stdin_read` signals EOF the controlling terminal can no longer communicate with the parent process OR the child process. Unless the child process will quit without any input, `spawn` will then loop forever. If `master_read` signals EOF the same behavior results (on linux at least).

If both callbacks signal EOF then `spawn` will probably never return, unless `select` throws an error on your platform when passed three empty lists. This is a bug, documented in [issue 26228](#).

Raises an *auditing event* `pty.spawn` with argument `argv`.

Berubah pada versi 3.4: `spawn()` now returns the status value from `os.waitpid()` on the child process.

### 35.8.1 Contoh

The following program acts like the Unix command `script(1)`, using a pseudo-terminal to record all input and output of a terminal session in a "typescript".

```
import argparse
import os
import pty
import sys
import time

parser = argparse.ArgumentParser()
parser.add_argument('-a', dest='append', action='store_true')
parser.add_argument('-p', dest='use_python', action='store_true')
parser.add_argument('filename', nargs='?', default='typescript')
options = parser.parse_args()

shell = sys.executable if options.use_python else os.environ.get('SHELL', 'sh')
filename = options.filename
mode = 'ab' if options.append else 'wb'

with open(filename, mode) as script:
    def read(fd):
        data = os.read(fd, 1024)
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
script.write(data)
return data

print('Script started, file is', filename)
script.write(('Script started on %s\n' % time.asctime()).encode())

pty.spawn(shell, read)

script.write(('Script done on %s\n' % time.asctime()).encode())
print('Script done, file is', filename)
```

---

## 35.9 fcntl --- The fcntl and ioctl system calls

---

This module performs file control and I/O control on file descriptors. It is an interface to the `fcntl()` and `ioctl()` Unix routines. For a complete description of these calls, see *fcntl(2)* and *ioctl(2)* Unix manual pages.

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or an *io.IOBase* object, such as `sys.stdin` itself, which provides a *fileno()* that returns a genuine file descriptor.

Berubah pada versi 3.3: Operations in this module used to raise an *IOError* where they now raise an *OSError*.

Berubah pada versi 3.8: The `fcntl` module now contains `F_ADD_SEALS`, `F_GET_SEALS`, and `F_SEAL_*` constants for sealing of *os.memfd\_create()* file descriptors.

The module defines the following functions:

`fcntl.fcntl(fd, cmd, arg=0)`

Perform the operation *cmd* on file descriptor *fd* (file objects providing a *fileno()* method are accepted as well). The values used for *cmd* are operating system dependent, and are available as constants in the *fcntl* module, using the same names as used in the relevant C header files. The argument *arg* can either be an integer value, or a *bytes* object. With an integer value, the return value of this function is the integer return value of the C `fcntl()` call. When the argument is bytes it represents a binary structure, e.g. created by *struct.pack()*. The binary data is copied to a buffer whose address is passed to the C `fcntl()` call. The return value after a successful call is the contents of the buffer, converted to a *bytes* object. The length of the returned object will be the same as the length of the *arg* argument. This is limited to 1024 bytes. If the information returned in the buffer by the operating system is larger than 1024 bytes, this is most likely to result in a segmentation violation or a more subtle data corruption.

If the `fcntl()` fails, an *OSError* is raised.

Raises an *auditing event* `fcntl.fcntl` with arguments *fd*, *cmd*, *arg*.

`fcntl.ioctl(fd, request, arg=0, mutate_flag=True)`

This function is identical to the *fcntl()* function, except that the argument handling is even more complicated.

The *request* parameter is limited to values that can fit in 32-bits. Additional constants of interest for use as the *request* argument can be found in the *termios* module, under the same names as used in the relevant C header files.

The parameter *arg* can be one of an integer, an object supporting the read-only buffer interface (like *bytes*) or an object supporting the read-write buffer interface (like *bytearray*).

In all but the last case, behaviour is as for the *fcntl()* function.

If a mutable buffer is passed, then the behaviour is determined by the value of the *mutate\_flag* parameter.

If it is false, the buffer's mutability is ignored and behaviour is as for a read-only buffer, except that the 1024 byte limit mentioned above is avoided -- so long as the buffer you pass is at least as long as what the operating system wants to put there, things should work.

If *mutate\_flag* is true (the default), then the buffer is (in effect) passed to the underlying *ioctl()* system call, the latter's return code is passed back to the calling Python, and the buffer's new contents reflect the action of the *ioctl()*. This is a slight simplification, because if the supplied buffer is less than 1024 bytes long it is first copied into a static buffer 1024 bytes long which is then passed to *ioctl()* and copied back into the supplied buffer.

If the *ioctl()* fails, an *OSError* exception is raised.

An example:

```
>>> import array, fcntl, struct, termios, os
>>> os.getpgrp()
13341
>>> struct.unpack('h', fcntl.ioctl(0, termios.TIOCGPGRP, "  ")) [0]
13341
>>> buf = array.array('h', [0])
>>> fcntl.ioctl(0, termios.TIOCGPGRP, buf, 1)
0
>>> buf
array('h', [13341])
```

Raises an *auditing event* *fcntl.ioctl* with arguments *fd*, *request*, *arg*.

*fcntl.flock* (*fd*, *operation*)

Perform the lock operation *operation* on file descriptor *fd* (file objects providing a *fileno()* method are accepted as well). See the Unix manual *flock(2)* for details. (On some systems, this function is emulated using *fcntl()*.)

If the *flock()* fails, an *OSError* exception is raised.

Raises an *auditing event* *fcntl.flock* with arguments *fd*, *operation*.

*fcntl.lockf* (*fd*, *cmd*, *len=0*, *start=0*, *whence=0*)

This is essentially a wrapper around the *fcntl()* locking calls. *fd* is the file descriptor (file objects providing a *fileno()* method are accepted as well) of the file to lock or unlock, and *cmd* is one of the following values:

- LOCK\_UN -- unlock
- LOCK\_SH -- acquire a shared lock
- LOCK\_EX -- acquire an exclusive lock

When *cmd* is LOCK\_SH or LOCK\_EX, it can also be bitwise ORed with LOCK\_NB to avoid blocking on lock acquisition. If LOCK\_NB is used and the lock cannot be acquired, an *OSError* will be raised and the exception will have an *errno* attribute set to EACCES or EAGAIN (depending on the operating system; for portability, check for both values). On at least some systems, LOCK\_EX can only be used if the file descriptor refers to a file opened for writing.

*len* is the number of bytes to lock, *start* is the byte offset at which the lock starts, relative to *whence*, and *whence* is as with *io.IOBase.seek()*, specifically:

- 0 -- relative to the start of the file (*os.SEEK\_SET*)
- 1 -- relative to the current buffer position (*os.SEEK\_CUR*)
- 2 -- relative to the end of the file (*os.SEEK\_END*)

The default for *start* is 0, which means to start at the beginning of the file. The default for *len* is 0 which means to lock to the end of the file. The default for *whence* is also 0.

Raises an *auditing event* `fcntl.lockf` with arguments `fd`, `cmd`, `len`, `start`, `whence`.

Examples (all on a SVR4 compliant system):

```
import struct, fcntl, os

f = open(...)
rv = fcntl.fcntl(f, fcntl.F_SETFL, os.O_NDELAY)

lockdata = struct.pack('hhllhh', fcntl.F_WRLCK, 0, 0, 0, 0, 0)
rv = fcntl.fcntl(f, fcntl.F_SETLKW, lockdata)
```

Note that in the first example the return value variable `rv` will hold an integer value; in the second example it will hold a *bytes* object. The structure lay-out for the `lockdata` variable is system dependent --- therefore using the `flock()` call may be better.

**Lihat juga:**

**Module `os`** If the locking flags `O_SHLOCK` and `O_EXLOCK` are present in the `os` module (on BSD only), the `os.open()` function provides an alternative to the `lockf()` and `flock()` functions.

## 35.10 pipes --- Interface to shell pipelines

**Source code:** [Lib/pipes.py](#)

---

The `pipes` module defines a class to abstract the concept of a *pipeline* --- a sequence of converters from one file to another.

Because the module uses `/bin/sh` command lines, a POSIX or compatible shell for `os.system()` and `os.popen()` is required.

The `pipes` module defines the following class:

```
class pipes.Template
    An abstraction of a pipeline.
```

Contoh:

```
>>> import pipes
>>> t = pipes.Template()
>>> t.append('tr a-z A-Z', '--')
>>> f = t.open('pipefile', 'w')
>>> f.write('hello world')
>>> f.close()
>>> open('pipefile').read()
'HELLO WORLD'
```

### 35.10.1 Template Objects

Template objects following methods:

`Template.reset()`

Restore a pipeline template to its initial state.

`Template.clone()`

Return a new, equivalent, pipeline template.

`Template.debug(flag)`

If *flag* is true, turn debugging on. Otherwise, turn debugging off. When debugging is on, commands to be executed are printed, and the shell is given `set -x` command to be more verbose.

`Template.append(cmd, kind)`

Append a new action at the end. The *cmd* variable must be a valid bourne shell command. The *kind* variable consists of two letters.

The first letter can be either of `'-'` (which means the command reads its standard input), `'f'` (which means the commands reads a given file on the command line) or `'.'` (which means the commands reads no input, and hence must be first.)

Similarly, the second letter can be either of `'-'` (which means the command writes to standard output), `'f'` (which means the command writes a file on the command line) or `'.'` (which means the command does not write anything, and hence must be last.)

`Template.prepend(cmd, kind)`

Add a new action at the beginning. See [append\(\)](#) for explanations of the arguments.

`Template.open(file, mode)`

Return a file-like object, open to *file*, but read from or written to by the pipeline. Note that only one of `'r'`, `'w'` may be given.

`Template.copy(infile, outfile)`

Copy *infile* to *outfile* through the pipe.

## 35.11 resource --- Resource usage information

This module provides basic mechanisms for measuring and controlling system resources utilized by a program.

Symbolic constants are used to specify particular system resources and to request usage information about either the current process or its children.

An [OSError](#) is raised on syscall failure.

**exception** `resource.error`

A deprecated alias of [OSError](#).

Berubah pada versi 3.3: Following [PEP 3151](#), this class was made an alias of [OSError](#).

### 35.11.1 Resource Limits

Resources usage can be limited using the `setrlimit()` function described below. Each resource is controlled by a pair of limits: a soft limit and a hard limit. The soft limit is the current limit, and may be lowered or raised by a process over time. The soft limit can never exceed the hard limit. The hard limit can be lowered to any value greater than the soft limit, but not raised. (Only processes with the effective UID of the super-user can raise a hard limit.)

The specific resources that can be limited are system dependent. They are described in the `getrlimit(2)` man page. The resources listed below are supported when the underlying operating system supports them; resources which cannot be checked or controlled by the operating system are not defined in this module for those platforms.

`resource.RLIM_INFINITY`

Constant used to represent the limit for an unlimited resource.

`resource.getrlimit(resource)`

Returns a tuple (soft, hard) with the current soft and hard limits of *resource*. Raises `ValueError` if an invalid resource is specified, or `error` if the underlying system call fails unexpectedly.

`resource.setrlimit(resource, limits)`

Sets new limits of consumption of *resource*. The *limits* argument must be a tuple (soft, hard) of two integers describing the new limits. A value of `RLIM_INFINITY` can be used to request a limit that is unlimited.

Raises `ValueError` if an invalid resource is specified, if the new soft limit exceeds the hard limit, or if a process tries to raise its hard limit. Specifying a limit of `RLIM_INFINITY` when the hard or system limit for that resource is not unlimited will result in a `ValueError`. A process with the effective UID of super-user can request any valid limit value, including unlimited, but `ValueError` will still be raised if the requested limit exceeds the system imposed limit.

`setrlimit` may also raise `error` if the underlying system call fails.

VxWorks only supports setting `RLIMIT_NOFILE`.

Raises an *auditing event* `resource.setrlimit` with arguments *resource*, *limits*.

`resource.prlimit(pid, resource[, limits])`

Combines `setrlimit()` and `getrlimit()` in one function and supports to get and set the resources limits of an arbitrary process. If *pid* is 0, then the call applies to the current process. *resource* and *limits* have the same meaning as in `setrlimit()`, except that *limits* is optional.

When *limits* is not given the function returns the *resource* limit of the process *pid*. When *limits* is given the *resource* limit of the process is set and the former resource limit is returned.

Raises `ProcessLookupError` when *pid* can't be found and `PermissionError` when the user doesn't have `CAP_SYS_RESOURCE` for the process.

Raises an *auditing event* `resource.prlimit` with arguments *pid*, *resource*, *limits*.

*Availability:* Linux 2.6.36 or later with glibc 2.13 or later.

Baru pada versi 3.4.

These symbols define resources whose consumption can be controlled using the `setrlimit()` and `getrlimit()` functions described below. The values of these symbols are exactly the constants used by C programs.

The Unix man page for `getrlimit(2)` lists the available resources. Note that not all systems use the same symbol or same value to denote the same resource. This module does not attempt to mask platform differences --- symbols not defined for a platform will not be available from this module on that platform.

`resource.RLIMIT_CORE`

The maximum size (in bytes) of a core file that the current process can create. This may result in the creation of a partial core file if a larger core would be required to contain the entire process image.

**resource.RLIMIT\_CPU**

The maximum amount of processor time (in seconds) that a process can use. If this limit is exceeded, a SIGXCPU signal is sent to the process. (See the [signal](#) module documentation for information about how to catch this signal and do something useful, e.g. flush open files to disk.)

**resource.RLIMIT\_FSIZE**

The maximum size of a file which the process may create.

**resource.RLIMIT\_DATA**

The maximum size (in bytes) of the process's heap.

**resource.RLIMIT\_STACK**

The maximum size (in bytes) of the call stack for the current process. This only affects the stack of the main thread in a multi-threaded process.

**resource.RLIMIT\_RSS**

The maximum resident set size that should be made available to the process.

**resource.RLIMIT\_NPROC**

The maximum number of processes the current process may create.

**resource.RLIMIT\_NOFILE**

The maximum number of open file descriptors for the current process.

**resource.RLIMIT\_OFILE**

The BSD name for [RLIMIT\\_NOFILE](#).

**resource.RLIMIT\_MEMLOCK**

The maximum address space which may be locked in memory.

**resource.RLIMIT\_VMEM**

The largest area of mapped memory which the process may occupy.

**resource.RLIMIT\_AS**

The maximum area (in bytes) of address space which may be taken by the process.

**resource.RLIMIT\_MSGQUEUE**

The number of bytes that can be allocated for POSIX message queues.

*Availability:* Linux 2.6.8 or later.

Baru pada versi 3.4.

**resource.RLIMIT\_NICE**

The ceiling for the process's nice level (calculated as 20 - rlim\_cur).

*Availability:* Linux 2.6.12 or later.

Baru pada versi 3.4.

**resource.RLIMIT\_RTPRIO**

The ceiling of the real-time priority.

*Availability:* Linux 2.6.12 or later.

Baru pada versi 3.4.

**resource.RLIMIT\_RTTIME**

The time limit (in microseconds) on CPU time that a process can spend under real-time scheduling without making a blocking syscall.

*Availability:* Linux 2.6.25 or later.

Baru pada versi 3.4.

`resource.RLIMIT_SIGPENDING`

The number of signals which the process may queue.

*Availability:* Linux 2.6.8 or later.

Baru pada versi 3.4.

`resource.RLIMIT_SBSIZE`

The maximum size (in bytes) of socket buffer usage for this user. This limits the amount of network memory, and hence the amount of mbufs, that this user may hold at any time.

*Availability:* FreeBSD 9 or later.

Baru pada versi 3.4.

`resource.RLIMIT_SWAP`

The maximum size (in bytes) of the swap space that may be reserved or used by all of this user id's processes. This limit is enforced only if bit 1 of the `vm.overcommit sysctl` is set. Please see [tuning\(7\)](#) for a complete description of this `sysctl`.

*Availability:* FreeBSD 9 or later.

Baru pada versi 3.4.

`resource.RLIMIT_NPTS`

The maximum number of pseudo-terminals created by this user id.

*Availability:* FreeBSD 9 or later.

Baru pada versi 3.4.

### 35.11.2 Resource Usage

These functions are used to retrieve resource usage information:

`resource.getrusage(who)`

This function returns an object that describes the resources consumed by either the current process or its children, as specified by the *who* parameter. The *who* parameter should be specified using one of the `RUSAGE_*` constants described below.

A simple example:

```
from resource import *
import time

# a non CPU-bound task
time.sleep(3)
print(getrusage(RUSAGE_SELF))

# a CPU-bound task
for i in range(10 ** 8):
    _ = 1 + 1
print(getrusage(RUSAGE_SELF))
```

The fields of the return value each describe how a particular system resource has been used, e.g. amount of time spent running in user mode or number of times the process was swapped out of main memory. Some values are dependent on the clock tick interval, e.g. the amount of memory the process is using.

For backward compatibility, the return value is also accessible as a tuple of 16 elements.

The fields `ru_utime` and `ru_stime` of the return value are floating point values representing the amount of time spent executing in user mode and the amount of time spent executing in system mode, respectively. The remaining

values are integers. Consult the *getrusage(2)* man page for detailed information about these values. A brief summary is presented here:

| Indeks | Field       | Sumber Daya, <i>Resource</i>        |
|--------|-------------|-------------------------------------|
| 0      | ru_utime    | time in user mode (float seconds)   |
| 1      | ru_stime    | time in system mode (float seconds) |
| 2      | ru_maxrss   | maximum resident set size           |
| 3      | ru_ixrss    | shared memory size                  |
| 4      | ru_idrss    | unshared memory size                |
| 5      | ru_isrss    | unshared stack size                 |
| 6      | ru_minflt   | page faults not requiring I/O       |
| 7      | ru_majflt   | page faults requiring I/O           |
| 8      | ru_nswap    | number of swap outs                 |
| 9      | ru_inblock  | block input operations              |
| 10     | ru_oublock  | block output operations             |
| 11     | ru_msgsnd   | messages sent                       |
| 12     | ru_msgrcv   | messages received                   |
| 13     | ru_nsignals | signals received                    |
| 14     | ru_nvcsw    | voluntary context switches          |
| 15     | ru_nivcsw   | involuntary context switches        |

This function will raise a *ValueError* if an invalid *who* parameter is specified. It may also raise *error* exception in unusual circumstances.

`resource.getpagesize()`

Returns the number of bytes in a system page. (This need not be the same as the hardware page size.)

The following `RUSAGE_*` symbols are passed to the *getrusage()* function to specify which processes information should be provided for.

`resource.RUSAGE_SELF`

Pass to *getrusage()* to request resources consumed by the calling process, which is the sum of resources used by all threads in the process.

`resource.RUSAGE_CHILDREN`

Pass to *getrusage()* to request resources consumed by child processes of the calling process which have been terminated and waited for.

`resource.RUSAGE_BOTH`

Pass to *getrusage()* to request resources consumed by both the current process and child processes. May not be available on all systems.

`resource.RUSAGE_THREAD`

Pass to *getrusage()* to request resources consumed by the current thread. May not be available on all systems.

Baru pada versi 3.2.

## 35.12 nis --- Interface to Sun's NIS (Yellow Pages)

---

The *nis* module gives a thin wrapper around the NIS library, useful for central administration of several hosts.

Because NIS exists only on Unix systems, this module is only available for Unix.

The *nis* module defines the following functions:

**nis.match** (*key*, *mapname*, *domain=default\_domain*)

Return the match for *key* in map *mapname*, or raise an error (*nis.error*) if there is none. Both should be strings, *key* is 8-bit clean. Return value is an arbitrary array of bytes (may contain NULL and other joys).

Note that *mapname* is first checked if it is an alias to another name.

The *domain* argument allows overriding the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

**nis.cat** (*mapname*, *domain=default\_domain*)

Return a dictionary mapping *key* to *value* such that `match(key, mapname) == value`. Note that both keys and values of the dictionary are arbitrary arrays of bytes.

Note that *mapname* is first checked if it is an alias to another name.

The *domain* argument allows overriding the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

**nis.maps** (*domain=default\_domain*)

Return a list of all valid maps.

The *domain* argument allows overriding the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

**nis.get\_default\_domain** ()

Return the system default NIS domain.

The *nis* module defines the following exception:

**exception nis.error**

An error raised when a NIS function returns an error code.

## 35.13 syslog --- Unix syslog library routines

---

This module provides an interface to the Unix *syslog* library routines. Refer to the Unix manual pages for a detailed description of the *syslog* facility.

This module wraps the system *syslog* family of routines. A pure Python library that can speak to a syslog server is available in the *logging.handlers* module as *SysLogHandler*.

The module defines the following functions:

**syslog.syslog** (*message*)

**syslog.syslog** (*priority*, *message*)

Send the string *message* to the system logger. A trailing newline is added if necessary. Each message is tagged with a priority composed of a *facility* and a *level*. The optional *priority* argument, which defaults to `LOG_INFO`, determines the message priority. If the facility is not encoded in *priority* using logical-or (`LOG_INFO | LOG_USER`), the value given in the *openlog* () call is used.

If `openlog()` has not been called prior to the call to `syslog()`, `openlog()` will be called with no arguments.

Raises an *auditing event* `syslog.syslog` with arguments `priority`, `message`.

`syslog.openlog([ident[, logoption[, facility]]])`

Logging options of subsequent `syslog()` calls can be set by calling `openlog()`. `syslog()` will call `openlog()` with no arguments if the log is not currently open.

The optional `ident` keyword argument is a string which is prepended to every message, and defaults to `sys.argv[0]` with leading path components stripped. The optional `logoption` keyword argument (default is 0) is a bit field -- see below for possible values to combine. The optional `facility` keyword argument (default is `LOG_USER`) sets the default facility for messages which do not have a facility explicitly encoded.

Raises an *auditing event* `syslog.openlog` with arguments `ident`, `logoption`, `facility`.

Berubah pada versi 3.2: In previous versions, keyword arguments were not allowed, and `ident` was required. The default for `ident` was dependent on the system libraries, and often was `python` instead of the name of the Python program file.

`syslog.closelog()`

Reset the syslog module values and call the system library `closelog()`.

This causes the module to behave as it does when initially imported. For example, `openlog()` will be called on the first `syslog()` call (if `openlog()` hasn't already been called), and `ident` and other `openlog()` parameters are reset to defaults.

Raises an *auditing event* `syslog.closelog` with no arguments.

`syslog.setlogmask(maskpri)`

Set the priority mask to `maskpri` and return the previous mask value. Calls to `syslog()` with a priority level not set in `maskpri` are ignored. The default is to log all priorities. The function `LOG_MASK(pri)` calculates the mask for the individual priority `pri`. The function `LOG_UPTO(pri)` calculates the mask for all priorities up to and including `pri`.

Raises an *auditing event* `syslog.setlogmask` with argument `maskpri`.

The module defines the following constants:

**Priority levels (high to low):** `LOG_EMERG`, `LOG_ALERT`, `LOG_CRIT`, `LOG_ERR`, `LOG_WARNING`, `LOG_NOTICE`, `LOG_INFO`, `LOG_DEBUG`.

**Facilities:** `LOG_KERN`, `LOG_USER`, `LOG_MAIL`, `LOG_DAEMON`, `LOG_AUTH`, `LOG_LPR`, `LOG_NEWS`, `LOG_UUCP`, `LOG_CRON`, `LOG_SYSLOG`, `LOG_LOCAL0` to `LOG_LOCAL7`, and, if defined in `<syslog.h>`, `LOG_AUTHPRIV`.

**Log options:** `LOG_PID`, `LOG_CONS`, `LOG_NDELAY`, and, if defined in `<syslog.h>`, `LOG_ODELAY`, `LOG_NOWAIT`, and `LOG_PERROR`.

## 35.13.1 Contoh-contoh

### Simple example

A simple set of examples:

```
import syslog

syslog.syslog('Processing started')
if error:
    syslog.syslog(syslog.LOG_ERR, 'Processing started')
```

An example of setting some log options, these would include the process ID in logged messages, and write the messages to the destination facility used for mail logging:

```
syslog.openlog(logoption=syslog.LOG_PID, facility=syslog.LOG_MAIL)
syslog.syslog('E-mail processing initiated...')
```

---

## Modul yang Diganti

---

Modul yang dijelaskan dalam bab ini tidak digunakan lagi dan hanya disimpan untuk kompatibilitas ke belakang. Mereka telah digantikan oleh modul lain.

### 36.1 `optparse` --- Parser for command line options

**Source code:** `Lib/optparse.py`

Ditinggalkan sejak versi 3.2: The `optparse` module is deprecated and will not be developed further; development will continue with the `argparse` module.

`optparse` is a more convenient, flexible, and powerful library for parsing command-line options than the old `getopt` module. `optparse` uses a more declarative style of command-line parsing: you create an instance of `OptionParser`, populate it with options, and parse the command line. `optparse` allows users to specify options in the conventional GNU/POSIX syntax, and additionally generates usage and help messages for you.

Here's an example of using `optparse` in a simple script:

```
from optparse import OptionParser
...
parser = OptionParser()
parser.add_option("-f", "--file", dest="filename",
                  help="write report to FILE", metavar="FILE")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose", default=True,
                  help="don't print status messages to stdout")

(options, args) = parser.parse_args()
```

With these few lines of code, users of your script can now do the "usual thing" on the command-line, for example:

```
<yourscript> --file=outfile -q
```

As it parses the command line, `optparse` sets attributes of the `options` object returned by `parse_args()` based on user-supplied command-line values. When `parse_args()` returns from parsing this command line, `options.filename` will be "outfile" and `options.verbose` will be `False`. `optparse` supports both long and short options, allows short options to be merged together, and allows options to be associated with their arguments in a variety of ways. Thus, the following command lines are all equivalent to the above example:

```
<yourscript> -f outfile --quiet
<yourscript> --quiet --file outfile
<yourscript> -q -foutfile
<yourscript> -qfoutfile
```

Additionally, users can run one of the following

```
<yourscript> -h
<yourscript> --help
```

and `optparse` will print out a brief summary of your script's options:

```
Usage: <yourscript> [options]

Options:
  -h, --help            show this help message and exit
  -f FILE, --file=FILE  write report to FILE
  -q, --quiet           don't print status messages to stdout
```

where the value of `yourscript` is determined at runtime (normally from `sys.argv[0]`).

### 36.1.1 Background

`optparse` was explicitly designed to encourage the creation of programs with straightforward, conventional command-line interfaces. To that end, it supports only the most common command-line syntax and semantics conventionally used under Unix. If you are unfamiliar with these conventions, read this section to acquaint yourself with them.

#### Terminology

**argumen** a string entered on the command-line, and passed by the shell to `execl()` or `execv()`. In Python, arguments are elements of `sys.argv[1:]` (`sys.argv[0]` is the name of the program being executed). Unix shells also use the term "word".

It is occasionally desirable to substitute an argument list other than `sys.argv[1:]`, so you should read "argument" as "an element of `sys.argv[1:]`, or of some other list provided as a substitute for `sys.argv[1:]`".

**option** an argument used to supply extra information to guide or customize the execution of a program. There are many different syntaxes for options; the traditional Unix syntax is a hyphen ("-") followed by a single letter, e.g. `-x` or `-F`. Also, traditional Unix syntax allows multiple options to be merged into a single argument, e.g. `-x -F` is equivalent to `-xF`. The GNU project introduced `--` followed by a series of hyphen-separated words, e.g. `--file` or `--dry-run`. These are the only two option syntaxes provided by `optparse`.

Some other option syntaxes that the world has seen include:

- a hyphen followed by a few letters, e.g. `-pf` (this is *not* the same as multiple options merged into a single argument)

- a hyphen followed by a whole word, e.g. `-file` (this is technically equivalent to the previous syntax, but they aren't usually seen in the same program)
- a plus sign followed by a single letter, or a few letters, or a word, e.g. `+f`, `+rgb`
- a slash followed by a letter, or a few letters, or a word, e.g. `/f`, `/file`

These option syntaxes are not supported by `optparse`, and they never will be. This is deliberate: the first three are non-standard on any environment, and the last only makes sense if you're exclusively targeting VMS, MS-DOS, and/or Windows.

**option argument** an argument that follows an option, is closely associated with that option, and is consumed from the argument list when that option is. With `optparse`, option arguments may either be in a separate argument from their option:

```
-f foo
--file foo
```

or included in the same argument:

```
-ffoo
--file=foo
```

Typically, a given option either takes an argument or it doesn't. Lots of people want an "optional option arguments" feature, meaning that some options will take an argument if they see it, and won't if they don't. This is somewhat controversial, because it makes parsing ambiguous: if `-a` takes an optional argument and `-b` is another option entirely, how do we interpret `-ab`? Because of this ambiguity, `optparse` does not support this feature.

**positional argument** something leftover in the argument list after options have been parsed, i.e. after options and their arguments have been parsed and removed from the argument list.

**required option** an option that must be supplied on the command-line; note that the phrase "required option" is self-contradictory in English. `optparse` doesn't prevent you from implementing required options, but doesn't give you much help at it either.

For example, consider this hypothetical command-line:

```
prog -v --report report.txt foo bar
```

`-v` and `--report` are both options. Assuming that `--report` takes one argument, `report.txt` is an option argument. `foo` and `bar` are positional arguments.

## What are options for?

Options are used to provide extra information to tune or customize the execution of a program. In case it wasn't clear, options are usually *optional*. A program should be able to run just fine with no options whatsoever. (Pick a random program from the Unix or GNU toolsets. Can it run without any options at all and still make sense? The main exceptions are `find`, `tar`, and `dd`—all of which are mutant oddballs that have been rightly criticized for their non-standard syntax and confusing interfaces.)

Lots of people want their programs to have "required options". Think about it. If it's required, then it's *not optional*! If there is a piece of information that your program absolutely requires in order to run successfully, that's what positional arguments are for.

As an example of good command-line interface design, consider the humble `cp` utility, for copying files. It doesn't make much sense to try to copy files without supplying a destination and at least one source. Hence, `cp` fails if you run it with no arguments. However, it has a flexible, useful syntax that does not require any options at all:

```
cp SOURCE DEST
cp SOURCE ... DEST-DIR
```

You can get pretty far with just that. Most `cp` implementations provide a bunch of options to tweak exactly how the files are copied: you can preserve mode and modification time, avoid following symlinks, ask before clobbering existing files, etc. But none of this distracts from the core mission of `cp`, which is to copy either one file to another, or several files to another directory.

### What are positional arguments for?

Positional arguments are for those pieces of information that your program absolutely, positively requires to run.

A good user interface should have as few absolute requirements as possible. If your program requires 17 distinct pieces of information in order to run successfully, it doesn't much matter *how* you get that information from the user---most people will give up and walk away before they successfully run the program. This applies whether the user interface is a command-line, a configuration file, or a GUI: if you make that many demands on your users, most of them will simply give up.

In short, try to minimize the amount of information that users are absolutely required to supply---use sensible defaults whenever possible. Of course, you also want to make your programs reasonably flexible. That's what options are for. Again, it doesn't matter if they are entries in a config file, widgets in the "Preferences" dialog of a GUI, or command-line options---the more options you implement, the more flexible your program is, and the more complicated its implementation becomes. Too much flexibility has drawbacks as well, of course; too many options can overwhelm users and make your code much harder to maintain.

## 36.1.2 Tutorial

While `optparse` is quite flexible and powerful, it's also straightforward to use in most cases. This section covers the code patterns that are common to any `optparse`-based program.

First, you need to import the `OptionParser` class; then, early in the main program, create an `OptionParser` instance:

```
from optparse import OptionParser
...
parser = OptionParser()
```

Then you can start defining options. The basic syntax is:

```
parser.add_option(opt_str, ...,
                  attr=value, ...)
```

Each option has one or more option strings, such as `-f` or `--file`, and several option attributes that tell `optparse` what to expect and what to do when it encounters that option on the command line.

Typically, each option will have one short option string and one long option string, e.g.:

```
parser.add_option("-f", "--file", ...)
```

You're free to define as many short option strings and as many long option strings as you like (including zero), as long as there is at least one option string overall.

The option strings passed to `OptionParser.add_option()` are effectively labels for the option defined by that call. For brevity, we will frequently refer to *encountering an option* on the command line; in reality, `optparse` encounters *option strings* and looks up options from them.

Once all of your options are defined, instruct `optparse` to parse your program's command line:

```
(options, args) = parser.parse_args()
```

(If you like, you can pass a custom argument list to `parse_args()`, but that's rarely necessary: by default it uses `sys.argv[1:]`.)

`parse_args()` returns two values:

- `options`, an object containing values for all of your options---e.g. if `--file` takes a single string argument, then `options.file` will be the filename supplied by the user, or `None` if the user did not supply that option
- `args`, the list of positional arguments leftover after parsing options

This tutorial section only covers the four most important option attributes: `action`, `type`, `dest` (destination), and `help`. Of these, `action` is the most fundamental.

## Understanding option actions

Actions tell `optparse` what to do when it encounters an option on the command line. There is a fixed set of actions hard-coded into `optparse`; adding new actions is an advanced topic covered in section [Extending `optparse`](#). Most actions tell `optparse` to store a value in some variable---for example, take a string from the command line and store it in an attribute of `options`.

If you don't specify an option action, `optparse` defaults to `store`.

## The store action

The most common option action is `store`, which tells `optparse` to take the next argument (or the remainder of the current argument), ensure that it is of the correct type, and store it to your chosen destination.

Sebagai contoh:

```
parser.add_option("-f", "--file",
                  action="store", type="string", dest="filename")
```

Now let's make up a fake command line and ask `optparse` to parse it:

```
args = ["-f", "foo.txt"]
(options, args) = parser.parse_args(args)
```

When `optparse` sees the option string `-f`, it consumes the next argument, `foo.txt`, and stores it in `options.filename`. So, after this call to `parse_args()`, `options.filename` is `"foo.txt"`.

Some other option types supported by `optparse` are `int` and `float`. Here's an option that expects an integer argument:

```
parser.add_option("-n", type="int", dest="num")
```

Note that this option has no long option string, which is perfectly acceptable. Also, there's no explicit action, since the default is `store`.

Let's parse another fake command-line. This time, we'll jam the option argument right up against the option: since `-n42` (one argument) is equivalent to `-n 42` (two arguments), the code

```
(options, args) = parser.parse_args(["-n42"])
print(options.num)
```

will print 42.

If you don't specify a type, *optparse* assumes `string`. Combined with the fact that the default action is `store`, that means our first example can be a lot shorter:

```
parser.add_option("-f", "--file", dest="filename")
```

If you don't supply a destination, *optparse* figures out a sensible default from the option strings: if the first long option string is `--foo-bar`, then the default destination is `foo_bar`. If there are no long option strings, *optparse* looks at the first short option string: the default destination for `-f` is `f`.

*optparse* also includes the built-in `complex` type. Adding types is covered in section [Extending optparse](#).

### Handling boolean (flag) options

Flag options---set a variable to true or false when a particular option is seen---are quite common. *optparse* supports them with two separate actions, `store_true` and `store_false`. For example, you might have a `verbose` flag that is turned on with `-v` and off with `-q`:

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose")
```

Here we have two different options with the same destination, which is perfectly OK. (It just means you have to be a bit careful when setting default values---see below.)

When *optparse* encounters `-v` on the command line, it sets `options.verbose` to `True`; when it encounters `-q`, `options.verbose` is set to `False`.

### Other actions

Some other actions supported by *optparse* are:

**"store\_const"** store a constant value

**"append"** append this option's argument to a list

**"count"** increment a counter by one

**"callback"** call a specified function

These are covered in section [Reference Guide](#), and section [Option Callbacks](#).

### Default values

All of the above examples involve setting some variable (the "destination") when certain command-line options are seen. What happens if those options are never seen? Since we didn't supply any defaults, they are all set to `None`. This is usually fine, but sometimes you want more control. *optparse* lets you supply a default value for each destination, which is assigned before the command line is parsed.

First, consider the `verbose/quiet` example. If we want *optparse* to set `verbose` to `True` unless `-q` is seen, then we can do this:

```
parser.add_option("-v", action="store_true", dest="verbose", default=True)
parser.add_option("-q", action="store_false", dest="verbose")
```

Since default values apply to the *destination* rather than to any particular option, and these two options happen to have the same destination, this is exactly equivalent:

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose", default=True)
```

Consider this:

```
parser.add_option("-v", action="store_true", dest="verbose", default=False)
parser.add_option("-q", action="store_false", dest="verbose", default=True)
```

Again, the default value for `verbose` will be `True`: the last default value supplied for any particular destination is the one that counts.

A clearer way to specify default values is the `set_defaults()` method of `OptionParser`, which you can call at any time before calling `parse_args()`:

```
parser.set_defaults(verbose=True)
parser.add_option(...)
(options, args) = parser.parse_args()
```

As before, the last value specified for a given option destination is the one that counts. For clarity, try to use one method or the other of setting default values, not both.

## Generating help

`optparse`'s ability to generate help and usage text automatically is useful for creating user-friendly command-line interfaces. All you have to do is supply a `help` value for each option, and optionally a short usage message for your whole program. Here's an `OptionParser` populated with user-friendly (documented) options:

```
usage = "usage: %prog [options] arg1 arg2"
parser = OptionParser(usage=usage)
parser.add_option("-v", "--verbose",
                  action="store_true", dest="verbose", default=True,
                  help="make lots of noise [default]")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose",
                  help="be vewwy quiet (I'm hunting wabbits)")
parser.add_option("-f", "--filename",
                  metavar="FILE", help="write output to FILE")
parser.add_option("-m", "--mode",
                  default="intermediate",
                  help="interaction mode: novice, intermediate, "
                  "or expert [default: %default]")
```

If `optparse` encounters either `-h` or `--help` on the command-line, or if you just call `parser.print_help()`, it prints the following to standard output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose          make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or
                        expert [default: intermediate]
```

(If the help output is triggered by a help option, *optparse* exits after printing the help text.)

There's a lot going on here to help *optparse* generate the best possible help message:

- the script defines its own usage message:

```
usage = "usage: %prog [options] arg1 arg2"
```

*optparse* expands `%prog` in the usage string to the name of the current program, i.e. `os.path.basename(sys.argv[0])`. The expanded string is then printed before the detailed option help.

If you don't supply a usage string, *optparse* uses a bland but sensible default: `"Usage: %prog [options]"`, which is fine if your script doesn't take any positional arguments.

- every option defines a help string, and doesn't worry about line-wrapping---*optparse* takes care of wrapping lines and making the help output look good.
- options that take a value indicate this fact in their automatically-generated help message, e.g. for the "mode" option:

```
-m MODE, --mode=MODE
```

Here, "MODE" is called the meta-variable: it stands for the argument that the user is expected to supply to `-m/--mode`. By default, *optparse* converts the destination variable name to uppercase and uses that for the meta-variable. Sometimes, that's not what you want---for example, the `--filename` option explicitly sets `metavar="FILE"`, resulting in this automatically-generated option description:

```
-f FILE, --filename=FILE
```

This is important for more than just saving space, though: the manually written help text uses the meta-variable `FILE` to clue the user in that there's a connection between the semi-formal syntax `-f FILE` and the informal semantic description "write output to `FILE`". This is a simple but effective way to make your help text a lot clearer and more useful for end users.

- options that have a default value can include `%default` in the help string---*optparse* will replace it with `str()` of the option's default value. If an option has no default value (or the default value is `None`), `%default` expands to `none`.

## Grouping Options

When dealing with many options, it is convenient to group these options for better help output. An *OptionParser* can contain several option groups, each of which can contain several options.

An option group is obtained using the class *OptionGroup*:

```
class optparse.OptionGroup (parser, title, description=None)
    where
```

- `parser` is the *OptionParser* instance the group will be inserted in to
- `title` is the group title
- `description`, optional, is a long description of the group

*OptionGroup* inherits from *OptionContainer* (like *OptionParser*) and so the `add_option()` method can be used to add an option to the group.

Once all the options are declared, using the *OptionParser* method `add_option_group()` the group is added to the previously defined parser.

Continuing with the parser defined in the previous section, adding an *OptionGroup* to a parser is easy:

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your own risk.  "
                    "It is believed that some of them bite.")
group.add_option("-g", action="store_true", help="Group option.")
parser.add_option_group(group)
```

This would result in the following help output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose          make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or
                        expert [default: intermediate]

Dangerous Options:
  Caution: use these options at your own risk.  It is believed that some
  of them bite.

  -g                    Group option.
```

A bit more complete example might involve using more than one group: still extending the previous example:

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your own risk.  "
                    "It is believed that some of them bite.")
group.add_option("-g", action="store_true", help="Group option.")
parser.add_option_group(group)

group = OptionGroup(parser, "Debug Options")
group.add_option("-d", "--debug", action="store_true",
                help="Print debug information")
group.add_option("-s", "--sql", action="store_true",
                help="Print all SQL statements executed")
group.add_option("-e", action="store_true", help="Print every action done")
parser.add_option_group(group)
```

that results in the following output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose          make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or expert
                        [default: intermediate]

Dangerous Options:
  Caution: use these options at your own risk.  It is believed that some
  of them bite.
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```

    -g                Group option.

Debug Options:
    -d, --debug       Print debug information
    -s, --sql         Print all SQL statements executed
    -e                Print every action done

```

Another interesting method, in particular when working programmatically with option groups is:

`OptionParser.get_option_group(opt_str)`

Return the *OptionGroup* to which the short or long option string *opt\_str* (e.g. `'-o'` or `'--option'`) belongs. If there's no such *OptionGroup*, return `None`.

## Printing a version string

Similar to the brief usage string, *optparse* can also print a version string for your program. You have to supply the string as the `version` argument to `OptionParser`:

```
parser = OptionParser(usage="%prog [-f] [-q]", version="%prog 1.0")
```

`%prog` is expanded just like it is in `usage`. Apart from that, `version` can contain anything you like. When you supply it, *optparse* automatically adds a `--version` option to your parser. If it encounters this option on the command line, it expands your `version` string (by replacing `%prog`), prints it to `stdout`, and exits.

For example, if your script is called `/usr/bin/foo`:

```
$ /usr/bin/foo --version
foo 1.0
```

The following two methods can be used to print and get the version string:

`OptionParser.print_version(file=None)`

Print the version message for the current program (`self.version`) to *file* (default `stdout`). As with `print_usage()`, any occurrence of `%prog` in `self.version` is replaced with the name of the current program. Does nothing if `self.version` is empty or undefined.

`OptionParser.get_version()`

Same as `print_version()` but returns the version string instead of printing it.

## How *optparse* handles errors

There are two broad classes of errors that *optparse* has to worry about: programmer errors and user errors. Programmer errors are usually erroneous calls to `OptionParser.add_option()`, e.g. invalid option strings, unknown option attributes, missing option attributes, etc. These are dealt with in the usual way: raise an exception (either `optparse.OptionError` or `TypeError`) and let the program crash.

Handling user errors is much more important, since they are guaranteed to happen no matter how stable your code is. *optparse* can automatically detect some user errors, such as bad option arguments (passing `-n 4x` where `-n` takes an integer argument), missing arguments (`-n` at the end of the command line, where `-n` takes an argument of any type). Also, you can call `OptionParser.error()` to signal an application-defined error condition:

```
(options, args) = parser.parse_args()
...
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
if options.a and options.b:
    parser.error("options -a and -b are mutually exclusive")
```

In either case, *optparse* handles the error the same way: it prints the program's usage message and an error message to standard error and exits with error status 2.

Consider the first example above, where the user passes 4x to an option that takes an integer:

```
$ /usr/bin/foo -n 4x
Usage: foo [options]

foo: error: option -n: invalid integer value: '4x'
```

Or, where the user fails to pass a value at all:

```
$ /usr/bin/foo -n
Usage: foo [options]

foo: error: -n option requires an argument
```

*optparse*-generated error messages take care always to mention the option involved in the error; be sure to do the same when calling `OptionParser.error()` from your application code.

If *optparse*'s default error-handling behaviour does not suit your needs, you'll need to subclass `OptionParser` and override its `exit()` and/or `error()` methods.

## Putting it all together

Here's what *optparse*-based scripts usually look like:

```
from optparse import OptionParser
...
def main():
    usage = "usage: %prog [options] arg"
    parser = OptionParser(usage)
    parser.add_option("-f", "--file", dest="filename",
                      help="read data from FILENAME")
    parser.add_option("-v", "--verbose",
                      action="store_true", dest="verbose")
    parser.add_option("-q", "--quiet",
                      action="store_false", dest="verbose")
    ...
    (options, args) = parser.parse_args()
    if len(args) != 1:
        parser.error("incorrect number of arguments")
    if options.verbose:
        print("reading %s..." % options.filename)
    ...

if __name__ == "__main__":
    main()
```

### 36.1.3 Reference Guide

#### Creating the parser

The first step in using *optparse* is to create an `OptionParser` instance.

**class** `optparse.OptionParser` (...)

The `OptionParser` constructor has no required arguments, but a number of optional keyword arguments. You should always pass them as keyword arguments, i.e. do not rely on the order in which the arguments are declared.

**usage** (default: "%prog [options]") The usage summary to print when your program is run incorrectly or with a help option. When *optparse* prints the usage string, it expands `%prog` to `os.path.basename(sys.argv[0])` (or to `prog` if you passed that keyword argument). To suppress a usage message, pass the special value `optparse.SUPPRESS_USAGE`.

**option\_list** (default: []) A list of `Option` objects to populate the parser with. The options in `option_list` are added after any options in `standard_option_list` (a class attribute that may be set by `OptionParser` subclasses), but before any version or help options. Deprecated; use *add\_option()* after creating the parser instead.

**option\_class** (default: `optparse.Option`) Class to use when adding options to the parser in *add\_option()*.

**version** (default: `None`) A version string to print when the user supplies a version option. If you supply a true value for `version`, *optparse* automatically adds a version option with the single option string `--version`. The substring `%prog` is expanded the same as for `usage`.

**conflict\_handler** (default: "error") Specifies what to do when options with conflicting option strings are added to the parser; see section *Conflicts between options*.

**description** (default: `None`) A paragraph of text giving a brief overview of your program. *optparse* reformats this paragraph to fit the current terminal width and prints it when the user requests help (after `usage`, but before the list of options).

**formatter** (default: a new `IndentedHelpFormatter`) An instance of `optparse.HelpFormatter` that will be used for printing help text. *optparse* provides two concrete classes for this purpose: `IndentedHelpFormatter` and `TitledHelpFormatter`.

**add\_help\_option** (default: `True`) If true, *optparse* will add a help option (with option strings `-h` and `--help`) to the parser.

**prog** The string to use when expanding `%prog` in `usage` and `version` instead of `os.path.basename(sys.argv[0])`.

**epilog** (default: `None`) A paragraph of help text to print after the option help.

#### Populating the parser

There are several ways to populate the parser with options. The preferred way is by using *OptionParser.add\_option()*, as shown in section *Tutorial*. *add\_option()* can be called in one of two ways:

- pass it an `Option` instance (as returned by *make\_option()*)
- pass it any combination of positional and keyword arguments that are acceptable to *make\_option()* (i.e., to the `Option` constructor), and it will create the `Option` instance for you

The other alternative is to pass a list of pre-constructed `Option` instances to the `OptionParser` constructor, as in:

```
option_list = [
    make_option("-f", "--filename",
                action="store", type="string", dest="filename"),
    make_option("-q", "--quiet",
                action="store_false", dest="verbose"),
]
parser = OptionParser(option_list=option_list)
```

(`make_option()` is a factory function for creating `Option` instances; currently it is an alias for the `Option` constructor. A future version of *optparse* may split `Option` into several classes, and `make_option()` will pick the right class to instantiate. Do not instantiate `Option` directly.)

## Defining options

Each `Option` instance represents a set of synonymous command-line option strings, e.g. `-f` and `--file`. You can specify any number of short or long option strings, but you must specify at least one overall option string.

The canonical way to create an `Option` instance is with the `add_option()` method of *OptionParser*.

```
OptionParser.add_option(option)
OptionParser.add_option(*opt_str, attr=value, ...)
```

To define an option with only a short option string:

```
parser.add_option("-f", attr=value, ...)
```

And to define an option with only a long option string:

```
parser.add_option("--foo", attr=value, ...)
```

The keyword arguments define attributes of the new `Option` object. The most important option attribute is *action*, and it largely determines which other attributes are relevant or required. If you pass irrelevant option attributes, or fail to pass required ones, *optparse* raises an `OptionError` exception explaining your mistake.

An option's *action* determines what *optparse* does when it encounters this option on the command-line. The standard option actions hard-coded into *optparse* are:

**"store"** store this option's argument (default)

**"store\_const"** store a constant value

**"store\_true"** store `True`

**"store\_false"** store `False`

**"append"** append this option's argument to a list

**"append\_const"** append a constant value to a list

**"count"** increment a counter by one

**"callback"** call a specified function

**"help"** print a usage message including all options and the documentation for them

(If you don't supply an action, the default is `"store"`. For this action, you may also supply *type* and *dest* option attributes; see *Standard option actions*.)

As you can see, most actions involve storing or updating a value somewhere. *optparse* always creates a special object for this, conventionally called `options` (it happens to be an instance of `optparse.Values`). Option arguments (and various other values) are stored as attributes of this object, according to the *dest* (destination) option attribute.

For example, when you call

```
parser.parse_args()
```

one of the first things *optparse* does is create the *options* object:

```
options = Values()
```

If one of the options in this parser is defined with

```
parser.add_option("-f", "--file", action="store", type="string", dest="filename")
```

and the command-line being parsed includes any of the following:

```
-ffoo
-f foo
--file=foo
--file foo
```

then *optparse*, on seeing this option, will do the equivalent of

```
options.filename = "foo"
```

The *type* and *dest* option attributes are almost as important as *action*, but *action* is the only one that makes sense for *all* options.

### Option attributes

The following option attributes may be passed as keyword arguments to *OptionParser.add\_option()*. If you pass an option attribute that is not relevant to a particular option, or fail to pass a required option attribute, *optparse* raises *OptionError*.

**Option.action**  
(default: "store")

Determines *optparse*'s behaviour when this option is seen on the command line; the available options are documented [here](#).

**Option.type**  
(default: "string")

The argument type expected by this option (e.g., "string" or "int"); the available option types are documented [here](#).

**Option.dest**  
(default: derived from option strings)

If the option's action implies writing or modifying a value somewhere, this tells *optparse* where to write it: *dest* names an attribute of the *options* object that *optparse* builds as it parses the command line.

**Option.default**  
The value to use for this option's destination if the option is not seen on the command line. See also *OptionParser.set\_defaults()*.

**Option.nargs**  
(default: 1)

How many arguments of type *type* should be consumed when this option is seen. If > 1, *optparse* will store a tuple of values to *dest*.

**Option.const**

For actions that store a constant value, the constant value to store.

**Option.choices**

For options of type "choice", the list of strings the user may choose from.

**Option.callback**

For options with action "callback", the callable to call when this option is seen. See section [Option Callbacks](#) for detail on the arguments passed to the callable.

**Option.callback\_args****Option.callback\_kwargs**

Additional positional and keyword arguments to pass to `callback` after the four standard callback arguments.

**Option.help**

Help text to print for this option when listing all available options after the user supplies a [help](#) option (such as `--help`). If no help text is supplied, the option will be listed without help text. To hide this option, use the special value `optparse.SUPPRESS_HELP`.

**Option.metavar**

(default: derived from option strings)

Stand-in for the option argument(s) to use when printing help text. See section [Tutorial](#) for an example.

## Standard option actions

The various option actions all have slightly different requirements and effects. Most actions have several relevant option attributes which you may specify to guide *optparse*'s behaviour; a few have required attributes, which you must specify for any option using that action.

- "store" [relevant: *type*, *dest*, *nargs*, *choices*]

The option must be followed by an argument, which is converted to a value according to *type* and stored in *dest*. If *nargs* > 1, multiple arguments will be consumed from the command line; all will be converted according to *type* and stored to *dest* as a tuple. See the [Standard option types](#) section.

If *choices* is supplied (a list or tuple of strings), the type defaults to "choice".

If *type* is not supplied, it defaults to "string".

If *dest* is not supplied, *optparse* derives a destination from the first long option string (e.g., `--foo-bar` implies `foo_bar`). If there are no long option strings, *optparse* derives a destination from the first short option string (e.g., `-f` implies `f`).

Contoh:

```
parser.add_option("-f")
parser.add_option("-p", type="float", nargs=3, dest="point")
```

As it parses the command line

```
-f foo.txt -p 1 -3.5 4 -fbar.txt
```

*optparse* will set

```
options.f = "foo.txt"
options.point = (1.0, -3.5, 4.0)
options.f = "bar.txt"
```

- "store\_const" [required: *const*; relevant: *dest*]

The value *const* is stored in *dest*.

Contoh:

```
parser.add_option("-q", "--quiet",
                  action="store_const", const=0, dest="verbose")
parser.add_option("-v", "--verbose",
                  action="store_const", const=1, dest="verbose")
parser.add_option("--noisy",
                  action="store_const", const=2, dest="verbose")
```

If `--noisy` is seen, *optparse* will set

```
options.verbose = 2
```

- "store\_true" [relevant: *dest*]

A special case of "store\_const" that stores True to *dest*.

- "store\_false" [relevant: *dest*]

Like "store\_true", but stores False.

Contoh:

```
parser.add_option("--clobber", action="store_true", dest="clobber")
parser.add_option("--no-clobber", action="store_false", dest="clobber")
```

- "append" [relevant: *type*, *dest*, *nargs*, *choices*]

The option must be followed by an argument, which is appended to the list in *dest*. If no default value for *dest* is supplied, an empty list is automatically created when *optparse* first encounters this option on the command-line. If *nargs* > 1, multiple arguments are consumed, and a tuple of length *nargs* is appended to *dest*.

The defaults for *type* and *dest* are the same as for the "store" action.

Contoh:

```
parser.add_option("-t", "--tracks", action="append", type="int")
```

If `-t3` is seen on the command-line, *optparse* does the equivalent of:

```
options.tracks = []
options.tracks.append(int("3"))
```

If, a little later on, `--tracks=4` is seen, it does:

```
options.tracks.append(int("4"))
```

The append action calls the append method on the current value of the option. This means that any default value specified must have an append method. It also means that if the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values:

```
>>> parser.add_option("--files", action="append", default=['~/mypkg/defaults'])
>>> opts, args = parser.parse_args(['--files', 'overrides.mypkg'])
>>> opts.files
['~/mypkg/defaults', 'overrides.mypkg']
```

- "append\_const" [required: *const*; relevant: *dest*]

Like "store\_const", but the value *const* is appended to *dest*; as with "append", *dest* defaults to None, and an empty list is automatically created the first time the option is encountered.

- "count" [relevant: *dest*]

Increment the integer stored at *dest*. If no default value is supplied, *dest* is set to zero before being incremented the first time.

Contoh:

```
parser.add_option("-v", action="count", dest="verbosity")
```

The first time `-v` is seen on the command line, *optparse* does the equivalent of:

```
options.verbosity = 0
options.verbosity += 1
```

Every subsequent occurrence of `-v` results in

```
options.verbosity += 1
```

- "callback" [required: *callback*; relevant: *type*, *nargs*, *callback\_args*, *callback\_kwargs*]

Call the function specified by *callback*, which is called as

```
func(option, opt_str, value, parser, *args, **kwargs)
```

See section *Option Callbacks* for more detail.

- "help"

Prints a complete help message for all the options in the current option parser. The help message is constructed from the usage string passed to *OptionParser*'s constructor and the *help* string passed to every option.

If no *help* string is supplied for an option, it will still be listed in the help message. To omit an option entirely, use the special value `optparse.SUPPRESS_HELP`.

*optparse* automatically adds a *help* option to all *OptionParsers*, so you do not normally need to create one.

Contoh:

```
from optparse import OptionParser, SUPPRESS_HELP

# usually, a help option is added automatically, but that can
# be suppressed using the add_help_option argument
parser = OptionParser(add_help_option=False)

parser.add_option("-h", "--help", action="help")
parser.add_option("-v", action="store_true", dest="verbose",
                  help="Be moderately verbose")
parser.add_option("--file", dest="filename",
                  help="Input file to read data from")
parser.add_option("--secret", help=SUPPRESS_HELP)
```

If *optparse* sees either `-h` or `--help` on the command line, it will print something like the following help message to stdout (assuming `sys.argv[0]` is `"foo.py"`):

```
Usage: foo.py [options]

Options:
  -h, --help            Show this help message and exit
  -v                    Be moderately verbose
  --file=FILENAME       Input file to read data from
```

After printing the help message, *optparse* terminates your process with `sys.exit(0)`.

- "version"

Prints the version number supplied to the `OptionParser` to stdout and exits. The version number is actually formatted and printed by the `print_version()` method of `OptionParser`. Generally only relevant if the `version` argument is supplied to the `OptionParser` constructor. As with *help* options, you will rarely create version options, since *optparse* automatically adds them when needed.

### Standard option types

*optparse* has five built-in option types: "string", "int", "choice", "float" and "complex". If you need to add new option types, see section *Extending optparse*.

Arguments to string options are not checked or converted in any way: the text on the command line is stored in the destination (or passed to the callback) as-is.

Integer arguments (type "int") are parsed as follows:

- if the number starts with 0x, it is parsed as a hexadecimal number
- if the number starts with 0, it is parsed as an octal number
- if the number starts with 0b, it is parsed as a binary number
- otherwise, the number is parsed as a decimal number

The conversion is done by calling `int()` with the appropriate base (2, 8, 10, or 16). If this fails, so will *optparse*, although with a more useful error message.

"float" and "complex" option arguments are converted directly with `float()` and `complex()`, with similar error-handling.

"choice" options are a subtype of "string" options. The *choices* option attribute (a sequence of strings) defines the set of allowed option arguments. `optparse.check_choice()` compares user-supplied option arguments against this master list and raises `OptionValueError` if an invalid string is given.

### Mengurai argumen

The whole point of creating and populating an `OptionParser` is to call its `parse_args()` method:

```
(options, args) = parser.parse_args(args=None, values=None)
```

where the input parameters are

**args** the list of arguments to process (default: `sys.argv[1:]`)

**values** an `optparse.Values` object to store option arguments in (default: a new instance of `Values`) -- if you give an existing object, the option defaults will not be initialized on it

and the return values are

**options** the same object that was passed in as `values`, or the `optparse.Values` instance created by *optparse*

**args** the leftover positional arguments after all options have been processed

The most common usage is to supply neither keyword argument. If you supply `values`, it will be modified with repeated `setattr()` calls (roughly one for every option argument stored to an option destination) and returned by `parse_args()`.

If `parse_args()` encounters any errors in the argument list, it calls the `OptionParser`'s `error()` method with an appropriate end-user error message. This ultimately terminates your process with an exit status of 2 (the traditional Unix exit status for command-line errors).

## Querying and manipulating your option parser

The default behavior of the option parser can be customized slightly, and you can also poke around your option parser and see what's there. `OptionParser` provides several methods to help you out:

`OptionParser.disable_interspersed_args()`

Set parsing to stop on the first non-option. For example, if `-a` and `-b` are both simple options that take no arguments, *optparse* normally accepts this syntax:

```
prog -a arg1 -b arg2
```

and treats it as equivalent to

```
prog -a -b arg1 arg2
```

To disable this feature, call `disable_interspersed_args()`. This restores traditional Unix syntax, where option parsing stops with the first non-option argument.

Use this if you have a command processor which runs another command which has options of its own and you want to make sure these options don't get confused. For example, each command might have a different set of options.

`OptionParser.enable_interspersed_args()`

Set parsing to not stop on the first non-option, allowing interspersing switches with command arguments. This is the default behavior.

`OptionParser.get_option(opt_str)`

Returns the `Option` instance with the option string `opt_str`, or `None` if no options have that option string.

`OptionParser.has_option(opt_str)`

Return `True` if the `OptionParser` has an option with option string `opt_str` (e.g., `-q` or `--verbose`).

`OptionParser.remove_option(opt_str)`

If the `OptionParser` has an option corresponding to `opt_str`, that option is removed. If that option provided any other option strings, all of those option strings become invalid. If `opt_str` does not occur in any option belonging to this `OptionParser`, raises `ValueError`.

## Conflicts between options

If you're not careful, it's easy to define options with conflicting option strings:

```
parser.add_option("-n", "--dry-run", ...)
...
parser.add_option("-n", "--noisy", ...)
```

(This is particularly true if you've defined your own `OptionParser` subclass with some standard options.)

Every time you add an option, *optparse* checks for conflicts with existing options. If it finds any, it invokes the current conflict-handling mechanism. You can set the conflict-handling mechanism either in the constructor:

```
parser = OptionParser(..., conflict_handler=handler)
```

or with a separate call:

```
parser.set_conflict_handler(handler)
```

The available conflict handlers are:

**"error"** (default) assume option conflicts are a programming error and raise `OptionConflictError`

**"resolve"** resolve option conflicts intelligently (see below)

As an example, let's define an `OptionParser` that resolves conflicts intelligently and add conflicting options to it:

```
parser = OptionParser(conflict_handler="resolve")
parser.add_option("-n", "--dry-run", ..., help="do no harm")
parser.add_option("-n", "--noisy", ..., help="be noisy")
```

At this point, `optparse` detects that a previously-added option is already using the `-n` option string. Since `conflict_handler` is `"resolve"`, it resolves the situation by removing `-n` from the earlier option's list of option strings. Now `--dry-run` is the only way for the user to activate that option. If the user asks for help, the help message will reflect that:

```
Options:
  --dry-run      do no harm
  ...
  -n, --noisy    be noisy
```

It's possible to whittle away the option strings for a previously-added option until there are none left, and the user has no way of invoking that option from the command-line. In that case, `optparse` removes that option completely, so it doesn't show up in help text or anywhere else. Carrying on with our existing `OptionParser`:

```
parser.add_option("--dry-run", ..., help="new dry-run option")
```

At this point, the original `-n/--dry-run` option is no longer accessible, so `optparse` removes it, leaving this help text:

```
Options:
  ...
  -n, --noisy    be noisy
  --dry-run      new dry-run option
```

### Cleanup

`OptionParser` instances have several cyclic references. This should not be a problem for Python's garbage collector, but you may wish to break the cyclic references explicitly by calling `destroy()` on your `OptionParser` once you are done with it. This is particularly useful in long-running applications where large object graphs are reachable from your `OptionParser`.

## Other methods

`OptionParser` supports several other public methods:

`OptionParser.set_usage(usage)`

Set the usage string according to the rules described above for the `usage` constructor keyword argument. Passing `None` sets the default usage string; use `optparse.SUPPRESS_USAGE` to suppress a usage message.

`OptionParser.print_usage(file=None)`

Print the usage message for the current program (`self.usage`) to `file` (default `stdout`). Any occurrence of the string `%prog` in `self.usage` is replaced with the name of the current program. Does nothing if `self.usage` is empty or not defined.

`OptionParser.get_usage()`

Same as `print_usage()` but returns the usage string instead of printing it.

`OptionParser.set_defaults(dest=value, ...)`

Set default values for several option destinations at once. Using `set_defaults()` is the preferred way to set default values for options, since multiple options can share the same destination. For example, if several "mode" options all set the same destination, any one of them can set the default, and the last one wins:

```
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced",
                  default="novice")    # overridden below
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice",
                  default="advanced")  # overrides above setting
```

To avoid this confusion, use `set_defaults()`:

```
parser.set_defaults(mode="advanced")
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced")
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice")
```

### 36.1.4 Option Callbacks

When `optparse`'s built-in actions and types aren't quite enough for your needs, you have two choices: extend `optparse` or define a callback option. Extending `optparse` is more general, but overkill for a lot of simple cases. Quite often a simple callback is all you need.

There are two steps to defining a callback option:

- define the option itself using the "callback" action
- write the callback; this is a function (or method) that takes at least four arguments, as described below

## Defining a callback option

As always, the easiest way to define a callback option is by using the `OptionParser.add_option()` method. Apart from `action`, the only option attribute you must specify is `callback`, the function to call:

```
parser.add_option("-c", action="callback", callback=my_callback)
```

`callback` is a function (or other callable object), so you must have already defined `my_callback()` when you create this callback option. In this simple case, `optparse` doesn't even know if `-c` takes any arguments, which usually means that the option takes no arguments---the mere presence of `-c` on the command-line is all it needs to know. In some circumstances, though, you might want your callback to consume an arbitrary number of command-line arguments. This is where writing callbacks gets tricky; it's covered later in this section.

`optparse` always passes four particular arguments to your callback, and it will only pass additional arguments if you specify them via `callback_args` and `callback_kwargs`. Thus, the minimal callback function signature is:

```
def my_callback(option, opt, value, parser):
```

The four arguments to a callback are described below.

There are several other option attributes that you can supply when you define a callback option:

**`type`** has its usual meaning: as with the "store" or "append" actions, it instructs `optparse` to consume one argument and convert it to `type`. Rather than storing the converted value(s) anywhere, though, `optparse` passes it to your callback function.

**`nargs`** also has its usual meaning: if it is supplied and `> 1`, `optparse` will consume `nargs` arguments, each of which must be convertible to `type`. It then passes a tuple of converted values to your callback.

**`callback_args`** a tuple of extra positional arguments to pass to the callback

**`callback_kwargs`** a dictionary of extra keyword arguments to pass to the callback

## How callbacks are called

All callbacks are called as follows:

```
func(option, opt_str, value, parser, *args, **kwargs)
```

where

**`option`** is the `Option` instance that's calling the callback

**`opt_str`** is the option string seen on the command-line that's triggering the callback. (If an abbreviated long option was used, `opt_str` will be the full, canonical option string---e.g. if the user puts `--foo` on the command-line as an abbreviation for `--foobar`, then `opt_str` will be `--foobar`.)

**`value`** is the argument to this option seen on the command-line. `optparse` will only expect an argument if `type` is set; the type of `value` will be the type implied by the option's type. If `type` for this option is `None` (no argument expected), then `value` will be `None`. If `nargs > 1`, `value` will be a tuple of values of the appropriate type.

**`parser`** is the `OptionParser` instance driving the whole thing, mainly useful because you can access some other interesting data through its instance attributes:

**`parser.largs`** the current list of leftover arguments, ie. arguments that have been consumed but are neither options nor option arguments. Feel free to modify `parser.largs`, e.g. by adding more arguments to it. (This list will become `args`, the second return value of `parse_args()`.)

**parser.rargs** the current list of remaining arguments, ie. with `opt_str` and `value` (if applicable) removed, and only the arguments following them still there. Feel free to modify `parser.rargs`, e.g. by consuming more arguments.

**parser.values** the object where option values are by default stored (an instance of `optparse.OptionValues`). This lets callbacks use the same mechanism as the rest of *optparse* for storing option values; you don't need to mess around with globals or closures. You can also access or modify the value(s) of any options already encountered on the command-line.

**args** is a tuple of arbitrary positional arguments supplied via the *callback\_args* option attribute.

**kwargs** is a dictionary of arbitrary keyword arguments supplied via *callback\_kwargs*.

### Raising errors in a callback

The callback function should raise `OptionValueError` if there are any problems with the option or its argument(s). *optparse* catches this and terminates the program, printing the error message you supply to `stderr`. Your message should be clear, concise, accurate, and mention the option at fault. Otherwise, the user will have a hard time figuring out what they did wrong.

### Callback example 1: trivial callback

Here's an example of a callback option that takes no arguments, and simply records that the option was seen:

```
def record_foo_seen(option, opt_str, value, parser):
    parser.values.saw_foo = True

parser.add_option("--foo", action="callback", callback=record_foo_seen)
```

Of course, you could do that with the "store\_true" action.

### Callback example 2: check option order

Here's a slightly more interesting example: record the fact that `-a` is seen, but blow up if it comes after `-b` in the command-line.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use -a after -b")
    parser.values.a = 1
    ...
parser.add_option("-a", action="callback", callback=check_order)
parser.add_option("-b", action="store_true", dest="b")
```

### Callback example 3: check option order (generalized)

If you want to re-use this callback for several similar options (set a flag, but blow up if `-b` has already been seen), it needs a bit of work: the error message and the flag that it sets must be generalized.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use %s after -b" % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("-a", action="callback", callback=check_order, dest='a')
parser.add_option("-b", action="store_true", dest="b")
parser.add_option("-c", action="callback", callback=check_order, dest='c')
```

### Callback example 4: check arbitrary condition

Of course, you could put any condition in there---you're not limited to checking the values of already-defined options. For example, if you have options that should not be called when the moon is full, all you have to do is this:

```
def check_moon(option, opt_str, value, parser):
    if is_moon_full():
        raise OptionValueError("%s option invalid when moon is full"
                                % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("--foo",
                  action="callback", callback=check_moon, dest="foo")
```

(The definition of `is_moon_full()` is left as an exercise for the reader.)

### Callback example 5: fixed arguments

Things get slightly more interesting when you define callback options that take a fixed number of arguments. Specifying that a callback option takes arguments is similar to defining a "store" or "append" option: if you define `type`, then the option takes one argument that must be convertible to that type; if you further define `nargs`, then the option takes `nargs` arguments.

Here's an example that just emulates the standard "store" action:

```
def store_value(option, opt_str, value, parser):
    setattr(parser.values, option.dest, value)
...
parser.add_option("--foo",
                  action="callback", callback=store_value,
                  type="int", nargs=3, dest="foo")
```

Note that `optparse` takes care of consuming 3 arguments and converting them to integers for you; all you have to do is store them. (Or whatever; obviously you don't need a callback for this example.)

### Callback example 6: variable arguments

Things get hairy when you want an option to take a variable number of arguments. For this case, you must write a callback, as `optparse` doesn't provide any built-in capabilities for it. And you have to deal with certain intricacies of conventional Unix command-line parsing that `optparse` normally handles for you. In particular, callbacks should implement the conventional rules for bare `--` and `-` arguments:

- either `--` or `-` can be option arguments
- bare `--` (if not the argument to some option): halt command-line processing and discard the `--`
- bare `-` (if not the argument to some option): halt command-line processing but keep the `-` (append it to `parser.largs`)

If you want an option that takes a variable number of arguments, there are several subtle, tricky issues to worry about. The exact implementation you choose will be based on which trade-offs you're willing to make for your application (which is why `optparse` doesn't support this sort of thing directly).

Nevertheless, here's a stab at a callback for an option with variable arguments:

```
def vararg_callback(option, opt_str, value, parser):
    assert value is None
    value = []

    def floatable(str):
        try:
            float(str)
            return True
        except ValueError:
            return False

    for arg in parser.rargs:
        # stop on --foo like options
        if arg[:2] == "--" and len(arg) > 2:
            break
        # stop on -a, but not on -3 or -3.0
        if arg[:1] == "-" and len(arg) > 1 and not floatable(arg):
            break
        value.append(arg)

    del parser.rargs[:len(value)]
    setattr(parser.values, option.dest, value)

...
parser.add_option("-c", "--callback", dest="vararg_attr",
                  action="callback", callback=vararg_callback)
```

### 36.1.5 Extending `optparse`

Since the two major controlling factors in how `optparse` interprets command-line options are the action and type of each option, the most likely direction of extension is to add new actions and new types.

## Adding new types

To add new types, you need to define your own subclass of `optparse`'s `Option` class. This class has a couple of attributes that define `optparse`'s types: `TYPES` and `TYPE_CHECKER`.

### `Option.TYPES`

A tuple of type names; in your subclass, simply define a new tuple `TYPES` that builds on the standard one.

### `Option.TYPE_CHECKER`

A dictionary mapping type names to type-checking functions. A type-checking function has the following signature:

```
def check_mytype(option, opt, value)
```

where `option` is an `Option` instance, `opt` is an option string (e.g., `-f`), and `value` is the string from the command line that must be checked and converted to your desired type. `check_mytype()` should return an object of the hypothetical type `mytype`. The value returned by a type-checking function will wind up in the `OptionValues` instance returned by `OptionParser.parse_args()`, or be passed to a callback as the `value` parameter.

Your type-checking function should raise `OptionValueError` if it encounters any problems. `OptionValueError` takes a single string argument, which is passed as-is to `OptionParser.error()` method, which in turn prepends the program name and the string `"error: "` and prints everything to `stderr` before terminating the process.

Here's a silly example that demonstrates adding a `"complex"` option type to parse Python-style complex numbers on the command line. (This is even sillier than it used to be, because `optparse` 1.3 added built-in support for complex numbers, but never mind.)

First, the necessary imports:

```
from copy import copy
from optparse import Option, OptionValueError
```

You need to define your type-checker first, since it's referred to later (in the `TYPE_CHECKER` class attribute of your `Option` subclass):

```
def check_complex(option, opt, value):
    try:
        return complex(value)
    except ValueError:
        raise OptionValueError(
            "option %s: invalid complex value: %r" % (opt, value))
```

Finally, the `Option` subclass:

```
class MyOption (Option):
    TYPES = Option.TYPES + ("complex",)
    TYPE_CHECKER = copy(Option.TYPE_CHECKER)
    TYPE_CHECKER["complex"] = check_complex
```

(If we didn't make a `copy()` of `Option.TYPE_CHECKER`, we would end up modifying the `TYPE_CHECKER` attribute of `optparse`'s `Option` class. This being Python, nothing stops you from doing that except good manners and common sense.)

That's it! Now you can write a script that uses the new option type just like any other `optparse`-based script, except you have to instruct your `OptionParser` to use `MyOption` instead of `Option`:

```
parser = OptionParser(option_class=MyOption)
parser.add_option("-c", type="complex")
```

Alternately, you can build your own option list and pass it to `OptionParser`; if you don't use `add_option()` in the above way, you don't need to tell `OptionParser` which option class to use:

```
option_list = [MyOption("-c", action="store", type="complex", dest="c")]
parser = OptionParser(option_list=option_list)
```

## Adding new actions

Adding new actions is a bit trickier, because you have to understand that *optparse* has a couple of classifications for actions:

**”store” actions** actions that result in *optparse* storing a value to an attribute of the current `OptionValues` instance; these options require a *dest* attribute to be supplied to the `Option` constructor.

**”typed” actions** actions that take a value from the command line and expect it to be of a certain type; or rather, a string that can be converted to a certain type. These options require a *type* attribute to the `Option` constructor.

These are overlapping sets: some default ”store” actions are `”store”`, `”store_const”`, `”append”`, and `”count”`, while the default ”typed” actions are `”store”`, `”append”`, and `”callback”`.

When you add an action, you need to categorize it by listing it in at least one of the following class attributes of `Option` (all are lists of strings):

`Option.ACTIONS`

All actions must be listed in `ACTIONS`.

`Option.STORE_ACTIONS`

”store” actions are additionally listed here.

`Option.TYPED_ACTIONS`

”typed” actions are additionally listed here.

`Option.ALWAYS_TYPED_ACTIONS`

Actions that always take a type (i.e. whose options always take a value) are additionally listed here. The only effect of this is that *optparse* assigns the default type, `”string”`, to options with no explicit type whose action is listed in `ALWAYS_TYPED_ACTIONS`.

In order to actually implement your new action, you must override `Option`’s `take_action()` method and add a case that recognizes your action.

For example, let’s add an `”extend”` action. This is similar to the standard `”append”` action, but instead of taking a single value from the command-line and appending it to an existing list, `”extend”` will take multiple values in a single comma-delimited string, and extend an existing list with them. That is, if `--names` is an `”extend”` option of type `”string”`, the command line

```
--names=foo,bar --names blah --names ding,dong
```

would result in a list

```
["foo", "bar", "blah", "ding", "dong"]
```

Again we define a subclass of `Option`:

```
class MyOption(Option):

    ACTIONS = Option.ACTIONS + ("extend",)
    STORE_ACTIONS = Option.STORE_ACTIONS + ("extend",)
    TYPED_ACTIONS = Option.TYPED_ACTIONS + ("extend",)
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
ALWAYS_TYPED_ACTIONS = Option.ALWAYS_TYPED_ACTIONS + ("extend",)

def take_action(self, action, dest, opt, value, values, parser):
    if action == "extend":
        lvalue = value.split(",")
        values.ensure_value(dest, []).extend(lvalue)
    else:
        Option.take_action(
            self, action, dest, opt, value, values, parser)
```

Features of note:

- "extend" both expects a value on the command-line and stores that value somewhere, so it goes in both `STORE_ACTIONS` and `TYPED_ACTIONS`.
- to ensure that `optparse` assigns the default type of "string" to "extend" actions, we put the "extend" action in `ALWAYS_TYPED_ACTIONS` as well.
- `MyOption.take_action()` implements just this one new action, and passes control back to `Option.take_action()` for the standard `optparse` actions.
- `values` is an instance of the `optparse.Values` class, which provides the very useful `ensure_value()` method. `ensure_value()` is essentially `getattr()` with a safety valve; it is called as

```
values.ensure_value(attr, value)
```

If the `attr` attribute of `values` doesn't exist or is `None`, then `ensure_value()` first sets it to `value`, and then returns `value`. This is very handy for actions like "extend", "append", and "count", all of which accumulate data in a variable and expect that variable to be of a certain type (a list for the first two, an integer for the latter). Using `ensure_value()` means that scripts using your action don't have to worry about setting a default value for the option destinations in question; they can just leave the default as `None` and `ensure_value()` will take care of getting it right when it's needed.

## 36.2 `imp` --- Access the import internals

Source code: [Lib/imp.py](#)

Ditinggalkan sejak versi 3.4: The `imp` module is deprecated in favor of `importlib`.

---

This module provides an interface to the mechanisms used to implement the `import` statement. It defines the following constants and functions:

`imp.get_magic()`

Return the magic string value used to recognize byte-compiled code files (`.pyc` files). (This value may be different for each Python version.)

Ditinggalkan sejak versi 3.4: Use `importlib.util.MAGIC_NUMBER` instead.

`imp.get_suffixes()`

Return a list of 3-element tuples, each describing a particular type of module. Each triple has the form `(suffix, mode, type)`, where `suffix` is a string to be appended to the module name to form the filename to search for, `mode` is the mode string to pass to the built-in `open()` function to open the file (this can be `'r'` for text files or `'rb'` for binary files), and `type` is the file type, which has one of the values `PY_SOURCE`, `PY_COMPILED`, or `C_EXTENSION`, described below.

Ditinggalkan sejak versi 3.3: Use the constants defined on `importlib.machinery` instead.

`imp.find_module(name[, path])`

Try to find the module *name*. If *path* is omitted or `None`, the list of directory names given by `sys.path` is searched, but first a few special places are searched: the function tries to find a built-in module with the given name (`C_BUILTIN`), then a frozen module (`PY_FROZEN`), and on some systems some other places are looked in as well (on Windows, it looks in the registry which may point to a specific file).

Otherwise, *path* must be a list of directory names; each directory is searched for files with any of the suffixes returned by `get_suffixes()` above. Invalid names in the list are silently ignored (but all list items must be strings).

If search is successful, the return value is a 3-element tuple (*file*, *pathname*, *description*):

*file* is an open *file object* positioned at the beginning, *pathname* is the pathname of the file found, and *description* is a 3-element tuple as contained in the list returned by `get_suffixes()` describing the kind of module found.

If the module is built-in or frozen then *file* and *pathname* are both `None` and the *description* tuple contains empty strings for its suffix and mode; the module type is indicated as given in parentheses above. If the search is unsuccessful, `ImportError` is raised. Other exceptions indicate problems with the arguments or environment.

If the module is a package, *file* is `None`, *pathname* is the package path and the last item in the *description* tuple is `PKG_DIRECTORY`.

This function does not handle hierarchical module names (names containing dots). In order to find *P.M*, that is, submodule *M* of package *P*, use `find_module()` and `load_module()` to find and load package *P*, and then use `find_module()` with the *path* argument set to `P.__path__`. When *P* itself has a dotted name, apply this recipe recursively.

Ditinggalkan sejak versi 3.3: Use `importlib.util.find_spec()` instead unless Python 3.3 compatibility is required, in which case use `importlib.find_loader()`. For example usage of the former case, see the *Contoh-contoh* section of the `importlib` documentation.

`imp.load_module(name, file, pathname, description)`

Load a module that was previously found by `find_module()` (or by an otherwise conducted search yielding compatible results). This function does more than importing the module: if the module was already imported, it will reload the module! The *name* argument indicates the full module name (including the package name, if this is a submodule of a package). The *file* argument is an open file, and *pathname* is the corresponding file name; these can be `None` and `' '`, respectively, when the module is a package or not being loaded from a file. The *description* argument is a tuple, as would be returned by `get_suffixes()`, describing what kind of module must be loaded.

If the load is successful, the return value is the module object; otherwise, an exception (usually `ImportError`) is raised.

**Important:** the caller is responsible for closing the *file* argument, if it was not `None`, even when an exception is raised. This is best done using a `try ... finally` statement.

Ditinggalkan sejak versi 3.3: If previously used in conjunction with `imp.find_module()` then consider using `importlib.import_module()`, otherwise use the loader returned by the replacement you chose for `imp.find_module()`. If you called `imp.load_module()` and related functions directly with file path arguments then use a combination of `importlib.util.spec_from_file_location()` and `importlib.util.module_from_spec()`. See the *Contoh-contoh* section of the `importlib` documentation for details of the various approaches.

`imp.new_module(name)`

Return a new empty module object called *name*. This object is *not* inserted in `sys.modules`.

Ditinggalkan sejak versi 3.4: Use `importlib.util.module_from_spec()` instead.

`imp.reload(module)`

Reload a previously imported *module*. The argument must be a module object, so it must have been successfully imported before. This is useful if you have edited the module source file using an external editor and want to try

out the new version without leaving the Python interpreter. The return value is the module object (the same as the *module* argument).

When `reload(module)` is executed:

- Python modules' code is recompiled and the module-level code reexecuted, defining a new set of objects which are bound to names in the module's dictionary. The `init` function of extension modules is not called a second time.
- As with all other objects in Python the old objects are only reclaimed after their reference counts drop to zero.
- The names in the module namespace are updated to point to any new or changed objects.
- Other references to the old objects (such as names external to the module) are not rebound to refer to the new objects and must be updated in each namespace where they occur if that is desired.

There are a number of other caveats:

When a module is reloaded, its dictionary (containing the module's global variables) is retained. Redefinitions of names will override the old definitions, so this is generally not a problem. If the new version of a module does not define a name that was defined by the old version, the old definition remains. This feature can be used to the module's advantage if it maintains a global table or cache of objects --- with a `try` statement it can test for the table's presence and skip its initialization if desired:

```
try:
    cache
except NameError:
    cache = {}
```

It is legal though generally not very useful to reload built-in or dynamically loaded modules, except for `sys`, `__main__` and `builtins`. In many cases, however, extension modules are not designed to be initialized more than once, and may fail in arbitrary ways when reloaded.

If a module imports objects from another module using `from ... import ...`, calling `reload()` for the other module does not redefine the objects imported from it --- one way around this is to re-execute the `from` statement, another is to use `import` and qualified names (`module.*name*`) instead.

If a module instantiates instances of a class, reloading the module that defines the class does not affect the method definitions of the instances --- they continue to use the old class definition. The same is true for derived classes.

Berubah pada versi 3.3: Relies on both `__name__` and `__loader__` being defined on the module being reloaded instead of just `__name__`.

Ditinggalkan sejak versi 3.4: Use `importlib.reload()` instead.

The following functions are conveniences for handling **PEP 3147** byte-compiled file paths.

Baru pada versi 3.2.

`imp.cache_from_source(path, debug_override=None)`

Return the **PEP 3147** path to the byte-compiled file associated with the source *path*. For example, if *path* is `/foo/bar/baz.py` the return value would be `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. The `cpython-32` string comes from the current magic tag (see `get_tag()`; if `sys.implementation.cache_tag` is not defined then `NotImplementedError` will be raised). By passing in `True` or `False` for *debug\_override* you can override the system's value for `__debug__`, leading to optimized bytecode.

*path* need not exist.

Berubah pada versi 3.3: If `sys.implementation.cache_tag` is `None`, then `NotImplementedError` is raised.

Ditinggalkan sejak versi 3.4: Use `importlib.util.cache_from_source()` instead.

Berubah pada versi 3.5: The *debug\_override* parameter no longer creates a *.pyo* file.

`imp.source_from_cache(path)`

Given the *path* to a [PEP 3147](#) file name, return the associated source code file path. For example, if *path* is */foo/bar/\_\_pycache\_\_/baz.cpython-32.pyc* the returned path would be */foo/bar/baz.py*. *path* need not exist, however if it does not conform to [PEP 3147](#) format, a *ValueError* is raised. If `sys.implementation.cache_tag` is not defined, *NotImplementedError* is raised.

Berubah pada versi 3.3: Raise *NotImplementedError* when `sys.implementation.cache_tag` is not defined.

Ditinggalkan sejak versi 3.4: Use `importlib.util.source_from_cache()` instead.

`imp.get_tag()`

Return the [PEP 3147](#) magic tag string matching this version of Python's magic number, as returned by `get_magic()`.

Ditinggalkan sejak versi 3.4: Use `sys.implementation.cache_tag` directly starting in Python 3.3.

The following functions help interact with the import system's internal locking mechanism. Locking semantics of imports are an implementation detail which may vary from release to release. However, Python ensures that circular imports work without any deadlocks.

`imp.lock_held()`

Return *True* if the global import lock is currently held, else *False*. On platforms without threads, always return *False*.

On platforms with threads, a thread executing an import first holds a global import lock, then sets up a per-module lock for the rest of the import. This blocks other threads from importing the same module until the original import completes, preventing other threads from seeing incomplete module objects constructed by the original thread. An exception is made for circular imports, which by construction have to expose an incomplete module object at some point.

Berubah pada versi 3.3: The locking scheme has changed to per-module locks for the most part. A global import lock is kept for some critical tasks, such as initializing the per-module locks.

Ditinggalkan sejak versi 3.4.

`imp.acquire_lock()`

Acquire the interpreter's global import lock for the current thread. This lock should be used by import hooks to ensure thread-safety when importing modules.

Once a thread has acquired the import lock, the same thread may acquire it again without blocking; the thread must release it once for each time it has acquired it.

On platforms without threads, this function does nothing.

Berubah pada versi 3.3: The locking scheme has changed to per-module locks for the most part. A global import lock is kept for some critical tasks, such as initializing the per-module locks.

Ditinggalkan sejak versi 3.4.

`imp.release_lock()`

Release the interpreter's global import lock. On platforms without threads, this function does nothing.

Berubah pada versi 3.3: The locking scheme has changed to per-module locks for the most part. A global import lock is kept for some critical tasks, such as initializing the per-module locks.

Ditinggalkan sejak versi 3.4.

The following constants with integer values, defined in this module, are used to indicate the search result of `find_module()`.

`imp.PY_SOURCE`

The module was found as a source file.

Ditinggalkan sejak versi 3.3.

`imp.PY_COMPILED`

The module was found as a compiled code object file.

Ditinggalkan sejak versi 3.3.

`imp.C_EXTENSION`

The module was found as dynamically loadable shared library.

Ditinggalkan sejak versi 3.3.

`imp.PKG_DIRECTORY`

The module was found as a package directory.

Ditinggalkan sejak versi 3.3.

`imp.C_BUILTIN`

The module was found as a built-in module.

Ditinggalkan sejak versi 3.3.

`imp.PY_FROZEN`

The module was found as a frozen module.

Ditinggalkan sejak versi 3.3.

**class** `imp.NullImporter` (*path\_string*)

The *NullImporter* type is a **PEP 302** import hook that handles non-directory path strings by failing to find any modules. Calling this type with an existing directory or empty string raises *ImportError*. Otherwise, a *NullImporter* instance is returned.

Instances have only one method:

**find\_module** (*fullname* [, *path*])

This method always returns *None*, indicating that the requested module could not be found.

Berubah pada versi 3.3: *None* is inserted into `sys.path_importer_cache` instead of an instance of *NullImporter*.

Ditinggalkan sejak versi 3.4: Insert *None* into `sys.path_importer_cache` instead.

## 36.2.1 Contoh-contoh

The following function emulates what was the standard import statement up to Python 1.4 (no hierarchical module names). (This *implementation* wouldn't work in that version, since *find\_module()* has been extended and *load\_module()* has been added in 1.4.)

```
import imp
import sys

def __import__(name, globals=None, locals=None, fromlist=None):
    # Fast path: see if the module has already been imported.
    try:
        return sys.modules[name]
    except KeyError:
        pass
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
# If any of the following calls raises an exception,  
# there's a problem we can't handle -- let the caller handle it.  
  
fp, pathname, description = imp.find_module(name)  
  
try:  
    return imp.load_module(name, fp, pathname, description)  
finally:  
    # Since we may exit via an exception, close fp explicitly.  
    if fp:  
        fp.close()
```

---

## Undocumented Modules

---

Here's a quick listing of modules that are currently undocumented, but that should be documented. Feel free to contribute documentation for them! (Send via email to [docs@python.org](mailto:docs@python.org).)

The idea and original contents for this chapter were taken from a posting by Fredrik Lundh; the specific contents of this chapter have been substantially revised.

### 37.1 Platform specific modules

These modules are used to implement the `os.path` module, and are not documented beyond this mention. There's little need to document these.

**`ntpath`** --- Implementation of `os.path` on Win32 and Win64 platforms.

**`posixpath`** --- Implementation of `os.path` on POSIX.

>>> Prompt Python bawaan dari *shell* interaktif. Sering terlihat untuk contoh kode yang dapat dieksekusi secara interaktif dalam *interpreter*.

. . . Dapat mengacu ke:

- Prompt Python bawaan dari *shell* interaktif saat memasukkan kode untuk blok kode indentasi, ketika berada dalam sepasang pembatas kiri dan kanan yang cocok (tanda kurung, kurung kotak, kurung kurawal atau tanda kutip tiga), atau setelah menentukan *decorator*.
- Konstanta *Ellipsis* bawaan.

**2to3** A tool that tries to convert Python 2.x code to Python 3.x code by handling most of the incompatibilities which can be detected by parsing the source and traversing the parse tree.

2to3 is available in the standard library as *lib2to3*; a standalone entry point is provided as `Tools/scripts/2to3`. See *2to3 - Automated Python 2 to 3 code translation*.

**kelas basis abstrak** Abstract base classes complement *duck-typing* by providing a way to define interfaces when other techniques like *hasattr()* would be clumsy or subtly wrong (for example with magic methods). ABCs introduce virtual subclasses, which are classes that don't inherit from a class but are still recognized by *isinstance()* and *issubclass()*; see the *abc* module documentation. Python comes with many built-in ABCs for data structures (in the *collections.abc* module), numbers (in the *numbers* module), streams (in the *io* module), import finders and loaders (in the *importlib.abc* module). You can create your own ABCs with the *abc* module.

**anotasi** A label associated with a variable, a class attribute or a function parameter or return value, used by convention as a *type hint*.

Annotations of local variables cannot be accessed at runtime, but annotations of global variables, class attributes, and functions are stored in the `__annotations__` special attribute of modules, classes, and functions, respectively.

See *variable annotation*, *function annotation*, **PEP 484** and **PEP 526**, which describe this functionality.

**argumen** A value passed to a *function* (or *method*) when calling the function. There are two kinds of argument:

- *keyword argument*: an argument preceded by an identifier (e.g. `name=`) in a function call or passed as a value in a dictionary preceded by `**`. For example, 3 and 5 are both keyword arguments in the following calls to *complex()*:

```
complex(real=3, imag=5)
complex(**{'real': 3, 'imag': 5})
```

- *positional argument*: an argument that is not a keyword argument. Positional arguments can appear at the beginning of an argument list and/or be passed as elements of an *iterable* preceded by \*. For example, 3 and 5 are both positional arguments in the following calls:

```
complex(3, 5)
complex(*(3, 5))
```

Arguments are assigned to the named local variables in a function body. See the calls section for the rules governing this assignment. Syntactically, any expression can be used to represent an argument; the evaluated value is assigned to the local variable.

See also the [parameter](#) glossary entry, the FAQ question on the difference between arguments and parameters, and [PEP 362](#).

**manajer konteks asinkron** An object which controls the environment seen in an `async with` statement by defining `__aenter__()` and `__aexit__()` methods. Introduced by [PEP 492](#).

**pembangkit asinkron** A function which returns an *asynchronous generator iterator*. It looks like a coroutine function defined with `async def` except that it contains `yield` expressions for producing a series of values usable in an `async for` loop.

Usually refers to an asynchronous generator function, but may refer to an *asynchronous generator iterator* in some contexts. In cases where the intended meaning isn't clear, using the full terms avoids ambiguity.

An asynchronous generator function may contain `await` expressions as well as `async for`, and `async with` statements.

**iterator generator asinkron** Sebuah objek dibuat oleh fungsi *asynchronous generator*.

This is an *asynchronous iterator* which when called using the `__anext__()` method returns an awaitable object which will execute the body of the asynchronous generator function until the next `yield` expression.

Each `yield` temporarily suspends processing, remembering the location execution state (including local variables and pending try-statements). When the *asynchronous generator iterator* effectively resumes with another awaitable returned by `__anext__()`, it picks up where it left off. See [PEP 492](#) and [PEP 525](#).

**asynchronous iterable** An object, that can be used in an `async for` statement. Must return an *asynchronous iterator* from its `__aiter__()` method. Introduced by [PEP 492](#).

**iterator asinkron** An object that implements the `__aiter__()` and `__anext__()` methods. `__anext__()` must return an *awaitable* object. `async for` resolves the awaitables returned by an asynchronous iterator's `__anext__()` method until it raises a *StopAsyncIteration* exception. Introduced by [PEP 492](#).

**atribut** A value associated with an object which is referenced by name using dotted expressions. For example, if an object *o* has an attribute *a* it would be referenced as *o.a*.

**menunggu** An object that can be used in an `await` expression. Can be a *coroutine* or an object with an `__await__()` method. See also [PEP 492](#).

**BDFL** Benevolent Dictator For Life, a.k.a. [Guido van Rossum](#), Python's creator.

**berkas biner** A *file object* able to read and write *bytes-like objects*. Examples of binary files are files opened in binary mode ('rb', 'wb' or 'rb+'), `sys.stdin.buffer`, `sys.stdout.buffer`, and instances of *io.BytesIO* and *gzip.GzipFile*.

See also *text file* for a file object able to read and write *str* objects.

**bytes-like object** An object that supports the `bufferobjects` and can export a *C-contiguous* buffer. This includes all `bytes`, `bytearray`, and `array.array` objects, as well as many common `memoryview` objects. Bytes-like objects can be used for various operations that work with binary data; these include compression, saving to a binary file, and sending over a socket.

Some operations need the binary data to be mutable. The documentation often refers to these as "read-write bytes-like objects". Example mutable buffer objects include `bytearray` and a `memoryview` of a `bytearray`. Other operations require the binary data to be stored in immutable objects ("read-only bytes-like objects"); examples of these include `bytes` and a `memoryview` of a `bytes` object.

**bytecode** Python source code is compiled into bytecode, the internal representation of a Python program in the CPython interpreter. The bytecode is also cached in `.pyc` files so that executing the same file is faster the second time (recompilation from source to bytecode can be avoided). This "intermediate language" is said to run on a *virtual machine* that executes the machine code corresponding to each bytecode. Do note that bytecodes are not expected to work between different Python virtual machines, nor to be stable between Python releases.

Daftar instruksi-instruksi bytecode dapat ditemukan di dokumentasi pada *the dis module*.

**callback** A subroutine function which is passed as an argument to be executed at some point in the future.

**kelas** A template for creating user-defined objects. Class definitions normally contain method definitions which operate on instances of the class.

**class variable** A variable defined in a class and intended to be modified only at class level (i.e., not in an instance of the class).

**paksa** The implicit conversion of an instance of one type to another during an operation which involves two arguments of the same type. For example, `int(3.15)` converts the floating point number to the integer 3, but in `3+4.5`, each argument is of a different type (one int, one float), and both must be converted to the same type before they can be added or it will raise a `TypeError`. Without coercion, all arguments of even compatible types would have to be normalized to the same value by the programmer, e.g., `float(3)+4.5` rather than just `3+4.5`.

**bilangan kompleks** An extension of the familiar real number system in which all numbers are expressed as a sum of a real part and an imaginary part. Imaginary numbers are real multiples of the imaginary unit (the square root of  $-1$ ), often written `i` in mathematics or `j` in engineering. Python has built-in support for complex numbers, which are written with this latter notation; the imaginary part is written with a `j` suffix, e.g., `3+1j`. To get access to complex equivalents of the `math` module, use `cmath`. Use of complex numbers is a fairly advanced mathematical feature. If you're not aware of a need for them, it's almost certain you can safely ignore them.

**manajer konteks** An object which controls the environment seen in a `with` statement by defining `__enter__()` and `__exit__()` methods. See [PEP 343](#).

**context variable** A variable which can have different values depending on its context. This is similar to Thread-Local Storage in which each execution thread may have a different value for a variable. However, with context variables, there may be several contexts in one execution thread and the main usage for context variables is to keep track of variables in concurrent asynchronous tasks. See *contextvars*.

**contiguous** A buffer is considered contiguous exactly if it is either *C-contiguous* or *Fortran contiguous*. Zero-dimensional buffers are C and Fortran contiguous. In one-dimensional arrays, the items must be laid out in memory next to each other, in order of increasing indexes starting from zero. In multidimensional C-contiguous arrays, the last index varies the fastest when visiting items in order of memory address. However, in Fortran contiguous arrays, the first index varies the fastest.

**coroutine** Coroutines are a more generalized form of subroutines. Subroutines are entered at one point and exited at another point. Coroutines can be entered, exited, and resumed at many different points. They can be implemented with the `async def` statement. See also [PEP 492](#).

**coroutine function** A function which returns a *coroutine* object. A coroutine function may be defined with the `async def` statement, and may contain `await`, `async for`, and `async with` keywords. These were introduced by [PEP 492](#).

**CPython** The canonical implementation of the Python programming language, as distributed on [python.org](https://python.org). The term “CPython” is used when necessary to distinguish this implementation from others such as Jython or IronPython.

**penghias** A function returning another function, usually applied as a function transformation using the `@wrapper` syntax. Common examples for decorators are `classmethod()` and `staticmethod()`.

The decorator syntax is merely syntactic sugar, the following two function definitions are semantically equivalent:

```
def f(...):
    ...
f = staticmethod(f)

@staticmethod
def f(...):
    ...
```

The same concept exists for classes, but is less commonly used there. See the documentation for function definitions and class definitions for more about decorators.

**descriptor** Any object which defines the methods `__get__()`, `__set__()`, or `__delete__()`. When a class attribute is a descriptor, its special binding behavior is triggered upon attribute lookup. Normally, using `a.b` to get, set or delete an attribute looks up the object named `b` in the class dictionary for `a`, but if `b` is a descriptor, the respective descriptor method gets called. Understanding descriptors is a key to a deep understanding of Python because they are the basis for many features including functions, methods, properties, class methods, static methods, and reference to super classes.

For more information about descriptors’ methods, see [descriptors](#).

**kamus** An associative array, where arbitrary keys are mapped to values. The keys can be any object with `__hash__()` and `__eq__()` methods. Called a hash in Perl.

**dictionary comprehension** A compact way to process all or part of the elements in an iterable and return a dictionary with the results. `results = {n: n ** 2 for n in range(10)}` generates a dictionary containing key `n` mapped to value `n ** 2`. See [comprehensions](#).

**dictionary view** The objects returned from `dict.keys()`, `dict.values()`, and `dict.items()` are called dictionary views. They provide a dynamic view on the dictionary’s entries, which means that when the dictionary changes, the view reflects these changes. To force the dictionary view to become a full list use `list(dictview)`. See [Dictionary view objects](#).

**docstring** A string literal which appears as the first expression in a class, function or module. While ignored when the suite is executed, it is recognized by the compiler and put into the `__doc__` attribute of the enclosing class, function or module. Since it is available via introspection, it is the canonical place for documentation of the object.

**duck-typing** A programming style which does not look at an object’s type to determine if it has the right interface; instead, the method or attribute is simply called or used (“If it looks like a duck and quacks like a duck, it must be a duck.”) By emphasizing interfaces rather than specific types, well-designed code improves its flexibility by allowing polymorphic substitution. Duck-typing avoids tests using `type()` or `isinstance()`. (Note, however, that duck-typing can be complemented with [abstract base classes](#).) Instead, it typically employs `hasattr()` tests or [EAFP](#) programming.

**EAFP** Easier to ask for forgiveness than permission. This common Python coding style assumes the existence of valid keys or attributes and catches exceptions if the assumption proves false. This clean and fast style is characterized by the presence of many `try` and `except` statements. The technique contrasts with the [LBYL](#) style common to many other languages such as C.

**ekspresi** A piece of syntax which can be evaluated to some value. In other words, an expression is an accumulation of expression elements like literals, names, attribute access, operators or function calls which all return a value. In contrast to many other languages, not all language constructs are expressions. There are also [statements](#) which cannot be used as expressions, such as `while`. Assignments are also statements, not expressions.

**modul tambahan** A module written in C or C++, using Python's C API to interact with the core and with user code.

**f-string** String literals prefixed with 'f' or 'F' are commonly called "f-strings" which is short for formatted string literals. See also [PEP 498](#).

**objek berkas** An object exposing a file-oriented API (with methods such as `read()` or `write()`) to an underlying resource. Depending on the way it was created, a file object can mediate access to a real on-disk file or to another type of storage or communication device (for example standard input/output, in-memory buffers, sockets, pipes, etc.). File objects are also called *file-like objects* or *streams*.

There are actually three categories of file objects: raw *binary files*, buffered *binary files* and *text files*. Their interfaces are defined in the `io` module. The canonical way to create a file object is by using the `open()` function.

**file-like object** A synonym for *file object*.

**finder** An object that tries to find the *loader* for a module that is being imported.

Since Python 3.3, there are two types of finder: *meta path finders* for use with `sys.meta_path`, and *path entry finders* for use with `sys.path_hooks`.

See [PEP 302](#), [PEP 420](#) and [PEP 451](#) for much more detail.

**floor division** Mathematical division that rounds down to nearest integer. The floor division operator is `//`. For example, the expression `11 // 4` evaluates to 2 in contrast to the `2.75` returned by float true division. Note that `(-11) // 4` is `-3` because that is `-2.75` rounded *downward*. See [PEP 238](#).

**fungsi** A series of statements which returns some value to a caller. It can also be passed zero or more *arguments* which may be used in the execution of the body. See also *parameter*, *method*, and the function section.

**anotasi fungsi** An *annotation* of a function parameter or return value.

Function annotations are usually used for *type hints*: for example, this function is expected to take two `int` arguments and is also expected to have an `int` return value:

```
def sum_two_numbers(a: int, b: int) -> int:
    return a + b
```

Function annotation syntax is explained in section function.

See *variable annotation* and [PEP 484](#), which describe this functionality.

**\_\_future\_\_** A pseudo-module which programmers can use to enable new language features which are not compatible with the current interpreter.

By importing the `__future__` module and evaluating its variables, you can see when a new feature was first added to the language and when it becomes the default:

```
>>> import __future__
>>> __future__.division
_Feature((2, 2, 0, 'alpha', 2), (3, 0, 0, 'alpha', 0), 8192)
```

**pengumpulan sampah** The process of freeing memory when it is not used anymore. Python performs garbage collection via reference counting and a cyclic garbage collector that is able to detect and break reference cycles. The garbage collector can be controlled using the `gc` module.

**pembangkit** A function which returns a *generator iterator*. It looks like a normal function except that it contains `yield` expressions for producing a series of values usable in a for-loop or that can be retrieved one at a time with the `next()` function.

Usually refers to a generator function, but may refer to a *generator iterator* in some contexts. In cases where the intended meaning isn't clear, using the full terms avoids ambiguity.

**generator iterator** An object created by a *generator* function.

Each `yield` temporarily suspends processing, remembering the location execution state (including local variables and pending try-statements). When the *generator iterator* resumes, it picks up where it left off (in contrast to functions which start fresh on every invocation).

**generator expression** An expression that returns an iterator. It looks like a normal expression followed by a `for` clause defining a loop variable, range, and an optional `if` clause. The combined expression generates values for an enclosing function:

```
>>> sum(i*i for i in range(10))           # sum of squares 0, 1, 4, ... 81
285
```

**fungsi generik** A function composed of multiple functions implementing the same operation for different types. Which implementation should be used during a call is determined by the dispatch algorithm.

See also the *single dispatch* glossary entry, the `functools.singledispatch()` decorator, and [PEP 443](#).

**GIL** Lihat *global interpreter lock*.

**kunci interpreter global** The mechanism used by the *CPython* interpreter to assure that only one thread executes Python *bytecode* at a time. This simplifies the CPython implementation by making the object model (including critical built-in types such as *dict*) implicitly safe against concurrent access. Locking the entire interpreter makes it easier for the interpreter to be multi-threaded, at the expense of much of the parallelism afforded by multi-processor machines.

However, some extension modules, either standard or third-party, are designed so as to release the GIL when doing computationally-intensive tasks such as compression or hashing. Also, the GIL is always released when doing I/O.

Past efforts to create a "free-threaded" interpreter (one which locks shared data at a much finer granularity) have not been successful because performance suffered in the common single-processor case. It is believed that overcoming this performance issue would make the implementation much more complicated and therefore costlier to maintain.

**hash-based pyc** A bytecode cache file that uses the hash rather than the last-modified time of the corresponding source file to determine its validity. See *pyc-invalidation*.

**hashable** An object is *hashable* if it has a hash value which never changes during its lifetime (it needs a `__hash__()` method), and can be compared to other objects (it needs an `__eq__()` method). Hashable objects which compare equal must have the same hash value.

Hashability makes an object usable as a dictionary key and a set member, because these data structures use the hash value internally.

Most of Python's immutable built-in objects are hashable; mutable containers (such as lists or dictionaries) are not; immutable containers (such as tuples and frozensets) are only hashable if their elements are hashable. Objects which are instances of user-defined classes are hashable by default. They all compare unequal (except with themselves), and their hash value is derived from their `id()`.

**IDLE** Sebuah Lingkungan Pengembangan Terpadu untuk Python. IDLE adalah editor dasar dan lingkungan interpreter yang digabungkan dengan distribusi standar dari Python.

**immutable** An object with a fixed value. Immutable objects include numbers, strings and tuples. Such an object cannot be altered. A new object has to be created if a different value has to be stored. They play an important role in places where a constant hash value is needed, for example as a key in a dictionary.

**import path** A list of locations (or *path entries*) that are searched by the *path based finder* for modules to import. During import, this list of locations usually comes from `sys.path`, but for subpackages it may also come from the parent package's `__path__` attribute.

**importing** The process by which Python code in one module is made available to Python code in another module.

**importer** An object that both finds and loads a module; both a *finder* and *loader* object.

**interaktif** Python has an interactive interpreter which means you can enter statements and expressions at the interpreter prompt, immediately execute them and see their results. Just launch `python` with no arguments (possibly by selecting it from your computer's main menu). It is a very powerful way to test out new ideas or inspect modules and packages (remember `help(x)`).

**diinterpretasi** Python is an interpreted language, as opposed to a compiled one, though the distinction can be blurry because of the presence of the bytecode compiler. This means that source files can be run directly without explicitly creating an executable which is then run. Interpreted languages typically have a shorter development/debug cycle than compiled ones, though their programs generally also run more slowly. See also *interactive*.

**interpreter shutdown** When asked to shut down, the Python interpreter enters a special phase where it gradually releases all allocated resources, such as modules and various critical internal structures. It also makes several calls to the *garbage collector*. This can trigger the execution of code in user-defined destructors or weakref callbacks. Code executed during the shutdown phase can encounter various exceptions as the resources it relies on may not function anymore (common examples are library modules or the warnings machinery).

The main reason for interpreter shutdown is that the `__main__` module or the script being run has finished executing.

**iterable** An object capable of returning its members one at a time. Examples of iterables include all sequence types (such as *list*, *str*, and *tuple*) and some non-sequence types like *dict*, *file objects*, and objects of any classes you define with an `__iter__()` method or with a `__getitem__()` method that implements *Sequence* semantics.

Iterables can be used in a `for` loop and in many other places where a sequence is needed (*zip()*, *map()*, ...). When an iterable object is passed as an argument to the built-in function *iter()*, it returns an iterator for the object. This iterator is good for one pass over the set of values. When using iterables, it is usually not necessary to call *iter()* or deal with iterator objects yourself. The `for` statement does that automatically for you, creating a temporary unnamed variable to hold the iterator for the duration of the loop. See also *iterator*, *sequence*, and *generator*.

**iterator** An object representing a stream of data. Repeated calls to the iterator's `__next__()` method (or passing it to the built-in function *next()*) return successive items in the stream. When no more data are available a *StopIteration* exception is raised instead. At this point, the iterator object is exhausted and any further calls to its `__next__()` method just raise *StopIteration* again. Iterators are required to have an `__iter__()` method that returns the iterator object itself so every iterator is also iterable and may be used in most places where other iterables are accepted. One notable exception is code which attempts multiple iteration passes. A container object (such as a *list*) produces a fresh new iterator each time you pass it to the *iter()* function or use it in a `for` loop. Attempting this with an iterator will just return the same exhausted iterator object used in the previous iteration pass, making it appear like an empty container.

Informasi lebih lanjut dapat ditemukan di *Iterator Types*.

**fungsi kunci** A key function or collation function is a callable that returns a value used for sorting or ordering. For example, *locale.strxfrm()* is used to produce a sort key that is aware of locale specific sort conventions.

A number of tools in Python accept key functions to control how elements are ordered or grouped. They include *min()*, *max()*, *sorted()*, *list.sort()*, *heapq.merge()*, *heapq.nsmallest()*, *heapq.nlargest()*, and *itertools.groupby()*.

There are several ways to create a key function. For example, the *str.lower()* method can serve as a key function for case insensitive sorts. Alternatively, a key function can be built from a lambda expression such as `lambda r: (r[0], r[2])`. Also, the *operator* module provides three key function constructors: *attrgetter()*, *itemgetter()*, and *methodcaller()*. See the Sorting HOW TO for examples of how to create and use key functions.

**argumen kata kunci** Lihat *argument*.

**lambda** An anonymous inline function consisting of a single *expression* which is evaluated when the function is called. The syntax to create a lambda function is `lambda [parameters]: expression`

**LBYL** Look before you leap. This coding style explicitly tests for pre-conditions before making calls or lookups. This style contrasts with the *EAFP* approach and is characterized by the presence of many `if` statements.

In a multi-threaded environment, the LBYL approach can risk introducing a race condition between “the looking” and “the leaping”. For example, the code, `if key in mapping: return mapping[key]` can fail if another thread removes *key* from *mapping* after the test, but before the lookup. This issue can be solved with locks or by using the EAFP approach.

**daftar** A built-in Python *sequence*. Despite its name it is more akin to an array in other languages than to a linked list since access to elements is  $O(1)$ .

**list comprehension** A compact way to process all or part of the elements in a sequence and return a list with the results. `result = ['{:04x}'.format(x) for x in range(256) if x % 2 == 0]` generates a list of strings containing even hex numbers (0x..) in the range from 0 to 255. The `if` clause is optional. If omitted, all elements in `range(256)` are processed.

**loader** An object that loads a module. It must define a method named `load_module()`. A loader is typically returned by a *finder*. See **PEP 302** for details and `importlib.abc.Loader` for an *abstract base class*.

**magic method** An informal synonym for *special method*.

**pemetaan** A container object that supports arbitrary key lookups and implements the methods specified in the *Mapping* or *MutableMapping abstract base classes*. Examples include `dict`, `collections.defaultdict`, `collections.OrderedDict` and `collections.Counter`.

**meta path finder** A *finder* returned by a search of `sys.meta_path`. Meta path finders are related to, but different from *path entry finders*.

See `importlib.abc.MetaPathFinder` for the methods that meta path finders implement.

**metaclass** The class of a class. Class definitions create a class name, a class dictionary, and a list of base classes. The metaclass is responsible for taking those three arguments and creating the class. Most object oriented programming languages provide a default implementation. What makes Python special is that it is possible to create custom metaclasses. Most users never need this tool, but when the need arises, metaclasses can provide powerful, elegant solutions. They have been used for logging attribute access, adding thread-safety, tracking object creation, implementing singletons, and many other tasks.

Informasi lebih lanjut dapat ditemukan di metaclasses.

**method** A function which is defined inside a class body. If called as an attribute of an instance of that class, the method will get the instance object as its first *argument* (which is usually called `self`). See *function* and *nested scope*.

**method resolution order** Method Resolution Order is the order in which base classes are searched for a member during lookup. See [The Python 2.3 Method Resolution Order](#) for details of the algorithm used by the Python interpreter since the 2.3 release.

**modul** An object that serves as an organizational unit of Python code. Modules have a namespace containing arbitrary Python objects. Modules are loaded into Python by the process of *importing*.

Lihat juga *package*.

**module spec** A namespace containing the import-related information used to load a module. An instance of `importlib.machinery.ModuleSpec`.

**MRO** Lihat *method resolution order*.

**mutable** Mutable objects can change their value but keep their `id()`. See also *immutable*.

**named tuple** The term “named tuple” applies to any type or class that inherits from tuple and whose indexable elements are also accessible using named attributes. The type or class may have other features as well.

Several built-in types are named tuples, including the values returned by `time.localtime()` and `os.stat()`. Another example is `sys.float_info`:

```

>>> sys.float_info[1]           # indexed access
1024
>>> sys.float_info.max_exp      # named field access
1024
>>> isinstance(sys.float_info, tuple) # kind of tuple
True

```

Some named tuples are built-in types (such as the above examples). Alternatively, a named tuple can be created from a regular class definition that inherits from `tuple` and that defines named fields. Such a class can be written by hand or it can be created with the factory function `collections.namedtuple()`. The latter technique also adds some extra methods that may not be found in hand-written or built-in named tuples.

**namespace** The place where a variable is stored. Namespaces are implemented as dictionaries. There are the local, global and built-in namespaces as well as nested namespaces in objects (in methods). Namespaces support modularity by preventing naming conflicts. For instance, the functions `builtins.open` and `os.open()` are distinguished by their namespaces. Namespaces also aid readability and maintainability by making it clear which module implements a function. For instance, writing `random.seed()` or `itertools.islice()` makes it clear that those functions are implemented by the `random` and `itertools` modules, respectively.

**namespace package** A [PEP 420 package](#) which serves only as a container for subpackages. Namespace packages may have no physical representation, and specifically are not like a [regular package](#) because they have no `__init__.py` file.

Lihat juga [module](#).

**nested scope** The ability to refer to a variable in an enclosing definition. For instance, a function defined inside another function can refer to variables in the outer function. Note that nested scopes by default work only for reference and not for assignment. Local variables both read and write in the innermost scope. Likewise, global variables read and write to the global namespace. The `nonlocal` allows writing to outer scopes.

**new-style class** Old name for the flavor of classes now used for all class objects. In earlier Python versions, only new-style classes could use Python's newer, versatile features like `__slots__`, descriptors, properties, `__getattr__()`, class methods, and static methods.

**objek** Any data with state (attributes or value) and defined behavior (methods). Also the ultimate base class of any [new-style class](#).

**paket** A Python [module](#) which can contain submodules or recursively, subpackages. Technically, a package is a Python module with an `__path__` attribute.

See also [regular package](#) and [namespace package](#).

**parameter** A named entity in a [function](#) (or method) definition that specifies an [argument](#) (or in some cases, arguments) that the function can accept. There are five kinds of parameter:

- *positional-or-keyword*: specifies an argument that can be passed either [positionally](#) or as a [keyword argument](#). This is the default kind of parameter, for example `foo` and `bar` in the following:

```
def func(foo, bar=None): ...
```

- *positional-only*: specifies an argument that can be supplied only by position. Positional-only parameters can be defined by including a `/` character in the parameter list of the function definition after them, for example `posonly1` and `posonly2` in the following:

```
def func(posonly1, posonly2, /, positional_or_keyword): ...
```

- *keyword-only*: specifies an argument that can be supplied only by keyword. Keyword-only parameters can be defined by including a single var-positional parameter or bare `*` in the parameter list of the function definition before them, for example `kw_only1` and `kw_only2` in the following:

```
def func(arg, *, kw_only1, kw_only2): ...
```

- *var-positional*: specifies that an arbitrary sequence of positional arguments can be provided (in addition to any positional arguments already accepted by other parameters). Such a parameter can be defined by prepending the parameter name with `*`, for example *args* in the following:

```
def func(*args, **kwargs): ...
```

- *var-keyword*: specifies that arbitrarily many keyword arguments can be provided (in addition to any keyword arguments already accepted by other parameters). Such a parameter can be defined by prepending the parameter name with `**`, for example *kwargs* in the example above.

Parameters can specify both optional and required arguments, as well as default values for some optional arguments.

See also the [argument](#) glossary entry, the FAQ question on the difference between arguments and parameters, the [inspect.Parameter](#) class, the function section, and [PEP 362](#).

**path entry** A single location on the *import path* which the *path based finder* consults to find modules for importing.

**path entry finder** A *finder* returned by a callable on `sys.path_hooks` (i.e. a *path entry hook*) which knows how to locate modules given a *path entry*.

See `importlib.abc.PathEntryFinder` for the methods that path entry finders implement.

**path entry hook** A callable on the `sys.path_hook` list which returns a *path entry finder* if it knows how to find modules on a specific *path entry*.

**path based finder** One of the default *meta path finders* which searches an *import path* for modules.

**path-like object** An object representing a file system path. A path-like object is either a *str* or *bytes* object representing a path, or an object implementing the `os.PathLike` protocol. An object that supports the `os.PathLike` protocol can be converted to a *str* or *bytes* file system path by calling the `os.fspath()` function; `os.fsdecode()` and `os.fsencode()` can be used to guarantee a *str* or *bytes* result instead, respectively. Introduced by [PEP 519](#).

**PEP** Python Enhancement Proposal. A PEP is a design document providing information to the Python community, or describing a new feature for Python or its processes or environment. PEPs should provide a concise technical specification and a rationale for proposed features.

PEPs are intended to be the primary mechanisms for proposing major new features, for collecting community input on an issue, and for documenting the design decisions that have gone into Python. The PEP author is responsible for building consensus within the community and documenting dissenting opinions.

Lihat [PEP 1](#).

**porsi** A set of files in a single directory (possibly stored in a zip file) that contribute to a namespace package, as defined in [PEP 420](#).

**positional argument** Lihat [argument](#).

**provisional API** A provisional API is one which has been deliberately excluded from the standard library's backwards compatibility guarantees. While major changes to such interfaces are not expected, as long as they are marked provisional, backwards incompatible changes (up to and including removal of the interface) may occur if deemed necessary by core developers. Such changes will not be made gratuitously -- they will occur only if serious fundamental flaws are uncovered that were missed prior to the inclusion of the API.

Even for provisional APIs, backwards incompatible changes are seen as a "solution of last resort" - every attempt will still be made to find a backwards compatible resolution to any identified problems.

This process allows the standard library to continue to evolve over time, without locking in problematic design errors for extended periods of time. See [PEP 411](#) for more details.

**provisional package** Lihat *provisional API*.

**Python 3000** Nickname for the Python 3.x release line (coined long ago when the release of version 3 was something in the distant future.) This is also abbreviated "Py3k".

**Pythonic** An idea or piece of code which closely follows the most common idioms of the Python language, rather than implementing code using concepts common to other languages. For example, a common idiom in Python is to loop over all elements of an iterable using a `for` statement. Many other languages don't have this type of construct, so people unfamiliar with Python sometimes use a numerical counter instead:

```
for i in range(len(food)):
    print(food[i])
```

As opposed to the cleaner, Pythonic method:

```
for piece in food:
    print(piece)
```

**nama yang memenuhi syarat** A dotted name showing the "path" from a module's global scope to a class, function or method defined in that module, as defined in [PEP 3155](#). For top-level functions and classes, the qualified name is the same as the object's name:

```
>>> class C:
...     class D:
...         def meth(self):
...             pass
...
>>> C.__qualname__
'C'
>>> C.D.__qualname__
'C.D'
>>> C.D.meth.__qualname__
'C.D.meth'
```

When used to refer to modules, the *fully qualified name* means the entire dotted path to the module, including any parent packages, e.g. `email.mime.text`:

```
>>> import email.mime.text
>>> email.mime.text.__name__
'email.mime.text'
```

**jumlah referensi** The number of references to an object. When the reference count of an object drops to zero, it is deallocated. Reference counting is generally not visible to Python code, but it is a key element of the *CPython* implementation. The `sys` module defines a `getrefcount()` function that programmers can call to return the reference count for a particular object.

**paket biasa** A traditional *package*, such as a directory containing an `__init__.py` file.

Lihat juga *namespace package*.

**\_\_slots\_\_** A declaration inside a class that saves memory by pre-declaring space for instance attributes and eliminating instance dictionaries. Though popular, the technique is somewhat tricky to get right and is best reserved for rare cases where there are large numbers of instances in a memory-critical application.

**urutan** An *iterable* which supports efficient element access using integer indices via the `__getitem__()` special method and defines a `__len__()` method that returns the length of the sequence. Some built-in sequence types are *list*, *str*, *tuple*, and *bytes*. Note that *dict* also supports `__getitem__()` and `__len__()`, but is considered a mapping rather than a sequence because the lookups use arbitrary *immutable* keys rather than integers.

The `collections.abc.Sequence` abstract base class defines a much richer interface that goes beyond just `__getitem__()` and `__len__()`, adding `count()`, `index()`, `__contains__()`, and `__reversed__()`. Types that implement this expanded interface can be registered explicitly using `register()`.

**set comprehension** A compact way to process all or part of the elements in an iterable and return a set with the results. `results = {c for c in 'abracadabra' if c not in 'abc'}` generates the set of strings `{'r', 'd'}`. See comprehensions.

**single dispatch** A form of *generic function* dispatch where the implementation is chosen based on the type of a single argument.

**slice** An object usually containing a portion of a *sequence*. A slice is created using the subscript notation, `[]` with colons between numbers when several are given, such as in `variable_name[1:3:5]`. The bracket (subscript) notation uses *slice* objects internally.

**special method** A method that is called implicitly by Python to execute a certain operation on a type, such as addition. Such methods have names starting and ending with double underscores. Special methods are documented in `specialnames`.

**pernyataan** A statement is part of a suite (a "block" of code). A statement is either an *expression* or one of several constructs with a keyword, such as `if`, `while` or `for`.

**text encoding** A codec which encodes Unicode strings to bytes.

**berkas teks** A *file object* able to read and write *str* objects. Often, a text file actually accesses a byte-oriented datastream and handles the *text encoding* automatically. Examples of text files are files opened in text mode (`'r'` or `'w'`), `sys.stdin`, `sys.stdout`, and instances of `io.StringIO`.

See also *binary file* for a file object able to read and write *bytes-like objects*.

**teks tiga-kutip** A string which is bound by three instances of either a quotation mark (`"`) or an apostrophe (`'`). While they don't provide any functionality not available with single-quoted strings, they are useful for a number of reasons. They allow you to include unescaped single and double quotes within a string and they can span multiple lines without the use of the continuation character, making them especially useful when writing docstrings.

**type** The type of a Python object determines what kind of object it is; every object has a type. An object's type is accessible as its `__class__` attribute or can be retrieved with `type(obj)`.

**type alias** A synonym for a type, created by assigning the type to an identifier.

Type aliases are useful for simplifying *type hints*. For example:

```
from typing import List, Tuple

def remove_gray_shades(
    colors: List[Tuple[int, int, int]]) -> List[Tuple[int, int, int]]:
    pass
```

could be made more readable like this:

```
from typing import List, Tuple

Color = Tuple[int, int, int]

def remove_gray_shades(colors: List[Color]) -> List[Color]:
    pass
```

See *typing* and **PEP 484**, which describe this functionality.

**type hint** An *annotation* that specifies the expected type for a variable, a class attribute, or a function parameter or return value.

Type hints are optional and are not enforced by Python but they are useful to static type analysis tools, and aid IDEs with code completion and refactoring.

Type hints of global variables, class attributes, and functions, but not local variables, can be accessed using `typing.get_type_hints()`.

See `typing` and [PEP 484](#), which describe this functionality.

**universal newlines** A manner of interpreting text streams in which all of the following are recognized as ending a line: the Unix end-of-line convention `'\n'`, the Windows convention `'\r\n'`, and the old Macintosh convention `'\r'`. See [PEP 278](#) and [PEP 3116](#), as well as `bytes.splitlines()` for an additional use.

**anotasi variabel** An *annotation* of a variable or a class attribute.

When annotating a variable or a class attribute, assignment is optional:

```
class C:
    field: 'annotation'
```

Variable annotations are usually used for *type hints*: for example this variable is expected to take `int` values:

```
count: int = 0
```

Variable annotation syntax is explained in section `annassign`.

See *function annotation*, [PEP 484](#) and [PEP 526](#), which describe this functionality.

**lingkungan virtual** Lingkungan runtime kooperatif yang memungkinkan pengguna dan aplikasi Python untuk menginstal dan memperbarui paket distribusi Python tanpa mengganggu perilaku aplikasi Python lain yang berjalan pada sistem yang sama.

Lihat juga `venv`.

**mesin virtual** A computer defined entirely in software. Python's virtual machine executes the *bytecode* emitted by the bytecode compiler.

**Zen of Python** Listing of Python design principles and philosophies that are helpful in understanding and using the language. The listing can be found by typing `"import this"` at the interactive prompt.

---

### Tentang dokumen-dokumen ini

---

Dokumen-dokumen ini dihasilkan dari [reStructuredText](#) dengan [Sphinx](#), sebuah pemroses dokumen yang khusus ditulis untuk dokumentasi Python.

Pengembangan dokumentasi dan perangkat pengembangannya sepenuhnya upaya sukarela, seperti halnya Python. Jika anda ingin berkontribusi, silakan lihat halaman [reporting-bugs](#) untuk informasi cara melakukannya. Relawan baru selalu diterima!

Terima kasih banyak untuk:

- Fred L. Drake, Jr., pembuat awal kumpulan alat dokumentasi Python dan penulis banyak konten;
- [Docutils](#) proyek untuk membuat [reStructuredText](#) dan [Docutils](#) suite;
- Fredrik Lundh untuk [Alternative Python Reference](#) proyek dimana Sphinx mendapatkan banyak ide bagus.

## B.1 Kontributor untuk dokumentasi Python

Banyak orang telah berkontribusi ke bahasa Python, pustaka standar Python, dan dokumentasi Python. Lihat [Misc/ACKS](#) di distribusi kode sumber Python untuk sebagian daftar kontributor-kontributor.

Hanya dengan masukan dan kontribusi dari komunitas Python sehingga Python memiliki dokumentasi yang sangat baik. Terima kasih!

---

Sejarah dan Lisensi

---

## C.1 Sejarah perangkat lunak

Python diciptakan pada awal 1990-an oleh Guido van Rossum di Stichting Mathematisch Centrum (CWI, lihat <https://www.cwi.nl/>) di Belanda sebagai penerus bahasa yang disebut ABC. Guido tetap menjadi penulis utama Python, meskipun ia memasukkan banyak kontribusi dari orang lain.

Pada tahun 1995, Guido melanjutkan karyanya tentang Python di Corporation for National Research Initiatives (CNRI, lihat <https://www.cnri.reston.va.us/>) di Reston, Virginia di mana ia merilis beberapa versi perangkat lunak.

In May 2000, Guido and the Python core development team moved to BeOpen.com to form the BeOpen PythonLabs team. In October of the same year, the PythonLabs team moved to Digital Creations (now Zope Corporation; see <https://www.zope.org/>). In 2001, the Python Software Foundation (PSF, see <https://www.python.org/psf/>) was formed, a non-profit organization created specifically to own Python-related Intellectual Property. Zope Corporation is a sponsoring member of the PSF.

Semua rilis Python adalah Sumber Terbuka (lihat <https://opensource.org/> untuk Definisi Sumber Terbuka). Secara historis, sebagian besar, tetapi tidak semua, rilis Python juga kompatibel dengan GPL; tabel di bawah ini merangkum berbagai rilis.

| Rilis            | Berasal dari | Tahun         | Pemilik    | GPL compatible? |
|------------------|--------------|---------------|------------|-----------------|
| 0.9.0 hingga 1.2 | t/a          | 1991-1995     | CWI        | ya              |
| 1.3 hingga 1.5.2 | 1.2          | 1995-1999     | CNRI       | ya              |
| 1.6              | 1.5.2        | 2000          | CNRI       | tidak           |
| 2.0              | 1.6          | 2000          | BeOpen.com | tidak           |
| 1.6.1            | 1.6          | 2001          | CNRI       | tidak           |
| 2.1              | 2.0+1.6.1    | 2001          | PSF        | tidak           |
| 2.0.1            | 2.0+1.6.1    | 2001          | PSF        | ya              |
| 2.1.1            | 2.1+2.0.1    | 2001          | PSF        | ya              |
| 2.1.2            | 2.1.1        | 2002          | PSF        | ya              |
| 2.1.3            | 2.1.2        | 2002          | PSF        | ya              |
| 2.2 dan ke atas  | 2.1.1        | 2001-sekarang | PSF        | ya              |

---

**Catatan:** GPL-compatible doesn't mean that we're distributing Python under the GPL. All Python licenses, unlike the GPL, let you distribute a modified version without making your changes open source. The GPL-compatible licenses make it possible to combine Python with other software that is released under the GPL; the others don't.

---

Terima kasih kepada banyak sukarelawan eksternal yang telah bekerja di bawah arahan Guido untuk mewujudkan rilis-rilis ini.

## C.2 Syarat dan ketentuan untuk mengakses atau menggunakan Python

Python software and documentation are licensed under the *PSF License Agreement*.

Starting with Python 3.8.6, examples, recipes, and other code in the documentation are dual licensed under the PSF License Agreement and the *Zero-Clause BSD license*.

Some software incorporated into Python is under different licenses. The licenses are listed with code falling under that license. See *Lisensi dan Ucapan Terima Kasih untuk Perangkat Lunak yang Tergabung* for an incomplete list of these licenses.

### C.2.1 LISENSI PERJANJIAN PSF UNTUK PYTHON 3.8.18

1. This LICENSE AGREEMENT is between the Python Software Foundation ("PSF"),  
→and  
the Individual or Organization ("Licensee") accessing and otherwise using  
→Python  
3.8.18 software in source or binary form and its associated documentation.
2. Subject to the terms and conditions of this License Agreement, PSF hereby  
grants Licensee a nonexclusive, royalty-free, world-wide license to  
→reproduce,  
analyze, test, perform and/or display publicly, prepare derivative works,  
distribute, and otherwise use Python 3.8.18 alone or in any derivative  
version, provided, however, that PSF's License Agreement and PSF's notice  
→of  
copyright, i.e., "Copyright © 2001–2023 Python Software Foundation; All  
→Rights  
Reserved" are retained in Python 3.8.18 alone or in any derivative version  
prepared by Licensee.
3. In the event Licensee prepares a derivative work that is based on or  
incorporates Python 3.8.18 or any part thereof, and wants to make the  
derivative work available to others as provided herein, then Licensee  
→hereby  
agrees to include in any such work a brief summary of the changes made to  
→Python  
3.8.18.
4. PSF is making Python 3.8.18 available to Licensee on an "AS IS" basis.  
PSF MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF

- EXAMPLE, BUT NOT LIMITATION, PSF MAKES NO AND DISCLAIMS ANY REPRESENTATION  
 ↳OR  
 WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT  
 ↳THE  
 USE OF PYTHON 3.8.18 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
5. PSF SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 3.8.18  
 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT  
 ↳OF  
 MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 3.8.18, OR ANY  
 ↳DERIVATIVE  
 THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.
6. This License Agreement will automatically terminate upon a material breach  
 ↳of  
 its terms and conditions.
7. Nothing in this License Agreement shall be deemed to create any  
 ↳relationship  
 of agency, partnership, or joint venture between PSF and Licensee. This  
 ↳License  
 Agreement does not grant permission to use PSF trademarks or trade name in  
 ↳a  
 trademark sense to endorse or promote products or services of Licensee, or  
 ↳any  
 third party.
8. By copying, installing or otherwise using Python 3.8.18, Licensee agrees  
 to be bound by the terms and conditions of this License Agreement.

## C.2.2 LISENSI PERJANJIAN BEOPEN.COM UNTUK PYTHON 2.0

### LISENSI PERJANJIAN BEOPEN SUMBER TERBUKA PYTHON VERSI 1

1. This LICENSE AGREEMENT is between BeOpen.com ("BeOpen"), having an office at 160 Saratoga Avenue, Santa Clara, CA 95051, and the Individual or Organization ("Licensee") accessing and otherwise using this software in source or binary form and its associated documentation ("the Software").
2. Subject to the terms and conditions of this BeOpen Python License Agreement, BeOpen hereby grants Licensee a non-exclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use the Software alone or in any derivative version, provided, however, that the BeOpen Python License is retained in the Software, alone or in any derivative version prepared by Licensee.
3. BeOpen is making the Software available to Licensee on an "AS IS" basis. BEOPEN MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, BEOPEN MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF THE SOFTWARE WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
4. BEOPEN SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF THE SOFTWARE FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF USING,

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

MODIFYING OR DISTRIBUTING THE SOFTWARE, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

5. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
6. This License Agreement shall be governed by and interpreted in all respects by the law of the State of California, excluding conflict of law provisions. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between BeOpen and Licensee. This License Agreement does not grant permission to use BeOpen trademarks or trade names in a trademark sense to endorse or promote products or services of Licensee, or any third party. As an exception, the "BeOpen Python" logos available at <http://www.pythonlabs.com/logos.html> may be used according to the permissions granted on that web page.
7. By copying, installing or otherwise using the software, Licensee agrees to be bound by the terms and conditions of this License Agreement.

### C.2.3 LISENSI PERJANJIAN CNRI UNTUK PYTHON 1.6.1

1. This LICENSE AGREEMENT is between the Corporation for National Research Initiatives, having an office at 1895 Preston White Drive, Reston, VA 20191 ("CNRI"), and the Individual or Organization ("Licensee") accessing and otherwise using Python 1.6.1 software in source or binary form and its associated documentation.
2. Subject to the terms and conditions of this License Agreement, CNRI hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python 1.6.1 alone or in any derivative version, provided, however, that CNRI's License Agreement and CNRI's notice of copyright, i.e., "Copyright © 1995-2001 Corporation for National Research Initiatives; All Rights Reserved" are retained in Python 1.6.1 alone or in any derivative version prepared by Licensee. Alternately, in lieu of CNRI's License Agreement, Licensee may substitute the following text (omitting the quotes): "Python 1.6.1 is made available subject to the terms and conditions in CNRI's License Agreement. This Agreement together with Python 1.6.1 may be located on the Internet using the following unique, persistent identifier (known as a handle): 1895.22/1013. This Agreement may also be obtained from a proxy server on the Internet using the following URL: <http://hdl.handle.net/1895.22/1013>."
3. In the event Licensee prepares a derivative work that is based on or incorporates Python 1.6.1 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python 1.6.1.
4. CNRI is making Python 1.6.1 available to Licensee on an "AS IS" basis. CNRI MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, CNRI MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON 1.6.1 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
5. CNRI SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 1.6.1 FOR

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 1.6.1, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
7. This License Agreement shall be governed by the federal intellectual property law of the United States, including without limitation the federal copyright law, and, to the extent such U.S. federal law does not apply, by the law of the Commonwealth of Virginia, excluding Virginia's conflict of law provisions. Notwithstanding the foregoing, with regard to derivative works based on Python 1.6.1 that incorporate non-separable material that was previously distributed under the GNU General Public License (GPL), the law of the Commonwealth of Virginia shall govern this License Agreement only as to issues arising under or with respect to Paragraphs 4, 5, and 7 of this License Agreement. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between CNRI and Licensee. This License Agreement does not grant permission to use CNRI trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.
8. By clicking on the "ACCEPT" button where indicated, or by copying, installing or otherwise using Python 1.6.1, Licensee agrees to be bound by the terms and conditions of this License Agreement.

## C.2.4 LISENSI PERJANJIAN CWI UNTUK PYTHON 0.9.0 SAMPAI 1.2

Copyright © 1991 - 1995, Stichting Mathematisch Centrum Amsterdam, The Netherlands. All rights reserved.

Permission to use, copy, modify, and distribute this software and its documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Stichting Mathematisch Centrum or CWI not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

STICHTING MATHEMATISCH CENTRUM DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS, IN NO EVENT SHALL STICHTING MATHEMATISCH CENTRUM BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

## C.2.5 ZERO-CLAUSE BSD LICENSE FOR CODE IN THE PYTHON 3.8.18 DOCUMENTATION

Permission to use, copy, modify, and/or distribute this software for any purpose with or without fee is hereby granted.

THE SOFTWARE IS PROVIDED "AS IS" AND THE AUTHOR DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS. IN NO EVENT SHALL THE AUTHOR BE LIABLE FOR ANY SPECIAL, DIRECT, INDIRECT, OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

## C.3 Lisensi dan Ucapan Terima Kasih untuk Perangkat Lunak yang Tergabung

Bagian ini tidak lengkap, tetapi daftar lisensi dan ucapan terima kasih yang terus bertambah untuk perangkat lunak pihak ketiga yang tergabung dalam distribusi Python.

### C.3.1 Mersenne Twister

The `_random` module includes code based on a download from <http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/MT2002/emt19937ar.html>. The following are the verbatim comments from the original code:

A C-program for MT19937, with initialization improved 2002/1/26.  
Coded by Takuji Nishimura and Makoto Matsumoto.

Before using, initialize the state by using `init_genrand(seed)`  
or `init_by_array(init_key, key_length)`.

Copyright (C) 1997 - 2002, Makoto Matsumoto and Takuji Nishimura,  
All rights reserved.

Redistribution and use in source and binary forms, with or without  
modification, are permitted provided that the following conditions  
are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
3. The names of its contributors may not be used to endorse or promote products derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS  
"AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT  
LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

Any feedback is very welcome.

<http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html>

email: m-mat @ math.sci.hiroshima-u.ac.jp (remove space)

### C.3.2 Soket

The *socket* module uses the functions, `getaddrinfo()`, and `getnameinfo()`, which are coded in separate source files from the WIDE Project, <http://www.wide.ad.jp/>.

Copyright (C) 1995, 1996, 1997, and 1998 WIDE Project.  
All rights reserved.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
3. Neither the name of the project nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED BY THE PROJECT AND CONTRIBUTORS ``AS IS'' AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE PROJECT OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

### C.3.3 Layanan soket asinkron

Modul `asynchat` dan `asyncore` berisi pemberitahuan berikut:

```
Copyright 1996 by Sam Rushing
```

```
    All Rights Reserved
```

```
Permission to use, copy, modify, and distribute this software and
its documentation for any purpose and without fee is hereby
granted, provided that the above copyright notice appear in all
copies and that both that copyright notice and this permission
notice appear in supporting documentation, and that the name of Sam
Rushing not be used in advertising or publicity pertaining to
distribution of the software without specific, written prior
permission.
```

```
SAM RUSHING DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE,
INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS, IN
NO EVENT SHALL SAM RUSHING BE LIABLE FOR ANY SPECIAL, INDIRECT OR
CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS
OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT,
NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN
CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.
```

### C.3.4 Pengelolaan *Cookie*

Modul `http.cookies` berisi pemberitahuan berikut:

```
Copyright 2000 by Timothy O'Malley <timo@alum.mit.edu>
```

```
    All Rights Reserved
```

```
Permission to use, copy, modify, and distribute this software
and its documentation for any purpose and without fee is hereby
granted, provided that the above copyright notice appear in all
copies and that both that copyright notice and this permission
notice appear in supporting documentation, and that the name of
Timothy O'Malley not be used in advertising or publicity
pertaining to distribution of the software without specific, written
prior permission.
```

```
Timothy O'Malley DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS
SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY
AND FITNESS, IN NO EVENT SHALL Timothy O'Malley BE LIABLE FOR
ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES
WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS,
WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS
ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR
PERFORMANCE OF THIS SOFTWARE.
```

### C.3.5 Pelacakan eksekusi

Modul `trace` berisi pemberitahuan berikut:

```
portions copyright 2001, Autonomous Zones Industries, Inc., all rights...
err... reserved and offered to the public under the terms of the
Python 2.2 license.
Author: Zooko O'Whielacronx
http://zooko.com/
mailto:zooko@zooko.com

Copyright 2000, Mojam Media, Inc., all rights reserved.
Author: Skip Montanaro

Copyright 1999, Bioreason, Inc., all rights reserved.
Author: Andrew Dalke

Copyright 1995-1997, Automatrix, Inc., all rights reserved.
Author: Skip Montanaro

Copyright 1991-1995, Stichting Mathematisch Centrum, all rights reserved.

Permission to use, copy, modify, and distribute this Python software and
its associated documentation for any purpose without fee is hereby
granted, provided that the above copyright notice appears in all copies,
and that both that copyright notice and this permission notice appear in
supporting documentation, and that the name of neither Automatrix,
Bioreason or Mojam Media be used in advertising or publicity pertaining to
distribution of the software without specific, written prior permission.
```

### C.3.6 UUencode and UUdecode functions

Modul `uu` berisi pemberitahuan berikut:

```
Copyright 1994 by Lance Ellinghouse
Cathedral City, California Republic, United States of America.
    All Rights Reserved
Permission to use, copy, modify, and distribute this software and its
documentation for any purpose and without fee is hereby granted,
provided that the above copyright notice appear in all copies and that
both that copyright notice and this permission notice appear in
supporting documentation, and that the name of Lance Ellinghouse
not be used in advertising or publicity pertaining to distribution
of the software without specific, written prior permission.
LANCE ELLINGHOUSE DISCLAIMS ALL WARRANTIES WITH REGARD TO
THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND
FITNESS, IN NO EVENT SHALL LANCE ELLINGHOUSE CENTRUM BE LIABLE
FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES
WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN
ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT
OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

Modified by Jack Jansen, CWI, July 1995:
- Use binascii module to do the actual line-by-line conversion
  between ascii and binary. This results in a 1000-fold speedup. The C
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
version is still 5 times faster, though.  
- Arguments more compliant with Python standard
```

### C.3.7 XML Remote Procedure Calls

Modul `xmlrpc.client` berisi pemberitahuan berikut:

```
The XML-RPC client interface is  
  
Copyright (c) 1999-2002 by Secret Labs AB  
Copyright (c) 1999-2002 by Fredrik Lundh  
  
By obtaining, using, and/or copying this software and/or its  
associated documentation, you agree that you have read, understood,  
and will comply with the following terms and conditions:  
  
Permission to use, copy, modify, and distribute this software and  
its associated documentation for any purpose and without fee is  
hereby granted, provided that the above copyright notice appears in  
all copies, and that both that copyright notice and this permission  
notice appear in supporting documentation, and that the name of  
Secret Labs AB or the author not be used in advertising or publicity  
pertaining to distribution of the software without specific, written  
prior permission.  
  
SECRET LABS AB AND THE AUTHOR DISCLAIMS ALL WARRANTIES WITH REGARD  
TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANT-  
ABILITY AND FITNESS. IN NO EVENT SHALL SECRET LABS AB OR THE AUTHOR  
BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY  
DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS,  
WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS  
ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE  
OF THIS SOFTWARE.
```

### C.3.8 test\_epoll

Modul `test_epoll` berisi pemberitahuan berikut:

```
Copyright (c) 2001-2006 Twisted Matrix Laboratories.  
  
Permission is hereby granted, free of charge, to any person obtaining  
a copy of this software and associated documentation files (the  
"Software"), to deal in the Software without restriction, including  
without limitation the rights to use, copy, modify, merge, publish,  
distribute, sublicense, and/or sell copies of the Software, and to  
permit persons to whom the Software is furnished to do so, subject to  
the following conditions:  
  
The above copyright notice and this permission notice shall be  
included in all copies or substantial portions of the Software.  
  
THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND,  
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF
```

(berlanjut ke halaman berikutnya)

(lanjutan dari halaman sebelumnya)

```
MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND
NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE
LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION

Solution inspired by code from:
  Samuel Neves (supercop/crypto_auth/siphhash24/little)
  djb (supercop/crypto_auth/siphhash24/little2)
  Jean-Philippe Aumasson (https://131002.net/siphhash/siphhash24.c)
```

### C.3.11 strtod dan dtoa

The file `Python/dtoa.c`, which supplies C functions `dtoa` and `strtod` for conversion of C doubles to and from strings, is derived from the file of the same name by David M. Gay, currently available from <http://www.netlib.org/fp/>. The original file, as retrieved on March 16, 2009, contains the following copyright and licensing notice:

```
/* *****
 *
 * The author of this software is David M. Gay.
 *
 * Copyright (c) 1991, 2000, 2001 by Lucent Technologies.
 *

```

### C.3.12 OpenSSL

The modules `hashlib`, `posix`, `ssl`, `crypt` use the OpenSSL library for added performance if made available by the operating system. Additionally, the Windows and Mac OS X installers for Python may include a copy of the OpenSSL libraries, so we include a copy of the OpenSSL license here:

```
LICENSE ISSUES
=====

The OpenSSL toolkit stays under a dual license, i.e. both the conditions of
the OpenSSL License and the original SSLeay license apply to the toolkit.
See below for the actual license texts. Actually both licenses are BSD-style
Open Source licenses. In case of any license issues related to OpenSSL
please contact openssl-core@openssl.org.

* OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF
* SUCH DAMAGE.
*
* The licence and distribution terms for any publically available version or
* derivative of this code cannot be changed. i.e. this code cannot simply be
* copied and put under another distribution licence
* [including the GNU Public Licence.]
*/

```

### C.3.13 expat

The `pyexpat` extension is built using an included copy of the `expat` sources unless the build is configured `--with-system-expat`:

```
Copyright (c) 1998, 1999, 2000 Thai Open Source Software Center Ltd
and Clark Cooper

Permission is hereby granted, free of charge, to any person obtaining
a copy of this software and associated documentation files (the
"Software"), to deal in the Software without restriction, including
without limitation the rights to use, copy, modify, merge, publish,
distribute, sublicense, and/or sell copies of the Software, and to
permit persons to whom the Software is furnished to do so, subject to
the following conditions:

The above copyright notice and this permission notice shall be included
in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND,
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF
MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT.
IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY
CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT,
TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE
SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.
```

### C.3.14 libffi

The `_ctypes` extension is built using an included copy of the `libffi` sources unless the build is configured `--with-system-libffi`:

```
Copyright (c) 1996-2008 Red Hat, Inc and others.

Permission is hereby granted, free of charge, to any person obtaining
a copy of this software and associated documentation files (the
``Software''), to deal in the Software without restriction, including
without limitation the rights to use, copy, modify, merge, publish,
distribute, sublicense, and/or sell copies of the Software, and to
permit persons to whom the Software is furnished to do so, subject to
the following conditions:

The above copyright notice and this permission notice shall be included
in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED ``AS IS'', WITHOUT WARRANTY OF ANY KIND,
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF
MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND
NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT
HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY,
WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM,
OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER
DEALINGS IN THE SOFTWARE.
```

### C.3.15 zlib

The `zlib` extension is built using an included copy of the zlib sources if the zlib version found on the system is too old to be used for the build:

```
Copyright (C) 1995-2011 Jean-loup Gailly and Mark Adler

This software is provided 'as-is', without any express or implied
warranty. In no event will the authors be held liable for any damages
arising from the use of this software.

Permission is granted to anyone to use this software for any purpose,
including commercial applications, and to alter it and redistribute it
freely, subject to the following restrictions:

1. The origin of this software must not be misrepresented; you must not
   claim that you wrote the original software. If you use this software
   in a product, an acknowledgment in the product documentation would be
   appreciated but is not required.

2. Altered source versions must be plainly marked as such, and must not be
   misrepresented as being the original software.

3. This notice may not be removed or altered from any source distribution.

Jean-loup Gailly          Mark Adler
jloup@gzip.org            madler@alumni.caltech.edu
```

### C.3.16 cfuhash

The implementation of the hash table used by the `tracemalloc` is based on the cfuhash project:

```
Copyright (c) 2005 Don Owens
All rights reserved.

This code is released under the BSD license:

Redistribution and use in source and binary forms, with or without
modification, are permitted provided that the following conditions
are met:

HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT,
STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE)
ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED
OF THE POSSIBILITY OF SUCH DAMAGE.
```

### C.3.17 libmpdec

The `_decimal` module is built using an included copy of the libmpdec library unless the build is configured `--with-system-libmpdec`:

```
Copyright (c) 2008-2016 Stefan Krah. All rights reserved.

Redistribution and use in source and binary forms, with or without
modification, are permitted provided that the following conditions
are met:

1. Redistributions of source code must retain the above copyright
   notice, this list of conditions and the following disclaimer.

2. Redistributions in binary form must reproduce the above copyright
   notice, this list of conditions and the following disclaimer in the
   documentation and/or other materials provided with the distribution.

THIS SOFTWARE IS PROVIDED BY THE AUTHOR AND CONTRIBUTORS "AS IS" AND
ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE
IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE
ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHOR OR CONTRIBUTORS BE LIABLE
FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL
DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS
OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION)
HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT
LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY
OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF
SUCH DAMAGE.
```

### C.3.18 Rangkaian pengujian W3C C14N

The C14N 2.0 test suite in the `test` package (`Lib/test/xmltestdata/c14n-20/`) was retrieved from the W3C website at <https://www.w3.org/TR/xml-c14n2-testcases/> and is distributed under the 3-clause BSD license:
