
The Python Library Reference

发布 3.6.8

**Guido van Rossum
and the Python development team**

六月 19, 2019

**Python Software Foundation
Email: docs@python.org**

1	概述	3
2	内置函数	5
3	内置常量	25
3.1	由 site 模块添加的常量	26
4	内置类型	27
4.1	逻辑值检测	27
4.2	Boolean Operations —and, or, not	28
4.3	比较	28
4.4	数字类型—int, float, complex	29
4.5	迭代器类型	34
4.6	序列类型—list, tuple, range	35
4.7	文本序列类型—str	40
4.8	二进制序列类型—bytes, bytearray, memoryview	49
4.9	集合类型—set, frozenset	69
4.10	映射类型—dict	71
4.11	上下文管理器类型	74
4.12	其他内置类型	75
4.13	特殊属性	77
5	内置异常	79
5.1	基类	80
5.2	具体异常	80
5.3	警告	85
5.4	异常层次结构	86
6	文本处理服务	89
6.1	string —常见的字符串操作	89
6.2	re —正则表达式操作	99
6.3	difflib —计算差异的辅助工具	117
6.4	textwrap —Text wrapping and filling	127
6.5	unicodedata —Unicode 数据库	130
6.6	stringprep —Internet String Preparation	132
6.7	readline —GNU readline interface	133
6.8	rlcompleter —GNU readline 的完成函数	138

7	二进制数据服务	139
7.1	struct — Interpret bytes as packed binary data	139
7.2	codecs — Codec registry and base classes	145
8	数据类型	163
8.1	datetime — 基础日期和时间数据类型	163
8.2	calendar — 日历相关函数	192
8.3	collections — 容器数据类型	195
8.4	collections.abc — 容器的抽象基类	210
8.5	heapq — 堆队列算法	214
8.6	bisect — Array bisection algorithm	218
8.7	array — Efficient arrays of numeric values	220
8.8	weakref — 弱引用	223
8.9	types — Dynamic type creation and names for built-in types	230
8.10	copy — 浅层 (shallow) 和深层 (deep) 复制操作	234
8.11	pprint — 数据美化输出	235
8.12	reprlib — Alternate repr() implementation	240
8.13	enum — Support for enumerations	242
9	数字和数学模块	261
9.1	numbers — 数字的抽象基类	261
9.2	math — 数学函数	264
9.3	cmath — 关于复数的数学函数	269
9.4	decimal — 十进制定点和浮点运算	272
9.5	fractions — 分数	298
9.6	random — 生成伪随机数	300
9.7	statistics — Mathematical statistics functions	306
10	函数式编程模块	313
10.1	itertools — 为高效循环而创建迭代器的函数	313
10.2	functools — 高阶函数和可调对象上的操作	327
10.3	operator — 标准运算符替代函数	333
11	文件和目录访问	341
11.1	pathlib — 面向对象的文件系统路径	341
11.2	os.path — 常见路径操作	357
11.3	fileinput — Iterate over lines from multiple input streams	361
11.4	stat — Interpreting stat() results	364
11.5	filecmp — File and Directory Comparisons	369
11.6	tempfile — Generate temporary files and directories	371
11.7	glob — Unix style pathname pattern expansion	375
11.8	fnmatch — Unix filename pattern matching	376
11.9	linecache — Random access to text lines	377
11.10	shutil — High-level file operations	378
11.11	macpath — Mac OS 9 路径操作函数	385
12	数据持久化	387
12.1	pickle — Python 对象序列化	387
12.2	copyreg — Register pickle support functions	400
12.3	shelve — Python object persistence	401
12.4	marshal — Internal Python object serialization	403
12.5	dbm — Interfaces to Unix “databases”	404
12.6	sqlite3 — SQLite 数据库 DB-API 2.0 接口模块	408
13	数据压缩和存档	429

13.1	zlib —与 gzip 兼容的压缩	429
13.2	gzip —对 gzip 格式的支持	432
13.3	bz2 —对 bzip2 压缩算法的支持	435
13.4	lzma —用 LZMA 算法压缩	438
13.5	zipfile —使用 ZIP 存档	443
13.6	tarfile —读写 tar 归档文件	451
14	文件格式	461
14.1	csv —CSV 文件读写	461
14.2	configparser —Configuration file parser	468
14.3	netrc —netrc file processing	485
14.4	xdrllib —Encode and decode XDR data	486
14.5	plistlib —Generate and parse Mac OS X .plist files	489
15	加密服务	493
15.1	hashlib —安全哈希与消息摘要	493
15.2	hmac —基于密钥的消息验证	503
15.3	secrets —Generate secure random numbers for managing secrets	505
16	通用操作系统服务	509
16.1	os —操作系统接口模块	509
16.2	io —处理流的核心工具	554
16.3	time —时间的访问和转换	566
16.4	argparse —命令行选项、参数和子命令解析器	573
16.5	getopt —C-style parser for command line options	603
16.6	模块 logging —Python 的日志记录工具	605
16.7	logging.config —日志记录配置	621
16.8	logging.handlers —Logging handlers	631
16.9	getpass —便携式密码输入工具	643
16.10	curses —终端字符单元显示的处理	644
16.11	curses.textpad —Text input widget for curses programs	661
16.12	curses.ascii —Utilities for ASCII characters	662
16.13	curses.panel —A panel stack extension for curses	665
16.14	platform —获取底层平台的标识数据	666
16.15	errno —Standard errno system symbols	669
16.16	ctypes —Python 的外部函数库	675
17	并发执行	709
17.1	threading —基于线程的并行	709
17.2	multiprocessing —基于进程的并行	720
17.3	concurrent 包	761
17.4	concurrent.futures —启动并行任务	761
17.5	subprocess —子进程管理	767
17.6	sched —事件调度器	782
17.7	queue —一个同步的队列类	783
17.8	dummy_threading —可直接替代 threading 模块。	785
17.9	_thread —底层多线程 API	786
17.10	_dummy_thread —_thread 的替代模块	787
18	Interprocess Communication and Networking	789
18.1	socket —底层网络接口	789
18.2	ssl —TLS/SSL wrapper for socket objects	810
18.3	select —Waiting for I/O completion	841
18.4	selectors —高级 I/O 复用库	848
18.5	asyncio —Asynchronous I/O, event loop, coroutines and tasks	852

18.6	asyncore —异步 socket 处理器	912
18.7	asynchat —异步 socket 指令/响应处理器	917
18.8	signal —Set handlers for asynchronous events	919
18.9	mmap —内存映射文件支持	924
19	互联网数据处理	929
19.1	email —电子邮件与 MIME 处理包	929
19.2	json —JSON 编码和解码器	986
19.3	mailcap —Mailcap file handling	995
19.4	mailbox —Manipulate mailboxes in various formats	996
19.5	mimetypes —Map filenames to MIME types	1014
19.6	base64 —Base16, Base32, Base64, Base85 数据编码	1017
19.7	binhex —对 binhex4 文件进行编码和解码	1019
19.8	binascii —二进制和 ASCII 码互转	1020
19.9	quopri —Encode and decode MIME quoted-printable data	1022
19.10	uu —Encode and decode uuencode files	1022
20	结构化标记处理工具	1025
20.1	html —超文本标记语言支持	1025
20.2	html.parser —简单的 HTML 和 XHTML 解析器	1026
20.3	html.entities —HTML 一般实体的定义	1030
20.4	XML 处理模块	1030
20.5	xml.etree.ElementTree —The ElementTree XML API	1032
20.6	xml.dom —The Document Object Model API	1047
20.7	xml.dom.minidom —Minimal DOM implementation	1057
20.8	xml.dom.pulldom —Support for building partial DOM trees	1061
20.9	xml.sax —Support for SAX2 parsers	1063
20.10	xml.sax.handler —Base classes for SAX handlers	1065
20.11	xml.sax.saxutils —SAX Utilities	1070
20.12	xml.sax.xmlreader —Interface for XML parsers	1071
20.13	xml.parsers.expat —Fast XML parsing using Expat	1075
21	互联网协议和支持	1085
21.1	webbrowser —方便的 Web 浏览器控制器	1085
21.2	cgi —Common Gateway Interface support	1087
21.3	cgitb —Traceback manager for CGI scripts	1094
21.4	wsgiref —WSGI Utilities and Reference Implementation	1095
21.5	urllib —URL 处理模块	1104
21.6	urllib.request —用于打开 URL 的可扩展库	1104
21.7	urllib.response —Response classes used by urllib	1122
21.8	urllib.parse —Parse URLs into components	1122
21.9	urllib.error —Exception classes raised by urllib.request	1129
21.10	urllib.robotparser —Parser for robots.txt	1130
21.11	http —HTTP 模块	1131
21.12	http.client —HTTP 协议客户端	1133
21.13	ftplib —FTP protocol client	1139
21.14	poplib —POP3 protocol client	1144
21.15	imaplib —IMAP4 protocol client	1147
21.16	nntplib —NNTP protocol client	1153
21.17	smtplib —SMTP 协议客户端	1160
21.18	smtpd —SMTP Server	1167
21.19	telnetlib —Telnet client	1170
21.20	uuid —UUID objects according to RFC 4122	1173
21.21	socketserver —A framework for network servers	1176

21.22	<code>http.server</code> —HTTP 服务器	1184
21.23	<code>http.cookies</code> —HTTP state management	1189
21.24	<code>http.cookiejar</code> —Cookie handling for HTTP clients	1192
21.25	<code>xmlrpc</code> —XMLRPC 服务端与客户端模块	1201
21.26	<code>xmlrpc.client</code> —XML-RPC client access	1201
21.27	<code>xmlrpc.server</code> —Basic XML-RPC servers	1209
21.28	<code>ipaddress</code> —IPv4/IPv6 manipulation library	1214
22	多媒体服务	1227
22.1	<code>audioop</code> —Manipulate raw audio data	1227
22.2	<code>aifc</code> —Read and write AIFF and AIFC files	1230
22.3	<code>sunau</code> —读写 Sun AU 文件	1232
22.4	<code>wave</code> —读写 WAV 格式文件	1235
22.5	<code>chunk</code> —Read IFF chunked data	1238
22.6	<code>colorsys</code> —Conversions between color systems	1239
22.7	<code>imghdr</code> —推测图像类型	1240
22.8	<code>sndhdr</code> —推测声音文件的类型	1240
22.9	<code>ossaudiodev</code> —Access to OSS-compatible audio devices	1241
23	国际化	1247
23.1	<code>gettext</code> —多语种国际化服务	1247
23.2	<code>locale</code> —国际化服务	1255
24	程序框架	1263
24.1	<code>turtle</code> —海龟绘图	1263
24.2	<code>cmd</code> —支持面向行的命令解释器	1296
24.3	<code>shlex</code> —Simple lexical analysis	1301
25	Tk 图形用户界面 (GUI)	1307
25.1	<code>tkinter</code> —Tcl/Tk 的 Python 接口	1307
25.2	<code>tkinter.ttk</code> —Tk themed widgets	1318
25.3	<code>tkinter.tix</code> —Extension widgets for Tk	1335
25.4	<code>tkinter.scrolledtext</code> —滚动文字控件	1340
25.5	<code>IDLE</code>	1340
25.6	其他图形用户界面 (GUI) 包	1349
26	开发工具	1351
26.1	<code>typing</code> —类型标注支持	1351
26.2	<code>pydoc</code> —Documentation generator and online help system	1366
26.3	<code>doctest</code> —测试交互性的 Python 示例	1368
26.4	<code>unittest</code> —单元测试框架	1391
26.5	<code>unittest.mock</code> —mock object library	1418
26.6	<code>unittest.mock</code> 上手指南	1453
26.7	<code>2to3</code> - 自动将 Python 2 代码转为 Python 3 代码	1472
26.8	<code>test</code> —Regression tests package for Python	1477
26.9	<code>test.support</code> —Utilities for the Python test suite	1480
27	调试和分析	1487
27.1	<code>bdb</code> —Debugger framework	1487
27.2	<code>faulthandler</code> —Dump the Python traceback	1491
27.3	<code>pdb</code> —Python 的调试器	1494
27.4	The Python Profilers	1499
27.5	<code>timeit</code> —测量小代码片段的执行时间	1507
27.6	<code>trace</code> —Trace or track Python statement execution	1512
27.7	<code>tracemalloc</code> —Trace memory allocations	1515

28 软件打包和分发	1525
28.1 distutils —构建和安装 Python 模块	1525
28.2 ensurepip —Bootstrapping the pip installer	1526
28.3 venv —创建虚拟环境	1527
28.4 zipapp —Manage executable python zip archives	1535
29 Python 运行时服务	1543
29.1 sys —系统相关的参数和函数	1543
29.2 sysconfig —Provide access to Python' s configuration information	1558
29.3 builtins —内建对象	1562
29.4 __main__ —顶层脚本环境	1563
29.5 warnings —Warning control	1563
29.6 contextlib —Utilities for with-statement contexts	1568
29.7 abc —抽象基类	1579
29.8 atexit —退出处理器	1584
29.9 traceback —打印或检索堆栈回溯	1585
29.10 __future__ —Future 语句定义	1591
29.11 gc —垃圾回收器接口	1592
29.12 inspect —检查对象	1595
29.13 site —Site-specific configuration hook	1610
29.14 fpectl —Floating point exception control	1613
30 自定义 Python 解释器	1615
30.1 code —Interpreter base classes	1615
30.2 codeop —Compile Python code	1617
31 导入模块	1619
31.1 zipimport —Import modules from Zip archives	1619
31.2 pkgutil —Package extension utility	1621
31.3 modulefinder —查找脚本使用的模块	1624
31.4 runpy —Locating and executing Python modules	1625
31.5 importlib —The implementation of import	1627
32 Python 语言服务	1645
32.1 parser —Access Python parse trees	1645
32.2 ast —抽象语法树	1649
32.3 symtable —Access to the compiler' s symbol tables	1654
32.4 symbol —与 Python 解析树一起使用的常量	1657
32.5 token —与 Python 解析树一起使用的常量	1657
32.6 keyword —检验 Python 关键字	1658
32.7 tokenize —Tokenizer for Python source	1659
32.8 tabnanny —模糊缩进检测	1662
32.9 pyclbr —Python class browser support	1663
32.10 py_compile —Compile Python source files	1664
32.11 compileall —Byte-compile Python libraries	1665
32.12 dis —Python 字节码反汇编器	1668
32.13 pickletools —Tools for pickle developers	1681
33 杂项服务	1683
33.1 formatter —Generic output formatting	1683
34 Windows 系统相关模块	1689
34.1 msilib —Read and write Microsoft Installer files	1689
34.2 msvcrt —Useful routines from the MS VC++ runtime	1694
34.3 winreg —Windows 注册表访问	1696

34.4	winsound —Sound-playing interface for Windows	1704
35	Unix 专有服务	1707
35.1	posix —The most common POSIX system calls	1707
35.2	pwd —用户密码数据库	1708
35.3	spwd —The shadow password database	1709
35.4	grp —The group database	1710
35.5	crypt —Function to check Unix passwords	1710
35.6	termios —POSIX style tty control	1712
35.7	tty —终端控制功能	1713
35.8	pty —Pseudo-terminal utilities	1714
35.9	fcntl —The fcntl and ioctl system calls	1715
35.10	pipes —Interface to shell pipelines	1717
35.11	resource —Resource usage information	1718
35.12	nis —Interface to Sun' s NIS (Yellow Pages)	1722
35.13	Unix syslog 库例程	1723
36	被取代的模块	1725
36.1	optparse —Parser for command line options	1725
36.2	imp —Access the import internals	1751
37	未创建文档的模块	1757
37.1	平台特定模块	1757
A	术语对照表	1759
B	文档说明	1771
B.1	Python 文档贡献者	1771
C	历史和许可证	1773
C.1	软件历史	1773
C.2	访问 Python 或以其他方式使用 Python 的条款和条件	1774
C.3	集成软件的许可和认可	1777
D	版权	1791
	Bibliography	1793
	Python 模块索引	1795
	索引	1799

`reference-index` 描述了 Python 语言的具体语法和语义，这份库参考则介绍了与 Python 一同发行的标准库。它还描述了通常包含在 Python 发行版中的一些可选组件。

Python 标准库非常庞大，所提供的组件涉及范围十分广泛，正如以下内容目录所显示的。这个库包含了多个内置模块 (以 C 编写)，Python 程序员必须依靠它们来实现系统级功能，例如文件 I/O，此外还有大量以 Python 编写的模块，提供了日常编程中许多问题的标准解决方案。其中有些模块经过专门设计，通过将特定平台功能抽象化为平台中立的 API 来鼓励和加强 Python 程序的可移植性。

Windows 版本的 Python 安装程序通常包含整个标准库，往往还包含许多额外组件。对于类 Unix 操作系统，Python 通常会分成一系列的软件包，因此可能需要使用操作系统所提供的包管理工具来获取部分或全部可选组件。

在这个标准库以外还存在成千上万并且不断增加的其他组件 (从单独的程序、模块、软件包直到完整的应用开发框架)，访问 [Python 包索引](#) 即可获取这些第三方包。

概述

“Python 库”中包含了几种不同的组件。

它包含通常被视为语言“核心”中的一部分的数据类型，例如数字和列表。对于这些类型，Python 语言核心定义了文字的形式，并对它们的语义设置了一些约束，但没有完全定义语义。（另一方面，语言核心确实定义了语法属性，如操作符的拼写和优先级。）

这个库也包含了内置函数和异常—不需要 `import` 语句就可以在所有 Python 代码中使用的对象。有一些是由语言核心定义的，但是许多对于核心语义不是必需的，并且仅在这里描述。

不过这个库主要是由一系列的模块组成。这些模块集可以不同方式分类。有些模块是用 C 编写并内置于 Python 解释器中；另一些模块则是用 Python 编写并以源码形式导入。有些模块提供专用于 Python 的接口，例如打印栈追踪信息；有些模块提供专用于特定操作系统的接口，例如操作特定的硬件；另一些模块则提供针对特定应用领域的接口，例如万维网。有些模块在所有更新和移植版本的 Python 中可用；另一些模块仅在底层系统支持或要求时可用；还有些模块则仅当编译和安装 Python 时选择了特定配置选项时才可用。

本手册以“从内到外”的顺序组织：首先描述内置函数、数据类型和异常，最后是根据相关性进行分组的各种模块。

这意味着如果你从头开始阅读本手册，并在感到厌烦时跳到下一章，你仍能对 Python 库的可用模块和所支持的应用领域有个大致了解。当然，你并非必须如同读小说一样从头读到尾—你也可以先浏览内容目录（在手册开头），或在索引（在手册末尾）中查找某个特定函数、模块或条目。最后，如果你喜欢随意学习某个主题，你可以选择一个随机页码（参见 `random` 模块）并读上一两小节。无论你想以怎样的顺序阅读本手册，还是建议先从内置函数这一章开始，因为本手册的其余内容都需要你熟悉其中的基本概念。

让我们开始吧！

内置函数

Python 解释器内置了很多函数和类型，您可以在任何时候使用它们。以下按字母表顺序列出它们。

		内置函数		
<i>abs()</i>	<i>dict()</i>	<i>help()</i>	<i>min()</i>	<i>setattr()</i>
<i>all()</i>	<i>dir()</i>	<i>hex()</i>	<i>next()</i>	<i>slice()</i>
<i>any()</i>	<i>divmod()</i>	<i>id()</i>	<i>object()</i>	<i>sorted()</i>
<i>ascii()</i>	<i>enumerate()</i>	<i>input()</i>	<i>oct()</i>	<i>staticmethod()</i>
<i>bin()</i>	<i>eval()</i>	<i>int()</i>	<i>open()</i>	<i>str()</i>
<i>bool()</i>	<i>exec()</i>	<i>isinstance()</i>	<i>ord()</i>	<i>sum()</i>
<i>bytearray()</i>	<i>filter()</i>	<i>issubclass()</i>	<i>pow()</i>	<i>super()</i>
<i>bytes()</i>	<i>float()</i>	<i>iter()</i>	<i>print()</i>	<i>tuple()</i>
<i>callable()</i>	<i>format()</i>	<i>len()</i>	<i>property()</i>	<i>type()</i>
<i>chr()</i>	<i>frozenset()</i>	<i>list()</i>	<i>range()</i>	<i>vars()</i>
<i>classmethod()</i>	<i>getattr()</i>	<i>locals()</i>	<i>repr()</i>	<i>zip()</i>
<i>compile()</i>	<i>globals()</i>	<i>map()</i>	<i>reversed()</i>	<i>__import__()</i>
<i>complex()</i>	<i>hasattr()</i>	<i>max()</i>	<i>round()</i>	
<i>delattr()</i>	<i>hash()</i>	<i>memoryview()</i>	<i>set()</i>	

abs(x)
返回一个数的绝对值。实参可以是整数或浮点数。如果实参是一个复数，返回它的模。

all(iterable)
如果 *iterable* 的所有元素为真（或迭代器为空），返回 True。等价于:

```
def all(iterable):
    for element in iterable:
        if not element:
            return False
    return True
```

any(iterable)
如果 *iterable* 的任一元素为真则返回 True。如果迭代器为空，返回 False。等价于:

```
def any(iterable):
    for element in iterable:
        if element:
            return True
    return False
```

ascii(object)

就像函数 `repr()`，返回一个对象可打印的字符串，但是 `repr()` 返回的字符串中非 ASCII 编码的字符，会使用 `\x`、`\u` 和 `\U` 来转义。生成的字符串和 Python 2 的 `repr()` 返回的结果相似。

bin(x)

将一个整数转变为一个前缀为“0b”的二进制字符串。结果是一个合法的 Python 表达式。如果 `x` 不是 Python 的 `int` 对象，那它需要定义 `__index__()` 方法返回一个整数。一些例子：

```
>>> bin(3)
'0b11'
>>> bin(-10)
'-0b1010'
```

如果不一定需要前缀“0b”，还可以使用如下的方法。

```
>>> format(14, '#b'), format(14, 'b')
('0b1110', '1110')
>>> f'{14:#b}', f'{14:b}'
('0b1110', '1110')
```

另见 `format()` 获取更多信息。

class bool([x])

返回一个布尔值，True 或者 False。`x` 使用标准的真值测试过程来转换。如果 `x` 是假的或者被省略，返回 False；其他情况返回 True。`bool` 类是 `int` 的子类（参见数字类型—`int`、`float`、`complex`）。其他类不能继承自它。它只有 False 和 True 两个实例（参见布尔值）。

class bytearray([source[, encoding[, errors]]])

返回一个新的 bytes 数组。`bytearray` 类是一个可变序列，包含范围为 $0 \leq x < 256$ 的整数。它有可变序列大部分常见的方法，见可变序列类型的描述；同时有 `bytes` 类型的大部分方法，参见 `bytes` 和 `bytearray` 操作。

可选形参 `source` 可以用不同的方式来初始化数组：

- 如果是一个 `string`，您必须提供 `encoding` 参数（`errors` 参数仍是可选的）；`bytearray()` 会使用 `str.encode()` 方法来将 `string` 转变成 `bytes`。
- 如果是一个 `integer`，会初始化大小为该数字的数组，并使用 `null` 字节填充。
- 如果是一个符合 `buffer` 接口的对象，该对象的只读 `buffer` 会用来初始化字节数组。
- 如果是一个 `iterable` 可迭代对象，它的元素的范围必须是 $0 \leq x < 256$ 的整数，它会被用作数组的初始内容。

如果没有实参，则创建大小为 0 的数组。

另见二进制序列类型—`bytes`、`bytearray`、`memoryview` 和 `bytearray` 对象。

class bytes([source[, encoding[, errors]]])

返回一个新的“bytes”对象，是一个不可变序列，包含范围为 $0 \leq x < 256$ 的整数。`bytes` 是 `bytearray` 的不可变版本 - 它有其中不改变序列的方法和相同的索引、切片操作。

因此，构造函数的实参和 `bytearray()` 相同。

字节对象还可以用字面值创建，参见 `strings`。

另见二进制序列类型—*bytes*, *bytearray*, *memoryview*, *bytes* 对象和*bytes*和*bytearray*操作。

callable (*object*)

如果实参 *object* 是可调用的, 返回 *True*, 否则返回 *False*。如果返回真, 调用仍可能会失败; 但如果返回假, 则调用 *object* 肯定会失败。注意类是可调用的 (调用类会返回一个新的实例)。如果实例的类有 `__call__()` 方法, 则它是可调用。

3.2 新版功能: 这个函数一开始在 Python 3.0 被移除了, 但在 Python 3.2 被重新加入。

chr (*i*)

返回 Unicode 码位为整数 *i* 的字符的字符串格式。例如, `chr(97)` 返回字符串 'a', `chr(8364)` 返回字符串 '€'。这是 `ord()` 的逆函数。

实参的合法范围是 0 到 1,114,111 (16 进制表示是 0x10FFFF)。如果 *i* 超过这个范围, 会触发 *ValueError* 异常。

@classmethod

把一个方法封装成类方法。

一个类方法把类自己作为第一个实参, 就像一个实例方法把实例自己作为第一个实参。请用以下习惯来声明类方法:

```
class C:
    @classmethod
    def f(cls, arg1, arg2, ...): ...
```

The `@classmethod` form is a function *decorator* – see the description of function definitions in function for details.

It can be called either on the class (such as `C.f()`) or on an instance (such as `C().f()`). The instance is ignored except for its class. If a class method is called for a derived class, the derived class object is passed as the implied first argument.

Class methods are different than C++ or Java static methods. If you want those, see `staticmethod()` in this section.

For more information on class methods, consult the documentation on the standard type hierarchy in types.

compile (*source*, *filename*, *mode*, *flags=0*, *dont_inherit=False*, *optimize=-1*)

将 *source* 编译成代码或 AST 对象。代码对象可以被 `exec()` 或 `eval()` 执行。*source* 可以是常规的字符串、字节字符串, 或者 AST 对象。参见 *ast* 模块的文档了解如何使用 AST 对象。

filename 实参需要是代码读取的文件名; 如果代码不需要从文件中读取, 可以传入一些可辨识的值 (经常会使用 '`<string>`').

mode 实参指定了编译代码必须用的模式。如果 *source* 是语句序列, 可以是 'exec'; 如果是单一表达式, 可以是 'eval'; 如果是单个交互式语句, 可以是 'single'。(在最后一种情况下, 如果表达式执行结果不是 *None* 将会被打印出来。)

可选参数 *flags* 和 *dont_inherit* 控制在编译 *source* 时要用到哪个 *future* 语句。如果两者都未提供 (或都为零) 则会使用调用 `compile()` 的代码中有效的 *future* 语句来编译代码。如果给出了 *flags* 参数但没有 *dont_inherit* (或是为零) 则 *flags* 参数所指定的以及那些无论如何都有效的 *future* 语句会被使用。如果 *dont_inherit* 为一个非零整数, 则只使用 *flags* 参数 – 在调用外围有效的 *future* 语句将被忽略。

Future 语句使用比特位来指定, 多个语句可以通过按位或来指定。具体特性的比特位可以通过 `__future__` 模块中的 `_Feature` 类的实例的 `compiler_flag` 属性来获得。

optimize 实参指定编译器的优化级别; 默认值 -1 选择与解释器的 -O 选项相同的优化级别。显式级别为 0 (没有优化; `__debug__` 为真)、1 (断言被删除, `__debug__` 为假) 或 2 (文档字符串也被删除)。

如果编译的源码不合法, 此函数会触发 *SyntaxError* 异常; 如果源码包含 *null* 字节, 则会触发 *ValueError* 异常。

如果您想分析 Python 代码的 AST 表示, 请参阅[ast.parse\(\)](#)。

注解: 在 'single' 或 'eval' 模式编译多行代码字符串时, 输入必须以至少一个换行符结尾。这使 `code` 模块更容易检测语句的完整性。

警告: 在将足够大或者足够复杂的字符串编译成 AST 对象时, Python 解释器有可能会因为 Python AST 编译器的栈深度限制而崩溃。

在 3.2 版更改: 允许使用 Windows 和 Mac 的换行符。在 'exec' 模式不再需要以换行符结尾。增加了 *optimize* 形参。

在 3.5 版更改: 之前 *source* 中包含 null 字节的话会触发 *TypeError* 异常。

class complex(*real*[, *imag*])

返回值为 *real* + *imag**1j 的复数, 或将字符串或数字转换为复数。如果第一个形参是字符串, 则它被解释为一个复数, 并且函数调用时必须没有第二个形参。第二个形参不能是字符串。每个实参都可以是任意的数值类型 (包括复数)。如果省略了 *imag*, 则默认值为零, 构造函数会像 *int* 和 *float* 一样进行数值转换。如果两个实参都省略, 则返回 0j。

注解: 当从字符串转换时, 字符串在 + 或 - 的周围必须不能有空格。例如 `complex('1+2j')` 是合法的, 但 `complex('1 + 2j')` 会触发 *ValueError* 异常。

数字类型—*int*, *float*, *complex* 描述了复数类型。

在 3.6 版更改: 您可以使用下划线将代码文字中的数字进行分组。

delattr(*object*, *name*)

[setattr\(\)](#) 相关的函数。实参是一个对象和一个字符串。该字符串必须是对象的某个属性。如果对象允许, 该函数将删除指定的属性。例如 `delattr(x, 'foobar')` 等价于 `del x.foobar`。

class dict(***kwarg*)

class dict(*mapping*, ***kwarg*)

class dict(*iterable*, ***kwarg*)

创建一个新的字典。*dict* 对象是一个字典类。参见 *dict* 和映射类型—*dict* 了解这个类。

其他容器类型, 请参见内置的 *list*、*set* 和 *tuple* 类, 以及 *collections* 模块。

dir(*[object]*)

如果没有实参, 则返回当前本地作用域中的名称列表。如果有实参, 它会尝试返回该对象的有效属性列表。

如果对象有一个名为 `__dir__()` 的方法, 那么该方法将被调用, 并且必须返回一个属性列表。这允许实现自定义 `__getattr__()` 或 `__getattribute__()` 函数的对象能够自定义 *dir()* 来报告它们的属性。

如果对象不提供 `__dir__()`, 这个函数会尝试从对象已定义的 `__dict__` 属性和类型对象收集信息。结果列表并不总是完整的, 如果对象有自定义 `__getattr__()`, 那结果可能不准确。

默认的 *dir()* 机制对不同类型的对象行为不同, 它会试图返回最相关而不是最全的信息:

- 如果对象是模块对象, 则列表包含模块的属性名称。
- 如果对象是类型或类对象, 则列表包含它们的属性名称, 并且递归查找所有基类的属性。
- 否则, 列表包含对象的属性名称, 它的类属性名称, 并且递归查找它的类的所有基类的属性。

返回的列表按字母表排序。例如:

```

>>> import struct
>>> dir()      # show the names in the module namespace
['__builtins__', '__name__', 'struct']
>>> dir(struct) # show the names in the struct module # doctest: +SKIP
['Struct', '__all__', '__builtins__', '__cached__', '__doc__', '__file__',
 '__initializing__', '__loader__', '__name__', '__package__',
 '__clearcache', 'calcsiz', 'error', 'pack', 'pack_into',
 'unpack', 'unpack_from']
>>> class Shape:
...     def __dir__(self):
...         return ['area', 'perimeter', 'location']
>>> s = Shape()
>>> dir(s)
['area', 'location', 'perimeter']

```

注解：因为`dir()`主要是为了便于在交互式时使用，所以它会试图返回人们感兴趣的名字集合，而不是试图保证结果的严格性或一致性，它具体的行为也可能在不同版本之间改变。例如，当实参是一个类时，`metaclass` 的属性不包含在结果列表中。

`divmod(a, b)`

它将两个（非复数）数字作为实参，并在执行整数除法时返回一对商和余数。对于混合操作数类型，适用双目算术运算符的规则。对于整数，结果和 $(a // b, a \% b)$ 一致。对于浮点数，结果是 $(q, a \% b)$ ， q 通常是 `math.floor(a / b)` 但可能会比 1 小。在任何情况下， $q * b + a \% b$ 和 a 基本相等；如果 $a \% b$ 非零，它的符号和 b 一样，并且 $0 \leq \text{abs}(a \% b) < \text{abs}(b)$ 。

`enumerate(iterable, start=0)`

返回一个枚举对象。`iterable` 必须是一个序列，或 `iterator`，或其他支持迭代的对象。`enumerate()` 返回的迭代器的 `__next__()` 方法返回一个元组，里面包含一个计数值（从 `start` 开始，默认为 0）和通过迭代 `iterable` 获得的值。

```

>>> seasons = ['Spring', 'Summer', 'Fall', 'Winter']
>>> list(enumerate(seasons))
[(0, 'Spring'), (1, 'Summer'), (2, 'Fall'), (3, 'Winter')]
>>> list(enumerate(seasons, start=1))
[(1, 'Spring'), (2, 'Summer'), (3, 'Fall'), (4, 'Winter')]

```

等价于：

```

def enumerate(sequence, start=0):
    n = start
    for elem in sequence:
        yield n, elem
        n += 1

```

`eval(expression, globals=None, locals=None)`

实参是一个字符串，以及可选的 `globals` 和 `locals`。`globals` 实参必须是一个字典。`locals` 可以是任何映射对象。

`expression` 参数会作为一个 Python 表达式（从技术上说是一个条件列表）被解析并求值，使用 `globals` 和 `locals` 字典作为全局和局部命名空间。如果 `globals` 字典存在且不包含以 `__builtins__` 为键的值，则会在解析 `expression` 之前插入以此为键的对内置模块 `builtins` 的字典的引用。这意味着 `expression` 通常具有对标准 `builtins` 模块的完全访问权限且受限的环境会被传播。如果省略 `locals` 字典则其默认值为 `globals` 字典。如果两个字典同时省略，表达式会在 `eval()` 被调用的环境中执行。返回值为表达式求值的结果。语法错误将作为异常被报告。例如：

```
>>> x = 1
>>> eval('x+1')
2
```

这个函数也可以用来执行任何代码对象（如`compile()`创建的）。这种情况下，参数是代码对象，而不是字符串。如果编译该对象时的 *mode* 实参是 `'exec'` 那么`eval()` 返回值为 `None`。

提示：`exec()` 函数支持动态执行语句。`globals()` 和 `locals()` 函数各自返回当前的全局和本地字典，因此您可以将它们传递给`eval()` 或`exec()` 来使用。

另外可以参阅`ast.literal_eval()`，该函数可以安全执行仅包含文字的表达式字符串。

exec(*object*[, *globals*[, *locals*]])

这个函数支持动态执行 Python 代码。*object* 必须是字符串或者代码对象。如果是字符串，那么该字符串将被解析为一系列 Python 语句并执行（除非发生语法错误）。¹ 如果是代码对象，它将被直接执行。在任何情况下，被执行的代码都需要和文件输入一样是有效的（见参考手册中关于文件输入的章节）。请注意即使在传递给`exec()` 函数的代码的上下文中，`return` 和 `yield` 语句也不能在函数定义之外使用。该函数返回值为 `None`。

无论哪种情况，如果省略了可选参数，代码将在当前范围内执行。如果提供了 *globals* 参数，就必须是字典类型，而且会被用作全局和本地变量。如果同时提供了 *globals* 和 *locals* 参数，它们分别被用作全局和本地变量。如果提供了 *locals* 参数，则它可以是任何映射型的对象。请记住在模块层级，全局和本地变量是相同的字典。如果 `exec` 有两个不同的 *globals* 和 *locals* 对象，代码就像嵌入在类定义中一样执行。

如果 *globals* 字典不包含 `__builtins__` 键值，则将为该键插入对内置 `builtins` 模块字典的引用。因此，在将执行的代码传递给`exec()` 之前，可以通过将自己的 `__builtins__` 字典插入到 *globals* 中来控制可以使用哪些内置代码。

注解： 内置`globals()` 和`locals()` 函数各自返回当前的全局和本地字典，因此可以将它们传递给`exec()` 的第二个和第三个实参。

注解： 默认情况下，*locals* 的行为如下面`locals()` 函数描述的一样：不要试图改变默认的 *locals* 字典。如果您想在`exec()` 函数返回时知道代码对 *locals* 的变动，请明确地传递 *locals* 字典。

filter(*function*, *iterable*)

用 *iterable* 中函数 *function* 返回真的那些元素，构建一个新的迭代器。*iterable* 可以是一个序列，一个支持迭代的容器，或一个迭代器。如果 *function* 是 `None`，则会假设它是一个身份函数，即 *iterable* 中所有返回假的元素会被移除。

请注意，`filter(function, iterable)` 相当于一个生成器表达式，当 *function* 不是 `None` 的时候为 `(item for item in iterable if function(item))`；*function* 是 `None` 的时候为 `(item for item in iterable if item)`。

请参阅`itertools.filterfalse()` 了解，只有 *function* 返回 `false` 时才选取 *iterable* 中元素的补充函数。

class float(*x*)

返回从数字或字符串 *x* 生成的浮点数。

如果实参是字符串，则它必须是包含十进制数字的字符串，字符串前面可以有符号，之前也可以有空格。可选的符号有 `'+'` 和 `'-'`；`'+'` 对创建的值没有影响。实参也可以是 `NaN`（非数字）、正负无穷大的字符串。确切地说，除去首尾的空格后，输入必须遵循以下语法：

¹ 解析器只接受 Unix 风格的行结束符。如果您从文件中读取代码，请确保用换行符转换模式转换 Windows 或 Mac 风格的换行符。

```

sign          ::=  "+" | "-"
infinity      ::=  "Infinity" | "inf"
nan           ::=  "nan"
numeric_value ::=  floatnumber | infinity | nan
numeric_string ::= [sign] numeric_value

```

这里，`floatnumber` 是 Python 浮点数的字符串形式，详见 [floating](#)。字母大小写都可以，例如，“inf”、“Inf”、“INFINITY”、“iNfINity”都可以表示正无穷大。

另一方面，如果实参是整数或浮点数，则返回具有相同值（在 Python 浮点精度范围内）的浮点数。如果实参在 Python 浮点精度范围外，则会触发 `OverflowError`。

对于一般的 Python 对象 `x`，`float(x)` 指派给 `x.__float__()`。

如果没有实参，则返回 `0.0`。

例如：

```

>>> float('+1.23')
1.23
>>> float('  -12345\n')
-12345.0
>>> float('1e-003')
0.001
>>> float('+1E6')
1000000.0
>>> float('-Infinity')
-inf

```

数字类型—`int`、`float`、`complex` 描述了浮点类型。

在 3.6 版更改：您可以使用下划线将代码文字中的数字进行分组。

format (*value* [, *format_spec*])

将 *value* 转换为 *format_spec* 控制的“格式化”表示。*format_spec* 的解释取决于 *value* 实参的类型，但是大多数内置类型使用标准格式化语法：[格式规格迷你语言](#)。

默认的 *format_spec* 是一个空字符串，它通常和调用 `str(value)` 的结果相同。

调用 `format(value, format_spec)` 会转换成 `type(value).__format__(value, format_spec)`，所以实例字典中的 `__format__()` 方法将不会调用。如果搜索到 `object` 有这个方法但 *format_spec* 不为空，*format_spec* 或返回值不是字符串，会触发 `TypeError` 异常。

在 3.4 版更改：当 *format_spec* 不是空字符串时，`object().__format__(format_spec)` 会触发 `TypeError`。

class frozenset ([*iterable*])

返回一个新的 `frozenset` 对象，它包含可选参数 *iterable* 中的元素。`frozenset` 是一个内置的类。有关此类的文档，请参阅 `frozenset` 和 [集合类型—set, frozenset](#)。

请参阅内建的 `set`、`list`、`tuple` 和 `dict` 类，以及 `collections` 模块来了解其它的容器。

getattr (*object*, *name* [, *default*])

返回对象命名属性的值。*name* 必须是字符串。如果该字符串是对象的属性之一，则返回该属性的值。例如，`getattr(x, 'foobar')` 等同于 `x.foobar`。如果指定的属性不存在，且提供了 *default* 值，则返回它，否则触发 `AttributeError`。

globals ()

返回表示当前全局符号表的字典。这总是当前模块的字典（在函数或方法中，不是调用它的模块，而是定义它的模块）。

hasattr (*object*, *name*)

该实参是一个对象和一个字符串。如果字符串是对象的属性之一的名称，则返回 `True`，否则返回 `False`。（此功能是通过调用 `getattr(object, name)` 看是否有 `AttributeError` 异常来实现的。）

hash (*object*)

返回该对象的哈希值（如果它有的话）。哈希值是整数。它们在字典查找元素时用来快速比较字典的键。相同大小的数字变量有相同的哈希值（即使它们类型不同，如 `1` 和 `1.0`）。

注解： 如果对象实现了自己的 `__hash__()` 方法，请注意，`hash()` 根据机器的字长来截断返回值。另请参阅 `__hash__()`。

help ([*object*])

启动内置的帮助系统（此函数主要在交互式中使用）。如果没有实参，解释器控制台里会启动交互式帮助系统。如果实参是一个字符串，则在模块、函数、类、方法、关键字或文档主题中搜索该字符串，并在控制台上打印帮助信息。如果实参是其他任意对象，则会生成该对象的帮助页。

该函数通过 `site` 模块加入到内置命名空间。

在 3.4 版更改: `pydoc` 和 `inspect` 的变更使得可调用对象的签名信息更加全面和一致。

hex (*x*)

将整数转换为以 “0x” 为前缀的小写十六进制字符串。如果 *x* 不是 Python `int` 对象，则必须定义返回整数的 `__index__()` 方法。一些例子：

```
>>> hex(255)
'0xff'
>>> hex(-42)
'-0x2a'
```

如果要将整数转换为大写或小写的十六进制字符串，并可选择有无 “0x” 前缀，则可以使用如下方法：

```
>>> '%#x' % 255, '%x' % 255, '%X' % 255
('0xff', 'ff', 'FF')
>>> format(255, '#x'), format(255, 'x'), format(255, 'X')
('0xff', 'ff', 'FF')
>>> f'{255:#x}', f'{255:x}', f'{255:X}'
('0xff', 'ff', 'FF')
```

另见 `format()` 获取更多信息。

另请参阅 `int()` 将十六进制字符串转换为以 16 为基数的整数。

注解： 如果要获取浮点数的十六进制字符串形式，请使用 `float.hex()` 方法。

id (*object*)

返回对象的 “标识值”。该值是一个整数，在此对象的生命周期中保证是唯一且恒定的。两个生命期不重叠的对象可能具有相同的 `id()` 值。

CPython implementation detail: This is the address of the object in memory.

input ([*prompt*])

如果存在 *prompt* 实参，则将其写入标准输出，末尾不带换行符。接下来，该函数从输入中读取一行，将其转换为字符串（除了末尾的换行符）并返回。当读取到 EOF 时，则触发 `EOFError`。例如：

```
>>> s = input('--> ')
--> Monty Python's Flying Circus
>>> s
"Monty Python's Flying Circus"
```

如果加载了 `readline` 模块, `input()` 将使用它来提供复杂的行编辑和历史记录功能。

class int (x=0)

class int (x, base=10)

返回一个使用数字或字符串 `x` 生成的整数对象, 或者没有实参的时候返回 0。如果 `x` 定义了 `__int__()`, `int(x)` 返回 `x.__int__()`。如果 `x` 定义了 `__trunc__()`, 它返回 `x.__trunc__()`。对于浮点数, 它向零舍入。

如果 `x` 不是数字, 或者有 `base` 参数, `x` 必须是字符串、`bytes`、表示进制为 `base` 的整数字面值的 `bytearray` 实例。该文字前可以有 + 或 - (中间不能有空格), 前后可以有空格。一个进制为 `n` 的数字包含 0 到 `n-1` 的数, 其中 a 到 z (或 A 到 Z) 表示 10 到 35。默认的 `base` 为 10, 允许的进制有 0、2-36。2、8、16 进制的数字可以在代码中用 `0b/0B`、`0o/0O`、`0x/0X` 前缀来表示。进制为 0 将按照代码的字面量来精确解释, 最后的结果会是 2、8、10、16 进制中的一个。所以 `int('010', 0)` 是非法的, 但 `int('010')` 和 `int('010', 8)` 是合法的。

整数类型定义请参阅 [数字类型—int, float, complex](#)。

在 3.4 版更改: 如果 `base` 不是 `int` 的实例, 但 `base` 对象有 `base.__index__` 方法, 则会调用该方法来获取进制数。以前的版本使用 `base.__int__` 而不是 `base.__index__`。

在 3.6 版更改: 您可以使用下划线将代码文字中的数字进行分组。

isinstance (object, classinfo)

如果 `object` 实参是 `classinfo` 实参的实例, 或者是 (直接、间接或虚拟) 子类的实例, 则返回 `true`。如果 `object` 不是给定类型的对象, 函数始终返回 `false`。如果 `classinfo` 是对象类型 (或多个递归元组) 的元组, 如果 `object` 是其中的任何一个的实例则返回 `true`。如果 `classinfo` 既不是类型, 也不是类型元组或类型的递归元组, 那么会触发 `TypeError` 异常。

issubclass (class, classinfo)

如果 `class` 是 `classinfo` 的子类 (直接、间接或虚拟的), 则返回 `true`。`classinfo` 可以是类对象的元组, 此时 `classinfo` 中的每个元素都会被检查。其他情况, 会触发 `TypeError` 异常。

iter (object[, sentinel])

返回一个 `iterator` 对象。根据是否存在第二个实参, 第一个实参的解释是非常不同的。如果没有第二个实参, `object` 必须是支持迭代协议 (有 `__iter__()` 方法) 的集合对象, 或必须支持序列协议 (有 `__getitem__()` 方法, 且数字参数从 0 开始)。如果它不支持这些协议, 会触发 `TypeError`。如果有第二个实参 `sentinel`, 那么 `object` 必须是可调用的对象。这种情况下生成的迭代器, 每次迭代调用它的 `__next__()` 方法时都会不带实参地调用 `object`; 如果返回的结果是 `sentinel` 则触发 `StopIteration`, 否则返回调用结果。

另请参阅 [迭代器类型](#)。

One useful application of the second form of `iter()` is to read lines of a file until a certain line is reached. The following example reads a file until the `readline()` method returns an empty string:

```
with open('mydata.txt') as fp:
    for line in iter(fp.readline, ''):
        process_line(line)
```

len (s)

返回对象的长度 (元素个数)。实参可以是序列 (如 `string`、`bytes`、`tuple`、`list` 或 `range` 等) 或集合 (如 `dictionary`、`set` 或 `frozen set` 等)。

class list ([iterable])

除了是函数, `list` 也是可变序列类型, 详情请参阅 [列表和序列类型—list, tuple, range](#)。

locals()

Update and return a dictionary representing the current local symbol table. Free variables are returned by `locals()` when it is called in function blocks, but not in class blocks.

注解： 不要更改此字典的内容；更改不会影响解释器使用的局部变量或自由变量的值。

map(function, iterable, ...)

产生一个将 `function` 应用于迭代器中所有元素并返回结果的迭代器。如果传递了额外的 `iterable` 实参，`function` 必须接受相同个数的实参，并使用所有迭代器中并行获取的元素。当有多个迭代器时，最短的迭代器耗尽则整个迭代结束。如果函数的输入已经是元组实参，请参阅 `itertools.starmap()`。

max(iterable, *, key, default)**max(arg1, arg2, *args, key)**

返回可迭代对象中最大的元素，或者返回两个及以上实参中最大的。

如果只提供了一个位置参数，它必须是非空 `iterable`，返回可迭代对象中最大的元素；如果提供了两个及以上的位置参数，则返回最大的位置参数。

有两个可选只能用关键字的实参。`key` 实参指定排序函数用的参数，如传给 `list.sort()` 的。`default` 实参是当可迭代对象为空时返回的值。如果可迭代对象为空，并且没有给 `default`，则会触发 `ValueError`。

如果有多个最大元素，则此函数将返回第一个找到的。这和其他稳定排序工具如 `sorted(iterable, key=keyfunc, reverse=True)[0]` 和 `heapq.nlargest(1, iterable, key=keyfunc)` 保持一致。

3.4 新版功能: keyword-only 实参 `default`。

memoryview(obj)

返回由给定实参创建的“内存视图”对象。有关详细信息，请参阅[内存视图](#)。

min(iterable, *, key, default)**min(arg1, arg2, *args, key)**

返回可迭代对象中最小的元素，或者返回两个及以上实参中最小的。

如果只提供了一个位置参数，它必须是 `iterable`，返回可迭代对象中最小的元素；如果提供了两个及以上的位置参数，则返回最小的位置参数。

有两个可选只能用关键字的实参。`key` 实参指定排序函数用的参数，如传给 `list.sort()` 的。`default` 实参是当可迭代对象为空时返回的值。如果可迭代对象为空，并且没有给 `default`，则会触发 `ValueError`。

如果有多个最小元素，则此函数将返回第一个找到的。这和其他稳定排序工具如 `sorted(iterable, key=keyfunc)[0]` 和 `heapq.nsmallest(1, iterable, key=keyfunc)` 保持一致。

3.4 新版功能: keyword-only 实参 `default`。

next(iterator[, default])

通过调用 `iterator` 的 `__next__()` 方法获取下一个元素。如果迭代器耗尽，则返回给定的 `default`，如果没有默认值则触发 `StopIteration`。

class object

返回一个没有特征的新对象。`object` 是所有类的基类。它具有所有 Python 类实例的通用方法。这个函数不接受任何实参。

注解： 由于 `object` 没有 `__dict__`，因此无法将任意属性赋给 `object` 的实例。

oct(x)

将一个整数转变为一个前缀为“0o”的八进制字符串。结果是一个合法的 Python 表达式。如果 `x` 不是 Python 的 `int` 对象，那它需要定义 `__index__()` 方法返回一个整数。一些例子：

```
>>> oct(8)
'0o10'
>>> oct(-56)
'-0o70'
```

如果要整数转换为八进制字符串，并可选择有无“0o”前缀，则可以使用如下方法：

```
>>> '%#o' % 10, '%o' % 10
('0o12', '12')
>>> format(10, '#o'), format(10, 'o')
('0o12', '12')
>>> f'{10:#o}', f'{10:o}'
('0o12', '12')
```

另见 `format()` 获取更多信息。

open (*file*, *mode*='r', *buffering*=-1, *encoding*=None, *errors*=None, *newline*=None, *closefd*=True, *opener*=None)

打开 *file* 并返回对应的 *file object*。如果该文件不能打开，则触发 `OSError`。

file 是一个 *path-like object*，表示将要打开的文件的路径（绝对路径或者当前工作目录的相对路径），也可以是要被封装的整数类型文件描述符。（如果是文件描述符，它会随着返回的 I/O 对象关闭而关闭，除非 *closefd* 被设为 `False`。）

mode 是一个可选字符串，用于指定打开文件的模式。默认值是 'r'，这意味着它以文本模式打开并读取。其他常见模式有：写入 'w'（截断已经存在的文件）；排它性创建 'x'；追加写 'a'（在一些 Unix 系统上，无论当前的文件指针在什么位置，所有写入都会追加到文件末尾）。在文本模式，如果 *encoding* 没有指定，则根据平台来决定使用的编码：使用 `locale.getpreferredencoding(False)` 来获取本地编码。（要读取和写入原始字节，请使用二进制模式并不要指定 *encoding*。）可用的模式有：

字符	意义
'r'	读取（默认）
'w'	写入，并先截断文件
'x'	排它性创建，如果文件已存在则失败
'a'	写入，如果文件存在则在末尾追加
'b'	二进制模式
't'	文本模式（默认）
'+'	更新磁盘文件（读取并写入）
'U'	<i>universal newlines mode</i> (deprecated)

默认的模式是 'r'（打开并读取文本，同 'rt'）。对于二进制写入，'w+b' 模式打开并把文件截断成 0 字节；'r+b' 则不会截断。

正如在概述中提到的，Python 区分二进制和文本 I/O。以二进制模式打开的文件（包括 *mode* 参数中的 'b'）返回的内容为 `bytes` 对象，不进行任何解码。在文本模式下（默认情况下，或者在 **mode** 参数中包含 't'）时，文件内容返回为 *str*，首先使用指定的 *encoding*（如果给定）或者使用平台默认的字节编码解码。

注解：Python 不依赖于底层操作系统的文本文件概念；所有处理都由 Python 本身完成，因此与平台无关。

buffering 是一个可选的整数，用于设置缓冲策略。传递 0 以切换缓冲关闭（仅允许在二进制模式下），1 选择行缓冲（仅在文本模式下可用），并且 >1 的整数以指示固定大小的块缓冲区的大小（以字节为单位）。如果没有给出 *buffering* 参数，则默认缓冲策略的工作方式如下：

- 二进制文件以固定大小的块进行缓冲；使用启发式方法选择缓冲区的大小，尝试确定底层设备的“块大小”或使用 `io.DEFAULT_BUFFER_SIZE`。在许多系统上，缓冲区的长度通常为 4096 或 8192 字节。
- “交互式”文本文件（`isatty()` 返回 True 的文件）使用行缓冲。其他文本文件使用上述策略用于二进制文件。

`encoding` 是用于解码或编码文件的编码的名称。这应该只在文本模式下使用。默认编码是依赖于平台的（不管 `locale.getpreferredencoding()` 返回何值），但可以使用任何 Python 支持的 *text encoding*。有关支持的编码列表，请参阅 `codecs` 模块。

`errors` 是一个可选的字符串参数，用于指定如何处理编码和解码错误 - 这不能在二进制模式下使用。可以使用各种标准错误处理程序（列在 *Error Handlers*），但是使用 `codecs.register_error()` 注册的任何错误处理名称也是有效的。标准名称包括：

- 如果存在编码错误，'strict' 会引发 `ValueError` 异常。默认值 `None` 具有相同的效果。
- 'ignore' 忽略错误。请注意，忽略编码错误可能会导致数据丢失。
- 'replace' 会将替换标记（例如 '?'）插入有错误数据的地方。
- 'surrogateescape' 将表示任何不正确的字节作为 Unicode 专用区中的代码点，范围从 U+DC80 到 U+DCFF。当在写入数据时使用 `surrogateescape` 错误处理程序时，这些私有代码点将被转回到相同的字节中。这对于处理未知编码的文件很有用。
- 只有在写入文件时才支持 'xmlcharrefreplace'。编码不支持的字符将替换为相应的 XML 字符引用 `&#nnn;`。
- 'backslashreplace' 用 Python 的反向转义序列替换格式错误的数据。
- 'namereplace'（也只在编写时支持）用 `\N{...}` 转义序列替换不支持的字符。

`newline` 控制 *universal newlines* 模式如何生效（它仅适用于文本模式）。它可以是 `None`，`''`，`'\n'`，`'\r'` 和 `'\r\n'`。它的工作原理：

- 从流中读取输入时，如果 `newline` 为 `None`，则启用通用换行模式。输入中的行可以以 `'\n'`，`'\r'` 或 `'\r\n'` 结尾，这些行被翻译成 `'\n'` 在返回调用者之前。如果它是 `''`，则启用通用换行模式，但行结尾将返回给调用者未翻译。如果它具有任何其他合法值，则输入行仅由给定字符串终止，并且行结尾将返回给未调用的调用者。
- 将输出写入流时，如果 `newline` 为 `None`，则写入的任何 `'\n'` 字符都将转换为系统默认行分隔符 `os.linesep`。如果 `newline` 是 `''` 或 `'\n'`，则不进行翻译。如果 `newline` 是任何其他合法值，则写入的任何 `'\n'` 字符将被转换为给定的字符串。

如果 `closefd` 是 `False` 并且给出了文件描述符而不是文件名，那么当文件关闭时，底层文件描述符将保持打开状态。如果给出文件名则 `closefd` 必须为 `True`（默认值），否则将引发错误。

可以通过传递可调用的 *opener* 来使用自定义开启器。然后通过使用参数（`file`，`flags`）调用 *opener* 获得文件对象的基础文件描述符。*opener* 必须返回一个打开的文件描述符（使用 `os.open as opener` 时与传递 `None` 的效果相同）。

新创建的文件是 *不可继承的*。

下面的示例使用 `os.open()` 函数的 `dir_fd` 的形参，从给定的目录中用相对路径打开文件：

```
>>> import os
>>> dir_fd = os.open('somedir', os.O_RDONLY)
>>> def opener(path, flags):
...     return os.open(path, flags, dir_fd=dir_fd)
...
>>> with open('spamspam.txt', 'w', opener=opener) as f:
...     print('This will be written to somedir/spamspam.txt', file=f)
```

(下页继续)

(续上页)

```
...
>>> os.close(dir_fd)  # don't leak a file descriptor
```

`open()` 函数所返回的 *file object* 类型取决于所用模式。当使用 `open()` 以文本模式 ('w', 'r', 'wt', 'rt' 等) 打开文件时, 它将返回 `io.TextIOBase` (特别是 `io.TextIOWrapper`) 的一个子类。当使用缓冲以二进制模式打开文件时, 返回的类是 `io.BufferedIOBase` 的一个子类。具体的类会有多种: 在只读的二进制模式下, 它将返回 `io.BufferedReader`; 在写入二进制和追加二进制模式下, 它将返回 `io.BufferedWriter`, 而在读/写模式下, 它将返回 `io.BufferedRandom`。当禁用缓冲时, 则会返回原始流, 即 `io.RawIOBase` 的一个子类 `io.FileIO`。

另请参阅文件操作模块, 例如 `fileinput`、`io` (声明了 `open()`)、`os`、`os.path`、`tempfile` 和 `shutil`。

在 3.3 版更改:

- 增加了 `opener` 形参。
- 增加了 'x' 模式。
- 过去触发的 `IOError`, 现在是 `OSError` 的别名。
- 如果文件已存在但使用了排它性创建模式 ('x'), 现在会触发 `FileExistsError`。

在 3.4 版更改:

- 文件现在禁止继承。

Deprecated since version 3.4, will be removed in version 4.0: 'U' 模式。

在 3.5 版更改:

- 如果系统调用被中断, 但信号处理程序没有触发异常, 此函数现在会重试系统调用, 而不是触发 `InterruptedError` 异常 (原因详见 [PEP 475](#))。
- 增加了 'namereplace' 错误处理接口。

在 3.6 版更改:

- 增加对实现了 `os.PathLike` 对象的支持。
- 在 Windows 上, 打开一个控制台缓冲区将返回 `io.RawIOBase` 的子类, 而不是 `io.FileIO`。

`ord(c)`

对表示单个 Unicode 字符的字符串, 返回代表它 Unicode 码点的整数。例如 `ord('a')` 返回整数 97, `ord('€')` (欧元符号) 返回 8364。这是 `chr()` 的逆函数。

`pow(x, y[, z])`

返回 x 的 y 次幂; 如果 z 存在, 则对 z 取余 (比直接 `pow(x, y) % z` 计算更高效)。两个参数形式的 `pow(x, y)` 等价于幂运算符: `x**y`。

参数必须为数值类型。对于混用的操作数类型, 则适用二元算术运算符的类型强制转换规则。对于 `int` 操作数, 结果具有与操作数相同的类型 (转换后), 除非第二个参数为负值; 在这种情况下, 所有参数将被转换为浮点数并输出浮点数结果。例如, `10**2` 返回 100, 但 `10**-2` 返回 0.01。如果第二个参数为负值, 则第三个参数必须省略。如果存在 z , 则 x 和 y 必须为整数类型, 且 y 必须为非负数。

`print(*objects, sep=' ', end='\n', file=sys.stdout, flush=False)`

将 `objects` 打印到 `file` 指定的文本流, 以 `sep` 分隔并在末尾加上 `end`。 `sep`, `end`, `file` 和 `flush` 如果存在, 它们必须以关键字参数的形式给出。

所有非关键字参数都会被转换为字符串，就像是执行了 `str()` 一样，并会被写入到流，以 `sep` 且在末尾加上 `end`。`sep` 和 `end` 都必须为字符串；它们也可以为 `None`，这意味着使用默认值。如果没有给出 `objects`，则 `print()` 将只写入 `end`。

`file` 参数必须是一个具有 `write(string)` 方法的对象；如果参数不存在或为 `None`，则将使用 `sys.stdout`。由于要打印的参数会被转换为文本字符串，因此 `print()` 不能用于二进制模式的文件对象。对于这些对象，应改用 `file.write(...)`。

输出是否被缓存通常决定于 `file`，但如果 `flush` 关键字参数为真值，流会被强制刷新。

在 3.3 版更改：增加了 `flush` 关键字参数。

class property (`fget=None, fset=None, fdel=None, doc=None`)

返回 `property` 属性。

`fget` 是获取属性值的函数。`fset` 是用于设置属性值的函数。`fdel` 是用于删除属性值的函数。并且 `doc` 为属性对象创建文档字符串。

一个典型的用法是定义一个托管属性 `x`：

```
class C:
    def __init__(self):
        self._x = None

    def getx(self):
        return self._x

    def setx(self, value):
        self._x = value

    def delx(self):
        del self._x

    x = property(getx, setx, delx, "I'm the 'x' property.")
```

如果 `c` 是 `C` 的实例，`c.x` 将调用 `getter`，`c.x = value` 将调用 `setter`，`del c.x` 将调用 `deleter`。

如果给出，`doc` 将成为该 `property` 属性的文档字符串。否则该 `property` 将拷贝 `fget` 的文档字符串（如果存在）。这令使用 `property()` 作为 *decorator* 来创建只读的特征属性可以很容易地实现：

```
class Parrot:
    def __init__(self):
        self._voltage = 100000

    @property
    def voltage(self):
        """Get the current voltage."""
        return self._voltage
```

以上 `@property` 装饰器会将 `voltage()` 方法转化为一个具有相同名称的只读属性的“getter”，并将 `voltage` 的文档字符串设置为“Get the current voltage.”

特征属性对象具有 `getter`、`setter` 以及 `deleter` 方法，它们可用作装饰器来创建该特征属性的副本，并将相应的访问函数设为所装饰的函数。这最好是用一个例子来解释：

```
class C:
    def __init__(self):
        self._x = None

    @property
```

(下页继续)

(续上页)

```

def x(self):
    """I'm the 'x' property."""
    return self._x

@x.setter
def x(self, value):
    self._x = value

@x.deleter
def x(self):
    del self._x

```

上述代码与第一个例子完全等价。注意一定要给附加函数与原始的特征属性相同的名称 (在本例中为 `x`。)

返回的特征属性对象同样具有与构造器参数相对应的属性 `fget`, `fset` 和 `fdel`。

在 3.5 版更改: 特性属性对象的文档字符串现在是可写的。

range (*stop*)

range (*start*, *stop* [, *step*])

虽然被称为函数, 但 *range* 实际上是一个不可变的序列类型, 参见在 *range* 对象与序列类型—*list*, *tuple*, *range* 中的文档说明。

repr (*object*)

返回包含一个对象的可打印表示形式的字符串。对于许多类型来说, 该函数会尝试返回的字符串将会与该对象被传递给 `eval()` 时所生成的对象具有相同的值, 在其他情况下表示形式会是一个括在尖括号中的字符串, 其中包含对象类型的名称与通常包括对象名称和地址的附加信息。类可以通过定义 `__repr__()` 方法来控制此函数为它的实例所返回的内容。

reversed (*seq*)

返回一个反向的 *iterator*。 *seq* 必须是一个具有 `__reversed__()` 方法的对象或者是支持该序列协议 (具有从 “0” 开始的整数类型参数的 `__len__()` 方法和 `__getitem__()` 方法)。

round (*number* [, *ndigits*])

返回 *number* 舍入到小数点后 *ndigits* 位精度的值。如果 *ndigits* 被省略或为 `None`, 则返回最接近输入值的整数。

对于支持 `round()` 的内置类型, 值会被舍入到最接近的 10 的负 *ndigits* 次幂的倍数; 如果与两个倍数的距离相等, 则选择偶数 (因此, `round(0.5)` 和 `round(-0.5)` 均为 0 而 `round(1.5)` 为 2)。任何整数值都可作为有效的 *ndigits* (正数、零或负数)。如果 *ndigits* 被省略或为 `None` 则返回值将为整数。否则返回值与 *number* 的类型相同。

对于一般的 Python 对象 *number*, `round` 将委托给 `number.__round__`。

注解: 对浮点数执行 `round()` 的行为可能会令人惊讶: 例如, `round(2.675, 2)` 将给出 2.67 而不是期望的 2.68。这不算是程序错误: 这一结果是由于大多数十进制小数实际上都不能以浮点数精确地表示。请参阅 `tut-fp-issues` 了解更多信息。

class set ([*iterable*])

返回一个新的 *set* 对象, 可以选择带有从 *iterable* 获取的元素。 *set* 是一个内置类型。请查看 *set* 和集合类型—*set*, *frozenset* 获取关于这个类的文档。

有关其他容器请参看内置的 *frozenset*, *list*, *tuple* 和 *dict* 类, 以及 *collections* 模块。

setattr (*object*, *name*, *value*)

此函数与 `getattr()` 两相对应。其参数为一个对象、一个字符串和一个任意值。字符串指定一个现有属

性或者新增属性。函数会将值赋给该属性，只要对象允许这种操作。例如，`setattr(x, 'foobar', 123)` 等价于 `x.foobar = 123`。

class slice (*stop*)

class slice (*start, stop* [, *step*])

返回一个表示由 `range(start, stop, step)` 所指定索引集的 *slice* 对象。其中 *start* 和 *step* 参数默认为 `None`。切片对象具有仅会返回对应参数值（或其默认值）的只读数据属性 *start*, *stop* 和 *step*。它们没有其他的显式功能；不过它们会被 NumPy 以及其他第三方扩展所使用。切片对象也会在使用扩展索引语法时被生成。例如：`a[start:stop:step]` 或 `a[start:stop, i]`。请参阅 `itertools.islice()` 了解返回迭代器的一种替代版本。

sorted (*iterable*, *, *key=None*, *reverse=False*)

根据 *iterable* 中的项返回一个新的已排序列表。

具有两个可选参数，它们都必须指定为关键字参数。

key 指定带有单个参数的函数，用于从 *iterable* 的每个元素中提取用于比较的键（例如 `key=str.lower`）。默认值为 `None`（直接比较元素）。

reverse 为一个布尔值。如果设为 `True`，则每个列表元素将按反向顺序比较进行排序。

使用 `functools.cmp_to_key()` 可将老式的 *cmp* 函数转换为 *key* 函数。

内置的 `sorted()` 确保是稳定的。如果一个排序确保不会改变比较结果相等的元素的相对顺序就称其为稳定——这有利于进行多重排序（例如先按部门、再按薪级排序）。

有关排序示例和简要排序教程，请参阅 `sortinghowto`。

@staticmethod

将方法转换为静态方法。

静态方法不会接收隐式的第一个参数。要声明一个静态方法，请使用此语法

```
class C:
    @staticmethod
    def f(arg1, arg2, ...): ...
```

The `@staticmethod` form is a function *decorator* – see the description of function definitions in function for details.

It can be called either on the class (such as `C.f()`) or on an instance (such as `C().f()`). The instance is ignored except for its class.

Python 中的静态方法与 Java 或 C++ 中的静态方法类似。另请参阅 `classmethod()`，用于创建备用类构造函数的变体。

像所有装饰器一样，也可以像常规函数一样调用 `staticmethod`，并对其结果执行某些操作。比如某些情况下需要从类主体引用函数并且您希望避免自动转换为实例方法。对于这些情况，请使用此语法：

```
class C:
    builtin_open = staticmethod(open)
```

For more information on static methods, consult the documentation on the standard type hierarchy in types.

class str (*object=""*)

class str (*object=b", encoding='utf-8', errors='strict'*)

返回一个 *str* 版本的 *object*。有关详细信息，请参阅 `str()`。

str 是内置字符串 *class*。更多关于字符串的信息查看 [文本序列类型—str](#)。

sum (*iterable* [, *start*])

从 *start* 开始自左向右对 *iterable* 中的项求和并返回总计值。*start* 默认为 0。*iterable* 的项通常为数字，开始值则不允许为字符串。

对某些用例来说，存在`sum()`的更好替代。拼接字符串序列的更好更快方式是调用`''.join(sequence)`。要以扩展精度对浮点值求和，请参阅`math.fsum()`。要拼接一系列可迭代对象，请考虑使用`itertools.chain()`。

super (`[type[, object-or-type]]`)

返回一个代理对象，它会将方法调用委托给 `type` 指定的父类或兄弟类。这对于访问已在类中被重载的继承方法很有用。搜索顺序与`getattr()`所使用的相同，只是 `type` 指定的类型本身会被跳过。

`type` 的`__mro__` 属性列出了`getattr()` 和`super()` 所使用的方法解析顺序。该属性是动态的，可以在继承层级结构更新的时候任意改变。

如果省略第二个参数，则返回的超类对象是未绑定的。如果第二个参数为一个对象，则`isinstance(obj, type)` 必须为真值。如果第二个参数为一个类型，则`issubclass(type2, type)` 必须为真值（这适用于类方法）。

`super` 有两个典型用例。在具有单继承的类层级结构中，`super` 可用来引用父类而不必显式地指定它们的名称，从而令代码更易维护。这种用法与其他编程语言中 `super` 的用法非常相似。

第二个用例是在动态执行环境中支持协作多重继承。此用例为 Python 所独有，在静态编译语言或仅支持单继承的语言中是不存在的。这使得实现“菱形图”成为可能，在这时会有多个基类实现相同的方法。好的设计强制要求这种方法在每个情况下具有相同的调用签名（因为调用顺序是在运行时确定的，也因为该顺序要适应类层级结构的更改，还因为该顺序可能包含在运行时之前未知的兄弟类）。

对于以上两个用例，典型的超类调用看起来是这样的：

```
class C(B):
    def method(self, arg):
        super().method(arg)      # This does the same thing as:
                                # super(C, self).method(arg)
```

请注意`super()` 是作为显式加点属性查找的绑定过程的一部分来实现的，例如`super().__getitem__(name)`。它做到这一点是通过实现自己的`__getattribute__()` 方法，这样就能以可预测的顺序搜索类，并且支持协作多重继承。对应地，`super()` 在像`super()[name]` 这样使用语句或操作符进行隐式查找时则未被定义。

还要注意的，除了零个参数的形式以外，`super()` 并不限于在方法内部调用。两个参数的形式明确指定参数并进行相应的引用。零个参数的形式仅适用于类定义内部，因为编译器需要填入必要的细节以正确地检索到被定义的类，还需要为普通访问当前实例。

对于有关如何使用`super()` 来如何设计协作类的实用建议，请参阅 使用 `super()` 的指南。

tuple (`[iterable]`)

虽然被称为函数，但`tuple` 实际上是一个不可变的序列类型，参见在元组 与 序列类型—`list`, `tuple`, `range` 中的文档说明。

class type (`object`)

class type (`name, bases, dict`)

传入一个参数时，返回 `object` 的类型。返回值是一个 `type` 对象，通常与`object.__class__` 所返回的对象相同。

推荐使用`isinstance()` 内置函数来检测对象的类型，因为它会考虑子类的情况。

传入三个参数时，返回一个新的 `type` 对象。这在本质上是 `class` 语句的一种动态形式。`name` 字符串即类名并且会成为`__name__` 属性；`bases` 元组列出基类并且会成为`__bases__` 属性；而 `dict` 字典为包含类主体定义的命名空间并且会被复制到一个标准字典成为`__dict__` 属性。例如，下面两条语句会创建相同的`type` 对象：

```
>>> class X:
...     a = 1
...
>>> X = type('X', (object,), dict(a=1))
```

另请参阅类型对象。

在 3.6 版更改: `type` 的子类如果未重载 `type.__new__`, 将不再能使用一个参数的形式来获取对象的类型。

vars (`[object]`)

返回模块、类、实例或任何其它具有 `__dict__` 属性的对象的 `__dict__` 属性。

模块和实例这样的对象具有可更新的 `__dict__` 属性; 但是, 其它对象的 `__dict__` 属性可能会设为限制写入 (例如, 类会使用 `types.MappingProxyType` 来防止直接更新字典)。

不带参数时, `vars()` 的行为类似 `locals()`。请注意, `locals` 字典仅对于读取起作用, 因为对 `locals` 字典的更新会被忽略。

zip (`*iterables`)

创建一个聚合了来自每个可迭代对象中的元素的迭代器。

返回一个元组的迭代器, 其中的第 *i* 个元组包含来自每个参数序列或可迭代对象的第 *i* 个元素。当所输入可迭代对象中最短的一个被耗尽时, 迭代器将停止迭代。当只有一个可迭代对象参数时, 它将返回一个单元组的迭代器。不带参数时, 它将返回一个空迭代器。相当于:

```
def zip(*iterables):
    # zip('ABCD', 'xy') --> Ax By
    sentinel = object()
    iterators = [iter(it) for it in iterables]
    while iterators:
        result = []
        for it in iterators:
            elem = next(it, sentinel)
            if elem is sentinel:
                return
            result.append(elem)
        yield tuple(result)
```

函数会保证可迭代对象按从左至右的顺序被求值。使得可以通过 `zip(*[iter(s)]*n)` 这样的惯用形式将一系列数据聚类为长度为 *n* 的分组。这将重复 同样的迭代器 *n* 次, 以便每个输出的元组具有第 *n* 次调用该迭代器的结果。它的作用效果就是将输入拆分为长度为 *n* 的数据块。

当你不用关心较长可迭代对象末尾不匹配的值时, 则 `zip()` 只须使用长度不相等的输入即可。如果那些值很重要, 则应改用 `itertools.zip_longest()`。

`zip()` 与 `*` 运算符相结合可以用来拆解一个列表:

```
>>> x = [1, 2, 3]
>>> y = [4, 5, 6]
>>> zipped = zip(x, y)
>>> list(zipped)
[(1, 4), (2, 5), (3, 6)]
>>> x2, y2 = zip(*zip(x, y))
>>> x == list(x2) and y == list(y2)
True
```

__import__ (`name, globals=None, locals=None, fromlist=(), level=0`)

注解: 与 `importlib.import_module()` 不同, 这是一个日常 Python 编程中不需要用到的高级函数。

This function is invoked by the `import` statement. It can be replaced (by importing the `builtins` module and assigning to `builtins.__import__`) in order to change semantics of the `import` statement, but doing so is **strongly** discouraged as it is usually simpler to use import hooks (see [PEP 302](#)) to attain the same goals and does not cause issues with code which assumes the default import implementation is in use. Direct use of `__import__()` is also discouraged in favor of `importlib.import_module()`.

该函数会导入 *name* 模块，有可能使用给定的 *globals* 和 *locals* 来确定如何在包的上下文中解读名称。*fromlist* 给出了应该从由 *name* 指定的模块导入对象或子模块的名称。标准实现完全不使用其 *locals* 参数，而仅使用 *globals* 参数来确定 `import` 语句的包上下文。

level 指定是使用绝对还是相对导入。0 (默认值) 意味着仅执行绝对导入。*level* 为正数值表示相对于模块调用 `__import__()` 的目录，将要搜索的父目录层数 (详情参见 [PEP 328](#))。

当 *name* 变量的形式为 `package.module` 时，通常将会返回最高层级的包 (第一个点号之前的名称)，而不是以 *name* 命名的模块。但是，当给出了非空的 *fromlist* 参数时，则将返回以 *name* 命名的模块。

例如，语句 `import spam` 的结果将为与以下代码作用相同的字节码：

```
spam = __import__('spam', globals(), locals(), [], 0)
```

语句 `import spam.ham` 的结果将为以下调用：

```
spam = __import__('spam.ham', globals(), locals(), [], 0)
```

请注意在这里 `__import__()` 是如何返回顶层模块的，因为这是通过 `import` 语句被绑定到特定名称的对象。

另一方面，语句 `from spam.ham import eggs, sausage as saus` 的结果将为

```
_temp = __import__('spam.ham', globals(), locals(), ['eggs', 'sausage'], 0)
eggs = _temp.eggs
saus = _temp.sausage
```

在这里，`spam.ham` 模块会由 `__import__()` 返回。要导入的对象将从此对象中提取并赋值给它们对应的名称。

如果您只想按名称导入模块 (可能在包中)，请使用 `importlib.import_module()`

在 3.3 版更改: Negative values for *level* are no longer supported (which also changes the default value to 0).

内置常量

有少数的常量存在于内置命名空间中。它们是：

False

`bool` 类型的假值。给 `False` 赋值是非法的并会引发 `SyntaxError`。

True

`bool` 类型的真值。给 `True` 赋值是非法的并会引发 `SyntaxError`。

None

`NoneType` 类型的唯一值。`None` 经常用于表示缺少值，当因为默认参数未传递给函数时。给 `None` 赋值是非法的并会引发 `SyntaxError`。

NotImplemented

二进制特殊方法应返回的特殊值（例如，`__eq__()`、`__lt__()`、`__add__()`、`__rsub__()` 等）表示操作没有针对其他类型实现；为了相同的目的，可以通过就地二进制特殊方法（例如，`__imul__()`、`__righnd__()` 等）返回。它的逻辑值为真。

注解：当二进制（或就地）方法返回“`NotImplemented`”时，解释器将尝试对另一种类型（或其他一些回滚操作，取决于运算符）的反射操作。如果所有尝试都返回“`NotImplemented`”，则解释器将引发适当的异常。错误返回的“`NotImplemented`”将导致误导性错误消息或返回到 Python 代码中的“`NotImplemented`”值。

参见 *Implementing the arithmetic operations* 为例。

注解：`NotImplementedError` 和 `NotImplemented` 不可互换，即使它们有相似的名称和用途。有关何时使用它的详细信息，请参阅 `NotImplementedError`。

Ellipsis

与省略号文字字面“...”相同。特殊值主要与用户定义的容器数据类型的扩展切片语法结合使用。

`__debug__`

如果 Python 没有以 `-O` 选项启动，则此常量为真值。另请参见 `assert` 语句。

注解： 变量名 `None`, `False`, `True` 和 `__debug__` 无法重新赋值（赋值给它们，即使是属性名，将引发 `SyntaxError`），所以它们可以被认为是“真正的”常数。

3.1 由 `site` 模块添加的常量

`site` 模块（在启动期间自动导入，除非给出 `-s` 命令行选项）将几个常量添加到内置命名空间。它们对交互式解释器 `shell` 很有用，并且不应在程序中使用。

quit (`code=None`)

exit (`code=None`)

当打印此对象时，会打印出一条消息，例如 “Use quit() or Ctrl-D (i.e. EOF) to exit”，当调用此对象时，将使用指定的退出代码来引发 `SystemExit`。

copyright

credits

打印或调用的对象分别打印版权或作者的文本。

license

当打印此对象时，会打印出一条消息 “Type license() to see the full license text”，当调用此对象时，将以分页形式显示完整的许可证文本（每次显示一屏）。

以下部分描述了解释器中内置的标准类型。

主要内置类型有数字、序列、映射、类、实例和异常。

有些多项集类是可变的。它们用于添加、移除或重排其成员的方法将原地执行，并不返回特定的项，绝对不会返回多项集实例自身而是返回 `None`。

有些操作受多种对象类型的支持；特别地，实际上所有对象都可以被比较、检测逻辑值，以及转换为字符串（使用 `repr()` 函数或略有差异的 `str()` 函数）。后一个函数是在对象由 `print()` 函数输出时被隐式地调用的。

4.1 逻辑值检测

任何对象都可以进行逻辑值的检测，以便在 `if` 或 `while` 作为条件或是作为下文所述布尔运算的操作数来使用。

一个对象在默认情况下均被视为真值，除非当该对象被调用时其所属类定义了 `__bool__()` 方法且返回 `False` 或是定义了 `__len__()` 方法且返回零。¹ 下面基本完整地列出了会被视为假值的内置对象：

- 被定义为假值的常量: `None` 和 `False`。
- 任何数值类型的零: `0`, `0.0`, `0j`, `Decimal(0)`, `Fraction(0, 1)`
- 空的序列和多项集: `''`, `()`, `[]`, `{}`, `set()`, `range(0)`

产生布尔值结果的运算和内置函数总是返回 `0` 或 `False` 作为假值，`1` 或 `True` 作为真值，除非另行说明。（重要例外：布尔运算 `or` 和 `and` 总是返回其中一个操作数。）

¹ 有关这些特殊方法的额外信息可参看 Python 参考指南 (customization)。

4.2 Boolean Operations —and, or, not

这些属于布尔运算，按优先级升序排列：

运算	结果	注释
<code>x or y</code>	if <i>x</i> is false, then <i>y</i> , else <i>x</i>	(1)
<code>x and y</code>	if <i>x</i> is false, then <i>x</i> , else <i>y</i>	(2)
<code>not x</code>	if <i>x</i> is false, then True, else False	(3)

注释：

- (1) 这是个短路运算符，因此只有在第一个参数为假值时才会对第二个参数求值。
- (2) 这是个短路运算符，因此只有在第一个参数为真值时才会对第二个参数求值。
- (3) `not` 的优先级比非布尔运算符低，因此 `not a == b` 会被解读为 `not (a == b)` 而 `a == not b` 会引发语法错误。

4.3 比较

在 Python 中有八种比较运算符。它们的优先级相同（比布尔运算的优先级高）。比较运算可以任意串连；例如，`x < y <= z` 等价于 `x < y and y <= z`，前者的不同之处在于 *y* 只被求值一次（但在两种情况下当 `x < y` 结果为假值时 *z* 都不会被求值）。

此表格汇总了比较运算：

运算	含义
<code><</code>	严格小于
<code><=</code>	小于或等于
<code>></code>	严格大于
<code>>=</code>	大于或等于
<code>==</code>	等于
<code>!=</code>	不等于
<code>is</code>	对象标识
<code>is not</code>	否定的对象标识

除了不同数字类型以外，不同类型的对象比较时绝对不会相等。而且，某些类型（例如函数对象）仅支持简化比较形式，即任何两个该种类型的对象必定不相等。`<`、`<=`、`>` 和 `>=` 运算符在以下情况中将引发 `TypeError` 异常：当比较复数与另一个内置数字类型时，当两个对象具有无法被比较的不同类型时，或在未定义次序的其他情况时。

具有不同标识的类的实例比较结果通常为不相等，除非类定义了 `__eq__()` 方法。

一个类实例不能与相同类或的其他实例或其他类型的对象进行排序，除非该类定义了足够多的方法，包括 `__lt__()`、`__le__()`、`__gt__()` 以及 `__ge__()`（而如果你想实现常规意义上的比较操作，通常只要有 `__lt__()` 和 `__eq__()` 就可以了）。

`is` 和 `is not` 运算符无法自定义；并且它们可以被应用于任意两个对象而不会引发异常。

还有两种具有相同语法优先级的运算 `in` 和 `not in`，它们被 *iterable* 或实现了 `__contains__()` 方法的类型所支持。

4.4 数字类型—int, float, complex

存在三种不同的数字类型：整数、浮点数和复数。此外，布尔值属于整数的子类型。整数具有无限的精度。浮点数通常使用 C 中的 `double` 来实现；有关你的程序运行所在机器上浮点数的精度和内部表示法可在 `sys.float_info` 中查看。复数包含实部和虚部，分别以一个浮点数表示。要从一个复数 `z` 中提取这两个部分，可使用 `z.real` 和 `z.imag`。（标准库包含附加的数字类型，如表示有理数的 `fractions` 以及以用户定制精度表示浮点数的 `decimal`。）

数字是由数字面值或内置函数与运算符的结果来创建的。不带修饰的整数字面值（包括十六进制、八进制和二进制数）会生成整数。包含小数点或幂运算符的数字面值会生成浮点数。在数字面值末尾加上 `'j'` 或 `'J'` 会生成虚数（实部为零的复数），你可以将其与整数或浮点数相加来得到具有实部和虚部的复数。

Python 完全支持混合算术：当一个二元运算符用于不同数字类型的操作数时，具有“较窄”类型的操作数会被扩展为另一个操作数的类型，整数比浮点数更窄，浮点数又比复数更窄。混合类型数字之间的比较也使用相同的规则。² 构造器 `int()`、`float()` 和 `complex()` 可被用于生成特定类型的数字。

所有数字类型（复数除外）都支持下列运算，按优先级升序排序（所有数字运算的优先级都高于比较运算）：

运算	结果	注释	完整文档
<code>x + y</code>	<code>x</code> 和 <code>y</code> 的和		
<code>x - y</code>	<code>x</code> 和 <code>y</code> 的差		
<code>x * y</code>	<code>x</code> 和 <code>y</code> 的乘积		
<code>x / y</code>	<code>x</code> 和 <code>y</code> 的商		
<code>x // y</code>	<code>x</code> 和 <code>y</code> 的商数	(1)	
<code>x % y</code>	remainder of <code>x / y</code>	(2)	
<code>-x</code>	<code>x</code> 取反		
<code>+x</code>	<code>x</code> 不变		
<code>abs(x)</code>	<code>x</code> 的绝对值或大小		<code>abs()</code>
<code>int(x)</code>	将 <code>x</code> 转换为整数	(3)(6)	<code>int()</code>
<code>float(x)</code>	将 <code>x</code> 转换为浮点数	(4)(6)	<code>float()</code>
<code>complex(re, im)</code>	一个带有实部 <code>re</code> 和虚部 <code>im</code> 的复数。 <code>im</code> 默认为 0。	(6)	<code>complex()</code>
<code>c.conjugate()</code>	复数 <code>c</code> 的共轭		
<code>divmod(x, y)</code>	<code>(x // y, x % y)</code>	(2)	<code>divmod()</code>
<code>pow(x, y)</code>	<code>x</code> 的 <code>y</code> 次幂	(5)	<code>pow()</code>
<code>x ** y</code>	<code>x</code> 的 <code>y</code> 次幂	(5)	

注释：

- (1) 也称为整数除法。结果值是一个整数，但结果的类型不一定是 `int`。运算结果总是向负无穷的方向舍入：`1//2` 为 0，`(-1)//2` 为 -1，`1//(-2)` 为 -1 而 `(-1)//(-2)` 为 0。
- (2) 不可用于复数。而应在适当条件下使用 `abs()` 转换为浮点数。
- (3) 从浮点数转换为整数会被舍入或是像在 C 语言中一样被截断；请参阅 `math.floor()` 和 `math.ceil()` 函数查看转换的完整定义。
- (4) `float` 也接受字符串“nan”和附带可选前缀“+”或“-”的“inf”分别表示非数字 (NaN) 以及正或负无穷。
- (5) Python 将 `pow(0, 0)` 和 `0 ** 0` 定义为 1，这是编程语言的普遍做法。
- (6) 接受的数字面值包括数码 0 到 9 或任何等效的 Unicode 字符（具有 `Nd` 特征属性的代码点）。

See <http://www.unicode.org/Public/9.0.0/ucd/extracted/DerivedNumericType.txt> for a complete list of code points with the `Nd` property.

² 作为结果，列表 `[1, 2]` 与 `[1.0, 2.0]` 是相等的，元组的情况也类似。

所有 `numbers.Real` 类型 (`int` 和 `float`) 还包括下列运算:

运算	结果
<code>math.trunc(x)</code>	x 截断为 <i>Integral</i>
<code>round(x[, n])</code>	x 舍入到 n 位小数, 半数值会舍入到偶数。如果省略 n , 则默认为 0。
<code>math.floor(x)</code>	$\leq x$ 的最大 <i>Integral</i>
<code>math.ceil(x)</code>	$\geq x$ 的最小 <i>Integral</i>

有关更多的数字运算请参阅 `math` 和 `cmath` 模块。

4.4.1 整数类型的按位运算

按位运算只对整数有意义。计算按位运算的结果, 就相当于使用无穷多个二进制符号位对二的补码执行操作。

二进制按位运算的优先级全都低于数字运算, 但又高于比较运算; 一元运算 `~` 具有与其他一元算术运算 (`+` 和 `-`) 相同的优先级。

此表格是以优先级升序排序的按位运算列表:

运算	结果	注释
<code>x y</code>	x 和 y 按位 或	(4)
<code>x ^ y</code>	x 和 y 按位 异或	(4)
<code>x & y</code>	x 和 y 按位 与	(4)
<code>x << n</code>	x 左移 n 位	(1)(2)
<code>x >> n</code>	x 右移 n 位	(1)(3)
<code>~x</code>	x 逐位取反	

注释:

- (1) 负的移位数是非法的, 会导致引发 `ValueError`。
- (2) 左移 n 位等价于不带溢出检测地乘以 `pow(2, n)`。
- (3) 右移 n 位等价于不带溢出检测地除以 `pow(2, n)`。
- (4) 使用带有至少一个额外符号扩展位的有限个二进制补码表示 (有效位宽度为 `1 + max(x.bit_length(), y.bit_length())` 或以上) 执行这些计算就足以获得相当于有无数个符号位时的同样结果。

4.4.2 整数类型的附加方法

`int` 类型实现了 `numbers.Integral abstract base class`。此外, 它还提供了其他几个方法:

`int.bit_length()`

返回以二进制表示一个整数所需要的位数, 不包括符号位和前面的零:

```
>>> n = -37
>>> bin(n)
'-0b100101'
>>> n.bit_length()
6
```

更准确地说, 如果 x 非零, 则 `x.bit_length()` 是使得 $2^{k-1} \leq \text{abs}(x) < 2^k$ 的唯一正整数 k 。同样地, 当 $\text{abs}(x)$ 小到足以具有正确的舍入对数时, 则 $k = 1 + \text{int}(\log(\text{abs}(x), 2))$ 。如果 x 为零, 则 `x.bit_length()` 返回 0。

等价于:

```
def bit_length(self):
    s = bin(self)          # binary representation: bin(-37) --> '-0b100101'
    s = s.lstrip('-0b')    # remove leading zeros and minus sign
    return len(s)          # len('100101') --> 6
```

3.1 新版功能.

`int.to_bytes(length, byteorder, *, signed=False)`

返回表示一个整数的字节数组。

```
>>> (1024).to_bytes(2, byteorder='big')
b'\x04\x00'
>>> (1024).to_bytes(10, byteorder='big')
b'\x00\x00\x00\x00\x00\x00\x00\x00\x04\x00'
>>> (-1024).to_bytes(10, byteorder='big', signed=True)
b'\xff\xff\xff\xff\xff\xff\xff\xff\xfc\x00'
>>> x = 1000
>>> x.to_bytes((x.bit_length() + 7) // 8, byteorder='little')
b'\xe8\x03'
```

整数会使用 `length` 个字节来表示。如果整数不能用给定的字节数来表示则会引发 `OverflowError`。

`byteorder` 参数确定用于表示整数的字节顺序。如果 `byteorder` 为 "big", 则最高位字节放在字节数组的开头。如果 `byteorder` 为 "little", 则最高位字节放在字节数组的末尾。要请求主机系统上的原生字节顺序, 请使用 `sys.byteorder` 作为字节顺序值。

`signed` 参数确定是否使用二的补码来表示整数。如果 `signed` 为 `False` 并且给出的是负整数, 则会引发 `OverflowError`。`signed` 的默认值为 `False`。

3.2 新版功能.

`classmethod int.from_bytes(bytes, byteorder, *, signed=False)`

返回由给定字节数组所表示的整数。

```
>>> int.from_bytes(b'\x00\x10', byteorder='big')
16
>>> int.from_bytes(b'\x00\x10', byteorder='little')
4096
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=True)
-1024
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=False)
64512
>>> int.from_bytes([255, 0, 0], byteorder='big')
16711680
```

`bytes` 参数必须为一个 *bytes-like object* 或是生成字节的可迭代对象。

`byteorder` 参数确定用于表示整数的字节顺序。如果 `byteorder` 为 "big", 则最高位字节放在字节数组的开头。如果 `byteorder` 为 "little", 则最高位字节放在字节数组的末尾。要请求主机系统上的原生字节顺序, 请使用 `sys.byteorder` 作为字节顺序值。

`signed` 参数指明是否使用二的补码来表示整数。

3.2 新版功能.

4.4.3 浮点类型的附加方法

`float` 类型实现了 *numbers.Real abstract base class*。`float` 还具有以下附加方法。

`float.as_integer_ratio()`

返回一对整数，其比率正好等于原浮点数并且分母为正数。无穷大会引发 `OverflowError` 而 NaN 则会引发 `ValueError`。

`float.is_integer()`

如果 `float` 实例可用有限位整数表示则返回 `True`，否则返回 `False`：

```
>>> (-2.0).is_integer()
True
>>> (3.2).is_integer()
False
```

两个方法均支持与十六进制数字字符串之间的转换。由于 Python 浮点数在内部存储为二进制数，因此浮点数与十进制数字字符串之间的转换往往会导致微小的舍入错误。而十六进制数字字符串却允许精确地表示和描述浮点数。这在进行调试和数值工作时非常有用。

`float.hex()`

以十六进制字符串的形式返回一个浮点数表示。对于有限浮点数，这种表示法将总是包含前导的 `0x` 和尾随的 `p` 加指数。

classmethod `float.fromhex(s)`

返回以十六进制字符串 `s` 表示的浮点数的类方法。字符串 `s` 可以带有前导和尾随的空格。

请注意 `float.hex()` 是实例方法，而 `float.fromhex()` 是类方法。

十六进制字符串采用的形式为：

```
[sign] ['0x'] integer ['.' fraction] ['p' exponent]
```

可选的 `sign` 可以是 `+` 或 `-`，`integer` 和 `fraction` 是十六进制数码组成的字符串，`exponent` 是带有可选前导符的十进制整数。大小写没有影响，在 `integer` 或 `fraction` 中必须至少有一个十六进制数码。此语法类似于 C99 标准的 6.4.4.2 小节中所描述的语法，也是 Java 1.5 以上所使用的语法。特别地，`float.hex()` 的输出可以用作 C 或 Java 代码中的十六进制浮点数字面值，而由 C 的 `%a` 格式字符或 Java 的 `Double.toHexString` 所生成的十六进制数字字符串由 `float.fromhex()` 所接受。

请注意 `exponent` 是十进制数而非十六进制数，它给出要与系数相乘的 2 的幂次。例如，十六进制数字字符串 `0x3.a7p10` 表示浮点数 $(3 + 10./16 + 7./16**2) * 2.0**10$ 即 `3740.0`：

```
>>> float.fromhex('0x3.a7p10')
3740.0
```

对 `3740.0` 应用反向转换会得到另一个代表相同数值的十六进制数字字符串：

```
>>> float.hex(3740.0)
'0x1.d380000000000p+11'
```

4.4.4 数字类型的哈希运算

对于可能为不同类型的数字 `x` 和 `y`，要求 `x == y` 时必定 `hash(x) == hash(y)` (详情参见 `__hash__()` 方法的文档)。为了便于在各种数字类型 (包括 `int`、`float`、`decimal.Decimal` 和 `fractions.Fraction`) 上实现并保证效率，Python 对数字类型的哈希运算是基于为任意有理数定义统一的数学函数，因此该运算对 `int` 和 `fractions.Fraction` 的全部实例，以及 `float` 和 `decimal.Decimal` 的全部有限实例均可用。

从本质上说，此函数是通过以一个固定质数 P 进行 P 降模给出的。 P 的值在 Python 中可以 `sys.hash_info` 的 `modulus` 属性的形式被访问。

CPython implementation detail: 目前所用的质数设定，在 C long 为 32 位的机器上 $P = 2^{31} - 1$ 而在 C long 为 64 位的机器上 $P = 2^{61} - 1$ 。

详细规则如下所述：

- 如果 $x = m / n$ 是一个非负的有理数且 n 不可被 P 整除，则定义 `hash(x)` 为 $m * \text{invmod}(n, P) \% P$ ，其中 `invmod(n, P)` 是对 n 模 P 取反。
- 如果 $x = m / n$ 是一个非负的有理数且 n 可被 P 整除（但 m 不能）则 n 不能对 P 降模，以上规则不适用；在此情况下则定义 `hash(x)` 为常数值 `sys.hash_info.inf`。
- 如果 $x = m / n$ 是一个负的有理数则定义 `hash(x)` 为 `-hash(-x)`。如果结果哈希值为 `-1` 则将其替换为 `-2`。
- 特定值 `sys.hash_info.inf`, `-sys.hash_info.inf` 和 `sys.hash_info.nan` 被用作正无穷、负无穷和空值（所分别对应的）哈希值。（所有可哈希的空值都具有相同的哈希值。）
- 对于一个 `complex` 值 z ，会通过计算 `hash(z.real) + sys.hash_info.imag * hash(z.imag)` 将实部和虚部的哈希值结合起来，并进行降模 $2^{**} \text{sys.hash_info.width}$ 以使其处于 `range(-2^{**}(\text{sys.hash_info.width} - 1), 2^{**}(\text{sys.hash_info.width} - 1))` 范围之内。同样地，如果结果为 `-1` 则将其替换为 `-2`。

为了阐明上述规则，这里有一些等价于内置哈希算法的 Python 代码示例，可用于计算有理数、`float` 或 `complex` 的哈希值：

```
import sys, math

def hash_fraction(m, n):
    """Compute the hash of a rational number m / n.

    Assumes m and n are integers, with n positive.
    Equivalent to hash(fractions.Fraction(m, n)).

    """
    P = sys.hash_info.modulus
    # Remove common factors of P. (Unnecessary if m and n already coprime.)
    while m % P == n % P == 0:
        m, n = m // P, n // P

    if n % P == 0:
        hash_value = sys.hash_info.inf
    else:
        # Fermat's Little Theorem: pow(n, P-1, P) is 1, so
        # pow(n, P-2, P) gives the inverse of n modulo P.
        hash_value = (abs(m) % P) * pow(n, P - 2, P) % P
    if m < 0:
        hash_value = -hash_value
    if hash_value == -1:
        hash_value = -2
    return hash_value

def hash_float(x):
    """Compute the hash of a float x."""

    if math.isnan(x):
        return sys.hash_info.nan
    elif math.isinf(x):
```

(下页继续)

(续上页)

```

        return sys.hash_info.inf if x > 0 else -sys.hash_info.inf
    else:
        return hash_fraction(*x.as_integer_ratio())

def hash_complex(z):
    """Compute the hash of a complex number z."""

    hash_value = hash_float(z.real) + sys.hash_info.imag * hash_float(z.imag)
    # do a signed reduction modulo 2**sys.hash_info.width
    M = 2**(sys.hash_info.width - 1)
    hash_value = (hash_value & (M - 1)) - (hash_value & M)
    if hash_value == -1:
        hash_value = -2
    return hash_value

```

4.5 迭代器类型

Python 支持在容器中进行迭代的概念。这是通过使用两个单独方法来实现的；它们被用于允许用户自定义类对迭代的支持。将在下文中详细描述序列总是支持迭代方法。

容器对象要提供迭代支持，必须定义一个方法：

`container.__iter__()`

返回一个迭代器对象。该对象需要支持下文所述的迭代器协议。如果容器支持不同的迭代类型，则可以提供额外的方法来专门地请求不同迭代类型的迭代器。（支持多种迭代形式的对象的例子有同时支持广度优先和深度优先遍历的树结构。）此方法对应于 Python/C API 中 Python 对象类型结构体的 `tp_iter` 槽位。

迭代器对象自身需要支持以下两个方法，它们共同组成了 迭代器协议：

`iterator.__iter__()`

返回迭代器对象本身。这是同时允许容器和迭代器配合 `for` 和 `in` 语句使用所必须的。此方法对应于 Python/C API 中 Python 对象类型结构体的 `tp_iter` 槽位。

`iterator.__next__()`

从容器中返回下一项。如果已经没有项可返回，则会引发 `StopIteration` 异常。此方法对应于 Python/C API 中 Python 对象类型结构体的 `tp_iternext` 槽位。

Python 定义了几种迭代器对象以支持对一般和特定序列类型、字典和其他更特别的形式进行迭代。除了迭代器协议的实现，特定类型的其他性质对迭代操作来说都不重要。

一旦迭代器的 `__next__()` 方法引发了 `StopIteration`，它必须一直对后续调用引发同样的异常。不遵循此行为特性的实现将无法正常使用。

4.5.1 生成器类型

Python 的 `generator` 提供了一种实现迭代器协议的便捷方式。如果容器对象 `__iter__()` 方法被实现为一个生成器，它将自动返回一个迭代器对象（从技术上说是一个生成器对象），该对象提供 `__iter__()` 和 `__next__()` 方法。有关生成器的更多信息可以参阅 `yield` 表达式的文档。

4.6 序列类型—list, tuple, range

有三种基本序列类型：list, tuple 和 range 对象。为处理二进制数据和文本字符串而特别定制的附加序列类型会在专门的小节中描述。

4.6.1 通用序列操作

大多数序列类型，包括可变类型和不可变类型都支持下表中的操作。`collections.abc.Sequence` ABC 被提供用来更容易地在自定义序列类型上正确地实现这些操作。

此表按优先级升序列出了序列操作。在表格中，*s* 和 *t* 是具有相同类型的序列，*n*, *i*, *j* 和 *k* 是整数而 *x* 是任何满足 *s* 所规定的类型和值限制的任意对象。

`in` 和 `not in` 操作具有与比较操作相同的优先级。`+` (拼接) 和 `*` (重复) 操作具有与对应数值运算相同的优先级。³

运算	结果	注释
<code>x in s</code>	如果 <i>s</i> 中的某项等于 <i>x</i> 则结果为 <code>True</code> ，否则为 <code>False</code>	(1)
<code>x not in s</code>	如果 <i>s</i> 中的某项等于 <i>x</i> 则结果为 <code>False</code> ，否则为 <code>True</code>	(1)
<code>s + t</code>	<i>s</i> 与 <i>t</i> 相拼接	(6)(7)
<code>s * n</code> 或 <code>n * s</code>	相当于 <i>s</i> 与自身进行 <i>n</i> 次拼接	(2)(7)
<code>s[i]</code>	<i>s</i> 的第 <i>i</i> 项，起始为 0	(3)
<code>s[i:j]</code>	<i>s</i> 从 <i>i</i> 到 <i>j</i> 的切片	(3)(4)
<code>s[i:j:k]</code>	<i>s</i> 从 <i>i</i> 到 <i>j</i> 步长为 <i>k</i> 的切片	(3)(5)
<code>len(s)</code>	<i>s</i> 的长度	
<code>min(s)</code>	<i>s</i> 的最小项	
<code>max(s)</code>	<i>s</i> 的最大项	
<code>s.index(x[, i[, j]])</code>	<i>x</i> 在 <i>s</i> 中首次出现项的索引号（索引号在 <i>i</i> 或其后且在 <i>j</i> 之前）	(8)
<code>s.count(x)</code>	<i>x</i> 在 <i>s</i> 中出现的总次数	

相同类型的序列也支持比较。特别地，tuple 和 list 的比较是通过比较对应元素的字典顺序。这意味着想要比较结果相等，则每个元素比较结果都必须相等，并且两个序列长度必须相同。（完整细节请参阅语言参考的 `comparisons` 部分。）

注释:

- (1) 虽然 `in` 和 `not in` 操作在通常情况下仅被用于简单的成员检测，某些专门化序列 (例如 `str`, `bytes` 和 `bytearray`) 也使用它们进行子序列检测:

```
>>> "gg" in "eggs"
True
```

- (2) 小于 0 的 *n* 值会被当作 0 来处理 (生成一个与 *s* 同类型的空序列)。请注意序列 *s* 中的项并不会被拷贝；它们会被多次引用。这一点经常会令 Python 编程新手感到困扰；例如:

```
>>> lists = [[]] * 3
>>> lists
[[], [], []]
>>> lists[0].append(3)
>>> lists
[[3], [3], [3]]
```

³ 它们必须如此，因为解析器无法区分这些操作数的类型。

具体的原因在于 `[]` 是一个包含了一个空列表的单元列表，所以 `[] * 3` 结果中的三个元素都是对这个空列表的引用。修改 `lists` 中的任何一个元素实际上都是对这个空列表的修改。你可以用以下方式创建以不同列表为元素的列表：

```
>>> lists = [[] for i in range(3)]
>>> lists[0].append(3)
>>> lists[1].append(5)
>>> lists[2].append(7)
>>> lists
[[3], [5], [7]]
```

进一步的解释可以在 FAQ 条目 [faq-multidimensional-list](#) 中查看。

- (3) 如果 *i* 或 *j* 为负值，则索引顺序是相对于序列 *s* 的末尾：索引号会被替换为 `len(s) + i` 或 `len(s) + j`。但要注意 `-0` 仍然为 `0`。
- (4) *s* 从 *i* 到 *j* 的切片被定义为所有满足 `i ≤ k < j` 的索引号 *k* 的项组成的序列。如果 *i* 或 *j* 大于 `len(s)`，则使用 `len(s)`。如果 *i* 被省略或为 `None`，则使用 `0`。如果 *j* 被省略或为 `None`，则使用 `len(s)`。如果 *i* 大于等于 *j*，则切片为空。
- (5) *s* 从 *i* 到 *j* 步长为 *k* 的切片被定义为所有满足 `0 ≤ n < (j-i)/k` 的索引号 `x = i + n*k` 的项组成的序列。换句话说，索引号为 `i, i+k, i+2*k, i+3*k`，以此类推，当达到 *j* 时停止（但一定不包括 *j*）。当 *k* 为正值时，*i* 和 *j* 会被减至不大于 `len(s)`。当 *k* 为负值时，*i* 和 *j* 会被减至不大于 `len(s) - 1`。如果 *i* 或 *j* 被省略或为 `None`，它们会成为“终止”值（是哪一端的终止值则取决于 *k* 的符号）。请注意，*k* 不可为零。如果 *k* 为 `None`，则当作 `1` 处理。
- (6) 拼接不可变序列总是会生成新的对象。这意味着通过重复拼接来构建序列的运行时开销将会基于序列总长度的乘方。想要获得线性的运行时开销，你必须改用下列替代方案之一：
 - 如果拼接 *str* 对象，你可以构建一个列表并在最后使用 `str.join()` 或是写入一个 `io.StringIO` 实例并在结束时获取它的值
 - 如果拼接 *bytes* 对象，你可以类似地使用 `bytes.join()` 或 `io.BytesIO`，或者你也可以使用 `bytearray` 对象进行原地拼接。`bytearray` 对象是可变的，并且具有高效的重分配机制
 - 如果拼接 *tuple* 对象，请改为扩展 `list` 类
 - 对于其它类型，请查看相应的文档
- (7) 某些序列类型（例如 `range`）仅支持遵循特定模式的项序列，因此并不支持序列拼接或重复。
- (8) 当 *x* 在 *s* 中找不到时 `index` 会引发 `ValueError`。不是所有实现都支持传入额外参数 *i* 和 *j*。这两个参数允许高效地搜索序列的子序列。传入这两个额外参数大致相当于使用 `s[i:j].index(x)`，但是不会复制任何数据，并且返回的索引是相对于序列的开头而非切片的开头。

4.6.2 不可变序列类型

不可变序列类型普遍实现而可变序列类型未实现的唯一操作就是对 `hash()` 内置函数的支持。

这种支持允许不可变类型，例如 `tuple` 实例被用作 `dict` 键，以及存储在 `set` 和 `frozenset` 实例中。

尝试对包含有不可哈希值的不可变序列进行哈希运算将会导致 `TypeError`。

4.6.3 可变序列类型

以下表格中的操作是在可变序列类型上定义的。`collections.abc.MutableSequence` ABC 被提供用来更容易地在自定义序列类型上正确实现这些操作。

表格中的 *s* 是可变序列类型的实例, *t* 是任意可迭代对象, 而 *x* 是符合对 *s* 所规定类型与值限制的任何对象 (例如, `bytearray` 仅接受满足 $0 \leq x \leq 255$ 值限制的整数)。

运算	结果	注释
<code>s[i] = x</code>	将 <i>s</i> 的第 <i>i</i> 项替换为 <i>x</i>	
<code>s[i:j] = t</code>	将 <i>s</i> 从 <i>i</i> 到 <i>j</i> 的切片替换为可迭代对象 <i>t</i> 的内容	
<code>del s[i:j]</code>	等同于 <code>s[i:j] = []</code>	
<code>s[i:j:k] = t</code>	将 <code>s[i:j:k]</code> 的元素替换为 <i>t</i> 的元素	(1)
<code>del s[i:j:k]</code>	从列表中移除 <code>s[i:j:k]</code> 的元素	
<code>s.append(x)</code>	将 <i>x</i> 添加到序列的末尾 (等同于 <code>s[len(s):len(s)] = [x]</code>)	
<code>s.clear()</code>	从 <i>s</i> 中移除所有项 (等同于 <code>del s[:]</code>)	(5)
<code>s.copy()</code>	创建 <i>s</i> 的浅拷贝 (等同于 <code>s[:]</code>)	(5)
<code>s.extend(t)</code> 或 <code>s += t</code>	用 <i>t</i> 的内容扩展 <i>s</i> (基本上等同于 <code>s[len(s):len(s)] = t</code>)	
<code>s *= n</code>	使用 <i>s</i> 的内容重复 <i>n</i> 次来对其进行更新	(6)
<code>s.insert(i, x)</code>	在由 <i>i</i> 给出的索引位置将 <i>x</i> 插入 <i>s</i> (等同于 <code>s[i:i] = [x]</code>)	
<code>s.pop([i])</code>	提取在 <i>i</i> 位置上的项, 并将其从 <i>s</i> 中移除	(2)
<code>s.remove(x)</code>	remove the first item from <i>s</i> where <code>s[i] == x</code>	(3)
<code>s.reverse()</code>	就地将列表中的元素逆序。	(4)

注释:

- (1) *t* 必须与它所替换的切片具有相同的长度。
- (2) 可选参数 *i* 默认为 -1, 因此在默认情况下会移除并返回最后一项。
- (3) 当在 *s* 中找不到 *x* 时 `remove` 操作会引发 `ValueError`。
- (4) 当反转大尺寸序列时 `reverse()` 方法会原地修改该序列以保证空间经济性。为提醒用户此操作是通过间接影响进行的, 它并不会返回反转后的序列。
- (5) 包括 `clear()` 和 `copy()` 是为了与不支持切片操作的可变容器 (例如 `dict` 和 `set`) 的接口保持一致
3.3 新版功能: `clear()` 和 `copy()` 方法。
- (6) *n* 值为一个整数, 或是一个实现了 `__index__()` 的对象。*n* 值为零或负数将清空序列。序列中的项不会被拷贝; 它们会被多次引用, 正如通用序列操作中有关 `s * n` 的说明。

4.6.4 列表

列表是可变序列, 通常用于存放同类项目的集合 (其中精确的相似程度将根据应用而变化)。

class list([iterable])

可以用多种方式构建列表:

- 使用一对方括号来表示空列表: `[]`
- 使用方括号, 其中的项以逗号分隔: `[a], [a, b, c]`
- 使用列表推导式: `[x for x in iterable]`
- 使用类型的构造器: `list()` 或 `list(iterable)`

构造器将构造一个列表, 其中的项与 *iterable* 中的项具有相同的值与顺序。*iterable* 可以是序列、支持迭代的容器或其它可迭代对象。如果 *iterable* 已经是一个列表, 将创建并返回其副本, 类似于 `iterable[:]`。例如, `list('abc')` 返回 `['a', 'b', 'c']` 而 `list((1, 2, 3))` 返回 `[1, 2, 3]`。如果没有给出参数, 构造器将创建一个空列表 `[]`。

其它许多操作也会产生列表, 包括 `sorted()` 内置函数。

列表实现了所有一般和可变序列的操作。列表还额外提供了以下方法:

sort (*, key=None, reverse=False)

此方法会对列表进行原地排序，只使用 < 来进行各项间比较。异常不会被屏蔽——如果有任何比较操作失败，整个排序操作将失败（而列表可能会处于被部分修改的状态）。

`sort()` 接受两个仅限以关键字形式传入的参数（仅限关键字参数）：

`key` 指定带有一个参数的函数，用于从每个列表元素中提取比较键（例如 `key=str.lower`）。对应于列表中每一项的键会被计算一次，然后在整个排序过程中使用。默认值 `None` 表示直接对列表项排序而不计算一个单独的键值。

可以使用 `functools.cmp_to_key()` 将 2.x 风格的 `cmp` 函数转换为 `key` 函数。

`reverse` 为一个布尔值。如果设为 `True`，则每个列表元素将按反向顺序比较进行排序。

当顺序大尺寸序列时此方法会原地修改该序列以保证空间经济性。为提醒用户此操作是通过间接影响进行的，它并不会返回排序后的序列（请使用 `sorted()` 显示地请求一个新的已排序列表实例）。

`sort()` 方法确保是稳定的。如果一个排序确保不会改变比较结果相等的元素的相对顺序就称其为稳定——这有利于进行多重排序（例如先按部门、再接薪级排序）。

CPython implementation detail: 在一个列表被排序期间，尝试改变甚至进行检测也会造成未定义的影响。Python 的 C 实现会在排序期间将列表显示为空，如果发现列表在排序期间被改变将会引发 `ValueError`。

4.6.5 元组

元组是不可变序列，通常用于储存异构数据的多项集（例如由 `enumerate()` 内置函数所产生的二元组）。元组也被用于需要同构数据的不可变序列的情况（例如允许存储到 `set` 或 `dict` 的实例）。

class tuple ([*iterable*])

可以用多种方式构建元组：

- 使用一对圆括号来表示空元组：()
- 使用一个后缀的逗号来表示单元组：`a,` 或 `(a,)`
- 使用以逗号分隔的多个项：`a, b, c` 或 `(a, b, c)`
- 使用内置的 `tuple()`：`tuple()` 或 `tuple(iterable)`

构造器将构造一个元组，其中的项与 `iterable` 中的项具有相同的值与顺序。`iterable` 可以是序列、支持迭代的容器或其他可迭代对象。如果 `iterable` 已经是一个元组，会不加改变地将其返回。例如，`tuple('abc')` 返回 ('a', 'b', 'c') 而 `tuple([1, 2, 3])` 返回 (1, 2, 3)。如果没有给出参数，构造器将创建一个空元组 ()。

请注意决定生成元组的其实是逗号而不是圆括号。圆括号只是可选的，生成空元组或需要避免语法歧义的情况除外。例如，`f(a, b, c)` 是在调用函数时附带三个参数，而 `f((a, b, c))` 则是在调用函数时附带一个三元组。

元组实现了所有一般序列的操作。

对于通过名称访问相比通过索引访问更清晰的异构数据多项集，`collections.namedtuple()` 可能是比简单元组对象更为合适的选择。

4.6.6 range 对象

`range` 类型表示不可变的数字序列，通常用于在 `for` 循环中循环指定的次数。

class range (stop)

class range (*start*, *stop*[, *step*])

`range` 构造器的参数必须为整数（可以是内置的 `int` 或任何实现了 `__index__` 特殊方法的对象）。如果省略 `step` 参数，其默认值为 1。如果省略 `start` 参数，其默认值为 0，如果 `step` 为零则会引发 `ValueError`。

如果 `step` 为正值，确定 `range` `r` 内容的公式为 $r[i] = \text{start} + \text{step} * i$ 其中 $i \geq 0$ 且 $r[i] < \text{stop}$ 。

如果 `step` 为负值，确定 `range` 内容的公式仍然为 $r[i] = \text{start} + \text{step} * i$ ，但限制条件改为 $i \geq 0$ 且 $r[i] > \text{stop}$ 。

如果 `r[0]` 不符合值的限制条件，则该 `range` 对象为空。`range` 对象确实支持负索引，但是会将其解读为从正索引所确定的序列的末尾开始索引。

元素绝对值大于 `sys.maxsize` 的 `range` 对象是被允许的，但某些特性（例如 `len()`）可能引发 `OverflowError`。

一些 `range` 对象的例子：

```
>>> list(range(10))
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> list(range(1, 11))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> list(range(0, 30, 5))
[0, 5, 10, 15, 20, 25]
>>> list(range(0, 10, 3))
[0, 3, 6, 9]
>>> list(range(0, -10, -1))
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
>>> list(range(0))
[]
>>> list(range(1, 0))
[]
```

`range` 对象实现了一般序列的所有操作，但拼接和重复除外（这是由于 `range` 对象只能表示符合严格模式的序列，而重复和拼接通常都会违反这样的模式）。

start

`start` 形参的值（如果该形参未提供则为 0）

stop

`stop` 形参的值

step

`step` 形参的值（如果该形参未提供则为 1）

`range` 类型相比常规 `list` 或 `tuple` 的优势在于一个 `range` 对象总是占用固定数量的（较小）内存，不论其所表示的范围有多大（因为它只保存了 `start`, `stop` 和 `step` 值，并会根据需要计算具体单项或子范围的值）。

`range` 对象实现了 `collections.abc.Sequence` ABC，提供如包含检测、元素索引查找、切片等特性，并支持负索引（参见序列类型—`list`, `tuple`, `range`）：

```
>>> r = range(0, 20, 2)
>>> r
range(0, 20, 2)
>>> 11 in r
False
>>> 10 in r
True
>>> r.index(10)
```

（下页继续）

(续上页)

```

5
>>> r[5]
10
>>> r[:5]
range(0, 10, 2)
>>> r[-1]
18

```

使用 `==` 和 `!=` 检测 `range` 对象是否相等是将其作为序列来比较。也就是说，如果两个 `range` 对象表示相同的值序列就认为它们是相等的。（请注意比较结果相等的两个 `range` 对象可能会具有不同的 `start`, `stop` 和 `step` 属性，例如 `range(0) == range(2, 1, 3)` 而 `range(0, 3, 2) == range(0, 4, 2)`。）

在 3.2 版更改：实现 Sequence ABC。支持切片和负数索引。使用 `int` 对象在固定时间内进行成员检测，而不是逐一迭代所有项。

在 3.3 版更改：定义 `'=='` 和 `'!='` 以根据 `range` 对象所定义的值序列来进行比较（而不是根据对象的标识）。

3.3 新版功能： `start`, `stop` 和 `step` 属性。

参见：

- `linspace recipe` 演示了如何实现一个延迟求值版本的适合浮点数应用的 `range` 对象。

4.7 文本序列类型—`str`

在 Python 中处理文本数据是使用 `str` 对象，也称为 字符串。字符串是由 Unicode 码位构成的不可变序列。字符串字面值有多种不同的写法：

- 单引号： `' '` 允许包含有 `" 双" 引号`
- 双引号： `" "` 允许包含有 `' 单' 引号`。
- 三重引号： `''' 三重单引号'''`, `""" 三重双引号"""`

使用三重引号的字符串可以跨越多行——其中所有的空白字符都将包含在该字符串字面值中。

作为单一表达式组成部分，之间只由空格分隔的多个字符串字面值会被隐式地转换为单个字符串字面值。也就是说，`("spam " "eggs") == "spam eggs"`。

请参阅 `strings` 有解有关不同字符串字面值的更多信息，包括所支持的转义序列，以及使用 `r`（“raw”）前缀来禁用大多数转义序列的处理。

字符串也可以通过使用 `str` 构造器从其他对象创建。

由于不存在单独的“字符”类型，对字符串做索引操作将产生一个长度为 1 的字符串。也就是说，对于一个非空字符串 `s`, `s[0] == s[0:1]`。

不存在可变的字符串类型，但是 `str.join()` 或 `io.StringIO` 可以被用来根据多个片段高效率地构建字符串。

在 3.3 版更改：为了与 Python 2 系列的向下兼容，再次允许字符串字面值使用 `u` 前缀。它对字符串字面值的含义没有影响，并且不能与 `r` 前缀同时出现。

```
class str(object="")
```

```
class str(object=b'', encoding='utf-8', errors='strict')
```

返回 `object` 的字符串版本。如果未提供 `object` 则返回空字符串。在其他情况下 `str()` 的行为取决于 `encoding` 或 `errors` 是否有给出，具体见下。

如果 *encoding* 或 *errors* 均未给出, `str(object)` 返回 `object.__str__()`, 这是 *object* 的“非正式”或格式良好的字符串表示。对于字符串对象, 这是该字符串本身。如果 *object* 没有 `__str__()` 方法, 则 `str()` 将回退为返回 `repr(object)`。

如果 *encoding* 或 *errors* 至少给出其中之一, 则 *object* 应该是一个 *bytes-like object* (例如 *bytes* 或 *bytearray*)。在此情况下, 如果 *object* 是一个 *bytes* (或 *bytearray*) 对象, 则 `str(bytes, encoding, errors)` 等价于 `bytes.decode(encoding, errors)`。否则的话, 会在调用 `bytes.decode()` 之前获取缓冲区对象下层的 *bytes* 对象。请参阅二进制序列类型—*bytes*, *bytearray*, *memoryview* 与 *bufferobjects* 了解有关缓冲区对象的信息。

将一个 *bytes* 对象传入 `str()` 而不给出 *encoding* 或 *errors* 参数的操作属于第一种情况, 将返回非正式的字符串表示 (另请参阅 Python 的 `-b` 命令行选项)。例如:

```
>>> str(b'Zoot!')
"b'Zoot!'"
```

有关 `str` 类及其方法的更多信息, 请参阅下面的文本序列类型—*str* 和字符串的方法 小节。要输出格式化字符串, 请参阅 *f-strings* 和格式字符串语法 小节。此外还可以参阅文本处理服务 小节。

4.7.1 字符串的方法

字符串实现了所有一般序列的操作, 还额外提供了以下列出的一些附加方法。

字符串还支持两种字符串格式化样式, 一种提供了很大程度的灵活性和可定制性 (参阅 `str.format()`, 格式字符串语法 和自定义字符串格式化) 而另一种是基于 `C printf` 样式的格式化, 它可处理的类型范围较窄, 并且更难以正确使用, 但对于它可处理的情况往往会更为快速 (*printf* 风格的字符串格式化)。

标准库的文本处理服务 部分涵盖了许多其他模块, 提供各种文本相关工具 (例如包含于 *re* 模块中的正则表达式支持)。

`str.capitalize()`

返回原字符串的副本, 其首个字符大写, 其余为小写。

`str.casefold()`

返回原字符串消除大小写的副本。消除大小写的字符串可用于忽略大小写的匹配。

消除大小写类似于转为小写, 但是更加彻底一些, 因为它会移除字符串中的所有大小写变化形式。例如, 德语小写字母 'ß' 相当于 "ss"。由于它已经是小写了, `lower()` 不会对 'ß' 做任何改变; 而 `casefold()` 则会将其转换为 "ss"。

消除大小写算法的描述请参见 Unicode 标准的 3.13 节。

3.3 新版功能.

`str.center(width[, fillchar])`

返回长度为 *width* 的字符串, 原字符串在其正中。使用指定的 *fillchar* 填充两边的空位 (默认使用 ASCII 空格符)。如果 *width* 小于等于 `len(s)` 则返回原字符串的副本。

`str.count(sub[, start[, end]])`

返回子字符串 *sub* 在 `[start, end]` 范围内非重叠出现的次数。可选参数 *start* 与 *end* 会被解读为切片表示法。

`str.encode(encoding="utf-8", errors="strict")`

返回原字符串编码为字节串对象的版本。默认编码为 'utf-8'。可以给出 *errors* 来设置不同的错误处理方案。*errors* 的默认值为 'strict', 表示编码错误会引发 *UnicodeError*。其他可用的值为 'ignore', 'replace', 'xmlcharrefreplace', 'backslashreplace' 以及任何其他通过 `codecs.register_error()` 注册的值, 请参阅 *Error Handlers* 小节。要查看可用的编码列表, 请参阅标准编码 小节。

在 3.1 版更改: 加入了对关键字参数的支持。

`str.endswith(suffix[, start[, end]])`

如果字符串以指定的 *suffix* 结束返回 `True`，否则返回 `False`。*suffix* 也可以为由多个供查找的后缀构成的元组。如果有可选项 *start*，将从所指定位置开始检查。如果有可选项 *end*，将在所指定位置停止比较。

`str.expandtabs(tabsize=8)`

返回字符串的副本，其中所有的制表符会由一个或多个空格替换，具体取决于当前列位置和给定的制表符宽度。每 *tabsize* 个字符设为一个制表位（默认值 8 时设定的制表位在列 0, 8, 16 依次类推）。要展开字符串，当前列将被设为零并逐一检查字符串中的每个字符。如果字符为制表符 (`\t`)，则会在结果中插入一个或多个空格符，直到当前列等于下一个制表位。（制表符本身不会被复制。）如果字符为换行符 (`\n`) 或回车符 (`\r`)，它会被复制并将当前列重设为零。任何其他字符会被不加修改地复制并将当前列加一，不论该字符在被打印时会如何显示。

```
>>> '01\t012\t0123\t01234'.expandtabs()
'01      012      0123      01234'
>>> '01\t012\t0123\t01234'.expandtabs(4)
'01  012 0123  01234'
```

`str.find(sub[, start[, end]])`

返回子字符串 *sub* 在 `s[start:end]` 切片内被找到的最小索引。可选参数 *start* 与 *end* 会被解读为切片表示法。如果 *sub* 未被找到则返回 `-1`。

注解： `find()` 方法应该只在你需要知道 *sub* 所在位置时使用。要检查 *sub* 是否为子字符串，请使用 `in` 操作符：

```
>>> 'Py' in 'Python'
True
```

`str.format(*args, **kwargs)`

执行字符串格式化操作。调用此方法的字符串可以包含字符串面值或者以花括号 `{}` 括起来的替换域。每个替换域可以包含一个位置参数的数字索引，或者一个关键字参数的名称。返回的字符串副本中每个替换域都会被替换为对应参数的字符串值。

```
>>> "The sum of 1 + 2 is {0}.".format(1+2)
'The sum of 1 + 2 is 3'
```

请参阅[格式字符串语法](#) 了解有关可以在格式字符串中指定的各种格式选项的说明。

注解： 当使用 *n* 类型 (例如: `'{:n}'.format(1234)`) 来格式化数字 (*int*, *float*, *complex*, *decimal.Decimal* 及其子类) 的时候，该函数会临时性地将 `LC_CTYPE` 区域设置为 `LC_NUMERIC` 区域以解码 `localeconv()` 的 `decimal_point` 和 `thousands_sep` 字段，如果它们是非 `ASCII` 字符或长度超过 1 字节的话，并且 `LC_NUMERIC` 区域会与 `LC_CTYPE` 区域不一致。这个临时更改会影响其他线程。

在 3.6.5 版更改: 当使用 *n* 类型格式化数字时，该函数在某些情况下会临时性地将 `LC_CTYPE` 区域设置为 `LC_NUMERIC` 区域。

`str.format_map(mapping)`

类似于 `str.format(**mapping)`，不同之处在于 *mapping* 会被直接使用而不是复制到一个 *dict*。适宜使用此方法的一个例子是当 *mapping* 为 *dict* 的子类的情况：

```
>>> class Default(dict):
...     def __missing__(self, key):
...         return key
```

(下页继续)

(续上页)

```
...
>>> '{name} was born in {country}'.format_map(Default(name='Guido'))
'Guido was born in country'
```

3.2 新版功能.

`str.index(sub[, start[, end]])`

类似于 `find()`，但在找不到子类时会引发 `ValueError`。

`str.isalnum()`

如果字符串中至少有一个字符且所有字符均为字母或数字则返回真值，否则返回假值。如果以下方法中的一个返回 `True` 则字符 `c` 为字母或数字: `c.isalpha()`, `c.isdecimal()`, `c.isdigit()`, or `c.isnumeric()`。

`str.isalpha()`

如果字符串中至少有一个字符且所有字符均为字母则返回真值，否则返回假值。字母类字符是在 Unicode 字符数据库中被定义为 “Letter” 的字符，即一般分类特征属性为 “Lm”，“Lt”，“Lu”，“Ll” 或 “Lo” 其中之一。请注意这不同于 Unicode 标准所定义的 “Alphabetic” 特征属性。

`str.isdecimal()`

如果字符串中至少有一个字符且所有字符均为十进制数字字符则返回真值，否则返回假值。十进制数字字符是以 10 为基数的计数制会用来组成数值的字符，例如 U+0660, ARABIC-INDIC DIGIT ZERO。正式的定义为：十进制数字字符就是 Unicode 一般分类 “Nd” 中的字符。

`str.isdigit()`

如果字符串中至少有一个字符且所有字符均为数字字符则返回真值，否则返回假值。数字字符包括十进制数字字符和需要特别处理的数字，例如兼容性上标数字。这也涵盖了不能被用来组成以 10 为基数的数值的数字，例如 Kharosthi 数字。正式的定义为：数字字符就是特征属性值 `Numeric_Type=Digit` 或 `Numeric_Type=Decimal` 的字符。

`str.isidentifier()`

如果字符串根据语言定义属于有效的标识符则返回真值，参见 `identifiers`。

请使用 `keyword.iskeyword()` 来检测保留标识符，例如 `def` 和 `class`。

`str.islower()`

如果字符串中至少有一个区分大小写的字符⁴ 且此类字符均为小写则返回真值，否则返回假值。

`str.isnumeric()`

如果字符串中至少有一个字符且所有字符均为数值字符则返回真值，否则返回假值。数值字符包括数字字符，以及所有在 Unicode 中设置了数值特性属性的字符，例如 U+2155, VULGAR FRACTION ONE FIFTH。正式的定义为：数值字符就是具有特征属性值 `Numeric_Type=Digit`, `Numeric_Type=Decimal` 或 `Numeric_Type=Numeric` 的字符。

`str.isprintable()`

如果字符串中所有字符均为可打印字符或字符串为空则返回真值，否则返回假值。不可打印字符是在 Unicode 字符数据库中被定义为 “Other” 或 “Separator” 的字符，例外情况是 ASCII 空格字符 (0x20) 被视作可打印字符。（请注意在此语境下可打印字符是指当对一个字符串发起调用 `repr()` 时不必被转义的字符。它们与字符串写入 `sys.stdout` 或 `sys.stderr` 时所需的处理无关。）

`str.isspace()`

如果字符串中至少有一个字符且所有字符均为空白字符则返回真值，否则返回假值。空白字符是在 Unicode 字符数据库中被定义为 “Other” 或 “Separator” 并且其双向特征属性为 “WS”，“B” 或 “S” 之一的字符。

`str.istitle()`

如果字符串中至少有一个字符且为标题字符串则返回真值，例如大写字符之后只能带非大写字符而小

⁴ 区分大小写的字符是指所属一般类别属性为 “Lu” (Letter, uppercase), “Ll” (Letter, lowercase) 或 “Lt” (Letter, titlecase) 之一的字符。

写字符必须有大写字符打头。否则返回假值。

`str.isupper()`

如果字符串中至少有一个区分大小写的字符⁴ 且此类字符均为大写则返回真值，否则返回假值。

`str.join(iterable)`

返回一个由 *iterable* 中的字符串拼接而成的字符串。如果 *iterable* 中存在任何非字符串值包括 *bytes* 对象则会引发 *TypeError*。调用该方法的字符串将作为元素之间的分隔。

`str.ljust(width[, fillchar])`

返回长度为 *width* 的字符串，原字符串在其中靠左对齐。使用指定的 *fillchar* 填充空位 (默认使用 ASCII 空格符)。如果 *width* 小于等于 `len(s)` 则返回原字符串的副本。

`str.lower()`

返回原字符串的副本，其所有区分大小写的字符⁴ 均转换为小写。

所用转换小写算法的描述请参见 Unicode 标准的 3.13 节。

`str.lstrip([chars])`

返回原字符串的副本，移除其中的前导字符。*chars* 参数为指定要移除字符的字符串。如果省略或为 *None*，则 *chars* 参数默认移除空格符。实际上 *chars* 参数并非指定单个前缀；而是会移除参数值的所有组合：

```
>>> '   spacious   '.lstrip()
'spacious'
>>> 'www.example.com'.lstrip('cmowz.')
'example.com'
```

`static str.maketrans(x[, y[, z]])`

此静态方法返回一个可供 *str.translate()* 使用的转换对照表。

如果只有一个参数，则它必须是一个将 Unicode 码位序号（整数）或字符（长度为 1 的字符串）映射到 Unicode 码位序号、（任意长度的）字符串或 *None* 的字典。字符键将会被转换为码位序号。

如果有两个参数，则它们必须是两个长度相等的字符串，并且在结果字典中，*x* 中每个字符将被映射到 *y* 中相同位置的字符。如果有第三个参数，它必须是一个字符串，其中的字符将在结果中被映射到 *None*。

`str.partition(sep)`

在 *sep* 首次出现的位置拆分字符串，返回一个 3 元组，其中包含分隔符之前的部分、分隔符本身，以及分隔符之后的部分。如果分隔符未找到，则返回的 3 元组中包含字符本身以及两个空字符串。

`str.replace(old, new[, count])`

返回字符串的副本，其中出现的所有子字符串 *old* 都将被替换为 *new*。如果给出了可选参数 *count*，则只替换前 *count* 次出现。

`str.rfind(sub[, start[, end]])`

返回子字符串 *sub* 在字符串内被找到的最大（最右）索引，这样 *sub* 将包含在 `s[start:end]` 当中。可选参数 *start* 与 *end* 会被解读为切片表示法。如果未找到则返回 -1。

`str.rindex(sub[, start[, end]])`

类似于 *rfind()*，但在子字符串 *sub* 未找到时会引发 *ValueError*。

`str.rjust(width[, fillchar])`

返回长度为 *width* 的字符串，原字符串在其中靠右对齐。使用指定的 *fillchar* 填充空位 (默认使用 ASCII 空格符)。如果 *width* 小于等于 `len(s)` 则返回原字符串的副本。

`str.rpartition(sep)`

在 *sep* 最后一次出现的位置拆分字符串，返回一个 3 元组，其中包含分隔符之前的部分、分隔符本身，以及分隔符之后的部分。如果分隔符未找到，则返回的 3 元组中包含两个空字符串以及字符串本身。

`str.rsplitleft (sep=None, maxsplit=-1)`

返回一个由字符串内单词组成的列表，使用 *sep* 作为分隔字符串。如果给出了 *maxsplit*，则最多进行 *maxsplit* 次拆分，从最右边开始。如果 *sep* 未指定或为 `None`，任何空白字符串都会被作为分隔符。除了从右边开始拆分，*rsplitleft()* 的其他行为都类似于下文所述的 *split()*。

`str.rstrip ([chars])`

返回原字符串的副本，移除其中的末尾字符。*chars* 参数为指定要移除字符的字符串。如果省略或为 `None`，则 *chars* 参数默认移除空格符。实际上 *chars* 参数并非指定单个后缀；而是会移除参数值的所有组合：

```
>>> '   spacious   '.rstrip()
'   spacious'
>>> 'mississippi'.rstrip('ipz')
'mississ'
```

`str.split (sep=None, maxsplit=-1)`

返回一个由字符串内单词组成的列表，使用 *sep* 作为分隔字符串。如果给出了 *maxsplit*，则最多进行 *maxsplit* 次拆分（因此，列表最多会有 *maxsplit*+1 个元素）。如果 *maxsplit* 未指定或为 -1，则不限制拆分次数（进行所有可能的拆分）。

如果给出了 *sep*，则连续的分隔符不会被组合在一起而是被视为分隔空字符串（例如 `'1,,2'.split(',')` 将返回 `['1', '', '2']`）。*sep* 参数可能由多个字符组成（例如 `'1<>2<>3'.split('<>')` 将返回 `['1', '2', '3']`）。使用指定的分隔符拆分空字符串将返回 `['']`。

例如：

```
>>> '1,2,3'.split(',')
['1', '2', '3']
>>> '1,2,3'.split(',', maxsplit=1)
['1', '2,3']
>>> '1,2,,3'.split(',')
['1', '2', '', '3', '']
```

如果 *sep* 未指定或为 `None`，则会应用另一种拆分算法：连续的空格会被视为单个分隔符，其结果将不包含开头或末尾的空字符串，如果字符串包含前缀或后缀空格的话。因此，使用 `None` 拆分空字符串或仅包含空格的字符串将返回 `[]`。

例如：

```
>>> '1 2 3'.split()
['1', '2', '3']
>>> '1 2 3'.split(maxsplit=1)
['1', '2 3']
>>> '   1   2   3   '.split()
['1', '2', '3']
```

`str.splitlines ([keepends])`

返回由原字符串中各行组成的列表，在行边界的位置拆分。结果列表中不包含行边界，除非给出了 *keepends* 且为真值。

此方法会以下列行边界进行拆分。特别地，行边界是 *universal newlines* 的一个超集。

表示符	描述
\n	换行
\r	回车
\r\n	回车 + 换行
\v 或 \x0b	行制表符
\f 或 \x0c	换表单
\x1c	文件分隔符
\x1d	组分隔符
\x1e	记录分隔符
\x85	下一行 (C1 控制码)
\u2028	行分隔符
\u2029	段分隔符

在 3.2 版更改: \v 和 \f 被添加到行边界列表

例如:

```
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines()
['ab c', '', 'de fg', 'kl']
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines(keepends=True)
['ab c\n', '\n', 'de fg\r', 'kl\r\n']
```

不同于 `split()`, 当给出了分隔字符串 `sep` 时, 对于空字符串此方法将返回一个空列表, 而末尾的换行不会令结果中增加额外的行:

```
>>> "".splitlines()
[]
>>> "One line\n".splitlines()
['One line']
```

作为比较, `split('\n')` 的结果为:

```
>>> ''.split('\n')
['']
>>> 'Two lines\n'.split('\n')
['Two lines', '']
```

`str.startswith(prefix[, start[, end]])`

如果字符串以指定的 `prefix` 开始则返回 `True`, 否则返回 `False`。 `prefix` 也可以为由多个供查找的前缀构成的元组。如果有可选项 `start`, 将从所指定位置开始检查。如果有可选项 `end`, 将在所指定位置停止比较。

`str.strip([chars])`

返回原字符串的副本, 移除其中的前导和末尾字符。 `chars` 参数为指定要移除字符的字符串。如果省略或为 `None`, 则 `chars` 参数默认移除空格符。实际上 `chars` 参数并非指定单个前缀或后缀; 而是会移除参数值的所有组合:

```
>>> '   spacious   '.strip()
'spacious'
>>> 'www.example.com'.strip('cmowz.')
'example'
```

最外侧的前导和末尾 `chars` 参数值将从字符串中移除。开头端的字符的移除将在遇到一个未包含于 `chars` 所指定字符集的字符时停止。类似的操作也将在结尾端发生。例如:

```
>>> comment_string = '#..... Section 3.2.1 Issue #32 .....'
>>> comment_string.strip('.#! ')
'Section 3.2.1 Issue #32'
```

str.swapcase()

返回原字符串的副本，其中大写字符转换为小写，反之亦然。请注意 `s.swapcase().swapcase() == s` 并不一定为真值。

str.title()

返回原字符串的标题版本，其中每个单词第一个字母为大写，其余字母为小写。

例如：

```
>>> 'Hello world'.title()
'Hello World'
```

该算法使用一种简单的与语言无关的定义，将连续的字母组合视为单词。该定义在多数情况下都很有效，但它也意味着代表缩写形式与所有格的撇号也会成为单词边界，这可能导致不希望的结果：

```
>>> "they're bill's friends from the UK".title()
'They'Re Bill'S Friends From The Uk'
```

可以使用正则表达式来构建针对撇号的特别处理：

```
>>> import re
>>> def titlecase(s):
...     return re.sub(r"[A-Za-z]+(' [A-Za-z]+)?",
...                   lambda mo: mo.group(0)[0].upper() +
...                               mo.group(0)[1:].lower(),
...                   s)
...
>>> titlecase("they're bill's friends.")
'They're Bill's Friends.'
```

str.translate(table)

返回原字符串的副本，其中每个字符按给定的转换表进行映射。转换表必须是一个使用 `__getitem__()` 来实现索引操作的对象，通常为 *mapping* 或 *sequence*。当以 Unicode 码位序号（整数）为索引时，转换表对象可以做以下任何一种操作：返回 Unicode 序号或字符串，将字符映射为一个或多个字符；返回 None，将字符从结果字符串中删除；或引发 `LookupError` 异常，将字符映射为其自身。

你可以使用 `str.maketrans()` 基于不同格式的字符到字符映射来创建一个转换映射表。

另请参阅 `codecs` 模块以了解定制字符映射的更灵活方式。

str.upper()

返回原字符串的副本，其中所有区分大小写的字符⁴ 均转换为大写。请注意如果 `s` 包含不区分大小写的字符或者如果结果字符的 Unicode 类别不是 “Lu” (Letter, uppercase) 而是 “Lt” (Letter, titlecase) 则 `s.upper().isupper()` 有可能为 False。

所用转换大写算法的描述请参见 Unicode 标准的 3.13 节。

str.zfill(width)

返回原字符串的副本，在左边填充 ASCII '0' 数码使其长度变为 `width`。正负值前缀 ('+'/'-') 的处理方式是在正负符号之后填充而非在之前。如果 `width` 小于等于 `len(s)` 则返回原字符串的副本。

例如：

```
>>> "42".zfill(5)
'00042'
>>> "-42".zfill(5)
'-0042'
```

4.7.2 printf 风格的字符串格式化

注解： The formatting operations described here exhibit a variety of quirks that lead to a number of common errors (such as failing to display tuples and dictionaries correctly). Using the newer formatted string literals or the `str.format()` interface helps avoid these errors. These alternatives also provide more powerful, flexible and extensible approaches to formatting text.

字符串具有一种特殊的内置操作：使用 `%` (取模) 运算符。这也被称为字符串的 格式化或 插值运算符。对于 `format % values` (其中 *format* 为一个字符串)，在 *format* 中的 `%` 转换标记符将被替换为零个或多个 *values* 条目。其效果类似于在 C 语言中使用 `sprintf()`。

如果 *format* 要求一个单独参数，则 *values* 可以为一个非元组对象。⁵ 否则的话，*values* 必须或者是一个包含项数与格式字符串中指定的转换符项数相同的元组，或者是一个单独映射对象（例如字典）。

转换标记符包含两个或更多字符并具有以下组成，且必须遵循此处规定的顺序：

1. `'%'` 字符，用于标记转换符的起始。
2. 映射键（可选），由加圆括号的字符序列组成（例如 `(somename)`）。
3. 转换旗标（可选），用于影响某些转换类型的结果。
4. 最小字段宽度（可选）。如果指定为 `'*'` (星号)，则实际宽度会从 *values* 元组的下一元素中读取，要转换的对象则为最小字段宽度和可选的精度之后的元素。
5. 精度（可选），以在 `'.'` (点号) 之后加精度值的形式给出。如果指定为 `'*'` (星号)，则实际精度会从 *values* 元组的下一元素中读取，要转换的对象则为精度之后的元素。
6. 长度修饰符（可选）。
7. 转换类型。

当右边的参数为一个字典（或其他映射类型）时，字符串中的格式 必须包含加圆括号的映射键，对应 `'%'` 字符之后字典中的每一项。映射键将从映射中选取要格式化的值。例如：

```
>>> print('%(language)s has %(number)03d quote types.' %
...       {'language': "Python", "number": 2})
Python has 002 quote types.
```

在此情况下格式中不能出现 `*` 标记符（因其需要一个序列类的参数列表）。

转换旗标为：

标志	含义
<code>'#'</code>	值的转换将使用“替代形式”（具体定义见下文）。
<code>'0'</code>	转换将为数字值填充零字符。
<code>'-'</code>	转换值将靠左对齐（如果同时给出 <code>'0'</code> 转换，则会覆盖后者）。
<code>' '</code>	(空格) 符号位转换产生的正数（或空字符串）前将留出一个空格。
<code>'+'</code>	符号字符 (<code>'+'</code> 或 <code>'-'</code>) 将显示于转换结果的开头（会覆盖“空格”旗标）。

⁵ 要格式化单独一个元组，那么你应当提供一个单例元组，其唯一的元素就是要被格式化的元组。

可以给出长度修饰符 (h, l 或 L)，但会被忽略，因为对 Python 来说没有必要 – 所以 `%ld` 等价于 `%d`。

转换类型为：

转换符	含义	注释
'd'	有符号十进制整数。	
'i'	有符号十进制整数。	
'o'	有符号八进制数。	(1)
'u'	过时类型 – 等价于 'd'。	(6)
'x'	有符号十六进制数 (小写)。	(2)
'X'	有符号十六进制数 (大写)。	(2)
'e'	浮点指数格式 (小写)。	(3)
'E'	浮点指数格式 (大写)。	(3)
'f'	浮点十进制格式。	(3)
'F'	浮点十进制格式。	(3)
'g'	浮点格式。如果指数小于 -4 或不小于精度则使用小写指数格式，否则使用十进制格式。	(4)
'G'	浮点格式。如果指数小于 -4 或不小于精度则使用大写指数格式，否则使用十进制格式。	(4)
'c'	单个字符 (接受整数或单个字符的字符串)。	
'r'	字符串 (使用 <code>repr()</code> 转换任何 Python 对象)。	(5)
's'	字符串 (使用 <code>str()</code> 转换任何 Python 对象)。	(5)
'a'	字符串 (使用 <code>ascii()</code> 转换任何 Python 对象)。	(5)
'%'	不转换参数，在结果中输出一个 '%' 字符。	

注释：

- (1) 此替代形式会在第一个数码之前插入标示八进制数的前缀 ('0o')。
- (2) 此替代形式会在第一个数码之前插入 '0x' 或 '0X' 前缀 (取决于是使用 'x' 还是 'X' 格式)。
- (3) 此替代形式总是会在结果中包含一个小数点，即使其后并没有数码。
小数点后的数码位数由精度决定，默认为 6。
- (4) 此替代形式总是会在结果中包含一个小数点，末尾各位的零不会如其他情况下那样被移除。
小数点前后的有效数码位数由精度决定，默认为 6。
- (5) 如果精度为 N，输出将截短为 N 个字符。
- (6) 参见 [PEP 237](#)。

由于 Python 字符串显式指明长度，`%s` 转换不会将 `'\0'` 视为字符串的结束。

在 3.1 版更改：绝对值超过 `1e50` 的 `%f` 转换不会再被替换为 `%g` 转换。

4.8 二进制序列类型—bytes, bytearray, memoryview

操作二进制数据的核心内置类型是 `bytes` 和 `bytearray`。它们由 `memoryview` 提供支持，该对象使用缓冲区协议来访问其他二进制对象所在内存，不需要创建对象的副本。

`array` 模块支持高效地存储基本数据类型，例如 32 位整数和 IEEE754 双精度浮点值。

4.8.1 bytes 对象

`bytes` 对象是由单个字节构成的不可变序列。由于许多主要二进制协议都基于 ASCII 文本编码，因此 `bytes` 对象提供了一些仅在处理 ASCII 兼容数据时可用，并且在许多特性上与字符串对象紧密相关的方法。

class bytes ([*source* [, *encoding* [, *errors*]]])

首先, 表示 `bytes` 字面值的语法与字符串字面值的大致相同, 只是添加了一个 `b` 前缀:

- 单引号: `b'` 同样允许嵌入 " 双 " 引号 `'`。
- 双引号: `b"` 同样允许嵌入 ' 单 ' 引号 `"`。
- 三重引号: `b'''` 三重单引号 `'''`, `b"""` 三重双引号 `"""`

`bytes` 字面值中只允许 ASCII 字符 (无论源代码声明的编码为何)。任何超出 127 的二进制值必须使用相应的转义序列形式加入 `bytes` 字面值。

像字符串字面值一样, `bytes` 字面值也可以使用 `r` 前缀来禁用转义序列处理。请参阅 `strings` 了解有关各种 `bytes` 字面值形式的详情, 包括所支持的转义序列。

虽然 `bytes` 字面值和表示法是基于 ASCII 文本的, 但 `bytes` 对象的行为实际上更像是不可变的整数序列, 序列中的每个值的大小被限制为 $0 \leq x < 256$ (如果违反此限制将引发 `ValueError`)。这种限制是有意设计用以强调以下事实, 虽然许多二进制格式都包含基于 ASCII 的元素, 可以通过某些面向文本的算法进行有用的操作, 但情况对于任意二进制数据来说通常却并非如此 (盲目地将文本处理算法应用于不兼容 ASCII 的二进制数据格式往往将导致数据损坏)。

除了字面值形式, `bytes` 对象还可以通过其他方式来创建:

- 指定长度的以零值填充的 `bytes` 对象: `bytes(10)`
- 通过由整数组成的可迭代对象: `bytes(range(20))`
- 通过缓冲区协议复制现有的二进制数据: `bytes(obj)`

另请参阅 `bytes` 内置类型。

由于两个十六进制数码精确对应一个字节, 因此十六进制数是描述二进制数据的常用格式。相应地, `bytes` 类型具有从此种格式读取数据的附加类方法:

classmethod fromhex (*string*)

此 `bytes` 类方法返回一个解码给定字符串的 `bytes` 对象。字符串必须由表示每个字节的两个十六进制数码构成, 其中的 ASCII 空白符会被忽略。

```
>>> bytes.fromhex('2Ef0 F1f2 ')
b'\xf0\xf1\xf2'
```

存在一个反向转换函数, 可以将 `bytes` 对象转换为对应的十六进制表示。

hex ()

返回一个字符串对象, 该对象包含实例中每个字节的两个十六进制数字。

```
>>> b'\xf0\xf1\xf2'.hex()
'f0f1f2'
```

3.5 新版功能.

由于 `bytes` 对象是由整数构成的序列 (类似于元组), 因此对于一个 `bytes` 对象 `b`, `b[0]` 将为一个整数, 而 `b[0:1]` 将为一个长度为 1 的 `bytes` 对象。(这与文本字符串不同, 索引和切片所产生的将都是一个长度为 1 的字符串)。

`bytes` 对象的表示使用字面值格式 (`b'...'`), 因为它通常都要比像 `bytes([46, 46, 46])` 这样的格式更好用。你总是可以使用 `list(b)` 将 `bytes` 对象转换为一个由整数构成的列表。

注解: 针对 Python 2.x 用户的说明: 在 Python 2.x 系列中, 允许 8 位字符串 (2.x 所提供的最接近内置二进制数据类型的对象) 与 Unicode 字符串进行各种隐式转换。这是为了实现向下兼容的变通做法, 以适应 Python

最初只支持 8 位文本而 Unicode 文本是后来才被加入这一事实。在 Python 3.x 中，这些隐式转换已被取消——8 位二进制数据与 Unicode 文本间的转换必须显式地进行，bytes 与字符串对象的比较结果将总是不相等。

4.8.2 bytearray 对象

`bytearray` 对象是 `bytes` 对象的可变对应物。

class bytearray ([*source* [, *encoding* [, *errors*]]])

`bytearray` 对象没有专属的字面值语法，它们总是通过调用构造器来创建：

- 创建一个空实例: `bytearray()`
- 创建一个指定长度的以零值填充的实例: `bytearray(10)`
- 通过由整数组成的可迭代对象: `bytearray(range(20))`
- 通过缓冲区协议复制现有的二进制数据: `bytearray(b'Hi!')`

由于 `bytearray` 对象是可变的，该对象除了 `bytes` 和 `bytearray` 操作中所描述的 `bytes` 和 `bytearray` 共有操作之外，还支持可变序列操作。

另请参见 `bytearray` 内置类型。

由于两个十六进制数码精确对应一个字节，因此十六进制数是描述二进制数据的常用格式。相应地，`bytearray` 类型具有从此种格式读取数据的附加类方法：

classmethod fromhex (*string*)

`bytearray` 类方法返回一个解码给定字符串的 `bytearray` 对象。字符串必须由表示每个字节的两个十六进制数码构成，其中的 ASCII 空白符会被忽略。

```
>>> bytearray.fromhex('2Ef0 F1f2 ')
bytearray(b'\xf0\xf1\xf2')
```

存在一个反向转换函数，可以将 `bytearray` 对象转换为对应的十六进制表示。

hex ()

返回一个字符串对象，该对象包含实例中每个字节的两个十六进制数字。

```
>>> bytearray(b'\xf0\xf1\xf2').hex()
'f0f1f2'
```

3.5 新版功能.

由于 `bytearray` 对象是由整数构成的序列（类似于列表），因此对于一个 `bytearray` 对象 `b`，`b[0]` 将为一个整数，而 `b[0:1]` 将为一个长度为 1 的 `bytearray` 对象。（这与文本字符串不同，索引和切片所产生的将都是一个长度为 1 的字符串）。

`bytearray` 对象的表示使用 `bytes` 对象字面值格式 (`bytearray(b'...')`)，因为它通常都要比 `bytearray([46, 46, 46])` 这样的格式更好用。你总是可以使用 `list(b)` 将 `bytearray` 对象转换为一个由整数构成的列表。

4.8.3 bytes 和 bytearray 操作

`bytes` 和 `bytearray` 对象都支持通用序列操作。它们不仅能与相同类型的操作数，也能与任何 *bytes-like object* 进行互操作。由于这样的灵活性，它们可以在操作中自由地混合而不会导致错误。但是，操作结果的返回值类型可能取决于操作数的顺序。

注解：bytes 和 bytearray 对象的方法不接受字符串作为其参数，就像字符串的方法不接受 bytes 对象作为其参数一样。例如，你必须使用以下写法：

```
a = "abc"
b = a.replace("a", "f")
```

和：

```
a = b"abc"
b = a.replace(b"a", b"f")
```

某些 bytes 和 bytearray 操作假定使用兼容 ASCII 的二进制格式，因此在处理任意二进制数据时应当避免使用。这些限制会在下文中说明。

注解：使用这些基于 ASCII 的操作来处理未以基于 ASCII 的格式存储的二进制数据可能会导致数据损坏。

bytes 和 bytearray 对象的下列方法可以用于任意二进制数据。

bytes.count(sub[, start[, end]])

bytearray.count(sub[, start[, end]])

返回子序列 sub 在 [start, end] 范围内非重叠出现的次数。可选参数 start 与 end 会被解读为切片表示法。

要搜索的子序列可以是任意 bytes-like object 或是 0 至 255 范围内的整数。

在 3.3 版更改：也接受 0 至 255 范围内的整数作为子序列。

bytes.decode(encoding="utf-8", errors="strict")

bytearray.decode(encoding="utf-8", errors="strict")

返回从给定 bytes 解码出来的字符串。默认编码为 'utf-8'。可以给出 errors 来设置不同的错误处理方案。errors 的默认值为 'strict'，表示编码错误会引发 `UnicodeError`。其他可用的值为 'ignore'，'replace' 以及任何其他通过 `codecs.register_error()` 注册的名称，请参阅 *Error Handlers* 小节。要查看可用的编码列表，请参阅 *标准编码* 小节。

注解：将 encoding 参数传给 str 允许直接解码任何 bytes-like object，无须创建临时的 bytes 或 bytearray 对象。

在 3.1 版更改：加入了对关键字参数的支持。

bytes.endswith(suffix[, start[, end]])

bytearray.endswith(suffix[, start[, end]])

如果二进制数据以指定的 suffix 结束则返回 True，否则返回 False。suffix 也可以为由多个供查找的后缀构成的元组。如果有可选项 start，将从所指定位置开始检查。如果有可选项 end，将在所指定位置停止比较。

要搜索的后缀可以是任意 bytes-like object。

bytes.find(sub[, start[, end]])

bytearray.find(sub[, start[, end]])

返回子序列 sub 在数据中被找到的最小索引，sub 包含于切片 s[start:end] 之内。可选参数 start 与 end 会被解读为切片表示法。如果 sub 未被找到则返回 -1。

要搜索的子序列可以是任意 bytes-like object 或是 0 至 255 范围内的整数。

注解: `find()` 方法应该只在你需要知道 `sub` 所在位置时使用。要检查 `sub` 是否为子串, 请使用 `in` 操作符:

```
>>> b'Py' in b'Python'
True
```

在 3.3 版更改: 也接受 0 至 255 范围内的整数作为子序列。

`bytes.index(sub[, start[, end]])`

`bytearray.index(sub[, start[, end]])`

类似于 `find()`, 但在找不到子序列时会引发 `ValueError`。

要搜索的子序列可以是任意 *bytes-like object* 或是 0 至 255 范围内的整数。

在 3.3 版更改: 也接受 0 至 255 范围内的整数作为子序列。

`bytes.join(iterable)`

`bytearray.join(iterable)`

返回一个由 `iterable` 中的二进制数据序列拼接而成的 `bytes` 或 `bytearray` 对象。如果 `iterable` 中存在任何非字节类对象 包括存在 `str` 对象值则会引发 `TypeError`。提供该方法的 `bytes` 或 `bytearray` 对象的内容将作为元素之间的分隔。

static `bytes.maketrans(from, to)`

static `bytearray.maketrans(from, to)`

此静态方法返回一个可用于 `bytes.translate()` 的转换对照表, 它将把 `from` 中的每个字符映射为 `to` 中相同位置上的字符; `from` 与 `to` 必须都是字节类对象 并且具有相同的长度。

3.1 新版功能。

`bytes.partition(sep)`

`bytearray.partition(sep)`

在 `sep` 首次出现的位置拆分序列, 返回一个 3 元组, 其中包含分隔符之前的部分、分隔符本身或其 `bytearray` 副本, 以及分隔符之后的部分。如果分隔符未找到, 则返回的 3 元组中包含原序列以及两个空的 `bytes` 或 `bytearray` 对象。

要搜索的分隔符可以是任意 *bytes-like object*。

`bytes.replace(old, new[, count])`

`bytearray.replace(old, new[, count])`

返回序列的副本, 其中出现的所有子序列 `old` 都将被替换为 `new`。如果给出了可选参数 `count`, 则只替换前 `count` 次出现。

要搜索的子序列及其替换序列可以是任意 *bytes-like object*。

注解: 此方法的 `bytearray` 版本 并非原地操作——它总是产生一个新对象, 即便没有做任何改变。

`bytes.rfind(sub[, start[, end]])`

`bytearray.rfind(sub[, start[, end]])`

返回子序列 `sub` 在序列内被找到的最大(最右)索引, 这样 `sub` 将包含在 `s[start:end]` 当中。可选参数 `start` 与 `end` 会被解读为切片表示法。如果未找到则返回 -1。

要搜索的子序列可以是任意 *bytes-like object* 或是 0 至 255 范围内的整数。

在 3.3 版更改: 也接受 0 至 255 范围内的整数作为子序列。

`bytes.rindex(sub[, start[, end]])`

`bytearray.rindex(sub[, start[, end]])`

类似于 `rfind()`, 但在子序列 `sub` 未找到时会引发 `ValueError`。

要搜索的子序列可以是任意 *bytes-like object* 或是 0 至 255 范围内的整数。

在 3.3 版更改: 也接受 0 至 255 范围内的整数作为子序列。

`bytes.rpartition(sep)`

`bytearray.rpartition(sep)`

Split the sequence at the last occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself or its bytearray copy, and the part after the separator. If the separator is not found, return a 3-tuple containing a copy of the original sequence, followed by two empty bytes or bytearray objects.

要搜索的分隔符可以是任意 *bytes-like object*。

`bytes.startswith(prefix[, start[, end]])`

`bytearray.startswith(prefix[, start[, end]])`

如果二进制数据以指定的 *prefix* 开头则返回 True, 否则返回 False。 *prefix* 也可以为由多个供查找的前缀构成的元组。如果有可选项 *start*, 将从所指定位置开始检查。如果有可选项 *end*, 将在所指定位置停止比较。

要搜索的前缀可以是任意 *bytes-like object*。

`bytes.translate(table, delete=b"")`

`bytearray.translate(table, delete=b"")`

返回原 bytes 或 bytearray 对象的副本, 移除其中所有在可选参数 *delete* 中出现的 bytes, 其余 bytes 将通过给定的转换表进行映射, 该转换表必须是长度为 256 的 bytes 对象。

你可以使用 `bytes.maketrans()` 方法来创建转换表。

对于仅需移除字符的转换, 请将 *table* 参数设为 None:

```
>>> b'read this short text'.translate(None, b'aeiou')
b'rd ths shrt txt'
```

在 3.6 版更改: 现在支持将 *delete* 作为关键字参数。

以下 bytes 和 bytearray 对象的方法的默认行为会假定使用兼容 ASCII 的二进制格式, 但通过传入适当的参数仍然可用于任意二进制数据。请注意本小节中所有的 bytearray 方法都不是原地执行操作, 而是会产生新的对象。

`bytes.center(width[, fillbyte])`

`bytearray.center(width[, fillbyte])`

返回原对象的副本, 在长度为 *width* 的序列内居中, 使用指定的 *fillbyte* 填充两边的空位 (默认使用 ASCII 空格符)。对于 *bytes* 对象, 如果 *width* 小于等于 `len(s)` 则返回原序列的副本。

注解: 此方法的 bytearray 版本并非原地操作——它总是产生一个新对象, 即便没有做任何改变。

`bytes.ljust(width[, fillbyte])`

`bytearray.ljust(width[, fillbyte])`

返回原对象的副本, 在长度为 *width* 的序列中靠左对齐。使用指定的 *fillbyte* 填充空位 (默认使用 ASCII 空格符)。对于 *bytes* 对象, 如果 *width* 小于等于 `len(s)` 则返回原序列的副本。

注解: 此方法的 bytearray 版本并非原地操作——它总是产生一个新对象, 即便没有做任何改变。

`bytes.lstrip([chars])`

`bytearray.lstrip([chars])`

返回原序列的副本, 移除指定的前导字节。 *chars* 参数为指定要移除字节值集合的二进制序列——这个名称表明此方法通常是用于 ASCII 字符。如果省略或为 None, 则 *chars* 参数默认移除 ASCII 空白符。 *chars* 参数并非指定单个前缀; 而是会移除参数值的所有组合:

```
>>> b'    spacious    '.lstrip()
b'spacious    '
>>> b'www.example.com'.lstrip(b'cmowz.')
b'example.com'
```

要移除的字节值二进制序列可以是任意 *bytes-like object*。

注解：此方法的 `bytearray` 版本 并非原地操作——它总是产生一个新对象，即便没有做任何改变。

`bytes.rjust(width[, fillbyte])`

`bytearray.rjust(width[, fillbyte])`

返回原对象的副本，在长度为 `width` 的序列中靠右对齐。使用指定的 `fillbyte` 填充空位（默认使用 ASCII 空格符）。对于 `bytes` 对象，如果 `width` 小于等于 `len(s)` 则返回原序列的副本。

注解：此方法的 `bytearray` 版本 并非原地操作——它总是产生一个新对象，即便没有做任何改变。

`bytes.rsplit(sep=None, maxsplit=-1)`

`bytearray.rsplit(sep=None, maxsplit=-1)`

将二进制序列拆分为相同类型的子序列，使用 `sep` 作为分隔符。如果给出了 `maxsplit`，则最多进行 `maxsplit` 次拆分，从最右边开始。如果 `sep` 未指定或为 `None`，任何只包含 ASCII 空白符的子序列都会被作为分隔符。除了从右边开始拆分，`rsplit()` 的其他行为都类似于下文所述的 `split()`。

`bytes.rstrip([chars])`

`bytearray.rstrip([chars])`

返回原序列的副本，移除指定的末尾字节。`chars` 参数为指定要移除字节值集合的二进制序列——这个名称表明此方法通常是用于 ASCII 字符。如果省略或为 `None`，则 `chars` 参数默认移除 ASCII 空白符。`chars` 参数并非指定单个后缀；而是会移除参数值的所有组合：

```
>>> b'    spacious    '.rstrip()
b'    spacious'
>>> b'mississippi'.rstrip(b'ipz')
b'mississ'
```

要移除的字节值二进制序列可以是任意 *bytes-like object*。

注解：此方法的 `bytearray` 版本 并非原地操作——它总是产生一个新对象，即便没有做任何改变。

`bytes.split(sep=None, maxsplit=-1)`

`bytearray.split(sep=None, maxsplit=-1)`

将二进制序列拆分为相同类型的子序列，使用 `sep` 作为分隔符。如果给出了 `maxsplit` 且非负值，则最多进行 `maxsplit` 次拆分（因此，列表最多会有 `maxsplit+1` 个元素）。如果 `maxsplit` 未指定或为 `-1`，则不限制拆分次数（进行所有可能的拆分）。

如果给出了 `sep`，则连续的分隔符不会被组合在一起而是被视为分隔空子序列（例如 `b'1,,2'.split(b',')` 将返回 `[b'1', b'', b'2']`）。`sep` 参数可能为一个多字节序列（例如 `b'1<>2<>3'.split(b'<>')` 将返回 `[b'1', b'2', b'3']`）。使用指定的分隔符拆分空序列将返回 `[b'']` 或 `[bytearray(b'')]`，具体取决于被拆分对象的类型。`sep` 参数可以是任意 *bytes-like object*。

例如：

```
>>> b'1,2,3'.split(b',')
[b'1', b'2', b'3']
```

(下页继续)

(续上页)

```
>>> b'1,2,3'.split(b',', maxsplit=1)
[b'1', b'2,3']
>>> b'1,2,,3,.'.split(b',')
[b'1', b'2', b'', b'3', b'']
```

如果 *sep* 未指定或为 `None`，则会应用另一种拆分算法：连续的 ASCII 空白符会被视为单个分隔符，其结果将不包含序列开头或末尾的空白符。因此，在不指定分隔符的情况下对空序列或仅包含 ASCII 空白符的序列进行拆分将返回 `[]`。

例如：

```
>>> b'1 2 3'.split()
[b'1', b'2', b'3']
>>> b'1 2 3'.split(maxsplit=1)
[b'1', b'2 3']
>>> b' 1 2 3 '.split()
[b'1', b'2', b'3']
```

`bytes.strip([chars])`

`bytearray.strip([chars])`

返回原序列的副本，移除指定的开头和末尾字节。*chars* 参数为指定要移除字节值集合的二进制序列——这个名称表明此方法通常是用于 ASCII 字符。如果省略或为 `None`，则 *chars* 参数默认移除 ASCII 空白符。*chars* 参数并非指定单个前缀或后缀；而是会移除参数值的所有组合：

```
>>> b'   spacious   '.strip()
b'spacious'
>>> b'www.example.com'.strip(b'cmowz.')
b'example'
```

要移除的字节值二进制序列可以是任意 *bytes-like object*。

注解：此方法的 `bytearray` 版本并非原地操作——它总是产生一个新对象，即便没有做任何改变。

以下 `bytes` 和 `bytearray` 对象的方法会假定使用兼容 ASCII 的二进制格式，不应当被应用于任意二进制数据。请注意本小节中所有的 `bytearray` 方法都不是原地执行操作，而是会产生新的对象。

`bytes.capitalize()`

`bytearray.capitalize()`

返回原序列的副本，其中每个字节都将被解读为一个 ASCII 字符，并且第一个字节的字符大写而其余的小写。非 ASCII 字节值将保持原样不变。

注解：此方法的 `bytearray` 版本并非原地操作——它总是产生一个新对象，即便没有做任何改变。

`bytes.expandtabs(tabsize=8)`

`bytearray.expandtabs(tabsize=8)`

返回序列的副本，其中所有的 ASCII 制表符会由一个或多个 ASCII 空格替换，具体取决于当前列位置和给定的制表符宽度。每 *tabsize* 个字节设为一个制表位（默认值 8 时设定的制表位在列 0, 8, 16 依次类推）。要展开序列，当前列位置将被设为零并逐一检查序列中的每个字节。如果字节为 ASCII 制表符 (`b'\t'`)，则并在结果中插入一个或多个空格符，直到当前列等于下一个制表位。（制表符本身不会被复制。）如果当前字节为 ASCII 换行符 (`b'\n'`) 或回车符 (`b'\r'`)，它会被复制并将当前列重设为零。任何其他字节会被不加修改地复制并将当前列加一，不论该字节值在被打印时会如何显示：

```
>>> b'01\t012\t0123\t01234'.expandtabs()
b'01      012      0123      01234'
>>> b'01\t012\t0123\t01234'.expandtabs(4)
b'01  012 0123  01234'
```

注解：此方法的 `bytearray` 版本并非原地操作——它总是产生一个新对象，即便没有做任何改变。

`bytes.isalnum()`

`bytearray.isalnum()`

如果序列中所有字节都是字母类 ASCII 字符或 ASCII 十进制数码并且序列非空则返回真值，否则返回假值。字母类 ASCII 字符就是字节值包含在序列 `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'` 中的字符。ASCII 十进制数码就是字节值包含在序列 `b'0123456789'` 中的字符。

例如：

```
>>> b'ABCabc1'.isalnum()
True
>>> b'ABC abc1'.isalnum()
False
```

`bytes.isalpha()`

`bytearray.isalpha()`

如果序列中所有字节都是字母类 ASCII 字符并且序列非空则返回真值，否则返回假值。字母类 ASCII 字符就是字节值包含在序列 `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'` 中的字符。

例如：

```
>>> b'ABCabc'.isalpha()
True
>>> b'ABCabc1'.isalpha()
False
```

`bytes.isdigit()`

`bytearray.isdigit()`

如果序列中所有字节都是 ASCII 十进制数码并且序列非空则返回真值，否则返回假值。ASCII 十进制数码就是字节值包含在序列 `b'0123456789'` 中的字符。

例如：

```
>>> b'1234'.isdigit()
True
>>> b'1.23'.isdigit()
False
```

`bytes.islower()`

`bytearray.islower()`

如果序列中至少有一个小写 ASCII 字符并且没有大写 ASCII 字符则返回真值，否则返回假值。

例如：

```
>>> b'hello world'.islower()
True
>>> b'Hello world'.islower()
False
```

小写 ASCII 字符就是字节值包含在序列 `b'abcdefghijklmnopqrstuvwxyz'` 中的字符。大写 ASCII 字符就是字节值包含在序列 `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'` 中的字符。

`bytes.isspace()`

`bytearray.isspace()`

如果序列中所有字节都是 ASCII 空白符并且序列非空则返回真值，否则返回假值。ASCII 空白符就是字节值包含在序列 `b' \t\n\r\x0b\f'` (空格, 制表, 换行, 回车, 垂直制表, 换页) 中的字符。

`bytes.istitle()`

`bytearray.istitle()`

如果序列为 ASCII 标题形式并且序列非空则返回真值，否则返回假值。请参阅 `bytes.title()` 了解有关“标题形式”的详细定义。

例如:

```
>>> b'Hello World'.istitle()
True
>>> b'Hello world'.istitle()
False
```

`bytes.isupper()`

`bytearray.isupper()`

如果序列中至少有一个大写字母 ASCII 字符并且没有小写 ASCII 字符则返回真值，否则返回假值。

例如:

```
>>> b'HELLO WORLD'.isupper()
True
>>> b'Hello world'.isupper()
False
```

小写 ASCII 字符就是字节值包含在序列 `b'abcdefghijklmnopqrstuvwxyz'` 中的字符。大写 ASCII 字符就是字节值包含在序列 `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'` 中的字符。

`bytes.lower()`

`bytearray.lower()`

返回原序列的副本，其所有大写 ASCII 字符均转换为对应的小写形式。

例如:

```
>>> b'Hello World'.lower()
b'hello world'
```

小写 ASCII 字符就是字节值包含在序列 `b'abcdefghijklmnopqrstuvwxyz'` 中的字符。大写 ASCII 字符就是字节值包含在序列 `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'` 中的字符。

注解: 此方法的 `bytearray` 版本 并非原地操作——它总是产生一个新对象，即便没有做任何改变。

`bytes.splitlines(keepends=False)`

`bytearray.splitlines(keepends=False)`

返回由原二进制序列中各行组成的列表，在 ASCII 行边界符的位置拆分。此方法使用 *universal newlines* 方式来分行。结果列表中不包含换行符，除非给出了 `keepends` 且为真值。

例如:

```
>>> b'ab c\n\nde fg\rkl\r\n'.splitlines()
[b'ab c', b'', b'de fg', b'kl']
```

(下页继续)

(续上页)

```
>>> b'ab c\n\nde fg\rkl\r\n'.splitlines(keepends=True)
[b'ab c\n', b'\n', b'de fg\r', b'kl\r\n']
```

不同于 `split()`，当给出了分隔符 `sep` 时，对于空字符串此方法将返回一个空列表，而末尾的换行不会令结果中增加额外的行：

```
>>> b"".split(b'\n'), b"Two lines\n".split(b'\n')
([b''], [b'Two lines', b''])
>>> b"".splitlines(), b"One line\n".splitlines()
([], [b'One line'])
```

`bytes.swapcase()`

`bytearray.swapcase()`

返回原序列的副本，其所有小写 ASCII 字符均转换为对应的大写形式，反之亦反。

例如：

```
>>> b'Hello World'.swapcase()
b'hELLO wORLD'
```

小写 ASCII 字符就是字节值包含在序列 `b'abcdefghijklmnopqrstuvwxyz'` 中的字符。大写 ASCII 字符就是字节值包含在序列 `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'` 中的字符。

不同于 `str.swapcase()`，在些二进制版本下 `bin.swapcase().swapcase() == bin` 总是成立。大小写转换在 ASCII 中是对称的，即使其对于任意 Unicode 码位来说并不总是成立。

注解：此方法的 `bytearray` 版本并非原地操作——它总是产生一个新对象，即便没有做任何改变。

`bytes.title()`

`bytearray.title()`

返回原二进制序列的标题版本，其中每个单词以一个大写 ASCII 字符为开头，其余字母为小写。不区别大小写的字节值将保持原样不变。

例如：

```
>>> b'Hello world'.title()
b'Hello World'
```

小写 ASCII 字符就是字节值包含在序列 `b'abcdefghijklmnopqrstuvwxyz'` 中的字符。大写 ASCII 字符就是字节值包含在序列 `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'` 中的字符。所有其他字节值都不区分大小写。

该算法使用一种简单的与语言无关的定义，将连续的字母组合视为单词。该定义在多数情况下都很有效，但它也意味着代表缩写形式与所有格的撇号也会成为单词边界，这可能导致不希望的结果：

```
>>> b"they're bill's friends from the UK".title()
b"They'Re Bill'S Friends From The Uk"
```

可以使用正则表达式来构建针对撇号的特别处理：

```
>>> import re
>>> def titlecase(s):
...     return re.sub(rb"[A-Za-z]+('[A-Za-z]+)?",
...                     lambda mo: mo.group(0)[0:1].upper() +
...                               mo.group(0)[1:].lower(),
```

(下页继续)

(续上页)

```

...         s)
...
>>> titlecase(b"they're bill's friends.")
b"They're Bill's Friends."

```

注解：此方法的 `bytearray` 版本 并非原地操作——它总是产生一个新对象，即便没有做任何改变。

`bytes.upper()`

`bytearray.upper()`

返回原序列的副本，其所有小写 ASCII 字符均转换为对应的大写形式。

例如：

```

>>> b'Hello World'.upper()
b'HELLO WORLD'

```

小写 ASCII 字符就是字节值包含在序列 `b'abcdefghijklmnopqrstuvwxyz'` 中的字符。大写 ASCII 字符就是字节值包含在序列 `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'` 中的字符。

注解：此方法的 `bytearray` 版本 并非原地操作——它总是产生一个新对象，即便没有做任何改变。

`bytes.zfill(width)`

`bytearray.zfill(width)`

返回原序列的副本，在左边填充 `b'0'` 数码使序列长度为 `width`。正负值前缀 (`b'+' / b'-'`) 的处理方式是在正负符号 之后填充而非在之前。对于 `bytes` 对象，如果 `width` 小于等于 `len(seq)` 则返回原序列。

例如：

```

>>> b"42".zfill(5)
b'00042'
>>> b"-42".zfill(5)
b'-0042'

```

注解：此方法的 `bytearray` 版本 并非原地操作——它总是产生一个新对象，即便没有做任何改变。

4.8.4 printf 风格的字节串格式化

注解：此处介绍的格式化操作具有多种怪异特性，可能导致许多常见错误（例如无法正确显示元组和字典）。如果要打印的值可能为元组或字典，请将其放入一个元组中。

字节串对象 (`bytes/bytearray`) 具有一种特殊的内置操作：使用 `%` (取模) 运算符。这也被称为字节串的 格式化或 插值运算符。对于 `format % values` (其中 `format` 为一个字节串对象)，在 `format` 中的 `%` 转换标记符将被替换为零个或多个 `values` 条目。其效果类似于在 C 语言中使用 `sprintf()`。

如果 `format` 要求一个单独参数，则 `values` 可以为一个非元组对象⁵。否则的话，`values` 必须或是是一个包含项数与格式字节串对象中指定的转换符项数相同的元组，或者是一个单独的映射对象（例如元组）。

转换标记符包含两个或更多字符并具有以下组成，且必须遵循此处规定的顺序：

1. '%' 字符，用于标记转换符的起始。
2. 映射键（可选），由加圆括号的字符序列组成（例如 (somename)）。
3. 转换旗标（可选），用于影响某些转换类型的结果。
4. 最小字段宽度（可选）。如果指定为 '*'（星号），则实际宽度会从 *values* 元组的下一元素中读取，要转换的对象则为最小字段宽度和可选的精度之后的元素。
5. 精度（可选），以在 '.'（点号）之后加精度值的形式给出。如果指定为 '*'（星号），则实际精度会从 *values* 元组的下一元素中读取，要转换的对象则为精度之后的元素。
6. 长度修饰符（可选）。
7. 转换类型。

当右边的参数为一个字典（或其他映射类型）时，字节串对象中的格式 必须包含加圆括号的映射键，对应 '%' 字符之后字典中的每一项。映射键将从映射中选取要格式化的值。例如：

```
>>> print(b'%(language)s has %(number)03d quote types.' %
...       {b'language': b"Python", b"number": 2})
b'Python has 002 quote types.'
```

在此情况下格式中不能出现 * 标记符（因其需要一个序列类的参数列表）。

转换旗标为：

标志	含义
'#'	值的转换将使用“替代形式”（具体定义见下文）。
'0'	转换将为数字值填充零字符。
'-'	转换值将靠左对齐（如果同时给出 '0' 转换，则会覆盖后者）。
' '	(空格) 符号位转换产生的正数（或空字符串）前将留出一个空格。
'+'	符号字符 ('+' 或 '-') 将显示于转换结果的开头（会覆盖“空格”旗标）。

可以给出长度修饰符 (h, l 或 L)，但会被忽略，因为对 Python 来说没有必要 – 所以 %ld 等价于 %d。

转换类型为：

转 换 符	含义	注 释
'd'	有符号十进制整数。	
'i'	有符号十进制整数。	
'o'	有符号八进制数。	(1)
'u'	过时类型 – 等价于 'd'。	(8)
'x'	有符号十六进制数 (小写)。	(2)
'X'	有符号十六进制数 (大写)。	(2)
'e'	浮点指数格式 (小写)。	(3)
'E'	浮点指数格式 (大写)。	(3)
'f'	浮点十进制格式。	(3)
'F'	浮点十进制格式。	(3)
'g'	浮点格式。如果指数小于 -4 或不小于精度则使用小写指数格式，否则使用十进制格式。	(4)
'G'	浮点格式。如果指数小于 -4 或不小于精度则使用大写指数格式，否则使用十进制格式。	(4)
'c'	单个字节 (接受整数或单个字节对象)。	
'b'	字节串 (任何遵循 缓冲区协议或是具有 <code>__bytes__()</code> 的对象)。	(5)
's'	's' 是 'b' 的一个别名，只应当在基于 Python2/3 的代码中使用。	(6)
'a'	字节串 (使用 <code>repr(obj).encode('ascii', 'backslashreplace)</code> 转换任何 Python 对象)。	(5)
'r'	'r' 是 'a' 的一个别名，只应当在基于 Python2/3 的代码中使用。	(7)
'%'	不转换参数，在结果中输出一个 '%' 字符。	

注释:

- (1) 此替代形式会在第一个数码之前插入标示八进制数的前缀 ('0o')。
- (2) 此替代形式会在第一个数码之前插入 '0x' 或 '0X' 前缀 (取决于是使用 'x' 还是 'X' 格式)。
- (3) 此替代形式总是会在结果中包含一个小数点，即使其后并没有数码。
小数点后的数码位数由精度决定，默认为 6。
- (4) 此替代形式总是会在结果中包含一个小数点，末尾各位的零不会如其他情况下那样被移除。
小数点前后的有效数码位数由精度决定，默认为 6。
- (5) 如果精度为 N，输出将截短为 N 个字符。
- (6) `b'%s'` 已弃用，但在 3.x 系列中将不会被移除。
- (7) `b'%r'` 已弃用，但在 3.x 系列中将不会被移除。
- (8) 参见 [PEP 237](#)。

注解: 此方法的 `bytearray` 版本 并非原地操作——它总是产生一个新对象，即便没有做任何改变。

参见:

[PEP 461](#) - 为 `bytes` 和 `bytearray` 添加 % 格式化

3.5 新版功能.

4.8.5 内存视图

`memoryview` 对象允许 Python 代码访问一个对象的内部数据，只要该对象支持 缓冲区协议而无需进行拷贝。

class memoryview(obj)

创建一个引用 *obj* 的 *memoryview*。 *obj* 必须支持缓冲区协议。支持缓冲区协议的内置对象包括 *bytes* 和 *bytearray*。

memoryview 具有 元素的概念，即由原始对象 *obj* 所处理的基本内存单元。对于许多简单类型例如 *bytes* 和 *bytearray* 来说，一个元素就是一个字节，但是其他的类型例如 *array.array* 可能有更大的元素。

`len(view)` 与 *tolist* 的长度相等。如果 `view.ndim = 0`，则其长度为 1。如果 `view.ndim = 1`，则其长度等于 *view* 中元素的数量。对于更高的维度，其长度等于表示 *view* 的嵌套列表的长度。*itemsize* 属性可向你给出单个元素所占的字节数。

memoryview 支持通过切片和索引访问其元素。一维切片的结果将是一个子视图：

```
>>> v = memoryview(b'abcefg')
>>> v[1]
98
>>> v[-1]
103
>>> v[1:4]
<memory at 0x7f3ddc9f4350>
>>> bytes(v[1:4])
b'bce'
```

如果 *format* 是一个来自于 *struct* 模块的原生格式说明符，则也支持使用整数或由整数构成的元组进行索引，并返回具有正确类型的单个 元素。一维内存视图可以使用一个整数或由一个整数构成的元组进行索引。多维内存视图可以使用由恰好 *ndim* 个整数构成的元素进行索引，*ndim* 即其维度。零维内存视图可以使用空元组进行索引。

这里是一个使用非字节格式的例子：

```
>>> import array
>>> a = array.array('l', [-11111111, 22222222, -33333333, 44444444])
>>> m = memoryview(a)
>>> m[0]
-11111111
>>> m[-1]
44444444
>>> m[::2].tolist()
[-11111111, -33333333]
```

如果下层对象是可写的，则内存视图支持一维切片赋值。改变大小则不被允许：

```
>>> data = bytearray(b'abcefg')
>>> v = memoryview(data)
>>> v.readonly
False
>>> v[0] = ord(b'z')
>>> data
bytearray(b'zbcefg')
>>> v[1:4] = b'123'
>>> data
bytearray(b'z123fg')
>>> v[2:3] = b'spam'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: memoryview assignment: lvalue and rvalue have different structures
>>> v[2:6] = b'spam'
```

(下页继续)

(续上页)

```
>>> data
bytearray(b'z!spam')
```

由带有格式符号 ‘B’，‘b’ 或 ‘c’ 的可哈希（只读）类型构成的一维内存视图同样是可哈希的。哈希定义为 `hash(m) == hash(m.tobytes())`：

```
>>> v = memoryview(b'abcefg')
>>> hash(v) == hash(b'abcefg')
True
>>> hash(v[2:4]) == hash(b'ce')
True
>>> hash(v[::-2]) == hash(b'abcefg'[::-2])
True
```

在 3.3 版更改：一维内存视图现在可以被切片。带有格式符号 ‘B’，‘b’ 或 ‘c’ 的一维内存视图现在是可哈希的。

在 3.4 版更改：内存视图现在会自动注册为 `collections.abc.Sequence`

在 3.5 版更改：内存视图现在可使用整数元组进行索引。

`memoryview` 具有以下一些方法：

`__eq__` (exporter)

`memoryview` 与 **PEP 3118** 中的导出器这两者如果形状相同，并且如果当使用 `struct` 语法解读操作数的相应格式代码时所有对应值都相同，则它们就是等价的。

对于 `tolist()` 当前所支持的 `struct` 格式字符串子集，如果 `v.tolist() == w.tolist()` 则 `v` 和 `w` 相等：

```
>>> import array
>>> a = array.array('I', [1, 2, 3, 4, 5])
>>> b = array.array('d', [1.0, 2.0, 3.0, 4.0, 5.0])
>>> c = array.array('b', [5, 3, 1])
>>> x = memoryview(a)
>>> y = memoryview(b)
>>> x == a == y == b
True
>>> x.tolist() == a.tolist() == y.tolist() == b.tolist()
True
>>> z = y[::-2]
>>> z == c
True
>>> z.tolist() == c.tolist()
True
```

如果两边的格式字符串都不被 `struct` 模块所支持，则两对象比较结果总是不相等（即使格式字符串和缓冲区内容相同）：

```
>>> from ctypes import BigEndianStructure, c_long
>>> class BEPoint(BigEndianStructure):
...     _fields_ = [("x", c_long), ("y", c_long)]
...
>>> point = BEPoint(100, 200)
>>> a = memoryview(point)
>>> b = memoryview(point)
>>> a == point
False
```

(下页继续)

(续上页)

```
>>> a == b
False
```

请注意，与浮点数的情况一样，对于内存视图对象来说，`v is w` 也并不意味着 `v == w`。

在 3.3 版更改：之前的版本比较原始内存时会忽略条目的格式与逻辑数组结构。

tobytes()

将缓冲区中的数据作为字节串返回。这相当于在内存视图上调用 `bytes` 构造器。

```
>>> m = memoryview(b"abc")
>>> m.tobytes()
b'abc'
>>> bytes(m)
b'abc'
```

对于非连续数组，结果等于平面化表示的列表，其中所有元素都转换为字节串。`tobytes()` 支持所有格式字符串，不符合 `struct` 模块语法的那些也包括在内。

hex()

返回一个字符串对象，其中分别以两个十六进制数码表示缓冲区里的每个字节。

```
>>> m = memoryview(b"abc")
>>> m.hex()
'616263'
```

3.5 新版功能.

tolist()

将缓冲区内的数据以一个元素列表的形式返回。

```
>>> memoryview(b'abc').tolist()
[97, 98, 99]
>>> import array
>>> a = array.array('d', [1.1, 2.2, 3.3])
>>> m = memoryview(a)
>>> m.tolist()
[1.1, 2.2, 3.3]
```

在 3.3 版更改：`tolist()` 现在支持 `struct` 模块语法中的所有单字符原生格式以及多维表示形式。

release()

释放由内存视图对象所公开的底层缓冲区。许多对象在被视图所获取时都会采取特殊动作（例如，`bytearray` 将会暂时禁止调整大小）；因此，调用 `release()` 可以方便地尽早去除这些限制（并释放任何多余的资源）。

在此方法被调用后，任何对视图的进一步操作将引发 `ValueError` (`release()` 本身除外，它可以被多次调用)：

```
>>> m = memoryview(b'abc')
>>> m.release()
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memoryview object
```

使用 `with` 语句，可以通过上下文管理协议达到类似的效果：

```
>>> with memoryview(b'abc') as m:
...     m[0]
...
97
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memoryview object
```

3.2 新版功能.

cast (*format* [, *shape*])

将内存视图转化为新的格式或形状。*shape* 默认为 `[byte_length//new_itemsize]`，这意味着结果视图将是一维的。返回值是一个新的内存视图，但缓冲区本身不会被复制。支持的转化有 1D -> C-contiguous 和 C-contiguous -> 1D。

目标格式仅限于 *struct* 语法中的单一元素原生格式。其中一种格式必须为字节格式（‘B’，‘b’或‘c’）。结果的字节长度必须与原始长度相同。

将 1D/long 转换为 1D/unsigned bytes:

```
>>> import array
>>> a = array.array('l', [1,2,3])
>>> x = memoryview(a)
>>> x.format
'l'
>>> x.itemsize
8
>>> len(x)
3
>>> x.nbytes
24
>>> y = x.cast('B')
>>> y.format
'B'
>>> y.itemsize
1
>>> len(y)
24
>>> y.nbytes
24
```

将 1D/unsigned bytes 转换为 1D/char:

```
>>> b = bytearray(b'zyz')
>>> x = memoryview(b)
>>> x[0] = b'a'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: memoryview: invalid value for format "B"
>>> y = x.cast('c')
>>> y[0] = b'a'
>>> b
bytearray(b'ayz')
```

将 1D/bytes 转换为 3D/ints 再转换为 1D/signed char:

```

>>> import struct
>>> buf = struct.pack("i"*12, *list(range(12)))
>>> x = memoryview(buf)
>>> y = x.cast('i', shape=[2,2,3])
>>> y.tolist()
[[[0, 1, 2], [3, 4, 5]], [[6, 7, 8], [9, 10, 11]]]
>>> y.format
'i'
>>> y.itemsize
4
>>> len(y)
2
>>> y.nbytes
48
>>> z = y.cast('b')
>>> z.format
'b'
>>> z.itemsize
1
>>> len(z)
48
>>> z.nbytes
48

```

将 1D/unsigned char 转换为 2D/unsigned long:

```

>>> buf = struct.pack("L"*6, *list(range(6)))
>>> x = memoryview(buf)
>>> y = x.cast('L', shape=[2,3])
>>> len(y)
2
>>> y.nbytes
48
>>> y.tolist()
[[0, 1, 2], [3, 4, 5]]

```

3.3 新版功能.

在 3.5 版更改: 当转换为字节视图时, 源格式将不再受限。

还存在一些可用的只读属性:

obj

内存视图的下层对象:

```

>>> b = bytearray(b'xyz')
>>> m = memoryview(b)
>>> m.obj is b
True

```

3.3 新版功能.

nbytes

`nbytes == product(shape) * itemsize == len(m.tobytes())`。这是数组在连续表示时将会占用的空间总字节数。它不一定等于 `len(m)`:

```

>>> import array
>>> a = array.array('i', [1,2,3,4,5])

```

(下页继续)

(续上页)

```

>>> m = memoryview(a)
>>> len(m)
5
>>> m.nbytes
20
>>> y = m[::2]
>>> len(y)
3
>>> y.nbytes
12
>>> len(y.tobytes())
12

```

多维数组:

```

>>> import struct
>>> buf = struct.pack("d"*12, *[1.5*x for x in range(12)])
>>> x = memoryview(buf)
>>> y = x.cast('d', shape=[3,4])
>>> y.tolist()
[[0.0, 1.5, 3.0, 4.5], [6.0, 7.5, 9.0, 10.5], [12.0, 13.5, 15.0, 16.5]]
>>> len(y)
3
>>> y.nbytes
96

```

3.3 新版功能.

readonly

一个表明内存是否只读的布尔值。

format

一个字符串，包含视图中每个元素的格式（表示为`struct`模块样式）。内存视图可以从具有任意格式字符串的导出器创建，但某些方法（例如`tolist()`）仅限于原生的单元元素格式。

在 3.3 版更改: 格式 'B' 现在会按照 `struct` 模块语法来处理。这意味着 `memoryview(b'abc')[0] == b'abc'[0] == 97`。

itemsize

`memoryview` 中每个元素以字节表示的大小:

```

>>> import array, struct
>>> m = memoryview(array.array('H', [32000, 32001, 32002]))
>>> m.itemsize
2
>>> m[0]
32000
>>> struct.calcsize('H') == m.itemsize
True

```

ndim

一个整数，表示内存所代表的多维数组具有多少个维度。

shape

一个整数元组，通过 `ndim` 的长度值给出内存所代表的 N 维数组的形状。

在 3.3 版更改: 当 `ndim = 0` 时值为空元组而不再为 `None`。

strides

一个整数元组，通过`ndim` 的长度给出以字节表示的大小，以便访问数组中每个维度上的每个元素。

在 3.3 版更改：当 `ndim = 0` 时值为空元组而不再为 `None`。

suboffsets

供 PIL 风格的数组内部使用。该值仅作为参考信息。

c_contiguous

一个表明内存是否为 C-*contiguous* 的布尔值。

3.3 新版功能。

f_contiguous

一个表明内存是否为 Fortran *contiguous* 的布尔值。

3.3 新版功能。

contiguous

一个表明内存是否为 *contiguous* 的布尔值。

3.3 新版功能。

4.9 集合类型—set, frozenset

set 对象是由具有唯一性的*hashable* 对象所组成的无序多项集。常见的用途包括成员检测、从序列中去除重复项以及数学中的集合类计算，例如交集、并集、差集与对称差集等等。（关于其他容器对象请参看`dict`、`list` 与 `tuple` 等内置类，以及`collections` 模块。）

与其他多项集一样，集合也支持 `x in set`、`len(set)` 和 `for x in set`。作为一种无序的多项集，集合并不记录元素位置或插入顺序。相应地，集合不支持索引、切片或其他序列类的操作。

目前有两种内置集合类型，*set* 和 *frozenset*。*set* 类型是可变的—其内容可以使用 `add()` 和 `remove()` 这样的方法来改变。由于是可变类型，它没有哈希值，且不能被用作字典的键或其他集合的元素。*frozenset* 类型是不可变并且为*hashable*—其内容在被创建后不能再改变；因此它可以被用作字典的键或其他集合的元素。

除了可以使用 *set* 构造器，非空的 *set* (不是 *frozenset*) 还可以通过将以逗号分隔的元素列表包含于花括号之内来创建，例如：`{'jack', 'sjoerd'}`。

两个类的构造器具有相同的作用方式：

```
class set([iterable])
class frozenset([iterable])
```

返回一个新的 *set* 或 *frozenset* 对象，其元素来自于 *iterable*。集合的元素必须为*hashable*。要表示由集合对象构成的集合，所有的内层集合必须为 *frozenset* 对象。如果未指定 *iterable*，则将返回一个新的空集合。

set 和 *frozenset* 的实例提供以下操作：

len(s)

返回集合 *s* 中的元素数量（即 *s* 的基数）。

x in s

检测 *x* 是否为 *s* 中的成员。

x not in s

检测 *x* 是否非 *s* 中的成员。

isdisjoint (*other*)

如果集合中没有与 *other* 共有的元素则返回 True。当且仅当两个集合的交集为空集合时，两者为不相交集。

issubset (*other*)

set <= **other**

检测是否集合中的每个元素都在 *other* 之中。

set < **other**

检测集合是否为 *other* 的真子集，即 `set <= other and set != other`。

issuperset (*other*)

set >= **other**

检测是否 *other* 中的每个元素都在集合之中。

set > **other**

检测集合是否为 *other* 的真超集，即 `set >= other and set != other`。

union (**others*)

set | **other** | ...

返回一个新集合，其中包含来自原集合以及 *others* 指定的所有集合中的元素。

intersection (**others*)

set & **other** & ...

返回一个新集合，其中包含原集合以及 *others* 指定的所有集合中共有的元素。

difference (**others*)

set - **other** - ...

返回一个新集合，其中包含原集合中在 *others* 指定的其他集合中不存在的元素。

symmetric_difference (*other*)

set ^ **other**

返回一个新集合，其中的元素或属于原集合或属于 *other* 指定的其他集合，但不能同时属于两者。

copy ()

Return a new set with a shallow copy of *s*.

请注意，非运算符版本的 `union()`、`intersection()`、`difference()`，以及 `symmetric_difference()`、`issubset()` 和 `issuperset()` 方法会接受任意可迭代对象作为参数。相比之下，它们所对应的运算符版本则要求其参数为集合。这就排除了容易出错的构造形式例如 `set('abc') & 'cbs'`，而推荐可读性更强的 `set('abc').intersection('cbs')`。

`set` 和 `frozenset` 均支持集合与集合的比较。两个集合当且仅当每个集合中的每个元素均包含于另一个集合之内（即各为对方的子集）时则相等。一个集合当且仅当其为另一个集合的真子集（即为后者的子集但两者不相等）时则小于另一个集合。一个集合当且仅当其为另一个集合的真超集（即为后者的超集但两者不相等）时则大于另一个集合。

`set` 的实例与 `frozenset` 的实例之间基于它们的成员进行比较。例如 `set('abc') == frozenset('abc')` 返回 True，`set('abc') in set([frozenset('abc')])` 也一样。

子集与相等比较并不能推广为完全排序函数。例如，任意两个非空且不相交的集合不相等且互不为对方的子集，因此以下所有比较均返回 False: `a < b`, `a == b`, or `a > b`。

由于集合仅定义了部分排序（子集关系），因此由集合构成的列表 `list.sort()` 方法的输出并无定义。集合的元素，与字典的键类似，必须为 *hashable*。

混合了 `set` 实例与 `frozenset` 的二进制位运算将返回与第一个操作数相同的类型。例如：`frozenset('ab') | set('bc')` 将返回 `frozenset` 的实例。

下表列出了可用于 `set` 而不能用于不可变的 `frozenset` 实例的操作：

update (**others*)

```

set |= other | ...
    更新集合，添加来自 others 中的所有元素。

intersection_update(*others)
set &= other & ...
    更新集合，只保留其中在所有 others 中也存在的元素。

difference_update(*others)
set -= other | ...
    更新集合，移除其中也存在于 others 中的元素。

symmetric_difference_update(other)
set ^= other
    更新集合，只保留存在于集合的一方而非共同存在的元素。

add(elem)
    将元素 elem 添加到集合中。

remove(elem)
    从集合中移除元素 elem。如果 elem 不存在于集合中则会引发 KeyError。

discard(elem)
    如果元素 elem 存在于集合中则将其移除。

pop()
    从集合中移除并返回任意一个元素。如果集合为空则会引发 KeyError。

clear()
    从集合中移除所有元素。

```

请注意，非运算符版本的 `update()`、`intersection_update()`、`difference_update()` 和 `symmetric_difference_update()` 方法将接受任意可迭代对象作为参数。

请注意，`__contains__()`、`remove()` 和 `discard()` 方法的 `elem` 参数可能是一个 `set`。为支持对一个等价的 `frozenset` 进行搜索，会根据 `elem` 临时创建一个该类型对象。

4.10 映射类型—dict

mapping 对象会将 *hashable* 值映射到任意对象。映射属于可变对象。目前仅有一种标准映射类型 字典。（关于其他容器对象请参看 *list*、*set* 与 *tuple* 等内置类，以及 *collections* 模块。）

字典的键 几乎可以是任何值。非 *hashable* 的值，即包含列表、字典或其他可变类型的值（此类对象基于值而非对象标识进行比较）不可用作键。数字类型用作键时遵循数字比较的一般规则：如果两个数值相等（例如 1 和 1.0）则两者可以被用来索引同一字典条目。（但是请注意，由于计算机对于浮点数存储的只是近似值，因此将其用作字典键是不明智的。）

字典可以通过将以逗号分隔的 键：值对列表包含于花括号之内来创建，例如：{'jack': 4098, 'sjoerd': 4127} 或 {4098: 'jack', 4127: 'sjoerd'}，也可以通过 *dict* 构造器来创建。

```

class dict(**kwarg)
class dict(mapping, **kwarg)
class dict(iterable, **kwarg)

```

返回一个新的字典，基于可选的位置参数和可能为空的关键字参数集来初始化。

如果没有给出位置参数，将创建一个空字典。如果给出一个位置参数并且其属于映射对象，将创建一个具有与映射对象相同键值对的字典。否则的话，位置参数必须为一个 *iterable* 对象。该可迭代对象中的每一项本身必须为一个刚好包含两个元素的可迭代对象。每一项中的第一个对象将成为新字典的一个键，第二个对象将成为其对应的值。如果一个键出现一次以上，该键的最后一个值将成为其在新字典中对应的值。

如果给出了关键字参数，则关键字参数及其值会被加入到基于位置参数创建的字典。如果要加入的键已存在，来自关键字参数的值将替代来自位置参数的值。

作为演示，以下示例返回的字典均等于 `{"one": 1, "two": 2, "three": 3}`：

```
>>> a = dict(one=1, two=2, three=3)
>>> b = {'one': 1, 'two': 2, 'three': 3}
>>> c = dict(zip(['one', 'two', 'three'], [1, 2, 3]))
>>> d = dict([('two', 2), ('one', 1), ('three', 3)])
>>> e = dict({'three': 3, 'one': 1, 'two': 2})
>>> a == b == c == d == e
True
```

像第一个例子那样提供关键字参数的方式只能使用有效的 Python 标识符作为键。其他方式则可使用任何有效的键。

这些是字典所支持的操作（因而自定义的映射类型也应当支持）：

len(d)

返回字典 *d* 中的项数。

d[key]

返回 *d* 中以 *key* 为键的项。如果映射中不存在 *key* 则会引发 `KeyError`。

如果字典的子类定义了方法 `__missing__()` 并且 *key* 不存在，则 `d[key]` 操作将调用该方法并附带键 *key* 作为参数。`d[key]` 随后将返回或引发 `__missing__(key)` 调用所返回或引发的任何对象或异常。没有其他操作或方法会发起调用 `__missing__()`。如果未定义 `__missing__()`，则会引发 `KeyError`。`__missing__()` 必须是一个方法；它不能是一个实例变量：

```
>>> class Counter(dict):
...     def __missing__(self, key):
...         return 0
>>> c = Counter()
>>> c['red']
0
>>> c['red'] += 1
>>> c['red']
1
```

上面的例子显示了 `collections.Counter` 实现的部分代码。还有另一个不同的 `__missing__` 方法是由 `collections.defaultdict` 所使用的。

d[key] = value

将 `d[key]` 设为 *value*。

del d[key]

将 `d[key]` 从 *d* 中移除。如果映射中不存在 *key* 则会引发 `KeyError`。

key in d

如果 *d* 中存在键 *key* 则返回 `True`，否则返回 `False`。

key not in d

等价于 `not key in d`。

iter(d)

返回以字典的键为元素的迭代器。这是 `iter(d.keys())` 的快捷方式。

clear()

移除字典中的所有元素。

copy()

返回原字典的浅拷贝。

classmethod fromkeys (*seq*[, *value*])

Create a new dictionary with keys from *seq* and values set to *value*.

fromkeys() 属于类方法，会返回一个新字典。*value* 默认为 `None`。

get (*key*[, *default*])

如果 *key* 存在于字典中则返回 *key* 的值，否则返回 *default*。如果 *default* 未给出则默认为 `None`，因而此方法绝不会引发 `KeyError`。

items ()

返回由字典项 ((键, 值) 对) 组成的一个新视图。参见视图对象文档。

keys ()

返回由字典键组成的一个新视图。参见视图对象文档。

pop (*key*[, *default*])

如果 *key* 存在于字典中则将其移除并返回其值，否则返回 *default*。如果 *default* 未给出且 *key* 不存在于字典中，则会引发 `KeyError`。

popitem ()

Remove and return an arbitrary (*key*, *value*) pair from the dictionary.

popitem() 适用于对字典进行消耗性的迭代，这在集合算法中经常被使用。如果字典为空，调用 *popitem()* 将引发 `KeyError`。

setdefault (*key*[, *default*])

如果字典存在键 *key*，返回它的值。如果不存在，插入值为 *default* 的键 *key*，并返回 *default*。*default* 默认为 `None`。

update ([*other*])

使用来自 *other* 的键/值对更新字典，覆盖原有的键。返回 `None`。

update() 接受另一个字典对象，或者一个包含键/值对（以长度为二的元组或其他可迭代对象表示）的可迭代对象。如果给出了关键字参数，则会以其所指定的键/值对更新字典：`d.update(red=1, blue=2)`。

values ()

返回由字典值组成的一个新视图。参见视图对象文档。

两个字典的比较当且仅当具有相同的（键，值）对时才会相等。顺序比较（‘<’，‘<=’，‘>=’，‘>’）会引发 `TypeError`。

参见：

`types.MappingProxyType` 可被用来创建一个 *dict* 的只读视图。

4.10.1 字典视图对象

由 `dict.keys()`、`dict.values()` 和 `dict.items()` 所返回的对象是视图对象。该对象提供字典条目的一个动态视图，这意味着当字典改变时，视图也会相应改变。

字典视图可以被迭代以产生与其对应的数据，并支持成员检测：

len(dictview)

返回字典中的条目数。

iter(dictview)

返回字典中的键、值或项（以（键，值）为元素的元组表示）的迭代器。

Keys and values are iterated over in an arbitrary order which is non-random, varies across Python implementations, and depends on the dictionary’s history of insertions and deletions. If keys, values and items views are iterated over with no intervening modifications to the dictionary, the order of items will directly correspond. This allows the

creation of (value, key) pairs using `zip()`: `pairs = zip(d.values(), d.keys())`. Another way to create the same list is `pairs = [(v, k) for (k, v) in d.items()]`.

在添加或删除字典中的条目期间对视图进行迭代可能引发 `RuntimeError` 或者无法完全迭代所有条目。

x in dictview

如果 `x` 是对应字典中存在的键、值或项（在最后一种情况下 `x` 应为一个（键，值）元组）则返回 `True`。

键视图类似于集合，因为其条目不重复且可哈希。如果所有值都是可哈希的，即（键，值）对也是不重复且可哈希的，那么条目视图也会类似于集合。（值视图则不被视为类似于集合，因其条目通常都是有重复的。）对于类似于集合的视图，为抽象基类 `collections.abc.Set` 所定义的全部操作都是有效的（例如 `==`, `<` 或 `^`）。

一个使用字典视图的示例：

```
>>> dishes = {'eggs': 2, 'sausage': 1, 'bacon': 1, 'spam': 500}
>>> keys = dishes.keys()
>>> values = dishes.values()

>>> # iteration
>>> n = 0
>>> for val in values:
...     n += val
>>> print(n)
504

>>> # keys and values are iterated over in the same order
>>> list(keys)
['eggs', 'bacon', 'sausage', 'spam']
>>> list(values)
[2, 1, 1, 500]

>>> # view objects are dynamic and reflect dict changes
>>> del dishes['eggs']
>>> del dishes['sausage']
>>> list(keys)
['spam', 'bacon']

>>> # set operations
>>> keys & {'eggs', 'bacon', 'salad'}
{'bacon'}
>>> keys ^ {'sausage', 'juice'}
{'juice', 'sausage', 'bacon', 'spam'}
```

4.11 上下文管理器类型

Python 的 `with` 语句支持通过上下文管理器所定义的运行时上下文这一概念。此对象的实现使用了一对专门方法，允许用户自定义类来定义运行时上下文，在语句体被执行前进入该上下文，并在语句执行完毕时退出该上下文：

`contextmanager.__enter__()`

Enter the runtime context and return either this object or another object related to the runtime context. The value returned by this method is bound to the identifier in the `as` clause of `with` statements using this context manager.

一个返回其自身的上下文管理器的例子是 *file object*。文件对象会从 `__enter__()` 返回其自身，以允许 `open()` 被用作 `with` 语句中的上下文表达式。

An example of a context manager that returns a related object is the one returned by `decimal.localcontext()`. These managers set the active decimal context to a copy of the original decimal context and then return the copy. This allows changes to be made to the current decimal context in the body of the `with` statement without affecting code outside the `with` statement.

`contextmanager.__exit__(exc_type, exc_val, exc_tb)`

退出运行时上下文并返回一个布尔值旗标来表明所发生的任何异常是否应当被屏蔽。如果在执行 `with` 语句的语句体期间发生了异常，则参数会包含异常的类型、值以及回溯信息。在其他情况下三个参数均为 `None`。

Returning a true value from this method will cause the `with` statement to suppress the exception and continue execution with the statement immediately following the `with` statement. Otherwise the exception continues propagating after this method has finished executing. Exceptions that occur during execution of this method will replace any exception that occurred in the body of the `with` statement.

传入的异常绝对不应当被显式地重新引发——相反地，此方法应当返回一个假值以表明方法已成功完成并且不希望屏蔽被引发的异常。这允许上下文管理代码方便地检测 `__exit__()` 方法是否确实已失败。

Python 定义了一些上下文管理器来支持简易的线程同步、文件或其他对象的快速关闭，以及更方便地操作活动的十进制算术上下文。除了实现上下文管理协议以外，不同类型不会被特殊处理。请参阅 `contextlib` 模块查看相关的示例。

Python 的 `generator` 和 `contextlib.contextmanager` 装饰器提供了实现这些协议的便捷方式。如果使用 `contextlib.contextmanager` 装饰器来装饰一个生成器函数，它将返回一个实现了必要的 `__enter__()` 和 `__exit__()` 方法的上下文管理器，而不再是由未经装饰的生成器函数所产生的迭代器。

请注意，Python/C API 中 Python 对象的类型结构中并没有针对这些方法的专门槽位。想要定义这些方法的扩展类型必须将它们作为普通的 Python 可访问方法来提供。与设置运行时上下文的开销相比，单个类字典查找的开销可以忽略不计。

4.12 其他内置类型

解释器支持一些其他种类的对象。这些对象大都仅支持一两种操作。

4.12.1 模块

模块唯一的特殊操作是属性访问: `m.name`，这里 `m` 为一个模块而 `name` 访问定义在 `m` 的符号表中的一个名称。模块属性可以被赋值。（请注意 `import` 语句严格来说也是对模块对象的一种操作；`import foo` 不求存在一个名为 `foo` 的模块对象，而是要求存在一个对于名为 `foo` 的模块的（永久性）定义。）

每个模块都有一个特殊属性 `__dict__`。这是包含模块的符号表的字典。修改此字典将实际改变模块的符号表，但是无法直接对 `__dict__` 赋值（你可以写 `m.__dict__['a'] = 1`，这会将 `m.a` 定义为 1，但是你不能写 `m.__dict__ = {}`）。不建议直接修改 `__dict__`。

内置于解释器中的模块会写成这样: `<module 'sys' (built-in)>`。如果是从一个文件加载，则会写成 `<module 'os' from '/usr/local/lib/pythonX.Y/os.pyc'>`。

4.12.2 类与类实例

关于这些类型请参阅 `objects` 和 `class`。

4.12.3 函数

函数对象是通过函数定义创建的。对函数对象的唯一操作是调用它: `func(argument-list)`。

实际上存在两种不同的函数对象: 内置函数和用户自定义函数。两者支持同样的操作 (调用函数), 但实现方式不同, 因此对象类型也不同。

更多信息请参阅 `function`。

4.12.4 方法

方法是使用属性表示法来调用的函数。存在两种形式: 内置方法 (例如列表的 `append()` 方法) 和类实例方法。内置方法由支持它们的类型来描述。

如果你通过一个实例来访问方法 (即定义在类命名空间内的函数), 你会得到一个特殊对象: 绑定方法 (或称实例方法) 对象。当被调用时, 它会将 `self` 参数添加到参数列表。绑定方法具有两个特殊的只读属性: `m.__self__` 操作该方法的对象, 而 `m.__func__` 是实现该方法的函数。调用 `m(arg-1, arg-2, ..., arg-n)` 完全等价于调用 `m.__func__(m.__self__, arg-1, arg-2, ..., arg-n)`。

与函数对象类似, 绑定方法对象也支持获取任意属性。但是, 由于方法属性实际上保存于下层的函数对象中 (`meth.__func__`), 因此不允许设置绑定方法的方法属性。尝试设置方法的属性将会导致引发 `AttributeError`。想要设置方法属性, 你必须在下层的函数对象中显式地对其进行设置:

```
>>> class C:
...     def method(self):
...         pass
...
>>> c = C()
>>> c.method.whoami = 'my name is method' # can't set on the method
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
AttributeError: 'method' object has no attribute 'whoami'
>>> c.method.__func__.whoami = 'my name is method'
>>> c.method.whoami
'my name is method'
```

更多信息请参阅 `types`。

4.12.5 代码对象

代码对象被具体实现用来表示“伪编译”的可执行 Python 代码, 例如一个函数体。它们不同于函数对象, 因为它们不包含对其全局执行环境的引用。代码对象由内置的 `compile()` 函数返回, 并可通过从函数对象的 `__code__` 属性从中提取。另请参阅 `code` 模块。

可以通过将代码对象 (而非源码字符串) 传给 `exec()` 或 `eval()` 内置函数来执行或求值。

更多信息请参阅 `types`。

4.12.6 类型对象

类型对象表示各种对象类型。对象的类型可通过内置函数 `type()` 来获取。类型没有特殊的操作。标准库模块 `types` 定义了所有标准内置类型的名称。

类型以这样的写法来表示: `<class 'int'>`。

4.12.7 空对象

此对象会由不显式地返回值的函数所返回。它不支持任何特殊的操作。空对象只有一种值 `None` (这是个内置名称)。`type(None)()` 会生成同一个单例。

该对象的写法为 `None`。

4.12.8 省略符对象

此对象常被用于切片 (参见 `slicings`)。它不支持任何特殊的操作。省略符对象只有一种值 `Ellipsis` (这是个内置名称)。`type(Ellipsis)()` 会生成 `Ellipsis` 单例。

该对象的写法为 `Ellipsis` 或 `...`。

4.12.9 未实现对象

此对象会被作为比较和二元运算被应用于它们所不支持的类型时的返回值。请参阅 `comparisons` 了解更多信息。未实现对象只有一种值 `NotImplemented`。`type(NotImplemented)()` 会生成这个单例。

该对象的写法为 `NotImplemented`。

4.12.10 布尔值

布尔值是两个常量对象 `False` 和 `True`。它们被用来表示逻辑上的真假 (不过其他值也可被当作真值或假值)。在数字类的上下文中 (例如被用作算术运算符的参数时), 它们的行为分别类似于整数 0 和 1。内置函数 `bool()` 可被用来将任意值转换为布尔值, 只要该值可被解析为一个逻辑值 (参见之前的 [逻辑值检测](#) 部分)。

该对象的写法分别为 `False` 和 `True`。

4.12.11 内部对象

有关此对象的信息请参阅 `types`。其中描述了栈帧对象、回溯对象以及切片对象等等。

4.13 特殊属性

语言实现为部分对象类型添加了一些特殊的只读属性, 它们具有各自的作用。其中一些并不会被 `dir()` 内置函数所列出。

`object.__dict__`

一个字典或其他类型的映射对象, 用于存储对象的 (可写) 属性。

`instance.__class__`

类实例所属的类。

`class.__bases__`

由类对象的基类所组成的元组。

`definition.__name__`

类、函数、方法、描述器或生成器实例的名称。

definition. **__qualname__**

类、函数、方法、描述器或生成器实例的`qualified name`。

3.3 新版功能.

class. **__mro__**

此属性是由类组成的元组，在方法解析期间会基于它来查找基类。

class. **mro()**

此方法可被一个元类来重载，以为其实例定制方法解析顺序。它会在类实例化时被调用，其结果存储于 `__mro__` 之中。

class. **__subclasses__()**

每个类会保存由对其直接子类的弱引用组成的列表。此方法将返回一个由仍然存在的所有此类引用组成的列表。例如：

```
>>> int.__subclasses__()
[<class 'bool'>]
```

内置异常

在 Python 中，所有异常必须为一个派生自 `BaseException` 的类的实例。在带有提及一个特定类的 `except` 子句的 `try` 语句中，该子句也会处理任何派生自该类的异常类（但不处理它所派生出的异常类）。通过子类化创建的两个不相关异常类永远是不等效的，即使它们具有相同的名称。

下面列出的内置异常可通过解释器或内置函数来生成。除非另有说明，它们都会具有一个提示导致错误详细原因的“关联值”。这可以是一个字符串或由多个信息项（例如一个错误码和一个解释错误的字符串）组成的元组。关联值通常会作为参数被传递给异常类的构造器。

用户代码可以引发内置异常。这可被用于测试异常处理程序或报告错误条件，“就像”在解释器引发了相同异常的情况时一样；但是请注意，没有任何机制能防止用户代码引发不适当的错误。

内置异常类可以被子类化以定义新的异常；鼓励程序员从 `Exception` 类或它的某个子类而不是从 `BaseException` 来派生新的异常。关于定义异常的更多信息可以在 Python 教程的 `tut-userexceptions` 部分查看。

当在 `except` 或 `finally` 子句中引发（或重新引发）异常时，`__context__` 会被自动设为所捕获的最后一个异常；如果新的异常未被处理，则最终显示的回溯信息将包括原始的异常和最后的异常。

当引发一个新的异常（而不是简单地使用 `raise` 来重新引发当前在处理的异常）时，隐式的异常上下文可以通过使用带有 `raise` 的 `from` 来补充一个显式的原因：

```
raise new_exc from original_exc
```

跟在 `from` 之后的表达式必须为一个异常或 `None`。它将在所引发的异常上被设置为 `__cause__`。设置 `__cause__` 还会隐式地将 `__suppress_context__` 属性设为 `True`，这样使用 `raise new_exc from None` 可以有效地将旧异常替换为新异常来显示其目的（例如将 `KeyError` 转换为 `AttributeError`），同时让旧异常在 `__context__` 中保持可用状态以便在调试时进行内省。

除了异常本身的回溯以外，默认的回溯还会显示这些串连的异常。`__cause__` 中的显式串连异常如果存在将总是显示。`__context__` 中的隐式串连异常仅在 `__cause__` 为 `None` 并且 `__suppress_context__` 为假值时显示。

不论在哪种情况下，异常本身总会在任何串连异常之后显示，以便回溯的最后一行总是显示所引发的最后一个异常。

5.1 基类

下列异常主要被用作其他异常的基类。

exception `BaseException`

所有内置异常的基类。它不应该被用户自定义类直接继承(这种情况请使用`Exception`)。如果在此类的实例上调用`str()`，则会返回实例的参数表示，或者当没有参数时返回空字符串。

`args`

传给异常构造器的参数元组。某些内置异常(例如`OSError`)接受特定数量的参数并赋予此元组中的元素特殊的含义，而其他异常通常只接受一个给出错误信息的单独字符串。

`with_traceback(tb)`

此方法将`tb`设为异常的新回溯信息并返回该异常对象。它通常以如下的形式在异常处理程序中使用：

```
try:
    ...
except SomeException:
    tb = sys.exc_info()[2]
    raise OtherException(...).with_traceback(tb)
```

exception `Exception`

所有内置的非系统退出类异常都派生自此类。所有用户自定义异常也应当派生自此类。

exception `ArithmeticError`

此基类用于派生针对各种算术类错误而引发的内置异常：`OverflowError`、`ZeroDivisionError`、`FloatingPointError`。

exception `BufferError`

当与缓冲区相关的操作无法执行时将被引发。

exception `LookupError`

此基类用于派生当映射或序列所使用的键或索引无效时引发的异常：`IndexError`、`KeyError`。这可以通过`codecs.lookup()`来直接引发。

5.2 具体异常

以下异常属于经常被引发的异常。

exception `AssertionError`

当`assert`语句失败时将被引发。

exception `AttributeError`

当属性引用(参见`attribute-references`)或赋值失败时将被引发。(当一个对象根本不支持属性引用或属性赋值时则将引发`TypeError`。)

exception `EOFError`

当`input()`函数未读取任何数据即达到文件结束条件(EOF)时将被引发。(另外，`io.IOBase.read()`和`io.IOBase.readline()`方法在遇到EOF则将返回一个空字符串。)

exception `FloatingPointError`

Raised when a floating point operation fails. This exception is always defined, but can only be raised when Python is configured with the `--with-fpectl` option, or the `WANT_SIGFPE_HANDLER` symbol is defined in the `pyconfig.h` file.

exception GeneratorExit

当一个 *generator* 或 *coroutine* 被关闭时将被引发；参见 `generator.close()` 和 `coroutine.close()`。它直接继承自 *BaseException* 而不是 *Exception*，因为从技术上来说它并不是一个错误。

exception ImportError

当 `import` 语句尝试加载模块遇到麻烦时将被引发。并且当 `from ... import` 中的“from list”存在无法找到的名称时也会被引发。

`name` 与 `path` 属性可通过对构造器使用仅关键字参数来设定。设定后它们将分别表示被尝试导入的模块名称与触发异常的任意文件所在路径。

在 3.3 版更改：添加了 `name` 与 `path` 属性。

exception ModuleNotFoundError

ImportError 的子类，当一个模块无法被定位时将由 `import` 引发。当在 `sys.modules` 中找到 `None` 时也会被引发。

3.6 新版功能。

exception IndexError

当序列抽取超出范围时将被引发。（切片索引会被静默截短到允许的范围；如果指定索引不是整数则 *TypeError* 会被引发。）

exception KeyError

当在现有键集中找不到指定的映射（字典）键时将被引发。

exception KeyboardInterrupt

当用户按下中断键（通常为 `Control-C` 或 `Delete`）时将被引发。在执行期间，会定期检测中断信号。该异常继承自 *BaseException* 以确保不会被处理 *Exception* 的代码意外捕获，这样可以避免退出解释器。

exception MemoryError

当一个操作耗尽内存但情况仍可（通过删除一些对象）进行挽救时将被引发。关联的值是一个字符串，指明是哪种（内部）操作耗尽了内存。请注意由于底层的内存管理架构（C 的 `malloc()` 函数），解释器也许并不总是能够从这种情况下完全恢复；但它毕竟可以引发一个异常，这样就能打印出栈回溯信息，以便找出导致问题的失控程序。

exception NameError

当某个局部或全局名称未找到时将被引发。此异常仅用于非限定名称。关联的值是一条错误信息，其中包含未找到的名称。

exception NotImplementedError

此异常派生自 *RuntimeError*。在用户自定义的基类中，抽象方法应当在其要求所派生类重载该方法，或是在其要求所开发的类提示具体实现尚待添加时引发此异常。

注解： 它不应当用来表示一个运算符或方法根本不能被支持 – 在此情况下应当让特定运算符 / 方法保持未定义，或者在子类中将其设为 *None*。

注解： *NotImplementedError* 和 *NotImplemented* 不可互换，即使它们有相似的名称和用途。请参阅 *NotImplemented* 了解有关何时使用它们的详细说明。

exception OSError ([arg])**exception OSError (errno, strerror[, filename[, winerror[, filename2]]])**

此异常在一个系统函数返回系统相关的错误时将被引发，此类错误包括 I/O 操作失败例如“文件未找到”或“磁盘已满”等（不包括非法参数类型或其他偶然性错误）。

构造器的第二种形式可设置如下所述的相应属性。如果未指定这些属性则默认为`None`。为了能向下兼容，如果传入了三个参数，则`args`属性将仅包含由前两个构造器参数组成的2元组。

构造器实际返回的往往是`OSError`的某个子类，如下文`OS exceptions`中所描述的。具体的子类取决于最终的`errno`值。此行为仅在直接或通过别名来构造`OSError`时发生，并且在子类化时不会被继承。

errno

来自于C变量`errno`的数字错误码。

winerror

在Windows下，此参数将给出原生的Windows错误码。而`errno`属性将是该原生错误码在POSIX平台下的近似转换形式。

在Windows下，如果`winerror`构造器参数是一个整数，则`errno`属性会根据Windows错误码来确定，而`errno`参数会被忽略。在其他平台上，`winerror`参数会被忽略，并且`winerror`属性将不存在。

strerror

操作系统所提供的相应错误信息。它在POSIX平台中由C函数`perror()`来格式化，在Windows中则是由`FormatMessage()`。

filename

filename2

对于与文件系统路径有关(例如`open()`或`os.unlink()`)的异常，`filename`是传给函数的文件名。对于涉及两个文件系统路径的函数(例如`os.rename()`)，`filename2`将是传给函数的第二个文件名。

在3.3版更改：`EnvironmentError`、`IOError`、`WindowsError`、`socket.error`、`select.error`与`mmap.error`已被合并到`OSError`，构造器可能返回其中一个子类。

在3.4版更改：`filename`属性现在将是传给函数的原始文件名，而不是经过编码或基于文件系统编码进行解码之后的名称。此外还添加了`filename2`构造器参数和属性。

exception OverflowError

当算术运算的结果大到无法表示时将被引发。这对整数来说不可能发生(宁可引发`MemoryError`也不会放弃尝试)。但是出于历史原因，有时也会在整数超出要求范围的情况下引发`OverflowError`。因为在C中缺少对浮点异常处理的标准化，大多数浮点运算都不会做检查。

exception RecursionError

此异常派生自`RuntimeError`。它会在解释器检测发现超过最大递归深度(参见`sys.getrecursionlimit()`)时被引发。

3.5新版功能: 在此之前将只引发`RuntimeError`。

exception ReferenceError

此异常将在使用`weakref.proxy()`函数所创建的弱引用来访问该引用的某个已被作为垃圾回收的属性时被引发。有关弱引用的更多信息请参阅`weakref`模块。

exception RuntimeError

当检测到一个不归属于任何其他类别的错误时将被引发。关联的值是一个指明究竟发生了什么问题的字符串。

exception StopIteration

由内置函数`next()`和`iterator`的`__next__()`方法所引发，用来表示该迭代器不能产生下一项。

该异常对象只有一个属性`value`，它在构造该异常时作为参数给出，默认值为`None`。

当一个`generator`或`coroutine`函数返回时，将引发一个新的`StopIteration`实例，函数返回的值将被用作异常构造器的`value`形参。

If a generator function defined in the presence of a `from __future__ import generator_stop` directive raises `StopIteration`, it will be converted into a `RuntimeError` (retaining the `StopIteration` as

the new exception' s cause).

在 3.3 版更改: 添加了 `value` 属性及其被生成器函数用作返回值的功能。

在 3.5 版更改: Introduced the `RuntimeError` transformation.

exception `StopAsyncIteration`

必须由一个 *asynchronous iterator* 对象的 `__anext__()` 方法来引发以停止迭代操作。

3.5 新版功能。

exception `SyntaxError`

当解析器遇到语法错误时将被引发。这可以发生在 `import` 语句, 对内置函数 `exec()` 或 `eval()` 的调用, 或者读取原始脚本或标准输入 (也包括交互模式) 的时候。

该类的实例包含有属性 `filename`, `lineno`, `offset` 和 `text` 用于方便地访问相应的详细信息。异常实例的 `str()` 仅返回消息文本。

exception `IndentationError`

与不正确的缩进相关的语法错误的基类。这是 `SyntaxError` 的一个子类。

exception `TabError`

当缩进包含对制表符和空格符不一致的使用时将被引发。这是 `IndentationError` 的一个子类。

exception `SystemError`

当解释器发现内部错误, 但情况看起来尚未严重到要放弃所有希望时将被引发。关联的值是一个指明发生了什么的字符串 (表示为低层级的符号)。

你应当将此问题报告给你所用 Python 解释器的作者或维护人员。请确认报告 Python 解释器的版本号 (`sys.version`; 它也会在交互式 Python 会话开始时被打印出来), 具体的错误消息 (异常所关联的值) 以及可能触发该错误的程序源码。

exception `SystemExit`

此异常由 `sys.exit()` 函数引发。它继承自 `BaseException` 而不是 `Exception` 以确保不会被处理 `Exception` 的代码意外捕获。这允许此异常正确地向上传播并导致解释器退出。如果它未被处理, 则 Python 解释器就将退出; 不会打印任何栈回溯信息。构造器接受的可选参数与传递给 `sys.exit()` 的相同。如果该值为一个整数, 则它指明系统退出状态码 (会传递给 C 的 `exit()` 函数); 如果该值为 `None`, 则退出状态码为零; 如果该值为其他类型 (例如字符串), 则会打印对象的值并将退出状态码设为一。

对 `sys.exit()` 的调用会被转换为一个异常以便能执行清理处理程序 (`try` 语句的 `finally` 子句), 并且使得调试器可以执行一段脚本而不必冒失去控制的风险。如果绝对确实地需要立即退出 (例如在调用 `os.fork()` 之后的子进程中) 则可使用 `os._exit()`。

code

传给构造器的退出状态码或错误信息 (默认为 `None`。)

exception `TypeError`

当一个操作或函数被应用于类型不适当的对象时将被引发。关联的值是一个字符串, 给出有关类型不匹配的详情。

此异常可以由用户代码引发, 以表明尝试对某个对象进行的操作不受支持也不应当受支持。如果某个对象应当支持给定的操作但尚未提供相应的实现, 所要引发的适当异常应为 `NotImplementedError`。

传入参数的类型错误 (例如在要求 `int` 时却传入了 `list`) 应当导致 `TypeError`, 但传入参数的值错误 (例如传入要求范围之外的数值) 则应当导致 `ValueError`。

exception `UnboundLocalError`

当在函数或方法中对某个局部变量进行引用, 但该变量并未绑定任何值时将被引发。此异常是 `NameError` 的一个子类。

exception `UnicodeError`

当发生与 Unicode 相关的编码或解码错误时将被引发。此异常是 `ValueError` 的一个子类。

UnicodeError 具有一些描述编码或解码错误的属性。例如 `err.object[err.start:err.end]` 会给出导致编解码器失败的特定无效输入。

encoding

引发错误的编码名称。

reason

描述特定编解码器错误的字符串。

object

编解码器试图要编码或解码的对象。

start

object 中无效数据的开始位置索引。

end

object 中无效数据的末尾位置索引（不含）。

exception UnicodeEncodeError

当在编码过程中发生与 Unicode 相关的错误时将被引发。此异常是 *UnicodeError* 的一个子类。

exception UnicodeDecodeError

当在解码过程中发生与 Unicode 相关的错误时将被引发。此异常是 *UnicodeError* 的一个子类。

exception UnicodeTranslateError

在转写过程中发生与 Unicode 相关的错误时将被引发。此异常是 *UnicodeError* 的一个子类。

exception ValueError

当操作或函数接收到具有正确类型但值不适合的参数，并且情况不能用更精确的异常例如 *IndexError* 来描述时将被引发。

exception ZeroDivisionError

当除法或取余运算的第二个参数为零时将被引发。关联的值是一个字符串，指明操作数和运算的类型。

下列异常被保留以与之前的版本相兼容；从 Python 3.3 开始，它们都是 *OSError* 的别名。

exception EnvironmentError**exception IOError****exception WindowsError**

限在 Windows 中可用。

5.2.1 OS 异常

下列异常均为 *OSError* 的子类，它们将根据系统错误代码被引发。

exception BlockingIOError

当一个操作会被某个设置为非阻塞操作的对象（例如套接字）所阻塞时将被引发。对应于 `errno` `EAGAIN`, `EALREADY`, `EWOULDBLOCK` 和 `EINPROGRESS`。

除了 *OSError* 已有的属性，*BlockingIOError* 还有一个额外属性：

characters_written

一个整数，表示在被阻塞前已写入到流的字符数。当使用来自 *io* 模块的带缓冲 I/O 类时此属性可用。

exception ChildProcessError

当一个子进程上的操作失败时将被引发。对应于 `errno` `ECHILD`。

exception ConnectionError

与连接相关问题的基类。

其子类有 *BrokenPipeError*, *ConnectionAbortedError*, *ConnectionRefusedError* 和 *ConnectionResetError*。

exception BrokenPipeError

ConnectionError 的子类, 当试图写入另一端已被关闭的管道, 或是试图写入已关闭写入的套接字时将被引发。对应于 `errno EPIPE` 和 `ESHUTDOWN`。

exception ConnectionAbortedError

ConnectionError 的子类, 当连接尝试被对端中止时将被引发。对应于 `errno ECONNABORTED`。

exception ConnectionRefusedError

ConnectionError 的子类, 当连接尝试被对端拒绝时将被引发。对应于 `errno ECONNREFUSED`。

exception ConnectionResetError

ConnectionError 的子类, 当连接被对端重置时将被引发。对应于 `errno ECONNRESET`。

exception FileExistsError

当试图创建一个已存在的文件或目录时将被引发。对应于 `errno EEXIST`。

exception FileNotFoundError

当所请求的文件或目录不存在时将被引发。对应于 `errno ENOENT`。

exception InterruptedError

当系统调用被输入信号中断时将被引发。对应于 `errno EINTR`。

在 3.5 版更改: 当系统调用被某个信号中断时, Python 现在会重试系统调用, 除非该信号的处理程序引发了其它异常 (原理参见 [PEP 475](#)) 而不是引发 *InterruptedError*。

exception IsADirectoryError

当请求对一个目录执行文件操作 (例如 `os.remove()`) 将被引发。对应于 `errno EISDIR`。

exception NotADirectoryError

当请求对一个非目录对象执行目录操作 (例如 `os.listdir()`) 时将被引发。对应于 `errno ENOTDIR`。

exception PermissionError

当在沒有足够操作权限的情况下试图执行某个操作时将被引发——例如缺少文件系统权限。对应于 `errno EACCES` 和 `EPERM`。

exception ProcessLookupError

当给定的进程不存在时将被引发。对应于 `errno ESRCH`。

exception TimeoutError

当一个系统函数发生系统级超时的情况下将被引发。对应于 `errno ETIMEDOUT`。

3.3 新版功能: 添加了以上所有 *OSError* 的子类。

参见:

[PEP 3151](#) - 重写 OS 和 IO 异常的层次结构

5.3 警告

The following exceptions are used as warning categories; see the *warnings* module for more information.

exception Warning

警告类别的基类。

exception UserWarning

用户代码所产生警告的基类。

exception DeprecationWarning

Base class for warnings about deprecated features.

exception PendingDeprecationWarning

Base class for warnings about features which will be deprecated in the future.

exception SyntaxWarning

与模糊的语法相关的警告的基类。

exception RuntimeWarning

与模糊的运行时行为相关的警告的基类。

exception FutureWarning

Base class for warnings about constructs that will change semantically in the future.

exception ImportError

与在模块导入中可能的错误相关的警告的基类。

exception UnicodeWarning

与 Unicode 相关的警告的基类。

exception BytesWarning

与 `bytes` 和 `bytearray` 相关的警告的基类。

exception ResourceWarning

Base class for warnings related to resource usage.

3.2 新版功能.

5.4 异常层次结构

内置异常的分类层级结构如下：

```
BaseException
+-- SystemExit
+-- KeyboardInterrupt
+-- GeneratorExit
+-- Exception
    +-- StopIteration
    +-- StopAsyncIteration
    +-- ArithmeticError
    |   +-- FloatingPointError

```

本章介绍的模块提供了广泛的字符串操作和其他文本处理服务。

在二进制数据服务之下描述的 *codecs* 模块也与文本处理高度相关。此外也请参阅 Python 内置字符串类型的文档文本序列类型—*str*。

6.1 string 一常见的字符串操作

源代码： [Lib/string.py](#)

参见：

文本序列类型—*str*

字符串的方法

6.1.1 字符串常量

此模块中定义的常量为：

`string.ascii_letters`

下文所述 *ascii_lowercase* 和 *ascii_uppercase* 常量的拼连。该值不依赖于语言区域。

`string.ascii_lowercase`

小写字母 'abcdefghijklmnopqrstuvwxyz'。该值不依赖于语言区域，不会发生改变。

`string.ascii_uppercase`

大写字母 'ABCDEFGHIJKLMNOPQRSTUVWXYZ'。该值不依赖于语言区域，不会发生改变。

`string.digits`

字符串 '0123456789'。

`string.hexdigits`

字符串 '0123456789abcdefABCDEF'。

`string.octdigits`

字符串 '01234567'。

`string.punctuation`

由在 C 语言区域中被视为标点符号的 ASCII 字符组成的字符串。

`string.printable`

由被视为可打印符号的 ASCII 字符组成的字符串。这是 *digits*, *ascii_letters*, *punctuation* 和 *whitespace* 的总和。

`string.whitespace`

由被视为空白符号的 ASCII 字符组成的字符串。其中包括空格、制表、换行、回车、进纸和纵向制表符。

6.1.2 自定义字符串格式化

内置的字符串类提供了通过使用 **PEP 3101** 所描述的 *format()* 方法进行复杂变量替换和值格式化的能力。*string* 模块中的 *Formatter* 类允许你使用与内置 *format()* 方法相同的实现来创建并定制你自己的字符串格式化行为。

class `string.Formatter`

Formatter 类包含下列公有方法：

format (*format_string*, **args*, ***kwargs*)

首要的 API 方法。它接受一个格式字符串和任意一组位置和关键字参数。它只是一个调用 *vformat()* 的包装器。

3.5 版后已移除: Passing a format string as keyword argument *format_string* has been deprecated.

vformat (*format_string*, *args*, *kwargs*)

此函数执行实际的格式化操作。它被公开为一个单独的函数，用于需要传入一个预定义字母作为参数，而不是使用 **args* 和 ***kwargs* 语法将字典解包为多个单独参数并重打包的情况。*vformat()* 完成将格式字符串分解为字符数据和替换字段的工作。它会调用下文所述的几种不同方法。

此外，*Formatter* 还定义了一些旨在被子类替换的方法：

parse (*format_string*)

循环遍历 *format_string* 并返回一个由可迭代对象组成的元组 (*literal_text*, *field_name*, *format_spec*, *conversion*)。它会被 *vformat()* 用来将字符串分解为文本字面值或替换字段。

元组中的值在概念上表示一段字面文本加上一个替换字段。如果没有字面文本（如果连续出现两个替换字段就会发生这种情况），则 *literal_text* 将是一个长度为零的字符串。如果没有替换字段，则 *field_name*, *format_spec* 和 *conversion* 的值将为 *None*。

get_field (*field_name*, *args*, *kwargs*)

给定 *field_name* 作为 *parse()* (见上文) 的返回值，将其转换为要格式化的对象。返回一个元组 (*obj*, *used_key*)。默认版本接受在 **PEP 3101** 所定义形式的字符串，例如 “0[name]” 或 “label.title”。*args* 和 *kwargs* 与传给 *vformat()* 的一样。返回值 *used_key* 与 *get_value()* 的 *key* 形参具有相同的含义。

get_value (*key*, *args*, *kwargs*)

提取给定的字段值。*key* 参数将为整数或字符串。如果是整数，它表示 *args* 中位置参数的索引；如果是字符串，它表示 *kwargs* 中的关键字参数名。

args 形参会被设为 *vformat()* 的位置参数列表，而 *kwargs* 形参会被设为由关键字参数组成的字典。

对于复合字段名称，仅会为字段名称的第一个组件调用这些函数；后续组件会通过普通属性和索引操作来进行处理。

因此举例来说，字段表达式 `'0.name'` 将导致调用 `get_value()` 时附带 `key` 参数值 `0`。在 `get_value()` 通过调用内置的 `getattr()` 函数返回后将会查找 `name` 属性。

如果索引或关键字引用了一个不存在的项，则将引发 `IndexError` 或 `KeyError`。

check_unused_args (*used_args, args, kwargs*)

在必要时实现对未使用参数进行检测。此函数的参数是是格式字符串中实际引用的所有参数键的集合（整数表示位置参数，字符串表示名称参数），以及被传给 `vformat` 的 `args` 和 `kwargs` 的引用。未使用参数的集合可以根据这些形参计算出来。如果检测失败则 `check_unused_args()` 应会引发一个异常。

format_field (*value, format_spec*)

`format_field()` 会简单地调用内置全局函数 `format()`。提供该方法是为了让子类能够重载它。

convert_field (*value, conversion*)

使用给定的转换类型（来自 `parse()` 方法所返回的元组）来转换（由 `get_field()` 所返回的）值。默认版本支持 `'s'` (`str`)、`'r'` (`repr`) 和 `'a'` (`ascii`) 等转换类型。

6.1.3 格式字符串语法

`str.format()` 方法和 `Formatter` 类共享相同的格式字符串语法（虽然对于 `Formatter` 来说，其子类可以定义它们自己的格式字符串语法）。具体语法与 格式化字符串字面值相似，但也存在区别。

格式字符串包含有以花括号 `{}` 括起来的“替换字段”。不在花括号之内的内容被视为字面文本，会不加修改地复制到输出中。如果你需要在字面文本中包含花括号字符，可以通过重复来转义：`{{ and }}`。

替换字段的语法如下：

```
replacement_field ::= "{" [field_name] ["!" conversion] [":" format_spec] "}"
field_name         ::= arg_name ("." attribute_name | "[" element_index "]")*
arg_name           ::= [identifier | digit+]
attribute_name     ::= identifier
element_index      ::= digit+ | index_string
index_string       ::= <any source character except "]"> +
conversion         ::= "r" | "s" | "a"
format_spec        ::= <described in the next section>
```

用不太正式的术语来描述，替换字段开头可以用一个 *field_name* 指定要对值进行格式化并取代替换字符被插入到输出结果的对象。*field_name* 之后有可选的 *conversion* 字段，它是一个感叹号 `!` 加一个 *format_spec*，并以一个冒号 `:` 打头。这些指明了替换值的非默认格式。

另请参阅[格式规格迷你语言](#)一节。

field_name 本身以一个数字或关键字 *arg_name* 打头。如果为数字，则它指向一个位置参数，而如果为关键字，则它指向一个命名关键字参数。如果格式字符串中的数字 *arg_names* 为 `0, 1, 2, …` 的序列，它们可以全部省略（而非部分省略），数字 `0, 1, 2, …` 将会按顺序自动插入。由于 *arg_name* 不使用引号分隔，因此无法在格式字符串中指定任意的字典键（例如字符串 `'10'` 或 `'[:-]'`）。*arg_name* 之后可以带上任意数量的索引或属性表达式。`'.name'` 形式的表达式会使用 `getattr()` 选择命名属性，而 `'[index]'` 形式的表达式会使用 `__getitem__()` 执行索引查找。

在 3.1 版更改：位置参数说明符对于 `str.format()` 可以省略，因此 `'{} {}'.format(a, b)` 等价于 `'{0} {1}'.format(a, b)`。

在 3.4 版更改: 位置参数说明符对于 *Formatter* 可以省略。

一些简单的格式字符串示例

```
"First, thou shalt count to {0}" # References first positional argument
"Bring me a {}"                 # Implicitly references the first positional_
↪ argument
"From {} to {}"                 # Same as "From {0} to {1}"
"My quest is {name}"            # References keyword argument 'name'
"Weight in tons {0.weight}"     # 'weight' attribute of first positional arg
"Units destroyed: {players[0]}" # First element of keyword argument 'players'.
```

使用 *conversion* 字段在格式化之前进行类型强制转换。通常, 格式化值的工作由值本身的 `__format__()` 方法来完成。但是, 在某些情况下最好强制将类型格式化为一个字符串, 覆盖其本身的格式化定义。通过在调用 `__format__()` 之前将值转换为字符串, 可以绕过正常的格式化逻辑。

目前支持的转换旗标有三种: `'!s'` 会对值调用 `str()`, `'!r'` 调用 `repr()` 而 `'!a'` 则调用 `ascii()`。

几个例子:

```
"Harold's a clever {0!s}"       # Calls str() on the argument first
"Bring out the holy {name!r}"   # Calls repr() on the argument first
"More {!a}"                    # Calls ascii() on the argument first
```

format_spec 字段包含值应如何呈现的规格描述, 例如字段宽度、对齐、填充、小数精度等细节信息。每种值类型可以定义自己的“格式化迷你语言”或对 *format_spec* 的解读方式。

大多数内置类型都支持同样的格式化迷你语言, 具体描述见下一节。

format_spec 字段还可以在其内部包含嵌套的替换字段。这些嵌套的替换字段可能包括字段名称、转换旗标和格式规格描述, 但是不再允许更深层的嵌套。*format_spec* 内部的替换字段会在解读 *format_spec* 字符串之前先被解读。这将允许动态地指定特定值的格式。

请参阅格式示例一节查看相关示例。

格式规格迷你语言

“格式规格”在格式字符串所包含的替换字段内部使用, 用于定义单个值应如何呈现 (参见格式字符串语法和 f-strings)。它们也可以被直接传给内置的 *format()* 函数。每种可格式化的类型都可以自行定义如何对格式规格进行解读。

大多数内置类型都为格式规格实现了下列选项, 不过某些格式化选项只被数值类型所支持。

一般约定空格式字符串 ("") 将产生与对值调用 *str()* 相同的结果。非空格式字符串通常会修改这一结果。

标准格式说明符的一般形式如下:

```
format_spec ::= [[fill]align][sign][#][0][width][grouping_option][.precision][type]
fill        ::= <any character>
align       ::= "<" | ">" | "=" | "^"
sign        ::= "+" | "-" | " "
width       ::= digit+
grouping_option ::= "_" | ","
precision  ::= digit+
type        ::= "b" | "c" | "d" | "e" | "E" | "f" | "F" | "g" | "G" | "n" | "o" | "s"
```

如果指定了一个有效的 *align* 值, 则可以在该值前面加一个 *fill* 字符, 它可以为任意字符, 如果省略则默认为空格符。在 格式化字符串字面值或在使用 *str.format()* 方法时是无法使用花括号字面值 (“{” or “}”)

作为 *fill* 字符的。但是，通过嵌套替换字段插入花括号则是可以的。这个限制不会影响 `format()` 函数。

各种对齐选项的含义如下：

选项	意义
'<'	强制字段在可用空间内左对齐（这是大多数对象的默认值）。
'>'	强制字段在可用空间内右对齐（这是数字的默认值）。
'= '	强制将填充放置在符号（如果有）之后但在数字之前。这用于以 “+000000120” 形式打印字段。此对齐选项仅对数字类型有效。当 ‘0’ 紧接在字段宽度之前时，它成为默认值。
'^ '	强制字段在可用空间内居中。

请注意，除非定义了最小字段宽度，否则字段宽度将始终与填充它的数据大小相同，因此在这种情况下，对齐选项没有意义。

sign 选项仅对数字类型有效，可以是以下之一：

选项	意义
'+'	表示标志应该用于正数和负数。
'- '	表示标志应仅用于负数（这是默认行为）。
space	表示应在正数上使用前导空格，在负数上使用减号。

'#' 选项可以让“替代形式”被用于转换。替代形式可针对不同类型分别定义。此选项仅对整数、浮点、复数和 `Decimal` 类型有效。对于整数类型，当使用二进制、八进制或十六进制输出时，此选项会为输出值添加相应的 '0b', '0o' 或 '0x' 前缀。对于浮点数、复数和 `Decimal` 类型，替代形式会使得转换结果总是包含小数点符号，即使其不带小数。通常只有在带有小数的情况下，此类转换的结果中才会出现小数点符号。此外，对于 'g' 和 'G' 转换，末尾的零不会从结果中被移除。

',' 选项表示使用逗号作为千位分隔符。对于感应区域设置的分隔符，请改用 'n' 整数表示类型。

在 3.1 版更改：添加了 ',' 选项（另请参阅 [PEP 378](#)）。

'_' 选项表示对浮点表示类型和整数表示类型 'd' 使用下划线作为千位分隔符。对于整数表示类型 'b', 'o', 'x' 和 'X'，将为每 4 个数位插入一个下划线。对于其他表示类型指定此选项则将导致错误。

在 3.6 版更改：添加了 '_' 选项（另请参阅 [PEP 515](#)）。

width 是一个定义最小字段宽度的十进制整数。如果未指定，则字段宽度将由内容确定。

当未显式给出对齐方式时，在 *width* 字段前加一个零 ('0') 字段将为数字类型启用感知正负号的零填充。这相当于设置 *fill* 字符为 '0' 且 *alignment* 类型为 '='。

precision 是一个十进制数字，表示对于以 'f' and 'F' 格式化的浮点数值要在小数点后显示多少个数位，或者对于以 'g' 或 'G' 格式化的浮点数值要在小数点前后共显示多少个数位。对于非数字类型，该字段表示最大字段大小——换句话说就是要使用多少个来自字段内容的字符。对于整数值则不允许使用 *precision*。

最后，*type* 确定了数据应如何呈现。

可用的字符串表示类型是：

类型	意义
's'	字符串格式。这是字符串的默认类型，可以省略。
None	和 's' 一样。

可用的整数表示类型是：

类型	意义
'b'	二进制格式。输出以 2 为基数的数字。
'c'	字符。在打印之前将整数转换为相应的 <code>unicode</code> 字符。
'd'	十进制整数。输出以 10 为基数的数字。
'o'	八进制格式。输出以 8 为基数的数字。
'x'	十六进制格式。输出以 16 为基数的数字，使用小写字母表示 9 以上的数码。
'X'	十六进制格式。输出以 16 为基数的数字，使用大写字母表示 9 以上的数码。
'n'	数字。这与 'd' 相似，不同之处在于它会使用当前区域设置来插入适当的数字分隔字符。
None	和 'd' 相同。

在上述的表示类型之外，整数还可以通过下列的浮点表示类型来格式化（除了 'n' 和 None）。当这样做时，会在格式化之前使用 `float()` 将整数转换为浮点数。

浮点数和小数值可用的表示类型有：

类型	意义
'e'	指数表示。以使用字母 'e' 来标示指数的科学计数法打印数字。默认的精度为 6。
'E'	指数表示。与 'e' 相似，不同之处在于它使用大写字母 'E' 作为分隔字符。
'f'	定点表示。将数字显示为一个定点数。默认的精确度为 6。
'F'	定点表示。与 'f' 相似，但会将 <code>nan</code> 转为 <code>NAN</code> 并将 <code>inf</code> 转为 <code>INF</code> 。
'g'	常规格式。对于给定的精度 $p \geq 1$ ，这会将数值舍入到 p 位有效数字，再将结果以定点格式或科学计数法进行格式化，具体取决于其值的大小。 准确的规则如下：假设使用表示类型 'e' 和精度 $p-1$ 进行格式化的结果具有指数值 <code>exp</code> 。则如果 $-4 \leq \text{exp} < p$ ，该数字将使用表示类型 'f' 和精度 $p-1-\text{exp}$ 进行格式化。否则的话，该数字将使用表示类型 'e' 和精度 $p-1$ 进行格式化。在两种情况下，都会从有效数字中移除无意义的末尾零，如果小数点之后没有数字则小数点也会被移除。 正负无穷，正负零和 <code>nan</code> 会分别被格式化为 <code>inf</code> , <code>-inf</code> , <code>0</code> , <code>-0</code> 和 <code>nan</code> ，无论精度如何设定。 精度 0 会被视为等同于精度 1。默认精度为 6。
'G'	常规格式。类似于 'g'，不同之处在于当数值非常大时会切换为 'E'。无穷与 <code>NaN</code> 也会表示为大写形式。
'n'	数字。这与 'g' 相似，不同之处在于它会使用当前区域设置来插入适当的数字分隔字符。
'%'	百分比。将数字乘以 100 并显示为定点 ('f') 格式，后面带一个百分号。
None	类似于 'g'，不同之处在于当使用定点表示法时，小数点后将至少显示一位。默认精度与表示给定值所需的精度一样。整体效果为与其他格式修饰符所调整的 <code>str()</code> 输出保持一致。

格式示例

本节包含 `str.format()` 语法的示例以及与旧式 `%` 格式化的比较。

该语法在大多数情况下与旧式的 `%` 格式化类似，只是增加了 `{}` 和 `:` 来取代 `%`。例如，`'%03.2f'` 可以被改写为 `'{:03.2f}'`。

新的格式语法还支持新增的不同选项，将在以下示例中说明。

按位置访问参数：

```
>>> '{0}, {1}, {2}'.format('a', 'b', 'c')
'a, b, c'
>>> '{} {}, {}'.format('a', 'b', 'c')  # 3.1+ only
'a, b, c'
>>> '{2}, {1}, {0}'.format('a', 'b', 'c')
'c, b, a'
>>> '{2}, {1}, {0}'.format(*'abc')      # unpacking argument sequence
'c, b, a'
>>> '{0}{1}{0}'.format('abra', 'cad')  # arguments' indices can be repeated
'abracadabra'
```

按名称访问参数:

```
>>> 'Coordinates: {latitude}, {longitude}'.format(latitude='37.24N', longitude='-115.81W')
'Coordinates: 37.24N, -115.81W'
>>> coord = {'latitude': '37.24N', 'longitude': '-115.81W'}
>>> 'Coordinates: {latitude}, {longitude}'.format(**coord)
'Coordinates: 37.24N, -115.81W'
```

访问参数的属性:

```
>>> c = 3-5j
>>> ('The complex number {0} is formed from the real part {0.real} '
... 'and the imaginary part {0.imag}.').format(c)
'The complex number (3-5j) is formed from the real part 3.0 and the imaginary part -5.0.'
>>> class Point:
...     def __init__(self, x, y):
...         self.x, self.y = x, y
...     def __str__(self):
...         return 'Point({self.x}, {self.y})'.format(self=self)
...
>>> str(Point(4, 2))
'Point(4, 2)'
```

访问参数的项:

```
>>> coord = (3, 5)
>>> 'X: {0[0]}; Y: {0[1]}'.format(coord)
'X: 3; Y: 5'
```

替代 %s 和 %r:

```
>>> "repr() shows quotes: {!r}; str() doesn't: {!s}".format('test1', 'test2')
'repr() shows quotes: \'test1\'; str() doesn\'t: test2'
```

对齐文本以及指定宽度:

```
>>> '{:<30}'.format('left aligned')
'left aligned'
>>> '{:>30}'.format('right aligned')
'right aligned'
>>> '{:^30}'.format('centered')
'centered'
>>> '{:*^30}'.format('centered')  # use '*' as a fill char
'*****centered*****'
```

替代 `%+f`, `%-f` 和 `% f` 以及指定正负号:

```
>>> '{:+f}; {:+f}'.format(3.14, -3.14) # show it always
'+3.140000; -3.140000'
>>> '{: f}; {: f}'.format(3.14, -3.14) # show a space for positive numbers
' 3.140000; -3.140000'
>>> '{:-f}; {:-f}'.format(3.14, -3.14) # show only the minus -- same as '{:f}; {:f}'
'3.140000; -3.140000'
```

替代 `%x` 和 `%o` 以及转换基于不同进位制的值:

```
>>> # format also supports binary numbers
>>> "int: {0:d}; hex: {0:x}; oct: {0:o}; bin: {0:b}".format(42)
'int: 42; hex: 2a; oct: 52; bin: 101010'
>>> # with 0x, 0o, or 0b as prefix:
>>> "int: {0:d}; hex: {0:#x}; oct: {0:#o}; bin: {0:#b}".format(42)
'int: 42; hex: 0x2a; oct: 0o52; bin: 0b101010'
```

使用逗号作为千位分隔符:

```
>>> '{:,}'.format(1234567890)
'1,234,567,890'
```

表示为百分数:

```
>>> points = 19
>>> total = 22
>>> 'Correct answers: {:.2%}'.format(points/total)
'Correct answers: 86.36%'
```

使用特定类型的专属格式化:

```
>>> import datetime
>>> d = datetime.datetime(2010, 7, 4, 12, 15, 58)
>>> '{:%Y-%m-%d %H:%M:%S}'.format(d)
'2010-07-04 12:15:58'
```

嵌套参数以及更复杂的示例:

```
>>> for align, text in zip('<^>', ['left', 'center', 'right']):
...     '{0:{fill}{align}16}'.format(text, fill=align, align=align)
...
'left<<<<<<<<<<'
'^^^^^center^^^^^'
'>>>>>>>>>>right'
>>>
>>> octets = [192, 168, 0, 1]
>>> '{:02X}{:02X}{:02X}{:02X}'.format(*octets)
'C0A80001'
>>> int(_, 16)
3232235521
>>>
>>> width = 5
>>> for num in range(5,12):
...     for base in 'dXob':
...         print('{0:{width}{base}}'.format(num, base=base, width=width), end=' ')
...     print()
... 
```

9	9	11	1001
10	A	12	1010
11	B	13	1011

6.1.4 模板字符串

模板字符串提供了由 [PEP 292](#) 所描述的更简便的字符串替换方式。模板字符串的一个主要用例是文本国际化 (i18n)，因为在此场景下，更简单的语法和功能使得文本翻译过程比使用 Python 的其他内置字符串格式化工具更为方便。作为基于模板字符串构建以实现 i18n 的库的一个示例，请参看 [flufl.i18n](#) 包。

模板字符串支持基于 `$` 的替换，使用以下规则：

- `$$` 为转义符号；它会被替换为单个的 `$`。
- `$identifier` 为替换占位符，它会匹配一个名为 "identifier" 的映射键。在默认情况下，"identifier" 限制为任意 ASCII 字母数字（包括下划线）组成的字符串，不区分大小写，以下划线或 ASCII 字母开头。在 `$` 字符之后的第一个非标识符字符将表明占位符的终结。
- `${identifier}` 等价于 `$identifier`。当占位符之后紧跟着有效的但又不是占位符一部分的标识符字符时需要使用，例如 `"${noun}ification"`。

在字符串的其他位置出现 `$` 将导致引发 `ValueError`。

`string` 模块提供了实现这些规则的 `Template` 类。`Template` 有下列方法：

class `string.Template(template)`

该构造器接受一个参数作为模板字符串。

substitute(mapping, **kws)

执行模板替换，返回一个新字符串。`mapping` 为任意字典类对象，其中的键将匹配模板中的占位符。或者你也可以提供一组关键字参数，其中的关键字即对应占位符。当同时给出 `mapping` 和 `kws` 并且存在重复时，则以 `kws` 中的占位符为优先。

safe_substitute(mapping, **kws)

类似于 `substitute()`，不同之处是如果有占位符未在 `mapping` 和 `kws` 中找到，不是引发 `KeyError` 异常，而是将原始占位符不加修改地显示在结果字符串中。另一个与 `substitute()` 的差异是任何在其他情况下出现的 `$` 将简单地返回 `$` 而不是引发 `ValueError`。

此方法被认为“安全”，因为虽然仍有可能发生其他异常，但它总是尝试返回可用的字符串而不是引发一个异常。从另一方面来说，`safe_substitute()` 也可能根本算不上安全，因为它将静默地忽略错误格式的模板，例如包含多余的分隔符、不成对的花括号或不是合法 Python 标识符的占位符等等。

`Template` 的实例还提供一个公有数据属性：

template

这是作为构造器的 `template` 参数被传入的对象。一般来说，你不应该修改它，但并不强制要求只读访问。

以下是一个如何使用模版的示例：

```
>>> from string import Template
>>> s = Template('$who likes $what')
>>> s.substitute(who='tim', what='kung pao')
```

(下页继续)

(续上页)

```
'tim likes kung pao'
>>> d = dict(who='tim')
>>> Template('Give $who $100').substitute(d)
Traceback (most recent call last):
...
ValueError: Invalid placeholder in string: line 1, col 11
>>> Template('$who likes $what').substitute(d)
Traceback (most recent call last):
...
KeyError: 'what'
>>> Template('$who likes $what').safe_substitute(d)
'tim likes $what'
```

进阶用法：你可以派生 *Template* 的子类来自定义占位符语法、分隔符，或用于解析模板字符串的整个正则表达式。为此目的，你可以重载这些类属性：

- *delimiter* – This is the literal string describing a placeholder introducing delimiter. The default value is `$`. Note that this should *not* be a regular expression, as the implementation will call `re.escape()` on this string as needed.
- *idpattern* – This is the regular expression describing the pattern for non-braced placeholders (the braces will be added automatically as appropriate). The default value is the regular expression `(? -i: [_a-zA-Z] [_a-zA-Z0-9]*)`.

注解： Since default *flags* is `re.IGNORECASE`, pattern `[a-z]` can match with some non-ASCII characters. That's why we use local `-i` flag here.

While *flags* is kept to `re.IGNORECASE` for backward compatibility, you can override it to `0` or `re.IGNORECASE | re.ASCII` when subclassing.

- *flags* – 将在编译用于识别替换内容的正则表达式被应用的正则表达式旗标。默认值为 `re.IGNORECASE`。请注意 `re.VERBOSE` 总是会被加为旗标，因此自定义的 *idpattern* 必须遵循详细正则表达式的约定。

3.2 新版功能.

作为另一种选项，你可以通过重载类属性 *pattern* 来提供整个正则表达式模式。如果你这样做，该值必须为一个具有四个命名捕获组的正则表达式对象。这些捕获组对应于上面已经给出的规则，以及无效占位符的规则：

- *escaped* – 这个组匹配转义序列，在默认模式中即 `$$`。
- *named* – 这个组匹配不带花括号的占位符名称；它不应当包含捕获组中的分隔符。
- *braced* – 这个组匹配带有花括号的占位符名称；它不应当包含捕获组中的分隔符或者花括号。
- *invalid* – 这个组匹配任何其他分隔符模式（通常为单个分隔符），并且它应当出现在正则表达式的末尾。

6.1.5 辅助函数

`string.capwords(s, sep=None)`

使用 `str.split()` 将参数拆分为单词，使用 `str.capitalize()` 将单词转为大写形式，使用 `str.join()` 将大写的单词进行拼接。如果可选的第二个参数 *sep* 被省略或为 `None`，则连续的空白字符会被替换为单个空格符并且开头和末尾的空白字符会被移除，否则 *sep* 会被用来拆分和拼接单词。

6.2 re — 正则表达式操作

源代码: [Lib/re.py](#)

这个模块提供了与 Perl 语言类似的正则表达式匹配操作。

模式和被搜索的字符串既可以是 Unicode 字符串 (*str*)，也可以是 8 位字节串 (*bytes*)。但是，Unicode 字符串与 8 位字节串不能混用：也就是说，你不能用一个字节串模式去匹配 Unicode 字符串，反之亦然；类似地，当进行替换操作时，替换字符串的类型也必须与所用的模式和搜索字符串的类型一致。

正则表达式使用反斜杠 (`'\'`) 来表示特殊形式，或者把特殊字符转义成普通字符。而反斜杠在普通的 Python 字符串里也有相同的作用，所以就产生了冲突。比如说，要匹配一个字面上的反斜杠，正则表达式模式不得不写成 `'\\\\'`，因为正则表达式里匹配一个反斜杠必须是 `\\`，而每个反斜杠在普通的 Python 字符串里都要写成 `\\`。

解决办法是对于正则表达式样式使用 Python 的原始字符串表示法；在带有 `'r'` 前缀的字符串字面值中，反斜杠不必做任何特殊处理。因此 `r"\n"` 表示包含 `'\'` 和 `'n'` 两个字符的字符串，而 `"\n"` 则表示只包含一个换行符的字符串。样式在 Python 代码中通常都会使用这种原始字符串表示法来表示。

绝大部分正则表达式操作都提供为模块函数和方法，在[编译正则表达式](#)。这些函数是一个捷径，不需要先编译一个正则对象，但是损失了一些优化参数。

参见：

第三方模块 [regex](#)，提供了与标准库 `re` 模块兼容的 API 接口，同时还提供了额外的功能和更全面的 Unicode 支持。

6.2.1 正则表达式语法

一个正则表达式（或 RE）指定了一集与之匹配的字符串；模块内的函数可以让你检查某个字符串是否跟给定的正则表达式匹配（或者一个正则表达式是否匹配到一个字符串，这两种说法含义相同）。

正则表达式可以拼接；如果 *A* 和 *B* 都是正则表达式，那么 *AB* 也是正则表达式。通常，如果字符串 *p* 匹配 *A* 并且另一个字符串 *q* 匹配 *B*，那么 *pq* 可以匹配 *AB*。除非 *A* 或者 *B* 包含低优先级操作，*A* 和 *B* 存在边界条件；或者命名组引用。所以，复杂表达式可以很容易的从这里描述的简单源语表达式构建。了解更多正则表达式理论和实现，参考 the Friedl book [Frie09]，或者其他编译器构建的书籍。

以下是正则表达式格式的简要说明。更详细的信息和演示，参考 [regex-howto](#)。

正则表达式可以包含普通或者特殊字符。绝大部分普通字符，比如 `'A'`，`'a'`，或者 `'0'`，都是最简单的正则表达式。它们就匹配自身。你可以拼接普通字符，所以 `last` 匹配字符串 `'last'`。（在这一节的其他部分，我们将用 `this special style` 这种方式表示正则表达式，通常不带引号，要匹配的字符串用 `'in single quotes'`，单引号形式。）

有些字符，比如 `'|'` 或者 `'('`，属于特殊字符。特殊字符既可以表示它的普通含义，也可以影响它旁边的正则表达式的解释。

重复修饰符 (`*`，`+`，`?`，`{m,n}`，等) 不能直接嵌套。这样避免了非贪婪后缀？修饰符，和其他实现中的修饰符产生的多义性。要应用一个内层重复嵌套，可以使用括号。比如，表达式 `(?:a{6})*` 匹配 6 个 `'a'` 字符重复任意次数。

特殊字符是：

- (点) 在默认模式，匹配除了换行的任意字符。如果指定了标签 `DOTALL`，它将匹配包括换行符的任意字符。
- ^ (插入符号) 匹配字符串的开头，并且在 `MULTILINE` 模式也匹配换行后的首个符号。

\$ 匹配字符串尾或者换行符的前一个字符，在 *MULTILINE* 模式匹配换行符的前一个字符。`foo` 匹配 `'foo'` 和 `'foobar'`，但正则 `foo$` 只匹配 `'foo'`。更有趣的是，在 `'foo1\nfoo2\n'` 搜索 `foo.$`，通常匹配 `'foo2'`，但在 *MULTILINE* 模式，可以匹配到 `'foo1'`；在 `'foo\n'` 搜索 `$` 会找到两个空串：一个在换行前，一个在字符串最后。

***** 对它前面的正则式匹配 0 到任意次重复，尽量多的匹配字符串。`ab*` 会匹配 `'a'`，`'ab'`，或者 `'a'``` 后面跟随任意个 `'b'`。

+ 对它前面的正则式匹配 1 到任意次重复。`ab+` 会匹配 `'a'` 后面跟随 1 个以上到任意个 `'b'`，它不会匹配 `'a'`。

? 对它前面的正则式匹配 0 到 1 次重复。`ab?` 会匹配 `'a'` 或者 `'ab'`。

, +, ?, ? `'*'`，`'+'`，和 `'?'` 修饰符都是贪婪的；它们在字符串进行尽可能多的匹配。有时候并不需要这种行为。如果正则式 `<.*>` 希望找到 `'<a> b <c>'`，它将会匹配整个字符串，而不仅是 `'<a>'`。在修饰符之后添加 `?` 将使样式以非贪婪方式或者 *dfn*：最小方式进行匹配；尽量少的字符将会被匹配。使用正则式 `<.*?>` 将会仅仅匹配 `'<a>'`。

{m} 对其之前的正则式指定匹配 *m* 个重复；少于 *m* 的话就会导致匹配失败。比如，`a{6}` 将匹配 6 个 `'a'`，但是不能是 5 个。

{m, n} 对正则式进行 *m* 到 *n* 次匹配，在 *m* 和 *n* 之间取尽量多。比如，`a{3, 5}` 将匹配 3 到 5 个 `'a'`。忽略 *m* 意为指定下界为 0，忽略 *n* 指定上界为无限次。比如 `a{4, }b` 将匹配 `'aaaab'` 或者 1000 个 `'a'` 尾随一个 `'b'`，但不能匹配 `'aaab'`。逗号不能省略，否则无法辨别修饰符应该忽略哪个边界。

{m, n}? 前一个修饰符的非贪婪模式，只匹配尽量少的字符次数。比如，对于 `'aaaaaa'`，`a{3, 5}` 匹配 5 个 `'a'`，而 `a{3, 5}?` 只匹配 3 个 `'a'`。

**** 转义特殊字符（允许你匹配 `'*'`，`'?'`，或者此类其他），或者表示一个特殊序列；特殊序列之后进行讨论。

如果你没有使用原始字符串 (`r'raw'`) 来表达样式，要牢记 Python 也使用反斜杠作为转义序列；如果转义序列不被 Python 的分析器识别，反斜杠和字符才能出现在字符串中。如果 Python 可以识别这个序列，那么反斜杠就应该重复两次。这将导致理解障碍，所以高度推荐，就算是最简单的表达式，也要使用原始字符串。

[] 用于表示一个字符集合。在一个集合中：

- 字符可以单独列出，比如 `[amk]` 匹配 `'a'`，`'m'`，或者 `'k'`。
- 可以表示字符范围，通过用 `'-'` 将两个字符连起来。比如 `[a-z]` 将匹配任何小写 ASCII 字符，`[0-5][0-9]` 将匹配从 00 到 59 的两位数字，`[0-9A-Fa-f]` 将匹配任何十六进制数位。如果进行了转义（比如 `[a\-z]`）或者它的位置在首位或者末尾（如 `[-a]` 或 `[a-]`），它就只表示普通字符 `'-'`。
- 特殊字符在集合中，失去它的特殊含义。比如 `[(+*)]` 只会匹配这几个文法字符 `'('`，`'+'`，`'*'`，或 `')'`。
- 字符类如 `\w` 或者 `\s` (如下定义) 在集合内可以接受，它们可以匹配的字符由 *ASCII* 或者 *LOCALE* 模式决定。
- 不在集合范围内的字符可以通过取反来进行匹配。如果集合首字符是 `'^'`，所有不在集合内的字符将会被匹配，比如 `[^5]` 将匹配所有字符，除了 `'5'`，`[^~]` 将匹配所有字符，除了 `'^'`。如果不在集合首位，就没有特殊含义。
- 在集合内要匹配一个字符 `']'`，有两种方法，要么就在它之前加上反斜杠，要么就把它放到集合首位。比如，`[(\)]{\}` 和 `[()]{}` 都可以匹配括号。

| `A|B`，*A* 和 *B* 可以是任意正则表达式，创建一个正则表达式，匹配 *A* 或者 *B*。任意个正则表达式可以用 `'|'` 连接。它也可以在组合（见下列）内使用。扫描目标字符串时，`'|'` 分隔开的正则样式从左到右进行匹配。当一个样式完全匹配时，这个分支就被接受。意思就是，一旦 *A* 匹配成功，*B* 就不再进行匹配，即便它能产生一个更好的匹配。或者说，`'|'` 操作符绝不贪婪。如果要匹配 `'|'` 字符，使用 `\|`，或者把它包含在字符集里，比如 `[|]`。

(...) (组合), 匹配括号内的任意正则表达式, 并标识出组合的开始和结尾。匹配完成后, 组合的内容可以被获取, 并可以在之后用 `\number` 转义序列进行再次匹配, 之后进行详细说明。要匹配字符 '(' 或者 ')', 用 `\(` 或 `\)`, 或者把它们包含在字符集合里: `[(), []]`。

(?...) 这是个扩展标记法 (一个 '?' 跟随 '(' 并无含义)。'?' 后面的第一个字符决定了这个构建采用什么样的语法。这种扩展通常并不创建新的组合; (`?P<name>...`) 是唯一的例外。以下是目前支持的扩展。

(**?aiLmsux**) ('a', 'i', 'L', 'm', 's', 'u', 'x' 中的一个或多个) 这个组合匹配一个空字符串; 这些字符对正则表达式设置以下标记 `re.A` (只匹配 ASCII 字符), `re.I` (忽略大小写), `re.L` (语言依赖), `re.M` (多行模式), `re.S` (点 `dot` 匹配全部字符), `re.U` (Unicode 匹配), and `re.X` (冗长模式)。(这些标记在模块内容中描述) 如果你想将这些标记包含在正则表达式中, 这个方法就很有用, 免去了在 `re.compile()` 中传递 `flag` 参数。标记应该在表达式字符串首位表示。

(?:...) 正则括号的非捕获版本。匹配在括号内的任何正则表达式, 但该分组所匹配的子字符串 不能在执行匹配后被获取或是之后在模式中被引用。

(**?imsx-imsx:...**) (Zero or more letters from the set 'i', 'm', 's', 'x', optionally followed by '-' followed by one or more letters from the same set.) The letters set or removes the corresponding flags: `re.I` (ignore case), `re.M` (multi-line), `re.S` (dot matches all), and `re.X` (verbose), for the part of the expression. (The flags are described in 模块内容.)

3.6 新版功能.

(**?P<name>...**) (命名组合) 类似正则组合, 但是匹配到的子串组在外部是通过定义的 `name` 来获取的。组合名必须是有效的 Python 标识符, 并且每个组合名只能用一个正则表达式定义, 只能定义一次。一个符号组合同样是一个数字组合, 就像这个组合没有被命名一样。

命名组合可以在三种上下文中引用。如果样式是 (`?P<quote>['"]`).`*?`(`?P=quote`) (也就是说, 匹配单引号或者双引号括起来的字符串):

引用组合 "quote" 的上下文	引用方法
在正则式自身内	<ul style="list-style-type: none"> (<code>?P=quote</code>) (如示) <code>\1</code>
处理匹配对象 <code>m</code>	<ul style="list-style-type: none"> <code>m.group('quote')</code> <code>m.end('quote')</code> (等)
传递到 <code>re.sub()</code> 里的 <code>repl</code> 参数中	<ul style="list-style-type: none"> <code>\g<quote></code> <code>\g<1></code> <code>\1</code>

(**?P=name**) 反向引用一个命名组合; 它匹配前面那个叫 `name` 的命名组中匹配到的串同样的字串。

(**?#...**) 注释; 里面的内容会被忽略。

(**?=...**) 匹配 ... 的内容, 但是并不消费样式的内容。这个叫做 *lookahead assertion*。比如, `Isaac (?=Asimov)` 匹配 'Isaac ' 只有在后面是 'Asimov' 的时候。

(**?!...**) 匹配 ... 不符合的情况。这个叫 *negative lookahead assertion* (前视取反)。比如说, `Isaac (?!Asimov)` 只有后面 不是 'Asimov' 的时候才匹配 'Isaac '。

(**?<=...**) 匹配字符串的当前位置, 它的前面匹配 ... 的内容到当前位置。这叫 *dfn:positive lookbehind assertion* (正向后视断定)。(`?<=abc`) `def` 会在 'abcdef' 中找到一个匹配, 因为后视会往后看 3 个字符并检查是否包含匹配的样式。包含的匹配样式必须是定长的, 意思就是 `abc` 或 `a|b` 是允许的, 但是 `a*` 和

`a{3,4}` 不可以。注意以 `positive lookbehind assertions` 开始的样式，如 `(?<=abc)def`，并不是从 `a` 开始搜索，而是从 `d` 往回看的。你可能更加愿意使用 `search()` 函数，而不是 `match()` 函数：

```
>>> import re
>>> m = re.search('(?!<=abc)def', 'abcdef')
>>> m.group(0)
'def'
```

这个例子搜索一个跟随在连字符后的单词：

```
>>> m = re.search(r'(?<=)\w+', 'spam-egg')
>>> m.group(0)
'egg'
```

在 3.5 版更改：添加定长组合引用的支持。

(?!...) 匹配当前位置之前不是 ... 的样式。这个叫 *dfn:negative lookbehind assertion*（后视断定取非）。类似正向后视断定，包含的样式匹配必须是定长的。由 *negative lookbehind assertion* 开始的样式可以从字符串搜索开始的位置进行匹配。

(?(id/name)yes-pattern|no-pattern) 如果给定的 *id* 或 *name* 存在，将会尝试匹配 *yes-pattern*，否则就尝试匹配 *no-pattern*，*no-pattern* 可选，也可以被忽略。比如，`(<)?(\w+@\w+(?:\.\w+)+)(?(1)>|$)` 是一个 email 样式匹配，将匹配 `<user@host.com>` 或 `'user@host.com'`，但不会匹配 `'<user@host.com'`，也不会匹配 `'user@host.com>'`。

由 `'\'` 和一个字符组成的特殊序列在以下列出。如果普通字符不是 ASCII 数位或者 ASCII 字母，那么正则样式将匹配第二个字符。比如，`\$` 匹配字符 `'$'`。

\number 匹配数字代表的组合。每个括号是一个组合，组合从 1 开始编号。比如 `(.+) \1` 匹配 `'the the'` 或者 `'55 55'`，但不会匹配 `'thethe'`（注意组合后面的空格）。这个特殊序列只能用于匹配前面 99 个组合。如果 *number* 的第一个数位是 0，或者 *number* 是三个八进制数，它将不会被看作是一个组合，而是八进制的数字值。在 `'['` 和 `']'` 字符集合内，任何数字转义都被看作是字符。

\A 只匹配字符串开始。

\b 匹配空字符串，但只在单词开始或结尾的位置。一个单词被定义为一个单词字符的序列。注意，通常 `\b` 定义为 `\w` 和 `\W` 字符之间，或者 `\w` 和字符串开始/结尾的边界，意思就是 `r'\bfoo\b'` 匹配 `'foo'`，`'foo.'`，`'(foo)'`，`'bar foo baz'` 但不匹配 `'foobar'` 或者 `'foo3'`。

默认情况下，Unicode 字母和数字是在 Unicode 样式中使用的，但是可以用 *ASCII* 标记来更改。如果 *LOCALE* 标记被设置的话，词的边界是由当前语言区域设置决定的，`\b` 表示退格字符，以便与 Python 字符串文本兼容。

\B 匹配空字符串，但不能在词的开头或者结尾。意思就是 `r'py\B'` 匹配 `'python'`，`'py3'`，`'py2'`，但不匹配 `'py'`，`'py.'`，或者 `'py!'`。`\B` 是 `\b` 的取非，所以 Unicode 样式的词语是由 Unicode 字母，数字或下划线构成的，虽然可以用 *ASCII* 标志来改变。如果使用了 *LOCALE* 标志，则词的边界由当前语言区域设置。

\d

对于 Unicode (str) 样式： Matches any Unicode decimal digit (that is, any character in Unicode character category [Nd]). This includes `[0-9]`, and also many other digit characters. If the *ASCII* flag is used only `[0-9]` is matched (but the flag affects the entire regular expression, so in such cases using an explicit `[0-9]` may be a better choice).

对于 8 位 (bytes) 样式： 匹配任何十进制数，就是 `[0-9]`。

\D Matches any character which is not a decimal digit. This is the opposite of `\d`. If the *ASCII* flag is used this becomes the equivalent of `[^0-9]` (but the flag affects the entire regular expression, so in such cases using an explicit `[^0-9]` may be a better choice).

\s

对于 Unicode (str) 样式： Matches Unicode whitespace characters (which includes [\t\n\r\f\v], and also many other characters, for example the non-breaking spaces mandated by typography rules in many languages). If the *ASCII* flag is used, only [\t\n\r\f\v] is matched (but the flag affects the entire regular expression, so in such cases using an explicit [\t\n\r\f\v] may be a better choice).

对于 8 位 (bytes) 样式： 匹配 ASCII 中的空白字符，就是 [\t\n\r\f\v] 。

\S Matches any character which is not a whitespace character. This is the opposite of \s. If the *ASCII* flag is used this becomes the equivalent of [^\t\n\r\f\v] (but the flag affects the entire regular expression, so in such cases using an explicit [^\t\n\r\f\v] may be a better choice).

\w

对于 Unicode (str) 样式： Matches Unicode word characters; this includes most characters that can be part of a word in any language, as well as numbers and the underscore. If the *ASCII* flag is used, only [a-zA-Z0-9_] is matched (but the flag affects the entire regular expression, so in such cases using an explicit [a-zA-Z0-9_] may be a better choice).

对于 8 位 (bytes) 样式： 匹配 ASCII 字符中的数字和字母和下划线，就是 [a-zA-Z0-9_]。如果设置了 *LOCALE* 标记，就匹配当前语言区域的数字和字母和下划线。

\W Matches any character which is not a word character. This is the opposite of \w. If the *ASCII* flag is used this becomes the equivalent of [^\a-zA-Z0-9_] (but the flag affects the entire regular expression, so in such cases using an explicit [^\a-zA-Z0-9_] may be a better choice). If the *LOCALE* flag is used, matches characters considered alphanumeric in the current locale and the underscore.

\Z 只匹配字符串尾。

绝大部分 Python 的标准转义字符也被正则表达式分析器支持。：

\a	\b	\f	\n
\r	\t	\u	\U
\v	\x	\\	

(注意 \b 被用于表示词语的边界，它只在字符集合内表示退格，比如 [\b]。)

'\u' and '\U' escape sequences are only recognized in Unicode patterns. In bytes patterns they are errors.

八进制转义包含为一个有限形式。如果首位数字是 0，或者有三个八进制数位，那么就认为它是八进制转义。其他的情况，就看作是组引用。对于字符串文本，八进制转义最多有三个数位长。

在 3.3 版更改：增加了 '\u' 和 '\U' 转义序列。

在 3.6 版更改：由 '\\' 和一个 ASCII 字符组成的未知转义会被看成错误。

6.2.2 模块内容

模块定义了几个函数，常量，和一个例外。有些函数是编译后的正则表达式方法的简化版本（少了一些特性）。绝大部分重要的应用，总是会先将正则表达式编译，之后在进行操作。

在 3.6 版更改：标志常量现在是 `RegexFlag` 类的实例，这个类是 `enum.IntFlag` 的子类。

`re.compile(pattern, flags=0)`

Compile a regular expression pattern into a *regular expression object*, which can be used for matching using its `match()`, `search()` and other methods, described below.

这个表达式的行为可以通过指定 标记的值来改变。值可以是以下任意变量，可以通过位的 OR 操作来结合 (| 操作符)。

序列

```
prog = re.compile(pattern)
result = prog.match(string)
```

等价于

```
result = re.match(pattern, string)
```

如果需要多次使用这个正则表达式的话，使用 `re.compile()` 和保存这个正则对象以便复用，可以让程序更加高效。

注解：通过 `re.compile()` 编译后的样式，和模块级的函数会被缓存，所以少数的正则表达式使用无需考虑编译的问题。

re.A

re.ASCII

让 `\w`, `\W`, `\b`, `\B`, `\d`, `\D`, `\s` 和 `\S` 只匹配 ASCII，而不是 Unicode。这只对 Unicode 样式有效，会被 byte 样式忽略。相当于前面语法中的内联标志 (`?a`)。

注意，为了保持向后兼容，`re.U` 标记依然存在（还有他的同义 `re.UNICODE` 和嵌入形式 (`?u`)），但是这些在 Python 3 是冗余的，因为默认字符串已经是 Unicode 了（并且 Unicode 匹配不允许 byte 出现）。

re.DEBUG

显示编译时的 debug 信息，没有内联标志。

re.I

re.IGNORECASE

进行忽略大小写匹配；表达式如 `[A-Z]` 也会匹配小写字符。Unicode 匹配（比如 `ü` 匹配 `ü`）同样有用，除非设置了 `re.ASCII` 标记来禁用非 ASCII 匹配。当前语言区域不会改变这个标记，除非设置了 `re.LOCALE` 标记。这个相当于内联标志 (`?i`)。

Note that when the Unicode patterns `[a-z]` or `[A-Z]` are used in combination with the `IGNORECASE` flag, they will match the 52 ASCII letters and 4 additional non-ASCII letters: ‘`İ`’ (U+0130, Latin capital letter I with dot above), ‘`ı`’ (U+0131, Latin small letter dotless i), ‘`ſ`’ (U+017F, Latin small letter long s) and ‘`℔`’ (U+212A, Kelvin sign). If the `ASCII` flag is used, only letters ‘`a`’ to ‘`z`’ and ‘`A`’ to ‘`Z`’ are matched (but the flag affects the entire regular expression, so in such cases using an explicit (`?-i: [a-zA-Z]`) may be a better choice).

re.L

re.LOCALE

由当前语言区域决定 `\w`, `\W`, `\b`, `\B` 和大小写敏感匹配。这个标记只能对 byte 样式有效。这个标记不推荐使用，因为语言区域机制很不可靠，它一次只能处理一个“习惯”，而且只对 8 位字节有效。Unicode 匹配在 Python 3 里默认启用，并可以处理不同语言。这个对应内联标志 (`?L`)。

在 3.6 版更改：`re.LOCALE` 只能用于 byte 样式，而且不能和 `re.ASCII` 一起用。

re.M

re.MULTILINE

设置以后，样式字符 ‘`^`’ 匹配字符串的开始，和每一行的开始（换行符后面紧跟的符号）；样式字符 ‘`$`’ 匹配字符串尾，和每一行的结尾（换行符前面那个符号）。默认情况下，‘`^`’ 匹配字符串头，‘`$`’ 匹配字符串尾。对应内联标志 (`?m`)。

re.S

re.DOTALL

让 ‘`.`’ 特殊字符匹配任何字符，包括换行符；如果没有这个标记，‘`.`’ 就匹配除了换行符的其他任意字符。对应内联标志 (`?s`)。

re.X

re.VERBOSE

这个标记允许你编写更具可读性更友好的正则表达式。通过分段和添加注释。空白符号会被忽略，除非在一个字符集合当中或者由反斜杠转义，或者在 `*?`, `(?: or (?P<...>` 分组之内。当一个行内有 `#` 不在字符集和转义序列，那么它之后的所有字符都是注释。

意思就是下面两个正则表达式等价地匹配一个十进制数字：

```
a = re.compile(r"""\d + # the integral part
                  \.    # the decimal point
                  \d *  # some fractional digits""", re.X)
b = re.compile(r"\d+\.\d*")
```

对应内联标记 `(?x)`。

re.search(pattern, string, flags=0)

扫描整个字符串找到匹配样式的第一个位置，并返回一个相应的匹配对象。如果没有匹配，就返回一个 `None`；注意这和找到一个零长度匹配是不同的。

re.match(pattern, string, flags=0)

如果 `string` 开始的 0 或者多个字符匹配到了正则表达式样式，就返回一个相应的匹配对象。如果没有匹配，就返回 `None`；注意它跟零长度匹配是不同的。

注意即便是 `MULTILINE` 多行模式，`re.match()` 也只匹配字符串的开始位置，而不匹配每行开始。

如果你想定位 `string` 的任何位置，使用 `search()` 来替代（也可参考 `search()` vs. `match()`）

re.fullmatch(pattern, string, flags=0)

如果整个 `string` 匹配到正则表达式样式，就返回一个相应的匹配对象。否则就返回一个 `None`；注意这跟零长度匹配是不同的。

3.4 新版功能.**re.split(pattern, string, maxsplit=0, flags=0)**

用 `pattern` 分开 `string`。如果在 `pattern` 中捕获到括号，那么所有的组里的文字也会包含在列表里。如果 `maxsplit` 非零，最多进行 `maxsplit` 次分隔，剩下的字符全部返回到列表的最后一个元素。

```
>>> re.split(r'\W+', 'Words, words, words.')
['Words', 'words', 'words', '']
>>> re.split(r'(\W+)', 'Words, words, words.')
['Words', '', ' ', 'words', '', ' ', 'words', '.', '']
>>> re.split(r'\W+', 'Words, words, words.', 1)
['Words', 'words, words.']
>>> re.split(r'[a-f]+', '0a3B9', flags=re.IGNORECASE)
['0', '3', '9']
```

如果分隔符里有捕获组合，并且匹配到字符串的开始，那么结果将会以一个空字符串开始。对于结尾也是一样

```
>>> re.split(r'(\W+)', '...words, words...')
['', '...', 'words', '', ' ', 'words', '...', '']
```

这样的话，分隔组将会出现在结果列表中同样的位置。

注解： `split()` doesn't currently split a string on an empty pattern match. For example:

```
>>> re.split(r'x*', 'axbc')
['a', 'bc']
```

Even though `'x*'` also matches 0 `'x'` before `'a'`, between `'b'` and `'c'`, and after `'c'`, currently these matches are ignored. The correct behavior (i.e. splitting on empty matches too and returning `['', 'a', 'b',`

'c', ' ']) will be implemented in future versions of Python, but since this is a backward incompatible change, a *FutureWarning* will be raised in the meanwhile.

Patterns that can only match empty strings currently never split the string. Since this doesn't match the expected behavior, a *ValueError* will be raised starting from Python 3.5:

```
>>> re.split("^$", "foo\n\nbar\n", flags=re.M)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
    ...
ValueError: split() requires a non-empty pattern match.
```

在 3.1 版更改: 增加了可选标记参数。

在 3.5 版更改: Splitting on a pattern that could match an empty string now raises a warning. Patterns that can only match empty strings are now rejected.

re.findall (*pattern*, *string*, *flags*=0)

对 *string* 返回一个不重复的 *pattern* 的匹配列表, *string* 从左到右进行扫描, 匹配按找到的顺序返回。如果样式里存在一到多个组, 就返回一个组合列表; 就是一个元组的列表 (如果样式里有超过一个组合的话)。空匹配也会包含在结果里。

注解: Due to the limitation of the current implementation the character following an empty match is not included in a next match, so `findall(r'^|\w+', 'two words')` returns `['', 'wo', 'words']` (note missed "t"). This is changed in Python 3.7.

re.finditer (*pattern*, *string*, *flags*=0)

Return an *iterator* yielding *match objects* over all non-overlapping matches for the RE *pattern* in *string*. The *string* is scanned left-to-right, and matches are returned in the order found. Empty matches are included in the result. See also the note about *findall* ().

re.sub (*pattern*, *repl*, *string*, *count*=0, *flags*=0)

Return the string obtained by replacing the leftmost non-overlapping occurrences of *pattern* in *string* by the replacement *repl*. If the pattern isn't found, *string* is returned unchanged. *repl* can be a string or a function; if it is a string, any backslash escapes in it are processed. That is, `\n` is converted to a single newline character, `\r` is converted to a carriage return, and so forth. Unknown escapes such as `\&` are left alone. Backreferences, such as `\6`, are replaced with the substring matched by group 6 in the pattern. For example:

```
>>> re.sub(r'def\s+([a-zA-Z_][a-zA-Z_0-9]*)\s*\(\s*\):',
...       r'static PyObject*\np_{1}(void)\n{',
...       'def myfunc():')
'static PyObject*\np_myfunc(void)\n{'
```

如果 *repl* 是一个函数, 那它会对每个非重复的 *pattern* 的情况调用。这个函数只能有一个 *匹配对象* 参数, 并返回一个替换后的字符串。比如

```
>>> def dashrepl(matchobj):
...     if matchobj.group(0) == '-': return ' '
...     else: return '-'
>>> re.sub('-{1,2}', dashrepl, 'pro---gram-files')
'pro--gram files'
>>> re.sub(r'\sAND\s', ' & ', 'Baked Beans And Spam', flags=re.IGNORECASE)
'Baked Beans & Spam'
```

样式可以是一个字符串或者一个样式对象。

The optional argument *count* is the maximum number of pattern occurrences to be replaced; *count* must be a non-negative integer. If omitted or zero, all occurrences will be replaced. Empty matches for the pattern are replaced only when not adjacent to a previous match, so `sub('x*', '-', 'abc')` returns `'-a-b-c-'`.

在字符串类型的 *repl* 参数里, 如上所述的转义和向后引用中, `\g<name>` 会使用命名组合 *name*, (在 `(?P<name>...)` 语法中定义) `\g<number>` 会使用数字组; `\g<2>` 就是 `\2`, 但它避免了二义性, 如 `\g<2>0`. `\20` 就会被解释为组 20, 而不是组 2 后面跟随一个字符 '0'. 向后引用 `\g<0>` 把 *pattern* 作为一个整个组进行引用。

在 3.1 版更改: 增加了可选标记参数。

在 3.5 版更改: 不匹配的组合替换为空字符串。

在 3.6 版更改: *pattern* 中的未知转义 (由 `'\'` 和一个 ASCII 字符组成) 被视为错误。

Deprecated since version 3.5, will be removed in version 3.7: Unknown escapes in *repl* consisting of `'\'` and an ASCII letter now raise a deprecation warning and will be forbidden in Python 3.7.

re.subn (*pattern*, *repl*, *string*, *count=0*, *flags=0*)

行为与 `sub()` 相同, 但是返回一个元组 (字符串, 替换次数)。

在 3.1 版更改: 增加了可选标记参数。

在 3.5 版更改: 不匹配的组合替换为空字符串。

re.escape (*pattern*)

Escape all the characters in *pattern* except ASCII letters, numbers and `'_'`. This is useful if you want to match an arbitrary literal string that may have regular expression metacharacters in it. For example:

```
>>> print(re.escape('python.exe'))
python\.exe

>>> legal_chars = string.ascii_lowercase + string.digits + "!#$%&'*+-.^_`|~:"
>>> print('[%s]+' % re.escape(legal_chars))
[abcdefghijklmnopqrstuvwxyz0123456789\!#\$\%&'\*\+\-\.\^_\`|\~\:]

>>> operators = ['+', '-', '*', '/', '**']
>>> print(''.join(map(re.escape, sorted(operators, reverse=True))))
\|\/\-\|\/\+\|\/\*\|\/\*
```

这个函数不能用在 `sub()` 和 `subn()` 的替换字符串里, 只有反斜杠应该被转义, 比如说

```
>>> digits_re = r'\d+'
>>> sample = '/usr/sbin/sendmail - 0 errors, 12 warnings'
>>> print(re.sub(digits_re, digits_re.replace('\', r'\\'), sample))
/usr/sbin/sendmail - \d+ errors, \d+ warnings
```

在 3.3 版更改: `'_'` 不再被转义。

re.purge ()

清除正则表达式缓存。

exception re.error (*msg*, *pattern=None*, *pos=None*)

raise 一个例外。当传递到函数的字符串不是一个有效正则表达式的时候 (比如, 包含一个不匹配的括号) 或者其他错误在编译时或匹配时产生。如果字符串不包含样式匹配, 是不会被视为错误的。错误实例有以下附加属性:

msg

未格式化的错误消息。

pattern

正则表达式样式。

pos

编译失败的 *pattern* 的位置索引 (可以是 None)。

lineno

对应 *pos* (可以是 None) 的行号。

colno

对应 *pos* (可以是 None) 的列号。

在 3.5 版更改: 添加了附加属性。

6.2.3 正则表达式对象 (正则对象)

编译后的正则表达式对象支持一下方法和属性:

regex.search (*string* [, *pos* [, *endpos*]])

扫描整个 *string* 寻找第一个匹配的位置, 并返回一个相应的匹配对象。如果没有匹配, 就返回 None; 注意它和零长度匹配是不同的。

可选的第二个参数 *pos* 给出了字符串中开始搜索的位置索引; 默认为 0, 它不完全等价于字符串切片; '^' 样式字符匹配字符串真正的开头, 和换行符后面的第一个字符, 但不会匹配索引规定开始的位置。

可选参数 *endpos* 限定了字符串搜索的结束; 它假定字符串长度到 *endpos*, 所以只有从 *pos* 到 *endpos* - 1 的字符会被匹配。如果 *endpos* 小于 *pos*, 就不会有匹配产生; 另外, 如果 *rx* 是一个编译后的正则对象, *rx.search*(*string*, 0, 50) 等价于 *rx.search*(*string*[:50], 0)。

```
>>> pattern = re.compile("d")
>>> pattern.search("dog")          # Match at index 0
<_sre.SRE_Match object; span=(0, 1), match='d'>
>>> pattern.search("dog", 1)      # No match; search doesn't include the "d"
```

regex.match (*string* [, *pos* [, *endpos*]])

如果 *string* 的开始位置能够找到这个正则样式的任意个匹配, 就返回一个相应的匹配对象。如果不匹配, 就返回 None; 注意它与零长度匹配是不同的。

The optional *pos* and *endpos* parameters have the same meaning as for the *search()* method.

```
>>> pattern = re.compile("o")
>>> pattern.match("dog")          # No match as "o" is not at the start of "dog".
>>> pattern.match("dog", 1)      # Match as "o" is the 2nd character of "dog".
<_sre.SRE_Match object; span=(1, 2), match='o'>
```

If you want to locate a match anywhere in *string*, use *search()* instead (see also *search()* vs. *match()*).

regex.fullmatch (*string* [, *pos* [, *endpos*]])

如果整个 *string* 匹配这个正则表达式, 就返回一个相应的匹配对象。否则就返回 None; 注意跟零长度匹配是不同的。

The optional *pos* and *endpos* parameters have the same meaning as for the *search()* method.

```
>>> pattern = re.compile("o[gh]")
>>> pattern.fullmatch("dog")      # No match as "o" is not at the start of "dog".
>>> pattern.fullmatch("ogre")     # No match as not the full string matches.
>>> pattern.fullmatch("doggie", 1, 3) # Matches within given limits.
<_sre.SRE_Match object; span=(1, 3), match='og'>
```

3.4 新版功能.

regex.split (*string*, *maxsplit*=0)

等价于 *split()* 函数, 使用了编译后的样式。

`regex.findall(string[, pos[, endpos]])`

类似函数 `findall()`，使用了编译后样式，但也可以接收可选参数 `pos` 和 `endpos`，限制搜索范围，就像 `search()`。

`regex.finditer(string[, pos[, endpos]])`

类似函数 `finditer()`，使用了编译后样式，但也可以接收可选参数 `pos` 和 `endpos`，限制搜索范围，就像 `search()`。

`regex.sub(repl, string, count=0)`

等价于 `sub()` 函数，使用了编译后的样式。

`regex.subn(repl, string, count=0)`

等价于 `subn()` 函数，使用了编译后的样式。

`regex.flags`

正则匹配标记。这是可以传递给 `compile()` 的参数，任何 (? ...) 内联标记，隐性标记比如 UNICODE 的结合。

`regex.groups`

捕获组合的数量。

`regex.groupindex`

映射由 (? P < id >) 定义的命名符号组合和数字组合的字典。如果没有符号组，那字典就是空的。

`regex.pattern`

The pattern string from which the RE object was compiled.

6.2.4 匹配对象

Match objects always have a boolean value of True. Since `match()` and `search()` return None when there is no match, you can test whether there was a match with a simple if statement:

```
match = re.search(pattern, string)
if match:
    process(match)
```

匹配对象支持以下方法和属性：

`match.expand(template)`

Return the string obtained by doing backslash substitution on the template string `template`, as done by the `sub()` method. Escapes such as `\n` are converted to the appropriate characters, and numeric backreferences (`\1`, `\2`) and named backreferences (`\g<1>`, `\g<name>`) are replaced by the contents of the corresponding group.

在 3.5 版更改：不匹配的组合替换为空字符串。

`match.group([group1, ...])`

返回一个或者多个匹配的子组。如果只有一个参数，结果就是一个字符串，如果有多个参数，结果就是一个元组（每个参数对应一个项），如果没有参数，组 1 默认到 0（整个匹配都被返回）。如果一个组 N 参数值为 0，相应的返回值就是整个匹配字符串；如果它是一个范围 [1..99]，结果就是相应的括号组字符串。如果一个组号是负数，或者大于样式中定义的组数，一个 `IndexError` 索引错误就 raise。如果一个组包含在样式的一部分，并被匹配多次，就返回最后一个匹配。：

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m.group(0)           # The entire match
'Isaac Newton'
>>> m.group(1)           # The first parenthesized subgroup.
'Isaac'
>>> m.group(2)           # The second parenthesized subgroup.
```

(下页继续)

(续上页)

```
'Newton'
>>> m.group(1, 2)    # Multiple arguments give us a tuple.
('Isaac', 'Newton')
```

如果正则表达式使用了 `(?P<name>...)` 语法, `groupN` 参数就也可能是命名组合的名字。如果一个字符串参数在样式中未定义为组合名, 一个 `IndexError` 就 `raise`。

一个相对复杂的例子

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.group('first_name')
'Malcolm'
>>> m.group('last_name')
'Reynolds'
```

命名组合同样可以通过索引值引用

```
>>> m.group(1)
'Malcolm'
>>> m.group(2)
'Reynolds'
```

如果一个组匹配成功多次, 就只返回最后一个匹配

```
>>> m = re.match(r"(..)+", "a1b2c3")    # Matches 3 times.
>>> m.group(1)                          # Returns only the last match.
'c3'
```

`match.__getitem__(g)`

这个等价于 `m.group(g)`。这允许更方便的引用一个匹配

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m[0]    # The entire match
'Isaac Newton'
>>> m[1]    # The first parenthesized subgroup.
'Isaac'
>>> m[2]    # The second parenthesized subgroup.
'Newton'
```

3.6 新版功能.

`match.groups(default=None)`

返回一个元组, 包含所有匹配的子组, 在样式中出现的从 1 到任意多的组合。`default` 参数用于不参与匹配的情况, 默认为 `None`。

例如

```
>>> m = re.match(r"(\d+)\.(\d+)", "24.1632")
>>> m.groups()
('24', '1632')
```

如果我们使小数点可选, 那么不是所有的组都会参与到匹配当中。这些组合默认会返回一个 `None`, 除非指定了 `default` 参数。

```
>>> m = re.match(r"(\d+)\.?(\\d+)?", "24")
>>> m.groups()    # Second group defaults to None.
('24', None)
```

(下页继续)

(续上页)

```
>>> m.groups('0')    # Now, the second group defaults to '0'.
('24', '0')
```

match.groupdict (*default=None*)

返回一个字典，包含了所有的命名子组。**key** 就是组名。*default* 参数用于不参与匹配的组合；默认为 *None*。例如

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.groupdict()
{'first_name': 'Malcolm', 'last_name': 'Reynolds'}
```

match.start (*[group]*)

match.end (*[group]*)

返回 *group* 匹配到的字串的开始和结束标号。*group* 默认为 0（意思是整个匹配的子串）。如果 *group* 存在，但未产生匹配，就返回 -1。对于一个匹配对象 *m*，和一个未参与匹配的组 *g*，组 *g*（等价于 *m.group(g)*）产生的匹配是

```
m.string[m.start(g):m.end(g)]
```

注意 *m.start(group)* 将会等于 *m.end(group)*，如果 *group* 匹配一个空字符串的话。比如，在 *m = re.search('b(c?)', 'cba')* 之后，*m.start(0)* 为 1，*m.end(0)* 为 2，*m.start(1)* 和 *m.end(1)* 都是 2，*m.start(2)* raise 一个 *IndexError* 例外。

这个例子会从 email 地址中移除掉 *remove_this*

```
>>> email = "tony@tiremove_thisger.net"
>>> m = re.search("remove_this", email)
>>> email[:m.start()] + email[m.end():]
'tony@tiger.net'
```

match.span (*[group]*)

对于一个匹配 *m*，返回一个二元组 (*m.start(group)*, *m.end(group)*)。注意如果 *group* 没有在这个匹配中，就返回 (-1, -1)。*group* 默认为 0，就是整个匹配。

match.pos

The value of *pos* which was passed to the *search()* or *match()* method of a *regex object*. This is the index into the string at which the RE engine started looking for a match.

match.endpos

The value of *endpos* which was passed to the *search()* or *match()* method of a *regex object*. This is the index into the string beyond which the RE engine will not go.

match.lastindex

捕获组的最后一个匹配的整数索引值，或者 *None* 如果没有匹配产生的话。比如，对于字符串 'ab'，表达式 (a)b, ((a)(b)), 和 ((ab)) 将得到 *lastindex == 1*，而 (a)(b) 会得到 *lastindex == 2*。

match.lastgroup

最后一个匹配的命名组名字，或者 *None* 如果没有产生匹配的话。

match.re

The *regular expression object* whose *match()* or *search()* method produced this match instance.

match.string

The string passed to *match()* or *search()*.

6.2.5 正则表达式例子

检查对子

在这个例子里，我们使用以下辅助函数来更好的显示匹配对象：

```
def displaymatch(match):
    if match is None:
        return None
    return '<Match: %r, groups=%r>' % (match.group(), match.groups())
```

假设你在写一个扑克程序，一个玩家的一手牌为五个字符的串，每个字符表示一张牌，”a”就是A，“k”K，“q”Q，“j”J，“t”为10，“2”到“9”表示2到9。

要看给定的字符串是否有效，我们可以按照以下步骤

```
>>> valid = re.compile(r"^[a2-9tjqk]{5}$")
>>> displaymatch(valid.match("akt5q")) # Valid.
"<Match: 'akt5q', groups=()>"
>>> displaymatch(valid.match("akt5e")) # Invalid.
>>> displaymatch(valid.match("akt")) # Invalid.
>>> displaymatch(valid.match("727ak")) # Valid.
"<Match: '727ak', groups=()>"
```

最后一手牌，“727ak”，包含了一个对子，或者两张同样数值的牌。要用正则表达式匹配它，应该使用向后引用如下

```
>>> pair = re.compile(r".*(.)\1")
>>> displaymatch(pair.match("717ak")) # Pair of 7s.
"<Match: '717', groups=('7',)>"
>>> displaymatch(pair.match("718ak")) # No pairs.
>>> displaymatch(pair.match("354aa")) # Pair of aces.
"<Match: '354aa', groups=('a',)>"
```

To find out what card the pair consists of, one could use the `group()` method of the match object in the following manner:

```
>>> pair.match("717ak").group(1)
'7'

# Error because re.match() returns None, which doesn't have a group() method:
>>> pair.match("718ak").group(1)
Traceback (most recent call last):
  File "<pyshell#23>", line 1, in <module>
    re.match(r".*(.)\1", "718ak").group(1)
AttributeError: 'NoneType' object has no attribute 'group'

>>> pair.match("354aa").group(1)
'a'
```

模拟 scanf()

Python 目前没有一个类似 c 函数 `scanf()` 的替代品。正则表达式通常比 `scanf()` 格式字符串要更强大一些，但也带来更多复杂性。下面的表格提供了 `scanf()` 格式符和正则表达式大致相同的映射。

scanf() 格式符	正则表达式
%c	.
%5c	{5}
%d	[+]? \d+
%e, %E, %f, %g	[+]? (\d+ (\.\d*)? \.\d+) ([eE] [+]? \d+)?
%i	[+]? (0[xX] [\dA-Fa-f]+ 0[0-7]* \d+)
%o	[+]? [0-7]+
%s	\S+
%u	\d+
%x, %X	[+]? (0[xX])? [\dA-Fa-f]+

从文件名和数字提取字符串

```
/usr/sbin/sendmail - 0 errors, 4 warnings
```

你可以使用 `scanf()` 格式化

```
%s - %d errors, %d warnings
```

等价的正则表达式是：

```
(\S+) - (\d+) errors, (\d+) warnings
```

search() vs. match()

Python 提供了两种不同的操作：基于 `re.match()` 检查字符串开头，或者 `re.search()` 检查字符串的任意位置（默认 Perl 中的行为）。

例如

```
>>> re.match("c", "abcdef")      # No match
>>> re.search("c", "abcdef")     # Match
<_sre.SRE_Match object; span=(2, 3), match='c'>
```

在 `search()` 中，可以用 `'^'` 作为开始来限制匹配到字符串的首位

```
>>> re.match("c", "abcdef")      # No match
>>> re.search("^c", "abcdef")    # No match
>>> re.search("^a", "abcdef")    # Match
<_sre.SRE_Match object; span=(0, 1), match='a'>
```

注意 `MULTILINE` 多行模式中函数 `match()` 只匹配字符串的开始，但使用 `search()` 和以 `'^'` 开始的正则表达式会匹配每行的开始

```
>>> re.match('X', 'A\nB\nX', re.MULTILINE) # No match
>>> re.search('^X', 'A\nB\nX', re.MULTILINE) # Match
<_sre.SRE_Match object; span=(4, 5), match='X'>
```

建立一个电话本

`split()` 将字符串用参数传递的样式分隔开。这个方法对于转换文本数据到易读而且容易修改的数据结构，是很有用的，如下面的例子证明。

首先，这里是输入。通常是一个文件，这里我们用三引号字符串语法

```
>>> text = """Ross McFluff: 834.345.1254 155 Elm Street
...
... Ronald Heathmore: 892.345.3428 436 Finley Avenue
... Frank Burger: 925.541.7625 662 South Dogwood Way
...
...
... Heather Albrecht: 548.326.4584 919 Park Place"""
```

条目用一个或者多个换行符分开。现在我们将字符串转换为一个列表，每个非空行都有一个条目：

```
>>> entries = re.split("\n+", text)
>>> entries
['Ross McFluff: 834.345.1254 155 Elm Street',
 'Ronald Heathmore: 892.345.3428 436 Finley Avenue',
 'Frank Burger: 925.541.7625 662 South Dogwood Way',
 'Heather Albrecht: 548.326.4584 919 Park Place']
```

最终，将每个条目分割为一个由名字、姓氏、电话号码和地址组成的列表。我们为`split()`使用了`maxsplit`形参，因为地址中包含有被我们作为分割模式的空格符：

```
>>> [re.split("?: ", entry, 3) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155 Elm Street'],
 ['Ronald', 'Heathmore', '892.345.3428', '436 Finley Avenue'],
 ['Frank', 'Burger', '925.541.7625', '662 South Dogwood Way'],
 ['Heather', 'Albrecht', '548.326.4584', '919 Park Place']]
```

`?:` 样式匹配姓后面的冒号，因此它不出现在结果列表中。如果`maxsplit` 设置为 4，我们还可以从地址中获取到房间号：

```
>>> [re.split("?: ", entry, 4) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155', 'Elm Street'],
 ['Ronald', 'Heathmore', '892.345.3428', '436', 'Finley Avenue'],
 ['Frank', 'Burger', '925.541.7625', '662', 'South Dogwood Way'],
 ['Heather', 'Albrecht', '548.326.4584', '919', 'Park Place']]
```

文字整理

`sub()` 替换字符串中出现的样式的每一个实例。这个例子证明了使用`sub()` 来整理文字，或者随机化每个字符的位置，除了首位和末尾字符

```
>>> def repl(m):
...     inner_word = list(m.group(2))
...     random.shuffle(inner_word)
...     return m.group(1) + "".join(inner_word) + m.group(3)
>>> text = "Professor Abdolmalek, please report your absences promptly."
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Poefsrorsr Aealmlbdk, pslae reorpt your abnseces plmrptoy.'
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Pofsroser Aodlambelk, plasee reorpt yuor asnebces potlmpy.'
```

找到所有副词

`findall()` 匹配样式 所有的出现，不仅是像`search()` 中的第一个匹配。比如，如果一个作者希望找到文字中的所有副词，他可能会按照以下方法用`findall()`

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> re.findall(r"\w+ly", text)
['carefully', 'quickly']
```

找到所有副词和位置

如果需要匹配样式的更多信息，`finditer()` 可以起到作用，它提供了匹配对象 作为返回值，而不是字符串。继续上面的例子，如果一个作者希望找到所有副词和它的位置，可以按照下面方法使用 `finditer()`

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> for m in re.finditer(r"\w+ly", text):
...     print('%02d-%02d: %s' % (m.start(), m.end(), m.group(0)))
07-16: carefully
40-47: quickly
```

原始字符记法

原始字符串记法 (`r"text"`) 保持正则表达式正常。否则，每个正则式里的反斜杠 (`'\'`) 都必须前缀一个反斜杠来转义。比如，下面两行代码功能就是完全一致的

```
>>> re.match(r"\W(.)\1\W", " ff ")
<_sre.SRE_Match object; span=(0, 4), match=' ff '>
>>> re.match("\\W(.)\\1\\W", " ff ")
<_sre.SRE_Match object; span=(0, 4), match=' ff '>
```

当需要匹配一个字符反斜杠，它必须在正则表达式中转义。在原始字符串记法，就是 `r"\\"`。否则就必须用 `"\\\\"`，来表示同样的意思

```
>>> re.match(r"\\\", r"\\")
<_sre.SRE_Match object; span=(0, 1), match='\\'>
>>> re.match("\\\\", r"\\")
<_sre.SRE_Match object; span=(0, 1), match='\\'>
```

写一个词法分析器

一个 词法器或词法分析器 分析字符串，并分类成目录组。这是写一个编译器或解释器的第一步。

文字目录是由正则表达式指定的。这个技术是通过将这些样式合并为一个主正则式，并且循环匹配来实现的

```
import collections
import re

Token = collections.namedtuple('Token', ['type', 'value', 'line', 'column'])

def tokenize(code):
    keywords = {'IF', 'THEN', 'ENDIF', 'FOR', 'NEXT', 'GOSUB', 'RETURN'}
    token_specification = [
        ('NUMBER',    r'\d+(\.\d*)?'), # Integer or decimal number
        ('ASSIGN',    r':='),          # Assignment operator
        ('END',       r';'),            # Statement terminator
        ('ID',        r'[A-Za-z]+'),   # Identifiers
        ('OP',        r'[+ \-*/]'),    # Arithmetic operators
```

(下页继续)

(续上页)

```

        ('NEWLINE', r'\n'),          # Line endings
        ('SKIP', r'[ \t]+'),        # Skip over spaces and tabs
        ('MISMATCH', r'.'),         # Any other character
    ]
    tok_regex = '|'.join('(?P<%s>%s)' % pair for pair in token_specification)
    line_num = 1
    line_start = 0
    for mo in re.finditer(tok_regex, code):
        kind = mo.lastgroup
        value = mo.group()
        column = mo.start() - line_start
        if kind == 'NUMBER':
            value = float(value) if '.' in value else int(value)
        elif kind == 'ID' and value in keywords:
            kind = value
        elif kind == 'NEWLINE':
            line_start = mo.end()
            line_num += 1
            continue
        elif kind == 'SKIP':
            continue
        elif kind == 'MISMATCH':
            raise RuntimeError(f'{value!r} unexpected on line {line_num}')
        yield Token(kind, value, line_num, column)

statements = '''
    IF quantity THEN
        total := total + price * quantity;
        tax := price * 0.05;
    ENDIF;
'''

for token in tokenize(statements):
    print(token)

```

这个词法器产生以下输出

```

Token(type='IF', value='IF', line=2, column=4)
Token(type='ID', value='quantity', line=2, column=7)
Token(type='THEN', value='THEN', line=2, column=16)
Token(type='ID', value='total', line=3, column=8)
Token(type='ASSIGN', value=':=', line=3, column=14)
Token(type='ID', value='total', line=3, column=17)
Token(type='OP', value='+', line=3, column=23)
Token(type='ID', value='price', line=3, column=25)
Token(type='OP', value='*', line=3, column=31)
Token(type='ID', value='quantity', line=3, column=33)
Token(type='END', value=';', line=3, column=41)
Token(type='ID', value='tax', line=4, column=8)
Token(type='ASSIGN', value=':=', line=4, column=12)
Token(type='ID', value='price', line=4, column=15)
Token(type='OP', value='*', line=4, column=21)
Token(type='NUMBER', value=0.05, line=4, column=23)
Token(type='END', value=';', line=4, column=27)
Token(type='ENDIF', value='ENDIF', line=5, column=4)
Token(type='END', value=';', line=5, column=9)

```

6.3 difflib — 计算差异的辅助工具

源代码: [Lib/difflib.py](#)

此模块提供用于比较序列的类和函数。例如，它可以用于比较文件，并可以产生各种格式的不同信息，包括 HTML 和上下文以及统一格式的差异点。有关目录和文件的比较，请参见 [filecmp](#) 模块。

`class difflib.SequenceMatcher`

This is a flexible class for comparing pairs of sequences of any type, so long as the sequence elements are *hashable*. The basic algorithm predates, and is a little fancier than, an algorithm published in the late 1980' s by Ratcliff and Obershelp under the hyperbolic name “gestalt pattern matching.” The idea is to find the longest contiguous matching subsequence that contains no “junk” elements; these “junk” elements are ones that are uninteresting in some sense, such as blank lines or whitespace. (Handling junk is an extension to the Ratcliff and Obershelp algorithm.) The same idea is then applied recursively to the pieces of the sequences to the left and to the right of the matching subsequence. This does not yield minimal edit sequences, but does tend to yield matches that “look right” to people.

Timing: The basic Ratcliff-Obershelp algorithm is cubic time in the worst case and quadratic time in the expected case. *SequenceMatcher* is quadratic time for the worst case and has expected-case behavior dependent in a complicated way on how many elements the sequences have in common; best case time is linear.

Automatic junk heuristic: *SequenceMatcher* supports a heuristic that automatically treats certain sequence items as junk. The heuristic counts how many times each individual item appears in the sequence. If an item' s duplicates (after the first one) account for more than 1% of the sequence and the sequence is at least 200 items long, this item is marked as “popular” and is treated as junk for the purpose of sequence matching. This heuristic can be turned off by setting the `autojunk` argument to `False` when creating the *SequenceMatcher*.

3.2 新版功能: The *autojunk* parameter.

`class difflib.Differ`

This is a class for comparing sequences of lines of text, and producing human-readable differences or deltas. Differ uses *SequenceMatcher* both to compare sequences of lines, and to compare sequences of characters within similar (near-matching) lines.

Each line of a *Differ* delta begins with a two-letter code:

状态码	意义
' - '	line unique to sequence 1
' + '	line unique to sequence 2
' '	line common to both sequences
' ? '	line not present in either input sequence

Lines beginning with ‘?’ attempt to guide the eye to intraline differences, and were not present in either input sequence. These lines can be confusing if the sequences contain tab characters.

`class difflib.HtmlDiff`

This class can be used to create an HTML table (or a complete HTML file containing the table) showing a side by side, line by line comparison of text with inter-line and intra-line change highlights. The table can be generated in either full or contextual difference mode.

这个类的构造函数:

`__init__` (*tabsize*=8, *wrapcolumn*=None, *linejunk*=None, *charjunk*=IS_CHARACTER_JUNK)

初始化 *HtmlDiff* 的实例。

tabsize is an optional keyword argument to specify tab stop spacing and defaults to 8.

wrapcolumn is an optional keyword to specify column number where lines are broken and wrapped, defaults to `None` where lines are not wrapped.

linejunk and *charjunk* are optional keyword arguments passed into `ndiff()` (used by `HtmlDiff` to generate the side by side HTML differences). See `ndiff()` documentation for argument default values and descriptions.

下列是公开的方法

make_file (*fromlines*, *tolines*, *fromdesc*="", *todesc*="", *context*=False, *numlines*=5, *, *charset*='utf-8')

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML file containing a table showing line by line differences with inter-line and intra-line changes highlighted.

fromdesc and *todesc* are optional keyword arguments to specify from/to file column header strings (both default to an empty string).

context and *numlines* are both optional keyword arguments. Set *context* to `True` when contextual differences are to be shown, else the default is `False` to show the full files. *numlines* defaults to 5. When *context* is `True` *numlines* controls the number of context lines which surround the difference highlights. When *context* is `False` *numlines* controls the number of lines which are shown before a difference highlight when using the “next” hyperlinks (setting to zero would cause the “next” hyperlinks to place the next difference highlight at the top of the browser without any leading context).

在 3.5 版更改: *charset* keyword-only argument was added. The default charset of HTML document changed from 'ISO-8859-1' to 'utf-8'.

make_table (*fromlines*, *tolines*, *fromdesc*="", *todesc*="", *context*=False, *numlines*=5)

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML table showing line by line differences with inter-line and intra-line changes highlighted.

The arguments for this method are the same as those for the `make_file()` method.

`Tools/scripts/diff.py` is a command-line front-end to this class and contains a good example of its use.

`difflib.context_diff(a, b, fromfile="", tofile="", fromfiledate="", tofiledate="", n=3, lineterm='\n')`

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in context diff format.

Context diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in a before/after style. The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with `***` or `---`) are created with a trailing newline. This is helpful so that inputs created from `io.IOBase.readlines()` result in diffs that are suitable for use with `io.IOBase.writelines()` since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to `" "` so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(context_diff(s1, s2, fromfile='before.py', tofile=
↪ 'after.py'))
*** before.py
--- after.py
*****
*** 1,4 ****
! bacon
! eggs
```

(下页继续)

(续上页)

```
! ham
  guido
--- 1,4 ----
! python
! eggy
! hamster
  guido
```

See [A command-line interface to difflib](#) for a more detailed example.

`difflib.get_close_matches(word, possibilities, n=3, cutoff=0.6)`

Return a list of the best “good enough” matches. *word* is a sequence for which close matches are desired (typically a string), and *possibilities* is a list of sequences against which to match *word* (typically a list of strings).

Optional argument *n* (default 3) is the maximum number of close matches to return; *n* must be greater than 0.

Optional argument *cutoff* (default 0.6) is a float in the range [0, 1]. Possibilities that don’t score at least that similar to *word* are ignored.

The best (no more than *n*) matches among the possibilities are returned in a list, sorted by similarity score, most similar first.

```
>>> get_close_matches('appel', ['ape', 'apple', 'peach', 'puppy'])
['apple', 'ape']
>>> import keyword
>>> get_close_matches('wheel', keyword.kwlist)
['while']
>>> get_close_matches('pineapple', keyword.kwlist)
[]
>>> get_close_matches('accept', keyword.kwlist)
['except']
```

`difflib.ndiff(a, b, linejunk=None, charjunk=IS_CHARACTER_JUNK)`

Compare *a* and *b* (lists of strings); return a *Differ*-style delta (a *generator* generating the delta lines).

Optional keyword parameters *linejunk* and *charjunk* are filtering functions (or None):

linejunk: A function that accepts a single string argument, and returns true if the string is junk, or false if not. The default is None. There is also a module-level function `IS_LINE_JUNK()`, which filters out lines without visible characters, except for at most one pound character ('#') – however the underlying *SequenceMatcher* class does a dynamic analysis of which lines are so frequent as to constitute noise, and this usually works better than using this function.

charjunk: A function that accepts a character (a string of length 1), and returns if the character is junk, or false if not. The default is module-level function `IS_CHARACTER_JUNK()`, which filters out whitespace characters (a blank or tab; it’s a bad idea to include newline in this!).

`Tools/scripts/ndiff.py` is a command-line front-end to this function.

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keepends=True),
...              'ore\ntree\nemu\n'.splitlines(keepends=True))
>>> print(''.join(diff), end="")
- one
?  ^
+ ore
?  ^
- two
- three
```

(下页继续)

(续上页)

```
? -
+ tree
+ emu
```

`difflib.restore(sequence, which)`

Return one of the two sequences that generated a delta.

Given a *sequence* produced by `Differ.compare()` or `ndiff()`, extract lines originating from file 1 or 2 (parameter *which*), stripping off line prefixes.

示例:

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keepends=True),
...              'ore\ntree\nemu\n'.splitlines(keepends=True))
>>> diff = list(diff) # materialize the generated delta into a list
>>> print(''.join	restore(diff, 1)), end="")
one
two
three
>>> print(''.join	restore(diff, 2)), end="")
ore
tree
emu
```

`difflib.unified_diff(a, b, fromfile=" ", tofile=" ", fromfiledate=" ", tofiledate=" ", n=3, lineterm='\n')`

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in unified diff format.

Unified diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in an inline style (instead of separate before/after blocks). The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with `---`, `+++`, or `@@`) are created with a trailing newline. This is helpful so that inputs created from `io.IOBase.readlines()` result in diffs that are suitable for use with `io.IOBase.writelines()` since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to `" "` so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(unified_diff(s1, s2, fromfile='before.py', tofile=
↪ 'after.py'))
--- before.py
+++ after.py
@@ -1,4 +1,4 @@
-bacon
-eggs
-ham
+python
+eggy
+hamster
 guido
```

See [A command-line interface to diff](#) for a more detailed example.

`difflib.diff_bytes(dfunc, a, b, fromfile=b'', tofile=b'', fromfiledate=b'', tofiledate=b'', n=3, lineterm=b'\n')`

Compare *a* and *b* (lists of bytes objects) using *dfunc*; yield a sequence of delta lines (also bytes) in the format returned by *dfunc*. *dfunc* must be a callable, typically either `unified_diff()` or `context_diff()`.

Allows you to compare data with unknown or inconsistent encoding. All inputs except *n* must be bytes objects, not str. Works by losslessly converting all inputs (except *n*) to str, and calling `dfunc(a, b, fromfile, tofile, fromfiledate, tofiledate, n, lineterm)`. The output of *dfunc* is then converted back to bytes, so the delta lines that you receive have the same unknown/inconsistent encodings as *a* and *b*.

3.5 新版功能.

`difflib.IS_LINE_JUNK(line)`

Return true for ignorable lines. The line *line* is ignorable if *line* is blank or contains a single '#', otherwise it is not ignorable. Used as a default for parameter *linejunk* in `ndiff()` in older versions.

`difflib.IS_CHARACTER_JUNK(ch)`

Return true for ignorable characters. The character *ch* is ignorable if *ch* is a space or tab, otherwise it is not ignorable. Used as a default for parameter *charjunk* in `ndiff()`.

参见:

Pattern Matching: The Gestalt Approach Discussion of a similar algorithm by John W. Ratcliff and D. E. Metzener. This was published in *Dr. Dobbs' s Journal* in July, 1988.

6.3.1 SequenceMatcher Objects

The `SequenceMatcher` class has this constructor:

class `difflib.SequenceMatcher(isjunk=None, a="", b="", autojunk=True)`

Optional argument *isjunk* must be `None` (the default) or a one-argument function that takes a sequence element and returns true if and only if the element is “junk” and should be ignored. Passing `None` for *isjunk* is equivalent to passing `lambda x: 0`; in other words, no elements are ignored. For example, pass:

```
lambda x: x in " \t"
```

if you're comparing lines as sequences of characters, and don't want to synch up on blanks or hard tabs.

The optional arguments *a* and *b* are sequences to be compared; both default to empty strings. The elements of both sequences must be *hashable*.

The optional argument *autojunk* can be used to disable the automatic junk heuristic.

3.2 新版功能: The *autojunk* parameter.

`SequenceMatcher` objects get three data attributes: *bjunk* is the set of elements of *b* for which *isjunk* is `True`; *bpopular* is the set of non-junk elements considered popular by the heuristic (if it is not disabled); *b2j* is a dict mapping the remaining elements of *b* to a list of positions where they occur. All three are reset whenever *b* is reset with `set_seqs()` or `set_seq2()`.

3.2 新版功能: The *bjunk* and *bpopular* attributes.

`SequenceMatcher` objects have the following methods:

set_seqs(a, b)

Set the two sequences to be compared.

`SequenceMatcher` computes and caches detailed information about the second sequence, so if you want to compare one sequence against many sequences, use `set_seq2()` to set the commonly used sequence once and call `set_seq1()` repeatedly, once for each of the other sequences.

set_seq1 (*a*)

Set the first sequence to be compared. The second sequence to be compared is not changed.

set_seq2 (*b*)

Set the second sequence to be compared. The first sequence to be compared is not changed.

find_longest_match (*alo, ahi, blo, bhi*)

Find longest matching block in *a*[*alo*:*ahi*] and *b*[*blo*:*bhi*].

If *isjunk* was omitted or *None*, *find_longest_match()* returns (*i*, *j*, *k*) such that *a*[*i*:*i*+*k*] is equal to *b*[*j*:*j*+*k*], where *alo* ≤ *i* ≤ *i*+*k* ≤ *ahi* and *blo* ≤ *j* ≤ *j*+*k* ≤ *bhi*. For all (*i'*, *j'*, *k'*) meeting those conditions, the additional conditions *k* ≥ *k'*, *i* ≤ *i'*, and if *i* == *i'*, *j* ≤ *j'* are also met. In other words, of all maximal matching blocks, return one that starts earliest in *a*, and of all those maximal matching blocks that start earliest in *a*, return the one that starts earliest in *b*.

```
>>> s = SequenceMatcher(None, " abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=0, b=4, size=5)
```

If *isjunk* was provided, first the longest matching block is determined as above, but with the additional restriction that no junk element appears in the block. Then that block is extended as far as possible by matching (only) junk elements on both sides. So the resulting block never matches on junk except as identical junk happens to be adjacent to an interesting match.

Here's the same example as before, but considering blanks to be junk. That prevents ' abcd' from matching the ' abcd' at the tail end of the second sequence directly. Instead only the 'abcd' can match, and matches the leftmost 'abcd' in the second sequence:

```
>>> s = SequenceMatcher(lambda x: x==" ", " abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=1, b=0, size=4)
```

If no blocks match, this returns (*alo*, *blo*, 0).

This method returns a *named tuple* *Match*(*a*, *b*, *size*).

get_matching_blocks ()

Return list of triples describing non-overlapping matching subsequences. Each triple is of the form (*i*, *j*, *n*), and means that *a*[*i*:*i*+*n*] == *b*[*j*:*j*+*n*]. The triples are monotonically increasing in *i* and *j*.

The last triple is a dummy, and has the value (*len*(*a*), *len*(*b*), 0). It is the only triple with *n* == 0. If (*i*, *j*, *n*) and (*i'*, *j'*, *n'*) are adjacent triples in the list, and the second is not the last triple in the list, then *i*+*n* < *i'* or *j*+*n* < *j'*; in other words, adjacent triples always describe non-adjacent equal blocks.

```
>>> s = SequenceMatcher(None, "abxcd", "abcd")
>>> s.get_matching_blocks()
[Match(a=0, b=0, size=2), Match(a=3, b=2, size=2), Match(a=5, b=4, size=0)]
```

get_opcodes ()

Return list of 5-tuples describing how to turn *a* into *b*. Each tuple is of the form (*tag*, *i1*, *i2*, *j1*, *j2*). The first tuple has *i1* == *j1* == 0, and remaining tuples have *i1* equal to the *i2* from the preceding tuple, and, likewise, *j1* equal to the previous *j2*.

The *tag* values are strings, with these meanings:

值	意义
'replace'	<code>a[i1:i2]</code> should be replaced by <code>b[j1:j2]</code> .
'delete'	<code>a[i1:i2]</code> should be deleted. Note that <code>j1 == j2</code> in this case.
'insert'	<code>b[j1:j2]</code> should be inserted at <code>a[i1:i1]</code> . Note that <code>i1 == i2</code> in this case.
'equal'	<code>a[i1:i2] == b[j1:j2]</code> (the sub-sequences are equal).

例如:

```
>>> a = "qabxcd"
>>> b = "abycdf"
>>> s = SequenceMatcher(None, a, b)
>>> for tag, i1, i2, j1, j2 in s.get_opcodes():
...     print('{:7}   a[{}:{}] --> b[{}:{}] {!r:>8} --> {!r}'.format(
...         tag, i1, i2, j1, j2, a[i1:i2], b[j1:j2]))
delete    a[0:1] --> b[0:0]      'q' --> ''
equal     a[1:3] --> b[0:2]      'ab' --> 'ab'
replace   a[3:4] --> b[2:3]      'x' --> 'y'
equal     a[4:6] --> b[3:5]      'cd' --> 'cd'
insert    a[6:6] --> b[5:6]      '' --> 'f'
```

get_grouped_opcodes (n=3)

Return a *generator* of groups with up to *n* lines of context.

Starting with the groups returned by `get_opcodes()`, this method splits out smaller change clusters and eliminates intervening ranges which have no changes.

The groups are returned in the same format as `get_opcodes()`.

ratio ()

Return a measure of the sequences' similarity as a float in the range [0, 1].

Where T is the total number of elements in both sequences, and M is the number of matches, this is $2.0 * M / T$. Note that this is 1.0 if the sequences are identical, and 0.0 if they have nothing in common.

This is expensive to compute if `get_matching_blocks()` or `get_opcodes()` hasn't already been called, in which case you may want to try `quick_ratio()` or `real_quick_ratio()` first to get an upper bound.

quick_ratio ()

Return an upper bound on `ratio()` relatively quickly.

real_quick_ratio ()

Return an upper bound on `ratio()` very quickly.

The three methods that return the ratio of matching to total characters can give different results due to differing levels of approximation, although `quick_ratio()` and `real_quick_ratio()` are always at least as large as `ratio()`:

```
>>> s = SequenceMatcher(None, "abcd", "bcde")
>>> s.ratio()
0.75
>>> s.quick_ratio()
0.75
>>> s.real_quick_ratio()
1.0
```

6.3.2 序列匹配的示例

This example compares two strings, considering blanks to be “junk” :

```
>>> s = SequenceMatcher(lambda x: x == " ",
...                       "private Thread currentThread;",
...                       "private volatile Thread currentThread;")
```

`ratio()` returns a float in $[0, 1]$, measuring the similarity of the sequences. As a rule of thumb, a `ratio()` value over 0.6 means the sequences are close matches:

```
>>> print(round(s.ratio(), 3))
0.866
```

If you're only interested in where the sequences match, `get_matching_blocks()` is handy:

```
>>> for block in s.get_matching_blocks():
...     print("a[%d] and b[%d] match for %d elements" % block)
a[0] and b[0] match for 8 elements
a[8] and b[17] match for 21 elements
a[29] and b[38] match for 0 elements
```

Note that the last tuple returned by `get_matching_blocks()` is always a dummy, `(len(a), len(b), 0)`, and this is the only case in which the last tuple element (number of elements matched) is 0.

If you want to know how to change the first sequence into the second, use `get_opcodes()`:

```
>>> for opcode in s.get_opcodes():
...     print("%6s a[%d:%d] b[%d:%d]" % opcode)
equal a[0:8] b[0:8]
insert a[8:8] b[8:17]
equal a[8:29] b[17:38]
```

参见:

- The `get_close_matches()` function in this module which shows how simple code building on `SequenceMatcher` can be used to do useful work.
- [Simple version control recipe](#) for a small application built with `SequenceMatcher`.

6.3.3 Differ Objects

Note that `Differ`-generated deltas make no claim to be **minimal** diffs. To the contrary, minimal diffs are often counter-intuitive, because they synch up anywhere possible, sometimes accidental matches 100 pages apart. Restricting synch points to contiguous matches preserves some notion of locality, at the occasional cost of producing a longer diff.

The `Differ` class has this constructor:

```
class difflib.Differ (linejunk=None, charjunk=None)
```

Optional keyword parameters `linejunk` and `charjunk` are for filter functions (or `None`):

linejunk: A function that accepts a single string argument, and returns true if the string is junk. The default is `None`, meaning that no line is considered junk.

charjunk: A function that accepts a single character argument (a string of length 1), and returns true if the character is junk. The default is `None`, meaning that no character is considered junk.

These junk-filtering functions speed up matching to find differences and do not cause any differing lines or characters to be ignored. Read the description of the `find_longest_match()` method's `isjunk` parameter for an explanation.

`Differ` objects are used (deltas generated) via a single method:

compare (*a*, *b*)

Compare two sequences of lines, and generate the delta (a sequence of lines).

Each sequence must contain individual single-line strings ending with newlines. Such sequences can be obtained from the `readlines()` method of file-like objects. The delta generated also consists of newline-terminated strings, ready to be printed as-is via the `writelines()` method of a file-like object.

6.3.4 Differ Example

This example compares two texts. First we set up the texts, sequences of individual single-line strings ending with newlines (such sequences can also be obtained from the `readlines()` method of file-like objects):

```
>>> text1 = ''' 1. Beautiful is better than ugly.
... 2. Explicit is better than implicit.
... 3. Simple is better than complex.
... 4. Complex is better than complicated.
... '''.splitlines(keepends=True)
>>> len(text1)
4
>>> text1[0][-1]
'\n'
>>> text2 = ''' 1. Beautiful is better than ugly.
... 3. Simple is better than complex.
... 4. Complicated is better than complex.
... 5. Flat is better than nested.
... '''.splitlines(keepends=True)
```

Next we instantiate a `Differ` object:

```
>>> d = Differ()
```

Note that when instantiating a `Differ` object we may pass functions to filter out line and character “junk.” See the `Differ()` constructor for details.

Finally, we compare the two:

```
>>> result = list(d.compare(text1, text2))
```

`result` is a list of strings, so let's pretty-print it:

```
>>> from pprint import pprint
>>> pprint(result)
[' 1. Beautiful is better than ugly.\n',
'- 2. Explicit is better than implicit.\n',
'- 3. Simple is better than complex.\n',
'+ 3. Simple is better than complex.\n',
'? ++\n',
'- 4. Complex is better than complicated.\n',
'? ^ ---- ^\n',
'+ 4. Complicated is better than complex.\n',
'? ++++ ^ ^\n',
'+ 5. Flat is better than nested.\n']
```

As a single multi-line string it looks like this:

```
>>> import sys
>>> sys.stdout.writelines(result)
```

(下页继续)

(续上页)

```

1. Beautiful is better than ugly.
- 2. Explicit is better than implicit.
- 3. Simple is better than complex.
+ 3.   Simple is better than complex.
?    ++
- 4. Complex is better than complicated.
?      ^          ---- ^
+ 4. Complicated is better than complex.
?      ++++ ^          ^
+ 5. Flat is better than nested.

```

6.3.5 A command-line interface to difflib

This example shows how to use difflib to create a diff-like utility. It is also contained in the Python source distribution, as Tools/scripts/diff.py.

```

#!/usr/bin/env python3
""" Command line interface to difflib.py providing diffs in four formats:

* ndiff:    lists every line and highlights interline changes.
* context:  highlights clusters of changes in a before/after format.
* unified:  highlights clusters of changes in an inline format.
* html:     generates side by side comparison with change highlights.

"""

import sys, os, difflib, argparse
from datetime import datetime, timezone

def file_mtime(path):
    t = datetime.fromtimestamp(os.stat(path).st_mtime,
                             timezone.utc)
    return t.astimezone().isoformat()

def main():

    parser = argparse.ArgumentParser()
    parser.add_argument('-c', action='store_true', default=False,
                        help='Produce a context format diff (default)')
    parser.add_argument('-u', action='store_true', default=False,
                        help='Produce a unified format diff')
    parser.add_argument('-m', action='store_true', default=False,
                        help='Produce HTML side by side diff '
                             '(can use -c and -l in conjunction)')
    parser.add_argument('-n', action='store_true', default=False,
                        help='Produce a ndiff format diff')
    parser.add_argument('-l', '--lines', type=int, default=3,
                        help='Set number of context lines (default 3)')
    parser.add_argument('fromfile')
    parser.add_argument('tofile')
    options = parser.parse_args()

    n = options.lines
    fromfile = options.fromfile
    tofile = options.tofile

```

(下页继续)

(续上页)

```

fromdate = file_mtime(fromfile)
todate = file_mtime(tofile)
with open(fromfile) as ff:
    fromlines = ff.readlines()
with open(tofile) as tf:
    tolines = tf.readlines()

→context=options.c, numlines=n)
else:
    diff = difflib.context_diff(fromlines, tolines, fromfile, tofile, fromdate,
→todate, n=n)

sys.stdout.writelines(diff)

if __name__ == '__main__':
    main()

```

6.4 textwrap —Text wrapping and filling

Source code: [Lib/textwrap.py](#)

The *textwrap* module provides some convenience functions, as well as *TextWrapper*, the class that does all the work. If you're just wrapping or filling one or two text strings, the convenience functions should be good enough; otherwise, you should use an instance of *TextWrapper* for efficiency.

`textwrap.wrap(text, width=70, **kwargs)`

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. Returns a list of output lines, without final newlines.

Optional keyword arguments correspond to the instance attributes of *TextWrapper*, documented below. *width* defaults to 70.

See the *TextWrapper.wrap()* method for additional details on how *wrap()* behaves.

`textwrap.fill(text, width=70, **kwargs)`

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph. *fill()* is shorthand for

```
"\n".join(wrap(text, ...))
```

In particular, *fill()* accepts exactly the same keyword arguments as *wrap()*.

`textwrap.shorten(text, width, **kwargs)`

Collapse and truncate the given *text* to fit in the given *width*.

First the whitespace in *text* is collapsed (all whitespace is replaced by single spaces). If the result fits in the *width*, it is returned. Otherwise, enough words are dropped from the end so that the remaining words plus the *placeholder* fit within *width*:

```
>>> textwrap.shorten("Hello world!", width=12)
'Hello world!'
>>> textwrap.shorten("Hello world!", width=11)
'Hello [...]'
>>> textwrap.shorten("Hello world", width=10, placeholder="...")
'Hello...'
```

Optional keyword arguments correspond to the instance attributes of *TextWrapper*, documented below. Note that the whitespace is collapsed before the text is passed to the *TextWrapper.fill()* function, so changing the value of *tabsize*, *expand_tabs*, *drop_whitespace*, and *replace_whitespace* will have no effect.

3.4 新版功能.

`textwrap.dedent` (*text*)

Remove any common leading whitespace from every line in *text*.

This can be used to make triple-quoted strings line up with the left edge of the display, while still presenting them in the source code in indented form.

Note that tabs and spaces are both treated as whitespace, but they are not equal: the lines " hello" and "\thello" are considered to have no common leading whitespace.

例如:

```
def test():
    # end first line with \ to avoid the empty line!
    s = '''\
    hello
        world
    '''
    print(repr(s))          # prints '    hello\n        world\n    '
    print(repr(dedent(s)))  # prints 'hello\n    world\n'
```

`textwrap.indent` (*text*, *prefix*, *predicate=None*)

Add *prefix* to the beginning of selected lines in *text*.

Lines are separated by calling `text.splitlines(True)`.

By default, *prefix* is added to all lines that do not consist solely of whitespace (including any line endings).

例如:

```
>>> s = 'hello\n\n \nworld'
>>> indent(s, ' ')
'  hello\n\n \n world'
```

The optional *predicate* argument can be used to control which lines are indented. For example, it is easy to add *prefix* to even empty and whitespace-only lines:

```
>>> print(indent(s, '+ ', lambda line: True))
+ hello
+
+
+ world
```

3.3 新版功能.

`wrap()`, `fill()` and `shorten()` work by creating a `TextWrapper` instance and calling a single method on it. That instance is not reused, so for applications that process many text strings using `wrap()` and/or `fill()`, it may be more efficient to create your own `TextWrapper` object.

Text is preferably wrapped on whitespaces and right after the hyphens in hyphenated words; only then will long words be broken if necessary, unless `TextWrapper.break_long_words` is set to false.

class `textwrap.TextWrapper` (***kwargs*)

The `TextWrapper` constructor accepts a number of optional keyword arguments. Each keyword argument corresponds to an instance attribute, so for example

```
wrapper = TextWrapper(initial_indent="* ")
```

is the same as

```
wrapper = TextWrapper()
wrapper.initial_indent = "* "
```

You can re-use the same `TextWrapper` object many times, and you can change any of its options through direct assignment to instance attributes between uses.

The `TextWrapper` instance attributes (and keyword arguments to the constructor) are as follows:

width

(default: 70) The maximum length of wrapped lines. As long as there are no individual words in the input text longer than `width`, `TextWrapper` guarantees that no output line will be longer than `width` characters.

expand_tabs

(default: True) If true, then all tab characters in `text` will be expanded to spaces using the `expandtabs()` method of `text`.

tabsize

(default: 8) If `expand_tabs` is true, then all tab characters in `text` will be expanded to zero or more spaces, depending on the current column and the given tab size.

3.3 新版功能.

replace_whitespace

(default: True) If true, after tab expansion but before wrapping, the `wrap()` method will replace each whitespace character with a single space. The whitespace characters replaced are as follows: tab, newline, vertical tab, formfeed, and carriage return (`'\t\n\v\f\r'`).

注解: If `expand_tabs` is false and `replace_whitespace` is true, each tab character will be replaced by a single space, which is *not* the same as tab expansion.

注解: If `replace_whitespace` is false, newlines may appear in the middle of a line and cause strange output. For this reason, text should be split into paragraphs (using `str.splitlines()` or similar) which are wrapped separately.

drop_whitespace

(default: True) If true, whitespace at the beginning and ending of every line (after wrapping but before indenting) is dropped. Whitespace at the beginning of the paragraph, however, is not dropped if non-whitespace follows it. If whitespace being dropped takes up an entire line, the whole line is dropped.

initial_indent

(default: ' ') String that will be prepended to the first line of wrapped output. Counts towards the length of the first line. The empty string is not indented.

subsequent_indent

(default: ' ') String that will be prepended to all lines of wrapped output except the first. Counts towards the length of each line except the first.

fix_sentence_endings

(default: False) If true, *TextWrapper* attempts to detect sentence endings and ensure that sentences are always separated by exactly two spaces. This is generally desired for text in a monospaced font. However, the sentence detection algorithm is imperfect: it assumes that a sentence ending consists of a lowercase letter followed by one of '.', '!', or '?', possibly followed by one of '"' or "'", followed by a space. One problem with this algorithm is that it is unable to detect the difference between “Dr.” in

```
[...] Dr. Frankenstein's monster [...]
```

and “Spot.” in

```
[...] See Spot. See Spot run [...]
```

fix_sentence_endings is false by default.

Since the sentence detection algorithm relies on `string.lowercase` for the definition of “lowercase letter,” and a convention of using two spaces after a period to separate sentences on the same line, it is specific to English-language texts.

break_long_words

(default: True) If true, then words longer than *width* will be broken in order to ensure that no lines are longer than *width*. If it is false, long words will not be broken, and some lines may be longer than *width*. (Long words will be put on a line by themselves, in order to minimize the amount by which *width* is exceeded.)

break_on_hyphens

(default: True) If true, wrapping will occur preferably on whitespaces and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set *break_long_words* to false if you want truly insecable words. Default behaviour in previous versions was to always allow breaking hyphenated words.

max_lines

(default: None) If not None, then the output will contain at most *max_lines* lines, with *placeholder* appearing at the end of the output.

3.4 新版功能.

placeholder

(default: ' [...] ') String that will appear at the end of the output text if it has been truncated.

3.4 新版功能.

TextWrapper also provides some public methods, analogous to the module-level convenience functions:

wrap (*text*)

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. All wrapping options are taken from instance attributes of the *TextWrapper* instance. Returns a list of output lines, without final newlines. If the wrapped output has no content, the returned list is empty.

fill (*text*)

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph.

6.5 unicodedata —Unicode 数据库

This module provides access to the Unicode Character Database (UCD) which defines character properties for all Unicode characters. The data contained in this database is compiled from the [UCD version 9.0.0](#).

该模块使用与 Unicode 标准附件 #44，“Unicode 字符数据库”定义的不同名称和符号。它定义了以下功能：

`unicodedata.lookup(name)`

按名称查找字符。如果找到具有给定名称的字符，则返回相应的字符。如果没有找到，则 `KeyError` 被引发。

在 3.3 版更改：已添加对名称别名¹ 和命名序列² 的支持。

`unicodedata.name(chr[, default])`

返回分配给字符 `chr` 的名称作为字符串。如果没有定义名称，则返回 `default`，如果没有给出，则 `ValueError` 被引发。

`unicodedata.decimal(chr[, default])`

返回分配给字符 `chr` 的十进制值作为整数。如果没有定义这样的值，则返回 `default`，如果没有给出，则 `ValueError` 被引发。

`unicodedata.digit(chr[, default])`

返回分配给字符 `chr` 的数字值作为整数。如果没有定义这样的值，则返回 `default`，如果没有给出，则 `ValueError` 被引发。

`unicodedata.numeric(chr[, default])`

返回分配给字符 `chr` 的数值作为浮点数。如果没有定义这样的值，则返回 `default`，如果没有给出，则 `ValueError` 被引发。

`unicodedata.category(chr)`

返回分配给字符 `chr` 的常规类别为字符串。

`unicodedata.bidirectional(chr)`

返回分配给字符 `chr` 的双向类作为字符串。如果未定义此类值，则返回空字符串。

`unicodedata.combining(chr)`

返回分配给字符 `chr` 的规范组合类作为整数。如果没有定义组合类，则返回 0。

`unicodedata.east_asian_width(chr)`

返回分配给字符 `chr` 的东亚宽度作为字符串。

`unicodedata.mirrored(chr)`

返回分配给字符 `chr` 的镜像属性为整数。如果字符在双向文本中被识别为“镜像”字符，则返回 1，否则返回 0。

`unicodedata.decomposition(chr)`

返回分配给字符 `chr` 的字符分解映射作为字符串。如果未定义此类映射，则返回空字符串。

`unicodedata.normalize(form, unistr)`

返回 Unicode 字符串 `unistr` 的正常形式 `form`。`form` 的有效值为 ‘NFC’、‘NFKC’、‘NFD’ 和 ‘NFKD’。

Unicode 标准基于规范等价和兼容性等效的定义定义了 Unicode 字符串的各种规范化形式。在 Unicode 中，可以以各种方式表示多个字符。例如，字符 U+00C7（带有 CEDILLA 的 LATIN CAPITAL LETTER C）也可以表示为序列 U+0043（LATIN CAPITAL LETTER C）U+0327（COMBINING CEDILLA）。

对于每个字符，有两种正规形式：正规形式 C 和正规形式 D。正规形式 D（NFD）也称为规范分解，并将每个字符转换为其分解形式。正规形式 C（NFC）首先应用规范分解，然后再次组合预组合字符。

除了这两种形式之外，还有两种基于兼容性等效的其他常规形式。在 Unicode 中，支持某些字符，这些字符通常与其他字符统一。例如，U+2160（ROMAN NUMERAL ONE）与 U+0049（LATIN CAPITAL LETTER I）完全相同。但是，Unicode 支持它与现有字符集（例如 gb2312）的兼容性。

¹ <http://www.unicode.org/Public/9.0.0/ucd/NameAliases.txt>

² <http://www.unicode.org/Public/9.0.0/ucd/NamedSequences.txt>

正规形式 KD (NFKD) 将应用兼容性分解, 即用其等价项替换所有兼容性字符。正规形式 KC (NFKC) 首先应用兼容性分解, 然后是规范组合。

即使两个 `unicode` 字符串被规范化并且人类读者看起来相同, 如果一个具有组合字符而另一个没有, 则它们可能无法相等。

此外, 该模块暴露了以下常量:

`unicodedata.unidata_version`

此模块中使用的 Unicode 数据库的版本。

`unicodedata.ucd_3_2_0`

这是一个与整个模块具有相同方法的对象, 但对于需要此特定版本的 Unicode 数据库 (如 IDNA) 的应用程序, 则使用 Unicode 数据库版本 3.2。

示例:

```
>>> import unicodedata
>>> unicodedata.lookup('LEFT CURLY BRACKET')
'{'
>>> unicodedata.name('/')
'SOLIDUS'
>>> unicodedata.decimal('9')
9
>>> unicodedata.decimal('a')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: not a decimal
>>> unicodedata.category('A') # 'L'etter, 'u'ppercase
'Lu'
>>> unicodedata.bidirectional('\u0660') # 'A'rabic, 'N'umber
'AN'
```

6.6 stringprep — Internet String Preparation

Source code: [Lib/stringprep.py](#)

When identifying things (such as host names) in the internet, it is often necessary to compare such identifications for “equality”. Exactly how this comparison is executed may depend on the application domain, e.g. whether it should be case-insensitive or not. It may be also necessary to restrict the possible identifications, to allow only identifications consisting of “printable” characters.

RFC 3454 defines a procedure for “preparing” Unicode strings in internet protocols. Before passing strings onto the wire, they are processed with the preparation procedure, after which they have a certain normalized form. The RFC defines a set of tables, which can be combined into profiles. Each profile must define which tables it uses, and what other optional parts of the `stringprep` procedure are part of the profile. One example of a `stringprep` profile is `nameprep`, which is used for internationalized domain names.

The module `stringprep` only exposes the tables from **RFC 3454**. As these tables would be very large to represent them as dictionaries or lists, the module uses the Unicode character database internally. The module source code itself was generated using the `mkstringprep.py` utility.

As a result, these tables are exposed as functions, not as data structures. There are two kinds of tables in the RFC: sets and mappings. For a set, `stringprep` provides the “characteristic function”, i.e. a function that returns true if the parameter is part of the set. For mappings, it provides the mapping function: given the key, it returns the associated value. Below is a list of all functions available in the module.

`stringprep.in_table_a1 (code)`
 Determine whether *code* is in tableA.1 (Unassigned code points in Unicode 3.2).

`stringprep.in_table_b1 (code)`
 Determine whether *code* is in tableB.1 (Commonly mapped to nothing).

`stringprep.map_table_b2 (code)`
 Return the mapped value for *code* according to tableB.2 (Mapping for case-folding used with NFKC).

`stringprep.map_table_b3 (code)`
 Return the mapped value for *code* according to tableB.3 (Mapping for case-folding used with no normalization).

`stringprep.in_table_c11 (code)`
 Determine whether *code* is in tableC.1.1 (ASCII space characters).

`stringprep.in_table_c12 (code)`
 Determine whether *code* is in tableC.1.2 (Non-ASCII space characters).

`stringprep.in_table_c11_c12 (code)`
 Determine whether *code* is in tableC.1 (Space characters, union of C.1.1 and C.1.2).

`stringprep.in_table_c21 (code)`
 Determine whether *code* is in tableC.2.1 (ASCII control characters).

`stringprep.in_table_c22 (code)`
 Determine whether *code* is in tableC.2.2 (Non-ASCII control characters).

`stringprep.in_table_c21_c22 (code)`
 Determine whether *code* is in tableC.2 (Control characters, union of C.2.1 and C.2.2).

`stringprep.in_table_c3 (code)`
 Determine whether *code* is in tableC.3 (Private use).

`stringprep.in_table_c4 (code)`
 Determine whether *code* is in tableC.4 (Non-character code points).

`stringprep.in_table_c5 (code)`
 Determine whether *code* is in tableC.5 (Surrogate codes).

`stringprep.in_table_c6 (code)`
 Determine whether *code* is in tableC.6 (Inappropriate for plain text).

`stringprep.in_table_c7 (code)`
 Determine whether *code* is in tableC.7 (Inappropriate for canonical representation).

`stringprep.in_table_c8 (code)`
 Determine whether *code* is in tableC.8 (Change display properties or are deprecated).

`stringprep.in_table_c9 (code)`
 Determine whether *code* is in tableC.9 (Tagging characters).

`stringprep.in_table_d1 (code)`
 Determine whether *code* is in tableD.1 (Characters with bidirectional property “R” or “AL”).

`stringprep.in_table_d2 (code)`
 Determine whether *code* is in tableD.2 (Characters with bidirectional property “L”).

6.7 readline —GNU readline interface

The `readline` module defines a number of functions to facilitate completion and reading/writing of history files from the Python interpreter. This module can be used directly, or via the `rlcompleter` module, which supports completion of Python identifiers at the interactive prompt. Settings made using this module affect the behaviour of both the interpreter's interactive prompt and the prompts offered by the built-in `input()` function.

注解: The underlying Readline library API may be implemented by the `libedit` library instead of GNU readline. On MacOS X the `readline` module detects which library is being used at run time.

The configuration file for `libedit` is different from that of GNU readline. If you programmatically load configuration strings you can check for the text “libedit” in `readline.__doc__` to differentiate between GNU readline and libedit.

Readline keybindings may be configured via an initialization file, typically `.inputrc` in your home directory. See [Readline Init File](#) in the GNU Readline manual for information about the format and allowable constructs of that file, and the capabilities of the Readline library in general.

6.7.1 Init file

The following functions relate to the init file and user configuration:

`readline.parse_and_bind(string)`
Execute the init line provided in the *string* argument. This calls `rl_parse_and_bind()` in the underlying library.

`readline.read_init_file([filename])`
Execute a readline initialization file. The default filename is the last filename used. This calls `rl_read_init_file()` in the underlying library.

6.7.2 Line buffer

The following functions operate on the line buffer:

`readline.get_line_buffer()`
Return the current contents of the line buffer (`rl_line_buffer` in the underlying library).

`readline.insert_text(string)`
Insert text into the line buffer at the cursor position. This calls `rl_insert_text()` in the underlying library, but ignores the return value.

`readline.redisplay()`
Change what's displayed on the screen to reflect the current contents of the line buffer. This calls `rl_redisplay()` in the underlying library.

6.7.3 History file

The following functions operate on a history file:

`readline.read_history_file([filename])`
Load a readline history file, and append it to the history list. The default filename is `~/.history`. This calls `read_history()` in the underlying library.

`readline.write_history_file([filename])`
Save the history list to a readline history file, overwriting any existing file. The default filename is `~/.history`. This calls `write_history()` in the underlying library.

`readline.append_history_file(nelements[, filename])`

Append the last *nelements* items of history to a file. The default filename is `~/.history`. The file must already exist. This calls `append_history()` in the underlying library. This function only exists if Python was compiled for a version of the library that supports it.

3.5 新版功能.

`readline.get_history_length()`

`readline.set_history_length(length)`

Set or return the desired number of lines to save in the history file. The `write_history_file()` function uses this value to truncate the history file, by calling `history_truncate_file()` in the underlying library. Negative values imply unlimited history file size.

6.7.4 History list

The following functions operate on a global history list:

`readline.clear_history()`

Clear the current history. This calls `clear_history()` in the underlying library. The Python function only exists if Python was compiled for a version of the library that supports it.

`readline.get_current_history_length()`

Return the number of items currently in the history. (This is different from `get_history_length()`, which returns the maximum number of lines that will be written to a history file.)

`readline.get_history_item(index)`

Return the current contents of history item at *index*. The item index is one-based. This calls `history_get()` in the underlying library.

`readline.remove_history_item(pos)`

Remove history item specified by its position from the history. The position is zero-based. This calls `remove_history()` in the underlying library.

`readline.replace_history_item(pos, line)`

Replace history item specified by its position with *line*. The position is zero-based. This calls `replace_history_entry()` in the underlying library.

`readline.add_history(line)`

Append *line* to the history buffer, as if it was the last line typed. This calls `add_history()` in the underlying library.

`readline.set_auto_history(enabled)`

Enable or disable automatic calls to `add_history()` when reading input via `readline`. The *enabled* argument should be a Boolean value that when true, enables auto history, and that when false, disables auto history.

3.6 新版功能.

CPython implementation detail: Auto history is enabled by default, and changes to this do not persist across multiple sessions.

6.7.5 Startup hooks

`readline.set_startup_hook([function])`

Set or remove the function invoked by the `rl_startup_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments just before `readline` prints the first prompt.

`readline.set_pre_input_hook([function])`

Set or remove the function invoked by the `rl_pre_input_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments after the first prompt has been printed and just before `readline` starts reading input characters. This function only exists if Python was compiled for a version of the library that supports it.

6.7.6 Completion

The following functions relate to implementing a custom word completion function. This is typically operated by the Tab key, and can suggest and automatically complete a word being typed. By default, `Readline` is set up to be used by `rlcompleter` to complete Python identifiers for the interactive interpreter. If the `readline` module is to be used with a custom completer, a different set of word delimiters should be set.

`readline.set_completer([function])`

Set or remove the completer function. If *function* is specified, it will be used as the new completer function; if omitted or `None`, any completer function already installed is removed. The completer function is called as `function(text, state)`, for *state* in 0, 1, 2, ..., until it returns a non-string value. It should return the next possible completion starting with *text*.

The installed completer function is invoked by the `entry_func` callback passed to `rl_completion_matches()` in the underlying library. The *text* string comes from the first parameter to the `rl_attempted_completion_function` callback of the underlying library.

`readline.get_completer()`

Get the completer function, or `None` if no completer function has been set.

`readline.get_completion_type()`

Get the type of completion being attempted. This returns the `rl_completion_type` variable in the underlying library as an integer.

`readline.get_begidx()`

`readline.get_endidx()`

Get the beginning or ending index of the completion scope. These indexes are the *start* and *end* arguments passed to the `rl_attempted_completion_function` callback of the underlying library.

`readline.set_completer_delims(string)`

`readline.get_completer_delims()`

Set or get the word delimiters for completion. These determine the start of the word to be considered for completion (the completion scope). These functions access the `rl_completer_word_break_characters` variable in the underlying library.

`readline.set_completion_display_matches_hook([function])`

Set or remove the completion display function. If *function* is specified, it will be used as the new completion display function; if omitted or `None`, any completion display function already installed is removed. This sets or clears the `rl_completion_display_matches_hook` callback in the underlying library. The completion display function is called as `function(substitution, [matches], longest_match_length)` once each time matches need to be displayed.

6.7.7 示例

The following example demonstrates how to use the `readline` module's history reading and writing functions to automatically load and save a history file named `.python_history` from the user's home directory. The code below would normally be executed automatically during interactive sessions from the user's `PYTHONSTARTUP` file.

```

import atexit
import os
import readline

histfile = os.path.join(os.path.expanduser("~"), ".python_history")
try:
    readline.read_history_file(histfile)
    # default history len is -1 (infinite), which may grow unruly
    readline.set_history_length(1000)
except FileNotFoundError:
    pass

atexit.register(readline.write_history_file, histfile)

```

This code is actually automatically run when Python is run in interactive mode (see [Readline configuration](#)).

The following example achieves the same goal but supports concurrent interactive sessions, by only appending the new history.

```

import atexit
import os
import readline

histfile = os.path.join(os.path.expanduser("~"), ".python_history")

try:
    readline.read_history_file(histfile)
    h_len = readline.get_current_history_length()
except FileNotFoundError:
    open(histfile, 'wb').close()
    h_len = 0

def save(prev_h_len, histfile):
    new_h_len = readline.get_current_history_length()
    readline.set_history_length(1000)
    readline.append_history_file(new_h_len - prev_h_len, histfile)
atexit.register(save, h_len, histfile)

```

The following example extends the `code.InteractiveConsole` class to support history save/restore.

```

import atexit
import code
import os
import readline

class HistoryConsole(code.InteractiveConsole):
    def __init__(self, locals=None, filename="<console>",
                 histfile=os.path.expanduser("~/console-history")):
        code.InteractiveConsole.__init__(self, locals, filename)
        self.init_history(histfile)

    def init_history(self, histfile):
        readline.parse_and_bind("tab: complete")
        if hasattr(readline, "read_history_file"):
            try:
                readline.read_history_file(histfile)
            except FileNotFoundError:
                pass
        atexit.register(self.save_history, histfile)

```

(下页继续)

(续上页)

```
def save_history(self, histfile):
    readline.set_history_length(1000)
    readline.write_history_file(histfile)
```

6.8 rlcompleter — GNU readline 的完成函数

源代码: [Lib/rlcompleter.py](#)

`rlcompeleter` 通过补全有效的 Python 标识符和关键字为 `readline` 模块定义了一个补全功能套装。

当此模块在具有可用的 `readline` 模块的 Unix 平台被导入, 一个 `Completer` 实例将被自动创建并且它的 `complete()` 方法将设置为 `readline` 的补全器。

示例:

```
>>> import rlcompleter
>>> import readline
>>> readline.parse_and_bind("tab: complete")
>>> readline. <TAB PRESSED>
readline.__doc__          readline.get_line_buffer(  readline.read_init_file(
readline.__file__        readline.insert_text(      readline.set_completer(
readline.__name__        readline.parse_and_bind(
>>> readline.
```

`rlcompleter` 模块是为了使用 Python 的 交互模式而设计的. 除非 Python 是通过 `-S` 选项运行, 这个模块总是自动地被导入且配置 (参考 [Readline configuration](#)).

在没有 `readline` 的平台, 此模块定义的 `Completer` 类仍然可以用于自定义行为。

6.8.1 Completer 对象

`Completer` 对象具有以下方法:

`Completer.complete(text, state)`

为 `text` 返回 `stateth` 补全。

如果要求 `text` 不包含句点字符 ('.'), 它将从当前定义的名称中完成 `__main__`, `builtins` 和 `keywords` (就和通过 `keyword` 模块定义的一样)。

如果为加点的名称执行调用, 它将尝试尽量求值直到最后一部分为止而不产生附带影响 (函数不会被求值, 但它生成对 `__getattr__()` 的调用), 并通过 `dir()` 函数来匹配剩余部分。在对表达式求值期间引发的任何异常都会被捕获、静默处理并返回 `None`。

二进制数据服务

本章介绍的模块提供了一些操作二进制数据的基本服务操作。有关二进制数据的其他操作，特别是与文件格式和网络协议有关的操作，将在相关章节中介绍。

下面描述的一些库文本处理服务也可以使用 ASCII 兼容的二进制格式（例如 `re`）或所有二进制数据（例如 `difflib`）。

另外，请参阅 Python 的内置二进制数据类型的文档二进制序列类型—`bytes`, `bytearray`, `memoryview`。

7.1 struct — Interpret bytes as packed binary data

源代码： `Lib/struct.py`

This module performs conversions between Python values and C structs represented as Python `bytes` objects. This can be used in handling binary data stored in files or from network connections, among other sources. It uses *Format Strings* as compact descriptions of the layout of the C structs and the intended conversion to/from Python values.

注解： By default, the result of packing a given C struct includes pad bytes in order to maintain proper alignment for the C types involved; similarly, alignment is taken into account when unpacking. This behavior is chosen so that the bytes of a packed struct correspond exactly to the layout in memory of the corresponding C struct. To handle platform-independent data formats or omit implicit pad bytes, use `standard` size and alignment instead of `native` size and alignment: see 字节顺序, 大小和对齐方式 for details.

Several `struct` functions (and methods of `Struct`) take a *buffer* argument. This refers to objects that implement the bufferobjects and provide either a readable or read-writable buffer. The most common types used for that purpose are `bytes` and `bytearray`, but many other types that can be viewed as an array of bytes implement the buffer protocol, so that they can be read/filled without additional copying from a `bytes` object.

7.1.1 Functions and Exceptions

The module defines the following exception and functions:

exception `struct.error`

Exception raised on various occasions; argument is a string describing what is wrong.

`struct.pack(fmt, v1, v2, ...)`

Return a bytes object containing the values *v1*, *v2*, ... packed according to the format string *fmt*. The arguments must match the values required by the format exactly.

`struct.pack_into(fmt, buffer, offset, v1, v2, ...)`

Pack the values *v1*, *v2*, ... according to the format string *fmt* and write the packed bytes into the writable buffer *buffer* starting at position *offset*. Note that *offset* is a required argument.

`struct.unpack(fmt, buffer)`

Unpack from the buffer *buffer* (presumably packed by `pack(fmt, ...)`) according to the format string *fmt*. The result is a tuple even if it contains exactly one item. The buffer's size in bytes must match the size required by the format, as reflected by `calcsize()`.

`struct.unpack_from(fmt, buffer, offset=0)`

Unpack from *buffer* starting at position *offset*, according to the format string *fmt*. The result is a tuple even if it contains exactly one item. The buffer's size in bytes, minus *offset*, must be at least the size required by the format, as reflected by `calcsize()`.

`struct.iter_unpack(fmt, buffer)`

Iteratively unpack from the buffer *buffer* according to the format string *fmt*. This function returns an iterator which will read equally-sized chunks from the buffer until all its contents have been consumed. The buffer's size in bytes must be a multiple of the size required by the format, as reflected by `calcsize()`.

Each iteration yields a tuple as specified by the format string.

3.4 新版功能.

`struct.calcsize(fmt)`

Return the size of the struct (and hence of the bytes object produced by `pack(fmt, ...)`) corresponding to the format string *fmt*.

7.1.2 Format Strings

Format strings are the mechanism used to specify the expected layout when packing and unpacking data. They are built up from 格式字符, which specify the type of data being packed/unpacked. In addition, there are special characters for controlling the 字节顺序, 大小和对齐方式.

字节顺序, 大小和对齐方式

默认情况下, C 类型以机器的本机格式和字节顺序表示, 并在必要时通过跳过填充字节进行正确对齐 (根据 C 编译器使用的规则)。

或者, 根据下表, 格式字符串的第一个字符可用于指示打包数据的字节顺序, 大小和对齐方式:

字符	字节顺序	大小	对齐方式
@	按原字节	按原字节	按原字节
=	按原字节	标准	无
<	小端	标准	无
>	大端	标准	无
!	网络 (= 大端)	标准	无

如果第一个字符不是其中之一，则假定为 '@' 。

Native byte order is big-endian or little-endian, depending on the host system. For example, Intel x86 and AMD64 (x86-64) are little-endian; Motorola 68000 and PowerPC G5 are big-endian; ARM and Intel Itanium feature switchable endianness (bi-endian). Use `sys.byteorder` to check the endianness of your system.

Native size and alignment are determined using the C compiler's `sizeof` expression. This is always combined with native byte order.

Standard size depends only on the format character; see the table in the 格式字符 section.

Note the difference between '@' and '=': both use native byte order, but the size and alignment of the latter is standardized.

The form '!' is available for those poor souls who claim they can't remember whether network byte order is big-endian or little-endian.

There is no way to indicate non-native byte order (force byte-swapping); use the appropriate choice of '<' or '>'.

注释:

- (1) Padding is only automatically added between successive structure members. No padding is added at the beginning or the end of the encoded struct.
- (2) No padding is added when using non-native size and alignment, e.g. with '<', '>', '=', and '!'.
- (3) To align the end of a structure to the alignment requirement of a particular type, end the format with the code for that type with a repeat count of zero. See 示例.

格式字符

Format characters have the following meaning; the conversion between C and Python values should be obvious given their types. The 'Standard size' column refers to the size of the packed value in bytes when using standard size; that is, when the format string starts with one of '<', '>', '!' or '='. When using native size, the size of the packed value is platform-dependent.

格式	C 类型	Python 数据类型	标准大小	注释
x	pad byte	没有价值		
c	char	长度为 1 的字节	1	
b	signed char	整数	1	(1),(3)
B	unsigned char	整数	1	(3)
?	_Bool	布尔	1	(1)
h	short	整数	2	(3)
H	unsigned short	整数	2	(3)
i	int	整数	4	(3)
I	unsigned int	整数	4	(3)
l	long	整数	4	(3)
L	unsigned long	整数	4	(3)
q	long long	整数	8	(2), (3)
Q	unsigned long long	整数	8	(2), (3)
n	ssize_t	整数		(4)
N	size_t	整数		(4)
e	(7)	浮点数	2	(5)
f	float	浮点数	4	(5)
d	double	浮点数	8	(5)
s	char[]	bytes		
p	char[]	bytes		
P	void *	整数		(6)

在 3.3 版更改: 增加了对 'n' 和 'N' 格式的支持

在 3.6 版更改: 增加了对 'e' 格式的支持。

注释:

- (1) The '?' conversion code corresponds to the _Bool type defined by C99. If this type is not available, it is simulated using a char. In standard mode, it is always represented by one byte.
- (2) The 'q' and 'Q' conversion codes are available in native mode only if the platform C compiler supports C long long, or, on Windows, __int64. They are always available in standard modes.
- (3) When attempting to pack a non-integer using any of the integer conversion codes, if the non-integer has a __index__() method then that method is called to convert the argument to an integer before packing.
在 3.2 版更改: Use of the __index__() method for non-integers is new in 3.2.
- (4) The 'n' and 'N' conversion codes are only available for the native size (selected as the default or with the '@' byte order character). For the standard size, you can use whichever of the other integer formats fits your application.
- (5) For the 'f', 'd' and 'e' conversion codes, the packed representation uses the IEEE 754 binary32, binary64 or binary16 format (for 'f', 'd' or 'e' respectively), regardless of the floating-point format used by the platform.
- (6) The 'P' format character is only available for the native byte ordering (selected as the default or with the '@' byte order character). The byte order character '=' chooses to use little- or big-endian ordering based on the host system. The struct module does not interpret this as native ordering, so the 'P' format is not available.
- (7) The IEEE 754 binary16 “half precision” type was introduced in the 2008 revision of the [IEEE 754 standard](#). It has a sign bit, a 5-bit exponent and 11-bit precision (with 10 bits explicitly stored), and can represent numbers between approximately 6.1×10^{-5} and 6.5×10^4 at full precision. This type is not widely supported by C compilers: on a typical machine, an unsigned short can be used for storage, but not for math operations. See the Wikipedia page on the [half-precision floating-point format](#) for more information.

A format character may be preceded by an integral repeat count. For example, the format string '4h' means exactly the same as 'hhhh'.

Whitespace characters between formats are ignored; a count and its format must not contain whitespace though.

For the 's' format character, the count is interpreted as the length of the bytes, not a repeat count like for the other format characters; for example, '10s' means a single 10-byte string, while '10c' means 10 characters. If a count is not given, it defaults to 1. For packing, the string is truncated or padded with null bytes as appropriate to make it fit. For unpacking, the resulting bytes object always has exactly the specified number of bytes. As a special case, '0s' means a single, empty string (while '0c' means 0 characters).

When packing a value *x* using one of the integer formats ('b', 'B', 'h', 'H', 'i', 'I', 'l', 'L', 'q', 'Q'), if *x* is outside the valid range for that format then `struct.error` is raised.

在 3.1 版更改: In 3.0, some of the integer formats wrapped out-of-range values and raised `DeprecationWarning` instead of `struct.error`.

The 'p' format character encodes a “Pascal string”, meaning a short variable-length string stored in a *fixed number of bytes*, given by the count. The first byte stored is the length of the string, or 255, whichever is smaller. The bytes of the string follow. If the string passed in to `pack()` is too long (longer than the count minus 1), only the leading `count-1` bytes of the string are stored. If the string is shorter than `count-1`, it is padded with null bytes so that exactly `count` bytes in all are used. Note that for `unpack()`, the 'p' format character consumes `count` bytes, but that the string returned can never contain more than 255 bytes.

For the '?' format character, the return value is either `True` or `False`. When packing, the truth value of the argument object is used. Either 0 or 1 in the native or standard bool representation will be packed, and any non-zero value will be `True` when unpacking.

示例

注解: All examples assume a native byte order, size, and alignment with a big-endian machine.

A basic example of packing/unpacking three integers:

```
>>> from struct import *
>>> pack('hhl', 1, 2, 3)
b'\x00\x01\x00\x02\x00\x00\x00\x03'
>>> unpack('hhl', b'\x00\x01\x00\x02\x00\x00\x00\x03')
(1, 2, 3)
>>> calcsize('hhl')
8
```

Unpacked fields can be named by assigning them to variables or by wrapping the result in a named tuple:

```
>>> record = b'raymond \x32\x12\x08\x01\x08'
>>> name, serialnum, school, gradelevel = unpack('<10sHHb', record)

>>> from collections import namedtuple
>>> Student = namedtuple('Student', 'name serialnum school gradelevel')
>>> Student._make(unpack('<10sHHb', record))
Student(name=b'raymond ', serialnum=4658, school=264, gradelevel=8)
```

The ordering of format characters may have an impact on size since the padding needed to satisfy alignment requirements is different:

```
>>> pack('ci', b'*', 0x12131415)
b'*\x00\x00\x00\x12\x13\x14\x15'
>>> pack('ic', 0x12131415, b'*)
```

(下页继续)

(续上页)

```
b'\x12\x13\x14\x15*'
>>> calcsiz('ci')
8
>>> calcsiz('ic')
5
```

The following format 'llh0l' specifies two pad bytes at the end, assuming longs are aligned on 4-byte boundaries:

```
>>> pack('llh0l', 1, 2, 3)
b'\x00\x00\x00\x01\x00\x00\x00\x02\x00\x03\x00\x00'
```

This only works when native size and alignment are in effect; standard size and alignment does not enforce any alignment.

Module `array` Packed binary storage of homogeneous data.

Module `xdrlib` Packing and unpacking of XDR data.

7.1.3 类

The `struct` module also defines the following type:

class `struct.Struct` (*format*)

Return a new Struct object which writes and reads binary data according to the format string *format*. Creating a Struct object once and calling its methods is more efficient than calling the `struct` functions with the same format since the format string only needs to be compiled once.

Compiled Struct objects support the following methods and attributes:

pack (*v1*, *v2*, ...)

Identical to the `pack()` function, using the compiled format. (`len(result)` will equal `size`.)

pack_into (*buffer*, *offset*, *v1*, *v2*, ...)

Identical to the `pack_into()` function, using the compiled format.

unpack (*buffer*)

Identical to the `unpack()` function, using the compiled format. The buffer's size in bytes must equal `size`.

unpack_from (*buffer*, *offset*=0)

Identical to the `unpack_from()` function, using the compiled format. The buffer's size in bytes, minus *offset*, must be at least `size`.

iter_unpack (*buffer*)

Identical to the `iter_unpack()` function, using the compiled format. The buffer's size in bytes must be a multiple of `size`.

3.4 新版功能.

format

The format string used to construct this Struct object.

size

The calculated size of the struct (and hence of the bytes object produced by the `pack()` method) corresponding to *format*.

7.2 codecs —Codec registry and base classes

Source code: [Lib/codecs.py](#)

This module defines base classes for standard Python codecs (encoders and decoders) and provides access to the internal Python codec registry, which manages the codec and error handling lookup process. Most standard codecs are *text encodings*, which encode text to bytes, but there are also codecs provided that encode text to text, and bytes to bytes. Custom codecs may encode and decode between arbitrary types, but some module features are restricted to use specifically with *text encodings*, or with codecs that encode to *bytes*.

The module defines the following functions for encoding and decoding with any codec:

`codecs.encode(obj, encoding='utf-8', errors='strict')`

Encodes *obj* using the codec registered for *encoding*.

Errors may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that encoding errors raise *ValueError* (or a more codec specific subclass, such as *UnicodeEncodeError*). Refer to *Codec Base Classes* for more information on codec error handling.

`codecs.decode(obj, encoding='utf-8', errors='strict')`

Decodes *obj* using the codec registered for *encoding*.

Errors may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that decoding errors raise *ValueError* (or a more codec specific subclass, such as *UnicodeDecodeError*). Refer to *Codec Base Classes* for more information on codec error handling.

The full details for each codec can also be looked up directly:

`codecs.lookup(encoding)`

Looks up the codec info in the Python codec registry and returns a *CodecInfo* object as defined below.

Encodings are first looked up in the registry's cache. If not found, the list of registered search functions is scanned. If no *CodecInfo* object is found, a *LookupError* is raised. Otherwise, the *CodecInfo* object is stored in the cache and returned to the caller.

class `codecs.CodecInfo` (*encode*, *decode*, *streamreader=None*, *streamwriter=None*, *incrementalencoder=None*, *incrementaldecoder=None*, *name=None*)

Codec details when looking up the codec registry. The constructor arguments are stored in attributes of the same name:

name

编码名称

encode

decode

The stateless encoding and decoding functions. These must be functions or methods which have the same interface as the *encode()* and *decode()* methods of Codec instances (see *Codec Interface*). The functions or methods are expected to work in a stateless mode.

incrementalencoder

incrementaldecoder

Incremental encoder and decoder classes or factory functions. These have to provide the interface defined by the base classes *IncrementalEncoder* and *IncrementalDecoder*, respectively. Incremental codecs can maintain state.

streamwriter

streamreader

Stream writer and reader classes or factory functions. These have to provide the interface defined by the base classes *StreamWriter* and *StreamReader*, respectively. Stream codecs can maintain state.

To simplify access to the various codec components, the module provides these additional functions which use `lookup()` for the codec lookup:

`codecs.getencoder(encoding)`

Look up the codec for the given encoding and return its encoder function.

Raises a `LookupError` in case the encoding cannot be found.

`codecs.getdecoder(encoding)`

Look up the codec for the given encoding and return its decoder function.

Raises a `LookupError` in case the encoding cannot be found.

`codecs.getincrementalencoder(encoding)`

Look up the codec for the given encoding and return its incremental encoder class or factory function.

Raises a `LookupError` in case the encoding cannot be found or the codec doesn't support an incremental encoder.

`codecs.getincrementaldecoder(encoding)`

Look up the codec for the given encoding and return its incremental decoder class or factory function.

Raises a `LookupError` in case the encoding cannot be found or the codec doesn't support an incremental decoder.

`codecs.getreader(encoding)`

Look up the codec for the given encoding and return its `StreamReader` class or factory function.

Raises a `LookupError` in case the encoding cannot be found.

`codecs.getwriter(encoding)`

Look up the codec for the given encoding and return its `StreamWriter` class or factory function.

Raises a `LookupError` in case the encoding cannot be found.

Custom codecs are made available by registering a suitable codec search function:

`codecs.register(search_function)`

Register a codec search function. Search functions are expected to take one argument, being the encoding name in all lower case letters, and return a `CodecInfo` object. In case a search function cannot find a given encoding, it should return `None`.

注解: Search function registration is not currently reversible, which may cause problems in some cases, such as unit testing or module reloading.

While the builtin `open()` and the associated `io` module are the recommended approach for working with encoded text files, this module provides additional utility functions and classes that allow the use of a wider range of codecs when working with binary files:

`codecs.open(filename, mode='r', encoding=None, errors='strict', buffering=1)`

Open an encoded file using the given `mode` and return an instance of `StreamReaderWriter`, providing transparent encoding/decoding. The default file mode is `'r'`, meaning to open the file in read mode.

注解: Underlying encoded files are always opened in binary mode. No automatic conversion of `'\n'` is done on reading and writing. The `mode` argument may be any binary mode acceptable to the built-in `open()` function; the `'b'` is automatically added.

`encoding` specifies the encoding which is to be used for the file. Any encoding that encodes to and decodes from bytes is allowed, and the data types supported by the file methods depend on the codec used.

errors may be given to define the error handling. It defaults to `'strict'` which causes a `ValueError` to be raised in case an encoding error occurs.

buffering has the same meaning as for the built-in `open()` function. It defaults to line buffered.

`codecs.EncodedFile` (*file*, *data_encoding*, *file_encoding=None*, *errors='strict'*)

Return a `StreamRecoder` instance, a wrapped version of *file* which provides transparent transcoding. The original file is closed when the wrapped version is closed.

Data written to the wrapped file is decoded according to the given *data_encoding* and then written to the original file as bytes using *file_encoding*. Bytes read from the original file are decoded according to *file_encoding*, and the result is encoded using *data_encoding*.

If *file_encoding* is not given, it defaults to *data_encoding*.

errors may be given to define the error handling. It defaults to `'strict'`, which causes `ValueError` to be raised in case an encoding error occurs.

`codecs.iterencode` (*iterator*, *encoding*, *errors='strict'*, ***kwargs*)

Uses an incremental encoder to iteratively encode the input provided by *iterator*. This function is a *generator*. The *errors* argument (as well as any other keyword argument) is passed through to the incremental encoder.

This function requires that the codec accept text `str` objects to encode. Therefore it does not support bytes-to-bytes encoders such as `base64_codec`.

`codecs.iterdecode` (*iterator*, *encoding*, *errors='strict'*, ***kwargs*)

Uses an incremental decoder to iteratively decode the input provided by *iterator*. This function is a *generator*. The *errors* argument (as well as any other keyword argument) is passed through to the incremental decoder.

This function requires that the codec accept `bytes` objects to decode. Therefore it does not support text-to-text encoders such as `rot_13`, although `rot_13` may be used equivalently with `iterencode()`.

The module also provides the following constants which are useful for reading and writing to platform dependent files:

```
codecs.BOM
codecs.BOM_BE
codecs.BOM_LE
codecs.BOM_UTF8
codecs.BOM_UTF16
codecs.BOM_UTF16_BE
codecs.BOM_UTF16_LE
codecs.BOM_UTF32
codecs.BOM_UTF32_BE
codecs.BOM_UTF32_LE
```

These constants define various byte sequences, being Unicode byte order marks (BOMs) for several encodings. They are used in UTF-16 and UTF-32 data streams to indicate the byte order used, and in UTF-8 as a Unicode signature. `BOM_UTF16` is either `BOM_UTF16_BE` or `BOM_UTF16_LE` depending on the platform's native byte order, `BOM` is an alias for `BOM_UTF16`, `BOM_LE` for `BOM_UTF16_LE` and `BOM_BE` for `BOM_UTF16_BE`. The others represent the BOM in UTF-8 and UTF-32 encodings.

7.2.1 Codec Base Classes

The `codecs` module defines a set of base classes which define the interfaces for working with codec objects, and can also be used as the basis for custom codec implementations.

Each codec has to define four interfaces to make it usable as codec in Python: stateless encoder, stateless decoder, stream reader and stream writer. The stream reader and writers typically reuse the stateless encoder/decoder to implement the file protocols. Codec authors also need to define how the codec will handle encoding and decoding errors.

Error Handlers

To simplify and standardize error handling, codecs may implement different error handling schemes by accepting the *errors* string argument. The following string values are defined and implemented by all standard Python codecs:

值	意义
'strict'	Raise <code>UnicodeError</code> (or a subclass); this is the default. Implemented in <code>strict_errors()</code> .
'ignore'	Ignore the malformed data and continue without further notice. Implemented in <code>ignore_errors()</code> .

The following error handlers are only applicable to *text encodings*:

值	意义
'replace'	Replace with a suitable replacement marker; Python will use the official U+FFFD REPLACEMENT CHARACTER for the built-in codecs on decoding, and '?' on encoding. Implemented in <code>replace_errors()</code> .
'xmlcharrefreplace'	Replace with the appropriate XML character reference (only for encoding). Implemented in <code>xmlcharrefreplace_errors()</code> .
'backslashreplace'	Replace with backslashed escape sequences. Implemented in <code>backslashreplace_errors()</code> .
'namereplace'	Replace with <code>\N{...}</code> escape sequences (only for encoding). Implemented in <code>namereplace_errors()</code> .
'surrogateescape'	On decoding, replace byte with individual surrogate code ranging from U+DC80 to U+DCFF. This code will then be turned back into the same byte when the 'surrogateescape' error handler is used when encoding the data. (See PEP 383 for more.)

In addition, the following error handler is specific to the given codecs:

值	Codecs	意义
'surrogatepass'	utf-8, 'utf-16, utf-32, utf-16-be, utf-16-le, utf-32-be, utf-32-le	Allow encoding and decoding of surrogate codes. These codecs normally treat the presence of surrogates as an error.

3.1 新版功能: The 'surrogateescape' and 'surrogatepass' error handlers.

在 3.4 版更改: The 'surrogatepass' error handlers now works with utf-16* and utf-32* codecs.

3.5 新版功能: The 'namereplace' error handler.

在 3.5 版更改: The 'backslashreplace' error handlers now works with decoding and translating.

The set of allowed values can be extended by registering a new named error handler:

`codecs.register_error` (*name*, *error_handler*)

Register the error handling function *error_handler* under the name *name*. The *error_handler* argument will be called during encoding and decoding in case of an error, when *name* is specified as the errors parameter.

For encoding, *error_handler* will be called with a `UnicodeEncodeError` instance, which contains information about the location of the error. The error handler must either raise this or a different exception, or return a tuple with a replacement for the unencodable part of the input and a position where encoding should continue. The replacement may be either *str* or *bytes*. If the replacement is bytes, the encoder will simply copy them into the output buffer. If the replacement is a string, the encoder will encode the replacement. Encoding continues on original input at the specified position. Negative position values will be treated as being relative to the end of the input string. If the resulting position is out of bound an `IndexError` will be raised.

Decoding and translating works similarly, except `UnicodeDecodeError` or `UnicodeTranslateError` will be passed to the handler and that the replacement from the error handler will be put into the output directly.

Previously registered error handlers (including the standard error handlers) can be looked up by name:

`codecs.lookup_error(name)`

Return the error handler previously registered under the name *name*.

Raises a `LookupError` in case the handler cannot be found.

The following standard error handlers are also made available as module level functions:

`codecs.strict_errors(exception)`

Implements the 'strict' error handling: each encoding or decoding error raises a `UnicodeError`.

`codecs.replace_errors(exception)`

Implements the 'replace' error handling (for *text encodings* only): substitutes '?' for encoding errors (to be encoded by the codec), and '\ufffd' (the Unicode replacement character) for decoding errors.

`codecs.ignore_errors(exception)`

Implements the 'ignore' error handling: malformed data is ignored and encoding or decoding is continued without further notice.

`codecs.xmlcharrefreplace_errors(exception)`

Implements the 'xmlcharrefreplace' error handling (for encoding with *text encodings* only): the unencodable character is replaced by an appropriate XML character reference.

`codecs.backslashreplace_errors(exception)`

Implements the 'backslashreplace' error handling (for *text encodings* only): malformed data is replaced by a backslashed escape sequence.

`codecs.namereplace_errors(exception)`

Implements the 'namereplace' error handling (for encoding with *text encodings* only): the unencodable character is replaced by a `\N{...}` escape sequence.

3.5 新版功能.

Stateless Encoding and Decoding

The base `Codec` class defines these methods which also define the function interfaces of the stateless encoder and decoder:

`Codec.encode(input[, errors])`

Encodes the object *input* and returns a tuple (output object, length consumed). For instance, *text encoding* converts a string object to a bytes object using a particular character set encoding (e.g., `cp1252` or `iso-8859-1`).

The *errors* argument defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the `Codec` instance. Use `StreamWriter` for codecs which have to keep state in order to make encoding efficient.

The encoder must be able to handle zero length input and return an empty object of the output object type in this situation.

`Codec.decode(input[, errors])`

Decodes the object *input* and returns a tuple (output object, length consumed). For instance, for a *text encoding*, decoding converts a bytes object encoded using a particular character set encoding to a string object.

For text encodings and bytes-to-bytes codecs, *input* must be a bytes object or one which provides the read-only buffer interface – for example, buffer objects and memory mapped files.

The *errors* argument defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the `Codec` instance. Use `StreamReader` for codecs which have to keep state in order to make decoding efficient.

The decoder must be able to handle zero length input and return an empty object of the output object type in this situation.

Incremental Encoding and Decoding

The *IncrementalEncoder* and *IncrementalDecoder* classes provide the basic interface for incremental encoding and decoding. Encoding/decoding the input isn't done with one call to the stateless encoder/decoder function, but with multiple calls to the *encode()*/*decode()* method of the incremental encoder/decoder. The incremental encoder/decoder keeps track of the encoding/decoding process during method calls.

The joined output of calls to the *encode()*/*decode()* method is the same as if all the single inputs were joined into one, and this input was encoded/decoded with the stateless encoder/decoder.

IncrementalEncoder Objects

The *IncrementalEncoder* class is used for encoding an input in multiple steps. It defines the following methods which every incremental encoder must define in order to be compatible with the Python codec registry.

class codecs.**IncrementalEncoder** (*errors*='strict')

Constructor for an *IncrementalEncoder* instance.

All incremental encoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *IncrementalEncoder* may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for possible values.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *IncrementalEncoder* object.

encode (*object* [, *final*])

Encodes *object* (taking the current state of the encoder into account) and returns the resulting encoded object. If this is the last call to *encode()* *final* must be true (the default is false).

reset ()

Reset the encoder to the initial state. The output is discarded: call *.encode(object, final=True)*, passing an empty byte or text string if necessary, to reset the encoder and to get the output.

getstate ()

Return the current state of the encoder which must be an integer. The implementation should make sure that 0 is the most common state. (States that are more complicated than integers can be converted into an integer by marshaling/pickling the state and encoding the bytes of the resulting string into an integer).

setstate (*state*)

Set the state of the encoder to *state*. *state* must be an encoder state returned by *getstate()*.

IncrementalDecoder Objects

The *IncrementalDecoder* class is used for decoding an input in multiple steps. It defines the following methods which every incremental decoder must define in order to be compatible with the Python codec registry.

class codecs.**IncrementalDecoder** (*errors*='strict')

Constructor for an *IncrementalDecoder* instance.

All incremental decoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *IncrementalDecoder* may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for possible values.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *IncrementalDecoder* object.

decode (*object* [, *final*])

Decodes *object* (taking the current state of the decoder into account) and returns the resulting decoded object. If this is the last call to *decode()* *final* must be true (the default is false). If *final* is true the decoder must decode the input completely and must flush all buffers. If this isn't possible (e.g. because of incomplete byte sequences at the end of the input) it must initiate error handling just like in the stateless case (which might raise an exception).

reset ()

Reset the decoder to the initial state.

getstate ()

Return the current state of the decoder. This must be a tuple with two items, the first must be the buffer containing the still undecoded input. The second must be an integer and can be additional state info. (The implementation should make sure that 0 is the most common additional state info.) If this additional state info is 0 it must be possible to set the decoder to the state which has no input buffered and 0 as the additional state info, so that feeding the previously buffered input to the decoder returns it to the previous state without producing any output. (Additional state info that is more complicated than integers can be converted into an integer by marshaling/pickling the info and encoding the bytes of the resulting string into an integer.)

setstate (*state*)

Set the state of the encoder to *state*. *state* must be a decoder state returned by *getstate()*.

Stream Encoding and Decoding

The *StreamWriter* and *StreamReader* classes provide generic working interfaces which can be used to implement new encoding submodules very easily. See `encodings.utf_8` for an example of how this is done.

StreamWriter Objects

The *StreamWriter* class is a subclass of *Codec* and defines the following methods which every stream writer must define in order to be compatible with the Python codec registry.

class `codecs.StreamWriter` (*stream*, *errors*='strict')

Constructor for a *StreamWriter* instance.

All stream writers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for writing text or binary data, as appropriate for the specific codec.

The *StreamWriter* may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *StreamWriter* object.

write (*object*)

Writes the object's contents encoded to the stream.

writelines (*list*)

Writes the concatenated list of strings to the stream (possibly by reusing the `write()` method). The standard bytes-to-bytes codecs do not support this method.

reset ()

Flushes and resets the codec buffers used for keeping state.

Calling this method should ensure that the data on the output is put into a clean state that allows appending of new fresh data without having to rescan the whole stream to recover state.

In addition to the above methods, the `StreamWriter` must also inherit all other methods and attributes from the underlying stream.

StreamReader Objects

The `StreamReader` class is a subclass of `Codec` and defines the following methods which every stream reader must define in order to be compatible with the Python codec registry.

class `codecs.StreamReader` (*stream*, *errors*='strict')

Constructor for a `StreamReader` instance.

All stream readers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for reading text or binary data, as appropriate for the specific codec.

The `StreamReader` may implement different error handling schemes by providing the *errors* keyword argument. See [Error Handlers](#) for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `StreamReader` object.

The set of allowed values for the *errors* argument can be extended with `register_error()`.

read ([*size*[, *chars*[, *firstline*]]])

Decodes data from the stream and returns the resulting object.

The *chars* argument indicates the number of decoded code points or bytes to return. The `read()` method will never return more data than requested, but it might return less, if there is not enough available.

The *size* argument indicates the approximate maximum number of encoded bytes or code points to read for decoding. The decoder can modify this setting as appropriate. The default value -1 indicates to read and decode as much as possible. This parameter is intended to prevent having to decode huge files in one step.

The *firstline* flag indicates that it would be sufficient to only return the first line, if there are decoding errors on later lines.

The method should use a greedy read strategy meaning that it should read as much data as is allowed within the definition of the encoding and the given size, e.g. if optional encoding endings or state markers are available on the stream, these should be read too.

readline ([*size*[, *keepends*]])

Read one line from the input stream and return the decoded data.

size, if given, is passed as size argument to the stream's `read()` method.

If *keepends* is false line-endings will be stripped from the lines returned.

readlines ([*sizehint*[, *keepends*]])

Read all lines available on the input stream and return them as a list of lines.

Line-endings are implemented using the codec's decoder method and are included in the list entries if *keepends* is true.

sizehint, if given, is passed as the *size* argument to the stream's *read()* method.

reset()

Resets the codec buffers used for keeping state.

Note that no stream repositioning should take place. This method is primarily intended to be able to recover from decoding errors.

In addition to the above methods, the *StreamReader* must also inherit all other methods and attributes from the underlying stream.

StreamReaderWriter Objects

The *StreamReaderWriter* is a convenience class that allows wrapping streams which work in both read and write modes.

The design is such that one can use the factory functions returned by the *lookup()* function to construct the instance.

class `codecs.StreamReaderWriter` (*stream*, *Reader*, *Writer*, *errors*='strict')

Creates a *StreamReaderWriter* instance. *stream* must be a file-like object. *Reader* and *Writer* must be factory functions or classes providing the *StreamReader* and *StreamWriter* interface resp. Error handling is done in the same way as defined for the stream readers and writers.

StreamReaderWriter instances define the combined interfaces of *StreamReader* and *StreamWriter* classes. They inherit all other methods and attributes from the underlying stream.

StreamRecoder Objects

The *StreamRecoder* translates data from one encoding to another, which is sometimes useful when dealing with different encoding environments.

The design is such that one can use the factory functions returned by the *lookup()* function to construct the instance.

class `codecs.StreamRecoder` (*stream*, *encode*, *decode*, *Reader*, *Writer*, *errors*='strict')

Creates a *StreamRecoder* instance which implements a two-way conversion: *encode* and *decode* work on the frontend—the data visible to code calling *read()* and *write()*, while *Reader* and *Writer* work on the backend—the data in *stream*.

You can use these objects to do transparent transcodings from e.g. Latin-1 to UTF-8 and back.

The *stream* argument must be a file-like object.

The *encode* and *decode* arguments must adhere to the `Codec` interface. *Reader* and *Writer* must be factory functions or classes providing objects of the *StreamReader* and *StreamWriter* interface respectively.

Error handling is done in the same way as defined for the stream readers and writers.

StreamRecoder instances define the combined interfaces of *StreamReader* and *StreamWriter* classes. They inherit all other methods and attributes from the underlying stream.

7.2.2 Encodings and Unicode

Strings are stored internally as sequences of code points in range 0x0–0x10FFFF. (See [PEP 393](#) for more details about the implementation.) Once a string object is used outside of CPU and memory, endianness and how these arrays are stored as bytes become an issue. As with other codecs, serialising a string into a sequence of bytes is known as *encoding*,

and recreating the string from the sequence of bytes is known as *decoding*. There are a variety of different text serialisation codecs, which are collectively referred to as *text encodings*.

The simplest text encoding (called 'latin-1' or 'iso-8859-1') maps the code points 0–255 to the bytes 0x0–0xff, which means that a string object that contains code points above U+00FF can't be encoded with this codec. Doing so will raise a `UnicodeEncodeError` that looks like the following (although the details of the error message may differ): `UnicodeEncodeError: 'latin-1' codec can't encode character '\u1234' in position 3: ordinal not in range(256)`.

There's another group of encodings (the so called charmap encodings) that choose a different subset of all Unicode code points and how these code points are mapped to the bytes 0x0–0xff. To see how this is done simply open e.g. `encodings/cp1252.py` (which is an encoding that is used primarily on Windows). There's a string constant with 256 characters that shows you which character is mapped to which byte value.

All of these encodings can only encode 256 of the 1114112 code points defined in Unicode. A simple and straightforward way that can store each Unicode code point, is to store each code point as four consecutive bytes. There are two possibilities: store the bytes in big endian or in little endian order. These two encodings are called UTF-32-BE and UTF-32-LE respectively. Their disadvantage is that if e.g. you use UTF-32-BE on a little endian machine you will always have to swap bytes on encoding and decoding. UTF-32 avoids this problem: bytes will always be in natural endianness. When these bytes are read by a CPU with a different endianness, then bytes have to be swapped though. To be able to detect the endianness of a UTF-16 or UTF-32 byte sequence, there's the so called BOM ("Byte Order Mark"). This is the Unicode character U+FEFF. This character can be prepended to every UTF-16 or UTF-32 byte sequence. The byte swapped version of this character (0xFFFE) is an illegal character that may not appear in a Unicode text. So when the first character in an UTF-16 or UTF-32 byte sequence appears to be a U+FFFE the bytes have to be swapped on decoding. Unfortunately the character U+FEFF had a second purpose as a ZERO WIDTH NO-BREAK SPACE: a character that has no width and doesn't allow a word to be split. It can e.g. be used to give hints to a ligature algorithm. With Unicode 4.0 using U+FEFF as a ZERO WIDTH NO-BREAK SPACE has been deprecated (with U+2060 (WORD JOINER) assuming this role). Nevertheless Unicode software still must be able to handle U+FEFF in both roles: as a BOM it's a device to determine the storage layout of the encoded bytes, and vanishes once the byte sequence has been decoded into a string; as a ZERO WIDTH NO-BREAK SPACE it's a normal character that will be decoded like any other.

There's another encoding that is able to encoding the full range of Unicode characters: UTF-8. UTF-8 is an 8-bit encoding, which means there are no issues with byte order in UTF-8. Each byte in a UTF-8 byte sequence consists of two parts: marker bits (the most significant bits) and payload bits. The marker bits are a sequence of zero to four 1 bits followed by a 0 bit. Unicode characters are encoded like this (with x being payload bits, which when concatenated give the Unicode character):

范围	编码
U-00000000 ... U-0000007F	0xxxxxxx
U-00000080 ... U-000007FF	110xxxxx 10xxxxxx
U-00000800 ... U-0000FFFF	1110xxxx 10xxxxxx 10xxxxxx
U-00010000 ... U-0010FFFF	11110xxx 10xxxxxx 10xxxxxx 10xxxxxx

The least significant bit of the Unicode character is the rightmost x bit.

As UTF-8 is an 8-bit encoding no BOM is required and any U+FEFF character in the decoded string (even if it's the first character) is treated as a ZERO WIDTH NO-BREAK SPACE.

Without external information it's impossible to reliably determine which encoding was used for encoding a string. Each charmap encoding can decode any random byte sequence. However that's not possible with UTF-8, as UTF-8 byte sequences have a structure that doesn't allow arbitrary byte sequences. To increase the reliability with which a UTF-8 encoding can be detected, Microsoft invented a variant of UTF-8 (that Python 2.5 calls "utf-8-sig") for its Notepad program: Before any of the Unicode characters is written to the file, a UTF-8 encoded BOM (which looks like this as a byte sequence: 0xef, 0xbb, 0xbf) is written. As it's rather improbable that any charmap encoded file starts with these byte values (which would e.g. map to

LATIN SMALL LETTER I WITH DIAERESIS
 RIGHT-POINTING DOUBLE ANGLE QUOTATION MARK
 INVERTED QUESTION MARK

in iso-8859-1), this increases the probability that a `utf-8-sig` encoding can be correctly guessed from the byte sequence. So here the BOM is not used to be able to determine the byte order used for generating the byte sequence, but as a signature that helps in guessing the encoding. On encoding the `utf-8-sig` codec will write `0xef, 0xbb, 0xbf` as the first three bytes to the file. On decoding `utf-8-sig` will skip those three bytes if they appear as the first three bytes in the file. In UTF-8, the use of the BOM is discouraged and should generally be avoided.

7.2.3 标准编码

Python comes with a number of codecs built-in, either implemented as C functions or with dictionaries as mapping tables. The following table lists the codecs by name, together with a few common aliases, and the languages for which the encoding is likely used. Neither the list of aliases nor the list of languages is meant to be exhaustive. Notice that spelling alternatives that only differ in case or use a hyphen instead of an underscore are also valid aliases; therefore, e.g. `'utf-8'` is a valid alias for the `'utf_8'` codec.

CPython implementation detail: Some common encodings can bypass the codecs lookup machinery to improve performance. These optimization opportunities are only recognized by CPython for a limited set of (case insensitive) aliases: `utf-8`, `utf8`, `latin-1`, `latin1`, `iso-8859-1`, `iso8859-1`, `mbcs` (Windows only), `ascii`, `us-ascii`, `utf-16`, `utf16`, `utf-32`, `utf32`, and the same using underscores instead of dashes. Using alternative aliases for these encodings may result in slower execution.

在 3.6 版更改: Optimization opportunity recognized for `us-ascii`.

Many of the character sets support the same languages. They vary in individual characters (e.g. whether the EURO SIGN is supported or not), and in the assignment of characters to code positions. For the European languages in particular, the following variants typically exist:

- an ISO 8859 codeset
- a Microsoft Windows code page, which is typically derived from an 8859 codeset, but replaces control characters with additional graphic characters
- an IBM EBCDIC code page
- an IBM PC code page, which is ASCII compatible

编码	别名	语言

utf_8_sig		所有语言

在 3.4 版更改: The utf-16* and utf-32* encoders no longer allow surrogate code points (U+D800–U+DFFF) to be encoded. The utf-32* decoders no longer decode byte sequences that correspond to surrogate code points.

7.2.4 Python Specific Encodings

A number of predefined codecs are specific to Python, so their codec names have no meaning outside Python. These are listed in the tables below based on the expected input and output types (note that while text encodings are the most common use case for codecs, the underlying codec infrastructure supports arbitrary data transforms rather than just text encodings). For asymmetric codecs, the stated purpose describes the encoding direction.

文字编码

The following codecs provide *str* to *bytes* encoding and *bytes-like object* to *str* decoding, similar to the Unicode text encodings.

编码	别名	目的
idna		Implements RFC 3490 , see also encodings.idna . Only <code>errors='strict'</code> is supported.
mbcs	ansi, dbcs	Windows only: Encode operand according to the ANSI codepage (CP_ACP)
oem		Windows only: Encode operand according to the OEM codepage (CP_OEMCP) 3.6 新版功能.
palmos		Encoding of PalmOS 3.5
punycode		Implements RFC 3492 . Stateful codecs are not supported.
raw_unicode_escape		Latin-1 encoding with <code>\uXXXX</code> and <code>\UXXXXXXXX</code> for other code points. Existing backslashes are not escaped in any way. It is used in the Python pickle protocol.
undefined		Raise an exception for all conversions, even empty strings. The error handler is ignored.
unicode_escape		Encoding suitable as the contents of a Unicode literal in ASCII-encoded Python source code, except that quotes are not escaped. Decodes from Latin-1 source code. Beware that Python source code actually uses UTF-8 by default.
unicode_internal		Return the internal representation of the operand. Stateful codecs are not supported. 3.3 版后已移除: This representation is obsoleted by PEP 393 .

二进制转换

The following codecs provide binary transforms: *bytes-like object* to *bytes* mappings. They are not supported by `bytes.decode()` (which only produces *str* output).

编码	别名	目的	编码器/解码器
base64_codec ¹	base64, base_64	Convert operand to multiline MIME base64 (the result always includes a trailing '\n') 在 3.4 版更改: accepts any <i>bytes-like object</i> as input for encoding and decoding	<code>base64.encodebytes()</code> / <code>base64.decodebytes()</code>
bz2_codec	bz2	使用 bz2 压缩操作数	<code>bz2.compress()</code> / <code>bz2.decompress()</code>
hex_codec	hex	将操作数转换为十六进制表示, 每个字节有两位数	<code>binascii.b2a_hex()</code> / <code>binascii.a2b_hex()</code>
quopri_codec	quopri, quotedprintable, quoted_printable	Convert operand to MIME quoted printable	<code>quopri.encode()</code> with <code>quotetabs=True</code> / <code>quopri.decode()</code>
uu_codec	uu	使用 uuencode 转换操作数	<code>uu.encode()</code> / <code>uu.decode()</code>
zlib_codec	zip, zlib	使用 gzip 压缩操作数	<code>zlib.compress()</code> / <code>zlib.decompress()</code>

3.2 新版功能: 恢复二进制转换。

在 3.4 版更改: 恢复二进制转换的别名。

文字转换

The following codec provides a text transform: a *str* to *str* mapping. It is not supported by `str.encode()` (which only produces *bytes* output).

编码	别名	目的
rot_13	rot13	Returns the Caesar-cypher encryption of the operand

3.2 新版功能: Restoration of the `rot_13` text transform.

在 3.4 版更改: Restoration of the `rot13` alias.

7.2.5 encodings.idna — 应用程序中的国际化域名

This module implements **RFC 3490** (Internationalized Domain Names in Applications) and **RFC 3492** (Nameprep: A Stringprep Profile for Internationalized Domain Names (IDN)). It builds upon the `punycode` encoding and `stringprep`.

These RFCs together define a protocol to support non-ASCII characters in domain names. A domain name containing non-ASCII characters (such as `www.Alliancefrançaise.nu`) is converted into an ASCII-compatible encoding (ACE, such as `www.xn--alliancefranaise-npb.nu`). The ACE form of the domain name is then used in all places where arbitrary characters are not allowed by the protocol, such as DNS queries, HTTP *Host* fields, and so on. This conversion is carried out in the application; if possible invisible to the user: The application should transparently convert Unicode domain labels to IDNA on the wire, and convert back ACE labels to Unicode before presenting them to the user.

¹ In addition to *bytes-like objects*, 'base64_codec' also accepts ASCII-only instances of *str* for decoding

Python supports this conversion in several ways: the `idna` codec performs conversion between Unicode and ACE, separating an input string into labels based on the separator characters defined in [section 3.1 of RFC 3490](#) and converting each label to ACE as required, and conversely separating an input byte string into labels based on the `.` separator and converting any ACE labels found into unicode. Furthermore, the `socket` module transparently converts Unicode host names to ACE, so that applications need not be concerned about converting host names themselves when they pass them to the `socket` module. On top of that, modules that have host names as function parameters, such as `http.client` and `ftplib`, accept Unicode host names (`http.client` then also transparently sends an IDNA hostname in the `Host` field if it sends that field at all).

When receiving host names from the wire (such as in reverse name lookup), no automatic conversion to Unicode is performed: Applications wishing to present such host names to the user should decode them to Unicode.

The module `encodings.idna` also implements the nameprep procedure, which performs certain normalizations on host names, to achieve case-insensitivity of international domain names, and to unify similar characters. The nameprep functions can be used directly if desired.

`encodings.idna.nameprep(label)`

Return the nameprepped version of *label*. The implementation currently assumes query strings, so `AllowUnassigned` is `true`.

`encodings.idna.ToASCII(label)`

Convert a label to ASCII, as specified in [RFC 3490](#). Use `STD3ASCIIRules` is assumed to be `false`.

`encodings.idna.ToUnicode(label)`

Convert a label to Unicode, as specified in [RFC 3490](#).

7.2.6 `encodings.mbc`s —Windows ANSI 代码页

根据 ANSI 代码页（CP_ACP）对操作数进行编码。

Availability: Windows only.

在 3.3 版更改: 支持任何错误处理

在 3.2 版更改: Before 3.2, the *errors* argument was ignored; `'replace'` was always used to encode, and `'ignore'` to decode.

7.2.7 `encodings.utf_8_sig` —带 BOM 签名的 UTF-8 编解码器

This module implements a variant of the UTF-8 codec: On encoding a UTF-8 encoded BOM will be prepended to the UTF-8 encoded bytes. For the stateful encoder this is only done once (on the first write to the byte stream). For decoding an optional UTF-8 encoded BOM at the start of the data will be skipped.

数据类型

本章节描述的模块提供了一系列专门的数据类型例如日期与实践，固定类型的数组，堆队列，同步队列与集合。

Python 同样提供一些内置的数据类型，特别的，`dict`，`list`，`set` 与 `fromzenset` 以及 `tuple`。`str` 类通常指 Unicode 字符串，并且 `bytes` 通常指二进制数据。

本章记录以下模块：

8.1 `datetime` — 基础日期和时间数据类型

源代码： [Lib/datetime.py](#)

`datetime` 模块提供了可以通过多种方式操作日期和时间的类。在支持日期时间数学运算的同时，实现的关注点更着重于如何能够更有效地解析其属性用于格式化输出和数据操作。相关功能可以参阅 `time` 和 `calendar` 模块。

有两种日期和时间的对象：天真型和觉悟型。

觉悟型对象有着用足以支持一些应用层面算法和国家层面时间调整的信息，例如时区和夏令时，来让自己和其他的觉悟型对象区别开来。觉悟型对象是用来表达不对解释器开放的特定时间信息¹。

天真型对象没包含足够多的信息来明确定位与之相关的“date”对象和“time”对象。天真型对象代表的是世界标准时间 (UTC)，当地时间或者是其它时区的时间完全取决于程序就像一个数字是代表的是米、英里或者质量完全取决于程序。天真型对象以忽略了一些现实情况的为代价使得它容易理解和使用。

对于需要觉悟型对象的应用，`datetime` 对象和 `time` 对象有一个可选的时区信息属性 `tzinfo`，这个属性可以设置给 `tzinfo` 类的子类实例。这些 `tzinfo` 对象捕获关于相对于世界标准时间 (UTC) 偏移、时区名字和夏令时是否有效等信息。需要注意的是，只有一个具体的 `tzinfo` 类，即由 `datetime` 模块提供的 `timezone` 类。`timezone` 类可以代表相对于世界标准时间 (UTC) 固定偏移的简单时区，比如世界标准时间 (UTC) 自己或者北美东部时间或者东部夏令时。支持时区的详细程度取决于应用。世界各地的时间调

¹ If, that is, we ignore the effects of Relativity

整规则相比理性更加政治性，经常会变更。也没有一个基于世界标准时间（UTC）的标准套件适合用于所有应用。

The `datetime` module exports the following constants:

`datetime.MINYEAR`

`date` 或者 `datetime` 对象允许的最小年份。常量 `MINYEAR` 是 1。

`datetime.MAXYEAR`

`date` 或 `datetime` 对象允许最大的年份。常量 `MAXYEAR` 是 9999。

参见:

模块 `calendar` 日历相关函数

模块 `time` 时间的访问和转换

8.1.1 有效的类型

class `datetime.date`

理想的天真型日期假设公历是永远有效的。属性: `year`, `month`, and `day`。

class `datetime.time`

一个理想的时间独立于任何一天，假设每一天一共有 24*60*60 秒（这里没有”闰秒”的概念）。属性: `hour`, `minute`, `second`, `microsecond`, 和 `tzinfo`。

class `datetime.datetime`

日期和时间的结合。属性: `year`, `month`, `day`, `hour`, `minute`, `second`, `microsecond`, and `tzinfo`。

class `datetime.timedelta`

表示两个 `date` 对象或者 `time` 对象, 或者 `datetime` 对象之间的时间间隔，精确到微秒。

class `datetime.tzinfo`

一个描述时区信息的抽象基类。用于给 `datetime` 类和 `time` 类提供自定义的时间调整概念（例如，负责时区或者夏令时）。

class `datetime.timezone`

一个实现了 `tzinfo` 抽象基类的子类，用于表示相对于世界标准时间（UTC）的偏移量。

3.2 新版功能.

这些类型的对象都是不可变的。

`date` 类型的对象都是天真型的。

An object of type `time` or `datetime` may be naive or aware. A `datetime` object `d` is aware if `d.tzinfo` is not `None` and `d.tzinfo.utcoffset(d)` does not return `None`. If `d.tzinfo` is `None`, or if `d.tzinfo` is not `None` but `d.tzinfo.utcoffset(d)` returns `None`, `d` is naive. A `time` object `t` is aware if `t.tzinfo` is not `None` and `t.tzinfo.utcoffset(None)` does not return `None`. Otherwise, `t` is naive.

天真型和觉悟型之间的差别不适用于 `timedelta` 对象。

子类关系

```
object
├── timedelta
├── tzinfo
│   └── timezone
├── time
├── date
│   └── datetime
```

8.1.2 timedelta 类对象

`timedelta` 对象表示两个 `date` 或者 `time` 的时间间隔。

class `datetime.timedelta` (`days=0, seconds=0, microseconds=0, milliseconds=0, minutes=0, hours=0, weeks=0`)

所有的参数都是可选的并且默认为 0。这些参数可以是整数或者浮点数，也可以是正数或者负数。

只有 `days`, `*seconds*` 和 `microseconds` 会存储在内部，即 python 内部以 `days`, `*seconds*` 和 `microseconds` 三个单位作为存储的基本单位。参数单位转换规则如下：

- 1 毫秒会转换成 1000 微秒。
- 1 分钟会转换成 60 秒。
- 1 小时会转换成 3600 秒。
- 1 星期会转换成 7 天。

`days`, `seconds`, `microseconds` 本身也是标准化的，以保证表达方式的唯一性，例：

- `0 <= microseconds < 1000000`
- `0 <= seconds < 3600*24` (一天的秒数)
- `-999999999 <= days <= 999999999`

在有任何浮点型参数或者微秒为小数的情况下，所有小数均会按照前面的换算规则叠加到下一级，并使用 `round-half-to-even` 的方法对微秒进行取舍。没有浮点型参数情况下，转换的过程就是精确的（没有信息丢失）。

如果标准化后的 `days` 数值超过了指定范围，将会抛出 `OverflowError` 异常。

需要注意的是，负数被标准化后的结果会让你大吃一惊。例如，

```
>>> from datetime import timedelta
>>> d = timedelta(microseconds=-1)
>>> (d.days, d.seconds, d.microseconds)
(-1, 86399, 999999)
```

类属性：

`timedelta.min`

The most negative `timedelta` object, `timedelta(-999999999)`.

`timedelta.max`

The most positive `timedelta` object, `timedelta(days=999999999, hours=23, minutes=59, seconds=59, microseconds=999999)`.

`timedelta.resolution`

两个不相等的 `timedelta` 类对象最小的间隔为 `timedelta(microseconds=1)`。

需要注意的是，因为标准化的缘故，`timedelta.max > -timedelta.min`，`-timedelta.max` 不可以表示一个 `timedelta` 类对象。

实例属性（只读）：

属性	值
<code>days</code>	-999999999 至 999999999，含 999999999
<code>seconds</code>	0 至 86399，包含 86399
<code>microseconds</code>	0 至 999999，包含 999999

支持的运算：

运算	结果
<code>t1 = t2 + t3</code>	<i>t2</i> 和 <i>t3</i> 的总和。 <i>t1-t2 == t3</i> 和 <i>t1-t3 == t2</i> 的值永远为真。(1)
<code>t1 = t2 - t3</code>	<i>t2</i> 减 <i>t3</i> 的差。 <i>t1 == t2 - t3</i> 和 <i>t2 == t1 + t3</i> 值为永远为的真。(1)(6)
<code>t1 = t2 * i or t1 = i * t2</code>	乘以一个整数。假如 <i>i != 0</i> 则 <i>t1 // i == t2</i> 的值为真。
	In general, <i>t1 * i == t1 * (i-1) + t1</i> is true. (1)
<code>t1 = t2 * f or t1 = f * t2</code>	乘以一个浮点数，小数结果使用 round-half-to-even 方式进行取舍。
<code>f = t2 / t3</code>	Division (3) of <i>t2</i> by <i>t3</i> . Returns a <i>float</i> object.
<code>t1 = t2 / f or t1 = t2 / i</code>	除以一个浮点数或者整数。小数结果采用 round-half-to-even 方法进行取舍。
<code>t1 = t2 // i or t1 = t2 // t3</code>	取整除，余数部分 (如果有的话) 将被丢弃。在第二种情况下，返回一个整数。(3)
<code>t1 = t2 % t3</code>	余数为一个 <i>timedelta</i> 对象。(3)
<code>q, r = divmod(t1, t2)</code>	通过: <i>q = t1 // t2</i> (3) and <i>r = t1 % t2</i> 计算出商和余数。 <i>q</i> 是一个整数， <i>r</i> 是一个 <i>timedelta</i> 对象。
<code>+t1</code>	返回一个相同数值的 <i>timedelta</i> 对象。
<code>-t1</code>	等价于 <i>timedelta(-t1.days, -t1.seconds, -t1.microseconds)</i> , 和 <i>t1 * -1</i> . (1)(4)
<code>abs(t)</code>	当 <i>t.days >= 0</i> 时等于 <i>+t</i> , 当 <i>t.days < 0</i> 时 <i>-t</i> 。(2)
<code>str(t)</code>	返回一个形如 <code>[D day[s],][H]H:MM:SS[.UUUUUU]</code> 的字符串，当 <i>t</i> 为负数的时候， <i>D</i> 也为负数。(5)
<code>repr(t)</code>	Returns a string in the form <code>datetime.timedelta(D[, S[, U]])</code> , where <i>D</i> is negative for negative <i>t</i> . (5)

注释:

- (1) 精确但可能会溢出。
- (2) 精确且不会溢出。
- (3) 除以 0 将会抛出异常 `ZeroDivisionError`。
- (4) `-timedelta.max` 不是一个 *timedelta* 类对象。
- (5) String representations of *timedelta* objects are normalized similarly to their internal representation. This leads to somewhat unusual results for negative timedeltas. For example:

```
>>> timedelta(hours=-5)
datetime.timedelta(-1, 68400)
>>> print(_)
-1 day, 19:00:00
```

- (6) 表达式 `t2 - t3` 通常与 `t2 + (-t3)` 是等价的，除非 *t3* 等于 `timedelta.max`; 在这种情况下前者会返回结果，而后者则会溢出。

除了上面列举的操作以外 *timedelta* 对象还支持与 *date* 和 *datetime* 对象进行特定的相加和相减运算 (见下文)。

在 3.2 版更改: Floor division and true division of a *timedelta* object by another *timedelta* object are now supported, as are remainder operations and the `divmod()` function. True division and multiplication of a *timedelta* object by a *float* object are now supported.

Comparisons of *timedelta* objects are supported with the *timedelta* object representing the smaller duration considered to be the smaller *timedelta*. In order to stop mixed-type comparisons from falling back to the default comparison by object address, when a *timedelta* object is compared to an object of a different type, `TypeError` is raised unless the comparison is `==` or `!=`. The latter cases return `False` or `True`, respectively.

`timedelta` 对象是 *hashable* 类型的 (可以作为字典关键字), 支持高效获取, 在布尔上下文中, `timedelta` 对象大多数情况下都被视为真, 仅在不等于 `timedelta(0)` 时。

实例方法:

`timedelta.total_seconds()`

Return the total number of seconds contained in the duration. Equivalent to `td / timedelta(seconds=1)`.

需要注意的是, 时间间隔较大时, 这个方法的结果中的微秒将会失真 (大多数平台上大于 270 年视为一个较大的时间间隔)。

3.2 新版功能.

用法示例:

```
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> another_year = timedelta(weeks=40, days=84, hours=23,
...                           minutes=50, seconds=600) # adds up to 365 days
>>> year.total_seconds()
31536000.0
>>> year == another_year
True
>>> ten_years = 10 * year
>>> ten_years, ten_years.days // 365
(datetime.timedelta(3650), 10)
>>> nine_years = ten_years - year
>>> nine_years, nine_years.days // 365
(datetime.timedelta(3285), 9)
>>> three_years = nine_years // 3;
>>> three_years, three_years.days // 365
(datetime.timedelta(1095), 3)
>>> abs(three_years - ten_years) == 2 * three_years + year
True
```

8.1.3 date 对象

A *date* object represents a date (year, month and day) in an idealized calendar, the current Gregorian calendar indefinitely extended in both directions. January 1 of year 1 is called day number 1, January 2 of year 1 is called day number 2, and so on. This matches the definition of the “proleptic Gregorian” calendar in Dershowitz and Reingold’s book *Calendrical Calculations*, where it’s the base calendar for all computations. See the book for algorithms for converting between proleptic Gregorian ordinals and many other calendar systems.

class `datetime.date` (*year, month, day*)

所有参数都是必选的。参数可以是在下面范围内的整数:

- `MINYEAR <= year <= MAXYEAR`
- `1 <= month <= 12`
- `1 <= 日期 <= 给定年月对应的天数`

如果参数不在这些范围内, 则抛出 `ValueError` 异常。

其它构造器, 所有的类方法:

classmethod `date.today()`

返回当地的当前日期。与 “`date.fromtimestamp(time.time())`” 等价。

classmethod `date.fromtimestamp` (*timestamp*)

Return the local date corresponding to the POSIX timestamp, such as is returned by `time.time()`. This

may raise `OverflowError`, if the timestamp is out of the range of values supported by the platform C `localtime()` function, and `OSError` on `localtime()` failure. It's common for this to be restricted to years from 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`.

在 3.3 版更改: Raise `OverflowError` instead of `ValueError` if the timestamp is out of the range of values supported by the platform C `localtime()` function. Raise `OSError` instead of `ValueError` on `localtime()` failure.

classmethod `date.fromordinal(ordinal)`

Return the date corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1. `ValueError` is raised unless $1 \leq \text{ordinal} \leq \text{date.max.toordinal}()$. For any date *d*, `date.fromordinal(d.toordinal()) == d`.

类属性:

`date.min`

最小的日期 `date(MINYEAR, 1, 1)`。

`date.max`

最大的日期, `date(MAXYEAR, 12, 31)`。

`date.resolution`

两个日期对象的最小间隔, `timedelta(days=1)`。

实例属性 (只读):

`date.year`

在 `MINYEAR` 和 `MAXYEAR` 之间, 包含边界。

`date.month`

1 至 12 (含)

`date.day`

返回 1 到指定年月的天数间的数字。

支持的运算:

运算	结果
<code>date2 = date1 + timedelta</code>	<i>date2</i> is <code>timedelta.days</code> days removed from <i>date1</i> . (1)
<code>date2 = date1 - timedelta</code>	Computes <i>date2</i> such that <code>date2 + timedelta == date1</code> . (2)
<code>timedelta = date1 - date2</code>	(3)
<code>date1 < date2</code>	<i>date1</i> is considered less than <i>date2</i> when <i>date1</i> precedes <i>date2</i> in time. (4)

注释:

- (1) *date2* is moved forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. Afterward `date2 - date1 == timedelta.days`. `timedelta.seconds` and `timedelta.microseconds` are ignored. `OverflowError` is raised if `date2.year` would be smaller than `MINYEAR` or larger than `MAXYEAR`.
- (2) `timedelta.seconds` 和 `timedelta.microseconds` 是被忽略的。
- (3) 精确且不会溢出。`timedelta.seconds` 和 `timedelta.microseconds` 均为 0, 同时 `date2 + timedelta == date1` 是成立的。
- (4) In other words, `date1 < date2` if and only if `date1.toordinal() < date2.toordinal()`. Date comparison raises `TypeError` if the other comparand isn't also a `date` object. However, `NotImplemented` is returned instead if the other comparand has a `timetuple()` attribute. This hook gives other kinds of date objects a chance at implementing mixed-type comparison. If not, when a `date` object is compared to an object

of a different type, `TypeError` is raised unless the comparison is `==` or `!=`. The latter cases return `False` or `True`, respectively.

日期可以作为字典的关键字。在布尔上下文中，所有的`date`对象都视为真。

实例方法：

`date.replace(year=self.year, month=self.month, day=self.day)`

Return a date with the same value, except for those parameters given new values by whichever keyword arguments are specified. For example, if `d == date(2002, 12, 31)`, then `d.replace(day=26) == date(2002, 12, 26)`.

`date.timetuple()`

Return a `time.struct_time` such as returned by `time.localtime()`. The hours, minutes and seconds are 0, and the DST flag is -1. `d.timetuple()` is equivalent to `time.struct_time((d.year, d.month, d.day, 0, 0, 0, d.weekday(), yday, -1))`, where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st.

`date.toordinal()`

Return the proleptic Gregorian ordinal of the date, where January 1 of year 1 has ordinal 1. For any `date` object `d`, `date.fromordinal(d.toordinal()) == d`.

`date.weekday()`

返回一个整数代表星期几，星期一为 0，星期天为 6。例如，`date(2002, 12, 4).weekday() == 2`，表示的是星期三。参阅 `isoweekday()`。

`date.isoweekday()`

返回一个整数代表星期几，星期一为 1，星期天为 7。例如：`date(2002, 12, 4).isoweekday() == 3`，表示星期三。参见 `weekday()`，`isocalendar()`。

`date.isocalendar()`

返回一个三元组，(ISO year, ISO week number, ISO weekday)。

ISO 日历是一个被广泛使用的公历。可以从 <https://www.staff.science.uu.nl/~gent0113/calendar/isocalendar.htm> 上查看更完整的说明。

The ISO year consists of 52 or 53 full weeks, and where a week starts on a Monday and ends on a Sunday. The first week of an ISO year is the first (Gregorian) calendar week of a year containing a Thursday. This is called week number 1, and the ISO year of that Thursday is the same as its Gregorian year.

For example, 2004 begins on a Thursday, so the first week of ISO year 2004 begins on Monday, 29 Dec 2003 and ends on Sunday, 4 Jan 2004, so that `date(2003, 12, 29).isocalendar() == (2004, 1, 1)` and `date(2004, 1, 4).isocalendar() == (2004, 1, 7)`.

`date.isoformat()`

返回一个 ISO 8601 格式的字符串，'YYYY-MM-DD'。例如 `date(2002, 12, 4).isoformat() == '2002-12-04'`。

`date.__str__()`

对于日期对象 `d`，`str(d)` 等价于 `d.isoformat()`。

`date.ctime()`

Return a string representing the date, for example `date(2002, 12, 4).ctime() == 'Wed Dec 4 00:00:00 2002'`. `d.ctime()` is equivalent to `time.ctime(time.mktime(d.timetuple()))` on platforms where the native C `ctime()` function (which `time.ctime()` invokes, but which `date.ctime()` does not invoke) conforms to the C standard.

`date.strftime(format)`

Return a string representing the date, controlled by an explicit format string. Format codes referring to hours,

minutes or seconds will see 0 values. For a complete list of formatting directives, see *strftime()* and *strptime() Behavior*.

`date.__format__ (format)`

Same as *date.strftime()*. This makes it possible to specify a format string for a *date* object in formatted string literals and when using *str.format()*. For a complete list of formatting directives, see *strftime()* and *strptime() Behavior*.

Example of counting days to an event:

```
>>> import time
>>> from datetime import date
>>> today = date.today()
>>> today
datetime.date(2007, 12, 5)
>>> today == date.fromtimestamp(time.time())
True
>>> my_birthday = date(today.year, 6, 24)
>>> if my_birthday < today:
...     my_birthday = my_birthday.replace(year=today.year + 1)
>>> my_birthday
datetime.date(2008, 6, 24)
>>> time_to_birthday = abs(my_birthday - today)
>>> time_to_birthday.days
202
```

Example of working with *date*:

```
>>> from datetime import date
>>> d = date.fromordinal(730920) # 730920th day after 1. 1. 0001
>>> d
datetime.date(2002, 3, 11)
>>> t = d.timetuple()
>>> for i in t:
...     print(i)
2002          # year
3             # month
11            # day
0
0
0
0             # weekday (0 = Monday)
70            # 70th day in the year
-1
>>> ic = d.isocalendar()
>>> for i in ic:
...     print(i)
2002          # ISO year
11            # ISO week number
1             # ISO day number ( 1 = Monday )
>>> d.isoformat()
'2002-03-11'
>>> d.strftime("%d/%m/%y")
'11/03/02'
>>> d.strftime("%A %d. %B %Y")
'Monday 11. March 2002'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}.'.format(d, "day", "month")
'The day is 11, the month is March.'
```

8.1.4 `datetime` 对象

A `datetime` object is a single object containing all the information from a `date` object and a `time` object. Like a `date` object, `datetime` assumes the current Gregorian calendar extended in both directions; like a time object, `datetime` assumes there are exactly 3600*24 seconds in every day.

构造器:

class `datetime.datetime`(*year, month, day, hour=0, minute=0, second=0, microsecond=0, tzinfo=None, *, fold=0*)

`year, month, day` 三个参数是必选的。`tzinfo` 可以是 `None`, 或者是是一个 `tzinfo` 子类的实例。其余的参数可以是在以下范围内的整数:

- `MINYEAR <= year <= MAXYEAR`,
- `1 <= month <= 12`,
- `1 <= day <= 指定年月的天数`,
- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- `fold` in `[0, 1]`.

如果参数不在这些范围内, 则抛出 `ValueError` 异常。

3.6 新版功能: 增加了 `fold` 参数。

其它构造器, 所有的类方法:

classmethod `datetime.today()`

Return the current local datetime, with `tzinfo` `None`. This is equivalent to `datetime.fromtimestamp(time.time())`. See also `now()`, `fromtimestamp()`.

classmethod `datetime.now`(*tz=None*)

Return the current local date and time. If optional argument `tz` is `None` or not specified, this is like `today()`, but, if possible, supplies more precision than can be gotten from going through a `time.time()` timestamp (for example, this may be possible on platforms supplying the C `gettimeofday()` function).

If `tz` is not `None`, it must be an instance of a `tzinfo` subclass, and the current date and time are converted to `tz`'s time zone. In this case the result is equivalent to `tz.fromutc(datetime.utcnow()).replace(tzinfo=tz)`. See also `today()`, `utcnow()`.

classmethod `datetime.utcnow()`

Return the current UTC date and time, with `tzinfo` `None`. This is like `now()`, but returns the current UTC date and time, as a naive `datetime` object. An aware current UTC datetime can be obtained by calling `datetime.now(timezone.utc)`. See also `now()`.

classmethod `datetime.fromtimestamp`(*timestamp, tz=None*)

Return the local date and time corresponding to the POSIX timestamp, such as is returned by `time.time()`. If optional argument `tz` is `None` or not specified, the timestamp is converted to the platform's local date and time, and the returned `datetime` object is naive.

If `tz` is not `None`, it must be an instance of a `tzinfo` subclass, and the timestamp is converted to `tz`'s time zone. In this case the result is equivalent to `tz.fromutc(datetime.utcfromtimestamp(timestamp)).replace(tzinfo=tz)`.

`fromtimestamp()` may raise `OverflowError`, if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions, and `OSError` on `localtime()` or `gmtime()`

failure. It's common for this to be restricted to years in 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`, and then it's possible to have two timestamps differing by a second that yield identical `datetime` objects. See also `utcfromtimestamp()`.

在 3.3 版更改: Raise `OverflowError` instead of `ValueError` if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions. Raise `OSError` instead of `ValueError` on `localtime()` or `gmtime()` failure.

在 3.6 版更改: `fromtimestamp()` may return instances with `fold` set to 1.

classmethod `datetime.utcnow(timestamp)`

Return the UTC `datetime` corresponding to the POSIX timestamp, with `tzinfo` None. This may raise `OverflowError`, if the timestamp is out of the range of values supported by the platform C `gmtime()` function, and `OSError` on `gmtime()` failure. It's common for this to be restricted to years in 1970 through 2038.

To get an aware `datetime` object, call `fromtimestamp()`:

```
datetime.fromtimestamp(timestamp, timezone.utc)
```

On the POSIX compliant platforms, it is equivalent to the following expression:

```
datetime(1970, 1, 1, tzinfo=timezone.utc) + timedelta(seconds=timestamp)
```

except the latter formula always supports the full years range: between `MINYEAR` and `MAXYEAR` inclusive.

在 3.3 版更改: Raise `OverflowError` instead of `ValueError` if the timestamp is out of the range of values supported by the platform C `gmtime()` function. Raise `OSError` instead of `ValueError` on `gmtime()` failure.

classmethod `datetime.fromordinal(ordinal)`

Return the `datetime` corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1. `ValueError` is raised unless $1 \leq \text{ordinal} \leq \text{datetime.max.toordinal}()$. The hour, minute, second and microsecond of the result are all 0, and `tzinfo` is None.

classmethod `datetime.combine(date, time, tzinfo=self.tzinfo)`

Return a new `datetime` object whose date components are equal to the given `date` object's, and whose time components are equal to the given `time` object's. If the `tzinfo` argument is provided, its value is used to set the `tzinfo` attribute of the result, otherwise the `tzinfo` attribute of the `time` argument is used.

For any `datetime` object `d`, `d == datetime.combine(d.date(), d.time(), d.tzinfo)`. If `date` is a `datetime` object, its time components and `tzinfo` attributes are ignored.

在 3.6 版更改: Added the `tzinfo` argument.

classmethod `datetime.strptime(date_string, format)`

Return a `datetime` corresponding to `date_string`, parsed according to `format`. This is equivalent to `datetime(*(time.strptime(date_string, format)[0:6]))`. `ValueError` is raised if the `date_string` and `format` can't be parsed by `time.strptime()` or if it returns a value which isn't a time tuple. For a complete list of formatting directives, see `strftime()` and `strptime() Behavior`.

类属性:

`datetime.min`

The earliest representable `datetime`, `datetime(MINYEAR, 1, 1, tzinfo=None)`.

`datetime.max`

The latest representable `datetime`, `datetime(MAXYEAR, 12, 31, 23, 59, 59, 999999, tzinfo=None)`.

`datetime.resolution`

The smallest possible difference between non-equal `datetime` objects, `timedelta(microseconds=1)`.

实例属性（只读）：

`datetime.year`

在`MINYEAR`和`MAXYEAR`之间，包含边界。

`datetime.month`

1 至 12（含）

`datetime.day`

返回 1 到指定年月的天数间的数字。

`datetime.hour`

In range(24).

`datetime.minute`

In range(60).

`datetime.second`

In range(60).

`datetime.microsecond`

In range(1000000).

`datetime.tzinfo`

The object passed as the `tzinfo` argument to the `datetime` constructor, or None if none was passed.

`datetime.fold`

In [0, 1]. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The value 0 (1) represents the earlier (later) of the two moments with the same wall time representation.

3.6 新版功能.

支持的运算：

运算	结果
<code>datetime2 = datetime1 + timedelta</code>	(1)
<code>datetime2 = datetime1 - timedelta</code>	(2)
<code>timedelta = datetime1 - datetime2</code>	(3)
<code>datetime1 < datetime2</code>	Compares <code>datetime</code> to <code>datetime</code> . (4)

- (1) `datetime2` is a duration of `timedelta` removed from `datetime1`, moving forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. The result has the same `tzinfo` attribute as the input `datetime`, and `datetime2 - datetime1 == timedelta` after. `OverflowError` is raised if `datetime2.year` would be smaller than `MINYEAR` or larger than `MAXYEAR`. Note that no time zone adjustments are done even if the input is an aware object.
- (2) Computes the `datetime2` such that `datetime2 + timedelta == datetime1`. As for addition, the result has the same `tzinfo` attribute as the input `datetime`, and no time zone adjustments are done even if the input is aware.
- (3) Subtraction of a `datetime` from a `datetime` is defined only if both operands are naive, or if both are aware. If one is aware and the other is naive, `TypeError` is raised.

If both are naive, or both are aware and have the same `tzinfo` attribute, the `tzinfo` attributes are ignored, and the result is a `timedelta` object `t` such that `datetime2 + t == datetime1`. No time zone adjustments are done in this case.

If both are aware and have different `tzinfo` attributes, `a-b` acts as if `a` and `b` were first converted to naive UTC datetimes first. The result is `(a.replace(tzinfo=None) - a.utcoffset()) - (b.replace(tzinfo=None) - b.utcoffset())` except that the implementation never overflows.

- (4) *datetime1* is considered less than *datetime2* when *datetime1* precedes *datetime2* in time.

If one comparand is naive and the other is aware, *TypeError* is raised if an order comparison is attempted. For equality comparisons, naive instances are never equal to aware instances.

If both comparands are aware, and have the same *tzinfo* attribute, the common *tzinfo* attribute is ignored and the base datetimes are compared. If both comparands are aware and have different *tzinfo* attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`).

在 3.3 版更改: Equality comparisons between naive and aware *datetime* instances don't raise *TypeError*.

注解: In order to stop comparison from falling back to the default scheme of comparing object addresses, *datetime* comparison normally raises *TypeError* if the other comparand isn't also a *datetime* object. However, *NotImplemented* is returned instead if the other comparand has a `timetuple()` attribute. This hook gives other kinds of date objects a chance at implementing mixed-type comparison. If not, when a *datetime* object is compared to an object of a different type, *TypeError* is raised unless the comparison is `==` or `!=`. The latter cases return *False* or *True*, respectively.

datetime objects can be used as dictionary keys. In Boolean contexts, all *datetime* objects are considered to be true.

实例方法:

`datetime.date()`

Return *date* object with same year, month and day.

`datetime.time()`

Return *time* object with same hour, minute, second, microsecond and fold. *tzinfo* is None. See also method `timetz()`.

在 3.6 版更改: The fold value is copied to the returned *time* object.

`datetime.timetz()`

Return *time* object with same hour, minute, second, microsecond, fold, and *tzinfo* attributes. See also method `time()`.

在 3.6 版更改: The fold value is copied to the returned *time* object.

`datetime.replace(year=self.year, month=self.month, day=self.day, hour=self.hour, minute=self.minute, second=self.second, microsecond=self.microsecond, tzinfo=self.tzinfo, *fold=0)`

Return a *datetime* with the same attributes, except for those attributes given new values by whichever keyword arguments are specified. Note that *tzinfo*=None can be specified to create a naive *datetime* from an aware *datetime* with no conversion of date and time data.

3.6 新版功能: 增加了 *fold* 参数。

`datetime.astimezone(tz=None)`

Return a *datetime* object with new *tzinfo* attribute *tz*, adjusting the date and time data so the result is the same UTC time as *self*, but in *tz*'s local time.

If provided, *tz* must be an instance of a *tzinfo* subclass, and its `utcoffset()` and `dst()` methods must not return None. If *self* is naive, it is presumed to represent time in the system timezone.

If called without arguments (or with *tz*=None) the system local timezone is assumed for the target timezone. The *.tzinfo* attribute of the converted *datetime* instance will be set to an instance of *timezone* with the zone name and offset obtained from the OS.

If *self.tzinfo* is *tz*, *self.astimezone(tz)* is equal to *self*: no adjustment of date or time data is performed. Else the result is local time in the timezone *tz*, representing the same UTC time as *self*: after `astz = dt.astimezone(tz)`, `astz - astz.utcoffset()` will have the same date and time data as `dt - dt.utcoffset()`.

If you merely want to attach a time zone object *tz* to a datetime *dt* without adjustment of date and time data, use `dt.replace(tzinfo=tz)`. If you merely want to remove the time zone object from an aware datetime *dt* without conversion of date and time data, use `dt.replace(tzinfo=None)`.

Note that the default `tzinfo.fromutc()` method can be overridden in a `tzinfo` subclass to affect the result returned by `astimezone()`. Ignoring error cases, `astimezone()` acts like:

```
def astimezone(self, tz):
    if self.tzinfo is tz:
        return self
    # Convert self to UTC, and attach the new time zone object.
    utc = (self - self.utcoffset()).replace(tzinfo=tz)
    # Convert from UTC to tz's local time.
    return tz.fromutc(utc)
```

在 3.3 版更改: *tz* now can be omitted.

在 3.6 版更改: The `astimezone()` method can now be called on naive instances that are presumed to represent system local time.

`datetime.utcoffset()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.utcoffset(self)`, and raises an exception if the latter doesn't return `None`, or a `timedelta` object representing a whole number of minutes with magnitude less than one day.

`datetime.dst()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.dst(self)`, and raises an exception if the latter doesn't return `None`, or a `timedelta` object representing a whole number of minutes with magnitude less than one day.

`datetime.tzname()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.tzname(self)`, raises an exception if the latter doesn't return `None` or a string object,

`datetime.timetuple()`

Return a `time.struct_time` such as returned by `time.localtime()`. `d.timetuple()` is equivalent to `time.struct_time((d.year, d.month, d.day, d.hour, d.minute, d.second, d.weekday(), yday, dst))`, where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st. The `tm_isdst` flag of the result is set according to the `dst()` method: `tzinfo` is `None` or `dst()` returns `None`, `tm_isdst` is set to -1; else if `dst()` returns a non-zero value, `tm_isdst` is set to 1; else `tm_isdst` is set to 0.

`datetime.utctimetuple()`

If `datetime` instance *d* is naive, this is the same as `d.timetuple()` except that `tm_isdst` is forced to 0 regardless of what `d.dst()` returns. DST is never in effect for a UTC time.

If *d* is aware, *d* is normalized to UTC time, by subtracting `d.utcoffset()`, and a `time.struct_time` for the normalized time is returned. `tm_isdst` is forced to 0. Note that an `OverflowError` may be raised if *d.year* was `MINYEAR` or `MAXYEAR` and UTC adjustment spills over a year boundary.

`datetime.toordinal()`

Return the proleptic Gregorian ordinal of the date. The same as `self.date().toordinal()`.

`datetime.timestamp()`

Return POSIX timestamp corresponding to the `datetime` instance. The return value is a `float` similar to that returned by `time.time()`.

Naive `datetime` instances are assumed to represent local time and this method relies on the platform `C mktime()` function to perform the conversion. Since `datetime` supports wider range of values than

`mktime()` on many platforms, this method may raise `OverflowError` for times far in the past or far in the future.

For aware `datetime` instances, the return value is computed as:

```
(dt - datetime(1970, 1, 1, tzinfo=timezone.utc)).total_seconds()
```

3.3 新版功能.

在 3.6 版更改: The `timestamp()` method uses the `fold` attribute to disambiguate the times during a repeated interval.

注解: There is no method to obtain the POSIX timestamp directly from a naive `datetime` instance representing UTC time. If your application uses this convention and your system timezone is not set to UTC, you can obtain the POSIX timestamp by supplying `tzinfo=timezone.utc`:

```
timestamp = dt.replace(tzinfo=timezone.utc).timestamp()
```

or by calculating the timestamp directly:

```
timestamp = (dt - datetime(1970, 1, 1)) / timedelta(seconds=1)
```

`datetime.weekday()`

Return the day of the week as an integer, where Monday is 0 and Sunday is 6. The same as `self.date().weekday()`. See also `isoweekday()`.

`datetime.isoweekday()`

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. The same as `self.date().isoweekday()`. See also `weekday()`, `isocalendar()`.

`datetime.isocalendar()`

Return a 3-tuple, (ISO year, ISO week number, ISO weekday). The same as `self.date().isocalendar()`.

`datetime.isoformat(sep='T', timespec='auto')`

Return a string representing the date and time in ISO 8601 format, YYYY-MM-DDTHH:MM:SS.mmmmmmm or, if `microsecond` is 0, YYYY-MM-DDTHH:MM:SS

If `utcoffset()` does not return `None`, a 6-character string is appended, giving the UTC offset in (signed) hours and minutes: YYYY-MM-DDTHH:MM:SS.mmmmmmm+HH:MM or, if `microsecond` is 0 YYYY-MM-DDTHH:MM:SS+HH:MM

The optional argument `sep` (default 'T') is a one-character separator, placed between the date and time portions of the result. For example,

```
>>> from datetime import tzinfo, timedelta, datetime
>>> class TZ(tzinfo):
...     def utcoffset(self, dt): return timedelta(minutes=-399)
...
>>> datetime(2002, 12, 25, tzinfo=TZ()).isoformat(' ')
'2002-12-25 00:00:00-06:39'
```

The optional argument `timespec` specifies the number of additional components of the time to include (the default is 'auto'). It can be one of the following:

- 'auto': Same as 'seconds' if `microsecond` is 0, same as 'microseconds' otherwise.
- 'hours': Include the `hour` in the two-digit HH format.
- 'minutes': Include `hour` and `minute` in HH:MM format.

- 'seconds': Include *hour*, *minute*, and *second* in HH:MM:SS format.
- 'milliseconds': Include full time, but truncate fractional second part to milliseconds. HH:MM:SS.sss format.
- 'microseconds': Include full time in HH:MM:SS.mmmmmm format.

注解: Excluded time components are truncated, not rounded.

`ValueError` will be raised on an invalid *timespec* argument.

```
>>> from datetime import datetime
>>> datetime.now().isoformat(timespec='minutes')
'2002-12-25T00:00'
>>> dt = datetime(2015, 1, 1, 12, 30, 59, 0)
>>> dt.isoformat(timespec='microseconds')
'2015-01-01T12:30:59.000000'
```

3.6 新版功能: Added the *timespec* argument.

`datetime.__str__()`

For a *datetime* instance *d*, `str(d)` is equivalent to `d.isoformat(' ')`.

`datetime.ctime()`

Return a string representing the date and time, for example `datetime(2002, 12, 4, 20, 30, 40).ctime() == 'Wed Dec 4 20:30:40 2002'`. `d.ctime()` is equivalent to `time.ctime(time.mktime(d.timetuple()))` on platforms where the native C `ctime()` function (which *time.ctime()* invokes, but which *datetime.ctime()* does not invoke) conforms to the C standard.

`datetime.strftime(format)`

Return a string representing the date and time, controlled by an explicit format string. For a complete list of formatting directives, see *strftime() and strptime() Behavior*.

`datetime.__format__(format)`

Same as *datetime.strftime()*. This makes it possible to specify a format string for a *datetime* object in formatted string literals and when using *str.format()*. For a complete list of formatting directives, see *strftime() and strptime() Behavior*.

Examples of working with datetime objects:

```
>>> from datetime import datetime, date, time
>>> # Using datetime.combine()
>>> d = date(2005, 7, 14)
>>> t = time(12, 30)
>>> datetime.combine(d, t)
datetime.datetime(2005, 7, 14, 12, 30)
>>> # Using datetime.now() or datetime.utcnow()
>>> datetime.now()
datetime.datetime(2007, 12, 6, 16, 29, 43, 79043) # GMT +1
>>> datetime.utcnow()
datetime.datetime(2007, 12, 6, 15, 29, 43, 79060)
>>> # Using datetime.strptime()
>>> dt = datetime.strptime("21/11/06 16:30", "%d/%m/%y %H:%M")
>>> dt
datetime.datetime(2006, 11, 21, 16, 30)
>>> # Using datetime.timetuple() to get tuple of all attributes
>>> tt = dt.timetuple()
>>> for it in tt:
```

(下页继续)

(续上页)

```

...     print(it)
...
2006    # year
11      # month
21      # day
16      # hour
30      # minute
0       # second
1       # weekday (0 = Monday)
325     # number of days since 1st January
-1      # dst - method tzinfo.dst() returned None
>>> # Date in ISO format
>>> ic = dt.isocalendar()
>>> for it in ic:
...     print(it)
...
2006    # ISO year
47      # ISO week
2       # ISO weekday
>>> # Formatting datetime
>>> dt.strftime("%A, %d. %B %Y %I:%M%p")
'Tuesday, 21. November 2006 04:30PM'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}, the {3} is {0:%I:%M%p}.'.format(dt, "day",
↪ "month", "time")
'The day is 21, the month is November, the time is 04:30PM.'

```

Using datetime with tzinfo:

```

>>> from datetime import timedelta, datetime, tzinfo
>>> class GMT1(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=1) + self.dst(dt)
...     def dst(self, dt):
...         # DST starts last Sunday in March
...         d = datetime(dt.year, 4, 1) # ends last Sunday in October
...         self.dston = d - timedelta(days=d.weekday() + 1)
...         d = datetime(dt.year, 11, 1)
...         self.dstoff = d - timedelta(days=d.weekday() + 1)
...         if self.dston <= dt.replace(tzinfo=None) < self.dstoff:
...             return timedelta(hours=1)
...         else:
...             return timedelta(0)
...     def tzname(self, dt):
...         return "GMT +1"
...
>>> class GMT2(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=2) + self.dst(dt)
...     def dst(self, dt):
...         d = datetime(dt.year, 4, 1)
...         self.dston = d - timedelta(days=d.weekday() + 1)
...         d = datetime(dt.year, 11, 1)
...         self.dstoff = d - timedelta(days=d.weekday() + 1)
...         if self.dston <= dt.replace(tzinfo=None) < self.dstoff:
...             return timedelta(hours=1)
...         else:

```

(下页继续)

(续上页)

```

...         return timedelta(0)
...     def tzname(self, dt):
...         return "GMT +2"
...
>>> gmt1 = GMT1()
>>> # Daylight Saving Time
>>> dt1 = datetime(2006, 11, 21, 16, 30, tzinfo=gmt1)
>>> dt1.dst()
datetime.timedelta(0)
>>> dt1.utcoffset()
datetime.timedelta(0, 3600)
>>> dt2 = datetime(2006, 6, 14, 13, 0, tzinfo=gmt1)
>>> dt2.dst()
datetime.timedelta(0, 3600)
>>> dt2.utcoffset()
datetime.timedelta(0, 7200)
>>> # Convert datetime to another time zone
>>> dt3 = dt2.astimezone(GMT2())
>>> dt3      # doctest: +ELLIPSIS
datetime.datetime(2006, 6, 14, 14, 0, tzinfo=<GMT2 object at 0x...>)
>>> dt2      # doctest: +ELLIPSIS
datetime.datetime(2006, 6, 14, 13, 0, tzinfo=<GMT1 object at 0x...>)
>>> dt2.utctimetuple() == dt3.utctimetuple()
True

```

8.1.5 time Objects

A time object represents a (local) time of day, independent of any particular day, and subject to adjustment via a *tzinfo* object.

class `datetime.time` (*hour=0, minute=0, second=0, microsecond=0, tzinfo=None, *, fold=0*)

All arguments are optional. *tzinfo* may be *None*, or an instance of a *tzinfo* subclass. The remaining arguments may be integers, in the following ranges:

- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- `fold` in `[0, 1]`.

If an argument outside those ranges is given, *ValueError* is raised. All default to 0 except *tzinfo*, which defaults to *None*.

类属性:

`time.min`

The earliest representable *time*, `time(0, 0, 0, 0)`.

`time.max`

The latest representable *time*, `time(23, 59, 59, 999999)`.

`time.resolution`

The smallest possible difference between non-equal *time* objects, `timedelta(microseconds=1)`, although note that arithmetic on *time* objects is not supported.

实例属性（只读）：

`time.hour`
In range(24).

`time.minute`
In range(60).

`time.second`
In range(60).

`time.microsecond`
In range(1000000).

`time.tzinfo`
The object passed as the `tzinfo` argument to the `time` constructor, or `None` if none was passed.

`time.fold`
In [0, 1]. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The value 0 (1) represents the earlier (later) of the two moments with the same wall time representation.

3.6 新版功能.

支持的运算：

- comparison of `time` to `time`, where *a* is considered less than *b* when *a* precedes *b* in time. If one comparand is naive and the other is aware, `TypeError` is raised if an order comparison is attempted. For equality comparisons, naive instances are never equal to aware instances.

If both comparands are aware, and have the same `tzinfo` attribute, the common `tzinfo` attribute is ignored and the base times are compared. If both comparands are aware and have different `tzinfo` attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`). In order to stop mixed-type comparisons from falling back to the default comparison by object address, when a `time` object is compared to an object of a different type, `TypeError` is raised unless the comparison is `==` or `!=`. The latter cases return `False` or `True`, respectively.

在 3.3 版更改: Equality comparisons between naive and aware `time` instances don't raise `TypeError`.

- hash, use as dict key
- efficient pickling

In boolean contexts, a `time` object is always considered to be true.

在 3.5 版更改: Before Python 3.5, a `time` object was considered to be false if it represented midnight in UTC. This behavior was considered obscure and error-prone and has been removed in Python 3.5. See [bpo-13936](#) for full details.

实例方法：

`time.replace(hour=self.hour, minute=self.minute, second=self.second, microsecond=self.microsecond, tzinfo=self.tzinfo, *fold=0)`

Return a `time` with the same value, except for those attributes given new values by whichever keyword arguments are specified. Note that `tzinfo=None` can be specified to create a naive `time` from an aware `time`, without conversion of the time data.

3.6 新版功能: 增加了 `fold` 参数。

`time.isoformat(timespec='auto')`

Return a string representing the time in ISO 8601 format, HH:MM:SS.mmmmmmm or, if `microsecond` is 0, HH:MM:SS If `utcoffset()` does not return `None`, a 6-character string is appended, giving the UTC offset in (signed) hours and minutes: HH:MM:SS.mmmmmmm+HH:MM or, if `self.microsecond` is 0, HH:MM:SS+HH:MM

The optional argument *timespec* specifies the number of additional components of the time to include (the default is 'auto'). It can be one of the following:

- 'auto': Same as 'seconds' if *microsecond* is 0, same as 'microseconds' otherwise.
- 'hours': Include the *hour* in the two-digit HH format.
- 'minutes': Include *hour* and *minute* in HH:MM format.
- 'seconds': Include *hour*, *minute*, and *second* in HH:MM:SS format.
- 'milliseconds': Include full time, but truncate fractional second part to milliseconds. HH:MM:SS.sss format.
- 'microseconds': Include full time in HH:MM:SS.mmmmmm format.

注解: Excluded time components are truncated, not rounded.

ValueError will be raised on an invalid *timespec* argument.

```
>>> from datetime import time
>>> time(hour=12, minute=34, second=56, microsecond=123456).isoformat(timespec=
↳ 'minutes')
'12:34'
>>> dt = time(hour=12, minute=34, second=56, microsecond=0)
>>> dt.isoformat(timespec='microseconds')
'12:34:56.000000'
>>> dt.isoformat(timespec='auto')
'12:34:56'
```

3.6 新版功能: Added the *timespec* argument.

`time.__str__()`

For a time *t*, `str(t)` is equivalent to `t.isoformat()`.

`time.strftime(format)`

Return a string representing the time, controlled by an explicit format string. For a complete list of formatting directives, see *strftime()* and *strptime()* Behavior.

`time.__format__(format)`

Same as `time.strftime()`. This makes it possible to specify a format string for a *time* object in formatted string literals and when using `str.format()`. For a complete list of formatting directives, see *strftime()* and *strptime()* Behavior.

`time.utcoffset()`

If *tzinfo* is None, returns None, else returns `self.tzinfo.utcoffset(None)`, and raises an exception if the latter doesn't return None or a *timedelta* object representing a whole number of minutes with magnitude less than one day.

`time.dst()`

If *tzinfo* is None, returns None, else returns `self.tzinfo.dst(None)`, and raises an exception if the latter doesn't return None, or a *timedelta* object representing a whole number of minutes with magnitude less than one day.

`time.tzname()`

If *tzinfo* is None, returns None, else returns `self.tzinfo.tzname(None)`, or raises an exception if the latter doesn't return None or a string object.

示例:

```

>>> from datetime import time, tzinfo, timedelta
>>> class GMT1(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=1)
...     def dst(self, dt):
...         return timedelta(0)
...     def tzname(self, dt):
...         return "Europe/Prague"
...
>>> t = time(12, 10, 30, tzinfo=GMT1())
>>> t                                     # doctest: +ELLIPSIS
datetime.time(12, 10, 30, tzinfo=<GMT1 object at 0x...>)
>>> gmt = GMT1()
>>> t.isoformat()
'12:10:30+01:00'
>>> t.dst()
datetime.timedelta(0)
>>> t.tzname()
'Europe/Prague'
>>> t.strftime("%H:%M:%S %Z")
'12:10:30 Europe/Prague'
>>> 'The {} is {:%H:%M}'.format("time", t)
'The time is 12:10.'

```

8.1.6 tzinfo 对象

class datetime.tzinfo

This is an abstract base class, meaning that this class should not be instantiated directly. You need to derive a concrete subclass, and (at least) supply implementations of the standard *tzinfo* methods needed by the *datetime* methods you use. The *datetime* module supplies a simple concrete subclass of *tzinfo*, *timezone*, which can represent timezones with fixed offset from UTC such as UTC itself or North American EST and EDT.

An instance of (a concrete subclass of) *tzinfo* can be passed to the constructors for *datetime* and *time* objects. The latter objects view their attributes as being in local time, and the *tzinfo* object supports methods revealing offset of local time from UTC, the name of the time zone, and DST offset, all relative to a date or time object passed to them.

Special requirement for pickling: A *tzinfo* subclass must have an `__init__()` method that can be called with no arguments, else it can be pickled but possibly not unpickled again. This is a technical requirement that may be relaxed in the future.

A concrete subclass of *tzinfo* may need to implement the following methods. Exactly which methods are needed depends on the uses made of aware *datetime* objects. If in doubt, simply implement all of them.

tzinfo.utcoffset(dt)

Return offset of local time from UTC, in minutes east of UTC. If local time is west of UTC, this should be negative. Note that this is intended to be the total offset from UTC; for example, if a *tzinfo* object represents both time zone and DST adjustments, *utcoffset()* should return their sum. If the UTC offset isn't known, return *None*. Else the value returned must be a *timedelta* object specifying a whole number of minutes in the range -1439 to 1439 inclusive (1440 = 24*60; the magnitude of the offset must be less than one day). Most implementations of *utcoffset()* will probably look like one of these two:

```

return CONSTANT                # fixed-offset class
return CONSTANT + self.dst(dt) # daylight-aware class

```

If *utcoffset()* does not return *None*, *dst()* should not return *None* either.

The default implementation of `utcoffset()` raises `NotImplementedError`.

`tzinfo.dst(dt)`

Return the daylight saving time (DST) adjustment, in minutes east of UTC, or `None` if DST information isn't known. Return `timedelta(0)` if DST is not in effect. If DST is in effect, return the offset as a `timedelta` object (see `utcoffset()` for details). Note that DST offset, if applicable, has already been added to the UTC offset returned by `utcoffset()`, so there's no need to consult `dst()` unless you're interested in obtaining DST info separately. For example, `datetime.datetime.timetuple()` calls its `tzinfo` attribute's `dst()` method to determine how the `tm_isdst` flag should be set, and `tzinfo.fromutc()` calls `dst()` to account for DST changes when crossing time zones.

An instance `tz` of a `tzinfo` subclass that models both standard and daylight times must be consistent in this sense:

```
tz.utcoffset(dt) - tz.dst(dt)
```

must return the same result for every `datetime dt` with `dt.tzinfo == tz`. For sane `tzinfo` subclasses, this expression yields the time zone's "standard offset", which should not depend on the date or the time, but only on geographic location. The implementation of `datetime.datetime.astimezone()` relies on this, but cannot detect violations; it's the programmer's responsibility to ensure it. If a `tzinfo` subclass cannot guarantee this, it may be able to override the default implementation of `tzinfo.fromutc()` to work correctly with `astimezone()` regardless.

Most implementations of `dst()` will probably look like one of these two:

```
def dst(self, dt):
    # a fixed-offset class: doesn't account for DST
    return timedelta(0)
```

or

```
def dst(self, dt):
    # Code to set dston and dstoff to the time zone's DST
    # transition times based on the input dt.year, and expressed
    # in standard local time. Then

    if dston <= dt.replace(tzinfo=None) < dstoff:
        return timedelta(hours=1)
    else:
        return timedelta(0)
```

The default implementation of `dst()` raises `NotImplementedError`.

`tzinfo.tzname(dt)`

Return the time zone name corresponding to the `datetime` object `dt`, as a string. Nothing about string names is defined by the `datetime` module, and there's no requirement that it mean anything in particular. For example, "GMT", "UTC", "-500", "-5:00", "EDT", "US/Eastern", "America/New York" are all valid replies. Return `None` if a string name isn't known. Note that this is a method rather than a fixed string primarily because some `tzinfo` subclasses will wish to return different names depending on the specific value of `dt` passed, especially if the `tzinfo` class is accounting for daylight time.

The default implementation of `tzname()` raises `NotImplementedError`.

These methods are called by a `datetime` or `time` object, in response to their methods of the same names. A `datetime` object passes itself as the argument, and a `time` object passes `None` as the argument. A `tzinfo` subclass's methods should therefore be prepared to accept a `dt` argument of `None`, or of class `datetime`.

When `None` is passed, it's up to the class designer to decide the best response. For example, returning `None` is appropriate if the class wishes to say that time objects don't participate in the `tzinfo` protocols. It may be more useful for `utcoffset(None)` to return the standard UTC offset, as there is no other convention for discovering the standard offset.

When a `datetime` object is passed in response to a `datetime` method, `dt.tzinfo` is the same object as `self`. `tzinfo` methods can rely on this, unless user code calls `tzinfo` methods directly. The intent is that the `tzinfo` methods interpret `dt` as being in local time, and not need worry about objects in other timezones.

There is one more `tzinfo` method that a subclass may wish to override:

`tzinfo.fromutc(dt)`

This is called from the default `datetime.astimezone()` implementation. When called from that, `dt.tzinfo` is `self`, and `dt`'s date and time data are to be viewed as expressing a UTC time. The purpose of `fromutc()` is to adjust the date and time data, returning an equivalent datetime in `self`'s local time.

Most `tzinfo` subclasses should be able to inherit the default `fromutc()` implementation without problems. It's strong enough to handle fixed-offset time zones, and time zones accounting for both standard and daylight time, and the latter even if the DST transition times differ in different years. An example of a time zone the default `fromutc()` implementation may not handle correctly in all cases is one where the standard offset (from UTC) depends on the specific date and time passed, which can happen for political reasons. The default implementations of `astimezone()` and `fromutc()` may not produce the result you want if the result is one of the hours straddling the moment the standard offset changes.

Skipping code for error cases, the default `fromutc()` implementation acts like:

```
def fromutc(self, dt):
    # raise ValueError error if dt.tzinfo is not self
    dtoff = dt.utcoffset()
    dtdst = dt.dst()
    # raise ValueError if dtoff is None or dtdst is None
    delta = dtoff - dtdst # this is self's standard offset
    if delta:
        dt += delta # convert to standard local time
        dtdst = dt.dst()
        # raise ValueError if dtdst is None
    if dtdst:
        return dt + dtdst
    else:
        return dt
```

Example `tzinfo` classes:

```
from datetime import tzinfo, timedelta, datetime, timezone

ZERO = timedelta(0)
HOUR = timedelta(hours=1)
SECOND = timedelta(seconds=1)

# A class capturing the platform's idea of local time.
# (May result in wrong values on historical times in
# timezones where UTC offset and/or the DST rules had
# changed in the past.)
import time as _time

STDOFFSET = timedelta(seconds = -_time.timezone)
if _time.daylight:
    DSTOFFSET = timedelta(seconds = -_time.altzone)
else:
    DSTOFFSET = STDOFFSET

DSTDIFF = DSTOFFSET - STDOFFSET
```

            return std_time
        if start <= std_time < end - HOUR:
            # Daylight saving time
            return dst_time

```

```

Eastern = USTimeZone(-5, "Eastern", "EST", "EDT")
Central = USTimeZone(-6, "Central", "CST", "CDT")
Mountain = USTimeZone(-7, "Mountain", "MST", "MDT")
Pacific = USTimeZone(-8, "Pacific", "PST", "PDT")

```

Note that there are unavoidable subtleties twice per year in a `tzinfo` subclass accounting for both standard and daylight time, at the DST transition points. For concreteness, consider US Eastern (UTC -0500), where EDT begins the minute after 1:59 (EST) on the second Sunday in March, and ends the minute after 1:59 (EDT) on the first Sunday in November:

UTC	3:MM	4:MM	5:MM	6:MM	7:MM	8:MM
EST	22:MM	23:MM	0:MM	1:MM	2:MM	3:MM
EDT	23:MM	0:MM	1:MM	2:MM	3:MM	4:MM
start	22:MM	23:MM	0:MM	1:MM	3:MM	4:MM
end	23:MM	0:MM	1:MM	1:MM	2:MM	3:MM

When DST starts (the “start” line), the local wall clock leaps from 1:59 to 3:00. A wall time of the form 2:MM doesn’t

`t` really make sense on that day, so `astimezone(Eastern)` won't deliver a result with `hour == 2` on the day DST begins. For example, at the Spring forward transition of 2016, we get

```
>>> u0 = datetime(2016, 3, 13, 5, tzinfo=timezone.utc)
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)
...     print(u.time(), 'UTC =', t.time(), t.tzname())
...
05:00:00 UTC = 00:00:00 EST
06:00:00 UTC = 01:00:00 EST
07:00:00 UTC = 03:00:00 EDT
08:00:00 UTC = 04:00:00 EDT
```

When DST ends (the “end” line), there's a potentially worse problem: there's an hour that can't be spelled unambiguously in local wall time: the last hour of daylight time. In Eastern, that's times of the form 5:MM UTC on the day daylight time ends. The local wall clock leaps from 1:59 (daylight time) back to 1:00 (standard time) again. Local times of the form 1:MM are ambiguous. `astimezone()` mimics the local clock's behavior by mapping two adjacent UTC hours into the same local hour then. In the Eastern example, UTC times of the form 5:MM and 6:MM both map to 1:MM when converted to Eastern, but earlier times have the *fold* attribute set to 0 and the later times have it set to 1. For example, at the Fall back transition of 2016, we get

```
>>> u0 = datetime(2016, 11, 6, 4, tzinfo=timezone.utc)
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)
...     print(u.time(), 'UTC =', t.time(), t.tzname(), t.fold)
...
04:00:00 UTC = 00:00:00 EDT 0
05:00:00 UTC = 01:00:00 EDT 0
06:00:00 UTC = 01:00:00 EST 1
07:00:00 UTC = 02:00:00 EST 0
```

Note that the *datetime* instances that differ only by the value of the *fold* attribute are considered equal in comparisons.

Applications that can't bear wall-time ambiguities should explicitly check the value of the *fold* attribute or avoid using hybrid *tzinfo* subclasses; there are no ambiguities when using *timezone*, or any other fixed-offset *tzinfo* subclass (such as a class representing only EST (fixed offset -5 hours), or only EDT (fixed offset -4 hours)).

参见:

dateutil.tz The standard library has *timezone* class for handling arbitrary fixed offsets from UTC and *timezone.utc* as UTC *timezone* instance.

dateutil.tz library brings the *IANA timezone database* (also known as the Olson database) to Python and its usage is recommended.

IANA timezone database The Time Zone Database (often called tz, tzdata or zoneinfo) contains code and data that represent the history of local time for many representative locations around the globe. It is updated periodically to reflect changes made by political bodies to time zone boundaries, UTC offsets, and daylight-saving rules.

8.1.7 timezone Objects

The *timezone* class is a subclass of *tzinfo*, each instance of which represents a timezone defined by a fixed offset from UTC. Note that objects of this class cannot be used to represent timezone information in the locations where different offsets are used in different days of the year or where historical changes have been made to civil time.

class `datetime.timezone` (*offset*, *name=None*)

The *offset* argument must be specified as a `timedelta` object representing the difference between the local time and UTC. It must be strictly between `-timedelta(hours=24)` and `timedelta(hours=24)` and represent a whole number of minutes, otherwise `ValueError` is raised.

The *name* argument is optional. If specified it must be a string that will be used as the value returned by the `datetime.tzname()` method.

3.2 新版功能.

`timezone.utcoffset(dt)`

Return the fixed value specified when the `timezone` instance is constructed. The *dt* argument is ignored. The return value is a `timedelta` instance equal to the difference between the local time and UTC.

`timezone.tzname(dt)`

Return the fixed value specified when the `timezone` instance is constructed. If *name* is not provided in the constructor, the name returned by `tzname(dt)` is generated from the value of the *offset* as follows. If *offset* is `timedelta(0)`, the name is “UTC”, otherwise it is a string ‘UTC±HH:MM’, where ± is the sign of *offset*, HH and MM are two digits of *offset.hours* and *offset.minutes* respectively.

在 3.6 版更改: Name generated from *offset*=`timedelta(0)` is now plain ‘UTC’, not ‘UTC+00:00’.

`timezone.dst(dt)`

Always returns None.

`timezone.fromutc(dt)`

Return *dt* + *offset*. The *dt* argument must be an aware `datetime` instance, with *tzinfo* set to *self*.

类属性:

`timezone.utc`

The UTC timezone, `timezone(timedelta(0))`.

8.1.8 strftime() and strptime() Behavior

`date`, `datetime`, and `time` objects all support a `strftime(format)` method, to create a string representing the time under the control of an explicit format string. Broadly speaking, `d.strftime(fmt)` acts like the `time` module’s `time.strftime(fmt, d.timetuple())` although not all objects support a `timetuple()` method.

Conversely, the `datetime.strptime()` class method creates a `datetime` object from a string representing a date and time and a corresponding format string. `datetime.strptime(date_string, format)` is equivalent to `datetime(*(time.strptime(date_string, format)[0:6]))`, except when the format includes sub-second components or timezone offset information, which are supported in `datetime.strptime` but are discarded by `time.strptime`.

For `time` objects, the format codes for year, month, and day should not be used, as time objects have no such values. If they’re used anyway, 1900 is substituted for the year, and 1 for the month and day.

For `date` objects, the format codes for hours, minutes, seconds, and microseconds should not be used, as `date` objects have no such values. If they’re used anyway, 0 is substituted for them.

The full set of format codes supported varies across platforms, because Python calls the platform C library’s `strftime()` function, and platform variations are common. To see the full set of format codes supported on your platform, consult the `strftime(3)` documentation.

The following is a list of all the format codes that the C standard (1989 version) requires, and these work on all platforms with a standard C implementation. Note that the 1999 version of the C standard added additional format codes.

指令	意义	示例	注释
%a	当地工作日的缩写。	Sun, Mon, ..., Sat (美国); So, Mo, ..., Sa (德国)	(1)
%A	当地工作日的全名。	Sunday, Monday, ..., Saturday (美国); Sonntag, Montag, ..., Samstag (德国)	(1)
%w	以十进制数显示的工作日，其中 0 表示星期日，6 表示星期六。	0, 1, ..., 6	
%d	补零后，以十进制数显示的月份中的一天。	01, 02, ..., 31	
%b	当地月份的缩写。	Jan, Feb, ..., Dec (美国); Jan, Feb, ..., Dez (德国)	(1)
%B	当地月份的全名。	January, February, ..., December (美国); Januar, Februar, ..., Dezember (德国)	(1)
%m	补零后，以十进制数显示的月份。	01, 02, ..., 12	
%y	补零后，以十进制数表示的，不带世纪的年份。	00, 01, ..., 99	
%Y	十进制数表示的带世纪的年份。	0001, 0002, ..., 2013, 2014, ..., 9998, 9999	(2)
%H	Hour (24-hour clock) as a zero-padded decimal number.	00, 01, ..., 23	
%I	Hour (12-hour clock) as a zero-padded decimal number.	01, 02, ..., 12	
%p	本地化的 AM 或 PM。	AM, PM (美国); am, pm (德国)	(1), (3)
%M	补零后，以十进制数显示的分钟。	00, 01, ..., 59	
%S	补零后，以十进制数显示的秒。	00, 01, ..., 59	(4)
%f	Microsecond as a decimal number, zero-padded on the left.	000000, 000001, ..., 999999	(5)
%z	UTC offset in the form +HHMM or -HHMM (empty string if the object is naive).	(empty), +0000, -0400, +1030	(6)
190			Chapter 8. 数据类型
%Z	Time zone name (empty string if the object is	(empty), UTC, EST, CST	

Several additional directives not required by the C89 standard are included for convenience. These parameters all correspond to ISO 8601 date values. These may not be available on all platforms when used with the `strptime()` method. The ISO 8601 year and ISO 8601 week directives are not interchangeable with the year and week number directives above. Calling `strptime()` with incomplete or ambiguous ISO 8601 directives will raise a `ValueError`.

指令	意义	示例	注释
%G	ISO 8601 year with century representing the year that contains the greater part of the ISO week (%V).	0001, 0002, ..., 2013, 2014, ..., 9998, 9999	(8)
%u	ISO 8601 weekday as a decimal number where 1 is Monday.	1, 2, ..., 7	
%V	ISO 8601 week as a decimal number with Monday as the first day of the week. Week 01 is the week containing Jan 4.	01, 02, ..., 53	(8)

3.6 新版功能: 增加了 %G, %u 和 %V。

注释:

- (1) Because the format depends on the current locale, care should be taken when making assumptions about the output value. Field orderings will vary (for example, “month/day/year” versus “day/month/year”), and the output may contain Unicode characters encoded using the locale’s default encoding (for example, if the current locale is `ja_JP`, the default encoding could be any one of `eucJP`, `SJIS`, or `utf-8`; use `locale.getlocale()` to determine the current locale’s encoding).
- (2) The `strptime()` method can parse years in the full [1, 9999] range, but years < 1000 must be zero-filled to 4-digit width.
在 3.2 版更改: In previous versions, `strptime()` method was restricted to years >= 1900.
在 3.3 版更改: 在版本 3.2 中, `strptime()` 方法只限于 years >= 1000。
- (3) When used with the `strptime()` method, the %p directive only affects the output hour field if the %I directive is used to parse the hour.
- (4) 与 `time` 模块不同的是, `datetime` 模块不支持闰秒。
- (5) When used with the `strptime()` method, the %f directive accepts from one to six digits and zero pads on the right. %f is an extension to the set of format characters in the C standard (but implemented separately in `datetime` objects, and therefore always available).
- (6) For a naive object, the %z and %Z format codes are replaced by empty strings.

对于一个觉悟型对象而言:

%z `utcoffset()` is transformed into a 5-character string of the form +HHMM or -HHMM, where HH is a 2-digit string giving the number of UTC offset hours, and MM is a 2-digit string giving the number of UTC offset minutes. For example, if `utcoffset()` returns `timedelta(hours=-3, minutes=-30)`, %z is replaced with the string '-0330'.

%Z If `tzname()` returns `None`, %Z is replaced by an empty string. Otherwise %Z is replaced by the returned value, which must be a string.

在 3.2 版更改: When the %z directive is provided to the `strptime()` method, an aware `datetime` object will be produced. The `tzinfo` of the result will be set to a `timezone` instance.

- (7) When used with the `strptime()` method, %U and %W are only used in calculations when the day of the week and the calendar year (%Y) are specified.
- (8) Similar to %U and %W, %V is only used in calculations when the day of the week and the ISO year (%G) are specified in a `strptime()` format string. Also note that %G and %Y are not interchangeable.

8.2 calendar — 日历相关函数

源代码: `Lib/calendar.py`

这个模块让你可以输出像 Unix `cal` 那样的日历, 它还提供了其它与日历相关的实用函数。默认情况下, 这些日历把星期一当作一周的第一天, 星期天为一周的最后一天 (按照欧洲惯例)。可以使用 `setfirstweekday()` 方法设置一周的第一天为星期天 (6) 或者其它任意一天。使用整数作为指定日期的参数。更多相关的函数, 参见 `datetime` 和 `time` 模块。

Most of these functions and classes rely on the `datetime` module which uses an idealized calendar, the current Gregorian calendar extended in both directions. This matches the definition of the “proleptic Gregorian” calendar in Dershowitz and Reingold’s book “Calendrical Calculations”, where it’s the base calendar for all computations.

class `calendar.Calendar` (*firstweekday=0*)

创建一个 `Calendar` 对象。*firstweekday* 是一个整数, 用于指定一周的第一天。0 是星期一 (默认值), 6 是星期天。

`Calendar` 对象提供了一些可被用于准备日历数据格式化的方法。这个类本身不执行任何格式化操作。这部分任务应由子类来完成。

`Calendar` 类的实例有下列方法:

iterweekdays ()

返回一个迭代器, 迭代器的内容为一星期的数字。迭代器的第一个值与 *firstweekday* 属性的值一至。

itermonthdates (*year, month*)

返回一个迭代器, 迭代器的内容为 *year* 年 *month* 月 (1-12) 的日期。这个迭代器返回当月的所有日期 (`datetime.date` 对象), 日期包含了本月头尾用于组成完整一周的日期。

itermonthdays2 (*year, month*)

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`. Days returned will be tuples consisting of a day number and a week day number.

itermonthdays (*year, month*)

Return an iterator for the month *month* in the year *year* similar to `itermonthdates()`. Days returned will simply be day numbers.

monthdatescalendar (*year, month*)

返回一个表示指定年月的周列表。周列表由七个 `datetime.date` 对象组成。

monthdays2calendar (*year, month*)

返回一个表示指定年月的周列表。周列表由七个代表日期的数字和代表周几的数字组成的二元元组。

monthdayscalendar (*year, month*)

返回一个表示指定年月的周列表。周列表由七个代表日期的数字组成。

yeardatescalendar (*year, width=3*)

返回可以用来格式化的指定年月的数据。返回的值是一个列表, 列表是月份组成的行。每一行包含了最多 *width* 个月 (默认为 3)。每个月包含了 4 到 6 周, 每周包含 1-7 天。每一天使用 `datetime.date` 对象。

yeardays2calendar (*year, width=3*)

返回可以用来模式化的指定年月的数据 (与 `yeardatescalendar()` 类似)。周列表的元素是由表示日期的数字和表示星期几的数字组成的元组。不在这个月的日子为 0。

yeardayscalendar (*year*, *width*=3)

返回可以用来模式化的指定年月的数据 (与 `yeardatescalendar()` 类似)。周列表的元素是表示日期的数字。不在这个月的日子为 0。

class `calendar.TextCalendar` (*firstweekday*=0)

可以使用这个类生成纯文本日历。

`TextCalendar` 实例有以下方法：

formatmonth (*theyear*, *themonth*, *w*=0, *l*=0)

返回一个多行字符串来表示指定年月的日历。*w* 为日期的宽度，但始终保持日期居中。*l* 指定了每星期占用的行数。以上这些还依赖于构造器或者 `setfirstweekday()` 方法指定的周的第一天是哪一天。

prmonth (*theyear*, *themonth*, *w*=0, *l*=0)

与 `formatmonth()` 方法一样，返回一个月的日历。

formatyear (*theyear*, *w*=2, *l*=1, *c*=6, *m*=3)

返回一个多行字符串，这个字符串为一个 *m* 列日历。可选参数 *w*, *l* 和 *c* 分别表示日期列数，周的行数，和月之间的间隔。同样，以上这些还依赖于构造器或者 `setfirstweekday()` 指定哪一天为一周的第一天。日历的第一年由平台依赖于使用的平台。

pryear (*theyear*, *w*=2, *l*=1, *c*=6, *m*=3)

与 `formatyear()` 方法一样，返回一整年的日历。

class `calendar.HTMLCalendar` (*firstweekday*=0)

可以使用这个类生成 HTML 日历。

`HTMLCalendar` instances have the following methods:

formatmonth (*theyear*, *themonth*, *withyear*=True)

返回一个 HTML 表格作为指定年月的日历。*withyear* 为真，则年份将会包含在表头，否则只显示月份。

formatyear (*theyear*, *width*=3)

返回一个 HTML 表格作为指定年份的日历。*width* (默认为 3) 用于规定每一行显示月份的数量。

formatyearpage (*theyear*, *width*=3, *css*='calendar.css', *encoding*=None)

返回一个完整的 HTML 页面作为指定年份的日历。*width**(默认为 3) 用于规定每一行显示的月份数量。**css* 为层叠样式表的名字。如果不使用任何层叠样式表，可以使用 `None`。*encoding* 为输出页面的编码 (默认为系统的默认编码)。

class `calendar.LocaleTextCalendar` (*firstweekday*=0, *locale*=None)

This subclass of `TextCalendar` can be passed a locale name in the constructor and will return month and weekday names in the specified locale. If this locale includes an encoding all strings containing month and weekday names will be returned as unicode.

class `calendar.LocaleHTMLCalendar` (*firstweekday*=0, *locale*=None)

This subclass of `HTMLCalendar` can be passed a locale name in the constructor and will return month and weekday names in the specified locale. If this locale includes an encoding all strings containing month and weekday names will be returned as unicode.

注解： The `formatweekday()` and `formatmonthname()` methods of these two classes temporarily change the current locale to the given *locale*. Because the current locale is a process-wide setting, they are not thread-safe.

对于简单的文本日历，这个模块提供了以下方法。

`calendar.setfirstweekday` (*weekday*)

设置每一周的开始 (0 表示星期一，6 表示星期天)。`calendar` 还提供了 MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY, SATURDAY 和 SUNDAY 几个常量方便使用。例如，设置每周的第一天为星期天

```
import calendar
calendar.setfirstweekday(calendar.SUNDAY)
```

`calendar.firstweekday()`

返回当前设置的每星期的第一天的数值。

`calendar.isleap(year)`

如果 *year* 是闰年则返回 *True* , 否则返回 *False*。

`calendar.leapdays(y1, y2)`

Returns the number of leap years in the range from *y1* to *y2* (exclusive), where *y1* and *y2* are years.

This function works for ranges spanning a century change.

`calendar.weekday(year, month, day)`

Returns the day of the week (0 is Monday) for *year* (1970–...), *month* (1–12), *day* (1–31).

`calendar.weekheader(n)`

Return a header containing abbreviated weekday names. *n* specifies the width in characters for one weekday.

`calendar.monthrange(year, month)`

Returns weekday of first day of the month and number of days in month, for the specified *year* and *month*.

`calendar.monthcalendar(year, month)`

Returns a matrix representing a month's calendar. Each row represents a week; days outside of the month are represented by zeros. Each week begins with Monday unless set by `setfirstweekday()`.

`calendar.prmonth(theyear, themonth, w=0, l=0)`

Prints a month's calendar as returned by `month()`.

`calendar.month(theyear, themonth, w=0, l=0)`

Returns a month's calendar in a multi-line string using the `formatmonth()` of the *TextCalendar* class.

`calendar.prcal(year, w=0, l=0, c=6, m=3)`

Prints the calendar for an entire year as returned by `calendar()`.

`calendar.calendar(year, w=2, l=1, c=6, m=3)`

Returns a 3-column calendar for an entire year as a multi-line string using the `formatyear()` of the *TextCalendar* class.

`calendar.timegm(tuple)`

An unrelated but handy function that takes a time tuple such as returned by the `gmtime()` function in the *time* module, and returns the corresponding Unix timestamp value, assuming an epoch of 1970, and the POSIX encoding. In fact, `time.gmtime()` and `timegm()` are each others' inverse.

The *calendar* module exports the following data attributes:

`calendar.day_name`

An array that represents the days of the week in the current locale.

`calendar.day_abbr`

An array that represents the abbreviated days of the week in the current locale.

`calendar.month_name`

An array that represents the months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_name[0]` is the empty string.

`calendar.month_abbr`

An array that represents the abbreviated months of the year in the current locale. This follows normal convention of January being month number 1, so it has a length of 13 and `month_abbr[0]` is the empty string.

参见:

模块 `datetime` 为日期和时间提供与 `time` 模块相似功能的面向对象接口。

模块 `time` 底层时间相关函数。

8.3 collections — 容器数据类型

Source code: `Lib/collections/__init__.py`

这个模块实现了特定目标的容器，以提供 Python 标准内建容器 `dict` , `list` , `set` , 和 `tuple` 的替代选择。

<code>namedtuple()</code>	创建命名元组子类的工厂函数
<code>deque</code>	类似列表 (list) 的容器，实现了在两端快速添加 (append) 和弹出 (pop)
<code>ChainMap</code>	类似字典 (dict) 的容器类，将多个映射集合到一个视图里面
<code>Counter</code>	字典的子类，提供了可哈希对象的计数功能
<code>OrderedDict</code>	字典的子类，保存了他们被添加的顺序
<code>defaultdict</code>	字典的子类，提供了一个工厂函数，为字典查询提供一个默认值
<code>UserDict</code>	封装了字典对象，简化了字典子类化
<code>UserList</code>	封装了列表对象，简化了列表子类化
<code>UserString</code>	封装了列表对象，简化了字符串子类化

在 3.3 版更改: Moved *Collections Abstract Base Classes* to the `collections.abc` module. For backwards compatibility, they continue to be visible in this module as well.

8.3.1 ChainMap 对象

3.3 新版功能.

一个 `ChainMap` 类是为了将多个映射快速的链接到一起，这样它们就可以作为一个单元处理。它通常比创建一个新字典和多次调用 `update()` 要快很多。

这个类可以用于模拟嵌套作用域，并且在模版化的时候比较有用。

class `collections.ChainMap(*maps)`

一个 `ChainMap` 将多个字典或者其他映射组合在一起，创建一个单独的可更新的视图。如果没有 `maps` 被指定，就提供一个默认的空字典，这样一个新链至少有一个映射。

底层映射被存储在一个列表中。这个列表是公开的，可以通过 `maps` 属性存取和更新。没有其他的状态。搜索查询底层映射，直到一个键被找到。不同的是，写，更新和删除只操作第一个映射。

一个 `ChainMap` 通过引用合并底层映射。所以，如果一个底层映射更新了，这些更改会反映到 `ChainMap`。

支持所有常用字典方法。另外还有一个 `maps` 属性 (attribute)，一个创建子上下文的方法 (method)，一个存取它们首个映射的属性 (property):

maps

一个可以更新的映射列表。这个列表是按照第一次搜索到最后一次搜索的顺序组织的。它是仅有的存储状态，可以被修改。列表最少包含一个映射。

new_child(m=None)

返回一个新的 `ChainMap` 类，包含了一个新映射 (map)，后面跟随当前实例的全部映射 (map)。如果 `m` 被指定，它就成为不同新的实例，就是在所有映射前加上 `m`，如果没有指定，就加上一个空

字典，这样的话一个 `d.new_child()` 调用等价于 `ChainMap({}, *d.maps)`。这个方法用于创建子上下文，不改变任何父映射的值。

在 3.4 版更改: 添加了 `m` 可选参数。

parents

属性返回一个新的 *ChainMap* 包含所有的当前实例的映射，除了第一个。这样可以在搜索的时候跳过第一个映射。使用的场景类似在 *nested scopes* 嵌套作用域中使用 `nonlocal` 关键词。用例也可以类比内建函数 `super()`。一个 `d.parents` 的引用等价于 `ChainMap(*d.maps[1:])`。

参见:

- *MultiContext class* 在 *Enthought CodeTools package* 有支持写映射的选项。
- Django' s *Context class* for templating is a read-only chain of mappings. It also features pushing and popping of contexts similar to the *new_child()* method and the *parents()* property.
- *Nested Contexts recipe* 提供了是否对第一个映射或其他映射进行写和其他修改的选项。
- 一个 极简的只读版 *Chainmap*.

ChainMap 例子和方法

这一节提供了多个使用链映射的案例。

模拟 Python 内部 lookup 链的例子

```
import builtins
pylookup = ChainMap(locals(), globals(), vars(builtins))
```

让用户指定的命令行参数优先于环境变量，优先于默认值的例子

```
import os, argparse

defaults = {'color': 'red', 'user': 'guest'}

parser = argparse.ArgumentParser()
parser.add_argument('-u', '--user')
parser.add_argument('-c', '--color')
namespace = parser.parse_args()
command_line_args = {k:v for k, v in vars(namespace).items() if v}

combined = ChainMap(command_line_args, os.environ, defaults)
print(combined['color'])
print(combined['user'])
```

用 *ChainMap* 类模拟嵌套上下文的例子

```
c = ChainMap()           # Create root context
d = c.new_child()        # Create nested child context
e = c.new_child()        # Child of c, independent from d
e.maps[0]                # Current context dictionary -- like Python's locals()
e.maps[-1]               # Root context -- like Python's globals()
e.parents                # Enclosing context chain -- like Python's nonlocals

d['x']                   # Get first key in the chain of contexts
d['x'] = 1               # Set value in current context
del d['x']                # Delete from current context
list(d)                  # All nested values
```

(下页继续)

(续上页)

```

k in d          # Check all nested values
len(d)          # Number of nested values
d.items()       # All nested items
dict(d)         # Flatten into a regular dictionary

```

`ChainMap` 类只更新链中的第一个映射，但 `lookup` 会搜索整个链。然而，如果需要深度写和删除，也可以很容易的通过定义一个子类来实现它

```

class DeepChainMap(ChainMap):
    'Variant of ChainMap that allows direct updates to inner scopes'

    def __setitem__(self, key, value):
        for mapping in self.maps:
            if key in mapping:
                mapping[key] = value
                return
        self.maps[0][key] = value

    def __delitem__(self, key):
        for mapping in self.maps:
            if key in mapping:
                del mapping[key]
                return
        raise KeyError(key)

>>> d = DeepChainMap({'zebra': 'black'}, {'elephant': 'blue'}, {'lion': 'yellow'})
>>> d['lion'] = 'orange'          # update an existing key two levels down
>>> d['snake'] = 'red'           # new keys get added to the topmost dict
>>> del d['elephant']            # remove an existing key one level down
>>> d                            # display result
DeepChainMap({'zebra': 'black', 'snake': 'red'}, {}, {'lion': 'orange'})

```

8.3.2 Counter 对象

一个计数器工具提供快速和方便的计数。比如

```

>>> # Tally occurrences of words in a list
>>> cnt = Counter()
>>> for word in ['red', 'blue', 'red', 'green', 'blue', 'blue']:
...     cnt[word] += 1
>>> cnt
Counter({'blue': 3, 'red': 2, 'green': 1})

>>> # Find the ten most common words in Hamlet
>>> import re
>>> words = re.findall(r'\w+', open('hamlet.txt').read().lower())
>>> Counter(words).most_common(10)
[('the', 1143), ('and', 966), ('to', 762), ('of', 669), ('i', 631),
 ('you', 554), ('a', 546), ('my', 514), ('hamlet', 471), ('in', 451)]

```

class `collections.Counter` (`[iterable-or-mapping]`)

A `Counter` is a `dict` subclass for counting hashable objects. It is an unordered collection where elements are stored as dictionary keys and their counts are stored as dictionary values. Counts are allowed to be any integer value including zero or negative counts. The `Counter` class is similar to bags or multisets in other languages.

元素从一个 *iterable* 被计数或从其他的 *mapping* (or *counter*) 初始化:

```
>>> c = Counter()                # a new, empty counter
>>> c = Counter('gallahad')      # a new counter from an iterable
>>> c = Counter({'red': 4, 'blue': 2}) # a new counter from a mapping
>>> c = Counter(cats=4, dogs=8)    # a new counter from keyword args
```

`Counter` 对象有一个字典接口, 如果引用的键没有任何记录, 就返回一个 0, 而不是弹出一个 `KeyError`:

```
>>> c = Counter(['eggs', 'ham'])
>>> c['bacon']                    # count of a missing element is zero
0
```

设置一个计数为 0 不会从计数器中移去一个元素。使用 `del` 来删除它:

```
>>> c['sausage'] = 0              # counter entry with a zero count
>>> del c['sausage']              # del actually removes the entry
```

3.1 新版功能.

计数器对象除了字典方法以外, 还提供了三个其他的方法:

`elements()`

返回一个迭代器, 每个元素重复计数的个数。元素顺序是任意的。如果一个元素的计数小于 1, `elements()` 就会忽略它。

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> sorted(c.elements())
['a', 'a', 'a', 'a', 'b', 'b']
```

`most_common([n])`

Return a list of the *n* most common elements and their counts from the most common to the least. If *n* is omitted or `None`, `most_common()` returns *all* elements in the counter. Elements with equal counts are ordered arbitrarily:

```
>>> Counter('abracadabra').most_common(3) # doctest: +SKIP
[('a', 5), ('r', 2), ('b', 2)]
```

`subtract([iterable-or-mapping])`

从迭代对象或映射对象减去元素。像 `dict.update()` 但是是减去, 而不是替换。输入和输出都可以是 0 或者负数。

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> d = Counter(a=1, b=2, c=3, d=4)
>>> c.subtract(d)
>>> c
Counter({'a': 3, 'b': 0, 'c': -3, 'd': -6})
```

3.2 新版功能.

通常字典方法都可用于 `Counter` 对象, 除了有两个方法工作方式与字典并不相同。

`fromkeys(iterable)`

这个类方法没有在 `Counter` 中实现。

`update([iterable-or-mapping])`

从迭代对象计数元素或者从另一个映射对象 (或计数器) 添加。像 `dict.update()` 但是是加上, 而不是替换。另外, 迭代对象应该是序列元素, 而不是一个 (key, value) 对。

`Counter` 对象的常用案例

```

sum(c.values())           # total of all counts
c.clear()                 # reset all counts
list(c)                   # list unique elements
set(c)                    # convert to a set
dict(c)                   # convert to a regular dictionary
c.items()                 # convert to a list of (elem, cnt) pairs
Counter(dict(list_of_pairs)) # convert from a list of (elem, cnt) pairs
c.most_common()[:n-1:-1]  # n least common elements
+c                         # remove zero and negative counts

```

提供了几个数学操作，可以结合 `Counter` 对象，以生产 **multisets** (计数器中大于 0 的元素)。加和减，结合计数器，通过加上或者减去元素的相应计数。交集和并集返回相应计数的最小或最大值。每种操作都可以接受带符号的计数，但是输出会忽略掉结果为零或者小于零的计数。

```

>>> c = Counter(a=3, b=1)
>>> d = Counter(a=1, b=2)
>>> c + d                               # add two counters together:  c[x] + d[x]
Counter({'a': 4, 'b': 3})
>>> c - d                               # subtract (keeping only positive counts)
Counter({'a': 2})
>>> c & d                               # intersection:  min(c[x], d[x]) # doctest: +SKIP
Counter({'a': 1, 'b': 1})
>>> c | d                               # union:  max(c[x], d[x])
Counter({'a': 3, 'b': 2})

```

单目加和减（一元操作符）意思是从空计数器加或者减去。

```

>>> c = Counter(a=2, b=-4)
>>> +c
Counter({'a': 2})
>>> -c
Counter({'b': 4})

```

3.3 新版功能: 添加了对一元加，一元减和位置集合操作的支持。

注解：计数器主要是为了表达运行的正的计数而设计；但是，小心不要预先排除负数或者其他类型。为了帮助这些用例，这一节记录了最小范围和类型限制。

- `Counter` 类是一个字典的子类，不限制键和值。值用于表示计数，但你实际上可以存储任何其他值。
- The `most_common()` method requires only that the values be orderable.
- For in-place operations such as `c[key] += 1`, the value type need only support addition and subtraction. So fractions, floats, and decimals would work and negative values are supported. The same is also true for `update()` and `subtract()` which allow negative and zero values for both inputs and outputs.
- Multiset 多集合方法只为正值的使用情况设计。输入可以是负数或者 0，但只输出计数为正值。没有类型限制，但值类型需要支持加，减和比较操作。
- The `elements()` method requires integer counts. It ignores zero and negative counts.

- To enumerate all distinct multisets of a given size over a given set of elements, see `itertools.combinations_with_replacement()`:

```
map(Counter, combinations_with_replacement('ABC', 2)) -> AA AB AC BB BC CC
```

8.3.3 deque 对象

class `collections.deque([iterable[, maxlen]])`

返回一个新的双向队列对象，从左到右初始化（用方法 `append()`），从 `iterable`（迭代对象）数据创建。如果 `iterable` 没有指定，新队列为空。

Deque 队列是由栈或者 queue 队列生成的（发音是“deck”，“double-ended queue”的简称）。Deque 支持线程安全，内存高效添加（`append`）和弹出（`pop`），从两端都可以，两个方向的大概开销都是 $O(1)$ 复杂度。

虽然 `list` 对象也支持类似操作，不过这里优化了定长操作和 `pop(0)` 和 `insert(0, v)` 的开销。它们引起 $O(n)$ 内存移动的操作，改变底层数据表达的大小和位置。

如果 `maxlen` 没有指定或者是 `None`，`deque`s 可以增长到任意长度。否则，`deque` 就限定到指定最大长度。一旦限定长度的 `deque` 满了，当新项加入时，同样数量的项就从另一端弹出。限定长度 `deque` 提供类似 Unix `filter tail` 的功能。它们同样可以用与追踪最近的交换和其他数据池活动。

双向队列（`deque`）对象支持以下方法：

append (*x*)

添加 *x* 到右端。

appendleft (*x*)

添加 *x* 到左端。

clear ()

移除所有元素，使其长度为 0。

copy ()

创建一份浅拷贝。

3.5 新版功能。

count (*x*)

计算 `deque` 中个数等于 *x* 的元素。

3.2 新版功能。

extend (*iterable*)

扩展 `deque` 的右侧，通过添加 `iterable` 参数中的元素。

extendleft (*iterable*)

扩展 `deque` 的左侧，通过添加 `iterable` 参数中的元素。注意，左添加时，在结果中 `iterable` 参数中的顺序将被反过来添加。

index (*x*[, *start*[, *stop*]])

返回第 *x* 个元素（从 *start* 开始计算，在 *stop* 之前）。返回第一个匹配，如果没找到的话，升起 `ValueError`。

3.5 新版功能。

insert (*i*, *x*)

在位置 *i* 插入 *x*。

如果插入会导致一个限长 `deque` 超出长度 `maxlen` 的话，就升起一个 `IndexError`。

3.5 新版功能.

pop()

移去并且返回一个元素，deque 最右侧的那一个。如果没有元素的话，就升起 `IndexError` 索引错误。

popleft()

移去并且返回一个元素，deque 最左侧的那一个。如果没有元素的话，就升起 `IndexError` 索引错误。

remove(value)

移去找到的第一个 `value`。如果没有的话就升起 `ValueError`。

reverse()

将 deque 逆序排列。返回 `None`。

3.2 新版功能.

rotate(n=1)

向右循环移动 `n` 步。如果 `n` 是负数，就向左循环。

如果 deque 不是空的，向右循环移动一步就等价于 `d.appendleft(d.pop())`，向左循环一步就等价于 `d.append(d.popleft())`。

Deque 对象同样提供了一个只读属性：

maxlen

Deque 的最大尺寸，如果没有限定的话就是 `None`。

3.1 新版功能.

除了以上，deque 还支持迭代，清洗，`len(d)`，`reversed(d)`，`copy.copy(d)`，`copy.deepcopy(d)`，成员测试 `in` 操作符，和下标引用 `d[-1]`。索引存取在两端的复杂度是 $O(1)$ ，在中间的复杂度比 $O(n)$ 略低。要快速存取，使用 `list` 来替代。

Deque 从版本 3.5 开始支持 `__add__()`，`__mul__()`，和 `__imul__()`。

示例：

```
>>> from collections import deque
>>> d = deque('ghi')                # make a new deque with three items
>>> for elem in d:                  # iterate over the deque's elements
...     print(elem.upper())
G
H
I

>>> d.append('j')                  # add a new entry to the right side
>>> d.appendleft('f')              # add a new entry to the left side
>>> d                              # show the representation of the deque
deque(['f', 'g', 'h', 'i', 'j'])

>>> d.pop()                        # return and remove the rightmost item
'j'
>>> d.popleft()                    # return and remove the leftmost item
'f'
>>> list(d)                        # list the contents of the deque
['g', 'h', 'i']
>>> d[0]                           # peek at leftmost item
'g'
>>> d[-1]                         # peek at rightmost item
'i'
```

(下页继续)

(续上页)

```

>>> list(reversed(d))           # list the contents of a deque in reverse
['i', 'h', 'g']
>>> 'h' in d                     # search the deque
True
>>> d.extend('jkl')             # add multiple elements at once
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])
>>> d.rotate(1)                 # right rotation
>>> d
deque(['l', 'g', 'h', 'i', 'j', 'k'])
>>> d.rotate(-1)                # left rotation
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])

>>> deque(reversed(d))          # make a new deque in reverse order
deque(['l', 'k', 'j', 'i', 'h', 'g'])
>>> d.clear()                   # empty the deque
>>> d.pop()                     # cannot pop from an empty deque
Traceback (most recent call last):
  File "<pyshell#6>", line 1, in -toplevel-
    d.pop()
IndexError: pop from an empty deque

>>> d.extendleft('abc')         # extendleft() reverses the input order
>>> d
deque(['c', 'b', 'a'])

```

deque 用法

这一节展示了 deque 的多种用法。

限长 deque 提供了类似 Unix tail 过滤功能

```

def tail(filename, n=10):
    'Return the last n lines of a file'
    with open(filename) as f:
        return deque(f, n)

```

另一个用法是维护一个近期添加元素的序列，通过从右边添加和从左边弹出

```

def moving_average(iterable, n=3):
    # moving_average([40, 30, 50, 46, 39, 44]) --> 40.0 42.0 45.0 43.0
    # http://en.wikipedia.org/wiki/Moving_average
    it = iter(iterable)
    d = deque(itertools.islice(it, n-1))
    d.appendleft(0)
    s = sum(d)
    for elem in it:
        s += elem - d.popleft()
        d.append(elem)
        yield s / n

```

The rotate() method provides a way to implement deque slicing and deletion. For example, a pure Python implementation of del d[n] relies on the rotate() method to position elements to be popped:

```
def delete_nth(d, n):
    d.rotate(-n)
    d.popleft()
    d.rotate(n)
```

To implement *deque* slicing, use a similar approach applying `rotate()` to bring a target element to the left side of the deque. Remove old entries with `popleft()`, add new entries with `extend()`, and then reverse the rotation. With minor variations on that approach, it is easy to implement Forth style stack manipulations such as `dup`, `drop`, `swap`, `over`, `pick`, `rot`, and `roll`.

8.3.4 defaultdict 对象

class `collections.defaultdict` (`[default_factory[, ...]]`)

返回一个新的类似字典的对象。*defaultdict* 是内置 *dict* 类的子类。它重载了一个方法并添加了一个可写的实例变量。其余的功能与 *dict* 类相同，此处不再重复说明。

第一个参数 *default_factory* 提供了一个初始值。它默认为 `None`。所有的其他参数都等同与 *dict* 构建器中的参数对待，包括关键词参数。

defaultdict 对象除了支持 *dict* 的操作，还支持下面的方法作为扩展：

`__missing__` (*key*)

如果 *default_factory* 是 `None`，它就升起一个 *KeyError* 并将 *key* 作为参数。

如果 *default_factory* 不为 `None`，它就会被调用，不带参数，为 *key* 提供一个默认值，这个值和 *key* 作为一个对被插入到字典中，并返回。

如果调用 *default_factory* 升起了一个例外，这个例外就被扩散传递，不经过改变。

这个方法在查询键值失败时，会被 *dict* 中的 `__getitem__()` 调用。不管它是返回值或升起例外，都会被 `__getitem__()` 传递。

注意 `__missing__()` 不会被 `__getitem__()` 以外的其他方法调用。意思就是 `get()` 会向正常的 *dict* 那样返回 `None`，而不是使用 *default_factory*。

defaultdict 支持以下实例变量：

`default_factory`

这个属性被 `__missing__()` 方法使用；它从构建器的第一个参数初始化，如果提供了的话，否则就是 `None`。

defaultdict 例子

Using *list* as the *default_factory*, it is easy to group a sequence of key-value pairs into a dictionary of lists:

```
>>> s = [('yellow', 1), ('blue', 2), ('yellow', 3), ('blue', 4), ('red', 1)]
>>> d = defaultdict(list)
>>> for k, v in s:
...     d[k].append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

When each key is encountered for the first time, it is not already in the mapping; so an entry is automatically created using the *default_factory* function which returns an empty *list*. The `list.append()` operation then attaches the value to the new list. When keys are encountered again, the look-up proceeds normally (returning the list for that key) and

the `list.append()` operation adds another value to the list. This technique is simpler and faster than an equivalent technique using `dict.setdefault()`:

```
>>> d = {}
>>> for k, v in s:
...     d.setdefault(k, []).append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

Setting the `default_factory` to `int` makes the `defaultdict` useful for counting (like a bag or multiset in other languages):

```
>>> s = 'mississippi'
>>> d = defaultdict(int)
>>> for k in s:
...     d[k] += 1
...
>>> sorted(d.items())
[('i', 4), ('m', 1), ('p', 2), ('s', 4)]
```

When a letter is first encountered, it is missing from the mapping, so the `default_factory` function calls `int()` to supply a default count of zero. The increment operation then builds up the count for each letter.

函数 `int()` 总是返回 0，是常数函数的特殊情况。一个更快和灵活的方法是使用 `lambda` 函数，可以提供任何常量值 (不只是 0)：

```
>>> def constant_factory(value):
...     return lambda: value
>>> d = defaultdict(constant_factory('<missing>'))
>>> d.update(name='John', action='ran')
>>> '%(name)s %(action)s to %(object)s' % d
'John ran to <missing>'
```

Setting the `default_factory` to `set` makes the `defaultdict` useful for building a dictionary of sets:

```
>>> s = [('red', 1), ('blue', 2), ('red', 3), ('blue', 4), ('red', 1), ('blue', 4)]
>>> d = defaultdict(set)
>>> for k, v in s:
...     d[k].add(v)
...
>>> sorted(d.items())
[('blue', {2, 4}), ('red', {1, 3})]
```

8.3.5 `namedtuple()` 命名元组的工厂函数

命名元组赋予每个位置一个含义，提供可读性和自文档性。它们可以用于任何普通元组，并添加了通过名字获取值的能力，通过索引值也是可以的。

`collections.namedtuple` (*typename*, *field_names*, *, *verbose=False*, *rename=False*, *module=None*)

返回一个新的元组子类，名为 *typename*。这个新的子类用于创建类元组的对象，可以通过域名来获取属性值，同样也可以通过索引和迭代获取值。子类实例同样有文档字符串（类名和域名）另外一个有用的 `__repr__()` 方法，以 `name=value` 格式列明了元组内容。

field_names 是一个像 `['x', 'y']` 一样的字符串序列。另外 *field_names* 可以是一个纯字符串，用空白或逗号分隔开元素名，比如 `'x y'` 或者 `'x, y'`。

任何有效的 Python 标识符都可以作为域名，除了下划线开头的那些。有效标识符由字母，数字，下划线组成，但首字母不能是数字或下划线，另外不能是关键词 *keyword* 比如 *class*, *for*, *return*, *global*, *pass*, 或 *raise*。

如果 *rename* 为真，无效域名会自动转换成位置名。比如 ['abc', 'def', 'ghi', 'abc'] 转换成 ['abc', '_1', 'ghi', '_3']，消除关键词 *def* 和重复域名 *abc*。

If *verbose* is true, the class definition is printed after it is built. This option is outdated; instead, it is simpler to print the `__source__` attribute.

如果 *module* 值有定义，命名元组的 `__module__` 属性值就被设置。

命名元组实例没有字典，所以它们要更轻量，并且占用更小内存。

在 3.1 版更改: 添加了对 *rename* 的支持。

在 3.6 版更改: *verbose* 和 *rename* 参数成为仅限关键字参数。

在 3.6 版更改: 添加了 *module* 参数。

```
>>> # Basic example
>>> Point = namedtuple('Point', ['x', 'y'])
>>> p = Point(11, y=22)           # instantiate with positional or keyword arguments
>>> p[0] + p[1]                   # indexable like the plain tuple (11, 22)
33
>>> x, y = p                      # unpack like a regular tuple
>>> x, y
(11, 22)
>>> p.x + p.y                    # fields also accessible by name
33
>>> p                            # readable __repr__ with a name=value style
Point(x=11, y=22)
```

命名元组尤其有助于赋值 *csv* *sqlite3* 模块返回的元组

```
EmployeeRecord = namedtuple('EmployeeRecord', 'name, age, title, department, paygrade
↪')

import csv
for emp in map(EmployeeRecord._make, csv.reader(open("employees.csv", "rb"))):
    print(emp.name, emp.title)

import sqlite3
conn = sqlite3.connect('/companydata')
cursor = conn.cursor()
cursor.execute('SELECT name, age, title, department, paygrade FROM employees')
for emp in map(EmployeeRecord._make, cursor.fetchall()):
    print(emp.name, emp.title)
```

除了继承元组的方法，命名元组还支持三个额外的方法和两个属性。为了防止域名冲突，方法和属性以下划线开始。

classmethod `somenamedtuple._make(iterable)`

类方法从存在的序列或迭代实例创建一个新实例。

```
>>> t = [11, 22]
>>> Point._make(t)
Point(x=11, y=22)
```

`somenamedtuple._asdict()`

Return a new *OrderedDict* which maps field names to their corresponding values:

```
>>> p = Point(x=11, y=22)
>>> p._asdict()
OrderedDict([('x', 11), ('y', 22)])
```

在 3.1 版更改: 返回一个 *OrderedDict* 而不是 *dict*。

`somenamedtuple._replace(**kwargs)`

返回一个新的命名元组实例, 并将指定域替换为新的值

```
>>> p = Point(x=11, y=22)
>>> p._replace(x=33)
Point(x=33, y=22)

>>> for partnum, record in inventory.items():
...     inventory[partnum] = record._replace(price=newprices[partnum],
↪ timestamp=time.now())
```

`somenamedtuple._source`

A string with the pure Python source code used to create the named tuple class. The source makes the named tuple self-documenting. It can be printed, executed using `exec()`, or saved to a file and imported.

3.3 新版功能.

`somenamedtuple._fields`

字符串元组列出了域名。用于提醒和从现有元组创建一个新的命名元组类型。

```
>>> p._fields          # view the field names
('x', 'y')

>>> Color = namedtuple('Color', 'red green blue')
>>> Pixel = namedtuple('Pixel', Point._fields + Color._fields)
>>> Pixel(11, 22, 128, 255, 0)
Pixel(x=11, y=22, red=128, green=255, blue=0)
```

要获取这个名字域的值, 使用 `getattr()` 函数:

```
>>> getattr(p, 'x')
11
```

To convert a dictionary to a named tuple, use the double-star-operator (as described in [tut-unpacking-arguments](#)):

```
>>> d = {'x': 11, 'y': 22}
>>> Point(**d)
Point(x=11, y=22)
```

因为一个命名元组是一个正常的 Python 类, 它可以很容易的通过子类更改功能。这里是如何添加一个计算域和定宽输出打印格式:

```
>>> class Point(namedtuple('Point', ['x', 'y'])):
...     __slots__ = ()
...     @property
...     def hypot(self):
...         return (self.x ** 2 + self.y ** 2) ** 0.5
...     def __str__(self):
...         return 'Point: x=%6.3f y=%6.3f hypot=%6.3f' % (self.x, self.y, self.
↪ hypot)

>>> for p in Point(3, 4), Point(14, 5/7):
```

(下页继续)

(续上页)

```
...     print(p)
Point: x= 3.000  y= 4.000  hypot= 5.000
Point: x=14.000  y= 0.714  hypot=14.018
```

上面的子类设置 `__slots__` 为一个空元组。通过阻止创建实例字典保持了较低的内存开销。

Subclassing is not useful for adding new, stored fields. Instead, simply create a new named tuple type from the `_fields` attribute:

```
>>> Point3D = namedtuple('Point3D', Point._fields + ('z',))
```

文档字符串可以自定义，通过直接赋值给 `__doc__` 属性：

```
>>> Book = namedtuple('Book', ['id', 'title', 'authors'])
>>> Book.__doc__ += ': Hardcover book in active collection'
>>> Book.id.__doc__ = '13-digit ISBN'
>>> Book.title.__doc__ = 'Title of first printing'
>>> Book.authors.__doc__ = 'List of authors sorted by last name'
```

在 3.5 版更改：文档字符串属性变成可写。

Default values can be implemented by using `_replace()` to customize a prototype instance:

```
>>> Account = namedtuple('Account', 'owner balance transaction_count')
>>> default_account = Account('<owner name>', 0.0, 0)
>>> johns_account = default_account._replace(owner='John')
>>> janes_account = default_account._replace(owner='Jane')
```

参见：

- [Recipe for named tuple abstract base class with a metaclass mix-in](#) by Jan Kaliszewski. Besides providing an *abstract base class* for named tuples, it also supports an alternate *metaclass*-based constructor that is convenient for use cases where named tuples are being subclassed.
- 对于以字典为底层的可变域名，参考 `types.SimpleNamespace()`。
- See `typing.NamedTuple()` for a way to add type hints for named tuples.

8.3.6 OrderedDict 对象

Ordered dictionaries are just like regular dictionaries but they remember the order that items were inserted. When iterating over an ordered dictionary, the items are returned in the order their keys were first added.

class `collections.OrderedDict` (`[items]`)

Return an instance of a dict subclass, supporting the usual *dict* methods. An *OrderedDict* is a dict that remembers the order that keys were first inserted. If a new entry overwrites an existing entry, the original insertion position is left unchanged. Deleting an entry and reinserting it will move it to the end.

3.1 新版功能.

popitem (`last=True`)

有序字典的 `popitem()` 方法移除并返回一个 (key, value) 键值对。如果 `last` 值为真，则按 LIFO (last-in, first-out) 后进先出的顺序返回键值对，否则就按 FIFO (first-in, first-out) 先进先出的顺序返回键值对。

move_to_end (`key`, `last=True`)

将现有 `key` 移动到有序字典的任一端。如果 `last` 为真值（默认）则将元素移至末尾；如果 `last` 为假值则将元素移至开头。如果 `key` 不存在则会触发 `KeyError`：

```
>>> d = OrderedDict.fromkeys('abcde')
>>> d.move_to_end('b')
>>> ''.join(d.keys())
'acdeb'
>>> d.move_to_end('b', last=False)
>>> ''.join(d.keys())
'bacde'
```

3.2 新版功能.

相对于通常的映射方法，有序字典还另外提供了逆序迭代的支持，通过 `reversed()`。

`OrderedDict` 之间的相等测试是顺序敏感的，实现为 `list(od1.items())==list(od2.items())`。`OrderedDict` 对象和其他的 `Mapping` 的相等测试，是顺序敏感的字典测试。这允许 `OrderedDict` 替换为任何字典可以使用的场所。

在 3.5 版更改: `OrderedDict` 的项 (item)，键 (key) 和值 (value) 视图现在支持逆序迭代，通过 `reversed()`。

在 3.6 版更改: **PEP 468** 赞成将关键词参数的顺序保留，通过传递给 `OrderedDict` 构造器和它的 `update()` 方法。

OrderedDict 例子和用法

Since an ordered dictionary remembers its insertion order, it can be used in conjunction with sorting to make a sorted dictionary:

```
>>> # regular unsorted dictionary
>>> d = {'banana': 3, 'apple': 4, 'pear': 1, 'orange': 2}

>>> # dictionary sorted by key
>>> OrderedDict(sorted(d.items(), key=lambda t: t[0]))
OrderedDict([('apple', 4), ('banana', 3), ('orange', 2), ('pear', 1)])

>>> # dictionary sorted by value
>>> OrderedDict(sorted(d.items(), key=lambda t: t[1]))
OrderedDict([('pear', 1), ('orange', 2), ('banana', 3), ('apple', 4)])

>>> # dictionary sorted by length of the key string
>>> OrderedDict(sorted(d.items(), key=lambda t: len(t[0])))
OrderedDict([('pear', 1), ('apple', 4), ('orange', 2), ('banana', 3)])
```

The new sorted dictionaries maintain their sort order when entries are deleted. But when new keys are added, the keys are appended to the end and the sort is not maintained.

It is also straight-forward to create an ordered dictionary variant that remembers the order the keys were *last* inserted. If a new entry overwrites an existing entry, the original insertion position is changed and moved to the end:

```
class LastUpdatedOrderedDict(OrderedDict):
    'Store items in the order the keys were last added'

    def __setitem__(self, key, value):
        if key in self:
            del self[key]
        OrderedDict.__setitem__(self, key, value)
```

An ordered dictionary can be combined with the `Counter` class so that the counter remembers the order elements are first encountered:

```
class OrderedCounter(Counter, OrderedDict):
    'Counter that remembers the order elements are first encountered'

    def __repr__(self):
        return '%s(%r)' % (self.__class__.__name__, OrderedDict(self))

    def __reduce__(self):
        return self.__class__, (OrderedDict(self),)
```

8.3.7 UserDict 对象

UserDict 类是用作字典对象的外包装。对这个类的需求已部分由直接创建 *dict* 的子类的功能所替代；不过，这个类处理起来更容易，因为底层的字典可以作为属性来访问。

```
class collections.UserDict([initialdata])
```

模拟一个字典类。这个实例的内容保存为一个正常字典，可以通过 *UserDict* 实例的 *data* 属性存取。如果提供了 *initialdata* 值，*data* 就被初始化为它的内容；注意一个 *initialdata* 的引用不会被保留作为其他用途。

UserDict 实例提供了以下属性作为扩展方法和操作的支持：

data

一个真实的字典，用于保存 *UserDict* 类的内容。

8.3.8 UserList 对象

这个类封装了列表对象。它是一个有用的基础类，对于你想自定义的类似列表的类，可以继承和覆盖现有的方法，也可以添加新的方法。这样我们可以对列表添加新的行为。

对这个类的需求已部分由直接创建 *list* 的子类的功能所替代；不过，这个类处理起来更容易，因为底层的列表可以作为属性来访问。

```
class collections.UserList([list])
```

模拟一个列表。这个实例的内容被保存为一个正常列表，通过 *UserList* 的 *data* 属性存取。实例内容被初始化为一个 *list* 的 *copy*，默认为 [] 空列表。*list* 可以是迭代对象，比如一个 Python 列表，或者一个 *UserList* 对象。

UserList 提供了以下属性作为可变序列的方法和操作的扩展：

data

一个 *list* 对象用于存储 *UserList* 的内容。

子类化的要求： *UserList* 的子类需要提供一个构造器，可以无参数调用，或者一个参数调用。返回一个新序列的列表操作需要创建一个实现类的实例。它假定了构造器可以以一个参数进行调用，这个参数是一个序列对象，作为数据源。

如果一个分离的类不希望依照这个需求，所有的特殊方法就必须重写；请参照源代码进行修改。

8.3.9 UserString 对象

UserString 类是用作字符串对象的外包装。对这个类的需求已部分由直接创建 *str* 的子类的功能所替代；不过，这个类处理起来更容易，因为底层的字符串可以作为属性来访问。

```
class collections.UserString([sequence])
```

Class that simulates a string or a Unicode string object. The instance's content is kept in a regular string object,

which is accessible via the `data` attribute of `UserString` instances. The instance's contents are initially set to a copy of `sequence`. The `sequence` can be an instance of `bytes`, `str`, `UserString` (or a subclass) or an arbitrary sequence which can be converted into a string using the built-in `str()` function.

在 3.5 版更改: 新方法 `__getnewargs__`, `__rmod__`, `casefold`, `format_map`, `isprintable`, 和 `maketrans`。

8.4 `collections.abc` —容器的抽象基类

3.3 新版功能: 该模块曾是 `collections` 模块的组成部分。

源代码: [Lib/_collections_abc.py](#)

该模块定义了一些抽象基类，它们可用于判断一个具体类是否具有某一特定的接口；例如，这个类是否可哈希，或其是否为映射类。

8.4.1 Collections Abstract Base Classes

The `collections` module offers the following ABCs:

ABC	Inherits from	Abstract Methods	Mixin Methods
<i>Container</i>		<code>__contains__</code>	
<i>Hashable</i>		<code>__hash__</code>	
<i>Iterable</i>		<code>__iter__</code>	
<i>Iterator</i>	<i>Iterable</i>	<code>__next__</code>	<code>__iter__</code>
<i>Reversible</i>	<i>Iterable</i>	<code>__reversed__</code>	
<i>Generator</i>	<i>Iterator</i>	<code>send</code> , <code>throw</code>	<code>close</code> , <code>__iter__</code> , <code>__next__</code>
<i>Sized</i>		<code>__len__</code>	
<i>Callable</i>		<code>__call__</code>	
<i>Collection</i>	<i>Sized</i> , <i>Iterable</i> , <i>Container</i>	<code>__contains__</code> , <code>__iter__</code> , <code>__len__</code>	
<i>Sequence</i>	<i>Reversible</i> , <i>Collection</i>	<code>__getitem__</code> , <code>__len__</code>	<code>__contains__</code> , <code>__iter__</code> , <code>__reversed__</code> , <code>index</code> , and <code>count</code>
<i>MutableSequence</i>	<i>Sequence</i>	<code>__getitem__</code> , <code>__setitem__</code> , <code>__delitem__</code> , <code>__len__</code> , <code>insert</code>	Inherited <i>Sequence</i> methods and <code>append</code> , <code>reverse</code> , <code>extend</code> , <code>pop</code> , <code>remove</code> , and <code>__iadd__</code>
<i>ByteString</i>	<i>Sequence</i>	<code>__getitem__</code> , <code>__len__</code>	Inherited <i>Sequence</i> methods
<i>Set</i>	<i>Collection</i>	<code>__contains__</code> , <code>__iter__</code> , <code>__len__</code>	<code>__le__</code> , <code>__lt__</code> , <code>__eq__</code> , <code>__ne__</code> , <code>__gt__</code> , <code>__ge__</code> , <code>__and__</code> , <code>__or__</code> , <code>__sub__</code> , <code>__xor__</code> , and <code>isdisjoint</code>
<i>MutableSet</i>	<i>Set</i>	<code>__contains__</code> , <code>__iter__</code> , <code>__len__</code> , <code>add</code> , <code>discard</code>	Inherited <i>Set</i> methods and <code>clear</code> , <code>pop</code> , <code>remove</code> , <code>__ior__</code> , <code>__iand__</code> , <code>__ixor__</code> , and <code>__isub__</code>
<i>Mapping</i>	<i>Collection</i>	<code>__getitem__</code> , <code>__iter__</code> , <code>__len__</code>	<code>__contains__</code> , <code>keys</code> , <code>items</code> , <code>values</code> , <code>get</code> , <code>__eq__</code> , and <code>__ne__</code>
<i>MutableMapping</i>	<i>Mapping</i>	<code>__getitem__</code> , <code>__setitem__</code> , <code>__delitem__</code> , <code>__iter__</code> , <code>__len__</code>	Inherited <i>Mapping</i> methods and <code>pop</code> , <code>popitem</code> , <code>clear</code> , <code>update</code> , and <code>setdefault</code>
<i>MappingView</i>	<i>Sized</i>		<code>__len__</code>
<i>ItemsView</i>	<i>MappingView</i> , <i>Set</i>		<code>__contains__</code> , <code>__iter__</code>
<i>KeysView</i>	<i>MappingView</i> , <i>Set</i>		<code>__contains__</code> , <code>__iter__</code>
<i>ValuesView</i>	<i>MappingView</i>		<code>__contains__</code> , <code>__iter__</code>
<i>Awaitable</i>		<code>__await__</code>	
<i>Coroutine</i>	<i>Awaitable</i>	<code>send</code> , <code>throw</code>	<code>close</code>
<i>AsyncIterable</i>		<code>__aiter__</code>	
<i>AsyncIterator</i>	<i>AsyncIterable</i>	<code>__anext__</code>	<code>__aiter__</code>
<i>AsyncGenerator</i>	<i>AsyncIterator</i>	<code>asend</code> , <code>athrow</code>	<code>aclose</code> , <code>__aiter__</code> , <code>__anext__</code>

```
class collections.abc.Container
```

```
class collections.abc.Hashable
```

```
class collections.abc.Sized
```

```
class collections.abc.Callable
```

ABCs for classes that provide respectively the methods `__contains__()`, `__hash__()`, `__len__()`, and `__call__()`.

```
class collections.abc.Iterable
```

ABC for classes that provide the `__iter__()` method.

Checking `isinstance(obj, Iterable)` detects classes that are registered as *Iterable* or that have an `__iter__()` method, but it does not detect classes that iterate with the `__getitem__()` method. The only reliable way to determine whether an object is *iterable* is to call `iter(obj)`.

class `collections.abc.Collection`

ABC for sized iterable container classes.

3.6 新版功能.

class `collections.abc.Iterator`

ABC for classes that provide the `__iter__()` and `__next__()` methods. See also the definition of *iterator*.

class `collections.abc.Reversible`

ABC for iterable classes that also provide the `__reversed__()` method.

3.6 新版功能.

class `collections.abc.Generator`

ABC for generator classes that implement the protocol defined in **PEP 342** that extends iterators with the `send()`, `throw()` and `close()` methods. See also the definition of *generator*.

3.5 新版功能.

class `collections.abc.Sequence`

class `collections.abc.MutableSequence`

class `collections.abc.ByteString`

ABCs for read-only and mutable *sequences*.

Implementation note: Some of the mixin methods, such as `__iter__()`, `__reversed__()` and `index()`, make repeated calls to the underlying `__getitem__()` method. Consequently, if `__getitem__()` is implemented with constant access speed, the mixin methods will have linear performance; however, if the underlying method is linear (as it would be with a linked list), the mixins will have quadratic performance and will likely need to be overridden.

在 3.5 版更改: The `index()` method added support for *stop* and *start* arguments.

class `collections.abc.Set`

class `collections.abc.MutableSet`

ABCs for read-only and mutable sets.

class `collections.abc.Mapping`

class `collections.abc.MutableMapping`

ABCs for read-only and mutable *mappings*.

class `collections.abc.MappingView`

class `collections.abc.ItemsView`

class `collections.abc.KeysView`

class `collections.abc.ValuesView`

ABCs for mapping, items, keys, and values *views*.

class `collections.abc.Awaitable`

ABC for *awaitable* objects, which can be used in `await` expressions. Custom implementations must provide the `__await__()` method.

Coroutine objects and instances of the *Coroutine* ABC are all instances of this ABC.

注解: In CPython, generator-based coroutines (generators decorated with `types.coroutine()` or `asyncio.coroutine()`) are *awaitables*, even though they do not have an `__await__()` method. Using

`isinstance(gencoro, Awaitable)` for them will return `False`. Use `inspect.isawaitable()` to detect them.

3.5 新版功能.

class `collections.abc.Coroutine`

ABC for coroutine compatible classes. These implement the following methods, defined in `coroutine-objects`: `send()`, `throw()`, and `close()`. Custom implementations must also implement `__await__()`. All *Coroutine* instances are also instances of *Awaitable*. See also the definition of *coroutine*.

注解: In CPython, generator-based coroutines (generators decorated with `types.coroutine()` or `asyncio.coroutine()`) are *awaitables*, even though they do not have an `__await__()` method. Using `isinstance(gencoro, Coroutine)` for them will return `False`. Use `inspect.isawaitable()` to detect them.

3.5 新版功能.

class `collections.abc.AsyncIterable`

ABC for classes that provide `__aiter__` method. See also the definition of *asynchronous iterable*.

3.5 新版功能.

class `collections.abc.AsyncIterator`

ABC for classes that provide `__aiter__` and `__anext__` methods. See also the definition of *asynchronous iterator*.

3.5 新版功能.

class `collections.abc.AsyncGenerator`

ABC for asynchronous generator classes that implement the protocol defined in **PEP 525** and **PEP 492**.

3.6 新版功能.

These ABCs allow us to ask classes or instances if they provide particular functionality, for example:

```
size = None
if isinstance(myvar, collections.abc.Sized):
    size = len(myvar)
```

Several of the ABCs are also useful as mixins that make it easier to develop classes supporting container APIs. For example, to write a class supporting the full *Set* API, it is only necessary to supply the three underlying abstract methods: `__contains__()`, `__iter__()`, and `__len__()`. The ABC supplies the remaining methods such as `__and__()` and `isdisjoint()`:

```
class ListBasedSet(collections.abc.Set):
    ''' Alternate set implementation favoring space over speed
        and not requiring the set elements to be hashable. '''
    def __init__(self, iterable):
        self.elements = lst = []
        for value in iterable:
            if value not in lst:
                lst.append(value)

    def __iter__(self):
        return iter(self.elements)

    def __contains__(self, value):
```

(下页继续)

(续上页)

```

        return value in self.elements

    def __len__(self):
        return len(self.elements)

s1 = ListBasedSet('abcdef')
s2 = ListBasedSet('defghi')
overlap = s1 & s2           # The __and__() method is supported automatically

```

Notes on using *Set* and *MutableSet* as a mixin:

- (1) Since some set operations create new sets, the default mixin methods need a way to create new instances from an iterable. The class constructor is assumed to have a signature in the form `ClassName(iterable)`. That assumption is factored-out to an internal classmethod called `_from_iterable()` which calls `cls(iterable)` to produce a new set. If the *Set* mixin is being used in a class with a different constructor signature, you will need to override `_from_iterable()` with a classmethod that can construct new instances from an iterable argument.
- (2) To override the comparisons (presumably for speed, as the semantics are fixed), redefine `__le__()` and `__ge__()`, then the other operations will automatically follow suit.
- (3) The *Set* mixin provides a `_hash()` method to compute a hash value for the set; however, `__hash__()` is not defined because not all sets are hashable or immutable. To add set hashability using mixins, inherit from both *Set()* and *Hashable()*, then define `__hash__ = Set._hash`.

参见:

- [OrderedSet recipe](#) for an example built on *MutableSet*.
- For more about ABCs, see the [abc](#) module and [PEP 3119](#).

8.5 heapq — 堆队列算法

源码: [Lib/heapq.py](#)

这个模块提供了堆队列算法的实现，也称为优先队列算法。

堆是一个二叉树，它的每个父节点的值都只会小于或大于所有孩子节点（的值）。它使用了数组来实现：从零开始计数，对于所有的 k ，都有 “ $\text{heap}[k] \leq \text{heap}[2*k+1]$ ” 和 $\text{heap}[k] \leq \text{heap}[2*k+2]$ 。为了便于比较，不存在的元素被认为是无限大。堆最有趣的特性在于最小的元素总是在根结点： $\text{heap}[0]$ 。

这个 API 与教材的堆算法实现不太一样，在于两方面：(a) 我们使用了基于零开始进行索引。这使得节点和其孩子节点索引之间的关系不太直观，但是更加适合

基于这两方面，把堆看作原生的 Python list 也没什么奇怪的： $\text{heap}[0]$ 表示最小的元素，同时 `heap.sort()` 维护了堆的不变性！

要创建一个堆，可以使用 list 来初始化为 `[]`，或者你可以通过一个函数 `heapify()`，来把一个 list 转换成堆。

定义了以下函数：

`heapq.heappush(heap, item)`

将 `item` 的值加入 `heap` 中，保持堆的不变性。

`heapq.heappop(heap)`

弹出并返回 `heap` 的最小的元素，保持堆的不变性。如果堆为空，抛出 `IndexError`。使用 `heap[0]`，可以只访问最小的元素而不弹出它。

`heapq.heappushpop(heap, item)`

将 *item* 放入堆中，然后弹出并返回 *heap* 的最小元素。该组合操作比先调用 `heappush()` 再调用 `heappop()` 运行起来更有效率。

`heapq.heapify(x)`

将 list *x* 转换成堆，原地，线性时间内。

`heapq.heapreplace(heap, item)`

Pop and return the smallest item from the *heap*, and also push the new *item*. The heap size doesn't change. If the heap is empty, `IndexError` is raised.

This one step operation is more efficient than a `heappop()` followed by `heappush()` and can be more appropriate when using a fixed-size heap. The pop/push combination always returns an element from the heap and replaces it with *item*.

The value returned may be larger than the *item* added. If that isn't desired, consider using `heappushpop()` instead. Its push/pop combination returns the smaller of the two values, leaving the larger value on the heap.

The module also offers three general purpose functions based on heaps.

`heapq.merge(*iterables, key=None, reverse=False)`

Merge multiple sorted inputs into a single sorted output (for example, merge timestamped entries from multiple log files). Returns an *iterator* over the sorted values.

Similar to `sorted(itertools.chain(*iterables))` but returns an iterable, does not pull the data into memory all at once, and assumes that each of the input streams is already sorted (smallest to largest).

具有两个可选参数，它们都必须指定为关键字参数。

key specifies a *key function* of one argument that is used to extract a comparison key from each input element. The default value is `None` (compare the elements directly).

reverse is a boolean value. If set to `True`, then the input elements are merged as if each comparison were reversed.

在 3.5 版更改: Added the optional *key* and *reverse* parameters.

`heapq.nlargest(n, iterable, key=None)`

Return a list with the *n* largest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). Equivalent to: `sorted(iterable, key=key, reverse=True)[:n]`.

`heapq.nsmallest(n, iterable, key=None)`

Return a list with the *n* smallest elements from the dataset defined by *iterable*. *key*, if provided, specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). Equivalent to: `sorted(iterable, key=key)[:n]`.

The latter two functions perform best for smaller values of *n*. For larger values, it is more efficient to use the `sorted()` function. Also, when *n*=1, it is more efficient to use the built-in `min()` and `max()` functions. If repeated usage of these functions is required, consider turning the iterable into an actual heap.

8.5.1 基本示例

A *heapsort* can be implemented by pushing all values onto a heap and then popping off the smallest values one at a time:

```
>>> def heapsort(iterable):
...     h = []
...     for value in iterable:
...         heappush(h, value)
...     return [heappop(h) for i in range(len(h))]
... 
```

(下页继续)

(续上页)

```
>>> heap sort([1, 3, 5, 7, 9, 2, 4, 6, 8, 0])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

This is similar to `sorted(iterable)`, but unlike `sorted()`, this implementation is not stable.

Heap elements can be tuples. This is useful for assigning comparison values (such as task priorities) alongside the main record being tracked:

```
>>> h = []
>>> heappush(h, (5, 'write code'))
>>> heappush(h, (7, 'release product'))
>>> heappush(h, (1, 'write spec'))
>>> heappush(h, (3, 'create tests'))
>>> heappop(h)
(1, 'write spec')
```

8.5.2 Priority Queue Implementation Notes

A **priority queue** is common use for a heap, and it presents several implementation challenges:

- Sort stability: how do you get two tasks with equal priorities to be returned in the order they were originally added?
- Tuple comparison breaks for (priority, task) pairs if the priorities are equal and the tasks do not have a default comparison order.
- If the priority of a task changes, how do you move it to a new position in the heap?
- Or if a pending task needs to be deleted, how do you find it and remove it from the queue?

A solution to the first two challenges is to store entries as 3-element list including the priority, an entry count, and the task. The entry count serves as a tie-breaker so that two tasks with the same priority are returned in the order they were added. And since no two entry counts are the same, the tuple comparison will never attempt to directly compare two tasks.

The remaining challenges revolve around finding a pending task and making changes to its priority or removing it entirely. Finding a task can be done with a dictionary pointing to an entry in the queue.

Removing the entry or changing its priority is more difficult because it would break the heap structure invariants. So, a possible solution is to mark the entry as removed and add a new entry with the revised priority:

```
pq = []                                # list of entries arranged in a heap
entry_finder = {}                       # mapping of tasks to entries
REMOVED = '<removed-task>'              # placeholder for a removed task
counter = itertools.count()             # unique sequence count

def add_task(task, priority=0):
    'Add a new task or update the priority of an existing task'
    if task in entry_finder:
        remove_task(task)
    count = next(counter)
    entry = [priority, count, task]
    entry_finder[task] = entry
    heappush(pq, entry)

def remove_task(task):
    'Mark an existing task as REMOVED. Raise KeyError if not found.'

            return task
    raise KeyError('pop from an empty priority queue')
```

8.5.3 Theory

Heaps are arrays for which $a[k] \leq a[2k+1]$ and $a[k] \leq a[2k+2]$ for all k , counting elements from 0. For the sake of comparison, non-existing elements are considered to be infinite. The interesting property of a heap is that $a[0]$ is always its smallest element.

The strange invariant above is meant to be an efficient memory representation for a tournament. The numbers below are k , not $a[k]$:

In the tree above, each cell k is topping $2k+1$ and $2k+2$. In a usual binary tournament we see in sports, each cell is the winner over the two cells it tops, and we can trace the winner down the tree to see all opponents s/he had. However, in many computer applications of such tournaments, we do not need to trace the history of a winner. To be more memory efficient, when a winner is promoted, we try to replace it by something else at a lower level, and the rule becomes that a cell and the two cells it tops contain three different items, but the top cell “wins” over the two topped cells.

If this heap invariant is protected at all time, index 0 is clearly the overall winner. The simplest algorithmic way to remove it and find the “next” winner is to move some loser (let’s say cell 30 in the diagram above) into the 0 position, and then percolate this new 0 down the tree, exchanging values, until the invariant is re-established. This is clearly logarithmic on the total number of items in the tree. By iterating over all items, you get an $O(n \log n)$ sort.

A nice feature of this sort is that you can efficiently insert new items while the sort is going on, provided that the inserted items are not “better” than the last 0th element you extracted. This is especially useful in simulation contexts, where the tree holds all incoming events, and the “win” condition means the smallest scheduled time. When an event schedules other events for execution, they are scheduled into the future, so they can easily go into the heap. So, a heap is a good structure for implementing schedulers (this is what I used for my MIDI sequencer :-).

Various structures for implementing schedulers have been extensively studied, and heaps are good for this, as they are reasonably speedy, the speed is almost constant, and the worst case is not much different than the average case. However, there are other representations which are more efficient overall, yet the worst cases might be terrible.

Heaps are also very useful in big disk sorts. You most probably all know that a big sort implies producing “runs” (which are pre-sorted sequences, whose size is usually related to the amount of CPU memory), followed by a merging passes for these runs, which merging is often very cleverly organised¹. It is very important that the initial sort produces the longest

¹ The disk balancing algorithms which are current, nowadays, are more annoying than clever, and this is a consequence of the seeking capabilities of the disks. On devices which cannot seek, like big tape drives, the story was quite different, and one had to be very clever to ensure (far in advance)

runs possible. Tournaments are a good way to achieve that. If, using all the memory available to hold a tournament, you replace and percolate items that happen to fit the current run, you'll produce runs which are twice the size of the memory for random input, and much better for input fuzzily ordered.

Moreover, if you output the 0th item on disk and get an input which may not fit in the current tournament (because the value “wins” over the last output value), it cannot fit in the heap, so the size of the heap decreases. The freed memory could be cleverly reused immediately for progressively building a second heap, which grows at exactly the same rate the first heap is melting. When the first heap completely vanishes, you switch heaps and start a new run. Clever and quite effective!

In a word, heaps are useful memory structures to know. I use them in a few applications, and I think it is good to keep a ‘heap’ module around. :-)

8.6 bisect —Array bisection algorithm

Source code: [Lib/bisect.py](#)

This module provides support for maintaining a list in sorted order without having to sort the list after each insertion. For long lists of items with expensive comparison operations, this can be an improvement over the more common approach. The module is called *bisect* because it uses a basic bisection algorithm to do its work. The source code may be most useful as a working example of the algorithm (the boundary conditions are already right!).

定义了以下函数：

`bisect.bisect_left(a, x, lo=0, hi=len(a))`

Locate the insertion point for *x* in *a* to maintain sorted order. The parameters *lo* and *hi* may be used to specify a subset of the list which should be considered; by default the entire list is used. If *x* is already present in *a*, the insertion point will be before (to the left of) any existing entries. The return value is suitable for use as the first parameter to `list.insert()` assuming that *a* is already sorted.

The returned insertion point *i* partitions the array *a* into two halves so that `all(val < x for val in a[lo:i])` for the left side and `all(val >= x for val in a[i:hi])` for the right side.

`bisect.bisect_right(a, x, lo=0, hi=len(a))`

`bisect.bisect(a, x, lo=0, hi=len(a))`

Similar to `bisect_left()`, but returns an insertion point which comes after (to the right of) any existing entries of *x* in *a*.

The returned insertion point *i* partitions the array *a* into two halves so that `all(val <= x for val in a[lo:i])` for the left side and `all(val > x for val in a[i:hi])` for the right side.

`bisect.insort_left(a, x, lo=0, hi=len(a))`

Insert *x* in *a* in sorted order. This is equivalent to `a.insert(bisect.bisect_left(a, x, lo, hi), x)` assuming that *a* is already sorted. Keep in mind that the $O(\log n)$ search is dominated by the slow $O(n)$ insertion step.

`bisect.insort_right(a, x, lo=0, hi=len(a))`

`bisect.insort(a, x, lo=0, hi=len(a))`

Similar to `insort_left()`, but inserting *x* in *a* after any existing entries of *x*.

参见：

[SortedCollection](#) recipe that uses `bisect` to build a full-featured collection class with straight-forward search methods and support for a key-function. The keys are precomputed to save unnecessary calls to the key function during searches.

that each tape movement will be the most effective possible (that is, will best participate at “progressing” the merge). Some tapes were even able to read backwards, and this was also used to avoid the rewinding time. Believe me, real good tape sorts were quite spectacular to watch! From all times, sorting has always been a Great Art! :-)

8.6.1 Searching Sorted Lists

The above `bisect()` functions are useful for finding insertion points but can be tricky or awkward to use for common searching tasks. The following five functions show how to transform them into the standard lookups for sorted lists:

```
def index(a, x):
    'Locate the leftmost value exactly equal to x'
    i = bisect_left(a, x)
    if i != len(a) and a[i] == x:
        return i
    raise ValueError

def find_lt(a, x):
    'Find rightmost value less than x'
    i = bisect_left(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_le(a, x):
    'Find rightmost value less than or equal to x'
    i = bisect_right(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_gt(a, x):
    'Find leftmost value greater than x'
    i = bisect_right(a, x)
    if i != len(a):
        return a[i]
    raise ValueError

def find_ge(a, x):
    'Find leftmost item greater than or equal to x'
    i = bisect_left(a, x)
    if i != len(a):
        return a[i]
    raise ValueError
```

8.6.2 Other Examples

The `bisect()` function can be useful for numeric table lookups. This example uses `bisect()` to look up a letter grade for an exam score (say) based on a set of ordered numeric breakpoints: 90 and up is an 'A', 80 to 89 is a 'B', and so on:

```
>>> def grade(score, breakpoints=[60, 70, 80, 90], grades='FDCBA'):
...     i = bisect(breakpoints, score)
...     return grades[i]
...
>>> [grade(score) for score in [33, 99, 77, 70, 89, 90, 100]]
['F', 'A', 'C', 'C', 'B', 'A', 'A']
```

Unlike the `sorted()` function, it does not make sense for the `bisect()` functions to have `key` or `reversed` arguments because that would lead to an inefficient design (successive calls to `bisect` functions would not “remember” all of the previous key lookups).

Instead, it is better to search a list of precomputed keys to find the index of the record in question:

```
>>> data = [('red', 5), ('blue', 1), ('yellow', 8), ('black', 0)]
>>> data.sort(key=lambda r: r[1])
>>> keys = [r[1] for r in data]           # precomputed list of keys
>>> data[bisect_left(keys, 0)]
('black', 0)
>>> data[bisect_left(keys, 1)]
('blue', 1)
>>> data[bisect_left(keys, 5)]
('red', 5)
>>> data[bisect_left(keys, 8)]
('yellow', 8)
```

8.7 array — Efficient arrays of numeric values

This module defines an object type which can compactly represent an array of basic values: characters, integers, floating point numbers. Arrays are sequence types and behave very much like lists, except that the type of objects stored in them is constrained. The type is specified at object creation time by using a *type code*, which is a single character. The following type codes are defined:

Type code	C 类型	Python Type	Minimum size in bytes	注释
'b'	signed char	int	1	
'B'	unsigned char	int	1	
'u'	Py_UNICODE	Unicode character	2	(1)
'h'	signed short	int	2	
'H'	unsigned short	int	2	
'i'	signed int	int	2	
'I'	无符号整型	int	2	
'l'	signed long	int	4	
'L'	无符号长整型	int	4	
'q'	signed long long	int	8	(2)
'Q'	无符号 long long	int	8	(2)
'f'	float	float	4	
'd'	double	float	8	

注释:

- (1) The 'u' type code corresponds to Python's obsolete unicode character (Py_UNICODE which is wchar_t). Depending on the platform, it can be 16 bits or 32 bits.

'u' will be removed together with the rest of the Py_UNICODE API.

Deprecated since version 3.3, will be removed in version 4.0.

- (2) The 'q' and 'Q' type codes are available only if the platform C compiler used to build Python supports C long long, or, on Windows, __int64.

3.3 新版功能.

The actual representation of values is determined by the machine architecture (strictly speaking, by the C implementation). The actual size can be accessed through the `itemsize` attribute.

The module defines the following type:

class `array.array`(*typecode*[, *initializer*])

A new array whose items are restricted by *typecode*, and initialized from the optional *initializer* value, which must be a list, a *bytes-like object*, or iterable over elements of the appropriate type.

If given a list or string, the initializer is passed to the new array's `fromlist()`, `frombytes()`, or `fromunicode()` method (see below) to add initial items to the array. Otherwise, the iterable initializer is passed to the `extend()` method.

`array.typecodes`

A string with all available type codes.

Array objects support the ordinary sequence operations of indexing, slicing, concatenation, and multiplication. When using slice assignment, the assigned value must be an array object with the same type code; in all other cases, `TypeError` is raised. Array objects also implement the buffer interface, and may be used wherever *bytes-like objects* are supported.

The following data items and methods are also supported:

`array.typecode`

The typecode character used to create the array.

`array.itemsize`

The length in bytes of one array item in the internal representation.

`array.append(x)`

Append a new item with value *x* to the end of the array.

`array.buffer_info()`

Return a tuple (*address*, *length*) giving the current memory address and the length in elements of the buffer used to hold array's contents. The size of the memory buffer in bytes can be computed as `array.buffer_info()[1] * array.itemsize`. This is occasionally useful when working with low-level (and inherently unsafe) I/O interfaces that require memory addresses, such as certain `ioctl()` operations. The returned numbers are valid as long as the array exists and no length-changing operations are applied to it.

注解: When using array objects from code written in C or C++ (the only way to effectively make use of this information), it makes more sense to use the buffer interface supported by array objects. This method is maintained for backward compatibility and should be avoided in new code. The buffer interface is documented in `bufferobjects`.

`array.byteswap()`

“Byteswap” all items of the array. This is only supported for values which are 1, 2, 4, or 8 bytes in size; for other types of values, `RuntimeError` is raised. It is useful when reading data from a file written on a machine with a different byte order.

`array.count(x)`

Return the number of occurrences of *x* in the array.

`array.extend(iterable)`

Append items from *iterable* to the end of the array. If *iterable* is another array, it must have *exactly* the same type code; if not, `TypeError` will be raised. If *iterable* is not an array, it must be iterable and its elements must be the right type to be appended to the array.

`array.frombytes(s)`

Appends items from the string, interpreting the string as an array of machine values (as if it had been read from a file using the `fromfile()` method).

3.2 新版功能: `fromstring()` is renamed to `frombytes()` for clarity.

`array.fromfile(f, n)`

Read *n* items (as machine values) from the *file object* *f* and append them to the end of the array. If less than *n*

items are available, `EOFError` is raised, but the items that were available are still inserted into the array. `f` must be a real built-in file object; something else with a `read()` method won't do.

`array.fromlist(list)`

Append items from the list. This is equivalent to `for x in list: a.append(x)` except that if there is a type error, the array is unchanged.

`array.fromstring()`

Deprecated alias for `frombytes()`.

`array.fromunicode(s)`

Extends this array with data from the given unicode string. The array must be a type 'u' array; otherwise a `ValueError` is raised. Use `array.frombytes(unicodestring.encode(enc))` to append Unicode data to an array of some other type.

`array.index(x)`

Return the smallest *i* such that *i* is the index of the first occurrence of *x* in the array.

`array.insert(i, x)`

Insert a new item with value *x* in the array before position *i*. Negative values are treated as being relative to the end of the array.

`array.pop([i])`

Removes the item with the index *i* from the array and returns it. The optional argument defaults to `-1`, so that by default the last item is removed and returned.

`array.remove(x)`

Remove the first occurrence of *x* from the array.

`array.reverse()`

Reverse the order of the items in the array.

`array.tobytes()`

Convert the array to an array of machine values and return the bytes representation (the same sequence of bytes that would be written to a file by the `tofile()` method.)

3.2 新版功能: `tostring()` is renamed to `tobytes()` for clarity.

`array.tofile(f)`

Write all items (as machine values) to the *file object* *f*.

`array.tolist()`

Convert the array to an ordinary list with the same items.

`array.tostring()`

Deprecated alias for `tobytes()`.

`array.tounicode()`

Convert the array to a unicode string. The array must be a type 'u' array; otherwise a `ValueError` is raised. Use `array.tobytes().decode(enc)` to obtain a unicode string from an array of some other type.

When an array object is printed or converted to a string, it is represented as `array(typecode, initializer)`. The *initializer* is omitted if the array is empty, otherwise it is a string if the *typecode* is 'u', otherwise it is a list of numbers. The string is guaranteed to be able to be converted back to an array with the same type and value using `eval()`, so long as the `array` class has been imported using `from array import array`. Examples:

```
array('l')
array('u', 'hello \u2641')
array('l', [1, 2, 3, 4, 5])
array('d', [1.0, 2.0, 3.14])
```

8.8 weakref — 弱引用

源码: [Lib/weakref.py](#)

`weakref` 模块允许 Python 程序员创建对象的 *weak references*。

在下文中，术语 *referent* 表示由弱引用引用的对象。

对对象的弱引用不能保证对象存活：当对象的引用只剩弱引用时，*garbage collection* 可以销毁引用并将其内存重用于其他内容。但是，在实际销毁对象之前，即使没有强引用，弱引用也一直能返回该对象。

弱引用的主要用途是实现保存大对象的高速缓存或映射，但又并希望大对象仅仅因为它出现在高速缓存或映射中而保持存活。

例如，如果您有许多大型二进制图像对象，则可能希望将名称与每个对象关联起来。如果您使用 Python 字典将名称映射到图像，或将图像映射到名称，则图像对象将保持活动状态，因为它们在字典中显示为值或键。`weakref` 模块提供的 `WeakKeyDictionary` 和 `WeakValueDictionary` 类可以替代 Python 字典，使用弱引用来构造映射，这些映射不会仅仅因为它们出现在映射对象中而使对象保持存活。例如，如果一个图像对象是 `WeakValueDictionary` 中的值，那么当对该图像对象的剩余引用是弱映射对象所持有的弱引用时，垃圾回收可以回收该对象并将其在弱映射对象中相应的条目删除。

`WeakKeyDictionary` 和 `WeakValueDictionary` 在它们的实现中使用弱引用，在弱引用上设置回调函数，当键或值被垃圾回收回收时通知弱字典。`WeakSet` 实现了 `set` 接口，但像 `WeakKeyDictionary` 一样，只持有其元素的弱引用。

`finalize` 提供了注册一个对象被垃圾收集时要调用的清理函数的方式。这比在原始弱引用上设置回调函数更简单，因为模块会自动确保对象被回收前终结器一直保持存活。

这些弱容器类型之一或者 `finalize` 就是大多数程序所需要的 - 通常不需要直接创建自己的弱引用。`weakref` 模块暴露了低级机制，以便于高级用途。

Not all objects can be weakly referenced; those objects which can include class instances, functions written in Python (but not in C), instance methods, sets, frozensets, some *file objects*, *generators*, type objects, sockets, arrays, dequeues, regular expression pattern objects, and code objects.

在 3.2 版更改: 添加了对 `thread.lock`，`threading.Lock` 和代码对象的支持。

几个内建类型如 `list` 和 `dict` 不直接支持弱引用，但可以通过子类化添加支持:

```
class Dict(dict):
    pass

obj = Dict(red=1, green=2, blue=3)  # this object is weak referenceable
```

Other built-in types such as `tuple` and `int` do not support weak references even when subclassed (This is an implementation detail and may be different across various Python implementations.).

Extension types can easily be made to support weak references; see `weakref-support`.

class `weakref.ref(object[, callback])`

返回对对象的弱引用。如果原始对象仍然存活，则可以通过调用引用对象来检索原始对象；如果引用的原始对象不再存在，则调用引用对象将得到`None`。如果提供了回调而且值不是`None`，并且返回的弱引用对象仍然存活，则在对象即将终结时将调用回调；弱引用对象将作为回调的唯一参数传递；指示物将不再可用。

It is allowable for many weak references to be constructed for the same object. Callbacks registered for each weak reference will be called from the most recently registered callback to the oldest registered callback.

Exceptions raised by the callback will be noted on the standard error output, but cannot be propagated; they are handled in exactly the same way as exceptions raised from an object's `__del__()` method.

Weak references are *hashable* if the *object* is hashable. They will maintain their hash value even after the *object* was deleted. If `hash()` is called the first time only after the *object* was deleted, the call will raise `TypeError`.

Weak references support tests for equality, but not ordering. If the referents are still alive, two references have the same equality relationship as their referents (regardless of the *callback*). If either referent has been deleted, the references are equal only if the reference objects are the same object.

This is a subclassable type rather than a factory function.

__callback__

This read-only attribute returns the callback currently associated to the weakref. If there is no callback or if the referent of the weakref is no longer alive then this attribute will have value `None`.

在 3.4 版更改: Added the `__callback__` attribute.

`weakref.proxy(object[, callback])`

Return a proxy to *object* which uses a weak reference. This supports use of the proxy in most contexts instead of requiring the explicit dereferencing used with weak reference objects. The returned object will have a type of either `ProxyType` or `CallableProxyType`, depending on whether *object* is callable. Proxy objects are not *hashable* regardless of the referent; this avoids a number of problems related to their fundamentally mutable nature, and prevent their use as dictionary keys. *callback* is the same as the parameter of the same name to the `ref()` function.

`weakref.getweakrefcount(object)`

Return the number of weak references and proxies which refer to *object*.

`weakref.getweakrefs(object)`

Return a list of all weak reference and proxy objects which refer to *object*.

class `weakref.WeakKeyDictionary([dict])`

Mapping class that references keys weakly. Entries in the dictionary will be discarded when there is no longer a strong reference to the key. This can be used to associate additional data with an object owned by other parts of an application without adding attributes to those objects. This can be especially useful with objects that override attribute accesses.

注解: Caution: Because a `WeakKeyDictionary` is built on top of a Python dictionary, it must not change size when iterating over it. This can be difficult to ensure for a `WeakKeyDictionary` because actions performed by the program during iteration may cause items in the dictionary to vanish “by magic” (as a side effect of garbage collection).

`WeakKeyDictionary` objects have an additional method that exposes the internal references directly. The references are not guaranteed to be “live” at the time they are used, so the result of calling the references needs to be checked before being used. This can be used to avoid creating references that will cause the garbage collector to keep the keys around longer than needed.

`WeakKeyDictionary.keyrefs()`

Return an iterable of the weak references to the keys.

class weakref.**WeakValueDictionary** (*[dict]*)

Mapping class that references values weakly. Entries in the dictionary will be discarded when no strong reference to the value exists any more.

注解: Caution: Because a *WeakValueDictionary* is built on top of a Python dictionary, it must not change size when iterating over it. This can be difficult to ensure for a *WeakValueDictionary* because actions performed by the program during iteration may cause items in the dictionary to vanish “by magic” (as a side effect of garbage collection).

WeakValueDictionary objects have an additional method that has the same issues as the *keyrefs()* method of *WeakKeyDictionary* objects.

WeakValueDictionary.**valuerefs**()

Return an iterable of the weak references to the values.

class weakref.**WeakSet** (*[elements]*)

Set class that keeps weak references to its elements. An element will be discarded when no strong reference to it exists any more.

class weakref.**WeakMethod** (*method*)

A custom *ref* subclass which simulates a weak reference to a bound method (i.e., a method defined on a class and looked up on an instance). Since a bound method is ephemeral, a standard weak reference cannot keep hold of it. *WeakMethod* has special code to recreate the bound method until either the object or the original function dies:

```
>>> class C:
...     def method(self):
...         print("method called!")
...
>>> c = C()
>>> r = weakref.ref(c.method)
>>> r()
>>> r = weakref.WeakMethod(c.method)
>>> r()
<bound method C.method of <__main__.C object at 0x7fc859830220>>
>>> r() ()
method called!
>>> del c
>>> gc.collect()
0
>>> r()
>>>
```

3.4 新版功能.

class weakref.**finalize** (*obj, func, *args, **kwargs*)

Return a callable finalizer object which will be called when *obj* is garbage collected. Unlike an ordinary weak reference, a finalizer will always survive until the reference object is collected, greatly simplifying lifecycle management.

A finalizer is considered *alive* until it is called (either explicitly or at garbage collection), and after that it is *dead*. Calling a live finalizer returns the result of evaluating *func(*arg, **kwargs)*, whereas calling a dead finalizer returns *None*.

Exceptions raised by finalizer callbacks during garbage collection will be shown on the standard error output, but cannot be propagated. They are handled in the same way as exceptions raised from an object's *__del__()* method or a weak reference's callback.

When the program exits, each remaining live finalizer is called unless its `atexit` attribute has been set to false. They are called in reverse order of creation.

A finalizer will never invoke its callback during the later part of the *interpreter shutdown* when module globals are liable to have been replaced by `None`.

`__call__()`

If *self* is alive then mark it as dead and return the result of calling `func(*args, **kwargs)`. If *self* is dead then return `None`.

`detach()`

If *self* is alive then mark it as dead and return the tuple `(obj, func, args, kwargs)`. If *self* is dead then return `None`.

`peek()`

If *self* is alive then return the tuple `(obj, func, args, kwargs)`. If *self* is dead then return `None`.

`alive`

Property which is true if the finalizer is alive, false otherwise.

`atexit`

A writable boolean property which by default is true. When the program exits, it calls all remaining live finalizers for which `atexit` is true. They are called in reverse order of creation.

注解: It is important to ensure that *func*, *args* and *kwargs* do not own any references to *obj*, either directly or indirectly, since otherwise *obj* will never be garbage collected. In particular, *func* should not be a bound method of *obj*.

3.4 新版功能.

`weakref.ReferenceType`

The type object for weak references objects.

`weakref.ProxyType`

The type object for proxies of objects which are not callable.

`weakref.CallableProxyType`

The type object for proxies of callable objects.

`weakref.ProxyTypes`

Sequence containing all the type objects for proxies. This can make it simpler to test if an object is a proxy without being dependent on naming both proxy types.

exception `weakref.ReferenceError`

Exception raised when a proxy object is used but the underlying object has been collected. This is the same as the standard `ReferenceError` exception.

参见:

PEP 205 - Weak References The proposal and rationale for this feature, including links to earlier implementations and information about similar features in other languages.

8.8.1 弱引用对象

Weak reference objects have no methods and no attributes besides `ref.__callback__`. A weak reference object allows the referent to be obtained, if it still exists, by calling it:

```
>>> import weakref
>>> class Object:
...     pass
...
>>> o = Object()
>>> r = weakref.ref(o)
>>> o2 = r()
>>> o is o2
True
```

If the referent no longer exists, calling the reference object returns *None*:

```
>>> del o, o2
>>> print(r())
None
```

Testing that a weak reference object is still live should be done using the expression `ref() is not None`. Normally, application code that needs to use a reference object should follow this pattern:

```
# r is a weak reference object
o = r()
if o is None:
    # referent has been garbage collected
    print("Object has been deallocated; can't frobnicate.")
else:
    print("Object is still live!")
    o.do_something_useful()
```

Using a separate test for “liveness” creates race conditions in threaded applications; another thread can cause a weak reference to become invalidated before the weak reference is called; the idiom shown above is safe in threaded applications as well as single-threaded applications.

Specialized versions of *ref* objects can be created through subclassing. This is used in the implementation of the *WeakValueDictionary* to reduce the memory overhead for each entry in the mapping. This may be most useful to associate additional information with a reference, but could also be used to insert additional processing on calls to retrieve the referent.

This example shows how a subclass of *ref* can be used to store additional information about an object and affect the value that’s returned when the referent is accessed:

```
import weakref

class ExtendedRef(weakref.ref):
    def __init__(self, ob, callback=None, **annotations):
        super(ExtendedRef, self).__init__(ob, callback)
        self.__counter = 0
        for k, v in annotations.items():
            setattr(self, k, v)

    def __call__(self):
        """Return a pair containing the referent and the number of
        times the reference has been called.
        """
        ob = super(ExtendedRef, self).__call__()
        if ob is not None:
            self.__counter += 1
            ob = (ob, self.__counter)
        return ob
```

8.8.2 示例

This simple example shows how an application can use object IDs to retrieve objects that it has seen before. The IDs of the objects can then be used in other data structures without forcing the objects to remain alive, but the objects can still be retrieved by ID if they do.

```
import weakref

_id2obj_dict = weakref.WeakValueDictionary()

def remember(obj):
    oid = id(obj)
    _id2obj_dict[oid] = obj
    return oid

def id2obj(oid):
    return _id2obj_dict[oid]
```

8.8.3 Finalizer Objects

The main benefit of using *finalize* is that it makes it simple to register a callback without needing to preserve the returned finalizer object. For instance

```
>>> import weakref
>>> class Object:
...     pass
...
>>> kenny = Object()
>>> weakref.finalize(kenny, print, "You killed Kenny!") #doctest:+ELLIPSIS
<finalize object at ...; for 'Object' at ...>
>>> del kenny
You killed Kenny!
```

The finalizer can be called directly as well. However the finalizer will invoke the callback at most once.

```
>>> def callback(x, y, z):
...     print("CALLBACK")
...     return x + y + z
...
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> assert f.alive
>>> assert f() == 6
CALLBACK
>>> assert not f.alive
>>> f() # callback not called because finalizer dead
>>> del obj # callback not called because finalizer dead
```

You can unregister a finalizer using its *detach()* method. This kills the finalizer and returns the arguments passed to the constructor when it was created.

```
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> f.detach() #doctest:+ELLIPSIS
(<__main__.Object object ...>, <function callback ...>, (1, 2), {'z': 3})
```

(下页继续)

(续上页)

```
>>> newobj, func, args, kwargs = _
>>> assert not f.alive
>>> assert newobj is obj
>>> assert func(*args, **kwargs) == 6
CALLBACK
```

Unless you set the `atexit` attribute to `False`, a finalizer will be called when the program exits if it is still alive. For instance

```
>>> obj = Object()
>>> weakref.finalize(obj, print, "obj dead or exiting") #doctest:+ELLIPSIS
<finalize object at ...; for 'Object' at ...>
>>> exit() #doctest:+SKIP
obj dead or exiting
```

8.8.4 Comparing finalizers with `__del__()` methods

Suppose we want to create a class whose instances represent temporary directories. The directories should be deleted with their contents when the first of the following events occurs:

- the object is garbage collected,
- the object's `remove()` method is called, or
- the program exits.

We might try to implement the class using a `__del__()` method as follows:

```
class TempDir:
    def __init__(self):
        self.name = tempfile.mkdtemp()

    def remove(self):
        if self.name is not None:
            shutil.rmtree(self.name)
            self.name = None

    @property
    def removed(self):
        return self.name is None

    def __del__(self):
        self.remove()
```

Starting with Python 3.4, `__del__()` methods no longer prevent reference cycles from being garbage collected, and module globals are no longer forced to `None` during *interpreter shutdown*. So this code should work without any issues on CPython.

However, handling of `__del__()` methods is notoriously implementation specific, since it depends on internal details of the interpreter's garbage collector implementation.

A more robust alternative can be to define a finalizer which only references the specific functions and objects that it needs, rather than having access to the full state of the object:

```
class TempDir:
    def __init__(self):
```

(下页继续)

(续上页)

```
self.name = tempfile.mkdtemp()
self._finalizer = weakref.finalize(self, shutil.rmtree, self.name)

def remove(self):
    self._finalizer()

@property
def removed(self):
    return not self._finalizer.alive
```

Defined like this, our finalizer only receives a reference to the details it needs to clean up the directory appropriately. If the object never gets garbage collected the finalizer will still be called at exit.

The other advantage of weakref based finalizers is that they can be used to register finalizers for classes where the definition is controlled by a third party, such as running code when a module is unloaded:

```
import weakref, sys
def unloading_module():
    # implicit reference to the module globals from the function body
    weakref.finalize(sys.modules[__name__], unloading_module)
```

注解: If you create a finalizer object in a daemon thread just as the program exits then there is the possibility that the finalizer does not get called at exit. However, in a daemon thread `atexit.register()`, `try: ... finally:` ... and `with: ...` do not guarantee that cleanup occurs either.

8.9 types —Dynamic type creation and names for built-in types

Source code: [Lib/types.py](#)

This module defines utility function to assist in dynamic creation of new types.

It also defines names for some object types that are used by the standard Python interpreter, but not exposed as builtins like `int` or `str` are.

Finally, it provides some additional type-related utility classes and functions that are not fundamental enough to be builtins.

8.9.1 Dynamic Type Creation

`types.new_class(name, bases=(), kwds=None, exec_body=None)`
Creates a class object dynamically using the appropriate metaclass.

The first three arguments are the components that make up a class definition header: the class name, the base classes (in order), the keyword arguments (such as `metaclass`).

The `exec_body` argument is a callback that is used to populate the freshly created class namespace. It should accept the class namespace as its sole argument and update the namespace directly with the class contents. If no callback is provided, it has the same effect as passing in `lambda ns: ns`.

3.3 新版功能.

`types.prepare_class` (*name*, *bases*=(), *kwds*=None)

Calculates the appropriate metaclass and creates the class namespace.

The arguments are the components that make up a class definition header: the class name, the base classes (in order) and the keyword arguments (such as `metaclass`).

The return value is a 3-tuple: `metaclass`, `namespace`, `kwds`

metaclass is the appropriate metaclass, *namespace* is the prepared class namespace and *kwds* is an updated copy of the passed in *kwds* argument with any 'metaclass' entry removed. If no *kwds* argument is passed in, this will be an empty dict.

3.3 新版功能.

在 3.6 版更改: The default value for the `namespace` element of the returned tuple has changed. Now an insertion-order-preserving mapping is used when the metaclass does not have a `__prepare__` method,

参见:

metaclasses Full details of the class creation process supported by these functions

PEP 3115 - Python 3000 中的元类 引入 `__prepare__` 命名空间钩子

8.9.2 Standard Interpreter Types

This module provides names for many of the types that are required to implement a Python interpreter. It deliberately avoids including some of the types that arise only incidentally during processing such as the `listiterator` type.

Typical use of these names is for `isinstance()` or `issubclass()` checks.

Standard names are defined for the following types:

`types.FunctionType`

`types.LambdaType`

用户自定义函数以及由 `lambda` 表达式所创建函数的类型。

`types.GeneratorType`

generator 迭代器对象的类型，由生成器函数创建。

`types.CoroutineType`

coroutine 对象的类型，由 `async def` 函数创建。

3.5 新版功能.

`types.AsyncGeneratorType`

asynchronous generator 迭代器对象的类型，由异步生成器函数创建。

3.6 新版功能.

`types.CodeType`

The type for code objects such as returned by `compile()`.

`types.MethodType`

The type of methods of user-defined class instances.

`types.BuiltinFunctionType`

`types.BuiltinMethodType`

The type of built-in functions like `len()` or `sys.exit()`, and methods of built-in classes. (Here, the term “built-in” means “written in C”.)

class `types.ModuleType` (*name*, *doc*=None)

The type of *modules*. Constructor takes the name of the module to be created and optionally its *docstring*.

注解: Use `importlib.util.module_from_spec()` to create a new module if you wish to set the various import-controlled attributes.

__doc__

The *docstring* of the module. Defaults to `None`.

__loader__

The *loader* which loaded the module. Defaults to `None`.

在 3.4 版更改: Defaults to `None`. Previously the attribute was optional.

__name__

模块的名字

__package__

Which *package* a module belongs to. If the module is top-level (i.e. not a part of any specific package) then the attribute should be set to `' '`, else it should be set to the name of the package (which can be `__name__` if the module is a package itself). Defaults to `None`.

在 3.4 版更改: Defaults to `None`. Previously the attribute was optional.

types.TracebackType

The type of traceback objects such as found in `sys.exc_info()[2]`.

types.FrameType

The type of frame objects such as found in `tb.tb_frame` if `tb` is a traceback object.

types.GetSetDescriptorType

The type of objects defined in extension modules with `PyGetSetDef`, such as `FrameType.f_locals` or `array.array.typecode`. This type is used as descriptor for object attributes; it has the same purpose as the *property* type, but for classes defined in extension modules.

types.MemberDescriptorType

The type of objects defined in extension modules with `PyMemberDef`, such as `datetime.timedelta.days`. This type is used as descriptor for simple C data members which use standard conversion functions; it has the same purpose as the *property* type, but for classes defined in extension modules.

CPython implementation detail: In other implementations of Python, this type may be identical to `GetSetDescriptorType`.

class types.MappingProxyType(mapping)

Read-only proxy of a mapping. It provides a dynamic view on the mapping's entries, which means that when the mapping changes, the view reflects these changes.

3.3 新版功能.

key in proxy

Return `True` if the underlying mapping has a key *key*, else `False`.

proxy[key]

Return the item of the underlying mapping with key *key*. Raises a *KeyError* if *key* is not in the underlying mapping.

iter(proxy)

Return an iterator over the keys of the underlying mapping. This is a shortcut for `iter(proxy.keys())`.

len(proxy)

Return the number of items in the underlying mapping.

copy()

Return a shallow copy of the underlying mapping.

get (*key* [, *default*])

Return the value for *key* if *key* is in the underlying mapping, else *default*. If *default* is not given, it defaults to `None`, so that this method never raises a `KeyError`.

items ()

Return a new view of the underlying mapping's items ((*key*, *value*) pairs).

keys ()

Return a new view of the underlying mapping's keys.

values ()

Return a new view of the underlying mapping's values.

8.9.3 Additional Utility Classes and Functions

`class types.SimpleNamespace`

A simple *object* subclass that provides attribute access to its namespace, as well as a meaningful repr.

Unlike *object*, with `SimpleNamespace` you can add and remove attributes. If a `SimpleNamespace` object is initialized with keyword arguments, those are directly added to the underlying namespace.

The type is roughly equivalent to the following code:

```
class SimpleNamespace:
    def __init__(self, **kwargs):
        self.__dict__.update(kwargs)

    def __repr__(self):
        keys = sorted(self.__dict__)
        items = ("{}={!r}".format(k, self.__dict__[k]) for k in keys)
        return "{}({})".format(type(self).__name__, ", ".join(items))

    def __eq__(self, other):
        return self.__dict__ == other.__dict__
```

`SimpleNamespace` may be useful as a replacement for `class NS: pass`. However, for a structured record type use `namedtuple()` instead.

3.3 新版功能.

`types.DynamicClassAttribute` (*fget=None, fset=None, fdel=None, doc=None*)

Route attribute access on a class to `__getattr__`.

This is a descriptor, used to define attributes that act differently when accessed through an instance and through a class. Instance access remains normal, but access to an attribute through a class will be routed to the class's `__getattr__` method; this is done by raising `AttributeError`.

This allows one to have properties active on an instance, and have virtual attributes on the class with the same name (see `Enum` for an example).

3.4 新版功能.

8.9.4 Coroutine Utility Functions

`types.coroutine` (*gen_func*)

This function transforms a *generator* function into a *coroutine function* which returns a generator-based coroutine. The generator-based coroutine is still a *generator iterator*, but is also considered to be a *coroutine* object and is *awaitable*. However, it may not necessarily implement the `__await__()` method.

If `gen_func` is a generator function, it will be modified in-place.

If `gen_func` is not a generator function, it will be wrapped. If it returns an instance of `collections.abc.Generator`, the instance will be wrapped in an *awaitable* proxy object. All other types of objects will be returned as is.

3.5 新版功能.

8.10 copy — 浅层 (shallow) 和深层 (deep) 复制操作

源代码: [Lib/copy.py](#)

Python 中赋值语句不复制对象，而是在目标和对象之间创建绑定 (bindings) 关系。对于自身可变或者包含可变项的集合对象，开发者有时需要生成其副本用于改变操作，进而避免改变原对象。本模块提供了通用的浅层复制和深层复制操作（如下所述）。

接口摘要：

`copy.copy(x)`
返回 `x` 的浅层复制。

`copy.deepcopy(x[, memo])`
返回 `x` 的深层复制。

exception `copy.error`
针对模块特定错误引发。

浅层复制和深层复制之间的区别仅与复合对象（即包含其他对象的对象，如列表或类的实例）相关：

- 一个 浅层复制会构造一个新的复合对象，然后（在可能的范围内）将原对象中找到的 引用插入其中。
- 一个 深层复制会构造一个新的复合对象，然后递归地将原始对象中所找到的对象的 副本插入。

深度复制操作通常存在两个问题，而浅层复制操作并不存在这些问题：

- 递归对象（直接或间接包含对自身引用的复合对象）可能会导致递归循环。
- 由于深层复制会复制所有内容，因此可能会过多复制（例如本应该在副本之间共享的数据）。

The `deepcopy()` function avoids these problems by:

- 保留在当前复制过程中已复制的对象的“备忘录” (memo) 字典；以及
- 允许用户定义的类型重载复制操作或复制的组件集合。

该模块不复制模块、方法、栈追踪 (stack trace)、栈帧 (stack frame)、文件、套接字、窗口、数组以及任何类似的类型。它通过不改变地返回原始对象来（浅层或深层地）“复制”函数和类；这与 `pickle` 模块处理这类问题的方式是相似的。

制作字典的浅层复制可以使用 `dict.copy()` 方法，而制作列表的浅层复制可以通过赋值整个列表的切片完成，例如，`copied_list = original_list[:]`。

类可以使用与控制序列化 (pickling) 操作相同的接口来控制复制操作，关于这些方法的描述信息请参考 `pickle` 模块。实际上，`copy` 模块使用的正是从 `copyreg` 模块中注册的 `pickle` 函数。

想要给一个类定义它自己的拷贝操作实现，可以通过定义特殊方法 `__copy__()` 和 `__deepcopy__()`。调用前者以实现浅层拷贝操作，该方法不用传入额外参数。调用后者以实现深层拷贝操作；它应传入一个参数即 memo 字典。如果 `__deepcopy__()` 实现需要创建一个组件的深层拷贝，它应当调用 `deepcopy()` 函数并以该组件作为第一个参数，而将 memo 字典作为第二个参数。

参见：

模块 `pickle` 讨论了支持对象状态检索和恢复的特殊方法。

8.11 pprint — 数据美化输出

源代码: `Lib/pprint.py`

The `pprint` module provides a capability to “pretty-print” arbitrary Python data structures in a form which can be used as input to the interpreter. If the formatted structures include objects which are not fundamental Python types, the representation may not be loadable. This may be the case if objects such as files, sockets or classes are included, as well as many other objects which are not representable as Python literals.

The formatted representation keeps objects on a single line if it can, and breaks them onto multiple lines if they don't fit within the allowed width. Construct `PrettyPrinter` objects explicitly if you need to adjust the width constraint.

Dictionaries are sorted by key before the display is computed. 字典在被计算前通过键值来排序。

`pprint` 模块定义了一个类:

class `pprint.PrettyPrinter` (`indent=1`, `width=80`, `depth=None`, `stream=None`, *, `compact=False`)

Construct a `PrettyPrinter` instance. This constructor understands several keyword parameters. An output stream may be set using the `stream` keyword; the only method used on the stream object is the file protocol's `write()` method. If not specified, the `PrettyPrinter` adopts `sys.stdout`. The amount of indentation added for each recursive level is specified by `indent`; the default is one. Other values can cause output to look a little odd, but can make nesting easier to spot. The number of levels which may be printed is controlled by `depth`; if the data structure being printed is too deep, the next contained level is replaced by `...`. By default, there is no constraint on the depth of the objects being formatted. The desired output width is constrained using the `width` parameter; the default is 80 characters. If a structure cannot be formatted within the constrained width, a best effort will be made. If `compact` is false (the default) each item of a long sequence will be formatted on a separate line. If `compact` is true, as many items as will fit within the `width` will be formatted on each output line.

在 3.4 版更改: 加入 `*compact*` 参数。

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff[:])
>>> pp = pprint.PrettyPrinter(indent=4)
>>> pp.pprint(stuff)
[  ['spam', 'eggs', 'lumberjack', 'knights', 'ni'],
   ['spam',
    'eggs',
    'lumberjack',
    'knights',
    'ni']]
>>> pp = pprint.PrettyPrinter(width=41, compact=True)
>>> pp.pprint(stuff)
[['spam', 'eggs', 'lumberjack',
  'knights', 'ni'],
 ['spam', 'eggs', 'lumberjack', 'knights',
  'ni']]
>>> tup = ('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead',
... ('parrot', ('fresh fruit',))))))))
>>> pp = pprint.PrettyPrinter(depth=6)
>>> pp.pprint(tup)
('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead', (...))))))
```

The `pprint` module also provides several shortcut functions:

`pprint.pformat(object, indent=1, width=80, depth=None, *, compact=False)`

Return the formatted representation of *object* as a string. *indent*, *width*, *depth* and *compact* will be passed to the `PrettyPrinter` constructor as formatting parameters.

在 3.4 版更改: 加入 **compact** 参数。

`pprint.pprint(object, stream=None, indent=1, width=80, depth=None, *, compact=False)`

Prints the formatted representation of *object* on *stream*, followed by a newline. If *stream* is `None`, `sys.stdout` is used. This may be used in the interactive interpreter instead of the `print()` function for inspecting values (you can even reassign `print = pprint.pprint` for use within a scope). *indent*, *width*, *depth* and *compact* will be passed to the `PrettyPrinter` constructor as formatting parameters.

在 3.4 版更改: 加入 **compact** 参数。

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff)
>>> pprint.pprint(stuff)
[<Recursion on list with id=...>,
 'spam',
 'eggs',
 'lumberjack',
 'knights',
 'ni']
```

`pprint.isreadable(object)`

Determine if the formatted representation of *object* is “readable,” or can be used to reconstruct the value using `eval()`. This always returns `False` for recursive objects.

```
>>> pprint.isreadable(stuff)
False
```

`pprint.isrecursive(object)`

Determine if *object* requires a recursive representation.

One more support function is also defined:

`pprint.saferepr(object)`

Return a string representation of *object*, protected against recursive data structures. If the representation of *object* exposes a recursive entry, the recursive reference will be represented as `<Recursion on typename with id=number>`. The representation is not otherwise formatted.

```
>>> pprint.saferepr(stuff)
"[<Recursion on list with id=...>, 'spam', 'eggs', 'lumberjack', 'knights', 'ni']"
```

8.11.1 PrettyPrinter Objects

`PrettyPrinter` instances have the following methods:

`PrettyPrinter.pformat(object)`

Return the formatted representation of *object*. This takes into account the options passed to the `PrettyPrinter` constructor.

`PrettyPrinter.pprint(object)`

Print the formatted representation of *object* on the configured stream, followed by a newline.

The following methods provide the implementations for the corresponding functions of the same names. Using these methods on an instance is slightly more efficient since new `PrettyPrinter` objects don't need to be created.

`PrettyPrinter.isreadable(object)`

Determine if the formatted representation of the object is “readable,” or can be used to reconstruct the value using `eval()`. Note that this returns `False` for recursive objects. If the `depth` parameter of the `PrettyPrinter` is set and the object is deeper than allowed, this returns `False`.

`PrettyPrinter.isrecursive(object)`

Determine if the object requires a recursive representation.

This method is provided as a hook to allow subclasses to modify the way objects are converted to strings. The default implementation uses the internals of the `saferepr()` implementation.

`PrettyPrinter.format(object, context, maxlevels, level)`

Returns three values: the formatted version of `object` as a string, a flag indicating whether the result is readable, and a flag indicating whether recursion was detected. The first argument is the object to be presented. The second is a dictionary which contains the `id()` of objects that are part of the current presentation context (direct and indirect containers for `object` that are affecting the presentation) as the keys; if an object needs to be presented which is already represented in `context`, the third return value should be `True`. Recursive calls to the `format()` method should add additional entries for containers to this dictionary. The third argument, `maxlevels`, gives the requested limit to recursion; this will be 0 if there is no requested limit. This argument should be passed unmodified to recursive calls. The fourth argument, `level`, gives the current level; recursive calls should be passed a value less than that of the current call.

8.11.2 示例

To demonstrate several uses of the `pprint()` function and its parameters, let’s fetch information about a project from PyPI:

```
>>> import json
>>> import pprint
>>> from urllib.request import urlopen
>>> with urlopen('https://pypi.org/pypi/sampleproject/json') as resp:
...     project_info = json.load(resp)['info']
```

In its basic form, `pprint()` shows the whole object:

```
>>> pprint.pprint(project_info)
{'author': 'The Python Packaging Authority',
 'author_email': 'pypa-dev@googlegroups.com',
 'bugtrack_url': None,

8.12 reprlib — Alternate repr() implementation

Source code: [Lib/reprlib.py](#)

The `reprlib` module provides a means for producing object representations with limits on the size of the resulting strings. This is used in the Python debugger and may be useful in other contexts as well.

This module provides a class, an instance, and a function:

class reprlib.Repr

Class which provides formatting services useful in implementing functions similar to the built-in `repr()`; size limits for different object types are added to avoid the generation of representations which are excessively long.

`reprlib.aRepr`

This is an instance of `Repr` which is used to provide the `repr()` function described below. Changing the attributes of this object will affect the size limits used by `repr()` and the Python debugger.

`reprlib.repr(obj)`

This is the `repr()` method of `aRepr`. It returns a string similar to that returned by the built-in function of the same name, but with limits on most sizes.

In addition to size-limiting tools, the module also provides a decorator for detecting recursive calls to `__repr__()` and substituting a placeholder string instead.

`@reprlib.recursive_repr(fillvalue="...")`

Decorator for `__repr__()` methods to detect recursive calls within the same thread. If a recursive call is made, the `fillvalue` is returned, otherwise, the usual `__repr__()` call is made. For example:

```
>>> class MyList(list):
...     @recursive_repr()
...     def __repr__(self):
...         return '<' + '|'.join(map(repr, self)) + '>'
...
>>> m = MyList('abc')
>>> m.append(m)
>>> m.append('x')
>>> print(m)
<'a'|'b'|'c'|...|'x'>
```

3.2 新版功能.

8.12.1 Repr Objects

Repr instances provide several attributes which can be used to provide size limits for the representations of different object types, and methods which format specific object types.

`Repr.maxlevel`

Depth limit on the creation of recursive representations. The default is 6.

`Repr.maxdict`

`Repr.maxlist`

`Repr.maxtuple`

`Repr.maxset`

`Repr.maxfrozenset`

`Repr.maxdeque`

`Repr.maxarray`

Limits on the number of entries represented for the named object type. The default is 4 for *maxdict*, 5 for *maxarray*, and 6 for the others.

`Repr.maxlong`

Maximum number of characters in the representation for an integer. Digits are dropped from the middle. The default is 40.

`Repr.maxstring`

Limit on the number of characters in the representation of the string. Note that the “normal” representation of the string is used as the character source: if escape sequences are needed in the representation, these may be mangled when the representation is shortened. The default is 30.

`Repr.maxother`

This limit is used to control the size of object types for which no specific formatting method is available on the *Repr* object. It is applied in a similar manner as *maxstring*. The default is 20.

`Repr.repr(obj)`

The equivalent to the built-in *repr()* that uses the formatting imposed by the instance.

`Repr.repr1(obj, level)`

Recursive implementation used by *repr()*. This uses the type of *obj* to determine which formatting method to call, passing it *obj* and *level*. The type-specific methods should call *repr1()* to perform recursive formatting, with *level - 1* for the value of *level* in the recursive call.

`Repr.repr_TYPE(obj, level)`

Formatting methods for specific types are implemented as methods with a name based on the type name. In the method name, **TYPE** is replaced by `'_'.join(type(obj).__name__.split())`. Dispatch to these methods is handled by *repr1()*. Type-specific methods which need to recursively format a value should call `self.repr1(subobj, level - 1)`.

8.12.2 Subclassing Repr Objects

The use of dynamic dispatching by *Repr.repr1()* allows subclasses of *Repr* to add support for additional built-in object types or to modify the handling of types already supported. This example shows how special support for file objects could be added:

```
import reprlib
import sys

class MyRepr(reprlib.Repr):

    def repr_TextIOWrapper(self, obj, level):
```

(下页继续)

(续上页)

```

    if obj.name in {'<stdin>', '<stdout>', '<stderr>'}:
        return obj.name
    return repr(obj)

aRepr = MyRepr()
print(aRepr.repr(sys.stdin))           # prints '<stdin>'

```

8.13 enum — Support for enumerations

3.4 新版功能.

Source code: [Lib/enum.py](#)

An enumeration is a set of symbolic names (members) bound to unique, constant values. Within an enumeration, the members can be compared by identity, and the enumeration itself can be iterated over.

8.13.1 模块内容

This module defines four enumeration classes that can be used to define unique sets of names and values: *Enum*, *IntEnum*, *Flag*, and *IntFlag*. It also defines one decorator, *unique()*, and one helper, *auto*.

class `enum.Enum`

Base class for creating enumerated constants. See section *Functional API* for an alternate construction syntax.

class `enum.IntEnum`

Base class for creating enumerated constants that are also subclasses of *int*.

class `enum.IntFlag`

Base class for creating enumerated constants that can be combined using the bitwise operators without losing their *IntFlag* membership. *IntFlag* members are also subclasses of *int*.

class `enum.Flag`

Base class for creating enumerated constants that can be combined using the bitwise operations without losing their *Flag* membership.

`enum.unique()`

Enum class decorator that ensures only one name is bound to any one value.

class `enum.auto`

Instances are replaced with an appropriate value for Enum members.

3.6 新版功能: `Flag`, `IntFlag`, `auto`

8.13.2 Creating an Enum

Enumerations are created using the `class` syntax, which makes them easy to read and write. An alternative creation method is described in *Functional API*. To define an enumeration, subclass *Enum* as follows:

```

>>> from enum import Enum
>>> class Color(Enum):
...     RED = 1

```

(下页继续)

(续上页)

```
...     GREEN = 2
...     BLUE = 3
...
```

注解: Enum member values

Member values can be anything: *int*, *str*, etc.. If the exact value is unimportant you may use *auto* instances and an appropriate value will be chosen for you. Care must be taken if you mix *auto* with other values.

注解: Nomenclature

- The class `Color` is an *enumeration* (or *enum*)
- The attributes `Color.RED`, `Color.GREEN`, etc., are *enumeration members* (or *enum members*) and are functionally constants.
- The enum members have *names* and *values* (the name of `Color.RED` is `RED`, the value of `Color.BLUE` is `3`, etc.)

注解: Even though we use the `class` syntax to create Enums, Enums are not normal Python classes. See [How are Enums different?](#) for more details.

Enumeration members have human readable string representations:

```
>>> print(Color.RED)
Color.RED
```

...while their `repr` has more information:

```
>>> print(repr(Color.RED))
<Color.RED: 1>
```

The *type* of an enumeration member is the enumeration it belongs to:

```
>>> type(Color.RED)
<enum 'Color'>
>>> isinstance(Color.GREEN, Color)
True
>>>
```

Enum members also have a property that contains just their item name:

```
>>> print(Color.RED.name)
RED
```

Enumerations support iteration, in definition order:

```
>>> class Shake(Enum):
...     VANILLA = 7
...     CHOCOLATE = 4
...     COOKIES = 9
...     MINT = 3
```

(下页继续)

(续上页)

```

...
>>> for shake in Shake:
...     print(shake)
...
Shake.VANILLA
Shake.CHOCOLATE
Shake.COOKIES
Shake.MINT

```

Enumeration members are hashable, so they can be used in dictionaries and sets:

```

>>> apples = {}
>>> apples[Color.RED] = 'red delicious'
>>> apples[Color.GREEN] = 'granny smith'
>>> apples == {Color.RED: 'red delicious', Color.GREEN: 'granny smith'}
True

```

8.13.3 Programmatic access to enumeration members and their attributes

Sometimes it's useful to access members in enumerations programmatically (i.e. situations where `Color.RED` won't do because the exact color is not known at program-writing time). Enum allows such access:

```

>>> Color(1)
<Color.RED: 1>
>>> Color(3)
<Color.BLUE: 3>

```

If you want to access enum members by *name*, use item access:

```

>>> Color['RED']
<Color.RED: 1>
>>> Color['GREEN']
<Color.GREEN: 2>

```

If you have an enum member and need its name or value:

```

>>> member = Color.RED
>>> member.name
'RED'
>>> member.value
1

```

8.13.4 Duplicating enum members and values

Having two enum members with the same name is invalid:

```

>>> class Shape(Enum):
...     SQUARE = 2
...     SQUARE = 3
...
Traceback (most recent call last):
...
TypeError: Attempted to reuse key: 'SQUARE'

```

(续上页)

```
>>> list(Color)
[<Color.RED: 1>, <Color.BLUE: 2>, <Color.GREEN: 3>]
```

The values are chosen by `_generate_next_value_()`, which can be overridden:

```
>>> class AutoName(Enum):
...     def _generate_next_value_(name, start, count, last_values):
...         return name
...
>>> class Ordinal(AutoName):
...     NORTH = auto()
...     SOUTH = auto()
...     EAST = auto()
...     WEST = auto()
...
>>> list(Ordinal)
[<Ordinal.NORTH: 'NORTH'>, <Ordinal.SOUTH: 'SOUTH'>, <Ordinal.EAST: 'EAST'>, <Ordinal.
↪WEST: 'WEST'>]
```

注解: The goal of the default `_generate_next_value_()` methods is to provide the next `int` in sequence with the last `int` provided, but the way it does this is an implementation detail and may change.

8.13.7 Iteration

Iterating over the members of an enum does not provide the aliases:

```
>>> list(Shape)
[<Shape.SQUARE: 2>, <Shape.DIAMOND: 1>, <Shape.CIRCLE: 3>]
```

The special attribute `__members__` is an ordered dictionary mapping names to members. It includes all names defined in the enumeration, including the aliases:

```
>>> for name, member in Shape.__members__.items():
...     name, member
...
('SQUARE', <Shape.SQUARE: 2>)
('DIAMOND', <Shape.DIAMOND: 1>)
('CIRCLE', <Shape.CIRCLE: 3>)
('ALIAS_FOR_SQUARE', <Shape.SQUARE: 2>)
```

The `__members__` attribute can be used for detailed programmatic access to the enumeration members. For example, finding all the aliases:

```
>>> [name for name, member in Shape.__members__.items() if member.name != name]
['ALIAS_FOR_SQUARE']
```

8.13.8 比较

Enumeration members are compared by identity:

```
>>> Color.RED is Color.RED
True
>>> Color.RED is Color.BLUE
False
>>> Color.RED is not Color.BLUE
True
```

Ordered comparisons between enumeration values are *not* supported. Enum members are not integers (but see [IntEnum](#) below):

```
>>> Color.RED < Color.BLUE
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: '<' not supported between instances of 'Color' and 'Color'
```

Equality comparisons are defined though:

```
>>> Color.BLUE == Color.RED
False
>>> Color.BLUE != Color.RED
True
>>> Color.BLUE == Color.BLUE
True
```

Comparisons against non-enumeration values will always compare not equal (again, [IntEnum](#) was explicitly designed to behave differently, see below):

```
>>> Color.BLUE == 2
False
```

8.13.9 Allowed members and attributes of enumerations

The examples above use integers for enumeration values. Using integers is short and handy (and provided by default by the [Functional API](#)), but not strictly enforced. In the vast majority of use-cases, one doesn't care what the actual value of an enumeration is. But if the value *is* important, enumerations can have arbitrary values.

Enumerations are Python classes, and can have methods and special methods as usual. If we have this enumeration:

```
>>> class Mood(Enum):
...     FUNKY = 1
...     HAPPY = 3
...
...     def describe(self):
...         # self is the member here
...         return self.name, self.value
...
...     def __str__(self):
...         return 'my custom str! {0}'.format(self.value)
...
...     @classmethod
...     def favorite_mood(cls):
...         # cls here is the enumeration
...         return cls.HAPPY
...
... 
```

Then:

```
>>> Mood.favorite_mood()
<Mood.HAPPY: 3>
>>> Mood.HAPPY.describe()
('HAPPY', 3)
>>> str(Mood.FUNKY)
'my custom str! 1'
```

The rules for what is allowed are as follows: names that start and end with a single underscore are reserved by enum and cannot be used; all other attributes defined within an enumeration will become members of this enumeration, with the exception of special methods (`__str__()`, `__add__()`, etc.) and descriptors (methods are also descriptors).

Note: if your enumeration defines `__new__()` and/or `__init__()` then whatever value(s) were given to the enum member will be passed into those methods. See [Planet](#) for an example.

8.13.10 Restricted subclassing of enumerations

Subclassing an enumeration is allowed only if the enumeration does not define any members. So this is forbidden:

```
>>> class MoreColor(Color):
...     PINK = 17
...
Traceback (most recent call last):
...
TypeError: Cannot extend enumerations
```

But this is allowed:

```
>>> class Foo(Enum):  
...     def some_behavior(self):  
...         pass  
...  
>>> class Bar(Foo):  
...     HAPPY = 1  
...     SAD = 2  
...
```

Allowing subclassing of enums that define members would lead to a violation of some important invariants of types and instances. On the other hand, it makes sense to allow sharing some common behavior between a group of enumerations. (See *OrderedEnum* for an example.)

8.13.11 Pickling

Enumerations can be pickled and unpickled:

```
>>> from test.test_enum import Fruit
>>> from pickle import dumps, loads
>>> Fruit.TOMATO is loads(dumps(Fruit.TOMATO))
True
```

The usual restrictions for pickling apply: picklable enums must be defined in the top level of a module, since unpickling requires them to be importable from that module.

注解: With pickle protocol version 4 it is possible to easily pickle enums nested in other classes.

It is possible to modify how Enum members are pickled/unpickled by defining `__reduce_ex__()` in the enumeration class.

8.13.12 Functional API

The `Enum` class is callable, providing the following functional API:

```
>>> Animal = Enum('Animal', 'ANT BEE CAT DOG')
>>> Animal
<enum 'Animal'>
>>> Animal.ANT
<Animal.ANT: 1>
>>> Animal.ANT.value
1
>>> list(Animal)
[<Animal.ANT: 1>, <Animal.BEE: 2>, <Animal.CAT: 3>, <Animal.DOG: 4>]
```

The semantics of this API resemble *namedtuple*. The first argument of the call to `Enum` is the name of the enumeration.

The second argument is the *source* of enumeration member names. It can be a whitespace-separated string of names, a sequence of names, a sequence of 2-tuples with key/value pairs, or a mapping (e.g. dictionary) of names to values. The last two options enable assigning arbitrary values to enumerations; the others auto-assign increasing integers starting with 1 (use the `start` parameter to specify a different starting value). A new class derived from `Enum` is returned. In other words, the above assignment to `Animal` is equivalent to:

```
>>> class Animal(Enum):
...     ANT = 1
...     BEE = 2
...     CAT = 3
...     DOG = 4
... 
```

The reason for defaulting to 1 as the starting number and not 0 is that 0 is `False` in a boolean sense, but enum members all evaluate to `True`.

Pickling enums created with the functional API can be tricky as frame stack implementation details are used to try and figure out which module the enumeration is being created in (e.g. it will fail if you use a utility function in separate module, and also may not work on IronPython or Jython). The solution is to specify the module name explicitly as follows:

```
>>> Animal = Enum('Animal', 'ANT BEE CAT DOG', module=__name__)
```

警告: If module is not supplied, and Enum cannot determine what it is, the new Enum members will not be unpicklable; to keep errors closer to the source, pickling will be disabled.

The new pickle protocol 4 also, in some circumstances, relies on `__qualname__` being set to the location where pickle will be able to find the class. For example, if the class was made available in class `SomeData` in the global scope:

```
>>> Animal = Enum('Animal', 'ANT BEE CAT DOG', qualname='SomeData.Animal')
```

The complete signature is:

```
Enum(value='NewEnumName', names=<...>, *, module='...', qualname='...', type=<mixed-
↳ in class>, start=1)
```

值 What the new Enum class will record as its name.

names The Enum members. This can be a whitespace or comma separated string (values will start at 1 unless otherwise specified):

```
'RED GREEN BLUE' | 'RED, GREEN, BLUE' | 'RED, GREEN, BLUE'
```

or an iterator of names:

```
['RED', 'GREEN', 'BLUE']
```

or an iterator of (name, value) pairs:

```
[('CYAN', 4), ('MAGENTA', 5), ('YELLOW', 6)]
```

or a mapping:

```
{'CHARTREUSE': 7, 'SEA_GREEN': 11, 'ROSEMARY': 42}
```

模块 name of module where new Enum class can be found.

qualname where in module new Enum class can be found.

类型 type to mix in to new Enum class.

start number to start counting at if only names are passed in.

在 3.5 版更改: The *start* parameter was added.

8.13.13 Derived Enumerations

IntEnum

The first variation of *Enum* that is provided is also a subclass of *int*. Members of an *IntEnum* can be compared to integers; by extension, integer enumerations of different types can also be compared to each other:

```
>>> from enum import IntEnum
>>> class Shape(IntEnum):
...     CIRCLE = 1
...     SQUARE = 2
...
>>> class Request(IntEnum):
...     POST = 1
...     GET = 2
...
>>> Shape == 1
False
>>> Shape.CIRCLE == 1
True
>>> Shape.CIRCLE == Request.POST
True
```

However, they still can't be compared to standard *Enum* enumerations:

```
>>> class Shape(IntEnum):
...     CIRCLE = 1
...     SQUARE = 2
...
```

(下页继续)

(续上页)

```
>>> class Color(Enum):
...     RED = 1
...     GREEN = 2
...
>>> Shape.CIRCLE == Color.RED
False
```

IntEnum values behave like integers in other ways you'd expect:

```
>>> int(Shape.CIRCLE)
1
>>> ['a', 'b', 'c'][Shape.CIRCLE]
'b'
>>> [i for i in range(Shape.SQUARE)]
[0, 1]
```

IntFlag

The next variation of *Enum* provided, *IntFlag*, is also based on *int*. The difference being *IntFlag* members can be combined using the bitwise operators (&, |, ^, ~) and the result is still an *IntFlag* member. However, as the name implies, *IntFlag* members also subclass *int* and can be used wherever an *int* is used. Any operation on an *IntFlag* member besides the bit-wise operations will lose the *IntFlag* membership.

3.6 新版功能.

Sample *IntFlag* class:

```
>>> from enum import IntFlag
>>> class Perm(IntFlag):
...     R = 4
...     W = 2
...     X = 1
...
>>> Perm.R | Perm.W
<Perm.R|W: 6>
>>> Perm.R + Perm.W
6
>>> RW = Perm.R | Perm.W
>>> Perm.R in RW
True
```

It is also possible to name the combinations:

```
>>> class Perm(IntFlag):
...     R = 4
...     W = 2
...     X = 1
...     RWX = 7
>>> Perm.RWX
<Perm.RWX: 7>
>>> ~Perm.RWX
<Perm.-8: -8>
```

Another important difference between *IntFlag* and *Enum* is that if no flags are set (the value is 0), its boolean evaluation is *False*:

```
>>> Perm.R & Perm.X
<Perm.0: 0>
>>> bool(Perm.R & Perm.X)
False
```

Because *IntFlag* members are also subclasses of *int* they can be combined with them:

```
>>> Perm.X | 8
<Perm.8|X: 9>
```

标志

The last variation is *Flag*. Like *IntFlag*, *Flag* members can be combined using the bitwise operators (&, |, ^, ~). Unlike *IntFlag*, they cannot be combined with, nor compared against, any other *Flag* enumeration, nor *int*. While it is possible to specify the values directly it is recommended to use *auto* as the value and let *Flag* select an appropriate value.

3.6 新版功能.

Like *IntFlag*, if a combination of *Flag* members results in no flags being set, the boolean evaluation is *False*:

```
>>> from enum import Flag, auto
>>> class Color(Flag):
...     RED = auto()
...     BLUE = auto()
...     GREEN = auto()
...
>>> Color.RED & Color.GREEN
<Color.0: 0>
>>> bool(Color.RED & Color.GREEN)
False
```

Individual flags should have values that are powers of two (1, 2, 4, 8, ...), while combinations of flags won't:

```
>>> class Color(Flag):
...     RED = auto()
...     BLUE = auto()
...     GREEN = auto()
...     WHITE = RED | BLUE | GREEN
...
>>> Color.WHITE
<Color.WHITE: 7>
```

Giving a name to the “no flags set” condition does not change its boolean value:

```
>>> class Color(Flag):
...     BLACK = 0
...     RED = auto()
...     BLUE = auto()
...     GREEN = auto()
...
>>> Color.BLACK
<Color.BLACK: 0>
>>> bool(Color.BLACK)
False
```

注解: For the majority of new code, `Enum` and `Flag` are strongly recommended, since `IntEnum` and `IntFlag` break some semantic promises of an enumeration (by being comparable to integers, and thus by transitivity to other unrelated enumerations). `IntEnum` and `IntFlag` should be used only in cases where `Enum` and `Flag` will not do; for example, when integer constants are replaced with enumerations, or for interoperability with other systems.

Others

While `IntEnum` is part of the `enum` module, it would be very simple to implement independently:

```
class IntEnum(int, Enum):
    pass
```

This demonstrates how similar derived enumerations can be defined; for example a `StrEnum` that mixes in `str` instead of `int`.

Some rules:

1. When subclassing `Enum`, mix-in types must appear before `Enum` itself in the sequence of bases, as in the `IntEnum` example above.
2. While `Enum` can have members of any type, once you mix in an additional type, all the members must have values of that type, e.g. `int` above. This restriction does not apply to mix-ins which only add methods and don't specify another data type such as `int` or `str`.
3. When another data type is mixed in, the `value` attribute is *not the same* as the enum member itself, although it is equivalent and will compare equal.
4. %-style formatting: `%s` and `%r` call the `Enum` class's `__str__()` and `__repr__()` respectively; other codes (such as `%i` or `%h` for `IntEnum`) treat the enum member as its mixed-in type.
5. Formatted string literals, `str.format()`, and `format()` will use the mixed-in type's `__format__()`. If the `Enum` class's `str()` or `repr()` is desired, use the `!s` or `!r` format codes.

8.13.14 Interesting examples

While `Enum`, `IntEnum`, `IntFlag`, and `Flag` are expected to cover the majority of use-cases, they cannot cover them all. Here are recipes for some different types of enumerations that can be used directly, or as examples for creating one's own.

Omitting values

In many use-cases one doesn't care what the actual value of an enumeration is. There are several ways to define this type of simple enumeration:

- use instances of `auto` for the value
- use instances of `object` as the value
- use a descriptive string as the value
- use a tuple as the value and a custom `__new__()` to replace the tuple with an `int` value

Using any of these methods signifies to the user that these values are not important, and also enables one to add, remove, or reorder members without having to renumber the remaining members.

Whichever method you choose, you should provide a `repr()` that also hides the (unimportant) value:

```
>>> class NoValue(Enum):
...     def __repr__(self):
...         return '<%s.%s>' % (self.__class__.__name__, self.name)
... 
```

Using auto

Using *auto* would look like:

```
>>> class Color(NoValue):
...     RED = auto()
...     BLUE = auto()
...     GREEN = auto()
...
>>> Color.GREEN
<Color.GREEN>
```

Using object

Using *object* would look like:

```
>>> class Color(NoValue):
...     RED = object()
...     GREEN = object()
...     BLUE = object()
...
>>> Color.GREEN
<Color.GREEN>
```

Using a descriptive string

Using a string as the value would look like:

```
>>> class Color(NoValue):
...     RED = 'stop'
...     GREEN = 'go'
...     BLUE = 'too fast!'
...
>>> Color.GREEN
<Color.GREEN>
>>> Color.GREEN.value
'go'
```

Using a custom __new__()

Using an auto-numbering *__new__()* would look like:

```
>>> class AutoNumber(NoValue):
...     def __new__(cls):
...         value = len(cls.__members__) + 1
```

(下页继续)

(续上页)

```

...     obj = object.__new__(cls)
...     obj._value_ = value
...     return obj
...
>>> class Color(AutoNumber):
...     RED = ()
...     GREEN = ()
...     BLUE = ()
...
>>> Color.GREEN
<Color.GREEN>
>>> Color.GREEN.value
2

```

注解: The `__new__()` method, if defined, is used during creation of the Enum members; it is then replaced by Enum's `__new__()` which is used after class creation for lookup of existing members.

OrderedEnum

An ordered enumeration that is not based on *IntEnum* and so maintains the normal *Enum* invariants (such as not being comparable to other enumerations):

```

>>> class OrderedEnum(Enum):
...     def __ge__(self, other):
...         if self.__class__ is other.__class__:
...             return self.value >= other.value
...         return NotImplemented
...     def __gt__(self, other):
...         if self.__class__ is other.__class__:
...             return self.value > other.value
...         return NotImplemented
...     def __le__(self, other):
...         if self.__class__ is other.__class__:
...             return self.value <= other.value
...         return NotImplemented
...     def __lt__(self, other):
...         if self.__class__ is other.__class__:
...             return self.value < other.value
...         return NotImplemented
...
>>> class Grade(OrderedEnum):
...     A = 5
...     B = 4
...     C = 3
...     D = 2
...     F = 1
...
>>> Grade.C < Grade.A
True

```

DuplicateFreeEnum

Raises an error if a duplicate member name is found instead of creating an alias:

```
>>> class DuplicateFreeEnum(Enum):
...     def __init__(self, *args):
...         cls = self.__class__
...         if any(self.value == e.value for e in cls):
...             a = self.name
...             e = cls(self.value).name
...             raise ValueError(
...                 "aliases not allowed in DuplicateFreeEnum: %r --> %r"
...                 % (a, e))
...
>>> class Color(DuplicateFreeEnum):
...     RED = 1
...     GREEN = 2
...     BLUE = 3
...     GRENE = 2
...
Traceback (most recent call last):
...
ValueError: aliases not allowed in DuplicateFreeEnum: 'GRENE' --> 'GREEN'
```

注解: This is a useful example for subclassing Enum to add or change other behaviors as well as disallowing aliases. If the only desired change is disallowing aliases, the `unique()` decorator can be used instead.

Planet

If `__new__()` or `__init__()` is defined the value of the enum member will be passed to those methods:

```
>>> class Planet(Enum):
...     MERCURY = (3.303e+23, 2.4397e6)
...     VENUS   = (4.869e+24, 6.0518e6)
...     EARTH   = (5.976e+24, 6.37814e6)
...     MARS    = (6.421e+23, 3.3972e6)
...     JUPITER = (1.9e+27, 7.1492e7)
...     SATURN  = (5.688e+26, 6.0268e7)
...     URANUS  = (8.686e+25, 2.5559e7)
...     NEPTUNE = (1.024e+26, 2.4746e7)
...     def __init__(self, mass, radius):
...         self.mass = mass      # in kilograms
...         self.radius = radius  # in meters
...     @property
...     def surface_gravity(self):
...         # universal gravitational constant (m3 kg-1 s-2)
...         G = 6.67300E-11
...         return G * self.mass / (self.radius * self.radius)
...
>>> Planet.EARTH.value
(5.976e+24, 6378140.0)
>>> Planet.EARTH.surface_gravity
9.802652743337129
```

8.13.15 How are Enums different?

Enums have a custom metaclass that affects many aspects of both derived Enum classes and their instances (members).

Enum Classes

The `EnumMeta` metaclass is responsible for providing the `__contains__()`, `__dir__()`, `__iter__()` and other methods that allow one to do things with an `Enum` class that fail on a typical class, such as `list(Color)` or `some_var in Color`. `EnumMeta` is responsible for ensuring that various other methods on the final `Enum` class are correct (such as `__new__()`, `__getnewargs__()`, `__str__()` and `__repr__()`).

Enum Members (aka instances)

The most interesting thing about Enum members is that they are singletons. `EnumMeta` creates them all while it is creating the `Enum` class itself, and then puts a custom `__new__()` in place to ensure that no new ones are ever instantiated by returning only the existing member instances.

Finer Points

Supported `__dunder__` names

`__members__` is an `OrderedDict` of `member_name:member` items. It is only available on the class.

`__new__()`, if specified, must create and return the enum members; it is also a very good idea to set the member's `_value_` appropriately. Once all the members are created it is no longer used.

Supported `_sunder_` names

- `_name_` – name of the member
- `_value_` – value of the member; can be set / modified in `__new__`
- `_missing_` – a lookup function used when a value is not found; may be overridden
- `_order_` – used in Python 2/3 code to ensure member order is consistent (class attribute, removed during class creation)
- `_generate_next_value_` – used by the *Functional API* and by *auto* to get an appropriate value for an enum member; may be overridden

3.6 新版功能: `_missing_`, `_order_`, `_generate_next_value_`

To help keep Python 2 / Python 3 code in sync an `_order_` attribute can be provided. It will be checked against the actual order of the enumeration and raise an error if the two do not match:

```
>>> class Color(Enum):
...     _order_ = 'RED GREEN BLUE'
...     RED = 1
...     BLUE = 3
...     GREEN = 2
...
Traceback (most recent call last):
...
TypeError: member order does not match _order_
```

注解: In Python 2 code the `_order_` attribute is necessary as definition order is lost before it can be recorded.

Enum member type

Enum members are instances of their *Enum* class, and are normally accessed as `EnumClass.member`. Under certain circumstances they can also be accessed as `EnumClass.member.member`, but you should never do this as that lookup may fail or, worse, return something besides the *Enum* member you are looking for (this is another good reason to use all-uppercase names for members):

```
>>> class FieldTypes(Enum):
...     name = 0
...     value = 1
...     size = 2
...
>>> FieldTypes.value.size
<FieldTypes.size: 2>
>>> FieldTypes.size.value
2
```

在 3.5 版更改.

Boolean value of Enum classes and members

Enum members that are mixed with non-*Enum* types (such as *int*, *str*, etc.) are evaluated according to the mixed-in type's rules; otherwise, all members evaluate as *True*. To make your own Enum's boolean evaluation depend on the member's value add the following to your class:

```
def __bool__(self):
    return bool(self.value)
```

Enum classes always evaluate as *True*.

Enum classes with methods

If you give your *Enum* subclass extra methods, like the *Planet* class above, those methods will show up in a `dir()` of the member, but not of the class:

```
>>> dir(Planet)
['EARTH', 'JUPITER', 'MARS', 'MERCURY', 'NEPTUNE', 'SATURN', 'URANUS', 'VENUS', '__class__', '__doc__', '__members__', '__module__']
>>> dir(Planet.EARTH)
['__class__', '__doc__', '__module__', 'name', 'surface_gravity', 'value']
```

Combining members of Flag

If a combination of Flag members is not named, the `repr()` will include all named flags and all named combinations of flags that are in the value:

```
>>> class Color(Flag):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...     MAGENTA = RED | BLUE
...     YELLOW = RED | GREEN
...     CYAN = GREEN | BLUE
...
>>> Color(3) # named combination
<Color.YELLOW: 3>
>>> Color(7) # not named combination
<Color.CYAN|MAGENTA|BLUE|YELLOW|GREEN|RED: 7>
```

数字和数学模块

本章介绍的模块提供与数字和数学相关的函数和数据类型。*numbers* 模块定义了数字类型的抽象层次结构。*math* 和 *cmath* 模块包含浮点数和复数的各种数学函数。*decimal* 模块支持使用任意精度算术的十进制数的精确表示。

本章记录以下模块：

9.1 *numbers* — 数字的抽象基类

源代码： [Lib/numbers.py](#)

numbers 模块 (PEP 3141) 定义了数字抽象基类的层次结构，其中逐级定义了更多操作。此模块中所定义的类型都不可被实例化。

class *numbers.Number*

数字的层次结构的基础。如果你只想确认参数 *x* 是不是数字而不关心其类型，则使用 “`isinstance(x, Number)`”。

9.1.1 数字的层次

class *numbers.Complex*

Subclasses of this type describe complex numbers and include the operations that work on the built-in *complex* type. These are: conversions to *complex* and *bool*, *real*, *imag*, `+`, `-`, `*`, `/`, *abs()*, *conjugate()*, `==`, and `!=`. All except `-` and `!=` are abstract.

real

Abstract. Retrieves the real component of this number.

imag

Abstract. Retrieves the imaginary component of this number.

abstractmethod conjugate()

Abstract. Returns the complex conjugate. For example, `(1+3j).conjugate() == (1-3j)`.

class numbers.Real

To *Complex*, *Real* adds the operations that work on real numbers.

In short, those are: a conversion to *float*, *math.trunc()*, *round()*, *math.floor()*, *math.ceil()*, *divmod()*, *//*, *%*, *<*, *<=*, *>*, and *>=*.

Real also provides defaults for *complex()*, *real*, *imag*, and *conjugate()*.

class numbers.Rational

Subtypes *Real* and adds *numerator* and *denominator* properties, which should be in lowest terms. With these, it provides a default for *float()*.

numerator

Abstract.

denominator

Abstract.

class numbers.Integral

Subtypes *Rational* and adds a conversion to *int*. Provides defaults for *float()*, *numerator*, and *denominator*. Adds abstract methods for **** and bit-string operations: *<<*, *>>*, *&*, *^*, *|*, *~*.

9.1.2 Notes for type implementors

Implementors should be careful to make equal numbers equal and hash them to the same values. This may be subtle if there are two different extensions of the real numbers. For example, *fractions.Fraction* implements *hash()* as follows:

```
def __hash__(self):
    if self.denominator == 1:
        # Get integers right.
        return hash(self.numerator)
    # Expensive check, but definitely correct.
    if self == float(self):
        return hash(float(self))
    else:
        # Use tuple's hash to avoid a high collision rate on
        # simple fractions.
        return hash((self.numerator, self.denominator))
```

Adding More Numeric ABCs

There are, of course, more possible ABCs for numbers, and this would be a poor hierarchy if it precluded the possibility of adding those. You can add *MyFoo* between *Complex* and *Real* with:

```
class MyFoo(Complex): ...
MyFoo.register(Real)
```

Implementing the arithmetic operations

We want to implement the arithmetic operations so that mixed-mode operations either call an implementation whose author knew about the types of both arguments, or convert both to the nearest built in type and do the operation there. For subtypes of *Integral*, this means that *__add__()* and *__radd__()* should be defined as:

```

class MyIntegral(Integral):

    def __add__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(self, other)
        elif isinstance(other, OtherTypeIKnowAbout):
            return do_my_other_adding_stuff(self, other)
        else:
            return NotImplemented

    def __radd__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(other, self)
        elif isinstance(other, OtherTypeIKnowAbout):
            return do_my_other_adding_stuff(other, self)
        elif isinstance(other, Integral):
            return int(other) + int(self)
        elif isinstance(other, Real):
            return float(other) + float(self)
        elif isinstance(other, Complex):
            return complex(other) + complex(self)
        else:
            return NotImplemented

```

There are 5 different cases for a mixed-type operation on subclasses of `Complex`. I'll refer to all of the above code that doesn't refer to `MyIntegral` and `OtherTypeIKnowAbout` as “boilerplate”. `a` will be an instance of `A`, which is a subtype of `Complex` (`a : A <: Complex`), and `b : B <: Complex`. I'll consider `a + b`:

1. If `A` defines an `__add__()` which accepts `b`, all is well.
2. If `A` falls back to the boilerplate code, and it were to return a value from `__add__()`, we'd miss the possibility that `B` defines a more intelligent `__radd__()`, so the boilerplate should return `NotImplemented` from `__add__()`. (Or `A` may not implement `__add__()` at all.)
3. Then `B`'s `__radd__()` gets a chance. If it accepts `a`, all is well.
4. If it falls back to the boilerplate, there are no more possible methods to try, so this is where the default implementation should live.
5. If `B <: A`, Python tries `B.__radd__` before `A.__add__`. This is ok, because it was implemented with knowledge of `A`, so it can handle those instances before delegating to `Complex`.

If `A <: Complex` and `B <: Real` without sharing any other knowledge, then the appropriate shared operation is the one involving the built in `complex`, and both `__radd__()`s land there, so `a+b == b+a`.

Because most of the operations on any given type will be very similar, it can be useful to define a helper function which generates the forward and reverse instances of any given operator. For example, `fractions.Fraction` uses:

```

def _operator_fallbacks(monomorphic_operator, fallback_operator):
    def forward(a, b):
        if isinstance(b, (int, Fraction)):
            return monomorphic_operator(a, b)
        elif isinstance(b, float):
            return fallback_operator(float(a), b)
        elif isinstance(b, complex):
            return fallback_operator(complex(a), b)
        else:
            return NotImplemented
    forward.__name__ = '__' + fallback_operator.__name__ + '__'

```

(下页继续)

(续上页)

```

forward.__doc__ = monomorphic_operator.__doc__

def reverse(b, a):
    if isinstance(a, Rational):
        # Includes ints.
        return monomorphic_operator(a, b)
    elif isinstance(a, numbers.Real):
        return fallback_operator(float(a), float(b))
    elif isinstance(a, numbers.Complex):
        return fallback_operator(complex(a), complex(b))
    else:
        return NotImplemented
reverse.__name__ = '__r' + fallback_operator.__name__ + '__'
reverse.__doc__ = monomorphic_operator.__doc__

return forward, reverse

def _add(a, b):
    """a + b"""
    return Fraction(a.numerator * b.denominator +
                    b.numerator * a.denominator,
                    a.denominator * b.denominator)

__add__, __radd__ = _operator_fallbacks(_add, operator.add)

# ...

```

9.2 math — 数学函数

This module is always available. It provides access to the mathematical functions defined by the C standard.

这些函数不适用于复数；如果你需要计算复数，请使用 `cmath` 模块中的同名函数。将支持计算复数的函数区分开的目的，来自于大多数开发者并不愿意像数学家一样需要学习复数的概念。得到一个异常而不是一个复数结果使得开发者能够更早地监测到传递给这些函数的参数中包含复数，进而调查其产生的原因。

该模块提供了以下函数。除非另有明确说明，否则所有返回值均为浮点数。

9.2.1 数论与表示函数

`math.ceil(x)`

返回 x 的上限，即大于或者等于 x 的最小整数。如果 x 不是一个浮点数，则委托 `x.__ceil__()`，返回一个 *Integral* 类的值。

`math.copysign(x, y)`

返回一个基于 x 的绝对值和 y 的符号的浮点数。在支持带符号零的平台上，`copysign(1.0, -0.0)` 返回 `-1.0`。

`math.fabs(x)`

返回 x 的绝对值。

`math.factorial(x)`

Return x factorial. Raises *ValueError* if x is not integral or is negative.

`math.floor(x)`

返回 x 的向下取整，小于或等于 x 的最大整数。如果 x 不是浮点数，则委托 `x.__floor__()`，它应返回 *Integral* 值。

`math.fmod(x, y)`

返回 `fmod(x, y)`，由平台 C 库定义。请注意，Python 表达式 `x % y` 可能不会返回相同的结果。C 标准的目的是 `fmod(x, y)` 完全（数学上；到无限精度）等于 $x - n*y$ 对于某个整数 n ，使得结果具有与 x 相同的符号和小于 `abs(y)` 的幅度。Python 的 `x % y` 返回带有 y 符号的结果，并且可能不能完全计算浮点参数。例如，`fmod(-1e-100, 1e100)` 是 $-1e-100$ ，但 Python 的 `-1e-100 % 1e100` 的结果是 $1e100-1e-100$ ，它不能完全表示为浮点数，并且取整为令人惊讶的 $1e100$ 。出于这个原因，函数 `fmod()` 在使用浮点数时通常是首选，而 Python 的 `x % y` 在使用整数时是首选。

`math.frexp(x)`

返回 x 的尾数和指数作为对“(m, e)”。 m 是一个浮点数， e 是一个整数，正好是 $x == m * 2**e$ 。如果 x 为零，则返回 $(0.0, 0)$ ，否则返回 $0.5 <= \text{abs}(m) < 1$ 。这用于以可移植方式“分离”浮点数的内部表示。

`math.fsum(iterable)`

返回迭代中的精确浮点值。通过跟踪多个中间部分和来避免精度损失：

```
>>> sum([.1, .1, .1, .1, .1, .1, .1, .1, .1, .1])
0.9999999999999999
>>> fsum([.1, .1, .1, .1, .1, .1, .1, .1, .1, .1])
1.0
```

该算法的准确性取决于 IEEE-754 算术保证和舍入模式为半偶的典型情况。在某些非 Windows 版本中，底层 C 库使用扩展精度添加，并且有时可能会使中间和加倍，导致它在最低有效位中关闭。

有关待进一步讨论和两种替代方法，参见 [ASPN cookbook recipes for accurate floating point summation](#)。

`math.gcd(a, b)`

返回整数 a 和 b 的最大公约数。如果 a 或 b 之一非零，则 `gcd(a, b)` 的值是能同时整除 a 和 b 的最大正整数。`gcd(0, 0)` 返回 0。

3.5 新版功能。

`math.isclose(a, b, *, rel_tol=1e-09, abs_tol=0.0)`

若 a 和 b 的值比较接近则返回 True，否则返回 False。

根据给定的绝对和相对容差确定两个值是否被认为是接近的。

`rel_tol` 是相对容差——它是 a 和 b 之间允许的最大差值，相对于 a 或 b 的较大绝对值。例如，要设置 5% 的容差，请传递 `rel_tol=0.05`。默认容差为 $1e-09$ ，确保两个值在大约 9 位十进制数字内相同。`rel_tol` 必须大于零。

`abs_tol` 是最小绝对容差——对于接近零的比较很有用。`abs_tol` 必须至少为零。

如果没有错误发生，结果将是：`abs(a-b) <= max(rel_tol * max(abs(a), abs(b)), abs_tol)`。

IEEE 754 特殊值 NaN，`inf` 和 `-inf` 将根据 IEEE 规则处理。具体来说，NaN 不被认为接近任何其他值，包括 NaN。`inf` 和 `-inf` 只被认为接近自己。

3.5 新版功能。

参见：

[PEP 485](#) ——用于测试近似相等的函数

`math.isfinite(x)`

如果 x 既不是无穷大也不是 NaN，则返回 True，否则返回 False。（注意 0.0 被认为是有限的。）

3.2 新版功能。

`math.isinf(x)`

如果 x 是正或负无穷大，则返回 `True`，否则返回 `False`。

`math.isnan(x)`

如果 x 是 NaN (不是数字)，则返回 `True`，否则返回 `False`。

`math.ldexp(x, i)`

返回 $x * (2^{**i})$ 。这基本上是函数 `frexp()` 的反函数。

`math.modf(x)`

返回 x 的小数和整数部分。两个结果都带有 x 的符号并且是浮点数。

`math.trunc(x)`

返回 *Real* 值 x 截断为 *Integral* (通常是整数)。委托给 `x.__trunc__()`。

注意 `frexp()` 和 `modf()` 具有与它们的 C 等价函数不同的调用/返回模式：它们采用单个参数并返回一对值，而不是通过‘输出形参’返回它们的第二个返回参数 (Python 中没有这样的东西)。

对于 `ceil()`，`floor()` 和 `modf()` 函数，请注意 所有足够大的浮点数都是精确整数。Python 浮点数通常不超过 53 位的精度 (与平台 C `double` 类型相同)，在这种情况下，任何浮点 x 与 `abs(x) >= 2**52` 必然没有小数位。

9.2.2 幂函数与对数函数

`math.exp(x)`

Return e^{**x} .

`math.expm1(x)`

Return $e^{**x} - 1$. For small floats x , the subtraction in `exp(x) - 1` can result in a *significant loss of precision*; the `expm1()` function provides a way to compute this quantity to full precision:

```
>>> from math import exp, expm1
>>> exp(1e-5) - 1 # gives result accurate to 11 places
1.0000050000069649e-05
>>> expm1(1e-5) # result accurate to full precision
1.0000050000166668e-05
```

3.2 新版功能.

`math.log(x[, base])`

使用一个参数，返回 x 的自然对数 (底为 e)。

使用两个参数，返回给定的 *base* 的对数 x ，计算为 `log(x) / log(base)`。

`math.log1p(x)`

返回 $1+x$ (base e) 的自然对数。以对于接近零的 x 精确的方式计算结果。

`math.log2(x)`

返回 x 以 2 为底的对数。这通常比 `log(x, 2)` 更准确。

3.3 新版功能.

参见:

`int.bit_length()` 返回表示二进制整数所需的位数，不包括符号和前导零。

`math.log10(x)`

返回 x 底为 10 的对数。这通常比 `log(x, 10)` 更准确。

`math.pow(x, y)`

将返回 x 的 y 次幂。特殊情况尽可能遵循 C99 标准的附录‘F’。特别是，`pow(1.0, x)` 和 `pow(x,`

0.0) 总是返回 1.0，即使 x 是零或 NaN。如果 x 和 y 都是有限的， x 是负数， y 不是整数那么 $\text{pow}(x, y)$ 是未定义的，并且引发 `ValueError`。

与内置的 `**` 运算符不同，`math.pow()` 将其参数转换为 `float` 类型。使用 `**` 或内置的 `pow()` 函数来计算精确的整数幂。

`math.sqrt(x)`
返回 x 的平方根。

9.2.3 三角函数

`math.acos(x)`
以弧度为单位返回 x 的反余弦值。

`math.asin(x)`
以弧度为单位返回 x 的反正弦值。

`math.atan(x)`
以弧度为单位返回 x 的反正切值。

`math.atan2(y, x)`
以弧度为单位返回 $\text{atan}(y / x)$ 。结果是在 $-\pi$ 和 π 之间。从原点到点 (x, y) 的平面矢量使该角度与正 X 轴成正比。`atan2()` 的点的两个输入的符号都是已知的，因此它可以计算角度的正确象限。例如， $\text{atan}(1)$ 和 $\text{atan2}(1, 1)$ 都是 $\pi/4$ ，但 $\text{atan2}(-1, -1)$ 是 $-3\pi/4$ 。

`math.cos(x)`
返回 x 弧度的余弦值。

`math.hypot(x, y)`
返回欧几里德范数， $\sqrt{x^2 + y^2}$ 。这是从原点到点 (x, y) 的向量长度。

`math.sin(x)`
返回 x 弧度的正弦值。

`math.tan(x)`
返回 x 弧度的正切值。

9.2.4 角度转换

`math.degrees(x)`
将角度 x 从弧度转换为度数。

`math.radians(x)`
将角度 x 从度数转换为弧度。

9.2.5 双曲函数

双曲函数是基于双曲线而非圆来对三角函数进行模拟。

`math.acosh(x)`
返回 x 的反双曲余弦值。

`math.asinh(x)`
返回 x 的反双曲正弦值。

`math.atanh(x)`
返回 x 的反双曲正切值。

`math.cosh(x)`
返回 x 的双曲余弦值。

`math.sinh(x)`
返回 x 的双曲正弦值。

`math.tanh(x)`
返回 x 的双曲正切值。

9.2.6 特殊函数

`math.erf(x)`
返回 x 处的 `error function` 。

`erf()` 函数可用于计算传统的统计函数，如 累积标准正态分布

```
def phi(x):  
    'Cumulative distribution function for the standard normal distribution'  
    return (1.0 + erf(x / sqrt(2.0))) / 2.0
```

3.2 新版功能.

`math.erfc(x)`
返回 x 处的互补误差函数。互补误差函数 定义为 $1.0 - \text{erf}(x)$ 。它用于 x 的大值，从其中减去一个会导致 有效位数损失。

3.2 新版功能.

`math.gamma(x)`
返回 x 处的 伽马函数 值。

3.2 新版功能.

`math.lgamma(x)`
返回 Gamma 函数在 x 绝对值的自然对数。

3.2 新版功能.

9.2.7 常数

`math.pi`
The mathematical constant $\pi = 3.141592\dots$, to available precision.

`math.e`
The mathematical constant $e = 2.718281\dots$, to available precision.

`math.tau`
The mathematical constant $\tau = 6.283185\dots$, to available precision. Tau is a circle constant equal to 2π , the ratio of a circle's circumference to its radius. To learn more about Tau, check out Vi Hart's video [Pi is \(still\) Wrong](#), and start celebrating [Tau day](#) by eating twice as much pie!

3.6 新版功能.

`math.inf`
浮点正无穷大。(对于负无穷大，使用 `-math.inf`。) 相当于 “`float('inf')`” 的输出。

3.5 新版功能.

`math.nan`

浮点“非数字”(NaN)值。相当于 `float('nan')` 的输出。

3.5 新版功能.

CPython implementation detail: `math` 模块主要包含围绕平台 C 数学库函数的简单包装器。特殊情况下的行为在适当情况下遵循 C99 标准的附录 F。当前的实现将引发 `ValueError` 用于无效操作, 如 `sqrt(-1.0)` 或 `log(0.0)` (其中 C99 附件 F 建议发出无效操作信号或被零除), 和 `OverflowError` 用于溢出的结果 (例如, `exp(1000.0)`)。除非一个或多个输入参数是 NaN, 否则不会从上述任何函数返回 NaN; 在这种情况下, 大多数函数将返回一个 NaN, 但是 (再次遵循 C99 附件 F) 这个规则有一些例外, 例如 `pow(float('nan'), 0.0)` 或 `hypot(float('nan'), float('inf'))`。

请注意, Python 不会将显式 NaN 与静默 NaN 区分开来, 并且显式 NaN 的行为仍未明确。典型的行为是将所有 NaN 视为静默的。

参见:

`cmath` 模块 这里很多函数的复数版本。

9.3 cmath —— 关于复数的数学函数

This module is always available. It provides access to mathematical functions for complex numbers. The functions in this module accept integers, floating-point numbers or complex numbers as arguments. They will also accept any Python object that has either a `__complex__()` or a `__float__()` method: these methods are used to convert the object to a complex or floating-point number, respectively, and the function is then applied to the result of the conversion.

注解: On platforms with hardware and system-level support for signed zeros, functions involving branch cuts are continuous on *both* sides of the branch cut: the sign of the zero distinguishes one side of the branch cut from the other. On platforms that do not support signed zeros the continuity is as specified below.

9.3.1 到极坐标和从极坐标的转换

A Python complex number `z` is stored internally using *rectangular* or *Cartesian* coordinates. It is completely determined by its *real part* `z.real` and its *imaginary part* `z.imag`. In other words:

```
z == z.real + z.imag*1j
```

Polar coordinates give an alternative way to represent a complex number. In polar coordinates, a complex number `z` is defined by the modulus `r` and the phase angle `phi`. The modulus `r` is the distance from `z` to the origin, while the phase `phi` is the counterclockwise angle, measured in radians, from the positive x-axis to the line segment that joins the origin to `z`.

下面的函数可用于原生直角坐标与极坐标的相互转换。

`cmath.phase(x)`

Return the phase of `x` (also known as the *argument* of `x`), as a float. `phase(x)` is equivalent to `math.atan2(x.imag, x.real)`. The result lies in the range $[-\pi, \pi]$, and the branch cut for this operation lies along the negative real axis, continuous from above. On systems with support for signed zeros (which includes most systems in current use), this means that the sign of the result is the same as the sign of `x.imag`, even when `x.imag` is zero:

```
>>> phase(complex(-1.0, 0.0))
3.141592653589793
>>> phase(complex(-1.0, -0.0))
-3.141592653589793
```

注解: The modulus (absolute value) of a complex number x can be computed using the built-in `abs()` function. There is no separate `cmath` module function for this operation.

`cmath.polar(x)`

Return the representation of x in polar coordinates. Returns a pair (r, phi) where r is the modulus of x and phi is the phase of x . `polar(x)` is equivalent to `(abs(x), phase(x))`.

`cmath.rect(r, phi)`

Return the complex number x with polar coordinates r and phi . Equivalent to $r * (\text{math.cos(phi)} + \text{math.sin(phi)} * 1j)$.

9.3.2 幂函数与对数函数

`cmath.exp(x)`

Return the exponential value e^{**x} .

`cmath.log(x[, base])`

Returns the logarithm of x to the given *base*. If the *base* is not specified, returns the natural logarithm of x . There is one branch cut, from 0 along the negative real axis to $-\infty$, continuous from above.

`cmath.log10(x)`

Return the base-10 logarithm of x . This has the same branch cut as `log()`.

`cmath.sqrt(x)`

Return the square root of x . This has the same branch cut as `log()`.

9.3.3 三角函数

`cmath.acos(x)`

Return the arc cosine of x . There are two branch cuts: One extends right from 1 along the real axis to ∞ , continuous from below. The other extends left from -1 along the real axis to $-\infty$, continuous from above.

`cmath.asin(x)`

Return the arc sine of x . This has the same branch cuts as `acos()`.

`cmath.atan(x)`

Return the arc tangent of x . There are two branch cuts: One extends from $1j$ along the imaginary axis to ∞j , continuous from the right. The other extends from $-1j$ along the imaginary axis to $-\infty j$, continuous from the left.

`cmath.cos(x)`

返回 $*x*$ 的余弦。

`cmath.sin(x)`

返回 $*x*$ 的正弦。

`cmath.tan(x)`

返回 $*x*$ 的正切。

9.3.4 双曲函数

`cmath.acosh(x)`

Return the inverse hyperbolic cosine of x . There is one branch cut, extending left from 1 along the real axis to $-\infty$, continuous from above.

`cmath.asinh(x)`

Return the inverse hyperbolic sine of x . There are two branch cuts: One extends from $1j$ along the imaginary axis to ∞j , continuous from the right. The other extends from $-1j$ along the imaginary axis to $-\infty j$, continuous from the left.

`cmath.atanh(x)`

Return the inverse hyperbolic tangent of x . There are two branch cuts: One extends from 1 along the real axis to ∞ , continuous from below. The other extends from -1 along the real axis to $-\infty$, continuous from above.

`cmath.cosh(x)`

返回 x 的双曲余弦值。

`cmath.sinh(x)`

返回 x 的双曲正弦值。

`cmath.tanh(x)`

返回 x 的双曲正切值。

9.3.5 Classification functions

`cmath.isfinite(x)`

Return `True` if both the real and imaginary parts of x are finite, and `False` otherwise.

3.2 新版功能。

`cmath.isinf(x)`

Return `True` if either the real or the imaginary part of x is an infinity, and `False` otherwise.

`cmath.isnan(x)`

Return `True` if either the real or the imaginary part of x is a NaN, and `False` otherwise.

`cmath.isclose(a, b, *, rel_tol=1e-09, abs_tol=0.0)`

若 a 和 b 的值比较接近则返回 `True`，否则返回 `False`。

根据给定的绝对和相对容差确定两个值是否被认为是接近的。

`rel_tol` 是相对容差——它是 a 和 b 之间允许的最大差值，相对于 a 或 b 的较大绝对值。例如，要设置 5% 的容差，请传递 `rel_tol=0.05`。默认容差为 `1e-09`，确保两个值在大约 9 位十进制数字内相同。`rel_tol` 必须大于零。

`abs_tol` 是最小绝对容差——对于接近零的比较很有用。`abs_tol` 必须至少为零。

如果没有错误发生，结果将是：`abs(a-b) <= max(rel_tol * max(abs(a), abs(b)), abs_tol)`。

IEEE 754 特殊值 NaN，`inf` 和 `-inf` 将根据 IEEE 规则处理。具体来说，NaN 不被认为接近任何其他值，包括 NaN。`inf` 和 `-inf` 只被认为接近自己。

3.5 新版功能。

参见：

[PEP 485](#) ——用于测试近似相等的函数

9.3.6 常数

`cmath.pi`

The mathematical constant π , as a float.

`cmath.e`

The mathematical constant e , as a float.

`cmath.tau`

The mathematical constant τ , as a float.

3.6 新版功能.

`cmath.inf`

Floating-point positive infinity. Equivalent to `float('inf')`.

3.6 新版功能.

`cmath.infj`

Complex number with zero real part and positive infinity imaginary part. Equivalent to `complex(0.0, float('inf'))`.

3.6 新版功能.

`cmath.nan`

A floating-point “not a number” (NaN) value. Equivalent to `float('nan')`.

3.6 新版功能.

`cmath.nanj`

Complex number with zero real part and NaN imaginary part. Equivalent to `complex(0.0, float('nan'))`.

3.6 新版功能.

Note that the selection of functions is similar, but not identical, to that in module `math`. The reason for having two modules is that some users aren't interested in complex numbers, and perhaps don't even know what they are. They would rather have `math.sqrt(-1)` raise an exception than return a complex number. Also note that the functions defined in `cmath` always return a complex number, even if the answer can be expressed as a real number (in which case the complex number has an imaginary part of zero).

A note on branch cuts: They are curves along which the given function fails to be continuous. They are a necessary feature of many complex functions. It is assumed that if you need to compute with complex functions, you will understand about branch cuts. Consult almost any (not too elementary) book on complex variables for enlightenment. For information of the proper choice of branch cuts for numerical purposes, a good reference should be the following:

参见:

Kahan, W: Branch cuts for complex elementary functions; or, Much ado about nothing's sign bit. In Iserles, A., and Powell, M. (eds.), The state of the art in numerical analysis. Clarendon Press (1987) pp165–211.

9.4 decimal — 十进制定点和浮点运算

源码: [Lib/decimal.py](#)

`decimal` 模块为快速正确舍入的十进制浮点运算提供支持。它提供了 `float` 数据类型以外的几个优点:

- Decimal “基于一个浮点模型，它是为人们设计的，并且必然具有最重要的指导原则——计算机必须提供与人们在学校学习的算法相同的算法。”——摘自十进制算术规范。

- 十进制数字可以准确表示。相比之下，数字如 1.1 和 2.2 在二进制浮点中没有精确的表示。最终用户通常不希望“1.1 + 2.2”显示为 3.3000000000000003，就像二进制浮点一样。
- 精确性延续到算术中。在十进制浮点数中， $0.1 + 0.1 + 0.1 - 0.3$ 恰好等于零。在二进制浮点数中，结果为 $5.5511151231257827e-017$ 。虽然接近于零，但差异妨碍了可靠的相等性检验，并且差异可能会累积。因此，在具有严格相等不变量的会计应用程序中，`decimal` 是首选。
- 十进制模块包含一个重要位置的概念，因此 1.30 + 1.20 是 2.50。保留尾随零以表示重要性。这是货币申请的惯常陈述。对于乘法，“教科书”方法使用被乘数中的所有数字。例如， $1.3 * 1.2$ 给出 1.56 而 $1.30 * 1.20$ 给出 1.5600。
- 与基于硬件的二进制浮点不同，十进制模块具有用户可更改的精度（默认为 28 个位置），可以与给定问题所需的一样大：

```
>>> from decimal import *
>>> getcontext().prec = 6
>>> Decimal(1) / Decimal(7)
Decimal('0.142857')
>>> getcontext().prec = 28
>>> Decimal(1) / Decimal(7)
Decimal('0.1428571428571428571428571428571429')
```

- 二进制和十进制浮点都是根据已发布的标准实现的。虽然内置浮点类型只公开其功能的一小部分，但十进制模块公开了标准的所有必需部分。在需要时，程序员可以完全控制舍入和信号处理。这包括通过使用异常来阻止任何不精确操作来强制执行精确算术的选项。
- 十进制模块旨在支持“无偏见，精确的非连续十进制算术（有时称为定点算术）和舍入浮点算术”。——摘自十进制算术规范。

模块设计以三个概念为中心：十进制数，算术上下文和信号。

十进制数是不可变的。它有一个符号，系数数字和一个指数。为了保持重要性，系数数字不会截断尾随零。十进制数也包括特殊值，例如 `Infinity`，`-Infinity`，和 `NaN`。该标准还区分 `-0` 和 `+0`。

算术的上下文是指定精度、舍入规则、指数限制、指示操作结果的标志以及确定符号是否被视为异常的陷阱启用器的环境。舍入选项包括 `ROUND_CEILING`、`ROUND_DOWN`、`ROUND_FLOOR`、`ROUND_HALF_DOWN`、`ROUND_HALF_EVEN`、`ROUND_HALF_UP`、`ROUND_UP` 以及 `ROUND_05UP`。

信号是在计算过程中出现的异常条件组。根据应用程序的需要，信号可能会被忽略，被视为信息，或被视为异常。十进制模块中的信号有：`Clamped`、`InvalidOperation`、`DivisionByZero`、`Inexact`、`Rounded`、`Subnormal`、`Overflow`、`Underflow` 以及 `FloatOperation`。

对于每个信号，都有一个标志和一个陷阱启动器。遇到信号时，其标志设置为 1，然后，如果陷阱启用器设置为 1，则引发异常。标志是粘性的，因此用户需要在监控计算之前重置它们。

参见：

- IBM 的通用十进制算术规范，[The General Decimal Arithmetic Specification](#).

9.4.1 快速入门教程

通常使用小数的开始是导入模块，使用 `getcontext()` 查看当前上下文，并在必要时为精度、舍入或启用的陷阱设置新值：

```
>>> from decimal import *
>>> getcontext()
Context(prec=28, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
        capitals=1, clamp=0, flags=[], traps=[Overflow, DivisionByZero,
        InvalidOperation])
```

(下页继续)

(续上页)

```
>>> getcontext().prec = 7          # Set a new precision
```

可以从整数、字符串、浮点数或元组构造十进制实例。从整数或浮点构造将执行该整数或浮点值的精确转换。十进制数包括特殊值，例如 NaN 代表“非数字”，正的和负的 Infinity，和 -0

```
>>> getcontext().prec = 28
>>> Decimal(10)
Decimal('10')
>>> Decimal('3.14')
Decimal('3.14')
>>> Decimal(3.14)
Decimal('3.1400000000000000124344978758017532527446746826171875')
>>> Decimal((0, (3, 1, 4), -2))
Decimal('3.14')
>>> Decimal(str(2.0 ** 0.5))
Decimal('1.4142135623730951')
>>> Decimal(2) ** Decimal('0.5')
Decimal('1.414213562373095048801688724')
>>> Decimal('NaN')
Decimal('NaN')
>>> Decimal('-Infinity')
Decimal('-Infinity')
```

如果`FloatOperation`信号被捕获，构造函数中的小数和浮点数的意外混合或排序比较会引发异常

```
>>> c = getcontext()
>>> c.traps[FloatOperation] = True
>>> Decimal(3.14)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: [
>>> Decimal('3.5') < 3.7
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: [
>>> Decimal('3.5') == 3.5
True
```

3.3 新版功能.

新 Decimal 的重要性仅由输入的位数决定。上下文精度和舍入仅在算术运算期间发挥作用。

```
>>> getcontext().prec = 6
>>> Decimal('3.0')
Decimal('3.0')
>>> Decimal('3.1415926535')
Decimal('3.1415926535')
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85987')
>>> getcontext().rounding = ROUND_UP
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85988')
```

如果超出了 C 版本的内部限制，则构造一个十进制将引发 *InvalidOperation*

```
>>> Decimal("1e999999999999999999")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.InvalidOperation: [
```

在 3.3 版更改.

小数与 Python 的其余部分很好地交互。这是一个小的十进制浮点飞行杂技团：

```
>>> data = list(map(Decimal, '1.34 1.87 3.45 2.35 1.00 0.03 9.25'.split()))
>>> max(data)
Decimal('9.25')
>>> min(data)
Decimal('0.03')
>>> sorted(data)
[Decimal('0.03'), Decimal('1.00'), Decimal('1.34'), Decimal('1.87'),
 Decimal('2.35'), Decimal('3.45'), Decimal('9.25')]
>>> sum(data)
Decimal('19.29')
>>> a,b,c = data[:3]
>>> str(a)
'1.34'
>>> float(a)
1.34
>>> round(a, 1)
Decimal('1.3')
>>> int(a)
1
>>> a * 5
Decimal('6.70')
>>> a * b
Decimal('2.5058')
>>> c % a
Decimal('0.77')
```

Decimal 也可以使用一些数学函数:

```
>>> getcontext().prec = 28
>>> Decimal(2).sqrt()
Decimal('1.414213562373095048801688724')
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal('10').ln()
Decimal('2.302585092994045684017991455')
>>> Decimal('10').log10()
Decimal('1')
```

`quantize()` 方法将数字四舍五入为固定指数。此方法对于将结果舍入到固定的位置的货币应用程序非常有用：

```
>>> Decimal('7.325').quantize(Decimal('.01'), rounding=ROUND_DOWN)
Decimal('7.32')
>>> Decimal('7.325').quantize(Decimal('1.'), rounding=ROUND_UP)
Decimal('8')
```

如上所示，`getcontext()` 函数访问当前上下文并允许更改设置。这种方法满足大多数应用程序的需求。

对于更高级的工作，使用 `Context()` 构造函数创建备用上下文可能很有用。要使用备用活动，请使用 `setcontext()` 函数。

根据标准，`decimal` 模块提供了两个现成的标准上下文 `BasicContext` 和 `ExtendedContext`。前者对调试特别有用，因为许多陷阱都已启用：

```
>>> myothercontext = Context(prec=60, rounding=ROUND_HALF_DOWN)
>>> setcontext(myothercontext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857142857142857142857142857142857142857142857142857')

>>> ExtendedContext
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
        capitals=1, clamp=0, flags=[], traps=[])
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857143')
>>> Decimal(42) / Decimal(0)
Decimal('Infinity')

>>> setcontext(BasicContext)
>>> Decimal(42) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#143>", line 1, in -toplevel-
    Decimal(42) / Decimal(0)
DivisionByZero: x / 0
```

上下文还具有用于监视计算期间遇到的异常情况的信号标志。标志保持设置直到明确清除，因此最好通过使用 `clear_flags()` 方法清除每组受监控计算之前的标志。：

```
>>> setcontext(ExtendedContext)
>>> getcontext().clear_flags()
>>> Decimal(355) / Decimal(113)
Decimal('3.14159292')
>>> getcontext()
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
        capitals=1, clamp=0, flags=[Inexact, Rounded], traps=[])
```

`flags` 条目显示对 π 的有理逼近被舍入（超出上下文精度的数字被抛弃）并且结果是不精确的（一些丢弃的数字不为零）。

使用上下文的 `traps` 字段中的字典设置单个陷阱：

```
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(0)
Decimal('Infinity')
>>> getcontext().traps[DivisionByZero] = 1
>>> Decimal(1) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#112>", line 1, in -toplevel-
    Decimal(1) / Decimal(0)
DivisionByZero: x / 0
```

大多数程序仅在程序开始时调整当前上下文一次。并且，在许多应用程序中，数据在循环内单个强制转换为 `Decimal`。通过创建上下文集和小数，程序的大部分操作数据与其他 Python 数字类型没有区别。

9.4.2 Decimal 对象

class `decimal.Decimal` (*value="0", context=None*)

根据 *value* 构造一个新的 `Decimal` 对象。

value 可以是整数，字符串，元组，*float*，或另一个 *Decimal* 对象。如果没有给出 *value*，则返回 `Decimal('0')`。如果 *value* 是一个字符串，它应该在前导和尾随空格字符以及下划线被删除之后符合十进制数字字符串语法：

```
sign      ::= '+' | '-'
digit     ::= '0' | '1' | '2' | '3' | '4' | '5' | '6' | '7' | '8' | '9'
indicator ::= 'e' | 'E'
digits    ::= digit [digit]...
decimal-part ::= digits '.' [digits] | ['.' ] digits
exponent-part ::= indicator [sign] digits
infinity  ::= 'Infinity' | 'Inf'
nan       ::= 'NaN' [digits] | 'sNaN' [digits]
numeric-value ::= decimal-part [exponent-part] | infinity
numeric-string ::= [sign] numeric-value | [sign] nan
```

当上面出现 *digit* 时也允许其他十进制数码。其中包括来自各种其他语言系统的十进制数码（例如阿拉伯-印地语和天城文的数码）以及全宽数码 `'\uff10'` 到 `'\uff19'`。

如果 *value* 是一个 *tuple*，它应该有三个组件，一个符号（0 表示正数或 1 表示负数），一个数字的 *tuple* 和整数指数。例如，`Decimal((0, (1, 4, 1, 4), -3))` 返回 `Decimal('1.414')`。

如果 *value* 是 *float*，则二进制浮点值无损地转换为其精确的十进制等效值。此转换通常需要 53 位或更多位数的精度。例如，`Decimal(float('1.1'))` 转换为 `Decimal('1.100000000000000088817841970012523233890533447265625')`。

context 精度不会影响存储的位数。这完全由 *value* 中的位数决定。例如，`Decimal('3.00000')` 记录所有五个零，即使上下文精度只有三。

context 参数的目的是确定 *value* 是格式错误的字符串时该怎么做。如果上下文陷阱 *InvalidOperation*，则引发异常；否则，构造函数返回一个新的 *Decimal*，其值为 NaN。

构造完成后，*Decimal* 对象是不可变的。

在 3.2 版更改：现在允许构造函数的参数为 *float* 实例。

在 3.3 版更改：*float* 参数在设置 *FloatOperation* 陷阱时引发异常。默认情况下，陷阱已关闭。

在 3.6 版更改：允许下划线进行分组，就像代码中的整数和浮点文字一样。

十进制浮点对象与其他内置数值类型共享许多属性，例如 *float* 和 *int*。所有常用的数学运算和特殊方法都适用。同样，十进制对象可以复制、pickle、打印、用作字典键、用作集合元素、比较、排序和强制转换为另一种类型（例如 *float* 或 *int*）。

算术对十进制对象和算术对整数和浮点数有一些小的差别。当余数运算符 `%` 应用于 *Decimal* 对象时，结果的符号是 被除数的符号，而不是除数的符号：

```
>>> (-7) % 4
1
>>> Decimal(-7) % Decimal(4)
Decimal('-3')
```

整数除法运算符 `//` 的行为类似，返回真商的整数部分（截断为零）而不是它的向下取整，以便保留通常的标识 `x == (x // y) * y + x % y`：

```
>>> -7 // 4
-2
>>> Decimal(-7) // Decimal(4)
Decimal('-1')
```

`%` 和 `//` 运算符实现了 *remainder* 和 *divide-integer* 操作（分别），如规范中所述。

十进制对象通常不能与浮点数或 `fractions.Fraction` 实例在算术运算中结合使用：例如，尝试将 `Decimal` 加到 `float`，将引发 `TypeError`。但是，可以使用 Python 的比较运算符来比较 `Decimal` 实例 `x` 和另一个数字 `y`。这样可以避免在对不同类型的数字进行相等比较时混淆结果。

在 3.2 版更改：现在完全支持 `Decimal` 实例和其他数字类型之间的混合类型比较。

除了标准的数字属性，十进制浮点对象还有许多专门的方法：

`adjusted()`

在移出系数最右边的数字之后返回调整后的指数，直到只剩下前导数字：`Decimal('321e+5').adjusted()` 返回 7。用于确定最高有效位相对于小数点的位置。

`as_integer_ratio()`

返回一对 `(n, d)` 整数，表示给定的 `Decimal` 实例作为分数、最简形式项并带有正分母：

```
>>> Decimal('-3.14').as_integer_ratio()
(-157, 50)
```

转换是精确的。在 `Infinity` 上引发 `OverflowError`，在 `NaN` 上引起 `ValueError`。

3.6 新版功能。

`as_tuple()`

返回一个 *named tuple* 表示的数字：`DecimalTuple(sign, digits, exponent)`。

`canonical()`

返回参数的规范编码。目前，一个 `Decimal` 实例的编码始终是规范的，因此该操作返回其参数不变。

`compare(other, context=None)`

比较两个 `Decimal` 实例的值。`compare()` 返回一个 `Decimal` 实例，如果任一操作数是 `NaN`，那么结果是 `NaN`

```
a or b is a NaN ==> Decimal('NaN')
a < b           ==> Decimal('-1')
a == b          ==> Decimal('0')
a > b           ==> Decimal('1')
```

`compare_signal(other, context=None)`

除了所有 `NaN` 信号之外，此操作与 `compare()` 方法相同。也就是说，如果两个操作数都不是信号 `NaN`，那么任何静默的 `NaN` 操作数都被视为信号 `NaN`。

`compare_total(other, context=None)`

使用它们的抽象表示而不是它们的数值来比较两个操作数。类似于 `compare()` 方法，但结果给出了一个总排序 `Decimal` 实例。两个 `Decimal` 实例具有相同的数值但不同的表示形式在此排序中比较不相等：

```
>>> Decimal('12.0').compare_total(Decimal('12'))
Decimal('-1')
```

静默和发出信号的 `NaN` 也包括在总排序中。这个函数的结果是 `Decimal('0')` 如果两个操作数具有相同的表示，或是 `Decimal('-1')` 如果第一个操作数的总顺序低于第二个操作数，或是 `Decimal('1')` 如果第一个操作数在总顺序中高于第二个操作数。有关总排序的详细信息，请参阅规范。

此操作不受上下文影响且静默：不更改任何标志且不执行舍入。作为例外，如果无法准确转换第二个操作数，则 C 版本可能会引发 `InvalidOperation`。

`compare_total_mag(other, context=None)`

比较两个操作数使用它们的抽象表示而不是它们的值，如 `compare_total()`，但忽略每个

操作数的符号。`x.compare_total_mag(y)` 相当于 `x.copy_abs().compare_total(y.copy_abs())`。

此操作不受上下文影响且静默：不更改任何标志且不执行舍入。作为例外，如果无法准确转换第二个操作数，则 C 版本可能会引发 `InvalidOperation`。

conjugate()

只返回 `self`，这种方法只符合 `Decimal` 规范。

copy_abs()

返回参数的绝对值。此操作不受上下文影响并且是静默的：没有更改标志且不执行舍入。

copy_negate()

回到参数的否定。此操作不受上下文影响并且是静默的：没有标志更改且不执行舍入。

copy_sign(other, context=None)

返回第一个操作数的副本，其符号设置为与第二个操作数的符号相同。例如：

```
>>> Decimal('2.3').copy_sign(Decimal('-1.5'))
Decimal('-2.3')
```

此操作不受上下文影响且静默：不更改任何标志且不执行舍入。作为例外，如果无法准确转换第二个操作数，则 C 版本可能会引发 `InvalidOperation`。

exp(context=None)

返回给定数字的（自然）指数函数“ e^x ”的值。结果使用 `ROUND_HALF_EVEN` 舍入模式正确舍入。

```
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal(321).exp()
Decimal('2.561702493119680037517373933E+139')
```

from_float(f)

将浮点数转换为十进制数的类方法。

注意，`Decimal.from_float(0.1)` 与 `Decimal('0.1')` 不同。由于 0.1 在二进制浮点中不能精确表示，因此该值存储为最接近的可表示值，即 `0x1.999999999999ap-4`。十进制的等效值是 `'0.1000000000000000055511151231257827021181583404541015625'`。

注解：从 Python 3.2 开始，`Decimal` 实例也可以直接从 `float` 构造。

```
>>> Decimal.from_float(0.1)
Decimal('0.1000000000000000055511151231257827021181583404541015625')
>>> Decimal.from_float(float('nan'))
Decimal('NaN')
>>> Decimal.from_float(float('inf'))
Decimal('Infinity')
>>> Decimal.from_float(float('-inf'))
Decimal('-Infinity')
```

3.1 新版功能.

fma(other, third, context=None)

混合乘法加法。返回 `self*other+third`，中间乘积 `self*other` 没有四舍五入。

```
>>> Decimal(2).fma(3, 5)
Decimal('11')
```

is_canonical()

如果参数是规范的，则为返回 *True*，否则为 *False*。目前，*Decimal* 实例总是规范的，所以这个操作总是返回 *True*。

is_finite()

如果参数是一个有限的数，则返回为 *True*；如果参数为无穷大或 NaN，则返回为 *False*。

is_infinite()

如果参数为正负无穷大，则返回为 *True*，否则为 *False*。

is_nan()

如果参数为 NaN（无论是否静默），则返回为 *True*，否则为 *False*。

is_normal(context=None)

如果参数是一个有限正规数，返回 *True*，如果参数是 0、次正规数、无穷大或是 NaN，返回 *False*。

is_qnan()

如果参数为静默 NaN，返回 *True*，否则返回 *False*。

is_signed()

如果参数带有负号，则返回为 *True*，否则返回 *False*。注意，0 和 NaN 都可带有符号。

is_snan()

如果参数为显式 NaN，则返回 *True*，否则返回 *False*。

is_subnormal(context=None)

如果参数为次正规数，则返回 *True*，否则返回 *False*。

is_zero()

如果参数是 0（正负皆可），则返回 *True*，否则返回 *False*。

ln(context=None)

Return the natural (base e) logarithm of the operand. The result is correctly rounded using the *ROUND_HALF_EVEN* rounding mode.

log10(context=None)

Return the base ten logarithm of the operand. The result is correctly rounded using the *ROUND_HALF_EVEN* rounding mode.

logb(context=None)

For a nonzero number, return the adjusted exponent of its operand as a *Decimal* instance. If the operand is a zero then *Decimal('-Infinity')* is returned and the *DivisionByZero* flag is raised. If the operand is an infinity then *Decimal('Infinity')* is returned.

logical_and(other, context=None)

logical_and() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise and of the two operands.

logical_invert(context=None)

logical_invert() is a logical operation. The result is the digit-wise inversion of the operand.

logical_or(other, context=None)

logical_or() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise or of the two operands.

logical_xor(other, context=None)

logical_xor() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise exclusive or of the two operands.

max(other, context=None)

Like *max(self, other)* except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

max_mag (*other*, *context=None*)

Similar to the `max()` method, but the comparison is done using the absolute values of the operands.

min (*other*, *context=None*)

Like `min(self, other)` except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

min_mag (*other*, *context=None*)

Similar to the `min()` method, but the comparison is done using the absolute values of the operands.

next_minus (*context=None*)

Return the largest number representable in the given context (or in the current thread's context if no context is given) that is smaller than the given operand.

next_plus (*context=None*)

Return the smallest number representable in the given context (or in the current thread's context if no context is given) that is larger than the given operand.

next_toward (*other*, *context=None*)

If the two operands are unequal, return the number closest to the first operand in the direction of the second operand. If both operands are numerically equal, return a copy of the first operand with the sign set to be the same as the sign of the second operand.

normalize (*context=None*)

Normalize the number by stripping the rightmost trailing zeros and converting any result equal to `Decimal('0')` to `Decimal('0e0')`. Used for producing canonical values for attributes of an equivalence class. For example, `Decimal('32.100')` and `Decimal('0.321000e+2')` both normalize to the equivalent value `Decimal('32.1')`.

number_class (*context=None*)

Return a string describing the *class* of the operand. The returned value is one of the following ten strings.

- `"-Infinity"`, indicating that the operand is negative infinity.
- `"-Normal"`, indicating that the operand is a negative normal number.
- `"-Subnormal"`, indicating that the operand is negative and subnormal.
- `"-Zero"`, indicating that the operand is a negative zero.
- `"+Zero"`, indicating that the operand is a positive zero.
- `"+Subnormal"`, indicating that the operand is positive and subnormal.
- `"+Normal"`, indicating that the operand is a positive normal number.
- `"+Infinity"`, indicating that the operand is positive infinity.
- `"NaN"`, indicating that the operand is a quiet NaN (Not a Number).
- `"sNaN"`, indicating that the operand is a signaling NaN.

quantize (*exp*, *rounding=None*, *context=None*)

Return a value equal to the first operand after rounding and having the exponent of the second operand.

```
>>> Decimal('1.41421356').quantize(Decimal('1.000'))
Decimal('1.414')
```

Unlike other operations, if the length of the coefficient after the quantize operation would be greater than precision, then an `InvalidOperation` is signaled. This guarantees that, unless there is an error condition, the quantized exponent is always equal to that of the right-hand operand.

Also unlike other operations, quantize never signals Underflow, even if the result is subnormal and inexact.

If the exponent of the second operand is larger than that of the first then rounding may be necessary. In this case, the rounding mode is determined by the `rounding` argument if given, else by the given `context` argument; if neither argument is given the rounding mode of the current thread's context is used.

An error is returned whenever the resulting exponent is greater than `Emax` or less than `Etiny`.

radix()

Return `Decimal(10)`, the radix (base) in which the `Decimal` class does all its arithmetic. Included for compatibility with the specification.

remainder_near (*other*, *context=None*)

Return the remainder from dividing *self* by *other*. This differs from `self % other` in that the sign of the remainder is chosen so as to minimize its absolute value. More precisely, the return value is `self - n * other` where *n* is the integer nearest to the exact value of `self / other`, and if two integers are equally near then the even one is chosen.

If the result is zero then its sign will be the sign of *self*.

```
>>> Decimal(18).remainder_near(Decimal(10))
Decimal('-2')
>>> Decimal(25).remainder_near(Decimal(10))
Decimal('5')
>>> Decimal(35).remainder_near(Decimal(10))
Decimal('-5')
```

rotate (*other*, *context=None*)

Return the result of rotating the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range `-precision` through `precision`. The absolute value of the second operand gives the number of places to rotate. If the second operand is positive then rotation is to the left; otherwise rotation is to the right. The coefficient of the first operand is padded on the left with zeros to length `precision` if necessary. The sign and exponent of the first operand are unchanged.

same_quantum (*other*, *context=None*)

Test whether *self* and *other* have the same exponent or whether both are NaN.

此操作不受上下文影响且静默：不更改任何标志且不执行舍入。作为例外，如果无法准确转换第二个操作数，则 C 版本可能会引发 `InvalidOperation`。

scaleb (*other*, *context=None*)

Return the first operand with exponent adjusted by the second. Equivalently, return the first operand multiplied by `10**other`. The second operand must be an integer.

shift (*other*, *context=None*)

Return the result of shifting the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range `-precision` through `precision`. The absolute value of the second operand gives the number of places to shift. If the second operand is positive then the shift is to the left; otherwise the shift is to the right. Digits shifted into the coefficient are zeros. The sign and exponent of the first operand are unchanged.

sqrt (*context=None*)

Return the square root of the argument to full precision.

to_eng_string (*context=None*)

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

For example, this converts `Decimal('123E+1')` to `Decimal('1.23E+3')`.

to_integral (*rounding=None, context=None*)

Identical to the `to_integral_value()` method. The `to_integral` name has been kept for compatibility with older versions.

to_integral_exact (*rounding=None, context=None*)

Round to the nearest integer, signaling *Inexact* or *Rounded* as appropriate if rounding occurs. The rounding mode is determined by the `rounding` parameter if given, else by the given `context`. If neither parameter is given then the rounding mode of the current context is used.

to_integral_value (*rounding=None, context=None*)

Round to the nearest integer without signaling *Inexact* or *Rounded*. If given, applies *rounding*; otherwise, uses the rounding method in either the supplied *context* or the current context.

Logical operands

The `logical_and()`, `logical_invert()`, `logical_or()`, and `logical_xor()` methods expect their arguments to be *logical operands*. A *logical operand* is a *Decimal* instance whose exponent and sign are both zero, and whose digits are all either 0 or 1.

9.4.3 Context objects

Contexts are environments for arithmetic operations. They govern precision, set rules for rounding, determine which signals are treated as exceptions, and limit the range for exponents.

Each thread has its own current context which is accessed or changed using the `getcontext()` and `setcontext()` functions:

`decimal.getcontext()`

Return the current context for the active thread.

`decimal.setcontext(c)`

Set the current context for the active thread to *c*.

You can also use the `with` statement and the `localcontext()` function to temporarily change the active context.

`decimal.localcontext(ctx=None)`

Return a context manager that will set the current context for the active thread to a copy of *ctx* on entry to the `with`-statement and restore the previous context when exiting the `with`-statement. If no context is specified, a copy of the current context is used.

For example, the following code sets the current decimal precision to 42 places, performs a calculation, and then automatically restores the previous context:

```
from decimal import localcontext

with localcontext() as ctx:
    ctx.prec = 42    # Perform a high precision calculation
    s = calculate_something()
s = +s    # Round the final result back to the default precision
```

New contexts can also be created using the *Context* constructor described below. In addition, the module provides three pre-made contexts:

class `decimal.BasicContext`

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to *ROUND_HALF_UP*. All flags are cleared. All traps are enabled (treated as exceptions) except *Inexact*, *Rounded*, and *Subnormal*.

Because many of the traps are enabled, this context is useful for debugging.

class decimal.ExtendedContext

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to `ROUND_HALF_EVEN`. All flags are cleared. No traps are enabled (so that exceptions are not raised during computations).

Because the traps are disabled, this context is useful for applications that prefer to have result value of NaN or Infinity instead of raising exceptions. This allows an application to complete a run in the presence of conditions that would otherwise halt the program.

class decimal.DefaultContext

This context is used by the `Context` constructor as a prototype for new contexts. Changing a field (such a precision) has the effect of changing the default for new contexts created by the `Context` constructor.

This context is most useful in multi-threaded environments. Changing one of the fields before threads are started has the effect of setting system-wide defaults. Changing the fields after threads have started is not recommended as it would require thread synchronization to prevent race conditions.

In single threaded environments, it is preferable to not use this context at all. Instead, simply create contexts explicitly as described below.

The default values are `prec=28`, `rounding=ROUND_HALF_EVEN`, and enabled traps for `Overflow`, `InvalidOperation`, and `DivisionByZero`.

In addition to the three supplied contexts, new contexts can be created with the `Context` constructor.

class decimal.Context (*prec=None, rounding=None, Emin=None, Emax=None, capitals=None, clamp=None, flags=None, traps=None*)

Creates a new context. If a field is not specified or is `None`, the default values are copied from the `DefaultContext`. If the `flags` field is not specified or is `None`, all flags are cleared.

`prec` is an integer in the range `[1, MAX_PREC]` that sets the precision for arithmetic operations in the context.

The `rounding` option is one of the constants listed in the section *Rounding Modes*.

The `traps` and `flags` fields list any signals to be set. Generally, new contexts should only set traps and leave the flags clear.

The `Emin` and `Emax` fields are integers specifying the outer limits allowable for exponents. `Emin` must be in the range `[MIN_EMIN, 0]`, `Emax` in the range `[0, MAX_EMAX]`.

The `capitals` field is either 0 or 1 (the default). If set to 1, exponents are printed with a capital E; otherwise, a lowercase e is used: `Decimal('6.02e+23')`.

The `clamp` field is either 0 (the default) or 1. If set to 1, the exponent `e` of a `Decimal` instance representable in this context is strictly limited to the range `Emin - prec + 1 <= e <= Emax - prec + 1`. If `clamp` is 0 then a weaker condition holds: the adjusted exponent of the `Decimal` instance is at most `Emax`. When `clamp` is 1, a large normal number will, where possible, have its exponent reduced and a corresponding number of zeros added to its coefficient, in order to fit the exponent constraints; this preserves the value of the number but loses information about significant trailing zeros. For example:

```
>>> Context(prec=6, Emax=999, clamp=1).create_decimal('1.23e999')
Decimal('1.23000E+999')
```

A `clamp` value of 1 allows compatibility with the fixed-width decimal interchange formats specified in IEEE 754.

The `Context` class defines several general purpose methods as well as a large number of methods for doing arithmetic directly in a given context. In addition, for each of the `Decimal` methods described above (with the exception of the `adjusted()` and `as_tuple()` methods) there is a corresponding `Context` method. For example, for a `Context` instance `C` and `Decimal` instance `x`, `C.exp(x)` is equivalent to `x.exp(context=C)`. Each `Context` method accepts a Python integer (an instance of `int`) anywhere that a `Decimal` instance is accepted.

clear_flags()

Resets all of the flags to 0.

clear_traps()

Resets all of the traps to 0.

3.3 新版功能.

copy()

Return a duplicate of the context.

copy_decimal(num)

Return a copy of the Decimal instance num.

create_decimal(num)

Creates a new Decimal instance from *num* but using *self* as context. Unlike the *Decimal* constructor, the context precision, rounding method, flags, and traps are applied to the conversion.

This is useful because constants are often given to a greater precision than is needed by the application. Another benefit is that rounding immediately eliminates unintended effects from digits beyond the current precision. In the following example, using unrounded inputs means that adding zero to a sum can change the result:

```
>>> getcontext().prec = 3
>>> Decimal('3.4445') + Decimal('1.0023')
Decimal('4.45')
>>> Decimal('3.4445') + Decimal(0) + Decimal('1.0023')
Decimal('4.44')
```

This method implements the to-number operation of the IBM specification. If the argument is a string, no leading or trailing whitespace or underscores are permitted.

create_decimal_from_float(f)

Creates a new Decimal instance from a float *f* but rounding using *self* as the context. Unlike the *Decimal.from_float()* class method, the context precision, rounding method, flags, and traps are applied to the conversion.

```
>>> context = Context(prec=5, rounding=ROUND_DOWN)
>>> context.create_decimal_from_float(math.pi)
Decimal('3.1415')
>>> context = Context(prec=5, traps=[Inexact])
>>> context.create_decimal_from_float(math.pi)
Traceback (most recent call last):
...
decimal.Inexact: None
```

3.1 新版功能.

Etiny()

Returns a value equal to $E_{min} - prec + 1$ which is the minimum exponent value for subnormal results. When underflow occurs, the exponent is set to *Etiny*.

Etop()

Returns a value equal to $E_{max} - prec + 1$.

The usual approach to working with decimals is to create *Decimal* instances and then apply arithmetic operations which take place within the current context for the active thread. An alternative approach is to use context methods for calculating within a specific context. The methods are similar to those for the *Decimal* class and are only briefly recounted here.

abs (*x*)
Returns the absolute value of *x*.

add (*x*, *y*)
Return the sum of *x* and *y*.

canonical (*x*)
Returns the same Decimal object *x*.

compare (*x*, *y*)
Compares *x* and *y* numerically.

compare_signal (*x*, *y*)
Compares the values of the two operands numerically.

compare_total (*x*, *y*)
Compares two operands using their abstract representation.

compare_total_mag (*x*, *y*)
Compares two operands using their abstract representation, ignoring sign.

copy_abs (*x*)
Returns a copy of *x* with the sign set to 0.

copy_negate (*x*)
Returns a copy of *x* with the sign inverted.

copy_sign (*x*, *y*)
Copies the sign from *y* to *x*.

divide (*x*, *y*)
Return *x* divided by *y*.

divide_int (*x*, *y*)
Return *x* divided by *y*, truncated to an integer.

divmod (*x*, *y*)
Divides two numbers and returns the integer part of the result.

exp (*x*)
Returns e^{**x} .

fma (*x*, *y*, *z*)
Returns *x* multiplied by *y*, plus *z*.

is_canonical (*x*)
Returns `True` if *x* is canonical; otherwise returns `False`.

is_finite (*x*)
Returns `True` if *x* is finite; otherwise returns `False`.

is_infinite (*x*)
Returns `True` if *x* is infinite; otherwise returns `False`.

is_nan (*x*)
Returns `True` if *x* is a qNaN or sNaN; otherwise returns `False`.

is_normal (*x*)
Returns `True` if *x* is a normal number; otherwise returns `False`.

is_qnan (*x*)
Returns `True` if *x* is a quiet NaN; otherwise returns `False`.

is_signed (*x*)
Returns True if *x* is negative; otherwise returns False.

is_snan (*x*)
Returns True if *x* is a signaling NaN; otherwise returns False.

is_subnormal (*x*)
Returns True if *x* is subnormal; otherwise returns False.

is_zero (*x*)
Returns True if *x* is a zero; otherwise returns False.

ln (*x*)
Returns the natural (base e) logarithm of *x*.

log10 (*x*)
Returns the base 10 logarithm of *x*.

logb (*x*)
Returns the exponent of the magnitude of the operand's MSD.

logical_and (*x*, *y*)
Applies the logical operation *and* between each operand's digits.

logical_invert (*x*)
Invert all the digits in *x*.

logical_or (*x*, *y*)
Applies the logical operation *or* between each operand's digits.

logical_xor (*x*, *y*)
Applies the logical operation *xor* between each operand's digits.

max (*x*, *y*)
Compares two values numerically and returns the maximum.

max_mag (*x*, *y*)
Compares the values numerically with their sign ignored.

min (*x*, *y*)
Compares two values numerically and returns the minimum.

min_mag (*x*, *y*)
Compares the values numerically with their sign ignored.

minus (*x*)
Minus corresponds to the unary prefix minus operator in Python.

multiply (*x*, *y*)
Return the product of *x* and *y*.

next_minus (*x*)
Returns the largest representable number smaller than *x*.

next_plus (*x*)
Returns the smallest representable number larger than *x*.

next_toward (*x*, *y*)
Returns the number closest to *x*, in direction towards *y*.

normalize (*x*)
Reduces *x* to its simplest form.

number_class (*x*)

Returns an indication of the class of *x*.

plus (*x*)

Plus corresponds to the unary prefix plus operator in Python. This operation applies the context precision and rounding, so it is *not* an identity operation.

power (*x*, *y*, *modulo*=None)

Return *x* to the power of *y*, reduced modulo *modulo* if given.

With two arguments, compute x^y . If *x* is negative then *y* must be integral. The result will be inexact unless *y* is integral and the result is finite and can be expressed exactly in ‘precision’ digits. The rounding mode of the context is used. Results are always correctly-rounded in the Python version.

在 3.3 版更改: The C module computes `power()` in terms of the correctly-rounded `exp()` and `ln()` functions. The result is well-defined but only “almost always correctly-rounded”.

With three arguments, compute $(x^y) \% modulo$. For the three argument form, the following restrictions on the arguments hold:

- all three arguments must be integral
- *y* must be nonnegative
- at least one of *x* or *y* must be nonzero
- *modulo* must be nonzero and have at most ‘precision’ digits

The value resulting from `Context.power(x, y, modulo)` is equal to the value that would be obtained by computing $(x^y) \% modulo$ with unbounded precision, but is computed more efficiently. The exponent of the result is zero, regardless of the exponents of *x*, *y* and *modulo*. The result is always exact.

quantize (*x*, *y*)

Returns a value equal to *x* (rounded), having the exponent of *y*.

radix ()

Just returns 10, as this is Decimal, :)

remainder (*x*, *y*)

Returns the remainder from integer division.

The sign of the result, if non-zero, is the same as that of the original dividend.

remainder_near (*x*, *y*)

Returns $x - y * n$, where *n* is the integer nearest the exact value of x / y (if the result is 0 then its sign will be the sign of *x*).

rotate (*x*, *y*)

Returns a rotated copy of *x*, *y* times.

same_quantum (*x*, *y*)

Returns `True` if the two operands have the same exponent.

scaleb (*x*, *y*)

Returns the first operand after adding the second value its exp.

shift (*x*, *y*)

Returns a shifted copy of *x*, *y* times.

sqrt (*x*)

Square root of a non-negative number to context precision.

subtract (*x*, *y*)Return the difference between *x* and *y*.**to_eng_string** (*x*)

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

to_integral_exact (*x*)

Rounds to an integer.

to_sci_string (*x*)

Converts a number to a string using scientific notation.

9.4.4 常数

The constants in this section are only relevant for the C module. They are also included in the pure Python version for compatibility.

	32-bit	64-bit
<code>decimal.MAX_PREC</code>	425000000	999999999999999999
<code>decimal.MAX_EMAX</code>	425000000	999999999999999999
<code>decimal.MIN_EMIN</code>	-425000000	-999999999999999999
<code>decimal.MIN_ETINY</code>	-849999999	-1999999999999999997

`decimal.HAVE_THREADS`

The default value is `True`. If Python is compiled without threads, the C version automatically disables the expensive thread local context machinery. In this case, the value is `False`.

9.4.5 Rounding modes

`decimal.ROUND_CEILING`

Round towards Infinity.

`decimal.ROUND_DOWN`

Round towards zero.

`decimal.ROUND_FLOOR`

Round towards -Infinity.

`decimal.ROUND_HALF_DOWN`

Round to nearest with ties going towards zero.

`decimal.ROUND_HALF_EVEN`

Round to nearest with ties going to nearest even integer.

`decimal.ROUND_HALF_UP`

Round to nearest with ties going away from zero.

`decimal.ROUND_UP`

Round away from zero.

`decimal.ROUND_05UP`

Round away from zero if last digit after rounding towards zero would have been 0 or 5; otherwise round towards zero.

9.4.6 Signals

Signals represent conditions that arise during computation. Each corresponds to one context flag and one context trap enabler.

The context flag is set whenever the condition is encountered. After the computation, flags may be checked for informational purposes (for instance, to determine whether a computation was exact). After checking the flags, be sure to clear all flags before starting the next computation.

If the context's trap enabler is set for the signal, then the condition causes a Python exception to be raised. For example, if the *DivisionByZero* trap is set, then a *DivisionByZero* exception is raised upon encountering the condition.

class `decimal.Clamped`

Altered an exponent to fit representation constraints.

Typically, clamping occurs when an exponent falls outside the context's `Emin` and `Emax` limits. If possible, the exponent is reduced to fit by adding zeros to the coefficient.

class `decimal.DecimalException`

Base class for other signals and a subclass of *ArithmeticError*.

class `decimal.DivisionByZero`

Signals the division of a non-infinite number by zero.

Can occur with division, modulo division, or when raising a number to a negative power. If this signal is not trapped, returns `Infinity` or `-Infinity` with the sign determined by the inputs to the calculation.

class `decimal.Inexact`

Indicates that rounding occurred and the result is not exact.

Signals when non-zero digits were discarded during rounding. The rounded result is returned. The signal flag or trap is used to detect when results are inexact.

class `decimal.InvalidOperation`

An invalid operation was performed.

Indicates that an operation was requested that does not make sense. If not trapped, returns `NaN`. Possible causes include:

```
Infinity - Infinity
0 * Infinity
Infinity / Infinity
x % 0
Infinity % x
sqrt(-x) and x > 0
0 ** 0
x ** (non-integer)
x ** Infinity
```

class `decimal.Overflow`

Numerical overflow.

Indicates the exponent is larger than `Emax` after rounding has occurred. If not trapped, the result depends on the rounding mode, either pulling inward to the largest representable finite number or rounding outward to `Infinity`. In either case, *Inexact* and *Rounded* are also signaled.

class `decimal.Rounded`

Rounding occurred though possibly no information was lost.

Signaled whenever rounding discards digits; even if those digits are zero (such as rounding `5.00` to `5.0`). If not trapped, returns the result unchanged. This signal is used to detect loss of significant digits.

class `decimal.Subnormal`

Exponent was lower than `Emin` prior to rounding.

Occurs when an operation result is subnormal (the exponent is too small). If not trapped, returns the result unchanged.

class `decimal.Underflow`

Numerical underflow with result rounded to zero.

Occurs when a subnormal result is pushed to zero by rounding. *Inexact* and *Subnormal* are also signaled.

class `decimal.FloatOperation`

Enable stricter semantics for mixing floats and Decimals.

If the signal is not trapped (default), mixing floats and Decimals is permitted in the *Decimal* constructor, *create_decimal()* and all comparison operators. Both conversion and comparisons are exact. Any occurrence of a mixed operation is silently recorded by setting *FloatOperation* in the context flags. Explicit conversions with *from_float()* or *create_decimal_from_float()* do not set the flag.

Otherwise (the signal is trapped), only equality comparisons and explicit conversions are silent. All other mixed operations raise *FloatOperation*.

The following table summarizes the hierarchy of signals:

```
exceptions.ArithmeticError(exceptions.Exception)
  DecimalException
    Clamped
    DivisionByZero(DecimalException, exceptions.ZeroDivisionError)
    Inexact
      Overflow(Inexact, Rounded)
      Underflow(Inexact, Rounded, Subnormal)
    InvalidOperation
    Rounded
    Subnormal
    FloatOperation(DecimalException, exceptions.TypeError)
```

9.4.7 Floating Point Notes

Mitigating round-off error with increased precision

The use of decimal floating point eliminates decimal representation error (making it possible to represent `0.1` exactly); however, some operations can still incur round-off error when non-zero digits exceed the fixed precision.

The effects of round-off error can be amplified by the addition or subtraction of nearly offsetting quantities resulting in loss of significance. Knuth provides two instructive examples where rounded floating point arithmetic with insufficient precision causes the breakdown of the associative and distributive properties of addition:

```
# Examples from Seminumerical Algorithms, Section 4.2.2.
>>> from decimal import Decimal, getcontext
>>> getcontext().prec = 8

>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.5111111')
>>> u + (v + w)
Decimal('10')

>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.01')
>>> u * (v+w)
Decimal('0.0060000')
```

The `decimal` module makes it possible to restore the identities by expanding the precision sufficiently to avoid loss of significance:

```
>>> getcontext().prec = 20
>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.51111111')
>>> u + (v + w)
Decimal('9.51111111')
>>>
>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.0060000')
>>> u * (v+w)
Decimal('0.0060000')
```

Special values

The number system for the `decimal` module provides special values including NaN, sNaN, -Infinity, Infinity, and two zeros, +0 and -0.

Infinities can be constructed directly with: `Decimal('Infinity')`. Also, they can arise from dividing by zero when the `DivisionByZero` signal is not trapped. Likewise, when the `Overflow` signal is not trapped, infinity can result from rounding beyond the limits of the largest representable number.

The infinities are signed (affine) and can be used in arithmetic operations where they get treated as very large, indeterminate numbers. For instance, adding a constant to infinity gives another infinite result.

Some operations are indeterminate and return NaN, or if the `InvalidOperation` signal is trapped, raise an exception. For example, `0/0` returns NaN which means “not a number”. This variety of NaN is quiet and, once created, will flow through other computations always resulting in another NaN. This behavior can be useful for a series of computations that occasionally have missing inputs—it allows the calculation to proceed while flagging specific results as invalid.

A variant is sNaN which signals rather than remaining quiet after every operation. This is a useful return value when an invalid result needs to interrupt a calculation for special handling.

The behavior of Python’s comparison operators can be a little surprising where a NaN is involved. A test for equality where one of the operands is a quiet or signaling NaN always returns `False` (even when doing `Decimal('NaN')==Decimal('NaN')`), while a test for inequality always returns `True`. An attempt to compare two Decimals using any of the `<`, `<=`, `>` or `>=` operators will raise the `InvalidOperation` signal if either

operand is a NaN, and return *False* if this signal is not trapped. Note that the General Decimal Arithmetic specification does not specify the behavior of direct comparisons; these rules for comparisons involving a NaN were taken from the IEEE 854 standard (see Table 3 in section 5.7). To ensure strict standards-compliance, use the `compare()` and `compare-signal()` methods instead.

The signed zeros can result from calculations that underflow. They keep the sign that would have resulted if the calculation had been carried out to greater precision. Since their magnitude is zero, both positive and negative zeros are treated as equal and their sign is informational.

In addition to the two signed zeros which are distinct yet equal, there are various representations of zero with differing precisions yet equivalent in value. This takes a bit of getting used to. For an eye accustomed to normalized floating point representations, it is not immediately obvious that the following calculation returns a value equal to zero:

```
>>> 1 / Decimal('Infinity')
Decimal('0E-1000026')
```

9.4.8 Working with threads

The `getcontext()` function accesses a different *Context* object for each thread. Having separate thread contexts means that threads may make changes (such as `getcontext().prec=10`) without interfering with other threads.

Likewise, the `setcontext()` function automatically assigns its target to the current thread.

If `setcontext()` has not been called before `getcontext()`, then `getcontext()` will automatically create a new context for use in the current thread.

The new context is copied from a prototype context called *DefaultContext*. To control the defaults so that each thread will use the same values throughout the application, directly modify the *DefaultContext* object. This should be done *before* any threads are started so that there won't be a race condition between threads calling `getcontext()`. For example:

```
# Set applicationwide defaults for all threads about to be launched
DefaultContext.prec = 12
DefaultContext.rounding = ROUND_DOWN
DefaultContext.traps = ExtendedContext.traps.copy()
DefaultContext.traps[InvalidOperation] = 1
setcontext(DefaultContext)

# Afterwards, the threads can be started
t1.start()
t2.start()
t3.start()
...
```

9.4.9 Recipes

Here are a few recipes that serve as utility functions and that demonstrate ways to work with the *Decimal* class:

```
def moneyfmt(value, places=2, curr='', sep=',', dp='.',
             pos='', neg='-', trailneg=''):
    """Convert Decimal to a money formatted string.

    places:  required number of places after the decimal point
    curr:    optional currency symbol before the sign (may be blank)
    sep:     optional grouping separator (comma, period, space, or blank)
    dp:      decimal point indicator (comma or period)
    pos:     sign of positive number
    neg:     sign of negative number
    trailneg:  trailing sign after positive numbers
    """
```

(下页继续)

(续上页)

```

        only specify as blank when places is zero
pos:      optional sign for positive numbers: '+', space or blank
neg:      optional sign for negative numbers: '-', '(', space or blank
trailneg: optional trailing minus indicator: '-', ')', space or blank

>>> d = Decimal('-1234567.8901')
>>> moneyfmt(d, curr='$')
'-$1,234,567.89'
>>> moneyfmt(d, places=0, sep='.', dp='', neg='', trailneg='-')
'1.234.568-'
>>> moneyfmt(d, curr='$', neg='(', trailneg='')
'($1,234,567.89)'
>>> moneyfmt(Decimal(123456789), sep=' ')
'123 456 789.00'
>>> moneyfmt(Decimal('-0.02'), neg='<', trailneg='>')
'<0.02>'

"""
q = Decimal(10) ** -places      # 2 places --> '0.01'
sign, digits, exp = value.quantize(q).as_tuple()
result = []
digits = list(map(str, digits))
build, next = result.append, digits.pop
if sign:
    build(trailneg)
for i in range(places):
    build(next() if digits else '0')
if places:
    build(dp)
if not digits:
    build('0')
i = 0
while digits:
    build(next())
    i += 1
    if i == 3 and digits:
        i = 0
        build(sep)
build(curr)
build(neg if sign else pos)
return ''.join(reversed(result))

def pi():
    """Compute Pi to the current precision.

    >>> print(pi())
    3.141592653589793238462643383

    """
    getcontext().prec += 2 # extra digits for intermediate steps
    three = Decimal(3)     # substitute "three=3.0" for regular floats
    lasts, t, s, n, na, d, da = 0, three, 3, 1, 0, 0, 24
    while s != lasts:
        lasts = s

getcontext().prec -= 2
return +s

```

9.4.10 Decimal FAQ

Q. It is cumbersome to type `decimal.Decimal('1234.5')`. Is there a way to minimize typing when using the interactive interpreter?

A. Some users abbreviate the constructor to just a single letter:

```

>>> D = decimal.Decimal
>>> D('1.23') + D('3.45')
Decimal('4.68')

```

Q. In a fixed-point application with two decimal places, some inputs have many places and need to be rounded. Others are not supposed to have excess digits and need to be validated. What methods should be used?

A. The `quantize()` method rounds to a fixed number of decimal places. If the *Inexact* trap is set, it is also useful for validation:

```

>>> TWOPLACES = Decimal(10) ** -2           # same as Decimal('0.01')

```

```

>>> # Round to two places
>>> Decimal('3.214').quantize(TWOPLACES)
Decimal('3.21')

```

```

>>> # Validate that a number does not exceed two places
>>> Decimal('3.21').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Decimal('3.21')

```

```

>>> Decimal('3.214').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Traceback (most recent call last):

```

(下页继续)

(续上页)

```
...
Inexact: None
```

Q. Once I have valid two place inputs, how do I maintain that invariant throughout an application?

A. Some operations like addition, subtraction, and multiplication by an integer will automatically preserve fixed point. Others operations, like division and non-integer multiplication, will change the number of decimal places and need to be followed-up with a `quantize()` step:

```
>>> a = Decimal('102.72')           # Initial fixed-point values
>>> b = Decimal('3.17')
>>> a + b                             # Addition preserves fixed-point
Decimal('105.89')
>>> a - b
Decimal('99.55')
>>> a * 42                            # So does integer multiplication
Decimal('4314.24')
>>> (a * b).quantize(TWOPLACES)       # Must quantize non-integer multiplication
Decimal('325.62')
>>> (b / a).quantize(TWOPLACES)       # And quantize division
Decimal('0.03')
```

In developing fixed-point applications, it is convenient to define functions to handle the `quantize()` step:

```
>>> def mul(x, y, fp=TWOPLACES):
...     return (x * y).quantize(fp)
>>> def div(x, y, fp=TWOPLACES):
...     return (x / y).quantize(fp)
```

```
>>> mul(a, b)                         # Automatically preserve fixed-point
Decimal('325.62')
>>> div(b, a)
Decimal('0.03')
```

Q. There are many ways to express the same value. The numbers 200, 200.000, 2E2, and 02E+4 all have the same value at various precisions. Is there a way to transform them to a single recognizable canonical value?

A. The `normalize()` method maps all equivalent values to a single representative:

```
>>> values = map(Decimal, '200 200.000 2E2 .02E+4'.split())
>>> [v.normalize() for v in values]
[Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2')]
```

Q. Some decimal values always print with exponential notation. Is there a way to get a non-exponential representation?

A. For some values, exponential notation is the only way to express the number of significant places in the coefficient. For example, expressing 5.0E+3 as 5000 keeps the value constant but cannot show the original's two-place significance.

If an application does not care about tracking significance, it is easy to remove the exponent and trailing zeroes, losing significance, but keeping the value unchanged:

```
>>> def remove_exponent(d):
...     return d.quantize(Decimal(1)) if d == d.to_integral() else d.normalize()
```

```
>>> remove_exponent(Decimal('5E+3'))
Decimal('5000')
```

Q. Is there a way to convert a regular float to a *Decimal*?

A. Yes, any binary floating point number can be exactly expressed as a *Decimal* though an exact conversion may take more precision than intuition would suggest:

```
>>> Decimal(math.pi)
Decimal('3.141592653589793115997963468544185161590576171875')
```

Q. Within a complex calculation, how can I make sure that I haven't gotten a spurious result because of insufficient precision or rounding anomalies.

A. The decimal module makes it easy to test results. A best practice is to re-run calculations using greater precision and with various rounding modes. Widely differing results indicate insufficient precision, rounding mode issues, ill-conditioned inputs, or a numerically unstable algorithm.

Q. I noticed that context precision is applied to the results of operations but not to the inputs. Is there anything to watch out for when mixing values of different precisions?

A. Yes. The principle is that all values are considered to be exact and so is the arithmetic on those values. Only the results are rounded. The advantage for inputs is that “what you type is what you get”. A disadvantage is that the results can look odd if you forget that the inputs haven't been rounded:

```
>>> getcontext().prec = 3
>>> Decimal('3.104') + Decimal('2.104')
Decimal('5.21')
>>> Decimal('3.104') + Decimal('0.000') + Decimal('2.104')
Decimal('5.20')
```

The solution is either to increase precision or to force rounding of inputs using the unary plus operation:

```
>>> getcontext().prec = 3
>>> +Decimal('1.23456789')      # unary plus triggers rounding
Decimal('1.23')
```

Alternatively, inputs can be rounded upon creation using the *Context.create_decimal()* method:

```
>>> Context(prec=5, rounding=ROUND_DOWN).create_decimal('1.2345678')
Decimal('1.2345')
```

9.5 fractions — 分数

源代码 [Lib/fractions.py](#)

fractions 模块支持分数运算。

分数实例可以由一对整数，一个分数，或者一个字符串构建而成。

```
class fractions.Fraction(numerator=0, denominator=1)
class fractions.Fraction(other_fraction)
class fractions.Fraction(float)
class fractions.Fraction(decimal)
class fractions.Fraction(string)
```

The first version requires that *numerator* and *denominator* are instances of *numbers.Rational* and returns a new *Fraction* instance with value *numerator/denominator*. If *denominator* is 0, it raises

a `ZeroDivisionError`. The second version requires that `other_fraction` is an instance of `numbers.Rational` and returns a `Fraction` instance with the same value. The next two versions accept either a `float` or a `decimal.Decimal` instance, and return a `Fraction` instance with exactly the same value. Note that due to the usual issues with binary floating-point (see [tut-fp-issues](#)), the argument to `Fraction(1.1)` is not exactly equal to `11/10`, and so `Fraction(1.1)` does *not* return `Fraction(11, 10)` as one might expect. (But see the documentation for the `limit_denominator()` method below.) The last version of the constructor expects a string or unicode instance. The usual form for this instance is:

```
[sign] numerator ['/' denominator]
```

where the optional sign may be either '+' or '-' and numerator and denominator (if present) are strings of decimal digits. In addition, any string that represents a finite value and is accepted by the `float` constructor is also accepted by the `Fraction` constructor. In either form the input string may also have leading and/or trailing whitespace. Here are some examples:

```
>>> from fractions import Fraction
>>> Fraction(16, -10)
Fraction(-8, 5)
>>> Fraction(123)
Fraction(123, 1)
>>> Fraction()
Fraction(0, 1)
>>> Fraction('3/7')
Fraction(3, 7)
>>> Fraction('-3/7 ')
Fraction(-3, 7)
>>> Fraction('1.414213 \t\n')
Fraction(1414213, 1000000)
>>> Fraction('-.125')
Fraction(-1, 8)
>>> Fraction('7e-6')
Fraction(7, 1000000)
>>> Fraction(2.25)
Fraction(9, 4)
>>> Fraction(1.1)
Fraction(2476979795053773, 2251799813685248)
>>> from decimal import Decimal
>>> Fraction(Decimal('1.1'))
Fraction(11, 10)
```

The `Fraction` class inherits from the abstract base class `numbers.Rational`, and implements all of the methods and operations from that class. `Fraction` instances are hashable, and should be treated as immutable. In addition, `Fraction` has the following properties and methods:

在 3.2 版更改: The `Fraction` constructor now accepts `float` and `decimal.Decimal` instances.

numerator

最简分数形式的分子。

denominator

最简分数形式的分母。

from_float (flt)

This class method constructs a `Fraction` representing the exact value of `flt`, which must be a `float`. Beware that `Fraction.from_float(0.3)` is not the same value as `Fraction(3, 10)`.

注解: From Python 3.2 onwards, you can also construct a `Fraction` instance directly from a `float`.

from_decimal (*dec*)

This class method constructs a *Fraction* representing the exact value of *dec*, which must be a *decimal.Decimal* instance.

注解: From Python 3.2 onwards, you can also construct a *Fraction* instance directly from a *decimal.Decimal* instance.

limit_denominator (*max_denominator=1000000*)

Finds and returns the closest *Fraction* to *self* that has denominator at most *max_denominator*. This method is useful for finding rational approximations to a given floating-point number:

```
>>> from fractions import Fraction
>>> Fraction('3.1415926535897932').limit_denominator(1000)
Fraction(355, 113)
```

or for recovering a rational number that's represented as a float:

```
>>> from math import pi, cos
>>> Fraction(cos(pi/3))
Fraction(4503599627370497, 9007199254740992)
>>> Fraction(cos(pi/3)).limit_denominator()
Fraction(1, 2)
>>> Fraction(1.1).limit_denominator()
Fraction(11, 10)
```

__floor__ ()

Returns the greatest *int* \leq *self*. This method can also be accessed through the *math.floor()* function:

```
>>> from math import floor
>>> floor(Fraction(355, 113))
3
```

__ceil__ ()

Returns the least *int* \geq *self*. This method can also be accessed through the *math.ceil()* function.

__round__ ()

__round__ (*ndigits*)

The first version returns the nearest *int* to *self*, rounding half to even. The second version rounds *self* to the nearest multiple of *Fraction(1, 10**ndigits)* (logically, if *ndigits* is negative), again rounding half toward even. This method can also be accessed through the *round()* function.

fractions.gcd (*a*, *b*)

返回整数 *a* 和 *b* 的最大公约数。如果 *a* 或 *b* 之一非零，则 *gcd* (*a*, *b*) 的绝对值是能同时整除 *a* 和 *b* 的最大整数。若 *b* 非零，则 *gcd* (*a*, *b*) 与 *b* 同号；否则返回值与 *a* 同号。*gcd* (0, 0) 返回 0。

3.5 版后已移除：由 *math.gcd()* 取代。

参见：

numbers 模块 The abstract base classes making up the numeric tower.

9.6 random — 生成伪随机数

源码： [Lib/random.py](#)

该模块实现了各种分布的伪随机数生成器。

对于整数，从范围中有统一的选择。对于序列，存在随机元素的统一选择、用于生成列表的随机排列的函数、以及用于随机抽样而无需替换的函数。

在实数轴上，有计算均匀、正态（高斯）、对数正态、负指数、伽马和贝塔分布的函数。为了生成角度分布，可以使用 von Mises 分布。

几乎所有模块函数都依赖于基本函数 `random()`，它在半开区间 `[0.0,1.0)` 内均匀生成随机浮点数。Python 使用 Mersenne Twister 作为核心生成器。它产生 53 位精度浮点数，周期为 $2^{19937}-1$ ，其在 C 中的底层实现既快又线程安全。Mersenne Twister 是现存最广泛测试的随机数发生器之一。但是，因为完全确定性，它不适用于所有目的，并且完全不适合加密目的。

这个模块提供的函数实际上是 `random.Random` 类的隐藏实例的绑定方法。你可以实例化自己的 `Random` 类实例以获取不共享状态的生成器。

如果你想使用自己设计的基础生成器，类 `Random` 也可以作为子类：在这种情况下，重载 `random()`、`seed()`、`getstate()` 以及 `setstate()` 方法。可选地，新生成器可以提供 `getrandbits()` 方法——这允许 `randrange()` 在任意大的范围内产生选择。

`random` 模块还提供 `SystemRandom` 类，它使用系统函数 `os.urandom()` 从操作系统提供的源生成随机数。

警告： 不应将此模块的伪随机生成器用于安全目的。有关安全性或加密用途，请参阅 `secrets` 模块。

参见：

M. Matsumoto and T. Nishimura, “Mersenne Twister: A 623-dimensionally equidistributed uniform pseudorandom number generator”, ACM Transactions on Modeling and Computer Simulation Vol. 8, No. 1, January pp.3–30 1998.

[Complementary-Multiply-with-Carry recipe](#) 用于兼容的替代随机数发生器，具有长周期和相对简单的更新操作。

9.6.1 簿记功能

`random.seed(a=None, version=2)`

初始化随机数生成器。

如果 `a` 被省略或为 `None`，则使用当前系统时间。如果操作系统提供随机源，则使用它们而不是系统时间（有关可用性的详细信息，请参阅 `os.urandom()` 函数）。

如果 `a` 是 `int` 类型，则直接使用。

对于版本 2（默认的），`str`、`bytes` 或 `bytearray` 对象转换为 `int` 并使用它的所有位。

对于版本 1（用于从旧版本的 Python 再现随机序列），用于 `str` 和 `bytes` 的算法生成更窄的种子范围。

在 3.2 版更改：已移至版本 2 方案，该方案使用字符串种子中的所有位。

`random.getstate()`

返回捕获生成器当前内部状态的对象。这个对象可以传递给 `setstate()` 来恢复状态。

`random.setstate(state)`

`state` 应该是从之前调用 `getstate()` 获得的，并且 `setstate()` 将生成器的内部状态恢复到 `getstate()` 被调用时的状态。

`random.getrandbits(k)`

返回带有 `k` 位随机的 Python 整数。此方法随 MersenneTwister 生成器一起提供，其他一些生成器也可以将其作为 API 的可选部分提供。如果可用，`getrandbits()` 启用 `randrange()` 来处理任意大范围。

9.6.2 整数用函数

`random.randrange(stop)`

`random.randrange(start, stop[, step])`

从 `range(start, stop, step)` 返回一个随机选择的元素。这相当于 `choice(range(start, stop, step))`，但实际上并没有构建一个 `range` 对象。

位置参数模式匹配 `range()`。不应使用关键字参数，因为该函数可能以意外的方式使用它们。

在 3.2 版更改：`randrange()` 在生成均匀分布的值方面更为复杂。以前它使用了像 `int(random()*n)`“这样的形式，它可以产生稍微不均匀的分布。

`random.randint(a, b)`

返回随机整数 N 满足 $a \leq N \leq b$ 。相当于 `randrange(a, b+1)`。

9.6.3 序列用函数

`random.choice(seq)`

从非空序列 `seq` 返回一个随机元素。如果 `seq` 为空，则引发 `IndexError`。

`random.choices(population, weights=None, *, cum_weights=None, k=1)`

从 `*population*` 中选择替换，返回大小为 `k` 的元素列表。如果 `population` 为空，则引发 `IndexError`。

如果指定了 `weight` 序列，则根据相对权重进行选择。或者，如果给出 `cum_weights` 序列，则根据累积权重（可能使用 `itertools.accumulate()` 计算）进行选择。例如，相对权重 “[10, 5, 30, 5]” 相当于累积权重 “[10, 15, 45, 50]”。在内部，相对权重在进行选择之前会转换为累积权重，因此提供累积权重可以节省工作量。

如果既未指定 `weight` 也未指定 `cum_weights`，则以相等的概率进行选择。如果提供了权重序列，则它必须与 `population` 序列的长度相同。一个 `TypeError` 指定了 `weights` 和 `*cum_weights*`。

`weights` 或 `cum_weights` 可以使用任何与 `random()` 返回的 `float` 值互操作的数值类型（包括整数，浮点数和分数但不包括十进制小数）。

3.6 新版功能。

`random.shuffle(x[, random])`

将序列 `x` 随机打乱位置。

可选参数 `random` 是一个 0 参数函数，在 `[0.0, 1.0)` 中返回随机浮点数；默认情况下，这是函数 `random()`。

要改变一个不可变的序列并返回一个新的打乱列表，请使用 `“sample(x, k=len(x))”`。

请注意，即使对于小的 `len(x)`，`x` 的排列总数也可以快速增长，大于大多数随机数生成器的周期。这意味着长序列的大多数排列永远不会产生。例如，长度为 2080 的序列是可以在 Mersenne Twister 随机数生成器的周期内拟合的最大序列。

`random.sample(population, k)`

返回从总体序列或集合中选择的唯一元素的 `k` 长度列表。用于无重复的随机抽样。

返回包含来自总体的元素的新列表，同时保持原始总体不变。结果列表按选择顺序排列，因此所有子切片也将是有效的随机样本。这允许抽奖获奖者（样本）被划分为大奖和第二名获胜者（子切片）。

总体成员不必是 `hashable` 或 `unique`。如果总体包含重复，则每次出现都是样本中可能的选择。

要从一系列整数中选择样本，请使用 `range()` 对象作为参数。对于从大量人群中采样，这种方法特别快速且节省空间：`sample(range(10000000), k=60)`。

如果样本大小大于总体大小，则引发 `ValueError`。

9.6.4 实值分布

以下函数生成特定的实值分布。如常用数学实践中所使用的那样，函数参数以分布方程中的相应变量命名；大多数这些方程都可以在任何统计学教材中找到。

`random.random()`

返回 $[0.0, 1.0)$ 范围内的下一个随机浮点数。

`random.uniform(a, b)`

返回一个随机浮点数 N ，当 $a \leq b$ 时 $a \leq N \leq b$ ，当 $b < a$ 时 $b \leq N \leq a$ 。

取决于等式 $a + (b-a) * \text{random}()$ 中的浮点舍入，终点 b 可以包括或不包括在该范围内。

`random.triangular(low, high, mode)`

返回一个随机浮点数 N ，使得 $low \leq N \leq high$ 并在这些边界之间使用指定的 *mode*。*low* 和 *high* 边界默认为零和一。*mode* 参数默认为边界之间的中点，给出对称分布。

`random.betavariate(alpha, beta)`

Beta 分布。参数的条件是 $\alpha > 0$ 和 $\beta > 0$ 。返回值的范围介于 0 和 1 之间。

`random.expovariate(lambd)`

指数分布。*lambd* 是 1.0 除以所需的平均值，它应该非零的。（该参数本应命名为“lambda”，但这是 Python 中的保留字。）如果 *lambd* 为正，则返回值的范围为 0 到正无穷大；如果 *lambd* 为负，则返回值从负无穷大到 0。

`random.gammavariate(alpha, beta)`

Gamma 分布。（不是 gamma 函数！）参数的条件是 $\alpha > 0$ 和 $\beta > 0$ 。

概率分布函数是：

$$\text{pdf}(x) = \frac{x^{(\alpha - 1)} * \text{math.exp}(-x / \beta)}{\text{math.gamma}(\alpha) * \beta^{**} \alpha}$$

`random.gauss(mu, sigma)`

高斯分布。*mu* 是平均值，*sigma* 是标准差。这比下面定义的 `normalvariate()` 函数略快。

`random.lognormvariate(mu, sigma)`

对数正态分布。如果你采用这个分布的自然对数，你将得到一个正态分布，平均值为 *mu* 和标准差为 *sigma*。*mu* 可以是任何值，*sigma* 必须大于零。

`random.normalvariate(mu, sigma)`

正态分布。*mu* 是平均值，*sigma* 是标准差。

`random.vonmisesvariate(mu, kappa)`

mu 是平均角度，以弧度表示，介于 0 和 2π 之间，*kappa* 是浓度参数，必须大于或等于零。如果 *kappa* 等于零，则该分布在 0 到 2π 的范围内减小到均匀的随机角度。

`random.paretovariate(alpha)`

帕累托分布。*alpha* 是形状参数。

`random.weibullvariate(alpha, beta)`

威布尔分布。*alpha* 是比例参数，*beta* 是形状参数。

9.6.5 替代生成器

`class random.SystemRandom([seed])`

使用 `os.urandom()` 函数的类，用从操作系统提供的源生成随机数。这并非适用于所有系统。也不依赖于软件状态，序列不可重现。因此，`seed()` 方法没有效果而被忽略。`getstate()` 和 `setstate()` 方法如果被调用则引发 `NotImplementedError`。

9.6.6 关于再现性的说明

有时能够重现伪随机数生成器给出的序列是有用的。通过重新使用种子值，只要多个线程没有运行，相同的序列就可以在两次不同运行之间重现。

大多数随机模块的算法和种子函数都会在 Python 版本中发生变化，但保证两个方面不会改变：

- 如果添加了新的播种方法，则将提供向后兼容的播种机。
- 当兼容的播种机被赋予相同的种子时，生成器的 `random()` 方法将继续产生相同的序列。

9.6.7 例子和配方

基本示例:

```
>>> random()                                # Random float:  0.0 <= x < 1.0
0.374444887175646646

>>> uniform(2.5, 10.0)                      # Random float:  2.5 <= x < 10.0
3.1800146073117523

>>> expovariate(1 / 5)                      # Interval between arrivals averaging 5.
↪seconds
5.148957571865031

>>> randrange(10)                          # Integer from 0 to 9 inclusive
7

>>> randrange(0, 101, 2)                    # Even integer from 0 to 100 inclusive
26

>>> choice(['win', 'lose', 'draw'])         # Single random element from a sequence
'draw'

>>> deck = 'ace two three four'.split()
>>> shuffle(deck)                          # Shuffle a list
>>> deck
['four', 'two', 'ace', 'three']

>>> sample([10, 20, 30, 40, 50], k=4)        # Four samples without replacement
[40, 10, 50, 30]
```

模拟:

```
>>> # Six roulette wheel spins (weighted sampling with replacement)
>>> choices(['red', 'black', 'green'], [18, 18, 2], k=6)
['red', 'green', 'black', 'black', 'red', 'black']

>>> # Deal 20 cards without replacement from a deck of 52 playing cards
>>> # and determine the proportion of cards with a ten-value
>>> # (a ten, jack, queen, or king).
>>> deck = collections.Counter(tens=16, low_cards=36)
>>> seen = sample(list(deck.elements()), k=20)
>>> seen.count('tens') / 20
0.15

>>> # Estimate the probability of getting 5 or more heads from 7 spins
```

(下页继续)

(续上页)

```
>>> # of a biased coin that settles on heads 60% of the time.
>>> trial = lambda: choices('HT', cum_weights=(0.60, 1.00), k=7).count('H') >= 5
>>> sum(trial() for i in range(10000)) / 10000
0.4169

>>> # Probability of the median of 5 samples being in middle two quartiles
>>> trial = lambda: 2500 <= sorted(choices(range(10000), k=5))[2] < 7500
>>> sum(trial() for i in range(10000)) / 10000
0.7958
```

statistical bootstrapping 使用重采样和替换来估计大小为五的样本的均值的置信区间的示例:

```
# http://statistics.about.com/od/Applications/a/Example-Of-Bootstrapping.htm
from statistics import mean
from random import choices

data = 1, 2, 4, 4, 10
means = sorted(mean(choices(data, k=5)) for i in range(20))
print(f'The sample mean of {mean(data):.1f} has a 90% confidence '
      f'interval from {means[1]:.1f} to {means[-2]:.1f}')
```

使用 重新采样排列测试 来确定统计学显著性或者使用 p-值 来观察药物与安慰剂的作用之间差异的示例:

```
# Example from "Statistics is Easy" by Dennis Shasha and Manda Wilson
from statistics import mean
from random import shuffle

drug = [54, 73, 53, 70, 73, 68, 52, 65, 65]
placebo = [54, 51, 58, 44, 55, 52, 42, 47, 58, 46]
observed_diff = mean(drug) - mean(placebo)

n = 10000
count = 0
combined = drug + placebo
for i in range(n):
    shuffle(combined)
    new_diff = mean(combined[:len(drug)]) - mean(combined[len(drug):])
    count += (new_diff >= observed_diff)

print(f'{n} label reshufflings produced only {count} instances with a difference')
print(f'at least as extreme as the observed difference of {observed_diff:.1f}.')
print(f'The one-sided p-value of {count / n:.4f} leads us to reject the null')
print(f'hypothesis that there is no difference between the drug and the placebo.')
```

模拟单个服务器队列中的到达时间和服务交付:

```
from random import expovariate, gauss
from statistics import mean, median, stdev

average_arrival_interval = 5.6
average_service_time = 5.0
stdev_service_time = 0.5

num_waiting = 0
arrivals = []
starts = []
```

(下页继续)

(续上页)

```
arrival = service_end = 0.0
for i in range(20000):
    if arrival <= service_end:
        num_waiting += 1
        arrival += expovariate(1.0 / average_arrival_interval)
        arrivals.append(arrival)
    else:
        num_waiting -= 1
        service_start = service_end if num_waiting else arrival
        service_time = gauss(average_service_time, stdev_service_time)
        service_end = service_start + service_time
        starts.append(service_start)

waits = [start - arrival for arrival, start in zip(arrivals, starts)]
print(f'Mean wait: {mean(waits):.1f}. Stdev wait: {stdev(waits):.1f}.')
print(f'Median wait: {median(waits):.1f}. Max wait: {max(waits):.1f}.')
```

9.7 statistics —Mathematical statistics functions

3.4 新版功能.

Source code: [Lib/statistics.py](#)

This module provides functions for calculating mathematical statistics of numeric (Real-valued) data.

注解: Unless explicitly noted otherwise, these functions support *int*, *float*, *decimal.Decimal* and *fractions.Fraction*. Behaviour with other types (whether in the numeric tower or not) is currently unsupported. Mixed types are also undefined and implementation-dependent. If your input data consists of mixed types, you may be able to use *map()* to ensure a consistent result, e.g. *map(float, input_data)*.

9.7.1 Averages and measures of central location

These functions calculate an average or typical value from a population or sample.

<code>mean()</code>	Arithmetic mean (“average”) of data.
<code>harmonic_mean()</code>	Harmonic mean of data.
<code>median()</code>	Median (middle value) of data.
<code>median_low()</code>	Low median of data.
<code>median_high()</code>	High median of data.
<code>median_grouped()</code>	Median, or 50th percentile, of grouped data.
<code>mode()</code>	Mode (most common value) of discrete data.

9.7.2 Measures of spread

These functions calculate a measure of how much the population or sample tends to deviate from the typical or average values.

<code>pstdev()</code>	Population standard deviation of data.
<code>pvariance()</code>	Population variance of data.
<code>stdev()</code>	Sample standard deviation of data.
<code>variance()</code>	Sample variance of data.

9.7.3 Function details

Note: The functions do not require the data given to them to be sorted. However, for reading convenience, most of the examples show sorted sequences.

`statistics.mean(data)`

Return the sample arithmetic mean of *data* which can be a sequence or iterator.

The arithmetic mean is the sum of the data divided by the number of data points. It is commonly called “the average”, although it is only one of many different mathematical averages. It is a measure of the central location of the data.

If *data* is empty, `StatisticsError` will be raised.

Some examples of use:

```
>>> mean([1, 2, 3, 4, 4])
2.8
>>> mean([-1.0, 2.5, 3.25, 5.75])
2.625

>>> from fractions import Fraction as F
>>> mean([F(3, 7), F(1, 21), F(5, 3), F(1, 3)])
Fraction(13, 21)

>>> from decimal import Decimal as D
>>> mean([D("0.5"), D("0.75"), D("0.625"), D("0.375")])
Decimal('0.5625')
```

注解： The mean is strongly affected by outliers and is not a robust estimator for central location: the mean is not necessarily a typical example of the data points. For more robust, although less efficient, measures of central location, see `median()` and `mode()`. (In this case, “efficient” refers to statistical efficiency rather than computational efficiency.)

The sample mean gives an unbiased estimate of the true population mean, which means that, taken on average over all the possible samples, `mean(sample)` converges on the true mean of the entire population. If *data* represents the entire population rather than a sample, then `mean(data)` is equivalent to calculating the true population mean μ .

`statistics.harmonic_mean(data)`

Return the harmonic mean of *data*, a sequence or iterator of real-valued numbers.

The harmonic mean, sometimes called the subcontrary mean, is the reciprocal of the arithmetic `mean()` of the reciprocals of the data. For example, the harmonic mean of three values *a*, *b* and *c* will be equivalent to $3 / (1/a + 1/b + 1/c)$.

The harmonic mean is a type of average, a measure of the central location of the data. It is often appropriate when averaging quantities which are rates or ratios, for example speeds. For example:

Suppose an investor purchases an equal value of shares in each of three companies, with P/E (price/earning) ratios of 2.5, 3 and 10. What is the average P/E ratio for the investor's portfolio?

```
>>> harmonic_mean([2.5, 3, 10]) # For an equal investment portfolio.
3.6
```

Using the arithmetic mean would give an average of about 5.167, which is too high.

`StatisticsError` is raised if *data* is empty, or any element is less than zero.

3.6 新版功能.

`statistics.median(data)`

Return the median (middle value) of numeric data, using the common “mean of middle two” method. If *data* is empty, `StatisticsError` is raised. *data* can be a sequence or iterator.

The median is a robust measure of central location, and is less affected by the presence of outliers in your data. When the number of data points is odd, the middle data point is returned:

```
>>> median([1, 3, 5])
3
```

When the number of data points is even, the median is interpolated by taking the average of the two middle values:

```
>>> median([1, 3, 5, 7])
4.0
```

This is suited for when your data is discrete, and you don't mind that the median may not be an actual data point.

If your data is ordinal (supports order operations) but not numeric (doesn't support addition), you should use `median_low()` or `median_high()` instead.

参见:

`median_low()`, `median_high()`, `median_grouped()`

`statistics.median_low(data)`

Return the low median of numeric data. If *data* is empty, `StatisticsError` is raised. *data* can be a sequence or iterator.

The low median is always a member of the data set. When the number of data points is odd, the middle value is returned. When it is even, the smaller of the two middle values is returned.

```
>>> median_low([1, 3, 5])
3
>>> median_low([1, 3, 5, 7])
3
```

Use the low median when your data are discrete and you prefer the median to be an actual data point rather than interpolated.

`statistics.median_high(data)`

Return the high median of data. If *data* is empty, *StatisticsError* is raised. *data* can be a sequence or iterator.

The high median is always a member of the data set. When the number of data points is odd, the middle value is returned. When it is even, the larger of the two middle values is returned.

```
>>> median_high([1, 3, 5])
3
>>> median_high([1, 3, 5, 7])
5
```

Use the high median when your data are discrete and you prefer the median to be an actual data point rather than interpolated.

`statistics.median_grouped(data, interval=1)`

Return the median of grouped continuous data, calculated as the 50th percentile, using interpolation. If *data* is empty, *StatisticsError* is raised. *data* can be a sequence or iterator.

```
>>> median_grouped([52, 52, 53, 54])
52.5
```

In the following example, the data are rounded, so that each value represents the midpoint of data classes, e.g. 1 is the midpoint of the class 0.5–1.5, 2 is the midpoint of 1.5–2.5, 3 is the midpoint of 2.5–3.5, etc. With the data given, the middle value falls somewhere in the class 3.5–4.5, and interpolation is used to estimate it:

```
>>> median_grouped([1, 2, 2, 3, 4, 4, 4, 4, 4, 5])
3.7
```

Optional argument *interval* represents the class interval, and defaults to 1. Changing the class interval naturally will change the interpolation:

```
>>> median_grouped([1, 3, 3, 5, 7], interval=1)
3.25
>>> median_grouped([1, 3, 3, 5, 7], interval=2)
3.5
```

This function does not check whether the data points are at least *interval* apart.

CPython implementation detail: Under some circumstances, *median_grouped()* may coerce data points to floats. This behaviour is likely to change in the future.

参见:

- “Statistics for the Behavioral Sciences” , Frederick J Gravetter and Larry B Wallnau (8th Edition).
- Calculating the [median](#).
- The [SSMEDIAN](#) function in the Gnome Gnumeric spreadsheet, including [this discussion](#).

`statistics.mode(data)`

Return the most common data point from discrete or nominal *data*. The mode (when it exists) is the most typical value, and is a robust measure of central location.

If *data* is empty, or if there is not exactly one most common value, `StatisticsError` is raised.

mode assumes discrete data, and returns a single value. This is the standard treatment of the mode as commonly taught in schools:

```
>>> mode([1, 1, 2, 3, 3, 3, 3, 4])
3
```

The mode is unique in that it is the only statistic which also applies to nominal (non-numeric) data:

```
>>> mode(["red", "blue", "blue", "red", "green", "red", "red"])
'red'
```

`statistics.pstdev(data, mu=None)`

Return the population standard deviation (the square root of the population variance). See `pvariance()` for arguments and other details.

```
>>> pstdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
0.986893273527251
```

`statistics.pvariance(data, mu=None)`

Return the population variance of *data*, a non-empty iterable of real-valued numbers. Variance, or second moment about the mean, is a measure of the variability (spread or dispersion) of data. A large variance indicates that the data is spread out; a small variance indicates it is clustered closely around the mean.

If the optional second argument *mu* is given, it should be the mean of *data*. If it is missing or `None` (the default), the mean is automatically calculated.

Use this function to calculate the variance from the entire population. To estimate the variance from a sample, the `variance()` function is usually a better choice.

Raises `StatisticsError` if *data* is empty.

示例:

```
>>> data = [0.0, 0.25, 0.25, 1.25, 1.5, 1.75, 2.75, 3.25]
>>> pvariance(data)
1.25
```

If you have already calculated the mean of your data, you can pass it as the optional second argument *mu* to avoid recalculation:

```
>>> mu = mean(data)
>>> pvariance(data, mu)
1.25
```

This function does not attempt to verify that you have passed the actual mean as *mu*. Using arbitrary values for *mu* may lead to invalid or impossible results.

Decimals and Fractions are supported:

```
>>> from decimal import Decimal as D
>>> pvariance([D("27.5"), D("30.25"), D("30.25"), D("34.5"), D("41.75")])
Decimal('24.815')
```

(下页继续)

(续上页)

```
>>> from fractions import Fraction as F
>>> pvariance([F(1, 4), F(5, 4), F(1, 2)])
Fraction(13, 72)
```

注解： When called with the entire population, this gives the population variance σ^2 . When called on a sample instead, this is the biased sample variance s^2 , also known as variance with N degrees of freedom.

If you somehow know the true population mean μ , you may use this function to calculate the variance of a sample, giving the known population mean as the second argument. Provided the data points are representative (e.g. independent and identically distributed), the result will be an unbiased estimate of the population variance.

`statistics.stdev(data, xbar=None)`

Return the sample standard deviation (the square root of the sample variance). See `variance()` for arguments and other details.

```
>>> stdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
1.0810874155219827
```

`statistics.variance(data, xbar=None)`

Return the sample variance of *data*, an iterable of at least two real-valued numbers. Variance, or second moment about the mean, is a measure of the variability (spread or dispersion) of data. A large variance indicates that the data is spread out; a small variance indicates it is clustered closely around the mean.

If the optional second argument *xbar* is given, it should be the mean of *data*. If it is missing or `None` (the default), the mean is automatically calculated.

Use this function when your data is a sample from a population. To calculate the variance from the entire population, see `pvariance()`.

Raises `StatisticsError` if *data* has fewer than two values.

示例：

```
>>> data = [2.75, 1.75, 1.25, 0.25, 0.5, 1.25, 3.5]
>>> variance(data)
1.3720238095238095
```

If you have already calculated the mean of your data, you can pass it as the optional second argument *xbar* to avoid recalculation:

```
>>> m = mean(data)
>>> variance(data, m)
1.3720238095238095
```

This function does not attempt to verify that you have passed the actual mean as *xbar*. Using arbitrary values for *xbar* can lead to invalid or impossible results.

Decimal and Fraction values are supported:

```
>>> from decimal import Decimal as D
>>> variance([D("27.5"), D("30.25"), D("30.25"), D("34.5"), D("41.75")])
Decimal('31.01875')

>>> from fractions import Fraction as F
>>> variance([F(1, 6), F(1, 2), F(5, 3)])
Fraction(67, 108)
```

注解: This is the sample variance s^2 with Bessel's correction, also known as variance with N-1 degrees of freedom. Provided that the data points are representative (e.g. independent and identically distributed), the result should be an unbiased estimate of the true population variance.

If you somehow know the actual population mean μ you should pass it to the `pvariance()` function as the *mu* parameter to get the variance of a sample.

9.7.4 异常

A single exception is defined:

exception `statistics.StatisticsError`

Subclass of `ValueError` for statistics-related exceptions.

本章里描述的模块提供了函数和类，以支持函数式编程风格和在可调用对象上的通用操作。

本章对下列模块进行说明：

10.1 `itertools` — 为高效循环而创建迭代器的函数

本模块实现一系列 *iterator*，这些迭代器受到 APL，Haskell 和 SML 的启发。为了适用于 Python，它们都被重新写过。

本模块标准化了一个快速、高效利用内存的核心工具集，这些工具本身或组合都很有用。它们一起形成了“迭代器代数”，这使得在纯 Python 中有可能创建简洁又高效的专用工具。

例如，SML 有一个制表工具： `tabulate(f)`，它可产生一个序列 `f(0)`， `f(1)`， ...。在 Python 中可以组合 `map()` 和 `count()` 实现： `map(f, count())`。

这些内置工具同时也能很好地与 *operator* 模块中的高效函数配合使用。例如，我们可以将两个向量的点积映射到乘法运算符： `sum(map(operator.mul, vector1, vector2))`。

无穷迭代器：

迭代器	实参	结果	示例
<code>count()</code>	start, [step]	start, start+step, start+2*step, ...	<code>count(10) --> 10 11 12 13 14 ...</code>
<code>cycle()</code>	p	p0, p1, ...,plast, p0, p1, ...	<code>cycle('ABCD') --> A B C D A B C D ...</code>
<code>repeat()</code>	elem [,n]	elem, elem, elem, ... 重复无限次或 n 次	<code>repeat(10, 3) --> 10 10 10</code>

根据最短输入序列长度停止的迭代器：

迭代器	实参	结果	示例
<code>accumulate()</code>	<code>p [,func]</code>	<code>p0, p0+p1, p0+p1+p2, ...</code>	<code>accumulate([1,2,3,4,5]) --> 1 3 6 10 15</code>
<code>chain()</code>	<code>p, q, ...</code>	<code>p0, p1, ...plast, q0, q1, ...</code>	<code>chain('ABC', 'DEF') --> A B C D E F</code>
<code>chain.from_iterable()</code>	iterable	<code>p0, p1, ...plast, q0, q1, ...</code>	<code>chain.from_iterable(['ABC', 'DEF']) --> A B C D E F</code>
<code>compress()</code>	<code>data, selectors</code>	<code>(d[0] if s[0]), (d[1] if s[1]), ...</code>	<code>compress('ABCDEF', [1,0,1,0,1,1]) --> A C E F</code>
<code>dropwhile()</code>	<code>pred, seq</code>	<code>seq[n], seq[n+1], ...</code> 从 <code>pred</code> 首次真值测试失败开始	<code>dropwhile(lambda x: x<5, [1,4,6,4,1]) --> 6 4 1</code>
<code>filterfalse()</code>	<code>pred, seq</code>	<code>seq</code> 中 <code>pred(x)</code> 为假值的元素, <code>x</code> 是 <code>seq</code> 中的元素。	<code>filterfalse(lambda x: x%2, range(10)) --> 0 2 4 6 8</code>
<code>groupby()</code>	iterable[, key]	根据 <code>key(v)</code> 值分组的迭代器	
<code>islice()</code>	<code>seq, [start,] stop [, step]</code>	<code>seq[start:stop:step]</code> 中的元素	<code>islice('ABCDEFG', 2, None) --> C D E F G</code>
<code>starmap()</code>	<code>func, seq</code>	<code>func(*seq[0]), func(*seq[1]), ...</code>	<code>starmap(pow, [(2,5), (3,2), (10,3)]) --> 32 9 1000</code>
<code>takewhile()</code>	<code>pred, seq</code>	<code>seq[0], seq[1], ...</code> , 直到 <code>pred</code> 真值测试失败	<code>takewhile(lambda x: x<5, [1,4,6,4,1]) --> 1 4</code>
<code>tee()</code>	<code>it, n</code>	<code>it1, it2, ...itn</code> 将一个迭代器拆分为 <code>n</code> 个迭代器	
<code>zip_longest()</code>	<code>p, q, ...</code>	<code>(p[0], q[0]), (p[1], q[1]), ...</code>	<code>zip_longest('ABCD', 'xy', fillvalue='-') --> Ax By C- D-</code>

排列组合迭代器:

迭代器	实参	结果
<code>product()</code>	<code>p, q, ...[repeat=1]</code>	笛卡尔积, 相当于嵌套的 <code>for</code> 循环
<code>permutations()</code>	<code>p[, r]</code>	长度 <code>r</code> 元组, 所有可能的排列, 无重复元素
<code>combinations()</code>	<code>p, r</code>	长度 <code>r</code> 元组, 有序, 无重复元素
<code>combinations_with_replacement()</code>	<code>p, r</code>	长度 <code>r</code> 元组, 有序, 元素可重复
<code>product('ABCD', repeat=2)</code>		AA AB AC AD BA BB BC BD CA CB CC CD DA DB DC DD
<code>permutations('ABCD', 2)</code>		AB AC AD BA BC BD CA CB CD DA DB DC
<code>combinations('ABCD', 2)</code>		AB AC AD BC BD CD
<code>combinations_with_replacement('ABCD', 2)</code>		AA AB AC AD BB BC BD CC CD DD

10.1.1 Itertool 函数

下列模块函数均创建并返回迭代器。有些迭代器不限制输出流长度, 所以它们只应在能截断输出流的函数或循环中使用。

`itertools.accumulate(iterable[, func])`

创建一个迭代器, 返回累加和或其他二元函数的累加结果 (通过可选参数 `func` 指定)。如果提供了 `func`, 它应是 2 个参数的函数。输入 `iterable` 元素类型应是 `func` 能支持的任意类型。(例如, 对于默认

法操作，元素可以是任一支持加法的类型，包括`Decimal` 或 `Fraction`)。如果可迭代对象的输入为空，输出也为空。

大致相当于：

```
def accumulate(iterable, func=operator.add):
    'Return running totals'
    # accumulate([1,2,3,4,5]) --> 1 3 6 10 15
    # accumulate([1,2,3,4,5], operator.mul) --> 1 2 6 24 120
    it = iter(iterable)
    try:
        total = next(it)
    except StopIteration:
        return
    yield total
    for element in it:
        total = func(total, element)
        yield total
```

`func` 参数有几种用法。它可以被设为`min()` 最终得到一个最小值，或者设为`max()` 最终得到一个最大值，或设为`operator.mul()` 最终得到一个乘积。摊销表可通过累加利息和支付款项得到。给 `iterable` 设置初始值并只将参数 `func` 设为累加总数可以对一阶 递归关系 建模。

```
>>> data = [3, 4, 6, 2, 1, 9, 0, 7, 5, 8]
>>> list(accumulate(data, operator.mul))      # running product
[3, 12, 72, 144, 144, 1296, 0, 0, 0, 0]
>>> list(accumulate(data, max))              # running maximum
[3, 4, 6, 6, 6, 9, 9, 9, 9, 9]

# Amortize a 5% loan of 1000 with 4 annual payments of 90
>>> cashflows = [1000, -90, -90, -90, -90]
>>> list(accumulate(cashflows, lambda bal, pmt: bal*1.05 + pmt))
[1000, 960.0, 918.0, 873.9000000000001, 827.5950000000001]

# Chaotic recurrence relation https://en.wikipedia.org/wiki/Logistic_map
>>> logistic_map = lambda x, _: r * x * (1 - x)
>>> r = 3.8
>>> x0 = 0.4
>>> inputs = repeat(x0, 36)      # only the initial value is used
>>> [format(x, '.2f') for x in accumulate(inputs, logistic_map)]
['0.40', '0.91', '0.30', '0.81', '0.60', '0.92', '0.29', '0.79', '0.63',
 '0.88', '0.39', '0.90', '0.33', '0.84', '0.52', '0.95', '0.18', '0.57',
 '0.93', '0.25', '0.71', '0.79', '0.63', '0.88', '0.39', '0.91', '0.32',
 '0.83', '0.54', '0.95', '0.20', '0.60', '0.91', '0.30', '0.80', '0.60']
```

参考一个类似函数`functools.reduce()`，它只返回一个最终累积值。

3.2 新版功能.

在 3.3 版更改: 增加可选参数 `func`。

`itertools.chain(*iterables)`

创建一个迭代器，它首先返回第一个可迭代对象中所有元素，接着返回下一个可迭代对象中所有元素，直到耗尽所有可迭代对象中的元素。可将多个序列处理为单个序列。大致相当于：

```
def chain(*iterables):
    # chain('ABC', 'DEF') --> A B C D E F
    for it in iterables:
```

(下页继续)

(续上页)

```

for element in it:
    yield element

```

classmethod `chain.from_iterable(iterable)`

构建类似`chain()` 迭代器的另一个选择。从一个单独的可迭代参数中得到链式输入，该参数是延迟计算的。大致相当于：

```

def from_iterable(iterables):
    # chain.from_iterable(['ABC', 'DEF']) --> A B C D E F
    for it in iterables:
        for element in it:
            yield element

```

itertools.combinations(iterable, r)

返回由输入 *iterable* 中元素组成长度为 *r* 的子序列。

组合按照字典序返回。所以如果输入 *iterable* 是有序的，生成的组合元组也是有序的。

即使元素的值相同，不同位置的元素也被认为是不同的。如果元素各自不同，那么每个组合中没有重复元素。

大致相当于：

```

def combinations(iterable, r):
    # combinations('ABCD', 2) --> AB AC AD BC BD CD
    # combinations(range(4), 3) --> 012 013 023 123
    pool = tuple(iterable)
    n = len(pool)
    if r > n:
        return
    indices = list(range(r))
    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != i + n - r:
                break
        else:
            return
        indices[i] += 1
        for j in range(i+1, r):
            indices[j] = indices[j-1] + 1
        yield tuple(pool[i] for i in indices)

```

`combinations()` 的代码可被改写为 `permutations()` 过滤后的子序列，（相对于元素在输入中的位置）元素不是有序的。

```

def combinations(iterable, r):
    pool = tuple(iterable)
    n = len(pool)
    for indices in permutations(range(n), r):
        if sorted(indices) == list(indices):
            yield tuple(pool[i] for i in indices)

```

当 $0 \leq r \leq n$ 时，返回项的个数是 $n! / r! / (n-r)!$ ；当 $r > n$ 时，返回项个数为 0。

itertools.combinations_with_replacement(iterable, r)

返回由输入 *iterable* 中元素组成的长度为 *r* 的子序列，允许每个元素可重复出现。

组合按照字典序返回。所以如果输入 *iterable* 是有序的，生成的组合元组也是有序的。

不同位置的元素是不同的，即使它们的值相同。因此如果输入中的元素都是不同的话，返回的组合中元素也都会不同。

大致相当于：

```
def combinations_with_replacement(iterable, r):
    # combinations_with_replacement('ABC', 2) --> AA AB AC BB BC CC
    pool = tuple(iterable)
    n = len(pool)
    if not n and r:
        return
    indices = [0] * r
    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != n - 1:
                break
        else:
            return
        indices[i:] = [indices[i] + 1] * (r - i)
        yield tuple(pool[i] for i in indices)
```

`combinations_with_replacement()` 的代码可被改写为 `production()` 过滤后的子序列，（相对于元素在输入中的位置）元素不是有序的。

```
def combinations_with_replacement(iterable, r):
    pool = tuple(iterable)
    n = len(pool)
    for indices in product(range(n), repeat=r):
        if sorted(indices) == list(indices):
            yield tuple(pool[i] for i in indices)
```

当 $n > 0$ 时，返回项个数为 $(n+r-1)! / r! / (n-1)!$ 。

3.1 新版功能.

`itertools.compress(data, selectors)`

创建一个迭代器，它返回 `data` 中经 `selectors` 真值测试为 `True` 的元素。迭代器在两者较短的长度处停止。大致相当于：

```
def compress(data, selectors):
    # compress('ABCDEF', [1,0,1,0,1,1]) --> A C E F
    return (d for d, s in zip(data, selectors) if s)
```

3.1 新版功能.

`itertools.count(start=0, step=1)`

创建一个迭代器，它从 `start` 值开始，返回均匀间隔的值。常用于 `map()` 中的实参来生成连续的数据点。此外，还用于 `zip()` 来添加序列号。大致相当于：

```
def count(start=0, step=1):
    # count(10) --> 10 11 12 13 14 ...
    # count(2.5, 0.5) -> 2.5 3.0 3.5 ...
    n = start
    while True:
        yield n
        n += step
```

当对浮点数计数时，替换为乘法代码有时精度会更好，例如：`(start + step * i for i in count())`。

在 3.1 版更改: 增加参数 *step* , 允许非整型。

`itertools.cycle(iterable)`

创建一个迭代器, 返回 *iterable* 中所有元素并保存一个副本。当取完 *iterable* 中所有元素, 返回副本中的所有元素。无限重复。大致相当于:

```
def cycle(iterable):
    # cycle('ABCD') --> A B C D A B C D A B C D ...
    saved = []
    for element in iterable:
        yield element
        saved.append(element)
    while saved:
        for element in saved:
            yield element
```

注意, 该函数可能需要相当大的辅助空间 (取决于 *iterable* 的长度)。

`itertools.dropwhile(predicate, iterable)`

创建一个迭代器, 如果 *predicate* 为 `true`, 迭代器丢弃这些元素, 然后返回其他元素。注意, 迭代器在 *predicate* 首次为 `false` 之前不会产生任何输出, 所以可能需要一定长度的启动时间。大致相当于:

```
def dropwhile(predicate, iterable):
    # dropwhile(lambda x: x<5, [1,4,6,4,1]) --> 6 4 1
    iterable = iter(iterable)
    for x in iterable:
        if not predicate(x):
            yield x
            break
    for x in iterable:
        yield x
```

`itertools.filterfalse(predicate, iterable)`

创建一个迭代器, 只返回 *iterable* 中 *predicate* 为 `False` 的元素。如果 *predicate* 是 `None`, 返回真值测试为 `false` 的元素。大致相当于:

```
def filterfalse(predicate, iterable):
    # filterfalse(lambda x: x%2, range(10)) --> 0 2 4 6 8
    if predicate is None:
        predicate = bool
    for x in iterable:
        if not predicate(x):
            yield x
```

`itertools.groupby(iterable, key=None)`

创建一个迭代器, 返回 *iterable* 中连续的键和组。*key* 是一个计算元素键值函数。如果未指定或为 `None`, *key* 缺省为恒等函数 (identity function), 返回元素不变。一般来说, *iterable* 需用同一个键值函数预先排序。

`groupby()` 操作类似于 Unix 中的 `uniq`。当每次 *key* 函数产生的键值改变时, 迭代器会分组或生成一个新组 (这就是为什么通常需要使用同一个键值函数先对数据进行排序)。这种行为与 SQL 的 `GROUP BY` 操作不同, SQL 的操作会忽略输入的顺序将相同键值的元素分在同组中。

返回的组本身也是一个迭代器, 它与 `groupby()` 共享底层的可迭代对象。因为源是共享的, 当 `groupby()` 对象向后迭代时, 前一个组将消失。因此如果稍后还需要返回结果, 可保存为列表:

```

groups = []
uniquekeys = []
data = sorted(data, key=keyfunc)
for k, g in groupby(data, keyfunc):
    groups.append(list(g))      # Store group iterator as a list
    uniquekeys.append(k)

```

`groupby()` 大致相当于:

```

class groupby:
    # [k for k, g in groupby('AAAABBBCCDAABBB')] --> A B C D A B
    # [list(g) for k, g in groupby('AAAABBBCCD')] --> AAAA BBB CC D
    def __init__(self, iterable, key=None):
        if key is None:
            key = lambda x: x
        self.keyfunc = key
        self.it = iter(iterable)
        self.tgtkey = self.currkey = self.currvalue = object()
    def __iter__(self):
        return self
    def __next__(self):
        while self.currkey == self.tgtkey:
            self.currvalue = next(self.it)      # Exit on StopIteration
            self.currkey = self.keyfunc(self.currvalue)
            self.tgtkey = self.currkey
        return (self.currkey, self._grouper(self.tgtkey))
    def _grouper(self, tgtkey):
        while self.currkey == tgtkey:
            yield self.currvalue
            try:
                self.currvalue = next(self.it)
            except StopIteration:
                return
            self.currkey = self.keyfunc(self.currvalue)

```

`itertools.islice(iterable, stop)`

`itertools.islice(iterable, start, stop[, step])`

创建一个迭代器，返回从 `iterable` 里选中的元素。如果 `start` 不是 0，跳过 `iterable` 中的元素，直到到达 `start` 这个位置。之后迭代器连续返回元素，除非 `step` 设置的值很高导致被跳过。如果 `stop` 为 `None`，迭代器耗光为止；否则，在指定的位置停止。与普通的切片不同，`islice()` 不支持将 `start`，`stop`，或 `step` 设为负值。可用来从内部数据结构被压平的数据中提取相关字段（例如一个多行报告，它的名称字段出现在每三行上）。大致相当于：

```

def islice(iterable, *args):
    # islice('ABCDEFGH', 2) --> A B
    # islice('ABCDEFGH', 2, 4) --> C D
    # islice('ABCDEFGH', 2, None) --> C D E F G
    # islice('ABCDEFGH', 0, None, 2) --> A C E G
    s = slice(*args)
    start, stop, step = s.start or 0, s.stop or sys.maxsize, s.step or 1
    it = iter(range(start, stop, step))
    try:
        nexti = next(it)
    except StopIteration:
        # Consume *iterable* up to the *start* position.
        for i, element in zip(range(start), iterable):
            pass

```

(下页继续)

(续上页)

```

    return
try:
    for i, element in enumerate(iterable):
        if i == nexti:
            yield element
            nexti = next(it)
except StopIteration:
    # Consume to *stop*.
    for i, element in zip(range(i + 1, stop), iterable):
        pass

```

如果 *start* 为 *None*，迭代从 0 开始。如果 *step* 为 *None*，步长缺省为 1。

`itertools.permutations(iterable, r=None)`

连续返回由 *iterable* 元素生成长度为 *r* 的排列。

如果 *r* 未指定或为 *None*，*r* 默认设置为 *iterable* 的长度，这种情况下，生成所有全长排列。

排列依字典序发出。因此，如果 *iterable* 是已排序的，排列元组将有序地产出。

即使元素的值相同，不同位置的元素也被认为是不同的。如果元素值都不同，每个排列中的元素值不会重复。

大致相当于：

```

def permutations(iterable, r=None):
    # permutations('ABCD', 2) --> AB AC AD BA BC BD CA CB CD DA DB DC
    # permutations(range(3)) --> 012 021 102 120 201 210
    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    if r > n:
        return
    indices = list(range(n))
    cycles = list(range(n, n-r, -1))
    yield tuple(pool[i] for i in indices[:r])
    while n:
        for i in reversed(range(r)):
            cycles[i] -= 1
            if cycles[i] == 0:
                indices[i:] = indices[i+1:] + indices[i:i+1]
                cycles[i] = n - i
            else:
                j = cycles[i]
                indices[i], indices[-j] = indices[-j], indices[i]
                yield tuple(pool[i] for i in indices[:r])
                break
        else:
            return

```

`permutations()` 的代码也可被改写为 `product()` 的子序列，只要将含有重复元素（来自输入中同一位置的）的项排除。

```

def permutations(iterable, r=None):
    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    for indices in product(range(n), repeat=r):

```

(下页继续)

(续上页)

```
if len(set(indices)) == r:
    yield tuple(pool[i] for i in indices)
```

当 $0 \leq r \leq n$ ，返回项个数为 $n! / (n-r)!$ ；当 $r > n$ ，返回项个数为 0。

`itertools.product(*iterables, repeat=1)`

可迭代对象输入的笛卡儿积。

大致相当于生成器表达式中的嵌套循环。例如，`product(A, B)` 和 `((x,y) for x in A for y in B)` 返回结果一样。

嵌套循环像里程表那样循环变动，每次迭代时将最右侧的元素向后迭代。这种模式形成了一种字典序，因此如果输入的可迭代对象是已排序的，笛卡尔积元组依次序发出。

要计算可迭代对象自身的笛卡尔积，将可选参数 `repeat` 设定为要重复的次数。例如，`product(A, repeat=4)` 和 `product(A, A, A, A)` 是一样的。

该函数大致相当于下面的代码，只不过实际实现方案不会在内存中创建中间结果。

```
def product(*args, repeat=1):
    # product('ABCD', 'xy') --> Ax Ay Bx By Cx Cy Dx Dy
    # product(range(2), repeat=3) --> 000 001 010 011 100 101 110 111
    pools = [tuple(pool) for pool in args] * repeat
    result = [[]]
    for pool in pools:
        result = [x+[y] for x in result for y in pool]
    for prod in result:
        yield tuple(prod)
```

`itertools.repeat(object[, times])`

创建一个迭代器，不断重复 `object`。除非设定参数 `times`，否则将无限重复。可用于 `map()` 函数中的参数，被调用函数可得到一个不变参数。也可用于 `zip()` 的参数以在元组记录中创建一个不变的部分。

大致相当于：

```
def repeat(object, times=None):
    # repeat(10, 3) --> 10 10 10
    if times is None:
        while True:
            yield object
    else:
        for i in range(times):
            yield object
```

`repeat` 最常见的用途就是在 `map` 或 `zip` 提供一个常量流：

```
>>> list(map(pow, range(10), repeat(2)))
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

`itertools.starmap(function, iterable)`

创建一个迭代器，使用从可迭代对象中获取的参数来计算该函数。当参数对应的形参已从一个单独可迭代对象组合为元组时（数据已被“预组对”）可用此函数代替 `map()`。`map()` 与 `starmap()` 之间的区别可以类比 `function(a,b)` 与 `function(*c)` 的区别。大致相当于：

```
def starmap(function, iterable):
    # starmap(pow, [(2,5), (3,2), (10,3)]) --> 32 9 1000
    for args in iterable:
        yield function(*args)
```

`itertools.takewhile` (*predicate, iterable*)

创建一个迭代器，只要 `predicate` 为真就从可迭代对象中返回元素。大致相当于：

```
def takewhile(predicate, iterable):
    # takewhile(lambda x: x<5, [1,4,6,4,1]) --> 1 4
    for x in iterable:
        if predicate(x):
            yield x
        else:
            break
```

`itertools.tee` (*iterable, n=2*)

从一个可迭代对象中返回 *n* 个独立的迭代器。

下面的 Python 代码能帮助解释 *tee* 做了什么（尽管实际的实现更复杂，而且仅使用了一个底层的 FIFO 队列）。

大致相当于：

```
def tee(iterable, n=2):
    it = iter(iterable)
    deque = [collections.deque() for i in range(n)]
    def gen(mydeque):
        while True:
            if not mydeque:           # when the local deque is empty
                try:
                    newval = next(it) # fetch a new value and
                except StopIteration:
                    return
            for d in deque:           # load it to all the deques
                d.append(newval)
            yield mydeque.popleft()
    return tuple(gen(d) for d in deque)
```

一旦 *tee()* 实施了一次分裂，原有的 *iterable* 不应再被使用；否则 *tee* 对象无法得知 *iterable* 可能已向后迭代。

该迭代工具可能需要相当大的辅助存储空间（这取决于要保存多少临时数据）。通常，如果一个迭代器在另一个迭代器开始之前就要使用大部份或全部数据，使用 *list()* 会比 *tee()* 更快。

`itertools.zip_longest` (**iterables, fillvalue=None*)

创建一个迭代器，从每个可迭代对象中收集元素。如果可迭代对象的长度未对齐，将根据 *fillvalue* 填充缺失值。迭代持续到耗光最长的可迭代对象。大致相当于：

```
class ZipExhausted(Exception):
    pass

def zip_longest(*args, **kwargs):
    # zip_longest('ABCD', 'xy', fillvalue='-') --> Ax By C- D-
    fillvalue = kwargs.get('fillvalue')
    counter = len(args) - 1
    def sentinel():
        nonlocal counter
        if not counter:
            raise ZipExhausted
        counter -= 1
        yield fillvalue
    fillers = repeat(fillvalue)
    iterators = [chain(it, sentinel(), fillers) for it in args]
```

(下页继续)

(续上页)

```

try:
    while iterators:
        yield tuple(map(next, iterators))
except ZipExhausted:
    pass

```

如果其中一个可迭代对象有无限长度，`zip_longest()` 函数应封装在限制调用次数的场景中（例如 `islice()` 或 `takewhile()`）。除非指定，`fillvalue` 默认为 `None`。

10.1.2 Itertools 食谱

本节将展示如何使用现有的 `itertools` 作为基础构件来创建扩展的工具集。

扩展的工具提供了与底层工具集相同的高性能。保持了超棒的内存利用率，因为一次只处理一个元素，而不是将整个可迭代对象加载到内存。代码量保持得很小，以函数式风格将这些工具连接在一起，有助于消除临时变量。速度依然很快，因为倾向于使用“矢量化”构件来取代解释器开销大的 `for` 循环和 *generator*。

```

def take(n, iterable):
    "Return first n items of the iterable as a list"
    return list(islice(iterable, n))

def prepend(value, iterator):
    "Prepend a single value in front of an iterator"
    # prepend(1, [2, 3, 4]) -> 1 2 3 4
    return chain([value], iterator)

def tabulate(function, start=0):
    "Return function(0), function(1), ..."
    return map(function, count(start))

def tail(n, iterable):
    "Return an iterator over the last n items"
    # tail(3, 'ABCDEFG') --> E F G
    return iter(collections.deque(iterable, maxlen=n))

def consume(iterator, n=None):
    "Advance the iterator n-steps ahead. If n is None, consume entirely."
    # Use functions that consume iterators at C speed.
    if n is None:
        # feed the entire iterator into a zero-length deque
        collections.deque(iterator, maxlen=0)
    else:
        # advance to the empty slice starting at position n
        next(islice(iterator, n, n), None)

def nth(iterable, n, default=None):
    "Returns the nth item or a default value"
    return next(islice(iterable, n, None), default)

def all_equal(iterable):
    "Returns True if all the elements are equal to each other"
    g = groupby(iterable)
    return next(g, True) and not next(g, False)

def quantify(iterable, pred=bool):

```

(下页继续)

(续上页)

```

    "Count how many times the predicate is true"
    return sum(map(pred, iterable))

def padnone(iterable):
    """Returns the sequence elements and then returns None indefinitely.

    Useful for emulating the behavior of the built-in map() function.
    """
    return chain(iterable, repeat(None))

def ncycles(iterable, n):
    "Returns the sequence elements n times"
    return chain.from_iterable(repeat(tuple(iterable), n))

def dotproduct(vec1, vec2):

    """ Call a function repeatedly until an exception is raised.

    Converts a call-until-exception interface to an iterator interface.
    Like builtins.iter(func, sentinel) but uses an exception instead
    of a sentinel to end the loop.

    Examples:
        iter_except(functools.partial(heappop, h), IndexError)   # priority queue_
    ↪ iterator
        iter_except(d.popitem, KeyError)                         # non-blocking dict_
    ↪ iterator
        iter_except(d.popleft, IndexError)                       # non-blocking deque_
    ↪ iterator
        iter_except(q.get_nowait, Queue.Empty)                  # loop over a_
    ↪ producer Queue
        iter_except(s.pop, KeyError)                             # non-blocking set_
    ↪ iterator

    """
    try:
        if first is not None:

```

(下页继续)

(续上页)

```

        yield first()                # For database APIs needing an initial cast to...
↪db.first()
        while True:
            yield func()
        except exception:
            pass

def first_true(iterable, default=False, pred=None):
    """Returns the first true value in the iterable.

    If no true value is found, returns *default*

    If *pred* is not None, returns the first item
    for which pred(item) is true.

    """
    # first_true([a,b,c], x) --> a or b or c or x
    # first_true([a,b], x, f) --> a if f(a) else b if f(b) else x
    return next(filter(pred, iterable), default)

def random_product(*args, repeat=1):
    "Random selection from itertools.product(*args, **kwargs)"
    pools = [tuple(pool) for pool in args] * repeat
    return tuple(random.choice(pool) for pool in pools)

def random_permutation(iterable, r=None):
    "Random selection from itertools.permutations(iterable, r)"
    pool = tuple(iterable)
    r = len(pool) if r is None else r
    return tuple(random.sample(pool, r))

def random_combination(iterable, r):
    "Random selection from itertools.combinations(iterable, r)"
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.sample(range(n), r))
    return tuple(pool[i] for i in indices)

def random_combination_with_replacement(iterable, r):
    "Random selection from itertools.combinations_with_replacement(iterable, r)"
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.randrange(n) for i in range(r))
    return tuple(pool[i] for i in indices)

def nth_combination(iterable, r, index):
    'Equivalent to list(combinations(iterable, r))[index]'
    pool = tuple(iterable)
    n = len(pool)
    if r < 0 or r > n:
        raise ValueError
    c = 1
    k = min(r, n-r)
    for i in range(1, k+1):
        c = c * (n - k + i) // i
    if index < 0:

```

(下页继续)

(续上页)

```

    index += c
    if index < 0 or index >= c:
        raise IndexError
    result = []
    while r:
        c, n, r = c*r//n, n-1, r-1
        while index >= c:
            index -= c
            c, n = c*(n-r)//n, n-1
        result.append(pool[-1-n])
    return tuple(result)

```

注意，通过将全局查找替换为局部变量的缺省值，上述配方中有很多可以这样优化。例如，*dotproduct* 配方可以这样写：

```

def dotproduct(vec1, vec2, sum=sum, map=map, mul=operator.mul):
    return sum(map(mul, vec1, vec2))

```

10.2 functools — 高阶函数和可调用对象上的操作

源代码: [Lib/functools.py](#)

functools 模块应用于高阶函数，即——参数或（和）返回值为其他函数的函数。通常来说，此模块的功能适用于所有可调用对象。

functools 模块定义了以下函数：

`functools.cmp_to_key(func)`

将（旧式的）比较函数转换为新式的 *key function*。在类似于 *sorted()*，*min()*，*max()*，*heapq.nlargest()*，*heapq.nsmallest()*，*itertools.groupby()* 等函数的 *key* 参数中使用。此函数主要用作将 Python 2 程序转换至新版的转换工具，以保持对比较函数的兼容。

比较函数意为一个可调用对象，该对象接受两个参数并比较它们，结果为小于则返回一个负数，相等则返回零，大于则返回一个正数。*key function* 则是一个接受一个参数，并返回另一个用以排序的值的可调用对象。

示例：

```
sorted(iterable, key=cmp_to_key(locale.strcoll)) # locale-aware sort order
```

有关排序示例和简要排序教程，请参阅 [sortinghowto](#)。

3.2 新版功能。

`@functools.lru_cache(maxsize=128, typed=False)`

一个为函数提供缓存功能的装饰器，缓存 *maxsize* 组传入参数，在下次以相同参数调用时直接返回上一次的结果。用以节约高开销或 I/O 函数的调用时间。

由于使用了字典存储缓存，所以该函数的固定参数和关键字参数必须是可哈希的。

如果 *maxsize* 设置为 *None*，LRU 功能将被禁用且缓存数量无上限。*maxsize* 设置为 2 的幂时可获得最佳性能。

如果 *typed* 设置为 *true*，不同类型的函数参数将被分别缓存。例如，*f(3)* 和 *f(3.0)* 将被视为不同而分别缓存。

为了衡量缓存的有效性以便调整 *maxsize* 形参，被装饰的函数带有一个 `cache_info()` 函数。当调用 `cache_info()` 函数时，返回一个具名元组，包含命中次数 *hits*，未命中次数 *misses*，最大缓存数量 *maxsize* 和当前缓存大小 *currsz*。在多线程环境中，命中数与未命中数是不完全准确的。

该装饰器也提供了一个用于清理/使缓存失效的函数 `cache_clear()`。

原始的未经装饰的函数可以通过 `__wrapped__` 属性访问。它可以用于检查、绕过缓存，或使用不同的缓存再次装饰原始函数。

“最久未使用算法”（LRU）缓存在“最近的调用是即将到来的调用的最佳预测因子”时性能最好（比如，新闻服务器上最受欢迎的文章倾向于每天更改）。“缓存大小限制”参数保证缓存不会在长时间运行的进程比如说网站服务器上无限制的增加自身的大小。

一般来说，LRU 缓存只在当你想要重用之前计算的结果时使用。因此，用它缓存具有副作用的函数、需要在每次调用时创建不同、易变的对象的函数或者诸如 `time()` 或 `random()` 之类的不纯函数是没有意义的。

静态 Web 内容的 LRU 缓存示例：

```
@lru_cache(maxsize=32)
def get_pep(num):
    'Retrieve text of a Python Enhancement Proposal'
    resource = 'http://www.python.org/dev/peps/pep-%04d/' % num
    try:
        with urllib.request.urlopen(resource) as s:
            return s.read()
    except urllib.error.HTTPError:
        return 'Not Found'

>>> for n in 8, 290, 308, 320, 8, 218, 320, 279, 289, 320, 9991:
...     pep = get_pep(n)
...     print(n, len(pep))

>>> get_pep.cache_info()
CacheInfo(hits=3, misses=8, maxsize=32, currsz=8)
```

以下是使用缓存通过 动态规划 计算 斐波那契数列 的例子。

```
@lru_cache(maxsize=None)
def fib(n):
    if n < 2:
        return n
    return fib(n-1) + fib(n-2)

>>> [fib(n) for n in range(16)]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610]

>>> fib.cache_info()
CacheInfo(hits=28, misses=16, maxsize=None, currsz=16)
```

3.2 新版功能.

在 3.3 版更改: 添加 *typed* 选项。

@functools.total_ordering

给定一个声明一个或多个全比较排序方法的类，这个类装饰器实现剩余的方法。这减轻了指定所有可能的全比较操作的工作。

此类必须包含以下方法之一：`__lt__()`、`__le__()`、`__gt__()` 或 `__ge__()`。另外，此类必须支持 `__eq__()` 方法。

例如:

```
@total_ordering
class Student:
    def __is_valid_operand(self, other):
        return (hasattr(other, "lastname") and
                hasattr(other, "firstname"))
    def __eq__(self, other):
        if not self.__is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()) ==
                (other.lastname.lower(), other.firstname.lower()))
    def __lt__(self, other):
        if not self.__is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()) <
                (other.lastname.lower(), other.firstname.lower()))
```

注解: While this decorator makes it easy to create well behaved totally ordered types, it *does* come at the cost of slower execution and more complex stack traces for the derived comparison methods. If performance benchmarking indicates this is a bottleneck for a given application, implementing all six rich comparison methods instead is likely to provide an easy speed boost.

3.2 新版功能.

在 3.4 版更改: Returning NotImplemented from the underlying comparison function for unrecognised types is now supported.

`functools.partial(func, *args, **keywords)`

Return a new *partial object* which when called will behave like *func* called with the positional arguments *args* and keyword arguments *keywords*. If more arguments are supplied to the call, they are appended to *args*. If additional keyword arguments are supplied, they extend and override *keywords*. Roughly equivalent to:

```
def partial(func, *args, **keywords):
    def newfunc(*fargs, **fkeywords):
        newkeywords = keywords.copy()
        newkeywords.update(fkeywords)
        return func(*args, *fargs, **newkeywords)
    newfunc.func = func
    newfunc.args = args
    newfunc.keywords = keywords
    return newfunc
```

The *partial()* is used for partial function application which “freezes” some portion of a function’s arguments and/or keywords resulting in a new object with a simplified signature. For example, *partial()* can be used to create a callable that behaves like the *int()* function where the *base* argument defaults to two:

```
>>> from functools import partial
>>> basetwo = partial(int, base=2)
>>> basetwo.__doc__ = 'Convert base 2 string to an int.'
>>> basetwo('10010')
18
```

`class functools.partialmethod(func, *args, **keywords)`

Return a new *partialmethod* descriptor which behaves like *partial* except that it is designed to be used as a method definition rather than being directly callable.

func must be a *descriptor* or a callable (objects which are both, like normal functions, are handled as descriptors).

When *func* is a descriptor (such as a normal Python function, *classmethod()*, *staticmethod()*, *abstractmethod()* or another instance of *partialmethod*), calls to *__get__* are delegated to the underlying descriptor, and an appropriate *partial object* returned as the result.

When *func* is a non-descriptor callable, an appropriate bound method is created dynamically. This behaves like a normal Python function when used as a method: the *self* argument will be inserted as the first positional argument, even before the *args* and *keywords* supplied to the *partialmethod* constructor.

示例:

```
>>> class Cell(object):
...     def __init__(self):
...         self._alive = False
...     @property
...     def alive(self):
...         return self._alive
...     def set_state(self, state):
...         self._alive = bool(state)
...     set_alive = partialmethod(set_state, True)
...     set_dead = partialmethod(set_state, False)
...
>>> c = Cell()
>>> c.alive
False
>>> c.set_alive()
>>> c.alive
True
```

3.4 新版功能.

`functools.reduce` (*function*, *iterable* [, *initializer*])

Apply *function* of two arguments cumulatively to the items of *sequence*, from left to right, so as to reduce the sequence to a single value. For example, `reduce(lambda x, y: x+y, [1, 2, 3, 4, 5])` calculates `(((1+2)+3)+4)+5`. The left argument, *x*, is the accumulated value and the right argument, *y*, is the update value from the *sequence*. If the optional *initializer* is present, it is placed before the items of the sequence in the calculation, and serves as a default when the sequence is empty. If *initializer* is not given and *sequence* contains only one item, the first item is returned.

大致相当于:

```
def reduce(function, iterable, initializer=None):
    it = iter(iterable)
    if initializer is None:
        value = next(it)
    else:
        value = initializer
    for element in it:
        value = function(value, element)
    return value
```

`@functools.singledispatch`

Transform a function into a *single-dispatch generic function*.

To define a generic function, decorate it with the `@singledispatch` decorator. Note that the dispatch happens on the type of the first argument, create your function accordingly:

```
>>> from functools import singledispatch
>>> @singledispatch
... def fun(arg, verbose=False):
...     if verbose:
...         print("Let me just say,", end=" ")
...     print(arg)
```

To add overloaded implementations to the function, use the `register()` attribute of the generic function. It is a decorator, taking a type parameter and decorating a function implementing the operation for that type:

```
>>> @fun.register(int)
... def _(arg, verbose=False):
...     if verbose:
...         print("Strength in numbers, eh?", end=" ")
...     print(arg)
...
>>> @fun.register(list)
... def _(arg, verbose=False):
...     if verbose:
...         print("Enumerate this:")
...     for i, elem in enumerate(arg):
...         print(i, elem)
```

To enable registering lambdas and pre-existing functions, the `register()` attribute can be used in a functional form:

```
>>> def nothing(arg, verbose=False):
...     print("Nothing.")
...
>>> fun.register(type(None), nothing)
```

The `register()` attribute returns the undecorated function which enables decorator stacking, pickling, as well as creating unit tests for each variant independently:

```
>>> @fun.register(float)
... @fun.register(Decimal)
... def fun_num(arg, verbose=False):
...     if verbose:
...         print("Half of your number:", end=" ")
...     print(arg / 2)
...
>>> fun_num is fun
False
```

When called, the generic function dispatches on the type of the first argument:

```
>>> fun("Hello, world.")
Hello, world.
>>> fun("test.", verbose=True)
Let me just say, test.
>>> fun(42, verbose=True)
Strength in numbers, eh? 42
>>> fun(['spam', 'spam', 'eggs', 'spam'], verbose=True)
Enumerate this:
0 spam
1 spam
2 eggs
```

(下页继续)

(续上页)

```
3 spam
>>> fun(None)
Nothing.
>>> fun(1.23)
0.615
```

Where there is no registered implementation for a specific type, its method resolution order is used to find a more generic implementation. The original function decorated with `@singledispatch` is registered for the base `object` type, which means it is used if no better implementation is found.

To check which implementation will the generic function choose for a given type, use the `dispatch()` attribute:

```
>>> fun.dispatch(float)
<function fun_num at 0x1035a2840>
>>> fun.dispatch(dict)      # note: default implementation
<function fun at 0x103fe0000>
```

To access all registered implementations, use the read-only `registry` attribute:

```
>>> fun.registry.keys()
dict_keys([<class 'NoneType'>, <class 'int'>, <class 'object'>,
          <class 'decimal.Decimal'>, <class 'list'>,
          <class 'float'>])
>>> fun.registry[float]
<function fun_num at 0x1035a2840>
>>> fun.registry[object]
<function fun at 0x103fe0000>
```

3.4 新版功能.

`functools.update_wrapper(wrapper, wrapped, assigned=WRAPPER_ASSIGNMENTS, updated=WRAPPER_UPDATES)`

Update a *wrapper* function to look like the *wrapped* function. The optional arguments are tuples to specify which attributes of the original function are assigned directly to the matching attributes on the wrapper function and which attributes of the wrapper function are updated with the corresponding attributes from the original function. The default values for these arguments are the module level constants `WRAPPER_ASSIGNMENTS` (which assigns to the wrapper function's `__module__`, `__name__`, `__qualname__`, `__annotations__` and `__doc__`, the documentation string) and `WRAPPER_UPDATES` (which updates the wrapper function's `__dict__`, i.e. the instance dictionary).

To allow access to the original function for introspection and other purposes (e.g. bypassing a caching decorator such as `lru_cache()`), this function automatically adds a `__wrapped__` attribute to the wrapper that refers to the function being wrapped.

The main intended use for this function is in *decorator* functions which wrap the decorated function and return the wrapper. If the wrapper function is not updated, the metadata of the returned function will reflect the wrapper definition rather than the original function definition, which is typically less than helpful.

`update_wrapper()` may be used with callables other than functions. Any attributes named in *assigned* or *updated* that are missing from the object being wrapped are ignored (i.e. this function will not attempt to set them on the wrapper function). `AttributeError` is still raised if the wrapper function itself is missing any attributes named in *updated*.

3.2 新版功能: Automatic addition of the `__wrapped__` attribute.

3.2 新版功能: Copying of the `__annotations__` attribute by default.

在 3.2 版更改: Missing attributes no longer trigger an `AttributeError`.

在 3.4 版更改: The `__wrapped__` attribute now always refers to the wrapped function, even if that function defined a `__wrapped__` attribute. (see [bpo-17482](#))

`@functools.wraps(wrapped, assigned=WRAPPER_ASSIGNMENTS, updated=WRAPPER_UPDATES)`

This is a convenience function for invoking `update_wrapper()` as a function decorator when defining a wrapper function. It is equivalent to `partial(update_wrapper, wrapped=wrapped, assigned=assigned, updated=updated)`. For example:

```
>>> from functools import wraps
>>> def my_decorator(f):
...     @wraps(f)
...     def wrapper(*args, **kwds):
...         print('Calling decorated function')
...         return f(*args, **kwds)
...     return wrapper
...
>>> @my_decorator
... def example():
...     """Docstring"""
...     print('Called example function')
...
>>> example()
Calling decorated function
Called example function
>>> example.__name__
'example'
>>> example.__doc__
'Docstring'
```

Without the use of this decorator factory, the name of the example function would have been 'wrapper', and the docstring of the original `example()` would have been lost.

10.2.1 partial Objects

`partial` objects are callable objects created by `partial()`. They have three read-only attributes:

`partial.func`

A callable object or function. Calls to the `partial` object will be forwarded to `func` with new arguments and keywords.

`partial.args`

The leftmost positional arguments that will be prepended to the positional arguments provided to a `partial` object call.

`partial.keywords`

The keyword arguments that will be supplied when the `partial` object is called.

`partial` objects are like function objects in that they are callable, weak referencable, and can have attributes. There are some important differences. For instance, the `__name__` and `__doc__` attributes are not created automatically. Also, `partial` objects defined in classes behave like static methods and do not transform into bound methods during instance attribute look-up.

10.3 operator — 标准运算符替代函数

源代码: [Lib/operator.py](#)

`operator` 模块提供了一套与 Python 的内置运算符对应的高效率函数。例如, `operator.add(x, y)` 与表达式 `x+y` 相同。许多函数名与特殊方法名相同, 只是没有双下划线。为了向后兼容性, 也保留了许多包含双下划线的函数。为了表述清楚, 建议使用没有双下划线的函数。

函数包含的种类有: 对象的比较运算、逻辑运算、数学运算以及序列运算。

对象比较函数适用于所有的对象, 函数名根据它们对应的比较运算符命名。

```
operator.lt(a, b)
operator.le(a, b)
operator.eq(a, b)
operator.ne(a, b)
operator.ge(a, b)
operator.gt(a, b)
operator.__lt__(a, b)
operator.__le__(a, b)
operator.__eq__(a, b)
operator.__ne__(a, b)
operator.__ge__(a, b)
operator.__gt__(a, b)
```

在 `a` 和 `b` 之间进行全比较。具体的, `lt(a, b)` 与 `a < b` 相同, `le(a, b)` 与 `a <= b` 相同, `eq(a, b)` 与 `a == b` 相同, `ne(a, b)` 与 `a != b` 相同, `gt(a, b)` 与 `a > b` 相同, `ge(a, b)` 与 `a >= b` 相同。注意这些函数可以返回任何值, 无论它是否可当作布尔值。关于全比较的更多信息请参考 `comparisons`。

The logical operations are also generally applicable to all objects, and support truth tests, identity tests, and boolean operations:

```
operator.not_(obj)
operator.__not__(obj)
```

Return the outcome of `not obj`. (Note that there is no `__not__()` method for object instances; only the interpreter core defines this operation. The result is affected by the `__bool__()` and `__len__()` methods.)

```
operator.truth(obj)
```

Return `True` if `obj` is true, and `False` otherwise. This is equivalent to using the `bool` constructor.

```
operator.is_(a, b)
```

Return `a is b`. Tests object identity.

```
operator.is_not(a, b)
```

Return `a is not b`. Tests object identity.

The mathematical and bitwise operations are the most numerous:

```
operator.abs(obj)
operator.__abs__(obj)
```

Return the absolute value of `obj`.

```
operator.add(a, b)
operator.__add__(a, b)
```

Return `a + b`, for `a` and `b` numbers.

```
operator.and_(a, b)
operator.__and__(a, b)
```

Return the bitwise and of `a` and `b`.

```
operator.floordiv(a, b)
```

`operator.__floordiv__ (a, b)`

Return $a // b$.

`operator.index (a)`

`operator.__index__ (a)`

Return a converted to an integer. Equivalent to `a.__index__()`.

`operator.inv (obj)`

`operator.invert (obj)`

`operator.__inv__ (obj)`

`operator.__invert__ (obj)`

Return the bitwise inverse of the number *obj*. This is equivalent to $\sim obj$.

`operator.lshift (a, b)`

`operator.__lshift__ (a, b)`

Return a shifted left by b .

`operator.mod (a, b)`

`operator.__mod__ (a, b)`

Return $a \% b$.

`operator.mul (a, b)`

`operator.__mul__ (a, b)`

Return $a * b$, for a and b numbers.

`operator.matmul (a, b)`

`operator.__matmul__ (a, b)`

Return $a @ b$.

3.5 新版功能.

`operator.neg (obj)`

`operator.__neg__ (obj)`

Return *obj* negated ($-obj$).

`operator.or_ (a, b)`

`operator.__or__ (a, b)`

Return the bitwise or of a and b .

`operator.pos (obj)`

`operator.__pos__ (obj)`

Return *obj* positive ($+obj$).

`operator.pow (a, b)`

`operator.__pow__ (a, b)`

Return $a ** b$, for a and b numbers.

`operator.rshift (a, b)`

`operator.__rshift__ (a, b)`

Return a shifted right by b .

`operator.sub (a, b)`

`operator.__sub__ (a, b)`

Return $a - b$.

`operator.truediv (a, b)`

`operator.__truediv__ (a, b)`

Return a / b where $2/3$ is .66 rather than 0. This is also known as “true” division.

`operator.xor (a, b)`

`operator.__xor__(a, b)`

Return the bitwise exclusive or of *a* and *b*.

Operations which work with sequences (some of them with mappings too) include:

`operator.concat(a, b)`

`operator.__concat__(a, b)`

Return *a* + *b* for *a* and *b* sequences.

`operator.contains(a, b)`

`operator.__contains__(a, b)`

Return the outcome of the test *b* in *a*. Note the reversed operands.

`operator.countOf(a, b)`

Return the number of occurrences of *b* in *a*.

`operator.delitem(a, b)`

`operator.__delitem__(a, b)`

Remove the value of *a* at index *b*.

`operatorgetitem(a, b)`

`operator.__getitem__(a, b)`

Return the value of *a* at index *b*.

`operator.indexOf(a, b)`

Return the index of the first occurrence of *b* in *a*.

`operator.setitem(a, b, c)`

`operator.__setitem__(a, b, c)`

Set the value of *a* at index *b* to *c*.

`operator.length_hint(obj, default=0)`

Return an estimated length for the object *o*. First try to return its actual length, then an estimate using `object.__length_hint__()`, and finally return the default value.

3.4 新版功能.

The `operator` module also defines tools for generalized attribute and item lookups. These are useful for making fast field extractors as arguments for `map()`, `sorted()`, `itertools.groupby()`, or other functions that expect a function argument.

`operator.attrgetter(attr)`

`operator.attrgetter(*attrs)`

Return a callable object that fetches *attr* from its operand. If more than one attribute is requested, returns a tuple of attributes. The attribute names can also contain dots. For example:

- After `f = attrgetter('name')`, the call `f(b)` returns `b.name`.
- After `f = attrgetter('name', 'date')`, the call `f(b)` returns `(b.name, b.date)`.
- After `f = attrgetter('name.first', 'name.last')`, the call `f(b)` returns `(b.name.first, b.name.last)`.

等价于:

```
def attrgetter(*items):
    if any(not isinstance(item, str) for item in items):
        raise TypeError('attribute name must be a string')
    if len(items) == 1:
        attr = items[0]
        def g(obj):
            return resolve_attr(obj, attr)
```

(下页继续)

(续上页)

```

else:
    def g(obj):
        return tuple(resolve_attr(obj, attr) for attr in items)
    return g

def resolve_attr(obj, attr):
    for name in attr.split("."):
        obj = getattr(obj, name)
    return obj

```

`operator.itemgetter(item)`

`operator.itemgetter(*items)`

Return a callable object that fetches *item* from its operand using the operand's `__getitem__()` method. If multiple items are specified, returns a tuple of lookup values. For example:

- After `f = itemgetter(2)`, the call `f(r)` returns `r[2]`.
- After `g = itemgetter(2, 5, 3)`, the call `g(r)` returns `(r[2], r[5], r[3])`.

等价于:

```

def itemgetter(*items):
    if len(items) == 1:
        item = items[0]
        def g(obj):
            return obj[item]
    else:
        def g(obj):
            return tuple(obj[item] for item in items)
    return g

```

The items can be any type accepted by the operand's `__getitem__()` method. Dictionaries accept any hashable value. Lists, tuples, and strings accept an index or a slice:

```

>>> itemgetter(1)('ABCDEFGH')
'B'
>>> itemgetter(1,3,5)('ABCDEFGH')
('B', 'D', 'F')
>>> itemgetter(slice(2,None))('ABCDEFGH')
'CDEFG'

```

Example of using `itemgetter()` to retrieve specific fields from a tuple record:

```

>>> inventory = [('apple', 3), ('banana', 2), ('pear', 5), ('orange', 1)]
>>> getcount = itemgetter(1)
>>> list(map(getcount, inventory))
[3, 2, 5, 1]
>>> sorted(inventory, key=getcount)
[('orange', 1), ('banana', 2), ('apple', 3), ('pear', 5)]

```

`operator.methodcaller(name[, args...])`

Return a callable object that calls the method *name* on its operand. If additional arguments and/or keyword arguments are given, they will be given to the method as well. For example:

- After `f = methodcaller('name')`, the call `f(b)` returns `b.name()`.
- After `f = methodcaller('name', 'foo', bar=1)`, the call `f(b)` returns `b.name('foo', bar=1)`.

等价于:

```
def methodcaller(name, *args, **kwargs):
    def caller(obj):
        return getattr(obj, name)(*args, **kwargs)
    return caller
```

10.3.1 Mapping Operators to Functions

This table shows how abstract operations correspond to operator symbols in the Python syntax and the functions in the `operator` module.

运算	Syntax	Function
Addition	<code>a + b</code>	<code>add(a, b)</code>
Concatenation	<code>seq1 + seq2</code>	<code>concat(seq1, seq2)</code>
Containment Test	<code>obj in seq</code>	<code>contains(seq, obj)</code>
Division	<code>a / b</code>	<code>truediv(a, b)</code>
Division	<code>a // b</code>	<code>floordiv(a, b)</code>
Bitwise And	<code>a & b</code>	<code>and_(a, b)</code>
Bitwise Exclusive Or	<code>a ^ b</code>	<code>xor(a, b)</code>
Bitwise Inversion	<code>~ a</code>	<code>invert(a)</code>
Bitwise Or	<code>a b</code>	<code>or_(a, b)</code>
Exponentiation	<code>a ** b</code>	<code>pow(a, b)</code>
Identity	<code>a 是 b</code>	<code>is_(a, b)</code>
Identity	<code>a 不是 b</code>	<code>is_not(a, b)</code>
Indexed Assignment	<code>obj[k] = v</code>	<code>setitem(obj, k, v)</code>
Indexed Deletion	<code>del obj[k]</code>	<code>delitem(obj, k)</code>
Indexing	<code>obj[k]</code>	<code>getitem(obj, k)</code>
Left Shift	<code>a << b</code>	<code>lshift(a, b)</code>
Modulo	<code>a % b</code>	<code>mod(a, b)</code>
Multiplication	<code>a * b</code>	<code>mul(a, b)</code>
Matrix Multiplication	<code>a @ b</code>	<code>matmul(a, b)</code>
Negation (Arithmetic)	<code>- a</code>	<code>neg(a)</code>
Negation (Logical)	<code>not a</code>	<code>not_(a)</code>
Positive	<code>+ a</code>	<code>pos(a)</code>
Right Shift	<code>a >> b</code>	<code>rshift(a, b)</code>
Slice Assignment	<code>seq[i:j] = values</code>	<code>setitem(seq, slice(i, j), values)</code>
Slice Deletion	<code>del seq[i:j]</code>	<code>delitem(seq, slice(i, j))</code>
Slicing	<code>seq[i:j]</code>	<code>getitem(seq, slice(i, j))</code>
String Formatting	<code>s % obj</code>	<code>mod(s, obj)</code>
Subtraction	<code>a - b</code>	<code>sub(a, b)</code>
Truth Test	<code>obj</code>	<code>truth(obj)</code>
Ordering	<code>a < b</code>	<code>lt(a, b)</code>
Ordering	<code>a <= b</code>	<code>le(a, b)</code>
Equality	<code>a == b</code>	<code>eq(a, b)</code>
Difference	<code>a != b</code>	<code>ne(a, b)</code>
Ordering	<code>a >= b</code>	<code>ge(a, b)</code>
Ordering	<code>a > b</code>	<code>gt(a, b)</code>

10.3.2 Inplace Operators

Many operations have an “in-place” version. Listed below are functions providing a more primitive access to in-place operators than the usual syntax does; for example, the *statement* `x += y` is equivalent to `x = operator.iadd(x, y)`. Another way to put it is to say that `z = operator.iadd(x, y)` is equivalent to the compound statement `z = x; z += y`.

In those examples, note that when an in-place method is called, the computation and assignment are performed in two separate steps. The in-place functions listed below only do the first step, calling the in-place method. The second step, assignment, is not handled.

For immutable targets such as strings, numbers, and tuples, the updated value is computed, but not assigned back to the input variable:

```
>>> a = 'hello'
>>> iadd(a, ' world')
'hello world'
>>> a
'hello'
```

For mutable targets such as lists and dictionaries, the inplace method will perform the update, so no subsequent assignment is necessary:

```
>>> s = ['h', 'e', 'l', 'l', 'o']
>>> iadd(s, [' ', 'w', 'o', 'r', 'l', 'd'])
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
>>> s
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
```

```
operator.iadd(a, b)
operator.__iadd__(a, b)
    a = iadd(a, b) is equivalent to a += b.
```

```
operator.iand(a, b)
operator.__iand__(a, b)
    a = iand(a, b) is equivalent to a &= b.
```

```
operator.iconcat(a, b)
operator.__iconcat__(a, b)
    a = iconcat(a, b) is equivalent to a += b for a and b sequences.
```

```
operator.ifloordiv(a, b)
operator.__ifloordiv__(a, b)
    a = ifloordiv(a, b) is equivalent to a //= b.
```

```
operator.ilshift(a, b)
operator.__ilshift__(a, b)
    a = ilshift(a, b) is equivalent to a <<= b.
```

```
operator.imod(a, b)
operator.__imod__(a, b)
    a = imod(a, b) is equivalent to a %= b.
```

```
operator.imul(a, b)
operator.__imul__(a, b)
    a = imul(a, b) is equivalent to a *= b.
```

```
operator.imatmul(a, b)
operator.__imatmul__(a, b)
    a = imatmul(a, b) is equivalent to a @= b.
```

3.5 新版功能.

```
operator.ior(a, b)
operator.__ior__(a, b)
    a = ior(a, b) is equivalent to a |= b.

operator.ipow(a, b)
operator.__ipow__(a, b)
    a = ipow(a, b) is equivalent to a **= b.

operator.irshift(a, b)
operator.__irshift__(a, b)
    a = irshift(a, b) is equivalent to a >>= b.

operator.isub(a, b)
operator.__isub__(a, b)
    a = isub(a, b) is equivalent to a -= b.

operator.itruediv(a, b)
operator.__itruediv__(a, b)
    a = itruediv(a, b) is equivalent to a /= b.

operator.ixor(a, b)
operator.__ixor__(a, b)
    a = ixor(a, b) is equivalent to a ^= b.
```

本章中描述的模块处理磁盘文件和目录。例如，有一些模块用于读取文件的属性，以可移植的方式操作路径以及创建临时文件。本章的完整模块列表如下：

11.1 `pathlib` — 面向对象的文件系统路径

3.4 新版功能.

源代码 [Lib/pathlib.py](#)

该模块提供表示文件系统路径的类，其语义适用于不同的操作系统。路径类被分为提供纯计算操作而没有 I/O 的 [纯路径](#)，以及从纯路径继承而来但提供 I/O 操作的 [具体路径](#)。

如果你以前从未使用过此模块或者不确定在项目中使用哪一个类是正确的，则`Path`总是你需要的。它在运行代码的平台上实例化为一个具体路径。

在一些用例中纯路径很有用，例如：

1. 如果你想要在 Unix 设备上操作 Windows 路径（或者相反）。你不应在 Unix 上实例化一个`WindowsPath`，但是你可以实例化`PureWindowsPath`。
2. 你只想操作路径但不想实际访问操作系统。在这种情况下，实例化一个纯路径是有用的，因为它们没有任何访问操作系统的操作。

参见：

PEP 428：pathlib 模块 – 面向对象的文件系统路径。

参见：

对于底层的路径字符串操作，你也可以使用`os.path`模块。

11.1.1 基础使用

导入主类:

```
>>> from pathlib import Path
```

列出子目录:

```
>>> p = Path('.')
>>> [x for x in p.iterdir() if x.is_dir()]
[PosixPath('.hg'), PosixPath('docs'), PosixPath('dist'),
 PosixPath('__pycache__'), PosixPath('build')]
```

列出当前目录树下的所有 Python 源代码文件:

```
>>> list(p.glob('**/*.py'))
[PosixPath('test_pathlib.py'), PosixPath('setup.py'),
 PosixPath('pathlib.py'), PosixPath('docs/conf.py'),
 PosixPath('build/lib/pathlib.py')]
```

在目录树中移动:

```
>>> p = Path('/etc')
>>> q = p / 'init.d' / 'reboot'
>>> q
PosixPath('/etc/init.d/reboot')
>>> q.resolve()
PosixPath('/etc/rc.d/init.d/halt')
```

查询路径的属性:

```
>>> q.exists()
True
>>> q.is_dir()
False
```

打开一个文件:

```
>>> with q.open() as f: f.readline()
...
'#!/bin/bash\n'
```

11.1.2 纯路径

纯路径对象提供了不实际访问文件系统的路径处理操作。有三种方式来访问这些类，也是不同的风格：

class `pathlib.PurePath(*pathsegments)`

一个通用的类，代表当前系统的路径风格（实例化为 `PurePosixPath` 或者 `PureWindowsPath`）：

```
>>> PurePath('setup.py')           # Running on a Unix machine
PurePosixPath('setup.py')
```

每一个 `pathsegments` 的元素可能是一个代表路径片段的字符串，一个返回字符串的实现了 `os.PathLike` 接口的对象，或者另一个路径对象：

```
>>> PurePath('foo', 'some/path', 'bar')
PurePosixPath('foo/some/path/bar')
>>> PurePath(Path('foo'), Path('bar'))
PurePosixPath('foo/bar')
```

当 *pathsegments* 为空的时候, 假定为当前目录:

```
>>> PurePath()
PurePosixPath('.')
```

当给出一些绝对路径, 最后一位将被当作锚 (模仿 *os.path.join()* 的行为):

```
>>> PurePath('/etc', '/usr', 'lib64')
PurePosixPath('/usr/lib64')
>>> PureWindowsPath('c:/Windows', 'd:bar')
PureWindowsPath('d:bar')
```

但是, 在 Windows 路径中, 改变本地根目录并不会丢弃之前盘符的设置:

```
>>> PureWindowsPath('c:/Windows', '/Program Files')
PureWindowsPath('c:/Program Files')
```

假斜线和单独的点都会被消除, 但是双点 ('..') 不会, 以防改变符号链接的含义。

```
>>> PurePath('foo//bar')
PurePosixPath('foo/bar')
>>> PurePath('foo/./bar')
PurePosixPath('foo/bar')
>>> PurePath('foo/../bar')
PurePosixPath('foo/../bar')
```

(如果你想让 *PurePosixPath('foo/../bar')* 等同于 *PurePosixPath('bar')*, 那么 you are too young, too simple, sometimes naive! 如果 *foo* 是一个指向其他其他目录的符号链接, 那就出毛病啦。)

纯路径对象实现了 *os.PathLike* 接口, 允许它们在任何接受此接口的地方使用。

在 3.6 版更改: 添加了 *os.PathLike* 接口支持。

class *pathlib.PurePosixPath* (**pathsegments*)
一个 *PurePath* 的子类, 路径风格不同于 Windows 文件系统:

```
>>> PurePosixPath('/etc')
PurePosixPath('/etc')
```

pathsegments 参数的指定和 *PurePath* 相同。

class *pathlib.PureWindowsPath* (**pathsegments*)
PurePath 的一个子类, 路径风格为 Windows 文件系统路径:

```
>>> PureWindowsPath('c:/Program Files/')
PureWindowsPath('c:/Program Files')
```

pathsegments 参数的指定和 *PurePath* 相同。

无论你是否运行什么系统, 你都可以实例化这些类, 因为它们提供的操作不做任何系统调用。

通用性质

路径是不可变并可哈希的。相同风格的路径可以排序与比较。这些性质尊重对应风格的大小写转换语义:

```
>>> PurePosixPath('foo') == PurePosixPath('FOO')
False
>>> PureWindowsPath('foo') == PureWindowsPath('FOO')
True
>>> PureWindowsPath('FOO') in { PureWindowsPath('foo') }
True
>>> PureWindowsPath('C:') < PureWindowsPath('d:')
True
```

不同风格的路径比较得到不等的结果并且无法被排序:

```
>>> PureWindowsPath('foo') == PurePosixPath('foo')
False
>>> PureWindowsPath('foo') < PurePosixPath('foo')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: '<' not supported between instances of 'PureWindowsPath' and 'PurePosixPath'
↪'
```

运算符

斜杠 / 操作符有助于创建子路径, 就像 `os.path.join()` 一样:

```
>>> p = PurePath('/etc')
>>> p
PurePosixPath('/etc')
>>> p / 'init.d' / 'apache2'
PurePosixPath('/etc/init.d/apache2')
>>> q = PurePath('bin')
>>> '/usr' / q
PurePosixPath('/usr/bin')
```

文件对象可用于任何接受 `os.PathLike` 接口实现的地方。

```
>>> import os
>>> p = PurePath('/etc')
>>> os.fspath(p)
'/etc'
```

路径的字符串表示法为它自己原始的文件系统路径 (以原生形式, 例如在 Windows 下使用反斜杠)。你可以传递给任何需要字符串形式路径的函数。

```
>>> p = PurePath('/etc')
>>> str(p)
'/etc'
>>> p = PureWindowsPath('c:/Program Files')
>>> str(p)
'c:\\Program Files'
```

类似地, 在路径上调用 `bytes` 将原始文件系统路径作为字节对象给出, 就像被 `os.fsencode()` 编码一样:

```
>>> bytes(p)
b'/etc'
```

注解：只推荐在 Unix 下调用 `bytes`。在 Windows，`unicode` 形式是文件系统路径的规范表示法。

访问个别部分

为了访问路径独立的部分（组件），使用以下特征属性：

`PurePath.parts`

一个元组，可以访问路径的多个组件：

```
>>> p = PurePath('/usr/bin/python3')
>>> p.parts
('/', 'usr', 'bin', 'python3')

>>> p = PureWindowsPath('c:/Program Files/PSF')
>>> p.parts
('c:\\', 'Program Files', 'PSF')
```

（注意盘符和本地根目录是如何重组的）

方法和特征属性

纯路径提供以下方法和特征属性：

`PurePath.drive`

一个表示驱动器盘符或命名的字符串，如果存在：

```
>>> PureWindowsPath('c:/Program Files/').drive
'c:'
>>> PureWindowsPath('/Program Files/').drive
''
>>> PurePosixPath('/etc').drive
''
```

UNC 分享也被认作驱动器：

```
>>> PureWindowsPath('//host/share/foo.txt').drive
'\\\\host\\share'
```

`PurePath.root`

一个表示（本地或全局）根的字符串，如果存在：

```
>>> PureWindowsPath('c:/Program Files/').root
'\\'
>>> PureWindowsPath('c:Program Files/').root
''
>>> PurePosixPath('/etc').root
'/'
```

UNC 分享一样拥有根：

```
>>> PureWindowsPath('//host/share').root
'\\'
```

`PurePath.anchor`

驱动器和根的联合：

```
>>> PureWindowsPath('c:/Program Files/').anchor
'c:\\'
>>> PureWindowsPath('c:Program Files/').anchor
'c:'
>>> PurePosixPath('/etc').anchor
 '/'
>>> PureWindowsPath('//host/share').anchor
 '\\\\host\\share\\'
```

PurePath.parents

An immutable sequence providing access to the logical ancestors of the path:

```
>>> p = PureWindowsPath('c:/foo/bar/setup.py')
>>> p.parents[0]
PureWindowsPath('c:/foo/bar')
>>> p.parents[1]
PureWindowsPath('c:/foo')
>>> p.parents[2]
PureWindowsPath('c:/')
```

PurePath.parent

此路径的逻辑父路径:

```
>>> p = PurePosixPath('/a/b/c/d')
>>> p.parent
PurePosixPath('/a/b/c')
```

你不能超过一个 anchor 或空路径:

```
>>> p = PurePosixPath('/')
>>> p.parent
PurePosixPath('/')
>>> p = PurePosixPath('.')
>>> p.parent
PurePosixPath('.')
```

注解: 这是一个单纯的词法操作, 因此有以下行为:

```
>>> p = PurePosixPath('foo/..')
>>> p.parent
PurePosixPath('foo')
```

如果你想要向上移动任意文件系统路径, 推荐先使用 `Path.resolve()` 来解析符号链接以及消除 `".."` 组件。

PurePath.name

一个表示最后路径组件的字符串, 排除了驱动器与根目录, 如果存在的话:

```
>>> PurePosixPath('my/library/setup.py').name
'setup.py'
```

UNC 驱动器名不被考虑:

```
>>> PureWindowsPath('//some/share/setup.py').name
'setup.py'
```

(下页继续)

(续上页)

```
>>> PureWindowsPath('//some/share').name
''
```

PurePath.suffix

最后一个组件的文件扩展名，如果存在：

```
>>> PurePosixPath('my/library/setup.py').suffix
'.py'
>>> PurePosixPath('my/library.tar.gz').suffix
'.gz'
>>> PurePosixPath('my/library').suffix
''
```

PurePath.suffixes

路径的文件扩展名列表：

```
>>> PurePosixPath('my/library.tar.gar').suffixes
['.tar', '.gar']
>>> PurePosixPath('my/library.tar.gz').suffixes
['.tar', '.gz']
>>> PurePosixPath('my/library').suffixes
[]
```

PurePath.stem

最后一个路径组件，除去后缀：

```
>>> PurePosixPath('my/library.tar.gz').stem
'library.tar'
>>> PurePosixPath('my/library.tar').stem
'library'
>>> PurePosixPath('my/library').stem
'library'
```

PurePath.as_posix()

返回使用正斜杠 (/) 的路径字符串：

```
>>> p = PureWindowsPath('c:\\windows')
>>> str(p)
'c:\\windows'
>>> p.as_posix()
'c:/windows'
```

PurePath.as_uri()

将路径表示为 file URL。如果并非绝对路径，抛出 *ValueError*。

```
>>> p = PurePosixPath('/etc/passwd')
>>> p.as_uri()
'file:///etc/passwd'
>>> p = PureWindowsPath('c:/Windows')
>>> p.as_uri()
'file:///c:/Windows'
```

PurePath.is_absolute()

返回此路径是否为绝对路径。如果路径同时拥有驱动器符与根路径（如果风格允许）则将被认作绝对路径。

```

>>> PurePosixPath('/a/b').is_absolute()
True
>>> PurePosixPath('a/b').is_absolute()
False

>>> PureWindowsPath('c:/a/b').is_absolute()
True
>>> PureWindowsPath('/a/b').is_absolute()
False
>>> PureWindowsPath('c:').is_absolute()
False
>>> PureWindowsPath('//some/share').is_absolute()
True

```

PurePath.is_reserved()

在 *PureWindowsPath*, 如果路径是被 Windows 保留的则返回 True, 否则 False。在 *PurePosixPath*, 总是返回 False。

```

>>> PureWindowsPath('nul').is_reserved()
True
>>> PurePosixPath('nul').is_reserved()
False

```

当保留路径上的文件系统被调用, 则可能出现玄学失败或者意料之外的效应。

PurePath.joinpath(*other)

调用此方法等同于将每个 *other* 参数中的项目连接在一起:

```

>>> PurePosixPath('/etc').joinpath('passwd')
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath(PurePosixPath('passwd'))
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath('init.d', 'apache2')
PurePosixPath('/etc/init.d/apache2')
>>> PureWindowsPath('c:').joinpath('/Program Files')
PureWindowsPath('c:/Program Files')

```

PurePath.match(pattern)

将此路径与提供的通配符风格的模式匹配。如果匹配成功则返回 True, 否则返回 False。

如果 *pattern* 是相对的, 则路径可以是相对路径或绝对路径, 并且匹配是从右侧完成的:

```

>>> PurePath('a/b.py').match('*.py')
True
>>> PurePath('/a/b/c.py').match('b/*.py')
True
>>> PurePath('/a/b/c.py').match('a/*.py')
False

```

如果 *pattern* 是绝对的, 则路径必须是绝对的, 并且路径必须完全匹配:

```

>>> PurePath('/a.py').match('/*.py')
True
>>> PurePath('a/b.py').match('/*.py')
False

```

与其他方法一样, 可以观察到大小写区分:

```
>>> PureWindowsPath('b.py').match('*.PY')
True
```

`PurePath.relative_to(*other)`

计算此路径相对 *other* 表示路径的版本。如果不可计算，则抛出 `ValueError`：

```
>>> p = PurePosixPath('/etc/passwd')
>>> p.relative_to('/')
PurePosixPath('etc/passwd')
>>> p.relative_to('/etc')
PurePosixPath('passwd')
>>> p.relative_to('/usr')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 694, in relative_to
    .format(str(self), str(formatted)))
ValueError: '/etc/passwd' does not start with '/usr'
```

`PurePath.with_name(name)`

返回一个新的路径并修改 *name*。如果原本路径没有 *name*，`ValueError` 被抛出：

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_name('setup.py')
PureWindowsPath('c:/Downloads/setup.py')
>>> p = PureWindowsPath('c:/')
>>> p.with_name('setup.py')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/antoine/cpython/default/Lib/pathlib.py", line 751, in with_name
    raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

`PurePath.with_suffix(suffix)`

返回一个新的路径并修改 *suffix*。如果原本的路径没有后缀，新的 *suffix* 则被追加以代替。如果 *suffix* 是空字符串，则原本的后缀被移除：

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_suffix('.bz2')
PureWindowsPath('c:/Downloads/pathlib.tar.bz2')
>>> p = PureWindowsPath('README')
>>> p.with_suffix('.txt')
PureWindowsPath('README.txt')
>>> p = PureWindowsPath('README.txt')
>>> p.with_suffix('')
PureWindowsPath('README')
```

11.1.3 具体路径

具体路径是纯路径的子类。除了后者提供的操作之外，它们还提供了对路径对象进行系统调用的方法。有三种方法可以实例化具体路径：

class `pathlib.Path(*pathsegments)`

一个 `PurePath` 的子类，此类以当前系统的路径风格表示路径（实例化为 `PosixPath` 或 `WindowsPath`）：

```
>>> Path('setup.py')
PosixPath('setup.py')
```

pathsegments 参数的指定和 *PurePath* 相同。

class `pathlib.PosixPath(*pathsegments)`

一个 *Path* 和 *PurePosixPath* 的子类，此类表示一个非 Windows 文件系统的具体路径：

```
>>> PosixPath('/etc')
PosixPath('/etc')
```

pathsegments 参数的指定和 *PurePath* 相同。

class `pathlib.WindowsPath(*pathsegments)`

Path 和 *PureWindowsPath* 的子类，从类表示一个 Windows 文件系统的具体路径：

```
>>> WindowsPath('c:/Program Files/')
WindowsPath('c:/Program Files')
```

pathsegments 参数的指定和 *PurePath* 相同。

你只能实例化与当前系统风格相同的类（允许系统调用作用于不兼容的路径风格可能在应用程序中导致缺陷或失败）：

```
>>> import os
>>> os.name
'posix'
>>> Path('setup.py')
PosixPath('setup.py')
>>> PosixPath('setup.py')
PosixPath('setup.py')
>>> WindowsPath('setup.py')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 798, in __new__
    % (cls.__name__,))
NotImplementedError: cannot instantiate 'WindowsPath' on your system
```

方法

除纯路径方法外，具体路径还提供以下方法。如果系统调用失败（例如因为路径不存在），其中许多方法都会引发 *OSError*：

classmethod `Path.cwd()`

返回一个新的表示当前目录的路径对象（和 *os.getcwd()* 返回的相同）：

```
>>> Path.cwd()
PosixPath('/home/antoine/pathlib')
```

classmethod `Path.home()`

返回一个表示当前用户家目录的新路径对象（和 *os.path.expanduser()* 构造含 ~ 路径返回的相同）：

```
>>> Path.home()
PosixPath('/home/antoine')
```

3.5 新版功能.

`Path.stat()`

返回此路径的信息（类似于 `os.stat()`）。结果在每次调用此方法时都重新产生。

```
>>> p = Path('setup.py')
>>> p.stat().st_size
956
>>> p.stat().st_mtime
1327883547.852554
```

`Path.chmod(mode)`

改变文件的模式和权限，和 `os.chmod()` 一样：

```
>>> p = Path('setup.py')
>>> p.stat().st_mode
33277
>>> p.chmod(0o444)
>>> p.stat().st_mode
33060
```

`Path.exists()`

此路径是否指向一个已存在的文件或目录：

```
>>> Path('.').exists()
True
>>> Path('setup.py').exists()
True
>>> Path('/etc').exists()
True
>>> Path('nonexistentfile').exists()
False
```

注解： 如果路径指向一个符号链接，`exists()` 返回此符号链接是否指向存在的文件或目录。

`Path.expanduser()`

返回展开了包含 `~` 和 `~user` 的构造，就和 `os.path.expanduser()` 一样：

```
>>> p = PosixPath('~ /films/Monty Python')
>>> p.expanduser()
PosixPath('/home/eric/films/Monty Python')
```

3.5 新版功能.

`Path.glob(pattern)`

Glob the given *pattern* in the directory represented by this path, yielding all matching files (of any kind):

```
>>> sorted(Path('.').glob('*.py'))
[PosixPath('pathlib.py'), PosixPath('setup.py'), PosixPath('test_pathlib.py')]
>>> sorted(Path('.').glob('*/*.py'))
[PosixPath('docs/conf.py')]
```

“`***`” 模式表示 “此目录以及所有子目录，递归”。换句话说，它启用递归通配：

```
>>> sorted(Path('.').glob('**/*.py'))
[PosixPath('build/lib/pathlib.py'),
 PosixPath('docs/conf.py'),
 PosixPath('pathlib.py'),
```

(下页继续)

(续上页)

```
PosixPath('setup.py'),
PosixPath('test_pathlib.py')]
```

注解： 在一个较大的目录树中使用 “**” 模式可能会消耗非常多的时间。

Path.group()

返回拥有此文件的用户组。如果文件的 GID 无法在系统数据库中找到，将抛出 `KeyError`。

Path.is_dir()

如果路径指向一个目录（或者一个指向目录的符号链接）则返回 `True`，如果指向其他类型的文件则返回 `False`。

当路径不存在或者是一个破损的符号链接时也会返回 `False`；其他错误（例如权限错误）被传播。

Path.is_file()

如果路径指向一个正常的文件（或者一个指向正常文件的符号链接）则返回 `True`，如果指向其他类型的文件则返回 `False`。

当路径不存在或者是一个破损的符号链接时也会返回 `False`；其他错误（例如权限错误）被传播。

Path.is_symlink()

如果路径指向符号链接则返回 `True`，否则 `False`。

如果路径不存在也返回 `False`；其他错误（例如权限错误）被传播。

Path.is_socket()

如果路径指向一个 Unix socket 文件（或者指向 Unix socket 文件的符号链接）则返回 `True`，如果指向其他类型的文件则返回 `False`。

当路径不存在或者是一个破损的符号链接时也会返回 `False`；其他错误（例如权限错误）被传播。

Path.is_fifo()

如果路径指向一个先进先出存储（或者指向先进先出存储的符号链接）则返回 `True`，指向其他类型的文件则返回 `False`。

当路径不存在或者是一个破损的符号链接时也会返回 `False`；其他错误（例如权限错误）被传播。

Path.is_block_device()

如果文件指向一个块设备（或者指向块设备的符号链接）则返回 `True`，指向其他类型的文件则返回 `False`。

当路径不存在或者是一个破损的符号链接时也会返回 `False`；其他错误（例如权限错误）被传播。

Path.is_char_device()

如果路径指向一个字符设备（或指向字符设备的符号链接）则返回 `True`，指向其他类型的文件则返回 `False`。

当路径不存在或者是一个破损的符号链接时也会返回 `False`；其他错误（例如权限错误）被传播。

Path.iterdir()

当路径指向一个目录时，产生该路径下的对象的路径：

```
>>> p = Path('docs')
>>> for child in p.iterdir(): child
...
PosixPath('docs/conf.py')
PosixPath('docs/_templates')
PosixPath('docs/make.bat')
PosixPath('docs/index.rst')
```

(下页继续)

(续上页)

```
PosixPath('docs/_build')
PosixPath('docs/_static')
PosixPath('docs/Makefile')
```

Path.lchmod(mode)

就像 `Path.chmod()` 但是如果路径指向符号链接则是修改符号链接的模式，而不是修改符号链接的目标。

Path.lstat()

就和 `Path.stat()` 一样，但是如果路径指向符号链接，则是返回符号链接而不是目标的信息。

Path.mkdir(mode=0o777, parents=False, exist_ok=False)

新建给定路径的目录。如果给出了 `mode`，它将与当前进程的 `umask` 值合并来决定文件模式和访问标志。如果路径已经存在，则抛出 `FileExistsError`。

如果 `parents` 为 `true`，任何找不到的父目录都会伴随着此路径被创建；它们会以默认权限被创建，而不考虑 `mode` 设置（模仿 POSIX 的 `mkdir -p` 命令）。

如果 `parents` 为 `false`（默认），则找不到的父级目录会导致 `FileNotFoundError` 被抛出。

如果 `exist_ok` 为 `false`（默认），则在目标已存在的情况下抛出 `FileExistsError`。

如果 `exist_ok` 为 `true`，则 `FileExistsError` 异常将被忽略（和 POSIX `mkdir -p` 命令行为相同），但是只有在最后一个路径组件不是现存的非目录文件时才生效。

在 3.5 版更改: `exist_ok` 形参被加入。

Path.open(mode='r', buffering=-1, encoding=None, errors=None, newline=None)

打开路径指向的文件，就像内置的 `open()` 函数所做的一样：

```
>>> p = Path('setup.py')
>>> with p.open() as f:
...     f.readline()
...
'#!/usr/bin/env python3\n'
```

Path.owner()

返回拥有此文件的用户名。如果文件的 UID 无法在系统数据库中找到，则抛出 `KeyError`。

Path.read_bytes()

以字节对象的形式返回路径指向的文件的二进制内容：

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

3.5 新版功能。

Path.read_text(encoding=None, errors=None)

以字符串形式返回路径指向的文件的解码后文本内容。

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

文件先被打开然后关闭。有和 `open()` 一样的可选形参。

3.5 新版功能.

`Path.rename(target)`

使用给定的 *target* 将文件重命名。在 Unix 上, 如果 *target* 已经存在并且为文件, 则只要用户拥有权限, 其将被静默地被覆盖。*target* 可以是一个字符串或者另一个路径对象:

```
>>> p = Path('foo')
>>> p.open('w').write('some text')
9
>>> target = Path('bar')
>>> p.rename(target)
>>> target.open().read()
'some text'
```

`Path.replace(target)`

使用给定的 *target* 重命名文件或目录。如果 *target* 指向现存的文件或目录, 则将被无条件覆盖。

`Path.resolve(strict=False)`

将路径绝对化, 解析任何符号链接。返回新的路径对象:

```
>>> p = Path()
>>> p
PosixPath('.')
>>> p.resolve()
PosixPath('/home/antoine/pathlib')
```

“..” 组件也将被消除 (只有这一种方法这么做):

```
>>> p = Path('docs/../setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
```

如果路径不存在并且 *strict* 设为 `True`, 则抛出 `FileNotFoundError`。如果 *strict* 为 `False`, 则路径将被尽可能地解析并且任何剩余部分都会被不检查是否存在地追加。如果在解析路径上发生无限循环, 则抛出 `RuntimeError`。

3.6 新版功能: The *strict* argument.

`Path.rglob(pattern)`

This is like calling `Path.glob()` with “**” added in front of the given *pattern*:

```
>>> sorted(Path().rglob("*.py"))
[PosixPath('build/lib/pathlib.py'),
 PosixPath('docs/conf.py'),
 PosixPath('pathlib.py'),
 PosixPath('setup.py'),
 PosixPath('test_pathlib.py')]
```

`Path.rmdir()`

移除此目录。此目录必须为空的。

`Path.samefile(other_path)`

返回此目录是否指向与可能是字符串或者另一个路径对象的 *other_path* 相同的文件。语义类似于 `os.path.samefile()` 与 `os.path.samestat()`。

如果两者都以同一原因无法访问, 则抛出 `OSError`。

```
>>> p = Path('spam')
>>> q = Path('eggs')
>>> p.samefile(q)
False
>>> p.samefile('spam')
True
```

3.5 新版功能.

`Path.symlink_to(target, target_is_directory=False)`

将此路径创建为指向 *target* 的符号链接。在 Windows 下，如果链接的目标是一个目录则 *target_is_directory* 必须为 `true`（默认为 `False`）。在 POSIX 下，*target_is_directory* 的值将被忽略。

```
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
>>> p.stat().st_size
956
>>> p.lstat().st_size
8
```

注解： 参数的顺序 (*link, target*) 和 `os.symlink()` 是相反的。

`Path.touch(mode=0o666, exist_ok=True)`

将给定的路径创建为文件。如果给出了 *mode* 它将与当前进程的 `umask` 值合并以确定文件的模式和访问标志。如果文件已经存在，则当 *exist_ok* 为 `true` 则函数仍会成功（并且将它的修改事件更新为当前事件），否则抛出 `FileExistsError`。

`Path.unlink()`

移除此文件或符号链接。如果路径指向目录，则用 `Path.rmdir()` 代替。

`Path.write_bytes(data)`

将文件以二进制模式打开，写入 *data* 并关闭：

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

一个同名的现存文件将被覆盖。

3.5 新版功能.

`Path.write_text(data, encoding=None, errors=None)`

将文件以文本模式打开，写入 *data* 并关闭：

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

3.5 新版功能.

11.2 `os.path` — 常见路径操作

源代码: `Lib/posixpath.py` (适用 POSIX), `Lib/ntpath.py` (适用 Windows NT), and `Lib/macpath.py` (适用 Macintosh)

This module implements some useful functions on pathnames. To read or write files see `open()`, and for accessing the filesystem see the `os` module. The path parameters can be passed as either strings, or bytes. Applications are encouraged to represent file names as (Unicode) character strings. Unfortunately, some file names may not be representable as strings on Unix, so applications that need to support arbitrary file names on Unix should use bytes objects to represent path names. Vice versa, using bytes objects cannot represent all file names on Windows (in the standard `mbcs` encoding), hence Windows applications should use string objects to access all files.

Unlike a unix shell, Python does not do any *automatic* path expansions. Functions such as `expanduser()` and `expandvars()` can be invoked explicitly when an application desires shell-like path expansion. (See also the `glob` module.)

参见:

The `pathlib` module offers high-level path objects.

注解: All of these functions accept either only bytes or only string objects as their parameters. The result is an object of the same type, if a path or file name is returned.

注解: Since different operating systems have different path name conventions, there are several versions of this module in the standard library. The `os.path` module is always the path module suitable for the operating system Python is running on, and therefore usable for local paths. However, you can also import and use the individual modules if you want to manipulate a path that is *always* in one of the different formats. They all have the same interface:

- `posixpath` for UNIX-style paths
- `ntpath` for Windows paths
- `macpath` for old-style MacOS paths

`os.path.abspath(path)`

Return a normalized absolutized version of the pathname `path`. On most platforms, this is equivalent to calling the function `normpath()` as follows: `normpath(join(os.getcwd(), path))`.

在 3.6 版更改: 接受一个类路径对象。

`os.path.basename(path)`

Return the base name of pathname `path`. This is the second element of the pair returned by passing `path` to the function `split()`. Note that the result of this function is different from the Unix `basename` program; where `basename` for `'/foo/bar/'` returns `'bar'`, the `basename()` function returns an empty string `''`.

在 3.6 版更改: 接受一个类路径对象。

`os.path.commonpath(paths)`

Return the longest common sub-path of each pathname in the sequence `paths`. Raise `ValueError` if `paths` contains both absolute and relative pathnames, or if `paths` is empty. Unlike `commonprefix()`, this returns a valid path.

Availability: Unix, Windows

3.5 新版功能.

在 3.6 版更改: Accepts a sequence of *path-like objects*.

`os.path.commonprefix(list)`

Return the longest path prefix (taken character-by-character) that is a prefix of all paths in *list*. If *list* is empty, return the empty string ('').

注解: This function may return invalid paths because it works a character at a time. To obtain a valid path, see `commonpath()`.

```
>>> os.path.commonprefix(['/usr/lib', '/usr/local/lib'])
'/usr/l'

>>> os.path.commonpath(['/usr/lib', '/usr/local/lib'])
'/usr'
```

在 3.6 版更改: 接受一个类路径对象。

`os.path.dirname(path)`

Return the directory name of pathname *path*. This is the first element of the pair returned by passing *path* to the function `split()`.

在 3.6 版更改: 接受一个类路径对象。

`os.path.exists(path)`

Return True if *path* refers to an existing path or an open file descriptor. Returns False for broken symbolic links. On some platforms, this function may return False if permission is not granted to execute `os.stat()` on the requested file, even if the *path* physically exists.

在 3.3 版更改: *path* can now be an integer: True is returned if it is an open file descriptor, False otherwise.

在 3.6 版更改: 接受一个类路径对象。

`os.path.lexists(path)`

Return True if *path* refers to an existing path. Returns True for broken symbolic links. Equivalent to `exists()` on platforms lacking `os.lstat()`.

在 3.6 版更改: 接受一个类路径对象。

`os.path.expanduser(path)`

On Unix and Windows, return the argument with an initial component of ~ or ~user replaced by that *user*'s home directory.

On Unix, an initial ~ is replaced by the environment variable HOME if it is set; otherwise the current user's home directory is looked up in the password directory through the built-in module `pwd`. An initial ~user is looked up directly in the password directory.

On Windows, HOME and USERPROFILE will be used if set, otherwise a combination of HOMEPATH and HOMEDRIVE will be used. An initial ~user is handled by stripping the last directory component from the created user path derived above.

If the expansion fails or if the path does not begin with a tilde, the path is returned unchanged.

在 3.6 版更改: 接受一个类路径对象。

`os.path.expandvars(path)`

Return the argument with environment variables expanded. Substrings of the form \$name or \${name} are replaced by the value of environment variable *name*. Malformed variable names and references to non-existing variables are left unchanged.

On Windows, %name% expansions are supported in addition to \$name and \${name}.

在 3.6 版更改: 接受一个类路径对象。

`os.path.getatime(path)`

Return the time of last access of *path*. The return value is a number giving the number of seconds since the epoch (see the *time* module). Raise *OSError* if the file does not exist or is inaccessible.

If `os.stat_float_times()` returns *True*, the result is a floating point number.

`os.path.getmtime(path)`

Return the time of last modification of *path*. The return value is a number giving the number of seconds since the epoch (see the *time* module). Raise *OSError* if the file does not exist or is inaccessible.

If `os.stat_float_times()` returns *True*, the result is a floating point number.

在 3.6 版更改: 接受一个类路径对象。

`os.path.getctime(path)`

Return the system's ctime which, on some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time for *path*. The return value is a number giving the number of seconds since the epoch (see the *time* module). Raise *OSError* if the file does not exist or is inaccessible.

在 3.6 版更改: 接受一个类路径对象。

`os.path.getsize(path)`

Return the size, in bytes, of *path*. Raise *OSError* if the file does not exist or is inaccessible.

在 3.6 版更改: 接受一个类路径对象。

`os.path.isabs(path)`

Return *True* if *path* is an absolute pathname. On Unix, that means it begins with a slash, on Windows that it begins with a (back)slash after chopping off a potential drive letter.

在 3.6 版更改: 接受一个类路径对象。

`os.path.isfile(path)`

Return *True* if *path* is an *existing* regular file. This follows symbolic links, so both *islink()* and *isfile()* can be true for the same path.

在 3.6 版更改: 接受一个类路径对象。

`os.path.isdir(path)`

Return *True* if *path* is an *existing* directory. This follows symbolic links, so both *islink()* and *isdir()* can be true for the same path.

在 3.6 版更改: 接受一个类路径对象。

`os.path.islink(path)`

Return *True* if *path* refers to an *existing* directory entry that is a symbolic link. Always *False* if symbolic links are not supported by the Python runtime.

在 3.6 版更改: 接受一个类路径对象。

`os.path.ismount(path)`

Return *True* if pathname *path* is a *mount point*: a point in a file system where a different file system has been mounted. On POSIX, the function checks whether *path*'s parent, *path/..*, is on a different device than *path*, or whether *path/..* and *path* point to the same i-node on the same device —this should detect mount points for all Unix and POSIX variants. On Windows, a drive letter root and a share UNC are always mount points, and for any other path *GetVolumePathName* is called to see if it is different from the input path.

3.4 新版功能: Support for detecting non-root mount points on Windows.

在 3.6 版更改: 接受一个类路径对象。

`os.path.join(path, *paths)`

Join one or more path components intelligently. The return value is the concatenation of *path* and any members of **paths* with exactly one directory separator (`os.sep`) following each non-empty part except the last, meaning

that the result will only end in a separator if the last part is empty. If a component is an absolute path, all previous components are thrown away and joining continues from the absolute path component.

On Windows, the drive letter is not reset when an absolute path component (e.g., `r'\foo'`) is encountered. If a component contains a drive letter, all previous components are thrown away and the drive letter is reset. Note that since there is a current directory for each drive, `os.path.join("c:", "foo")` represents a path relative to the current directory on drive C: (`c:foo`), not `c:\foo`.

在 3.6 版更改: Accepts a *path-like object* for *path* and *paths*.

`os.path.normcase(path)`

Normalize the case of a pathname. On Unix and Mac OS X, this returns the path unchanged; on case-insensitive filesystems, it converts the path to lowercase. On Windows, it also converts forward slashes to backward slashes. Raise a `TypeError` if the type of *path* is not `str` or `bytes` (directly or indirectly through the `os.PathLike` interface).

在 3.6 版更改: 接受一个类路径对象。

`os.path.normpath(path)`

Normalize a pathname by collapsing redundant separators and up-level references so that `A//B`, `A/B/`, `A/./B` and `A/foo/./B` all become `A/B`. This string manipulation may change the meaning of a path that contains symbolic links. On Windows, it converts forward slashes to backward slashes. To normalize case, use `normcase()`.

在 3.6 版更改: 接受一个类路径对象。

`os.path.realpath(path)`

Return the canonical path of the specified filename, eliminating any symbolic links encountered in the path (if they are supported by the operating system).

在 3.6 版更改: 接受一个类路径对象。

`os.path.relpath(path, start=os.curdir)`

Return a relative filepath to *path* either from the current directory or from an optional *start* directory. This is a path computation: the filesystem is not accessed to confirm the existence or nature of *path* or *start*.

start defaults to `os.curdir`.

Availability: Unix, Windows.

在 3.6 版更改: 接受一个类路径对象。

`os.path.samefile(path1, path2)`

Return `True` if both pathname arguments refer to the same file or directory. This is determined by the device number and i-node number and raises an exception if an `os.stat()` call on either pathname fails.

Availability: Unix, Windows.

在 3.2 版更改: Added Windows support.

在 3.4 版更改: Windows now uses the same implementation as all other platforms.

在 3.6 版更改: 接受一个类路径对象。

`os.path.sameopenfile(fp1, fp2)`

Return `True` if the file descriptors *fp1* and *fp2* refer to the same file.

Availability: Unix, Windows.

在 3.2 版更改: Added Windows support.

在 3.6 版更改: 接受一个类路径对象。

`os.path.samestat(stat1, stat2)`

Return `True` if the stat tuples *stat1* and *stat2* refer to the same file. These structures may have been returned by

`os.fstat()`, `os.lstat()`, or `os.stat()`. This function implements the underlying comparison used by `samefile()` and `sameopenfile()`.

Availability: Unix, Windows.

在 3.4 版更改: Added Windows support.

在 3.6 版更改: 接受一个类路径对象。

`os.path.split(path)`

Split the pathname *path* into a pair, (*head*, *tail*) where *tail* is the last pathname component and *head* is everything leading up to that. The *tail* part will never contain a slash; if *path* ends in a slash, *tail* will be empty. If there is no slash in *path*, *head* will be empty. If *path* is empty, both *head* and *tail* are empty. Trailing slashes are stripped from *head* unless it is the root (one or more slashes only). In all cases, `join(head, tail)` returns a path to the same location as *path* (but the strings may differ). Also see the functions `dirname()` and `basename()`.

在 3.6 版更改: 接受一个类路径对象。

`os.path.splitdrive(path)`

Split the pathname *path* into a pair (*drive*, *tail*) where *drive* is either a mount point or the empty string. On systems which do not use drive specifications, *drive* will always be the empty string. In all cases, *drive* + *tail* will be the same as *path*.

On Windows, splits a pathname into drive/UNC sharepoint and relative path.

If the path contains a drive letter, *drive* will contain everything up to and including the colon. e.g. `splitdrive("c:/dir")` returns ("c:", "/dir")

If the path contains a UNC path, *drive* will contain the host name and share, up to but not including the fourth separator. e.g. `splitdrive("//host/computer/dir")` returns ("//host/computer", "/dir")

在 3.6 版更改: 接受一个类路径对象。

`os.path.splitext(path)`

Split the pathname *path* into a pair (*root*, *ext*) such that *root* + *ext* == *path*, and *ext* is empty or begins with a period and contains at most one period. Leading periods on the basename are ignored; `splitext('.cshrc')` returns ('.cshrc', '').

在 3.6 版更改: 接受一个类路径对象。

`os.path.splitunc(path)`

3.1 版后已移除: Use `splitdrive` instead.

Split the pathname *path* into a pair (*unc*, *rest*) so that *unc* is the UNC mount point (such as `r'\\host\\mount'`), if present, and *rest* the rest of the path (such as `r'\\path\\file.ext'`). For paths containing drive letters, *unc* will always be the empty string.

Availability: Windows.

`os.path.supports_unicode_filenames`

True if arbitrary Unicode strings can be used as file names (within limitations imposed by the file system).

11.3 fileinput —Iterate over lines from multiple input streams

Source code: [Lib/fileinput.py](#)

This module implements a helper class and functions to quickly write a loop over standard input or a list of files. If you just want to read or write one file see `open()`.

The typical use is:

```
import fileinput
for line in fileinput.input():
    process(line)
```

This iterates over the lines of all files listed in `sys.argv[1:]`, defaulting to `sys.stdin` if the list is empty. If a filename is `'-'`, it is also replaced by `sys.stdin`. To specify an alternative list of filenames, pass it as the first argument to `input()`. A single file name is also allowed.

All files are opened in text mode by default, but you can override this by specifying the *mode* parameter in the call to `input()` or `FileInput`. If an I/O error occurs during opening or reading a file, `OSError` is raised.

在 3.3 版更改: `IOError` used to be raised; it is now an alias of `OSError`.

If `sys.stdin` is used more than once, the second and further use will return no lines, except perhaps for interactive use, or if it has been explicitly reset (e.g. using `sys.stdin.seek(0)`).

Empty files are opened and immediately closed; the only time their presence in the list of filenames is noticeable at all is when the last file opened is empty.

Lines are returned with any newlines intact, which means that the last line in a file may not have one.

You can control how files are opened by providing an opening hook via the *openhook* parameter to `fileinput.input()` or `FileInput`. The hook must be a function that takes two arguments, *filename* and *mode*, and returns an accordingly opened file-like object. Two useful hooks are already provided by this module.

The following function is the primary interface of this module:

`fileinput.input(files=None, inplace=False, backup="", bufsize=0, mode='r', openhook=None)`

Create an instance of the `FileInput` class. The instance will be used as global state for the functions of this module, and is also returned to use during iteration. The parameters to this function will be passed along to the constructor of the `FileInput` class.

The `FileInput` instance can be used as a context manager in the `with` statement. In this example, `input` is closed after the `with` statement is exited, even if an exception occurs:

```
with fileinput.input(files=('spam.txt', 'eggs.txt')) as f:
    for line in f:
        process(line)
```

在 3.2 版更改: Can be used as a context manager.

Deprecated since version 3.6, will be removed in version 3.8: The *bufsize* parameter.

The following functions use the global state created by `fileinput.input()`; if there is no active state, `RuntimeError` is raised.

`fileinput.filename()`

Return the name of the file currently being read. Before the first line has been read, returns `None`.

`fileinput.fileno()`

Return the integer “file descriptor” for the current file. When no file is opened (before the first line and between files), returns `-1`.

`fileinput.lineno()`

Return the cumulative line number of the line that has just been read. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line.

`fileinput.filelineno()`

Return the line number in the current file. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line within the file.

`fileinput.isfirstline()`

Returns true if the line just read is the first line of its file, otherwise returns false.

`fileinput.isstdin()`

Returns true if the last line was read from `sys.stdin`, otherwise returns false.

`fileinput.nextfile()`

Close the current file so that the next iteration will read the first line from the next file (if any); lines not read from the file will not count towards the cumulative line count. The filename is not changed until after the first line of the next file has been read. Before the first line has been read, this function has no effect; it cannot be used to skip the first file. After the last line of the last file has been read, this function has no effect.

`fileinput.close()`

Close the sequence.

The class which implements the sequence behavior provided by the module is available for subclassing as well:

class `fileinput.FileInput` (*files=None*, *inplace=False*, *backup=""*, *bufsize=0*, *mode='r'*, *openhook=None*)

Class `FileInput` is the implementation; its methods `filename()`, `fileno()`, `lineno()`, `filelineno()`, `isfirstline()`, `isstdin()`, `nextfile()` and `close()` correspond to the functions of the same name in the module. In addition it has a `readline()` method which returns the next input line, and a `__getitem__()` method which implements the sequence behavior. The sequence must be accessed in strictly sequential order; random access and `readline()` cannot be mixed.

With *mode* you can specify which file mode will be passed to `open()`. It must be one of `'r'`, `'rU'`, `'U'` and `'rb'`.

The *openhook*, when given, must be a function that takes two arguments, *filename* and *mode*, and returns an accordingly opened file-like object. You cannot use *inplace* and *openhook* together.

A `FileInput` instance can be used as a context manager in the `with` statement. In this example, *input* is closed after the `with` statement is exited, even if an exception occurs:

```
with FileInput(files=('spam.txt', 'eggs.txt')) as input:
    process(input)
```

在 3.2 版更改: Can be used as a context manager.

3.4 版后已移除: The `'rU'` and `'U'` modes.

Deprecated since version 3.6, will be removed in version 3.8: The *bufsize* parameter.

Optional in-place filtering: if the keyword argument *inplace=True* is passed to `fileinput.input()` or to the `FileInput` constructor, the file is moved to a backup file and standard output is directed to the input file (if a file of the same name as the backup file already exists, it will be replaced silently). This makes it possible to write a filter that rewrites its input file in place. If the *backup* parameter is given (typically as *backup='.<some extension>'*), it specifies the extension for the backup file, and the backup file remains around; by default, the extension is `'.bak'` and it is deleted when the output file is closed. In-place filtering is disabled when standard input is read.

The two following opening hooks are provided by this module:

`fileinput.hook_compressed(filename, mode)`

Transparently opens files compressed with `gzip` and `bzip2` (recognized by the extensions `'.gz'` and `'.bz2'`) using the `gzip` and `bz2` modules. If the filename extension is not `'.gz'` or `'.bz2'`, the file is opened normally (ie, using `open()` without any decompression).

Usage example: `fi = fileinput.FileInput(openhook=fileinput.hook_compressed)`

`fileinput.hook_encoded(encoding, errors=None)`

Returns a hook which opens each file with `open()`, using the given *encoding* and *errors* to read the file.

```
Usage          example:          fi = fileinput.FileInput(openhook=fileinput.
hook_encoded("utf-8", "surrogateescape"))
```

在 3.6 版更改: Added the optional *errors* parameter.

11.4 stat —Interpreting stat () results

Source code: [Lib/stat.py](#)

The *stat* module defines constants and functions for interpreting the results of *os.stat()*, *os.fstat()* and *os.lstat()* (if they exist). For complete details about the *stat()*, *fstat()* and *lstat()* calls, consult the documentation for your system.

在 3.4 版更改: The *stat* module is backed by a C implementation.

The *stat* module defines the following functions to test for specific file types:

stat.S_ISDIR(mode)

Return non-zero if the mode is from a directory.

stat.S_ISCHR(mode)

Return non-zero if the mode is from a character special device file.

stat.S_ISBLK(mode)

Return non-zero if the mode is from a block special device file.

stat.S_ISREG(mode)

Return non-zero if the mode is from a regular file.

stat.S_ISFIFO(mode)

Return non-zero if the mode is from a FIFO (named pipe).

stat.S_ISLNK(mode)

Return non-zero if the mode is from a symbolic link.

stat.S_ISSOCK(mode)

Return non-zero if the mode is from a socket.

stat.S_ISDOOR(mode)

Return non-zero if the mode is from a door.

3.4 新版功能.

stat.S_ISPORT(mode)

Return non-zero if the mode is from an event port.

3.4 新版功能.

stat.S_ISWHT(mode)

Return non-zero if the mode is from a whiteout.

3.4 新版功能.

Two additional functions are defined for more general manipulation of the file's mode:

stat.S_IMODE(mode)

Return the portion of the file's mode that can be set by *os.chmod()*—that is, the file's permission bits, plus the sticky bit, set-group-id, and set-user-id bits (on systems that support them).

stat.S_IFMT(mode)

Return the portion of the file's mode that describes the file type (used by the *S_IS**() functions above).

Normally, you would use the `os.path.is*()` functions for testing the type of a file; the functions here are useful when you are doing multiple tests of the same file and wish to avoid the overhead of the `stat()` system call for each test. These are also useful when checking for information about a file that isn't handled by `os.path`, like the tests for block and character devices.

示例:

```
import os, sys
from stat import *

def walktree(top, callback):
    '''recursively descend the directory tree rooted at top,
       calling the callback function for each regular file'''

    for f in os.listdir(top):
        pathname = os.path.join(top, f)
        mode = os.stat(pathname).st_mode
        if S_ISDIR(mode):
            # It's a directory, recurse into it
            walktree(pathname, callback)
        elif S_ISREG(mode):
            # It's a file, call the callback function
            callback(pathname)
        else:
            # Unknown file type, print a message
            print('Skipping %s' % pathname)

def visitfile(file):
    print('visiting', file)

if __name__ == '__main__':
    walktree(sys.argv[1], visitfile)
```

An additional utility function is provided to convert a file's mode in a human readable string:

`stat.filemode(mode)`
Convert a file's mode to a string of the form `'-rwxrwxrwx'`.

3.3 新版功能.

在 3.4 版更改: The function supports `S_IFDOOR`, `S_IFPORT` and `S_IFWHT`.

All the variables below are simply symbolic indexes into the 10-tuple returned by `os.stat()`, `os.fstat()` or `os.lstat()`.

`stat.ST_MODE`
Inode protection mode.

`stat.ST_INO`
Inode number.

`stat.ST_DEV`
Device inode resides on.

`stat.ST_NLINK`
Number of links to the inode.

`stat.ST_UID`
User id of the owner.

`stat.ST_GID`
Group id of the owner.

`stat.ST_SIZE`

Size in bytes of a plain file; amount of data waiting on some special files.

`stat.ST_ATIME`

Time of last access.

`stat.ST_MTIME`

Time of last modification.

`stat.ST_CTIME`

The “ctime” as reported by the operating system. On some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time (see platform documentation for details).

The interpretation of “file size” changes according to the file type. For plain files this is the size of the file in bytes. For FIFOs and sockets under most flavors of Unix (including Linux in particular), the “size” is the number of bytes waiting to be read at the time of the call to `os.stat()`, `os.fstat()`, or `os.lstat()`; this can sometimes be useful, especially for polling one of these special files after a non-blocking open. The meaning of the size field for other character and block devices varies more, depending on the implementation of the underlying system call.

The variables below define the flags used in the `ST_MODE` field.

Use of the functions above is more portable than use of the first set of flags:

`stat.S_IFSOCK`

Socket.

`stat.S_IFLNK`

Symbolic link.

`stat.S_IFREG`

Regular file.

`stat.S_IFBLK`

Block device.

`stat.S_IFDIR`

Directory.

`stat.S_IFCHR`

Character device.

`stat.S_IFIFO`

FIFO.

`stat.S_IFDOOR`

Door.

3.4 新版功能.

`stat.S_IFPORT`

Event port.

3.4 新版功能.

`stat.S_IFWHT`

Whiteout.

3.4 新版功能.

注解: `S_IFDOOR`, `S_IFPORT` or `S_IFWHT` are defined as 0 when the platform does not have support for the file types.

The following flags can also be used in the *mode* argument of `os.chmod()`:

`stat.S_ISUID`
Set UID bit.

`stat.S_ISGID`
Set-group-ID bit. This bit has several special uses. For a directory it indicates that BSD semantics is to be used for that directory: files created there inherit their group ID from the directory, not from the effective group ID of the creating process, and directories created there will also get the `S_ISGID` bit set. For a file that does not have the group execution bit (`S_IXGRP`) set, the set-group-ID bit indicates mandatory file/record locking (see also `S_ENFMT`).

`stat.S_ISVTX`
Sticky bit. When this bit is set on a directory it means that a file in that directory can be renamed or deleted only by the owner of the file, by the owner of the directory, or by a privileged process.

`stat.S_IRWXU`
Mask for file owner permissions.

`stat.S_IRUSR`
Owner has read permission.

`stat.S_IWUSR`
Owner has write permission.

`stat.S_IXUSR`
Owner has execute permission.

`stat.S_IRWXG`
Mask for group permissions.

`stat.S_IRGRP`
Group has read permission.

`stat.S_IWGRP`
Group has write permission.

`stat.S_IXGRP`
Group has execute permission.

`stat.S_IRWXO`
Mask for permissions for others (not in group).

`stat.S_IROTH`
Others have read permission.

`stat.S_IWOTH`
Others have write permission.

`stat.S_IXOTH`
Others have execute permission.

`stat.S_ENFMT`
System V file locking enforcement. This flag is shared with `S_ISGID`: file/record locking is enforced on files that do not have the group execution bit (`S_IXGRP`) set.

`stat.S_IREAD`
Unix V7 synonym for `S_IRUSR`.

`stat.S_IWRITE`
Unix V7 synonym for `S_IWUSR`.

`stat.S_IXEXEC`

Unix V7 synonym for `S_IXUSR`.

The following flags can be used in the *flags* argument of `os.chflags()`:

`stat.UF_NODUMP`

Do not dump the file.

`stat.UF_IMMUTABLE`

The file may not be changed.

`stat.UF_APPEND`

The file may only be appended to.

`stat.UF_OPAQUE`

The directory is opaque when viewed through a union stack.

`stat.UF_NOUNLINK`

The file may not be renamed or deleted.

`stat.UF_COMPRESSED`

The file is stored compressed (Mac OS X 10.6+).

`stat.UF_HIDDEN`

The file should not be displayed in a GUI (Mac OS X 10.5+).

`stat.SF_ARCHIVED`

The file may be archived.

`stat.SF_IMMUTABLE`

The file may not be changed.

`stat.SF_APPEND`

The file may only be appended to.

`stat.SF_NOUNLINK`

The file may not be renamed or deleted.

`stat.SF_SNAPSHOT`

The file is a snapshot file.

See the *BSD or Mac OS systems man page `chflags(2)` for more information.

On Windows, the following file attribute constants are available for use when testing bits in the `st_file_attributes` member returned by `os.stat()`. See the [Windows API documentation](#) for more detail on the meaning of these constants.

`stat.FILE_ATTRIBUTE_ARCHIVE`

`stat.FILE_ATTRIBUTE_COMPRESSED`

`stat.FILE_ATTRIBUTE_DEVICE`

`stat.FILE_ATTRIBUTE_DIRECTORY`

`stat.FILE_ATTRIBUTE_ENCRYPTED`

`stat.FILE_ATTRIBUTE_HIDDEN`

`stat.FILE_ATTRIBUTE_INTEGRITY_STREAM`

`stat.FILE_ATTRIBUTE_NORMAL`

`stat.FILE_ATTRIBUTE_NOT_CONTENT_INDEXED`

`stat.FILE_ATTRIBUTE_NO_SCRUB_DATA`

`stat.FILE_ATTRIBUTE_OFFLINE`

`stat.FILE_ATTRIBUTE_READONLY`

`stat.FILE_ATTRIBUTE_REPARSE_POINT`

`stat.FILE_ATTRIBUTE_SPARSE_FILE`

`stat.FILE_ATTRIBUTE_SYSTEM`

`stat.FILE_ATTRIBUTE_TEMPORARY`
`stat.FILE_ATTRIBUTE_VIRTUAL`
 3.5 新版功能.

11.5 filecmp —File and Directory Comparisons

Source code: [Lib/filecmp.py](#)

The *filecmp* module defines functions to compare files and directories, with various optional time/correctness trade-offs. For comparing files, see also the *difflib* module.

The *filecmp* module defines the following functions:

`filecmp.cmp(f1, f2, shallow=True)`

Compare the files named *f1* and *f2*, returning `True` if they seem equal, `False` otherwise.

If *shallow* is true, files with identical `os.stat()` signatures are taken to be equal. Otherwise, the contents of the files are compared.

Note that no external programs are called from this function, giving it portability and efficiency.

This function uses a cache for past comparisons and the results, with cache entries invalidated if the `os.stat()` information for the file changes. The entire cache may be cleared using `clear_cache()`.

`filecmp.cmpfiles(dir1, dir2, common, shallow=True)`

Compare the files in the two directories *dir1* and *dir2* whose names are given by *common*.

Returns three lists of file names: *match*, *mismatch*, *errors*. *match* contains the list of files that match, *mismatch* contains the names of those that don't, and *errors* lists the names of files which could not be compared. Files are listed in *errors* if they don't exist in one of the directories, the user lacks permission to read them or if the comparison could not be done for some other reason.

The *shallow* parameter has the same meaning and default value as for `filecmp.cmp()`.

For example, `cmpfiles('a', 'b', ['c', 'd/e'])` will compare *a/c* with *b/c* and *a/d/e* with *b/d/e*. *'c'* and *'d/e'* will each be in one of the three returned lists.

`filecmp.clear_cache()`

Clear the filecmp cache. This may be useful if a file is compared so quickly after it is modified that it is within the mtime resolution of the underlying filesystem.

3.4 新版功能.

11.5.1 The dircmp class

`class filecmp.dircmp(a, b, ignore=None, hide=None)`

Construct a new directory comparison object, to compare the directories *a* and *b*. *ignore* is a list of names to ignore, and defaults to `filecmp.DEFAULT_IGNORES`. *hide* is a list of names to hide, and defaults to `[os.curdir, os.pardir]`.

The *dircmp* class compares files by doing *shallow* comparisons as described for `filecmp.cmp()`.

The *dircmp* class provides the following methods:

`report()`

Print (to `sys.stdout`) a comparison between *a* and *b*.

report_partial_closure()

Print a comparison between *a* and *b* and common immediate subdirectories.

report_full_closure()

Print a comparison between *a* and *b* and common subdirectories (recursively).

The `dircmp` class offers a number of interesting attributes that may be used to get various bits of information about the directory trees being compared.

Note that via `__getattr__()` hooks, all attributes are computed lazily, so there is no speed penalty if only those attributes which are lightweight to compute are used.

left

The directory *a*.

right

The directory *b*.

left_list

Files and subdirectories in *a*, filtered by *hide* and *ignore*.

right_list

Files and subdirectories in *b*, filtered by *hide* and *ignore*.

common

Files and subdirectories in both *a* and *b*.

left_only

Files and subdirectories only in *a*.

right_only

Files and subdirectories only in *b*.

common_dirs

Subdirectories in both *a* and *b*.

common_files

Files in both *a* and *b*.

common_funny

Names in both *a* and *b*, such that the type differs between the directories, or names for which `os.stat()` reports an error.

same_files

Files which are identical in both *a* and *b*, using the class' s file comparison operator.

diff_files

Files which are in both *a* and *b*, whose contents differ according to the class' s file comparison operator.

funny_files

Files which are in both *a* and *b*, but could not be compared.

subdirs

A dictionary mapping names in `common_dirs` to `dircmp` objects.

`filecmp.DEFAULT_IGNORES`

3.4 新版功能.

List of directories ignored by `dircmp` by default.

Here is a simplified example of using the `subdirs` attribute to search recursively through two directories to show common different files:

```
>>> from filecmp import dircmp
>>> def print_diff_files(dcmp):
...     for name in dcmp.diff_files:
...         print("diff_file %s found in %s and %s" % (name, dcmp.left,
...             dcmp.right))
...     for sub_dcmp in dcmp.subdirs.values():
...         print_diff_files(sub_dcmp)
...
>>> dcmp = dircmp('dir1', 'dir2')
>>> print_diff_files(dcmp)
```

11.6 tempfile —Generate temporary files and directories

Source code: [Lib/tempfile.py](#)

This module creates temporary files and directories. It works on all supported platforms. *TemporaryFile*, *NamedTemporaryFile*, *TemporaryDirectory*, and *SpooledTemporaryFile* are high-level interfaces which provide automatic cleanup and can be used as context managers. *mkstemp()* and *mkdtemp()* are lower-level functions which require manual cleanup.

All the user-callable functions and constructors take additional arguments which allow direct control over the location and name of temporary files and directories. Files names used by this module include a string of random characters which allows those files to be securely created in shared temporary directories. To maintain backward compatibility, the argument order is somewhat odd; it is recommended to use keyword arguments for clarity.

The module defines the following user-callable items:

`tempfile.TemporaryFile(mode='w+b', buffering=None, encoding=None, newline=None, suffix=None, prefix=None, dir=None)`

Return a *file-like object* that can be used as a temporary storage area. The file is created securely, using the same rules as *mkstemp()*. It will be destroyed as soon as it is closed (including an implicit close when the object is garbage collected). Under Unix, the directory entry for the file is either not created at all or is removed immediately after the file is created. Other platforms do not support this; your code should not rely on a temporary file created using this function having or not having a visible name in the file system.

The resulting object can be used as a context manager (see 示例). On completion of the context or destruction of the file object the temporary file will be removed from the filesystem.

The *mode* parameter defaults to 'w+b' so that the file created can be read and written without being closed. Binary mode is used so that it behaves consistently on all platforms without regard for the data that is stored. *buffering*, *encoding* and *newline* are interpreted as for *open()*.

The *dir*, *prefix* and *suffix* parameters have the same meaning and defaults as with *mkstemp()*.

The returned object is a true file object on POSIX platforms. On other platforms, it is a file-like object whose *file* attribute is the underlying true file object.

The *os.O_TMPFILE* flag is used if it is available and works (Linux-specific, requires Linux kernel 3.11 or later).

在 3.5 版更改: The *os.O_TMPFILE* flag is now used if available.

`tempfile.NamedTemporaryFile(mode='w+b', buffering=None, encoding=None, newline=None, suffix=None, prefix=None, dir=None, delete=True)`

This function operates exactly as *TemporaryFile()* does, except that the file is guaranteed to have a visible name in the file system (on Unix, the directory entry is not unlinked). That name can be retrieved from the *name* attribute of the returned file-like object. Whether the name can be used to open the file a second time, while the

named temporary file is still open, varies across platforms (it can be so used on Unix; it cannot on Windows NT or later). If *delete* is true (the default), the file is deleted as soon as it is closed. The returned object is always a file-like object whose *file* attribute is the underlying true file object. This file-like object can be used in a *with* statement, just like a normal file.

`tempfile.SpooledTemporaryFile` (*max_size=0, mode='w+b', buffering=None, encoding=None, new-line=None, suffix=None, prefix=None, dir=None*)

This function operates exactly as `TemporaryFile()` does, except that data is spooled in memory until the file size exceeds *max_size*, or until the file's `fileno()` method is called, at which point the contents are written to disk and operation proceeds as with `TemporaryFile()`.

The resulting file has one additional method, `rollover()`, which causes the file to roll over to an on-disk file regardless of its size.

The returned object is a file-like object whose `_file` attribute is either an `io.BytesIO` or `io.StringIO` object (depending on whether binary or text *mode* was specified) or a true file object, depending on whether `rollover()` has been called. This file-like object can be used in a *with* statement, just like a normal file.

在 3.3 版更改: the truncate method now accepts a *size* argument.

`tempfile.TemporaryDirectory` (*suffix=None, prefix=None, dir=None*)

This function securely creates a temporary directory using the same rules as `mkdtemp()`. The resulting object can be used as a context manager (see 示例). On completion of the context or destruction of the temporary directory object the newly created temporary directory and all its contents are removed from the filesystem.

The directory name can be retrieved from the *name* attribute of the returned object. When the returned object is used as a context manager, the *name* will be assigned to the target of the *as* clause in the *with* statement, if there is one.

The directory can be explicitly cleaned up by calling the `cleanup()` method.

3.2 新版功能.

`tempfile.mkstemp` (*suffix=None, prefix=None, dir=None, text=False*)

Creates a temporary file in the most secure manner possible. There are no race conditions in the file's creation, assuming that the platform properly implements the `os.O_EXCL` flag for `os.open()`. The file is readable and writable only by the creating user ID. If the platform uses permission bits to indicate whether a file is executable, the file is executable by no one. The file descriptor is not inherited by child processes.

Unlike `TemporaryFile()`, the user of `mkstemp()` is responsible for deleting the temporary file when done with it.

If *suffix* is not *None*, the file name will end with that suffix, otherwise there will be no suffix. `mkstemp()` does not put a dot between the file name and the suffix; if you need one, put it at the beginning of *suffix*.

If *prefix* is not *None*, the file name will begin with that prefix; otherwise, a default prefix is used. The default is the return value of `gettempprefix()` or `gettempprefixb()`, as appropriate.

If *dir* is not *None*, the file will be created in that directory; otherwise, a default directory is used. The default directory is chosen from a platform-dependent list, but the user of the application can control the directory location by setting the `TMPDIR`, `TEMP` or `TMP` environment variables. There is thus no guarantee that the generated filename will have any nice properties, such as not requiring quoting when passed to external commands via `os.popen()`.

If any of *suffix*, *prefix*, and *dir* are not *None*, they must be the same type. If they are bytes, the returned name will be bytes instead of str. If you want to force a bytes return value with otherwise default behavior, pass `suffix=b''`.

If *text* is specified, it indicates whether to open the file in binary mode (the default) or text mode. On some platforms, this makes no difference.

`mkstemp()` returns a tuple containing an OS-level handle to an open file (as would be returned by `os.open()`) and the absolute pathname of that file, in that order.

在 3.5 版更改: *suffix*, *prefix*, and *dir* may now be supplied in bytes in order to obtain a bytes return value. Prior to this, only str was allowed. *suffix* and *prefix* now accept and default to `None` to cause an appropriate default value to be used.

`tempfile.mkdtemp(suffix=None, prefix=None, dir=None)`

Creates a temporary directory in the most secure manner possible. There are no race conditions in the directory's creation. The directory is readable, writable, and searchable only by the creating user ID.

The user of `mkdtemp()` is responsible for deleting the temporary directory and its contents when done with it.

The *prefix*, *suffix*, and *dir* arguments are the same as for `mkstemp()`.

`mkdtemp()` returns the absolute pathname of the new directory.

在 3.5 版更改: *suffix*, *prefix*, and *dir* may now be supplied in bytes in order to obtain a bytes return value. Prior to this, only str was allowed. *suffix* and *prefix* now accept and default to `None` to cause an appropriate default value to be used.

`tempfile.gettempdir()`

Return the name of the directory used for temporary files. This defines the default value for the *dir* argument to all functions in this module.

Python searches a standard list of directories to find one which the calling user can create files in. The list is:

1. The directory named by the `TMPDIR` environment variable.
2. The directory named by the `TEMP` environment variable.
3. The directory named by the `TMP` environment variable.
4. A platform-specific location:
 - On Windows, the directories `C:\TEMP`, `C:\TMP`, `\TEMP`, and `\TMP`, in that order.
 - On all other platforms, the directories `/tmp`, `/var/tmp`, and `/usr/tmp`, in that order.
5. As a last resort, the current working directory.

The result of this search is cached, see the description of `tempdir` below.

`tempfile.gettempdirb()`

Same as `gettempdir()` but the return value is in bytes.

3.5 新版功能.

`tempfile.gettempprefix()`

Return the filename prefix used to create temporary files. This does not contain the directory component.

`tempfile.gettempprefixb()`

Same as `gettempprefix()` but the return value is in bytes.

3.5 新版功能.

The module uses a global variable to store the name of the directory used for temporary files returned by `gettempdir()`. It can be set directly to override the selection process, but this is discouraged. All functions in this module take a *dir* argument which can be used to specify the directory and this is the recommended approach.

`tempfile.tempdir`

When set to a value other than `None`, this variable defines the default value for the *dir* argument to the functions defined in this module.

If `tempdir` is `None` (the default) at any call to any of the above functions except `gettempprefix()` it is initialized following the algorithm described in `gettempdir()`.

11.6.1 示例

Here are some examples of typical usage of the `tempfile` module:

```
>>> import tempfile

# create a temporary file and write some data to it
>>> fp = tempfile.TemporaryFile()
>>> fp.write(b'Hello world!')
# read data from file
>>> fp.seek(0)
>>> fp.read()
b'Hello world!'
# close the file, it will be removed
>>> fp.close()

# create a temporary file using a context manager
>>> with tempfile.TemporaryFile() as fp:
...     fp.write(b'Hello world!')
...     fp.seek(0)
...     fp.read()
b'Hello world!'
>>>
# file is now closed and removed

# create a temporary directory using the context manager
>>> with tempfile.TemporaryDirectory() as tmpdirname:
...     print('created temporary directory', tmpdirname)
>>>
# directory and contents have been removed
```

11.6.2 Deprecated functions and variables

A historical way to create temporary files was to first generate a file name with the `mktemp()` function and then create a file using this name. Unfortunately this is not secure, because a different process may create a file with this name in the time between the call to `mktemp()` and the subsequent attempt to create the file by the first process. The solution is to combine the two steps and create the file immediately. This approach is used by `mkstemp()` and the other functions described above.

`tempfile.mktemp(suffix='', prefix='tmp', dir=None)`

2.3 版后已移除: Use `mkstemp()` instead.

Return an absolute pathname of a file that did not exist at the time the call is made. The *prefix*, *suffix*, and *dir* arguments are similar to those of `mkstemp()`, except that bytes file names, `suffix=None` and `prefix=None` are not supported.

警告: Use of this function may introduce a security hole in your program. By the time you get around to doing anything with the file name it returns, someone else may have beaten you to the punch. `mktemp()` usage can be replaced easily with `NamedTemporaryFile()`, passing it the `delete=False` parameter:

```
>>> f = NamedTemporaryFile(delete=False)
>>> f.name
'/tmp/tmpjtujjt'
>>> f.write(b"Hello World!\n")
13
>>> f.close()
>>> os.unlink(f.name)
>>> os.path.exists(f.name)
False
```

11.7 glob —Unix style pathname pattern expansion

Source code: [Lib/glob.py](#)

The `glob` module finds all the pathnames matching a specified pattern according to the rules used by the Unix shell, although results are returned in arbitrary order. No tilde expansion is done, but `*`, `?`, and character ranges expressed with `[]` will be correctly matched. This is done by using the `os.scandir()` and `fnmatch.fnmatch()` functions in concert, and not by actually invoking a subshell. Note that unlike `fnmatch.fnmatch()`, `glob` treats filenames beginning with a dot (`.`) as special cases. (For tilde and shell variable expansion, use `os.path.expanduser()` and `os.path.expandvars()`.)

For a literal match, wrap the meta-characters in brackets. For example, `'[?]'` matches the character `'?'`.

参见:

The `pathlib` module offers high-level path objects.

`glob.glob(pathname, *, recursive=False)`

Return a possibly-empty list of path names that match `pathname`, which must be a string containing a path specification. `pathname` can be either absolute (like `/usr/src/Python-1.5/Makefile`) or relative (like `../Tools/*/*.gif`), and can contain shell-style wildcards. Broken symlinks are included in the results (as in the shell).

If `recursive` is true, the pattern `"**"` will match any files and zero or more directories and subdirectories. If the pattern is followed by an `os.sep`, only directories and subdirectories match.

注解: 在一个较大的目录树中使用 `"**"` 模式可能会消耗非常多的时间。

在 3.5 版更改: Support for recursive globs using `"**"`.

`glob.iglob(pathname, *, recursive=False)`

Return an *iterator* which yields the same values as `glob()` without actually storing them all simultaneously.

`glob.escape(pathname)`

Escape all special characters (`'?'`, `'*'` and `'['`). This is useful if you want to match an arbitrary literal string that may have special characters in it. Special characters in drive/UNC sharepoints are not escaped, e.g. on Windows `escape('///?/c:/Quo vadis?.txt')` returns `'///?/c:/Quo vadis[?].txt'`.

3.4 新版功能.

For example, consider a directory containing the following files: `1.gif`, `2.txt`, `card.gif` and a subdirectory `sub` which contains only the file `3.txt`. `glob()` will produce the following results. Notice how any leading components of the path are preserved.

```
>>> import glob
>>> glob.glob('./[0-9].*')
['./1.gif', './2.txt']
>>> glob.glob('*.gif')
['1.gif', 'card.gif']
>>> glob.glob('?.gif')
['1.gif']
>>> glob.glob('**/*.txt', recursive=True)
```

(下页继续)

(续上页)

```
['2.txt', 'sub/3.txt']
>>> glob.glob('.**/', recursive=True)
['./', './sub/']
```

If the directory contains files starting with `.` they won't be matched by default. For example, consider a directory containing `card.gif` and `.card.gif`:

```
>>> import glob
>>> glob.glob('*.gif')
['card.gif']
>>> glob.glob('.*')
['.card.gif']
```

参见:

Module `fnmatch` Shell-style filename (not path) expansion

11.8 fnmatch — Unix filename pattern matching

Source code: [Lib/fnmatch.py](#)

This module provides support for Unix shell-style wildcards, which are *not* the same as regular expressions (which are documented in the `re` module). The special characters used in shell-style wildcards are:

模式	意义
<code>*</code>	匹配所有
<code>?</code>	匹配任何单个字符
<code>[seq]</code>	匹配 <code>seq</code> 中的任何字符
<code>[!seq]</code>	匹配任何不在 <code>seq</code> 中的字符

For a literal match, wrap the meta-characters in brackets. For example, `'[?]'` matches the character `'?'`.

Note that the filename separator (`'/'` on Unix) is *not* special to this module. See module `glob` for pathname expansion (`glob` uses `filter()` to match pathname segments). Similarly, filenames starting with a period are not special for this module, and are matched by the `*` and `?` patterns.

`fnmatch.fnmatch(filename, pattern)`

Test whether the *filename* string matches the *pattern* string, returning `True` or `False`. Both parameters are case-normalized using `os.path.normcase()`. `fnmatchcase()` can be used to perform a case-sensitive comparison, regardless of whether that's standard for the operating system.

This example will print all file names in the current directory with the extension `.txt`:

```
import fnmatch
import os

for file in os.listdir('.'):
    if fnmatch.fnmatch(file, '*.txt'):
        print(file)
```

`fnmatch.fnmatchcase(filename, pattern)`

Test whether *filename* matches *pattern*, returning `True` or `False`; the comparison is case-sensitive and does not apply `os.path.normcase()`.

`fnmatch.filter(names, pattern)`

Return the subset of the list of *names* that match *pattern*. It is the same as `[n for n in names if fnmatch(n, pattern)]`, but implemented more efficiently.

`fnmatch.translate(pattern)`

Return the shell-style *pattern* converted to a regular expression for using with `re.match()`.

示例:

```
>>> import fnmatch, re
>>>
>>> regex = fnmatch.translate('*.txt')
>>> regex
'(?s:.*\\.txt)\\Z'
>>> reobj = re.compile(regex)
>>> reobj.match('foobar.txt')
<_sre.SRE_Match object; span=(0, 10), match='foobar.txt'>
```

参见:

Module `glob` Unix shell-style path expansion.

11.9 linecache — Random access to text lines

Source code: [Lib/linecache.py](#)

The `linecache` module allows one to get any line from a Python source file, while attempting to optimize internally, using a cache, the common case where many lines are read from a single file. This is used by the `traceback` module to retrieve source lines for inclusion in the formatted traceback.

The `tokenize.open()` function is used to open files. This function uses `tokenize.detect_encoding()` to get the encoding of the file; in the absence of an encoding token, the file encoding defaults to UTF-8.

The `linecache` module defines the following functions:

`linecache.getline(filename, lineno, module_globals=None)`

Get line *lineno* from file named *filename*. This function will never raise an exception—it will return `' '` on errors (the terminating newline character will be included for lines that are found).

If a file named *filename* is not found, the function will look for it in the module search path, `sys.path`, after first checking for a [PEP 302](#) `__loader__` in *module_globals*, in case the module was imported from a zipfile or other non-filesystem import source.

`linecache.clearcache()`

Clear the cache. Use this function if you no longer need lines from files previously read using `getline()`.

`linecache.checkcache(filename=None)`

Check the cache for validity. Use this function if files in the cache may have changed on disk, and you require the updated version. If *filename* is omitted, it will check all the entries in the cache.

`linecache.lazycache(filename, module_globals)`

Capture enough detail about a non-file-based module to permit getting its lines later via `getline()` even if *module_globals* is `None` in the later call. This avoids doing I/O until a line is actually needed, without having to carry the module globals around indefinitely.

3.5 新版功能.

示例:

```
>>> import linecache
>>> linecache.getline(linecache.__file__, 8)
'import sys\n'
```

11.10 `shutil` —High-level file operations

Source code: [Lib/shutil.py](#)

The `shutil` module offers a number of high-level operations on files and collections of files. In particular, functions are provided which support file copying and removal. For operations on individual files, see also the `os` module.

警告: Even the higher-level file copying functions (`shutil.copy()`, `shutil.copy2()`) cannot copy all file metadata.

On POSIX platforms, this means that file owner and group are lost as well as ACLs. On Mac OS, the resource fork and other metadata are not used. This means that resources will be lost and file type and creator codes will not be correct. On Windows, file owners, ACLs and alternate data streams are not copied.

11.10.1 Directory and files operations

`shutil.copyfileobj(fsrc, fdst[, length])`

Copy the contents of the file-like object *fsrc* to the file-like object *fdst*. The integer *length*, if given, is the buffer size. In particular, a negative *length* value means to copy the data without looping over the source data in chunks; by default the data is read in chunks to avoid uncontrolled memory consumption. Note that if the current file position of the *fsrc* object is not 0, only the contents from the current file position to the end of the file will be copied.

`shutil.copyfile(src, dst, *, follow_symlinks=True)`

Copy the contents (no metadata) of the file named *src* to a file named *dst* and return *dst*. *src* and *dst* are path names given as strings. *dst* must be the complete target file name; look at `shutil.copy()` for a copy that accepts a target directory path. If *src* and *dst* specify the same file, `SameFileError` is raised.

The destination location must be writable; otherwise, an `OSError` exception will be raised. If *dst* already exists, it will be replaced. Special files such as character or block devices and pipes cannot be copied with this function.

If *follow_symlinks* is false and *src* is a symbolic link, a new symbolic link will be created instead of copying the file *src* points to.

在 3.3 版更改: `IOError` used to be raised instead of `OSError`. Added *follow_symlinks* argument. Now returns *dst*.

在 3.4 版更改: Raise `SameFileError` instead of `Error`. Since the former is a subclass of the latter, this change is backward compatible.

exception `shutil.SameFileError`

This exception is raised if source and destination in `copyfile()` are the same file.

3.4 新版功能.

`shutil.copymode(src, dst, *, follow_symlinks=True)`

Copy the permission bits from *src* to *dst*. The file contents, owner, and group are unaffected. *src* and *dst* are path names given as strings. If *follow_symlinks* is false, and both *src* and *dst* are symbolic links, `copymode()` will attempt to modify the mode of *dst* itself (rather than the file it points to). This functionality is not available on every

platform; please see `copystat()` for more information. If `copymode()` cannot modify symbolic links on the local platform, and it is asked to do so, it will do nothing and return.

在 3.3 版更改: Added `follow_symlinks` argument.

`shutil.copystat(src, dst, *, follow_symlinks=True)`

Copy the permission bits, last access time, last modification time, and flags from `src` to `dst`. On Linux, `copystat()` also copies the “extended attributes” where possible. The file contents, owner, and group are unaffected. `src` and `dst` are path names given as strings.

If `follow_symlinks` is false, and `src` and `dst` both refer to symbolic links, `copystat()` will operate on the symbolic links themselves rather than the files the symbolic links refer to—reading the information from the `src` symbolic link, and writing the information to the `dst` symbolic link.

注解: Not all platforms provide the ability to examine and modify symbolic links. Python itself can tell you what functionality is locally available.

- If `os.chmod` in `os.supports_follow_symlinks` is True, `copystat()` can modify the permission bits of a symbolic link.
- If `os.utime` in `os.supports_follow_symlinks` is True, `copystat()` can modify the last access and modification times of a symbolic link.
- If `os.chflags` in `os.supports_follow_symlinks` is True, `copystat()` can modify the flags of a symbolic link. (`os.chflags` is not available on all platforms.)

On platforms where some or all of this functionality is unavailable, when asked to modify a symbolic link, `copystat()` will copy everything it can. `copystat()` never returns failure.

Please see `os.supports_follow_symlinks` for more information.

在 3.3 版更改: Added `follow_symlinks` argument and support for Linux extended attributes.

`shutil.copy(src, dst, *, follow_symlinks=True)`

Copies the file `src` to the file or directory `dst`. `src` and `dst` should be strings. If `dst` specifies a directory, the file will be copied into `dst` using the base filename from `src`. Returns the path to the newly created file.

If `follow_symlinks` is false, and `src` is a symbolic link, `dst` will be created as a symbolic link. If `follow_symlinks` is true and `src` is a symbolic link, `dst` will be a copy of the file `src` refers to.

`copy()` copies the file data and the file’s permission mode (see `os.chmod()`). Other metadata, like the file’s creation and modification times, is not preserved. To preserve all file metadata from the original, use `copy2()` instead.

在 3.3 版更改: Added `follow_symlinks` argument. Now returns path to the newly created file.

`shutil.copy2(src, dst, *, follow_symlinks=True)`

Identical to `copy()` except that `copy2()` also attempts to preserve file metadata.

When `follow_symlinks` is false, and `src` is a symbolic link, `copy2()` attempts to copy all metadata from the `src` symbolic link to the newly-created `dst` symbolic link. However, this functionality is not available on all platforms. On platforms where some or all of this functionality is unavailable, `copy2()` will preserve all the metadata it can; `copy2()` never returns failure.

`copy2()` uses `copystat()` to copy the file metadata. Please see `copystat()` for more information about platform support for modifying symbolic link metadata.

在 3.3 版更改: Added `follow_symlinks` argument, try to copy extended file system attributes too (currently Linux only). Now returns path to the newly created file.

`shutil.ignore_patterns(*patterns)`

This factory function creates a function that can be used as a callable for `copytree()`'s `ignore` argument, ignoring files and directories that match one of the glob-style `patterns` provided. See the example below.

`shutil.copytree(src, dst, symlinks=False, ignore=None, copy_function=copy2, ignore_dangling_symlinks=False)`

Recursively copy an entire directory tree rooted at `src`, returning the destination directory. The destination directory, named by `dst`, must not already exist; it will be created as well as missing parent directories. Permissions and times of directories are copied with `copystat()`, individual files are copied using `shutil.copy2()`.

If `symlinks` is true, symbolic links in the source tree are represented as symbolic links in the new tree and the metadata of the original links will be copied as far as the platform allows; if false or omitted, the contents and metadata of the linked files are copied to the new tree.

When `symlinks` is false, if the file pointed by the symlink doesn't exist, an exception will be added in the list of errors raised in an `Error` exception at the end of the copy process. You can set the optional `ignore_dangling_symlinks` flag to true if you want to silence this exception. Notice that this option has no effect on platforms that don't support `os.symlink()`.

If `ignore` is given, it must be a callable that will receive as its arguments the directory being visited by `copytree()`, and a list of its contents, as returned by `os.listdir()`. Since `copytree()` is called recursively, the `ignore` callable will be called once for each directory that is copied. The callable must return a sequence of directory and file names relative to the current directory (i.e. a subset of the items in its second argument); these names will then be ignored in the copy process. `ignore_patterns()` can be used to create such a callable that ignores names based on glob-style patterns.

If exception(s) occur, an `Error` is raised with a list of reasons.

If `copy_function` is given, it must be a callable that will be used to copy each file. It will be called with the source path and the destination path as arguments. By default, `shutil.copy2()` is used, but any function that supports the same signature (like `shutil.copy()`) can be used.

在 3.3 版更改: Copy metadata when `symlinks` is false. Now returns `dst`.

在 3.2 版更改: Added the `copy_function` argument to be able to provide a custom copy function. Added the `ignore_dangling_symlinks` argument to silent dangling symlinks errors when `symlinks` is false.

`shutil.rmtree(path, ignore_errors=False, onerror=None)`

Delete an entire directory tree; `path` must point to a directory (but not a symbolic link to a directory). If `ignore_errors` is true, errors resulting from failed removals will be ignored; if false or omitted, such errors are handled by calling a handler specified by `onerror` or, if that is omitted, they raise an exception.

注解: On platforms that support the necessary fd-based functions a symlink attack resistant version of `rmtree()` is used by default. On other platforms, the `rmtree()` implementation is susceptible to a symlink attack: given proper timing and circumstances, attackers can manipulate symlinks on the filesystem to delete files they wouldn't be able to access otherwise. Applications can use the `rmtree.avoids_symlink_attacks` function attribute to determine which case applies.

If `onerror` is provided, it must be a callable that accepts three parameters: `function`, `path`, and `excinfo`.

The first parameter, `function`, is the function which raised the exception; it depends on the platform and implementation. The second parameter, `path`, will be the path name passed to `function`. The third parameter, `excinfo`, will be the exception information returned by `sys.exc_info()`. Exceptions raised by `onerror` will not be caught.

在 3.3 版更改: Added a symlink attack resistant version that is used automatically if platform supports fd-based functions.

`rmtree.avoids_symlink_attacks`

Indicates whether the current platform and implementation provides a symlink attack resistant version of

`rmtree()`. Currently this is only true for platforms supporting fd-based directory access functions.

3.3 新版功能.

`shutil.move(src, dst, copy_function=copy2)`

Recursively move a file or directory (*src*) to another location (*dst*) and return the destination.

If the destination is an existing directory, then *src* is moved inside that directory. If the destination already exists but is not a directory, it may be overwritten depending on `os.rename()` semantics.

If the destination is on the current filesystem, then `os.rename()` is used. Otherwise, *src* is copied to *dst* using `copy_function` and then removed. In case of symlinks, a new symlink pointing to the target of *src* will be created in or as *dst* and *src* will be removed.

If `copy_function` is given, it must be a callable that takes two arguments *src* and *dst*, and will be used to copy *src* to *dst* if `os.rename()` cannot be used. If the source is a directory, `copytree()` is called, passing it the `copy_function()`. The default `copy_function` is `copy2()`. Using `copy()` as the `copy_function` allows the move to succeed when it is not possible to also copy the metadata, at the expense of not copying any of the metadata.

在 3.3 版更改: Added explicit symlink handling for foreign filesystems, thus adapting it to the behavior of GNU's `mv`. Now returns *dst*.

在 3.5 版更改: Added the `copy_function` keyword argument.

`shutil.disk_usage(path)`

Return disk usage statistics about the given path as a *named tuple* with the attributes *total*, *used* and *free*, which are the amount of total, used and free space, in bytes. On Windows, *path* must be a directory; on Unix, it can be a file or directory.

3.3 新版功能.

Availability: Unix, Windows.

`shutil.chown(path, user=None, group=None)`

Change owner *user* and/or *group* of the given *path*.

user can be a system user name or a uid; the same applies to *group*. At least one argument is required.

See also `os.chown()`, the underlying function.

Availability: Unix.

3.3 新版功能.

`shutil.which(cmd, mode=os.F_OK | os.X_OK, path=None)`

Return the path to an executable which would be run if the given *cmd* was called. If no *cmd* would be called, return *None*.

mode is a permission mask passed to `os.access()`, by default determining if the file exists and executable.

When no *path* is specified, the results of `os.environ()` are used, returning either the “PATH” value or a fallback of `os.defpath`.

On Windows, the current directory is always prepended to the *path* whether or not you use the default or provide your own, which is the behavior the command shell uses when finding executables. Additionally, when finding the *cmd* in the *path*, the `PATHEXT` environment variable is checked. For example, if you call `shutil.which("python")`, `which()` will search `PATHEXT` to know that it should look for `python.exe` within the *path* directories. For example, on Windows:

```
>>> shutil.which("python")
'C:\\Python33\\python.EXE'
```

3.3 新版功能.

exception `shutil.Error`

This exception collects exceptions that are raised during a multi-file operation. For `copytree()`, the exception argument is a list of 3-tuples (`srcname`, `dstname`, `exception`).

copytree example

This example is the implementation of the `copytree()` function, described above, with the docstring omitted. It demonstrates many of the other functions provided by this module.

```
def copytree(src, dst, symlinks=False):
    names = os.listdir(src)
    os.makedirs(dst)
    errors = []
    for name in names:
        srcname = os.path.join(src, name)
        dstname = os.path.join(dst, name)
        try:
            if symlinks and os.path.islink(srcname):
                linkto = os.readlink(srcname)
                os.symlink(linkto, dstname)
            elif os.path.isdir(srcname):
                copytree(srcname, dstname, symlinks)
            else:
                copy2(srcname, dstname)
                # XXX What about devices, sockets etc.?
        except OSError as why:
            errors.append((srcname, dstname, str(why)))
        # catch the Error from the recursive copytree so that we can
        # continue with other files
        except Error as err:
            errors.extend(err.args[0])
    try:
        copystat(src, dst)
    except OSError as why:
        # can't copy file access times on Windows
        if why.winerror is None:
            errors.extend((src, dst, str(why)))
    if errors:
        raise Error(errors)
```

Another example that uses the `ignore_patterns()` helper:

```
from shutil import copytree, ignore_patterns

copytree(source, destination, ignore=ignore_patterns('*.pyc', 'tmp*'))
```

This will copy everything except `.pyc` files and files or directories whose name starts with `tmp`.

Another example that uses the `ignore` argument to add a logging call:

```
from shutil import copytree
import logging

def _logpath(path, names):
    logging.info('Working in %s', path)
    return [] # nothing will be ignored
```

(下页继续)

(续上页)

```
copytree(source, destination, ignore=_logpath)
```

rmtree example

This example shows how to remove a directory tree on Windows where some of the files have their read-only bit set. It uses the `onerror` callback to clear the readonly bit and reattempt the remove. Any subsequent failure will propagate.

```
import os, stat
import shutil

def remove_readonly(func, path, _):
    "Clear the readonly bit and reattempt the removal"
    os.chmod(path, stat.S_IWRITE)
    func(path)

shutil.rmtree(directory, onerror=remove_readonly)
```

11.10.2 Archiving operations

3.2 新版功能.

在 3.5 版更改: Added support for the *xz*tar format.

High-level utilities to create and read compressed and archived files are also provided. They rely on the *zipfile* and *tarfile* modules.

```
shutil.make_archive(base_name, format[, root_dir[, base_dir[, verbose[, dry_run[, owner[, group[,
                        logger]]]]]])
```

Create an archive file (such as zip or tar) and return its name.

base_name is the name of the file to create, including the path, minus any format-specific extension. *format* is the archive format: one of “zip” (if the *zlib* module is available), “tar”, “gztar” (if the *zlib* module is available), “bztar” (if the *bz2* module is available), or “xztar” (if the *lzma* module is available).

root_dir is a directory that will be the root directory of the archive; for example, we typically `chdir` into *root_dir* before creating the archive.

base_dir is the directory where we start archiving from; i.e. *base_dir* will be the common prefix of all files and directories in the archive.

root_dir and *base_dir* both default to the current directory.

If *dry_run* is true, no archive is created, but the operations that would be executed are logged to *logger*.

owner and *group* are used when creating a tar archive. By default, uses the current owner and group.

logger must be an object compatible with **PEP 282**, usually an instance of *logging.Logger*.

The *verbose* argument is unused and deprecated.

```
shutil.get_archive_formats()
```

Return a list of supported formats for archiving. Each element of the returned sequence is a tuple (name, description).

By default *shutil* provides these formats:

- *zip*: ZIP file (if the *zlib* module is available).

- *tar*: uncompressed tar file.
- *gztar*: gzip' ed tar-file (if the *zlib* module is available).
- *bztar*: bzip2' ed tar-file (if the *bz2* module is available).
- *xztar*: xz' ed tar-file (if the *lzma* module is available).

You can register new formats or provide your own archiver for any existing formats, by using `register_archive_format()`.

`shutil.register_archive_format(name, function[, extra_args[, description]])`

Register an archiver for the format *name*.

function is the callable that will be used to unpack archives. The callable will receive the *base_name* of the file to create, followed by the *base_dir* (which defaults to `os.curdir`) to start archiving from. Further arguments are passed as keyword arguments: *owner*, *group*, *dry_run* and *logger* (as passed in `make_archive()`).

If given, *extra_args* is a sequence of (name, value) pairs that will be used as extra keywords arguments when the archiver callable is used.

description is used by `get_archive_formats()` which returns the list of archivers. Defaults to an empty string.

`shutil.unregister_archive_format(name)`

Remove the archive format *name* from the list of supported formats.

`shutil.unpack_archive(filename[, extract_dir[, format]])`

Unpack an archive. *filename* is the full path of the archive.

extract_dir is the name of the target directory where the archive is unpacked. If not provided, the current working directory is used.

format is the archive format: one of “zip”, “tar”, “gztar”, “bztar”, or “xztar”. Or any other format registered with `register_unpack_format()`. If not provided, `unpack_archive()` will use the archive file name extension and see if an unpacker was registered for that extension. In case none is found, a *ValueError* is raised.

`shutil.register_unpack_format(name, extensions, function[, extra_args[, description]])`

Registers an unpack format. *name* is the name of the format and *extensions* is a list of extensions corresponding to the format, like `.zip` for Zip files.

function is the callable that will be used to unpack archives. The callable will receive the path of the archive, followed by the directory the archive must be extracted to.

When provided, *extra_args* is a sequence of (name, value) tuples that will be passed as keywords arguments to the callable.

description can be provided to describe the format, and will be returned by the `get_unpack_formats()` function.

`shutil.unregister_unpack_format(name)`

Unregister an unpack format. *name* is the name of the format.

`shutil.get_unpack_formats()`

Return a list of all registered formats for unpacking. Each element of the returned sequence is a tuple (name, extensions, description).

By default *shutil* provides these formats:

- *zip*: ZIP file (unpacking compressed files works only if the corresponding module is available).
- *tar*: uncompressed tar file.
- *gztar*: gzip' ed tar-file (if the *zlib* module is available).

- *bztar*: bzip2' ed tar-file (if the *bz2* module is available).
- *xztar*: xz' ed tar-file (if the *lzma* module is available).

You can register new formats or provide your own unpacker for any existing formats, by using `register_unpack_format()`.

Archiving example

In this example, we create a gzip' ed tar-file archive containing all files found in the `.ssh` directory of the user:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~', 'myarchive'))
>>> root_dir = os.path.expanduser(os.path.join('~', '.ssh'))
>>> make_archive(archive_name, 'gztar', root_dir)
'/Users/tarek/myarchive.tar.gz'
```

The resulting archive contains:

```
$ tar -tzvf /Users/tarek/myarchive.tar.gz
drwx----- tarek/staff      0 2010-02-01 16:23:40 ./
-rw-r--r-- tarek/staff     609 2008-06-09 13:26:54 ./authorized_keys
-rwxr-xr-x tarek/staff      65 2008-06-09 13:26:54 ./config
-rwx----- tarek/staff     668 2008-06-09 13:26:54 ./id_dsa
-rwxr-xr-x tarek/staff     609 2008-06-09 13:26:54 ./id_dsa.pub
-rw----- tarek/staff    1675 2008-06-09 13:26:54 ./id_rsa
-rw-r--r-- tarek/staff     397 2008-06-09 13:26:54 ./id_rsa.pub
-rw-r--r-- tarek/staff   37192 2010-02-06 18:23:10 ./known_hosts
```

11.10.3 Querying the size of the output terminal

`shutil.get_terminal_size(fallback=(columns, lines))`

Get the size of the terminal window.

For each of the two dimensions, the environment variable, `COLUMNS` and `LINES` respectively, is checked. If the variable is defined and the value is a positive integer, it is used.

When `COLUMNS` or `LINES` is not defined, which is the common case, the terminal connected to `sys.__stdout__` is queried by invoking `os.get_terminal_size()`.

If the terminal size cannot be successfully queried, either because the system doesn't support querying, or because we are not connected to a terminal, the value given in `fallback` parameter is used. `fallback` defaults to (80, 24) which is the default size used by many terminal emulators.

The value returned is a named tuple of type `os.terminal_size`.

See also: The Single UNIX Specification, Version 2, [Other Environment Variables](#).

3.3 新版功能.

11.11 macpath —Mac OS 9 路径操作函数

源码: [Lib/macpath.py](#)

该模块是 `os.path` 模块的 Mac OS 9（及更早版本）实现。它可用于在 Mac OS X（或任何其他平台）上操作旧式 Macintosh 路径名。

该模块中提供了以下函数： `normcase()`、`normpath()`、`isabs()`、`join()`、`split()`、`isdir()`、`isfile()`、`walk()`、`exists()`。对于其他可用的函数 `os.path` 虚拟对应可用。

参见：

模块 `os` 操作系统接口，包括处理比 Python 文件对象 更低级别文件的功能。

模块 `io` Python 的内置 I/O 库，包括抽象类和一些具体的类，如文件 I/O。

内置函数 `open()` 使用 Python 打开文件进行读写的标准方法。

本章中描述的模块支持在磁盘上以持久形式存储 Python 数据。`pickle` 和 `marshal` 模块可以将许多 Python 数据类型转换为字节流，然后从字节中重新创建对象。各种与 DBM 相关的模块支持一系列基于散列的文件格式，这些格式存储字符串到其他字符串的映射。

本章中描述的模块列表是：

12.1 `pickle` —— Python 对象序列化

源代码：Lib/pickle.py

模块 `pickle` 实现了对一个 Python 对象结构的二进制序列化和反序列化。“Pickling”是将 Python 对象和所拥有的层次结构被转化为一个字节流的过程，而 “unpickling”是相反的操作，会将（来自一个 *binary file* 或者 *bytes-like object* 的）字节流转化回一个对象层次结构。Pickling（和 unpickling）也被称为“序列化”，“编组”¹ 或者“平面化”。而为了避免混乱，此处采用术语 “pickling” 和 “unpickling”。

警告： `pickle` 模块在接受被错误地构造或者被恶意地构造的数据时不安全。永远不要 unpickle 来自于不受信任的或者未经验证的来源的数据。

12.1.1 与其他 Python 模块间的关系

与 `marshal` 间的关系

Python 有一个更原始的序列化模块称为 `marshal`，但一般地 `pickle` 应该是序列化 Python 对象时的首选。`marshal` 存在主要是为了支持 Python 的 `.pyc` 文件。

`pickle` 模块与 `marshal` 在如下几方面显著地不同：

¹ Don't confuse this with the `marshal` module

- `pickle` 模块会跟踪已被序列化的对象，所以该对象之后再次被引用时不会再次被序列化。`marshal` 不会这么做。

这隐含了递归对象和共享对象。递归对象指包含对自己的引用的对象。这种对象并不会被 `marshal` 接受，并且实际上尝试 `marshal` 递归对象会让你的 Python 解释器崩溃。对象共享发生在对象层级中存在多处引用同一对象时。`pickle` 只会存储这些对象一次，并确保其他的引用指向同一个主副本。共享对象将保持共享，这可能对可变对象非常重要。

- `marshal` 不能被用于序列化用户定义类及其实例。`pickle` 能够透明地存储并保存类实例，然而此时类定义必须能够从与被存储时相同的模块被引入。
- The `marshal` serialization format is not guaranteed to be portable across Python versions. Because its primary job in life is to support `.pyc` files, the Python implementers reserve the right to change the serialization format in non-backwards compatible ways should the need arise. The `pickle` serialization format is guaranteed to be backwards compatible across Python releases.

与 json 模块的比较

Pickle 协议和 JSON (JavaScript Object Notation) 间有着本质的不同：

- JSON 是一个文本序列化格式（它输出 unicode 文本，尽管在大多数时候它会接着以 utf-8 编码），而 pickle 是一个二进制序列化格式；
- JSON is human-readable, while pickle is not; JSON 是我们很容易理解的，而 pickle 不是；
- JSON 是可互操作的，在 Python 系统之外广泛使用，而 pickle 则是 Python 专用的；
- JSON, by default, can only represent a subset of the Python built-in types, and no custom classes; pickle can represent an extremely large number of Python types (many of them automatically, by clever usage of Python's introspection facilities; complex cases can be tackled by implementing *specific object APIs*).

参见：

`json` 模块：一个允许 JSON 序列化和反序列化的标准库模块

12.1.2 Data stream format

The data format used by `pickle` is Python-specific. This has the advantage that there are no restrictions imposed by external standards such as JSON or XDR (which can't represent pointer sharing); however it means that non-Python programs may not be able to reconstruct pickled Python objects.

By default, the `pickle` data format uses a relatively compact binary representation. If you need optimal size characteristics, you can efficiently *compress* pickled data.

The module `pickletools` contains tools for analyzing data streams generated by `pickle`. `pickletools` source code has extensive comments about opcodes used by pickle protocols.

There are currently 5 different protocols which can be used for pickling. The higher the protocol used, the more recent the version of Python needed to read the pickle produced.

- Protocol version 0 is the original “human-readable” protocol and is backwards compatible with earlier versions of Python.
- Protocol version 1 is an old binary format which is also compatible with earlier versions of Python.
- Protocol version 2 was introduced in Python 2.3. It provides much more efficient pickling of *new-style classes*. Refer to **PEP 307** for information about improvements brought by protocol 2.

- Protocol version 3 was added in Python 3.0. It has explicit support for *bytes* objects and cannot be unpickled by Python 2.x. This is the default protocol, and the recommended protocol when compatibility with other Python 3 versions is required.
- Protocol version 4 was added in Python 3.4. It adds support for very large objects, pickling more kinds of objects, and some data format optimizations. Refer to [PEP 3154](#) for information about improvements brought by protocol 4.

注解: Serialization is a more primitive notion than persistence; although *pickle* reads and writes file objects, it does not handle the issue of naming persistent objects, nor the (even more complicated) issue of concurrent access to persistent objects. The *pickle* module can transform a complex object into a byte stream and it can transform the byte stream into an object with the same internal structure. Perhaps the most obvious thing to do with these byte streams is to write them onto a file, but it is also conceivable to send them across a network or store them in a database. The *shelve* module provides a simple interface to pickle and unpickle objects on DBM-style database files.

12.1.3 Module Interface

To serialize an object hierarchy, you simply call the *dumps()* function. Similarly, to de-serialize a data stream, you call the *loads()* function. However, if you want more control over serialization and de-serialization, you can create a *Pickler* or an *Unpickler* object, respectively.

The *pickle* module provides the following constants:

`pickle.HIGHEST_PROTOCOL`

An integer, the highest *protocol version* available. This value can be passed as a *protocol* value to functions *dump()* and *dumps()* as well as the *Pickler* constructor.

`pickle.DEFAULT_PROTOCOL`

An integer, the default *protocol version* used for pickling. May be less than *HIGHEST_PROTOCOL*. Currently the default protocol is 3, a new protocol designed for Python 3.

The *pickle* module provides the following functions to make the pickling process more convenient:

`pickle.dump(obj, file, protocol=None, *, fix_imports=True)`

Write a pickled representation of *obj* to the open *file object file*. This is equivalent to `Pickler(file, protocol).dump(obj)`.

The optional *protocol* argument, an integer, tells the pickler to use the given protocol; supported protocols are 0 to *HIGHEST_PROTOCOL*. If not specified, the default is *DEFAULT_PROTOCOL*. If a negative number is specified, *HIGHEST_PROTOCOL* is selected.

The *file* argument must have a `write()` method that accepts a single bytes argument. It can thus be an on-disk file opened for binary writing, an *io.BytesIO* instance, or any other custom object that meets this interface.

If *fix_imports* is true and *protocol* is less than 3, pickle will try to map the new Python 3 names to the old module names used in Python 2, so that the pickle data stream is readable with Python 2.

`pickle.dumps(obj, protocol=None, *, fix_imports=True)`

Return the pickled representation of the object as a *bytes* object, instead of writing it to a file.

Arguments *protocol* and *fix_imports* have the same meaning as in *dump()*.

`pickle.load(file, *, fix_imports=True, encoding="ASCII", errors="strict")`

Read a pickled object representation from the open *file object file* and return the reconstituted object hierarchy specified therein. This is equivalent to `Unpickler(file).load()`.

The protocol version of the pickle is detected automatically, so no protocol argument is needed. Bytes past the pickled object's representation are ignored.

The argument *file* must have two methods, a `read()` method that takes an integer argument, and a `readline()` method that requires no arguments. Both methods should return bytes. Thus *file* can be an on-disk file opened for binary reading, an `io.BytesIO` object, or any other custom object that meets this interface.

Optional keyword arguments are *fix_imports*, *encoding* and *errors*, which are used to control compatibility support for pickle stream generated by Python 2. If *fix_imports* is true, pickle will try to map the old Python 2 names to the new names used in Python 3. The *encoding* and *errors* tell pickle how to decode 8-bit string instances pickled by Python 2; these default to 'ASCII' and 'strict', respectively. The *encoding* can be 'bytes' to read these 8-bit string instances as bytes objects. Using *encoding*='latin1' is required for unpickling NumPy arrays and instances of *datetime*, *date* and *time* pickled by Python 2.

`pickle.loads(bytes_object, *, fix_imports=True, encoding="ASCII", errors="strict")`

Read a pickled object hierarchy from a *bytes* object and return the reconstituted object hierarchy specified therein.

The protocol version of the pickle is detected automatically, so no protocol argument is needed. Bytes past the pickled object's representation are ignored.

Optional keyword arguments are *fix_imports*, *encoding* and *errors*, which are used to control compatibility support for pickle stream generated by Python 2. If *fix_imports* is true, pickle will try to map the old Python 2 names to the new names used in Python 3. The *encoding* and *errors* tell pickle how to decode 8-bit string instances pickled by Python 2; these default to 'ASCII' and 'strict', respectively. The *encoding* can be 'bytes' to read these 8-bit string instances as bytes objects. Using *encoding*='latin1' is required for unpickling NumPy arrays and instances of *datetime*, *date* and *time* pickled by Python 2.

The *pickle* module defines three exceptions:

exception `pickle.PickleError`

Common base class for the other pickling exceptions. It inherits *Exception*.

exception `pickle.PicklingError`

Error raised when an unpicklable object is encountered by *Pickler*. It inherits *PickleError*.

Refer to *What can be pickled and unpickled?* to learn what kinds of objects can be pickled.

exception `pickle.UnpicklingError`

Error raised when there is a problem unpickling an object, such as a data corruption or a security violation. It inherits *PickleError*.

Note that other exceptions may also be raised during unpickling, including (but not necessarily limited to) *AttributeError*, *EOFError*, *ImportError*, and *IndexError*.

The *pickle* module exports two classes, *Pickler* and *Unpickler*:

class `pickle.Pickler(file, protocol=None, *, fix_imports=True)`

This takes a binary file for writing a pickle data stream.

The optional *protocol* argument, an integer, tells the pickler to use the given protocol; supported protocols are 0 to *HIGHEST_PROTOCOL*. If not specified, the default is *DEFAULT_PROTOCOL*. If a negative number is specified, *HIGHEST_PROTOCOL* is selected.

The *file* argument must have a `write()` method that accepts a single bytes argument. It can thus be an on-disk file opened for binary writing, an `io.BytesIO` instance, or any other custom object that meets this interface.

If *fix_imports* is true and *protocol* is less than 3, pickle will try to map the new Python 3 names to the old module names used in Python 2, so that the pickle data stream is readable with Python 2.

dump (*obj*)

Write a pickled representation of *obj* to the open file object given in the constructor.

persistent_id (*obj*)

Do nothing by default. This exists so a subclass can override it.

If `persistent_id()` returns `None`, `obj` is pickled as usual. Any other value causes `Pickler` to emit the returned value as a persistent ID for `obj`. The meaning of this persistent ID should be defined by `Unpickler.persistent_load()`. Note that the value returned by `persistent_id()` cannot itself have a persistent ID.

See *Persistence of External Objects* for details and examples of uses.

dispatch_table

A pickler object's dispatch table is a registry of *reduction functions* of the kind which can be declared using `copyreg.pickle()`. It is a mapping whose keys are classes and whose values are reduction functions. A reduction function takes a single argument of the associated class and should conform to the same interface as a `__reduce__()` method.

By default, a pickler object will not have a `dispatch_table` attribute, and it will instead use the global dispatch table managed by the `copyreg` module. However, to customize the pickling for a specific pickler object one can set the `dispatch_table` attribute to a dict-like object. Alternatively, if a subclass of `Pickler` has a `dispatch_table` attribute then this will be used as the default dispatch table for instances of that class.

See *Dispatch Tables* for usage examples.

3.3 新版功能.

fast

Deprecated. Enable fast mode if set to a true value. The fast mode disables the usage of memo, therefore speeding the pickling process by not generating superfluous PUT opcodes. It should not be used with self-referential objects, doing otherwise will cause `Pickler` to recurse infinitely.

Use `pickletools.optimize()` if you need more compact pickles.

class `pickle.Unpickler` (*file*, *, *fix_imports*=`True`, *encoding*=`"ASCII"`, *errors*=`"strict"`)

This takes a binary file for reading a pickle data stream.

The protocol version of the pickle is detected automatically, so no protocol argument is needed.

The argument *file* must have two methods, a `read()` method that takes an integer argument, and a `readline()` method that requires no arguments. Both methods should return bytes. Thus *file* can be an on-disk file object opened for binary reading, an `io.BytesIO` object, or any other custom object that meets this interface.

Optional keyword arguments are *fix_imports*, *encoding* and *errors*, which are used to control compatibility support for pickle stream generated by Python 2. If *fix_imports* is true, pickle will try to map the old Python 2 names to the new names used in Python 3. The *encoding* and *errors* tell pickle how to decode 8-bit string instances pickled by Python 2; these default to `'ASCII'` and `'strict'`, respectively. The *encoding* can be `'bytes'` to read these 8-bit string instances as bytes objects.

load()

Read a pickled object representation from the open file object given in the constructor, and return the reconstituted object hierarchy specified therein. Bytes past the pickled object's representation are ignored.

persistent_load(pid)

Raise an `UnpicklingError` by default.

If defined, `persistent_load()` should return the object specified by the persistent ID *pid*. If an invalid persistent ID is encountered, an `UnpicklingError` should be raised.

See *Persistence of External Objects* for details and examples of uses.

find_class (*module*, *name*)

Import *module* if necessary and return the object called *name* from it, where the *module* and *name* arguments are `str` objects. Note, unlike its name suggests, `find_class()` is also used for finding functions.

Subclasses may override this to gain control over what type of objects and how they can be loaded, potentially reducing security risks. Refer to *Restricting Globals* for details.

12.1.4 What can be pickled and unpickled?

The following types can be pickled:

- `None`, `True`, and `False`
- integers, floating point numbers, complex numbers
- strings, bytes, bytearrays
- tuples, lists, sets, and dictionaries containing only picklable objects
- functions defined at the top level of a module (using `def`, not `lambda`)
- built-in functions defined at the top level of a module
- classes that are defined at the top level of a module
- instances of such classes whose `__dict__` or the result of calling `__getstate__()` is picklable (see section *Pickling Class Instances* for details).

Attempts to pickle unpicklable objects will raise the *PicklingError* exception; when this happens, an unspecified number of bytes may have already been written to the underlying file. Trying to pickle a highly recursive data structure may exceed the maximum recursion depth, a *RecursionError* will be raised in this case. You can carefully raise this limit with `sys.setrecursionlimit()`.

Note that functions (built-in and user-defined) are pickled by “fully qualified” name reference, not by value.² This means that only the function name is pickled, along with the name of the module the function is defined in. Neither the function’s code, nor any of its function attributes are pickled. Thus the defining module must be importable in the unpickling environment, and the module must contain the named object, otherwise an exception will be raised.³

Similarly, classes are pickled by named reference, so the same restrictions in the unpickling environment apply. Note that none of the class’s code or data is pickled, so in the following example the class attribute `attr` is not restored in the unpickling environment:

```
class Foo:
    attr = 'A class attribute'

picklestring = pickle.dumps(Foo)
```

These restrictions are why picklable functions and classes must be defined in the top level of a module.

Similarly, when class instances are pickled, their class’s code and data are not pickled along with them. Only the instance data are pickled. This is done on purpose, so you can fix bugs in a class or add methods to the class and still load objects that were created with an earlier version of the class. If you plan to have long-lived objects that will see many versions of a class, it may be worthwhile to put a version number in the objects so that suitable conversions can be made by the class’s `__setstate__()` method.

12.1.5 Pickling Class Instances

In this section, we describe the general mechanisms available to you to define, customize, and control how class instances are pickled and unpickled.

² This is why `lambda` functions cannot be pickled: all `lambda` functions share the same name: `<lambda>`.

³ The exception raised will likely be an *ImportError* or an *AttributeError* but it could be something else.

In most cases, no additional code is needed to make instances picklable. By default, pickle will retrieve the class and the attributes of an instance via introspection. When a class instance is unpickled, its `__init__()` method is usually *not* invoked. The default behaviour first creates an uninitialized instance and then restores the saved attributes. The following code shows an implementation of this behaviour:

```
def save(obj):
    return (obj.__class__, obj.__dict__)

def load(cls, attributes):
    obj = cls.__new__(cls)
    obj.__dict__.update(attributes)
    return obj
```

Classes can alter the default behaviour by providing one or several special methods:

`object.__getnewargs_ex__()`

In protocols 2 and newer, classes that implements the `__getnewargs_ex__()` method can dictate the values passed to the `__new__()` method upon unpickling. The method must return a pair `(args, kwargs)` where `args` is a tuple of positional arguments and `kwargs` a dictionary of named arguments for constructing the object. Those will be passed to the `__new__()` method upon unpickling.

You should implement this method if the `__new__()` method of your class requires keyword-only arguments. Otherwise, it is recommended for compatibility to implement `__getnewargs__()`.

在 3.6 版更改: `__getnewargs_ex__()` is now used in protocols 2 and 3.

`object.__getnewargs__()`

This method serves a similar purpose as `__getnewargs_ex__()`, but supports only positional arguments. It must return a tuple of arguments `args` which will be passed to the `__new__()` method upon unpickling.

`__getnewargs__()` will not be called if `__getnewargs_ex__()` is defined.

在 3.6 版更改: Before Python 3.6, `__getnewargs__()` was called instead of `__getnewargs_ex__()` in protocols 2 and 3.

`object.__getstate__()`

Classes can further influence how their instances are pickled; if the class defines the method `__getstate__()`, it is called and the returned object is pickled as the contents for the instance, instead of the contents of the instance's dictionary. If the `__getstate__()` method is absent, the instance's `__dict__` is pickled as usual.

`object.__setstate__(state)`

Upon unpickling, if the class defines `__setstate__()`, it is called with the unpickled state. In that case, there is no requirement for the state object to be a dictionary. Otherwise, the pickled state must be a dictionary and its items are assigned to the new instance's dictionary.

注解: If `__getstate__()` returns a false value, the `__setstate__()` method will not be called upon unpickling.

Refer to the section *Handling Stateful Objects* for more information about how to use the methods `__getstate__()` and `__setstate__()`.

注解: At unpickling time, some methods like `__getattr__()`, `__getattribute__()`, or `__setattr__()` may be called upon the instance. In case those methods rely on some internal invariant being true, the type should implement `__getnewargs__()` or `__getnewargs_ex__()` to establish such an invariant; otherwise, neither `__new__()` nor `__init__()` will be called.

As we shall see, pickle does not use directly the methods described above. In fact, these methods are part of the copy protocol which implements the `__reduce__()` special method. The copy protocol provides a unified interface for retrieving the data necessary for pickling and copying objects.⁴

Although powerful, implementing `__reduce__()` directly in your classes is error prone. For this reason, class designers should use the high-level interface (i.e., `__getnewargs_ex__()`, `__getstate__()` and `__setstate__()`) whenever possible. We will show, however, cases where using `__reduce__()` is the only option or leads to more efficient pickling or both.

`object.__reduce__()`

The interface is currently defined as follows. The `__reduce__()` method takes no argument and shall return either a string or preferably a tuple (the returned object is often referred to as the “reduce value”).

If a string is returned, the string should be interpreted as the name of a global variable. It should be the object’s local name relative to its module; the pickle module searches the module namespace to determine the object’s module. This behaviour is typically useful for singletons.

When a tuple is returned, it must be between two and five items long. Optional items can either be omitted, or `None` can be provided as their value. The semantics of each item are in order:

- A callable object that will be called to create the initial version of the object.
- A tuple of arguments for the callable object. An empty tuple must be given if the callable does not accept any argument.
- Optionally, the object’s state, which will be passed to the object’s `__setstate__()` method as previously described. If the object has no such method then, the value must be a dictionary and it will be added to the object’s `__dict__` attribute.
- Optionally, an iterator (and not a sequence) yielding successive items. These items will be appended to the object either using `obj.append(item)` or, in batch, using `obj.extend(list_of_items)`. This is primarily used for list subclasses, but may be used by other classes as long as they have `append()` and `extend()` methods with the appropriate signature. (Whether `append()` or `extend()` is used depends on which pickle protocol version is used as well as the number of items to append, so both must be supported.)
- Optionally, an iterator (not a sequence) yielding successive key-value pairs. These items will be stored to the object using `obj[key] = value`. This is primarily used for dictionary subclasses, but may be used by other classes as long as they implement `__setitem__()`.

`object.__reduce_ex__(protocol)`

Alternatively, a `__reduce_ex__()` method may be defined. The only difference is this method should take a single integer argument, the protocol version. When defined, pickle will prefer it over the `__reduce__()` method. In addition, `__reduce__()` automatically becomes a synonym for the extended version. The main use for this method is to provide backwards-compatible reduce values for older Python releases.

Persistence of External Objects

For the benefit of object persistence, the `pickle` module supports the notion of a reference to an object outside the pickled data stream. Such objects are referenced by a persistent ID, which should be either a string of alphanumeric characters (for protocol 0)⁵ or just an arbitrary object (for any newer protocol).

The resolution of such persistent IDs is not defined by the `pickle` module; it will delegate this resolution to the user defined methods on the pickler and unpickler, `persistent_id()` and `persistent_load()` respectively.

To pickle objects that have an external persistent id, the pickler must have a custom `persistent_id()` method that takes an object as an argument and returns either `None` or the persistent id for that object. When `None` is returned, the

⁴ The `copy` module uses this protocol for shallow and deep copying operations.

⁵ The limitation on alphanumeric characters is due to the fact the persistent IDs, in protocol 0, are delimited by the newline character. Therefore if any kind of newline characters occurs in persistent IDs, the resulting pickle will become unreadable.

pickler simply pickles the object as normal. When a persistent ID string is returned, the pickler will pickle that object, along with a marker so that the unpickler will recognize it as a persistent ID.

To unpickle external objects, the unpickler must have a custom `persistent_load()` method that takes a persistent ID object and returns the referenced object.

Here is a comprehensive example presenting how persistent ID can be used to pickle external objects by reference.

```
# Simple example presenting how persistent ID can be used to pickle
# external objects by reference.

import pickle
import sqlite3
from collections import namedtuple

# Simple class representing a record in our database.
MemoRecord = namedtuple("MemoRecord", "key, task")

class DBPickler(pickle.Pickler):

    def persistent_id(self, obj):
        # Instead of pickling MemoRecord as a regular class instance, we emit a
        # persistent ID.
        if isinstance(obj, MemoRecord):
            # Here, our persistent ID is simply a tuple, containing a tag and a
            # key, which refers to a specific record in the database.
            return ("MemoRecord", obj.key)
        else:
            # If obj does not have a persistent ID, return None. This means obj
            # needs to be pickled as usual.
            return None

class DBUnpickler(pickle.Unpickler):

    def __init__(self, file, connection):
        super().__init__(file)
        self.connection = connection

    def persistent_load(self, pid):
        # This method is invoked whenever a persistent ID is encountered.
        # Here, pid is the tuple returned by DBPickler.
        cursor = self.connection.cursor()
        type_tag, key_id = pid
        if type_tag == "MemoRecord":
            # Fetch the referenced record from the database and return it.
            cursor.execute("SELECT * FROM memos WHERE key=?", (str(key_id),))
            key, task = cursor.fetchone()
            return MemoRecord(key, task)
        else:
            # Always raises an error if you cannot return the correct object.
            # Otherwise, the unpickler will think None is the object referenced
            # by the persistent ID.
            raise pickle.UnpicklingError("unsupported persistent object")

def main():
    import io
    import pprint
```

(下页继续)

(续上页)

```

# Initialize and populate our database.
conn = sqlite3.connect(":memory:")
cursor = conn.cursor()
cursor.execute("CREATE TABLE memos(key INTEGER PRIMARY KEY, task TEXT)")
tasks = (
    'give food to fish',
    'prepare group meeting',
    'fight with a zebra',
)
for task in tasks:
    cursor.execute("INSERT INTO memos VALUES(NULL, ?)", (task,))

# Fetch the records to be pickled.
cursor.execute("SELECT * FROM memos")
memos = [MemoRecord(key, task) for key, task in cursor]
# Save the records using our custom DBPickler.
file = io.BytesIO()
DBPickler(file).dump(memos)

print("Pickled records:")
pprint.pprint(memos)

# Update a record, just for good measure.
cursor.execute("UPDATE memos SET task='learn italian' WHERE key=1")

# Load the records from the pickle data stream.
file.seek(0)
memos = DBUnpickler(file, conn).load()

print("Unpickled records:")
pprint.pprint(memos)

if __name__ == '__main__':
    main()

```

Dispatch Tables

If one wants to customize pickling of some classes without disturbing any other code which depends on pickling, then one can create a pickler with a private dispatch table.

The global dispatch table managed by the `copyreg` module is available as `copyreg.dispatch_table`. Therefore, one may choose to use a modified copy of `copyreg.dispatch_table` as a private dispatch table.

For example

```

f = io.BytesIO()
p = pickle.Pickler(f)
p.dispatch_table = copyreg.dispatch_table.copy()
p.dispatch_table[SomeClass] = reduce_SomeClass

```

creates an instance of `pickle.Pickler` with a private dispatch table which handles the `SomeClass` class specially. Alternatively, the code

```
class MyPickler(pickle.Pickler):
    dispatch_table = copyreg.dispatch_table.copy()
    dispatch_table[SomeClass] = reduce_SomeClass
f = io.BytesIO()
p = MyPickler(f)
```

does the same, but all instances of `MyPickler` will by default share the same dispatch table. The equivalent code using the `copyreg` module is

```
copyreg.pickle(SomeClass, reduce_SomeClass)
f = io.BytesIO()
p = pickle.Pickler(f)
```

Handling Stateful Objects

Here's an example that shows how to modify pickling behavior for a class. The `TextReader` class opens a text file, and returns the line number and line contents each time its `readline()` method is called. If a `TextReader` instance is pickled, all attributes *except* the file object member are saved. When the instance is unpickled, the file is reopened, and reading resumes from the last location. The `__setstate__()` and `__getstate__()` methods are used to implement this behavior.

```
class TextReader:
    """Print and number lines in a text file."""

    def __init__(self, filename):
        self.filename = filename
        self.file = open(filename)
        self.lineno = 0

    def readline(self):
        self.lineno += 1
        line = self.file.readline()
        if not line:
            return None
        if line.endswith('\n'):
            line = line[:-1]
        return "%i: %s" % (self.lineno, line)

    def __getstate__(self):
        # Copy the object's state from self.__dict__ which contains
        # all our instance attributes. Always use the dict.copy()
        # method to avoid modifying the original state.
        state = self.__dict__.copy()
        # Remove the unpicklable entries.
        del state['file']
        return state

    def __setstate__(self, state):
        # Restore instance attributes (i.e., filename and lineno).
        self.__dict__.update(state)
        # Restore the previously opened file's state. To do so, we need to
        # reopen it and read from it until the line count is restored.
        file = open(self.filename)
        for _ in range(self.lineno):
            file.readline()
```

(下页继续)

(续上页)

```
# Finally, save the file.
self.file = file
```

A sample usage might be something like this:

```
>>> reader = TextReader("hello.txt")
>>> reader.readline()
'1: Hello world!'
>>> reader.readline()
'2: I am line number two.'
>>> new_reader = pickle.loads(pickle.dumps(reader))
>>> new_reader.readline()
'3: Goodbye!'
```

12.1.6 Restricting Globals

By default, unpickling will import any class or function that it finds in the pickle data. For many applications, this behaviour is unacceptable as it permits the unpickler to import and invoke arbitrary code. Just consider what this hand-crafted pickle data stream does when loaded:

```
>>> import pickle
>>> pickle.loads(b"cos\nsystem\n(S'echo hello world'\ntr.")
hello world
0
```

In this example, the unpickler imports the `os.system()` function and then apply the string argument “echo hello world”. Although this example is inoffensive, it is not difficult to imagine one that could damage your system.

For this reason, you may want to control what gets unpickled by customizing `Unpickler.find_class()`. Unlike its name suggests, `Unpickler.find_class()` is called whenever a global (i.e., a class or a function) is requested. Thus it is possible to either completely forbid globals or restrict them to a safe subset.

Here is an example of an unpickler allowing only few safe classes from the `builtins` module to be loaded:

```
import builtins
import io
import pickle

safe_builtins = {
    'range',
    'complex',
    'set',
    'frozenset',
    'slice',
}

class RestrictedUnpickler(pickle.Unpickler):

    def find_class(self, module, name):
        # Only allow safe classes from builtins.
        if module == "builtins" and name in safe_builtins:
            return getattr(builtins, name)
        # Forbid everything else.
        raise pickle.UnpicklingError("global '%s.%s' is forbidden" %
                                      (module, name))
```

(下页继续)

(续上页)

```
def restricted_loads(s):
    """Helper function analogous to pickle.loads()."""
    return RestrictedUnpickler(io.BytesIO(s)).load()
```

A sample usage of our unpickler working has intended:

```
>>> restricted_loads(pickle.dumps([1, 2, range(15)]))
[1, 2, range(0, 15)]
>>> restricted_loads(b"cos\nsystem\n(S'echo hello world'\nR.")
Traceback (most recent call last):
...
pickle.UnpicklingError: global 'os.system' is forbidden
>>> restricted_loads(b'cbuiltins\neval\n'
...                  b'(S\'getattr(__import__("os"), "system")'
...                  b'("echo hello world")\'\nR.')
Traceback (most recent call last):
...
pickle.UnpicklingError: global 'builtins.eval' is forbidden
```

As our examples shows, you have to be careful with what you allow to be unpickled. Therefore if security is a concern, you may want to consider alternatives such as the marshalling API in *xmlrpc.client* or third-party solutions.

12.1.7 性能

Recent versions of the pickle protocol (from protocol 2 and upwards) feature efficient binary encodings for several common features and built-in types. Also, the *pickle* module has a transparent optimizer written in C.

12.1.8 示例

For the simplest code, use the *dump()* and *load()* functions.

```
import pickle

# An arbitrary collection of objects supported by pickle.
data = {
    'a': [1, 2.0, 3, 4+6j],
    'b': ("character string", b"byte string"),
    'c': {None, True, False}
}

with open('data.pickle', 'wb') as f:
    # Pickle the 'data' dictionary using the highest protocol available.
    pickle.dump(data, f, pickle.HIGHEST_PROTOCOL)
```

The following example reads the resulting pickled data.

```
import pickle

with open('data.pickle', 'rb') as f:
    # The protocol version used is detected automatically, so we do not
    # have to specify it.
    data = pickle.load(f)
```

参见:

模块 `shelve` Indexed databases of objects; uses `pickle`.

Module `copy` Shallow and deep object copying.

Module `marshal` High-performance serialization of built-in types.

12.2 copyreg — Register pickle support functions

Source code: `Lib/copyreg.py`

The `copyreg` module offers a way to define functions used while pickling specific objects. The `pickle` and `copy` modules use those functions when pickling/copying those objects. The module provides configuration information about object constructors which are not classes. Such constructors may be factory functions or class instances.

`copyreg.constructor(object)`

Declares *object* to be a valid constructor. If *object* is not callable (and hence not valid as a constructor), raises `TypeError`.

`copyreg.pickle(type, function, constructor=None)`

Declares that *function* should be used as a “reduction” function for objects of type *type*. *function* should return either a string or a tuple containing two or three elements.

The optional *constructor* parameter, if provided, is a callable object which can be used to reconstruct the object when called with the tuple of arguments returned by *function* at pickling time. `TypeError` will be raised if *object* is a class or *constructor* is not callable.

See the `pickle` module for more details on the interface expected of *function* and *constructor*. Note that the `dispatch_table` attribute of a pickler object or subclass of `pickle.Pickler` can also be used for declaring reduction functions.

12.2.1 示例

The example below would like to show how to register a pickle function and how it will be used:

```
>>> import copyreg, copy, pickle
>>> class C(object):
...     def __init__(self, a):
...         self.a = a
...
>>> def pickle_c(c):
...     print("pickling a C instance...")
...     return C, (c.a,)
...
>>> copyreg.pickle(C, pickle_c)
>>> c = C(1)
>>> d = copy.copy(c)
pickling a C instance...
>>> p = pickle.dumps(c)
pickling a C instance...
```

12.3 `shelve` —Python object persistence

Source code: [Lib/shelve.py](#)

A “shelf” is a persistent, dictionary-like object. The difference with “dbm” databases is that the values (not the keys!) in a shelf can be essentially arbitrary Python objects —anything that the `pickle` module can handle. This includes most class instances, recursive data types, and objects containing lots of shared sub-objects. The keys are ordinary strings.

`shelve.open(filename, flag='c', protocol=None, writeback=False)`

Open a persistent dictionary. The filename specified is the base filename for the underlying database. As a side-effect, an extension may be added to the filename and more than one file may be created. By default, the underlying database file is opened for reading and writing. The optional `flag` parameter has the same interpretation as the `flag` parameter of `dbm.open()`.

By default, version 3 pickles are used to serialize values. The version of the pickle protocol can be specified with the `protocol` parameter.

Because of Python semantics, a shelf cannot know when a mutable persistent-dictionary entry is modified. By default modified objects are written *only* when assigned to the shelf (see 示例). If the optional `writeback` parameter is set to `True`, all entries accessed are also cached in memory, and written back on `sync()` and `close()`; this can make it handier to mutate mutable entries in the persistent dictionary, but, if many entries are accessed, it can consume vast amounts of memory for the cache, and it can make the close operation very slow since all accessed entries are written back (there is no way to determine which accessed entries are mutable, nor which ones were actually mutated).

注解: Do not rely on the shelf being closed automatically; always call `close()` explicitly when you don't need it any more, or use `shelve.open()` as a context manager:

```
with shelve.open('spam') as db:
    db['eggs'] = 'eggs'
```

警告: Because the `shelve` module is backed by `pickle`, it is insecure to load a shelf from an untrusted source. Like with pickle, loading a shelf can execute arbitrary code.

Shelf objects support all methods supported by dictionaries. This eases the transition from dictionary based scripts to those requiring persistent storage.

Two additional methods are supported:

`Shelf.sync()`

Write back all entries in the cache if the shelf was opened with `writeback` set to `True`. Also empty the cache and synchronize the persistent dictionary on disk, if feasible. This is called automatically when the shelf is closed with `close()`.

`Shelf.close()`

Synchronize and close the persistent `dict` object. Operations on a closed shelf will fail with a `ValueError`.

参见:

[Persistent dictionary recipe](#) with widely supported storage formats and having the speed of native dictionaries.

12.3.1 Restrictions

- The choice of which database package will be used (such as `dbm.ndbm` or `dbm.gnu`) depends on which interface is available. Therefore it is not safe to open the database directly using `dbm`. The database is also (unfortunately) subject to the limitations of `dbm`, if it is used —this means that (the pickled representation of) the objects stored in the database should be fairly small, and in rare cases key collisions may cause the database to refuse updates.
- The `shelve` module does not support *concurrent* read/write access to shelved objects. (Multiple simultaneous read accesses are safe.) When a program has a shelf open for writing, no other program should have it open for reading or writing. Unix file locking can be used to solve this, but this differs across Unix versions and requires knowledge about the database implementation used.

class `shelve.Shelf` (*dict*, *protocol=None*, *writeback=False*, *keyencoding='utf-8'*)

A subclass of `collections.abc.MutableMapping` which stores pickled values in the *dict* object.

By default, version 3 pickles are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter. See the `pickle` documentation for a discussion of the pickle protocols.

If the *writeback* parameter is `True`, the object will hold a cache of all entries accessed and write them back to the *dict* at sync and close times. This allows natural operations on mutable entries, but can consume much more memory and make sync and close take a long time.

The *keyencoding* parameter is the encoding used to encode keys before they are used with the underlying dict.

A `Shelf` object can also be used as a context manager, in which case it will be automatically closed when the `with` block ends.

在 3.2 版更改: Added the *keyencoding* parameter; previously, keys were always encoded in UTF-8.

在 3.4 版更改: 添加了上下文管理器支持

class `shelve.BsddbShelf` (*dict*, *protocol=None*, *writeback=False*, *keyencoding='utf-8'*)

A subclass of `Shelf` which exposes `first()`, `next()`, `previous()`, `last()` and `set_location()` which are available in the third-party `bsddb` module from `pybsddb` but not in other database modules. The *dict* object passed to the constructor must support those methods. This is generally accomplished by calling one of `bsddb.hashopen()`, `bsddb.btopen()` or `bsddb.rnopen()`. The optional *protocol*, *writeback*, and *keyencoding* parameters have the same interpretation as for the `Shelf` class.

class `shelve.DbfilenameShelf` (*filename*, *flag='c'*, *protocol=None*, *writeback=False*)

A subclass of `Shelf` which accepts a *filename* instead of a dict-like object. The underlying file will be opened using `dbm.open()`. By default, the file will be created and opened for both read and write. The optional *flag* parameter has the same interpretation as for the `open()` function. The optional *protocol* and *writeback* parameters have the same interpretation as for the `Shelf` class.

12.3.2 示例

To summarize the interface (key is a string, data is an arbitrary object):

```
import shelve

d = shelve.open(filename) # open -- file may get suffix added by low-level
                           # library

d[key] = data              # store data at key (overwrites old data if
                           # using an existing key)
data = d[key]              # retrieve a COPY of data at key (raise KeyError
```

(下页继续)

(续上页)

```

                                # if no such key)
del d[key]                      # delete data stored at key (raises KeyError)
                                # if no such key)

flag = key in d                  # true if the key exists
klist = list(d.keys())          # a list of all existing keys (slow!)

# as d was opened WITHOUT writeback=True, beware:
d['xx'] = [0, 1, 2]             # this works as expected, but...
d['xx'].append(3)               # *this doesn't!* -- d['xx'] is STILL [0, 1, 2]!

# having opened d without writeback=True, you need to code carefully:
temp = d['xx']                  # extracts the copy
temp.append(5)                  # mutates the copy
d['xx'] = temp                  # stores the copy right back, to persist it

# or, d=shelve.open(filename,writeback=True) would let you just code
# d['xx'].append(5) and have it work as expected, BUT it would also
# consume more memory and make the d.close() operation slower.

d.close()                      # close it

```

参见:**Module `dbm`** Generic interface to dbm-style databases.**模块 `pickle`** Object serialization used by `shelve`.

12.4 `marshal` —Internal Python object serialization

This module contains functions that can read and write Python values in a binary format. The format is specific to Python, but independent of machine architecture issues (e.g., you can write a Python value to a file on a PC, transport the file to a Sun, and read it back there). Details of the format are undocumented on purpose; it may change between Python versions (although it rarely does).¹

This is not a general “persistence” module. For general persistence and transfer of Python objects through RPC calls, see the modules `pickle` and `shelve`. The `marshal` module exists mainly to support reading and writing the “pseudo-compiled” code for Python modules of `.pyc` files. Therefore, the Python maintainers reserve the right to modify the marshal format in backward incompatible ways should the need arise. If you’re serializing and de-serializing Python objects, use the `pickle` module instead – the performance is comparable, version independence is guaranteed, and pickle supports a substantially wider range of objects than marshal.

警告: The `marshal` module is not intended to be secure against erroneous or maliciously constructed data. Never unmarshal data received from an untrusted or unauthenticated source.

Not all Python object types are supported; in general, only objects whose value is independent from a particular invocation of Python can be written and read by this module. The following types are supported: booleans, integers, floating point numbers, complex numbers, strings, bytes, bytearray, tuples, lists, sets, frozensets, dictionaries, and code objects, where

¹ The name of this module stems from a bit of terminology used by the designers of Modula-3 (amongst others), who use the term “marshalling” for shipping of data around in a self-contained form. Strictly speaking, “to marshal” means to convert some data from internal to external form (in an RPC buffer for instance) and “unmarshalling” for the reverse process.

it should be understood that tuples, lists, sets, frozensets and dictionaries are only supported as long as the values contained therein are themselves supported. The singletons *None*, *Ellipsis* and *StopIteration* can also be marshalled and unmarshalled. For format *version* lower than 3, recursive lists, sets and dictionaries cannot be written (see below).

There are functions that read/write files as well as functions operating on bytes-like objects.

The module defines these functions:

`marshal.dump(value, file[, version])`

Write the value on the open file. The value must be a supported type. The file must be a writeable *binary file*.

If the value has (or contains an object that has) an unsupported type, a *ValueError* exception is raised—but garbage data will also be written to the file. The object will not be properly read back by *load()*.

The *version* argument indicates the data format that *dump* should use (see below).

`marshal.load(file)`

Read one value from the open file and return it. If no valid value is read (e.g. because the data has a different Python version's incompatible marshal format), raise *EOFError*, *ValueError* or *TypeError*. The file must be a readable *binary file*.

注解: If an object containing an unsupported type was marshalled with *dump()*, *load()* will substitute *None* for the unmarshallable type.

`marshal.dumps(value[, version])`

Return the bytes object that would be written to a file by *dump(value, file)*. The value must be a supported type. Raise a *ValueError* exception if value has (or contains an object that has) an unsupported type.

The *version* argument indicates the data format that *dumps* should use (see below).

`marshal.loads(bytes)`

Convert the *bytes-like object* to a value. If no valid value is found, raise *EOFError*, *ValueError* or *TypeError*. Extra bytes in the input are ignored.

In addition, the following constants are defined:

`marshal.version`

Indicates the format that the module uses. Version 0 is the historical format, version 1 shares interned strings and version 2 uses a binary format for floating point numbers. Version 3 adds support for object instancing and recursion. The current version is 4.

12.5 dbm —Interfaces to Unix “databases”

源代码: [Lib/dbm/__init__.py](#)

dbm is a generic interface to variants of the DBM database—*dbm.gnu* or *dbm.ndbm*. If none of these modules is installed, the slow-but-simple implementation in module *dbm.dumb* will be used. There is a *third party interface* to the Oracle Berkeley DB.

exception `dbm.error`

A tuple containing the exceptions that can be raised by each of the supported modules, with a unique exception also named *dbm.error* as the first item—the latter is used when *dbm.error* is raised.

`dbm.whichdb(filename)`

This function attempts to guess which of the several simple database modules available—*dbm.gnu*, *dbm.ndbm* or *dbm.dumb*—should be used to open a given file.

Returns one of the following values: `None` if the file can't be opened because it's unreadable or doesn't exist; the empty string (`''`) if the file's format can't be guessed; or a string containing the required module name, such as `'dbm.ndbm'` or `'dbm.gnu'`.

`dbm.open(file, flag='r', mode=0o666)`

Open the database file *file* and return a corresponding object.

If the database file already exists, the `whichdb()` function is used to determine its type and the appropriate module is used; if it does not exist, the first module listed above that can be imported is used.

可选的 *flag* 参数可以是：

值	意义
'r'	以只读方式打开现有数据库（默认）
'w'	以读写方式打开现有数据库
'c'	以读写方式打开数据库，如果不存在则创建它
'n'	始终创建一个新的空数据库，以读写方式打开

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666` (and will be modified by the prevailing `umask`).

The object returned by `open()` supports the same basic functionality as dictionaries; keys and their corresponding values can be stored, retrieved, and deleted, and the `in` operator and the `keys()` method are available, as well as `get()` and `setdefault()`.

在 3.2 版更改: `get()` and `setdefault()` are now available in all database modules.

Key and values are always stored as bytes. This means that when strings are used they are implicitly converted to the default encoding before being stored.

These objects also support being used in a `with` statement, which will automatically close them when done.

在 3.4 版更改: Added native support for the context management protocol to the objects returned by `open()`.

The following example records some hostnames and a corresponding title, and then prints out the contents of the database:

```
import dbm

# Open database, creating it if necessary.
with dbm.open('cache', 'c') as db:

    # Record some values
    db[b'hello'] = b'there'
    db['www.python.org'] = 'Python Website'
    db['www.cnn.com'] = 'Cable News Network'

    # Note that the keys are considered bytes now.
    assert db[b'www.python.org'] == b'Python Website'
    # Notice how the value is now in bytes.
    assert db['www.cnn.com'] == b'Cable News Network'

    # Often-used methods of the dict interface work too.
    print(db.get('python.org', b'not present'))

    # Storing a non-string key or value will raise an exception (most
    # likely a TypeError).
    db['www.yahoo.com'] = 4

# db is automatically closed when leaving the with statement.
```

参见:

模块 [shelve](#) Persistence module which stores non-string data.

The individual submodules are described in the following sections.

12.5.1 `dbm.gnu` —GNU' s reinterpretation of `dbm`

源代码: [Lib/dbm/gnu.py](#)

This module is quite similar to the `dbm` module, but uses the GNU library `gdbm` instead to provide some additional functionality. Please note that the file formats created by `dbm.gnu` and `dbm.ndbm` are incompatible.

The `dbm.gnu` module provides an interface to the GNU DBM library. `dbm.gnu.gdbm` objects behave like mappings (dictionaries), except that keys and values are always converted to bytes before storing. Printing a `gdbm` object doesn't print the keys and values, and the `items()` and `values()` methods are not supported.

exception `dbm.gnu.error`

Raised on `dbm.gnu`-specific errors, such as I/O errors. `KeyError` is raised for general mapping errors like specifying an incorrect key.

`dbm.gnu.open(filename[, flag[, mode]])`

Open a `gdbm` database and return a `gdbm` object. The `filename` argument is the name of the database file.

可选的 `flag` 参数可以是:

值	意义
'r'	以只读方式打开现有数据库 (默认)
'w'	以读写方式打开现有数据库
'c'	以读写方式打开数据库, 如果不存在则创建它
'n'	始终创建一个新的空数据库, 以读写方式打开

The following additional characters may be appended to the flag to control how the database is opened:

值	意义
'f'	以快速模式打开数据库。写入数据库将不会同步。
's'	同步模式。这将导致数据库的更改立即写入文件。
'u'	不要锁定数据库。

Not all flags are valid for all versions of `gdbm`. The module constant `open_flags` is a string of supported flag characters. The exception `error` is raised if an invalid flag is specified.

The optional `mode` argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666`.

In addition to the dictionary-like methods, `gdbm` objects have the following methods:

`gdbm.firstkey()`

It's possible to loop over every key in the database using this method and the `nextkey()` method. The traversal is ordered by `gdbm`'s internal hash values, and won't be sorted by the key values. This method returns the starting key.

`gdbm.nextkey(key)`

Returns the key that follows `key` in the traversal. The following code prints every key in the database `db`, without having to create a list in memory that contains them all:

```
k = db.firstkey()
while k != None:
    print(k)
    k = db.nextkey(k)
```

`gdbm.reorganize()`

If you have carried out a lot of deletions and would like to shrink the space used by the `gdbm` file, this routine will reorganize the database. `gdbm` objects will not shorten the length of a database file except by using this reorganization; otherwise, deleted file space will be kept and reused as new (key, value) pairs are added.

`gdbm.sync()`

When the database has been opened in fast mode, this method forces any unwritten data to be written to the disk.

`gdbm.close()`

Close the `gdbm` database.

12.5.2 `dbm.ndbm` —Interface based on `ndbm`

源代码: [Lib/dbm/ndbm.py](#)

The `dbm.ndbm` module provides an interface to the Unix “(n)dbm” library. Dbm objects behave like mappings (dictionaries), except that keys and values are always stored as bytes. Printing a dbm object doesn’t print the keys and values, and the `items()` and `values()` methods are not supported.

This module can be used with the “classic” `ndbm` interface or the GNU GDBM compatibility interface. On Unix, the **configure** script will attempt to locate the appropriate header file to simplify building this module.

exception `dbm.ndbm.error`

Raised on `dbm.ndbm`-specific errors, such as I/O errors. `KeyError` is raised for general mapping errors like specifying an incorrect key.

`dbm.ndbm.library`

Name of the `ndbm` implementation library used.

`dbm.ndbm.open(filename[, flag[, mode]])`

Open a dbm database and return a `ndbm` object. The *filename* argument is the name of the database file (without the `.dir` or `.pag` extensions).

The optional *flag* argument must be one of these values:

值	意义
'r'	以只读方式打开现有数据库（默认）
'w'	以读写方式打开现有数据库
'c'	以读写方式打开数据库，如果不存在则创建它
'n'	始终创建一个新的空数据库，以读写方式打开

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal 0o666 (and will be modified by the prevailing `umask`).

In addition to the dictionary-like methods, `ndbm` objects provide the following method:

`ndbm.close()`

Close the `ndbm` database.

12.5.3 dbm.dumb —Portable DBM implementation

源代码: [Lib/dbm/dumb.py](#)

注解: The `dbm.dumb` module is intended as a last resort fallback for the `dbm` module when a more robust module is not available. The `dbm.dumb` module is not written for speed and is not nearly as heavily used as the other database modules.

The `dbm.dumb` module provides a persistent dictionary-like interface which is written entirely in Python. Unlike other modules such as `dbm.gnu` no external library is required. As with other persistent mappings, the keys and values are always stored as bytes.

The module defines the following:

exception `dbm.dumb.error`

Raised on `dbm.dumb`-specific errors, such as I/O errors. `KeyError` is raised for general mapping errors like specifying an incorrect key.

`dbm.dumb.open(filename[, flag[, mode]])`

Open a dumbdbm database and return a dumbdbm object. The `filename` argument is the basename of the database file (without any specific extensions). When a dumbdbm database is created, files with `.dat` and `.dir` extensions are created.

The optional `flag` argument supports only the semantics of `'c'` and `'n'` values. Other values will default to database being always opened for update, and will be created if it does not exist.

The optional `mode` argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666` (and will be modified by the prevailing `umask`).

在 3.5 版更改: `open()` always creates a new database when the flag has the value `'n'`.

Deprecated since version 3.6, will be removed in version 3.8: Creating database in `'r'` and `'w'` modes. Modifying database in `'r'` mode.

In addition to the methods provided by the `collections.abc.MutableMapping` class, dumbdbm objects provide the following methods:

`dumbdbm.sync()`

Synchronize the on-disk directory and data files. This method is called by the `Shelve.sync()` method.

`dumbdbm.close()`

Close the dumbdbm database.

12.6 sqlite3 —SQLite 数据库 DB-API 2.0 接口模块

源代码: [Lib/sqlite3/](#)

SQLite 是一个 C 语言库, 它可以提供一种轻量级的基于磁盘的数据库, 这种数据库不需要独立的服务器进程, 也允许需要使用一种非标准的 SQL 查询语言来访问它。一些应用程序可以使用 SQLite 作为内部数据存储。可以用它来创建一个应用程序原型, 然后再迁移到更大的数据库, 比如 PostgreSQL 或 Oracle。

sqlite3 模块是由 Gerhard Häring 编写。它提供了符合 DB-API 2.0 规范的接口, 这个规范是 [PEP 249](#)。

要使用这个模块, 必须先创建一个 `Connection` 对象, 它代表数据库。下面例子中, 数据将存储在 `example.db` 文件中:

```
import sqlite3
conn = sqlite3.connect('example.db')
```

你也可以使用 `:memory:` 来创建一个内存中的数据库

当有了 `Connection` 对象后，你可以创建一个 `Cursor` 游标对象，然后调用它的 `execute()` 方法来执行 SQL 语句：

```
c = conn.cursor()

# Create table
c.execute('CREATE TABLE stocks
          (date text, trans text, symbol text, qty real, price real)')

# Insert a row of data
c.execute("INSERT INTO stocks VALUES ('2006-01-05','BUY','RHAT',100,35.14)")

# Save (commit) the changes
conn.commit()

# We can also close the connection if we are done with it.
# Just be sure any changes have been committed or they will be lost.
conn.close()
```

这些数据被持久化保存了，而且可以在之后的会话中使用它们：

```
import sqlite3
conn = sqlite3.connect('example.db')
c = conn.cursor()
```

通常你的 SQL 操作需要使用一些 Python 变量的值。你不应该使用 Python 的字符串操作来创建你的查询语句，因为那样做不安全；它会使你的程序容易受到 SQL 注入攻击（在 <https://xkcd.com/327/> 上有一个搞笑的例子，看看有什么后果）

推荐另外一种方法：使用 DB-API 的参数替换。在你的 SQL 语句中，使用 `?` 占位符来代替值，然后把对应的值组成的元组做为 `execute()` 方法的第二个参数。（其他数据库可能会使用不同的占位符，比如 `%s` 或者 `:1`）例如：

```
# Never do this -- insecure!
symbol = 'RHAT'
c.execute("SELECT * FROM stocks WHERE symbol = '%s'" % symbol)

# Do this instead
t = ('RHAT',)
c.execute('SELECT * FROM stocks WHERE symbol=?', t)
print(c.fetchone())

# Larger example that inserts many records at a time
purchases = [('2006-03-28', 'BUY', 'IBM', 1000, 45.00),
              ('2006-04-05', 'BUY', 'MSFT', 1000, 72.00),
              ('2006-04-06', 'SELL', 'IBM', 500, 53.00),
              ]
c.executemany('INSERT INTO stocks VALUES (?, ?, ?, ?, ?)', purchases)
```

要在执行 `SELECT` 语句后获取数据，你可以把游标作为 `iterator`，然后调用它的 `fetchone()` 方法来获取一条匹配的行，也可以调用 `fetchall()` 来得到包含多个匹配行的列表。

下面是一个使用迭代器形式的例子：

```
>>> for row in c.execute('SELECT * FROM stocks ORDER BY price'):
    print(row)

('2006-01-05', 'BUY', 'RHAT', 100, 35.14)
('2006-03-28', 'BUY', 'IBM', 1000, 45.0)
('2006-04-06', 'SELL', 'IBM', 500, 53.0)
('2006-04-05', 'BUY', 'MSFT', 1000, 72.0)
```

PEP 249 - DB-API 2.0 规范 Marc-André Lemburg 写的 PEP。

12.6.1 模块函数和常量

sqlite3.version

这个模块的版本号，是一个字符串。不是 SQLite 库的版本号。

sqlite3.version_info

这个模块的版本号，是一个由整数组成的元组。不是 SQLite 库的版本号。

sqlite3.sqlite_version

使用中的 SQLite 库的版本号，是一个字符串。

sqlite3.sqlite_version_info

使用中的 SQLite 库的版本号，是一个整数组成的元组。

sqlite3.PARSE_DECLTYPES

这个常量可以作为 `connect()` 函数的 `detect_types` 参数。

设置这个参数后，`sqlite3` 模块将解析它返回的每一列声明的类型。它会声明的类型的第一个单词，比如 “integer primary key”，它会解析出 “integer”，再比如 “number(10)”，它会解析出 “number”。然后，它会在转换器字典里查找那个类型注册的转换器函数，并调用它。

sqlite3.PARSE_COLNAMES

这个常量可以作为 `connect()` 函数的 `detect_types` 参数。

设置这个参数后，SQLite 接口将解析它返回的每一列的列名。它会在其中查找 [mytype] 这个形式的字符串，然后用 ‘mytype’ 来决定那个列的类型。它会尝试在转换器字典中查找 ‘mytype’ 键对应的转换器函数，然后用这个转换器函数返回的值来做为列的类型。在 `Cursor.description` 中找到的列名仅仅是列名的第一个单词，比如你在 SQL 中使用 ‘as “x [datetime]”’，然后它会解析出第一个空白字符前的所有字符来作为列名：列名就是 “x”。

sqlite3.connect (*database* [, *timeout*, *detect_types*, *isolation_level*, *check_same_thread*, *factory*, *cached_statements*, *uri*])

Opens a connection to the SQLite database file *database*. You can use “:memory:” to open a database connection to a database that resides in RAM instead of on disk.

当一个数据库被多个连接访问的时候，如果其中一个进程修改这个数据库，在这个事务提交之前，这个 SQLite 数据库将会被一直锁定。*timeout* 参数指定了这个连接等待锁释放的超时时间，超时之后会引发一个异常。这个超时时间默认是 5.0（5 秒）。

isolation_level 参数，请查看 `Connection` 对象的 `isolation_level` 属性。

SQLite 原生只支持 5 种类型：TEXT，INTEGER，REAL，BLOB 和 NULL。如果你想用其它类型，你必须自己添加相应的支持。使用 `detect_types` 参数和模块级别的 `register_converter()` 函数注册 ** 转换器 ** 可以简单的实现。

`detect_types` 默认为 0 (即关闭, 没有类型检测)。你也可以组合 `PARSE_DECLTYPES` 和 `PARSE_COLNAMES` 来开启类型检测。

默认情况下, `check_same_thread` 为 `True`, 只有当前的线程可以使用该连接。如果设置为 `False`, 则多个线程可以共享返回的连接。当多个线程使用同一个连接的时候, 用户应该把写操作进行序列化, 以避免数据损坏。

默认情况下, 当调用 `connect` 方法的时候, `sqlite3` 模块使用了它的 `Connection` 类。当然, 你也可以创建 `Connection` 类的子类, 然后创建提供了 `factory` 参数的 `connect()` 方法。

详情请查阅当前手册的 [SQLite 与 Python 类型](#) 部分。

`sqlite3` 模块在内部使用语句缓存来避免 SQL 解析开销。如果要显式设置当前连接可以缓存的语句数, 可以设置 `cached_statements` 参数。当前实现的默认值是缓存 100 条语句。

如果 `uri` 为真, 则 `database` 被解释为 URI。它允许您指定选项。例如, 以只读模式打开数据库:

```
db = sqlite3.connect('file:path/to/database?mode=ro', uri=True)
```

有关此功能的更多信息, 包括已知选项的列表, 可以在 ‘SQLite URI 文档 <<https://www.sqlite.org/uri.html>>’ 中找到。

在 3.4 版更改: 增加了 `uri` 参数。

`sqlite3.register_converter(typename, callable)`

注册一个回调对象 `callable`, 用来转换数据库中的字节串为自定的 Python 类型。所有类型为 `typename` 的数据库的值在转换时, 都会调用这个回调对象。通过指定 `connect()` 函数的 `detect-types` 参数来设置类型检测的方式。注意, `typename` 与查询语句中的类型名进行匹配时不区分大小写。

`sqlite3.register_adapter(type, callable)`

注册一个回调对象 `callable`, 用来转换自定义 Python 类型为一个 SQLite 支持的类型。这个回调对象 `callable` 仅接受一个 Python 值作为参数, 而且必须返回以下某个类型的值: `int`, `float`, `str` 或 `bytes`。

`sqlite3.complete_statement(sql)`

如果字符串 `sql` 包含一个或多个完整的 SQL 语句 (以分号结束) 则返回 `True`。它不会验证 SQL 语法是否正确, 仅会验证字符串字面上是否完整, 以及是否以分号结束。

它可以用来构建一个 SQLite shell, 下面是一个例子:

```
# A minimal SQLite shell for experiments

import sqlite3

con = sqlite3.connect(":memory:")
con.isolation_level = None
cur = con.cursor()

buffer = ""

print("Enter your SQL commands to execute in sqlite3.")
print("Enter a blank line to exit.")

while True:
    line = input()
    if line == "":
        break
    buffer += line
```

(下页继续)

(续上页)

```

if sqlite3.complete_statement(buffer):
    try:
        buffer = buffer.strip()
        cur.execute(buffer)

        if buffer.lstrip().upper().startswith("SELECT"):
            print(cur.fetchall())
    except sqlite3.Error as e:
        print("An error occurred:", e.args[0])
    buffer = ""

con.close()

```

`sqlite3.enable_callback_tracebacks(flag)`

默认情况下，您不会获得任何用户定义函数中的回溯消息，比如聚合，转换器，授权器回调等。如果要调试它们，可以设置 `flag` 参数为 `True` 并调用此函数。之后，回调中的回溯信息将会输出到 `sys.stderr`。再次使用 `False` 来禁用该功能。

12.6.2 连接对象 (Connection)

class `sqlite3.Connection`

SQLite 数据库连接对象有如下的属性和方法：

isolation_level

获取或设置当前默认的隔离级别。表示自动提交模式的 `None` 以及 “DEFERRED”，“IMMEDIATE” 或 “EXCLUSIVE” 其中之一。详细描述请参阅 *Controlling Transactions*。

in_transaction

如果是在活动事务中（还没有提交改变），返回 `True`，否则，返回 `False`。它是一个只读属性。

3.2 新版功能。

cursor (`factory=Cursor`)

这个方法接受一个可选参数 `factory`，如果要指定这个参数，它必须是一个可调用对象，而且必须返回 `Cursor` 类的一个实例或者子类。

commit()

这个方法提交当前事务。如果没有调用这个方法，那么从上一次提交 `commit()` 以来所有的变化在其他数据库连接上都是不可见的。如果你往数据库里写了数据，但是又查询不到，请检查是否忘记了调用这个方法。

rollback()

这个方法回滚从上一次调用 `commit()` 以来所有数据库的改变。

close()

关闭数据库连接。注意，它不会自动调用 `commit()` 方法。如果在关闭数据库连接之前没有调用 `commit()`，那么你的修改将会丢失！

execute (`sql[, parameters]`)

这是一个非标准的快捷方法，它会调用 `cursor()` 方法来创建一个游标对象，并使用给定的 `parameters` 参数来调用游标对象的 `execute()` 方法，最后返回这个游标对象。

executemany (`sql[, parameters]`)

这是一个非标准的快捷方法，它会调用 `cursor()` 方法来创建一个游标对象，并使用给定的 `parameters` 参数来调用游标对象的 `executemany()` 方法，最后返回这个游标对象。

executescript (*sql_script*)

这是一个非标准的快捷方法，它会调用 `cursor()` 方法来创建一个游标对象，并使用给定的 `sql_script` 参数来调用游标对象的 `executescript()` 方法，最后返回这个游标对象。

create_function (*name, num_params, func*)

创建一个可以在 SQL 语句中使用的自定义函数，其中参数 *name* 为 SQL 语句中使用的函数名，*num_params* 是这个函数接受的参数个数（如果 *num_params* 为 -1，那这个函数可以接受任意数量的参数），最后一个参数 *func* 是作为 SQL 函数调用的一个 Python 可调用对象。

此函数可返回任何 SQLite 所支持的类型：bytes, str, int, float 和 None。

示例：

```
import sqlite3
import hashlib

def md5sum(t):
    return hashlib.md5(t).hexdigest()

con = sqlite3.connect(":memory:")
con.create_function("md5", 1, md5sum)
cur = con.cursor()
cur.execute("select md5(?)", (b"foo",))
print(cur.fetchone()[0])
```

create_aggregate (*name, num_params, aggregate_class*)

创建一个自定义的聚合函数。

参数中 *aggregate_class* 类必须实现两个方法：step 和 finalize。step 方法接受 *num_params* 个参数（如果 *num_params* 为 -1，那么这个函数可以接受任意数量的参数）；finalize 方法返回最终的聚合结果。

finalize 方法可以返回任何 SQLite 支持的类型：bytes, str, int, float 和 None。

示例：

```
import sqlite3

class MySum:
    def __init__(self):
        self.count = 0

    def step(self, value):
        self.count += value

    def finalize(self):
        return self.count

con = sqlite3.connect(":memory:")
con.create_aggregate("mysum", 1, MySum)
cur = con.cursor()
cur.execute("create table test(i)")
cur.execute("insert into test(i) values (1)")
cur.execute("insert into test(i) values (2)")
cur.execute("select mysum(i) from test")
print(cur.fetchone()[0])
```

create_collation (*name, callable*)

使用 *name* 和 *callable* 创建排序规则。这个 *callable* 接受两个字符串对象，如果第一个小于第二个

则返回 -1，如果两个相等则返回 0，如果第一个大于第二个则返回 1。注意，这是用来控制排序的 (SQL 中的 ORDER BY)，所以它不会影响其它的 SQL 操作。

注意，这个 *callable* 可调用对象会把它的参数作为 Python 字节串，通常会以 UTF-8 编码格式对它进行编码。

以下示例显示了使用“错误方式”进行排序的自定义排序规则：

```
import sqlite3

def collate_reverse(string1, string2):
    if string1 == string2:
        return 0
    elif string1 < string2:
        return 1
    else:
        return -1

con = sqlite3.connect(":memory:")
con.create_collation("reverse", collate_reverse)

cur = con.cursor()
cur.execute("create table test(x)")
cur.executemany("insert into test(x) values (?)", [("a",), ("b",)])
cur.execute("select x from test order by x collate reverse")
for row in cur:
    print(row)
con.close()
```

要移除一个排序规则，需要调用 `create_collation` 并设置 `callable` 参数为 `None`。

```
con.create_collation("reverse", None)
```

`interrupt()`

可以从不同的线程调用这个方法来终止所有查询操作，这些查询操作可能正在连接上执行。此方法调用之后，查询将会终止，而且查询的调用者会获得一个异常。

`set_authorizer(authorizer_callback)`

此方法注册一个授权回调对象。每次在访问数据库中某个表的某一列的时候，这个回调对象将会被调用。如果要允许访问，则返回 `SQLITE_OK`，如果要终止整个 SQL 语句，则返回 `SQLITE_DENY`，如果这一列需要当做 `NULL` 值处理，则返回 `SQLITE_IGNORE`。这些常量可以在 `sqlite3` 模块中找到。

回调的第一个参数表示要授权的操作类型。第二个和第三个参数将是参数或 `None`，具体取决于第一个参数的值。第 4 个参数是数据库的名称（“main”，“temp”等），如果需要的话。第 5 个参数是负责访问尝试的最内层触发器或视图的名称，或者如果此访问尝试直接来自输入 SQL 代码，则为 `None`。

请参阅 SQLite 文档，了解第一个参数的可能值以及第二个和第三个参数的含义，具体取决于第一个参数。所有必需的常量都可以在 `sqlite3` 模块中找到。

`set_progress_handler(handler, n)`

此例程注册回调。对 SQLite 虚拟机的每个多指令调用回调。如果要在长时间运行的操作期间从 SQLite 调用（例如更新用户界面），这非常有用。

如果要清除以前安装的任何进度处理程序，调用该方法时请将 `handler` 参数设置为 `None`。

从处理函数返回非零值将终止当前正在执行的查询并导致它引发 `OperationalError` 异常。

`set_trace_callback(trace_callback)`

为每个 SQLite 后端实际执行的 SQL 语句注册要调用的 `trace_callback`。

传递给回调的唯一参数是正在执行的语句（作为字符串）。回调的返回值将被忽略。请注意，后端不仅运行传递给 `Cursor.execute()` 方法的语句。其他来源包括 Python 模块的事务管理和当前数据库中定义的触发器的执行。

将传入的 `trace_callback` 设为 `None` 将禁用跟踪回调。

3.3 新版功能.

`enable_load_extension(enabled)`

此例程允许/禁止 SQLite 引擎从共享库加载 SQLite 扩展。SQLite 扩展可以定义新功能，聚合或全新的虚拟表实现。一个众所周知的扩展是与 SQLite 一起分发的全文搜索扩展。

默认情况下禁用可加载扩展。见¹。

3.2 新版功能.

```
import sqlite3

con = sqlite3.connect(":memory:")

# enable extension loading
con.enable_load_extension(True)

# Load the fulltext search extension
con.execute("select load_extension('./fts3.so')")

# alternatively you can load the extension using an API call:
# con.load_extension("./fts3.so")

# disable extension loading again
con.enable_load_extension(False)

# example from SQLite wiki
con.execute("create virtual table recipe using fts3(name, ingredients)")
con.executescript("""
    insert into recipe (name, ingredients) values ('broccoli stew', 'broccoli
↪peppers cheese tomatoes');
    insert into recipe (name, ingredients) values ('pumpkin stew', 'pumpkin
↪onions garlic celery');
    insert into recipe (name, ingredients) values ('broccoli pie', 'broccoli
↪cheese onions flour');
    insert into recipe (name, ingredients) values ('pumpkin pie', 'pumpkin
↪sugar flour butter');
""")
for row in con.execute("select rowid, name, ingredients from recipe where
↪name match 'pie'"):
    print(row)
```

`load_extension(path)`

此例程从共享库加载 SQLite 扩展。在使用此例程之前，必须使用 `enable_load_extension()` 启用扩展加载。

默认情况下禁用可加载扩展。见¹。

3.2 新版功能.

`row_factory`

您可以将此属性更改为可接受游标和原始行作为元组的可调用对象，并将返回实际结果行。这样，您可以实现更高级的返回结果的方法，例如返回一个可以按名称访问列的对象。

¹ `sqlite3` 模块默认没有构建可加载扩展支持，因为有一些平台带有不支持这个特性的 SQLite 库（特别是 Mac OS X）。要获得可加载扩展的支持，那么在编译配置的时候必须指定 `-enable-loadable-sqlite-extensions` 选项。

示例:

```
import sqlite3

def dict_factory(cursor, row):
    d = {}
    for idx, col in enumerate(cursor.description):
        d[col[0]] = row[idx]
    return d

con = sqlite3.connect(":memory:")
con.row_factory = dict_factory
cur = con.cursor()
cur.execute("select 1 as a")
print(cur.fetchone()["a"])
```

如果返回一个元组是不够的, 并且你想要对列进行基于名称的访问, 你应该考虑将 `row_factory` 设置为高度优化的 `sqlite3.Row` 类型。 `Row` 提供基于索引和不区分大小写的基于名称的访问, 几乎没有内存开销。它可能比您自己的基于字典的自定义方法甚至基于 `db_row` 的解决方案更好。

text_factory

使用此属性可以控制为 TEXT 数据类型返回的对象。默认情况下, 此属性设置为 `str` 和 `sqlite3` 模块将返回 TEXT 的 Unicode 对象。如果要返回字节串, 可以将其设置为 `bytes`。

您还可以将其设置为接受单个 `bytestring` 参数的任何其他可调用对象, 并返回结果对象。

请参阅以下示例代码以进行说明:

```
import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()

AUSTRIA = "\xd6sterreich"

# by default, rows are returned as Unicode
cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert row[0] == AUSTRIA

# but we can make sqlite3 always return bytestrings ...
con.text_factory = bytes
cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert type(row[0]) is bytes
# the bytestrings will be encoded in UTF-8, unless you stored garbage in the
# database ...
assert row[0] == AUSTRIA.encode("utf-8")

# we can also implement a custom text_factory ...
# here we implement one that appends "foo" to all strings
con.text_factory = lambda x: x.decode("utf-8") + "foo"
cur.execute("select ?", ("bar",))
row = cur.fetchone()
assert row[0] == "barfoo"
```

total_changes

返回自打开数据库连接以来已修改, 插入或删除的数据库行的总数。

iterdump()

返回以 SQL 文本格式转储数据库的迭代器。保存内存数据库以便以后恢复时很有用。此函数提供与 `sqlite3` shell 中的 `.dump` 命令相同的功能。

示例:

```
# Convert file existing_db.db to SQL dump file dump.sql
import sqlite3

con = sqlite3.connect('existing_db.db')
with open('dump.sql', 'w') as f:
    for line in con.iterdump():
        f.write('%s\n' % line)
```

12.6.3 Cursor 对象

class `sqlite3.Cursor`

Cursor 游标实例具有以下属性和方法。

execute (*sql* [, *parameters*])

执行 SQL 语句。可以是参数化 SQL 语句（即，在 SQL 语句中使用占位符）。`sqlite3` 模块支持两种占位符：问号（qmark 风格）和命名占位符（命名风格）。

以下是两种风格的示例：

```
import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table people (name_last, age)")

who = "Yeltsin"
age = 72

# This is the qmark style:
cur.execute("insert into people values (?, ?)", (who, age))

# And this is the named style:
cur.execute("select * from people where name_last=:who and age=:age", {"who": who, "age": age})

print(cur.fetchone())
```

`execute()` will only execute a single SQL statement. If you try to execute more than one statement with it, it will raise a *Warning*. Use `executescript()` if you want to execute multiple SQL statements with one call.

executemany (*sql*, *seq_of_parameters*)

Executes an SQL command against all parameter sequences or mappings found in the sequence *seq_of_parameters*. The `sqlite3` module also allows using an *iterator* yielding parameters instead of a sequence.

```
import sqlite3

class IterChars:
    def __init__(self):
        self.count = ord('a')
```

(下页继续)

(续上页)

```

def __iter__(self):
    return self

def __next__(self):
    if self.count > ord('z'):
        raise StopIteration
    self.count += 1
    return (chr(self.count - 1),) # this is a 1-tuple

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table characters(c)")

theIter = IterChars()
cur.executemany("insert into characters(c) values (?)", theIter)

cur.execute("select c from characters")
print(cur.fetchall())

```

这是一个使用生成器generator的简短示例：

```

import sqlite3
import string

def char_generator():
    for c in string.ascii_lowercase:
        yield (c,)

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table characters(c)")

cur.executemany("insert into characters(c) values (?)", char_generator())

cur.execute("select c from characters")
print(cur.fetchall())

```

executescript (sql_script)

This is a nonstandard convenience method for executing multiple SQL statements at once. It issues a COMMIT statement first, then executes the SQL script it gets as a parameter.

sql_script can be an instance of *str*.

示例：

```

import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.executescript("""
    create table person(
        firstname,
        lastname,
        age
    );

    create table book(

```

(下页继续)

(续上页)

```

        title,
        author,
        published
    );

    insert into book(title, author, published)
    values (
        'Dirk Gently's Holistic Detective Agency',
        'Douglas Adams',
        1987
    );
    """

```

fetchone()

Fetches the next row of a query result set, returning a single sequence, or *None* when no more data is available.

fetchmany() (*size=cursor.arraysize*)

Fetches the next set of rows of a query result, returning a list. An empty list is returned when no more rows are available.

The number of rows to fetch per call is specified by the *size* parameter. If it is not given, the cursor's *arraysize* determines the number of rows to be fetched. The method should try to fetch as many rows as indicated by the *size* parameter. If this is not possible due to the specified number of rows not being available, fewer rows may be returned.

Note there are performance considerations involved with the *size* parameter. For optimal performance, it is usually best to use the *arraysize* attribute. If the *size* parameter is used, then it is best for it to retain the same value from one *fetchmany()* call to the next.

fetchall()

Fetches all (remaining) rows of a query result, returning a list. Note that the cursor's *arraysize* attribute can affect the performance of this operation. An empty list is returned when no rows are available.

close()

Close the cursor now (rather than whenever `__del__` is called).

The cursor will be unusable from this point forward; a *ProgrammingError* exception will be raised if any operation is attempted with the cursor.

rowcount

Although the *Cursor* class of the *sqlite3* module implements this attribute, the database engine's own support for the determination of “rows affected” / “rows selected” is quirky.

For *executemany()* statements, the number of modifications are summed up into *rowcount*.

As required by the Python DB API Spec, the *rowcount* attribute “is -1 in case no *executeXX()* has been performed on the cursor or the rowcount of the last operation is not determinable by the interface”. This includes *SELECT* statements because we cannot determine the number of rows a query produced until all rows were fetched.

With SQLite versions before 3.6.5, *rowcount* is set to 0 if you make a *DELETE FROM table* without any condition.

lastrowid

This read-only attribute provides the *rowid* of the last modified row. It is only set if you issued an *INSERT* or a *REPLACE* statement using the *execute()* method. For operations other than *INSERT* or *REPLACE* or when *executemany()* is called, *lastrowid* is set to *None*.

If the *INSERT* or *REPLACE* statement failed to insert the previous successful *rowid* is returned.

在 3.6 版更改: 增加了 REPLACE 语句的支持。

arraysize

Read/write attribute that controls the number of rows returned by `fetchmany()`. The default value is 1 which means a single row would be fetched per call.

description

This read-only attribute provides the column names of the last query. To remain compatible with the Python DB API, it returns a 7-tuple for each column where the last six items of each tuple are `None`.

It is set for SELECT statements without any matching rows as well.

connection

This read-only attribute provides the SQLite database `Connection` used by the `Cursor` object. A `Cursor` object created by calling `con.cursor()` will have a `connection` attribute that refers to `con`:

```
>>> con = sqlite3.connect(":memory:")
>>> cur = con.cursor()
>>> cur.connection == con
True
```

12.6.4 行对象 *Row*

class `sqlite3.Row`

A `Row` instance serves as a highly optimized `row_factory` for `Connection` objects. It tries to mimic a tuple in most of its features.

It supports mapping access by column name and index, iteration, representation, equality testing and `len()`.

If two `Row` objects have exactly the same columns and their members are equal, they compare equal.

keys()

This method returns a list of column names. Immediately after a query, it is the first member of each tuple in `Cursor.description`.

在 3.5 版更改: Added support of slicing.

Let's assume we initialize a table as in the example given above:

```
conn = sqlite3.connect(":memory:")
c = conn.cursor()
c.execute('create table stocks
(date text, trans text, symbol text,
qty real, price real)')
c.execute("""insert into stocks
values ('2006-01-05', 'BUY', 'RHAT', 100, 35.14)""")
conn.commit()
c.close()
```

Now we plug `Row` in:

```
>>> conn.row_factory = sqlite3.Row
>>> c = conn.cursor()
>>> c.execute('select * from stocks')
<sqlite3.Cursor object at 0x7f4e7dd8fa80>
>>> r = c.fetchone()
>>> type(r)
<class 'sqlite3.Row'>
```

(下页继续)

(续上页)

```

>>> tuple(r)
('2006-01-05', 'BUY', 'RHAT', 100.0, 35.14)
>>> len(r)
5
>>> r[2]
'RHAT'
>>> r.keys()
['date', 'trans', 'symbol', 'qty', 'price']
>>> r['qty']
100.0
>>> for member in r:
...     print(member)
...
2006-01-05
BUY
RHAT
100.0
35.14

```

12.6.5 异常

exception `sqlite3.Warning`

Exception 的一个子类。

exception `sqlite3.Error`

此模块中其他异常的基类。它是 *Exception* 的一个子类。

exception `sqlite3.DatabaseError`

Exception raised for errors that are related to the database.

exception `sqlite3.IntegrityError`

Exception raised when the relational integrity of the database is affected, e.g. a foreign key check fails. It is a subclass of *DatabaseError*.

exception `sqlite3.ProgrammingError`

Exception raised for programming errors, e.g. table not found or already exists, syntax error in the SQL statement, wrong number of parameters specified, etc. It is a subclass of *DatabaseError*.

exception `sqlite3.OperationalError`

Exception raised for errors that are related to the database's operation and not necessarily under the control of the programmer, e.g. an unexpected disconnect occurs, the data source name is not found, a transaction could not be processed, etc. It is a subclass of *DatabaseError*.

exception `sqlite3.NotSupportedError`

Exception raised in case a method or database API was used which is not supported by the database, e.g. calling the *rollback()* method on a connection that does not support transaction or has transactions turned off. It is a subclass of *DatabaseError*.

12.6.6 SQLite 与 Python 类型

概述

SQLite 原生支持如下的类型：NULL，INTEGER，REAL，TEXT，BLOB。

因此可以将以下 Python 类型发送到 SQLite 而不会出现任何问题：

Python 类型	SQLite 类型
<code>None</code>	NULL
<code>int</code>	INTEGER
<code>float</code>	REAL
<code>str</code>	TEXT
<code>bytes</code>	BLOB

这是 SQLite 类型默认转换为 Python 类型的方式:

SQLite 类型	Python 类型
NULL	<code>None</code>
INTEGER	<code>int</code>
REAL	<code>float</code>
TEXT	取决于 <code>text_factory</code> , 默认为 <code>str</code>
BLOB	<code>bytes</code>

The type system of the `sqlite3` module is extensible in two ways: you can store additional Python types in a SQLite database via object adaptation, and you can let the `sqlite3` module convert SQLite types to different Python types via converters.

Using adapters to store additional Python types in SQLite databases

As described before, SQLite supports only a limited set of types natively. To use other Python types with SQLite, you must **adapt** them to one of the `sqlite3` module's supported types for SQLite: one of `NoneType`, `int`, `float`, `str`, `bytes`.

There are two ways to enable the `sqlite3` module to adapt a custom Python type to one of the supported ones.

Letting your object adapt itself

This is a good approach if you write the class yourself. Let's suppose you have a class like this:

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y
```

Now you want to store the point in a single SQLite column. First you'll have to choose one of the supported types first to be used for representing the point. Let's just use `str` and separate the coordinates using a semicolon. Then you need to give your class a method `__conform__(self, protocol)` which must return the converted value. The parameter `protocol` will be `PrepareProtocol`.

```
import sqlite3

class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __conform__(self, protocol):
        if protocol is sqlite3.PrepareProtocol:
            return "%f;%f" % (self.x, self.y)

con = sqlite3.connect(":memory:")
cur = con.cursor()
```

(下页继续)

(续上页)

```
p = Point(4.0, -3.2)
cur.execute("select ?", (p,))
print(cur.fetchone()[0])
```

Registering an adapter callable

The other possibility is to create a function that converts the type to the string representation and register the function with `register_adapter()`.

```
import sqlite3

class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

def adapt_point(point):
    return "%f;%f" % (point.x, point.y)

sqlite3.register_adapter(Point, adapt_point)

con = sqlite3.connect(":memory:")
cur = con.cursor()

p = Point(4.0, -3.2)
cur.execute("select ?", (p,))
print(cur.fetchone()[0])
```

The `sqlite3` module has two default adapters for Python's built-in `datetime.date` and `datetime.datetime` types. Now let's suppose we want to store `datetime.datetime` objects not in ISO representation, but as a Unix timestamp.

```
import sqlite3
import datetime
import time

def adapt_datetime(ts):
    return time.mktime(ts.timetuple())

sqlite3.register_adapter(datetime.datetime, adapt_datetime)

con = sqlite3.connect(":memory:")
cur = con.cursor()

now = datetime.datetime.now()
cur.execute("select ?", (now,))
print(cur.fetchone()[0])
```

Converting SQLite values to custom Python types

Writing an adapter lets you send custom Python types to SQLite. But to make it really useful we need to make the Python to SQLite to Python roundtrip work.

Enter converters.

Let's go back to the `Point` class. We stored the `x` and `y` coordinates separated via semicolons as strings in SQLite. First, we'll define a converter function that accepts the string as a parameter and constructs a `Point` object from it.

注解: Converter functions **always** get called with a `bytes` object, no matter under which data type you sent the value to SQLite.

```
def convert_point(s):
    x, y = map(float, s.split(b";"))
    return Point(x, y)
```

Now you need to make the `sqlite3` module know that what you select from the database is actually a point. There are two ways of doing this:

- Implicitly via the declared type
- Explicitly via the column name

Both ways are described in section 模块函数和常量, in the entries for the constants `PARSE_DECLTYPES` and `PARSE_COLNAMES`.

The following example illustrates both approaches.

```
import sqlite3

class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __repr__(self):
        return "(%f;%f)" % (self.x, self.y)

def adapt_point(point):
    return "(%f;%f)" % (point.x, point.y).encode('ascii')

def convert_point(s):
    x, y = list(map(float, s.split(b";")))
    return Point(x, y)

# Register the adapter
sqlite3.register_adapter(Point, adapt_point)

# Register the converter
sqlite3.register_converter("point", convert_point)

p = Point(4.0, -3.2)

#####
# 1) Using declared types
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES)
cur = con.cursor()
cur.execute("create table test(p point)")

cur.execute("insert into test(p) values (?)", (p,))
cur.execute("select p from test")
print("with declared types:", cur.fetchone()[0])
cur.close()
con.close()
```

(下页继续)

(续上页)

```
#####
# 1) Using column names
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_COLNAMES)
cur = con.cursor()
cur.execute("create table test(p)")

cur.execute("insert into test(p) values (?)", (p,))
cur.execute('select p as "p [point]" from test')
print("with column names:", cur.fetchone()[0])
cur.close()
con.close()
```

Default adapters and converters

There are default adapters for the date and datetime types in the datetime module. They will be sent as ISO dates/ISO timestamps to SQLite.

The default converters are registered under the name “date” for *datetime.date* and under the name “timestamp” for *datetime.datetime*.

This way, you can use date/timestamps from Python without any additional fiddling in most cases. The format of the adapters is also compatible with the experimental SQLite date/time functions.

The following example demonstrates this.

```
import sqlite3
import datetime

con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES|sqlite3.PARSE_
↳COLNAMES)
cur = con.cursor()
cur.execute("create table test(d date, ts timestamp)")

today = datetime.date.today()
now = datetime.datetime.now()

cur.execute("insert into test(d, ts) values (?, ?)", (today, now))
cur.execute("select d, ts from test")
row = cur.fetchone()
print(today, "=>", row[0], type(row[0]))
print(now, "=>", row[1], type(row[1]))

cur.execute('select current_date as "d [date]", current_timestamp as "ts [timestamp]"
↳')
row = cur.fetchone()
print("current_date", row[0], type(row[0]))
print("current_timestamp", row[1], type(row[1]))
```

If a timestamp stored in SQLite has a fractional part longer than 6 numbers, its value will be truncated to microsecond precision by the timestamp converter.

12.6.7 Controlling Transactions

The underlying `sqlite3` library operates in `autocommit` mode by default, but the Python `sqlite3` module by default does not.

`autocommit` mode means that statements that modify the database take effect immediately. A `BEGIN` or `SAVEPOINT` statement disables `autocommit` mode, and a `COMMIT`, a `ROLLBACK`, or a `RELEASE` that ends the outermost transaction, turns `autocommit` mode back on.

The Python `sqlite3` module by default issues a `BEGIN` statement implicitly before a Data Modification Language (DML) statement (i.e. `INSERT/UPDATE/DELETE/REPLACE`).

You can control which kind of `BEGIN` statements `sqlite3` implicitly executes via the `isolation_level` parameter to the `connect()` call, or via the `isolation_level` property of connections. If you specify no `isolation_level`, a plain `BEGIN` is used, which is equivalent to specifying `DEFERRED`. Other possible values are `IMMEDIATE` and `EXCLUSIVE`.

You can disable the `sqlite3` module's implicit transaction management by setting `isolation_level` to `None`. This will leave the underlying `sqlite3` library operating in `autocommit` mode. You can then completely control the transaction state by explicitly issuing `BEGIN`, `ROLLBACK`, `SAVEPOINT`, and `RELEASE` statements in your code.

在 3.6 版更改: `sqlite3` used to implicitly commit an open transaction before DDL statements. This is no longer the case.

12.6.8 Using `sqlite3` efficiently

Using shortcut methods

Using the nonstandard `execute()`, `executemany()` and `executescript()` methods of the `Connection` object, your code can be written more concisely because you don't have to create the (often superfluous) `Cursor` objects explicitly. Instead, the `Cursor` objects are created implicitly and these shortcut methods return the cursor objects. This way, you can execute a `SELECT` statement and iterate over it directly using only a single call on the `Connection` object.

```
import sqlite3

persons = [
    ("Hugo", "Boss"),
    ("Calvin", "Klein")
]

con = sqlite3.connect(":memory:")

# Create the table
con.execute("create table person(firstname, lastname)")

# Fill the table
con.executemany("insert into person(firstname, lastname) values (?, ?)", persons)

# Print the table contents
for row in con.execute("select firstname, lastname from person"):
    print(row)

print("I just deleted", con.execute("delete from person").rowcount, "rows")
```

Accessing columns by name instead of by index

One useful feature of the `sqlite3` module is the built-in `sqlite3.Row` class designed to be used as a row factory.

Rows wrapped with this class can be accessed both by index (like tuples) and case-insensitively by name:

```
import sqlite3

con = sqlite3.connect(":memory:")
con.row_factory = sqlite3.Row

cur = con.cursor()
cur.execute("select 'John' as name, 42 as age")
for row in cur:
    assert row[0] == row["name"]
    assert row["name"] == row["nAmE"]
    assert row[1] == row["age"]
    assert row[1] == row["AgE"]
```

使用连接作为上下文管理器

连接对象可以用来作为上下文管理器，它可以自动提交或者回滚事务。如果出现异常，事务会被回滚；否则，事务会被提交。

```
import sqlite3

con = sqlite3.connect(":memory:")
con.execute("create table person (id integer primary key, firstname varchar unique)")

# Successful, con.commit() is called automatically afterwards
with con:
    con.execute("insert into person(firstname) values (?)", ("Joe",))

# con.rollback() is called after the with block finishes with an exception, the
# exception is still raised and must be caught
try:
    with con:
        con.execute("insert into person(firstname) values (?)", ("Joe",))
except sqlite3.IntegrityError:
    print("couldn't add Joe twice")
```

12.6.9 常见问题

多线程

Older SQLite versions had issues with sharing connections between threads. That's why the Python module disallows sharing connections and cursors between threads. If you still try to do so, you will get an exception at runtime.

The only exception is calling the `interrupt()` method, which only makes sense to call from a different thread.

数据压缩和存档

本章中描述的模块支持 `zlib`、`gzip`、`bzip2` 和 `lzma` 数据压缩算法，以及创建 ZIP 和 tar 格式的归档文件。参见由 `shutil` 模块提供的 *Archiving operations*。

13.1 `zlib` 一与 `gzip` 兼容的压缩

此模块为需要数据压缩的程序提供了一系列函数，用于压缩和解压缩。这些函数使用了 `zlib` 库。`zlib` 库的项目主页是 <http://www.zlib.net>。版本低于 1.1.3 的 `zlib` 与此 Python 模块之间存在已知的不兼容。1.1.3 版本的 `zlib` 存在一个安全漏洞，我们推荐使用 1.1.4 或更新的版本。

`zlib` 的函数有很多选项，一般需要按特定顺序使用。本文档没有覆盖全部的用法。更多详细信息请于 <http://www.zlib.net/manual.html> 参阅官方手册。

要读写 `.gz` 格式的文件，请参考 `gzip` 模块。

此模块中可用的异常和函数如下：

exception `zlib.error`

在压缩或解压缩过程中发生错误时的异常。

`zlib.adler32(data[, value])`

计算 `data` 的 Adler-32 校验值。(Adler-32 校验的可靠性与 CRC32 基本相当，但比计算 CRC32 更高效。) 计算的结果是一个 32 位的整数。参数 `value` 是校验时的起始值，其默认值为 1。借助参数 `value` 可为分段的输入计算校验值。此算法没有加密强度，不应用于身份验证和数字签名。此算法的目的仅为验证数据的正确性，不适合作为通用散列算法。

在 3.0 版更改：返回值永远是无符号数。要在所有的 Python 版本和平台上获得相同的值，请使用 `adler32(data) & 0xffffffff`。

`zlib.compress(data, level=-1)`

压缩 `data` 中的字节，返回含有已压缩内容的 `bytes` 对象。参数 `level` 为整数，可取值为 0 到 9 或 -1，用于指定压缩等级。1 (`Z_BEST_SPEED`) 表示最快速度和最低压缩率，9 (`Z_BEST_COMPRESSION`) 表示最慢速度和最高压缩率。0 (`Z_NO_COMPRESSION`) 表示不压缩。参数默认值为 -1

(Z_DEFAULT_COMPRESSION)。Z_DEFAULT_COMPRESSION 是速度和压缩率之间的平衡 (一般相当于设压缩等级为 6)。函数发生错误时抛出 `error` 异常。

在 3.6 版更改: 现在, `level` 可作为关键字参数。

```
zlib.compressobj (level=-1, method=DEFLATED, wbits=MAX_WBITS, memLevel=DEF_MEM_LEVEL,
                  strategy=Z_DEFAULT_STRATEGY[, zdict])
```

返回一个压缩对象, 用来压缩内存中难以容下的数据流。

参数 `level` 为压缩等级, 是整数, 可取值为 0 到 9 或 -1。1 (Z_BEST_SPEED) 表示最快速度和最低压缩率, 9 (Z_BEST_COMPRESSION) 表示最慢速度和最高压缩率。0 (Z_NO_COMPRESSION) 表示不压缩。参数默认值为 -1 (Z_DEFAULT_COMPRESSION)。Z_DEFAULT_COMPRESSION 是速度和压缩率之间的平衡 (一般相当于设压缩等级为 6)。

`method` 表示压缩算法。现在只支持 DEFLATED 这个算法。

参数 `wbits` 指定压缩数据时所使用的历史缓冲区的大小 (窗口大小), 并指定压缩输出是否包含头部或尾部。参数的默认值是 15 (MAX_WBITS)。参数的值分为几个范围:

- +9 到 +15: 窗口大小以 2 为底的对数。即这些值对应着 512 到 32768 的窗口大小。更大的值会提供更好的压缩, 同时内存开销也会更大。压缩输出会包含 zlib 特定格式的头部和尾部。
- -9 到 -15: 绝对值为窗口大小以 2 为底的对数。压缩输出仅包含压缩数据, 没有头部和尾部。
- +25 到 +31 = 16 + (9 到 15): 后 4 个比特位为窗口大小以 2 为底的对数。压缩输出包含一个基本的 **gzip** 头部, 并以校验和为尾部。

参数 `memLevel` 指定内部压缩操作时所占用内存大小。参数取 1 到 9。更大的值占用更多的内存, 同时速度也更快输出也更小。

参数 `strategy` 用于调节压缩算法。可取值为 Z_DEFAULT_STRATEGY、Z_FILTERED、Z_HUFFMAN_ONLY、Z_RLE (zlib 1.2.0.1) 或 Z_FIXED (zlib 1.2.2.2)。

参数 `zdict` 指定预定义的压缩字典。它是一个字节序列 (如 `bytes` 对象), 其中包含用户认为要压缩的数据中可能频繁出现的子序列。频率高的子序列应当放在字典的尾部。

在 3.3 版更改: 添加关键字参数 `zdict`。

```
zlib.crc32 (data[, value])
```

计算 `data` 的 CRC (循环冗余校验) 值。计算的结果是一个 32 位的整数。参数 `value` 是校验时的起始值, 其默认值为 0。借助参数 `value` 可为分段的输入计算校验值。此算法没有加密强度, 不应用于身份验证和数字签名。此算法的目的仅为验证数据的正确性, 不适合作为通用散列算法。

在 3.0 版更改: 返回值永远是无符号数。要在所有的 Python 版本和平台上获得相同的值, 请使用 `crc32(data) & 0xffffffff`。

```
zlib.decompress (data, wbits=MAX_WBITS, bufsize=DEF_BUF_SIZE)
```

解压 `data` 中的字节, 返回含有已解压内容的 `bytes` 对象。参数 `wbits` 取决于 `data` 的格式, 具体参见下边的说明。`bufsize` 为输出缓冲区的起始大小。函数发生错误时抛出 `error` 异常。

The `wbits` parameter controls the size of the history buffer (or “window size”), and what header and trailer format is expected. It is similar to the parameter for `compressobj()`, but accepts more ranges of values:

- +8 to +15: The base-two logarithm of the window size. The input must include a zlib header and trailer.
- 0: Automatically determine the window size from the zlib header. Only supported since zlib 1.2.3.5.
- -8 to -15: Uses the absolute value of `wbits` as the window size logarithm. The input must be a raw stream with no header or trailer.
- +24 to +31 = 16 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm. The input must include a gzip header and trailer.

- +40 to +47 = 32 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm, and automatically accepts either the zlib or gzip format.

When decompressing a stream, the window size must not be smaller than the size originally used to compress the stream; using a too-small value may result in an *error* exception. The default *wbits* value corresponds to the largest window size and requires a zlib header and trailer to be included.

bufsize is the initial size of the buffer used to hold decompressed data. If more space is required, the buffer size will be increased as needed, so you don't have to get this value exactly right; tuning it will only save a few calls to `malloc()`.

在 3.6 版更改: *wbits* and *bufsize* can be used as keyword arguments.

`zlib.decompressobj(wbits=MAX_WBITS[, zdict])`

Returns a decompression object, to be used for decompressing data streams that won't fit into memory at once.

The *wbits* parameter controls the size of the history buffer (or the “window size”), and what header and trailer format is expected. It has the same meaning as *described for decompress()*.

The *zdict* parameter specifies a predefined compression dictionary. If provided, this must be the same dictionary as was used by the compressor that produced the data that is to be decompressed.

注解: If *zdict* is a mutable object (such as a *bytearray*), you must not modify its contents between the call to *decompressobj()* and the first call to the decompressor's *decompress()* method.

在 3.3 版更改: Added the *zdict* parameter.

压缩对象支持以下方法:

`Compress.compress(data)`

压缩 *data* 并返回 *bytes* 对象, 这个对象含有 *data* 的部分或全部内容的已压缩数据。所得的对象必须拼接在上一次调用 *compress()* 方法所得数据的后面。缓冲区中可能留存部分输入以供下一次调用。

`Compress.flush([mode])`

压缩所有缓冲区的数据并返回已压缩的数据。参数 *mode* 可以传入的常量为: `Z_NO_FLUSH`、`Z_PARTIAL_FLUSH`、`Z_SYNC_FLUSH`、`Z_FULL_FLUSH`、`Z_BLOCK` (zlib 1.2.3.4) 或 `Z_FINISH`。默认值为 `Z_FINISH`。`Z_FINISH` 关闭已压缩数据流并不允许再压缩其他数据, `Z_FINISH` 以外的值皆允许这个对象继续压缩数据。调用 *flush()* 方法并将 *mode* 设为 `Z_FINISH` 后会无法再次调用 *compress()*, 此时只能删除这个对象。

`Compress.copy()`

返回此压缩对象的一个拷贝。它可以用来高效压缩一系列拥有相同前缀的数据。

解压缩对象支持以下方法:

`Decompress.unused_data`

A *bytes* object which contains any bytes past the end of the compressed data. That is, this remains `b""` until the last byte that contains compression data is available. If the whole bytestring turned out to contain compressed data, this is `b""`, an empty *bytes* object.

`Decompress.unconsumed_tail`

A *bytes* object that contains any data that was not consumed by the last *decompress()* call because it exceeded the limit for the uncompressed data buffer. This data has not yet been seen by the zlib machinery, so you must feed it (possibly with further data concatenated to it) back to a subsequent *decompress()* method call in order to get correct output.

`Decompress.eof`

A boolean indicating whether the end of the compressed data stream has been reached.

This makes it possible to distinguish between a properly-formed compressed stream, and an incomplete or truncated one.

3.3 新版功能.

`Decompress.decompress (data, max_length=0)`

Decompress *data*, returning a bytes object containing the uncompressed data corresponding to at least part of the data in *string*. This data should be concatenated to the output produced by any preceding calls to the `decompress()` method. Some of the input data may be preserved in internal buffers for later processing.

If the optional parameter *max_length* is non-zero then the return value will be no longer than *max_length*. This may mean that not all of the compressed input can be processed; and unconsumed data will be stored in the attribute `unconsumed_tail`. This bytestring must be passed to a subsequent call to `decompress()` if decompression is to continue. If *max_length* is zero then the whole input is decompressed, and `unconsumed_tail` is empty.

在 3.6 版更改: *max_length* can be used as a keyword argument.

`Decompress.flush ([length])`

All pending input is processed, and a bytes object containing the remaining uncompressed output is returned. After calling `flush()`, the `decompress()` method cannot be called again; the only realistic action is to delete the object.

The optional parameter *length* sets the initial size of the output buffer.

`Decompress.copy ()`

Returns a copy of the decompression object. This can be used to save the state of the decompressor midway through the data stream in order to speed up random seeks into the stream at a future point.

通过下列常量可获取模块所使用的 zlib 库的版本信息:

`zlib.ZLIB_VERSION`

构建此模块时所用的 zlib 库的版本字符串。它的值可能与运行时所加载的 zlib 不同。运行时加载的 zlib 库的版本字符串为 `ZLIB_RUNTIME_VERSION`。

`zlib.ZLIB_RUNTIME_VERSION`

解释器所加载的 zlib 库的版本字符串。

3.3 新版功能.

模块 `gzip` 读写 `gzip` 格式的文件。

<http://www.zlib.net> zlib 库项目主页。

<http://www.zlib.net/manual.html> zlib 库用户手册。提供了库的许多功能的解释和用法。

13.2 gzip — 对 gzip 格式的支持

源代码: `Lib/gzip.py`

此模块提供的简单接口帮助用户压缩和解压缩文件, 功能类似于 GNU 应用程序 `gzip` 和 `gunzip`。

数据压缩由 `zlib` 模块提供。

`gzip` 模块提供 `GzipFile` 类和 `open()`、`compress()`、`decompress()` 几个便利的函数。`GzipFile` 类可以读写 `gzip` 格式的文件, 还能自动压缩和解压缩数据, 这让操作压缩文件如同操作普通的 *file object* 一样方便。

注意, 此模块不支持部分可以被 `gzip` 和 `gunzip` 解压的格式, 如利用 `compress` 或 `pack` 压缩所得的文件。

这个模块定义了以下内容：

`gzip.open(filename, mode='rb', compresslevel=9, encoding=None, errors=None, newline=None)`

以二进制方式或者文本方式打开一个 `gzip` 格式的压缩文件，返回一个 *file object*。

filename 参数可以是一个实际的文件名（一个 *a str* 对象或者 *bytes* 对象），或者是一个用来读写的已存在的文件对象。

mode 参数可以是二进制模式：'r', 'rb', 'a', 'ab', 'w', 'wb', 'x' or 'xb'，或者是文本模式 'rt', 'at', 'wt', or 'xt'。默认值是 'rb'。

The *compresslevel* argument is an integer from 0 to 9, as for the *GzipFile* constructor.

对于二进制模式，这个函数等价于 *GzipFile* 构造器：`GzipFile(filename, mode, compresslevel)`。在这个例子中，*encoding*, *errors* 和 *newline* 三个参数一定不要设置。

对于文本模式，将会创建一个 *GzipFile* 对象，并将它封装到一个 *io.TextIOWrapper* 实例中，这个实例默认了指定编码，错误捕获行为和行。

在 3.3 版更改：支持 *filename* 为一个文件对象，支持文本模式和 *encoding*, *errors* 和 *newline* 参数。

在 3.4 版更改：支持 'x', 'xb' 和 “xt” 三种模式。

在 3.6 版更改：接受一个 *path-like object*。

class `gzip.GzipFile(filename=None, mode=None, compresslevel=9, fileobj=None, mtime=None)`

Constructor for the *GzipFile* class, which simulates most of the methods of a *file object*, with the exception of the `truncate()` method. At least one of *fileobj* and *filename* must be given a non-trivial value.

新的实例基于 *fileobj*，它可以是一个普通文件，一个 *io.BytesIO* 对象，或者任何一个与文件相似的对象。当 *filename* 是一个文件对象时，它的默认值是 `None`。

当 *fileobj* 为 `None` 时，*filename* 参数只用于 `gzip` 文件头中，这个文件有可能包含未压缩文件的源文件名。如果文件可以被识别，默认 *fileobj* 的文件名；否则默认为空字符串，在这种情况下文件头将不包含源文件名。

The *mode* argument can be any of 'r', 'rb', 'a', 'ab', 'w', 'wb', 'x', or 'xb', depending on whether the file will be read or written. The default is the mode of *fileobj* if discernible; otherwise, the default is 'rb'.

需要注意的是，文件默认使用二进制模式打开。如果要以文本模式打开文件一个压缩文件，请使用 `open()` 方法（或者使用 *io.TextIOWrapper* 包装 *GzipFile*）。

compresslevel 参数是一个从 0 to 9 的整数，用于控制压缩等级；1 最快但压缩比例最小，9 最慢但压缩比例最大。0 不压缩。默认为 9。

The *mtime* argument is an optional numeric timestamp to be written to the last modification time field in the stream when compressing. It should only be provided in compression mode. If omitted or `None`, the current time is used. See the *mtime* attribute for more details.

调用 *GzipFile* 的 `close()` 方法不会关闭 *fileobj*，因为你可以希望增加其它内容到已经压缩的数中。你可以将一个 *io.BytesIO* 对象作为 *fileobj*，也可以使用 *io.BytesIO* 的 `getvalue()` 方法从内存缓存中恢复数据。

GzipFile 支持 *io.BufferedIOBase* 类的接口，包括迭代和 `with` 语句。只有 `truncate()` 方法没有实现。

GzipFile 还提供了以下的方法和属性：

peek(*n*)

在不移动文件指针的情况下读取 *n* 个未压缩字节。最多只有一个单独的读取流来服务这个方法调用。返回的字节数不一定刚好等于要求的数量。

注解: 调用`peek()` 并没有改变`GzipFile` 的文件指针, 它可能改变潜在文件对象 (例如: `GzipFile` 使用 `fileobj` 参数进行初始化)。

3.2 新版功能.

mtime

在解压的过程中, 最后修改时间字段的值可能来自于这个属性, 以整数的形式出现。在读取任何文件头信息前, 初始值为 `None`。

所有 **gzip** 东方压缩流中必须包含时间戳这个字段。以便于像 **gunzip** 这样的程序可以使用时间戳。格式与`time.time()` 的返回值和`os.stat()` 对象的`st_mtime` 属性值一样。

在 3.1 版更改: 支持 `with` 语句, 构造器参数 `mtime` 和`mtime` 属性。

在 3.2 版更改: 添加了对零填充和不可搜索文件的支持。

在 3.3 版更改: 实现`io.BufferedIOBase.read1()` 方法。

在 3.4 版更改: 支持 `'x'` and `'xb'` 两种模式。

在 3.5 版更改: 支持写入任意`bytes-like objects`。 `read()` 方法可以接受 `None` 为参数。

在 3.6 版更改: 接受一个`path-like object`。

`gzip.compress(data, compresslevel=9)`

压缩 `data` 返回一个包含压缩数据的`bytes` 对象。`compresslevel` 的意义与上面提到的`GzipFile` 构造器一至。

3.2 新版功能.

`gzip.decompress(data)`

解压数据, 返回一个`bytes` 包含未解压数据的对象。

3.2 新版功能.

13.2.1 用法示例

读取压缩文件示例:

```
import gzip
with gzip.open('/home/joe/file.txt.gz', 'rb') as f:
    file_content = f.read()
```

创建 GZIP 文件示例:

```
import gzip
content = b"Lots of content here"
with gzip.open('/home/joe/file.txt.gz', 'wb') as f:
    f.write(content)
```

使用 GZIP 压缩已有的文件示例:

```
import gzip
import shutil
with open('/home/joe/file.txt', 'rb') as f_in:
    with gzip.open('/home/joe/file.txt.gz', 'wb') as f_out:
        shutil.copyfileobj(f_in, f_out)
```

使用 GZIP 压缩二进制字符串示例:

```
import gzip
s_in = b"Lots of content here"
s_out = gzip.compress(s_in)
```

参见:

模块 `zlib` 支持 `gzip` 格式所需要的基本压缩模块。

13.3 bz2 — 对 bzip2 压缩算法的支持

源代码: `Lib/bz2.py`

此模块提供了使用 `bzip2` 压缩算法压缩和解压数据的一套完整的接口。

`bz2` 模块包含:

- 用于读写压缩文件的 `open()` 函数和 `BZ2File` 类。
- 用于增量压缩和解压的 `BZ2Compressor` 和 `BZ2Decompressor` 类。
- 用于一次性压缩和解压的 `compress()` 和 `decompress()` 函数。

此模块中的所有类都能安全地从多个线程访问。

13.3.1 文件压缩和解压

`bz2.open(filename, mode='r', compresslevel=9, encoding=None, errors=None, newline=None)`

以二进制或文本模式打开 `bzip2` 压缩文件, 返回一个 *file object*。

和 `BZ2File` 的构造函数类似, `filename` 参数可以是一个实际的文件名 (*str* 或 *bytes* 对象), 或是已有的可供读取或写入的文件对象。

`mode` 参数可设为二进制模式的 `'r'`、`'rb'`、`'w'`、`'wb'`、`'x'`、`'xb'`、`'a'` 或 `'ab'`, 或者文本模式的 `'rt'`、`'wt'`、`'xt'` 或 `'at'`。默认是 `'rb'`。

`compresslevel` 参数是 1 到 9 的整数, 和 `BZ2File` 的构造函数一样。

For binary mode, this function is equivalent to the `BZ2File` constructor: `BZ2File(filename, mode, compresslevel=compresslevel)`. In this case, the `encoding`, `errors` and `newline` arguments must not be provided.

For text mode, a `BZ2File` object is created, and wrapped in an `io.TextIOWrapper` instance with the specified encoding, error handling behavior, and line ending(s).

3.3 新版功能.

在 3.4 版更改: 添加了 `'x'` (仅创建) 模式。

在 3.6 版更改: 接受一个类路径对象。

class `bz2.BZ2File(filename, mode='r', buffering=None, compresslevel=9)`

用二进制模式打开 `bzip2` 压缩文件。

If `filename` is a *str* or *bytes* object, open the named file directly. Otherwise, `filename` should be a *file object*, which will be used to read or write the compressed data.

The `mode` argument can be either `'r'` for reading (default), `'w'` for overwriting, `'x'` for exclusive creation, or `'a'` for appending. These can equivalently be given as `'rb'`, `'wb'`, `'xb'` and `'ab'` respectively.

If *filename* is a file object (rather than an actual file name), a mode of 'w' does not truncate the file, and is instead equivalent to 'a'.

The *buffering* argument is ignored. Its use is deprecated.

If *mode* is 'w' or 'a', *compresslevel* can be a number between 1 and 9 specifying the level of compression: 1 produces the least compression, and 9 (default) produces the most compression.

If *mode* is 'r', the input file may be the concatenation of multiple compressed streams.

BZ2File provides all of the members specified by the *io.BufferedIOBase*, except for *detach()* and *truncate()*. Iteration and the *with* statement are supported.

BZ2File also provides the following method:

peek (*[n]*)

Return buffered data without advancing the file position. At least one byte of data will be returned (unless at EOF). The exact number of bytes returned is unspecified.

注解: While calling *peek()* does not change the file position of the *BZ2File*, it may change the position of the underlying file object (e.g. if the *BZ2File* was constructed by passing a file object for *filename*).

3.3 新版功能.

在 3.1 版更改: 支持了 *with* 语句。

在 3.3 版更改: The *fileno()*, *readable()*, *seekable()*, *writable()*, *read1()* and *readinto()* methods were added.

在 3.3 版更改: Support was added for *filename* being a *file object* instead of an actual filename.

在 3.3 版更改: The 'a' (append) mode was added, along with support for reading multi-stream files.

在 3.4 版更改: 添加了 'x' (仅创建) 模式。

在 3.5 版更改: The *read()* method now accepts an argument of *None*.

在 3.6 版更改: 接受一个类路径对象。

13.3.2 增量压缩和解压

class *bz2.BZ2Compressor* (*compresslevel=9*)

Create a new compressor object. This object may be used to compress data incrementally. For one-shot compression, use the *compress()* function instead.

compresslevel, if given, must be a number between 1 and 9. The default is 9.

compress (*data*)

Provide data to the compressor object. Returns a chunk of compressed data if possible, or an empty byte string otherwise.

When you have finished providing data to the compressor, call the *flush()* method to finish the compression process.

flush ()

结束压缩进程，返回内部缓冲中剩余的压缩完成的数据。

The compressor object may not be used after this method has been called.

class bz2.BZ2Decompressor

Create a new decompressor object. This object may be used to decompress data incrementally. For one-shot compression, use the `decompress()` function instead.

注解: This class does not transparently handle inputs containing multiple compressed streams, unlike `decompress()` and `BZ2File`. If you need to decompress a multi-stream input with `BZ2Decompressor`, you must use a new decompressor for each stream.

decompress (*data*, *max_length=-1*)

Decompress *data* (a *bytes-like object*), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to `decompress()`. The returned data should be concatenated with the output of any previous calls to `decompress()`.

If *max_length* is nonnegative, returns at most *max_length* bytes of decompressed data. If this limit is reached and further output can be produced, the `needs_input` attribute will be set to `False`. In this case, the next call to `decompress()` may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max_length* bytes, or because *max_length* was negative), the `needs_input` attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an `EOFError`. Any data found after the end of the stream is ignored and saved in the `unused_data` attribute.

在 3.5 版更改: Added the *max_length* parameter.

eof

若达到了数据流末尾标识符则为 `True`。

3.3 新版功能。

unused_data

压缩数据流的末尾还有数据。

If this attribute is accessed before the end of the stream has been reached, its value will be `b''`.

needs_input

`False` if the `decompress()` method can provide more decompressed data before requiring new uncompressed input.

3.5 新版功能。

13.3.3 一次性压缩或解压

bz2.compress (*data*, *compresslevel=9*)

Compress *data*.

compresslevel, if given, must be a number between 1 and 9. The default is 9.

For incremental compression, use a `BZ2Compressor` instead.

bz2.decompress (*data*)

Decompress *data*.

If *data* is the concatenation of multiple compressed streams, decompress all of the streams.

For incremental decompression, use a `BZ2Decompressor` instead.

在 3.3 版更改: 支持了多数据流的输入。

13.4 lzma — 用 LZMA 算法压缩

3.3 新版功能.

源代码: [Lib/lzma.py](#)

This module provides classes and convenience functions for compressing and decompressing data using the LZMA compression algorithm. Also included is a file interface supporting the `.xz` and legacy `.lzma` file formats used by the `xz` utility, as well as raw compressed streams.

The interface provided by this module is very similar to that of the `bz2` module. However, note that `LZMAFile` is *not* thread-safe, unlike `bz2.BZ2File`, so if you need to use a single `LZMAFile` instance from multiple threads, it is necessary to protect it with a lock.

exception `lzma.LZMAError`

This exception is raised when an error occurs during compression or decompression, or while initializing the compressor/decompressor state.

13.4.1 Reading and writing compressed files

`lzma.open(filename, mode="rb", *, format=None, check=-1, preset=None, filters=None, encoding=None, errors=None, newline=None)`

Open an LZMA-compressed file in binary or text mode, returning a *file object*.

The *filename* argument can be either an actual file name (given as a *str*, *bytes* or *path-like* object), in which case the named file is opened, or it can be an existing file object to read from or write to.

The *mode* argument can be any of "r", "rb", "w", "wb", "x", "xb", "a" or "ab" for binary mode, or "rt", "wt", "xt", or "at" for text mode. The default is "rb".

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for `LZMADecompressor`. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for `LZMACompressor`.

For binary mode, this function is equivalent to the `LZMAFile` constructor: `LZMAFile(filename, mode, ...)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a `LZMAFile` object is created, and wrapped in an `io.TextIOWrapper` instance with the specified encoding, error handling behavior, and line ending(s).

在 3.4 版更改: Added support for the "x", "xb" and "xt" modes.

在 3.6 版更改: 接受一个类路径对象。

class `lzma.LZMAFile(filename=None, mode="r", *, format=None, check=-1, preset=None, filters=None)`

Open an LZMA-compressed file in binary mode.

An `LZMAFile` can wrap an already-open *file object*, or operate directly on a named file. The *filename* argument specifies either the file object to wrap, or the name of the file to open (as a *str*, *bytes* or *path-like* object). When wrapping an existing file object, the wrapped file will not be closed when the `LZMAFile` is closed.

The *mode* argument can be either "r" for reading (default), "w" for overwriting, "x" for exclusive creation, or "a" for appending. These can equivalently be given as "rb", "wb", "xb" and "ab" respectively.

If *filename* is a file object (rather than an actual file name), a mode of "w" does not truncate the file, and is instead equivalent to "a".

When opening a file for reading, the input file may be the concatenation of multiple separate compressed streams. These are transparently decoded as a single logical stream.

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for *LZMADecompressor*. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for *LZMACompressor*.

LZMAFile supports all the members specified by *io.BufferedIOBase*, except for *detach()* and *truncate()*. Iteration and the *with* statement are supported.

The following method is also provided:

peek (*size=-1*)

Return buffered data without advancing the file position. At least one byte of data will be returned, unless EOF has been reached. The exact number of bytes returned is unspecified (the *size* argument is ignored).

注解: While calling *peek()* does not change the file position of the *LZMAFile*, it may change the position of the underlying file object (e.g. if the *LZMAFile* was constructed by passing a file object for *filename*).

在 3.4 版更改: Added support for the "x" and "xb" modes.

在 3.5 版更改: The *read()* method now accepts an argument of *None*.

在 3.6 版更改: 接受一个类路径对象。

13.4.2 Compressing and decompressing data in memory

class *lzma.LZMACompressor* (*format=FORMAT_XZ, check=-1, preset=None, filters=None*)

Create a compressor object, which can be used to compress data incrementally.

For a more convenient way of compressing a single chunk of data, see *compress()*.

The *format* argument specifies what container format should be used. Possible values are:

- **FORMAT_XZ: The .xz container format.** This is the default format.
- **FORMAT_ALONE: The legacy .lzma container format.** This format is more limited than .xz – it does not support integrity checks or multiple filters.
- **FORMAT_RAW: A raw data stream, not using any container format.** This format specifier does not support integrity checks, and requires that you always specify a custom filter chain (for both compression and decompression). Additionally, data compressed in this manner cannot be decompressed using *FORMAT_AUTO* (see *LZMADecompressor*).

The *check* argument specifies the type of integrity check to include in the compressed data. This check is used when decompressing, to ensure that the data has not been corrupted. Possible values are:

- **CHECK_NONE: No integrity check.** This is the default (and the only acceptable value) for *FORMAT_ALONE* and *FORMAT_RAW*.
- **CHECK_CRC32: 32-bit Cyclic Redundancy Check.**
- **CHECK_CRC64: 64-bit Cyclic Redundancy Check.** This is the default for *FORMAT_XZ*.
- **CHECK_SHA256: 256-bit Secure Hash Algorithm.**

If the specified check is not supported, an *LZMAError* is raised.

The compression settings can be specified either as a preset compression level (with the *preset* argument), or in detail as a custom filter chain (with the *filters* argument).

The *preset* argument (if provided) should be an integer between 0 and 9 (inclusive), optionally OR-ed with the constant `PRESET_EXTREME`. If neither *preset* nor *filters* are given, the default behavior is to use `PRESET_DEFAULT` (preset level 6). Higher presets produce smaller output, but make the compression process slower.

注解: In addition to being more CPU-intensive, compression with higher presets also requires much more memory (and produces output that needs more memory to decompress). With preset 9 for example, the overhead for an `LZMACompressor` object can be as high as 800 MiB. For this reason, it is generally best to stick with the default preset.

The *filters* argument (if provided) should be a filter chain specifier. See *Specifying custom filter chains* for details.

compress (*data*)

Compress *data* (a *bytes* object), returning a *bytes* object containing compressed data for at least part of the input. Some of *data* may be buffered internally, for use in later calls to `compress()` and `flush()`. The returned data should be concatenated with the output of any previous calls to `compress()`.

flush ()

Finish the compression process, returning a *bytes* object containing any data stored in the compressor's internal buffers.

The compressor cannot be used after this method has been called.

class `lzma.LZMADecompressor` (*format*=`FORMAT_AUTO`, *memlimit*=`None`, *filters*=`None`)

Create a decompressor object, which can be used to decompress data incrementally.

For a more convenient way of decompressing an entire compressed stream at once, see `decompress()`.

The *format* argument specifies the container format that should be used. The default is `FORMAT_AUTO`, which can decompress both `.xz` and `.lzma` files. Other possible values are `FORMAT_XZ`, `FORMAT_ALONE`, and `FORMAT_RAW`.

The *memlimit* argument specifies a limit (in bytes) on the amount of memory that the decompressor can use. When this argument is used, decompression will fail with an `LZMAError` if it is not possible to decompress the input within the given memory limit.

The *filters* argument specifies the filter chain that was used to create the stream being decompressed. This argument is required if *format* is `FORMAT_RAW`, but should not be used for other formats. See *Specifying custom filter chains* for more information about filter chains.

注解: This class does not transparently handle inputs containing multiple compressed streams, unlike `decompress()` and `LZMAFile`. To decompress a multi-stream input with `LZMADecompressor`, you must create a new decompressor for each stream.

decompress (*data*, *max_length*=-1)

Decompress *data* (a *bytes-like object*), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to `decompress()`. The returned data should be concatenated with the output of any previous calls to `decompress()`.

If *max_length* is nonnegative, returns at most *max_length* bytes of decompressed data. If this limit is reached and further output can be produced, the *needs_input* attribute will be set to `False`. In this case, the next call to `decompress()` may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max_length* bytes, or because *max_length* was negative), the *needs_input* attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an *EOFError*. Any data found after the end of the stream is ignored and saved in the *unused_data* attribute.

在 3.5 版更改: Added the *max_length* parameter.

check

The ID of the integrity check used by the input stream. This may be *CHECK_UNKNOWN* until enough of the input has been decoded to determine what integrity check it uses.

eof

若达到了数据流末尾标识符则为 *True*。

unused_data

压缩数据流的末尾还有数据。

Before the end of the stream is reached, this will be *b""*.

needs_input

False if the *decompress()* method can provide more decompressed data before requiring new uncompressed input.

3.5 新版功能.

`lzma.compress(data, format=FORMAT_XZ, check=-1, preset=None, filters=None)`

Compress *data* (a *bytes* object), returning the compressed data as a *bytes* object.

See *LZMACompressor* above for a description of the *format*, *check*, *preset* and *filters* arguments.

`lzma.decompress(data, format=FORMAT_AUTO, memlimit=None, filters=None)`

Decompress *data* (a *bytes* object), returning the uncompressed data as a *bytes* object.

If *data* is the concatenation of multiple distinct compressed streams, decompress all of these streams, and return the concatenation of the results.

See *LZMADecompressor* above for a description of the *format*, *memlimit* and *filters* arguments.

13.4.3 杂项

`lzma.is_check_supported(check)`

Returns true if the given integrity check is supported on this system.

CHECK_NONE and *CHECK_CRC32* are always supported. *CHECK_CRC64* and *CHECK_SHA256* may be unavailable if you are using a version of **liblzma** that was compiled with a limited feature set.

13.4.4 Specifying custom filter chains

A filter chain specifier is a sequence of dictionaries, where each dictionary contains the ID and options for a single filter. Each dictionary must contain the key *"id"*, and may contain additional keys to specify filter-dependent options. Valid filter IDs are as follows:

- **Compression filters:**
 - *FILTER_LZMA1* (for use with *FORMAT_ALONE*)
 - *FILTER_LZMA2* (for use with *FORMAT_XZ* and *FORMAT_RAW*)
- **Delta filter:**
 - *FILTER_DELTA*
- **Branch-Call-Jump (BCJ) filters:**

- FILTER_X86
- FILTER_IA64
- FILTER_ARM
- FILTER_ARMTHUMB
- FILTER_POWERPC
- FILTER_SPARC

A filter chain can consist of up to 4 filters, and cannot be empty. The last filter in the chain must be a compression filter, and any other filters must be delta or BCJ filters.

Compression filters support the following options (specified as additional entries in the dictionary representing the filter):

- `preset`: A compression preset to use as a source of default values for options that are not specified explicitly.
- `dict_size`: Dictionary size in bytes. This should be between 4 KiB and 1.5 GiB (inclusive).
- `lc`: Number of literal context bits.
- `lp`: Number of literal position bits. The sum `lc + lp` must be at most 4.
- `pb`: Number of position bits; must be at most 4.
- `mode`: `MODE_FAST` or `MODE_NORMAL`.
- `nice_len`: What should be considered a “nice length” for a match. This should be 273 or less.
- `mf`: What match finder to use – `MF_HC3`, `MF_HC4`, `MF_BT2`, `MF_BT3`, or `MF_BT4`.
- `depth`: Maximum search depth used by match finder. 0 (default) means to select automatically based on other filter options.

The delta filter stores the differences between bytes, producing more repetitive input for the compressor in certain circumstances. It supports one option, `dist`. This indicates the distance between bytes to be subtracted. The default is 1, i.e. take the differences between adjacent bytes.

The BCJ filters are intended to be applied to machine code. They convert relative branches, calls and jumps in the code to use absolute addressing, with the aim of increasing the redundancy that can be exploited by the compressor. These filters support one option, `start_offset`. This specifies the address that should be mapped to the beginning of the input data. The default is 0.

13.4.5 示例

Reading in a compressed file:

```
import lzma
with lzma.open("file.xz") as f:
    file_content = f.read()
```

Creating a compressed file:

```
import lzma
data = b"Insert Data Here"
with lzma.open("file.xz", "w") as f:
    f.write(data)
```

Compressing data in memory:

```
import lzma
data_in = b"Insert Data Here"
data_out = lzma.compress(data_in)
```

Incremental compression:

```
import lzma
lzc = lzma.LZMACompressor()
out1 = lzc.compress(b"Some data\n")
out2 = lzc.compress(b"Another piece of data\n")
out3 = lzc.compress(b"Even more data\n")
out4 = lzc.flush()
# Concatenate all the partial results:
result = b"".join([out1, out2, out3, out4])
```

Writing compressed data to an already-open file:

```
import lzma
with open("file.xz", "wb") as f:
    f.write(b"This data will not be compressed\n")
    with lzma.open(f, "w") as lzf:
        lzf.write(b"This *will* be compressed\n")
    f.write(b"Not compressed\n")
```

Creating a compressed file using a custom filter chain:

```
import lzma
my_filters = [
    {"id": lzma.FILTER_DELTA, "dist": 5},
    {"id": lzma.FILTER_LZMA2, "preset": 7 | lzma.PRESET_EXTREME},
]
with lzma.open("file.xz", "w", filters=my_filters) as f:
    f.write(b"blah blah blah")
```

13.5 zipfile — 使用 ZIP 存档

源代码: [Lib/zipfile.py](#)

ZIP 文件格式是一个常用的归档与压缩标准。这个模块提供了创建、读取、写入、添加及列出 ZIP 文件的工具。任何对此模块的进阶使用都将需要理解此格式，其定义参见 [PKZIP 应用程序笔记](#)。

此模块目前不能处理分卷 ZIP 文件。它可以处理使用 ZIP64 扩展（超过 4 GB 的 ZIP 文件）的 ZIP 文件。它支持解密 ZIP 归档中的加密文件，但是目前不能创建一个加密的文件。解密非常慢，因为它是使用原生 Python 而不是 C 实现的。

这个模块定义了以下内容：

exception `zipfile.BadZipFile`

为损坏的 ZIP 文件抛出的错误。

3.2 新版功能。

exception `zipfile.BadZipfile`

`BadZipFile` 的别名，与旧版本 Python 保持兼容性。

3.2 版后已移除。

exception zipfile.LargeZipFile

当 ZIP 文件取药 ZIP64 功能但是未启用时抛出此错误。

class zipfile.ZipFile

用于读写 ZIP 文件的类。欲了解构造函数的描述，参阅段落 [ZipFile 对象](#)。

class zipfile.PyZipFile

用于创建包含 Python 库的 ZIP 归档的类。

class zipfile.ZipInfo (filename='NoName', date_time=(1980, 1, 1, 0, 0, 0))

用于表示档案内一个成员信息的类。此类的实例会由 [ZipFile](#) 对象的 [getinfo\(\)](#) 和 [infolist\(\)](#) 方法返回。大多数 [zipfile](#) 模块的用户都不必创建它们，只需使用此模块所创建的实例。*filename* 应当是档案成员的全名，*date_time* 应当是包含六个字段的描述最近修改时间的元组；这些字段的描述请参阅 [ZipInfo Objects](#)。

zipfile.is_zipfile (filename)

根据文件的 Magic Number，如果 *filename* 是一个有效的 ZIP 文件则返回 True，否则返回 False。*filename* 也可能是一个文件或类文件对象。

在 3.1 版更改：支持文件或类文件对象。

zipfile.ZIP_STORED

未被压缩的归档成员的数字常数。

zipfile.ZIP_DEFLATED

常用的 ZIP 压缩方法的数字常数。需要 [zlib](#) 模块。

zipfile.ZIP_BZIP2

BZIP2 压缩方法的数字常数。需要 [bz2](#) 模块。

3.3 新版功能。

zipfile.ZIP_LZMA

LZMA 压缩方法的数字常数。需要 [lzma](#) 模块。

3.3 新版功能。

注解： ZIP 文件格式规范包括自 2001 年以来对 bzip2 压缩的支持，以及自 2006 年以来对 LZMA 压缩的支持。但是，一些工具（包括较旧的 Python 版本）不支持这些压缩方法，并且可能拒绝完全处理 ZIP 文件，或者无法提取单个文件。

参见：

PKZIP 应用程序笔记 Phil Katz 编写的 ZIP 文件格式文档，此格式和使用的算法的创建者。

Info-ZIP 主页 有关 Info-ZIP 项目的 ZIP 存档程序和开发库的信息。

13.5.1 ZipFile 对象

class zipfile.ZipFile (file, mode='r', compression=ZIP_STORED, allowZip64=True)

Open a ZIP file, where *file* can be a path to a file (a string), a file-like object or a [path-like object](#). The *mode* parameter should be 'r' to read an existing file, 'w' to truncate and write a new file, 'a' to append to an existing file, or 'x' to exclusively create and write a new file. If *mode* is 'x' and *file* refers to an existing file, a [FileExistsError](#) will be raised. If *mode* is 'a' and *file* refers to an existing ZIP file, then additional files are added to it. If *file* does not refer to a ZIP file, then a new ZIP archive is appended to the file. This is meant for adding a ZIP archive to another file (such as `python.exe`). If *mode* is 'a' and the file does not exist at all, it is created. If *mode* is 'r' or 'a', the file should be seekable. *compression* is the ZIP compression method to use when writing the archive, and should be [ZIP_STORED](#), [ZIP_DEFLATED](#), [ZIP_BZIP2](#) or [ZIP_LZMA](#);

unrecognized values will cause `NotImplementedError` to be raised. If `ZIP_DEFLATED`, `ZIP_BZIP2` or `ZIP_LZMA` is specified but the corresponding module (`zlib`, `bz2` or `lzma`) is not available, `RuntimeError` is raised. The default is `ZIP_STORED`. If `allowZip64` is `True` (the default) zipfile will create ZIP files that use the ZIP64 extensions when the zipfile is larger than 4 GiB. If it is false `zipfile` will raise an exception when the ZIP file would require ZIP64 extensions.

If the file is created with mode `'w'`, `'x'` or `'a'` and then `closed` without adding any files to the archive, the appropriate ZIP structures for an empty archive will be written to the file.

`ZipFile` is also a context manager and therefore supports the `with` statement. In the example, `myzip` is closed after the `with` statement's suite is finished—even if an exception occurs:

```
with ZipFile('spam.zip', 'w') as myzip:
    myzip.write('eggs.txt')
```

3.2 新版功能: Added the ability to use `ZipFile` as a context manager.

在 3.3 版更改: Added support for `bzip2` and `lzma` compression.

在 3.4 版更改: ZIP64 extensions are enabled by default.

在 3.5 版更改: Added support for writing to unseekable streams. Added support for the `'x'` mode.

在 3.6 版更改: Previously, a plain `RuntimeError` was raised for unrecognized compression values.

在 3.6.2 版更改: The `file` parameter accepts a *path-like object*.

`ZipFile.close()`

Close the archive file. You must call `close()` before exiting your program or essential records will not be written.

`ZipFile.getinfo(name)`

Return a `ZipInfo` object with information about the archive member `name`. Calling `getinfo()` for a name not currently contained in the archive will raise a `KeyError`.

`ZipFile.infolist()`

Return a list containing a `ZipInfo` object for each member of the archive. The objects are in the same order as their entries in the actual ZIP file on disk if an existing archive was opened.

`ZipFile.namelist()`

Return a list of archive members by name.

`ZipFile.open(name, mode='r', pwd=None, *, force_zip64=False)`

Access a member of the archive as a binary file-like object. `name` can be either the name of a file within the archive or a `ZipInfo` object. The `mode` parameter, if included, must be `'r'` (the default) or `'w'`. `pwd` is the password used to decrypt encrypted ZIP files.

`open()` is also a context manager and therefore supports the `with` statement:

```
with ZipFile('spam.zip') as myzip:
    with myzip.open('eggs.txt') as myfile:
        print(myfile.read())
```

With mode `'r'` the file-like object (`ZipExtFile`) is read-only and provides the following methods: `read()`, `readline()`, `readlines()`, `__iter__()`, `__next__()`. These objects can operate independently of the `ZipFile`.

With mode `'w'`, a writable file handle is returned, which supports the `write()` method. While a writable file handle is open, attempting to read or write other files in the ZIP file will raise a `ValueError`.

When writing a file, if the file size is not known in advance but may exceed 2 GiB, pass `force_zip64=True` to ensure that the header format is capable of supporting large files. If the file size is known in advance, construct a `ZipInfo` object with `file_size` set, and use that as the `name` parameter.

注解: The `open()`, `read()` and `extract()` methods can take a filename or a `ZipInfo` object. You will appreciate this when trying to read a ZIP file that contains members with duplicate names.

在 3.6 版更改: Removed support of `mode='U'`. Use `io.TextIOWrapper` for reading compressed text files in *universal newlines* mode.

在 3.6 版更改: `open()` can now be used to write files into the archive with the `mode='w'` option.

在 3.6 版更改: Calling `open()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.extract(member, path=None, pwd=None)`

Extract a member from the archive to the current working directory; *member* must be its full name or a `ZipInfo` object. Its file information is extracted as accurately as possible. *path* specifies a different directory to extract to. *member* can be a filename or a `ZipInfo` object. *pwd* is the password used for encrypted files.

Returns the normalized path created (a directory or new file).

注解: If a member filename is an absolute path, a drive/UNC sharepoint and leading (back)slashes will be stripped, e.g.: `///foo/bar` becomes `foo/bar` on Unix, and `C:\foo\bar` becomes `foo\bar` on Windows. And all `".."` components in a member filename will be removed, e.g.: `../..foo../..ba..r` becomes `foo../ba..r`. On Windows illegal characters (`:`, `<`, `>`, `|`, `"`, `?`, and `*`) replaced by underscore (`_`).

在 3.6 版更改: Calling `extract()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

在 3.6.2 版更改: The *path* parameter accepts a *path-like object*.

`ZipFile.extractall(path=None, members=None, pwd=None)`

Extract all members from the archive to the current working directory. *path* specifies a different directory to extract to. *members* is optional and must be a subset of the list returned by `namelist()`. *pwd* is the password used for encrypted files.

警告: Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `".."`. This module attempts to prevent that. See `extract()` note.

在 3.6 版更改: Calling `extractall()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

在 3.6.2 版更改: The *path* parameter accepts a *path-like object*.

`ZipFile.printdir()`

Print a table of contents for the archive to `sys.stdout`.

`ZipFile.setpassword(pwd)`

Set *pwd* as default password to extract encrypted files.

`ZipFile.read(name, pwd=None)`

Return the bytes of the file *name* in the archive. *name* is the name of the file in the archive, or a `ZipInfo` object. The archive must be open for read or append. *pwd* is the password used for encrypted files and, if specified, it will override the default password set with `setpassword()`. Calling `read()` on a `ZipFile` that uses a compression method other than `ZIP_STORED`, `ZIP_DEFLATED`, `ZIP_BZIP2` or `ZIP_LZMA` will raise a `NotImplementedError`. An error will also be raised if the corresponding compression module is not available.

在 3.6 版更改: Calling `read()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.testzip()`

Read all the files in the archive and check their CRC's and file headers. Return the name of the first bad file, or else return `None`.

在 3.6 版更改: Calling `testzip()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.write(filename, arcname=None, compress_type=None)`

Write the file named `filename` to the archive, giving it the archive name `arcname` (by default, this will be the same as `filename`, but without a drive letter and with leading path separators removed). If given, `compress_type` overrides the value given for the `compression` parameter to the constructor for the new entry. The archive must be open with mode `'w'`, `'x'` or `'a'`.

注解: Archive names should be relative to the archive root, that is, they should not start with a path separator.

注解: If `arcname` (or `filename`, if `arcname` is not given) contains a null byte, the name of the file in the archive will be truncated at the null byte.

在 3.6 版更改: Calling `write()` on a `ZipFile` created with mode `'r'` or a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.writestr(zinfo_or_arcname, data[, compress_type])`

Write a file into the archive. The contents is `data`, which may be either a `str` or a `bytes` instance; if it is a `str`, it is encoded as UTF-8 first. `zinfo_or_arcname` is either the file name it will be given in the archive, or a `ZipInfo` instance. If it's an instance, at least the filename, date, and time must be given. If it's a name, the date and time is set to the current date and time. The archive must be opened with mode `'w'`, `'x'` or `'a'`.

If given, `compress_type` overrides the value given for the `compression` parameter to the constructor for the new entry, or in the `zinfo_or_arcname` (if that is a `ZipInfo` instance).

注解: When passing a `ZipInfo` instance as the `zinfo_or_arcname` parameter, the compression method used will be that specified in the `compress_type` member of the given `ZipInfo` instance. By default, the `ZipInfo` constructor sets this member to `ZIP_STORED`.

在 3.2 版更改: The `compress_type` argument.

在 3.6 版更改: Calling `writestr()` on a `ZipFile` created with mode `'r'` or a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

The following data attributes are also available:

`ZipFile.filename`

Name of the ZIP file.

`ZipFile.debug`

The level of debug output to use. This may be set from 0 (the default, no output) to 3 (the most output). Debugging information is written to `sys.stdout`.

`ZipFile.comment`

The comment associated with the ZIP file as a `bytes` object. If assigning a comment to a `ZipFile` instance created with mode `'w'`, `'x'` or `'a'`, it should be no longer than 65535 bytes. Comments longer than this will be truncated.

13.5.2 PyZipFile Objects

The `PyZipFile` constructor takes the same parameters as the `ZipFile` constructor, and one additional parameter, `optimize`.

class `zipfile.PyZipFile` (*file*, *mode*='r', *compression*=ZIP_STORED, *allowZip64*=True, *optimize*=-1)

3.2 新版功能: The `optimize` parameter.

在 3.4 版更改: ZIP64 extensions are enabled by default.

Instances have one method in addition to those of `ZipFile` objects:

writepy (*pathname*, *basename*="", *filterfunc*=None)

Search for files `*.py` and add the corresponding file to the archive.

If the `optimize` parameter to `PyZipFile` was not given or `-1`, the corresponding file is a `*.pyc` file, compiling if necessary.

If the `optimize` parameter to `PyZipFile` was `0`, `1` or `2`, only files with that optimization level (see `compile()`) are added to the archive, compiling if necessary.

If *pathname* is a file, the filename must end with `.py`, and just the (corresponding `*.pyc`) file is added at the top level (no path information). If *pathname* is a file that does not end with `.py`, a `RuntimeError` will be raised. If it is a directory, and the directory is not a package directory, then all the `*.pyc` are added at the top level. If the directory is a package directory, then all `*.pyc` are added under the package name as a file path, and if any subdirectories are package directories, all of these are added recursively.

basename is intended for internal use only.

filterfunc, if given, must be a function taking a single string argument. It will be passed each path (including each individual full file path) before it is added to the archive. If *filterfunc* returns a false value, the path will not be added, and if it is a directory its contents will be ignored. For example, if our test files are all either in test directories or start with the string `test_`, we can use a *filterfunc* to exclude them:

```
>>> zf = PyZipFile('myprog.zip')
>>> def notests(s):
...     fn = os.path.basename(s)
...     return (not (fn == 'test' or fn.startswith('test_')))
>>> zf.writepy('myprog', filterfunc=notests)
```

The `writepy()` method makes archives with file names like this:

```
string.pyc           # Top level name
test/__init__.pyc    # Package directory
test/testall.pyc     # Module test.testall
test/bogus/__init__.pyc # Subpackage directory
test/bogus/myfile.pyc # Submodule test.bogus.myfile
```

3.4 新版功能: The *filterfunc* parameter.

在 3.6.2 版更改: The *pathname* parameter accepts a *path-like object*.

13.5.3 ZipInfo Objects

Instances of the `ZipInfo` class are returned by the `getinfo()` and `infolist()` methods of `ZipFile` objects. Each object stores information about a single member of the ZIP archive.

There is one classmethod to make a `ZipInfo` instance for a filesystem file:

classmethod `ZipInfo.from_file(filename, arcname=None)`

Construct a `ZipInfo` instance for a file on the filesystem, in preparation for adding it to a zip file.

`filename` should be the path to a file or directory on the filesystem.

If `arcname` is specified, it is used as the name within the archive. If `arcname` is not specified, the name will be the same as `filename`, but with any drive letter and leading path separators removed.

3.6 新版功能.

在 3.6.2 版更改: The `filename` parameter accepts a *path-like object*.

Instances have the following methods and attributes:

`ZipInfo.is_dir()`

Return `True` if this archive member is a directory.

This uses the entry's name: directories should always end with `/`.

3.6 新版功能.

`ZipInfo.filename`

Name of the file in the archive.

`ZipInfo.date_time`

上次修改存档成员的时间和日期。这是六个值的元组:

索引	值
0	Year (≥ 1980)
1	月 (1 为基数)
2	月份中的日期 (1 为基数)
3	小时 (0 为基数)
4	分钟 (0 为基数)
5	秒 (0 为基数)

注解: ZIP 文件格式不支持 1980 年以前的时间戳。

`ZipInfo.compress_type`

Type of compression for the archive member.

`ZipInfo.comment`

Comment for the individual archive member as a *bytes* object.

`ZipInfo.extra`

Expansion field data. The [PKZIP Application Note](#) contains some comments on the internal structure of the data contained in this *bytes* object.

`ZipInfo.create_system`

System which created ZIP archive.

`ZipInfo.create_version`

PKZIP version which created ZIP archive.

`ZipInfo.extract_version`

PKZIP version needed to extract archive.

`ZipInfo.reserved`

必须为零。

`ZipInfo.flag_bits`
ZIP 标志位。

`ZipInfo.volume`
Volume number of file header.

`ZipInfo.internal_attr`
Internal attributes.

`ZipInfo.external_attr`
External file attributes.

`ZipInfo.header_offset`
Byte offset to the file header.

`ZipInfo.CRC`
CRC-32 of the uncompressed file.

`ZipInfo.compress_size`
Size of the compressed data.

`ZipInfo.file_size`
Size of the uncompressed file.

13.5.4 命令行界面

The `zipfile` module provides a simple command-line interface to interact with ZIP archives.

If you want to create a new ZIP archive, specify its name after the `-c` option and then list the filename(s) that should be included:

```
$ python -m zipfile -c monty.zip spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m zipfile -c monty.zip life-of-brian_1979/
```

If you want to extract a ZIP archive into the specified directory, use the `-e` option:

```
$ python -m zipfile -e monty.zip target-dir/
```

For a list of the files in a ZIP archive, use the `-l` option:

```
$ python -m zipfile -l monty.zip
```

命令行选项

`-l <zipfile>`
List files in a zipfile.

`-c <zipfile> <source1> ... <sourceN>`
Create zipfile from source files.

`-e <zipfile> <output_dir>`
Extract zipfile into target directory.

`-t <zipfile>`
Test whether the zipfile is valid or not.

13.6 tarfile —读写 tar 归档文件

源代码: [Lib/tarfile.py](#)

The *tarfile* module makes it possible to read and write tar archives, including those using *gzip*, *bz2* and *lzma* compression. Use the *zipfile* module to read or write *.zip* files, or the higher-level functions in *shutil*.

Some facts and figures:

- reads and writes *gzip*, *bz2* and *lzma* compressed archives if the respective modules are available.
- read/write support for the POSIX.1-1988 (ustar) format.
- read/write support for the GNU tar format including *longname* and *longlink* extensions, read-only support for all variants of the *sparse* extension including restoration of sparse files.
- read/write support for the POSIX.1-2001 (pax) format.
- handles directories, regular files, hardlinks, symbolic links, fifos, character devices and block devices and is able to acquire and restore file information like timestamp, access permissions and owner.

在 3.3 版更改: Added support for *lzma* compression.

`tarfile.open(name=None, mode='r', fileobj=None, bufsize=10240, **kwargs)`

Return a *TarFile* object for the pathname *name*. For detailed information on *TarFile* objects and the keyword arguments that are allowed, see *TarFile Objects*.

mode has to be a string of the form `'filemode[:compression]'`, it defaults to `'r'`. Here is a full list of mode combinations:

模式	动作
'r' or 'r:*	打开和读取使用透明压缩（推荐）。
'r:'	打开和读取不使用压缩。
'r:gz'	打开和读取使用 <i>gzip</i> 压缩。
'r:bz2'	打开和读取使用 <i>bzip2</i> 压缩。
'r:xz'	打开和读取使用 <i>lzma</i> 压缩。
'x' or 'x:'	创建 <i>tarfile</i> 不进行压缩。如果文件已经存在，则抛出 <i>FileExistsError</i> 异常。
'x:gz'	使用 <i>gzip</i> 压缩创建 <i>tarfile</i> 。如果文件已经存在，则抛出 <i>FileExistsError</i> 异常。
'x:bz2'	使用 <i>bzip2</i> 压缩创建 <i>tarfile</i> 。如果文件已经存在，则抛出 <i>FileExistsError</i> 异常。
'x:xz'	使用 <i>lzma</i> 压缩创建 <i>tarfile</i> 。如果文件已经存在，则抛出 <i>FileExistsError</i> 异常。
'a' or 'a:'	打开以便在没有压缩的情况下追加。如果文件不存在，则创建该文件。
'w' or 'w:'	Open for uncompressed writing.
'w:gz'	Open for <i>gzip</i> compressed writing.
'w:bz2'	Open for <i>bzip2</i> compressed writing.
'w:xz'	Open for <i>lzma</i> compressed writing.

Note that `'a:gz'`, `'a:bz2'` or `'a:xz'` is not possible. If *mode* is not suitable to open a certain (compressed) file for reading, *ReadError* is raised. Use *mode* `'r'` to avoid this. If a compression method is not supported, *CompressionError* is raised.

If *fileobj* is specified, it is used as an alternative to a *file object* opened in binary mode for *name*. It is supposed to be at position 0.

For modes `'w:gz'`, `'r:gz'`, `'w:bz2'`, `'r:bz2'`, `'x:gz'`, `'x:bz2'`, `tarfile.open()` accepts the keyword argument `compresslevel` (default 9) to specify the compression level of the file.

For special purposes, there is a second format for `mode`: `'filemode|[compression]'`. `tarfile.open()` will return a `TarFile` object that processes its data as a stream of blocks. No random seeking will be done on the file. If given, `fileobj` may be any object that has a `read()` or `write()` method (depending on the `mode`). `bufsize` specifies the blocksize and defaults to `20 * 512` bytes. Use this variant in combination with e.g. `sys.stdin`, a socket *file object* or a tape device. However, such a `TarFile` object is limited in that it does not allow random access, see 示例. The currently possible modes:

模式	动作
<code>'r *'</code>	Open a <i>stream</i> of tar blocks for reading with transparent compression.
<code>'r '</code>	Open a <i>stream</i> of uncompressed tar blocks for reading.
<code>'r gz'</code>	Open a gzip compressed <i>stream</i> for reading.
<code>'r bz2'</code>	Open a bzip2 compressed <i>stream</i> for reading.
<code>'r xz'</code>	Open an lzma compressed <i>stream</i> for reading.
<code>'w '</code>	Open an uncompressed <i>stream</i> for writing.
<code>'w gz'</code>	Open a gzip compressed <i>stream</i> for writing.
<code>'w bz2'</code>	Open a bzip2 compressed <i>stream</i> for writing.
<code>'w xz'</code>	Open an lzma compressed <i>stream</i> for writing.

在 3.5 版更改: 添加了 `'x'` (仅创建) 模式。

在 3.6 版更改: The `name` parameter accepts a *path-like object*.

class `tarfile.TarFile`

Class for reading and writing tar archives. Do not use this class directly: use `tarfile.open()` instead. See *TarFile Objects*.

`tarfile.is_tarfile` (*name*)

Return `True` if *name* is a tar archive file, that the `tarfile` module can read.

The `tarfile` module defines the following exceptions:

exception `tarfile.TarError`

Base class for all `tarfile` exceptions.

exception `tarfile.ReadError`

Is raised when a tar archive is opened, that either cannot be handled by the `tarfile` module or is somehow invalid.

exception `tarfile.CompressionError`

Is raised when a compression method is not supported or when the data cannot be decoded properly.

exception `tarfile.StreamError`

Is raised for the limitations that are typical for stream-like `TarFile` objects.

exception `tarfile.ExtractError`

Is raised for *non-fatal* errors when using `TarFile.extract()`, but only if `TarFile.errorlevel == 2`.

exception `tarfile.HeaderError`

Is raised by `TarInfo.frombuf()` if the buffer it gets is invalid.

The following constants are available at the module level:

`tarfile.ENCODING`

The default character encoding: `'utf-8'` on Windows, the value returned by `sys.getfilesystemencoding()` otherwise.

Each of the following constants defines a tar archive format that the `tarfile` module is able to create. See section *Supported tar formats* for details.

`tarfile.USTAR_FORMAT`
POSIX.1-1988 (ustar) format.

`tarfile.GNU_FORMAT`
GNU tar format.

`tarfile.PAX_FORMAT`
POSIX.1-2001 (pax) format.

`tarfile.DEFAULT_FORMAT`
The default format for creating archives. This is currently `GNU_FORMAT`.

参见:

Module `zipfile` Documentation of the `zipfile` standard module.

Archiving operations Documentation of the higher-level archiving facilities provided by the standard `shutil` module.

GNU tar manual, Basic Tar Format Documentation for tar archive files, including GNU tar extensions.

13.6.1 TarFile Objects

The `TarFile` object provides an interface to a tar archive. A tar archive is a sequence of blocks. An archive member (a stored file) is made up of a header block followed by data blocks. It is possible to store a file in a tar archive several times. Each archive member is represented by a `TarInfo` object, see *TarInfo Objects* for details.

A `TarFile` object can be used as a context manager in a `with` statement. It will automatically be closed when the block is completed. Please note that in the event of an exception an archive opened for writing will not be finalized; only the internally used file object will be closed. See the 示例 section for a use case.

3.2 新版功能: Added support for the context management protocol.

```
class tarfile.TarFile(name=None, mode='r', fileobj=None, format=DEFAULT_FORMAT, tar-
                      info=TarInfo, dereference=False, ignore_zeros=False, encoding=ENCODING,
                      errors='surrogateescape', pax_headers=None, debug=0, errorlevel=0)
```

All following arguments are optional and can be accessed as instance attributes as well.

`name` is the pathname of the archive. `name` may be a *path-like object*. It can be omitted if `fileobj` is given. In this case, the file object's `name` attribute is used if it exists.

`mode` is either `'r'` to read from an existing archive, `'a'` to append data to an existing file, `'w'` to create a new file overwriting an existing one, or `'x'` to create a new file only if it does not already exist.

If `fileobj` is given, it is used for reading or writing data. If it can be determined, `mode` is overridden by `fileobj`'s `mode`. `fileobj` will be used from position 0.

注解: `fileobj` is not closed, when `TarFile` is closed.

`format` controls the archive format. It must be one of the constants `USTAR_FORMAT`, `GNU_FORMAT` or `PAX_FORMAT` that are defined at module level.

The `tarinfo` argument can be used to replace the default `TarInfo` class with a different one.

If `dereference` is `False`, add symbolic and hard links to the archive. If it is `True`, add the content of the target files to the archive. This has no effect on systems that do not support symbolic links.

If `ignore_zeros` is `False`, treat an empty block as the end of the archive. If it is `True`, skip empty (and invalid) blocks and try to get as many members as possible. This is only useful for reading concatenated or damaged archives.

`debug` can be set from 0 (no debug messages) up to 3 (all debug messages). The messages are written to `sys.stderr`.

If `errorlevel` is 0, all errors are ignored when using `TarFile.extract()`. Nevertheless, they appear as error messages in the debug output, when debugging is enabled. If 1, all *fatal* errors are raised as `OSError` exceptions. If 2, all *non-fatal* errors are raised as `TarError` exceptions as well.

The `encoding` and `errors` arguments define the character encoding to be used for reading or writing the archive and how conversion errors are going to be handled. The default settings will work for most users. See section [Unicode issues](#) for in-depth information.

The `pax_headers` argument is an optional dictionary of strings which will be added as a pax global header if `format` is `PAX_FORMAT`.

在 3.2 版更改: Use 'surrogateescape' as the default for the `errors` argument.

在 3.5 版更改: 添加了 'x' (仅创建) 模式。

在 3.6 版更改: The `name` parameter accepts a *path-like object*.

classmethod `TarFile.open(...)`

Alternative constructor. The `tarfile.open()` function is actually a shortcut to this classmethod.

`TarFile.getmember(name)`

Return a `TarInfo` object for member `name`. If `name` can not be found in the archive, `KeyError` is raised.

注解: If a member occurs more than once in the archive, its last occurrence is assumed to be the most up-to-date version.

`TarFile.getmembers()`

Return the members of the archive as a list of `TarInfo` objects. The list has the same order as the members in the archive.

`TarFile.getnames()`

Return the members as a list of their names. It has the same order as the list returned by `getmembers()`.

`TarFile.list(verbose=True, *, members=None)`

Print a table of contents to `sys.stdout`. If `verbose` is `False`, only the names of the members are printed. If it is `True`, output similar to that of `ls -l` is produced. If optional `members` is given, it must be a subset of the list returned by `getmembers()`.

在 3.5 版更改: Added the `members` parameter.

`TarFile.next()`

Return the next member of the archive as a `TarInfo` object, when `TarFile` is opened for reading. Return `None` if there is no more available.

`TarFile.extractall(path=".", members=None, *, numeric_owner=False)`

Extract all members from the archive to the current working directory or directory `path`. If optional `members` is given, it must be a subset of the list returned by `getmembers()`. Directory information like owner, modification time and permissions are set after all members have been extracted. This is done to work around two problems: A directory's modification time is reset each time a file is created in it. And, if a directory's permissions do not allow writing, extracting files to it will fail.

If `numeric_owner` is `True`, the uid and gid numbers from the tarfile are used to set the owner/group for the extracted files. Otherwise, the named values from the tarfile are used.

警告： Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `" / "` or filenames with two dots `" . . "`.

在 3.5 版更改: Added the *numeric_owner* parameter.

在 3.6 版更改: The *path* parameter accepts a *path-like object*.

`TarFile.extract(member, path="", set_attrs=True, *, numeric_owner=False)`

Extract a member from the archive to the current working directory, using its full name. Its file information is extracted as accurately as possible. *member* may be a filename or a *TarInfo* object. You can specify a different directory using *path*. *path* may be a *path-like object*. File attributes (owner, mtime, mode) are set unless *set_attrs* is false.

If *numeric_owner* is *True*, the uid and gid numbers from the tarfile are used to set the owner/group for the extracted files. Otherwise, the named values from the tarfile are used.

注解： The *extract()* method does not take care of several extraction issues. In most cases you should consider using the *extractall()* method.

警告： See the warning for *extractall()*.

在 3.2 版更改: Added the *set_attrs* parameter.

在 3.5 版更改: Added the *numeric_owner* parameter.

在 3.6 版更改: The *path* parameter accepts a *path-like object*.

`TarFile.extractfile(member)`

Extract a member from the archive as a file object. *member* may be a filename or a *TarInfo* object. If *member* is a regular file or a link, an *io.BufferedReader* object is returned. Otherwise, *None* is returned.

在 3.3 版更改: Return an *io.BufferedReader* object.

`TarFile.add(name, arcname=None, recursive=True, exclude=None, *, filter=None)`

Add the file *name* to the archive. *name* may be any type of file (directory, fifo, symbolic link, etc.). If given, *arcname* specifies an alternative name for the file in the archive. Directories are added recursively by default. This can be avoided by setting *recursive* to *False*. If *exclude* is given, it must be a function that takes one filename argument and returns a boolean value. Depending on this value the respective file is either excluded (*True*) or added (*False*). If *filter* is specified it must be a keyword argument. It should be a function that takes a *TarInfo* object argument and returns the changed *TarInfo* object. If it instead returns *None* the *TarInfo* object will be excluded from the archive. See 示例 for an example.

在 3.2 版更改: Added the *filter* parameter.

3.2 版后已移除: The *exclude* parameter is deprecated, please use the *filter* parameter instead.

`TarFile.addfile(tarinfo, fileobj=None)`

Add the *TarInfo* object *tarinfo* to the archive. If *fileobj* is given, it should be a *binary file*, and *tarinfo.size* bytes are read from it and added to the archive. You can create *TarInfo* objects directly, or by using *gettinfo()*.

`TarFile.gettarinfo(name=None, arcname=None, fileobj=None)`

Create a *TarInfo* object from the result of *os.stat()* or equivalent on an existing file. The file is either named by *name*, or specified as a *file object* *fileobj* with a file descriptor. *name* may be a *path-like object*. If given, *arcname*

specifies an alternative name for the file in the archive, otherwise, the name is taken from *fileobj*'s *name* attribute, or the *name* argument. The name should be a text string.

You can modify some of the *TarInfo*'s attributes before you add it using *addfile()*. If the file object is not an ordinary file object positioned at the beginning of the file, attributes such as *size* may need modifying. This is the case for objects such as *GzipFile*. The *name* may also be modified, in which case *arcname* could be a dummy string.

在 3.6 版更改: The *name* parameter accepts a *path-like object*.

TarFile.close()

Close the *TarFile*. In write mode, two finishing zero blocks are appended to the archive.

TarFile.pax_headers

A dictionary containing key-value pairs of pax global headers.

13.6.2 TarInfo Objects

A *TarInfo* object represents one member in a *TarFile*. Aside from storing all required attributes of a file (like file type, size, time, permissions, owner etc.), it provides some useful methods to determine its type. It does *not* contain the file's data itself.

TarInfo objects are returned by *TarFile*'s methods *getmember()*, *getmembers()* and *gettarinfo()*.

class tarfile.TarInfo (name='')

Create a *TarInfo* object.

classmethod TarInfo.frombuf (buf, encoding, errors)

Create and return a *TarInfo* object from string buffer *buf*.

Raises *HeaderError* if the buffer is invalid.

classmethod TarInfo.fromtarfile (tarfile)

Read the next member from the *TarFile* object *tarfile* and return it as a *TarInfo* object.

TarInfo.tobuf (format=DEFAULT_FORMAT, encoding=ENCODING, errors='surrogateescape')

Create a string buffer from a *TarInfo* object. For information on the arguments see the constructor of the *TarFile* class.

在 3.2 版更改: Use 'surrogateescape' as the default for the *errors* argument.

A *TarInfo* object has the following public data attributes:

TarInfo.name

Name of the archive member.

TarInfo.size

Size in bytes.

TarInfo.mtime

Time of last modification.

TarInfo.mode

Permission bits.

TarInfo.type

File type. *type* is usually one of these constants: REGTYPE, AREGTYPE, LNKTYPE, SYMTYPE, DIRTYPE, FIFOTYPE, CONTTYPE, CHRTYPE, BLKTYPE, GNUTYPE_SPARSE. To determine the type of a *TarInfo* object more conveniently, use the *is*()* methods below.

TarInfo.linkname

Name of the target file name, which is only present in *TarInfo* objects of type LNKTYPE and SYMTYPE.

`TarInfo.uid`
User ID of the user who originally stored this member.

`TarInfo.gid`
Group ID of the user who originally stored this member.

`TarInfo.uname`
User name.

`TarInfo.gname`
Group name.

`TarInfo.pax_headers`
A dictionary containing key-value pairs of an associated pax extended header.

A `TarInfo` object also provides some convenient query methods:

`TarInfo.isfile()`
Return `True` if the `TarInfo` object is a regular file.

`TarInfo.isreg()`
Same as `isfile()`.

`TarInfo.isdir()`
Return `True` if it is a directory.

`TarInfo.issym()`
Return `True` if it is a symbolic link.

`TarInfo.islnk()`
Return `True` if it is a hard link.

`TarInfo.ischr()`
Return `True` if it is a character device.

`TarInfo.isblk()`
Return `True` if it is a block device.

`TarInfo.isfifo()`
Return `True` if it is a FIFO.

`TarInfo.isdev()`
Return `True` if it is one of character device, block device or FIFO.

13.6.3 命令行界面

3.4 新版功能.

The `tarfile` module provides a simple command-line interface to interact with tar archives.

If you want to create a new tar archive, specify its name after the `-c` option and then list the filename(s) that should be included:

```
$ python -m tarfile -c monty.tar spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m tarfile -c monty.tar life-of-brian_1979/
```

If you want to extract a tar archive into the current directory, use the `-e` option:

```
$ python -m tarfile -e monty.tar
```

You can also extract a tar archive into a different directory by passing the directory's name:

```
$ python -m tarfile -e monty.tar other-dir/
```

For a list of the files in a tar archive, use the `-l` option:

```
$ python -m tarfile -l monty.tar
```

命令行选项

```
-l <tarfile>
--list <tarfile>
    List files in a tarfile.

-c <tarfile> <source1> ... <sourceN>
--create <tarfile> <source1> ... <sourceN>
    Create tarfile from source files.

-e <tarfile> [<output_dir>]
--extract <tarfile> [<output_dir>]
    Extract tarfile into the current directory if output_dir is not specified.

-t <tarfile>
--test <tarfile>
    Test whether the tarfile is valid or not.

-v, --verbose
    Verbose output.
```

13.6.4 示例

How to extract an entire tar archive to the current working directory:

```
import tarfile
tar = tarfile.open("sample.tar.gz")
tar.extractall()
tar.close()
```

How to extract a subset of a tar archive with `TarFile.extractall()` using a generator function instead of a list:

```
import os
import tarfile

def py_files(members):
    for tarinfo in members:
        if os.path.splitext(tarinfo.name)[1] == ".py":
            yield tarinfo

tar = tarfile.open("sample.tar.gz")
tar.extractall(members=py_files(tar))
tar.close()
```

How to create an uncompressed tar archive from a list of filenames:

```
import tarfile
tar = tarfile.open("sample.tar", "w")
for name in ["foo", "bar", "quux"]:
    tar.add(name)
tar.close()
```

The same example using the with statement:

```
import tarfile
with tarfile.open("sample.tar", "w") as tar:
    for name in ["foo", "bar", "quux"]:
        tar.add(name)
```

How to read a gzip compressed tar archive and display some member information:

```
import tarfile
tar = tarfile.open("sample.tar.gz", "r:gz")
for tarinfo in tar:
    print(tarinfo.name, "is", tarinfo.size, "bytes in size and is", end="")
    if tarinfo.isreg():
        print("a regular file.")
    elif tarinfo.isdir():
        print("a directory.")
    else:
        print("something else.")
tar.close()
```

How to create an archive and reset the user information using the *filter* parameter in *TarFile.add()*:

```
import tarfile
def reset(tarinfo):
    tarinfo.uid = tarinfo.gid = 0
    tarinfo.uname = tarinfo.gname = "root"
    return tarinfo
tar = tarfile.open("sample.tar.gz", "w:gz")
tar.add("foo", filter=reset)
tar.close()
```

13.6.5 Supported tar formats

There are three tar formats that can be created with the *tarfile* module:

- The POSIX.1-1988 ustar format (*USTAR_FORMAT*). It supports filenames up to a length of at best 256 characters and linknames up to 100 characters. The maximum file size is 8 GiB. This is an old and limited but widely supported format.
- The GNU tar format (*GNU_FORMAT*). It supports long filenames and linknames, files bigger than 8 GiB and sparse files. It is the de facto standard on GNU/Linux systems. *tarfile* fully supports the GNU tar extensions for long names, sparse file support is read-only.
- The POSIX.1-2001 pax format (*PAX_FORMAT*). It is the most flexible format with virtually no limits. It supports long filenames and linknames, large files and stores pathnames in a portable way. However, not all tar implementations today are able to handle pax archives properly.

The *pax* format is an extension to the existing *ustar* format. It uses extra headers for information that cannot be stored otherwise. There are two flavours of pax headers: Extended headers only affect the subsequent file header,

global headers are valid for the complete archive and affect all following files. All the data in a pax header is encoded in *UTF-8* for portability reasons.

There are some more variants of the tar format which can be read, but not created:

- The ancient V7 format. This is the first tar format from Unix Seventh Edition, storing only regular files and directories. Names must not be longer than 100 characters, there is no user/group name information. Some archives have miscalculated header checksums in case of fields with non-ASCII characters.
- The SunOS tar extended format. This format is a variant of the POSIX.1-2001 pax format, but is not compatible.

13.6.6 Unicode issues

The tar format was originally conceived to make backups on tape drives with the main focus on preserving file system information. Nowadays tar archives are commonly used for file distribution and exchanging archives over networks. One problem of the original format (which is the basis of all other formats) is that there is no concept of supporting different character encodings. For example, an ordinary tar archive created on a *UTF-8* system cannot be read correctly on a *Latin-1* system if it contains non-ASCII characters. Textual metadata (like filenames, linknames, user/group names) will appear damaged. Unfortunately, there is no way to autodetect the encoding of an archive. The pax format was designed to solve this problem. It stores non-ASCII metadata using the universal character encoding *UTF-8*.

The details of character conversion in *tarfile* are controlled by the *encoding* and *errors* keyword arguments of the *TarFile* class.

encoding defines the character encoding to use for the metadata in the archive. The default value is *sys.getfilesystemencoding()* or 'ascii' as a fallback. Depending on whether the archive is read or written, the metadata must be either decoded or encoded. If *encoding* is not set appropriately, this conversion may fail.

The *errors* argument defines how characters are treated that cannot be converted. Possible values are listed in section *Error Handlers*. The default scheme is 'surrogateescape' which Python also uses for its file system calls, see 文件名, 命令行参数, 以及环境变量。.

In case of *PAX_FORMAT* archives, *encoding* is generally not needed because all the metadata is stored using *UTF-8*. *encoding* is only used in the rare cases when binary pax headers are decoded or when strings with surrogate characters are stored.

本章中描述的模块解析各种不是标记语言且与电子邮件无关的杂项文件格式。

14.1 csv — CSV 文件读写

源代码： `Lib/csv.py`

CSV (Comma Separated Vaules) 格式是电子表格和数据库中最常见的输入、输出文件格式。在 [RFC 4180](#) 规范推出的很多年前，CSV 格式就已经被开始使用了，由于当时并没有合理的标准，不同应用程序读写的数据会存在细微的差别。这种差别让处理多个来源的 CSV 文件变得困难。但尽管分隔符会变化，此类文件的大致格式是相似的，所以编写一个单独的模块以高效处理此类数据，将程序员从读写数据的繁琐细节中解放出来是有可能的。

The `csv` module implements classes to read and write tabular data in CSV format. It allows programmers to say, “write this data in the format preferred by Excel,” or “read data from this file which was generated by Excel,” without knowing the precise details of the CSV format used by Excel. Programmers can also describe the CSV formats understood by other applications or define their own special-purpose CSV formats.

`csv` 模块中的 `reader` 类和 `writer` 类可用于读写序列化的数据。也可使用 `DictReader` 类和 `DictWriter` 类以字典的形式读写数据。

参见：

该实现在“Python 增强提议” - PEP 305 (CSV 文件 API) 中被提出 The Python Enhancement Proposal which proposed this addition to Python.

14.1.1 模块内容

`csv` 模块定义了以下函数：

`csv.reader(csvfile, dialect='excel', **fmtparams)`

Return a reader object which will iterate over lines in the given *csvfile*. *csvfile* can be any object which supports the *iterator* protocol and returns a string each time its `__next__()` method is called — *file objects* and list objects are both suitable. If *csvfile* is a file object, it should be opened with `newline=''`.¹ An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the *Dialect* class or one of the strings returned by the `list_dialects()` function. The other optional *fmtparams* keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section *Dialects and Formatting Parameters*.

Each row read from the csv file is returned as a list of strings. No automatic data type conversion is performed unless the `QUOTE_NONNUMERIC` format option is specified (in which case unquoted fields are transformed into floats).

一个简短的用法示例:

```
>>> import csv
>>> with open('eggs.csv', newline='') as csvfile:
...     spamreader = csv.reader(csvfile, delimiter=' ', quotechar='|')
...     for row in spamreader:
...         print(', '.join(row))
Spam, Spam, Spam, Spam, Baked Beans
Spam, Lovely Spam, Wonderful Spam
```

`csv.writer(csvfile, dialect='excel', **fmtparams)`

Return a writer object responsible for converting the user's data into delimited strings on the given file-like object. *csvfile* can be any object with a `write()` method. If *csvfile* is a file object, it should be opened with `newline=''`. An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the *Dialect* class or one of the strings returned by the `list_dialects()` function. The other optional *fmtparams* keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section *Dialects and Formatting Parameters*. To make it as easy as possible to interface with modules which implement the DB API, the value *None* is written as the empty string. While this isn't a reversible transformation, it makes it easier to dump SQL NULL data values to CSV files without preprocessing the data returned from a `cursor.fetch*` call. All other non-string data are stringified with `str()` before being written.

一个简短的用法示例:

```
import csv
with open('eggs.csv', 'w', newline='') as csvfile:
    spamwriter = csv.writer(csvfile, delimiter=' ',
                            quotechar='|', quoting=csv.QUOTE_MINIMAL)
    spamwriter.writerow(['Spam'] * 5 + ['Baked Beans'])
    spamwriter.writerow(['Spam', 'Lovely Spam', 'Wonderful Spam'])
```

`csv.register_dialect(name[, dialect[, **fmtparams]])`

Associate *dialect* with *name*. *name* must be a string. The dialect can be specified either by passing a sub-class of *Dialect*, or by *fmtparams* keyword arguments, or both, with keyword arguments overriding parameters of the dialect. For full details about the dialect and formatting parameters, see section *Dialects and Formatting Parameters*.

`csv.unregister_dialect(name)`

Delete the dialect associated with *name* from the dialect registry. An *Error* is raised if *name* is not a registered dialect name.

`csv.get_dialect(name)`

Return the dialect associated with *name*. An *Error* is raised if *name* is not a registered dialect name. This function

¹ If `newline=''` is not specified, newlines embedded inside quoted fields will not be interpreted correctly, and on platforms that use `\r\n` line endings on write an extra `\r` will be added. It should always be safe to specify `newline=''`, since the csv module does its own (*universal*) newline handling.

returns an immutable *Dialect*.

`csv.list_dialects()`
Return the names of all registered dialects.

`csv.field_size_limit([new_limit])`
Returns the current maximum field size allowed by the parser. If *new_limit* is given, this becomes the new limit.

The `csv` module defines the following classes:

class `csv.DictReader`(*f*, *fieldnames*=None, *restkey*=None, *restval*=None, *dialect*='excel', *args, **kwargs)
Create an object that operates like a regular reader but maps the information in each row to an *OrderedDict* whose keys are given by the optional *fieldnames* parameter.

The *fieldnames* parameter is a *sequence*. If *fieldnames* is omitted, the values in the first row of file *f* will be used as the fieldnames. Regardless of how the fieldnames are determined, the ordered dictionary preserves their original ordering.

If a row has more fields than fieldnames, the remaining data is put in a list and stored with the fieldname specified by *restkey* (which defaults to None). If a non-blank row has fewer fields than fieldnames, the missing values are filled-in with None.

All other optional or keyword arguments are passed to the underlying *reader* instance.

在 3.6 版更改: Returned rows are now of type *OrderedDict*.

一个简短的用法示例:

```
>>> import csv
>>> with open('names.csv', newline='') as csvfile:
...     reader = csv.DictReader(csvfile)
...     for row in reader:
...         print(row['first_name'], row['last_name'])
...
Eric Idle
John Cleese

>>> print(row)
OrderedDict([('first_name', 'John'), ('last_name', 'Cleese')])
```

class `csv.DictWriter`(*f*, *fieldnames*, *restval*="", *extrasaction*='raise', *dialect*='excel', *args, **kwargs)
Create an object which operates like a regular writer but maps dictionaries onto output rows. The *fieldnames* parameter is a *sequence* of keys that identify the order in which values in the dictionary passed to the *writerow()* method are written to file *f*. The optional *restval* parameter specifies the value to be written if the dictionary is missing a key in *fieldnames*. If the dictionary passed to the *writerow()* method contains a key not found in *fieldnames*, the optional *extrasaction* parameter indicates what action to take. If it is set to 'raise', the default value, a *ValueError* is raised. If it is set to 'ignore', extra values in the dictionary are ignored. Any other optional or keyword arguments are passed to the underlying *writer* instance.

Note that unlike the *DictReader* class, the *fieldnames* parameter of the *DictWriter* is not optional. Since Python's *dict* objects are not ordered, there is not enough information available to deduce the order in which the row should be written to file *f*.

一个简短的用法示例:

```
import csv

with open('names.csv', 'w', newline='') as csvfile:
    fieldnames = ['first_name', 'last_name']
    writer = csv.DictWriter(csvfile, fieldnames=fieldnames)
```

(下页继续)

(续上页)

```

writer.writeheader()
writer.writerow({'first_name': 'Baked', 'last_name': 'Beans'})
writer.writerow({'first_name': 'Lovely', 'last_name': 'Spam'})
writer.writerow({'first_name': 'Wonderful', 'last_name': 'Spam'})

```

class csv.Dialect

The *Dialect* class is a container class relied on primarily for its attributes, which are used to define the parameters for a specific *reader* or *writer* instance.

class csv.excel

The *excel* class defines the usual properties of an Excel-generated CSV file. It is registered with the dialect name 'excel'.

class csv.excel_tab

The *excel_tab* class defines the usual properties of an Excel-generated TAB-delimited file. It is registered with the dialect name 'excel-tab'.

class csv.unix_dialect

The *unix_dialect* class defines the usual properties of a CSV file generated on UNIX systems, i.e. using '\n' as line terminator and quoting all fields. It is registered with the dialect name 'unix'.

3.2 新版功能.

class csv.Sniffer

The *Sniffer* class is used to deduce the format of a CSV file.

Sniffer 类提供了两个方法:

sniff (*sample*, *delimiters=None*)

Analyze the given *sample* and return a *Dialect* subclass reflecting the parameters found. If the optional *delimiters* parameter is given, it is interpreted as a string containing possible valid delimiter characters.

has_header (*sample*)

Analyze the sample text (presumed to be in CSV format) and return *True* if the first row appears to be a series of column headers.

使用 *Sniffer* 的示例:

```

with open('example.csv', newline='') as csvfile:
    dialect = csv.Sniffer().sniff(csvfile.read(1024))
    csvfile.seek(0)
    reader = csv.reader(csvfile, dialect)
    # ... process CSV file contents here ...

```

The *csv* module defines the following constants:

csv.QUOTE_ALL

Instructs *writer* objects to quote all fields.

csv.QUOTE_MINIMAL

Instructs *writer* objects to only quote those fields which contain special characters such as *delimiter*, *quotechar* or any of the characters in *lineterminator*.

csv.QUOTE_NONNUMERIC

Instructs *writer* objects to quote all non-numeric fields.

Instructs the reader to convert all non-quoted fields to type *float*.

csv.QUOTE_NONE

Instructs *writer* objects to never quote fields. When the current *delimiter* occurs in output data it is preceded by

the current *escapechar* character. If *escapechar* is not set, the writer will raise *Error* if any characters that require escaping are encountered.

Instructs *reader* to perform no special processing of quote characters.

The *csv* module defines the following exception:

exception *csv.Error*

Raised by any of the functions when an error is detected.

14.1.2 Dialects and Formatting Parameters

To make it easier to specify the format of input and output records, specific formatting parameters are grouped together into dialects. A dialect is a subclass of the *Dialect* class having a set of specific methods and a single *validate()* method. When creating *reader* or *writer* objects, the programmer can specify a string or a subclass of the *Dialect* class as the dialect parameter. In addition to, or instead of, the *dialect* parameter, the programmer can also specify individual formatting parameters, which have the same names as the attributes defined below for the *Dialect* class.

Dialects support the following attributes:

Dialect.delimiter

A one-character string used to separate fields. It defaults to *','*.

Dialect.doublequote

Controls how instances of *quotechar* appearing inside a field should themselves be quoted. When *True*, the character is doubled. When *False*, the *escapechar* is used as a prefix to the *quotechar*. It defaults to *True*.

On output, if *doublequote* is *False* and no *escapechar* is set, *Error* is raised if a *quotechar* is found in a field.

Dialect.escapechar

A one-character string used by the writer to escape the *delimiter* if *quoting* is set to *QUOTE_NONE* and the *quotechar* if *doublequote* is *False*. On reading, the *escapechar* removes any special meaning from the following character. It defaults to *None*, which disables escaping.

Dialect.lineterminator

The string used to terminate lines produced by the *writer*. It defaults to *'\r\n'*.

注解: The *reader* is hard-coded to recognise either *'\r'* or *'\n'* as end-of-line, and ignores *lineterminator*. This behavior may change in the future.

Dialect.quotechar

A one-character string used to quote fields containing special characters, such as the *delimiter* or *quotechar*, or which contain new-line characters. It defaults to *'\"'*.

Dialect.quoting

Controls when quotes should be generated by the writer and recognised by the reader. It can take on any of the *QUOTE_** constants (see section 模块内容) and defaults to *QUOTE_MINIMAL*.

Dialect.skipinitialspace

When *True*, whitespace immediately following the *delimiter* is ignored. The default is *False*.

Dialect.strict

When *True*, raise exception *Error* on bad CSV input. The default is *False*.

14.1.3 Reader Objects

Reader objects (*DictReader* instances and objects returned by the *reader()* function) have the following public methods:

`csvreader.__next__()`
Return the next row of the reader's iterable object as a list (if the object was returned from *reader()*) or a dict (if it is a *DictReader* instance), parsed according to the current dialect. Usually you should call this as `next(reader)`.

Reader objects have the following public attributes:

`csvreader.dialect`
A read-only description of the dialect in use by the parser.

`csvreader.line_num`
The number of lines read from the source iterator. This is not the same as the number of records returned, as records can span multiple lines.

DictReader objects have the following public attribute:

`csvreader.fieldnames`
If not passed as a parameter when creating the object, this attribute is initialized upon first access or when the first record is read from the file.

14.1.4 Writer Objects

Writer objects (*DictWriter* instances and objects returned by the *writer()* function) have the following public methods. A *row* must be an iterable of strings or numbers for *Writer* objects and a dictionary mapping fieldnames to strings or numbers (by passing them through *str()* first) for *DictWriter* objects. Note that complex numbers are written out surrounded by parens. This may cause some problems for other programs which read CSV files (assuming they support complex numbers at all).

`csvwriter.writerow(row)`
Write the *row* parameter to the writer's file object, formatted according to the current dialect.

在 3.5 版更改: Added support of arbitrary iterables.

`csvwriter.writerows(rows)`
Write all elements in *rows* (an iterable of *row* objects as described above) to the writer's file object, formatted according to the current dialect.

Writer objects have the following public attribute:

`csvwriter.dialect`
A read-only description of the dialect in use by the writer.

DictWriter objects have the following public method:

`DictWriter.writeheader()`
Write a row with the field names (as specified in the constructor).

3.2 新版功能.

14.1.5 示例

读取 CSV 文件最简单的一个例子:

```
import csv
with open('some.csv', newline='') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

Reading a file with an alternate format:

```
import csv
with open('passwd', newline='') as f:
    reader = csv.reader(f, delimiter=':', quoting=csv.QUOTE_NONE)
    for row in reader:
        print(row)
```

The corresponding simplest possible writing example is:

```
import csv
with open('some.csv', 'w', newline='') as f:
    writer = csv.writer(f)
    writer.writerows(someiterable)
```

Since `open()` is used to open a CSV file for reading, the file will by default be decoded into unicode using the system default encoding (see `locale.getpreferredencoding()`). To decode a file using a different encoding, use the encoding argument of `open`:

```
import csv
with open('some.csv', newline='', encoding='utf-8') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

The same applies to writing in something other than the system default encoding: specify the encoding argument when opening the output file.

Registering a new dialect:

```
import csv
csv.register_dialect('unixpwd', delimiter=':', quoting=csv.QUOTE_NONE)
with open('passwd', newline='') as f:
    reader = csv.reader(f, 'unixpwd')
```

A slightly more advanced use of the reader — catching and reporting errors:

```
import csv, sys
filename = 'some.csv'
with open(filename, newline='') as f:
    reader = csv.reader(f)
    try:
        for row in reader:
            print(row)
    except csv.Error as e:
        sys.exit('file {}, line {}: {}'.format(filename, reader.line_num, e))
```

And while the module doesn't directly support parsing strings, it can easily be done:

```
import csv
for row in csv.reader(['one,two,three']):
    print(row)
```

14.2 configparser — Configuration file parser

Source code: [Lib/configparser.py](#)

This module provides the *ConfigParser* class which implements a basic configuration language which provides a structure similar to what's found in Microsoft Windows INI files. You can use this to write Python programs which can be customized by end users easily.

注解: This library does *not* interpret or write the value-type prefixes used in the Windows Registry extended version of INI syntax.

参见:

模块 *shlex* Support for creating Unix shell-like mini-languages which can be used as an alternate format for application configuration files.

模块 *json* The json module implements a subset of JavaScript syntax which can also be used for this purpose.

14.2.1 Quick Start

Let's take a very basic configuration file that looks like this:

```
[DEFAULT]
ServerAliveInterval = 45
Compression = yes
CompressionLevel = 9
ForwardX11 = yes

[bitbucket.org]
User = hg

[topsecret.server.com]
Port = 50022
ForwardX11 = no
```

The structure of INI files is described *in the following section*. Essentially, the file consists of sections, each of which contains keys with values. *configparser* classes can read and write such files. Let's start by creating the above configuration file programmatically.

```
>>> import configparser
>>> config = configparser.ConfigParser()
>>> config['DEFAULT'] = {'ServerAliveInterval': '45',
...                     'Compression': 'yes',
...                     'CompressionLevel': '9'}
>>> config['bitbucket.org'] = {}
>>> config['bitbucket.org']['User'] = 'hg'
>>> config['topsecret.server.com'] = {}
>>> topsecret = config['topsecret.server.com']
>>> topsecret['Port'] = '50022'      # mutates the parser
>>> topsecret['ForwardX11'] = 'no'  # same here
>>> config['DEFAULT']['ForwardX11'] = 'yes'
>>> with open('example.ini', 'w') as configfile:
...     config.write(configfile)
... 
```

As you can see, we can treat a config parser much like a dictionary. There are differences, *outlined later*, but the behavior is very close to what you would expect from a dictionary.

Now that we have created and saved a configuration file, let's read it back and explore the data it holds.

```
>>> import configparser
>>> config = configparser.ConfigParser()
>>> config.sections()
[]
>>> config.read('example.ini')
['example.ini']
>>> config.sections()
['bitbucket.org', 'topsecret.server.com']
>>> 'bitbucket.org' in config
True
>>> 'bytebong.com' in config
False
>>> config['bitbucket.org']['User']
'hg'
>>> config['DEFAULT']['Compression']
'yes'
>>> topsecret = config['topsecret.server.com']
>>> topsecret['ForwardX11']
'no'
>>> topsecret['Port']
'50022'
>>> for key in config['bitbucket.org']: print(key)
...
user
compressionlevel
serveraliveinterval
compression
forwardx11
>>> config['bitbucket.org']['ForwardX11']
'yes'
```

As we can see above, the API is pretty straightforward. The only bit of magic involves the `DEFAULT` section which provides default values for all other sections¹. Note also that keys in sections are case-insensitive and stored in lowercase¹.

14.2.2 Supported Datatypes

Config parsers do not guess datatypes of values in configuration files, always storing them internally as strings. This means that if you need other datatypes, you should convert on your own:

```
>>> int(topsecret['Port'])
50022
>>> float(topsecret['CompressionLevel'])
9.0
```

Since this task is so common, config parsers provide a range of handy getter methods to handle integers, floats and booleans. The last one is the most interesting because simply passing the value to `bool()` would do no good since `bool('False')` is still `True`. This is why config parsers also provide `getboolean()`. This method is case-insensitive and recognizes Boolean values from 'yes'/'no', 'on'/'off', 'true'/'false' and '1'/'0'¹. For example:

¹ Config parsers allow for heavy customization. If you are interested in changing the behaviour outlined by the footnote reference, consult the *Customizing Parser Behaviour* section.

```
>>> topsecret.getboolean('ForwardX11')
False
>>> config['bitbucket.org'].getboolean('ForwardX11')
True
>>> config.getboolean('bitbucket.org', 'Compression')
True
```

Apart from *getboolean()*, config parsers also provide equivalent *getint()* and *getfloat()* methods. You can register your own converters and customize the provided ones.¹

14.2.3 Fallback Values

As with a dictionary, you can use a section's *get()* method to provide fallback values:

```
>>> topsecret.get('Port')
'50022'
>>> topsecret.get('CompressionLevel')
'9'
>>> topsecret.get('Cipher')
>>> topsecret.get('Cipher', '3des-cbc')
'3des-cbc'
```

Please note that default values have precedence over fallback values. For instance, in our example the 'CompressionLevel' key was specified only in the 'DEFAULT' section. If we try to get it from the section 'topsecret.server.com', we will always get the default, even if we specify a fallback:

```
>>> topsecret.get('CompressionLevel', '3')
'9'
```

One more thing to be aware of is that the parser-level *get()* method provides a custom, more complex interface, maintained for backwards compatibility. When using this method, a fallback value can be provided via the *fallback* keyword-only argument:

```
>>> config.get('bitbucket.org', 'monster',
...           fallback='No such things as monsters')
'No such things as monsters'
```

The same fallback argument can be used with the *getint()*, *getfloat()* and *getboolean()* methods, for example:

```
>>> 'BatchMode' in topsecret
False
>>> topsecret.getboolean('BatchMode', fallback=True)
True
>>> config['DEFAULT']['BatchMode'] = 'no'
>>> topsecret.getboolean('BatchMode', fallback=True)
False
```

14.2.4 Supported INI File Structure

A configuration file consists of sections, each led by a [section] header, followed by key/value entries separated by a specific string (= or : by default¹). By default, section names are case sensitive but keys are not¹. Leading and trailing whitespace is removed from keys and values. Values can be omitted, in which case the key/value delimiter may also be

left out. Values can also span multiple lines, as long as they are indented deeper than the first line of the value. Depending on the parser's mode, blank lines may be treated as parts of multiline values or ignored.

Configuration files may include comments, prefixed by specific characters (`#` and `;` by default¹). Comments may appear on their own on an otherwise empty line, possibly indented.¹

例如:

```
[Simple Values]
key=value
spaces in keys=allowed
spaces in values=allowed as well
spaces around the delimiter = obviously
you can also use : to delimit keys from values

[All Values Are Strings]
values like this: 1000000
or this: 3.14159265359
are they treated as numbers? : no
integers, floats and booleans are held as: strings
can use the API to get converted values directly: true

[Multiline Values]
chorus: I'm a lumberjack, and I'm okay
       I sleep all night and I work all day

[No Values]
key_without_value
empty string value here =

[You can use comments]
# like this
; or this

# By default only in an empty line.
# Inline comments can be harmful because they prevent users
# from using the delimiting characters as parts of values.
# That being said, this can be customized.

    [Sections Can Be Indented]
        can_values_be_as_well = True
        does_that_mean_anything_special = False
        purpose = formatting for readability
        multiline_values = are
            handled just fine as
            long as they are indented
            deeper than the first line
            of a value
        # Did I mention we can indent comments, too?
```

14.2.5 Interpolation of values

On top of the core functionality, `ConfigParser` supports interpolation. This means values can be preprocessed before returning them from `get()` calls.

class `configparser.BasicInterpolation`

The default implementation used by `ConfigParser`. It enables values to contain format strings which refer to

other values in the same section, or values in the special default section¹. Additional default values can be provided on initialization.

例如:

```
[Paths]
home_dir: /Users
my_dir: %(home_dir)s/lumberjack
my_pictures: %(my_dir)s/Pictures
```

In the example above, `ConfigParser` with `interpolation` set to `BasicInterpolation()` would resolve `%(home_dir)s` to the value of `home_dir` (`/Users` in this case). `%(my_dir)s` in effect would resolve to `/Users/lumberjack`. All interpolations are done on demand so keys used in the chain of references do not have to be specified in any specific order in the configuration file.

With `interpolation` set to `None`, the parser would simply return `%(my_dir)s/Pictures` as the value of `my_pictures` and `%(home_dir)s/lumberjack` as the value of `my_dir`.

class `configparser.ExtendedInterpolation`

An alternative handler for interpolation which implements a more advanced syntax, used for instance in `zc.buildout`. Extended interpolation is using `${section:option}` to denote a value from a foreign section. Interpolation can span multiple levels. For convenience, if the `section:` part is omitted, interpolation defaults to the current section (and possibly the default values from the special section).

For example, the configuration specified above with basic interpolation, would look like this with extended interpolation:

```
[Paths]
home_dir: /Users
my_dir: ${home_dir}/lumberjack
my_pictures: ${my_dir}/Pictures
```

Values from other sections can be fetched as well:

```
[Common]
home_dir: /Users
library_dir: /Library
system_dir: /System
macports_dir: /opt/local

[Frameworks]
Python: 3.2
path: ${Common:system_dir}/Library/Frameworks/

[Arthur]
nickname: Two Sheds
last_name: Jackson
my_dir: ${Common:home_dir}/twosheds
my_pictures: ${my_dir}/Pictures
python_dir: ${Frameworks:path}/Python/Versions/${Frameworks:Python}
```

14.2.6 Mapping Protocol Access

3.2 新版功能.

Mapping protocol access is a generic name for functionality that enables using custom objects as if they were dictionaries. In case of `configparser`, the mapping interface implementation is using the `parser['section']['option']` notation.

`parser['section']` in particular returns a proxy for the section's data in the parser. This means that the values are not copied but they are taken from the original parser on demand. What's even more important is that when values are changed on a section proxy, they are actually mutated in the original parser.

`configparser` objects behave as close to actual dictionaries as possible. The mapping interface is complete and adheres to the *MutableMapping* ABC. However, there are a few differences that should be taken into account:

- By default, all keys in sections are accessible in a case-insensitive manner¹. E.g. for option in `parser["section"]` yields only optionxform'ed option key names. This means lowercased keys by default. At the same time, for a section that holds the key 'a', both expressions return `True`:

```
"a" in parser["section"]
"A" in parser["section"]
```

- All sections include `DEFAULTSECT` values as well which means that `.clear()` on a section may not leave the section visibly empty. This is because default values cannot be deleted from the section (because technically they are not there). If they are overridden in the section, deleting causes the default value to be visible again. Trying to delete a default value causes a `KeyError`.
- `DEFAULTSECT` cannot be removed from the parser:
 - trying to delete it raises `ValueError`,
 - `parser.clear()` leaves it intact,
 - `parser.popitem()` never returns it.
- `parser.get(section, option, **kwargs)` - the second argument is **not** a fallback value. Note however that the section-level `get()` methods are compatible both with the mapping protocol and the classic config-parser API.
- `parser.items()` is compatible with the mapping protocol (returns a list of *section_name, section_proxy* pairs including the `DEFAULTSECT`). However, this method can also be invoked with arguments: `parser.items(section, raw, vars)`. The latter call returns a list of *option, value* pairs for a specified section, with all interpolations expanded (unless `raw=True` is provided).

The mapping protocol is implemented on top of the existing legacy API so that subclasses overriding the original interface still should have mappings working as expected.

14.2.7 Customizing Parser Behaviour

There are nearly as many INI format variants as there are applications using it. `configparser` goes a long way to provide support for the largest sensible set of INI styles available. The default functionality is mainly dictated by historical background and it's very likely that you will want to customize some of the features.

The most common way to change the way a specific config parser works is to use the `__init__()` options:

- *defaults*, default value: `None`

This option accepts a dictionary of key-value pairs which will be initially put in the `DEFAULT` section. This makes for an elegant way to support concise configuration files that don't specify values which are the same as the documented default.

Hint: if you want to specify default values for a specific section, use `read_dict()` before you read the actual file.

- *dict_type*, default value: `collections.OrderedDict`

This option has a major impact on how the mapping protocol will behave and how the written configuration files look. With the default ordered dictionary, every section is stored in the order they were added to the parser. Same goes for options within sections.

An alternative dictionary type can be used for example to sort sections and options on write-back. You can also use a regular dictionary for performance reasons.

Please note: there are ways to add a set of key-value pairs in a single operation. When you use a regular dictionary in those operations, the order of the keys may be random. For example:

```
>>> parser = configparser.ConfigParser()
>>> parser.read_dict({'section1': {'key1': 'value1',
...                               'key2': 'value2',
...                               'key3': 'value3'},
...                  'section2': {'keyA': 'valueA',
...                               'keyB': 'valueB',
...                               'keyC': 'valueC'},
...                  'section3': {'foo': 'x',
...                               'bar': 'y',
...                               'baz': 'z'}})
>>> parser.sections()
['section3', 'section2', 'section1']
>>> [option for option in parser['section3']]
['baz', 'foo', 'bar']
```

In these operations you need to use an ordered dictionary as well:

```
>>> from collections import OrderedDict
>>> parser = configparser.ConfigParser()
>>> parser.read_dict(
...     OrderedDict((
...         ('s1',
...          OrderedDict((
...              ('1', '2'),
...              ('3', '4'),
...              ('5', '6'),
...          ))),
...         ('s2',
...          OrderedDict((
...              ('a', 'b'),
...              ('c', 'd'),
...              ('e', 'f'),
...          ))),
...     ))
>>> parser.sections()
['s1', 's2']
>>> [option for option in parser['s1']]
['1', '3', '5']
>>> [option for option in parser['s2'].values()]
['b', 'd', 'f']
```

- *allow_no_value*, default value: False

Some configuration files are known to include settings without values, but which otherwise conform to the syntax supported by *configparser*. The *allow_no_value* parameter to the constructor can be used to indicate that such values should be accepted:

```
>>> import configparser
```

(下页继续)

(续上页)

```

>>> sample_config = """
... [mysqld]
...   user = mysql
...   pid-file = /var/run/mysqld/mysqld.pid
...   skip-external-locking
...   old_passwords = 1
...   skip-bdb
...   # we don't need ACID today
...   skip-innodb
... """
>>> config = configparser.ConfigParser(allow_no_value=True)
>>> config.read_string(sample_config)

>>> # Settings with values are treated as before:
>>> config["mysqld"]["user"]
'mysql'

>>> # Settings without values provide None:
>>> config["mysqld"]["skip-bdb"]

>>> # Settings which aren't specified still raise an error:
>>> config["mysqld"]["does-not-exist"]
Traceback (most recent call last):
...
KeyError: 'does-not-exist'

```

- *delimiters*, default value: ('=', ':')

Delimiters are substrings that delimit keys from values within a section. The first occurrence of a delimiting substring on a line is considered a delimiter. This means values (but not keys) can contain the delimiters.

See also the *space_around_delimiters* argument to *ConfigParser.write()*.

- *comment_prefixes*, default value: ('# ', '; ')
- *inline_comment_prefixes*, default value: None

Comment prefixes are strings that indicate the start of a valid comment within a config file. *comment_prefixes* are used only on otherwise empty lines (optionally indented) whereas *inline_comment_prefixes* can be used after every valid value (e.g. section names, options and empty lines as well). By default inline comments are disabled and '# ' and ';' are used as prefixes for whole line comments.

在 3.2 版更改: In previous versions of *configparser* behaviour matched *comment_prefixes*=('# ', '; ') and *inline_comment_prefixes*=('; ',).

Please note that config parsers don't support escaping of comment prefixes so using *inline_comment_prefixes* may prevent users from specifying option values with characters used as comment prefixes. When in doubt, avoid setting *inline_comment_prefixes*. In any circumstances, the only way of storing comment prefix characters at the beginning of a line in multiline values is to interpolate the prefix, for example:

```

>>> from configparser import ConfigParser, ExtendedInterpolation
>>> parser = ConfigParser(interpolation=ExtendedInterpolation())
>>> # the default BasicInterpolation could be used as well
>>> parser.read_string("""
... [DEFAULT]
... hash = #
...

```

(下页继续)

(续上页)

```

... [hashes]
... shebang =
...     ${hash}!/usr/bin/env python
...     ${hash} -*- coding: utf-8 -*-
...
... extensions =
...     enabled_extension
...     another_extension
...     #disabled_by_comment
...     yet_another_extension
...
... interpolation not necessary = if # is not at line start
... even in multiline values = line #1
...     line #2
...     line #3
... """
>>> print(parser['hashes']['shebang'])

#!/usr/bin/env python
# -*- coding: utf-8 -*-
>>> print(parser['hashes']['extensions'])

enabled_extension
another_extension
yet_another_extension
>>> print(parser['hashes']['interpolation not necessary'])
if # is not at line start
>>> print(parser['hashes']['even in multiline values'])
line #1
line #2
line #3

```

- *strict*, default value: True

When set to True, the parser will not allow for any section or option duplicates while reading from a single source (using `read_file()`, `read_string()` or `read_dict()`). It is recommended to use strict parsers in new applications.

在 3.2 版更改: In previous versions of *configparser* behaviour matched `strict=False`.

- *empty_lines_in_values*, default value: True

In config parsers, values can span multiple lines as long as they are indented more than the key that holds them. By default parsers also let empty lines to be parts of values. At the same time, keys can be arbitrarily indented themselves to improve readability. In consequence, when configuration files get big and complex, it is easy for the user to lose track of the file structure. Take for instance:

```

[Section]
key = multiline
    value with a gotcha

    this = is still a part of the multiline value of 'key'

```

This can be especially problematic for the user to see if she's using a proportional font to edit the file. That is why when your application does not need values with empty lines, you should consider disallowing them. This will make empty lines split keys every time. In the example above, it would produce two keys, `key` and `this`.

- *default_section*, default value: `configparser.DEFAULTSECT` (that is: "DEFAULT")

The convention of allowing a special section of default values for other sections or interpolation purposes is a powerful concept of this library, letting users create complex declarative configurations. This section is normally called "DEFAULT" but this can be customized to point to any other valid section name. Some typical values include: "general" or "common". The name provided is used for recognizing default sections when reading from any source and is used when writing configuration back to a file. Its current value can be retrieved using the `parser_instance.default_section` attribute and may be modified at runtime (i.e. to convert files from one format to another).

- *interpolation*, default value: `configparser.BasicInterpolation`

Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. `None` can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the [dedicated documentation section](#). `RawConfigParser` has a default value of `None`.

- *converters*, default value: not set

Config parsers provide option value getters that perform type conversion. By default `getint()`, `getfloat()`, and `getboolean()` are implemented. Should other getters be desirable, users may define them in a subclass or pass a dictionary where each key is a name of the converter and each value is a callable implementing said conversion. For instance, passing `{'decimal': decimal.Decimal}` would add `getdecimal()` on both the parser object and all section proxies. In other words, it will be possible to write both `parser_instance.getdecimal('section', 'key', fallback=0)` and `parser_instance['section'].getdecimal('key', 0)`.

If the converter needs to access the state of the parser, it can be implemented as a method on a config parser subclass. If the name of this method starts with `get`, it will be available on all section proxies, in the dict-compatible form (see the `getdecimal()` example above).

More advanced customization may be achieved by overriding default values of these parser attributes. The defaults are defined on the classes, so they may be overridden by subclasses or by attribute assignment.

`ConfigParser.BOOLEAN_STATES`

By default when using `getboolean()`, config parsers consider the following values `True`: '1', 'yes', 'true', 'on' and the following values `False`: '0', 'no', 'false', 'off'. You can override this by specifying a custom dictionary of strings and their Boolean outcomes. For example:

```
>>> custom = configparser.ConfigParser()
>>> custom['section1'] = {'funky': 'nope'}
>>> custom['section1'].getboolean('funky')
Traceback (most recent call last):
...
ValueError: Not a boolean: nope
>>> custom.BOOLEAN_STATES = {'sure': True, 'nope': False}
>>> custom['section1'].getboolean('funky')
False
```

Other typical Boolean pairs include `accept/reject` or `enabled/disabled`.

`ConfigParser.optionxform(option)`

This method transforms option names on every read, get, or set operation. The default converts the name to lowercase. This also means that when a configuration file gets written, all keys will be lowercase. Override this method if that's unsuitable. For example:

```
>>> config = """
... [Section1]
... Key = Value
...
... [Section2]
```

(下页继续)

(续上页)

```

... AnotherKey = Value
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> list(typical['Section1'].keys())
['key']
>>> list(typical['Section2'].keys())
['anotherkey']
>>> custom = configparser.RawConfigParser()
>>> custom.optionxform = lambda option: option
>>> custom.read_string(config)
>>> list(custom['Section1'].keys())
['Key']
>>> list(custom['Section2'].keys())
['AnotherKey']

```

ConfigParser.SECTCRE

A compiled regular expression used to parse section headers. The default matches `[section]` to the name "section". Whitespace is considered part of the section name, thus `[larch]` will be read as a section of name " larch ". Override this attribute if that's unsuitable. For example:

```

>>> config = """
... [Section 1]
... option = value
...
... [ Section 2 ]
... another = val
... """
>>> typical = ConfigParser()
>>> typical.read_string(config)
>>> typical.sections()
['Section 1', ' Section 2 ']
>>> custom = ConfigParser()
>>> custom.SECTCRE = re.compile(r"\[ *(?P<header>[^\]]+?) *\]")
>>> custom.read_string(config)
>>> custom.sections()
['Section 1', 'Section 2']

```

注解: While ConfigParser objects also use an OPTCRE attribute for recognizing option lines, it's not recommended to override it because that would interfere with constructor options *allow_no_value* and *delimiters*.

14.2.8 Legacy API Examples

Mainly because of backwards compatibility concerns, `configparser` provides also a legacy API with explicit get/set methods. While there are valid use cases for the methods outlined below, mapping protocol access is preferred for new projects. The legacy API is at times more advanced, low-level and downright counterintuitive.

An example of writing to a configuration file:

```

import configparser

config = configparser.RawConfigParser()

```

(下页继续)

(续上页)

```
# Please note that using RawConfigParser's set functions, you can assign
# non-string values to keys internally, but will receive an error when
# attempting to write to a file or when you get it in non-row mode. Setting
# values using the mapping protocol or ConfigParser's set() does not allow
# such assignments to take place.
config.add_section('Section1')
config.set('Section1', 'an_int', '15')
config.set('Section1', 'a_bool', 'true')
config.set('Section1', 'a_float', '3.1415')
config.set('Section1', 'baz', 'fun')
config.set('Section1', 'bar', 'Python')
config.set('Section1', 'foo', '%(bar)s is %(baz)s!')

# Writing our configuration file to 'example.cfg'
with open('example.cfg', 'w') as configfile:
    config.write(configfile)
```

An example of reading the configuration file again:

```
import configparser

config = configparser.RawConfigParser()
config.read('example.cfg')

# getfloat() raises an exception if the value is not a float
# getint() and getboolean() also do this for their respective types
a_float = config.getfloat('Section1', 'a_float')
an_int = config.getint('Section1', 'an_int')
print(a_float + an_int)

# Notice that the next output does not interpolate '%(bar)s' or '%(baz)s'.
# This is because we are using a RawConfigParser().
if config.getboolean('Section1', 'a_bool'):
    print(config.get('Section1', 'foo'))
```

To get interpolation, use *ConfigParser*:

```
import configparser

cfg = configparser.ConfigParser()
cfg.read('example.cfg')

# Set the optional *raw* argument of get() to True if you wish to disable
# interpolation in a single get operation.
print(cfg.get('Section1', 'foo', raw=False)) # -> "Python is fun!"
print(cfg.get('Section1', 'foo', raw=True))  # -> "%(bar)s is %(baz)s!"

# The optional *vars* argument is a dict with members that will take
# precedence in interpolation.
print(cfg.get('Section1', 'foo', vars={'bar': 'Documentation',
                                       'baz': 'evil'}))

# The optional *fallback* argument can be used to provide a fallback value
print(cfg.get('Section1', 'foo'))
# -> "Python is fun!"
```

(下页继续)

(续上页)

```

print(cfg.get('Section1', 'foo', fallback='Monty is not.'))
# -> "Python is fun!"

print(cfg.get('Section1', 'monster', fallback='No such things as monsters.'))
# -> "No such things as monsters."

# A bare print(cfg.get('Section1', 'monster')) would raise NoOptionError
# but we can also use:

print(cfg.get('Section1', 'monster', fallback=None))
# -> None

```

Default values are available in both types of ConfigParsers. They are used in interpolation if an option used is not defined elsewhere.

```

import configparser

# New instance with 'bar' and 'baz' defaulting to 'Life' and 'hard' each
config = configparser.ConfigParser({'bar': 'Life', 'baz': 'hard'})
config.read('example.cfg')

print(config.get('Section1', 'foo'))      # -> "Python is fun!"
config.remove_option('Section1', 'bar')
config.remove_option('Section1', 'baz')
print(config.get('Section1', 'foo'))      # -> "Life is hard!"

```

14.2.9 ConfigParser Objects

```

class configparser.ConfigParser (defaults=None, dict_type=collections.OrderedDict,
                                allow_no_value=False, delimiters=('=', ':'), comment_prefixes=(';', '#'), inline_comment_prefixes=None,
                                strict=True, empty_lines_in_values=True, default_section=configparser.DEFAULTSECT, interpolation=BasicInterpolation(), converters={})

```

The main configuration parser. When *defaults* is given, it is initialized into the dictionary of intrinsic defaults. When *dict_type* is given, it will be used to create the dictionary objects for the list of sections, for the options within a section, and for the default values.

When *delimiters* is given, it is used as the set of substrings that divide keys from values. When *comment_prefixes* is given, it will be used as the set of substrings that prefix comments in otherwise empty lines. Comments can be indented. When *inline_comment_prefixes* is given, it will be used as the set of substrings that prefix comments in non-empty lines.

When *strict* is *True* (the default), the parser won't allow for any section or option duplicates while reading from a single source (file, string or dictionary), raising *DuplicateSectionError* or *DuplicateOptionError*. When *empty_lines_in_values* is *False* (default: *True*), each empty line marks the end of an option. Otherwise, internal empty lines of a multiline option are kept as part of the value. When *allow_no_value* is *True* (default: *False*), options without values are accepted; the value held for these is *None* and they are serialized without the trailing delimiter.

When *default_section* is given, it specifies the name for the special section holding default values for other sections and interpolation purposes (normally named "DEFAULT"). This value can be retrieved and changed on runtime using the *default_section* instance attribute.

Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument.

`None` can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the [dedicated documentation section](#).

All option names used in interpolation will be passed through the `optionxform()` method just like any other option name reference. For example, using the default implementation of `optionxform()` (which converts option names to lower case), the values `foo %(bar)s` and `foo %(BAR)s` are equivalent.

When `converters` is given, it should be a dictionary where each key represents the name of a type converter and each value is a callable implementing the conversion from string to the desired datatype. Every converter gets its own corresponding `get*()` method on the parser object and section proxies.

在 3.1 版更改: The default `dict_type` is `collections.OrderedDict`.

在 3.2 版更改: `allow_no_value`, `delimiters`, `comment_prefixes`, `strict`, `empty_lines_in_values`, `default_section` and `interpolation` were added.

在 3.5 版更改: The `converters` argument was added.

defaults()

Return a dictionary containing the instance-wide defaults.

sections()

Return a list of the sections available; the *default section* is not included in the list.

add_section(section)

Add a section named *section* to the instance. If a section by the given name already exists, `DuplicateSectionError` is raised. If the *default section* name is passed, `ValueError` is raised. The name of the section must be a string; if not, `TypeError` is raised.

在 3.2 版更改: Non-string section names raise `TypeError`.

has_section(section)

Indicates whether the named *section* is present in the configuration. The *default section* is not acknowledged.

options(section)

Return a list of options available in the specified *section*.

has_option(section, option)

If the given *section* exists, and contains the given *option*, return `True`; otherwise return `False`. If the specified *section* is `None` or an empty string, `DEFAULT` is assumed.

read(filename, encoding=None)

Attempt to read and parse an iterable of filenames, returning a list of filenames which were successfully parsed.

If *filenames* is a string or *path-like object*, it is treated as a single filename. If a file named in *filenames* cannot be opened, that file will be ignored. This is designed so that you can specify an iterable of potential configuration file locations (for example, the current directory, the user's home directory, and some system-wide directory), and all existing configuration files in the iterable will be read.

If none of the named files exist, the `ConfigParser` instance will contain an empty dataset. An application which requires initial values to be loaded from a file should load the required file or files using `read_file()` before calling `read()` for any optional files:

```
import configparser, os

config = configparser.ConfigParser()
config.read_file(open('defaults.cfg'))
config.read(['site.cfg', os.path.expanduser('~/.myapp.cfg')],
            encoding='cp1250')
```

3.2 新版功能: The *encoding* parameter. Previously, all files were read using the default encoding for `open()`.

3.6.1 新版功能: The *filenames* parameter accepts a *path-like object*.

read_file (*f*, *source=None*)

Read and parse configuration data from *f* which must be an iterable yielding Unicode strings (for example files opened in text mode).

Optional argument *source* specifies the name of the file being read. If not given and *f* has a *name* attribute, that is used for *source*; the default is '`<???`'.

3.2 新版功能: Replaces `readfp()`.

read_string (*string*, *source='<string>'*)

Parse configuration data from a string.

Optional argument *source* specifies a context-specific name of the string passed. If not given, '`<string>`' is used. This should commonly be a filesystem path or a URL.

3.2 新版功能.

read_dict (*dictionary*, *source='<dict>'*)

Load configuration from any object that provides a dict-like `items()` method. Keys are section names, values are dictionaries with keys and values that should be present in the section. If the used dictionary type preserves order, sections and their keys will be added in order. Values are automatically converted to strings.

Optional argument *source* specifies a context-specific name of the dictionary passed. If not given, `<dict>` is used.

This method can be used to copy state between parsers.

3.2 新版功能.

get (*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

Get an *option* value for the named *section*. If *vars* is provided, it must be a dictionary. The *option* is looked up in *vars* (if provided), *section*, and in `DEFAULTSECT` in that order. If the key is not found and *fallback* is provided, it is used as a fallback value. `None` can be provided as a *fallback* value.

All the '`%`' interpolations are expanded in the return values, unless the *raw* argument is true. Values for interpolation keys are looked up in the same manner as the *option*.

在 3.2 版更改: Arguments *raw*, *vars* and *fallback* are keyword only to protect users from trying to use the third argument as the *fallback* fallback (especially when using the mapping protocol).

getint (*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to an integer. See `get()` for explanation of *raw*, *vars* and *fallback*.

getfloat (*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to a floating point number. See `get()` for explanation of *raw*, *vars* and *fallback*.

getboolean (*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to a Boolean value. Note that the accepted values for the *option* are '`1`', '`yes`', '`true`', and '`on`', which cause this method to return `True`, and '`0`', '`no`', '`false`', and '`off`', which cause it to return `False`. These string values are checked in a case-insensitive manner. Any other value will cause it to raise `ValueError`. See `get()` for explanation of *raw*, *vars* and *fallback*.

items (*raw=False*, *vars=None*)

items (*section*, *raw=False*, *vars=None*)

When *section* is not given, return a list of *section_name*, *section_proxy* pairs, including `DEFAULTSECT`.

Otherwise, return a list of *name*, *value* pairs for the options in the given *section*. Optional arguments have the same meaning as for the `get()` method.

set (*section*, *option*, *value*)

If the given section exists, set the given option to the specified value; otherwise raise `NoSectionError`. *option* and *value* must be strings; if not, `TypeError` is raised.

write (*fileobject*, *space_around_delimiters=True*)

Write a representation of the configuration to the specified *file object*, which must be opened in text mode (accepting strings). This representation can be parsed by a future `read()` call. If *space_around_delimiters* is true, delimiters between keys and values are surrounded by spaces.

remove_option (*section*, *option*)

Remove the specified *option* from the specified *section*. If the section does not exist, raise `NoSectionError`. If the option existed to be removed, return `True`; otherwise return `False`.

remove_section (*section*)

Remove the specified *section* from the configuration. If the section in fact existed, return `True`. Otherwise return `False`.

optionxform (*option*)

Transforms the option name *option* as found in an input file or as passed in by client code to the form that should be used in the internal structures. The default implementation returns a lower-case version of *option*; subclasses may override this or client code can set an attribute of this name on instances to affect this behavior.

You don't need to subclass the parser to use this method, you can also set it on an instance, to a function that takes a string argument and returns a string. Setting it to `str`, for example, would make option names case sensitive:

```
cfgparser = ConfigParser()
cfgparser.optionxform = str
```

Note that when reading configuration files, whitespace around the option names is stripped before `optionxform()` is called.

readfp (*fp*, *filename=None*)

3.2 版后已移除: Use `read_file()` instead.

在 3.2 版更改: `readfp()` now iterates on *fp* instead of calling `fp.readline()`.

For existing code calling `readfp()` with arguments which don't support iteration, the following generator may be used as a wrapper around the file-like object:

```
def readline_generator(fp):
    line = fp.readline()
    while line:
        yield line
        line = fp.readline()
```

Instead of `parser.readfp(fp)` use `parser.read_file(readline_generator(fp))`.

`configparser.MAX_INTERPOLATION_DEPTH`

The maximum depth for recursive interpolation for `get()` when the *raw* parameter is false. This is relevant only when the default *interpolation* is used.

14.2.10 RawConfigParser Objects

```
class configparser.RawConfigParser (defaults=None, dict_type=collections.OrderedDict,
                                     allow_no_value=False, *, delimiters=('=', ':'),
                                     comment_prefixes=(';', '#'), inline_comment_prefixes=None,
                                     strict=True, empty_lines_in_values=True,
                                     default_section=configparser.DEFAULTSECT[, interpolation
                                     ])
```

Legacy variant of the `ConfigParser` with interpolation disabled by default and unsafe `add_section` and `set` methods.

注解: Consider using `ConfigParser` instead which checks types of the values to be stored internally. If you don't want interpolation, you can use `ConfigParser(interpolation=None)`.

add_section (*section*)

Add a section named *section* to the instance. If a section by the given name already exists, `DuplicateSectionError` is raised. If the *default section* name is passed, `ValueError` is raised.

Type of *section* is not checked which lets users create non-string named sections. This behaviour is unsupported and may cause internal errors.

set (*section, option, value*)

If the given section exists, set the given option to the specified value; otherwise raise `NoSectionError`. While it is possible to use `RawConfigParser` (or `ConfigParser` with *raw* parameters set to true) for *internal* storage of non-string values, full functionality (including interpolation and output to files) can only be achieved using string values.

This method lets users assign non-string values to keys internally. This behaviour is unsupported and will cause errors when attempting to write to a file or get it in non-raw mode. **Use the mapping protocol API** which does not allow such assignments to take place.

14.2.11 异常

exception configparser.Error

Base class for all other `configparser` exceptions.

exception configparser.NoSectionError

Exception raised when a specified section is not found.

exception configparser.DuplicateSectionError

Exception raised if `add_section()` is called with the name of a section that is already present or in strict parsers when a section is found more than once in a single input file, string or dictionary.

3.2 新版功能: Optional `source` and `lineno` attributes and arguments to `__init__()` were added.

exception configparser.DuplicateOptionError

Exception raised by strict parsers if a single option appears twice during reading from a single file, string or dictionary. This catches misspellings and case sensitivity-related errors, e.g. a dictionary may have two keys representing the same case-insensitive configuration key.

exception configparser.NoOptionError

Exception raised when a specified option is not found in the specified section.

exception configparser.InterpolationError

Base class for exceptions raised when problems occur performing string interpolation.

exception configparser.InterpolationDepthError

Exception raised when string interpolation cannot be completed because the number of iterations exceeds `MAX_INTERPOLATION_DEPTH`. Subclass of `InterpolationError`.

exception configparser.InterpolationMissingOptionError

Exception raised when an option referenced from a value does not exist. Subclass of `InterpolationError`.

exception configparser.InterpolationSyntaxError

Exception raised when the source text into which substitutions are made does not conform to the required syntax. Subclass of `InterpolationError`.

exception configparser.MissingSectionHeaderError

Exception raised when attempting to parse a file which has no section headers.

exception configparser.ParsingError

Exception raised when errors occur attempting to parse a file.

在 3.2 版更改: The `filename` attribute and `__init__()` argument were renamed to `source` for consistency.

14.3 netrc —netrc file processing

Source code: [Lib/netrc.py](#)

The `netrc` class parses and encapsulates the netrc file format used by the Unix **ftp** program and other FTP clients.

class netrc.netrc([file])

A `netrc` instance or subclass instance encapsulates data from a netrc file. The initialization argument, if present, specifies the file to parse. If no argument is given, the file `.netrc` in the user's home directory will be read. Parse errors will raise `NetrcParseError` with diagnostic information including the file name, line number, and terminating token. If no argument is specified on a POSIX system, the presence of passwords in the `.netrc` file will raise a `NetrcParseError` if the file ownership or permissions are insecure (owned by a user other than the user running the process, or accessible for read or write by any other user). This implements security behavior equivalent to that of ftp and other programs that use `.netrc`.

在 3.4 版更改: Added the POSIX permission check.

exception netrc.NetrcParseError

Exception raised by the `netrc` class when syntactical errors are encountered in source text. Instances of this exception provide three interesting attributes: `msg` is a textual explanation of the error, `filename` is the name of the source file, and `lineno` gives the line number on which the error was found.

14.3.1 netrc Objects

A `netrc` instance has the following methods:

netrc.authenticators(host)

Return a 3-tuple (`login`, `account`, `password`) of authenticators for `host`. If the netrc file did not contain an entry for the given host, return the tuple associated with the 'default' entry. If neither matching host nor default entry is available, return `None`.

netrc.__repr__()

Dump the class data as a string in the format of a netrc file. (This discards comments and may reorder the entries.)

Instances of `netrc` have public instance variables:

`netrc.hosts`

Dictionary mapping host names to (login, account, password) tuples. The ‘default’ entry, if any, is represented as a pseudo-host by that name.

`netrc.macros`

Dictionary mapping macro names to string lists.

注解: Passwords are limited to a subset of the ASCII character set. All ASCII punctuation is allowed in passwords, however, note that whitespace and non-printable characters are not allowed in passwords. This is a limitation of the way the .netrc file is parsed and may be removed in the future.

14.4 xdrlib —Encode and decode XDR data

Source code: [Lib/xdrlib.py](#)

The `xdrlib` module supports the External Data Representation Standard as described in [RFC 1014](#), written by Sun Microsystems, Inc. June 1987. It supports most of the data types described in the RFC.

The `xdrlib` module defines two classes, one for packing variables into XDR representation, and another for unpacking from XDR representation. There are also two exception classes.

class `xdrlib.Packer`

`Packer` is the class for packing data into XDR representation. The `Packer` class is instantiated with no arguments.

class `xdrlib.Unpacker` (*data*)

`Unpacker` is the complementary class which unpacks XDR data values from a string buffer. The input buffer is given as *data*.

参见:

[RFC 1014 - XDR: External Data Representation Standard](#) This RFC defined the encoding of data which was XDR at the time this module was originally written. It has apparently been obsoleted by [RFC 1832](#).

[RFC 1832 - XDR: External Data Representation Standard](#) Newer RFC that provides a revised definition of XDR.

14.4.1 Packer Objects

`Packer` instances have the following methods:

`Packer.get_buffer()`

Returns the current pack buffer as a string.

`Packer.reset()`

Resets the pack buffer to the empty string.

In general, you can pack any of the most common XDR data types by calling the appropriate `pack_type()` method. Each method takes a single argument, the value to pack. The following simple data type packing methods are supported: `pack_uint()`, `pack_int()`, `pack_enum()`, `pack_bool()`, `pack_uhyper()`, and `pack_hyper()`.

`Packer.pack_float(value)`

Packs the single-precision floating point number *value*.

`Packer.pack_double(value)`

Packs the double-precision floating point number *value*.

The following methods support packing strings, bytes, and opaque data:

`Packer.pack_fstring(n, s)`

Packs a fixed length string, *s*. *n* is the length of the string but it is *not* packed into the data buffer. The string is padded with null bytes if necessary to guaranteed 4 byte alignment.

`Packer.pack_fopaque(n, data)`

Packs a fixed length opaque data stream, similarly to `pack_fstring()`.

`Packer.pack_string(s)`

Packs a variable length string, *s*. The length of the string is first packed as an unsigned integer, then the string data is packed with `pack_fstring()`.

`Packer.pack_opaque(data)`

Packs a variable length opaque data string, similarly to `pack_string()`.

`Packer.pack_bytes(bytes)`

Packs a variable length byte stream, similarly to `pack_string()`.

The following methods support packing arrays and lists:

`Packer.pack_list(list, pack_item)`

Packs a *list* of homogeneous items. This method is useful for lists with an indeterminate size; i.e. the size is not available until the entire list has been walked. For each item in the list, an unsigned integer 1 is packed first, followed by the data value from the list. *pack_item* is the function that is called to pack the individual item. At the end of the list, an unsigned integer 0 is packed.

For example, to pack a list of integers, the code might appear like this:

```
import xdrlib
p = xdrlib.Packer()
p.pack_list([1, 2, 3], p.pack_int)
```

`Packer.pack_farray(n, array, pack_item)`

Packs a fixed length list (*array*) of homogeneous items. *n* is the length of the list; it is *not* packed into the buffer, but a `ValueError` exception is raised if `len(array)` is not equal to *n*. As above, *pack_item* is the function used to pack each element.

`Packer.pack_array(list, pack_item)`

Packs a variable length *list* of homogeneous items. First, the length of the list is packed as an unsigned integer, then each element is packed as in `pack_farray()` above.

14.4.2 Unpacker Objects

The `Unpacker` class offers the following methods:

`Unpacker.reset(data)`

Resets the string buffer with the given *data*.

`Unpacker.get_position()`

Returns the current unpack position in the data buffer.

`Unpacker.set_position(position)`

Sets the data buffer unpack position to *position*. You should be careful about using `get_position()` and `set_position()`.

`Unpacker.get_buffer()`

Returns the current unpack data buffer as a string.

`Unpacker.done()`

Indicates unpack completion. Raises an *Error* exception if all of the data has not been unpacked.

In addition, every data type that can be packed with a *Packer*, can be unpacked with an *Unpacker*. Unpacking methods are of the form `unpack_type()`, and take no arguments. They return the unpacked object.

`Unpacker.unpack_float()`

Unpacks a single-precision floating point number.

`Unpacker.unpack_double()`

Unpacks a double-precision floating point number, similarly to `unpack_float()`.

In addition, the following methods unpack strings, bytes, and opaque data:

`Unpacker.unpack_fstring(n)`

Unpacks and returns a fixed length string. *n* is the number of characters expected. Padding with null bytes to guaranteed 4 byte alignment is assumed.

`Unpacker.unpack_fopaque(n)`

Unpacks and returns a fixed length opaque data stream, similarly to `unpack_fstring()`.

`Unpacker.unpack_string()`

Unpacks and returns a variable length string. The length of the string is first unpacked as an unsigned integer, then the string data is unpacked with `unpack_fstring()`.

`Unpacker.unpack_opaque()`

Unpacks and returns a variable length opaque data string, similarly to `unpack_string()`.

`Unpacker.unpack_bytes()`

Unpacks and returns a variable length byte stream, similarly to `unpack_string()`.

The following methods support unpacking arrays and lists:

`Unpacker.unpack_list(unpack_item)`

Unpacks and returns a list of homogeneous items. The list is unpacked one element at a time by first unpacking an unsigned integer flag. If the flag is 1, then the item is unpacked and appended to the list. A flag of 0 indicates the end of the list. `unpack_item` is the function that is called to unpack the items.

`Unpacker.unpack_farray(n, unpack_item)`

Unpacks and returns (as a list) a fixed length array of homogeneous items. *n* is number of list elements to expect in the buffer. As above, `unpack_item` is the function used to unpack each element.

`Unpacker.unpack_array(unpack_item)`

Unpacks and returns a variable length *list* of homogeneous items. First, the length of the list is unpacked as an unsigned integer, then each element is unpacked as in `unpack_farray()` above.

14.4.3 异常

Exceptions in this module are coded as class instances:

exception `xdrlib.Error`

The base exception class. *Error* has a single public attribute `msg` containing the description of the error.

exception `xdrlib.ConversionError`

Class derived from *Error*. Contains no additional instance variables.

Here is an example of how you would catch one of these exceptions:

```
import xdrlib
p = xdrlib.Packer()
try:
```

(下页继续)

(续上页)

```
p.pack_double(8.01)
except xdrlib.ConversionError as instance:
    print('packing the double failed:', instance.msg)
```

14.5 plistlib —Generate and parse Mac OS X .plist files

Source code: [Lib/plistlib.py](#)

This module provides an interface for reading and writing the “property list” files used mainly by Mac OS X and supports both binary and XML plist files.

The property list (`.plist`) file format is a simple serialization supporting basic object types, like dictionaries, lists, numbers and strings. Usually the top level object is a dictionary.

To write out and to parse a plist file, use the `dump()` and `load()` functions.

To work with plist data in bytes objects, use `dumps()` and `loads()`.

Values can be strings, integers, floats, booleans, tuples, lists, dictionaries (but only with string keys), `Data`, `bytes`, `bytesarray` or `datetime.datetime` objects.

在 3.4 版更改: New API, old API deprecated. Support for binary format plists added.

参见:

PList manual page Apple’s documentation of the file format.

这个模块定义了以下函数:

`plistlib.load(fp, *, fmt=None, use_builtin_types=True, dict_type=dict)`

Read a plist file. `fp` should be a readable and binary file object. Return the unpacked root object (which usually is a dictionary).

The `fmt` is the format of the file and the following values are valid:

- `None`: Autodetect the file format
- `FMT_XML`: XML file format
- `FMT_BINARY`: Binary plist format

If `use_builtin_types` is true (the default) binary data will be returned as instances of `bytes`, otherwise it is returned as instances of `Data`.

The `dict_type` is the type used for dictionaries that are read from the plist file. The exact structure of the plist can be recovered by using `collections.OrderedDict` (although the order of keys shouldn’t be important in plist files).

XML data for the `FMT_XML` format is parsed using the Expat parser from `xml.parsers.expat` – see its documentation for possible exceptions on ill-formed XML. Unknown elements will simply be ignored by the plist parser.

The parser for the binary format raises `InvalidFileException` when the file cannot be parsed.

3.4 新版功能.

`plistlib.loads(data, *, fmt=None, use_builtin_types=True, dict_type=dict)`

Load a plist from a bytes object. See `load()` for an explanation of the keyword arguments.

3.4 新版功能.

`plistlib.dump(value, fp, *, fmt=FMT_XML, sort_keys=True, skipkeys=False)`

Write *value* to a plist file. *Fp* should be a writable, binary file object.

The *fmt* argument specifies the format of the plist file and can be one of the following values:

- `FMT_XML`: XML formatted plist file
- `FMT_BINARY`: Binary formatted plist file

When *sort_keys* is true (the default) the keys for dictionaries will be written to the plist in sorted order, otherwise they will be written in the iteration order of the dictionary.

When *skipkeys* is false (the default) the function raises `TypeError` when a key of a dictionary is not a string, otherwise such keys are skipped.

A `TypeError` will be raised if the object is of an unsupported type or a container that contains objects of unsupported types.

An `OverflowError` will be raised for integer values that cannot be represented in (binary) plist files.

3.4 新版功能.

`plistlib.dumps(value, *, fmt=FMT_XML, sort_keys=True, skipkeys=False)`

Return *value* as a plist-formatted bytes object. See the documentation for `dump()` for an explanation of the keyword arguments of this function.

3.4 新版功能.

The following functions are deprecated:

`plistlib.readPlist(pathOrFile)`

Read a plist file. *pathOrFile* may be either a file name or a (readable and binary) file object. Returns the unpacked root object (which usually is a dictionary).

This function calls `load()` to do the actual work, see the documentation of *that function* for an explanation of the keyword arguments.

注解: Dict values in the result have a `__getattr__` method that defers to `__getitem__`. This means that you can use attribute access to access items of these dictionaries.

3.4 版后已移除: Use `load()` instead.

`plistlib.writePlist(rootObject, pathOrFile)`

Write *rootObject* to an XML plist file. *pathOrFile* may be either a file name or a (writable and binary) file object

3.4 版后已移除: Use `dump()` instead.

`plistlib.readPlistFromBytes(data)`

Read a plist data from a bytes object. Return the root object.

See `load()` for a description of the keyword arguments.

注解: Dict values in the result have a `__getattr__` method that defers to `__getitem__`. This means that you can use attribute access to access items of these dictionaries.

3.4 版后已移除: Use `loads()` instead.

`plistlib.writePlistToBytes(rootObject)`

Return *rootObject* as an XML plist-formatted bytes object.

3.4 版后已移除: Use `dumps()` instead.

The following classes are available:

Dict ([dict]) :

Return an extended mapping object with the same value as dictionary *dict*.

This class is a subclass of *dict* where attribute access can be used to access items. That is, `aDict.key` is the same as `aDict['key']` for getting, setting and deleting items in the mapping.

3.0 版后已移除.

class plistlib.Data (data)

Return a “data” wrapper object around the bytes object *data*. This is used in functions converting from/to plists to represent the `<data>` type available in plists.

It has one attribute, `data`, that can be used to retrieve the Python bytes object stored in it.

3.4 版后已移除: Use a *bytes* object instead.

The following constants are available:

plistlib.FMT_XML

The XML format for plist files.

3.4 新版功能.

plistlib.FMT_BINARY

The binary format for plist files

3.4 新版功能.

14.5.1 示例

Generating a plist:

```
pl = dict(
    aString = "Doodah",
    aList = ["A", "B", 12, 32.1, [1, 2, 3]],
    aFloat = 0.1,
    anInt = 728,
    aDict = dict(
        anotherString = "<hello & hi there!>",
        aThirdString = "M\ue4ssig, Ma\xdf",
        aTrueValue = True,
        aFalseValue = False,
    ),
    someData = b"<binary gunk>",
    someMoreData = b"<lots of binary gunk>" * 10,
    aDate = datetime.datetime.fromtimestamp(time.mktime(time.gmtime()))),
)
with open(fileName, 'wb') as fp:
    dump(pl, fp)
```

Parsing a plist:

```
with open(fileName, 'rb') as fp:
    pl = load(fp)
    print(pl["aKey"])
```

本章中描述的模块实现了加密性质的各种算法。它们可由安装人员自行决定。在 Unix 系统上，`crypt` 模块也可以使用。这是一个概述：

15.1 hashlib — 安全哈希与消息摘要

Source code: [Lib/hashlib.py](#)

This module implements a common interface to many different secure hash and message digest algorithms. Included are the FIPS secure hash algorithms SHA1, SHA224, SHA256, SHA384, and SHA512 (defined in FIPS 180-2) as well as RSA's MD5 algorithm (defined in Internet [RFC 1321](#)). The terms “secure hash” and “message digest” are interchangeable. Older algorithms were called message digests. The modern term is secure hash.

注解：如果你想找到 `adler32` 或 `crc32` 哈希函数，它们在 `zlib` 模块中。

警告：有些算法已知存在哈希碰撞弱点，请参考最后的“另请参阅”段。

15.1.1 哈希算法

There is one constructor method named for each type of *hash*. All return a hash object with the same simple interface. For example: use `sha256()` to create a SHA-256 hash object. You can now feed this object with *bytes-like objects* (normally *bytes*) using the `update()` method. At any point you can ask it for the *digest* of the concatenation of the data fed to it so far using the `digest()` or `hexdigest()` methods.

注解: For better multithreading performance, the Python *GIL* is released for data larger than 2047 bytes at object creation or on update.

注解: Feeding string objects into `update()` is not supported, as hashes work on bytes, not on characters.

Constructors for hash algorithms that are always present in this module are `sha1()`, `sha224()`, `sha256()`, `sha384()`, `sha512()`, `blake2b()`, and `blake2s()`. `md5()` is normally available as well, though it may be missing if you are using a rare “FIPS compliant” build of Python. Additional algorithms may also be available depending upon the OpenSSL library that Python uses on your platform. On most platforms the `sha3_224()`, `sha3_256()`, `sha3_384()`, `sha3_512()`, `shake_128()`, `shake_256()` are also available.

3.6 新版功能: SHA3 (Keccak) and SHAKE constructors `sha3_224()`, `sha3_256()`, `sha3_384()`, `sha3_512()`, `shake_128()`, `shake_256()`.

3.6 新版功能: 添加了 `blake2b()` 和 `blake2s()`。

For example, to obtain the digest of the byte string `b'Nobody inspects the spammish repetition'`:

```
>>> import hashlib
>>> m = hashlib.sha256()
>>> m.update(b"Nobody inspects")
>>> m.update(b" the spammish repetition")
>>> m.digest()
b'\x03\x1e\xdd
↪Ae\x15\x93\xc5\xfe\\x00o\xa5u+7\xfd\xdf\xf7\xbcN\x84:\xa6\xaf\x0c\x95\x0fK\x94\x06'
>>> m.digest_size
32
>>> m.block_size
64
```

More condensed:

```
>>> hashlib.sha224(b"Nobody inspects the spammish repetition").hexdigest()
'a4337bc45a8fc544c03f52dc550cd6e1e87021bc896588bd79e901e2'
```

`hashlib.new(name[, data])`

Is a generic constructor that takes the string *name* of the desired algorithm as its first parameter. It also exists to allow access to the above listed hashes as well as any other algorithms that your OpenSSL library may offer. The named constructors are much faster than `new()` and should be preferred.

Using `new()` with an algorithm provided by OpenSSL:

```
>>> h = hashlib.new('ripemd160')
>>> h.update(b"Nobody inspects the spammish repetition")
>>> h.hexdigest()
'cc4a5ce1b3df48aec5d22d1f16b894a0b894eccc'
```

Hashlib 提供下列常量属性:

`hashlib.algorithms_guaranteed`

A set containing the names of the hash algorithms guaranteed to be supported by this module on all platforms. Note that ‘md5’ is in this list despite some upstream vendors offering an odd “FIPS compliant” Python build that excludes it.

3.2 新版功能.

hashlib.algorithms_available

A set containing the names of the hash algorithms that are available in the running Python interpreter. These names will be recognized when passed to `new()`. `algorithms_guaranteed` will always be a subset. The same algorithm may appear multiple times in this set under different names (thanks to OpenSSL).

3.2 新版功能.

The following values are provided as constant attributes of the hash objects returned by the constructors:

hash.digest_size

The size of the resulting hash in bytes.

hash.block_size

The internal block size of the hash algorithm in bytes.

A hash object has the following attributes:

hash.name

The canonical name of this hash, always lowercase and always suitable as a parameter to `new()` to create another hash of this type.

在 3.4 版更改: The name attribute has been present in CPython since its inception, but until Python 3.4 was not formally specified, so may not exist on some platforms.

A hash object has the following methods:

hash.update(data)

Update the hash object with the *bytes-like object*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a+b)`.

在 3.1 版更改: The Python GIL is released to allow other threads to run while hash updates on data larger than 2047 bytes is taking place when using hash algorithms supplied by OpenSSL.

hash.digest()

Return the digest of the data passed to the `update()` method so far. This is a bytes object of size `digest_size` which may contain bytes in the whole range from 0 to 255.

hash.hexdigest()

Like `digest()` except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

hash.copy()

Return a copy (“clone”) of the hash object. This can be used to efficiently compute the digests of data sharing a common initial substring.

15.1.2 SHAKE variable length digests

The `shake_128()` and `shake_256()` algorithms provide variable length digests with `length_in_bits//2` up to 128 or 256 bits of security. As such, their digest methods require a length. Maximum length is not limited by the SHAKE algorithm.

shake.digest(length)

Return the digest of the data passed to the `update()` method so far. This is a bytes object of size `length` which may contain bytes in the whole range from 0 to 255.

shake.hexdigest(length)

Like `digest()` except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

15.1.3 Key derivation

Key derivation and key stretching algorithms are designed for secure password hashing. Naive algorithms such as `sha1(password)` are not resistant against brute-force attacks. A good password hashing function must be tunable, slow, and include a *salt*.

`hashlib.pbkdf2_hmac` (*hash_name*, *password*, *salt*, *iterations*, *dklen=None*)

The function provides PKCS#5 password-based key derivation function 2. It uses HMAC as pseudorandom function.

The string *hash_name* is the desired name of the hash digest algorithm for HMAC, e.g. ‘sha1’ or ‘sha256’. *password* and *salt* are interpreted as buffers of bytes. Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. `os.urandom()`.

The number of *iterations* should be chosen based on the hash algorithm and computing power. As of 2013, at least 100,000 iterations of SHA-256 are suggested.

dklen is the length of the derived key. If *dklen* is `None` then the digest size of the hash algorithm *hash_name* is used, e.g. 64 for SHA-512.

```
>>> import hashlib, binascii
>>> dk = hashlib.pbkdf2_hmac('sha256', b'password', b'salt', 100000)
>>> binascii.hexlify(dk)
b'0394a2ede332c9a13eb82e9b24631604c31df978b4e2f0fbd2c549944f9d79a5'
```

3.4 新版功能.

注解: A fast implementation of `pbkdf2_hmac` is available with OpenSSL. The Python implementation uses an inline version of `hmac`. It is about three times slower and doesn't release the GIL.

`hashlib.scrypt` (*password*, *, *salt*, *n*, *r*, *p*, *maxmem=0*, *dklen=64*)

The function provides scrypt password-based key derivation function as defined in [RFC 7914](#).

password and *salt* must be *bytes-like objects*. Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. `os.urandom()`.

n is the CPU/Memory cost factor, *r* the block size, *p* parallelization factor and *maxmem* limits memory (OpenSSL 1.1.0 defaults to 32 MB). *dklen* is the length of the derived key.

Availability: OpenSSL 1.1+

3.6 新版功能.

15.1.4 BLAKE2

BLAKE2 is a cryptographic hash function defined in [RFC 7693](#) that comes in two flavors:

- **BLAKE2b**, optimized for 64-bit platforms and produces digests of any size between 1 and 64 bytes,
- **BLAKE2s**, optimized for 8- to 32-bit platforms and produces digests of any size between 1 and 32 bytes.

BLAKE2 supports **keyed mode** (a faster and simpler replacement for **HMAC**), **salted hashing**, **personalization**, and **tree hashing**.

Hash objects from this module follow the API of standard library's `hashlib` objects.

Creating hash objects

New hash objects are created by calling constructor functions:

```
hashlib.blake2b (data=b", *, digest_size=64, key=b", salt=b", person=b", fanout=1, depth=1, leaf_size=0,
                  node_offset=0, node_depth=0, inner_size=0, last_node=False)
hashlib.blake2s (data=b", *, digest_size=32, key=b", salt=b", person=b", fanout=1, depth=1, leaf_size=0,
                  node_offset=0, node_depth=0, inner_size=0, last_node=False)
```

These functions return the corresponding hash objects for calculating BLAKE2b or BLAKE2s. They optionally take these general parameters:

- *data*: initial chunk of data to hash, which must be *bytes-like object*. It can be passed only as positional argument.
- *digest_size*: size of output digest in bytes.
- *key*: key for keyed hashing (up to 64 bytes for BLAKE2b, up to 32 bytes for BLAKE2s).
- *salt*: salt for randomized hashing (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).
- *person*: personalization string (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).

The following table shows limits for general parameters (in bytes):

Hash	digest_size	len(key)	len(salt)	len(person)
BLAKE2b	64	64	16	16
BLAKE2s	32	32	8	8

注解: BLAKE2 specification defines constant lengths for salt and personalization parameters, however, for convenience, this implementation accepts byte strings of any size up to the specified length. If the length of the parameter is less than specified, it is padded with zeros, thus, for example, `b'salt'` and `b'salt\x00'` is the same value. (This is not the case for *key*.)

These sizes are available as module *constants* described below.

Constructor functions also accept the following tree hashing parameters:

- *fanout*: fanout (0 to 255, 0 if unlimited, 1 in sequential mode).
- *depth*: maximal depth of tree (1 to 255, 255 if unlimited, 1 in sequential mode).
- *leaf_size*: maximal byte length of leaf (0 to 2**32-1, 0 if unlimited or in sequential mode).
- *node_offset*: node offset (0 to 2**64-1 for BLAKE2b, 0 to 2**48-1 for BLAKE2s, 0 for the first, leftmost, leaf, or in sequential mode).
- *node_depth*: node depth (0 to 255, 0 for leaves, or in sequential mode).
- *inner_size*: inner digest size (0 to 64 for BLAKE2b, 0 to 32 for BLAKE2s, 0 in sequential mode).
- *last_node*: boolean indicating whether the processed node is the last one (*False* for sequential mode).

See section 2.10 in [BLAKE2 specification](#) for comprehensive review of tree hashing.

常数

```
blake2b.SALT_SIZE
blake2s.SALT_SIZE
```

Salt length (maximum length accepted by constructors).

`blake2b.PERSON_SIZE`

`blake2s.PERSON_SIZE`

Personalization string length (maximum length accepted by constructors).

`blake2b.MAX_KEY_SIZE`

`blake2s.MAX_KEY_SIZE`

Maximum key size.

`blake2b.MAX_DIGEST_SIZE`

`blake2s.MAX_DIGEST_SIZE`

Maximum digest size that the hash function can output.

示例

Simple hashing

To calculate hash of some data, you should first construct a hash object by calling the appropriate constructor function (`blake2b()` or `blake2s()`), then update it with the data by calling `update()` on the object, and, finally, get the digest out of the object by calling `digest()` (or `hexdigest()` for hex-encoded string).

```
>>> from hashlib import blake2b
>>> h = blake2b()
```

(下页继续)

(续上页)

```
>>> h.update(b'Hello world')
>>> h.hexdigest()
```

```
↪ '6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495d'
↪ '
```

As a shortcut, you can pass the first chunk of data to update directly to the constructor as the positional argument:

```
>>> from hashlib import blake2b
>>> blake2b(b'Hello world').hexdigest()
```

```
↪ '6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495d'
↪ '
```

You can call `hash.update()` as many times as you need to iteratively update the hash:

```
>>> from hashlib import blake2b
>>> items = [b'Hello', b' ', b'world']
>>> h = blake2b()
>>> for item in items:
...     h.update(item)
>>> h.hexdigest()
```

```
↪ '6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495d'
↪ '
```

Using different digest sizes

BLAKE2 has configurable size of digests up to 64 bytes for BLAKE2b and up to 32 bytes for BLAKE2s. For example, to replace SHA-1 with BLAKE2b without changing the size of output, we can tell BLAKE2b to produce 20-byte digests:

```
>>> from hashlib import blake2b
>>> h = blake2b(digest_size=20)
>>> h.update(b'Replacing SHA1 with the more secure function')
>>> h.hexdigest()
'd24f26cf8de66472d58d4e1b1774b4c9158b1f4c'
>>> h.digest_size
20
>>> len(h.digest())
20
```

Hash objects with different digest sizes have completely different outputs (shorter hashes are *not* prefixes of longer hashes); BLAKE2b and BLAKE2s produce different outputs even if the output length is the same:

```
>>> from hashlib import blake2b, blake2s
>>> blake2b(digest_size=10).hexdigest()
'6fa1d8fcfd719046d762'
>>> blake2b(digest_size=11).hexdigest()
'eb6ec15daf9546254f0809'
>>> blake2s(digest_size=10).hexdigest()
'1bf21a98c78a1c376ae9'
>>> blake2s(digest_size=11).hexdigest()
'567004bf96e4a25773ebf4'
```

Keyed hashing

Keyed hashing can be used for authentication as a faster and simpler replacement for [Hash-based message authentication code](#) (HMAC). BLAKE2 can be securely used in prefix-MAC mode thanks to the indistinguishability property inherited from BLAKE.

This example shows how to get a (hex-encoded) 128-bit authentication code for message `b'message data'` with key `b'pseudorandom key'`:

```
>>> from hashlib import blake2b
>>> h = blake2b(key=b'pseudorandom key', digest_size=16)
>>> h.update(b'message data')
>>> h.hexdigest()
'3d363ff7401e02026f4a4687d4863ced'
```

As a practical example, a web application can symmetrically sign cookies sent to users and later verify them to make sure they weren't tampered with:

```
>>> from hashlib import blake2b
>>> from hmac import compare_digest
>>>
>>> SECRET_KEY = b'pseudorandomly generated server secret key'
>>> AUTH_SIZE = 16
>>>
>>> def sign(cookie):
...     h = blake2b(digest_size=AUTH_SIZE, key=SECRET_KEY)
...     h.update(cookie)
...     return h.hexdigest().encode('utf-8')
>>>
>>> def verify(cookie, sig):
...     good_sig = sign(cookie)
...     return compare_digest(good_sig, sig)
>>>
>>> cookie = b'user-alice'
>>> sig = sign(cookie)
>>> print("{}{1}".format(cookie.decode('utf-8'), sig))
user-alice,b'43b3c982cf697e0c5ab22172d1ca7421'
>>> verify(cookie, sig)
True
>>> verify(b'user-bob', sig)
False
>>> verify(cookie, b'0102030405060708090a0b0c0d0e0f00')
False
```

Even though there's a native keyed hashing mode, BLAKE2 can, of course, be used in HMAC construction with *hmac* module:

```
>>> import hmac, hashlib
>>> m = hmac.new(b'secret key', digestmod=hashlib.blake2s)
>>> m.update(b'message')
>>> m.hexdigest()
'e3c8102868d28b5ff85fc35dda07329970d1a01e273c37481326fe0c861c8142'
```

Randomized hashing

By setting *salt* parameter users can introduce randomization to the hash function. Randomized hashing is useful for protecting against collision attacks on the hash function used in digital signatures.

Randomized hashing is designed for situations where one party, the message preparer, generates all or part of a message to be signed by a second party, the message signer. If the message preparer is able to find cryptographic hash function collisions (i.e., two messages producing the same hash value), then they might prepare meaningful versions of the message that would produce the same hash value and digital signature, but with different results (e.g., transferring \$1,000,000 to an account, rather than \$10). Cryptographic hash functions have been designed with collision resistance as a major goal, but the current concentration on attacking cryptographic hash functions may result in a given cryptographic hash function providing less collision resistance than expected. Randomized hashing offers the signer additional protection by reducing the likelihood that a preparer can generate two or more messages that ultimately yield the same hash value during the digital signature generation process—even if it is practical to find collisions for the hash function. However, the use of randomized hashing may reduce the amount of security provided by a digital signature when all portions of the message are prepared by the signer.

(NIST SP-800-106 “Randomized Hashing for Digital Signatures”)

In BLAKE2 the salt is processed as a one-time input to the hash function during initialization, rather than as an input to each compression function.

警告: *Salted hashing* (or just hashing) with BLAKE2 or any other general-purpose cryptographic hash function, such as SHA-256, is not suitable for hashing passwords. See [BLAKE2 FAQ](#) for more information.

```
>>> import os
>>> from hashlib import blake2b
>>> msg = b'some message'
>>> # Calculate the first hash with a random salt.
>>> salt1 = os.urandom(blake2b.SALT_SIZE)
>>> h1 = blake2b(salt=salt1)
>>> h1.update(msg)
>>> # Calculate the second hash with a different random salt.
>>> salt2 = os.urandom(blake2b.SALT_SIZE)
>>> h2 = blake2b(salt=salt2)
>>> h2.update(msg)
>>> # The digests are different.
>>> h1.digest() != h2.digest()
True
```

Personalization

Sometimes it is useful to force hash function to produce different digests for the same input for different purposes. Quoting the authors of the Skein hash function:

We recommend that all application designers seriously consider doing this; we have seen many protocols where a hash that is computed in one part of the protocol can be used in an entirely different part because two hash computations were done on similar or related data, and the attacker can force the application to make the hash inputs the same. Personalizing each hash function used in the protocol summarily stops this type of attack.

(The Skein Hash Function Family, p. 21)

BLAKE2 can be personalized by passing bytes to the *person* argument:

```
>>> from hashlib import blake2b
>>> FILES_HASH_PERSON = b'MyApp Files Hash'
>>> BLOCK_HASH_PERSON = b'MyApp Block Hash'
>>> h = blake2b(digest_size=32, person=FILES_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'20d9cd024d4fb086aae819a1432dd2466de12947831b75c5a30cf2676095d3b4'
>>> h = blake2b(digest_size=32, person=BLOCK_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'cf68fb5761b9c44e7878bf2c4c9aea52264a80b75005e65619778de59f383a3'
```

Personalization together with the keyed mode can also be used to derive different keys from a single one.

```
>>> from hashlib import blake2s
>>> from base64 import b64decode, b64encode
>>> orig_key = b64decode(b'Rm5EPJai72qcK3RGBpW3vPNfZy5OZothY+kHY6h21KM=')
>>> enc_key = blake2s(key=orig_key, person=b'kEncrypt').digest()
>>> mac_key = blake2s(key=orig_key, person=b'kMAC').digest()
>>> print(b64encode(enc_key).decode('utf-8'))
rbPb15S/Z9t+agffno5wuhB77VbRi6F9Iv2qIxU7WHw=
>>> print(b64encode(mac_key).decode('utf-8'))
G9GtHFE1YluXY1zWP1Yk1e/nWfu0WSEb0KRcjhDeP/o=
```

Tree mode

Here's an example of hashing a minimal tree with two leaf nodes:

```
  10
 /  \
00  01
```

This example uses 64-byte internal digests, and returns the 32-byte final digest:

```
>>> from hashlib import blake2b
>>>
>>> FANOUT = 2
>>> DEPTH = 2
>>> LEAF_SIZE = 4096
>>> INNER_SIZE = 64
>>>
>>> buf = bytearray(6000)
>>>
>>> # Left leaf
... h00 = blake2b(buf[0:LEAF_SIZE], fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=0, node_depth=0, last_node=False)
>>> # Right leaf
... h01 = blake2b(buf[LEAF_SIZE:], fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=1, node_depth=0, last_node=True)
>>> # Root node
... h10 = blake2b(digest_size=32, fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=0, node_depth=1, last_node=True)
```

(下页继续)

(续上页)

```
>>> h10.update(h00.digest())
>>> h10.update(h01.digest())
>>> h10.hexdigest()
'3ad2a9b37c6070e374c7a8c508fe20ca86b6ed54e286e93a0318e95e881db5aa'
```

Credits

BLAKE2 was designed by *Jean-Philippe Aumasson, Samuel Neves, Zooko Wilcox-O' Hearn, and Christian Winnerlein* based on SHA-3 finalist BLAKE created by *Jean-Philippe Aumasson, Luca Henzen, Willi Meier, and Raphael C.-W. Phan*.

It uses core algorithm from ChaCha cipher designed by *Daniel J. Bernstein*.

The stdlib implementation is based on `pyblake2` module. It was written by *Dmitry Chestnykh* based on C implementation written by *Samuel Neves*. The documentation was copied from `pyblake2` and written by *Dmitry Chestnykh*.

The C code was partly rewritten for Python by *Christian Heimes*.

The following public domain dedication applies for both C hash function implementation, extension code, and this documentation:

15.2 hmac — 基于密钥的消息验证

Source code: `Lib/hmac.py`

This module implements the HMAC algorithm as described by **RFC 2104**.

`hmac.new(key, msg=None, digestmod=None)`

Return a new hmac object. `key` is a bytes or bytearray object giving the secret key. If `msg` is present, the method call `update(msg)` is made. `digestmod` is the digest name, digest constructor or module for the HMAC object to use. It supports any name suitable to `hashlib.new()` and defaults to the `hashlib.md5` constructor.

在 3.4 版更改: Parameter *key* can be a bytes or bytearray object. Parameter *msg* can be of any type supported by *hashlib*. Parameter *digestmod* can be the name of a hash algorithm.

3.4 版后已移除: MD5 as implicit default digest for *digestmod* is deprecated.

An HMAC object has the following methods:

HMAC.update(*msg*)

Update the hmac object with *msg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a + b)`.

在 3.4 版更改: Parameter *msg* can be of any type supported by *hashlib*.

HMAC.digest()

Return the digest of the bytes passed to the *update()* method so far. This bytes object will be the same length as the *digest_size* of the digest given to the constructor. It may contain non-ASCII bytes, including NUL bytes.

警告: When comparing the output of *digest()* to an externally-supplied digest during a verification routine, it is recommended to use the *compare_digest()* function instead of the `==` operator to reduce the vulnerability to timing attacks.

HMAC.hexdigest()

Like *digest()* except the digest is returned as a string twice the length containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

警告: When comparing the output of *hexdigest()* to an externally-supplied digest during a verification routine, it is recommended to use the *compare_digest()* function instead of the `==` operator to reduce the vulnerability to timing attacks.

HMAC.copy()

Return a copy (“clone”) of the hmac object. This can be used to efficiently compute the digests of strings that share a common initial substring.

A hash object has the following attributes:

HMAC.digest_size

The size of the resulting HMAC digest in bytes.

HMAC.block_size

The internal block size of the hash algorithm in bytes.

3.4 新版功能.

HMAC.name

The canonical name of this HMAC, always lowercase, e.g. `hmac-md5`.

3.4 新版功能.

This module also provides the following helper function:

hmac.compare_digest(*a*, *b*)

Return `a == b`. This function uses an approach designed to prevent timing analysis by avoiding content-based short circuiting behaviour, making it appropriate for cryptography. *a* and *b* must both be of the same type: either *str* (ASCII only, as e.g. returned by *HMAC.hexdigest()*), or a *bytes-like object*.

注解: If *a* and *b* are of different lengths, or if an error occurs, a timing attack could theoretically reveal information about the types and lengths of *a* and *b*—but not their values.

3.3 新版功能.

参见:

Module `hashlib` The Python module providing secure hash functions.

15.3 `secrets` —Generate secure random numbers for managing secrets

3.6 新版功能.

Source code: [Lib/secrets.py](#)

The `secrets` module is used for generating cryptographically strong random numbers suitable for managing data such as passwords, account authentication, security tokens, and related secrets.

In particular, `secrets` should be used in preference to the default pseudo-random number generator in the `random` module, which is designed for modelling and simulation, not security or cryptography.

参见:

PEP 506

15.3.1 Random numbers

The `secrets` module provides access to the most secure source of randomness that your operating system provides.

class `secrets.SystemRandom`

A class for generating random numbers using the highest-quality sources provided by the operating system. See `random.SystemRandom` for additional details.

`secrets.choice(sequence)`

Return a randomly-chosen element from a non-empty sequence.

`secrets.randbelow(n)`

Return a random int in the range $[0, n)$.

`secrets.randbits(k)`

Return an int with *k* random bits.

15.3.2 Generating tokens

The `secrets` module provides functions for generating secure tokens, suitable for applications such as password resets, hard-to-guess URLs, and similar.

`secrets.token_bytes([nbytes=None])`

Return a random byte string containing *nbytes* number of bytes. If *nbytes* is `None` or not supplied, a reasonable default is used.

```
>>> token_bytes(16)
b'\xeb\r\x17D*t\xae\xd4\xe3S\xb6\xe2\xebP1\x8b'
```

`secrets.token_hex([nbytes=None])`

Return a random text string, in hexadecimal. The string has *nbytes* random bytes, each byte converted to two hex digits. If *nbytes* is `None` or not supplied, a reasonable default is used.

```
>>> token_hex(16)
'f9bf78b9a18ce6d46a0cd2b0b86df9da'
```

`secrets.token_urlsafe([nbytes=None])`

Return a random URL-safe text string, containing *nbytes* random bytes. The text is Base64 encoded, so on average each byte results in approximately 1.3 characters. If *nbytes* is `None` or not supplied, a reasonable default is used.

```
>>> token_urlsafe(16)
'Drmhze6EPcv0fN_81Bj-nA'
```

How many bytes should tokens use?

To be secure against [brute-force attacks](#), tokens need to have sufficient randomness. Unfortunately, what is considered sufficient will necessarily increase as computers get more powerful and able to make more guesses in a shorter period. As of 2015, it is believed that 32 bytes (256 bits) of randomness is sufficient for the typical use-case expected for the `secrets` module.

For those who want to manage their own token length, you can explicitly specify how much randomness is used for tokens by giving an `int` argument to the various `token_*` functions. That argument is taken as the number of bytes of randomness to use.

Otherwise, if no argument is provided, or if the argument is `None`, the `token_*` functions will use a reasonable default instead.

注解: That default is subject to change at any time, including during maintenance releases.

15.3.3 其他功能

`secrets.compare_digest(a, b)`

Return `True` if strings *a* and *b* are equal, otherwise `False`, in such a way as to reduce the risk of [timing attacks](#). See `hmac.compare_digest()` for additional details.

15.3.4 Recipes and best practices

This section shows recipes and best practices for using `secrets` to manage a basic level of security.

Generate an eight-character alphanumeric password:

```
import string
alphabet = string.ascii_letters + string.digits
password = ''.join(choice(alphabet) for i in range(8))
```

注解: Applications should not [store passwords in a recoverable format](#), whether plain text or encrypted. They should be salted and hashed using a cryptographically-strong one-way (irreversible) hash function.

Generate a ten-character alphanumeric password with at least one lowercase character, at least one uppercase character, and at least three digits:

```
import string
alphabet = string.ascii_letters + string.digits
while True:
    password = ''.join(choice(alphabet) for i in range(10))
    if (any(c.islower() for c in password)
        and any(c.isupper() for c in password)
        and sum(c.isdigit() for c in password) >= 3):
        break
```

Generate an XKCD-style passphrase:

```
# On standard Linux systems, use a convenient dictionary file.
# Other platforms may need to provide their own word-list.
with open('/usr/share/dict/words') as f:
    words = [word.strip() for word in f]
    password = ' '.join(choice(words) for i in range(4))
```

Generate a hard-to-guess temporary URL containing a security token suitable for password recovery applications:

```
url = 'https://mydomain.com/reset=' + token_urlsafe()
```

通用操作系统服务

本章中描述的各模块提供了在（几乎）所有的操作系统上可用的操作系统特性的接口，例如文件和时钟。这些接口通常以 Unix 或 C 接口为参照对象设计，不过在大多数其他系统上也可用。这里有一个概述：

16.1 `os` — 操作系统接口模块

源代码： [Lib/os.py](#)

该模块提供了一些方便使用操作系统相关功能的函数。如果你想读写一个文件，请参阅 `open()`，如果你想操作路径，请参阅 `os.path` 模块，如果你想在命令行上读取所有文件中的所有行请参阅 `fileinput` 模块。有关创建临时文件和目录的方法，请参阅 `tempfile` 模块，对于高级文件目录处理，请参阅 `shutil` 模块。

关于这些函数的可用性的说明：

- 所有 Python 内建的操作系统相关的模块的设计都是为了使得在同一功能可用的情况下，保持接口的一致性；例如，函数 `os.stat(path)` 以相同的格式返回关于 `path` 的统计信息（这个函数同时也是起源于 POSIX 接口）。
- 针对特定的操作的拓展同样在可用于 `os` 模块，但是使用它们必然会对可移植性产生威胁。
- 所有接受路径或文件名的函数都同时支持字节串和字符串对象，并在返回路径或文件名时使用相应类型的对象作为结果。
- An “Availability: Unix” note means that this function is commonly found on Unix systems. It does not make any claims about its existence on a specific operating system.
- If not separately noted, all functions that claim “Availability: Unix” are supported on Mac OS X, which builds on a Unix core.

注解：此模块的所有函数在遇到不可用或不可访问的文件名或路径，以及其他类型正确，但不被操作系统接受的参数时，会引发 `OSError` 异常。

exception `os.error`

内建的`OSError` 异常的一个别名。

`os.name`

导入的依赖特定操作系统的模块的名称。以下名称目前已注册: 'posix', 'nt', 'java'.

参见:

`sys.platform` 有更详细的描述. `os.uname()` 只给出系统提供的版本信息。

`platform` 模块对系统的标识有更详细的检查。

16.1.1 文件名，命令行参数，以及环境变量。

在 Python 中，使用字符串类型表示文件名、命令行参数和环境变量。在某些系统上，在将这些字符串传递给操作系统之前，必须将这些字符串解码为字节。Python 使用文件系统编码来执行此转换（请参阅`sys.getfilesystemencoding()`）。

在 3.1 版更改: 在某些系统上，使用文件系统编码进行转换可能会失败。在这种情况下，Python 会使用代理转义编码错误处理器，这意味着在解码时，不可解码的字节被 Unicode 字符 U+DCxx 替换，并且这些字节在编码时再次转换为原始字节。

文件系统编码必须保证成功解码小于 128 的所有字节。如果文件系统编码无法提供此保证，API 函数可能会引发 `UnicodeErrors`。

16.1.2 进程参数

这些函数和数据项提供了操作当前进程和用户的信息。

`os.ctermid()`

返回与进程控制终端对应的文件名。

Availability: Unix.

`os.environ`

一个表示字符串环境的 *mapping* 对象。例如，`environ['HOME']` 是你的主目录（在某些平台上）的路径名，相当于 C 中的 `getenv("HOME")`。

这个映射是在第一次导入 `os` 模块时捕获的，通常作为 Python 启动时处理 `site.py` 的一部分。除了通过直接修改 `os.environ` 之外，在此之后对环境所做的更改不会反映在 `os.environ` 中。

如果平台支持 `putenv()` 函数，这个映射除了可以用于查询环境外还能用于修改环境。当这个映射被修改时，`putenv()` 将被自动调用。

在 Unix 系统上，键和值会使用 `sys.getfilesystemencoding()` 和 'surrogateescape' 的错误处理。如果你想使用其他的编码，使用 `environb`。

注解: 直接调用 `putenv()` 并不会影响 `os.environ`，所以推荐直接修改“`os.environ`”。

注解: 在某些平台上，包括 FreeBSD 和 Mac OS X，设置 `environ` 可能导致内存泄露。参阅 `putenv()` 的系统文档。

如果平台没有提供 `putenv()`，为了使启动的子进程使用修改后的环境，一份修改后的映射会被传给合适的进程创建函数。

如果平台支持`unsetenv()` 函数, 你可以通过删除映射中元素的方式来删除对应的环境变量。当一个元素被从`os.environ` 删除时, 以及`pop()` 或`clear()` 被调用时, `unsetenv()` 会被自动调用。

`os.environb`

字节版本的`environ`: 一个以字节串表示环境的`mapping` 对象。`environ` 和`environb` 是同步的 (修改`environb` 会更新`environ`, 反之亦然)。

只有在`supports_bytes_environ` 为 `True` 的时候`environb` 才是可用的。

3.2 新版功能.

`os.chdir(path)`

`os.fchdir(fd)`

`os.getcwd()`

以上函数请参阅[Files and Directories](#) 。

`os.fsencode(filename)`

编码路径类 文件名为文件系统接受的形式, 使用 `'surrogateescape'` 代理转义编码错误处理器, 在 Windows 系统上会使用 `'strict'`; 返回`bytes` 字节类型不变。

`fsdecode()` 是此函数的逆向函数。

3.2 新版功能.

在 3.6 版更改: 增加对实现了`os.PathLike` 接口的对象的支持。

`os.fsdecode(filename)`

从文件系统编码方式解码为路径类 文件名, 使用 `'surrogateescape'` 代理转义编码错误处理器, 在 Windows 系统上会使用 `'strict'`; 返回`str` 字符串不变。

`fsencode()` 是此函数的逆向函数。

3.2 新版功能.

在 3.6 版更改: 增加对实现了`os.PathLike` 接口的对象的支持。

`os.fspath(path)`

返回路径的文件系统表示。

如果传入的是`str` 或`bytes` 类型的字符串, 将原样返回。否则`__fspath__()` 将被调用, 如果得到的是一个`str` 或`bytes` 类型的对象, 那就返回这个值。其他所有情况则会抛出`TypeError` 异常。

3.6 新版功能.

`class os.PathLike`

描述表示一个文件系统路径的`abstract base class` , 如`pathlib.PurePath` 。

3.6 新版功能.

`abstractmethod __fspath__()`

返回当前对象的文件系统表示。

这个方法只应该返回一个`str` 字符串或`bytes` 字节串, 请优先选择`str` 字符串。

`os.getenv(key, default=None)`

如果存在, 返回环境变量 `key` 的值, 否则返回 `default`。 `key` , `default` 和返回值均为 `str` 字符串类型。

在 Unix 系统上, 键和值会使用`sys.getfilesystemencoding()` 和 `'surrogateescape'` “错误处理进行解码。如果你想使用其他的编码, 使用`os.getenvb()`。

Availability: most flavors of Unix, Windows.

`os.getenvb(key, default=None)`

如果存在环境变量 `key` 那么返回其值, 否则返回 `default`。 `key` , `default` 和返回值均为 `bytes` 字节串类型。

`getenvb()` 仅在`supports_bytes_environ` 为 `True` 时可用

Availability: most flavors of Unix.

3.2 新版功能.

`os.get_exec_path(env=None)`

返回将用于搜索可执行文件的目录列表，与在外壳程序中启动一个进程时相似。指定的 *env* 应为用于搜索 PATH 的环境变量字典。默认情况下，当 *env* 为 None 时，将会使用 *environ*。

3.2 新版功能.

`os.getegid()`

返回当前进程的有效组 ID。对应当前进程执行文件的 “set id” 位。

Availability: Unix.

`os.geteuid()`

返回当前进程的有效用户 ID。

Availability: Unix.

`os.getgid()`

返回当前进程的实际组 ID。

Availability: Unix.

`os.getgrouplist(user, group)`

返回该用户所在的组 ID 列表。可能 *group* 参数没有在返回的列表中，实际上用户应该也是属于该 *group*。*group* 参数一般可以从储存账户信息的密码记录文件中找到。

Availability: Unix.

3.3 新版功能.

`os.getgroups()`

返回当前进程对应的组 ID 列表

Availability: Unix.

注解： 在 Mac OS X 系统中，*getgroups()* 会和其他 Unix 平台有些不同。如果 Python 解释器是在 10.5 或更早版本中部署，*getgroups()* 返回当前用户进程相关的有效组 ID 列表。该列表长度由于系统预设的接口限制，最长为 16。而且在适当的权限下，返回结果还会因 *getgroups()* 而发生变化；如果 Python 解释器是在 10.5 以上版本中部署，*getgroups()* 返回进程所属有效用户 ID 所对应的用户的组 ID 列表，组用户列表可能因为进程的生存周期而发生变动，而且也不会因为 *setgroups()* 的调用而发生，返回的组用户列表长度也没有长度 16 的限制。在部署中，Python 解释器用到的变量 `MACOSX_DEPLOYMENT_TARGET` 可以用 *sysconfig.get_config_var()*。

`os.getlogin()`

返回通过控制终端进程进行登录的用户名。在多数情况下，使用 *getpass.getuser()* 会更有效，因为后者会通过检查环境变量 LOGNAME 或 USERNAME 来查找用户，再由 *pwd.getpwuid(os.getuid())[0]* 来获取当前用户 ID 的登录名。

Availability: Unix, Windows.

`os.getpgid(pid)`

根据进程 id *pid* 返回进程的组 ID 列表。如果 *pid* 为 0，则返回当前进程的进程组 ID 列表

Availability: Unix.

`os.getpgrp()`

返回当时进程组的 ID

Availability: Unix.

`os.getpid()`

返回当前进程 ID

`os.getppid()`

返回父进程 ID。当父进程已经结束，在 Unix 中返回的 ID 是初始进程 (1) 中的一个，在 Windows 中仍然是同一个进程 ID，该进程 ID 有可能已经被进行进程所占用。

Availability: Unix, Windows.

在 3.2 版更改: 添加 Windows 的支持。

`os.getpriority(which, who)`

获取程序调度优先级。*which* 参数值可以是 `PRIO_PROCESS`、`PRIO_PGRP`，或 `PRIO_USER` 中的一个，*who* 是相对于 *which* (`PRIO_PROCESS` 的进程标识符，`PRIO_PGRP` 的进程组标识符和 `PRIO_USER` 的用户 ID)。当 *who* 为 0 时（分别）表示调用的进程，调用进程的进程组或调用进程所属的真实用户 ID。

Availability: Unix.

3.3 新版功能。

`os.PRIO_PROCESS`

`os.PRIO_PGRP`

`os.PRIO_USER`

函数 `getpriority()` 和 `setpriority()` 的参数。

Availability: Unix.

3.3 新版功能。

`os.getresuid()`

返回一个由 (ruid, euid, suid) 所组成的元组，分别表示当前进程的真实用户 ID，有效用户 ID 和甲暂存用户 ID。

Availability: Unix.

3.2 新版功能。

`os.getresgid()`

返回一个由 (rgid, egid, sgid) 所组成的元组，分别表示当前进程的真实组 ID，有效组 ID 和暂存组 ID。

Availability: Unix.

3.2 新版功能。

`os.getuid()`

返回当前进程的真实用户 ID。

Availability: Unix.

`os.initgroups(username, gid)`

调用系统 `initgroups()`，使用指定用户所在的所有值来初始化组访问列表，包括指定的组 ID。

Availability: Unix.

3.2 新版功能。

`os.putenv(key, value)`

将名为 *key* 的环境变量值设置为 *value*。该变量名修改会影响由 `os.system()`、`popen()`、`fork()` 和 `execv()` 发起的子进程。

Availability: most flavors of Unix, Windows.

注解： 在一些平台，包括 FreeBSD 和 Mac OS X，设置 `environ` 可能导致内存泄露。详情参考 `putenv` 相关系统文档。

当系统支持 `putenv()` 时，`os.environ` 中的参数赋值会自动转换为对 `putenv()` 的调用。不过 `putenv()` 的调用不会更新 `os.environ`，因此最好使用 `os.environ` 对变量赋值。

`os.setegid(egid)`

设置当前进程的有效组 ID。

Availability: Unix.

`os.seteuid(euid)`

设置当前进程的有效用户 ID。

Availability: Unix.

`os.setgid(gid)`

设置当前进程的组 ID。

Availability: Unix.

`os.setgroups(groups)`

将 `group` 参数值设置为与当进程相关联的附加组 ID 列表。`group` 参数必须为一个序列，每个元素应为每个组的数字 ID。该操作通常只适用于超级用户。

Availability: Unix.

注解： 在 Mac OS X 中，`groups` 的长度不能超过系统定义的最大有效组 ID 个数，一般为 16。如果它没有返回与调用 `setgroups()` 所设置的相同的组列表，请参阅 `getgroups()` 的文档。

`os.setpgrp()`

根据已实现的版本（如果有）来调用系统 `setpgrp()` 或 `setpgrp(0, 0)`。相关说明，请参考 Unix 手册。

Availability: Unix.

`os.setpgid(pid, pgrp)`

使用系统调用 `setpgid()`，将 `pid` 对应进程的组 ID 设置为 `pgrp`。相关说明，请参考 Unix 手册。

Availability: Unix.

`os.setpriority(which, who, priority)`

设置程序调度优先级。`which` 的值为 `PRIO_PROCESS`、`PRIO_PGRP` 或 `PRIO_USER` 之一，而 `who` 会相对于 `which` (`PRIO_PROCESS` 的进程标识符，`PRIO_PGRP` 的进程组标识符和 `PRIO_USER` 的用户 ID) 被解析。`who` 值为零 (分别) 表示调用进程，调用进程的进程组或调用进程的真实用户 ID。`priority` 是范围在 -20 至 19 的值。默认优先级为 0；较小的优先级数值会更优先被调度。

Availability: Unix

3.3 新版功能.

`os.setregid(rgid, egid)`

设置当前进程的真实和有效组 ID。

Availability: Unix.

`os.setresgid(rgid, egid, sgid)`

设置当前进程的真实，有效和暂存组 ID。

Availability: Unix.

3.2 新版功能.

`os.setresuid(ruid, euid, suid)`

设置当前进程的真实，有效和暂存用户 ID。

Availability: Unix.

3.2 新版功能.

`os.setreuid(ruid, euid)`

设置当前进程的真实和有效用户 ID。

Availability: Unix.

`os.getsid(pid)`

调用系统调用 `getsid()`。相关语义请参阅 Unix 手册。

Availability: Unix.

`os.setsid()`

使用系统调用 `getsid()`。相关说明，请参考 Unix 手册。

Availability: Unix.

`os.setuid(uid)`

设置当前进程的用户 ID。

Availability: Unix.

`os.strerror(code)`

根据 `code` 中的错误码返回错误消息。在某些平台上当给出未知错误码时 `strerror()` 将返回 `NULL` 并会引发 `ValueError`。

`os.supports_bytes_environ`

如果操作系统上原生环境类型是字节型则为 `True` (例如在 Windows 上为 `False`)。

3.2 新版功能.

`os.umask(mask)`

设定当前数值掩码并返回之前的掩码。

`os.uname()`

返回当前操作系统的识别信息。返回值是一个有 5 个属性的对象：

- `sysname` - 操作系统名
- `nodename` - 机器在网络上的名称（需要先设定）
- `release` - 操作系统发行信息
- `version` - 操作系统版本信息
- `machine` - 硬件标识符

为了向后兼容，该对象也是可迭代的，像是一个按照 `sysname`, `nodename`, `release`, `version`, 和 `machine` 顺序组成的元组。

有些系统会将 `nodename` 截短为 8 个字符或截短至前缀部分；获取主机名的一个更好方式是 `socket.gethostname()` 或甚至可以用 `socket.gethostbyaddr(socket.gethostname())`。

Availability: recent flavors of Unix.

在 3.3 版更改: 返回结果的类型由元组变成一个类似元组的对象，同时具有命名的属性。

`os.unsetenv(key)`

取消设置（删除）名为 `key` 的环境变量。变量名的改变会影响由 `os.system()`, `popen()`, `fork()` 和 `execv()` 触发的子进程。

当系统支持`unsetenv()`，删除在`os.environ`中的变量会自动转换为对`unsetenv()`的调用。但是`unsetenv()`不能更新`os.environ`，因此最好直接删除`os.environ`中的变量。

Availability: most flavors of Unix, Windows.

16.1.3 创建文件对象

该函数创建新的文件对象。（另见`open()`关于打开文件的说明。）

`os.fdupen(fd, *args, **kwargs)`

返回打开文件描述符`fd`对应文件的对象。类似内建`open()`函数，二者接受同样的参数。不同之处在于`fdopen()`第一个参数应该为整数。

16.1.4 文件描述符操作

这些函数对文件描述符所引用的 I/O 流进行操作。

文件描述符是一些小的整数，对应于当前进程所打开的文件。例如，标准输入的文件描述符通常是 0，标准输出是 1，标准错误是 2。之后被进程打开的文件的文件描述符会被依次指定为 3, 4, 5 等。“文件描述符”这个词有点误导性，在 Unix 平台中套接字和管道也被文件描述符所引用。

当需要时，可以用`fileno()`可以获得`file object`所对应的文件描述符。需要注意的是，直接使用文件描述符会绕过文件对象的方法，会忽略如数据内部缓冲等情况。

`os.close(fd)`

关闭文件描述符`fd`。

注解：该功能适用于低级 I/O 操作，必须用于`os.open()`或`pipe()`返回的文件描述符。关闭由内建函数`open()`，`popen()`或`fdopen()`返回的“文件对象”，则使用其相应的`close()`方法。

`os.closerange(fd_low, fd_high)`

关闭从`fd_low`（包括）到`fd_high`（排除）间的文件描述符，并忽略错误。类似（但快于）：

```
for fd in range(fd_low, fd_high):
    try:
        os.close(fd)
    except OSError:
        pass
```

`os.device_encoding(fd)`

如果连接到终端，则返回一个与`fd`关联的设备描述字符，否则返回`None`。

`os.dup(fd)`

返回一个文件描述符`fd`的副本。该文件描述符的副本是**不可继承的**。

在 Windows 中，当复制一个标准流（0: stdin, 1: stdout, 2: stderr）时，新的文件描述符是**可继承的**。

在 3.4 版更改：新的文件描述符现在是**不可继承的**。

`os.dup2(fd, fd2, inheritable=True)`

Duplicate file descriptor `fd` to `fd2`, closing the latter first if necessary. The file descriptor `fd2` is *inheritable* by default, or non-inheritable if *inheritable* is `False`.

在 3.4 版更改：添加可选参数 *inheritable*。

os.fchmod(*fd*, *mode*)

将 *fd* 指定文件的权限状态修改为 *mode*。可以参考 `chmod()` 中列出 *mode* 的可用值。从 Python 3.3 开始, 这相当于 `os.chmod(fd, mode)`。

Availability: Unix.

os.fchown(*fd*, *uid*, *gid*)

分别将 *fd* 指定文件的所有者和组 ID 修改为 *uid* 和 *gid* 的值。若不想变更其中的某个 ID, 可将相应值设为 -1。参考 `chown()`。从 Python 3.3 开始, 这相当于 `os.chown(fd, uid, gid)`。

Availability: Unix.

os.fdatasync(*fd*)

强制将文件描述符 *fd* 指定文件写入磁盘。不强制更新元数据。

Availability: Unix.

注解: 该功能在 MacOS 中不可用。

os.fpathconf(*fd*, *name*)

Return system configuration information relevant to an open file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

从 Python 3.3 起, 此功能等价于 `os.pathconf(fd, name)`。

Availability: Unix.

os.fstat(*fd*)

获取文件描述符 *fd* 的状态。返回一个 `stat_result` 对象。

从 Python 3.3 起, 此功能等价于 `os.stat(fd)`。

参见:

`stat()` 函数。

os.fstatvfs(*fd*)

Return information about the filesystem containing the file associated with file descriptor *fd*, like `statvfs()`. As of Python 3.3, this is equivalent to `os.statvfs(fd)`.

Availability: Unix.

os.fsync(*fd*)

Force write of file with filedescriptor *fd* to disk. On Unix, this calls the native `fsync()` function; on Windows, the `MS_commit()` function.

If you're starting with a buffered Python *file object* *f*, first do `f.flush()`, and then do `os.fsync(f.fileno())`, to ensure that all internal buffers associated with *f* are written to disk.

Availability: Unix, Windows.

os.ftruncate(*fd*, *length*)

Truncate the file corresponding to file descriptor *fd*, so that it is at most *length* bytes in size. As of Python 3.3, this is equivalent to `os.truncate(fd, length)`.

Availability: Unix, Windows.

在 3.5 版更改: 添加了 Windows 支持

`os.get_blocking(fd)`

Get the blocking mode of the file descriptor: `False` if the `O_NONBLOCK` flag is set, `True` if the flag is cleared.

See also `set_blocking()` and `socket.socket.setblocking()`.

Availability: Unix.

3.5 新版功能.

`os.isatty(fd)`

Return `True` if the file descriptor `fd` is open and connected to a tty(-like) device, else `False`.

`os.lockf(fd, cmd, len)`

Apply, test or remove a POSIX lock on an open file descriptor. `fd` is an open file descriptor. `cmd` specifies the command to use - one of `F_LOCK`, `F_TLOCK`, `F_ULOCK` or `F_TEST`. `len` specifies the section of the file to lock.

Availability: Unix.

3.3 新版功能.

`os.F_LOCK`

`os.F_TLOCK`

`os.F_ULOCK`

`os.F_TEST`

Flags that specify what action `lockf()` will take.

Availability: Unix.

3.3 新版功能.

`os.lseek(fd, pos, how)`

Set the current position of file descriptor `fd` to position `pos`, modified by `how`: `SEEK_SET` or 0 to set the position relative to the beginning of the file; `SEEK_CUR` or 1 to set it relative to the current position; `SEEK_END` or 2 to set it relative to the end of the file. Return the new cursor position in bytes, starting from the beginning.

`os.SEEK_SET`

`os.SEEK_CUR`

`os.SEEK_END`

Parameters to the `lseek()` function. Their values are 0, 1, and 2, respectively.

3.3 新版功能: Some operating systems could support additional values, like `os.SEEK_HOLE` or `os.SEEK_DATA`.

`os.open(path, flags, mode=0o777, *, dir_fd=None)`

Open the file `path` and set various flags according to `flags` and possibly its mode according to `mode`. When computing `mode`, the current umask value is first masked out. Return the file descriptor for the newly opened file. The new file descriptor is *non-inheritable*.

For a description of the flag and mode values, see the C run-time documentation; flag constants (like `O_RDONLY` and `O_WRONLY`) are defined in the `os` module. In particular, on Windows adding `O_BINARY` is needed to open files in binary mode.

This function can support *paths relative to directory descriptors* with the `dir_fd` parameter.

在 3.4 版更改: 新的文件描述符现在是不可继承的。

注解: This function is intended for low-level I/O. For normal usage, use the built-in function `open()`, which returns a *file object* with `read()` and `write()` methods (and many more). To wrap a file descriptor in a file

object, use `fdopen()`.

3.3 新版功能: `dir_fd` 参数。

在 3.5 版更改: 如果系统调用被中断, 但信号处理程序没有触发异常, 此函数现在会重试系统调用, 而不是触发 `InterruptedError` 异常 (原因详见 [PEP 475](#))。

在 3.6 版更改: 接受一个类路径对象。

The following constants are options for the `flags` parameter to the `open()` function. They can be combined using the bitwise OR operator `|`. Some of them are not available on all platforms. For descriptions of their availability and use, consult the `open(2)` manual page on Unix or [the MSDN](#) on Windows.

```
os.O_RDONLY
os.O_WRONLY
os.O_RDWR
os.O_APPEND
os.O_CREAT
os.O_EXCL
os.O_TRUNC
```

The above constants are available on Unix and Windows.

```
os.O_DSYNC
os.O_RSYNC
os.O_SYNC
os.O_NDELAY
os.O_NONBLOCK
os.O_NOCTTY
os.O_CLOEXEC
```

这个常数仅在 Unix 系统中可用。

在 3.3 版更改: Add `O_CLOEXEC` constant.

```
os.O_BINARY
os.O_NOINHERIT
os.O_SHORT_LIVED
os.O_TEMPORARY
os.O_RANDOM
os.O_SEQUENTIAL
os.O_TEXT
```

这个常数仅在 Windows 系统中可用。

```
os.O_ASYNC
os.O_DIRECT
os.O_DIRECTORY
os.O_NOFOLLOW
os.O_NOATIME
os.O_PATH
os.O_TMPFILE
os.O_SHLOCK
os.O_EXLOCK
```

The above constants are extensions and not present if they are not defined by the C library.

在 3.4 版更改: Add `O_PATH` on systems that support it. Add `O_TMPFILE`, only available on Linux Kernel 3.11 or newer.

```
os.openpty()
```

Open a new pseudo-terminal pair. Return a pair of file descriptors (`master`, `slave`) for the pty and the tty,

respectively. The new file descriptors are *non-inheritable*. For a (slightly) more portable approach, use the *pty* module.

Availability: some flavors of Unix.

在 3.4 版更改: 新的文件描述符不再可继承。

os.**pipe** ()

Create a pipe. Return a pair of file descriptors (*r*, *w*) usable for reading and writing, respectively. The new file descriptor is *non-inheritable*.

Availability: Unix, Windows.

在 3.4 版更改: 新的文件描述符不再可继承。

os.**pipe2** (*flags*)

Create a pipe with *flags* set atomically. *flags* can be constructed by ORing together one or more of these values: *O_NONBLOCK*, *O_CLOEXEC*. Return a pair of file descriptors (*r*, *w*) usable for reading and writing, respectively.

Availability: some flavors of Unix.

3.3 新版功能.

os.**posix_fallocate** (*fd*, *offset*, *len*)

Ensures that enough disk space is allocated for the file specified by *fd* starting from *offset* and continuing for *len* bytes.

Availability: Unix.

3.3 新版功能.

os.**posix_fadvise** (*fd*, *offset*, *len*, *advice*)

Announces an intention to access data in a specific pattern thus allowing the kernel to make optimizations. The advice applies to the region of the file specified by *fd* starting at *offset* and continuing for *len* bytes. *advice* is one of *POSIX_FADV_NORMAL*, *POSIX_FADV_SEQUENTIAL*, *POSIX_FADV_RANDOM*, *POSIX_FADV_NOREUSE*, *POSIX_FADV_WILLNEED* or *POSIX_FADV_DONTNEED*.

Availability: Unix.

3.3 新版功能.

os.**POSIX_FADV_NORMAL**

os.**POSIX_FADV_SEQUENTIAL**

os.**POSIX_FADV_RANDOM**

os.**POSIX_FADV_NOREUSE**

os.**POSIX_FADV_WILLNEED**

os.**POSIX_FADV_DONTNEED**

Flags that can be used in *advice* in *posix_fadvise()* that specify the access pattern that is likely to be used.

Availability: Unix.

3.3 新版功能.

os.**pread** (*fd*, *bufferize*, *offset*)

Read from a file descriptor, *fd*, at a position of *offset*. It will read up to *bufferize* number of bytes. The file offset remains unchanged.

Availability: Unix.

3.3 新版功能.

os.**pwrite** (*fd*, *str*, *offset*)

Write *bytestring* to a file descriptor, *fd*, from *offset*, leaving the file offset unchanged.

Availability: Unix.

3.3 新版功能.

`os.read(fd, n)`

Read at most *n* bytes from file descriptor *fd*. Return a bytearray containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

注解: This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To read a “file object” returned by the built-in function `open()` or by `popen()` or `fdopen()`, or `sys.stdin`, use its `read()` or `readline()` methods.

在 3.5 版更改: 如果系统调用被中断, 但信号处理程序没有触发异常, 此函数现在会重试系统调用, 而不是触发 `InterruptedError` 异常 (原因详见 [PEP 475](#))。

`os.sendfile(out, in, offset, count)`

`os.sendfile(out, in, offset, count[, headers][, trailers], flags=0)`

Copy *count* bytes from file descriptor *in* to file descriptor *out* starting at *offset*. Return the number of bytes sent. When EOF is reached return 0.

The first function notation is supported by all platforms that define `sendfile()`.

On Linux, if *offset* is given as `None`, the bytes are read from the current position of *in* and the position of *in* is updated.

The second case may be used on Mac OS X and FreeBSD where *headers* and *trailers* are arbitrary sequences of buffers that are written before and after the data from *in* is written. It returns the same as the first case.

On Mac OS X and FreeBSD, a value of 0 for *count* specifies to send until the end of *in* is reached.

All platforms support sockets as *out* file descriptor, and some platforms allow other types (e.g. regular file, pipe) as well.

Cross-platform applications should not use *headers*, *trailers* and *flags* arguments.

Availability: Unix.

注解: For a higher-level wrapper of `sendfile()`, see `socket.socket.sendfile()`.

3.3 新版功能.

`os.set_blocking(fd, blocking)`

Set the blocking mode of the specified file descriptor. Set the `O_NONBLOCK` flag if *blocking* is `False`, clear the flag otherwise.

See also `get_blocking()` and `socket.socket.setblocking()`.

Availability: Unix.

3.5 新版功能.

`os.SF_NODISKIO`

`os.SF_MNOWAIT`

`os.SF_SYNC`

Parameters to the `sendfile()` function, if the implementation supports them.

Availability: Unix.

3.3 新版功能.

os.readv(*fd*, *buffers*)

Read from a file descriptor *fd* into a number of mutable *bytes-like objects buffers*. *readv()* will transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data. *readv()* returns the total number of bytes read (which may be less than the total capacity of all the objects).

Availability: Unix.

3.3 新版功能.

os.tcgetpgrp(*fd*)

Return the process group associated with the terminal given by *fd* (an open file descriptor as returned by *os.open()*).

Availability: Unix.

os.tcsetpgrp(*fd*, *pg*)

Set the process group associated with the terminal given by *fd* (an open file descriptor as returned by *os.open()*) to *pg*.

Availability: Unix.

os.ttyname(*fd*)

Return a string which specifies the terminal device associated with file descriptor *fd*. If *fd* is not associated with a terminal device, an exception is raised.

Availability: Unix.

os.write(*fd*, *str*)

Write the bytestring in *str* to file descriptor *fd*. Return the number of bytes actually written.

注解: This function is intended for low-level I/O and must be applied to a file descriptor as returned by *os.open()* or *pipe()*. To write a “file object” returned by the built-in function *open()* or by *popen()* or *fdopen()*, or *sys.stdout* or *sys.stderr*, use its *write()* method.

在 3.5 版更改: 如果系统调用被中断, 但信号处理程序没有触发异常, 此函数现在会重试系统调用, 而不是触发 *InterruptedError* 异常 (原因详见 [PEP 475](#)).

os.writev(*fd*, *buffers*)

Write the contents of *buffers* to file descriptor *fd*. *buffers* must be a sequence of *bytes-like objects*. Buffers are processed in array order. Entire contents of first buffer is written before proceeding to second, and so on. The operating system may set a limit (*sysconf()* value *SC_IOV_MAX*) on the number of buffers that can be used.

writev() writes the contents of each object to the file descriptor and returns the total number of bytes written.

Availability: Unix.

3.3 新版功能.

Querying the size of a terminal

3.3 新版功能.

os.get_terminal_size(*fd=STDOUT_FILENO*)

Return the size of the terminal window as (*columns*, *lines*), tuple of type *terminal_size*.

The optional argument *fd* (default *STDOUT_FILENO*, or standard output) specifies which file descriptor should be queried.

If the file descriptor is not connected to a terminal, an *OSError* is raised.

`shutil.get_terminal_size()` is the high-level function which should normally be used, `os.get_terminal_size` is the low-level implementation.

Availability: Unix, Windows.

class `os.terminal_size`

A subclass of tuple, holding (`columns`, `lines`) of the terminal window size.

columns

Width of the terminal window in characters.

lines

Height of the terminal window in characters.

Inheritance of File Descriptors

3.4 新版功能.

A file descriptor has an “inheritable” flag which indicates if the file descriptor can be inherited by child processes. Since Python 3.4, file descriptors created by Python are non-inheritable by default.

On UNIX, non-inheritable file descriptors are closed in child processes at the execution of a new program, other file descriptors are inherited.

On Windows, non-inheritable handles and file descriptors are closed in child processes, except for standard streams (file descriptors 0, 1 and 2: `stdin`, `stdout` and `stderr`), which are always inherited. Using `spawn*` functions, all inheritable handles and all inheritable file descriptors are inherited. Using the `subprocess` module, all file descriptors except standard streams are closed, and inheritable handles are only inherited if the `close_fds` parameter is `False`.

`os.get_inheritable(fd)`

Get the “inheritable” flag of the specified file descriptor (a boolean).

`os.set_inheritable(fd, inheritable)`

Set the “inheritable” flag of the specified file descriptor.

`os.get_handle_inheritable(handle)`

Get the “inheritable” flag of the specified handle (a boolean).

Availability: Windows.

`os.set_handle_inheritable(handle, inheritable)`

Set the “inheritable” flag of the specified handle.

Availability: Windows.

16.1.5 Files and Directories

On some Unix platforms, many of these functions support one or more of these features:

- **specifying a file descriptor:** For some functions, the `path` argument can be not only a string giving a path name, but also a file descriptor. The function will then operate on the file referred to by the descriptor. (For POSIX systems, Python will call the `f...f` version of the function.)

You can check whether or not `path` can be specified as a file descriptor on your platform using `os.supports_fd`. If it is unavailable, using it will raise a `NotImplementedError`.

If the function also supports `dir_fd` or `follow_symlinks` arguments, it is an error to specify one of those when supplying `path` as a file descriptor.

- **paths relative to directory descriptors:** If `dir_fd` is not `None`, it should be a file descriptor referring to a directory, and the path to operate on should be relative; path will then be relative to that directory. If the path is absolute, `dir_fd` is ignored. (For POSIX systems, Python will call the `...at` or `f...at` version of the function.)

You can check whether or not `dir_fd` is supported on your platform using `os.supports_dir_fd`. If it is unavailable, using it will raise a `NotImplementedError`.

- **not following symlinks:** If `follow_symlinks` is `False`, and the last element of the path to operate on is a symbolic link, the function will operate on the symbolic link itself instead of the file the link points to. (For POSIX systems, Python will call the `l...` version of the function.)

You can check whether or not `follow_symlinks` is supported on your platform using `os.supports_follow_symlinks`. If it is unavailable, using it will raise a `NotImplementedError`.

`os.access(path, mode, *, dir_fd=None, effective_ids=False, follow_symlinks=True)`

Use the real uid/gid to test for access to `path`. Note that most operations will use the effective uid/gid, therefore this routine can be used in a `suid/sgid` environment to test if the invoking user has the specified access to `path`. `mode` should be `F_OK` to test the existence of `path`, or it can be the inclusive OR of one or more of `R_OK`, `W_OK`, and `X_OK` to test permissions. Return `True` if access is allowed, `False` if not. See the Unix man page `access(2)` for more information.

This function can support specifying *paths relative to directory descriptors* and *not following symlinks*.

If `effective_ids` is `True`, `access()` will perform its access checks using the effective uid/gid instead of the real uid/gid. `effective_ids` may not be supported on your platform; you can check whether or not it is available using `os.supports_effective_ids`. If it is unavailable, using it will raise a `NotImplementedError`.

注解: Using `access()` to check if a user is authorized to e.g. open a file before actually doing so using `open()` creates a security hole, because the user might exploit the short time interval between checking and opening the file to manipulate it. It's preferable to use *EAFP* techniques. For example:

```
if os.access("myfile", os.R_OK):
    with open("myfile") as fp:
        return fp.read()
return "some default data"
```

is better written as:

```
try:
    fp = open("myfile")
except PermissionError:
    return "some default data"
else:
    with fp:
        return fp.read()
```

注解: I/O operations may fail even when `access()` indicates that they would succeed, particularly for operations on network filesystems which may have permissions semantics beyond the usual POSIX permission-bit model.

在 3.3 版更改: Added the `dir_fd`, `effective_ids`, and `follow_symlinks` parameters.

在 3.6 版更改: 接受一个类路径对象。

`os.F_OK`

`os.R_OK`

`os.W_OK`

os.X_OK

Values to pass as the *mode* parameter of `access()` to test the existence, readability, writability and executability of *path*, respectively.

os.chdir(*path*)

Change the current working directory to *path*.

This function can support *specifying a file descriptor*. The descriptor must refer to an opened directory, not an open file.

3.3 新版功能: Added support for specifying *path* as a file descriptor on some platforms.

在 3.6 版更改: 接受一个类路径对象。

os.chflags(*path*, *flags*, *, *follow_symlinks*=True)

Set the flags of *path* to the numeric *flags*. *flags* may take a combination (bitwise OR) of the following values (as defined in the `stat` module):

- `stat.UF_NODUMP`
- `stat.UF_IMMUTABLE`
- `stat.UF_APPEND`
- `stat.UF_OPAQUE`
- `stat.UF_NOUNLINK`
- `stat.UF_COMPRESSED`
- `stat.UF_HIDDEN`
- `stat.SF_ARCHIVED`
- `stat.SF_IMMUTABLE`
- `stat.SF_APPEND`
- `stat.SF_NOUNLINK`
- `stat.SF_SNAPSHOT`

This function can support *not following symlinks*.

Availability: Unix.

3.3 新版功能: The *follow_symlinks* argument.

在 3.6 版更改: 接受一个类路径对象。

os.chmod(*path*, *mode*, *, *dir_fd*=None, *follow_symlinks*=True)

Change the mode of *path* to the numeric *mode*. *mode* may take one of the following values (as defined in the `stat` module) or bitwise ORed combinations of them:

- `stat.S_ISUID`
- `stat.S_ISGID`
- `stat.S_ENFMT`
- `stat.S_ISVTX`
- `stat.S_IREAD`
- `stat.S_IWRITE`
- `stat.S_IEXEC`
- `stat.S_IRWXU`

- `stat.S_IRUSR`
- `stat.S_IWUSR`
- `stat.S_IXUSR`
- `stat.S_IRWXG`
- `stat.S_IRGRP`
- `stat.S_IWGRP`
- `stat.S_IXGRP`
- `stat.S_IRWXO`
- `stat.S_IROTH`
- `stat.S_IWOTH`
- `stat.S_IXOTH`

This function can support *specifying a file descriptor, paths relative to directory descriptors* and *not following symlinks*.

注解: Although Windows supports `chmod()`, you can only set the file's read-only flag with it (via the `stat.S_IWRITE` and `stat.S_IREAD` constants or a corresponding integer value). All other bits are ignored.

3.3 新版功能: Added support for specifying *path* as an open file descriptor, and the *dir_fd* and *follow_symlinks* arguments.

在 3.6 版更改: 接受一个类路径对象。

○ `os.chown(path, uid, gid, *, dir_fd=None, follow_symlinks=True)`

Change the owner and group id of *path* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1.

This function can support *specifying a file descriptor, paths relative to directory descriptors* and *not following symlinks*.

See `shutil.chown()` for a higher-level function that accepts names in addition to numeric ids.

Availability: Unix.

3.3 新版功能: Added support for specifying an open file descriptor for *path*, and the *dir_fd* and *follow_symlinks* arguments.

在 3.6 版更改: Supports a *path-like object*.

○ `os.chroot(path)`

Change the root directory of the current process to *path*.

Availability: Unix.

在 3.6 版更改: 接受一个类路径对象。

○ `os.fchdir(fd)`

Change the current working directory to the directory represented by the file descriptor *fd*. The descriptor must refer to an opened directory, not an open file. As of Python 3.3, this is equivalent to `os.chdir(fd)`.

Availability: Unix.

○ `os.getcwd()`

Return a string representing the current working directory.

`os.getcwd()`

Return a bytestring representing the current working directory.

`os.lchflags(path, flags)`

Set the flags of *path* to the numeric *flags*, like `chflags()`, but do not follow symbolic links. As of Python 3.3, this is equivalent to `os.chflags(path, flags, follow_symlinks=False)`.

Availability: Unix.

在 3.6 版更改: 接受一个类路径对象。

`os.lchmod(path, mode)`

Change the mode of *path* to the numeric *mode*. If *path* is a symlink, this affects the symlink rather than the target. See the docs for `chmod()` for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(path, mode, follow_symlinks=False)`.

Availability: Unix.

在 3.6 版更改: 接受一个类路径对象。

`os.lchown(path, uid, gid)`

Change the owner and group id of *path* to the numeric *uid* and *gid*. This function will not follow symbolic links. As of Python 3.3, this is equivalent to `os.chown(path, uid, gid, follow_symlinks=False)`.

Availability: Unix.

在 3.6 版更改: 接受一个类路径对象。

`os.link(src, dst, *, src_dir_fd=None, dst_dir_fd=None, follow_symlinks=True)`

Create a hard link pointing to *src* named *dst*.

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*, and *not following symlinks*.

Availability: Unix, Windows.

在 3.2 版更改: Added Windows support.

3.3 新版功能: Added the *src_dir_fd*, *dst_dir_fd*, and *follow_symlinks* arguments.

在 3.6 版更改: Accepts a *path-like object* for *src* and *dst*.

`os.listdir(path='.')`

Return a list containing the names of the entries in the directory given by *path*. The list is in arbitrary order, and does not include the special entries `'.'` and `'..'` even if they are present in the directory.

path may be a *path-like object*. If *path* is of type `bytes` (directly or indirectly through the *PathLike* interface), the filenames returned will also be of type `bytes`; in all other circumstances, they will be of type `str`.

This function can also support *specifying a file descriptor*; the file descriptor must refer to a directory.

注解: To encode `str` filenames to `bytes`, use `fsencode()`.

参见:

The `scandir()` function returns directory entries along with file attribute information, giving better performance for many common use cases.

在 3.2 版更改: The *path* parameter became optional.

3.3 新版功能: Added support for specifying an open file descriptor for *path*.

在 3.6 版更改: 接受一个类路径对象。

`os.lstat(path, *, dir_fd=None)`

Perform the equivalent of an `lstat()` system call on the given path. Similar to `stat()`, but does not follow symbolic links. Return a `stat_result` object.

On platforms that do not support symbolic links, this is an alias for `stat()`.

As of Python 3.3, this is equivalent to `os.stat(path, dir_fd=dir_fd, follow_symlinks=False)`.

This function can also support *paths relative to directory descriptors*.

参见:

`stat()` 函数。

在 3.2 版更改: Added support for Windows 6.0 (Vista) symbolic links.

在 3.3 版更改: Added the `dir_fd` parameter.

在 3.6 版更改: Accepts a *path-like object* for `src` and `dst`.

`os.mkdir(path, mode=0o777, *, dir_fd=None)`

Create a directory named `path` with numeric mode `mode`.

If the directory already exists, `FileExistsError` is raised.

On some systems, `mode` is ignored. Where it is used, the current umask value is first masked out. If bits other than the last 9 (i.e. the last 3 digits of the octal representation of the `mode`) are set, their meaning is platform-dependent. On some platforms, they are ignored and you should call `chmod()` explicitly to set them.

This function can also support *paths relative to directory descriptors*.

It is also possible to create temporary directories; see the `tempfile` module's `tempfile.mkdtemp()` function.

3.3 新版功能: `dir_fd` 参数。

在 3.6 版更改: 接受一个类路径对象。

`os.makedirs(name, mode=0o777, exist_ok=False)`

Recursive directory creation function. Like `mkdir()`, but makes all intermediate-level directories needed to contain the leaf directory.

The `mode` parameter is passed to `mkdir()`; see *the mkdir() description* for how it is interpreted.

If `exist_ok` is `False` (the default), an `OSError` is raised if the target directory already exists.

注解: `makedirs()` will become confused if the path elements to create include *pardir* (eg. “..” on UNIX systems).

This function handles UNC paths correctly.

3.2 新版功能: The `exist_ok` parameter.

在 3.4.1 版更改: Before Python 3.4.1, if `exist_ok` was `True` and the directory existed, `makedirs()` would still raise an error if `mode` did not match the mode of the existing directory. Since this behavior was impossible to implement safely, it was removed in Python 3.4.1. See [bpo-21082](#).

在 3.6 版更改: 接受一个类路径对象。

`os.mkfifo(path, mode=0o666, *, dir_fd=None)`

Create a FIFO (a named pipe) named `path` with numeric mode `mode`. The current umask value is first masked out from the mode.

This function can also support *paths relative to directory descriptors*.

FIFOs are pipes that can be accessed like regular files. FIFOs exist until they are deleted (for example with `os.unlink()`). Generally, FIFOs are used as rendezvous between “client” and “server” type processes: the server opens the FIFO for reading, and the client opens it for writing. Note that `mkfifo()` doesn’t open the FIFO — it just creates the rendezvous point.

Availability: Unix.

3.3 新版功能: `dir_fd` 参数。

在 3.6 版更改: 接受一个类路径对象。

`os.mknod(path, mode=0o600, device=0, *, dir_fd=None)`

Create a filesystem node (file, device special file or named pipe) named *path*. *mode* specifies both the permissions to use and the type of node to be created, being combined (bitwise OR) with one of `stat.S_IFREG`, `stat.S_IFCHR`, `stat.S_IFBLK`, and `stat.S_IFIFO` (those constants are available in `stat`). For `stat.S_IFCHR` and `stat.S_IFBLK`, *device* defines the newly created device special file (probably using `os.makedev()`), otherwise it is ignored.

This function can also support *paths relative to directory descriptors*.

Availability: Unix.

3.3 新版功能: `dir_fd` 参数。

在 3.6 版更改: 接受一个类路径对象。

`os.major(device)`

Extract the device major number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.minor(device)`

Extract the device minor number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.makedev(major, minor)`

Compose a raw device number from the major and minor device numbers.

`os.pathconf(path, name)`

Return system configuration information relevant to a named file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

This function can support *specifying a file descriptor*.

Availability: Unix.

在 3.6 版更改: 接受一个类路径对象。

`os.pathconf_names`

Dictionary mapping names accepted by `pathconf()` and `fpathconf()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

`os.readlink(path, *, dir_fd=None)`

Return a string representing the path to which the symbolic link points. The result may be either an absolute or relative pathname; if it is relative, it may be converted to an absolute pathname using `os.path.join(os.path.dirname(path), result)`.

If the *path* is a string object (directly or indirectly through a *PathLike* interface), the result will also be a string object, and the call may raise a `UnicodeDecodeError`. If the *path* is a bytes object (direct or indirectly), the result will be a bytes object.

This function can also support *paths relative to directory descriptors*.

Availability: Unix, Windows

在 3.2 版更改: Added support for Windows 6.0 (Vista) symbolic links.

3.3 新版功能: *dir_fd* 参数。

在 3.6 版更改: 接受一个类路径对象。

`os.remove(path, *, dir_fd=None)`

Remove (delete) the file *path*. If *path* is a directory, `OSError` is raised. Use `rmdir()` to remove directories.

This function can support *paths relative to directory descriptors*.

On Windows, attempting to remove a file that is in use causes an exception to be raised; on Unix, the directory entry is removed but the storage allocated to the file is not made available until the original file is no longer in use.

This function is semantically identical to `unlink()`.

3.3 新版功能: *dir_fd* 参数。

在 3.6 版更改: 接受一个类路径对象。

`os.removedirs(name)`

Remove directories recursively. Works like `rmdir()` except that, if the leaf directory is successfully removed, `removedirs()` tries to successively remove every parent directory mentioned in *path* until an error is raised (which is ignored, because it generally means that a parent directory is not empty). For example, `os.removedirs('foo/bar/baz')` will first remove the directory `'foo/bar/baz'`, and then remove `'foo/bar'` and `'foo'` if they are empty. Raises `OSError` if the leaf directory could not be successfully removed.

在 3.6 版更改: 接受一个类路径对象。

`os.rename(src, dst, *, src_dir_fd=None, dst_dir_fd=None)`

Rename the file or directory *src* to *dst*. If *dst* is a directory, `OSError` will be raised. On Unix, if *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail on some Unix flavors if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement). On Windows, if *dst* already exists, `OSError` will be raised even if it is a file.

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*.

If you want cross-platform overwriting of the destination, use `replace()`.

3.3 新版功能: The *src_dir_fd* and *dst_dir_fd* arguments.

在 3.6 版更改: Accepts a *path-like object* for *src* and *dst*.

`os.rename(old, new)`

Recursive directory or file renaming function. Works like `rename()`, except creation of any intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned away using `removedirs()`.

注解: This function can fail with the new directory structure made if you lack permissions needed to remove the leaf directory or file.

在 3.6 版更改: Accepts a *path-like object* for *old* and *new*.

`os.replace(src, dst, *, src_dir_fd=None, dst_dir_fd=None)`

Rename the file or directory *src* to *dst*. If *dst* is a directory, *OSError* will be raised. If *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*.

3.3 新版功能.

在 3.6 版更改: Accepts a *path-like object* for *src* and *dst*.

`os.rmdir(path, *, dir_fd=None)`

Remove (delete) the directory *path*. Only works when the directory is empty, otherwise, *OSError* is raised. In order to remove whole directory trees, *shutil.rmtree()* can be used.

This function can support *paths relative to directory descriptors*.

3.3 新版功能: The *dir_fd* parameter.

在 3.6 版更改: 接受一个类路径对象。

`os.scandir(path='.')`

Return an iterator of *os.DirEntry* objects corresponding to the entries in the directory given by *path*. The entries are yielded in arbitrary order, and the special entries *'.'* and *'..'* are not included.

Using *scandir()* instead of *listdir()* can significantly increase the performance of code that also needs file type or file attribute information, because *os.DirEntry* objects expose this information if the operating system provides it when scanning a directory. All *os.DirEntry* methods may perform a system call, but *is_dir()* and *is_file()* usually only require a system call for symbolic links; *os.DirEntry.stat()* always requires a system call on Unix but only requires one for symbolic links on Windows.

path may be a *path-like object*. If *path* is of type *bytes* (directly or indirectly through the *PathLike* interface), the type of the *name* and *path* attributes of each *os.DirEntry* will be *bytes*; in all other circumstances, they will be of type *str*.

The *scandir()* iterator supports the *context manager* protocol and has the following method:

`scandir.close()`

Close the iterator and free acquired resources.

This is called automatically when the iterator is exhausted or garbage collected, or when an error happens during iterating. However it is advisable to call it explicitly or use the *with* statement.

3.6 新版功能.

The following example shows a simple use of *scandir()* to display all the files (excluding directories) in the given *path* that don't start with *'.'*. The *entry.is_file()* call will generally not make an additional system call:

```
with os.scandir(path) as it:
    for entry in it:
        if not entry.name.startswith('.') and entry.is_file():
            print(entry.name)
```

注解: On Unix-based systems, *scandir()* uses the system's *opendir()* and *readdir()* functions. On Windows, it uses the Win32 *FindFirstFileW* and *FindNextFileW* functions.

3.5 新版功能.

3.6 新版功能: Added support for the *context manager* protocol and the *close()* method. If a *scandir()* iterator is neither exhausted nor explicitly closed a *ResourceWarning* will be emitted in its destructor.

The function accepts a *path-like object*.

class `os.DirEntry`

Object yielded by `scandir()` to expose the file path and other file attributes of a directory entry.

`scandir()` will provide as much of this information as possible without making additional system calls. When a `stat()` or `lstat()` system call is made, the `os.DirEntry` object will cache the result.

`os.DirEntry` instances are not intended to be stored in long-lived data structures; if you know the file metadata has changed or if a long time has elapsed since calling `scandir()`, call `os.stat(entry.path)` to fetch up-to-date information.

Because the `os.DirEntry` methods can make operating system calls, they may also raise `OSError`. If you need very fine-grained control over errors, you can catch `OSError` when calling one of the `os.DirEntry` methods and handle as appropriate.

To be directly usable as a *path-like object*, `os.DirEntry` implements the `PathLike` interface.

Attributes and methods on a `os.DirEntry` instance are as follows:

name

The entry's base filename, relative to the `scandir()` *path* argument.

The `name` attribute will be `bytes` if the `scandir()` *path* argument is of type `bytes` and `str` otherwise. Use `fsdecode()` to decode byte filenames.

path

The entry's full path name: equivalent to `os.path.join(scandir_path, entry.name)` where `scandir_path` is the `scandir()` *path* argument. The path is only absolute if the `scandir()` *path* argument was absolute.

The `path` attribute will be `bytes` if the `scandir()` *path* argument is of type `bytes` and `str` otherwise. Use `fsdecode()` to decode byte filenames.

inode()

Return the inode number of the entry.

The result is cached on the `os.DirEntry` object. Use `os.stat(entry.path, follow_symlinks=False).st_ino` to fetch up-to-date information.

On the first, uncached call, a system call is required on Windows but not on Unix.

is_dir (*, *follow_symlinks=True*)

Return `True` if this entry is a directory or a symbolic link pointing to a directory; return `False` if the entry is or points to any other kind of file, or if it doesn't exist anymore.

If *follow_symlinks* is `False`, return `True` only if this entry is a directory (without following symlinks); return `False` if the entry is any other kind of file or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object, with a separate cache for *follow_symlinks* `True` and `False`. Call `os.stat()` along with `stat.S_ISDIR()` to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, for non-symlinks, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`. If the entry is a symlink, a system call will be required to follow the symlink unless *follow_symlinks* is `False`.

This method can raise `OSError`, such as `PermissionError`, but `FileNotFoundError` is caught and not raised.

is_file (*, *follow_symlinks=True*)

Return `True` if this entry is a file or a symbolic link pointing to a file; return `False` if the entry is or points to a directory or other non-file entry, or if it doesn't exist anymore.

If `follow_symlinks` is `False`, return `True` only if this entry is a file (without following symlinks); return `False` if the entry is a directory or other non-file entry, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Caching, system calls made, and exceptions raised are as per `is_dir()`.

`is_symlink()`

Return `True` if this entry is a symbolic link (even if broken); return `False` if the entry points to a directory or any kind of file, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Call `os.path.islink()` to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`.

This method can raise `OSError`, such as `PermissionError`, but `FileNotFoundError` is caught and not raised.

`stat(*, follow_symlinks=True)`

Return a `stat_result` object for this entry. This method follows symbolic links by default; to stat a symbolic link add the `follow_symlinks=False` argument.

On Unix, this method always requires a system call. On Windows, it only requires a system call if `follow_symlinks` is `True` and the entry is a symbolic link.

On Windows, the `st_ino`, `st_dev` and `st_nlink` attributes of the `stat_result` are always set to zero. Call `os.stat()` to get these attributes.

The result is cached on the `os.DirEntry` object, with a separate cache for `follow_symlinks` `True` and `False`. Call `os.stat()` to fetch up-to-date information.

Note that there is a nice correspondence between several attributes and methods of `os.DirEntry` and of `pathlib.Path`. In particular, the `name` attribute has the same meaning, as do the `is_dir()`, `is_file()`, `is_symlink()` and `stat()` methods.

3.5 新版功能.

在 3.6 版更改: Added support for the `PathLike` interface. Added support for `bytes` paths on Windows.

`os.stat(path, *, dir_fd=None, follow_symlinks=True)`

Get the status of a file or a file descriptor. Perform the equivalent of a `stat()` system call on the given path. `path` may be specified as either a string or bytes – directly or indirectly through the `PathLike` interface – or as an open file descriptor. Return a `stat_result` object.

This function normally follows symlinks; to stat a symlink add the argument `follow_symlinks=False`, or use `lstat()`.

This function can support *specifying a file descriptor* and *not following symlinks*.

示例:

```
>>> import os
>>> statinfo = os.stat('somefile.txt')
>>> statinfo
os.stat_result(st_mode=33188, st_ino=7876932, st_dev=234881026,
st_nlink=1, st_uid=501, st_gid=501, st_size=264, st_atime=1297230295,
st_mtime=1297230027, st_ctime=1297230027)
>>> statinfo.st_size
264
```

参见:

`fstat()` and `lstat()` functions.

3.3 新版功能: Added the `dir_fd` and `follow_symlinks` arguments, specifying a file descriptor instead of a path.

在 3.6 版更改: 接受一个类路径对象。

class `os.stat_result`

Object whose attributes correspond roughly to the members of the `stat` structure. It is used for the result of `os.stat()`, `os.fstat()` and `os.lstat()`.

Attributes:

st_mode

File mode: file type and file mode bits (permissions).

st_ino

Platform dependent, but if non-zero, uniquely identifies the file for a given value of `st_dev`. Typically:

- the inode number on Unix,
- the [file index](#) on Windows

st_dev

Identifier of the device on which this file resides.

st_nlink

Number of hard links.

st_uid

User identifier of the file owner.

st_gid

Group identifier of the file owner.

st_size

Size of the file in bytes, if it is a regular file or a symbolic link. The size of a symbolic link is the length of the pathname it contains, without a terminating null byte.

Timestamps:

st_atime

Time of most recent access expressed in seconds.

st_mtime

Time of most recent content modification expressed in seconds.

st_ctime

Platform dependent:

- the time of most recent metadata change on Unix,
- the time of creation on Windows, expressed in seconds.

st_atime_ns

Time of most recent access expressed in nanoseconds as an integer.

st_mtime_ns

Time of most recent content modification expressed in nanoseconds as an integer.

st_ctime_ns

Platform dependent:

- the time of most recent metadata change on Unix,

- the time of creation on Windows, expressed in nanoseconds as an integer.

See also the `stat_float_times()` function.

注解: The exact meaning and resolution of the `st_atime`, `st_mtime`, and `st_ctime` attributes depend on the operating system and the file system. For example, on Windows systems using the FAT or FAT32 file systems, `st_mtime` has 2-second resolution, and `st_atime` has only 1-day resolution. See your operating system documentation for details.

Similarly, although `st_atime_ns`, `st_mtime_ns`, and `st_ctime_ns` are always expressed in nanoseconds, many systems do not provide nanosecond precision. On systems that do provide nanosecond precision, the floating-point object used to store `st_atime`, `st_mtime`, and `st_ctime` cannot preserve all of it, and as such will be slightly inexact. If you need the exact timestamps you should always use `st_atime_ns`, `st_mtime_ns`, and `st_ctime_ns`.

On some Unix systems (such as Linux), the following attributes may also be available:

st_blocks

Number of 512-byte blocks allocated for file. This may be smaller than `st_size/512` when the file has holes.

st_blksize

“Preferred” blocksize for efficient file system I/O. Writing to a file in smaller chunks may cause an inefficient read-modify-rewrite.

st_rdev

Type of device if an inode device.

st_flags

User defined flags for file.

On other Unix systems (such as FreeBSD), the following attributes may be available (but may be only filled out if root tries to use them):

st_gen

File generation number.

st_birthtime

Time of file creation.

On Mac OS systems, the following attributes may also be available:

st_rsize

Real size of the file.

st_creator

Creator of the file.

st_type

File type.

On Windows systems, the following attribute is also available:

st_file_attributes

Windows file attributes: `dwFileAttributes` member of the `BY_HANDLE_FILE_INFORMATION` structure returned by `GetFileInformationByHandle()`. See the `FILE_ATTRIBUTE_*` constants in the `stat` module.

The standard module `stat` defines functions and constants that are useful for extracting information from a `stat` structure. (On Windows, some items are filled with dummy values.)

For backward compatibility, a `stat_result` instance is also accessible as a tuple of at least 10 integers giving the most important (and portable) members of the `stat` structure, in the order `st_mode`, `st_ino`, `st_dev`, `st_nlink`, `st_uid`, `st_gid`, `st_size`, `st_atime`, `st_mtime`, `st_ctime`. More items may be added at the end by some implementations. For compatibility with older Python versions, accessing `stat_result` as a tuple always returns integers.

3.3 新版功能: Added the `st_atime_ns`, `st_mtime_ns`, and `st_ctime_ns` members.

3.5 新版功能: Added the `st_file_attributes` member on Windows.

在 3.5 版更改: Windows now returns the file index as `st_ino` when available.

`os.stat_float_times([newvalue])`

Determine whether `stat_result` represents time stamps as float objects. If `newvalue` is `True`, future calls to `stat()` return floats, if it is `False`, future calls return ints. If `newvalue` is omitted, return the current setting.

For compatibility with older Python versions, accessing `stat_result` as a tuple always returns integers.

Python now returns float values by default. Applications which do not work correctly with floating point time stamps can use this function to restore the old behaviour.

The resolution of the timestamps (that is the smallest possible fraction) depends on the system. Some systems only support second resolution; on these systems, the fraction will always be zero.

It is recommended that this setting is only changed at program startup time in the `__main__` module; libraries should never change this setting. If an application uses a library that works incorrectly if floating point time stamps are processed, this application should turn the feature off until the library has been corrected.

3.3 版后已移除.

`os.statvfs(path)`

Perform a `statvfs()` system call on the given path. The return value is an object whose attributes describe the filesystem on the given path, and correspond to the members of the `statvfs` structure, namely: `f_bsize`, `f_frsize`, `f_blocks`, `f_bfree`, `f_bavail`, `f_files`, `f_ffree`, `f_favail`, `f_flag`, `f_namemax`.

Two module-level constants are defined for the `f_flag` attribute's bit-flags: if `ST_RDONLY` is set, the filesystem is mounted read-only, and if `ST_NOSUID` is set, the semantics of `setuid/setgid` bits are disabled or not supported.

Additional module-level constants are defined for GNU/glibc based systems. These are `ST_NODEV` (disallow access to device special files), `ST_NOEXEC` (disallow program execution), `ST_SYNCHRONOUS` (writes are synced at once), `ST_MANDLOCK` (allow mandatory locks on an FS), `ST_WRITE` (write on file/directory/symlink), `ST_APPEND` (append-only file), `ST_IMMUTABLE` (immutable file), `ST_NOATIME` (do not update access times), `ST_NODIRATIME` (do not update directory access times), `ST_RELATIME` (update atime relative to mtime/ctime).

This function can support *specifying a file descriptor*.

Availability: Unix.

在 3.2 版更改: The `ST_RDONLY` and `ST_NOSUID` constants were added.

3.3 新版功能: Added support for specifying an open file descriptor for `path`.

在 3.4 版更改: The `ST_NODEV`, `ST_NOEXEC`, `ST_SYNCHRONOUS`, `ST_MANDLOCK`, `ST_WRITE`, `ST_APPEND`, `ST_IMMUTABLE`, `ST_NOATIME`, `ST_NODIRATIME`, and `ST_RELATIME` constants were added.

在 3.6 版更改: 接受一个类路径对象。

`os.supports_dir_fd`

A `Set` object indicating which functions in the `os` module permit use of their `dir_fd` parameter. Different platforms provide different functionality, and an option that might work on one might be unsupported on another.

For consistency's sakes, functions that support *dir_fd* always allow specifying the parameter, but will raise an exception if the functionality is not actually available.

To check whether a particular function permits use of its *dir_fd* parameter, use the `in` operator on `supports_dir_fd`. As an example, this expression determines whether the *dir_fd* parameter of `os.stat()` is locally available:

```
os.stat in os.supports_dir_fd
```

Currently *dir_fd* parameters only work on Unix platforms; none of them work on Windows.

3.3 新版功能.

`os.supports_effective_ids`

A *Set* object indicating which functions in the `os` module permit use of the *effective_ids* parameter for `os.access()`. If the local platform supports it, the collection will contain `os.access()`, otherwise it will be empty.

To check whether you can use the *effective_ids* parameter for `os.access()`, use the `in` operator on `supports_effective_ids`, like so:

```
os.access in os.supports_effective_ids
```

Currently *effective_ids* only works on Unix platforms; it does not work on Windows.

3.3 新版功能.

`os.supports_fd`

A *Set* object indicating which functions in the `os` module permit specifying their *path* parameter as an open file descriptor. Different platforms provide different functionality, and an option that might work on one might be unsupported on another. For consistency's sakes, functions that support *fd* always allow specifying the parameter, but will raise an exception if the functionality is not actually available.

To check whether a particular function permits specifying an open file descriptor for its *path* parameter, use the `in` operator on `supports_fd`. As an example, this expression determines whether `os.chdir()` accepts open file descriptors when called on your local platform:

```
os.chdir in os.supports_fd
```

3.3 新版功能.

`os.supports_follow_symlinks`

A *Set* object indicating which functions in the `os` module permit use of their *follow_symlinks* parameter. Different platforms provide different functionality, and an option that might work on one might be unsupported on another. For consistency's sakes, functions that support *follow_symlinks* always allow specifying the parameter, but will raise an exception if the functionality is not actually available.

To check whether a particular function permits use of its *follow_symlinks* parameter, use the `in` operator on `supports_follow_symlinks`. As an example, this expression determines whether the *follow_symlinks* parameter of `os.stat()` is locally available:

```
os.stat in os.supports_follow_symlinks
```

3.3 新版功能.

`os.symlink(src, dst, target_is_directory=False, *, dir_fd=None)`

Create a symbolic link pointing to *src* named *dst*.

On Windows, a symlink represents either a file or a directory, and does not morph to the target dynamically. If the target is present, the type of the symlink will be created to match. Otherwise, the symlink will be created as

a directory if *target_is_directory* is `True` or a file symlink (the default) otherwise. On non-Windows platforms, *target_is_directory* is ignored.

Symbolic link support was introduced in Windows 6.0 (Vista). `symlink()` will raise a `NotImplementedError` on Windows versions earlier than 6.0.

This function can support *paths relative to directory descriptors*.

注解: On Windows, the `SeCreateSymbolicLinkPrivilege` is required in order to successfully create symlinks. This privilege is not typically granted to regular users but is available to accounts which can escalate privileges to the administrator level. Either obtaining the privilege or running your application as an administrator are ways to successfully create symlinks.

`OSError` is raised when the function is called by an unprivileged user.

Availability: Unix, Windows.

在 3.2 版更改: Added support for Windows 6.0 (Vista) symbolic links.

3.3 新版功能: Added the *dir_fd* argument, and now allow *target_is_directory* on non-Windows platforms.

在 3.6 版更改: Accepts a *path-like object* for *src* and *dst*.

os.sync()

Force write of everything to disk.

Availability: Unix.

3.3 新版功能.

os.truncate(path, length)

Truncate the file corresponding to *path*, so that it is at most *length* bytes in size.

This function can support *specifying a file descriptor*.

Availability: Unix, Windows.

3.3 新版功能.

在 3.5 版更改: 添加了 Windows 支持

在 3.6 版更改: 接受一个类路径对象。

os.unlink(path, *, dir_fd=None)

Remove (delete) the file *path*. This function is semantically identical to `remove()`; the `unlink` name is its traditional Unix name. Please see the documentation for `remove()` for further information.

3.3 新版功能: The *dir_fd* parameter.

在 3.6 版更改: 接受一个类路径对象。

os.utime(path, times=None, *[ns], dir_fd=None, follow_symlinks=True)

Set the access and modified times of the file specified by *path*.

`utime()` takes two optional parameters, *times* and *ns*. These specify the times set on *path* and are used as follows:

- If *ns* is specified, it must be a 2-tuple of the form `(atime_ns, mtime_ns)` where each member is an int expressing nanoseconds.
- If *times* is not `None`, it must be a 2-tuple of the form `(atime, mtime)` where each member is an int or float expressing seconds.
- If *times* is `None` and *ns* is unspecified, this is equivalent to specifying `ns=(atime_ns, mtime_ns)` where both times are the current time.

It is an error to specify tuples for both *times* and *ns*.

Whether a directory can be given for *path* depends on whether the operating system implements directories as files (for example, Windows does not). Note that the exact times you set here may not be returned by a subsequent `stat()` call, depending on the resolution with which your operating system records access and modification times; see `stat()`. The best way to preserve exact times is to use the `st_atime_ns` and `st_mtime_ns` fields from the `os.stat()` result object with the *ns* parameter to `utime`.

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

3.3 新版功能: Added support for specifying an open file descriptor for *path*, and the *dir_fd*, *follow_symlinks*, and *ns* parameters.

在 3.6 版更改: 接受一个类路径对象。

`os.walk(top, topdown=True, onerror=None, followlinks=False)`

Generate the file names in a directory tree by walking the tree either top-down or bottom-up. For each directory in the tree rooted at directory *top* (including *top* itself), it yields a 3-tuple (*dirpath*, *dirnames*, *filenames*).

dirpath is a string, the path to the directory. *dirnames* is a list of the names of the subdirectories in *dirpath* (excluding `'.'` and `'..'`). *filenames* is a list of the names of the non-directory files in *dirpath*. Note that the names in the lists contain no path components. To get a full path (which begins with *top*) to a file or directory in *dirpath*, do `os.path.join(dirpath, name)`.

If optional argument *topdown* is `True` or not specified, the triple for a directory is generated before the triples for any of its subdirectories (directories are generated top-down). If *topdown* is `False`, the triple for a directory is generated after the triples for all of its subdirectories (directories are generated bottom-up). No matter the value of *topdown*, the list of subdirectories is retrieved before the tuples for the directory and its subdirectories are generated.

When *topdown* is `True`, the caller can modify the *dirnames* list in-place (perhaps using `del` or slice assignment), and `walk()` will only recurse into the subdirectories whose names remain in *dirnames*; this can be used to prune the search, impose a specific order of visiting, or even to inform `walk()` about directories the caller creates or renames before it resumes `walk()` again. Modifying *dirnames* when *topdown* is `False` has no effect on the behavior of the walk, because in bottom-up mode the directories in *dirnames* are generated before *dirpath* itself is generated.

By default, errors from the `scandir()` call are ignored. If optional argument *onerror* is specified, it should be a function; it will be called with one argument, an `OSError` instance. It can report the error to continue with the walk, or raise the exception to abort the walk. Note that the filename is available as the *filename* attribute of the exception object.

By default, `walk()` will not walk down into symbolic links that resolve to directories. Set *followlinks* to `True` to visit directories pointed to by symlinks, on systems that support them.

注解: Be aware that setting *followlinks* to `True` can lead to infinite recursion if a link points to a parent directory of itself. `walk()` does not keep track of the directories it visited already.

注解: If you pass a relative pathname, don't change the current working directory between resumptions of `walk()`. `walk()` never changes the current directory, and assumes that its caller doesn't either.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
from os.path import join, getsize
for root, dirs, files in os.walk('python/Lib/email'):
    print(root, "consumes", end=" ")
    print(sum(getsize(join(root, name)) for name in files), end=" ")
    print("bytes in", len(files), "non-directory files")
    if 'CVS' in dirs:
        dirs.remove('CVS') # don't visit CVS directories
```

In the next example (simple implementation of `shutil.rmtree()`), walking the tree bottom-up is essential, `rmdir()` doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION: This is dangerous! For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files in os.walk(top, topdown=False):
    for name in files:
        os.remove(os.path.join(root, name))
    for name in dirs:
        os.rmdir(os.path.join(root, name))
```

在 3.5 版更改: This function now calls `os.scandir()` instead of `os.listdir()`, making it faster by reducing the number of calls to `os.stat()`.

在 3.6 版更改: 接受一个类路径对象。

`os.fwalk` (`top='.'`, `topdown=True`, `onerror=None`, *, `follow_symlinks=False`, `dir_fd=None`)

This behaves exactly like `walk()`, except that it yields a 4-tuple (`dirpath`, `dirnames`, `filenames`, `dirfd`), and it supports `dir_fd`.

`dirpath`, `dirnames` and `filenames` are identical to `walk()` output, and `dirfd` is a file descriptor referring to the directory `dirpath`.

This function always supports *paths relative to directory descriptors* and *not following symlinks*. Note however that, unlike other functions, the `fwalk()` default value for `follow_symlinks` is `False`.

注解: Since `fwalk()` yields file descriptors, those are only valid until the next iteration step, so you should duplicate them (e.g. with `dup()`) if you want to keep them longer.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
for root, dirs, files, rootfd in os.fwalk('python/Lib/email'):
    print(root, "consumes", end=" ")
    print(sum([os.stat(name, dir_fd=rootfd).st_size for name in files]),
          end=" ")
    print("bytes in", len(files), "non-directory files")
    if 'CVS' in dirs:
        dirs.remove('CVS') # don't visit CVS directories
```

In the next example, walking the tree bottom-up is essential: `rmdir()` doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION: This is dangerous! For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files, rootfd in os.fwalk(top, topdown=False):
    for name in files:
        os.unlink(name, dir_fd=rootfd)
    for name in dirs:
        os.rmdir(name, dir_fd=rootfd)
```

Availability: Unix.

3.3 新版功能.

在 3.6 版更改: 接受一个类路径对象。

Linux extended attributes

3.3 新版功能.

These functions are all available on Linux only.

`os.getxattr(path, attribute, *, follow_symlinks=True)`

Return the value of the extended filesystem attribute *attribute* for *path*. *attribute* can be bytes or str (directly or indirectly through the *PathLike* interface). If it is str, it is encoded with the filesystem encoding.

This function can support *specifying a file descriptor* and *not following symlinks*.

在 3.6 版更改: Accepts a *path-like object* for *path* and *attribute*.

`os.listdirxattr(path=None, *, follow_symlinks=True)`

Return a list of the extended filesystem attributes on *path*. The attributes in the list are represented as strings decoded with the filesystem encoding. If *path* is None, `listxattr()` will examine the current directory.

This function can support *specifying a file descriptor* and *not following symlinks*.

在 3.6 版更改: 接受一个类路径对象。

`os.removexattr(path, attribute, *, follow_symlinks=True)`

Removes the extended filesystem attribute *attribute* from *path*. *attribute* should be bytes or str (directly or indirectly through the *PathLike* interface). If it is a string, it is encoded with the filesystem encoding.

This function can support *specifying a file descriptor* and *not following symlinks*.

在 3.6 版更改: Accepts a *path-like object* for *path* and *attribute*.

`os.setxattr(path, attribute, value, flags=0, *, follow_symlinks=True)`

Set the extended filesystem attribute *attribute* on *path* to *value*. *attribute* must be a bytes or str with no embedded NULs (directly or indirectly through the *PathLike* interface). If it is a str, it is encoded with the filesystem encoding. *flags* may be `XATTR_REPLACE` or `XATTR_CREATE`. If `XATTR_REPLACE` is given and the attribute does not exist, `EEXIST` will be raised. If `XATTR_CREATE` is given and the attribute already exists, the attribute will not be created and `ENODATA` will be raised.

This function can support *specifying a file descriptor* and *not following symlinks*.

注解: A bug in Linux kernel versions less than 2.6.39 caused the flags argument to be ignored on some filesystems.

在 3.6 版更改: Accepts a *path-like object* for *path* and *attribute*.

os.XATTR_SIZE_MAX

The maximum size the value of an extended attribute can be. Currently, this is 64 KiB on Linux.

os.XATTR_CREATE

This is a possible value for the flags argument in `setxattr()`. It indicates the operation must create an attribute.

os.XATTR_REPLACE

This is a possible value for the flags argument in `setxattr()`. It indicates the operation must replace an existing attribute.

16.1.6 Process Management

These functions may be used to create and manage processes.

The various `exec*` functions take a list of arguments for the new program loaded into the process. In each case, the first of these arguments is passed to the new program as its own name rather than as an argument a user may have typed on a command line. For the C programmer, this is the `argv[0]` passed to a program's `main()`. For example, `os.execv('/bin/echo', ['foo', 'bar'])` will only print `bar` on standard output; `foo` will seem to be ignored.

os.abort()

Generate a SIGABRT signal to the current process. On Unix, the default behavior is to produce a core dump; on Windows, the process immediately returns an exit code of 3. Be aware that calling this function will not call the Python signal handler registered for SIGABRT with `signal.signal()`.

os.execl(path, arg0, arg1, ...)**os.execle(path, arg0, arg1, ..., env)****os.execlp(file, arg0, arg1, ...)****os.execlpe(file, arg0, arg1, ..., env)****os.execv(path, args)****os.execve(path, args, env)****os.execvp(file, args)****os.execvpe(file, args, env)**

These functions all execute a new program, replacing the current process; they do not return. On Unix, the new executable is loaded into the current process, and will have the same process id as the caller. Errors will be reported as `OSError` exceptions.

The current process is replaced immediately. Open file objects and descriptors are not flushed, so if there may be data buffered on these open files, you should flush them using `sys.stdout.flush()` or `os.fsync()` before calling an `exec*` function.

The “l” and “v” variants of the `exec*` functions differ in how command-line arguments are passed. The “l” variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the `execl*()` functions. The “v” variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the `args` parameter. In either case, the arguments to the child process should start with the name of the command being run, but this is not enforced.

The variants which include a “p” near the end (`execlp()`, `execlpe()`, `execvp()`, and `execvpe()`) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the `exec*e` variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, `execl()`, `execle()`, `execv()`, and `execve()`, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For `execle()`, `execlpe()`, `execve()`, and `execvpe()` (note that these all end in “e”), the *env* parameter must be a mapping which is used to define the environment variables for the new process (these are used instead of

the current process' environment); the functions `execl()`, `execvp()`, and `execvp()` all cause the new process to inherit the environment of the current process.

For `execve()` on some platforms, *path* may also be specified as an open file descriptor. This functionality may not be supported on your platform; you can check whether or not it is available using `os.supports_fd`. If it is unavailable, using it will raise a `NotImplementedError`.

Availability: Unix, Windows.

3.3 新版功能: Added support for specifying an open file descriptor for *path* for `execve()`.

在 3.6 版更改: 接受一个类路径对象。

`os._exit(n)`

Exit the process with status *n*, without calling cleanup handlers, flushing stdio buffers, etc.

注解: The standard way to exit is `sys.exit(n)`. `_exit()` should normally only be used in the child process after a `fork()`.

The following exit codes are defined and can be used with `_exit()`, although they are not required. These are typically used for system programs written in Python, such as a mail server's external command delivery program.

注解: Some of these may not be available on all Unix platforms, since there is some variation. These constants are defined where they are defined by the underlying platform.

`os.EX_OK`

Exit code that means no error occurred.

Availability: Unix.

`os.EX_USAGE`

Exit code that means the command was used incorrectly, such as when the wrong number of arguments are given.

Availability: Unix.

`os.EX_DATAERR`

Exit code that means the input data was incorrect.

Availability: Unix.

`os.EX_NOINPUT`

Exit code that means an input file did not exist or was not readable.

Availability: Unix.

`os.EX_NOUSER`

Exit code that means a specified user did not exist.

Availability: Unix.

`os.EX_NOHOST`

Exit code that means a specified host did not exist.

Availability: Unix.

`os.EX_UNAVAILABLE`

Exit code that means that a required service is unavailable.

Availability: Unix.

os.**EX_SOFTWARE**

Exit code that means an internal software error was detected.

Availability: Unix.

os.**EX_OSERR**

Exit code that means an operating system error was detected, such as the inability to fork or create a pipe.

Availability: Unix.

os.**EX_OSFILE**

Exit code that means some system file did not exist, could not be opened, or had some other kind of error.

Availability: Unix.

os.**EX_CANTCREAT**

Exit code that means a user specified output file could not be created.

Availability: Unix.

os.**EX_IOERR**

Exit code that means that an error occurred while doing I/O on some file.

Availability: Unix.

os.**EX_TEMPFAIL**

Exit code that means a temporary failure occurred. This indicates something that may not really be an error, such as a network connection that couldn't be made during a retryable operation.

Availability: Unix.

os.**EX_PROTOCOL**

Exit code that means that a protocol exchange was illegal, invalid, or not understood.

Availability: Unix.

os.**EX_NOPERM**

Exit code that means that there were insufficient permissions to perform the operation (but not intended for file system problems).

Availability: Unix.

os.**EX_CONFIG**

Exit code that means that some kind of configuration error occurred.

Availability: Unix.

os.**EX_NOTFOUND**

Exit code that means something like “an entry was not found” .

Availability: Unix.

os.**fork()**

Fork a child process. Return 0 in the child and the child's process id in the parent. If an error occurs *OSError* is raised.

Note that some platforms including FreeBSD <= 6.3 and Cygwin have known issues when using `fork()` from a thread.

警告: See *ssl* for applications that use the SSL module with `fork()`.

Availability: Unix.

os.forkpty()

Fork a child process, using a new pseudo-terminal as the child's controlling terminal. Return a pair of (*pid*, *fd*), where *pid* is 0 in the child, the new child's process id in the parent, and *fd* is the file descriptor of the master end of the pseudo-terminal. For a more portable approach, use the *pty* module. If an error occurs *OSError* is raised.

Availability: some flavors of Unix.

os.kill(pid, sig)

Send signal *sig* to the process *pid*. Constants for the specific signals available on the host platform are defined in the *signal* module.

Windows: The *signal.CTRL_C_EVENT* and *signal.CTRL_BREAK_EVENT* signals are special signals which can only be sent to console processes which share a common console window, e.g., some subprocesses. Any other value for *sig* will cause the process to be unconditionally killed by the *TerminateProcess* API, and the exit code will be set to *sig*. The Windows version of *kill()* additionally takes process handles to be killed.

See also *signal.thread_kill()*.

3.2 新版功能: Windows support.

os.killpg(pgid, sig)

Send the signal *sig* to the process group *pgid*.

Availability: Unix.

os.nice(increment)

Add *increment* to the process's "niceness". Return the new niceness.

Availability: Unix.

os.lock(op)

Lock program segments into memory. The value of *op* (defined in *<sys/lock.h>*) determines which segments are locked.

Availability: Unix.

os.popen(cmd, mode='r', buffering=-1)

Open a pipe to or from command *cmd*. The return value is an open file object connected to the pipe, which can be read or written depending on whether *mode* is 'r' (default) or 'w'. The *buffering* argument has the same meaning as the corresponding argument to the built-in *open()* function. The returned file object reads or writes text strings rather than bytes.

The *close* method returns *None* if the subprocess exited successfully, or the subprocess's return code if there was an error. On POSIX systems, if the return code is positive it represents the return value of the process left-shifted by one byte. If the return code is negative, the process was terminated by the signal given by the negated value of the return code. (For example, the return value might be *- signal.SIGKILL* if the subprocess was killed.) On Windows systems, the return value contains the signed integer return code from the child process.

This is implemented using *subprocess.Popen*; see that class's documentation for more powerful ways to manage and communicate with subprocesses.

os.spawnl(mode, path, ...)**os.spawnle(mode, path, ..., env)****os.spawnlp(mode, file, ...)****os.spawnlpe(mode, file, ..., env)****os.spawnv(mode, path, args)****os.spawnve(mode, path, args, env)****os.spawnvp(mode, file, args)****os.spawnvpe(mode, file, args, env)**

Execute the program *path* in a new process.

(Note that the `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using these functions. Check especially the [Replacing Older Functions with the subprocess Module](#) section.)

If `mode` is `P_NOWAIT`, this function returns the process id of the new process; if `mode` is `P_WAIT`, returns the process' s exit code if it exits normally, or `-signal`, where `signal` is the signal that killed the process. On Windows, the process id will actually be the process handle, so can be used with the `waitpid()` function.

The “l” and “v” variants of the `spawn*` functions differ in how command-line arguments are passed. The “l” variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the `spawnl*()` functions. The “v” variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the `args` parameter. In either case, the arguments to the child process must start with the name of the command being run.

The variants which include a second “p” near the end (`spawnlp()`, `spawnlpe()`, `spawnvp()`, and `spawnvpe()`) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the `spawn*e` variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, `spawnl()`, `spawnle()`, `spawnv()`, and `spawnve()`, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For `spawnle()`, `spawnlpe()`, `spawnve()`, and `spawnvpe()` (note that these all end in “e”), the `env` parameter must be a mapping which is used to define the environment variables for the new process (they are used instead of the current process' environment); the functions `spawnl()`, `spawnlp()`, `spawnv()`, and `spawnvp()` all cause the new process to inherit the environment of the current process. Note that keys and values in the `env` dictionary must be strings; invalid keys or values will cause the function to fail, with a return value of 127.

As an example, the following calls to `spawnlp()` and `spawnvpe()` are equivalent:

```
import os
os.spawnlp(os.P_WAIT, 'cp', 'cp', 'index.html', '/dev/null')

L = ['cp', 'index.html', '/dev/null']
os.spawnvpe(os.P_WAIT, 'cp', L, os.environ)
```

Availability: Unix, Windows. `spawnlp()`, `spawnlpe()`, `spawnvp()` and `spawnvpe()` are not available on Windows. `spawnle()` and `spawnve()` are not thread-safe on Windows; we advise you to use the `subprocess` module instead.

在 3.6 版更改: 接受一个类路径对象。

os.P_NOWAIT

os.P_NOWAITO

Possible values for the `mode` parameter to the `spawn*` family of functions. If either of these values is given, the `spawn*()` functions will return as soon as the new process has been created, with the process id as the return value.

Availability: Unix, Windows.

os.P_WAIT

Possible value for the `mode` parameter to the `spawn*` family of functions. If this is given as `mode`, the `spawn*()` functions will not return until the new process has run to completion and will return the exit code of the process the run is successful, or `-signal` if a signal kills the process.

Availability: Unix, Windows.

os.P_DETACH

os.P_OVERLAY

Possible values for the `mode` parameter to the `spawn*` family of functions. These are less portable than those

listed above. `P_DETACH` is similar to `P_NOWAIT`, but the new process is detached from the console of the calling process. If `P_OVERLAY` is used, the current process will be replaced; the `spawn*` function will not return.

Availability: Windows.

`os.startfile(path[, operation])`

Start a file with its associated application.

When `operation` is not specified or `'open'`, this acts like double-clicking the file in Windows Explorer, or giving the file name as an argument to the `start` command from the interactive command shell: the file is opened with whatever application (if any) its extension is associated.

When another `operation` is given, it must be a “command verb” that specifies what should be done with the file. Common verbs documented by Microsoft are `'print'` and `'edit'` (to be used on files) as well as `'explore'` and `'find'` (to be used on directories).

`startfile()` returns as soon as the associated application is launched. There is no option to wait for the application to close, and no way to retrieve the application’s exit status. The `path` parameter is relative to the current directory. If you want to use an absolute path, make sure the first character is not a slash (`'/'`); the underlying Win32 `ShellExecute()` function doesn’t work if it is. Use the `os.path.normpath()` function to ensure that the path is properly encoded for Win32.

To reduce interpreter startup overhead, the Win32 `ShellExecute()` function is not resolved until this function is first called. If the function cannot be resolved, `NotImplementedError` will be raised.

Availability: Windows.

`os.system(command)`

Execute the command (a string) in a subshell. This is implemented by calling the Standard C function `system()`, and has the same limitations. Changes to `sys.stdin`, etc. are not reflected in the environment of the executed command. If `command` generates any output, it will be sent to the interpreter standard output stream.

On Unix, the return value is the exit status of the process encoded in the format specified for `wait()`. Note that POSIX does not specify the meaning of the return value of the C `system()` function, so the return value of the Python function is system-dependent.

On Windows, the return value is that returned by the system shell after running `command`. The shell is given by the Windows environment variable `COMSPEC`; it is usually `cmd.exe`, which returns the exit status of the command run; on systems using a non-native shell, consult your shell documentation.

The `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using this function. See the [Replacing Older Functions with the subprocess Module](#) section in the `subprocess` documentation for some helpful recipes.

Availability: Unix, Windows.

`os.times()`

Returns the current global process times. The return value is an object with five attributes:

- `user` - user time
- `system` - system time
- `children_user` - user time of all child processes
- `children_system` - system time of all child processes
- `elapsed` - elapsed real time since a fixed point in the past

For backwards compatibility, this object also behaves like a five-tuple containing `user`, `system`, `children_user`, `children_system`, and `elapsed` in that order.

See the Unix manual page `times(2)` or the corresponding Windows Platform API documentation. On Windows, only `user` and `system` are known; the other attributes are zero.

Availability: Unix, Windows.

在 3.3 版更改: 返回结果的类型由元组变成一个类似元组的对象, 同时具有命名的属性。

`os.wait()`

Wait for completion of a child process, and return a tuple containing its pid and exit status indication: a 16-bit number, whose low byte is the signal number that killed the process, and whose high byte is the exit status (if the signal number is zero); the high bit of the low byte is set if a core file was produced.

Availability: Unix.

`os.waitid(idtype, id, options)`

Wait for the completion of one or more child processes. *idtype* can be `P_PID`, `P_PGID` or `P_ALL`. *id* specifies the pid to wait on. *options* is constructed from the ORing of one or more of `WEXITED`, `WSTOPPED` or `WCONTINUED` and additionally may be ORed with `WNOHANG` or `WNOWAIT`. The return value is an object representing the data contained in the `siginfo_t` structure, namely: `si_pid`, `si_uid`, `si_signo`, `si_status`, `si_code` or `None` if `WNOHANG` is specified and there are no children in a waitable state.

Availability: Unix.

3.3 新版功能.

`os.P_PID`

`os.P_PGID`

`os.P_ALL`

These are the possible values for *idtype* in `waitid()`. They affect how *id* is interpreted.

Availability: Unix.

3.3 新版功能.

`os.WEXITED`

`os.WSTOPPED`

`os.WNOWAIT`

Flags that can be used in *options* in `waitid()` that specify what child signal to wait for.

Availability: Unix.

3.3 新版功能.

`os.CLD_EXITED`

`os.CLD_DUMPED`

`os.CLD_TRAPPED`

`os.CLD_CONTINUED`

These are the possible values for `si_code` in the result returned by `waitid()`.

Availability: Unix.

3.3 新版功能.

`os.waitpid(pid, options)`

The details of this function differ on Unix and Windows.

On Unix: Wait for completion of a child process given by process id *pid*, and return a tuple containing its process id and exit status indication (encoded as for `wait()`). The semantics of the call are affected by the value of the integer *options*, which should be 0 for normal operation.

If *pid* is greater than 0, `waitpid()` requests status information for that specific process. If *pid* is 0, the request is for the status of any child in the process group of the current process. If *pid* is -1, the request pertains to any child of the current process. If *pid* is less than -1, status is requested for any process in the process group -*pid* (the absolute value of *pid*).

An `OSError` is raised with the value of `errno` when the syscall returns -1.

On Windows: Wait for completion of a process given by process handle *pid*, and return a tuple containing *pid*, and its exit status shifted left by 8 bits (shifting makes cross-platform use of the function easier). A *pid* less than or equal to 0 has no special meaning on Windows, and raises an exception. The value of integer *options* has no effect. *pid* can refer to any process whose id is known, not necessarily a child process. The *spawn** functions called with *P_NOWAIT* return suitable process handles.

在 3.5 版更改: 如果系统调用被中断, 但信号处理程序没有触发异常, 此函数现在会重试系统调用, 而不是触发 *InterruptedError* 异常 (原因详见 [PEP 475](#))。

os.wait3 (options)

Similar to *waitpid()*, except no process id argument is given and a 3-element tuple containing the child's process id, exit status indication, and resource usage information is returned. Refer to *resource.getrusage()* for details on resource usage information. The option argument is the same as that provided to *waitpid()* and *wait4()*.

Availability: Unix.

os.wait4 (pid, options)

Similar to *waitpid()*, except a 3-element tuple, containing the child's process id, exit status indication, and resource usage information is returned. Refer to *resource.getrusage()* for details on resource usage information. The arguments to *wait4()* are the same as those provided to *waitpid()*.

Availability: Unix.

os.WNOHANG

The option for *waitpid()* to return immediately if no child process status is available immediately. The function returns (0, 0) in this case.

Availability: Unix.

os.WCONTINUED

This option causes child processes to be reported if they have been continued from a job control stop since their status was last reported.

Availability: some Unix systems.

os.WUNTRACED

This option causes child processes to be reported if they have been stopped but their current state has not been reported since they were stopped.

Availability: Unix.

The following functions take a process status code as returned by *system()*, *wait()*, or *waitpid()* as a parameter. They may be used to determine the disposition of a process.

os.WCOREDUMP (status)

Return True if a core dump was generated for the process, otherwise return False.

Availability: Unix.

os.WIFCONTINUED (status)

Return True if the process has been continued from a job control stop, otherwise return False.

Availability: Unix.

os.WIFSTOPPED (status)

Return True if the process has been stopped, otherwise return False.

Availability: Unix.

os.WIFSIGNALED (status)

Return True if the process exited due to a signal, otherwise return False.

Availability: Unix.

`os.WIFEXITED(status)`

Return `True` if the process exited using the `exit(2)` system call, otherwise return `False`.

Availability: Unix.

`os.WEXITSTATUS(status)`

If `WIFEXITED(status)` is true, return the integer parameter to the `exit(2)` system call. Otherwise, the return value is meaningless.

Availability: Unix.

`os.WSTOPSIG(status)`

Return the signal which caused the process to stop.

Availability: Unix.

`os.WTERMSIG(status)`

Return the signal which caused the process to exit.

Availability: Unix.

16.1.7 Interface to the scheduler

These functions control how a process is allocated CPU time by the operating system. They are only available on some Unix platforms. For more detailed information, consult your Unix manpages.

3.3 新版功能.

The following scheduling policies are exposed if they are supported by the operating system.

`os.SCHED_OTHER`

The default scheduling policy.

`os.SCHED_BATCH`

Scheduling policy for CPU-intensive processes that tries to preserve interactivity on the rest of the computer.

`os.SCHED_IDLE`

Scheduling policy for extremely low priority background tasks.

`os.SCHED_SPORADIC`

Scheduling policy for sporadic server programs.

`os.SCHED_FIFO`

A First In First Out scheduling policy.

`os.SCHED_RR`

A round-robin scheduling policy.

`os.SCHED_RESET_ON_FORK`

This flag can be OR'ed with any other scheduling policy. When a process with this flag set forks, its child's scheduling policy and priority are reset to the default.

class `os.sched_param(sched_priority)`

This class represents tunable scheduling parameters used in `sched_setparam()`, `sched_setscheduler()`, and `sched_getparam()`. It is immutable.

At the moment, there is only one possible parameter:

`sched_priority`

The scheduling priority for a scheduling policy.

`os.sched_get_priority_min(policy)`

Get the minimum priority value for *policy*. *policy* is one of the scheduling policy constants above.

- `os.sched_get_priority_max(policy)`
Get the maximum priority value for *policy*. *policy* is one of the scheduling policy constants above.
- `os.sched_setscheduler(pid, policy, param)`
Set the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. *policy* is one of the scheduling policy constants above. *param* is a *sched_param* instance.
- `os.sched_getscheduler(pid)`
Return the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. The result is one of the scheduling policy constants above.
- `os.sched_setparam(pid, param)`
Set a scheduling parameters for the process with PID *pid*. A *pid* of 0 means the calling process. *param* is a *sched_param* instance.
- `os.sched_getparam(pid)`
Return the scheduling parameters as a *sched_param* instance for the process with PID *pid*. A *pid* of 0 means the calling process.
- `os.sched_rr_get_interval(pid)`
Return the round-robin quantum in seconds for the process with PID *pid*. A *pid* of 0 means the calling process.
- `os.sched_yield()`
Voluntarily relinquish the CPU.
- `os.sched_setaffinity(pid, mask)`
Restrict the process with PID *pid* (or the current process if zero) to a set of CPUs. *mask* is an iterable of integers representing the set of CPUs to which the process should be restricted.
- `os.sched_getaffinity(pid)`
Return the set of CPUs the process with PID *pid* (or the current process if zero) is restricted to.

16.1.8 Miscellaneous System Information

- `os.confstr(name)`
Return string-valued system configuration values. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given as the keys of the `confstr_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If the configuration value specified by *name* isn't defined, `None` is returned.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `confstr_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

Availability: Unix.
- `os.confstr_names`
Dictionary mapping names accepted by `confstr()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.
- `os.cpu_count()`
Return the number of CPUs in the system. Returns `None` if undetermined.

该数量不同于当前进程可以使用的 CPU 数量。可用的 CPU 数量可以由 `len(os.sched_getaffinity(0))` 方法获得。

3.4 新版功能.

os.getloadavg()

Return the number of processes in the system run queue averaged over the last 1, 5, and 15 minutes or raises *OSError* if the load average was unobtainable.

Availability: Unix.

os.sysconf(name)

Return integer-valued system configuration values. If the configuration value specified by *name* isn't defined, -1 is returned. The comments regarding the *name* parameter for *confstr()* apply here as well; the dictionary that provides information on the known names is given by *sysconf_names*.

Availability: Unix.

os.sysconf_names

Dictionary mapping names accepted by *sysconf()* to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

The following data values are used to support path manipulation operations. These are defined for all platforms.

Higher-level operations on pathnames are defined in the *os.path* module.

os.curdir

The constant string used by the operating system to refer to the current directory. This is *'.'* for Windows and POSIX. Also available via *os.path*.

os.pardir

The constant string used by the operating system to refer to the parent directory. This is *'..'* for Windows and POSIX. Also available via *os.path*.

os.sep

The character used by the operating system to separate pathname components. This is *'/'* for POSIX and *'\\'* for Windows. Note that knowing this is not sufficient to be able to parse or concatenate pathnames —use *os.path.split()* and *os.path.join()* —but it is occasionally useful. Also available via *os.path*.

os.altsep

An alternative character used by the operating system to separate pathname components, or *None* if only one separator character exists. This is set to *'/'* on Windows systems where *sep* is a backslash. Also available via *os.path*.

os.extsep

The character which separates the base filename from the extension; for example, the *'.'* in *os.py*. Also available via *os.path*.

os.pathsep

The character conventionally used by the operating system to separate search path components (as in *PATH*), such as *':'* for POSIX or *';'* for Windows. Also available via *os.path*.

os.defpath

The default search path used by *exec*p** and *spawn*p** if the environment doesn't have a *'PATH'* key. Also available via *os.path*.

os.linesep

The string used to separate (or, rather, terminate) lines on the current platform. This may be a single character, such as *'\n'* for POSIX, or multiple characters, for example, *'\r\n'* for Windows. Do not use *os.linesep* as a line terminator when writing files opened in text mode (the default); use a single *'\n'* instead, on all platforms.

os.devnull

The file path of the null device. For example: `'/dev/null'` for POSIX, `'nul'` for Windows. Also available via `os.path`.

os.RTLD_LAZY**os.RTLD_NOW****os.RTLD_GLOBAL****os.RTLD_LOCAL****os.RTLD_NODELETE****os.RTLD_NOLOAD****os.RTLD_DEEPBIND**

Flags for use with the `setdlopenflags()` and `getdlopenflags()` functions. See the Unix manual page `dlopen(3)` for what the different flags mean.

3.3 新版功能.

16.1.9 Random numbers

os.getrandom(size, flags=0)

Get up to *size* random bytes. The function can return less bytes than requested.

These bytes can be used to seed user-space random number generators or for cryptographic purposes.

`getrandom()` relies on entropy gathered from device drivers and other sources of environmental noise. Unnecessarily reading large quantities of data will have a negative impact on other users of the `/dev/random` and `/dev/urandom` devices.

The flags argument is a bit mask that can contain zero or more of the following values ORed together: `os.GRND_RANDOM` and `GRND_NONBLOCK`.

See also the [Linux getrandom\(\) manual page](#).

Availability: Linux 3.17 and newer.

3.6 新版功能.

os.urandom(size)

Return a string of *size* random bytes suitable for cryptographic use.

This function returns random bytes from an OS-specific randomness source. The returned data should be unpredictable enough for cryptographic applications, though its exact quality depends on the OS implementation.

On Linux, if the `getrandom()` syscall is available, it is used in blocking mode: block until the system urandom entropy pool is initialized (128 bits of entropy are collected by the kernel). See the [PEP 524](#) for the rationale. On Linux, the `getrandom()` function can be used to get random bytes in non-blocking mode (using the `GRND_NONBLOCK` flag) or to poll until the system urandom entropy pool is initialized.

On a Unix-like system, random bytes are read from the `/dev/urandom` device. If the `/dev/urandom` device is not available or not readable, the `NotImplementedError` exception is raised.

On Windows, it will use `CryptGenRandom()`.

参见:

The `secrets` module provides higher level functions. For an easy-to-use interface to the random number generator provided by your platform, please see `random.SystemRandom`.

在 3.6.0 版更改: On Linux, `getrandom()` is now used in blocking mode to increase the security.

在 3.5.2 版更改: On Linux, if the `getrandom()` syscall blocks (the urandom entropy pool is not initialized yet), fall back on reading `/dev/urandom`.

在 3.5 版更改: On Linux 3.17 and newer, the `getrandom()` syscall is now used when available. On OpenBSD 5.6 and newer, the C `getentropy()` function is now used. These functions avoid the usage of an internal file descriptor.

`os.GRND_NONBLOCK`

By default, when reading from `/dev/random`, `getrandom()` blocks if no random bytes are available, and when reading from `/dev/urandom`, it blocks if the entropy pool has not yet been initialized.

If the `GRND_NONBLOCK` flag is set, then `getrandom()` does not block in these cases, but instead immediately raises `BlockingIOError`.

3.6 新版功能.

`os.GRND_RANDOM`

If this bit is set, then random bytes are drawn from the `/dev/random` pool instead of the `/dev/urandom` pool.

3.6 新版功能.

16.2 `io` — 处理流的核心工具

源代码: [Lib/io.py](#)

16.2.1 概述

`io` 模块提供了 Python 用于处理各种 I/O 类型的主要工具。三种主要的 I/O 类型分别为: 文本 I/O, 二进制 I/O 和 原始 I/O。这些是泛型类型, 有很多种后端存储可以用在他们上面。一个隶属于任何这些类型的具体对象被称作 *file object*。其他同类的术语还有 流和 类文件对象。

独立于其类别, 每个具体流对象也将具有各种功能: 它可以是只读, 只写或读写。它还可以允许任意随机访问 (向前或向后寻找任何位置), 或仅允许顺序访问 (例如在套接字或管道的情况下)。

All streams are careful about the type of data you give to them. For example giving a `str` object to the `write()` method of a binary stream will raise a `TypeError`. So will giving a `bytes` object to the `write()` method of a text stream.

在 3.3 版更改: Operations that used to raise `IOError` now raise `OSError`, since `IOError` is now an alias of `OSError`.

Text I/O

Text I/O expects and produces `str` objects. This means that whenever the backing store is natively made of bytes (such as in the case of a file), encoding and decoding of data is made transparently as well as optional translation of platform-specific newline characters.

The easiest way to create a text stream is with `open()`, optionally specifying an encoding:

```
f = open("myfile.txt", "r", encoding="utf-8")
```

In-memory text streams are also available as `StringIO` objects:

```
f = io.StringIO("some initial text data")
```

The text stream API is described in detail in the documentation of `TextIOBase`.

Binary I/O

Binary I/O (also called *buffered I/O*) expects *bytes-like objects* and produces *bytes* objects. No encoding, decoding, or newline translation is performed. This category of streams can be used for all kinds of non-text data, and also when manual control over the handling of text data is desired.

The easiest way to create a binary stream is with `open()` with 'b' in the mode string:

```
f = open("myfile.jpg", "rb")
```

In-memory binary streams are also available as *BytesIO* objects:

```
f = io.BytesIO(b"some initial binary data: \x00\x01")
```

The binary stream API is described in detail in the docs of *BufferedIOBase*.

Other library modules may provide additional ways to create text or binary streams. See `socket.socket.makefile()` for example.

Raw I/O

Raw I/O (also called *unbuffered I/O*) is generally used as a low-level building-block for binary and text streams; it is rarely useful to directly manipulate a raw stream from user code. Nevertheless, you can create a raw stream by opening a file in binary mode with buffering disabled:

```
f = open("myfile.jpg", "rb", buffering=0)
```

The raw stream API is described in detail in the docs of *RawIOBase*.

16.2.2 High-level Module Interface

`io.DEFAULT_BUFFER_SIZE`

An int containing the default buffer size used by the module's buffered I/O classes. `open()` uses the file's blksize (as obtained by `os.stat()`) if possible.

`io.open(file, mode='r', buffering=-1, encoding=None, errors=None, newline=None, closefd=True, opener=None)`

This is an alias for the builtin `open()` function.

`exception io.BlockingIOError`

This is a compatibility alias for the builtin *BlockingIOError* exception.

`exception io.UnsupportedOperation`

An exception inheriting *OSError* and *ValueError* that is raised when an unsupported operation is called on a stream.

In-memory streams

It is also possible to use a *str* or *bytes-like object* as a file for both reading and writing. For strings *StringIO* can be used like a file opened in text mode. *BytesIO* can be used like a file opened in binary mode. Both provide full read-write capabilities with random access.

参见:

sys contains the standard IO streams: `sys.stdin`, `sys.stdout`, and `sys.stderr`.

16.2.3 Class hierarchy

The implementation of I/O streams is organized as a hierarchy of classes. First *abstract base classes* (ABCs), which are used to specify the various categories of streams, then concrete classes providing the standard stream implementations.

注解: The abstract base classes also provide default implementations of some methods in order to help implementation of concrete stream classes. For example, *BufferedIOBase* provides unoptimized implementations of `readinto()` and `readline()`.

At the top of the I/O hierarchy is the abstract base class *IOBase*. It defines the basic interface to a stream. Note, however, that there is no separation between reading and writing to streams; implementations are allowed to raise *UnsupportedOperation* if they do not support a given operation.

The *RawIOBase* ABC extends *IOBase*. It deals with the reading and writing of bytes to a stream. *FileIO* subclasses *RawIOBase* to provide an interface to files in the machine's file system.

The *BufferedIOBase* ABC deals with buffering on a raw byte stream (*RawIOBase*). Its subclasses, *BufferedWriter*, *BufferedReader*, and *BufferedRWPair* buffer streams that are readable, writable, and both readable and writable. *BufferedRandom* provides a buffered interface to random access streams. Another *BufferedIOBase* subclass, *BytesIO*, is a stream of in-memory bytes.

The *TextIOBase* ABC, another subclass of *IOBase*, deals with streams whose bytes represent text, and handles encoding and decoding to and from strings. *TextIOWrapper*, which extends it, is a buffered text interface to a buffered raw stream (*BufferedIOBase*). Finally, *StringIO* is an in-memory stream for text.

Argument names are not part of the specification, and only the arguments of `open()` are intended to be used as keyword arguments.

The following table summarizes the ABCs provided by the *io* module:

ABC	Inherits	Stub Methods	Mixin Methods and Properties
<i>IOBase</i>		<code>fileno</code> , <code>seek</code> , 和 <code>truncate</code>	<code>close</code> , <code>closed</code> , <code>__enter__</code> , <code>__exit__</code> , <code>flush</code> , <code>isatty</code> , <code>__iter__</code> , <code>__next__</code> , <code>readable</code> , <code>readline</code> , <code>readlines</code> , <code>seekable</code> , <code>tell</code> , <code>writable</code> , 和 <code>writelines</code>
<i>RawIOBase</i>	<i>IOBase</i>	<code>readinto</code> 和 <code>write</code>	Inherited <i>IOBase</i> methods, <code>read</code> , and <code>readall</code>
<i>BufferedIOBase</i>	<i>IOBase</i>	<code>detach</code> , <code>read</code> , <code>read1</code> , 和 <code>write</code>	Inherited <i>IOBase</i> methods, <code>readinto</code> , and <code>readinto1</code>
<i>TextIOBase</i>	<i>IOBase</i>	<code>detach</code> , <code>read</code> , <code>readline</code> , 和 <code>write</code>	Inherited <i>IOBase</i> methods, <code>encoding</code> , <code>errors</code> , and <code>newlines</code>

I/O Base Classes

class `io.IOBase`

The abstract base class for all I/O classes, acting on streams of bytes. There is no public constructor.

This class provides empty abstract implementations for many methods that derived classes can override selectively; the default implementations represent a file that cannot be read, written or seeked.

Even though `IOBase` does not declare `read()`, `readinto()`, or `write()` because their signatures will vary, implementations and clients should consider those methods part of the interface. Also, implementations may raise a `ValueError` (or `UnsupportedOperation`) when operations they do not support are called.

The basic type used for binary data read from or written to a file is `bytes`. Other *bytes-like objects* are accepted as method arguments too. In some cases, such as `readinto()`, a writable object such as `bytearray` is required. Text I/O classes work with `str` data.

Note that calling any method (even inquiries) on a closed stream is undefined. Implementations may raise `ValueError` in this case.

`IOBase` (and its subclasses) supports the iterator protocol, meaning that an `IOBase` object can be iterated over yielding the lines in a stream. Lines are defined slightly differently depending on whether the stream is a binary stream (yielding bytes), or a text stream (yielding character strings). See `readline()` below.

`IOBase` is also a context manager and therefore supports the `with` statement. In this example, `file` is closed after the `with` statement's suite is finished—even if an exception occurs:

```
with open('spam.txt', 'w') as file:
    file.write('Spam and eggs!')
```

`IOBase` provides these data attributes and methods:

close()

Flush and close this stream. This method has no effect if the file is already closed. Once the file is closed, any operation on the file (e.g. reading or writing) will raise a `ValueError`.

As a convenience, it is allowed to call this method more than once; only the first call, however, will have an effect.

closed

True if the stream is closed.

fileno()

Return the underlying file descriptor (an integer) of the stream if it exists. An `OSError` is raised if the IO object does not use a file descriptor.

flush()

Flush the write buffers of the stream if applicable. This does nothing for read-only and non-blocking streams.

isatty()

Return True if the stream is interactive (i.e., connected to a terminal/tty device).

readable()

Return True if the stream can be read from. If False, `read()` will raise `OSError`.

readline (size=-1)

Read and return one line from the stream. If `size` is specified, at most `size` bytes will be read.

The line terminator is always `b'\n'` for binary files; for text files, the `newline` argument to `open()` can be used to select the line terminator(s) recognized.

readlines (hint=-1)

Read and return a list of lines from the stream. `hint` can be specified to control the number of lines read: no more lines will be read if the total size (in bytes/characters) of all lines so far exceeds `hint`.

Note that it's already possible to iterate on file objects using `for line in file: ...` without calling `file.readlines()`.

seek (offset[, whence])

Change the stream position to the given byte `offset`. `offset` is interpreted relative to the position indicated by `whence`. The default value for `whence` is `SEEK_SET`. Values for `whence` are:

- `SEEK_SET` or 0 – start of the stream (the default); *offset* should be zero or positive
- `SEEK_CUR` or 1 – current stream position; *offset* may be negative
- `SEEK_END` or 2 – end of the stream; *offset* is usually negative

Return the new absolute position.

3.1 新版功能: The `SEEK_*` constants.

3.3 新版功能: Some operating systems could support additional values, like `os.SEEK_HOLE` or `os.SEEK_DATA`. The valid values for a file could depend on it being open in text or binary mode.

seekable()

Return True if the stream supports random access. If False, `seek()`, `tell()` and `truncate()` will raise `OSError`.

tell()

Return the current stream position.

truncate(size=None)

Resize the stream to the given *size* in bytes (or the current position if *size* is not specified). The current stream position isn't changed. This resizing can extend or reduce the current file size. In case of extension, the contents of the new file area depend on the platform (on most systems, additional bytes are zero-filled). The new file size is returned.

在 3.5 版更改: Windows will now zero-fill files when extending.

writable()

Return True if the stream supports writing. If False, `write()` and `truncate()` will raise `OSError`.

writelines(lines)

Write a list of lines to the stream. Line separators are not added, so it is usual for each of the lines provided to have a line separator at the end.

__del__()

Prepare for object destruction. `IOBase` provides a default implementation of this method that calls the instance's `close()` method.

class io.RawIOBase

Base class for raw binary I/O. It inherits `IOBase`. There is no public constructor.

Raw binary I/O typically provides low-level access to an underlying OS device or API, and does not try to encapsulate it in high-level primitives (this is left to Buffered I/O and Text I/O, described later in this page).

In addition to the attributes and methods from `IOBase`, `RawIOBase` provides the following methods:

read(size=-1)

Read up to *size* bytes from the object and return them. As a convenience, if *size* is unspecified or -1, all bytes until EOF are returned. Otherwise, only one system call is ever made. Fewer than *size* bytes may be returned if the operating system call returns fewer than *size* bytes.

If 0 bytes are returned, and *size* was not 0, this indicates end of file. If the object is in non-blocking mode and no bytes are available, `None` is returned.

The default implementation defers to `readall()` and `readinto()`.

readall()

Read and return all the bytes from the stream until EOF, using multiple calls to the stream if necessary.

readinto(b)

Read bytes into a pre-allocated, writable *bytes-like object* *b*, and return the number of bytes read. If the object is in non-blocking mode and no bytes are available, `None` is returned.

write(*b*)

Write the given *bytes-like object*, *b*, to the underlying raw stream, and return the number of bytes written. This can be less than the length of *b* in bytes, depending on specifics of the underlying raw stream, and especially if it is in non-blocking mode. *None* is returned if the raw stream is set not to block and no single byte could be readily written to it. The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

class io.BufferedIOBase

Base class for binary streams that support some kind of buffering. It inherits *IOBase*. There is no public constructor.

The main difference with *RawIOBase* is that methods *read()*, *readinto()* and *write()* will try (respectively) to read as much input as requested or to consume all given output, at the expense of making perhaps more than one system call.

In addition, those methods can raise *BlockingIOError* if the underlying raw stream is in non-blocking mode and cannot take or give enough data; unlike their *RawIOBase* counterparts, they will never return *None*.

Besides, the *read()* method does not have a default implementation that defers to *readinto()*.

A typical *BufferedIOBase* implementation should not inherit from a *RawIOBase* implementation, but wrap one, like *BufferedWriter* and *BufferedReader* do.

BufferedIOBase provides or overrides these methods and attribute in addition to those from *IOBase*:

raw

The underlying raw stream (a *RawIOBase* instance) that *BufferedIOBase* deals with. This is not part of the *BufferedIOBase* API and may not exist on some implementations.

detach()

Separate the underlying raw stream from the buffer and return it.

After the raw stream has been detached, the buffer is in an unusable state.

Some buffers, like *BytesIO*, do not have the concept of a single raw stream to return from this method. They raise *UnsupportedOperation*.

3.1 新版功能.

read(*size=-1*)

Read and return up to *size* bytes. If the argument is omitted, *None*, or negative, data is read and returned until EOF is reached. An empty *bytes* object is returned if the stream is already at EOF.

If the argument is positive, and the underlying raw stream is not interactive, multiple raw reads may be issued to satisfy the byte count (unless EOF is reached first). But for interactive raw streams, at most one raw read will be issued, and a short result does not imply that EOF is imminent.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

read1(*size=-1*)

Read and return up to *size* bytes, with at most one call to the underlying raw stream's *read()* (or *readinto()*) method. This can be useful if you are implementing your own buffering on top of a *BufferedIOBase* object.

readinto(*b*)

Read bytes into a pre-allocated, writable *bytes-like object* *b* and return the number of bytes read.

Like *read()*, multiple reads may be issued to the underlying raw stream, unless the latter is interactive.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

readinto1(b)

Read bytes into a pre-allocated, writable *bytes-like object* *b*, using at most one call to the underlying raw stream's *read()* (or *readinto()*) method. Return the number of bytes read.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

3.5 新版功能.

write(b)

Write the given *bytes-like object*, *b*, and return the number of bytes written (always equal to the length of *b* in bytes, since if the write fails an *OSError* will be raised). Depending on the actual implementation, these bytes may be readily written to the underlying stream, or held in a buffer for performance and latency reasons.

When in non-blocking mode, a *BlockingIOError* is raised if the data needed to be written to the raw stream but it couldn't accept all the data without blocking.

The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

Raw File I/O

class `io.FileIO(name, mode='r', closefd=True, opener=None)`

FileIO represents an OS-level file containing bytes data. It implements the *RawIOBase* interface (and therefore the *IOBase* interface, too).

The *name* can be one of two things:

- a character string or *bytes* object representing the path to the file which will be opened. In this case *closefd* must be *True* (the default) otherwise an error will be raised.
- an integer representing the number of an existing OS-level file descriptor to which the resulting *FileIO* object will give access. When the *FileIO* object is closed this *fd* will be closed as well, unless *closefd* is set to *False*.

The *mode* can be 'r', 'w', 'x' or 'a' for reading (default), writing, exclusive creation or appending. The file will be created if it doesn't exist when opened for writing or appending; it will be truncated when opened for writing. *FileExistsError* will be raised if it already exists when opened for creating. Opening a file for creating implies writing, so this mode behaves in a similar way to 'w'. Add a '+' to the mode to allow simultaneous reading and writing.

The *read()* (when called with a positive argument), *readinto()* and *write()* methods on this class will only make one system call.

A custom opener can be used by passing a callable as *opener*. The underlying file descriptor for the file object is then obtained by calling *opener* with (*name*, *flags*). *opener* must return an open file descriptor (passing *os.open* as *opener* results in functionality similar to passing *None*).

新创建的文件是不可继承的。

See the *open()* built-in function for examples on using the *opener* parameter.

在 3.3 版更改: The *opener* parameter was added. The 'x' mode was added.

在 3.4 版更改: 文件现在禁止继承。

In addition to the attributes and methods from *IOBase* and *RawIOBase*, *FileIO* provides the following data attributes:

mode

The mode as given in the constructor.

name

The file name. This is the file descriptor of the file when no name is given in the constructor.

Buffered Streams

Buffered I/O streams provide a higher-level interface to an I/O device than raw I/O does.

class `io.BytesIO([initial_bytes])`

A stream implementation using an in-memory bytes buffer. It inherits `BufferedIOBase`. The buffer is discarded when the `close()` method is called.

The optional argument `initial_bytes` is a *bytes-like object* that contains initial data.

`BytesIO` provides or overrides these methods in addition to those from `BufferedIOBase` and `IOBase`:

getbuffer()

Return a readable and writable view over the contents of the buffer without copying them. Also, mutating the view will transparently update the contents of the buffer:

```
>>> b = io.BytesIO(b"abcdef")
>>> view = b.getbuffer()
>>> view[2:4] = b"56"
>>> b.getvalue()
b'ab56ef'
```

注解: As long as the view exists, the `BytesIO` object cannot be resized or closed.

3.2 新版功能.

getvalue()

Return *bytes* containing the entire contents of the buffer.

read1()

In `BytesIO`, this is the same as `read()`.

readinto1()

In `BytesIO`, this is the same as `readinto()`.

3.5 新版功能.

class `io.BufferedReader(raw, buffer_size=DEFAULT_BUFFER_SIZE)`

A buffer providing higher-level access to a readable, sequential `RawIOBase` object. It inherits `BufferedIOBase`. When reading data from this object, a larger amount of data may be requested from the underlying raw stream, and kept in an internal buffer. The buffered data can then be returned directly on subsequent reads.

The constructor creates a `BufferedReader` for the given readable `raw` stream and `buffer_size`. If `buffer_size` is omitted, `DEFAULT_BUFFER_SIZE` is used.

`BufferedReader` provides or overrides these methods in addition to those from `BufferedIOBase` and `IOBase`:

peek([size])

Return bytes from the stream without advancing the position. At most one single read on the raw stream is done to satisfy the call. The number of bytes returned may be less or more than requested.

read([size])

Read and return `size` bytes, or if `size` is not given or negative, until EOF or if the read call would block in non-blocking mode.

read1 (*size*)

Read and return up to *size* bytes with only one call on the raw stream. If at least one byte is buffered, only buffered bytes are returned. Otherwise, one raw stream read call is made.

class `io.BufferedWriter` (*raw*, *buffer_size*=`DEFAULT_BUFFER_SIZE`)

A buffer providing higher-level access to a writeable, sequential `RawIOBase` object. It inherits `BufferedIOBase`. When writing to this object, data is normally placed into an internal buffer. The buffer will be written out to the underlying `RawIOBase` object under various conditions, including:

- when the buffer gets too small for all pending data;
- when `flush()` is called;
- when a `seek()` is requested (for `BufferedRandom` objects);
- when the `BufferedWriter` object is closed or destroyed.

The constructor creates a `BufferedWriter` for the given writeable *raw* stream. If the *buffer_size* is not given, it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedWriter` provides or overrides these methods in addition to those from `BufferedIOBase` and `IOBase`:

flush ()

Force bytes held in the buffer into the raw stream. A `BlockingIOError` should be raised if the raw stream blocks.

write (*b*)

Write the *bytes-like object*, *b*, and return the number of bytes written. When in non-blocking mode, a `BlockingIOError` is raised if the buffer needs to be written out but the raw stream blocks.

class `io.BufferedReader` (*raw*, *buffer_size*=`DEFAULT_BUFFER_SIZE`)

A buffered interface to random access streams. It inherits `BufferedReader` and `BufferedWriter`, and further supports `seek()` and `tell()` functionality.

The constructor creates a reader and writer for a seekable raw stream, given in the first argument. If the *buffer_size* is omitted it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedReader` is capable of anything `BufferedReader` or `BufferedWriter` can do.

class `io.BufferedRWPair` (*reader*, *writer*, *buffer_size*=`DEFAULT_BUFFER_SIZE`)

A buffered I/O object combining two unidirectional `RawIOBase` objects – one readable, the other writeable – into a single bidirectional endpoint. It inherits `BufferedIOBase`.

reader and *writer* are `RawIOBase` objects that are readable and writeable respectively. If the *buffer_size* is omitted it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedRWPair` implements all of `BufferedIOBase`'s methods except for `detach()`, which raises `UnsupportedOperation`.

警告: `BufferedRWPair` does not attempt to synchronize accesses to its underlying raw streams. You should not pass it the same object as reader and writer; use `BufferedReader` instead.

Text I/O

class `io.TextIOBase`

Base class for text streams. This class provides a character and line based interface to stream I/O. There is no `readinto()` method because Python's character strings are immutable. It inherits `IOBase`. There is no public constructor.

TextIOBase provides or overrides these data attributes and methods in addition to those from *IOBase*:

encoding

The name of the encoding used to decode the stream's bytes into strings, and to encode strings into bytes.

errors

The error setting of the decoder or encoder.

newlines

A string, a tuple of strings, or *None*, indicating the newlines translated so far. Depending on the implementation and the initial constructor flags, this may not be available.

buffer

The underlying binary buffer (a *BufferedIOBase* instance) that *TextIOBase* deals with. This is not part of the *TextIOBase* API and may not exist in some implementations.

detach()

Separate the underlying binary buffer from the *TextIOBase* and return it.

After the underlying buffer has been detached, the *TextIOBase* is in an unusable state.

Some *TextIOBase* implementations, like *StringIO*, may not have the concept of an underlying buffer and calling this method will raise *UnsupportedOperation*.

3.1 新版功能.

read(size=-1)

Read and return at most *size* characters from the stream as a single *str*. If *size* is negative or *None*, reads until EOF.

readline(size=-1)

Read until newline or EOF and return a single *str*. If the stream is already at EOF, an empty string is returned.

If *size* is specified, at most *size* characters will be read.

seek(offset[, whence])

Change the stream position to the given *offset*. Behaviour depends on the *whence* parameter. The default value for *whence* is *SEEK_SET*.

- *SEEK_SET* or 0: seek from the start of the stream (the default); *offset* must either be a number returned by *TextIOBase.tell()*, or zero. Any other *offset* value produces undefined behaviour.
- *SEEK_CUR* or 1: “seek” to the current position; *offset* must be zero, which is a no-operation (all other values are unsupported).
- *SEEK_END* or 2: seek to the end of the stream; *offset* must be zero (all other values are unsupported).

Return the new absolute position as an opaque number.

3.1 新版功能: The *SEEK_** constants.

tell()

Return the current stream position as an opaque number. The number does not usually represent a number of bytes in the underlying binary storage.

write(s)

Write the string *s* to the stream and return the number of characters written.

class io.TextIOWrapper(buffer, encoding=None, errors=None, newline=None, line_buffering=False, write_through=False)

A buffered text stream over a *BufferedIOBase* binary stream. It inherits *TextIOBase*.

encoding gives the name of the encoding that the stream will be decoded or encoded with. It defaults to *locale.getpreferredencoding(False)*.

errors is an optional string that specifies how encoding and decoding errors are to be handled. Pass `'strict'` to raise a `ValueError` exception if there is an encoding error (the default of `None` has the same effect), or pass `'ignore'` to ignore errors. (Note that ignoring encoding errors can lead to data loss.) `'replace'` causes a replacement marker (such as `'?'`) to be inserted where there is malformed data. `'backslashreplace'` causes malformed data to be replaced by a backslashed escape sequence. When writing, `'xmlcharrefreplace'` (replace with the appropriate XML character reference) or `'namereplace'` (replace with `\N{...}` escape sequences) can be used. Any other error handling name that has been registered with `codecs.register_error()` is also valid.

newline controls how line endings are handled. It can be `None`, `''`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows:

- When reading input from the stream, if *newline* is `None`, *universal newlines* mode is enabled. Lines in the input can end in `'\n'`, `'\r'`, or `'\r\n'`, and these are translated into `'\n'` before being returned to the caller. If it is `''`, universal newlines mode is enabled, but line endings are returned to the caller untranslated. If it has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- 将输出写入流时，如果 *newline* 为 `None`，则写入的任何 `'\n'` 字符都将转换为系统默认行分隔符 `os.linesep`。如果 *newline* 是 `''` 或 `'\n'`，则不进行翻译。如果 *newline* 是任何其他合法值，则写入的任何 `'\n'` 字符将被转换为给定的字符串。

If *line_buffering* is `True`, `flush()` is implied when a call to write contains a newline character or a carriage return.

If *write_through* is `True`, calls to `write()` are guaranteed not to be buffered: any data written on the `TextIOWrapper` object is immediately handled to its underlying binary *buffer*.

在 3.3 版更改: The *write_through* argument has been added.

在 3.3 版更改: The default *encoding* is now `locale.getpreferredencoding(False)` instead of `locale.getpreferredencoding()`. Don't change temporary the locale encoding using `locale.setlocale()`, use the current locale encoding instead of the user preferred encoding.

`TextIOWrapper` provides one attribute in addition to those of `TextIOBase` and its parents:

line_buffering

Whether line buffering is enabled.

class `io.StringIO` (*initial_value*="", *newline*='\n')

An in-memory stream for text I/O. The text buffer is discarded when the `close()` method is called.

The initial value of the buffer can be set by providing *initial_value*. If newline translation is enabled, newlines will be encoded as if by `write()`. The stream is positioned at the start of the buffer.

The *newline* argument works like that of `TextIOWrapper`. The default is to consider only `\n` characters as ends of lines and to do no newline translation. If *newline* is set to `None`, newlines are written as `\n` on all platforms, but universal newline decoding is still performed when reading.

`StringIO` provides this method in addition to those from `TextIOBase` and its parents:

getvalue()

Return a `str` containing the entire contents of the buffer. Newlines are decoded as if by `read()`, although the stream position is not changed.

Example usage:

```
import io

output = io.StringIO()
output.write('First line.\n')
```

(下页继续)

(续上页)

```
print('Second line.', file=output)

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

class io.IncrementalNewlineDecoder

A helper codec that decodes newlines for *universal newlines* mode. It inherits *codecs.IncrementalDecoder*.

16.2.4 性能

This section discusses the performance of the provided concrete I/O implementations.

Binary I/O

By reading and writing only large chunks of data even when the user asks for a single byte, buffered I/O hides any inefficiency in calling and executing the operating system's unbuffered I/O routines. The gain depends on the OS and the kind of I/O which is performed. For example, on some modern OSes such as Linux, unbuffered disk I/O can be as fast as buffered I/O. The bottom line, however, is that buffered I/O offers predictable performance regardless of the platform and the backing device. Therefore, it is almost always preferable to use buffered I/O rather than unbuffered I/O for binary data.

Text I/O

Text I/O over a binary storage (such as a file) is significantly slower than binary I/O over the same storage, because it requires conversions between unicode and binary data using a character codec. This can become noticeable handling huge amounts of text data like large log files. Also, `TextIOWrapper.tell()` and `TextIOWrapper.seek()` are both quite slow due to the reconstruction algorithm used.

StringIO, however, is a native in-memory unicode container and will exhibit similar speed to *BytesIO*.

多线程

FileIO objects are thread-safe to the extent that the operating system calls (such as `read(2)` under Unix) they wrap are thread-safe too.

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) protect their internal structures using a lock; it is therefore safe to call them from multiple threads at once.

TextIOWrapper objects are not thread-safe.

Reentrancy

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) are not reentrant. While reentrant calls will not happen in normal situations, they can arise

from doing I/O in a `signal` handler. If a thread tries to re-enter a buffered object which it is already accessing, a `RuntimeError` is raised. Note this doesn't prohibit a different thread from entering the buffered object.

The above implicitly extends to text files, since the `open()` function will wrap a buffered object inside a `TextIOWrapper`. This includes standard streams and therefore affects the built-in function `print()` as well.

16.3 `time` — 时间的访问和转换

该模块提供了各种时间相关的函数。相关功能还可以参阅 `datetime` 和 `calendar` 模块。

尽管此模块始终可用，但并非所有平台上都提供所有功能。此模块中定义的大多数函数调用都具有相同名称的平台 C 库函数。因为这些函数的语义因平台而异，所以使用时最好查阅平台相关文档。

下面是一些术语和惯例的解释。

- **epoch** 是时间开始的点，并且取决于平台。对于 Unix，epoch 是 1970 年 1 月 1 日 00:00:00 (UTC)。要找出给定平台上的 epoch，请查看 `time.gmtime(0)`。
- 术语 **Unix 纪元秒数** 是指自国际标准时间 1970 年 1 月 1 日零时以来经过的总秒数，通常不包括 闰秒。在所有符合 POSIX 标准的平台上，闰秒都会从总秒数中被扣除。
- 此模块中的功能可能无法处理纪元之前或将来的远期日期和时间。未来的截止点由 C 库决定；对于 32 位系统，它通常在 2038 年。
- **2000 年 (Y2K) 问题**：Python 依赖于平台的 C 库，它通常没有 2000 年问题，因为所有日期和时间都在内部表示为自纪元以来的秒数。函数 `strptime()` 在给出 `%Y` 格式代码时可以解析 2 位数年份。当解析 2 位数年份时，它们将根据 POSIX 和 ISO C 标准进行转换：值 69–99 映射到 1969–1999，值 0–68 映射到 2000–2068。
- **UTC** 是协调世界时（以前称为格林威治标准时间，或 GMT）。缩写 UTC 不是错误，而是英语和法语之间的妥协。
- **DST** 是夏令时，在一年中的一部分时间（通常）调整时区一小时。DST 规则很神奇（由当地法律确定），并且每年都会发生变化。C 库有一个包含本地规则的表（通常是从系统文件中读取以获得灵活性），并且在这方面是 True Wisdom 的唯一来源。
- 各种实时函数的精度可能低于表示其值或参数的单位所建议的精度。例如，在大多数 Unix 系统上，时钟 “ticks” 仅为每秒 50 或 100 次。
- 另一方面，`time()` 和 `sleep()` 的精度优于它们的 Unix 等价物：时间表示为浮点数，`time()` 返回最准确的时间（使用 Unix `gettimeofday()` 如果可用），并且 `sleep()` 将接受非零分数的时间（Unix `select()` 用于实现此功能，如果可用）。
- 时间值由 `gmtime()`、`localtime()` 和 `strptime()` 返回，并被 `asctime()`、`mktime()` 和 `strftime()` 接受，是一个 9 个整数的序列。`gmtime()`、`localtime()` 和 `strptime()` 的返回值还提供各个字段的属性名称。

请参阅 `struct_time` 以获取这些对象的描述。

在 3.3 版更改：在平台支持相应的 `struct tm` 成员时，`struct_time` 类型被扩展提供 `tm_gmtoff` 和 `tm_zone` 属性。

在 3.6 版更改：`struct_time` 的属性 `tm_gmtoff` 和 `tm_zone` 现在可在所有平台上使用。

- 使用以下函数在时间表示之间进行转换：

从	到	使用
seconds since the epoch	UTC 的 <code>struct_time</code>	<code>gmtime()</code>
seconds since the epoch	本地时间的 <code>struct_time</code>	<code>localtime()</code>
UTC 的 <code>struct_time</code>	seconds since the epoch	<code>calendar.timegm()</code>
本地时间的 <code>struct_time</code>	seconds since the epoch	<code>mktime()</code>

16.3.1 函数

`time.asctime([t])`
转换一个元组或 `struct_time` 表示的时间，由 `gmtime()` 或 `localtime()` 返回为以下形式的字符串：'Sun Jun 20 23:21:05 1993'。如果未提供 `t`，则使用由 `localtime()` 返回的当前时间。区域信息不被函数 `asctime()` 使用。

注解：与同名的 C 函数不同，`asctime()` 不添加尾随换行符。

`time.clock()`
在 Unix 上，将当前处理器时间返回为以秒为单位的浮点数。精确度，实际上是“处理器时间”含义的定义，取决于同名 C 函数的精度。
在 Windows 上，此函数返回自第一次调用此函数以来经过的 `wallclock` 秒数，作为浮点数，基于 Win32 函数 `QueryPerformanceCounter()`。分辨率通常优于 1 微秒。
3.3 版后已移除：此函数的行为取决于平台：根据你的需求，使用 `perf_counter()` 或 `process_time()` 获得具有明确定义的行为。

`time.clock_getres(clk_id)`
返回指定时钟 `clk_id` 的分辨率（精度）。有关 `clk_id` 的可接受值列表，请参阅 `Clock ID 常量`。
Availability: Unix.
3.3 新版功能.

`time.clock_gettime(clk_id)`
返回指定 `clk_id` 时钟的时间。有关 `clk_id` 的可接受值列表，请参阅 `Clock ID 常量`。
Availability: Unix.
3.3 新版功能.

`time.clock_settime(clk_id, time)`
设置指定 `clk_id` 时钟的时间。目前，`CLOCK_REALTIME` 是 `clk_id` 唯一可接受的值。
Availability: Unix.
3.3 新版功能.

`time.ctime([secs])`
将自 seconds since the epoch 表示的时间转换为表示本地时间的字符串。如果未提供 `secs` 或为 `None`，则使用由 `time()` 返回的当前时间。`ctime(secs)` 相当于 `asctime(localtime(secs))`。区域信息不被 `ctime()` 使用。

`time.get_clock_info(name)`
获取有关指定时钟的信息作为命名空间对象。支持的时钟名称和读取其值的相应函数是：

- 'clock': `time.clock()`
- 'monotonic': `time.monotonic()`
- 'perf_counter': `time.perf_counter()`

- `'process_time': time.process_time()`
- `'time': time.time()`

结果具有以下属性:

- *adjustable*: 如果时钟可以自动更改 (例如通过 NTP 守护程序) 或由系统管理员手动更改, 则为 `True`, 否则为 `False`。
- *implementation*: 用于获取时钟值的基础 C 函数的名称。有关可能的值, 请参阅 *Clock ID 常量*。
- *monotonic*: 如果时钟不能倒退, 则为 `True`, 否则为 `False`。
- *resolution*: 以秒为单位的时钟分辨率 (*float*)

3.3 新版功能.

`time.gmtime([secs])`

将 seconds since the epoch 为单位的时间转换为 UTC 的 *struct_time*, 其中 *dst* 标志始终为零。如果未提供 *secs* 或为 `None`, 则使用由 *time()* 返回的当前时间。忽略一秒的分数。有关 *struct_time* 对象的说明, 请参见上文。有关此函数的反函数, 请参阅 *calendar.timegm()*。

`time.localtime([secs])`

与 *gmtime()* 相似但转换为当地时间。如果未提供 *secs* 或为 `None`, 则使用由 *time()* 返回的当前时间。当 DST 适用于给定时间时, *dst* 标志设置为 1。

`time.mktime(t)`

这是 *localtime()* 的反函数。它的参数是 *struct_time* 或者完整的 9 元组 (因为需要 *dst* 标志; 如果它是未知的则使用 -1 作为 *dst* 标志), 它表示 *local* 的时间, 而不是 UTC。它返回一个浮点数, 以便与 *time()* 兼容。如果输入值不能表示为有效时间, 则 *OverflowError* 或 *ValueError* 将被引发 (这取决于 Python 或底层 C 库是否捕获到无效值)。它可以生成时间的最早日期取决于平台。

`time.monotonic()`

返回单调时钟的值 (以小数秒为单位), 即不能倒退的时钟。时钟不受系统时钟更新的影响。返回值的参考点未定义, 因此只有连续调用结果之间的差异才有效。

On Windows versions older than Vista, *monotonic()* detects `GetTickCount()` integer overflow (32 bits, roll-over after 49.7 days). It increases an internal epoch (reference time) by 2^{32} each time that an overflow is detected. The epoch is stored in the process-local state and so the value of *monotonic()* may be different in two Python processes running for more than 49 days. On more recent versions of Windows and on other operating systems, *monotonic()* is system-wide.

3.3 新版功能.

在 3.5 版更改: The function is now always available.

`time.perf_counter()`

返回性能计数器的值 (以小数秒为单位), 即具有最高可用分辨率的时钟, 以测量短持续时间。它确实包括睡眠期间经过的时间, 并且是系统范围的。返回值的参考点未定义, 因此只有连续调用结果之间的差异才有效。

3.3 新版功能.

`time.process_time()`

返回当前进程的系统和用户 CPU 时间总和的值 (以小数秒为单位)。它不包括睡眠期间经过的时间。根据定义, 它在整个进程范围中。返回值的参考点未定义, 因此只有连续调用结果之间的差异才有效。

3.3 新版功能.

`time.sleep(secs)`

暂停执行调用线程达到给定的秒数。参数可以是浮点数, 以指示更精确的睡眠时间。实际的暂停时间可能小于请求的时间, 因为任何捕获的信号将在执行该信号的捕获例程后终止 *sleep()*。此外, 由于系统中其他活动的安排, 暂停时间可能比请求的时间长任意量。

在 3.5 版更改: 即使睡眠被信号中断, 该函数现在至少睡眠 *secs*, 除非信号处理程序引发异常 (参见 [PEP 475](#) 作为基本原理)。

`time.strptime(format[, t])`

转换一个元组或 *struct_time* 表示的由 *gmtime()* 或 *localtime()* 返回的时间到由 *format* 参数指定的字符串。如果未提供 *t*, 则使用由 *localtime()* 返回的当前时间。*format* 必须是一个字符串。如果 *t* 中的任何字段超出允许范围, 则引发 *ValueError*。

0 是时间元组中任何位置的合法参数; 如果它通常是非法的, 则该值被强制改为正确的值。

以下指令可以嵌入 *format* 字符串中。它们显示时没有可选的字段宽度和精度规范, 并被 *strptime()* 结果中的指示字符替换:

指令	意义	注释
%a	本地化的缩写星期中每日的名称。	
%A	本地化的星期中每日的完整名称。	
%b	本地化的月缩写名称。	
%B	本地化的月完整名称。	
%c	本地化的适当日期和时间表示。	
%d	十进制数 [01,31] 表示的月中日。	
%H	十进制数 [00,23] 表示的小时 (24 小时制)。	
%I	十进制数 [01,12] 表示的小时 (12 小时制)。	
%j	十进制数 [001,366] 表示的年中日。	
%m	十进制数 [01,12] 表示的月。	
%M	十进制数 [00,59] 表示的分钟。	
%p	本地化的 AM 或 PM。	(1)
%S	十进制数 [00,61] 表示的秒。	(2)
%U	十进制数 [00,53] 表示的一年中的周数 (星期日作为一周的第一天) 作为。在第一个星期日之前的新年中的所有日子都被认为是在第 0 周。	(3)
%w	十进制数 [0(星期日),6] 表示的周中日。	
%W	十进制数 [00,53] 表示的一年中的周数 (星期一作为一周的第一天) 作为。在第一个星期一之前的新年中的所有日子被认为是在第 0 周。	(3)
%x	本地化的适当日期表示。	
%X	本地化的适当时间表示。	
%y	十进制数 [00,99] 表示的没有世纪的年份。	
%Y	十进制数表示的带世纪的年份。	
%z	时区偏移以格式 +HHMM 或 -HHMM 形式的 UTC/GMT 的正或负时差指示, 其中 H 表示十进制小时数字, M 表示小数分钟数字 [-23:59, +23:59]。	
%Z	时区名称 (如果不存在时区, 则不包含字符)。	
%%	字面的 '%' 字符。	

注释:

- (1) 当与 *strptime()* 函数一起使用时, 如果使用 %I 指令来解析小时, %p 指令只影响输出小时字段。
- (2) 范围真的是 0 到 61; 值 60 在表示 *leap seconds* 的时间戳中有效, 并且由于历史原因支持值 61。
- (3) 当与 *strptime()* 函数一起使用时, %U 和 %W 仅用于指定星期几和年份的计算。

下面是一个示例, 一个与 [RFC 2822](#) Internet 电子邮件标准以兼容的日期格式。¹

¹ 现在不推荐使用 %Z, 但是所有 ANSI C 库都不支持扩展为首选小时/分钟偏移量的 “%z” 转义符。此外, 严格的 1982 年原始 [RFC 822](#) 标准要求两位数的年份 (%y 而不是 %Y), 但是实际在 2000 年之前很久就转移到了 4 位数年。之后, [RFC 822](#) 已经废弃了, 4 位数的年份首先被推荐 [RFC 1123](#), 然后被 [RFC 2822](#) 强制执行。

```
>>> from time import gmtime, strftime
>>> strftime("%a, %d %b %Y %H:%M:%S +0000", gmtime())
'Thu, 28 Jun 2001 14:17:15 +0000'
```

某些平台可能支持其他指令，但只有此处列出的指令具有 ANSI C 标准化的含义。要查看平台支持的完整格式代码集，请参阅 `strftime(3)` 文档。

在某些平台上，可选的字段宽度和精度规范可以按照以下顺序紧跟在指令的初始 '%' 之后；这也不可移植。字段宽度通常为 2，除了 %j，它是 3。

`time.strptime(string[, format])`

根据格式解析表示时间的字符串。返回值为一个被 `gmtime()` 或 `localtime()` 返回的 `struct_time`。

`format` 参数使用与 `strftime()`；使用的指令相同的指令。它默认为匹配 `ctime()` 返回格式的 "%a %b %d %H:%M:%S %Y"。如果 `string` 不能根据 `*format` 解析，或者解析后它有多余的数据，则引发 `ValueError`。当无法推断出更准确的值时，用于填充任何缺失数据的默认值是 (1900, 1, 1, 0, 0, 0, 0, 1, -1)。`string` 和 `format` 都必须是字符串。

例如：

```
>>> import time
>>> time.strptime("30 Nov 00", "%d %b %y") # doctest: +NORMALIZE_WHITESPACE
time.struct_time(tm_year=2000, tm_mon=11, tm_mday=30, tm_hour=0, tm_min=0,
                  tm_sec=0, tm_wday=3, tm_yday=335, tm_isdst=-1)
```

支持 %Z 指令是基于 `tzname` 中包含的值以及 `daylight` 是否为真。因此，它是特定于平台的，除了识别始终已知的 UTC 和 GMT（并且被认为是非夏令时时区）。

仅支持文档中指定的指令。因为每个平台都实现了 `strftime()`，它有时会提供比列出的指令更多的指令。但是 `strptime()` 独立于任何平台，因此不一定支持所有未记录为支持的可用指令。

class `time.struct_time`

返回的时间值序列的类型为 `gmtime()`、`localtime()` 和 `strptime()`。它是一个带有 *named tuple* 接口的对象：可以通过索引和属性名访问值。存在以下值：

索引	属性	值
0	<code>tm_year</code>	(例如, 1993)
1	<code>tm_mon</code>	range [1, 12]
2	<code>tm_mday</code>	range [1, 31]
3	<code>tm_hour</code>	range [0, 23]
4	<code>tm_min</code>	range [0, 59]
5	<code>tm_sec</code>	range [0, 61]; 见 <code>strftime()</code> 介绍中的 (2)
6	<code>tm_wday</code>	range [0, 6], 周一为 0
7	<code>tm_yday</code>	range [1, 366]
8	<code>tm_isdst</code>	0, 1 或 -1; 如下所示
N/A	<code>tm_zone</code>	时区名称的缩写
N/A	<code>tm_gmtoff</code>	以秒为单位的 UTC 以东偏离

请注意，与 C 结构不同，月份值是 [1,12] 的范围，而不是 [0,11]。

在调用 `mktime()` 时，`tm_isdst` 可以在夏令时生效时设置为 1，而在夏令时不生效时设置为 0。值 -1 表示这是未知的，并且通常会导致填写正确的状态。

当一个长度不正确的元组被传递给期望 `struct_time` 的函数，或者具有错误类型的元素时，会引发 `TypeError`。

`time.time()`

返回浮点数的 seconds since the *epoch*。*epoch* 的具体日期和 *leap seconds* 的处理取决于平台。在 Windows 和大多数 Unix 系统上，*epoch* 是 1970 年 1 月 1 日 00:00:00 (UTC)，并且闰秒不计入 seconds since the *epoch*。这通常被称为 *Unix time*。要找出给定平台上的 *epoch*，请查看 `gmtime(0)`。

请注意，即使时间总是作为浮点数返回，但并非所有系统都提供高于 1 秒的精度。虽然此函数通常返回非递减值，但如果在两次调用之间设置了系统时钟，则它可以返回比先前调用更低的值。

返回的数字 `time()` 可以通过将其传递给 `gmtime()` 函数或转换为 UTC 中更常见的时间格式（即年、月、日、小时等）或通过将它传递给 `localtime()` 函数获得本地时间。在这两种情况下都返回一个 `struct_time` 对象，日历日期组件可以从中作为属性访问。

`time.tzset()`

Resets the time conversion rules used by the library routines. The environment variable TZ specifies how this is done.

Availability: Unix.

注解： 虽然在很多情况下，更改 TZ 环境变量而不调用 `tzset()` 可能会影响函数的输出，例如 `localtime()`，不应该依赖此行为。

TZ 不应该包含空格。

TZ 环境变量的标准格式是（为了清晰起见，添加了空格）：

```
std offset [dst [offset [,start[/time], end[/time]]]]
```

组件的位置是：

std 和 **dst** 三个或更多字母数字，给出时区缩写。这些将传到 `time.tzname`

offset 偏移量的形式为：± hh[:mm[:ss]]。这表示添加到达 UTC 的本地时间的值。如果前面有 ‘-’，则时区位于本初子午线的东边；否则，在它是西边。如果 **dst** 之后没有偏移，则假设夏令时比标准时间提前一小时。

start[/time], end[/time] 指示何时更改为 DST 和从 DST 返回。开始日期和结束日期的格式为以下之一：

Jn Julian 日 *n* ($1 \leq n \leq 365$)。闰日不计算在内，因此在所有年份中，2 月 28 日是第 59 天，3 月 1 日是第 60 天。

n 从零开始的 Julian 日 ($0 \leq n \leq 365$)。闰日计入，可以引用 2 月 29 日。

Mm.n.d 一年中 *m* 月的第 *n* 周 ($1 \leq n \leq 5$ ， $1 \leq m \leq 12$ ，第 5 周表示“可能在 *m* 月第 4 周或第 5 周出现的最后第 *d* 日”) 的第 *d* 天 ($0 \leq d \leq 6$)。第 1 周是第 *d* 天发生的第一周。第 0 天是星期天。

`time` 的格式与 `offset` 的格式相同，但不允许使用前导符号（‘-’或‘+’）。如果没有给出时间，则默认值为 02:00:00。

```
>>> os.environ['TZ'] = 'EST+05EDT,M4.1.0,M10.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'02:07:36 05/08/03 EDT'
>>> os.environ['TZ'] = 'AEST-10AEDT-11,M10.5.0,M3.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'16:08:12 05/08/03 AEST'
```

在许多 Unix 系统（包括 *BSD，Linux，Solaris 和 Darwin 上），使用系统的区域信息（*tzfile(5)*）数据库来指定时区规则会更方便。为此，将 TZ 环境变量设置为所需时区数据文件的路径，相对于系统 ‘zoneinfo’ 时区数据库的根目录，通常位于 /usr/share/zoneinfo。例如，‘US/Eastern’、‘Australia/Melbourne’、‘Egypt’ 或 ‘Europe/Amsterdam’。

```
>>> os.environ['TZ'] = 'US/Eastern'
>>> time.tzset()
>>> time.tzname
('EST', 'EDT')
>>> os.environ['TZ'] = 'Egypt'
>>> time.tzset()
>>> time.tzname
('EET', 'EEST')
```

16.3.2 Clock ID 常量

这些常量用作 *clock_getres()* 和 *clock_gettime()* 的参数。

time.CLOCK_HIGHRES

Solaris OS 有一个 CLOCK_HIGHRES 计时器，试图使用最佳硬件源，并可能提供接近纳秒的分辨率。CLOCK_HIGHRES 是不可调节的高分辨率时钟。

Availability: Solaris.

3.3 新版功能.

time.CLOCK_MONOTONIC

无法设置的时钟，表示自某些未指定的起点以来的单调时间。

Availability: Unix.

3.3 新版功能.

time.CLOCK_MONOTONIC_RAW

类似于 *CLOCK_MONOTONIC*，但可以访问不受 NTP 调整影响的原始硬件时间。

Availability: Linux 2.6.28 or later.

3.3 新版功能.

time.CLOCK_PROCESS_CPUTIME_ID

来自 CPU 的高分辨率每进程计时器。

Availability: Unix.

3.3 新版功能.

time.CLOCK_THREAD_CPUTIME_ID

特定于线程的 CPU 时钟。

Availability: Unix.

3.3 新版功能.

以下常量是唯一可以发送到 *clock_settime()* 的参数。

time.CLOCK_REALTIME

系统范围的实时时钟。设置此时钟需要适当的权限。

Availability: Unix.

3.3 新版功能.

16.3.3 时区常量

`time.altzone`

本地 DST 时区的偏移量，以 UTC 为单位的秒数，如果已定义。如果当地 DST 时区在 UTC 以东（如在西欧，包括英国），则是负数。只有当 `daylight` 非零时才使用它。见下面的注释。

`time.daylight`

如果定义了 DST 时区，则为非零。见下面的注释。

`time.timezone`

本地（非 DST）时区的偏移量，UTC 以西的秒数（西欧大部分地区为负，美国为正，英国为零）。见下面的注释。

`time.tzname`

两个字符串的元组：第一个是本地非 DST 时区的名称，第二个是本地 DST 时区的名称。如果未定义 DST 时区，则不应使用第二个字符串。见下面的注释。

注解：对于上述时区常量（`altzone`、`daylight`、`timezone` 和 `tzname`），该值由模块加载时有效的时区规则确定，或者最后一次 `tzset()` 被调用时，并且在过去的时间可能不正确。建议使用来自 `localtime()` 结果的 `tm_gmtoff` 和 `tm_zone` 来获取时区信息。

参见：

模块 `datetime` 更多面向对象的日期和时间接口。

模块 `locale` 国际化服务。区域设置会影响 `strftime()` 和 `strptime()` 中许多格式说明符的解析。

模块 `calendar` 一般日历相关功能。这个模块的 `timegm()` 是函数 `gmtime()` 的反函数。

16.4 argparse — 命令行选项、参数和子命令解析器

3.2 新版功能.

源代码： [Lib/argparse.py](#)

教程

此页面包含该 API 的参考信息。有关 Python 命令行解析更细致的介绍，请参阅 `argparse` 教程。

`argparse` 模块可以让人轻松编写用户友好的命令行接口。程序定义它需要的参数，然后 `argparse` 将弄清如何从 `sys.argv` 解析出那些参数。`argparse` 模块还会自动生成帮助和使用手册，并在用户给程序传入无效参数时报出错误信息。

16.4.1 示例

以下代码是一个 Python 程序，它获取一个整数列表并计算总和或者最大值：

```
import argparse

parser = argparse.ArgumentParser(description='Process some integers.')
parser.add_argument('integers', metavar='N', type=int, nargs='+',
```

(下页继续)

(续上页)

```

        help='an integer for the accumulator')
parser.add_argument('--sum', dest='accumulate', action='store_const',
                    const=sum, default=max,
                    help='sum the integers (default: find the max)')

args = parser.parse_args()
print(args.accumulate(args.integers))

```

假设上面的 Python 代码保存在名为 prog.py 的文件中，它可以在命令行运行并提供有用的帮助消息：

```

$ python prog.py -h
usage: prog.py [-h] [--sum] N [N ...]

Process some integers.

positional arguments:
  N              an integer for the accumulator

optional arguments:
  -h, --help    show this help message and exit
  --sum         sum the integers (default: find the max)

```

当使用适当的参数运行时，它会输出命令行传入整数的总和或者最大值：

```

$ python prog.py 1 2 3 4
4

$ python prog.py 1 2 3 4 --sum
10

```

如果传入无效参数，则会报出错误：

```

$ python prog.py a b c
usage: prog.py [-h] [--sum] N [N ...]
prog.py: error: argument N: invalid int value: 'a'

```

以下部分将引导你完成这个示例。

创建一个解析器

使用 `argparse` 的第一步是创建一个 `ArgumentParser` 对象：

```
>>> parser = argparse.ArgumentParser(description='Process some integers.')
```

`ArgumentParser` 对象包含将命令行解析成 Python 数据类型所需的全部信息。

添加参数

给一个 `ArgumentParser` 添加程序参数信息是通过调用 `add_argument()` 方法完成的。通常，这些调用指定 `ArgumentParser` 如何获取命令行字符串并将其转换为对象。这些信息在 `parse_args()` 调用时被存储和使用。例如：

```
>>> parser.add_argument('integers', metavar='N', type=int, nargs='+',
...                       help='an integer for the accumulator')
>>> parser.add_argument('--sum', dest='accumulate', action='store_const',
...                     const=sum, default=max,
...                     help='sum the integers (default: find the max)')
```

稍后，调用 `parse_args()` 将返回一个具有 `integers` 和 `accumulate` 两个属性的对象。`integers` 属性将是一个包含一个或多个整数的列表，而 `accumulate` 属性当命令行中指定了 `--sum` 参数时将是 `sum()` 函数，否则则是 `max()` 函数。

解析参数

`ArgumentParser` 通过 `parse_args()` 方法解析参数。它将检查命令行，把每个参数转换为适当的类型然后调用相应的操作。在大多数情况下，这意味着一个简单的 `Namespace` 对象将从命令行参数中解析出的属性构建：

```
>>> parser.parse_args(['--sum', '7', '-1', '42'])
Namespace(accumulate=<built-in function sum>, integers=[7, -1, 42])
```

在脚本中，通常 `parse_args()` 会被不带参数调用，而 `ArgumentParser` 将自动从 `sys.argv` 中确定命令行参数。

16.4.2 ArgumentParser 对象

```
class argparse.ArgumentParser(prog=None, usage=None, description=None, epilog=None,
                               parents=[], formatter_class=argparse.HelpFormatter, prefix_chars='-',
                               fromfile_prefix_chars=None, argument_default=None, conflict_handler='error', add_help=True, allow_abbrev=True)
```

创建一个新的 `ArgumentParser` 对象。所有的参数都应当作为关键字参数传入。每个参数在下面都有它更详细的描述，但简而言之，它们是：

- `prog` - 程序的名称（默认： `sys.argv[0]`）
- `usage` - 描述程序用途的字符串（默认值：从添加到解析器的参数生成）
- `description` - 在参数帮助文档之前显示的文本（默认值：无）
- `epilog` - 在参数帮助文档之后显示的文本（默认值：无）
- `parents` - 一个 `ArgumentParser` 对象的列表，它们的参数也应包含在内
- `formatter_class` - 用于自定义帮助文档输出格式的类
- `prefix_chars` - 可选参数的前缀字符集合（默认值：' - '）
- `fromfile_prefix_chars` - 当需要从文件中读取其他参数时，用于标识文件名的前缀字符集合（默认值：None）
- `argument_default` - 参数的全局默认值（默认值：None）
- `conflict_handler` - 解决冲突选项的策略（通常是不必要的）
- `add_help` - 为解析器添加一个 `-h/--help` 选项（默认值：True）
- `allow_abbrev` - 如果缩写是无歧义的，则允许缩写长选项（默认值：True）

在 3.5 版更改：添加 `allow_abbrev` 参数。

以下部分描述这些参数如何使用。

prog

默认情况下, *ArgumentParser* 对象使用 `sys.argv[0]` 来确定如何在帮助消息中显示程序名称。这一默认值几乎总是可取的, 因为它将使帮助消息与从命令行调用此程序的方式相匹配。例如, 对于有如下代码的名为 `myprogram.py` 的文件:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

该程序的帮助信息将显示 `myprogram.py` 作为程序名称 (无论程序从何处被调用):

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   foo help
$ cd ..
$ python subdir/myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   foo help
```

要更改这样的默认行为, 可以使用 `prog=` 参数为 *ArgumentParser* 提供另一个值:

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.print_help()
usage: myprogram [-h]

optional arguments:
  -h, --help  show this help message and exit
```

需要注意的是, 无论是从 `sys.argv[0]` 或是从 `prog=` 参数确定的程序名称, 都可以在帮助消息里通过 `%(prog)s` 格式串来引用。

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.add_argument('--foo', help='foo of the %(prog)s program')
>>> parser.print_help()
usage: myprogram [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO   foo of the myprogram program
```

usage

默认情况下, *ArgumentParser* 根据它包含的参数来构建用法消息:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
```

(下页继续)

(续上页)

```
usage: PROG [-h] [--foo [FOO]] bar [bar ...]

positional arguments:
  bar                bar help

optional arguments:
  -h, --help        show this help message and exit
  --foo [FOO]       foo help
```

可以通过 `usage=` 关键字参数覆盖这一默认消息：

```
>>> parser = argparse.ArgumentParser(prog='PROG', usage='% (prog)s [options]')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [options]

positional arguments:
  bar                bar help

optional arguments:
  -h, --help        show this help message and exit
  --foo [FOO]       foo help
```

在用法消息中可以使用 `%(prog)s` 格式说明符来填入程序名称。

description

大多数对 `ArgumentParser` 构造方法的调用都会使用 `description=` 关键字参数。这个参数简要描述这个程度做什么以及怎么做。在帮助消息中，这个描述会显示在命令行用法字符串和各种参数的帮助消息之间：

```
>>> parser = argparse.ArgumentParser(description='A foo that bars')
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

optional arguments:
  -h, --help  show this help message and exit
```

在默认情况下，`description` 将被换行以便适应给定的空间。如果想改变这种行为，见 `formatter_class` 参数。

epilog

一些程序喜欢在 `description` 参数后显示额外的对程序的描述。这种文字能够通过给 `ArgumentParser::` 提供 `epilog=` 参数而被指定。

```
>>> parser = argparse.ArgumentParser(
...     description='A foo that bars',
...     epilog="And that's how you'd foo a bar")
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

And that's how you'd foo a bar
```

(下页继续)

(续上页)

```
optional arguments:
  -h, --help  show this help message and exit
```

```
And that's how you'd foo a bar
```

和 *description* 参数一样, *epilog= text* 在默认情况下会换行, 但是这种行为能够被调整通过提供 *formatter_class* 参数给 *ArgumentParser*.

parents

有些时候, 少数解析器会使用同一系列参数。单个解析器能够通过提供 *parents=* 参数给 *ArgumentParser* 而使用相同的参数而不是重复这些参数的定义。*parents=* 参数使用 *ArgumentParser* 对象的列表, 从它们那里收集所有的位置和可选的行为, 然后将这写行为加到正在构建的 *ArgumentParser* 对象。

```
>>> parent_parser = argparse.ArgumentParser(add_help=False)
>>> parent_parser.add_argument('--parent', type=int)

>>> foo_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> foo_parser.add_argument('foo')
>>> foo_parser.parse_args(['--parent', '2', 'XXX'])
Namespace(foo='XXX', parent=2)

>>> bar_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> bar_parser.add_argument('--bar')
>>> bar_parser.parse_args(['--bar', 'YYY'])
Namespace(bar='YYY', parent=None)
```

请注意大多数父解析器会指定 *add_help=False*. 否则, *ArgumentParser* 将会看到两个 *-h/--help* 选项 (一个在父参数中一个在子参数中) 并且产生一个错误。

注解: 你在传 “*parents=*” 给那些解析器时必须完全初始化它们。如果你在子解析器之后改变父解析器是, 这些改变不会反映在子解析器上。

formatter_class

ArgumentParser 对象允许通过指定备用格式化类来自定义帮助格式。目前, 有四种这样的类。

```
class argparse.RawDescriptionHelpFormatter
class argparse.RawTextHelpFormatter
class argparse.ArgumentDefaultsHelpFormatter
class argparse.MetavarTypeHelpFormatter
```

RawDescriptionHelpFormatter 和 *RawTextHelpFormatter* 在正文的描述和展示上给与了更多的控制。*ArgumentParser* 对象会将 *description* 和 *epilog* 的文字在命令行中自动换行。

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     description='''this description
...         was indented weird
...         but that is okay''',
...     epilog='')
... 
```

(下页继续)

(续上页)

```

...         likewise for this epilog whose whitespace will
...         be cleaned up and whose words will be wrapped
...         across a couple lines'''
>>> parser.print_help()
usage: PROG [-h]

this description was indented weird but that is okay

optional arguments:
  -h, --help  show this help message and exit

likewise for this epilog whose whitespace will be cleaned up and whose words
will be wrapped across a couple lines

```

传 *RawDescriptionHelpFormatter* 给 `formatter_class=` 表示 *description* 和 *epilog* 已经被正确的格式化了, 不能在命令行中被自动换行:

```

>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.RawDescriptionHelpFormatter,
...     description=textwrap.dedent('''\
...         Please do not mess up this text!
...         -----
...         I have indented it
...         exactly the way
...         I want it
...     '''))
>>> parser.print_help()
usage: PROG [-h]

Please do not mess up this text!
-----
    I have indented it
    exactly the way
    I want it

optional arguments:
  -h, --help  show this help message and exit

```

RawTextHelpFormatter 保留所有种类文字的空格, 包括参数的描述。然而, 多重的新行会被替换成一行。如果你想保留多重的空白行, 可以在新行之间加空格。

ArgumentDefaultsHelpFormatter 自动添加默认的值的信息到每一个帮助信息的参数中:

```

>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.ArgumentDefaultsHelpFormatter)
>>> parser.add_argument('--foo', type=int, default=42, help='FOO!')
>>> parser.add_argument('bar', nargs='*', default=[1, 2, 3], help='BAR!')
>>> parser.print_help()
usage: PROG [-h] [--foo FOO] [bar [bar ...]]

positional arguments:
  bar          BAR! (default: [1, 2, 3])

optional arguments:
  -h, --help  show this help message and exit

```

(下页继续)

(续上页)

```
--foo FOO    FOO! (default: 42)
```

`MetavarTypeHelpFormatter` 为它的值在每一个参数中使用 *type* 的参数名当作它的显示名（而不是使用通常的格式 *dest*）:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.MetavarTypeHelpFormatter)
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', type=float)
>>> parser.print_help()
usage: PROG [-h] [--foo int] float

positional arguments:
  float

optional arguments:
  -h, --help  show this help message and exit
  --foo int
```

prefix_chars

许多命令行会使用 `-` 当作前缀，比如 `-f/--foo`。如果解析器需要支持不同的或者额外的字符，比如像 `+f` 或者 `/foo` 的选项，可以在参数解析构建器中使用 `prefix_chars=` 参数。

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='-+')
>>> parser.add_argument('+f')
>>> parser.add_argument('++bar')
>>> parser.parse_args('+f X ++bar Y'.split())
Namespace(bar='Y', f='X')
```

The `prefix_chars=` 参数默认使用 `'-'`。支持一系列字符，但是不包括 `-`，这样会产生不被允许的 `-f/` `--foo` 选项。

fromfile_prefix_chars

有些时候，先举个例子，当处理一个特别长的参数列表的时候，把它存入一个文件中而不是在命令行打出来会很有意义。如果 `fromfile_prefix_chars=` 参数提供给 `ArgumentParser` 构造函数，之后所有类型的字符的参数都会被当成文件处理，并且会被文件包含的参数替代。举个例子:

```
>>> with open('args.txt', 'w') as fp:
...     fp.write('-f\nbar')
>>> parser = argparse.ArgumentParser(fromfile_prefix_chars='@')
>>> parser.add_argument('-f')
>>> parser.parse_args(['-f', 'foo', '@args.txt'])
Namespace(f='bar')
```

从文件读取的参数在默认情况下必须一个一行（但是可参见 `convert_arg_line_to_args()`）并且它们被视为与命令行上的原始文件引用参数位于同一位置。所以在以上例子中，`['-f', 'foo', '@args.txt']` 的表示和 `['-f', 'foo', '-f', 'bar']` 的表示相同。

`fromfile_prefix_chars=` 参数默认为 `None`，意味着参数不会被当作文件对待。

argument_default

一般情况下，参数默认会通过设置一个默认到 `add_argument()` 或者调用带一组指定键值对的 `ArgumentParser.set_defaults()` 方法。但是有些时候，为参数指定一个普遍适用的解析器会更有用。这能够通过传输 `argument_default=` 关键词参数给 `ArgumentParser` 来完成。举个例子，要全局禁止在 `parse_args()` 中创建属性，我们提供 `argument_default=SUPPRESS`：

```
>>> parser = argparse.ArgumentParser(argument_default=argparse.SUPPRESS)
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar', nargs='?')
>>> parser.parse_args(['--foo', '1', 'BAR'])
Namespace(bar='BAR', foo='1')
>>> parser.parse_args([])
Namespace()
```

allow_abbrev

正常情况下，当你向 `ArgumentParser` 的 `parse_args()` 方法传入一个参数列表时，它会 *recognizes abbreviations*。

这个特性可以设置 `allow_abbrev` 为 `False` 来关闭：

```
>>> parser = argparse.ArgumentParser(prog='PROG', allow_abbrev=False)
>>> parser.add_argument('--foobar', action='store_true')
>>> parser.add_argument('--foonley', action='store_false')
>>> parser.parse_args(['--foon'])
usage: PROG [-h] [--foobar] [--foonley]
PROG: error: unrecognized arguments: --foon
```

3.5 新版功能.

conflict_handler

`ArgumentParser` 对象不允许在相同选项字符串下有两种行为。默认情况下，`ArgumentParser` 对象会产生一个异常如果去创建一个正在使用的选项字符串参数。

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
Traceback (most recent call last):
..
ArgumentError: argument --foo: conflicting option string(s): --foo
```

有些时候（例如：使用 *parents*），重写旧的有相同选项字符串的参数会更有用。为了产生这种行为，`'resolve'` 值可以提供给 `ArgumentParser` 的 `conflict_handler=` 参数：

```
>>> parser = argparse.ArgumentParser(prog='PROG', conflict_handler='resolve')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
>>> parser.print_help()
usage: PROG [-h] [-f FOO] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
```

(下页继续)

(续上页)

```
-f FOO      old foo help
--foo FOO   new foo help
```

注意 `ArgumentParser` 对象只能移除一个行为如果它所有的选项字符串都被重写。所以，在上面的例子中，旧的 `-f/--foo` 行为回合 `-f` 行为保持一致，因为只有 `--foo` 选项字符串被重写。

add_help

默认情况下，`ArgumentParser` 对象添加一个简单的显示解析器帮助信息的选项。举个栗子，考虑一个名为 `myprogram.py` 的文件包含如下代码：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

如果 `-h` or `--help` 在命令行中被提供，参数解析器帮助信息会打印：

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO  foo help
```

有时候可能会需要关闭额外的帮助信息。这可以通过在 `ArgumentParser` 中设置 `add_help=` 参数为 `False` 来实现。

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> parser.add_argument('--foo', help='foo help')
>>> parser.print_help()
usage: PROG [--foo FOO]

optional arguments:
  --foo FOO  foo help
```

帮助选项一般为 `-h/--help`。如果 `prefix_chars=` 被指定并且没有包含 `-` 字符，在这种情况下，`-h` `--help` 不是有效的选项。此时，`prefix_chars` 的第一个字符将用作帮助选项的前缀。

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='+/')
>>> parser.print_help()
usage: PROG [+h]

optional arguments:
  +h, ++help  show this help message and exit
```

16.4.3 add_argument() 方法

`ArgumentParser.add_argument` (*name or flags...* [, *action*] [, *nargs*] [, *const*] [, *default*] [, *type*] [, *choices*] [, *required*] [, *help*] [, *metavar*] [, *dest*])

定义单个的命令行参数应当如何解析。每个形参都在下面有它自己更多的描述，长话短说有：

- *name or flags* - 一个命名或者一个选项字符串的列表，例如 `foo` 或 `-f`，`--foo`。

- *action* - 当参数在命令行中出现时使用的动作基本类型。
- *nargs* - 命令行参数应当消耗的数目。
- *const* - 被一些*action* 和*nargs* 选择所需求的常数。
- *default* - 当参数未在命令行中出现时使用的值。
- *type* - 命令行参数应当被转换成的类型。
- *choices* - 可用的参数的容器。
- *required* - 此命令行选项是否可省略（仅选项可用）。
- *help* - 一个此选项作用的简单描述。
- *metavar* - 在使用方法消息中使用的参数值示例。
- *dest* - 被添加到`parse_args()` 所返回对象上的属性名。

以下部分描述这些参数如何使用。

name or flags

`add_argument()` 方法必须知道它是否是一个选项，例如 `-f` 或 `--foo`，或是一个位置参数，例如一组文件名。第一个传递给`add_argument()` 的参数必须是一系列 **flags** 或者是一个简单的参数名。例如，可以选项可以被这样创建：

```
>>> parser.add_argument('-f', '--foo')
```

而位置参数可以这么创建：

```
>>> parser.add_argument('bar')
```

当`parse_args()` 被调用，选项会以 `-` 前缀识别，剩下的参数则会被假定为位置参数：

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args(['BAR'])
Namespace(bar='BAR', foo=None)
>>> parser.parse_args(['BAR', '--foo', 'FOO'])
Namespace(bar='BAR', foo='FOO')
>>> parser.parse_args(['--foo', 'FOO'])
usage: PROG [-h] [-f FOO] bar
PROG: error: the following arguments are required: bar
```

action

`ArgumentParser` 对象将命令行参数与动作相关联。这些动作可以做与它们相关联的命令行参数的任何事，尽管大多数动作只是简单的向`parse_args()` 返回的对象上添加属性。`action` 命名参数指定了这个命令行参数应当如何处理。供应的动作有：

- `'store'` - 存储参数的值。这是默认的动作。例如：

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args('--foo 1'.split())
Namespace(foo='1')
```

- 'store_const' - 存储被`const` 命名参数指定的值。'store_const' 动作通常用在选项中来指定一些标志。例如:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_const', const=42)
>>> parser.parse_args(['--foo'])
Namespace(foo=42)
```

- 'store_true' and 'store_false' - 这些是 'store_const' 分别用作存储 True 和 False 值的特殊用例。另外，它们的默认值分别为 False 和 True。例如:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('--bar', action='store_false')
>>> parser.add_argument('--baz', action='store_false')
>>> parser.parse_args('--foo --bar'.split())
Namespace(foo=True, bar=False, baz=True)
```

- 'append' - 存储一个列表，并且将每个参数值追加到列表中。在允许多次使用选项时很有用。例如:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='append')
>>> parser.parse_args('--foo 1 --foo 2'.split())
Namespace(foo=['1', '2'])
```

- 'append_const' - 这存储一个列表，并将`const` 命名参数指定的值追加到列表中。(注意`const` 命名参数默认为 None。)“append_const” 动作一般在多个参数需要在同一列表中存储常数时会有用。例如:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--str', dest='types', action='append_const', const=str)
>>> parser.add_argument('--int', dest='types', action='append_const', const=int)
>>> parser.parse_args('--str --int'.split())
Namespace(types=[<class 'str'>, <class 'int'>])
```

- 'count' - 计算一个关键字参数出现的数目或次数。例如，对于一个增长的详情等级来说有用:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--verbose', '-v', action='count')
>>> parser.parse_args(['-vvv'])
Namespace(verbose=3)
```

- 'help' - 打印所有当前解析器中的选项和参数的完整帮助信息，然后退出。默认情况下，一个 help 动作会被自动加入解析器。关于输出是如何创建的，参与`ArgumentParser`。
- 'version' - 期望有一个 version= 命名参数在`add_argument()` 调用中，并打印版本信息并在调用后退出:

```
>>> import argparse
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--version', action='version', version='%s 2.0' % (prog))
>>> parser.parse_args(['--version'])
PROG 2.0
```

您还可以通过传递 Action 子类或实现相同接口的其他对象来指定任意操作。建议的方法是扩展`Action`，覆盖 `__call__` 方法和可选的 `__init__` 方法。

一个自定义动作的例子:

```
>>> class FooAction(argparse.Action):
...     def __init__(self, option_strings, dest, nargs=None, **kwargs):
...         if nargs is not None:
...             raise ValueError("nargs not allowed")
...         super(FooAction, self).__init__(option_strings, dest, **kwargs)
...     def __call__(self, parser, namespace, values, option_string=None):
...         print('%r %r %r' % (namespace, values, option_string))
...         setattr(namespace, self.dest, values)
...
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=FooAction)
>>> parser.add_argument('bar', action=FooAction)
>>> args = parser.parse_args('1 --foo 2'.split())
Namespace(bar=None, foo=None) '1' None
Namespace(bar='1', foo=None) '2' '--foo'
>>> args
Namespace(bar='1', foo='2')
```

更多描述，见 [Action](#)。

nargs

`ArgumentParser` 对象通常关联一个单独的命令行参数到一个单独的被执行的动作。`nargs` 命名参数关联不同数目的命令行参数到单一动作。支持的值有：

- `N`（一个整数）。命令行中的 `N` 个参数会被聚集到一个列表中。例如：

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs=2)
>>> parser.add_argument('bar', nargs=1)
>>> parser.parse_args('c --foo a b'.split())
Namespace(bar=['c'], foo=['a', 'b'])
```

注意 `nargs=1` 会产生一个单元素列表。这和默认的元素本身是不同的。

- `'?'`。如果可能的话，会从命令行中消耗一个参数，并产生一个单一项。如果当前没有命令行参数，则会产生 *default* 值。注意，对于选项，有另外的用例 - 选项字符串出现但没有跟随命令行参数，则会产生 *const* 值。一些说用用例：

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='?', const='c', default='d')
>>> parser.add_argument('bar', nargs='?', default='d')
>>> parser.parse_args(['XX', '--foo', 'YY'])
Namespace(bar='XX', foo='YY')
>>> parser.parse_args(['XX', '--foo'])
Namespace(bar='XX', foo='c')
>>> parser.parse_args([])
Namespace(bar='d', foo='d')
```

`nargs='?'` 的一个更普遍用法是允许可选的输入或输出文件：

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', nargs='?', type=argparse.FileType('r'),
...                     default=sys.stdin)
>>> parser.add_argument('outfile', nargs='?', type=argparse.FileType('w'),
...                     default=sys.stdout)
```

(下页继续)

(续上页)

```
>>> parser.parse_args(['input.txt', 'output.txt'])
Namespace(infile=<_io.TextIOWrapper name='input.txt' encoding='UTF-8'>,
          outfile=<_io.TextIOWrapper name='output.txt' encoding='UTF-8'>)
>>> parser.parse_args([])
Namespace(infile=<_io.TextIOWrapper name='<stdin>' encoding='UTF-8'>,
          outfile=<_io.TextIOWrapper name='<stdout>' encoding='UTF-8'>)
```

- `'*'`。所有当前命令行参数被聚集到一个列表中。注意通过 `nargs='*'` 来实现多个位置参数通常没有意义，但是多个选项是可能的。例如：

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='*')
>>> parser.add_argument('--bar', nargs='*')
>>> parser.add_argument('baz', nargs='*')
>>> parser.parse_args('a b --foo x y --bar 1 2'.split())
Namespace(bar=['1', '2'], baz=['a', 'b'], foo=['x', 'y'])
```

- `'+'`。和 `'*'` 类似，所有当前命令行参数被聚集到一个列表中。另外，当前没有至少一个命令行参数时会产生一个错误信息。例如：

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', nargs='+')
>>> parser.parse_args(['a', 'b'])
Namespace(foo=['a', 'b'])
>>> parser.parse_args([])
usage: PROG [-h] foo [foo ...]
PROG: error: the following arguments are required: foo
```

- `argparse.REMAINDER`。所有剩余的命令行参数被聚集到一个列表中。这通常在从一个命令行功能传递参数到另一个命令行功能中时有用：

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo')
>>> parser.add_argument('command')
>>> parser.add_argument('args', nargs=argparse.REMAINDER)
>>> print(parser.parse_args('--foo B cmd --arg1 XX ZZ'.split()))
Namespace(args=['--arg1', 'XX', 'ZZ'], command='cmd', foo='B')
```

如果不提供 `nargs` 命名参数，则消耗参数的数目将被 *action* 决定。通常这意味着单一项目（非列表）消耗单一命令行参数。

const

`add_argument()` 的 `“const”` 参数用于保存不从命令行中读取但被各种 *ArgumentParser* 动作需求的常数值。最常用的两例为：

- 当 `add_argument()` 通过 `action='store_const'` 或 `action='append_const'` 调用时。这些动作将 `const` 值添加到 `parse_args()` 返回的对象的属性中。在 *action* 的描述中查看案例。
- 当 `add_argument()` 通过选项（例如 `-f` 或 `--foo`）调用并且 `nargs='?'` 时。这会创建一个可以跟随零个或一个命令行参数的选项。当解析命令行时，如果选项后没有参数，则用 `const` 代替。在 *nargs* 描述中查看案例。

对 `'store_const'` 和 `'append_const'` 动作，`const` 命名参数必须给出。对其他动作，默认为 `None`。

default

所有选项和一些位置参数可能在命令行中被忽略。`add_argument()` 的命名参数 `default`，默认值为 `None`，指定了在命令行参数未出现时应当使用的值。对于选项，`default` 值在选项未在命令行中出现时使用：

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args(['--foo', '2'])
Namespace(foo='2')
>>> parser.parse_args([])
Namespace(foo=42)
```

如果 `default` 值是一个字符串，解析器解析此值就像一个命令行参数。特别是，在将属性设置在 `Namespace` 的返回值之前，解析器应用任何提供的 `type` 转换参数。否则解析器使用原值：

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--length', default='10', type=int)
>>> parser.add_argument('--width', default=10.5, type=int)
>>> parser.parse_args()
Namespace(length=10, width=10.5)
```

对于 `nargs` 等于 `?` 或 `*` 的位置参数，`default` 值在没有命令行参数出现时使用。

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', nargs='?', default=42)
>>> parser.parse_args(['a'])
Namespace(foo='a')
>>> parser.parse_args([])
Namespace(foo=42)
```

提供 `default=argparse.SUPPRESS` 导致命令行参数未出现时没有属性被添加：

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=argparse.SUPPRESS)
>>> parser.parse_args([])
Namespace()
>>> parser.parse_args(['--foo', '1'])
Namespace(foo='1')
```

type

By default, `ArgumentParser` objects read command-line arguments in as simple strings. However, quite often the command-line string should instead be interpreted as another type, like a `float` or `int`. The `type` keyword argument of `add_argument()` allows any necessary type-checking and type conversions to be performed. Common built-in types and functions can be used directly as the value of the `type` argument:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.add_argument('bar', type=open)
>>> parser.parse_args('2 temp.txt'.split())
Namespace(bar=<_io.TextIOWrapper name='temp.txt' encoding='UTF-8'>, foo=2)
```

See the section on the `default` keyword argument for information on when the `type` argument is applied to default arguments.

To ease the use of various types of files, the `argparse` module provides the factory `FileType` which takes the `mode=`, `bufsize=`, `encoding=` and `errors=` arguments of the `open()` function. For example, `FileType('w')` can be used to create a writable file:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar', type=argparse.FileType('w'))
>>> parser.parse_args(['out.txt'])
Namespace(bar=<_io.TextIOWrapper name='out.txt' encoding='UTF-8'>)
```

`type=` can take any callable that takes a single string argument and returns the converted value:

```
>>> def perfect_square(string):
...     value = int(string)
...     sqrt = math.sqrt(value)
...     if sqrt != int(sqrt):
...         msg = "%r is not a perfect square" % string
...         raise argparse.ArgumentTypeError(msg)
...     return value
...
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', type=perfect_square)
>>> parser.parse_args(['9'])
Namespace(foo=9)
>>> parser.parse_args(['7'])
usage: PROG [-h] foo
PROG: error: argument foo: '7' is not a perfect square
```

The *choices* keyword argument may be more convenient for type checkers that simply check against a range of values:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', type=int, choices=range(5, 10))
>>> parser.parse_args(['7'])
Namespace(foo=7)
>>> parser.parse_args(['11'])
usage: PROG [-h] {5,6,7,8,9}
PROG: error: argument foo: invalid choice: 11 (choose from 5, 6, 7, 8, 9)
```

See the *choices* section for more details.

选择

Some command-line arguments should be selected from a restricted set of values. These can be handled by passing a container object as the *choices* keyword argument to `add_argument()`. When the command line is parsed, argument values will be checked, and an error message will be displayed if the argument was not one of the acceptable values:

```
>>> parser = argparse.ArgumentParser(prog='game.py')
>>> parser.add_argument('move', choices=['rock', 'paper', 'scissors'])
>>> parser.parse_args(['rock'])
Namespace(move='rock')
>>> parser.parse_args(['fire'])
usage: game.py [-h] {rock,paper,scissors}
game.py: error: argument move: invalid choice: 'fire' (choose from 'rock',
'paper', 'scissors')
```

Note that inclusion in the *choices* container is checked after any *type* conversions have been performed, so the type of the objects in the *choices* container should match the *type* specified:

```
>>> parser = argparse.ArgumentParser(prog='doors.py')
>>> parser.add_argument('door', type=int, choices=range(1, 4))
>>> print(parser.parse_args(['3']))
Namespace(door=3)
>>> parser.parse_args(['4'])
usage: doors.py [-h] {1,2,3}
doors.py: error: argument door: invalid choice: 4 (choose from 1, 2, 3)
```

Any object that supports the `in` operator can be passed as the *choices* value, so *dict* objects, *set* objects, custom containers, etc. are all supported.

required

In general, the *argparse* module assumes that flags like `-f` and `--bar` indicate *optional* arguments, which can always be omitted at the command line. To make an option *required*, `True` can be specified for the `required=` keyword argument to *add_argument()*:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', required=True)
>>> parser.parse_args(['--foo', 'BAR'])
Namespace(foo='BAR')
>>> parser.parse_args([])
usage: argparse.py [-h] [--foo FOO]
argparse.py: error: option --foo is required
```

As the example shows, if an option is marked as required, *parse_args()* will report an error if that option is not present at the command line.

注解： Required options are generally considered bad form because users expect *options* to be *optional*, and thus they should be avoided when possible.

help

The *help* value is a string containing a brief description of the argument. When a user requests help (usually by using `-h` or `--help` at the command line), these help descriptions will be displayed with each argument:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', action='store_true',
...                     help='foo the bars before frobbling')
>>> parser.add_argument('bar', nargs='+',
...                     help='one of the bars to be frobbled')
>>> parser.parse_args(['-h'])
usage: frobble [-h] [--foo] bar [bar ...]

positional arguments:
  bar                one of the bars to be frobbled

optional arguments:
  -h, --help        show this help message and exit
  --foo            foo the bars before frobbling
```

The *help* strings can include various format specifiers to avoid repetition of things like the program name or the argument *default*. The available specifiers include the program name, `%(prog)s` and most keyword arguments to

`add_argument()`, e.g. `%(default)s`, `%(type)s`, etc.:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('bar', nargs='?', type=int, default=42,
...                     help='the bar to %(prog)s (default: %(default)s)')
>>> parser.print_help()
usage: frobble [-h] [bar]

positional arguments:
  bar      the bar to frobble (default: 42)

optional arguments:
  -h, --help  show this help message and exit
```

As the help string supports %-formatting, if you want a literal % to appear in the help string, you must escape it as %%.

`argparse` supports silencing the help entry for certain options, by setting the help value to `argparse.SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', help=argparse.SUPPRESS)
>>> parser.print_help()
usage: frobble [-h]

optional arguments:
  -h, --help  show this help message and exit
```

metavar

When `ArgumentParser` generates help messages, it needs some way to refer to each expected argument. By default, `ArgumentParser` objects use the `dest` value as the “name” of each object. By default, for positional argument actions, the `dest` value is used directly, and for optional argument actions, the `dest` value is uppercased. So, a single positional argument with `dest='bar'` will be referred to as `bar`. A single optional argument `--foo` that should be followed by a single command-line argument will be referred to as `FOO`. An example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage: [-h] [--foo FOO] bar

positional arguments:
  bar

optional arguments:
  -h, --help  show this help message and exit
  --foo FOO
```

An alternative name can be specified with `metavar`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', metavar='YYY')
>>> parser.add_argument('bar', metavar='XXX')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
```

(下页继续)

(续上页)

```
>>> parser.print_help()
usage:  [-h] [--foo YYY] XXX

positional arguments:
  XXX

optional arguments:
  -h, --help  show this help message and exit
  --foo YYY
```

Note that `metavar` only changes the *displayed* name - the name of the attribute on the `parse_args()` object is still determined by the *dest* value.

Different values of `nargs` may cause the metavar to be used multiple times. Providing a tuple to `metavar` specifies a different display for each of the arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', nargs=2)
>>> parser.add_argument('--foo', nargs=2, metavar=('bar', 'baz'))
>>> parser.print_help()
usage: PROG [-h] [-x X X] [--foo bar baz]

optional arguments:
  -h, --help            show this help message and exit
  -x X X
  --foo bar baz
```

dest

Most `ArgumentParser` actions add some value as an attribute of the object returned by `parse_args()`. The name of this attribute is determined by the `dest` keyword argument of `add_argument()`. For positional argument actions, `dest` is normally supplied as the first argument to `add_argument()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar')
>>> parser.parse_args(['XXX'])
Namespace(bar='XXX')
```

For optional argument actions, the value of `dest` is normally inferred from the option strings. `ArgumentParser` generates the value of `dest` by taking the first long option string and stripping away the initial `--` string. If no long option strings were supplied, `dest` will be derived from the first short option string by stripping the initial `-` character. Any internal `-` characters will be converted to `_` characters to make sure the string is a valid attribute name. The examples below illustrate this behavior:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('-f', '--foo-bar', '--foo')
>>> parser.add_argument('-x', '-y')
>>> parser.parse_args('-f 1 -x 2'.split())
Namespace(foo_bar='1', x='2')
>>> parser.parse_args('--foo 1 -y 2'.split())
Namespace(foo_bar='1', x='2')
```

`dest` allows a custom attribute name to be provided:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', dest='bar')
>>> parser.parse_args('--foo XXX'.split())
Namespace(bar='XXX')
```

Action classes

Action classes implement the Action API, a callable which returns a callable which processes arguments from the command-line. Any object which follows this API may be passed as the `action` parameter to `add_argument()`.

class `argparse.Action`(*option_strings*, *dest*, *nargs=None*, *const=None*, *default=None*, *type=None*, *choices=None*, *required=False*, *help=None*, *metavar=None*)

Action objects are used by an `ArgumentParser` to represent the information needed to parse a single argument from one or more strings from the command line. The Action class must accept the two positional arguments plus any keyword arguments passed to `ArgumentParser.add_argument()` except for the `action` itself.

Instances of Action (or return value of any callable to the `action` parameter) should have attributes “`dest`”, “`option_strings`”, “`default`”, “`type`”, “`required`”, “`help`”, etc. defined. The easiest way to ensure these attributes are defined is to call `Action.__init__`.

Action instances should be callable, so subclasses must override the `__call__` method, which should accept four parameters:

- `parser` - The `ArgumentParser` object which contains this action.
- `namespace` - The `Namespace` object that will be returned by `parse_args()`. Most actions add an attribute to this object using `setattr()`.
- `values` - The associated command-line arguments, with any type conversions applied. Type conversions are specified with the `type` keyword argument to `add_argument()`.
- `option_string` - The option string that was used to invoke this action. The `option_string` argument is optional, and will be absent if the action is associated with a positional argument.

The `__call__` method may perform arbitrary actions, but will typically set attributes on the `namespace` based on `dest` and `values`.

16.4.4 The `parse_args()` method

`ArgumentParser.parse_args`(*args=None*, *namespace=None*)

Convert argument strings to objects and assign them as attributes of the namespace. Return the populated namespace.

Previous calls to `add_argument()` determine exactly what objects are created and how they are assigned. See the documentation for `add_argument()` for details.

- *args* - List of strings to parse. The default is taken from `sys.argv`.
- *namespace* - An object to take the attributes. The default is a new empty `Namespace` object.

Option value syntax

The `parse_args()` method supports several ways of specifying the value of an option (if it takes one). In the simplest case, the option and its value are passed as two separate arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('--foo')
>>> parser.parse_args(['-x', 'X'])
Namespace(foo=None, x='X')
>>> parser.parse_args(['--foo', 'FOO'])
Namespace(foo='FOO', x=None)
```

For long options (options with names longer than a single character), the option and value can also be passed as a single command-line argument, using `=` to separate them:

```
>>> parser.parse_args(['--foo=FOO'])
Namespace(foo='FOO', x=None)
```

For short options (options only one character long), the option and its value can be concatenated:

```
>>> parser.parse_args(['-xX'])
Namespace(foo=None, x='X')
```

Several short options can be joined together, using only a single `-` prefix, as long as only the last option (or none of them) requires a value:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', action='store_true')
>>> parser.add_argument('-y', action='store_true')
>>> parser.add_argument('-z')
>>> parser.parse_args(['-xyzZ'])
Namespace(x=True, y=True, z='Z')
```

Invalid arguments

While parsing the command line, `parse_args()` checks for a variety of errors, including ambiguous options, invalid types, invalid options, wrong number of positional arguments, etc. When it encounters such an error, it exits and prints the error along with a usage message:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', nargs='?')

>>> # invalid type
>>> parser.parse_args(['--foo', 'spam'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: argument --foo: invalid int value: 'spam'

>>> # invalid option
>>> parser.parse_args(['--bar'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: no such option: --bar

>>> # wrong number of arguments
>>> parser.parse_args(['spam', 'badger'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: extra arguments found: badger
```

Arguments containing –

The `parse_args()` method attempts to give errors whenever the user has clearly made a mistake, but some situations are inherently ambiguous. For example, the command-line argument `-1` could either be an attempt to specify an option or an attempt to provide a positional argument. The `parse_args()` method is cautious here: positional arguments may only begin with `-` if they look like negative numbers and there are no options in the parser that look like negative numbers:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('foo', nargs='?')

>>> # no negative number options, so -1 is a positional argument
>>> parser.parse_args(['-x', '-1'])
Namespace(foo=None, x='-1')

>>> # no negative number options, so -1 and -5 are positional arguments
>>> parser.parse_args(['-x', '-1', '-5'])
Namespace(foo='-5', x='-1')

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-1', dest='one')
>>> parser.add_argument('foo', nargs='?')

>>> # negative number options present, so -1 is an option
>>> parser.parse_args(['-1', 'X'])
Namespace(foo=None, one='X')

>>> # negative number options present, so -2 is an option
>>> parser.parse_args(['-2'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: no such option: -2

>>> # negative number options present, so both -1s are options
>>> parser.parse_args(['-1', '-1'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: argument -1: expected one argument
```

If you have positional arguments that must begin with `-` and don't look like negative numbers, you can insert the pseudo-argument `--` which tells `parse_args()` that everything after that is a positional argument:

```
>>> parser.parse_args(['--', '-f'])
Namespace(foo='-f', one=None)
```

Argument abbreviations (prefix matching)

The `parse_args()` method *by default* allows long options to be abbreviated to a prefix, if the abbreviation is unambiguous (the prefix matches a unique option):

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-bacon')
>>> parser.add_argument('-badger')
>>> parser.parse_args(['-bac MMM'].split())
Namespace(bacon='MMM', badger=None)
>>> parser.parse_args(['-bad WOOD'].split())
Namespace(bacon=None, badger='WOOD')
```

(下页继续)

(续上页)

```
>>> parser.parse_args('-ba BA'.split())
usage: PROG [-h] [-bacon BACON] [-badger BADGER]
PROG: error: ambiguous option: -ba could match -badger, -bacon
```

An error is produced for arguments that could produce more than one options. This feature can be disabled by setting `allow_abbrev` to `False`.

Beyond `sys.argv`

Sometimes it may be useful to have an `ArgumentParser` parse arguments other than those of `sys.argv`. This can be accomplished by passing a list of strings to `parse_args()`. This is useful for testing at the interactive prompt:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument(
...     'integers', metavar='int', type=int, choices=range(10),
...     nargs='+', help='an integer in the range 0..9')
>>> parser.add_argument(
...     '--sum', dest='accumulate', action='store_const', const=sum,
...     default=max, help='sum the integers (default: find the max)')
>>> parser.parse_args(['1', '2', '3', '4'])
Namespace(accumulate=<built-in function max>, integers=[1, 2, 3, 4])
>>> parser.parse_args(['1', '2', '3', '4', '--sum'])
Namespace(accumulate=<built-in function sum>, integers=[1, 2, 3, 4])
```

The Namespace object

`class` `argparse.Namespace`

Simple class used by default by `parse_args()` to create an object holding attributes and return it.

This class is deliberately simple, just an `object` subclass with a readable string representation. If you prefer to have dict-like view of the attributes, you can use the standard Python idiom, `vars()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> args = parser.parse_args(['--foo', 'BAR'])
>>> vars(args)
{'foo': 'BAR'}
```

It may also be useful to have an `ArgumentParser` assign attributes to an already existing object, rather than a new `Namespace` object. This can be achieved by specifying the `namespace=` keyword argument:

```
>>> class C:
...     pass
...
>>> c = C()
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args(args=['--foo', 'BAR'], namespace=c)
>>> c.foo
'BAR'
```

16.4.5 Other utilities

Sub-commands

`ArgumentParser.add_subparsers` (`[title][, description][, prog][, parser_class][, action][, option_string][, dest][, help][, metavar]`)

Many programs split up their functionality into a number of sub-commands, for example, the `svn` program can invoke sub-commands like `svn checkout`, `svn update`, and `svn commit`. Splitting up functionality this way can be a particularly good idea when a program performs several different functions which require different kinds of command-line arguments. `ArgumentParser` supports the creation of such sub-commands with the `add_subparsers()` method. The `add_subparsers()` method is normally called with no arguments and returns a special action object. This object has a single method, `add_parser()`, which takes a command name and any `ArgumentParser` constructor arguments, and returns an `ArgumentParser` object that can be modified as usual.

Description of parameters:

- `title` - title for the sub-parser group in help output; by default “subcommands” if description is provided, otherwise uses title for positional arguments
- `description` - description for the sub-parser group in help output, by default `None`
- `prog` - usage information that will be displayed with sub-command help, by default the name of the program and any positional arguments before the subparser argument
- `parser_class` - class which will be used to create sub-parser instances, by default the class of the current parser (e.g. `ArgumentParser`)
- `action` - the basic type of action to be taken when this argument is encountered at the command line
- `dest` - name of the attribute under which sub-command name will be stored; by default `None` and no value is stored
- `help` - help for sub-parser group in help output, by default `None`
- `metavar` - string presenting available sub-commands in help; by default it is `None` and presents sub-commands in form `{cmd1, cmd2, ..}`

Some example usage:

```
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', action='store_true', help='foo help')
>>> subparsers = parser.add_subparsers(help='sub-command help')
>>>
>>> # create the parser for the "a" command
>>> parser_a = subparsers.add_parser('a', help='a help')
>>> parser_a.add_argument('bar', type=int, help='bar help')
>>>
>>> # create the parser for the "b" command
>>> parser_b = subparsers.add_parser('b', help='b help')
>>> parser_b.add_argument('--baz', choices='XYZ', help='baz help')
>>>
>>> # parse some argument lists
>>> parser.parse_args(['a', '12'])
Namespace(bar=12, foo=False)
>>> parser.parse_args(['--foo', 'b', '--baz', 'Z'])
Namespace(baz='Z', foo=True)
```

Note that the object returned by `parse_args()` will only contain attributes for the main parser and the subparser that was selected by the command line (and not any other subparsers). So in the example above, when the `a` command is specified, only the `foo` and `bar` attributes are present, and when the `b` command is specified, only the `foo` and `baz` attributes are present.

Similarly, when a help message is requested from a subparser, only the help for that particular parser will be printed. The help message will not include parent parser or sibling parser messages. (A help message for each subparser command, however, can be given by supplying the `help=` argument to `add_parser()` as above.)

```
>>> parser.parse_args(['--help'])
usage: PROG [-h] [--foo] {a,b} ...

positional arguments:
  {a,b}    sub-command help
  a        a help
  b        b help

optional arguments:
  -h, --help  show this help message and exit
  --foo      foo help

>>> parser.parse_args(['a', '--help'])
usage: PROG a [-h] bar

positional arguments:
  bar      bar help

optional arguments:
  -h, --help  show this help message and exit

>>> parser.parse_args(['b', '--help'])
usage: PROG b [-h] [--baz {X,Y,Z}]

optional arguments:
  -h, --help      show this help message and exit
  --baz {X,Y,Z}  baz help
```

The `add_subparsers()` method also supports `title` and `description` keyword arguments. When either is present, the subparser's commands will appear in their own group in the help output. For example:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(title='subcommands',
...                                   description='valid subcommands',
...                                   help='additional help')
>>> subparsers.add_parser('foo')
>>> subparsers.add_parser('bar')
>>> parser.parse_args(['-h'])
usage: [-h] {foo,bar} ...

optional arguments:
  -h, --help  show this help message and exit

subcommands:
  valid subcommands

  {foo,bar}  additional help
```

Furthermore, `add_parser` supports an additional `aliases` argument, which allows multiple strings to refer to the same subparser. This example, like `svn`, aliases `co` as a shorthand for `checkout`:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>> checkout = subparsers.add_parser('checkout', aliases=['co'])
```

(下页继续)

(续上页)

```
>>> checkout.add_argument('foo')
>>> parser.parse_args(['co', 'bar'])
Namespace(foo='bar')
```

One particularly effective way of handling sub-commands is to combine the use of the `add_subparsers()` method with calls to `set_defaults()` so that each subparser knows which Python function it should execute. For example:

```
>>> # sub-command functions
>>> def foo(args):
...     print(args.x * args.y)
...
>>> def bar(args):
...     print('((%s))' % args.z)
...
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>>
>>> # create the parser for the "foo" command
>>> parser_foo = subparsers.add_parser('foo')
>>> parser_foo.add_argument('-x', type=int, default=1)
>>> parser_foo.add_argument('y', type=float)
>>> parser_foo.set_defaults(func=foo)
>>>
>>> # create the parser for the "bar" command
>>> parser_bar = subparsers.add_parser('bar')
>>> parser_bar.add_argument('z')
>>> parser_bar.set_defaults(func=bar)
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('foo 1 -x 2'.split())
>>> args.func(args)
2.0
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('bar XYZYX'.split())
>>> args.func(args)
((XYZYX))
```

This way, you can let `parse_args()` do the job of calling the appropriate function after argument parsing is complete. Associating functions with actions like this is typically the easiest way to handle the different actions for each of your subparsers. However, if it is necessary to check the name of the subparser that was invoked, the `dest` keyword argument to the `add_subparsers()` call will work:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(dest='subparser_name')
>>> subparser1 = subparsers.add_parser('1')
>>> subparser1.add_argument('-x')
>>> subparser2 = subparsers.add_parser('2')
>>> subparser2.add_argument('y')
>>> parser.parse_args(['2', 'frobble'])
Namespace(subparser_name='2', y='frobble')
```

FileType objects

class `argparse.FileType` (*mode='r', bufsize=-1, encoding=None, errors=None*)

The `FileType` factory creates objects that can be passed to the `type` argument of `ArgumentParser.add_argument()`. Arguments that have `FileType` objects as their type will open command-line arguments as files with the requested modes, buffer sizes, encodings and error handling (see the `open()` function for more details):

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--raw', type=argparse.FileType('wb', 0))
>>> parser.add_argument('out', type=argparse.FileType('w', encoding='UTF-8'))
>>> parser.parse_args(['--raw', 'raw.dat', 'file.txt'])
Namespace(out=<_io.TextIOWrapper name='file.txt' mode='w' encoding='UTF-8'>, raw=
↳ <_io.FileIO name='raw.dat' mode='wb'>)
```

`FileType` objects understand the pseudo-argument `'-'` and automatically convert this into `sys.stdin` for readable `FileType` objects and `sys.stdout` for writable `FileType` objects:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', type=argparse.FileType('r'))
>>> parser.parse_args(['-'])
Namespace(infile=<_io.TextIOWrapper name='<stdin>' encoding='UTF-8'>)
```

3.4 新版功能: The *encodings* and *errors* keyword arguments.

Argument groups

`ArgumentParser.add_argument_group` (*title=None, description=None*)

By default, `ArgumentParser` groups command-line arguments into “positional arguments” and “optional arguments” when displaying help messages. When there is a better conceptual grouping of arguments than this default one, appropriate groups can be created using the `add_argument_group()` method:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group = parser.add_argument_group('group')
>>> group.add_argument('--foo', help='foo help')
>>> group.add_argument('bar', help='bar help')
>>> parser.print_help()
usage: PROG [--foo FOO] bar

group:
  bar      bar help
  --foo FOO  foo help
```

The `add_argument_group()` method returns an argument group object which has an `add_argument()` method just like a regular `ArgumentParser`. When an argument is added to the group, the parser treats it just like a normal argument, but displays the argument in a separate group for help messages. The `add_argument_group()` method accepts *title* and *description* arguments which can be used to customize this display:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group1 = parser.add_argument_group('group1', 'group1 description')
>>> group1.add_argument('foo', help='foo help')
>>> group2 = parser.add_argument_group('group2', 'group2 description')
>>> group2.add_argument('--bar', help='bar help')
>>> parser.print_help()
```

(下页继续)

(续上页)

```
usage: PROG [--bar BAR] foo

group1:
  group1 description

  foo      foo help

group2:
  group2 description

  --bar BAR  bar help
```

Note that any arguments not in your user-defined groups will end up back in the usual “positional arguments” and “optional arguments” sections.

Mutual exclusion

`ArgumentParser.add_mutually_exclusive_group(required=False)`

创建一个互斥组。`argparse` 将会确保互斥组中只有一个参数在命令行中可用:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group()
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args(['--foo'])
Namespace(bar=True, foo=True)
>>> parser.parse_args(['--bar'])
Namespace(bar=False, foo=False)
>>> parser.parse_args(['--foo', '--bar'])
usage: PROG [-h] [--foo | --bar]
PROG: error: argument --bar: not allowed with argument --foo
```

`add_mutually_exclusive_group()` 方法也接受一个 `required` 参数, 表示在互斥组中至少有一个参数是需要的:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group(required=True)
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args([])
usage: PROG [-h] (--foo | --bar)
PROG: error: one of the arguments --foo --bar is required
```

注意, 目前互斥参数组不支持 `add_argument_group()` 的 `title` 和 `description` 参数。

Parser defaults

`ArgumentParser.set_defaults(**kwargs)`

Most of the time, the attributes of the object returned by `parse_args()` will be fully determined by inspecting the command-line arguments and the argument actions. `set_defaults()` allows some additional attributes that are determined without any inspection of the command line to be added:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.set_defaults(bar=42, baz='badger')
>>> parser.parse_args(['736'])
Namespace(bar=42, baz='badger', foo=736)
```

Note that parser-level defaults always override argument-level defaults:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='bar')
>>> parser.set_defaults(foo='spam')
>>> parser.parse_args([])
Namespace(foo='spam')
```

Parser-level defaults can be particularly useful when working with multiple parsers. See the `add_subparsers()` method for an example of this type.

`ArgumentParser.get_default(dest)`

Get the default value for a namespace attribute, as set by either `add_argument()` or by `set_defaults()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='badger')
>>> parser.get_default('foo')
'badger'
```

Printing help

In most typical applications, `parse_args()` will take care of formatting and printing any usage or error messages. However, several formatting methods are available:

`ArgumentParser.print_usage(file=None)`

Print a brief description of how the `ArgumentParser` should be invoked on the command line. If `file` is `None`, `sys.stdout` is assumed.

`ArgumentParser.print_help(file=None)`

Print a help message, including the program usage and information about the arguments registered with the `ArgumentParser`. If `file` is `None`, `sys.stdout` is assumed.

There are also variants of these methods that simply return a string instead of printing it:

`ArgumentParser.format_usage()`

Return a string containing a brief description of how the `ArgumentParser` should be invoked on the command line.

`ArgumentParser.format_help()`

Return a string containing a help message, including the program usage and information about the arguments registered with the `ArgumentParser`.

Partial parsing

`ArgumentParser.parse_known_args(args=None, namespace=None)`

Sometimes a script may only parse a few of the command-line arguments, passing the remaining arguments on to another script or program. In these cases, the `parse_known_args()` method can be useful. It works much like `parse_args()` except that it does not produce an error when extra arguments are present. Instead, it returns a two item tuple containing the populated namespace and the list of remaining argument strings.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('bar')
>>> parser.parse_known_args(['--foo', '--badger', 'BAR', 'spam'])
(Namespace(bar='BAR', foo=True), ['--badger', 'spam'])
```

警告: *Prefix matching* rules apply to `parse_known_args()`. The parser may consume an option even if it's just a prefix of one of its known options, instead of leaving it in the remaining arguments list.

Customizing file parsing

`ArgumentParser.convert_arg_line_to_args(arg_line)`

Arguments that are read from a file (see the *fromfile_prefix_chars* keyword argument to the *ArgumentParser* constructor) are read one argument per line. *convert_arg_line_to_args()* can be overridden for fancier reading.

This method takes a single argument *arg_line* which is a string read from the argument file. It returns a list of arguments parsed from this string. The method is called once per line read from the argument file, in order.

A useful override of this method is one that treats each space-separated word as an argument. The following example demonstrates how to do this:

```
class MyArgumentParser(argparse.ArgumentParser):
    def convert_arg_line_to_args(self, arg_line):
        return arg_line.split()
```

Exiting methods

`ArgumentParser.exit(status=0, message=None)`

This method terminates the program, exiting with the specified *status* and, if given, it prints a *message* before that.

`ArgumentParser.error(message)`

This method prints a usage message including the *message* to the standard error and terminates the program with a status code of 2.

16.4.6 Upgrading optparse code

Originally, the *argparse* module had attempted to maintain compatibility with *optparse*. However, *optparse* was difficult to extend transparently, particularly with the changes required to support the new *nargs=* specifiers and better usage messages. When most everything in *optparse* had either been copy-pasted over or monkey-patched, it no longer seemed practical to try to maintain the backwards compatibility.

The *argparse* module improves on the standard library *optparse* module in a number of ways including:

- Handling positional arguments.
- Supporting sub-commands.
- Allowing alternative option prefixes like `+` and `/`.
- Handling zero-or-more and one-or-more style arguments.
- Producing more informative usage messages.

- Providing a much simpler interface for custom type and action.

A partial upgrade path from *optparse* to *argparse*:

- Replace all `optparse.OptionParser.add_option()` calls with `ArgumentParser.add_argument()` calls.
- Replace `(options, args) = parser.parse_args()` with `args = parser.parse_args()` and add additional `ArgumentParser.add_argument()` calls for the positional arguments. Keep in mind that what was previously called `options`, now in the *argparse* context is called `args`.
- Replace `optparse.OptionParser.disable_interspersed_args()` by setting `nargs` of a positional argument to `argparse.REMAINDER`, or use `parse_known_args()` to collect unparsed argument strings in a separate list.
- Replace callback actions and the `callback_*` keyword arguments with `type` or `action` arguments.
- Replace string names for `type` keyword arguments with the corresponding type objects (e.g. `int`, `float`, `complex`, etc).
- Replace `optparse.Values` with `Namespace` and `optparse.OptionError` and `optparse.OptionValueError` with `ArgumentError`.
- Replace strings with implicit arguments such as `%default` or `%prog` with the standard Python syntax to use dictionaries to format strings, that is, `%(default)s` and `%(prog)s`.
- Replace the `OptionParser` constructor `version` argument with a call to `parser.add_argument('--version', action='version', version='<the version>')`.

16.5 getopt —C-style parser for command line options

Source code: [Lib/getopt.py](#)

注解: The *getopt* module is a parser for command line options whose API is designed to be familiar to users of the C `getopt()` function. Users who are unfamiliar with the C `getopt()` function or who would like to write less code and get better help and error messages should consider using the *argparse* module instead.

This module helps scripts to parse the command line arguments in `sys.argv`. It supports the same conventions as the Unix `getopt()` function (including the special meanings of arguments of the form `'-'` and `'--'`). Long options similar to those supported by GNU software may be used as well via an optional third argument.

This module provides two functions and an exception:

`getopt.getopt(args, shortopts, longopts=[])`

Parses command line options and parameter list. *args* is the argument list to be parsed, without the leading reference to the running program. Typically, this means `sys.argv[1:]`. *shortopts* is the string of option letters that the script wants to recognize, with options that require an argument followed by a colon (':'); i.e., the same format that Unix `getopt()` uses).

注解: Unlike GNU `getopt()`, after a non-option argument, all further arguments are considered also non-options. This is similar to the way non-GNU Unix systems work.

longopts, if specified, must be a list of strings with the names of the long options which should be supported. The leading `'--'` characters should not be included in the option name. Long options which require an argument

should be followed by an equal sign ('='). Optional arguments are not supported. To accept only long options, *shortopts* should be an empty string. Long options on the command line can be recognized so long as they provide a prefix of the option name that matches exactly one of the accepted options. For example, if *longopts* is ['foo', 'frob'], the option --fo will match as --foo, but --f will not match uniquely, so *GetoptError* will be raised.

The return value consists of two elements: the first is a list of (option, value) pairs; the second is the list of program arguments left after the option list was stripped (this is a trailing slice of *args*). Each option-and-value pair returned has the option as its first element, prefixed with a hyphen for short options (e.g., '-x') or two hyphens for long options (e.g., '--long-option'), and the option argument as its second element, or an empty string if the option has no argument. The options occur in the list in the same order in which they were found, thus allowing multiple occurrences. Long and short options may be mixed.

`getopt.gnu_getopt (args, shortopts, longopts=[])`

This function works like *getopt()*, except that GNU style scanning mode is used by default. This means that option and non-option arguments may be intermixed. The *getopt()* function stops processing options as soon as a non-option argument is encountered.

If the first character of the option string is '+', or if the environment variable `POSIIXLY_CORRECT` is set, then option processing stops as soon as a non-option argument is encountered.

exception `getopt.GetoptError`

This is raised when an unrecognized option is found in the argument list or when an option requiring an argument is given none. The argument to the exception is a string indicating the cause of the error. For long options, an argument given to an option which does not require one will also cause this exception to be raised. The attributes *msg* and *opt* give the error message and related option; if there is no specific option to which the exception relates, *opt* is an empty string.

exception `getopt.error`

Alias for *GetoptError*; for backward compatibility.

An example using only Unix style options:

```
>>> import getopt
>>> args = '-a -b -cfoo -d bar a1 a2'.split()
>>> args
['-a', '-b', '-cfoo', '-d', 'bar', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'abc:d:')
>>> optlist
[('-a', ''), ('-b', ''), ('-c', 'foo'), ('-d', 'bar')]
>>> args
['a1', 'a2']
```

Using long option names is equally easy:

```
>>> s = '--condition=foo --testing --output-file abc.def -x a1 a2'
>>> args = s.split()
>>> args
['--condition=foo', '--testing', '--output-file', 'abc.def', '-x', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'x', [
...     'condition=', 'output-file=', 'testing'])
>>> optlist
[('--condition', 'foo'), ('--testing', ''), ('--output-file', 'abc.def'), ('-x', '')]
>>> args
['a1', 'a2']
```

In a script, typical usage is something like this:

```

import getopt, sys

def main():
    try:
        opts, args = getopt.getopt(sys.argv[1:], "ho:v", ["help", "output="])
    except getopt.GetoptError as err:
        # print help information and exit:
        print(err) # will print something like "option -a not recognized"
        usage()
        sys.exit(2)
    output = None
    verbose = False
    for o, a in opts:
        if o == "-v":
            verbose = True
        elif o in ("-h", "--help"):
            usage()
            sys.exit()
        elif o in ("-o", "--output"):
            output = a
        else:
            assert False, "unhandled option"
    # ...

if __name__ == "__main__":
    main()

```

Note that an equivalent command line interface could be produced with less code and more informative help and error messages by using the [argparse](#) module:

```

import argparse

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument('-o', '--output')
    parser.add_argument('-v', dest='verbose', action='store_true')
    args = parser.parse_args()
    # ... do something with args.output ...
    # ... do something with args.verbose ..

```

16.6 模块 logging —Python 的日志记录工具

源代码: [Lib/logging/__init__.py](#)

Important

此页面仅包含 API 参考信息。有关更多高级主题的教程信息和讨论，请参阅

- 基础教程
- 进阶教程

这个模块为应用与库定义了实现灵活的事件日志系统的函数与类。

使用标准库提供的 logging API 最主要的好处是，所有的 Python 模块都可能参与日志输出，包括你的日志消息和第三方模块的日志消息。

这个模块提供许多强大而灵活的功能。如果你对 logging 不太熟悉的话，掌握它最好的方式就是查看它对应的教程（详见右侧的链接）。

该模块定义的基础类和函数都列在下面。

- 记录器暴露了应用程序代码直接使用的接口。
- 处理程序将日志记录（由记录器创建）发送到适当的目标。
- 过滤器提供了更精细的设施，用于确定要输出的日志记录。
- 格式化程序指定最终输出中日志记录的样式。

16.6.1 Logger 对象

Loggers 有下面的属性和方法。要注意的是，不要直接实例化 Loggers，但是可以通过模块级的函数“`logging.getLogger(name)`”。多次使用相同的名字调用 `getLogger()` 函数只会返回指向同一个 Logger 对象。

The name is potentially a period-separated hierarchical value, like `foo.bar.baz` (though it could also be just plain `foo`, for example). Loggers that are further down in the hierarchical list are children of loggers higher up in the list. For example, given a logger with a name of `foo`, loggers with names of `foo.bar`, `foo.bar.baz`, and `foo.bam` are all descendants of `foo`. The logger name hierarchy is analogous to the Python package hierarchy, and identical to it if you organise your loggers on a per-module basis using the recommended construction `logging.getLogger(__name__)`. That's because in a module, `__name__` is the module's name in the Python package namespace.

```
class logging.Logger
```

propagate

If this attribute evaluates to true, events logged to this logger will be passed to the handlers of higher level (ancestor) loggers, in addition to any handlers attached to this logger. Messages are passed directly to the ancestor loggers' handlers - neither the level nor filters of the ancestor loggers in question are considered.

If this evaluates to false, logging messages are not passed to the handlers of ancestor loggers.

构造器将这个属性初始化为 `True`。

注解： If you attach a handler to a logger *and* one or more of its ancestors, it may emit the same record multiple times. In general, you should not need to attach a handler to more than one logger - if you just attach it to the appropriate logger which is highest in the logger hierarchy, then it will see all events logged by all descendant loggers, provided that their propagate setting is left set to `True`. A common scenario is to attach handlers only to the root logger, and to let propagation take care of the rest.

setLevel (level)

Sets the threshold for this logger to *level*. Logging messages which are less severe than *level* will be ignored; logging messages which have severity *level* or higher will be emitted by whichever handler or handlers service this logger, unless a handler's level has been set to a higher severity level than *level*.

When a logger is created, the level is set to `NOTSET` (which causes all messages to be processed when the logger is the root logger, or delegation to the parent when the logger is a non-root logger). Note that the root logger is created with level `WARNING`.

The term ‘delegation to the parent’ means that if a logger has a level of `NOTSET`, its chain of ancestor loggers is traversed until either an ancestor with a level other than `NOTSET` is found, or the root is reached.

If an ancestor is found with a level other than `NOTSET`, then that ancestor’s level is treated as the effective level of the logger where the ancestor search began, and is used to determine how a logging event is handled.

If the root is reached, and it has a level of `NOTSET`, then all messages will be processed. Otherwise, the root’s level will be used as the effective level.

See [日志级别](#) for a list of levels.

在 3.2 版更改: The *level* parameter now accepts a string representation of the level such as ‘`INFO`’ as an alternative to the integer constants such as `INFO`. Note, however, that levels are internally stored as integers, and methods such as e.g. `getEffectiveLevel()` and `isEnabledFor()` will return/expect to be passed integers.

`isEnabledFor(lvl)`

Indicates if a message of severity *lvl* would be processed by this logger. This method checks first the module-level level set by `logging.disable(lvl)` and then the logger’s effective level as determined by `getEffectiveLevel()`.

`getEffectiveLevel()`

Indicates the effective level for this logger. If a value other than `NOTSET` has been set using `setLevel()`, it is returned. Otherwise, the hierarchy is traversed towards the root until a value other than `NOTSET` is found, and that value is returned. The value returned is an integer, typically one of `logging.DEBUG`, `logging.INFO` etc.

`getChild(suffix)`

Returns a logger which is a descendant to this logger, as determined by the suffix. Thus, `logging.getLogger('abc').getChild('def.ghi')` would return the same logger as would be returned by `logging.getLogger('abc.def.ghi')`. This is a convenience method, useful when the parent logger is named using e.g. `__name__` rather than a literal string.

3.2 新版功能.

`debug(msg, *args, **kwargs)`

Logs a message with level `DEBUG` on this logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are three keyword arguments in *kwargs* which are inspected: *exc_info*, *stack_info*, and *extra*.

If *exc_info* does not evaluate as false, it causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) or an exception instance is provided, it is used; otherwise, `sys.exc_info()` is called to get the exception information.

The second optional keyword argument is *stack_info*, which defaults to `False`. If true, stack information is added to the logging message, including the actual logging call. Note that this is not the same stack information as that displayed through specifying *exc_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify *stack_info* independently of *exc_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback` (most recent call last): which is used when displaying exception frames.

The third keyword argument is *extra* which can be used to pass a dictionary which is used to populate the `__dict__` of the `LogRecord` created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)-15s %(clientip)s %(user)-8s %(message)s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logger = logging.getLogger('tcpserver')
logger.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs Protocol problem: connection_
↪reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the *Formatter* documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the *Formatter* has been set up with a format string which expects 'clientip' and 'user' in the attribute dictionary of the `LogRecord`. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized *Formatters* would be used with particular *Handlers*.

3.2 新版功能: The *stack_info* parameter was added.

在 3.5 版更改: The *exc_info* parameter can now accept exception instances.

info (*msg*, **args*, ***kwargs*)

Logs a message with level INFO on this logger. The arguments are interpreted as for *debug()*.

warning (*msg*, **args*, ***kwargs*)

Logs a message with level WARNING on this logger. The arguments are interpreted as for *debug()*.

注解: There is an obsolete method `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

error (*msg*, **args*, ***kwargs*)

Logs a message with level ERROR on this logger. The arguments are interpreted as for *debug()*.

critical (*msg*, **args*, ***kwargs*)

Logs a message with level CRITICAL on this logger. The arguments are interpreted as for *debug()*.

log (*lvl*, *msg*, **args*, ***kwargs*)

Logs a message with integer level *lvl* on this logger. The other arguments are interpreted as for *debug()*.

exception (*msg*, **args*, ***kwargs*)

Logs a message with level ERROR on this logger. The arguments are interpreted as for *debug()*. Exception info is added to the logging message. This method should only be called from an exception handler.

addFilter (*filter*)

Adds the specified filter *filter* to this logger.

removeFilter (*filter*)

Removes the specified filter *filter* from this logger.

filter (*record*)

Applies this logger's filters to the record and returns a true value if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be processed (passed to handlers). If one returns a false value, no further processing of the record occurs.

addHandler (*hdlr*)

Adds the specified handler *hdlr* to this logger.

removeHandler (*hdlr*)

Removes the specified handler *hdlr* from this logger.

findCaller (*stack_info=False*)

Finds the caller's source filename and line number. Returns the filename, line number, function name and stack information as a 4-element tuple. The stack information is returned as `None` unless *stack_info* is `True`.

handle (*record*)

Handles a record by passing it to all handlers associated with this logger and its ancestors (until a false value of *propagate* is found). This method is used for unpickled records received from a socket, as well as those created locally. Logger-level filtering is applied using *filter()*.

makeRecord (*name, lvl, fn, lno, msg, args, exc_info, func=None, extra=None, sinfo=None*)

This is a factory method which can be overridden in subclasses to create specialized *LogRecord* instances.

hasHandlers ()

Checks to see if this logger has any handlers configured. This is done by looking for handlers in this logger and its parents in the logger hierarchy. Returns `True` if a handler was found, else `False`. The method stops searching up the hierarchy whenever a logger with the 'propagate' attribute set to false is found - that will be the last logger which is checked for the existence of handlers.

3.2 新版功能.

在 3.7 版更改: Loggers can now be pickled and unpickled.

16.6.2 日志级别

日志记录级别的数值在下表中给出。如果你想要定义自己的级别，并且需要它们具有相对于预定义级别的特定值，那么这些内容可能是你感兴趣的。如果你定义具有相同数值的级别，它将覆盖预定义的值；预定义的名称丢失。

级别	数值
CRITICAL	50
ERROR	40
WARNING	30
INFO	20
DEBUG	10
NOTSET	0

16.6.3 Handler Objects

Handlers have the following attributes and methods. Note that *Handler* is never instantiated directly; this class acts as a base for more useful subclasses. However, the `__init__()` method in subclasses needs to call *Handler*.
`__init__()`.

class logging.**Handler**

__init__ (*level*=NOTSET)

Initializes the *Handler* instance by setting its level, setting the list of filters to the empty list and creating a lock (using *createLock()*) for serializing access to an I/O mechanism.

createLock ()

Initializes a thread lock which can be used to serialize access to underlying I/O functionality which may not be threadsafe.

acquire ()

Acquires the thread lock created with *createLock()*.

release ()

Releases the thread lock acquired with *acquire()*.

setLevel (*level*)

Sets the threshold for this handler to *level*. Logging messages which are less severe than *level* will be ignored. When a handler is created, the level is set to NOTSET (which causes all messages to be processed).

See 日志级别 for a list of levels.

在 3.2 版更改: The *level* parameter now accepts a string representation of the level such as ‘INFO’ as an alternative to the integer constants such as INFO.

setFormatter (*fmt*)

Sets the *Formatter* for this handler to *fmt*.

addFilter (*filter*)

Adds the specified filter *filter* to this handler.

removeFilter (*filter*)

Removes the specified filter *filter* from this handler.

filter (*record*)

Applies this handler’s filters to the record and returns a true value if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be emitted. If one returns a false value, the handler will not emit the record.

flush ()

Ensure all logging output has been flushed. This version does nothing and is intended to be implemented by subclasses.

close ()

Tidy up any resources used by the handler. This version does no output but removes the handler from an internal list of handlers which is closed when *shutdown()* is called. Subclasses should ensure that this gets called from overridden *close()* methods.

handle (*record*)

Conditionally emits the specified logging record, depending on filters which may have been added to the handler. Wraps the actual emission of the record with acquisition/release of the I/O thread lock.

handleError (*record*)

This method should be called from handlers when an exception is encountered during an *emit()* call. If the module-level attribute *raiseExceptions* is False, exceptions get silently ignored. This is what is

mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors. You could, however, replace this with a custom handler if you wish. The specified record is the one which was being processed when the exception occurred. (The default value of `raiseExceptions` is `True`, as that is more useful during development).

format (*record*)

Do formatting for a record - if a formatter is set, use it. Otherwise, use the default formatter for the module.

emit (*record*)

Do whatever it takes to actually log the specified logging record. This version is intended to be implemented by subclasses and so raises a `NotImplementedError`.

For a list of handlers included as standard, see `logging.handlers`.

16.6.4 Formatter Objects

`Formatter` objects have the following attributes and methods. They are responsible for converting a `LogRecord` to (usually) a string which can be interpreted by either a human or an external system. The base `Formatter` allows a formatting string to be specified. If none is supplied, the default value of `'%(message)s'` is used, which just includes the message in the logging call. To have additional items of information in the formatted output (such as a timestamp), keep reading.

A Formatter can be initialized with a format string which makes use of knowledge of the `LogRecord` attributes - such as the default value mentioned above making use of the fact that the user's message and arguments are pre-formatted into a `LogRecord`'s `message` attribute. This format string contains standard Python %-style mapping keys. See section `printf 风格的字符串格式化` for more information on string formatting.

The useful mapping keys in a `LogRecord` are given in the section on `LogRecord attributes`.

class `logging.Formatter` (*fmt=None, datefmt=None, style='%*)

Returns a new instance of the `Formatter` class. The instance is initialized with a format string for the message as a whole, as well as a format string for the date/time portion of a message. If no *fmt* is specified, `'%(message)s'` is used. If no *datefmt* is specified, a format is used which is described in the `formatTime()` documentation.

The *style* parameter can be one of `'%'`, `'{'` or `'$'` and determines how the format string will be merged with its data: using one of %-formatting, `str.format()` or `string.Template`. See formatting-styles for more information on using `{- and $-formatting` for log messages.

在 3.2 版更改: The *style* parameter was added.

format (*record*)

The record's attribute dictionary is used as the operand to a string formatting operation. Returns the resulting string. Before formatting the dictionary, a couple of preparatory steps are carried out. The `message` attribute of the record is computed using `msg % args`. If the formatting string contains `'(asctime)'`, `formatTime()` is called to format the event time. If there is exception information, it is formatted using `formatException()` and appended to the message. Note that the formatted exception information is cached in attribute `exc_text`. This is useful because the exception information can be pickled and sent across the wire, but you should be careful if you have more than one `Formatter` subclass which customizes the formatting of exception information. In this case, you will have to clear the cached value after a formatter has done its formatting, so that the next formatter to handle the event doesn't use the cached value but recalculates it afresh.

If stack information is available, it's appended after the exception information, using `formatStack()` to transform it if necessary.

formatTime (*record, datefmt=None*)

This method should be called from `format()` by a formatter which wants to make use of a formatted time. This method can be overridden in formatters to provide for any specific requirement, but the basic behavior

is as follows: if *datefmt* (a string) is specified, it is used with *time.strftime()* to format the creation time of the record. Otherwise, the format `'%Y-%m-%d %H:%M:%S,uuu'` is used, where the *uuu* part is a millisecond value and the other letters are as per the *time.strftime()* documentation. An example time in this format is `2003-01-23 00:29:50,411`. The resulting string is returned.

This function uses a user-configurable function to convert the creation time to a tuple. By default, *time.localtime()* is used; to change this for a particular formatter instance, set the *converter* attribute to a function with the same signature as *time.localtime()* or *time.gmtime()*. To change it for all formatters, for example if you want all logging times to be shown in GMT, set the *converter* attribute in the *Formatter* class.

在 3.3 版更改: Previously, the default format was hard-coded as in this example: `2010-09-06 22:38:15,292` where the part before the comma is handled by a *strftime* format string (`'%Y-%m-%d %H:%M:%S'`), and the part after the comma is a millisecond value. Because *strftime* does not have a format placeholder for milliseconds, the millisecond value is appended using another format string, `'%s,%03d'` —and both of these format strings have been hardcoded into this method. With the change, these strings are defined as class-level attributes which can be overridden at the instance level when desired. The names of the attributes are *default_time_format* (for the *strftime* format string) and *default_msec_format* (for appending the millisecond value).

formatException (*exc_info*)

Formats the specified exception information (a standard exception tuple as returned by *sys.exc_info()*) as a string. This default implementation just uses *traceback.print_exception()*. The resulting string is returned.

formatStack (*stack_info*)

Formats the specified stack information (a string as returned by *traceback.print_stack()*, but with the last newline removed) as a string. This default implementation just returns the input value.

16.6.5 Filter Objects

Filters can be used by *Handlers* and *Loggers* for more sophisticated filtering than is provided by levels. The base filter class only allows events which are below a certain point in the logger hierarchy. For example, a filter initialized with `'A.B'` will allow events logged by loggers `'A.B'`, `'A.B.C'`, `'A.B.C.D'`, `'A.B.D'` etc. but not `'A.BB'`, `'B.A.B'` etc. If initialized with the empty string, all events are passed.

class *logging.Filter* (*name=""*)

Returns an instance of the *Filter* class. If *name* is specified, it names a logger which, together with its children, will have its events allowed through the filter. If *name* is the empty string, allows every event.

filter (*record*)

Is the specified record to be logged? Returns zero for no, nonzero for yes. If deemed appropriate, the record may be modified in-place by this method.

Note that filters attached to handlers are consulted before an event is emitted by the handler, whereas filters attached to loggers are consulted whenever an event is logged (using *debug()*, *info()*, etc.), before sending an event to handlers. This means that events which have been generated by descendant loggers will not be filtered by a logger's filter setting, unless the filter has also been applied to those descendant loggers.

You don't actually need to subclass *Filter*: you can pass any instance which has a *filter* method with the same semantics.

在 3.2 版更改: You don't need to create specialized *Filter* classes, or use other classes with a *filter* method: you can use a function (or other callable) as a filter. The filtering logic will check to see if the filter object has a *filter* attribute: if it does, it's assumed to be a *Filter* and its *filter()* method is called. Otherwise, it's assumed to be a callable and called with the record as the single parameter. The returned value should conform to that returned by *filter()*.

Although filters are used primarily to filter records based on more sophisticated criteria than levels, they get to see every record which is processed by the handler or logger they're attached to: this can be useful if you want to do things like counting how many records were processed by a particular logger or handler, or adding, changing or removing attributes in the `LogRecord` being processed. Obviously changing the `LogRecord` needs to be done with some care, but it does allow the injection of contextual information into logs (see `filters-contextual`).

16.6.6 LogRecord Objects

`LogRecord` instances are created automatically by the `Logger` every time something is logged, and can be created manually via `makeLogRecord()` (for example, from a pickled event received over the wire).

class `logging.LogRecord` (*name, level, pathname, lineno, msg, args, exc_info, func=None, sinfo=None*)
Contains all the information pertinent to the event being logged.

The primary information is passed in `msg` and `args`, which are combined using `msg % args` to create the message field of the record.

参数

- **name** – The name of the logger used to log the event represented by this `LogRecord`. Note that this name will always have this value, even though it may be emitted by a handler attached to a different (ancestor) logger.
- **level** – The numeric level of the logging event (one of `DEBUG`, `INFO` etc.) Note that this is converted to *two* attributes of the `LogRecord`: `lineno` for the numeric value and `levelname` for the corresponding level name.
- **pathname** – The full pathname of the source file where the logging call was made.
- **lineno** – The line number in the source file where the logging call was made.
- **msg** – The event description message, possibly a format string with placeholders for variable data.
- **args** – Variable data to merge into the `msg` argument to obtain the event description.
- **exc_info** – An exception tuple with the current exception information, or `None` if no exception information is available.
- **func** – The name of the function or method from which the logging call was invoked.
- **sinfo** – A text string representing stack information from the base of the stack in the current thread, up to the logging call.

`getMessage()`

Returns the message for this `LogRecord` instance after merging any user-supplied arguments with the message. If the user-supplied message argument to the logging call is not a string, `str()` is called on it to convert it to a string. This allows use of user-defined classes as messages, whose `__str__` method can return the actual format string to be used.

在 3.2 版更改: The creation of a `LogRecord` has been made more configurable by providing a factory which is used to create the record. The factory can be set using `getLogRecordFactory()` and `setLogRecordFactory()` (see this for the factory's signature).

This functionality can be used to inject your own values into a `LogRecord` at creation time. You can use the following pattern:

```
old_factory = logging.getLogRecordFactory()

def record_factory(*args, **kwargs):
```

(下页继续)

(续上页)

```
record = old_factory(*args, **kwargs)
record.custom_attribute = 0xdecafbad
return record

logging.setLogRecordFactory(record_factory)
```

With this pattern, multiple factories could be chained, and as long as they don't overwrite each other's attributes or unintentionally overwrite the standard attributes listed above, there should be no surprises.

16.6.7 LogRecord attributes

The LogRecord has a number of attributes, most of which are derived from the parameters to the constructor. (Note that the names do not always correspond exactly between the LogRecord constructor parameters and the LogRecord attributes.) These attributes can be used to merge data from the record into the format string. The following table lists (in alphabetical order) the attribute names, their meanings and the corresponding placeholder in a %-style format string.

If you are using {}-formatting (*str.format()*), you can use {attrname} as the placeholder in the format string. If you are using \$-formatting (*string.Template*), use the form \${attrname}. In both cases, of course, replace attrname with the actual attribute name you want to use.

In the case of {}-formatting, you can specify formatting flags by placing them after the attribute name, separated from it with a colon. For example: a placeholder of {msecs:03d} would format a millisecond value of 4 as 004. Refer to the *str.format()* documentation for full details on the options available to you.

属性名称	格式	描述
args	You shouldn't need to format this yourself.	The tuple of arguments merged into <code>msg</code> to produce <code>message</code> , or a dict whose values are used for the merge (when there is only one argument, and it is a dictionary).
asctime	<code>%(asctime)s</code>	Human-readable time when the <code>LogRecord</code> was created. By default this is of the form <code>'2003-07-08 16:49:45,896'</code> (the numbers after the comma are millisecond portion of the time).
created	<code>%(created)f</code>	Time when the <code>LogRecord</code> was created (as returned by <code>time.time()</code>).
exc_info	You shouldn't need to format this yourself.	Exception tuple (à la <code>sys.exc_info</code>) or, if no exception has occurred, <code>None</code> .
filename	<code>%(filename)s</code>	Filename portion of <code>pathname</code> .
funcName	<code>%(funcName)s</code>	Name of function containing the logging call.
levelname	<code>%(levelname)s</code>	Text logging level for the message (<code>'DEBUG'</code> , <code>'INFO'</code> , <code>'WARNING'</code> , <code>'ERROR'</code> , <code>'CRITICAL'</code>).
levelno	<code>%(levelno)s</code>	Numeric logging level for the message (<code>DEBUG</code> , <code>INFO</code> , <code>WARNING</code> , <code>ERROR</code> , <code>CRITICAL</code>).
lineno	<code>%(lineno)d</code>	Source line number where the logging call was issued (if available).
message	<code>%(message)s</code>	The logged message, computed as <code>msg % args</code> . This is set when <code>Formatter.format()</code> is invoked.
module	<code>%(module)s</code>	Module (name portion of <code>filename</code>).
msecs	<code>%(msecs)d</code>	Millisecond portion of the time when the <code>LogRecord</code> was created.
msg	You shouldn't need to format this yourself.	The format string passed in the original logging call. Merged with <code>args</code> to produce <code>message</code> , or an arbitrary object (see arbitrary-object-messages).
name	<code>%(name)s</code>	Name of the logger used to log the call.
pathname	<code>%(pathname)s</code>	Full pathname of the source file where the logging call was issued (if available).
process	<code>%(process)d</code>	Process ID (if available).
processName	<code>%(processName)s</code>	Process name (if available).
relativeCreated	<code>%(relativeCreated)d</code>	Time in milliseconds when the <code>LogRecord</code> was created, relative to the time the logging module was loaded.
stack_info	You shouldn't need to format this yourself.	Stack frame information (where available) from the bottom of the stack in the current thread, up to and including the stack frame of the logging call which resulted in the creation of this record.
thread	<code>%(thread)d</code>	Thread ID (if available).
threadName	<code>%(threadName)s</code>	Thread name (if available).

在 3.1 版更改: `processName` was added.

16.6.8 LoggerAdapter Objects

LoggerAdapter instances are used to conveniently pass contextual information into logging calls. For a usage example, see the section on adding contextual information to your logging output.

class `logging.LoggerAdapter` (*logger*, *extra*)

Returns an instance of *LoggerAdapter* initialized with an underlying *Logger* instance and a dict-like object.

process (*msg*, *kwargs*)

Modifies the message and/or keyword arguments passed to a logging call in order to insert contextual information. This implementation takes the object passed as *extra* to the constructor and adds it to *kwargs* using key 'extra'. The return value is a (*msg*, *kwargs*) tuple which has the (possibly modified) versions of the arguments passed in.

In addition to the above, *LoggerAdapter* supports the following methods of *Logger*: *debug()*, *info()*, *warning()*, *error()*, *exception()*, *critical()*, *log()*, *isEnabledFor()*, *getEffectiveLevel()*, *setLevel()* and *hasHandlers()*. These methods have the same signatures as their counterparts in *Logger*, so you can use the two types of instances interchangeably.

在 3.2 版更改: The *isEnabledFor()*, *getEffectiveLevel()*, *setLevel()* and *hasHandlers()* methods were added to *LoggerAdapter*. These methods delegate to the underlying logger.

16.6.9 线程安全

The logging module is intended to be thread-safe without any special work needing to be done by its clients. It achieves this though using threading locks; there is one lock to serialize access to the module's shared data, and each handler also creates a lock to serialize access to its underlying I/O.

If you are implementing asynchronous signal handlers using the *signal* module, you may not be able to use logging from within such handlers. This is because lock implementations in the *threading* module are not always re-entrant, and so cannot be invoked from such signal handlers.

16.6.10 模块级别函数

In addition to the classes described above, there are a number of module-level functions.

`logging.getLogger` (*name=None*)

Return a logger with the specified name or, if *name* is *None*, return a logger which is the root logger of the hierarchy. If specified, the name is typically a dot-separated hierarchical name like 'a', 'a.b' or 'a.b.c.d'. Choice of these names is entirely up to the developer who is using logging.

All calls to this function with a given name return the same logger instance. This means that logger instances never need to be passed between different parts of an application.

`logging.getLoggerClass` ()

Return either the standard *Logger* class, or the last class passed to *setLoggerClass()*. This function may be called from within a new class definition, to ensure that installing a customized *Logger* class will not undo customizations already applied by other code. For example:

```
class MyLogger(logging.getLoggerClass()):
    # ... override behaviour here
```

`logging.getLogRecordFactory` ()

Return a callable which is used to create a *LogRecord*.

3.2 新版功能: This function has been provided, along with *setLogRecordFactory()*, to allow developers more control over how the *LogRecord* representing a logging event is constructed.

See `setLogRecordFactory()` for more information about the how the factory is called.

`logging.debug(msg, *args, **kwargs)`

Logs a message with level `DEBUG` on the root logger. The `msg` is the message format string, and the `args` are the arguments which are merged into `msg` using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are three keyword arguments in `kwargs` which are inspected: `exc_info` which, if it does not evaluate as false, causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) or an exception instance is provided, it is used; otherwise, `sys.exc_info()` is called to get the exception information.

The second optional keyword argument is `stack_info`, which defaults to `False`. If true, stack information is added to the logging message, including the actual logging call. Note that this is not the same stack information as that displayed through specifying `exc_info`: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify `stack_info` independently of `exc_info`, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback (most recent call last):` which is used when displaying exception frames.

The third optional keyword argument is `extra` which can be used to pass a dictionary which is used to populate the `__dict__` of the `LogRecord` created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)-15s %(clientip)s %(user)-8s %(message)s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logging.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like:

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs Protocol problem: connection reset
```

The keys in the dictionary passed in `extra` should not clash with the keys used by the logging system. (See the `Formatter` documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the `Formatter` has been set up with a format string which expects ‘clientip’ and ‘user’ in the attribute dictionary of the `LogRecord`. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the `extra` dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized `Formatters` would be used with particular `Handlers`.

3.2 新版功能: The `stack_info` parameter was added.

`logging.info(msg, *args, **kwargs)`

Logs a message with level `INFO` on the root logger. The arguments are interpreted as for `debug()`.

`logging.warning(msg, *args, **kwargs)`

Logs a message with level `WARNING` on the root logger. The arguments are interpreted as for `debug()`.

注解: There is an obsolete function `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

`logging.error(msg, *args, **kwargs)`

Logs a message with level `ERROR` on the root logger. The arguments are interpreted as for `debug()`.

`logging.critical(msg, *args, **kwargs)`

Logs a message with level `CRITICAL` on the root logger. The arguments are interpreted as for `debug()`.

`logging.exception(msg, *args, **kwargs)`

Logs a message with level `ERROR` on the root logger. The arguments are interpreted as for `debug()`. Exception info is added to the logging message. This function should only be called from an exception handler.

`logging.log(level, msg, *args, **kwargs)`

Logs a message with level `level` on the root logger. The other arguments are interpreted as for `debug()`.

注解: The above module-level convenience functions, which delegate to the root logger, call `basicConfig()` to ensure that at least one handler is available. Because of this, they should *not* be used in threads, in versions of Python earlier than 2.7.1 and 3.2, unless at least one handler has been added to the root logger *before* the threads are started. In earlier versions of Python, due to a thread safety shortcoming in `basicConfig()`, this can (under rare circumstances) lead to handlers being added multiple times to the root logger, which can in turn lead to multiple messages for the same event.

`logging.disable(lvl=CRITICAL)`

Provides an overriding level `lvl` for all loggers which takes precedence over the logger's own level. When the need arises to temporarily throttle logging output down across the whole application, this function can be useful. Its effect is to disable all logging calls of severity `lvl` and below, so that if you call it with a value of `INFO`, then all `INFO` and `DEBUG` events would be discarded, whereas those of severity `WARNING` and above would be processed according to the logger's effective level. If `logging.disable(logging.NOTSET)` is called, it effectively removes this overriding level, so that logging output again depends on the effective levels of individual loggers.

Note that if you have defined any custom logging level higher than `CRITICAL` (this is not recommended), you won't be able to rely on the default value for the `lvl` parameter, but will have to explicitly supply a suitable value.

在 3.7 版更改: The `lvl` parameter was defaulted to level `CRITICAL`. See Issue #28524 for more information about this change.

`logging.addLevelName(lvl, levelName)`

Associates level `lvl` with text `levelName` in an internal dictionary, which is used to map numeric levels to a textual representation, for example when a `Formatter` formats a message. This function can also be used to define your own levels. The only constraints are that all levels used must be registered using this function, levels should be positive integers and they should increase in increasing order of severity.

注解: If you are thinking of defining your own levels, please see the section on custom-levels.

`logging.getLevelName(lvl)`

Returns the textual representation of logging level `lvl`. If the level is one of the predefined levels `CRITICAL`, `ERROR`, `WARNING`, `INFO` or `DEBUG` then you get the corresponding string. If you have associated levels with names using `addLevelName()` then the name you have associated with `lvl` is returned. If a numeric value corresponding to one of the defined levels is passed in, the corresponding string representation is returned. Otherwise, the string 'Level %s' % `lvl` is returned.

注解: Levels are internally integers (as they need to be compared in the logging logic). This function is used

to convert between an integer level and the level name displayed in the formatted log output by means of the `% (levelname)s` format specifier (see *LogRecord attributes*).

在 3.4 版更改: In Python versions earlier than 3.4, this function could also be passed a text level, and would return the corresponding numeric value of the level. This undocumented behaviour was considered a mistake, and was removed in Python 3.4, but reinstated in 3.4.2 due to retain backward compatibility.

```
logging.makeLogRecord(attrdict)
```

Creates and returns a new *LogRecord* instance whose attributes are defined by *attrdict*. This function is useful for taking a pickled *LogRecord* attribute dictionary, sent over a socket, and reconstituting it as a *LogRecord* instance at the receiving end.

```
logging.basicConfig(**kwargs)
```

Does basic configuration for the logging system by creating a *StreamHandler* with a default *Formatter* and adding it to the root logger. The functions *debug()*, *info()*, *warning()*, *error()* and *critical()* will call *basicConfig()* automatically if no handlers are defined for the root logger.

This function does nothing if the root logger already has handlers configured for it.

注解: This function should be called from the main thread before other threads are started. In versions of Python prior to 2.7.1 and 3.2, if this function is called from multiple threads, it is possible (in rare circumstances) that a handler will be added to the root logger more than once, leading to unexpected results such as messages being duplicated in the log.

The following keyword arguments are supported.

格式	描述
<i>filename</i>	Specifies that a <code>FileHandler</code> be created, using the specified filename, rather than a <code>StreamHandler</code> .
<i>filemode</i>	If <i>filename</i> is specified, open the file in this <i>mode</i> . Defaults to 'a'.
<i>format</i>	Use the specified format string for the handler.
<i>datefmt</i>	Use the specified date/time format, as accepted by <code>time.strftime()</code> .
<i>style</i>	If <i>format</i> is specified, use this style for the format string. One of '%', '{' or '\$' for <i>printf-style</i> , <code>str.format()</code> or <i>string.Template</i> respectively. Defaults to '%'
<i>level</i>	Set the root logger level to the specified <i>level</i> .
<i>stream</i>	Use the specified stream to initialize the <code>StreamHandler</code> . Note that this argument is incompatible with <i>filename</i> - if both are present, a <code>ValueError</code> is raised.
<i>handlers</i>	If specified, this should be an iterable of already created handlers to add to the root logger. Any handlers which don't already have a formatter set will be assigned the default formatter created in this function. Note that this argument is incompatible with <i>filename</i> or <i>stream</i> - if both are present, a <code>ValueError</code> is raised.

在 3.2 版更改: The *style* argument was added.

In 3.3 版更改: The *handlers* argument was added. Additional checks were added to catch situations where incompatible arguments are specified (e.g. *handlers* together with *stream* or *filename*, or *stream* together with *filename*).

```
logging.shutdown()
```

Informs the logging system to perform an orderly shutdown by flushing and closing all handlers. This should be called at application exit and no further use of the logging system should be made after this call.

```
logging.setLoggerClass(klass)
```

Tells the logging system to use the class *klass* when instantiating a logger. The class should define `__init__()` such that only a name argument is required, and the `__init__()` should call `Logger.__init__()`. This function is typically called before any loggers are instantiated by applications which need to use custom logger behavior.

`logging.setLogRecordFactory(factory)`

Set a callable which is used to create a *LogRecord*.

参数 factory – The factory callable to be used to instantiate a log record.

3.2 新版功能: This function has been provided, along with `getLogRecordFactory()`, to allow developers more control over how the *LogRecord* representing a logging event is constructed.

The factory has the following signature:

```
factory(name, level, fn, lno, msg, args, exc_info, func=None, sinfo=None,
**kwargs)
```

name The logger name.

level The logging level (numeric).

fn The full pathname of the file where the logging call was made.

lno The line number in the file where the logging call was made.

msg The logging message.

args The arguments for the logging message.

exc_info An exception tuple, or None.

func The name of the function or method which invoked the logging call.

sinfo A stack traceback such as is provided by `traceback.print_stack()`, showing the call hierarchy.

kwargs Additional keyword arguments.

16.6.11 Module-Level Attributes

`logging.lastResort`

A “handler of last resort” is available through this attribute. This is a *StreamHandler* writing to `sys.stderr` with a level of `WARNING`, and is used to handle logging events in the absence of any logging configuration. The end result is to just print the message to `sys.stderr`. This replaces the earlier error message saying that “no handlers could be found for logger XYZ”. If you need the earlier behaviour for some reason, `lastResort` can be set to None.

3.2 新版功能.

16.6.12 Integration with the warnings module

The `captureWarnings()` function can be used to integrate *logging* with the *warnings* module.

`logging.captureWarnings(capture)`

This function is used to turn the capture of warnings by logging on and off.

If `capture` is `True`, warnings issued by the *warnings* module will be redirected to the logging system. Specifically, a warning will be formatted using `warnings.formatwarning()` and the resulting string logged to a logger named `'py.warnings'` with a severity of `WARNING`.

If `capture` is `False`, the redirection of warnings to the logging system will stop, and warnings will be redirected to their original destinations (i.e. those in effect before `captureWarnings(True)` was called).

PEP 282 - A Logging System 该提案描述了 Python 标准库中包含的这个特性。

Original Python logging package This is the original source for the `logging` package. The version of the package available from this site is suitable for use with Python 1.5.2, 2.1.x and 2.2.x, which do not include the `logging` package in the standard library.

16.7 logging.config — 日志记录配置

源代码: [Lib/logging/config.py](#)

Important

此页面仅包含参考信息。有关教程，请参阅

- 基础教程
- Advanced Tutorial
- Logging Cookbook

This section describes the API for configuring the logging module.

16.7.1 Configuration functions

The following functions configure the logging module. They are located in the `logging.config` module. Their use is optional—you can configure the logging module using these functions or by making calls to the main API (defined in `logging` itself) and defining handlers which are declared either in `logging` or `logging.handlers`.

`logging.config.dictConfig(config)`

Takes the logging configuration from a dictionary. The contents of this dictionary are described in *Configuration dictionary schema* below.

If an error is encountered during configuration, this function will raise a `ValueError`, `TypeError`, `AttributeError` or `ImportError` with a suitably descriptive message. The following is a (possibly incomplete) list of conditions which will raise an error:

- A `level` which is not a string or which is a string not corresponding to an actual logging level.
- A `propagate` value which is not a boolean.
- An `id` which does not have a corresponding destination.
- A non-existent handler `id` found during an incremental call.
- An invalid logger name.
- Inability to resolve to an internal or external object.

Parsing is performed by the `DictConfigurator` class, whose constructor is passed the dictionary used for configuration, and has a `configure()` method. The `logging.config` module has a callable attribute `dictConfigClass` which is initially set to `DictConfigurator`. You can replace the value of `dictConfigClass` with a suitable implementation of your own.

`dictConfig()` calls `dictConfigClass` passing the specified dictionary, and then calls the `configure()` method on the returned object to put the configuration into effect:

```
def dictConfig(config):
    dictConfigClass(config).configure()
```

For example, a subclass of `DictConfigurator` could call `DictConfigurator.__init__()` in its own `__init__()`, then set up custom prefixes which would be usable in the subsequent `configure()` call. `dictConfigClass` would be bound to this new subclass, and then `dictConfig()` could be called exactly as in the default, uncustomized state.

3.2 新版功能.

`logging.config.fileConfig(fname, defaults=None, disable_existing_loggers=True)`

Reads the logging configuration from a `configparser`-format file. The format of the file should be as described in *Configuration file format*. This function can be called several times from an application, allowing an end user to select from various pre-canned configurations (if the developer provides a mechanism to present the choices and load the chosen configuration).

参数

- **fname** – A filename, or a file-like object, or an instance derived from `RawConfigParser`. If a `RawConfigParser`-derived instance is passed, it is used as is. Otherwise, a `Configparser` is instantiated, and the configuration read by it from the object passed in `fname`. If that has a `readline()` method, it is assumed to be a file-like object and read using `read_file()`; otherwise, it is assumed to be a filename and passed to `read()`.
- **defaults** – Defaults to be passed to the `ConfigParser` can be specified in this argument.
- **disable_existing_loggers** – If specified as `False`, loggers which exist when this call is made are left enabled. The default is `True` because this enables old behaviour in a backward-compatible way. This behaviour is to disable any existing loggers unless they or their ancestors are explicitly named in the logging configuration.

在 3.4 版更改: An instance of a subclass of `RawConfigParser` is now accepted as a value for `fname`. This facilitates:

- Use of a configuration file where logging configuration is just part of the overall application configuration.
- Use of a configuration read from a file, and then modified by the using application (e.g. based on command-line parameters or other aspects of the runtime environment) before being passed to `fileConfig`.

`logging.config.listen(port=DEFAULT_LOGGING_CONFIG_PORT, verify=None)`

Starts up a socket server on the specified port, and listens for new configurations. If no port is specified, the module's default `DEFAULT_LOGGING_CONFIG_PORT` is used. Logging configurations will be sent as a file suitable for processing by `dictConfig()` or `fileConfig()`. Returns a `Thread` instance on which you can call `start()` to start the server, and which you can `join()` when appropriate. To stop the server, call `stopListening()`.

The `verify` argument, if specified, should be a callable which should verify whether bytes received across the socket are valid and should be processed. This could be done by encrypting and/or signing what is sent across the socket, such that the `verify` callable can perform signature verification and/or decryption. The `verify` callable is called with a single argument - the bytes received across the socket - and should return the bytes to be processed, or `None` to indicate that the bytes should be discarded. The returned bytes could be the same as the passed in bytes (e.g. when only verification is done), or they could be completely different (perhaps if decryption were performed).

To send a configuration to the socket, read in the configuration file and send it to the socket as a sequence of bytes preceded by a four-byte length string packed in binary using `struct.pack('>L', n)`.

注解: Because portions of the configuration are passed through `eval()`, use of this function may open its users

to a security risk. While the function only binds to a socket on `localhost`, and so does not accept connections from remote machines, there are scenarios where untrusted code could be run under the account of the process which calls `listen()`. Specifically, if the process calling `listen()` runs on a multi-user machine where users cannot trust each other, then a malicious user could arrange to run essentially arbitrary code in a victim user's process, simply by connecting to the victim's `listen()` socket and sending a configuration which runs whatever code the attacker wants to have executed in the victim's process. This is especially easy to do if the default port is used, but not hard even if a different port is used). To avoid the risk of this happening, use the `verify` argument to `listen()` to prevent unrecognised configurations from being applied.

在 3.4 版更改: The `verify` argument was added.

注解: If you want to send configurations to the listener which don't disable existing loggers, you will need to use a JSON format for the configuration, which will use `dictConfig()` for configuration. This method allows you to specify `disable_existing_loggers` as `False` in the configuration you send.

`logging.config.stopListening()`

Stops the listening server which was created with a call to `listen()`. This is typically called before calling `join()` on the return value from `listen()`.

16.7.2 Configuration dictionary schema

Describing a logging configuration requires listing the various objects to create and the connections between them; for example, you may create a handler named 'console' and then say that the logger named 'startup' will send its messages to the 'console' handler. These objects aren't limited to those provided by the `logging` module because you might write your own formatter or handler class. The parameters to these classes may also need to include external objects such as `sys.stderr`. The syntax for describing these objects and connections is defined in *Object connections* below.

Dictionary Schema Details

The dictionary passed to `dictConfig()` must contain the following keys:

- *version* - to be set to an integer value representing the schema version. The only valid value at present is 1, but having this key allows the schema to evolve while still preserving backwards compatibility.

All other keys are optional, but if present they will be interpreted as described below. In all cases below where a 'configuring dict' is mentioned, it will be checked for the special '()' key to see if a custom instantiation is required. If so, the mechanism described in *User-defined objects* below is used to create an instance; otherwise, the context is used to determine what to instantiate.

- *formatters* - the corresponding value will be a dict in which each key is a formatter id and each value is a dict describing how to configure the corresponding *Formatter* instance.

The configuring dict is searched for keys `format` and `datefmt` (with defaults of `None`) and these are used to construct a *Formatter* instance.

- *filters* - the corresponding value will be a dict in which each key is a filter id and each value is a dict describing how to configure the corresponding *Filter* instance.

The configuring dict is searched for the key `name` (defaulting to the empty string) and this is used to construct a *logging.Filter* instance.

- *handlers* - the corresponding value will be a dict in which each key is a handler id and each value is a dict describing how to configure the corresponding *Handler* instance.

The configuring dict is searched for the following keys:

- `class` (mandatory). This is the fully qualified name of the handler class.
- `level` (optional). The level of the handler.
- `formatter` (optional). The id of the formatter for this handler.
- `filters` (optional). A list of ids of the filters for this handler.

All *other* keys are passed through as keyword arguments to the handler's constructor. For example, given the snippet:

```
handlers:
  console:
    class : logging.StreamHandler
    formatter: brief
    level  : INFO
    filters: [allow_foo]
    stream : ext://sys.stdout
  file:
    class : logging.handlers.RotatingFileHandler
    formatter: precise
    filename: logconfig.log
    maxBytes: 1024
    backupCount: 3
```

the handler with id `console` is instantiated as a `logging.StreamHandler`, using `sys.stdout` as the underlying stream. The handler with id `file` is instantiated as a `logging.handlers.RotatingFileHandler` with the keyword arguments `filename='logconfig.log'`, `maxBytes=1024`, `backupCount=3`.

- *loggers* - the corresponding value will be a dict in which each key is a logger name and each value is a dict describing how to configure the corresponding Logger instance.

The configuring dict is searched for the following keys:

- `level` (optional). The level of the logger.
- `propagate` (optional). The propagation setting of the logger.
- `filters` (optional). A list of ids of the filters for this logger.
- `handlers` (optional). A list of ids of the handlers for this logger.

The specified loggers will be configured according to the level, propagation, filters and handlers specified.

- *root* - this will be the configuration for the root logger. Processing of the configuration will be as for any logger, except that the `propagate` setting will not be applicable.
- *incremental* - whether the configuration is to be interpreted as incremental to the existing configuration. This value defaults to `False`, which means that the specified configuration replaces the existing configuration with the same semantics as used by the existing `fileConfig()` API.

If the specified value is `True`, the configuration is processed as described in the section on *Incremental Configuration*.

- *disable_existing_loggers* - whether any existing loggers are to be disabled. This setting mirrors the parameter of the same name in `fileConfig()`. If absent, this parameter defaults to `True`. This value is ignored if *incremental* is `True`.

Incremental Configuration

It is difficult to provide complete flexibility for incremental configuration. For example, because objects such as filters and formatters are anonymous, once a configuration is set up, it is not possible to refer to such anonymous objects when augmenting a configuration.

Furthermore, there is not a compelling case for arbitrarily altering the object graph of loggers, handlers, filters, formatters at run-time, once a configuration is set up; the verbosity of loggers and handlers can be controlled just by setting levels (and, in the case of loggers, propagation flags). Changing the object graph arbitrarily in a safe way is problematic in a multi-threaded environment; while not impossible, the benefits are not worth the complexity it adds to the implementation.

Thus, when the `incremental` key of a configuration dict is present and is `True`, the system will completely ignore any `formatters` and `filters` entries, and process only the `level` settings in the `handlers` entries, and the `level` and `propagate` settings in the `loggers` and `root` entries.

Using a value in the configuration dict lets configurations to be sent over the wire as pickled dicts to a socket listener. Thus, the logging verbosity of a long-running application can be altered over time with no need to stop and restart the application.

Object connections

The schema describes a set of logging objects - loggers, handlers, formatters, filters - which are connected to each other in an object graph. Thus, the schema needs to represent connections between the objects. For example, say that, once configured, a particular logger has attached to it a particular handler. For the purposes of this discussion, we can say that the logger represents the source, and the handler the destination, of a connection between the two. Of course in the configured objects this is represented by the logger holding a reference to the handler. In the configuration dict, this is done by giving each destination object an id which identifies it unambiguously, and then using the id in the source object's configuration to indicate that a connection exists between the source and the destination object with that id.

So, for example, consider the following YAML snippet:

```
formatters:
  brief:
    # configuration for formatter with id 'brief' goes here
  precise:
    # configuration for formatter with id 'precise' goes here
handlers:
  h1: #This is an id
    # configuration of handler with id 'h1' goes here
    formatter: brief
  h2: #This is another id
    # configuration of handler with id 'h2' goes here
    formatter: precise
loggers:
  foo.bar.baz:
    # other configuration for logger 'foo.bar.baz'
    handlers: [h1, h2]
```

(Note: YAML used here because it's a little more readable than the equivalent Python source form for the dictionary.)

The ids for loggers are the logger names which would be used programmatically to obtain a reference to those loggers, e.g. `foo.bar.baz`. The ids for Formatters and Filters can be any string value (such as `brief`, `precise` above) and they are transient, in that they are only meaningful for processing the configuration dictionary and used to determine connections between objects, and are not persisted anywhere when the configuration call is complete.

The above snippet indicates that logger named `foo.bar.baz` should have two handlers attached to it, which are described by the handler ids `h1` and `h2`. The formatter for `h1` is that described by id `brief`, and the formatter for `h2` is that described by id `precise`.

User-defined objects

The schema supports user-defined objects for handlers, filters and formatters. (Loggers do not need to have different types for different instances, so there is no support in this configuration schema for user-defined logger classes.)

Objects to be configured are described by dictionaries which detail their configuration. In some places, the logging system will be able to infer from the context how an object is to be instantiated, but when a user-defined object is to be instantiated, the system will not know how to do this. In order to provide complete flexibility for user-defined object instantiation, the user needs to provide a ‘factory’ - a callable which is called with a configuration dictionary and which returns the instantiated object. This is signalled by an absolute import path to the factory being made available under the special key ‘()’. Here’s a concrete example:

```
formatters:
  brief:
    format: '%(message)s'
  default:
    format: '%(asctime)s %(levelname)-8s %(name)-15s %(message)s'
    datefmt: '%Y-%m-%d %H:%M:%S'
  custom:
    (): my.package.customFormatterFactory
    bar: baz
    spam: 99.9
    answer: 42
```

The above YAML snippet defines three formatters. The first, with id `brief`, is a standard `logging.Formatter` instance with the specified format string. The second, with id `default`, has a longer format and also defines the time format explicitly, and will result in a `logging.Formatter` initialized with those two format strings. Shown in Python source form, the `brief` and `default` formatters have configuration sub-dictionaries:

```
{
  'format' : '%(message)s'
}
```

和:

```
{
  'format' : '%(asctime)s %(levelname)-8s %(name)-15s %(message)s',
  'datefmt' : '%Y-%m-%d %H:%M:%S'
}
```

respectively, and as these dictionaries do not contain the special key ‘()’, the instantiation is inferred from the context: as a result, standard `logging.Formatter` instances are created. The configuration sub-dictionary for the third formatter, with id `custom`, is:

```
{
  '()' : 'my.package.customFormatterFactory',
  'bar' : 'baz',
  'spam' : 99.9,
  'answer' : 42
}
```

and this contains the special key ‘()’, which means that user-defined instantiation is wanted. In this case, the specified factory callable will be used. If it is an actual callable it will be used directly - otherwise, if you specify a string (as in the example) the actual callable will be located using normal import mechanisms. The callable will be called with the **remaining** items in the configuration sub-dictionary as keyword arguments. In the above example, the formatter with id `custom` will be assumed to be returned by the call:

```
my.package.customFormatterFactory(bar='baz', spam=99.9, answer=42)
```

The key '()' has been used as the special key because it is not a valid keyword parameter name, and so will not clash with the names of the keyword arguments used in the call. The '()' also serves as a mnemonic that the corresponding value is a callable.

Access to external objects

There are times where a configuration needs to refer to objects external to the configuration, for example `sys.stderr`. If the configuration dict is constructed using Python code, this is straightforward, but a problem arises when the configuration is provided via a text file (e.g. JSON, YAML). In a text file, there is no standard way to distinguish `sys.stderr` from the literal string `'sys.stderr'`. To facilitate this distinction, the configuration system looks for certain special prefixes in string values and treat them specially. For example, if the literal string `'ext://sys.stderr'` is provided as a value in the configuration, then the `ext://` will be stripped off and the remainder of the value processed using normal import mechanisms.

The handling of such prefixes is done in a way analogous to protocol handling: there is a generic mechanism to look for prefixes which match the regular expression `^(?P<prefix>[a-z]+):/(?P<suffix>.*)$` whereby, if the `prefix` is recognised, the `suffix` is processed in a prefix-dependent manner and the result of the processing replaces the string value. If the prefix is not recognised, then the string value will be left as-is.

Access to internal objects

As well as external objects, there is sometimes also a need to refer to objects in the configuration. This will be done implicitly by the configuration system for things that it knows about. For example, the string value `'DEBUG'` for a level in a logger or handler will automatically be converted to the value `logging.DEBUG`, and the `handlers`, `filters` and `formatter` entries will take an object id and resolve to the appropriate destination object.

However, a more generic mechanism is needed for user-defined objects which are not known to the `logging` module. For example, consider `logging.handlers.MemoryHandler`, which takes a `target` argument which is another handler to delegate to. Since the system already knows about this class, then in the configuration, the given `target` just needs to be the object id of the relevant target handler, and the system will resolve to the handler from the id. If, however, a user defines a `my.package.MyHandler` which has an `alternate` handler, the configuration system would not know that the `alternate` referred to a handler. To cater for this, a generic resolution system allows the user to specify:

```
handlers:
  file:
    # configuration of file handler goes here

  custom:
    (): my.package.MyHandler
    alternate: cfg://handlers.file
```

The literal string `'cfg://handlers.file'` will be resolved in an analogous way to strings with the `ext://` prefix, but looking in the configuration itself rather than the import namespace. The mechanism allows access by dot or by index, in a similar way to that provided by `str.format`. Thus, given the following snippet:

```
handlers:
  email:
    class: logging.handlers.SMTPHandler
    mailhost: localhost
    fromaddr: my_app@domain.tld
    toaddrs:
      - support_team@domain.tld
```

(下页继续)

(续上页)

```
- dev_team@domain.tld
subject: Houston, we have a problem.
```

in the configuration, the string `'cfg://handlers'` would resolve to the dict with key `handlers`, the string `'cfg://handlers.email'` would resolve to the dict with key `email` in the `handlers` dict, and so on. The string `'cfg://handlers.email.toaddrs[1]'` would resolve to `'dev_team.domain.tld'` and the string `'cfg://handlers.email.toaddrs[0]'` would resolve to the value `'support_team@domain.tld'`. The subject value could be accessed using either `'cfg://handlers.email.subject'` or, equivalently, `'cfg://handlers.email[subject]'`. The latter form only needs to be used if the key contains spaces or non-alphanumeric characters. If an index value consists only of decimal digits, access will be attempted using the corresponding integer value, falling back to the string value if needed.

Given a string `cfg://handlers.myhandler.mykey.123`, this will resolve to `config_dict['handlers']['myhandler']['mykey']['123']`. If the string is specified as `cfg://handlers.myhandler.mykey[123]`, the system will attempt to retrieve the value from `config_dict['handlers']['myhandler']['mykey'][123]`, and fall back to `config_dict['handlers']['myhandler']['mykey']['123']` if that fails.

Import resolution and custom importers

Import resolution, by default, uses the builtin `__import__()` function to do its importing. You may want to replace this with your own importing mechanism: if so, you can replace the `importer` attribute of the `DictConfigurator` or its superclass, the `BaseConfigurator` class. However, you need to be careful because of the way functions are accessed from classes via descriptors. If you are using a Python callable to do your imports, and you want to define it at class level rather than instance level, you need to wrap it with `staticmethod()`. For example:

```
from importlib import import_module
from logging.config import BaseConfigurator

BaseConfigurator.importer = staticmethod(import_module)
```

You don't need to wrap with `staticmethod()` if you're setting the import callable on a configurator *instance*.

16.7.3 Configuration file format

The configuration file format understood by `fileConfig()` is based on `configparser` functionality. The file must contain sections called `[loggers]`, `[handlers]` and `[formatters]` which identify by name the entities of each type which are defined in the file. For each such entity, there is a separate section which identifies how that entity is configured. Thus, for a logger named `log01` in the `[loggers]` section, the relevant configuration details are held in a section `[logger_log01]`. Similarly, a handler called `hand01` in the `[handlers]` section will have its configuration held in a section called `[handler_hand01]`, while a formatter called `form01` in the `[formatters]` section will have its configuration specified in a section called `[formatter_form01]`. The root logger configuration must be specified in a section called `[logger_root]`.

注解: The `fileConfig()` API is older than the `dictConfig()` API and does not provide functionality to cover certain aspects of logging. For example, you cannot configure `Filter` objects, which provide for filtering of messages beyond simple integer levels, using `fileConfig()`. If you need to have instances of `Filter` in your logging configuration, you will need to use `dictConfig()`. Note that future enhancements to configuration functionality will be added to `dictConfig()`, so it's worth considering transitioning to this newer API when it's convenient to do so.

Examples of these sections in the file are given below.

```
[loggers]
keys=root,log02,log03,log04,log05,log06,log07

[handlers]
keys=hand01,hand02,hand03,hand04,hand05,hand06,hand07,hand08,hand09

[formatters]
keys=form01,form02,form03,form04,form05,form06,form07,form08,form09
```

The root logger must specify a level and a list of handlers. An example of a root logger section is given below.

```
[logger_root]
level=NOTSET
handlers=hand01
```

The `level` entry can be one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL` or `NOTSET`. For the root logger only, `NOTSET` means that all messages will be logged. Level values are *eval()*uated in the context of the logging package's namespace.

The `handlers` entry is a comma-separated list of handler names, which must appear in the `[handlers]` section. These names must appear in the `[handlers]` section and have corresponding sections in the configuration file.

For loggers other than the root logger, some additional information is required. This is illustrated by the following example.

```
[logger_parser]
level=DEBUG
handlers=hand01
propagate=1
qualname=compiler.parser
```

The `level` and `handlers` entries are interpreted as for the root logger, except that if a non-root logger's level is specified as `NOTSET`, the system consults loggers higher up the hierarchy to determine the effective level of the logger. The `propagate` entry is set to 1 to indicate that messages must propagate to handlers higher up the logger hierarchy from this logger, or 0 to indicate that messages are **not** propagated to handlers up the hierarchy. The `qualname` entry is the hierarchical channel name of the logger, that is to say the name used by the application to get the logger.

Sections which specify handler configuration are exemplified by the following.

```
[handler_hand01]
class=StreamHandler
level=NOTSET
formatter=form01
args=(sys.stdout,)
```

The `class` entry indicates the handler's class (as determined by *eval()* in the logging package's namespace). The `level` is interpreted as for loggers, and `NOTSET` is taken to mean 'log everything'.

The `formatter` entry indicates the key name of the formatter for this handler. If blank, a default formatter (`logging._defaultFormatter`) is used. If a name is specified, it must appear in the `[formatters]` section and have a corresponding section in the configuration file.

The `args` entry, when *eval()*uated in the context of the logging package's namespace, is the list of arguments to the constructor for the handler class. Refer to the constructors for the relevant handlers, or to the examples below, to see how typical entries are constructed.

```
[handler_hand02]
class=FileHandler
level=DEBUG
```

(下页继续)

(续上页)

```

formatter=form02
args=('python.log', 'w')

[handler_hand03]
class=handlers.SocketHandler
level=INFO
formatter=form03
args=('localhost', handlers.DEFAULT_TCP_LOGGING_PORT)

[handler_hand04]
class=handlers.DatagramHandler
level=WARN
formatter=form04
args=('localhost', handlers.DEFAULT_UDP_LOGGING_PORT)

[handler_hand05]
class=handlers.SysLogHandler
level=ERROR
formatter=form05
args= (('localhost', handlers.SYSLOG_UDP_PORT), handlers.SysLogHandler.LOG_USER)

[handler_hand06]
class=handlers.NTEventLogHandler
level=CRITICAL
formatter=form06
args=('Python Application', '', 'Application')

[handler_hand07]
class=handlers.SMTPHandler
level=WARN
formatter=form07
args=('localhost', 'from@abc', ['user1@abc', 'user2@xyz'], 'Logger Subject')

[handler_hand08]
class=handlers.MemoryHandler
level=NOTSET
formatter=form08
target=
args=(10, ERROR)

[handler_hand09]
class=handlers.HTTPHandler
level=NOTSET
formatter=form09
args=('localhost:9022', '/log', 'GET')

```

Sections which specify formatter configuration are typified by the following.

```

[formatter_form01]
format=F1 %(asctime)s %(levelname)s %(message)s
datefmt=
class=logging.Formatter

```

The `format` entry is the overall format string, and the `datefmt` entry is the `strftime()`-compatible date/time format string. If empty, the package substitutes something which is almost equivalent to specifying the date format string `'%Y-%m-%d %H:%M:%S'`. This format also specifies milliseconds, which are appended to the result of using the above format string, with a comma separator. An example time in this format is `2003-01-23 00:29:50,411`.

The `class` entry is optional. It indicates the name of the formatter's class (as a dotted module and class name.) This option is useful for instantiating a *Formatter* subclass. Subclasses of *Formatter* can present exception tracebacks in an expanded or condensed format.

注解: Due to the use of `eval()` as described above, there are potential security risks which result from using the `listen()` to send and receive configurations via sockets. The risks are limited to where multiple users with no mutual trust run code on the same machine; see the `listen()` documentation for more information.

16.8 logging.handlers —Logging handlers

源代码: `Lib/logging/handlers.py`

Important

此页面仅包含参考信息。有关教程，请参阅

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

The following useful handlers are provided in the package. Note that three of the handlers (*StreamHandler*, *FileHandler* and *NullHandler*) are actually defined in the `logging` module itself, but have been documented here along with the other handlers.

16.8.1 StreamHandler

The *StreamHandler* class, located in the core `logging` package, sends logging output to streams such as `sys.stdout`, `sys.stderr` or any file-like object (or, more precisely, any object which supports `write()` and `flush()` methods).

class `logging.StreamHandler` (*stream=None*)

Returns a new instance of the *StreamHandler* class. If *stream* is specified, the instance will use it for logging output; otherwise, `sys.stderr` will be used.

emit (*record*)

If a formatter is specified, it is used to format the record. The record is then written to the stream with a terminator. If exception information is present, it is formatted using `traceback.print_exception()` and appended to the stream.

flush ()

Flushes the stream by calling its `flush()` method. Note that the `close()` method is inherited from *Handler* and so does no output, so an explicit `flush()` call may be needed at times.

在 3.2 版更改: The `StreamHandler` class now has a `terminator` attribute, default value `'\n'`, which is used as the terminator when writing a formatted record to a stream. If you don't want this newline termination, you can set the handler instance's `terminator` attribute to the empty string. In earlier versions, the terminator was hardcoded as `'\n'`.

16.8.2 FileHandler

The `FileHandler` class, located in the core `logging` package, sends logging output to a disk file. It inherits the output functionality from `StreamHandler`.

class `logging.FileHandler` (*filename*, *mode*='a', *encoding*=None, *delay*=False)

Returns a new instance of the `FileHandler` class. The specified file is opened and used as the stream for logging. If *mode* is not specified, 'a' is used. If *encoding* is not None, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely.

在 3.6 版更改: As well as string values, `Path` objects are also accepted for the *filename* argument.

close()

Closes the file.

emit (*record*)

Outputs the record to the file.

16.8.3 NullHandler

3.1 新版功能.

The `NullHandler` class, located in the core `logging` package, does not do any formatting or output. It is essentially a 'no-op' handler for use by library developers.

class `logging.NullHandler`

Returns a new instance of the `NullHandler` class.

emit (*record*)

This method does nothing.

handle (*record*)

This method does nothing.

createLock ()

This method returns None for the lock, since there is no underlying I/O to which access needs to be serialized.

See library-config for more information on how to use `NullHandler`.

16.8.4 WatchedFileHandler

The `WatchedFileHandler` class, located in the `logging.handlers` module, is a `FileHandler` which watches the file it is logging to. If the file changes, it is closed and reopened using the file name.

A file change can happen because of usage of programs such as `newsyslog` and `logrotate` which perform log file rotation. This handler, intended for use under Unix/Linux, watches the file to see if it has changed since the last emit. (A file is deemed to have changed if its device or inode have changed.) If the file has changed, the old file stream is closed, and the file opened to get a new stream.

This handler is not appropriate for use under Windows, because under Windows open log files cannot be moved or renamed - logging opens the files with exclusive locks - and so there is no need for such a handler. Furthermore, `ST_INO` is not supported under Windows; `stat()` always returns zero for this value.

class `logging.handlers.WatchedFileHandler` (*filename*, *mode*='a', *encoding*=None, *delay*=False)

Returns a new instance of the `WatchedFileHandler` class. The specified file is opened and used as the stream for logging. If *mode* is not specified, 'a' is used. If *encoding* is not None, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely.

在 3.6 版更改: As well as string values, `Path` objects are also accepted for the *filename* argument.

reopenIfNeeded()

Checks to see if the file has changed. If it has, the existing stream is flushed and closed and the file opened again, typically as a precursor to outputting the record to the file.

3.6 新版功能.

emit (*record*)

Outputs the record to the file, but first calls `reopenIfNeeded()` to reopen the file if it has changed.

16.8.5 BaseRotatingHandler

The `BaseRotatingHandler` class, located in the `logging.handlers` module, is the base class for the rotating file handlers, `RotatingFileHandler` and `TimedRotatingFileHandler`. You should not need to instantiate this class, but it has attributes and methods you may need to override.

class `logging.handlers.BaseRotatingHandler` (*filename*, *mode*, *encoding*=None, *delay*=False)

The parameters are as for `FileHandler`. The attributes are:

namer

If this attribute is set to a callable, the `rotation_filename()` method delegates to this callable. The parameters passed to the callable are those passed to `rotation_filename()`.

注解: The namer function is called quite a few times during rollover, so it should be as simple and as fast as possible. It should also return the same output every time for a given input, otherwise the rollover behaviour may not work as expected.

3.3 新版功能.

rotator

If this attribute is set to a callable, the `rotate()` method delegates to this callable. The parameters passed to the callable are those passed to `rotate()`.

3.3 新版功能.

rotation_filename (*default_name*)

Modify the filename of a log file when rotating.

This is provided so that a custom filename can be provided.

The default implementation calls the 'namer' attribute of the handler, if it's callable, passing the default name to it. If the attribute isn't callable (the default is None), the name is returned unchanged.

参数 default_name – The default name for the log file.

3.3 新版功能.

rotate (*source*, *dest*)

When rotating, rotate the current log.

The default implementation calls the ‘rotator’ attribute of the handler, if it’s callable, passing the source and dest arguments to it. If the attribute isn’t callable (the default is `None`), the source is simply renamed to the destination.

参数

- **source** – The source filename. This is normally the base filename, e.g. ‘test.log’.
- **dest** – The destination filename. This is normally what the source is rotated to, e.g. ‘test.log.1’.

3.3 新版功能.

The reason the attributes exist is to save you having to subclass - you can use the same callables for instances of `RotatingFileHandler` and `TimedRotatingFileHandler`. If either the namer or rotator callable raises an exception, this will be handled in the same way as any other exception during an `emit()` call, i.e. via the `handleError()` method of the handler.

If you need to make more significant changes to rotation processing, you can override the methods.

For an example, see `cookbook-rotator-namer`.

16.8.6 RotatingFileHandler

The `RotatingFileHandler` class, located in the `logging.handlers` module, supports rotation of disk log files.

class `logging.handlers.RotatingFileHandler` (*filename*, *mode*='a', *maxBytes*=0, *backupCount*=0, *encoding*=None, *delay*=False)

Returns a new instance of the `RotatingFileHandler` class. The specified file is opened and used as the stream for logging. If *mode* is not specified, 'a' is used. If *encoding* is not None, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely.

You can use the *maxBytes* and *backupCount* values to allow the file to *rollover* at a predetermined size. When the size is about to be exceeded, the file is closed and a new file is silently opened for output. Rollover occurs whenever the current log file is nearly *maxBytes* in length; but if either of *maxBytes* or *backupCount* is zero, rollover never occurs, so you generally want to set *backupCount* to at least 1, and have a non-zero *maxBytes*. When *backupCount* is non-zero, the system will save old log files by appending the extensions ‘.1’, ‘.2’ etc., to the filename. For example, with a *backupCount* of 5 and a base file name of `app.log`, you would get `app.log`, `app.log.1`, `app.log.2`, up to `app.log.5`. The file being written to is always `app.log`. When this file is filled, it is closed and renamed to `app.log.1`, and if files `app.log.1`, `app.log.2`, etc. exist, then they are renamed to `app.log.2`, `app.log.3` etc. respectively.

在 3.6 版更改: As well as string values, `Path` objects are also accepted for the *filename* argument.

doRollover()

Does a rollover, as described above.

emit (*record*)

Outputs the record to the file, catering for rollover as described previously.

16.8.7 TimedRotatingFileHandler

The `TimedRotatingFileHandler` class, located in the `logging.handlers` module, supports rotation of disk log files at certain timed intervals.

class logging.handlers.TimedRotatingFileHandler (filename, when='h', interval=1, backup-Count=0, encoding=None, delay=False, utc=False, atTime=None)

Returns a new instance of the `TimedRotatingFileHandler` class. The specified file is opened and used as the stream for logging. On rotating it also sets the filename suffix. Rotating happens based on the product of *when* and *interval*.

You can use the *when* to specify the type of *interval*. The list of possible values is below. Note that they are not case sensitive.

值	间隔类型	如果/如何使用 <i>atTime</i>
'S'	秒	忽略
'M'	分钟	忽略
'H'	小时	忽略
'D'	天	忽略
'W0'-'W6'	工作日 (0= 星期一)	Used to compute initial rollover time
'midnight'	Roll over at midnight, if <i>atTime</i> not specified, else at time <i>atTime</i>	Used to compute initial rollover time

When using weekday-based rotation, specify 'W0' for Monday, 'W1' for Tuesday, and so on up to 'W6' for Sunday. In this case, the value passed for *interval* isn't used.

The system will save old log files by appending extensions to the filename. The extensions are date-and-time based, using the strftime format `%Y-%m-%d_%H-%M-%S` or a leading portion thereof, depending on the rollover interval.

When computing the next rollover time for the first time (when the handler is created), the last modification time of an existing log file, or else the current time, is used to compute when the next rotation will occur.

If the *utc* argument is true, times in UTC will be used; otherwise local time is used.

If *backupCount* is nonzero, at most *backupCount* files will be kept, and if more would be created when rollover occurs, the oldest one is deleted. The deletion logic uses the interval to determine which files to delete, so changing the interval may leave old files lying around.

If *delay* is true, then file opening is deferred until the first call to `emit()`.

If *atTime* is not `None`, it must be a `datetime.time` instance which specifies the time of day when rollover occurs, for the cases where rollover is set to happen "at midnight" or "on a particular weekday". Note that in these cases, the *atTime* value is effectively used to compute the *initial* rollover, and subsequent rollovers would be calculated via the normal interval calculation.

注解: Calculation of the initial rollover time is done when the handler is initialised. Calculation of subsequent rollover times is done only when rollover occurs, and rollover occurs only when emitting output. If this is not kept in mind, it might lead to some confusion. For example, if an interval of "every minute" is set, that does not mean you will always see log files with times (in the filename) separated by a minute; if, during application execution, logging output is generated more frequently than once a minute, *then* you can expect to see log files with times separated by a minute. If, on the other hand, logging messages are only output once every five minutes (say), then there will be gaps in the file times corresponding to the minutes where no output (and hence no rollover) occurred.

在 3.4 版更改: *atTime* parameter was added.

在 3.6 版更改: As well as string values, `Path` objects are also accepted for the *filename* argument.

doRollover()

Does a rollover, as described above.

emit (*record*)

Outputs the record to the file, catering for rollover as described above.

16.8.8 SocketHandler

The *SocketHandler* class, located in the *logging.handlers* module, sends logging output to a network socket. The base class uses a TCP socket.

class *logging.handlers.SocketHandler* (*host*, *port*)

Returns a new instance of the *SocketHandler* class intended to communicate with a remote machine whose address is given by *host* and *port*.

在 3.4 版更改: If *port* is specified as *None*, a Unix domain socket is created using the value in *host* - otherwise, a TCP socket is created.

close ()

Closes the socket.

emit ()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. If the connection was previously lost, re-establishes the connection. To unpickle the record at the receiving end into a *LogRecord*, use the *makeLogRecord()* function.

handleError ()

Handles an error which has occurred during *emit()*. The most likely cause is a lost connection. Closes the socket so that we can retry on the next event.

makeSocket ()

This is a factory method which allows subclasses to define the precise type of socket they want. The default implementation creates a TCP socket (*socket.SOCK_STREAM*).

makePickle (*record*)

Pickles the record's attribute dictionary in binary format with a length prefix, and returns it ready for transmission across the socket.

Note that pickles aren't completely secure. If you are concerned about security, you may want to override this method to implement a more secure mechanism. For example, you can sign pickles using HMAC and then verify them on the receiving end, or alternatively you can disable unpickling of global objects on the receiving end.

send (*packet*)

Send a pickled string *packet* to the socket. This function allows for partial sends which can happen when the network is busy.

createSocket ()

Tries to create a socket; on failure, uses an exponential back-off algorithm. On initial failure, the handler will drop the message it was trying to send. When subsequent messages are handled by the same instance, it will not try connecting until some time has passed. The default parameters are such that the initial delay is one second, and if after that delay the connection still can't be made, the handler will double the delay each time up to a maximum of 30 seconds.

This behaviour is controlled by the following handler attributes:

- *retryStart* (initial delay, defaulting to 1.0 seconds).
- *retryFactor* (multiplier, defaulting to 2.0).
- *retryMax* (maximum delay, defaulting to 30.0 seconds).

This means that if the remote listener starts up *after* the handler has been used, you could lose messages (since the handler won't even attempt a connection until the delay has elapsed, but just silently drop messages during the delay period).

16.8.9 DatagramHandler

The `DatagramHandler` class, located in the `logging.handlers` module, inherits from `SocketHandler` to support sending logging messages over UDP sockets.

class `logging.handlers.DatagramHandler` (*host*, *port*)

Returns a new instance of the `DatagramHandler` class intended to communicate with a remote machine whose address is given by *host* and *port*.

在 3.4 版更改: If *port* is specified as `None`, a Unix domain socket is created using the value in *host* - otherwise, a UDP socket is created.

emit ()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. To unpickle the record at the receiving end into a `LogRecord`, use the `makeLogRecord()` function.

makeSocket ()

The factory method of `SocketHandler` is here overridden to create a UDP socket (`socket.SOCK_DGRAM`).

send (*s*)

Send a pickled string to a socket.

16.8.10 SysLogHandler

The `SysLogHandler` class, located in the `logging.handlers` module, supports sending logging messages to a remote or local Unix syslog.

class `logging.handlers.SysLogHandler` (*address*=(`'localhost'`, `SYSLOG_UDP_PORT`), *facility*=`LOG_USER`, *socktype*=`socket.SOCK_DGRAM`)

Returns a new instance of the `SysLogHandler` class intended to communicate with a remote Unix machine whose address is given by *address* in the form of a (*host*, *port*) tuple. If *address* is not specified, (`'localhost'`, `514`) is used. The address is used to open a socket. An alternative to providing a (*host*, *port*) tuple is providing an address as a string, for example `'/dev/log '`. In this case, a Unix domain socket is used to send the message to the syslog. If *facility* is not specified, `LOG_USER` is used. The type of socket opened depends on the *socktype* argument, which defaults to `socket.SOCK_DGRAM` and thus opens a UDP socket. To open a TCP socket (for use with the newer syslog daemons such as `rsyslog`), specify a value of `socket.SOCK_STREAM`.

Note that if your server is not listening on UDP port 514, `SysLogHandler` may appear not to work. In that case, check what address you should be using for a domain socket - it's system dependent. For example, on Linux it's usually `'/dev/log '` but on OS/X it's `'/var/run/syslog '`. You'll need to check your platform and use the appropriate address (you may need to do this check at runtime if your application needs to run on several platforms). On Windows, you pretty much have to use the UDP option.

在 3.2 版更改: *socktype* was added.

close ()

Closes the socket to the remote host.

emit (*record*)

The record is formatted, and then sent to the syslog server. If exception information is present, it is *not* sent to the server.

在 3.2.1 版更改: (See: [bpo-12168](#).) In earlier versions, the message sent to the syslog daemons was always terminated with a NUL byte, because early versions of these daemons expected a NUL terminated message - even though it's not in the relevant specification ([RFC 5424](#)). More recent versions of these daemons don't expect the NUL byte but strip it off if it's there, and even more recent daemons (which adhere more closely to RFC 5424) pass the NUL byte on as part of the message.

To enable easier handling of syslog messages in the face of all these differing daemon behaviours, the appending of the NUL byte has been made configurable, through the use of a class-level attribute, `append_nul`. This defaults to `True` (preserving the existing behaviour) but can be set to `False` on a `SysLogHandler` instance in order for that instance to *not* append the NUL terminator.

在 3.3 版更改: (See: [bpo-12419](#).) In earlier versions, there was no facility for an “ident” or “tag” prefix to identify the source of the message. This can now be specified using a class-level attribute, defaulting to `""` to preserve existing behaviour, but which can be overridden on a `SysLogHandler` instance in order for that instance to prepend the ident to every message handled. Note that the provided ident must be text, not bytes, and is prepended to the message exactly as is.

`encodePriority` (*facility, priority*)

Encodes the facility and priority into an integer. You can pass in strings or integers - if strings are passed, internal mapping dictionaries are used to convert them to integers.

The symbolic `LOG_` values are defined in `SysLogHandler` and mirror the values defined in the `sys/syslog.h` header file.

优先级

名称 (字符串)	符号值
alert	LOG_ALERT
crit 或 critical	LOG_CRIT
debug	LOG_DEBUG
emerg 或 panic	LOG_EMERG
err 或 error	LOG_ERR
info	LOG_INFO
notice	LOG_NOTICE
warn 或 warning	LOG_WARNING

设备

名称 (字符串)	符号值
auth	LOG_AUTH
authpriv	LOG_AUTHPRIV
cron	LOG_CRON
daemon	LOG_DAEMON
ftp	LOG_FTP
kern	LOG_KERN
lpr	LOG_LPR
mail	LOG_MAIL
news	LOG_NEWS
syslog	LOG_SYSLOG
user	LOG_USER
uucp	LOG_UUCP
local0	LOG_LOCAL0
local1	LOG_LOCAL1
local2	LOG_LOCAL2
local3	LOG_LOCAL3
local4	LOG_LOCAL4
local5	LOG_LOCAL5
local6	LOG_LOCAL6
local7	LOG_LOCAL7

mapPriority (*levelname*)

Maps a logging level name to a syslog priority name. You may need to override this if you are using custom levels, or if the default algorithm is not suitable for your needs. The default algorithm maps DEBUG, INFO, WARNING, ERROR and CRITICAL to the equivalent syslog names, and all other level names to ‘warning’.

16.8.11 NTEventLogHandler

The *NTEventLogHandler* class, located in the *logging.handlers* module, supports sending logging messages to a local Windows NT, Windows 2000 or Windows XP event log. Before you can use it, you need Mark Hammond’s Win32 extensions for Python installed.

class *logging.handlers.NTEventLogHandler* (*appname*, *dllname=None*, *logtype='Application'*)

Returns a new instance of the *NTEventLogHandler* class. The *appname* is used to define the application name as it appears in the event log. An appropriate registry entry is created using this name. The *dllname* should give the fully qualified pathname of a .dll or .exe which contains message definitions to hold in the log (if not specified, 'win32service.pyd' is used - this is installed with the Win32 extensions and contains some basic placeholder message definitions. Note that use of these placeholders will make your event logs big, as the entire message source is held in the log. If you want slimmer logs, you have to pass in the name of your own .dll or .exe which contains the message definitions you want to use in the event log). The *logtype* is one of 'Application', 'System' or 'Security', and defaults to 'Application'.

close ()

At this point, you can remove the application name from the registry as a source of event log entries. However, if you do this, you will not be able to see the events as you intended in the Event Log Viewer - it needs to be able to access the registry to get the .dll name. The current version does not do this.

emit (*record*)

Determines the message ID, event category and event type, and then logs the message in the NT event log.

getEventCategory (*record*)

Returns the event category for the record. Override this if you want to specify your own categories. This version returns 0.

getEventType (*record*)

Returns the event type for the record. Override this if you want to specify your own types. This version does a mapping using the handler's `typemap` attribute, which is set up in `__init__()` to a dictionary which contains mappings for `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL`. If you are using your own levels, you will either need to override this method or place a suitable dictionary in the handler's `typemap` attribute.

getMessageID (*record*)

Returns the message ID for the record. If you are using your own messages, you could do this by having the *msg* passed to the logger being an ID rather than a format string. Then, in here, you could use a dictionary lookup to get the message ID. This version returns 1, which is the base message ID in `win32service.pyd`.

16.8.12 SMTPHandler

The `SMTPHandler` class, located in the `logging.handlers` module, supports sending logging messages to an email address via SMTP.

class `logging.handlers.SMTPHandler` (*mailhost*, *fromaddr*, *toaddrs*, *subject*, *credentials=None*, *secure=None*, *timeout=1.0*)

Returns a new instance of the `SMTPHandler` class. The instance is initialized with the from and to addresses and subject line of the email. The *toaddrs* should be a list of strings. To specify a non-standard SMTP port, use the (host, port) tuple format for the *mailhost* argument. If you use a string, the standard SMTP port is used. If your SMTP server requires authentication, you can specify a (username, password) tuple for the *credentials* argument.

To specify the use of a secure protocol (TLS), pass in a tuple to the *secure* argument. This will only be used when authentication credentials are supplied. The tuple should be either an empty tuple, or a single-value tuple with the name of a keyfile, or a 2-value tuple with the names of the keyfile and certificate file. (This tuple is passed to the `smtplib.SMTP.starttls()` method.)

A timeout can be specified for communication with the SMTP server using the *timeout* argument.

3.3 新版功能: The *timeout* argument was added.

emit (*record*)

Formats the record and sends it to the specified addressees.

getSubject (*record*)

If you want to specify a subject line which is record-dependent, override this method.

16.8.13 MemoryHandler

The `MemoryHandler` class, located in the `logging.handlers` module, supports buffering of logging records in memory, periodically flushing them to a *target* handler. Flushing occurs whenever the buffer is full, or when an event of a certain severity or greater is seen.

`MemoryHandler` is a subclass of the more general `BufferingHandler`, which is an abstract class. This buffers logging records in memory. Whenever each record is added to the buffer, a check is made by calling `shouldFlush()` to see if the buffer should be flushed. If it should, then `flush()` is expected to do the flushing.

class `logging.handlers.BufferingHandler` (*capacity*)

Initializes the handler with a buffer of the specified capacity.

emit (*record*)

Appends the record to the buffer. If `shouldFlush()` returns true, calls `flush()` to process the buffer.

flush()

You can override this to implement custom flushing behavior. This version just zaps the buffer to empty.

shouldFlush(record)

Returns true if the buffer is up to capacity. This method can be overridden to implement custom flushing strategies.

class logging.handlers.**MemoryHandler**(*capacity*, *flushLevel*=ERROR, *target*=None, *flushOnClose*=True)

Returns a new instance of the *MemoryHandler* class. The instance is initialized with a buffer size of *capacity*. If *flushLevel* is not specified, ERROR is used. If no *target* is specified, the target will need to be set using *setTarget()* before this handler does anything useful. If *flushOnClose* is specified as False, then the buffer is *not* flushed when the handler is closed. If not specified or specified as True, the previous behaviour of flushing the buffer will occur when the handler is closed.

在 3.6 版更改: The *flushOnClose* parameter was added.

close()

Calls *flush()*, sets the target to None and clears the buffer.

flush()

For a *MemoryHandler*, flushing means just sending the buffered records to the target, if there is one. The buffer is also cleared when this happens. Override if you want different behavior.

setTarget(target)

Sets the target handler for this handler.

shouldFlush(record)

Checks for buffer full or a record at the *flushLevel* or higher.

16.8.14 HTTPHandler

The *HTTPHandler* class, located in the *logging.handlers* module, supports sending logging messages to a Web server, using either GET or POST semantics.

class logging.handlers.**HTTPHandler**(*host*, *url*, *method*='GET', *secure*=False, *credentials*=None, *context*=None)

Returns a new instance of the *HTTPHandler* class. The *host* can be of the form *host:port*, should you need to use a specific port number. If no *method* is specified, GET is used. If *secure* is true, a HTTPS connection will be used. The *context* parameter may be set to a *ssl.SSLContext* instance to configure the SSL settings used for the HTTPS connection. If *credentials* is specified, it should be a 2-tuple consisting of userid and password, which will be placed in a HTTP 'Authorization' header using Basic authentication. If you specify credentials, you should also specify *secure*=True so that your userid and password are not passed in cleartext across the wire.

在 3.5 版更改: The *context* parameter was added.

mapLogRecord(record)

Provides a dictionary, based on *record*, which is to be URL-encoded and sent to the web server. The default implementation just returns *record.__dict__*. This method can be overridden if e.g. only a subset of *LogRecord* is to be sent to the web server, or if more specific customization of what's sent to the server is required.

emit(record)

Sends the record to the Web server as a URL-encoded dictionary. The *mapLogRecord()* method is used to convert the record to the dictionary to be sent.

注解: Since preparing a record for sending it to a Web server is not the same as a generic formatting operation, using *setFormatter()* to specify a *Formatter* for a *HTTPHandler* has no effect. Instead of calling

`format()`, this handler calls `mapLogRecord()` and then `urllib.parse.urlencode()` to encode the dictionary in a form suitable for sending to a Web server.

16.8.15 QueueHandler

3.2 新版功能.

The `QueueHandler` class, located in the `logging.handlers` module, supports sending logging messages to a queue, such as those implemented in the `queue` or `multiprocessing` modules.

Along with the `QueueListener` class, `QueueHandler` can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in Web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via `SMTPHandler`) are done on a separate thread.

class `logging.handlers.QueueHandler` (*queue*)

Returns a new instance of the `QueueHandler` class. The instance is initialized with the queue to send messages to. The queue can be any queue-like object; it's used as-is by the `enqueue()` method, which needs to know how to send messages to it.

emit (*record*)

Enqueues the result of preparing the LogRecord.

prepare (*record*)

Prepares a record for queuing. The object returned by this method is enqueued.

The base implementation formats the record to merge the message and arguments, and removes unpickleable items from the record in-place.

You might want to override this method if you want to convert the record to a dict or JSON string, or send a modified copy of the record while leaving the original intact.

enqueue (*record*)

Enqueues the record on the queue using `put_nowait()`; you may want to override this if you want to use blocking behaviour, or a timeout, or a customized queue implementation.

16.8.16 QueueListener

3.2 新版功能.

The `QueueListener` class, located in the `logging.handlers` module, supports receiving logging messages from a queue, such as those implemented in the `queue` or `multiprocessing` modules. The messages are received from a queue in an internal thread and passed, on the same thread, to one or more handlers for processing. While `QueueListener` is not itself a handler, it is documented here because it works hand-in-hand with `QueueHandler`.

Along with the `QueueHandler` class, `QueueListener` can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in Web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via `SMTPHandler`) are done on a separate thread.

class `logging.handlers.QueueListener` (*queue*, **handlers*, *respect_handler_level=False*)

Returns a new instance of the `QueueListener` class. The instance is initialized with the queue to send messages to and a list of handlers which will handle entries placed on the queue. The queue can be any queue-like object; it's passed as-is to the `dequeue()` method, which needs to know how to get messages from it. If `respect_handler_level` is True, a handler's level is respected (compared with the level for the message) when deciding whether to pass messages to that handler; otherwise, the behaviour is as in previous Python versions - to always pass each message to each handler.

在 3.5 版更改: The `respect_handler_levels` argument was added.

dequeue (*block*)

Dequeues a record and return it, optionally blocking.

The base implementation uses `get()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

prepare (*record*)

Prepare a record for handling.

This implementation just returns the passed-in record. You may want to override this method if you need to do any custom marshalling or manipulation of the record before passing it to the handlers.

handle (*record*)

Handle a record.

This just loops through the handlers offering them the record to handle. The actual object passed to the handlers is that which is returned from `prepare()`.

start ()

Starts the listener.

This starts up a background thread to monitor the queue for LogRecords to process.

stop ()

Stops the listener.

This asks the thread to terminate, and then waits for it to do so. Note that if you don't call this before your application exits, there may be some records still left on the queue, which won't be processed.

enqueue_sentinel ()

Writes a sentinel to the queue to tell the listener to quit. This implementation uses `put_nowait()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

3.3 新版功能.

参见:

模块 `logging` 日志记录模块的 API 参考。

模块 `logging.config` 日志记录模块的配置 API。

16.9 getpass — 便携式密码输入工具

源代码: [Lib/getpass.py](#)

`getpass` 模块提供了两个函数:

`getpass.getpass` (*prompt='Password: ', stream=None*)

提示用户输入一个密码且不会回显。用户会看到字符串 *prompt* 作为提示, 其默认值为 'Password: '。在 Unix 上, 如有必要提示会使用替换错误句柄写入到文件类对象 *stream*。*stream* 默认指向控制终端 (/dev/tty), 如果不可用则指向 `sys.stderr` (此参数在 Windows 上会被忽略)。

如果回显自由输入不可用则 `getpass()` 将回退为打印一条警告消息到 *stream* 并且从 `sys.stdin` 读取同时发出 `GetPassWarning`。

注解：如果你从 IDLE 内部调用 `getpass`，输入可能是在你启动 IDLE 的终端中而非在 IDLE 窗口本身中完成。

exception `getpass.GetPassWarning`

一个当密码输入可能被回显时发出的 `UserWarning` 子类。

`getpass.getuser()`

返回用户的“登录名称”。

此函数会按顺序检查环境变量 `LOGNAME`, `USER`, `LNAME` 和 `USERNAME`，并返回其中第一个被设置为非空字符串的值。如果均未设置，则在支持 `pwd` 模块的系统上将返回来自密码数据库的登录名，否则将引发一个异常。

通常情况下，此函数应优先于 `os.getlogin()` 使用。

16.10 curses — 终端字符单元显示的处理

`curses` 模块提供了 `curses` 库的接口，这是可移植高级终端处理的事实标准。

虽然 `curses` 在 Unix 环境中使用最为广泛，但也有适用于 Windows, DOS 以及其他可能的系统的版本。此扩展模块旨在匹配 `ncurses` 的 API，这是一个部署在 Linux 和 Unix 的 BSD 变体上的开源 `curses` 库。

注解：每当文档提到 **字符**时，它可以被指定为一个整数，一个单字符 Unicode 字符串或者一个单字节的字节字符串。

每当此文档提到 **字符串**时，它可以被指定为一个 Unicode 字符串或者一个字节字符串。

注解：从 5.4 版本开始，`ncurses` 库使用 `nl_langinfo` 函数来决定如何解释非 ASCII 数据。这意味着你需要在程序中调用 `locale.setlocale()` 函数，并使用一种系统中可用的编码方法来编码 Unicode 字符串。这个例子使用了系统默认的编码：

```
import locale
locale.setlocale(locale.LC_ALL, '')
code = locale.getpreferredencoding()
```

然后使用 `code` 作为 `str.encode()` 调用的编码。

模块 `curses.ascii` 在 ASCII 字符上工作的工具，无论你的区域设置是什么。

模块 `curses.panel` A panel stack extension that adds depth to curses windows.

Module `curses.textpad` Editable text widget for curses supporting **Emacs**-like bindings.

curses-howto Tutorial material on using curses with Python, by Andrew Kuchling and Eric Raymond.

The `Tools/demo/` directory in the Python source distribution contains some example programs using the curses bindings provided by this module.

16.10.1 函数

`curses` 模块定义了以下异常:

exception `curses.error`

当 `curses` 库中函数返回一个错误时引发的异常。

注解: Whenever *x* or *y* arguments to a function or a method are optional, they default to the current cursor location. Whenever *attr* is optional, it defaults to `A_NORMAL`.

`curses` 模块定义了以下函数:

`curses.baudrate()`

Return the output speed of the terminal in bits per second. On software terminal emulators it will have a fixed high value. Included for historical reasons; in former times, it was used to write output loops for time delays and occasionally to change interfaces depending on the line speed.

`curses.beep()`

Emit a short attention sound.

`curses.can_change_color()`

Return True or False, depending on whether the programmer can change the colors displayed by the terminal.

`curses.cbreak()`

Enter cbreak mode. In cbreak mode (sometimes called “rare” mode) normal tty line buffering is turned off and characters are available to be read one by one. However, unlike raw mode, special characters (interrupt, quit, suspend, and flow control) retain their effects on the tty driver and calling program. Calling first `raw()` then `cbreak()` leaves the terminal in cbreak mode.

`curses.color_content(color_number)`

Return the intensity of the red, green, and blue (RGB) components in the color *color_number*, which must be between 0 and `COLORS`. Return a 3-tuple, containing the R,G,B values for the given color, which will be between 0 (no component) and 1000 (maximum amount of component).

`curses.color_pair(color_number)`

Return the attribute value for displaying text in the specified color. This attribute value can be combined with `A_STANDOUT`, `A_REVERSE`, and the other `A_*` attributes. `pair_number()` is the counterpart to this function.

`curses.curs_set(visibility)`

Set the cursor state. *visibility* can be set to 0, 1, or 2, for invisible, normal, or very visible. If the terminal supports the visibility requested, return the previous cursor state; otherwise raise an exception. On many terminals, the “visible” mode is an underline cursor and the “very visible” mode is a block cursor.

`curses.def_prog_mode()`

Save the current terminal mode as the “program” mode, the mode when the running program is using `curses`. (Its counterpart is the “shell” mode, for when the program is not in `curses`.) Subsequent calls to `reset_prog_mode()` will restore this mode.

`curses.def_shell_mode()`

Save the current terminal mode as the “shell” mode, the mode when the running program is not using `curses`. (Its counterpart is the “program” mode, when the program is using `curses` capabilities.) Subsequent calls to `reset_shell_mode()` will restore this mode.

`curses.delay_output(ms)`

Insert an *ms* millisecond pause in output.

`curses.doupdate()`

Update the physical screen. The `curses` library keeps two data structures, one representing the current physical

screen contents and a virtual screen representing the desired next state. The `doupdate()` ground updates the physical screen to match the virtual screen.

The virtual screen may be updated by a `noutrefresh()` call after write operations such as `addstr()` have been performed on a window. The normal `refresh()` call is simply `noutrefresh()` followed by `doupdate()`; if you have to update multiple windows, you can speed performance and perhaps reduce screen flicker by issuing `noutrefresh()` calls on all windows, followed by a single `doupdate()`.

`curses.echo()`

Enter echo mode. In echo mode, each character input is echoed to the screen as it is entered.

`curses.endwin()`

De-initialize the library, and return terminal to normal status.

`curses.erasechar()`

Return the user's current erase character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

`curses.filter()`

The `filter()` routine, if used, must be called before `initscr()` is called. The effect is that, during those calls, `LINES` is set to 1; the capabilities `clear`, `cup`, `cud`, `cud1`, `cuu1`, `cuu`, `vpa` are disabled; and the home string is set to the value of `cr`. The effect is that the cursor is confined to the current line, and so are screen updates. This may be used for enabling character-at-a-time line editing without touching the rest of the screen.

`curses.flash()`

Flash the screen. That is, change it to reverse-video and then change it back in a short interval. Some people prefer such as 'visible bell' to the audible attention signal produced by `beep()`.

`curses.flushinp()`

Flush all input buffers. This throws away any typeahead that has been typed by the user and has not yet been processed by the program.

`curses.getmouse()`

After `getch()` returns `KEY_MOUSE` to signal a mouse event, this method should be call to retrieve the queued mouse event, represented as a 5-tuple (`id`, `x`, `y`, `z`, `bstate`). `id` is an ID value used to distinguish multiple devices, and `x`, `y`, `z` are the event's coordinates. (`z` is currently unused.) `bstate` is an integer value whose bits will be set to indicate the type of event, and will be the bitwise OR of one or more of the following constants, where `n` is the button number from 1 to 4: `BUTTONn_PRESSED`, `BUTTONn_RELEASED`, `BUTTONn_CLICKED`, `BUTTONn_DOUBLE_CLICKED`, `BUTTONn_TRIPLE_CLICKED`, `BUTTON_SHIFT`, `BUTTON_CTRL`, `BUTTON_ALT`.

`curses.getsyx()`

Return the current coordinates of the virtual screen cursor as a tuple (`y`, `x`). If `leaveok` is currently `True`, then return `(-1, -1)`.

`curses.getwin(file)`

Read window related data stored in the file by an earlier `putwin()` call. The routine then creates and initializes a new window using that data, returning the new window object.

`curses.has_colors()`

Return `True` if the terminal can display colors; otherwise, return `False`.

`curses.has_ic()`

Return `True` if the terminal has insert- and delete-character capabilities. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.has_il()`

Return `True` if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.has_key(ch)`

Take a key value *ch*, and return True if the current terminal type recognizes a key with that value.

`curses.halfdelay(tenths)`

Used for half-delay mode, which is similar to cbreak mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, raise an exception if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

`curses.init_color(color_number, r, g, b)`

Change the definition of a color, taking the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of *color_number* must be between 0 and COLORS. Each of *r*, *g*, *b*, must be a value between 0 and 1000. When `init_color()` is used, all occurrences of that color on the screen immediately change to the new definition. This function is a no-op on most terminals; it is active only if `can_change_color()` returns True.

`curses.init_pair(pair_number, fg, bg)`

Change the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of *pair_number* must be between 1 and COLOR_PAIRS - 1 (the 0 color pair is wired to white on black and cannot be changed). The value of *fg* and *bg* arguments must be between 0 and COLORS. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair are changed to the new definition.

`curses.initscr()`

Initialize the library. Return a `Window` object which represents the whole screen.

注解: If there is an error opening the terminal, the underlying curses library may cause the interpreter to exit.

`curses.is_term_resized(nlines, ncols)`

Return True if `resize_term()` would modify the window structure, False otherwise.

`curses.isendwin()`

Return True if `endwin()` has been called (that is, the curses library has been deinitialized).

`curses.keyname(k)`

Return the name of the key numbered *k* as a bytes object. The name of a key generating printable ASCII character is the key's character. The name of a control-key combination is a two-byte bytes object consisting of a caret (b'^') followed by the corresponding printable ASCII character. The name of an alt-key combination (128–255) is a bytes object consisting of the prefix b'M-' followed by the name of the corresponding ASCII character.

`curses.killchar()`

Return the user's current line kill character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

`curses.longname()`

Return a bytes object containing the terminfo long name field describing the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to `initscr()`.

`curses.meta(flag)`

If *flag* is True, allow 8-bit characters to be input. If *flag* is False, allow only 7-bit chars.

`curses.mouseinterval(interval)`

Set the maximum time in milliseconds that can elapse between press and release events in order for them to be recognized as a click, and return the previous interval value. The default value is 200 msec, or one fifth of a second.

`curses.mousemask(mousemask)`

Set the mouse events to be reported, and return a tuple (*availmask*, *oldmask*). *availmask* indicates which

of the specified mouse events can be reported; on complete failure it returns 0. *oldmask* is the previous value of the given window's mouse event mask. If this function is never called, no mouse events are ever reported.

`curses.napms(ms)`

Sleep for *ms* milliseconds.

`curses.newpad(nlines, ncols)`

Create and return a pointer to a new pad data structure with the given number of lines and columns. Return a pad as a window object.

A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (such as from scrolling or echoing of input) do not occur. The `refresh()` and `noutrefresh()` methods of a pad require 6 arguments to specify the part of the pad to be displayed and the location on the screen to be used for the display. The arguments are *pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*; the *p* arguments refer to the upper left corner of the pad region to be displayed and the *s* arguments define a clipping box on the screen within which the pad region is to be displayed.

`curses.newwin(nlines, ncols)`

`curses.newwin(nlines, ncols, begin_y, begin_x)`

Return a new *window*, whose left-upper corner is at (*begin_y*, *begin_x*), and whose height/width is *nlines/ncols*.

By default, the window will extend from the specified position to the lower right corner of the screen.

`curses.nl()`

Enter newline mode. This mode translates the return key into newline on input, and translates newline into return and line-feed on output. Newline mode is initially on.

`curses.nocbreak()`

Leave cbreak mode. Return to normal “cooked” mode with line buffering.

`curses.noecho()`

Leave echo mode. Echoing of input characters is turned off.

`curses.nonl()`

Leave newline mode. Disable translation of return into newline on input, and disable low-level translation of newline into newline/return on output (but this does not change the behavior of `addch('\n')`, which always does the equivalent of return and line feed on the virtual screen). With translation off, curses can sometimes speed up vertical motion a little; also, it will be able to detect the return key on input.

`curses.noqiflush()`

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the INTR, QUIT and SUSP characters will not be done. You may want to call `noqiflush()` in a signal handler if you want output to continue as though the interrupt had not occurred, after the handler exits.

`curses.noraw()`

Leave raw mode. Return to normal “cooked” mode with line buffering.

`curses.pair_content(pair_number)`

Return a tuple (*fg*, *bg*) containing the colors for the requested color pair. The value of *pair_number* must be between 1 and `COLOR_PAIRS - 1`.

`curses.pair_number(attr)`

Return the number of the color-pair set by the attribute value *attr*. `color_pair()` is the counterpart to this function.

`curses.putp(str)`

Equivalent to `tputs(str, 1, putchar)`; emit the value of a specified terminfo capability for the current terminal. Note that the output of `putp()` always goes to standard output.

`curses.qiflush([flag])`

If *flag* is `False`, the effect is the same as calling `noqiflush()`. If *flag* is `True`, or no argument is provided, the queues will be flushed when these control characters are read.

`curses.raw()`

Enter raw mode. In raw mode, normal line buffering and processing of interrupt, quit, suspend, and flow control keys are turned off; characters are presented to curses input functions one by one.

`curses.reset_prog_mode()`

Restore the terminal to “program” mode, as previously saved by `def_prog_mode()`.

`curses.reset_shell_mode()`

Restore the terminal to “shell” mode, as previously saved by `def_shell_mode()`.

`curses.resetty()`

Restore the state of the terminal modes to what it was at the last call to `savetty()`.

`curses.resize_term(nlines, ncols)`

Backend function used by `resizeterm()`, performing most of the work; when resizing the windows, `resize_term()` blank-fills the areas that are extended. The calling application should fill in these areas with appropriate data. The `resize_term()` function attempts to resize all windows. However, due to the calling convention of pads, it is not possible to resize these without additional interaction with the application.

`curses.resizeterm(nlines, ncols)`

Resize the standard and current windows to the specified dimensions, and adjusts other bookkeeping data used by the curses library that record the window dimensions (in particular the SIGWINCH handler).

`curses.savetty()`

Save the current state of the terminal modes in a buffer, usable by `resetty()`.

`curses.setsyx(y, x)`

Set the virtual screen cursor to *y*, *x*. If *y* and *x* are both `-1`, then `leaveok` is set `True`.

`curses.setupterm(term=None, fd=-1)`

Initialize the terminal. *term* is a string giving the terminal name, or `None`; if omitted or `None`, the value of the `TERM` environment variable will be used. *fd* is the file descriptor to which any initialization sequences will be sent; if not supplied or `-1`, the file descriptor for `sys.stdout` will be used.

`curses.start_color()`

Must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after `initscr()`.

`start_color()` initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables in the `curses` module, `COLORS` and `COLOR_PAIRS`, containing the maximum number of colors and color-pairs the terminal can support. It also restores the colors on the terminal to the values they had when the terminal was just turned on.

`curses.termattrs()`

Return a logical OR of all video attributes supported by the terminal. This information is useful when a curses program needs complete control over the appearance of the screen.

`curses.termname()`

Return the value of the environment variable `TERM`, as a bytes object, truncated to 14 characters.

`curses.tigetflag(capname)`

Return the value of the Boolean capability corresponding to the terminfo capability name *capname* as an integer. Return the value `-1` if *capname* is not a Boolean capability, or `0` if it is canceled or absent from the terminal description.

`curses.tigetnum(capname)`

Return the value of the numeric capability corresponding to the terminfo capability name *capname* as an integer.

Return the value `-2` if *capname* is not a numeric capability, or `-1` if it is canceled or absent from the terminal description.

`curses.tigetstr(capname)`

Return the value of the string capability corresponding to the terminfo capability name *capname* as a bytes object. Return `None` if *capname* is not a terminfo “string capability”, or is canceled or absent from the terminal description.

`curses.tparm(str[, ...])`

Instantiate the bytes object *str* with the supplied parameters, where *str* should be a parameterized string obtained from the terminfo database. E.g. `tparm(tigetstr("cup"), 5, 3)` could result in `b'\033[6;4H'`, the exact result depending on terminal type.

`curses.typeahead(fd)`

Specify that the file descriptor *fd* be used for typeahead checking. If *fd* is `-1`, then no typeahead checking is done.

The curses library does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh` or `doupdate` is called again, allowing faster response to commands typed in advance. This function allows specifying a different file descriptor for typeahead checking.

`curses.unctrl(ch)`

Return a bytes object which is a printable representation of the character *ch*. Control characters are represented as a caret followed by the character, for example as `b'^C'`. Printing characters are left as they are.

`curses.ungetch(ch)`

Push *ch* so the next `getch()` will return it.

注解: Only one *ch* can be pushed before `getch()` is called.

`curses.update_lines_cols()`

Update `LINES` and `COLS`. Useful for detecting manual screen resize.

3.5 新版功能.

`curses.unget_wch(ch)`

Push *ch* so the next `get_wch()` will return it.

注解: Only one *ch* can be pushed before `get_wch()` is called.

3.3 新版功能.

`curses.ungetmouse(id, x, y, z, bstate)`

Push a `KEY_MOUSE` event onto the input queue, associating the given state data with it.

`curses.use_env(flag)`

If used, this function should be called before `initscr()` or `newterm` are called. When *flag* is `False`, the values of lines and columns specified in the terminfo database will be used, even if environment variables `LINES` and `COLUMNS` (used by default) are set, or if curses is running in a window (in which case default behavior would be to use the window size if `LINES` and `COLUMNS` are not set).

`curses.use_default_colors()`

Allow use of default values for colors on terminals supporting this feature. Use this to support transparency in your application. The default color is assigned to the color number `-1`. After calling this function, `init_pair(x, curses.COLOR_RED, -1)` initializes, for instance, color pair *x* to a red foreground color on the default background.

`curses.wrapper(func, ...)`

Initialize curses and call another callable object, *func*, which should be the rest of your curses-using application.

If the application raises an exception, this function will restore the terminal to a sane state before re-raising the exception and generating a traceback. The callable object *func* is then passed the main window `'stdscr'` as its first argument, followed by any other arguments passed to `wrapper()`. Before calling *func*, `wrapper()` turns on cbreak mode, turns off echo, enables the terminal keypad, and initializes colors if the terminal has color support. On exit (whether normally or by exception) it restores cooked mode, turns on echo, and disables the terminal keypad.

16.10.2 Window Objects

Window objects, as returned by `initscr()` and `newwin()` above, have the following methods and attributes:

`window.addch(ch[, attr])`

`window.addch(y, x, ch[, attr])`

Paint character *ch* at (*y*, *x*) with attributes *attr*, overwriting any character previously painter at that location. By default, the character position and attributes are the current settings for the window object.

注解: Writing outside the window, subwindow, or pad raises a `curses.error`. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the character is printed.

`window.addnstr(str, n[, attr])`

`window.addnstr(y, x, str, n[, attr])`

Paint at most *n* characters of the character string *str* at (*y*, *x*) with attributes *attr*, overwriting anything previously on the display.

`window.addstr(str[, attr])`

`window.addstr(y, x, str[, attr])`

Paint the character string *str* at (*y*, *x*) with attributes *attr*, overwriting anything previously on the display.

注解: Writing outside the window, subwindow, or pad raises `curses.error`. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the string is printed.

`window.attroff(attr)`

Remove attribute *attr* from the “background” set applied to all writes to the current window.

`window.attron(attr)`

Add attribute *attr* from the “background” set applied to all writes to the current window.

`window.attrset(attr)`

Set the “background” set of attributes to *attr*. This set is initially 0 (no attributes).

`window.bkgd(ch[, attr])`

Set the background property of the window to the character *ch*, with attributes *attr*. The change is then applied to every character position in that window:

- The attribute of every character in the window is changed to the new background attribute.
- Wherever the former background character appears, it is changed to the new background character.

`window.bkgdset(ch[, attr])`

Set the window's background. A window's background consists of a character and any combination of attributes. The attribute part of the background is combined (OR'ed) with all non-blank characters that are written into the window. Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations.

`window.border([ls[, rs[, ts[, bs[, tl[, tr[, bl[, br]]]]]]])`

在窗口边缘绘制边框。每个参数指定用于边界特定部分的字符; 请参阅下表了解更多详情。

注解: A 0 value for any parameter will cause the default character to be used for that parameter. Keyword parameters can *not* be used. The defaults are listed in this table:

参数	描述	默认值
<i>ls</i>	左侧	ACS_VLINE
<i>rs</i>	右侧	ACS_VLINE
<i>ts</i>	顶部	ACS_HLINE
<i>bs</i>	底部	ACS_HLINE
<i>tl</i>	左上角	ACS_ULCORNER
<i>tr</i>	右上角	ACS_URCORNER
<i>bl</i>	左下角	ACS_LLCORNER
<i>br</i>	右下角	ACS_LRCORNER

`window.box([vertch, horch])`

Similar to `border()`, but both *ls* and *rs* are *vertch* and both *ts* and *bs* are *horch*. The default corner characters are always used by this function.

`window.chgat(attr)`

`window.chgat(num, attr)`

`window.chgat(y, x, attr)`

`window.chgat(y, x, num, attr)`

Set the attributes of *num* characters at the current cursor position, or at position (*y*, *x*) if supplied. If *num* is not given or is -1, the attribute will be set on all the characters to the end of the line. This function moves cursor to position (*y*, *x*) if supplied. The changed line will be touched using the `touchline()` method so that the contents will be redisplayed by the next window refresh.

`window.clear()`

Like `erase()`, but also cause the whole window to be repainted upon next call to `refresh()`.

`window.clearok(flag)`

If *flag* is True, the next call to `refresh()` will clear the window completely.

`window.clrtoebot()`

Erase from cursor to the end of the window: all lines below the cursor are deleted, and then the equivalent of `clrtoeol()` is performed.

`window.clrtoeol()`

Erase from cursor to the end of the line.

`window.cursyncup()`

Update the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

`window.delch([y, x])`

Delete any character at (*y*, *x*).

`window.deleteln()`

Delete the line under the cursor. All following lines are moved up by one line.

`window.derwin(begin_y, begin_x)`

`window.derwin(nlines, ncols, begin_y, begin_x)`

An abbreviation for “derive window”, `derwin()` is the same as calling `subwin()`, except that *begin_y* and

begin_x are relative to the origin of the window, rather than relative to the entire screen. Return a window object for the derived window.

`window.echochar(ch[, attr])`

Add character *ch* with attribute *attr*, and immediately call `refresh()` on the window.

`window.enclose(y, x)`

Test whether the given pair of screen-relative character-cell coordinates are enclosed by the given window, returning True or False. It is useful for determining what subset of the screen windows enclose the location of a mouse event.

`window.encoding`

Encoding used to encode method arguments (Unicode strings and characters). The encoding attribute is inherited from the parent window when a subwindow is created, for example with `window.subwin()`. By default, the locale encoding is used (see `locale.getpreferredencoding()`).

3.3 新版功能.

`window.erase()`

Clear the window.

`window.getbegyx()`

Return a tuple (*y*, *x*) of co-ordinates of upper-left corner.

`window.getbkgd()`

Return the given window's current background character/attribute pair.

`window.getch([y, x])`

Get a character. Note that the integer returned does *not* have to be in ASCII range: function keys, keypad keys and so on are represented by numbers higher than 255. In no-delay mode, return -1 if there is no input, otherwise wait until a key is pressed.

`window.get_wch([y, x])`

Get a wide character. Return a character for most keys, or an integer for function keys, keypad keys, and other special keys. In no-delay mode, raise an exception if there is no input.

3.3 新版功能.

`window.getkey([y, x])`

Get a character, returning a string instead of an integer, as `getch()` does. Function keys, keypad keys and other special keys return a multibyte string containing the key name. In no-delay mode, raise an exception if there is no input.

`window.getmaxyx()`

Return a tuple (*y*, *x*) of the height and width of the window.

`window.getparyx()`

Return the beginning coordinates of this window relative to its parent window as a tuple (*y*, *x*). Return (-1, -1) if this window has no parent.

`window.getstr()`

`window.getstr(n)`

`window.getstr(y, x)`

`window.getstr(y, x, n)`

Read a bytes object from the user, with primitive line editing capacity.

`window.getyx()`

Return a tuple (*y*, *x*) of current cursor position relative to the window's upper-left corner.

`window.hline(ch, n)`

`window.hline(y, x, ch, n)`

Display a horizontal line starting at (*y*, *x*) with length *n* consisting of the character *ch*.

`window.idcok(flag)`

If *flag* is `False`, `curses` no longer considers using the hardware insert/delete character feature of the terminal; if *flag* is `True`, use of character insertion and deletion is enabled. When `curses` is first initialized, use of character insert/delete is enabled by default.

`window.idlok(flag)`

If *flag* is `True`, `curses` will try and use hardware line editing facilities. Otherwise, line insertion/deletion are disabled.

`window.immedok(flag)`

If *flag* is `True`, any change in the window image automatically causes the window to be refreshed; you no longer have to call `refresh()` yourself. However, it may degrade performance considerably, due to repeated calls to `wrefresh`. This option is disabled by default.

`window.inch([y, x])`

Return the character at the given position in the window. The bottom 8 bits are the character proper, and upper bits are the attributes.

`window.insch(ch[, attr])`

`window.insch(y, x, ch[, attr])`

Paint character *ch* at (*y*, *x*) with attributes *attr*, moving the line from position *x* right by one character.

`window.insdelln(nlines)`

Insert *nlines* lines into the specified window above the current line. The *nlines* bottom lines are lost. For negative *nlines*, delete *nlines* lines starting with the one under the cursor, and move the remaining lines up. The bottom *nlines* lines are cleared. The current cursor position remains the same.

`window.insertln()`

Insert a blank line under the cursor. All following lines are moved down by one line.

`window.insnstr(str, n[, attr])`

`window.insnstr(y, x, str, n[, attr])`

Insert a character string (as many characters as will fit on the line) before the character under the cursor, up to *n* characters. If *n* is zero or negative, the entire string is inserted. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

`window.insstr(str[, attr])`

`window.insstr(y, x, str[, attr])`

Insert a character string (as many characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

`window.instr([n])`

`window.instr(y, x[, n])`

Return a bytes object of characters, extracted from the window starting at the current cursor position, or at *y*, *x* if specified. Attributes are stripped from the characters. If *n* is specified, `instr()` returns a string at most *n* characters long (exclusive of the trailing NUL).

`window.is_linetouched(line)`

Return `True` if the specified line was modified since the last call to `refresh()`; otherwise return `False`. Raise a `curses.error` exception if *line* is not valid for the given window.

`window.is_wintouched()`

Return `True` if the specified window was modified since the last call to `refresh()`; otherwise return `False`.

`window.keypad(flag)`

If *flag* is `True`, escape sequences generated by some keys (keypad, function keys) will be interpreted by `curses`. If *flag* is `False`, escape sequences will be left as is in the input stream.

`window.leaveok(flag)`

If *flag* is `True`, cursor is left where it is on update, instead of being at “cursor position.” This reduces cursor movement where possible. If possible the cursor will be made invisible.

If *flag* is `False`, cursor will always be at “cursor position” after an update.

`window.move(new_y, new_x)`

Move cursor to `(new_y, new_x)`.

`window.mvderwin(y, x)`

Move the window inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

`window.mvwin(new_y, new_x)`

Move the window so its upper-left corner is at `(new_y, new_x)`.

`window.nodelay(flag)`

If *flag* is `True`, `getch()` will be non-blocking.

`window.notimeout(flag)`

If *flag* is `True`, escape sequences will not be timed out.

If *flag* is `False`, after a few milliseconds, an escape sequence will not be interpreted, and will be left in the input stream as is.

`window.noutrefresh()`

Mark for refresh but wait. This function updates the data structure representing the desired state of the window, but does not force an update of the physical screen. To accomplish that, call `doupdate()`.

`window.overlay(destwin[, sminrow, smincol, dminrow, dmincol, dmaxrow, dmaxcol])`

Overlay the window on top of *destwin*. The windows need not be the same size, only the overlapping region is copied. This copy is non-destructive, which means that the current background character does not overwrite the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of `overlay()` can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, and the other variables mark a rectangle in the destination window.

`window.overwrite(destwin[, sminrow, smincol, dminrow, dmincol, dmaxrow, dmaxcol])`

Overwrite the window on top of *destwin*. The windows need not be the same size, in which case only the overlapping region is copied. This copy is destructive, which means that the current background character overwrites the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of `overwrite()` can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, the other variables mark a rectangle in the destination window.

`window.putwin(file)`

Write all data associated with the window into the provided file object. This information can be later retrieved using the `getwin()` function.

`window.redrawln(beg, num)`

Indicate that the *num* screen lines, starting at line *beg*, are corrupted and should be completely redrawn on the next `refresh()` call.

`window.redrawwin()`

Touch the entire window, causing it to be completely redrawn on the next `refresh()` call.

`window.refresh([pminrow, pmincol, sminrow, smincol, smaxrow, smaxcol])`

Update the display immediately (sync actual screen with previous drawing/deleting methods).

The 6 optional arguments can only be specified when the window is a pad created with `newpad()`. The additional parameters are needed to indicate what part of the pad and screen are involved. `pminrow` and `pmincol` specify the upper left-hand corner of the rectangle to be displayed in the pad. `sminrow`, `smincol`, `smaxrow`, and `smaxcol` specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of `pminrow`, `pmincol`, `sminrow`, or `smincol` are treated as if they were zero.

`window.resize(nlines, ncols)`

Reallocate storage for a curses window to adjust its dimensions to the specified values. If either dimension is larger than the current values, the window's data is filled with blanks that have the current background rendition (as set by `bkgdset()`) merged into them.

`window.scroll([lines=1])`

Scroll the screen or scrolling region upward by *lines* lines.

`window.scrollok(flag)`

Control what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If *flag* is `False`, the cursor is left on the bottom line. If *flag* is `True`, the window is scrolled up one line. Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call `idlok()`.

`window.setscrreg(top, bottom)`

Set the scrolling region from line *top* to line *bottom*. All scrolling actions will take place in this region.

`window.standend()`

Turn off the standout attribute. On some terminals this has the side effect of turning off all attributes.

`window.standout()`

Turn on attribute `A_STANDOUT`.

`window.subpad(begin_y, begin_x)`

`window.subpad(nlines, ncols, begin_y, begin_x)`

Return a sub-window, whose upper-left corner is at (*begin_y*, *begin_x*), and whose width/height is *ncols/nlines*.

`window.subwin(begin_y, begin_x)`

`window.subwin(nlines, ncols, begin_y, begin_x)`

Return a sub-window, whose upper-left corner is at (*begin_y*, *begin_x*), and whose width/height is *ncols/nlines*.

By default, the sub-window will extend from the specified position to the lower right corner of the window.

`window.syncdown()`

Touch each location in the window that has been touched in any of its ancestor windows. This routine is called by `refresh()`, so it should almost never be necessary to call it manually.

`window.syncok(flag)`

If *flag* is `True`, then `syncup()` is called automatically whenever there is a change in the window.

`window.syncup()`

Touch all locations in ancestors of the window that have been changed in the window.

`window.timeout(delay)`

Set blocking or non-blocking read behavior for the window. If *delay* is negative, blocking read is used (which will wait indefinitely for input). If *delay* is zero, then non-blocking read is used, and `getch()` will return `-1` if no input is waiting. If *delay* is positive, then `getch()` will block for *delay* milliseconds, and return `-1` if there is still no input at the end of that time.

`window.touchline (start, count[, changed])`

Pretend *count* lines have been changed, starting with line *start*. If *changed* is supplied, it specifies whether the affected lines are marked as having been changed (*changed*=True) or unchanged (*changed*=False).

`window.touchwin ()`

Pretend the whole window has been changed, for purposes of drawing optimizations.

`window.untouchwin ()`

Mark all lines in the window as unchanged since the last call to `refresh()`.

`window.vline (ch, n)`

`window.vline (y, x, ch, n)`

Display a vertical line starting at (*y*, *x*) with length *n* consisting of the character *ch*.

16.10.3 常量

The `curses` module defines the following data members:

`curses.ERR`

Some curses routines that return an integer, such as `getch()`, return `ERR` upon failure.

`curses.OK`

Some curses routines that return an integer, such as `napms()`, return `OK` upon success.

`curses.version`

A bytes object representing the current version of the module. Also available as `__version__`.

Some constants are available to specify character cell attributes. The exact constants available are system dependent.

属性	意义
<code>A_ALTCHARSET</code>	备用字符集模式
<code>A_BLINK</code>	闪烁模式
<code>A_BOLD</code>	粗体模式
<code>A_DIM</code>	暗淡模式
<code>A_INVIS</code>	不可见或空白模式
<code>A_NORMAL</code>	正常属性
<code>A_PROTECT</code>	保护模式
<code>A_REVERSE</code>	反转背景色和前景色
<code>A_STANDOUT</code>	突出模式
<code>A_UNDERLINE</code>	下划线模式
<code>A_HORIZONTAL</code>	水平突出显示
<code>A_LEFT</code>	左高亮
<code>A_LOW</code>	底部高亮
<code>A_RIGHT</code>	右高亮
<code>A_TOP</code>	顶部高亮
<code>A_VERTICAL</code>	垂直突出显示
<code>A_CHARTEXT</code>	用于提取字符的位掩码

有几个常量可用于提取某些方法返回的相应属性。

位掩码	意义
<code>A_ATTRIBUTES</code>	用于提取属性的位掩码
<code>A_CHARTEXT</code>	用于提取字符的位掩码
<code>A_COLOR</code>	用于提取颜色对字段信息的位掩码

键由名称以 KEY_ 开头的整数常量引用。确切的可用键取决于系统。

关键常数	(Windows 注册表的) 键 (Windows 注册表的) 键
KEY_MIN	最小键值
KEY_BREAK	中断键 (不可靠)
KEY_DOWN	向下箭头
KEY_UP	向上箭头
KEY_LEFT	向左箭头
KEY_RIGHT	向右箭头
KEY_HOME	Home key (upward+left arrow)
KEY_BACKSPACE	退格 (不可靠)
KEY_F0	Function keys. Up to 64 function keys are supported.
KEY_Fn	Value of function key <i>n</i>
KEY_DL	删除行
KEY_IL	插入行
KEY_DC	Delete character
KEY_IC	Insert char or enter insert mode
KEY_EIC	Exit insert char mode
KEY_CLEAR	Clear screen
KEY_EOS	Clear to end of screen
KEY_EOL	Clear to end of line
KEY_SF	Scroll 1 line forward
KEY_SR	Scroll 1 line backward (reverse)
KEY_NPAGE	下一页
KEY_PPAGE	上一页
KEY_STAB	Set tab
KEY_CTAB	Clear tab
KEY_CATAB	Clear all tabs
KEY_ENTER	Enter or send (unreliable)
KEY_SRESET	Soft (partial) reset (unreliable)
KEY_RESET	Reset or hard reset (unreliable)
KEY_PRINT	打印
KEY_LL	Home down or bottom (lower left)
KEY_A1	键盘的左上角
KEY_A3	键盘的右上角
KEY_B2	键盘的中心
KEY_C1	键盘左下方
KEY_C3	键盘右下方
KEY_BTAB	Back tab
KEY_BEG	Beg (beginning)
KEY_CANCEL	取消
KEY_CLOSE	关闭
KEY_COMMAND	Cmd (命令行)
KEY_COPY	复制
KEY_CREATE	创建
KEY_END	End
KEY_EXIT	退出
KEY_FIND	查找
KEY_HELP	帮助
KEY_MARK	标记
KEY_MESSAGE	消息

表 1 - 续上页

关键常数	(Windows 注册表的) 键 (Windows 注册表的) 键
KEY_MOVE	移动
KEY_NEXT	下一个
KEY_OPEN	打开
KEY_OPTIONS	选项
KEY_PREVIOUS	Prev (previous)
KEY_REDO	重做
KEY_REFERENCE	Ref (reference)
KEY_REFRESH	刷新
KEY_REPLACE	替换
KEY_RESTART	重启
KEY_RESUME	恢复
KEY_SAVE	保存
KEY_SBEG	Shifted Beg (beginning)
KEY_SCANCEL	Shifted Cancel
KEY_SCOMMAND	Shifted Command
KEY_SCOPY	Shifted Copy
KEY_SCREATE	Shifted Create
KEY_SDC	Shifted Delete char
KEY_SDL	Shifted Delete line
KEY_SELECT	Select
KEY_SEND	Shifted End
KEY_SEOL	Shifted Clear line
KEY_SEXIT	Shifted Exit
KEY_SFIND	Shifted Find
KEY_SHELP	Shifted Help
KEY_SHOME	Shifted Home
KEY_SIC	Shifted Input
KEY_SLEFT	Shifted Left arrow
KEY_SMESSAGE	Shifted Message
KEY_SMOVE	Shifted Move
KEY_SNEXT	Shifted Next
KEY_SOPTIONS	Shifted Options
KEY_SPREVIOUS	Shifted Prev
KEY_SPRINT	Shifted Print
KEY_SREDO	Shifted Redo
KEY_SREPLACE	Shifted Replace
KEY_SRIGHT	Shifted Right arrow
KEY_SRSUME	Shifted Resume
KEY_SSAVE	Shifted Save
KEY_SSUSPEND	Shifted Suspend
KEY_SUNDO	Shifted Undo
KEY_SUSPEND	Suspend
KEY_UNDO	撤销操作
KEY_MOUSE	Mouse event has occurred
KEY_RESIZE	Terminal resize event
KEY_MAX	Maximum key value

在 VT100 及其软件仿真（例如 X 终端仿真器）上，通常至少有四个功能键（KEY_F1, KEY_F2, KEY_F3, KEY_F4）可用，并且箭头键以明显的方式映射到 KEY_UP, KEY_DOWN, KEY_LEFT 和 KEY_RIGHT。如果您的机器有一个 PC 键盘，可以安全地使用箭头键和十二个功能键（旧的 PC 键盘可能只有十个功能键）；此外，

以下键盘映射是标准的：

键帽	常数
Insert	KEY_IC
Delete	KEY_DC
Home	KEY_HOME
End	KEY_END
Page Up	KEY_PPAGE
Page Down	KEY_NPAGE

The following table lists characters from the alternate character set. These are inherited from the VT100 terminal, and will generally be available on software emulations such as X terminals. When there is no graphic available, curses falls back on a crude printable ASCII approximation.

注解： 只有在调用 `initscr()` 之后才能使用它们

ACS 代码	意义
ACS_BBSS	右上角的别名
ACS_BLOCK	实心方块
ACS_BOARD	正方形
ACS_BSBS	水平线的别名

COLOR_GREEN	绿色
COLOR_MAGENTA	洋红色（紫红色）
COLOR_RED	红色
COLOR_WHITE	白色
COLOR_YELLOW	黄色

16.11 `curses.textpad` —Text input widget for curses programs

The `curses.textpad` module provides a `Textbox` class that handles elementary text editing in a curses window, supporting a set of keybindings resembling those of Emacs (thus, also of Netscape Navigator, BBedit 6.x, FrameMaker, and many other programs). The module also provides a rectangle-drawing function useful for framing text boxes or for other purposes.

The module `curses.textpad` defines the following function:

`curses.textpad.rectangle(win, uly, ulx, lry, lrx)`

Draw a rectangle. The first argument must be a window object; the remaining arguments are coordinates relative to that window. The second and third arguments are the y and x coordinates of the upper left hand corner of the rectangle to be drawn; the fourth and fifth arguments are the y and x coordinates of the lower right hand corner. The rectangle will be drawn using VT100/IBM PC forms characters on terminals that make this possible (including xterm and most other software terminal emulators). Otherwise it will be drawn with ASCII dashes, vertical bars, and plus signs.

16.11.1 文本框对象

You can instantiate a `Textbox` object as follows:

class `curses.textpad.Textbox(win)`

Return a textbox widget object. The `win` argument should be a curses `window` object in which the textbox is to be contained. The edit cursor of the textbox is initially located at the upper left hand corner of the containing window, with coordinates `(0, 0)`. The instance's `stripspaces` flag is initially on.

`Textbox` objects have the following methods:

edit ([*validator*])

This is the entry point you will normally use. It accepts editing keystrokes until one of the termination keystrokes is entered. If *validator* is supplied, it must be a function. It will be called for each keystroke entered with the keystroke as a parameter; command dispatch is done on the result. This method returns the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* attribute.

do_command (*ch*)

处理单个按键命令。以下是支持的特殊按键：

按键	动作
Control-A	转到窗口的左边缘。
Control-B	光标向左，如果可能，包含前一行。
Control-D	删除光标下的字符。
Control-E	Go to right edge (stripspaces off) or end of line (stripspaces on).
Control-F	向右移动光标，适当时换行到下一行。
Control-G	终止，返回窗口内容。
Control-H	向后删除字符。
Control-J	如果窗口是 1 行则终止，否则插入换行符。
Control-K	如果行为空，则删除它，否则清除到行尾。
Control-L	刷新屏幕。
Control-N	光标向下; 向下移动一行。
Control-O	在光标位置插入一个空行。
Control-P	光标向上; 向上移动一行。

如果光标位于无法移动的边缘，则移动操作不执行任何操作。在可能的情况下，支持以下同义词：

常数	按键
KEY_LEFT	Control-B
KEY_RIGHT	Control-F
KEY_UP	Control-P
KEY_DOWN	Control-N
KEY_BACKSPACE	Control-h

All other keystrokes are treated as a command to insert the given character and move right (with line wrapping).

gather ()

Return the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* member.

stripspaces

This attribute is a flag which controls the interpretation of blanks in the window. When it is on, trailing blanks on each line are ignored; any cursor motion that would land the cursor on a trailing blank goes to the end of that line instead, and trailing blanks are stripped when the window contents are gathered.

16.12 curses.ascii —Utilities for ASCII characters

The `curses.ascii` module supplies name constants for ASCII characters and functions to test membership in various ASCII character classes. The constants supplied are names for control characters as follows:

名称	意义
NUL	
SOH	Start of heading, console interrupt
STX	Start of text
ETX	End of text
EOT	End of transmission
ENQ	Enquiry, goes with ACK flow control
ACK	Acknowledgement
BEL	Bell
BS	Backspace
TAB	Tab
HT	Alias for TAB: “Horizontal tab”
LF	Line feed
NL	Alias for LF: “New line”
VT	Vertical tab
FF	Form feed
CR	Carriage return
SO	Shift-out, begin alternate character set
SI	Shift-in, resume default character set
DLE	Data-link escape
DC1	XON, for flow control
DC2	Device control 2, block-mode flow control
DC3	XOFF, for flow control
DC4	Device control 4
NAK	Negative acknowledgement
SYN	Synchronous idle
ETB	End transmission block
CAN	取消
EM	End of medium
SUB	Substitute
ESC	Escape
FS	File separator
GS	Group separator
RS	Record separator, block-mode terminator
US	Unit separator
SP	Space
DEL	Delete

Note that many of these have little practical significance in modern usage. The mnemonics derive from teleprinter conventions that predate digital computers.

The module supplies the following functions, patterned on those in the standard C library:

`curses.ascii.isalnum(c)`

Checks for an ASCII alphanumeric character; it is equivalent to `isalpha(c)` or `isdigit(c)`.

`curses.ascii.isalpha(c)`

Checks for an ASCII alphabetic character; it is equivalent to `isupper(c)` or `islower(c)`.

`curses.ascii.isascii(c)`

Checks for a character value that fits in the 7-bit ASCII set.

`curses.ascii.isblank(c)`

Checks for an ASCII whitespace character; space or horizontal tab.

`curses.ascii.iscntrl(c)`

Checks for an ASCII control character (in the range 0x00 to 0x1f or 0x7f).

`curses.ascii.isdigit(c)`

Checks for an ASCII decimal digit, '0' through '9'. This is equivalent to `c in string.digits`.

`curses.ascii.isgraph(c)`

Checks for ASCII any printable character except space.

`curses.ascii.islower(c)`

Checks for an ASCII lower-case character.

`curses.ascii.isprint(c)`

Checks for any ASCII printable character including space.

`curses.ascii.ispunct(c)`

Checks for any printable ASCII character which is not a space or an alphanumeric character.

`curses.ascii.isspace(c)`

Checks for ASCII white-space characters; space, line feed, carriage return, form feed, horizontal tab, vertical tab.

`curses.ascii.isupper(c)`

Checks for an ASCII uppercase letter.

`curses.ascii.isxdigit(c)`

Checks for an ASCII hexadecimal digit. This is equivalent to `c in string.hexdigits`.

`curses.ascii.isctrl(c)`

Checks for an ASCII control character (ordinal values 0 to 31).

`curses.ascii.ismeta(c)`

Checks for a non-ASCII character (ordinal values 0x80 and above).

These functions accept either integers or single-character strings; when the argument is a string, it is first converted using the built-in function `ord()`.

Note that all these functions check ordinal bit values derived from the character of the string you pass in; they do not actually know anything about the host machine's character encoding.

The following two functions take either a single-character string or integer byte value; they return a value of the same type.

`curses.ascii.ascii(c)`

Return the ASCII value corresponding to the low 7 bits of *c*.

`curses.ascii.ctrl(c)`

Return the control character corresponding to the given character (the character bit value is bitwise-anded with 0x1f).

`curses.ascii.alt(c)`

Return the 8-bit character corresponding to the given ASCII character (the character bit value is bitwise-ored with 0x80).

The following function takes either a single-character string or integer value; it returns a string.

`curses.ascii.unctrl(c)`

Return a string representation of the ASCII character *c*. If *c* is printable, this string is the character itself. If the character is a control character (0x00–0x1f) the string consists of a caret ('^') followed by the corresponding uppercase letter. If the character is an ASCII delete (0x7f) the string is '^?'. If the character has its meta bit (0x80) set, the meta bit is stripped, the preceding rules applied, and '!' prepended to the result.

`curses.ascii.controlnames`

A 33-element string array that contains the ASCII mnemonics for the thirty-two ASCII control characters from 0 (NUL) to 0x1f (US), in order, plus the mnemonic `SP` for the space character.

16.13 `curses.panel` —A panel stack extension for `curses`

Panels are windows with the added feature of depth, so they can be stacked on top of each other, and only the visible portions of each window will be displayed. Panels can be added, moved up or down in the stack, and removed.

16.13.1 函数

The module `curses.panel` defines the following functions:

`curses.panel.bottom_panel()`

Returns the bottom panel in the panel stack.

`curses.panel.new_panel(win)`

Returns a panel object, associating it with the given window *win*. Be aware that you need to keep the returned panel object referenced explicitly. If you don't, the panel object is garbage collected and removed from the panel stack.

`curses.panel.top_panel()`

Returns the top panel in the panel stack.

`curses.panel.update_panels()`

Updates the virtual screen after changes in the panel stack. This does not call `curses.doupdate()`, so you'll have to do this yourself.

16.13.2 Panel Objects

Panel objects, as returned by `new_panel()` above, are windows with a stacking order. There's always a window associated with a panel which determines the content, while the panel methods are responsible for the window's depth in the panel stack.

Panel objects have the following methods:

`Panel.above()`

Returns the panel above the current panel.

`Panel.below()`

Returns the panel below the current panel.

`Panel.bottom()`

Push the panel to the bottom of the stack.

`Panel.hidden()`

Returns `True` if the panel is hidden (not visible), `False` otherwise.

`Panel.hide()`

Hide the panel. This does not delete the object, it just makes the window on screen invisible.

`Panel.move(y, x)`

Move the panel to the screen coordinates `(y, x)`.

`Panel.replace(win)`

Change the window associated with the panel to the window *win*.

`Panel.set_userptr(obj)`

Set the panel's user pointer to *obj*. This is used to associate an arbitrary piece of data with the panel, and can be any Python object.

`Panel.show()`

Display the panel (which might have been hidden).

`Panel.top()`

Push panel to the top of the stack.

`Panel.userptr()`

Returns the user pointer for the panel. This might be any Python object.

`Panel.window()`

Returns the window object associated with the panel.

16.14 platform — 获取底层平台的标识数据

示例代码: [Lib/platform.py](#)

注解: Specific platforms listed alphabetically, with Linux included in the Unix section.

16.14.1 跨平台

`platform.architecture(executable=sys.executable, bits="", linkage="")`

Queries the given executable (defaults to the Python interpreter binary) for various architecture information.

Returns a tuple (*bits*, *linkage*) which contain information about the bit architecture and the linkage format used for the executable. Both values are returned as strings.

Values that cannot be determined are returned as given by the parameter presets. If *bits* is given as `''`, the `sizeof(pointer)` (or `sizeof(long)` on Python version < 1.5.2) is used as indicator for the supported pointer size.

The function relies on the system's `file` command to do the actual work. This is available on most if not all Unix platforms and some non-Unix platforms and then only if the executable points to the Python interpreter. Reasonable defaults are used when the above needs are not met.

注解: On Mac OS X (and perhaps other platforms), executable files may be universal files containing multiple architectures.

To get at the “64-bitness” of the current interpreter, it is more reliable to query the `sys.maxsize` attribute:

```
is_64bits = sys.maxsize > 2**32
```

`platform.machine()`

Returns the machine type, e.g. `'i386'`. An empty string is returned if the value cannot be determined.

`platform.node()`

Returns the computer's network name (may not be fully qualified!). An empty string is returned if the value cannot be determined.

`platform.platform(aliased=0, terse=0)`

Returns a single string identifying the underlying platform with as much useful information as possible.

The output is intended to be *human readable* rather than machine parseable. It may look different on different platforms and this is intended.

If *aliased* is true, the function will use aliases for various platforms that report system names which differ from their common names, for example SunOS will be reported as Solaris. The `system_alias()` function is used to implement this.

Setting *terse* to true causes the function to return only the absolute minimum information needed to identify the platform.

`platform.processor()`

Returns the (real) processor name, e.g. 'amd64'.

An empty string is returned if the value cannot be determined. Note that many platforms do not provide this information or simply return the same value as for `machine()`. NetBSD does this.

`platform.python_build()`

Returns a tuple (buildno, builddate) stating the Python build number and date as strings.

`platform.python_compiler()`

Returns a string identifying the compiler used for compiling Python.

`platform.python_branch()`

Returns a string identifying the Python implementation SCM branch.

`platform.python_implementation()`

Returns a string identifying the Python implementation. Possible return values are: 'CPython', 'IronPython', 'Jython', 'PyPy'.

`platform.python_revision()`

Returns a string identifying the Python implementation SCM revision.

`platform.python_version()`

Returns the Python version as string 'major.minor.patchlevel'.

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to 0).

`platform.python_version_tuple()`

Returns the Python version as tuple (major, minor, patchlevel) of strings.

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to '0').

`platform.release()`

Returns the system's release, e.g. '2.2.0' or 'NT'. An empty string is returned if the value cannot be determined.

`platform.system()`

返回系统/OS 的名字, e.g. 'Linux', 'Windows', 或者 'Java'。如果这个值不能被确定则会返回一个空字符串。

`platform.system_alias(system, release, version)`

Returns (system, release, version) aliased to common marketing names used for some systems. It also does some reordering of the information in some cases where it would otherwise cause confusion.

`platform.version()`

Returns the system's release version, e.g. '#3 on degas'. An empty string is returned if the value cannot be determined.

`platform.uname()`

Fairly portable `uname` interface. Returns a `namedtuple()` containing six attributes: `system`, `node`, `release`, `version`, `machine`, and `processor`.

Note that this adds a sixth attribute (`processor`) not present in the `os.uname()` result. Also, the attribute names are different for the first two attributes; `os.uname()` names them `sysname` and `nodename`.

Entries which cannot be determined are set to `' '`.

在 3.3 版更改: 将结果从元组改为命名元组。

16.14.2 Java 平台

`platform.java_ver(release="", vendor="", vminfo=("", "", ""), osinfo=("", "", ""))`

Jython 的版本接口

Returns a tuple (`release`, `vendor`, `vminfo`, `osinfo`) with `vminfo` being a tuple (`vm_name`, `vm_release`, `vm_vendor`) and `osinfo` being a tuple (`os_name`, `os_version`, `os_arch`). Values which cannot be determined are set to the defaults given as parameters (which all default to `' '`).

16.14.3 Windows 平台

`platform.win32_ver(release="", version="", csd="", ptype="")`

Get additional version information from the Windows Registry and return a tuple (`release`, `version`, `csd`, `ptype`) referring to OS release, version number, CSD level (service pack) and OS type (multi/single processor).

As a hint: `ptype` is `'Uniprocessor Free'` on single processor NT machines and `'Multiprocessor Free'` on multi processor machines. The `'Free'` refers to the OS version being free of debugging code. It could also state `'Checked'` which means the OS version uses debugging code, i.e. code that checks arguments, ranges, etc.

注解: This function works best with Mark Hammond's `win32all` package installed, but also on Python 2.3 and later (support for this was added in Python 2.6). It obviously only runs on Win32 compatible platforms.

Win95/98 specific

`platform.popen(cmd, mode='r', bufsize=-1)`

Portable `popen()` interface. Find a working `popen` implementation preferring `win32pipe.popen()`. On Windows NT, `win32pipe.popen()` should work; on Windows 9x it hangs due to bugs in the MS C library.

3.3 版后已移除: This function is obsolete. Use the `subprocess` module. Check especially the [Replacing Older Functions with the subprocess Module](#) section.

16.14.4 Mac OS 平台

`platform.mac_ver(release="", versioninfo=("", "", ""), machine="")`

Get Mac OS version information and return it as tuple (`release`, `versioninfo`, `machine`) with `versioninfo` being a tuple (`version`, `dev_stage`, `non_release_version`).

Entries which cannot be determined are set to `' '`. All tuple entries are strings.

16.14.5 Unix Platforms

`platform.dist` (*distname*=", *version*", *id*", *supported_dists*=('SuSE', 'debian', 'redhat', 'mandrake', ...))
这是 `linux_distribution()` 的另外一个名字。

Deprecated since version 3.5, will be removed in version 3.8: See alternative like the `distro` package.

`platform.linux_distribution` (*distname*=", *version*", *id*", *supported_dists*=('SuSE', 'debian', 'redhat', 'mandrake', ...), *full_distribution_name*=1)

Tries to determine the name of the Linux OS distribution name.

supported_dists may be given to define the set of Linux distributions to look for. It defaults to a list of currently supported Linux distributions identified by their release file name.

If *full_distribution_name* is true (default), the full distribution read from the OS is returned. Otherwise the short name taken from *supported_dists* is used.

Returns a tuple (*distname*, *version*, *id*) which defaults to the args given as parameters. *id* is the item in parentheses after the version number. It is usually the version codename.

Deprecated since version 3.5, will be removed in version 3.8: See alternative like the `distro` package.

`platform.libc_ver` (*executable*=`sys.executable`, *lib*", *version*", *chunksize*=16384)

Tries to determine the libc version against which the file *executable* (defaults to the Python interpreter) is linked. Returns a tuple of strings (*lib*, *version*) which default to the given parameters in case the lookup fails.

Note that this function has intimate knowledge of how different libc versions add symbols to the executable is probably only usable for executables compiled using `gcc`.

The file is read and scanned in chunks of *chunksize* bytes.

16.15 `errno` —Standard `errno` system symbols

This module makes available standard `errno` system symbols. The value of each symbol is the corresponding integer value. The names and descriptions are borrowed from `linux/include/errno.h`, which should be pretty all-inclusive.

`errno.errorcode`

Dictionary providing a mapping from the `errno` value to the string name in the underlying system. For instance, `errno.errorcode[errno.EPERM]` maps to `'EPERM'`.

To translate a numeric error code to an error message, use `os.strerror()`.

Of the following list, symbols that are not used on the current platform are not defined by the module. The specific list of defined symbols is available as `errno.errorcode.keys()`. Symbols available can include:

`errno.EPERM`

Operation not permitted

`errno.ENOENT`

No such file or directory

`errno.ESRCH`

No such process

`errno.EINTR`

Interrupted system call.

参见:

This error is mapped to the exception *InterruptedError*.

errno.EIO
I/O error

errno.ENXIO
No such device or address

errno.E2BIG
Arg list too long

errno.ENOEXEC
Exec format error

errno.EBADF
Bad file number

errno.ECHILD
No child processes

errno.EAGAIN
Try again

errno.ENOMEM
Out of memory

errno.EACCES
Permission denied

errno.EFAULT
Bad address

errno.ENOTBLK
Block device required

errno.EBUSY
Device or resource busy

errno.EEXIST
File exists

errno.EXDEV
Cross-device link

errno.ENODEV
No such device

errno.ENOTDIR
Not a directory

errno.EISDIR
Is a directory

errno.EINVAL
Invalid argument

errno.ENFILE
File table overflow

errno.EMFILE
Too many open files

errno.ENOTTY
Not a typewriter

`errno.ETXTBSY`
Text file busy

`errno.EFBIG`
File too large

`errno.ENOSPC`
No space left on device

`errno.ESPIPE`
Illegal seek

`errno.EROFS`
Read-only file system

`errno.EMLINK`
Too many links

`errno.EPIPE`
Broken pipe

`errno.EDOM`
Math argument out of domain of func

`errno.ERANGE`
Math result not representable

`errno.EDEADLK`
Resource deadlock would occur

`errno.ENAMETOOLONG`
File name too long

`errno.ENOLCK`
No record locks available

`errno.ENOSYS`
Function not implemented

`errno.ENOTEMPTY`
Directory not empty

`errno.ELOOP`
Too many symbolic links encountered

`errno.EWOULDBLOCK`
Operation would block

`errno.ENOMSG`
No message of desired type

`errno.EIDRM`
Identifier removed

`errno.ECHRNG`
Channel number out of range

`errno.EL2NSYNC`
Level 2 not synchronized

`errno.EL3HLT`
Level 3 halted

`errno.EL3RST`
Level 3 reset

`errno.ELNRNG`
Link number out of range

`errno.EUNATCH`
Protocol driver not attached

`errno.ENOCSI`
No CSI structure available

`errno.EL2HLT`
Level 2 halted

`errno.EBADE`
Invalid exchange

`errno.EBADR`
Invalid request descriptor

`errno.EXFULL`
Exchange full

`errno.ENOANO`
No anode

`errno.EBADRQC`
Invalid request code

`errno.EBADSLT`
Invalid slot

`errno.EDEADLOCK`
File locking deadlock error

`errno.EBFONT`
Bad font file format

`errno.ENOSTR`
Device not a stream

`errno.ENODATA`
No data available

`errno.ETIME`
Timer expired

`errno.ENOSR`
Out of streams resources

`errno.ENONET`
Machine is not on the network

`errno.ENOPKG`
Package not installed

`errno.EREMOTE`
Object is remote

`errno.ENOLINK`
Link has been severed

`errno.EADV`
Advertise error

`errno.ESRMNT`
Srmount error

`errno.ECOMM`
Communication error on send

`errno.EPROTO`
Protocol error

`errno.EMULTIHOP`
Multihop attempted

`errno.EDOTDOT`
RFS specific error

`errno.EBADMSG`
Not a data message

`errno.EOVERFLOW`
Value too large for defined data type

`errno.ENOTUNIQ`
Name not unique on network

`errno.EBADFD`
File descriptor in bad state

`errno.EREMCHG`
Remote address changed

`errno.ELIBACC`
Can not access a needed shared library

`errno.ELIBBAD`
Accessing a corrupted shared library

`errno.ELIBSCN`
.lib section in a.out corrupted

`errno.ELIBMAX`
Attempting to link in too many shared libraries

`errno.ELIBEXEC`
Cannot exec a shared library directly

`errno.EILSEQ`
Illegal byte sequence

`errno.ERESTART`
Interrupted system call should be restarted

`errno.ESTRPIPE`
Streams pipe error

`errno.EUSERS`
Too many users

`errno.ENOTSOCK`
Socket operation on non-socket

`errno.EDESTADDRREQ`
Destination address required

`errno.EMSGSIZE`
Message too long

`errno.EPROTOTYPE`
Protocol wrong type for socket

`errno.ENOPROTOOPT`
Protocol not available

`errno.EPROTONOSUPPORT`
Protocol not supported

`errno.ESOCKTNOSUPPORT`
Socket type not supported

`errno.EOPNOTSUPP`
Operation not supported on transport endpoint

`errno.EPFNOSUPPORT`
Protocol family not supported

`errno.EAFNOSUPPORT`
Address family not supported by protocol

`errno.EADDRINUSE`
Address already in use

`errno.EADDRNOTAVAIL`
Cannot assign requested address

`errno.ENETDOWN`
Network is down

`errno.ENETUNREACH`
Network is unreachable

`errno.ENETRESET`
Network dropped connection because of reset

`errno.ECONNABORTED`
Software caused connection abort

`errno.ECONNRESET`
Connection reset by peer

`errno.ENOBUFS`
No buffer space available

`errno.EISCONN`
Transport endpoint is already connected

`errno.ENOTCONN`
Transport endpoint is not connected

`errno.ESHUTDOWN`
Cannot send after transport endpoint shutdown

`errno.ETOOMANYREFS`
Too many references: cannot splice

`errno.ETIMEDOUT`
Connection timed out

`errno.ECONNREFUSED`
Connection refused

`errno.EHOSTDOWN`
Host is down

`errno.EHOSTUNREACH`
No route to host

`errno.EALREADY`
Operation already in progress

`errno.EINPROGRESS`
Operation now in progress

`errno.ESTALE`
Stale NFS file handle

`errno.EUCLEAN`
Structure needs cleaning

`errno.ENOTNAM`
Not a XENIX named type file

`errno.ENAVAIL`
No XENIX semaphores available

`errno.EISNAM`
Is a named type file

`errno.EREMOTEIO`
Remote I/O error

`errno.EDQUOT`
Quota exceeded

16.16 ctypes —Python 的外部函数库

`ctypes` 是 Python 的外部函数库。它提供了与 C 兼容的数据类型，并允许调用 DLL 或共享库中的函数。可使用该模块以纯 Python 形式对这些库进行封装。

16.16.1 ctypes 教程

注意：在本教程中的示例代码使用 `doctest` 进行过测试，保证其正确运行。由于有些代码在 Linux，Windows 或 Mac OS X 下的表现不同，这些代码会在 `doctest` 中包含相关的指令注解。

注意：部分示例代码引用了 `ctypes.c_int` 类型。在 `sizeof(long) == sizeof(int)` 的平台上此类型是 `c_long` 的一个别名。所以，在程序输出 `c_long` 而不是你期望的 `c_int` 时不必感到迷惑——它们实际上是同一种类型。

载入动态链接库

`ctypes` 导出了 `cdll` 对象，在 Windows 系统中还导出了 `windll` 和 `oledll` 对象用于载入动态链接库。

通过操作这些对象的属性，你可以载入外部的动态链接库。`cdll` 载入按标准的 `cdecl` 调用协议导出的函数，而 `windll` 导入的库按 `stdcall` 调用协议调用其中的函数。`oledll` 也按 `stdcall` 调用协议调用其中的函数，并假定该函数返回的是 Windows HRESULT 错误代码，并当函数调用失败时，自动根据该代码甩出一个 `OSError` 异常。

在 3.3 版更改：原来在 Windows 下甩出的异常类型 `WindowsError` 现在是 `OSError` 的一个别名。

这是一些 Windows 下的例子。注意：`msvcrt` 是微软 C 标准库，包含了大部分 C 标准函数，这些函数都是以 `cdecl` 调用协议进行调用的。

```
>>> from ctypes import *
>>> print(windll.kernel32)
<WinDLL 'kernel32', handle ... at ...>
>>> print(cdll.msvcrt)
<CDLL 'msvcrt', handle ... at ...>
>>> libc = cdll.msvcrt
>>>
```

Windows 会自动添加通常的 `.dll` 文件扩展名。

注解：通过 `cdll.msvcrt` 调用的标准 C 函数，可能会导致调用一个过时的，与当前 Python 所不兼容的函数。因此，请尽量使用标准的 Python 函数，而不要使用 `msvcrt` 模块。

在 Linux 下，必须使用包含文件扩展名的文件名来导入共享库。因此不能简单使用对象属性的方式来导入库。因此，你可以使用方法 `LoadLibrary()`，或构造 `CDLL` 对象来导入库。

```
>>> cdll.LoadLibrary("libc.so.6")
<CDLL 'libc.so.6', handle ... at ...>
>>> libc = CDLL("libc.so.6")
>>> libc
<CDLL 'libc.so.6', handle ... at ...>
>>>
```

操作导入的动态链接库中的函数

通过操作 `dll` 对象的属性来操作这些函数。

```
>>> from ctypes import *
>>> libc.printf
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.GetModuleHandleA)
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.MyOwnFunction)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 239, in __getattr__
    func = _StdcallFuncPtr(name, self)
AttributeError: function 'MyOwnFunction' not found
>>>
```

注意：Win32 系统的动态库，比如 `kernel32` 和 `user32`，通常会同时导出同一个函数的 ANSI 版本和 UNICODE 版本。UNICODE 版本通常会在名字最后以 `w` 结尾，而 ANSI 版本的则以 `A` 结尾。win32 的

GetModuleHandle 函数会根据一个模块名返回一个 模块句柄，该函数暨同时包含这样的两个版本的原型函数，并通过宏 UNICODE 是否定义，来决定宏 GetModuleHandle 导出的是哪个具体函数。

```
/* ANSI version */
HMODULE GetModuleHandleA(LPCSTR lpModuleName);
/* UNICODE version */
HMODULE GetModuleHandleW(LPCWSTR lpModuleName);
```

windll 不会通过这样的魔法手段来帮你决定选择哪一种函数，你必须显式的调用 GetModuleHandleA 或 GetModuleHandleW，并分别使用字节对象或字符串对象作参数。

有时候，dlls 的导出的函数名不符合 Python 的标识符规范，比如 "??2@YAPAXI@Z"。此时，你必须使用 `getattr()` 方法来获得该函数。

```
>>> getattr(cdll.msvcrt, "??2@YAPAXI@Z")
<_FuncPtr object at 0x...>
>>>
```

Windows 下，有些 dll 导出的函数没有函数名，而是通过其顺序号调用。对此类函数，你也可以通过 dll 对象的数值索引来操作这些函数。

```
>>> cdll.kernel32[1]
<_FuncPtr object at 0x...>
>>> cdll.kernel32[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 310, in __getitem__
    func = _StdcallFuncPtr(name, self)
AttributeError: function ordinal 0 not found
>>>
```

调用函数

你可以貌似是调用其它 Python 函数那样直接调用这些函数。在这个例子中，我们调用了 `time()` 函数，该函数返回一个系统时间戳（从 Unix 时间起点到现在的秒数），而“`GetModuleHandleA()`”函数返回一个 win32 模块句柄。

此函数中调用的两个函数都使用了空指针（用 `None` 作为空指针）：

```
>>> print(libc.time(None))
1150640792
>>> print(hex(windll.kernel32.GetModuleHandleA(None)))
0x1d000000
>>>
```

注解：调用该函数，若 `ctypes` 发现传入的参数个数不符，则会甩出一个异常 `ValueError`。但该行为并不可靠。它在 3.6.2 中被废弃，会在 3.7 中彻底移除。

如果你用 `cdecl` 调用方式调用 `stdcall` 约定的函数，则会甩出一个异常 `ValueError`。反之亦然。

```
>>> cdll.kernel32.GetModuleHandleA(None)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with not enough arguments (4 bytes missing)
```

(下页继续)

(续上页)

```
>>>
>>> windll.msvcrt.printf(b"spam")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with too many arguments (4 bytes in excess)
>>>
```

你必须阅读这些库的头文件或说明文档来确定它们的调用协议。

在 Windows 中, `ctypes` 使用 win32 结构化异常处理来防止由于在调用函数时使用非法参数导致的程序崩溃。

```
>>> windll.kernel32.GetModuleHandleA(32)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
OSError: exception: access violation reading 0x00000020
>>>
```

然而, 总有许多办法, 通过调用 `ctypes` 使得 Python 程序崩溃。因此, 你必须小心使用。 `faulthandler` 模块可以用于帮助诊断程序崩溃的原因。(比如由于错误的 C 库函数调用导致的段错误)。

None, 整型, 字节对象和 (UNICODE) 字符串是仅有的可以直接作为函数参数使用的四种 Python 本地数据类型。None 作为 C 的空指针 (NULL), 字节和字符串类型作为一个指向其保存数据的内存块指针 (char * 或 wchar_t *)。Python 的整型则作为平台默认的 C 的 int 类型, 他们的数值被截断以适应 C 类型的整型长度。

在我们开始调用函数前, 我们必须先了解作为函数参数的 `ctypes` 数据类型。

基础数据类型

`ctypes` 定义了一些和 C 兼容的基本数据类型:

ctypes 类型	C 类型	Python 数据类型
<code>c_bool</code>	<code>_Bool</code>	<code>bool</code> (1)
<code>c_char</code>	<code>char</code>	单字符字节对象
<code>c_wchar</code>	<code>wchar_t</code>	单字符字符串
<code>c_byte</code>	<code>char</code>	<code>int</code>
<code>c_ubyte</code>	<code>unsigned char</code>	<code>int</code>
<code>c_short</code>	<code>short</code>	<code>int</code>
<code>c_ushort</code>	<code>unsigned short</code>	<code>int</code>
<code>c_int</code>	<code>int</code>	<code>int</code>
<code>c_uint</code>	<code>unsigned int</code>	<code>int</code>
<code>c_long</code>	<code>long</code>	<code>int</code>
<code>c_ulong</code>	<code>unsigned long</code>	<code>int</code>
<code>c_longlong</code>	<code>__int64</code> 或 <code>long long</code>	<code>int</code>
<code>c_ulonglong</code>	<code>unsigned __int64</code> 或 <code>unsigned long long</code>	<code>int</code>
<code>c_size_t</code>	<code>size_t</code>	<code>int</code>
<code>c_ssize_t</code>	<code>ssize_t</code> 或 <code>Py_ssize_t</code>	<code>int</code>
<code>c_float</code>	<code>float</code>	<code>float</code>
<code>c_double</code>	<code>double</code>	<code>float</code>
<code>c_longdouble</code>	<code>long double</code>	<code>float</code>
<code>c_char_p</code>	<code>char *</code> (NUL terminated)	字节串对象或 <code>None</code>
<code>c_wchar_p</code>	<code>wchar_t *</code> (NUL terminated)	字符串或 <code>None</code>
<code>c_void_p</code>	<code>void *</code>	<code>int</code> 或 <code>None</code>

(1) 构造函数接受任何具有真值的对象。

所有这些类型都可以通过使用正确类型和值的可选初始值调用它们来创建:

```
>>> c_int()
c_long(0)
>>> c_wchar_p("Hello, World")
c_wchar_p(140018365411392)
>>> c_ushort(-3)
c_ushort(65533)
>>>
```

由于这些类型是可变的，它们的值也可以在以后更改:

```
>>> i = c_int(42)
>>> print(i)
c_long(42)
>>> print(i.value)
42
>>> i.value = -99
>>> print(i.value)
-99
>>>
```

当给指针类型的对象 `c_char_p`, `c_wchar_p` 和 `c_void_p` 等赋值时，将改变它们所指向的内存地址，而不是它们所指向的内存区域的内容 (这是理所当然的，因为 Python 的 `bytes` 对象是不可变的):

```
>>> s = "Hello, World"
>>> c_s = c_wchar_p(s)
>>> print(c_s)
c_wchar_p(139966785747344)
>>> print(c_s.value)
```

(下页继续)

(续上页)

```

Hello World
>>> c_s.value = "Hi, there"
>>> print(c_s)           # the memory location has changed
c_wchar_p(139966783348904)
>>> print(c_s.value)
Hi, there
>>> print(s)             # first object is unchanged
Hello, World
>>>

```

但你要注意不能将它们传递给会改变指针所指内存的函数。如果你需要可改变的内存块，`ctypes` 提供了 `create_string_buffer()` 函数，它提供多种方式创建这种内存块。当前的内存块内容可以通过 `raw` 属性存取，如果你希望将它作为 NUL 结束的字符串，请使用 `value` 属性：

```

>>> from ctypes import *
>>> p = create_string_buffer(3)           # create a 3 byte buffer, initialized to_
↳ NUL bytes
>>> print(sizeof(p), repr(p.raw))
3 b'\x00\x00\x00'
>>> p = create_string_buffer(b"Hello")    # create a buffer containing a NUL_
↳ terminated string
>>> print(sizeof(p), repr(p.raw))
6 b'Hello\x00'
>>> print(repr(p.value))
b'Hello'
>>> p = create_string_buffer(b"Hello", 10) # create a 10 byte buffer
>>> print(sizeof(p), repr(p.raw))
10 b'Hello\x00\x00\x00\x00\x00'
>>> p.value = b"Hi"
>>> print(sizeof(p), repr(p.raw))
10 b'Hi\x00lo\x00\x00\x00\x00'
>>>

```

`create_string_buffer()` 函数替代以前的 `ctypes` 版本中的 `c_buffer()` 函数（仍然可当作别名使用）和 `c_string()` 函数。`create_unicode_buffer()` 函数创建包含 `unicode` 字符的可变内存块，与之对应的 C 语言类型是 `wchar_t`。

调用函数，继续

注意 `printf` 将打印到真正标准输出设备，而 `*` 不是 `* sys.stdout`，因此这些实例只能在控制台提示符下工作，而不能在 `IDLE` 或 `PythonWin` 中运行。

```

>>> printf = libc.printf
>>> printf(b"Hello, %s\n", b"World!")
Hello, World!
14
>>> printf(b"Hello, %S\n", "World!")
Hello, World!
14
>>> printf(b"%d bottles of beer\n", 42)
42 bottles of beer
19
>>> printf(b"%f bottles of beer\n", 42.5)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>

```

(下页继续)

(续上页)

```
ArgumentError: argument 2: exceptions.TypeError: Don't know how to convert parameter 2
>>>
```

正如前面所提到过的, 除了整数、字符串以及字节串之外, 所有的 Python 类型都必须使用它们对应的 *ctypes* 类型包装, 才能够被正确地转换为所需的 C 语言类型。

```
>>> printf(b"An int %d, a double %f\n", 1234, c_double(3.14))
An int 1234, a double 3.140000
31
>>>
```

使用自定义的数据类型调用函数

You can also customize *ctypes* argument conversion to allow instances of your own classes be used as function arguments. *ctypes* looks for an `_as_parameter_` attribute and uses this as the function argument. Of course, it must be one of integer, string, or bytes:

```
>>> class Bottles:
...     def __init__(self, number):
...         self._as_parameter_ = number
...
>>> bottles = Bottles(42)
>>> printf(b"%d bottles of beer\n", bottles)
42 bottles of beer
19
>>>
```

If you don't want to store the instance's data in the `_as_parameter_` instance variable, you could define a *property* which makes the attribute available on request.

Specifying the required argument types (function prototypes)

It is possible to specify the required argument types of functions exported from DLLs by setting the `argtypes` attribute.

`argtypes` must be a sequence of C data types (the `printf` function is probably not a good example here, because it takes a variable number and different types of parameters depending on the format string, on the other hand this is quite handy to experiment with this feature):

```
>>> printf.argtypes = [c_char_p, c_char_p, c_int, c_double]
>>> printf(b"String '%s', Int %d, Double %f\n", b"Hi", 10, 2.2)
String 'Hi', Int 10, Double 2.200000
37
>>>
```

Specifying a format protects against incompatible argument types (just as a prototype for a C function), and tries to convert the arguments to valid types:

```
>>> printf(b"%d %d %d", 1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: wrong type
>>> printf(b"%s %d %f\n", b"X", 2, 3)
X 2 3.000000
```

(下页继续)

(续上页)

```
13
>>>
```

If you have defined your own classes which you pass to function calls, you have to implement a `from_param()` class method for them to be able to use them in the `argtypes` sequence. The `from_param()` class method receives the Python object passed to the function call, it should do a typecheck or whatever is needed to make sure this object is acceptable, and then return the object itself, its `_as_parameter_` attribute, or whatever you want to pass as the C function argument in this case. Again, the result should be an integer, string, bytes, a `ctypes` instance, or an object with an `_as_parameter_` attribute.

Return types

By default functions are assumed to return the C `int` type. Other return types can be specified by setting the `restype` attribute of the function object.

Here is a more advanced example, it uses the `strchr` function, which expects a string pointer and a char, and returns a pointer to a string:

```
>>> strchr = libc.strchr
>>> strchr(b"abcdef", ord("d"))
8059983
>>> strchr.restype = c_char_p      # c_char_p is a pointer to a string
>>> strchr(b"abcdef", ord("d"))
b'def'
>>> print(strchr(b"abcdef", ord("x")))
None
>>>
```

If you want to avoid the `ord("x")` calls above, you can set the `argtypes` attribute, and the second argument will be converted from a single character Python bytes object into a C char:

```
>>> strchr.restype = c_char_p
>>> strchr.argtypes = [c_char_p, c_char]
>>> strchr(b"abcdef", b"d")
'def'
>>> strchr(b"abcdef", b"def")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: one character string expected
>>> print(strchr(b"abcdef", b"x"))
None
>>> strchr(b"abcdef", b"d")
'def'
>>>
```

You can also use a callable Python object (a function or a class for example) as the `restype` attribute, if the foreign function returns an integer. The callable will be called with the *integer* the C function returns, and the result of this call will be used as the result of your function call. This is useful to check for error return values and automatically raise an exception:

```
>>> GetModuleHandle = windll.kernel32.GetModuleHandleA
>>> def ValidHandle(value):
...     if value == 0:
...         raise WinError()
...     return value
```

(下页继续)

(续上页)

```

...
>>>
>>> GetModuleHandle.restype = ValidHandle
>>> GetModuleHandle(None)
486539264
>>> GetModuleHandle("something silly")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 3, in ValidHandle
OSError: [Errno 126] The specified module could not be found.
>>>

```

`WinError` is a function which will call `Windows.FormatMessage()` api to get the string representation of an error code, and *returns* an exception. `WinError` takes an optional error code parameter, if no one is used, it calls `GetLastError()` to retrieve it.

Please note that a much more powerful error checking mechanism is available through the `errcheck` attribute; see the reference manual for details.

Passing pointers (or: passing parameters by reference)

Sometimes a C api function expects a *pointer* to a data type as parameter, probably to write into the corresponding location, or if the data is too large to be passed by value. This is also known as *passing parameters by reference*.

`ctypes` exports the `byref()` function which is used to pass parameters by reference. The same effect can be achieved with the `pointer()` function, although `pointer()` does a lot more work since it constructs a real pointer object, so it is faster to use `byref()` if you don't need the pointer object in Python itself:

```

>>> i = c_int()
>>> f = c_float()
>>> s = create_string_buffer(b'\000' * 32)
>>> print(i.value, f.value, repr(s.value))
0 0.0 b''
>>> libc.sscanf(b"1 3.14 Hello", b"%d %f %s",
...             byref(i), byref(f), s)
3
>>> print(i.value, f.value, repr(s.value))
1 3.1400001049 b'Hello'
>>>

```

Structures and unions

Structures and unions must derive from the `Structure` and `Union` base classes which are defined in the `ctypes` module. Each subclass must define a `_fields_` attribute. `_fields_` must be a list of 2-tuples, containing a *field name* and a *field type*.

The field type must be a `ctypes` type like `c_int`, or any other derived `ctypes` type: structure, union, array, pointer.

Here is a simple example of a `POINT` structure, which contains two integers named `x` and `y`, and also shows how to initialize a structure in the constructor:

```

>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = [("x", c_int),

```

(下页继续)

(续上页)

```

...         ("y", c_int)]
...
>>> point = POINT(10, 20)
>>> print(point.x, point.y)
10 20
>>> point = POINT(y=5)
>>> print(point.x, point.y)
0 5
>>> POINT(1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: too many initializers
>>>

```

You can, however, build much more complicated structures. A structure can itself contain other structures by using a structure as a field type.

Here is a RECT structure which contains two POINTs named *upperleft* and *lowerright*:

```

>>> class RECT(Structure):
...     _fields_ = [("upperleft", POINT),
...                 ("lowerright", POINT)]
...
>>> rc = RECT(point)
>>> print(rc.upperleft.x, rc.upperleft.y)
0 5
>>> print(rc.lowerright.x, rc.lowerright.y)
0 0
>>>

```

Nested structures can also be initialized in the constructor in several ways:

```

>>> r = RECT(POINT(1, 2), POINT(3, 4))
>>> r = RECT((1, 2), (3, 4))

```

Field *descriptors* can be retrieved from the *class*, they are useful for debugging because they can provide useful information:

```

>>> print(POINT.x)
<Field type=c_long, ofs=0, size=4>
>>> print(POINT.y)
<Field type=c_long, ofs=4, size=4>
>>>

```

警告: *ctypes* does not support passing unions or structures with bit-fields to functions by value. While this may work on 32-bit x86, it's not guaranteed by the library to work in the general case. Unions and structures with bit-fields should always be passed to functions by pointer.

Structure/union alignment and byte order

By default, Structure and Union fields are aligned in the same way the C compiler does it. It is possible to override this behavior by specifying a `_pack_` class attribute in the subclass definition. This must be set to a positive integer and specifies the maximum alignment for the fields. This is what `#pragma pack(n)` also does in MSVC.

`ctypes` uses the native byte order for Structures and Unions. To build structures with non-native byte order, you can use one of the `BigEndianStructure`, `LittleEndianStructure`, `BigEndianUnion`, and `LittleEndianUnion` base classes. These classes cannot contain pointer fields.

Bit fields in structures and unions

It is possible to create structures and unions containing bit fields. Bit fields are only possible for integer fields, the bit width is specified as the third item in the `_fields_` tuples:

```
>>> class Int(Structure):
...     _fields_ = [("first_16", c_int, 16),
...                 ("second_16", c_int, 16)]
...
>>> print(Int.first_16)
<Field type=c_long, ofs=0:0, bits=16>
>>> print(Int.second_16)
<Field type=c_long, ofs=0:16, bits=16>
>>>
```

Arrays

Arrays are sequences, containing a fixed number of instances of the same type.

The recommended way to create array types is by multiplying a data type with a positive integer:

```
TenPointsArrayType = POINT * 10
```

Here is an example of a somewhat artificial data type, a structure containing 4 POINTs among other stuff:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class MyStruct(Structure):
...     _fields_ = [("a", c_int),
...                 ("b", c_float),
...                 ("point_array", POINT * 4)]
>>>
>>> print(len(MyStruct().point_array))
4
>>>
```

Instances are created in the usual way, by calling the class:

```
arr = TenPointsArrayType()
for pt in arr:
    print(pt.x, pt.y)
```

The above code print a series of 0 0 lines, because the array contents is initialized to zeros.

Initializers of the correct type can also be specified:

```
>>> from ctypes import *
>>> TenIntegers = c_int * 10
>>> ii = TenIntegers(1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
```

(下页继续)

(续上页)

```
>>> print(ii)
<c_long_Array_10 object at 0x...>
>>> for i in ii: print(i, end=" ")
...
1 2 3 4 5 6 7 8 9 10
>>>
```

Pointers

Pointer instances are created by calling the `pointer()` function on a `ctypes` type:

```
>>> from ctypes import *
>>> i = c_int(42)
>>> pi = pointer(i)
>>>
```

Pointer instances have a `contents` attribute which returns the object to which the pointer points, the `i` object above:

```
>>> pi.contents
c_long(42)
>>>
```

Note that `ctypes` does not have OOR (original object return), it constructs a new, equivalent object each time you retrieve an attribute:

```
>>> pi.contents is i
False
>>> pi.contents is pi.contents
False
>>>
```

Assigning another `c_int` instance to the pointer's `contents` attribute would cause the pointer to point to the memory location where this is stored:

```
>>> i = c_int(99)
>>> pi.contents = i
>>> pi.contents
c_long(99)
>>>
```

Pointer instances can also be indexed with integers:

```
>>> pi[0]
99
>>>
```

Assigning to an integer index changes the pointed to value:

```
>>> print(i)
c_long(99)
>>> pi[0] = 22
>>> print(i)
c_long(22)
>>>
```

It is also possible to use indexes different from 0, but you must know what you're doing, just as in C: You can access or change arbitrary memory locations. Generally you only use this feature if you receive a pointer from a C function, and you *know* that the pointer actually points to an array instead of a single item.

Behind the scenes, the `pointer()` function does more than simply create pointer instances, it has to create pointer *types* first. This is done with the `POINTER()` function, which accepts any *ctypes* type, and returns a new type:

```
>>> PI = POINTER(c_int)
>>> PI
<class 'ctypes.LP_c_long'>
>>> PI(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: expected c_long instead of int
>>> PI(c_int(42))
<ctypes.LP_c_long object at 0x...>
>>>
```

Calling the pointer type without an argument creates a NULL pointer. NULL pointers have a `False` boolean value:

```
>>> null_ptr = POINTER(c_int)()
>>> print(bool(null_ptr))
False
>>>
```

ctypes checks for NULL when dereferencing pointers (but dereferencing invalid non-NULL pointers would crash Python):

```
>>> null_ptr[0]
Traceback (most recent call last):
  ....
ValueError: NULL pointer access
>>>

>>> null_ptr[0] = 1234
Traceback (most recent call last):
  ....
ValueError: NULL pointer access
>>>
```

Type conversions

Usually, *ctypes* does strict type checking. This means, if you have `POINTER(c_int)` in the `argtypes` list of a function or as the type of a member field in a structure definition, only instances of exactly the same type are accepted. There are some exceptions to this rule, where *ctypes* accepts other objects. For example, you can pass compatible array instances instead of pointer types. So, for `POINTER(c_int)`, *ctypes* accepts an array of `c_int`:

```
>>> class Bar(Structure):
...     _fields_ = [("count", c_int), ("values", POINTER(c_int))]
...
>>> bar = Bar()
>>> bar.values = (c_int * 3)(1, 2, 3)
>>> bar.count = 3
>>> for i in range(bar.count):
...     print(bar.values[i])
...
>>>
```

(下页继续)

(续上页)

```
1
2
3
>>>
```

In addition, if a function argument is explicitly declared to be a pointer type (such as `POINTER(c_int)`) in `argtypes`, an object of the pointed type (`c_int` in this case) can be passed to the function. `ctypes` will apply the required `byref()` conversion in this case automatically.

To set a `POINTER` type field to `NULL`, you can assign `None`:

```
>>> bar.values = None
>>>
```

Sometimes you have instances of incompatible types. In C, you can cast one type into another type. `ctypes` provides a `cast()` function which can be used in the same way. The `Bar` structure defined above accepts `POINTER(c_int)` pointers or `c_int` arrays for its `values` field, but not instances of other types:

```
>>> bar.values = (c_byte * 4)()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: incompatible types, c_byte_Array_4 instance instead of LP_c_long instance
>>>
```

For these cases, the `cast()` function is handy.

The `cast()` function can be used to cast a `ctypes` instance into a pointer to a different `ctypes` data type. `cast()` takes two parameters, a `ctypes` object that is or can be converted to a pointer of some kind, and a `ctypes` pointer type. It returns an instance of the second argument, which references the same memory block as the first argument:

```
>>> a = (c_byte * 4)()
>>> cast(a, POINTER(c_int))
<ctypes.LP_c_long object at ...>
>>>
```

So, `cast()` can be used to assign to the `values` field of `Bar` the structure:

```
>>> bar = Bar()
>>> bar.values = cast((c_byte * 4)(), POINTER(c_int))
>>> print(bar.values[0])
0
>>>
```

Incomplete Types

Incomplete Types are structures, unions or arrays whose members are not yet specified. In C, they are specified by forward declarations, which are defined later:

```
struct cell; /* forward declaration */

struct cell {
    char *name;
    struct cell *next;
};
```

The straightforward translation into `ctypes` code would be this, but it does not work:

```
>>> class cell(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("next", POINTER(cell))]
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in cell
NameError: name 'cell' is not defined
>>>
```

because the new class `cell` is not available in the class statement itself. In `ctypes`, we can define the `cell` class and set the `_fields_` attribute later, after the class statement:

```
>>> from ctypes import *
>>> class cell(Structure):
...     pass
...
>>> cell._fields_ = [("name", c_char_p),
...                  ("next", POINTER(cell))]
>>>
```

Lets try it. We create two instances of `cell`, and let them point to each other, and finally follow the pointer chain a few times:

```
>>> c1 = cell()
>>> c1.name = "foo"
>>> c2 = cell()
>>> c2.name = "bar"
>>> c1.next = pointer(c2)
>>> c2.next = pointer(c1)
>>> p = c1
>>> for i in range(8):
...     print(p.name, end=" ")
...     p = p.next[0]
...
foo bar foo bar foo bar foo bar
>>>
```

Callback functions

`ctypes` allows creating C callable function pointers from Python callables. These are sometimes called *callback functions*.

First, you must create a class for the callback function. The class knows the calling convention, the return type, and the number and types of arguments this function will receive.

The `CFUNCTYPE()` factory function creates types for callback functions using the `cdecl` calling convention. On Windows, the `WINFUNCTYPE()` factory function creates types for callback functions using the `stdcall` calling convention.

Both of these factory functions are called with the result type as first argument, and the callback functions expected argument types as the remaining arguments.

I will present an example here which uses the standard C library's `qsort()` function, that is used to sort items with the help of a callback function. `qsort()` will be used to sort an array of integers:

```
>>> IntArray5 = c_int * 5
>>> ia = IntArray5(5, 1, 7, 33, 99)
>>> qsort = libc.qsort
>>> qsort.restype = None
>>>
```

`qsort()` must be called with a pointer to the data to sort, the number of items in the data array, the size of one item, and a pointer to the comparison function, the callback. The callback will then be called with two pointers to items, and it must return a negative integer if the first item is smaller than the second, a zero if they are equal, and a positive integer otherwise.

So our callback function receives pointers to integers, and must return an integer. First we create the `type` for the callback function:

```
>>> CMPFUNC = CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
>>>
```

To get started, here is a simple callback that shows the values it gets passed:

```
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return 0
...
>>> cmp_func = CMPFUNC(py_cmp_func)
>>>
```

The result:

```
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 5 7
py_cmp_func 1 7
>>>
```

Now we can actually compare the two items and return a useful result:

```
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>>
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_func))
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>
```

As we can easily check, our array is sorted now:

```
>>> for i in ia: print(i, end=" ")
...
1 5 7 33 99
>>>
```

The function factories can be used as decorator factories, so we may as well write:

```
>>> @CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
... def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>> qsort(ia, len(ia), sizeof(c_int), py_cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>
```

注解: Make sure you keep references to `CFUNCTYPE()` objects as long as they are used from C code. `ctypes` doesn't, and if you don't, they may be garbage collected, crashing your program when a callback is made.

Also, note that if the callback function is called in a thread created outside of Python's control (e.g. by the foreign code that calls the callback), `ctypes` creates a new dummy Python thread on every invocation. This behavior is correct for most purposes, but it means that values stored with `threading.local` will *not* survive across different callbacks, even when those calls are made from the same C thread.

Accessing values exported from dlls

Some shared libraries not only export functions, they also export variables. An example in the Python library itself is the `Py_OptimizeFlag`, an integer set to 0, 1, or 2, depending on the `-O` or `-OO` flag given on startup.

`ctypes` can access values like this with the `in_dll()` class methods of the type. `pythonapi` is a predefined symbol giving access to the Python C api:

```
>>> opt_flag = c_int.in_dll(pythonapi, "Py_OptimizeFlag")
>>> print(opt_flag)
c_long(0)
>>>
```

If the interpreter would have been started with `-O`, the sample would have printed `c_long(1)`, or `c_long(2)` if `-OO` would have been specified.

An extended example which also demonstrates the use of pointers accesses the `PyImport_FrozenModules` pointer exported by Python.

Quoting the docs for that value:

This pointer is initialized to point to an array of struct `_frozen` records, terminated by one whose members are all `NULL` or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

So manipulating this pointer could even prove useful. To restrict the example size, we show only how this table can be read with `ctypes`:

```
>>> from ctypes import *
>>>
>>> class struct_frozen(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("code", POINTER(c_ubyte)),
```

(下页继续)

(续上页)

```
...         ("size", c_int)]
...
>>>
```

We have defined the struct `_frozen` data type, so we can get the pointer to the table:

```
>>> FrozenTable = POINTER(struct_frozen)
>>> table = FrozenTable.in_dll(pythonapi, "PyImport_FrozenModules")
>>>
```

Since `table` is a pointer to the array of `struct_frozen` records, we can iterate over it, but we just have to make sure that our loop terminates, because pointers have no size. Sooner or later it would probably crash with an access violation or whatever, so it's better to break out of the loop when we hit the NULL entry:

```
>>> for item in table:
...     if item.name is None:
...         break
...     print(item.name.decode("ascii"), item.size)
...
_frozen_importlib 31764
_frozen_importlib_external 41499
__hello__ 161
__phello__ -161
__phello__.spam 161
>>>
```

The fact that standard Python has a frozen module and a frozen package (indicated by the negative size member) is not well known, it is only used for testing. Try it out with `import __hello__` for example.

Surprises

There are some edges in `ctypes` where you might expect something other than what actually happens.

Consider the following example:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class RECT(Structure):
...     _fields_ = ("a", POINT), ("b", POINT)
...
>>> p1 = POINT(1, 2)
>>> p2 = POINT(3, 4)
>>> rc = RECT(p1, p2)
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
1 2 3 4
>>> # now swap the two points
>>> rc.a, rc.b = rc.b, rc.a
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
3 4 3 4
>>>
```

Hm. We certainly expected the last statement to print `3 4 1 2`. What happened? Here are the steps of the `rc.a, rc.b = rc.b, rc.a` line above:

```
>>> temp0, temp1 = rc.b, rc.a
>>> rc.a = temp0
>>> rc.b = temp1
>>>
```

Note that `temp0` and `temp1` are objects still using the internal buffer of the `rc` object above. So executing `rc.a = temp0` copies the buffer contents of `temp0` into `rc`'s buffer. This, in turn, changes the contents of `temp1`. So, the last assignment `rc.b = temp1`, doesn't have the expected effect.

Keep in mind that retrieving sub-objects from Structure, Unions, and Arrays doesn't *copy* the sub-object, instead it retrieves a wrapper object accessing the root-object's underlying buffer.

Another example that may behave different from what one would expect is this:

```
>>> s = c_char_p()
>>> s.value = "abc def ghi"
>>> s.value
'abc def ghi'
>>> s.value is s.value
False
>>>
```

Why is it printing `False`? `ctypes` instances are objects containing a memory block plus some *descriptors* accessing the contents of the memory. Storing a Python object in the memory block does not store the object itself, instead the contents of the object is stored. Accessing the contents again constructs a new Python object each time!

Variable-sized data types

`ctypes` provides some support for variable-sized arrays and structures.

The `resize()` function can be used to resize the memory buffer of an existing `ctypes` object. The function takes the object as first argument, and the requested size in bytes as the second argument. The memory block cannot be made smaller than the natural memory block specified by the objects type, a `ValueError` is raised if this is tried:

```
>>> short_array = (c_short * 4)()
>>> print(sizeof(short_array))
8
>>> resize(short_array, 4)
Traceback (most recent call last):
...
ValueError: minimum size is 8
>>> resize(short_array, 32)
>>> sizeof(short_array)
32
>>> sizeof(type(short_array))
8
>>>
```

This is nice and fine, but how would one access the additional elements contained in this array? Since the type still only knows about 4 elements, we get errors accessing other elements:

```
>>> short_array[:]
[0, 0, 0, 0]
>>> short_array[7]
Traceback (most recent call last):
...
```

(下页继续)

(续上页)

```

IndexError: invalid index
>>>

```

Another way to use variable-sized data types with `ctypes` is to use the dynamic nature of Python, and (re-)define the data type after the required size is already known, on a case by case basis.

16.16.2 ctypes reference

Finding shared libraries

When programming in a compiled language, shared libraries are accessed when compiling/linking a program, and when the program is run.

The purpose of the `find_library()` function is to locate a library in a way similar to what the compiler or runtime loader does (on platforms with several versions of a shared library the most recent should be loaded), while the `ctypes` library loaders act like when a program is run, and call the runtime loader directly.

The `ctypes.util` module provides a function which can help to determine the library to load.

`ctypes.util.find_library(name)`

Try to find a library and return a pathname. *name* is the library name without any prefix like *lib*, suffix like *.so*, *.dylib* or version number (this is the form used for the *posix* linker option *-l*). If no library can be found, returns *None*.

The exact functionality is system dependent.

On Linux, `find_library()` tries to run external programs (*/sbin/ldconfig*, *gcc*, *objdump* and *ld*) to find the library file. It returns the filename of the library file.

在 3.6 版更改: On Linux, the value of the environment variable `LD_LIBRARY_PATH` is used when searching for libraries, if a library cannot be found by any other means.

Here are some examples:

```

>>> from ctypes.util import find_library
>>> find_library("m")
'libm.so.6'
>>> find_library("c")
'libc.so.6'
>>> find_library("bz2")
'libbz2.so.1.0'
>>>

```

On OS X, `find_library()` tries several predefined naming schemes and paths to locate the library, and returns a full pathname if successful:

```

>>> from ctypes.util import find_library
>>> find_library("c")
'/usr/lib/libc.dylib'
>>> find_library("m")
'/usr/lib/libm.dylib'
>>> find_library("bz2")
'/usr/lib/libbz2.dylib'
>>> find_library("AGL")
'/System/Library/Frameworks/AGL.framework/AGL'
>>>

```

On Windows, `find_library()` searches along the system search path, and returns the full pathname, but since there is no predefined naming scheme a call like `find_library("c")` will fail and return `None`.

If wrapping a shared library with `ctypes`, it *may* be better to determine the shared library name at development time, and hardcode that into the wrapper module instead of using `find_library()` to locate the library at runtime.

Loading shared libraries

There are several ways to load shared libraries into the Python process. One way is to instantiate one of the following classes:

class `ctypes.CDLL`(*name*, *mode*=`DEFAULT_MODE`, *handle*=`None`, *use_errno*=`False`,
 use_last_error=`False`)
Instances of this class represent loaded shared libraries. Functions in these libraries use the standard C calling convention, and are assumed to return `int`.

class `ctypes.OleDLL`(*name*, *mode*=`DEFAULT_MODE`, *handle*=`None`, *use_errno*=`False`,
 use_last_error=`False`)
Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return the windows specific `HRESULT` code. `HRESULT` values contain information specifying whether the function call failed or succeeded, together with additional error code. If the return value signals a failure, an `OSError` is automatically raised.

在 3.3 版更改: `WindowsError` used to be raised.

class `ctypes.WinDLL`(*name*, *mode*=`DEFAULT_MODE`, *handle*=`None`, *use_errno*=`False`,
 use_last_error=`False`)
Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return `int` by default.

On Windows CE only the standard calling convention is used, for convenience the `WinDLL` and `OleDLL` use the standard calling convention on this platform.

The Python *global interpreter lock* is released before calling any function exported by these libraries, and reacquired afterwards.

class `ctypes.PyDLL`(*name*, *mode*=`DEFAULT_MODE`, *handle*=`None`)
Instances of this class behave like `CDLL` instances, except that the Python GIL is *not* released during the function call, and after the function execution the Python error flag is checked. If the error flag is set, a Python exception is raised.

Thus, this is only useful to call Python C api functions directly.

All these classes can be instantiated by calling them with at least one argument, the pathname of the shared library. If you have an existing handle to an already loaded shared library, it can be passed as the `handle` named parameter, otherwise the underlying platforms `dlopen` or `LoadLibrary` function is used to load the library into the process, and to get a handle to it.

The *mode* parameter can be used to specify how the library is loaded. For details, consult the `dlopen(3)` manpage. On Windows, *mode* is ignored. On posix systems, `RTLD_NOW` is always added, and is not configurable.

The *use_errno* parameter, when set to true, enables a ctypes mechanism that allows accessing the system `errno` error number in a safe way. `ctypes` maintains a thread-local copy of the systems `errno` variable; if you call foreign functions created with `use_errno=True` then the `errno` value before the function call is swapped with the ctypes private copy, the same happens immediately after the function call.

The function `ctypes.get_errno()` returns the value of the ctypes private copy, and the function `ctypes.set_errno()` changes the ctypes private copy to a new value and returns the former value.

The `use_last_error` parameter, when set to true, enables the same mechanism for the Windows error code which is managed by the `GetLastError()` and `SetLastError()` Windows API functions; `ctypes.get_last_error()` and `ctypes.set_last_error()` are used to request and change the ctypes private copy of the windows error code.

`ctypes.RTLD_GLOBAL`

Flag to use as `mode` parameter. On platforms where this flag is not available, it is defined as the integer zero.

`ctypes.RTLD_LOCAL`

Flag to use as `mode` parameter. On platforms where this is not available, it is the same as `RTLD_GLOBAL`.

`ctypes.DEFAULT_MODE`

The default mode which is used to load shared libraries. On OSX 10.3, this is `RTLD_GLOBAL`, otherwise it is the same as `RTLD_LOCAL`.

Instances of these classes have no public methods. Functions exported by the shared library can be accessed as attributes or by index. Please note that accessing the function through an attribute caches the result and therefore accessing it repeatedly returns the same object each time. On the other hand, accessing it through an index returns a new object each time:

```
>>> libc.time == libc.time
True
>>> libc['time'] == libc['time']
False
```

The following public attributes are available, their name starts with an underscore to not clash with exported function names:

`PyDLL._handle`

The system handle used to access the library.

`PyDLL._name`

The name of the library passed in the constructor.

Shared libraries can also be loaded by using one of the prefabricated objects, which are instances of the `LibraryLoader` class, either by calling the `LoadLibrary()` method, or by retrieving the library as attribute of the loader instance.

class `ctypes.LibraryLoader` (*dlltype*)

Class which loads shared libraries. *dlltype* should be one of the `CDLL`, `PyDLL`, `WinDLL`, or `OleDLL` types.

`__getattr__()` has special behavior: It allows loading a shared library by accessing it as attribute of a library loader instance. The result is cached, so repeated attribute accesses return the same library each time.

LoadLibrary (*name*)

Load a shared library into the process and return it. This method always returns a new instance of the library.

These prefabricated library loaders are available:

`ctypes.cdll`

Creates `CDLL` instances.

`ctypes.windll`

仅 Windows 中: 创建 `WinDLL` 实例。

`ctypes.oledll`

仅 Windows 中: 创建 `OleDLL` 实例。

`ctypes.pydll`

创建 `PyDLL` 实例。

For accessing the C Python api directly, a ready-to-use Python shared library object is available:

ctypes.pythonapi

An instance of *PyDLL* that exposes Python C API functions as attributes. Note that all these functions are assumed to return C `int`, which is of course not always the truth, so you have to assign the correct `restype` attribute to use these functions.

Foreign functions

As explained in the previous section, foreign functions can be accessed as attributes of loaded shared libraries. The function objects created in this way by default accept any number of arguments, accept any ctypes data instances as arguments, and return the default result type specified by the library loader. They are instances of a private class:

class ctypes._FuncPtr

Base class for C callable foreign functions.

Instances of foreign functions are also C compatible data types; they represent C function pointers.

This behavior can be customized by assigning to special attributes of the foreign function object.

restype

Assign a ctypes type to specify the result type of the foreign function. Use `None` for `void`, a function not returning anything.

It is possible to assign a callable Python object that is not a ctypes type, in this case the function is assumed to return a C `int`, and the callable will be called with this integer, allowing further processing or error checking. Using this is deprecated, for more flexible post processing or error checking use a ctypes data type as *restype* and assign a callable to the *errcheck* attribute.

argtypes

Assign a tuple of ctypes types to specify the argument types that the function accepts. Functions using the `stdcall` calling convention can only be called with the same number of arguments as the length of this tuple; functions using the C calling convention accept additional, unspecified arguments as well.

When a foreign function is called, each actual argument is passed to the `from_param()` class method of the items in the *argtypes* tuple, this method allows adapting the actual argument to an object that the foreign function accepts. For example, a *c_char_p* item in the *argtypes* tuple will convert a string passed as argument into a bytes object using ctypes conversion rules.

New: It is now possible to put items in *argtypes* which are not ctypes types, but each item must have a `from_param()` method which returns a value usable as argument (integer, string, ctypes instance). This allows defining adapters that can adapt custom objects as function parameters.

errcheck

Assign a Python function or another callable to this attribute. The callable will be called with three or more arguments:

callable (*result, func, arguments*)

result is what the foreign function returns, as specified by the *restype* attribute.

func is the foreign function object itself, this allows reusing the same callable object to check or post process the results of several functions.

arguments is a tuple containing the parameters originally passed to the function call, this allows specializing the behavior on the arguments used.

The object that this function returns will be returned from the foreign function call, but it can also check the result value and raise an exception if the foreign function call failed.

exception ctypes.ArgumentError

This exception is raised when a foreign function call cannot convert one of the passed arguments.

Function prototypes

Foreign functions can also be created by instantiating function prototypes. Function prototypes are similar to function prototypes in C; they describe a function (return type, argument types, calling convention) without defining an implementation. The factory functions must be called with the desired result type and the argument types of the function, and can be used as decorator factories, and as such, be applied to functions through the `@wrapper` syntax. See [Callback functions](#) for examples.

`ctypes.CFUNCTYPE (restype, *argtypes, use_errno=False, use_last_error=False)`

The returned function prototype creates functions that use the standard C calling convention. The function will release the GIL during the call. If `use_errno` is set to true, the ctypes private copy of the system `errno` variable is exchanged with the real `errno` value before and after the call; `use_last_error` does the same for the Windows error code.

`ctypes.WINFUNCTYPE (restype, *argtypes, use_errno=False, use_last_error=False)`

Windows only: The returned function prototype creates functions that use the `stdcall` calling convention, except on Windows CE where `WINFUNCTYPE ()` is the same as `CFUNCTYPE ()`. The function will release the GIL during the call. `use_errno` and `use_last_error` have the same meaning as above.

`ctypes.PYFUNCTYPE (restype, *argtypes)`

The returned function prototype creates functions that use the Python calling convention. The function will *not* release the GIL during the call.

Function prototypes created by these factory functions can be instantiated in different ways, depending on the type and number of the parameters in the call:

prototype (*address*)

Returns a foreign function at the specified address which must be an integer.

prototype (*callable*)

Create a C callable function (a callback function) from a Python *callable*.

prototype (*func_spec* [, *paramflags*])

Returns a foreign function exported by a shared library. *func_spec* must be a 2-tuple (*name_or_ordinal*, *library*). The first item is the name of the exported function as string, or the ordinal of the exported function as small integer. The second item is the shared library instance.

prototype (*vtbl_index*, *name* [, *paramflags* [, *iid*]])

Returns a foreign function that will call a COM method. *vtbl_index* is the index into the virtual function table, a small non-negative integer. *name* is name of the COM method. *iid* is an optional pointer to the interface identifier which is used in extended error reporting.

COM methods use a special calling convention: They require a pointer to the COM interface as first argument, in addition to those parameters that are specified in the *argtypes* tuple.

The optional *paramflags* parameter creates foreign function wrappers with much more functionality than the features described above.

paramflags must be a tuple of the same length as *argtypes*.

Each item in this tuple contains further information about a parameter, it must be a tuple containing one, two, or three items.

The first item is an integer containing a combination of direction flags for the parameter:

- 1 Specifies an input parameter to the function.
- 2 Output parameter. The foreign function fills in a value.
- 4 Input parameter which defaults to the integer zero.

The optional second item is the parameter name as string. If this is specified, the foreign function can be called with named parameters.

The optional third item is the default value for this parameter.

This example demonstrates how to wrap the Windows `MessageBoxW` function so that it supports default parameters and named arguments. The C declaration from the windows header file is this:

```
WINUSERAPI int WINAPI
MessageBoxW(
    HWND hWnd,
    LPCWSTR lpText,
    LPCWSTR lpCaption,
    UINT uType);
```

Here is the wrapping with `ctypes`:

```
>>> from ctypes import c_int, WINFUNCTYPE, windll
>>> from ctypes.wintypes import HWND, LPCWSTR, UINT
>>> prototype = WINFUNCTYPE(c_int, HWND, LPCWSTR, LPCWSTR, UINT)
>>> paramflags = (1, "hwnd", 0), (1, "text", "Hi"), (1, "caption", "Hello from ctypes"), (1, "flags", 0)
>>> MessageBox = prototype(("MessageBoxW", windll.user32), paramflags)
```

The `MessageBox` foreign function can now be called in these ways:

```
>>> MessageBox()
>>> MessageBox(text="Spam, spam, spam")
>>> MessageBox(flags=2, text="foo bar")
```

A second example demonstrates output parameters. The win32 `GetWindowRect` function retrieves the dimensions of a specified window by copying them into `RECT` structure that the caller has to supply. Here is the C declaration:

```
WINUSERAPI BOOL WINAPI
GetWindowRect(
    HWND hWnd,
    LPRECT lpRect);
```

Here is the wrapping with `ctypes`:

```
>>> from ctypes import POINTER, WINFUNCTYPE, windll, WinError
>>> from ctypes.wintypes import BOOL, HWND, RECT
>>> prototype = WINFUNCTYPE(BOOL, HWND, POINTER(RECT))
>>> paramflags = (1, "hwnd"), (2, "lprect")
>>> GetWindowRect = prototype(("GetWindowRect", windll.user32), paramflags)
>>>
```

Functions with output parameters will automatically return the output parameter value if there is a single one, or a tuple containing the output parameter values when there are more than one, so the `GetWindowRect` function now returns a `RECT` instance, when called.

Output parameters can be combined with the `errcheck` protocol to do further output processing and error checking. The win32 `GetWindowRect` api function returns a `BOOL` to signal success or failure, so this function could do the error checking, and raises an exception when the api call failed:

```
>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
```

(下页继续)

(续上页)

```

...     return args
...
>>> GetWindowRect.errcheck = errcheck
>>>

```

If the `errcheck` function returns the argument tuple it receives unchanged, `ctypes` continues the normal processing it does on the output parameters. If you want to return a tuple of window coordinates instead of a `RECT` instance, you can retrieve the fields in the function and return them instead, the normal processing will no longer take place:

```

>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     rc = args[1]
...     return rc.left, rc.top, rc.bottom, rc.right
...
>>> GetWindowRect.errcheck = errcheck
>>>

```

Utility functions

`ctypes.addressof(obj)`

Returns the address of the memory buffer as integer. *obj* must be an instance of a `ctypes` type.

`ctypes.alignment(obj_or_type)`

Returns the alignment requirements of a `ctypes` type. *obj_or_type* must be a `ctypes` type or instance.

`ctypes.byref(obj[, offset])`

Returns a light-weight pointer to *obj*, which must be an instance of a `ctypes` type. *offset* defaults to zero, and must be an integer that will be added to the internal pointer value.

`byref(obj, offset)` corresponds to this C code:

```
((char *)&obj) + offset)
```

The returned object can only be used as a foreign function call parameter. It behaves similar to `pointer(obj)`, but the construction is a lot faster.

`ctypes.cast(obj, type)`

This function is similar to the cast operator in C. It returns a new instance of *type* which points to the same memory block as *obj*. *type* must be a pointer type, and *obj* must be an object that can be interpreted as a pointer.

`ctypes.create_string_buffer(init_or_size, size=None)`

This function creates a mutable character buffer. The returned object is a `ctypes` array of `c_char`.

init_or_size must be an integer which specifies the size of the array, or a bytes object which will be used to initialize the array items.

If a bytes object is specified as first argument, the buffer is made one item larger than its length so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the bytes should not be used.

`ctypes.create_unicode_buffer(init_or_size, size=None)`

This function creates a mutable unicode character buffer. The returned object is a `ctypes` array of `c_wchar`.

init_or_size must be an integer which specifies the size of the array, or a string which will be used to initialize the array items.

If a string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the string should not be used.

`ctypes.DllCanUnloadNow()`

Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the `DllCanUnloadNow` function that the `_ctypes` extension dll exports.

`ctypes.DllGetClassObject()`

Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the `DllGetClassObject` function that the `_ctypes` extension dll exports.

`ctypes.util.find_library(name)`

Try to find a library and return a pathname. *name* is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

`ctypes.util.find_msvcrt()`

Windows only: return the filename of the VC runtime library used by Python, and by the extension modules. If the name of the library cannot be determined, `None` is returned.

If you need to free memory, for example, allocated by an extension module with a call to the `free(void *)`, it is important that you use the function in the same library that allocated the memory.

`ctypes.FormatError([code])`

Windows only: Returns a textual description of the error code *code*. If no error code is specified, the last error code is used by calling the Windows api function `GetLastError`.

`ctypes.GetLastError()`

Windows only: Returns the last error code set by Windows in the calling thread. This function calls the Windows `GetLastError()` function directly, it does not return the ctypes-private copy of the error code.

`ctypes.get_errno()`

Returns the current value of the ctypes-private copy of the system `errno` variable in the calling thread.

`ctypes.get_last_error()`

Windows only: returns the current value of the ctypes-private copy of the system `LastError` variable in the calling thread.

`ctypes.memmove(dst, src, count)`

Same as the standard C `memmove` library function: copies *count* bytes from *src* to *dst*. *dst* and *src* must be integers or ctypes instances that can be converted to pointers.

`ctypes.memset(dst, c, count)`

Same as the standard C `memset` library function: fills the memory block at address *dst* with *count* bytes of value *c*. *dst* must be an integer specifying an address, or a ctypes instance.

`ctypes.POINTER(type)`

This factory function creates and returns a new ctypes pointer type. Pointer types are cached and reused internally, so calling this function repeatedly is cheap. *type* must be a ctypes type.

`ctypes.pointer(obj)`

This function creates a new pointer instance, pointing to *obj*. The returned object is of the type `POINTER(type(obj))`.

Note: If you just want to pass a pointer to an object to a foreign function call, you should use `byref(obj)` which is much faster.

`ctypes.resize(obj, size)`

This function resizes the internal memory buffer of *obj*, which must be an instance of a ctypes type. It is not possible

to make the buffer smaller than the native size of the objects type, as given by `sizeof(type(obj))`, but it is possible to enlarge the buffer.

`ctypes.set_errno(value)`

Set the current value of the ctypes-private copy of the system `errno` variable in the calling thread to *value* and return the previous value.

`ctypes.set_last_error(value)`

Windows only: set the current value of the ctypes-private copy of the system `LastError` variable in the calling thread to *value* and return the previous value.

`ctypes.sizeof(obj_or_type)`

Returns the size in bytes of a ctypes type or instance memory buffer. Does the same as the C `sizeof` operator.

`ctypes.string_at(address, size=-1)`

This function returns the C string starting at memory address *address* as a bytes object. If *size* is specified, it is used as size, otherwise the string is assumed to be zero-terminated.

`ctypes.WinError(code=None, descr=None)`

Windows only: this function is probably the worst-named thing in ctypes. It creates an instance of `OSError`. If *code* is not specified, `GetLastError` is called to determine the error code. If *descr* is not specified, `FormatError()` is called to get a textual description of the error.

在 3.3 版更改: An instance of `WindowsError` used to be created.

`ctypes.wstring_at(address, size=-1)`

This function returns the wide character string starting at memory address *address* as a string. If *size* is specified, it is used as the number of characters of the string, otherwise the string is assumed to be zero-terminated.

Data types

class `ctypes._CData`

This non-public class is the common base class of all ctypes data types. Among other things, all ctypes type instances contain a memory block that hold C compatible data; the address of the memory block is returned by the `addressof()` helper function. Another instance variable is exposed as `_objects`; this contains other Python objects that need to be kept alive in case the memory block contains pointers.

Common methods of ctypes data types, these are all class methods (to be exact, they are methods of the *metaclass*):

from_buffer (*source*[, *offset*])

This method returns a ctypes instance that shares the buffer of the *source* object. The *source* object must support the writeable buffer interface. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a `ValueError` is raised.

from_buffer_copy (*source*[, *offset*])

This method creates a ctypes instance, copying the buffer from the *source* object buffer which must be readable. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a `ValueError` is raised.

from_address (*address*)

This method returns a ctypes type instance using the memory specified by *address* which must be an integer.

from_param (*obj*)

This method adapts *obj* to a ctypes type. It is called with the actual object used in a foreign function call when the type is present in the foreign function's `argtypes` tuple; it must return an object that can be used as a function call parameter.

All ctypes data types have a default implementation of this classmethod that normally returns *obj* if that is an instance of the type. Some types accept other objects as well.

in_dll (*library*, *name*)

This method returns a ctypes type instance exported by a shared library. *name* is the name of the symbol that exports the data, *library* is the loaded shared library.

Common instance variables of ctypes data types:

_b_base_

Sometimes ctypes data instances do not own the memory block they contain, instead they share part of the memory block of a base object. The `_b_base_` read-only member is the root ctypes object that owns the memory block.

_b_needsfree_

This read-only variable is true when the ctypes data instance has allocated the memory block itself, false otherwise.

_objects

This member is either `None` or a dictionary containing Python objects that need to be kept alive so that the memory block contents is kept valid. This object is only exposed for debugging; never modify the contents of this dictionary.

基础数据类型

class ctypes._SimpleCData

This non-public class is the base class of all fundamental ctypes data types. It is mentioned here because it contains the common attributes of the fundamental ctypes data types. `_SimpleCData` is a subclass of `_CData`, so it inherits their methods and attributes. ctypes data types that are not and do not contain pointers can now be pickled.

Instances have a single attribute:

value

This attribute contains the actual value of the instance. For integer and pointer types, it is an integer, for character types, it is a single character bytes object or string, for character pointer types it is a Python bytes object or string.

When the `value` attribute is retrieved from a ctypes instance, usually a new object is returned each time. `ctypes` does *not* implement original object return, always a new object is constructed. The same is true for all other ctypes object instances.

Fundamental data types, when returned as foreign function call results, or, for example, by retrieving structure field members or array items, are transparently converted to native Python types. In other words, if a foreign function has a `restype` of `c_char_p`, you will always receive a Python bytes object, *not* a `c_char_p` instance.

Subclasses of fundamental data types do *not* inherit this behavior. So, if a foreign functions `restype` is a subclass of `c_void_p`, you will receive an instance of this subclass from the function call. Of course, you can get the value of the pointer by accessing the `value` attribute.

These are the fundamental ctypes data types:

class ctypes.c_byte

Represents the C `signed char` datatype, and interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_char

Represents the C `char` datatype, and interprets the value as a single character. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class ctypes.c_char_p

Represents the C `char *` datatype when it points to a zero-terminated string. For a general character pointer that may also point to binary data, `POINTER(c_char)` must be used. The constructor accepts an integer address, or a bytes object.

class ctypes.c_double

Represents the C double datatype. The constructor accepts an optional float initializer.

class ctypes.c_longdouble

Represents the C long double datatype. The constructor accepts an optional float initializer. On platforms where `sizeof(long double) == sizeof(double)` it is an alias to `c_double`.

class ctypes.c_float

Represents the C float datatype. The constructor accepts an optional float initializer.

class ctypes.c_int

Represents the C signed int datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias to `c_long`.

class ctypes.c_int8

Represents the C 8-bit signed int datatype. Usually an alias for `c_byte`.

class ctypes.c_int16

Represents the C 16-bit signed int datatype. Usually an alias for `c_short`.

class ctypes.c_int32

Represents the C 32-bit signed int datatype. Usually an alias for `c_int`.

class ctypes.c_int64

Represents the C 64-bit signed int datatype. Usually an alias for `c_longlong`.

class ctypes.c_long

Represents the C signed long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_longlong

Represents the C signed long long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_short

Represents the C signed short datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_size_t

Represents the C size_t datatype.

class ctypes.c_ssize_t

Represents the C ssize_t datatype.

3.2 新版功能.

class ctypes.c_ubyte

Represents the C unsigned char datatype, it interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_uint

Represents the C unsigned int datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias for `c_ulong`.

class ctypes.c_uint8

Represents the C 8-bit unsigned int datatype. Usually an alias for `c_ubyte`.

class ctypes.c_uint16

Represents the C 16-bit unsigned int datatype. Usually an alias for `c_ushort`.

class ctypes.c_uint32

Represents the C 32-bit unsigned int datatype. Usually an alias for `c_uint`.

class `ctypes.c_uint64`

Represents the C 64-bit unsigned int datatype. Usually an alias for `c_ulonglong`.

class `ctypes.c_ulong`

Represents the C unsigned long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class `ctypes.c_ulonglong`

Represents the C unsigned long long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class `ctypes.c_ushort`

Represents the C unsigned short datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class `ctypes.c_void_p`

Represents the C void * type. The value is represented as integer. The constructor accepts an optional integer initializer.

class `ctypes.c_wchar`

Represents the C wchar_t datatype, and interprets the value as a single character unicode string. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class `ctypes.c_wchar_p`

Represents the C wchar_t * datatype, which must be a pointer to a zero-terminated wide character string. The constructor accepts an integer address, or a string.

class `ctypes.c_bool`

Represent the C bool datatype (more accurately, _Bool from C99). Its value can be True or False, and the constructor accepts any object that has a truth value.

class `ctypes.HRESULT`

Windows only: Represents a HRESULT value, which contains success or error information for a function or method call.

class `ctypes.py_object`

Represents the C PyObject * datatype. Calling this without an argument creates a NULL PyObject * pointer.

The `ctypes.wintypes` module provides quite some other Windows specific data types, for example `HWND`, `WPARAM`, or `DWORD`. Some useful structures like `MSG` or `RECT` are also defined.

Structured data types

class `ctypes.Union(*args, **kw)`

Abstract base class for unions in native byte order.

class `ctypes.BigEndianStructure(*args, **kw)`

Abstract base class for structures in *big endian* byte order.

class `ctypes.LittleEndianStructure(*args, **kw)`

Abstract base class for structures in *little endian* byte order.

Structures with non-native byte order cannot contain pointer type fields, or any other data types containing pointer type fields.

class `ctypes.Structure(*args, **kw)`

Abstract base class for structures in *native* byte order.

Concrete structure and union types must be created by subclassing one of these types, and at least define a `__fields__` class variable. `ctypes` will create *descriptors* which allow reading and writing the fields by direct attribute accesses. These are the

`__fields__`

A sequence defining the structure fields. The items must be 2-tuples or 3-tuples. The first item is the name of the field, the second item specifies the type of the field; it can be any `ctypes` data type.

For integer type fields like `c_int`, a third optional item can be given. It must be a small positive integer defining the bit width of the field.

Field names must be unique within one structure or union. This is not checked, only one field can be accessed when names are repeated.

It is possible to define the `__fields__` class variable *after* the class statement that defines the Structure subclass, this allows creating data types that directly or indirectly reference themselves:

```
class List(Structure):
    pass
List.__fields__ = [("pNext", POINTER(List)),
                  ...
                  ]
```

The `__fields__` class variable must, however, be defined before the type is first used (an instance is created, `sizeof()` is called on it, and so on). Later assignments to the `__fields__` class variable will raise an `AttributeError`.

It is possible to defined sub-subclasses of structure types, they inherit the fields of the base class plus the `__fields__` defined in the sub-subclass, if any.

`__pack__`

An optional small integer that allows overriding the alignment of structure fields in the instance. `__pack__` must already be defined when `__fields__` is assigned, otherwise it will have no effect.

`__anonymous__`

An optional sequence that lists the names of unnamed (anonymous) fields. `__anonymous__` must be already defined when `__fields__` is assigned, otherwise it will have no effect.

The fields listed in this variable must be structure or union type fields. `ctypes` will create descriptors in the structure type that allows accessing the nested fields directly, without the need to create the structure or union field.

Here is an example type (Windows):

```
class _U(Union):
    __fields__ = [("lptdesc", POINTER(TYPEDESC)),
                  ("lpadesc", POINTER(ARRAYDESC)),
                  ("hreftype", HREFTYPE)]

class TYPEDESC(Structure):
    __anonymous__ = ("u",)
    __fields__ = [("u", _U),
                  ("vt", VARTYPE)]
```

The `TYPEDESC` structure describes a COM data type, the `vt` field specifies which one of the union fields is valid. Since the `u` field is defined as anonymous field, it is now possible to access the members directly off the `TYPEDESC` instance. `td.lptdesc` and `td.u.lptdesc` are equivalent, but the former is faster since it does not need to create a temporary union instance:

```
td = TYPEDESC()
td.vt = VT_PTR
td.lptdesc = POINTER(some_type)
td.u.lptdesc = POINTER(some_type)
```

It is possible to defined sub-subclasses of structures, they inherit the fields of the base class. If the subclass definition has a separate `__fields__` variable, the fields specified in this are appended to the fields of the base class.

Structure and union constructors accept both positional and keyword arguments. Positional arguments are used to initialize member fields in the same order as they are appear in `__fields__`. Keyword arguments in the constructor are interpreted as attribute assignments, so they will initialize `__fields__` with the same name, or create new attributes for names not present in `__fields__`.

Arrays and pointers

class `ctypes.Array(*args)`

Abstract base class for arrays.

The recommended way to create concrete array types is by multiplying any `ctypes` data type with a positive integer. Alternatively, you can subclass this type and define `__length__` and `__type__` class variables. Array elements can be read and written using standard subscript and slice accesses; for slice reads, the resulting object is *not* itself an `Array`.

__length__

A positive integer specifying the number of elements in the array. Out-of-range subscripts result in an `IndexError`. Will be returned by `len()`.

__type__

Specifies the type of each element in the array.

Array subclass constructors accept positional arguments, used to initialize the elements in order.

class `ctypes._Pointer`

Private, abstract base class for pointers.

Concrete pointer types are created by calling `POINTER()` with the type that will be pointed to; this is done automatically by `pointer()`.

If a pointer points to an array, its elements can be read and written using standard subscript and slice accesses. Pointer objects have no size, so `len()` will raise `TypeError`. Negative subscripts will read from the memory *before* the pointer (as in C), and out-of-range subscripts will probably crash with an access violation (if you're lucky).

__type__

Specifies the type pointed to.

contents

Returns the object to which to pointer points. Assigning to this attribute changes the pointer to point to the assigned object.

并发执行

本章中描述的模块支持并发执行代码。适当的工具选择取决于要执行的任务（CPU 密集型或 IO 密集型）和偏好的开发风格（事件驱动的协作式多任务或抢占式多任务处理）。这是一个概述：

17.1 threading — 基于线程的并行

源代码: [Lib/threading.py](#)

这个模块在较低级的模块 `_thread` 基础上建立较高级的线程接口。参见: `queue` 模块。

The `dummy_threading` module is provided for situations where `threading` cannot be used because `_thread` is missing.

注解：虽然他们没有在下面列出，这个模块仍然支持 Python 2.x 系列的这个模块下以 camelCase（驼峰法）命名的方法和函数。

这个模块定义了以下函数：

`threading.active_count()`

返回当前存活的线程类 `Thread` 对象。返回的计数等于 `enumerate()` 返回的列表长度。

`threading.current_thread()`

返回当前对应调用者的控制线程的 `Thread` 对象。如果调用者的控制线程不是利用 `threading` 创建，会返回一个功能受限的虚拟线程对象。

`threading.get_ident()`

返回当前线程的“线程标识符”。它是一个非零的整数。它的值没有直接含义，主要是用作 magic cookie，比如作为含有线程相关数据的字典的索引。线程标识符可能会在线程退出，新线程创建时被复用。

3.3 新版功能.

`threading.enumerate()`

以列表形式返回当前所有存活的`Thread`对象。该列表包含守护线程, `current_thread()` 创建的虚拟线程对象和主线程。它不包含已终结的线程和尚未开始的线程。

`threading.main_thread()`

返回主`Thread`对象。一般情况下, 主线程是 Python 解释器开始时创建的线程。

3.4 新版功能.

`threading.settrace(func)`

为所有`threading`模块开始的线程设置追踪函数。在每个线程的`run()`方法被调用前, `func`会被传递给`sys.settrace()`。

`threading.setprofile(func)`

为所有`threading`模块开始的线程设置性能测试函数。在每个线程的`run()`方法被调用前, `func`会被传递给`sys.setprofile()`。

`threading.stack_size([size])`

Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, a `RuntimeError` is raised. If the specified stack size is invalid, a `ValueError` is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability: Windows, systems with POSIX threads.

这个模块同时定义了以下常量:

`threading.TIMEOUT_MAX`

阻塞函数 (`Lock.acquire()`, `RLock.acquire()`, `Condition.wait()`, ...) 中形参 *timeout* 允许的最大值。传入超过这个值的 *timeout* 会抛出 `OverflowError` 异常。

3.2 新版功能.

这个模块定义了许多类, 详见以下部分。

该模块的设计基于 Java 的线程模型。但是, 在 Java 里面, 锁和条件变量是每个对象的基础特性, 而在 Python 里面, 这些被独立成了单独的对象。Python 的`Thread`类只是 Java 的 `Thread` 类的一个子集; 目前还没有优先级, 没有线程组, 线程还不能被销毁、停止、暂停、恢复或中断。Java 的 `Thread` 类的静态方法在实现时会映射为模块级函数。

下列描述的方法都是自动执行的。

17.1.1 线程本地数据

线程本地数据是特定线程的数据。管理线程本地数据, 只需要创建一个`local` (或者一个子类型) 的实例并在实例中储存属性:

```
mydata = threading.local()
mydata.x = 1
```

在不同的线程中, 实例的值会不同。

class `threading.local`

一个代表线程本地数据的类。

更多相关细节和大量示例, 参见 `_threading_local` 模块的文档。

17.1.2 线程对象

The `Thread` class represents an activity that is run in a separate thread of control. There are two ways to specify the activity: by passing a callable object to the constructor, or by overriding the `run()` method in a subclass. No other methods (except for the constructor) should be overridden in a subclass. In other words, *only* override the `__init__()` and `run()` methods of this class.

当线程对象一旦被创建，其活动一定会因调用线程的 `start()` 方法开始。这会在独立的控制线程调用 `run()` 方法。

一旦线程活动开始，该线程会被认为是‘存活的’。当它的 `run()` 方法终结了（不管是正常的还是抛出未被处理的异常），就不是‘存活的’。`is_alive()` 方法用于检查线程是否存活。

其他线程可以调用一个线程的 `join()` 方法。这会阻塞调用该方法的线程，直到被调用 `join()` 方法的线程终结。

线程有名字。名字可以传递给构造函数，也可以通过 `name` 属性读取或者修改。

一个线程可以被标记成一个“守护线程”。这个标志的意义是，只有守护线程都终结，整个 Python 程序才会退出。初始值继承于创建线程。这个标志可以通过 `daemon` 特征属性或者 守护构造函数参数来设置。

注解：守护线程在程序关闭时会突然关闭。他们的资源（例如已经打开的文档，数据库事务等等）可能没有被正确释放。如果你想你的线程正常停止，设置他们成为非守护模式并且使用合适的信号机制，例如：`Event`。

有个“主线程”对象；这对应 Python 程序里面初始的控制线程。它不是一个守护线程。

“虚拟线程对象”是可以被创建的。这些是对应于“外部线程”的线程对象，它们是在线程模块外部启动的控制线程，例如直接来自 C 代码。虚拟线程对象功能受限；他们总是被认为是存活的和守护模式，不能被 `join()`。因为无法检测外来线程的终结，它们永远不会被删除。

```
class threading.Thread(group=None, target=None, name=None, args=(), kwargs={}, *, daemon=None)
```

调用这个构造函数时，必需带有关键字参数。参数如下：

`group` 应该为 `None`；为了日后扩展 `ThreadGroup` 类实现而保留。

`target` 是用于 `run()` 方法调用的可调用对象。默认是 `None`，表示不需要调用任何方法。

`name` 是线程名称。默认情况下，由“Thread-*N*”格式构成一个唯一的名称，其中 *N* 是小的十进制数。

`args` 是用于调用目标函数的参数元组。默认是 `()`。

`kwargs` 是用于调用目标函数的关键字参数字典。默认是 `{}`。

如果不是 `None`，线程将被显式的设置为 守护模式，不管该线程是否是守护模式。如果是 `None`（默认值），线程将继承当前线程的守护模式属性。

如果子类型重载了构造函数，它一定要确保在做任何事前，先发起调用基类构造器 (`Thread.__init__()`)。

在 3.3 版更改：加入 `daemon` 参数。

start()

开始线程活动。

它在一个线程里最多只能被调用一次。它安排对象的 `run()` 方法在一个独立的控制进程中调用。

如果同一个线程对象中调用这个方法的次数大于一次，会抛出 `RuntimeError`。

run()

代表线程活动的方法。

You may override this method in a subclass. The standard `run()` method invokes the callable object passed to the object's constructor as the *target* argument, if any, with sequential and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

join (timeout=None)

等待，直到线程终结。这会阻塞调用这个方法的线程，直到被调用`join()`的线程终结 – 不管是正常终结还是抛出未处理异常 – 或者直到发生超时，超时选项是可选的。

当 *timeout* 参数存在而且不是 `None` 时，它应该是一个用于指定操作超时的以秒为单位的浮点数（或者分数）。因为`join()`总是返回 `None`，所以你一定要在`join()`后调用`is_alive()`才能判断是否发生超时 – 如果线程仍然存活，则`join()`超时。

当 *timeout* 参数不存在或者是 `None`，这个操作会阻塞直到线程终结。

一个线程可以被`join()`很多次。

如果尝试加入当前线程会导致死锁，`join()`会引起`RuntimeError`异常。如果尝试`join()`一个尚未开始的线程，也会抛出相同的异常。

name

只用于识别的字符串。它没有语义。多个线程可以赋予相同的名称。初始名称由构造函数设置。

getName ()

setName ()

旧的`name`取值/设值 API；直接当做特征属性使用它。

ident

这个线程的‘线程标识符’，如果线程尚未开始则为 `None`。这是个非零整数。参见`get_ident()`函数。当一个线程退出而另外一个线程被创建，线程标识符会被复用。即使线程退出后，仍可得到标识符。

is_alive ()

返回线程是否存活。

当`run()`方法刚开始直到`run()`方法刚结束，这个方法返回 `True`。模块函数`enumerate()`返回包含所有存活线程的列表。

daemon

一个表示这个线程是 (`True`) 否 (`False`) 守护线程的布尔值。一定要在调用`start()`前设置好，否则会抛出`RuntimeError`。初始值继承于创建线程；主线程不是守护线程，因此主线程创建的所有线程默认都是`daemon=False`。

当没有存活的非守护线程时，整个 Python 程序才会退出。

isDaemon ()

setDaemon ()

旧的`name`取值/设值 API；建议直接当做特征属性使用它。

CPython implementation detail: CPython 下，因为`Global Interpreter Lock`，一个时刻只有一个线程可以执行 Python 代码（尽管如此，某些性能导向的库可能会克服这个限制）。如果你想让你的应用更好的利用多核计算机的计算性能，推荐你使用`multiprocessing`或者`concurrent.futures.ProcessPoolExecutor`。但是如果你想同时运行多个 I/O 绑定任务，线程仍然是一个合适的模型。

17.1.3 锁对象

原始锁是一个在锁定时不属于特定线程的同步基元组件。在 Python 中，它是能用的最低级的同步基元组件，由`_thread`扩展模块直接实现。

原始锁处于“锁定”或者“非锁定”两种状态之一。它被创建时为非锁定状态。它有两个基本方法，`acquire()`和`release()`。当状态为非锁定时，`acquire()`将状态改为锁定并立即返回。当状态是锁定时，`acquire()`

将阻塞至其他线程调用 `release()` 将其改为非锁定状态，然后 `acquire()` 调用重置其为锁定状态并返回。`release()` 只在锁定状态下调用；它将状态改为非锁定并立即返回。如果尝试释放一个非锁定的锁，则会引发 `RuntimeError` 异常。

锁同样支持上下文管理协议。

当多个线程在 `acquire()` 等待状态转变为未锁定被阻塞，然后 `release()` 重置状态为未锁定时，只有一个线程能继续执行；至于哪个等待线程继续执行没有定义，并且会根据实现而不同。

所有方法都是自动执行的。

class `threading.Lock`

实现原始锁对象的类。一旦一个线程获得一个锁，会阻塞随后尝试获得锁的线程，直到它被释放；任何线程都可以释放它。

需要注意的是 `Lock` 其实是一个工厂函数，返回平台支持的具体锁类中最有效的版本的实例。

acquire (*blocking=True, timeout=-1*)

可以阻塞或非阻塞地获得锁。

当调用时参数 *blocking* 设置为 `True`（缺省值），阻塞直到锁被释放，然后将锁锁定并返回 `True`。

在参数 *blocking* 被设置为 `False` 的情况下调用，将不会发生阻塞。如果调用时 *blocking* 设为 `True` 会阻塞，并立即返回 `False`；否则，将锁锁定并返回 `True`。

当浮点型 *timeout* 参数被设置为正值调用时，只要无法获得锁，将最多阻塞 *timeout* 设定的秒数。*timeout* 参数被设置为 `-1` 时将无限等待。当 *blocking* 为 `false` 时，*timeout* 指定的值将被忽略。

如果成功获得锁，则返回 `True`，否则返回 `False`（例如发生 超时的时候）。

在 3.2 版更改：新的 *timeout* 形参。

在 3.2 版更改：现在如果底层线程实现支持，则可以通过 POSIX 上的信号中断锁的获取。

release ()

释放一个锁。这个方法可以在任何线程中调用，不单指获得锁的线程。

当锁被锁定，将它重置为未锁定，并返回。如果其他线程正在等待这个锁解锁而被阻塞，只允许其中一个允许。

在未锁定的锁调用时，会引发 `RuntimeError` 异常。

没有返回值。

17.1.4 递归锁对象

重入锁是一个可以被同一个线程多次获取的同步基元组件。在内部，它在基元锁的锁定/非锁定状态上附加了“所属线程”和“递归等级”的概念。在锁定状态下，某些线程拥有锁；在非锁定状态下，没有线程拥有它。

若要锁定锁，线程调用其 `acquire()` 方法；一旦线程拥有了锁，方法将返回。若要解锁，线程调用 `release()` 方法。`acquire()/release()` 对可以嵌套；只有最终 `release()`（最外面一对的 `release()`）将锁解开，才能让其他线程继续处理 `acquire()` 阻塞。

递归锁也支持上下文管理协议。

class `threading.RLock`

此类实现了重入锁对象。重入锁必须由获取它的线程释放。一旦线程获得了重入锁，同一个线程再次获取它将不阻塞；线程必须在每次获取它时释放一次。

需要注意的是 `RLock` 其实是一个工厂函数，返回平台支持的具体递归锁类中最有效的版本的实例。

acquire (*blocking=True, timeout=-1*)

可以阻塞或非阻塞地获得锁。

当无参数调用时：如果这个线程已经拥有锁，递归级别增加一，并立即返回。否则，如果其他线程拥有该锁，则阻塞至该锁解锁。一旦锁被解锁（不属于任何线程），则抢夺所有权，设置递归等级为一，并返回。如果多个线程被阻塞，等待锁被解锁，一次只有一个线程能抢到锁的所有权。在这种情况下，没有返回值。

当调用时参数 *blocking* 设置为 `True`，和没带参数调用一样做同样的事，然后返回 `True`。

当 *blocking* 参数设置为 `false` 的情况下调用，不进行阻塞。如果一个无参数的调用已经阻塞，立即返回 `false`；否则，执行和无参数调用一样的操作，并返回 `true`。

当浮点数 *timeout* 参数被设置为正值调用时，只要无法获得锁，将最多阻塞 *timeout* 设定的秒数。如果锁被获取返回 `true`，如果超时返回 `false`。

在 3.2 版更改：新的 *timeout* 形参。

`release()`

释放锁，自减递归等级。如果减到零，则将锁重置为非锁定状态（不被任何线程拥有），并且，如果其他线程正被阻塞着等待锁被解锁，则仅允许其中一个线程继续。如果自减后，递归等级仍然不是零，则锁保持锁定，仍由调用线程拥有。

只有当前线程拥有锁才能调用这个方法。如果锁被释放后调用这个方法，会引起 `RuntimeError` 异常。

没有返回值。

17.1.5 条件对象

条件变量总是与某种类型的锁对象相关联，锁对象可以通过传入获得，或者在缺省的情况下自动创建。当多个条件变量需要共享同一个锁时，传入一个锁很有用。锁是条件对象的一部分，你不必单独地跟踪它。

条件变量服从上下文管理协议：使用 `with` 语句会在它包围的代码块内获取关联的锁。`acquire()` 和 `release()` 方法也能调用关联锁的相关方法。

其它方法必须在持有关联的锁的情况下调用。`wait()` 方法释放锁，然后阻塞直到其它线程调用 `notify()` 方法或 `notify_all()` 方法唤醒它。一旦被唤醒，`wait()` 方法重新获取锁并返回。它也可以指定超时时间。

The `notify()` method wakes up one of the threads waiting for the condition variable, if any are waiting. The `notify_all()` method wakes up all threads waiting for the condition variable.

注意：`notify()` 方法和 `notify_all()` 方法并不会释放锁，这意味着被唤醒的线程不会立即从它们的 `wait()` 方法调用中返回，而是会在调用了 `notify()` 方法或 `notify_all()` 方法的线程最终放弃了锁的所有权后返回。

使用条件变量的典型编程风格是将锁用于同步某些共享状态的权限，那些对状态的某些特定改变感兴趣的线程，它们重复调用 `wait()` 方法，直到看到所期望的改变发生；而对于修改状态的线程，它们将当前状态改变为可能是等待者所期待的新状态后，调用 `notify()` 方法或者 `notify_all()` 方法。例如，下面的代码是一个通用的无限缓冲区容量的生产者-消费者情形：

```
# Consume one item
with cv:
    while not an_item_is_available():
        cv.wait()
    get_an_available_item()

# Produce one item
with cv:
    make_an_item_available()
    cv.notify()
```

使用 `while` 循环检查所要求的条件成立与否是有必要的，因为 `wait()` 方法可能要经过不确定长度的时间后才会返回，而此时导致 `notify()` 方法调用的那个条件可能已经不再成立。这是多线程编程所固有的问题。`wait_for()` 方法可自动化条件检查，并简化超时计算。

```
# Consume an item
with cv:
    cv.wait_for(an_item_is_available)
    get_an_available_item()
```

选择 `notify()` 还是 `notify_all()`，取决于一次状态改变是只能被一个还是能被多个等待线程所用。例如在一个典型的生产者-消费者情形中，添加一个项目到缓冲区只需唤醒一个消费者线程。

class `threading.Condition` (`lock=None`)

实现条件变量对象的类。一个条件变量对象允许一个或多个线程在被其它线程所通知之前进行等待。

如果给出了非 `None` 的 `lock` 参数，则它必须为 `Lock` 或者 `RLock` 对象，并且它将被用作底层锁。否则，将会创建新的 `RLock` 对象，并将其用作底层锁。

在 3.3 版更改：从工厂函数变为类。

acquire (`*args`)

请求底层锁。此方法调用底层锁的相应方法，返回值是底层锁相应方法的返回值。

release ()

释放底层锁。此方法调用底层锁的相应方法。没有返回值。

wait (`timeout=None`)

等待直到被通知或发生超时。如果线程在调用此方法时没有获得锁，将会引发 `RuntimeError` 异常。

这个方法释放底层锁，然后阻塞，直到在另外一个线程中调用同一个条件变量的 `notify()` 或 `notify_all()` 唤醒它，或者直到可选的超时发生。一旦被唤醒或者超时，它重新获得锁并返回。

当提供了 `timeout` 参数且不是 `None` 时，它应该是一个浮点数，代表操作的超时时间，以秒为单位（可以为小数）。

当底层锁是个 `RLock`，不会使用它的 `release()` 方法释放锁，因为当它被递归多次获取时，实际上可能无法解锁。相反，使用了 `RLock` 类的内部接口，即使多次递归获取它也能解锁它。然后，在重新获取锁时，使用另一个内部接口来恢复递归级别。

返回 `True`，除非提供的 `timeout` 过期，这种情况下返回 `False`。

在 3.2 版更改：很明显，方法总是返回 `None`。

wait_for (`predicate, timeout=None`)

等待，直到条件计算为真。`predicate` 应该是一个可调用对象而且它的返回值可被解释为一个布尔值。可以提供 `timeout` 参数给出最大等待时间。

这个实用方法会重复地调用 `wait()` 直到满足判断式或者发生超时。返回值是判断式最后一个返回值，而且如果方法发生超时会返回 `False`。

忽略超时功能，调用此方法大致相当于编写：

```
while not predicate():
    cv.wait()
```

因此，规则同样适用于 `wait()`：锁必须在被调用时保持获取，并在返回时重新获取。随着锁定执行判断式。

3.2 新版功能。

notify(*n*=1)

默认唤醒一个等待这个条件的线程。如果调用线程在没有获得锁的情况下调用这个方法，会引发 `RuntimeError` 异常。

这个方法唤醒最多 *n* 个正在等待这个条件变量的线程；如果没有线程在等待，这是一个空操作。

当前实现中，如果至少有 *n* 个线程正在等待，准确唤醒 *n* 个线程。但是依赖这个行为并不安全。未来，优化的实现有时会唤醒超过 *n* 个线程。

注意：被唤醒的线程实际上不会返回它调用的 `wait()`，直到它可以重新获得锁。因为 `notify()` 不会释放锁，只有它的调用者应该这样做。

notify_all()

唤醒所有正在等待这个条件的线程。这个方法行为与 `notify()` 相似，但并不只唤醒单一线程，而是唤醒所有等待线程。如果调用线程在调用这个方法时没有获得锁，会引发 `RuntimeError` 异常。

17.1.6 信号量对象

这是计算机科学史上最古老的同步原语之一，早期的荷兰科学家 Edsger W. Dijkstra 发明了它。（他使用名称 `P()` 和 `V()` 而不是 `acquire()` 和 `release()`）。

一个信号量管理一个内部计数器，该计数器因 `acquire()` 方法的调用而递减，因 `release()` 方法的调用而递增。计数器的值永远不会小于零；当 `acquire()` 方法发现计数器为零时，将会阻塞，直到其它线程调用 `release()` 方法。

信号量对象也支持上下文管理协议。

class threading.Semaphore(*value*=1)

该类实现信号量对象。信号量对象管理一个原子性的计数器，代表 `release()` 方法的调用次数减去 `acquire()` 的调用次数再加上一个初始值。如果需要，`acquire()` 方法将会阻塞直到可以返回而不会使得计数器变成负数。在没有显式给出 *value* 的值时，默认为 1。

可选参数 *value* 赋予内部计数器初始值，默认值为 1。如果 *value* 被赋予小于 0 的值，将会引发 `ValueError` 异常。

在 3.3 版更改：从工厂函数变为类。

acquire(*blocking*=True, *timeout*=None)

获取一个信号量。

在不带参数的情况下调用时：

- 如果在进入时，内部计数器的值大于 0，将其减 1 并立即返回 `true`。
- 如果在进入时，内部计数器的值为 0，将会阻塞直到被 `release()` 方法的调用唤醒。一旦被唤醒（并且计数器值大于 0），将计数器值减少 1 并返回 `true`。线程会被每次 `release()` 方法的调用唤醒。线程被唤醒的次序是不确定的。

在参数 *blocking* 被设置为 `false` 的情况下调用，将不会发生阻塞。如果不带参数的调用会发生阻塞的话，带参数的调用在相同情况下将会立即返回 `false`。否则，执行和不带参数的调用一样的操作并返回 `true`。

当参数 *timeout* 不为 `None` 时，将最多阻塞 *timeout* 秒。如果未能在时间间隔内成功获取信号量，将返回 `false`，否则返回 `true`。

在 3.2 版更改：新的 *timeout* 形参。

release()

释放一个信号量，将内部计数器的值增加 1。当计数器原先的值为 0 且有其它线程正在等待它再次大于 0 时，唤醒正在等待的线程。

class `threading.BoundedSemaphore` (*value=1*)

该类实现有界信号量。有界信号量通过检查以确保它当前的值不会超过初始值。如果超过了初始值，将会引发 `ValueError` 异常。在大多情况下，信号量用于保护数量有限的资源。如果信号量被释放的次数过多，则表明出现了错误。没有指定时，*value* 的值默认为 1。

在 3.3 版更改: 从工厂函数变为类。

Semaphore 例子

信号量通常用于保护数量有限的资源，例如数据库服务器。在资源数量固定的任何情况下，都应该使用有界信号量。在生成任何工作线程前，应该在主线程中初始化信号量。

```
maxconnections = 5
# ...
pool_sema = BoundedSemaphore(value=maxconnections)
```

工作线程生成后，当需要连接服务器时，这些线程将调用信号量的 `acquire` 和 `release` 方法：

```
with pool_sema:
    conn = connectdb()
    try:
        # ... use connection ...
    finally:
        conn.close()
```

使用有界信号量能减少这种编程错误：信号量的释放次数多于其请求次数。

17.1.7 事件对象

这是线程之间通信的最简单机制之一：一个线程发出事件信号，而其他线程等待该信号。

一个事件对象管理一个内部标志，调用 `set()` 方法可将其设置为 `true`，调用 `clear()` 方法可将其设置为 `false`，调用 `wait()` 方法将进入阻塞直到标志为 `true`。

class `threading.Event`

实现事件对象的类。事件对象管理一个内部标志，调用 `set()` 方法可将其设置为 `true`。调用 `clear()` 方法可将其设置为 `false`。调用 `wait()` 方法将进入阻塞直到标志为 `true`。这个标志初始时为 `false`。

在 3.3 版更改: 从工厂函数变为类。

is_set()

当且仅当内部标志为 `true` 时返回 `true`。

set()

将内部标志设置为 `true`。所有正在等待这个事件的线程将被唤醒。当标志为 `true` 时，调用 `wait()` 方法的线程不会被阻塞。

clear()

将内部标志设置为 `false`。之后调用 `wait()` 方法的线程将会被阻塞，直到调用 `set()` 方法将内部标志再次设置为 `true`。

wait (*timeout=None*)

阻塞线程直到内部变量为 `true`。如果调用时内部标志为 `true`，将立即返回。否则将阻塞线程，直到调用 `set()` 方法将标志设置为 `true` 或者发生可选的超时。

当提供了 `timeout` 参数且不是 `None` 时，它应该是一个浮点数，代表操作的超时时间，以秒为单位（可以为小数）。

当内部标志在调用 `wait` 进入阻塞后被设置为 `true`，或者调用 `wait` 时已经被设置为 `true` 时，方法返回 `true`。也就是说，除非设定了超时且发生了超时的情况下将会返回 `false`，其他情况该方法都将返回 `True`。

在 3.1 版更改：很明显，方法总是返回 `None`。

17.1.8 定时器对象

此类表示一个操作应该在等待一定的时间之后运行—相当于一个定时器。`Timer` 类是 `Thread` 类的子类，因此可以像一个自定义线程一样工作。

与线程一样，通过调用 `start()` 方法启动定时器。而 `cancel()` 方法可以停止计时器（在计时结束前），定时器在执行其操作之前等待的时间间隔可能与用户指定的时间间隔不完全相同。

例如：

```
def hello():
    print("hello, world")

t = Timer(30.0, hello)
t.start()  # after 30 seconds, "hello, world" will be printed
```

class `threading.Timer` (*interval*, *function*, *args=None*, *kwargs=None*)

创建一个定时器，在经过 *interval* 秒的间隔事件后，将会用参数 *args* 和关键字参数 *kwargs* 调用 *function*。如果 *args* 为 `None`（默认值），则会使用一个空列表。如果 *kwargs* 为 `None`（默认值），则会使用一个空字典。

在 3.3 版更改：从工厂函数变为类。

cancel()

停止定时器并取消执行计时器将要执行的操作。仅当计时器仍处于等待状态时有效。

17.1.9 栅栏对象

3.2 新版功能。

栅栏类提供一个简单的同步原语，用于应对固定数量的线程需要彼此相互等待的情况。线程调用 `wait()` 方法后将阻塞，直到所有线程都调用了 `wait()` 方法。此时所有线程将被同时释放。

栅栏对象可以被多次使用，但进程的数量不能改变。

这是一个使用简便的方法实现客户端进程与服务端进程同步的例子：

```
b = Barrier(2, timeout=5)

def server():
    start_server()
    b.wait()
    while True:
        connection = accept_connection()
        process_server_connection(connection)

def client():
    b.wait()
    while True:
        connection = make_connection()
        process_client_connection(connection)
```

class `threading.Barrier` (*parties*, *action=None*, *timeout=None*)

创建一个需要 *parties* 个线程的栅栏对象。如果提供了可调用的 *action* 参数，它会在所有线程被释放时在其中一个线程中自动调用。*timeout* 是默认的超时时间，如果没有在 `wait()` 方法中指定超时时间的话。

wait (*timeout=None*)

冲出栅栏。当栅栏中所有线程都已经调用了这个函数，它们将同时被释放。如果提供了 *timeout* 参数，这里的 *timeout* 参数优先于创建栅栏对象时提供的 *timeout* 参数。

函数返回值是一个整数，取值范围在 0 到 *parties* - 1，在每个线程中的返回值不相同。可用于从所有线程中选择唯一的一个线程执行一些特别的工作。例如：

```
i = barrier.wait()
if i == 0:
    # Only one thread needs to print this
    print("passed the barrier")
```

如果创建栅栏对象时在构造函数中提供了 *action* 参数，它将在其中一个线程释放前被调用。如果此调用引发了异常，栅栏对象将进入损坏态。

如果发生了超时，栅栏对象将进入破损态。

如果栅栏对象进入破损态，或重置栅栏时仍有线程等待释放，将会引发 `BrokenBarrierError` 异常。

reset ()

重置栅栏为默认的初始态。如果栅栏中仍有线程等待释放，这些线程将会收到 `BrokenBarrierError` 异常。

注意使用此函数时，如果有某些线程状态未知，则可能需其它的同步来确保线程已被释放。如果栅栏进入了破损态，最好废弃它并新建一个栅栏。

abort ()

使栅栏进入破损态。这将导致所有已经调用和未来调用的 `wait()` 方法中引发 `BrokenBarrierError` 异常。使用这个方法的一种情况是需要中止程序以避免死锁。

更好的方式是：创建栅栏时提供一个合理的超时时间，来自动避免某个线程出错。

parties

冲出栅栏所需要的线程数量。

n_waiting

当前时刻正在栅栏中阻塞的线程数量。

broken

一个布尔值，值为 `True` 表明栅栏为破损态。

exception `threading.BrokenBarrierError`

异常类，是 `RuntimeError` 异常的子类，在 `Barrier` 对象重置时仍有线程阻塞时和对象进入破损态时被引发。

17.1.10 Using locks, conditions, and semaphores in the with statement

这个模块提供的带有 `acquire()` 和 `release()` 方法的对象，可以被用作 `with` 语句的上下文管理器。当进入语句块时 `acquire()` 方法会被调用，退出语句块时 `release()` 会被调用。因此，以下片段：

```
with some_lock:
    # do something...
```

相当于：

```
some_lock.acquire()
try:
    # do something...
finally:
    some_lock.release()
```

现在`Lock`、`RLock`、`Condition`、`Semaphore`和`BoundedSemaphore`对象可以用作`with`语句的上下文管理器。

17.2 multiprocessing — 基于进程的并行

源代码 `Lib/multiprocessing/`

17.2.1 概述

`multiprocessing` 是一个用与`threading` 模块相似 API 的支持产生进程的包。`multiprocessing` 包同时提供本地和远程并发，使用子进程代替线程，有效避免`Global Interpreter Lock` 带来的影响。因此，`multiprocessing` 模块允许程序员充分利用机器上的多个核心。Unix 和 Windows 上都可以运行。

`multiprocessing` 模块还引入了在`threading` 模块中没有类似物的 API。这方面的一个主要例子是`Pool` 对象，它提供了一种方便的方法，可以跨多个输入值并行化函数的执行，跨进程分配输入数据（数据并行）。以下示例演示了在模块中定义此类函数的常见做法，以便子进程可以成功导入该模块。这个数据并行的基本例子使用`Pool`，

```
from multiprocessing import Pool

def f(x):
    return x*x

if __name__ == '__main__':
    with Pool(5) as p:
        print(p.map(f, [1, 2, 3]))
```

将打印到标准输出

```
[1, 4, 9]
```

Process 类

在`multiprocessing` 中，通过创建一个`Process` 对象然后调用它的 `start()` 方法来生成进程。`Process` 和`threading.Thread` API 相同。一个简单的多进程序序示例是：

```
from multiprocessing import Process

def f(name):
    print('hello', name)

if __name__ == '__main__':
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

要显示所涉及的所有进程 ID，这是一个扩展示例：

```
from multiprocessing import Process
import os

def info(title):
    print(title)
    print('module name:', __name__)
    print('parent process:', os.getppid())
    print('process id:', os.getpid())

def f(name):
    info('function f')
    print('hello', name)

if __name__ == '__main__':
    info('main line')
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

为了解释为什么 `if __name__ == '__main__':` 部分是必需的，请参见 *Programming guidelines*。

上下文和启动方法

根据不同的平台，*multiprocessing* 支持三种启动进程的方法。这些启动方法有

spawn 父进程启动一个新的 Python 解释器进程。子进程只会继承那些运行进程对象的 *run()* 方法所需的资源。特别是父进程中非必须的文件描述符和句柄不会被继承。相对于使用 *fork* 或者 *forkserver*，使用这个方法启动进程相当慢。

可在 Unix 和 Windows 上使用。Windows 上的默认设置。

fork 父进程使用 *os.fork()* 来产生 Python 解释器分叉。子进程在开始时实际上与父进程相同。父进程的所有资源都由子进程继承。请注意，安全分叉多线程进程是棘手的。

只存在于 Unix。Unix 中的默认值。

forkserver 程序启动并选择 * *forkserver* * 启动方法时，将启动服务器进程。从那时起，每当需要一个新进程时，父进程就会连接到服务器并请求它分叉一个新进程。分叉服务器进程是单线程的，因此使用 *os.fork()* 是安全的。没有不必要的资源被继承。

可在 Unix 平台上使用，支持通过 Unix 管道传递文件描述符。

在 3.4 版更改：*spawn* 在所有 unix 平台上添加，并且为一些 unix 平台添加了 *forkserver*。子进程不再继承 Windows 上的所有上级进程可继承的句柄。

在 Unix 上使用 *spawn* 或 *forkserver* 启动方法也将启动一个信号量跟踪器进程，该进程跟踪由程序进程创建的未链接的命名信号量。当所有进程退出时，信号量跟踪器取消链接任何剩余的信号量。通常不应该有，但如果一个进程被信号杀死，可能会有一些“泄露”的信号量。（取消链接命名的信号量是一个严重的问题，因为系统只允许有限的数量，并且在下次重新启动之前它们不会自动取消链接。）

要选择一个启动方法，你应该在主模块的 `if __name__ == '__main__':` 子句中调用 *set_start_method()*。例如：

```
import multiprocessing as mp

def foo(q):
    q.put('hello')
```

(下页继续)

(续上页)

```

if __name__ == '__main__':
    mp.set_start_method('spawn')
    q = mp.Queue()
    p = mp.Process(target=foo, args=(q,))
    p.start()
    print(q.get())
    p.join()

```

在程序中 `set_start_method()` 不应该被多次调用。

或者，你可以使用 `get_context()` 来获取上下文对象。上下文对象与多处理模块具有相同的 API，并允许在同一程序中使用多个启动方法。：

```

import multiprocessing as mp

def foo(q):
    q.put('hello')

if __name__ == '__main__':
    ctx = mp.get_context('spawn')
    q = ctx.Queue()
    p = ctx.Process(target=foo, args=(q,))
    p.start()
    print(q.get())
    p.join()

```

请注意，与一个上下文相关的对象可能与不同上下文的进程不兼容。特别是，使用 `fork` 上下文创建的锁不能传递给使用 `spawn` 或 `forkserver` 启动方法启动的进程。

想要使用特定启动方法的库应该使用 `get_context()` 以避免干扰库用户的选择。

在进程之间交换对象

`multiprocessing` 支持进程之间的两种通信通道：

队列

`Queue` 类是一个近似 `queue.Queue` 的克隆。例如：

```

from multiprocessing import Process, Queue

def f(q):
    q.put([42, None, 'hello'])

if __name__ == '__main__':
    q = Queue()
    p = Process(target=f, args=(q,))
    p.start()
    print(q.get())    # prints "[42, None, 'hello']"
    p.join()

```

队列是线程和进程安全的。

管道

`Pipe()` 函数返回一个由管道连接的连接对象，默认情况下是双工（双向）。例如：

```

from multiprocessing import Process, Pipe

def f(conn):
    conn.send([42, None, 'hello'])
    conn.close()

if __name__ == '__main__':
    parent_conn, child_conn = Pipe()
    p = Process(target=f, args=(child_conn,))
    p.start()
    print(parent_conn.recv())    # prints "[42, None, 'hello']"
    p.join()

```

返回的两个连接对象`Pipe()`表示管道的两端。每个连接对象都有`send()`和`recv()`方法（相互之间的）。请注意，如果两个进程（或线程）同时尝试读取或写入管道的同一端，则管道中的数据可能会损坏。当然，同时使用管道的不同端的进程不存在损坏的风险。

进程之间的同步

`multiprocessing` 包含来自`threading`的所有同步基本体的等价物。例如，可以使用锁来确保一次只有一个进程打印到标准输出：

```

from multiprocessing import Process, Lock

def f(l, i):
    l.acquire()
    try:
        print('hello world', i)
    finally:
        l.release()

if __name__ == '__main__':
    lock = Lock()

    for num in range(10):
        Process(target=f, args=(lock, num)).start()

```

不使用来自不同进程的锁输出容易产生混淆。

在进程之间共享状态

如上所述，在进行并发编程时，通常最好尽量避免使用共享状态。使用多个进程时尤其如此。

但是，如果你真的需要使用一些共享数据，那么`multiprocessing`提供了两种方法。

共享内存

可以使用`Value`或`Array`将数据存储在共享内存映射中。例如，以下代码：

```

from multiprocessing import Process, Value, Array

def f(n, a):
    n.value = 3.1415927
    for i in range(len(a)):
        a[i] = -a[i]

```

(下页继续)

(续上页)

```

if __name__ == '__main__':
    num = Value('d', 0.0)
    arr = Array('i', range(10))

    p = Process(target=f, args=(num, arr))
    p.start()
    p.join()

    print(num.value)
    print(arr[:])

```

将打印

```

3.1415927
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]

```

创建 `num` 和 `arr` 时使用的 `'d'` 和 `'i'` 参数是 `array` 模块使用的类型的 `typecode`：`'d'` 表示双精度浮点数，`'i'` 表示有符号整数。这些共享对象将是进程和线程安全的。

为了更灵活地使用共享内存，可以使用 `multiprocessing.sharedctypes` 模块，该模块支持创建从共享内存分配的任意 `ctypes` 对象。

服务器进程

由 `Manager()` 返回的管理器对象控制一个服务器进程，该进程保存 Python 对象并允许其他进程使用代理操作它们。

`Manager()` 返回的管理器支持类型：`list`、`dict`、`Namespace`、`Lock`、`RLock`、`Semaphore`、`BoundedSemaphore`、`Condition`、`Event`、`Barrier`、`Queue`、`Value` 和 `Array`。例如

```

from multiprocessing import Process, Manager

def f(d, l):
    d[1] = '1'
    d['2'] = 2
    d[0.25] = None
    l.reverse()

if __name__ == '__main__':
    with Manager() as manager:
        d = manager.dict()
        l = manager.list(range(10))

        p = Process(target=f, args=(d, l))
        p.start()
        p.join()

        print(d)
        print(l)

```

将打印

```

{0.25: None, 1: '1', '2': 2}
[9, 8, 7, 6, 5, 4, 3, 2, 1, 0]

```

服务器进程管理器比使用共享内存对象更灵活，因为它们可以支持任意对象类型。此外，单个管理器可以通过网络由不同计算机上的进程共享。但是，它们比使用共享内存慢。

使用工作进程

`Pool` 类表示一个工作进程池。它具有允许以几种不同方式将任务分配到工作进程的方法。

例如:

```
from multiprocessing import Pool, TimeoutError
import time
import os

def f(x):
    return x*x

if __name__ == '__main__':
    # start 4 worker processes
    with Pool(processes=4) as pool:

        # print "[0, 1, 4,..., 81]"
        print(pool.map(f, range(10)))

        # print same numbers in arbitrary order
        for i in pool.imap_unordered(f, range(10)):
            print(i)

        # evaluate "f(20)" asynchronously
        res = pool.apply_async(f, (20,)) # runs in *only* one process
        print(res.get(timeout=1))        # prints "400"

        # evaluate "os.getpid()" asynchronously
        res = pool.apply_async(os.getpid, ()) # runs in *only* one process
        print(res.get(timeout=1))          # prints the PID of that process

        # launching multiple evaluations asynchronously *may* use more processes
        multiple_results = [pool.apply_async(os.getpid, ()) for i in range(4)]
        print([res.get(timeout=1) for res in multiple_results])

        # make a single worker sleep for 10 secs
        res = pool.apply_async(time.sleep, (10,))
        try:
            print(res.get(timeout=1))
        except TimeoutError:
            print("We lacked patience and got a multiprocessing.TimeoutError")

        print("For the moment, the pool remains available for more work")

    # exiting the 'with'-block has stopped the pool
    print("Now the pool is closed and no longer available")
```

请注意，池的方法只能由创建它的进程使用。

注解：该软件包中的功能要求子项可以导入 `__main__` 模块。这包含在 *Programming guidelines* 中，但值得指出。这意味着一些示例，例如 `multiprocessing.pool.Pool` 示例在交互式解释器中不起作用。例如：

```
>>> from multiprocessing import Pool
>>> p = Pool(5)
>>> def f(x):
...     return x*x
```

(下页继续)

(续上页)

```

...
>>> p.map(f, [1,2,3])
Process PoolWorker-1:
Process PoolWorker-2:
Process PoolWorker-3:
Traceback (most recent call last):
AttributeError: 'module' object has no attribute 'f'
AttributeError: 'module' object has no attribute 'f'
AttributeError: 'module' object has no attribute 'f'

```

(如果你尝试这个，它实际上会以半随机的方式输出三个完整的回溯，然后你可能不得不以某种方式停止主进程。)

17.2.2 参考

`multiprocessing` 包大部分复制了 `threading` 模块的 API。

Process 和异常

class multiprocessing.**Process** (*group=None, target=None, name=None, args=(), kwargs={}, *, daemon=None*)

进程对象表示在单独进程中运行的活动。`Process` 类等价于 `threading.Thread`。

应始终使用关键字参数调用构造函数。`group` 应该始终是 `None`；它仅用于兼容 `threading.Thread`。`target` 是由 `run()` 方法调用的可调用对象。它默认为 `None`，意味着什么都没有被调用。`name` 是进程名称（有关详细信息，请参阅 `name`）。`args` 是目标调用的参数元组。`kwargs` 是目标调用的关键字参数字典。如果提供，则键参数 `daemon` 将进程 `daemon` 标志设置为 `True` 或 `False`。如果是 `None`（默认值），则该标志将从创建的进程继承。

默认情况下，不会将任何参数传递给 `target`。

如果子类重写构造函数，它必须确保它在对进程执行任何其他操作之前调用基类构造函数 (`Process.__init__()`)。

在 3.3 版更改：加入 `daemon` 参数。

run()

表示进程活动的方法。

你可以在子类中重载此方法。标准 `run()` 方法调用传递给对象构造函数的可调用对象作为目标参数（如果有），分别从 `args` 和 `kwargs` 参数中获取顺序和关键字参数。

start()

启动进程活动。

每个进程对象最多只能调用一次。它安排对象的 `run()` 方法在一个单独的进程中调用。

join([*timeout*])

如果可选参数 `timeout` 是 `None`（默认值），则该方法将阻塞，直到调用 `join()` 方法的进程终止。如果 `timeout` 是一个正数，它最多会阻塞 `timeout` 秒。请注意，如果进程终止或方法超时，则该方法返回 `None`。检查进程的 `exitcode` 以确定它是否终止。

一个进程可以合并多次。

进程无法并入自身，因为这会导致死锁。尝试在启动进程之前合并进程是错误的。

name

进程的名称。该名称是一个字符串，仅用于识别目的。它没有语义。可以为多个进程指定相同的名称。

初始名称由构造器设定。如果没有为构造器提供显式名称，则会构造一个形式为 ‘Process-N₁:N₂:...:N_k’ 的名称，其中每个 N_k 是其父亲的第 N 个孩子。

is_alive()

返回进程是否还活着。

粗略地说，从 `start()` 方法返回到子进程终止之前，进程对象仍处于活动状态。

daemon

进程的守护标志，一个布尔值。这必须在 `start()` 被调用之前设置。

初始值继承自创建进程。

当进程退出时，它会尝试终止其所有守护进程子进程。

请注意，不允许守护进程创建子进程。否则，守护进程会在子进程退出时终止其子进程。另外，这些 **不是** Unix 守护进程或服务，它们是正常进程，如果非守护进程已经退出，它们将被终止（并且不被合并）。

除了 `threading.Thread` API，`Process` 对象还支持以下属性和方法：

pid

返回进程 ID。在生成该进程之前，这将是 `None`。

exitcode

的退子进程出代码。如果进程尚未终止，这将是 `None`。负值 `-N` 表示孩子被信号 `N` 终止。

authkey

进程的身份验证密钥（字节字符串）。

当 `multiprocessing` 初始化时，主进程使用 `os.urandom()` 分配一个随机字符串。

当创建 `Process` 对象时，它将继承其父进程的身份验证密钥，尽管可以通过将 `authkey` 设置为另一个字节字符串来更改。

参见 *Authentication keys*。

sentinel

系统对象的数字句柄，当进程结束时将变为 “ready”。

如果要使用 `multiprocessing.connection.wait()` 一次等待多个事件，可以使用此值。否则调用 `join()` 更简单。

在 Windows 上，这是一个操作系统句柄，可以与 `WaitForSingleObject` 和 `WaitForMultipleObjects` 系列 API 调用一起使用。在 Unix 上，这是一个文件描述符，可以使用来自 `select` 模块的原语。

3.3 新版功能。

terminate()

终止进程。在 Unix 上，这是使用 `SIGTERM` 信号完成的；在 Windows 上使用 `TerminateProcess()`。请注意，不会执行退出处理程序和 `finally` 子句等。

请注意，进程的后代进程将不会被终止——它们将简单地变成孤立的。

警告： 如果在关联进程使用管道或队列时使用此方法，则管道或队列可能会损坏，并可能无法被其他进程使用。类似地，如果进程已获得锁或信号量等，则终止它可能导致其他进程死锁。

注意`start()`、`join()`、`is_alive()`、`terminate()`和`exitcode`方法只能由创建进程对象的进程调用。

Process 一些方法的示例用法：

```
>>> import multiprocessing, time, signal
>>> p = multiprocessing.Process(target=time.sleep, args=(1000,))
>>> print(p, p.is_alive())
<Process(Process-1, initial)> False
>>> p.start()
>>> print(p, p.is_alive())
<Process(Process-1, started)> True
>>> p.terminate()
>>> time.sleep(0.1)
>>> print(p, p.is_alive())
<Process(Process-1, stopped[SIGTERM])> False
>>> p.exitcode == -signal.SIGTERM
True
```

exception `multiprocessing.ProcessError`

所有`multiprocessing`异常的基类。

exception `multiprocessing.BufferTooShort`

当提供的缓冲区对象太小而无法读取消息时，`Connection.recv_bytes_into()`引发的异常。

如果 `e` 是一个 `BufferTooShort` 实例，那么 `e.args[0]` 将把消息作为字节字符串给出。

exception `multiprocessing.AuthenticationError`

出现身份验证错误时引发。

exception `multiprocessing.TimeoutError`

有超时的方法超时引发。

管道和队列

使用多进程时，一般使用消息机制实现进程间通信，尽可能避免使用同步原语，例如锁。

消息机制包含：`Pipe()`（可以用于在两个进程间传递消息），以及队列（能够在多个生产者和消费者之间通信）。

The `Queue`, `SimpleQueue` and `JoinableQueue` types are multi-producer, multi-consumer FIFO queues modelled on the `queue.Queue` class in the standard library. They differ in that `Queue` lacks the `task_done()` and `join()` methods introduced into Python 2.5's `queue.Queue` class.

如果你使用了 `JoinableQueue`，那么你 ** 必须 ** 对每个已经移出队列的任务调用 `JoinableQueue.task_done()`。不然的话用于统计未完成任务的信号量最终会溢出并抛出异常。

另外还可以通过使用一个管理器对象创建一个共享队列，详见 *Managers*。

注解： `multiprocessing` 使用了普通的 `queue.Empty` 和 `queue.Full` 异常去表示超时。你需要从 `queue` 中导入它们，因为它们并不在 `multiprocessing` 的命名空间中。

注解： 当一个对象被放入一个队列中时，这个对象首先会被一个后台线程用 `pickle` 序列化，并将序列化后的数据通过一个底层管道的管道传递到队列中。这种做法会有点让人惊讶，但一般不会出现什么问题。如果它们确实妨碍了你，你可以使用一个由管理器 *manager* 创建的队列替换它。

- (1) 将一个对象放入一个空队列后，可能需要极小的延迟，队列的方法`empty()` 才会返回`False`。而`get_nowait()` 可以不抛出`queue.Empty` 直接返回。
- (2) 如果有多个进程同时将对象放入队列，那么在队列的另一端接受到的对象可能是无序的。但是由同一个进程放入的多个对象的顺序在另一端输出时总是一样的。

警告： 如果一个进程通过调用`Process.terminate()` 或`os.kill()` 在尝试使用`Queue` 期间被终止了，那么队列中的数据很可能被破坏。这可能导致其他进程在尝试使用该队列时遇到异常。

警告： 正如刚才提到的，如果一个子进程将一些对象放进队列中 (并且它没有用`JoinableQueue.cancel_join_thread` 方法)，那么这个进程在所有缓冲区的对象被刷新进管道之前，是不会终止的。

这意味着，除非你确定所有放入队列中的对象都已经被消费了，否则如果你试图等待这个进程，你可能会陷入死锁中。相似地，如果该子进程不是后台进程，那么父进程可能在试图等待所有非后台进程退出时挂起。

注意用管理器创建的队列不存在这个问题，详见[Programming guidelines](#)。

该示例 展示了如何使用队列实现进程间通信。

`multiprocessing.Pipe([duplex])`

返回一对 `Connection` 对象 `` (conn1, conn2)`, 分别表示管道的两端。

如果 `duplex` 被置为 `True` (默认值)，那么该管道是双向的。如果 `duplex` 被置为 `False`，那么该管道是单向的，即 `conn1` 只能用于接收消息，而 `conn2` 仅能用于发送消息。

`class multiprocessing.Queue([maxsize])`

返回一个使用一个管道和少量锁和信号量实现的共享队列实例。当一个进程将一个对象放进队列中时，一个写入线程会启动并将对象从缓冲区写入管道中。

一旦超时，将抛出标准库`queue` 模块中常见的异常`queue.Empty` 和`queue.Full`。

除了`task_done()` 和`join()` 之外，`Queue` 实现了标准库类`queue.Queue` 中所有的方法。

`qsize()`

返回队列的大致长度。由于多线程或者多进程的上下文，这个数字是不可靠的。

注意，在 Unix 平台上，例如 Mac OS X，这个方法可能会抛出`NotImplementedError` 异常，因为该平台没有实现 `sem_getvalue()`。

`empty()`

如果队列是空的，返回 `True`，反之返回 `False`。由于多线程或多进程的环境，该状态是不可靠的。

`full()`

如果队列是满的，返回 `True`，反之返回 `False`。由于多线程或多进程的环境，该状态是不可靠的。

`put(obj[, block[, timeout]])`

将 `obj` 放入队列。如果可选参数 `block` 是 `True` (默认值) 而且 `timeout` 是 `None` (默认值)，将会阻塞当前进程，直到有空的缓冲槽。如果 `timeout` 是正数，将会在阻塞了最多 `timeout` 秒之后还是没有可用的缓冲槽时抛出`queue.Full` 异常。反之 (`block` 是 `False` 时)，仅当有可用缓冲槽时才放入对象，否则抛出`queue.Full` 异常 (在这种情形下 `timeout` 参数会被忽略)。

`put_nowait(obj)`

相当于 `put(obj, False)`。

get ([*block*, *timeout*]])

从队列中取出并返回对象。如果可选参数 *block* 是 `True` (默认值) 而且 *timeout* 是 `None` (默认值), 将会阻塞当前进程, 直到队列中出现可用的对象。如果 *timeout* 是正数, 将会在阻塞了最多 *timeout* 秒之后还是没有可用的对象时抛出 `queue.Empty` 异常。反之 (*block* 是 `False` 时), 仅当有可用对象能够取出时返回, 否则抛出 `queue.Empty` 异常 (在这种情形下 *timeout* 参数会被忽略)。

get_nowait ()

相当于 `get(False)`。

`multiprocessing.Queue` 类有一些在 `queue.Queue` 类中没有出现的方法。这些方法在大多数情形下并不是必须的。

close ()

指示当前进程将不会再往队列中放入对象。一旦所有缓冲区中的数据被写入管道之后, 后台的线程会退出。这个方法在队列被 `gc` 回收时会自动调用。

join_thread ()

等待后台线程。这个方法仅在调用了 `close()` 方法之后可用。这会阻塞当前进程, 直到后台线程退出, 确保所有缓冲区中的数据都被写入管道中。

默认情况下, 如果一个不是队列创建者的进程试图退出, 它会尝试等待这个队列的后台线程。这个进程可以使用 `cancel_join_thread()` 让 `join_thread()` 方法什么都不做直接跳过。

cancel_join_thread ()

防止 `join_thread()` 方法阻塞当前进程。具体而言, 这防止进程退出时自动等待后台线程退出。详见 `join_thread()`。

可能这个方法称为 “`allow_exit_without_flush()`” 会更好。这有可能会产生正在排队进入队列的数据丢失, 大多数情况下你不需要用到这个方法, 仅当你不关心底层管道中可能丢失的数据, 只是希望进程能够马上退出时使用。

注解: 该类的功能依赖于宿主操作系统具有可用的共享信号量实现。否则该类将被禁用, 任何试图实例化一个 `Queue` 对象的操作都会抛出 `ImportError` 异常, 更多信息详见 [bpo-3770](#)。后续说明的任何专用队列对象亦如此。

class `multiprocessing.SimpleQueue`

这是一个简化的 `Queue` 类的实现, 很像带锁的 `Pipe`。

empty ()

如果队列为空返回 `True`, 否则返回 `False`。

get ()

从队列中移出并返回一个对象。

put (*item*)

将 *item* 放入队列。

class `multiprocessing.JoinableQueue` ([*maxsize*])

`JoinableQueue` 类是 `Queue` 的子类, 额外添加了 `task_done()` 和 `join()` 方法。

task_done ()

指出之前进入队列的任务已经完成。由队列的消费者进程使用。对于每次调用 `get()` 获取的任务, 执行完成后调用 `task_done()` 告诉队列该任务已经处理完成。

如果 `join()` 方法正在阻塞之中, 该方法会在所有对象都被处理完的时候返回 (即对之前使用 `put()` 放进队列中的所有对象都已经返回了对应的 `task_done()`)。

如果被调用的次数多于放入队列中的项目数量, 将引发 `ValueError` 异常。

join()

阻塞至队列中所有的元素都被接收和处理完毕。

当条目添加到队列的时候，未完成任务的计数就会增加。每当消费者进程调用`task_done()`表示这个条目已经被回收，该条目所有工作已经完成，未完成计数就会减少。当未完成计数降到零的时候，`join()` 阻塞被解除。

杂项**multiprocessing.active_children()**

返回当前进程存活的子进程的列表。

调用该方法有“等待”已经结束的进程的副作用。

multiprocessing.cpu_count()

返回系统的 CPU 数量。

该数量不同于当前进程可以使用的 CPU 数量。可用的 CPU 数量可以由 `len(os.sched_getaffinity(0))` 方法获得。

可能引发`NotImplementedError`。

参见：

`os.cpu_count()`

multiprocessing.current_process()

返回与当前进程相对应的`Process`对象。

和`threading.current_thread()`相同。

multiprocessing.freeze_support()

为使用了`multiprocessing`的程序，提供冻结以产生 Windows 可执行文件的支持。(在 `py2exe`, `PyInstaller` 和 `cx_Freeze` 上测试通过)

需要在 main 模块的 `if __name__ == '__main__':` 该行之后马上调用该函数。例如：

```
from multiprocessing import Process, freeze_support

def f():
    print('hello world!')

if __name__ == '__main__':
    freeze_support()
    Process(target=f).start()
```

如果没有调用 `freeze_support()` 在尝试运行被冻结的可执行文件时会抛出`RuntimeError`异常。

对 `freeze_support()` 的调用在非 Windows 平台上是无效的。如果该模块在 Windows 平台的 Python 解释器中正常运行(该程序没有被冻结)，调用“`freeze_support()`”也是无效的。

multiprocessing.get_all_start_methods()

返回支持的启动方法的列表，该列表的首项即为默认选项。可能的启动方法有 `'fork'`, `'spawn'` 和 `“'forkserver’`”。在 Windows 中，只有 `“'spawn’` 是可用的。Unix 平台总是支持 `“'fork’`”和 `“'spawn’`”，且 `“'fork’` 是默认值。

3.4 新版功能。

multiprocessing.get_context(method=None)

返回一个 Context 对象。该对象具有和`multiprocessing`模块相同的 API。

如果 *method* 设置成 `None` 那么将返回默认上下文对象。否则 *method* 应该是 `'fork'`, `'spawn'`, `'forkserver'`。如果指定的启动方法不存在, 将抛出 `ValueError` 异常。

3.4 新版功能.

`multiprocessing.get_start_method(allow_none=False)`

返回启动进程时使用的启动方法名。

如果启动方法已经固定, 并且 *allow_none* 被设置成 `False`, 那么启动方法将被固定为默认的启动方法, 并且返回其方法名。如果启动方法没有设定, 并且 *allow_none* 被设置成 `True`, 那么将返回 `None`。

返回值将为 `'fork'`, `'spawn'`, `'forkserver'` 或者 `None`。`'fork'` 是 Unix 的默认值, `'spawn'` 是 Windows 的默认值。

3.4 新版功能.

`multiprocessing.set_executable()`

设置在启动子进程时使用的 Python 解释器路径。(默认使用 `sys.executable`) 嵌入式编程人员可能需要这样做:

```
set_executable(os.path.join(sys.exec_prefix, 'pythonw.exe'))
```

以使他们可以创建子进程。

在 3.4 版更改: 现在在 Unix 平台上使用 `'spawn'` 启动方法时支持调用该方法。

`multiprocessing.set_start_method(method)`

设置启动子进程的方法。*method* 可以是 `'fork'`, `'spawn'` 或者 `'forkserver'`。

注意这最多只能调用一次, 并且需要藏在 `main` 模块中, 由 `if __name__ == '__main__':` 保护着。

3.4 新版功能.

注解: `multiprocessing` 并没有包含类似 `threading.active_count()`, `threading.enumerate()`, `threading.settrace()`, `threading.setprofile()`, `threading.Timer`, 或者 `threading.local` 的方法和类。

连接 (Connection) 对象

`Connection` 对象允许收发可以序列化的对象或字符串。它们可以看作面向消息的连接套接字。

通常使用 `Pipe` 创建 `Connection` 对象。详见: [Listeners and Clients](#).

class `multiprocessing.connection.Connection`

send(obj)

将一个对象发送到连接的另一端, 可以用 `recv()` 读取。

The object must be picklable. Very large pickles (approximately 32 MB+, though it depends on the OS) may raise a `ValueError` exception.

recv()

返回一个由另一端使用 `send()` 发送的对象。该方法会一直阻塞直到接收到对象。如果对端关闭了连接或者没有东西可接收, 将抛出 `EOFError` 异常。

fileno()

返回由连接对象使用的描述符或者句柄。

close()

关闭连接对象。

当连接对象被垃圾回收时会自动调用。

poll([timeout])

返回连接对象中是否有可以读取的数据。

如果未指定 *timeout*，此方法会马上返回。如果 *timeout* 是一个数字，则指定了最大阻塞的秒数。如果 *timeout* 是 *None*，那么将一直等待，不会超时。

注意通过使用 `multiprocessing.connection.wait()` 可以一次轮询多个连接对象。

send_bytes(buffer[, offset[, size]])

从一个 *bytes-like object*（字节类对象）对象中取出字节数组并作为一条完整消息发送。

If *offset* is given then data is read from that position in *buffer*. If *size* is given then that many bytes will be read from *buffer*. Very large buffers (approximately 32 MB+, though it depends on the OS) may raise a *ValueError* exception

recv_bytes([maxlength])

以字符串形式返回一条从连接对象另一端发送过来的字节数据。此方法在接收到数据前将一直阻塞。如果连接对象被对端关闭或者没有数据可读取，将抛出 *EOFError* 异常。

如果给定了 *maxlength* 并且消息短于 *maxlength* 那么将抛出 *OSError* 并且该连接对象将不再可读。

在 3.3 版更改：曾经该函数抛出 *IOError*，现在这是 *OSError* 的别名。

recv_bytes_into(buffer[, offset])

将一条完整的字节数据消息读入 *buffer* 中并返回消息的字节数。此方法在接收到数据前将一直阻塞。如果连接对象被对端关闭或者没有数据可读取，将抛出 *EOFError* 异常。

buffer must be a writable *bytes-like object*. If *offset* is given then the message will be written into the buffer from that position. Offset must be a non-negative integer less than the length of *buffer* (in bytes).

如果缓冲区太小，则将引发 *BufferTooShort* 异常，并且完整的消息将会存放在异常实例 *e* 的 *e.args[0]* 中。

在 3.3 版更改：现在连接对象自身可以通过 `Connection.send()` 和 `Connection.recv()` 在进程之间传递。

3.3 新版功能：连接对象现已支持上下文管理协议 – 参见 `see 上下文管理器类型`。`__enter__()` 返回连接对象，`__exit__()` 会调用 `close()`。

例如：

```
>>> from multiprocessing import Pipe
>>> a, b = Pipe()
>>> a.send([1, 'hello', None])
>>> b.recv()
[1, 'hello', None]
>>> b.send_bytes(b'thank you')
>>> a.recv_bytes()
b'thank you'
>>> import array
>>> arr1 = array.array('i', range(5))
>>> arr2 = array.array('i', [0] * 10)
>>> a.send_bytes(arr1)
>>> count = b.recv_bytes_into(arr2)
>>> assert count == len(arr1) * arr1.itemsize
>>> arr2
array('i', [0, 1, 2, 3, 4, 0, 0, 0, 0, 0])
```

警告： The `Connection.recv()` method automatically unpickles the data it receives, which can be a security risk unless you can trust the process which sent the message.

因此，除非连接对象是由 `Pipe()` 产生的，在通过一些认证手段之前你应该只使用 `recv()` 和 `send()` 方法。参考 *Authentication keys*。

警告： 如果一个进程在试图读写管道时被终止了，那么管道中的数据很可能是不完整的，因为此时可能无法确定消息的边界。

同步原语

通常来说同步愿意在多进程环境中并不像它们多线程环境中那么必要。参考 *threading* 模块的文档。

注意可以使用管理器对象创建同步原语，参考 *Managers*。

class multiprocessing.**Barrier** (*parties*[, *action*[, *timeout*]])

类似 *threading.Barrier* 的栅栏对象。

3.3 新版功能。

class multiprocessing.**BoundedSemaphore** ([*value*])

非常类似 *threading.BoundedSemaphore* 的有界信号量对象。

一个小小的不同在于，它的 `acquire` 方法的第一个参数名是和 *Lock.acquire()* 一样的 *block*。

注解： 在 Mac OS X 平台上，该对象于 *Semaphore* 不同在于 `sem_getvalue()` 方法并没有在该平台上实现。

class multiprocessing.**Condition** ([*lock*])

条件变量：*threading.Condition* 的别名。

指定的 *lock* 参数应该是 *multiprocessing* 模块中的 *Lock* 或者 *RLock* 对象。

在 3.3 版更改：新增了 `wait_for()` 方法。

class multiprocessing.**Event**

A clone of *threading.Event*.

class multiprocessing.**Lock**

原始锁（非递归锁）对象，类似于 *threading.Lock*。一旦一个进程或者线程拿到了锁，后续的任何其他进程或线程的其他请求都会被阻塞直到锁被释放。任何进程或线程都可以释放锁。除非另有说明，否则 *multiprocessing.Lock* 用于进程或者线程的概念和行为都和 *threading.Lock* 一致。

注意 *Lock* 实际上是一个工厂函数。它返回由默认上下文初始化的 *multiprocessing.synchronize.Lock* 对象。

Lock supports the *context manager* protocol and thus may be used in `with` statements.

acquire (*block=True*, *timeout=None*)

获得锁，阻塞或非阻塞的。

如果 *block* 参数被设为 `True` (默认值)，对该方法的调用在锁处于释放状态之前都会阻塞，然后将锁设置为锁住状态并返回 `True`。需要注意的是第一个参数名与 *threading.Lock.acquire()* 的不同。

如果 *block* 参数被设置成 `False`，方法的调用将不会阻塞。如果锁当前处于锁住状态，将返回 `False`；否则将锁设置成锁住状态，并返回 `True`。

When invoked with a positive, floating-point value for *timeout*, block for at most the number of seconds specified by *timeout* as long as the lock can not be acquired. Invocations with a negative value for *timeout* are equivalent to a *timeout* of zero. Invocations with a *timeout* value of `None` (the default) set the timeout period to infinite. Note that the treatment of negative or `None` values for *timeout* differs from the implemented behavior in `threading.Lock.acquire()`. The *timeout* argument has no practical implications if the *block* argument is set to `False` and is thus ignored. Returns `True` if the lock has been acquired or `False` if the timeout period has elapsed.

release()

Release a lock. This can be called from any process or thread, not only the process or thread which originally acquired the lock.

Behavior is the same as in `threading.Lock.release()` except that when invoked on an unlocked lock, a `ValueError` is raised.

class multiprocessing.RLock

A recursive lock object: a close analog of `threading.RLock`. A recursive lock must be released by the process or thread that acquired it. Once a process or thread has acquired a recursive lock, the same process or thread may acquire it again without blocking; that process or thread must release it once for each time it has been acquired.

Note that `RLock` is actually a factory function which returns an instance of `multiprocessing.synchronize.RLock` initialized with a default context.

`RLock` supports the *context manager* protocol and thus may be used in `with` statements.

acquire(block=True, timeout=None)

获得锁，阻塞或非阻塞的。

When invoked with the *block* argument set to `True`, block until the lock is in an unlocked state (not owned by any process or thread) unless the lock is already owned by the current process or thread. The current process or thread then takes ownership of the lock (if it does not already have ownership) and the recursion level inside the lock increments by one, resulting in a return value of `True`. Note that there are several differences in this first argument's behavior compared to the implementation of `threading.RLock.acquire()`, starting with the name of the argument itself.

When invoked with the *block* argument set to `False`, do not block. If the lock has already been acquired (and thus is owned) by another process or thread, the current process or thread does not take ownership and the recursion level within the lock is not changed, resulting in a return value of `False`. If the lock is in an unlocked state, the current process or thread takes ownership and the recursion level is incremented, resulting in a return value of `True`.

Use and behaviors of the *timeout* argument are the same as in `Lock.acquire()`. Note that some of these behaviors of *timeout* differ from the implemented behaviors in `threading.RLock.acquire()`.

release()

Release a lock, decrementing the recursion level. If after the decrement the recursion level is zero, reset the lock to unlocked (not owned by any process or thread) and if any other processes or threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling process or thread.

Only call this method when the calling process or thread owns the lock. An `AssertionError` is raised if this method is called by a process or thread other than the owner or if the lock is in an unlocked (un-owned) state. Note that the type of exception raised in this situation differs from the implemented behavior in `threading.RLock.release()`.

class multiprocessing.Semaphore([value])

A semaphore object: a close analog of `threading.Semaphore`.

一个小小的不同在于，它的 `acquire` 方法的第一个参数名是和 `Lock.acquire()` 一样的 `block`。

注解： On Mac OS X, `sem_timedwait` is unsupported, so calling `acquire()` with a timeout will emulate that function's behavior using a sleeping loop.

注解： If the SIGINT signal generated by Ctrl-C arrives while the main thread is blocked by a call to `BoundedSemaphore.acquire()`, `Lock.acquire()`, `RLock.acquire()`, `Semaphore.acquire()`, `Condition.acquire()` or `Condition.wait()` then the call will be immediately interrupted and `KeyboardInterrupt` will be raised.

This differs from the behaviour of `threading` where SIGINT will be ignored while the equivalent blocking calls are in progress.

注解： Some of this package's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the `multiprocessing.synchronize` module will be disabled, and attempts to import it will result in an `ImportError`. See [bpo-3770](#) for additional information.

Shared ctypes Objects

It is possible to create shared objects using shared memory which can be inherited by child processes.

`multiprocessing.Value` (*typecode_or_type*, **args*, *lock=True*)

Return a `ctypes` object allocated from shared memory. By default the return value is actually a synchronized wrapper for the object. The object itself can be accessed via the `value` attribute of a `Value`.

typecode_or_type determines the type of the returned object: it is either a `ctypes` type or a one character typecode of the kind used by the `array` module. **args* is passed on to the constructor for the type.

If *lock* is `True` (the default) then a new recursive lock object is created to synchronize access to the value. If *lock* is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Operations like `+=` which involve a read and write are not atomic. So if, for instance, you want to atomically increment a shared value it is insufficient to just do

```
counter.value += 1
```

Assuming the associated lock is recursive (which it is by default) you can instead do

```
with counter.get_lock():
    counter.value += 1
```

Note that *lock* is a keyword-only argument.

`multiprocessing.Array` (*typecode_or_type*, *size_or_initializer*, *, *lock=True*)

Return a `ctypes` array allocated from shared memory. By default the return value is actually a synchronized wrapper for the array.

typecode_or_type determines the type of the elements of the returned array: it is either a `ctypes` type or a one character typecode of the kind used by the `array` module. If *size_or_initializer* is an integer, then it determines the length of the array, and the array will be initially zeroed. Otherwise, *size_or_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that *lock* is a keyword only argument.

Note that an array of `ctypes.c_char` has *value* and *raw* attributes which allow one to use it to store and retrieve strings.

The `multiprocessing.sharedctypes` module

The `multiprocessing.sharedctypes` module provides functions for allocating `ctypes` objects from shared memory which can be inherited by child processes.

注解: Although it is possible to store a pointer in shared memory remember that this will refer to a location in the address space of a specific process. However, the pointer is quite likely to be invalid in the context of a second process and trying to dereference the pointer from the second process may cause a crash.

`multiprocessing.sharedctypes.RawArray` (*typecode_or_type*, *size_or_initializer*)

Return a `ctypes` array allocated from shared memory.

typecode_or_type determines the type of the elements of the returned array: it is either a `ctypes` type or a one character typecode of the kind used by the `array` module. If *size_or_initializer* is an integer then it determines the length of the array, and the array will be initially zeroed. Otherwise *size_or_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

Note that setting and getting an element is potentially non-atomic – use `Array()` instead to make sure that access is automatically synchronized using a lock.

`multiprocessing.sharedctypes.RawValue` (*typecode_or_type*, **args*)

Return a `ctypes` object allocated from shared memory.

typecode_or_type determines the type of the returned object: it is either a `ctypes` type or a one character typecode of the kind used by the `array` module. **args* is passed on to the constructor for the type.

Note that setting and getting the value is potentially non-atomic – use `Value()` instead to make sure that access is automatically synchronized using a lock.

Note that an array of `ctypes.c_char` has *value* and *raw* attributes which allow one to use it to store and retrieve strings – see documentation for `ctypes`.

`multiprocessing.sharedctypes.Array` (*typecode_or_type*, *size_or_initializer*, *, *lock=True*)

The same as `RawArray()` except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw `ctypes` array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that *lock* is a keyword-only argument.

`multiprocessing.sharedctypes.Value` (*typecode_or_type*, **args*, *lock=True*)

The same as `RawValue()` except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw `ctypes` object.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that *lock* is a keyword-only argument.

`multiprocessing.sharedctypes.copy(obj)`

Return a ctypes object allocated from shared memory which is a copy of the ctypes object *obj*.

`multiprocessing.sharedctypes.synchronized(obj[, lock])`

Return a process-safe wrapper object for a ctypes object which uses *lock* to synchronize access. If *lock* is None (the default) then a `multiprocessing.RLock` object is created automatically.

A synchronized wrapper will have two methods in addition to those of the object it wraps: `get_obj()` returns the wrapped object and `get_lock()` returns the lock object used for synchronization.

Note that accessing the ctypes object through the wrapper can be a lot slower than accessing the raw ctypes object.

在 3.5 版更改: Synchronized objects support the *context manager* protocol.

The table below compares the syntax for creating shared ctypes objects from shared memory with the normal ctypes syntax. (In the table `MyStruct` is some subclass of `ctypes.Structure`.)

ctypes	使用类型的共享 ctypes	使用 typecode 的共享 ctypes
<code>c_double(2.4)</code>	<code>RawValue(c_double, 2.4)</code>	<code>RawValue('d', 2.4)</code>
<code>MyStruct(4, 6)</code>	<code>RawValue(MyStruct, 4, 6)</code>	
<code>(c_short * 7)()</code>	<code>RawArray(c_short, 7)</code>	<code>RawArray('h', 7)</code>
<code>(c_int * 3)(9, 2, 8)</code>	<code>RawArray(c_int, (9, 2, 8))</code>	<code>RawArray('i', (9, 2, 8))</code>

Below is an example where a number of ctypes objects are modified by a child process:

```
from multiprocessing import Process, Lock
from multiprocessing.sharedctypes import Value, Array
from ctypes import Structure, c_double

class Point(Structure):
    _fields_ = [('x', c_double), ('y', c_double)]

def modify(n, x, s, A):
    n.value **= 2
    x.value **= 2
    s.value = s.value.upper()
    for a in A:
        a.x **= 2
        a.y **= 2

if __name__ == '__main__':
    lock = Lock()

    n = Value('i', 7)
    x = Value(c_double, 1.0/3.0, lock=False)
    s = Array('c', b'hello world', lock=lock)
    A = Array(Point, [(1.875, -6.25), (-5.75, 2.0), (2.375, 9.5)], lock=lock)

    p = Process(target=modify, args=(n, x, s, A))
    p.start()
    p.join()

    print(n.value)
    print(x.value)
    print(s.value)
    print([(a.x, a.y) for a in A])
```

The results printed are

```
49
0.11111111111111111
HELLO WORLD
[(3.515625, 39.0625), (33.0625, 4.0), (5.640625, 90.25)]
```

Managers

Managers provide a way to create data which can be shared between different processes, including sharing over a network between processes running on different machines. A manager object controls a server process which manages *shared objects*. Other processes can access the shared objects by using proxies.

`multiprocessing.Manager()`

Returns a started *SyncManager* object which can be used for sharing objects between processes. The returned manager object corresponds to a spawned child process and has methods which will create shared objects and return corresponding proxies.

Manager processes will be shutdown as soon as they are garbage collected or their parent process exits. The manager classes are defined in the `multiprocessing.managers` module:

class `multiprocessing.managers.BaseManager([address[, authkey]])`

Create a BaseManager object.

Once created one should call `start()` or `get_server().serve_forever()` to ensure that the manager object refers to a started manager process.

address is the address on which the manager process listens for new connections. If *address* is `None` then an arbitrary one is chosen.

authkey is the authentication key which will be used to check the validity of incoming connections to the server process. If *authkey* is `None` then `current_process().authkey` is used. Otherwise *authkey* is used and it must be a byte string.

start `([initializer[, initargs]])`

Start a subprocess to start the manager. If *initializer* is not `None` then the subprocess will call `initializer(*initargs)` when it starts.

get_server `()`

Returns a *Server* object which represents the actual server under the control of the Manager. The *Server* object supports the `serve_forever()` method:

```
>>> from multiprocessing.managers import BaseManager
>>> manager = BaseManager(address=(' ', 50000), authkey=b'abc')
>>> server = manager.get_server()
>>> server.serve_forever()
```

Server additionally has an *address* attribute.

connect `()`

Connect a local manager object to a remote manager process:

```
>>> from multiprocessing.managers import BaseManager
>>> m = BaseManager(address=('127.0.0.1', 5000), authkey=b'abc')
>>> m.connect()
```

shutdown `()`

Stop the process used by the manager. This is only available if `start()` has been used to start the server process.

它可以被多次调用。

register (*typeid*[, *callable*[, *proxytype*[, *exposed*[, *method_to_typeid*[, *create_method*]]]]])

A classmethod which can be used for registering a type or callable with the manager class.

typeid is a “type identifier” which is used to identify a particular type of shared object. This must be a string.

callable is a callable used for creating objects for this type identifier. If a manager instance will be connected to the server using the `connect()` method, or if the *create_method* argument is `False` then this can be left as `None`.

proxytype is a subclass of `BaseProxy` which is used to create proxies for shared objects with this *typeid*. If `None` then a proxy class is created automatically.

exposed is used to specify a sequence of method names which proxies for this *typeid* should be allowed to access using `BaseProxy._callmethod()`. (If *exposed* is `None` then `proxytype._exposed_` is used instead if it exists.) In the case where no exposed list is specified, all “public methods” of the shared object will be accessible. (Here a “public method” means any attribute which has a `__call__()` method and whose name does not begin with `'_'`.)

method_to_typeid is a mapping used to specify the return type of those exposed methods which should return a proxy. It maps method names to *typeid* strings. (If *method_to_typeid* is `None` then `proxytype._method_to_typeid_` is used instead if it exists.) If a method’s name is not a key of this mapping or if the mapping is `None` then the object returned by the method will be copied by value.

create_method determines whether a method should be created with name *typeid* which can be used to tell the server process to create a new shared object and return a proxy for it. By default it is `True`.

`BaseManager` instances also have one read-only property:

address

管理器所用的地址。

在 3.3 版更改: Manager objects support the context management protocol – see [上下文管理器类型](#). `__enter__()` starts the server process (if it has not already started) and then returns the manager object. `__exit__()` calls `shutdown()`.

In previous versions `__enter__()` did not start the manager’s server process if it was not already started.

class `multiprocessing.managers.SyncManager`

A subclass of `BaseManager` which can be used for the synchronization of processes. Objects of this type are returned by `multiprocessing.Manager()`.

Its methods create and return 代理对象 for a number of commonly used data types to be synchronized across processes. This notably includes shared lists and dictionaries.

Barrier (*parties*[, *action*[, *timeout*]])

Create a shared `threading.Barrier` object and return a proxy for it.

3.3 新版功能.

BoundedSemaphore ([*value*])

Create a shared `threading.BoundedSemaphore` object and return a proxy for it.

Condition ([*lock*])

Create a shared `threading.Condition` object and return a proxy for it.

If *lock* is supplied then it should be a proxy for a `threading.Lock` or `threading.RLock` object.

在 3.3 版更改: 新增了 `wait_for()` 方法。

Event ()

Create a shared `threading.Event` object and return a proxy for it.

Lock()Create a shared `threading.Lock` object and return a proxy for it.**Namespace()**Create a shared `Namespace` object and return a proxy for it.**Queue([maxsize])**Create a shared `queue.Queue` object and return a proxy for it.**RLock()**Create a shared `threading.RLock` object and return a proxy for it.**Semaphore([value])**Create a shared `threading.Semaphore` object and return a proxy for it.**Array(typecode, sequence)**

Create an array and return a proxy for it.

Value(typecode, value)Create an object with a writable `value` attribute and return a proxy for it.**dict()****dict(mapping)****dict(sequence)**Create a shared `dict` object and return a proxy for it.**list()****list(sequence)**Create a shared `list` object and return a proxy for it.

在 3.6 版更改: Shared objects are capable of being nested. For example, a shared container object such as a shared list can contain other shared objects which will all be managed and synchronized by the `SyncManager`.

class multiprocessing.managers.NamespaceA type that can register with `SyncManager`.

A namespace object has no public methods, but does have writable attributes. Its representation shows the values of its attributes.

However, when using a proxy for a namespace object, an attribute beginning with `'_'` will be an attribute of the proxy and not an attribute of the referent:

```
>>> manager = multiprocessing.Manager()
>>> Global = manager.Namespace()
>>> Global.x = 10
>>> Global.y = 'hello'
>>> Global._z = 12.3      # this is an attribute of the proxy
>>> print(Global)
Namespace(x=10, y='hello')
```

Customized managers

To create one's own manager, one creates a subclass of `BaseManager` and uses the `register()` classmethod to register new types or callables with the manager class. For example:

```
from multiprocessing.managers import BaseManager

class MathsClass:
    def add(self, x, y):
```

(下页继续)

(续上页)

```

        return x + y
    def mul(self, x, y):
        return x * y

class MyManager(BaseManager):
    pass

MyManager.register('Maths', MathsClass)

if __name__ == '__main__':
    with MyManager() as manager:
        maths = manager.Maths()
        print(maths.add(4, 3))          # prints 7
        print(maths.mul(7, 8))         # prints 56

```

Using a remote manager

It is possible to run a manager server on one machine and have clients use it from other machines (assuming that the firewalls involved allow it).

Running the following commands creates a server for a single shared queue which remote clients can access:

```

>>> from multiprocessing.managers import BaseManager
>>> from queue import Queue
>>> queue = Queue()
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=('', 50000), authkey=b'abracadabra')
>>> s = m.get_server()
>>> s.serve_forever()

```

One client can access the server as follows:

```

>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey=b'abracadabra')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.put('hello')

```

Another client can also use it:

```

>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey=b'abracadabra')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.get()
'hello'

```

Local processes can also access that queue, using the code from above on the client to access it remotely:

```

>>> from multiprocessing import Process, Queue
>>> from multiprocessing.managers import BaseManager
>>> class Worker(Process):
...     def __init__(self, q):
...         self.q = q
...         super(Worker, self).__init__()
...     def run(self):
...         self.q.put('local hello')
...
>>> queue = Queue()
>>> w = Worker(queue)
>>> w.start()
>>> class QueueManager(BaseManager): pass
...
>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=('', 50000), authkey=b'abracadabra')
>>> s = m.get_server()
>>> s.serve_forever()

```

代理对象

A proxy is an object which *refers* to a shared object which lives (presumably) in a different process. The shared object is said to be the *referent* of the proxy. Multiple proxy objects may have the same referent.

A proxy object has methods which invoke corresponding methods of its referent (although not every method of the referent will necessarily be available through the proxy). In this way, a proxy can be used just like its referent can:

```

>>> from multiprocessing import Manager
>>> manager = Manager()
>>> l = manager.list([i*i for i in range(10)])
>>> print(l)
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
>>> print(repr(l))
<ListProxy object, typeid 'list' at 0x...>
>>> l[4]
16
>>> l[2:5]
[4, 9, 16]

```

Notice that applying `str()` to a proxy will return the representation of the referent, whereas applying `repr()` will return the representation of the proxy.

An important feature of proxy objects is that they are picklable so they can be passed between processes. As such, a referent can contain 代理对象. This permits nesting of these managed lists, dicts, and other 代理对象:

```

>>> a = manager.list()
>>> b = manager.list()
>>> a.append(b)           # referent of a now contains referent of b
>>> print(a, b)
[<ListProxy object, typeid 'list' at ...>] []
>>> b.append('hello')
>>> print(a[0], b)
['hello'] ['hello']

```

Similarly, dict and list proxies may be nested inside one another:

```
>>> l_outer = manager.list([ manager.dict() for i in range(2) ])
>>> d_first_inner = l_outer[0]
>>> d_first_inner['a'] = 1
>>> d_first_inner['b'] = 2
>>> l_outer[1]['c'] = 3
>>> l_outer[1]['z'] = 26
>>> print(l_outer[0])
{'a': 1, 'b': 2}
>>> print(l_outer[1])
{'c': 3, 'z': 26}
```

If standard (non-proxy) *list* or *dict* objects are contained in a referent, modifications to those mutable values will not be propagated through the manager because the proxy has no way of knowing when the values contained within are modified. However, storing a value in a container proxy (which triggers a `__setitem__` on the proxy object) does propagate through the manager and so to effectively modify such an item, one could re-assign the modified value to the container proxy:

```
# create a list proxy and append a mutable object (a dictionary)
lproxy = manager.list()
lproxy.append({})
# now mutate the dictionary
d = lproxy[0]
d['a'] = 1
d['b'] = 2
# at this point, the changes to d are not yet synced, but by
# updating the dictionary, the proxy is notified of the change
lproxy[0] = d
```

This approach is perhaps less convenient than employing nested 代理对象 for most use cases but also demonstrates a level of control over the synchronization.

注解: The proxy types in *multiprocessing* do nothing to support comparisons by value. So, for instance, we have:

```
>>> manager.list([1,2,3]) == [1,2,3]
False
```

One should just use a copy of the referent instead when making comparisons.

class `multiprocessing.managers.BaseProxy`

Proxy objects are instances of subclasses of *BaseProxy*.

`__callmethod` (*methodname* [, *args* [, *kwargs*]])

Call and return the result of a method of the proxy's referent.

If proxy is a proxy whose referent is *obj* then the expression

```
proxy._callmethod(methodname, args, kwargs)
```

will evaluate the expression

```
getattr(obj, methodname)(*args, **kwargs)
```

in the manager's process.

The returned value will be a copy of the result of the call or a proxy to a new shared object – see documentation for the *method_to_typeid* argument of *BaseManager.register()*.

If an exception is raised by the call, then is re-raised by `_callmethod()`. If some other exception is raised in the manager's process then this is converted into a `RemoteError` exception and is raised by `_callmethod()`.

Note in particular that an exception will be raised if *methodname* has not been *exposed*.

An example of the usage of `_callmethod()`:

```
>>> l = manager.list(range(10))
>>> l._callmethod('__len__')
10
>>> l._callmethod('__getitem__', (slice(2, 7),)) # equivalent to l[2:7]
[2, 3, 4, 5, 6]
>>> l._callmethod('__getitem__', (20,))          # equivalent to l[20]
Traceback (most recent call last):
...
IndexError: list index out of range
```

`_getvalue()`

Return a copy of the referent.

If the referent is unpicklable then this will raise an exception.

`__repr__()`

Return a representation of the proxy object.

`__str__()`

Return the representation of the referent.

Cleanup

A proxy object uses a weakref callback so that when it gets garbage collected it deregisters itself from the manager which owns its referent.

A shared object gets deleted from the manager process when there are no longer any proxies referring to it.

进程池

One can create a pool of processes which will carry out tasks submitted to it with the `Pool` class.

```
class multiprocessing.pool.Pool([processes[, initializer[, initargs[, maxtasksperchild[, context]]]])
```

A process pool object which controls a pool of worker processes to which jobs can be submitted. It supports asynchronous results with timeouts and callbacks and has a parallel map implementation.

processes is the number of worker processes to use. If *processes* is `None` then the number returned by `os.cpu_count()` is used.

If *initializer* is not `None` then each worker process will call `initializer(*initargs)` when it starts.

maxtasksperchild is the number of tasks a worker process can complete before it will exit and be replaced with a fresh worker process, to enable unused resources to be freed. The default *maxtasksperchild* is `None`, which means worker processes will live as long as the pool.

context can be used to specify the context used for starting the worker processes. Usually a pool is created using the function `multiprocessing.Pool()` or the `Pool()` method of a context object. In both cases *context* is set appropriately.

Note that the methods of the pool object should only be called by the process which created the pool.

3.2 新版功能: *maxtasksperchild*

3.4 新版功能: *context*

注解: Worker processes within a *Pool* typically live for the complete duration of the Pool's work queue. A frequent pattern found in other systems (such as Apache, *mod_wsgi*, etc) to free resources held by workers is to allow a worker within a pool to complete only a set amount of work before being exiting, being cleaned up and a new process spawned to replace the old one. The *maxtasksperchild* argument to the *Pool* exposes this ability to the end user.

apply (*func*[, *args*[, *kws*]])

Call *func* with arguments *args* and keyword arguments *kws*. It blocks until the result is ready. Given this blocks, *apply_async()* is better suited for performing work in parallel. Additionally, *func* is only executed in one of the workers of the pool.

apply_async (*func*[, *args*[, *kws*[, *callback*[, *error_callback*]]]])

A variant of the *apply()* method which returns a result object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it, that is unless the call failed, in which case the *error_callback* is applied instead.

If *error_callback* is specified then it should be a callable which accepts a single argument. If the target function fails, then the *error_callback* is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

map (*func*, *iterable*[, *chunksize*])

A parallel equivalent of the *map()* built-in function (it supports only one *iterable* argument though). It blocks until the result is ready.

This method chops the iterable into a number of chunks which it submits to the process pool as separate tasks. The (approximate) size of these chunks can be specified by setting *chunksize* to a positive integer.

map_async (*func*, *iterable*[, *chunksize*[, *callback*[, *error_callback*]]])

A variant of the *map()* method which returns a result object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it, that is unless the call failed, in which case the *error_callback* is applied instead.

If *error_callback* is specified then it should be a callable which accepts a single argument. If the target function fails, then the *error_callback* is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

imap (*func*, *iterable*[, *chunksize*])

A lazier version of *map()*.

The *chunksize* argument is the same as the one used by the *map()* method. For very long iterables using a large value for *chunksize* can make the job complete **much** faster than using the default value of 1.

Also if *chunksize* is 1 then the *next()* method of the iterator returned by the *imap()* method has an optional *timeout* parameter: *next(timeout)* will raise *multiprocessing.TimeoutError* if the result cannot be returned within *timeout* seconds.

imap_unordered (*func*, *iterable*[, *chunksize*])

The same as *imap()* except that the ordering of the results from the returned iterator should be considered arbitrary. (Only when there is only one worker process is the order guaranteed to be "correct".)

starmap (*func*, *iterable*[, *chunksize*])

Like *map()* except that the elements of the *iterable* are expected to be iterables that are unpacked as arguments.

Hence an *iterable* of `[(1, 2), (3, 4)]` results in `[func(1, 2), func(3, 4)]`.

3.3 新版功能.

starmap_async (*func, iterable*[, *chunksize*[, *callback*[, *error_callback*]]])

A combination of `starmap()` and `map_async()` that iterates over *iterable* of iterables and calls *func* with the iterables unpacked. Returns a result object.

3.3 新版功能.

close ()

Prevents any more tasks from being submitted to the pool. Once all the tasks have been completed the worker processes will exit.

terminate ()

Stops the worker processes immediately without completing outstanding work. When the pool object is garbage collected `terminate()` will be called immediately.

join ()

Wait for the worker processes to exit. One must call `close()` or `terminate()` before using `join()`.

3.3 新版功能: Pool objects now support the context management protocol – see 上下文管理器类型. `__enter__()` returns the pool object, and `__exit__()` calls `terminate()`.

class multiprocessing.pool.**AsyncResult**

The class of the result returned by `Pool.apply_async()` and `Pool.map_async()`.

get ([*timeout*])

Return the result when it arrives. If *timeout* is not None and the result does not arrive within *timeout* seconds then `multiprocessing.TimeoutError` is raised. If the remote call raised an exception then that exception will be reraised by `get()`.

wait ([*timeout*])

Wait until the result is available or until *timeout* seconds pass.

ready ()

Return whether the call has completed.

successful ()

Return whether the call completed without raising an exception. Will raise `AssertionError` if the result is not ready.

The following example demonstrates the use of a pool:

```
from multiprocessing import Pool
import time

def f(x):
    return x*x

if __name__ == '__main__':
    with Pool(processes=4) as pool:          # start 4 worker processes
        result = pool.apply_async(f, (10,)) # evaluate "f(10)" asynchronously in a
        ↪ single process
        print(result.get(timeout=1))         # prints "100" unless your computer is
        ↪ *very* slow

        print(pool.map(f, range(10)))       # prints "[0, 1, 4, ..., 81]"

        it = pool.imap(f, range(10))
        print(next(it))                     # prints "0"
```

(下页继续)

(续上页)

```

print(next(it))                # prints "1"
print(it.next(timeout=1))      # prints "4" unless your computer is
↪ *very* slow

result = pool.apply_async(time.sleep, (10,))
print(result.get(timeout=1))    # raises multiprocessing.TimeoutError

```

Listeners and Clients

Usually message passing between processes is done using queues or by using *Connection* objects returned by *Pipe()*.

However, the *multiprocessing.connection* module allows some extra flexibility. It basically gives a high level message oriented API for dealing with sockets or Windows named pipes. It also has support for *digest authentication* using the *hmac* module, and for polling multiple connections at the same time.

multiprocessing.connection.deliver_challenge (*connection*, *authkey*)

Send a randomly generated message to the other end of the connection and wait for a reply.

If the reply matches the digest of the message using *authkey* as the key then a welcome message is sent to the other end of the connection. Otherwise *AuthenticationError* is raised.

multiprocessing.connection.answer_challenge (*connection*, *authkey*)

Receive a message, calculate the digest of the message using *authkey* as the key, and then send the digest back.

If a welcome message is not received, then *AuthenticationError* is raised.

multiprocessing.connection.Client (*address*[, *family*[, *authkey*]])

Attempt to set up a connection to the listener which is using address *address*, returning a *Connection*.

The type of the connection is determined by *family* argument, but this can generally be omitted since it can usually be inferred from the format of *address*. (See *Address Formats*)

If *authkey* is given and not None, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if *authkey* is None. *AuthenticationError* is raised if authentication fails. See *Authentication keys*.

class *multiprocessing.connection.Listener* ([*address*[, *family*[, *backlog*[, *authkey*]]]])

A wrapper for a bound socket or Windows named pipe which is 'listening' for connections.

address is the address to be used by the bound socket or named pipe of the listener object.

注解: If an address of '0.0.0.0' is used, the address will not be a connectable end point on Windows. If you require a connectable end-point, you should use '127.0.0.1'.

family is the type of socket (or named pipe) to use. This can be one of the strings 'AF_INET' (for a TCP socket), 'AF_UNIX' (for a Unix domain socket) or 'AF_PIPE' (for a Windows named pipe). Of these only the first is guaranteed to be available. If *family* is None then the family is inferred from the format of *address*. If *address* is also None then a default is chosen. This default is the family which is assumed to be the fastest available. See *Address Formats*. Note that if *family* is 'AF_UNIX' and *address* is None then the socket will be created in a private temporary directory created using *tempfile.mkstemp()*.

If the listener object uses a socket then *backlog* (1 by default) is passed to the *listen()* method of the socket once it has been bound.

If *authkey* is given and not None, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if *authkey* is None. *AuthenticationError* is raised if authentication fails. See *Authentication keys*.

accept ()

Accept a connection on the bound socket or named pipe of the listener object and return a *Connection* object. If authentication is attempted and fails, then *AuthenticationError* is raised.

close ()

Close the bound socket or named pipe of the listener object. This is called automatically when the listener is garbage collected. However it is advisable to call it explicitly.

Listener objects have the following read-only properties:

address

The address which is being used by the Listener object.

last_accepted

The address from which the last accepted connection came. If this is unavailable then it is *None*.

3.3 新版功能: Listener objects now support the context management protocol – see 上下文管理器类型. `__enter__()` returns the listener object, and `__exit__()` calls `close()`.

`multiprocessing.connection.wait (object_list, timeout=None)`

Wait till an object in *object_list* is ready. Returns the list of those objects in *object_list* which are ready. If *timeout* is a float then the call blocks for at most that many seconds. If *timeout* is *None* then it will block for an unlimited period. A negative timeout is equivalent to a zero timeout.

For both Unix and Windows, an object can appear in *object_list* if it is

- a readable *Connection* object;
- a connected and readable *socket.socket* object; or
- the *sentinel* attribute of a *Process* object.

A connection or socket object is ready when there is data available to be read from it, or the other end has been closed.

Unix: `wait(object_list, timeout)` almost equivalent `select.select(object_list, [], [], timeout)`. The difference is that, if `select.select()` is interrupted by a signal, it can raise *OSError* with an error number of *EINTR*, whereas `wait()` will not.

Windows: An item in *object_list* must either be an integer handle which is waitable (according to the definition used by the documentation of the Win32 function `WaitForMultipleObjects()`) or it can be an object with a `fileno()` method which returns a socket handle or pipe handle. (Note that pipe handles and socket handles are **not** waitable handles.)

3.3 新版功能.

Examples

The following server code creates a listener which uses 'secret password' as an authentication key. It then waits for a connection and sends some data to the client:

```
from multiprocessing.connection import Listener
from array import array

address = ('localhost', 6000)      # family is deduced to be 'AF_INET'

with Listener(address, authkey=b'secret password') as listener:
    with listener.accept() as conn:
        print('connection accepted from', listener.last_accepted)

        conn.send([2.25, None, 'junk', float])
```

(下页继续)

(续上页)

```
conn.send_bytes(b'hello')

conn.send_bytes(array('i', [42, 1729]))
```

The following code connects to the server and receives some data from the server:

```
from multiprocessing.connection import Client
from array import array

address = ('localhost', 6000)

with Client(address, authkey=b'secret password') as conn:
    print(conn.recv())           # => [2.25, None, 'junk', float]

    print(conn.recv_bytes())     # => 'hello'

    arr = array('i', [0, 0, 0, 0, 0])
    print(conn.recv_bytes_into(arr)) # => 8
    print(arr)                   # => array('i', [42, 1729, 0, 0, 0])
```

The following code uses `wait()` to wait for messages from multiple processes at once:

```
import time, random
from multiprocessing import Process, Pipe, current_process
from multiprocessing.connection import wait

def foo(w):
    for i in range(10):
        w.send((i, current_process().name))
    w.close()

if __name__ == '__main__':
    readers = []

    for i in range(4):
        r, w = Pipe(duplex=False)
        readers.append(r)
        p = Process(target=foo, args=(w,))
        p.start()
        # We close the writable end of the pipe now to be sure that
        # p is the only process which owns a handle for it. This
        # ensures that when p closes its handle for the writable end,
        # wait() will promptly report the readable end as being ready.
        w.close()

    while readers:
        for r in wait(readers):
            try:
                msg = r.recv()
            except EOFError:
                readers.remove(r)
            else:
                print(msg)
```

Address Formats

- An 'AF_INET' address is a tuple of the form (hostname, port) where *hostname* is a string and *port* is an integer.
- An 'AF_UNIX' address is a string representing a filename on the filesystem.
- An 'AF_PIPE' address is a string of the form `r'\.\pipe{PipeName}'`. To use `Client()` to connect to a named pipe on a remote computer called *ServerName* one should use an address of the form `r'\ServerName\pipe{PipeName}'` instead.

Note that any string beginning with two backslashes is assumed by default to be an 'AF_PIPE' address rather than an 'AF_UNIX' address.

Authentication keys

When one uses `Connection.recv`, the data received is automatically unpickled. Unfortunately unpickling data from an untrusted source is a security risk. Therefore `Listener` and `Client()` use the `hmac` module to provide digest authentication.

An authentication key is a byte string which can be thought of as a password: once a connection is established both ends will demand proof that the other knows the authentication key. (Demonstrating that both ends are using the same key does **not** involve sending the key over the connection.)

If authentication is requested but no authentication key is specified then the return value of `current_process().authkey` is used (see `Process`). This value will be automatically inherited by any `Process` object that the current process creates. This means that (by default) all processes of a multi-process program will share a single authentication key which can be used when setting up connections between themselves.

Suitable authentication keys can also be generated by using `os.urandom()`.

日志

Some support for logging is available. Note, however, that the `logging` package does not use process shared locks so it is possible (depending on the handler type) for messages from different processes to get mixed up.

`multiprocessing.get_logger()`

Returns the logger used by `multiprocessing`. If necessary, a new one will be created.

When first created the logger has level `logging.NOTSET` and no default handler. Messages sent to this logger will not by default propagate to the root logger.

Note that on Windows child processes will only inherit the level of the parent process' s logger – any other customization of the logger will not be inherited.

`multiprocessing.log_to_stderr()`

This function performs a call to `get_logger()` but in addition to returning the logger created by `get_logger`, it adds a handler which sends output to `sys.stderr` using format `'%(levelname)s/%(processName)s] %(message)s'`.

Below is an example session with logging turned on:

```
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
>>> logger.setLevel(logging.INFO)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
```

(下页继续)

(续上页)

```
>>> m = multiprocessing.Manager()
[INFO/SyncManager-...] child process calling self.run()
[INFO/SyncManager-...] created temp directory /.../pymp-...
[INFO/SyncManager-...] manager serving at '/.../listener-...'
>>> del m
[INFO/MainProcess] sending shutdown message to manager
[INFO/SyncManager-...] manager exiting with exitcode 0
```

For a full table of logging levels, see the *logging* module.

The `multiprocessing.dummy` module

multiprocessing.dummy replicates the API of *multiprocessing* but is no more than a wrapper around the *threading* module.

17.2.3 Programming guidelines

There are certain guidelines and idioms which should be adhered to when using *multiprocessing*.

All start methods

The following applies to all start methods.

Avoid shared state

As far as possible one should try to avoid shifting large amounts of data between processes.

It is probably best to stick to using queues or pipes for communication between processes rather than using the lower level synchronization primitives.

Picklability

Ensure that the arguments to the methods of proxies are picklable.

Thread safety of proxies

Do not use a proxy object from more than one thread unless you protect it with a lock.

(There is never a problem with different processes using the *same* proxy.)

Joining zombie processes

On Unix when a process finishes but has not been joined it becomes a zombie. There should never be very many because each time a new process starts (or *active_children()* is called) all completed processes which have not yet been joined will be joined. Also calling a finished process' s *Process.is_alive* will join the process. Even so it is probably good practice to explicitly join all the processes that you start.

Better to inherit than pickle/unpickle

When using the *spawn* or *forkserver* start methods many types from *multiprocessing* need to be picklable so that child processes can use them. However, one should generally avoid sending shared objects to other processes using pipes or queues. Instead you should arrange the program so that a process which needs access to a shared resource created elsewhere can inherit it from an ancestor process.

Avoid terminating processes

Using the `Process.terminate` method to stop a process is liable to cause any shared resources (such as locks, semaphores, pipes and queues) currently being used by the process to become broken or unavailable to other processes.

Therefore it is probably best to only consider using `Process.terminate` on processes which never use any shared resources.

Joining processes that use queues

Bear in mind that a process that has put items in a queue will wait before terminating until all the buffered items are fed by the “feeder” thread to the underlying pipe. (The child process can call the `Queue.cancel_join_thread` method of the queue to avoid this behaviour.)

This means that whenever you use a queue you need to make sure that all items which have been put on the queue will eventually be removed before the process is joined. Otherwise you cannot be sure that processes which have put items on the queue will terminate. Remember also that non-daemonic processes will be joined automatically.

An example which will deadlock is the following:

```
from multiprocessing import Process, Queue

def f(q):
    q.put('X' * 1000000)

if __name__ == '__main__':
    queue = Queue()
    p = Process(target=f, args=(queue,))
    p.start()
    p.join()                # this deadlocks
    obj = queue.get()
```

A fix here would be to swap the last two lines (or simply remove the `p.join()` line).

Explicitly pass resources to child processes

On Unix using the *fork* start method, a child process can make use of a shared resource created in a parent process using a global resource. However, it is better to pass the object as an argument to the constructor for the child process.

Apart from making the code (potentially) compatible with Windows and the other start methods this also ensures that as long as the child process is still alive the object will not be garbage collected in the parent process. This might be important if some resource is freed when the object is garbage collected in the parent process.

所以对于实例：

```
from multiprocessing import Process, Lock

def f():
    ... do something using "lock" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f).start()
```

应当重写成这样：

```
from multiprocessing import Process, Lock

def f(l):
    ... do something using "l" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f, args=(lock,)).start()
```

Beware of replacing `sys.stdin` with a “file like object”

`multiprocessing` originally unconditionally called:

```
os.close(sys.stdin.fileno())
```

in the `multiprocessing.Process._bootstrap()` method —this resulted in issues with processes-in-processes. This has been changed to:

```
sys.stdin.close()
sys.stdin = open(os.open(os.devnull, os.O_RDONLY), closefd=False)
```

Which solves the fundamental issue of processes colliding with each other resulting in a bad file descriptor error, but introduces a potential danger to applications which replace `sys.stdin()` with a “file-like object” with output buffering. This danger is that if multiple processes call `close()` on this file-like object, it could result in the same data being flushed to the object multiple times, resulting in corruption.

If you write a file-like object and implement your own caching, you can make it fork-safe by storing the pid whenever you append to the cache, and discarding the cache when the pid changes. For example:

```
@property
def cache(self):
    pid = os.getpid()
    if pid != self._pid:
        self._pid = pid
        self._cache = []
    return self._cache
```

For more information, see [bpo-5155](#), [bpo-5313](#) and [bpo-5331](#)

The `spawn` and `forkserver` start methods

There are a few extra restriction which don’t apply to the `fork` start method.

More picklability

Ensure that all arguments to `Process.__init__()` are picklable. Also, if you subclass `Process` then make sure that instances will be picklable when the `Process.start` method is called.

Global variables

Bear in mind that if code run in a child process tries to access a global variable, then the value it sees (if any) may not be the same as the value in the parent process at the time that `Process.start` was called.

However, global variables which are just module level constants cause no problems.

Safe importing of main module

Make sure that the main module can be safely imported by a new Python interpreter without causing unintended side effects (such as starting a new process).

For example, using the *spawn* or *forkserver* start method running the following module would fail with a *RuntimeError*:

```
from multiprocessing import Process

def foo():
    print('hello')

p = Process(target=foo)
p.start()
```

Instead one should protect the “entry point” of the program by using `if __name__ == '__main__':` as follows:

```
from multiprocessing import Process, freeze_support, set_start_method

def foo():
    print('hello')

if __name__ == '__main__':
    freeze_support()
    set_start_method('spawn')
    p = Process(target=foo)
    p.start()
```

(The `freeze_support()` line can be omitted if the program will be run normally instead of frozen.)

This allows the newly spawned Python interpreter to safely import the module and then run the module's `foo()` function.

Similar restrictions apply if a pool or manager is created in the main module.

17.2.4 示例

Demonstration of how to create and use customized managers and proxies:

```
from multiprocessing import freeze_support
from multiprocessing.managers import BaseManager, BaseProxy
import operator

##

class Foo:
    def f(self):
        print('you called Foo.f()')
    def g(self):
        print('you called Foo.g()')
    def _h(self):
        print('you called Foo._h()')

# A simple generator function
def baz():
    for i in range(10):
        yield i*i
```

(下页继续)

(续上页)

```

# Proxy type for generator objects
class GeneratorProxy(BaseProxy):
    _exposed_ = ['__next__']
    def __iter__(self):
        return self
    def __next__(self):
        return self._callmethod('__next__')

# Function to return the operator module
def get_operator_module():
    return operator

##

class MyManager(BaseManager):
    pass

An example showing how to use queues to feed tasks to a collection of worker processes and collect the results:

```
import time
import random

from multiprocessing import Process, Queue, current_process, freeze_support

#
# Function run by worker processes
#

def worker(input, output):
    for func, args in iter(input.get, 'STOP'):
        result = calculate(func, args)
        output.put(result)

#
# Function used to calculate result
#

def calculate(func, args):
    result = func(*args)
    return '%s says that %s%s = %s' % \
        (current_process().name, func.__name__, args, result)

#
# Functions referenced by tasks
#

def mul(a, b):
    time.sleep(0.5*random.random())
    return a * b

def plus(a, b):
    time.sleep(0.5*random.random())
    return a + b

#
#
#

def test():
    NUMBER_OF_PROCESSES = 4
    TASKS1 = [(mul, (i, 7)) for i in range(20)]
    TASKS2 = [(plus, (i, 8)) for i in range(10)]

    # Create queues
    task_queue = Queue()
    done_queue = Queue()

    # Submit tasks
    for task in TASKS1:
```

(下页继续)

(续上页)

```

        task_queue.put(task)

    # Start worker processes
    for i in range(NUMBER_OF_PROCESSES):
        Process(target=worker, args=(task_queue, done_queue)).start()

    # Get and print results
    print('Unordered results:')
    for i in range(len(TASKS1)):
        print('\t', done_queue.get())

    # Add more tasks using `put()`
    for task in TASKS2:
        task_queue.put(task)

    # Get and print some more results
    for i in range(len(TASKS2)):
        print('\t', done_queue.get())

    # Tell child processes to stop
    for i in range(NUMBER_OF_PROCESSES):
        task_queue.put('STOP')

if __name__ == '__main__':
    freeze_support()
    test()

```

17.3 concurrent 包

目前，此包中只有一个模块：

- `concurrent.futures` —— 启动并行任务

17.4 concurrent.futures — 启动并行任务

3.2 新版功能.

源码: `Lib/concurrent/futures/thread.py` 和 `Lib/concurrent/futures/process.py`

`concurrent.futures` 模块提供异步执行回调高层接口。

异步执行可以由 `ThreadPoolExecutor` 使用线程或由 `ProcessPoolExecutor` 使用单独的进程来实现。两者都是实现抽象类 `Executor` 定义的接口。

17.4.1 执行器对象

class `concurrent.futures.Executor`

抽象类提供异步执行调用方法。要通过它的子类调用，而不是直接调用。

submit (*fn*, **args*, ***kwargs*)

调度可调用对象 *fn*，以 *fn*(**args* ***kwargs*) 方式执行并返回 *Future* 对象代表可调用对象的执行。：

```
with ThreadPoolExecutor(max_workers=1) as executor:
    future = executor.submit(pow, 323, 1235)
    print(future.result())
```

map (*func*, **iterables*, *timeout=None*, *chunksize=1*)

类似于 *map(func, *iterables)* 除去：

- 应立即收集 *iterables* 不要延迟再收集；
- *func* 是异步执行的且对 *func* 的调用可以并发执行。

如果 *__next__()* 已被调用且返回的结果在对 *Executor.map()* 的原始调用经过 *timeout* 秒后还不可用，则已返回的迭代器将引发 *concurrent.futures.TimeoutError*。*timeout* 可以为 *int* 或 *float* 类型。如果 *timeout* 未指定或为 *None*，则不限制等待时间。

如果 *func* 调用引发一个异常，当从迭代器中取回它的值时这个异常将被引发。

使用 *ProcessPoolExecutor* 时，这个方法会将 *iterables* 分割任务块并作为独立的的任务并提交到执行池中。这些块的大概数量可以由 *chunksize* 指定正整数设置。对很长的迭代器来说，使用大的 *chunksize* 值比默认值 1 能显著地提高性能。*chunksize* 对 *ThreadPoolExecutor* 没有效果。

在 3.5 版更改：加入 *chunksize* 参数。

shutdown (*wait=True*)

当待执行的期程完成执行后向执行者发送信号，它就会释放正在使用的任何资源。调用 *Executor.submit()* 和 *Executor.submit()* 会在关闭后触发 *RuntimeError*。

如果 *wait* 为 *True* 则此方法只有在所有待执行的期程完成执行且释放已分配的资源后才会返回。如果 *wait* 为 *False*，方法立即返回，所有待执行的期程完成执行后会释放已分配的资源。不管 *wait* 的值是什么，整个 Python 程序将等到所有待执行的期程完成执行后才退出。

如果使用 *with* 语句，你就可以避免显式调用这个方法，它将会停止 *Executor* (就好像 *Executor.shutdown()* 调用时 *wait* 设为 *True* 一样等待)：

```
import shutil
with ThreadPoolExecutor(max_workers=4) as e:
    e.submit(shutil.copy, 'src1.txt', 'dest1.txt')
    e.submit(shutil.copy, 'src2.txt', 'dest2.txt')
    e.submit(shutil.copy, 'src3.txt', 'dest3.txt')
    e.submit(shutil.copy, 'src4.txt', 'dest4.txt')
```

17.4.2 ThreadPoolExecutor

ThreadPoolExecutor 是 *Executor* 的子类，它使用线程池来异步执行调用。

当回调已关联了一个 *Future* 然后再等待另一个 *Future* 的结果时就会发生死锁情况。例如：

```
import time
def wait_on_b():
    time.sleep(5)
    print(b.result()) # b will never complete because it is waiting on a.
    return 5

def wait_on_a():
```

(下页继续)

(续上页)

```

time.sleep(5)
print(a.result()) # a will never complete because it is waiting on b.
return 6

executor = ThreadPoolExecutor(max_workers=2)
a = executor.submit(wait_on_b)
b = executor.submit(wait_on_a)

```

And:

```

def wait_on_future():
    f = executor.submit(pow, 5, 2)
    # This will never complete because there is only one worker thread and
    # it is executing this function.
    print(f.result())

executor = ThreadPoolExecutor(max_workers=1)
executor.submit(wait_on_future)

```

class `concurrent.futures.ThreadPoolExecutor` (*max_workers=None, thread_name_prefix=""*)
Executor 的一个子类，使用最多 *max_workers* 个线程的线程池来异步执行调用。

在 3.5 版更改：如果 *max_workers* 为 `None` 或没有指定，将默认为机器处理器的个数，假如 *ThreadPoolExecutor* 则重于 I/O 操作而不是 CPU 运算，那么可以乘以 5，同时工作线程的数量可以比 *ProcessPoolExecutor* 的数量高。

3.6 新版功能：添加 *thread_name_prefix* 参数允许用户控制由线程池创建的 *threading.Thread* 工作线程名称以方便调试。

ThreadPoolExecutor 例子

```

import concurrent.futures
import urllib.request

URLS = ['http://www.foxnews.com/',
        'http://www.cnn.com/',
        'http://europe.wsj.com/',
        'http://www.bbc.co.uk/',
        'http://some-made-up-domain.com/']

# Retrieve a single page and report the URL and contents
def load_url(url, timeout):
    with urllib.request.urlopen(url, timeout=timeout) as conn:
        return conn.read()

# We can use a with statement to ensure threads are cleaned up promptly
with concurrent.futures.ThreadPoolExecutor(max_workers=5) as executor:
    # Start the load operations and mark each future with its URL
    future_to_url = {executor.submit(load_url, url, 60): url for url in URLS}
    for future in concurrent.futures.as_completed(future_to_url):
        url = future_to_url[future]
        try:
            data = future.result()
        except Exception as exc:

```

(下页继续)

(续上页)

```

        print('%r generated an exception: %s' % (url, exc))
    else:
        print('%r page is %d bytes' % (url, len(data)))

```

17.4.3 ProcessPoolExecutor

ProcessPoolExecutor 是 *Executor* 的子类，它使用进程池来实现异步执行调用。*ProcessPoolExecutor* 使用 *multiprocessing* 回避 *Global Interpreter Lock* 但也意味着只可以处理和返回可序列化的对象。

`__main__` 模块必须可以被工作者子进程导入。这意味着 *ProcessPoolExecutor* 不可以工作在交互式解释器中。

从提交给 *ProcessPoolExecutor* 的回调中调用 *Executor* 或 *Future* 方法会导致死锁。

class `concurrent.futures.ProcessPoolExecutor` (*max_workers=None*)

An *Executor* subclass that executes calls asynchronously using a pool of at most *max_workers* processes. If *max_workers* is `None` or not given, it will default to the number of processors on the machine. If *max_workers* is lower or equal to 0, then a *ValueError* will be raised.

在 3.3 版更改: 如果其中一个工作进程被突然终止, `BrokenProcessPool` 就会马上触发。可预计的行为没有定义, 但执行器上的操作或它的期程会被冻结或死锁。

ProcessPoolExecutor 例子

```

import concurrent.futures
import math

PRIMES = [
    112272535095293,
    112582705942171,
    112272535095293,
    115280095190773,
    115797848077099,
    1099726899285419]

def is_prime(n):
    if n % 2 == 0:
        return False

    sqrt_n = int(math.floor(math.sqrt(n)))
    for i in range(3, sqrt_n + 1, 2):
        if n % i == 0:
            return False
    return True

def main():
    with concurrent.futures.ProcessPoolExecutor() as executor:
        for number, prime in zip(PRIMES, executor.map(is_prime, PRIMES)):
            print('%d is prime: %s' % (number, prime))

if __name__ == '__main__':
    main()

```

17.4.4 期程对象

`Future` 类将可调对象封装为异步执行。`Future` 实例由 `Executor.submit()` 创建。

class `concurrent.futures.Future`

将可调对象封装为异步执行。`Future` 实例由 `Executor.submit()` 创建，除非测试，不应直接创建。

cancel()

Attempt to cancel the call. If the call is currently being executed and cannot be cancelled then the method will return `False`, otherwise the call will be cancelled and the method will return `True`.

cancelled()

如果调用成功取消返回 `True`。

running()

如果调用正在执行而且不能被取消那么返回 `True`。

done()

如果调用已被取消或正常结束那么返回 `True`。

result(timeout=None)

返回调用返回的值。如果调用还没完成那么这个方法将等待 `timeout` 秒。如果在 `timeout` 秒内没有执行完成，`concurrent.futures.TimeoutError` 将会被触发。`timeout` 可以是整数或浮点数。如果 `timeout` 没有指定或为 `None`，那么等待时间就没有限制。

如果 `future` 在完成前被取消则 `CancelledError` 将被触发。

如果调用引发了一个异常，这个方法也会引发同样的异常。

exception(timeout=None)

返回由调用引发的异常。如果调用还没完成那么这个方法将等待 `timeout` 秒。如果在 `timeout` 秒内没有执行完成，`concurrent.futures.TimeoutError` 将会被触发。`timeout` 可以是整数或浮点数。如果 `timeout` 没有指定或为 `None`，那么等待时间就没有限制。

如果 `future` 在完成前被取消则 `CancelledError` 将被触发。

如果调用正常完成那么返回 `None`。

add_done_callback(fn)

附加可调 `fn` 到期程。当期程被取消或完成运行时，将会调用 `fn`，而这个期程将作为它唯一的参数。

加入的可调对象总被属于添加它们的进程中的线程按加入的顺序调用。如果可调对象引发一个 `Exception` 子类，它会被记录下来并被忽略掉。如果可调对象引发一个 `BaseException` 子类，这个行为没有定义。

如果期程已经完成或已取消，`fn` 会被立即调用。

下面这些 `Future` 方法用于单元测试和 `Executor` 实现。

set_running_or_notify_cancel()

这个方法只可以在执行关联 `Future` 工作之前由 `Executor` 实现调用或由单元测试调用。

如果这个方法返回 `False` 那么 `Future` 已被取消，即 `Future.cancel()` 已被调用并返回 `True`。等待 `Future` 完成(即通过 `as_completed()` 或 `wait()`)的线程将被唤醒。

如果这个方法返回 `True` 那么 `Future` 不会被取消并已将它变为正在运行状态，也就是说调用 `Future.running()` 时将返回 `True`。

这个方法只可以被调用一次并且不能在调用 `Future.set_result()` 或 `Future.set_exception()` 之后再调用。

set_result (*result*)

设置将`Future` 关联工作的结果给 *result* 。

这个方法只可以由`Executor` 实现和单元测试使用。

set_exception (*exception*)

设置`Future` 关联工作的结果给`Exception exception` 。

这个方法只可以由`Executor` 实现和单元测试使用。

17.4.5 模块函数

`concurrent.futures.wait` (*fs*, *timeout=None*, *return_when=ALL_COMPLETED*)

Wait for the `Future` instances (possibly created by different `Executor` instances) given by *fs* to complete. Returns a named 2-tuple of sets. The first set, named `done`, contains the futures that completed (finished or were cancelled) before the wait completed. The second set, named `not_done`, contains uncompleted futures.

timeout 可以用来控制返回前最大的等待秒数。*timeout* 可以为 `int` 或 `float` 类型。如果 *timeout* 未指定或为 `None` , 则不限制等待时间。

return_when 指定此函数应在何时返回。它必须为以下常数之一:

常数	描述
<code>FIRST_COMPLETED</code>	函数将在任意可等待对象结束或取消时返回。
<code>FIRST_EXCEPTION</code>	函数将在任意可等待对象因引发异常而结束时返回。当没有引发任何异常时它就相当于 <code>ALL_COMPLETED</code> 。
<code>ALL_COMPLETED</code>	函数将在所有可等待对象结束或取消时返回。

`concurrent.futures.as_completed` (*fs*, *timeout=None*)

Returns an iterator over the `Future` instances (possibly created by different `Executor` instances) given by *fs* that yields futures as they complete (finished or were cancelled). Any futures given by *fs* that are duplicated will be returned once. Any futures that completed before `as_completed()` is called will be yielded first. The returned iterator raises a `concurrent.futures.TimeoutError` if `__next__()` is called and the result isn't available after *timeout* seconds from the original call to `as_completed()`. *timeout* can be an `int` or `float`. If *timeout* is not specified or `None`, there is no limit to the wait time.

参见:

PEP 3148 – futures - 异步执行指令。 该提案描述了 Python 标准库中包含的这个特性。

17.4.6 Exception 类

exception `concurrent.futures.CancelledError`

future 被取消时会触发。

exception `concurrent.futures.TimeoutError`

future 运算超出给定的超时数值时触发。

exception `concurrent.futures.process.BrokenProcessPool`

Derived from `RuntimeError`, this exception class is raised when one of the workers of a `ProcessPoolExecutor` has terminated in a non-clean fashion (for example, if it was killed from the outside).

3.3 新版功能.

17.5 subprocess — 子进程管理

源代码: [Lib/subprocess.py](#)

`subprocess` 模块允许你生成新的进程，连接它们的输入、输出、错误管道，并且获取它们的返回码。此模块打算代替一些老旧的模块与功能：

```
os.system
os.spawn*
```

在下面的段落中，你可以找到关于 `subprocess` 模块如何代替这些模块和功能的相关信息。

参见：

PEP 324 – 提出 `subprocess` 模块的 PEP

17.5.1 使用 `subprocess` 模块

推荐的调用子进程的方式是在任何它支持的用例中使用 `run()` 函数。对于更进阶的用例，也可以使用底层的 `Popen` 接口。

`run()` 函数是在 Python 3.5 被添加的；如果你需要与旧版本保持兼容，查看 [Older high-level API](#) 段落。

`subprocess.run(args, *, stdin=None, input=None, stdout=None, stderr=None, shell=False, cwd=None, timeout=None, check=False, encoding=None, errors=None, env=None)`
运行被 `arg` 描述的指令。等待指令完成，然后返回一个 `CompletedProcess` 示例。

The arguments shown above are merely the most common ones, described below in [常用参数](#) (hence the use of keyword-only notation in the abbreviated signature). The full function signature is largely the same as that of the `Popen` constructor - apart from `timeout`, `input` and `check`, all the arguments to this function are passed through to that interface.

This does not capture stdout or stderr by default. To do so, pass `PIPE` for the `stdout` and/or `stderr` arguments.

`timeout` 参数将被传递给 `Popen.communicate()`。如果发生超时，子进程将被杀死并等待。`TimeoutExpired` 异常将在子进程中断后被抛出。

The `input` argument is passed to `Popen.communicate()` and thus to the subprocess's stdin. If used it must be a byte sequence, or a string if `encoding` or `errors` is specified or `universal_newlines` is true. When used, the internal `Popen` object is automatically created with `stdin=PIPE`, and the `stdin` argument may not be used as well.

如果 `check` 设为 `True`，并且进程以非零状态码退出，一个 `CalledProcessError` 异常将被抛出。这个异常的属性将设置为参数，退出码，以及标准输出和标准错误，如果被捕获到。

If `encoding` or `errors` are specified, or `universal_newlines` is true, file objects for stdin, stdout and stderr are opened in text mode using the specified `encoding` and `errors` or the `io.TextIOWrapper` default. Otherwise, file objects are opened in binary mode.

如果 `env` 不是 `None`，它必须是一个字典，为新的进程设置环境变量；它用于替换继承的当前进程的环境的默认行为。它将直接被传递给 `Popen`。

例如：

```
>>> subprocess.run(["ls", "-l"]) # doesn't capture output
CompletedProcess(args=['ls', '-l'], returncode=0)

>>> subprocess.run("exit 1", shell=True, check=True)
```

(下页继续)

(续上页)

```
Traceback (most recent call last):
...
subprocess.CalledProcessError: Command 'exit 1' returned non-zero exit status 1

>>> subprocess.run(["ls", "-l", "/dev/null"], stdout=subprocess.PIPE)
CompletedProcess(args=['ls', '-l', '/dev/null'], returncode=0,
stdout=b'crw-rw-rw- 1 root root 1, 3 Jan 23 16:23 /dev/null\n')
```

3.5 新版功能.

在 3.6 版更改: 添加了 *encoding* 和 *errors* 形参.

class `subprocess.CompletedProcess`
`run()` 的返回值, 代表一个进程已经结束.

args
 被用作启动进程的参数. 可能是一个列表或字符串.

returncode
 子进程的退出状态码. 通常来说, 一个为 0 的退出码表示进程运行正常.
 一个负值 $-N$ 表示子进程被信号 N 中断 (仅 POSIX).

stdout
 Captured stdout from the child process. A bytes sequence, or a string if `run()` was called with an encoding or errors. None if stdout was not captured.

如果你通过 `stderr=subprocess.STDOUT` 运行, 标准输入和标准错误将被组合在一起, 并且 `stderr`` 将为 None.

stderr
 Captured stderr from the child process. A bytes sequence, or a string if `run()` was called with an encoding or errors. None if stderr was not captured.

check_returncode()
 如果 `returncode` 非零, 抛出 `CalledProcessError`.

3.5 新版功能.

subprocess.DEVNULL
 可被 `Popen` 的 `stdin`, `stdout` 或者 `stderr` 参数使用的特殊值, 表示使用特殊文件 `os.devnull`.

3.3 新版功能.

subprocess.PIPE
 可被 `Popen` 的 `stdin`, `stdout` 或者 `stderr` 参数使用的特殊值, 表示打开标准流的管道. 常用于 `Popen.communicate()`.

subprocess.STDOUT
 可被 `Popen` 的 `stdin`, `stdout` 或者 `stderr` 参数使用的特殊值, 表示标准错误与标准输出使用同一句柄。

exception `subprocess.SubprocessError`
 此模块的其他异常的基类。

3.3 新版功能.

exception `subprocess.TimeoutExpired`
`SubprocessError` 的子类, 等待子进程的过程中发生超时时被抛出。

cmd
 用于创建子进程的指令。

timeout

超时秒数。

output

子进程的输出，如果被`run()`或`check_output()`捕获。否则为`None`。

stdout

对`output`的别名，对应的有`stderr`。

stderr

子进程的标准错误输出，如果被`run()`捕获。否则为`None`。

3.3 新版功能.

在 3.5 版更改: 添加了`stdout`和`stderr`属性。

exception subprocess.CalledProcessError

`SubprocessError` 的子类，当一个被`check_call()`或`check_output()`函数运行的子进程返回了非零退出码时被抛出。

returncode

子进程的退出状态。如果程序由一个信号终止，这将会被设为一个负的信号码。

cmd

用于创建子进程的指令。

output

子进程的输出，如果被`run()`或`check_output()`捕获。否则为`None`。

stdout

对`output`的别名，对应的有`stderr`。

stderr

子进程的标准错误输出，如果被`run()`捕获。否则为`None`。

在 3.5 版更改: 添加了`stdout`和`stderr`属性。

常用参数

为了支持丰富的使用案例，`Popen`的构造函数（以及方便的函数）接受大量可选的参数。对于大多数典型的用例，许多参数可以被安全地留以它们的默认值。通常需要的参数有：

`args` 被所有调用需要，应当为一个字符串，或者一个程序参数序列。提供一个参数序列通常更好，它可以更小心地使用参数中的转义字符以及引用（例如允许文件名中的空格）。如果传递一个简单的字符串，则`shell`参数必须为`True`（见下文）或者该字符串中将被运行的程序名必须用简单的命名而不指定任何参数。

`stdin`、`stdout`和`stderr`分别指定了执行的程序的标准输入、输出和标准错误文件句柄。合法的值有`PIPE`、`DEVNULL`、一个现存的文件描述符（一个正整数）、一个现存的文件对象以及`None`。`PIPE`表示应该新建一个对子进程的管道。`DEVNULL`表示使用特殊的文件`os.devnull`。当使用默认设置`None`时，将不会进行重定向，子进程的文件流将继承自父进程。另外，`stderr`可能为`STDOUT`，表示来自于子进程的标准错误数据应该被`stdout`相同的句柄捕获。

If `encoding` or `errors` are specified, or `universal_newlines` is true, the file objects `stdin`, `stdout` and `stderr` will be opened in text mode using the `encoding` and `errors` specified in the call or the defaults for `io.TextIOWrapper`.

当构造函数的`newline`参数为`None`时。对于`stdin`，输入的换行符`'\n'`将被转换为默认的换行符`os.linesep`。对于`stdout`和`stderr`，所有输出的换行符都被转换为`'\n'`。更多信息，查看`io.TextIOWrapper`类的文档。

如果文本模式未被使用, `stdin`, `stdout` 和 `stderr` 将会以二进制流模式打开。没有编码与换行符转换发生。

3.6 新版功能: 添加了 `encoding` 和 `errors` 形参。

注解: 文件对象 `Popen.stdin`、`Popen.stdout` 和 `Popen.stderr` 的换行符属性不会被 `Popen.communicate()` 方法更新。

如果 `shell` 设为 `True`, 则使用 `shell` 执行指定的指令。如果您主要使用 Python 增强的控制流 (它比大多数系统 `shell` 提供的强大), 并且仍然希望方便地使用其他 `shell` 功能, 如 `shell` 管道、文件通配符、环境变量展开以及 `~` 展开到用户家目录, 这将非常有用。但是, 注意 Python 自己也实现了许多类似 `shell` 的特性 (例如 `glob`, `fnmatch`, `os.walk()`, `os.path.expandvars()`, `os.path.expanduser()` 和 `shutil`)。

在 3.3 版更改: 当 `universal_newline` 被设为 `True`, 则类使用 `locale.getpreferredencoding(False)` 编码来代替 `locale.getpreferredencoding()`。关于它们的区别的更多信息, 见 `io.TextIOWrapper`。

注解: 在使用 `shell=True` 之前, 请阅读 [Security Considerations](#) 段落。

这些选项以及所有其他选项在 `Popen` 构造函数文档中有更详细的描述。

Popen 构造函数

此模块的底层的进程创建与管理由 `Popen` 类处理。它提供了很大的灵活性, 因此开发者能够处理未被便利函数覆盖的不常见用例。

```
class subprocess.Popen(args, bufsize=-1, executable=None, stdin=None, stdout=None, stderr=None,
                        preexec_fn=None, close_fds=True, shell=False, cwd=None, env=None, univer-
                        sal_newlines=False, startupinfo=None, creationflags=0, restore_signals=True,
                        start_new_session=False, pass_fds=(), *, encoding=None, errors=None)
```

在一个新的进程中执行子程序。在 POSIX, 此类使用类似于 `os.execvp()` 的行为来执行子程序。在 Windows, 此类使用了 Windows `CreateProcess()` 函数。 `Popen` 的参数如下:

`args` 应当是一个程序的参数列表或者一个简单的字符串。默认情况下, 如果 `args` 是一个序列, 将运行的程序是此序列的第一项。如果 `args` 是一个字符串, 解释是平台相关的, 如下所述。有关默认行为的其他差异, 见 `shell` 和 `executable` 参数。除非另有说明, 推荐将 `args` 作为序列传递。

在 POSIX, 如果 `args` 是一个字符串, 此字符串被作为将被执行的程序的命名或路径解释。但是, 只有在不传递任何参数给程序的情况下才能这么做。

注解: `shlex.split()` 在确定正确 `args` 的正确标记化时非常有用, 尤其是在复杂情况下:

```
>>> import shlex, subprocess
>>> command_line = input()
/bin/vikings -input eggs.txt -output "spam spam.txt" -cmd "echo '$MONEY'"
>>> args = shlex.split(command_line)
>>> print(args)
['/bin/vikings', '-input', 'eggs.txt', '-output', 'spam spam.txt', '-cmd', "echo '
↪$MONEY'"]
>>> p = subprocess.Popen(args) # Success!
```

特别注意，由 `shell` 中的空格分隔的选项（例如 `-input`）和参数（例如 `eggs.txt`）位于分开的列表元素中，而在需要时使用引号或反斜杠转义的参数在 `shell`（例如包含空格的文件名或上面显示的 `echo` 命令）是单独的列表元素。

在 Windows，如果 `args` 是一个序列，他将通过一个在 *Converting an argument sequence to a string on Windows* 描述的方式被转换为一个字符串。这是因为底层的 `CreateProcess()` 只处理字符串。

参数 `shell`（默认为 `False`）指定是否使用 `shell` 执行程序。如果 `shell` 为 `True`，更推荐将 `args` 作为字符串传递而非序列。

在 POSIX，当 `shell=True`，`shell` 默认为 `/bin/sh`。如果 `args` 是一个字符串，此字符串指定将通过 `shell` 执行的命令。这意味着字符串的格式必须和在命令提示符中所输入的完全相同。这包括，例如，引号和反斜杠转义包含空格的文件名。如果 `args` 是一个序列，第一项指定了命令，另外的项目将作为传递给 `shell`（而非命令）的参数对待。也就是说，`Popen` 等同于：

```
Popen(['/bin/sh', '-c', args[0], args[1], ...])
```

在 Windows，使用 `shell=True`，环境变量 `COMSPEC` 指定了默认 `shell`。在 Windows 你唯一需要指定 `shell=True` 的情况是你想要执行内置在 `shell` 中的命令（例如 `dir` 或者 `copy`）。在运行一个批处理文件或者基于控制台的可执行文件时，不需要 `shell=True`。

注解： 在使用 `shell=True` 之前，请阅读 *Security Considerations* 段落。

`bufsize` 将在 `open()` 函数创建了 `stdin/stdout/stderr` 管道文件对象时作为对应的参数供应：

- 0 表示不使用缓冲区（读取与写入是一个系统调用并且可以返回短内容）
- 1 表示行缓冲（只有 `universal_newlines=True` 时才有用，例如，在文本模式中）
- 任何其他正值表示使用一个约为对应大小的缓冲区
- 负的 `bufsize`（默认）表示使用系统默认的 `io.DEFAULT_BUFFER_SIZE`。

在 3.3.1 版更改： `bufsize` 现在默认为 -1 来启用缓冲，以符合大多数代码所期望的行为。在 Python 3.2.4 和 3.3.1 之前的版本中，它错误地将默认值设为了 0，这是无缓冲的并且允许短读取。这是无意的，并且与大多数代码所期望的 Python 2 的行为不一致。

`executable` 参数指定一个要执行的替换程序。这很少需要。当 `shell=True`，`executable` 替换 `args` 指定运行的程序。但是，原始的 `args` 仍然被传递给程序。大多数程序将被 `args` 指定的程序作为命令名对待，这可以与实际运行的程序不同。在 POSIX，`args` 名作为实际调用程序中可执行文件的显示名称，例如 `ps`。如果 `shell=True`，在 POSIX，`executable` 参数指定用于替换默认 `shell /bin/sh` 的 `shell`。

`stdin`，`stdout` 和 `stderr` 分别指定被运行的程序的标准输入、输出和标准错误的文件句柄。合法的值有 `PIPE`，`DEVNULL`，一个存在的文件描述符（一个正整数），一个存在的文件对象以及 `None`。`PIPE` 表示应创建一个新的对子进程的管道。`DEVNULL` 表示使用特殊的 `os.devnull` 文件。使用默认的 `None`，则不进行成定向；子进程的文件流将继承自父进程。另外，`stderr` 可设为 `STDOUT`，表示应用程序的标准错误数据应和标准输出一同捕获。

如果 `preexec_fn` 被设为一个可调用对象，此对象将在子进程刚创建时被调用。（仅 POSIX）

警告： `preexec_fn` 形参在应用程序中存在多线程时是不安全的。子进程在调用前可能死锁。如果你必须使用它，保持警惕！最小化你调用的库的数量。

注解： 如果你需要修改子进程环境，使用 `env` 形参而非在 `preexec_fn` 中进行。`start_new_session` 形参可以

代替之前常用的 `preexec_fn` 来在子进程中调用 `os.setsid()`。

If `close_fds` is true, all file descriptors except 0, 1 and 2 will be closed before the child process is executed. (POSIX only). The default varies by platform: Always true on POSIX. On Windows it is true when `stdin/stdout/stderr` are `None`, false otherwise. On Windows, if `close_fds` is true then no handles will be inherited by the child process. Note that on Windows, you cannot set `close_fds` to true and also redirect the standard handles by setting `stdin`, `stdout` or `stderr`.

在 3.2 版更改: `close_fds` 的默认值已经从 `False` 修改为上述值。

`pass_fds` 是一个可选的在父子进程间保持打开的文件描述符序列。提供任何 `pass_fds` 将强制 `close_fds` 为 `True`。(仅 POSIX)

3.2 新版功能: 加入了 `pass_fds` 形参。

如果 `cwd` 不为 `None`, 此函数在执行子进程前改变当前工作目录为 `cwd`。`cwd` 可以为一个 `str` 和 `path-like` 对象。特别要注意, 当可执行文件的路径为相对路径时, 此函数按相对于 `cwd` 的路径来寻找 `executable` (或者 `args` 的第一项)。

在 3.6 版更改: `cwd` 形参接受一个 `path-like object`。

如果 `restore_signals` 为 true (默认值), 则 Python 设置为 `SIG_IGN` 的所有信号将在 `exec` 之前的子进程中恢复为 `SIG_DFL`。目前, 这包括 `SIGPIPE`, `SIGXFZ` 和 `SIGXFSZ` 信号。(仅 POSIX)

在 3.2 版更改: `restore_signals` 被加入。

如果 `start_new_session` 为 true, 则 `setsid()` 系统调用将在子进程执行之前被执行。(仅 POSIX)

在 3.2 版更改: `start_new_session` 被添加。

如果 `env` 不为 `None`, 则必须为一个为新进程定义了环境变量的字典; 这些用于替换继承的当前进程环境的默认行为。

注解: 如果指定, `env` 必须提供所有被子进程需求的变量。在 Windows, 为了运行一个 `side-by-side assembly`, 指定的 `env` 必须包含一个有效的 `SystemRoot`。

If `encoding` or `errors` are specified, the file objects `stdin`, `stdout` and `stderr` are opened in text mode with the specified encoding and `errors`, as described above in 常用参数. If `universal_newlines` is True, they are opened in text mode with default encoding. Otherwise, they are opened as binary streams.

3.6 新版功能: `encoding` 和 `errors` 被添加。

If given, `startupinfo` will be a `STARTUPINFO` object, which is passed to the underlying `CreateProcess` function. `creationflags`, if given, can be `CREATE_NEW_CONSOLE` or `CREATE_NEW_PROCESS_GROUP`. (Windows only)

`Popen` 对象支持通过 `with` 语句作为上下文管理器, 在退出时关闭文件描述符并等待进程:

```
with Popen(["ifconfig"], stdout=PIPE) as proc:
    log.write(proc.stdout.read())
```

在 3.2 版更改: 添加了上下文管理器支持。

在 3.6 版更改: 现在, 如果 `Popen` 析构时子进程仍然在运行, 则析构器会发送一个 `ResourceWarning` 警告。

异常

Exceptions raised in the child process, before the new program has started to execute, will be re-raised in the parent. Additionally, the exception object will have one extra attribute called `child_traceback`, which is a string containing traceback information from the child's point of view.

最常见的被抛出异常是 `OSError`。例如, 当尝试执行一个不存在的文件时就会发生。应用程序需要为 `OSError` 异常做好准备。

如果 `Popen` 调用时有无效的参数, 则一个 `ValueError` 将被抛出。

`check_all()` 与 `check_output()` 在调用的进程返回非零退出码时将抛出 `CalledProcessError`。

所有接受 `timeout` 形参的函数与方法, 例如 `call()` 和 `Popen.communicate()` 将会在进程退出前超时到期时抛出 `TimeoutExpired`。

此模块中定义的异常都继承自 `SubprocessError`。

3.3 新版功能: 基类 `SubprocessError` 被添加。

17.5.2 安全考量

不像一些其他的 `popen` 功能, 此实现绝不会隐式调用一个系统 `shell`。这意味着任何字符, 包括 `shell` 元字符, 可以安全地被传递给子进程。如果 `shell` 被明确地调用, 通过 `shell=True` 设置, 则确保所有空白字符和元字符被恰当地包裹在引号内以避免 `shell` 注入漏洞就由应用程序负责了。

当使用 `shell=True`, `shlex.quote()` 函数可以作为在将被用于构造 `shell` 指令的字符串中转义空白字符以及 `shell` 元字符的方案。

17.5.3 Popen 对象

`Popen` 类的实例拥有以下方法:

`Popen.poll()`

检查子进程是否已被终止。设置并返回 `returncode` 属性。否则返回 `None`。

`Popen.wait(timeout=None)`

等待子进程被终止。设置并返回 `returncode` 属性。

如果进程在 `timeout` 秒后未中断, 抛出一个 `TimeoutExpired` 异常, 可以安全地捕获此异常并重新等待。

注解: 当 `stdout=PIPE` 或者 `stderr=PIPE` 并且子进程产生了足以阻塞 OS 管道缓冲区接收更多数据的输出到管道时, 将会发生死锁。当使用管道时用 `Popen.communicate()` 来规避它。

注解: 此函数使用了一个 `busy loop` (非阻塞调用以及短睡眠) 实现。使用 `asyncio` 模块进行异步等待: 参阅 `asyncio.create_subprocess_exec`。

在 3.3 版更改: `timeout` 被添加

3.4 版后已移除: Do not use the `endtime` parameter. It is was unintentionally exposed in 3.3 but was left undocumented as it was intended to be private for internal use. Use `timeout` instead.

`Popen.communicate(input=None, timeout=None)`

与进程交互：向 `stdin` 传输数据。从 `stdout` 和 `stderr` 读取数据，直到文件结束符。等待进程终止。可选的 `input` 参数应当未被传输给子进程的数据，如果没有数据应被传输给子进程则为 `None`。如果流以文本模式打开，`input` 必须为字符串。否则，它必须为字节。

`communicate()` 返回一个 `(stdout_data, stderr_data)` 元组。如果文件以文本模式打开则为字符串；否则字节。

注意如果你想要向进程的 `stdin` 传输数据，你需要通过 `stdin=PIPE` 创建此 `Popen` 对象。类似的，要从结果元组获取任何非 `None` 值，你同样需要设置 `stdout=PIPE` 或者 `stderr=PIPE`。

如果进程在 `timeout` 秒后未终止，一个 `TimeoutExpired` 异常将被抛出。捕获此异常并重新等待将不会丢失任何输出。

如果超时到期，子进程不会被杀死，所以为了正确清理一个行为良好的应用程序应该杀死子进程并完成通讯。

```
proc = subprocess.Popen(...)
try:
    outs, errs = proc.communicate(timeout=15)
except TimeoutExpired:
    proc.kill()
    outs, errs = proc.communicate()
```

注解： 内存里数据读取是缓冲的，所以如果数据尺寸过大或无限，不要使用此方法。

在 3.3 版更改: `timeout` 被添加

`Popen.send_signal(signal)`

将信号 `signal` 发送给子进程。

注解： 在 Windows, `SIGTERM` 是一个 `terminate()` 的别名。`CTRL_C_EVENT` 和 `CTRL_BREAK_EVENT` 可以被发送给以包含 `CREATE_NEW_PROCESS` 的 `creationflags` 形参启动的进程。

`Popen.terminate()`

停止子进程。在 Posix 操作系统上，此方法发送 `SIGTERM`。在 Windows，调用 Win32 API 函数 `TerminateProcess()` 来停止子进程。

`Popen.kill()`

杀死子进程。在 Posix 操作系统上，此函数给子进程发送 `SIGKILL` 信号。在 Windows 上，`kill()` 是 `terminate()` 的别名。

以下属性也是可用的：

`Popen.args`

`args` 参数传递给 `Popen` — 一个程序参数的序列或者一个简单字符串。

3.3 新版功能。

`Popen.stdin`

如果 `stdin` 参数为 `PIPE`，此属性是一个类似 `open()` 返回的可写的流对象。如果 `encoding` 或 `errors` 参数被指定或者 `universal_newlines` 参数为 `True`，则此流是一个文本流，否则是字节流。如果 `stdin` 参数非 `PIPE`，此属性为 `None`。

`Popen.stdout`

如果 `stdout` 参数是 `PIPE`，此属性是一个类似 `open()` 返回的可读流。从流中读取子进程提供的输出。

如果 *encoding* 或 *errors* 参数被指定或者 *universal_newlines* 参数为 `True`，此流为文本流，否则为字节流。如果 *stdout* 参数非 *PIPE*，此属性为 `None`。

`Popen.stderr`

如果 *stderr* 参数是 *PIPE*，此属性是一个类似 *open()* 返回的可读流。从流中读取子进程提供的输出。如果 *encoding* 或 *errors* 参数被指定或者 *universal_newlines* 参数为 `True`，此流为文本流，否则为字节流。如果 *stderr* 参数非 *PIPE*，此属性为 `None`。

警告： 使用 *communicate()* 而非 *.stdin.write*、*.stdout.read* 或者 *.stderr.read* 来避免由于任意其他 OS 管道缓冲区被子进程填满阻塞而导致的死锁。

`Popen.pid`

子进程的进程号。

注意如果你设置了 *shell* 参数为 `True`，则这是生成的子 *shell* 的进程号。

`Popen.returncode`

此进程的退出码，由 *poll()* 和 *wait()* 设置（以及直接由 *communicate()* 设置）。一个 `None` 值表示此进程仍未结束。

一个负值 `-N` 表示子进程被信号 `N` 中断（仅 POSIX）。

17.5.4 Windows Popen 助手

STARTUPINFO 类和以下常数仅在 Windows 有效。

`class subprocess.STARTUPINFO`

Partial support of the Windows *STARTUPINFO* structure is used for *Popen* creation.

`dwFlags`

A bit field that determines whether certain *STARTUPINFO* attributes are used when the process creates a window.

```
si = subprocess.STARTUPINFO()
si.dwFlags = subprocess.STARTF_USESTDHANDLES | subprocess.STARTF_USESHOWWINDOW
```

`hStdInput`

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard input handle for the process. If *STARTF_USESTDHANDLES* is not specified, the default for standard input is the keyboard buffer.

`hStdOutput`

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard output handle for the process. Otherwise, this attribute is ignored and the default for standard output is the console window's buffer.

`hStdError`

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard error handle for the process. Otherwise, this attribute is ignored and the default for standard error is the console window's buffer.

`wShowWindow`

If *dwFlags* specifies *STARTF_USESHOWWINDOW*, this attribute can be any of the values that can be specified in the *nCmdShow* parameter for the *ShowWindow* function, except for *SW_SHOWDEFAULT*. Otherwise, this attribute is ignored.

SW_HIDE is provided for this attribute. It is used when *Popen* is called with *shell=True*.

Constants

The `subprocess` module exposes the following constants.

`subprocess.STD_INPUT_HANDLE`

The standard input device. Initially, this is the console input buffer, `CONIN$`.

`subprocess.STD_OUTPUT_HANDLE`

The standard output device. Initially, this is the active console screen buffer, `CONOUT$`.

`subprocess.STD_ERROR_HANDLE`

The standard error device. Initially, this is the active console screen buffer, `CONOUT$`.

`subprocess.SW_HIDE`

Hides the window. Another window will be activated.

`subprocess.STARTF_USESTDHANDLES`

Specifies that the `STARTUPINFO.hStdInput`, `STARTUPINFO.hStdOutput`, and `STARTUPINFO.hStdError` attributes contain additional information.

`subprocess.STARTF_USESHOWWINDOW`

Specifies that the `STARTUPINFO.wShowWindow` attribute contains additional information.

`subprocess.CREATE_NEW_CONSOLE`

The new process has a new console, instead of inheriting its parent's console (the default).

`subprocess.CREATE_NEW_PROCESS_GROUP`

A `Popen` `creationflags` parameter to specify that a new process group will be created. This flag is necessary for using `os.kill()` on the subprocess.

This flag is ignored if `CREATE_NEW_CONSOLE` is specified.

17.5.5 Older high-level API

Prior to Python 3.5, these three functions comprised the high level API to `subprocess`. You can now use `run()` in many cases, but lots of existing code calls these functions.

`subprocess.call(args, *, stdin=None, stdout=None, stderr=None, shell=False, cwd=None, timeout=None)`

Run the command described by `args`. Wait for command to complete, then return the `returncode` attribute.

这相当于:

```
run(...).returncode
```

(except that the `input` and `check` parameters are not supported)

The arguments shown above are merely the most common ones. The full function signature is largely the same as that of the `Popen` constructor - this function passes all supplied arguments other than `timeout` directly through to that interface.

注解: Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

在 3.3 版更改: `timeout` 被添加

`subprocess.check_call(args, *, stdin=None, stdout=None, stderr=None, shell=False, cwd=None, timeout=None)`

Run command with arguments. Wait for command to complete. If the return code was zero then return, oth-

otherwise raise `CalledProcessError`. The `CalledProcessError` object will have the return code in the `returncode` attribute.

这相当于:

```
run(..., check=True)
```

(except that the `input` parameter is not supported)

The arguments shown above are merely the most common ones. The full function signature is largely the same as that of the `Popen` constructor - this function passes all supplied arguments other than `timeout` directly through to that interface.

注解: Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

在 3.3 版更改: `timeout` 被添加

`subprocess.check_output` (*args*, *, *stdin=None*, *stderr=None*, *shell=False*, *cwd=None*, *encoding=None*, *errors=None*, *universal_newlines=False*, *timeout=None*)
Run command with arguments and return its output.

If the return code was non-zero it raises a `CalledProcessError`. The `CalledProcessError` object will have the return code in the `returncode` attribute and any output in the `output` attribute.

这相当于:

```
run(..., check=True, stdout=PIPE).stdout
```

The arguments shown above are merely the most common ones. The full function signature is largely the same as that of `run()` - most arguments are passed directly through to that interface. However, explicitly passing `input=None` to inherit the parent's standard input file handle is not supported.

By default, this function will return the data as encoded bytes. The actual encoding of the output data may depend on the command being invoked, so the decoding to text will often need to be handled at the application level.

This behaviour may be overridden by setting `universal_newlines` to `True` as described above in 常用参数.

To also capture standard error in the result, use `stderr=subprocess.STDOUT`:

```
>>> subprocess.check_output (
...     "ls non_existent_file; exit 0",
...     stderr=subprocess.STDOUT,
...     shell=True)
'ls: non_existent_file: No such file or directory\n'
```

3.1 新版功能.

在 3.3 版更改: `timeout` 被添加

在 3.4 版更改: Support for the `input` keyword argument was added.

在 3.6 版更改: `encoding` and `errors` were added. See `run()` for details.

17.5.6 Replacing Older Functions with the `subprocess` Module

In this section, “a becomes b” means that b can be used as a replacement for a.

注解： All “a” functions in this section fail (more or less) silently if the executed program cannot be found; the “b” replacements raise `OSError` instead.

In addition, the replacements using `check_output()` will fail with a `CalledProcessError` if the requested operation produces a non-zero return code. The output is still available as the `output` attribute of the raised exception.

In the following examples, we assume that the relevant functions have already been imported from the `subprocess` module.

Replacing `/bin/sh` shell backquote

```
output=`mycmd myarg`
```

becomes:

```
output = check_output(["mycmd", "myarg"])
```

Replacing shell pipeline

```
output=`dmesg | grep hda`
```

becomes:

```
p1 = Popen(["dmesg"], stdout=PIPE)
p2 = Popen(["grep", "hda"], stdin=p1.stdout, stdout=PIPE)
p1.stdout.close() # Allow p1 to receive a SIGPIPE if p2 exits.
output = p2.communicate()[0]
```

The `p1.stdout.close()` call after starting the `p2` is important in order for `p1` to receive a `SIGPIPE` if `p2` exits before `p1`.

Alternatively, for trusted input, the shell’s own pipeline support may still be used directly:

```
output=`dmesg | grep hda`
```

becomes:

```
output=check_output("dmesg | grep hda", shell=True)
```

Replacing `os.system()`

```
sts = os.system("mycmd" + " myarg")
# becomes
sts = call("mycmd" + " myarg", shell=True)
```

注释:

- Calling the program through the shell is usually not required.

A more realistic example would look like this:

```

try:
    retcode = call("mycmd" + " myarg", shell=True)
    if retcode < 0:
        print("Child was terminated by signal", -retcode, file=sys.stderr)
    else:
        print("Child returned", retcode, file=sys.stderr)
except OSError as e:
    print("Execution failed:", e, file=sys.stderr)

```

Replacing the `os.spawn` family

P_NOWAIT example:

```

pid = os.spawnlp(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg")
==>
pid = Popen(["/bin/mycmd", "myarg"]).pid

```

P_WAIT example:

```

retcode = os.spawnlp(os.P_WAIT, "/bin/mycmd", "mycmd", "myarg")
==>
retcode = call(["/bin/mycmd", "myarg"])

```

Vector example:

```

os.spawnvp(os.P_NOWAIT, path, args)
==>
Popen([path] + args[1:])

```

Environment example:

```

os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg", env)
==>
Popen(["/bin/mycmd", "myarg"], env={"PATH": "/usr/bin"})

```

Replacing `os.popen()`, `os.popen2()`, `os.popen3()`

```

(child_stdin, child_stdout) = os.popen2(cmd, mode, bufsize)
==>
p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdin, child_stdout) = (p.stdin, p.stdout)

```

```

(child_stdin,
 child_stdout,
 child_stderr) = os.popen3(cmd, mode, bufsize)
==>
p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=PIPE, close_fds=True)
(child_stdin,
 child_stdout,
 child_stderr) = (p.stdin, p.stdout, p.stderr)

```

```
(child_stdin, child_stdout_and_stderr) = os.popen4(cmd, mode, bufsize)
==>
p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=STDOUT, close_fds=True)
(child_stdin, child_stdout_and_stderr) = (p.stdin, p.stdout)
```

Return code handling translates as follows:

```
pipe = os.popen(cmd, 'w')
...
rc = pipe.close()
if rc is not None and rc >> 8:
    print("There were some errors")
==>
process = Popen(cmd, stdin=PIPE)
...
process.stdin.close()
if process.wait() != 0:
    print("There were some errors")
```

Replacing functions from the `popen2` module

注解: If the `cmd` argument to `popen2` functions is a string, the command is executed through `/bin/sh`. If it is a list, the command is directly executed.

```
(child_stdout, child_stdin) = popen2.popen2("somestring", bufsize, mode)
==>
p = Popen("somestring", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

```
(child_stdout, child_stdin) = popen2.popen2(["mycmd", "myarg"], bufsize, mode)
==>
p = Popen(["mycmd", "myarg"], bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

`popen2.Popen3` and `popen2.Popen4` basically work as `subprocess.Popen`, except that:

- `Popen` raises an exception if the execution fails.
- the `capturestderr` argument is replaced with the `stderr` argument.
- `stdin=PIPE` and `stdout=PIPE` must be specified.
- `popen2` closes all file descriptors by default, but you have to specify `close_fds=True` with `Popen` to guarantee this behavior on all platforms or past Python versions.

17.5.7 Legacy Shell Invocation Functions

This module also provides the following legacy functions from the `2.x commands` module. These operations implicitly invoke the system shell and none of the guarantees described above regarding security and exception handling consistency are valid for these functions.

`subprocess.getstatusoutput(cmd)`

Return (exitcode, output) of executing *cmd* in a shell.

Execute the string *cmd* in a shell with `Popen.check_output()` and return a 2-tuple (exitcode, output). The locale encoding is used; see the notes on [常用参数](#) for more details.

A trailing newline is stripped from the output. The exit code for the command can be interpreted as the return code of `subprocess`. Example:

```
>>> subprocess.getstatusoutput('ls /bin/ls')
(0, '/bin/ls')
>>> subprocess.getstatusoutput('cat /bin/junk')
(1, 'cat: /bin/junk: No such file or directory')
>>> subprocess.getstatusoutput('/bin/junk')
(127, 'sh: /bin/junk: not found')
>>> subprocess.getstatusoutput('/bin/kill $$')
(-15, '')
```

Availability: POSIX & Windows

在 3.3.4 版更改: Windows support was added.

The function now returns (exitcode, output) instead of (status, output) as it did in Python 3.3.3 and earlier. exitcode has the same value as [returncode](#).

`subprocess.getoutput(cmd)`

Return output (stdout and stderr) of executing *cmd* in a shell.

Like [getstatusoutput\(\)](#), except the exit code is ignored and the return value is a string containing the command's output. Example:

```
>>> subprocess.getoutput('ls /bin/ls')
'/bin/ls'
```

Availability: POSIX & Windows

在 3.3.4 版更改: Windows support added

17.5.8 注释

Converting an argument sequence to a string on Windows

On Windows, an *args* sequence is converted to a string that can be parsed using the following rules (which correspond to the rules used by the MS C runtime):

1. Arguments are delimited by white space, which is either a space or a tab.
2. A string surrounded by double quotation marks is interpreted as a single argument, regardless of white space contained within. A quoted string can be embedded in an argument.
3. A double quotation mark preceded by a backslash is interpreted as a literal double quotation mark.
4. Backslashes are interpreted literally, unless they immediately precede a double quotation mark.
5. If backslashes immediately precede a double quotation mark, every pair of backslashes is interpreted as a literal backslash. If the number of backslashes is odd, the last backslash escapes the next double quotation mark as described in rule 3.

参见:

[shlex](#) Module which provides function to parse and escape command lines.

17.6 sched — 事件调度器

源码: [Lib/sched.py](#)

`sched` 模块定义了一个实现通用事件调度程序的类:

class `sched.scheduler` (*timefunc=time.monotonic, delayfunc=time.sleep*)

The `scheduler` class defines a generic interface to scheduling events. It needs two functions to actually deal with the “outside world” — *timefunc* should be callable without arguments, and return a number (the “time”, in any units whatsoever). If `time.monotonic` is not available, the *timefunc* default is `time.time` instead. The *delayfunc* function should be callable with one argument, compatible with the output of *timefunc*, and should delay that many time units. *delayfunc* will also be called with the argument 0 after each event is run to allow other threads an opportunity to run in multi-threaded applications.

在 3.3 版更改: *timefunc* 和 *delayfunc* 参数是可选的。

在 3.3 版更改: `scheduler` 类可以安全的在多线程环境中使用。

示例:

```
>>> import sched, time
>>> s = sched.scheduler(time.time, time.sleep)
>>> def print_time(a='default'):
...     print("From print_time", time.time(), a)
...
>>> def print_some_times():
...     print(time.time())
...     s.enter(10, 1, print_time)
...     s.enter(5, 2, print_time, argument=('positional',))
...     s.enter(5, 1, print_time, kwargs={'a': 'keyword'})
...     s.run()
...     print(time.time())
...
>>> print_some_times()
930343690.257
From print_time 930343695.274 positional
From print_time 930343695.275 keyword
From print_time 930343700.273 default
930343700.276
```

17.6.1 调度器对象

`scheduler` 实例拥有以下方法和属性:

`scheduler.enterabs` (*time, priority, action, argument=(), kwargs={}*)

安排一个新事件。*time* 参数应该有一个数字类型兼容的返回值, 与传递给构造函数的 *timefunc* 函数的返回值兼容。计划在相同 *time* 的事件将按其 *priority* 的顺序执行。数字越小表示优先级越高。

执行事件意为执行 `action(*argument, **kwargs)`。*argument* 是包含有 *action* 的位置参数的序列。*kwargs* 是包含 *action* 的关键字参数的字典。

返回值是一个事件, 可用于以后取消事件 (参见 `cancel()`)。

在 3.3 版更改: *argument* 参数是可选的。

3.3 新版功能: 添加了 *kwargs* 形参。

`scheduler.enter(delay, priority, action, argument=(), kwargs={})`

安排延后 *delay* 时间单位的事件。除了相对时间，其他参数、效果和返回值与 `enterabs()` 的相同。

在 3.3 版更改: *argument* 参数是可选的。

3.3 新版功能: 添加了 *kwargs* 形参。

`scheduler.cancel(event)`

从队列中删除事件。如果 *event* 不是当前队列中的事件，则此方法将引发 `ValueError`。

`scheduler.empty()`

如果事件队列为空，则返回真值。

`scheduler.run(blocking=True)`

运行所有预定事件。此方法将等待（使用传递给构造函数的 `delayfunc()` 函数）进行下一个事件，然后执行它，依此类推，直到没有更多的计划事件。

如果 *blocking* 为 `false`，则执行由于最快到期（如果有）的预定事件，然后在调度程序中返回下一个预定调用的截止时间（如果有）。

action 或 *delayfunc* 都可以引发异常。在任何一种情况下，调度程序都将保持一致状态并传播异常。如果 *action* 引发异常，则在将来调用 `run()` 时不会尝试该事件。

如果一系列事件的运行时间比下一个事件之前的可用时间长，那么调度程序将完全落后。不会发生任何事件；调用代码负责取消不再相关的事件。

3.3 新版功能: 添加了 *blocking* 形参。

`scheduler.queue`

只读属性按照将要运行的顺序返回即将发生的事件列表。每个事件都显示为 *named tuple*，包含以下字段: *time*、*priority*、*action*、*argument*、*kwargs*。

17.7 queue — 一个同步的队列类

源代码: `Lib/queue.py`

`queue` 模块实现多生产者，多消费者队列。当信息必须安全的在多线程之间交换时，它在线程编程中是特别有用的。此模块中的 `Queue` 类实现了所有锁定需求的语义。它依赖于 Python 支持的线程可用性；请参阅 `threading` 模块。

模块实现了三种类型的队列，它们的区别仅仅是条目取回的顺序。在 FIFO 队列中，先添加的任务先取回。在 LIFO 队列中，最近被添加的条目先取回（操作类似一个堆栈）。优先级队列中，条目将保持排序（使用 `heapq` 模块）并且最小值的条目第一个返回。

Internally, the module uses locks to temporarily block competing threads; however, it is not designed to handle reentrancy within a thread.

`queue` 模块定义了下列类和异常：

class `queue.Queue(maxsize=0)`

Constructor for a FIFO queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

class `queue.LifoQueue(maxsize=0)`

LIFO 队列构造函数。*maxsize* 是个整数，用于设置可以放入队列中的项目数的上限。当达到这个大小的时候，插入操作将阻塞至队列中的项目被消费掉。如果 *maxsize* 小于等于零，队列尺寸为无限大。

class queue.PriorityQueue (maxsize=0)

优先级队列构造函数。maxsize 是个整数，用于设置可以放入队列中的项目数的上限。当达到这个大小的时候，插入操作将阻塞至队列中的项目被消费掉。如果 maxsize 小于等于零，队列尺寸为无限大。

最小值先被取出（最小值条目是由 sorted(list(entries))[0] 返回的条目）。条目的典型模式是一个以下形式的元组：(priority_number, data)。

exception queue.Empty

对空的 Queue 对象，调用非阻塞的 get() (or get_nowait()) 时，引发的异常。

exception queue.Full

对满的 Queue 对象，调用非阻塞的 put() (or put_nowait()) 时，引发的异常。

17.7.1 Queue 对象

队列对象 (Queue, LifoQueue, 或者 PriorityQueue) 提供下列描述的公共方法。

Queue.qsize()

返回队列的大致大小。注意，qsize() > 0 不保证后续的 get() 不被阻塞，qsize() < maxsize 也不保证 put() 不被阻塞。

Queue.empty()

如果队列为空，返回 True，否则返回 False。如果 empty() 返回 True，不保证后续调用的 put() 不被阻塞。类似的，如果 empty() 返回 False，也不保证后续调用的 get() 不被阻塞。

Queue.full()

如果队列是满的返回 True，否则返回 False。如果 full() 返回 True 不保证后续调用的 get() 不被阻塞。类似的，如果 full() 返回 False 也不保证后续调用的 put() 不被阻塞。

Queue.put (item, block=True, timeout=None)

将 item 放入队列。如果可选参数 block 是 true 并且 timeout 是 None (默认)，则在必要时阻塞至有空闲插槽可用。如果 timeout 是个正数，将最多阻塞 timeout 秒，如果在这段时间没有可用的空闲插槽，将引发 Full 异常。反之 (block 是 false)，如果空闲插槽立即可用，则把 item 放入队列，否则引发 Full 异常 (在这种情况下，timeout 将被忽略)。

Queue.put_nowait (item)

相当于 put(item, False)。

Queue.get (block=True, timeout=None)

从队列中移除并返回一个项目。如果可选参数 block 是 true 并且 timeout 是 None (默认值)，则在必要时阻塞至项目可得到。如果 timeout 是个正数，将最多阻塞 timeout 秒，如果在这段时间内项目不能得到，将引发 Empty 异常。反之 (block 是 false)，如果一个项目立即可得到，则返回一个项目，否则引发 Empty 异常 (这种情况下，timeout 将被忽略)。

Queue.get_nowait ()

相当于 get(False)。

提供了两个方法，用于支持跟踪排队的任务是否被守护的消费者线程完整的处理。

Queue.task_done()

表示前面排队的任务已经被完成。被队列的消费者线程使用。每个 get() 被用于获取一个任务，后续调用 task_done() 告诉队列，该任务的处理已经完成。

如果 join() 当前正在阻塞，在所有条目都被处理后，将解除阻塞 (意味着每个 put() 进队列的条目的 task_done() 都被收到)。

如果被调用的次数多于放入队列中的项目数量，将引发 ValueError 异常。

Queue.join()

阻塞至队列中所有的元素都被接收和处理完毕。

当条目添加到队列的时候，未完成任务的计数就会增加。每当消费者线程调用`task_done()` 表示这个条目已经被回收，该条目所有工作已经完成，未完成计数就会减少。当未完成计数降到零的时候，`join()` 阻塞被解除。

如何等待排队的任务被完成的示例：

```
def worker():
    while True:
        item = q.get()
        if item is None:
            break
        do_work(item)
        q.task_done()

q = queue.Queue()
threads = []
for i in range(num_worker_threads):
    t = threading.Thread(target=worker)
    t.start()
    threads.append(t)

for item in source():
    q.put(item)

# block until all tasks are done
q.join()

# stop workers
for i in range(num_worker_threads):
    q.put(None)
for t in threads:
    t.join()
```

参见：

类`multiprocessing.Queue` 一个用于多进程上下文的队列类（而不是多线程）。

`collections.deque` 是无界队列的替代实现，具有快速原子的`append()` 和`popleft()` 操作，不需要锁定。

以下是上述某些服务的支持模块：

17.8 dummy_threading —可直接替代 threading 模块。

源代码： [Lib/dummy_threading.py](#)

This module provides a duplicate interface to the `threading` module. It is meant to be imported when the `_thread` module is not provided on a platform.

Suggested usage is:

```
try:
    import threading
except ImportError:
    import dummy_threading as threading
```

如果线程需要阻塞等待另一个线程被创建的话，可能会造成死锁，这通常是由于阻塞 I/O 引起的。这种场景下请不要使用这个模块。

17.9 `_thread` — 底层多线程 API

该模块提供了操作多个线程（也被称为 轻量级进程或 任务）的底层原语——多个控制线程共享全局数据空间。为了处理同步问题，也提供了简单的锁机制（也称为 互斥锁或 二进制信号）。`threading` 模块基于该模块提供了更易用的高级多线程 API。

The module is optional. It is supported on Windows, Linux, SGI IRIX, Solaris 2.x, as well as on systems that have a POSIX thread (a.k.a. “pthread”) implementation. For systems lacking the `_thread` module, the `_dummy_thread` module is available. It duplicates this module’s interface and can be used as a drop-in replacement.

It defines the following constants and functions:

exception `_thread.error`

发生线程相关错误时抛出。

在 3.3 版更改：现在是内建异常 `RuntimeError` 的别名。

`_thread.LockType`

锁对象的类型。

`_thread.start_new_thread(function, args[, kwargs])`

启动一个线程，并返回其标识符。线程会用 `args` 作为参数（必须是元组）执行 `function` 函数。可选的 `kwargs` 参数使用字典来指定有名参数。当函数返回时，线程会静默退出，当函数由于未处理的异常而中止时，会打印一条堆栈追踪信息，然后该线程会退出（但其他线程还是会继续运行）。

`_thread.interrupt_main()`

Raise a `KeyboardInterrupt` exception in the main thread. A subthread can use this function to interrupt the main thread.

`_thread.exit()`

抛出 `SystemExit` 异常。如果没有捕获的话，这个异常会使线程退出。

`_thread.allocate_lock()`

返回一个新的锁对象。锁中的方法在后面描述。初始情况下锁处于解锁状态。

`_thread.get_ident()`

返回当前线程的“线程描述符”。它是一个非零的整型数。它的值没有什么含义，主要是作为 magic cookie 使用，比如作为含有线程相关数据的字典的索引。线程描述符可能会在线程退出，新线程创建时复用。

`_thread.stack_size([size])`

Return the thread stack size used when creating new threads. The optional `size` argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If `size` is not specified, 0 is used. If changing the thread stack size is unsupported, a `RuntimeError` is raised. If the specified stack size is invalid, a `ValueError` is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability: Windows, systems with POSIX threads.

_thread.TIMEOUT_MAX

Lock.acquire() 方法中 *timeout* 参数允许的最大值。传入超过这个值的 *timeout* 会抛出 *OverflowError* 异常。

3.2 新版功能。

锁对象有以下方法：

lock.acquire(waitflag=1, timeout=-1)

没有任何可选参数时，该方法无条件申请获得锁，有必要的话会等待其他线程释放锁（同时只有一个线程能获得锁——这正是锁存在的原因）。

如果传入了整型参数 *waitflag*，具体的行为取决于传入的值：如果是 0 的话，只会在能够立刻获取到锁时才获取，不会等待，如果是非零的话，会像之前提到的一样，无条件获取锁。

如果传入正浮点数参数 *timeout*，相当于指定了返回之前等待得最大秒数。如果传入负的 *timeout*，相当于无限期等待。如果 *waitflag* 是 0 的话，不能指定 *timeout*。

如果成功获取到锁会返回 True，否则返回 False。

在 3.2 版更改：*timeout* 形参是新增的。

在 3.2 版更改：现在获取锁的操作可以被 POSIX 信号中断。

lock.release()

释放锁。锁必须已经被获取过，但不一定是同一个线程获取的。

lock.locked()

返回锁的状态：如果已被某个线程获取，返回 True，否则返回 False。

除了这些方法之外，锁对象也可以通过 with 语句使用，例如：

```
import _thread

a_lock = _thread.allocate_lock()

with a_lock:
    print("a_lock is locked while this executes")
```

注意事项：

- 线程与中断奇怪地交互：*KeyboardInterrupt* 异常可能会被任意一个线程捕获。（如果 *signal* 模块可用的话，中断总是会进入主线程。）
- 调用 *sys.exit()* 或是抛出 *SystemExit* 异常等效于调用 *_thread.exit()*。
- 不可能中断锁的 *acquire()* 方法——*KeyboardInterrupt* 一场会在锁获取到之后发生。
- 当主线程退出时，由系统决定其他线程是否存活。在大多数系统中，这些线程会直接被杀掉，不会执行 *try...finally* 语句，也不会执行对象析构函数。
- 当主线程退出时，不会进行正常的清理工作（除非使用了 *try...finally* 语句），标准 I/O 文件也不会刷新。

17.10 _dummy_thread — _thread 的替代模块

源代码： [Lib/_dummy_thread.py](#)

This module provides a duplicate interface to the `_thread` module. It is meant to be imported when the `_thread` module is not provided on a platform.

Suggested usage is:

```
try:
    import _thread
except ImportError:
    import _dummy_thread as _thread
```

如果线程需要阻塞等待另一个线程被创建的话，可能会造成死锁，这通常是由于阻塞 I/O 引起的。这种场景下请不要使用这个模块。

Interprocess Communication and Networking

The modules described in this chapter provide mechanisms for different processes to communicate.

某些模块仅适用于同一台机器上的两个进程，例如 *signal* 和 *mmap*。其他模块支持两个或多个进程可用于跨机器通信的网络协议。

本章中描述的模块列表是：

18.1 socket — 底层网络接口

源代码: [Lib/socket.py](#)

这个模块提供了访问 BSD* 套接字 * 的接口。在所有现代 Unix 系统、Windows、macOS 和其他一些平台上可用。

注解：一些行为可能因平台不同而异，因为调用的是操作系统的套接字 API。

这个 Python 接口是用 Python 的面向对象风格对 Unix 系统调用和套接字库接口的直译：函数 *socket()* 返回一个套接字对象，其方法是对各种套接字系统调用的实现。形参类型一般与 C 接口相比更高级：例如在 Python 文件 *read()* 和 *write()* 操作中，接收操作的缓冲区分配是自动的，发送操作的缓冲区长度是隐式的。

参见：

模块 *socketserver* 用于简化网络服务端编写的类。

模块 *ssl* 套接字对象的 TLS/SSL 封装。

18.1.1 套接字协议族

Depending on the system and the build options, various socket families are supported by this module.

The address format required by a particular socket object is automatically selected based on the address family specified when the socket object was created. Socket addresses are represented as follows:

- The address of an `AF_UNIX` socket bound to a file system node is represented as a string, using the file system encoding and the 'surrogateescape' error handler (see [PEP 383](#)). An address in Linux's abstract namespace is returned as a *bytes-like object* with an initial null byte; note that sockets in this namespace can communicate with normal file system sockets, so programs intended to run on Linux may need to deal with both types of address. A string or bytes-like object can be used for either type of address when passing it as an argument.

在 3.3 版更改: Previously, `AF_UNIX` socket paths were assumed to use UTF-8 encoding.

在 3.5 版更改: Writable *bytes-like object* is now accepted.

- A pair (`host`, `port`) is used for the `AF_INET` address family, where `host` is a string representing either a hostname in Internet domain notation like 'daring.cwi.nl' or an IPv4 address like '100.50.200.5', and `port` is an integer.
 - For IPv4 addresses, two special forms are accepted instead of a host address: '' represents `INADDR_ANY`, which is used to bind to all interfaces, and the string '<broadcast>' represents `INADDR_BROADCAST`. This behavior is not compatible with IPv6, therefore, you may want to avoid these if you intend to support IPv6 with your Python programs.
- For `AF_INET6` address family, a four-tuple (`host`, `port`, `flowinfo`, `scopeid`) is used, where `flowinfo` and `scopeid` represent the `sin6_flowinfo` and `sin6_scope_id` members in `struct sockaddr_in6` in C. For `socket` module methods, `flowinfo` and `scopeid` can be omitted just for backward compatibility. Note, however, omission of `scopeid` can cause problems in manipulating scoped IPv6 addresses.
- `AF_NETLINK` sockets are represented as pairs (`pid`, `groups`).
- Linux-only support for TIPC is available using the `AF_TIPC` address family. TIPC is an open, non-IP based networked protocol designed for use in clustered computer environments. Addresses are represented by a tuple, and the fields depend on the address type. The general tuple form is (`addr_type`, `v1`, `v2`, `v3` [, `scope`]), where:
 - `addr_type` is one of `TIPC_ADDR_NAMESEQ`, `TIPC_ADDR_NAME`, or `TIPC_ADDR_ID`.
 - `scope` is one of `TIPC_ZONE_SCOPE`, `TIPC_CLUSTER_SCOPE`, and `TIPC_NODE_SCOPE`.
 - If `addr_type` is `TIPC_ADDR_NAME`, then `v1` is the server type, `v2` is the port identifier, and `v3` should be 0.
If `addr_type` is `TIPC_ADDR_NAMESEQ`, then `v1` is the server type, `v2` is the lower port number, and `v3` is the upper port number.
If `addr_type` is `TIPC_ADDR_ID`, then `v1` is the node, `v2` is the reference, and `v3` should be set to 0.
- A tuple (`interface`,) is used for the `AF_CAN` address family, where `interface` is a string representing a network interface name like 'can0'. The network interface name '' can be used to receive packets from all network interfaces of this family.
- A string or a tuple (`id`, `unit`) is used for the `SYSPROTO_CONTROL` protocol of the `PF_SYSTEM` family. The string is the name of a kernel control using a dynamically-assigned ID. The tuple can be used if ID and unit number of the kernel control are known or if a registered ID is used.

3.3 新版功能.

- `AF_BLUETOOTH` supports the following protocols and address formats:
 - `BTPROTO_L2CAP` accepts (`bdaddr`, `psm`) where `bdaddr` is the Bluetooth address as a string and `psm` is an integer.

- BTPROTO_RFCOMM accepts (bdaddr, channel) where bdaddr is the Bluetooth address as a string and channel is an integer.
- BTPROTO_HCI accepts (device_id,) where device_id is either an integer or a string with the Bluetooth address of the interface. (This depends on your OS; NetBSD and DragonFlyBSD expect a Bluetooth address while everything else expects an integer.)

在 3.2 版更改: NetBSD and DragonFlyBSD support added.

- BTPROTO_SCO accepts bdaddr where bdaddr is a *bytes* object containing the Bluetooth address in a string format. (ex. b'12:23:34:45:56:67') This protocol is not supported under FreeBSD.
- *AF_ALG* is a Linux-only socket based interface to Kernel cryptography. An algorithm socket is configured with a tuple of two to four elements (type, name [, feat [, mask]]), where:
 - type is the algorithm type as string, e.g. aead, hash, skcipher or rng.
 - name is the algorithm name and operation mode as string, e.g. sha256, hmac (sha256), cbc (aes) or drbg_nopr_ctr_aes256.
 - feat and mask are unsigned 32bit integers.

Availability Linux 2.6.38, some algorithm types require more recent Kernels.

3.6 新版功能.

- *AF_PACKET* is a low-level interface directly to network devices. The packets are represented by the tuple (ifname, proto[, pkttype[, hatype[, addr]]]) where:
 - ifname - String specifying the device name.
 - proto - An in network-byte-order integer specifying the Ethernet protocol number.
 - pkttype - Optional integer specifying the packet type:
 - * PACKET_HOST (the default) - Packet addressed to the local host.
 - * PACKET_BROADCAST - Physical-layer broadcast packet.
 - * PACKET_MULTICAST - Packet sent to a physical-layer multicast address.
 - * PACKET_OTHERHOST - Packet to some other host that has been caught by a device driver in promiscuous mode.
 - * PACKET_OUTGOING - Packet originating from the local host that is looped back to a packet socket.
 - hatype - Optional integer specifying the ARP hardware address type.
 - addr - Optional bytes-like object specifying the hardware physical address, whose interpretation depends on the device.

If you use a hostname in the *host* portion of IPv4/v6 socket address, the program may show a nondeterministic behavior, as Python uses the first address returned from the DNS resolution. The socket address will be resolved differently into an actual IPv4/v6 address, depending on the results from DNS resolution and/or the host configuration. For deterministic behavior use a numeric address in *host* portion.

All errors raise exceptions. The normal exceptions for invalid argument types and out-of-memory conditions can be raised; starting from Python 3.3, errors related to socket or address semantics raise *OSError* or one of its subclasses (they used to raise *socket.error*).

Non-blocking mode is supported through *setblocking()*. A generalization of this based on timeouts is supported through *settimeout()*.

18.1.2 Module contents

The module `socket` exports the following elements.

异常

exception `socket.error`

A deprecated alias of `OSError`.

在 3.3 版更改: Following [PEP 3151](#), this class was made an alias of `OSError`.

exception `socket.herror`

A subclass of `OSError`, this exception is raised for address-related errors, i.e. for functions that use `h_errno` in the POSIX C API, including `gethostbyname_ex()` and `gethostbyaddr()`. The accompanying value is a pair (`h_errno`, `string`) representing an error returned by a library call. `h_errno` is a numeric value, while `string` represents the description of `h_errno`, as returned by the `hstrerror()` C function.

在 3.3 版更改: This class was made a subclass of `OSError`.

exception `socket.gaierror`

A subclass of `OSError`, this exception is raised for address-related errors by `getaddrinfo()` and `getnameinfo()`. The accompanying value is a pair (`error`, `string`) representing an error returned by a library call. `string` represents the description of `error`, as returned by the `gai_strerror()` C function. The numeric `error` value will match one of the `EAI_*` constants defined in this module.

在 3.3 版更改: This class was made a subclass of `OSError`.

exception `socket.timeout`

A subclass of `OSError`, this exception is raised when a timeout occurs on a socket which has had timeouts enabled via a prior call to `settimeout()` (or implicitly through `setdefaulttimeout()`). The accompanying value is a string whose value is currently always “timed out”.

在 3.3 版更改: This class was made a subclass of `OSError`.

常数

The `AF_*` and `SOCK_*` constants are now `AddressFamily` and `SocketKind` `IntEnum` collections.

3.4 新版功能.

`socket.AF_UNIX`

`socket.AF_INET`

`socket.AF_INET6`

These constants represent the address (and protocol) families, used for the first argument to `socket()`. If the `AF_UNIX` constant is not defined then this protocol is unsupported. More constants may be available depending on the system.

`socket.SOCK_STREAM`

`socket.SOCK_DGRAM`

`socket.SOCK_RAW`

`socket.SOCK_RDM`

`socket.SOCK_SEQPACKET`

These constants represent the socket types, used for the second argument to `socket()`. More constants may be available depending on the system. (Only `SOCK_STREAM` and `SOCK_DGRAM` appear to be generally useful.)

`socket.SOCK_CLOEXEC`

socket.SOCK_NONBLOCK

These two constants, if defined, can be combined with the socket types and allow you to set some flags atomically (thus avoiding possible race conditions and the need for separate calls).

参见:

[Secure File Descriptor Handling](#) for a more thorough explanation.

Availability: Linux >= 2.6.27.

3.2 新版功能.

SO_***socket.SOMAXCONN****MSG_*****SOL_*****SCM_*****IPPROTO_*****IPPORT_*****INADDR_*****IP_*****IPV6_*****EAI_*****AI_*****NI_*****TCP_***

Many constants of these forms, documented in the Unix documentation on sockets and/or the IP protocol, are also defined in the socket module. They are generally used in arguments to the `setsockopt()` and `getsockopt()` methods of socket objects. In most cases, only those symbols that are defined in the Unix header files are defined; for a few symbols, default values are provided.

在 3.6 版更改: `SO_DOMAIN`, `SO_PROTOCOL`, `SO_PEERSEC`, `SO_PASSSEC`, `TCP_USER_TIMEOUT`, `TCP_CONGESTION` were added.

在 3.6.5 版更改: On Windows, `TCP_FASTOPEN`, `TCP_KEEPCNT` appear if run-time Windows supports.

socket.AF_CAN**socket.PF_CAN****SOL_CAN_*****CAN_***

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.25.

3.3 新版功能.

socket.CAN_BCM**CAN_BCM_***

`CAN_BCM`, in the CAN protocol family, is the broadcast manager (BCM) protocol. Broadcast manager constants, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.25.

3.4 新版功能.

socket.CAN_RAW_FD_FRAMES

Enables CAN FD support in a `CAN_RAW` socket. This is disabled by default. This allows your application to send both CAN and CAN FD frames; however, you one must accept both CAN and CAN FD frames when reading from the socket.

This constant is documented in the Linux documentation.

Availability: Linux >= 3.6.

3.5 新版功能.

`socket.AF_PACKET`

`socket.PF_PACKET`

PACKET_*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.2.

`socket.AF_RDS`

`socket.PF_RDS`

`socket.SOL_RDS`

RDS_*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.30.

3.3 新版功能.

`socket.SIO_RCVALL`

`socket.SIO_KEEPA_LIVE_VALS`

`socket.SIO_LOOPBACK_FAST_PATH`

RCVALL_*

Constants for Windows' `WSAIoctl()`. The constants are used as arguments to the `ioctl()` method of socket objects.

在 3.6 版更改: `SIO_LOOPBACK_FAST_PATH` was added.

TIPC_*

TIPC related constants, matching the ones exported by the C socket API. See the TIPC documentation for more information.

`socket.AF_ALG`

`socket.SOL_ALG`

ALG_*

Constants for Linux Kernel cryptography.

Availability: Linux >= 2.6.38.

3.6 新版功能.

`socket.AF_LINK`

Availability: BSD, OSX.

3.4 新版功能.

`socket.has_ipv6`

This constant contains a boolean value which indicates if IPv6 is supported on this platform.

`socket.BDADDR_ANY`

`socket.BDADDR_LOCAL`

These are string constants containing Bluetooth addresses with special meanings. For example, `BDADDR_ANY` can be used to indicate any address when specifying the binding socket with `BTPROTO_RFCOMM`.

`socket.HCI_FILTER`

`socket.HCI_TIME_STAMP`

`socket.HCI_DATA_DIR`

For use with `BTPROTO_HCI`. `HCI_FILTER` is not available for NetBSD or DragonFlyBSD. `HCI_TIME_STAMP` and `HCI_DATA_DIR` are not available for FreeBSD, NetBSD, or DragonFlyBSD.

函数

Creating sockets

The following functions all create *socket objects*.

`socket.socket (family=AF_INET, type=SOCK_STREAM, proto=0, fileno=None)`

Create a new socket using the given address family, socket type and protocol number. The address family should be `AF_INET` (the default), `AF_INET6`, `AF_UNIX`, `AF_CAN`, `AF_PACKET`, or `AF_RDS`. The socket type should be `SOCK_STREAM` (the default), `SOCK_DGRAM`, `SOCK_RAW` or perhaps one of the other `SOCK_` constants. The protocol number is usually zero and may be omitted or in the case where the address family is `AF_CAN` the protocol should be one of `CAN_RAW` or `CAN_BCM`. If `fileno` is specified, the other arguments are ignored, causing the socket with the specified file descriptor to return. Unlike `socket.fromfd()`, `fileno` will return the same socket and not a duplicate. This may help close a detached socket using `socket.close()`.

The newly created socket is *non-inheritable*.

在 3.3 版更改: The `AF_CAN` family was added. The `AF_RDS` family was added.

在 3.4 版更改: The `CAN_BCM` protocol was added.

在 3.4 版更改: The returned socket is now non-inheritable.

`socket.socketpair ([family[, type[, proto]]])`

Build a pair of connected socket objects using the given address family, socket type, and protocol number. Address family, socket type, and protocol number are as for the `socket()` function above. The default family is `AF_UNIX` if defined on the platform; otherwise, the default is `AF_INET`.

The newly created sockets are *non-inheritable*.

在 3.2 版更改: The returned socket objects now support the whole socket API, rather than a subset.

在 3.4 版更改: The returned sockets are now non-inheritable.

在 3.5 版更改: Windows support added.

`socket.create_connection (address[, timeout[, source_address]])`

Connect to a TCP service listening on the Internet *address* (a 2-tuple (host, port)), and return the socket object. This is a higher-level function than `socket.connect()`: if *host* is a non-numeric hostname, it will try to resolve it for both `AF_INET` and `AF_INET6`, and then try to connect to all possible addresses in turn until a connection succeeds. This makes it easy to write clients that are compatible to both IPv4 and IPv6.

Passing the optional *timeout* parameter will set the timeout on the socket instance before attempting to connect. If no *timeout* is supplied, the global default timeout setting returned by `getdefaulttimeout()` is used.

If supplied, *source_address* must be a 2-tuple (host, port) for the socket to bind to as its source address before connecting. If host or port are `''` or 0 respectively the OS default behavior will be used.

在 3.2 版更改: 添加了 *source_address*。

`socket.fromfd (fd, family, type, proto=0)`

Duplicate the file descriptor *fd* (an integer as returned by a file object's `fileno()` method) and build a socket object from the result. Address family, socket type and protocol number are as for the `socket()` function above. The file descriptor should refer to a socket, but this is not checked —subsequent operations on the object may fail if the file descriptor is invalid. This function is rarely needed, but can be used to get or set socket options on a socket passed to a program as standard input or output (such as a server started by the Unix inet daemon). The socket is assumed to be in blocking mode.

The newly created socket is *non-inheritable*.

在 3.4 版更改: The returned socket is now non-inheritable.

`socket.fromshare(data)`

Instantiate a socket from data obtained from the `socket.share()` method. The socket is assumed to be in blocking mode.

Availability: Windows.

3.3 新版功能.

`socket.SocketType`

This is a Python type object that represents the socket object type. It is the same as `type(socket(...))`.

其他功能

The `socket` module also offers various network-related services:

`socket.getaddrinfo(host, port, family=0, type=0, proto=0, flags=0)`

Translate the *host/port* argument into a sequence of 5-tuples that contain all the necessary arguments for creating a socket connected to that service. *host* is a domain name, a string representation of an IPv4/v6 address or `None`. *port* is a string service name such as `'http'`, a numeric port number or `None`. By passing `None` as the value of *host* and *port*, you can pass `NULL` to the underlying C API.

The *family*, *type* and *proto* arguments can be optionally specified in order to narrow the list of addresses returned. Passing zero as a value for each of these arguments selects the full range of results. The *flags* argument can be one or several of the `AI_*` constants, and will influence how results are computed and returned. For example, `AI_NUMERICHOST` will disable domain name resolution and will raise an error if *host* is a domain name.

The function returns a list of 5-tuples with the following structure:

```
(family, type, proto, canonname, sockaddr)
```

In these tuples, *family*, *type*, *proto* are all integers and are meant to be passed to the `socket()` function. *canonname* will be a string representing the canonical name of the *host* if `AI_CANONNAME` is part of the *flags* argument; else *canonname* will be empty. *sockaddr* is a tuple describing a socket address, whose format depends on the returned *family* (a (address, port) 2-tuple for `AF_INET`, a (address, port, flow info, scope id) 4-tuple for `AF_INET6`), and is meant to be passed to the `socket.connect()` method.

The following example fetches address information for a hypothetical TCP connection to `example.org` on port 80 (results may differ on your system if IPv6 isn't enabled):

```
>>> socket.getaddrinfo("example.org", 80, proto=socket.IPPROTO_TCP)
[(<AddressFamily.AF_INET6: 10>, <SocketType.SOCK_STREAM: 1>,
  6, '', ('2606:2800:220:1:248:1893:25c8:1946', 80, 0, 0)),
 (<AddressFamily.AF_INET: 2>, <SocketType.SOCK_STREAM: 1>,
  6, '', ('93.184.216.34', 80))]
```

在 3.2 版更改: parameters can now be passed using keyword arguments.

`socket.getfqdn([name])`

Return a fully qualified domain name for *name*. If *name* is omitted or empty, it is interpreted as the local host. To find the fully qualified name, the hostname returned by `gethostbyaddr()` is checked, followed by aliases for the host, if available. The first name which includes a period is selected. In case no fully qualified domain name is available, the hostname as returned by `gethostname()` is returned.

`socket.gethostbyname(hostname)`

Translate a host name to IPv4 address format. The IPv4 address is returned as a string, such as `'100.50.200.5'`. If the host name is an IPv4 address itself it is returned unchanged. See `gethostbyname_ex()` for a more complete interface. `gethostbyname()` does not support IPv6 name resolution, and `getaddrinfo()` should be used instead for IPv4/v6 dual stack support.

`socket.gethostbyname_ex(hostname)`

Translate a host name to IPv4 address format, extended interface. Return a triple (`hostname`, `aliaslist`, `ipaddrlist`) where `hostname` is the primary host name responding to the given `ip_address`, `aliaslist` is a (possibly empty) list of alternative host names for the same address, and `ipaddrlist` is a list of IPv4 addresses for the same interface on the same host (often but not always a single address). `gethostbyname_ex()` does not support IPv6 name resolution, and `getaddrinfo()` should be used instead for IPv4/v6 dual stack support.

`socket.gethostname()`

Return a string containing the hostname of the machine where the Python interpreter is currently executing.

Note: `gethostname()` doesn't always return the fully qualified domain name; use `getfqdn()` for that.

`socket.gethostbyaddr(ip_address)`

Return a triple (`hostname`, `aliaslist`, `ipaddrlist`) where `hostname` is the primary host name responding to the given `ip_address`, `aliaslist` is a (possibly empty) list of alternative host names for the same address, and `ipaddrlist` is a list of IPv4/v6 addresses for the same interface on the same host (most likely containing only a single address). To find the fully qualified domain name, use the function `getfqdn()`. `gethostbyaddr()` supports both IPv4 and IPv6.

`socket.getnameinfo(sockaddr, flags)`

Translate a socket address `sockaddr` into a 2-tuple (`host`, `port`). Depending on the settings of `flags`, the result can contain a fully-qualified domain name or numeric address representation in `host`. Similarly, `port` can contain a string port name or a numeric port number.

`socket.getprotobyname(protocolname)`

Translate an Internet protocol name (for example, `'icmp'`) to a constant suitable for passing as the (optional) third argument to the `socket()` function. This is usually only needed for sockets opened in “raw” mode (`SOCK_RAW`); for the normal socket modes, the correct protocol is chosen automatically if the protocol is omitted or zero.

`socket.getservbyname(servicename[, protocolname])`

Translate an Internet service name and protocol name to a port number for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

`socket.getservbyport(port[, protocolname])`

Translate an Internet port number and protocol name to a service name for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

`socket.ntohl(x)`

Convert 32-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

`socket.ntohs(x)`

Convert 16-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

`socket.htonl(x)`

Convert 32-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

`socket.htons(x)`

Convert 16-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

`socket.inet_aton(ip_string)`

Convert an IPv4 address from dotted-quad string format (for example, `'123.45.67.89'`) to 32-bit packed binary format, as a bytes object four characters in length. This is useful when conversing with a program that uses the standard C library and needs objects of type `struct in_addr`, which is the C type for the 32-bit packed binary this function returns.

`inet_aton()` also accepts strings with less than three dots; see the Unix manual page `inet(3)` for details.

If the IPv4 address string passed to this function is invalid, `OSError` will be raised. Note that exactly what is valid depends on the underlying C implementation of `inet_aton()`.

`inet_aton()` does not support IPv6, and `inet_pton()` should be used instead for IPv4/v6 dual stack support.

`socket.inet_ntoa(packed_ip)`

Convert a 32-bit packed IPv4 address (a *bytes-like object* four bytes in length) to its standard dotted-quad string representation (for example, `'123.45.67.89'`). This is useful when conversing with a program that uses the standard C library and needs objects of type `struct in_addr`, which is the C type for the 32-bit packed binary data this function takes as an argument.

If the byte sequence passed to this function is not exactly 4 bytes in length, `OSError` will be raised. `inet_ntoa()` does not support IPv6, and `inet_ntop()` should be used instead for IPv4/v6 dual stack support.

在 3.5 版更改: Writable *bytes-like object* is now accepted.

`socket.inet_pton(address_family, ip_string)`

Convert an IP address from its family-specific string format to a packed, binary format. `inet_pton()` is useful when a library or network protocol calls for an object of type `struct in_addr` (similar to `inet_aton()`) or `struct in6_addr`.

Supported values for `address_family` are currently `AF_INET` and `AF_INET6`. If the IP address string `ip_string` is invalid, `OSError` will be raised. Note that exactly what is valid depends on both the value of `address_family` and the underlying implementation of `inet_pton()`.

Availability: Unix (maybe not all platforms), Windows.

在 3.4 版更改: Windows support added

`socket.inet_ntop(address_family, packed_ip)`

Convert a packed IP address (a *bytes-like object* of some number of bytes) to its standard, family-specific string representation (for example, `'7.10.0.5'` or `'5aef:2b::8'`). `inet_ntop()` is useful when a library or network protocol returns an object of type `struct in_addr` (similar to `inet_ntoa()`) or `struct in6_addr`.

Supported values for `address_family` are currently `AF_INET` and `AF_INET6`. If the bytes object `packed_ip` is not the correct length for the specified address family, `ValueError` will be raised. `OSError` is raised for errors from the call to `inet_ntop()`.

Availability: Unix (maybe not all platforms), Windows.

在 3.4 版更改: Windows support added

在 3.5 版更改: Writable *bytes-like object* is now accepted.

`socket.CMSG_LEN(length)`

Return the total length, without trailing padding, of an ancillary data item with associated data of the given `length`. This value can often be used as the buffer size for `recvmsg()` to receive a single item of ancillary data, but **RFC 3542** requires portable applications to use `CMSG_SPACE()` and thus include space for padding, even when the item will be the last in the buffer. Raises `OverflowError` if `length` is outside the permissible range of values.

Availability: most Unix platforms, possibly others.

3.3 新版功能.

`socket.CMSG_SPACE(length)`

Return the buffer size needed for `recvmsg()` to receive an ancillary data item with associated data of the given `length`, along with any trailing padding. The buffer space needed to receive multiple items is the sum of the `CMSG_SPACE()` values for their associated data lengths. Raises `OverflowError` if `length` is outside the permissible range of values.

Note that some systems might support ancillary data without providing this function. Also note that setting the buffer size using the results of this function may not precisely limit the amount of ancillary data that can be received, since additional data may be able to fit into the padding area.

Availability: most Unix platforms, possibly others.

3.3 新版功能.

`socket.getdefaulttimeout()`

Return the default timeout in seconds (float) for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

`socket.setdefaulttimeout(timeout)`

Set the default timeout in seconds (float) for new socket objects. When the socket module is first imported, the default is `None`. See `settimeout()` for possible values and their respective meanings.

`socket.sethostname(name)`

Set the machine's hostname to *name*. This will raise an `OSError` if you don't have enough rights.

Availability: Unix.

3.3 新版功能.

`socket.if_nameindex()`

Return a list of network interface information (index int, name string) tuples. `OSError` if the system call fails.

Availability: Unix.

3.3 新版功能.

`socket.if_nameindex(if_name)`

Return a network interface index number corresponding to an interface name. `OSError` if no interface with the given name exists.

Availability: Unix.

3.3 新版功能.

`socket.if_indextoname(if_index)`

Return a network interface name corresponding to an interface index number. `OSError` if no interface with the given index exists.

Availability: Unix.

3.3 新版功能.

18.1.3 Socket Objects

Socket objects have the following methods. Except for `makefile()`, these correspond to Unix system calls applicable to sockets.

在 3.2 版更改: Support for the *context manager* protocol was added. Exiting the context manager is equivalent to calling `close()`.

`socket.accept()`

Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair (*conn*, *address*) where *conn* is a new socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection.

The newly created socket is *non-inheritable*.

在 3.4 版更改: The socket is now non-inheritable.

在 3.5 版更改: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](#) for the rationale).

`socket.bind(address)`

Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family—see above.)

`socket.close()`

Mark the socket closed. The underlying system resource (e.g. a file descriptor) is also closed when all file objects from `makefile()` are closed. Once that happens, all future operations on the socket object will fail. The remote end will receive no more data (after queued data is flushed).

Sockets are automatically closed when they are garbage-collected, but it is recommended to `close()` them explicitly, or to use a `with` statement around them.

在 3.6 版更改: `OSError` is now raised if an error occurs when the underlying `close()` call is made.

注解: `close()` releases the resource associated with a connection but does not necessarily close the connection immediately. If you want to close the connection in a timely fashion, call `shutdown()` before `close()`.

`socket.connect(address)`

Connect to a remote socket at *address*. (The format of *address* depends on the address family—see above.)

If the connection is interrupted by a signal, the method waits until the connection completes, or raise a `socket.timeout` on timeout, if the signal handler doesn't raise an exception and the socket is blocking or has a timeout. For non-blocking sockets, the method raises an `InterruptedError` exception if the connection is interrupted by a signal (or the exception raised by the signal handler).

在 3.5 版更改: The method now waits until the connection completes instead of raising an `InterruptedError` exception if the connection is interrupted by a signal, the signal handler doesn't raise an exception and the socket is blocking or has a timeout (see the [PEP 475](#) for the rationale).

`socket.connect_ex(address)`

Like `connect(address)`, but return an error indicator instead of raising an exception for errors returned by the C-level `connect()` call (other problems, such as “host not found,” can still raise exceptions). The error indicator is 0 if the operation succeeded, otherwise the value of the `errno` variable. This is useful to support, for example, asynchronous connects.

`socket.detach()`

Put the socket object into closed state without actually closing the underlying file descriptor. The file descriptor is returned, and can be reused for other purposes.

3.2 新版功能.

`socket.dup()`

Duplicate the socket.

The newly created socket is *non-inheritable*.

在 3.4 版更改: The socket is now non-inheritable.

`socket.fileno()`

Return the socket's file descriptor (a small integer), or -1 on failure. This is useful with `select.select()`.

Under Windows the small integer returned by this method cannot be used where a file descriptor can be used (such as `os.fdopen()`). Unix does not have this limitation.

`socket.get_inheritable()`

Get the *inheritable flag* of the socket's file descriptor or socket's handle: `True` if the socket can be inherited in child processes, `False` if it cannot.

3.4 新版功能.

`socket.getpeername()`

Return the remote address to which the socket is connected. This is useful to find out the port number of a remote IPv4/v6 socket, for instance. (The format of the address returned depends on the address family —see above.) On some systems this function is not supported.

`socket.getsockname()`

Return the socket's own address. This is useful to find out the port number of an IPv4/v6 socket, for instance. (The format of the address returned depends on the address family —see above.)

`socket.getsockopt(level, optname[, buflen])`

Return the value of the given socket option (see the Unix man page *getsockopt(2)*). The needed symbolic constants (`SO_*` etc.) are defined in this module. If *buflen* is absent, an integer option is assumed and its integer value is returned by the function. If *buflen* is present, it specifies the maximum length of the buffer used to receive the option in, and this buffer is returned as a bytes object. It is up to the caller to decode the contents of the buffer (see the optional built-in module *struct* for a way to decode C structures encoded as byte strings).

`socket.gettimeout()`

Return the timeout in seconds (float) associated with socket operations, or `None` if no timeout is set. This reflects the last call to *setblocking()* or *settimeout()*.

`socket.ioctl(control, option)`**Platform Windows**

The *ioctl()* method is a limited interface to the `WSAIoctl` system interface. Please refer to the [Win32 documentation](#) for more information.

On other platforms, the generic *fcntl.fcntl()* and *fcntl.ioctl()* functions may be used; they accept a socket object as their first argument.

Currently only the following control codes are supported: `SIO_RCVALL`, `SIO_KEEPA_LIVE_VALS`, and `SIO_LOOPBACK_FAST_PATH`.

在 3.6 版更改: `SIO_LOOPBACK_FAST_PATH` was added.

`socket.listen([backlog])`

Enable a server to accept connections. If *backlog* is specified, it must be at least 0 (if it is lower, it is set to 0); it specifies the number of unaccepted connections that the system will allow before refusing new connections. If not specified, a default reasonable value is chosen.

在 3.5 版更改: The *backlog* parameter is now optional.

`socket.makefile(mode='r', buffering=None, *, encoding=None, errors=None, newline=None)`

Return a *file object* associated with the socket. The exact returned type depends on the arguments given to *makefile()*. These arguments are interpreted the same way as by the built-in *open()* function, except the only supported *mode* values are `'r'` (default), `'w'` and `'b'`.

The socket must be in blocking mode; it can have a timeout, but the file object's internal buffer may end up in an inconsistent state if a timeout occurs.

Closing the file object returned by *makefile()* won't close the original socket unless all other file objects have been closed and *socket.close()* has been called on the socket object.

注解: On Windows, the file-like object created by *makefile()* cannot be used where a file object with a file descriptor is expected, such as the stream arguments of *subprocess.Popen()*.

`socket.recv(buFSIZE[, flags])`

Receive data from the socket. The return value is a bytes object representing the data received. The maximum

amount of data to be received at once is specified by *bufsize*. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero.

注解: For best match with hardware and network realities, the value of *bufsize* should be a relatively small power of 2, for example, 4096.

在 3.5 版更改: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see [PEP 475](#) for the rationale).

`socket.recvfrom(bufsize[, flags])`

Receive data from the socket. The return value is a pair (*bytes*, *address*) where *bytes* is a bytes object representing the data received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family —see above.)

在 3.5 版更改: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see [PEP 475](#) for the rationale).

`socket.recvmsg(bufsize[, ancbufsize[, flags]])`

Receive normal data (up to *bufsize* bytes) and ancillary data from the socket. The *ancbufsize* argument sets the size in bytes of the internal buffer used to receive the ancillary data; it defaults to 0, meaning that no ancillary data will be received. Appropriate buffer sizes for ancillary data can be calculated using *MSG_SPACE()* or *MSG_LEN()*, and items which do not fit into the buffer might be truncated or discarded. The *flags* argument defaults to 0 and has the same meaning as for *recv()*.

The return value is a 4-tuple: (*data*, *ancdata*, *msg_flags*, *address*). The *data* item is a *bytes* object holding the non-ancillary data received. The *ancdata* item is a list of zero or more tuples (*cmsg_level*, *cmsg_type*, *cmsg_data*) representing the ancillary data (control messages) received: *cmsg_level* and *cmsg_type* are integers specifying the protocol level and protocol-specific type respectively, and *cmsg_data* is a *bytes* object holding the associated data. The *msg_flags* item is the bitwise OR of various flags indicating conditions on the received message; see your system documentation for details. If the receiving socket is unconnected, *address* is the address of the sending socket, if available; otherwise, its value is unspecified.

On some systems, *sendmsg()* and *recvmsg()* can be used to pass file descriptors between processes over an *AF_UNIX* socket. When this facility is used (it is often restricted to *SOCK_STREAM* sockets), *recvmsg()* will return, in its ancillary data, items of the form (*socket.SOL_SOCKET*, *socket.SCM_RIGHTS*, *fds*), where *fds* is a *bytes* object representing the new file descriptors as a binary array of the native C *int* type. If *recvmsg()* raises an exception after the system call returns, it will first attempt to close any file descriptors received via this mechanism.

Some systems do not indicate the truncated length of ancillary data items which have been only partially received. If an item appears to extend beyond the end of the buffer, *recvmsg()* will issue a *RuntimeWarning*, and will return the part of it which is inside the buffer provided it has not been truncated before the start of its associated data.

On systems which support the *SCM_RIGHTS* mechanism, the following function will receive up to *maxfds* file descriptors, returning the message data and a list containing the descriptors (while ignoring unexpected conditions such as unrelated control messages being received). See also *sendmsg()*.

```
import socket, array

def recv_fds(sock, msglen, maxfds):
    fds = array.array("i")    # Array of ints
    msg, ancdata, flags, addr = sock.recvmsg(msglen, socket.CMSG_LEN(maxfds * fds.
    ↪ itemsize))
    for cmsg_level, cmsg_type, cmsg_data in ancdata:
```

(下页继续)

(续上页)

```

    if (cmsg_level == socket.SOL_SOCKET and cmsg_type == socket.SCM_RIGHTS):
        # Append data, ignoring any truncated integers at the end.
        fds.fromstring(cmsg_data[:len(cmsg_data) - (len(cmsg_data) % fds.
↪itemsize)])
    return msg, list(fds)

```

Availability: most Unix platforms, possibly others.

3.3 新版功能.

在 3.5 版更改: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see [PEP 475](#) for the rationale).

`socket.recvmsg_into(buffers[, ancbufsize[, flags]])`

Receive normal data and ancillary data from the socket, behaving as *recvmsg()* would, but scatter the non-ancillary data into a series of buffers instead of returning a new bytes object. The *buffers* argument must be an iterable of objects that export writable buffers (e.g. *bytearray* objects); these will be filled with successive chunks of the non-ancillary data until it has all been written or there are no more buffers. The operating system may set a limit (*sysconf()* value *SC_IOV_MAX*) on the number of buffers that can be used. The *ancbufsize* and *flags* arguments have the same meaning as for *recvmsg()*.

The return value is a 4-tuple: (*nbytes*, *ancdata*, *msg_flags*, *address*), where *nbytes* is the total number of bytes of non-ancillary data written into the buffers, and *ancdata*, *msg_flags* and *address* are the same as for *recvmsg()*.

示例:

```

>>> import socket
>>> s1, s2 = socket.socketpair()
>>> b1 = bytearray(b'----')
>>> b2 = bytearray(b'0123456789')
>>> b3 = bytearray(b'-----')
>>> s1.send(b'Mary had a little lamb')
22
>>> s2.recvmsg_into([b1, memoryview(b2)[2:9], b3])
(22, [], 0, None)
>>> [b1, b2, b3]
[bytearray(b'Mary'), bytearray(b'01 had a 9'), bytearray(b'little lamb---')]

```

Availability: most Unix platforms, possibly others.

3.3 新版功能.

`socket.recvfrom_into(buffer[, nbytes[, flags]])`

Receive data from the socket, writing it into *buffer* instead of creating a new bytestring. The return value is a pair (*nbytes*, *address*) where *nbytes* is the number of bytes received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.)

`socket.recv_into(buffer[, nbytes[, flags]])`

Receive up to *nbytes* bytes from the socket, storing the data into a buffer rather than creating a new bytestring. If *nbytes* is not specified (or 0), receive up to the size available in the given buffer. Returns the number of bytes received. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero.

`socket.send(bytes[, flags])`

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for *recv()* above. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data. For further information on this topic, consult the socket-howto.

在 3.5 版更改: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see [PEP 475](#) for the rationale).

`socket.sendall(bytes[, flags])`

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for *recv()* above. Unlike *send()*, this method continues to send data from *bytes* until either all data has been sent or an error occurs. *None* is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

在 3.5 版更改: The socket timeout is no more reset each time data is sent successfully. The socket timeout is now the maximum total duration to send all data.

在 3.5 版更改: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see [PEP 475](#) for the rationale).

`socket.sendto(bytes, address)`

`socket.sendto(bytes, flags, address)`

Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by *address*. The optional *flags* argument has the same meaning as for *recv()* above. Return the number of bytes sent. (The format of *address* depends on the address family —see above.)

在 3.5 版更改: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see [PEP 475](#) for the rationale).

`socket.sendmsg(buffers[, ancdata[, flags[, address]]])`

Send normal and ancillary data to the socket, gathering the non-ancillary data from a series of buffers and concatenating it into a single message. The *buffers* argument specifies the non-ancillary data as an iterable of *bytes-like objects* (e.g. *bytes* objects); the operating system may set a limit (*sysconf()* value *SC_IOV_MAX*) on the number of buffers that can be used. The *ancdata* argument specifies the ancillary data (control messages) as an iterable of zero or more tuples (*cmsg_level*, *cmsg_type*, *cmsg_data*), where *cmsg_level* and *cmsg_type* are integers specifying the protocol level and protocol-specific type respectively, and *cmsg_data* is a bytes-like object holding the associated data. Note that some systems (in particular, systems without *CMSG_SPACE()*) might support sending only one control message per call. The *flags* argument defaults to 0 and has the same meaning as for *send()*. If *address* is supplied and not *None*, it sets a destination address for the message. The return value is the number of bytes of non-ancillary data sent.

The following function sends the list of file descriptors *fds* over an *AF_UNIX* socket, on systems which support the *SCM_RIGHTS* mechanism. See also *recvmsg()*.

```
import socket, array

def send_fds(sock, msg, fds):
    return sock.sendmsg([msg], [(socket.SOL_SOCKET, socket.SCM_RIGHTS, array.
    ↪array("i", fds))])
```

Availability: most Unix platforms, possibly others.

3.3 新版功能.

在 3.5 版更改: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see [PEP 475](#) for the rationale).

`socket.sendmsg_afalg([msg], *, op[, iv[, assoclen[, flags]]])`

Specialized version of *sendmsg()* for *AF_ALG* socket. Set mode, IV, AEAD associated data length and flags for *AF_ALG* socket.

Availability: Linux >= 2.6.38

3.6 新版功能.

`socket.sendfile(file, offset=0, count=None)`

Send a file until EOF is reached by using high-performance `os.sendfile` and return the total number of bytes which were sent. `file` must be a regular file object opened in binary mode. If `os.sendfile` is not available (e.g. Windows) or `file` is not a regular file `send()` will be used instead. `offset` tells from where to start reading the file. If specified, `count` is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is updated on return or also in case of error in which case `file.tell()` can be used to figure out the number of bytes which were sent. The socket must be of `SOCK_STREAM` type. Non-blocking sockets are not supported.

3.5 新版功能.

`socket.set_inheritable(inheritable)`

Set the *inheritable flag* of the socket's file descriptor or socket's handle.

3.4 新版功能.

`socket.setblocking(flag)`

Set blocking or non-blocking mode of the socket: if `flag` is false, the socket is set to non-blocking, else to blocking mode.

This method is a shorthand for certain `settimeout()` calls:

- `sock.setblocking(True)` is equivalent to `sock.settimeout(None)`
- `sock.setblocking(False)` is equivalent to `sock.settimeout(0.0)`

`socket.settimeout(value)`

Set a timeout on blocking socket operations. The `value` argument can be a nonnegative floating point number expressing seconds, or `None`. If a non-zero value is given, subsequent socket operations will raise a `timeout` exception if the timeout period `value` has elapsed before the operation has completed. If zero is given, the socket is put in non-blocking mode. If `None` is given, the socket is put in blocking mode.

For further information, please consult the [notes on socket timeouts](#).

`socket.setsockopt(level, optname, value: int)`

`socket.setsockopt(level, optname, value: buffer)`

`socket.setsockopt(level, optname, None, optlen: int)`

Set the value of the given socket option (see the Unix manual page `setsockopt(2)`). The needed symbolic constants are defined in the `socket` module (`SO_*` etc.). The value can be an integer, `None` or a *bytes-like object* representing a buffer. In the later case it is up to the caller to ensure that the bytestring contains the proper bits (see the optional built-in module `struct` for a way to encode C structures as bytestrings). When value is set to `None`, `optlen` argument is required. It's equivalent to call `setsockopt` C function with `optval=NULL` and `optlen=optlen`.

在 3.5 版更改: Writable *bytes-like object* is now accepted.

在 3.6 版更改: `setsockopt(level, optname, None, optlen: int)` form added.

`socket.shutdown(how)`

Shut down one or both halves of the connection. If `how` is `SHUT_RD`, further receives are disallowed. If `how` is `SHUT_WR`, further sends are disallowed. If `how` is `SHUT_RDWR`, further sends and receives are disallowed.

`socket.share(process_id)`

Duplicate a socket and prepare it for sharing with a target process. The target process must be provided with `process_id`. The resulting bytes object can then be passed to the target process using some form of interprocess communication and the socket can be recreated there using `fromshare()`. Once this method has been called, it is safe to close the socket since the operating system has already duplicated it for the target process.

Availability: Windows.

3.3 新版功能.

Note that there are no methods `read()` or `write()`; use `recv()` and `send()` without *flags* argument instead.

Socket objects also have these (read-only) attributes that correspond to the values given to the `socket` constructor.

`socket.family`

The socket family.

`socket.type`

The socket type.

`socket.proto`

The socket protocol.

18.1.4 Notes on socket timeouts

A socket object can be in one of three modes: blocking, non-blocking, or timeout. Sockets are by default always created in blocking mode, but this can be changed by calling `setdefaulttimeout()`.

- In *blocking mode*, operations block until complete or the system returns an error (such as connection timed out).
- In *non-blocking mode*, operations fail (with an error that is unfortunately system-dependent) if they cannot be completed immediately: functions from the `select` can be used to know when and whether a socket is available for reading or writing.
- In *timeout mode*, operations fail if they cannot be completed within the timeout specified for the socket (they raise a `timeout` exception) or if the system returns an error.

注解: At the operating system level, sockets in *timeout mode* are internally set in non-blocking mode. Also, the blocking and timeout modes are shared between file descriptors and socket objects that refer to the same network endpoint. This implementation detail can have visible consequences if e.g. you decide to use the `fileno()` of a socket.

Timeouts and the `connect` method

The `connect()` operation is also subject to the timeout setting, and in general it is recommended to call `settimeout()` before calling `connect()` or pass a timeout parameter to `create_connection()`. However, the system network stack may also return a connection timeout error of its own regardless of any Python socket timeout setting.

Timeouts and the `accept` method

If `getdefaulttimeout()` is not `None`, sockets returned by the `accept()` method inherit that timeout. Otherwise, the behaviour depends on settings of the listening socket:

- if the listening socket is in *blocking mode* or in *timeout mode*, the socket returned by `accept()` is in *blocking mode*;
- if the listening socket is in *non-blocking mode*, whether the socket returned by `accept()` is in blocking or non-blocking mode is operating system-dependent. If you want to ensure cross-platform behaviour, it is recommended you manually override this setting.

18.1.5 示例

Here are four minimal example programs using the TCP/IP protocol: a server that echoes all data that it receives back (servicing only one client), and a client using it. Note that a server must perform the sequence `socket()`, `bind()`, `listen()`, `accept()` (possibly repeating the `accept()` to service more than one client), while a client only needs the sequence `socket()`, `connect()`. Also note that the server does not `sendall()/recv()` on the socket it is listening on but on the new socket returned by `accept()`.

The first two examples support IPv4 only.

```
# Echo server program
import socket

HOST = ''          # Symbolic name meaning all available interfaces
PORT = 50007       # Arbitrary non-privileged port
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as s:
    s.bind((HOST, PORT))
    s.listen(1)
    conn, addr = s.accept()
    with conn:
        print('Connected by', addr)
        while True:
            data = conn.recv(1024)
            if not data: break
            conn.sendall(data)
```

```
# Echo client program
import socket

HOST = 'daring.cwi.nl' # The remote host
PORT = 50007           # The same port as used by the server
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as s:
    s.connect((HOST, PORT))
    s.sendall(b'Hello, world')
    data = s.recv(1024)
print('Received', repr(data))
```

The next two examples are identical to the above two, but support both IPv4 and IPv6. The server side will listen to the first address family available (it should listen to both instead). On most of IPv6-ready systems, IPv6 will take precedence and the server may not accept IPv4 traffic. The client side will try to connect to the all addresses returned as a result of the name resolution, and sends traffic to the first one connected successfully.

```
# Echo server program
import socket
import sys

HOST = None        # Symbolic name meaning all available interfaces
PORT = 50007       # Arbitrary non-privileged port
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC,
                              socket.SOCK_STREAM, 0, socket.AI_PASSIVE):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except OSError as msg:
        s = None
        continue
```

(下页继续)

(续上页)

```

    try:
        s.bind(sa)
        s.listen(1)
    except OSError as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print('could not open socket')
    sys.exit(1)
conn, addr = s.accept()
with conn:
    print('Connected by', addr)
    while True:
        data = conn.recv(1024)
        if not data: break
        conn.send(data)

```

```

# Echo client program
import socket
import sys

HOST = 'daring.cwi.nl'      # The remote host
PORT = 50007                # The same port as used by the server
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC, socket.SOCK_STREAM):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except OSError as msg:
        s = None
        continue
    try:
        s.connect(sa)
    except OSError as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print('could not open socket')
    sys.exit(1)
with s:
    s.sendall(b'Hello, world')
    data = s.recv(1024)
print('Received', repr(data))

```

The next example shows how to write a very simple network sniffer with raw sockets on Windows. The example requires administrator privileges to modify the interface:

```

import socket

# the public network interface
HOST = socket.gethostname(socket.gethostname())

```

(下页继续)

(续上页)

```
# create a raw socket and bind it to the public interface
s = socket.socket(socket.AF_INET, socket.SOCK_RAW, socket.IPPROTO_IP)
s.bind((HOST, 0))

# Include IP headers
s.setsockopt(socket.IPPROTO_IP, socket.IP_HDRINCL, 1)

# receive all packages
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_ON)

# receive a package
print(s.recvfrom(65565))

# disabled promiscuous mode
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_OFF)
```

The last example shows how to use the socket interface to communicate to a CAN network using the raw socket protocol. To use CAN with the broadcast manager protocol instead, open a socket with:

```
socket.socket(socket.AF_CAN, socket.SOCK_DGRAM, socket.CAN_BCM)
```

After binding (`CAN_RAW`) or connecting (`CAN_BCM`) the socket, you can use the `socket.send()`, and the `socket.recv()` operations (and their counterparts) on the socket object as usual.

This example might require special privileges:

```
import socket
import struct

# CAN frame packing/unpacking (see 'struct can_frame' in <linux/can.h>)

can_frame_fmt = "=IB3x8s"
can_frame_size = struct.calcsize(can_frame_fmt)

def build_can_frame(can_id, data):
    can_dlc = len(data)
    data = data.ljust(8, b'\x00')
    return struct.pack(can_frame_fmt, can_id, can_dlc, data)

def dissect_can_frame(frame):
    can_id, can_dlc, data = struct.unpack(can_frame_fmt, frame)
    return (can_id, can_dlc, data[:can_dlc])

# create a raw socket and bind it to the 'vcan0' interface
s = socket.socket(socket.AF_CAN, socket.SOCK_RAW, socket.CAN_RAW)
s.bind(('vcan0',))

while True:
    cf, addr = s.recvfrom(can_frame_size)

    print('Received: can_id=%x, can_dlc=%x, data=%s' % dissect_can_frame(cf))

    try:
        s.send(cf)
    except OSError:
```

(下页继续)

(续上页)

```
print('Error sending CAN frame')

try:
    s.send(build_can_frame(0x01, b'\x01\x02\x03'))
except OSError:
    print('Error sending CAN frame')
```

Running an example several times with too small delay between executions, could lead to this error:

```
OSError: [Errno 98] Address already in use
```

This is because the previous execution has left the socket in a `TIME_WAIT` state, and can't be immediately reused.

There is a `socket` flag to set, in order to prevent this, `socket.SO_REUSEADDR`:

```
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.setsockopt(socket.SOL_SOCKET, socket.SO_REUSEADDR, 1)
s.bind((HOST, PORT))
```

the `SO_REUSEADDR` flag tells the kernel to reuse a local socket in `TIME_WAIT` state, without waiting for its natural timeout to expire.

参见:

For an introduction to socket programming (in C), see the following papers:

- *An Introductory 4.3BSD Interprocess Communication Tutorial*, by Stuart Sechrest
- *An Advanced 4.3BSD Interprocess Communication Tutorial*, by Samuel J. Leffler et al,

both in the UNIX Programmer's Manual, Supplementary Documents 1 (sections PS1:7 and PS1:8). The platform-specific reference material for the various socket-related system calls are also a valuable source of information on the details of socket semantics. For Unix, refer to the manual pages; for Windows, see the WinSock (or Winsock 2) specification. For IPv6-ready APIs, readers may want to refer to [RFC 3493](#) titled Basic Socket Interface Extensions for IPv6.

18.2 `ssl` — TLS/SSL wrapper for socket objects

Source code: [Lib/ssl.py](#)

This module provides access to Transport Layer Security (often known as “Secure Sockets Layer”) encryption and peer authentication facilities for network sockets, both client-side and server-side. This module uses the OpenSSL library. It is available on all modern Unix systems, Windows, Mac OS X, and probably additional platforms, as long as OpenSSL is installed on that platform.

注解: Some behavior may be platform dependent, since calls are made to the operating system socket APIs. The installed version of OpenSSL may also cause variations in behavior. For example, TLSv1.1 and TLSv1.2 come with openssl version 1.0.1.

警告: Don't use this module without reading the [Security considerations](#). Doing so may lead to a false sense of security, as the default settings of the `ssl` module are not necessarily appropriate for your application.

This section documents the objects and functions in the `ssl` module; for more general information about TLS, SSL, and certificates, the reader is referred to the documents in the “See Also” section at the bottom.

This module provides a class, `ssl.SSLSocket`, which is derived from the `socket.socket` type, and provides a socket-like wrapper that also encrypts and decrypts the data going over the socket with SSL. It supports additional methods such as `getpeercert()`, which retrieves the certificate of the other side of the connection, and `cipher()`, which retrieves the cipher being used for the secure connection.

For more sophisticated applications, the `ssl.SSLContext` class helps manage settings and certificates, which can then be inherited by SSL sockets created through the `SSLContext.wrap_socket()` method.

在 3.5.3 版更改: Updated to support linking with OpenSSL 1.1.0

在 3.6 版更改: OpenSSL 0.9.8, 1.0.0 and 1.0.1 are deprecated and no longer supported. In the future the `ssl` module will require at least OpenSSL 1.0.2 or 1.1.0.

18.2.1 Functions, Constants, and Exceptions

exception `ssl.SSLError`

Raised to signal an error from the underlying SSL implementation (currently provided by the OpenSSL library). This signifies some problem in the higher-level encryption and authentication layer that’s superimposed on the underlying network connection. This error is a subtype of `OSError`. The error code and message of `SSLError` instances are provided by the OpenSSL library.

在 3.3 版更改: `SSLError` used to be a subtype of `socket.error`.

library

A string mnemonic designating the OpenSSL submodule in which the error occurred, such as `SSL`, `PEM` or `X509`. The range of possible values depends on the OpenSSL version.

3.3 新版功能.

reason

A string mnemonic designating the reason this error occurred, for example `CERTIFICATE_VERIFY_FAILED`. The range of possible values depends on the OpenSSL version.

3.3 新版功能.

exception `ssl.SSLZeroReturnError`

A subclass of `SSLError` raised when trying to read or write and the SSL connection has been closed cleanly. Note that this doesn’t mean that the underlying transport (read TCP) has been closed.

3.3 新版功能.

exception `ssl.SSLWantReadError`

A subclass of `SSLError` raised by a *non-blocking SSL socket* when trying to read or write data, but more data needs to be received on the underlying TCP transport before the request can be fulfilled.

3.3 新版功能.

exception `ssl.SSLWantWriteError`

A subclass of `SSLError` raised by a *non-blocking SSL socket* when trying to read or write data, but more data needs to be sent on the underlying TCP transport before the request can be fulfilled.

3.3 新版功能.

exception `ssl.SSLSyscallError`

A subclass of `SSLError` raised when a system error was encountered while trying to fulfill an operation on a SSL socket. Unfortunately, there is no easy way to inspect the original `errno` number.

3.3 新版功能.

exception `ssl.SSLEOFError`

A subclass of `SSLError` raised when the SSL connection has been terminated abruptly. Generally, you shouldn't try to reuse the underlying transport when this error is encountered.

3.3 新版功能.

exception `ssl.CertificateError`

Raised to signal an error with a certificate (such as mismatching hostname). Certificate errors detected by OpenSSL, though, raise an `SSLError`.

Socket creation

The following function allows for standalone socket creation. Starting from Python 3.2, it can be more flexible to use `SSLContext.wrap_socket()` instead.

`ssl.wrap_socket(sock, keyfile=None, certfile=None, server_side=False, cert_reqs=CERT_NONE, ssl_version={see docs}, ca_certs=None, do_handshake_on_connect=True, suppress_ragged_eofs=True, ciphers=None)`

Takes an instance `sock` of `socket.socket`, and returns an instance of `ssl.SSLSocket`, a subtype of `socket.socket`, which wraps the underlying socket in an SSL context. `sock` must be a `SOCK_STREAM` socket; other socket types are unsupported.

For client-side sockets, the context construction is lazy; if the underlying socket isn't connected yet, the context construction will be performed after `connect()` is called on the socket. For server-side sockets, if the socket has no remote peer, it is assumed to be a listening socket, and the server-side SSL wrapping is automatically performed on client connections accepted via the `accept()` method. `wrap_socket()` may raise `SSLError`.

The `keyfile` and `certfile` parameters specify optional files which contain a certificate to be used to identify the local side of the connection. See the discussion of [Certificates](#) for more information on how the certificate is stored in the `certfile`.

The parameter `server_side` is a boolean which identifies whether server-side or client-side behavior is desired from this socket.

The parameter `cert_reqs` specifies whether a certificate is required from the other side of the connection, and whether it will be validated if provided. It must be one of the three values `CERT_NONE` (certificates ignored), `CERT_OPTIONAL` (not required, but validated if provided), or `CERT_REQUIRED` (required and validated). If the value of this parameter is not `CERT_NONE`, then the `ca_certs` parameter must point to a file of CA certificates.

The `ca_certs` file contains a set of concatenated “certification authority” certificates, which are used to validate certificates passed from the other end of the connection. See the discussion of [Certificates](#) for more information about how to arrange the certificates in this file.

The parameter `ssl_version` specifies which version of the SSL protocol to use. Typically, the server chooses a particular protocol version, and the client must adapt to the server's choice. Most of the versions are not interoperable with the other versions. If not specified, the default is `PROTOCOL_TLS`; it provides the most compatibility with other versions.

Here's a table showing which versions in a client (down the side) can connect to which versions in a server (along the top):

<i>client / server</i>	SSLv2	SSLv3	TLS ³	TLSv1	TLSv1.1	TLSv1.2
SSLv2	yes	no	no ¹	no	no	no
SSLv3	no	yes	no ²	no	no	no
TLS (SSLv23) ³	no ¹	no ²	yes	yes	yes	yes
TLSv1	no	no	yes	yes	no	no
TLSv1.1	no	no	yes	no	yes	no
TLSv1.2	no	no	yes	no	no	yes

注解： Which connections succeed will vary depending on the version of OpenSSL. For example, before OpenSSL 1.0.0, an SSLv23 client would always attempt SSLv2 connections.

The *ciphers* parameter sets the available ciphers for this SSL object. It should be a string in the [OpenSSL cipher list format](#).

The parameter *do_handshake_on_connect* specifies whether to do the SSL handshake automatically after doing a `socket.connect()`, or whether the application program will call it explicitly, by invoking the `SSLSocket.do_handshake()` method. Calling `SSLSocket.do_handshake()` explicitly gives the program control over the blocking behavior of the socket I/O involved in the handshake.

The parameter *suppress_ragged_eofs* specifies how the `SSLSocket.recv()` method should signal unexpected EOF from the other end of the connection. If specified as *True* (the default), it returns a normal EOF (an empty bytes object) in response to unexpected EOF errors raised from the underlying socket; if *False*, it will raise the exceptions back to the caller.

在 3.2 版更改: New optional argument *ciphers*.

Context creation

A convenience function helps create `SSLContext` objects for common purposes.

`ssl.create_default_context(purpose=Purpose.SERVER_AUTH, cafile=None, capath=None, cadata=None)`

Return a new `SSLContext` object with default settings for the given *purpose*. The settings are chosen by the `ssl` module, and usually represent a higher security level than when calling the `SSLContext` constructor directly.

cafile, *capath*, *cadata* represent optional CA certificates to trust for certificate verification, as in `SSLContext.load_verify_locations()`. If all three are *None*, this function can choose to trust the system's default CA certificates instead.

The settings are: `PROTOCOL_TLS`, `OP_NO_SSLv2`, and `OP_NO_SSLv3` with high encryption cipher suites without RC4 and without unauthenticated cipher suites. Passing `SERVER_AUTH` as *purpose* sets *verify_mode* to `CERT_REQUIRED` and either loads CA certificates (when at least one of *cafile*, *capath* or *cadata* is given) or uses `SSLContext.load_default_certs()` to load default CA certificates.

注解： The protocol, options, cipher and other settings may change to more restrictive values anytime without prior deprecation. The values represent a fair balance between compatibility and security.

If your application needs specific settings, you should create a `SSLContext` and apply the settings yourself.

注解： If you find that when certain older clients or servers attempt to connect with a `SSLContext` created by this function that they get an error stating “Protocol or cipher suite mismatch”, it may be that they only support SSL3.0 which this function excludes using the `OP_NO_SSLv3`. SSL3.0 is widely considered to be [completely broken](#). If you still wish to continue to use this function but still allow SSL 3.0 connections you can re-enable them using:

```
ctx = ssl.create_default_context(Purpose.CLIENT_AUTH)
ctx.options |= ~ssl.OP_NO_SSLv3
```

³ TLS 1.3 protocol will be available with `PROTOCOL_TLS` in OpenSSL \geq 1.1.1. There is no dedicated PROTOCOL constant for just TLS 1.3.

¹ `SSLContext` disables SSLv2 with `OP_NO_SSLv2` by default.

² `SSLContext` disables SSLv3 with `OP_NO_SSLv3` by default.

3.4 新版功能.

在 3.4.4 版更改: RC4 was dropped from the default cipher string.

在 3.6 版更改: ChaCha20/Poly1305 was added to the default cipher string.

3DES was dropped from the default cipher string.

Random generation

`ssl.RAND_bytes(num)`

Return *num* cryptographically strong pseudo-random bytes. Raises an *SSL**Error* if the PRNG has not been seeded with enough data or if the operation is not supported by the current RAND method. *RAND_status()* can be used to check the status of the PRNG and *RAND_add()* can be used to seed the PRNG.

For almost all applications *os.urandom()* is preferable.

Read the Wikipedia article, [Cryptographically secure pseudorandom number generator \(CSPRNG\)](#), to get the requirements of a cryptographically generator.

3.3 新版功能.

`ssl.RAND_pseudo_bytes(num)`

Return (bytes, is_cryptographic): bytes are *num* pseudo-random bytes, is_cryptographic is *True* if the bytes generated are cryptographically strong. Raises an *SSL**Error* if the operation is not supported by the current RAND method.

Generated pseudo-random byte sequences will be unique if they are of sufficient length, but are not necessarily unpredictable. They can be used for non-cryptographic purposes and for certain purposes in cryptographic protocols, but usually not for key generation etc.

For almost all applications *os.urandom()* is preferable.

3.3 新版功能.

3.6 版后已移除: OpenSSL has deprecated *ssl.RAND_pseudo_bytes()*, use *ssl.RAND_bytes()* instead.

`ssl.RAND_status()`

Return *True* if the SSL pseudo-random number generator has been seeded with ‘enough’ randomness, and *False* otherwise. You can use *ssl.RAND_egd()* and *ssl.RAND_add()* to increase the randomness of the pseudo-random number generator.

`ssl.RAND_egd(path)`

If you are running an entropy-gathering daemon (EGD) somewhere, and *path* is the pathname of a socket connection open to it, this will read 256 bytes of randomness from the socket, and add it to the SSL pseudo-random number generator to increase the security of generated secret keys. This is typically only necessary on systems without better sources of randomness.

See <http://egd.sourceforge.net/> or <http://prngd.sourceforge.net/> for sources of entropy-gathering daemons.

Availability: not available with LibreSSL and OpenSSL > 1.1.0

`ssl.RAND_add(bytes, entropy)`

Mix the given *bytes* into the SSL pseudo-random number generator. The parameter *entropy* (a float) is a lower bound on the entropy contained in string (so you can always use 0.0). See [RFC 1750](#) for more information on sources of entropy.

在 3.5 版更改: Writable *bytes-like object* is now accepted.

Certificate handling

`ssl.match_hostname(cert, hostname)`

Verify that *cert* (in decoded format as returned by `SSLSocket.getpeercert()`) matches the given *hostname*. The rules applied are those for checking the identity of HTTPS servers as outlined in [RFC 2818](#), [RFC 5280](#) and [RFC 6125](#). In addition to HTTPS, this function should be suitable for checking the identity of servers in various SSL-based protocols such as FTPS, IMAPS, POPS and others.

`CertificateError` is raised on failure. On success, the function returns nothing:

```
>>> cert = {'subject': (('commonName', 'example.com'),),)}
>>> ssl.match_hostname(cert, "example.com")
>>> ssl.match_hostname(cert, "example.org")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/py3k/Lib/ssl.py", line 130, in match_hostname
ssl.CertificateError: hostname 'example.org' doesn't match 'example.com'
```

3.2 新版功能.

在 3.3.3 版更改: The function now follows [RFC 6125](#), section 6.4.3 and does neither match multiple wildcards (e.g. `*.*.com` or `*a*.example.org`) nor a wildcard inside an internationalized domain names (IDN) fragment. IDN A-labels such as `www*.xn--python-kva.org` are still supported, but `x*.python.org` no longer matches `xn--tda.python.org`.

在 3.5 版更改: Matching of IP addresses, when present in the `subjectAltName` field of the certificate, is now supported.

`ssl.cert_time_to_seconds(cert_time)`

Return the time in seconds since the Epoch, given the *cert_time* string representing the “notBefore” or “notAfter” date from a certificate in “%b %d %H:%M:%S %Y %Z” `strptime` format (C locale).

Here’s an example:

```
>>> import ssl
>>> timestamp = ssl.cert_time_to_seconds("Jan  5 09:34:43 2018 GMT")
>>> timestamp
1515144883
>>> from datetime import datetime
>>> print(datetime.utcfromtimestamp(timestamp))
2018-01-05 09:34:43
```

“notBefore” or “notAfter” dates must use GMT ([RFC 5280](#)).

在 3.5 版更改: Interpret the input time as a time in UTC as specified by ‘GMT’ timezone in the input string. Local timezone was used previously. Return an integer (no fractions of a second in the input format)

`ssl.get_server_certificate(addr, ssl_version=PROTOCOL_TLS, ca_certs=None)`

Given the address *addr* of an SSL-protected server, as a (*hostname*, *port-number*) pair, fetches the server’s certificate, and returns it as a PEM-encoded string. If *ssl_version* is specified, uses that version of the SSL protocol to attempt to connect to the server. If *ca_certs* is specified, it should be a file containing a list of root certificates, the same format as used for the same parameter in `wrap_socket()`. The call will attempt to validate the server certificate against that set of root certificates, and will fail if the validation attempt fails.

在 3.3 版更改: This function is now IPv6-compatible.

在 3.5 版更改: The default *ssl_version* is changed from `PROTOCOL_SSLv3` to `PROTOCOL_TLS` for maximum compatibility with modern servers.

`ssl.DER_cert_to_PEM_cert(DER_cert_bytes)`

Given a certificate as a DER-encoded blob of bytes, returns a PEM-encoded string version of the same certificate.

`ssl.PEM_cert_to_DER_cert (PEM_cert_string)`

Given a certificate as an ASCII PEM string, returns a DER-encoded sequence of bytes for that same certificate.

`ssl.get_default_verify_paths ()`

Returns a named tuple with paths to OpenSSL's default cafile and capath. The paths are the same as used by `SSLContext.set_default_verify_paths()`. The return value is a *named tuple* `DefaultVerifyPaths`:

- `cafile` - resolved path to cafile or `None` if the file doesn't exist,
- `capath` - resolved path to capath or `None` if the directory doesn't exist,
- `openssl_cafile_env` - OpenSSL's environment key that points to a cafile,
- `openssl_cafile` - hard coded path to a cafile,
- `openssl_capath_env` - OpenSSL's environment key that points to a capath,
- `openssl_capath` - hard coded path to a capath directory

Availability: LibreSSL ignores the environment vars `openssl_cafile_env` and `openssl_capath_env`

3.4 新版功能.

`ssl.enum_certificates (store_name)`

Retrieve certificates from Windows' system cert store. `store_name` may be one of `CA`, `ROOT` or `MY`. Windows may provide additional cert stores, too.

The function returns a list of (cert_bytes, encoding_type, trust) tuples. The `encoding_type` specifies the encoding of cert_bytes. It is either `x509_asn` for X.509 ASN.1 data or `pkcs_7_asn` for PKCS#7 ASN.1 data. Trust specifies the purpose of the certificate as a set of OIDs or exactly `True` if the certificate is trustworthy for all purposes.

示例:

```
>>> ssl.enum_certificates("CA")
[(b'data...', 'x509_asn', {'1.3.6.1.5.5.7.3.1', '1.3.6.1.5.5.7.3.2'}),
 (b'data...', 'x509_asn', True)]
```

Availability: Windows.

3.4 新版功能.

`ssl.enum_crls (store_name)`

Retrieve CRLs from Windows' system cert store. `store_name` may be one of `CA`, `ROOT` or `MY`. Windows may provide additional cert stores, too.

The function returns a list of (cert_bytes, encoding_type, trust) tuples. The `encoding_type` specifies the encoding of cert_bytes. It is either `x509_asn` for X.509 ASN.1 data or `pkcs_7_asn` for PKCS#7 ASN.1 data.

Availability: Windows.

3.4 新版功能.

常数

All constants are now `enum.IntEnum` or `enum.IntFlag` collections.

3.6 新版功能.

ssl.CERT_NONE

Possible value for `SSLContext.verify_mode`, or the `cert_reqs` parameter to `wrap_socket()`. Except for `PROTOCOL_TLS_CLIENT`, it is the default mode. With client-side sockets, just about any cert is accepted. Validation errors, such as untrusted or expired cert, are ignored and do not abort the TLS/SSL handshake.

In server mode, no certificate is requested from the client, so the client does not send any for client cert authentication.

See the discussion of *Security considerations* below.

ssl.CERT_OPTIONAL

Possible value for `SSLContext.verify_mode`, or the `cert_reqs` parameter to `wrap_socket()`. In client mode, `CERT_OPTIONAL` has the same meaning as `CERT_REQUIRED`. It is recommended to use `CERT_REQUIRED` for client-side sockets instead.

In server mode, a client certificate request is sent to the client. The client may either ignore the request or send a certificate in order to perform TLS client cert authentication. If the client chooses to send a certificate, it is verified. Any verification error immediately aborts the TLS handshake.

Use of this setting requires a valid set of CA certificates to be passed, either to `SSLContext.load_verify_locations()` or as a value of the `ca_certs` parameter to `wrap_socket()`.

ssl.CERT_REQUIRED

Possible value for `SSLContext.verify_mode`, or the `cert_reqs` parameter to `wrap_socket()`. In this mode, certificates are required from the other side of the socket connection; an `SSLError` will be raised if no certificate is provided, or if its validation fails. This mode is **not** sufficient to verify a certificate in client mode as it does not match hostnames. `check_hostname` must be enabled as well to verify the authenticity of a cert. `PROTOCOL_TLS_CLIENT` uses `CERT_REQUIRED` and enables `check_hostname` by default.

With server socket, this mode provides mandatory TLS client cert authentication. A client certificate request is sent to the client and the client must provide a valid and trusted certificate.

Use of this setting requires a valid set of CA certificates to be passed, either to `SSLContext.load_verify_locations()` or as a value of the `ca_certs` parameter to `wrap_socket()`.

class ssl.VerifyMode

enum.IntEnum collection of `CERT_*` constants.

3.6 新版功能.

ssl.VERIFY_DEFAULT

Possible value for `SSLContext.verify_flags`. In this mode, certificate revocation lists (CRLs) are not checked. By default OpenSSL does neither require nor verify CRLs.

3.4 新版功能.

ssl.VERIFY_CRL_CHECK_LEAF

Possible value for `SSLContext.verify_flags`. In this mode, only the peer cert is checked but none of the intermediate CA certificates. The mode requires a valid CRL that is signed by the peer cert's issuer (its direct ancestor CA). If no proper has been loaded `SSLContext.load_verify_locations`, validation will fail.

3.4 新版功能.

ssl.VERIFY_CRL_CHECK_CHAIN

Possible value for `SSLContext.verify_flags`. In this mode, CRLs of all certificates in the peer cert chain are checked.

3.4 新版功能.

ssl.VERIFY_X509_STRICT

Possible value for `SSLContext.verify_flags` to disable workarounds for broken X.509 certificates.

3.4 新版功能.

`ssl.VERIFY_X509_TRUSTED_FIRST`

Possible value for `SSLContext.verify_flags`. It instructs OpenSSL to prefer trusted certificates when building the trust chain to validate a certificate. This flag is enabled by default.

3.4.4 新版功能.

class `ssl.VerifyFlags`

`enum.IntFlag` collection of `VERIFY_*` constants.

3.6 新版功能.

`ssl.PROTOCOL_TLS`

Selects the highest protocol version that both the client and server support. Despite the name, this option can select both “SSL” and “TLS” protocols.

3.6 新版功能.

`ssl.PROTOCOL_TLS_CLIENT`

Auto-negotiate the highest protocol version like `PROTOCOL_TLS`, but only support client-side `SSLSocket` connections. The protocol enables `CERT_REQUIRED` and `check_hostname` by default.

3.6 新版功能.

`ssl.PROTOCOL_TLS_SERVER`

Auto-negotiate the highest protocol version like `PROTOCOL_TLS`, but only support server-side `SSLSocket` connections.

3.6 新版功能.

`ssl.PROTOCOL_SSLv23`

Alias for data:`PROTOCOL_TLS`.

3.6 版后已移除: Use `PROTOCOL_TLS` instead.

`ssl.PROTOCOL_SSLv2`

Selects SSL version 2 as the channel encryption protocol.

This protocol is not available if OpenSSL is compiled with the `OPENSSL_NO_SSL2` flag.

警告: SSL version 2 is insecure. Its use is highly discouraged.

3.6 版后已移除: OpenSSL has removed support for SSLv2.

`ssl.PROTOCOL_SSLv3`

Selects SSL version 3 as the channel encryption protocol.

This protocol is not be available if OpenSSL is compiled with the `OPENSSL_NO_SSLv3` flag.

警告: SSL version 3 is insecure. Its use is highly discouraged.

3.6 版后已移除: OpenSSL has deprecated all version specific protocols. Use the default protocol `PROTOCOL_TLS` with flags like `OP_NO_SSLv3` instead.

`ssl.PROTOCOL_TLSv1`

Selects TLS version 1.0 as the channel encryption protocol.

3.6 版后已移除: OpenSSL has deprecated all version specific protocols. Use the default protocol `PROTOCOL_TLS` with flags like `OP_NO_SSLv3` instead.

ssl.PROTOCOL_TLSv1_1

Selects TLS version 1.1 as the channel encryption protocol. Available only with openssl version 1.0.1+.

3.4 新版功能.

3.6 版后已移除: OpenSSL has deprecated all version specific protocols. Use the default protocol *PROTOCOL_TLS* with flags like *OP_NO_SSLv3* instead.

ssl.PROTOCOL_TLSv1_2

Selects TLS version 1.2 as the channel encryption protocol. This is the most modern version, and probably the best choice for maximum protection, if both sides can speak it. Available only with openssl version 1.0.1+.

3.4 新版功能.

3.6 版后已移除: OpenSSL has deprecated all version specific protocols. Use the default protocol *PROTOCOL_TLS* with flags like *OP_NO_SSLv3* instead.

ssl.OP_ALL

Enables workarounds for various bugs present in other SSL implementations. This option is set by default. It does not necessarily set the same flags as OpenSSL's *SSL_OP_ALL* constant.

3.2 新版功能.

ssl.OP_NO_SSLv2

Prevents an SSLv2 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing SSLv2 as the protocol version.

3.2 新版功能.

3.6 版后已移除: SSLv2 is deprecated

ssl.OP_NO_SSLv3

Prevents an SSLv3 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing SSLv3 as the protocol version.

3.2 新版功能.

3.6 版后已移除: SSLv3 is deprecated

ssl.OP_NO_TLSv1

Prevents a TLSv1 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing TLSv1 as the protocol version.

3.2 新版功能.

ssl.OP_NO_TLSv1_1

Prevents a TLSv1.1 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing TLSv1.1 as the protocol version. Available only with openssl version 1.0.1+.

3.4 新版功能.

ssl.OP_NO_TLSv1_2

Prevents a TLSv1.2 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing TLSv1.2 as the protocol version. Available only with openssl version 1.0.1+.

3.4 新版功能.

ssl.OP_NO_TLSv1_3

Prevents a TLSv1.3 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing TLSv1.3 as the protocol version. TLS 1.3 is available with OpenSSL 1.1.1 or later. When Python has been compiled against an older version of OpenSSL, the flag defaults to 0.

3.6.3 新版功能.

`ssl.OP_CIPHER_SERVER_PREFERENCE`

Use the server's cipher ordering preference, rather than the client's. This option has no effect on client sockets and SSLv2 server sockets.

3.3 新版功能.

`ssl.OP_SINGLE_DH_USE`

Prevents re-use of the same DH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

3.3 新版功能.

`ssl.OP_SINGLE_ECDH_USE`

Prevents re-use of the same ECDH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

3.3 新版功能.

`ssl.OP_ENABLE_MIDDLEBOX_COMPAT`

Send dummy Change Cipher Spec (CCS) messages in TLS 1.3 handshake to make a TLS 1.3 connection look more like a TLS 1.2 connection.

This option is only available with OpenSSL 1.1.1 and later.

3.6.7 新版功能.

`ssl.OP_NO_COMPRESSION`

Disable compression on the SSL channel. This is useful if the application protocol supports its own compression scheme.

This option is only available with OpenSSL 1.0.0 and later.

3.3 新版功能.

`class ssl.Options`

`enum.IntFlag` collection of `OP_*` constants.

`ssl.OP_NO_TICKET`

Prevent client side from requesting a session ticket.

3.6 新版功能.

`ssl.HAS_ALPN`

Whether the OpenSSL library has built-in support for the *Application-Layer Protocol Negotiation* TLS extension as described in [RFC 7301](#).

3.5 新版功能.

`ssl.HAS_ECDH`

Whether the OpenSSL library has built-in support for Elliptic Curve-based Diffie-Hellman key exchange. This should be true unless the feature was explicitly disabled by the distributor.

3.3 新版功能.

`ssl.HAS_SNI`

Whether the OpenSSL library has built-in support for the *Server Name Indication* extension (as defined in [RFC 6066](#)).

3.2 新版功能.

`ssl.HAS_NPN`

Whether the OpenSSL library has built-in support for *Next Protocol Negotiation* as described in the [NPN draft specification](#). When true, you can use the `SSLContext.set_npn_protocols()` method to advertise which protocols you want to support.

3.3 新版功能.

`ssl.HAS_TLSv1_3`

Whether the OpenSSL library has built-in support for the TLS 1.3 protocol.

3.6.3 新版功能.

`ssl.CHANNEL_BINDING_TYPES`

List of supported TLS channel binding types. Strings in this list can be used as arguments to `SSLSocket.get_channel_binding()`.

3.3 新版功能.

`ssl.OPENSSSL_VERSION`

The version string of the OpenSSL library loaded by the interpreter:

```
>>> ssl.OPENSSSL_VERSION
'OpenSSL 1.0.2k  26 Jan 2017'
```

3.2 新版功能.

`ssl.OPENSSSL_VERSION_INFO`

A tuple of five integers representing version information about the OpenSSL library:

```
>>> ssl.OPENSSSL_VERSION_INFO
(1, 0, 2, 11, 15)
```

3.2 新版功能.

`ssl.OPENSSSL_VERSION_NUMBER`

The raw version number of the OpenSSL library, as a single integer:

```
>>> ssl.OPENSSSL_VERSION_NUMBER
268443839
>>> hex(ssl.OPENSSSL_VERSION_NUMBER)
'0x100020bf'
```

3.2 新版功能.

`ssl.ALERT_DESCRIPTION_HANDSHAKE_FAILURE`

`ssl.ALERT_DESCRIPTION_INTERNAL_ERROR`

`ALERT_DESCRIPTION_*`

Alert Descriptions from [RFC 5246](#) and others. The [IANA TLS Alert Registry](#) contains this list and references to the RFCs where their meaning is defined.

Used as the return value of the callback function in `SSLContext.set_servername_callback()`.

3.4 新版功能.

class `ssl.AlertDescription`

`enum.IntEnum` collection of `ALERT_DESCRIPTION_*` constants.

3.6 新版功能.

`Purpose.SERVER_AUTH`

Option for `create_default_context()` and `SSLContext.load_default_certs()`. This value indicates that the context may be used to authenticate Web servers (therefore, it will be used to create client-side sockets).

3.4 新版功能.

Purpose. **CLIENT_AUTH**

Option for `create_default_context()` and `SSLContext.load_default_certs()`. This value indicates that the context may be used to authenticate Web clients (therefore, it will be used to create server-side sockets).

3.4 新版功能.

class `ssl.SSLErrorNumber`

`enum.IntEnum` collection of `SSL_ERROR_*` constants.

3.6 新版功能.

18.2.2 SSL Sockets

class `ssl.SSLSocket` (*socket.socket*)

SSL sockets provide the following methods of *Socket Objects*:

- `accept()`
- `bind()`
- `close()`
- `connect()`
- `detach()`
- `fileno()`
- `getpeername()`, `getsockname()`
- `getsockopt()`, `setsockopt()`
- `gettimeout()`, `settimeout()`, `setblocking()`
- `listen()`
- `makefile()`
- `recv()`, `recv_into()` (but passing a non-zero `flags` argument is not allowed)
- `send()`, `sendall()` (with the same limitation)
- `sendfile()` (but `os.sendfile` will be used for plain-text sockets only, else `send()` will be used)
- `shutdown()`

However, since the SSL (and TLS) protocol has its own framing atop of TCP, the SSL sockets abstraction can, in certain respects, diverge from the specification of normal, OS-level sockets. See especially the *notes on non-blocking sockets*.

Usually, `SSLSocket` are not created directly, but using the `SSLContext.wrap_socket()` method.

在 3.5 版更改: The `sendfile()` method was added.

在 3.5 版更改: The `shutdown()` does not reset the socket timeout each time bytes are received or sent. The socket timeout is now to maximum total duration of the shutdown.

3.6 版后已移除: It is deprecated to create a `SSLSocket` instance directly, use `SSLContext.wrap_socket()` to wrap a socket.

SSL sockets also have the following additional methods and attributes:

`SSLSocket.read(len=1024, buffer=None)`

Read up to *len* bytes of data from the SSL socket and return the result as a `bytes` instance. If *buffer* is specified, then read into the buffer instead, and return the number of bytes read.

Raise `SSLWantReadError` or `SSLWantWriteError` if the socket is *non-blocking* and the read would block.

As at any time a re-negotiation is possible, a call to `read()` can also cause write operations.

在 3.5 版更改: The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration to read up to *len* bytes.

3.6 版后已移除: Use `recv()` instead of `read()`.

`SSLSocket.write(buf)`

Write *buf* to the SSL socket and return the number of bytes written. The *buf* argument must be an object supporting the buffer interface.

Raise `SSLWantReadError` or `SSLWantWriteError` if the socket is *non-blocking* and the write would block.

As at any time a re-negotiation is possible, a call to `write()` can also cause read operations.

在 3.5 版更改: The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration to write *buf*.

3.6 版后已移除: Use `send()` instead of `write()`.

注解: The `read()` and `write()` methods are the low-level methods that read and write unencrypted, application-level data and decrypt/encrypt it to encrypted, wire-level data. These methods require an active SSL connection, i.e. the handshake was completed and `SSLSocket.unwrap()` was not called.

Normally you should use the socket API methods like `recv()` and `send()` instead of these methods.

`SSLSocket.do_handshake()`

Perform the SSL setup handshake.

在 3.4 版更改: The handshake method also performs `match_hostname()` when the `check_hostname` attribute of the socket's `context` is true.

在 3.5 版更改: The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration of the handshake.

`SSLSocket.getpeercert(binary_form=False)`

If there is no certificate for the peer on the other end of the connection, return `None`. If the SSL handshake hasn't been done yet, raise `ValueError`.

If the `binary_form` parameter is `False`, and a certificate was received from the peer, this method returns a `dict` instance. If the certificate was not validated, the dict is empty. If the certificate was validated, it returns a dict with several keys, amongst them `subject` (the principal for which the certificate was issued) and `issuer` (the principal issuing the certificate). If a certificate contains an instance of the *Subject Alternative Name* extension (see [RFC 3280](#)), there will also be a `subjectAltName` key in the dictionary.

The `subject` and `issuer` fields are tuples containing the sequence of relative distinguished names (RDNs) given in the certificate's data structure for the respective fields, and each RDN is a sequence of name-value pairs. Here is a real-world example:

```
{ 'issuer': ((('countryName', 'IL'),),
              (('organizationName', 'StartCom Ltd.'),),
              (('organizationalUnitName',
                'Secure Digital Certificate Signing'),),
              (('commonName',
```

(下页继续)

(续上页)

```

        'StartCom Class 2 Primary Intermediate Server CA'),)),

```

注解: To validate a certificate for a particular service, you can use the `match_hostname()` function.

If the `binary_form` parameter is `True`, and a certificate was provided, this method returns the DER-encoded form of the entire certificate as a sequence of bytes, or `None` if the peer did not provide a certificate. Whether the peer provides a certificate depends on the SSL socket's role:

- for a client SSL socket, the server will always provide a certificate, regardless of whether validation was required;
- for a server SSL socket, the client will only provide a certificate when requested by the server; therefore `getpeercert()` will return `None` if you used `CERT_NONE` (rather than `CERT_OPTIONAL` or `CERT_REQUIRED`).

在 3.2 版更改: The returned dictionary includes additional items such as `issuer` and `notBefore`.

在 3.4 版更改: `ValueError` is raised when the handshake isn't done. The returned dictionary includes additional X509v3 extension items such as `crlDistributionPoints`, `caIssuers` and `OCSP URIs`.

`SSLSocket.cipher()`

Returns a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used. If no connection has been established, returns `None`.

`SSLSocket.shared_ciphers()`

Return the list of ciphers shared by the client during the handshake. Each entry of the returned list is a three-value tuple containing the name of the cipher, the version of the SSL protocol that defines its use, and the number of secret bits the cipher uses. `shared_ciphers()` returns `None` if no connection has been established or the socket is a client socket.

3.5 新版功能.

`SSLSocket.compression()`

Return the compression algorithm being used as a string, or `None` if the connection isn't compressed.

If the higher-level protocol supports its own compression mechanism, you can use `OP_NO_COMPRESSION` to disable SSL-level compression.

3.3 新版功能.

`SSLSocket.get_channel_binding(cb_type="tls-unique")`

Get channel binding data for current connection, as a bytes object. Returns `None` if not connected or the handshake has not been completed.

The `cb_type` parameter allow selection of the desired channel binding type. Valid channel binding types are listed in the `CHANNEL_BINDING_TYPES` list. Currently only the 'tls-unique' channel binding, defined by [RFC 5929](#),

is supported. *ValueError* will be raised if an unsupported channel binding type is requested.

3.3 新版功能.

`SSLSocket.selected_alpn_protocol()`

Return the protocol that was selected during the TLS handshake. If `SSLContext.set_alpn_protocols()` was not called, if the other party does not support ALPN, if this socket does not support any of the client's proposed protocols, or if the handshake has not happened yet, `None` is returned.

3.5 新版功能.

`SSLSocket.selected_npn_protocol()`

Return the higher-level protocol that was selected during the TLS/SSL handshake. If `SSLContext.set_npn_protocols()` was not called, or if the other party does not support NPN, or if the handshake has not yet happened, this will return `None`.

3.3 新版功能.

`SSLSocket.unwrap()`

Performs the SSL shutdown handshake, which removes the TLS layer from the underlying socket, and returns the underlying socket object. This can be used to go from encrypted operation over a connection to unencrypted. The returned socket should always be used for further communication with the other side of the connection, rather than the original socket.

`SSLSocket.verify_client_post_handshake()`

Requests post-handshake authentication (PHA) from a TLS 1.3 client. PHA can only be initiated for a TLS 1.3 connection from a server-side socket, after the initial TLS handshake and with PHA enabled on both sides, see `SSLContext.post_handshake_auth`.

The method does not perform a cert exchange immediately. The server-side sends a `CertificateRequest` during the next write event and expects the client to respond with a certificate on the next read event.

If any precondition isn't met (e.g. not TLS 1.3, PHA not enabled), an *SSLError* is raised.

3.6.7 新版功能.

注解: Only available with OpenSSL 1.1.1 and TLS 1.3 enabled. Without TLS 1.3 support, the method raises *NotImplementedError*.

`SSLSocket.version()`

Return the actual SSL protocol version negotiated by the connection as a string, or `None` if no secure connection is established. As of this writing, possible return values include `"SSLv2"`, `"SSLv3"`, `"TLSv1"`, `"TLSv1.1"` and `"TLSv1.2"`. Recent OpenSSL versions may define more return values.

3.5 新版功能.

`SSLSocket.pending()`

Returns the number of already decrypted bytes available for read, pending on the connection.

`SSLSocket.context`

The *SSLContext* object this SSL socket is tied to. If the SSL socket was created using the top-level `wrap_socket()` function (rather than `SSLContext.wrap_socket()`), this is a custom context object created for this SSL socket.

3.2 新版功能.

`SSLSocket.server_side`

A boolean which is `True` for server-side sockets and `False` for client-side sockets.

3.2 新版功能.

SSLSocket.server_hostname

Hostname of the server: *str* type, or None for server-side socket or if the hostname was not specified in the constructor.

3.2 新版功能.

SSLSocket.session

The *SSLSession* for this SSL connection. The session is available for client and server side sockets after the TLS handshake has been performed. For client sockets the session can be set before *do_handshake()* has been called to reuse a session.

3.6 新版功能.

SSLSocket.session_reused

3.6 新版功能.

18.2.3 SSL Contexts

3.2 新版功能.

An SSL context holds various data longer-lived than single SSL connections, such as SSL configuration options, certificate(s) and private key(s). It also manages a cache of SSL sessions for server-side sockets, in order to speed up repeated connections from the same clients.

class ssl.SSLContext (protocol=PROTOCOL_TLS)

Create a new SSL context. You may pass *protocol* which must be one of the `PROTOCOL_*` constants defined in this module. *PROTOCOL_TLS* is currently recommended for maximum interoperability and default value.

参见:

create_default_context() lets the *ssl* module choose security settings for a given purpose.

在 3.6 版更改: The context is created with secure default values. The options *OP_NO_COMPRESSION*, *OP_CIPHER_SERVER_PREFERENCE*, *OP_SINGLE_DH_USE*, *OP_SINGLE_ECDH_USE*, *OP_NO_SSLv2* (except for *PROTOCOL_SSLv2*), and *OP_NO_SSLv3* (except for *PROTOCOL_SSLv3*) are set by default. The initial cipher suite list contains only HIGH ciphers, no NULL ciphers and no MD5 ciphers (except for *PROTOCOL_SSLv2*).

SSLContext objects have the following methods and attributes:

SSLContext.cert_store_stats()

Get statistics about quantities of loaded X.509 certificates, count of X.509 certificates flagged as CA certificates and certificate revocation lists as dictionary.

Example for a context with one CA cert and one other cert:

```
>>> context.cert_store_stats()
{'crl': 0, 'x509_ca': 1, 'x509': 2}
```

3.4 新版功能.

SSLContext.load_cert_chain (certfile, keyfile=None, password=None)

Load a private key and the corresponding certificate. The *certfile* string must be the path to a single file in PEM format containing the certificate as well as any number of CA certificates needed to establish the certificate's authenticity. The *keyfile* string, if present, must point to a file containing the private key in. Otherwise the private key will be taken from *certfile* as well. See the discussion of *Certificates* for more information on how the certificate is stored in the *certfile*.

The *password* argument may be a function to call to get the password for decrypting the private key. It will only be called if the private key is encrypted and a password is necessary. It will be called with no arguments, and it

should return a string, bytes, or bytearray. If the return value is a string it will be encoded as UTF-8 before using it to decrypt the key. Alternatively a string, bytes, or bytearray value may be supplied directly as the *password* argument. It will be ignored if the private key is not encrypted and no password is needed.

If the *password* argument is not specified and a password is required, OpenSSL's built-in password prompting mechanism will be used to interactively prompt the user for a password.

An *SSLError* is raised if the private key doesn't match with the certificate.

在 3.3 版更改: New optional argument *password*.

`SSLContext.load_default_certs(purpose=Purpose.SERVER_AUTH)`

Load a set of default “certification authority” (CA) certificates from default locations. On Windows it loads CA certs from the CA and ROOT system stores. On other systems it calls `SSLContext.set_default_verify_paths()`. In the future the method may load CA certificates from other locations, too.

The *purpose* flag specifies what kind of CA certificates are loaded. The default settings `Purpose.SERVER_AUTH` loads certificates, that are flagged and trusted for TLS web server authentication (client side sockets). `Purpose.CLIENT_AUTH` loads CA certificates for client certificate verification on the server side.

3.4 新版功能.

`SSLContext.load_verify_locations(cafile=None, capath=None, cadata=None)`

Load a set of “certification authority” (CA) certificates used to validate other peers' certificates when *verify_mode* is other than `CERT_NONE`. At least one of *cafile* or *capath* must be specified.

This method can also load certification revocation lists (CRLs) in PEM or DER format. In order to make use of CRLs, `SSLContext.verify_flags` must be configured properly.

The *cafile* string, if present, is the path to a file of concatenated CA certificates in PEM format. See the discussion of *Certificates* for more information about how to arrange the certificates in this file.

The *capath* string, if present, is the path to a directory containing several CA certificates in PEM format, following an *OpenSSL specific layout*.

The *cadata* object, if present, is either an ASCII string of one or more PEM-encoded certificates or a *bytes-like object* of DER-encoded certificates. Like with *capath* extra lines around PEM-encoded certificates are ignored but at least one certificate must be present.

在 3.4 版更改: New optional argument *cadata*

`SSLContext.get_ca_certs(binary_form=False)`

Get a list of loaded “certification authority” (CA) certificates. If the *binary_form* parameter is *False* each list entry is a dict like the output of `SSLSocket.getpeercert()`. Otherwise the method returns a list of DER-encoded certificates. The returned list does not contain certificates from *capath* unless a certificate was requested and loaded by a SSL connection.

注解: Certificates in a *capath* directory aren't loaded unless they have been used at least once.

3.4 新版功能.

`SSLContext.get_ciphers()`

Get a list of enabled ciphers. The list is in order of cipher priority. See `SSLContext.set_ciphers()`.

示例:

```
>>> ctx = ssl.SSLContext(ssl.PROTOCOL_SSLv23)
>>> ctx.set_ciphers('ECDHE+AESGCM:!ECDSA')
>>> ctx.get_ciphers() # OpenSSL 1.0.x
```

(下页继续)

(续上页)

```
[{'alg_bits': 256,
  'description': 'ECDHE-RSA-AES256-GCM-SHA384 TLSv1.2 Kx=ECDH      Au=RSA  '
                  'Enc=AESGCM(256) Mac=AEAD',
  'id': 50380848,
  'name': 'ECDHE-RSA-AES256-GCM-SHA384',
  'protocol': 'TLSv1/SSLv3',
  'strength_bits': 256},
 {'alg_bits': 128,
  'description': 'ECDHE-RSA-AES128-GCM-SHA256 TLSv1.2 Kx=ECDH      Au=RSA  '
                  'Enc=AESGCM(128) Mac=AEAD',
  'id': 50380847,
  'name': 'ECDHE-RSA-AES128-GCM-SHA256',
  'protocol': 'TLSv1/SSLv3',
  'strength_bits': 128}]
```

On OpenSSL 1.1 and newer the cipher dict contains additional fields::

```
>>> ctx.get_ciphers() # OpenSSL 1.1+
[{'aead': True,
  'alg_bits': 256,
  'auth': 'auth-rsa',
  'description': 'ECDHE-RSA-AES256-GCM-SHA384 TLSv1.2 Kx=ECDH      Au=RSA  '
                  'Enc=AESGCM(256) Mac=AEAD',
  'digest': None,
  'id': 50380848,
  'kea': 'kx-ecdh',
  'name': 'ECDHE-RSA-AES256-GCM-SHA384',
  'protocol': 'TLSv1.2',
  'strength_bits': 256,
  'symmetric': 'aes-256-gcm'},
 {'aead': True,
  'alg_bits': 128,
  'auth': 'auth-rsa',
  'description': 'ECDHE-RSA-AES128-GCM-SHA256 TLSv1.2 Kx=ECDH      Au=RSA  '
                  'Enc=AESGCM(128) Mac=AEAD',
  'digest': None,
  'id': 50380847,
  'kea': 'kx-ecdh',
  'name': 'ECDHE-RSA-AES128-GCM-SHA256',
  'protocol': 'TLSv1.2',
  'strength_bits': 128,
  'symmetric': 'aes-128-gcm'}]
```

Availability: OpenSSL 1.0.2+

3.6 新版功能.

`SSLContext.set_default_verify_paths()`

Load a set of default “certification authority” (CA) certificates from a filesystem path defined when building the OpenSSL library. Unfortunately, there’s no easy way to know whether this method succeeds: no error is returned if no certificates are to be found. When the OpenSSL library is provided as part of the operating system, though, it is likely to be configured properly.

`SSLContext.set_ciphers(ciphers)`

Set the available ciphers for sockets created with this context. It should be a string in the [OpenSSL cipher list format](#). If no cipher can be selected (because compile-time options or other configuration forbids use of all the specified ciphers), an `SSL.Error` will be raised.

注解: when connected, the `SSLSocket.cipher()` method of SSL sockets will give the currently selected cipher.

OpenSSL 1.1.1 has TLS 1.3 cipher suites enabled by default. The suites cannot be disabled with `set_ciphers()`.

`SSLContext.set_alpn_protocols (protocols)`

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of ASCII strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to [RFC 7301](#). After a successful handshake, the `SSLSocket.selected_alpn_protocol()` method will return the agreed-upon protocol.

This method will raise `NotImplementedError` if `HAS_ALPN` is False.

OpenSSL 1.1.0 to 1.1.0e will abort the handshake and raise `SSLError` when both sides support ALPN but cannot agree on a protocol. 1.1.0f+ behaves like 1.0.2, `SSLSocket.selected_alpn_protocol()` returns None.

3.5 新版功能.

`SSLContext.set_npn_protocols (protocols)`

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to the [NPN draft specification](#). After a successful handshake, the `SSLSocket.selected_npn_protocol()` method will return the agreed-upon protocol.

This method will raise `NotImplementedError` if `HAS_NPN` is False.

3.3 新版功能.

`SSLContext.set_servername_callback (server_name_callback)`

Register a callback function that will be called after the TLS Client Hello handshake message has been received by the SSL/TLS server when the TLS client specifies a server name indication. The server name indication mechanism is specified in [RFC 6066](#) section 3 - Server Name Indication.

Only one callback can be set per `SSLContext`. If `server_name_callback` is None then the callback is disabled. Calling this function a subsequent time will disable the previously registered callback.

The callback function, `server_name_callback`, will be called with three arguments; the first being the `ssl.SSLSocket`, the second is a string that represents the server name that the client is intending to communicate (or None if the TLS Client Hello does not contain a server name) and the third argument is the original `SSLContext`. The server name argument is the IDNA decoded server name.

A typical use of this callback is to change the `ssl.SSLSocket`'s `SSLSocket.context` attribute to a new object of type `SSLContext` representing a certificate chain that matches the server name.

Due to the early negotiation phase of the TLS connection, only limited methods and attributes are usable like `SSLSocket.selected_alpn_protocol()` and `SSLSocket.context`. `SSLSocket.getpeercert()`, `SSLSocket.getpeername()`, `SSLSocket.cipher()` and `SSLSocket.compress()` methods require that the TLS connection has progressed beyond the TLS Client Hello and therefore will not contain return meaningful values nor can they be called safely.

The `server_name_callback` function must return None to allow the TLS negotiation to continue. If a TLS failure is required, a constant `ALERT_DESCRIPTION_*` can be returned. Other return values will result in a TLS fatal error with `ALERT_DESCRIPTION_INTERNAL_ERROR`.

If there is an IDNA decoding error on the server name, the TLS connection will terminate with an `ALERT_DESCRIPTION_INTERNAL_ERROR` fatal TLS alert message to the client.

If an exception is raised from the `server_name_callback` function the TLS connection will terminate with a fatal TLS alert message `ALERT_DESCRIPTION_HANDSHAKE_FAILURE`.

This method will raise `NotImplementedError` if the OpenSSL library had `OPENSSL_NO_TLSEXT` defined when it was built.

3.4 新版功能.

`SSLContext.load_dh_params(dhfile)`

Load the key generation parameters for Diffie-Hellman (DH) key exchange. Using DH key exchange improves forward secrecy at the expense of computational resources (both on the server and on the client). The *dhfile* parameter should be the path to a file containing DH parameters in PEM format.

This setting doesn't apply to client sockets. You can also use the `OP_SINGLE_DH_USE` option to further improve security.

3.3 新版功能.

`SSLContext.set_ecdh_curve(curve_name)`

Set the curve name for Elliptic Curve-based Diffie-Hellman (ECDH) key exchange. ECDH is significantly faster than regular DH while arguably as secure. The *curve_name* parameter should be a string describing a well-known elliptic curve, for example `prime256v1` for a widely supported curve.

This setting doesn't apply to client sockets. You can also use the `OP_SINGLE_ECDH_USE` option to further improve security.

This method is not available if `HAS_ECDH` is `False`.

3.3 新版功能.

参见:

SSL/TLS & Perfect Forward Secrecy Vincent Bernat.

`SSLContext.wrap_socket(sock, server_side=False, do_handshake_on_connect=True, suppress_ragged_eofs=True, server_hostname=None, session=None)`

Wrap an existing Python socket *sock* and return an `SSLSocket` object. *sock* must be a `SOCK_STREAM` socket; other socket types are unsupported.

The returned SSL socket is tied to the context, its settings and certificates. The parameters *server_side*, *do_handshake_on_connect* and *suppress_ragged_eofs* have the same meaning as in the top-level `wrap_socket()` function.

On client connections, the optional parameter *server_hostname* specifies the hostname of the service which we are connecting to. This allows a single server to host multiple SSL-based services with distinct certificates, quite similarly to HTTP virtual hosts. Specifying *server_hostname* will raise a `ValueError` if *server_side* is true.

session, see `session`.

在 3.5 版更改: Always allow a *server_hostname* to be passed, even if OpenSSL does not have SNI.

在 3.6 版更改: *session* argument was added.

`SSLContext.wrap_bio(incoming, outgoing, server_side=False, server_hostname=None, session=None)`

Create a new `SSLObject` instance by wrapping the BIO objects *incoming* and *outgoing*. The SSL routines will read input data from the incoming BIO and write data to the outgoing BIO.

The *server_side*, *server_hostname* and *session* parameters have the same meaning as in `SSLContext.wrap_socket()`.

在 3.6 版更改: *session* argument was added.

`SSLContext.session_stats()`

Get statistics about the SSL sessions created or managed by this context. A dictionary is returned which maps the names of each `piece of information` to their numeric values. For example, here is the total number of hits and misses in the session cache since the context was created:

```
>>> stats = context.session_stats()
>>> stats['hits'], stats['misses']
(0, 0)
```

SSLContext.check_hostname

Whether to match the peer cert's hostname with `match_hostname()` in `SSLSocket.do_handshake()`. The context's `verify_mode` must be set to `CERT_OPTIONAL` or `CERT_REQUIRED`, and you must pass `server_hostname` to `wrap_socket()` in order to match the hostname.

示例:

```
import socket, ssl

context = ssl.SSLContext()
context.verify_mode = ssl.CERT_REQUIRED
context.check_hostname = True
context.load_default_certs()

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
ssl_sock = context.wrap_socket(s, server_hostname='www.verisign.com')
ssl_sock.connect(('www.verisign.com', 443))
```

3.4 新版功能.

注解: This features requires OpenSSL 0.9.8f or newer.

SSLContext.options

An integer representing the set of SSL options enabled on this context. The default value is `OP_ALL`, but you can specify other options such as `OP_NO_SSLv2` by ORing them together.

注解: With versions of OpenSSL older than 0.9.8m, it is only possible to set options, not to clear them. Attempting to clear an option (by resetting the corresponding bits) will raise a `ValueError`.

在 3.6 版更改: `SSLContext.options` returns `Options` flags:

```
>>> ssl.create_default_context().options
<Options.OP_ALL|OP_NO_SSLv3|OP_NO_SSLv2|OP_NO_COMPRESSION: 2197947391>
```

SSLContext.post_handshake_auth

Enable TLS 1.3 post-handshake client authentication. Post-handshake auth is disabled by default and a server can only request a TLS client certificate during the initial handshake. When enabled, a server may request a TLS client certificate at any time after the handshake.

When enabled on client-side sockets, the client signals the server that it supports post-handshake authentication.

When enabled on server-side sockets, `SSLContext.verify_mode` must be set to `CERT_OPTIONAL` or `CERT_REQUIRED`, too. The actual client cert exchange is delayed until `SSLSocket.verify_client_post_handshake()` is called and some I/O is performed.

3.6.7 新版功能.

注解: Only available with OpenSSL 1.1.1 and TLS 1.3 enabled. Without TLS 1.3 support, the property value is `None` and can't be modified

SSLContext.protocol

The protocol version chosen when constructing the context. This attribute is read-only.

SSLContext.verify_flags

The flags for certificate verification operations. You can set flags like `VERIFY_CRL_CHECK_LEAF` by ORing them together. By default OpenSSL does neither require nor verify certificate revocation lists (CRLs). Available only with openssl version 0.9.8+.

3.4 新版功能.

在 3.6 版更改: `SSLContext.verify_flags` returns `VerifyFlags` flags:

```
>>> ssl.create_default_context().verify_flags
<VerifyFlags.VERIFY_X509_TRUSTED_FIRST: 32768>
```

SSLContext.verify_mode

Whether to try to verify other peers' certificates and how to behave if verification fails. This attribute must be one of `CERT_NONE`, `CERT_OPTIONAL` or `CERT_REQUIRED`.

在 3.6 版更改: `SSLContext.verify_mode` returns `VerifyMode` enum:

```
>>> ssl.create_default_context().verify_mode
<VerifyMode.CERT_REQUIRED: 2>
```

18.2.4 Certificates

Certificates in general are part of a public-key / private-key system. In this system, each *principal*, (which may be a machine, or a person, or an organization) is assigned a unique two-part encryption key. One part of the key is public, and is called the *public key*; the other part is kept secret, and is called the *private key*. The two parts are related, in that if you encrypt a message with one of the parts, you can decrypt it with the other part, and **only** with the other part.

A certificate contains information about two principals. It contains the name of a *subject*, and the subject's public key. It also contains a statement by a second principal, the *issuer*, that the subject is who they claim to be, and that this is indeed the subject's public key. The issuer's statement is signed with the issuer's private key, which only the issuer knows. However, anyone can verify the issuer's statement by finding the issuer's public key, decrypting the statement with it, and comparing it to the other information in the certificate. The certificate also contains information about the time period over which it is valid. This is expressed as two fields, called "notBefore" and "notAfter".

In the Python use of certificates, a client or server can use a certificate to prove who they are. The other side of a network connection can also be required to produce a certificate, and that certificate can be validated to the satisfaction of the client or server that requires such validation. The connection attempt can be set to raise an exception if the validation fails. Validation is done automatically, by the underlying OpenSSL framework; the application need not concern itself with its mechanics. But the application does usually need to provide sets of certificates to allow this process to take place.

Python uses files to contain certificates. They should be formatted as "PEM" (see [RFC 1422](#)), which is a base-64 encoded form wrapped with a header line and a footer line:

```
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

Certificate chains

The Python files which contain certificates can contain a sequence of certificates, sometimes called a *certificate chain*. This chain should start with the specific certificate for the principal who "is" the client or server, and then the certificate for the issuer of that certificate, and then the certificate for the issuer of *that* certificate, and so on up the chain till you

get to a certificate which is *self-signed*, that is, a certificate which has the same subject and issuer, sometimes called a *root certificate*. The certificates should just be concatenated together in the certificate file. For example, suppose we had a three certificate chain, from our server certificate to the certificate of the certification authority that signed our server certificate, to the root certificate of the agency which issued the certification authority's certificate:

```
-----BEGIN CERTIFICATE-----
... (certificate for your server)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the certificate for the CA)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the root certificate for the CA's issuer)...
-----END CERTIFICATE-----
```

CA certificates

If you are going to require validation of the other side of the connection's certificate, you need to provide a “CA certs” file, filled with the certificate chains for each issuer you are willing to trust. Again, this file just contains these chains concatenated together. For validation, Python will use the first chain it finds in the file which matches. The platform's certificates file can be used by calling `SSLContext.load_default_certs()`, this is done automatically with `create_default_context()`.

Combined key and certificate

Often the private key is stored in the same file as the certificate; in this case, only the `certfile` parameter to `SSLContext.load_cert_chain()` and `wrap_socket()` needs to be passed. If the private key is stored with the certificate, it should come before the first certificate in the certificate chain:

```
-----BEGIN RSA PRIVATE KEY-----
... (private key in base64 encoding) ...
-----END RSA PRIVATE KEY-----
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

Self-signed certificates

If you are going to create a server that provides SSL-encrypted connection services, you will need to acquire a certificate for that service. There are many ways of acquiring appropriate certificates, such as buying one from a certification authority. Another common practice is to generate a self-signed certificate. The simplest way to do this is with the OpenSSL package, using something like the following:

```
% openssl req -new -x509 -days 365 -nodes -out cert.pem -keyout cert.pem
Generating a 1024 bit RSA private key
.....+++++
.....+++++
writing new private key to 'cert.pem'
-----
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
```

(下页继续)

(续上页)

```

There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MyState
Locality Name (eg, city) []:Some City

```

The disadvantage of a self-signed certificate is that it is its own root certificate, and no one else will have it in their cache of known (and trusted) root certificates.

18.2.5 示例

Testing for SSL support

To test for the presence of SSL support in a Python installation, user code should use the following idiom:

```

try:
    import ssl
except ImportError:
    pass
else:
    ... # do something that requires SSL support
```

Client-side operation

This example creates a SSL context with the recommended security settings for client sockets, including automatic certificate verification:

```
>>> context = ssl.create_default_context()
```

If you prefer to tune security settings yourself, you might create a context from scratch (but beware that you might not get the settings right):

```

>>> context = ssl.SSLContext()
>>> context.verify_mode = ssl.CERT_REQUIRED
>>> context.check_hostname = True
>>> context.load_verify_locations("/etc/ssl/certs/ca-bundle.crt")
```

(this snippet assumes your operating system places a bundle of all CA certificates in /etc/ssl/certs/ca-bundle.crt; if not, you'll get an error and have to adjust the location)

When you use the context to connect to a server, `CERT_REQUIRED` validates the server certificate: it ensures that the server certificate was signed with one of the CA certificates, and checks the signature for correctness:

```

>>> conn = context.wrap_socket(socket.socket(socket.AF_INET),
...                             server_hostname="www.python.org")
>>> conn.connect(("www.python.org", 443))
```

You may then fetch the certificate:

```
>>> cert = conn.getpeercert()
```

Visual inspection shows that the certificate does identify the desired service (that is, the HTTPS host `www.python.org`):

```
>>> pprint.pprint(cert)
{'OCSP': ('http://ocsp.digicert.com',),
 'caIssuers': ('http://cacerts.digicert.com/DigiCertSHA2ExtendedValidationServerCA.crt',),
 'crlDistributionPoints': ('http://crl3.digicert.com/sha2-ev-server-g1.crl',
                           'http://crl4.digicert.com/sha2-ev-server-g1.crl'),
 'issuer': (((('countryName', 'US'),),
               (('organizationName', 'DigiCert Inc'),),
               (('organizationalUnitName', 'www.digicert.com'),),
               (('commonName', 'DigiCert SHA2 Extended Validation Server CA'),)),),
 'notAfter': 'Sep  9 12:00:00 2016 GMT',
 'notBefore': 'Sep  5 00:00:00 2014 GMT',
 'serialNumber': '01BB6F00122B177F36CAB49CEA8B6B26',
 'subject': (((('businessCategory', 'Private Organization'),),
                (('1.3.6.1.4.1.311.60.2.1.3', 'US'),),
                (('1.3.6.1.4.1.311.60.2.1.2', 'Delaware'),),
                (('serialNumber', '3359300'),),
                (('streetAddress', '16 Allen Rd'),),
                (('postalCode', '03894-4801'),),
                (('countryName', 'US'),),
                (('stateOrProvinceName', 'NH'),),
                (('localityName', 'Wolfeboro,'),),
                (('organizationName', 'Python Software Foundation'),),
                (('commonName', 'www.python.org'),)),),
 'subjectAltName': (('DNS', 'www.python.org'),
                    ('DNS', 'python.org'),
                    ('DNS', 'pypi.org'),
                    ('DNS', 'docs.python.org'),
                    ('DNS', 'testpypi.org'),
                    ('DNS', 'bugs.python.org'),
                    ('DNS', 'wiki.python.org'),
                    ('DNS', 'hg.python.org'),
                    ('DNS', 'mail.python.org'),
                    ('DNS', 'packaging.python.org'),
                    ('DNS', 'pythonhosted.org'),
                    ('DNS', 'www.pythonhosted.org'),
                    ('DNS', 'test.pythonhosted.org'),
                    ('DNS', 'us.pycon.org'),
                    ('DNS', 'id.python.org')),
 'version': 3}
```

Now the SSL channel is established and the certificate verified, you can proceed to talk with the server:

```
>>> conn.sendall(b"HEAD / HTTP/1.0\r\nHost: linuxfr.org\r\n\r\n")
>>> pprint.pprint(conn.recv(1024).split(b"\r\n"))
[b'HTTP/1.1 200 OK',
 b'Date: Sat, 18 Oct 2014 18:27:20 GMT',
 b'Server: nginx',
 b'Content-Type: text/html; charset=utf-8',
 b'X-Frame-Options: SAMEORIGIN',
 b'Content-Length: 45679',
```

```

See the discussion of *Security considerations* below.

Server-side operation

For server operation, typically you'll need to have a server certificate, and private key, each in a file. You'll first create a context holding the key and the certificate, so that clients can check your authenticity. Then you'll open a socket, bind it to a port, call `listen()` on it, and start waiting for clients to connect:

```

import socket, ssl

context = ssl.create_default_context(ssl.Purpose.CLIENT_AUTH)
context.load_cert_chain(certfile="mycertfile", keyfile="mykeyfile")

bindsocket = socket.socket()
bindsocket.bind(('myaddr.mydomain.com', 10023))
bindsocket.listen(5)

```

When a client connects, you'll call `accept()` on the socket to get the new socket from the other end, and use the context's `SSLContext.wrap_socket()` method to create a server-side SSL socket for the connection:

```

while True:
    newsocket, fromaddr = bindsocket.accept()
    connstream = context.wrap_socket(newsocket, server_side=True)
    try:
        deal_with_client(connstream)
    finally:
        connstream.shutdown(socket.SHUT_RDWR)
        connstream.close()

```

Then you'll read data from the `connstream` and do something with it till you are finished with the client (or the client is finished with you):

```

def deal_with_client(connstream):
    data = connstream.recv(1024)
    # empty data means the client is finished with us
    while data:
        if not do_something(connstream, data):
            # we'll assume do_something returns False
            # when we're finished with client
            break
        data = connstream.recv(1024)
    # finished with client

```

And go back to listening for new client connections (of course, a real server would probably handle each client connection in a separate thread, or put the sockets in *non-blocking mode* and use an event loop).

18.2.6 Notes on non-blocking sockets

SSL sockets behave slightly different than regular sockets in non-blocking mode. When working with non-blocking sockets, there are thus several things you need to be aware of:

- Most `SSLSocket` methods will raise either `SSLWantWriteError` or `SSLWantReadError` instead of `BlockingIOError` if an I/O operation would block. `SSLWantReadError` will be raised if a read operation on the underlying socket is necessary, and `SSLWantWriteError` for a write operation on the underlying socket. Note that attempts to *write* to an SSL socket may require *reading* from the underlying socket first, and attempts to *read* from the SSL socket may require a prior *write* to the underlying socket.

在 3.5 版更改: In earlier Python versions, the `SSLSocket.send()` method returned zero instead of raising `SSLWantWriteError` or `SSLWantReadError`.

- Calling `select()` tells you that the OS-level socket can be read from (or written to), but it does not imply that there is sufficient data at the upper SSL layer. For example, only part of an SSL frame might have arrived. Therefore, you must be ready to handle `SSLSocket.recv()` and `SSLSocket.send()` failures, and retry after another call to `select()`.
- Conversely, since the SSL layer has its own framing, a SSL socket may still have data available for reading without `select()` being aware of it. Therefore, you should first call `SSLSocket.recv()` to drain any potentially available data, and then only block on a `select()` call if still necessary.

(of course, similar provisions apply when using other primitives such as `poll()`, or those in the `selectors` module)

- The SSL handshake itself will be non-blocking: the `SSLSocket.do_handshake()` method has to be retried until it returns successfully. Here is a synopsis using `select()` to wait for the socket's readiness:

```
while True:
    try:
        sock.do_handshake()
        break
    except ssl.SSLWantReadError:
        select.select([sock], [], [])
    except ssl.SSLWantWriteError:
        select.select([], [sock], [])
```

参见:

The `asyncio` module supports *non-blocking SSL sockets* and provides a higher level API. It polls for events using the `selectors` module and handles `SSLWantWriteError`, `SSLWantReadError` and `BlockingIOError` exceptions. It runs the SSL handshake asynchronously as well.

18.2.7 Memory BIO Support

3.5 新版功能.

Ever since the SSL module was introduced in Python 2.6, the `SSLSocket` class has provided two related but distinct areas of functionality:

- SSL protocol handling
- Network IO

The network IO API is identical to that provided by `socket.socket`, from which `SSLSocket` also inherits. This allows an SSL socket to be used as a drop-in replacement for a regular socket, making it very easy to add SSL support to an existing application.

Combining SSL protocol handling and network IO usually works well, but there are some cases where it doesn't. An example is async IO frameworks that want to use a different IO multiplexing model than the “select/poll on a file descriptor” (readiness based) model that is assumed by `socket.socket` and by the internal OpenSSL socket IO routines. This is mostly relevant for platforms like Windows where this model is not efficient. For this purpose, a reduced scope variant of `SSLSocket` called `SSLObject` is provided.

class `ssl.SSLObject`

A reduced-scope variant of `SSLSocket` representing an SSL protocol instance that does not contain any network IO methods. This class is typically used by framework authors that want to implement asynchronous IO for SSL through memory buffers.

This class implements an interface on top of a low-level SSL object as implemented by OpenSSL. This object captures the state of an SSL connection but does not provide any network IO itself. IO needs to be performed through separate “BIO” objects which are OpenSSL's IO abstraction layer.

An `SSLObject` instance can be created using the `wrap_bio()` method. This method will create the `SSLObject` instance and bind it to a pair of BIOs. The *incoming* BIO is used to pass data from Python to the SSL protocol instance, while the *outgoing* BIO is used to pass data the other way around.

The following methods are available:

- `context`
- `server_side`
- `server_hostname`
- `session`
- `session_reused`
- `read()`
- `write()`
- `getpeercert()`
- `selected_npn_protocol()`
- `cipher()`
- `shared_ciphers()`
- `compression()`
- `pending()`
- `do_handshake()`
- `unwrap()`
- `get_channel_binding()`

When compared to `SSLSocket`, this object lacks the following features:

- Any form of network IO; `recv()` and `send()` read and write only to the underlying `MemoryBIO` buffers.
- There is no `do_handshake_on_connect` machinery. You must always manually call `do_handshake()` to start the handshake.
- There is no handling of `suppress_ragged_eofs`. All end-of-file conditions that are in violation of the protocol are reported via the `SSLEOFError` exception.

- The method `unwrap()` call does not return anything, unlike for an SSL socket where it returns the underlying socket.
- The `server_name_callback` callback passed to `SSLContext.set_servername_callback()` will get an `SSLObject` instance instead of a `SSLSocket` instance as its first parameter.

Some notes related to the use of `SSLObject`:

- All IO on an `SSLObject` is *non-blocking*. This means that for example `read()` will raise an `SSLWantReadError` if it needs more data than the incoming BIO has available.
- There is no module-level `wrap_bio()` call like there is for `wrap_socket()`. An `SSLObject` is always created via an `SSLContext`.

An `SSLObject` communicates with the outside world using memory buffers. The class `MemoryBIO` provides a memory buffer that can be used for this purpose. It wraps an OpenSSL memory BIO (Basic IO) object:

class `ssl.MemoryBIO`

A memory buffer that can be used to pass data between Python and an SSL protocol instance.

pending

Return the number of bytes currently in the memory buffer.

eof

A boolean indicating whether the memory BIO is current at the end-of-file position.

read (*n=-1*)

Read up to *n* bytes from the memory buffer. If *n* is not specified or negative, all bytes are returned.

write (*buf*)

Write the bytes from *buf* to the memory BIO. The *buf* argument must be an object supporting the buffer protocol.

The return value is the number of bytes written, which is always equal to the length of *buf*.

write_eof ()

Write an EOF marker to the memory BIO. After this method has been called, it is illegal to call `write()`. The attribute `eof` will become true after all data currently in the buffer has been read.

18.2.8 SSL session

3.6 新版功能.

class `ssl.SSLSession`

Session object used by `session`.

id

time

timeout

ticket_lifetime_hint

has_ticket

18.2.9 Security considerations

Best defaults

For **client use**, if you don't have any special requirements for your security policy, it is highly recommended that you use the `create_default_context()` function to create your SSL context. It will load the system's trusted CA certificates, enable certificate validation and hostname checking, and try to choose reasonably secure protocol and cipher settings.

For example, here is how you would use the `smtplib.SMTP` class to create a trusted, secure connection to a SMTP server:

```
>>> import ssl, smtplib
>>> smtp = smtplib.SMTP("mail.python.org", port=587)
>>> context = ssl.create_default_context()
>>> smtp.starttls(context=context)
(220, b'2.0.0 Ready to start TLS')
```

If a client certificate is needed for the connection, it can be added with `SSLContext.load_cert_chain()`.

By contrast, if you create the SSL context by calling the `SSLContext` constructor yourself, it will not have certificate validation nor hostname checking enabled by default. If you do so, please read the paragraphs below to achieve a good security level.

Manual settings

Verifying certificates

When calling the `SSLContext` constructor directly, `CERT_NONE` is the default. Since it does not authenticate the other peer, it can be insecure, especially in client mode where most of time you would like to ensure the authenticity of the server you're talking to. Therefore, when in client mode, it is highly recommended to use `CERT_REQUIRED`. However, it is in itself not sufficient; you also have to check that the server certificate, which can be obtained by calling `SSLSocket.getpeercert()`, matches the desired service. For many protocols and applications, the service can be identified by the hostname; in this case, the `match_hostname()` function can be used. This common check is automatically performed when `SSLContext.check_hostname` is enabled.

In server mode, if you want to authenticate your clients using the SSL layer (rather than using a higher-level authentication mechanism), you'll also have to specify `CERT_REQUIRED` and similarly check the client certificate.

Protocol versions

SSL versions 2 and 3 are considered insecure and are therefore dangerous to use. If you want maximum compatibility between clients and servers, it is recommended to use `PROTOCOL_TLS_CLIENT` or `PROTOCOL_TLS_SERVER` as the protocol version. SSLv2 and SSLv3 are disabled by default.

```
>>> client_context = ssl.SSLContext(ssl.PROTOCOL_TLS_CLIENT)
>>> client_context.options |= ssl.OP_NO_TLSv1
>>> client_context.options |= ssl.OP_NO_TLSv1_1
```

The SSL context created above will only allow TLSv1.2 and later (if supported by your system) connections to a server. `PROTOCOL_TLS_CLIENT` implies certificate validation and hostname checks by default. You have to load certificates into the context.

Cipher selection

If you have advanced security requirements, fine-tuning of the ciphers enabled when negotiating a SSL session is possible through the `SSLContext.set_ciphers()` method. Starting from Python 3.2.3, the `ssl` module disables certain weak ciphers by default, but you may want to further restrict the cipher choice. Be sure to read OpenSSL's documentation about the [cipher list format](#). If you want to check which ciphers are enabled by a given cipher list, use `SSLContext.get_ciphers()` or the `openssl ciphers` command on your system.

Multi-processing

If using this module as part of a multi-processed application (using, for example the `multiprocessing` or `concurrent.futures` modules), be aware that OpenSSL's internal random number generator does not properly handle forked processes. Applications must change the PRNG state of the parent process if they use any SSL feature with `os.fork()`. Any successful call of `RAND_add()`, `RAND_bytes()` or `RAND_pseudo_bytes()` is sufficient.

18.2.10 LibreSSL support

LibreSSL is a fork of OpenSSL 1.0.1. The `ssl` module has limited support for LibreSSL. Some features are not available when the `ssl` module is compiled with LibreSSL.

- LibreSSL >= 2.6.1 no longer supports NPN. The methods `SSLContext.set_npn_protocols()` and `SSLSocket.selected_npn_protocol()` are not available.
- `SSLContext.set_default_verify_paths()` ignores the env vars `SSL_CERT_FILE` and `SSL_CERT_PATH` although `get_default_verify_paths()` still reports them.

18.3 select —Waiting for I/O completion

This module provides access to the `select()` and `poll()` functions available in most operating systems, `devpoll()` available on Solaris and derivatives, `epoll()` available on Linux 2.5+ and `kqueue()` available on most BSD. Note

that on Windows, it only works for sockets; on other operating systems, it also works for other file types (in particular, on Unix, it works on pipes). It cannot be used on regular files to determine whether a file has grown since it was last read.

注解: The `selectors` module allows high-level and efficient I/O multiplexing, built upon the `select` module primitives. Users are encouraged to use the `selectors` module instead, unless they want precise control over the OS-level primitives used.

The module defines the following:

exception `select.error`

A deprecated alias of `OSError`.

在 3.3 版更改: Following [PEP 3151](#), this class was made an alias of `OSError`.

`select.devpoll()`

(Only supported on Solaris and derivatives.) Returns a `/dev/poll` polling object; see section [/dev/poll Polling Objects](#) below for the methods supported by devpoll objects.

`devpoll()` objects are linked to the number of file descriptors allowed at the time of instantiation. If your program reduces this value, `devpoll()` will fail. If your program increases this value, `devpoll()` may return an incomplete list of active file descriptors.

The new file descriptor is *non-inheritable*.

3.3 新版功能.

在 3.4 版更改: 新的文件描述符现在是不可继承的。

`select.epoll(sizehint=-1, flags=0)`

(Only supported on Linux 2.5.44 and newer.) Return an edge polling object, which can be used as Edge or Level Triggered interface for I/O events.

sizehint informs `epoll` about the expected number of events to be registered. It must be positive, or `-1` to use the default. It is only used on older systems where `epoll_create1()` is not available; otherwise it has no effect (though its value is still checked).

flags is deprecated and completely ignored. However, when supplied, its value must be `0` or `select.EPOLL_CLOEXEC`, otherwise `OSError` is raised.

See the [Edge and Level Trigger Polling \(epoll\) Objects](#) section below for the methods supported by epolling objects.

`epoll` objects support the context management protocol: when used in a `with` statement, the new file descriptor is automatically closed at the end of the block.

The new file descriptor is *non-inheritable*.

在 3.3 版更改: Added the *flags* parameter.

在 3.4 版更改: Support for the `with` statement was added. The new file descriptor is now non-inheritable.

3.4 版后已移除: The *flags* parameter. `select.EPOLL_CLOEXEC` is used by default now. Use `os.set_inheritable()` to make the file descriptor inheritable.

`select.poll()`

(Not supported by all operating systems.) Returns a polling object, which supports registering and unregistering file descriptors, and then polling them for I/O events; see section [Polling Objects](#) below for the methods supported by polling objects.

`select.kqueue()`

(Only supported on BSD.) Returns a kernel queue object; see section [Kqueue Objects](#) below for the methods supported by kqueue objects.

The new file descriptor is *non-inheritable*.

在 3.4 版更改: 新的文件描述符现在是不可继承的。

`select.kevent` (*ident*, *filter*=`KQ_FILTER_READ`, *flags*=`KQ_EV_ADD`, *f*flags=0, *data*=0, *udata*=0)
(Only supported on BSD.) Returns a kernel event object; see section [Kevent Objects](#) below for the methods supported by kevent objects.

`select.select` (*rlist*, *wlist*, *xlist*[, *timeout*])

This is a straightforward interface to the Unix `select()` system call. The first three arguments are sequences of ‘waitable objects’: either integers representing file descriptors or objects with a parameterless method named `fileno()` returning such an integer:

- *rlist*: wait until ready for reading
- *wlist*: wait until ready for writing
- *xlist*: wait for an “exceptional condition” (see the manual page for what your system considers such a condition)

Empty sequences are allowed, but acceptance of three empty sequences is platform-dependent. (It is known to work on Unix but not on Windows.) The optional *timeout* argument specifies a time-out as a floating point number in seconds. When the *timeout* argument is omitted the function blocks until at least one file descriptor is ready. A time-out value of zero specifies a poll and never blocks.

The return value is a triple of lists of objects that are ready: subsets of the first three arguments. When the time-out is reached without a file descriptor becoming ready, three empty lists are returned.

Among the acceptable object types in the sequences are Python *file objects* (e.g. `sys.stdin`, or objects returned by `open()` or `os.popen()`), socket objects returned by `socket.socket()`. You may also define a *wrapper* class yourself, as long as it has an appropriate `fileno()` method (that really returns a file descriptor, not just a random integer).

注解: File objects on Windows are not acceptable, but sockets are. On Windows, the underlying `select()` function is provided by the WinSock library, and does not handle file descriptors that don’t originate from WinSock.

在 3.5 版更改: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see [PEP 475](#) for the rationale), instead of raising `InterruptedError`.

`select.PIPE_BUF`

The minimum number of bytes which can be written without blocking to a pipe when the pipe has been reported as ready for writing by `select()`, `poll()` or another interface in this module. This doesn’t apply to other kind of file-like objects such as sockets.

This value is guaranteed by POSIX to be at least 512. Availability: Unix.

3.2 新版功能.

18.3.1 /dev/poll Polling Objects

Solaris and derivatives have `/dev/poll`. While `select()` is $O(\text{highest file descriptor})$ and `poll()` is $O(\text{number of file descriptors})$, `/dev/poll` is $O(\text{active file descriptors})$.

`/dev/poll` behaviour is very close to the standard `poll()` object.

`devpoll.close()`

Close the file descriptor of the polling object.

3.4 新版功能.

`devpoll.closed`

True if the polling object is closed.

3.4 新版功能.

`devpoll.fileno()`

Return the file descriptor number of the polling object.

3.4 新版功能.

`devpoll.register(fd[, eventmask])`

Register a file descriptor with the polling object. Future calls to the `poll()` method will then check whether the file descriptor has any pending I/O events. `fd` can be either an integer, or an object with a `fileno()` method that returns an integer. File objects implement `fileno()`, so they can also be used as the argument.

`eventmask` is an optional bitmask describing the type of events you want to check for. The constants are the same that with `poll()` object. The default value is a combination of the constants `POLLIN`, `POLLPRI`, and `POLLOUT`.

警告: Registering a file descriptor that's already registered is not an error, but the result is undefined. The appropriate action is to unregister or modify it first. This is an important difference compared with `poll()`.

`devpoll.modify(fd[, eventmask])`

This method does an `unregister()` followed by a `register()`. It is (a bit) more efficient than doing the same explicitly.

`devpoll.unregister(fd)`

Remove a file descriptor being tracked by a polling object. Just like the `register()` method, `fd` can be an integer or an object with a `fileno()` method that returns an integer.

Attempting to remove a file descriptor that was never registered is safely ignored.

`devpoll.poll([timeout])`

Polls the set of registered file descriptors, and returns a possibly-empty list containing `(fd, event)` 2-tuples for the descriptors that have events or errors to report. `fd` is the file descriptor, and `event` is a bitmask with bits set for the reported events for that descriptor — `POLLIN` for waiting input, `POLLOUT` to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If `timeout` is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If `timeout` is omitted, `-1`, or `None`, the call will block until there is an event for this poll object.

在 3.5 版更改: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see [PEP 475](#) for the rationale), instead of raising `InterruptedError`.

18.3.2 Edge and Level Trigger Polling (epoll) Objects

<http://linux.die.net/man/4/epoll>

`eventmask`

常数	意义
<code>EPOLLIN</code>	Available for read
<code>EPOLLOUT</code>	Available for write
<code>EPOLLPRI</code>	Urgent data for read
<code>EPOLLERR</code>	Error condition happened on the assoc. fd
<code>EPOLLHUP</code>	Hang up happened on the assoc. fd
<code>EPOLLET</code>	Set Edge Trigger behavior, the default is Level Trigger behavior
<code>EPOLLONESHOT</code>	Set one-shot behavior. After one event is pulled out, the fd is internally disabled
<code>EPOLLEXCLUSIVE</code>	Wake only one epoll object when the associated fd has an event. The default (if this flag is not set) is to wake all epoll objects polling on a fd.
<code>EPOLLRDHUP</code>	Stream socket peer closed connection or shut down writing half of connection.
<code>EPOLLRDNONE</code>	Equivalent to <code>EPOLLIN</code>
<code>EPOLLRDBAND</code>	Priority data band can be read.
<code>EPOLLWRNONE</code>	Equivalent to <code>EPOLLOUT</code>
<code>EPOLLWRBAND</code>	Priority data may be written.
<code>EPOLLMSG</code>	Ignored.

`epoll.close()`

Close the control file descriptor of the epoll object.

`epoll.closed`

True if the epoll object is closed.

`epoll.fileno()`

Return the file descriptor number of the control fd.

`epoll.fromfd(fd)`

Create an epoll object from a given file descriptor.

`epoll.register(fd[, eventmask])`

Register a fd descriptor with the epoll object.

`epoll.modify(fd, eventmask)`

Modify a registered file descriptor.

`epoll.unregister(fd)`

Remove a registered file descriptor from the epoll object.

`epoll.poll(timeout=-1, maxevents=-1)`

Wait for events. timeout in seconds (float)

在 3.5 版更改: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see [PEP 475](#) for the rationale), instead of raising `InterruptedError`.

18.3.3 Polling Objects

The `poll()` system call, supported on most Unix systems, provides better scalability for network servers that service many, many clients at the same time. `poll()` scales better because the system call only requires listing the file descriptors of interest, while `select()` builds a bitmap, turns on bits for the fds of interest, and then afterward the whole bitmap has to be linearly scanned again. `select()` is $O(\text{highest file descriptor})$, while `poll()` is $O(\text{number of file descriptors})$.

`poll.register(fd[, eventmask])`

Register a file descriptor with the polling object. Future calls to the `poll()` method will then check whether the file descriptor has any pending I/O events. `fd` can be either an integer, or an object with a `fileno()` method that returns an integer. File objects implement `fileno()`, so they can also be used as the argument.

eventmask is an optional bitmask describing the type of events you want to check for, and can be a combination of the constants `POLLIN`, `POLLPRI`, and `POLLOUT`, described in the table below. If not specified, the default value used will check for all 3 types of events.

常数	意义
<code>POLLIN</code>	There is data to read
<code>POLLPRI</code>	There is urgent data to read
<code>POLLOUT</code>	Ready for output: writing will not block
<code>POLLERR</code>	Error condition of some sort
<code>POLLHUP</code>	Hung up
<code>POLLRDHUP</code>	Stream socket peer closed connection, or shut down writing half of connection
<code>POLLNVAL</code>	Invalid request: descriptor not open

Registering a file descriptor that's already registered is not an error, and has the same effect as registering the descriptor exactly once.

`poll.modify(fd, eventmask)`

Modifies an already registered *fd*. This has the same effect as `register(fd, eventmask)`. Attempting to modify a file descriptor that was never registered causes an `OSError` exception with `errno` `ENOENT` to be raised.

`poll.unregister(fd)`

Remove a file descriptor being tracked by a polling object. Just like the `register()` method, *fd* can be an integer or an object with a `fileno()` method that returns an integer.

Attempting to remove a file descriptor that was never registered causes a `KeyError` exception to be raised.

`poll.poll([timeout])`

Polls the set of registered file descriptors, and returns a possibly-empty list containing (*fd*, *event*) 2-tuples for the descriptors that have events or errors to report. *fd* is the file descriptor, and *event* is a bitmask with bits set for the reported events for that descriptor — `POLLIN` for waiting input, `POLLOUT` to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If *timeout* is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If *timeout* is omitted, negative, or `None`, the call will block until there is an event for this poll object.

在 3.5 版更改: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see [PEP 475](#) for the rationale), instead of raising `InterruptedError`.

18.3.4 Kqueue Objects

`kqueue.close()`

Close the control file descriptor of the kqueue object.

`kqueue.closed`

True if the kqueue object is closed.

`kqueue.fileno()`

Return the file descriptor number of the control fd.

`kqueue.fromfd(fd)`

Create a kqueue object from a given file descriptor.

`kqueue.control(changelist, max_events[, timeout=None])` → eventlist

Low level interface to kevent

- *changelist* must be an iterable of kevent object or `None`
- *max_events* must be 0 or a positive integer

- timeout in seconds (floats possible)

在 3.5 版更改: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see [PEP 475](#) for the rationale), instead of raising `InterruptedError`.

18.3.5 Kevent Objects

<https://www.freebsd.org/cgi/man.cgi?query=kqueue&sektion=2>

`kevent.ident`

Value used to identify the event. The interpretation depends on the filter but it's usually the file descriptor. In the constructor `ident` can either be an int or an object with a `fileno()` method. `kevent` stores the integer internally.

`kevent.filter`

Name of the kernel filter.

常数	意义
<code>KQ_FILTER_READ</code>	Takes a descriptor and returns whenever there is data available to read
<code>KQ_FILTER_WRITE</code>	Takes a descriptor and returns whenever there is data available to write
<code>KQ_FILTER_AIO</code>	AIO requests
<code>KQ_FILTER_VNODE</code>	Returns when one or more of the requested events watched in <i>fflag</i> occurs
<code>KQ_FILTER_PROC</code>	Watch for events on a process id
<code>KQ_FILTER_NETDEV</code>	Watch for events on a network device [not available on Mac OS X]
<code>KQ_FILTER_SIGNAL</code>	Returns whenever the watched signal is delivered to the process
<code>KQ_FILTER_TIMER</code>	Establishes an arbitrary timer

`kevent.flags`

Filter action.

常数	意义
<code>KQ_EV_ADD</code>	Adds or modifies an event
<code>KQ_EV_DELETE</code>	Removes an event from the queue
<code>KQ_EV_ENABLE</code>	Permits <code>control()</code> to return the event
<code>KQ_EV_DISABLE</code>	Disable event
<code>KQ_EV_ONESHOT</code>	Removes event after first occurrence
<code>KQ_EV_CLEAR</code>	Reset the state after an event is retrieved
<code>KQ_EV_SYSFLAGS</code>	internal event
<code>KQ_EV_FLAG1</code>	internal event
<code>KQ_EV_EOF</code>	Filter specific EOF condition
<code>KQ_EV_ERROR</code>	See return values

`kevent.fflags`

Filter specific flags.

`KQ_FILTER_READ` and `KQ_FILTER_WRITE` filter flags:

常数	意义
<code>KQ_NOTE_LOWAT</code>	low water mark of a socket buffer

`KQ_FILTER_VNODE` filter flags:

常数	意义
KQ_NOTE_DELETE	<i>unlink()</i> was called
KQ_NOTE_WRITE	a write occurred
KQ_NOTE_EXTEND	the file was extended
KQ_NOTE_ATTRIB	an attribute was changed
KQ_NOTE_LINK	the link count has changed
KQ_NOTE_RENAME	the file was renamed
KQ_NOTE_REVOKE	access to the file was revoked

KQ_FILTER_PROC filter flags:

常数	意义
KQ_NOTE_EXIT	the process has exited
KQ_NOTE_FORK	the process has called <i>fork()</i>
KQ_NOTE_EXEC	the process has executed a new process
KQ_NOTE_PCTRLMASK	internal filter flag
KQ_NOTE_PDATAMASK	internal filter flag
KQ_NOTE_TRACK	follow a process across <i>fork()</i>
KQ_NOTE_CHILD	returned on the child process for <i>NOTE_TRACK</i>
KQ_NOTE_TRACKERR	unable to attach to a child

KQ_FILTER_NETDEV filter flags (not available on Mac OS X):

常数	意义
KQ_NOTE_LINKUP	link is up
KQ_NOTE_LINKDOWN	link is down
KQ_NOTE_LINKINV	link state is invalid

`kevent.data`

Filter specific data.

`kevent.udata`

User defined value.

18.4 selectors —高级 I/O 复用库

3.4 新版功能.

源码: [Lib/selectors.py](#)

18.4.1 概述

This module allows high-level and efficient I/O multiplexing, built upon the *select* module primitives. Users are encouraged to use this module instead, unless they want precise control over the OS-level primitives used.

It defines a *BaseSelector* abstract base class, along with several concrete implementations (*KqueueSelector*, *EpollSelector*…), that can be used to wait for I/O readiness notification on multiple file objects. In the following, “file object” refers to any object with a `fileno()` method, or a raw file descriptor. See *file object*.

`DefaultSelector` is an alias to the most efficient implementation available on the current platform: this should be the default choice for most users.

注解： The type of file objects supported depends on the platform: on Windows, sockets are supported, but not pipes, whereas on Unix, both are supported (some other types may be supported as well, such as fifos or special file devices).

参见：

`select` Low-level I/O multiplexing module.

18.4.2 类

Classes hierarchy:

```
BaseSelector
+-- SelectSelector
+-- PollSelector
+-- EpollSelector
+-- DevpollSelector
+-- KqueueSelector
```

In the following, *events* is a bitwise mask indicating which I/O events should be waited for on a given file object. It can be a combination of the modules constants below:

常数	意义
EVENT_READ	Available for read
EVENT_WRITE	Available for write

class selectors.SelectorKey

A *SelectorKey* is a *namedtuple* used to associate a file object to its underlying file descriptor, selected event mask and attached data. It is returned by several *BaseSelector* methods.

fileobj

File object registered.

fd

Underlying file descriptor.

events

Events that must be waited for on this file object.

data

Optional opaque data associated to this file object: for example, this could be used to store a per-client session ID.

class selectors.BaseSelector

A *BaseSelector* is used to wait for I/O event readiness on multiple file objects. It supports file stream registration, unregistration, and a method to wait for I/O events on those streams, with an optional timeout. It's an abstract base class, so cannot be instantiated. Use *DefaultSelector* instead, or one of *SelectSelector*, *KqueueSelector* etc. if you want to specifically use an implementation, and your platform supports it. *BaseSelector* and its concrete implementations support the *context manager* protocol.

abstractmethod register (*fileobj*, *events*, *data=None*)

Register a file object for selection, monitoring it for I/O events.

fileobj is the file object to monitor. It may either be an integer file descriptor or an object with a `fileno()` method. *events* is a bitwise mask of events to monitor. *data* is an opaque object.

This returns a new `SelectorKey` instance, or raises a `ValueError` in case of invalid event mask or file descriptor, or `KeyError` if the file object is already registered.

abstractmethod unregister (*fileobj*)

Unregister a file object from selection, removing it from monitoring. A file object shall be unregistered prior to being closed.

fileobj must be a file object previously registered.

This returns the associated `SelectorKey` instance, or raises a `KeyError` if *fileobj* is not registered. It will raise `ValueError` if *fileobj* is invalid (e.g. it has no `fileno()` method or its `fileno()` method has an invalid return value).

modify (*fileobj*, *events*, *data=None*)

Change a registered file object's monitored events or attached data.

This is equivalent to `BaseSelector.unregister(fileobj)()` followed by `BaseSelector.register(fileobj, events, data)()`, except that it can be implemented more efficiently.

This returns a new `SelectorKey` instance, or raises a `ValueError` in case of invalid event mask or file descriptor, or `KeyError` if the file object is not registered.

abstractmethod select (*timeout=None*)

Wait until some registered file objects become ready, or the timeout expires.

If *timeout* > 0, this specifies the maximum wait time, in seconds. If *timeout* ≤ 0, the call won't block, and will report the currently ready file objects. If *timeout* is `None`, the call will block until a monitored file object becomes ready.

This returns a list of (*key*, *events*) tuples, one for each ready file object.

key is the `SelectorKey` instance corresponding to a ready file object. *events* is a bitmask of events ready on this file object.

注解: This method can return before any file object becomes ready or the timeout has elapsed if the current process receives a signal: in this case, an empty list will be returned.

在 3.5 版更改: The selector is now retried with a recomputed timeout when interrupted by a signal if the signal handler did not raise an exception (see [PEP 475](#) for the rationale), instead of returning an empty list of events before the timeout.

close ()

Close the selector.

This must be called to make sure that any underlying resource is freed. The selector shall not be used once it has been closed.

get_key (*fileobj*)

Return the key associated with a registered file object.

This returns the `SelectorKey` instance associated to this file object, or raises `KeyError` if the file object is not registered.

abstractmethod get_map ()

Return a mapping of file objects to selector keys.

This returns a `Mapping` instance mapping registered file objects to their associated `SelectorKey` instance.

class `selectors.DefaultSelector`

The default selector class, using the most efficient implementation available on the current platform. This should be the default choice for most users.

class `selectors.SelectSelector`

`select.select()`-based selector.

class `selectors.PollSelector`

`select.poll()`-based selector.

class `selectors.EpollSelector`

`select.epoll()`-based selector.

fileno()

This returns the file descriptor used by the underlying `select.epoll()` object.

class `selectors.DevpollSelector`

`select.devpoll()`-based selector.

fileno()

This returns the file descriptor used by the underlying `select.devpoll()` object.

3.5 新版功能.

class `selectors.KqueueSelector`

`select.kqueue()`-based selector.

fileno()

This returns the file descriptor used by the underlying `select.kqueue()` object.

18.4.3 示例

Here is a simple echo server implementation:

```
import selectors
import socket

sel = selectors.DefaultSelector()

def accept(sock, mask):
    conn, addr = sock.accept() # Should be ready
    print('accepted', conn, 'from', addr)
    conn.setblocking(False)
    sel.register(conn, selectors.EVENT_READ, read)

def read(conn, mask):
    data = conn.recv(1000) # Should be ready
    if data:
        print('echoing', repr(data), 'to', conn)
        conn.send(data) # Hope it won't block
    else:
        print('closing', conn)
        sel.unregister(conn)
        conn.close()

sock = socket.socket()
sock.bind(('localhost', 1234))
sock.listen(100)
sock.setblocking(False)
```

(下页继续)

(续上页)

```
sel.register(sock, selectors.EVENT_READ, accept)

while True:
    events = sel.select()
    for key, mask in events:
        callback = key.data
        callback(key.fileobj, mask)
```

18.5 `asyncio` —Asynchronous I/O, event loop, coroutines and tasks

3.4 新版功能.

Source code: [Lib/asyncio/](#)

This module provides infrastructure for writing single-threaded concurrent code using coroutines, multiplexing I/O access over sockets and other resources, running network clients and servers, and other related primitives. Here is a more detailed list of the package contents:

- a pluggable *event loop* with various system-specific implementations;
- *transport* and *protocol* abstractions (similar to those in *Twisted*);
- concrete support for TCP, UDP, SSL, subprocess pipes, delayed calls, and others (some may be system-dependent);
- a *Future* class that mimics the one in the *concurrent.futures* module, but adapted for use with the event loop;
- coroutines and tasks based on `yield from` (PEP 380), to help write concurrent code in a sequential fashion;
- cancellation support for *Futures* and coroutines;
- *synchronization primitives* for use between coroutines in a single thread, mimicking those in the *threading* module;
- an interface for passing work off to a threadpool, for times when you absolutely, positively have to use a library that makes blocking I/O calls.

Asynchronous programming is more complex than classical “sequential” programming: see the *Develop with asyncio* page which lists common traps and explains how to avoid them. *Enable the debug mode* during development to detect common issues.

Table of contents:

18.5.1 Base Event Loop

Source code: [Lib/asyncio/events.py](#)

The event loop is the central execution device provided by *asyncio*. It provides multiple facilities, including:

- Registering, executing and cancelling delayed calls (timeouts).
- Creating client and server *transports* for various kinds of communication.
- Launching subprocesses and the associated *transports* for communication with an external program.
- Delegating costly function calls to a pool of threads.

class `asyncio.BaseEventLoop`

This class is an implementation detail. It is a subclass of `AbstractEventLoop` and may be a base class of concrete event loop implementations found in `asyncio`. It should not be used directly; use `AbstractEventLoop` instead. `BaseEventLoop` should not be subclassed by third-party code; the internal interface is not stable.

class `asyncio.AbstractEventLoop`

Abstract base class of event loops.

This class is *not thread safe*.

Run an event loop`AbstractEventLoop.run_forever()`

Run until `stop()` is called. If `stop()` is called before `run_forever()` is called, this polls the I/O selector once with a timeout of zero, runs all callbacks scheduled in response to I/O events (and those that were already scheduled), and then exits. If `stop()` is called while `run_forever()` is running, this will run the current batch of callbacks and then exit. Note that callbacks scheduled by callbacks will not run in that case; they will run the next time `run_forever()` is called.

在 3.5.1 版更改.

`AbstractEventLoop.run_until_complete(future)`

Run until the `Future` is done.

If the argument is a *coroutine object*, it is wrapped by `ensure_future()`.

Return the `Future`'s result, or raise its exception.

`AbstractEventLoop.is_running()`

Returns running status of event loop.

`AbstractEventLoop.stop()`

Stop running the event loop.

This causes `run_forever()` to exit at the next suitable opportunity (see there for more details).

在 3.5.1 版更改.

`AbstractEventLoop.is_closed()`

Returns True if the event loop was closed.

3.4.2 新版功能.

`AbstractEventLoop.close()`

Close the event loop. The loop must not be running. Pending callbacks will be lost.

This clears the queues and shuts down the executor, but does not wait for the executor to finish.

This is idempotent and irreversible. No other methods should be called after this one.

coroutine `AbstractEventLoop.shutdown_asyncgens()`

Schedule all currently open *asynchronous generator* objects to close with an `aclose()` call. After calling this method, the event loop will issue a warning whenever a new asynchronous generator is iterated. Should be used to finalize all scheduled asynchronous generators reliably. Example:

```
try:
    loop.run_forever()
finally:
    loop.run_until_complete(loop.shutdown_asyncgens())
    loop.close()
```

3.6 新版功能.

Calls

Most *asyncio* functions don't accept keywords. If you want to pass keywords to your callback, use *functools.partial()*. For example, `loop.call_soon(functools.partial(print, "Hello", flush=True))` will call `print("Hello", flush=True)`.

注解: *functools.partial()* is better than lambda functions, because *asyncio* can inspect *functools.partial()* object to display parameters in debug mode, whereas lambda functions have a poor representation.

`AbstractEventLoop.call_soon(callback, *args)`

Arrange for a callback to be called as soon as possible. The callback is called after *call_soon()* returns, when control returns to the event loop.

This operates as a FIFO queue, callbacks are called in the order in which they are registered. Each callback will be called exactly once.

Any positional arguments after the callback will be passed to the callback when it is called.

An instance of *asyncio.Handle* is returned, which can be used to cancel the callback.

Use functools.partial to pass keywords to the callback.

`AbstractEventLoop.call_soon_threadsafe(callback, *args)`

Like *call_soon()*, but thread safe.

查看并发和多线程 章节的文档。

Delayed calls

The event loop has its own internal clock for computing timeouts. Which clock is used depends on the (platform-specific) event loop implementation; ideally it is a monotonic clock. This will generally be a different clock than *time.time()*.

注解: Timeouts (relative *delay* or absolute *when*) should not exceed one day.

`AbstractEventLoop.call_later(delay, callback, *args)`

Arrange for the *callback* to be called after the given *delay* seconds (either an int or float).

An instance of *asyncio.Handle* is returned, which can be used to cancel the callback.

callback will be called exactly once per call to *call_later()*. If two callbacks are scheduled for exactly the same time, it is undefined which will be called first.

The optional positional *args* will be passed to the callback when it is called. If you want the callback to be called with some named arguments, use a closure or *functools.partial()*.

Use functools.partial to pass keywords to the callback.

`AbstractEventLoop.call_at(when, callback, *args)`

Arrange for the *callback* to be called at the given absolute timestamp *when* (an int or float), using the same time reference as *AbstractEventLoop.time()*.

这个函数的行为与*call_later()* 相同。

An instance of *asyncio.Handle* is returned, which can be used to cancel the callback.

Use functools.partial to pass keywords to the callback.

`AbstractEventLoop.time()`

Return the current time, as a *float* value, according to the event loop's internal clock.

参见:

`asyncio.sleep()` 函数

Futures

`AbstractEventLoop.create_future()`

Create an `asyncio.Future` object attached to the loop.

This is a preferred way to create futures in `asyncio`, as event loop implementations can provide alternative implementations of the `Future` class (with better performance or instrumentation).

3.5.2 新版功能.

Tasks

`AbstractEventLoop.create_task(coro)`

Schedule the execution of a *coroutine object*: wrap it in a future. Return a `Task` object.

三方的事件循环可以使用它们自己定义的`Task`类的子类来实现互操作性。这个例子里，返回值的类型是`Task`的子类。

This method was added in Python 3.4.2. Use the `async()` function to support also older Python versions.

3.4.2 新版功能.

`AbstractEventLoop.set_task_factory(factory)`

Set a task factory that will be used by `AbstractEventLoop.create_task()`.

If `factory` is `None` the default task factory will be set.

If `factory` is a *callable*, it should have a signature matching `(loop, coro)`, where `loop` will be a reference to the active event loop, `coro` will be a coroutine object. The callable must return an `asyncio.Future` compatible object.

3.4.4 新版功能.

`AbstractEventLoop.get_task_factory()`

Return a task factory, or `None` if the default one is in use.

3.4.4 新版功能.

Creating connections

coroutine `AbstractEventLoop.create_connection(protocol_factory, host=None, port=None, *, ssl=None, family=0, proto=0, flags=0, sock=None, local_addr=None, server_hostname=None)`

Create a streaming transport connection to a given Internet *host* and *port*: socket family `AF_INET` or `AF_INET6` depending on *host* (or *family* if specified), socket type `SOCK_STREAM`. `protocol_factory` must be a callable returning a *protocol* instance.

This method is a *coroutine* which will try to establish the connection in the background. When successful, the coroutine returns a `(transport, protocol)` pair.

基本操作的时间顺序如下:

1. The connection is established, and a *transport* is created to represent it.
2. `protocol_factory` is called without arguments and must return a *protocol* instance.

3. The protocol instance is tied to the transport, and its `connection_made()` method is called.
4. The coroutine returns successfully with the `(transport, protocol)` pair.

创建的 `transport` 是一个实现相关的双向流。

注解: `protocol_factory` can be any kind of callable, not necessarily a class. For example, if you want to use a pre-created protocol instance, you can pass `lambda: my_protocol`.

Options that change how the connection is created:

- `ssl`: if given and not false, a SSL/TLS transport is created (by default a plain TCP transport is created). If `ssl` is a `ssl.SSLContext` object, this context is used to create the transport; if `ssl` is `True`, a context with some unspecified default settings is used.

参见:

[SSL/TLS 安全事项](#)

- `server_hostname`, is only for use together with `ssl`, and sets or overrides the hostname that the target server's certificate will be matched against. By default the value of the `host` argument is used. If `host` is empty, there is no default and you must pass a value for `server_hostname`. If `server_hostname` is an empty string, hostname matching is disabled (which is a serious security risk, allowing for man-in-the-middle-attacks).
- `family`, `proto`, `flags` 是可选的地址族, 协议和标志, 通过传递给 `getaddrinfo()` 来解析 `host`. 如果给出, 这些应该都是来自 `socket` 模块相应的常量的整数。
- `sock`, 如果给出的话, 应该是一个现有的, 已经连接的 `socket.socket` 对象, 这个对象将被 `transport` 使用。如果给出 `sock`, 则 `host`, `port`, `family`, `proto`, `flags` 和 `local_addr` 中的任何一个都不应该指定。
- `local_addr`, if given, is a `(local_host, local_port)` tuple used to bind the socket to locally. The `local_host` and `local_port` are looked up using `getaddrinfo()`, similarly to `host` and `port`.

在 3.5 版更改: On Windows with `ProactorEventLoop`, SSL/TLS is now supported.

参见:

The `open_connection()` function can be used to get a pair of `(StreamReader, StreamWriter)` instead of a protocol.

```
coroutine AbstractEventLoop.create_datagram_endpoint (protocol_factory,          lo-
                                                         cal_addr=None,          re-
                                                         mote_addr=None,        *, fam-
                                                         ily=0, proto=0, flags=0,
                                                         reuse_address=None,
                                                         reuse_port=None,        al-
                                                         low_broadcast=None,
                                                         sock=None)
```

Create datagram connection: socket family `AF_INET` or `AF_INET6` depending on `host` (or `family` if specified), socket type `SOCK_DGRAM`. `protocol_factory` must be a callable returning a `protocol` instance.

This method is a *coroutine* which will try to establish the connection in the background. When successful, the coroutine returns a `(transport, protocol)` pair.

Options changing how the connection is created:

- `local_addr`, 如果指定的话, 就是一个 `(local_host, local_port)` 元组, 用于在本地绑定套接字。 `local_host` 和 `local_port` 是使用 `getaddrinfo()` 来查找的。
- `remote_addr`, 如果指定的话, 就是一个 `(remote_host, remote_port)` 元组, 用于同一个远程地址连接。 `remote_host` 和 `remote_port` 是使用 `getaddrinfo()` 来查找的。

- *family, proto, flags* 是可选的地址族, 协议和标志, 其会被传递给 `getaddrinfo()` 来完成 *host* 的解析。如果要指定的话, 这些都应该是来自于 `socket` 模块的对应常量。
- *reuse_address* tells the kernel to reuse a local socket in `TIME_WAIT` state, without waiting for its natural timeout to expire. If not specified will automatically be set to `True` on UNIX.
- *reuse_port* tells the kernel to allow this endpoint to be bound to the same port as other existing endpoints are bound to, so long as they all set this flag when being created. This option is not supported on Windows and some UNIX' s. If the `SO_REUSEPORT` constant is not defined then this capability is unsupported.
- *allow_broadcast* 告知内核允许此端点向广播地址发送消息。
- *sock* 可选择通过指定此值用于使用一个预先存在的, 已经处于连接状态的 `socket.socket` 对象, 并将其提供给此传输对象使用。如果指定了这个值, *local_addr* 和 *remote_addr* 就应该被忽略 (必须为 `None`)。

On Windows with `ProactorEventLoop`, this method is not supported.

参见 `UDP echo` 客户端协议 和 `UDP echo` 服务端协议 的例子。

在 3.4.4 版更改: 添加了 *family, proto, flags, reuse_address, reuse_port, allow_broadcast* 和 *sock* 等参数。

```
coroutine AbstractEventLoop.create_unix_connection(protocol_factory,          path,
                                                    *,      ssl=None,      sock=None,
                                                    server_hostname=None)
```

Create UNIX connection: socket family `AF_UNIX`, socket type `SOCK_STREAM`. The `AF_UNIX` socket family is used to communicate between processes on the same machine efficiently.

This method is a *coroutine* which will try to establish the connection in the background. When successful, the coroutine returns a (transport, protocol) pair.

path is the name of a UNIX domain socket, and is required unless a *sock* parameter is specified. Abstract UNIX sockets, *str*, and *bytes* paths are supported.

See the `AbstractEventLoop.create_connection()` method for parameters.

Availability: UNIX.

Creating listening connections

```
coroutine AbstractEventLoop.create_server(protocol_factory,  host=None,  port=None,
                                           *,      family=socket.AF_UNSPEC,
                                           flags=socket.AI_PASSIVE, sock=None, back-
                                           log=100,  ssl=None,  reuse_address=None,
                                           reuse_port=None)
```

Create a TCP server (socket type `SOCK_STREAM`) bound to *host* and *port*.

Return a `Server` object, its *sockets* attribute contains created sockets. Use the `Server.close()` method to stop the server: close listening sockets.

参数:

- The *host* parameter can be a string, in that case the TCP server is bound to *host* and *port*. The *host* parameter can also be a sequence of strings and in that case the TCP server is bound to all hosts of the sequence. If *host* is an empty string or `None`, all interfaces are assumed and a list of multiple sockets will be returned (most likely one for IPv4 and another one for IPv6).
- *family* can be set to either `socket.AF_INET` or `AF_INET6` to force the socket to use IPv4 or IPv6. If not set it will be determined from host (defaults to `socket.AF_UNSPEC`).
- *flags* 是用于 `getaddrinfo()` 的位掩码。

- *sock* can optionally be specified in order to use a preexisting socket object. If specified, *host* and *port* should be omitted (must be *None*).
- *backlog* 是传递给 *listen()* 的最大排队连接的数量 (默认为 100)。
- *ssl* 可被设置为一个 *SSLContext* 以在接受的连接上启用 SSL。
- *reuse_address* tells the kernel to reuse a local socket in TIME_WAIT state, without waiting for its natural timeout to expire. If not specified will automatically be set to *True* on UNIX.
- *reuse_port* 告知内核, 只要在创建的时候都设置了这个标志, 就允许此端点绑定到其它端点列表所绑定的同样的端口上。这个选项在 Windows 上是不支持的。

This method is a *coroutine*.

在 3.5 版更改: On Windows with *ProactorEventLoop*, SSL/TLS is now supported.

参见:

The function *start_server()* creates a (*StreamReader*, *StreamWriter*) pair and calls back a function with this pair.

在 3.5.1 版更改: The *host* parameter can now be a sequence of strings.

coroutine *AbstractEventLoop.create_unix_server* (*protocol_factory*, *path=None*, *,
sock=None, *backlog=100*, *ssl=None*)
Similar to *AbstractEventLoop.create_server()*, but specific to the socket family *AF_UNIX*.

This method is a *coroutine*.

Availability: UNIX.

coroutine *BaseEventLoop.connect_accepted_socket* (*protocol_factory*, *sock*, *, *ssl=None*)
Handle an accepted connection.

This is used by servers that accept connections outside of *asyncio* but that use *asyncio* to handle them.

参数:

- *sock* is a preexisting socket object returned from an *accept* call.
- *ssl* 可被设置为一个 *SSLContext* 以在接受的连接上启用 SSL。

This method is a *coroutine*. When completed, the coroutine returns a (*transport*, *protocol*) pair.

3.5.3 新版功能.

Watch file descriptors

On Windows with *SelectorEventLoop*, only socket handles are supported (ex: pipe file descriptors are not supported).

On Windows with *ProactorEventLoop*, these methods are not supported.

AbstractEventLoop.add_reader (*fd*, *callback*, **args*)
Start watching the file descriptor for read availability and then call the *callback* with specified arguments.
Use functools.partial to pass keywords to the callback.

AbstractEventLoop.remove_reader (*fd*)
Stop watching the file descriptor for read availability.

AbstractEventLoop.add_writer (*fd*, *callback*, **args*)
Start watching the file descriptor for write availability and then call the *callback* with specified arguments.
Use functools.partial to pass keywords to the callback.

`AbstractEventLoop.remove_writer(fd)`

Stop watching the file descriptor for write availability.

The *watch a file descriptor for read events* example uses the low-level `AbstractEventLoop.add_reader()` method to register the file descriptor of a socket.

Low-level socket operations

coroutine `AbstractEventLoop.sock_recv(sock, nbytes)`

Receive data from the socket. Modeled after blocking `socket.socket.recv()` method.

The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by `nbytes`.

With `SelectorEventLoop` event loop, the socket `sock` must be non-blocking.

This method is a *coroutine*.

coroutine `AbstractEventLoop.sock_sendall(sock, data)`

Send data to the socket. Modeled after blocking `socket.socket.sendall()` method.

The socket must be connected to a remote socket. This method continues to send data from `data` until either all data has been sent or an error occurs. `None` is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully processed by the receiving end of the connection.

With `SelectorEventLoop` event loop, the socket `sock` must be non-blocking.

This method is a *coroutine*.

coroutine `AbstractEventLoop.sock_connect(sock, address)`

Connect to a remote socket at `address`. Modeled after blocking `socket.socket.connect()` method.

With `SelectorEventLoop` event loop, the socket `sock` must be non-blocking.

This method is a *coroutine*.

在 3.5.2 版更改: `address` no longer needs to be resolved. `sock_connect` will try to check if the `address` is already resolved by calling `socket.inet_pton()`. If not, `AbstractEventLoop.getaddrinfo()` will be used to resolve the `address`.

参见:

`AbstractEventLoop.create_connection()` and `asyncio.open_connection()`.

coroutine `AbstractEventLoop.sock_accept(sock)`

Accept a connection. Modeled after blocking `socket.socket.accept()`.

此 `socket` 必须绑定到一个地址上并且监听连接。返回值是一个 `(conn, address)` 对, 其中 `conn` 是一个新 * 的套接字对象, 用于在此连接上收发数据, *`address` 是连接的另一端的套接字所绑定的地址。

The socket `sock` must be non-blocking.

This method is a *coroutine*.

参见:

`AbstractEventLoop.create_server()` and `start_server()`.

Resolve host name

coroutine `AbstractEventLoop.getaddrinfo(host, port, *, family=0, type=0, proto=0, flags=0)`

This method is a *coroutine*, similar to `socket.getaddrinfo()` function but non-blocking.

coroutine `AbstractEventLoop.getnameinfo(sockaddr, flags=0)`

This method is a *coroutine*, similar to `socket.getnameinfo()` function but non-blocking.

Connect pipes

On Windows with *SelectorEventLoop*, these methods are not supported. Use *ProactorEventLoop* to support pipes on Windows.

coroutine `AbstractEventLoop.connect_read_pipe(protocol_factory, pipe)`

Register read pipe in eventloop.

protocol_factory should instantiate object with *Protocol* interface. *pipe* is a *file-like object*. Return pair `(transport, protocol)`, where *transport* supports the *ReadTransport* interface.

使用 *SelectorEventLoop* 事件循环, *pipe* 被设置为非阻塞模式。

This method is a *coroutine*.

coroutine `AbstractEventLoop.connect_write_pipe(protocol_factory, pipe)`

Register write pipe in eventloop.

protocol_factory should instantiate object with *BaseProtocol* interface. *pipe* is *file-like object*. Return pair `(transport, protocol)`, where *transport* supports *WriteTransport* interface.

使用 *SelectorEventLoop* 事件循环, *pipe* 被设置为非阻塞模式。

This method is a *coroutine*.

参见:

The `AbstractEventLoop.subprocess_exec()` and `AbstractEventLoop.subprocess_shell()` methods.

UNIX signals

Availability: UNIX only.

`AbstractEventLoop.add_signal_handler(signum, callback, *args)`

Add a handler for a signal.

如果信号数字非法或者不可捕获, 就抛出一个 *ValueError*。如果建立处理器的过程中出现问题, 会抛出一个 *RuntimeError*。

Use *functools.partial* to pass keywords to the callback.

`AbstractEventLoop.remove_signal_handler(sig)`

Remove a handler for a signal.

Return True if a signal handler was removed, False if not.

参见:

signal 模块。

Executor

Call a function in an *Executor* (pool of threads or pool of processes). By default, an event loop uses a thread pool executor (*ThreadPoolExecutor*).

coroutine `AbstractEventLoop.run_in_executor(executor, func, *args)`

Arrange for a *func* to be called in the specified executor.

The *executor* argument should be an *Executor* instance. The default executor is used if *executor* is *None*.

Use *functools.partial* to pass keywords to the **func**.

This method is a *coroutine*.

在 3.5.3 版更改: `BaseEventLoop.run_in_executor()` no longer configures the `max_workers` of the thread pool executor it creates, instead leaving it up to the thread pool executor (*ThreadPoolExecutor*) to set the default.

`AbstractEventLoop.set_default_executor(executor)`

Set the default executor used by *run_in_executor()*.

错误处理 API

允许自定义事件循环中如何去处理异常。

`AbstractEventLoop.set_exception_handler(handler)`

将 *handler* 设置为新的事件循环异常处理器。

If *handler* is *None*, the default exception handler will be set.

If *handler* is a callable object, it should have a matching signature to `(loop, context)`, where *loop* will be a reference to the active event loop, *context* will be a dict object (see *call_exception_handler()* documentation for details about context).

`AbstractEventLoop.get_exception_handler()`

Return the exception handler, or *None* if the default one is in use.

3.5.2 新版功能.

`AbstractEventLoop.default_exception_handler(context)`

默认的异常处理器。

This is called when an exception occurs and no exception handler is set, and can be called by a custom exception handler that wants to defer to the default behavior.

context 参数和 *call_exception_handler()* 中的同名参数完全相同。

`AbstractEventLoop.call_exception_handler(context)`

调用当前事件循环异常处理器。

context is a dict object containing the following keys (new keys may be introduced later):

- ‘message’: 错误消息;
- ‘exception’ (可选): 异常对象;
- ‘future’ (可选): *asyncio.Future* 实例。
- ‘handle’ (可选): *asyncio.Handle* 实例;
- ‘protocol’ (可选): *Protocol* 实例;
- ‘transport’ (可选): *Transport* 实例;
- ‘socket’ (可选): *socket.socket* 实例。

注解: Note: this method should not be overloaded in subclassed event loops. For any custom exception handling, use *set_exception_handler()* method.

Debug mode

`AbstractEventLoop.get_debug()`
获取事件循环调试模式状态 (*bool*)。

如果环境变量 `PYTHONASYNCIODEBUG` 是一个非空字符串，就返回 `True`，否则就返回 `False`。

3.4.2 新版功能。

`AbstractEventLoop.set_debug(enabled: bool)`
设置事件循环的调试模式。

3.4.2 新版功能。

参见：

debug mode of asyncio.

Server

class `asyncio.Server`
Server listening on sockets.

Object created by the `AbstractEventLoop.create_server()` method and the `start_server()` function. Don't instantiate the class directly.

close()
停止服务：关闭监听的套接字并且设置 `sockets` 属性为 `None`。

用于表示已经连进来的客户端连接会保持打开的状态。

服务器是被异步关闭的，使用 `wait_closed()` 协程来等待服务器关闭。

coroutine wait_closed()
等待 `close()` 方法执行完毕。

This method is a *coroutine*.

sockets
List of `socket.socket` objects the server is listening to, or `None` if the server is closed.

Handle

class `asyncio.Handle`
A callback wrapper object returned by `AbstractEventLoop.call_soon()`, `AbstractEventLoop.call_soon_threadsafe()`, `AbstractEventLoop.call_later()`, and `AbstractEventLoop.call_at()`.

cancel()
Cancel the call. If the callback is already canceled or executed, this method has no effect.

Event loop examples

`call_soon()` 的 Hello World 示例。

Example using the `AbstractEventLoop.call_soon()` method to schedule a callback. The callback displays "Hello World" and then stops the event loop:

```
import asyncio

def hello_world(loop):
    print('Hello World')
    loop.stop()

loop = asyncio.get_event_loop()

# Schedule a call to hello_world()
loop.call_soon(hello_world, loop)

# Blocking call interrupted by loop.stop()
loop.run_forever()
loop.close()
```

参见:

The *Hello World coroutine* example uses a *coroutine*.

使用 `call_later()` 来展示当前的日期

Example of callback displaying the current date every second. The callback uses the *AbstractEventLoop.call_later()* method to reschedule itself during 5 seconds, and then stops the event loop:

```
import asyncio
import datetime

def display_date(end_time, loop):
    print(datetime.datetime.now())
    if (loop.time() + 1.0) < end_time:
        loop.call_later(1, display_date, end_time, loop)
    else:
        loop.stop()

loop = asyncio.get_event_loop()

# Schedule the first call to display_date()
end_time = loop.time() + 5.0
loop.call_soon(display_date, end_time, loop)

# Blocking call interrupted by loop.stop()
loop.run_forever()
loop.close()
```

参见:

The *coroutine displaying the current date* example uses a *coroutine*.

监控一个文件描述符的读事件

Wait until a file descriptor received some data using the *AbstractEventLoop.add_reader()* method and then close the event loop:

```
import asyncio
try:
```

(下页继续)

(续上页)

```

    from socket import socketpair
except ImportError:
    from asyncio.windows_utils import socketpair

# Create a pair of connected file descriptors
rsock, wsock = socketpair()
loop = asyncio.get_event_loop()

def reader():
    data = rsock.recv(100)
    print("Received:", data.decode())
    # We are done: unregister the file descriptor
    loop.remove_reader(rsock)
    # Stop the event loop
    loop.stop()

# Register the file descriptor for read event
loop.add_reader(rsock, reader)

# Simulate the reception of data from the network
loop.call_soon(wsock.send, 'abc'.encode())

# Run the event loop
loop.run_forever()

# We are done, close sockets and the event loop
rsock.close()
wsock.close()
loop.close()

```

参见:

The *register an open socket to wait for data using a protocol* example uses a low-level protocol created by the `AbstractEventLoop.create_connection()` method.

The *register an open socket to wait for data using streams* example uses high-level streams created by the `open_connection()` function in a coroutine.

为 SIGINT 和 SIGTERM 设置信号处理器

Register handlers for signals SIGINT and SIGTERM using the `AbstractEventLoop.add_signal_handler()` method:

```

import asyncio
import functools
import os
import signal

def ask_exit(signame):
    print("got signal %s: exit" % signame)
    loop.stop()

loop = asyncio.get_event_loop()
for signame in ('SIGINT', 'SIGTERM'):
    loop.add_signal_handler(getattr(signal, signame),

```

(下页继续)

(续上页)

```

                                functools.partial(ask_exit, signame))

print("Event loop running forever, press Ctrl+C to interrupt.")
print("pid %s: send SIGINT or SIGTERM to exit." % os.getpid())
try:
    loop.run_forever()
finally:
    loop.close()

```

This example only works on UNIX.

18.5.2 事件循环

源码: `Lib/asyncio/events.py`

事件循环函数

下面的函数是访问全局策略方法的便利快捷方式。注意这只是提供了对默认策略的访问，除非要在进程开始之前设置替代的策略。

```

asyncio.get_event_loop()
    与调用 get_event_loop_policy().get_event_loop() 等价。

asyncio.set_event_loop(loop)
    等价于调用 get_event_loop_policy().set_event_loop(loop)。

asyncio.new_event_loop()
    等价于调用 get_event_loop_policy().new_event_loop()。

```

可用的事件循环

asyncio 当前提供两种事件循环实现: *SelectorEventLoop* 和 *ProactorEventLoop*。

class `asyncio.SelectorEventLoop`

基于 *selectors* 模块的事件循环。*AbstractEventLoop* 的子类。

使用对应平台上最高效的选择器。

在 Windows 上，只支持套接字（举例：不支持管线）：参见 *MSDN* 关于 *select* 的文档 <<https://msdn.microsoft.com/en-us/library/windows/desktop/ms740141%28v=vs.85%29.aspx>> _。

class `asyncio.ProactorEventLoop`

Windows 上的 Proactor 事件循环，使用的是 “I/O 完成端口”，也叫做 IOCP。为 *AbstractEventLoop* 的子类。

可用性: Windows。

参见:

MSDN 上关于 I/O 完成端口的文档。

在 Windows 上使用 *ProactorEventLoop* 的例子:

```
import asyncio, sys

if sys.platform == 'win32':
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
```

平台支持

`asyncio` 模块被设计为可移植的，但是每个平台仍旧有细微的不同，而且不一定支持 `asyncio` 的所有特性。

Windows

Windows 事件循环的一般限制：

- 不支持 `create_unix_connection()` 和 `create_unix_server()`： `socket.AF_UNIX` 套接字族只在 UNIX 上可用
- 不支持 `add_signal_handler()` 和 `remove_signal_handler()`
- 不支持 `EventLoopPolicy.set_child_watcher()`。`ProactorEventLoop` 支持子进程。监控子进程的实现只有一种，不需要对其进行设置。

特定于 `SelectorEventLoop` 的限制：

- `SelectSelector` 只被用于支持套接字，并且最多支持 512 个套接字。
- `add_reader()` 和 `add_writer()` 只接受套接字的文件描述符
- 不支持管线（示例： `connect_read_pipe()`, `connect_write_pipe()`）
- 不支持 `Subprocesses`（示例： `subprocess_exec()`, `subprocess_shell()`）

特定于 `ProactorEventLoop` 的限制：

- 不支持 `create_datagram_endpoint()` (UDP)
- 不支持 `add_reader()` 和 `add_writer()`

Windows 上单调时钟的分辨率大约为 15.6 毫秒。最佳的分辨率是 0.5 毫秒。分辨率依赖于具体的硬件（HPET 的可用性）和 Windows 的设置。参见：[ref:asyncio delayed calls <asyncio-delayed-calls>](#)。

在 3.5 版更改：`ProactorEventLoop` 现在支持 SSL 了。

Mac OS X

类似于 PTY 的字符设备在 Mavericks（Mac OS 10.9）之前并未有很好的支持。在 Mac OS 10.5 以及更老的版本上则根本不支持。

在 Mac OS 10.6、10.7 和 10.8 上，默认的事件循环是 `SelectorEventLoop`，其使用了 `selectors.KqueueSelector`。`selectors.KqueueSelector` 在这些版本上并不支持字符设备。`SelectorEventLoop` 可用同 `SelectSelector` 或者 `PollSelector` 一同使用来在这些版本的 Mac OS X 上支持块设备。例如：

```
import asyncio
import selectors

selector = selectors.SelectSelector()
```

(下页继续)

(续上页)

```
loop = asyncio.SelectorEventLoop(selector)
asyncio.set_event_loop(loop)
```

事件循环策略和默认策略

使用一个策略模式对事件循环进行管理，用以为特定平台和框架提供最大限度的灵活性。在一个进程的执行中，唯一的全局策略对象，基于调用的上下文，管理着此进程所有可用的事件循环。一个策略就是一个实现了 *AbstractEventLoopPolicy* 的对象。

对于 *asyncio* 的多数使用者来说，从来都不需要显式地处理策略，因为默认的全局策略就已经足够了（看下面）。

模块级别的函数 *get_event_loop()* 和 *set_event_loop()* 对于默认策略管理的事件循环的便利访问方式。

事件循环策略接口

一个事件循环必须实现如下的接口：

class *asyncio.AbstractEventLoopPolicy*

事件循环策略。

get_event_loop()

为当前上下文获取事件循环。

返回一个实现了 *AbstractEventLoop* 接口的事件循环对象。如果是从一个协程中调用，就会返回当前正在运行的事件循环。

如果没有为当前上下文设置一个事件循环，并且当前策略不能创建一个事件循环，就会抛出一个错误。其务必不能返回 *None*。

在 3.6 版更改。

set_event_loop(loop)

将当前上下文的事件循环设置为 *loop*。

new_event_loop()

根据策略的规则，创建并返回一个新的事件循环对象。

如果有需要设置这个循环作为当前上下文的事件循环，就必须显式调用 *set_event_loop()*。

The default policy defines context as the current thread, and manages an event loop per thread that interacts with *asyncio*. If the current thread doesn't already have an event loop associated with it, the default policy's *get_event_loop()* method creates one when called from the main thread, but raises *RuntimeError* otherwise.

访问全局循环策略

asyncio.get_event_loop_policy()

获取当前事件循环策略。

asyncio.set_event_loop_policy(policy)

设置当前事件循环策略。如果 *policy* 为 *None*，就会恢复使用默认的策略。

自定义事件循环策略

要实现一个新的事件循环策略，推荐你继承具体的默认事件循环策略 `DefaultEventLoopPolicy` 并且重写你想要改变行为的方法，例如：

```
class MyEventLoopPolicy(asyncio.DefaultEventLoopPolicy):

    def get_event_loop(self):
        """Get the event loop.

        This may be None or an instance of EventLoop.
        """
        loop = super().get_event_loop()
        # Do something with loop ...
        return loop

asyncio.set_event_loop_policy(MyEventLoopPolicy())
```

18.5.3 Tasks and coroutines

Source code: `Lib/asyncio/tasks.py`

Source code: `Lib/asyncio/coroutines.py`

协程

Coroutines used with `asyncio` may be implemented using the `async def` statement, or by using *generators*. The `async def` type of coroutine was added in Python 3.5, and is recommended if there is no need to support older Python versions.

Generator-based coroutines should be decorated with `@asyncio.coroutine`, although this is not strictly enforced. The decorator enables compatibility with `async def` coroutines, and also serves as documentation. Generator-based coroutines use the `yield from` syntax introduced in **PEP 380**, instead of the original `yield` syntax.

The word “coroutine”, like the word “generator”, is used for two different (though related) concepts:

- The function that defines a coroutine (a function definition using `async def` or decorated with `@asyncio.coroutine`). If disambiguation is needed we will call this a *coroutine function* (`iscoroutinefunction()` returns True).
- The object obtained by calling a coroutine function. This object represents a computation or an I/O operation (usually a combination) that will complete eventually. If disambiguation is needed we will call it a *coroutine object* (`iscoroutine()` returns True).

Things a coroutine can do:

- `result = await future` or `result = yield from future` – suspends the coroutine until the future is done, then returns the future’s result, or raises an exception, which will be propagated. (If the future is cancelled, it will raise a `CancelledError` exception.) Note that tasks are futures, and everything said about futures also applies to tasks.
- `result = await coroutine` or `result = yield from coroutine` – wait for another coroutine to produce a result (or raise an exception, which will be propagated). The `coroutine` expression must be a *call* to another coroutine.
- `return expression` – produce a result to the coroutine that is waiting for this one using `await` or `yield from`.

- `raise exception` – raise an exception in the coroutine that is waiting for this one using `await` or `yield from`.

Calling a coroutine does not start its code running – the coroutine object returned by the call doesn't do anything until you schedule its execution. There are two basic ways to start it running: call `await coroutine` or `yield from coroutine` from another coroutine (assuming the other coroutine is already running!), or schedule its execution using the `ensure_future()` function or the `AbstractEventLoop.create_task()` method.

Coroutines (and tasks) can only run when the event loop is running.

`@asyncio.coroutine`

Decorator to mark generator-based coroutines. This enables the generator use `yield from` to call `async def` coroutines, and also enables the generator to be called by `async def` coroutines, for instance using an `await` expression.

There is no need to decorate `async def` coroutines themselves.

If the generator is not yielded from before it is destroyed, an error message is logged. See *Detect coroutines never scheduled*.

注解: In this documentation, some methods are documented as coroutines, even if they are plain Python functions returning a `Future`. This is intentional to have a freedom of tweaking the implementation of these functions in the future. If such a function is needed to be used in a callback-style code, wrap its result with `ensure_future()`.

Example: Hello World coroutine

Example of coroutine displaying "Hello World":

```
import asyncio

async def hello_world():
    print("Hello World!")

loop = asyncio.get_event_loop()
# Blocking call which returns when the hello_world() coroutine is done
loop.run_until_complete(hello_world())
loop.close()
```

参见:

The *Hello World with call_soon()* example uses the `AbstractEventLoop.call_soon()` method to schedule a callback.

Example: Coroutine displaying the current date

Example of coroutine displaying the current date every second during 5 seconds using the `sleep()` function:

```
import asyncio
import datetime

async def display_date(loop):
    end_time = loop.time() + 5.0
    while True:
        print(datetime.datetime.now())
```

(下页继续)

(续上页)

```
        if (loop.time() + 1.0) >= end_time:
            break
        await asyncio.sleep(1)

loop = asyncio.get_event_loop()
# Blocking call which returns when the display_date() coroutine is done
loop.run_until_complete(display_date(loop))
loop.close()
```

参见:

The *display the current date with call_later()* example uses a callback with the *AbstractEventLoop.call_later()* method.

Example: Chain coroutines

Example chaining coroutines:

```
import asyncio

async def compute(x, y):
    print("Compute %s + %s ..." % (x, y))
    await asyncio.sleep(1.0)
    return x + y

async def print_sum(x, y):
    result = await compute(x, y)
    print("%s + %s = %s" % (x, y, result))

loop = asyncio.get_event_loop()
loop.run_until_complete(print_sum(1, 2))
loop.close()
```

`compute()` is chained to `print_sum()`: `print_sum()` coroutine waits until `compute()` is completed before returning its result.

Sequence diagram of the example:

The “Task” is created by the `AbstractEventLoop.run_until_complete()` method when it gets a coroutine object instead of a task.

The diagram shows the control flow, it does not describe exactly how things work internally. For example, the sleep coroutine creates an internal future which uses `AbstractEventLoop.call_later()` to wake up the task in 1 second.

InvalidStateError

exception `asyncio.InvalidStateError`
The operation is not allowed in this state.

TimeoutError

exception `asyncio.TimeoutError`
The operation exceeded the given deadline.

注解: This exception is different from the builtin `TimeoutError` exception!

Future

class `asyncio.Future` (*, loop=None)
This class is *almost* compatible with `concurrent.futures.Future`.

Differences:

- `result()` and `exception()` do not take a timeout argument and raise an exception when the future isn't done yet.
- Callbacks registered with `add_done_callback()` are always called via the event loop's `call_soon()`.

- This class is not compatible with the `wait()` and `as_completed()` functions in the `concurrent.futures` package.

This class is *not thread safe*.

cancel()

Cancel the future and schedule callbacks.

If the future is already done or cancelled, return `False`. Otherwise, change the future's state to cancelled, schedule the callbacks and return `True`.

cancelled()

Return `True` if the future was cancelled.

done()

Return `True` if the future is done.

Done means either that a result / exception are available, or that the future was cancelled.

result()

Return the result this future represents.

If the future has been cancelled, raises `CancelledError`. If the future's result isn't yet available, raises `InvalidStateError`. If the future is done and has an exception set, this exception is raised.

exception()

Return the exception that was set on this future.

The exception (or `None` if no exception was set) is returned only if the future is done. If the future has been cancelled, raises `CancelledError`. If the future isn't done yet, raises `InvalidStateError`.

add_done_callback(fn)

Add a callback to be run when the future becomes done.

The callback is called with a single argument - the future object. If the future is already done when this is called, the callback is scheduled with `call_soon()`.

Use `functools.partial` to pass parameters to the callback. For example, `fut.add_done_callback(functools.partial(print, "Future:", flush=True))` will call `print("Future:", fut, flush=True)`.

remove_done_callback(fn)

Remove all instances of a callback from the "call when done" list.

Returns the number of callbacks removed.

set_result(result)

Mark the future done and set its result.

If the future is already done when this method is called, raises `InvalidStateError`.

set_exception(exception)

Mark the future done and set an exception.

If the future is already done when this method is called, raises `InvalidStateError`.

Example: Future with `run_until_complete()`

Example combining a *Future* and a *coroutine function*:

```
import asyncio

async def slow_operation(future):
    await asyncio.sleep(1)
    future.set_result('Future is done!')

loop = asyncio.get_event_loop()
future = asyncio.Future()
asyncio.ensure_future(slow_operation(future))
loop.run_until_complete(future)
print(future.result())
loop.close()
```

The coroutine function is responsible for the computation (which takes 1 second) and it stores the result into the future. The `run_until_complete()` method waits for the completion of the future.

注解: The `run_until_complete()` method uses internally the `add_done_callback()` method to be notified when the future is done.

Example: Future with `run_forever()`

The previous example can be written differently using the `Future.add_done_callback()` method to describe explicitly the control flow:

```
import asyncio

async def slow_operation(future):
    await asyncio.sleep(1)
    future.set_result('Future is done!')

def got_result(future):
    print(future.result())
    loop.stop()

loop = asyncio.get_event_loop()
future = asyncio.Future()
asyncio.ensure_future(slow_operation(future))
future.add_done_callback(got_result)
try:
    loop.run_forever()
finally:
    loop.close()
```

In this example, the future is used to link `slow_operation()` to `got_result()`: when `slow_operation()` is done, `got_result()` is called with the result.

Task

class `asyncio.Task` (*coro*, *, *loop=None*)

Schedule the execution of a *coroutine*: wrap it in a future. A task is a subclass of *Future*.

A task is responsible for executing a coroutine object in an event loop. If the wrapped coroutine yields from a future, the task suspends the execution of the wrapped coroutine and waits for the completion of the future. When

the future is done, the execution of the wrapped coroutine restarts with the result or the exception of the future.

Event loops use cooperative scheduling: an event loop only runs one task at a time. Other tasks may run in parallel if other event loops are running in different threads. While a task waits for the completion of a future, the event loop executes a new task.

The cancellation of a task is different from the cancellation of a future. Calling `cancel()` will throw a `CancelledError` to the wrapped coroutine. `cancelled()` only returns `True` if the wrapped coroutine did not catch the `CancelledError` exception, or raised a `CancelledError` exception.

If a pending task is destroyed, the execution of its wrapped *coroutine* did not complete. It is probably a bug and a warning is logged: see *Pending task destroyed*.

Don't directly create `Task` instances: use the `ensure_future()` function or the `AbstractEventLoop.create_task()` method.

This class is *not thread safe*.

classmethod `all_tasks(loop=None)`
返回一个事件循环中所有任务的集合。

By default all tasks for the current event loop are returned.

classmethod `current_task(loop=None)`
Return the currently running task in an event loop or `None`.
By default the current task for the current event loop is returned.
`None` is returned when called not in the context of a `Task`.

cancel()
Request that this task cancel itself.

This arranges for a `CancelledError` to be thrown into the wrapped coroutine on the next cycle through the event loop. The coroutine then has a chance to clean up or even deny the request using `try/except/finally`.

Unlike `Future.cancel()`, this does not guarantee that the task will be cancelled: the exception might be caught and acted upon, delaying cancellation of the task or preventing cancellation completely. The task may also return a value or raise a different exception.

Immediately after this method is called, `cancelled()` will not return `True` (unless the task was already cancelled). A task will be marked as cancelled when the wrapped coroutine terminates with a `CancelledError` exception (even if `cancel()` was not called).

get_stack(*, limit=None)
Return the list of stack frames for this task's coroutine.

If the coroutine is not done, this returns the stack where it is suspended. If the coroutine has completed successfully or was cancelled, this returns an empty list. If the coroutine was terminated by an exception, this returns the list of traceback frames.

框架总是从按从旧到新排序。

The optional `limit` gives the maximum number of frames to return; by default all available frames are returned. Its meaning differs depending on whether a stack or a traceback is returned: the newest frames of a stack are returned, but the oldest frames of a traceback are returned. (This matches the behavior of the traceback module.)

For reasons beyond our control, only one stack frame is returned for a suspended coroutine.

print_stack(*, limit=None, file=None)
Print the stack or traceback for this task's coroutine.

This produces output similar to that of the `traceback` module, for the frames retrieved by `get_stack()`. The `limit` argument is passed to `get_stack()`. The `file` argument is an I/O stream to which the output is written; by default output is written to `sys.stderr`.

Example: Parallel execution of tasks

Example executing 3 tasks (A, B, C) in parallel:

```
import asyncio

async def factorial(name, number):
    f = 1
    for i in range(2, number+1):
        print("Task %s: Compute factorial(%s)..." % (name, i))
        await asyncio.sleep(1)
        f *= i
    print("Task %s: factorial(%s) = %s" % (name, number, f))

loop = asyncio.get_event_loop()
loop.run_until_complete(asyncio.gather(
    factorial("A", 2),
    factorial("B", 3),
    factorial("C", 4),
))
loop.close()
```

Output:

```
Task A: Compute factorial(2)...
Task B: Compute factorial(2)...
Task C: Compute factorial(2)...
Task A: factorial(2) = 2
Task B: Compute factorial(3)...
Task C: Compute factorial(3)...
Task B: factorial(3) = 6
Task C: Compute factorial(4)...
Task C: factorial(4) = 24
```

A task is automatically scheduled for execution when it is created. The event loop stops when all tasks are done.

Task functions

注解: In the functions below, the optional `loop` argument allows explicitly setting the event loop object used by the underlying task or coroutine. If it's not provided, the default event loop is used.

`asyncio.as_completed(fs, *, loop=None, timeout=None)`

Return an iterator whose values, when waited for, are `Future` instances.

如果在所有 `Future` 对象完成前发生超时则将引发 `asyncio.TimeoutError`。

示例:

```
for f in as_completed(fs):
    result = yield from f # The 'yield from' may raise
    # Use result
```

注解: The futures `f` are not necessarily members of `fs`.

`asyncio.ensure_future(coro_or_future, *, loop=None)`

Schedule the execution of a *coroutine object*: wrap it in a future. Return a *Task* object.

If the argument is a *Future*, it is returned directly.

3.4.4 新版功能.

在 3.5.1 版更改: The function accepts any *awaitable* object.

参见:

The `AbstractEventLoop.create_task()` method.

`asyncio.async(coro_or_future, *, loop=None)`

A deprecated alias to `ensure_future()`.

3.4.4 版后已移除.

`asyncio.wrap_future(future, *, loop=None)`

Wrap a `concurrent.futures.Future` object in a *Future* object.

`asyncio.gather(*coros_or_futures, loop=None, return_exceptions=False)`

Return a future aggregating results from the given coroutine objects or futures.

All futures must share the same event loop. If all the tasks are done successfully, the returned future's result is the list of results (in the order of the original sequence, not necessarily the order of results arrival). If `return_exceptions` is true, exceptions in the tasks are treated the same as successful results, and gathered in the result list; otherwise, the first raised exception will be immediately propagated to the returned future.

Cancellation: if the outer Future is cancelled, all children (that have not completed yet) are also cancelled. If any child is cancelled, this is treated as if it raised `CancelledError` – the outer Future is *not* cancelled in this case. (This is to prevent the cancellation of one child to cause other children to be cancelled.)

在 3.6.6 版更改: 如果 `gather` 本身被取消, 则无论 `return_exceptions` 取值为何, 消息都会被传播。

`asyncio.iscoroutine(obj)`

Return True if `obj` is a *coroutine object*, which may be based on a generator or an `async def` coroutine.

`asyncio.iscoroutinefunction(func)`

Return True if `func` is determined to be a *coroutine function*, which may be a decorated generator function or an `async def` function.

`asyncio.run_coroutine_threadsafe(coro, loop)`

Submit a *coroutine object* to a given event loop.

Return a `concurrent.futures.Future` to access the result.

This function is meant to be called from a different thread than the one where the event loop is running. Usage:

```
# Create a coroutine
coro = asyncio.sleep(1, result=3)
# Submit the coroutine to a given loop
future = asyncio.run_coroutine_threadsafe(coro, loop)
# Wait for the result with an optional timeout argument
assert future.result(timeout) == 3
```

If an exception is raised in the coroutine, the returned future will be notified. It can also be used to cancel the task in the event loop:

```
try:
    result = future.result(timeout)
except asyncio.TimeoutError:
    print('The coroutine took too long, cancelling the task...')
    future.cancel()
except Exception as exc:
    print('The coroutine raised an exception: {!r}'.format(exc))
else:
    print('The coroutine returned: {!r}'.format(result))
```

查看并发和多线程 章节的文档。

注解： Unlike other functions from the module, `run_coroutine_threadsafe()` requires the `loop` argument to be passed explicitly.

3.5.1 新版功能.

coroutine `asyncio.sleep(delay, result=None, *, loop=None)`

Create a *coroutine* that completes after a given time (in seconds). If *result* is provided, it is produced to the caller when the coroutine completes.

The resolution of the sleep depends on the *granularity of the event loop*.

This function is a *coroutine*.

coroutine `asyncio.shield(arg, *, loop=None)`

Wait for a future, shielding it from cancellation.

以下语句:

```
res = yield from shield(something())
```

is exactly equivalent to the statement:

```
res = yield from something()
```

except that if the coroutine containing it is cancelled, the task running in `something()` is not cancelled. From the point of view of `something()`, the cancellation did not happen. But its caller is still cancelled, so the `yield-from` expression still raises `CancelledError`. Note: If `something()` is cancelled by other means this will still cancel `shield()`.

If you want to completely ignore cancellation (not recommended) you can combine `shield()` with a `try/except` clause, as follows:

```
try:
    res = yield from shield(something())
except CancelledError:
    res = None
```

coroutine `asyncio.wait(futures, *, loop=None, timeout=None, return_when=ALL_COMPLETED)`

Wait for the Futures and coroutine objects given by the sequence *futures* to complete. Coroutines will be wrapped in Tasks. Returns two sets of *Future*: (done, pending).

The sequence *futures* must not be empty.

timeout can be used to control the maximum number of seconds to wait before returning. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

return_when indicates when this function should return. It must be one of the following constants of the `concurrent.futures` module:

常数	描述
<code>FIRST_COMPLETED</code>	函数将在任意可等待对象结束或取消时返回。
<code>FIRST_EXCEPTION</code>	函数将在任意可等待对象因引发异常而结束时返回。当没有引发任何异常时它就相当于 <code>ALL_COMPLETED</code> 。
<code>ALL_COMPLETED</code>	函数将在所有可等待对象结束或取消时返回。

This function is a *coroutine*.

用法:

```
done, pending = yield from asyncio.wait(fs)
```

注解: This does not raise `asyncio.TimeoutError`! Futures that aren't done when the timeout occurs are returned in the second set.

coroutine `asyncio.wait_for(fut, timeout, *, loop=None)`

Wait for the single *Future* or *coroutine object* to complete with timeout. If *timeout* is `None`, block until the future completes.

Coroutine will be wrapped in *Task*.

Returns result of the Future or coroutine. When a timeout occurs, it cancels the task and raises `asyncio.TimeoutError`. To avoid the task cancellation, wrap it in `shield()`.

If the wait is cancelled, the future *fut* is also cancelled.

This function is a *coroutine*, usage:

```
result = yield from asyncio.wait_for(fut, 60.0)
```

在 3.4.3 版更改: If the wait is cancelled, the future *fut* is now also cancelled.

18.5.4 Transports and protocols (callback based API)

Source code: `Lib/asyncio/transports.py`

Source code: `Lib/asyncio/protocols.py`

传输

Transports are classes provided by `asyncio` in order to abstract various kinds of communication channels. You generally won't instantiate a transport yourself; instead, you will call an `AbstractEventLoop` method which will create the transport and try to initiate the underlying communication channel, calling you back when it succeeds.

Once the communication channel is established, a transport is always paired with a *protocol* instance. The protocol can then call the transport's methods for various purposes.

`asyncio` currently implements transports for TCP, UDP, SSL, and subprocess pipes. The methods available on a transport depend on the transport's kind.

传输类属于线程不安全。

在 3.6 版更改: The socket option `TCP_NODELAY` is now set by default.

BaseTransport

class `asyncio.BaseTransport`

Base class for transports.

close()

Close the transport. If the transport has a buffer for outgoing data, buffered data will be flushed asynchronously. No more data will be received. After all buffered data is flushed, the protocol's `connection_lost()` method will be called with `None` as its argument.

is_closing()

返回 `True`，如果传输正在关闭或已经关闭。

3.5.1 新版功能.

get_extra_info(*name*, *default=None*)

Return optional transport information. *name* is a string representing the piece of transport-specific information to get, *default* is the value to return if the information doesn't exist.

This method allows transport implementations to easily expose channel-specific information.

- socket:
 - 'peername': the remote address to which the socket is connected, result of `socket.socket.getpeername()` (None on error)
 - 'socket': `socket.socket` instance
 - 'sockname': the socket's own address, result of `socket.socket.getsockname()`
- SSL socket:
 - 'compression': the compression algorithm being used as a string, or None if the connection isn't compressed; result of `ssl.SSLSocket.compression()`
 - 'cipher': a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used; result of `ssl.SSLSocket.cipher()`
 - 'peercert': peer certificate; result of `ssl.SSLSocket.getpeercert()`
 - 'sslcontext': `ssl.SSLContext` instance
 - 'ssl_object': `ssl.SSLObject` or `ssl.SSLSocket` instance
- pipe:
 - 'pipe': pipe object
- subprocess:
 - 'subprocess': `subprocess.Popen` instance

set_protocol(*protocol*)

Set a new protocol. Switching protocol should only be done when both protocols are documented to support the switch.

3.5.3 新版功能.

get_protocol()

返回当前协议。

3.5.3 新版功能。

在 3.5.1 版更改: 'ssl_object' info was added to SSL sockets.

ReadTransport

class `asyncio.ReadTransport`

Interface for read-only transports.

pause_reading()

Pause the receiving end of the transport. No data will be passed to the protocol's `data_received()` method until `resume_reading()` is called.

在 3.6.7 版更改: The method is idempotent, i.e. it can be called when the transport is already paused or closed.

resume_reading()

Resume the receiving end. The protocol's `data_received()` method will be called once again if some data is available for reading.

在 3.6.7 版更改: The method is idempotent, i.e. it can be called when the transport is already reading.

WriteTransport

class `asyncio.WriteTransport`

Interface for write-only transports.

abort()

Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's `connection_lost()` method will eventually be called with `None` as its argument.

can_write_eof()

Return `True` if the transport supports `write_eof()`, `False` if not.

get_write_buffer_size()

Return the current size of the output buffer used by the transport.

get_write_buffer_limits()

Get the *high*- and *low*-water limits for write flow control. Return a tuple (*low*, *high*) where *low* and *high* are positive number of bytes.

Use `set_write_buffer_limits()` to set the limits.

3.4.2 新版功能。

set_write_buffer_limits (*high=None*, *low=None*)

Set the *high*- and *low*-water limits for write flow control.

These two values (measured in number of bytes) control when the protocol's `pause_writing()` and `resume_writing()` methods are called. If specified, the low-water limit must be less than or equal to the high-water limit. Neither *high* nor *low* can be negative.

`pause_writing()` is called when the buffer size becomes greater than or equal to the *high* value. If writing has been paused, `resume_writing()` is called when the buffer size becomes less than or equal to the *low* value.

The defaults are implementation-specific. If only the high-water limit is given, the low-water limit defaults to an implementation-specific value less than or equal to the high-water limit. Setting *high* to zero forces *low* to zero as well, and causes `pause_writing()` to be called whenever the buffer becomes non-empty. Setting *low* to zero causes `resume_writing()` to be called only once the buffer is empty. Use of zero for either limit is generally sub-optimal as it reduces opportunities for doing I/O and computation concurrently.

Use `get_write_buffer_limits()` to get the limits.

write (*data*)

Write some *data* bytes to the transport.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

writelines (*list_of_data*)

Write a list (or any iterable) of data bytes to the transport. This is functionally equivalent to calling `write()` on each element yielded by the iterable, but may be implemented more efficiently.

write_eof ()

Close the write end of the transport after flushing buffered data. Data may still be received.

This method can raise `NotImplementedError` if the transport (e.g. SSL) doesn't support half-closes.

DatagramTransport

`DatagramTransport.sendto` (*data*, *addr=None*)

Send the *data* bytes to the remote peer given by *addr* (a transport-dependent target address). If *addr* is `None`, the data is sent to the target address given on transport creation.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

`DatagramTransport.abort` ()

Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's `connection_lost()` method will eventually be called with `None` as its argument.

BaseSubprocessTransport

class `asyncio.BaseSubprocessTransport`

get_pid ()

Return the subprocess process id as an integer.

get_pipe_transport (*fd*)

Return the transport for the communication pipe corresponding to the integer file descriptor *fd*:

- 0: readable streaming transport of the standard input (*stdin*), or `None` if the subprocess was not created with `stdin=PIPE`
- 1: writable streaming transport of the standard output (*stdout*), or `None` if the subprocess was not created with `stdout=PIPE`
- 2: writable streaming transport of the standard error (*stderr*), or `None` if the subprocess was not created with `stderr=PIPE`
- other *fd*: `None`

get_returncode()

Return the subprocess returncode as an integer or *None* if it hasn't returned, similarly to the *subprocess.Popen.returncode* attribute.

kill()

Kill the subprocess, as in *subprocess.Popen.kill()*.

On POSIX systems, the function sends SIGKILL to the subprocess. On Windows, this method is an alias for *terminate()*.

send_signal(signal)

Send the *signal* number to the subprocess, as in *subprocess.Popen.send_signal()*.

terminate()

Ask the subprocess to stop, as in *subprocess.Popen.terminate()*. This method is an alias for the *close()* method.

On POSIX systems, this method sends SIGTERM to the subprocess. On Windows, the Windows API function *TerminateProcess()* is called to stop the subprocess.

close()

Ask the subprocess to stop by calling the *terminate()* method if the subprocess hasn't returned yet, and close transports of all pipes (*stdin*, *stdout* and *stderr*).

协议

asyncio provides base classes that you can subclass to implement your network protocols. Those classes are used in conjunction with *transports* (see below): the protocol parses incoming data and asks for the writing of outgoing data, while the transport is responsible for the actual I/O and buffering.

When subclassing a protocol class, it is recommended you override certain methods. Those methods are callbacks: they will be called by the transport on certain events (for example when some data is received); you shouldn't call them yourself, unless you are implementing a transport.

注解: All callbacks have default implementations, which are empty. Therefore, you only need to implement the callbacks for the events in which you are interested.

Protocol classes

class asyncio.Protocol

The base class for implementing streaming protocols (for use with e.g. TCP and SSL transports).

class asyncio.DatagramProtocol

The base class for implementing datagram protocols (for use with e.g. UDP transports).

class asyncio.SubprocessProtocol

The base class for implementing protocols communicating with child processes (through a set of unidirectional pipes).

Connection callbacks

These callbacks may be called on *Protocol*, *DatagramProtocol* and *SubprocessProtocol* instances:

`BaseProtocol.connection_made(transport)`

链接建立时被调用。

The *transport* argument is the transport representing the connection. You are responsible for storing it somewhere (e.g. as an attribute) if you need to.

`BaseProtocol.connection_lost(exc)`

链接丢失或关闭时被调用。

The argument is either an exception object or *None*. The latter means a regular EOF is received, or the connection was aborted or closed by this side of the connection.

`connection_made()` and `connection_lost()` are called exactly once per successful connection. All other callbacks will be called between those two methods, which allows for easier resource management in your protocol implementation.

The following callbacks may be called only on *SubprocessProtocol* instances:

`SubprocessProtocol.pipe_data_received(fd, data)`

Called when the child process writes data into its stdout or stderr pipe. *fd* is the integer file descriptor of the pipe. *data* is a non-empty bytes object containing the data.

`SubprocessProtocol.pipe_connection_lost(fd, exc)`

Called when one of the pipes communicating with the child process is closed. *fd* is the integer file descriptor that was closed.

`SubprocessProtocol.process_exited()`

子进程退出时被调用。

Streaming protocols

The following callbacks are called on *Protocol* instances:

`Protocol.data_received(data)`

Called when some data is received. *data* is a non-empty bytes object containing the incoming data.

注解: Whether the data is buffered, chunked or reassembled depends on the transport. In general, you shouldn't rely on specific semantics and instead make your parsing generic and flexible enough. However, data is always received in the correct order.

`Protocol.eof_received()`

Called when the other end signals it won't send any more data (for example by calling `write_eof()`, if the other end also uses `asyncio`).

This method may return a false value (including *None*), in which case the transport will close itself. Conversely, if this method returns a true value, closing the transport is up to the protocol. Since the default implementation returns *None*, it implicitly closes the connection.

注解: Some transports such as SSL don't support half-closed connections, in which case returning true from this method will not prevent closing the connection.

`data_received()` can be called an arbitrary number of times during a connection. However, `eof_received()` is called at most once and, if called, `data_received()` won't be called after it.

State machine:

```
start -> connection_made() [-> data_received() *] [-> eof_received() ?] ->
connection_lost() -> end
```

Datagram protocols

The following callbacks are called on *DatagramProtocol* instances.

DatagramProtocol.**datagram_received**(*data*, *addr*)

Called when a datagram is received. *data* is a bytes object containing the incoming data. *addr* is the address of the peer sending the data; the exact format depends on the transport.

DatagramProtocol.**error_received**(*exc*)

Called when a previous send or receive operation raises an *OSError*. *exc* is the *OSError* instance.

This method is called in rare conditions, when the transport (e.g. UDP) detects that a datagram couldn't be delivered to its recipient. In many conditions though, undeliverable datagrams will be silently dropped.

Flow control callbacks

These callbacks may be called on *Protocol*, *DatagramProtocol* and *SubprocessProtocol* instances:

BaseProtocol.**pause_writing**()

Called when the transport's buffer goes over the high-water mark.

BaseProtocol.**resume_writing**()

Called when the transport's buffer drains below the low-water mark.

pause_writing() and *resume_writing()* calls are paired – *pause_writing()* is called once when the buffer goes strictly over the high-water mark (even if subsequent writes increases the buffer size even more), and eventually *resume_writing()* is called once when the buffer size reaches the low-water mark.

注解: If the buffer size equals the high-water mark, *pause_writing()* is not called – it must go strictly over. Conversely, *resume_writing()* is called when the buffer size is equal or lower than the low-water mark. These end conditions are important to ensure that things go as expected when either mark is zero.

注解: On BSD systems (OS X, FreeBSD, etc.) flow control is not supported for *DatagramProtocol*, because send failures caused by writing too many packets cannot be detected easily. The socket always appears 'ready' and excess packets are dropped; an *OSError* with *errno* set to *errno.ENOBUFS* may or may not be raised; if it is raised, it will be reported to *DatagramProtocol.error_received()* but otherwise ignored.

Coroutines and protocols

Coroutines can be scheduled in a protocol method using *ensure_future()*, but there is no guarantee made about the execution order. Protocols are not aware of coroutines created in protocol methods and so will not wait for them.

To have a reliable execution order, use *stream objects* in a coroutine with *yield from*. For example, the *StreamWriter.drain()* coroutine can be used to wait until the write buffer is flushed.

Protocol examples

TCP echo client protocol

TCP echo client using the `AbstractEventLoop.create_connection()` method, send data and wait until the connection is closed:

```
import asyncio

class EchoClientProtocol(asyncio.Protocol):
    def __init__(self, message, loop):
        self.message = message
        self.loop = loop

    def connection_made(self, transport):
        transport.write(self.message.encode())
        print('Data sent: {!r}'.format(self.message))

    def data_received(self, data):
        print('Data received: {!r}'.format(data.decode()))

    def connection_lost(self, exc):
        print('The server closed the connection')
        print('Stop the event loop')
        self.loop.stop()

loop = asyncio.get_event_loop()
message = 'Hello World!'
coro = loop.create_connection(lambda: EchoClientProtocol(message, loop),
                              '127.0.0.1', 8888)
loop.run_until_complete(coro)
loop.run_forever()
loop.close()
```

The event loop is running twice. The `run_until_complete()` method is preferred in this short example to raise an exception if the server is not listening, instead of having to write a short coroutine to handle the exception and stop the running loop. At `run_until_complete()` exit, the loop is no longer running, so there is no need to stop the loop in case of an error.

参见:

The *TCP echo client using streams* example uses the `asyncio.open_connection()` function.

TCP echo server protocol

TCP echo server using the `AbstractEventLoop.create_server()` method, send back received data and close the connection:

```
import asyncio

class EchoServerClientProtocol(asyncio.Protocol):
    def connection_made(self, transport):
        peername = transport.get_extra_info('peername')
        print('Connection from {}'.format(peername))
        self.transport = transport
```

(下页继续)

(续上页)

```

def data_received(self, data):
    message = data.decode()
    print('Data received: {!r}'.format(message))

    print('Send: {!r}'.format(message))
    self.transport.write(data)

    print('Close the client socket')
    self.transport.close()

loop = asyncio.get_event_loop()
# Each client connection will create a new protocol instance
coro = loop.create_server(EchoServerClientProtocol, '127.0.0.1', 8888)
server = loop.run_until_complete(coro)

# Serve requests until Ctrl+C is pressed
print('Serving on {}'.format(server.sockets[0].getsockname()))
try:
    loop.run_forever()
except KeyboardInterrupt:
    pass

# Close the server
server.close()
loop.run_until_complete(server.wait_closed())
loop.close()

```

`Transport.close()` can be called immediately after `WriteTransport.write()` even if data are not sent yet on the socket: both methods are asynchronous. `yield from` is not needed because these transport methods are not coroutines.

参见:

The *TCP echo server using streams* example uses the `asyncio.start_server()` function.

UDP echo client protocol

UDP echo client using the `AbstractEventLoop.create_datagram_endpoint()` method, send data and close the transport when we received the answer:

```

import asyncio

class EchoClientProtocol:
    def __init__(self, message, loop):
        self.message = message
        self.loop = loop
        self.transport = None

    def connection_made(self, transport):
        self.transport = transport
        print('Send:', self.message)
        self.transport.sendto(self.message.encode())

    def datagram_received(self, data, addr):
        print("Received:", data.decode())

```

(下页继续)

(续上页)

```

        print("Close the socket")
        self.transport.close()

    def error_received(self, exc):
        print('Error received:', exc)

    def connection_lost(self, exc):
        print("Socket closed, stop the event loop")
        loop = asyncio.get_event_loop()
        loop.stop()

loop = asyncio.get_event_loop()
message = "Hello World!"
connect = loop.create_datagram_endpoint(
    lambda: EchoClientProtocol(message, loop),
    remote_addr=('127.0.0.1', 9999))
transport, protocol = loop.run_until_complete(connect)
loop.run_forever()
transport.close()
loop.close()

```

UDP echo server protocol

UDP echo server using the `AbstractEventLoop.create_datagram_endpoint()` method, send back received data:

```

import asyncio

class EchoServerProtocol:
    def connection_made(self, transport):
        self.transport = transport

    def datagram_received(self, data, addr):
        message = data.decode()
        print('Received %r from %s' % (message, addr))
        print('Send %r to %s' % (message, addr))
        self.transport.sendto(data, addr)

loop = asyncio.get_event_loop()
print("Starting UDP server")
# One protocol instance will be created to serve all client requests
listen = loop.create_datagram_endpoint(
    EchoServerProtocol, local_addr=('127.0.0.1', 9999))
transport, protocol = loop.run_until_complete(listen)

try:
    loop.run_forever()
except KeyboardInterrupt:
    pass

transport.close()
loop.close()

```

Register an open socket to wait for data using a protocol

Wait until a socket receives data using the `AbstractEventLoop.create_connection()` method with a protocol, and then close the event loop

```
import asyncio
try:
    from socket import socketpair
except ImportError:
    from asyncio.windows_utils import socketpair

# Create a pair of connected sockets
rsock, wsock = socketpair()
loop = asyncio.get_event_loop()

class MyProtocol(asyncio.Protocol):
    transport = None

    def connection_made(self, transport):
        self.transport = transport

    def data_received(self, data):
        print("Received:", data.decode())

        # We are done: close the transport (it will call connection_lost())
        self.transport.close()

    def connection_lost(self, exc):
        # The socket has been closed, stop the event loop
        loop.stop()

# Register the socket to wait for data
connect_coro = loop.create_connection(MyProtocol, sock=rsock)
transport, protocol = loop.run_until_complete(connect_coro)

# Simulate the reception of data from the network
loop.call_soon(wsock.send, 'abc'.encode())

# Run the event loop
loop.run_forever()

# We are done, close sockets and the event loop
rsock.close()
wsock.close()
loop.close()
```

参见:

The *watch a file descriptor for read events* example uses the low-level `AbstractEventLoop.add_reader()` method to register the file descriptor of a socket.

The *register an open socket to wait for data using streams* example uses high-level streams created by the `open_connection()` function in a coroutine.

18.5.5 Streams (coroutine based API)

Source code: `Lib/asyncio/streams.py`

Stream functions

注解: The top-level functions in this module are meant as convenience wrappers only; there's really nothing special there, and if they don't do exactly what you want, feel free to copy their code.

coroutine `asyncio.open_connection` (*host=None, port=None, *, loop=None, limit=None, **kws*)

A wrapper for `create_connection()` returning a (reader, writer) pair.

The reader returned is a `StreamReader` instance; the writer is a `StreamWriter` instance.

The arguments are all the usual arguments to `AbstractEventLoop.create_connection()` except `protocol_factory`; most common are positional `host` and `port`, with various optional keyword arguments following.

Additional optional keyword arguments are `loop` (to set the event loop instance to use) and `limit` (to set the buffer limit passed to the `StreamReader`).

This function is a *coroutine*.

coroutine `asyncio.start_server` (*client_connected_cb, host=None, port=None, *, loop=None, limit=None, **kws*)

Start a socket server, with a callback for each client connected. The return value is the same as `create_server()`.

The `client_connected_cb` parameter is called with two parameters: `client_reader`, `client_writer`. `client_reader` is a `StreamReader` object, while `client_writer` is a `StreamWriter` object. The `client_connected_cb` parameter can either be a plain callback function or a *coroutine function*; if it is a coroutine function, it will be automatically converted into a *Task*.

The rest of the arguments are all the usual arguments to `create_server()` except `protocol_factory`; most common are positional `host` and `port`, with various optional keyword arguments following.

Additional optional keyword arguments are `loop` (to set the event loop instance to use) and `limit` (to set the buffer limit passed to the `StreamReader`).

This function is a *coroutine*.

coroutine `asyncio.open_unix_connection` (*path=None, *, loop=None, limit=None, **kws*)

A wrapper for `create_unix_connection()` returning a (reader, writer) pair.

See `open_connection()` for information about return value and other details.

This function is a *coroutine*.

Availability: UNIX.

coroutine `asyncio.start_unix_server` (*client_connected_cb, path=None, *, loop=None, limit=None, **kws*)

Start a UNIX Domain Socket server, with a callback for each client connected.

See `start_server()` for information about return value and other details.

This function is a *coroutine*.

Availability: UNIX.

StreamReader

class `asyncio.StreamReader` (*limit=_DEFAULT_LIMIT, loop=None*)

This class is *not thread safe*.

The `limit` argument's default value is set to `_DEFAULT_LIMIT` which is `2**16` (64 KiB)

exception()

Get the exception.

feed_eof()

Acknowledge the EOF.

feed_data(data)

Feed *data* bytes in the internal buffer. Any operations waiting for the data will be resumed.

set_exception(exc)

Set the exception.

set_transport(transport)

Set the transport.

coroutine read(n=-1)

Read up to *n* bytes. If *n* is not provided, or set to `-1`, read until EOF and return all read bytes.

If the EOF was received and the internal buffer is empty, return an empty `bytes` object.

This method is a *coroutine*.

coroutine readline()

Read one line, where “line” is a sequence of bytes ending with `\n`.

If EOF is received, and `\n` was not found, the method will return the partial read bytes.

If the EOF was received and the internal buffer is empty, return an empty `bytes` object.

This method is a *coroutine*.

coroutine readexactly(n)

Read exactly *n* bytes. Raise an *IncompleteReadError* if the end of the stream is reached before *n* can be read, the *IncompleteReadError.partial* attribute of the exception contains the partial read bytes.

This method is a *coroutine*.

coroutine readuntil(separator=b'\n')

Read data from the stream until *separator* is found.

On success, the data and separator will be removed from the internal buffer (consumed). Returned data will include the separator at the end.

Configured stream limit is used to check result. Limit sets the maximal length of data that can be returned, not counting the separator.

If an EOF occurs and the complete separator is still not found, an *IncompleteReadError* exception will be raised, and the internal buffer will be reset. The *IncompleteReadError.partial* attribute may contain the separator partially.

If the data cannot be read because of over limit, a *LimitOverrunError* exception will be raised, and the data will be left in the internal buffer, so it can be read again.

3.5.2 新版功能.

at_eof()

Return `True` if the buffer is empty and *feed_eof()* was called.

StreamWriter

class `asyncio.StreamWriter(transport, protocol, reader, loop)`

Wraps a Transport.

This exposes `write()`, `writelines()`, `can_write_eof()`, `write_eof()`, `get_extra_info()` and `close()`. It adds `drain()` which returns an optional *Future* on which you can wait for flow control. It also adds a transport attribute which references the Transport directly.

This class is *not thread safe*.

transport

Transport.

can_write_eof()

Return *True* if the transport supports `write_eof()`, *False* if not. See *WriteTransport.can_write_eof()*.

close()

Close the transport: see *BaseTransport.close()*.

coroutine drain()

Let the write buffer of the underlying transport a chance to be flushed.

The intended use is to write:

```
w.write(data)
yield from w.drain()
```

When the size of the transport buffer reaches the high-water limit (the protocol is paused), block until the size of the buffer is drained down to the low-water limit and the protocol is resumed. When there is nothing to wait for, the yield-from continues immediately.

Yielding from `drain()` gives the opportunity for the loop to schedule the write operation and flush the buffer. It should especially be used when a possibly large amount of data is written to the transport, and the coroutine does not yield-from between calls to `write()`.

This method is a *coroutine*.

get_extra_info(name, default=None)

Return optional transport information: see *BaseTransport.get_extra_info()*.

write(data)

Write some *data* bytes to the transport: see *WriteTransport.write()*.

writelines(data)

Write a list (or any iterable) of data bytes to the transport: see *WriteTransport.writelines()*.

write_eof()

Close the write end of the transport after flushing buffered data: see *WriteTransport.write_eof()*.

StreamReaderProtocol

class `asyncio.StreamReaderProtocol` (*stream_reader*, *client_connected_cb=None*, *loop=None*)

Trivial helper class to adapt between *Protocol* and *StreamReader*. Subclass of *Protocol*.

stream_reader is a *StreamReader* instance, *client_connected_cb* is an optional function called with (stream_reader, stream_writer) when a connection is made, *loop* is the event loop instance to use.

(This is a helper class instead of making *StreamReader* itself a *Protocol* subclass, because the *StreamReader* has other potential uses, and to prevent the user of the *StreamReader* from accidentally calling inappropriate methods of the protocol.)

IncompleteReadError

exception `asyncio.IncompleteReadError`

Incomplete read error, subclass of `EOFError`.

expected

Total number of expected bytes (*int*).

partial

Read bytes string before the end of stream was reached (*bytes*).

LimitOverrunError

exception `asyncio.LimitOverrunError`

Reached the buffer limit while looking for a separator.

consumed

Total number of to be consumed bytes.

Stream examples

TCP echo client using streams

TCP echo client using the `asyncio.open_connection()` function:

```
import asyncio

@asyncio.coroutine
def tcp_echo_client(message, loop):
    reader, writer = yield from asyncio.open_connection('127.0.0.1', 8888,
                                                         loop=loop)

    print('Send: %r' % message)
    writer.write(message.encode())

    data = yield from reader.read(100)
    print('Received: %r' % data.decode())

    print('Close the socket')
    writer.close()

message = 'Hello World!'
loop = asyncio.get_event_loop()
loop.run_until_complete(tcp_echo_client(message, loop))
loop.close()
```

参见:

The *TCP echo client protocol* example uses the `AbstractEventLoop.create_connection()` method.

TCP echo server using streams

TCP echo server using the `asyncio.start_server()` function:

```

import asyncio

@asyncio.coroutine
def handle_echo(reader, writer):
    data = yield from reader.read(100)
    message = data.decode()
    addr = writer.get_extra_info('peername')
    print("Received %r from %r" % (message, addr))

    print("Send: %r" % message)
    writer.write(data)
    yield from writer.drain()

    print("Close the client socket")
    writer.close()

loop = asyncio.get_event_loop()
coro = asyncio.start_server(handle_echo, '127.0.0.1', 8888, loop=loop)
server = loop.run_until_complete(coro)

# Serve requests until Ctrl+C is pressed
print('Serving on {}'.format(server.sockets[0].getsockname()))
try:
    loop.run_forever()
except KeyboardInterrupt:
    pass

# Close the server
server.close()
loop.run_until_complete(server.wait_closed())
loop.close()

```

参见:

The *TCP echo server protocol* example uses the `AbstractEventLoop.create_server()` method.

Get HTTP headers

Simple example querying HTTP headers of the URL passed on the command line:

```

import asyncio
import urllib.parse
import sys

@asyncio.coroutine
def print_http_headers(url):
    url = urllib.parse.urlsplit(url)
    if url.scheme == 'https':
        connect = asyncio.open_connection(url.hostname, 443, ssl=True)
    else:
        connect = asyncio.open_connection(url.hostname, 80)
    reader, writer = yield from connect
    query = ('HEAD {path} HTTP/1.0\r\n'
            'Host: {hostname}\r\n'
            '\r\n').format(path=url.path or '/', hostname=url.hostname)
    writer.write(query.encode('latin-1'))

```

(下页继续)

(续上页)

```

while True:
    line = yield from reader.readline()
    if not line:
        break
    line = line.decode('latin1').rstrip()
    if line:
        print('HTTP header> %s' % line)

# Ignore the body, close the socket
writer.close()

url = sys.argv[1]
loop = asyncio.get_event_loop()
task = asyncio.ensure_future(print_http_headers(url))
loop.run_until_complete(task)
loop.close()

```

用法:

```
python example.py http://example.com/path/page.html
```

or with HTTPS:

```
python example.py https://example.com/path/page.html
```

Register an open socket to wait for data using streams

Coroutine waiting until a socket receives data using the `open_connection()` function:

```

import asyncio
try:
    from socket import socketpair
except ImportError:
    from asyncio.windows_utils import socketpair

@asyncio.coroutine
def wait_for_data(loop):
    # Create a pair of connected sockets
    rsock, wsock = socketpair()

    # Register the open socket to wait for data
    reader, writer = yield from asyncio.open_connection(sock=rsock, loop=loop)

    # Simulate the reception of data from the network
    loop.call_soon(wsock.send, 'abc'.encode())

    # Wait for data
    data = yield from reader.read(100)

    # Got data, we are done: close the socket
    print("Received:", data.decode())
    writer.close()

    # Close the second socket
    wsock.close()

```

(下页继续)

(续上页)

```

loop = asyncio.get_event_loop()
loop.run_until_complete(wait_for_data(loop))
loop.close()

```

参见:

The *register an open socket to wait for data using a protocol* example uses a low-level protocol created by the `AbstractEventLoop.create_connection()` method.

The *watch a file descriptor for read events* example uses the low-level `AbstractEventLoop.add_reader()` method to register the file descriptor of a socket.

18.5.6 Subprocess

Source code: `Lib/asyncio/subprocess.py`

Windows event loop

On Windows, the default event loop is `SelectorEventLoop` which does not support subprocesses. `ProactorEventLoop` should be used instead. Example to use it on Windows:

```

import asyncio, sys

if sys.platform == 'win32':
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)

```

参见:

Available event loops and *Platform support*.

Create a subprocess: high-level API using Process

coroutine `asyncio.create_subprocess_exec(*args, stdin=None, stdout=None, stderr=None, loop=None, limit=None, **kwds)`

创建一个子进程。

The *limit* parameter sets the buffer limit passed to the `StreamReader`. See `AbstractEventLoop.subprocess_exec()` for other parameters.

Return a `Process` instance.

This function is a *coroutine*.

coroutine `asyncio.create_subprocess_shell(cmd, stdin=None, stdout=None, stderr=None, loop=None, limit=None, **kwds)`

Run the shell command *cmd*.

The *limit* parameter sets the buffer limit passed to the `StreamReader`. See `AbstractEventLoop.subprocess_shell()` for other parameters.

Return a `Process` instance.

It is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid *shell injection* vulnerabilities. The `shlex.quote()` function can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

This function is a *coroutine*.

Use the `AbstractEventLoop.connect_read_pipe()` and `AbstractEventLoop.connect_write_pipe()` methods to connect pipes.

Create a subprocess: low-level API using `subprocess.Popen`

Run subprocesses asynchronously using the `subprocess` module.

```
coroutine AbstractEventLoop.subprocess_exec(protocol_factory,          *args,
                                             stdin=subprocess.PIPE,      std-
                                             out=subprocess.PIPE, stderr=subprocess.PIPE,
                                             **kwargs)
```

Create a subprocess from one or more string arguments (character strings or bytes strings encoded to the *filesystem encoding*), where the first string specifies the program to execute, and the remaining strings specify the program's arguments. (Thus, together the string arguments form the `sys.argv` value of the program, assuming it is a Python script.) This is similar to the standard library `subprocess.Popen` class called with `shell=False` and the list of strings passed as the first argument; however, where `Popen` takes a single argument which is list of strings, `subprocess_exec()` takes multiple string arguments.

The `protocol_factory` must instantiate a subclass of the `asyncio.SubprocessProtocol` class.

Other parameters:

- `stdin`: Either a file-like object representing the pipe to be connected to the subprocess's standard input stream using `connect_write_pipe()`, or the constant `subprocess.PIPE` (the default). By default a new pipe will be created and connected.
- `stdout`: Either a file-like object representing the pipe to be connected to the subprocess's standard output stream using `connect_read_pipe()`, or the constant `subprocess.PIPE` (the default). By default a new pipe will be created and connected.
- `stderr`: Either a file-like object representing the pipe to be connected to the subprocess's standard error stream using `connect_read_pipe()`, or one of the constants `subprocess.PIPE` (the default) or `subprocess.STDOUT`. By default a new pipe will be created and connected. When `subprocess.STDOUT` is specified, the subprocess's standard error stream will be connected to the same pipe as the standard output stream.
- All other keyword arguments are passed to `subprocess.Popen` without interpretation, except for `bufsize`, `universal_newlines` and `shell`, which should not be specified at all.

Returns a pair of (transport, protocol), where `transport` is an instance of `BaseSubprocessTransport`.

This method is a *coroutine*.

See the constructor of the `subprocess.Popen` class for parameters.

```
coroutine AbstractEventLoop.subprocess_shell(protocol_factory,      cmd,
                                             *,                      stdin=subprocess.PIPE,
                                             stdout=subprocess.PIPE,
                                             stderr=subprocess.PIPE, **kwargs)
```

Create a subprocess from `cmd`, which is a character string or a bytes string encoded to the *filesystem encoding*, using the platform's "shell" syntax. This is similar to the standard library `subprocess.Popen` class called with `shell=True`.

The `protocol_factory` must instantiate a subclass of the `asyncio.SubprocessProtocol` class.

See `subprocess_exec()` for more details about the remaining arguments.

Returns a pair of `(transport, protocol)`, where *transport* is an instance of `BaseSubprocessTransport`.

It is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid [shell injection](#) vulnerabilities. The `shlex.quote()` function can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

This method is a *coroutine*.

参见:

The `AbstractEventLoop.connect_read_pipe()` and `AbstractEventLoop.connect_write_pipe()` methods.

常数

`asyncio.subprocess.PIPE`

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to `create_subprocess_shell()` and `create_subprocess_exec()` and indicates that a pipe to the standard stream should be opened.

`asyncio.subprocess.STDOUT`

Special value that can be used as the *stderr* argument to `create_subprocess_shell()` and `create_subprocess_exec()` and indicates that standard error should go into the same handle as standard output.

`asyncio.subprocess.DEVNULL`

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to `create_subprocess_shell()` and `create_subprocess_exec()` and indicates that the special file `os.devnull` will be used.

Process

class `asyncio.subprocess.Process`

A subprocess created by the `create_subprocess_exec()` or the `create_subprocess_shell()` function.

The API of the `Process` class was designed to be close to the API of the `subprocess.Popen` class, but there are some differences:

- There is no explicit `poll()` method
- The `communicate()` and `wait()` methods don't take a *timeout* parameter: use the `wait_for()` function
- The *universal_newlines* parameter is not supported (only bytes strings are supported)
- The `wait()` method of the `Process` class is asynchronous whereas the `wait()` method of the `Popen` class is implemented as a busy loop.

This class is *not thread safe*. See also the *Subprocess and threads* section.

coroutine `wait()`

Wait for child process to terminate. Set and return *returncode* attribute.

This method is a *coroutine*.

注解: This will deadlock when using `stdout=PIPE` or `stderr=PIPE` and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use the `communicate()` method when using pipes to avoid that.

coroutine communicate (*input=None*)

Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate. The optional *input* argument should be data to be sent to the child process, or `None`, if no data should be sent to the child. The type of *input* must be bytes.

communicate() returns a tuple (`stdout_data`, `stderr_data`).

If a `BrokenPipeError` or `ConnectionResetError` exception is raised when writing *input* into stdin, the exception is ignored. It occurs when the process exits before all data are written into stdin.

Note that if you want to send data to the process's stdin, you need to create the `Process` object with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, you need to give `stdout=PIPE` and/or `stderr=PIPE` too.

This method is a *coroutine*.

注解: The data read is buffered in memory, so do not use this method if the data size is large or unlimited.

在 3.4.2 版更改: The method now ignores `BrokenPipeError` and `ConnectionResetError`.

send_signal (*signal*)

Sends the signal *signal* to the child process.

注解: On Windows, `SIGTERM` is an alias for `terminate()`. `CTRL_C_EVENT` and `CTRL_BREAK_EVENT` can be sent to processes started with a *creationflags* parameter which includes `CREATE_NEW_PROCESS_GROUP`.

terminate ()

Stop the child. On Posix OSs the method sends `signal.SIGTERM` to the child. On Windows the `Win32 API` function `TerminateProcess()` is called to stop the child.

kill ()

Kills the child. On Posix OSs the function sends `SIGKILL` to the child. On Windows *kill()* is an alias for *terminate()*.

stdin

Standard input stream (*StreamWriter*), `None` if the process was created with `stdin=None`.

stdout

Standard output stream (*StreamReader*), `None` if the process was created with `stdout=None`.

stderr

Standard error stream (*StreamReader*), `None` if the process was created with `stderr=None`.

警告: Use the *communicate()* method rather than *.stdin.write*, *.stdout.read* or *.stderr.read* to avoid deadlocks due to streams pausing reading or writing and blocking the child process.

pid

The identifier of the process.

Note that for processes created by the *create_subprocess_shell()* function, this attribute is the process identifier of the spawned shell.

returncode

Return code of the process when it exited. A `None` value indicates that the process has not terminated yet.

A negative value `-N` indicates that the child was terminated by signal `N` (Unix only).

Subprocess and threads

`asyncio` supports running subprocesses from different threads, but there are limits:

- An event loop must run in the main thread
- The child watcher must be instantiated in the main thread, before executing subprocesses from other threads. Call the `get_child_watcher()` function in the main thread to instantiate the child watcher.

The `asyncio.subprocess.Process` class is not thread safe.

参见:

The *Concurrency and multithreading in asyncio* section.

Subprocess examples

Subprocess using transport and protocol

Example of a subprocess protocol using to get the output of a subprocess and to wait for the subprocess exit. The subprocess is created by the `AbstractEventLoop.subprocess_exec()` method:

```
import asyncio
import sys

class DateProtocol(asyncio.SubprocessProtocol):
    def __init__(self, exit_future):
        self.exit_future = exit_future
        self.output = bytearray()

    def pipe_data_received(self, fd, data):
        self.output.extend(data)

    def process_exited(self):
        self.exit_future.set_result(True)

@asyncio.coroutine
def get_date(loop):
    code = 'import datetime; print(datetime.datetime.now())'
    exit_future = asyncio.Future(loop=loop)

    # Create the subprocess controlled by the protocol DateProtocol,
    # redirect the standard output into a pipe
    create = loop.subprocess_exec(lambda: DateProtocol(exit_future),
                                  sys.executable, '-c', code,
                                  stdin=None, stderr=None)

    transport, protocol = yield from create

    # Wait for the subprocess exit using the process_exited() method
    # of the protocol
    yield from exit_future

    # Close the stdout pipe
    transport.close()
```

(下页继续)

(续上页)

```

    # Read the output which was collected by the pipe_data_received()
    # method of the protocol
    data = bytes(protocol.output)
    return data.decode('ascii').rstrip()

if sys.platform == "win32":
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
else:
    loop = asyncio.get_event_loop()

date = loop.run_until_complete(get_date(loop))
print("Current date: %s" % date)
loop.close()

```

Subprocess using streams

Example using the *Process* class to control the subprocess and the *StreamReader* class to read from the standard output. The subprocess is created by the *create_subprocess_exec()* function:

```

import asyncio.subprocess
import sys

@asyncio.coroutine
def get_date():
    code = 'import datetime; print(datetime.datetime.now())'

    # Create the subprocess, redirect the standard output into a pipe
    create = asyncio.create_subprocess_exec(sys.executable, '-c', code,
                                             stdout=asyncio.subprocess.PIPE)

    proc = yield from create

    # Read one line of output
    data = yield from proc.stdout.readline()
    line = data.decode('ascii').rstrip()

    # Wait for the subprocess exit
    yield from proc.wait()
    return line

if sys.platform == "win32":
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
else:
    loop = asyncio.get_event_loop()

date = loop.run_until_complete(get_date())
print("Current date: %s" % date)
loop.close()

```

18.5.7 Synchronization primitives

Source code: [Lib/asyncio/locks.py](#)

Locks:

- `Lock`
- `Event`
- `Condition`

Semaphores:

- `Semaphore`
- `BoundedSemaphore`

asyncio lock API was designed to be close to classes of the `threading` module (`Lock`, `Event`, `Condition`, `Semaphore`, `BoundedSemaphore`), but it has no `timeout` parameter. The `asyncio.wait_for()` function can be used to cancel a task after a timeout.

Locks

Lock

class `asyncio.Lock` (*, `loop=None`)

Primitive lock objects.

A primitive lock is a synchronization primitive that is not owned by a particular coroutine when locked. A primitive lock is in one of two states, ‘locked’ or ‘unlocked’.

It is created in the unlocked state. It has two basic methods, `acquire()` and `release()`. When the state is unlocked, `acquire()` changes the state to locked and returns immediately. When the state is locked, `acquire()` blocks until a call to `release()` in another coroutine changes it to unlocked, then the `acquire()` call resets it to locked and returns. The `release()` method should only be called in the locked state; it changes the state to unlocked and returns immediately. If an attempt is made to release an unlocked lock, a `RuntimeError` will be raised.

When more than one coroutine is blocked in `acquire()` waiting for the state to turn to unlocked, only one coroutine proceeds when a `release()` call resets the state to unlocked; first coroutine which is blocked in `acquire()` is being processed.

`acquire()` is a coroutine and should be called with `yield from`.

Locks also support the context management protocol. `(yield from lock)` should be used as the context manager expression.

This class is *not thread safe*.

Usage:

```
lock = Lock()
...
yield from lock
try:
    ...
finally:
    lock.release()
```

Context manager usage:

```
lock = Lock()
...
with (yield from lock):
    ...
```

Lock objects can be tested for locking state:

```
if not lock.locked():
    yield from lock
else:
    # lock is acquired
    ...
```

locked()

Return True if the lock is acquired.

coroutine acquire()

Acquire a lock.

This method blocks until the lock is unlocked, then sets it to locked and returns True.

This method is a *coroutine*.

release()

Release a lock.

When the lock is locked, reset it to unlocked, and return. If any other coroutines are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

在未锁定的锁调用时，会引发`RuntimeError`异常。

There is no return value.

Event

class `asyncio.Event` (*, loop=None)

An Event implementation, asynchronous equivalent to `threading.Event`.

Class implementing event objects. An event manages a flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true. The flag is initially false.

This class is *not thread safe*.

clear()

Reset the internal flag to false. Subsequently, coroutines calling `wait()` will block until `set()` is called to set the internal flag to true again.

is_set()

Return True if and only if the internal flag is true.

set()

Set the internal flag to true. All coroutines waiting for it to become true are awakened. Coroutine that call `wait()` once the flag is true will not block at all.

coroutine wait()

Block until the internal flag is true.

If the internal flag is true on entry, return True immediately. Otherwise, block until another coroutine calls `set()` to set the flag to true, then return True.

This method is a *coroutine*.

Condition

class `asyncio.Condition` (*lock=None*, *, *loop=None*)

A Condition implementation, asynchronous equivalent to `threading.Condition`.

This class implements condition variable objects. A condition variable allows one or more coroutines to wait until they are notified by another coroutine.

If the *lock* argument is given and not `None`, it must be a `Lock` object, and it is used as the underlying lock. Otherwise, a new `Lock` object is created and used as the underlying lock.

This class is *not thread safe*.

coroutine `acquire()`

Acquire the underlying lock.

This method blocks until the lock is unlocked, then sets it to locked and returns `True`.

This method is a *coroutine*.

notify (*n=1*)

By default, wake up one coroutine waiting on this condition, if any. If the calling coroutine has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method wakes up at most *n* of the coroutines waiting for the condition variable; it is a no-op if no coroutines are waiting.

注解: An awakened coroutine does not actually return from its `wait()` call until it can reacquire the lock. Since `notify()` does not release the lock, its caller should.

locked()

Return `True` if the underlying lock is acquired.

notify_all()

Wake up all coroutines waiting on this condition. This method acts like `notify()`, but wakes up all waiting coroutines instead of one. If the calling coroutine has not acquired the lock when this method is called, a `RuntimeError` is raised.

release()

Release the underlying lock.

When the lock is locked, reset it to unlocked, and return. If any other coroutines are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

在未锁定的锁调用时，会引发`RuntimeError`异常。

There is no return value.

coroutine `wait()`

Wait until notified.

If the calling coroutine has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method releases the underlying lock, and then blocks until it is awakened by a `notify()` or `notify_all()` call for the same condition variable in another coroutine. Once awakened, it re-acquires the lock and returns `True`.

This method is a *coroutine*.

coroutine `wait_for(predicate)`

Wait until a predicate becomes true.

The predicate should be a callable which result will be interpreted as a boolean value. The final predicate value is the return value.

This method is a *coroutine*.

Semaphores

Semaphore

class `asyncio.Semaphore` (*value=1, *, loop=None*)

A Semaphore implementation.

A semaphore manages an internal counter which is decremented by each `acquire()` call and incremented by each `release()` call. The counter can never go below zero; when `acquire()` finds that it is zero, it blocks, waiting until some other coroutine calls `release()`.

Semaphores also support the context management protocol.

The optional argument gives the initial value for the internal counter; it defaults to 1. If the value given is less than 0, `ValueError` is raised.

This class is *not thread safe*.

coroutine `acquire()`

获取一个信号量。

If the internal counter is larger than zero on entry, decrement it by one and return `True` immediately. If it is zero on entry, block, waiting until some other coroutine has called `release()` to make it larger than 0, and then return `True`.

This method is a *coroutine*.

locked()

Returns `True` if semaphore can not be acquired immediately.

release()

Release a semaphore, incrementing the internal counter by one. When it was zero on entry and another coroutine is waiting for it to become larger than zero again, wake up that coroutine.

BoundedSemaphore

class `asyncio.BoundedSemaphore` (*value=1, *, loop=None*)

A bounded semaphore implementation. Inherit from `Semaphore`.

This raises `ValueError` in `release()` if it would increase the value above the initial value.

18.5.8 队列集

Source code: `Lib/asyncio/queues.py`

Queues:

- `Queue`
- `PriorityQueue`
- `LifoQueue`

asyncio queue API was designed to be close to classes of the `queue` module (`Queue`, `PriorityQueue`, `LifoQueue`), but it has no `timeout` parameter. The `asyncio.wait_for()` function can be used to cancel a task after a timeout.

队列

class `asyncio.Queue` (*maxsize=0*, *, *loop=None*)

A queue, useful for coordinating producer and consumer coroutines.

If *maxsize* is less than or equal to zero, the queue size is infinite. If it is an integer greater than 0, then `yield` from `put()` will block when the queue reaches *maxsize*, until an item is removed by `get()`.

Unlike the standard library `queue`, you can reliably know this `Queue`'s size with `qsize()`, since your single-threaded asyncio application won't be interrupted between calling `qsize()` and doing an operation on the `Queue`.

这个类不是线程安全的。

在 3.4.4 版更改: New `join()` and `task_done()` methods.

empty()

如果队列为空返回 `True`，否则返回 `False`。

full()

如果有 *maxsize* 个条目在队列中，则返回 `True`。

注解: If the `Queue` was initialized with *maxsize*=0 (the default), then `full()` is never `True`.

coroutine `get()`

从队列中删除并返回一个元素。如果队列为空，则等待，直到队列中有元素。

This method is a *coroutine*.

参见:

The `empty()` method.

get_nowait()

Remove and return an item from the queue.

立即返回一个队列中的元素，如果队列内有值，否则引发异常 `QueueEmpty`。

coroutine `join()`

Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls `task_done()` to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, `join()` unblocks.

This method is a *coroutine*.

3.4.4 新版功能.

coroutine `put(item)`

Put an item into the queue. If the queue is full, wait until a free slot is available before adding item.

This method is a *coroutine*.

参见:

The `full()` method.

put_nowait (item)

不阻塞的放一个元素入队列。

如果没有立即可用的空闲槽，引发 `QueueFull` 异常。

qsize ()

Number of items in the queue.

task_done ()

表明前面排队的任务已经完成，即 `get` 出来的元素相关操作已经完成。

由队列使用者控制。每个 `get ()` 用于获取一个任务，任务最后调用 `task_done ()` 告诉队列，这个任务已经完成。

如果 `join ()` 当前正在阻塞，在所有条目都被处理后，将解除阻塞 (意味着每个 `put ()` 进队列的条目的 `task_done ()` 都被收到)。

如果被调用的次数多于放入队列中的项目数量，将引发 `ValueError`。

3.4.4 新版功能.

maxsize

队列中可存放的元素数量。

PriorityQueue

class `asyncio.PriorityQueue`

A subclass of `Queue`; retrieves entries in priority order (lowest first).

Entries are typically tuples of the form: (priority number, data).

LifoQueue

class `asyncio.LifoQueue`

A subclass of `Queue` that retrieves most recently added entries first.

异常

exception `asyncio.QueueEmpty`

Exception raised when the `get_nowait ()` method is called on a `Queue` object which is empty.

exception `asyncio.QueueFull`

Exception raised when the `put_nowait ()` method is called on a `Queue` object which is full.

18.5.9 Develop with asyncio

Asynchronous programming is different than classical “sequential” programming. This page lists common traps and explains how to avoid them.

Debug mode of asyncio

The implementation of `asyncio` has been written for performance. In order to ease the development of asynchronous code, you may wish to enable *debug mode*.

To enable all debug checks for an application:

- Enable the asyncio debug mode globally by setting the environment variable `PYTHONASYNCIODEBUG` to 1, or by calling `AbstractEventLoop.set_debug()`.
- Set the log level of the *asyncio logger* to `logging.DEBUG`. For example, call `logging.basicConfig(level=logging.DEBUG)` at startup.
- Configure the *warnings* module to display *ResourceWarning* warnings. For example, use the `-Wdefault` command line option of Python to display them.

Examples debug checks:

- Log *coroutines defined but never “yielded from”*
- `call_soon()` and `call_at()` methods raise an exception if they are called from the wrong thread.
- Log the execution time of the selector
- Log callbacks taking more than 100 ms to be executed. The `AbstractEventLoop.slow_callback_duration` attribute is the minimum duration in seconds of “slow” callbacks.
- *ResourceWarning* warnings are emitted when transports and event loops are *not closed explicitly*.

参见:

The `AbstractEventLoop.set_debug()` method and the *asyncio logger*.

Cancellation

Cancellation of tasks is not common in classic programming. In asynchronous programming, not only is it something common, but you have to prepare your code to handle it.

Futures and tasks can be cancelled explicitly with their `Future.cancel()` method. The `wait_for()` function cancels the waited task when the timeout occurs. There are many other cases where a task can be cancelled indirectly.

Don't call `set_result()` or `set_exception()` method of *Future* if the future is cancelled: it would fail with an exception. For example, write:

```
if not fut.cancelled():
    fut.set_result('done')
```

Don't schedule directly a call to the `set_result()` or the `set_exception()` method of a future with `AbstractEventLoop.call_soon()`: the future can be cancelled before its method is called.

If you wait for a future, you should check early if the future was cancelled to avoid useless operations. Example:

```
@coroutine
def slow_operation(fut):
    if fut.cancelled():
        return
    # ... slow computation ...
    yield from fut
    # ...
```

The `shield()` function can also be used to ignore cancellation.

Concurrency and multithreading

An event loop runs in a thread and executes all callbacks and tasks in the same thread. While a task is running in the event loop, no other task is running in the same thread. But when the task uses `yield from`, the task is suspended and the event loop executes the next task.

To schedule a callback from a different thread, the `AbstractEventLoop.call_soon_threadsafe()` method should be used. Example:

```
loop.call_soon_threadsafe(callback, *args)
```

Most `asyncio` objects are not thread safe. You should only worry if you access objects outside the event loop. For example, to cancel a future, don't call directly its `Future.cancel()` method, but:

```
loop.call_soon_threadsafe(fut.cancel)
```

为了能够处理信号和执行子进程，事件循环必须运行于主线程中。

To schedule a coroutine object from a different thread, the `run_coroutine_threadsafe()` function should be used. It returns a `concurrent.futures.Future` to access the result:

```
future = asyncio.run_coroutine_threadsafe(coro_func(), loop)
result = future.result(timeout) # Wait for the result with a timeout
```

The `AbstractEventLoop.run_in_executor()` method can be used with a thread pool executor to execute a callback in different thread to not block the thread of the event loop.

参见:

The *Synchronization primitives* section describes ways to synchronize tasks.

The *Subprocess and threads* section lists `asyncio` limitations to run subprocesses from different threads.

Handle blocking functions correctly

Blocking functions should not be called directly. For example, if a function blocks for 1 second, other tasks are delayed by 1 second which can have an important impact on reactivity.

For networking and subprocesses, the `asyncio` module provides high-level APIs like *protocols*.

An executor can be used to run a task in a different thread or even in a different process, to not block the thread of the event loop. See the `AbstractEventLoop.run_in_executor()` method.

参见:

The *Delayed calls* section details how the event loop handles time.

日志

The `asyncio` module logs information with the `logging` module in the logger `'asyncio'`.

The default log level for the `asyncio` module is `logging.INFO`. For those not wanting such verbosity from `asyncio` the log level can be changed. For example, to change the level to `logging.WARNING`:

```
logging.getLogger('asyncio').setLevel(logging.WARNING)
```

Detect coroutine objects never scheduled

When a coroutine function is called and its result is not passed to `ensure_future()` or to the `AbstractEventLoop.create_task()` method, the execution of the coroutine object will never be scheduled which is probably a bug. *Enable the debug mode of asyncio* to *log a warning* to detect it.

Example with the bug:

```
import asyncio

@asyncio.coroutine
def test():
    print("never scheduled")

test()
```

调试模式的输出:

```
Coroutine test() at test.py:3 was never yielded from
Coroutine object created at (most recent call last):
  File "test.py", line 7, in <module>
    test()
```

The fix is to call the `ensure_future()` function or the `AbstractEventLoop.create_task()` method with the coroutine object.

参见:

Pending task destroyed.

Detect exceptions never consumed

Python usually calls `sys.excepthook()` on unhandled exceptions. If `Future.set_exception()` is called, but the exception is never consumed, `sys.excepthook()` is not called. Instead, *a log is emitted* when the future is deleted by the garbage collector, with the traceback where the exception was raised.

Example of unhandled exception:

```
import asyncio

@asyncio.coroutine
def bug():
    raise Exception("not consumed")

loop = asyncio.get_event_loop()
asyncio.ensure_future(bug())
loop.run_forever()
loop.close()
```

输出:

```
Task exception was never retrieved
future: <Task finished coro=<coro() done, defined at asyncio/coroutines.py:139>_
↳exception=Exception('not consumed',)>
Traceback (most recent call last):
  File "asyncio/tasks.py", line 237, in _step
    result = next(coro)
  File "asyncio/coroutines.py", line 141, in coro
    res = func(*args, **kw)
  File "test.py", line 5, in bug
    raise Exception("not consumed")
Exception: not consumed
```

Enable the debug mode of asyncio to get the traceback where the task was created. Output in debug mode:

```

Task exception was never retrieved
future: <Task finished coro=<bug() done, defined at test.py:3> exception=Exception(
↪ 'not consumed',) created at test.py:8>
source_traceback: Object created at (most recent call last):
  File "test.py", line 8, in <module>
    asyncio.ensure_future(bug())
Traceback (most recent call last):
  File "asyncio/tasks.py", line 237, in _step
    result = next(coro)
  File "asyncio/coroutines.py", line 79, in __next__
    return next(self.gen)
  File "asyncio/coroutines.py", line 141, in coro
    res = func(*args, **kw)
  File "test.py", line 5, in bug
    raise Exception("not consumed")
Exception: not consumed

```

There are different options to fix this issue. The first option is to chain the coroutine in another coroutine and use classic try/except:

```

@asyncio.coroutine
def handle_exception():
    try:
        yield from bug()
    except Exception:
        print("exception consumed")

loop = asyncio.get_event_loop()
asyncio.ensure_future(handle_exception())
loop.run_forever()
loop.close()

```

Another option is to use the `AbstractEventLoop.run_until_complete()` function:

```

task = asyncio.ensure_future(bug())
try:
    loop.run_until_complete(task)
except Exception:
    print("exception consumed")

```

参见:

The `Future.exception()` method.

Chain coroutines correctly

When a coroutine function calls other coroutine functions and tasks, they should be chained explicitly with `yield from`. Otherwise, the execution is not guaranteed to be sequential.

Example with different bugs using `asyncio.sleep()` to simulate slow operations:

```

import asyncio

@asyncio.coroutine
def create():
    yield from asyncio.sleep(3.0)

```

(下页继续)

(续上页)

```

    print("(1) create file")

@asyncio.coroutine
def write():
    yield from asyncio.sleep(1.0)
    print("(2) write into file")

@asyncio.coroutine
def close():
    print("(3) close file")

@asyncio.coroutine
def test():
    asyncio.ensure_future(create())
    asyncio.ensure_future(write())
    asyncio.ensure_future(close())
    yield from asyncio.sleep(2.0)
    loop.stop()

loop = asyncio.get_event_loop()
asyncio.ensure_future(test())
loop.run_forever()
print("Pending tasks at exit: %s" % asyncio.Task.all_tasks(loop))
loop.close()

```

Expected output:

```

(1) create file
(2) write into file
(3) close file
Pending tasks at exit: set()

```

Actual output:

```

(3) close file
(2) write into file
Pending tasks at exit: {<Task pending create() at test.py:7 wait_for=<Future pending_
↪cb=[Task._wakeup()]>>>}
Task was destroyed but it is pending!
task: <Task pending create() done at test.py:5 wait_for=<Future pending cb=[Task._
↪wakeup()]>>>

```

The loop stopped before the `create()` finished, `close()` has been called before `write()`, whereas coroutine functions were called in this order: `create()`, `write()`, `close()`.

To fix the example, tasks must be marked with `yield from`:

```

@asyncio.coroutine
def test():
    yield from asyncio.ensure_future(create())
    yield from asyncio.ensure_future(write())
    yield from asyncio.ensure_future(close())
    yield from asyncio.sleep(2.0)
    loop.stop()

```

Or without `asyncio.ensure_future()`:

```
@asyncio.coroutine
def test():
    yield from create()
    yield from write()
    yield from close()
    yield from asyncio.sleep(2.0)
    loop.stop()
```

Pending task destroyed

If a pending task is destroyed, the execution of its wrapped *coroutine* did not complete. It is probably a bug and so a warning is logged.

Example of log:

```
Task was destroyed but it is pending!
task: <Task pending coro=<kill_me() done, defined at test.py:5> wait_for=<Future_
↳pending cb=[Task._wakeup()]>>
```

Enable the debug mode of asyncio to get the traceback where the task was created. Example of log in debug mode:

```
Task was destroyed but it is pending!
source_traceback: Object created at (most recent call last):
  File "test.py", line 15, in <module>
    task = asyncio.ensure_future(coro, loop=loop)
task: <Task pending coro=<kill_me() done, defined at test.py:5> wait_for=<Future_
↳pending cb=[Task._wakeup()] created at test.py:7> created at test.py:15>
```

参见:

Detect coroutine objects never scheduled.

Close transports and event loops

When a transport is no more needed, call its `close()` method to release resources. Event loops must also be closed explicitly.

If a transport or an event loop is not closed explicitly, a *ResourceWarning* warning will be emitted in its destructor. By default, *ResourceWarning* warnings are ignored. The *Debug mode of asyncio* section explains how to display them.

参见:

The *asyncio* module was designed in **PEP 3156**. For a motivational primer on transports and protocols, see **PEP 3153**.

18.6 asyncore — 异步 socket 处理器

源码: `Lib/asyncore.py`

3.6 版后已移除: 请使用 *asyncio* 替代。

注解：该模块仅为提供向后兼容。我们推荐在新代码中使用 `asyncio`。

该模块提供用于编写异步套接字服务客户端与服务端的基础构件。

只有两种方法让单个处理器上的程序“同一时间完成不止一件事”。多线程编程是最简单和最流行的方法，但是还有另一种非常不同的技术，它可以让你拥有多线程的几乎所有优点，而无需实际使用多线程。它仅仅在你的程序主要受 I/O 限制时有用，那么。如果你的程序受处理器限制，那么先发制人的预定线程可能就是你需要。但是，网络服务器很少受处理器限制。

如果你的操作系统在其 I/O 库中支持 `select()` 系统调用（几乎所有操作系统），那么你可以使用它来同时处理多个通信通道；在 I/O 正在“后台”时进行其他工作。虽然这种策略看起来很奇怪和复杂，特别是起初，它在很多方面比多线程编程更容易理解和控制。`asyncore` 模块为您解决了许多难题，使得构建复杂的高性能网络服务器和客户端的任务变得轻而易举。对于“会话”应用程序和协议，伴侣 `asynchat` 模块是非常宝贵的。

这两个模块背后的基本思想是创建一个或多个网络通道，类的实例 `asyncore.dispatcher` 和 `asynchat.async_chat`。创建通道会将它们添加到全局映射中，如果你不为它提供自己的映射，则由 `loop()` 函数使用。

一旦创建了初始通道，调用 `loop()` 函数将激活通道服务，该服务将一直持续到最后一个通道（包括在异步服务期间已添加到映射中的任何通道）关闭。

```
asyncore.loop([timeout[, use_poll[, map[, count]]]])
```

进入一个轮询循环，其在循环计数超出或所有打开的通道关闭后终止。所有参数都是可选的。`count` 形参默认为 `None`，导致循环仅在所有通道关闭时终止。`timeout` 形参为适当的 `select()` 或 `poll()` 调用设置超时参数，以秒为单位；默认值为 30 秒。`use_poll` 形参，如果为 `True`，则表示 `poll()` 应优先使用 `select`（默认为 `False`）。

The `map` parameter is a dictionary whose items are the channels to watch. As channels are closed they are deleted from their map. If `map` is omitted, a global map is used. Channels (instances of `asyncore.dispatcher`, `asynchat.async_chat` and subclasses thereof) can freely be mixed in the map.

class `asyncore.dispatcher`

The `dispatcher` class is a thin wrapper around a low-level socket object. To make it more useful, it has a few methods for event-handling which are called from the asynchronous loop. Otherwise, it can be treated as a normal non-blocking socket object.

The firing of low-level events at certain times or in certain connection states tells the asynchronous loop that certain higher-level events have taken place. For example, if we have asked for a socket to connect to another host, we know that the connection has been made when the socket becomes writable for the first time (at this point you know that you may write to it with the expectation of success). The implied higher-level events are:

Event	描述
<code>handle_connect()</code>	Implied by the first read or write event
<code>handle_close()</code>	Implied by a read event with no data available
<code>handle_accepted()</code>	Implied by a read event on a listening socket

During asynchronous processing, each mapped channel's `readable()` and `writable()` methods are used to determine whether the channel's socket should be added to the list of channels `select()`ed or `poll()`ed for read and write events.

Thus, the set of channel events is larger than the basic socket events. The full set of methods that can be overridden in your subclass follows:

handle_read()

Called when the asynchronous loop detects that a `read()` call on the channel's socket will succeed.

handle_write()

Called when the asynchronous loop detects that a writable socket can be written. Often this method will implement the necessary buffering for performance. For example:

```
def handle_write(self):
    sent = self.send(self.buffer)
    self.buffer = self.buffer[sent:]
```

handle_expt()

Called when there is out of band (OOB) data for a socket connection. This will almost never happen, as OOB is tenuously supported and rarely used.

handle_connect()

Called when the active opener's socket actually makes a connection. Might send a "welcome" banner, or initiate a protocol negotiation with the remote endpoint, for example.

handle_close()

Called when the socket is closed.

handle_error()

Called when an exception is raised and not otherwise handled. The default version prints a condensed trace-back.

handle_accept()

Called on listening channels (passive openers) when a connection can be established with a new remote endpoint that has issued a `connect()` call for the local endpoint. Deprecated in version 3.2; use `handle_accepted()` instead.

3.2 版后已移除.

handle_accepted(sock, addr)

Called on listening channels (passive openers) when a connection has been established with a new remote endpoint that has issued a `connect()` call for the local endpoint. `sock` is a new socket object usable to send and receive data on the connection, and `addr` is the address bound to the socket on the other end of the connection.

3.2 新版功能.

readable()

Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which read events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in read events.

writable()

Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which write events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in write events.

In addition, each channel delegates or extends many of the socket methods. Most of these are nearly identical to their socket partners.

create_socket(family=socket.AF_INET, type=socket.SOCK_STREAM)

This is identical to the creation of a normal socket, and will use the same options for creation. Refer to the `socket` documentation for information on creating sockets.

在 3.3 版更改: `family` and `type` arguments can be omitted.

connect(address)

As with the normal socket object, `address` is a tuple with the first element the host to connect to, and the second the port number.

send(*data*)Send *data* to the remote end-point of the socket.**recv**(*buffer_size*)Read at most *buffer_size* bytes from the socket's remote end-point. An empty bytes object implies that the channel has been closed from the other end.Note that *recv()* may raise *BlockingIOError*, even though *select.select()* or *select.poll()* has reported the socket ready for reading.**listen**(*backlog*)Listen for connections made to the socket. The *backlog* argument specifies the maximum number of queued connections and should be at least 1; the maximum value is system-dependent (usually 5).**bind**(*address*)Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family—refer to the *socket* documentation for more information.) To mark the socket as re-usable (setting the *SO_REUSEADDR* option), call the *dispatcher* object's *set_reuse_addr()* method.**accept**()Accept a connection. The socket must be bound to an address and listening for connections. The return value can be either *None* or a pair (*conn*, *address*) where *conn* is a new socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection. When *None* is returned it means the connection didn't take place, in which case the server should just ignore this event and keep listening for further incoming connections.**close**()

Close the socket. All future operations on the socket object will fail. The remote end-point will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

class *asyncore.dispatcher_with_send*A *dispatcher* subclass which adds simple buffered output capability, useful for simple clients. For more sophisticated usage use *asynchat.async_chat*.**class** *asyncore.file_dispatcher*A *file_dispatcher* takes a file descriptor or *file object* along with an optional *map* argument and wraps it for use with the *poll()* or *loop()* functions. If provided a file object or anything with a *fileno()* method, that method will be called and passed to the *file_wrapper* constructor. Availability: UNIX.**class** *asyncore.file_wrapper*A *file_wrapper* takes an integer file descriptor and calls *os.dup()* to duplicate the handle so that the original handle may be closed independently of the *file_wrapper*. This class implements sufficient methods to emulate a socket for use by the *file_dispatcher* class. Availability: UNIX.

18.6.1 *asyncore* Example basic HTTP client

Here is a very basic HTTP client that uses the *dispatcher* class to implement its socket handling:

```
import asyncore

class HTTPClient(asyncore.dispatcher):

    def __init__(self, host, path):
        asyncore.dispatcher.__init__(self)
        self.create_socket()
        self.connect((host, 80))
        self.buffer = bytes('GET %s HTTP/1.0\r\nHost: %s\r\n\r\n' %
                             (path, host), 'ascii')
```

(下页继续)

(续上页)

```

def handle_connect(self):
    pass

def handle_close(self):
    self.close()

def handle_read(self):
    print(self.recv(8192))

def writable(self):
    return (len(self.buffer) > 0)

def handle_write(self):
    sent = self.send(self.buffer)
    self.buffer = self.buffer[sent:]

client = HTTPClient('www.python.org', '/')
asyncore.loop()

```

18.6.2 asyncore Example basic echo server

Here is a basic echo server that uses the *dispatcher* class to accept connections and dispatches the incoming connections to a handler:

```

import asyncore

class EchoHandler(asyncore.dispatcher_with_send):

    def handle_read(self):
        data = self.recv(8192)
        if data:
            self.send(data)

class EchoServer(asyncore.dispatcher):

    def __init__(self, host, port):
        asyncore.dispatcher.__init__(self)
        self.create_socket()
        self.set_reuse_addr()
        self.bind((host, port))
        self.listen(5)

    def handle_accepted(self, sock, addr):
        print('Incoming connection from %s' % repr(addr))
        handler = EchoHandler(sock)

server = EchoServer('localhost', 8080)
asyncore.loop()

```

18.7 `asyncchat` — 异步 socket 指令/响应处理器

Source code: `Lib/asyncchat.py`

3.6 版后已移除: 请使用 `asyncio` 替代。

注解: 该模块仅为提供向后兼容。我们推荐在新代码中使用 `asyncio`。

This module builds on the `asyncore` infrastructure, simplifying asynchronous clients and servers and making it easier to handle protocols whose elements are terminated by arbitrary strings, or are of variable length. `asyncchat` defines the abstract class `async_chat` that you subclass, providing implementations of the `collect_incoming_data()` and `found_terminator()` methods. It uses the same asynchronous loop as `asyncore`, and the two types of channel, `asyncore.dispatcher` and `asyncchat.async_chat`, can freely be mixed in the channel map. Typically an `asyncore.dispatcher` server channel generates new `asyncchat.async_chat` channel objects as it receives incoming connection requests.

`class asyncchat.async_chat`

This class is an abstract subclass of `asyncore.dispatcher`. To make practical use of the code you must subclass `async_chat`, providing meaningful `collect_incoming_data()` and `found_terminator()` methods. The `asyncore.dispatcher` methods can be used, although not all make sense in a message/response context.

Like `asyncore.dispatcher`, `async_chat` defines a set of events that are generated by an analysis of socket conditions after a `select()` call. Once the polling loop has been started the `async_chat` object's methods are called by the event-processing framework with no action on the part of the programmer.

Two class attributes can be modified, to improve performance, or possibly even to conserve memory.

`ac_in_buffer_size`

The asynchronous input buffer size (default 4096).

`ac_out_buffer_size`

The asynchronous output buffer size (default 4096).

Unlike `asyncore.dispatcher`, `async_chat` allows you to define a FIFO queue of *producers*. A producer need have only one method, `more()`, which should return data to be transmitted on the channel. The producer indicates exhaustion (*i.e.* that it contains no more data) by having its `more()` method return the empty bytes object. At this point the `async_chat` object removes the producer from the queue and starts using the next producer, if any. When the producer queue is empty the `handle_write()` method does nothing. You use the channel object's `set_terminator()` method to describe how to recognize the end of, or an important breakpoint in, an incoming transmission from the remote endpoint.

To build a functioning `async_chat` subclass your input methods `collect_incoming_data()` and `found_terminator()` must handle the data that the channel receives asynchronously. The methods are described below.

`async_chat.close_when_done()`

Pushes a `None` on to the producer queue. When this producer is popped off the queue it causes the channel to be closed.

`async_chat.collect_incoming_data(data)`

Called with `data` holding an arbitrary amount of received data. The default method, which must be overridden, raises a `NotImplementedError` exception.

`async_chat.discard_buffers()`

In emergencies this method will discard any data held in the input and/or output buffers and the producer queue.

`async_chat.found_terminator()`

Called when the incoming data stream matches the termination condition set by `set_terminator()`. The default method, which must be overridden, raises a `NotImplementedError` exception. The buffered input data should be available via an instance attribute.

`async_chat.get_terminator()`

Returns the current terminator for the channel.

`async_chat.push(data)`

Pushes data on to the channel's queue to ensure its transmission. This is all you need to do to have the channel write the data out to the network, although it is possible to use your own producers in more complex schemes to implement encryption and chunking, for example.

`async_chat.push_with_producer(producer)`

Takes a producer object and adds it to the producer queue associated with the channel. When all currently-pushed producers have been exhausted the channel will consume this producer's data by calling its `more()` method and send the data to the remote endpoint.

`async_chat.set_terminator(term)`

Sets the terminating condition to be recognized on the channel. `term` may be any of three types of value, corresponding to three different ways to handle incoming protocol data.

term	描述
<i>string</i>	Will call <code>found_terminator()</code> when the string is found in the input stream
<i>integer</i>	Will call <code>found_terminator()</code> when the indicated number of characters have been received
<code>None</code>	The channel continues to collect data forever

Note that any data following the terminator will be available for reading by the channel after `found_terminator()` is called.

18.7.1 asynchat Example

The following partial example shows how HTTP requests can be read with `asynchat`. A web server might create an `http_request_handler` object for each incoming client connection. Notice that initially the channel terminator is set to match the blank line at the end of the HTTP headers, and a flag indicates that the headers are being read.

Once the headers have been read, if the request is of type POST (indicating that further data are present in the input stream) then the `Content-Length:` header is used to set a numeric terminator to read the right amount of data from the channel.

The `handle_request()` method is called once all relevant input has been marshalled, after setting the channel terminator to `None` to ensure that any extraneous data sent by the web client are ignored.

```
import asynchat

class http_request_handler(asynchat.async_chat):

    def __init__(self, sock, addr, sessions, log):
        asynchat.async_chat.__init__(self, sock=sock)
        self.addr = addr
        self.sessions = sessions
        self.ibuffer = []
        self.obuffer = b""
        self.set_terminator(b"\r\n\r\n")
        self.reading_headers = True
        self.handling = False
```

(下页继续)

(续上页)

```

self.cgi_data = None
self.log = log

def collect_incoming_data(self, data):
    """Buffer the data"""
    self.ibuffer.append(data)

def found_terminator(self):
    if self.reading_headers:
        self.reading_headers = False
        self.parse_headers(b"".join(self.ibuffer))
        self.ibuffer = []
        if self.op.upper() == b"POST":
            clen = self.headers.getheader("content-length")
            self.set_terminator(int(clen))
        else:
            self.handling = True
            self.set_terminator(None)
            self.handle_request()
    elif not self.handling:
        self.set_terminator(None) # browsers sometimes over-send
        self.cgi_data = parse(self.headers, b"".join(self.ibuffer))
        self.handling = True
        self.ibuffer = []
        self.handle_request()

```

18.8 signal —Set handlers for asynchronous events

This module provides mechanisms to use signal handlers in Python.

18.8.1 General rules

The `signal.signal()` function allows defining custom handlers to be executed when a signal is received. A small number of default handlers are installed: `SIGPIPE` is ignored (so write errors on pipes and sockets can be reported as ordinary Python exceptions) and `SIGINT` is translated into a `KeyboardInterrupt` exception.

A handler for a particular signal, once set, remains installed until it is explicitly reset (Python emulates the BSD style interface regardless of the underlying implementation), with the exception of the handler for `SIGCHLD`, which follows the underlying implementation.

Execution of Python signal handlers

A Python signal handler does not get executed inside the low-level (C) signal handler. Instead, the low-level signal handler sets a flag which tells the *virtual machine* to execute the corresponding Python signal handler at a later point (for example at the next *bytecode* instruction). This has consequences:

- It makes little sense to catch synchronous errors like `SIGFPE` or `SIGSEGV` that are caused by an invalid operation in C code. Python will return from the signal handler to the C code, which is likely to raise the same signal again, causing Python to apparently hang. From Python 3.3 onwards, you can use the `faulthandler` module to report on synchronous errors.

- A long-running calculation implemented purely in C (such as regular expression matching on a large body of text) may run uninterrupted for an arbitrary amount of time, regardless of any signals received. The Python signal handlers will be called when the calculation finishes.

Signals and threads

Python signal handlers are always executed in the main Python thread, even if the signal was received in another thread. This means that signals can't be used as a means of inter-thread communication. You can use the synchronization primitives from the *threading* module instead.

Besides, only the main thread is allowed to set a new signal handler.

18.8.2 Module contents

在 3.5 版更改: `signal` (`SIG*`), `handler` (`SIG_DFL`, `SIG_IGN`) and `sigmask` (`SIG_BLOCK`, `SIG_UNBLOCK`, `SIG_SETMASK`) related constants listed below were turned into *enums*. `getsignal()`, `pthread_sigmask()`, `sigpending()` and `sigwait()` functions return human-readable *enums*.

The variables defined in the *signal* module are:

`signal.SIG_DFL`

This is one of two standard signal handling options; it will simply perform the default function for the signal. For example, on most systems the default action for `SIGQUIT` is to dump core and exit, while the default action for `SIGCHLD` is to simply ignore it.

`signal.SIG_IGN`

This is another standard signal handler, which will simply ignore the given signal.

SIG*

All the signal numbers are defined symbolically. For example, the hangup signal is defined as `signal.SIGHUP`; the variable names are identical to the names used in C programs, as found in `<signal.h>`. The Unix man page for '`signal()`' lists the existing signals (on some systems this is `signal(2)`, on others the list is in `signal(7)`). Note that not all systems define the same set of signal names; only those names defined by the system are defined by this module.

`signal.CTRL_C_EVENT`

The signal corresponding to the `Ctrl+C` keystroke event. This signal can only be used with `os.kill()`.

Availability: Windows.

3.2 新版功能.

`signal.CTRL_BREAK_EVENT`

The signal corresponding to the `Ctrl+Break` keystroke event. This signal can only be used with `os.kill()`.

Availability: Windows.

3.2 新版功能.

`signal.NSIG`

One more than the number of the highest signal number.

`signal.ITIMER_REAL`

Decrements interval timer in real time, and delivers `SIGALRM` upon expiration.

`signal.ITIMER_VIRTUAL`

Decrements interval timer only when the process is executing, and delivers `SIGVTALRM` upon expiration.

signal.ITIMER_PROF

Decrements interval timer both when the process executes and when the system is executing on behalf of the process. Coupled with `ITIMER_VIRTUAL`, this timer is usually used to profile the time spent by the application in user and kernel space. `SIGPROF` is delivered upon expiration.

signal.SIG_BLOCK

A possible value for the *how* parameter to `pthread_sigmask()` indicating that signals are to be blocked.

3.3 新版功能.

signal.SIG_UNBLOCK

A possible value for the *how* parameter to `pthread_sigmask()` indicating that signals are to be unblocked.

3.3 新版功能.

signal.SIG_SETMASK

A possible value for the *how* parameter to `pthread_sigmask()` indicating that the signal mask is to be replaced.

3.3 新版功能.

The `signal` module defines one exception:

exception signal.ItimerError

Raised to signal an error from the underlying `setitimer()` or `getitimer()` implementation. Expect this error if an invalid interval timer or a negative time is passed to `setitimer()`. This error is a subtype of `OSError`.

3.3 新版功能: This error used to be a subtype of `IOError`, which is now an alias of `OSError`.

The `signal` module defines the following functions:

signal.alarm(*time*)

If *time* is non-zero, this function requests that a `SIGALRM` signal be sent to the process in *time* seconds. Any previously scheduled alarm is canceled (only one alarm can be scheduled at any time). The returned value is then the number of seconds before any previously set alarm was to have been delivered. If *time* is zero, no alarm is scheduled, and any scheduled alarm is canceled. If the return value is zero, no alarm is currently scheduled. (See the Unix man page `alarm(2)`.) Availability: Unix.

signal.getsignal(*signalnum*)

Return the current signal handler for the signal *signalnum*. The returned value may be a callable Python object, or one of the special values `signal.SIG_IGN`, `signal.SIG_DFL` or `None`. Here, `signal.SIG_IGN` means that the signal was previously ignored, `signal.SIG_DFL` means that the default way of handling the signal was previously in use, and `None` means that the previous signal handler was not installed from Python.

signal.pause()

Cause the process to sleep until a signal is received; the appropriate handler will then be called. Returns nothing. Not on Windows. (See the Unix man page `signal(2)`.)

See also `sigwait()`, `sigwaitinfo()`, `sigtimedwait()` and `sigpending()`.

signal.pthread_kill(*thread_id*, *signalnum*)

Send the signal *signalnum* to the thread *thread_id*, another thread in the same process as the caller. The target thread can be executing any code (Python or not). However, if the target thread is executing the Python interpreter, the Python signal handlers will be *executed by the main thread*. Therefore, the only point of sending a signal to a particular Python thread would be to force a running system call to fail with `InterruptedError`.

Use `threading.get_ident()` or the `ident` attribute of `threading.Thread` objects to get a suitable value for *thread_id*.

If *signalnum* is 0, then no signal is sent, but error checking is still performed; this can be used to check if the target thread is still running.

Availability: Unix (see the man page `pthread_kill(3)` for further information).

See also `os.kill()`.

3.3 新版功能.

`signal.thread_sigmask(how, mask)`

Fetch and/or change the signal mask of the calling thread. The signal mask is the set of signals whose delivery is currently blocked for the caller. Return the old signal mask as a set of signals.

The behavior of the call is dependent on the value of *how*, as follows.

- `SIG_BLOCK`: The set of blocked signals is the union of the current set and the *mask* argument.
- `SIG_UNBLOCK`: The signals in *mask* are removed from the current set of blocked signals. It is permissible to attempt to unblock a signal which is not blocked.
- `SIG_SETMASK`: The set of blocked signals is set to the *mask* argument.

mask is a set of signal numbers (e.g. `{signal.SIGINT, signal.SIGTERM}`). Use `range(1, signal.NSIG)` for a full mask including all signals.

For example, `signal.thread_sigmask(signal.SIG_BLOCK, [])` reads the signal mask of the calling thread.

Availability: Unix. See the man page `sigprocmask(3)` and `pthread_sigmask(3)` for further information.

See also `pause()`, `sigpending()` and `sigwait()`.

3.3 新版功能.

`signal.setitimer(which, seconds[, interval])`

Sets given interval timer (one of `signal.ITIMER_REAL`, `signal.ITIMER_VIRTUAL` or `signal.ITIMER_PROF`) specified by *which* to fire after *seconds* (float is accepted, different from `alarm()`) and after that every *interval* seconds. The interval timer specified by *which* can be cleared by setting *seconds* to zero.

When an interval timer fires, a signal is sent to the process. The signal sent is dependent on the timer being used; `signal.ITIMER_REAL` will deliver `SIGALRM`, `signal.ITIMER_VIRTUAL` sends `SIGVTALRM`, and `signal.ITIMER_PROF` will deliver `SIGPROF`.

The old values are returned as a tuple: (delay, interval).

Attempting to pass an invalid interval timer will cause an `ItimerError`. Availability: Unix.

`signal.getitimer(which)`

Returns current value of a given interval timer specified by *which*. Availability: Unix.

`signal.set_wakeup_fd(fd)`

Set the wakeup file descriptor to *fd*. When a signal is received, the signal number is written as a single byte into the *fd*. This can be used by a library to wakeup a poll or select call, allowing the signal to be fully processed.

The old wakeup fd is returned (or -1 if file descriptor wakeup was not enabled). If *fd* is -1, file descriptor wakeup is disabled. If not -1, *fd* must be non-blocking. It is up to the library to remove any bytes from *fd* before calling poll or select again.

Use for example `struct.unpack('%uB' % len(data), data)` to decode the signal numbers list.

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

在 3.5 版更改: On Windows, the function now also supports socket handles.

`signal.siginterrupt(signalnum, flag)`

Change system call restart behaviour: if *flag* is `False`, system calls will be restarted when interrupted by signal *signalnum*, otherwise system calls will be interrupted. Returns nothing. Availability: Unix (see the man page `siginterrupt(3)` for further information).

Note that installing a signal handler with `signal()` will reset the restart behaviour to interruptible by implicitly calling `siginterrupt()` with a true *flag* value for the given signal.

`signal.signal(signalnum, handler)`

Set the handler for signal *signalnum* to the function *handler*. *handler* can be a callable Python object taking two arguments (see below), or one of the special values `signal.SIG_IGN` or `signal.SIG_DFL`. The previous signal handler will be returned (see the description of `getsignal()` above). (See the Unix man page `signal(2)`.)

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

The *handler* is called with two arguments: the signal number and the current stack frame (`None` or a frame object; for a description of frame objects, see the description in the type hierarchy or see the attribute descriptions in the `inspect` module).

On Windows, `signal()` can only be called with `SIGABRT`, `SIGFPE`, `SIGILL`, `SIGINT`, `SIGSEGV`, `SIGTERM`, or `SIGBREAK`. A `ValueError` will be raised in any other case. Note that not all systems define the same set of signal names; an `AttributeError` will be raised if a signal name is not defined as `SIG*` module level constant.

`signal.sigpending()`

Examine the set of signals that are pending for delivery to the calling thread (i.e., the signals which have been raised while blocked). Return the set of the pending signals.

Availability: Unix (see the man page `sigpending(2)` for further information).

See also `pause()`, `pthread_sigmask()` and `sigwait()`.

3.3 新版功能.

`signal.sigwait(sigset)`

Suspend execution of the calling thread until the delivery of one of the signals specified in the signal set *sigset*. The function accepts the signal (removes it from the pending list of signals), and returns the signal number.

Availability: Unix (see the man page `sigwait(3)` for further information).

See also `pause()`, `pthread_sigmask()`, `sigpending()`, `sigwaitinfo()` and `sigtimedwait()`.

3.3 新版功能.

`signal.sigwaitinfo(sigset)`

Suspend execution of the calling thread until the delivery of one of the signals specified in the signal set *sigset*. The function accepts the signal and removes it from the pending list of signals. If one of the signals in *sigset* is already pending for the calling thread, the function will return immediately with information about that signal. The signal handler is not called for the delivered signal. The function raises an `InterruptedError` if it is interrupted by a signal that is not in *sigset*.

The return value is an object representing the data contained in the `siginfo_t` structure, namely: `si_signo`, `si_code`, `si_errno`, `si_pid`, `si_uid`, `si_status`, `si_band`.

Availability: Unix (see the man page `sigwaitinfo(2)` for further information).

See also `pause()`, `sigwait()` and `sigtimedwait()`.

3.3 新版功能.

在 3.5 版更改: The function is now retried if interrupted by a signal not in *sigset* and the signal handler does not raise an exception (see [PEP 475](#) for the rationale).

`signal.sigtimedwait(sigset, timeout)`

Like `sigwaitinfo()`, but takes an additional *timeout* argument specifying a timeout. If *timeout* is specified as 0, a poll is performed. Returns `None` if a timeout occurs.

Availability: Unix (see the man page *sigtimedwait(2)* for further information).

See also `pause()`, `sigwait()` and `sigwaitinfo()`.

3.3 新版功能.

在 3.5 版更改: The function is now retried with the recomputed *timeout* if interrupted by a signal not in *sigset* and the signal handler does not raise an exception (see [PEP 475](#) for the rationale).

18.8.3 示例

Here is a minimal example program. It uses the `alarm()` function to limit the time spent waiting to open a file; this is useful if the file is for a serial device that may not be turned on, which would normally cause the `os.open()` to hang indefinitely. The solution is to set a 5-second alarm before opening the file; if the operation takes too long, the alarm signal will be sent, and the handler raises an exception.

```
import signal, os

def handler(signum, frame):
    print('Signal handler called with signal', signum)
    raise OSError("Couldn't open device!")

# Set the signal handler and a 5-second alarm
signal.signal(signal.SIGALRM, handler)
signal.alarm(5)

# This open() may hang indefinitely
fd = os.open('/dev/ttyS0', os.O_RDWR)

signal.alarm(0)           # Disable the alarm
```

18.9 mmap — 内存映射文件支持

内存映射 (mmap) 文件对象的行为既像 `bytearray` 又像 `文件对象`。你可以在大部分接受 `bytearray` 的地方使用 `mmap` 对象；例如，你可以使用 `re` 模块来搜索一个内存映射文件。你也可以通过执行 `obj[index] = 97` 来修改单个字节，或者通过对切片赋值来修改一个子序列: `obj[i1:i2] = b'...`。你还可以在文件的当前位置开始读取和写入数据，并使用 `seek()` 前往另一个位置。

A memory-mapped file is created by the `mmap` constructor, which is different on Unix and on Windows. In either case you must provide a file descriptor for a file opened for update. If you wish to map an existing Python file object, use its `fileno()` method to obtain the correct value for the *fileno* parameter. Otherwise, you can open the file using the `os.open()` function, which returns a file descriptor directly (the file still needs to be closed when done).

注解: If you want to create a memory-mapping for a writable, buffered file, you should `flush()` the file first. This is necessary to ensure that local modifications to the buffers are actually available to the mapping.

For both the Unix and Windows versions of the constructor, *access* may be specified as an optional keyword parameter. *access* accepts one of three values: `ACCESS_READ`, `ACCESS_WRITE`, or `ACCESS_COPY` to specify read-only, write-through or copy-on-write memory respectively. *access* can be used on both Unix and Windows. If *access* is not specified, Windows `mmap` returns a write-through mapping. The initial memory values for all three access types are taken from the specified file. Assignment to an `ACCESS_READ` memory map raises a `TypeError` exception. Assignment to an

ACCESS_WRITE memory map affects both memory and the underlying file. Assignment to an ACCESS_COPY memory map affects memory but does not update the underlying file.

To map anonymous memory, -1 should be passed as the *fileno* along with the length.

class `mmap.mmap` (*fileno*, *length*, *tagname*=None, *access*=ACCESS_DEFAULT[, *offset*])

(Windows version) Maps *length* bytes from the file specified by the file handle *fileno*, and creates a `mmap` object. If *length* is larger than the current size of the file, the file is extended to contain *length* bytes. If *length* is 0, the maximum length of the map is the current size of the file, except that if the file is empty Windows raises an exception (you cannot create an empty mapping on Windows).

tagname, if specified and not None, is a string giving a tag name for the mapping. Windows allows you to have many different mappings against the same file. If you specify the name of an existing tag, that tag is opened, otherwise a new tag of this name is created. If this parameter is omitted or None, the mapping is created without a name. Avoiding the use of the tag parameter will assist in keeping your code portable between Unix and Windows.

offset may be specified as a non-negative integer offset. `mmap` references will be relative to the offset from the beginning of the file. *offset* defaults to 0. *offset* must be a multiple of the ALLOCATIONGRANULARITY.

class `mmap.mmap` (*fileno*, *length*, *flags*=MAP_SHARED, *prot*=PROT_WRITE|PROT_READ, *access*=ACCESS_DEFAULT[, *offset*])

(Unix version) Maps *length* bytes from the file specified by the file descriptor *fileno*, and returns a `mmap` object. If *length* is 0, the maximum length of the map will be the current size of the file when `mmap` is called.

flags specifies the nature of the mapping. MAP_PRIVATE creates a private copy-on-write mapping, so changes to the contents of the `mmap` object will be private to this process, and MAP_SHARED creates a mapping that's shared with all other processes mapping the same areas of the file. The default value is MAP_SHARED.

prot, if specified, gives the desired memory protection; the two most useful values are PROT_READ and PROT_WRITE, to specify that the pages may be read or written. *prot* defaults to PROT_READ | PROT_WRITE.

access may be specified in lieu of *flags* and *prot* as an optional keyword parameter. It is an error to specify both *flags*, *prot* and *access*. See the description of *access* above for information on how to use this parameter.

offset may be specified as a non-negative integer offset. `mmap` references will be relative to the offset from the beginning of the file. *offset* defaults to 0. *offset* must be a multiple of ALLOCATIONGRANULARITY which is equal to PAGE_SIZE on Unix systems.

To ensure validity of the created memory mapping the file specified by the descriptor *fileno* is internally automatically synchronized with physical backing store on Mac OS X and OpenVMS.

This example shows a simple way of using `mmap`:

```
import mmap

# write a simple example file
with open("hello.txt", "wb") as f:
    f.write(b"Hello Python!\n")

with open("hello.txt", "r+b") as f:
    # memory-map the file, size 0 means whole file
    mm = mmap.mmap(f.fileno(), 0)
    # read content via standard file methods
    print(mm.readline()) # prints b"Hello Python!\n"
    # read content via slice notation
    print(mm[:5]) # prints b"Hello"
    # update content using slice notation;
    # note that new content must have same size
    mm[6:] = b" world!\n"
    # ... and read again using standard file methods
```

(下页继续)

(续上页)

```
mm.seek(0)
print(mm.readline()) # prints b"Hello world!\n"
# close the map
mm.close()
```

`mmap` can also be used as a context manager in a `with` statement:

```
import mmap

with mmap.mmap(-1, 13) as mm:
    mm.write(b"Hello world!")
```

3.2 新版功能: Context manager support.

The next example demonstrates how to create an anonymous map and exchange data between the parent and child processes:

```
import mmap
import os

mm = mmap.mmap(-1, 13)
mm.write(b"Hello world!")

pid = os.fork()

if pid == 0: # In a child process
    mm.seek(0)
    print(mm.readline())

    mm.close()
```

Memory-mapped file objects support the following methods:

close()

Closes the `mmap`. Subsequent calls to other methods of the object will result in a `ValueError` exception being raised. This will not close the open file.

closed

True if the file is closed.

3.2 新版功能.

find(sub[, start[, end]])

Returns the lowest index in the object where the subsequence *sub* is found, such that *sub* is contained in the range *[start, end]*. Optional arguments *start* and *end* are interpreted as in slice notation. Returns `-1` on failure.

在 3.5 版更改: Writable *bytes-like object* is now accepted.

flush([offset[, size]])

Flushes changes made to the in-memory copy of a file back to disk. Without use of this call there is no guarantee that changes are written back before the object is destroyed. If *offset* and *size* are specified, only changes to the given range of bytes will be flushed to disk; otherwise, the whole extent of the mapping is flushed. *offset* must be a multiple of the `PAGESIZE` or `ALLOCATIONGRANULARITY`.

(Windows version) A nonzero value returned indicates success; zero indicates failure.

(Unix version) A zero value is returned to indicate success. An exception is raised when the call failed.

move (*dest, src, count*)

Copy the *count* bytes starting at offset *src* to the destination index *dest*. If the mmap was created with `ACCESS_READ`, then calls to move will raise a `TypeError` exception.

read (*[n]*)

Return a *bytes* containing up to *n* bytes starting from the current file position. If the argument is omitted, `None` or negative, return all bytes from the current file position to the end of the mapping. The file position is updated to point after the bytes that were returned.

在 3.3 版更改: Argument can be omitted or `None`.

read_byte ()

Returns a byte at the current file position as an integer, and advances the file position by 1.

readline ()

Returns a single line, starting at the current file position and up to the next newline.

resize (*newsize*)

Resizes the map and the underlying file, if any. If the mmap was created with `ACCESS_READ` or `ACCESS_COPY`, resizing the map will raise a `TypeError` exception.

rfind (*sub* [, *start* [, *end*]])

Returns the highest index in the object where the subsequence *sub* is found, such that *sub* is contained in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation. Returns `-1` on failure.

在 3.5 版更改: Writable *bytes-like object* is now accepted.

seek (*pos* [, *whence*])

Set the file's current position. *whence* argument is optional and defaults to `os.SEEK_SET` or 0 (absolute file positioning); other values are `os.SEEK_CUR` or 1 (seek relative to the current position) and `os.SEEK_END` or 2 (seek relative to the file's end).

size ()

Return the length of the file, which can be larger than the size of the memory-mapped area.

tell ()

Returns the current position of the file pointer.

write (*bytes*)

Write the bytes in *bytes* into memory at the current position of the file pointer and return the number of bytes written (never less than `len(bytes)`, since if the write fails, a `ValueError` will be raised). The file position is updated to point after the bytes that were written. If the mmap was created with `ACCESS_READ`, then writing to it will raise a `TypeError` exception.

在 3.5 版更改: Writable *bytes-like object* is now accepted.

在 3.6 版更改: The number of bytes written is now returned.

write_byte (*byte*)

Write the integer *byte* into memory at the current position of the file pointer; the file position is advanced by 1. If the mmap was created with `ACCESS_READ`, then writing to it will raise a `TypeError` exception.

本章介绍了支持处理互联网上常用数据格式的模块。

19.1 email — 电子邮件与 MIME 处理包

源码: `Lib/email/__init__.py`

The `email` package is a library for managing email messages. It is specifically *not* designed to do any sending of email messages to SMTP ([RFC 2821](#)), NNTP, or other servers; those are functions of modules such as `smtplib` and `nntplib`. The `email` package attempts to be as RFC-compliant as possible, supporting [RFC 5233](#) and [RFC 6532](#), as well as such MIME-related RFCs as [RFC 2045](#), [RFC 2046](#), [RFC 2047](#), [RFC 2183](#), and [RFC 2231](#).

The overall structure of the email package can be divided into three major components, plus a fourth component that controls the behavior of the other components.

The central component of the package is an “object model” that represents email messages. An application interacts with the package primarily through the object model interface defined in the `message` sub-module. The application can use this API to ask questions about an existing email, to construct a new email, or to add or remove email subcomponents that themselves use the same object model interface. That is, following the nature of email messages and their MIME subcomponents, the email object model is a tree structure of objects that all provide the `EmailMessage` API.

The other two major components of the package are the `parser` and the `generator`. The parser takes the serialized version of an email message (a stream of bytes) and converts it into a tree of `EmailMessage` objects. The generator takes an `EmailMessage` and turns it back into a serialized byte stream. (The parser and generator also handle streams of text characters, but this usage is discouraged as it is too easy to end up with messages that are not valid in one way or another.)

The control component is the `policy` module. Every `EmailMessage`, every `generator`, and every `parser` has an associated `policy` object that controls its behavior. Usually an application only needs to specify the policy when an `EmailMessage` is created, either by directly instantiating an `EmailMessage` to create a new email, or by parsing an input stream using a `parser`. But the policy can be changed when the message is serialized using a `generator`.

This allows, for example, a generic email message to be parsed from disk, but to serialize it using standard SMTP settings when sending it to an email server.

The email package does its best to hide the details of the various governing RFCs from the application. Conceptually the application should be able to treat the email message as a structured tree of unicode text and binary attachments, without having to worry about how these are represented when serialized. In practice, however, it is often necessary to be aware of at least some of the rules governing MIME messages and their structure, specifically the names and nature of the MIME “content types” and how they identify multipart documents. For the most part this knowledge should only be required for more complex applications, and even then it should only be the high level structure in question, and not the details of how those structures are represented. Since MIME content types are used widely in modern internet software (not just email), this will be a familiar concept to many programmers.

The following sections describe the functionality of the `email` package. We start with the `message` object model, which is the primary interface an application will use, and follow that with the `parser` and `generator` components. Then we cover the `policy` controls, which completes the treatment of the main components of the library.

The next three sections cover the exceptions the package may raise and the defects (non-compliance with the RFCs) that the `parser` may detect. Then we cover the `headerregistry` and the `contentmanager` sub-components, which provide tools for doing more detailed manipulation of headers and payloads, respectively. Both of these components contain features relevant to consuming and producing non-trivial messages, but also document their extensibility APIs, which will be of interest to advanced applications.

Following those is a set of examples of using the fundamental parts of the APIs covered in the preceding sections.

The foregoing represent the modern (unicode friendly) API of the email package. The remaining sections, starting with the `Message` class, cover the legacy `compat32` API that deals much more directly with the details of how email messages are represented. The `compat32` API does *not* hide the details of the RFCs from the application, but for applications that need to operate at that level, they can be useful tools. This documentation is also relevant for applications that are still using the `compat32` API for backward compatibility reasons.

在 3.6 版更改: Docs reorganized and rewritten to promote the new `EmailMessage/EmailPolicy` API.

Contents of the `email` package documentation:

19.1.1 `email.message`: Representing an email message

Source code: `Lib/email/message.py`

3.6 新版功能:¹

The central class in the `email` package is the `EmailMessage` class, imported from the `email.message` module. It is the base class for the `email` object model. `EmailMessage` provides the core functionality for setting and querying header fields, for accessing message bodies, and for creating or modifying structured messages.

An email message consists of *headers* and a *payload* (which is also referred to as the *content*). Headers are **RFC 5322** or **RFC 6532** style field names and values, where the field name and value are separated by a colon. The colon is not part of either the field name or the field value. The payload may be a simple text message, or a binary object, or a structured sequence of sub-messages each with their own set of headers and their own payload. The latter type of payload is indicated by the message having a MIME type such as `multipart/*` or `message/rfc822`.

The conceptual model provided by an `EmailMessage` object is that of an ordered dictionary of headers coupled with a *payload* that represents the **RFC 5322** body of the message, which might be a list of sub-`EmailMessage` objects. In addition to the normal dictionary methods for accessing the header names and values, there are methods for accessing specialized information from the headers (for example the MIME content type), for operating on the payload, for generating a serialized version of the message, and for recursively walking over the object tree.

¹ Originally added in 3.4 as a *provisional module*. Docs for legacy message class moved to `email.message.Message: Representing an email message using the compat32 API`.

The `EmailMessage` dictionary-like interface is indexed by the header names, which must be ASCII values. The values of the dictionary are strings with some extra methods. Headers are stored and returned in case-preserving form, but field names are matched case-insensitively. Unlike a real dict, there is an ordering to the keys, and there can be duplicate keys. Additional methods are provided for working with headers that have duplicate keys.

The *payload* is either a string or bytes object, in the case of simple message objects, or a list of `EmailMessage` objects, for MIME container documents such as `multipart/*` and `message/rfc822` message objects.

class `email.message.EmailMessage` (*policy=default*)

If *policy* is specified use the rules it specifies to update and serialize the representation of the message. If *policy* is not set, use the `default` policy, which follows the rules of the email RFCs except for line endings (instead of the RFC mandated `\r\n`, it uses the Python standard `\n` line endings). For more information see the *policy* documentation.

as_string (*unixfrom=False, maxheaderlen=None, policy=None*)

Return the entire message flattened as a string. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. For backward compatibility with the base `Message` class *maxheaderlen* is accepted, but defaults to `None`, which means that by default the line length is controlled by the *max_line_length* of the policy. The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the `Generator`.

Flattening the message may trigger changes to the `EmailMessage` if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See `email.generator.Generator` for a more flexible API for serializing messages. Note also that this method is restricted to producing messages serialized as “7 bit clean” when *utf8* is `False`, which is the default.

在 3.6 版更改: the default behavior when *maxheaderlen* is not specified was changed from defaulting to 0 to defaulting to the value of *max_line_length* from the policy.

__str__ ()

Equivalent to `as_string(policy=self.policy.clone(utf8=True))`. Allows `str(msg)` to produce a string containing the serialized message in a readable format.

在 3.4 版更改: the method was changed to use `utf8=True`, thus producing an **RFC 6531**-like message representation, instead of being a direct alias for `as_string()`.

as_bytes (*unixfrom=False, policy=None*)

Return the entire message flattened as a bytes object. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the `BytesGenerator`.

Flattening the message may trigger changes to the `EmailMessage` if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See `email.generator.BytesGenerator` for a more flexible API for serializing messages.

__bytes__ ()

Equivalent to `as_bytes()`. Allows `bytes(msg)` to produce a bytes object containing the serialized message.

is_multipart ()

Return `True` if the message's payload is a list of sub-`EmailMessage` objects, otherwise return `False`. When `is_multipart()` returns `False`, the payload should be a string object (which might be a CTE

encoded binary payload). Note that `is_multipart()` returning `True` does not necessarily mean that `msg.get_content_maintype() == 'multipart'` will return the `True`. For example, `is_multipart` will return `True` when the `EmailMessage` is of type `message/rfc822`.

set_unixfrom (*unixfrom*)

Set the message's envelope header to *unixfrom*, which should be a string. (See `mbboxMessage` for a brief description of this header.)

get_unixfrom ()

Return the message's envelope header. Defaults to `None` if the envelope header was never set.

The following methods implement the mapping-like interface for accessing the message's headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by `keys()`, but in an `EmailMessage` object, headers are always returned in the order they appeared in the original message, or in which they were added to the message later. Any header deleted and then re-added is always appended to the end of the header list.

These semantic differences are intentional and are biased toward convenience in the most common use cases.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

__len__ ()

Return the total number of headers, including duplicates.

__contains__ (*name*)

Return `true` if the message object has a field named *name*. Matching is done without regard to case and *name* does not include the trailing colon. Used for the `in` operator. For example:

```
if 'message-id' in myMessage:
    print('Message-ID:', myMessage['message-id'])
```

__getitem__ (*name*)

Return the value of the named header field. *name* does not include the colon field separator. If the header is missing, `None` is returned; a `KeyError` is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field values will be returned is undefined. Use the `get_all()` method to get the values of all the extant headers named *name*.

Using the standard (non-`compat32`) policies, the returned value is an instance of a subclass of `email.headerregistry.BaseHeader`.

__setitem__ (*name*, *val*)

Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message's existing headers.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g.:

```
del msg['subject']
msg['subject'] = 'Python roolz!'
```

If the policy defines certain headers to be unique (as the standard policies do), this method may raise a `ValueError` when an attempt is made to assign a value to such a header when one already exists. This behavior is intentional for consistency's sake, but do not depend on it as we may choose to make such assignments do an automatic deletion of the existing header in the future.

__delitem__ (*name*)

Delete all occurrences of the field with name *name* from the message's headers. No exception is raised if the named field isn't present in the headers.

keys()

Return a list of all the message's header field names.

values()

Return a list of all the message's field values.

items()

Return a list of 2-tuples containing all the message's field headers and values.

get(name, failobj=None)

Return the value of the named header field. This is identical to `__getitem__()` except that optional *failobj* is returned if the named header is missing (*failobj* defaults to `None`).

Here are some additional useful header related methods:

get_all(name, failobj=None)

Return a list of all the values for the field named *name*. If there are no such named headers in the message, *failobj* is returned (defaults to `None`).

add_header(_name, _value, **_params)

Extended header setting. This method is similar to `__setitem__()` except that additional header parameters can be provided as keyword arguments. *_name* is the header field to add and *_value* is the *primary* value for the header.

For each item in the keyword argument dictionary *_params*, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as `key="value"` unless the value is `None`, in which case only the key will be added.

If the value contains non-ASCII characters, the charset and language may be explicitly controlled by specifying the value as a three tuple in the format `(CHARSET, LANGUAGE, VALUE)`, where *CHARSET* is a string naming the charset to be used to encode the value, *LANGUAGE* can usually be set to `None` or the empty string (see [RFC 2231](#) for other possibilities), and *VALUE* is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in [RFC 2231](#) format using a *CHARSET* of `utf-8` and a *LANGUAGE* of `None`.

Here is an example:

```
msg.add_header('Content-Disposition', 'attachment', filename='bud.gif')
```

This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.gif"
```

An example of the extended interface with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachment',
               filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

replace_header(_name, _value)

Replace a header. Replace the first header found in the message that matches *_name*, retaining header order and field name case of the original header. If no matching header is found, raise a *KeyError*.

get_content_type()

Return the message's content type, coerced to lower case of the form *maintype/subtype*. If there is no *Content-Type* header in the message return the value returned by `get_default_type()`. If the *Content-Type* header is invalid, return `text/plain`.

(According to [RFC 2045](#), messages always have a default type, `get_content_type()` will always return a value. [RFC 2045](#) defines a message's default type to be `text/plain` unless it appears inside a

multipart/digest container, in which case it would be *message/rfc822*. If the *Content-Type* header has an invalid type specification, **RFC 2045** mandates that the default type be *text/plain*.)

get_content_maintype()

Return the message's main content type. This is the *maintype* part of the string returned by *get_content_type()*.

get_content_subtype()

Return the message's sub-content type. This is the *subtype* part of the string returned by *get_content_type()*.

get_default_type()

Return the default content type. Most messages have a default content type of *text/plain*, except for messages that are subparts of *multipart/digest* containers. Such subparts have a default content type of *message/rfc822*.

set_default_type(ctype)

Set the default content type. *ctype* should either be *text/plain* or *message/rfc822*, although this is not enforced. The default content type is not stored in the *Content-Type* header, so it only affects the return value of the *get_content_type* methods when no *Content-Type* header is present in the message.

set_param(param, value, header='Content-Type', requote=True, charset=None, language="", replace=False)

Set a parameter in the *Content-Type* header. If the parameter already exists in the header, replace its value with *value*. When *header* is *Content-Type* (the default) and the header does not yet exist in the message, add it, set its value to *text/plain*, and append the new parameter value. Optional *header* specifies an alternative header to *Content-Type*.

If the value contains non-ASCII characters, the charset and language may be explicitly specified using the optional *charset* and *language* parameters. Optional *language* specifies the **RFC 2231** language, defaulting to the empty string. Both *charset* and *language* should be strings. The default is to use the *utf8* charset and *None* for the *language*.

If *replace* is *False* (the default) the header is moved to the end of the list of headers. If *replace* is *True*, the header will be updated in place.

Use of the *requote* parameter with *EmailMessage* objects is deprecated.

Note that existing parameter values of headers may be accessed through the *params* attribute of the header value (for example, `msg['Content-Type'].params['charset']`).

在 3.4 版更改: *replace* keyword was added.

del_param(param, header='content-type', requote=True)

Remove the given parameter completely from the *Content-Type* header. The header will be re-written in place without the parameter or its value. Optional *header* specifies an alternative to *Content-Type*.

Use of the *requote* parameter with *EmailMessage* objects is deprecated.

get_filename(failobj=None)

Return the value of the *filename* parameter of the *Content-Disposition* header of the message. If the header does not have a *filename* parameter, this method falls back to looking for the *name* parameter on the *Content-Type* header. If neither is found, or the header is missing, then *failobj* is returned. The returned string will always be unquoted as per *email.utils.unquote()*.

get_boundary(failobj=None)

Return the value of the *boundary* parameter of the *Content-Type* header of the message, or *failobj* if either the header is missing, or has no *boundary* parameter. The returned string will always be unquoted as per *email.utils.unquote()*.

set_boundary (*boundary*)

Set the boundary parameter of the *Content-Type* header to *boundary*. *set_boundary()* will always quote *boundary* if necessary. A *HeaderParseError* is raised if the message object has no *Content-Type* header.

Note that using this method is subtly different from deleting the old *Content-Type* header and adding a new one with the new boundary via *add_header()*, because *set_boundary()* preserves the order of the *Content-Type* header in the list of headers.

get_content_charset (*failobj=None*)

Return the charset parameter of the *Content-Type* header, coerced to lower case. If there is no *Content-Type* header, or if that header has no charset parameter, *failobj* is returned.

get_charsets (*failobj=None*)

Return a list containing the character set names in the message. If the message is a *multipart*, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the charset parameter in the *Content-Type* header for the represented subpart. If the subpart has no *Content-Type* header, no charset parameter, or is not of the *text* main MIME type, then that item in the returned list will be *failobj*.

is_attachment ()

Return True if there is a *Content-Disposition* header and its (case insensitive) value is attachment, False otherwise.

在 3.4.2 版更改: *is_attachment* is now a method instead of a property, for consistency with *is_multipart()*.

get_content_disposition ()

Return the lowercased value (without parameters) of the message's *Content-Disposition* header if it has one, or None. The possible values for this method are *inline*, *attachment* or None if the message follows [RFC 2183](#).

3.5 新版功能.

The following methods relate to interrogating and manipulating the content (payload) of the message.

walk ()

The *walk()* method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use *walk()* as the iterator in a for loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:

```
>>> for part in msg.walk():
...     print(part.get_content_type())
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
```

walk iterates over the subparts of any part where *is_multipart()* returns True, even though *msg.get_content_maintype() == 'multipart'* may return False. We can see this in our example by making use of the *_structure* debug helper function:

```
>>> for part in msg.walk():
...     print(part.get_content_maintype() == 'multipart',
```

(下页继续)

(续上页)

```

...         part.is_multipart()
True True
False False
False True
False False
False False
False True
False False
>>> _structure(msg)
multipart/report
    text/plain
    message/delivery-status
        text/plain
        text/plain
    message/rfc822
        text/plain

```

Here the message parts are not multipart, but they do contain subparts. `is_multipart()` returns True and walk descends into the subparts.

get_body (*preferencelist*=('related', 'html', 'plain'))

Return the MIME part that is the best candidate to be the “body” of the message.

preferencelist must be a sequence of strings from the set `related`, `html`, and `plain`, and indicates the order of preference for the content type of the part returned.

Start looking for candidate matches with the object on which the `get_body` method is called.

If `related` is not included in *preferencelist*, consider the root part (or subpart of the root part) of any related encountered as a candidate if the (sub-)part matches a preference.

When encountering a `multipart/related`, check the `start` parameter and if a part with a matching *Content-ID* is found, consider only it when looking for candidate matches. Otherwise consider only the first (default root) part of the `multipart/related`.

If a part has a *Content-Disposition* header, only consider the part a candidate match if the value of the header is `inline`.

If none of the candidates matches any of the preferences in *preferencelist*, return `None`.

Notes: (1) For most applications the only *preferencelist* combinations that really make sense are `('plain',)`, `('html', 'plain')`, and the default `('related', 'html', 'plain')`. (2) Because matching starts with the object on which `get_body` is called, calling `get_body` on a `multipart/related` will return the object itself unless *preferencelist* has a non-default value. (3) Messages (or message parts) that do not specify a *Content-Type* or whose *Content-Type* header is invalid will be treated as if they are of type `text/plain`, which may occasionally cause `get_body` to return unexpected results.

iter_attachments ()

Return an iterator over all of the immediate sub-parts of the message that are not candidate “body” parts. That is, skip the first occurrence of each of `text/plain`, `text/html`, `multipart/related`, or `multipart/alternative` (unless they are explicitly marked as attachments via *Content-Disposition: attachment*), and return all remaining parts. When applied directly to a `multipart/related`, return an iterator over the all the related parts except the root part (ie: the part pointed to by the `start` parameter, or the first part if there is no `start` parameter or the `start` parameter doesn't match the *Content-ID* of any of the parts). When applied directly to a `multipart/alternative` or a non-multipart, return an empty iterator.

iter_parts ()

Return an iterator over all of the immediate sub-parts of the message, which will be empty for a non-multipart. (See also `walk()`.)

get_content (*args, content_manager=None, **kw)

Call the `get_content()` method of the `content_manager`, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If `content_manager` is not specified, use the `content_manager` specified by the current `policy`.

set_content (*args, content_manager=None, **kw)

Call the `set_content()` method of the `content_manager`, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If `content_manager` is not specified, use the `content_manager` specified by the current `policy`.

make_related (boundary=None)

Convert a non-multipart message into a multipart/related message, moving any existing `Content-` headers and payload into a (new) first part of the multipart. If `boundary` is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

make_alternative (boundary=None)

Convert a non-multipart or a multipart/related into a multipart/alternative, moving any existing `Content-` headers and payload into a (new) first part of the multipart. If `boundary` is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

make_mixed (boundary=None)

Convert a non-multipart, a multipart/related, or a multipart-alternative into a multipart/mixed, moving any existing `Content-` headers and payload into a (new) first part of the multipart. If `boundary` is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

add_related (*args, content_manager=None, **kw)

If the message is a multipart/related, create a new message object, pass all of the arguments to its `set_content()` method, and `attach()` it to the multipart. If the message is a non-multipart, call `make_related()` and then proceed as above. If the message is any other type of multipart, raise a `TypeError`. If `content_manager` is not specified, use the `content_manager` specified by the current `policy`. If the added part has no `Content-Disposition` header, add one with the value `inline`.

add_alternative (*args, content_manager=None, **kw)
