`test.support.record_original_stdout(stdout)`

Store the value from *stdout*. It is meant to hold the stdout at the time the regrtest began.

`test.support.get_original_stdout()`

Return the original stdout set by `record_original_stdout()` or `sys.stdout` if it's not set.

`test.support.args_from_interpreter_flags()`

Return a list of command line arguments reproducing the current settings in `sys.flags` and `sys.warnoptions`.

`test.support.optim_args_from_interpreter_flags()`

Return a list of command line arguments reproducing the current optimization settings in `sys.flags`.

`test.support.captured_stdin()`

`test.support.captured_stdout()`

`test.support.captured_stderr()`

A context managers that temporarily replaces the named stream with `io.StringIO` object.

使用輸出串流的範例：

```
with captured_stdout() as stdout, captured_stderr() as stderr:
    print("hello")
    print("error", file=sys.stderr)
assert stdout.getvalue() == "hello\n"
assert stderr.getvalue() == "error\n"
```

使用輸入串流的範例：

```
with captured_stdin() as stdin:
    stdin.write('hello\n')
    stdin.seek(0)
    # call test code that consumes from sys.stdin
    captured = input()
self.assertEqual(captured, "hello")
```

`test.support.disable_faulthandler()`

A context manager that temporary disables `faulthandler`.

`test.support.gc_collect()`

Force as many objects as possible to be collected. This is needed because timely deallocation is not guaranteed by the garbage collector. This means that `__del__` methods may be called later than expected and weakrefs may remain alive for longer than expected.

`test.support.disable_gc()`

A context manager that disables the garbage collector on entry. On exit, the garbage collector is restored to its prior state.

`test.support.swap_attr(obj, attr, new_val)`

Context manager to swap out an attribute with a new object.

用法:

```
with swap_attr(obj, "attr", 5):  
    ...
```

This will set `obj.attr` to 5 for the duration of the `with` block, restoring the old value at the end of the block. If `attr` doesn't exist on `obj`, it will be created and then deleted at the end of the block.

The old value (or `None` if it doesn't exist) will be assigned to the target of the "as" clause, if there is one.

`test.support.swap_item(obj, attr, new_val)`

Context manager to swap out an item with a new object.

用法:

```
with swap_item(obj, "item", 5):  
    ...
```

This will set `obj["item"]` to 5 for the duration of the `with` block, restoring the old value at the end of the block. If `item` doesn't exist on `obj`, it will be created and then deleted at the end of the block.

The old value (or `None` if it doesn't exist) will be assigned to the target of the "as" clause, if there is one.

`test.support.flush_std_streams()`

Call the `flush()` method on `sys.stdout` and then on `sys.stderr`. It can be used to make sure that the logs order is consistent before writing into `stderr`.

在 3.11 版被加入。

`test.support.print_warning(msg)`

Print a warning into `sys.__stderr__`. Format the message as: `f"Warning -- {msg}"`. If `msg` is made of multiple lines, add `"Warning -- "` prefix to each line.

在 3.9 版被加入。

`test.support.wait_process(pid, *, exitcode, timeout=None)`

Wait until process `pid` completes and check that the process exit code is `exitcode`.

如果行程退出代號不等於 `exitcode` 則引發 `AssertionError`。

If the process runs longer than `timeout` seconds (`SHORT_TIMEOUT` by default), kill the process and raise an `AssertionError`. The timeout feature is not available on Windows.

在 3.9 版被加入。

`test.support.calcobjsize(fmt)`

Return the size of the `PyObject` whose structure members are defined by `fmt`. The returned value includes the size of the Python object header and alignment.

`test.support.calcvobjsize(fmt)`

Return the size of the `PyVarObject` whose structure members are defined by `fmt`. The returned value includes the size of the Python object header and alignment.

`test.support.checksizeof(test, o, size)`

For testcase `test`, assert that the `sys.getsizeof` for `o` plus the GC header size equals `size`.

`@test.support.anticipate_failure (condition)`

A decorator to conditionally mark tests with `unittest.expectedFailure()`. Any use of this decorator should have an associated comment identifying the relevant tracker issue.

`test.support.system_must_validate_cert (f)`

A decorator that skips the decorated test on TLS certification validation failures.

`@test.support.run_with_locale (catstr, *locales)`

A decorator for running a function in a different locale, correctly resetting it after it has finished. *catstr* is the locale category as a string (for example "LC_ALL"). The *locales* passed will be tried sequentially, and the first valid locale will be used.

`@test.support.run_with_tz (tz)`

A decorator for running a function in a specific timezone, correctly resetting it after it has finished.

`@test.support.requires_freebsd_version (*min_version)`

Decorator for the minimum version when running test on FreeBSD. If the FreeBSD version is less than the minimum, the test is skipped.

`@test.support.requires_linux_version (*min_version)`

Decorator for the minimum version when running test on Linux. If the Linux version is less than the minimum, the test is skipped.

`@test.support.requires_mac_version (*min_version)`

Decorator for the minimum version when running test on macOS. If the macOS version is less than the minimum, the test is skipped.

`@test.support.requires_gil_enabled`

Decorator for skipping tests on the free-threaded build. If the *GIL* is disabled, the test is skipped.

`@test.support.requires_ieee_754`

Decorator for skipping tests on non-IEEE 754 platforms.

`@test.support.requires_zlib`

如果 *zlib* 不存在則跳過測試的裝飾器。

`@test.support.requires_gzip`

如果 *gzip* 不存在則跳過測試的裝飾器。

`@test.support.requires_bz2`

如果 *bz2* 不存在則跳過測試的裝飾器。

`@test.support.requires_lzma`

如果 *lzma* 不存在則跳過測試的裝飾器。

`@test.support.requires_resource (resource)`

如果 *resource* 不可用則跳過測試的裝飾器。

`@test.support.requires_docstrings`

Decorator for only running the test if *HAVE_DOCSTRINGS*.

`@test.support.requires_limited_api`

Decorator for only running the test if Limited C API is available.

`@test.support.cpython_only`

Decorator for tests only applicable to CPython.

`@test.support.impl_detail (msg=None, **guards)`

Decorator for invoking `check_impl_detail()` on *guards*. If that returns *False*, then uses *msg* as the reason for skipping the test.

`@test.support.no_tracing`

Decorator to temporarily turn off tracing for the duration of the test.

`@test.support.refcount_test`

Decorator for tests which involve reference counting. The decorator does not run the test if it is not run by CPython. Any trace function is unset for the duration of the test to prevent unexpected refcounts caused by the trace function.

`@test.support.bigmemtest (size, memuse, dry_run=True)`

大記憶體測試的裝飾器。

size is a requested size for the test (in arbitrary, test-interpreted units.) *memuse* is the number of bytes per unit for the test, or a good estimate of it. For example, a test that needs two byte buffers, of 4 GiB each, could be decorated with `@bigmemtest(size=_4G, memuse=2)`.

The *size* argument is normally passed to the decorated test method as an extra argument. If *dry_run* is `True`, the value passed to the test method may be less than the requested value. If *dry_run* is `False`, it means the test doesn't support dummy runs when `-M` is not specified.

`@test.support.bigaddrspace_test`

Decorator for tests that fill the address space.

`test.support.check_syntax_error (testcase, statement, errtext="", *, lineno=None, offset=None)`

Test for syntax errors in *statement* by attempting to compile *statement*. *testcase* is the `unittest` instance for the test. *errtext* is the regular expression which should match the string representation of the raised `SyntaxError`. If *lineno* is not `None`, compares to the line of the exception. If *offset* is not `None`, compares to the offset of the exception.

`test.support.open_urlresource (url, *args, **kw)`

Open *url*. If open fails, raises `TestFailed`.

`test.support.reap_children()`

Use this at the end of `test_main` whenever sub-processes are started. This will help ensure that no extra children (zombies) stick around to hog resources and create problems when looking for reflinks.

`test.support.get_attribute (obj, name)`

Get an attribute, raising `unittest.SkipTest` if `AttributeError` is raised.

`test.support.catch_unraisable_exception()`

Context manager catching unraisable exception using `sys.unraisablehook()`.

Storing the exception value (`cm.unraisable.exc_value`) creates a reference cycle. The reference cycle is broken explicitly when the context manager exits.

Storing the object (`cm.unraisable.object`) can resurrect it if it is set to an object which is being finalized. Exiting the context manager clears the stored object.

用法：

```
with support.catch_unraisable_exception() as cm:
    # code creating an "unraisable exception"
    ...

    # check the unraisable exception: use cm.unraisable
    ...

# cm.unraisable attribute no longer exists at this point
# (to break a reference cycle)
```

在 3.8 版被加入。

`test.support.load_package_tests(pkg_dir, loader, standard_tests, pattern)`

Generic implementation of the `unittest` `load_tests` protocol for use in test packages. `pkg_dir` is the root directory of the package; `loader`, `standard_tests`, and `pattern` are the arguments expected by `load_tests`. In simple cases, the test package's `__init__.py` can be the following:

```
import os
from test.support import load_package_tests

def load_tests(*args):
    return load_package_tests(os.path.dirname(__file__), *args)
```

`test.support.detect_api_mismatch(ref_api, other_api, *, ignore=())`

Returns the set of attributes, functions or methods of `ref_api` not found on `other_api`, except for a defined list of items to be ignored in this check specified in `ignore`.

這預設會跳過以 `'_'` 開頭的私有屬性，但會包含所有魔術方法，即以 `'__'` 開頭和結尾的方法。

在 3.5 版被加入。

`test.support.patch(test_instance, object_to_patch, attr_name, new_value)`

Override `object_to_patch.attr_name` with `new_value`. Also add cleanup procedure to `test_instance` to restore `object_to_patch` for `attr_name`. The `attr_name` should be a valid attribute for `object_to_patch`.

`test.support.run_in_subinterp(code)`

Run `code` in subinterpreter. Raise `unittest.SkipTest` if `tracemalloc` is enabled.

`test.support.check_free_after_iterating(test, iter, cls, args=())`

Assert instances of `cls` are deallocated after iterating.

`test.support.missing_compiler_executable(cmd_names=[])`

Check for the existence of the compiler executables whose names are listed in `cmd_names` or all the compiler executables when `cmd_names` is empty and return the first missing executable or `None` when none is found missing.

`test.support.check__all__(test_case, module, name_of_module=None, extra=(), not_exported=())`

Assert that the `__all__` variable of `module` contains all public names.

The module's public names (its API) are detected automatically based on whether they match the public name convention and were defined in `module`.

The `name_of_module` argument can specify (as a string or tuple thereof) what module(s) an API could be defined in order to be detected as a public API. One case for this is when `module` imports part of its public API from other modules, possibly a C backend (like `csv` and its `_csv`).

The `extra` argument can be a set of names that wouldn't otherwise be automatically detected as "public", like objects without a proper `__module__` attribute. If provided, it will be added to the automatically detected ones.

The `not_exported` argument can be a set of names that must not be treated as part of the public API even though their names indicate otherwise.

用法範例：

```
import bar
import foo
import unittest
from test import support

class MiscTestCase(unittest.TestCase):
    def test__all__(self):
        support.check__all__(self, foo)

class OtherTestCase(unittest.TestCase):
```

(繼續下一頁)

(繼續上一頁)

```
def test__all__(self):
    extra = {'BAR_CONST', 'FOO_CONST'}
    not_exported = {'baz'} # Undocumented name.
    # bar imports part of its API from _bar.
    support.check__all__(self, bar, ('bar', '_bar'),
                           extra=extra, not_exported=not_exported)
```

在 3.6 版被加入。

`test.support.skip_if_broken_multiprocessing_synchronize()`

Skip tests if the `multiprocessing.synchronize` module is missing, if there is no available semaphore implementation, or if creating a lock raises an `OSError`.

在 3.10 版被加入。

`test.support.check_disallow_instantiation(test_case, tp, *args, **kwargs)`

Assert that type `tp` cannot be instantiated using `args` and `kwargs`.

在 3.10 版被加入。

`test.support.adjust_int_max_str_digits(max_digits)`

This function returns a context manager that will change the global `sys.set_int_max_str_digits()` setting for the duration of the context to allow execution of test code that needs a different limit on the number of digits when converting between an integer and string.

在 3.11 版被加入。

`test.support` 模組定義了以下類別：

class `test.support.SuppressCrashReport`

A context manager used to try to prevent crash dialog popups on tests that are expected to crash a subprocess.

On Windows, it disables Windows Error Reporting dialogs using `SetErrorMode`.

On UNIX, `resource.setrlimit()` is used to set `resource.RLIMIT_CORE`'s soft limit to 0 to prevent coredump file creation.

在兩個平台上，舊值會被 `__exit__()` 還原。

class `test.support.SaveSignals`

Class to save and restore signal handlers registered by the Python signal handler.

save (*self*)

Save the signal handlers to a dictionary mapping signal numbers to the current signal handler.

restore (*self*)

Set the signal numbers from the `save()` dictionary to the saved handler.

class `test.support.Matcher`

matches (*self*, *d*, ***kwargs*)

Try to match a single dict with the supplied arguments.

match_value (*self*, *k*, *dv*, *v*)

Try to match a single stored value (*dv*) with a supplied value (*v*).

26.10 `test.support.socket_helper` --- 用於 socket 測試的工具

The `test.support.socket_helper` module provides support for socket tests.

在 3.9 版被加入。

`test.support.socket_helper.IPV6_ENABLED`

Set to True if IPv6 is enabled on this host, False otherwise.

`test.support.socket_helper.find_unused_port` (*family=socket.AF_INET, socktype=socket.SOCK_STREAM*)

Returns an unused port that should be suitable for binding. This is achieved by creating a temporary socket with the same family and type as the `sock` parameter (default is `AF_INET`, `SOCK_STREAM`), and binding it to the specified host address (defaults to `0.0.0.0`) with the port set to 0, eliciting an unused ephemeral port from the OS. The temporary socket is then closed and deleted, and the ephemeral port is returned.

Either this method or `bind_port()` should be used for any tests where a server socket needs to be bound to a particular port for the duration of the test. Which one to use depends on whether the calling code is creating a Python socket, or if an unused port needs to be provided in a constructor or passed to an external program (i.e. the `-accept` argument to openssl's `s_server` mode). Always prefer `bind_port()` over `find_unused_port()` where possible. Using a hard coded port is discouraged since it can make multiple instances of the test impossible to run simultaneously, which is a problem for buildbots.

`test.support.socket_helper.bind_port` (*sock, host=HOST*)

Bind the socket to a free port and return the port number. Relies on ephemeral ports in order to ensure we are using an unbound port. This is important as many tests may be running simultaneously, especially in a buildbot environment. This method raises an exception if the `sock.family` is `AF_INET` and `sock.type` is `SOCK_STREAM`, and the socket has `SO_REUSEADDR` or `SO_REUSEPORT` set on it. Tests should never set these socket options for TCP/IP sockets. The only case for setting these options is testing multicasting via multiple UDP sockets.

Additionally, if the `SO_EXCLUSIVEADDRUSE` socket option is available (i.e. on Windows), it will be set on the socket. This will prevent anyone else from binding to our host/port for the duration of the test.

`test.support.socket_helper.bind_unix_socket` (*sock, addr*)

Bind a Unix socket, raising `unittest.SkipTest` if `PermissionError` is raised.

`@test.support.socket_helper.skip_unless_bind_unix_socket`

A decorator for running tests that require a functional `bind()` for Unix sockets.

`test.support.socket_helper.transient_internet` (*resource_name, *, timeout=30.0, errnos=()*)

A context manager that raises `ResourceDenied` when various issues with the internet connection manifest themselves as exceptions.

26.11 `test.support.script_helper` --- 用於 Python 執行測試的工具

`test.support.script_helper` 模組提供 Python 的本機執行測試的支援。

`test.support.script_helper.interpreter_requires_environment` ()

Return True if `sys.executable` interpreter requires environment variables in order to be able to run at all.

This is designed to be used with `@unittest.skipIf()` to annotate tests that need to use an `assert_python*()` function to launch an isolated mode (`-I`) or no environment mode (`-E`) sub-interpreter process.

A normal build & test does not run into this situation but it can happen when trying to run the standard library test suite from an interpreter that doesn't have an obvious home with Python's current home finding logic.

Setting `PYTHONHOME` is one way to get most of the testsuite to run in that situation. `PYTHONPATH` or `PYTHONUSERSITE` are other common environment variables that might impact whether or not the interpreter can start.

`test.support.script_helper.run_python_until_end(*args, **env_vars)`

Set up the environment based on *env_vars* for running the interpreter in a subprocess. The values can include `__isolated`, `__cleanenv`, `__cwd`, and `TERM`.

在 3.9 版的變更: 此函式不再從 *stderr* 中移除空白。

`test.support.script_helper.assert_python_ok(*args, **env_vars)`

Assert that running the interpreter with *args* and optional environment variables *env_vars* succeeds (`rc == 0`) and return a (return code, stdout, stderr) tuple.

If the `__cleanenv` keyword-only parameter is set, *env_vars* is used as a fresh environment.

Python is started in isolated mode (command line option `-I`), except if the `__isolated` keyword-only parameter is set to `False`.

在 3.9 版的變更: 此函式不再從 *stderr* 中移除空白。

`test.support.script_helper.assert_python_failure(*args, **env_vars)`

Assert that running the interpreter with *args* and optional environment variables *env_vars* fails (`rc != 0`) and return a (return code, stdout, stderr) tuple.

更多選項請見 `assert_python_ok()`。

在 3.9 版的變更: 此函式不再從 *stderr* 中移除空白。

`test.support.script_helper.spawn_python(*args, stdout=subprocess.PIPE,
stderr=subprocess.STDOUT, **kw)`

Run a Python subprocess with the given arguments.

kw is extra keyword args to pass to `subprocess.Popen()`. Returns a `subprocess.Popen` object.

`test.support.script_helper.kill_python(p)`

Run the given `subprocess.Popen` process until completion and return stdout.

`test.support.script_helper.make_script(script_dir, script_basename, source, omit_suffix=False)`

Create script containing *source* in path *script_dir* and *script_basename*. If *omit_suffix* is `False`, append `.py` to the name. Return the full script path.

`test.support.script_helper.make_zip_script(zip_dir, zip_basename, script_name,
name_in_zip=None)`

Create zip file at *zip_dir* and *zip_basename* with extension `zip` which contains the files in *script_name*. *name_in_zip* is the archive name. Return a tuple containing (full path, full path of archive name).

`test.support.script_helper.make_pkg(pkg_dir, init_source="")`

Create a directory named *pkg_dir* containing an `__init__` file with *init_source* as its contents.

`test.support.script_helper.make_zip_pkg(zip_dir, zip_basename, pkg_name, script_basename,
source, depth=1, compiled=False)`

Create a zip package directory with a path of *zip_dir* and *zip_basename* containing an empty `__init__` file and a file *script_basename* containing the *source*. If *compiled* is `True`, both source files will be compiled and added to the zip package. Return a tuple of the full zip path and the archive name for the zip file.

26.12 `test.support.bytecode_helper` --- 用於測試位元組碼能正確 生的支援工具

`test.support.bytecode_helper` 模組提供測試和檢查位元組碼 生的支援。

在 3.9 版被加入。

此模組定義了以下類：

class `test.support.bytecode_helper.BytecodeTestCase` (`unittest.TestCase`)

This class has custom assertion methods for inspecting bytecode.

`BytecodeTestCase.get_disassembly_as_string` (`co`)

Return the disassembly of `co` as string.

`BytecodeTestCase.assertInBytecode` (`x`, `opname`, `argval=_UNSPECIFIED`)

Return instr if `opname` is found, otherwise throws `AssertionError`.

`BytecodeTestCase.assertNotInBytecode` (`x`, `opname`, `argval=_UNSPECIFIED`)

Throws `AssertionError` if `opname` is found.

26.13 `test.support.threading_helper` --- Utilities for threading tests

The `test.support.threading_helper` module provides support for threading tests.

在 3.10 版被加入。

`test.support.threading_helper.join_thread` (`thread`, `timeout=None`)

Join a `thread` within `timeout`. Raise an `AssertionError` if thread is still alive after `timeout` seconds.

@`test.support.threading_helper.reap_threads`

Decorator to ensure the threads are cleaned up even if the test fails.

`test.support.threading_helper.start_threads` (`threads`, `unlock=None`)

Context manager to start `threads`, which is a sequence of threads. `unlock` is a function called after the threads are started, even if an exception was raised; an example would be `threading.Event.set()`. `start_threads` will attempt to join the started threads upon exit.

`test.support.threading_helper.threading_cleanup` (`*original_values`)

Cleanup up threads not specified in `original_values`. Designed to emit a warning if a test leaves running threads in the background.

`test.support.threading_helper.threading_setup` ()

Return current thread count and copy of dangling threads.

`test.support.threading_helper.wait_threads_exit` (`timeout=None`)

Context manager to wait until all threads created in the `with` statement exit.

`test.support.threading_helper.catch_threading_exception` ()

Context manager catching `threading.Thread` exception using `threading.excepthook()`.

當捕捉到例外時會設定的屬性：

- `exc_type`
- `exc_value`
- `exc_traceback`
- `thread`

參閱 `threading.excepthook()` 文件。

這些屬性會在離開情境管理器時被刪除。

用法：

```
with threading_helper.catch_threading_exception() as cm:
    # code spawning a thread which raises an exception
    ...

    # check the thread exception, use cm attributes:
    # exc_type, exc_value, exc_traceback, thread
    ...

# exc_type, exc_value, exc_traceback, thread attributes of cm no longer
# exists at this point
# (to avoid reference cycles)
```

在 3.8 版被加入。

26.14 test.support.os_helper --- 用於 os 測試的工具

`test.support.os_helper` 模組提供 os 測試的支援。

在 3.10 版被加入。

`test.support.os_helper.FS_NONASCII`

A non-ASCII character encodable by `os.fsencode()`.

`test.support.os_helper.SAVEDCWD`

設定為 `os.getcwd()`。

`test.support.os_helper.TESTFN`

Set to a name that is safe to use as the name of a temporary file. Any temporary file that is created should be closed and unlinked (removed).

`test.support.os_helper.TESTFN_NONASCII`

Set to a filename containing the `FS_NONASCII` character, if it exists. This guarantees that if the filename exists, it can be encoded and decoded with the default filesystem encoding. This allows tests that require a non-ASCII filename to be easily skipped on platforms where they can't work.

`test.support.os_helper.TESTFN_UNENCODABLE`

Set to a filename (str type) that should not be able to be encoded by file system encoding in strict mode. It may be None if it's not possible to generate such a filename.

`test.support.os_helper.TESTFN_UNDECODABLE`

Set to a filename (bytes type) that should not be able to be decoded by file system encoding in strict mode. It may be None if it's not possible to generate such a filename.

`test.support.os_helper.TESTFN_UNICODE`

Set to a non-ASCII name for a temporary file.

class `test.support.os_helper.EnvironmentVarGuard`

Class used to temporarily set or unset environment variables. Instances can be used as a context manager and have a complete dictionary interface for querying/modifying the underlying `os.environ`. After exit from the context manager all changes to environment variables done through this instance will be rolled back.

在 3.1 版的變更: 新增字典介面。

class `test.support.os_helper.FakePath(path)`

Simple *path-like object*. It implements the `__fspath__()` method which just returns the `path` argument. If `path` is an exception, it will be raised in `__fspath__()`.

`EnvironmentVarGuard.set(envvar, value)`

Temporarily set the environment variable `envvar` to the value of `value`.

`EnvironmentVarGuard.unset(envvar)`

暫時取消環境變數 `envvar`。

`test.support.os_helper.can_symlink()`

如果作業系統支援符號連結則回傳 `True`，否則回傳 `False`。

`test.support.os_helper.can_xattr()`

如果作業系統支援 `xattr` 則回傳 `True`，否則回傳 `False`。

`test.support.os_helper.change_cwd(path, quiet=False)`

A context manager that temporarily changes the current working directory to `path` and yields the directory.

If `quiet` is `False`, the context manager raises an exception on error. Otherwise, it issues only a warning and keeps the current working directory the same.

`test.support.os_helper.create_empty_file(filename)`

Create an empty file with `filename`. If it already exists, truncate it.

`test.support.os_helper.fd_count()`

Count the number of open file descriptors.

`test.support.os_helper.fs_is_case_insensitive(directory)`

Return `True` if the file system for `directory` is case-insensitive.

`test.support.os_helper.make_bad_fd()`

Create an invalid file descriptor by opening and closing a temporary file, and returning its descriptor.

`test.support.os_helper.rmdir(filename)`

Call `os.rmdir()` on `filename`. On Windows platforms, this is wrapped with a wait loop that checks for the existence of the file, which is needed due to antivirus programs that can hold files open and prevent deletion.

`test.support.os_helper.rmtree(path)`

Call `shutil.rmtree()` on `path` or call `os.lstat()` and `os.rmdir()` to remove a path and its contents. As with `rmdir()`, on Windows platforms this is wrapped with a wait loop that checks for the existence of the files.

`@test.support.os_helper.skip_unless_symlink`

A decorator for running tests that require support for symbolic links.

`@test.support.os_helper.skip_unless_xattr`

A decorator for running tests that require support for `xattr`.

`test.support.os_helper.temp_cwd(name='tempcwd', quiet=False)`

A context manager that temporarily creates a new directory and changes the current working directory (CWD).

The context manager creates a temporary directory in the current directory with name `name` before temporarily changing the current working directory. If `name` is `None`, the temporary directory is created using `tempfile.mkdtemp()`.

If `quiet` is `False` and it is not possible to create or change the CWD, an error is raised. Otherwise, only a warning is raised and the original CWD is used.

`test.support.os_helper.temp_dir(path=None, quiet=False)`

A context manager that creates a temporary directory at `path` and yields the directory.

If `path` is `None`, the temporary directory is created using `tempfile.mkdtemp()`. If `quiet` is `False`, the context manager raises an exception on error. Otherwise, if `path` is specified and cannot be created, only a warning is issued.

`test.support.os_helper.temp_umask(umask)`

A context manager that temporarily sets the process umask.

```
test.support.os_helper.unlink(filename)
```

Call `os.unlink()` on *filename*. As with `rmdir()`, on Windows platforms, this is wrapped with a wait loop that checks for the existence of the file.

26.15 test.support.import_helper --- 用於 import 測試的工具

`test.support.import_helper` 模組提供 import 測試的支援。

在 3.10 版被加入。

```
test.support.import_helper.forget(module_name)
```

Remove the module named *module_name* from `sys.modules` and delete any byte-compiled files of the module.

```
test.support.import_helper.import_fresh_module(name, fresh=(), blocked=(),
                                                deprecated=False)
```

This function imports and returns a fresh copy of the named Python module by removing the named module from `sys.modules` before doing the import. Note that unlike `reload()`, the original module is not affected by this operation.

fresh is an iterable of additional module names that are also removed from the `sys.modules` cache before doing the import.

blocked is an iterable of module names that are replaced with `None` in the module cache during the import to ensure that attempts to import them raise `ImportError`.

The named module and any modules named in the *fresh* and *blocked* parameters are saved before starting the import and then reinserted into `sys.modules` when the fresh import is complete.

Module and package deprecation messages are suppressed during this import if *deprecated* is `True`.

如果無法引入指定的模組則此函式會引發 `ImportError`。

用法範例：

```
# Get copies of the warnings module for testing without affecting the
# version being used by the rest of the test suite. One copy uses the
# C implementation, the other is forced to use the pure Python fallback
# implementation
py_warnings = import_fresh_module('warnings', blocked=['_warnings'])
c_warnings = import_fresh_module('warnings', fresh=['_warnings'])
```

在 3.1 版被加入。

```
test.support.import_helper.import_module(name, deprecated=False, *, required_on=())
```

This function imports and returns the named module. Unlike a normal import, this function raises `unittest.SkipTest` if the module cannot be imported.

Module and package deprecation messages are suppressed during this import if *deprecated* is `True`. If a module is required on a platform but optional for others, set *required_on* to an iterable of platform prefixes which will be compared against `sys.platform`.

在 3.1 版被加入。

```
test.support.import_helper.modules_setup()
```

回傳 `sys.modules` 的副本。

```
test.support.import_helper.modules_cleanup(oldmodules)
```

Remove modules except for *oldmodules* and encodings in order to preserve internal cache.

```
test.support.import_helper.unload(name)
```

從 `sys.modules` 中刪除 *name*。

`test.support.import_helper.make_legacy_pyc(source)`

Move a [PEP 3147/PEP 488](#) pyc file to its legacy pyc location and return the file system path to the legacy pyc file. The *source* value is the file system path to the source file. It does not need to exist, however the PEP 3147/488 pyc file must exist.

class `test.support.import_helper.CleanImport(*module_names)`

A context manager to force import to return a new module reference. This is useful for testing module-level behaviors, such as the emission of a [DeprecationWarning](#) on import. Example usage:

```
with CleanImport('foo'):
    importlib.import_module('foo') # New reference.
```

class `test.support.import_helper.DirsOnSysPath(*paths)`

A context manager to temporarily add directories to `sys.path`.

This makes a copy of `sys.path`, appends any directories given as positional arguments, then reverts `sys.path` to the copied settings when the context ends.

Note that *all* `sys.path` modifications in the body of the context manager, including replacement of the object, will be reverted at the end of the block.

26.16 test.support.warnings_helper --- 用於 warnings 測試的工具

`test.support.warnings_helper` 模組提供 warnings 測試的支援。

在 3.10 版被加入。

`test.support.warnings_helper.ignore_warnings(*, category)`

Suppress warnings that are instances of *category*, which must be [Warning](#) or a subclass. Roughly equivalent to `warnings.catch_warnings()` with `warnings.simplefilter('ignore', category=category)`. For example:

```
@warning_helper.ignore_warnings(category=DeprecationWarning)
def test_suppress_warning():
    # do something
```

在 3.8 版被加入。

`test.support.warnings_helper.check_no_resource_warning(testcase)`

Context manager to check that no [ResourceWarning](#) was raised. You must remove the object which may emit [ResourceWarning](#) before the end of the context manager.

`test.support.warnings_helper.check_syntax_warning(testcase, statement, errtext="*", lineno=1, offset=None)`

Test for syntax warning in *statement* by attempting to compile *statement*. Test also that the [SyntaxWarning](#) is emitted only once, and that it will be converted to a [SyntaxError](#) when turned into error. *testcase* is the [unittest](#) instance for the test. *errtext* is the regular expression which should match the string representation of the emitted [SyntaxWarning](#) and raised [SyntaxError](#). If *lineno* is not None, compares to the line of the warning and exception. If *offset* is not None, compares to the offset of the exception.

在 3.8 版被加入。

`test.support.warnings_helper.check_warnings(*filters, quiet=True)`

A convenience wrapper for `warnings.catch_warnings()` that makes it easier to test that a warning was correctly raised. It is approximately equivalent to calling `warnings.catch_warnings(record=True)` with `warnings.simplefilter()` set to always and with the option to automatically validate the results that are recorded.

`check_warnings` accepts 2-tuples of the form `("message regexp", WarningCategory)` as positional arguments. If one or more *filters* are provided, or if the optional keyword argument *quiet* is `False`, it checks to make sure the warnings are as expected: each specified filter must match at least one of the warnings raised by the enclosed code or the test fails, and if any warnings are raised that do not match any of the specified filters the test fails. To disable the first of these checks, set *quiet* to `True`.

如果有指定引數，預設：

```
check_warnings(("", Warning), quiet=True)
```

In this case all warnings are caught and no errors are raised.

On entry to the context manager, a `WarningRecorder` instance is returned. The underlying warnings list from `catch_warnings()` is available via the recorder object's `warnings` attribute. As a convenience, the attributes of the object representing the most recent warning can also be accessed directly through the recorder object (see example below). If no warning has been raised, then any of the attributes that would otherwise be expected on an object representing a warning will return `None`.

The recorder object also has a `reset()` method, which clears the warnings list.

The context manager is designed to be used like this:

```
with check_warnings(("assertion is always true", SyntaxWarning),
                    ("", UserWarning)):
    exec('assert(False, "Hey!")')
    warnings.warn(UserWarning("Hide me!"))
```

In this case if either warning was not raised, or some other warning was raised, `check_warnings()` would raise an error.

When a test needs to look more deeply into the warnings, rather than just checking whether or not they occurred, code like this can be used:

```
with check_warnings(quiet=True) as w:
    warnings.warn("foo")
    assert str(w.args[0]) == "foo"
    warnings.warn("bar")
    assert str(w.args[0]) == "bar"
    assert str(w.warnings[0].args[0]) == "foo"
    assert str(w.warnings[1].args[0]) == "bar"
    w.reset()
    assert len(w.warnings) == 0
```

Here all warnings will be caught, and the test code tests the captured warnings directly.

在 3.2 版的變更: 新的可選引數 *filters* 和 *quiet*。

class `test.support.warnings_helper.WarningRecorder`

Class used to record warnings for unit tests. See documentation of `check_warnings()` above for more details.

除錯與效能分析

這些函式庫幫助你進行 Python 程式開發：除錯器允許你在程式碼中單步 (step) 執行、分析堆疊框 (stack frames) 以及設置中斷點 (breakpoints) 等，效能分析工具執行程式碼提供關於執行時間的詳細分析，讓你找到程式中的瓶頸 (bottlenecks)。事件稽核 (auditing events) 提供執行時期行為的可見性，否則的話可能需要更侵入性的除錯或修補。

27.1 稽核事件表

這張表包含了所有在 CPython 運行環境 (runtime) 與標準函式庫對於 `sys.audit()` 或 `PySys_Audit()` 的呼叫所觸發的事件。這些呼叫是在 3.8 或更新的版本中被新增 (請見 [PEP 578](#))。

請參考 `sys.addaudithook()` 及 `PySys_AddAuditHook()` 來了解如何處理這些事件。

CPython 實作細節：這張表是從 CPython 文件生成的，可能不包含其它實作所觸發的事件。請參考你的運行環境 (runtime) 特定文件來了解實際會觸發的事件。

Audit event	Arguments

27.2 bdb --- 偵錯器框架

原始碼: [Lib/bdb.py](#)

The `bdb` module handles basic debugger functions, like setting breakpoints or managing execution via the debugger. 有定義以下例外:

exception `bdb.BdbQuit`

由 `Bdb` 類所引發的例外，用來退出偵錯器。

`bdb` 模組也定義了兩個類:

class `bdb.Breakpoint` (*self, file, line, temporary=False, cond=None, funcname=None*)

This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

Breakpoints are indexed by number through a list called `bpbynumber` and by (`file`, `line`) pairs through `bplist`. The former points to a single instance of class `Breakpoint`. The latter points to a list of such instances since there may be more than one breakpoint per line.

When creating a breakpoint, its associated `file name` should be in canonical form. If a `funcname` is defined, a breakpoint `hit` will be counted when the first line of that function is executed. A `conditional` breakpoint always counts a `hit`.

`Breakpoint` 實例有以下方法:

deleteMe ()

Delete the breakpoint from the list associated to a file/line. If it is the last breakpoint in that position, it also deletes the entry for the file/line.

enable ()

Mark the breakpoint as enabled.

disable ()

Mark the breakpoint as disabled.

bpformat ()

Return a string with all the information about the breakpoint, nicely formatted:

- Breakpoint number.
- Temporary status (del or keep).
- File/line position.
- Break condition.
- Number of times to ignore.

- Number of times hit.

在 3.2 版被加入。

bpprint (*out=None*)

Print the output of *bpformat* () to the file *out*, or if it is None, to standard output.

Breakpoint instances have the following attributes:

file

File name of the *Breakpoint*.

line

Line number of the *Breakpoint* within *file*.

temporary

True if a *Breakpoint* at (file, line) is temporary.

cond

Condition for evaluating a *Breakpoint* at (file, line).

funcname

Function name that defines whether a *Breakpoint* is hit upon entering the function.

enabled

如 *Breakpoint* 有被用則 True。

bpbynumber

Numeric index for a single instance of a *Breakpoint*.

bplist

Dictionary of *Breakpoint* instances indexed by (*file*, *line*) tuples.

ignore

Number of times to ignore a *Breakpoint*.

hits

Count of the number of times a *Breakpoint* has been hit.

class `bdb.Bdb` (*skip=None*)

The *Bdb* class acts as a generic Python debugger base class.

This class takes care of the details of the trace facility; a derived class should implement user interaction. The standard debugger class (*pdb.Pdb*) is an example.

The *skip* argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

在 3.1 版的變更: 新增 *skip* 引數。

The following methods of *Bdb* normally don't need to be overridden.

canonic (*filename*)

Return canonical form of *filename*.

For real file names, the canonical form is an operating-system-dependent, *case-normalized absolute path*. A *filename* with angle brackets, such as "<stdin>" generated in interactive mode, is returned unchanged.

reset ()

Set the *botframe*, *stopframe*, *returnframe* and *quitting* attributes with values ready to start debugging.

trace_dispatch (*frame, event, arg*)

This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. *event* can be one of the following:

- "line": A new line of code is going to be executed.
- "call": A function is about to be called, or another code block entered.
- "return": A function or other code block is about to return.
- "exception": An exception has occurred.
- "c_call": A C function is about to be called.
- "c_return": A C function has returned.
- "c_exception": A C function has raised an exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

The *arg* parameter depends on the previous event.

See the documentation for `sys.settrace()` for more information on the trace function. For more information on code and frame objects, refer to types.

dispatch_line (*frame*)

If the debugger should stop on the current line, invoke the `user_line()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `quitting` flag is set (which can be set from `user_line()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

dispatch_call (*frame, arg*)

If the debugger should stop on this function call, invoke the `user_call()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `quitting` flag is set (which can be set from `user_call()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

dispatch_return (*frame, arg*)

If the debugger should stop on this function return, invoke the `user_return()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `quitting` flag is set (which can be set from `user_return()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

dispatch_exception (*frame, arg*)

If the debugger should stop at this exception, invokes the `user_exception()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `quitting` flag is set (which can be set from `user_exception()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

Normally derived classes don't override the following methods, but they may if they want to redefine the definition of stopping and breakpoints.

is_skipped_line (*module_name*)

Return True if *module_name* matches any skip pattern.

stop_here (*frame*)

Return True if *frame* is below the starting frame in the stack.

break_here (*frame*)

Return True if there is an effective breakpoint for this line.

Check whether a line or function breakpoint exists and is in effect. Delete temporary breakpoints based on information from `effective()`.

break_anywhere (*frame*)

Return True if any breakpoint exists for *frame*'s filename.

Derived classes should override these methods to gain control over debugger operation.

user_call (*frame*, *argument_list*)

Called from `dispatch_call()` if a break might stop inside the called function.

argument_list is not used anymore and will always be None. The argument is kept for backwards compatibility.

user_line (*frame*)

Called from `dispatch_line()` when either `stop_here()` or `break_here()` returns True.

user_return (*frame*, *return_value*)

Called from `dispatch_return()` when `stop_here()` returns True.

user_exception (*frame*, *exc_info*)

Called from `dispatch_exception()` when `stop_here()` returns True.

do_clear (*arg*)

Handle how a breakpoint must be removed when it is a temporary one.

This method must be implemented by derived classes.

Derived classes and clients can call the following methods to affect the stepping state.

set_step ()

Stop after one line of code.

set_next (*frame*)

Stop on the next line in or below the given frame.

set_return (*frame*)

Stop when returning from the given frame.

set_until (*frame*, *lineno=None*)

Stop when the line with the *lineno* greater than the current one is reached or when returning from current frame.

set_trace ([*frame*])

Start debugging from *frame*. If *frame* is not specified, debugging starts from caller's frame.

在 3.13 版的變更: `set_trace()` will enter the debugger immediately, rather than on the next line of code to be executed.

set_continue ()

Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to None.

set_quit ()

Set the quitting attribute to True. This raises `BdbQuit` in the next call to one of the `dispatch_*()` methods.

Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or None if all is well.

set_break (*filename*, *lineno*, *temporary=False*, *cond=None*, *funcname=None*)

Set a new breakpoint. If the *lineno* line doesn't exist for the *filename* passed as argument, return an error message. The *filename* should be in canonical form, as described in the `canonic()` method.

clear_break (*filename*, *lineno*)

Delete the breakpoints in *filename* and *lineno*. If none were set, return an error message.

clear_bpbynumber (*arg*)

Delete the breakpoint which has the index *arg* in the `Breakpoint.bpbynumber`. If *arg* is not numeric or out of range, return an error message.

clear_all_file_breaks (*filename*)

Delete all breakpoints in *filename*. If none were set, return an error message.

clear_all_breaks ()

Delete all existing breakpoints. If none were set, return an error message.

get_bpbynumber (*arg*)

Return a breakpoint specified by the given number. If *arg* is a string, it will be converted to a number. If *arg* is a non-numeric string, if the given breakpoint never existed or has been deleted, a `ValueError` is raised.

在 3.2 版被加入。

get_break (*filename*, *lineno*)

Return `True` if there is a breakpoint for *lineno* in *filename*.

get_breaks (*filename*, *lineno*)

Return all breakpoints for *lineno* in *filename*, or an empty list if none are set.

get_file_breaks (*filename*)

Return all breakpoints in *filename*, or an empty list if none are set.

get_all_breaks ()

Return all breakpoints that are set.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

get_stack (*f*, *t*)

Return a list of (frame, lineno) tuples in a stack trace, and a size.

The most recently called frame is last in the list. The size is the number of frames below the frame where the debugger was invoked.

format_stack_entry (*frame_lineno*, *lprefix*=': ')

Return a string with information about a stack entry, which is a (frame, lineno) tuple. The return string contains:

- The canonical filename which contains the frame.
- 函式名稱或 "<lambda>"。
- 輸入引數。
- 回傳值。
- The line of code (if it exists).

The following two methods can be called by clients to use a debugger to debug a *statement*, given as a string.

run (*cmd*, *globals*=None, *locals*=None)

Debug a statement executed via the `exec()` function. *globals* defaults to `__main__.__dict__`, *locals* defaults to *globals*.

runeval (*expr*, *globals*=None, *locals*=None)

Debug an expression executed via the `eval()` function. *globals* and *locals* have the same meaning as in `run()`.

runctx (*cmd*, *globals*, *locals*)

For backwards compatibility. Calls the `run()` method.

runcall (*func*, /, **args*, ***kws*)

Debug a single function call, and return its result.

Finally, the module defines the following functions:

bdb.checkfuncname (*b*, *frame*)

Return `True` if we should break here, depending on the way the *Breakpoint* *b* was set.

If it was set via line number, it checks if *b.line* is the same as the one in *frame*. If the breakpoint was set via *function name*, we have to check we are in the right *frame* (the right function) and if we are on its first executable line.

bdb.effective (*file*, *line*, *frame*)

Return (active breakpoint, delete temporary flag) or (`None`, `None`) as the breakpoint to act upon.

The *active breakpoint* is the first entry in *bplist* for the (*file*, *line*) (which must exist) that is *enabled*, for which *checkfuncname*() is true, and that has neither a false *condition* nor positive *ignore* count. The *flag*, meaning that a temporary breakpoint should be deleted, is `False` only when the *cond* cannot be evaluated (in which case, *ignore* count is ignored).

If no such entry exists, then (`None`, `None`) is returned.

bdb.set_trace ()

Start debugging with a *Bdb* instance from caller's frame.

27.3 faulthandler --- 傾印 Python 回溯

在 3.3 版被加入。

This module contains functions to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal. Call *faulthandler.enable*() to install fault handlers for the *SIGSEGV*, *SIGFPE*, *SIGABRT*, *SIGBUS*, and *SIGILL* signals. You can also enable them at startup by setting the `PYTHONFAULTHANDLER` environment variable or by using the `-X faulthandler` command line option.

The fault handler is compatible with system fault handlers like Apport or the Windows fault handler. The module uses an alternative stack for signal handlers if the *sigaltstack*() function is available. This allows it to dump the traceback even on a stack overflow.

The fault handler is called on catastrophic cases and therefore can only use signal-safe functions (e.g. it cannot allocate memory on the heap). Because of this limitation traceback dumping is minimal compared to normal Python tracebacks:

- Only ASCII is supported. The *backslashreplace* error handler is used on encoding.
- Each string is limited to 500 characters.
- Only the filename, the function name and the line number are displayed. (no source code)
- It is limited to 100 frames and 100 threads.
- The order is reversed: the most recent call is shown first.

By default, the Python traceback is written to *sys.stderr*. To see tracebacks, applications must be run in the terminal. A log file can alternatively be passed to *faulthandler.enable*().

The module is implemented in C, so tracebacks can be dumped on a crash or when Python is deadlocked.

The *Python Development Mode* calls *faulthandler.enable*() at Python startup.

也參考

***pdb* 模組**

Interactive source code debugger for Python programs.

***traceback* 模組**

Standard interface to extract, format and print stack traces of Python programs.

27.3.1 Dumping the traceback

`faulthandler.dump_traceback (file=sys.stderr, all_threads=True)`

Dump the tracebacks of all threads into *file*. If *all_threads* is `False`, dump only the current thread.

也參考

`traceback.print_tb()`, which can be used to print a traceback object.

在 3.5 版的變更: Added support for passing file descriptor to this function.

27.3.2 Fault handler state

`faulthandler.enable (file=sys.stderr, all_threads=True)`

Enable the fault handler: install handlers for the `SIGSEGV`, `SIGFPE`, `SIGABRT`, `SIGBUS` and `SIGILL` signals to dump the Python traceback. If *all_threads* is `True`, produce tracebacks for every running thread. Otherwise, dump only the current thread.

The *file* must be kept open until the fault handler is disabled: see *issue with file descriptors*.

在 3.5 版的變更: Added support for passing file descriptor to this function.

在 3.6 版的變更: On Windows, a handler for Windows exception is also installed.

在 3.10 版的變更: The dump now mentions if a garbage collector collection is running if *all_threads* is `true`.

`faulthandler.disable()`

Disable the fault handler: uninstall the signal handlers installed by `enable()`.

`faulthandler.is_enabled()`

Check if the fault handler is enabled.

27.3.3 Dumping the tracebacks after a timeout

`faulthandler.dump_traceback_later (timeout, repeat=False, file=sys.stderr, exit=False)`

Dump the tracebacks of all threads, after a timeout of *timeout* seconds, or every *timeout* seconds if *repeat* is `True`. If *exit* is `True`, call `_exit()` with status=1 after dumping the tracebacks. (Note `_exit()` exits the process immediately, which means it doesn't do any cleanup like flushing file buffers.) If the function is called twice, the new call replaces previous parameters and resets the timeout. The timer has a sub-second resolution.

The *file* must be kept open until the traceback is dumped or `cancel_dump_traceback_later()` is called: see *issue with file descriptors*.

This function is implemented using a watchdog thread.

在 3.5 版的變更: Added support for passing file descriptor to this function.

在 3.7 版的變更: This function is now always available.

`faulthandler.cancel_dump_traceback_later()`

Cancel the last call to `dump_traceback_later()`.

27.3.4 Dumping the traceback on a user signal

`faulthandler.register` (*signum*, *file=sys.stderr*, *all_threads=True*, *chain=False*)

Register a user signal: install a handler for the *signum* signal to dump the traceback of all threads, or of the current thread if *all_threads* is `False`, into *file*. Call the previous handler if *chain* is `True`.

The *file* must be kept open until the signal is unregistered by `unregister()`: see *issue with file descriptors*.

Not available on Windows.

在 3.5 版的變更: Added support for passing file descriptor to this function.

`faulthandler.unregister` (*signum*)

Unregister a user signal: uninstall the handler of the *signum* signal installed by `register()`. Return `True` if the signal was registered, `False` otherwise.

Not available on Windows.

27.3.5 Issue with file descriptors

`enable()`, `dump_traceback_later()` and `register()` keep the file descriptor of their *file* argument. If the file is closed and its file descriptor is reused by a new file, or if `os.dup2()` is used to replace the file descriptor, the traceback will be written into a different file. Call these functions again each time that the file is replaced.

27.3.6 范例

Example of a segmentation fault on Linux with and without enabling the fault handler:

```
$ python -c "import ctypes; ctypes.string_at(0)"
Segmentation fault

$ python -q -X faulthandler
>>> import ctypes
>>> ctypes.string_at(0)
Fatal Python error: Segmentation fault

Current thread 0x00007fb899f39700 (most recent call first):
  File "/home/python/cpython/Lib/ctypes/__init__.py", line 486 in string_at
  File "<stdin>", line 1 in <module>
Segmentation fault
```

27.4 pdb --- The Python Debugger

原始碼: [Lib/pdb.py](#)

The module `pdb` defines an interactive source code debugger for Python programs. It supports setting (conditional) breakpoints and single stepping at the source line level, inspection of stack frames, source code listing, and evaluation of arbitrary Python code in the context of any stack frame. It also supports post-mortem debugging and can be called under program control.

The debugger is extensible -- it is actually defined as the class `Pdb`. This is currently undocumented but easily understood by reading the source. The extension interface uses the modules `bdb` and `cmd`.

也參考

faulthandler 模組

Used to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal.

traceback 模組

Standard interface to extract, format and print stack traces of Python programs.

The typical usage to break into the debugger is to insert:

```
import pdb; pdb.set_trace()
```

或：

```
breakpoint()
```

at the location you want to break into the debugger, and then run the program. You can then step through the code following this statement, and continue running without the debugger using the *continue* command.

在 3.7 版的變更: The built-in *breakpoint()*, when called with defaults, can be used instead of `import pdb; pdb.set_trace()`.

```
def double(x):
    breakpoint()
    return x * 2
val = 3
print(f"{val} * 2 is {double(val)}")
```

The debugger's prompt is (Pdb), which is the indicator that you are in debug mode:

```
> ... (2) double()
-> breakpoint()
(Pdb) p x
3
(Pdb) continue
3 * 2 is 6
```

在 3.3 版的變更: Tab-completion via the *readline* module is available for commands and command arguments, e.g. the current global and local names are offered as arguments of the `p` command.

You can also invoke *pdb* from the command line to debug other scripts. For example:

```
python -m pdb myscript.py
```

When invoked as a module, *pdb* will automatically enter post-mortem debugging if the program being debugged exits abnormally. After post-mortem debugging (or after normal exit of the program), *pdb* will restart the program. Automatic restarting preserves *pdb*'s state (such as breakpoints) and in most cases is more useful than quitting the debugger upon program's exit.

在 3.2 版的變更: Added the `-c` option to execute commands as if given in a `.pdbrc` file; see *Debugger Commands*.

在 3.7 版的變更: Added the `-m` option to execute modules similar to the way `python -m` does. As with a script, the debugger will pause execution just before the first line of the module.

Typical usage to execute a statement under control of the debugger is:

```
>>> import pdb
>>> def f(x):
...     print(1 / x)
>>> pdb.run("f(2)")
> <string>(1)<module>()
(Pdb) continue
0.5
>>>
```

The typical usage to inspect a crashed program is:

```
>>> import pdb
>>> def f(x):
...     print(1 / x)
...
>>> f(0)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in f
ZeroDivisionError: division by zero
>>> pdb.pm()
> <stdin> (2) f()
(Pdb) p x
0
(Pdb)
```

在 3.13 版的變更: The implementation of [PEP 667](#) means that name assignments made via `pdb` will immediately affect the active scope, even when running inside an *optimized scope*.

The module defines the following functions; each enters the debugger in a slightly different way:

`pdb.run(statement, globals=None, locals=None)`

Execute the *statement* (given as a string or a code object) under debugger control. The debugger prompt appears before any code is executed; you can set breakpoints and type *continue*, or you can step through the statement using *step* or *next* (all these commands are explained below). The optional *globals* and *locals* arguments specify the environment in which the code is executed; by default the dictionary of the module `__main__` is used. (See the explanation of the built-in *exec()* or *eval()* functions.)

`pdb.runeval(expression, globals=None, locals=None)`

Evaluate the *expression* (given as a string or a code object) under debugger control. When *runeval()* returns, it returns the value of the *expression*. Otherwise this function is similar to *run()*.

`pdb.runcall(function, *args, **kwargs)`

Call the *function* (a function or method object, not a string) with the given arguments. When *runcall()* returns, it returns whatever the function call returned. The debugger prompt appears as soon as the function is entered.

`pdb.set_trace(*, header=None)`

Enter the debugger at the calling stack frame. This is useful to hard-code a breakpoint at a given point in a program, even if the code is not otherwise being debugged (e.g. when an assertion fails). If given, *header* is printed to the console just before debugging begins.

在 3.7 版的變更: The keyword-only argument *header*.

在 3.13 版的變更: *set_trace()* will enter the debugger immediately, rather than on the next line of code to be executed.

`pdb.post_mortem(traceback=None)`

Enter post-mortem debugging of the given *traceback* object. If no *traceback* is given, it uses the one of the exception that is currently being handled (an exception must be being handled if the default is to be used).

`pdb.pm()`

Enter post-mortem debugging of the exception found in `sys.last_exc`.

The *run** functions and *set_trace()* are aliases for instantiating the *Pdb* class and calling the method of the same name. If you want to access further features, you have to do this yourself:

class `pdb.Pdb` (*completekey='tab', stdin=None, stdout=None, skip=None, nosigint=False, readrc=True*)

Pdb is the debugger class.

The *completekey*, *stdin* and *stdout* arguments are passed to the underlying `cmd.Cmd` class; see the description there.

The *skip* argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns.¹

By default, Pdb sets a handler for the SIGINT signal (which is sent when the user presses Ctrl-C on the console) when you give a *continue* command. This allows you to break into the debugger again by pressing Ctrl-C. If you want Pdb not to touch the SIGINT handler, set *nosigint* to true.

The *readrc* argument defaults to true and controls whether Pdb will load .pdbrc files from the filesystem.

Example call to enable tracing with *skip*:

```
import pdb; pdb.Pdb(skip=['django.*']).set_trace()
```

引發一個不附帶引數的稽核事件 `pdb.Pdb`。

在 3.1 版的變更: Added the *skip* parameter.

在 3.2 版的變更: Added the *nosigint* parameter. Previously, a SIGINT handler was never set by Pdb.

在 3.6 版的變更: *readrc* 引數。

```
run (statement, globals=None, locals=None)
runeval (expression, globals=None, locals=None)
runcall (function, *args, **kwargs)
set_trace ()
```

See the documentation for the functions explained above.

27.4.1 Debugger Commands

The commands recognized by the debugger are listed below. Most commands can be abbreviated to one or two letters as indicated; e.g. `h(elp)` means that either `h` or `help` can be used to enter the help command (but not `he` or `hel`, nor `H` or `Help` or `HELP`). Arguments to commands must be separated by whitespace (spaces or tabs). Optional arguments are enclosed in square brackets (`[]`) in the command syntax; the square brackets must not be typed. Alternatives in the command syntax are separated by a vertical bar (`|`).

Entering a blank line repeats the last command entered. Exception: if the last command was a *list* command, the next 11 lines are listed.

Commands that the debugger doesn't recognize are assumed to be Python statements and are executed in the context of the program being debugged. Python statements can also be prefixed with an exclamation point (`!`). This is a powerful way to inspect the program being debugged; it is even possible to change a variable or call a function. When an exception occurs in such a statement, the exception name is printed but the debugger's state is not changed.

在 3.13 版的變更: Expressions/Statements whose prefix is a `pdb` command are now correctly identified and executed.

The debugger supports *aliases*. Aliases can have parameters which allows one a certain level of adaptability to the context under examination.

Multiple commands may be entered on a single line, separated by `;;`. (A single `;` is not used as it is the separator for multiple commands in a line that is passed to the Python parser.) No intelligence is applied to separating the commands; the input is split at the first `;;` pair, even if it is in the middle of a quoted string. A workaround for strings with double semicolons is to use implicit string concatenation `';;'` or `"";`.

To set a temporary global variable, use a *convenience variable*. A *convenience variable* is a variable whose name starts with `$`. For example, `$foo = 1` sets a global variable `$foo` which you can use in the debugger session. The *convenience variables* are cleared when the program resumes execution so it's less likely to interfere with your program compared to using normal variables like `foo = 1`.

There are three preset *convenience variables*:

- `$_frame`: the current frame you are debugging
- `$_retval`: the return value if the frame is returning

¹ Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

- `$_exception`: the exception if the frame is raising an exception

在 3.12 版被加入: Added the *convenience variable* feature.

If a file `.pdbrc` exists in the user's home directory or in the current directory, it is read with `'utf-8'` encoding and executed as if it had been typed at the debugger prompt, with the exception that empty lines and lines starting with `#` are ignored. This is particularly useful for aliases. If both files exist, the one in the home directory is read first and aliases defined there can be overridden by the local file.

在 3.2 版的變更: `.pdbrc` can now contain commands that continue debugging, such as `continue` or `next`. Previously, these commands had no effect.

在 3.11 版的變更: `.pdbrc` is now read with `'utf-8'` encoding. Previously, it was read with the system locale encoding.

h(elp) [command]

Without argument, print the list of available commands. With a *command* as argument, print help about that command. `help pdb` displays the full documentation (the docstring of the `pdb` module). Since the *command* argument must be an identifier, `help exec` must be entered to get help on the `!` command.

w(here)

Print a stack trace, with the most recent frame at the bottom. An arrow (`>`) indicates the current frame, which determines the context of most commands.

d(own) [count]

Move the current frame *count* (default one) levels down in the stack trace (to a newer frame).

u(p) [count]

Move the current frame *count* (default one) levels up in the stack trace (to an older frame).

b(reak) [(`[filename:]lineno` | *function*) [, *condition*]]

With a *lineno* argument, set a break at line *lineno* in the current file. The line number may be prefixed with a *filename* and a colon, to specify a breakpoint in another file (possibly one that hasn't been loaded yet). The file is searched on `sys.path`. Acceptable forms of *filename* are `/abspath/to/file.py`, `relpath/file.py`, `module` and `package.module`.

With a *function* argument, set a break at the first executable statement within that function. *function* can be any expression that evaluates to a function in the current namespace.

If a second argument is present, it is an expression which must evaluate to true before the breakpoint is honored.

Without argument, list all breaks, including for each breakpoint, the number of times that breakpoint has been hit, the current ignore count, and the associated condition if any.

Each breakpoint is assigned a number to which all the other breakpoint commands refer.

tbreak [(`[filename:]lineno` | *function*) [, *condition*]]

Temporary breakpoint, which is removed automatically when it is first hit. The arguments are the same as for `break`.

cl(ear) [`filename:lineno` | *bpnumber* ...]

With a `filename:lineno` argument, clear all the breakpoints at this line. With a space separated list of breakpoint numbers, clear those breakpoints. Without argument, clear all breaks (but first ask confirmation).

disable *bpnumber* [*bpnumber* ...]

Disable the breakpoints given as a space separated list of breakpoint numbers. Disabling a breakpoint means it cannot cause the program to stop execution, but unlike clearing a breakpoint, it remains in the list of breakpoints and can be (re-)enabled.

enable *bpnumber* [*bpnumber* ...]

Enable the breakpoints specified.

ignore *bpnumber* [*count*]

Set the ignore count for the given breakpoint number. If *count* is omitted, the ignore count is set to 0. A breakpoint becomes active when the ignore count is zero. When non-zero, the *count* is decremented each time the breakpoint is reached and the breakpoint is not disabled and any associated condition evaluates to true.

condition *bpnumber* [*condition*]

Set a new *condition* for the breakpoint, an expression which must evaluate to true before the breakpoint is honored. If *condition* is absent, any existing condition is removed; i.e., the breakpoint is made unconditional.

commands [*bpnumber*]

Specify a list of commands for breakpoint number *bpnumber*. The commands themselves appear on the following lines. Type a line containing just *end* to terminate the commands. An example:

```
(Pdb) commands 1
(com) p some_variable
(com) end
(Pdb)
```

To remove all commands from a breakpoint, type *commands* and follow it immediately with *end*; that is, give no commands.

With no *bpnumber* argument, *commands* refers to the last breakpoint set.

You can use breakpoint commands to start your program up again. Simply use the *continue* command, or *step*, or any other command that resumes execution.

Specifying any command resuming execution (currently *continue*, *step*, *next*, *return*, *jump*, *quit* and their abbreviations) terminates the command list (as if that command was immediately followed by *end*). This is because any time you resume execution (even with a simple *next* or *step*), you may encounter another breakpoint—which could have its own command list, leading to ambiguities about which list to execute.

If you use the *silent* command in the command list, the usual message about stopping at a breakpoint is not printed. This may be desirable for breakpoints that are to print a specific message and then continue. If none of the other commands print anything, you see no sign that the breakpoint was reached.

s (step)

Execute the current line, stop at the first possible occasion (either in a function that is called or on the next line in the current function).

n (next)

Continue execution until the next line in the current function is reached or it returns. (The difference between *next* and *step* is that *step* stops inside a called function, while *next* executes called functions at (nearly) full speed, only stopping at the next line in the current function.)

unt (il) [*lineno*]

Without argument, continue execution until the line with a number greater than the current one is reached.

With *lineno*, continue execution until a line with a number greater or equal to *lineno* is reached. In both cases, also stop when the current frame returns.

在 3.2 版的變更: Allow giving an explicit line number.

r (return)

Continue execution until the current function returns.

c (ont (inue))

Continue execution, only stop when a breakpoint is encountered.

j (ump) *lineno*

Set the next line that will be executed. Only available in the bottom-most frame. This lets you jump back and execute code again, or jump forward to skip code that you don't want to run.

It should be noted that not all jumps are allowed -- for instance it is not possible to jump into the middle of a *for* loop or out of a *finally* clause.

l(ist) [first[, last]]

List source code for the current file. Without arguments, list 11 lines around the current line or continue the previous listing. With `.` as argument, list 11 lines around the current line. With one argument, list 11 lines around at that line. With two arguments, list the given range; if the second argument is less than the first, it is interpreted as a count.

The current line in the current frame is indicated by `->`. If an exception is being debugged, the line where the exception was originally raised or propagated is indicated by `>>`, if it differs from the current line.

在 3.2 版的變更: Added the `>>` marker.

ll | `longlist`

List all source code for the current function or frame. Interesting lines are marked as for `list`.

在 3.2 版被加入.

a(rgs)

Print the arguments of the current function and their current values.

p *expression*

Evaluate *expression* in the current context and print its value.

備F

`print()` can also be used, but is not a debugger command --- this executes the Python `print()` function.

pp *expression*

Like the `p` command, except the value of *expression* is pretty-printed using the `pprint` module.

whatis *expression*

Print the type of *expression*.

source *expression*

Try to get source code of *expression* and display it.

在 3.2 版被加入.

display [*expression*]

Display the value of *expression* if it changed, each time execution stops in the current frame.

Without *expression*, list all display expressions for the current frame.

備F

Display evaluates *expression* and compares to the result of the previous evaluation of *expression*, so when the result is mutable, display may not be able to pick up the changes.

範例:

```
lst = []
breakpoint()
pass
lst.append(1)
print(lst)
```

Display won't realize `lst` has been changed because the result of evaluation is modified in place by `lst.append(1)` before being compared:

```
> example.py(3)<module>()
-> pass
(Pdb) display lst
display lst: []
(Pdb) n
> example.py(4)<module>()
-> lst.append(1)
(Pdb) n
> example.py(5)<module>()
-> print(lst)
(Pdb)
```

You can do some tricks with copy mechanism to make it work:

```
> example.py(3)<module>()
-> pass
(Pdb) display lst[:]
display lst[:]: []
(Pdb) n
> example.py(4)<module>()
-> lst.append(1)
(Pdb) n
> example.py(5)<module>()
-> print(lst)
display lst[:]: [1] [old: []]
(Pdb)
```

在 3.2 版被加入。

undisplay [expression]

Do not display *expression* anymore in the current frame. Without *expression*, clear all display expressions for the current frame.

在 3.2 版被加入。

interact

Start an interactive interpreter (using the `code` module) in a new global namespace initialised from the local and global namespaces for the current scope. Use `exit()` or `quit()` to exit the interpreter and return to the debugger.

備 F

As `interact` creates a new dedicated namespace for code execution, assignments to variables will not affect the original namespaces. However, modifications to any referenced mutable objects will be reflected in the original namespaces as usual.

在 3.2 版被加入。

在 3.13 版的變更: `exit()` and `quit()` can be used to exit the `interact` command.

在 3.13 版的變更: `interact` directs its output to the debugger's output channel rather than `sys.stderr`.

alias [name [command]]

Create an alias called *name* that executes *command*. The *command* must *not* be enclosed in quotes. Replaceable parameters can be indicated by `%1`, `%2`, ... and `%9`, while `.*` is replaced by all the parameters. If *command* is omitted, the current alias for *name* is shown. If no arguments are given, all aliases are listed.

Aliases may be nested and can contain anything that can be legally typed at the pdb prompt. Note that internal pdb commands *can* be overridden by aliases. Such a command is then hidden until the alias is removed. Aliasing is recursively applied to the first word of the command line; all other words in the line are left alone.

As an example, here are two useful aliases (especially when placed in the `.pdbrc` file):

```
# Print instance variables (usage "pi classInst")
alias pi for k in %1.__dict__.keys(): print(f"%1.{k} = {%1.__dict__[k]}")
# Print instance variables in self
alias ps pi self
```

unalias *name*

Delete the specified alias *name*.

! *statement*

Execute the (one-line) *statement* in the context of the current stack frame. The exclamation point can be omitted unless the first word of the statement resembles a debugger command, e.g.:

```
(Pdb) ! n=42
(Pdb)
```

To set a global variable, you can prefix the assignment command with a `global` statement on the same line, e.g.:

```
(Pdb) global list_options; list_options = ['-l']
(Pdb)
```

run [*args* ...]

restart [*args* ...]

Restart the debugged Python program. If *args* is supplied, it is split with `shlex` and the result is used as the new `sys.argv`. History, breakpoints, actions and debugger options are preserved. *restart* is an alias for *run*.

q(uit)

Quit from the debugger. The program being executed is aborted.

debug *code*

Enter a recursive debugger that steps through *code* (which is an arbitrary expression or statement to be executed in the current environment).

retval

Print the return value for the last return of the current function.

exceptions [*excnumber*]

List or jump between chained exceptions.

When using `pdb.pm()` or `Pdb.post_mortem(...)` with a chained exception instead of a traceback, it allows the user to move between the chained exceptions using `exceptions` command to list exceptions, and `exception <number>` to switch to that exception.

範例：

```
def out():
    try:
        middle()
    except Exception as e:
        raise ValueError("reraise middle() error") from e

def middle():
    try:
        return inner(0)
    except Exception as e:
        raise ValueError("Middle fail")

def inner(x):
    1 / x

out()
```

calling `pdb.pm()` will allow to move between exceptions:

```
> example.py(5)out()
-> raise ValueError("reraise middle() error") from e

(Pdb) exceptions
  0 ZeroDivisionError('division by zero')
  1 ValueError('Middle fail')
> 2 ValueError('reraise middle() error')

(Pdb) exceptions 0
> example.py(16)inner()
-> 1 / x

(Pdb) up
> example.py(10)middle()
-> return inner(0)
```

在 3.13 版被加入。

27.5 Python 的分析器

原始碼: `Lib/profile.py` 與 `Lib/pstats.py`

27.5.1 Introduction to the profilers

`cProfile` and `profile` provide *deterministic profiling* of Python programs. A *profile* is a set of statistics that describes how often and for how long various parts of the program executed. These statistics can be formatted into reports via the `pstats` module.

The Python standard library provides two different implementations of the same profiling interface:

1. `cProfile` is recommended for most users; it's a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on `lsprof`, contributed by Brett Rosen and Ted Czotter.
2. `profile`, a pure Python module whose interface is imitated by `cProfile`, but which adds significant overhead to profiled programs. If you're trying to extend the profiler in some way, the task might be easier with this module. Originally designed and written by Jim Roskind.

備 F

The profiler modules are designed to provide an execution profile for a given program, not for benchmarking purposes (for that, there is `timeit` for reasonably accurate results). This particularly applies to benchmarking Python code against C code: the profilers introduce overhead for Python code, but not for C-level functions, and so the C code would seem faster than any Python one.

27.5.2 Instant User's Manual

This section is provided for users that "don't want to read the manual." It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile a function that takes a single argument, you can do:

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")')
```

(Use `profile` instead of `cProfile` if the latter is not available on your system.)

The above action would run `re.compile()` and print profile results like the following:

```
214 function calls (207 primitive calls) in 0.002 seconds

Ordered by: cumulative time
```

ncalls	tottime	percall	cumtime	percall	filename:lineno(function)
1	0.000	0.000	0.002	0.002	{built-in method builtins.exec}
1	0.000	0.000	0.001	0.001	<string>:1(<module>)
1	0.000	0.000	0.001	0.001	__init__.py:250(compile)
1	0.000	0.000	0.001	0.001	__init__.py:289(_compile)
1	0.000	0.000	0.000	0.000	_compiler.py:759(compile)
1	0.000	0.000	0.000	0.000	_parser.py:937(parse)
1	0.000	0.000	0.000	0.000	_compiler.py:598(_code)
1	0.000	0.000	0.000	0.000	_parser.py:435(_parse_sub)

The first line indicates that 214 calls were monitored. Of those calls, 207 were *primitive*, meaning that the call was not induced via recursion. The next line: Ordered by: cumulative time indicates the output is sorted by the `cumtime` values. The column headings include:

ncalls

for the number of calls.

tottime

for the total time spent in the given function (and excluding time made in calls to sub-functions)

percall

is the quotient of `tottime` divided by `ncalls`

cumtime

is the cumulative time spent in this and all subfunctions (from invocation till exit). This figure is accurate *even* for recursive functions.

percall

is the quotient of `cumtime` divided by primitive calls

filename:lineno(function)

provides the respective data of each function

When there are two numbers in the first column (for example 3/1), it means that the function recursed. The second value is the number of primitive calls and the former is the total number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

Instead of printing the output at the end of the profile run, you can save the results to a file by specifying a filename to the `run()` function:

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")', 'restats')
```

The `pstats.Stats` class reads profile results from a file and formats them in various ways.

The files `cProfile` and `profile` can also be invoked as a script to profile another script. For example:

```
python -m cProfile [-o output_file] [-s sort_order] (-m module | myscript.py)
```

`-o` writes the profile results to a file instead of to stdout

`-s` specifies one of the `sort_stats()` sort values to sort the output by. This only applies when `-o` is not supplied.

`-m` specifies that a module is being profiled instead of a script.

在 3.7 版被加入: 新增 `-m` 選項到 `cProfile`。

在 3.8 版被加入: 新增 `-m` 選項到 `profile`。

The `pstats` module's `Stats` class has a variety of methods for manipulating and printing the data saved into a profile results file:

```
import pstats
from pstats import SortKey
p = pstats.Stats('restats')
p.strip_dirs().sort_stats(-1).print_stats()
```

The `strip_dirs()` method removed the extraneous path from all the module names. The `sort_stats()` method sorted all the entries according to the standard module/line/name string that is printed. The `print_stats()` method printed out all the statistics. You might try the following sort calls:

```
p.sort_stats(SortKey.NAME)
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls to experiment with:

```
p.sort_stats(SortKey.CUMULATIVE).print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.

If you were looking to see what functions were looping a lot, and taking a lot of time, you would do:

```
p.sort_stats(SortKey.TIME).print_stats(10)
```

to sort according to time spent within each function, and then print the statistics for the top ten functions.

You might also try:

```
p.sort_stats(SortKey.FILENAME).print_stats('__init__')
```

This will sort all the statistics by file name, and then print out statistics for only the class init methods (since they are spelled with `__init__` in them). As one final example, you could try:

```
p.sort_stats(SortKey.TIME, SortKey.CUMULATIVE).print_stats(.5, 'init')
```

This line sorts statistics with a primary key of time, and a secondary key of cumulative time, and then prints out some of the statistics. To be specific, the list is first culled down to 50% (re: `.5`) of its original size, then only lines containing `init` are maintained, and that sub-sub-list is printed.

If you wondered what functions called the above functions, you could now (`p` is still sorted according to the last criteria) do:

```
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you're going to have to read the manual, or guess what the following functions do:

```
p.print_callees()
p.add('restats')
```

Invoked as a script, the `pstats` module is a statistics browser for reading and examining profile dumps. It has a simple line-oriented interface (implemented using `cmd`) and interactive help.

27.5.3 `profile` and `cProfile` Module Reference

Both the `profile` and `cProfile` modules provide the following functions:

`profile.run(command, filename=None, sort=-1)`

This function takes a single argument that can be passed to the `exec()` function, and an optional file name. In all cases this routine executes:

```
exec(command, __main__.__dict__, __main__.__dict__)
```

and gathers profiling statistics from the execution. If no file name is present, then this function automatically creates a `Stats` instance and prints a simple profiling report. If the sort value is specified, it is passed to this `Stats` instance to control how the results are sorted.

`profile.runctx(command, globals, locals, filename=None, sort=-1)`

This function is similar to `run()`, with added arguments to supply the globals and locals mappings for the `command` string. This routine executes:

```
exec(command, globals, locals)
```

and gathers profiling statistics as in the `run()` function above.

class `profile.Profile(timer=None, timeunit=0.0, subcalls=True, builtins=True)`

This class is normally only used if more precise control over profiling is needed than what the `cProfile.run()` function provides.

A custom timer can be supplied for measuring how long code takes to run via the `timer` argument. This must be a function that returns a single number representing the current time. If the number is an integer, the `timeunit` specifies a multiplier that specifies the duration of each unit of time. For example, if the timer returns times measured in thousands of seconds, the time unit would be `.001`.

Directly using the `Profile` class allows formatting profile results without writing the profile data to a file:

```
import cProfile, pstats, io
from pstats import SortKey
pr = cProfile.Profile()
pr.enable()
# ... do something ...
pr.disable()
s = io.StringIO()
sortby = SortKey.CUMULATIVE
ps = pstats.Stats(pr, stream=s).sort_stats(sortby)
ps.print_stats()
print(s.getvalue())
```

The `Profile` class can also be used as a context manager (supported only in `cProfile` module. see 情境管理器型 發):

```
import cProfile

with cProfile.Profile() as pr:
    # ... do something ...

pr.print_stats()
```

在 3.8 版的變更: 新增情境管理器的支援。

enable()Start collecting profiling data. Only in *cProfile*.**disable()**Stop collecting profiling data. Only in *cProfile*.**create_stats()**

Stop collecting profiling data and record the results internally as the current profile.

print_stats(sort=-1)Create a *Stats* object based on the current profile and print the results to stdout.

The *sort* parameter specifies the sorting order of the displayed statistics. It accepts a single key or a tuple of keys to enable multi-level sorting, as in *Stats.sort_stats*.

在 3.13 版被加入: *print_stats()* now accepts a tuple of keys.

dump_stats(filename)Write the results of the current profile to *filename*.**run(cmd)**Profile the *cmd* via *exec()*.**runctx(cmd, globals, locals)**Profile the *cmd* via *exec()* with the specified global and local environment.**runcall(func, /, *args, **kwargs)**Profile *func(*args, **kwargs)*

Note that profiling will only work if the called command/function actually returns. If the interpreter is terminated (e.g. via a *sys.exit()* call during the called command/function execution) no profiling results will be printed.

27.5.4 The Stats Class

Analysis of the profiler data is done using the *Stats* class.

class pstats.Stats(*filenames or profile, stream=sys.stdout)

This class constructor creates an instance of a "statistics object" from a *filename* (or list of filenames) or from a *Profile* instance. Output will be printed to the stream specified by *stream*.

The file selected by the above constructor must have been created by the corresponding version of *profile* or *cProfile*. To be specific, there is *no* file compatibility guaranteed with future versions of this profiler, and there is no compatibility with files produced by other profilers, or the same profiler run on a different operating system. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be combined with data in an existing *Stats* object, the *add()* method can be used.

Instead of reading the profile data from a file, a *cProfile.Profile* or *profile.Profile* object can be used as the profile data source.

Stats objects have the following methods:

strip_dirs()

This method for the *Stats* class removes all leading path information from file names. It is very useful in reducing the size of the printout to fit within (close to) 80 columns. This method modifies the object, and the stripped information is lost. After performing a strip operation, the object is considered to have its entries in a "random" order, as it was just after object initialization and loading. If *strip_dirs()* causes two function names to be indistinguishable (they are on the same line of the same filename, and have the same function name), then the statistics for these two entries are accumulated into a single entry.

add (*filenames)

This method of the `Stats` class accumulates additional profiling information into the current profiling object. Its arguments should refer to filenames created by the corresponding version of `profile.run()` or `cProfile.run()`. Statistics for identically named (re: file, line, name) functions are automatically accumulated into single function statistics.

dump_stats (filename)

Save the data loaded into the `Stats` object to a file named *filename*. The file is created if it does not exist, and is overwritten if it already exists. This is equivalent to the method of the same name on the `profile.Profile` and `cProfile.Profile` classes.

sort_stats (*keys)

This method modifies the `Stats` object by sorting it according to the supplied criteria. The argument can be either a string or a `SortKey` enum identifying the basis of a sort (example: 'time', 'name', `SortKey.TIME` or `SortKey.NAME`). The `SortKey` enums argument have advantage over the string argument in that it is more robust and less error prone.

When more than one key is provided, then additional keys are used as secondary criteria when there is equality in all keys selected before them. For example, `sort_stats(SortKey.NAME, SortKey.FILE)` will sort all the entries according to their function name, and resolve all ties (identical function names) by sorting by file name.

For the string argument, abbreviations can be used for any key names, as long as the abbreviation is unambiguous.

The following are the valid string and `SortKey`:

Valid String Arg	Valid enum Arg	含義
'calls'	<code>SortKey.CALLS</code>	call count
'cumulative'	<code>SortKey.CUMULATIVE</code>	cumulative time
'cumtime'	N/A	cumulative time
'file'	N/A	file name (檔案名稱)
'filename'	<code>SortKey.FILENAME</code>	file name (檔案名稱)
'module'	N/A	file name (檔案名稱)
'ncalls'	N/A	call count
'pcalls'	<code>SortKey.PCALLS</code>	primitive call count
'line'	<code>SortKey.LINE</code>	列號
'name'	<code>SortKey.NAME</code>	function name
'nfl'	<code>SortKey.NFL</code>	name/file/line
'stdname'	<code>SortKey.STDNAME</code>	standard name
'time'	<code>SortKey.TIME</code>	internal time
'tottime'	N/A	internal time

Note that all sorts on statistics are in descending order (placing most time consuming items first), where as name, file, and line number searches are in ascending order (alphabetical). The subtle distinction between `SortKey.NFL` and `SortKey.STDNAME` is that the standard name is a sort of the name as printed, which means that the embedded line numbers get compared in an odd way. For example, lines 3, 20, and 40 would (if the file names were the same) appear in the string order 20, 3 and 40. In contrast, `SortKey.NFL` does a numeric compare of the line numbers. In fact, `sort_stats(SortKey.NFL)` is the same as `sort_stats(SortKey.NAME, SortKey.FILENAME, SortKey.LINE)`.

For backward-compatibility reasons, the numeric arguments -1, 0, 1, and 2 are permitted. They are interpreted as 'stdname', 'calls', 'time', and 'cumulative' respectively. If this old style format (numeric) is used, only one sort key (the numeric key) will be used, and additional arguments will be silently ignored.

在 3.7 版被加入: Added the `SortKey` enum.

reverse_order()

This method for the `Stats` class reverses the ordering of the basic list within the object. Note that by default ascending vs descending order is properly selected based on the sort key of choice.

print_stats(*restrictions)

This method for the `Stats` class prints out a report as described in the `profile.run()` definition.

The order of the printing is based on the last `sort_stats()` operation done on the object (subject to caveats in `add()` and `strip_dirs()`).

The arguments provided (if any) can be used to limit the list down to the significant entries. Initially, the list is taken to be the complete set of profiled functions. Each restriction is either an integer (to select a count of lines), or a decimal fraction between 0.0 and 1.0 inclusive (to select a percentage of lines), or a string that will interpreted as a regular expression (to pattern match the standard name that is printed). If several restrictions are provided, then they are applied sequentially. For example:

```
print_stats(.1, 'foo:')
```

would first limit the printing to first 10% of list, and then only print functions that were part of filename `. *foo:.` In contrast, the command:

```
print_stats('foo:', .1)
```

would limit the list to all functions having file names `. *foo:`, and then proceed to only print the first 10% of them.

print_callers(*restrictions)

This method for the `Stats` class prints a list of all functions that called each function in the profiled database. The ordering is identical to that provided by `print_stats()`, and the definition of the restricting argument is also identical. Each caller is reported on its own line. The format differs slightly depending on the profiler that produced the stats:

- With `profile`, a number is shown in parentheses after each caller to show how many times this specific call was made. For convenience, a second non-parenthesized number repeats the cumulative time spent in the function at the right.
- With `cProfile`, each caller is preceded by three numbers: the number of times this specific call was made, and the total and cumulative times spent in the current function while it was invoked by this specific caller.

print_callees(*restrictions)

This method for the `Stats` class prints a list of all function that were called by the indicated function. Aside from this reversal of direction of calls (re: called vs was called by), the arguments and ordering are identical to the `print_callers()` method.

get_stats_profile()

This method returns an instance of `StatsProfile`, which contains a mapping of function names to instances of `FunctionProfile`. Each `FunctionProfile` instance holds information related to the function's profile such as how long the function took to run, how many times it was called, etc...

在 3.9 版被加入: Added the following dataclasses: `StatsProfile`, `FunctionProfile`. Added the following function: `get_stats_profile`.

27.5.5 What Is Deterministic Profiling?

Deterministic profiling is meant to reflect the fact that all *function call*, *function return*, and *exception* events are monitored, and precise timings are made for the intervals between these events (during which time the user's code is executing). In contrast, *statistical profiling* (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required in order to do deterministic profiling. Python automatically provides a *hook* (optional callback) for each event. In addition, the interpreted nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify "hot loops" that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.

27.5.6 限制

One limitation has to do with accuracy of timing information. There is a fundamental problem with deterministic profilers involving accuracy. The most obvious restriction is that the underlying "clock" is only ticking at a rate (typically) of about .001 seconds. Hence no measurements will be more accurate than the underlying clock. If enough measurements are taken, then the "error" will tend to average out. Unfortunately, removing this first error induces a second source of error.

The second problem is that it "takes a while" from when an event is dispatched until the profiler's call to get the time actually *gets* the state of the clock. Similarly, there is a certain lag when exiting the profiler event handler from the time that the clock's value was obtained (and then squirreled away), until the user's code is once again executing. As a result, functions that are called many times, or call many functions, will typically accumulate this error. The error that accumulates in this fashion is typically less than the accuracy of the clock (less than one clock tick), but it *can* accumulate and become very significant.

The problem is more important with `profile` than with the lower-overhead `cProfile`. For this reason, `profile` provides a means of calibrating itself for a given platform so that this error can be probabilistically (on the average) removed. After the profiler is calibrated, it will be more accurate (in a least square sense), but it will sometimes produce negative numbers (when call counts are exceptionally low, and the gods of probability work against you :-).) Do *not* be alarmed by negative numbers in the profile. They should *only* appear if you have calibrated your profiler, and the results are actually better than without calibration.

27.5.7 校正

The profiler of the `profile` module subtracts a constant from each event handling time to compensate for the overhead of calling the time function, and socking away the results. By default, the constant is 0. The following procedure can be used to obtain a better constant for a given platform (see [限制](#)).

```
import profile
pr = profile.Profile()
for i in range(5):
    print(pr.calibrate(10000))
```

The method executes the number of Python calls given by the argument, directly and again under the profiler, measuring the time for both. It then computes the hidden overhead per profiler event, and returns that as a float. For example, on a 1.8Ghz Intel Core i5 running macOS, and using Python's `time.process_time()` as the timer, the magical number is about 4.04e-6.

The object of this exercise is to get a fairly consistent result. If your computer is *very* fast, or your timer function has poor resolution, you might have to pass 100000, or even 1000000, to get consistent results.

When you have a consistent answer, there are three ways you can use it:

```
import profile

# 1. Apply computed bias to all Profile instances created hereafter.
profile.Profile.bias = your_computed_bias

# 2. Apply computed bias to a specific Profile instance.
pr = profile.Profile()
pr.bias = your_computed_bias

# 3. Specify computed bias in instance constructor.
pr = profile.Profile(bias=your_computed_bias)
```

If you have a choice, you are better off choosing a smaller constant, and then your results will “less often” show up as negative in profile statistics.

27.5.8 Using a custom timer

If you want to change how current time is determined (for example, to force use of wall-clock time or elapsed process time), pass the timing function you want to the `Profile` class constructor:

```
pr = profile.Profile(your_time_func)
```

The resulting profiler will then call `your_time_func`. Depending on whether you are using `profile.Profile` or `cProfile.Profile`, `your_time_func`’s return value will be interpreted differently:

`profile.Profile`

`your_time_func` should return a single number, or a list of numbers whose sum is the current time (like what `os.times()` returns). If the function returns a single time number, or the list of returned numbers has length 2, then you will get an especially fast version of the dispatch routine.

Be warned that you should calibrate the profiler class for the timer function that you choose (see 校正). For most machines, a timer that returns a lone integer value will provide the best results in terms of low overhead during profiling. (`os.times()` is *pretty* bad, as it returns a tuple of floating-point values). If you want to substitute a better timer in the cleanest fashion, derive a class and hardwire a replacement dispatch method that best handles your timer call, along with the appropriate calibration constant.

`cProfile.Profile`

`your_time_func` should return a single number. If it returns integers, you can also invoke the class constructor with a second argument specifying the real duration of one unit of time. For example, if `your_integer_time_func` returns times measured in thousands of seconds, you would construct the `Profile` instance as follows:

```
pr = cProfile.Profile(your_integer_time_func, 0.001)
```

As the `cProfile.Profile` class cannot be calibrated, custom timer functions should be used with care and should be as fast as possible. For the best results with a custom timer, it might be necessary to hard-code it in the C source of the internal `_lsprof` module.

Python 3.3 adds several new functions in `time` that can be used to make precise measurements of process or wall-clock time. For example, see `time.perf_counter()`.

27.6 timeit --- 測量小量程式片段的執行時間

原始碼: [Lib/timeit.py](#)

該模組提供了一種對少量 Python 程式碼進行計時的簡單方法。它有一個命令列介面和一個可呼叫介面，它避免了許多測量執行時間的常見陷阱。另請參閱由 O'Reilly 出版的 *Python 錦囊妙計 (Python Cookbook)* 第二版中 Tim Peters 所寫的「演算法」章節的介紹。

27.6.1 基礎范例

以下範例展示了如何使用命令列介面來比較三個不同的運算式：

```
$ python -m timeit "'-'.join(str(n) for n in range(100))"
10000 loops, best of 5: 30.2 usec per loop
$ python -m timeit "'-'.join([str(n) for n in range(100)])"
10000 loops, best of 5: 27.5 usec per loop
$ python -m timeit "'-'.join(map(str, range(100)))"
10000 loops, best of 5: 23.2 usec per loop
```

這可以透過 *Python* 介面來實現：

```
>>> import timeit
>>> timeit.timeit('"-'.join(str(n) for n in range(100))', number=10000)
0.3018611848820001
>>> timeit.timeit('"-'.join([str(n) for n in range(100)])', number=10000)
0.2727368790656328
>>> timeit.timeit('"-'.join(map(str, range(100)))', number=10000)
0.23702679807320237
```

也可以在 *Python* 介面傳遞可呼叫物件：

```
>>> timeit.timeit(lambda: "-".join(map(str, range(100))), number=10000)
0.19665591977536678
```

但請注意，僅當使用命令列介面時 `timeit()` 才會自動確定重覆次數。在範例章節中有更進階的範例。

27.6.2 Python 介面

該模組定義了三個便利函式和一個公開類別：

`timeit.timeit(stmt='pass', setup='pass', timer=<default timer>, number=1000000, globals=None)`

使用給定的陳述式、`setup` 程式碼和 `timer` 函式建立一個 `Timer` 實例，執行其 `timeit()` 方法 `number` 次。可選的 `globals` 引數指定會在其中執行程式碼的命名空間。

在 3.5 版的變更：新增 `globals` 選用參數。

`timeit.repeat(stmt='pass', setup='pass', timer=<default timer>, repeat=5, number=1000000, globals=None)`

使用給定的陳述式、`setup` 程式碼和 `timer` 函式建立一個 `Timer` 實例，使用給定的 `repeat` 計數和 `number` 來運行其 `repeat()` 方法。可選的 `globals` 引數指定會在其中執行程式碼的命名空間。

在 3.5 版的變更：新增 `globals` 選用參數。

在 3.7 版的變更：`repeat` 的預設值從 3 更改為 5。

`timeit.default_timer()`

預設計時器始終使用 `time.perf_counter()`，會回傳浮點秒數。另一種方法是 `time.perf_counter_ns`，會回傳整數奈秒。

在 3.3 版的變更：`time.perf_counter()` 現在是預設計時器。

```
class timeit.Timer(stmt='pass', setup='pass', timer=<timer function>, globals=None)
```

用於計時小程序碼片段執行速度的類。

建構函式接受一個要計時的陳述式、一個用於設定的附加陳述式和一個計時器函式。兩個陳述式都預設 'pass'；計時器函式會與平台相依（請參閱模組文件字串 (doc string)）。*stmt* 和 *setup* 還可以包含；或行符號分隔的多個陳述式，只要它們不包含多行字串文字即可。預設情況下，該陳述式將在 *timeit* 的命名空間執行；可以透過將命名空間傳遞給 *globals* 來控制此行。

要測量第一個陳述式的執行時間，請使用 *timeit()* 方法。*repeat()* 和 *autorange()* 方法是多次呼叫 *timeit()* 的便捷方法。

setup 的執行時間不包含在總體運行計時中。

stmt 和 *setup* 參數還可以接受無需引數即可呼叫的物件。這會把對它們的呼叫嵌入到計時器函式中，然後由 *timeit()* 去執行。請注意，在這種情況下，因有額外的函式呼叫，時間開銷 (timing overhead) 會稍大一些。

在 3.5 版的變更：新增 *globals* 選用參數。

```
timeit (number=1000000)
```

主陳述式執行 *number* 次的時間。這將執行一次設定陳述式，然後回傳多次執行主陳述式所需的時間。預設計時器以浮點形式回傳秒數，引數是圈數，預設一百萬次。要使用的主陳述式、設定陳述式和計時器函式會被傳遞給建構函式。

備

預設情況下 *timeit()* 在計時期間會暫時關閉垃圾回收。這種方法的優點是它使獨立時序更具可比性，缺點是 GC 可能是被測函式性能的重要組成部分。如果是這樣，可以將 GC 作 *setup* 字串中的第一個陳述式以重新啟用。例如：

```
timeit.Timer('for i in range(10): oct(i)', 'gc.enable()').timeit()
```

```
autorange (callback=None)
```

自動固定呼叫 *timeit()* 次數。

這是一個便捷函式，它重呼叫 *timeit()* 以使得總時間 ≥ 0.2 秒，再回傳最終結果（圈數、該圈數所花費的時間）。它以 1、2、5、10、20、50... 的順序遞增數字來呼叫 *timeit()* 直到所用時間至少 0.2 秒。

如果有給定 *callback* 且不是 *None*，則每次試驗後都會使用兩個引數來呼叫它：*callback(number, time_taken)*。

在 3.6 版被加入。

```
repeat (repeat=5, number=1000000)
```

呼叫 *timeit()* 數次。

這是一個方便的函式，它會重呼叫 *timeit()* 回傳結果列表。第一個引數指定呼叫 *timeit()* 的次數，第二個引數指定 *timeit()* 的 *number* 引數。

備

人們很容易根據結果向量來計算出平均值和標準差將其作依歸，然而這不是很有用。在典型情況下，最低值給出了機器運行給定程式碼片段的速度的下限；結果向量中較高的值通常不是由 Python 速度的變化所引起，而是由干擾計時精度的其他行程造成的。因此，結果中的 *min()* 可能是你應該感興趣的唯一數字。在解讀該數據後，你應該查看整個向量以常識判讀而非單純仰賴統計資訊。

在 3.7 版的變更：*repeat* 的預設值從 3 更改 5。

print_exc (*file=None*)

從計時程式碼印出回溯 (traceback) 的輔助函式。

典型用法：

```
t = Timer(...)           # outside the try/except
try:
    t.timeit(...)        # or t.repeat(...)
except Exception:
    t.print_exc()
```

相對於標準回溯的優點是，已編譯模板中的原始程式碼會被顯示出來。可選的 *file* 引數指定回溯的發送位置；它預設為 `sys.stderr`。

27.6.3 命令列介面

當從命令列作程式呼叫時，請使用以下形式：

```
python -m timeit [-n N] [-r N] [-u U] [-s S] [-p] [-v] [-h] [statement ...]
```

其中之以下選項：

-n N, --number=N

執行 'statement' 多少次

-r N, --repeat=N

計時器重覆多少次（預設 5）

-s S, --setup=S

會在一開始執行一次的陳述式（預設為 `pass`）

-p, --process

若要測量行程時間 (process time) 而非鐘時間 (wallclock time)，請使用 `time.process_time()` 而不是預設的 `time.perf_counter()`

在 3.3 版被加入。

-u, --unit=U

指定定時器輸出的時間單位；可以選擇 `nsec`、`usec`、`msec` 或 `sec`

在 3.5 版被加入。

-v, --verbose

印出原始計時結果；重覆執行以獲得更高的數字精度

-h, --help

印出一條簡短的使用訊息並退出

可以透過將每一列陳述式指定單獨引數來給定多列陳述式；可透過將引數括在引號中或使用前導空格以實現縮進列 (indented lines)。多個 `-s` 選項的作用類似。

如果有給定 `-n`，則透過嘗試從序列 1, 2, 5, 10, 20, 50, ... 中增加數字來計算合適的圈次數，直到總時間至少 0.2 秒。

`default_timer()` 測量可能會受到同一台機器上運行的其他程式的影響，因此，當需要精確計時時，最好的做法是重覆計時幾次並使用最佳時間。`-r` 選項對此很有用；在大多數情況下，預設的重覆 5 次可能就足夠了。你可以使用 `time.process_time()` 來測量 CPU 時間。

備註

執行 `pass` 陳述式會產生一定的基本開銷。這的程式碼不試圖隱藏它，但你應該意識到它的存在。可以透過不帶引數呼叫程式來測量這個基本開銷，且不同 Python 版本之間的基本開銷可能有所不同。

27.6.4 范例

可以提供一個僅會在開始時執行一次的設定陳述式：

```
$ python -m timeit -s "text = 'sample string'; char = 'g'" "char in text"
5000000 loops, best of 5: 0.0877 usec per loop
$ python -m timeit -s "text = 'sample string'; char = 'g'" "text.find(char)"
1000000 loops, best of 5: 0.342 usec per loop
```

輸出中包含三個欄位。圈計數，它告訴你每次計時圈重運行陳述式主體的次數。重計數（「最好的 5 次」）告訴你計時圈重了多少次。以及最後陳述式主體在計時的最佳的幾次重執行平均花費的時間。也就是圈，最快的幾次重執行所花費的總時間除以圈計數。

```
>>> import timeit
>>> timeit.timeit('char in text', setup='text = "sample string"; char = "g"')
0.41440500499993504
>>> timeit.timeit('text.find(char)', setup='text = "sample string"; char = "g"')
1.7246671520006203
```

同樣可以使用 *Timer* 類及其方法來完成：

```
>>> import timeit
>>> t = timeit.Timer('char in text', setup='text = "sample string"; char = "g"')
>>> t.timeit()
0.3955516149999312
>>> t.repeat()
[0.40183617287970225, 0.37027556854118704, 0.38344867356679524, 0.3712595970846668,
↪ 0.37866875250654886]
```

以下範例展示如何對包含多行的運算式進行計時。這我們使用 *hasattr()* 與 *try/except* 來測試缺失和存在之物件屬性比較其花費 (cost)：

```
$ python -m timeit "try: " " str.__bool__ " except AttributeError: " " pass"
20000 loops, best of 5: 15.7 usec per loop
$ python -m timeit "if hasattr(str, '__bool__'): pass"
50000 loops, best of 5: 4.26 usec per loop

$ python -m timeit "try: " " int.__bool__ " except AttributeError: " " pass"
200000 loops, best of 5: 1.43 usec per loop
$ python -m timeit "if hasattr(int, '__bool__'): pass"
100000 loops, best of 5: 2.23 usec per loop
```

```
>>> import timeit
>>> # attribute is missing
>>> s = ""
... try:
...     str.__bool__
... except AttributeError:
...     pass
... ""
>>> timeit.timeit(stmt=s, number=100000)
0.9138244460009446
>>> s = "if hasattr(str, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.5829014980008651
>>>
>>> # attribute is present
>>> s = ""
... try:
...     int.__bool__
... except AttributeError:
```

(繼續下一頁)

(繼續上一頁)

```

...     pass
...     """
>>> timeit.timeit(stmt=s, number=100000)
0.04215312199994514
>>> s = "if hasattr(int, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.08588060699912603

```

要讓 `timeit` 模組存取你定義的函式，你可以傳遞一個包含 `import` 陳述式的 `setup` 參數：

```

def test():
    """Stupid test function"""
    L = [i for i in range(100)]

if __name__ == '__main__':
    import timeit
    print(timeit.timeit("test()", setup="from __main__ import test"))

```

另一種選擇是將 `globals()` 傳遞給 `globals` 參數，這將導致程式碼在當前的全域命名空間中執行，這比單獨指定 `import` 更方便：

```

def f(x):
    return x**2
def g(x):
    return x**4
def h(x):
    return x**8

import timeit
print(timeit.timeit('[func(42) for func in (f,g,h)]', globals=globals()))

```

27.7 trace --- 追 或追查 Python 陳述式執行

原始碼：Lib/trace.py

The `trace` module allows you to trace program execution, generate annotated statement coverage listings, print caller/callee relationships and list functions executed during a program run. It can be used in another program or from the command line.

也參考

Coverage.py

A popular third-party coverage tool that provides HTML output along with advanced features such as branch coverage.

27.7.1 Command-Line Usage

The `trace` module can be invoked from the command line. It can be as simple as

```
python -m trace --count -C . somefile.py ...
```

The above will execute `somefile.py` and generate annotated listings of all Python modules imported during the execution into the current directory.

--help

Display usage and exit.

--version

Display the version of the module and exit.

在 3.8 版被加入: Added `--module` option that allows to run an executable module.

Main options

At least one of the following options must be specified when invoking `trace`. The `--listfuncs` option is mutually exclusive with the `--trace` and `--count` options. When `--listfuncs` is provided, neither `--count` nor `--trace` are accepted, and vice versa.

-c, --count

Produce a set of annotated listing files upon program completion that shows how many times each statement was executed. See also `--coverdir`, `--file` and `--no-report` below.

-t, --trace

Display lines as they are executed.

-l, --listfuncs

Display the functions executed by running the program.

-r, --report

Produce an annotated list from an earlier program run that used the `--count` and `--file` option. This does not execute any code.

-T, --trackcalls

Display the calling relationships exposed by running the program.

Modifiers

-f, --file=<file>

Name of a file to accumulate counts over several tracing runs. Should be used with the `--count` option.

-C, --coverdir=<dir>

Directory where the report files go. The coverage report for `package.module` is written to file `dir/package/module.cover`.

-m, --missing

When generating annotated listings, mark lines which were not executed with `>>>>>`.

-s, --summary

When using `--count` or `--report`, write a brief summary to stdout for each file processed.

-R, --no-report

Do not generate annotated listings. This is useful if you intend to make several runs with `--count`, and then produce a single set of annotated listings at the end.

-g, --timing

Prefix each line with the time since the program started. Only used while tracing.

Filters

These options may be repeated multiple times.

--ignore-module=<mod>

Ignore each of the given module names and its submodules (if it is a package). The argument can be a list of names separated by a comma.

--ignore-dir=<dir>

Ignore all modules and packages in the named directory and subdirectories. The argument can be a list of directories separated by `os.pathsep`.

27.7.2 Programmatic Interface

```
class trace.Trace (count=1, trace=1, countfuncs=0, countcallers=0, ignoremods=(), ignoredirs=(),  
                   infile=None, outfile=None, timing=False)
```

Create an object to trace execution of a single statement or expression. All parameters are optional. *count* enables counting of line numbers. *trace* enables line execution tracing. *countfuncs* enables listing of the functions called during the run. *countcallers* enables call relationship tracking. *ignoremods* is a list of modules or packages to ignore. *ignoredirs* is a list of directories whose modules or packages should be ignored. *infile* is the name of the file from which to read stored count information. *outfile* is the name of the file in which to write updated count information. *timing* enables a timestamp relative to when tracing was started to be displayed.

run (cmd)

Execute the command and gather statistics from the execution with the current tracing parameters. *cmd* must be a string or code object, suitable for passing into `exec()`.

runtctx (cmd, globals=None, locals=None)

Execute the command and gather statistics from the execution with the current tracing parameters, in the defined global and local environments. If not defined, *globals* and *locals* default to empty dictionaries.

runfunc (func, /, *args, **kwds)

Call *func* with the given arguments under control of the *Trace* object with the current tracing parameters.

results ()

Return a *CoverageResults* object that contains the cumulative results of all previous calls to `run`, `runtctx` and `runfunc` for the given *Trace* instance. Does not reset the accumulated trace results.

```
class trace.CoverageResults
```

A container for coverage results, created by `Trace.results()`. Should not be created directly by the user.

update (other)

Merge in data from another *CoverageResults* object.

write_results (show_missing=True, summary=False, coverdir=None, *, ignore_missing_files=False)

Write coverage results. Set *show_missing* to show lines that had no hits. Set *summary* to include in the output the coverage summary per module. *coverdir* specifies the directory into which the coverage result files will be output. If `None`, the results for each source file are placed in its directory.

If *ignore_missing_files* is `True`, coverage counts for files that no longer exist are silently ignored. Otherwise, a missing file will raise a *FileNotFoundError*.

在 3.13 版的變更: Added *ignore_missing_files* parameter.

A simple example demonstrating the use of the programmatic interface:

```
import sys
import trace

# create a Trace object, telling it what to ignore, and whether to
# do tracing or line-counting or both.
tracer = trace.Trace(
    ignoredirs=[sys.prefix, sys.exec_prefix],
    trace=0,
    count=1)

# run the new command using the given tracer
tracer.run('main()')

# make a report, placing output in the current directory
r = tracer.results()
r.write_results(show_missing=True, coverdir=".")
```

27.8 tracemalloc --- 追 記憶體配置

在 3.4 版被加入。

原始碼: [Lib/tracemalloc.py](#)

The tracemalloc module is a debug tool to trace memory blocks allocated by Python. It provides the following information:

- Traceback where an object was allocated
- Statistics on allocated memory blocks per filename and per line number: total size, number and average size of allocated memory blocks
- Compute the differences between two snapshots to detect memory leaks

To trace most memory blocks allocated by Python, the module should be started as early as possible by setting the PYTHONTRACEMALLOC environment variable to 1, or by using `-X tracemalloc` command line option. The `tracemalloc.start()` function can be called at runtime to start tracing Python memory allocations.

By default, a trace of an allocated memory block only stores the most recent frame (1 frame). To store 25 frames at startup: set the PYTHONTRACEMALLOC environment variable to 25, or use the `-X tracemalloc=25` command line option.

27.8.1 范例

Display the top 10

Display the 10 files allocating the most memory:

```
import tracemalloc

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('lineno')

print("[ Top 10 ]")
```

(繼續下一頁)

(繼續上一頁)

```
for stat in top_stats[:10]:
    print(stat)
```

Example of output of the Python test suite:

```
[ Top 10 ]
<frozen importlib._bootstrap>:716: size=4855 KiB, count=39328, average=126 B
<frozen importlib._bootstrap>:284: size=521 KiB, count=3199, average=167 B
/usr/lib/python3.4/collections/__init__.py:368: size=244 KiB, count=2315, ↵
↪ average=108 B
/usr/lib/python3.4/unittest/case.py:381: size=185 KiB, count=779, average=243 B
/usr/lib/python3.4/unittest/case.py:402: size=154 KiB, count=378, average=416 B
/usr/lib/python3.4/abc.py:133: size=88.7 KiB, count=347, average=262 B
<frozen importlib._bootstrap>:1446: size=70.4 KiB, count=911, average=79 B
<frozen importlib._bootstrap>:1454: size=52.0 KiB, count=25, average=2131 B
<string>:5: size=49.7 KiB, count=148, average=344 B
/usr/lib/python3.4/sysconfig.py:411: size=48.0 KiB, count=1, average=48.0 KiB
```

We can see that Python loaded 4855 KiB data (bytecode and constants) from modules and that the *collections* module allocated 244 KiB to build *namedtuple* types.

更多選項請見 `Snapshot.statistics()`。

Compute differences

Take two snapshots and display the differences:

```
import tracemalloc
tracemalloc.start()
# ... start your application ...

snapshot1 = tracemalloc.take_snapshot()
# ... call the function leaking memory ...
snapshot2 = tracemalloc.take_snapshot()

top_stats = snapshot2.compare_to(snapshot1, 'lineno')

print("[ Top 10 differences ]")
for stat in top_stats[:10]:
    print(stat)
```

Example of output before/after running some tests of the Python test suite:

```
[ Top 10 differences ]
<frozen importlib._bootstrap>:716: size=8173 KiB (+4428 KiB), count=71332 (+39369),
↪ average=117 B
/usr/lib/python3.4/linecache.py:127: size=940 KiB (+940 KiB), count=8106 (+8106), ↵
↪ average=119 B
/usr/lib/python3.4/unittest/case.py:571: size=298 KiB (+298 KiB), count=589 (+589),
↪ average=519 B
<frozen importlib._bootstrap>:284: size=1005 KiB (+166 KiB), count=7423 (+1526), ↵
↪ average=139 B
/usr/lib/python3.4/mimetypes.py:217: size=112 KiB (+112 KiB), count=1334 (+1334), ↵
↪ average=86 B
/usr/lib/python3.4/http/server.py:848: size=96.0 KiB (+96.0 KiB), count=1 (+1), ↵
↪ average=96.0 KiB
/usr/lib/python3.4/inspect.py:1465: size=83.5 KiB (+83.5 KiB), count=109 (+109), ↵
↪ average=784 B
/usr/lib/python3.4/unittest/mock.py:491: size=77.7 KiB (+77.7 KiB), count=143 ↵
↪ (+143), average=557 B
```

(繼續下一頁)

(繼續上一頁)

```
/usr/lib/python3.4/urllib/parse.py:476: size=71.8 KiB (+71.8 KiB), count=969
↪(+969), average=76 B
/usr/lib/python3.4/contextlib.py:38: size=67.2 KiB (+67.2 KiB), count=126 (+126),
↪average=546 B
```

We can see that Python has loaded 8173 KiB of module data (bytecode and constants), and that this is 4428 KiB more than had been loaded before the tests, when the previous snapshot was taken. Similarly, the *linecache* module has cached 940 KiB of Python source code to format tracebacks, all of it since the previous snapshot.

If the system has little free memory, snapshots can be written on disk using the *Snapshot.dump()* method to analyze the snapshot offline. Then use the *Snapshot.load()* method reload the snapshot.

Get the traceback of a memory block

Code to display the traceback of the biggest memory block:

```
import tracemalloc

# Store 25 frames
tracemalloc.start(25)

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('traceback')

# pick the biggest memory block
stat = top_stats[0]
print("%s memory blocks: %.1f KiB" % (stat.count, stat.size / 1024))
for line in stat.traceback.format():
    print(line)
```

Example of output of the Python test suite (traceback limited to 25 frames):

```
903 memory blocks: 870.1 KiB
File "<frozen importlib._bootstrap>", line 716
File "<frozen importlib._bootstrap>", line 1036
File "<frozen importlib._bootstrap>", line 934
File "<frozen importlib._bootstrap>", line 1068
File "<frozen importlib._bootstrap>", line 619
File "<frozen importlib._bootstrap>", line 1581
File "<frozen importlib._bootstrap>", line 1614
File "/usr/lib/python3.4/doctest.py", line 101
import pdb
File "<frozen importlib._bootstrap>", line 284
File "<frozen importlib._bootstrap>", line 938
File "<frozen importlib._bootstrap>", line 1068
File "<frozen importlib._bootstrap>", line 619
File "<frozen importlib._bootstrap>", line 1581
File "<frozen importlib._bootstrap>", line 1614
File "/usr/lib/python3.4/test/support/__init__.py", line 1728
import doctest
File "/usr/lib/python3.4/test/test_pikletools.py", line 21
    support.run_doctest(pickletools)
File "/usr/lib/python3.4/test/regtest.py", line 1276
    test_runner()
File "/usr/lib/python3.4/test/regtest.py", line 976
    display_failure=not verbose)
File "/usr/lib/python3.4/test/regtest.py", line 761
    match_tests=ns.match_tests)
```

(繼續下一頁)

(繼續上一頁)

```
File "/usr/lib/python3.4/test/regrtest.py", line 1563
    main()
File "/usr/lib/python3.4/test/__main__.py", line 3
    regrtest.main_in_temp_cwd()
File "/usr/lib/python3.4/runpy.py", line 73
    exec(code, run_globals)
File "/usr/lib/python3.4/runpy.py", line 160
    "__main__", fname, loader, pkg_name)
```

We can see that the most memory was allocated in the `importlib` module to load data (bytecode and constants) from modules: 870.1 KiB. The traceback is where the `importlib` loaded data most recently: on the `import` `pdb` line of the `doctest` module. The traceback may change if a new module is loaded.

Pretty top

Code to display the 10 lines allocating the most memory with a pretty output, ignoring `<frozen importlib._bootstrap>` and `<unknown>` files:

```
import linecache
import os
import tracemalloc

def display_top(snapshot, key_type='lineno', limit=10):
    snapshot = snapshot.filter_traces((
        tracemalloc.Filter(False, "<frozen importlib._bootstrap>"),
        tracemalloc.Filter(False, "<unknown>"),
    ))
    top_stats = snapshot.statistics(key_type)

    print("Top %s lines" % limit)
    for index, stat in enumerate(top_stats[:limit], 1):
        frame = stat.traceback[0]
        print("#%s: %s:%s: %.1f KiB"
              % (index, frame.filename, frame.lineno, stat.size / 1024))
        line = linecache.getline(frame.filename, frame.lineno).strip()
        if line:
            print('    %s' % line)

    other = top_stats[limit:]
    if other:
        size = sum(stat.size for stat in other)
        print("%s other: %.1f KiB" % (len(other), size / 1024))
    total = sum(stat.size for stat in top_stats)
    print("Total allocated size: %.1f KiB" % (total / 1024))

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
display_top(snapshot)
```

Example of output of the Python test suite:

```
Top 10 lines
#1: Lib/base64.py:414: 419.8 KiB
    _b85chars2 = [(a + b) for a in _b85chars for b in _b85chars]
#2: Lib/base64.py:306: 419.8 KiB

    _b32tab2 = [a + b for a in _b32tab for b in _b32tab]
6220 other: 3602.8 KiB
Total allocated size: 5303.1 KiB

```

更多選項請見 `Snapshot.statistics()`。

Record the current and peak size of all traced memory blocks

The following code computes two sums like $0 + 1 + 2 + \dots$ inefficiently, by creating a list of those numbers. This list consumes a lot of memory temporarily. We can use `get_traced_memory()` and `reset_peak()` to observe the small memory usage after the sum is computed as well as the peak memory usage during the computations:

```

import tracemalloc

tracemalloc.start()

# Example code: compute a sum with a large temporary list
large_sum = sum(list(range(100000)))

first_size, first_peak = tracemalloc.get_traced_memory()

tracemalloc.reset_peak()

# Example code: compute a sum with a small temporary list
small_sum = sum(list(range(1000)))

second_size, second_peak = tracemalloc.get_traced_memory()

print(f"first_size=, {first_peak=}")
print(f"second_size=, {second_peak=}")

```

輸出：

```

first_size=664, first_peak=3592984
second_size=804, second_peak=29704

```

Using `reset_peak()` ensured we could accurately record the peak during the computation of `small_sum`, even though it is much smaller than the overall peak size of memory blocks since the `start()` call. Without the call to `reset_peak()`, `second_peak` would still be the peak from the computation `large_sum` (that is, equal to `first_peak`). In this case, both peaks are much higher than the final memory usage, and which suggests we could optimise (by removing the unnecessary call to `list`, and writing `sum(range(...))`).

27.8.2 API

函式

`tracemalloc.clear_traces()`

Clear traces of memory blocks allocated by Python.

另請參 `stop()`。

`tracemalloc.get_object_traceback(obj)`

Get the traceback where the Python object *obj* was allocated. Return a *Traceback* instance, or None if the *tracemalloc* module is not tracing memory allocations or did not trace the allocation of the object.

另請參 `gc.get_referrers()` 與 `sys.getsizeof()` 函式。

`tracemalloc.get_traceback_limit()`

Get the maximum number of frames stored in the traceback of a trace.

The *tracemalloc* module must be tracing memory allocations to get the limit, otherwise an exception is raised.

The limit is set by the *start()* function.

`tracemalloc.get_traced_memory()`

Get the current size and peak size of memory blocks traced by the *tracemalloc* module as a tuple: (current: int, peak: int).

`tracemalloc.reset_peak()`

Set the peak size of memory blocks traced by the *tracemalloc* module to the current size.

Do nothing if the *tracemalloc* module is not tracing memory allocations.

This function only modifies the recorded peak size, and does not modify or clear any traces, unlike *clear_traces()*. Snapshots taken with *take_snapshot()* before a call to *reset_peak()* can be meaningfully compared to snapshots taken after the call.

另請參 `get_traced_memory()`。

在 3.9 版被加入。

`tracemalloc.get_tracemalloc_memory()`

Get the memory usage in bytes of the *tracemalloc* module used to store traces of memory blocks. Return an *int*.

`tracemalloc.is_tracing()`

True if the *tracemalloc* module is tracing Python memory allocations, False otherwise.

另請參 `start()` 與 `stop()` 函式。

`tracemalloc.start(nframe: int = 1)`

Start tracing Python memory allocations: install hooks on Python memory allocators. Collected tracebacks of traces will be limited to *nframe* frames. By default, a trace of a memory block only stores the most recent frame: the limit is 1. *nframe* must be greater or equal to 1.

You can still read the original number of total frames that composed the traceback by looking at the *Traceback.total_nframe* attribute.

Storing more than 1 frame is only useful to compute statistics grouped by 'traceback' or to compute cumulative statistics: see the *Snapshot.compare_to()* and *Snapshot.statistics()* methods.

Storing more frames increases the memory and CPU overhead of the *tracemalloc* module. Use the *get_tracemalloc_memory()* function to measure how much memory is used by the *tracemalloc* module.

The PYTHONTRACEMALLOC environment variable (PYTHONTRACEMALLOC=NFRAME) and the `-X tracemalloc=NFRAME` command line option can be used to start tracing at startup.

See also `stop()`, `is_tracing()` and `get_traceback_limit()` functions.

`tracemalloc.stop()`

Stop tracing Python memory allocations: uninstall hooks on Python memory allocators. Also clears all previously collected traces of memory blocks allocated by Python.

Call `take_snapshot()` function to take a snapshot of traces before clearing them.

See also `start()`, `is_tracing()` and `clear_traces()` functions.

`tracemalloc.take_snapshot()`

Take a snapshot of traces of memory blocks allocated by Python. Return a new `Snapshot` instance.

The snapshot does not include memory blocks allocated before the `tracemalloc` module started to trace memory allocations.

Tracebacks of traces are limited to `get_traceback_limit()` frames. Use the `nframe` parameter of the `start()` function to store more frames.

The `tracemalloc` module must be tracing memory allocations to take a snapshot, see the `start()` function.

另請參閱 `get_object_traceback()` 函式。

DomainFilter

class `tracemalloc.DomainFilter` (*inclusive*: bool, *domain*: int)

Filter traces of memory blocks by their address space (domain).

在 3.6 版被加入。

inclusive

If *inclusive* is True (include), match memory blocks allocated in the address space *domain*.

If *inclusive* is False (exclude), match memory blocks not allocated in the address space *domain*.

domain

Address space of a memory block (int). Read-only property.

Filter

class `tracemalloc.Filter` (*inclusive*: bool, *filename_pattern*: str, *lineno*: int = None, *all_frames*: bool = False, *domain*: int = None)

Filter on traces of memory blocks.

See the `fnmatch.fnmatch()` function for the syntax of *filename_pattern*. The `'.pyc'` file extension is replaced with `'.py'`.

範例：

- `Filter(True, subprocess.__file__)` only includes traces of the `subprocess` module
- `Filter(False, tracemalloc.__file__)` excludes traces of the `tracemalloc` module
- `Filter(False, "<unknown>")` excludes empty tracebacks

在 3.5 版的變更: The `'.pyo'` file extension is no longer replaced with `'.py'`.

在 3.6 版的變更: 新增 *domain* 屬性。

domain

Address space of a memory block (int or None).

`tracemalloc` uses the domain 0 to trace memory allocations made by Python. C extensions can use other domains to trace other resources.

inclusive

If *inclusive* is `True` (include), only match memory blocks allocated in a file with a name matching *filename_pattern* at line number *lineno*.

If *inclusive* is `False` (exclude), ignore memory blocks allocated in a file with a name matching *filename_pattern* at line number *lineno*.

lineno

Line number (`int`) of the filter. If *lineno* is `None`, the filter matches any line number.

filename_pattern

Filename pattern of the filter (`str`). Read-only property.

all_frames

If *all_frames* is `True`, all frames of the traceback are checked. If *all_frames* is `False`, only the most recent frame is checked.

This attribute has no effect if the traceback limit is 1. See the `get_traceback_limit()` function and `Snapshot.traceback_limit` attribute.

Frame

class tracemalloc.**Frame**

Frame of a traceback.

The `Traceback` class is a sequence of `Frame` instances.

filename

Filename (`str`).

lineno

Line number (`int`).

Snapshot

class tracemalloc.**Snapshot**

Snapshot of traces of memory blocks allocated by Python.

The `take_snapshot()` function creates a snapshot instance.

compare_to (*old_snapshot*: `Snapshot`, *key_type*: `str`, *cumulative*: `bool` = `False`)

Compute the differences with an old snapshot. Get statistics as a sorted list of `StatisticDiff` instances grouped by *key_type*.

See the `Snapshot.statistics()` method for *key_type* and *cumulative* parameters.

The result is sorted from the biggest to the smallest by: absolute value of `StatisticDiff.size_diff`, `StatisticDiff.size`, absolute value of `StatisticDiff.count_diff`, `StatisticDiff.count` and then by `StatisticDiff.traceback`.

dump (*filename*)

Write the snapshot into a file.

Use `load()` to reload the snapshot.

filter_traces (*filters*)

Create a new `Snapshot` instance with a filtered *traces* sequence, *filters* is a list of `DomainFilter` and `Filter` instances. If *filters* is an empty list, return a new `Snapshot` instance with a copy of the traces.

All inclusive filters are applied at once, a trace is ignored if no inclusive filters match it. A trace is ignored if at least one exclusive filter matches it.

在 3.6 版的變更: *DomainFilter* instances are now also accepted in *filters*.

classmethod `load(filename)`

Load a snapshot from a file.

另請參 `dump()`。

statistics (*key_type*: str, *cumulative*: bool = False)

Get statistics as a sorted list of *Statistic* instances grouped by *key_type*:

key_type	描述
'filename'	filename
'lineno'	filename and line number
'traceback'	traceback

If *cumulative* is True, cumulate size and count of memory blocks of all frames of the traceback of a trace, not only the most recent frame. The cumulative mode can only be used with *key_type* equals to 'filename' and 'lineno'.

The result is sorted from the biggest to the smallest by: *Statistic.size*, *Statistic.count* and then by *Statistic.traceback*.

traceback_limit

Maximum number of frames stored in the traceback of *traces*: result of the `get_traceback_limit()` when the snapshot was taken.

traces

Traces of all memory blocks allocated by Python: sequence of *Trace* instances.

The sequence has an undefined order. Use the `Snapshot.statistics()` method to get a sorted list of statistics.

Statistic

class `tracemalloc.Statistic`

Statistic on memory allocations.

`Snapshot.statistics()` returns a list of *Statistic* instances.

See also the *StatisticDiff* class.

count

Number of memory blocks (int).

size

Total size of memory blocks in bytes (int).

traceback

Traceback where the memory block was allocated, *Traceback* instance.

StatisticDiff

class tracemalloc.StatisticDiff

Statistic difference on memory allocations between an old and a new *Snapshot* instance.

Snapshot.compare_to() returns a list of *StatisticDiff* instances. See also the *Statistic* class.

count

Number of memory blocks in the new snapshot (*int*): 0 if the memory blocks have been released in the new snapshot.

count_diff

Difference of number of memory blocks between the old and the new snapshots (*int*): 0 if the memory blocks have been allocated in the new snapshot.

size

Total size of memory blocks in bytes in the new snapshot (*int*): 0 if the memory blocks have been released in the new snapshot.

size_diff

Difference of total size of memory blocks in bytes between the old and the new snapshots (*int*): 0 if the memory blocks have been allocated in the new snapshot.

traceback

Traceback where the memory blocks were allocated, *Traceback* instance.

Trace

class tracemalloc.Trace

Trace of a memory block.

The *Snapshot.traces* attribute is a sequence of *Trace* instances.

在 3.6 版的變更: 新增 *domain* 屬性。

domain

Address space of a memory block (*int*). Read-only property.

tracemalloc uses the domain 0 to trace memory allocations made by Python. C extensions can use other domains to trace other resources.

size

Size of the memory block in bytes (*int*).

traceback

Traceback where the memory block was allocated, *Traceback* instance.

Traceback

class tracemalloc.Traceback

Sequence of *Frame* instances sorted from the oldest frame to the most recent frame.

A traceback contains at least 1 frame. If the tracemalloc module failed to get a frame, the filename "<unknown>" at line number 0 is used.

When a snapshot is taken, tracebacks of traces are limited to *get_traceback_limit()* frames. See the *take_snapshot()* function. The original number of frames of the traceback is stored in the *Traceback.total_nframe* attribute. That allows to know if a traceback has been truncated by the traceback limit.

The `Trace.traceback` attribute is an instance of `Traceback` instance.

在 3.7 版的變更: Frames are now sorted from the oldest to the most recent, instead of most recent to oldest.

total_nframe

Total number of frames that composed the traceback before truncation. This attribute can be set to `None` if the information is not available.

在 3.9 版的變更: The `Traceback.total_nframe` attribute was added.

format (*limit=None, most_recent_first=False*)

Format the traceback as a list of lines. Use the `linecache` module to retrieve lines from the source code. If *limit* is set, format the *limit* most recent frames if *limit* is positive. Otherwise, format the `abs(limit)` oldest frames. If *most_recent_first* is `True`, the order of the formatted frames is reversed, returning the most recent frame first instead of last.

Similar to the `traceback.format_tb()` function, except that `format()` does not include new-lines.

範例:

```
print("Traceback (most recent call first):")
for line in traceback:
    print(line)
```

輸出:

```
Traceback (most recent call first):
  File "test.py", line 9
    obj = Object()
  File "test.py", line 12
    tb = tracemalloc.get_object_traceback(f())
```

These libraries help you with publishing and installing Python software. While these modules are designed to work in conjunction with the [Python Package Index](#), they can also be used with a local index server, or without any index server at all.

28.1 ensurepip --- pip 安裝器的初始建置 (bootstrapping)

在 3.4 版被加入。

原始碼: [Lib/ensurepip](#)

`ensurepip` 套件 (package) 在既有的 Python 安裝或擬環境提供 `pip` 安裝器初始建置 (bootstrapping) 的支援。這個初始建置的方式應證了事實——`pip` 是有其獨立發布期的專案，且其最新可用穩定的版本，會與 CPython 直譯器 (interpreter) 之維護和功能發布綁定。

大多數情況下，Python 的終端使用者不需要直接調用此模組（因 `pip` 預設應初始建置），但若安裝 Python 時 `pip` 被省略（或建立一擬環境時），又或是 `pip` 被明確解除安裝時，則此模組的初始建置仍有可能用上。

備註

此模組不會通過網路存取。所有需要用來初始建置 `pip` 的元件都已包含在套件之內。

也參考

installing-index

對於終端使用者安裝 Python 套件的指引

PEP 453: 在 Python 安裝中的 `pip` 明確初始建置

此模組的最初設計理念與規範。

Availability: not WASI, not iOS.

This module does not work or is not available on WebAssembly platforms, or on iOS. See [WebAssembly 平台](#) for more information on WASM availability; see [iOS](#) for more information on iOS availability.

28.1.1 命令列介面

使用直譯器 (interpreter) 的 `-m` 來調用命令列介面

最簡單可行的調用：

```
python -m ensurepip
```

若 `pip` 未安裝，此調用會將其安裝；否則甚也不做。可透過傳入 `--upgrade` 參數來確保 `pip` 的安裝版本至少與當前 `ensurepip` 中最新可用的版本：

```
python -m ensurepip --upgrade
```

預設上，`pip` 會被安裝至當前虛擬環境（若已啟動虛擬環境）或系統端的套件（若沒有啟動的虛擬環境）。安裝位置可透過兩個額外的命令列選項來控制：

- `--root <dir>`：安裝 `pip` 到給定的根目錄 (root directory) 的相對路徑，而不是當前虛擬環境（若存在）的根目錄，或當前 Python 安裝版所預設的根目錄。
- `--user`：安裝 `pip` 到使用者端的套件目錄，而不是全域安裝到當前的 Python 安裝版（此選項不允許在一個啟動的虛擬環境中使用）。

預設會安裝 `pipX` 和 `pipX.Y` 版本（`X.Y` 代表用來調用 `ensurepip` 的 Python 之版本）。安裝的版本可透過兩個額外的命令列選項來控制：

- `--altinstall`：若要求一個替代安裝版，則不會安裝 `pipX` 版本。
- `--default-pip`：若要求安裝「預設 `pip`」，則會安裝 `pip` 版本，及 2 個常規版本。

提供兩種指令選項將會導致例外 (exception)。

28.1.2 模組 API

`ensurepip` 開放了兩個用於編寫程式的函式：

`ensurepip.version()`

回傳一個字串，用以標明初始建置時，安裝的 `pip` 的可行版本號。

`ensurepip.bootstrap (root=None, upgrade=False, user=False, altinstall=False, default_pip=False, verbosity=0)`

在當前或指定的環境之中建立 `pip`。

`root` 指定一個替代的根目錄，作為安裝的相對路徑。若 `root` 為 `None`，則安裝使用當前環境的預設安裝位置。

`upgrade` 指出是否要將一個既有的較早版本的 `pip` 升級至可用的新版。

`user` 指出是否要使用使用者的安裝方案而不是全域安裝。

預設會安裝 `pipX` 和 `pipX.Y` 版本（`X.Y` 代表 Python 的當前版本）。

如果用了 `altinstall`，則不會安裝 `pipX`。

如果用了 `default_pip`，則會安裝 `pip`，以及 2 個常規版本。

同時用 `altinstall` 跟 `default_pip`，將會觸發 `ValueError`。

`verbosity` 用來控制初始建置操作，對於 `sys.stdout` 的輸出等級。

引發一個附帶引數 `root` 的稽核事件 `ensurepip.bootstrap`。

備

初始建置的過程對於 `sys.path` 及 `os.environ` 均有副作用。改在一子行程 (subprocess) 調用命令列介面可避免這些副作用。

備

初始建置的過程也許會安裝 `pip` 所需要的額外的模組，但其他軟體不應該假設這些相依 (dependency) 總是預設存在（因這些相依很可能會在未來版本的 `pip` 中被移除）。

28.2 `venv` --- 建立 擬環境

在 3.3 版被加入。

原始碼: [Lib/venv/](#)

The `venv` module supports creating lightweight “virtual environments”, each with their own independent set of Python packages installed in their *site* directories. A virtual environment is created on top of an existing Python installation, known as the virtual environment’s “base” Python, and may optionally be isolated from the packages in the base environment, so only those explicitly installed in the virtual environment are available.

When used from within a virtual environment, common installation tools such as `pip` will install Python packages into a virtual environment without needing to be told to do so explicitly.

A virtual environment is (amongst other things):

- Used to contain a specific Python interpreter and software libraries and binaries which are needed to support a project (library or application). These are by default isolated from software in other virtual environments and Python interpreters and libraries installed in the operating system.
- Contained in a directory, conventionally either named `venv` or `.venv` in the project directory, or under a container directory for lots of virtual environments, such as `~/.virtualenvs`.
- Not checked into source control systems such as Git.
- Considered as disposable -- it should be simple to delete and recreate it from scratch. You don’t place any project code in the environment
- Not considered as movable or copyable -- you just recreate the same environment in the target location.

更多關於 Python 擬環境的背景資訊請見 [PEP 405](#)。

也參考

Python Packaging User Guide: Creating and using virtual environments

Availability: not WASI, not iOS.

This module does not work or is not available on WebAssembly platforms, or on iOS. See [WebAssembly 平台](#) for more information on WASM availability; see [iOS](#) for more information on iOS availability.

28.2.1 建立擬環境

建立擬環境的方法是透過執行指令 `venv`:

```
python -m venv /path/to/new/virtual/environment
```

執行此命令會建立目標目錄（同時也會建立任何還不存在的父目錄）。在目標目錄中放置一個名 `pyvenv.cfg` 的檔案，其中包含一個指向執行該命令的 Python 安裝路徑的 `home` 鍵（目標目錄的常見名稱 `.venv`）。同時，它會建立一個 `bin`（在 Windows 上 `Scripts`）子目錄，其中包含一個 Python 二進位檔案的副本/符號連結（根據建立環境時使用的平台或引數而定）。此外，它還會建立一個（最初空的）`lib/pythonX.Y/site-packages` 子目錄（在 Windows 上 `Lib\site-packages`）。如果指定的目錄已存在，則將重新使用該目錄。

在 3.5 版的變更：目前建議使用 `venv` 來建立擬環境。

在 3.6 版之後被採用：`pyvenv` 是在 Python 3.3 和 3.4 中建立擬環境的推薦工具，但在 Python 3.6 中已被採用。

在 Windows 上，執行以下命令以使用 `venv`:

```
c:\>Python35\python -m venv c:\path\to\myenv
```

或者，如果你已經將你的 Python 安裝配置了 `PATH` 和 `PATHEXT` 變數，則可以執行以下命令：

```
c:\>python -m venv c:\path\to\myenv
```

如果使用 `-h` 選項執行該命令，將會顯示可用的選項：

```
usage: venv [-h] [--system-site-packages] [--symlinks | --copies] [--clear]
            [--upgrade] [--without-pip] [--prompt PROMPT] [--upgrade-deps]
            [--without-scm-ignore-file]
            ENV_DIR [ENV_DIR ...]

Creates virtual Python environments in one or more target directories.

positional arguments:
ENV_DIR                A directory to create the environment in.

options:
-h, --help            show this help message and exit
--system-site-packages
                    Give the virtual environment access to the system
                    site-packages dir.
--symlinks            Try to use symlinks rather than copies, when
                    symlinks are not the default for the platform.
--copies             Try to use copies rather than symlinks, even when
                    symlinks are the default for the platform.
--clear              Delete the contents of the environment directory if
                    it already exists, before environment creation.
--upgrade            Upgrade the environment directory to use this
                    version of Python, assuming Python has been upgraded
                    in-place.
--without-pip        Skips installing or upgrading pip in the virtual
                    environment (pip is bootstrapped by default)
--prompt PROMPT      Provides an alternative prompt prefix for this
                    environment.
--upgrade-deps       Upgrade core dependencies (pip) to the latest
                    version in PyPI
--without-scm-ignore-file
                    Skips adding the default SCM ignore file to the
                    environment directory (the default is a .gitignore
                    file).
```

(繼續下一頁)

(繼續上一頁)

Once an environment has been created, you may wish to activate it, e.g. by sourcing an activate script in its bin directory.

在 3.13 版的變更: `--without-scm-ignore-file` was added along with creating an ignore file for git by default.

在 3.12 版的變更: `setuptools` is no longer a core `venv` dependency.

在 3.9 版的變更: 新增 `--upgrade-deps` 選項以將 `pip` 和 `setuptools` 升級至 PyPI 上的最新版本

在 3.4 版的變更: 預設情況下安裝 `pip`, 新增了 `--without-pip` 和 `--copies` 選項

在 3.4 版的變更: 在較早的版本中, 如果目標目錄已存在, 除非提供了 `--clear` 或 `--upgrade` 選項, 否則會引發錯誤。

備

雖然在 Windows 上支援符號連結, 但不建議使用。特需要注意的是, 在檔案總管中按兩下 `python.exe` 會急切地解析符號連結而忽略擬環境。

備

在 Microsoft Windows 上, 可能需要通過設置使用者的執行策略來用 `Activate.ps1` 本。你可以發出以下 PowerShell 命令來執行此操作:

```
PS C:> Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope CurrentUser
```

有關更多資訊, 請參閱關於執行策略。

被建立的 `pyvenv.cfg` 檔案還包括了 `include-system-site-packages` 的鍵, 如果使用 `venv` 執行時帶有 `--system-site-packages` 選項, 則設置 `true`, 否則設置 `false`。

除非 `--without-pip` 選項被提供, 否則將調用 `ensurepip` 來動 `pip` 到擬環境中。

可以向 `venv` 提供多個路徑, 這樣每個提供的路徑都將根據給定的選項建立一個相同的擬環境。

28.2.2 擬環境如何運作

當 Python 直譯器跑在擬環境時, `sys.prefix` 和 `sys.exec_prefix` 會指向擬環境的目錄, 而 `sys.base_prefix` 和 `sys.base_exec_prefix` 會指向建立擬環境的基礎 Python 的目錄。檢查 `sys.prefix != sys.base_prefix` 就可以確定目前的直譯器是否跑在擬環境中。

擬環境可以透過位於二進位檔案目錄中的本「用」(在 POSIX 上 `bin`; 在 Windows 上 `Scripts`) 這會將該目錄加入到你的 `PATH`, 當你運行 `python` 時就會調用該環境的直譯器且執行已安裝的本, 而不需要使用完整的路徑。動本的方式因平台而 (`<venv>` 需要替成包含擬環境的目錄路徑)

平台	Shell	動擬環境的指令
POSIX	<code>bash/zsh</code>	<code>\$ source <venv>/bin/activate</code>
	<code>fish</code>	<code>\$ source <venv>/bin/activate.fish</code>
	<code>csh/tcsh</code>	<code>\$ source <venv>/bin/activate.csh</code>
	<code>PowerShell</code>	<code>\$ <venv>/bin/Activate.ps1</code>
Windows	<code>cmd.exe</code>	<code>C:\> <venv>\Scripts\activate.bat</code>
	<code>PowerShell</code>	<code>PS C:\> <venv>\Scripts\Activate.ps1</code>

在 3.4 版被加入: `fish` 和 `csh` 動本。

在 3.8 版被加入: PowerShell 的動本安裝在 POSIX 上支援 PowerShell Core。

你不用特開虛擬環境，你可以在調用 Python 時指定該環境下 Python 直譯器的完整路徑。此外，所有安裝在環境內的脚本都應該都可以在未用虛擬環境的情況下運行。

為了實現這一點，安裝在虛擬環境中的脚本會有一個“shebang”列，此列指向該環境的 Python 直譯器，例如：`#!/<path-to-venv>/bin/python`。這代表無論 PATH 的值為何，該脚本都會在直譯器上運行。在 Windows 上，如果你安裝了 launcher，則支援“shebang”列處理。因此，在 Windows 檔案總管 (Windows Explorer) 中雙擊已安裝的脚本，應該可以在有環境或將其加入 PATH 的情況下正確地運行。

當虛擬環境被用時，VIRTUAL_ENV 環境變數會被設置為該環境的路徑。由於不需要明確用虛擬環境才能使用它。因此，無法依賴 VIRTUAL_ENV 來判斷是否正在使用虛擬環境。

警告

因安裝在環境中的脚本不應該預期該環境已經被啟動，所以它們的 shebang 列會包含環境直譯器的相對路徑。因此，在一般情況下，環境本質上是不可帶的。你應該使用一個簡單的方法來重新建立一個環境（例如：如果你有一個名 requirements.txt 的需求檔案，你可以使用環境的 `pip install -r requirements.txt` 來安裝環境所需的所有套件）。如果出於某種原因，你需要將環境移至新位置，你應該在所需位置重新建立它，刪除舊位置的環境。如果你移動環境是因移動了其父目錄，你應該在新位置重新建立環境。否則，安裝在該環境中的軟體可能無法正常運作。

你可以在 shell 輸入 `deactivate` 來關閉虛擬環境。具體的使用方式因平台而異，是內部實作的細節（通常會使用脚本或是 shell 函式）

28.2.3 API

上述提到的高階 method（方法）透過簡單的 API 使用，由第三方虛擬環境建立者提供可以依據他們需求來建立環境的客制化機制：`EnvBuilder` class。

```
class venv.EnvBuilder(system_site_packages=False, clear=False, symlinks=False, upgrade=False,
                      with_pip=False, prompt=None, upgrade_deps=False, *,
                      scm_ignore_files=frozenset())
```

進行實例化時，class `EnvBuilder` 接受下列的關鍵字引數：

- `system_site_packages` -- 一個 Boolean（布林值），表明系統的 Python site-packages 是否可以在環境中可用（預設 `False`）。
- `clear` -- 一個 Boolean，如果 `true`，則在建立環境之前，刪除目標目錄內所有存在的內容。
- `symlinks` -- 一個 Boolean，表明是否嘗試與 Python 二進位檔案建立符號連結而不是硬連結該檔案。
- `upgrade` -- 一個 Boolean，若 `true`，則會在執行 Python 時對現有的環境進行升級。目的是讓 Python 可以升級到位（預設 `False`）。
- `with_pip` -- 一個 Boolean，若 `true`，則確保 pip 有安裝至虛擬環境之中。當有 `--default-pip` 的選項時，會使用 `ensurepip`。
- `prompt` -- 一個 String（字串），該字串會在虛擬環境啟動時被使用。（預設 `None`，代表該環境的目錄名稱會被使用）倘若出現特殊字串 `"."`，則當前目錄的 `basename` 會做為提示路徑使用。
- `upgrade_deps` -- 更新基礎 venv 模組至 PyPI 的最新版本
- `scm_ignore_files` -- Create ignore files based for the specified source control managers (SCM) in the iterable. Support is defined by having a method named `create_{scm}_ignore_file`. The only value supported by default is "git" via `create_git_ignore_file()`.

在 3.4 版的變更：新增 `with_pip` 參數

在 3.6 版的變更：新增 `prompt` 參數

在 3.9 版的變更：新增 `upgrade_deps` 參數

在 3.13 版的變更: Added the `scm_ignore_files` parameter

第三方擬環境工具的建立者可以自由地使用 `EnvBuilder` class 作 base class (基底類) 使用。回傳的 `env-builder` 一個物件，且帶有一個 method `create`:

create (*env_dir*)

透過指定將會容納擬環境的目標目錄來建立一個擬環境 (對路徑或相對路徑到該目錄)，也就是在該目錄中容納擬環境。`create` method 將會在指定的目錄下建立環境，或是觸發適當的例外。

`EnvBuilder` class 的 `create` method 會闡述可用的 Hooks 以客化 subclass (子類):

```
def create(self, env_dir):
    """
    Create a virtualized Python environment in a directory.
    env_dir is the target directory to create an environment in.
    """
    env_dir = os.path.abspath(env_dir)
    context = self.ensure_directories(env_dir)
    self.create_configuration(context)
    self.setup_python(context)
    self.setup_scripts(context)
    self.post_setup(context)
```

每個 methods `ensure_directories()`、`create_configuration()`、`setup_python()`、`setup_scripts()` 及 `post_setup()` 都可以被覆寫。

ensure_directories (*env_dir*)

建立還不存在的環境目錄及必要的子目錄，回傳一個情境物件 (context object)。這個情境物件只是一個屬性 (例如: 路徑) 的所有者，可被其他 method 使用。如果 `EnvBuilder` 已被建立且帶有 `clear=True` 的引數，該環境目錄下的內容將被清空，以及所有必要的子目錄將被重新建立。

回傳的情境物件 (context object) 其型會是 `types.SimpleNamespace`，包含以下屬性:

- `env_dir` - The location of the virtual environment. Used for `__VENV_DIR__` in activation scripts (see `install_scripts()`).
- `env_name` - The name of the virtual environment. Used for `__VENV_NAME__` in activation scripts (see `install_scripts()`).
- `prompt` - The prompt to be used by the activation scripts. Used for `__VENV_PROMPT__` in activation scripts (see `install_scripts()`).
- `executable` - The underlying Python executable used by the virtual environment. This takes into account the case where a virtual environment is created from another virtual environment.
- `inc_path` - The include path for the virtual environment.
- `lib_path` - The purelib path for the virtual environment.
- `bin_path` - The script path for the virtual environment.
- `bin_name` - The name of the script path relative to the virtual environment location. Used for `__VENV_BIN_NAME__` in activation scripts (see `install_scripts()`).
- `env_exe` - The name of the Python interpreter in the virtual environment. Used for `__VENV_PYTHON__` in activation scripts (see `install_scripts()`).
- `env_exec_cmd` - The name of the Python interpreter, taking into account filesystem redirections. This can be used to run Python in the virtual environment.

在 3.11 版的變更: The `venv sysconfig installation scheme` is used to construct the paths of the created directories.

在 3.12 版的變更: The attribute `lib_path` was added to the context, and the context object was documented.

create_configuration (*context*)

Creates the `pyenv.config` configuration file in the environment.

setup_python (*context*)

Creates a copy or symlink to the Python executable in the environment. On POSIX systems, if a specific executable `python3.x` was used, symlinks to `python` and `python3` will be created pointing to that executable, unless files with those names already exist.

setup_scripts (*context*)

Installs activation scripts appropriate to the platform into the virtual environment.

upgrade_dependencies (*context*)

Upgrades the core venv dependency packages (currently `pip`) in the environment. This is done by shelling out to the `pip` executable in the environment.

在 3.9 版被加入。

在 3.12 版的變更: `setuptools` is no longer a core venv dependency.

post_setup (*context*)

A placeholder method which can be overridden in third party implementations to pre-install packages in the virtual environment or perform other post-creation steps.

在 3.7.2 版的變更: Windows now uses redirector scripts for `python[w].exe` instead of copying the actual binaries. In 3.7.2 only `setup_python()` does nothing unless running from a build in the source tree.

在 3.7.3 版的變更: Windows copies the redirector scripts as part of `setup_python()` instead of `setup_scripts()`. This was not the case in 3.7.2. When using symlinks, the original executables will be linked.

In addition, `EnvBuilder` provides this utility method that can be called from `setup_scripts()` or `post_setup()` in subclasses to assist in installing custom scripts into the virtual environment.

install_scripts (*context*, *path*)

path is the path to a directory that should contain subdirectories "common", "posix", "nt", each containing scripts destined for the bin directory in the environment. The contents of "common" and the directory corresponding to `os.name` are copied after some text replacement of placeholders:

- `__VENV_DIR__` is replaced with the absolute path of the environment directory.
- `__VENV_NAME__` is replaced with the environment name (final path segment of environment directory).
- `__VENV_PROMPT__` is replaced with the prompt (the environment name surrounded by parentheses and with a following space)
- `__VENV_BIN_NAME__` is replaced with the name of the bin directory (either `bin` or `Scripts`).
- `__VENV_PYTHON__` is replaced with the absolute path of the environment's executable.

The directories are allowed to exist (for when an existing environment is being upgraded).

create_git_ignore_file (*context*)

Creates a `.gitignore` file within the virtual environment that causes the entire directory to be ignored by the `git` source control manager.

在 3.13 版被加入。

There is also a module-level convenience function:

```
venv.create(env_dir, system_site_packages=False, clear=False, symlinks=False, with_pip=False,
            prompt=None, upgrade_deps=False, *, scm_ignore_files=frozenset())
```

Create an `EnvBuilder` with the given keyword arguments, and call its `create()` method with the *env_dir* argument.

在 3.3 版被加入。

在 3.4 版的變更: 新增 `with_pip` 參數

在 3.6 版的變更: 新增 `prompt` 參數

在 3.9 版的變更: 新增 `upgrade_deps` 參數

在 3.13 版的變更: Added the `scm_ignore_files` parameter

28.2.4 An example of extending `EnvBuilder`

The following script shows how to extend `EnvBuilder` by implementing a subclass which installs `setuptools` and `pip` into a created virtual environment:

```
import os
import os.path
from subprocess import Popen, PIPE
import sys
from threading import Thread
from urllib.parse import urlparse
from urllib.request import urlretrieve
import venv

class ExtendedEnvBuilder(venv.EnvBuilder):
    """
    This builder installs setuptools and pip so that you can pip or
    easy_install other packages into the created virtual environment.

    :param nodist: If true, setuptools and pip are not installed into the
        created virtual environment.
    :param nopip: If true, pip is not installed into the created
        virtual environment.
    :param progress: If setuptools or pip are installed, the progress of the
        installation can be monitored by passing a progress
        callable. If specified, it is called with two
        arguments: a string indicating some progress, and a
        context indicating where the string is coming from.
        The context argument can have one of three values:
        'main', indicating that it is called from virtualize()
        itself, and 'stdout' and 'stderr', which are obtained
        by reading lines from the output streams of a subprocess
        which is used to install the app.

        If a callable is not specified, default progress
        information is output to sys.stderr.
    """

    def __init__(self, *args, **kwargs):
        self.nodist = kwargs.pop('nodist', False)
        self.nopip = kwargs.pop('nopip', False)
        self.progress = kwargs.pop('progress', None)
        self.verbose = kwargs.pop('verbose', False)
        super().__init__(*args, **kwargs)

    def post_setup(self, context):
        """
        Set up any packages which need to be pre-installed into the
        virtual environment being created.

        :param context: The information for the virtual environment
            creation request being processed.
        """
        os.environ['VIRTUAL_ENV'] = context.env_dir

28.3 zipapp --- 管理可執行的 Python zip 封存檔案

在 3.5 版被加入。

原始碼: [Lib/zipapp.py](#)

This module provides tools to manage the creation of zip files containing Python code, which can be executed directly by the Python interpreter. The module provides both a [命令執行列介面](#) and a *Python API*.

28.3.1 基本范例

The following example shows how the 命令執行列介面 can be used to create an executable archive from a directory containing Python code. When run, the archive will execute the `main` function from the module `myapp` in the archive.

```
$ python -m zipapp myapp -m "myapp:main"
$ python myapp.pyz
<output from myapp>
```

28.3.2 命令執行列介面

When called as a program from the command line, the following form is used:

```
$ python -m zipapp source [options]
```

If *source* is a directory, this will create an archive from the contents of *source*. If *source* is a file, it should be an archive, and it will be copied to the target archive (or the contents of its shebang line will be displayed if the `--info` option is specified).

The following options are understood:

-o <output>, **--output**=<output>

Write the output to a file named *output*. If this option is not specified, the output filename will be the same as the input *source*, with the extension `.pyz` added. If an explicit filename is given, it is used as is (so a `.pyz` extension should be included if required).

An output filename must be specified if the *source* is an archive (and in that case, *output* must not be the same as *source*).

-p <interpreter>, **--python**=<interpreter>

Add a `#!` line to the archive specifying *interpreter* as the command to run. Also, on POSIX, make the archive executable. The default is to write no `#!` line, and not make the file executable.

-m <mainfn>, **--main**=<mainfn>

Write a `__main__.py` file to the archive that executes *mainfn*. The *mainfn* argument should have the form "pkg.mod:fn", where "pkg.mod" is a package/module in the archive, and "fn" is a callable in the given module. The `__main__.py` file will execute that callable.

`--main` cannot be specified when copying an archive.

-c, **--compress**

Compress files with the deflate method, reducing the size of the output file. By default, files are stored uncompressed in the archive.

`--compress` has no effect when copying an archive.

在 3.7 版被加入.

--info

Display the interpreter embedded in the archive, for diagnostic purposes. In this case, any other options are ignored and *SOURCE* must be an archive, not a directory.

-h, **--help**

Print a short usage message and exit.

28.3.3 Python API

The module defines two convenience functions:

`zipapp.create_archive` (*source*, *target=None*, *interpreter=None*, *main=None*, *filter=None*, *compressed=False*)

Create an application archive from *source*. The source can be any of the following:

- The name of a directory, or a *path-like object* referring to a directory, in which case a new application archive will be created from the content of that directory.
- The name of an existing application archive file, or a *path-like object* referring to such a file, in which case the file is copied to the target (modifying it to reflect the value given for the *interpreter* argument). The file name should include the `.pyz` extension, if required.
- A file object open for reading in bytes mode. The content of the file should be an application archive, and the file object is assumed to be positioned at the start of the archive.

The *target* argument determines where the resulting archive will be written:

- If it is the name of a file, or a *path-like object*, the archive will be written to that file.
- If it is an open file object, the archive will be written to that file object, which must be open for writing in bytes mode.
- If the target is omitted (or `None`), the source must be a directory and the target will be a file with the same name as the source, with a `.pyz` extension added.

The *interpreter* argument specifies the name of the Python interpreter with which the archive will be executed. It is written as a “shebang” line at the start of the archive. On POSIX, this will be interpreted by the OS, and on Windows it will be handled by the Python launcher. Omitting the *interpreter* results in no shebang line being written. If an interpreter is specified, and the target is a filename, the executable bit of the target file will be set.

The *main* argument specifies the name of a callable which will be used as the main program for the archive. It can only be specified if the source is a directory, and the source does not already contain a `__main__.py` file. The *main* argument should take the form “`pkg.module:callable`” and the archive will be run by importing “`pkg.module`” and executing the given callable with no arguments. It is an error to omit *main* if the source is a directory and does not contain a `__main__.py` file, as otherwise the resulting archive would not be executable.

The optional *filter* argument specifies a callback function that is passed a `Path` object representing the path to the file being added (relative to the source directory). It should return `True` if the file is to be added.

The optional *compressed* argument determines whether files are compressed. If set to `True`, files in the archive are compressed with the deflate method; otherwise, files are stored uncompressed. This argument has no effect when copying an existing archive.

If a file object is specified for *source* or *target*, it is the caller’s responsibility to close it after calling `create_archive`.

When copying an existing archive, file objects supplied only need `read` and `readline`, or `write` methods. When creating an archive from a directory, if the target is a file object it will be passed to the `zipfile.ZipFile` class, and must supply the methods needed by that class.

在 3.7 版的變更: 新增 *filter* 與 *compressed* 參數。

`zipapp.get_interpreter` (*archive*)

Return the interpreter specified in the `#!` line at the start of the archive. If there is no `#!` line, return `None`. The *archive* argument can be a filename or a file-like object open for reading in bytes mode. It is assumed to be at the start of the archive.

28.3.4 范例

Pack up a directory into an archive, and run it.

```
$ python -m zipapp myapp
$ python myapp.pyz
<output from myapp>
```

The same can be done using the `create_archive()` function:

```
>>> import zipapp
>>> zipapp.create_archive('myapp', 'myapp.pyz')
```

To make the application directly executable on POSIX, specify an interpreter to use.

```
$ python -m zipapp myapp -p "/usr/bin/env python"
$ ./myapp.pyz
<output from myapp>
```

To replace the shebang line on an existing archive, create a modified archive using the `create_archive()` function:

```
>>> import zipapp
>>> zipapp.create_archive('old_archive.pyz', 'new_archive.pyz', '/usr/bin/python3')
```

To update the file in place, do the replacement in memory using a `BytesIO` object, and then overwrite the source afterwards. Note that there is a risk when overwriting a file in place that an error will result in the loss of the original file. This code does not protect against such errors, but production code should do so. Also, this method will only work if the archive fits in memory:

```
>>> import zipapp
>>> import io
>>> temp = io.BytesIO()
>>> zipapp.create_archive('myapp.pyz', temp, '/usr/bin/python2')
>>> with open('myapp.pyz', 'wb') as f:
>>>     f.write(temp.getvalue())
```

28.3.5 Specifying the Interpreter

Note that if you specify an interpreter and then distribute your application archive, you need to ensure that the interpreter used is portable. The Python launcher for Windows supports most common forms of POSIX `#!` line, but there are other issues to consider:

- If you use `"/usr/bin/env python"` (or other forms of the `"python"` command, such as `"/usr/bin/python"`), you need to consider that your users may have either Python 2 or Python 3 as their default, and write your code to work under both versions.
- If you use an explicit version, for example `"/usr/bin/env python3"` your application will not work for users who do not have that version. (This may be what you want if you have not made your code Python 2 compatible).
- There is no way to say `"python X.Y or later"`, so be careful of using an exact version like `"/usr/bin/env python3.4"` as you will need to change your shebang line for users of Python 3.5, for example.

Typically, you should use an `"/usr/bin/env python2"` or `"/usr/bin/env python3"`, depending on whether your code is written for Python 2 or 3.

28.3.6 Creating Standalone Applications with zipapp

Using the `zipapp` module, it is possible to create self-contained Python programs, which can be distributed to end users who only need to have a suitable version of Python installed on their system. The key to doing this is to bundle all of the application's dependencies into the archive, along with the application code.

The steps to create a standalone archive are as follows:

1. Create your application in a directory as normal, so you have a `myapp` directory containing a `__main__.py` file, and any supporting application code.
2. Install all of your application's dependencies into the `myapp` directory, using `pip`:

```
$ python -m pip install -r requirements.txt --target myapp
```

(this assumes you have your project requirements in a `requirements.txt` file - if not, you can just list the dependencies manually on the `pip` command line).

3. Package the application using:

```
$ python -m zipapp -p "interpreter" myapp
```

This will produce a standalone executable, which can be run on any machine with the appropriate interpreter available. See *Specifying the Interpreter* for details. It can be shipped to users as a single file.

On Unix, the `myapp.pyz` file is executable as it stands. You can rename the file to remove the `.pyz` extension if you prefer a "plain" command name. On Windows, the `myapp.pyz[w]` file is executable by virtue of the fact that the Python interpreter registers the `.pyz` and `.pyzw` file extensions when installed.

Caveats

If your application depends on a package that includes a C extension, that package cannot be run from a zip file (this is an OS limitation, as executable code must be present in the filesystem for the OS loader to load it). In this case, you can exclude that dependency from the zipfile, and either require your users to have it installed, or ship it alongside your zipfile and add code to your `__main__.py` to include the directory containing the unzipped module in `sys.path`. In this case, you will need to make sure to ship appropriate binaries for your target architecture(s) (and potentially pick the correct version to add to `sys.path` at runtime, based on the user's machine).

28.3.7 The Python Zip Application Archive Format

Python has been able to execute zip files which contain a `__main__.py` file since version 2.6. In order to be executed by Python, an application archive simply has to be a standard zip file containing a `__main__.py` file which will be run as the entry point for the application. As usual for any Python script, the parent of the script (in this case the zip file) will be placed on `sys.path` and thus further modules can be imported from the zip file.

The zip file format allows arbitrary data to be prepended to a zip file. The zip application format uses this ability to prepend a standard POSIX "shebang" line to the file (`#!/path/to/interpreter`).

Formally, the Python zip application format is therefore:

1. An optional shebang line, containing the characters `b'#!'` followed by an interpreter name, and then a newline (`b'\n'`) character. The interpreter name can be anything acceptable to the OS "shebang" processing, or the Python launcher on Windows. The interpreter should be encoded in UTF-8 on Windows, and in `sys.getfilesystemencoding()` on POSIX.
2. Standard zipfile data, as generated by the `zipfile` module. The zipfile content *must* include a file called `__main__.py` (which must be in the "root" of the zipfile - i.e., it cannot be in a subdirectory). The zipfile data can be compressed or uncompressed.

If an application archive has a shebang line, it may have the executable bit set on POSIX systems, to allow it to be executed directly.

There is no requirement that the tools in this module are used to create application archives - the module is a convenience, but archives in the above format created by any means are acceptable to Python.

The modules described in this chapter provide a wide range of services related to the Python interpreter and its interaction with its environment. Here's an overview:

29.1 `sys` --- 系統特定的參數與函式

This module provides access to some variables used or maintained by the interpreter and to functions that interact strongly with the interpreter. It is always available.

`sys.abiflags`

On POSIX systems where Python was built with the standard `configure` script, this contains the ABI flags as specified by [PEP 3149](#).

在 3.2 版被加入。

在 3.8 版的變更: Default flags became an empty string (m flag for pymalloc has been removed).

適用: Unix。

`sys.addaudithook(hook)`

Append the callable *hook* to the list of active auditing hooks for the current (sub)interpreter.

When an auditing event is raised through the `sys.audit()` function, each hook will be called in the order it was added with the event name and the tuple of arguments. Native hooks added by `PySys_AddAuditHook()` are called first, followed by hooks added in the current (sub)interpreter. Hooks can then log the event, raise an exception to abort the operation, or terminate the process entirely.

Note that audit hooks are primarily for collecting information about internal or otherwise unobservable actions, whether by Python or libraries written in Python. They are not suitable for implementing a "sandbox". In particular, malicious code can trivially disable or bypass hooks added using this function. At a minimum, any security-sensitive hooks must be added using the C API `PySys_AddAuditHook()` before initialising the runtime, and any modules allowing arbitrary memory modification (such as `ctypes`) should be completely removed or closely monitored.

呼叫 `sys.addaudithook()` 本身會引發一個不帶任何引數、名為 `sys.addaudithook` 的稽核事件。如果任何現有的 `hook` 引發從 `RuntimeError` 衍生的例外，則不會添加新的 `hook`。抑制。因此，除非呼叫者控制所有已存在的 `hook`，他們不能假設他們的 `hook` 已被添加。

所有會被 CPython 所引發的事件請參考稽核事件總表、設計相關討論請見 [PEP 578](#)。

在 3.8 版被加入。

在 3.8.1 版的變更: Exceptions derived from *Exception* but not *RuntimeError* are no longer suppressed.

CPython 實作細節: When tracing is enabled (see `settrace()`), Python hooks are only traced if the callable has a `__cantrace__` member that is set to a true value. Otherwise, trace functions will skip the hook.

`sys.argv`

The list of command line arguments passed to a Python script. `argv[0]` is the script name (it is operating system dependent whether this is a full pathname or not). If the command was executed using the `-c` command line option to the interpreter, `argv[0]` is set to the string `'-c'`. If no script name was passed to the Python interpreter, `argv[0]` is the empty string.

To loop over the standard input, or the list of files given on the command line, see the `fileinput` module.

另請參 `sys.orig_argv`。

備

On Unix, command line arguments are passed by bytes from OS. Python decodes them with filesystem encoding and "surrogateescape" error handler. When you need original bytes, you can get it by `[os.fsencode(arg) for arg in sys.argv]`.

`sys.audit(event, *args)`

Raise an auditing event and trigger any active auditing hooks. *event* is a string identifying the event, and *args* may contain optional arguments with more information about the event. The number and types of arguments for a given event are considered a public and stable API and should not be modified between releases.

舉例來，一個名 `os.chdir` 的稽核事件擁有一個引數 *path*，其內容所要求的新工作目錄。

`sys.audit()` will call the existing auditing hooks, passing the event name and arguments, and will re-raise the first exception from any hook. In general, if an exception is raised, it should not be handled and the process should be terminated as quickly as possible. This allows hook implementations to decide how to respond to particular events: they can merely log the event or abort the operation by raising an exception.

Hooks are added using the `sys.addaudithook()` or `PySys_AddAuditHook()` functions.

The native equivalent of this function is `PySys_Audit()`. Using the native function is preferred when possible.

所有會被 CPython 所引發的事件請參考稽核事件總表。

在 3.8 版被加入。

`sys.base_exec_prefix`

Set during Python startup, before `site.py` is run, to the same value as `exec_prefix`. If not running in a *virtual environment*, the values will stay the same; if `site.py` finds that a virtual environment is in use, the values of `prefix` and `exec_prefix` will be changed to point to the virtual environment, whereas `base_prefix` and `base_exec_prefix` will remain pointing to the base Python installation (the one which the virtual environment was created from).

在 3.3 版被加入。

`sys.base_prefix`

Set during Python startup, before `site.py` is run, to the same value as `prefix`. If not running in a *virtual environment*, the values will stay the same; if `site.py` finds that a virtual environment is in use, the values of `prefix` and `exec_prefix` will be changed to point to the virtual environment, whereas `base_prefix` and `base_exec_prefix` will remain pointing to the base Python installation (the one which the virtual environment was created from).

在 3.3 版被加入。

`sys.byteorder`

An indicator of the native byte order. This will have the value 'big' on big-endian (most-significant byte first) platforms, and 'little' on little-endian (least-significant byte first) platforms.

`sys.builtin_module_names`

A tuple of strings containing the names of all modules that are compiled into this Python interpreter. (This information is not available in any other way --- `modules.keys()` only lists the imported modules.)

另請參閱 `sys.stdlib_module_names` 清單。

`sys.call_tracing(func, args)`

Call `func(*args)`, while tracing is enabled. The tracing state is saved, and restored afterwards. This is intended to be called from a debugger from a checkpoint, to recursively debug or profile some other code.

Tracing is suspended while calling a tracing function set by `settrace()` or `setprofile()` to avoid infinite recursion. `call_tracing()` enables explicit recursion of the tracing function.

`sys.copyright`

A string containing the copyright pertaining to the Python interpreter.

`sys._clear_type_cache()`

Clear the internal type cache. The type cache is used to speed up attribute and method lookups. Use the function *only* to drop unnecessary references during reference leak debugging.

This function should be used for internal and specialized purposes only.

在 3.13 版之後被禁用: Use the more general `_clear_internal_caches()` function instead.

`sys._clear_internal_caches()`

Clear all internal performance-related caches. Use this function *only* to release unnecessary references and memory blocks when hunting for leaks.

在 3.13 版被加入。

`sys._current_frames()`

Return a dictionary mapping each thread's identifier to the topmost stack frame currently active in that thread at the time the function is called. Note that functions in the `traceback` module can build the call stack given such a frame.

This is most useful for debugging deadlock: this function does not require the deadlocked threads' cooperation, and such threads' call stacks are frozen for as long as they remain deadlocked. The frame returned for a non-deadlocked thread may bear no relationship to that thread's current activity by the time calling code examines the frame.

This function should be used for internal and specialized purposes only.

引發一個不附帶引數的稽核事件 `sys._current_frames`。

`sys._current_exceptions()`

Return a dictionary mapping each thread's identifier to the topmost exception currently active in that thread at the time the function is called. If a thread is not currently handling an exception, it is not included in the result dictionary.

This is most useful for statistical profiling.

This function should be used for internal and specialized purposes only.

引發一個不附帶引數的稽核事件 `sys._current_exceptions`。

在 3.12 版的變更: Each value in the dictionary is now a single exception instance, rather than a 3-tuple as returned from `sys.exc_info()`.

`sys.breakpointhook()`

This hook function is called by built-in `breakpoint()`. By default, it drops you into the `pdb` debugger, but it can be set to any other function so that you can choose which debugger gets used.

The signature of this function is dependent on what it calls. For example, the default binding (e.g. `pdb.set_trace()`) expects no arguments, but you might bind it to a function that expects additional arguments (positional and/or keyword). The built-in `breakpoint()` function passes its `*args` and `**kws` straight through. Whatever `breakpointhooks()` returns is returned from `breakpoint()`.

The default implementation first consults the environment variable `PYTHONBREAKPOINT`. If that is set to `"0"` then this function returns immediately; i.e. it is a no-op. If the environment variable is not set, or is set to the empty string, `pdb.set_trace()` is called. Otherwise this variable should name a function to run, using Python's dotted-import nomenclature, e.g. `package.subpackage.module.function`. In this case, `package.subpackage.module` would be imported and the resulting module must have a callable named `function()`. This is run, passing in `*args` and `**kws`, and whatever `function()` returns, `sys.breakpointhook()` returns to the built-in `breakpoint()` function.

Note that if anything goes wrong while importing the callable named by `PYTHONBREAKPOINT`, a `RuntimeWarning` is reported and the breakpoint is ignored.

Also note that if `sys.breakpointhook()` is overridden programmatically, `PYTHONBREAKPOINT` is *not* consulted.

在 3.7 版被加入。

`sys._debugmallocstats()`

Print low-level information to `stderr` about the state of CPython's memory allocator.

If Python is built in debug mode (configure `--with-pydebug` option), it also performs some expensive internal consistency checks.

在 3.3 版被加入。

CPython 實作細節： This function is specific to CPython. The exact output format is not defined here, and may change.

`sys.dllhandle`

Integer specifying the handle of the Python DLL.

適用：Windows。

`sys.displayhook(value)`

If `value` is not `None`, this function prints `repr(value)` to `sys.stdout`, and saves `value` in `builtins._`. If `repr(value)` is not encodable to `sys.stdout.encoding` with `sys.stdout.errors` error handler (which is probably `'strict'`), encode it to `sys.stdout.encoding` with `'backslashreplace'` error handler.

`sys.displayhook` is called on the result of evaluating an *expression* entered in an interactive Python session. The display of these values can be customized by assigning another one-argument function to `sys.displayhook`.

Pseudo-code:

```
def displayhook(value):
    if value is None:
        return
    # Set '_' to None to avoid recursion
    builtins._ = None
    text = repr(value)
    try:
        sys.stdout.write(text)
    except UnicodeEncodeError:
        bytes = text.encode(sys.stdout.encoding, 'backslashreplace')
        if hasattr(sys.stdout, 'buffer'):
            sys.stdout.buffer.write(bytes)
```

(繼續下一頁)

(繼續上一頁)

```

else:
    text = bytes.decode(sys.stdout.encoding, 'strict')
    sys.stdout.write(text)
sys.stdout.write("\n")
builtins._ = value

```

在 3.2 版的變更: Use 'backslashreplace' error handler on *UnicodeEncodeError*.

`sys.dont_write_bytecode`

If this is true, Python won't try to write `.pyc` files on the import of source modules. This value is initially set to True or False depending on the `-B` command line option and the `PYTHONDONTWRITEBYTECODE` environment variable, but you can set it yourself to control bytecode file generation.

`sys._emscripten_info`

A *named tuple* holding information about the environment on the *wasm32-emscripten* platform. The named tuple is provisional and may change in the future.

`_emscripten_info.emscripten_version`

Emscripten version as tuple of ints (major, minor, micro), e.g. (3, 1, 8).

`_emscripten_info.runtime`

運行環境字串, 例如 瀏覽器使用者代理 (browser user agent) 'Node.js v14.18.2' 或 'UNKNOWN'。

`_emscripten_info.pthreads`

True if Python is compiled with Emscripten pthreads support.

`_emscripten_info.shared_memory`

True if Python is compiled with shared memory support.

適用: Emscripten。

在 3.11 版被加入。

`sys.pycache_prefix`

If this is set (not None), Python will write bytecode-cache `.pyc` files to (and read them from) a parallel directory tree rooted at this directory, rather than from `__pycache__` directories in the source code tree. Any `__pycache__` directories in the source code tree will be ignored and new `.pyc` files written within the pycache prefix. Thus if you use *compileall* as a pre-build step, you must ensure you run it with the same pycache prefix (if any) that you will use at runtime.

A relative path is interpreted relative to the current working directory.

This value is initially set based on the value of the `-X pycache_prefix=PATH` command-line option or the `PYTHONPYCACHEPREFIX` environment variable (command-line takes precedence). If neither are set, it is None.

在 3.8 版被加入。

`sys.excepthook (type, value, traceback)`

This function prints out a given traceback and exception to `sys.stderr`.

When an exception other than *SystemExit* is raised and uncaught, the interpreter calls `sys.excepthook` with three arguments, the exception class, exception instance, and a traceback object. In an interactive session this happens just before control is returned to the prompt; in a Python program this happens just before the program exits. The handling of such top-level exceptions can be customized by assigning another three-argument function to `sys.excepthook`.

Raise an auditing event `sys.excepthook` with arguments `hook, type, value, traceback` when an uncaught exception occurs. If no hook has been set, `hook` may be None. If any hook raises an exception derived from *RuntimeError* the call to the hook will be suppressed. Otherwise, the audit hook exception will be reported as unraisable and `sys.excepthook` will be called.

也參考

The `sys.unraisablehook()` function handles unraisable exceptions and the `threading.excepthook()` function handles exception raised by `threading.Thread.run()`.

`sys.__breakpointhook__`

`sys.__displayhook__`

`sys.__excepthook__`

`sys.__unraisablehook__`

These objects contain the original values of `breakpointhook`, `displayhook`, `excepthook`, and `unraisablehook` at the start of the program. They are saved so that `breakpointhook`, `displayhook` and `excepthook`, `unraisablehook` can be restored in case they happen to get replaced with broken or alternative objects.

在 3.7 版被加入: `__breakpointhook__`

在 3.8 版被加入: `__unraisablehook__`

`sys.exception()`

This function, when called while an exception handler is executing (such as an `except` or `except*` clause), returns the exception instance that was caught by this handler. When exception handlers are nested within one another, only the exception handled by the innermost handler is accessible.

If no exception handler is executing, this function returns `None`.

在 3.11 版被加入.

`sys.exc_info()`

This function returns the old-style representation of the handled exception. If an exception `e` is currently handled (so `exception()` would return `e`), `exc_info()` returns the tuple `(type(e), e, e.__traceback__)`. That is, a tuple containing the type of the exception (a subclass of `BaseException`), the exception itself, and a traceback object which typically encapsulates the call stack at the point where the exception last occurred.

If no exception is being handled anywhere on the stack, this function return a tuple containing three `None` values.

在 3.11 版的變更: The `type` and `traceback` fields are now derived from the value (the exception instance), so when an exception is modified while it is being handled, the changes are reflected in the results of subsequent calls to `exc_info()`.

`sys.exec_prefix`

A string giving the site-specific directory prefix where the platform-dependent Python files are installed; by default, this is also `'/usr/local'`. This can be set at build time with the `--exec-prefix` argument to the **configure** script. Specifically, all configuration files (e.g. the `pyconfig.h` header file) are installed in the directory `exec_prefix/lib/pythonX.Y/config`, and shared library modules are installed in `exec_prefix/lib/pythonX.Y/lib-dynload`, where `X.Y` is the version number of Python, for example 3.2.

備F

If a *virtual environment* is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via `base_exec_prefix`.

`sys.executable`

A string giving the absolute path of the executable binary for the Python interpreter, on systems where this makes sense. If Python is unable to retrieve the real path to its executable, `sys.executable` will be an empty string or `None`.

`sys.exit([arg])`

Raise a *SystemExit* exception, signaling an intention to exit the interpreter.

The optional argument *arg* can be an integer giving the exit status (defaulting to zero), or another type of object. If it is an integer, zero is considered "successful termination" and any nonzero value is considered "abnormal termination" by shells and the like. Most systems require it to be in the range 0--127, and produce undefined results otherwise. Some systems have a convention for assigning specific meanings to specific exit codes, but these are generally underdeveloped; Unix programs generally use 2 for command line syntax errors and 1 for all other kind of errors. If another type of object is passed, *None* is equivalent to passing zero, and any other object is printed to *stderr* and results in an exit code of 1. In particular, `sys.exit("some error message")` is a quick way to exit a program when an error occurs.

Since *exit()* ultimately "only" raises an exception, it will only exit the process when called from the main thread, and the exception is not intercepted. Cleanup actions specified by finally clauses of `try` statements are honored, and it is possible to intercept the exit attempt at an outer level.

在 3.6 版的變更: If an error occurs in the cleanup after the Python interpreter has caught *SystemExit* (such as an error flushing buffered data in the standard streams), the exit status is changed to 120.

`sys.flags`

The *named tuple flags* exposes the status of command line flags. The attributes are read only.

<code>flags.debug</code>	<code>-d</code>
<code>flags.inspect</code>	<code>-i</code>
<code>flags.interactive</code>	<code>-i</code>
<code>flags.isolated</code>	<code>-I</code>
<code>flags.optimize</code>	<code>-O</code> 或 <code>-OO</code>
<code>flags.dont_write_bytecode</code>	<code>-B</code>
<code>flags.no_user_site</code>	<code>-s</code>
<code>flags.no_site</code>	<code>-S</code>
<code>flags.ignore_environment</code>	<code>-E</code>
<code>flags.verbose</code>	<code>-v</code>
<code>flags.bytes_warning</code>	<code>-b</code>
<code>flags.quiet</code>	<code>-q</code>
<code>flags.hash_randomization</code>	<code>-R</code>
<code>flags.dev_mode</code>	<code>-X dev</code> (<i>Python 開發模式</i>)
<code>flags.utf8_mode</code>	<code>-X utf8</code>
<code>flags.safe_path</code>	<code>-P</code>
<code>flags.int_max_str_digits</code>	<code>-X int_max_str_digits</code> (<i>integer string conversion length limitation</i>)
<code>flags.warn_default_encoding</code>	<code>-X warn_default_encoding</code>

在 3.2 版的變更: 新增 `quiet` 屬性, 用於新的 `-q` 旗標。

在 3.2.3 版被加入: `hash_randomization` 屬性。

在 3.3 版的變更: 移除過時的 `division_warning` 屬性。

在 3.4 版的變更: 新增 `isolated` 屬性, 用於 `-I isolated` 旗標。

在 3.7 版的變更: Added the `dev_mode` attribute for the new *Python Development Mode* and the `utf8_mode` attribute for the new `-X utf8` flag.

在 3.10 版的變更: 新增 `warn_default_encoding` 屬性, 用於 `-X warn_default_encoding` 旗標。

在 3.11 版的變更: 新增 `safe_path` 屬性, 用於 `-P` 選項。

在 3.11 版的變更: 新增 `int_max_str_digits` 屬性。

`sys.float_info`

A *named tuple* holding information about the float type. It contains low level information about the precision and internal representation. The values correspond to the various floating-point constants defined in the standard header file `float.h` for the 'C' programming language; see section 5.2.4.2.2 of the 1999 ISO/IEC C standard [C99], 'Characteristics of floating types', for details.

表格 1: Attributes of the float_info named tuple

屬性	float.h macro	解釋
float_info.epsilon	DBL_EPSILON	difference between 1.0 and the least value greater than 1.0 that is representable as a float. 另請參 <code>math.ulp()</code> 。
float_info.dig	DBL_DIG	The maximum number of decimal digits that can be faithfully represented in a float; see below.
float_info.mant_dig	DBL_MANT_DIG	Float precision: the number of base-radix digits in the significand of a float.
float_info.max	DBL_MAX	The maximum representable positive finite float.
float_info.max_exp	DBL_MAX_EXP	The maximum integer e such that radix^{e-1} is a representable finite float.
float_info.max_10_exp	DBL_MAX_10_EXP	The maximum integer e such that 10^e is in the range of representable finite floats.
float_info.min	DBL_MIN	The minimum representable positive <i>normalized</i> float. Use <code>math.ulp(0.0)</code> to get the smallest positive <i>denormalized</i> representable float.
float_info.min_exp	DBL_MIN_EXP	The minimum integer e such that radix^{e-1} is a normalized float.
float_info.min_10_exp	DBL_MIN_10_EXP	The minimum integer e such that 10^e is a normalized float.
float_info.radix	FLT_RADIX	The radix of exponent representation.
float_info.rounds	FLT_ROUNDS	An integer representing the rounding mode for floating-point arithmetic. This reflects the value of the system <code>FLT_ROUNDS</code> macro at interpreter startup time: <ul style="list-style-type: none">• -1: indeterminate• 0: toward zero• 1: to nearest• 2: toward positive infinity• 3: toward negative infinity All other values for <code>FLT_ROUNDS</code> characterize implementation-defined rounding behavior.

The attribute `sys.float_info.dig` needs further explanation. If `s` is any string representing a decimal number with at most `sys.float_info.dig` significant digits, then converting `s` to a float and back again will recover a string representing the same decimal value:

```
>>> import sys
>>> sys.float_info.dig
```

(繼續下一頁)

(繼續上一頁)

```

15
>>> s = '3.14159265358979'      # decimal string with 15 significant digits
>>> format(float(s), '.15g')    # convert to float and back -> same value
'3.14159265358979'

```

But for strings with more than `sys.float_info.dig` significant digits, this isn't always true:

```

>>> s = '9876543211234567'    # 16 significant digits is too many!
>>> format(float(s), '.16g')    # conversion changes value
'9876543211234568'

```

`sys.float_repr_style`

A string indicating how the `repr()` function behaves for floats. If the string has value `'short'` then for a finite float `x`, `repr(x)` aims to produce a short string with the property that `float(repr(x)) == x`. This is the usual behaviour in Python 3.1 and later. Otherwise, `float_repr_style` has value `'legacy'` and `repr(x)` behaves in the same way as it did in versions of Python prior to 3.1.

在 3.1 版被加入。

`sys.getallocatedblocks()`

Return the number of memory blocks currently allocated by the interpreter, regardless of their size. This function is mainly useful for tracking and debugging memory leaks. Because of the interpreter's internal caches, the result can vary from call to call; you may have to call `_clear_internal_caches()` and `gc.collect()` to get more predictable results.

If a Python build or implementation cannot reasonably compute this information, `getallocatedblocks()` is allowed to return 0 instead.

在 3.4 版被加入。

`sys.getunicodeinternedsize()`

Return the number of unicode objects that have been interned.

在 3.12 版被加入。

`sys.getandroidapilevel()`

Return the build-time API level of Android as an integer. This represents the minimum version of Android this build of Python can run on. For runtime version information, see `platform.android_ver()`.

適用：Android。

在 3.7 版被加入。

`sys.getdefaultencoding()`

Return the name of the current default string encoding used by the Unicode implementation.

`sys.getdlopenflags()`

Return the current value of the flags that are used for `dlopen()` calls. Symbolic names for the flag values can be found in the `os` module (RTLD_XXX constants, e.g. `os.RTLD_LAZY`).

適用：Unix。

`sys.getfilesystemencoding()`

Get the *filesystem encoding*: the encoding used with the *filesystem error handler* to convert between Unicode filenames and bytes filenames. The filesystem error handler is returned from `getfilesystemencodeerrors()`.

For best compatibility, str should be used for filenames in all cases, although representing filenames as bytes is also supported. Functions accepting or returning filenames should support either str or bytes and internally convert to the system's preferred representation.

`os.fsencode()` and `os.fsdecode()` should be used to ensure that the correct encoding and errors mode are used.

The *filesystem encoding and error handler* are configured at Python startup by the `PyConfig_Read()` function: see `filesystem_encoding` and `filesystem_errors` members of `PyConfig`.

在 3.2 版的變更: `getfilesystemencoding()` 的結果不再 `None`。

在 3.6 版的變更: Windows is no longer guaranteed to return `'mbcs'`. See [PEP 529](#) and `_enablelegacywindowsfsencoding()` for more information.

在 3.7 版的變更: Return `'utf-8'` if the *Python UTF-8 Mode* is enabled.

`sys.getfilesystemcodeerrors()`

Get the *filesystem error handler*: the error handler used with the *filesystem encoding* to convert between Unicode filenames and bytes filenames. The filesystem encoding is returned from `getfilesystemencoding()`.

`os.fsencode()` and `os.fsdecode()` should be used to ensure that the correct encoding and errors mode are used.

The *filesystem encoding and error handler* are configured at Python startup by the `PyConfig_Read()` function: see `filesystem_encoding` and `filesystem_errors` members of `PyConfig`.

在 3.6 版被加入。

`sys.get_int_max_str_digits()`

Returns the current value for the *integer string conversion length limitation*. See also `set_int_max_str_digits()`.

在 3.11 版被加入。

`sys.getrefcount(object)`

Return the reference count of the *object*. The count returned is generally one higher than you might expect, because it includes the (temporary) reference as an argument to `getrefcount()`.

Note that the returned value may not actually reflect how many references to the object are actually held. For example, some objects are *immortal* and have a very high refcount that does not reflect the actual number of references. Consequently, do not rely on the returned value to be accurate, other than a value of 0 or 1.

在 3.12 版的變更: Immortal objects have very large refcounts that do not match the actual number of references to the object.

`sys.getrecursionlimit()`

Return the current value of the recursion limit, the maximum depth of the Python interpreter stack. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python. It can be set by `setrecursionlimit()`.

`sys.getsizeof(object[, default])`

Return the size of an object in bytes. The object can be any type of object. All built-in objects will return correct results, but this does not have to hold true for third-party extensions as it is implementation specific.

Only the memory consumption directly attributed to the object is accounted for, not the memory consumption of objects it refers to.

If given, *default* will be returned if the object does not provide means to retrieve the size. Otherwise a `TypeError` will be raised.

`getsizeof()` calls the object's `__sizeof__` method and adds an additional garbage collector overhead if the object is managed by the garbage collector.

See [recursive sizeof recipe](#) for an example of using `getsizeof()` recursively to find the size of containers and all their contents.

`sys.getswitchinterval()`

Return the interpreter's "thread switch interval"; see `setswitchinterval()`.

在 3.2 版被加入。

`sys._getframe([depth])`

Return a frame object from the call stack. If optional integer *depth* is given, return the frame object that many calls below the top of the stack. If that is deeper than the call stack, `ValueError` is raised. The default for *depth* is zero, returning the frame at the top of the call stack.

引發一個附帶引數 *frame* 的稽核事件 `sys._getframe`。

CPython 實作細節： This function should be used for internal and specialized purposes only. It is not guaranteed to exist in all implementations of Python.

`sys._getframemodule([depth])`

Return the name of a module from the call stack. If optional integer *depth* is given, return the module that many calls below the top of the stack. If that is deeper than the call stack, or if the module is unidentifiable, `None` is returned. The default for *depth* is zero, returning the module at the top of the call stack.

引發一個附帶引數 *depth* 的稽核事件 `sys._getframemodule`。

CPython 實作細節： This function should be used for internal and specialized purposes only. It is not guaranteed to exist in all implementations of Python.

`sys.getprofile()`

Get the profiler function as set by `setprofile()`.

`sys.gettrace()`

Get the trace function as set by `settrace()`.

CPython 實作細節： The `gettrace()` function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

`sys.getwindowsversion()`

Return a named tuple describing the Windows version currently running. The named elements are *major*, *minor*, *build*, *platform*, *service_pack*, *service_pack_minor*, *service_pack_major*, *suite_mask*, *product_type* and *platform_version*. *service_pack* contains a string, *platform_version* a 3-tuple and all other values are integers. The components can also be accessed by name, so `sys.getwindowsversion()[0]` is equivalent to `sys.getwindowsversion().major`. For compatibility with prior versions, only the first 5 elements are retrievable by indexing.

platform will be 2 (VER_PLATFORM_WIN32_NT).

product_type may be one of the following values:

Constant	含義
1 (VER_NT_WORKSTATION)	The system is a workstation.
2 (VER_NT_DOMAIN_CONTROLLER)	The system is a domain controller.
3 (VER_NT_SERVER)	The system is a server, but not a domain controller.

This function wraps the Win32 `GetVersionEx()` function; see the Microsoft documentation on `OSVERSIONINFOEX()` for more information about these fields.

platform_version returns the major version, minor version and build number of the current operating system, rather than the version that is being emulated for the process. It is intended for use in logging rather than for feature detection.

備F

platform_version derives the version from `kernel32.dll` which can be of a different version than the OS version. Please use `platform` module for achieving accurate OS version.

適用：Windows。

在 3.2 版的變更: Changed to a named tuple and added *service_pack_minor*, *service_pack_major*, *suite_mask*, and *product_type*.

在 3.6 版的變更: 新增 *platform_version*

`sys.get_asyncgen_hooks()`

Returns an *asyncgen_hooks* object, which is similar to a *namedtuple* of the form (*firstiter*, *finalizer*), where *firstiter* and *finalizer* are expected to be either None or functions which take an *asynchronous generator iterator* as an argument, and are used to schedule finalization of an asynchronous generator by an event loop.

在 3.6 版被加入: 更多細節請見 [PEP 525](#)。

備F

This function has been added on a provisional basis (see [PEP 411](#) for details.)

`sys.get_coroutine_origin_tracking_depth()`

Get the current coroutine origin tracking depth, as set by *set_coroutine_origin_tracking_depth()*.

在 3.7 版被加入.

備F

This function has been added on a provisional basis (see [PEP 411](#) for details.) Use it only for debugging purposes.

`sys.hash_info`

A *named tuple* giving parameters of the numeric hash implementation. For more details about hashing of numeric types, see [數值型F的雜F](#).

`hash_info.width`

The width in bits used for hash values

`hash_info.modulus`

The prime modulus P used for numeric hash scheme

`hash_info.inf`

The hash value returned for a positive infinity

`hash_info.nan`

(This attribute is no longer used)

`hash_info.imag`

The multiplier used for the imaginary part of a complex number

`hash_info.algorithm`

The name of the algorithm for hashing of str, bytes, and memoryview

`hash_info.hash_bits`

The internal output size of the hash algorithm

`hash_info.seed_bits`

The size of the seed key of the hash algorithm

在 3.2 版被加入.

在 3.4 版的變更: 新增 *algorithm*、*hash_bits* 與 *seed_bits*

sys.hexversion

The version number encoded as a single integer. This is guaranteed to increase with each version, including proper support for non-production releases. For example, to test that the Python interpreter is at least version 1.5.2, use:

```
if sys.hexversion >= 0x010502F0:
    # use some advanced feature
    ...
else:
    # use an alternative implementation or warn the user
    ...
```

This is called `hexversion` since it only really looks meaningful when viewed as the result of passing it to the built-in `hex()` function. The *named tuple* `sys.version_info` may be used for a more human-friendly encoding of the same information.

More details of `hexversion` can be found at `apiabiversion`.

sys.implementation

An object containing information about the implementation of the currently running Python interpreter. The following attributes are required to exist in all Python implementations.

name is the implementation's identifier, e.g. 'cpython'. The actual string is defined by the Python implementation, but it is guaranteed to be lower case.

version is a named tuple, in the same format as `sys.version_info`. It represents the version of the Python *implementation*. This has a distinct meaning from the specific version of the Python *language* to which the currently running interpreter conforms, which `sys.version_info` represents. For example, for PyPy 1.8 `sys.implementation.version` might be `sys.version_info(1, 8, 0, 'final', 0)`, whereas `sys.version_info` would be `sys.version_info(2, 7, 2, 'final', 0)`. For CPython they are the same value, since it is the reference implementation.

hexversion is the implementation version in hexadecimal format, like `sys.hexversion`.

cache_tag is the tag used by the import machinery in the filenames of cached modules. By convention, it would be a composite of the implementation's name and version, like 'cpython-33'. However, a Python implementation may use some other value if appropriate. If *cache_tag* is set to `None`, it indicates that module caching should be disabled.

`sys.implementation` may contain additional attributes specific to the Python implementation. These non-standard attributes must start with an underscore, and are not described here. Regardless of its contents, `sys.implementation` will not change during a run of the interpreter, nor between implementation versions. (It may change between Python language versions, however.) See [PEP 421](#) for more information.

在 3.3 版被加入。

備 註

The addition of new required attributes must go through the normal PEP process. See [PEP 421](#) for more information.

sys.int_info

A *named tuple* that holds information about Python's internal representation of integers. The attributes are read only.

int_info.bits_per_digit

The number of bits held in each digit. Python integers are stored internally in base $2^{\text{int_info.bits_per_digit}}$.

int_info.sizeof_digit

The size in bytes of the C type used to represent a digit.

`int_info.default_max_str_digits`

The default value for `sys.get_int_max_str_digits()` when it is not otherwise explicitly configured.

`int_info.str_digits_check_threshold`

The minimum non-zero value for `sys.set_int_max_str_digits()`, `PYTHONINTMAXSTRDIGITS`, or `-X int_max_str_digits`.

在 3.1 版被加入。

在 3.11 版的變更: 新增 `default_max_str_digits` 和 `str_digits_check_threshold`。

`sys.__interactivehook__`

When this attribute exists, its value is automatically called (with no arguments) when the interpreter is launched in interactive mode. This is done after the `PYTHONSTARTUP` file is read, so that you can set this hook there. The `site` module *sets this*.

Raises an *auditing event* `cpython.run_interactivehook` with the hook object as the argument when the hook is called on startup.

在 3.4 版被加入。

`sys.intern(string)`

Enter *string* in the table of "interned" strings and return the interned string -- which is *string* itself or a copy. Interning strings is useful to gain a little performance on dictionary lookup -- if the keys in a dictionary are interned, and the lookup key is interned, the key comparisons (after hashing) can be done by a pointer compare instead of a string compare. Normally, the names used in Python programs are automatically interned, and the dictionaries used to hold module, class or instance attributes have interned keys.

Interned strings are not *immortal*; you must keep a reference to the return value of `intern()` around to benefit from it.

`sys._is_gil_enabled()`

Return *True* if the *GIL* is enabled and *False* if it is disabled.

在 3.13 版被加入。

`sys.is_finalizing()`

Return *True* if the main Python interpreter is *shutting down*. Return *False* otherwise.

See also the `PythonFinalizationError` exception.

在 3.5 版被加入。

`sys.last_exc`

This variable is not always defined; it is set to the exception instance when an exception is not handled and the interpreter prints an error message and a stack traceback. Its intended use is to allow an interactive user to import a debugger module and engage in post-mortem debugging without having to re-execute the command that caused the error. (Typical use is `import pdb; pdb.pm()` to enter the post-mortem debugger; see `pdb` module for more information.)

在 3.12 版被加入。

`sys._is_interned(string)`

Return *True* if the given string is "interned", *False* otherwise.

在 3.13 版被加入。

CPython 實作細節: It is not guaranteed to exist in all implementations of Python.

`sys.last_type`

`sys.last_value`

sys.last_traceback

These three variables are deprecated; use `sys.last_exc` instead. They hold the legacy representation of `sys.last_exc`, as returned from `exc_info()` above.

sys.maxsize

An integer giving the maximum value a variable of type `Py_ssize_t` can take. It's usually $2^{31} - 1$ on a 32-bit platform and $2^{63} - 1$ on a 64-bit platform.

sys.maxunicode

An integer giving the value of the largest Unicode code point, i.e. 1114111 (0x10FFFF in hexadecimal).

在 3.3 版的變更: Before **PEP 393**, `sys.maxunicode` used to be either 0xFFFF or 0x10FFFF, depending on the configuration option that specified whether Unicode characters were stored as UCS-2 or UCS-4.

sys.meta_path

A list of *meta path finder* objects that have their `find_spec()` methods called to see if one of the objects can find the module to be imported. By default, it holds entries that implement Python's default import semantics. The `find_spec()` method is called with at least the absolute name of the module being imported. If the module to be imported is contained in a package, then the parent package's `__path__` attribute is passed in as a second argument. The method returns a *module spec*, or `None` if the module cannot be found.

也參考

`importlib.abc.MetaPathFinder`

The abstract base class defining the interface of finder objects on `meta_path`.

`importlib.machinery.ModuleSpec`

The concrete class which `find_spec()` should return instances of.

在 3.4 版的變更: *Module specs* were introduced in Python 3.4, by **PEP 451**.

在 3.12 版的變更: Removed the fallback that looked for a `find_module()` method if a `meta_path` entry didn't have a `find_spec()` method.

sys.modules

This is a dictionary that maps module names to modules which have already been loaded. This can be manipulated to force reloading of modules and other tricks. However, replacing the dictionary will not necessarily work as expected and deleting essential items from the dictionary may cause Python to fail. If you want to iterate over this global dictionary always use `sys.modules.copy()` or `tuple(sys.modules)` to avoid exceptions as its size may change during iteration as a side effect of code or activity in other threads.

sys.orig_argv

The list of the original command line arguments passed to the Python executable.

The elements of `sys.orig_argv` are the arguments to the Python interpreter, while the elements of `sys.argv` are the arguments to the user's program. Arguments consumed by the interpreter itself will be present in `sys.orig_argv` and missing from `sys.argv`.

在 3.10 版被加入。

sys.path

A list of strings that specifies the search path for modules. Initialized from the environment variable `PYTHONPATH`, plus an installation-dependent default.

By default, as initialized upon program startup, a potentially unsafe path is prepended to `sys.path` (before the entries inserted as a result of `PYTHONPATH`):

- `python -m module` command line: prepend the current working directory.
- `python script.py` command line: prepend the script's directory. If it's a symbolic link, resolve symbolic links.

- `python -c code` and `python` (REPL) command lines: prepend an empty string, which means the current working directory.

To not prepend this potentially unsafe path, use the `-P` command line option or the `PYTHONSAFEPATH` environment variable.

A program is free to modify this list for its own purposes. Only strings should be added to `sys.path`; all other data types are ignored during import.

也參考

- Module `site` This describes how to use `.pth` files to extend `sys.path`.

`sys.path_hooks`

A list of callables that take a path argument to try to create a *finder* for the path. If a finder can be created, it is to be returned by the callable, else raise `ImportError`.

Originally specified in [PEP 302](#).

`sys.path_importer_cache`

A dictionary acting as a cache for *finder* objects. The keys are paths that have been passed to `sys.path_hooks` and the values are the finders that are found. If a path is a valid file system path but no finder is found on `sys.path_hooks` then `None` is stored.

Originally specified in [PEP 302](#).

`sys.platform`

A string containing a platform identifier. Known values are:

System	platform value
AIX	'aix'
Android	'android'
Emscripten	'emscripten'
iOS	'ios'
Linux	'linux'
macOS	'darwin'
Windows	'win32'
Windows/Cygwin	'cygwin'
WASI	'wasi'

On Unix systems not listed in the table, the value is the lowercased OS name as returned by `uname -s`, with the first part of the version as returned by `uname -r` appended, e.g. `'sunos5'` or `'freebsd8'`, *at the time when Python was built*. Unless you want to test for a specific system version, it is therefore recommended to use the following idiom:

```
if sys.platform.startswith('freebsd'):
    # FreeBSD-specific code here...
```

在 3.3 版的變更: On Linux, `sys.platform` doesn't contain the major version anymore. It is always `'linux'`, instead of `'linux2'` or `'linux3'`.

在 3.8 版的變更: On AIX, `sys.platform` doesn't contain the major version anymore. It is always `'aix'`, instead of `'aix5'` or `'aix7'`.

在 3.13 版的變更: On Android, `sys.platform` now returns `'android'` rather than `'linux'`.

也參考

`os.name` has a coarser granularity. `os.uname()` gives system-dependent version information.

The `platform` module provides detailed checks for the system's identity.

sys.platlibdir

Name of the platform-specific library directory. It is used to build the path of standard library and the paths of installed extension modules.

It is equal to "lib" on most platforms. On Fedora and SuSE, it is equal to "lib64" on 64-bit platforms which gives the following `sys.path` paths (where X.Y is the Python major.minor version):

- `/usr/lib64/pythonX.Y/`: Standard library (like `os.py` of the `os` module)
- `/usr/lib64/pythonX.Y/lib-dynload/`: C extension modules of the standard library (like the `errno` module, the exact filename is platform specific)
- `/usr/lib/pythonX.Y/site-packages/` (always use `lib`, not `sys.platlibdir`): Third-party modules
- `/usr/lib64/pythonX.Y/site-packages/`: C extension modules of third-party packages

在 3.9 版被加入。

sys.prefix

A string giving the site-specific directory prefix where the platform independent Python files are installed; on Unix, the default is `/usr/local`. This can be set at build time with the `--prefix` argument to the `configure` script. See *Installation paths* for derived paths.

備 F

If a *virtual environment* is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via `base_prefix`.

sys.ps1**sys.ps2**

Strings specifying the primary and secondary prompt of the interpreter. These are only defined if the interpreter is in interactive mode. Their initial values in this case are `'>>> '` and `'... '`. If a non-string object is assigned to either variable, its `str()` is re-evaluated each time the interpreter prepares to read a new interactive command; this can be used to implement a dynamic prompt.

sys.setdlopenflags(n)

Set the flags used by the interpreter for `dlopen()` calls, such as when the interpreter loads extension modules. Among other things, this will enable a lazy resolving of symbols when importing a module, if called as `sys.setdlopenflags(0)`. To share symbols across extension modules, call as `sys.setdlopenflags(os.RTLD_GLOBAL)`. Symbolic names for the flag values can be found in the `os` module (`RTLD_XXX` constants, e.g. `os.RTLD_LAZY`).

適用：Unix。

sys.set_int_max_str_digits(maxdigits)

Set the *integer string conversion length limitation* used by this interpreter. See also `get_int_max_str_digits()`.

在 3.11 版被加入。

sys.setprofile(profilefunc)

Set the system's profile function, which allows you to implement a Python source code profiler in Python. See chapter *Python 的分析器* for more information on the Python profiler. The system's profile function is called

similarly to the system's trace function (see `settrace()`), but it is called with different events, for example it isn't called for each executed line of code (only on call and return, but the return event is reported even when an exception has been set). The function is thread-specific, but there is no way for the profiler to know about context switches between threads, so it does not make sense to use this in the presence of multiple threads. Also, its return value is not used, so it can simply return `None`. Error in the profile function will cause itself unset.

備F

The same tracing mechanism is used for `setprofile()` as `settrace()`. To trace calls with `setprofile()` inside a tracing function (e.g. in a debugger breakpoint), see `call_tracing()`.

Profile functions should have three arguments: *frame*, *event*, and *arg*. *frame* is the current stack frame. *event* is a string: 'call', 'return', 'c_call', 'c_return', or 'c_exception'. *arg* depends on the event type.

The events have the following meaning:

'call'

A function is called (or some other code block entered). The profile function is called; *arg* is `None`.

'return'

A function (or other code block) is about to return. The profile function is called; *arg* is the value that will be returned, or `None` if the event is caused by an exception being raised.

'c_call'

A C function is about to be called. This may be an extension function or a built-in. *arg* is the C function object.

'c_return'

A C function has returned. *arg* is the C function object.

'c_exception'

A C function has raised an exception. *arg* is the C function object.

引發一個不附帶引數的稽核事件 `sys.setprofile`。

`sys.setrecursionlimit(limit)`

Set the maximum depth of the Python interpreter stack to *limit*. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python.

The highest possible limit is platform-dependent. A user may need to set the limit higher when they have a program that requires deep recursion and a platform that supports a higher limit. This should be done with care, because a too-high limit can lead to a crash.

If the new limit is too low at the current recursion depth, a `RecursionError` exception is raised.

在 3.5.1 版的變更: A `RecursionError` exception is now raised if the new limit is too low at the current recursion depth.

`sys.setswitchinterval(interval)`

Set the interpreter's thread switch interval (in seconds). This floating-point value determines the ideal duration of the "timeslices" allocated to concurrently running Python threads. Please note that the actual value can be higher, especially if long-running internal functions or methods are used. Also, which thread becomes scheduled at the end of the interval is the operating system's decision. The interpreter doesn't have its own scheduler.

在 3.2 版被加入。

`sys.settrace(tracefunc)`

Set the system's trace function, which allows you to implement a Python source code debugger in Python. The function is thread-specific; for a debugger to support multiple threads, it must register a trace function using `settrace()` for each thread being debugged or use `threading.settrace()`.

Trace functions should have three arguments: *frame*, *event*, and *arg*. *frame* is the current stack frame. *event* is a string: 'call', 'line', 'return', 'exception' or 'opcode'. *arg* depends on the event type.

The trace function is invoked (with *event* set to 'call') whenever a new local scope is entered; it should return a reference to a local trace function to be used for the new scope, or `None` if the scope shouldn't be traced.

The local trace function should return a reference to itself, or to another function which would then be used as the local trace function for the scope.

If there is any error occurred in the trace function, it will be unset, just like `settrace(None)` is called.

備

Tracing is disabled while calling the trace function (e.g. a function set by `settrace()`). For recursive tracing see `call_tracing()`.

The events have the following meaning:

'call'

A function is called (or some other code block entered). The global trace function is called; *arg* is `None`; the return value specifies the local trace function.

'line'

The interpreter is about to execute a new line of code or re-execute the condition of a loop. The local trace function is called; *arg* is `None`; the return value specifies the new local trace function. See `Objects/lnotab_notes.txt` for a detailed explanation of how this works. Per-line events may be disabled for a frame by setting `f_trace_lines` to `False` on that frame.

'return'

A function (or other code block) is about to return. The local trace function is called; *arg* is the value that will be returned, or `None` if the event is caused by an exception being raised. The trace function's return value is ignored.

'exception'

An exception has occurred. The local trace function is called; *arg* is a tuple (`exception`, `value`, `traceback`); the return value specifies the new local trace function.

'opcode'

The interpreter is about to execute a new opcode (see `dis` for opcode details). The local trace function is called; *arg* is `None`; the return value specifies the new local trace function. Per-opcode events are not emitted by default: they must be explicitly requested by setting `f_trace_opcodes` to `True` on the frame.

Note that as an exception is propagated down the chain of callers, an 'exception' event is generated at each level.

For more fine-grained usage, it's possible to set a trace function by assigning `frame.f_trace = tracefunc` explicitly, rather than relying on it being set indirectly via the return value from an already installed trace function. This is also required for activating the trace function on the current frame, which `settrace()` doesn't do. Note that in order for this to work, a global tracing function must have been installed with `settrace()` in order to enable the runtime tracing machinery, but it doesn't need to be the same tracing function (e.g. it could be a low overhead tracing function that simply returns `None` to disable itself immediately on each frame).

For more information on code and frame objects, refer to types.

引發一個不附帶引數的稽核事件 `sys.settrace`.

CPython 實作細節： The `settrace()` function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

在 3.7 版的變更: 'opcode' event type added; f_trace_lines and f_trace_opcodes attributes added to frames

`sys.set_asyncgen_hooks([firstiter], [finalizer])`

Accepts two optional keyword arguments which are callables that accept an *asynchronous generator iterator* as an argument. The *firstiter* callable will be called when an asynchronous generator is iterated for the first time. The *finalizer* will be called when an asynchronous generator is about to be garbage collected.

引發一個不附帶引數的稽核事件 `sys.set_asyncgen_hooks_firstiter`。

引發一個不附帶引數的稽核事件 `sys.set_asyncgen_hooks_finalizer`。

Two auditing events are raised because the underlying API consists of two calls, each of which must raise its own event.

在 3.6 版被加入: See [PEP 525](#) for more details, and for a reference example of a *finalizer* method see the implementation of `asyncio.Loop.shutdown_asyncgens` in [Lib/asyncio/base_events.py](#)

備 F

This function has been added on a provisional basis (see [PEP 411](#) for details.)

`sys.set_coroutine_origin_tracking_depth(depth)`

Allows enabling or disabling coroutine origin tracking. When enabled, the `cr_origin` attribute on coroutine objects will contain a tuple of (filename, line number, function name) tuples describing the traceback where the coroutine object was created, with the most recent call first. When disabled, `cr_origin` will be `None`.

To enable, pass a *depth* value greater than zero; this sets the number of frames whose information will be captured. To disable, pass set *depth* to zero.

This setting is thread-specific.

在 3.7 版被加入。

備 F

This function has been added on a provisional basis (see [PEP 411](#) for details.) Use it only for debugging purposes.

`sys.activate_stack_trampoline(backend, /)`

Activate the stack profiler trampoline *backend*. The only supported backend is "perf".

適用: Linux。

在 3.12 版被加入。

也參考

- `perf_profiling`
- <https://perf.wiki.kernel.org>

`sys.deactivate_stack_trampoline()`

Deactivate the current stack profiler trampoline backend.

If no stack profiler is activated, this function has no effect.

適用: Linux。

在 3.12 版被加入。

`sys.is_stack_trampoline_active()`

Return True if a stack profiler trampoline is active.

適用：Linux。

在 3.12 版被加入。

`sys._enablelegacywindowsfsencoding()`

Changes the *filesystem encoding and error handler* to 'mbcs' and 'replace' respectively, for consistency with versions of Python prior to 3.6.

This is equivalent to defining the PYTHONLEGACYWINDOWSFSENCODING environment variable before launching Python.

See also `sys.getfilesystemencoding()` and `sys.getfilesystemencodeerrors()`.

適用：Windows。

備 註

Changing the filesystem encoding after Python startup is risky because the old fsencoding or paths encoded by the old fsencoding may be cached somewhere. Use PYTHONLEGACYWINDOWSFSENCODING instead.

在 3.6 版被加入：更多細節請見 [PEP 529](#)。

Deprecated since version 3.13, will be removed in version 3.16: Use PYTHONLEGACYWINDOWSFSENCODING instead.

`sys.stdin`

`sys.stdout`

`sys.stderr`

File objects used by the interpreter for standard input, output and errors:

- `stdin` is used for all interactive input (including calls to `input()`);
- `stdout` is used for the output of `print()` and *expression* statements and for the prompts of `input()`;
- The interpreter's own prompts and its error messages go to `stderr`.

These streams are regular *text files* like those returned by the `open()` function. Their parameters are chosen as follows:

- The encoding and error handling are initialized from `PyConfig.stdio_encoding` and `PyConfig.stdio_errors`.

On Windows, UTF-8 is used for the console device. Non-character devices such as disk files and pipes use the system locale encoding (i.e. the ANSI codepage). Non-console character devices such as NUL (i.e. where `isatty()` returns True) use the value of the console input and output codepages at startup, respectively for `stdin` and `stdout/stderr`. This defaults to the system *locale encoding* if the process is not initially attached to a console.

The special behaviour of the console can be overridden by setting the environment variable PYTHONLEGACYWINDOWSSTDIO before starting Python. In that case, the console codepages are used as for any other character device.

Under all platforms, you can override the character encoding by setting the PYTHONIOENCODING environment variable before starting Python or by using the new `-X utf8` command line option and PYTHONUTF8 environment variable. However, for the Windows console, this only applies when PYTHONLEGACYWINDOWSSTDIO is also set.

- When interactive, the `stdout` stream is line-buffered. Otherwise, it is block-buffered like regular text files. The `stderr` stream is line-buffered in both cases. You can make both streams unbuffered by passing the `-u` command-line option or setting the PYTHONUNBUFFERED environment variable.

在 3.9 版的變更: Non-interactive `stderr` is now line-buffered instead of fully buffered.

備 F

To write or read binary data from/to the standard streams, use the underlying binary *buffer* object. For example, to write bytes to `stdout`, use `sys.stdout.buffer.write(b'abc')`.

However, if you are writing a library (and do not control in which context its code will be executed), be aware that the standard streams may be replaced with file-like objects like `io.StringIO` which do not support the `buffer` attribute.

```
sys.__stdin__
sys.__stdout__
sys.__stderr__
```

These objects contain the original values of `stdin`, `stderr` and `stdout` at the start of the program. They are used during finalization, and could be useful to print to the actual standard stream no matter if the `sys.std*` object has been redirected.

It can also be used to restore the actual files to known working file objects in case they have been overwritten with a broken object. However, the preferred way to do this is to explicitly save the previous stream before replacing it, and restore the saved object.

備 F

Under some conditions `stdin`, `stdout` and `stderr` as well as the original values `__stdin__`, `__stdout__` and `__stderr__` can be `None`. It is usually the case for Windows GUI apps that aren't connected to a console and Python apps started with **pythonw**.

```
sys.stdlib_module_names
```

A frozenset of strings containing the names of standard library modules.

It is the same on all platforms. Modules which are not available on some platforms and modules disabled at Python build are also listed. All module kinds are listed: pure Python, built-in, frozen and extension modules. Test modules are excluded.

For packages, only the main package is listed: sub-packages and sub-modules are not listed. For example, the `email` package is listed, but the `email.mime` sub-package and the `email.message` sub-module are not listed.

另請參 F `sys.builtin_module_names` 清單。

在 3.10 版被加入。

```
sys.thread_info
```

A *named tuple* holding information about the thread implementation.

```
thread_info.name
```

The name of the thread implementation:

- "nt": Windows 執行緒
- "pthread": POSIX 執行緒
- "pthread-stubs": stub POSIX threads (on WebAssembly platforms without threading support)
- "solaris": Solaris threads

```
thread_info.lock
```

The name of the lock implementation:

- "semaphore": a lock uses a semaphore

- "mutex+cond": a lock uses a mutex and a condition variable
- `None` 表示此資訊未知

`thread_info.version`

The name and version of the thread library. It is a string, or `None` if this information is unknown.

在 3.3 版被加入。

`sys.tracebacklimit`

When this variable is set to an integer value, it determines the maximum number of levels of traceback information printed when an unhandled exception occurs. The default is 1000. When set to 0 or less, all traceback information is suppressed and only the exception type and value are printed.

`sys.unraisablehook` (*unraisable*, /)

處理一個不可被引發的例外。

Called when an exception has occurred but there is no way for Python to handle it. For example, when a destructor raises an exception or during garbage collection (`gc.collect()`).

The *unraisable* argument has the following attributes:

- `exc_type`: 例外型。
- `exc_value`: 例外值，可以 `None`。
- `exc_traceback`: 例外追，可以 `None`。
- `err_msg`: 錯誤訊息，可以 `None`。
- `object`: 導致例外的物件，可以 `None`。

The default hook formats `err_msg` and `object` as: `f'{err_msg}: {object!r}'`; use "Exception ignored in" error message if `err_msg` is `None`.

`sys.unraisablehook()` can be overridden to control how unraisable exceptions are handled.

也參考

處理未被捕捉到例外的 `excepthook()`。

警告

Storing `exc_value` using a custom hook can create a reference cycle. It should be cleared explicitly to break the reference cycle when the exception is no longer needed.

Storing `object` using a custom hook can resurrect it if it is set to an object which is being finalized. Avoid storing `object` after the custom hook completes to avoid resurrecting objects.

Raise an auditing event `sys.unraisablehook` with arguments *hook*, *unraisable* when an exception that cannot be handled occurs. The *unraisable* object is the same as what will be passed to the hook. If no hook has been set, *hook* may be `None`.

在 3.8 版被加入。

`sys.version`

A string containing the version number of the Python interpreter plus additional information on the build number and compiler used. This string is displayed when the interactive interpreter is started. Do not extract version information out of it, rather, use `version_info` and the functions provided by the `platform` module.

sys.api_version

The C API version for this interpreter. Programmers may find this useful when debugging version conflicts between Python and extension modules.

sys.version_info

A tuple containing the five components of the version number: *major*, *minor*, *micro*, *releaselevel*, and *serial*. All values except *releaselevel* are integers; the release level is 'alpha', 'beta', 'candidate', or 'final'. The `version_info` value corresponding to the Python version 2.0 is (2, 0, 0, 'final', 0). The components can also be accessed by name, so `sys.version_info[0]` is equivalent to `sys.version_info.major` and so on.

在 3.1 版的變更: 新增了附名的元件屬性。

sys.warnoptions

This is an implementation detail of the warnings framework; do not modify this value. Refer to the *warnings* module for more information on the warnings framework.

sys.winver

The version number used to form registry keys on Windows platforms. This is stored as string resource 1000 in the Python DLL. The value is normally the major and minor versions of the running Python interpreter. It is provided in the *sys* module for informational purposes; modifying this value has no effect on the registry keys used by Python.

適用: Windows。

sys.monitoring

Namespace containing functions and constants for register callbacks and controlling monitoring events. See *sys.monitoring* for details.

sys._xoptions

A dictionary of the various implementation-specific flags passed through the `-X` command-line option. Option names are either mapped to their values, if given explicitly, or to *True*. Example:

```
$ ./python -Xa=b -Xc
Python 3.2a3+ (py3k, Oct 16 2010, 20:14:50)
[GCC 4.4.3] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import sys
>>> sys._xoptions
{'a': 'b', 'c': True}
```

CPython 實作細節: This is a CPython-specific way of accessing options passed through `-X`. Other implementations may export them through other means, or not at all.

引用

29.2 sys.monitoring --- Execution event monitoring

在 3.12 版被加入。

備 註

sys.monitoring is a namespace within the *sys* module, not an independent module, so there is no need to import *sys.monitoring*, simply import *sys* and then use *sys.monitoring*.

This namespace provides access to the functions and constants necessary to activate and control event monitoring.

As programs execute, events occur that might be of interest to tools that monitor execution. The `sys.monitoring` namespace provides means to receive callbacks when events of interest occur.

The monitoring API consists of three components:

- *Tool identifiers*
- *Events*
- 回呼 (*callbacks*)

29.2.1 Tool identifiers

A tool identifier is an integer and the associated name. Tool identifiers are used to discourage tools from interfering with each other and to allow multiple tools to operate at the same time. Currently tools are completely independent and cannot be used to monitor each other. This restriction may be lifted in the future.

Before registering or activating events, a tool should choose an identifier. Identifiers are integers in the range 0 to 5 inclusive.

Registering and using tools

`sys.monitoring.use_tool_id(tool_id: int, name: str, /) → None`

Must be called before `tool_id` can be used. `tool_id` must be in the range 0 to 5 inclusive. Raises a `ValueError` if `tool_id` is in use.

`sys.monitoring.free_tool_id(tool_id: int, /) → None`

Should be called once a tool no longer requires `tool_id`.

備 注

`free_tool_id()` will not disable global or local events associated with `tool_id`, nor will it unregister any callback functions. This function is only intended to be used to notify the VM that the particular `tool_id` is no longer in use.

`sys.monitoring.get_tool(tool_id: int, /) → str | None`

Returns the name of the tool if `tool_id` is in use, otherwise it returns `None`. `tool_id` must be in the range 0 to 5 inclusive.

All IDs are treated the same by the VM with regard to events, but the following IDs are pre-defined to make co-operation of tools easier:

```
sys.monitoring.DEBUGGER_ID = 0
sys.monitoring.COVERAGE_ID = 1
sys.monitoring.PROFILER_ID = 2
sys.monitoring.OPTIMIZER_ID = 5
```

29.2.2 事件

The following events are supported:

`sys.monitoring.events.BRANCH`

A conditional branch is taken (or not).

`sys.monitoring.events.CALL`

A call in Python code (event occurs before the call).

`sys.monitoring.events.C_RAISE`

An exception raised from any callable, except for Python functions (event occurs after the exit).

`sys.monitoring.events.C_RETURN`

Return from any callable, except for Python functions (event occurs after the return).

`sys.monitoring.events.EXCEPTION_HANDLED`

An exception is handled.

`sys.monitoring.events.INSTRUCTION`

A VM instruction is about to be executed.

`sys.monitoring.events.JUMP`

An unconditional jump in the control flow graph is made.

`sys.monitoring.events.LINE`

An instruction is about to be executed that has a different line number from the preceding instruction.

`sys.monitoring.events.PY_RESUME`

Resumption of a Python function (for generator and coroutine functions), except for `throw()` calls.

`sys.monitoring.events.PY_RETURN`

Return from a Python function (occurs immediately before the return, the callee's frame will be on the stack).

`sys.monitoring.events.PY_START`

Start of a Python function (occurs immediately after the call, the callee's frame will be on the stack)

`sys.monitoring.events.PY_THROW`

A Python function is resumed by a `throw()` call.

`sys.monitoring.events.PY_UNWIND`

Exit from a Python function during exception unwinding.

`sys.monitoring.events.PY_YIELD`

Yield from a Python function (occurs immediately before the yield, the callee's frame will be on the stack).

`sys.monitoring.events.RAISE`

An exception is raised, except those that cause a *STOP_ITERATION* event.

`sys.monitoring.events.RERAISE`

An exception is re-raised, for example at the end of a `finally` block.

`sys.monitoring.events.STOP_ITERATION`

An artificial *StopIteration* is raised; see *the STOP_ITERATION event*.

More events may be added in the future.

These events are attributes of the `sys.monitoring.events` namespace. Each event is represented as a power-of-2 integer constant. To define a set of events, simply bitwise or the individual events together. For example, to specify both *PY_RETURN* and *PY_START* events, use the expression `PY_RETURN | PY_START`.

`sys.monitoring.events.NO_EVENTS`

An alias for 0 so users can do explicit comparisons like:

```
if get_events(DEBUGGER_ID) == NO_EVENTS:
    ...
```

Events are divided into three groups:

Local events

Local events are associated with normal execution of the program and happen at clearly defined locations. All local events can be disabled. The local events are:

- *PY_START*
- *PY_RESUME*
- *PY_RETURN*
- *PY_YIELD*
- *CALL*
- *LINE*
- *INSTRUCTION*
- *JUMP*
- *BRANCH*
- *STOP_ITERATION*

輔助事件

Ancillary events can be monitored like other events, but are controlled by another event:

- *C_RAISE*
- *C_RETURN*

The *C_RETURN* and *C_RAISE* events are controlled by the *CALL* event. *C_RETURN* and *C_RAISE* events will only be seen if the corresponding *CALL* event is being monitored.

其他事件

Other events are not necessarily tied to a specific location in the program and cannot be individually disabled.

The other events that can be monitored are:

- *PY_THROW*
- *PY_UNWIND*
- *RAISE*
- *EXCEPTION_HANDLED*

The STOP_ITERATION event

PEP 380 specifies that a *StopIteration* exception is raised when returning a value from a generator or coroutine. However, this is a very inefficient way to return a value, so some Python implementations, notably CPython 3.12+, do not raise an exception unless it would be visible to other code.

To allow tools to monitor for real exceptions without slowing down generators and coroutines, the *STOP_ITERATION* event is provided. *STOP_ITERATION* can be locally disabled, unlike *RAISE*.

29.2.3 Turning events on and off

In order to monitor an event, it must be turned on and a corresponding callback must be registered. Events can be turned on or off by setting the events either globally or for a particular code object.

Setting events globally

Events can be controlled globally by modifying the set of events being monitored.

`sys.monitoring.get_events(tool_id: int, /) → int`

Returns the `int` representing all the active events.

`sys.monitoring.set_events(tool_id: int, event_set: int, /) → None`

Activates all events which are set in *event_set*. Raises a *ValueError* if *tool_id* is not in use.

No events are active by default.

Per code object events

Events can also be controlled on a per code object basis. The functions defined below which accept a *types.CodeType* should be prepared to accept a look-alike object from functions which are not defined in Python (see *monitoring*).

`sys.monitoring.get_local_events(tool_id: int, code: CodeType, /) → int`

Returns all the local events for *code*

`sys.monitoring.set_local_events(tool_id: int, code: CodeType, event_set: int, /) → None`

Activates all the local events for *code* which are set in *event_set*. Raises a *ValueError* if *tool_id* is not in use.

Local events add to global events, but do not mask them. In other words, all global events will trigger for a code object, regardless of the local events.

停用事件

`sys.monitoring.DISABLE`

A special value that can be returned from a callback function to disable events for the current code location.

Local events can be disabled for a specific code location by returning *sys.monitoring.DISABLE* from a callback function. This does not change which events are set, or any other code locations for the same event.

Disabling events for specific locations is very important for high performance monitoring. For example, a program can be run under a debugger with no overhead if the debugger disables all monitoring except for a few breakpoints.

`sys.monitoring.restart_events() → None`

Enable all the events that were disabled by *sys.monitoring.DISABLE* for all tools.

29.2.4 回呼函式

To register a callable for events call

```
sys.monitoring.register_callback(tool_id: int, event: int, func: Callable | None, /) → Callable | None
```

Registers the callable *func* for the *event* with the given *tool_id*

If another callback was registered for the given *tool_id* and *event*, it is unregistered and returned. Otherwise *register_callback()* returns *None*.

Functions can be unregistered by calling `sys.monitoring.register_callback(tool_id, event, None)`.

Callback functions can be registered and unregistered at any time.

Registering or unregistering a callback function will generate a `sys.audit()` event.

回呼函式引數

`sys.monitoring.MISSING`

A special value that is passed to a callback function to indicate that there are no arguments to the call.

When an active event occurs, the registered callback function is called. Different events will provide the callback function with different arguments, as follows:

- `PY_START` 和 `PY_RESUME`:

```
func(code: CodeType, instruction_offset: int) -> DISABLE | Any
```

- `PY_RETURN` 和 `PY_YIELD`:

```
func(code: CodeType, instruction_offset: int, retval: object) -> DISABLE | Any
```

- `CALL`, `C_RAISE` 和 `C_RETURN`:

```
func(code: CodeType, instruction_offset: int, callable: object, arg0: object | MISSING) -> DISABLE | Any
```

If there are no arguments, *arg0* is set to `sys.monitoring.MISSING`.

- `RAISE`, `RERAISE`, `EXCEPTION_HANDLED`, `PY_UNWIND`, `PY_THROW` 和 `STOP_ITERATION`:

```
func(code: CodeType, instruction_offset: int, exception: BaseException) -> DISABLE | Any
```

- `LINE`:

```
func(code: CodeType, line_number: int) -> DISABLE | Any
```

- `BRANCH` 和 `JUMP`:

```
func(code: CodeType, instruction_offset: int, destination_offset: int) -> DISABLE | Any
```

Note that the *destination_offset* is where the code will next execute. For an untaken branch this will be the offset of the instruction following the branch.

- `INSTRUCTION`:

```
func(code: CodeType, instruction_offset: int) -> DISABLE | Any
```

29.3 `sysconfig` --- 提供 Python 設定資訊的存取

在 3.2 版被加入.

Source code: [Lib/sysconfig](#)

The `sysconfig` module provides access to Python's configuration information like the list of installation paths and the configuration variables relevant for the current platform.

29.3.1 Configuration variables

A Python distribution contains a `Makefile` and a `pyconfig.h` header file that are necessary to build both the Python binary itself and third-party C extensions compiled using `setuptools`.

`sysconfig` puts all variables found in these files in a dictionary that can be accessed using `get_config_vars()` or `get_config_var()`.

Notice that on Windows, it's a much smaller set.

`sysconfig.get_config_vars(*args)`

With no arguments, return a dictionary of all configuration variables relevant for the current platform.

With arguments, return a list of values that result from looking up each argument in the configuration variable dictionary.

For each argument, if the value is not found, return `None`.

`sysconfig.get_config_var(name)`

Return the value of a single variable `name`. Equivalent to `get_config_vars().get(name)`.

If `name` is not found, return `None`.

用法範例:

```
>>> import sysconfig
>>> sysconfig.get_config_var('Py_ENABLE_SHARED')
0
>>> sysconfig.get_config_var('LIBDIR')
'/usr/local/lib'
>>> sysconfig.get_config_vars('AR', 'CXX')
['ar', 'g++']
```

29.3.2 Installation paths

Python uses an installation scheme that differs depending on the platform and on the installation options. These schemes are stored in `sysconfig` under unique identifiers based on the value returned by `os.name`. The schemes are used by package installers to determine where to copy files to.

Python currently supports nine schemes:

- `posix_prefix`: scheme for POSIX platforms like Linux or macOS. This is the default scheme used when Python or a component is installed.
- `posix_home`: scheme for POSIX platforms, when the `home` option is used. This scheme defines paths located under a specific home prefix.
- `posix_user`: scheme for POSIX platforms, when the `user` option is used. This scheme defines paths located under the user's home directory (`site.USER_BASE`).
- `posix_venv`: scheme for *Python virtual environments* on POSIX platforms; by default it is the same as `posix_prefix`.

- *nt*: scheme for Windows. This is the default scheme used when Python or a component is installed.
- *nt_user*: scheme for Windows, when the *user* option is used.
- *nt_venv*: scheme for *Python virtual environments* on Windows; by default it is the same as *nt*.
- *venv*: a scheme with values from either *posix_venv* or *nt_venv* depending on the platform Python runs on.
- *osx_framework_user*: scheme for macOS, when the *user* option is used.

Each scheme is itself composed of a series of paths and each path has a unique identifier. Python currently uses eight paths:

- *stdlib*: directory containing the standard Python library files that are not platform-specific.
- *platstdlib*: directory containing the standard Python library files that are platform-specific.
- *platlib*: directory for site-specific, platform-specific files.
- *purelib*: directory for site-specific, non-platform-specific files ('pure' Python).
- *include*: directory for non-platform-specific header files for the Python C-API.
- *platinclude*: directory for platform-specific header files for the Python C-API.
- *scripts*: directory for script files.
- *data*: directory for data files.

29.3.3 User scheme

This scheme is designed to be the most convenient solution for users that don't have write permission to the global site-packages directory or don't want to install into it.

Files will be installed into subdirectories of *site.USER_BASE* (written as *userbase* hereafter). This scheme installs pure Python modules and extension modules in the same location (also known as *site.USER_SITE*).

posix_user

Path	Installation directory
<i>stdlib</i>	<i>userbase/lib/pythonX.Y</i>
<i>platstdlib</i>	<i>userbase/lib/pythonX.Y</i>
<i>platlib</i>	<i>userbase/lib/pythonX.Y/site-packages</i>
<i>purelib</i>	<i>userbase/lib/pythonX.Y/site-packages</i>
<i>include</i>	<i>userbase/include/pythonX.Y</i>
<i>scripts</i>	<i>userbase/bin</i>
<i>data</i>	<i>userbase</i>

nt_user

Path	Installation directory
<i>stdlib</i>	<i>userbase\PythonXY</i>
<i>platstdlib</i>	<i>userbase\PythonXY</i>
<i>platlib</i>	<i>userbase\PythonXY\site-packages</i>
<i>purelib</i>	<i>userbase\PythonXY\site-packages</i>
<i>include</i>	<i>userbase\PythonXY\Include</i>
<i>scripts</i>	<i>userbase\PythonXY\Scripts</i>
<i>data</i>	<i>userbase</i>

Path	Installation directory
<i>stdlib</i>	<i>userbase/lib/python</i>
<i>platstdlib</i>	<i>userbase/lib/python</i>
<i>platlib</i>	<i>userbase/lib/python/site-packages</i>
<i>purelib</i>	<i>userbase/lib/python/site-packages</i>
<i>include</i>	<i>userbase/include/pythonX.Y</i>
<i>scripts</i>	<i>userbase/bin</i>
<i>data</i>	<i>userbase</i>

29.3.4 Home scheme

The idea behind the “home scheme” is that you build and maintain a personal stash of Python modules. This scheme’s name is derived from the idea of a “home” directory on Unix, since it’s not unusual for a Unix user to make their home directory have a layout similar to `/usr/` or `/usr/local/`. This scheme can be used by anyone, regardless of the operating system they are installing for.

posix_home

Path	Installation directory
<i>stdlib</i>	<i>home/lib/python</i>
<i>platstdlib</i>	<i>home/lib/python</i>
<i>platlib</i>	<i>home/lib/python</i>
<i>purelib</i>	<i>home/lib/python</i>
<i>include</i>	<i>home/include/python</i>
<i>platinclude</i>	<i>home/include/python</i>
<i>scripts</i>	<i>home/bin</i>
<i>data</i>	<i>home</i>

29.3.5 Prefix scheme

The “prefix scheme” is useful when you wish to use one Python installation to perform the build/install (i.e., to run the setup script), but install modules into the third-party module directory of a different Python installation (or something that looks like a different Python installation). If this sounds a trifle unusual, it is---that’s why the user and home schemes come before. However, there are at least two known cases where the prefix scheme will be useful.

First, consider that many Linux distributions put Python in `/usr`, rather than the more traditional `/usr/local`. This is entirely appropriate, since in those cases Python is part of “the system” rather than a local add-on. However, if you are installing Python modules from source, you probably want them to go in `/usr/local/lib/python2.X` rather than `/usr/lib/python2.X`.

Another possibility is a network filesystem where the name used to write to a remote directory is different from the name used to read it: for example, the Python interpreter accessed as `/usr/local/bin/python` might search for modules in `/usr/local/lib/python2.X`, but those modules would have to be installed to, say, `/mnt/@server/export/lib/python2.X`.

<i>data</i>	<i>prefix</i>

29.3.6 安裝路徑函式

sysconfig provides some functions to determine these installation paths.

`sysconfig.get_scheme_names()`

Return a tuple containing all schemes currently supported in *sysconfig*.

`sysconfig.get_default_scheme()`

Return the default scheme name for the current platform.

在 3.10 版被加入: This function was previously named `_get_default_scheme()` and considered an implementation detail.

在 3.11 版的變更: When Python runs from a virtual environment, the *venv* scheme is returned.

`sysconfig.get_preferred_scheme(key)`

Return a preferred scheme name for an installation layout specified by *key*.

key must be either "prefix", "home", or "user".

The return value is a scheme name listed in `get_scheme_names()`. It can be passed to *sysconfig* functions that take a *scheme* argument, such as `get_paths()`.

在 3.10 版被加入.

在 3.11 版的變更: When Python runs from a virtual environment and *key*="prefix", the *venv* scheme is returned.

`sysconfig._get_preferred_schemes()`

Return a dict containing preferred scheme names on the current platform. Python implementers and redistributors may add their preferred schemes to the `_INSTALL_SCHEMES` module-level global value, and modify this function to return those scheme names, to e.g. provide different schemes for system and language package managers to use, so packages installed by either do not mix with those by the other.

End users should not use this function, but `get_default_scheme()` and `get_preferred_scheme()` instead.

在 3.10 版被加入。

`sysconfig.get_path_names()`

Return a tuple containing all path names currently supported in `sysconfig`.

`sysconfig.get_path(name[, scheme[, vars[, expand]]])`

Return an installation path corresponding to the path *name*, from the install scheme named *scheme*.

name has to be a value from the list returned by `get_path_names()`.

`sysconfig` stores installation paths corresponding to each path name, for each platform, with variables to be expanded. For instance the *stdlib* path for the *nt* scheme is: `{base}/Lib`.

`get_path()` will use the variables returned by `get_config_vars()` to expand the path. All variables have default values for each platform so one may call this function and get the default value.

If *scheme* is provided, it must be a value from the list returned by `get_scheme_names()`. Otherwise, the default scheme for the current platform is used.

If *vars* is provided, it must be a dictionary of variables that will update the dictionary returned by `get_config_vars()`.

If *expand* is set to `False`, the path will not be expanded using the variables.

如果找不到 *name*, 則引發 `KeyError`。

`sysconfig.get_paths([scheme[, vars[, expand]]])`

Return a dictionary containing all installation paths corresponding to an installation scheme. See `get_path()` for more information.

If *scheme* is not provided, will use the default scheme for the current platform.

If *vars* is provided, it must be a dictionary of variables that will update the dictionary used to expand the paths.

If *expand* is set to `false`, the paths will not be expanded.

If *scheme* is not an existing scheme, `get_paths()` will raise a `KeyError`.

29.3.7 其他函式

`sysconfig.get_python_version()`

回傳 MAJOR.MINOR Python 版本號碼字串。類似於 `'%d.%d' % sys.version_info[:2]`。

`sysconfig.get_platform()`

Return a string that identifies the current platform.

This is used mainly to distinguish platform-specific build directories and platform-specific built distributions. Typically includes the OS name and version and the architecture (as supplied by `os.uname()`), although the exact information included depends on the OS; e.g., on Linux, the kernel version isn't particularly important.

Examples of returned values:

- linux-i586
- linux-alpha (?)
- solaris-2.6-sun4u

Windows will return one of:

- win-amd64 (64bit Windows on AMD64, aka x86_64, Intel64, and EM64T)
- win32 (all others - specifically, `sys.platform` is returned)

macOS can return:

- macosx-10.6-ppc
- macosx-10.4-ppc64
- macosx-10.3-i386
- macosx-10.4-fat

For other non-POSIX platforms, currently just returns `sys.platform`.

`sysconfig.is_python_build()`

Return True if the running Python interpreter was built from source and is being run from its built location, and not from a location resulting from e.g. running `make install` or installing via a binary installer.

`sysconfig.parse_config_h(fp[, vars])`

Parse a `config.h`-style file.

`fp` is a file-like object pointing to the `config.h`-like file.

A dictionary containing name/value pairs is returned. If an optional dictionary is passed in as the second argument, it is used instead of a new dictionary, and updated with the values read in the file.

`sysconfig.get_config_h_filename()`

回傳 `pyconfig.h` 的路徑。

`sysconfig.get_makefile_filename()`

回傳 `Makefile` 的路徑。

29.3.8 將 `sysconfig` 作本使用

You can use `sysconfig` as a script with Python's `-m` option:

```
$ python -m sysconfig
Platform: "macosx-10.4-i386"
Python version: "3.2"
Current installation scheme: "posix_prefix"

Paths:
    data = "/usr/local"
    include = "/Users/tarek/Dev/svn.python.org/py3k/Include"
    platinclude = "."
    platlib = "/usr/local/lib/python3.2/site-packages"
    platstdlib = "/usr/local/lib/python3.2"
    purelib = "/usr/local/lib/python3.2/site-packages"
    scripts = "/usr/local/bin"
    stdlib = "/usr/local/lib/python3.2"

Variables:
    AC_APPLE_UNIVERSAL_BUILD = "0"
    AIX_GENUINE_CPLUSPLUS = "0"
    AR = "ar"
    ARFLAGS = "rc"
    ...
```

This call will print in the standard output the information returned by `get_platform()`, `get_python_version()`, `get_path()` and `get_config_vars()`.

29.4 builtins --- 物件

該模組提供對 Python 所有'內建'識符號的直接存取；例如 `builtins.open` 是內建函式 `open()` 的全名。請參閱內建函式和內建常數的文件。

大多數應用程式通常不會顯式地存取此模組，但在提供與內建值同名之物件的模組中可能很有用，不過其中還會需要內建該名稱。例如，在一個將內建 `open()` 包裝起來以實現另一版本 `open()` 函式的模組中，這個模組可以直接被使用：

```
import builtins

def open(path):
    f = builtins.open(path, 'r')
    return UpperCaser(f)

class UpperCaser:
    '''Wrapper around a file that converts output to uppercase.'''

    def __init__(self, f):
        self._f = f

    def read(self, count=-1):
        return self._f.read(count).upper()

# ...
```

有個實作細節是，大多數模組都將名稱 `__builtins__` 作其全域性變數的一部分以提使用。`__builtins__` 的值通常是這個模組或者這個模組的 `__dict__` 屬性值。由於這是一個實作細節，因此 Python 的其他實作可能不會使用它。

29.5 __main__ --- 頂層程式碼環境

在 Python 中，特殊名稱 `__main__` 用於兩個重要的建構：

1. 程式頂層環境的名稱，可以使用 `__name__ == '__main__'` 運算式進行檢查；和
2. 在 Python 套件中的 `__main__.py` 檔案。

這兩種機制都與 Python 模組有關；使用者如何與它們互動以及它們如何彼此互動。下面會詳細解釋它們。如果你不熟悉 Python 模組，請參閱教學章節 `tut-modules` 的介紹。

29.5.1 __name__ == '__main__'

當引入 Python 模組或套件時，`__name__` 設定內建模組的名稱。通常來，這是 Python 檔案本身的名稱，且不含 `.py` 副檔名：

```
>>> import configparser
>>> configparser.__name__
'configparser'
```

如果檔案是套件的一部分，則 `__name__` 也會包含父套件 (parent package) 的路徑：

```
>>> from concurrent.futures import process
>>> process.__name__
'concurrent.futures.process'
```

但是，如果模組在頂層程式碼環境中執行，則其 `__name__` 將被設定為字串 `'__main__'`。

什麼是「頂層程式碼環境」？

`__main__` 是執行頂層程式碼的環境名稱。「頂層程式碼」是使用者指定且第一個開始運作的 Python 模組。它是「頂層」的原因是因它引入程式所需的所有其他模組。有時「頂層程式碼」被稱作應用程式的入口點。

頂層程式碼環境可以是：

- 互動式提示字元的作用域：

```
>>> __name__
'__main__'
```

- 將 Python 模組作檔案引數傳遞給 Python 直譯器：

```
$ python helloworld.py
Hello, world!
```

- 使用 `-m` 引數傳遞給 Python 直譯器的 Python 模組或套件：

```
$ python -m tarfile
usage: tarfile.py [-h] [-v] (...)
```

- Python 直譯器從標準輸入讀取 Python 程式碼：

```
$ echo "import this" | python
The Zen of Python, by Tim Peters

Beautiful is better than ugly.
Explicit is better than implicit.
...
```

- 使用 `-c` 引數傳遞給 Python 直譯器的 Python 程式碼：

```
$ python -c "import this"
The Zen of Python, by Tim Peters

Beautiful is better than ugly.
Explicit is better than implicit.
...
```

在這些情況下，頂層模組的 `__name__` 都會設定為 `'__main__'`。

因此，模組可以透過檢查自己的 `__name__` 來發現它是否在頂層環境中執行，這允許當模組未從 `import` 陳述式初始化時，使用常見的慣用語法 (idiom) 來有條件地執行程式碼：

```
if __name__ == '__main__':
    # Execute when the module is not initialized from an import statement.
    ...
```

也參考

若要更詳細地了解如何在所有情況下設定 `__name__`，請參見教學章節 `tut-modules`。

慣用 (Idiomatic) 用法

某些模組包含僅供本使用的程式碼，例如剖析命令列引數或從標準輸入取得資料。如果從不同的模組匯入這樣的模組（例如對其進行單元測試 (unit test)），則本程式碼也會無意間執行。

這就是使用 `if __name__ == '__main__':` 程式碼區塊派上用場的地方。除非該模組在頂層環境中執行，否則此區塊中的程式碼不會執行。

在 `if __name__ == '__main__':` 下面的區塊中放置盡可能少的陳述式可以提高程式碼的清晰度和正確性。大多數情況下，名 `main` 的函式封裝 (encapsulate) 了程式的主要行：

```
# echo.py

import shlex
import sys

def echo(phrase: str) -> None:
    """A dummy wrapper around print."""
    # for demonstration purposes, you can imagine that there is some
    # valuable and reusable logic inside this function
    print(phrase)

def main() -> int:
    """Echo the input arguments to standard output"""
    phrase = shlex.join(sys.argv)
    echo(phrase)
    return 0

if __name__ == '__main__':
    sys.exit(main()) # next section explains the use of sys.exit
```

請注意，如果模組有將程式碼封裝在 `main` 函式中，而是直接將其放在 `if __name__ == '__main__':` 區塊中，則 `phrase` 變數對於整個模組來將是全域的。這很容易出錯，因模組中的其他函式可能會無意中使用此全域變數而不是區域變數。`main` 函式解了這個問題。

使用 `main` 函式還有一個額外的好處，`echo` 函式本身是隔離的 (isolated) 且可以在其他地方引入。當引入 `echo.py` 時，`echo` 和 `main` 函式將被定義，但它們都不會被呼叫，因 `__name__ != '__main__'`。

打包時須考慮的事情

`main` 函式通常用於透過將它們指定控制台本的入口點來建立命令列工具。完成後，`pip` 將函式呼叫插入到模板本中，其中 `main` 的回傳值被傳遞到 `sys.exit()` 中。例如：

```
sys.exit(main())
```

由於對 `main` 的呼叫包含在 `sys.exit()` 中，因此期望你的函式將傳回一些可接受作 `sys.exit()` 輸入的值；通常來，會是一個整數或 `None`（如果你的函式有 `return` 陳述式，則相當於回傳此值）。

透過我們自己主動遵循這個慣例，我們的模組在直接執行時（即 `python echo.py`）的行，將和我們稍後將其打包 `pip` 可安裝套件中的控制台本入口點相同。

特別是，要謹慎處理從 `main` 函式回傳字串。`sys.exit()` 會將字串引數直譯失敗訊息，因此你的程式將有一個表示失敗的結束代碼 1，且該字串將被寫入 `sys.stderr`。前面的 `echo.py` 範例使用慣例的 `sys.exit(main())` 進行示範。

Python 打包使用者指南包含一系列如何使用現代工具發行和安裝 Python 套件的教學和參考資料。

29.5.2 Python 套件中的 `__main__.py`

如果你不熟悉 Python 套件，請參閱 [tut-packages](#) 的教學章節。最常見的是，`__main__.py` 檔案用於提供命令列介面。假設下面有結構的套件“bandclass”：

```
bandclass
├── __init__.py
├── __main__.py
└── student.py
```

當使用 `-m` 旗標 (flag) 直接從命令列呼叫套件本身時，將執行 `__main__.py`。例如：

```
$ python -m bandclass
```

該命令將導致 `__main__.py` 執行。如何利用此機制將取於你正在編寫的套件的性質，但在這種情況下，允許教師搜尋學生可能是有意義的：

```
# bandclass/__main__.py

import sys
from .student import search_students

student_name = sys.argv[1] if len(sys.argv) >= 2 else ''
print(f'Found student: {search_students(student_name)}')
```

請注意，`from .student import search_students` 是相對引入的範例。在引用套件的模組時，可以使用此引入樣式。有關更多詳細資訊，請參閱 [tut-modules](#) 教學章節中的 `intra-package-references`。

慣用 (Idiomatic) 用法

`__main__.py` 的內容通常不會被 `if __name__ == '__main__':` 區塊包圍。相反的，這些檔案保持簡短引入其他模組的函式來執行。那些其他模組就可以輕鬆地進行單元測試且可以正確地重用。

如果在套件的 `__main__.py` 檔案使用 `if __name__ == '__main__':` 區塊，它依然會如預期般地運作。因為當引入套件，其 `__name__` 屬性將會包含套件的路徑：

```
>>> import asyncio.__main__
>>> asyncio.__main__.__name__
'asyncio.__main__'
```

但這對於 `.zip` 檔案根目中的 `__main__.py` 檔案不起作用。因此，為了保持一致性，最小的、有 `__name__` 檢查的 `__main__.py` 會是首選。

也參考

請參閱 [venv](#) 作標準函式庫中具有最小 `__main__.py` 的套件範例。它不包含 `if __name__ == '__main__':` 區塊。你可以使用 `python -m venv [directory]` 來呼叫它。

請參閱 [runpy](#) 取得有關直譯器可執行檔的 `-m` 旗標的更多詳細資訊。

請參閱 [zipapp](#) 了解如何執行打包成 `.zip` 檔案的應用程式。在這種情況下，Python 會在封存檔案的根目中尋找 `__main__.py` 檔案。

29.5.3 import __main__

無論 Python 程式是從哪個模組啟動的，在同一程式中執行的其他模組都可以透過匯入 `__main__` 模組來引入頂層環境的作用域 (*namespace*)。這不會引入 `__main__.py` 檔案，而是引入接收特殊名稱 `'__main__'` 的模組。

這是一個使用 `__main__` 命名空間的範例模組：

```
# namely.py

import __main__

def did_user_define_their_name():
    return 'my_name' in dir(__main__)

def print_user_name():
    if not did_user_define_their_name():
        raise ValueError('Define the variable `my_name`!')

    if '__file__' in dir(__main__):
        print(__main__.my_name, "found in file", __main__.__file__)
    else:
        print(__main__.my_name)
```

該模組的範例用法如下：

```
# start.py

import sys

from namely import print_user_name

# my_name = "Dinsdale"

def main():
    try:
        print_user_name()
    except ValueError as ve:
        return str(ve)

if __name__ == "__main__":
    sys.exit(main())
```

現在，如果我們啟動程式，結果將如下所示：

```
$ python start.py
Define the variable `my_name`!
```

程式的結束代碼將 1，表示出現錯誤。取消 1 解 `my_name = "Dinsdale"` 而修復程式後，現在它以狀態碼 0 結束，表示成功：

```
$ python start.py
Dinsdale found in file /path/to/start.py
```

請注意，引入 `__main__` 不會因 1 不經意地執行放在 `start` 模組中 `if __name__ == "__main__"` 區塊的頂層程式碼（本來是給 1 本使用的）而造成任何問題。1 什 1 這樣做會如預期運作？

當 Python 直譯器 1 動時，會在 `sys.modules` 中插入一個空的 `__main__` 模組，1 透過執行頂層程式碼來填充它。在我們的範例中，這是 `start` 模組，它將逐行執行 1 引入 `namely`。接著，`namely` 引入 `__main__`（其實是 `start`）。這就是一個引入循環！幸運的是，由於部分填充的 `__main__` 模組存在於 `sys.modules` 中，Python 將其傳遞給 `namely`。請參 1 引入系統參考文件中的關於 `__main__` 的特 1 考量了解其工作原理的詳細資訊。

Python REPL 是「頂層環境」的另一個範例，因此 REPL 中定義的任何內容都成作用域的一部分：

```
>>> import namely
>>> namely.did_user_define_their_name()
False
>>> namely.print_user_name()
Traceback (most recent call last):
...
ValueError: Define the variable `my_name`!
>>> my_name = 'Jabberwocky'
>>> namely.did_user_define_their_name()
True
>>> namely.print_user_name()
Jabberwocky
```

請注意，在這種情況下，`__main__` 作用域不包含 `__file__` 屬性，因為它是互動式的。

`__main__` 作用域用於 `pdb` 和 `rlcompleter` 的實作。

29.6 warnings --- 警告控制

原始碼：Lib/warnings.py

Warning messages are typically issued in situations where it is useful to alert the user of some condition in a program, where that condition (normally) doesn't warrant raising an exception and terminating the program. For example, one might want to issue a warning when a program uses an obsolete module.

Python programmers issue warnings by calling the `warn()` function defined in this module. (C programmers use `PyErr_WarnEx()`; see exceptionhandling for details).

Warning messages are normally written to `sys.stderr`, but their disposition can be changed flexibly, from ignoring all warnings to turning them into exceptions. The disposition of warnings can vary based on the *warning category*, the text of the warning message, and the source location where it is issued. Repetitions of a particular warning for the same source location are typically suppressed.

There are two stages in warning control: first, each time a warning is issued, a determination is made whether a message should be issued or not; next, if a message is to be issued, it is formatted and printed using a user-settable hook.

The determination whether to issue a warning message is controlled by the *warning filter*, which is a sequence of matching rules and actions. Rules can be added to the filter by calling `filterwarnings()` and reset to its default state by calling `resetwarnings()`.

The printing of warning messages is done by calling `showwarning()`, which may be overridden; the default implementation of this function formats the message by calling `formatwarning()`, which is also available for use by custom implementations.

也參考

`logging.captureWarnings()` allows you to handle all warnings with the standard logging infrastructure.

29.6.1 Warning Categories

There are a number of built-in exceptions that represent warning categories. This categorization is useful to be able to filter out groups of warnings.

While these are technically *built-in exceptions*, they are documented here, because conceptually they belong to the warnings mechanism.

User code can define additional warning categories by subclassing one of the standard warning categories. A warning category must always be a subclass of the *Warning* class.

The following warnings category classes are currently defined:

Class	描述
<i>Warning</i>	This is the base class of all warning category classes. It is a subclass of <i>Exception</i> .
<i>UserWarning</i>	The default category for <i>warn()</i> .
<i>DeprecationWarning</i>	Base category for warnings about deprecated features when those warnings are intended for other Python developers (ignored by default, unless triggered by code in <code>__main__</code>).
<i>SyntaxWarning</i>	Base category for warnings about dubious syntactic features.
<i>RuntimeWarning</i>	Base category for warnings about dubious runtime features.
<i>FutureWarning</i>	Base category for warnings about deprecated features when those warnings are intended for end users of applications that are written in Python.
<i>PendingDeprecationWarning</i>	Base category for warnings about features that will be deprecated in the future (ignored by default).
<i>ImportWarning</i>	Base category for warnings triggered during the process of importing a module (ignored by default).
<i>UnicodeWarning</i>	Base category for warnings related to Unicode.
<i>BytesWarning</i>	Base category for warnings related to <i>bytes</i> and <i>bytearray</i> .
<i>ResourceWarning</i>	Base category for warnings related to resource usage (ignored by default).

在 3.7 版的變更: Previously *DeprecationWarning* and *FutureWarning* were distinguished based on whether a feature was being removed entirely or changing its behaviour. They are now distinguished based on their intended audience and the way they're handled by the default warnings filters.

29.6.2 The Warnings Filter

The warnings filter controls whether warnings are ignored, displayed, or turned into errors (raising an exception).

Conceptually, the warnings filter maintains an ordered list of filter specifications; any specific warning is matched against each filter specification in the list in turn until a match is found; the filter determines the disposition of the match. Each entry is a tuple of the form (*action*, *message*, *category*, *module*, *lineno*), where:

- action* is one of the following strings:

Value	Disposition
"default"	print the first occurrence of matching warnings for each location (module + line number) where the warning is issued
"error"	turn matching warnings into exceptions
"ignore"	never print matching warnings
"always"	always print matching warnings
"module"	print the first occurrence of matching warnings for each module where the warning is issued (regardless of line number)
"once"	print only the first occurrence of matching warnings, regardless of location

- *message* is a string containing a regular expression that the start of the warning message must match, case-insensitively. In `-W` and `PYTHONWARNINGS`, *message* is a literal string that the start of the warning message must contain (case-insensitively), ignoring any whitespace at the start or end of *message*.
- *category* is a class (a subclass of `Warning`) of which the warning category must be a subclass in order to match.
- *module* is a string containing a regular expression that the start of the fully qualified module name must match, case-sensitively. In `-W` and `PYTHONWARNINGS`, *module* is a literal string that the fully qualified module name must be equal to (case-sensitively), ignoring any whitespace at the start or end of *module*.
- *lineno* is an integer that the line number where the warning occurred must match, or 0 to match all line numbers.

Since the `Warning` class is derived from the built-in `Exception` class, to turn a warning into an error we simply raise `category(message)`.

If a warning is reported and doesn't match any registered filter then the "default" action is applied (hence its name).

Describing Warning Filters

The warnings filter is initialized by `-W` options passed to the Python interpreter command line and the `PYTHONWARNINGS` environment variable. The interpreter saves the arguments for all supplied entries without interpretation in `sys.warnoptions`; the `warnings` module parses these when it is first imported (invalid options are ignored, after printing a message to `sys.stderr`).

Individual warnings filters are specified as a sequence of fields separated by colons:

```
action:message:category:module:line
```

The meaning of each of these fields is as described in *The Warnings Filter*. When listing multiple filters on a single line (as for `PYTHONWARNINGS`), the individual filters are separated by commas and the filters listed later take precedence over those listed before them (as they're applied left-to-right, and the most recently applied filters take precedence over earlier ones).

Commonly used warning filters apply to either all warnings, warnings in a particular category, or warnings raised by particular modules or packages. Some examples:

```
default          # Show all warnings (even those ignored by default)
ignore          # Ignore all warnings
error           # Convert all warnings to errors
error::ResourceWarning # Treat ResourceWarning messages as errors
default::DeprecationWarning # Show DeprecationWarning messages
ignore,default::mymodule # Only report warnings triggered by "mymodule"
error::mymodule   # Convert warnings to errors in "mymodule"
```

Default Warning Filter

By default, Python installs several warning filters, which can be overridden by the `-W` command-line option, the `PYTHONWARNINGS` environment variable and calls to `filterwarnings()`.

In regular release builds, the default warning filter has the following entries (in order of precedence):

```
default::DeprecationWarning:__main__
ignore::DeprecationWarning
ignore::PendingDeprecationWarning
ignore::ImportWarning
ignore::ResourceWarning
```

In a debug build, the list of default warning filters is empty.

在 3.2 版的變更: `DeprecationWarning` is now ignored by default in addition to `PendingDeprecationWarning`.

在 3.7 版的變更: `DeprecationWarning` is once again shown by default when triggered directly by code in `__main__`.

在 3.7 版的變更: `BytesWarning` no longer appears in the default filter list and is instead configured via `sys.warnoptions` when `-b` is specified twice.

Overriding the default filter

Developers of applications written in Python may wish to hide *all* Python level warnings from their users by default, and only display them when running tests or otherwise working on the application. The `sys.warnoptions` attribute used to pass filter configurations to the interpreter can be used as a marker to indicate whether or not warnings should be disabled:

```
import sys

if not sys.warnoptions:
    import warnings
    warnings.simplefilter("ignore")
```

Developers of test runners for Python code are advised to instead ensure that *all* warnings are displayed by default for the code under test, using code like:

```
import sys

if not sys.warnoptions:
    import os, warnings
    warnings.simplefilter("default") # Change the filter in this process
    os.environ["PYTHONWARNINGS"] = "default" # Also affect subprocesses
```

Finally, developers of interactive shells that run user code in a namespace other than `__main__` are advised to ensure that `DeprecationWarning` messages are made visible by default, using code like the following (where `user_ns` is the module used to execute code entered interactively):

```
import warnings
warnings.filterwarnings("default", category=DeprecationWarning,
                        module=user_ns.get("__name__"))
```

29.6.3 Temporarily Suppressing Warnings

If you are using code that you know will raise a warning, such as a deprecated function, but do not want to see the warning (even when warnings have been explicitly configured via the command line), then it is possible to suppress the warning using the `catch_warnings` context manager:

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings():
    warnings.simplefilter("ignore")
    fxn()
```

While within the context manager all warnings will simply be ignored. This allows you to use known-deprecated code without having to see the warning while not suppressing the warning for other code that might not be aware of its use of deprecated code. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

29.6.4 Testing Warnings

To test warnings raised by code, use the `catch_warnings` context manager. With it you can temporarily mutate the warnings filter to facilitate your testing. For instance, do the following to capture all raised warnings to check:

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings(record=True) as w:
    # Cause all warnings to always be triggered.
    warnings.simplefilter("always")
    # Trigger a warning.
    fxn()
    # Verify some things
    assert len(w) == 1
    assert isinstance(w[-1].category, DeprecationWarning)
    assert "deprecated" in str(w[-1].message)
```

One can also cause all warnings to be exceptions by using `error` instead of `always`. One thing to be aware of is that if a warning has already been raised because of a `once/default` rule, then no matter what filters are set the warning will not be seen again unless the warnings registry related to the warning has been cleared.

Once the context manager exits, the warnings filter is restored to its state when the context was entered. This prevents tests from changing the warnings filter in unexpected ways between tests and leading to indeterminate test results. The `showwarning()` function in the module is also restored to its original value. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

When testing multiple operations that raise the same kind of warning, it is important to test them in a manner that confirms each operation is raising a new warning (e.g. set warnings to be raised as exceptions and check the operations raise exceptions, check that the length of the warning list continues to increase after each operation, or else delete the previous entries from the warnings list before each new operation).

29.6.5 Updating Code For New Versions of Dependencies

Warning categories that are primarily of interest to Python developers (rather than end users of applications written in Python) are ignored by default.

Notably, this "ignored by default" list includes `DeprecationWarning` (for every module except `__main__`), which means developers should make sure to test their code with typically ignored warnings made visible in order to receive timely notifications of future breaking API changes (whether in the standard library or third party packages).

In the ideal case, the code will have a suitable test suite, and the test runner will take care of implicitly enabling all warnings when running tests (the test runner provided by the `unittest` module does this).

In less ideal cases, applications can be checked for use of deprecated interfaces by passing `-Wd` to the Python interpreter (this is shorthand for `-W default`) or setting `PYTHONWARNINGS=default` in the environment. This enables default handling for all warnings, including those that are ignored by default. To change what action is taken for encountered warnings you can change what argument is passed to `-W` (e.g. `-W error`). See the `-W` flag for more details on what is possible.

29.6.6 Available Functions

`warnings.warn(message, category=None, stacklevel=1, source=None, *, skip_file_prefixes=None)`

Issue a warning, or maybe ignore it or raise an exception. The *category* argument, if given, must be a *warning category class*; it defaults to *UserWarning*. Alternatively, *message* can be a *Warning* instance, in which case *category* will be ignored and *message.__class__* will be used. In this case, the message text will be `str(message)`. This function raises an exception if the particular warning issued is changed into an error by the *warnings filter*. The *stacklevel* argument can be used by wrapper functions written in Python, like this:

```
def deprecated_api(message):
    warnings.warn(message, DeprecationWarning, stacklevel=2)
```

This makes the warning refer to `deprecated_api`'s caller, rather than to the source of `deprecated_api` itself (since the latter would defeat the purpose of the warning message).

The *skip_file_prefixes* keyword argument can be used to indicate which stack frames are ignored when counting stack levels. This can be useful when you want the warning to always appear at call sites outside of a package when a constant *stacklevel* does not fit all call paths or is otherwise challenging to maintain. If supplied, it must be a tuple of strings. When prefixes are supplied, *stacklevel* is implicitly overridden to be `max(2, stacklevel)`. To cause a warning to be attributed to the caller from outside of the current package you might write:

```
# example/lower.py
_warn_skips = (os.path.dirname(__file__),)

def one_way(r_luxury_yacht=None, t_wobbler_mangrove=None):
    if r_luxury_yacht:
        warnings.warn("Please migrate to t_wobbler_mangrove=",
                      skip_file_prefixes=_warn_skips)

# example/higher.py
from . import lower

def another_way(**kw):
    lower.one_way(**kw)
```

This makes the warning refer to both the `example.lower.one_way()` and `package.higher.another_way()` call sites only from calling code living outside of `example` package.

source, if supplied, is the destroyed object which emitted a *ResourceWarning*.

在 3.6 版的變更: 新增 *source* 參數。

在 3.12 版的變更: 新增 *skip_file_prefixes*。

`warnings.warn_explicit(message, category, filename, lineno, module=None, registry=None, module_globals=None, source=None)`

This is a low-level interface to the functionality of `warn()`, passing in explicitly the message, category, filename and line number, and optionally the module name and the registry (which should be the `__warningregistry__` dictionary of the module). The module name defaults to the filename with `.py` stripped; if no registry is passed, the warning is never suppressed. *message* must be a string and *category* a subclass of *Warning* or *message* may be a *Warning* instance, in which case *category* will be ignored.

module_globals, if supplied, should be the global namespace in use by the code for which the warning is issued. (This argument is used to support displaying source for modules found in zipfiles or other non-filesystem import sources).

source, if supplied, is the destroyed object which emitted a *ResourceWarning*.

在 3.6 版的變更: Add the *source* parameter.

`warnings.showwarning(message, category, filename, lineno, file=None, line=None)`

Write a warning to a file. The default implementation calls `formatwarning(message, category,`

`filename`, `lineno`, `line`) and writes the resulting string to `file`, which defaults to `sys.stderr`. You may replace this function with any callable by assigning to `warnings.showwarning`. `line` is a line of source code to be included in the warning message; if `line` is not supplied, `showwarning()` will try to read the line specified by `filename` and `lineno`.

`warnings.formatwarning(message, category, filename, lineno, line=None)`

Format a warning the standard way. This returns a string which may contain embedded newlines and ends in a newline. `line` is a line of source code to be included in the warning message; if `line` is not supplied, `formatwarning()` will try to read the line specified by `filename` and `lineno`.

`warnings.filterwarnings(action, message="", category=Warning, module="", lineno=0, append=False)`

Insert an entry into the list of [warnings filter specifications](#). The entry is inserted at the front by default; if `append` is true, it is inserted at the end. This checks the types of the arguments, compiles the `message` and `module` regular expressions, and inserts them as a tuple in the list of warnings filters. Entries closer to the front of the list override entries later in the list, if both match a particular warning. Omitted arguments default to a value that matches everything.

`warnings.simplefilter(action, category=Warning, lineno=0, append=False)`

Insert a simple entry into the list of [warnings filter specifications](#). The meaning of the function parameters is as for `filterwarnings()`, but regular expressions are not needed as the filter inserted always matches any message in any module as long as the category and line number match.

`warnings.resetwarnings()`

Reset the warnings filter. This discards the effect of all previous calls to `filterwarnings()`, including that of the `-W` command line options and calls to `simplefilter()`.

`@warnings.deprecated(msg, *, category=DeprecationWarning, stacklevel=1)`

Decorator to indicate that a class, function or overload is deprecated.

When this decorator is applied to an object, deprecation warnings may be emitted at runtime when the object is used. *static type checkers* will also generate a diagnostic on usage of the deprecated object.

Usage:

```
from warnings import deprecated
from typing import overload

@deprecated("Use B instead")
class A:
    pass

@deprecated("Use g instead")
def f():
    pass

@overload
@deprecated("int support is deprecated")
def g(x: int) -> int: ...
@overload
def g(x: str) -> int: ...
```

The warning specified by `category` will be emitted at runtime on use of deprecated objects. For functions, that happens on calls; for classes, on instantiation and on creation of subclasses. If the `category` is `None`, no warning is emitted at runtime. The `stacklevel` determines where the warning is emitted. If it is 1 (the default), the warning is emitted at the direct caller of the deprecated object; if it is higher, it is emitted further up the stack. Static type checker behavior is not affected by the `category` and `stacklevel` arguments.

The deprecation message passed to the decorator is saved in the `__deprecated__` attribute on the decorated object. If applied to an overload, the decorator must be after the `@overload` decorator for the attribute to exist on the overload as returned by `typing.get_overloads()`.

在 3.13 版被加入: See [PEP 702](#).

29.6.7 Available Context Managers

class `warnings.catch_warnings` (*, *record=False*, *module=None*, *action=None*, *category=Warning*, *lineno=0*, *append=False*)

A context manager that copies and, upon exit, restores the warnings filter and the `showwarning()` function. If the *record* argument is *False* (the default) the context manager returns *None* on entry. If *record* is *True*, a list is returned that is progressively populated with objects as seen by a custom `showwarning()` function (which also suppresses output to `sys.stdout`). Each object in the list has attributes with the same names as the arguments to `showwarning()`.

The *module* argument takes a module that will be used instead of the module returned when you import `warnings` whose filter will be protected. This argument exists primarily for testing the `warnings` module itself.

If the *action* argument is not *None*, the remaining arguments are passed to `simplefilter()` as if it were called immediately on entering the context.

備 註

The `catch_warnings` manager works by replacing and then later restoring the module's `showwarning()` function and internal list of filter specifications. This means the context manager is modifying global state and therefore is not thread-safe.

在 3.11 版的變更: 新增 *action*、*category*、*lineno* 和 *append* 參數。

29.7 dataclasses --- Data Classes

原始碼: [Lib/dataclasses.py](#)

This module provides a decorator and functions for automatically adding generated *special methods* such as `__init__()` and `__repr__()` to user-defined classes. It was originally described in [PEP 557](#).

The member variables to use in these generated methods are defined using [PEP 526](#) type annotations. For example, this code:

```
from dataclasses import dataclass

@dataclass
class InventoryItem:
    """Class for keeping track of an item in inventory."""
    name: str
    unit_price: float
    quantity_on_hand: int = 0

    def total_cost(self) -> float:
        return self.unit_price * self.quantity_on_hand
```

will add, among other things, a `__init__()` that looks like:

```
def __init__(self, name: str, unit_price: float, quantity_on_hand: int = 0):
    self.name = name
    self.unit_price = unit_price
    self.quantity_on_hand = quantity_on_hand
```

Note that this method is automatically added to the class: it is not directly specified in the `InventoryItem` definition shown above.

在 3.7 版被加入。

29.7.1 模組內容

```
@dataclasses.dataclass (*, init=True, repr=True, eq=True, order=False, unsafe_hash=False,
                        frozen=False, match_args=True, kw_only=False, slots=False,
                        weakref_slot=False)
```

This function is a *decorator* that is used to add generated *special methods* to classes, as described below.

The `@dataclass` decorator examines the class to find *fields*. A *field* is defined as a class variable that has a *type annotation*. With two exceptions described below, nothing in `@dataclass` examines the type specified in the variable annotation.

The order of the fields in all of the generated methods is the order in which they appear in the class definition.

The `@dataclass` decorator will add various "dunder" methods to the class, described below. If any of the added methods already exist in the class, the behavior depends on the parameter, as documented below. The decorator returns the same class that it is called on; no new class is created.

If `@dataclass` is used just as a simple decorator with no parameters, it acts as if it has the default values documented in this signature. That is, these three uses of `@dataclass` are equivalent:

```
@dataclass
class C:
    ...

@dataclass()
class C:
    ...

@dataclass(init=True, repr=True, eq=True, order=False, unsafe_hash=False,
            frozen=False, match_args=True, kw_only=False, slots=False, weakref_slot=False)
class C:
    ...
```

`@dataclass` 的參數是：

- *init*: If true (the default), a `__init__()` method will be generated.
If the class already defines `__init__()`, this parameter is ignored.
- *repr*: If true (the default), a `__repr__()` method will be generated. The generated repr string will have the class name and the name and repr of each field, in the order they are defined in the class. Fields that are marked as being excluded from the repr are not included. For example: `InventoryItem(name='widget', unit_price=3.0, quantity_on_hand=10)`.
If the class already defines `__repr__()`, this parameter is ignored.
- *eq*: If true (the default), an `__eq__()` method will be generated. This method compares the class as if it were a tuple of its fields, in order. Both instances in the comparison must be of the identical type.
If the class already defines `__eq__()`, this parameter is ignored.
- *order*: If true (the default is `False`), `__lt__()`, `__le__()`, `__gt__()`, and `__ge__()` methods will be generated. These compare the class as if it were a tuple of its fields, in order. Both instances in the comparison must be of the identical type. If *order* is true and *eq* is false, a `ValueError` is raised.
If the class already defines any of `__lt__()`, `__le__()`, `__gt__()`, or `__ge__()`, then `TypeError` is raised.
- *unsafe_hash*: If `False` (the default), a `__hash__()` method is generated according to how *eq* and *frozen* are set.
`__hash__()` is used by built-in `hash()`, and when objects are added to hashed collections such as dictionaries and sets. Having a `__hash__()` implies that instances of the class are immutable. Mutability is a complicated property that depends on the programmer's intent, the existence and behavior of `__eq__()`, and the values of the *eq* and *frozen* flags in the `@dataclass` decorator.

By default, `@dataclass` will not implicitly add a `__hash__()` method unless it is safe to do so. Neither will it add or change an existing explicitly defined `__hash__()` method. Setting the class attribute `__hash__ = None` has a specific meaning to Python, as described in the `__hash__()` documentation.

If `__hash__()` is not explicitly defined, or if it is set to `None`, then `@dataclass` *may* add an implicit `__hash__()` method. Although not recommended, you can force `@dataclass` to create a `__hash__()` method with `unsafe_hash=True`. This might be the case if your class is logically immutable but can still be mutated. This is a specialized use case and should be considered carefully.

Here are the rules governing implicit creation of a `__hash__()` method. Note that you cannot both have an explicit `__hash__()` method in your dataclass and set `unsafe_hash=True`; this will result in a `TypeError`.

If `eq` and `frozen` are both true, by default `@dataclass` will generate a `__hash__()` method for you. If `eq` is true and `frozen` is false, `__hash__()` will be set to `None`, marking it unhashable (which it is, since it is mutable). If `eq` is false, `__hash__()` will be left untouched meaning the `__hash__()` method of the superclass will be used (if the superclass is *object*, this means it will fall back to id-based hashing).

- *frozen*: If true (the default is `False`), assigning to fields will generate an exception. This emulates read-only frozen instances. If `__setattr__()` or `__delattr__()` is defined in the class, then `TypeError` is raised. See the discussion below.
- *match_args*: If true (the default is `True`), the `__match_args__` tuple will be created from the list of parameters to the generated `__init__()` method (even if `__init__()` is not generated, see above). If false, or if `__match_args__` is already defined in the class, then `__match_args__` will not be generated.

在 3.10 版被加入。

- *kw_only*: If true (the default value is `False`), then all fields will be marked as keyword-only. If a field is marked as keyword-only, then the only effect is that the `__init__()` parameter generated from a keyword-only field must be specified with a keyword when `__init__()` is called. There is no effect on any other aspect of dataclasses. See the *parameter* glossary entry for details. Also see the *KW_ONLY* section.

在 3.10 版被加入。

- *slots*: If true (the default is `False`), `__slots__` attribute will be generated and new class will be returned instead of the original one. If `__slots__` is already defined in the class, then `TypeError` is raised.

警告

Calling no-arg `super()` in dataclasses using `slots=True` will result in the following exception being raised: `TypeError: super(type, obj): obj must be an instance or subtype of type`. The two-arg `super()` is a valid workaround. See [gh-90562](#) for full details.

警告

Passing parameters to a base class `__init_subclass__()` when using `slots=True` will result in a `TypeError`. Either use `__init_subclass__` with no parameters or use default values as a workaround. See [gh-91126](#) for full details.

在 3.10 版被加入。

在 3.11 版的變更: If a field name is already included in the `__slots__` of a base class, it will not be included in the generated `__slots__` to prevent overriding them. Therefore, do not use `__slots__` to retrieve the field names of a dataclass. Use `fields()` instead. To be able to determine inherited slots, base class `__slots__` may be any iterable, but *not* an iterator.

- `weakref_slot`: If true (the default is `False`), add a slot named `"__weakref__"`, which is required to make an instance *weakref-able*. It is an error to specify `weakref_slot=True` without also specifying `slots=True`.

在 3.11 版被加入.

`fields` may optionally specify a default value, using normal Python syntax:

```
@dataclass
class C:
    a: int          # 'a' has no default value
    b: int = 0      # assign a default value for 'b'
```

In this example, both `a` and `b` will be included in the added `__init__()` method, which will be defined as:

```
def __init__(self, a: int, b: int = 0):
```

`TypeError` will be raised if a field without a default value follows a field with a default value. This is true whether this occurs in a single class, or as a result of class inheritance.

`dataclasses.field(*, default=MISSING, default_factory=MISSING, init=True, repr=True, hash=None, compare=True, metadata=None, kw_only=MISSING)`

For common and simple use cases, no other functionality is required. There are, however, some dataclass features that require additional per-field information. To satisfy this need for additional information, you can replace the default field value with a call to the provided `field()` function. For example:

```
@dataclass
class C:
    mylist: list[int] = field(default_factory=list)

c = C()
c.mylist += [1, 2, 3]
```

As shown above, the `MISSING` value is a sentinel object used to detect if some parameters are provided by the user. This sentinel is used because `None` is a valid value for some parameters with a distinct meaning. No code should directly use the `MISSING` value.

`field()` 的參數是:

- `default`: If provided, this will be the default value for this field. This is needed because the `field()` call itself replaces the normal position of the default value.
- `default_factory`: If provided, it must be a zero-argument callable that will be called when a default value is needed for this field. Among other purposes, this can be used to specify fields with mutable default values, as discussed below. It is an error to specify both `default` and `default_factory`.
- `init`: If true (the default), this field is included as a parameter to the generated `__init__()` method.
- `repr`: If true (the default), this field is included in the string returned by the generated `__repr__()` method.
- `hash`: This can be a bool or `None`. If true, this field is included in the generated `__hash__()` method. If `None` (the default), use the value of `compare`: this would normally be the expected behavior. A field should be considered in the hash if it's used for comparisons. Setting this value to anything other than `None` is discouraged.

One possible reason to set `hash=False` but `compare=True` would be if a field is expensive to compute a hash value for, that field is needed for equality testing, and there are other fields that contribute to the type's hash value. Even if a field is excluded from the hash, it will still be used for comparisons.

- *compare*: If true (the default), this field is included in the generated equality and comparison methods (`__eq__()`, `__gt__()`, et al.).
- *metadata*: This can be a mapping or `None`. `None` is treated as an empty dict. This value is wrapped in `MappingProxyType()` to make it read-only, and exposed on the `Field` object. It is not used at all by Data Classes, and is provided as a third-party extension mechanism. Multiple third-parties can each have their own key, to use as a namespace in the metadata.
- *kw_only*: If true, this field will be marked as keyword-only. This is used when the generated `__init__()` method's parameters are computed.

在 3.10 版被加入。

If the default value of a field is specified by a call to `field()`, then the class attribute for this field will be replaced by the specified *default* value. If *default* is not provided, then the class attribute will be deleted. The intent is that after the `@dataclass` decorator runs, the class attributes will all contain the default values for the fields, just as if the default value itself were specified. For example, after:

```
@dataclass
class C:
    x: int
    y: int = field(repr=False)
    z: int = field(repr=False, default=10)
    t: int = 20
```

The class attribute `C.z` will be 10, the class attribute `C.t` will be 20, and the class attributes `C.x` and `C.y` will not be set.

`class dataclasses.Field`

`Field` objects describe each defined field. These objects are created internally, and are returned by the `fields()` module-level method (see below). Users should never instantiate a `Field` object directly. Its documented attributes are:

- *name*: 欄位的名稱。
- *type*: 欄位的型。
- *default*, *default_factory*, *init*, *repr*, *hash*, *compare*, *metadata*, and *kw_only* have the identical meaning and values as they do in the `field()` function.

Other attributes may exist, but they are private and must not be inspected or relied on.

`dataclasses.fields(class_or_instance)`

Returns a tuple of `Field` objects that define the fields for this dataclass. Accepts either a dataclass, or an instance of a dataclass. Raises `TypeError` if not passed a dataclass or instance of one. Does not return pseudo-fields which are `ClassVar` or `InitVar`.

`dataclasses.asdict(obj, *, dict_factory=dict)`

Converts the dataclass *obj* to a dict (by using the factory function *dict_factory*). Each dataclass is converted to a dict of its fields, as *name: value* pairs. dataclasses, dicts, lists, and tuples are recursed into. Other objects are copied with `copy.deepcopy()`.

Example of using `asdict()` on nested dataclasses:

```
@dataclass
class Point:
    x: int
    y: int

@dataclass
class C:
    mylist: list[Point]
```

(繼續下一頁)

(繼續上一頁)

```
p = Point(10, 20)
assert asdict(p) == {'x': 10, 'y': 20}

c = C([Point(0, 0), Point(10, 4)])
assert asdict(c) == {'mylist': [{'x': 0, 'y': 0}, {'x': 10, 'y': 4}]}
```

To create a shallow copy, the following workaround may be used:

```
{field.name: getattr(obj, field.name) for field in fields(obj)}
```

`asdict()` raises `TypeError` if *obj* is not a dataclass instance.

`dataclasses.astuple(obj, *, tuple_factory=tuple)`

Converts the dataclass *obj* to a tuple (by using the factory function *tuple_factory*). Each dataclass is converted to a tuple of its field values. dataclasses, dicts, lists, and tuples are recursed into. Other objects are copied with `copy.deepcopy()`.

從前面的例子繼續：

```
assert astuple(p) == (10, 20)
assert astuple(c) == ((0, 0), (10, 4)),)
```

To create a shallow copy, the following workaround may be used:

```
tuple(getattr(obj, field.name) for field in dataclasses.fields(obj))
```

`astuple()` raises `TypeError` if *obj* is not a dataclass instance.

`dataclasses.make_dataclass(cls_name, fields, *, bases=(), namespace=None, init=True, repr=True, eq=True, order=False, unsafe_hash=False, frozen=False, match_args=True, kw_only=False, slots=False, weakref_slot=False, module=None)`

Creates a new dataclass with name *cls_name*, fields as defined in *fields*, base classes as given in *bases*, and initialized with a namespace as given in *namespace*. *fields* is an iterable whose elements are each either name, (name, type), or (name, type, Field). If just name is supplied, `typing.Any` is used for type. The values of *init*, *repr*, *eq*, *order*, *unsafe_hash*, *frozen*, *match_args*, *kw_only*, *slots*, and *weakref_slot* have the same meaning as they do in `@dataclass`.

If *module* is defined, the `__module__` attribute of the dataclass is set to that value. By default, it is set to the module name of the caller.

This function is not strictly required, because any Python mechanism for creating a new class with `__annotations__` can then apply the `@dataclass` function to convert that class to a dataclass. This function is provided as a convenience. For example:

```
C = make_dataclass('C',
                  [('x', int),
                   ('y',
                    ('z', int, field(default=5))],
                  namespace={'add_one': lambda self: self.x + 1})
```

相當於：

```
@dataclass
class C:
    x: int
    y: typing.Any
    z: int = 5

    def add_one(self):
        return self.x + 1
```

`dataclasses.replace(obj, /, **changes)`

Creates a new object of the same type as *obj*, replacing fields with values from *changes*. If *obj* is not a Data Class, raises *TypeError*. If keys in *changes* are not field names of the given dataclass, raises *TypeError*.

The newly returned object is created by calling the `__init__()` method of the dataclass. This ensures that `__post_init__()`, if present, is also called.

Init-only variables without default values, if any exist, must be specified on the call to `replace()` so that they can be passed to `__init__()` and `__post_init__()`.

It is an error for *changes* to contain any fields that are defined as having `init=False`. A *ValueError* will be raised in this case.

Be forewarned about how `init=False` fields work during a call to `replace()`. They are not copied from the source object, but rather are initialized in `__post_init__()`, if they're initialized at all. It is expected that `init=False` fields will be rarely and judiciously used. If they are used, it might be wise to have alternate class constructors, or perhaps a custom `replace()` (or similarly named) method which handles instance copying.

Dataclass instances are also supported by generic function `copy.replace()`.

`dataclasses.is_dataclass(obj)`

Return `True` if its parameter is a dataclass (including subclasses of a dataclass) or an instance of one, otherwise return `False`.

If you need to know if a class is an instance of a dataclass (and not a dataclass itself), then add a further check for `not isinstance(obj, type)`:

```
def is_dataclass_instance(obj):
    return is_dataclass(obj) and not isinstance(obj, type)
```

`dataclasses.MISSING`

A sentinel value signifying a missing default or default_factory.

`dataclasses.KW_ONLY`

A sentinel value used as a type annotation. Any fields after a pseudo-field with the type of `KW_ONLY` are marked as keyword-only fields. Note that a pseudo-field of type `KW_ONLY` is otherwise completely ignored. This includes the name of such a field. By convention, a name of `_` is used for a `KW_ONLY` field. Keyword-only fields signify `__init__()` parameters that must be specified as keywords when the class is instantiated.

In this example, the fields *y* and *z* will be marked as keyword-only fields:

```
@dataclass
class Point:
    x: float
    _: KW_ONLY
    y: float
    z: float

p = Point(0, y=1.5, z=2.0)
```

In a single dataclass, it is an error to specify more than one field whose type is `KW_ONLY`.

在 3.10 版被加入.

exception `dataclasses.FrozenInstanceError`

Raised when an implicitly defined `__setattr__()` or `__delattr__()` is called on a dataclass which was defined with `frozen=True`. It is a subclass of *AttributeError*.

29.7.2 Post-init processing

`dataclasses.__post_init__()`

When defined on the class, it will be called by the generated `__init__()`, normally as `self.__post_init__()`. However, if any `InitVar` fields are defined, they will also be passed to `__post_init__()` in the order they were defined in the class. If no `__init__()` method is generated, then `__post_init__()` will not automatically be called.

Among other uses, this allows for initializing field values that depend on one or more other fields. For example:

```
@dataclass
class C:
    a: float
    b: float
    c: float = field(init=False)

    def __post_init__(self):
        self.c = self.a + self.b
```

The `__init__()` method generated by `@dataclass` does not call base class `__init__()` methods. If the base class has an `__init__()` method that has to be called, it is common to call this method in a `__post_init__()` method:

```
class Rectangle:
    def __init__(self, height, width):
        self.height = height
        self.width = width

@dataclass
class Square(Rectangle):
    side: float

    def __post_init__(self):
        super().__init__(self.side, self.side)
```

Note, however, that in general the dataclass-generated `__init__()` methods don't need to be called, since the derived dataclass will take care of initializing all fields of any base class that is a dataclass itself.

See the section below on init-only variables for ways to pass parameters to `__post_init__()`. Also see the warning about how `replace()` handles `init=False` fields.

29.7.3 類變數

One of the few places where `@dataclass` actually inspects the type of a field is to determine if a field is a class variable as defined in [PEP 526](#). It does this by checking if the type of the field is `typing.ClassVar`. If a field is a `ClassVar`, it is excluded from consideration as a field and is ignored by the dataclass mechanisms. Such `ClassVar` pseudo-fields are not returned by the module-level `fields()` function.

29.7.4 Init-only variables

Another place where `@dataclass` inspects a type annotation is to determine if a field is an init-only variable. It does this by seeing if the type of a field is of type `dataclasses.InitVar`. If a field is an `InitVar`, it is considered a pseudo-field called an init-only field. As it is not a true field, it is not returned by the module-level `fields()` function. Init-only fields are added as parameters to the generated `__init__()` method, and are passed to the optional `__post_init__()` method. They are not otherwise used by dataclasses.

For example, suppose a field will be initialized from a database, if a value is not provided when creating the class:

```
@dataclass
class C:
    i: int
    j: int | None = None
    database: InitVar[DatabaseType | None] = None

    def __post_init__(self, database):
        if self.j is None and database is not None:
            self.j = database.lookup('j')

c = C(10, database=my_database)
```

In this case, `fields()` will return `Field` objects for `i` and `j`, but not for `database`.

29.7.5 凍結實例

It is not possible to create truly immutable Python objects. However, by passing `frozen=True` to the `@dataclass` decorator you can emulate immutability. In that case, dataclasses will add `__setattr__()` and `__delattr__()` methods to the class. These methods will raise a `FrozenInstanceError` when invoked.

There is a tiny performance penalty when using `frozen=True`: `__init__()` cannot use simple assignment to initialize fields, and must use `object.__setattr__()`.

29.7.6 繼承

When the dataclass is being created by the `@dataclass` decorator, it looks through all of the class's base classes in reverse MRO (that is, starting at `object`) and, for each dataclass that it finds, adds the fields from that base class to an ordered mapping of fields. After all of the base class fields are added, it adds its own fields to the ordered mapping. All of the generated methods will use this combined, calculated ordered mapping of fields. Because the fields are in insertion order, derived classes override base classes. An example:

```
@dataclass
class Base:
    x: Any = 15.0
    y: int = 0

@dataclass
class C(Base):
    z: int = 10
    x: int = 15
```

The final list of fields is, in order, `x`, `y`, `z`. The final type of `x` is `int`, as specified in class `C`.

The generated `__init__()` method for `C` will look like:

```
def __init__(self, x: int = 15, y: int = 0, z: int = 10):
```

29.7.7 Re-ordering of keyword-only parameters in `__init__()`

After the parameters needed for `__init__()` are computed, any keyword-only parameters are moved to come after all regular (non-keyword-only) parameters. This is a requirement of how keyword-only parameters are implemented in Python: they must come after non-keyword-only parameters.

In this example, `Base.y`, `Base.w`, and `D.t` are keyword-only fields, and `Base.x` and `D.z` are regular fields:

```
@dataclass
class Base:
```

(繼續下一頁)

(繼續上一頁)

```

x: Any = 15.0
_: KW_ONLY
y: int = 0
w: int = 1

@dataclass
class D(Base):
    z: int = 10
    t: int = field(kw_only=True, default=0)

```

The generated `__init__()` method for `D` will look like:

```

def __init__(self, x: Any = 15.0, z: int = 10, *, y: int = 0, w: int = 1, t: int = 0):
    ...

```

Note that the parameters have been re-ordered from how they appear in the list of fields: parameters derived from regular fields are followed by parameters derived from keyword-only fields.

The relative ordering of keyword-only parameters is maintained in the re-ordered `__init__()` parameter list.

29.7.8 預設工廠函式

If a `field()` specifies a `default_factory`, it is called with zero arguments when a default value for the field is needed. For example, to create a new instance of a list, use:

```

mylist: list = field(default_factory=list)

```

If a field is excluded from `__init__()` (using `init=False`) and the field also specifies `default_factory`, then the default factory function will always be called from the generated `__init__()` function. This happens because there is no other way to give the field an initial value.

29.7.9 可變預設值

Python stores default member variable values in class attributes. Consider this example, not using dataclasses:

```

class C:
    x = []
    def add(self, element):
        self.x.append(element)

o1 = C()
o2 = C()
o1.add(1)
o2.add(2)
assert o1.x == [1, 2]
assert o1.x is o2.x

```

Note that the two instances of class `C` share the same class variable `x`, as expected.

Using dataclasses, *if* this code was valid:

```

@dataclass
class D:
    x: list = [] # This code raises ValueError
    def add(self, element):
        self.x.append(element)

```

它會生成類似的程式碼：

```
class D:
    x = []
    def __init__(self, x=x):
        self.x = x
    def add(self, element):
        self.x.append(element)

assert D().x is D().x
```

This has the same issue as the original example using class C. That is, two instances of class D that do not specify a value for x when creating a class instance will share the same copy of x. Because dataclasses just use normal Python class creation they also share this behavior. There is no general way for Data Classes to detect this condition. Instead, the `@dataclass` decorator will raise a `ValueError` if it detects an unhashable default parameter. The assumption is that if a value is unhashable, it is mutable. This is a partial solution, but it does protect against many common errors.

Using default factory functions is a way to create new instances of mutable types as default values for fields:

```
@dataclass
class D:
    x: list = field(default_factory=list)

assert D().x is not D().x
```

在 3.11 版的變更: Instead of looking for and disallowing objects of type `list`, `dict`, or `set`, unhashable objects are now not allowed as default values. Unhashability is used to approximate mutability.

29.7.10 Descriptor-typed fields

Fields that are assigned descriptor objects as their default value have the following special behaviors:

- The value for the field passed to the dataclass's `__init__()` method is passed to the descriptor's `__set__()` method rather than overwriting the descriptor object.
- Similarly, when getting or setting the field, the descriptor's `__get__()` or `__set__()` method is called rather than returning or overwriting the descriptor object.
- To determine whether a field contains a default value, `@dataclass` will call the descriptor's `__get__()` method using its class access form: `descriptor.__get__(obj=None, type=cls)`. If the descriptor returns a value in this case, it will be used as the field's default. On the other hand, if the descriptor raises `AttributeError` in this situation, no default value will be provided for the field.

```
class IntConversionDescriptor:
    def __init__(self, *, default):
        self._default = default

    def __set_name__(self, owner, name):
        self._name = "_" + name

    def __get__(self, obj, type):
        if obj is None:
            return self._default

        return getattr(obj, self._name, self._default)

    def __set__(self, obj, value):
        setattr(obj, self._name, int(value))

@dataclass
class InventoryItem:
    quantity_on_hand: IntConversionDescriptor = _
```

(繼續下一頁)

(繼續上一頁)

```

↪ IntConversionDescriptor(default=100)

i = InventoryItem()
print(i.quantity_on_hand)      # 100
i.quantity_on_hand = 2.5      # calls __set__ with 2.5
print(i.quantity_on_hand)      # 2

```

Note that if a field is annotated with a descriptor type, but is not assigned a descriptor object as its default value, the field will act like a normal field.

29.8 contextlib --- Utilities for with-statement contexts

原始碼: [Lib/contextlib.py](#)

This module provides utilities for common tasks involving the `with` statement. For more information see also [情境管理器型 F](#) and [context-managers](#).

29.8.1 Utilities

Functions and classes provided:

class `contextlib.AbstractContextManager`

An *abstract base class* for classes that implement `object.__enter__()` and `object.__exit__()`. A default implementation for `object.__enter__()` is provided which returns `self` while `object.__exit__()` is an abstract method which by default returns `None`. See also the definition of [情境管理器型 F](#).

在 3.6 版被加入.

class `contextlib.AbstractAsyncContextManager`

An *abstract base class* for classes that implement `object.__aenter__()` and `object.__aexit__()`. A default implementation for `object.__aenter__()` is provided which returns `self` while `object.__aexit__()` is an abstract method which by default returns `None`. See also the definition of [async-context-managers](#).

在 3.7 版被加入.

@contextlib.contextmanager

This function is a *decorator* that can be used to define a factory function for `with` statement context managers, without needing to create a class or separate `__enter__()` and `__exit__()` methods.

While many objects natively support use in `with` statements, sometimes a resource needs to be managed that isn't a context manager in its own right, and doesn't implement a `close()` method for use with `contextlib.closing`

An abstract example would be the following to ensure correct resource management:

```

from contextlib import contextmanager

@contextmanager
def managed_resource(*args, **kwargs):
    # Code to acquire resource, e.g.:
    resource = acquire_resource(*args, **kwargs)
    try:
        yield resource
    finally:

```

(繼續下一頁)

(繼續上一頁)

```
# Code to release resource, e.g.:
release_resource(resource)
```

The function can then be used like this:

```
>>> with managed_resource(timeout=3600) as resource:
...     # Resource is released at the end of this block,
...     # even if code in the block raises an exception
```

The function being decorated must return a *generator*-iterator when called. This iterator must yield exactly one value, which will be bound to the targets in the `with` statement's `as` clause, if any.

At the point where the generator yields, the block nested in the `with` statement is executed. The generator is then resumed after the block is exited. If an unhandled exception occurs in the block, it is reraised inside the generator at the point where the yield occurred. Thus, you can use a `try...except...finally` statement to trap the error (if any), or ensure that some cleanup takes place. If an exception is trapped merely in order to log it or to perform some action (rather than to suppress it entirely), the generator must reraise that exception. Otherwise the generator context manager will indicate to the `with` statement that the exception has been handled, and execution will resume with the statement immediately following the `with` statement.

`contextmanager()` uses `ContextDecorator` so the context managers it creates can be used as decorators as well as in `with` statements. When used as a decorator, a new generator instance is implicitly created on each function call (this allows the otherwise "one-shot" context managers created by `contextmanager()` to meet the requirement that context managers support multiple invocations in order to be used as decorators).

在 3.2 版的變更: Use of `ContextDecorator`.

@contextlib.asynccontextmanager

Similar to `contextmanager()`, but creates an asynchronous context manager.

This function is a *decorator* that can be used to define a factory function for `async with` statement asynchronous context managers, without needing to create a class or separate `__aenter__()` and `__aexit__()` methods. It must be applied to an *asynchronous generator* function.

一個簡單範例:

```
from contextlib import asynccontextmanager

@asynccontextmanager
async def get_connection():
    conn = await acquire_db_connection()
    try:
        yield conn
    finally:
        await release_db_connection(conn)

async def get_all_users():
    async with get_connection() as conn:
        return conn.query('SELECT ...')
```

在 3.7 版被加入.

Context managers defined with `asynccontextmanager()` can be used either as decorators or with `async with` statements:

```
import time
from contextlib import asynccontextmanager

@asynccontextmanager
```

(繼續下一頁)

(繼續上一頁)

```

async def timeit():
    now = time.monotonic()
    try:
        yield
    finally:
        print(f'it took {time.monotonic() - now}s to run')

@timeit()
async def main():
    # ... async code ...

```

When used as a decorator, a new generator instance is implicitly created on each function call. This allows the otherwise “one-shot” context managers created by `asynccontextmanager()` to meet the requirement that context managers support multiple invocations in order to be used as decorators.

在 3.10 版的變更: Async context managers created with `asynccontextmanager()` can be used as decorators.

`contextlib.closing(thing)`

Return a context manager that closes *thing* upon completion of the block. This is basically equivalent to:

```

from contextlib import contextmanager

@contextmanager
def closing(thing):
    try:
        yield thing
    finally:
        thing.close()

```

And lets you write code like this:

```

from contextlib import closing
from urllib.request import urlopen

with closing(urlopen('https://www.python.org')) as page:
    for line in page:
        print(line)

```

without needing to explicitly close `page`. Even if an error occurs, `page.close()` will be called when the `with` block is exited.

備 註

Most types managing resources support the *context manager* protocol, which closes *thing* on leaving the `with` statement. As such, `closing()` is most useful for third party types that don't support context managers. This example is purely for illustration purposes, as `urlopen()` would normally be used in a context manager.

`contextlib.aclosing(thing)`

Return an async context manager that calls the `aclose()` method of *thing* upon completion of the block. This is basically equivalent to:

```

from contextlib import asynccontextmanager

@asynccontextmanager
async def aclosing(thing):
    try:

```

(繼續下一頁)

(繼續上一頁)

```

yield thing
finally:
    await thing.aclose()

```

Significantly, `aclosing()` supports deterministic cleanup of async generators when they happen to exit early by `break` or an exception. For example:

```

from contextlib import aclosing

async with aclosing(my_generator()) as values:
    async for value in values:
        if value == 42:
            break

```

This pattern ensures that the generator's async exit code is executed in the same context as its iterations (so that exceptions and context variables work as expected, and the exit code isn't run after the lifetime of some task it depends on).

在 3.10 版被加入.

`contextlib.nullcontext` (`enter_result=None`)

Return a context manager that returns `enter_result` from `__enter__`, but otherwise does nothing. It is intended to be used as a stand-in for an optional context manager, for example:

```

def myfunction(arg, ignore_exceptions=False):
    if ignore_exceptions:
        # Use suppress to ignore all exceptions.
        cm = contextlib.suppress(Exception)
    else:
        # Do not ignore any exceptions, cm has no effect.
        cm = contextlib.nullcontext()
    with cm:
        # Do something

```

一個使用 `enter_result` 的範例:

```

def process_file(file_or_path):
    if isinstance(file_or_path, str):
        # If string, open file
        cm = open(file_or_path)
    else:
        # Caller is responsible for closing file
        cm = nullcontext(file_or_path)

    with cm as file:
        # Perform processing on the file

```

It can also be used as a stand-in for asynchronous context managers:

```

async def send_http(session=None):
    if not session:
        # If no http session, create it with aiohttp
        cm = aiohttp.ClientSession()
    else:
        # Caller is responsible for closing the session
        cm = nullcontext(session)

    async with cm as session:
        # Send http requests with session

```

在 3.7 版被加入.

在 3.10 版的變更: *asynchronous context manager* support was added.

`contextlib.suppress(*exceptions)`

Return a context manager that suppresses any of the specified exceptions if they occur in the body of a `with` statement and then resumes execution with the first statement following the end of the `with` statement.

As with any other mechanism that completely suppresses exceptions, this context manager should be used only to cover very specific errors where silently continuing with program execution is known to be the right thing to do.

舉例來:

```
from contextlib import suppress

with suppress(FileNotFoundError):
    os.remove('somefile.tmp')

with suppress(FileNotFoundError):
    os.remove('someotherfile.tmp')
```

This code is equivalent to:

```
try:
    os.remove('somefile.tmp')
except FileNotFoundError:
    pass

try:
    os.remove('someotherfile.tmp')
except FileNotFoundError:
    pass
```

This context manager is *reentrant*.

If the code within the `with` block raises a *BaseExceptionGroup*, suppressed exceptions are removed from the group. Any exceptions of the group which are not suppressed are re-raised in a new group which is created using the original group's *derive()* method.

在 3.4 版被加入.

在 3.12 版的變更: `suppress` now supports suppressing exceptions raised as part of a *BaseExceptionGroup*.

`contextlib.redirect_stdout(new_target)`

Context manager for temporarily redirecting `sys.stdout` to another file or file-like object.

This tool adds flexibility to existing functions or classes whose output is hardwired to `stdout`.

For example, the output of `help()` normally is sent to `sys.stdout`. You can capture that output in a string by redirecting the output to an *io.StringIO* object. The replacement stream is returned from the `__enter__` method and so is available as the target of the `with` statement:

```
with redirect_stdout(io.StringIO()) as f:
    help(pow)
s = f.getvalue()
```

To send the output of `help()` to a file on disk, redirect the output to a regular file:

```
with open('help.txt', 'w') as f:
    with redirect_stdout(f):
        help(pow)
```

To send the output of `help()` to `sys.stderr`:

```
with redirect_stdout(sys.stderr):
    help(pow)
```

Note that the global side effect on `sys.stdout` means that this context manager is not suitable for use in library code and most threaded applications. It also has no effect on the output of subprocesses. However, it is still a useful approach for many utility scripts.

This context manager is *reentrant*.

在 3.4 版被加入。

`contextlib.redirect_stderr(new_target)`

Similar to `redirect_stdout()` but redirecting `sys.stderr` to another file or file-like object.

This context manager is *reentrant*.

在 3.5 版被加入。

`contextlib.chdir(path)`

Non parallel-safe context manager to change the current working directory. As this changes a global state, the working directory, it is not suitable for use in most threaded or async contexts. It is also not suitable for most non-linear code execution, like generators, where the program execution is temporarily relinquished -- unless explicitly desired, you should not yield when this context manager is active.

This is a simple wrapper around `chdir()`, it changes the current working directory upon entering and restores the old one on exit.

This context manager is *reentrant*.

在 3.11 版被加入。

class `contextlib.ContextDecorator`

A base class that enables a context manager to also be used as a decorator.

Context managers inheriting from `ContextDecorator` have to implement `__enter__` and `__exit__` as normal. `__exit__` retains its optional exception handling even when used as a decorator.

`ContextDecorator` is used by `contextmanager()`, so you get this functionality automatically.

`ContextDecorator` 範例：

```
from contextlib import ContextDecorator

class mycontext(ContextDecorator):
    def __enter__(self):
        print('Starting')
        return self

    def __exit__(self, *exc):
        print('Finishing')
        return False
```

The class can then be used like this:

```
>>> @mycontext()
... def function():
...     print('The bit in the middle')
...
>>> function()
Starting
The bit in the middle
Finishing

>>> with mycontext():
...     print('The bit in the middle')
```

(繼續下一頁)

(繼續上一頁)

```
...
Starting
The bit in the middle
Finishing
```

This change is just syntactic sugar for any construct of the following form:

```
def f():
    with cm():
        # Do stuff
```

`ContextDecorator` lets you instead write:

```
@cm()
def f():
    # Do stuff
```

It makes it clear that the `cm` applies to the whole function, rather than just a piece of it (and saving an indentation level is nice, too).

Existing context managers that already have a base class can be extended by using `ContextDecorator` as a mixin class:

```
from contextlib import ContextDecorator

class mycontext(ContextBaseClass, ContextDecorator):
    def __enter__(self):
        return self

    def __exit__(self, *exc):
        return False
```

備

As the decorated function must be able to be called multiple times, the underlying context manager must support use in multiple `with` statements. If this is not the case, then the original construct with the explicit `with` statement inside the function should be used.

在 3.2 版被加入.

`class contextlib.AsyncContextDecorator`

Similar to `ContextDecorator` but only for asynchronous functions.

`AsyncContextDecorator` 範例:

```
from asyncio import run
from contextlib import AsyncContextDecorator

class mycontext(AsyncContextDecorator):
    async def __aenter__(self):
        print('Starting')
        return self

    async def __aexit__(self, *exc):
        print('Finishing')
        return False
```

The class can then be used like this:

```

>>> @mycontext()
... async def function():
...     print('The bit in the middle')
...
>>> run(function())
Starting
The bit in the middle
Finishing

>>> async def function():
...     async with mycontext():
...         print('The bit in the middle')
...
>>> run(function())
Starting
The bit in the middle
Finishing

```

在 3.10 版被加入。

class contextlib.**ExitStack**

A context manager that is designed to make it easy to programmatically combine other context managers and cleanup functions, especially those that are optional or otherwise driven by input data.

For example, a set of files may easily be handled in a single with statement as follows:

```

with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for fname in filenames]
    # All opened files will automatically be closed at the end of
    # the with statement, even if attempts to open files later
    # in the list raise an exception

```

The `__enter__()` method returns the *ExitStack* instance, and performs no additional operations.

Each instance maintains a stack of registered callbacks that are called in reverse order when the instance is closed (either explicitly or implicitly at the end of a `with` statement). Note that callbacks are *not* invoked implicitly when the context stack instance is garbage collected.

This stack model is used so that context managers that acquire their resources in their `__init__` method (such as file objects) can be handled correctly.

Since registered callbacks are invoked in the reverse order of registration, this ends up behaving as if multiple nested `with` statements had been used with the registered set of callbacks. This even extends to exception handling - if an inner callback suppresses or replaces an exception, then outer callbacks will be passed arguments based on that updated state.

This is a relatively low level API that takes care of the details of correctly unwinding the stack of exit callbacks. It provides a suitable foundation for higher level context managers that manipulate the exit stack in application specific ways.

在 3.3 版被加入。

enter_context (*cm*)

Enters a new context manager and adds its `__exit__()` method to the callback stack. The return value is the result of the context manager's own `__enter__()` method.

These context managers may suppress exceptions just as they normally would if used directly as part of a `with` statement.

在 3.11 版的變更: Raises *TypeError* instead of *AttributeError* if *cm* is not a context manager.

push (*exit*)

Adds a context manager's `__exit__()` method to the callback stack.

As `__enter__` is *not* invoked, this method can be used to cover part of an `__enter__()` implementation with a context manager's own `__exit__()` method.

If passed an object that is not a context manager, this method assumes it is a callback with the same signature as a context manager's `__exit__()` method and adds it directly to the callback stack.

By returning true values, these callbacks can suppress exceptions the same way context manager `__exit__()` methods can.

The passed in object is returned from the function, allowing this method to be used as a function decorator.

callback (*callback*, /, **args*, ***kws*)

Accepts an arbitrary callback function and arguments and adds it to the callback stack.

Unlike the other methods, callbacks added this way cannot suppress exceptions (as they are never passed the exception details).

The passed in callback is returned from the function, allowing this method to be used as a function decorator.

pop_all()

Transfers the callback stack to a fresh `ExitStack` instance and returns it. No callbacks are invoked by this operation - instead, they will now be invoked when the new stack is closed (either explicitly or implicitly at the end of a `with` statement).

For example, a group of files can be opened as an "all or nothing" operation as follows:

```
with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for fname in filenames]
    # Hold onto the close method, but don't call it yet.
    close_files = stack.pop_all().close
    # If opening any file fails, all previously opened files will be
    # closed automatically. If all files are opened successfully,
    # they will remain open even after the with statement ends.
    # close_files() can then be invoked explicitly to close them all.
```

close()

Immediately unwinds the callback stack, invoking callbacks in the reverse order of registration. For any context managers and exit callbacks registered, the arguments passed in will indicate that no exception occurred.

class `contextlib.AsyncExitStack`

An asynchronous context manager, similar to `ExitStack`, that supports combining both synchronous and asynchronous context managers, as well as having coroutines for cleanup logic.

The `close()` method is not implemented; `aclose()` must be used instead.

coroutine `enter_async_context(cm)`

Similar to `ExitStack.enter_context()` but expects an asynchronous context manager.

在 3.11 版的變更: Raises `TypeError` instead of `AttributeError` if `cm` is not an asynchronous context manager.

push_async_exit(exit)

Similar to `ExitStack.push()` but expects either an asynchronous context manager or a coroutine function.

push_async_callback(callback, /, *args, **kws)

Similar to `ExitStack.callback()` but expects a coroutine function.

coroutine `aclose()`

Similar to `ExitStack.close()` but properly handles awaitables.

Continuing the example for `asynccontextmanager()`:

```
async with AsyncExitStack() as stack:
    connections = [await stack.enter_async_context(get_connection())
                    for i in range(5)]
    # All opened connections will automatically be released at the end of
    # the async with statement, even if attempts to open a connection
    # later in the list raise an exception.
```

在 3.7 版被加入。

29.8.2 Examples and Recipes

This section describes some examples and recipes for making effective use of the tools provided by *contextlib*.

Supporting a variable number of context managers

The primary use case for *ExitStack* is the one given in the class documentation: supporting a variable number of context managers and other cleanup operations in a single `with` statement. The variability may come from the number of context managers needed being driven by user input (such as opening a user specified collection of files), or from some of the context managers being optional:

```
with ExitStack() as stack:
    for resource in resources:
        stack.enter_context(resource)
    if need_special_resource():
        special = acquire_special_resource()
        stack.callback(release_special_resource, special)
    # Perform operations that use the acquired resources
```

As shown, *ExitStack* also makes it quite easy to use `with` statements to manage arbitrary resources that don't natively support the context management protocol.

Catching exceptions from `__enter__` methods

It is occasionally desirable to catch exceptions from an `__enter__` method implementation, *without* inadvertently catching exceptions from the `with` statement body or the context manager's `__exit__` method. By using *ExitStack* the steps in the context management protocol can be separated slightly in order to allow this:

```
stack = ExitStack()
try:
    x = stack.enter_context(cm)
except Exception:
    # handle __enter__ exception
else:
    with stack:
        # Handle normal case
```

Actually needing to do this is likely to indicate that the underlying API should be providing a direct resource management interface for use with `try/except/finally` statements, but not all APIs are well designed in that regard. When a context manager is the only resource management API provided, then *ExitStack* can make it easier to handle various situations that can't be handled directly in a `with` statement.

Cleaning up in an `__enter__` implementation

As noted in the documentation of `ExitStack.push()`, this method can be useful in cleaning up an already allocated resource if later steps in the `__enter__()` implementation fail.

Here's an example of doing this for a context manager that accepts resource acquisition and release functions, along with an optional validation function, and maps them to the context management protocol:

```
from contextlib import contextmanager, AbstractContextManager, ExitStack

class ResourceManager(AbstractContextManager):

    def __init__(self, acquire_resource, release_resource, check_resource_ok=None):
        self.acquire_resource = acquire_resource
        self.release_resource = release_resource
        if check_resource_ok is None:
            def check_resource_ok(resource):
                return True
        self.check_resource_ok = check_resource_ok

    @contextmanager
    def _cleanup_on_error(self):
        with ExitStack() as stack:
            stack.push(self)
            yield
            # The validation check passed and didn't raise an exception
            # Accordingly, we want to keep the resource, and pass it
            # back to our caller
            stack.pop_all()

    def __enter__(self):
        resource = self.acquire_resource()
        with self._cleanup_on_error():
            if not self.check_resource_ok(resource):
                msg = "Failed validation for {!r}"
                raise RuntimeError(msg.format(resource))
        return resource

    def __exit__(self, *exc_details):
        # We don't need to duplicate any of our resource release logic
        self.release_resource()
```

Replacing any use of `try-finally` and flag variables

A pattern you will sometimes see is a `try-finally` statement with a flag variable to indicate whether or not the body of the `finally` clause should be executed. In its simplest form (that can't already be handled just by using an `except` clause instead), it looks something like this:

```
cleanup_needed = True
try:
    result = perform_operation()
    if result:
        cleanup_needed = False
finally:
    if cleanup_needed:
        cleanup_resources()
```

As with any `try` statement based code, this can cause problems for development and review, because the setup code and the cleanup code can end up being separated by arbitrarily long sections of code.

`ExitStack` makes it possible to instead register a callback for execution at the end of a `with` statement, and then later decide to skip executing that callback:

```
from contextlib import ExitStack

with ExitStack() as stack:
    stack.callback(cleanup_resources)
    result = perform_operation()
    if result:
        stack.pop_all()
```

This allows the intended cleanup behaviour to be made explicit up front, rather than requiring a separate flag variable.

If a particular application uses this pattern a lot, it can be simplified even further by means of a small helper class:

```
from contextlib import ExitStack

class Callback(ExitStack):
    def __init__(self, callback, /, *args, **kwargs):
        super().__init__()
        self.callback(callback, *args, **kwargs)

    def cancel(self):
        self.pop_all()

with Callback(cleanup_resources) as cb:
    result = perform_operation()
    if result:
        cb.cancel()
```

If the resource cleanup isn't already neatly bundled into a standalone function, then it is still possible to use the decorator form of `ExitStack.callback()` to declare the resource cleanup in advance:

```
from contextlib import ExitStack

with ExitStack() as stack:
    @stack.callback
    def cleanup_resources():
        ...
    result = perform_operation()
    if result:
        stack.pop_all()
```

Due to the way the decorator protocol works, a callback function declared this way cannot take any parameters. Instead, any resources to be released must be accessed as closure variables.

Using a context manager as a function decorator

`ContextDecorator` makes it possible to use a context manager in both an ordinary `with` statement and also as a function decorator.

For example, it is sometimes useful to wrap functions or groups of statements with a logger that can track the time of entry and time of exit. Rather than writing both a function decorator and a context manager for the task, inheriting from `ContextDecorator` provides both capabilities in a single definition:

```
from contextlib import ContextDecorator
import logging

logging.basicConfig(level=logging.INFO)

class track_entry_and_exit(ContextDecorator):
    def __init__(self, name):
        self.name = name
```

(繼續下一頁)

(繼續上一頁)

```
def __enter__(self):
    logging.info('Entering: %s', self.name)

def __exit__(self, exc_type, exc, exc_tb):
    logging.info('Exiting: %s', self.name)
```

Instances of this class can be used as both a context manager:

```
with track_entry_and_exit('widget loader'):
    print('Some time consuming activity goes here')
    load_widget()
```

And also as a function decorator:

```
@track_entry_and_exit('widget loader')
def activity():
    print('Some time consuming activity goes here')
    load_widget()
```

Note that there is one additional limitation when using context managers as function decorators: there's no way to access the return value of `__enter__()`. If that value is needed, then it is still necessary to use an explicit `with` statement.

也參考

PEP 343 - "with" 陳述式

The specification, background, and examples for the Python `with` statement.

29.8.3 Single use, reusable and reentrant context managers

Most context managers are written in a way that means they can only be used effectively in a `with` statement once. These single use context managers must be created afresh each time they're used - attempting to use them a second time will trigger an exception or otherwise not work correctly.

This common limitation means that it is generally advisable to create context managers directly in the header of the `with` statement where they are used (as shown in all of the usage examples above).

Files are an example of effectively single use context managers, since the first `with` statement will close the file, preventing any further IO operations using that file object.

Context managers created using `contextmanager()` are also single use context managers, and will complain about the underlying generator failing to yield if an attempt is made to use them a second time:

```
>>> from contextlib import contextmanager
>>> @contextmanager
... def singleuse():
...     print("Before")
...     yield
...     print("After")
...
>>> cm = singleuse()
>>> with cm:
...     pass
...
Before
After
>>> with cm:
...     pass
```

(繼續下一頁)

(繼續上一頁)

```
...
Traceback (most recent call last):
...
RuntimeError: generator didn't yield
```

Reentrant context managers

More sophisticated context managers may be “reentrant”. These context managers can not only be used in multiple with statements, but may also be used *inside* a with statement that is already using the same context manager.

`threading.RLock` is an example of a reentrant context manager, as are `suppress()`, `redirect_stdout()`, and `chdir()`. Here’s a very simple example of reentrant use:

```
>>> from contextlib import redirect_stdout
>>> from io import StringIO
>>> stream = StringIO()
>>> write_to_stream = redirect_stdout(stream)
>>> with write_to_stream:
...     print("This is written to the stream rather than stdout")
...     with write_to_stream:
...         print("This is also written to the stream")
...
>>> print("This is written directly to stdout")
This is written directly to stdout
>>> print(stream.getvalue())
This is written to the stream rather than stdout
This is also written to the stream
```

Real world examples of reentrancy are more likely to involve multiple functions calling each other and hence be far more complicated than this example.

Note also that being reentrant is *not* the same thing as being thread safe. `redirect_stdout()`, for example, is definitely not thread safe, as it makes a global modification to the system state by binding `sys.stdout` to a different stream.

Reusable context managers

Distinct from both single use and reentrant context managers are “reusable” context managers (or, to be completely explicit, “reusable, but not reentrant” context managers, since reentrant context managers are also reusable). These context managers support being used multiple times, but will fail (or otherwise not work correctly) if the specific context manager instance has already been used in a containing with statement.

`threading.Lock` is an example of a reusable, but not reentrant, context manager (for a reentrant lock, it is necessary to use `threading.RLock` instead).

Another example of a reusable, but not reentrant, context manager is `ExitStack`, as it invokes *all* currently registered callbacks when leaving any with statement, regardless of where those callbacks were added:

```
>>> from contextlib import ExitStack
>>> stack = ExitStack()
>>> with stack:
...     stack.callback(print, "Callback: from first context")
...     print("Leaving first context")
...
Leaving first context
Callback: from first context
>>> with stack:
...     stack.callback(print, "Callback: from second context")
...     print("Leaving second context")
```

(繼續下一頁)

(繼續上一頁)

```

...
Leaving second context
Callback: from second context
>>> with stack:
...     stack.callback(print, "Callback: from outer context")
...     with stack:
...         stack.callback(print, "Callback: from inner context")
...         print("Leaving inner context")
...     print("Leaving outer context")
...
Leaving inner context
Callback: from inner context
Callback: from outer context
Leaving outer context

```

As the output from the example shows, reusing a single stack object across multiple with statements works correctly, but attempting to nest them will cause the stack to be cleared at the end of the innermost with statement, which is unlikely to be desirable behaviour.

Using separate *ExitStack* instances instead of reusing a single instance avoids that problem:

```

>>> from contextlib import ExitStack
>>> with ExitStack() as outer_stack:
...     outer_stack.callback(print, "Callback: from outer context")
...     with ExitStack() as inner_stack:
...         inner_stack.callback(print, "Callback: from inner context")
...         print("Leaving inner context")
...     print("Leaving outer context")
...
Leaving inner context
Callback: from inner context
Leaving outer context
Callback: from outer context

```

29.9 abc --- 抽象基底類

原始碼: Lib/abc.py

如同在 [PEP 3119](#) 中所述，該模組提供了在 Python 中定義抽象基底類 (ABC) 的基礎元件；若想解什麼需要在 Python 中增加這個模組，請見 PEP 文件。（也請見 [PEP 3141](#) 以及 *numbers* 模組以解基於 ABC 的數字型階層關。）

collections 模組中有一些衍生自 ABC 的具體類；當然這些類還可以進一步衍生出其他類。此外，*collections.abc* 子模組中有一些 ABC 可被用於測試一個類或實例是否提供特定介面，例如它是否可雜 (*hashable*) 或它是否對映。

該模組提供了一個用來定義 ABC 的元類 (metaclass) *ABCMeta* 和另一個以繼承的方式定義 ABC 的工具類 *ABC*：

```
class abc.ABC
```

一個使用 *ABCMeta* 作元類的工具類。抽象基底類可以透過自 ABC 衍生而建立，這就避免了在某些情況下會令人混淆的元類用法，用法如下範例：

```

from abc import ABC

class MyABC(ABC):
    pass

```

注意 ABC 的型仍然是 `ABCMeta`，因此繼承 ABC 仍然需要關注使用元類的注意事項，如多重繼承可能會導致元類衝突。當然你也可以傳入元類關鍵字直接使用 `ABCMeta` 來定義一個抽象基底類，例如：

```
from abc import ABCMeta

class MyABC(metaclass=ABCMeta):
    pass
```

在 3.4 版被加入。

class `abc.ABCMeta`

用於定義抽象基底類 (ABC) 的元類。

使用該元類以建立一個 ABC。一個 ABC 可以像 mix-in 類一樣直接被子類繼承。你也可以將不相關的具體類 (甚至是建類) 和 ABC 擬子類 (virtual subclass) —— 這些類以及它們的子類會被建函式 `issubclass()` 識已 ABC 的子類，但是該 ABC 不會出現在其 MRO (Method Resolution Order, 方法解析順序) 中，由該 ABC 所定義的方法實作也不可呼叫 (即使透過 `super()` 呼叫也不行)。¹

使用 `ABCMeta` 作元類建立的類含有以下的方法：

register (*subclass*)

將子類加入該 ABC 的「抽象子類」，例如：

```
from abc import ABC

class MyABC(ABC):
    pass

MyABC.register(tuple)

assert issubclass(tuple, MyABC)
assert isinstance((), MyABC)
```

在 3.3 版的變更：回傳已的子類，使其能作類裝飾器。

在 3.4 版的變更：你可以使用 `get_cache_token()` 函式來檢測對 `register()` 的呼叫。

你也可以覆寫 (override) 擬基底類中的這個方法：

__subclasshook__ (*subclass*)

(必須定義類方法。)

檢查 *subclass* 是否該被認是該 ABC 的子類，也就是你可以直接自訂 `issubclass()` 的行，而不用對於那些你希望定義該 ABC 的子類的類都個呼叫 `register()` 方法。(這個類方法是在 ABC 的 `__subclasscheck__()` 方法中呼叫。)

此方法必須回傳 `True`、`False` 或是 `NotImplemented`。如果回傳 `True`，*subclass* 就會被認是這個 ABC 的子類。如果回傳 `False`，*subclass* 就會被判定非該 ABC 的子類，即使正常情應如此。如果回傳 `NotImplemented`，子類檢查會按照正常機制繼續執行。

了對這些概念做一演示，請見以下定義 ABC 的範例：

```
class Foo:
    def __getitem__(self, index):
        ...
    def __len__(self):
        ...
    def get_iterator(self):
        return iter(self)
```

(繼續下一頁)

¹ C++ 程式設計師需要注意到 Python 中擬基底類的概念和 C++ 中的不相同。

(繼續上一頁)

```

class MyIterable(ABC):

    @abstractmethod
    def __iter__(self):
        while False:
            yield None

    def get_iterator(self):
        return self.__iter__()

    @classmethod
    def __subclasshook__(cls, C):
        if cls is MyIterable:
            if any("__iter__" in B.__dict__ for B in C.__mro__):
                return True
            return NotImplemented

MyIterable.register(Foo)

```

ABC `MyIterable` 定義了作抽象方法的一個標準代理方法 `__iter__()`。這給定的實作仍可在子類中被呼叫。`get_iterator()` 方法也是 `MyIterable` 抽象基底類的一部分，但它不必被非抽象衍生類覆寫。

這定義的 `__subclasshook__()` 類方法明任何在其 `__dict__` (或在其透過 `__mro__` 列表訪問的基底類) 中具有 `__iter__()` 方法的類也都會被視 `MyIterable`。

最後，即使 `Foo` 有定義 `__iter__()` 方法 (它使用了以 `__len__()` 和 `__getitem__()` 所定義的舊式可代物件協定)，最末一行使其成 `MyIterable` 的一個擬子類。請注意這不會使 `get_iterator` 成 `Foo` 的一個可用方法，所以它是需要被另外提供的。

`abc` 模組也提供了這些裝飾器：

`@abc.abstractmethod`

用於表示抽象方法的裝飾器。

類的元類是 `ABCMeta` 或是從該類衍生才能使用此裝飾器。一個具有衍生自 `ABCMeta` 之元類的類不可以被實例化，除非它全部的抽象方法和特性均已被覆寫。抽象方法可透過任何一般的 `'super'` 呼叫機制來呼叫。`abstractmethod()` 可被用於特性和描述器宣告的抽象方法。

僅在使用 `update_abstractmethods()` 函式時，才能動態地一個類新增抽象方法，或者嘗試在方法或類被建立後修改其抽象狀態。`abstractmethod()` 只會影響使用常規繼承所衍生出的子類；透過 ABC 的 `register()` 方法「擬子類」不會受到影響。

當 `abstractmethod()` 與其他方法描述器 (method descriptor) 配合應用時，它應被當最層的裝飾器，如以下用法範例所示：

```

class C(ABC):
    @abstractmethod
    def my_abstract_method(self, arg1):
        ...

    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, arg2):
        ...

    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(arg3):
        ...

    @property
    @abstractmethod
    def my_abstract_property(self):

```

(繼續下一頁)

(繼續上一頁)

```

...
@my_abstract_property.setter
@abstractmethod
def my_abstract_property(self, val):
    ...

@abstractmethod
def _get_x(self):
    ...

@abstractmethod
def _set_x(self, val):
    ...

x = property(_get_x, _set_x)

```

為了能正確地與 ABC 機制實作相互操作，描述器必須使用 `__isabstractmethod__` 將自身標識為抽象的。一般來說，如果被用於組成描述器的任一方法是抽象的，則此屬性應當為 `True`。例如，Python 的 `property` 所做的就等價於：

```

class Descriptor:
    ...
    @property
    def __isabstractmethod__(self):
        return any(getattr(f, '__isabstractmethod__', False) for
                    f in (self._fget, self._fset, self._fdel))

```

備註

不同於 Java 抽象方法，這些抽象方法可能具有一個實作。這個實作可在覆寫它的類上透過 `super()` 機制來呼叫。這在使用協作多重繼承 (cooperative multiple-inheritance) 的框架中，可以被用作 `super` 呼叫的一個端點 (end-point)。

abc 模組還支援下列舊式裝飾器：

`@abc.abstractmethod`

在 3.2 版被加入。

在 3.3 版之後被重用：現在可以讓 `classmethod` 配合 `abstractmethod()` 使用，使得此裝飾器變得冗余。

建立 `classmethod()` 的子類，表示一個抽象類方法。在其他方面它都類似於 `abstractmethod()`。

這個特例已被重用，因為現在當 `classmethod()` 裝飾器應用於抽象方法時已會被正確地標識為抽象的：

```

class C(ABC):
    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, arg):
        ...

```

`@abc.abstractstaticmethod`

在 3.2 版被加入。

在 3.3 版之後被重用：現在可以讓 `staticmethod` 配合 `abstractmethod()` 使用，使得此裝飾器變得冗余。

建立 `staticmethod()` 的子類，表示一個抽象靜態方法。在其他方面它都類似於 `abstractmethod()`。

這個特例已被用，因現在當 `staticmethod()` 裝飾器應用於抽象方法時已會被正確地標識是抽象的：

```
class C(ABC):
    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(arg):
        ...
```

@abc.abstractproperty

在 3.3 版之後被用：現在可以讓 `property`、`property.getter()`、`property.setter()` 和 `property.deleter()` 配合 `abstractmethod()` 使用，使得此裝飾器變得冗余。

建 `property()` 的子類，表示一個抽象特性。

這個特例已被用，因現在當 `property()` 裝飾器應用於抽象方法時已會被正確地標識是抽象的：

```
class C(ABC):
    @property
    @abstractmethod
    def my_abstract_property(self):
        ...
```

上面的例子定義了一個唯讀特性；你也可以透過適當地將一個或多個底層方法標記抽象的來定義可讀寫的抽象特性：

```
class C(ABC):
    @property
    def x(self):
        ...

    @x.setter
    @abstractmethod
    def x(self, val):
        ...
```

如果只有某些元件是抽象的，則只需更新那些元件即可在子類中建立具體的特性：

```
class D(C):
    @C.x.setter
    def x(self, val):
        ...
```

abc 模組也提供了這些函式：

abc.get_cache_token()

回傳當前 ABC 快取令牌 (cache token)。

此令牌是一個（支援相等性測試的）不透明物件 (opaque object)，用於擬子類標識抽象基底類快取的當前版本。此令牌會在任何 ABC 上每次呼叫 `ABCMeta.register()` 時發生更改。

在 3.4 版被加入。

abc.update_abstractmethods(cls)

重新計算一個抽象類之抽象狀態的函式。如果一個類的抽象方法在建立後被實作或被修改，則應當呼叫此函式。通常此函式應在一個類裝飾器部被呼叫。

回傳 `cls`，使其能用作類的裝飾器。

如果 `cls` 不是 `ABCMeta` 的實例則不做任何操作。

備

此函式會假定 `cls` 的超類 (superclass) 已經被更新。它不會更新任何子類。

在 3.10 版被加入。

解

29.10 atexit --- 退出處理函式

`atexit` 模組定義了 **和** 銷清理函式 (cleanup function) 的函式，這樣的 **和** 函式會在直譯器正常終止時自動執行。`atexit` 按照這些函式之反序來運行這些函式；如果你有 **和** A、B 和 C，則在直譯器終止時它們將按 C、B、A 的順序運行。

注意：當程式被一個不是來自 Python 的訊號終止、偵測到有 Python 嚴重 **和** 部錯誤時或者 `os._exit()` 被呼叫時，透過此模組 **和** 的函式就不會被呼叫。

注意：在清理函式中 **和** 或 **和** 銷函式的作用 **和** 未定義。

在 3.7 版的變更：當與 C-API 子直譯器 (subinterpreter) 一起使用時，已 **和** 函式對於它們所 **和** 的直譯器來 **和** 是區域的 (local)。

`atexit.register(func, *args, **kwargs)`

將 `func` **和** **和** 要在終止時執行的函式。任何要傳遞給 `func` 的可選引數都必須作 **和** 引數傳遞給 `register()`。可以多次 **和** 相同的函式和引數。

在程式正常終止時（例如呼叫 `sys.exit()` 或主要模組執行完成），所有已 **和** 函式都會依照後進先出的順序呼叫。這邊做的假設是較低階的模組通常會在較高階模組之前被引入，因此較低階模組必須在比較後面才被清理。

如果在執行退出處理函式期間引發例外，則會列印回溯 (traceback)（除非引發 `SystemExit`）**和** 儲存例外資訊。在所有退出處理函式都有嘗試運作過後，將重新引發最後一個引發的例外。

該函式回傳 `func`，這使得可以將其作 **和** 裝飾器使用。

警告

和 動新執行緒或從已 **和** 函式呼叫 `os.fork()` 可能會導致 Python 主要 runtime 執行緒釋放執行緒狀態，而 **和** 部 `threading` 例程或新行程嘗試使用該狀態所形成的競態條件 (race condition)。這可能會導致崩潰 (crash) 而不是完整關閉中止。

在 3.12 版的變更：嘗試在已 **和** 函式中 **和** 動新執行緒或 `os.fork()` 新行程現在會導致 `RuntimeError`。

`atexit.unregister(func)`

從在直譯器中止時會執行之函式串列中 **和** 除 `func`。如果 `func` 先前未被 **和**，則 `unregister()` 不會執行任何操作。如果 `func` 已被 **和** 多次，則該函式在 `atexit` 呼叫堆 (call stack) 中的所有存在都會被 **和**。會在 **和** 銷期間於 **和** 部使用相等性比較 (`==`)，因此函式參照不需要具有匹配的識 **和** 性。

也參考**readline** 模組

`atexit` 用於讀取和寫入 `readline` 歷史檔案的一個不錯的範例。

29.10.1 atexit 范例

以下的簡單範例示範了模組如何在被引入時以檔案來初始化計數器，在程式終止時自動儲存計數器的更新值，而不需要仰賴應用程式在終止時明確呼叫該模組。

```
try:
    with open('counterfile') as infile:
        _count = int(infile.read())
except FileNotFoundError:
    _count = 0

def incrcounter(n):
    global _count
    _count = _count + n

def savecounter():
    with open('counterfile', 'w') as outfile:
        outfile.write('%d' % _count)

import atexit

atexit.register(savecounter)
```

位置引數和關鍵字引數也可以被傳遞給 `register()`，以便在呼叫時也傳遞給已函式：

```
def goodbye(name, adjective):
    print('Goodbye %s, it was %s to meet you.' % (name, adjective))

import atexit

atexit.register(goodbye, 'Donny', 'nice')
# or:
atexit.register(goodbye, adjective='nice', name='Donny')
```

作裝飾器使用：

```
import atexit

@atexit.register
def goodbye():
    print('You are now leaving the Python sector.')
```

這只適用於可以不帶引數呼叫的函式。

29.11 traceback --- 列印或取得堆回溯 (stack traceback)

原始碼： [Lib/traceback.py](#)

This module provides a standard interface to extract, format and print stack traces of Python programs. It exactly mimics the behavior of the Python interpreter when it prints a stack trace. This is useful when you want to print stack traces under program control, such as in a “wrapper” around the interpreter.

The module uses traceback objects --- these are objects of type `types.TracebackType`, which are assigned to the `__traceback__` field of `BaseException` instances.

也參考

faulthandler 模組

Used to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal.

pdb 模組

Interactive source code debugger for Python programs.

此模組定義了以下函式：

`traceback.print_tb(tb, limit=None, file=None)`

Print up to *limit* stack trace entries from traceback object *tb* (starting from the caller's frame) if *limit* is positive. Otherwise, print the last `abs(limit)` entries. If *limit* is omitted or `None`, all entries are printed. If *file* is omitted or `None`, the output goes to `sys.stderr`; otherwise it should be an open *file* or *file-like object* to receive the output.

備

The meaning of the *limit* parameter is different than the meaning of `sys.tracebacklimit`. A negative *limit* value corresponds to a positive value of `sys.tracebacklimit`, whereas the behaviour of a positive *limit* value cannot be achieved with `sys.tracebacklimit`.

在 3.5 版的變更: 新增負數 *limit* 的支援。

`traceback.print_exception(exc, /, [value, tb,], limit=None, file=None, chain=True)`

Print exception information and stack trace entries from traceback object *tb* to *file*. This differs from `print_tb()` in the following ways:

- if *tb* is not `None`, it prints a header `Traceback (most recent call last):`
- it prints the exception type and *value* after the stack trace
- if `type(value)` is `SyntaxError` and *value* has the appropriate format, it prints the line where the syntax error occurred with a caret indicating the approximate position of the error.

Since Python 3.10, instead of passing *value* and *tb*, an exception object can be passed as the first argument. If *value* and *tb* are provided, the first argument is ignored in order to provide backwards compatibility.

The optional *limit* argument has the same meaning as for `print_tb()`. If *chain* is true (the default), then chained exceptions (the `__cause__` or `__context__` attributes of the exception) will be printed as well, like the interpreter itself does when printing an unhandled exception.

在 3.5 版的變更: The *etype* argument is ignored and inferred from the type of *value*.

在 3.10 版的變更: The *etype* parameter has been renamed to *exc* and is now positional-only.

`traceback.print_exc(limit=None, file=None, chain=True)`

This is a shorthand for `print_exception(sys.exception(), limit, file, chain)`.

`traceback.print_last(limit=None, file=None, chain=True)`

This is a shorthand for `print_exception(sys.last_exc, limit, file, chain)`. In general it will work only after an exception has reached an interactive prompt (see `sys.last_exc`).

`traceback.print_stack(f=None, limit=None, file=None)`

Print up to *limit* stack trace entries (starting from the invocation point) if *limit* is positive. Otherwise, print the last `abs(limit)` entries. If *limit* is omitted or `None`, all entries are printed. The optional *f* argument can be used to specify an alternate stack frame to start. The optional *file* argument has the same meaning as for `print_tb()`.

在 3.5 版的變更: 新增負數 *limit* 的支援。

```
traceback.extract_tb(tb, limit=None)
```

Return a *StackSummary* object representing a list of “pre-processed” stack trace entries extracted from the traceback object *tb*. It is useful for alternate formatting of stack traces. The optional *limit* argument has the same meaning as for *print_tb()*. A “pre-processed” stack trace entry is a *FrameSummary* object containing attributes *filename*, *lineno*, *name*, and *line* representing the information that is usually printed for a stack trace.

```
traceback.extract_stack(f=None, limit=None)
```

Extract the raw traceback from the current stack frame. The return value has the same format as for *extract_tb()*. The optional *f* and *limit* arguments have the same meaning as for *print_stack()*.

```
traceback.format_list(extracted_list)
```

Given a list of tuples or *FrameSummary* objects as returned by *extract_tb()* or *extract_stack()*, return a list of strings ready for printing. Each string in the resulting list corresponds to the item with the same index in the argument list. Each string ends in a newline; the strings may contain internal newlines as well, for those items whose source text line is not *None*.

```
traceback.format_exception_only(exc, /, [value, ]*, show_group=False)
```

Format the exception part of a traceback using an exception value such as given by *sys.last_value*. The return value is a list of strings, each ending in a newline. The list contains the exception’s message, which is normally a single string; however, for *SyntaxError* exceptions, it contains several lines that (when printed) display detailed information about where the syntax error occurred. Following the message, the list contains the exception’s *notes*.

Since Python 3.10, instead of passing *value*, an exception object can be passed as the first argument. If *value* is provided, the first argument is ignored in order to provide backwards compatibility.

When *show_group* is *True*, and the exception is an instance of *BaseExceptionGroup*, the nested exceptions are included as well, recursively, with indentation relative to their nesting depth.

在 3.10 版的變更: The *etype* parameter has been renamed to *exc* and is now positional-only.

在 3.11 版的變更: The returned list now includes any *notes* attached to the exception.

在 3.13 版的變更: *show_group* parameter was added.

```
traceback.format_exception(exc, /, [value, tb, ]limit=None, chain=True)
```

Format a stack trace and the exception information. The arguments have the same meaning as the corresponding arguments to *print_exception()*. The return value is a list of strings, each ending in a newline and some containing internal newlines. When these lines are concatenated and printed, exactly the same text is printed as does *print_exception()*.

在 3.5 版的變更: The *etype* argument is ignored and inferred from the type of *value*.

在 3.10 版的變更: This function’s behavior and signature were modified to match *print_exception()*.

```
traceback.format_exc(limit=None, chain=True)
```

This is like *print_exc(limit)* but returns a string instead of printing to a file.

```
traceback.format_tb(tb, limit=None)
```

format_list(extract_tb(tb, limit)) 的簡寫。

```
traceback.format_stack(f=None, limit=None)
```

format_list(extract_stack(f, limit)) 的簡寫。

```
traceback.clear_frames(tb)
```

Clears the local variables of all the stack frames in a traceback *tb* by calling the *clear()* method of each frame object.

在 3.4 版被加入。

```
traceback.walk_stack(f)
```

Walk a stack following *f.f_back* from the given frame, yielding the frame and line number for each frame. If *f* is *None*, the current stack is used. This helper is used with *StackSummary.extract()*.

在 3.5 版被加入.

`traceback.walk_tb(tb)`

Walk a traceback following `tb_next` yielding the frame and line number for each frame. This helper is used with `StackSummary.extract()`.

在 3.5 版被加入.

The module also defines the following classes:

29.11.1 TracebackException 物件

在 3.5 版被加入.

`TracebackException` objects are created from actual exceptions to capture data for later printing in a lightweight fashion.

```
class traceback.TracebackException(exc_type, exc_value, exc_traceback, *, limit=None,  
                                     lookup_lines=True, capture_locals=False, compact=False,  
                                     max_group_width=15, max_group_depth=10)
```

Capture an exception for later rendering. *limit*, *lookup_lines* and *capture_locals* are as for the `StackSummary` class.

If *compact* is true, only data that is required by `TracebackException`'s `format()` method is saved in the class attributes. In particular, the `__context__` field is calculated only if `__cause__` is None and `__suppress_context__` is false.

Note that when locals are captured, they are also shown in the traceback.

max_group_width and *max_group_depth* control the formatting of exception groups (see `BaseExceptionGroup`). The depth refers to the nesting level of the group, and the width refers to the size of a single exception group's exceptions array. The formatted output is truncated when either limit is exceeded.

在 3.10 版的變更: 新增 *compact* 參數。

在 3.11 版的變更: 新增 *max_group_width* 和 *max_group_depth* 參數。

`__cause__`

A `TracebackException` of the original `__cause__`.

`__context__`

A `TracebackException` of the original `__context__`.

exceptions

If `self` represents an `ExceptionGroup`, this field holds a list of `TracebackException` instances representing the nested exceptions. Otherwise it is None.

在 3.11 版被加入.

`__suppress_context__`

The `__suppress_context__` value from the original exception.

`__notes__`

The `__notes__` value from the original exception, or None if the exception does not have any notes. If it is not None is it formatted in the traceback after the exception string.

在 3.11 版被加入.

stack

A `StackSummary` representing the traceback.

exc_type

The class of the original traceback.

在 3.13 版之後被用。

exc_type_str

String display of the class of the original exception.

在 3.13 版被加入。

filename

For syntax errors - the file name where the error occurred.

lineno

For syntax errors - the line number where the error occurred.

end_lineno

For syntax errors - the end line number where the error occurred. Can be `None` if not present.

在 3.10 版被加入。

text

For syntax errors - the text where the error occurred.

offset

For syntax errors - the offset into the text where the error occurred.

end_offset

For syntax errors - the end offset into the text where the error occurred. Can be `None` if not present.

在 3.10 版被加入。

msg

For syntax errors - the compiler error message.

classmethod from_exception (*exc*, *, *limit=None*, *lookup_lines=True*, *capture_locals=False*)

Capture an exception for later rendering. *limit*, *lookup_lines* and *capture_locals* are as for the `StackSummary` class.

Note that when locals are captured, they are also shown in the traceback.

print (*, *file=None*, *chain=True*)

Print to *file* (default `sys.stderr`) the exception information returned by `format()`.

在 3.11 版被加入。

format (*, *chain=True*)

Format the exception.

If *chain* is not `True`, `__cause__` and `__context__` will not be formatted.

The return value is a generator of strings, each ending in a newline and some containing internal newlines. `print_exception()` is a wrapper around this method which just prints the lines to a file.

format_exception_only (*, *show_group=False*)

Format the exception part of the traceback.

The return value is a generator of strings, each ending in a newline.

When *show_group* is `False`, the generator emits the exception's message followed by its notes (if it has any). The exception message is normally a single string; however, for `SyntaxError` exceptions, it consists of several lines that (when printed) display detailed information about where the syntax error occurred.

When *show_group* is `True`, and the exception is an instance of `BaseExceptionGroup`, the nested exceptions are included as well, recursively, with indentation relative to their nesting depth.

在 3.11 版的變更: The exception's *notes* are now included in the output.

在 3.13 版的變更: Added the *show_group* parameter.

29.11.2 StackSummary 物件

在 3.5 版被加入.

StackSummary objects represent a call stack ready for formatting.

class traceback.StackSummary

classmethod extract (*frame_gen*, *, *limit=None*, *lookup_lines=True*, *capture_locals=False*)

Construct a StackSummary object from a frame generator (such as is returned by *walk_stack()* or *walk_tb()*).

If *limit* is supplied, only this many frames are taken from *frame_gen*. If *lookup_lines* is *False*, the returned *FrameSummary* objects will not have read their lines in yet, making the cost of creating the StackSummary cheaper (which may be valuable if it may not actually get formatted). If *capture_locals* is *True* the local variables in each *FrameSummary* are captured as object representations.

在 3.12 版的變更: Exceptions raised from *repr()* on a local variable (when *capture_locals* is *True*) are no longer propagated to the caller.

classmethod from_list (*a_list*)

Construct a StackSummary object from a supplied list of *FrameSummary* objects or old-style list of tuples. Each tuple should be a 4-tuple with *filename*, *lineno*, *name*, *line* as the elements.

format ()

Returns a list of strings ready for printing. Each string in the resulting list corresponds to a single frame from the stack. Each string ends in a newline; the strings may contain internal newlines as well, for those items with source text lines.

For long sequences of the same frame and line, the first few repetitions are shown, followed by a summary line stating the exact number of further repetitions.

在 3.6 版的變更: Long sequences of repeated frames are now abbreviated.

format_frame_summary (*frame_summary*)

Returns a string for printing one of the frames involved in the stack. This method is called for each *FrameSummary* object to be printed by *StackSummary.format()*. If it returns *None*, the frame is omitted from the output.

在 3.11 版被加入.

29.11.3 FrameSummary 物件

在 3.5 版被加入.

A FrameSummary object represents a single frame in a traceback.

class traceback.FrameSummary (*filename*, *lineno*, *name*, *lookup_line=True*, *locals=None*, *line=None*)

Represents a single frame in the traceback or stack that is being formatted or printed. It may optionally have a stringified version of the frame's locals included in it. If *lookup_line* is *False*, the source code is not looked up until the *FrameSummary* has the *line* attribute accessed (which also happens when casting it to a *tuple*). *line* may be directly provided, and will prevent line lookups happening at all. *locals* is an optional local variable mapping, and if supplied the variable representations are stored in the summary for later display.

FrameSummary instances have the following attributes:

filename

The filename of the source code for this frame. Equivalent to accessing `f.f_code.co_filename` on a frame object `f`.

lineno

The line number of the source code for this frame.

name

Equivalent to accessing `f.f_code.co_name` on a frame object `f`.

line

A string representing the source code for this frame, with leading and trailing whitespace stripped. If the source is not available, it is `None`.

29.11.4 Traceback Examples

This simple example implements a basic read-eval-print loop, similar to (but less useful than) the standard Python interactive interpreter loop. For a more complete implementation of the interpreter loop, refer to the `code` module.

```
import sys, traceback

def run_user_code(envdir):
    source = input(">>> ")
    try:
        exec(source, envdir)
    except Exception:
        print("Exception in user code:")
        print("-"*60)
        traceback.print_exc(file=sys.stdout)
        print("-"*60)

envdir = {}
while True:
    run_user_code(envdir)
```

The following example demonstrates the different ways to print and format the exception and traceback:

```
import sys, traceback

def lumberjack():
    bright_side_of_life()

def bright_side_of_life():
    return tuple()[0]

try:
    lumberjack()
except IndexError:
    exc = sys.exception()
    print("*** print_tb:")
    traceback.print_tb(exc.__traceback__, limit=1, file=sys.stdout)
    print("*** print_exception:")
    traceback.print_exception(exc, limit=2, file=sys.stdout)
    print("*** print_exc:")
    traceback.print_exc(limit=2, file=sys.stdout)
    print("*** format_exc, first and last line:")
    formatted_lines = traceback.format_exc().splitlines()
    print(formatted_lines[0])
    print(formatted_lines[-1])
    print("*** format_exception:")
    print(repr(traceback.format_exception(exc)))
```

(繼續下一頁)

(繼續上一頁)

```

print ("*** extract_tb:")
print (repr(traceback.extract_tb(exc.__traceback__)))
print ("*** format_tb:")
print (repr(traceback.format_tb(exc.__traceback__)))
print ("*** tb_lineno:", exc.__traceback__.tb_lineno)

```

The output for the example would look similar to this:

```

*** print_tb:
File "<doctest...>", line 10, in <module>
    lumberjack()
    ~~~~~^
*** print_exception:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
    lumberjack()
    ~~~~~^

  File "<doctest...>", line 4, in lumberjack
    bright_side_of_life()
    ~~~~~^
IndexError: tuple index out of range
*** print_exc:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
    lumberjack()
    ~~~~~^

  File "<doctest...>", line 4, in lumberjack
    bright_side_of_life()
    ~~~~~^
IndexError: tuple index out of range
*** format_exc, first and last line:
Traceback (most recent call last):
IndexError: tuple index out of range
*** format_exception:
['Traceback (most recent call last):\n',
 '  File "<doctest default[0]>", line 10, in <module>\n    lumberjack()\n    ~~~~~\n',
 '  File "<doctest default[0]>", line 4, in lumberjack\n    bright_side_of_life()\n',
 '  File "<doctest default[0]>", line 7, in bright_side_of_life\n    return_\n',
 'tuple() [0]\n    ~~~~~\n',
 'IndexError: tuple index out of range\n']
*** extract_tb:
[<FrameSummary file <doctest...>, line 10 in <module>>,
 <FrameSummary file <doctest...>, line 4 in lumberjack>,
 <FrameSummary file <doctest...>, line 7 in bright_side_of_life>]
*** format_tb:
['  File "<doctest default[0]>", line 10, in <module>\n    lumberjack()\n    ~~~~~\n',
 '  File "<doctest default[0]>", line 4, in lumberjack\n    bright_side_of_life()\n',
 '  File "<doctest default[0]>", line 7, in bright_side_of_life\n    return_\n',
 'tuple() [0]\n    ~~~~~\n']
*** tb_lineno: 10

```

The following example shows the different ways to print and format the stack:

```

>>> import traceback
>>> def another_function():
...     lumberstack()
...

```

(繼續下一頁)

(繼續上一頁)

```
>>> def lumberstack():
...     traceback.print_stack()
...     print(repr(traceback.extract_stack()))
...     print(repr(traceback.format_stack()))
...
>>> another_function()
File "<doctest>", line 10, in <module>
    another_function()
File "<doctest>", line 3, in another_function
    lumberstack()
File "<doctest>", line 6, in lumberstack
    traceback.print_stack()
[('<doctest>', 10, '<module>', 'another_function()'),
 ('<doctest>', 3, 'another_function', 'lumberstack()'),
 ('<doctest>', 7, 'lumberstack', 'print(repr(traceback.extract_stack()))')]
[' File "<doctest>", line 10, in <module>\n    another_function()\n',
 ' File "<doctest>", line 3, in another_function\n    lumberstack()\n',
 ' File "<doctest>", line 8, in lumberstack\n    print(repr(traceback.format_
↳ stack()))\n']
```

This last example demonstrates the final few formatting functions:

```
>>> import traceback
>>> traceback.format_list([('spam.py', 3, '<module>', 'spam.eggs()'),
...                       ('eggs.py', 42, 'eggs', 'return "bacon"')])
[' File "spam.py", line 3, in <module>\n    spam.eggs()\n',
 ' File "eggs.py", line 42, in eggs\n    return "bacon"\n']
>>> an_error = IndexError('tuple index out of range')
>>> traceback.format_exception_only(type(an_error), an_error)
['IndexError: tuple index out of range\n']
```

29.12 __future__ --- Future 陳述式定義

原始碼: Lib/__future__.py

from __future__ import feature 形式的引入被稱作 future 陳述式。這些是 Python 編譯器的特殊情況，允許在該功能成為標準版本之前在包含 future 陳述式的模組中使用新的 Python 功能。

雖然這些 future 陳述式被 Python 編譯器賦予了額外的特殊意義，但它們仍然像任何其他 import 陳述式一樣執行，且 __future__ 由引入系統以和任何其他 Python 模組相同的方式處理。這個設計有三個目的：

- 為了避免混淆分析引入陳述式預期要找到它們正在引入之模組的現有工具。
- 記何時出現不相容的變更，以及何時開始限制執行這些變更。這是一種可執行文件的形式，可以透過引入 __future__ 檢查其內容以程式化的方式進行檢查。
- 確保 future 陳述式在 Python 2.1 之前的版本中運行至少會產生 runtime 例外 (__future__ 的引入將會失敗，因為 2.1 之前沒有該名稱的模組)。

29.12.1 模組 `__future__`

不會從 `__future__` 中除任何功能描述。自從在 Python 2.1 中引入以來，以下功能已透過這種機制引入到該語言中：

功能	可選的版本	制性的版本	影響
nested_scopes	2.1.0b1	2.2	PEP 227 : 態巢狀作用域 (<i>Statically Nested Scopes</i>)
generators	2.2.0a1	2.3	PEP 255 : 簡單生器 (<i>Simple Generators</i>)
division	2.2.0a2	3.0	PEP 238 : 更改除法運算子 (<i>Changing the Division Operator</i>)
absolute_import	2.5.0a1	3.0	PEP 328 : 引入: 多列與對/相對 (<i>Imports: Multi-Line and Absolute/Relative</i>)
with_statement	2.5.0a1	2.6	PEP 343 : "with" 陳述式 (<i>The "with" Statement</i>)
print_function	2.6.0a2	3.0	PEP 3105 : 使 <code>print</code> 成一個函式 (<i>Make print a function</i>)
unicode_literals	2.6.0a2	3.0	PEP 3112 : Python 3000 中的位元組字面值 (<i>Bytes literals in Python 3000</i>)
generator_stop	3.5.0b1	3.7	PEP 479 : 生器部的 <code>StopIteration</code> 處理 (<i>StopIteration handling inside generators</i>)
annotations	3.7.0b1	TBD ¹	PEP 563 : 推遲對釋的求值 (<i>Postponed evaluation of annotations</i>)

class `__future__._Feature`

`__future__.py` 中的每個陳述式的形式如下：

```
FeatureName = _Feature(OptionalRelease, MandatoryRelease,
                        CompilerFlag)
```

通常，`OptionalRelease` 會小於 `MandatoryRelease`，且兩者都是與 `sys.version_info` 形式相同的 5 元組 (5-tuple)：

```
(PY_MAJOR_VERSION, # the 2 in 2.1.0a3; an int
 PY_MINOR_VERSION, # the 1; an int
 PY_MICRO_VERSION, # the 0; an int
 PY_RELEASE_LEVEL, # "alpha", "beta", "candidate" or "final"; string
 PY_RELEASE_SERIAL # the 3; an int
)
```

`_Feature.getOptionalRelease()`

`OptionalRelease` 記該功能首次發布時的 Python 版本。

`_Feature.getMandatoryRelease()`

如果 `MandatoryRelease` 尚未發布，`MandatoryRelease` 會預測該功能將成該語言一部分的版本。

否則 `MandatoryRelease` 會記該功能是何時成該語言的一部分；在該版本或之後的版本中，模組不再需要 `future` 聲明來使用相關功能，但可以繼續使用此種引入方式。

`MandatoryRelease` 也可能是 `None`，這意味著計劃中的功能被或或者仍未定。

`_Feature.compiler_flag`

`CompilerFlag` 是 (位元欄位 (bitfield)) 旗標，應在第四個引數中傳遞給建函式 `compile()` 以在動態編譯的程式碼中用該功能。此旗標存儲在 `_Feature` 實例上的 `_Feature.compiler_flag` 屬性中。

也參考

¹ 之前原本計劃在 Python 3.10 中制使用 `from __future__ import annotations`，但 Python 指導委員會 (Python Steering Council) 兩次推遲這一變動 (Python 3.10 的公告；Python 3.11 的公告)。目前還尚未做出定。另請參 [PEP 563](#) 和 [PEP 649](#)。

future

編譯器如何處理 future 引入。

PEP 236 - 回到 `__future__`

`__future__` 機制的原始提案。

29.13 gc --- 垃圾回收器介面 (Garbage Collector interface)

此 module (模組) 提供可選的垃圾回收器介面, 提供的功能包括: 關閉回收器、調整回收頻率、設定除錯選項。它同時提供對回收器有找到但是無法釋放的不可達物件 (unreachable object) 的存取。由於 Python 使用了帶有參照計數的回收器, 如果你確定你的程式不會產生參照圈 (reference cycle), 你可以關閉回收器。可以透過呼叫 `gc.disable()` 關閉自動垃圾回收。若要一個存在記憶體流失的程式 (leaking program) 除錯, 請呼叫 `gc.set_debug(gc.DEBUG_LEAK)`; 需要注意的是, 它包含 `gc.DEBUG_SAVEALL`, 使得被回收的物件會被存放在 `gc.garbage` 中以待檢查。

`gc` module 提供下列函式:

`gc.enable()`

啟用自動垃圾回收。

`gc.disable()`

停用自動垃圾回收。

`gc.isenabled()`

如果啟用了自動回收則回傳 True。

`gc.collect (generation=2)`

Perform a collection. The optional argument *generation* may be an integer specifying which generation to collect (from 0 to 2). A `ValueError` is raised if the generation number is invalid. The sum of collected objects and uncollectable objects is returned.

Calling `gc.collect(0)` will perform a GC collection on the young generation.

Calling `gc.collect(1)` will perform a GC collection on the young generation and an increment of the old generation.

Calling `gc.collect(2)` or `gc.collect()` performs a full collection

每當執行完整回收或最高代 (2) 回收時, 多個建型所維護的空列表會被清空。了特定型的實現, 特別是 `float`, 在某些空列表中非所有項目都會被釋放。

The effect of calling `gc.collect()` while the interpreter is already performing a collection is undefined.

在 3.13 版的變更: `generation=1` performs an increment of collection.

`gc.set_debug (flags)`

設定垃圾回收器的除錯旗標。除錯資訊會被寫入 `sys.stderr`。請見下方的除錯旗標列表, 可以使用位元操作 (bit operation) 進行設定以控制除錯程式。

`gc.get_debug()`

回傳當前設置的除錯旗標。

`gc.get_objects (generation=None)`

Returns a list of all objects tracked by the collector, excluding the list returned. If *generation* is not None, return only the objects as follows:

- 0: All objects in the young generation
- 1: No objects, as there is no generation 1 (as of Python 3.13)

- 2: All objects in the old generation

在 3.8 版的變更: 新增 *generation* 參數。

在 3.13 版的變更: Generation 1 is removed

引發一個附帶引數 *generation* 的稽核事件 (*auditing event*) `gc.get_objects`。

`gc.get_stats()`

回傳一個包含三個字典物件的 `list`，每個字典分包含對應代中自從直譯器開始執行後的垃圾回收統計資料。字典的鍵的數目在將來可能會改變，但目前每個字典包含以下項目：

- `collections` 是該代被回收的次數；
- `collected` 是該代中被回收的物件總數；
- `uncollectable` 是在這一代中被發現無法回收的物件總數（因此被移到 *garbage list* 中）。

在 3.4 版被加入。

`gc.set_threshold(threshold0[, threshold1[, threshold2]])`

設定垃圾回收閾值（回收頻率）。將 `threshold0` 設零會停止回收。

The GC classifies objects into two generations depending on whether they have survived a collection. New objects are placed in the young generation. If an object survives a collection it is moved into the old generation.

In order to decide when to run, the collector keeps track of the number of object allocations and deallocations since the last collection. When the number of allocations minus the number of deallocations exceeds *threshold0*, collection starts. For each collection, all the objects in the young generation and some fraction of the old generation is collected.

The fraction of the old generation that is collected is **inversely** proportional to *threshold1*. The larger *threshold1* is, the slower objects in the old generation are collected. For the default value of 10, 1% of the old generation is scanned during each collection.

threshold2 is ignored.

See [Garbage collector design](#) for more information.

在 3.13 版的變更: *threshold2* is ignored

`gc.get_count()`

將當前回收計數以 `(count0, count1, count2)` 形式的 `tuple` 回傳。

`gc.get_threshold()`

將當前回收閾值以 `(threshold0, threshold1, threshold2)` 形式的 `tuple` 回傳。

`gc.get_referrers(*objs)`

回傳包含直接參照 `objs` 中任一個物件的物件 `list`。這個函式只定位支援垃圾回收的容器；參照了其它物件但不支援垃圾回收的擴充套件型無法被找到。

需要注意的是，已經解除參照的物件，但仍存在於參照圈中未被回收時，該物件仍然會被作參照者出現在回傳的 `list` 中。若只要獲取當前正在參照的物件，需要在呼叫 `get_referrers()` 之前呼叫 `collect()`。

警告

在使用 `get_referrers()` 回傳的物件時必須要小心，因為其中的一些物件可能仍在建構中而處於暫時無效的狀態。不要把 `get_referrers()` 用於除錯以外的其它目的。

引發一個附帶引數 `objs` 的稽核事件 `gc.get_referrers`。

`gc.get_referents(*objs)`

回傳包含被任意一個引數直接參照之物件的 list。回傳的被參照物件是有被引數的 C 語言級 `tp_traverse` 方法（若存在）訪問到的物件，可能不是所有的實際直接可達物件。只有支援垃圾回收的物件支援 `tp_traverse` 方法，且此方法只會訪問涉及參照圈的物件。因此，可以有以下例子：一個整數對於一個引數是直接可達的，這個整數物件有可能出現或不出現在結果的 list 當中。

引發一個附帶引數 `objs` 的稽核事件 `gc.get_referents`。

`gc.is_tracked(obj)`

當物件正在被垃圾回收器追蹤時回傳 `True`，否則回傳 `False`。一般來講，原子型（atomic type）的實例不會被追蹤，而非原子型（如容器、使用者自己定義的物件）會被追蹤。然而，有一些特定型最佳化會被用來減少垃圾回收器在簡單實例（如只含有原子性的鍵和值的字典）上的足跡：

```
>>> gc.is_tracked(0)
False
>>> gc.is_tracked("a")
False
>>> gc.is_tracked([])
True
>>> gc.is_tracked({})
False
>>> gc.is_tracked({"a": 1})
False
>>> gc.is_tracked({"a": []})
True
```

在 3.1 版被加入。

`gc.is_finalized(obj)`

如果給定物件已被垃圾回收器終結則回傳 `True`，否則回傳 `False`。

```
>>> x = None
>>> class Lazarus:
...     def __del__(self):
...         global x
...         x = self
...
>>> lazarus = Lazarus()
>>> gc.is_finalized(lazarus)
False
>>> del lazarus
>>> gc.is_finalized(x)
True
```

在 3.9 版被加入。

`gc.freeze()`

凍結 (freeze) 垃圾回收器所追蹤的所有物件；將它們移至永久代忽略所有未來的收集動作。

如果一個行程將在有 `exec()` 的情況下進行 `fork()`，避免子行程中不必要的寫入時將最大化記憶體共享減少整體記憶體使用。這需要避免在父行程的記憶體頁面中建立已釋放的「漏洞」，確保子行程中的 GC 收集不會觸及源自父行程的長壽命物件的 `gc_refs` 計數器。要實現這兩個目標，請在父行程的早期呼叫 `gc.disable()`，在 `fork()` 之前呼叫 `gc.freeze()`，在子行程中呼叫 `gc.enable()`。

在 3.7 版被加入。

`gc.unfreeze()`

解凍 (unfreeze) 永久代中的物件，將它們放回到最年老代中。

在 3.7 版被加入。

`gc.get_freeze_count()`

回傳永久代中的物件數量。

在 3.7 版被加入。

以下變數僅供唯讀存取（你可以修改其值但不應該重新綁結 (rebind) 它們）：

`gc.garbage`

一個回收器發現不可達而又無法被釋放的物件（不可回收物件）list。從 Python 3.4 開始，該 list 在大多數時候都應該是空的，除非使用了有非 `NULL tp_del` 槽位的 C 擴充套件型別的實例。

如果設定了 `DEBUG_SAVEALL`，則所有不可達物件將被加進該 list 而不會被釋放。

在 3.2 版的變更：當 *interpreter shutdown* 即直譯器關閉時，若此 list 非空，會產生 `ResourceWarning`，在預設情況下此警告不會被提醒。如果設定了 `DEBUG_UNCOLLECTABLE`，所有無法被回收的物件會被印出。

在 3.4 版的變更：根據 [PEP 442](#)，帶有 `__del__()` method 的物件最終不會在 `gc.garbage` 。

`gc.callbacks`

會被垃圾回收器在回收開始前和完成後呼叫的一系列回呼函式 (callback)。這些回呼函式在被呼叫時附帶兩個引數：*phase* 和 *info*。

phase 可以下兩者之一：

”start”：垃圾回收即將開始。

”stop”：垃圾回收已結束。

info 是一個字典，提供回呼函式更多資訊。已有定義的鍵有：

”generation”（代）：正在被回收的最年老的一代。

”collected”（已回收的）：當 *phase* 為 ”stop” 時，被成功回收的物件的數目。

”uncollectable”（不可回收的）：當 *phase* 為 ”stop” 時，不能被回收被放入 *garbage* 的物件的數目。

應用程式可以把他們自己的回呼函式加入此 list。主要的使用場景有：

收集垃圾回收的統計資料，如：不同代的回收頻率、回收任務所花費的時間。

讓應用程式可以識別和清理他們自己在 *garbage* 中的不可回收型別物件。

在 3.3 版被加入。

以下常數是和 `set_debug()` 一起使用所提供：

`gc.DEBUG_STATS`

在回收完成後印出統計資訊。當調校回收頻率設定時，這些資訊會很有用。

`gc.DEBUG_COLLECTABLE`

當發現可回收物件時印出資訊。

`gc.DEBUG_UNCOLLECTABLE`

印出找到的不可回收物件的資訊（指不能被回收器回收的不可達物件）。這些物件會被新增到 *garbage* list 中。

在 3.2 版的變更：當 *interpreter shutdown*（直譯器關閉）時，若 *garbage* list 不是空的，那這些內容也會被印出。

`gc.DEBUG_SAVEALL`

設定後，所有回收器找到的不可達物件會被加進 *garbage* 而不是直接被釋放。這在一個記憶體流失的程式除錯時會很有用。

`gc.DEBUG_LEAK`

要印出記憶體流失程式之相關資訊時，回收器所需的除錯旗標。（等同於 `DEBUG_COLLECTABLE | DEBUG_UNCOLLECTABLE | DEBUG_SAVEALL`）。

29.14 inspect --- 檢視活動物件

原始碼: [Lib/inspect.py](#)

The *inspect* module provides several useful functions to help get information about live objects such as modules, classes, methods, functions, tracebacks, frame objects, and code objects. For example, it can help you examine the contents of a class, retrieve the source code of a method, extract and format the argument list for a function, or get all the information you need to display a detailed traceback.

There are four main kinds of services provided by this module: type checking, getting source code, inspecting classes and functions, and examining the interpreter stack.

29.14.1 Types and members

The *getmembers()* function retrieves the members of an object such as a class or module. The functions whose names begin with "is" are mainly provided as convenient choices for the second argument to *getmembers()*. They also help you determine when you can expect to find the following special attributes (see *import-mod-attrs* for module attributes):

Type	屬性	描述
class	<code>__doc__</code>	documentation string
	<code>__name__</code>	name with which this class was defined
	<code>__qualname__</code>	qualified name
	<code>__module__</code>	name of module in which this class was defined
method	<code>__type_params__</code>	A tuple containing the type parameters of a generic class
	<code>__doc__</code>	documentation string
	<code>__name__</code>	name with which this method was defined
	<code>__qualname__</code>	qualified name
函式	<code>__func__</code>	function object containing implementation of method
	<code>__self__</code>	instance to which this method is bound, or <code>None</code>
	<code>__module__</code>	name of module in which this method was defined
	<code>__doc__</code>	documentation string
	<code>__name__</code>	name with which this function was defined
	<code>__qualname__</code>	qualified name
	<code>__code__</code>	code object containing compiled function <i>bytecode</i>
	<code>__defaults__</code>	tuple of any default values for positional or keyword parameters
	<code>__kwdefaults__</code>	mapping of any default values for keyword-only parameters
	<code>__globals__</code>	global namespace in which this function was defined
traceback	<code>__builtins__</code>	builtins namespace
	<code>__annotations__</code>	mapping of parameters names to annotations; "return" key is reserved for return annotation
	<code>__type_params__</code>	A tuple containing the type parameters of a generic function
	<code>__module__</code>	name of module in which this function was defined
	<code>tb_frame</code>	frame object at this level
frame	<code>tb_lasti</code>	index of last attempted instruction in bytecode
	<code>tb_lineno</code>	current line number in Python source code
	<code>tb_next</code>	next inner traceback object (called by this level)
	<code>f_back</code>	next outer frame object (this frame's caller)
	<code>f_builtins</code>	builtins namespace seen by this frame
	<code>f_code</code>	code object being executed in this frame
	<code>f_globals</code>	global namespace seen by this frame
	<code>f_lasti</code>	index of last attempted instruction in bytecode
	<code>f_lineno</code>	current line number in Python source code
	<code>f_locals</code>	local namespace seen by this frame
	<code>f_trace</code>	tracing function for this frame, or <code>None</code>

表格 2 – 繼續上一頁

Type	屬性	描述
code (程式碼)	co_argcount	number of arguments (not including keyword only arguments, * or ** args)
	co_code	string of raw compiled bytecode
	co_cellvars	tuple of names of cell variables (referenced by containing scopes)
	co_consts	tuple of constants used in the bytecode
	co_filename	name of file in which this code object was created
	co_firstlineno	number of first line in Python source code
	co_flags	bitmap of CO_* flags, read more here
	co_lnotab	encoded mapping of line numbers to bytecode indices
	co_freevars	tuple of names of free variables (referenced via a function's closure)
	co_posonlyargcount	number of positional only arguments
	co_kwonlyargcount	number of keyword only arguments (not including ** arg)
	co_name	name with which this code object was defined
	co_qualname	fully qualified name with which this code object was defined
	co_names	tuple of names other than arguments and function locals
	co_nlocals	number of local variables
	co_stacksize	virtual machine stack space required
	co_varnames	tuple of names of arguments and local variables
generator	__name__	name
	__qualname__	qualified name
	gi_frame	frame
	gi_running	is the generator running?
	gi_code	code (程式碼)
async generator	gi_yieldfrom	object being iterated by <code>yield from</code> , or <code>None</code>
	__name__	name
	__qualname__	qualified name
	ag_await	object being awaited on, or <code>None</code>
	ag_frame	frame
coroutine	ag_running	is the generator running?
	ag_code	code (程式碼)
	__name__	name
	__qualname__	qualified name
	cr_await	object being awaited on, or <code>None</code>
builtin	cr_frame	frame
	cr_running	is the coroutine running?
	cr_code	code (程式碼)
	cr_origin	where coroutine was created, or <code>None</code> . See <code>sys.set_coroutine_origin_tracking</code>
	__doc__	documentation string
	__name__	original name of this function or method
	__qualname__	qualified name
	__self__	instance to which a method is bound, or <code>None</code>

在 3.5 版的變更: 將 `__qualname__` 和 `gi_yieldfrom` 屬性加到生成器。

The `__name__` attribute of generators is now set from the function name, instead of the code name, and it can now be modified.

在 3.7 版的變更: 新增協程的 `cr_origin` 屬性。

在 3.10 版的變更: 新增函式的 `__builtins__` 屬性。

`inspect.getmembers(object[, predicate])`

Return all the members of an object in a list of (name, value) pairs sorted by name. If the optional *predicate* argument—which will be called with the value object of each member—is supplied, only members for which the predicate returns a true value are included.

備

`getmembers()` will only return class attributes defined in the metaclass when the argument is a class and those attributes have been listed in the metaclass' custom `__dir__()`.

`inspect.getmembers_static(object[, predicate])`

Return all the members of an object in a list of (name, value) pairs sorted by name without triggering dynamic lookup via the descriptor protocol, `__getattr__` or `__getattribute__`. Optionally, only return members that satisfy a given predicate.

備

`getmembers_static()` may not be able to retrieve all members that `getmembers` can fetch (like dynamically created attributes) and may find members that `getmembers` can't (like descriptors that raise `AttributeError`). It can also return descriptor objects instead of instance members in some cases.

在 3.11 版被加入。

`inspect.getmodulename(path)`

Return the name of the module named by the file *path*, without including the names of enclosing packages. The file extension is checked against all of the entries in `importlib.machinery.all_suffixes()`. If it matches, the final path component is returned with the extension removed. Otherwise, `None` is returned.

Note that this function *only* returns a meaningful name for actual Python modules - paths that potentially refer to Python packages will still return `None`.

在 3.3 版的變更: 此函式直接基於 `importlib`。

`inspect.ismodule(object)`

如果物件是模組，則回傳 `True`。

`inspect.isclass(object)`

Return `True` if the object is a class, whether built-in or created in Python code.

`inspect.ismethod(object)`

Return `True` if the object is a bound method written in Python.

`inspect.isfunction(object)`

Return `True` if the object is a Python function, which includes functions created by a *lambda* expression.

`inspect.isgeneratorfunction(object)`

如果物件是 Python 生成器函式，則回傳 `True`。

在 3.8 版的變更: Functions wrapped in `functools.partial()` now return `True` if the wrapped function is a Python generator function.

在 3.13 版的變更: Functions wrapped in `functools.partialmethod()` now return `True` if the wrapped function is a Python generator function.

`inspect.isgenerator(object)`

如果物件是生成器，則回傳 `True`。

`inspect.iscoroutinefunction(object)`

Return `True` if the object is a *coroutine function* (a function defined with an `async def` syntax), a `functools.partial()` wrapping a *coroutine function*, or a sync function marked with `markcoroutinefunction()`.

在 3.5 版被加入。

在 3.8 版的變更: Functions wrapped in `functools.partial()` now return `True` if the wrapped function is a *coroutine function*.

在 3.12 版的變更: Sync functions marked with `markcoroutinefunction()` now return True.

在 3.13 版的變更: Functions wrapped in `functools.partialmethod()` now return True if the wrapped function is a *coroutine function*.

`inspect.markcoroutinefunction(func)`

Decorator to mark a callable as a *coroutine function* if it would not otherwise be detected by `iscoroutinefunction()`.

This may be of use for sync functions that return a *coroutine*, if the function is passed to an API that requires `iscoroutinefunction()`.

When possible, using an `async def` function is preferred. Also acceptable is calling the function and testing the return with `iscoroutine()`.

在 3.12 版被加入.

`inspect.iscoroutine(object)`

Return True if the object is a *coroutine* created by an `async def` function.

在 3.5 版被加入.

`inspect.isawaitable(object)`

Return True if the object can be used in `await` expression.

Can also be used to distinguish generator-based coroutines from regular generators:

```
import types

def gen():
    yield
@types.coroutine
def gen_coro():
    yield

assert not isawaitable(gen())
assert isawaitable(gen_coro())
```

在 3.5 版被加入.

`inspect.isasyncgenfunction(object)`

Return True if the object is an *asynchronous generator* function, for example:

```
>>> async def agen():
...     yield 1
...
>>> inspect.isasyncgenfunction(agen)
True
```

在 3.6 版被加入.

在 3.8 版的變更: Functions wrapped in `functools.partial()` now return True if the wrapped function is an *asynchronous generator* function.

在 3.13 版的變更: Functions wrapped in `functools.partialmethod()` now return True if the wrapped function is a *coroutine function*.

`inspect.isasyncgen(object)`

Return True if the object is an *asynchronous generator iterator* created by an *asynchronous generator* function.

在 3.6 版被加入.

`inspect.istraceback(object)`

Return True if the object is a *traceback*.

`inspect.isframe(object)`

Return True if the object is a frame.

`inspect.iscode(object)`

如果物件是程式碼，則回傳 True。

`inspect.isbuiltin(object)`

Return True if the object is a built-in function or a bound built-in method.

`inspect.ismethodwrapper(object)`

Return True if the type of object is a `MethodWrapperType`.

These are instances of `MethodWrapperType`, such as `__str__()`, `__eq__()` and `__repr__()`.

在 3.11 版被加入。

`inspect.isroutine(object)`

如果物件是使用者定義或建立的函式或方法，則回傳 True。

`inspect.isabstract(object)`

如果物件是抽象基底類，則回傳 True。

`inspect.ismethoddescriptor(object)`

Return True if the object is a method descriptor, but not if `ismethod()`, `isclass()`, `isfunction()` or `isbuiltin()` are true.

This, for example, is true of `int.__add__`. An object passing this test has a `__get__()` method, but not a `__set__()` method or a `__delete__()` method. Beyond that, the set of attributes varies. A `__name__` attribute is usually sensible, and `__doc__` often is.

Methods implemented via descriptors that also pass one of the other tests return False from the `ismethoddescriptor()` test, simply because the other tests promise more -- you can, e.g., count on having the `__func__` attribute (etc) when an object passes `ismethod()`.

在 3.13 版的變更: This function no longer incorrectly reports objects with `__get__()` and `__delete__()`, but not `__set__()`, as being method descriptors (such objects are data descriptors, not method descriptors).

`inspect.isdatadescriptor(object)`

如果物件是資料描述器，則回傳 True。

Data descriptors have a `__set__` or a `__delete__` method. Examples are properties (defined in Python), getsets, and members. The latter two are defined in C and there are more specific tests available for those types, which is robust across Python implementations. Typically, data descriptors will also have `__name__` and `__doc__` attributes (properties, getsets, and members have both of these attributes), but this is not guaranteed.

`inspect.isgetsetdescriptor(object)`

Return True if the object is a getset descriptor.

CPython 實作細節: getsets are attributes defined in extension modules via `PyGetSetDef` structures. For Python implementations without such types, this method will always return False.

`inspect.ismemberdescriptor(object)`

如果物件是成員描述器，則回傳 True。

CPython 實作細節: Member descriptors are attributes defined in extension modules via `PyMemberDef` structures. For Python implementations without such types, this method will always return False.

29.14.2 取得原始碼

`inspect.getdoc(object)`

Get the documentation string for an object, cleaned up with `cleandoc()`. If the documentation string for an object is not provided and the object is a class, a method, a property or a descriptor, retrieve the documentation string from the inheritance hierarchy. Return `None` if the documentation string is invalid or missing.

在 3.5 版的變更: Documentation strings are now inherited if not overridden.

`inspect.getcomments(object)`

Return in a single string any lines of comments immediately preceding the object's source code (for a class, function, or method), or at the top of the Python source file (if the object is a module). If the object's source code is unavailable, return `None`. This could happen if the object has been defined in C or the interactive shell.

`inspect.getfile(object)`

Return the name of the (text or binary) file in which an object was defined. This will fail with a `TypeError` if the object is a built-in module, class, or function.

`inspect.getmodule(object)`

Try to guess which module an object was defined in. Return `None` if the module cannot be determined.

`inspect.getsourcefile(object)`

Return the name of the Python source file in which an object was defined or `None` if no way can be identified to get the source. This will fail with a `TypeError` if the object is a built-in module, class, or function.

`inspect.getsourcelines(object)`

Return a list of source lines and starting line number for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a list of the lines corresponding to the object and the line number indicates where in the original source file the first line of code was found. An `OSError` is raised if the source code cannot be retrieved. A `TypeError` is raised if the object is a built-in module, class, or function.

在 3.3 版的變更: `OSError` is raised instead of `IOError`, now an alias of the former.

`inspect.getsource(object)`

Return the text of the source code for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a single string. An `OSError` is raised if the source code cannot be retrieved. A `TypeError` is raised if the object is a built-in module, class, or function.

在 3.3 版的變更: `OSError` is raised instead of `IOError`, now an alias of the former.

`inspect.cleandoc(doc)`

Clean up indentation from docstrings that are indented to line up with blocks of code.

All leading whitespace is removed from the first line. Any leading whitespace that can be uniformly removed from the second line onwards is removed. Empty lines at the beginning and end are subsequently removed. Also, all tabs are expanded to spaces.

29.14.3 Introspecting callables with the Signature object

在 3.3 版被加入.

The `Signature` object represents the call signature of a callable object and its return annotation. To retrieve a `Signature` object, use the `signature()` function.

`inspect.signature(callable, *, follow_wrapped=True, globals=None, locals=None, eval_str=False)`

Return a `Signature` object for the given `callable`:

```
>>> from inspect import signature
>>> def foo(a, *, b:int, **kwargs):
...     pass
```

(繼續下一頁)

(繼續上一頁)

```

>>> sig = signature(foo)

>>> str(sig)
'(a, *, b: int, **kwargs)'

>>> str(sig.parameters['b'])
'b: int'

>>> sig.parameters['b'].annotation
<class 'int'>

```

Accepts a wide range of Python callables, from plain functions and classes to `functools.partial()` objects.

For objects defined in modules using stringized annotations (from `__future__` import annotations), `signature()` will attempt to automatically un-stringize the annotations using `get_annotations()`. The `globals`, `locals`, and `eval_str` parameters are passed into `get_annotations()` when resolving the annotations; see the documentation for `get_annotations()` for instructions on how to use these parameters.

Raises `ValueError` if no signature can be provided, and `TypeError` if that type of object is not supported. Also, if the annotations are stringized, and `eval_str` is not false, the `eval()` call(s) to un-stringize the annotations in `get_annotations()` could potentially raise any kind of exception.

A slash(/) in the signature of a function denotes that the parameters prior to it are positional-only. For more info, see the FAQ entry on positional-only parameters.

在 3.5 版的變更: The `follow_wrapped` parameter was added. Pass `False` to get a signature of `callable` specifically (`callable.__wrapped__` will not be used to unwrap decorated callables.)

在 3.10 版的變更: The `globals`, `locals`, and `eval_str` parameters were added.

備註

Some callables may not be introspectable in certain implementations of Python. For example, in CPython, some built-in functions defined in C provide no metadata about their arguments.

CPython 實作細節: If the passed object has a `__signature__` attribute, we may use it to create the signature. The exact semantics are an implementation detail and are subject to unannounced changes. Consult the source code for current semantics.

class `inspect.Signature` (`parameters=None`, `*`, `return_annotation=Signature.empty`)

A `Signature` object represents the call signature of a function and its return annotation. For each parameter accepted by the function it stores a `Parameter` object in its `parameters` collection.

The optional `parameters` argument is a sequence of `Parameter` objects, which is validated to check that there are no parameters with duplicate names, and that the parameters are in the right order, i.e. positional-only first, then positional-or-keyword, and that parameters with defaults follow parameters without defaults.

The optional `return_annotation` argument can be an arbitrary Python object. It represents the "return" annotation of the callable.

`Signature` objects are *immutable*. Use `Signature.replace()` or `copy.replace()` to make a modified copy.

在 3.5 版的變更: `Signature` objects are now picklable and *hashable*.

`empty`

A special class-level marker to specify absence of a return annotation.

parameters

An ordered mapping of parameters' names to the corresponding *Parameter* objects. Parameters appear in strict definition order, including keyword-only parameters.

在 3.7 版的變更: Python only explicitly guaranteed that it preserved the declaration order of keyword-only parameters as of version 3.7, although in practice this order had always been preserved in Python 3.

return_annotation

The "return" annotation for the callable. If the callable has no "return" annotation, this attribute is set to *Signature.empty*.

bind(*args, **kwargs)

Create a mapping from positional and keyword arguments to parameters. Returns *BoundArguments* if **args* and ***kwargs* match the signature, or raises a *TypeError*.

bind_partial(*args, **kwargs)

Works the same way as *Signature.bind()*, but allows the omission of some required arguments (mimics *functools.partial()* behavior.) Returns *BoundArguments*, or raises a *TypeError* if the passed arguments do not match the signature.

replace(*[, parameters][, return_annotation])

Create a new *Signature* instance based on the instance *replace()* was invoked on. It is possible to pass different *parameters* and/or *return_annotation* to override the corresponding properties of the base signature. To remove *return_annotation* from the copied *Signature*, pass in *Signature.empty*.

```
>>> def test(a, b):
...     pass
...
>>> sig = signature(test)
>>> new_sig = sig.replace(return_annotation="new return anno")
>>> str(new_sig)
"(a, b) -> 'new return anno'"
```

Signature objects are also supported by the generic function *copy.replace()*.

format(*, max_width=None)

Create a string representation of the *Signature* object.

If *max_width* is passed, the method will attempt to fit the signature into lines of at most *max_width* characters. If the signature is longer than *max_width*, all parameters will be on separate lines.

在 3.13 版被加入。

classmethod from_callable(obj, *, follow_wrapped=True, globals=None, locals=None, eval_str=False)

Return a *Signature* (or its subclass) object for a given callable *obj*.

This method simplifies subclassing of *Signature*:

```
class MySignature(Signature):
    pass
sig = MySignature.from_callable(sum)
assert isinstance(sig, MySignature)
```

Its behavior is otherwise identical to that of *signature()*.

在 3.5 版被加入。

在 3.10 版的變更: The *globals*, *locals*, and *eval_str* parameters were added.

class `inspect.Parameter` (*name, kind, *, default=Parameter.empty, annotation=Parameter.empty*)

Parameter objects are *immutable*. Instead of modifying a `Parameter` object, you can use `Parameter.replace()` or `copy.replace()` to create a modified copy.

在 3.5 版的變更: Parameter objects are now picklable and *hashable*.

empty

A special class-level marker to specify absence of default values and annotations.

name

The name of the parameter as a string. The name must be a valid Python identifier.

CPython 實作細節: CPython generates implicit parameter names of the form `.0` on the code objects used to implement comprehensions and generator expressions.

在 3.6 版的變更: These parameter names are now exposed by this module as names like `implicit0`.

default

The default value for the parameter. If the parameter has no default value, this attribute is set to `Parameter.empty`.

annotation

The annotation for the parameter. If the parameter has no annotation, this attribute is set to `Parameter.empty`.

kind

Describes how argument values are bound to the parameter. The possible values are accessible via `Parameter` (like `Parameter.KEYWORD_ONLY`), and support comparison and ordering, in the following order:

名徵	意義
<code>POSITIONAL_ONLY</code>	Value must be supplied as a positional argument. Positional only parameters are those which appear before a <code>/</code> entry (if present) in a Python function definition.
<code>POSITIONAL_OR_KEYWORD</code>	Value may be supplied as either a keyword or positional argument (this is the standard binding behaviour for functions implemented in Python.)
<code>VAR_POSITIONAL</code>	A tuple of positional arguments that aren't bound to any other parameter. This corresponds to a <code>*args</code> parameter in a Python function definition.
<code>KEYWORD_ONLY</code>	Value must be supplied as a keyword argument. Keyword only parameters are those which appear after a <code>*</code> or <code>*args</code> entry in a Python function definition.
<code>VAR_KEYWORD</code>	A dict of keyword arguments that aren't bound to any other parameter. This corresponds to a <code>**kwargs</code> parameter in a Python function definition.

Example: print all keyword-only arguments without default values:

```
>>> def foo(a, b, *, c, d=10):
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     if (param.kind == param.KEYWORD_ONLY and
...         param.default is param.empty):
...         print('Parameter:', param)
Parameter: c
```

kind.description

Describes an enum value of `Parameter.kind`.

在 3.8 版被加入。

範例：列印所有引數的描述：

```
>>> def foo(a, b, *, c, d=10):
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     print(param.kind.description)
positional or keyword
positional or keyword
keyword-only
keyword-only
```

replace(*[, name][, kind][, default][, annotation])

Create a new `Parameter` instance based on the instance replaced was invoked on. To override a `Parameter` attribute, pass the corresponding argument. To remove a default value or/and an annotation from a `Parameter`, pass `Parameter.empty`.

```
>>> from inspect import Parameter
>>> param = Parameter('foo', Parameter.KEYWORD_ONLY, default=42)
>>> str(param)
'foo=42'

>>> str(param.replace()) # Will create a shallow copy of 'param'
'foo=42'

>>> str(param.replace(default=Parameter.empty, annotation='spam'))
'foo: 'spam''
```

`Parameter` objects are also supported by the generic function `copy.replace()`.

在 3.4 版的變更：In Python 3.3 `Parameter` objects were allowed to have name set to `None` if their kind was set to `POSITIONAL_ONLY`. This is no longer permitted.

class inspect.BoundsArguments

Result of a `Signature.bind()` or `Signature.bind_partial()` call. Holds the mapping of arguments to the function's parameters.

arguments

A mutable mapping of parameters' names to arguments' values. Contains only explicitly bound arguments. Changes in `arguments` will reflect in `args` and `kwargs`.

Should be used in conjunction with `Signature.parameters` for any argument processing purposes.

備 F

Arguments for which `Signature.bind()` or `Signature.bind_partial()` relied on a default value are skipped. However, if needed, use `BoundsArguments.apply_defaults()` to add them.

在 3.9 版的變更： `arguments` is now of type `dict`. Formerly, it was of type `collections.OrderedDict`.

args

A tuple of positional arguments values. Dynamically computed from the `arguments` attribute.

kwargs

A dict of keyword arguments values. Dynamically computed from the *arguments* attribute.

signature

A reference to the parent *Signature* object.

apply_defaults()

遺漏的引數設定預設值。

For variable-positional arguments (*args) the default is an empty tuple.

For variable-keyword arguments (**kwargs) the default is an empty dict.

```
>>> def foo(a, b='ham', *args): pass
>>> ba = inspect.signature(foo).bind('spam')
>>> ba.apply_defaults()
>>> ba.arguments
{'a': 'spam', 'b': 'ham', 'args': ()}
```

在 3.5 版被加入。

The *args* and *kwargs* properties can be used to invoke functions:

```
def test(a, *, b):
    ...

sig = signature(test)
ba = sig.bind(10, b=20)
test(*ba.args, **ba.kwargs)
```

也參考**PEP 362 - Function Signature Object.**

The detailed specification, implementation details and examples.

29.14.4 類與函式

`inspect.getclasstree(classes, unique=False)`

Arrange the given list of classes into a hierarchy of nested lists. Where a nested list appears, it contains classes derived from the class whose entry immediately precedes the list. Each entry is a 2-tuple containing a class and a tuple of its base classes. If the *unique* argument is true, exactly one entry appears in the returned structure for each class in the given list. Otherwise, classes using multiple inheritance and their descendants will appear multiple times.

`inspect.getfullargspec(func)`

Get the names and default values of a Python function's parameters. A *named tuple* is returned:

```
FullArgSpec(args, varargs, varkw, defaults, kwonlyargs, kwonlydefaults,
             annotations)
```

args is a list of the positional parameter names. *varargs* is the name of the * parameter or None if arbitrary positional arguments are not accepted. *varkw* is the name of the ** parameter or None if arbitrary keyword arguments are not accepted. *defaults* is an *n*-tuple of default argument values corresponding to the last *n* positional parameters, or None if there are no such defaults defined. *kwonlyargs* is a list of keyword-only parameter names in declaration order. *kwonlydefaults* is a dictionary mapping parameter names from *kwonlyargs* to the default values used if no argument is supplied. *annotations* is a dictionary mapping parameter names to annotations. The special key "return" is used to report the function return value annotation (if any).

Note that `signature()` and `Signature Object` provide the recommended API for callable introspection, and support additional behaviours (like positional-only arguments) that are sometimes encountered in extension module APIs. This function is retained primarily for use in code that needs to maintain compatibility with the Python 2 `inspect` module API.

在 3.4 版的變更: This function is now based on `signature()`, but still ignores `__wrapped__` attributes and includes the already bound first parameter in the signature output for bound methods.

在 3.6 版的變更: This method was previously documented as deprecated in favour of `signature()` in Python 3.5, but that decision has been reversed in order to restore a clearly supported standard interface for single-source Python 2/3 code migrating away from the legacy `getargspec()` API.

在 3.7 版的變更: Python only explicitly guaranteed that it preserved the declaration order of keyword-only parameters as of version 3.7, although in practice this order had always been preserved in Python 3.

`inspect.getargvalues(frame)`

Get information about arguments passed into a particular frame. A `named tuple` `ArgInfo(args, varargs, keywords, locals)` is returned. `args` is a list of the argument names. `varargs` and `keywords` are the names of the `*` and `**` arguments or `None`. `locals` is the locals dictionary of the given frame.

備

This function was inadvertently marked as deprecated in Python 3.5.

`inspect.formatargvalues(args[, varargs, varkw, locals, formatarg, formatvarargs, formatvarkw, formatvalue])`

Format a pretty argument spec from the four values returned by `getargvalues()`. The `format*` arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

備

This function was inadvertently marked as deprecated in Python 3.5.

`inspect.getmro(cls)`

Return a tuple of class `cls`'s base classes, including `cls`, in method resolution order. No class appears more than once in this tuple. Note that the method resolution order depends on `cls`'s type. Unless a very peculiar user-defined metatype is in use, `cls` will be the first element of the tuple.

`inspect.getcallargs(func, /, *args, **kwargs)`

Bind the `args` and `kwargs` to the argument names of the Python function or method `func`, as if it was called with them. For bound methods, bind also the first argument (typically named `self`) to the associated instance. A dict is returned, mapping the argument names (including the names of the `*` and `**` arguments, if any) to their values from `args` and `kwargs`. In case of invoking `func` incorrectly, i.e. whenever `func(*args, **kwargs)` would raise an exception because of incompatible signature, an exception of the same type and the same or similar message is raised. For example:

```
>>> from inspect import getcallargs
>>> def f(a, b=1, *pos, **named):
...     pass
...
>>> getcallargs(f, 1, 2, 3) == {'a': 1, 'named': {}, 'b': 2, 'pos': (3,)}
True
>>> getcallargs(f, a=2, x=4) == {'a': 2, 'named': {'x': 4}, 'b': 1, 'pos': ()}
True
>>> getcallargs(f)
Traceback (most recent call last):
...
TypeError: f() missing 1 required positional argument: 'a'
```

在 3.2 版被加入。

在 3.5 版之後被採用: 請改用 `Signature.bind()` 與 `Signature.bind_partial()`。

`inspect.getclosurevars(func)`

Get the mapping of external name references in a Python function or method *func* to their current values. A *named tuple* `ClosureVars(nonlocals, globals, builtins, unbound)` is returned. *nonlocals* maps referenced names to lexical closure variables, *globals* to the function's module globals and *builtins* to the builtins visible from the function body. *unbound* is the set of names referenced in the function that could not be resolved at all given the current module globals and builtins.

如果 *func* 不是 Python 函式或方法, 則引發 `TypeError`。

在 3.3 版被加入。

`inspect.unwrap(func, *, stop=None)`

Get the object wrapped by *func*. It follows the chain of `__wrapped__` attributes returning the last object in the chain.

stop is an optional callback accepting an object in the wrapper chain as its sole argument that allows the unwrapping to be terminated early if the callback returns a true value. If the callback never returns a true value, the last object in the chain is returned as usual. For example, `signature()` uses this to stop unwrapping if any object in the chain has a `__signature__` attribute defined.

如果遇到循環, 則引發 `ValueError`。

在 3.4 版被加入。

`inspect.get_annotations(obj, *, globals=None, locals=None, eval_str=False)`

Compute the annotations dict for an object.

obj may be a callable, class, or module. Passing in an object of any other type raises `TypeError`.

Returns a dict. `get_annotations()` returns a new dict every time it's called; calling it twice on the same object will return two different but equivalent dicts.

This function handles several details for you:

- If *eval_str* is true, values of type *str* will be un-stringized using `eval()`. This is intended for use with stringized annotations (from `__future__` import `annotations`).
- If *obj* doesn't have an annotations dict, returns an empty dict. (Functions and methods always have an annotations dict; classes, modules, and other types of callables may not.)
- Ignores inherited annotations on classes. If a class doesn't have its own annotations dict, returns an empty dict.
- All accesses to object members and dict values are done using `getattr()` and `dict.get()` for safety.
- Always, always, always returns a freshly created dict.

eval_str controls whether or not values of type *str* are replaced with the result of calling `eval()` on those values:

- If *eval_str* is true, `eval()` is called on values of type *str*. (Note that `get_annotations` doesn't catch exceptions; if `eval()` raises an exception, it will unwind the stack past the `get_annotations` call.)
- If *eval_str* is false (the default), values of type *str* are unchanged.

globals and *locals* are passed in to `eval()`; see the documentation for `eval()` for more information. If *globals* or *locals* is *None*, this function may replace that value with a context-specific default, contingent on type(*obj*):

- If *obj* is a module, *globals* defaults to `obj.__dict__`.
- If *obj* is a class, *globals* defaults to `sys.modules[obj.__module__].__dict__` and *locals* defaults to the *obj* class namespace.

- If `obj` is a callable, `globals` defaults to `obj.__globals__`, although if `obj` is a wrapped function (using `functools.update_wrapper()`) it is first unwrapped.

Calling `get_annotations` is best practice for accessing the annotations dict of any object. See [annotations-howto](#) for more information on annotations best practices.

在 3.10 版被加入.

29.14.5 直譯器堆 F

Some of the following functions return `FrameInfo` objects. For backwards compatibility these objects allow tuple-like operations on all attributes except `positions`. This behavior is considered deprecated and may be removed in the future.

class `inspect.FrameInfo`

frame

The frame object that the record corresponds to.

filename

The file name associated with the code being executed by the frame this record corresponds to.

lineno

The line number of the current line associated with the code being executed by the frame this record corresponds to.

function

The function name that is being executed by the frame this record corresponds to.

code_context

A list of lines of context from the source code that's being executed by the frame this record corresponds to.

index

The index of the current line being executed in the `code_context` list.

positions

A `dis.Positions` object containing the start line number, end line number, start column offset, and end column offset associated with the instruction being executed by the frame this record corresponds to.

在 3.5 版的變更: Return a *named tuple* instead of a *tuple*.

在 3.11 版的變更: `FrameInfo` is now a class instance (that is backwards compatible with the previous *named tuple*).

class `inspect.Traceback`

filename

The file name associated with the code being executed by the frame this traceback corresponds to.

lineno

The line number of the current line associated with the code being executed by the frame this traceback corresponds to.

function

The function name that is being executed by the frame this traceback corresponds to.

code_context

A list of lines of context from the source code that's being executed by the frame this traceback corresponds to.

index

The index of the current line being executed in the `code_context` list.

positions

A `dis.Positions` object containing the start line number, end line number, start column offset, and end column offset associated with the instruction being executed by the frame this traceback corresponds to.

在 3.11 版的變更: `Traceback` is now a class instance (that is backwards compatible with the previous *named tuple*).

備 註

Keeping references to frame objects, as found in the first element of the frame records these functions return, can cause your program to create reference cycles. Once a reference cycle has been created, the lifespan of all objects which can be accessed from the objects which form the cycle can become much longer even if Python's optional cycle detector is enabled. If such cycles must be created, it is important to ensure they are explicitly broken to avoid the delayed destruction of objects and increased memory consumption which occurs.

Though the cycle detector will catch these, destruction of the frames (and local variables) can be made deterministic by removing the cycle in a `finally` clause. This is also important if the cycle detector was disabled when Python was compiled or using `gc.disable()`. For example:

```
def handle_stackframe_without_leak():
    frame = inspect.currentframe()
    try:
        # do something with the frame
    finally:
        del frame
```

If you want to keep the frame around (for example to print a traceback later), you can also break reference cycles by using the `frame.clear()` method.

The optional `context` argument supported by most of these functions specifies the number of lines of context to return, which are centered around the current line.

`inspect.getframeinfo(frame, context=1)`

Get information about a frame or traceback object. A `Traceback` object is returned.

在 3.11 版的變更: A `Traceback` object is returned instead of a named tuple.

`inspect.getouterframes(frame, context=1)`

Get a list of `FrameInfo` objects for a frame and all outer frames. These frames represent the calls that lead to the creation of `frame`. The first entry in the returned list represents `frame`; the last entry represents the outermost call on `frame`'s stack.

在 3.5 版的變更: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

在 3.11 版的變更: 回傳一個 `FrameInfo` 物件串列。

`inspect.getinnerframes(traceback, context=1)`

Get a list of `FrameInfo` objects for a traceback's frame and all inner frames. These frames represent calls made as a consequence of `frame`. The first entry in the list represents `traceback`; the last entry represents where the exception was raised.

在 3.5 版的變更: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

在 3.11 版的變更: 回傳一個 `FrameInfo` 物件串列。

`inspect.currentframe()`

Return the frame object for the caller's stack frame.

CPython 實作細節： This function relies on Python stack frame support in the interpreter, which isn't guaranteed to exist in all implementations of Python. If running in an implementation without Python stack frame support this function returns `None`.

`inspect.stack(context=1)`

Return a list of `FrameInfo` objects for the caller's stack. The first entry in the returned list represents the caller; the last entry represents the outermost call on the stack.

在 3.5 版的變更: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

在 3.11 版的變更: 回傳一個 `FrameInfo` 物件串列。

`inspect.trace(context=1)`

Return a list of `FrameInfo` objects for the stack between the current frame and the frame in which an exception currently being handled was raised in. The first entry in the list represents the caller; the last entry represents where the exception was raised.

在 3.5 版的變更: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

在 3.11 版的變更: 回傳一個 `FrameInfo` 物件串列。

29.14.6 Fetching attributes statically

Both `getattr()` and `hasattr()` can trigger code execution when fetching or checking for the existence of attributes. Descriptors, like properties, will be invoked and `__getattr__()` and `__getattribute__()` may be called.

For cases where you want passive introspection, like documentation tools, this can be inconvenient. `getattr_static()` has the same signature as `getattr()` but avoids executing code when it fetches attributes.

`inspect.getattr_static(obj, attr, default=None)`

Retrieve attributes without triggering dynamic lookup via the descriptor protocol, `__getattr__()` or `__getattribute__()`.

Note: this function may not be able to retrieve all attributes that `getattr` can fetch (like dynamically created attributes) and may find attributes that `getattr` can't (like descriptors that raise `AttributeError`). It can also return descriptors objects instead of instance members.

If the instance `__dict__` is shadowed by another member (for example a property) then this function will be unable to find instance members.

在 3.2 版被加入。

`getattr_static()` does not resolve descriptors, for example slot descriptors or getset descriptors on objects implemented in C. The descriptor object is returned instead of the underlying attribute.

You can handle these with code like the following. Note that for arbitrary getset descriptors invoking these may trigger code execution:

```
# example code for resolving the builtin descriptor types
class _foo:
    __slots__ = ['foo']

slot_descriptor = type(_foo.foo)
getset_descriptor = type(type(open(__file__)).name)
wrapper_descriptor = type(str.__dict__['__add__'])
descriptor_types = (slot_descriptor, getset_descriptor, wrapper_descriptor)
```

(繼續下一頁)

(繼續上一頁)

```

result = getattr_static(some_object, 'foo')
if type(result) in descriptor_types:
    try:
        result = result.__get__()
    except AttributeError:
        # descriptors can raise AttributeError to
        # indicate there is no underlying value
        # in which case the descriptor itself will
        # have to do
    pass

```

29.14.7 Current State of Generators, Coroutines, and Asynchronous Generators

When implementing coroutine schedulers and for other advanced uses of generators, it is useful to determine whether a generator is currently executing, is waiting to start or resume or execution, or has already terminated. `getgeneratorstate()` allows the current state of a generator to be determined easily.

`inspect.getgeneratorstate(generator)`

Get current state of a generator-iterator.

Possible states are:

- `GEN_CREATED`: Waiting to start execution.
- `GEN_RUNNING`: Currently being executed by the interpreter.
- `GEN_SUSPENDED`: Currently suspended at a yield expression.
- `GEN_CLOSED`: Execution has completed.

在 3.2 版被加入。

`inspect.getcoroutinestate(coroutine)`

Get current state of a coroutine object. The function is intended to be used with coroutine objects created by `async def` functions, but will accept any coroutine-like object that has `cr_running` and `cr_frame` attributes.

Possible states are:

- `CORO_CREATED`: Waiting to start execution.
- `CORO_RUNNING`: Currently being executed by the interpreter.
- `CORO_SUSPENDED`: Currently suspended at an await expression.
- `CORO_CLOSED`: Execution has completed.

在 3.5 版被加入。

`inspect.getasyncgenstate(agen)`

Get current state of an asynchronous generator object. The function is intended to be used with asynchronous iterator objects created by `async def` functions which use the `yield` statement, but will accept any asynchronous generator-like object that has `ag_running` and `ag_frame` attributes.

Possible states are:

- `AGEN_CREATED`: 等待開始執行。
- `AGEN_RUNNING`: 目前正在被直譯器執行。
- `AGEN_SUSPENDED`: 目前於 `yield` 運算式暫停。
- `AGEN_CLOSED`: 執行已完成。

在 3.12 版被加入。

The current internal state of the generator can also be queried. This is mostly useful for testing purposes, to ensure that internal state is being updated as expected:

`inspect.getgeneratorlocals(generator)`

Get the mapping of live local variables in *generator* to their current values. A dictionary is returned that maps from variable names to values. This is the equivalent of calling `locals()` in the body of the generator, and all the same caveats apply.

If *generator* is a *generator* with no currently associated frame, then an empty dictionary is returned. *TypeError* is raised if *generator* is not a Python generator object.

CPython 實作細節： This function relies on the generator exposing a Python stack frame for introspection, which isn't guaranteed to be the case in all implementations of Python. In such cases, this function will always return an empty dictionary.

在 3.3 版被加入。

`inspect.getcoroutinelocals(coroutine)`

This function is analogous to `getgeneratorlocals()`, but works for coroutine objects created by `async def` functions.

在 3.5 版被加入。

`inspect.getasyncgenlocals(agen)`

This function is analogous to `getgeneratorlocals()`, but works for asynchronous generator objects created by `async def` functions which use the `yield` statement.

在 3.12 版被加入。

29.14.8 Code Objects Bit Flags

Python code objects have a `co_flags` attribute, which is a bitmap of the following flags:

`inspect.CO_OPTIMIZED`

The code object is optimized, using fast locals.

`inspect.CO_NEWLOCALS`

If set, a new dict will be created for the frame's `f_locals` when the code object is executed.

`inspect.CO_VARARGS`

The code object has a variable positional parameter (`*args`-like).

`inspect.CO_VARKEYWORDS`

The code object has a variable keyword parameter (`**kwargs`-like).

`inspect.CO_NESTED`

The flag is set when the code object is a nested function.

`inspect.CO_GENERATOR`

The flag is set when the code object is a generator function, i.e. a generator object is returned when the code object is executed.

`inspect.CO_COROUTINE`

The flag is set when the code object is a coroutine function. When the code object is executed it returns a coroutine object. See [PEP 492](#) for more details.

在 3.5 版被加入。

`inspect.CO_ITERABLE_COROUTINE`

The flag is used to transform generators into generator-based coroutines. Generator objects with this flag can be used in `await` expression, and can `yield` from coroutine objects. See [PEP 492](#) for more details.

在 3.5 版被加入。

`inspect.CO_ASYNC_GENERATOR`

The flag is set when the code object is an asynchronous generator function. When the code object is executed it returns an asynchronous generator object. See [PEP 525](#) for more details.

在 3.6 版被加入。

備 註

The flags are specific to CPython, and may not be defined in other Python implementations. Furthermore, the flags are an implementation detail, and can be removed or deprecated in future Python releases. It's recommended to use public APIs from the `inspect` module for any introspection needs.

29.14.9 Buffer flags

class `inspect.BufferFlags`

This is an *enum.IntFlag* that represents the flags that can be passed to the `__buffer__()` method of objects implementing the buffer protocol.

The meaning of the flags is explained at [buffer-request-types](#).

29.14.10 命令列介面

The *inspect* module also provides a basic introspection capability from the command line.

By default, accepts the name of a module and prints the source of that module. A class or function within the module can be printed instead by appended a colon and the qualified name of the target object.

--details

Print information about the specified object rather than the source code

29.15 site --- Site-specific configuration hook

原始碼: [Lib/site.py](#)

This module is automatically imported during initialization. The automatic import can be suppressed using the interpreter's `-S` option.

Importing this module normally appends site-specific paths to the module search path and adds *callable*s, including *help()* to the built-in namespace. However, Python startup option `-S` blocks this and this module can be safely imported with no automatic modifications to the module search path or additions to the builtins. To explicitly trigger the usual site-specific additions, call the *main()* function.

在 3.3 版的變更: Importing the module used to trigger paths manipulation even when using `-S`.

It starts by constructing up to four directories from a head and a tail part. For the head part, it uses `sys.prefix` and `sys.exec_prefix`; empty heads are skipped. For the tail part, it uses the empty string and then `lib/site-packages` (on Windows) or `lib/pythonX.Y[t]/site-packages` (on Unix and macOS). (The optional suffix `"t"` indicates the *free threading* build, and is appended if `"t"` is present in the `sys.abiflags` constant.) For each of the distinct head-tail combinations, it sees if it refers to an existing directory, and if so, adds it to `sys.path` and also inspects the newly added path for configuration files.

在 3.5 版的變更: Support for the `"site-python"` directory has been removed.

在 3.13 版的變更: On Unix, *Free threading* Python installations are identified by the `"t"` suffix in the version-specific directory name, such as `lib/python3.13t/`.

If a file named `"pyenv.cfg"` exists one directory above `sys.executable`, `sys.prefix` and `sys.exec_prefix` are set to that directory and it is also checked for site-packages (`sys.base_prefix` and `sys.base_exec_prefix` will always be the "real" prefixes of the Python installation). If `"pyenv.cfg"` (a bootstrap configuration file) contains the key `"include-system-site-packages"` set to anything other than `"true"` (case-insensitive), the system-level prefixes will not be searched for site-packages; otherwise they will.

A path configuration file is a file whose name has the form `name.pth` and exists in one of the four directories mentioned above; its contents are additional items (one per line) to be added to `sys.path`. Non-existing items are never added to `sys.path`, and no check is made that the item refers to a directory rather than a file. No item is added to `sys.path` more than once. Blank lines and lines beginning with `#` are skipped. Lines starting with `import` (followed by space or tab) are executed.

備F

An executable line in a `.pth` file is run at every Python startup, regardless of whether a particular module is actually going to be used. Its impact should thus be kept to a minimum. The primary intended purpose of executable lines is to make the corresponding module(s) importable (load 3rd-party import hooks, adjust `PATH` etc). Any other initialization is supposed to be done upon a module's actual import, if and when it happens. Limiting a code chunk to a single line is a deliberate measure to discourage putting anything more complex here.

在 3.13 版的變更: The `.pth` files are now decoded by UTF-8 at first and then by the *locale encoding* if it fails.

For example, suppose `sys.prefix` and `sys.exec_prefix` are set to `/usr/local`. The Python X.Y library is then installed in `/usr/local/lib/pythonX.Y`. Suppose this has a subdirectory `/usr/local/lib/pythonX.Y/site-packages` with three subsubdirectories, `foo`, `bar` and `spam`, and two path configuration files, `foo.pth` and `bar.pth`. Assume `foo.pth` contains the following:

```
# foo package configuration

foo
bar
bletch
```

and `bar.pth` contains:

```
# bar package configuration

bar
```

Then the following version-specific directories are added to `sys.path`, in this order:

```
/usr/local/lib/pythonX.Y/site-packages/bar
/usr/local/lib/pythonX.Y/site-packages/foo
```

Note that `bletch` is omitted because it doesn't exist; the `bar` directory precedes the `foo` directory because `bar.pth` comes alphabetically before `foo.pth`; and `spam` is omitted because it is not mentioned in either path configuration file.

29.15.1 sitecustomize

After these path manipulations, an attempt is made to import a module named `sitecustomize`, which can perform arbitrary site-specific customizations. It is typically created by a system administrator in the `site-packages` directory. If this import fails with an `ImportError` or its subclass exception, and the exception's `name` attribute equals to `'sitecustomize'`, it is silently ignored. If Python is started without output streams available, as with `pythonw.exe` on Windows (which is used by default to start IDLE), attempted output from `sitecustomize` is ignored. Any other exception causes a silent and perhaps mysterious failure of the process.

29.15.2 usercustomize

After this, an attempt is made to import a module named `usercustomize`, which can perform arbitrary user-specific customizations, if `ENABLE_USER_SITE` is true. This file is intended to be created in the user `site-packages` directory (see below), which is part of `sys.path` unless disabled by `-s`. If this import fails with an `ImportError` or its subclass exception, and the exception's `name` attribute equals to `'usercustomize'`, it is silently ignored.

Note that for some non-Unix systems, `sys.prefix` and `sys.exec_prefix` are empty, and the path manipulations are skipped; however the import of `sitecustomize` and `usercustomize` is still attempted.

29.15.3 Readline configuration

On systems that support `readline`, this module will also import and configure the `rlcompleter` module, if Python is started in interactive mode and without the `-S` option. The default behavior is enable tab-completion and to use `~/.python_history` as the history save file. To disable it, delete (or override) the `sys.__interactivehook__` attribute in your `sitecustomize` or `usercustomize` module or your `PYTHONSTARTUP` file.

在 3.4 版的變更: Activation of `rlcompleter` and history was made automatic.

29.15.4 模組內容

`site.PREFIXES`

A list of prefixes for site-packages directories.

`site.ENABLE_USER_SITE`

Flag showing the status of the user site-packages directory. `True` means that it is enabled and was added to `sys.path`. `False` means that it was disabled by user request (with `-s` or `PYTHONNOUSERSITE`). `None` means it was disabled for security reasons (mismatch between user or group id and effective id) or by an administrator.

`site.USER_SITE`

Path to the user site-packages for the running Python. Can be `None` if `getusersitepackages()` hasn't been called yet. Default value is `~/.local/lib/pythonX.Y[t]/site-packages` for UNIX and non-framework macOS builds, `~/Library/Python/X.Y/lib/python/site-packages` for macOS framework builds, and `%APPDATA%\Python\PythonXY\site-packages` on Windows. The optional "t" indicates the free-threaded build. This directory is a site directory, which means that `.pth` files in it will be processed.

`site.USER_BASE`

Path to the base directory for the user site-packages. Can be `None` if `getuserbase()` hasn't been called yet. Default value is `~/.local` for UNIX and macOS non-framework builds, `~/Library/Python/X.Y` for macOS framework builds, and `%APPDATA%\Python` for Windows. This value is used to compute the installation directories for scripts, data files, Python modules, etc. for the *user installation scheme*. See also `PYTHONUSERBASE`.

`site.main()`

Adds all the standard site-specific directories to the module search path. This function is called automatically when this module is imported, unless the Python interpreter was started with the `-S` flag.

在 3.3 版的變更: This function used to be called unconditionally.

`site.addsitedir(sitedir, known_paths=None)`

Add a directory to `sys.path` and process its `.pth` files. Typically used in *sitecustomize* or *usercustomize* (see above).

`site.getsitepackages()`

Return a list containing all global site-packages directories.

在 3.2 版被加入.

`site.getuserbase()`

Return the path of the user base directory, `USER_BASE`. If it is not initialized yet, this function will also set it, respecting `PYTHONUSERBASE`.

在 3.2 版被加入.

`site.getusersitepackages()`

Return the path of the user-specific site-packages directory, `USER_SITE`. If it is not initialized yet, this function will also set it, respecting `USER_BASE`. To determine if the user-specific site-packages was added to `sys.path` `ENABLE_USER_SITE` should be used.

在 3.2 版被加入.

29.15.5 命令列介面

The `site` module also provides a way to get the user directories from the command line:

```
$ python -m site --user-site
/home/user/.local/lib/python3.11/site-packages
```

If it is called without arguments, it will print the contents of `sys.path` on the standard output, followed by the value of `USER_BASE` and whether the directory exists, then the same thing for `USER_SITE`, and finally the value of `ENABLE_USER_SITE`.

--user-base

Print the path to the user base directory.

--user-site

Print the path to the user site-packages directory.

If both options are given, user base and user site will be printed (always in this order), separated by `os.pathsep`.

If any option is given, the script will exit with one of these values: 0 if the user site-packages directory is enabled, 1 if it was disabled by the user, 2 if it is disabled for security reasons or by an administrator, and a value greater than 2 if there is an error.

自訂 Python 直譯器

The modules described in this chapter allow writing interfaces similar to Python's interactive interpreter. If you want a Python interpreter that supports some special feature in addition to the Python language, you should look at the `code` module. (The `codeop` module is lower-level, used to support compiling a possibly incomplete chunk of Python code.)

本章節所描述的模組清單^[F]:

30.1 `code` --- 直譯器基底類^[F]

原始碼: [Lib/code.py](#)

The `code` module provides facilities to implement read-eval-print loops in Python. Two classes and convenience functions are included which can be used to build applications which provide an interactive interpreter prompt.

class `code.InteractiveInterpreter` (*locals=None*)

This class deals with parsing and interpreter state (the user's namespace); it does not deal with input buffering or prompting or input file naming (the filename is always passed in explicitly). The optional *locals* argument specifies a mapping to use as the namespace in which code will be executed; it defaults to a newly created dictionary with key `'__name__'` set to `'__console__'` and key `'__doc__'` set to `None`.

class `code.InteractiveConsole` (*locals=None, filename='<console>', local_exit=False*)

Closely emulate the behavior of the interactive Python interpreter. This class builds on `InteractiveInterpreter` and adds prompting using the familiar `sys.ps1` and `sys.ps2`, and input buffering. If *local_exit* is true, `exit()` and `quit()` in the console will not raise `SystemExit`, but instead return to the calling code.

在 3.13 版的變更: Added *local_exit* parameter.

code.interact (*banner=None, readfunc=None, local=None, exitmsg=None, local_exit=False*)

Convenience function to run a read-eval-print loop. This creates a new instance of `InteractiveConsole` and sets *readfunc* to be used as the `InteractiveConsole.raw_input()` method, if provided. If *local* is provided, it is passed to the `InteractiveConsole` constructor for use as the default namespace for the interpreter loop. If *local_exit* is provided, it is passed to the `InteractiveConsole` constructor. The `interact()` method of the instance is then run with *banner* and *exitmsg* passed as the banner and exit message to use, if provided. The console object is discarded after use.

在 3.6 版的變更: 新增 `exitmsg` 參數。

在 3.13 版的變更: Added `local_exit` parameter.

code `.compile_command(source, filename='<input>', symbol='single')`

This function is useful for programs that want to emulate Python's interpreter main loop (a.k.a. the read-eval-print loop). The tricky part is to determine when the user has entered an incomplete command that can be completed by entering more text (as opposed to a complete command or a syntax error). This function *almost* always makes the same decision as the real interpreter main loop.

`source` is the source string; `filename` is the optional filename from which source was read, defaulting to '`<input>`'; and `symbol` is the optional grammar start symbol, which should be '`single`' (the default), '`eval`' or '`exec`'.

Returns a code object (the same as `compile(source, filename, symbol)`) if the command is complete and valid; `None` if the command is incomplete; raises `SyntaxError` if the command is complete and contains a syntax error, or raises `OverflowError` or `ValueError` if the command contains an invalid literal.

30.1.1 Interactive Interpreter Objects

`InteractiveInterpreter.runsource(source, filename='<input>', symbol='single')`

Compile and run some source in the interpreter. Arguments are the same as for `compile_command()`; the default for `filename` is '`<input>`', and for `symbol` is '`single`'. One of several things can happen:

- The input is incorrect; `compile_command()` raised an exception (`SyntaxError` or `OverflowError`). A syntax traceback will be printed by calling the `showsyntaxerror()` method. `runsource()` returns `False`.
- The input is incomplete, and more input is required; `compile_command()` returned `None`. `runsource()` returns `True`.
- The input is complete; `compile_command()` returned a code object. The code is executed by calling the `runcode()` (which also handles run-time exceptions, except for `SystemExit`). `runsource()` returns `False`.

The return value can be used to decide whether to use `sys.ps1` or `sys.ps2` to prompt the next line.

`InteractiveInterpreter.runcode(code)`

Execute a code object. When an exception occurs, `showtraceback()` is called to display a traceback. All exceptions are caught except `SystemExit`, which is allowed to propagate.

A note about `KeyboardInterrupt`: this exception may occur elsewhere in this code, and may not always be caught. The caller should be prepared to deal with it.

`InteractiveInterpreter.showsyntaxerror(filename=None)`

Display the syntax error that just occurred. This does not display a stack trace because there isn't one for syntax errors. If `filename` is given, it is stuffed into the exception instead of the default filename provided by Python's parser, because it always uses '`<string>`' when reading from a string. The output is written by the `write()` method.

`InteractiveInterpreter.showtraceback()`

Display the exception that just occurred. We remove the first stack item because it is within the interpreter object implementation. The output is written by the `write()` method.

在 3.5 版的變更: The full chained traceback is displayed instead of just the primary traceback.

`InteractiveInterpreter.write(data)`

Write a string to the standard error stream (`sys.stderr`). Derived classes should override this to provide the appropriate output handling as needed.

30.1.2 Interactive Console Objects

The `InteractiveConsole` class is a subclass of `InteractiveInterpreter`, and so offers all the methods of the interpreter objects as well as the following additions.

`InteractiveConsole.interact (banner=None, exitmsg=None)`

Closely emulate the interactive Python console. The optional `banner` argument specifies the banner to print before the first interaction; by default it prints a banner similar to the one printed by the standard Python interpreter, followed by the class name of the console object in parentheses (so as not to confuse this with the real interpreter -- since it's so close!).

The optional `exitmsg` argument specifies an exit message printed when exiting. Pass the empty string to suppress the exit message. If `exitmsg` is not given or `None`, a default message is printed.

在 3.4 版的變更: To suppress printing any banner, pass an empty string.

在 3.6 版的變更: Print an exit message when exiting.

`InteractiveConsole.push (line)`

Push a line of source text to the interpreter. The line should not have a trailing newline; it may have internal newlines. The line is appended to a buffer and the interpreter's `runsource()` method is called with the concatenated contents of the buffer as source. If this indicates that the command was executed or invalid, the buffer is reset; otherwise, the command is incomplete, and the buffer is left as it was after the line was appended. The return value is `True` if more input is required, `False` if the line was dealt with in some way (this is the same as `runsource()`).

`InteractiveConsole.resetbuffer ()`

Remove any unhandled source text from the input buffer.

`InteractiveConsole.raw_input (prompt=)`

Write a prompt and read a line. The returned line does not include the trailing newline. When the user enters the EOF key sequence, `EOFError` is raised. The base implementation reads from `sys.stdin`; a subclass may replace this with a different implementation.

30.2 codeop --- 編譯 Python 程式碼

原始碼: [Lib/codeop.py](#)

The `codeop` module provides utilities upon which the Python read-eval-print loop can be emulated, as is done in the `code` module. As a result, you probably don't want to use the module directly; if you want to include such a loop in your program you probably want to use the `code` module instead.

There are two parts to this job:

1. Being able to tell if a line of input completes a Python statement: in short, telling whether to print `'>>>'` or `'...'` next.
2. Remembering which future statements the user has entered, so subsequent input can be compiled with these in effect.

The `codeop` module provides a way of doing each of these things, and a way of doing them both.

To do just the former:

`codeop.compile_command (source, filename='<input>', symbol='single')`

Tries to compile `source`, which should be a string of Python code and return a code object if `source` is valid Python code. In that case, the filename attribute of the code object will be `filename`, which defaults to `'<input>'`. Returns `None` if `source` is not valid Python code, but is a prefix of valid Python code.

If there is a problem with `source`, an exception will be raised. `SyntaxError` is raised if there is invalid Python syntax, and `OverflowError` or `ValueError` if there is an invalid literal.

The *symbol* argument determines whether *source* is compiled as a statement ('single', the default), as a sequence of *statement* ('exec') or as an *expression* ('eval'). Any other value will cause *ValueError* to be raised.

備 F

It is possible (but not likely) that the parser stops parsing with a successful outcome before reaching the end of the source; in this case, trailing symbols may be ignored instead of causing an error. For example, a backslash followed by two newlines may be followed by arbitrary garbage. This will be fixed once the API for the parser is better.

class `codeop.Compile`

Instances of this class have `__call__()` methods identical in signature to the built-in function `compile()`, but with the difference that if the instance compiles program text containing a `__future__` statement, the instance 'remembers' and compiles all subsequent program texts with the statement in force.

class `codeop.CommandCompiler`

Instances of this class have `__call__()` methods identical in signature to `compile_command()`; the difference is that if the instance compiles program text containing a `__future__` statement, the instance 'remembers' and compiles all subsequent program texts with the statement in force.

The modules described in this chapter provide new ways to import other Python modules and hooks for customizing the import process.

The full list of modules described in this chapter is:

31.1 `zipimport` --- 從 Zip 封存檔案匯入模組

原始碼: [Lib/zipimport.py](#)

This module adds the ability to import Python modules (`*.py`, `*.pyc`) and packages from ZIP-format archives. It is usually not needed to use the `zipimport` module explicitly; it is automatically used by the built-in import mechanism for `sys.path` items that are paths to ZIP archives.

Typically, `sys.path` is a list of directory names as strings. This module also allows an item of `sys.path` to be a string naming a ZIP file archive. The ZIP archive can contain a subdirectory structure to support package imports, and a path within the archive can be specified to only import from a subdirectory. For example, the path `example.zip/lib/` would only import from the `lib/` subdirectory within the archive.

Any files may be present in the ZIP archive, but importers are only invoked for `.py` and `.pyc` files. ZIP import of dynamic modules (`.pyd`, `.so`) is disallowed. Note that if an archive only contains `.py` files, Python will not attempt to modify the archive by adding the corresponding `.pyc` file, meaning that if a ZIP archive doesn't contain `.pyc` files, importing may be rather slow.

在 3.13 版的變更: ZIP64 is supported

在 3.8 版的變更: Previously, ZIP archives with an archive comment were not supported.

也參考

PKZIP Application Note

Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

PEP 273 - Import Modules from Zip Archives

Written by James C. Ahlstrom, who also provided an implementation. Python 2.3 follows the specification in [PEP 273](#), but uses an implementation written by Just van Rossum that uses the import hooks described in [PEP 302](#).

`importlib` - The implementation of the import machinery

Package providing the relevant protocols for all importers to implement.

This module defines an exception:

exception `zipimport.ZipImportError`

Exception raised by zipimporter objects. It's a subclass of `ImportError`, so it can be caught as `ImportError`, too.

31.1.1 zipimporter 物件

`zipimporter` is the class for importing ZIP files.

class `zipimport.zipimporter` (*archivepath*)

Create a new zipimporter instance. *archivepath* must be a path to a ZIP file, or to a specific path within a ZIP file. For example, an *archivepath* of `foo/bar.zip/lib` will look for modules in the `lib` directory inside the ZIP file `foo/bar.zip` (provided that it exists).

`ZipImportError` is raised if *archivepath* doesn't point to a valid ZIP archive.

在 3.12 版的變更: Methods `find_loader()` and `find_module()`, deprecated in 3.10 are now removed. Use `find_spec()` instead.

create_module (*spec*)

Implementation of `importlib.abc.Loader.create_module()` that returns `None` to explicitly request the default semantics.

在 3.10 版被加入.

exec_module (*module*)

Implementation of `importlib.abc.Loader.exec_module()`.

在 3.10 版被加入.

find_spec (*fullname*, *target=None*)

An implementation of `importlib.abc.PathEntryFinder.find_spec()`.

在 3.10 版被加入.

get_code (*fullname*)

Return the code object for the specified module. Raise `ZipImportError` if the module couldn't be imported.

get_data (*pathname*)

Return the data associated with *pathname*. Raise `OSError` if the file wasn't found.

在 3.3 版的變更: `IOError` used to be raised, it is now an alias of `OSError`.

get_filename (*fullname*)

Return the value `__file__` would be set to if the specified module was imported. Raise `ZipImportError` if the module couldn't be imported.

在 3.1 版被加入.

get_source (*fullname*)

Return the source code for the specified module. Raise `ZipImportError` if the module couldn't be found, return `None` if the archive does contain the module, but has no source for it.

is_package (*fullname*)

Return `True` if the module specified by *fullname* is a package. Raise `ZipImportError` if the module couldn't be found.

load_module (*fullname*)

Load the module specified by *fullname*. *fullname* must be the fully qualified (dotted) module name. Returns the imported module on success, raises *ZipImportError* on failure.

在 3.10 版之後被用: Use *exec_module()* instead.

invalidate_caches ()

Clear out the internal cache of information about files found within the ZIP archive.

在 3.10 版被加入.

archive

The file name of the importer's associated ZIP file, without a possible subpath.

prefix

The subpath within the ZIP file where modules are searched. This is the empty string for *zipimporter* objects which point to the root of the ZIP file.

The *archive* and *prefix* attributes, when combined with a slash, equal the original *archivepath* argument given to the *zipimporter* constructor.

31.1.2 范例

Here is an example that imports a module from a ZIP archive - note that the *zipimport* module is not explicitly used.

```
$ unzip -l example.zip
Archive:  example.zip
  Length      Date    Time    Name
-----
   8467      11-26-02  22:30    jwzthreading.py
-----
   8467                      1 file

$ ./python
Python 2.3 (#1, Aug 1 2003, 19:54:32)
>>> import sys
>>> sys.path.insert(0, 'example.zip') # 將 .zip 檔案新增到系統路徑的最前面
>>> import jwzthreading
>>> jwzthreading.__file__
'example.zip/jwzthreading.py'
```

31.2 pkgutil --- 套件擴充工具程式

原始碼: [Lib/pkgutil.py](#)

此模組提供了引入系統 (import system) 的工具程式, 特別是套件相關支援。

class *pkgutil.ModuleInfo* (*module_finder*, *name*, *ispkg*)

一個包含模組資訊之簡短摘要的附名元組 (namedtuple)。

在 3.6 版被加入.

pkgutil.extend_path (*path*, *name*)

擴充組成一個套件之模組的搜尋路徑。預期用法是將以下程式碼放入套件的 `__init__.py`:

```
from pkgutil import extend_path
__path__ = extend_path(__path__, __name__)
```

對於 `sys.path` 上具有與套件名稱相符的子目，將該子目新增至套件的 `__path__` 中。如果想要將單一邏輯套件的不同部分給分配到多個目時，這會非常有用。

它還會尋找 `*.pkg` 檔案，其中開頭的 `*` 與 `name` 引數相符。此功能類似於 `*.pth` 檔案（更多資訊請參 `site` 模組），但他不特處理以 `import` 開頭的行。`*.pkg` 檔案從表面上看是受信任的：除了跳過空行和備註之外，在 `*.pkg` 檔案中找到的所有條目都將新增到路徑中，無論它們是否存在於檔案系統。（這是一個功能。）

如果輸入路徑不是串列（像是凍結套件 (frozen package) 的情況），它將原封不動地被回傳。輸入路徑不會被修改；而是回傳擴充後的副本。僅將項目附加到副本的尾端。

`sys.path` 被假設是一個序列，`sys.path` 中的項目，若不是代表現存目的字串則將被忽略。`sys.path` 上用作檔案名稱時導致錯誤的 Unicode 項目可能會導致此函式引發例外（與 `os.path.isdir()` 行一致）。

`pkgutil.find_loader(fullname)`

取得給定之 `fullname` 的模組 `loader`。

這是一個 `importlib.util.find_spec()` 的向後相容包裝器，它將大多數的失敗轉成 `ImportError` 且僅回傳載入器而不是完整的 `importlib.machinery.ModuleSpec`。

在 3.3 版的變更：更新直接基於 `importlib`，而不是依賴套件部 PEP 302 的引入模擬 (import emulation)。

在 3.4 版的變更：基於 PEP 451 來更新

Deprecated since version 3.12, will be removed in version 3.14: 改用 `importlib.util.find_spec()`。

`pkgutil.get_importer(path_item)`

取得給定之 `path_item` 的 `finder`。

如果回傳的尋檢器 (finder) 是由路徑勾點 (path hook) 所新建立的，則它會被快取在 `sys.path_importer_cache` 中。

如果需要重新掃描 `sys.path_hooks`，可以手動清除快取（或部分快取）。

在 3.3 版的變更：更新直接基於 `importlib`，而不是依賴套件部 PEP 302 的引入模擬 (import emulation)。

`pkgutil.get_loader(module_or_name)`

取得 `module_or_name` 的 `loader` 物件。

如果可以透過正常引入機制存取模組或套件，則回傳該機制相關部分的包裝器。如果找不到或無法引入模組，則回傳 `None`。如果指定的模組尚未被引入，則引入其包含的套件（如有存在）以建立套件 `__path__`。

在 3.3 版的變更：更新直接基於 `importlib`，而不是依賴套件部 PEP 302 的引入模擬 (import emulation)。

在 3.4 版的變更：基於 PEP 451 來更新

Deprecated since version 3.12, will be removed in version 3.14: 改用 `importlib.util.find_spec()`。

`pkgutil.iter_importers(fullname="")`

yield 給定模組名稱的 `finder` 物件。

如果 `fullname` 包含 `'.'`，則尋檢器將針對包含 `fullname` 的套件，否則它們全部會是在頂層被 `__init__.py` 的尋檢器（即 `sys.meta_path` 和 `sys.path_hooks` 上的尋檢器）。

如果指定的模組位於套件中，則作呼叫此函式的副作用 (side effect)，該套件會被引入。

如果未指定模組名稱，則會生成所有頂層尋檢器。

在 3.3 版的變更：更新直接基於 `importlib`，而不是依賴套件部 PEP 302 的引入模擬 (import emulation)。

`pkgutil.iter_modules(path=None, prefix=)`

yield `path` 上所有子模組的 `ModuleInfo`，或者如果 `path` 是 `None`，則生成 `sys.path` 上的所有頂層模組。

`path` 應該是 `None` 或用來尋找模組的路徑串列。

`prefix` 是在輸出的每個模組名稱前面的輸出字串。

備註

僅適用於有定義 `iter_modules()` 方法的 *finder*。此介面非是標準的，因此該模組還提供了 `importlib.machinery.FileFinder` 和 `zipimport.zipimporter` 的實作。

在 3.3 版的變更: 更新直接基於 `importlib`，而不是依賴套件部 **PEP 302** 的引入模擬 (import emulation)。

`pkgutil.walk_packages(path=None, prefix=, onerror=None)`

在 `path` 上的所有模組遞歸 yield 出 `ModuleInfo`，或如果 `path` 是 `None` 則 yield 所有可存取的模組。

`path` 應該是 `None` 或用來尋找模組的路徑串列。

`prefix` 是在輸出的每個模組名稱前面的輸出字串。

請注意，此函式必須引入給定之 `path` 上的所有套件（不是所有模組！），以便存取 `__path__` 屬性來尋找子模組。

`onerror` 是一個函式，如果在嘗試引入套件時發生任何例外，則使用一個引數（正在引入之套件的名稱）來呼叫函式。如果未提供 `onerror` 函式，則會捕獲並忽略 `ImportError`，同時傳播所有其他例外並終止搜尋。

範例：

```
# list all modules python can access
walk_packages()

# list all submodules of ctypes
walk_packages(ctypes.__path__, ctypes.__name__ + '.')

```

備註

僅適用於有定義 `iter_modules()` 方法的 *finder*。此介面非是標準的，因此該模組還提供了 `importlib.machinery.FileFinder` 和 `zipimport.zipimporter` 的實作。

在 3.3 版的變更: 更新直接基於 `importlib`，而不是依賴套件部 **PEP 302** 的引入模擬 (import emulation)。

`pkgutil.get_data(package, resource)`

從套件中取得資源。

這是 *loader* `get_data` API 的包裝器。`package` 引數應該是採用標準模組格式 (`foo.bar`) 的套件名稱。`resource` 引數應採用相對檔案名稱的形式，使用 `/` 作路徑分隔符號。不允許使用父目名稱 `..`，也不允許使用根目名稱（以 `/` 開頭）。

該函式回傳一個二進位字串，它是指定資源的內容。

對於位於檔案系統中且已被引入過的套件，這大致相當於：

```
d = os.path.dirname(sys.modules[package].__file__)
data = open(os.path.join(d, resource), 'rb').read()

```

如果無法定位或載入套件，或者它使用不支援 `get_data` 的 *loader* 則回傳 `None`。特別是命名空間套件的 *loader* 不支援 `get_data`。

`pkgutil.resolve_name(name)`

將名稱解析物件。

標準函式庫中的許多地方都使用了此功能（請參 [bpo-12915](#)），且相同功能也被用於擁有廣大使用者的第三方套件，如 `setuptools`、`Django` 和 `Pyramid`。

`name` 預期要是以下格式之一的字串，其中 `W` 是有效 Python 識字的簡寫，而點（dot）代表這些正規表示式（pseudo-regex）中的字面句點（literal period）：

- `W(.W)*`
- `W(.W)*:(W(.W)*)?`

第一種形式僅是為了要向後相容。它假設點名稱（dotted name）的某些部分是一個套件，其餘部分是該套件某處的物件，其可能巢狀地存在於（nested）其他物件。由於無法透過檢查（inspection）來推斷出套件停止的位置和物件層次結構的開始位置，因此必須使用此形式來重嘗試引入。

在第二種形式中，呼叫者透過使用一個冒號來明確標明分隔點：冒號左側的點名稱是要引入的套件，右側的點名稱是該套件的物件層次結構。這種形式只需要一次引入。如果它以冒號結尾，則回傳一個模組物件。

此函式會回傳一個物件（可能是一個模組），或引發以下其中一個例外：

`ValueError` -- 如果 `name` 不是可辨識的格式。

`ImportError` -- 如果在不應該失敗的情況下引入失敗。

`AttributeError` -- 如果在遍歷引入套件中的物件層次結構以取得所需物件時發生失敗。

在 3.9 版被加入。

31.3 modulefinder --- 搜尋本所使用的模組

原始碼：[Lib/modulefinder.py](#)

此模組提供了一個 `ModuleFinder` 類，可用於確定本引入的模組集合。`modulefinder.py` 也可以作本運行，其將 Python 本的檔案名稱作它的引數，在之後會列印出引入模組的報告。

`modulefinder.AddPackagePath(pkg_name, path)`

記在指定的 `path` 中可以找到名 `pkg_name` 的套件。

`modulefinder.ReplacePackage(oldname, newname)`

允許指定名 `oldname` 的模組實際上是名 `newname` 的套件。

`class modulefinder.ModuleFinder(path=None, debug=0, excludes=[], replace_paths=[])`

此類提供 `run_script()` 和 `report()` 方法來定本引入的模組集合。`path` 可以是搜尋模組的目串列；如果未指定，則使用 `sys.path`。`debug` 設定偵錯等級；較高的值可使類列印有關其即將執行之操作的偵錯訊息。`excludes` 是要從分析中排除的模組名稱串列。`replace_paths` 是將在模組路徑中替換的 (`oldpath`, `newpath`) 元組串列。

`report()`

將報告列印到標準輸出，其中列出了本引入的模組及其路徑，以及失或似乎失的模組。

`run_script(pathname)`

分析 `pathname` 檔案的內容，該檔案必須包含 Python 程式碼。

`modules`

將模組名稱對應到模組的字典。請參 `ModuleFinder` 的用法範例。

31.3.1 ModuleFinder 的用法范例

將被分析的檔案 (bacon.py):

```
import re, itertools

try:
    import baconhameggs
except ImportError:
    pass

try:
    import guido.python.ham
except ImportError:
    pass
```

將輸出 bacon.py 報告的檔案:

```
from modulefinder import ModuleFinder

finder = ModuleFinder()
finder.run_script('bacon.py')

print('Loaded modules:')
for name, mod in finder.modules.items():
    print('%s: ' % name, end='')
    print(', '.join(list(mod.globalnames.keys())[:3]))

print('-'*50)
print('Modules not imported:')
print('\n'.join(finder.badmodules.keys()))
```

範例輸出 (可能因架構而異):

```
Loaded modules:
_types:
copyreg:  _inverted_registry, _slotnames, __all__
re._compiler:  isstring, _sre, _optimize_unicode
_sre:
re._constants:  REPEAT_ONE, makedict, AT_END_LINE
sys:
re:  __module__, finditer, _expand
itertools:
__main__:  re, itertools, baconhameggs
re._parser:  _PATTERNENDERS, SRE_FLAG_UNICODE
array:
types:  __module__, IntType, TypeType
-----
Modules not imported:
guido.python.ham
baconhameggs
```

31.4 runpy --- 定位執行 Python 模組

原始碼: [Lib/runpy.py](#)

The `runpy` module is used to locate and run Python modules without importing them first. Its main use is to implement the `-m` command line switch that allows scripts to be located using the Python module namespace rather than the filesystem.

Note that this is *not* a sandbox module - all code is executed in the current process, and any side effects (such as cached imports of other modules) will remain in place after the functions have returned.

Furthermore, any functions and classes defined by the executed code are not guaranteed to work correctly after a `runpy` function has returned. If that limitation is not acceptable for a given use case, `importlib` is likely to be a more suitable choice than this module.

The `runpy` module provides two functions:

`runpy.run_module(mod_name, init_globals=None, run_name=None, alter_sys=False)`

Execute the code of the specified module and return the resulting module's globals dictionary. The module's code is first located using the standard import mechanism (refer to [PEP 302](#) for details) and then executed in a fresh module namespace.

The `mod_name` argument should be an absolute module name. If the module name refers to a package rather than a normal module, then that package is imported and the `__main__` submodule within that package is then executed and the resulting module globals dictionary returned.

The optional dictionary argument `init_globals` may be used to pre-populate the module's globals dictionary before the code is executed. `init_globals` will not be modified. If any of the special global variables below are defined in `init_globals`, those definitions are overridden by `run_module()`.

The special global variables `__name__`, `__spec__`, `__file__`, `__cached__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed. (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail.)

`__name__` is set to `run_name` if this optional argument is not `None`, to `mod_name + '.__main__'` if the named module is a package and to the `mod_name` argument otherwise.

`__spec__` will be set appropriately for the *actually* imported module (that is, `__spec__.name` will always be `mod_name` or `mod_name + '.__main__'`, never `run_name`).

`__file__`, `__cached__`, `__loader__` and `__package__` are set as normal based on the module spec.

If the argument `alter_sys` is supplied and evaluates to `True`, then `sys.argv[0]` is updated with the value of `__file__` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. Both `sys.argv[0]` and `sys.modules[__name__]` are restored to their original values before the function returns.

Note that this manipulation of `sys` is not thread-safe. Other threads may see the partially initialised module, as well as the altered list of arguments. It is recommended that the `sys` module be left alone when invoking this function from threaded code.

也參考

The `-m` option offering equivalent functionality from the command line.

在 3.1 版的變更: Added ability to execute packages by looking for a `__main__` submodule.

在 3.2 版的變更: Added `__cached__` global variable (see [PEP 3147](#)).

在 3.4 版的變更: Updated to take advantage of the module spec feature added by [PEP 451](#). This allows `__cached__` to be set correctly for modules run this way, as well as ensuring the real module name is always accessible as `__spec__.name`.

在 3.12 版的變更: The setting of `__cached__`, `__loader__`, and `__package__` are deprecated. See [ModuleSpec](#) for alternatives.

`runpy.run_path(path_name, init_globals=None, run_name=None)`

Execute the code at the named filesystem location and return the resulting module's globals dictionary. As with a script name supplied to the CPython command line, `file_path` may refer to a Python source file, a compiled bytecode file or a valid `sys.path` entry containing a `__main__` module (e.g. a zipfile containing a top-level `__main__.py` file).

For a simple script, the specified code is simply executed in a fresh module namespace. For a valid `sys.path` entry (typically a zipfile or directory), the entry is first added to the beginning of `sys.path`. The function then looks for and executes a `__main__` module using the updated path. Note that there is no special protection against invoking an existing `__main__` entry located elsewhere on `sys.path` if there is no such module at the specified location.

The optional dictionary argument `init_globals` may be used to pre-populate the module's globals dictionary before the code is executed. `init_globals` will not be modified. If any of the special global variables below are defined in `init_globals`, those definitions are overridden by `run_path()`.

The special global variables `__name__`, `__spec__`, `__file__`, `__cached__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed. (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail.)

`__name__` is set to `run_name` if this optional argument is not `None` and to `'<run_path>'` otherwise.

If `file_path` directly references a script file (whether as source or as precompiled byte code), then `__file__` will be set to `file_path`, and `__spec__`, `__cached__`, `__loader__` and `__package__` will all be set to `None`.

If `file_path` is a reference to a valid `sys.path` entry, then `__spec__` will be set appropriately for the imported `__main__` module (that is, `__spec__.name` will always be `__main__`). `__file__`, `__cached__`, `__loader__` and `__package__` will be set as normal based on the module spec.

A number of alterations are also made to the `sys` module. Firstly, `sys.path` may be altered as described above. `sys.argv[0]` is updated with the value of `file_path` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. All modifications to items in `sys` are reverted before the function returns.

Note that, unlike `run_module()`, the alterations made to `sys` are not optional in this function as these adjustments are essential to allowing the execution of `sys.path` entries. As the thread-safety limitations still apply, use of this function in threaded code should be either serialised with the import lock or delegated to a separate process.

The `importlib.import_module()` function

31.5 importlib --- import 的實作

在 3.1 版被加入.

原始碼: `Lib/importlib/__init__.py`

31.5.1 簡介

The purpose of the `importlib` package is three-fold.

One is to provide the implementation of the `import` statement (and thus, by extension, the `__import__()` function) in Python source code. This provides an implementation of `import` which is portable to any Python interpreter. This also provides an implementation which is easier to comprehend than one implemented in a programming language other than Python.

Two, the components to implement `import` are exposed in this package, making it easier for users to create their own custom objects (known generically as an *importer*) to participate in the import process.

Three, the package contains modules exposing additional functionality for managing aspects of Python packages:

- `importlib.metadata` presents access to metadata from third-party distributions.
- `importlib.resources` provides routines for accessing non-code "resources" from Python packages.

31.5.2 函式

`importlib.__import__(name, globals=None, locals=None, fromlist=(), level=0)`An implementation of the built-in `__import__()` function.**備F**Programmatic importing of modules should use `import_module()` instead of this function.`importlib.import_module(name, package=None)`

Import a module. The *name* argument specifies what module to import in absolute or relative terms (e.g. either `pkg.mod` or `..mod`). If the name is specified in relative terms, then the *package* argument must be set to the name of the package which is to act as the anchor for resolving the package name (e.g. `import_module('..mod', 'pkg.subpkg')` will import `pkg.mod`).

The `import_module()` function acts as a simplifying wrapper around `importlib.__import__()`. This means all semantics of the function are derived from `importlib.__import__()`. The most important difference between these two functions is that `import_module()` returns the specified package or module (e.g. `pkg.mod`), while `__import__()` returns the top-level package or module (e.g. `pkg`).

If you are dynamically importing a module that was created since the interpreter began execution (e.g., created a Python source file), you may need to call `invalidate_caches()` in order for the new module to be noticed by the import system.

在 3.3 版的變更: Parent packages are automatically imported.

`importlib.invalidate_caches()`

Invalidate the internal caches of finders stored at `sys.meta_path`. If a finder implements `invalidate_caches()` then it will be called to perform the invalidation. This function should be called if any modules are created/installed while your program is running to guarantee all finders will notice the new module's existence.

在 3.3 版被加入。

在 3.10 版的變更: Namespace packages created/installed in a different `sys.path` location after the same namespace was already imported are noticed.

`importlib.reload(module)`

Reload a previously imported *module*. The argument must be a module object, so it must have been successfully imported before. This is useful if you have edited the module source file using an external editor and want to try out the new version without leaving the Python interpreter. The return value is the module object (which can be different if re-importing causes a different object to be placed in `sys.modules`).

When `reload()` is executed:

- Python module's code is recompiled and the module-level code re-executed, defining a new set of objects which are bound to names in the module's dictionary by reusing the *loader* which originally loaded the module. The `init` function of extension modules is not called a second time.
- As with all other objects in Python the old objects are only reclaimed after their reference counts drop to zero.
- The names in the module namespace are updated to point to any new or changed objects.
- Other references to the old objects (such as names external to the module) are not rebound to refer to the new objects and must be updated in each namespace where they occur if that is desired.

There are a number of other caveats:

When a module is reloaded, its dictionary (containing the module's global variables) is retained. Redefinitions of names will override the old definitions, so this is generally not a problem. If the new version of a module does not define a name that was defined by the old version, the old definition remains. This feature can be used to the module's advantage if it maintains a global table or cache of objects --- with a `try` statement it can test for the table's presence and skip its initialization if desired:

```
try:
    cache
except NameError:
    cache = {}
```

It is generally not very useful to reload built-in or dynamically loaded modules. Reloading `sys`, `__main__`, `builtins` and other key modules is not recommended. In many cases extension modules are not designed to be initialized more than once, and may fail in arbitrary ways when reloaded.

If a module imports objects from another module using `from ... import ...`, calling `reload()` for the other module does not redefine the objects imported from it --- one way around this is to re-execute the `from` statement, another is to use `import` and qualified names (*module.name*) instead.

If a module instantiates instances of a class, reloading the module that defines the class does not affect the method definitions of the instances --- they continue to use the old class definition. The same is true for derived classes.

在 3.4 版被加入。

在 3.7 版的變更: `ModuleNotFoundError` is raised when the module being reloaded lacks a `ModuleSpec`.

31.5.3 `importlib.abc` -- Abstract base classes related to import

原始碼: `Lib/importlib/abc.py`

The `importlib.abc` module contains all of the core abstract base classes used by `import`. Some subclasses of the core abstract base classes are also provided to help in implementing the core ABCs.

ABC hierarchy:

```
object
+-- MetaPathFinder
+-- PathEntryFinder
+-- Loader
    +-- ResourceLoader -----+
    +-- InspectLoader          |
        +-- ExecutionLoader --+
                                +-- FileLoader
                                +-- SourceLoader
```

class `importlib.abc.MetaPathFinder`

An abstract base class representing a *meta path finder*.

在 3.3 版被加入.

在 3.10 版的變更: No longer a subclass of `Finder`.

find_spec (*fullname, path, target=None*)

An abstract method for finding a *spec* for the specified module. If this is a top-level import, *path* will be `None`. Otherwise, this is a search for a subpackage or module and *path* will be the value of `__path__` from the parent package. If a spec cannot be found, `None` is returned. When passed in, *target* is a module object that the finder may use to make a more educated guess about what spec to return. `importlib.util.spec_from_loader()` may be useful for implementing concrete `MetaPathFinders`.

在 3.4 版被加入.

invalidate_caches ()

An optional method which, when called, should invalidate any internal cache used by the finder. Used by `importlib.invalidate_caches()` when invalidating the caches of all finders on `sys.meta_path`.

在 3.4 版的變更: Returns `None` when called instead of `NotImplemented`.

class `importlib.abc.PathEntryFinder`

An abstract base class representing a *path entry finder*. Though it bears some similarities to `MetaPathFinder`, `PathEntryFinder` is meant for use only within the path-based import subsystem provided by `importlib.machinery.PathFinder`.

在 3.3 版被加入.

在 3.10 版的變更: No longer a subclass of `Finder`.

find_spec (*fullname, target=None*)

An abstract method for finding a *spec* for the specified module. The finder will search for the module only within the *path entry* to which it is assigned. If a spec cannot be found, `None` is returned. When passed in, *target* is a module object that the finder may use to make a more educated guess about what spec to return. `importlib.util.spec_from_loader()` may be useful for implementing concrete `PathEntryFinders`.

在 3.4 版被加入.

invalidate_caches()

An optional method which, when called, should invalidate any internal cache used by the finder. Used by `importlib.machinery.PathFinder.invalidate_caches()` when invalidating the caches of all cached finders.

class importlib.abc.Loader

An abstract base class for a *loader*. See [PEP 302](#) for the exact definition for a loader.

Loaders that wish to support resource reading should implement a `get_resource_reader()` method as specified by `importlib.resources.abc.ResourceReader`.

在 3.7 版的變更: Introduced the optional `get_resource_reader()` method.

create_module(spec)

A method that returns the module object to use when importing a module. This method may return `None`, indicating that default module creation semantics should take place.

在 3.4 版被加入.

在 3.6 版的變更: This method is no longer optional when `exec_module()` is defined.

exec_module(module)

An abstract method that executes the module in its own namespace when a module is imported or reloaded. The module should already be initialized when `exec_module()` is called. When this method exists, `create_module()` must be defined.

在 3.4 版被加入.

在 3.6 版的變更: `create_module()` 也必須被定義。

load_module(fullname)

A legacy method for loading a module. If the module cannot be loaded, `ImportError` is raised, otherwise the loaded module is returned.

If the requested module already exists in `sys.modules`, that module should be used and reloaded. Otherwise the loader should create a new module and insert it into `sys.modules` before any loading begins, to prevent recursion from the import. If the loader inserted a module and the load fails, it must be removed by the loader from `sys.modules`; modules already in `sys.modules` before the loader began execution should be left alone.

The loader should set several attributes on the module (note that some of these attributes can change when a module is reloaded):

- **__name__**
The module's fully qualified name. It is `'__main__'` for an executed module.
- **__file__**
The location the *loader* used to load the module. For example, for modules loaded from a .py file this is the filename. It is not set on all modules (e.g. built-in modules).
- **__cached__**
The filename of a compiled version of the module's code. It is not set on all modules (e.g. built-in modules).
- **__path__**
The list of locations where the package's submodules will be found. Most of the time this is a single directory. The import system passes this attribute to `__import__()` and to finders in the same way as `sys.path` but just for the package. It is not set on non-package modules so it can be used as an indicator that the module is a package.
- **__package__**
The fully qualified name of the package the module is in (or the empty string for a top-level module). If the module is a package then this is the same as `__name__`.
- **__loader__**
The *loader* used to load the module.

When `exec_module()` is available then backwards-compatible functionality is provided.

在 3.4 版的變更: Raise `ImportError` when called instead of `NotImplementedError`. Functionality provided when `exec_module()` is available.

在 3.4 版之後被 用: The recommended API for loading a module is `exec_module()` (and `create_module()`). Loaders should implement it instead of `load_module()`. The import machinery takes care of all the other responsibilities of `load_module()` when `exec_module()` is implemented.

class `importlib.abc.ResourceLoader`

An abstract base class for a *loader* which implements the optional **PEP 302** protocol for loading arbitrary resources from the storage back-end.

在 3.7 版之後被 用: This ABC is deprecated in favour of supporting resource loading through `importlib.resources.abc.ResourceReader`.

abstractmethod `get_data(path)`

An abstract method to return the bytes for the data located at *path*. Loaders that have a file-like storage back-end that allows storing arbitrary data can implement this abstract method to give direct access to the data stored. `OSError` is to be raised if the *path* cannot be found. The *path* is expected to be constructed using a module's `__file__` attribute or an item from a package's `__path__`.

在 3.4 版的變更: Raises `OSError` instead of `NotImplementedError`.

class `importlib.abc.InspectLoader`

An abstract base class for a *loader* which implements the optional **PEP 302** protocol for loaders that inspect modules.

get_code (*fullname*)

Return the code object for a module, or `None` if the module does not have a code object (as would be the case, for example, for a built-in module). Raise an `ImportError` if loader cannot find the requested module.

備 用

While the method has a default implementation, it is suggested that it be overridden if possible for performance.

在 3.4 版的變更: No longer abstract and a concrete implementation is provided.

abstractmethod `get_source(fullname)`

An abstract method to return the source of a module. It is returned as a text string using *universal newlines*, translating all recognized line separators into `'\n'` characters. Returns `None` if no source is available (e.g. a built-in module). Raises `ImportError` if the loader cannot find the module specified.

在 3.4 版的變更: Raises `ImportError` instead of `NotImplementedError`.

is_package (*fullname*)

An optional method to return a true value if the module is a package, a false value otherwise. `ImportError` is raised if the *loader* cannot find the module.

在 3.4 版的變更: Raises `ImportError` instead of `NotImplementedError`.

static `source_to_code(data, path=<string>)`

Create a code object from Python source.

The *data* argument can be whatever the `compile()` function supports (i.e. string or bytes). The *path* argument should be the "path" to where the source code originated from, which can be an abstract concept (e.g. location in a zip file).

With the subsequent code object one can execute it in a module by running `exec(code, module.__dict__)`.

在 3.4 版被加入。

在 3.5 版的變更: Made the method static.

exec_module (*module*)

Loader.exec_module() 的實作。

在 3.4 版被加入。

load_module (*fullname*)

Loader.load_module() 的實作。

在 3.4 版之後被用: 請改用 *exec_module()*。

class `importlib.abc.ExecutionLoader`

An abstract base class which inherits from *InspectLoader* that, when implemented, helps a module to be executed as a script. The ABC represents an optional **PEP 302** protocol.

abstractmethod `get_filename` (*fullname*)

An abstract method that is to return the value of `__file__` for the specified module. If no path is available, *ImportError* is raised.

If source code is available, then the method should return the path to the source file, regardless of whether a bytecode was used to load the module.

在 3.4 版的變更: Raises *ImportError* instead of *NotImplementedError*.

class `importlib.abc.FileLoader` (*fullname*, *path*)

An abstract base class which inherits from *ResourceLoader* and *ExecutionLoader*, providing concrete implementations of *ResourceLoader.get_data()* and *ExecutionLoader.get_filename()*.

The *fullname* argument is a fully resolved name of the module the loader is to handle. The *path* argument is the path to the file for the module.

在 3.3 版被加入。

name

The name of the module the loader can handle.

path

Path to the file of the module.

load_module (*fullname*)

Calls super's *load_module()*.

在 3.4 版之後被用: Use *Loader.exec_module()* instead.

abstractmethod `get_filename` (*fullname*)

Returns *path*.

abstractmethod `get_data` (*path*)

Reads *path* as a binary file and returns the bytes from it.

class `importlib.abc.SourceLoader`

An abstract base class for implementing source (and optionally bytecode) file loading. The class inherits from both *ResourceLoader* and *ExecutionLoader*, requiring the implementation of:

- *ResourceLoader.get_data()*
- ***ExecutionLoader.get_filename()***
 - Should only return the path to the source file; sourceless loading is not supported.

The abstract methods defined by this class are to add optional bytecode file support. Not implementing these optional methods (or causing them to raise *NotImplementedError*) causes the loader to only work with source code. Implementing the methods allows the loader to work with source *and* bytecode files; it does not

allow for *sourceless* loading where only bytecode is provided. Bytecode files are an optimization to speed up loading by removing the parsing step of Python's compiler, and so no bytecode-specific API is exposed.

path_stats (*path*)

Optional abstract method which returns a *dict* containing metadata about the specified path. Supported dictionary keys are:

- 'mtime' (mandatory): an integer or floating-point number representing the modification time of the source code;
- 'size' (optional): the size in bytes of the source code.

Any other keys in the dictionary are ignored, to allow for future extensions. If the path cannot be handled, *OSError* is raised.

在 3.3 版被加入.

在 3.4 版的變更: Raise *OSError* instead of *NotImplementedError*.

path_mtime (*path*)

Optional abstract method which returns the modification time for the specified path.

在 3.3 版之後被 用: This method is deprecated in favour of *path_stats()*. You don't have to implement it, but it is still available for compatibility purposes. Raise *OSError* if the path cannot be handled.

在 3.4 版的變更: Raise *OSError* instead of *NotImplementedError*.

set_data (*path*, *data*)

Optional abstract method which writes the specified bytes to a file path. Any intermediate directories which do not exist are to be created automatically.

When writing to the path fails because the path is read-only (*errno.EACCES/PermissionError*), do not propagate the exception.

在 3.4 版的變更: No longer raises *NotImplementedError* when called.

get_code (*fullname*)

Concrete implementation of *InspectLoader.get_code()*.

exec_module (*module*)

Concrete implementation of *Loader.exec_module()*.

在 3.4 版被加入.

load_module (*fullname*)

Concrete implementation of *Loader.load_module()*.

在 3.4 版之後被 用: Use *exec_module()* instead.

get_source (*fullname*)

Concrete implementation of *InspectLoader.get_source()*.

is_package (*fullname*)

Concrete implementation of *InspectLoader.is_package()*. A module is determined to be a package if its file path (as provided by *ExecutionLoader.get_filename()*) is a file named `__init__` when the file extension is removed **and** the module name itself does not end in `__init__`.

class `importlib.abc.ResourceReader`

Superseded by TraversableResources

An *abstract base class* to provide the ability to read *resources*.

From the perspective of this ABC, a *resource* is a binary artifact that is shipped within a package. Typically this is something like a data file that lives next to the `__init__.py` file of the package. The purpose of this class is to help abstract out the accessing of such data files so that it does not matter if the package and its data file(s) are stored e.g. in a zip file versus on the file system.

For any of methods of this class, a *resource* argument is expected to be a *path-like object* which represents conceptually just a file name. This means that no subdirectory paths should be included in the *resource* argument. This is because the location of the package the reader is for, acts as the "directory". Hence the metaphor for directories and file names is packages and resources, respectively. This is also why instances of this class are expected to directly correlate to a specific package (instead of potentially representing multiple packages or a module).

Loaders that wish to support resource reading are expected to provide a method called `get_resource_reader(fullname)` which returns an object implementing this ABC's interface. If the module specified by `fullname` is not a package, this method should return `None`. An object compatible with this ABC should only be returned when the specified module is a package.

在 3.7 版被加入.

Deprecated since version 3.12, will be removed in version 3.14: Use `importlib.resources.abc.TraversableResources` instead.

abstractmethod `open_resource(resource)`

Returns an opened, *file-like object* for binary reading of the *resource*.

If the resource cannot be found, `FileNotFoundError` is raised.

abstractmethod `resource_path(resource)`

Returns the file system path to the *resource*.

If the resource does not concretely exist on the file system, raise `FileNotFoundError`.

abstractmethod `is_resource(name)`

Returns `True` if the named *name* is considered a resource. `FileNotFoundError` is raised if *name* does not exist.

abstractmethod `contents()`

Returns an *iterable* of strings over the contents of the package. Do note that it is not required that all names returned by the iterator be actual resources, e.g. it is acceptable to return names for which `is_resource()` would be false.

Allowing non-resource names to be returned is to allow for situations where how a package and its resources are stored are known a priori and the non-resource names would be useful. For instance, returning subdirectory names is allowed so that when it is known that the package and resources are stored on the file system then those subdirectory names can be used directly.

The abstract method returns an iterable of no items.

class `importlib.abc.Traversable`

An object with a subset of `pathlib.Path` methods suitable for traversing directories and opening files.

For a representation of the object on the file-system, use `importlib.resources.as_file()`.

在 3.9 版被加入.

Deprecated since version 3.12, will be removed in version 3.14: Use `importlib.resources.abc.Traversable` instead.

name

Abstract. The base name of this object without any parent references.

abstractmethod `iterdir()`

Yield `Traversable` objects in `self`.

abstractmethod `is_dir()`

Return `True` if `self` is a directory.

abstractmethod `is_file()`

Return `True` if `self` is a file.

abstractmethod `joinpath(child)`

Return Traversable child in `self`.

abstractmethod `__truediv__(child)`

Return Traversable child in `self`.

abstractmethod `open(mode='r', *args, **kwargs)`

`mode` may be 'r' or 'rb' to open as text or binary. Return a handle suitable for reading (same as `pathlib.Path.open`).

When opening as text, accepts encoding parameters such as those accepted by `io.TextIOWrapper`.

read_bytes()

Read contents of `self` as bytes.

read_text(encoding=None)

Read contents of `self` as text.

class `importlib.abc.TraversableResources`

An abstract base class for resource readers capable of serving the `importlib.resources.files()` interface. Subclasses `importlib.resources.abc.ResourceReader` and provides concrete implementations of the `importlib.resources.abc.ResourceReader`'s abstract methods. Therefore, any loader supplying `importlib.abc.TraversableResources` also supplies `ResourceReader`.

Loaders that wish to support resource reading are expected to implement this interface.

在 3.9 版被加入。

Deprecated since version 3.12, will be removed in version 3.14: Use `importlib.resources.abc.TraversableResources` instead.

abstractmethod `files()`

Returns a `importlib.resources.abc.Traversable` object for the loaded package.

31.5.4 `importlib.machinery` -- Importers and path hooks

原始碼: `Lib/importlib/machinery.py`

This module contains the various objects that help `import` find and load modules.

`importlib.machinery.SOURCE_SUFFIXES`

A list of strings representing the recognized file suffixes for source modules.

在 3.3 版被加入。

`importlib.machinery.DEBUG_BYTECODE_SUFFIXES`

A list of strings representing the file suffixes for non-optimized bytecode modules.

在 3.3 版被加入。

在 3.5 版之後被 用: Use `BYTECODE_SUFFIXES` instead.

`importlib.machinery.OPTIMIZED_BYTECODE_SUFFIXES`

A list of strings representing the file suffixes for optimized bytecode modules.

在 3.3 版被加入。

在 3.5 版之後被 用: Use `BYTECODE_SUFFIXES` instead.

`importlib.machinery.BYTECODE_SUFFIXES`

A list of strings representing the recognized file suffixes for bytecode modules (including the leading dot).

在 3.3 版被加入。

在 3.5 版的變更: The value is no longer dependent on `__debug__`.

`importlib.machinery.EXTENSION_SUFFIXES`

A list of strings representing the recognized file suffixes for extension modules.

在 3.3 版被加入。

`importlib.machinery.all_suffixes()`

Returns a combined list of strings representing all file suffixes for modules recognized by the standard import machinery. This is a helper for code which simply needs to know if a filesystem path potentially refers to a module without needing any details on the kind of module (for example, `inspect.getmodulename()`).

在 3.3 版被加入。

class `importlib.machinery.BuiltinImporter`

An *importer* for built-in modules. All known built-in modules are listed in `sys.builtin_module_names`. This class implements the `importlib.abc.MetaPathFinder` and `importlib.abc.InspectLoader` ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

在 3.5 版的變更: As part of **PEP 489**, the builtin importer now implements `Loader.create_module()` and `Loader.exec_module()`

class `importlib.machinery.FrozenImporter`

An *importer* for frozen modules. This class implements the `importlib.abc.MetaPathFinder` and `importlib.abc.InspectLoader` ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

在 3.4 版的變更: Gained `create_module()` and `exec_module()` methods.

class `importlib.machinery.WindowsRegistryFinder`

A *Finder* for modules declared in the Windows registry. This class implements the `importlib.abc.MetaPathFinder` ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

在 3.3 版被加入。

在 3.6 版之後被禁用: Use `site` configuration instead. Future versions of Python may not enable this finder by default.

class `importlib.machinery.PathFinder`

A *Finder* for `sys.path` and package `__path__` attributes. This class implements the `importlib.abc.MetaPathFinder` ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

classmethod `find_spec(fullname, path=None, target=None)`

Class method that attempts to find a *spec* for the module specified by *fullname* on `sys.path` or, if defined, on *path*. For each path entry that is searched, `sys.path_importer_cache` is checked. If a non-false object is found then it is used as the *path entry finder* to look for the module being searched for. If no entry is found in `sys.path_importer_cache`, then `sys.path_hooks` is searched for a finder for the path entry and, if found, is stored in `sys.path_importer_cache` along with being queried about the module. If no finder is ever found then `None` is both stored in the cache and returned.

在 3.4 版被加入。

在 3.5 版的變更: If the current working directory -- represented by an empty string -- is no longer valid then `None` is returned but no value is cached in `sys.path_importer_cache`.

classmethod `invalidate_caches()`

Calls `importlib.abc.PathEntryFinder.invalidate_caches()` on all finders stored in `sys.path_importer_cache` that define the method. Otherwise entries in `sys.path_importer_cache` set to `None` are deleted.

在 3.7 版的變更: Entries of `None` in `sys.path_importer_cache` are deleted.

在 3.4 版的變更: Calls objects in `sys.path_hooks` with the current working directory for `' '` (i.e. the empty string).

class `importlib.machinery.FileFinder` (*path*, **loader_details*)

A concrete implementation of `importlib.abc.PathEntryFinder` which caches results from the file system.

The *path* argument is the directory for which the finder is in charge of searching.

The *loader_details* argument is a variable number of 2-item tuples each containing a loader and a sequence of file suffixes the loader recognizes. The loaders are expected to be callables which accept two arguments of the module's name and the path to the file found.

The finder will cache the directory contents as necessary, making stat calls for each module search to verify the cache is not outdated. Because cache staleness relies upon the granularity of the operating system's state information of the file system, there is a potential race condition of searching for a module, creating a new file, and then searching for the module the new file represents. If the operations happen fast enough to fit within the granularity of stat calls, then the module search will fail. To prevent this from happening, when you create a module dynamically, make sure to call `importlib.invalidate_caches()`.

在 3.3 版被加入.

path

The path the finder will search in.

find_spec (*fullname*, *target=None*)

Attempt to find the spec to handle *fullname* within *path*.

在 3.4 版被加入.

invalidate_caches()

Clear out the internal cache.

classmethod `path_hook` (**loader_details*)

A class method which returns a closure for use on `sys.path_hooks`. An instance of `FileFinder` is returned by the closure using the *path* argument given to the closure directly and *loader_details* indirectly.

If the argument to the closure is not an existing directory, `ImportError` is raised.

class `importlib.machinery.SourceFileLoader` (*fullname*, *path*)

A concrete implementation of `importlib.abc.SourceLoader` by subclassing `importlib.abc.FileLoader` and providing some concrete implementations of other methods.

在 3.3 版被加入.

name

The name of the module that this loader will handle.

path

The path to the source file.

is_package (*fullname*)

Return `True` if *path* appears to be for a package.

path_stats (*path*)

Concrete implementation of `importlib.abc.SourceLoader.path_stats()`.

set_data (*path*, *data*)

Concrete implementation of `importlib.abc.SourceLoader.set_data()`.

load_module (*name=None*)

Concrete implementation of `importlib.abc.Loader.load_module()` where specifying the name of the module to load is optional.

在 3.6 版之後被用: Use `importlib.abc.Loader.exec_module()` instead.

class `importlib.machinery.SourcelessFileLoader` (*fullname*, *path*)

A concrete implementation of `importlib.abc.FileLoader` which can import bytecode files (i.e. no source code files exist).

Please note that direct use of bytecode files (and thus not source code files) inhibits your modules from being usable by all Python implementations or new versions of Python which change the bytecode format.

在 3.3 版被加入.

name

The name of the module the loader will handle.

path

The path to the bytecode file.

is_package (*fullname*)

Determines if the module is a package based on *path*.

get_code (*fullname*)

Returns the code object for *name* created from *path*.

get_source (*fullname*)

Returns None as bytecode files have no source when this loader is used.

load_module (*name=None*)

Concrete implementation of `importlib.abc.Loader.load_module()` where specifying the name of the module to load is optional.

在 3.6 版之後被用: Use `importlib.abc.Loader.exec_module()` instead.

class `importlib.machinery.ExtensionFileLoader` (*fullname*, *path*)

A concrete implementation of `importlib.abc.ExecutionLoader` for extension modules.

The *fullname* argument specifies the name of the module the loader is to support. The *path* argument is the path to the extension module's file.

Note that, by default, importing an extension module will fail in subinterpreters if it doesn't implement multi-phase init (see [PEP 489](#)), even if it would otherwise import successfully.

在 3.3 版被加入.

在 3.12 版的變更: Multi-phase init is now required for use in subinterpreters.

name

Name of the module the loader supports.

path

Path to the extension module.

create_module (*spec*)

Creates the module object from the given specification in accordance with [PEP 489](#).

在 3.5 版被加入.

exec_module (*module*)

Initializes the given module object in accordance with [PEP 489](#).

在 3.5 版被加入。

is_package (*fullname*)

Returns True if the file path points to a package's `__init__` module based on [EXTENSION_SUFFIXES](#).

get_code (*fullname*)

Returns None as extension modules lack a code object.

get_source (*fullname*)

Returns None as extension modules do not have source code.

get_filename (*fullname*)

Returns *path*.

在 3.4 版被加入。

class `importlib.machinery.NamespaceLoader` (*name, path, path_finder*)

A concrete implementation of [importlib.abc.InspectLoader](#) for namespace packages. This is an alias for a private class and is only made public for introspecting the `__loader__` attribute on namespace packages:

```
>>> from importlib.machinery import NamespaceLoader
>>> import my_namespace
>>> isinstance(my_namespace.__loader__, NamespaceLoader)
True
>>> import importlib.abc
>>> isinstance(my_namespace.__loader__, importlib.abc.Loader)
True
```

在 3.11 版被加入。

class `importlib.machinery.ModuleSpec` (*name, loader, *, origin=None, loader_state=None, is_package=None*)

A specification for a module's import-system-related state. This is typically exposed as the module's `__spec__` attribute. In the descriptions below, the names in parentheses give the corresponding attribute available directly on the module object, e.g. `module.__spec__.origin == module.__file__`. Note, however, that while the *values* are usually equivalent, they can differ since there is no synchronization between the two objects. For example, it is possible to update the module's `__file__` at runtime and this will not be automatically reflected in the module's `__spec__.origin`, and vice versa.

在 3.4 版被加入。

name

(`__name__`)

The module's fully qualified name. The *finder* should always set this attribute to a non-empty string.

loader

(`__loader__`)

The *loader* used to load the module. The *finder* should always set this attribute.

origin

(`__file__`)

The location the *loader* should use to load the module. For example, for modules loaded from a .py file this is the filename. The *finder* should always set this attribute to a meaningful value for the *loader* to use. In the uncommon case that there is not one (like for namespace packages), it should be set to None.

submodule_search_locations`(__path__)`

The list of locations where the package's submodules will be found. Most of the time this is a single directory. The *finder* should set this attribute to a list, even an empty one, to indicate to the import system that the module is a package. It should be set to `None` for non-package modules. It is set automatically later to a special object for namespace packages.

loader_state

The *finder* may set this attribute to an object containing additional, module-specific data to use when loading the module. Otherwise it should be set to `None`.

cached`(__cached__)`

The filename of a compiled version of the module's code. The *finder* should always set this attribute but it may be `None` for modules that do not need compiled code stored.

parent`(__package__)`

(Read-only) The fully qualified name of the package the module is in (or the empty string for a top-level module). If the module is a package then this is the same as *name*.

has_location

True if the spec's *origin* refers to a loadable location,

False otherwise. This value impacts how *origin* is interpreted and how the module's `__file__` is populated.

class `importlib.machinery.AppleFrameworkLoader` (*name, path*)

A specialization of `importlib.machinery.ExtensionFileLoader` that is able to load extension modules in Framework format.

For compatibility with the iOS App Store, *all* binary modules in an iOS app must be dynamic libraries, contained in a framework with appropriate metadata, stored in the `Frameworks` folder of the packaged app. There can be only a single binary per framework, and there can be no executable binary material outside the `Frameworks` folder.

To accommodate this requirement, when running on iOS, extension module binaries are *not* packaged as `.so` files on `sys.path`, but as individual standalone frameworks. To discover those frameworks, this loader is registered against the `.framework` file extension, with a `.framework` file acting as a placeholder in the original location of the binary on `sys.path`. The `.framework` file contains the path of the actual binary in the `Frameworks` folder, relative to the app bundle. To allow for resolving a framework-packaged binary back to the original location, the framework is expected to contain a `.origin` file that contains the location of the `.framework` file, relative to the app bundle.

For example, consider the case of an import from `foo.bar` import `_whiz`, where `_whiz` is implemented with the binary module `sources/foo/bar/_whiz.abi3.so`, with `sources` being the location registered on `sys.path`, relative to the application bundle. This module *must* be distributed as `Frameworks/foo.bar._whiz.framework/foo.bar._whiz` (creating the framework name from the full import path of the module), with an `Info.plist` file in the `.framework` directory identifying the binary as a framework. The `foo.bar._whiz` module would be represented in the original location with a `sources/foo/bar/_whiz.abi3.framework` marker file, containing the path `Frameworks/foo.bar._whiz/framework/foo.bar._whiz`. The framework would also contain `Frameworks/foo.bar._whiz.framework/foo.bar._whiz.origin`, containing the path to the `.framework` file.

When a module is loaded with this loader, the `__file__` for the module will report as the location of the `.framework` file. This allows code to use the `__file__` of a module as an anchor for file system traversal. However, the spec *origin* will reference the location of the *actual* binary in the `.framework` folder.

The Xcode project building the app is responsible for converting any `.so` files from wherever they exist in the `PYTHONPATH` into frameworks in the `Frameworks` folder (including stripping extensions from the module file, the addition of framework metadata, and signing the resulting framework), and creating the `.framework` and `.origin` files. This will usually be done with a build step in the Xcode project; see the iOS documentation for details on how to construct this build step.

在 3.13 版被加入。

Availability: iOS.

name

Name of the module the loader supports.

path

Path to the `.framework` file for the extension module.

31.5.5 `importlib.util` -- Utility code for importers

原始碼: [Lib/importlib/util.py](#)

This module contains the various objects that help in the construction of an *importer*.

`importlib.util.MAGIC_NUMBER`

The bytes which represent the bytecode version number. If you need help with loading/writing bytecode then consider `importlib.abc.SourceLoader`.

在 3.4 版被加入。

`importlib.util.cache_from_source(path, debug_override=None, *, optimization=None)`

Return the [PEP 3147/PEP 488](#) path to the byte-compiled file associated with the source *path*. For example, if *path* is `/foo/bar/baz.py` the return value would be `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. The `cpython-32` string comes from the current magic tag (see `get_tag()`; if `sys.implementation.cache_tag` is not defined then `NotImplementedError` will be raised).

The *optimization* parameter is used to specify the optimization level of the bytecode file. An empty string represents no optimization, so `/foo/bar/baz.py` with an *optimization* of `' '` will result in a bytecode path of `/foo/bar/__pycache__/baz.cpython-32.pyc`. `None` causes the interpreter's optimization level to be used. Any other value's string representation is used, so `/foo/bar/baz.py` with an *optimization* of `2` will lead to the bytecode path of `/foo/bar/__pycache__/baz.cpython-32.opt-2.pyc`. The string representation of *optimization* can only be alphanumeric, else `ValueError` is raised.

The *debug_override* parameter is deprecated and can be used to override the system's value for `__debug__`. A `True` value is the equivalent of setting *optimization* to the empty string. A `False` value is the same as setting *optimization* to `1`. If both *debug_override* and *optimization* are not `None` then `TypeError` is raised.

在 3.4 版被加入。

在 3.5 版的變更: The *optimization* parameter was added and the *debug_override* parameter was deprecated.

在 3.6 版的變更: Accepts a *path-like object*.

`importlib.util.source_from_cache(path)`

Given the *path* to a [PEP 3147](#) file name, return the associated source code file path. For example, if *path* is `/foo/bar/__pycache__/baz.cpython-32.pyc` the returned path would be `/foo/bar/baz.py`. *path* need not exist, however if it does not conform to [PEP 3147](#) or [PEP 488](#) format, a `ValueError` is raised. If `sys.implementation.cache_tag` is not defined, `NotImplementedError` is raised.

在 3.4 版被加入。

在 3.6 版的變更: Accepts a *path-like object*.

`importlib.util.decode_source(source_bytes)`

Decode the given bytes representing source code and return it as a string with universal newlines (as required by `importlib.abc.InspectLoader.get_source()`).

在 3.4 版被加入。

`importlib.util.resolve_name(name, package)`

Resolve a relative module name to an absolute one.

If **name** has no leading dots, then **name** is simply returned. This allows for usage such as `importlib.util.resolve_name('sys', __spec__.parent)` without doing a check to see if the **package** argument is needed.

`ImportError` is raised if **name** is a relative module name but **package** is a false value (e.g. `None` or the empty string). `ImportError` is also raised if a relative name would escape its containing package (e.g. requesting `..bacon` from within the `spam` package).

在 3.3 版被加入。

在 3.9 版的變更: To improve consistency with import statements, raise `ImportError` instead of `ValueError` for invalid relative import attempts.

`importlib.util.find_spec(name, package=None)`

Find the *spec* for a module, optionally relative to the specified **package** name. If the module is in `sys.modules`, then `sys.modules[name].__spec__` is returned (unless the spec would be `None` or is not set, in which case `ValueError` is raised). Otherwise a search using `sys.meta_path` is done. `None` is returned if no spec is found.

If **name** is for a submodule (contains a dot), the parent module is automatically imported.

name and **package** work the same as for `import_module()`.

在 3.4 版被加入。

在 3.7 版的變更: Raises `ModuleNotFoundError` instead of `AttributeError` if **package** is in fact not a package (i.e. lacks a `__path__` attribute).

`importlib.util.module_from_spec(spec)`

Create a new module based on **spec** and `spec.loader.create_module`.

If `spec.loader.create_module` does not return `None`, then any pre-existing attributes will not be reset. Also, no `AttributeError` will be raised if triggered while accessing **spec** or setting an attribute on the module.

This function is preferred over using `types.ModuleType` to create a new module as **spec** is used to set as many import-controlled attributes on the module as possible.

在 3.5 版被加入。

`importlib.util.spec_from_loader(name, loader, *, origin=None, is_package=None)`

A factory function for creating a `ModuleSpec` instance based on a loader. The parameters have the same meaning as they do for `ModuleSpec`. The function uses available *loader* APIs, such as `InspectLoader.is_package()`, to fill in any missing information on the spec.

在 3.4 版被加入。

`importlib.util.spec_from_file_location(name, location, *, loader=None, submodule_search_locations=None)`

A factory function for creating a `ModuleSpec` instance based on the path to a file. Missing information will be filled in on the spec by making use of loader APIs and by the implication that the module will be file-based.

在 3.4 版被加入。

在 3.6 版的變更: Accepts a *path-like object*.

```
importlib.util.source_hash(source_bytes)
```

Return the hash of *source_bytes* as bytes. A hash-based `.pyc` file embeds the `source_hash()` of the corresponding source file's contents in its header.

在 3.7 版被加入。

```
importlib.util.__incompatible_extension_module_restrictions(* , disable_check)
```

A context manager that can temporarily skip the compatibility check for extension modules. By default the check is enabled and will fail when a single-phase init module is imported in a subinterpreter. It will also fail for a multi-phase init module that doesn't explicitly support a per-interpreter GIL, when imported in an interpreter with its own GIL.

Note that this function is meant to accommodate an unusual case; one which is likely to eventually go away. There's a pretty good chance this is not what you were looking for.

You can get the same effect as this function by implementing the basic interface of multi-phase init ([PEP 489](#)) and lying about support for multiple interpreters (or per-interpreter GIL).

警告

Using this function to disable the check can lead to unexpected behavior and even crashes. It should only be used during extension module development.

在 3.12 版被加入。

```
class importlib.util.LazyLoader(loader)
```

A class which postpones the execution of the loader of a module until the module has an attribute accessed.

This class **only** works with loaders that define `exec_module()` as control over what module type is used for the module is required. For those same reasons, the loader's `create_module()` method must return `None` or a type for which its `__class__` attribute can be mutated along with not using `slots`. Finally, modules which substitute the object placed into `sys.modules` will not work as there is no way to properly replace the module references throughout the interpreter safely; `ValueError` is raised if such a substitution is detected.

備 註

For projects where startup time is critical, this class allows for potentially minimizing the cost of loading a module if it is never used. For projects where startup time is not essential then use of this class is **heavily** discouraged due to error messages created during loading being postponed and thus occurring out of context.

在 3.5 版被加入。

在 3.6 版的變更: Began calling `create_module()`, removing the compatibility warning for `importlib.machinery.BuiltinImporter` and `importlib.machinery.ExtensionFileLoader`.

```
classmethod factory(loader)
```

A class method which returns a callable that creates a lazy loader. This is meant to be used in situations where the loader is passed by class instead of by instance.

```
suffixes = importlib.machinery.SOURCE_SUFFIXES
loader = importlib.machinery.SourceFileLoader
lazy_loader = importlib.util.LazyLoader.factory(loader)
finder = importlib.machinery.FileFinder(path, (lazy_loader, suffixes))
```

31.5.6 范例

Importing programmatically

To programmatically import a module, use `importlib.import_module()`.

```
import importlib

itertools = importlib.import_module('itertools')
```

Checking if a module can be imported

If you need to find out if a module can be imported without actually doing the import, then you should use `importlib.util.find_spec()`.

Note that if name is a submodule (contains a dot), `importlib.util.find_spec()` will import the parent module.

```
import importlib.util
import sys

# For illustrative purposes.
name = 'itertools'

if name in sys.modules:
    print(f"{name!r} already in sys.modules")
elif (spec := importlib.util.find_spec(name)) is not None:
    # If you chose to perform the actual import ...
    module = importlib.util.module_from_spec(spec)
    sys.modules[name] = module
    spec.loader.exec_module(module)
    print(f"{name!r} has been imported")
else:
    print(f"can't find the {name!r} module")
```

Importing a source file directly

To import a Python source file directly, use the following recipe:

```
import importlib.util
import sys

# For illustrative purposes.
import tokenize
file_path = tokenize.__file__
module_name = tokenize.__name__

spec = importlib.util.spec_from_file_location(module_name, file_path)
module = importlib.util.module_from_spec(spec)
sys.modules[module_name] = module
spec.loader.exec_module(module)
```

Implementing lazy imports

The example below shows how to implement lazy imports:

```
>>> import importlib.util
>>> import sys
>>> def lazy_import(name):
...     spec = importlib.util.find_spec(name)
...     loader = importlib.util.LazyLoader(spec.loader)
...     spec.loader = loader
...     module = importlib.util.module_from_spec(spec)
...     sys.modules[name] = module
...     loader.exec_module(module)
...     return module
...
>>> lazy_typing = lazy_import("typing")
>>> #lazy_typing is a real module object,
>>> #but it is not loaded in memory yet.
>>> lazy_typing.TYPE_CHECKING
False
```

Setting up an importer

For deep customizations of import, you typically want to implement an *importer*. This means managing both the *finder* and *loader* side of things. For finders there are two flavours to choose from depending on your needs: a *meta path finder* or a *path entry finder*. The former is what you would put on `sys.meta_path` while the latter is what you create using a *path entry hook* on `sys.path_hooks` which works with `sys.path` entries to potentially create a finder. This example will show you how to register your own importers so that import will use them (for creating an importer for yourself, read the documentation for the appropriate classes defined within this package):

```
import importlib.machinery
import sys

# For illustrative purposes only.
SpamMetaPathFinder = importlib.machinery.PathFinder
SpamPathEntryFinder = importlib.machinery.FileFinder
loader_details = (importlib.machinery.SourceFileLoader,
                  importlib.machinery.SOURCE_SUFFIXES)

# Setting up a meta path finder.
# Make sure to put the finder in the proper location in the list in terms of
# priority.
sys.meta_path.append(SpamMetaPathFinder)

# Setting up a path entry finder.
# Make sure to put the path hook in the proper location in the list in terms
# of priority.
sys.path_hooks.append(SpamPathEntryFinder.path_hook(loader_details))
```

Approximating `importlib.import_module()`

Import itself is implemented in Python code, making it possible to expose most of the import machinery through `importlib`. The following helps illustrate the various APIs that `importlib` exposes by providing an approximate implementation of `importlib.import_module()`:

```
import importlib.util
import sys

def import_module(name, package=None):
    """An approximate implementation of import."""
    absolute_name = importlib.util.resolve_name(name, package)
    try:
        return sys.modules[absolute_name]
    except KeyError:
        pass

    path = None
    if '.' in absolute_name:
        parent_name, _, child_name = absolute_name.rpartition('.')
        parent_module = import_module(parent_name)
        path = parent_module.__spec__.submodule_search_locations
        for finder in sys.meta_path:
            spec = finder.find_spec(absolute_name, path)
            if spec is not None:
                break
        else:
            msg = f'No module named {absolute_name!r}'
            raise ModuleNotFoundError(msg, name=absolute_name)
    module = importlib.util.module_from_spec(spec)
    sys.modules[absolute_name] = module
    spec.loader.exec_module(module)
    if path is not None:
        setattr(parent_module, child_name, module)
    return module
```

31.6 `importlib.resources` -- Package resource reading, opening and access

原始碼: `Lib/importlib/resources/__init__.py`

在 3.7 版被加入。

This module leverages Python's import system to provide access to *resources* within *packages*.

”Resources” are file-like resources associated with a module or package in Python. The resources may be contained directly in a package, within a subdirectory contained in that package, or adjacent to modules outside a package. Resources may be text or binary. As a result, Python module sources (.py) of a package and compilation artifacts (pycache) are technically de-facto resources of that package. In practice, however, resources are primarily those non-Python artifacts exposed specifically by the package author.

Resources can be opened or read in either binary or text mode.

Resources are roughly akin to files inside directories, though it's important to keep in mind that this is just a metaphor. Resources and packages **do not** have to exist as physical files and directories on the file system: for example, a package and its resources can be imported from a zip file using `zipimport`.

備 F

This module provides functionality similar to `pkg_resources Basic Resource Access` without the performance overhead of that package. This makes reading resources included in packages easier, with more stable and consistent semantics.

The standalone backport of this module provides more information on [using `importlib.resources`](#) and [migrating from `pkg_resources` to `importlib.resources`](#).

Loaders that wish to support resource reading should implement a `get_resource_reader(fullname)` method as specified by `importlib.resources.abc.ResourceReader`.

class `importlib.resources.Anchor`

Represents an anchor for resources, either a *module object* or a module name as a string. Defined as `Union[str, ModuleType]`.

`importlib.resources.files(anchor: Anchor | None = None)`

Returns a *Traversable* object representing the resource container (think directory) and its resources (think files). A *Traversable* may contain other containers (think subdirectories).

anchor is an optional *Anchor*. If the anchor is a package, resources are resolved from that package. If a module, resources are resolved adjacent to that module (in the same package or the package root). If the anchor is omitted, the caller's module is used.

在 3.9 版被加入.

在 3.12 版的變更: *package* parameter was renamed to *anchor*. *anchor* can now be a non-package module and if omitted will default to the caller's module. *package* is still accepted for compatibility but will raise a *DeprecationWarning*. Consider passing the anchor positionally or using `importlib_resources >= 5.10` for a compatible interface on older Pythons.

`importlib.resources.as_file(traversable)`

Given a *Traversable* object representing a file or directory, typically from `importlib.resources.files()`, return a context manager for use in a `with` statement. The context manager provides a *pathlib.Path* object.

Exiting the context manager cleans up any temporary file or directory created when the resource was extracted from e.g. a zip file.

Use `as_file` when the *Traversable* methods (`read_text`, etc) are insufficient and an actual file or directory on the file system is required.

在 3.9 版被加入.

在 3.12 版的變更: Added support for *traversable* representing a directory.

31.6.1 Functional API

A set of simplified, backwards-compatible helpers is available. These allow common operations in a single function call.

For all the following functions:

- *anchor* is an *Anchor*, as in `files()`. Unlike in `files`, it may not be omitted.
- *path_names* are components of a resource's path name, relative to the anchor. For example, to get the text of resource named `info.txt`, use:

```
importlib.resources.read_text(my_module, "info.txt")
```

Like *Traversable.joinpath*, The individual components should use forward slashes (/) as path separators. For example, the following are equivalent:

```
importlib.resources.read_binary(my_module, "pics/painting.png")
importlib.resources.read_binary(my_module, "pics", "painting.png")
```

For backward compatibility reasons, functions that read text require an explicit *encoding* argument if multiple *path_names* are given. For example, to get the text of `info/chapter1.txt`, use:

```
importlib.resources.read_text(my_module, "info", "chapter1.txt",
                             encoding='utf-8')
```

`importlib.resources.open_binary(anchor, *path_names)`

Open the named resource for binary reading.

See [the introduction](#) for details on *anchor* and *path_names*.

This function returns a *BinaryIO* object, that is, a binary stream open for reading.

This function is roughly equivalent to:

```
files(anchor).joinpath(*path_names).open('rb')
```

在 3.13 版的變更: Multiple *path_names* are accepted.

`importlib.resources.open_text(anchor, *path_names, encoding='utf-8', errors='strict')`

Open the named resource for text reading. By default, the contents are read as strict UTF-8.

See [the introduction](#) for details on *anchor* and *path_names*. *encoding* and *errors* have the same meaning as in built-in `open()`.

For backward compatibility reasons, the *encoding* argument must be given explicitly if there are multiple *path_names*. This limitation is scheduled to be removed in Python 3.15.

This function returns a *TextIO* object, that is, a text stream open for reading.

This function is roughly equivalent to:

```
files(anchor).joinpath(*path_names).open('r', encoding=encoding)
```

在 3.13 版的變更: Multiple *path_names* are accepted. *encoding* and *errors* must be given as keyword arguments.

`importlib.resources.read_binary(anchor, *path_names)`

Read and return the contents of the named resource as *bytes*.

See [the introduction](#) for details on *anchor* and *path_names*.

This function is roughly equivalent to:

```
files(anchor).joinpath(*path_names).read_bytes()
```

在 3.13 版的變更: Multiple *path_names* are accepted.

`importlib.resources.read_text(anchor, *path_names, encoding='utf-8', errors='strict')`

Read and return the contents of the named resource as *str*. By default, the contents are read as strict UTF-8.

See [the introduction](#) for details on *anchor* and *path_names*. *encoding* and *errors* have the same meaning as in built-in `open()`.

For backward compatibility reasons, the *encoding* argument must be given explicitly if there are multiple *path_names*. This limitation is scheduled to be removed in Python 3.15.

This function is roughly equivalent to:

```
files(anchor).joinpath(*path_names).read_text(encoding=encoding)
```

在 3.13 版的變更: Multiple *path_names* are accepted. *encoding* and *errors* must be given as keyword arguments.

`importlib.resources.path(anchor, *path_names)`

Provides the path to the *resource* as an actual file system path. This function returns a context manager for use in a `with` statement. The context manager provides a `pathlib.Path` object.

Exiting the context manager cleans up any temporary files created, e.g. when the resource needs to be extracted from a zip file.

For example, the `stat()` method requires an actual file system path; it can be used like this:

```
with importlib.resources.path(anchor, "resource.txt") as fspath:
    result = fspath.stat()
```

See [the introduction](#) for details on *anchor* and *path_names*.

This function is roughly equivalent to:

```
as_file(files(anchor).joinpath(*path_names))
```

在 3.13 版的變更: Multiple *path_names* are accepted. *encoding* and *errors* must be given as keyword arguments.

`importlib.resources.is_resource(anchor, *path_names)`

Return True if the named resource exists, otherwise False. This function does not consider directories to be resources.

See [the introduction](#) for details on *anchor* and *path_names*.

This function is roughly equivalent to:

```
files(anchor).joinpath(*path_names).is_file()
```

在 3.13 版的變更: Multiple *path_names* are accepted.

`importlib.resources.contents(anchor, *path_names)`

Return an iterable over the named items within the package or path. The iterable returns names of resources (e.g. files) and non-resources (e.g. directories) as *str*. The iterable does not recurse into subdirectories.

See [the introduction](#) for details on *anchor* and *path_names*.

This function is roughly equivalent to:

```
for resource in files(anchor).joinpath(*path_names).iterdir():
    yield resource.name
```

在 3.11 版之後被 F 用: Prefer `iterdir()` as above, which offers more control over the results and richer functionality.

31.7 importlib.resources.abc -- 資源的抽象基底類 F

原始碼: [Lib/importlib/resources/abc.py](#)

在 3.11 版被加入.

class `importlib.resources.abc.ResourceReader`

Superseded by TraversableResources

An *abstract base class* to provide the ability to read *resources*.

From the perspective of this ABC, a *resource* is a binary artifact that is shipped within a package. Typically this is something like a data file that lives next to the `__init__.py` file of the package. The purpose of this class is to help abstract out the accessing of such data files so that it does not matter if the package and its data file(s) are stored e.g. in a zip file versus on the file system.

For any of methods of this class, a *resource* argument is expected to be a *path-like object* which represents conceptually just a file name. This means that no subdirectory paths should be included in the *resource* argument. This is because the location of the package the reader is for, acts as the "directory". Hence the metaphor for directories and file names is packages and resources, respectively. This is also why instances of this class are expected to directly correlate to a specific package (instead of potentially representing multiple packages or a module).

Loaders that wish to support resource reading are expected to provide a method called `get_resource_reader(fullname)` which returns an object implementing this ABC's interface. If the module specified by `fullname` is not a package, this method should return `None`. An object compatible with this ABC should only be returned when the specified module is a package.

Deprecated since version 3.12, will be removed in version 3.14: Use `importlib.resources.abc.TraversableResources` instead.

abstractmethod `open_resource(resource)`

Returns an opened, *file-like object* for binary reading of the *resource*.

If the resource cannot be found, `FileNotFoundError` is raised.

abstractmethod `resource_path(resource)`

Returns the file system path to the *resource*.

If the resource does not concretely exist on the file system, raise `FileNotFoundError`.

abstractmethod `is_resource(name)`

Returns `True` if the named *name* is considered a resource. `FileNotFoundError` is raised if *name* does not exist.

abstractmethod `contents()`

Returns an *iterable* of strings over the contents of the package. Do note that it is not required that all names returned by the iterator be actual resources, e.g. it is acceptable to return names for which `is_resource()` would be false.

Allowing non-resource names to be returned is to allow for situations where how a package and its resources are stored are known a priori and the non-resource names would be useful. For instance, returning subdirectory names is allowed so that when it is known that the package and resources are stored on the file system then those subdirectory names can be used directly.

The abstract method returns an iterable of no items.

class `importlib.resources.abc.Traversable`

An object with a subset of `pathlib.Path` methods suitable for traversing directories and opening files.

For a representation of the object on the file-system, use `importlib.resources.as_file()`.

name

Abstract. The base name of this object without any parent references.

abstractmethod `iterdir()`

Yield `Traversable` objects in self.

abstractmethod `is_dir()`

Return `True` if self is a directory.

abstractmethod `is_file()`

Return `True` if self is a file.

abstractmethod `joinpath(*pathsegments)`

Traverse directories according to *pathsegments* and return the result as `Traversable`.

Each *pathsegments* argument may contain multiple names separated by forward slashes (`/`, `posixpath.sep`). For example, the following are equivalent:

```
files.joinpath('subdir', 'subsudir', 'file.txt')
files.joinpath('subdir/subsudir/file.txt')
```

Note that some `Traversable` implementations might not be updated to the latest version of the protocol. For compatibility with such implementations, provide a single argument without path separators to each call to `joinpath`. For example:

```
files.joinpath('subdir').joinpath('subsudir').joinpath('file.txt')
```

在 3.11 版的變更: `joinpath` accepts multiple *pathsegments*, and these segments may contain forward slashes as path separators. Previously, only a single *child* argument was accepted.

abstractmethod `__truediv__(child)`

Return `Traversable` child in self. Equivalent to `joinpath(child)`.

abstractmethod `open(mode='r', *args, **kwargs)`

mode may be 'r' or 'rb' to open as text or binary. Return a handle suitable for reading (same as `pathlib.Path.open`).

When opening as text, accepts encoding parameters such as those accepted by `io.TextIOWrapper`.

read_bytes()

Read contents of self as bytes.

read_text(encoding=None)

Read contents of self as text.

class `importlib.resources.abc.TraversableResources`

An abstract base class for resource readers capable of serving the `importlib.resources.files()` interface. Subclasses `ResourceReader` and provides concrete implementations of the `ResourceReader`'s abstract methods. Therefore, any loader supplying `TraversableResources` also supplies `ResourceReader`.

Loaders that wish to support resource reading are expected to implement this interface.

abstractmethod `files()`

Returns a `importlib.resources.abc.Traversable` object for the loaded package.

31.8 importlib.metadata -- 存取套件的元資料

在 3.8 版被加入。

在 3.10 版的變更: `importlib.metadata` is no longer provisional.

原始碼: `Lib/importlib/metadata/__init__.py`

`importlib.metadata` is a library that provides access to the metadata of an installed [Distribution Package](#), such as its entry points or its top-level names ([Import Packages](#), modules, if any). Built in part on Python's import system, this library intends to replace similar functionality in the [entry point API](#) and [metadata API](#) of `pkg_resources`. Along with `importlib.resources`, this package can eliminate the need to use the older and less efficient `pkg_resources` package.

`importlib.metadata` operates on third-party *distribution packages* installed into Python's site-packages directory via tools such as [pip](#). Specifically, it works with distributions with discoverable `dist-info` or `egg-info` directories, and metadata defined by the [Core metadata specifications](#).

重要

These are *not* necessarily equivalent to or correspond 1:1 with the top-level *import package* names that can be imported inside Python code. One *distribution package* can contain multiple *import packages* (and single modules),

and one top-level *import package* may map to multiple *distribution packages* if it is a namespace package. You can use `packages_distributions()` to get a mapping between them.

By default, distribution metadata can live on the file system or in zip archives on `sys.path`. Through an extension mechanism, the metadata can live almost anywhere.

也參考

<https://importlib-metadata.readthedocs.io/>

The documentation for `importlib_metadata`, which supplies a backport of `importlib.metadata`. This includes an [API reference](#) for this module's classes and functions, as well as a [migration guide](#) for existing users of `pkg_resources`.

31.8.1 Overview

Let's say you wanted to get the version string for a [Distribution Package](#) you've installed using `pip`. We start by creating a virtual environment and installing something into it:

```
$ python -m venv example
$ source example/bin/activate
(example) $ python -m pip install wheel
```

You can get the version string for `wheel` by running the following:

```
(example) $ python
>>> from importlib.metadata import version
>>> version('wheel')
'0.32.3'
```

You can also get a collection of entry points selectable by properties of the `EntryPoint` (typically 'group' or 'name'), such as `console_scripts`, `distutils.commands` and others. Each group contains a collection of [Entry-Point](#) objects.

You can get the *metadata for a distribution*:

```
>>> list(metadata('wheel'))
['Metadata-Version', 'Name', 'Version', 'Summary', 'Home-page', 'Author', 'Author-
→email', 'Maintainer', 'Maintainer-email', 'License', 'Project-URL', 'Project-URL
→', 'Project-URL', 'Keywords', 'Platform', 'Classifier', 'Classifier', 'Classifier
→', 'Classifier', 'Classifier', 'Classifier', 'Classifier', 'Classifier',
→'Classifier', 'Classifier', 'Classifier', 'Classifier', 'Requires-Python',
→'Provides-Extra', 'Requires-Dist', 'Requires-Dist']
```

You can also get a *distribution's version number*, list its *constituent files*, and get a list of the distribution's *Distribution requirements*.

31.8.2 Functional API

This package provides the following functionality via its public API.

Entry points

The `entry_points()` function returns a collection of entry points. Entry points are represented by `EntryPoint` instances; each `EntryPoint` has a `.name`, `.group`, and `.value` attributes and a `.load()` method to resolve the value. There are also `.module`, `.attr`, and `.extras` attributes for getting the components of the `.value` attribute.

Query all entry points:

```
>>> eps = entry_points()
```

The `entry_points()` function returns an `EntryPoints` object, a collection of all `EntryPoint` objects with `names` and `groups` attributes for convenience:

```
>>> sorted(eps.groups)
['console_scripts', 'distutils.commands', 'distutils.setup_keywords', 'egg_info.
↳ writers', 'setuptools.installation']
```

`EntryPoints` has a `select` method to select entry points matching specific properties. Select entry points in the `console_scripts` group:

```
>>> scripts = eps.select(group='console_scripts')
```

Equivalently, since `entry_points` passes keyword arguments through to `select`:

```
>>> scripts = entry_points(group='console_scripts')
```

Pick out a specific script named "wheel" (found in the wheel project):

```
>>> 'wheel' in scripts.names
True
>>> wheel = scripts['wheel']
```

Equivalently, query for that entry point during selection:

```
>>> (wheel,) = entry_points(group='console_scripts', name='wheel')
>>> (wheel,) = entry_points().select(group='console_scripts', name='wheel')
```

Inspect the resolved entry point:

```
>>> wheel
EntryPoint(name='wheel', value='wheel.cli:main', group='console_scripts')
>>> wheel.module
'wheel.cli'
>>> wheel.attr
'main'
>>> wheel.extras
[]
>>> main = wheel.load()
>>> main
<function main at 0x103528488>
```

The `group` and `name` are arbitrary values defined by the package author and usually a client will wish to resolve all entry points for a particular group. Read [the setuptools docs](#) for more information on entry points, their definition, and usage.

在 3.12 版的變更: The "selectable" entry points were introduced in `importlib_metadata` 3.6 and Python 3.10. Prior to those changes, `entry_points` accepted no parameters and always returned a dictionary of entry

points, keyed by group. With `importlib_metadata 5.0` and Python 3.12, `entry_points` always returns an `EntryPoint` object. See [backports.entry_points_selectable](#) for compatibility options.

在 3.13 版的變更: `EntryPoint` objects no longer present a tuple-like interface (`__getitem__()`).

Distribution metadata

Every [Distribution Package](#) includes some metadata, which you can extract using the `metadata()` function:

```
>>> wheel_metadata = metadata('wheel')
```

The keys of the returned data structure, a `PackageMetadata`, name the metadata keywords, and the values are returned unparsed from the distribution metadata:

```
>>> wheel_metadata['Requires-Python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
```

`PackageMetadata` also presents a `json` attribute that returns all the metadata in a JSON-compatible form per [PEP 566](#):

```
>>> wheel_metadata.json['requires_python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
```

備 F

The actual type of the object returned by `metadata()` is an implementation detail and should be accessed only through the interface described by the [PackageMetadata protocol](#).

在 3.10 版的變更: The `Description` is now included in the metadata when presented through the payload. Line continuation characters have been removed.

新增 `json` 屬性。

Distribution versions

The `version()` function is the quickest way to get a [Distribution Package](#)'s version number, as a string:

```
>>> version('wheel')
'0.32.3'
```

Distribution files

You can also get the full set of files contained within a distribution. The `files()` function takes a [Distribution Package](#) name and returns all of the files installed by this distribution. Each file object returned is a `PackagePath`, a `pathlib.PurePath` derived object with additional `dist`, `size`, and `hash` properties as indicated by the metadata. For example:

```
>>> util = [p for p in files('wheel') if 'util.py' in str(p)][0]
>>> util
PackagePath('wheel/util.py')
>>> util.size
859
>>> util.dist
<importlib.metadata._hooks.PathDistribution object at 0x101e0cef0>
>>> util.hash
<FileHash mode: sha256 value: bYkw5oMccfazVCoYQwKkkemoVyMAFoR34mmKBx8R1NI>
```

Once you have the file, you can also read its contents:

```
>>> print(util.read_text())
import base64
import sys
...
def as_bytes(s):
    if isinstance(s, text_type):
        return s.encode('utf-8')
    return s
```

You can also use the `locate` method to get a the absolute path to the file:

```
>>> util.locate()
PosixPath('/home/gustav/example/lib/site-packages/wheel/util.py')
```

In the case where the metadata file listing files (RECORD or SOURCES.txt) is missing, `files()` will return `None`. The caller may wish to wrap calls to `files()` in `always_iterable` or otherwise guard against this condition if the target distribution is not known to have the metadata present.

Distribution requirements

To get the full set of requirements for a [Distribution Package](#), use the `requires()` function:

```
>>> requires('wheel')
["pytest (>=3.0.0) ; extra == 'test'", "pytest-cov ; extra == 'test'"]
```

Mapping import to distribution packages

A convenience method to resolve the [Distribution Package](#) name (or names, in the case of a namespace package) that provide each importable top-level Python module or [Import Package](#):

```
>>> packages_distributions()
{'importlib_metadata': ['importlib-metadata'], 'yaml': ['PyYAML'], 'jaraco': [
  ↳ 'jaraco.classes', 'jaraco.functools'], ...}
```

Some editable installs, [do not supply top-level names](#), and thus this function is not reliable with such installs.

在 3.10 版被加入.

31.8.3 Distributions

While the above API is the most common and convenient usage, you can get all of that information from the `Distribution` class. A `Distribution` is an abstract object that represents the metadata for a Python [Distribution Package](#). You can get the `Distribution` instance:

```
>>> from importlib.metadata import distribution
>>> dist = distribution('wheel')
```

Thus, an alternative way to get the version number is through the `Distribution` instance:

```
>>> dist.version
'0.32.3'
```

There are all kinds of additional metadata available on the `Distribution` instance:

```
>>> dist.metadata['Requires-Python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
>>> dist.metadata['License']
'MIT'
```

For editable packages, an `origin` property may present **PEP 610** metadata:

```
>>> dist.origin.url
'file:///path/to/wheel-0.32.3.editable-py3-none-any.whl'
```

The full set of available metadata is not described here. See the [Core metadata specifications](#) for additional details.

在 3.13 版被加入: The `.origin` property was added.

31.8.4 Distribution Discovery

By default, this package provides built-in support for discovery of metadata for file system and zip file [Distribution Packages](#). This metadata finder search defaults to `sys.path`, but varies slightly in how it interprets those values from how other import machinery does. In particular:

- `importlib.metadata` does not honor *bytes* objects on `sys.path`.
- `importlib.metadata` will incidentally honor *pathlib.Path* objects on `sys.path` even though such values will be ignored for imports.

31.8.5 Extending the search algorithm

Because [Distribution Package](#) metadata is not available through *sys.path* searches, or package loaders directly, the metadata for a distribution is found through import system finders. To find a distribution package's metadata, `importlib.metadata` queries the list of *meta path finders* on *sys.meta_path*.

By default `importlib.metadata` installs a finder for distribution packages found on the file system. This finder doesn't actually find any *distributions*, but it can find their metadata.

The abstract class `importlib.abc.MetaPathFinder` defines the interface expected of finders by Python's import system. `importlib.metadata` extends this protocol by looking for an optional `find_distributions` callable on the finders from *sys.meta_path* and presents this extended interface as the `DistributionFinder` abstract base class, which defines this abstract method:

```
@abc.abstractmethod
def find_distributions(context=DistributionFinder.Context()):
    """Return an iterable of all Distribution instances capable of
    loading the metadata for packages for the indicated ``context``.
    """
```

The `DistributionFinder.Context` object provides `.path` and `.name` properties indicating the path to search and name to match and may supply other relevant context.

What this means in practice is that to support finding distribution package metadata in locations other than the file system, subclass `DistributionFinder` and implement the abstract methods. Then from a custom finder, return instances of this derived `Distribution` in the `find_distributions()` method.

Example

Consider for example a custom finder that loads Python modules from a database:

```
class DatabaseImporter(importlib.abc.MetaPathFinder):
    def __init__(self, db):
        self.db = db

    def find_spec(self, fullname, target=None) -> ModuleSpec:
        return self.db.spec_from_name(fullname)

sys.meta_path.append(DatabaseImporter(connect_db(...)))
```

That importer now presumably provides importable modules from a database, but it provides no metadata or entry points. For this custom importer to provide metadata, it would also need to implement `DistributionFinder`:

```
from importlib.metadata import DistributionFinder

class DatabaseImporter(DistributionFinder):
    ...

    def find_distributions(self, context=DistributionFinder.Context()):
        query = dict(name=context.name if context.name else {}
        for dist_record in self.db.query_distributions(query):
            yield DatabaseDistribution(dist_record)
```

In this way, `query_distributions` would return records for each distribution served by the database matching the query. For example, if `requests-1.0` is in the database, `find_distributions` would yield a `DatabaseDistribution` for `Context(name='requests')` or `Context(name=None)`.

For the sake of simplicity, this example ignores `context.path`. The `path` attribute defaults to `sys.path` and is the set of import paths to be considered in the search. A `DatabaseImporter` could potentially function without any concern for a search path. Assuming the importer does no partitioning, the “path” would be irrelevant. In order to illustrate the purpose of `path`, the example would need to illustrate a more complex `DatabaseImporter` whose behavior varied depending on `sys.path`/`PYTHONPATH`. In that case, the `find_distributions` should honor the `context.path` and only yield `Distributions` pertinent to that path.

`DatabaseDistribution`, then, would look something like:

```
class DatabaseDistribution(importlib.metadata.Distribution):
    def __init__(self, record):
        self.record = record

    def read_text(self, filename):
        """
        Read a file like "METADATA" for the current distribution.
        """
        if filename == "METADATA":
            return f"""Name: {self.record.name}
Version: {self.record.version}
"""
        if filename == "entry_points.txt":
            return "\n".join(
                f"[{ep.group}]\n{ep.name}={ep.value}"
                for ep in self.record.entry_points)

    def locate_file(self, path):
        raise RuntimeError("This distribution has no file system")
```

This basic implementation should provide metadata and entry points for packages served by the `DatabaseImporter`, assuming that the record supplies suitable `.name`, `.version`, and `.entry_points` attributes.

The `DatabaseDistribution` may also provide other metadata files, like `RECORD` (required for `Distribution.files`) or override the implementation of `Distribution.files`. See the source for more inspiration.

31.9 The initialization of the `sys.path` module search path

A module search path is initialized when Python starts. This module search path may be accessed at `sys.path`.

The first entry in the module search path is the directory that contains the input script, if there is one. Otherwise, the first entry is the current directory, which is the case when executing the interactive shell, a `-c` command, or `-m` module.

The `PYTHONPATH` environment variable is often used to add directories to the search path. If this environment variable is found then the contents are added to the module search path.

備 發

`PYTHONPATH` will affect all installed Python versions/environments. Be wary of setting this in your shell profile or global environment variables. The `site` module offers more nuanced techniques as mentioned below.

The next items added are the directories containing standard Python modules as well as any *extension modules* that these modules depend on. Extension modules are `.pyd` files on Windows and `.so` files on other platforms. The directory with the platform-independent Python modules is called `prefix`. The directory with the extension modules is called `exec_prefix`.

The `PYTHONHOME` environment variable may be used to set the `prefix` and `exec_prefix` locations. Otherwise these directories are found by using the Python executable as a starting point and then looking for various 'landmark' files and directories. Note that any symbolic links are followed so the real Python executable location is used as the search starting point. The Python executable location is called `home`.

Once `home` is determined, the `prefix` directory is found by first looking for `pythonmajorversionminorversion.zip` (`python311.zip`). On Windows the zip archive is searched for in `home` and on Unix the archive is expected to be in `lib`. Note that the expected zip archive location is added to the module search path even if the archive does not exist. If no archive was found, Python on Windows will continue the search for `prefix` by looking for `Lib\os.py`. Python on Unix will look for `lib/pythonmajorversion.minorversion/os.py` (`lib/python3.11/os.py`). On Windows `prefix` and `exec_prefix` are the same, however on other platforms `lib/pythonmajorversion.minorversion/lib-dynload` (`lib/python3.11/lib-dynload`) is searched for and used as an anchor for `exec_prefix`. On some platforms `lib` may be `lib64` or another value, see `sys.platlibdir` and `PYTHONPLATLIBDIR`.

Once found, `prefix` and `exec_prefix` are available at `sys.prefix` and `sys.exec_prefix` respectively.

Finally, the `site` module is processed and `site-packages` directories are added to the module search path. A common way to customize the search path is to create `sitecustomize` or `usercustomize` modules as described in the `site` module documentation.

備 發

Certain command line options may further affect path calculations. See `-E`, `-I`, `-s` and `-S` for further details.

31.9.1 Virtual environments

If Python is run in a virtual environment (as described at [tut-venv](#)) then `prefix` and `exec_prefix` are specific to the virtual environment.

If a `pyvenv.cfg` file is found alongside the main executable, or in the directory one level above the executable, the following variations apply:

- If `home` is an absolute path and `PYTHONHOME` is not set, this path is used instead of the path to the main executable when deducing `prefix` and `exec_prefix`.

31.9.2 `._pth` files

To completely override `sys.path` create a `._pth` file with the same name as the shared library or executable (`python._pth` or `python311._pth`). The shared library path is always known on Windows, however it may not be available on other platforms. In the `._pth` file specify one line for each path to add to `sys.path`. The file based on the shared library name overrides the one based on the executable, which allows paths to be restricted for any program loading the runtime if desired.

When the file exists, all registry and environment variables are ignored, isolated mode is enabled, and `site` is not imported unless one line in the file specifies `import site`. Blank paths and lines starting with `#` are ignored. Each path may be absolute or relative to the location of the file. Import statements other than to `site` are not permitted, and arbitrary code cannot be specified.

Note that `._pth` files (without leading underscore) will be processed normally by the `site` module when `import site` has been specified.

31.9.3 Embedded Python

If Python is embedded within another application `Py_InitializeFromConfig()` and the `PyConfig` structure can be used to initialize Python. The path specific details are described at [init-path-config](#).

也参考

- [windows_finding_modules](#) for detailed Windows notes.
- [using-on-unix](#) for Unix details.

Python provides a number of modules to assist in working with the Python language. These modules support tokenizing, parsing, syntax analysis, bytecode disassembly, and various other facilities.

這些模組包括：

32.1 ast --- 抽象語法樹 (Abstract Syntax Trees)

原始碼：[Lib/ast.py](#)

`ast` 模組可以幫助 Python 應用程式處理 Python 抽象語法文法 (abstract syntax grammar) 樹狀資料結構。抽象語法本身可能會隨著每個 Python 版本發布而改變；此模組有助於以程式化的方式來得知當前文法的面貌。

要生成抽象語法樹，可以透過將 `ast.PyCF_ONLY_AST` 作旗標傳遞給 `compile()` 或使用此模組所提供的 `parse()` 輔助函式。結果將會是一個物件的樹，其類都繼承自 `ast.AST`。可以使用 `compile()` 函式將抽象語法樹編譯成 Python 程式碼物件。

32.1.1 抽象文法 (Abstract Grammar)

抽象文法目前定義如下：

```
-- ASDL's 4 builtin types are:
-- identifier, int, string, constant

module Python
{
    mod = Module(stmt* body, type_ignore* type_ignores)
        | Interactive(stmt* body)
        | Expression(expr body)
        | FunctionType(expr* argtypes, expr returns)

    stmt = FunctionDef(identifier name, arguments args,
                       stmt* body, expr* decorator_list, expr? returns,
                       string? type_comment, type_param* type_params)
```

(繼續下一頁)

(繼續上一頁)

```

| AsyncFunctionDef(identifier name, arguments args,
                    stmt* body, expr* decorator_list, expr? returns,
                    string? type_comment, type_param* type_params)

| ClassDef(identifier name,
            expr* bases,
            keyword* keywords,
            stmt* body,
            expr* decorator_list,
            type_param* type_params)
| Return(expr? value)

| Delete(expr* targets)
| Assign(expr* targets, expr value, string? type_comment)
| TypeAlias(expr name, type_param* type_params, expr value)
| AugAssign(expr target, operator op, expr value)
-- 'simple' indicates that we annotate simple name without parens
| AnnAssign(expr target, expr annotation, expr? value, int simple)

-- use 'orelse' because else is a keyword in target languages
| For(expr target, expr iter, stmt* body, stmt* orelse, string? type_
↪comment)
| AsyncFor(expr target, expr iter, stmt* body, stmt* orelse, string? ↪
↪type_comment)
| While(expr test, stmt* body, stmt* orelse)
| If(expr test, stmt* body, stmt* orelse)
| With(withitem* items, stmt* body, string? type_comment)
| AsyncWith(withitem* items, stmt* body, string? type_comment)

| Match(expr subject, match_case* cases)

| Raise(expr? exc, expr? cause)
| Try(stmt* body, excepthandler* handlers, stmt* orelse, stmt* finalbody)
↪finalbody)
| TryStar(stmt* body, excepthandler* handlers, stmt* orelse, stmt* ↪
↪finalbody)
| Assert(expr test, expr? msg)

| Import(alias* names)
| ImportFrom(identifier? module, alias* names, int? level)

| Global(identifier* names)
| Nonlocal(identifier* names)
| Expr(expr value)
| Pass | Break | Continue

-- col_offset is the byte offset in the utf8 string the parser uses
attributes (int lineno, int col_offset, int? end_lineno, int? end_col_
↪offset)

-- BoolOp() can use left & right?
expr = BoolOp(boolop op, expr* values)
| NamedExpr(expr target, expr value)
| BinOp(expr left, operator op, expr right)
| UnaryOp(unaryop op, expr operand)
| Lambda(arguments args, expr body)
| IfExp(expr test, expr body, expr orelse)

}

```

32.1.2 節點 (Node) 類

class ast.AST

這是所有 AST 節點類的基礎。實際的節點類是衍生自 Parser/Python.asdl 檔案，該檔案在上方重現。它們被定義於 `_ast` 的 C 模組中，在 `ast` 中重新匯出。

抽象文法中每個左側符號定義了一個類（例如 `ast.stmt` 或 `ast.expr`）。此外，也每個右側的建構函式 (constructor) 定義了一個類；這些類繼承自左側樹的類。例如，`ast.BinOp` 繼承自 `ast.expr`。對於具有替代方案（即「和 (sums)」的生規則，左側類是抽象的：僅有特定建構函式節點的實例會被建立。

`_fields`

Each concrete class has an attribute `_fields` which gives the names of all child nodes.

具體類的每個實例對於每個子節點都有一個屬性，其型如文法中所定義。例如，`ast.BinOp` 實例具有型 `ast.expr` 的屬性 `left`。

如果這些屬性在文法中被標記可選（使用問號），則該值可能 `None`。如果屬性可以有零個或多個值（用星號標記），則這些值將表示 Python 串列。使用 `compile()` 編譯 AST 時，所有可能的屬性都必須存在且具有有效值。

`_field_types`

The `_field_types` attribute on each concrete class is a dictionary mapping field names (as also listed in `_fields`) to their types.

```

>>> ast.TypeVar._field_types
{'name': <class 'str'>, 'bound': ast.expr | None, 'default_value': ast.
↵expr | None}

```

在 3.13 版被加入。

`lineno`

`col_offset`

`end_lineno`

`end_col_offset`

`ast.expr` 和 `ast.stmt` 子類 的實例具有 `lineno`、`col_offset`、`end_lineno` 和 `end_col_offset` 屬性。`lineno` 和 `end_lineno` 是原始文本跨度 (source text span) 的第一個和最後一個列號 (1-indexed, 因此第一列號是 1) 以及 `col_offset` 和 `end_col_offset` 是生成節點的第一個和最後一個標記對應的 UTF-8 位元組偏移量。會記 UTF-8 偏移量是因 剖析器 (parser) 部使用 UTF-8。

請注意，編譯器 不需要結束位置，因此其 可選的。結束偏移量在最後一個符號之後，例如可以使用 `source_line[node.col_offset : node.end_col_offset]` 來獲取單列運算式節點 (expression node) 的原始片段。

`ast.T` 類 的建構函式按以下方式剖析其引數：

- 如果有位置引數，則必須與 `T._fields` 中的項目一樣多；它們將被賦 這些名稱的屬性。
- 如果有關鍵字引數，它們會將相同名稱的屬性設定 給定值。

例如，要建立 填充 (populate) `ast.UnaryOp` 節點，你可以使用：

```
node = ast.UnaryOp(ast.USub(), ast.Constant(5, lineno=0, col_offset=0),
                  lineno=0, col_offset=0)
```

If a field that is optional in the grammar is omitted from the constructor, it defaults to `None`. If a list field is omitted, it defaults to the empty list. If a field of type `ast.expr_context` is omitted, it defaults to `Load()`. If any other field is omitted, a `DeprecationWarning` is raised and the AST node will not have this field. In Python 3.15, this condition will raise an error.

在 3.8 版的變更: `ast.Constant` 類 現在用於所有常數。

在 3.9 版的變更: 以它們的值表示簡單索引，擴充切片 (slice) 則以元組 (tuple) 表示。

在 3.8 版之後被 用: 舊的類 `ast.Num`、`ast.Str`、`ast.Bytes`、`ast.NameConstant` 和 `ast.Ellipsis` 仍然可用，但它們將在未來的 Python 釋出版本中移除。與此同時，實例化它們將回傳不同類 的實例。

在 3.9 版之後被 用: 舊的類 `ast.Index` 和 `ast.ExtSlice` 仍然可用，但它們將在未來的 Python 版本中 除。同時，實例化它們會回傳不同類 的實例。

Deprecated since version 3.13, will be removed in version 3.15: Previous versions of Python allowed the creation of AST nodes that were missing required fields. Similarly, AST node constructors allowed arbitrary keyword arguments that were set as attributes of the AST node, even if they did not match any of the fields of the AST node. This behavior is deprecated and will be removed in Python 3.15.

備

這 顯示的特定節點類 的描述最初是從出色的 [Green Tree Snakes](#) 專案和所有貢獻者那 改編而來的。

根節點

class `ast.Module` (*body*, *type_ignores*)

一個 Python 模組，與檔案輸入一樣。由 `ast.parse()` 在預設的 "exec" *mode* 下生成的節點型。 *body* 是模組的陳述式的一個 *list*。

type_ignores 是模組的忽略型解的 *list*；有關更多詳細資訊，請參 `ast.parse()`。

```
>>> print(ast.dump(ast.parse('x = 1'), indent=4))
Module(
  body=[
    Assign(
      targets=[
        Name(id='x', ctx=Store())],
      value=Constant(value=1))])
```

class `ast.Expression` (*body*)

單個 Python 運算式輸入。當 *mode* 是 "eval" 時節點型由 `ast.parse()` 生成。

body 是單個節點，是運算式型的其中之一。

```
>>> print(ast.dump(ast.parse('123', mode='eval'), indent=4))
Expression(
  body=Constant(value=123))
```

class `ast.Interactive` (*body*)

單個互動式輸入，和 `tut-interac` 中所述的相似。當 *mode* 是 "single" 時節點型由 `ast.parse()` 生成。

body 是陳述式節點 (*statement nodes*) 的 *list*。

```
>>> print(ast.dump(ast.parse('x = 1; y = 2', mode='single'), indent=4))
Interactive(
  body=[
    Assign(
      targets=[
        Name(id='x', ctx=Store())],
      value=Constant(value=1)),
    Assign(
      targets=[
        Name(id='y', ctx=Store())],
      value=Constant(value=2))])
```

class `ast.FunctionType` (*argtypes*, *returns*)

函式的舊式型解的表示法，因 3.5 之前的 Python 版本不支援 [PEP 484](#) 釋。當 *mode* 是 "func_type" 時節點型由 `ast.parse()` 生成。

這種型的解看起來像這樣：

```
def sum_two_number(a, b):
    # type: (int, int) -> int
    return a + b
```

argtypes 是運算式節點的 *list*。

returns 是單個運算式節點。

```
>>> print(ast.dump(ast.parse('(int, str) -> List[int]', mode='func_type'),
    ↪indent=4))
FunctionType(
  argtypes=[
    Name(id='int', ctx=Load()),
```

(繼續下一頁)

(繼續上一頁)

```

    Name(id='str', ctx=Load())],
    returns=Subscript(
        value=Name(id='List', ctx=Load()),
        slice=Name(id='int', ctx=Load()),
        ctx=Load())

```

在 3.8 版被加入。

文本 (Literals)

class `ast.Constant` (*value*)

一個常數值。Constant 文本的 `value` 屬性包含它所代表的 Python 物件。表示的值可以是簡單型 `值`，例如數字、字串或 `None`，但如果它們的所有元素都是常數，也可以是不可變的 (immutable) 容器型 `值` (元組和凍結集合 (frozensets))。

```

>>> print(ast.dump(ast.parse('123', mode='eval'), indent=4))
Expression(
    body=Constant(value=123))

```

class `ast.FormattedValue` (*value, conversion, format_spec*)

表示 f 字串 (f-string) 中的單個格式化欄位的節點。如果字串包含單個格式欄位 `值` 且 `值` 有其他 `值` 容，則可以隔離 (isolate) 該節點，否則它將出現在 `JoinedStr` 中。

- `value` `值` 任何運算式節點 (例如文字、變數或函式呼叫)。
- `conversion` 是一個整數：
 - -1: 無格式化
 - 115: !s 字串格式化
 - 114: !r 重 `值` 格式化化
 - 97: ! a ascii 格式化
- `format_spec` 是一個 `JoinedStr` 節點，表示值的格式，若未指定格式則 `值` `None`。
`conversion` 和 `format_spec` 可以同時設定。

class `ast.JoinedStr` (*values*)

一個 f 字串，包含一系列 `FormattedValue` 和 `Constant` 節點。

```

>>> print(ast.dump(ast.parse('f"sin({a}) is {sin(a):.3}"', mode='eval'),
→indent=4))
Expression(
    body=JoinedStr(
        values=[
            Constant(value='sin('),
            FormattedValue(
                value=Name(id='a', ctx=Load()),
                conversion=-1),
            Constant(value=') is '),
            FormattedValue(
                value=Call(
                    func=Name(id='sin', ctx=Load()),
                    args=[
                        Name(id='a', ctx=Load())],
                    conversion=-1,
                    format_spec=JoinedStr(
                        values=[
                            Constant(value='.3')]))))]

```

class `ast.List` (*elts, ctx*)

class `ast.Tuple (elts, ctx)`

串列或元組。elts 保存表示元素的節點串列。如果容器是賦值目標（即 `(x,y)=something`），則 ctx 是 *Store*，否則是 *Load*。

```
>>> print(ast.dump(ast.parse('[1, 2, 3]', mode='eval'), indent=4))
Expression(
  body=List(
    elts=[
      Constant(value=1),
      Constant(value=2),
      Constant(value=3)],
    ctx=Load()))
>>> print(ast.dump(ast.parse('(1, 2, 3)', mode='eval'), indent=4))
Expression(
  body=Tuple(
    elts=[
      Constant(value=1),
      Constant(value=2),
      Constant(value=3)],
    ctx=Load()))
```

class `ast.Set (elts)`

一個集合。elts 保存表示集合之元素的節點串列。

```
>>> print(ast.dump(ast.parse('{1, 2, 3}', mode='eval'), indent=4))
Expression(
  body=Set(
    elts=[
      Constant(value=1),
      Constant(value=2),
      Constant(value=3)]))
```

class `ast.Dict (keys, values)`

一個字典 (dictionary)。keys 和 values 分別按匹配順序保存表示鍵和值的節點串列（呼叫 `dictionary.keys()` 和 `dictionary.values()` 時將回傳的內容）。

當使用字典文本進行字典解包 (unpack) 時，要擴充的運算式位於 values 串列中，在 keys 中的相應位置有一個 `None`。

```
>>> print(ast.dump(ast.parse('{ "a":1, **d}', mode='eval'), indent=4))
Expression(
  body=Dict(
    keys=[
      Constant(value='a'),
      None],
    values=[
      Constant(value=1),
      Name(id='d', ctx=Load())]))
```

變數

class `ast.Name (id, ctx)`

一個變數名稱。id 將名稱以字串形式保存，且 ctx 是以下型之一。

class `ast.Load`

class `ast.Store`

class `ast.Del`

變數參照可用於載入變數的值、分配新值或刪除它。變數參照被賦予情境 (context) 來區分這些情況。

```
>>> print(ast.dump(ast.parse('a'), indent=4))
Module(
  body=[
    Expr(
      value=Name(id='a', ctx=Load())))]

>>> print(ast.dump(ast.parse('a = 1'), indent=4))
Module(
  body=[
    Assign(
      targets=[
        Name(id='a', ctx=Store())],
      value=Constant(value=1)))]

>>> print(ast.dump(ast.parse('del a'), indent=4))
Module(
  body=[
    Delete(
      targets=[
        Name(id='a', ctx=Del())])])]
```

class `ast.Starred(value, ctx)`

一個 `*var` 變數參照。value 保存變數，通常是一個 `Name` 節點。在使用 `*args` 建置 `Call` 節點時必須使用此型。

```
>>> print(ast.dump(ast.parse('a, *b = it'), indent=4))
Module(
  body=[
    Assign(
      targets=[
        Tuple(
          elts=[
            Name(id='a', ctx=Store()),
            Starred(
              value=Name(id='b', ctx=Store()),
              ctx=Store())],
          ctx=Store())],
      value=Name(id='it', ctx=Load())))]]
```

運算式

class `ast.Expr(value)`

當運算式（例如函式呼叫）本身作為陳述式出現且未使用或儲存其回傳值時，它將被包裝在此容器中。value 保存此區段 (section) 中的一個其他節點：`Constant`、`Name`、`Lambda`、`Yield` 或 `YieldFrom`

```
>>> print(ast.dump(ast.parse('-a'), indent=4))
Module(
  body=[
    Expr(
      value=UnaryOp(
        op=USub(),
        operand=Name(id='a', ctx=Load())))]]
```

class `ast.UnaryOp(op, operand)`

一元運算 (unary operation)。op 是運算子，operand 是任何運算式節點。

class `ast.UAdd`

class `ast.USub`

```
class ast.Not
```

```
class ast.Invert
```

一元運算子標記。*Not* 是 not 關鍵字、*Invert* 是 ~ 運算子。

```
>>> print(ast.dump(ast.parse('not x', mode='eval'), indent=4))
Expression(
  body=UnaryOp(
    op=Not(),
    operand=Name(id='x', ctx=Load())))
```

```
class ast.BinOp(left, op, right)
```

二元運算 (binary operation) (如加法或除法)。op 是運算子、left 和 right 是任意運算式節點。

```
>>> print(ast.dump(ast.parse('x + y', mode='eval'), indent=4))
Expression(
  body=BinOp(
    left=Name(id='x', ctx=Load()),
    op=Add(),
    right=Name(id='y', ctx=Load())))
```

```
class ast.Add
```

```
class ast.Sub
```

```
class ast.Mult
```

```
class ast.Div
```

```
class ast.FloorDiv
```

```
class ast.Mod
```

```
class ast.Pow
```

```
class ast.LShift
```

```
class ast.RShift
```

```
class ast.BitOr
```

```
class ast.BitXor
```

```
class ast.BitAnd
```

```
class ast.MatMult
```

二元運算子 token。

```
class ast.BoolOp(op, values)
```

布林運算 'or' 或 'and'。op 是 *Or* 或 *And*。values 是有所涉及的值。使用同一運算子的連續操作 (例如 a or b or c) 會被折成具有多個值的一個節點。

這不包括 not, 它是一個 *UnaryOp*。

```
>>> print(ast.dump(ast.parse('x or y', mode='eval'), indent=4))
Expression(
  body=BoolOp(
    op=Or(),
    values=[
      Name(id='x', ctx=Load()),
      Name(id='y', ctx=Load())])
```

```
class ast.And
```

```
class ast.Or
```

布林運算子 token。

```
class ast.Compare(left, ops, comparators)
```

兩個或多個值的比較。left 是比較中的第一個值、ops 是運算子串列、comparators 是要比較的第一個元素之後值的串列。

```
>>> print(ast.dump(ast.parse('1 <= a < 10', mode='eval'), indent=4))
Expression(
  body=Compare(
    left=Constant(value=1),
    ops=[
      LtE(),
      Lt()],
    comparators=[
      Name(id='a', ctx=Load()),
      Constant(value=10)]))
```

```
class ast.Eq
class ast.NotEq
class ast.Lt
class ast.LtE
class ast.Gt
class ast.GtE
class ast.Is
class ast.IsNot
class ast.In
class ast.NotIn
```

比較運算子 token。

```
class ast.Call(func, args, keywords)
```

一個函式呼叫。func 是該函式，通常是一個 *Name* 或 *Attribute* 物件。而在引數中：

- args 保存按位置傳遞的引數串列。
- keywords 保存一個 *keyword* 物件串列，表示透過關鍵字傳遞的引數。

The args and keywords arguments are optional and default to empty lists.

```
>>> print(ast.dump(ast.parse('func(a, b=c, *d, **e)', mode='eval'), indent=4))
Expression(
  body=Call(
    func=Name(id='func', ctx=Load()),
    args=[
      Name(id='a', ctx=Load()),
      Starred(
        value=Name(id='d', ctx=Load()),
        ctx=Load())],
    keywords=[
      keyword(
        arg='b',
        value=Name(id='c', ctx=Load())),
      keyword(
        value=Name(id='e', ctx=Load()))]))
```

```
class ast.keyword(arg, value)
```

函式呼叫或類定義的關鍵字引數。arg 是參數名稱的原始字串，value 是要傳入的節點。

```
class ast.IfExp(test, body, orelse)
```

像是 `a if b else c` 之類的運算式。每個欄位都保存一個節點，因此在以下範例中，所有三個都是 *Name* 節點。

```
>>> print(ast.dump(ast.parse('a if b else c', mode='eval'), indent=4))
Expression(
  body=IfExp(
    test=Name(id='b', ctx=Load()),
```

(繼續下一頁)

(繼續上一頁)

```
body=Name(id='a', ctx=Load()),
    orelse=Name(id='c', ctx=Load()))))
```

class `ast.Attribute` (*value, attr, ctx*)

屬性的存取，例如 `d.keys`。 *value* 是一個節點，通常是一個 *Name*。 *attr* 是一個屬性名稱的字串， *ctx* 根據屬性的作用方式可能是 *Load*、*Store* 或 *Del*。

```
>>> print(ast.dump(ast.parse('snake.colour', mode='eval'), indent=4))
Expression(
  body=Attribute(
    value=Name(id='snake', ctx=Load()),
    attr='colour',
    ctx=Load()))
```

class `ast.NamedExpr` (*target, value*)

一個附名運算式 (named expression)。該 AST 節點由賦值運算式運算子（也稱海象運算子）產生。相對於 *Assign* 節點之第一個引數可多個節點，在這種情況下 *target* 和 *value* 都必須是單個節點。

```
>>> print(ast.dump(ast.parse('(x := 4)', mode='eval'), indent=4))
Expression(
  body=NamedExpr(
    target=Name(id='x', ctx=Store()),
    value=Constant(value=4)))
```

在 3.8 版被加入。

下標 (Subscripting)

class `ast.Subscript` (*value, slice, ctx*)

一個下標，例如 `l[1]`。 *value* 是下標物件（通常是序列或對映）。 *slice* 是索引、切片或鍵。它可以是一個 *Tuple* 包含一個 *Slice*。根據下標執行的操作不同， *ctx* 可以是 *Load*、*Store* 或 *Del*。

```
>>> print(ast.dump(ast.parse('l[1:2, 3]', mode='eval'), indent=4))
Expression(
  body=Subscript(
    value=Name(id='l', ctx=Load()),
    slice=Tuple(
      elts=[
        Slice(
          lower=Constant(value=1),
          upper=Constant(value=2)),
        Constant(value=3)],
      ctx=Load()),
    ctx=Load()))
```

class `ast.Slice` (*lower, upper, step*)

常規切片（形式 `lower:upper` 或 `lower:upper:step`）。只能直接或者或者作 *Tuple* 的元素出現在 *Subscript* 的 *slice* 欄位。

```
>>> print(ast.dump(ast.parse('l[1:2]', mode='eval'), indent=4))
Expression(
  body=Subscript(
    value=Name(id='l', ctx=Load()),
    slice=Slice(
      lower=Constant(value=1),
      upper=Constant(value=2)),
    ctx=Load()))
```

綜合運算式 (comprehensions)

```

class ast.ListComp (elt, generators)
class ast.SetComp (elt, generators)
class ast.GeneratorExp (elt, generators)
class ast.DictComp (key, value, generators)

```

串列和集合綜合運算、生成器運算式和字典綜合運算。elt (或 key 和 value) 是單個節點，表示各個項目會被求值 (evaluate) 的部分。

generators 是一個 *comprehension* 節點的串列。

```

>>> print(ast.dump(
...     ast.parse('[x for x in numbers]', mode='eval'),
...     indent=4,
... ))
Expression(
  body=ListComp(
    elt=Name(id='x', ctx=Load()),
    generators=[
      comprehension(
        target=Name(id='x', ctx=Store()),
        iter=Name(id='numbers', ctx=Load()),
        is_async=0)])
>>> print(ast.dump(
...     ast.parse('{x: x**2 for x in numbers}', mode='eval'),
...     indent=4,
... ))
Expression(
  body=DictComp(
    key=Name(id='x', ctx=Load()),
    value=BinOp(
      left=Name(id='x', ctx=Load()),
      op=Pow(),
      right=Constant(value=2)),
    generators=[
      comprehension(
        target=Name(id='x', ctx=Store()),
        iter=Name(id='numbers', ctx=Load()),
        is_async=0)])
>>> print(ast.dump(
...     ast.parse('{x for x in numbers}', mode='eval'),
...     indent=4,
... ))
Expression(
  body=SetComp(
    elt=Name(id='x', ctx=Load()),
    generators=[
      comprehension(
        target=Name(id='x', ctx=Store()),
        iter=Name(id='numbers', ctx=Load()),
        is_async=0)])

```

```

class ast.comprehension (target, iter, ifs, is_async)

```

綜合運算中的一個 for 子句。target 是用於每個元素的參照 - 通常是 *Name* 或 *Tuple* 節點。iter 是要迭代的物件。ifs 是測試運算式的串列：每個 for 子句可以有 multiple ifs。

is_async 表示綜合運算式是非同步的 (使用 `async for` 而不是 `for`)。該值為整數 (0 或 1)。

```

>>> print(ast.dump(ast.parse('[ord(c) for line in file for c in line]', mode=
...     'eval'),
...     indent=4)) # Multiple comprehensions in one.

```

(繼續下一頁)

(繼續上一頁)

```

Expression(
  body=ListComp(
    elt=Call(
      func=Name(id='ord', ctx=Load()),
      args=[
        Name(id='c', ctx=Load())],
      generators=[
        comprehension(
          target=Name(id='line', ctx=Store()),
          iter=Name(id='file', ctx=Load()),
          is_async=0),
        comprehension(
          target=Name(id='c', ctx=Store()),
          iter=Name(id='line', ctx=Load()),
          is_async=0)])

>>> print(ast.dump(ast.parse('(n**2 for n in it if n>5 if n<10)', mode='eval'),
...                      indent=4)) # generator comprehension
Expression(
  body=GeneratorExp(
    elt=BinOp(
      left=Name(id='n', ctx=Load()),
      op=Pow(),
      right=Constant(value=2)),
    generators=[
      comprehension(
        target=Name(id='n', ctx=Store()),
        iter=Name(id='it', ctx=Load()),
        ifs=[
          Compare(
            left=Name(id='n', ctx=Load()),
            ops=[
              Gt()],
            comparators=[
              Constant(value=5)]),
          Compare(
            left=Name(id='n', ctx=Load()),
            ops=[
              Lt()],
            comparators=[
              Constant(value=10)])),
        is_async=0)])

>>> print(ast.dump(ast.parse('[i async for i in soc]', mode='eval'),
...                      indent=4)) # Async comprehension
Expression(
  body=ListComp(
    elt=Name(id='i', ctx=Load()),
    generators=[
      comprehension(
        target=Name(id='i', ctx=Store()),
        iter=Name(id='soc', ctx=Load()),
        is_async=1)])

```

陳述式

class `ast.Assign(targets, value, type_comment)`

一個賦值。targets 是節點串列，value 是單個節點。

targets 中的多個節點表示每個節點分配相同的值。解包是透過在 targets 中放置一個 *Tuple* 或 *List* 來表示的。

type_comment

type_comment 是一個可選字串，其中的解型釋。

```
>>> print(ast.dump(ast.parse('a = b = 1'), indent=4)) # Multiple assignment
Module(
  body=[
    Assign(
      targets=[
        Name(id='a', ctx=Store()),
        Name(id='b', ctx=Store())],
      value=Constant(value=1)))

>>> print(ast.dump(ast.parse('a,b = c'), indent=4)) # Unpacking
Module(
  body=[
    Assign(
      targets=[
        Tuple(
          elts=[
            Name(id='a', ctx=Store()),
            Name(id='b', ctx=Store())],
          ctx=Store())],
      value=Name(id='c', ctx=Load()))])
```

class `ast.AnnAssign(target, annotation, value, simple)`

帶有型釋的賦值。target 是單個節點，可以是 *Name*、*Attribute* 或 *Subscript*。annotation 是型釋，例如 *Constant* 或 *Name* 節點。value 是單個可選節點。

simple 總會是 0（表示一個「複雜」目標）或 1（表示一個「簡單」目標）。一個「簡單」目標僅包含一個 *Name* 節點，且不出現在括號之間；所有其他目標都被視是複雜的。只有簡單目標會出現在模組和類的 `__annotations__` 字典中。

```
>>> print(ast.dump(ast.parse('c: int'), indent=4))
Module(
  body=[
    AnnAssign(
      target=Name(id='c', ctx=Store()),
      annotation=Name(id='int', ctx=Load()),
      simple=1)])

>>> print(ast.dump(ast.parse('(a): int = 1'), indent=4)) # Annotation with
↳parenthesis
Module(
  body=[
    AnnAssign(
      target=Name(id='a', ctx=Store()),
      annotation=Name(id='int', ctx=Load()),
      value=Constant(value=1),
      simple=0)])

>>> print(ast.dump(ast.parse('a.b: int'), indent=4)) # Attribute annotation
Module(
  body=[
    AnnAssign(
```

(繼續下一頁)

(繼續上一頁)

```

        target=Attribute(
            value=Name(id='a', ctx=Load()),
            attr='b',
            ctx=Store()),
        annotation=Name(id='int', ctx=Load()),
        simple=0)])

>>> print(ast.dump(ast.parse('a[1]: int'), indent=4)) # Subscript annotation
Module(
  body=[
    AnnAssign(
      target=Subscript(
        value=Name(id='a', ctx=Load()),
        slice=Constant(value=1),
        ctx=Store()),
      annotation=Name(id='int', ctx=Load()),
      simple=0)])

```

class `ast.AugAssign(target, op, value)`

增加賦值 (augmented assignment), 例如 `a += 1`。在下面的範例中, `target` 是 `x` 的 *Name* 節點 (帶有 *Store* 情境), `op` 是 *Add*, `value` 是一個值 1 的 *Constant*。

與 *Assign* 的目標不同, `target` 屬性不能屬於 *Tuple* 或 *List* 類。

```

>>> print(ast.dump(ast.parse('x += 2'), indent=4))
Module(
  body=[
    AugAssign(
      target=Name(id='x', ctx=Store()),
      op=Add(),
      value=Constant(value=2)))]

```

class `ast.Raise(exc, cause)`

一個 `raise` 陳述式。 `exc` 是要引發的例外物件, 通常是 *Call* 或 *Name*, 若是獨立的 `raise` 則 `None`。 `cause` 是 `raise x from y` 中的可選部分 `y`。

```

>>> print(ast.dump(ast.parse('raise x from y'), indent=4))
Module(
  body=[
    Raise(
      exc=Name(id='x', ctx=Load()),
      cause=Name(id='y', ctx=Load())))]

```

class `ast.Assert(test, msg)`

一個斷言 (assertion)。 `test` 保存條件, 例如 *Compare* 節點。 `msg` 保存失敗訊息。

```

>>> print(ast.dump(ast.parse('assert x,y'), indent=4))
Module(
  body=[
    Assert(
      test=Name(id='x', ctx=Load()),
      msg=Name(id='y', ctx=Load())))]

```

class `ast.Delete(targets)`

代表一個 `del` 陳述式。 `targets` 是節點串列, 例如 *Name*、*Attribute* 或 *Subscript* 節點。

```

>>> print(ast.dump(ast.parse('del x,y,z'), indent=4))
Module(
  body=[
    Delete(

```

(繼續下一頁)

(繼續上一頁)

```

    targets=[
        Name(id='x', ctx=Del()),
        Name(id='y', ctx=Del()),
        Name(id='z', ctx=Del())]]])

```

class `ast.Pass`

一個 `pass` 陳述式。

```

>>> print(ast.dump(ast.parse('pass'), indent=4))
Module(
  body=[
    Pass()])

```

class `ast.TypeAlias` (*name, type_params, value*)

透過 `type` 陳述式建立的型別名 (*type alias*)。name 是型別名的名稱、`type_params` 是型別參數 (*type parameter*) 的串列、`value` 是型別名的值。

```

>>> print(ast.dump(ast.parse('type Alias = int'), indent=4))
Module(
  body=[
    TypeAlias(
      name=Name(id='Alias', ctx=Store()),
      value=Name(id='int', ctx=Load()))])

```

在 3.12 版被加入。

其他僅適用於函式或圈塊的陳述式將在其他部分中描述。

引入 (imports)**class** `ast.Import` (*names*)

一個 `import` 陳述式。names 是 *alias* 節點的串列。

```

>>> print(ast.dump(ast.parse('import x,y,z'), indent=4))
Module(
  body=[
    Import(
      names=[
        alias(name='x'),
        alias(name='y'),
        alias(name='z')])]])

```

class `ast.ImportFrom` (*module, names, level*)

代表 `from x import y`。module 是 'from' 名稱的原始字串，前面有任何的點 (dot)，或者對於諸如 `from . import foo` 之類的陳述式則為 None。level 是一個整數，保存相對引入的級數 (0 表示對引入)。

```

>>> print(ast.dump(ast.parse('from y import x,y,z'), indent=4))
Module(
  body=[
    ImportFrom(
      module='y',
      names=[
        alias(name='x'),
        alias(name='y'),
        alias(name='z')],
      level=0)])

```

```
>>> print(ast.dump(ast.parse("""
... for x in y:
...     ...
... else:
...     ...
... """), indent=4))
Module(
  body=[
    For(
      target=Name(id='x', ctx=Store()),
      iter=Name(id='y', ctx=Load()),
      body=[
        Expr(
          value=Constant(value=Ellipsis)),
        orelse=[
          Expr(
            value=Constant(value=Ellipsis))]]])
```

class `ast.While`(*test, body, orelse*)

一個 while 圈。test 保存條件，例如 *Compare* 節點。

```
>> print(ast.dump(ast.parse("""
... while x:
...     ...
... else:
...     ...
... """), indent=4))
Module(
  body=[
    While(
      test=Name(id='x', ctx=Load()),
      body=[
        Expr(
          value=Constant(value=Ellipsis))],
      orelse=[
        Expr(
          value=Constant(value=Ellipsis))]]])
```

class `ast.Break`

class `ast.Continue`

break 和 continue 陳述式。

```
>>> print(ast.dump(ast.parse("""\
... for a in b:
...     if a > 5:
...         break
...     else:
...         continue
... """), indent=4))
Module(
  body=[
    For(
      target=Name(id='a', ctx=Store()),
      iter=Name(id='b', ctx=Load()),
      body=[
        If(
          test=Compare(
            left=Name(id='a', ctx=Load()),
            ops=[
              Gt()],
```

(繼續下一頁)

(繼續上一頁)

```

        comparators=[
            Constant(value=5)]),
    body=[
        Break()],
    orelse=[
        Continue()]]))

```

class `ast.Try` (*body, handlers, orelse, finalbody*)

try 區塊。除 `handlers` 是 *ExceptHandler* 節點的串列外，其他所有屬性都是要執行之節點的串列。

```

>>> print(ast.dump(ast.parse("""
... try:
...     ...
... except Exception:
...     ...
... except OtherException as e:
...     ...
... else:
...     ...
... finally:
...     ...
... """), indent=4))
Module(
  body=[
    Try(
      body=[
        Expr(
          value=Constant(value=Ellipsis))),
      handlers=[
        ExceptHandler(
          type=Name(id='Exception', ctx=Load()),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]),
        ExceptHandler(
          type=Name(id='OtherException', ctx=Load()),
          name='e',
          body=[
            Expr(
              value=Constant(value=Ellipsis))]),
      orelse=[
        Expr(
          value=Constant(value=Ellipsis))],
      finalbody=[
        Expr(
          value=Constant(value=Ellipsis))])])

```

class `ast.TryStar` (*body, handlers, orelse, finalbody*)

try 區塊，後面跟著 `except *` 子句。這些屬性與 *Try* 相同，但是 `handlers` 中的 *ExceptHandler* 節點被直譯 (interpret) F `except *` 區塊而不是 `except`。

```

>>> print(ast.dump(ast.parse("""
... try:
...     ...
... except* Exception:
...     ...
... """), indent=4))
Module(
  body=[

```

(繼續下一頁)

(繼續上一頁)

```

TryStar(
    body=[
        Expr(
            value=Constant(value=Ellipsis)),
        handlers=[
            ExceptHandler(
                type=Name(id='Exception', ctx=Load()),
                body=[
                    Expr(
                        value=Constant(value=Ellipsis))])])])

```

在 3.11 版被加入。

class `ast.ExceptHandler` (*type, name, body*)

單個 `except` 子句。 *type* 是會被匹配的例外型，通常是一個 *Name* 節點（或者 `None` 表示會捕捉到所有例外的 `except:` 子句）。 *name* 是用於保存例外的名稱之原始字串，如果子句有 `as foo`，則 `None`。 *body* 是節點串列。

```

>>> print(ast.dump(ast.parse("""\
... try:
...     a + 1
... except TypeError:
...     pass
... """), indent=4))
Module(
  body=[
    Try(
      body=[
        Expr(
          value=BinOp(
            left=Name(id='a', ctx=Load()),
            op=Add(),
            right=Constant(value=1))),
        handlers=[
          ExceptHandler(
            type=Name(id='TypeError', ctx=Load()),
            body=[
              Pass()])])])])

```

class `ast.With` (*items, body, type_comment*)

一個 `with` 區塊。 *items* 是表示情境管理器的 *withitem* 節點串列， *body* 是情境的縮進區塊。

type_comment

type_comment 是一個可選字串，其中的解型釋。

class `ast.withitem` (*context_expr, optional_vars*)

`with` 區塊中的單個情境管理器。 *context_expr* 是情境管理器，通常是一個 *Call* 節點。 *Optional_vars* 是 `as foo` 部分的 *Name*、*Tuple* 或 *List*，或者如果不使用則 `None`。

```

>>> print(ast.dump(ast.parse("""\
... with a as b, c as d:
...     something(b, d)
... """), indent=4))
Module(
  body=[
    With(
      items=[
        withitem(
          context_expr=Name(id='a', ctx=Load()),
          optional_vars=Name(id='b', ctx=Store())),
        withitem(

```

(繼續下一頁)

(繼續上一頁)

```

        context_expr=Name(id='c', ctx=Load()),
        optional_vars=Name(id='d', ctx=Store()))],
    body=[
        Expr(
            value=Call(
                func=Name(id='something', ctx=Load()),
                args=[
                    Name(id='b', ctx=Load()),
                    Name(id='d', ctx=Load())])])])])])

```

模式匹配 (pattern matching)

class `ast.Match` (*subject, cases*)

一個 `match` 陳述式。 `subject` 保存匹配的主題（與案例匹配的物件）， `cases` 包含具有不同案例的 `match_case` 節點的可迭代物件。

在 3.10 版被加入。

class `ast.match_case` (*pattern, guard, body*)

`match` 陳述式中的單個案例模式。 `pattern` 包含主題將與之匹配的匹配模式。請注意，模式生成的 `AST` 節點與運算式生成的節點不同，即使它們共享相同的語法。

`guard` 屬性包含一個運算式，如果模式與主題匹配，則將對該運算式求值。

`body` 包含一個節點串列，如果模式匹配且防護運算式 (`guard expression`) 的求值 (`evaluate`) 結果為真，則會執行該節點串列。

```

>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] if x>0:
...         ...
...     case tuple():
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchSequence(
            patterns=[
              MatchAs(name='x')]),
          guard=Compare(
            left=Name(id='x', ctx=Load()),
            ops=[
              Gt()],
            comparators=[
              Constant(value=0)]),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]),
        match_case(
          pattern=MatchClass(
            cls=Name(id='tuple', ctx=Load()),
            body=[
              Expr(
                value=Constant(value=Ellipsis))])])])])

```

在 3.10 版被加入。

class `ast.MatchValue` (*value*)

以相等性進行比較的匹配文本或值的模式。*value* 是一個運算式節點。允許值節點受到匹配陳述式文件中所述的限制。如果匹配主題等於求出值，則此模式成功。

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case "Relevant":
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchValue(
            value=Constant(value='Relevant')),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]]))])
```

在 3.10 版被加入。

class `ast.MatchSingleton` (*value*)

按識別性 (identity) 進行比較的匹配文本模式。*value* 是要與 `None`、`True` 或 `False` 進行比較的單例 (singleton)。如果匹配主題是給定的常數，則此模式成功。

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case None:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchSingleton(value=None),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]]))])
```

在 3.10 版被加入。

class `ast.MatchSequence` (*patterns*)

匹配序列模式。如果主題是一個序列，*patterns* 包含與主題元素匹配的模式。如果子模式之一是 `MatchStar` 節點，則匹配可變長度序列，否則匹配固定長度序列。

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [1, 2]:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchSequence(
            patterns=[
```

(繼續下一頁)

(繼續上一頁)

```

        MatchValue(
            value=Constant(value=1)),
        MatchValue(
            value=Constant(value=2))]),
    body=[
        Expr(
            value=Constant(value=Ellipsis)))])))]))

```

在 3.10 版被加入。

class `ast.MatchStar(name)`

以可變長度匹配序列模式匹配序列的其余部分。如果 `name` 不是 `None`，則如果整體序列模式成功，則包含其余序列元素的串列將綁定到該名稱。

```

>>> print(ast.dump(ast.parse("""
... match x:
...     case [1, 2, *rest]:
...         ...
...     case [*_]:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchSequence(
            patterns=[
              MatchValue(
                value=Constant(value=1)),
              MatchValue(
                value=Constant(value=2)),
              MatchStar(name='rest')]),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]),
        match_case(
          pattern=MatchSequence(
            patterns=[
              MatchStar()]),
          body=[
            Expr(
              value=Constant(value=Ellipsis)))])))]))

```

在 3.10 版被加入。

class `ast.MatchMapping(keys, patterns, rest)`

匹配對映模式。`keys` 是運算式節點的序列。`patterns` 是相應的模式節點序列。`rest` 是一個可選名稱，可以指定它來捕獲剩余的對映元素。允許的鍵運算式受到匹配陳述式文件中所述的限制。

如果主題是對映，所有求值出的鍵運算式都存在於對映中，且與每個鍵對應的值與相應的子模式匹配，則此模式成功。如果 `rest` 不是 `None`，則如果整體對映模式成功，則包含其余對映元素的字典將綁定到該名稱。

```

>>> print(ast.dump(ast.parse("""
... match x:
...     case {1: _, 2: _}:
...         ...
...     case {**rest}:
...         ...
... """))

```

(繼續下一頁)

(繼續上一頁)

```

... """), indent=4))
Module(
    body=[
        Match(
            subject=Name(id='x', ctx=Load()),
            cases=[
                match_case(
                    pattern=MatchMapping(
                        keys=[
                            Constant(value=1),
                            Constant(value=2)],
                        patterns=[
                            MatchAs(),
                            MatchAs()],
                    body=[
                        Expr(
                            value=Constant(value=Ellipsis))),
                match_case(
                    pattern=MatchMapping(rest='rest'),
                    body=[
                        Expr(
                            value=Constant(value=Ellipsis))]))])

```

在 3.10 版被加入。

class `ast.MatchClass` (*cls, patterns, kwd_attrs, kwd_patterns*)

匹配類模式。cls 是一個給定要匹配的名義類 (nominal class) 的運算式。patterns 是要與類定義的模式匹配屬性序列進行匹配的模式節點序列。kwd_attrs 是要匹配的附加屬性序列（在類模式中指定關鍵字引數），kwd_patterns 是相應的模式（在類模式中指定關鍵字的值）。

如果主題是指定類的實例，所有位置模式都與相應的類定義屬性匹配，且任何指定的關鍵字屬性與其相應模式匹配，則此模式成功。

注意：類可以定義一個回傳 self 的特性 (property)，以便將模式節點與正在匹配的實例進行匹配。一些建型也以這種方式匹配，如同匹配陳述式文件中所述。

```

>>> print(ast.dump(ast.parse("""
... match x:
...     case Point2D(0, 0):
...         ...
...     case Point3D(x=0, y=0, z=0):
...         ...
... """), indent=4))
Module(
    body=[
        Match(
            subject=Name(id='x', ctx=Load()),
            cases=[
                match_case(
                    pattern=MatchClass(
                        cls=Name(id='Point2D', ctx=Load()),
                        patterns=[
                            MatchValue(
                                value=Constant(value=0)),
                            MatchValue(
                                value=Constant(value=0))]),
                    body=[
                        Expr(
                            value=Constant(value=Ellipsis))]),
                match_case(

```

(繼續下一頁)

(繼續上一頁)

```

pattern=MatchClass(
    cls=Name(id='Point3D', ctx=Load()),
    kwd_attrs=[
        'x',
        'y',
        'z'],
    kwd_patterns=[
        MatchValue(
            value=Constant(value=0)),
        MatchValue(
            value=Constant(value=0)),
        MatchValue(
            value=Constant(value=0))]),
    body=[
        Expr(
            value=Constant(value=Ellipsis)))]))

```

在 3.10 版被加入。

class `ast.MatchAs(pattern, name)`

匹配的「as 模式 (as-pattern)」，`pattern` 捕獲模式 (capture pattern) 或通配模式 (wildcard pattern)。包含主題將與之匹配的匹配模式。如果模式 `None`，則該節點代表捕獲模式（即裸名 (bare name)）且始終會成功。

`name` 屬性包含模式成功時將綁定的名稱。如果 `name` `None`，則 `pattern` 也必須 `None`，且節點代表通配模式。

```

>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] as y:
...         ...
...     case _:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchAs(
            pattern=MatchSequence(
              patterns=[
                MatchAs(name='x')]),
            name='y'),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]),
        match_case(
          pattern=MatchAs(),
          body=[
            Expr(
              value=Constant(value=Ellipsis))])])])

```

在 3.10 版被加入。

class `ast.MatchOr(patterns)`

匹配的「or 模式 (or-pattern)」。`or` 模式依次將其每個子模式與主題進行匹配，直到成功`False`止，然後 `or` 模式就會被認為成功的。如果`False`有一個子模式成功，則 `or` 模式將失敗。`patterns` 屬性包含將與主題進行匹配的匹配模式節點串列。

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] | (y):
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchOr(
            patterns=[
              MatchSequence(
                patterns=[
                  MatchAs(name='x')]),
              MatchAs(name='y')]),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]]))])]
```

在 3.10 版被加入。

型參數 (type parameters)

型參數可以存在於類、函式和型名上。

class `ast.TypeVar` (*name*, *bound*, *default_value*)

A `typing.TypeVar`. *name* is the name of the type variable. *bound* is the bound or constraints, if any. If *bound* is a `tuple`, it represents constraints; otherwise it represents the bound. *default_value* is the default value; if the `TypeVar` has no default, this attribute will be set to `None`.

```
>>> print(ast.dump(ast.parse("type Alias[T: int = bool] = list[T]"), indent=4))
Module(
  body=[
    TypeAlias(
      name=Name(id='Alias', ctx=Store()),
      type_params=[
        TypeVar(
          name='T',
          bound=Name(id='int', ctx=Load()),
          default_value=Name(id='bool', ctx=Load()))],
      value=Subscript(
        value=Name(id='list', ctx=Load()),
        slice=Name(id='T', ctx=Load()),
        ctx=Load()))])]
```

在 3.12 版被加入。

在 3.13 版的變更: Added the *default_value* parameter.

class `ast.ParamSpec` (*name*, *default_value*)

A `typing.ParamSpec`. *name* is the name of the parameter specification. *default_value* is the default value; if the `ParamSpec` has no default, this attribute will be set to `None`.

```
>>> print(ast.dump(ast.parse("type Alias[*P = (int, str)] = Callable[P, int]"), indent=4))
Module(
  body=[
    TypeAlias(
      name=Name(id='Alias', ctx=Store()),
```

(繼續下一頁)

(繼續上一頁)

```

type_params=[
    ParamSpec(
        name='P',
        default_value=Tuple(
            elts=[
                Name(id='int', ctx=Load()),
                Name(id='str', ctx=Load())],
            ctx=Load()))],
value=Subscript(
    value=Name(id='Callable', ctx=Load()),
    slice=Tuple(
        elts=[
            Name(id='P', ctx=Load()),
            Name(id='int', ctx=Load())],
        ctx=Load()),
    ctx=Load()))])

```

在 3.12 版被加入。

在 3.13 版的變更: Added the *default_value* parameter.

class `ast.TypeVarTuple` (*name*, *default_value*)

A *typing.TypeVarTuple*. *name* is the name of the type variable tuple. *default_value* is the default value; if the *TypeVarTuple* has no default, this attribute will be set to *None*.

```

>>> print(ast.dump(ast.parse("type Alias[*Ts = ()] = tuple[*Ts]"), indent=4))
Module(
  body=[
    TypeAlias(
      name=Name(id='Alias', ctx=Store()),
      type_params=[
        TypeVarTuple(
          name='Ts',
          default_value=Tuple(ctx=Load()))],
      value=Subscript(
        value=Name(id='tuple', ctx=Load()),
        slice=Tuple(
          elts=[
            Starred(
              value=Name(id='Ts', ctx=Load()),
              ctx=Load())],
          ctx=Load()),
        ctx=Load()))])

```

在 3.12 版被加入。

在 3.13 版的變更: Added the *default_value* parameter.

函式和類 定義

class `ast.FunctionDef` (*name*, *args*, *body*, *decorator_list*, *returns*, *type_comment*, *type_params*)

一個函式定義。

- *name* 是函式名稱的原始字串。
- *args* 是一個 *arguments* 節點。
- *body* 是函式 節點的串列。
- *decorator_list* 是要應用的裝飾器串列，在最外層者會被儲存在首位（即串列中首位將會是最後一個被應用的那個）。
- *returns* 是回傳 釋。

- `type_params` 是型參數的串列。

`type_comment`

`type_comment` 是一個可選字串，其中的解型釋。

在 3.12 版的變更: 新增了 `type_params`。

`class ast.Lambda (args, body)`

`lambda` 是可以在運算式使用的最小函式定義。與 `FunctionDef` 不同，`body` 保存單個節點。

```
>>> print(ast.dump(ast.parse('lambda x,y: ...'), indent=4))
Module(
  body=[
    Expr(
      value=Lambda(
        args=arguments(
          args=[
            arg(arg='x'),
            arg(arg='y')],
          body=Constant(value=Ellipsis)))])])
```

`class ast.arguments (posonlyargs, args, vararg, kwonlyargs, kw_defaults, kwarg, defaults)`

函式的引數。

- `posonlyargs`、`args` 和 `kwonlyargs` 是 `arg` 節點的串列。
- `vararg` 和 `kwarg` 是單個 `arg` 節點，指的是 `*args`，`**kwargs` 參數。
- `kw_defaults` 是僅限關鍵字引數的預設值串列。如果其中某個 `None`，則相應參數就會是必要的。
- `defaults` 是可以按位置傳遞的引數的預設值串列。如果預設值較少，則它們對應於最後 `n` 個引數。

`class ast.arg (arg, annotation, type_comment)`

串列中的單個引數。`arg` 是引數名稱的原始字串，`annotation` 是它的解釋，例如 `Name` 節點。

`type_comment`

`type_comment` 是一個可選字串，其解型釋

```
>>> print(ast.dump(ast.parse("""\
... @decorator1
... @decorator2
... def f(a: 'annotation', b=1, c=2, *d, e, f=3, **g) -> 'return annotation':
...     pass
... """), indent=4))
Module(
  body=[
    FunctionDef(
      name='f',
      args=arguments(
        args=[
          arg(
            arg='a',
            annotation=Constant(value='annotation')),
          arg(arg='b'),
          arg(arg='c')],
        vararg=arg(arg='d'),
        kwonlyargs=[
          arg(arg='e'),
          arg(arg='f')],
        kw_defaults=[
          None,
          Constant(value=3)],
```

(繼續下一頁)

(繼續上一頁)

```

        kwarg=arg(arg='g'),
        defaults=[
            Constant(value=1),
            Constant(value=2)]),
    body=[
        Pass()],
    decorator_list=[
        Name(id='decorator1', ctx=Load()),
        Name(id='decorator2', ctx=Load())],
    returns=Constant(value='return annotation'))])

```

class `ast.Return(value)`

一個 `return` 陳述式。

```

>>> print(ast.dump(ast.parse('return 4'), indent=4))
Module(
  body=[
    Return(
      value=Constant(value=4))])

```

class `ast.Yield(value)`

class `ast.YieldFrom(value)`

一個 `yield` 或 `yield from` 運算式。因為這些是運算式，所以如果不使用發送回來的值，則必須將它們包裝在 *Expr* 節點中。

```

>>> print(ast.dump(ast.parse('yield x'), indent=4))
Module(
  body=[
    Expr(
      value=Yield(
        value=Name(id='x', ctx=Load())))]])

>>> print(ast.dump(ast.parse('yield from x'), indent=4))
Module(
  body=[
    Expr(
      value=YieldFrom(
        value=Name(id='x', ctx=Load())))]])

```

class `ast.Global(names)`

class `ast.Nonlocal(names)`

`global` 和 `nonlocal` 陳述式。names 是原始字串的串列。

```

>>> print(ast.dump(ast.parse('global x,y,z'), indent=4))
Module(
  body=[
    Global(
      names=[
        'x',
        'y',
        'z'])])

>>> print(ast.dump(ast.parse('nonlocal x,y,z'), indent=4))
Module(
  body=[
    Nonlocal(
      names=[
        'x',
        'y',
        'z'])])

```

class `ast.ClassDef` (*name, bases, keywords, body, decorator_list, type_params*)

一個類定義。

- `name` 是類名的原始字串
- `bases` 是被顯式指定的基底類節點串列。
- `keywords` 是一個 *keyword* 節點的串列，主要用於 'metaclass' (元類)。如 [PEP-3115](#) 所述，其他關鍵字將被傳遞到 `metaclass`。
- `body` 是表示類定義中程式碼的節點串列。
- `decorator_list` 是一個節點串列，如 `FunctionDef` 中所示。
- `type_params` 是型參數的串列。

```
>>> print(ast.dump(ast.parse("""\
... @decorator1
... @decorator2
... class Foo(base1, base2, metaclass=meta):
...     pass
... """), indent=4))
Module(
  body=[
    ClassDef(
      name='Foo',
      bases=[
        Name(id='base1', ctx=Load()),
        Name(id='base2', ctx=Load())],
      keywords=[
        keyword(
          arg='metaclass',
          value=Name(id='meta', ctx=Load()))],
      body=[
        Pass()],
      decorator_list=[
        Name(id='decorator1', ctx=Load()),
        Name(id='decorator2', ctx=Load())])])
```

在 3.12 版的變更: 新增了 `type_params`。

async 和 await

class `ast.AsyncFunctionDef` (*name, args, body, decorator_list, returns, type_comment, type_params*)

一個 `async def` 函式定義。與 `FunctionDef` 具有相同的欄位。

在 3.12 版的變更: 新增了 `type_params`。

class `ast.Await` (*value*)

一個 `await` 運算式。 `value` 是它等待的東西。僅在 `AsyncFunctionDef` 主體 (`body`) 中有效。

```
>>> print(ast.dump(ast.parse("""\
... async def f():
...     await other_func()
... """), indent=4))
Module(
  body=[
    AsyncFunctionDef(
      name='f',
      args=arguments(),
      body=[
        Expr(
          value=Await(
```

(繼續下一頁)

(繼續上一頁)

```
value=Call(
    func=Name(id='other_func', ctx=Load()))))]]))
```

```
class ast.AsyncFor(target, iter, body, orelse, type_comment)
```

```
class ast.AsyncWith(items, body, type_comment)
```

async for 圈和 async with 情境管理器。它們分具有與 *For* 和 *With* 相同的欄位。僅在 *AsyncFunctionDef* 主體中有效。

備

當字串被 *ast.parse()* 剖析時，回傳樹的運算子節點 (*ast.operator*、*ast.unaryop*、*ast.cmpop*、*ast.class*、*ast.boolop* 和 *ast.expr_context*) 將是單例。對其中之一的更改將反映在所有其他出現的相同值中 (例如 *ast.Add*)。

32.1.3 ast 輔助程式

除了節點類之外，*ast* 模組還定義了這些用於遍歷 (traverse) 抽象語法樹的實用函式和類：

```
ast.parse(source, filename='<unknown>', mode='exec', *, type_comments=False, feature_version=None,
          optimize=-1)
```

Parse the source into an AST node. Equivalent to `compile(source, filename, mode, flags=FLAGS_VALUE, optimize=optimize)`, where `FLAGS_VALUE` is `ast.PyCF_ONLY_AST` if `optimize <= 0` and `ast.PyCF_OPTIMIZED_AST` otherwise.

如果給定 `type_comments=True`，剖析器將被修改檢查回傳 **PEP 484** 和 **PEP 526** 指定的型釋。這相當於將 `ast.PyCF_TYPE_COMMENTS` 新增到傳遞給 `compile()` 的旗標中。這將報告錯誤型釋的語法錯誤。如果有此旗標，型釋將被忽略，且所選 AST 節點上的 `type_comment` 欄位將始終為 `None`。此外，`# type: ignore` 的位置將作 `Module` 的 `type_ignores` 屬性回傳 (否則它始終是一個空串列)。

此外，如果 `mode` 是 `'func_type'`，則輸入語法將會依據 **PEP 484**「簽名型解 (signature type comments)」而被修改，例如 `(str, int) -> List[str]`。

Setting `feature_version` to a tuple (major, minor) will result in a "best-effort" attempt to parse using that Python version's grammar. For example, setting `feature_version=(3, 9)` will attempt to disallow parsing of `match` statements. Currently major must equal to 3. The lowest supported version is (3, 7) (and this may increase in future Python versions); the highest is `sys.version_info[0:2]`. "Best-effort" attempt means there is no guarantee that the parse (or success of the parse) is the same as when run on the Python version corresponding to `feature_version`.

如果來源包含 null 字元 (`\0`)，則會引發 *ValueError*。

警告

請注意，成功將原始碼剖析成 AST 物件不能保證提供的原始碼是可以執行的有效 Python 程式碼，因編譯步驟可能會引發進一步的 *SyntaxError* 例外。例如，原始的 `return 42` 陳述式生成一個有效的 AST 節點，但它不能單獨編譯 (它需要位於函式節點)。

特別是 *ast.parse()* 不會執行任何範圍檢查，而編譯步驟才會執行此操作。

警告

由於 Python AST 編譯器中的堆 (stack) 深度限制，太大或太雜的字串可能會導致 Python 直譯器崩潰。

在 3.8 版的變更: 新增 `type_comments`、`mode='func_type'` 與 `feature_version`。

在 3.13 版的變更: The minimum supported version for `feature_version` is now (3, 7). The `optimize` argument was added.

`ast.unparse(ast_obj)`

反剖析 `ast.AST` 物件生成一個帶有程式碼的字串，如果使用 `ast.parse()` 剖析回來，該程式碼將生成等效的 `ast.AST` 物件。

警告

生成的程式碼字串不一定等於生成 `ast.AST` 物件的原始程式碼（有任何編譯器最佳化，例如常數元組/凍結集合）。

警告

嘗試剖析高度複雜的運算式會導致 `RecursionError`。

在 3.9 版被加入。

`ast.literal_eval(node_or_string)`

僅包含 Python 文本或容器之顯示的運算式節點或字串來求值。提供的字串或節點只能包含以下 Python 文本結構：字串、位元組、數字、元組、串列、字典、集合、布林值、None 和 Ellipsis。

這可用於包含 Python 值的字串求值，而無需自己剖析這些值。它無法計算任意複雜的運算式，例如涉及運算子或索引。

該函式過去被記「安全」，但它有定義其含義，這有點誤導讀者，它是特設計不去執行 Python 程式碼，與更通用的 `eval()` 不同。它有命名空間、有名稱查找、也有呼叫的能力。但它也不能免受攻擊：相對較小的輸入可能會導致記憶體耗盡或 C 堆耗盡，從而導致行程崩潰。某些輸入也可能會出現 CPU 消耗過多而導致拒絕服務的情況。因此不建議在不受信任的資料上呼叫它。

警告

由於 Python AST 編譯器的堆深度限制，Python 直譯器可能會崩潰。

它可能會引發 `ValueError`、`TypeError`、`SyntaxError`、`MemoryError` 和 `RecursionError`，具體取決於格式錯誤的輸入。

在 3.2 版的變更: 現在允許位元組和集合文本 (set literal)。

在 3.9 版的變更: 現在支援使用 `'set()'` 建立空集合。

在 3.10 版的變更: 對於字串輸入，前導空格和定位字元 (tab) 現在已被去除。

`ast.get_docstring(node, clean=True)`

回傳給定 `node` 的文件字串 (docstring) (必須是 `FunctionDef`、`AsyncFunctionDef`、`ClassDef` 或 `Module` 節點) 或如果它沒有文件字串則 None。如果 `clean` 為 true，則使用 `inspect.cleandoc()` 清理文件字串的縮排。

在 3.5 版的變更: 目前已支援 `AsyncFunctionDef`。

`ast.get_source_segment(source, node, *, padded=False)`

獲取生成 `node` 的 `source` 的原始碼片段。如果某些位置資訊 (`lineno`、`end_lineno`、`col_offset` 或 `end_col_offset`) 遺漏，則回傳 None。

如果 `padded` 為 True，則多列陳述式的第一列將用空格填充 (padded) 以匹配其原始位置。

在 3.8 版被加入。

`ast.fix_missing_locations (node)`

當你使用 `compile()` 編譯節點樹時，對於每個有支援 `lineno` 和 `col_offset` 屬性之節點，編譯器預期他們的這些屬性都要存在。填入生成的節點相當繁瑣，因此該輔助工具透過將這些屬性設定回父節點的值，在尚未設定的地方遞地新增這些屬性。它從 `node` 開始遞地作用。

`ast.increment_lineno (node, n=1)`

將樹中從 `node` 開始的每個節點的列號和結束列號增加 `n`。這對於「移動程式碼」到檔案中的不同位置很有用。

`ast.copy_location (new_node, old_node)`

如果可行，將原始位置 (`lineno`、`col_offset`、`end_lineno` 和 `end_col_offset`) 從 `old_node` 到 `new_node`，回傳 `new_node`。

`ast.iter_fields (node)`

在 `node` 上存在的 `node.__fields` 中的每個欄位生成一個 (`fieldname`, `value`) 元組。

`ast.iter_child_nodes (node)`

生成 `node` 的所有直接子節點，即作節點的所有欄位以及作節點串列欄位的所有項目。

`ast.walk (node)`

遞地生成樹中從 `node` 開始的所有後代節點（包括 `node` 本身），不按指定順序。如果你只想就地修改節點而不關心情境，這非常有用。

class `ast.NodeVisitor`

節點訪問者基底類，它遍歷抽象語法樹找到的每個節點呼叫訪問者函式。該函式可能會回傳一個由 `visit()` 方法轉發的值。

這個類應該被子類化，子類新增訪問者方法。

visit (`node`)

訪問一個節點。預設實作呼叫名 `self.visit_classname` 的方法，其中 `classname` 是節點類的名稱，或者在該方法不存在時呼叫 `generic_visit()`。

generic_visit (`node`)

該訪問者對該節點的所有子節點呼叫 `visit()`。

請注意，除非訪問者呼叫 `generic_visit()` 或訪問它們本身，否則不會訪問具有自定義訪問者方法的節點之子節點。

visit_Constant (`node`)

處理所有常數節點。

如果你想在遍歷期間將變更應用 (apply) 於節點，請不要使用 `NodeVisitor`。因此，有個允許修改的特殊遍歷訪問者工具 `NodeTransformer`。

在 3.8 版之後被用：`visit_Num()`、`visit_Str()`、`visit_Bytes()`、`visit_NameConstant()` 和 `visit_Ellipsis()` 方法現已用，且不會在未來的 Python 版本中被呼叫。新增 `visit_Constant()` 方法來處理所有常數節點。

class `ast.NodeTransformer`

一個 `NodeVisitor` 子類，它會遍歷抽象語法樹允許修改節點。

`NodeTransformer` 將遍歷 AST 使用訪問者方法的回傳值來替或除舊節點。如果訪問者方法的回傳值 `None`，則該節點將從其位置中除，否則將被替回傳值。回傳值可能是原始節點，在這種情況下不會發生替。

下面是一個示範用的 transformer，它將查找所有出現名稱 (`foo`) 改寫 `data['foo']`：

```
class RewriteName(NodeTransformer):

    def visit_Name(self, node):
        return Subscript(
            value=Name(id='data', ctx=Load()),
```

(繼續下一頁)

(繼續上一頁)

```

        slice=Constant(value=node.id),
        ctx=node.ctx
    )

```

請記住，如果你正在操作的節點有子節點，你必須自己轉子節點或先呼叫該節點的 `generic_visit()` 方法。

對於屬於陳述式總集 (collection) 一部分的節點（適用於所有陳述式節點），訪問者還可以回傳節點串列，而不僅僅是單個節點。

如果 `NodeTransformer` 引進了新節點（不屬於原始樹的一部分），但仍有給它們提供位置資訊（例如 `lineno`），則應使用新的子樹呼叫 `fix_missing_locations()` 以重新計算位置資訊：

```

tree = ast.parse('foo', mode='eval')
new_tree = fix_missing_locations(RewriteName().visit(tree))

```

你通常會像這樣使用 transformer：

```
node = YourTransformer().visit(node)
```

`ast.dump(node, annotate_fields=True, include_attributes=False, *, indent=None, show_empty=False)`

回傳 `node` 中樹的格式化傾印 (formatted dump)，這主要用於除錯。如果 `annotate_fields` 為 `true`（預設值），則回傳的字串將顯示欄位的名稱和值。如果 `annotate_fields` 為 `false`，則透過省略明確的欄位名稱，結果字串將更加縮簡簡潔。預設情況下，不會傾印列號和行偏移量等屬性。如果需要，可以設定 `include_attributes` 為 `true`。

如果 `indent` 是非負整數或字串，那樹將使用該縮排級來做漂亮印出 (pretty-print)。縮排級 0、負數或 "" 只會插入列符號 (newlines)。None（預設值）代表選擇單列表示。使用正整數縮排可以在每個級縮排相同數量的空格。如果 `indent` 是一個字串（例如 "\t"），則該字串用於縮排每個級。

If `show_empty` is `False` (the default), empty lists and fields that are `None` will be omitted from the output.

在 3.9 版的變更：新增 `indent` 選項。

在 3.13 版的變更：Added the `show_empty` option.

```

>>> print(ast.dump(ast.parse("""\
... async def f():
...     await other_func()
... """), indent=4, show_empty=True))
Module(
  body=[
    AsyncFunctionDef(
      name='f',
      args=arguments(
        posonlyargs=[],
        args=[],
        kwonlyargs=[],
        kw_defaults=[],
        defaults=[]),
      body=[
        Expr(
          value=Await(
            value=Call(
              func=Name(id='other_func', ctx=Load()),
              args=[],
              keywords=[]))),
        decorator_list=[],
        type_params=[]),
    type_ignores=[])]

```

32.1.4 編譯器旗標

可以將以下旗標傳遞給 `compile()` 以變更對程式的編譯效果：

`ast.PyCF_ALLOW_TOP_LEVEL_AWAIT`

☐ 用對最高階 `await`、`async for`、`async with` 和非同步綜合運算的支援。

在 3.8 版被加入。

`ast.PyCF_ONLY_AST`

生成☐回傳抽象語法樹，而不是回傳已編譯的程式碼物件。

`ast.PyCF_OPTIMIZED_AST`

The returned AST is optimized according to the *optimize* argument in `compile()` or `ast.parse()`.

在 3.13 版被加入。

`ast.PyCF_TYPE_COMMENTS`

☐ 用對 **PEP 484** 和 **PEP 526** 樣式型☐☐釋的支援 (`# type: <type>`, `# type: ignore <stuff>`)。

在 3.8 版被加入。

32.1.5 命令列用法

在 3.9 版被加入。

`ast` 模組可以作☐☐本從命令列執行，可以像這樣簡單地做到：

```
python -m ast [-m <mode>] [-a] [infile]
```

以下選項可被接受：

-h, --help

顯示幫助訊息☐退出。

-m <mode>

--mode <mode>

指定必須編譯哪種類型的程式碼，像是 `parse()` 中的 *mode* 引數。

--no-type-comments

不要剖析型☐☐解。

-a, --include-attributes

包括列號和行偏移量等屬性。

-i <indent>

--indent <indent>

AST 中節點的縮進（空格數）。

如果指定了 `infile`，則其☐容將被剖析☐ AST ☐傾印 (dump) 到 `stdout`。否則會從 `stdin` 讀取☐容。

也參考

Green Tree Snakes 是一個外部文件資源，提供了有關使用 Python AST 的詳細資訊。

ASTTokens 使用生成它們的原始碼中的標記和文本的位置來☐釋 Python AST。這對於進行原始碼轉☐的工具很有幫助。

leoAst.py 透過在 `token` 和 `ast` 節點之間插入雙向鏈結，統一了 `python` 程式的基於 `token` 和基於剖析樹的視圖。

LibCST 將程式碼剖析成具體語法樹 (Concrete Syntax Tree)，看起來像 **ast** 樹但保留所有格式詳細資訊。它對於建置自動重構 (codemod) 應用程式和 linter 非常有用。

Parso 是一個 Python 剖析器，支援不同 Python 版本的錯誤復原和往返剖析。**Parso** 還能列出 Python 檔案中的多個語法錯誤。

32.2 symtable --- 存取編譯器的符號表

原始碼：Lib/symtable.py

符號表 (symbol table) 是在生成位元組碼 (bytecode) 之前由編譯器從 AST 生成的。符號表負責計算程式碼中每個識別器 (identifier) 的範圍。`symtable` 提供了一個介面來檢查這些表。

32.2.1 生成符號表

`symtable.symtable (code, filename, compile_type)`

回傳 Python 原始 `code` 的頂層 `SymbolTable`。`filename` 是包含程式碼之檔案之名稱。`compile_type` 類似於 `compile()` 的 `mode` 引數。

32.2.2 檢查符號表

class `symtable.SymbolTableType`

An enumeration indicating the type of a `SymbolTable` object.

MODULE = "module"

Used for the symbol table of a module.

FUNCTION = "function"

Used for the symbol table of a function.

CLASS = "class"

Used for the symbol table of a class.

The following members refer to different flavors of annotation scopes.

ANNOTATION = "annotation"

Used for annotations if `from __future__ import annotations` is active.

TYPE_ALIAS = "type alias"

Used for the symbol table of `type` constructions.

TYPE_PARAMETERS = "type parameters"

Used for the symbol table of generic functions or generic classes.

TYPE_VARIABLE = "type variable"

Used for the symbol table of the bound, the constraint tuple or the default value of a single type variable in the formal sense, i.e., a `TypeVar`, a `TypeVarTuple` or a `ParamSpec` object (the latter two do not support a bound or a constraint tuple).

在 3.13 版被加入。

class `symtable.SymbolTable`

一個區塊 (block) 的命名空間表 (namespace table)。建構函式 (constructor) 不公開。

get_type()

Return the type of the symbol table. Possible values are members of the *SymbolTableType* enumeration.

在 3.12 版的變更: 新增了 'annotation'、'TypeVar bound'、'type alias' 和 'type parameter' 作可能的回傳值。

在 3.13 版的變更: Return values are members of the *SymbolTableType* enumeration.

The exact values of the returned string may change in the future, and thus, it is recommended to use *SymbolTableType* members instead of hard-coded strings.

get_id()

回傳表的識別器。

get_name()

回傳表的名稱。如果表用於類，則這是類的名稱；如果表用於函式，則這是函式的名稱；如果表是全域的，則 'top' (*get_type()* 會回傳 'module')。對於型參數作用域（用於泛型類、函式和型名），它是底層類、函式或型名的名稱。對於型名作用域，它是型名的名稱。對於 *TypeVar* 綁定範圍，它會是 *TypeVar* 的名稱。

get_lineno()

回傳此表所代表的區塊中第一行的編號。

is_optimized()

如果可以最佳化該表中的區域變數，則回傳 True。

is_nested()

如果區塊是巢狀類或函式，則回傳 True。

has_children()

如果區塊有巢狀命名空間，則回傳 True。這些可以通過 *get_children()* 獲得。

get_identifiers()

回傳包含表中符號之名稱的視圖物件 (view object)。請參閱視圖物件的文件。

lookup(name)

在表中查找 *name* 回傳一個 *Symbol* 實例。

get_symbols()

回傳表中名稱的 *Symbol* 實例串列。

get_children()

回傳巢狀符號表的串列。

class symtable.Function

一個函式或方法的命名空間。該類繼承自 *SymbolTable*。

get_parameters()

回傳一個包含此函式參數名稱的元組 (tuple)。

get_locals()

回傳一個包含此函式中區域變數 (locals) 名稱的元組。

get_globals()

回傳一個包含此函式中全域變數 (globals) 名稱的元組。

get_nonlocals()

回傳一個包含此函式中非區域變數 (nonlocals) 名稱的元組。

get_frees()

回傳一個包含此函式中自由變數 (free variables) 名稱的元組。

class `syntable.Class`

一個類型的命名空間。該類繼承自 `SymbolTable`。

get_methods()

回傳一個包含類型中聲明的類似方法之函式名稱的元組。

Here, the term 'method' designates *any* function defined in the class body via `def` or `async def`.

Functions defined in a deeper scope (e.g., in an inner class) are not picked up by `get_methods()`.

舉例來：

```
>>> import syntable
>>> st = syntable.syntable('')
... def outer(): pass
...
... class A:
...     def f():
...         def w(): pass
...
...     def g(self): pass
...
...     @classmethod
...     async def h(cls): pass
...
...     global outer
...     def outer(self): pass
...     '', 'test', 'exec')
>>> class_A = st.get_children()[1]
>>> class_A.get_methods()
('f', 'g', 'h')
```

Although `A().f()` raises `TypeError` at runtime, `A.f` is still considered as a method-like function.

class `syntable.Symbol`

`SymbolTable` 中的條目對應於來源中的識別器。建構函式不是公開的。

get_name()

回傳符號的名稱。

is_referenced()

如果該符號在其區塊中使用，則回傳 `True`。

is_imported()

如果符號是從 `import` 陳述式建立的，則回傳 `True`。

is_parameter()

如果符號是一個參數，則回傳 `True`。

is_global()

如果符號是全域的，則回傳 `True`。

is_nonlocal()

如果符號是非區域的，則回傳 `True`。

is_declared_global()

如果使用全域陳述式將符號聲明為全域的，則回傳 `True`。

is_local()

如果符號是其區塊的區域符號，則回傳 `True`。

is_annotated()

如果符號有被解釋，則回傳 `True`。

在 3.6 版被加入。

is_free()

如果該符號在其區塊中被參照 (referenced) 但未被賦值 (assigned), 則回傳 True。

is_assigned()

如果該符號被賦值到其區塊中, 則回傳 True。

is_namespace()

如果名稱綁定引入 (introduce) 新的命名空間, 則回傳 True。

如果名稱用作函式或類陳述式的目標, 則這將會是 true。

舉例來:

```
>>> table = symtable.symtable("def some_func(): pass", "string", "exec")
>>> table.lookup("some_func").is_namespace()
True
```

請注意, 單個名稱可以綁定到多個物件。如果結果 True, 則該名稱也可能被綁定到其他物件, 例如 int 或 list, 而不會引入新的命名空間。

get_namespaces()

回傳綁定到該名稱的命名空間的串列。

get_namespace()

回傳綁定到該名稱的命名空間。如果該名稱綁定了多個命名空間或有命名空間, 則會引發 *ValueError*。

32.2.3 Command-Line Usage

在 3.13 版被加入。

The *symtable* module can be executed as a script from the command line.

```
python -m symtable [infile...]
```

Symbol tables are generated for the specified Python source files and dumped to stdout. If no input file is specified, the content is read from stdin.

32.3 token --- 與 Python 剖析樹一起使用的常數

原始碼: [Lib/token.py](#)

This module provides constants which represent the numeric values of leaf nodes of the parse tree (terminal tokens). Refer to the file *Grammar/Tokens* in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

The module also provides a mapping from numeric codes to names and some functions. The functions mirror definitions in the Python C header files.

token.tok_name

Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.

token.ISTERMINAL(x)

Return True for terminal token values.

token.ISNONTERMINAL(x)

Return True for non-terminal token values.

`token.ISEOF` (*x*)

Return `True` if *x* is the marker indicating the end of input.

The token constants are:

`token.ENDMARKER`

`token.NAME`

`token.NUMBER`

`token.STRING`

`token.NEWLINE`

`token.INDENT`

`token.DEDENT`

`token.LPAR`

Token value for " (".

`token.RPAR`

Token value for ")".

`token.LSQB`

Token value for "[".

`token.RSQB`

Token value for "]".

`token.COLON`

Token value for ":".

`token.COMMA`

Token value for ",".

`token.SEMI`

Token value for ";".

`token.PLUS`

Token value for "+".

`token.MINUS`

Token value for "-".

`token.STAR`

Token value for "*".

`token.SLASH`

Token value for "/".

`token.VBAR`

Token value for "|".

`token.AMPER`

Token value for "&".

`token.LESS`

Token value for "<".

`token.GREATER`

Token value for ">".

`token.EQUAL`

Token value for "=".

`token.DOT`

Token value for ".".

`token.PERCENT`

Token value for "%".

`token.LBRACE`

Token value for "{".

`token.RBRACE`

Token value for "}".

`token.EQEQUAL`

Token value for "==".

`token.NOTEQUAL`

Token value for "!=".

`token.LESSEQUAL`

Token value for "<=".

`token.GREATEREQUAL`

Token value for ">=".

`token.TILDE`

Token value for "~".

`token.CIRCUMFLEX`

Token value for "^".

`token.LEFTSHIFT`

Token value for "<<".

`token.RIGHTSHIFT`

Token value for ">>".

`token.DOUBLESTAR`

Token value for "**".

`token.PLUSEQUAL`

Token value for "+=".

`token.MINEQUAL`

Token value for "-=".

`token.STAREQUAL`

Token value for "*=".

`token.SLASHEQUAL`

Token value for "/=".

`token.PERCENTEQUAL`

Token value for "%=".

`token.AMPEREQUAL`

Token value for "&=".

`token.VBAREQUAL`

Token value for "|=".

`token.CIRCUMFLEXEQUAL`

Token value for "`^=`".

`token.LEFTSHIFTEQUAL`

Token value for "`<=<`".

`token.RIGHTSHIFTEQUAL`

Token value for "`>=>`".

`token.DOUBLESTAREQUAL`

Token value for "`**=`".

`token.DOUBLESLASH`

Token value for "`//`".

`token.DOUBLESLASHEQUAL`

Token value for "`/=`".

`token.AT`

Token value for "`@`".

`token.ATEQUAL`

Token value for "`@=`".

`token.RARROW`

Token value for "`->`".

`token.ELLIPSIS`

Token value for "`...`".

`token.COLONEQUAL`

Token value for "`:=`".

`token.EXCLAMATION`

Token value for "`!`".

`token.OP`

`token.TYPE_IGNORE`

`token.TYPE_COMMENT`

`token.SOFT_KEYWORD`

`token.FSTRING_START`

`token.FSTRING_MIDDLE`

`token.FSTRING_END`

`token.COMMENT`

`token.NL`

`token.ERRORTOKEN`

`token.N_TOKENS`

`token.NT_OFFSET`

The following token type values aren't used by the C tokenizer but are needed for the *tokenize* module.

`token.COMMENT`

Token value used to indicate a comment.

`token.NL`

Token value used to indicate a non-terminating newline. The `NEWLINE` token indicates the end of a logical line of Python code; NL tokens are generated when a logical line of code is continued over multiple physical lines.

`token.ENCODING`

Token value that indicates the encoding used to decode the source bytes into text. The first token returned by `tokenize.tokenize()` will always be an `ENCODING` token.

`token.TYPE_COMMENT`

Token value indicating that a type comment was recognized. Such tokens are only produced when `ast.parse()` is invoked with `type_comments=True`.

在 3.5 版的變更: Added `AWAIT` and `ASYNC` tokens.

在 3.7 版的變更: Added `COMMENT`, `NL` and `ENCODING` tokens.

在 3.7 版的變更: Removed `AWAIT` and `ASYNC` tokens. "async" and "await" are now tokenized as `NAME` tokens.

在 3.8 版的變更: Added `TYPE_COMMENT`, `TYPE_IGNORE`, `COLONEQUAL`. Added `AWAIT` and `ASYNC` tokens back (they're needed to support parsing older Python versions for `ast.parse()` with `feature_version` set to 6 or lower).

在 3.13 版的變更: Removed `AWAIT` and `ASYNC` tokens again.

32.4 keyword --- 檢驗 Python 關鍵字

原始碼: [Lib/keyword.py](#)

此模組允許 Python 程式確定某個字串是否為關鍵字或軟關鍵字 (soft keyword)。

`keyword.iskeyword(s)`

如果 `s` 是一個 Python 關鍵字則回傳 `True`。

`keyword.kwlist`

包含直譯器定義的所有關鍵字的序列。如果所定義的任何關鍵字僅在特定 `__future__` 陳述式生效時被使用，它們也將被包含在內。

`keyword.issoftkeyword(s)`

如果 `s` 是一個 Python 軟關鍵字則回傳 `True`。

在 3.9 版被加入。

`keyword.softkwlist`

包含直譯器定義的所有軟關鍵字的序列。如果所定義的任何軟關鍵字僅在特定 `__future__` 陳述式生效時被使用，它們也將被包含在內。

在 3.9 版被加入。

32.5 tokenize --- Tokenizer for Python source

原始碼: [Lib/tokenize.py](#)

The `tokenize` module provides a lexical scanner for Python source code, implemented in Python. The scanner in this module returns comments as tokens as well, making it useful for implementing "pretty-printers", including colorizers for on-screen displays.

To simplify token stream handling, all operator and delimiter tokens and *Ellipsis* are returned using the generic *OP* token type. The exact type can be determined by checking the `exact_type` property on the *named tuple* returned from `tokenize.tokenize()`.

警告

Note that the functions in this module are only designed to parse syntactically valid Python code (code that does not raise when parsed using `ast.parse()`). The behavior of the functions in this module is **undefined** when providing invalid Python code and it can change at any point.

32.5.1 Tokenizing Input

The primary entry point is a *generator*:

`tokenize.tokenize(readline)`

The `tokenize()` generator requires one argument, *readline*, which must be a callable object which provides the same interface as the `io.IOBase.readline()` method of file objects. Each call to the function should return one line of input as bytes.

The generator produces 5-tuples with these members: the token type; the token string; a 2-tuple (*srow*, *scol*) of ints specifying the row and column where the token begins in the source; a 2-tuple (*erow*, *ecol*) of ints specifying the row and column where the token ends in the source; and the line on which the token was found. The line passed (the last tuple item) is the *physical* line. The 5 tuple is returned as a *named tuple* with the field names: `type string start end line`.

The returned *named tuple* has an additional property named `exact_type` that contains the exact operator type for *OP* tokens. For all other token types `exact_type` equals the *named tuple* `type` field.

在 3.1 版的變更: 新增附名元組 (named tuple) 的支援。

在 3.3 版的變更: 新增 `exact_type` 的支援。

`tokenize()` determines the source encoding of the file by looking for a UTF-8 BOM or encoding cookie, according to **PEP 263**.

`tokenize.generate_tokens(readline)`

Tokenize a source reading unicode strings instead of bytes.

Like `tokenize()`, the *readline* argument is a callable returning a single line of input. However, `generate_tokens()` expects *readline* to return a str object rather than bytes.

The result is an iterator yielding named tuples, exactly like `tokenize()`. It does not yield an *ENCODING* token.

All constants from the `token` module are also exported from `tokenize`.

Another function is provided to reverse the tokenization process. This is useful for creating tools that tokenize a script, modify the token stream, and write back the modified script.

`tokenize.untokenize(iterable)`

Converts tokens back into Python source code. The *iterable* must return sequences with at least two elements, the token type and the token string. Any additional sequence elements are ignored.

The reconstructed script is returned as a single string. The result is guaranteed to tokenize back to match the input so that the conversion is lossless and round-trips are assured. The guarantee applies only to the token type and token string as the spacing between tokens (column positions) may change.

It returns bytes, encoded using the *ENCODING* token, which is the first token sequence output by `tokenize()`. If there is no encoding token in the input, it returns a str instead.

`tokenize()` needs to detect the encoding of source files it tokenizes. The function it uses to do this is available:

`tokenize.detect_encoding(readline)`

The `detect_encoding()` function is used to detect the encoding that should be used to decode a Python source file. It requires one argument, `readline`, in the same way as the `tokenize()` generator.

It will call `readline` a maximum of twice, and return the encoding used (as a string) and a list of any lines (not decoded from bytes) it has read in.

It detects the encoding from the presence of a UTF-8 BOM or an encoding cookie as specified in [PEP 263](#). If both a BOM and a cookie are present, but disagree, a `SyntaxError` will be raised. Note that if the BOM is found, `'utf-8-sig'` will be returned as an encoding.

If no encoding is specified, then the default of `'utf-8'` will be returned.

Use `open()` to open Python source files: it uses `detect_encoding()` to detect the file encoding.

`tokenize.open(filename)`

Open a file in read only mode using the encoding detected by `detect_encoding()`.

在 3.2 版被加入。

exception `tokenize.TokenError`

Raised when either a docstring or expression that may be split over several lines is not completed anywhere in the file, for example:

```
"""Beginning of
docstring
```

或是：

```
[1,
 2,
 3
```

32.5.2 Command-Line Usage

在 3.3 版被加入。

The `tokenize` module can be executed as a script from the command line. It is as simple as:

```
python -m tokenize [-e] [filename.py]
```

The following options are accepted:

-h, --help

show this help message and exit

-e, --exact

display token names using the exact type

If `filename.py` is specified its contents are tokenized to stdout. Otherwise, tokenization is performed on stdin.

32.5.3 范例

Example of a script rewriter that transforms float literals into Decimal objects:

```
from tokenize import tokenize, untokenize, NUMBER, STRING, NAME, OP
from io import BytesIO

def decistmt(s):
    """Substitute Decimals for floats in a string of statements.
```

(繼續下一頁)

(繼續上一頁)

```
>>> from decimal import Decimal
>>> s = 'print(+21.3e-5*-.1234/81.7) '
>>> decistmt(s)
"print (+Decimal ('21.3e-5')*-Decimal ('.1234')/Decimal ('81.7'))"

The format of the exponent is inherited from the platform C library.
Known cases are "e-007" (Windows) and "e-07" (not Windows). Since
we're only showing 12 digits, and the 13th isn't close to 5, the
rest of the output should be platform-independent.

>>> exec(s) #doctest: +ELLIPSIS
-3.21716034272e-0...7

Output from calculations with Decimal should be identical across all
platforms.

>>> exec(decistmt(s))
-3.217160342717258261933904529E-7
"""
result = []
g = tokenize(BytesIO(s.encode('utf-8')).readline) # tokenize the string
for toknum, tokval, _, _, _ in g:
    if toknum == NUMBER and '.' in tokval: # replace NUMBER tokens
        result.extend([
            (NAME, 'Decimal'),
            (OP, '('),
            (STRING, repr(tokval)),
            (OP, ')')
        ])
    else:
        result.append((toknum, tokval))
return untokenize(result).decode('utf-8')
```

Example of tokenizing from the command line. The script:

```
def say_hello():
    print("Hello, World!")

say_hello()
```

will be tokenized to the following output where the first column is the range of the line/column coordinates where the token is found, the second column is the name of the token, and the final column is the value of the token (if any)

```
$ python -m tokenize hello.py
0,0-0,0:      ENCODING      'utf-8'
1,0-1,3:      NAME          'def'
1,4-1,13:     NAME          'say_hello'
1,13-1,14:    OP            '('
1,14-1,15:    OP            ')'
1,15-1,16:    OP            ':'
1,16-1,17:    NEWLINE      '\n'
2,0-2,4:      INDENT       '    '
2,4-2,9:      NAME          'print'
2,9-2,10:     OP            '('
2,10-2,25:    STRING        '"Hello, World!"'
2,25-2,26:    OP            ')'
2,26-2,27:    NEWLINE      '\n'
3,0-3,1:      NL           '\n'
4,0-4,0:      DEDENT       ''
4,0-4,9:      NAME          'say_hello'
4,9-4,10:     OP            '('
```

(繼續下一頁)

(繼續上一頁)

```

4,10-4,11:      OP          ')'
4,11-4,12:      NEWLINE    '\n'
5,0-5,0:        ENDMARKER  ''

```

The exact token type names can be displayed using the `-e` option:

```

$ python -m tokenize -e hello.py
0,0-0,0:      ENCODING      'utf-8'
1,0-1,3:      NAME          'def'
1,4-1,13:     NAME          'say_hello'
1,13-1,14:    LPAR          '('
1,14-1,15:    RPAR          ')'
1,15-1,16:    COLON         ':'
1,16-1,17:    NEWLINE      '\n'
2,0-2,4:      INDENT        '    '
2,4-2,9:      NAME          'print'
2,9-2,10:     LPAR          '('
2,10-2,25:    STRING        '"Hello, World!"'
2,25-2,26:    RPAR          ')'
2,26-2,27:    NEWLINE      '\n'
3,0-3,1:      NL           '\n'
4,0-4,0:      DEDENT        ''
4,0-4,9:      NAME          'say_hello'
4,9-4,10:     LPAR          '('
4,10-4,11:    RPAR          ')'
4,11-4,12:    NEWLINE      '\n'
5,0-5,0:      ENDMARKER    ''

```

Example of tokenizing a file programmatically, reading unicode strings instead of bytes with `generate_tokens()`:

```

import tokenize

with tokenize.open('hello.py') as f:
    tokens = tokenize.generate_tokens(f.readline)
    for token in tokens:
        print(token)

```

Or reading bytes directly with `tokenize()`:

```

import tokenize

with open('hello.py', 'rb') as f:
    tokens = tokenize.tokenize(f.readline)
    for token in tokens:
        print(token)

```

32.6 tabnanny --- 偵測不良縮排

原始碼: [Lib/tabnanny.py](#)

目前現 是此模組打算以 本方式被呼叫使用，但也可以將其引入於 IDE 中 使用下方 述的 `check()` 函式。

備

此模組所提供的 API 很有可能會在未來的發版本中有所變更，且有可能不具有向後相容性。

`tabnanny.check(file_or_dir)`

如果 `file_or_dir` 是個目且非符號鏈接 (symbolic link)，則會遞地在名 `file_or_dir` 的目樹 (directory tree) 中不斷下行檢查所有 `.py` 檔案。如果 `file_or_dir` 是個一般 Python 原始檔案，則其檢查空格相關問題。診斷訊息會以 `print()` 函式輸出至標準輸出 (standard output) 當中。

`tabnanny.verbose`

標示是否要印出詳細訊息 (verbose message) 的旗標，若是以本方式呼叫的話則可以用 `-v` 選項來增加。

`tabnanny.filename_only`

標示是否要只印出那些有空白相關問題檔案之檔名的旗標，若是以本方式呼叫的話則可以用 `-q` 選項來設真值。

exception `tabnanny.NannyNag`

當偵測到不良縮排時，此例外會被 `process_tokens()` 引發，會在 `check()` 中捕獲與處理。

`tabnanny.process_tokens(tokens)`

此函式被 `check()` 用來處理由 `tokenize` 生的標記 (token)。

也參考

`tokenize` 模組

Python 原始程式碼的詞掃描器 (lexical scanner)。

32.7 pycldr --- Python 模組覽器支援

原始碼：Lib/pycldr.py

The `pycldr` module provides limited information about the functions, classes, and methods defined in a Python-coded module. The information is sufficient to implement a module browser. The information is extracted from the Python source code rather than by importing the module, so this module is safe to use with untrusted code. This restriction makes it impossible to use this module with modules not implemented in Python, including all standard and optional extension modules.

`pycldr.readmodule(module, path=None)`

Return a dictionary mapping module-level class names to class descriptors. If possible, descriptors for imported base classes are included. Parameter `module` is a string with the name of the module to read; it may be the name of a module within a package. If given, `path` is a sequence of directory paths prepended to `sys.path`, which is used to locate the module source code.

This function is the original interface and is only kept for back compatibility. It returns a filtered version of the following.

`pycldr.readmodule_ex(module, path=None)`

Return a dictionary-based tree containing a function or class descriptors for each function and class defined in the module with a `def` or `class` statement. The returned dictionary maps module-level function and class names to their descriptors. Nested objects are entered into the children dictionary of their parent. As with `readmodule`, `module` names the module to be read and `path` is prepended to `sys.path`. If the module being read is a package, the returned dictionary has a key `'__path__'` whose value is a list containing the package search path.

在 3.7 版被加入: Descriptors for nested definitions. They are accessed through the new `children` attribute. Each has a new `parent` attribute.

The descriptors returned by these functions are instances of `Function` and `Class` classes. Users are not expected to create instances of these classes.

32.7.1 函式物件

class `pyclbr.Function`

Class `Function` instances describe functions defined by `def` statements. They have the following attributes:

file

Name of the file in which the function is defined.

module

The name of the module defining the function described.

name

The name of the function.

lineno

The line number in the file where the definition starts.

parent

For top-level functions, `None`. For nested functions, the parent.

在 3.7 版被加入.

children

A *dictionary* mapping names to descriptors for nested functions and classes.

在 3.7 版被加入.

is_async

True for functions that are defined with the `async` prefix, False otherwise.

在 3.10 版被加入.

32.7.2 Class Objects

class `pyclbr.Class`

Class `Class` instances describe classes defined by class statements. They have the same attributes as *Functions* and two more.

file

Name of the file in which the class is defined.

module

The name of the module defining the class described.

name

The name of the class.

lineno

The line number in the file where the definition starts.

parent

For top-level classes, `None`. For nested classes, the parent.

在 3.7 版被加入.

children

A dictionary mapping names to descriptors for nested functions and classes.

在 3.7 版被加入。

super

A list of `Class` objects which describe the immediate base classes of the class being described. Classes which are named as superclasses but which are not discoverable by `readmodule_ex()` are listed as a string with the class name instead of as `Class` objects.

methods

A *dictionary* mapping method names to line numbers. This can be derived from the newer *children* dictionary, but remains for back-compatibility.

32.8 py_compile — 編譯 Python 來源檔案

原始碼: `Lib/py_compile.py`

The `py_compile` module provides a function to generate a byte-code file from a source file, and another function used when the module source file is invoked as a script.

Though not often needed, this function can be useful when installing modules for shared use, especially if some of the users may not have permission to write the byte-code cache files in the directory containing the source code.

exception `py_compile.PyCompileError`

Exception raised when an error occurs while attempting to compile the file.

`py_compile.compile(file, cfile=None, dfile=None, doraise=False, optimize=-1, invalidation_mode=PycInvalidationMode.TIMESTAMP, quiet=0)`

Compile a source file to byte-code and write out the byte-code cache file. The source code is loaded from the file named *file*. The byte-code is written to *cfile*, which defaults to the **PEP 3147/PEP 488** path, ending in `.pyc`. For example, if *file* is `/foo/bar/baz.py` *cfile* will default to `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. If *dfile* is specified, it is used instead of *file* as the name of the source file from which source lines are obtained for display in exception tracebacks. If *doraise* is true, a `PyCompileError` is raised when an error is encountered while compiling *file*. If *doraise* is false (the default), an error string is written to `sys.stderr`, but no exception is raised. This function returns the path to byte-compiled file, i.e. whatever *cfile* value was used.

The *doraise* and *quiet* arguments determine how errors are handled while compiling file. If *quiet* is 0 or 1, and *doraise* is false, the default behaviour is enabled: an error string is written to `sys.stderr`, and the function returns `None` instead of a path. If *doraise* is true, a `PyCompileError` is raised instead. However if *quiet* is 2, no message is written, and *doraise* has no effect.

If the path that *cfile* becomes (either explicitly specified or computed) is a symlink or non-regular file, `FileExistsError` will be raised. This is to act as a warning that import will turn those paths into regular files if it is allowed to write byte-compiled files to those paths. This is a side-effect of import using file renaming to place the final byte-compiled file into place to prevent concurrent file writing issues.

optimize controls the optimization level and is passed to the built-in `compile()` function. The default of `-1` selects the optimization level of the current interpreter.

invalidation_mode should be a member of the `PycInvalidationMode` enum and controls how the generated bytecode cache is invalidated at runtime. The default is `PycInvalidationMode.CHECKED_HASH` if the `SOURCE_DATE_EPOCH` environment variable is set, otherwise the default is `PycInvalidationMode.TIMESTAMP`.

在 3.2 版的變更: Changed default value of *cfile* to be **PEP 3147**-compliant. Previous default was `file + '.c'` (`'.o'` if optimization was enabled). Also added the *optimize* parameter.

在 3.4 版的變更: Changed code to use *importlib* for the byte-code cache file writing. This means file creation/writing semantics now match what *importlib* does, e.g. permissions, write-and-move semantics, etc. Also added the caveat that *FileExistsError* is raised if *cfile* is a symlink or non-regular file.

在 3.7 版的變更: The *invalidation_mode* parameter was added as specified in **PEP 552**. If the *SOURCE_DATE_EPOCH* environment variable is set, *invalidation_mode* will be forced to *PycInvalidationMode.CHECKED_HASH*.

在 3.7.2 版的變更: The *SOURCE_DATE_EPOCH* environment variable no longer overrides the value of the *invalidation_mode* argument, and determines its default value instead.

在 3.8 版的變更: 新增 *quiet* 參數。

class `py_compile.PycInvalidationMode`

An enumeration of possible methods the interpreter can use to determine whether a bytecode file is up to date with a source file. The *.pyc* file indicates the desired invalidation mode in its header. See *pyc-invalidation* for more information on how Python invalidates *.pyc* files at runtime.

在 3.7 版被加入.

TIMESTAMP

The *.pyc* file includes the timestamp and size of the source file, which Python will compare against the metadata of the source file at runtime to determine if the *.pyc* file needs to be regenerated.

CHECKED_HASH

The *.pyc* file includes a hash of the source file content, which Python will compare against the source at runtime to determine if the *.pyc* file needs to be regenerated.

UNCHECKED_HASH

Like *CHECKED_HASH*, the *.pyc* file includes a hash of the source file content. However, Python will at runtime assume the *.pyc* file is up to date and not validate the *.pyc* against the source file at all.

This option is useful when the *.pycs* are kept up to date by some system external to Python like a build system.

32.8.1 Command-Line Interface

This module can be invoked as a script to compile several source files. The files named in *filenames* are compiled and the resulting bytecode is cached in the normal manner. This program does not search a directory structure to locate source files; it only compiles files named explicitly. The exit status is nonzero if one of the files could not be compiled.

<file> ... <fileN>

-

Positional arguments are files to compile. If **-** is the only parameter, the list of files is taken from standard input.

-q, --quiet

Suppress errors output.

在 3.2 版的變更: 新增對 **-** 的支援。

在 3.10 版的變更: 新增對 **-q** 的支援。

也參考

compileall 模組

Utilities to compile all Python source files in a directory tree.

32.9 compileall --- 位元組編譯 Python 函式庫

原始碼: [Lib/compileall.py](#)

This module provides some utility functions to support installing Python libraries. These functions compile Python source files in a directory tree. This module can be used to create the cached byte-code files at library installation time, which makes them available for use even by users who don't have write permission to the library directories.

Availability: not WASI.

This module does not work or is not available on WebAssembly. See [WebAssembly 平台](#) for more information.

32.9.1 Command-line use

This module can work as a script (using `python -m compileall`) to compile Python sources.

directory ...

file ...

Positional arguments are files to compile or directories that contain source files, traversed recursively. If no argument is given, behave as if the command line was `-l <directories from sys.path>`.

-l

Do not recurse into subdirectories, only compile source code files directly contained in the named or implied directories.

-f

Force rebuild even if timestamps are up-to-date.

-q

Do not print the list of files compiled. If passed once, error messages will still be printed. If passed twice (`-qq`), all output is suppressed.

-d *destdir*

Directory prepended to the path to each file being compiled. This will appear in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

-s *strip_prefix*

-p *prepend_prefix*

Remove (`-s`) or append (`-p`) the given prefix of paths recorded in the `.pyc` files. Cannot be combined with `-d`.

-x *regex*

regex is used to search the full path to each file considered for compilation, and if the regex produces a match, the file is skipped.

-i *list*

Read the file *list* and add each line that it contains to the list of files and directories to compile. If *list* is `-`, read lines from `stdin`.

-b

Write the byte-code files to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their [PEP 3147](#) locations and names, which allows byte-code files from multiple versions of Python to coexist.

-r

Control the maximum recursion level for subdirectories. If this is given, then `-l` option will not be taken into account. `python -m compileall <directory> -r 0` is equivalent to `python -m compileall <directory> -l`.

-j N

Use *N* workers to compile the files within the given directory. If 0 is used, then the result of `os.process_cpu_count()` will be used.

--invalidation-mode [timestamp|checked-hash|unchecked-hash]

Control how the generated byte-code files are invalidated at runtime. The `timestamp` value, means that `.pyc` files with the source timestamp and size embedded will be generated. The `checked-hash` and `unchecked-hash` values cause hash-based pycs to be generated. Hash-based pycs embed a hash of the source file contents rather than a timestamp. See `pyc-invalidation` for more information on how Python validates bytecode cache files at runtime. The default is `timestamp` if the `SOURCE_DATE_EPOCH` environment variable is not set, and `checked-hash` if the `SOURCE_DATE_EPOCH` environment variable is set.

-o level

Compile with the given optimization level. May be used multiple times to compile for multiple levels at a time (for example, `compileall -o 1 -o 2`).

-e dir

Ignore symlinks pointing outside the given directory.

--hardlink-dupes

If two `.pyc` files with different optimization level have the same content, use hard links to consolidate duplicate files.

在 3.2 版的變更: 新增選項 `-i`、`-b` 與 `-h`。

在 3.5 版的變更: Added the `-j`, `-r`, and `-qq` options. `-q` option was changed to a multilevel value. `-b` will always produce a byte-code file ending in `.pyc`, never `.pyo`.

在 3.7 版的變更: 新增選項 `--invalidation-mode`。

在 3.9 版的變更: Added the `-s`, `-p`, `-e` and `--hardlink-dupes` options. Raised the default recursion limit from 10 to `sys.getrecursionlimit()`. Added the possibility to specify the `-o` option multiple times.

There is no command-line option to control the optimization level used by the `compile()` function, because the Python interpreter itself already provides the option: `python -O -m compileall`.

Similarly, the `compile()` function respects the `sys.pycache_prefix` setting. The generated bytecode cache will only be useful if `compile()` is run with the same `sys.pycache_prefix` (if any) that will be used at runtime.

32.9.2 Public functions

`compileall.compile_dir` (*dir*, *maxlevels*=`sys.getrecursionlimit()`, *ddir*=`None`, *force*=`False`, *rx*=`None`, *quiet*=`0`, *legacy*=`False`, *optimize*=`-1`, *workers*=`1`, *invalidation_mode*=`None`, *, *stripdir*=`None`, *prependdir*=`None`, *limit_sl_dest*=`None`, *hardlink_dupes*=`False`)

Recursively descend the directory tree named by *dir*, compiling all `.py` files along the way. Return a true value if all the files compiled successfully, and a false value otherwise.

The *maxlevels* parameter is used to limit the depth of the recursion; it defaults to `sys.getrecursionlimit()`.

If *ddir* is given, it is prepended to the path to each file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If *force* is true, modules are re-compiled even if the timestamps are up to date.

If *rx* is given, its `search` method is called on the complete path to each file considered for compilation, and if it returns a true value, the file is skipped. This can be used to exclude files matching a regular expression, given as a *re.Pattern* object.

If *quiet* is `False` or 0 (the default), the filenames and other information are printed to standard out. Set to 1, only errors are printed. Set to 2, all output is suppressed.

If *legacy* is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their **PEP 3147** locations and names, which allows byte-code files from multiple versions of Python to coexist.

optimize specifies the optimization level for the compiler. It is passed to the built-in `compile()` function. Accepts also a sequence of optimization levels which lead to multiple compilations of one `.py` file in one call.

The argument *workers* specifies how many workers are used to compile files in parallel. The default is to not use multiple workers. If the platform can't use multiple workers and *workers* argument is given, then sequential compilation will be used as a fallback. If *workers* is 0, the number of cores in the system is used. If *workers* is lower than 0, a *ValueError* will be raised.

invalidation_mode should be a member of the `py_compile.PycInvalidationMode` enum and controls how the generated pycs are invalidated at runtime.

The *stripdir*, *prependdir* and *limit_sl_dest* arguments correspond to the `-s`, `-p` and `-e` options described above. They may be specified as `str` or *os.PathLike*.

If *hardlink_dupes* is true and two `.pyc` files with different optimization level have the same content, use hard links to consolidate duplicate files.

在 3.2 版的變更: 新增 *legacy* 與 *optimize* 參數。

在 3.5 版的變更: 新增 *workers* 參數。

在 3.5 版的變更: *quiet* parameter was changed to a multilevel value.

在 3.5 版的變更: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

在 3.6 版的變更: Accepts a *path-like object*.

在 3.7 版的變更: 新增 *invalidation_mode* 參數。

在 3.7.2 版的變更: 新增 *invalidation_mode* 參數的預設值被更新 `None`。

在 3.8 版的變更: Setting *workers* to 0 now chooses the optimal number of cores.

在 3.9 版的變更: Added *stripdir*, *prependdir*, *limit_sl_dest* and *hardlink_dupes* arguments. Default value of *maxlevels* was changed from 10 to `sys.getrecursionlimit()`

```
compileall.compile_file(fullname, ddir=None, force=False, rx=None, quiet=0, legacy=False,
                        optimize=-1, invalidation_mode=None, *, stripdir=None, prependdir=None,
                        limit_sl_dest=None, hardlink_dupes=False)
```

Compile the file with path *fullname*. Return a true value if the file compiled successfully, and a false value otherwise.

If *ddir* is given, it is prepended to the path to the file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If *rx* is given, its `search` method is passed the full path name to the file being compiled, and if it returns a true value, the file is not compiled and `True` is returned. This can be used to exclude files matching a regular expression, given as a *re.Pattern* object.

If *quiet* is `False` or 0 (the default), the filenames and other information are printed to standard out. Set to 1, only errors are printed. Set to 2, all output is suppressed.

If *legacy* is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their **PEP 3147** locations and names, which allows byte-code files from multiple versions of Python to coexist.

optimize specifies the optimization level for the compiler. It is passed to the built-in `compile()` function. Accepts also a sequence of optimization levels which lead to multiple compilations of one `.py` file in one call.

invalidation_mode should be a member of the `py_compile.PycInvalidationMode` enum and controls how the generated pycs are invalidated at runtime.

The *stripdir*, *prependdir* and *limit_sl_dest* arguments correspond to the `-s`, `-p` and `-e` options described above. They may be specified as `str` or `os.PathLike`.

If *hardlink_dupes* is true and two `.pyc` files with different optimization level have the same content, use hard links to consolidate duplicate files.

在 3.2 版被加入。

在 3.5 版的變更: *quiet* parameter was changed to a multilevel value.

在 3.5 版的變更: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

在 3.7 版的變更: 新增 *invalidation_mode* 參數。

在 3.7.2 版的變更: 新增 *invalidation_mode* 參數的預設值被更新 成 `None`。

在 3.9 版的變更: Added *stripdir*, *prependdir*, *limit_sl_dest* and *hardlink_dupes* arguments.

```
compileall.compile_path(skip_curdir=True, maxlevels=0, force=False, quiet=0, legacy=False,
                        optimize=-1, invalidation_mode=None)
```

Byte-compile all the `.py` files found along `sys.path`. Return a true value if all the files compiled successfully, and a false value otherwise.

If *skip_curdir* is true (the default), the current directory is not included in the search. All other parameters are passed to the `compile_dir()` function. Note that unlike the other compile functions, *maxlevels* defaults to 0.

在 3.2 版的變更: 新增 *legacy* 與 *optimize* 參數。

在 3.5 版的變更: *quiet* parameter was changed to a multilevel value.

在 3.5 版的變更: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

在 3.7 版的變更: 新增 *invalidation_mode* 參數。

在 3.7.2 版的變更: 新增 *invalidation_mode* 參數的預設值被更新 成 `None`。

To force a recompile of all the `.py` files in the `Lib/` subdirectory and all its subdirectories:

```
import compileall

compileall.compile_dir('Lib/', force=True)

# Perform same compilation, excluding files in .svn directories.
import re
compileall.compile_dir('Lib/', rx=re.compile(r'[/\\][.]svn'), force=True)

# pathlib.Path objects can also be used.
import pathlib
compileall.compile_dir(pathlib.Path('Lib/'), force=True)
```

`py_compile` 模組

Byte-compile a single source file.

32.10 `dis` --- Python bytecode 的反組譯器

原始碼: `Lib/dis.py`

`dis` 模組支援反組譯分析 CPython *bytecode*。CPython bytecode 作輸入的模組被定義於 `Include/opcode.h` 且被編譯器和直譯器所使用。

CPython 實作細節： Bytecode is an implementation detail of the CPython interpreter. No guarantees are made that bytecode will not be added, removed, or changed between versions of Python. Use of this module should not be considered to work across Python VMs or Python releases.

在 3.6 版的變更: Use 2 bytes for each instruction. Previously the number of bytes varied by instruction.

在 3.10 版的變更: The argument of jump, exception handling and loop instructions is now the instruction offset rather than the byte offset.

在 3.11 版的變更: Some instructions are accompanied by one or more inline cache entries, which take the form of *CACHE* instructions. These instructions are hidden by default, but can be shown by passing `show_caches=True` to any `dis` utility. Furthermore, the interpreter now adapts the bytecode to specialize it for different runtime conditions. The adaptive bytecode can be shown by passing `adaptive=True`.

在 3.12 版的變更: The argument of a jump is the offset of the target instruction relative to the instruction that appears immediately after the jump instruction's *CACHE* entries.

As a consequence, the presence of the *CACHE* instructions is transparent for forward jumps but needs to be taken into account when reasoning about backward jumps.

在 3.13 版的變更: The output shows logical labels rather than instruction offsets for jump targets and exception handlers. The `-O` command line option and the `show_offsets` argument were added.

Example: Given the function `myfunc()`:

```
def myfunc(alist):
    return len(alist)
```

the following command can be used to display the disassembly of `myfunc()`:

```
>>> dis.dis(myfunc)
2          RESUME                     0

3          LOAD_GLOBAL                1 (len + NULL)
          LOAD_FAST                   0 (alist)
          CALL                        1
          RETURN_VALUE
```

(The "2" is a line number).

32.10.1 Command-line interface

The `dis` module can be invoked as a script from the command line:

```
python -m dis [-h] [-C] [-O] [infile]
```

The following options are accepted:

-h, --help

Display usage and exit.

-C, --show-caches

Show inline caches.

-O, --show-offsets

Show offsets of instructions.

If `infile` is specified, its disassembled code will be written to stdout. Otherwise, disassembly is performed on compiled source code received from stdin.

32.10.2 Bytecode analysis

在 3.4 版被加入.

The bytecode analysis API allows pieces of Python code to be wrapped in a `Bytecode` object that provides easy access to details of the compiled code.

```
class dis.Bytecode (x, *, first_line=None, current_offset=None, show_caches=False, adaptive=False,
                    show_offsets=False)
```

Analyse the bytecode corresponding to a function, generator, asynchronous generator, coroutine, method, string of source code, or a code object (as returned by `compile()`).

This is a convenience wrapper around many of the functions listed below, most notably `get_instructions()`, as iterating over a `Bytecode` instance yields the bytecode operations as `Instruction` instances.

If `first_line` is not `None`, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

If `current_offset` is not `None`, it refers to an instruction offset in the disassembled code. Setting this means `dis()` will display a "current instruction" marker against the specified opcode.

If `show_caches` is `True`, `dis()` will display inline cache entries used by the interpreter to specialize the bytecode.

If `adaptive` is `True`, `dis()` will display specialized bytecode that may be different from the original bytecode.

If `show_offsets` is `True`, `dis()` will include instruction offsets in the output.

```
classmethod from_traceback (tb, *, show_caches=False)
```

Construct a `Bytecode` instance from the given traceback, setting `current_offset` to the instruction responsible for the exception.

codeobj

The compiled code object.

first_line

The first source line of the code object (if available)

dis()

Return a formatted view of the bytecode operations (the same as printed by `dis.dis()`), but returned as a multi-line string).

info()

Return a formatted multi-line string with detailed information about the code object, like `code_info()`.

在 3.7 版的變更: This can now handle coroutine and asynchronous generator objects.

在 3.11 版的變更: 新增 `show_caches` 與 `adaptive` 參數。

範例:

```
>>> bytecode = dis.Bytecode(myfunc)
>>> for instr in bytecode:
...     print(instr.opname)
...
```

(繼續下一頁)

(繼續上一頁)

```

RESUME
LOAD_GLOBAL
LOAD_FAST
CALL
RETURN_VALUE

```

32.10.3 Analysis functions

The `dis` module also defines the following analysis functions that convert the input directly to the desired output. They can be useful if only a single operation is being performed, so the intermediate analysis object isn't useful:

`dis.code_info(x)`

Return a formatted multi-line string with detailed code object information for the supplied function, generator, asynchronous generator, coroutine, method, source code string or code object.

Note that the exact contents of code info strings are highly implementation dependent and they may change arbitrarily across Python VMs or Python releases.

在 3.2 版被加入。

在 3.7 版的變更: This can now handle coroutine and asynchronous generator objects.

`dis.show_code(x, *, file=None)`

Print detailed code object information for the supplied function, method, source code string or code object to `file` (or `sys.stdout` if `file` is not specified).

This is a convenient shorthand for `print(code_info(x), file=file)`, intended for interactive exploration at the interpreter prompt.

在 3.2 版被加入。

在 3.4 版的變更: 新增 `file` 參數。

`dis.dis(x=None, *, file=None, depth=None, show_caches=False, adaptive=False)`

Disassemble the `x` object. `x` can denote either a module, a class, a method, a function, a generator, an asynchronous generator, a coroutine, a code object, a string of source code or a byte sequence of raw bytecode. For a module, it disassembles all functions. For a class, it disassembles all methods (including class and static methods). For a code object or sequence of raw bytecode, it prints one line per bytecode instruction. It also recursively disassembles nested code objects. These can include generator expressions, nested functions, the bodies of nested classes, and the code objects used for annotation scopes. Strings are first compiled to code objects with the `compile()` built-in function before being disassembled. If no object is provided, this function disassembles the last traceback.

The disassembly is written as text to the supplied `file` argument if provided and to `sys.stdout` otherwise.

The maximal depth of recursion is limited by `depth` unless it is `None`. `depth=0` means no recursion.

If `show_caches` is `True`, this function will display inline cache entries used by the interpreter to specialize the bytecode.

If `adaptive` is `True`, this function will display specialized bytecode that may be different from the original bytecode.

在 3.4 版的變更: 新增 `file` 參數。

在 3.7 版的變更: Implemented recursive disassembling and added `depth` parameter.

在 3.7 版的變更: This can now handle coroutine and asynchronous generator objects.

在 3.11 版的變更: 新增 `show_caches` 與 `adaptive` 參數。

`distb(tb=None, *, file=None, show_caches=False, adaptive=False,`

show_offset=False)

Disassemble the top-of-stack function of a traceback, using the last traceback if none was passed. The instruction causing the exception is indicated.

The disassembly is written as text to the supplied *file* argument if provided and to `sys.stdout` otherwise.

在 3.4 版的變更: 新增 *file* 參數。

在 3.11 版的變更: 新增 *show_caches* 與 *adaptive* 參數。

在 3.13 版的變更: Added the *show_offsets* parameter.

`dis.disassemble (code, lasti=-1, *, file=None, show_caches=False, adaptive=False)`

disco (code, lasti=-1, *, file=None, show_caches=False, adaptive=False, show_offsets=False)

Disassemble a code object, indicating the last instruction if *lasti* was provided. The output is divided in the following columns:

1. the line number, for the first instruction of each line
2. the current instruction, indicated as `-->`,
3. a labelled instruction, indicated with `>>`,
4. the address of the instruction,
5. the operation code name,
6. operation parameters, and
7. interpretation of the parameters in parentheses.

The parameter interpretation recognizes local and global variable names, constant values, branch targets, and compare operators.

The disassembly is written as text to the supplied *file* argument if provided and to `sys.stdout` otherwise.

在 3.4 版的變更: 新增 *file* 參數。

在 3.11 版的變更: 新增 *show_caches* 與 *adaptive* 參數。

在 3.13 版的變更: Added the *show_offsets* parameter.

`dis.get_instructions (x, *, first_line=None, show_caches=False, adaptive=False)`

Return an iterator over the instructions in the supplied function, method, source code string or code object.

The iterator generates a series of *Instruction* named tuples giving the details of each operation in the supplied code.

If *first_line* is not `None`, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

The *adaptive* parameter works as it does in `dis()`.

在 3.4 版被加入。

在 3.11 版的變更: 新增 *show_caches* 與 *adaptive* 參數。

在 3.13 版的變更: The *show_caches* parameter is deprecated and has no effect. The iterator generates the *Instruction* instances with the *cache_info* field populated (regardless of the value of *show_caches*) and it no longer generates separate items for the cache entries.

`dis.findlinestarts (code)`

This generator function uses the `co_lines()` method of the code object *code* to find the offsets which are starts of lines in the source code. They are generated as (*offset*, *lineno*) pairs.

在 3.6 版的變更: Line numbers can be decreasing. Before, they were always increasing.

在 3.10 版的變更: The [PEP 626](#) `co_lines()` method is used instead of the `co_firstlineno` and `co_notab` attributes of the code object.

在 3.13 版的變更: Line numbers can be `None` for bytecode that does not map to source lines.

`dis.findlabels (code)`

Detect all offsets in the raw compiled bytecode string *code* which are jump targets, and return a list of these offsets.

`dis.stack_effect (opcode, oparg=None, *, jump=None)`

Compute the stack effect of *opcode* with argument *oparg*.

If the code has a jump target and *jump* is `True`, `stack_effect()` will return the stack effect of jumping. If *jump* is `False`, it will return the stack effect of not jumping. And if *jump* is `None` (default), it will return the maximal stack effect of both cases.

在 3.4 版被加入.

在 3.8 版的變更: 新增 *jump* 參數.

在 3.13 版的變更: If *oparg* is omitted (or `None`), the stack effect is now returned for *oparg*=0. Previously this was an error for opcodes that use their arg. It is also no longer an error to pass an integer *oparg* when the opcode does not use it; the *oparg* in this case is ignored.

32.10.4 Python Bytecode Instructions

The `get_instructions()` function and `Bytecode` class provide details of bytecode instructions as `Instruction` instances:

class `dis.Instruction`

Details for a bytecode operation

opcode

numeric code for operation, corresponding to the opcode values listed below and the bytecode values in the [Opcode collections](#).

opname

human readable name for operation

baseopcode

numeric code for the base operation if operation is specialized; otherwise equal to *opcode*

baseopname

human readable name for the base operation if operation is specialized; otherwise equal to *opname*

arg

numeric argument to operation (if any), otherwise `None`

oparg

alias for *arg*

argval

resolved arg value (if any), otherwise `None`

argrepr

human readable description of operation argument (if any), otherwise an empty string.

offset

start index of operation within bytecode sequence

start_offset

start index of operation within bytecode sequence, including prefixed `EXTENDED_ARG` operations if present; otherwise equal to *offset*

cache_offset

start index of the cache entries following the operation

end_offset

end index of the cache entries following the operation

starts_line

True if this opcode starts a source line, otherwise False

line_number

source line number associated with this opcode (if any), otherwise None

is_jump_target

True if other code jumps to here, otherwise False

jump_target

bytecode index of the jump target if this is a jump operation, otherwise None

positions

dis.Positions object holding the start and end locations that are covered by this instruction.

在 3.4 版被加入.

在 3.11 版的變更: Field `positions` is added.

在 3.13 版的變更: Changed field `starts_line`.

Added fields `start_offset`, `cache_offset`, `end_offset`, `baseopname`, `baseopcode`, `jump_target`, `oparg`, `line_number` and `cache_info`.

class `dis.Positions`

In case the information is not available, some fields might be None.

lineno**end_lineno****col_offset****end_col_offset**

在 3.11 版被加入.

The Python compiler currently generates the following bytecode instructions.

General instructions

In the following, We will refer to the interpreter stack as `STACK` and describe operations on it as if it was a Python list. The top of the stack corresponds to `STACK[-1]` in this language.

NOP

Do nothing code. Used as a placeholder by the bytecode optimizer, and to generate line tracing events.

POP_TOP

Removes the top-of-stack item:

```
STACK.pop()
```

END_FOR

Removes the top-of-stack item. Equivalent to `POP_TOP`. Used to clean up at the end of loops, hence the name.

在 3.12 版被加入.

END_SEND

Implements `del STACK[-2]`. Used to clean up when a generator exits.

在 3.12 版被加入。

COPY (*i*)

Push the *i*-th item to the top of the stack without removing it from its original location:

```
assert i > 0
STACK.append(STACK[-i])
```

在 3.11 版被加入。

SWAP (*i*)

Swap the top of the stack with the *i*-th element:

```
STACK[-i], STACK[-1] = STACK[-1], STACK[-i]
```

在 3.11 版被加入。

CACHE

Rather than being an actual instruction, this opcode is used to mark extra space for the interpreter to cache useful data directly in the bytecode itself. It is automatically hidden by all `dis` utilities, but can be viewed with `show_caches=True`.

Logically, this space is part of the preceding instruction. Many opcodes expect to be followed by an exact number of caches, and will instruct the interpreter to skip over them at runtime.

Populated caches can look like arbitrary instructions, so great care should be taken when reading or modifying raw, adaptive bytecode containing quickened data.

在 3.11 版被加入。

Unary operations

Unary operations take the top of the stack, apply the operation, and push the result back on the stack.

UNARY_NEGATIVE

Implements `STACK[-1] = -STACK[-1]`.

UNARY_NOT

Implements `STACK[-1] = not STACK[-1]`.

在 3.13 版的變更: This instruction now requires an exact *bool* operand.

UNARY_INVERT

Implements `STACK[-1] = ~STACK[-1]`.

GET_ITER

Implements `STACK[-1] = iter(STACK[-1])`.

GET_YIELD_FROM_ITER

If `STACK[-1]` is a *generator iterator* or *coroutine* object it is left as is. Otherwise, implements `STACK[-1] = iter(STACK[-1])`.

在 3.5 版被加入。

TO_BOOL

Implements `STACK[-1] = bool(STACK[-1])`.

在 3.13 版被加入。

Binary and in-place operations

Binary operations remove the top two items from the stack (`STACK[-1]` and `STACK[-2]`). They perform the operation, then put the result back on the stack.

In-place operations are like binary operations, but the operation is done in-place when `STACK[-2]` supports it, and the resulting `STACK[-1]` may be (but does not have to be) the original `STACK[-2]`.

BINARY_OP (*op*)

Implements the binary and in-place operators (depending on the value of *op*):

```
rhs = STACK.pop()
lhs = STACK.pop()
STACK.append(lhs op rhs)
```

在 3.11 版被加入.

BINARY_SUBSCR

Implements:

```
key = STACK.pop()
container = STACK.pop()
STACK.append(container[key])
```

STORE_SUBSCR

Implements:

```
key = STACK.pop()
container = STACK.pop()
value = STACK.pop()
container[key] = value
```

DELETE_SUBSCR

Implements:

```
key = STACK.pop()
container = STACK.pop()
del container[key]
```

BINARY_SLICE

Implements:

```
end = STACK.pop()
start = STACK.pop()
container = STACK.pop()
STACK.append(container[start:end])
```

在 3.12 版被加入.

STORE_SLICE

Implements:

```
end = STACK.pop()
start = STACK.pop()
container = STACK.pop()
values = STACK.pop()
container[start:end] = value
```

在 3.12 版被加入.

Coroutine opcodes**GET_AWAITABLE** (*where*)

Implements `STACK[-1] = get_awaitable(STACK[-1])`, where `get_awaitable(o)` returns `o` if `o` is a coroutine object or a generator object with the `CO_ITERABLE_COROUTINE` flag, or resolves `o.__await__`.

If the *where* operand is nonzero, it indicates where the instruction occurs:

- 1: After a call to `__aenter__`
- 2: After a call to `__aexit__`

在 3.5 版被加入。

在 3.11 版的變更: Previously, this instruction did not have an `oparg`.

GET_AITER

Implements `STACK[-1] = STACK[-1].__aiter__()`.

在 3.5 版被加入。

在 3.7 版的變更: Returning awaitable objects from `__aiter__` is no longer supported.

GET_ANEXT

Implement `STACK.append(get_awaitable(STACK[-1].__anext__()))` to the stack. See `GET_AWAITABLE` for details about `get_awaitable`.

在 3.5 版被加入。

END_ASYNC_FOR

Terminates an `async for` loop. Handles an exception raised when awaiting a next item. The stack contains the `async iterable` in `STACK[-2]` and the raised exception in `STACK[-1]`. Both are popped. If the exception is not `StopAsyncIteration`, it is re-raised.

在 3.8 版被加入。

在 3.11 版的變更: Exception representation on the stack now consist of one, not three, items.

CLEANUP_THROW

Handles an exception raised during a `throw()` or `close()` call through the current frame. If `STACK[-1]` is an instance of `StopIteration`, pop three values from the stack and push its `value` member. Otherwise, re-raise `STACK[-1]`.

在 3.12 版被加入。

BEFORE_ASYNC_WITH

Resolves `__aenter__` and `__aexit__` from `STACK[-1]`. Pushes `__aexit__` and result of `__aenter__()` to the stack:

```
STACK.extend((__aexit__, __aenter__()))
```

在 3.5 版被加入。

Miscellaneous opcodes

SET_ADD (i)

Implements:

```
item = STACK.pop()
set.add(STACK[-i], item)
```

Used to implement set comprehensions.

LIST_APPEND (i)

Implements:

```
item = STACK.pop()
list.append(STACK[-i], item)
```

Used to implement list comprehensions.

MAP_ADD (i)

Implements:

```
value = STACK.pop()
key = STACK.pop()
dict.__setitem__(STACK[-i], key, value)
```

Used to implement dict comprehensions.

在 3.1 版被加入.

在 3.8 版的變更: Map value is `STACK[-1]` and map key is `STACK[-2]`. Before, those were reversed.

For all of the `SET_ADD`, `LIST_APPEND` and `MAP_ADD` instructions, while the added value or key/value pair is popped off, the container object remains on the stack so that it is available for further iterations of the loop.

RETURN_VALUE

Returns with `STACK[-1]` to the caller of the function.

RETURN_CONST (*consti*)

Returns with `co_consts[consti]` to the caller of the function.

在 3.12 版被加入.

YIELD_VALUE

Yields `STACK.pop()` from a *generator*.

在 3.11 版的變更: `oparg` set to be the stack depth.

在 3.12 版的變更: `oparg` set to be the exception block depth, for efficient closing of generators.

在 3.13 版的變更: `oparg` is 1 if this instruction is part of a `yield-from` or `await`, and 0 otherwise.

SETUP_ANNOTATIONS

Checks whether `__annotations__` is defined in `locals()`, if not it is set up to an empty dict. This opcode is only emitted if a class or module body contains *variable annotations* statically.

在 3.6 版被加入.

POP_EXCEPT

Pops a value from the stack, which is used to restore the exception state.

在 3.11 版的變更: Exception representation on the stack now consist of one, not three, items.

RERAISE

Re-raises the exception currently on top of the stack. If `oparg` is non-zero, pops an additional value from the stack which is used to set `f_lasti` of the current frame.

在 3.9 版被加入.

在 3.11 版的變更: Exception representation on the stack now consist of one, not three, items.

PUSH_EXC_INFO

Pops a value from the stack. Pushes the current exception to the top of the stack. Pushes the value originally popped back to the stack. Used in exception handlers.

在 3.11 版被加入.

CHECK_EXC_MATCH

Performs exception matching for `except`. Tests whether the `STACK[-2]` is an exception matching `STACK[-1]`. Pops `STACK[-1]` and pushes the boolean result of the test.

在 3.11 版被加入.

CHECK_EG_MATCH

Performs exception matching for `except*`. Applies `split(STACK[-1])` on the exception group representing `STACK[-2]`.

In case of a match, pops two items from the stack and pushes the non-matching subgroup (`None` in case of full match) followed by the matching subgroup. When there is no match, pops one item (the match type) and pushes `None`.

在 3.11 版被加入。

WITH_EXCEPT_START

Calls the function in position 4 on the stack with arguments (type, val, tb) representing the exception at the top of the stack. Used to implement the call `context_manager.__exit__(*exc_info())` when an exception has occurred in a `with` statement.

在 3.9 版被加入。

在 3.11 版的變更: The `__exit__` function is in position 4 of the stack rather than 7. Exception representation on the stack now consist of one, not three, items.

LOAD_ASSERTION_ERROR

Pushes `AssertionError` onto the stack. Used by the `assert` statement.

在 3.9 版被加入。

LOAD_BUILD_CLASS

Pushes `builtins.__build_class__()` onto the stack. It is later called to construct a class.

BEFORE_WITH

This opcode performs several operations before a `with` block starts. First, it loads `__exit__()` from the context manager and pushes it onto the stack for later use by `WITH_EXCEPT_START`. Then, `__enter__()` is called. Finally, the result of calling the `__enter__()` method is pushed onto the stack.

在 3.11 版被加入。

GET_LEN

Perform `STACK.append(len(STACK[-1]))`.

在 3.10 版被加入。

MATCH_MAPPING

If `STACK[-1]` is an instance of `collections.abc.Mapping` (or, more technically: if it has the `Py_TPFLAGS_MAPPING` flag set in its `tp_flags`), push `True` onto the stack. Otherwise, push `False`.

在 3.10 版被加入。

MATCH_SEQUENCE

If `STACK[-1]` is an instance of `collections.abc.Sequence` and is *not* an instance of `str/bytes/bytearray` (or, more technically: if it has the `Py_TPFLAGS_SEQUENCE` flag set in its `tp_flags`), push `True` onto the stack. Otherwise, push `False`.

在 3.10 版被加入。

MATCH_KEYS

`STACK[-1]` is a tuple of mapping keys, and `STACK[-2]` is the match subject. If `STACK[-2]` contains all of the keys in `STACK[-1]`, push a `tuple` containing the corresponding values. Otherwise, push `None`.

在 3.10 版被加入。

在 3.11 版的變更: Previously, this instruction also pushed a boolean value indicating success (`True`) or failure (`False`).

STORE_NAME (*namei*)

Implements `name = STACK.pop()`. *namei* is the index of *name* in the attribute `co_names` of the code object. The compiler tries to use `STORE_FAST` or `STORE_GLOBAL` if possible.

DELETE_NAME (*namei*)

Implements `del name`, where *namei* is the index into `co_names` attribute of the code object.

UNPACK_SEQUENCE (*count*)

Unpacks `STACK[-1]` into *count* individual values, which are put onto the stack right-to-left. Require there to be exactly *count* values.:

```
assert (len(STACK[-1]) == count)
STACK.extend(STACK.pop()[:-count-1:-1])
```

UNPACK_EX (*counts*)

Implements assignment with a starred target: Unpacks an iterable in `STACK[-1]` into individual values, where the total number of values can be smaller than the number of items in the iterable: one of the new values will be a list of all leftover items.

The number of values before and after the list value is limited to 255.

The number of values before the list value is encoded in the argument of the opcode. The number of values after the list if any is encoded using an `EXTENDED_ARG`. As a consequence, the argument can be seen as a two bytes values where the low byte of *counts* is the number of values before the list value, the high byte of *counts* the number of values after it.

The extracted values are put onto the stack right-to-left, i.e. `a, *b, c = d` will be stored after execution as `STACK.extend((a, b, c))`.

STORE_ATTR (*namei*)

Implements:

```
obj = STACK.pop()
value = STACK.pop()
obj.name = value
```

where *namei* is the index of *name* in `co_names` of the code object.

DELETE_ATTR (*namei*)

Implements:

```
obj = STACK.pop()
del obj.name
```

where *namei* is the index of *name* into `co_names` of the code object.

STORE_GLOBAL (*namei*)

Works as [STORE_NAME](#), but stores the name as a global.

DELETE_GLOBAL (*namei*)

Works as [DELETE_NAME](#), but deletes a global name.

LOAD_CONST (*consti*)

Pushes `co_consts[consti]` onto the stack.

LOAD_NAME (*namei*)

Pushes the value associated with `co_names[namei]` onto the stack. The name is looked up within the locals, then the globals, then the builtins.

LOAD_LOCALS

Pushes a reference to the locals dictionary onto the stack. This is used to prepare namespace dictionaries for [LOAD_FROM_DICT_OR_DEREF](#) and [LOAD_FROM_DICT_OR_GLOBALS](#).

在 3.12 版被加入.

LOAD_FROM_DICT_OR_GLOBALS (*i*)

Pops a mapping off the stack and looks up the value for `co_names[namei]`. If the name is not found there, looks it up in the globals and then the builtins, similar to [LOAD_GLOBAL](#). This is used for loading global variables in annotation scopes within class bodies.

在 3.12 版被加入.

BUILD_TUPLE (*count*)

Creates a tuple consuming *count* items from the stack, and pushes the resulting tuple onto the stack:

```
if count == 0:
    value = ()
else:
    value = tuple(STACK[-count:])
    STACK = STACK[:-count]

STACK.append(value)
```

BUILD_LIST (*count*)

Works as *BUILD_TUPLE*, but creates a list.

BUILD_SET (*count*)

Works as *BUILD_TUPLE*, but creates a set.

BUILD_MAP (*count*)

Pushes a new dictionary object onto the stack. Pops $2 * count$ items so that the dictionary holds *count* entries: $\{\dots, STACK[-4]: STACK[-3], STACK[-2]: STACK[-1]\}$.

在 3.5 版的變更: The dictionary is created from stack items instead of creating an empty dictionary pre-sized to hold *count* items.

BUILD_CONST_KEY_MAP (*count*)

The version of *BUILD_MAP* specialized for constant keys. Pops the top element on the stack which contains a tuple of keys, then starting from $STACK[-2]$, pops *count* values to form values in the built dictionary.

在 3.6 版被加入.

BUILD_STRING (*count*)

Concatenates *count* strings from the stack and pushes the resulting string onto the stack.

在 3.6 版被加入.

LIST_EXTEND (*i*)

Implements:

```
seq = STACK.pop()
list.extend(STACK[-i], seq)
```

Used to build lists.

在 3.9 版被加入.

SET_UPDATE (*i*)

Implements:

```
seq = STACK.pop()
set.update(STACK[-i], seq)
```

Used to build sets.

在 3.9 版被加入.

DICTIONARY_UPDATE (*i*)

Implements:

```
map = STACK.pop()
dict.update(STACK[-i], map)
```

Used to build dicts.

在 3.9 版被加入.

DICT_MERGE (*i*)

Like *DICT_UPDATE* but raises an exception for duplicate keys.

在 3.9 版被加入。

LOAD_ATTR (*namei*)

If the low bit of *namei* is not set, this replaces `STACK[-1]` with `getattr(STACK[-1], co_names[namei>>1])`.

If the low bit of *namei* is set, this will attempt to load a method named `co_names[namei>>1]` from the `STACK[-1]` object. `STACK[-1]` is popped. This bytecode distinguishes two cases: if `STACK[-1]` has a method with the correct name, the bytecode pushes the unbound method and `STACK[-1]`. `STACK[-1]` will be used as the first argument (*self*) by *CALL* or *CALL_KW* when calling the unbound method. Otherwise, `NULL` and the object returned by the attribute lookup are pushed.

在 3.12 版的變更: If the low bit of *namei* is set, then a `NULL` or *self* is pushed to the stack before the attribute or unbound method respectively.

LOAD_SUPER_ATTR (*namei*)

This opcode implements *super()*, both in its zero-argument and two-argument forms (e.g. `super().method()`, `super().attr` and `super(cls, self).method()`, `super(cls, self).attr`).

It pops three values from the stack (from top of stack down):

- *self*: the first argument to the current method
- *cls*: the class within which the current method was defined
- the global *super*

With respect to its argument, it works similarly to *LOAD_ATTR*, except that *namei* is shifted left by 2 bits instead of 1.

The low bit of *namei* signals to attempt a method load, as with *LOAD_ATTR*, which results in pushing `NULL` and the loaded method. When it is unset a single value is pushed to the stack.

The second-low bit of *namei*, if set, means that this was a two-argument call to *super()* (unset means zero-argument).

在 3.12 版被加入。

COMPARE_OP (*opname*)

Performs a Boolean operation. The operation name can be found in `cmp_op[opname >> 5]`. If the fifth-lowest bit of *opname* is set (`opname & 16`), the result should be coerced to `bool`.

在 3.13 版的變更: The fifth-lowest bit of the *oparg* now indicates a forced conversion to *bool*.

IS_OP (*invert*)

Performs *is* comparison, or *is not* if *invert* is 1.

在 3.9 版被加入。

CONTAINS_OP (*invert*)

Performs *in* comparison, or *not in* if *invert* is 1.

在 3.9 版被加入。

IMPORT_NAME (*namei*)

Imports the module `co_names[namei]`. `STACK[-1]` and `STACK[-2]` are popped and provide the *fromlist* and *level* arguments of `__import__()`. The module object is pushed onto the stack. The current namespace is not affected: for a proper import statement, a subsequent *STORE_FAST* instruction modifies the namespace.

IMPORT_FROM (*namei*)

Loads the attribute `co_names[namei]` from the module found in `STACK[-1]`. The resulting object is pushed onto the stack, to be subsequently stored by a `STORE_FAST` instruction.

JUMP_FORWARD (*delta*)

Increments bytecode counter by *delta*.

JUMP_BACKWARD (*delta*)

Decrements bytecode counter by *delta*. Checks for interrupts.

在 3.11 版被加入。

JUMP_BACKWARD_NO_INTERRUPT (*delta*)

Decrements bytecode counter by *delta*. Does not check for interrupts.

在 3.11 版被加入。

POP_JUMP_IF_TRUE (*delta*)

If `STACK[-1]` is true, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

在 3.11 版的變更: The oparg is now a relative delta rather than an absolute target. This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

在 3.12 版的變更: This is no longer a pseudo-instruction.

在 3.13 版的變更: This instruction now requires an exact *bool* operand.

POP_JUMP_IF_FALSE (*delta*)

If `STACK[-1]` is false, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

在 3.11 版的變更: The oparg is now a relative delta rather than an absolute target. This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

在 3.12 版的變更: This is no longer a pseudo-instruction.

在 3.13 版的變更: This instruction now requires an exact *bool* operand.

POP_JUMP_IF_NOT_NONE (*delta*)

If `STACK[-1]` is not None, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

在 3.11 版被加入。

在 3.12 版的變更: This is no longer a pseudo-instruction.

POP_JUMP_IF_NONE (*delta*)

If `STACK[-1]` is None, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

在 3.11 版被加入。

在 3.12 版的變更: This is no longer a pseudo-instruction.

FOR_ITER (*delta*)

`STACK[-1]` is an *iterator*. Call its `__next__()` method. If this yields a new value, push it on the stack (leaving the iterator below it). If the iterator indicates it is exhausted then the byte code counter is incremented by *delta*.

在 3.12 版的變更: Up until 3.11 the iterator was popped when it was exhausted.

LOAD_GLOBAL (*namei*)

Loads the global named `co_names[namei>>1]` onto the stack.

在 3.11 版的變更: If the low bit of *namei* is set, then a NULL is pushed to the stack before the global variable.

LOAD_FAST (*var_num*)

Pushes a reference to the local `co_varnames[var_num]` onto the stack.

在 3.12 版的變更: This opcode is now only used in situations where the local variable is guaranteed to be initialized. It cannot raise `UnboundLocalError`.

LOAD_FAST_CHECK (*var_num*)

Pushes a reference to the local `co_varnames[var_num]` onto the stack, raising an `UnboundLocalError` if the local variable has not been initialized.

在 3.12 版被加入.

LOAD_FAST_AND_CLEAR (*var_num*)

Pushes a reference to the local `co_varnames[var_num]` onto the stack (or pushes `NULL` onto the stack if the local variable has not been initialized) and sets `co_varnames[var_num]` to `NULL`.

在 3.12 版被加入.

STORE_FAST (*var_num*)

Stores `STACK.pop()` into the local `co_varnames[var_num]`.

DELETE_FAST (*var_num*)

Deletes local `co_varnames[var_num]`.

MAKE_CELL (*i*)

Creates a new cell in slot *i*. If that slot is nonempty then that value is stored into the new cell.

在 3.11 版被加入.

LOAD_DEREF (*i*)

Loads the cell contained in slot *i* of the "fast locals" storage. Pushes a reference to the object the cell contains on the stack.

在 3.11 版的變更: *i* is no longer offset by the length of `co_varnames`.

LOAD_FROM_DICT_OR_DEREF (*i*)

Pops a mapping off the stack and looks up the name associated with slot *i* of the "fast locals" storage in this mapping. If the name is not found there, loads it from the cell contained in slot *i*, similar to `LOAD_DEREF`. This is used for loading free variables in class bodies (which previously used `LOAD_CLASSDEREF`) and in annotation scopes within class bodies.

在 3.12 版被加入.

STORE_DEREF (*i*)

Stores `STACK.pop()` into the cell contained in slot *i* of the "fast locals" storage.

在 3.11 版的變更: *i* is no longer offset by the length of `co_varnames`.

DELETE_DEREF (*i*)

Empties the cell contained in slot *i* of the "fast locals" storage. Used by the `del` statement.

在 3.2 版被加入.

在 3.11 版的變更: *i* is no longer offset by the length of `co_varnames`.

COPY_FREE_VARS (*n*)

Copies the *n* free variables from the closure into the frame. Removes the need for special code on the caller's side when calling closures.

在 3.11 版被加入.

RAISE_VARARGS (*argc*)

Raises an exception using one of the 3 forms of the `raise` statement, depending on the value of *argc*:

- 0: `raise` (re-raise previous exception)
- 1: `raise STACK[-1]` (raise exception instance or type at `STACK[-1]`)

- 2: raise STACK[-2] from STACK[-1] (raise exception instance or type at STACK[-2] with `__cause__` set to STACK[-1])

CALL (*argc*)

Calls a callable object with the number of arguments specified by *argc*. On the stack are (in ascending order):

- The callable
- `self` or `NULL`
- The remaining positional arguments

argc is the total of the positional arguments, excluding `self`.

CALL pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

在 3.11 版被加入.

在 3.13 版的變更: The callable now always appears at the same position on the stack.

在 3.13 版的變更: Calls with keyword arguments are now handled by **CALL_KW**.

CALL_KW (*argc*)

Calls a callable object with the number of arguments specified by *argc*, including one or more named arguments. On the stack are (in ascending order):

- The callable
- `self` or `NULL`
- The remaining positional arguments
- The named arguments
- A *tuple* of keyword argument names

argc is the total of the positional and named arguments, excluding `self`. The length of the tuple of keyword argument names is the number of named arguments.

CALL_KW pops all arguments, the keyword names, and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

在 3.13 版被加入.

CALL_FUNCTION_EX (*flags*)

Calls a callable object with variable set of positional and keyword arguments. If the lowest bit of *flags* is set, the top of the stack contains a mapping object containing additional keyword arguments. Before the callable is called, the mapping object and iterable object are each "unpacked" and their contents passed in as keyword and positional arguments respectively. **CALL_FUNCTION_EX** pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

在 3.6 版被加入.

PUSH_NULL

Pushes a `NULL` to the stack. Used in the call sequence to match the `NULL` pushed by **LOAD_METHOD** for non-method calls.

在 3.11 版被加入.

MAKE_FUNCTION

Pushes a new function object on the stack built from the code object at STACK[1].

在 3.10 版的變更: Flag value 0x04 is a tuple of strings instead of dictionary

在 3.11 版的變更: Qualified name at STACK[-1] was removed.

在 3.13 版的變更: Extra function attributes on the stack, signaled by oparg flags, were removed. They now use **SET_FUNCTION_ATTRIBUTE**.

SET_FUNCTION_ATTRIBUTE (*flag*)

Sets an attribute on a function object. Expects the function at `STACK[-1]` and the attribute value to set at `STACK[-2]`; consumes both and leaves the function at `STACK[-1]`. The flag determines which attribute to set:

- `0x01` a tuple of default values for positional-only and positional-or-keyword parameters in positional order
- `0x02` a dictionary of keyword-only parameters' default values
- `0x04` a tuple of strings containing parameters' annotations
- `0x08` a tuple containing cells for free variables, making a closure

在 3.13 版被加入.

BUILD_SLICE (*argc*)

Pushes a slice object on the stack. *argc* must be 2 or 3. If it is 2, implements:

```
end = STACK.pop()
start = STACK.pop()
STACK.append(slice(start, end))
```

if it is 3, implements:

```
step = STACK.pop()
end = STACK.pop()
start = STACK.pop()
STACK.append(slice(start, end, step))
```

See the `slice()` built-in function for more information.

EXTENDED_ARG (*ext*)

Prefixes any opcode which has an argument too big to fit into the default one byte. *ext* holds an additional byte which act as higher bits in the argument. For each opcode, at most three prefixal `EXTENDED_ARG` are allowed, forming an argument from two-byte to four-byte.

CONVERT_VALUE (*oparg*)

Convert value to a string, depending on *oparg*:

```
value = STACK.pop()
result = func(value)
STACK.append(result)
```

- *oparg* == 1: call `str()` on *value*
- *oparg* == 2: call `repr()` on *value*
- *oparg* == 3: call `ascii()` on *value*

Used for implementing formatted literal strings (f-strings).

在 3.13 版被加入.

FORMAT_SIMPLE

Formats the value on top of stack:

```
value = STACK.pop()
result = value.__format__("")
STACK.append(result)
```

Used for implementing formatted literal strings (f-strings).

在 3.13 版被加入.

FORMAT_SPEC

Formats the given value with the given format spec:

```
spec = STACK.pop()
value = STACK.pop()
result = value.__format__(spec)
STACK.append(result)
```

Used for implementing formatted literal strings (f-strings).

在 3.13 版被加入。

MATCH_CLASS (*count*)

STACK[-1] is a tuple of keyword attribute names, STACK[-2] is the class being matched against, and STACK[-3] is the match subject. *count* is the number of positional sub-patterns.

Pop STACK[-1], STACK[-2], and STACK[-3]. If STACK[-3] is an instance of STACK[-2] and has the positional and keyword attributes required by *count* and STACK[-1], push a tuple of extracted attributes. Otherwise, push None.

在 3.10 版被加入。

在 3.11 版的變更: Previously, this instruction also pushed a boolean value indicating success (True) or failure (False).

RESUME (*context*)

A no-op. Performs internal tracing, debugging and optimization checks.

The *context* operand consists of two parts. The lowest two bits indicate where the RESUME occurs:

- 0 The start of a function, which is neither a generator, coroutine nor an async generator
- 1 After a `yield` expression
- 2 After a `yield from` expression
- 3 After an `await` expression

The next bit is 1 if the RESUME is at except-depth 1, and 0 otherwise.

在 3.11 版被加入。

在 3.13 版的變更: The *oparg* value changed to include information about except-depth

RETURN_GENERATOR

Create a generator, coroutine, or async generator from the current frame. Used as first opcode of in code object for the above mentioned callables. Clear the current frame and return the newly created generator.

在 3.11 版被加入。

SEND (*delta*)

Equivalent to `STACK[-1] = STACK[-2].send(STACK[-1])`. Used in `yield from` and `await` statements.

If the call raises `StopIteration`, pop the top value from the stack, push the exception's `value` attribute, and increment the bytecode counter by *delta*.

在 3.11 版被加入。

HAVE_ARGUMENT

This is not really an opcode. It identifies the dividing line between opcodes in the range [0,255] which don't use their argument and those that do (< HAVE_ARGUMENT and >= HAVE_ARGUMENT, respectively).

If your application uses pseudo instructions or specialized instructions, use the `hasarg` collection instead.

在 3.6 版的變更: Now every instruction has an argument, but opcodes < HAVE_ARGUMENT ignore it. Before, only opcodes >= HAVE_ARGUMENT had an argument.

在 3.12 版的變更: Pseudo instructions were added to the `dis` module, and for them it is not true that comparison with `HAVE_ARGUMENT` indicates whether they use their arg.

在 3.13 版之後被用: Use `hasarg` instead.

CALL_INTRINSIC_1

Calls an intrinsic function with one argument. Passes `STACK[-1]` as the argument and sets `STACK[-1]` to the result. Used to implement functionality that is not performance critical.

The operand determines which intrinsic function is called:

Operand	Description
INTRINSIC_1_INVALID	Not valid
INTRINSIC_PRINT	Prints the argument to standard out. Used in the REPL.
INTRINSIC_IMPORT	Performs <code>import *</code> for the named module.
INTRINSIC_STOPITER	Extracts the return value from a <code>StopIteration</code> exception.
INTRINSIC_ASYNC_GEN_WRAP	Wraps an async generator value
INTRINSIC_UNARY_POSITIVE	Performs the unary <code>+</code> operation
INTRINSIC_LIST_TO_TUPLE	Converts a list to a tuple
INTRINSIC_TYPEVAR_CREATE	Creates a <code>typing.TypeVar</code>
INTRINSIC_PARAMSPEC_CREATE	Creates a <code>typing.ParamSpec</code>
INTRINSIC_TYPEVARTUPLE_CREATE	Creates a <code>typing.TypeVarTuple</code>
INTRINSIC_GENERIC_SUBSCRIPT	Returns <code>typing.Generic</code> subscripted with the argument
INTRINSIC_TYPEALIAS_CREATE	Creates a <code>typing.TypeAliasType</code> ; used in the <code>type</code> statement. The argument is a tuple of the type alias's name, type parameters, and value.

在 3.12 版被加入.

CALL_INTRINSIC_2

Calls an intrinsic function with two arguments. Used to implement functionality that is not performance critical:

```
arg2 = STACK.pop()
arg1 = STACK.pop()
result = intrinsic2(arg1, arg2)
STACK.append(result)
```

The operand determines which intrinsic function is called:

Operand	Description
INTRINSIC_2_INVALID	Not valid
INTRINSIC_PREP_RERAISE_STAR	Calculates the <code>ExceptionGroup</code> to raise from a <code>try-except*</code> .
INTRINSIC_TYPEVAR_WITH_BOUND	Creates a <code>typing.TypeVar</code> with a bound.
INTRINSIC_TYPEVAR_WITH_CONSTRAINTS	Creates a <code>typing.TypeVar</code> with constraints.
INTRINSIC_SET_FUNCTION_TYPE_PARAMS	Sets the <code>__type_params__</code> attribute of a function.

在 3.12 版被加入.

Pseudo-instructions

These opcodes do not appear in Python bytecode. They are used by the compiler but are replaced by real opcodes or removed before bytecode is generated.

SETUP_FINALLY (target)

Set up an exception handler for the following code block. If an exception occurs, the value stack level is restored to its current state and control is transferred to the exception handler at `target`.

SETUP_CLEANUP (*target*)

Like `SETUP_FINALLY`, but in case of an exception also pushes the last instruction (`lasti`) to the stack so that `RERAISE` can restore it. If an exception occurs, the value stack level and the last instruction on the frame are restored to their current state, and control is transferred to the exception handler at `target`.

SETUP_WITH (*target*)

Like `SETUP_CLEANUP`, but in case of an exception one more item is popped from the stack before control is transferred to the exception handler at `target`.

This variant is used in `with` and `async with` constructs, which push the return value of the context manager's `__enter__()` or `__aenter__()` to the stack.

POP_BLOCK

Marks the end of the code block associated with the last `SETUP_FINALLY`, `SETUP_CLEANUP` or `SETUP_WITH`.

JUMP**JUMP_NO_INTERRUPT**

Undirected relative jump instructions which are replaced by their directed (forward/backward) counterparts by the assembler.

LOAD_CLOSURE (*i*)

Pushes a reference to the cell contained in slot `i` of the "fast locals" storage.

Note that `LOAD_CLOSURE` is replaced with `LOAD_FAST` in the assembler.

在 3.13 版的變更: This opcode is now a pseudo-instruction.

LOAD_METHOD

Optimized unbound method lookup. Emitted as a `LOAD_ATTR` opcode with a flag set in the arg.

32.10.5 Opcode collections

These collections are provided for automatic introspection of bytecode instructions:

在 3.12 版的變更: The collections now contain pseudo instructions and instrumented instructions as well. These are opcodes with values `>= MIN_PSEUDO_OPCODE` and `>= MIN_INSTRUMENTED_OPCODE`.

dis.opname

Sequence of operation names, indexable using the bytecode.

dis.opmap

Dictionary mapping operation names to bytecodes.

dis.cmp_op

Sequence of all compare operation names.

dis.hasarg

Sequence of bytecodes that use their argument.

在 3.12 版被加入.

dis.hasconst

Sequence of bytecodes that access a constant.

dis.hasfree

Sequence of bytecodes that access a free variable. 'free' in this context refers to names in the current scope that are referenced by inner scopes or names in outer scopes that are referenced from this scope. It does *not* include references to global or builtin scopes.

`dis.hasname`

Sequence of bytecodes that access an attribute by name.

`dis.hasjump`

Sequence of bytecodes that have a jump target. All jumps are relative.

在 3.13 版被加入。

`dis.haslocal`

Sequence of bytecodes that access a local variable.

`dis.hascompare`

Sequence of bytecodes of Boolean operations.

`dis.hasexc`

Sequence of bytecodes that set an exception handler.

在 3.12 版被加入。

`dis.hasjrel`

Sequence of bytecodes that have a relative jump target.

在 3.13 版之後被啟用: All jumps are now relative. Use *hasjump*.

`dis.hasjabs`

Sequence of bytecodes that have an absolute jump target.

在 3.13 版之後被啟用: All jumps are now relative. This list is empty.

32.11 pickletools --- pickle 開發者的工具

原始碼: [Lib/pickletools.py](#)

該模組包含與 *pickle* 模組的詳細資訊相關的各種常數、一些有關實作的冗長解釋以及一些用於分析已 pickle 資料的有用函式。該模組的內容對於有 *pickle* 相關工作的 Python 核心開發人員很有用；*pickle* 模組的一般使用者可能不會發現 *pickletools* 模組。

32.11.1 命令列用法

在 3.2 版被加入。

當從命令列呼叫時，`python -m pickletools` 將拆解 (disassemble) 一個或多個 pickle 檔案的內容。請注意，如果你想查看儲存在 pickle 中的 Python 物件而不是 pickle 格式的詳細資訊，你可能需要使用 `-m pickle`。但是，當你要檢查的 pickle 檔案來自不受信任的來源時，`-m pickletools` 是一個更安全的選項，因為它不執行 pickle 位元組碼。

例如，pickle 於檔案 `x.pickle` 中的元組 (1, 2)：

```
$ python -m pickle x.pickle
(1, 2)

$ python -m pickletools x.pickle
0: \x80 PROTO      3
2: K    BININT1    1
4: K    BININT1    2
6: \x86 TUPLE2
7: q    BINPUT     0
9: .    STOP
highest protocol among opcodes = 2
```

命令列選項

-a, --annotate

用簡短的操作碼 (opcode) 描述釋每一行。

-o, --output=<file>

應將輸出結果寫入之檔案的名稱。

-l, --indentlevel=<num>

新 MARK 級縮進的空格數。

-m, --memo

當拆解多個物件時，會在拆解間保留備忘。

-p, --preamble=<preamble>

當指定多個 pickle 檔案時，會在每次拆解之前印出給定的一段序言 (preamble)。

32.11.2 程式化介面

`pickletools.dis (pickle, out=None, memo=None, indentlevel=4, annotate=0)`

將 pickle 的符號拆解 (symbolic disassembly) 輸出到類檔案物件 *out*，預設 `sys.stdout`。*pickle* 可以是字串或類檔案物件。*memo* 可以是一個 Python 字典，將用作 pickle 的備忘；它可用於對同一 pickler 建立的多個 pickle 執行拆解。串流中由 MARK 操作碼指示的連續級由 *indentlevel* 空格縮進。如果 *annotate* 指定非零值，則輸出中的每個操作碼都會用簡短的描述進行釋。*annotate* 的值用作釋之起始行提示。

在 3.2 版的變更: 新增 *annotate* 參數。

`pickletools.genops (pickle)`

提供 pickle 中所有操作碼的一個 *iterator*，回傳形式 `(opcode, arg, pos)` 三元組序列。*opcode* 是 `OpcodeInfo` 類的實例；*arg* 是操作碼引數的解碼值（作 Python 物件）；*pos* 是該操作碼所在的位置。*pickle* 可以是字串或類檔案物件。

`pickletools.optimize (picklestring)`

消除未使用的 PUT 操作碼後回傳一個新的等效 pickle 字串。最佳化後的 pickle 更短、傳輸時間更少、需要更小的儲存空間，且 unpickle 效率也更高。

MS Windows 特有服務

此章節描述僅在 MS Windows 系統上可用的模組 (module)。

33.1 msvcrt --- MS VC++ runtime 提供的有用例程

These functions provide access to some useful capabilities on Windows platforms. Some higher-level modules use these functions to build the Windows implementations of their services. For example, the *getpass* module uses this in the implementation of the *getpass()* function.

Further documentation on these functions can be found in the Platform API documentation.

The module implements both the normal and wide char variants of the console I/O api. The normal API deals only with ASCII characters and is of limited use for internationalized applications. The wide char API should be used where ever possible.

在 3.3 版的變更: Operations in this module now raise *OSError* where *IOError* was raised.

33.1.1 File Operations

`msvcrt.locking(fd, mode, nbytes)`

Lock part of a file based on file descriptor *fd* from the C runtime. Raises *OSError* on failure. The locked region of the file extends from the current file position for *nbytes* bytes, and may continue beyond the end of the file. *mode* must be one of the `LK_*` constants listed below. Multiple regions in a file may be locked at the same time, but may not overlap. Adjacent regions are not merged; they must be unlocked individually.

引發一個附帶引數 *fd*、*mode*、*nbytes* 的稽核事件 `msvcrt.locking`。

`msvcrt.LK_LOCK`

`msvcrt.LK_RLCK`

Locks the specified bytes. If the bytes cannot be locked, the program immediately tries again after 1 second. If, after 10 attempts, the bytes cannot be locked, *OSError* is raised.

`msvcrt.LK_NBLCK`

`msvcrt.LK_NBRLCK`

Locks the specified bytes. If the bytes cannot be locked, `OSError` is raised.

`msvcrt.LK_UNLCK`

Unlocks the specified bytes, which must have been previously locked.

`msvcrt.setmode(fd, flags)`

Set the line-end translation mode for the file descriptor `fd`. To set it to text mode, `flags` should be `os.O_TEXT`; for binary, it should be `os.O_BINARY`.

`msvcrt.open_osfhandle(handle, flags)`

Create a C runtime file descriptor from the file handle `handle`. The `flags` parameter should be a bitwise OR of `os.O_APPEND`, `os.O_RDONLY`, `os.O_TEXT` and `os.O_NOINHERIT`. The returned file descriptor may be used as a parameter to `os.fdopen()` to create a file object.

The file descriptor is inheritable by default. Pass `os.O_NOINHERIT` flag to make it non inheritable.

引發一個附帶引數 `handle`、`flags` 的稽核事件 `msvcrt.open_osfhandle`。

`msvcrt.get_osfhandle(fd)`

Return the file handle for the file descriptor `fd`. Raises `OSError` if `fd` is not recognized.

引發一個附帶引數 `fd` 的稽核事件 `msvcrt.get_osfhandle`。

33.1.2 Console I/O

`msvcrt.kbhit()`

Returns a nonzero value if a keypress is waiting to be read. Otherwise, return 0.

`msvcrt.getch()`

Read a keypress and return the resulting character as a byte string. Nothing is echoed to the console. This call will block if a keypress is not already available, but will not wait for Enter to be pressed. If the pressed key was a special function key, this will return `'\000'` or `'\xe0'`; the next call will return the keycode. The Control-C keypress cannot be read with this function.

`msvcrt.getwch()`

Wide char variant of `getch()`, returning a Unicode value.

`msvcrt.getche()`

Similar to `getch()`, but the keypress will be echoed if it represents a printable character.

`msvcrt.getwche()`

Wide char variant of `getche()`, returning a Unicode value.

`msvcrt.putch(char)`

Print the byte string `char` to the console without buffering.

`msvcrt.putwch(unicode_char)`

Wide char variant of `putch()`, accepting a Unicode value.

`msvcrt.ungetch(char)`

Cause the byte string `char` to be "pushed back" into the console buffer; it will be the next character read by `getch()` or `getche()`.

`msvcrt.ungetwch(unicode_char)`

Wide char variant of `ungetch()`, accepting a Unicode value.

33.1.3 Other Functions

`msvcrt.heapmin()`

Force the `malloc()` heap to clean itself up and return unused blocks to the operating system. On failure, this raises `OSError`.

`msvcrt.set_error_mode(mode)`

Changes the location where the C runtime writes an error message for an error that might end the program. *mode* must be one of the `OUT_*` constants listed below or `REPORT_ERRMODE`. Returns the old setting or -1 if an error occurs. Only available in debug build of Python.

`msvcrt.OUT_TO_DEFAULT`

Error sink is determined by the app's type. Only available in debug build of Python.

`msvcrt.OUT_TO_STDERR`

Error sink is a standard error. Only available in debug build of Python.

`msvcrt.OUT_TO_MSGBOX`

Error sink is a message box. Only available in debug build of Python.

`msvcrt.REPORT_ERRMODE`

Report the current error mode value. Only available in debug build of Python.

`msvcrt.CrtSetReportMode(type, mode)`

Specifies the destination or destinations for a specific report type generated by `_CrtDbgReport()` in the MS VC++ runtime. *type* must be one of the `CRT_*` constants listed below. *mode* must be one of the `CRTDBG_*` constants listed below. Only available in debug build of Python.

`msvcrt.CrtSetReportFile(type, file)`

After you use `CrtSetReportMode()` to specify `CRTDBG_MODE_FILE`, you can specify the file handle to receive the message text. *type* must be one of the `CRT_*` constants listed below. *file* should be the file handle you want specified. Only available in debug build of Python.

`msvcrt.CRT_WARN`

Warnings, messages, and information that doesn't need immediate attention.

`msvcrt.CRT_ERROR`

Errors, unrecoverable problems, and issues that require immediate attention.

`msvcrt.CRT_ASSERT`

Assertion failures.

`msvcrt.CRTDBG_MODE_DEBUG`

Writes the message to the debugger's output window.

`msvcrt.CRTDBG_MODE_FILE`

Writes the message to a user-supplied file handle. `CrtSetReportFile()` should be called to define the specific file or stream to use as the destination.

`msvcrt.CRTDBG_MODE_WNDW`

Creates a message box to display the message along with the Abort, Retry, and Ignore buttons.

`msvcrt.CRTDBG_REPORT_MODE`

Returns current *mode* for the specified *type*.

`msvcrt.CRT_ASSEMBLY_VERSION`

The CRT Assembly version, from the `crtassem.h` header file.

`msvcrt.VC_ASSEMBLY_PUBLICKEYTOKEN`

The VC Assembly public key token, from the `crtassem.h` header file.

`msvcrt.LIBRARIES_ASSEMBLY_NAME_PREFIX`

The Libraries Assembly name prefix, from the `crtassem.h` header file.

33.2 winreg --- Windows 表存取

These functions expose the Windows registry API to Python. Instead of using an integer as the registry handle, a *handle object* is used to ensure that the handles are closed correctly, even if the programmer neglects to explicitly close them.

在 3.3 版的變更: Several functions in this module used to raise a *WindowsError*, which is now an alias of *OSError*.

33.2.1 函式

This module offers the following functions:

`winreg.CloseKey(hkey)`

Closes a previously opened registry key. The *hkey* argument specifies a previously opened key.

備

If *hkey* is not closed using this method (or via *hkey.Close()*), it is closed when the *hkey* object is destroyed by Python.

`winreg.ConnectRegistry(computer_name, key)`

Establishes a connection to a predefined registry handle on another computer, and returns a *handle object*.

computer_name is the name of the remote computer, of the form `r"\\computername"`. If `None`, the local computer is used.

key is the predefined handle to connect to.

The return value is the handle of the opened key. If the function fails, an *OSError* exception is raised.

引發一個附帶引數 *computer_name*、*key* 的稽核事件 `winreg.ConnectRegistry`。

在 3.3 版的變更: See *above*.

`winreg.CreateKey(key, sub_key)`

Creates or opens the specified key, returning a *handle object*.

key is an already open key, or one of the predefined *HKEY_* constants*.

sub_key is a string that names the key this method opens or creates.

If *key* is one of the predefined keys, *sub_key* may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an *OSError* exception is raised.

引發一個附帶引數 *key*、*sub_key*、*access* 的稽核事件 `winreg.CreateKey`。

引發一個附帶引數 *key* 的稽核事件 `winreg.OpenKey/result`。

在 3.3 版的變更: See *above*.

`winreg.CreateKeyEx(key, sub_key, reserved=0, access=KEY_WRITE)`

Creates or opens the specified key, returning a *handle object*.

key is an already open key, or one of the predefined *HKEY_* constants*.

sub_key is a string that names the key this method opens or creates.

reserved is a reserved integer, and must be zero. The default is zero.

access is an integer that specifies an access mask that describes the desired security access for the key. Default is `KEY_WRITE`. See [Access Rights](#) for other allowed values.

If *key* is one of the predefined keys, *sub_key* may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an `OSError` exception is raised.

引發一個附帶引數 *key*、*sub_key*、*access* 的稽核事件 `winreg.CreateKey`。

引發一個附帶引數 *key* 的稽核事件 `winreg.OpenKey/result`。

在 3.2 版被加入。

在 3.3 版的變更: See [above](#).

`winreg.DeleteKey` (*key*, *sub_key*)

Deletes the specified key.

key is an already open key, or one of the predefined `HKEY_* constants`.

sub_key is a string that must be a subkey of the key identified by the *key* parameter. This value must not be `None`, and the key may not have subkeys.

This method can not delete keys with subkeys.

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an `OSError` exception is raised.

引發一個附帶引數 *key*、*sub_key*、*access* 的稽核事件 `winreg.DeleteKey`。

在 3.3 版的變更: See [above](#).

`winreg.DeleteKeyEx` (*key*, *sub_key*, *access*=`KEY_WOW64_64KEY`, *reserved*=0)

Deletes the specified key.

key is an already open key, or one of the predefined `HKEY_* constants`.

sub_key is a string that must be a subkey of the key identified by the *key* parameter. This value must not be `None`, and the key may not have subkeys.

reserved is a reserved integer, and must be zero. The default is zero.

access is an integer that specifies an access mask that describes the desired security access for the key. Default is `KEY_WOW64_64KEY`. On 32-bit Windows, the WOW64 constants are ignored. See [Access Rights](#) for other allowed values.

This method can not delete keys with subkeys.

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an `OSError` exception is raised.

On unsupported Windows versions, `NotImplementedError` is raised.

引發一個附帶引數 *key*、*sub_key*、*access* 的稽核事件 `winreg.DeleteKey`。

在 3.2 版被加入。

在 3.3 版的變更: See [above](#).

`winreg.DeleteValue` (*key*, *value*)

Removes a named value from a registry key.

key is an already open key, or one of the predefined `HKEY_* constants`.

value is a string that identifies the value to remove.

引發一個附帶引數 *key*、*value* 的稽核事件 `winreg.DeleteValue`。

`winreg.EnumKey(key, index)`

Enumerates subkeys of an open registry key, returning a string.

key is an already open key, or one of the predefined *HKEY_* constants*.

index is an integer that identifies the index of the key to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly until an *OSError* exception is raised, indicating, no more values are available.

引發一個附帶引數 *key*、*index* 的稽核事件 `winreg.EnumKey`。

在 3.3 版的變更: See *above*.

`winreg.EnumValue(key, index)`

Enumerates values of an open registry key, returning a tuple.

key is an already open key, or one of the predefined *HKEY_* constants*.

index is an integer that identifies the index of the value to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly, until an *OSError* exception is raised, indicating no more values.

The result is a tuple of 3 items:

Index	含義
0	A string that identifies the value name
1	An object that holds the value data, and whose type depends on the underlying registry type
2	An integer that identifies the type of the value data (see table in docs for <i>SetValueEx()</i>)

引發一個附帶引數 *key*、*index* 的稽核事件 `winreg.EnumValue`。

在 3.3 版的變更: See *above*.

`winreg.ExpandEnvironmentStrings(str)`

Expands environment variable placeholders *%NAME%* in strings like *REG_EXPAND_SZ*:

```
>>> ExpandEnvironmentStrings('%windir%')
'C:\\Windows'
```

引發一個附帶引數 *str* 的稽核事件 `winreg.ExpandEnvironmentStrings`。

`winreg.FlushKey(key)`

Writes all the attributes of a key to the registry.

key is an already open key, or one of the predefined *HKEY_* constants*.

It is not necessary to call *FlushKey()* to change a key. Registry changes are flushed to disk by the registry using its lazy flusher. Registry changes are also flushed to disk at system shutdown. Unlike *CloseKey()*, the *FlushKey()* method returns only when all the data has been written to the registry. An application should only call *FlushKey()* if it requires absolute certainty that registry changes are on disk.

備F

If you don't know whether a *FlushKey()* call is required, it probably isn't.

`winreg.LoadKey(key, sub_key, file_name)`

Creates a subkey under the specified key and stores registration information from a specified file into that subkey.

key is a handle returned by *ConnectRegistry()* or one of the constants *HKEY_USERS* or *HKEY_LOCAL_MACHINE*.

sub_key is a string that identifies the subkey to load.

file_name is the name of the file to load registry data from. This file must have been created with the [SaveKey\(\)](#) function. Under the file allocation table (FAT) file system, the filename may not have an extension.

A call to [LoadKey\(\)](#) fails if the calling process does not have the SE_RESTORE_PRIVILEGE privilege. Note that privileges are different from permissions -- see the [RegLoadKey documentation](#) for more details.

If *key* is a handle returned by [ConnectRegistry\(\)](#), then the path specified in *file_name* is relative to the remote computer.

引發一個附帶引數 *key*、*sub_key*、*file_name* 的稽核事件 `winreg.LoadKey`。

`winreg.OpenKey(key, sub_key, reserved=0, access=KEY_READ)`

`winreg.OpenKeyEx(key, sub_key, reserved=0, access=KEY_READ)`

Opens the specified key, returning a *handle object*.

key is an already open key, or one of the predefined [HKEY_* constants](#).

sub_key is a string that identifies the sub_key to open.

reserved is a reserved integer, and must be zero. The default is zero.

access is an integer that specifies an access mask that describes the desired security access for the key. Default is [KEY_READ](#). See [Access Rights](#) for other allowed values.

The result is a new handle to the specified key.

If the function fails, [OSError](#) is raised.

引發一個附帶引數 *key*、*sub_key*、*access* 的稽核事件 `winreg.OpenKey`。

引發一個附帶引數 *key* 的稽核事件 `winreg.OpenKey/result`。

在 3.2 版的變更: Allow the use of named arguments.

在 3.3 版的變更: See [above](#).

`winreg.QueryInfoKey(key)`

Returns information about a key, as a tuple.

key is an already open key, or one of the predefined [HKEY_* constants](#).

The result is a tuple of 3 items:

In- dex	含義
0	An integer giving the number of sub keys this key has.
1	An integer giving the number of values this key has.
2	An integer giving when the key was last modified (if available) as 100's of nanoseconds since Jan 1, 1601.

引發一個附帶引數 *key* 的稽核事件 `winreg.QueryInfoKey`。

`winreg.QueryValue(key, sub_key)`

Retrieves the unnamed value for a key, as a string.

key is an already open key, or one of the predefined [HKEY_* constants](#).

sub_key is a string that holds the name of the subkey with which the value is associated. If this parameter is None or empty, the function retrieves the value set by the [SetValue\(\)](#) method for the key identified by *key*.

Values in the registry have name, type, and data components. This method retrieves the data for a key's first value that has a NULL name. But the underlying API call doesn't return the type, so always use [QueryValueEx\(\)](#) if possible.

引發一個附帶引數 `key`、`sub_key`、`value_name` 的稽核事件 `winreg.QueryKey`。

`winreg.QueryValueEx(key, value_name)`

Retrieves the type and data for a specified value name associated with an open registry key.

`key` is an already open key, or one of the predefined *HKEY_* constants*.

`value_name` is a string indicating the value to query.

The result is a tuple of 2 items:

Index	含義
0	The value of the registry item.
1	An integer giving the registry type for this value (see table in docs for <code>SetValueEx()</code>)

引發一個附帶引數 `key`、`sub_key`、`value_name` 的稽核事件 `winreg.QueryKey`。

`winreg.SaveKey(key, file_name)`

Saves the specified key, and all its subkeys to the specified file.

`key` is an already open key, or one of the predefined *HKEY_* constants*.

`file_name` is the name of the file to save registry data to. This file cannot already exist. If this filename includes an extension, it cannot be used on file allocation table (FAT) file systems by the `LoadKey()` method.

If `key` represents a key on a remote computer, the path described by `file_name` is relative to the remote computer. The caller of this method must possess the **SeBackupPrivilege** security privilege. Note that privileges are different than permissions -- see the [Conflicts Between User Rights and Permissions](#) documentation for more details.

This function passes `NULL` for `security_attributes` to the API.

引發一個附帶引數 `key`、`file_name` 的稽核事件 `winreg.SaveKey`。

`winreg.SetValue(key, sub_key, type, value)`

Associates a value with a specified key.

`key` is an already open key, or one of the predefined *HKEY_* constants*.

`sub_key` is a string that names the subkey with which the value is associated.

`type` is an integer that specifies the type of the data. Currently this must be `REG_SZ`, meaning only strings are supported. Use the `SetValueEx()` function for support for other data types.

`value` is a string that specifies the new value.

If the key specified by the `sub_key` parameter does not exist, the `SetValue` function creates it.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

The key identified by the `key` parameter must have been opened with `KEY_SET_VALUE` access.

引發一個附帶引數 `key`、`sub_key`、`type`、`value` 的稽核事件 `winreg.SetValue`。

`winreg.SetValueEx(key, value_name, reserved, type, value)`

Stores data in the value field of an open registry key.

`key` is an already open key, or one of the predefined *HKEY_* constants*.

`value_name` is a string that names the subkey with which the value is associated.

`reserved` can be anything -- zero is always passed to the API.

`type` is an integer that specifies the type of the data. See *Value Types* for the available types.

`value` is a string that specifies the new value.

This method can also set additional value and type information for the specified key. The key identified by the key parameter must have been opened with `KEY_SET_VALUE` access.

To open the key, use the `CreateKey()` or `OpenKey()` methods.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

引發一個附帶引數 key、sub_key、type、value 的稽核事件 `winreg.SetValue`。

`winreg.DisableReflectionKey(key)`

Disables registry reflection for 32-bit processes running on a 64-bit operating system.

key is an already open key, or one of the predefined `HKEY_* constants`.

Will generally raise `NotImplementedError` if executed on a 32-bit operating system.

If the key is not on the reflection list, the function succeeds but has no effect. Disabling reflection for a key does not affect reflection of any subkeys.

引發一個附帶引數 key 的稽核事件 `winreg.DisableReflectionKey`。

`winreg.EnableReflectionKey(key)`

Restores registry reflection for the specified disabled key.

key is an already open key, or one of the predefined `HKEY_* constants`.

Will generally raise `NotImplementedError` if executed on a 32-bit operating system.

Restoring reflection for a key does not affect reflection of any subkeys.

引發一個附帶引數 key 的稽核事件 `winreg.EnableReflectionKey`。

`winreg.QueryReflectionKey(key)`

Determines the reflection state for the specified key.

key is an already open key, or one of the predefined `HKEY_* constants`.

Returns `True` if reflection is disabled.

Will generally raise `NotImplementedError` if executed on a 32-bit operating system.

引發一個附帶引數 key 的稽核事件 `winreg.QueryReflectionKey`。

33.2.2 常數

The following constants are defined for use in many `winreg` functions.

HKEY_* Constants

`winreg.HKEY_CLASSES_ROOT`

Registry entries subordinate to this key define types (or classes) of documents and the properties associated with those types. Shell and COM applications use the information stored under this key.

`winreg.HKEY_CURRENT_USER`

Registry entries subordinate to this key define the preferences of the current user. These preferences include the settings of environment variables, data about program groups, colors, printers, network connections, and application preferences.

`winreg.HKEY_LOCAL_MACHINE`

Registry entries subordinate to this key define the physical state of the computer, including data about the bus type, system memory, and installed hardware and software.

`winreg.HKEY_USERS`

Registry entries subordinate to this key define the default user configuration for new users on the local computer and the user configuration for the current user.

`winreg.HKEY_PERFORMANCE_DATA`

Registry entries subordinate to this key allow you to access performance data. The data is not actually stored in the registry; the registry functions cause the system to collect the data from its source.

`winreg.HKEY_CURRENT_CONFIG`

Contains information about the current hardware profile of the local computer system.

`winreg.HKEY_DYN_DATA`

This key is not used in versions of Windows after 98.

Access Rights

For more information, see [Registry Key Security and Access](#).

`winreg.KEY_ALL_ACCESS`

Combines the `STANDARD_RIGHTS_REQUIRED`, `KEY_QUERY_VALUE`, `KEY_SET_VALUE`, `KEY_CREATE_SUB_KEY`, `KEY_ENUMERATE_SUB_KEYS`, `KEY_NOTIFY`, and `KEY_CREATE_LINK` access rights.

`winreg.KEY_WRITE`

Combines the `STANDARD_RIGHTS_WRITE`, `KEY_SET_VALUE`, and `KEY_CREATE_SUB_KEY` access rights.

`winreg.KEY_READ`

Combines the `STANDARD_RIGHTS_READ`, `KEY_QUERY_VALUE`, `KEY_ENUMERATE_SUB_KEYS`, and `KEY_NOTIFY` values.

`winreg.KEY_EXECUTE`

Equivalent to `KEY_READ`.

`winreg.KEY_QUERY_VALUE`

Required to query the values of a registry key.

`winreg.KEY_SET_VALUE`

Required to create, delete, or set a registry value.

`winreg.KEY_CREATE_SUB_KEY`

Required to create a subkey of a registry key.

`winreg.KEY_ENUMERATE_SUB_KEYS`

Required to enumerate the subkeys of a registry key.

`winreg.KEY_NOTIFY`

Required to request change notifications for a registry key or for subkeys of a registry key.

`winreg.KEY_CREATE_LINK`

Reserved for system use.

64-bit Specific

For more information, see [Accessing an Alternate Registry View](#).

`winreg.KEY_WOW64_64KEY`

Indicates that an application on 64-bit Windows should operate on the 64-bit registry view. On 32-bit Windows, this constant is ignored.

`winreg.KEY_WOW64_32KEY`

Indicates that an application on 64-bit Windows should operate on the 32-bit registry view. On 32-bit Windows, this constant is ignored.

Value Types

For more information, see [Registry Value Types](#).

`winreg.REG_BINARY`

Binary data in any form.

`winreg.REG_DWORD`

32-bit number.

`winreg.REG_DWORD_LITTLE_ENDIAN`

A 32-bit number in little-endian format. Equivalent to `REG_DWORD`.

`winreg.REG_DWORD_BIG_ENDIAN`

A 32-bit number in big-endian format.

`winreg.REG_EXPAND_SZ`

Null-terminated string containing references to environment variables (%PATH%).

`winreg.REG_LINK`

A Unicode symbolic link.

`winreg.REG_MULTI_SZ`

A sequence of null-terminated strings, terminated by two null characters. (Python handles this termination automatically.)

`winreg.REG_NONE`

No defined value type.

`winreg.REG_QWORD`

A 64-bit number.

在 3.6 版被加入.

`winreg.REG_QWORD_LITTLE_ENDIAN`

A 64-bit number in little-endian format. Equivalent to `REG_QWORD`.

在 3.6 版被加入.

`winreg.REG_RESOURCE_LIST`

A device-driver resource list.

`winreg.REG_FULL_RESOURCE_DESCRIPTOR`

A hardware setting.

`winreg.REG_RESOURCE_REQUIREMENTS_LIST`

A hardware resource list.

`winreg.REG_SZ`

A null-terminated string.

33.2.3 Registry Handle Objects

This object wraps a Windows HKEY object, automatically closing it when the object is destroyed. To guarantee cleanup, you can call either the `Close()` method on the object, or the `CloseKey()` function.

All registry functions in this module return one of these objects.

All registry functions in this module which accept a handle object also accept an integer, however, use of the handle object is encouraged.

Handle objects provide semantics for `__bool__()` -- thus

```
if handle:
    print("Yes")
```

will print `Yes` if the handle is currently valid (has not been closed or detached).

The object also support comparison semantics, so handle objects will compare true if they both reference the same underlying Windows handle value.

Handle objects can be converted to an integer (e.g., using the built-in `int()` function), in which case the underlying Windows handle value is returned. You can also use the `Detach()` method to return the integer handle, and also disconnect the Windows handle from the handle object.

`PyHKEY.Close()`

Closes the underlying Windows handle.

If the handle is already closed, no error is raised.

`PyHKEY.Detach()`

Detaches the Windows handle from the handle object.

The result is an integer that holds the value of the handle before it is detached. If the handle is already detached or closed, this will return zero.

After calling this function, the handle is effectively invalidated, but the handle is not closed. You would call this function when you need the underlying Win32 handle to exist beyond the lifetime of the handle object.

引發一個附帶引數 `key` 的稽核事件 `winreg.PyHKEY.Detach`。

`PyHKEY.__enter__()`

`PyHKEY.__exit__(*exc_info)`

The HKEY object implements `__enter__()` and `__exit__()` and thus supports the context protocol for the `with` statement:

```
with OpenKey(HKEY_LOCAL_MACHINE, "foo") as key:
    ... # work with key
```

will automatically close `key` when control leaves the `with` block.

33.3 winsound --- Windows 的聲音播放介面

The `winsound` module provides access to the basic sound-playing machinery provided by Windows platforms. It includes functions and several constants.

`winsound.Beep(frequency, duration)`

Beep the PC's speaker. The *frequency* parameter specifies frequency, in hertz, of the sound, and must be in the range 37 through 32,767. The *duration* parameter specifies the number of milliseconds the sound should last. If the system is not able to beep the speaker, `RuntimeError` is raised.

`winsound.PlaySound(sound, flags)`

Call the underlying `PlaySound()` function from the Platform API. The *sound* parameter may be a filename, a system sound alias, audio data as a *bytes-like object*, or `None`. Its interpretation depends on the value of *flags*, which can be a bitwise ORed combination of the constants described below. If the *sound* parameter is `None`, any currently playing waveform sound is stopped. If the system indicates an error, `RuntimeError` is raised.

`winsound.MessageBeep(type=MB_OK)`

Call the underlying `MessageBeep()` function from the Platform API. This plays a sound as specified in the registry. The *type* argument specifies which sound to play; possible values are `-1`, `MB_ICONASTERISK`, `MB_ICONEXCLAMATION`, `MB_ICONHAND`, `MB_ICONQUESTION`, and `MB_OK`, all described below. The value `-1` produces a "simple beep"; this is the final fallback if a sound cannot be played otherwise. If the system indicates an error, `RuntimeError` is raised.

`winsound.SND_FILENAME`

The *sound* parameter is the name of a WAV file. Do not use with `SND_ALIAS`.

`winsound.SND_ALIAS`

The *sound* parameter is a sound association name from the registry. If the registry contains no such name, play the system default sound unless `SND_NODEFAULT` is also specified. If no default sound is registered, raise `RuntimeError`. Do not use with `SND_FILENAME`.

All Win32 systems support at least the following; most systems support many more:

<i>PlaySound()</i> name	Corresponding Control Panel Sound name
'SystemAsterisk'	Asterisk
'SystemExclamation'	Exclamation
'SystemExit'	Exit Windows
'SystemHand'	Critical Stop
'SystemQuestion'	Question

例如 例 1:

```
import winsound
# Play Windows exit sound.
winsound.PlaySound("SystemExit", winsound.SND_ALIAS)

# Probably play Windows default sound, if any is registered (because
# "*" probably isn't the registered name of any sound).
winsound.PlaySound("*", winsound.SND_ALIAS)
```

`winsound.SND_LOOP`

Play the sound repeatedly. The `SND_ASYNC` flag must also be used to avoid blocking. Cannot be used with `SND_MEMORY`.

`winsound.SND_MEMORY`

The *sound* parameter to `PlaySound()` is a memory image of a WAV file, as a *bytes-like object*.

備 註

This module does not support playing from a memory image asynchronously, so a combination of this flag and `SND_ASYNC` will raise `RuntimeError`.

`winsound.SND_PURGE`

Stop playing all instances of the specified sound.

備

This flag is not supported on modern Windows platforms.

`winsound.SND_ASYNC`

Return immediately, allowing sounds to play asynchronously.

`winsound.SND_NODEFAULT`

If the specified sound cannot be found, do not play the system default sound.

`winsound.SND_NOSTOP`

Do not interrupt sounds currently playing.

`winsound.SND_NOWAIT`

Return immediately if the sound driver is busy.

備

This flag is not supported on modern Windows platforms.

`winsound.MB_ICONASTERISK`

播放 SystemDefault 聲音。

`winsound.MB_ICONEXCLAMATION`

播放 SystemExclamation 聲音。

`winsound.MB_ICONHAND`

播放 SystemHand 聲音。

`winsound.MB_ICONQUESTION`

播放 SystemQuestion 聲音。

`winsound.MB_OK`

播放 SystemDefault 聲音。

此章節所描述的模組 (module) 提供了針對 Unix 作業系統獨有特性的介面，或在某些情況下可用於其他 Unix 變形版本。以下概述：

34.1 `posix` --- 最常見的 POSIX 系統呼叫

該模組提供對由 C 標準和 POSIX 標準（一種包裝的 Unix 介面）所標準化的作業系統功能的存取。

適用：Unix。

不要直接引入此模組。請改用引入 `os` 模組，它提供了此介面的可移植 (*portable*) 版本。在 Unix 上，`os` 模組提供了 `posix` 介面的超集 (superset)。在非 Unix 作業系統上，`posix` 模組不可用，但始終可以通過 `os` 介面使用一個子集。一旦 `os` 有被引入，使用它代替 `posix` 不會有性能損失。此外，`os` 提供了一些額外的功能，例如當 `os.environ` 中的條目更改時自動呼叫 `putenv()`。

錯誤會以例外的形式被回報；常見的例外是因類型錯誤而給出的，而系統呼叫回報的錯誤會引發 `OSError`。

34.1.1 對大檔案 (Large File) 的支援

一些作業系統（包括 AIX 和 Solaris）支援來自 C 程式模型且大於 2 GiB 的檔案，其中 `int` 和 `long` 是 32-bit (32 位元) 的值。這通常透過將相關大小和偏移量 (offset) 種類定義為 64-bit 值來實作。此類檔案有時被稱作「大檔案 (*large files*)」。

當 `off_t` 的大小大於 `long` 且 `long long` 的大小至少與 `off_t` 相同時，對大檔案的支援會被啟用。可能需要使用某些編譯器旗標來配置和編譯 Python 以啟用此模式。例如，對於 Solaris 2.6 和 2.7，你需要執行如下操作：

```
CFLAGS=`getconf LFS_CFLAGS` OPT="-g -O2 $CFLAGS" \  
./configure
```

在支援大檔案的 Linux 系統上，這可能有效：

```
CFLAGS='-D_LARGEFILE64_SOURCE -D_FILE_OFFSET_BITS=64' OPT="-g -O2 $CFLAGS" \  
./configure
```

34.1.2 值得注意的模組內容

除了 `os` 模組中明文件中描述的許多函式外，`posix` 還定義了以下資料項目：

`posix.environ`

表示直譯器啟動時的字串環境的字典。鍵和值在 Unix 上是位元組，在 Windows 上是 `str`。例如，`environ[b'HOME']` (Windows 上 `environ['HOME']`) 是你的主目錄的路徑名，等同於 C 語言中的 `getenv("HOME")`。

修改這個字典不會影響由 `execv()`、`popen()` 或 `system()` 傳遞的字串環境；如果你需要更改環境，請將 `environ` 傳遞給 `execve()` 或將變數賦值和匯出陳述句新增到 `system()` 或 `popen()` 的指令字串中。

在 3.2 版的變更：在 Unix 上，鍵和值是位元組。

備

`os` 模組提供了 `environ` 的替代實作，會在修改時更新環境。另請注意，更新 `os.environ` 將使該字典變成過時的。建議使用 `os` 模組版本，而不是直接存取 `posix` 模組。

34.2 pwd --- 密碼資料庫

此模組提供對 Unix 使用者帳和密碼資料庫的存取介面。它適用於所有 Unix 版本。

Availability: Unix, not WASI, not iOS.

密碼資料庫條目被報告類似元組的物件 (tuple-like object)，其屬性會對應於 `passwd` 結構的成員（屬性欄位請見下面的 `<pwd.h>`）：

索引	屬性	意義
0	<code>pw_name</code>	登入名
1	<code>pw_passwd</code>	可選的加密密碼
2	<code>pw_uid</code>	數值的使用者 ID
3	<code>pw_gid</code>	數值的群組 ID
4	<code>pw_gecos</code>	使用者名稱或解欄位
5	<code>pw_dir</code>	使用者主目錄 (home directory)
6	<code>pw_shell</code>	使用者命令直譯器

`uid` 和 `gid` 項目是整數，其他項目都是字串。如果找不到請求的條目，則會引發 `KeyError`。

備

In traditional Unix the field `pw_passwd` usually contains a password encrypted with a DES derived algorithm. However most modern unices use a so-called *shadow password* system. On those unices the `pw_passwd` field only contains an asterisk ('*') or the letter 'x' where the encrypted password is stored in a file `/etc/shadow` which is not world readable. Whether the `pw_passwd` field contains anything useful is system-dependent.

它定義了以下項目：

`pwd.getpwuid(uid)`

回傳給定數值使用者 ID 的密碼資料庫條目。

`pwd.getpwnam(name)`

回傳給定使用者名稱的密碼資料庫條目。

`pwd.getpwall()`

以任意順序回傳所有可用密碼資料庫條目的 list。

也參考

`grp` 模組

群組資料庫的介面，與此模組類似。

34.3 grp --- 群組資料庫

This module provides access to the Unix group database. It is available on all Unix versions.

Availability: Unix, not WASI, not iOS.

Group database entries are reported as a tuple-like object, whose attributes correspond to the members of the group structure (Attribute field below, see `<grp.h>`):

Index	屬性	含義
0	<code>gr_name</code>	the name of the group
1	<code>gr_passwd</code>	the (encrypted) group password; often empty
2	<code>gr_gid</code>	the numerical group ID
3	<code>gr_mem</code>	all the group member's user names

The gid is an integer, name and password are strings, and the member list is a list of strings. (Note that most users are not explicitly listed as members of the group they are in according to the password database. Check both databases to get complete membership information. Also note that a `gr_name` that starts with a + or - is likely to be a YP/NIS reference and may not be accessible via `getgrnam()` or `getgrgid().`)

It defines the following items:

`grp.getgrgid(id)`

Return the group database entry for the given numeric group ID. `KeyError` is raised if the entry asked for cannot be found.

在 3.10 版的變更: `TypeError` is raised for non-integer arguments like floats or strings.

`grp.getgrnam(name)`

Return the group database entry for the given group name. `KeyError` is raised if the entry asked for cannot be found.

`grp.getgrall()`

Return a list of all available group entries, in arbitrary order.

也參考

`pwd` 模組

An interface to the user database, similar to this.

34.4 `termios` --- POSIX 風格 tty 控制

This module provides an interface to the POSIX calls for tty I/O control. For a complete description of these calls, see *termios(3)* Unix manual page. It is only available for those Unix versions that support POSIX *termios* style tty I/O control configured during installation.

適用：Unix。

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or a *file object*, such as `sys.stdin` itself.

This module also defines all the constants needed to work with the functions provided here; these have the same name as their counterparts in C. Please refer to your system documentation for more information on using these terminal control interfaces.

The module defines the following functions:

`termios.tcgetattr(fd)`

Return a list containing the tty attributes for file descriptor *fd*, as follows: [*iflag*, *oflag*, *cflag*, *lflag*, *ispeed*, *ospeed*, *cc*] where *cc* is a list of the tty special characters (each a string of length 1, except the items with indices *VMIN* and *VTIME*, which are integers when these fields are defined). The interpretation of the flags and the speeds as well as the indexing in the *cc* array must be done using the symbolic constants defined in the *termios* module.

`termios.tcsetattr(fd, when, attributes)`

Set the tty attributes for file descriptor *fd* from the *attributes*, which is a list like the one returned by *tcgetattr()*. The *when* argument determines when the attributes are changed:

`termios.TCSANOW`

Change attributes immediately.

`termios.TCSADRAIN`

Change attributes after transmitting all queued output.

`termios.TCSAFLUSH`

Change attributes after transmitting all queued output and discarding all queued input.

`termios.tcsendbreak(fd, duration)`

Send a break on file descriptor *fd*. A zero *duration* sends a break for 0.25--0.5 seconds; a nonzero *duration* has a system dependent meaning.

`termios.tcdrain(fd)`

Wait until all output written to file descriptor *fd* has been transmitted.

`termios.tcflush(fd, queue)`

Discard queued data on file descriptor *fd*. The *queue* selector specifies which queue: *TCIFLUSH* for the input queue, *TCOFLUSH* for the output queue, or *TCIOFLUSH* for both queues.

`termios.tcflow(fd, action)`

Suspend or resume input or output on file descriptor *fd*. The *action* argument can be *TCOOFF* to suspend output, *TCOON* to restart output, *TCIOFF* to suspend input, or *TCION* to restart input.

`termios.tcgetwinsize(fd)`

Return a tuple (*ws_row*, *ws_col*) containing the tty window size for file descriptor *fd*. Requires *termios.TIOCGWINSZ* or *termios.TIOCGSIZE*.

在 3.11 版被加入。

`termios.tcsetwinsize(fd, winsize)`

Set the tty window size for file descriptor *fd* from *winsize*, which is a two-item tuple (*ws_row*, *ws_col*) like the one returned by `tcgetwinsize()`. Requires at least one of the pairs (`termios.TIOCGWINSZ`, `termios.TIOCSWINSZ`); (`termios.TIOCGSIZE`, `termios.TIOCSSIZE`) to be defined.

在 3.11 版被加入。

也參考

`tty` 模組

Convenience functions for common terminal control operations.

34.4.1 范例

Here's a function that prompts for a password with echoing turned off. Note the technique using a separate `tcgetattr()` call and a try ... finally statement to ensure that the old tty attributes are restored exactly no matter what happens:

```
def getpass(prompt="Password: "):
    import termios, sys
    fd = sys.stdin.fileno()
    old = termios.tcgetattr(fd)
    new = termios.tcgetattr(fd)
    new[3] = new[3] & ~termios.ECHO          # lflags
    try:
        termios.tcsetattr(fd, termios.TCSADRAIN, new)
        passwd = input(prompt)
    finally:
        termios.tcsetattr(fd, termios.TCSADRAIN, old)
    return passwd
```

34.5 tty --- 終端機控制函式

原始碼: [Lib/tty.py](#)

`tty` 模組定義了將 tty 放入 cbreak 和 raw 模式的函式。

適用: Unix。

因它需要 `termios` 模組，所以只能在 Unix 上執行。

`tty` 模組定義了以下函式：

`tty.cfmakeraw(mode)`

Convert the tty attribute list *mode*, which is a list like the one returned by `termios.tcgetattr()`, to that of a tty in raw mode.

在 3.12 版被加入。

`tty.cfmakecbreak(mode)`

Convert the tty attribute list *mode*, which is a list like the one returned by `termios.tcgetattr()`, to that of a tty in cbreak mode.

This clears the ECHO and ICANON local mode flags in *mode* as well as setting the minimum input to 1 byte with no delay.

在 3.12 版被加入。

在 3.12.2 版的變更: The `ICRNL` flag is no longer cleared. This matches Linux and macOS `stty cbreak` behavior and what `setcbreak()` historically did.

`tty.setraw(fd, when=termios.TCSAFLUSH)`

將檔案描述器 `fd` 的模式更改為 `raw`。如果 `when` 被省略，則預設為 `termios.TCSAFLUSH`，傳遞給 `termios.tcsetattr()`。`termios.tcgetattr()` 的回傳值會在設定 `fd` 模式為 `raw` 之前先儲存起來。此函數回傳這個值。

在 3.12 版的變更: 現在的回傳值為原本的 `tty` 屬性，而不是 `None`。

`tty.setcbreak(fd, when=termios.TCSAFLUSH)`

將檔案描述器 `fd` 的模式更改為 `cbreak`。如果 `when` 被省略，則預設為 `termios.TCSAFLUSH`，傳遞給 `termios.tcsetattr()`。`termios.tcgetattr()` 的回傳值會在設定 `fd` 模式為 `raw` 之前先儲存起來。此函數回傳這個值。

This clears the `ECHO` and `ICANON` local mode flags as well as setting the minimum input to 1 byte with no delay.

在 3.12 版的變更: 現在的回傳值為原本的 `tty` 屬性，而不是 `None`。

在 3.12.2 版的變更: The `ICRNL` flag is no longer cleared. This restores the behavior of Python 3.11 and earlier as well as matching what Linux, macOS, & BSDs describe in their `stty(1)` man pages regarding `cbreak` mode.

也參考

`termios` 模組

低階終端機控制介面。

34.6 pty --- 終端工具

原始碼: [Lib/pty.py](#)

The `pty` module defines operations for handling the pseudo-terminal concept: starting another process and being able to write to and read from its controlling terminal programmatically.

適用: Unix。

Pseudo-terminal handling is highly platform dependent. This code is mainly tested on Linux, FreeBSD, and macOS (it is supposed to work on other POSIX platforms but it's not been thoroughly tested).

The `pty` module defines the following functions:

`pty.fork()`

Fork. Connect the child's controlling terminal to a pseudo-terminal. Return value is `(pid, fd)`. Note that the child gets `pid 0`, and the `fd` is `invalid`. The parent's return value is the `pid` of the child, and `fd` is a file descriptor connected to the child's controlling terminal (and also to the child's standard input and output).

警告

On macOS the use of this function is unsafe when mixed with using higher-level system APIs, and that includes using `urllib.request`.

`pty.openpty()`

Open a new pseudo-terminal pair, using `os.openpty()` if possible, or emulation code for generic Unix systems. Return a pair of file descriptors `(master, slave)`, for the master and the slave end, respectively.

```
pty.spawn(argv[, master_read[, stdin_read]])
```

Spawn a process, and connect its controlling terminal with the current process's standard io. This is often used to baffle programs which insist on reading from the controlling terminal. It is expected that the process spawned behind the pty will eventually terminate, and when it does *spawn* will return.

A loop copies STDIN of the current process to the child and data received from the child to STDOUT of the current process. It is not signaled to the child if STDIN of the current process closes down.

The functions *master_read* and *stdin_read* are passed a file descriptor which they should read from, and they should always return a byte string. In order to force spawn to return before the child process exits an empty byte array should be returned to signal end of file.

The default implementation for both functions will read and return up to 1024 bytes each time the function is called. The *master_read* callback is passed the pseudoterminal's master file descriptor to read output from the child process, and *stdin_read* is passed file descriptor 0, to read from the parent process's standard input.

Returning an empty byte string from either callback is interpreted as an end-of-file (EOF) condition, and that callback will not be called after that. If *stdin_read* signals EOF the controlling terminal can no longer communicate with the parent process OR the child process. Unless the child process will quit without any input, *spawn* will then loop forever. If *master_read* signals EOF the same behavior results (on linux at least).

Return the exit status value from *os.waitpid()* on the child process.

os.waitstatus_to_exitcode() can be used to convert the exit status into an exit code.

引發一個附帶引數 *argv* 的稽核事件 *pty.spawn*。

在 3.4 版的變更: *spawn()* now returns the status value from *os.waitpid()* on the child process.

34.6.1 范例

The following program acts like the Unix command *script(1)*, using a pseudo-terminal to record all input and output of a terminal session in a "typescript".

```
import argparse
import os
import pty
import sys
import time

parser = argparse.ArgumentParser()
parser.add_argument('-a', dest='append', action='store_true')
parser.add_argument('-p', dest='use_python', action='store_true')
parser.add_argument('filename', nargs='?', default='typescript')
options = parser.parse_args()

shell = sys.executable if options.use_python else os.environ.get('SHELL', 'sh')
filename = options.filename
mode = 'ab' if options.append else 'wb'

with open(filename, mode) as script:
    def read(fd):
        data = os.read(fd, 1024)
        script.write(data)
        return data

    print('Script started, file is', filename)
    script.write(('Script started on %s\n' % time.asctime()).encode())

    pty.spawn(shell, read)

    script.write(('Script done on %s\n' % time.asctime()).encode())
    print('Script done, file is', filename)
```

34.7 fcntl --- fcntl 和 ioctl 系統呼叫

This module performs file and I/O control on file descriptors. It is an interface to the `fcntl()` and `ioctl()` Unix routines. See the *fcntl(2)* and *ioctl(2)* Unix manual pages for full details.

Availability: Unix, not WASI.

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or an *io.IOBase* object, such as `sys.stdin` itself, which provides a *fileno()* that returns a genuine file descriptor.

在 3.3 版的變更: Operations in this module used to raise an *IOError* where they now raise an *OSError*.

在 3.8 版的變更: The *fcntl* module now contains `F_ADD_SEALS`, `F_GET_SEALS`, and `F_SEAL_*` constants for sealing of *os.memfd_create()* file descriptors.

在 3.9 版的變更: On macOS, the *fcntl* module exposes the `F_GETPATH` constant, which obtains the path of a file from a file descriptor. On Linux(>=3.15), the *fcntl* module exposes the `F_OFD_GETLK`, `F_OFD_SETLK` and `F_OFD_SETLKW` constants, which are used when working with open file description locks.

在 3.10 版的變更: On Linux >= 2.6.11, the *fcntl* module exposes the `F_GETPIPE_SZ` and `F_SETPIPE_SZ` constants, which allow to check and modify a pipe's size respectively.

在 3.11 版的變更: On FreeBSD, the *fcntl* module exposes the `F_DUP2FD` and `F_DUP2FD_CLOEXEC` constants, which allow to duplicate a file descriptor, the latter setting `FD_CLOEXEC` flag in addition.

在 3.12 版的變更: On Linux >= 4.5, the *fcntl* module exposes the `FICLONE` and `FICLONERANGE` constants, which allow to share some data of one file with another file by reflinking on some filesystems (e.g., btrfs, OCFS2, and XFS). This behavior is commonly referred to as "copy-on-write".

在 3.13 版的變更: On Linux >= 2.6.32, the *fcntl* module exposes the `F_GETOWN_EX`, `F_SETOWN_EX`, `F_OWNER_TID`, `F_OWNER_PID`, `F_OWNER_PGRP` constants, which allow to direct I/O availability signals to a specific thread, process, or process group. On Linux >= 4.13, the *fcntl* module exposes the `F_GET_RW_HINT`, `F_SET_RW_HINT`, `F_GET_FILE_RW_HINT`, `F_SET_FILE_RW_HINT`, and `RWH_WRITE_LIFE_*` constants, which allow to inform the kernel about the relative expected lifetime of writes on a given inode or via a particular open file description. On Linux >= 5.1 and NetBSD, the *fcntl* module exposes the `F_SEAL_FUTURE_WRITE` constant for use with `F_ADD_SEALS` and `F_GET_SEALS` operations. On FreeBSD, the *fcntl* module exposes the `F_READAHEAD`, `F_ISUNIONSTACK`, and `F_KINFO` constants. On macOS and FreeBSD, the *fcntl* module exposes the `F_RDAHEAD` constant. On NetBSD and AIX, the *fcntl* module exposes the `F_CLOSEM` constant. On NetBSD, the *fcntl* module exposes the `F_MAXFD` constant. On macOS and NetBSD, the *fcntl* module exposes the `F_GETNOSIGPIPE` and `F_SETNOSIGPIPE` constant.

The module defines the following functions:

`fcntl.fcntl(fd, cmd, arg=0)`

Perform the operation *cmd* on file descriptor *fd* (file objects providing a *fileno()* method are accepted as well). The values used for *cmd* are operating system dependent, and are available as constants in the *fcntl* module, using the same names as used in the relevant C header files. The argument *arg* can either be an integer value, or a *bytes* object. With an integer value, the return value of this function is the integer return value of the C `fcntl()` call. When the argument is bytes it represents a binary structure, e.g. created by *struct.pack()*. The binary data is copied to a buffer whose address is passed to the C `fcntl()` call. The return value after a successful call is the contents of the buffer, converted to a *bytes* object. The length of the returned object will be the same as the length of the *arg* argument. This is limited to 1024 bytes. If the information returned in the buffer by the operating system is larger than 1024 bytes, this is most likely to result in a segmentation violation or a more subtle data corruption.

If the `fcntl()` call fails, an *OSError* is raised.

引發一個附帶引數 *fd*、*cmd*、*arg* 的稽核事件 `fcntl.fcntl`。

`fcntl.ioctl` (*fd*, *request*, *arg*=0, *mutate_flag*=True)

This function is identical to the `fcntl()` function, except that the argument handling is even more complicated.

The *request* parameter is limited to values that can fit in 32-bits. Additional constants of interest for use as the *request* argument can be found in the `termios` module, under the same names as used in the relevant C header files.

The parameter *arg* can be one of an integer, an object supporting the read-only buffer interface (like `bytes`) or an object supporting the read-write buffer interface (like `bytearray`).

In all but the last case, behaviour is as for the `fcntl()` function.

If a mutable buffer is passed, then the behaviour is determined by the value of the *mutate_flag* parameter.

If it is false, the buffer's mutability is ignored and behaviour is as for a read-only buffer, except that the 1024 byte limit mentioned above is avoided -- so long as the buffer you pass is at least as long as what the operating system wants to put there, things should work.

If *mutate_flag* is true (the default), then the buffer is (in effect) passed to the underlying `ioctl()` system call, the latter's return code is passed back to the calling Python, and the buffer's new contents reflect the action of the `ioctl()`. This is a slight simplification, because if the supplied buffer is less than 1024 bytes long it is first copied into a static buffer 1024 bytes long which is then passed to `ioctl()` and copied back into the supplied buffer.

If the `ioctl()` call fails, an `OSError` exception is raised.

範例：

```
>>> import array, fcntl, struct, termios, os
>>> os.getpgrp()
13341
>>> struct.unpack('h', fcntl.ioctl(0, termios.TIOCGPGRP, "  ")) [0]
13341
>>> buf = array.array('h', [0])
>>> fcntl.ioctl(0, termios.TIOCGPGRP, buf, 1)
0
>>> buf
array('h', [13341])
```

引發一個附帶引數 *fd*、*request*、*arg* 的稽核事件 `fcntl.ioctl`。

`fcntl.flock` (*fd*, *operation*)

Perform the lock operation *operation* on file descriptor *fd* (file objects providing a `fileno()` method are accepted as well). See the Unix manual `flock(2)` for details. (On some systems, this function is emulated using `fcntl()`.)

If the `flock()` call fails, an `OSError` exception is raised.

引發一個附帶引數 *fd*、*operation* 的稽核事件 `fcntl.flock`。

`fcntl.lockf` (*fd*, *cmd*, *len*=0, *start*=0, *whence*=0)

This is essentially a wrapper around the `fcntl()` locking calls. *fd* is the file descriptor (file objects providing a `fileno()` method are accepted as well) of the file to lock or unlock, and *cmd* is one of the following values:

`fcntl.LOCK_UN`

Release an existing lock.

`fcntl.LOCK_SH`

Acquire a shared lock.

`fcntl.LOCK_EX`

Acquire an exclusive lock.

`fcntl.LOCK_NB`

Bitwise OR with any of the other three `LOCK_*` constants to make the request non-blocking.

If `LOCK_NB` is used and the lock cannot be acquired, an `OSError` will be raised and the exception will have an `errno` attribute set to `EACCES` or `EAGAIN` (depending on the operating system; for portability, check for both values). On at least some systems, `LOCK_EX` can only be used if the file descriptor refers to a file opened for writing.

`len` is the number of bytes to lock, `start` is the byte offset at which the lock starts, relative to `whence`, and `whence` is as with `io.IOBase.seek()`, specifically:

- 0 -- relative to the start of the file (`os.SEEK_SET`)
- 1 -- relative to the current buffer position (`os.SEEK_CUR`)
- 2 -- relative to the end of the file (`os.SEEK_END`)

The default for `start` is 0, which means to start at the beginning of the file. The default for `len` is 0 which means to lock to the end of the file. The default for `whence` is also 0.

引發一個附帶引數 `fd`、`cmd`、`len`、`start`、`whence` 的稽核事件 `fcntl.lockf`。

Examples (all on a SVR4 compliant system):

```
import struct, fcntl, os

f = open(...)
rv = fcntl.fcntl(f, fcntl.F_SETFL, os.O_NDELAY)

lockdata = struct.pack('hhllhh', fcntl.F_WRLCK, 0, 0, 0, 0, 0)
rv = fcntl.fcntl(f, fcntl.F_SETLKW, lockdata)
```

Note that in the first example the return value variable `rv` will hold an integer value; in the second example it will hold a `bytes` object. The structure lay-out for the `lockdata` variable is system dependent --- therefore using the `flock()` call may be better.

也參考

os 模組

If the locking flags `O_SHLOCK` and `O_EXLOCK` are present in the `os` module (on BSD only), the `os.open()` function provides an alternative to the `lockf()` and `flock()` functions.

34.8 resource --- 資源使用資訊

This module provides basic mechanisms for measuring and controlling system resources utilized by a program.

Availability: Unix, not WASI.

Symbolic constants are used to specify particular system resources and to request usage information about either the current process or its children.

An `OSError` is raised on syscall failure.

exception resource.error

A deprecated alias of `OSError`.

在 3.3 版的變更: Following [PEP 3151](#), this class was made an alias of `OSError`.

34.8.1 Resource Limits

Resources usage can be limited using the `setrlimit()` function described below. Each resource is controlled by a pair of limits: a soft limit and a hard limit. The soft limit is the current limit, and may be lowered or raised by a process over time. The soft limit can never exceed the hard limit. The hard limit can be lowered to any value greater than the soft limit, but not raised. (Only processes with the effective UID of the super-user can raise a hard limit.)

The specific resources that can be limited are system dependent. They are described in the `getrlimit(2)` man page. The resources listed below are supported when the underlying operating system supports them; resources which cannot be checked or controlled by the operating system are not defined in this module for those platforms.

`resource.RLIM_INFINITY`

Constant used to represent the limit for an unlimited resource.

`resource.getrlimit(resource)`

Returns a tuple (soft, hard) with the current soft and hard limits of *resource*. Raises `ValueError` if an invalid resource is specified, or `error` if the underlying system call fails unexpectedly.

`resource.setrlimit(resource, limits)`

Sets new limits of consumption of *resource*. The *limits* argument must be a tuple (soft, hard) of two integers describing the new limits. A value of `RLIM_INFINITY` can be used to request a limit that is unlimited.

Raises `ValueError` if an invalid resource is specified, if the new soft limit exceeds the hard limit, or if a process tries to raise its hard limit. Specifying a limit of `RLIM_INFINITY` when the hard or system limit for that resource is not unlimited will result in a `ValueError`. A process with the effective UID of super-user can request any valid limit value, including unlimited, but `ValueError` will still be raised if the requested limit exceeds the system imposed limit.

`setrlimit` may also raise `error` if the underlying system call fails.

VxWorks only supports setting `RLIMIT_NOFILE`.

引發一個附帶引數 *resource*、*limits* 的稽核事件 `resource.setrlimit`。

`resource.prlimit(pid, resource[, limits])`

Combines `setrlimit()` and `getrlimit()` in one function and supports to get and set the resources limits of an arbitrary process. If *pid* is 0, then the call applies to the current process. *resource* and *limits* have the same meaning as in `setrlimit()`, except that *limits* is optional.

When *limits* is not given the function returns the *resource* limit of the process *pid*. When *limits* is given the *resource* limit of the process is set and the former resource limit is returned.

Raises `ProcessLookupError` when *pid* can't be found and `PermissionError` when the user doesn't have `CAP_SYS_RESOURCE` for the process.

引發一個附帶引數 *pid*、*resource*、*limits* 的稽核事件 `resource.prlimit`。

適用：Linux 2.6.36 以上且具有 glibc 2.13 以上。

在 3.4 版被加入。

These symbols define resources whose consumption can be controlled using the `setrlimit()` and `getrlimit()` functions described below. The values of these symbols are exactly the constants used by C programs.

The Unix man page for `getrlimit(2)` lists the available resources. Note that not all systems use the same symbol or same value to denote the same resource. This module does not attempt to mask platform differences --- symbols not defined for a platform will not be available from this module on that platform.

`resource.RLIMIT_CORE`

The maximum size (in bytes) of a core file that the current process can create. This may result in the creation of a partial core file if a larger core would be required to contain the entire process image.

resource.RLIMIT_CPU

The maximum amount of processor time (in seconds) that a process can use. If this limit is exceeded, a SIGXCPU signal is sent to the process. (See the *signal* module documentation for information about how to catch this signal and do something useful, e.g. flush open files to disk.)

resource.RLIMIT_FSIZE

The maximum size of a file which the process may create.

resource.RLIMIT_DATA

The maximum size (in bytes) of the process's heap.

resource.RLIMIT_STACK

The maximum size (in bytes) of the call stack for the current process. This only affects the stack of the main thread in a multi-threaded process.

resource.RLIMIT_RSS

The maximum resident set size that should be made available to the process.

resource.RLIMIT_NPROC

The maximum number of processes the current process may create.

resource.RLIMIT_NOFILE

The maximum number of open file descriptors for the current process.

resource.RLIMIT_OFILE

The BSD name for *RLIMIT_NOFILE*.

resource.RLIMIT_MEMLOCK

The maximum address space which may be locked in memory.

resource.RLIMIT_VMEM

The largest area of mapped memory which the process may occupy.

適用：FreeBSD 11 以上。

resource.RLIMIT_AS

The maximum area (in bytes) of address space which may be taken by the process.

resource.RLIMIT_MSGQUEUE

The number of bytes that can be allocated for POSIX message queues.

適用：Linux 2.6.8 以上。

在 3.4 版被加入。

resource.RLIMIT_NICE

The ceiling for the process's nice level (calculated as $20 - \text{rlim_cur}$).

適用：Linux 2.6.12 以上。

在 3.4 版被加入。

resource.RLIMIT_RTPRIO

The ceiling of the real-time priority.

適用：Linux 2.6.12 以上。

在 3.4 版被加入。

resource.RLIMIT_RTTIME

The time limit (in microseconds) on CPU time that a process can spend under real-time scheduling without making a blocking syscall.

適用：Linux 2.6.25 以上。

在 3.4 版被加入。

resource.RLIMIT_SIGPENDING

The number of signals which the process may queue.

適用：Linux 2.6.8 以上。

在 3.4 版被加入。

resource.RLIMIT_SBSIZE

The maximum size (in bytes) of socket buffer usage for this user. This limits the amount of network memory, and hence the amount of mbufs, that this user may hold at any time.

適用：FreeBSD。

在 3.4 版被加入。

resource.RLIMIT_SWAP

The maximum size (in bytes) of the swap space that may be reserved or used by all of this user id's processes. This limit is enforced only if bit 1 of the `vm.overcommit sysctl` is set. Please see [tuning\(7\)](#) for a complete description of this `sysctl`.

適用：FreeBSD。

在 3.4 版被加入。

resource.RLIMIT_NPTS

The maximum number of pseudo-terminals created by this user id.

適用：FreeBSD。

在 3.4 版被加入。

resource.RLIMIT_KQUEUES

The maximum number of kqueues this user id is allowed to create.

適用：FreeBSD 11 以上。

在 3.10 版被加入。

34.8.2 Resource Usage

These functions are used to retrieve resource usage information:

resource.getrusage (*who*)

This function returns an object that describes the resources consumed by either the current process or its children, as specified by the *who* parameter. The *who* parameter should be specified using one of the `RUSAGE_*` constants described below.

一個簡單範例：

```
from resource import *
import time

# a non CPU-bound task
time.sleep(3)
print(getrusage(RUSAGE_SELF))

# a CPU-bound task
for i in range(10 ** 8):
    _ = 1 + 1
print(getrusage(RUSAGE_SELF))
```

The fields of the return value each describe how a particular system resource has been used, e.g. amount of time spent running is user mode or number of times the process was swapped out of main memory. Some values are dependent on the clock tick interval, e.g. the amount of memory the process is using.

For backward compatibility, the return value is also accessible as a tuple of 16 elements.

The fields `ru_utime` and `ru_stime` of the return value are floating-point values representing the amount of time spent executing in user mode and the amount of time spent executing in system mode, respectively. The remaining values are integers. Consult the `getrusage(2)` man page for detailed information about these values. A brief summary is presented here:

Index	Field	Resource
0	<code>ru_utime</code>	time in user mode (float seconds)
1	<code>ru_stime</code>	time in system mode (float seconds)
2	<code>ru_maxrss</code>	maximum resident set size
3	<code>ru_ixrss</code>	shared memory size
4	<code>ru_idrss</code>	unshared memory size
5	<code>ru_isrss</code>	unshared stack size
6	<code>ru_minflt</code>	page faults not requiring I/O
7	<code>ru_majflt</code>	page faults requiring I/O
8	<code>ru_nswap</code>	number of swap outs
9	<code>ru_inblock</code>	block input operations
10	<code>ru_oublock</code>	block output operations
11	<code>ru_msgsnd</code>	messages sent
12	<code>ru_msgrcv</code>	messages received
13	<code>ru_nsignals</code>	signals received
14	<code>ru_nvcsw</code>	voluntary context switches
15	<code>ru_nivcsw</code>	involuntary context switches

This function will raise a `ValueError` if an invalid `who` parameter is specified. It may also raise `error` exception in unusual circumstances.

`resource.getpagesize()`

Returns the number of bytes in a system page. (This need not be the same as the hardware page size.)

The following `RUSAGE_*` symbols are passed to the `getrusage()` function to specify which processes information should be provided for.

`resource.RUSAGE_SELF`

Pass to `getrusage()` to request resources consumed by the calling process, which is the sum of resources used by all threads in the process.

`resource.RUSAGE_CHILDREN`

Pass to `getrusage()` to request resources consumed by child processes of the calling process which have been terminated and waited for.

`resource.RUSAGE_BOTH`

Pass to `getrusage()` to request resources consumed by both the current process and child processes. May not be available on all systems.

`resource.RUSAGE_THREAD`

Pass to `getrusage()` to request resources consumed by the current thread. May not be available on all systems.

在 3.2 版被加入。

34.9 syslog --- Unix syslog 函式庫例程

This module provides an interface to the Unix `syslog` library routines. Refer to the Unix manual pages for a detailed description of the `syslog` facility.

Availability: Unix, not WASI, not iOS.

This module wraps the system `syslog` family of routines. A pure Python library that can speak to a syslog server is available in the `logging.handlers` module as `SysLogHandler`.

該模組定義了以下函式：

`syslog.syslog(message)`

`syslog.syslog(priority, message)`

Send the string *message* to the system logger. A trailing newline is added if necessary. Each message is tagged with a priority composed of a *facility* and a *level*. The optional *priority* argument, which defaults to `LOG_INFO`, determines the message priority. If the facility is not encoded in *priority* using logical-or (`LOG_INFO | LOG_USER`), the value given in the `openlog()` call is used.

If `openlog()` has not been called prior to the call to `syslog()`, `openlog()` will be called with no arguments.

引發一個附帶引數 `priority`、`message` 的稽核事件 `syslog.syslog`。

在 3.2 版的變更: In previous versions, `openlog()` would not be called automatically if it wasn't called prior to the call to `syslog()`, deferring to the syslog implementation to call `openlog()`.

在 3.12 版的變更: This function is restricted in subinterpreters. (Only code that runs in multiple interpreters is affected and the restriction is not relevant for most users.) `openlog()` must be called in the main interpreter before `syslog()` may be used in a subinterpreter. Otherwise it will raise `RuntimeError`.

`syslog.openlog([ident[, logoption[, facility]]])`

Logging options of subsequent `syslog()` calls can be set by calling `openlog()`. `syslog()` will call `openlog()` with no arguments if the log is not currently open.

The optional *ident* keyword argument is a string which is prepended to every message, and defaults to `sys.argv[0]` with leading path components stripped. The optional *logoption* keyword argument (default is 0) is a bit field -- see below for possible values to combine. The optional *facility* keyword argument (default is `LOG_USER`) sets the default facility for messages which do not have a facility explicitly encoded.

引發一個附帶引數 `ident`、`logoption`、`facility` 的稽核事件 `syslog.openlog`。

在 3.2 版的變更: In previous versions, keyword arguments were not allowed, and *ident* was required.

在 3.12 版的變更: This function is restricted in subinterpreters. (Only code that runs in multiple interpreters is affected and the restriction is not relevant for most users.) This may only be called in the main interpreter. It will raise `RuntimeError` if called in a subinterpreter.

`syslog.closelog()`

Reset the syslog module values and call the system library `closelog()`.

This causes the module to behave as it does when initially imported. For example, `openlog()` will be called on the first `syslog()` call (if `openlog()` hasn't already been called), and *ident* and other `openlog()` parameters are reset to defaults.

引發一個不附帶引數的稽核事件 `syslog.closelog`。

在 3.12 版的變更: This function is restricted in subinterpreters. (Only code that runs in multiple interpreters is affected and the restriction is not relevant for most users.) This may only be called in the main interpreter. It will raise `RuntimeError` if called in a subinterpreter.

`syslog.setlogmask(maskpri)`

Set the priority mask to *maskpri* and return the previous mask value. Calls to `syslog()` with a priority level not set in *maskpri* are ignored. The default is to log all priorities. The function `LOG_MASK(pri)` calculates the mask for the individual priority *pri*. The function `LOG_UPTO(pri)` calculates the mask for all priorities up to and including *pri*.

引發一個附帶引數 *maskpri* 的稽核事件 `syslog.setlogmask`。

The module defines the following constants:

```
syslog.LOG_EMERG
syslog.LOG_ALERT
syslog.LOG_CRIT
syslog.LOG_ERR
syslog.LOG_WARNING
syslog.LOG_NOTICE
syslog.LOG_INFO
syslog.LOG_DEBUG
    Priority levels (high to low).
```

```
syslog.LOG_AUTH
syslog.LOG_AUTHPRIV
syslog.LOG_CRON
syslog.LOG_DAEMON
syslog.LOG_FTP
syslog.LOG_INSTALL
syslog.LOG_KERN
syslog.LOG_LAUNCHD
syslog.LOG_LPR
syslog.LOG_MAIL
syslog.LOG_NETINFO
syslog.LOG_NEWS
syslog.LOG_RAS
syslog.LOG_REMOTEAUTH
syslog.LOG_SYSLOG
syslog.LOG_USER
syslog.LOG_UUCP
syslog.LOG_LOCAL0
syslog.LOG_LOCAL1
syslog.LOG_LOCAL2
syslog.LOG_LOCAL3
syslog.LOG_LOCAL4
syslog.LOG_LOCAL5
syslog.LOG_LOCAL6
syslog.LOG_LOCAL7
```

Facilities, depending on availability in `<syslog.h>` for `LOG_AUTHPRIV`, `LOG_FTP`, `LOG_NETINFO`, `LOG_REMOTEAUTH`, `LOG_INSTALL` and `LOG_RAS`.

在 3.13 版的變更: Added `LOG_FTP`, `LOG_NETINFO`, `LOG_REMOTEAUTH`, `LOG_INSTALL`, `LOG_RAS`, and `LOG_LAUNCHD`.

```
syslog.LOG_PID
syslog.LOG_CONS
```

```
syslog.LOG_NDELAY
syslog.LOG_ODELAY
syslog.LOG_NOWAIT
syslog.LOG_PERROR
```

Log options, depending on availability in <syslog.h> for *LOG_ODELAY*, *LOG_NOWAIT* and *LOG_PERROR*.

34.9.1 范例

簡單范例

一組簡單範例：

```
import syslog

syslog.syslog('Processing started')
if error:
    syslog.syslog(syslog.LOG_ERR, 'Processing started')
```

An example of setting some log options, these would include the process ID in logged messages, and write the messages to the destination facility used for mail logging:

```
syslog.openlog(logoption=syslog.LOG_PID, facility=syslog.LOG_MAIL)
syslog.syslog('E-mail processing initiated...')
```

已被取代的模組

The modules described in this chapter are deprecated or *soft deprecated* and only kept for backwards compatibility. They have been superseded by other modules.

36.1 getopt --- 用於命令列選項的 C 風格剖析器

原始碼: [Lib/getopt.py](#)

在 3.13 版之後被[ⓘ]用: The *getopt* module is *soft deprecated* and will not be developed further; development will continue with the *argparse* module.

備[ⓘ]

The *getopt* module is a parser for command line options whose API is designed to be familiar to users of the C `getopt()` function. Users who are unfamiliar with the C `getopt()` function or who would like to write less code and get better help and error messages should consider using the *argparse* module instead.

This module helps scripts to parse the command line arguments in `sys.argv`. It supports the same conventions as the Unix `getopt()` function (including the special meanings of arguments of the form `'-'` and `'--'`). Long options similar to those supported by GNU software may be used as well via an optional third argument.

This module provides two functions and an exception:

`getopt.getopt(args, shortopts, longopts=[])`

Parses command line options and parameter list. *args* is the argument list to be parsed, without the leading reference to the running program. Typically, this means `sys.argv[1:]`. *shortopts* is the string of option letters that the script wants to recognize, with options that require an argument followed by a colon (':'); i.e., the same format that Unix `getopt()` uses).

備[ⓘ]

Unlike GNU `getopt()`, after a non-option argument, all further arguments are considered also non-options. This is similar to the way non-GNU Unix systems work.

longopts, if specified, must be a list of strings with the names of the long options which should be supported. The leading '--' characters should not be included in the option name. Long options which require an argument should be followed by an equal sign ('='). Optional arguments are not supported. To accept only long options, *shortopts* should be an empty string. Long options on the command line can be recognized so long as they provide a prefix of the option name that matches exactly one of the accepted options. For example, if *longopts* is ['foo', 'frob'], the option --fo will match as --foo, but --f will not match uniquely, so *GetoptError* will be raised.

The return value consists of two elements: the first is a list of (option, value) pairs; the second is the list of program arguments left after the option list was stripped (this is a trailing slice of *args*). Each option-and-value pair returned has the option as its first element, prefixed with a hyphen for short options (e.g., '-x') or two hyphens for long options (e.g., '--long-option'), and the option argument as its second element, or an empty string if the option has no argument. The options occur in the list in the same order in which they were found, thus allowing multiple occurrences. Long and short options may be mixed.

`getopt.gnu_getopt(args, shortopts, longopts=[])`

This function works like *getopt()*, except that GNU style scanning mode is used by default. This means that option and non-option arguments may be intermixed. The *getopt()* function stops processing options as soon as a non-option argument is encountered.

If the first character of the option string is '+', or if the environment variable `POSIIXLY_CORRECT` is set, then option processing stops as soon as a non-option argument is encountered.

exception `getopt.GetoptError`

This is raised when an unrecognized option is found in the argument list or when an option requiring an argument is given none. The argument to the exception is a string indicating the cause of the error. For long options, an argument given to an option which does not require one will also cause this exception to be raised. The attributes `msg` and `opt` give the error message and related option; if there is no specific option to which the exception relates, `opt` is an empty string.

exception `getopt.error`

Alias for *GetoptError*; for backward compatibility.

An example using only Unix style options:

```
>>> import getopt
>>> args = '-a -b -cfoo -d bar a1 a2'.split()
>>> args
['-a', '-b', '-cfoo', '-d', 'bar', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'abc:d:')
>>> optlist
[('-a', ''), ('-b', ''), ('-c', 'foo'), ('-d', 'bar')]
>>> args
['a1', 'a2']
```

Using long option names is equally easy:

```
>>> s = '--condition=foo --testing --output-file abc.def -x a1 a2'
>>> args = s.split()
>>> args
['--condition=foo', '--testing', '--output-file', 'abc.def', '-x', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'x', [
...     'condition=', 'output-file=', 'testing'])
>>> optlist
[('--condition', 'foo'), ('--testing', ''), ('--output-file', 'abc.def'), ('-x', '
↪')]
>>> args
['a1', 'a2']
```

In a script, typical usage is something like this:

```

import getopt, sys

def main():
    try:
        opts, args = getopt.getopt(sys.argv[1:], "ho:v", ["help", "output="])
    except getopt.GetoptError as err:
        # print help information and exit:
        print(err) # will print something like "option -a not recognized"
        usage()
        sys.exit(2)
    output = None
    verbose = False
    for o, a in opts:
        if o == "-v":
            verbose = True
        elif o in ("-h", "--help"):
            usage()
            sys.exit()
        elif o in ("-o", "--output"):
            output = a
        else:
            assert False, "unhandled option"
    # ...

if __name__ == "__main__":
    main()

```

Note that an equivalent command line interface could be produced with less code and more informative help and error messages by using the *argparse* module:

```

import argparse

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument('-o', '--output')
    parser.add_argument('-v', dest='verbose', action='store_true')
    args = parser.parse_args()
    # ... do something with args.output ...
    # ... do something with args.verbose ..

```

也參考

argparse 模組

Alternative command line option and argument parsing library.

36.2 optparse --- 命令列選項剖析器

原始碼: [Lib/optparse.py](#)

在 3.2 版之後被廢用: The *optparse* module is *soft deprecated* and will not be developed further; development will continue with the *argparse* module.

optparse is a more convenient, flexible, and powerful library for parsing command-line options than the old *getopt* module. *optparse* uses a more declarative style of command-line parsing: you create an instance of *OptionParser*, populate it with options, and parse the command line. *optparse* allows users to specify options in the conventional GNU/POSIX syntax, and additionally generates usage and help messages for you.

Here's an example of using *optparse* in a simple script:

```
from optparse import OptionParser
...
parser = OptionParser()
parser.add_option("-f", "--file", dest="filename",
                  help="write report to FILE", metavar="FILE")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose", default=True,
                  help="don't print status messages to stdout")

(options, args) = parser.parse_args()
```

With these few lines of code, users of your script can now do the "usual thing" on the command-line, for example:

```
<yourscript> --file=outfile -q
```

As it parses the command line, *optparse* sets attributes of the options object returned by *parse_args()* based on user-supplied command-line values. When *parse_args()* returns from parsing this command line, *options.filename* will be "outfile" and *options.verbose* will be False. *optparse* supports both long and short options, allows short options to be merged together, and allows options to be associated with their arguments in a variety of ways. Thus, the following command lines are all equivalent to the above example:

```
<yourscript> -f outfile --quiet
<yourscript> --quiet --file outfile
<yourscript> -q -foutfile
<yourscript> -qfoutfile
```

Additionally, users can run one of the following

```
<yourscript> -h
<yourscript> --help
```

and *optparse* will print out a brief summary of your script's options:

```
Usage: <yourscript> [options]

Options:
  -h, --help            show this help message and exit
  -f FILE, --file=FILE  write report to FILE
  -q, --quiet            don't print status messages to stdout
```

where the value of *yourscript* is determined at runtime (normally from *sys.argv[0]*).

36.2.1 背景

`optparse` was explicitly designed to encourage the creation of programs with straightforward, conventional command-line interfaces. To that end, it supports only the most common command-line syntax and semantics conventionally used under Unix. If you are unfamiliar with these conventions, read this section to acquaint yourself with them.

術語

argument

a string entered on the command-line, and passed by the shell to `execl()` or `execv()`. In Python, arguments are elements of `sys.argv[1:]` (`sys.argv[0]` is the name of the program being executed). Unix shells also use the term "word".

It is occasionally desirable to substitute an argument list other than `sys.argv[1:]`, so you should read "argument" as "an element of `sys.argv[1:]`", or of some other list provided as a substitute for `sys.argv[1:]`".

option

an argument used to supply extra information to guide or customize the execution of a program. There are many different syntaxes for options; the traditional Unix syntax is a hyphen ("-") followed by a single letter, e.g. `-x` or `-F`. Also, traditional Unix syntax allows multiple options to be merged into a single argument, e.g. `-x -F` is equivalent to `-xF`. The GNU project introduced `--` followed by a series of hyphen-separated words, e.g. `--file` or `--dry-run`. These are the only two option syntaxes provided by `optparse`.

Some other option syntaxes that the world has seen include:

- a hyphen followed by a few letters, e.g. `-pf` (this is *not* the same as multiple options merged into a single argument)
- a hyphen followed by a whole word, e.g. `-file` (this is technically equivalent to the previous syntax, but they aren't usually seen in the same program)
- a plus sign followed by a single letter, or a few letters, or a word, e.g. `+f`, `+rgb`
- a slash followed by a letter, or a few letters, or a word, e.g. `/f`, `/file`

These option syntaxes are not supported by `optparse`, and they never will be. This is deliberate: the first three are non-standard on any environment, and the last only makes sense if you're exclusively targeting Windows or certain legacy platforms (e.g. VMS, MS-DOS).

option argument

an argument that follows an option, is closely associated with that option, and is consumed from the argument list when that option is. With `optparse`, option arguments may either be in a separate argument from their option:

```
-f foo
--file foo
```

or included in the same argument:

```
-ffoo
--file=foo
```

Typically, a given option either takes an argument or it doesn't. Lots of people want an "optional option arguments" feature, meaning that some options will take an argument if they see it, and won't if they don't. This is somewhat controversial, because it makes parsing ambiguous: if `-a` takes an optional argument and `-b` is another option entirely, how do we interpret `-ab`? Because of this ambiguity, `optparse` does not support this feature.

positional argument

something leftover in the argument list after options have been parsed, i.e. after options and their arguments have been parsed and removed from the argument list.

required option

an option that must be supplied on the command-line; note that the phrase “required option” is self-contradictory in English. `optparse` doesn’t prevent you from implementing required options, but doesn’t give you much help at it either.

For example, consider this hypothetical command-line:

```
prog -v --report report.txt foo bar
```

`-v` and `--report` are both options. Assuming that `--report` takes one argument, `report.txt` is an option argument. `foo` and `bar` are positional arguments.

What are options for?

Options are used to provide extra information to tune or customize the execution of a program. In case it wasn’t clear, options are usually *optional*. A program should be able to run just fine with no options whatsoever. (Pick a random program from the Unix or GNU toolsets. Can it run without any options at all and still make sense? The main exceptions are `find`, `tar`, and `dd`—all of which are mutant oddballs that have been rightly criticized for their non-standard syntax and confusing interfaces.)

Lots of people want their programs to have “required options”. Think about it. If it’s required, then it’s *not optional*! If there is a piece of information that your program absolutely requires in order to run successfully, that’s what positional arguments are for.

As an example of good command-line interface design, consider the humble `cp` utility, for copying files. It doesn’t make much sense to try to copy files without supplying a destination and at least one source. Hence, `cp` fails if you run it with no arguments. However, it has a flexible, useful syntax that does not require any options at all:

```
cp SOURCE DEST
cp SOURCE ... DEST-DIR
```

You can get pretty far with just that. Most `cp` implementations provide a bunch of options to tweak exactly how the files are copied: you can preserve mode and modification time, avoid following symlinks, ask before clobbering existing files, etc. But none of this distracts from the core mission of `cp`, which is to copy either one file to another, or several files to another directory.

What are positional arguments for?

Positional arguments are for those pieces of information that your program absolutely, positively requires to run.

A good user interface should have as few absolute requirements as possible. If your program requires 17 distinct pieces of information in order to run successfully, it doesn’t much matter *how* you get that information from the user—most people will give up and walk away before they successfully run the program. This applies whether the user interface is a command-line, a configuration file, or a GUI: if you make that many demands on your users, most of them will simply give up.

In short, try to minimize the amount of information that users are absolutely required to supply—use sensible defaults whenever possible. Of course, you also want to make your programs reasonably flexible. That’s what options are for. Again, it doesn’t matter if they are entries in a config file, widgets in the “Preferences” dialog of a GUI, or command-line options—the more options you implement, the more flexible your program is, and the more complicated its implementation becomes. Too much flexibility has drawbacks as well, of course; too many options can overwhelm users and make your code much harder to maintain.

36.2.2 教學

While `optparse` is quite flexible and powerful, it's also straightforward to use in most cases. This section covers the code patterns that are common to any `optparse`-based program.

First, you need to import the `OptionParser` class; then, early in the main program, create an `OptionParser` instance:

```
from optparse import OptionParser
...
parser = OptionParser()
```

Then you can start defining options. The basic syntax is:

```
parser.add_option(opt_str, ...,
                  attr=value, ...)
```

Each option has one or more option strings, such as `-f` or `--file`, and several option attributes that tell `optparse` what to expect and what to do when it encounters that option on the command line.

Typically, each option will have one short option string and one long option string, e.g.:

```
parser.add_option("-f", "--file", ...)
```

You're free to define as many short option strings and as many long option strings as you like (including zero), as long as there is at least one option string overall.

The option strings passed to `OptionParser.add_option()` are effectively labels for the option defined by that call. For brevity, we will frequently refer to *encountering an option* on the command line; in reality, `optparse` encounters *option strings* and looks up options from them.

Once all of your options are defined, instruct `optparse` to parse your program's command line:

```
(options, args) = parser.parse_args()
```

(If you like, you can pass a custom argument list to `parse_args()`, but that's rarely necessary: by default it uses `sys.argv[1:]`.)

`parse_args()` 回傳兩個值:

- `options`, an object containing values for all of your options---e.g. if `--file` takes a single string argument, then `options.file` will be the filename supplied by the user, or `None` if the user did not supply that option
- `args`, the list of positional arguments leftover after parsing options

This tutorial section only covers the four most important option attributes: `action`, `type`, `dest` (destination), and `help`. Of these, `action` is the most fundamental.

Understanding option actions

Actions tell `optparse` what to do when it encounters an option on the command line. There is a fixed set of actions hard-coded into `optparse`; adding new actions is an advanced topic covered in section *Extending optparse*. Most actions tell `optparse` to store a value in some variable---for example, take a string from the command line and store it in an attribute of `options`.

If you don't specify an option action, `optparse` defaults to `store`.

The store action

The most common option action is `store`, which tells `optparse` to take the next argument (or the remainder of the current argument), ensure that it is of the correct type, and store it to your chosen destination.

舉例來：

```
parser.add_option("-f", "--file",
                  action="store", type="string", dest="filename")
```

Now let's make up a fake command line and ask `optparse` to parse it:

```
args = ["-f", "foo.txt"]
(options, args) = parser.parse_args(args)
```

When `optparse` sees the option string `-f`, it consumes the next argument, `foo.txt`, and stores it in `options.filename`. So, after this call to `parse_args()`, `options.filename` is `"foo.txt"`.

Some other option types supported by `optparse` are `int` and `float`. Here's an option that expects an integer argument:

```
parser.add_option("-n", type="int", dest="num")
```

Note that this option has no long option string, which is perfectly acceptable. Also, there's no explicit action, since the default is `store`.

Let's parse another fake command-line. This time, we'll jam the option argument right up against the option: since `-n42` (one argument) is equivalent to `-n 42` (two arguments), the code

```
(options, args) = parser.parse_args(["-n42"])
print(options.num)
```

will print 42.

If you don't specify a type, `optparse` assumes `string`. Combined with the fact that the default action is `store`, that means our first example can be a lot shorter:

```
parser.add_option("-f", "--file", dest="filename")
```

If you don't supply a destination, `optparse` figures out a sensible default from the option strings: if the first long option string is `--foo-bar`, then the default destination is `foo_bar`. If there are no long option strings, `optparse` looks at the first short option string: the default destination for `-f` is `f`.

`optparse` also includes the built-in complex type. Adding types is covered in section [Extending optparse](#).

Handling boolean (flag) options

Flag options---set a variable to true or false when a particular option is seen---are quite common. `optparse` supports them with two separate actions, `store_true` and `store_false`. For example, you might have a `verbose` flag that is turned on with `-v` and off with `-q`:

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose")
```

Here we have two different options with the same destination, which is perfectly OK. (It just means you have to be a bit careful when setting default values---see below.)

When `optparse` encounters `-v` on the command line, it sets `options.verbose` to `True`; when it encounters `-q`, `options.verbose` is set to `False`.

Other actions

Some other actions supported by *optparse* are:

```
"store_const"
    store a constant value, pre-set via Option.const

"append"
    append this option's argument to a list

"count"
    increment a counter by one

"callback"
    call a specified function
```

These are covered in section *Reference Guide*, and section *Option Callbacks*.

Default values

All of the above examples involve setting some variable (the "destination") when certain command-line options are seen. What happens if those options are never seen? Since we didn't supply any defaults, they are all set to *None*. This is usually fine, but sometimes you want more control. *optparse* lets you supply a default value for each destination, which is assigned before the command line is parsed.

First, consider the verbose/quiet example. If we want *optparse* to set *verbose* to *True* unless *-q* is seen, then we can do this:

```
parser.add_option("-v", action="store_true", dest="verbose", default=True)
parser.add_option("-q", action="store_false", dest="verbose")
```

Since default values apply to the *destination* rather than to any particular option, and these two options happen to have the same destination, this is exactly equivalent:

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose", default=True)
```

Consider this:

```
parser.add_option("-v", action="store_true", dest="verbose", default=False)
parser.add_option("-q", action="store_false", dest="verbose", default=True)
```

Again, the default value for *verbose* will be *True*: the last default value supplied for any particular destination is the one that counts.

A clearer way to specify default values is the *set_defaults()* method of *OptionParser*, which you can call at any time before calling *parse_args()*:

```
parser.set_defaults(verbose=True)
parser.add_option(...)
(options, args) = parser.parse_args()
```

As before, the last value specified for a given option destination is the one that counts. For clarity, try to use one method or the other of setting default values, not both.

Generating help

`optparse`'s ability to generate help and usage text automatically is useful for creating user-friendly command-line interfaces. All you have to do is supply a `help` value for each option, and optionally a short usage message for your whole program. Here's an `OptionParser` populated with user-friendly (documented) options:

```
usage = "usage: %prog [options] arg1 arg2"
parser = OptionParser(usage=usage)
parser.add_option("-v", "--verbose",
                  action="store_true", dest="verbose", default=True,
                  help="make lots of noise [default]")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose",
                  help="be vewwy quiet (I'm hunting wabbits)")
parser.add_option("-f", "--filename",
                  metavar="FILE", help="write output to FILE")
parser.add_option("-m", "--mode",
                  default="intermediate",
                  help="interaction mode: novice, intermediate, "
                        "or expert [default: %default]")
```

If `optparse` encounters either `-h` or `--help` on the command-line, or if you just call `parser.print_help()`, it prints the following to standard output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose         make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or
                        expert [default: intermediate]
```

(If the help output is triggered by a help option, `optparse` exits after printing the help text.)

There's a lot going on here to help `optparse` generate the best possible help message:

- the script defines its own usage message:

```
usage = "usage: %prog [options] arg1 arg2"
```

`optparse` expands `%prog` in the usage string to the name of the current program, i.e. `os.path.basename(sys.argv[0])`. The expanded string is then printed before the detailed option help.

If you don't supply a usage string, `optparse` uses a bland but sensible default: `"Usage: %prog [options]"`, which is fine if your script doesn't take any positional arguments.

- every option defines a help string, and doesn't worry about line-wrapping---`optparse` takes care of wrapping lines and making the help output look good.
- options that take a value indicate this fact in their automatically generated help message, e.g. for the "mode" option:

```
-m MODE, --mode=MODE
```

Here, "MODE" is called the meta-variable: it stands for the argument that the user is expected to supply to `-m/--mode`. By default, `optparse` converts the destination variable name to uppercase and uses that for the meta-variable. Sometimes, that's not what you want---for example, the `--filename` option explicitly sets `metavar="FILE"`, resulting in this automatically generated option description:

```
-f FILE, --filename=FILE
```

This is important for more than just saving space, though: the manually written help text uses the meta-variable `FILE` to clue the user in that there's a connection between the semi-formal syntax `-f FILE` and the informal semantic description "write output to `FILE`". This is a simple but effective way to make your help text a lot clearer and more useful for end users.

- options that have a default value can include `%default` in the help string---`optparse` will replace it with `str()` of the option's default value. If an option has no default value (or the default value is `None`), `%default` expands to `none`.

Grouping Options

When dealing with many options, it is convenient to group these options for better help output. An `OptionParser` can contain several option groups, each of which can contain several options.

An option group is obtained using the class `OptionGroup`:

```
class optparse.OptionGroup (parser, title, description=None)
```

where

- `parser` is the `OptionParser` instance the group will be inserted in to
- `title` is the group title
- `description`, optional, is a long description of the group

`OptionGroup` inherits from `OptionContainer` (like `OptionParser`) and so the `add_option()` method can be used to add an option to the group.

Once all the options are declared, using the `OptionParser` method `add_option_group()` the group is added to the previously defined parser.

Continuing with the parser defined in the previous section, adding an `OptionGroup` to a parser is easy:

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your own risk. "
                    "It is believed that some of them bite.")
group.add_option("-g", action="store_true", help="Group option.")
parser.add_option_group(group)
```

This would result in the following help output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose          make lots of noise [default]
  -q, --quiet            be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or
                        expert [default: intermediate]

Dangerous Options:
  Caution: use these options at your own risk.  It is believed that some
  of them bite.

  -g                    Group option.
```

A bit more complete example might involve using more than one group: still extending the previous example:

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your own risk. "
                    "It is believed that some of them bite.")
```

(繼續下一頁)

(繼續上一頁)

```
group.add_option("-g", action="store_true", help="Group option.")
parser.add_option_group(group)

group = OptionGroup(parser, "Debug Options")
group.add_option("-d", "--debug", action="store_true",
                 help="Print debug information")
group.add_option("-s", "--sql", action="store_true",
                 help="Print all SQL statements executed")
group.add_option("-e", action="store_true", help="Print every action done")
parser.add_option_group(group)
```

that results in the following output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose          make lots of noise [default]
  -q, --quiet            be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or expert
                        [default: intermediate]

Dangerous Options:
  Caution: use these options at your own risk.  It is believed that some
  of them bite.

  -g                    Group option.

Debug Options:
  -d, --debug          Print debug information
  -s, --sql            Print all SQL statements executed
  -e                  Print every action done
```

Another interesting method, in particular when working programmatically with option groups is:

`OptionParser.get_option_group(opt_str)`

Return the *OptionGroup* to which the short or long option string *opt_str* (e.g. `'-o'` or `'--option'`) belongs. If there's no such *OptionGroup*, return `None`.

Printing a version string

Similar to the brief usage string, *optparse* can also print a version string for your program. You have to supply the string as the *version* argument to *OptionParser*:

```
parser = OptionParser(usage="%prog [-f] [-q]", version="%prog 1.0")
```

`%prog` is expanded just like it is in *usage*. Apart from that, *version* can contain anything you like. When you supply it, *optparse* automatically adds a `--version` option to your parser. If it encounters this option on the command line, it expands your *version* string (by replacing `%prog`), prints it to `stdout`, and exits.

For example, if your script is called `/usr/bin/foo`:

```
$ /usr/bin/foo --version
foo 1.0
```

The following two methods can be used to print and get the *version* string:

`OptionParser.print_version(file=None)`

Print the version message for the current program (`self.version`) to *file* (default `stdout`). As with `print_usage()`, any occurrence of `%prog` in `self.version` is replaced with the name of the current program. Does nothing if `self.version` is empty or undefined.

`OptionParser.get_version()`

Same as `print_version()` but returns the version string instead of printing it.

How `optparse` handles errors

There are two broad classes of errors that `optparse` has to worry about: programmer errors and user errors. Programmer errors are usually erroneous calls to `OptionParser.add_option()`, e.g. invalid option strings, unknown option attributes, missing option attributes, etc. These are dealt with in the usual way: raise an exception (either `optparse.OptionError` or `TypeError`) and let the program crash.

Handling user errors is much more important, since they are guaranteed to happen no matter how stable your code is. `optparse` can automatically detect some user errors, such as bad option arguments (passing `-n 4x` where `-n` takes an integer argument), missing arguments (`-n` at the end of the command line, where `-n` takes an argument of any type). Also, you can call `OptionParser.error()` to signal an application-defined error condition:

```
(options, args) = parser.parse_args()
...
if options.a and options.b:
    parser.error("options -a and -b are mutually exclusive")
```

In either case, `optparse` handles the error the same way: it prints the program's usage message and an error message to standard error and exits with error status 2.

Consider the first example above, where the user passes `4x` to an option that takes an integer:

```
$ /usr/bin/foo -n 4x
Usage: foo [options]

foo: error: option -n: invalid integer value: '4x'
```

Or, where the user fails to pass a value at all:

```
$ /usr/bin/foo -n
Usage: foo [options]

foo: error: -n option requires an argument
```

`optparse`-generated error messages take care always to mention the option involved in the error; be sure to do the same when calling `OptionParser.error()` from your application code.

If `optparse`'s default error-handling behaviour does not suit your needs, you'll need to subclass `OptionParser` and override its `exit()` and/or `error()` methods.

Putting it all together

Here's what `optparse`-based scripts usually look like:

```
from optparse import OptionParser
...
def main():
    usage = "usage: %prog [options] arg"
    parser = OptionParser(usage)
    parser.add_option("-f", "--file", dest="filename",
                    help="read data from FILENAME")
    parser.add_option("-v", "--verbose",
```

(繼續下一頁)

(繼續上一頁)

```

        action="store_true", dest="verbose")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose")
...
(options, args) = parser.parse_args()
if len(args) != 1:
    parser.error("incorrect number of arguments")
if options.verbose:
    print("reading %s..." % options.filename)
...

if __name__ == "__main__":
    main()

```

36.2.3 Reference Guide

Creating the parser

The first step in using *optparse* is to create an `OptionParser` instance.

class `optparse.OptionParser(...)`

The `OptionParser` constructor has no required arguments, but a number of optional keyword arguments. You should always pass them as keyword arguments, i.e. do not rely on the order in which the arguments are declared.

usage (default: "%prog [options]")

The usage summary to print when your program is run incorrectly or with a help option. When *optparse* prints the usage string, it expands `%prog` to `os.path.basename(sys.argv[0])` (or to `prog` if you passed that keyword argument). To suppress a usage message, pass the special value `optparse.SUPPRESS_USAGE`.

option_list (default: [])

A list of `Option` objects to populate the parser with. The options in `option_list` are added after any options in `standard_option_list` (a class attribute that may be set by `OptionParser` subclasses), but before any version or help options. Deprecated; use *add_option()* after creating the parser instead.

option_class (default: `optparse.Option`)

Class to use when adding options to the parser in *add_option()*.

version (default: `None`)

A version string to print when the user supplies a version option. If you supply a true value for `version`, *optparse* automatically adds a version option with the single option string `--version`. The substring `%prog` is expanded the same as for usage.

conflict_handler (default: "error")

Specifies what to do when options with conflicting option strings are added to the parser; see section *Conflicts between options*.

description (default: `None`)

A paragraph of text giving a brief overview of your program. *optparse* reformats this paragraph to fit the current terminal width and prints it when the user requests help (after usage, but before the list of options).

formatter (default: a new `IndentedHelpFormatter`)

An instance of `optparse.HelpFormatter` that will be used for printing help text. *optparse* provides two concrete classes for this purpose: `IndentedHelpFormatter` and `TitledHelpFormatter`.

add_help_option (default: `True`)

If true, *optparse* will add a help option (with option strings `-h` and `--help`) to the parser.

prog

The string to use when expanding %prog in usage and version instead of os.path.basename(sys.argv[0]).

epilog (default: None)

A paragraph of help text to print after the option help.

Populating the parser

There are several ways to populate the parser with options. The preferred way is by using *OptionParser.add_option()*, as shown in section 教學. *add_option()* can be called in one of two ways:

- pass it an *Option* instance (as returned by *make_option()*)
- pass it any combination of positional and keyword arguments that are acceptable to *make_option()* (i.e., to the *Option* constructor), and it will create the *Option* instance for you

The other alternative is to pass a list of pre-constructed *Option* instances to the *OptionParser* constructor, as in:

```
option_list = [
    make_option("-f", "--filename",
                action="store", type="string", dest="filename"),
    make_option("-q", "--quiet",
                action="store_false", dest="verbose"),
]
parser = OptionParser(option_list=option_list)
```

(*make_option()* is a factory function for creating *Option* instances; currently it is an alias for the *Option* constructor. A future version of *optparse* may split *Option* into several classes, and *make_option()* will pick the right class to instantiate. Do not instantiate *Option* directly.)

Defining options

Each *Option* instance represents a set of synonymous command-line option strings, e.g. *-f* and *--file*. You can specify any number of short or long option strings, but you must specify at least one overall option string.

The canonical way to create an *Option* instance is with the *add_option()* method of *OptionParser*.

OptionParser.add_option(option)

*OptionParser.add_option(*opt_str, attr=value, ...)*

To define an option with only a short option string:

```
parser.add_option("-f", attr=value, ...)
```

And to define an option with only a long option string:

```
parser.add_option("--foo", attr=value, ...)
```

The keyword arguments define attributes of the new *Option* object. The most important option attribute is *action*, and it largely determines which other attributes are relevant or required. If you pass irrelevant option attributes, or fail to pass required ones, *optparse* raises an *OptionError* exception explaining your mistake.

An option's *action* determines what *optparse* does when it encounters this option on the command-line. The standard option actions hard-coded into *optparse* are:

"store"

store this option's argument (default)

"store_const"

store a constant value, pre-set via *Option.const*

```

"store_true"
    store True

"store_false"
    store False

"append"
    append this option's argument to a list

"append_const"
    append a constant value to a list, pre-set via Option.const

"count"
    increment a counter by one

"callback"
    call a specified function

"help"
    print a usage message including all options and the documentation for them

```

(If you don't supply an action, the default is "store". For this action, you may also supply *type* and *dest* option attributes; see *Standard option actions*.)

As you can see, most actions involve storing or updating a value somewhere. *optparse* always creates a special object for this, conventionally called *options*, which is an instance of *optparse.Values*.

class *optparse.Values*

An object holding parsed argument names and values as attributes. Normally created by calling when calling *OptionParser.parse_args()*, and can be overridden by a custom subclass passed to the *values* argument of *OptionParser.parse_args()* (as described in 剖析引數).

Option arguments (and various other values) are stored as attributes of this object, according to the *dest* (destination) option attribute.

例如，當你呼叫：

```
parser.parse_args()
```

one of the first things *optparse* does is create the *options* object:

```
options = Values()
```

If one of the options in this parser is defined with

```
parser.add_option("-f", "--file", action="store", type="string", dest="filename")
```

and the command-line being parsed includes any of the following:

```

-ffoo
-f foo
--file=foo
--file foo

```

then *optparse*, on seeing this option, will do the equivalent of

```
options.filename = "foo"
```

The *type* and *dest* option attributes are almost as important as *action*, but *action* is the only one that makes sense for *all* options.

Option attributes

`class optparse.Option`

A single command line argument, with various attributes passed by keyword to the constructor. Normally created with `OptionParser.add_option()` rather than directly, and can be overridden by a custom class via the `option_class` argument to `OptionParser`.

The following option attributes may be passed as keyword arguments to `OptionParser.add_option()`. If you pass an option attribute that is not relevant to a particular option, or fail to pass a required option attribute, `optparse` raises `OptionError`.

`Option.action`

(預設值: "store")

Determines `optparse`'s behaviour when this option is seen on the command line; the available options are documented [here](#).

`Option.type`

(預設值: "string")

The argument type expected by this option (e.g., "string" or "int"); the available option types are documented [here](#).

`Option.dest`

(default: derived from option strings)

If the option's action implies writing or modifying a value somewhere, this tells `optparse` where to write it: `dest` names an attribute of the `options` object that `optparse` builds as it parses the command line.

`Option.default`

The value to use for this option's destination if the option is not seen on the command line. See also `OptionParser.set_defaults()`.

`Option.nargs`

(預設值: 1)

How many arguments of type `type` should be consumed when this option is seen. If > 1 , `optparse` will store a tuple of values to `dest`.

`Option.const`

For actions that store a constant value, the constant value to store.

`Option.choices`

For options of type "choice", the list of strings the user may choose from.

`Option.callback`

For options with action "callback", the callable to call when this option is seen. See section [Option Callbacks](#) for detail on the arguments passed to the callable.

`Option.callback_args`

`Option.callback_kwargs`

Additional positional and keyword arguments to pass to `callback` after the four standard callback arguments.

`Option.help`

Help text to print for this option when listing all available options after the user supplies a `help` option (such as `--help`). If no help text is supplied, the option will be listed without help text. To hide this option, use the special value `optparse.SUPPRESS_HELP`.

`Option.metavar`

(default: derived from option strings)

Stand-in for the option argument(s) to use when printing help text. See section [教學](#) for an example.

Standard option actions

The various option actions all have slightly different requirements and effects. Most actions have several relevant option attributes which you may specify to guide *optparse*'s behaviour; a few have required attributes, which you must specify for any option using that action.

- "store" [relevant: *type*, *dest*, *nargs*, *choices*]

The option must be followed by an argument, which is converted to a value according to *type* and stored in *dest*. If *nargs* > 1, multiple arguments will be consumed from the command line; all will be converted according to *type* and stored to *dest* as a tuple. See the *Standard option types* section.

If *choices* is supplied (a list or tuple of strings), the type defaults to "choice".

If *type* is not supplied, it defaults to "string".

If *dest* is not supplied, *optparse* derives a destination from the first long option string (e.g., `--foo-bar` implies `foo_bar`). If there are no long option strings, *optparse* derives a destination from the first short option string (e.g., `-f` implies `f`).

範例：

```
parser.add_option("-f")
parser.add_option("-p", type="float", nargs=3, dest="point")
```

As it parses the command line

```
-f foo.txt -p 1 -3.5 4 -fbar.txt
```

optparse will set

```
options.f = "foo.txt"
options.point = (1.0, -3.5, 4.0)
options.f = "bar.txt"
```

- "store_const" [required: *const*; relevant: *dest*]

The value *const* is stored in *dest*.

範例：

```
parser.add_option("-q", "--quiet",
                  action="store_const", const=0, dest="verbose")
parser.add_option("-v", "--verbose",
                  action="store_const", const=1, dest="verbose")
parser.add_option("--noisy",
                  action="store_const", const=2, dest="verbose")
```

If `--noisy` is seen, *optparse* will set

```
options.verbose = 2
```

- "store_true" [relevant: *dest*]

A special case of "store_const" that stores True to *dest*.

- "store_false" [relevant: *dest*]

Like "store_true", but stores False.

範例：

```
parser.add_option("--clobber", action="store_true", dest="clobber")
parser.add_option("--no-clobber", action="store_false", dest="clobber")
```

- "append" [relevant: *type*, *dest*, *nargs*, *choices*]

The option must be followed by an argument, which is appended to the list in *dest*. If no default value for *dest* is supplied, an empty list is automatically created when *optparse* first encounters this option on the command-line. If *nargs* > 1, multiple arguments are consumed, and a tuple of length *nargs* is appended to *dest*.

The defaults for *type* and *dest* are the same as for the "store" action.

範例：

```
parser.add_option("-t", "--tracks", action="append", type="int")
```

If `-t3` is seen on the command-line, *optparse* does the equivalent of:

```
options.tracks = []
options.tracks.append(int("3"))
```

If, a little later on, `--tracks=4` is seen, it does:

```
options.tracks.append(int("4"))
```

The append action calls the append method on the current value of the option. This means that any default value specified must have an append method. It also means that if the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values:

```
>>> parser.add_option("--files", action="append", default=['~/mypkg/defaults',
↳'])
>>> opts, args = parser.parse_args(['--files', 'overrides.mypkg'])
>>> opts.files
['~/mypkg/defaults', 'overrides.mypkg']
```

- "append_const" [required: *const*; relevant: *dest*]

Like "store_const", but the value *const* is appended to *dest*; as with "append", *dest* defaults to None, and an empty list is automatically created the first time the option is encountered.

- "count" [relevant: *dest*]

Increment the integer stored at *dest*. If no default value is supplied, *dest* is set to zero before being incremented the first time.

範例：

```
parser.add_option("-v", action="count", dest="verbosity")
```

The first time `-v` is seen on the command line, *optparse* does the equivalent of:

```
options.verbosity = 0
options.verbosity += 1
```

Every subsequent occurrence of `-v` results in

```
options.verbosity += 1
```

- "callback" [required: *callback*; relevant: *type*, *nargs*, *callback_args*, *callback_kwargs*]

Call the function specified by *callback*, which is called as

```
func(option, opt_str, value, parser, *args, **kwargs)
```

更多細節請見 *Option Callbacks*。

- "help"

Prints a complete help message for all the options in the current option parser. The help message is constructed from the `usage` string passed to `OptionParser`'s constructor and the `help` string passed to every option.

If no `help` string is supplied for an option, it will still be listed in the help message. To omit an option entirely, use the special value `optparse.SUPPRESS_HELP`.

`optparse` automatically adds a `help` option to all `OptionParsers`, so you do not normally need to create one.

範例：

```
from optparse import OptionParser, SUPPRESS_HELP

# usually, a help option is added automatically, but that can
# be suppressed using the add_help_option argument
parser = OptionParser(add_help_option=False)

parser.add_option("-h", "--help", action="help")
parser.add_option("-v", action="store_true", dest="verbose",
                  help="Be moderately verbose")
parser.add_option("--file", dest="filename",
                  help="Input file to read data from")
parser.add_option("--secret", help=SUPPRESS_HELP)
```

If `optparse` sees either `-h` or `--help` on the command line, it will print something like the following help message to stdout (assuming `sys.argv[0]` is `"foo.py"`):

```
Usage: foo.py [options]

Options:
  -h, --help          Show this help message and exit
  -v                  Be moderately verbose
  --file=FILENAME     Input file to read data from
```

After printing the help message, `optparse` terminates your process with `sys.exit(0)`.

- "version"

Prints the version number supplied to the `OptionParser` to stdout and exits. The version number is actually formatted and printed by the `print_version()` method of `OptionParser`. Generally only relevant if the `version` argument is supplied to the `OptionParser` constructor. As with `help` options, you will rarely create version options, since `optparse` automatically adds them when needed.

Standard option types

`optparse` has five built-in option types: `"string"`, `"int"`, `"choice"`, `"float"` and `"complex"`. If you need to add new option types, see section [Extending optparse](#).

Arguments to string options are not checked or converted in any way: the text on the command line is stored in the destination (or passed to the callback) as-is.

Integer arguments (type `"int"`) are parsed as follows:

- if the number starts with `0x`, it is parsed as a hexadecimal number
- if the number starts with `0`, it is parsed as an octal number
- if the number starts with `0b`, it is parsed as a binary number
- otherwise, the number is parsed as a decimal number

The conversion is done by calling `int()` with the appropriate base (2, 8, 10, or 16). If this fails, so will `optparse`, although with a more useful error message.

"float" and "complex" option arguments are converted directly with `float()` and `complex()`, with similar error-handling.

"choice" options are a subtype of "string" options. The `choices` option attribute (a sequence of strings) defines the set of allowed option arguments. `optparse.check_choice()` compares user-supplied option arguments against this master list and raises `OptionValueError` if an invalid string is given.

剖析引數

The whole point of creating and populating an `OptionParser` is to call its `parse_args()` method.

`OptionParser.parse_args(args=None, values=None)`

Parse the command-line options found in `args`.

The input parameters are

args

the list of arguments to process (default: `sys.argv[1:]`)

values

a `Values` object to store option arguments in (default: a new instance of `Values`) -- if you give an existing object, the option defaults will not be initialized on it

and the return value is a pair (`options`, `args`) where

options

the same object that was passed in as `values`, or the `optparse.Values` instance created by `optparse`

args

the leftover positional arguments after all options have been processed

The most common usage is to supply neither keyword argument. If you supply `values`, it will be modified with repeated `setattr()` calls (roughly one for every option argument stored to an option destination) and returned by `parse_args()`.

If `parse_args()` encounters any errors in the argument list, it calls the `OptionParser.error()` method with an appropriate end-user error message. This ultimately terminates your process with an exit status of 2 (the traditional Unix exit status for command-line errors).

Querying and manipulating your option parser

The default behavior of the option parser can be customized slightly, and you can also poke around your option parser and see what's there. `OptionParser` provides several methods to help you out:

`OptionParser.disable_interspersed_args()`

Set parsing to stop on the first non-option. For example, if `-a` and `-b` are both simple options that take no arguments, `optparse` normally accepts this syntax:

```
prog -a arg1 -b arg2
```

and treats it as equivalent to

```
prog -a -b arg1 arg2
```

To disable this feature, call `disable_interspersed_args()`. This restores traditional Unix syntax, where option parsing stops with the first non-option argument.

Use this if you have a command processor which runs another command which has options of its own and you want to make sure these options don't get confused. For example, each command might have a different set of options.

`OptionParser.enable_interspersed_args()`

Set parsing to not stop on the first non-option, allowing interspersing switches with command arguments. This is the default behavior.

`OptionParser.get_option(opt_str)`

Returns the `Option` instance with the option string `opt_str`, or `None` if no options have that option string.

`OptionParser.has_option(opt_str)`

Return `True` if the `OptionParser` has an option with option string `opt_str` (e.g., `-q` or `--verbose`).

`OptionParser.remove_option(opt_str)`

If the `OptionParser` has an option corresponding to `opt_str`, that option is removed. If that option provided any other option strings, all of those option strings become invalid. If `opt_str` does not occur in any option belonging to this `OptionParser`, raises `ValueError`.

Conflicts between options

If you're not careful, it's easy to define options with conflicting option strings:

```
parser.add_option("-n", "--dry-run", ...)
...
parser.add_option("-n", "--noisy", ...)
```

(This is particularly true if you've defined your own `OptionParser` subclass with some standard options.)

Every time you add an option, `optparse` checks for conflicts with existing options. If it finds any, it invokes the current conflict-handling mechanism. You can set the conflict-handling mechanism either in the constructor:

```
parser = OptionParser(..., conflict_handler=handler)
```

or with a separate call:

```
parser.set_conflict_handler(handler)
```

The available conflict handlers are:

"error" (default)

assume option conflicts are a programming error and raise `OptionConflictError`

"resolve"

resolve option conflicts intelligently (see below)

As an example, let's define an `OptionParser` that resolves conflicts intelligently and add conflicting options to it:

```
parser = OptionParser(conflict_handler="resolve")
parser.add_option("-n", "--dry-run", ..., help="do no harm")
parser.add_option("-n", "--noisy", ..., help="be noisy")
```

At this point, `optparse` detects that a previously added option is already using the `-n` option string. Since `conflict_handler` is `"resolve"`, it resolves the situation by removing `-n` from the earlier option's list of option strings. Now `--dry-run` is the only way for the user to activate that option. If the user asks for help, the help message will reflect that:

```
Options:
  --dry-run      do no harm
  ...
  -n, --noisy    be noisy
```

It's possible to whittle away the option strings for a previously added option until there are none left, and the user has no way of invoking that option from the command-line. In that case, `optparse` removes that option completely, so it doesn't show up in help text or anywhere else. Carrying on with our existing `OptionParser`:

```
parser.add_option("--dry-run", ..., help="new dry-run option")
```

At this point, the original `-n/--dry-run` option is no longer accessible, so `optparse` removes it, leaving this help text:

```
Options:
...
-n, --noisy      be noisy
--dry-run       new dry-run option
```

Cleanup

`OptionParser` instances have several cyclic references. This should not be a problem for Python's garbage collector, but you may wish to break the cyclic references explicitly by calling `destroy()` on your `OptionParser` once you are done with it. This is particularly useful in long-running applications where large object graphs are reachable from your `OptionParser`.

其他方法

`OptionParser` supports several other public methods:

`OptionParser.set_usage(usage)`

Set the usage string according to the rules described above for the `usage` constructor keyword argument. Passing `None` sets the default usage string; use `optparse.SUPPRESS_USAGE` to suppress a usage message.

`OptionParser.print_usage(file=None)`

Print the usage message for the current program (`self.usage`) to `file` (default `stdout`). Any occurrence of the string `%prog` in `self.usage` is replaced with the name of the current program. Does nothing if `self.usage` is empty or not defined.

`OptionParser.get_usage()`

Same as `print_usage()` but returns the usage string instead of printing it.

`OptionParser.set_defaults(dest=value, ...)`

Set default values for several option destinations at once. Using `set_defaults()` is the preferred way to set default values for options, since multiple options can share the same destination. For example, if several "mode" options all set the same destination, any one of them can set the default, and the last one wins:

```
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced",
                  default="novice")      # overridden below
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice",
                  default="advanced")    # overrides above setting
```

To avoid this confusion, use `set_defaults()`:

```
parser.set_defaults(mode="advanced")
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced")
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice")
```

36.2.4 Option Callbacks

When *optparse*'s built-in actions and types aren't quite enough for your needs, you have two choices: extend *optparse* or define a callback option. Extending *optparse* is more general, but overkill for a lot of simple cases. Quite often a simple callback is all you need.

There are two steps to defining a callback option:

- define the option itself using the "callback" action
- write the callback; this is a function (or method) that takes at least four arguments, as described below

Defining a callback option

As always, the easiest way to define a callback option is by using the *OptionParser.add_option()* method. Apart from *action*, the only option attribute you must specify is *callback*, the function to call:

```
parser.add_option("-c", action="callback", callback=my_callback)
```

callback is a function (or other callable object), so you must have already defined *my_callback()* when you create this callback option. In this simple case, *optparse* doesn't even know if *-c* takes any arguments, which usually means that the option takes no arguments---the mere presence of *-c* on the command-line is all it needs to know. In some circumstances, though, you might want your callback to consume an arbitrary number of command-line arguments. This is where writing callbacks gets tricky; it's covered later in this section.

optparse always passes four particular arguments to your callback, and it will only pass additional arguments if you specify them via *callback_args* and *callback_kwargs*. Thus, the minimal callback function signature is:

```
def my_callback(option, opt, value, parser):
```

The four arguments to a callback are described below.

There are several other option attributes that you can supply when you define a callback option:

type

has its usual meaning: as with the "store" or "append" actions, it instructs *optparse* to consume one argument and convert it to *type*. Rather than storing the converted value(s) anywhere, though, *optparse* passes it to your callback function.

nargs

also has its usual meaning: if it is supplied and > 1 , *optparse* will consume *nargs* arguments, each of which must be convertible to *type*. It then passes a tuple of converted values to your callback.

callback_args

a tuple of extra positional arguments to pass to the callback

callback_kwargs

a dictionary of extra keyword arguments to pass to the callback

How callbacks are called

All callbacks are called as follows:

```
func(option, opt_str, value, parser, *args, **kwargs)
```

where

option

is the Option instance that's calling the callback

opt_str

is the option string seen on the command-line that's triggering the callback. (If an abbreviated long option was used, `opt_str` will be the full, canonical option string--e.g. if the user puts `--foo` on the command-line as an abbreviation for `--foobar`, then `opt_str` will be `"--foobar"`.)

value

is the argument to this option seen on the command-line. `optparse` will only expect an argument if `type` is set; the type of `value` will be the type implied by the option's type. If `type` for this option is `None` (no argument expected), then `value` will be `None`. If `nargs > 1`, `value` will be a tuple of values of the appropriate type.

parser

is the `OptionParser` instance driving the whole thing, mainly useful because you can access some other interesting data through its instance attributes:

parser.largs

the current list of leftover arguments, ie. arguments that have been consumed but are neither options nor option arguments. Feel free to modify `parser.largs`, e.g. by adding more arguments to it. (This list will become `args`, the second return value of `parse_args()`.)

parser.rargs

the current list of remaining arguments, ie. with `opt_str` and `value` (if applicable) removed, and only the arguments following them still there. Feel free to modify `parser.rargs`, e.g. by consuming more arguments.

parser.values

the object where option values are by default stored (an instance of `optparse.OptionValues`). This lets callbacks use the same mechanism as the rest of `optparse` for storing option values; you don't need to mess around with globals or closures. You can also access or modify the value(s) of any options already encountered on the command-line.

args

is a tuple of arbitrary positional arguments supplied via the `callback_args` option attribute.

kwargs

is a dictionary of arbitrary keyword arguments supplied via `callback_kwargs`.

Raising errors in a callback

The callback function should raise `OptionValueError` if there are any problems with the option or its argument(s). `optparse` catches this and terminates the program, printing the error message you supply to `stderr`. Your message should be clear, concise, accurate, and mention the option at fault. Otherwise, the user will have a hard time figuring out what they did wrong.

Callback example 1: trivial callback

Here's an example of a callback option that takes no arguments, and simply records that the option was seen:

```
def record_foo_seen(option, opt_str, value, parser):
    parser.values.saw_foo = True

parser.add_option("--foo", action="callback", callback=record_foo_seen)
```

Of course, you could do that with the `"store_true"` action.

Callback example 2: check option order

Here's a slightly more interesting example: record the fact that `-a` is seen, but blow up if it comes after `-b` in the command-line.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use -a after -b")
    parser.values.a = 1
...
parser.add_option("-a", action="callback", callback=check_order)
parser.add_option("-b", action="store_true", dest="b")
```

Callback example 3: check option order (generalized)

If you want to reuse this callback for several similar options (set a flag, but blow up if `-b` has already been seen), it needs a bit of work: the error message and the flag that it sets must be generalized.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use %s after -b" % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("-a", action="callback", callback=check_order, dest='a')
parser.add_option("-b", action="store_true", dest="b")
parser.add_option("-c", action="callback", callback=check_order, dest='c')
```

Callback example 4: check arbitrary condition

Of course, you could put any condition in there---you're not limited to checking the values of already-defined options. For example, if you have options that should not be called when the moon is full, all you have to do is this:

```
def check_moon(option, opt_str, value, parser):
    if is_moon_full():
        raise OptionValueError("%s option invalid when moon is full"
                                % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("--foo",
                  action="callback", callback=check_moon, dest="foo")
```

(The definition of `is_moon_full()` is left as an exercise for the reader.)

Callback example 5: fixed arguments

Things get slightly more interesting when you define callback options that take a fixed number of arguments. Specifying that a callback option takes arguments is similar to defining a "store" or "append" option: if you define `type`, then the option takes one argument that must be convertible to that type; if you further define `nargs`, then the option takes `nargs` arguments.

Here's an example that just emulates the standard "store" action:

```
def store_value(option, opt_str, value, parser):
    setattr(parser.values, option.dest, value)
...
parser.add_option("--foo",
                  action="callback", callback=store_value,
                  type="int", nargs=3, dest="foo")
```

Note that `optparse` takes care of consuming 3 arguments and converting them to integers for you; all you have to do is store them. (Or whatever; obviously you don't need a callback for this example.)

Callback example 6: variable arguments

Things get hairy when you want an option to take a variable number of arguments. For this case, you must write a callback, as `optparse` doesn't provide any built-in capabilities for it. And you have to deal with certain intricacies of conventional Unix command-line parsing that `optparse` normally handles for you. In particular, callbacks should implement the conventional rules for bare `--` and `-` arguments:

- either `--` or `-` can be option arguments
- bare `--` (if not the argument to some option): halt command-line processing and discard the `--`
- bare `-` (if not the argument to some option): halt command-line processing but keep the `-` (append it to `parser.largs`)

If you want an option that takes a variable number of arguments, there are several subtle, tricky issues to worry about. The exact implementation you choose will be based on which trade-offs you're willing to make for your application (which is why `optparse` doesn't support this sort of thing directly).

Nevertheless, here's a stab at a callback for an option with variable arguments:

```
def vararg_callback(option, opt_str, value, parser):
    assert value is None
    value = []

    def floatable(str):
        try:
            float(str)
            return True
        except ValueError:
            return False

    for arg in parser.rargs:
        # stop on --foo like options
        if arg[:2] == "--" and len(arg) > 2:
            break
        # stop on -a, but not on -3 or -3.0
        if arg[:1] == "-" and len(arg) > 1 and not floatable(arg):
            break
        value.append(arg)

    del parser.rargs[:len(value)]
    setattr(parser.values, option.dest, value)

...
parser.add_option("-c", "--callback", dest="vararg_attr",
                  action="callback", callback=vararg_callback)
```

36.2.5 Extending `optparse`

Since the two major controlling factors in how `optparse` interprets command-line options are the action and type of each option, the most likely direction of extension is to add new actions and new types.

Adding new types

To add new types, you need to define your own subclass of *optparse*'s *Option* class. This class has a couple of attributes that define *optparse*'s types: *TYPES* and *TYPE_CHECKER*.

Option.*TYPES*

A tuple of type names; in your subclass, simply define a new tuple *TYPES* that builds on the standard one.

Option.*TYPE_CHECKER*

A dictionary mapping type names to type-checking functions. A type-checking function has the following signature:

```
def check_mytype(option, opt, value)
```

where *option* is an *Option* instance, *opt* is an option string (e.g., *-f*), and *value* is the string from the command line that must be checked and converted to your desired type. *check_mytype()* should return an object of the hypothetical type *mytype*. The value returned by a type-checking function will wind up in the *OptionValues* instance returned by *OptionParser.parse_args()*, or be passed to a callback as the *value* parameter.

Your type-checking function should raise *OptionValueError* if it encounters any problems. *OptionValueError* takes a single string argument, which is passed as-is to *OptionParser*'s *error()* method, which in turn prepends the program name and the string "error: " and prints everything to *stderr* before terminating the process.

Here's a silly example that demonstrates adding a "complex" option type to parse Python-style complex numbers on the command line. (This is even sillier than it used to be, because *optparse* 1.3 added built-in support for complex numbers, but never mind.)

First, the necessary imports:

```
from copy import copy
from optparse import Option, OptionValueError
```

You need to define your type-checker first, since it's referred to later (in the *TYPE_CHECKER* class attribute of your *Option* subclass):

```
def check_complex(option, opt, value):
    try:
        return complex(value)
    except ValueError:
        raise OptionValueError(
            "option %s: invalid complex value: %r" % (opt, value))
```

Finally, the *Option* subclass:

```
class MyOption (Option):
    TYPES = Option.TYPES + ("complex",)
    TYPE_CHECKER = copy(Option.TYPE_CHECKER)
    TYPE_CHECKER["complex"] = check_complex
```

(If we didn't make a *copy()* of *Option.TYPE_CHECKER*, we would end up modifying the *TYPE_CHECKER* attribute of *optparse*'s *Option* class. This being Python, nothing stops you from doing that except good manners and common sense.)

That's it! Now you can write a script that uses the new option type just like any other *optparse*-based script, except you have to instruct your *OptionParser* to use *MyOption* instead of *Option*:

```
parser = OptionParser(option_class=MyOption)
parser.add_option("-c", type="complex")
```

Alternately, you can build your own option list and pass it to *OptionParser*; if you don't use *add_option()* in the above way, you don't need to tell *OptionParser* which option class to use:

```
option_list = [MyOption("-c", action="store", type="complex", dest="c")]
parser = OptionParser(option_list=option_list)
```

Adding new actions

Adding new actions is a bit trickier, because you have to understand that *optparse* has a couple of classifications for actions:

”store” actions

actions that result in *optparse* storing a value to an attribute of the current *OptionValues* instance; these options require a *dest* attribute to be supplied to the *Option* constructor.

”typed” actions

actions that take a value from the command line and expect it to be of a certain type; or rather, a string that can be converted to a certain type. These options require a *type* attribute to the *Option* constructor.

These are overlapping sets: some default ”store” actions are "store", "store_const", "append", and "count", while the default ”typed” actions are "store", "append", and "callback".

When you add an action, you need to categorize it by listing it in at least one of the following class attributes of *Option* (all are lists of strings):

Option.ACTIONS

All actions must be listed in ACTIONS.

Option.STORE_ACTIONS

”store” actions are additionally listed here.

Option.TYPED_ACTIONS

”typed” actions are additionally listed here.

Option.ALWAYS_TYPED_ACTIONS

Actions that always take a type (i.e. whose options always take a value) are additionally listed here. The only effect of this is that *optparse* assigns the default type, "string", to options with no explicit type whose action is listed in *ALWAYS_TYPED_ACTIONS*.

In order to actually implement your new action, you must override *Option*’s *take_action()* method and add a case that recognizes your action.

For example, let’s add an "extend" action. This is similar to the standard "append" action, but instead of taking a single value from the command-line and appending it to an existing list, "extend" will take multiple values in a single comma-delimited string, and extend an existing list with them. That is, if --names is an "extend" option of type "string", the command line

```
--names=foo,bar --names blah --names ding,dong
```

would result in a list

```
["foo", "bar", "blah", "ding", "dong"]
```

Again we define a subclass of *Option*:

```
class MyOption(Option):

    ACTIONS = Option.ACTIONS + ("extend",)
    STORE_ACTIONS = Option.STORE_ACTIONS + ("extend",)
    TYPED_ACTIONS = Option.TYPED_ACTIONS + ("extend",)
    ALWAYS_TYPED_ACTIONS = Option.ALWAYS_TYPED_ACTIONS + ("extend",)

    def take_action(self, action, dest, opt, value, values, parser):
        if action == "extend":
```

(繼續下一頁)

(繼續上一頁)

```

    lvalue = value.split(",")
    values.ensure_value(dest, []).extend(lvalue)
else:
    Option.take_action(
        self, action, dest, opt, value, values, parser)

```

Features of note:

- "extend" both expects a value on the command-line and stores that value somewhere, so it goes in both *STORE_ACTIONS* and *TYPED_ACTIONS*.
- to ensure that *optparse* assigns the default type of "string" to "extend" actions, we put the "extend" action in *ALWAYS_TYPED_ACTIONS* as well.
- `MyOption.take_action()` implements just this one new action, and passes control back to `Option.take_action()` for the standard *optparse* actions.
- `values` is an instance of the `optparse_parser.Values` class, which provides the very useful `ensure_value()` method. `ensure_value()` is essentially `getattr()` with a safety valve; it is called as

```
values.ensure_value(attr, value)
```

If the `attr` attribute of `values` doesn't exist or is `None`, then `ensure_value()` first sets it to `value`, and then returns `value`. This is very handy for actions like "extend", "append", and "count", all of which accumulate data in a variable and expect that variable to be of a certain type (a list for the first two, an integer for the latter). Using `ensure_value()` means that scripts using your action don't have to worry about setting a default value for the option destinations in question; they can just leave the default as `None` and `ensure_value()` will take care of getting it right when it's needed.

36.2.6 例外

exception `optparse.OptionError`

Raised if an *Option* instance is created with invalid or inconsistent arguments.

exception `optparse.OptionConflictError`

Raised if conflicting options are added to an *OptionParser*.

exception `optparse.OptionValueError`

Raised if an invalid option value is encountered on the command line.

exception `optparse.BadOptionError`

Raised if an invalid option is passed on the command line.

exception `optparse.AmbiguousOptionError`

Raised if an ambiguous option is passed on the command line.

安全性注意事項

以下模組具有特定的安全性注意事項：

- `base64`: `base64` 安全性注意事項在 **RFC 4648**
- `hashlib`: 所有建構函式都Ⓕ用 "usedforsecurity" 僅限關鍵字引數，Ⓕ禁用已知的不安全與被阻擋的演算法
- `http.server` 不適合在正式環境使用，因其僅實作基本的安全檢查。請參Ⓕ安全注意事項。
- `logging`: 日Ⓕ配置使用 `eval()`
- `multiprocessing`: `Connection.recv()` 使用 `pickle`
- `pickle`: 限制 `pickle` 中的全域變數
- `random` 不該用於安全性相關用途，請改用 `secrets`
- `shelve`: `shelve` Ⓕ基於 `pickle`，因此不適合用來處理不受信任的來源
- `ssl`: `SSL/TLS` 安全性注意事項
- `subprocess`: 子行程安全性注意事項
- `tempfile`: `mktemp` 由於存在競Ⓕ條件 (*race condition*) 漏洞而被Ⓕ用
- `xml`: `XML` 漏洞
- `zipfile`: 惡意準備的 `zip` 檔案可能會導致硬碟空間耗盡

`-I` 命令列選項可用於在隔離模式下運行 Python。若其無法使用，可以改用 `-P` 選項或 `PYTHONSAFEPATH` 環境變數，避免 `sys.path` 新增Ⓕ在的不安全路徑，例如當前目Ⓕ、Ⓕ本的目Ⓕ或空字串。

>>>

The default Python prompt of the *interactive* shell. Often seen for code examples which can be executed interactively in the interpreter.

...

可以表示：

- The default Python prompt of the *interactive* shell when entering the code for an indented code block, when within a pair of matching left and right delimiters (parentheses, square brackets, curly braces or triple quotes), or after specifying a decorator.
- 建立常數 *Ellipsis*。

abstract base class (抽象基底類)

抽象基底類 (又稱 ABC) 提供了一種定義介面的方法，作 *duck-typing* (鴨子型) 的補充。其他類似的技術，像是 *hasattr()*，則顯得笨拙或是帶有細微的錯誤 (例如使用魔術方法 (magic method))。ABC 用擬的 subclass (子類)，它們不繼承自另一個 class (類)，但仍可被 *isinstance()* 及 *issubclass()* 辨識；請參 *abc* 模組的說明文件。Python 有許多建的 ABC，用於資料結構 (在 *collections.abc* 模組)、數字 (在 *numbers* 模組)、串流 (在 *io* 模組) 及 import 尋檢器和載入器 (在 *importlib.abc* 模組)。你可以使用 *abc* 模組建立自己的 ABC。

annotation (釋)

一個與變數、class 屬性、函式的參數或回傳值相關聯的標。照慣例，它被用來作 *type hint* (型提示)。

在執行環境 (runtime)，區域變數的釋無法被存取，但全域變數、class 屬性和函式的解，會分被儲存在模組、class 和函式的 `__annotations__` 特殊屬性中。

請參 *variable annotation*、*function annotation*、**PEP 484** 和 **PEP 526**，這些章節皆有此功能的說明。關於釋的最佳實踐方法也請參 *annotations-howto*。

argument (引數)

呼叫函式時被傳遞給 *function* (或 *method*) 的值。引數有兩種：

- 關鍵字引數 (*keyword argument*): 在函式呼叫中，以識字 (identifier，例如 `name=`) 開頭的引數，或是以 `**` 後面 dictionary (字典) 的值被傳遞的引數。例如，3 和 5 都是以下 *complex()* 呼叫中的關鍵字引數：

```
complex(real=3, imag=5)
complex(**{'real': 3, 'imag': 5})
```

- 位置引數 (*positional argument*): 不是關鍵字引數的引數。位置引數可在一個引數列表的起始處出現, 和 (或) 作 `*` 之後的 *iterable* (可代物件) 中的元素被傳遞。例如, 3 和 5 都是以下呼叫中的位置引數:

```
complex(3, 5)
complex(*(3, 5))
```

引數會被指定給函式主體中的附名區域變數。關於支配這個指定過程的規則, 請參 [calls](#) 章節。在語法上, 任何運算式都可以被用來表示一個引數; 其評估值會被指定給區域變數。

另請參術語表的 *parameter* (參數) 條目、常見問題中的引數和參數之間的差別, 以及 [PEP 362](#)。

asynchronous context manager (非同步情境管理器)

一個可以控制 `async with` 陳述式中所見環境的物件, 而它是透過定義 `__aenter__()` 和 `__aexit__()` method (方法) 來控制的。由 [PEP 492](#) 引入。

asynchronous generator (非同步生成器)

一個會回傳 *asynchronous generator iterator* (非同步生成器代器) 的函式。它看起來像一個以 `async def` 定義的協程函式 (coroutine function), 但不同的是它包含了 `yield` 運算式, 能生成一系列可用於 `async for` 圈的值。

這個術語通常用來表示一個非同步生成器函式, 但在某些情境中, 也可能是表示非同步生成器代器 (*asynchronous generator iterator*)。萬一想表達的意思不清楚, 那就使用完整的術語, 以避免歧義。

一個非同步生成器函式可能包含 `await` 運算式, 以及 `async for` 和 `async with` 陳述式。

asynchronous generator iterator (非同步生成器代器)

一個由 *asynchronous generator* (非同步生成器) 函式所建立的物件。

這是一個 *asynchronous iterator* (非同步代器), 當它以 `__anext__()` method 被呼叫時, 會回傳一個可等待物件 (awaitable object), 該物件將執行非同步生成器的函式主體, 直到遇到下一個 `yield` 運算式。

每個 `yield` 會暫停處理程序, 記住位置執行狀態 (包括區域變數及擱置中的 `try` 陳述式)。當非同步生成器代器以另一個被 `__anext__()` 回傳的可等待物件有效地回復時, 它會從停止的地方繼續執行。請參 [PEP 492](#) 和 [PEP 525](#)。

asynchronous iterable (非同步可代物件)

一個物件, 它可以在 `async for` 陳述式中被使用。必須從它的 `__aiter__()` method 回傳一個 *asynchronous iterator* (非同步代器)。由 [PEP 492](#) 引入。

asynchronous iterator (非同步代器)

一個實作 `__aiter__()` 和 `__anext__()` method 的物件。`__anext__()` 必須回傳一個 *awaitable* (可等待物件)。`async for` 會解析非同步代器的 `__anext__()` method 所回傳的可等待物件, 直到它引發 `StopAsyncIteration` 例外。由 [PEP 492](#) 引入。

attribute (屬性)

一個與某物件相關聯的值, 該值大多能透過使用點分隔運算式 (dotted expression) 的名稱被參照。例如, 如果物件 `o` 有一個屬性 `a`, 則該屬性能以 `o.a` 被參照。

如果一個物件允許, 給予該物件一個名稱不是由 `identifiers` 所定義之識別符 (identifier) 的屬性是有可能的, 例如使用 `setattr()`。像這樣的屬性將無法使用點分隔運算式來存取, 而是需要使用 `getattr()` 來取得它。

awaitable (可等待物件)

一個可以在 `await` 運算式中被使用的物件。它可以是一個 *coroutine* (協程), 或是一個有 `__await__()` method 的物件。另請參 [PEP 492](#)。

BDFL

Benevolent Dictator For Life (終身仁慈獨裁者), 又名 [Guido van Rossum](#), Python 的創造者。

binary file (二進位檔案)

一個能讀取和寫入 *bytes-like objects* (類位元組串物件) 的 *file object* (檔案物件)。二進位檔案的例子有: 以二進位模式 ('rb'、'wb' 或 'rb+') 開的檔案、`sys.stdin.buffer`、`sys.stdout.buffer`, 以及 `io.BytesIO` 和 `gzip.GzipFile` 實例。

另請參 [text file](#) (文字檔案)，它是一個能讀取和寫入 `str` 物件的檔案物件。

borrowed reference (借用參照)

在 Python 的 C API 中，借用參照是一個對物件的參照，其中使用該物件的程式碼不擁有這個參照。如果該物件被銷毀，它會成一個迷途指標 (dangling pointer)。例如，一次垃圾回收 (garbage collection) 可以移除對物件的最後一個 *strong reference* (參照)，而將該物件銷毀。

對 *borrowed reference* 呼叫 `Py_INCREF()` 以將它原地 (in-place) 轉為 *strong reference* 是被建議的做法，除非該物件不能在最後一次使用借用參照之前被銷毀。`Py_NewRef()` 函式可用於建立一個新的 *strong reference*。

bytes-like object (類位元組串物件)

一個支援 `bufferobjects` 且能匯出 C-contiguous 緩衝區的物件。這包括所有的 `bytes`、`bytearray` 和 `array.array` 物件，以及許多常見的 `memoryview` 物件。類位元組串物件可用於處理二進位資料的各種運算；這些運算包括壓縮、儲存至二進位檔案和透過 `socket` (插座) 發送。

有些運算需要二進位資料是可變的。明文文件通常會將這些物件稱「可讀寫的類位元組串物件」。可變緩衝區的物件包括 `bytearray`，以及 `bytearray` 的 `memoryview`。其他的運算需要讓二進位資料被儲存在不可變物件 (「唯讀的類位元組串物件」) 中；這些物件包括 `bytes`，以及 `bytes` 物件的 `memoryview`。

bytecode (位元組碼)

Python 的原始碼會被編譯成位元組碼，它是 Python 程式在 CPython 直譯器中的內部表示法。該位元組碼也會被暫存在 `.pyc` 檔案中，以便第二次執行同一個檔案時能更快 (可以不用從原始碼重新編譯位元組碼)。這種「中間語言 (intermediate language)」據說是運行在一個 *virtual machine* (擬機器) 上，該擬機器會執行與每個位元組碼對應的機器碼 (machine code)。要注意的是，位元組碼理論上是無法在不同的 Python 擬機器之間運作的，也不能在不同版本的 Python 之間保持穩定。

位元組碼的指令列表可以在 `dis` 模組的明文文件中找到。

callable (可呼叫物件)

一個 callable 是可以被呼叫的物件，呼叫時可能以下列形式帶有一組引數 (請見 [argument](#)):

```
callable(argument1, argument2, argumentN)
```

一個 *function* 與其延伸的 *method* 都是 callable。一個有實作 `__call__()` 方法的 `class` 之實例也是個 callable。

callback (回呼)

作引數被傳遞的一個副程式 (subroutine) 函式，會在未來的某個時間點被執行。

class (類)

一個用於建立使用者定義物件的模板。Class 的定義通常會包含 `method` 的定義，這些 `method` 可以在 `class` 的實例上進行操作。

class variable (類變數)

一個在 `class` 中被定義，且應該只能在 `class` 層次 (意即不是在 `class` 的實例中) 被修改的變數。

complex number (複數)

一個我們熟悉的實數系統的擴充，在此所有數字都會被表示為一個實部和一個虛部之和。複數就是複數單位 (-1 的平方根) 的實數倍，此單位通常在數學中被寫為 i ，在工程學中被寫為 j 。Python 建了對複數的支援，它是用後者的記法來表示複數；虛部會帶著一個後綴的 j 被編寫，例如 $3+1j$ 。若要將 `math` 模組的工具等效地用於複數，請使用 `cmath` 模組。複數的使用是一個相當進階的數學功能。如果你有察覺到對它們的需求，那你幾乎能確定你可以安全地忽略它們。

context manager (情境管理器)

一個可以控制 `with` 陳述式中所見環境的物件，而它是透過定義 `__enter__()` 和 `__exit__()` `method` 來控制的。請參 [PEP 343](#)。

context variable (情境變數)

一個變數，其值可以根據上下文的情境而有所不同。這類似執行緒區域儲存區 (Thread-Local Storage)，在其中，一個變數在每個執行緒可能具有不同的值。然而，關於情境變數，在一個執行緒中可能會有多个情境，而情境變數的主要用途，是在行的非同步任務 (concurrent asynchronous task) 中，對於變數狀態的追蹤。請參 [contextvars](#)。

contiguous (連續的)

如果一個緩衝區是 *C-contiguous* 或是 *Fortran contiguous*，則它會確切地被視爲是連續的。零維 (zero-dimensional) 的緩衝區都是 C 及 Fortran contiguous。在一維 (one-dimensional) 陣列中，各項目必須在記憶體中彼此相鄰地排列，而其索引順序是從零開始遞增。在多維的 (multidimensional) C-contiguous 陣列中，按記憶體位址的順序訪問各個項目時，最後一個索引的變化最快。然而，在 Fortran contiguous 陣列中，第一個索引的變化最快。

coroutine (協程)

協程是副程式 (subroutine) 的一種更廣義的形式。副程式是在某個時間點被進入在另一個時間點被退出。協程可以在許多不同的時間點被進入、退出和回復。它們能以 `async def` 陳述式被實作。另請參 [PEP 492](#)。

coroutine function (協程函式)

一個回傳 *coroutine* (協程) 物件的函式。一個協程函式能以 `async def` 陳述式被定義，可能包含 `await`、`async for` 和 `async with` 關鍵字。這些關鍵字由 [PEP 492](#) 引入。

CPython

Python 程式語言的標準實作 (canonical implementation)，被發布在 python.org 上。「CPython」這個術語在必要時被使用，以區分此實作與其它語言的實作，例如 Jython 或 IronPython。

decorator (裝飾器)

一個函式，它會回傳另一個函式，通常它會使用 `@wrapper` 語法，被應用一種函式的變 (function transformation)。裝飾器的常見範例是 `classmethod()` 和 `staticmethod()`。

裝飾器語法只是語法糖。以下兩個函式定義在語義上是等效的：

```
def f(arg):
    ...
f = staticmethod(f)

@staticmethod
def f(arg):
    ...
```

Class 也存在相同的概念，但在那比較不常用。關於裝飾器的更多內容，請參函式定義和 class 定義的說明文件。

descriptor (描述器)

任何定義了 `__get__()`、`__set__()` 或 `__delete__()` method 的物件。當一個 class 屬性是一個描述器時，它的特殊連結行會在屬性查找時被觸發。通常，使用 `a.b` 來取得、設定或除某個屬性時，會在 `a` 的 class 字典中查找名稱 `b` 的物件，但如果 `b` 是一個描述器，則相對應的描述器 method 會被呼叫。對描述器的理解是深入理解 Python 的關鍵，因它們是許多功能的基礎，這些功能包括函式、method、屬性 (property)、class method、態 method，以及對 super class (父類) 的參照。

關於描述器 method 的更多資訊，請參 [descriptors](#) 或描述器使用指南。

dictionary (字典)

一個關聯陣列 (associative array)，其中任意的鍵會被映射到值。鍵可以是任何帶有 `__hash__()` 和 `__eq__()` method 的物件。在 Perl 中被稱爲雜 (hash)。

dictionary comprehension (字典綜合運算)

一種緊密的方法，用來處理一個可代物件中的全部或部分元素，將處理結果以一個字典回傳。`results = {n: n ** 2 for n in range(10)}` 會生一個字典，它包含了鍵 `n` 映射到值 `n ** 2`。請參 [comprehensions](#)。

dictionary view (字典檢視)

從 `dict.keys()`、`dict.values()` 及 `dict.items()` 回傳的物件被稱爲字典檢視。它們提供了字典中項目的動態檢視，這表示當字典有變動時，該檢視會反映這些變動。若要制將字典檢視轉完整的 list (串列)，須使用 `list(dictview)`。請參 [字典視圖物件](#)。

docstring (說明字串)

一個在 class、函式或模組中，作第一個運算式出現的字串文本。雖然它在套件執行時會被忽略，

但它會被編譯器辨識，被放入所屬 class、函式或模組的 `__doc__` 屬性中。由於明字串可以透過省 (introspection) 來覽，因此它是物件的明文件存放的標準位置。

duck-typing (鴨子型)

一種程式設計風格，它不是藉由檢查一個物件的型來確定它是否具有正確的介面；取而代之的是，method 或屬性會單純地被呼叫或使用。（「如果它看起來像一鴨子而且叫起來像一鴨子，那它一定是一鴨子。」）因調介面而非特定型，精心設計的程式碼能讓多形替代 (polymorphic substitution) 來增進它的靈活性。鴨子型要避免使用 `type()` 或 `isinstance()` 進行測試。（但是請注意，鴨子型可以用抽象基底類 (abstract base class) 來補充。）然而，它通常會用 `hasattr()` 測試，或是 EAFP 程式設計風格。

EAFP

Easier to ask for forgiveness than permission.（請求寬恕比請求許可更容易。）這種常見的 Python 編碼風格會先假設有效的鍵或屬性的存在，在該假設被推翻時再捕獲例外。這種乾且快速的風格，其特色是存在許多的 `try` 和 `except` 陳述式。該技術與許多其他語言（例如 C）常見的 LBYL 風格形成了對比。

expression (運算式)

一段可以被評估求值的語法。句話，一個運算式就是文字、名稱、屬性存取、運算子或函式呼叫等運算式元件的累積，而這些元件都能回傳一個值。與許多其他語言不同的是，非所有的 Python 語言構造都是運算式。另外有一些 *statement*（陳述式）不能被用作運算式，例如 `while`。賦值 (assignment) 也是陳述式，而不是運算式。

extension module (擴充模組)

一個以 C 或 C++ 編寫的模組，它使用 Python 的 C API 來與核心及使用者程式碼進行互動。

f-string (f 字串)

以 `'f'` 或 `'F'` 前綴的字串文本通常被稱「f 字串」，它是格式化的字串文本的縮寫。另請參 PEP 498。

file object (檔案物件)

一個讓使用者透過檔案導向 (file-oriented) API（如 `read()` 或 `write()` 等 method）來操作底層資源的物件。根據檔案物件被建立的方式，它能協調對真實磁碟檔案或是其他類型的儲存器或通訊裝置（例如標準輸入 / 輸出、記憶體緩衝區、socket（插座）、管 (pipe) 等）的存取。檔案物件也被稱類檔案物件 (file-like object) 或串流 (stream)。

實際上，有三種檔案物件：原始的二進位檔案、緩衝的二進位檔案和文字檔案。它們的介面在 `io` 模組中被定義。建立檔案物件的標準方法是使用 `open()` 函式。

file-like object (類檔案物件)

file object（檔案物件）的同義字。

filesystem encoding and error handler (檔案系統編碼和錯誤處理函式)

Python 所使用的一種編碼和錯誤處理函式，用來解碼來自作業系統的位元組，以及將 Unicode 編碼到作業系統。

檔案系統編碼必須保證能成功解碼所有小於 128 的位元組。如果檔案系統編碼無法提供此保證，則 API 函式會引發 `UnicodeError`。

`sys.getfilesystemencoding()` 和 `sys.getfilesystemencodeerrors()` 函式可用於取得檔案系統編碼和錯誤處理函式。

filesystem encoding and error handler（檔案系統編碼和錯誤處理函式）會在 Python 動時由 `PyConfig_Read()` 函式來配置：請參 `filesystem_encoding`，以及 `PyConfig` 的成員 `filesystem_errors`。

另請參 *locale encoding*（區域編碼）。

finder (尋檢器)

一個物件，它會嘗試正在被 `import` 的模組尋找 *loader*（載入器）。

有兩種類型的尋檢器：*元路徑尋檢器* (*meta path finder*) 會使用 `sys.meta_path`，而路徑項目尋檢器 (*path entry finder*) 會使用 `sys.path_hooks`。

請參 `importsystem` 和 `importlib` 以了解更多細節。

floor division (向下取整除法)

向下無條件舍去到最接近整數的數學除法。向下取整除法的運算子是 `//`。例如，運算式 `11 // 4` 的計算結果是 `2`，與 `float` (浮點數) 真除法所回傳的 `2.75` 不同。請注意，`(-11) // 4` 的結果是 `-3`，因 `-2.75` 被向下無條件舍去。請參 [PEP 238](#)。

free threading

A threading model where multiple threads can run Python bytecode simultaneously within the same interpreter. This is in contrast to the *global interpreter lock* which allows only one thread to execute Python bytecode at a time. See [PEP 703](#).

function (函式)

一連串的陳述式，它能向呼叫者回傳一些值。它也可以被傳遞零個或多個引數，這些引數可被使用於函式本體的執行。另請參 [parameter](#) (參數)、[method](#) (方法)，以及 [function](#) 章節。

function annotation (函式釋)

函式參數或回傳值的一個 [annotation](#) (釋)。

函式釋通常被使用於 [type hint](#)：例如，這個函式預期會得到兩個 `int` 引數，會有一個 `int` 回傳值：

```
def sum_two_numbers(a: int, b: int) -> int:
    return a + b
```

函式釋的語法在 [function](#) 章節有詳細解釋。

請參 [variable annotation](#) 和 [PEP 484](#)，皆有此功能的描述。關於釋的最佳實踐方法，另請參 [annotations-howto](#)。

`__future__`

`future` 陳述式：`from __future__ import <feature>`，會指示編譯器使用那些在 Python 未來的發布版本中將成標準的語法或語義，來編譯當前的模組。而 `__future__` 模組則記了 *feature* (功能) 可能的值。透過 `import` 此模組對其變數求值，你可以看見一個新的功能是何時首次被新增到此語言中，以及它何時將會 (或已經) 成預設的功能：

```
>>> import __future__
>>> __future__.division
_Feature((2, 2, 0, 'alpha', 2), (3, 0, 0, 'alpha', 0), 8192)
```

garbage collection (垃圾回收)

當記憶體不再被使用時，將其釋放的過程。Python 執行垃圾回收，是透過參照計數 (reference counting)，以及一個能檢測和中斷參照循環 (reference cycle) 的循環垃圾回收器 (cyclic garbage collector) 來完成。垃圾回收器可以使用 `gc` 模組對其進行控制。

generator (生成器)

一個會回傳 [generator iterator](#) (生成器代器) 的函式。它看起來像一個正常的函式，但不同的是它包含了 `yield` 運算式，能生一系列的值的值，這些值可用於 `for` 圈，或是以 `next()` 函式，每次檢索其中的一個值。

這個術語通常用來表示一個生成器函式，但在某些情境中，也可能是表示生成器代器。萬一想表達的意思不清楚，那就使用完整的術語，以避免歧義。

generator iterator (生成器代器)

一個由 [generator](#) (生成器) 函式所建立的物件。

每個 `yield` 會暫停處理程序，記住位置執行狀態 (包括區域變數及擱置中的 `try` 陳述式)。當生成器代器回復時，它會從停止的地方繼續執行 (與那些每次調用時都要重新開始的函式有所不同)。

generator expression (生成器運算式)

An *expression* that returns an *iterator*. It looks like a normal expression followed by a `for` clause defining a loop variable, range, and an optional `if` clause. The combined expression generates values for an enclosing function:

```
>>> sum(i*i for i in range(10))      # sum of squares 0, 1, 4, ... 81
285
```

generic function (泛型函式)

一個由多個函式組成的函式，該函式會對不同的型實作相同的運算。呼叫期間應該使用哪種實作，是由調度演算法 (dispatch algorithm) 來決定。

另請參 [single dispatch](#) (單一調度) 術語表條目、`functools.singledispatch()` 裝飾器和 [PEP 443](#)。

generic type (泛型型)

一個能被參數化 (parameterized) 的 [type](#) (型)；通常是一個容器型，像是 `list` 和 `dict`。它被用於 [型提示](#) 和 [型釋](#)。

詳情請參 [泛型型名](#)、[PEP 483](#)、[PEP 484](#)、[PEP 585](#) 和 `typing` 模組。

GIL

請參 [global interpreter lock](#) (全域直譯器鎖)。

global interpreter lock (全域直譯器鎖)

`CPython` 直譯器所使用的機制，用以確保每次都只有一個執行緒能執行 Python 的 `bytecode` (位元組碼)。透過使物件模型 (包括關鍵的 [型建型](#)，如 `dict`) 自動地避免 [行存取](#) (concurrent access) 的危險，此機制可以簡化 `CPython` 的實作。鎖定整個直譯器，會使直譯器更容易成為 [多執行緒](#) (multi-threaded)，但代價是會犧牲掉多處理器的機器能提供的 [一大部分平行性](#) (parallelism)。

然而，有些擴充模組，無論是標準的或是第三方的，它們被設計成在執行壓縮或雜等計算密集 (computationally intensive) 的任務時，可以解除 GIL。另外，在執行 I/O 時，GIL 總是會被解除。

As of Python 3.13, the GIL can be disabled using the `--disable-gil` build configuration. After building Python with this option, code must be run with `-X gil 0` or after setting the `PYTHON_GIL=0` environment variable. This feature enables improved performance for multi-threaded applications and makes it easier to use multi-core CPUs efficiently. For more details, see [PEP 703](#).

hash-based pyc (雜架構的 pyc)

一個位元組碼 (bytecode) 暫存檔，它使用雜值而不是對應原始檔案的最後修改時間，來確定其有效性。請參 [pyc-invalidation](#)。

hashable (可雜的)

如果一個物件有一個雜值，該值在其生命期中永不改變 (它需要一個 `__hash__()` method)，且可與其他物件互相比較 (它需要一個 `__eq__()` method)，那麼它就是一個可雜物件。比較結果相等的多個可雜物件，它們必須擁有相同的雜值。

可雜性 (hashability) 使一個物件可用作 `dictionary` (字典) 的鍵和 `set` (集合) 的成員，因為這些資料結構都在其內部使用了雜值。

大多數的 Python 不可變物件都是可雜的；可變的容器 (例如 `list` 或 `dictionary`) 不是；而不可變的容器 (例如 `tuple` (元組) 和 `frozenset`)，只有當它們的元素是可雜的，它們本身才是可雜的。若物件是使用者自定 `class` 的實例，則這些物件會被預設為可雜的。它們在互相比較時都是不相等的 (除非它們與自己比較)，而它們的雜值則是衍生自它們的 `id()`。

IDLE

Python 的 Integrated Development and Learning Environment (整合開發與學習環境)。`IDLE` 是一個基本的編輯器和直譯器環境，它和 Python 的標準發行版本一起被提供。

immortal

Immortal objects are a CPython implementation detail introduced in [PEP 683](#).

If an object is immortal, its *reference count* is never modified, and therefore it is never deallocated while the interpreter is running. For example, `True` and `None` are immortal in CPython.

immutable (不可變物件)

一個具有固定值的物件。不可變物件包括數字、字串和 `tuple` (元組)。這類物件是不能被改變的。如果一個不同的值必須被儲存，則必須建立一個新的物件。它們在需要固定雜值的地方，扮演重要的角色，例如 `dictionary` (字典) 中的一個鍵。

import path (引入路徑)

一個位置 (或路徑項目) 的列表，而那些位置就是在 `import` 模組時，會被 *path based finder* (基於路徑的尋檢器) 搜尋模組的位置。在 `import` 期間，此位置列表通常是來自 `sys.path`，但對於子套件 (subpackage) 而言，它也可能是來自父套件的 `__path__` 屬性。

importing (引入)

一個過程。一個模組中的 Python 程式碼可以透過此過程，被另一個模組中的 Python 程式碼使用。

importer (引入器)

一個能尋找及載入模組的物件；它既是 *finder* (尋檢器) 也是 *loader* (載入器) 物件。

interactive (互動的)

Python has an interactive interpreter which means you can enter statements and expressions at the interpreter prompt, immediately execute them and see their results. Just launch `python` with no arguments (possibly by selecting it from your computer's main menu). It is a very powerful way to test out new ideas or inspect modules and packages (remember `help(x)`). For more on interactive mode, see `tut-interac`.

interpreted (直譯的)

Python 是一種直譯語言，而不是編譯語言，不過這個區分可能有些模糊，因為有位元組碼 (bytecode) 編譯器的存在。這表示原始檔案可以直接被運行，而不需明確地建立另一個執行檔，然後再執行它。直譯語言通常比編譯語言有更短的開發 / 除錯期，不過它們的程式通常也運行得較慢。另請參 *interactive* (互動的)。

interpreter shutdown (直譯器關閉)

當 Python 直譯器被要求關閉時，它會進入一個特殊階段，在此它逐漸釋放所有被配置的資源，例如模組和各種關鍵部結構。它也會多次呼叫 *垃圾回收器* (*garbage collector*)。這能觸發使用者自定的解構函式 (destructor) 或弱引用的回呼 (*weakref callback*)，執行其中的程式碼。在關閉階段被執行的程式碼會遇到各種例外，因為它所依賴的資源可能不再有作用了 (常見的例子是函式庫模組或是警告機制)。

直譯器關閉的主要原因，是 `__main__` 模組或正被運行的腳本已經執行完成。

iterable (可迭代物件)

一種能一次回傳一個其中成員的物件。可迭代物件的例子包括所有的序列型 (像是 *list*、*str* 和 *tuple*) 和某些非序列型，像是 *dict*、檔案物件，以及你所定義的任何 `class` 物件，只要那些 `class` 有 `__iter__()` method 或是實作 *sequence* (序列) 語意的 `__getitem__()` method，該物件就是可迭代物件。

可迭代物件可用於 `for` 圈和許多其他需要一個序列的地方 (*zip()*、*map()*...)。當一個可迭代物件作引數被傳遞給 `iter()` 時，它會回傳該物件回傳一個迭代器。此迭代器適用於針對一組值進行一遍 (one pass) 運算。使用迭代器時，通常不一定要呼叫 `iter()` 或自行處理迭代器物件。`for` 陳述式會自動地為你處理這些事，它會建立一個暫時性的未命名變數，用於在圈期間保有該迭代器。另請參 *iterator* (迭代器)、*sequence* (序列) 和 *generator* (生成器)。

iterator (迭代器)

一個表示資料流的物件。重地呼叫迭代器的 `__next__()` method (或是將它傳遞給 `iter()` 會依序回傳資料流中的各項目。當不再有資料時，則會引發 *StopIteration* 例外。此時，該迭代器物件已被用盡，而任何對其 `__next__()` method 的進一步呼叫，都只會再次引發 *StopIteration*。迭代器必須有一個 `__iter__()` method，它會回傳迭代器物件本身，所以每個迭代器也都是可迭代物件，且可以用於大多數適用其他可迭代物件的場合。一個明顯的例外，是嘗試多遍迭代 (multiple iteration passes) 的程式碼。一個容器物件 (像是 *list*) 在每次你將它傳遞給 `iter()` 函式或在 `for` 圈中使用它時，都會生成一個全新的迭代器。使用迭代器嘗試此事 (多遍迭代) 時，只會回傳在前一遍迭代中被用過的、同一個已被用盡的迭代器物件，使其看起來就像一個空的容器。

在 *迭代器型* 文中可以找到更多資訊。

CPython 實作細節： CPython does not consistently apply the requirement that an iterator define `__iter__()`. And also please note that the free-threading CPython does not guarantee the thread-safety of iterator operations.

key function (鍵函式)

鍵函式或理序函式 (collation function) 是一個可呼叫 (callable) 函式，它會回傳一個用於排序 (sorting)

或定序 (ordering) 的值。例如, `locale.strxfrm()` 被用來生一個了解區域特定排序慣例的排序鍵。

Python 中的許多工具, 都接受以鍵函式來控制元素被定序或分組的方式。它們包括 `min()`、`max()`、`sorted()`、`list.sort()`、`heapq.merge()`、`heapq.nsmallest()`、`heapq.nlargest()` 和 `itertools.groupby()`。

有幾種方法可以建立一個鍵函式。例如, `str.lower()` method 可以作不分大小寫排序的鍵函式。或者, 一個鍵函式也可以從 lambda 運算式被建造, 例如 `lambda r: (r[0], r[2])`。另外, `operator.attrgetter()`、`operator.itemgetter()` 和 `operator.methodcaller()` 三個鍵函式的建構函式 (constructor)。關於如何建立和使用鍵函式的範例, 請參如何排序。

keyword argument (關鍵字引數)

請參 `argument` (引數)。

lambda

由單一 *expression* (運算式) 所組成的一個匿名行函式 (inline function), 於該函式被呼叫時求值。建立 lambda 函式的語法是 `lambda [parameters]: expression`

LBYL

Look before you leap. (三思而後行。) 這種編碼風格會在進行呼叫或查找之前, 明確地測試先條件。這種風格與 *EAFP* 方式形成對比, 且它的特色是會有許多 `if` 陳述式的存在。

在一個多執行緒環境中, LBYL 方式有在「三思」和「後行」之間引入了競條件 (race condition) 的風險。例如以下程式碼 `if key in mapping: return mapping[key]`, 如果另一個執行緒在測試之後但在查找之前, 從 *mapping* 中移除了 *key*, 則該程式碼就會失效。這個問題可以用鎖 (lock) 或使用 *EAFP* 編碼方式來解。

list (串列)

一個 Python 建的 *sequence* (序列)。管它的名字是 `list`, 它其實更類似其他語言中的一個陣列 (array) 而較不像一個鏈結串列 (linked list), 因存取元素的時間複雜度是 $O(1)$ 。

list comprehension (串列綜合運算)

一種用來處理一個序列中的全部或部分元素, 將處理結果以一個 `list` 回傳的簡要方法。`result = ['{:04x}'.format(x) for x in range(256) if x % 2 == 0]` 會生一個字串 `list`, 其中包含 0 到 255 範圍, 所有偶數的十六進位數 (0x..)。`if` 子句是選擇性的。如果省略它, 則 `range(256)` 中的所有元素都會被處理。

loader (載入器)

一個能載入模組的物件。它必須定義一個名 `load_module()` 的 method (方法)。載入器通常是被 *finder* (尋檢器) 回傳。更多細節請參 [PEP 302](#), 關於 *abstract base class* (抽象基底類), 請參 `importlib.abc.Loader`。

locale encoding (區域編碼)

在 Unix 上, 它是 `LC_CTYPE` 區域設定的編碼。它可以用 `locale.setlocale(locale.LC_CTYPE, new_locale)` 來設定。

在 Windows 上, 它是 ANSI 代碼頁 (code page, 例如 "cp1252")。

在 Android 和 VxWorks 上, Python 使用 "utf-8" 作區域編碼。

`locale.getencoding()` 可以用來取得區域編碼。

也請參考 *filesystem encoding and error handler*。

magic method (魔術方法)

special method (特殊方法) 的一個非正式同義詞。

mapping (對映)

一個容器物件, 它支援任意鍵的查找, 且能實作 *abstract base classes* (抽象基底類) 中, `collections.abc.Mapping` 或 `collections.abc.MutableMapping` 所指定的 method。範例包括 `dict`、`collections.defaultdict`、`collections.OrderedDict` 和 `collections.Counter`。

meta path finder (元路徑尋檢器)

一種經由搜尋 `sys.meta_path` 而回傳的 *finder* (尋檢器)。元路徑尋檢器與路徑項目尋檢器 (*path entry finder*) 相關但是不同。

關於元路徑尋檢器實作的 `method`，請參 `importlib.abc.MetaPathFinder`。

metaclass (元類)

一種 `class` 的 `class`。`Class` 定義過程會建立一個 `class` 名稱、一個 `class` `dictionary` (字典)，以及一個 `base class` (基底類) 的列表。`Metaclass` 負責接受這三個引數，建立該 `class`。大多數的物件導向程式語言會提供一個預設的實作。`Python` 的特之處在於它能建立自訂的 `metaclass`。大部分的使用者從未需要此工具，但是當需要時，`metaclass` 可以提供大且優雅的解方案。它們已被用於記屬性存取、增加執行緒安全性、追物件建立、實作單例模式 (`singleton`)，以及許多其他的任務。

更多資訊可以在 `metaclasses` 章節中找到。

method (方法)

一個在 `class` 本體被定義的函式。如果 `method` 作其 `class` 實例的一個屬性被呼叫，則它將會得到該實例物件成它的第一個 *argument* (引數) (此引數通常被稱 `self`)。請參 `function` (函式) 和 *nested scope* (巢狀作用域)。

method resolution order (方法解析順序)

方法解析順序是在查找某個成員的過程中，`base class` (基底類) 被搜尋的順序。關於 `Python` 自 2.3 版直譯器所使用的演算法細節，請參 `python_2.3_mro`。

module (模組)

一個擔任 `Python` 程式碼的組織單位 (*organizational unit*) 的物件。模組有一個命名空間，它包含任意的 `Python` 物件。模組是藉由 *importing* 的過程，被載入至 `Python`。

另請參 `package` (套件)。

module spec (模組規格)

一個命名空間，它包含用於載入模組的 `import` 相關資訊。它是 `importlib.machinery.ModuleSpec` 的一個實例。

MRO

請參 `method resolution order` (方法解析順序)。

mutable (可變物件)

可變物件可以改變它們的值，但維持它們的 `id()`。另請參 `immutable` (不可變物件)。

named tuple (附名元組)

術語「`named tuple` (附名元組)」是指從 `tuple` 繼承的任何型或 `class`，且它的可索引 (*indexable*) 元素也可以用附名屬性來存取。這些型或 `class` 也可以具有其他的特性。

有些建型是 `named tuple`，包括由 `time.localtime()` 和 `os.stat()` 回傳的值。另一個例子是 `sys.float_info`:

```
>>> sys.float_info[1]           # indexed access
1024
>>> sys.float_info.max_exp      # named field access
1024
>>> isinstance(sys.float_info, tuple) # kind of tuple
True
```

有些 `named tuple` 是建型 (如上例)。或者，一個 `named tuple` 也可以從一個正規的 `class` 定義來建立，只要該 `class` 是繼承自 `tuple`，且定義了附名欄位 (*named field*) 即可。這類的 `class` 可以手工編寫、可以繼承自 `typing.NamedTuple` 來建立，也可以使用工廠函式 (*factory function*) `collections.namedtuple()` 來建立。後者技術也增加了一些額外的 `method`，這些 `method` 可能是在手寫或建的 `named tuple` 中，無法找到的。

namespace (命名空間)

變數被儲存的地方。命名空間是以 `dictionary` (字典) 被實作。有區域的、全域的及建的命名空間，而在物件中 (在 `method` 中) 也有巢狀的命名空間。命名空間藉由防止命名衝突，來支援模組化。例如，函式 `builtins.open` 和 `os.open()` 是透過它們的命名空間來區分彼此。命名空間也藉由明確地區分是哪個模組在實作一個函式，來增進可讀性及可維護性。例如，寫出 `random.seed()` 或 `itertools.islice()` 明確地表示，這些函式分是由 `random` 和 `itertools` 模組在實作。

namespace package (命名空間套件)

一個 `PEP 420 package` (套件)，它只能作子套件 (*subpackage*) 的一個容器。命名空間套件可能

有實體的表示法，而且具體來它們不像是一個 *regular package* (正規套件)，因它們有 `__init__.py` 這個檔案。

另請參 *module* (模組)。

nested scope (巢狀作用域)

能參照外層定義 (enclosing definition) 中的變數的能力。舉例來，一個函式如果是在另一個函式中被定義，則它便能參照外層函式中的變數。請注意，在預設情況下，巢狀作用域僅適用於參照，而無法用於賦值。區域變數能在最層作用域中讀取及寫入。同樣地，全域變數是在全域命名空間中讀取及寫入。`nonlocal` 容許對外層作用域進行寫入。

new-style class (新式類)

一個舊名，它是指現在所有的 class 物件所使用的 class 風格。在早期的 Python 版本中，只有新式 class 才能使用 Python 較新的、多樣的功能，像是 `__slots__`、描述器 (descriptor)、屬性 (property)、`__getattr__()`、class method (類方法) 和 static method (態方法)。

object (物件)

具有狀態 (屬性或值) 及被定義的行 (method) 的任何資料。它也是任何 *new-style class* (新式類) 的最終 base class (基底類)。

optimized scope

A scope where target local variable names are reliably known to the compiler when the code is compiled, allowing optimization of read and write access to these names. The local namespaces for functions, generators, coroutines, comprehensions, and generator expressions are optimized in this fashion. Note: most interpreter optimizations are applied to all scopes, only those relying on a known set of local and nonlocal variable names are restricted to optimized scopes.

package (套件)

一個 Python 的 *module* (模組)，它可以包含子模組 (submodule) 或是遞的子套件 (subpackage)。技術上而言，套件就是具有 `__path__` 屬性的一個 Python 模組。

另請參 *regular package* (正規套件) 和 *namespace package* (命名空間套件)。

parameter (參數)

在 *function* (函式) 或 *method* 定義中的一個命名實體 (named entity)，它指明該函式能接受的一個 *argument* (引數)，或在某些情況下指示多個引數。共有有五種不同的參數類型：

- *positional-or-keyword* (位置或關鍵字)：指明一個可以按照位置或是作關鍵字引數被傳遞的引數。這是參數的預設類型，例如以下的 *foo* 和 *bar*：

```
def func(foo, bar=None): ...
```

- *positional-only* (僅限位置)：指明一個只能按照位置被提供的引數。在函式定義的參數列表中包含一個 `/` 字元，就可以在該字元前面定義僅限位置參數，例如以下的 *posonly1* 和 *posonly2*：

```
def func(posonly1, posonly2, /, positional_or_keyword): ...
```

- *keyword-only* (僅限關鍵字)：指明一個只能以關鍵字被提供的引數。在函式定義的參數列表中，包含一個任意數量位置參數 (var-positional parameter) 或是單純的 `*` 字元，就可以在其後定義僅限關鍵字參數，例如以下的 *kw_only1* 和 *kw_only2*：

```
def func(arg, *, kw_only1, kw_only2): ...
```

- *var-positional* (任意數量位置)：指明一串能以任意序列被提供的位置引數 (在已被其他參數接受的任何位置引數之外)。這類參數是透過在其參數名稱字首加上 `*` 來定義的，例如以下的 *args*：

```
def func(*args, **kwargs): ...
```

- *var-keyword* (任意數量關鍵字)：指明可被提供的任意數量關鍵字引數 (在已被其他參數接受的任何關鍵字引數之外)。這類參數是透過在其參數名稱字首加上 `**` 來定義的，例如上面範例中的 *kwargs*。

參數可以指明引數是選擇性的或必需的，也可以一些選擇性的引數指定預設值。

另請參術語表的 *argument* (引數) 條目、常見問題中的引數和參數之間的差別、*inspect.Parameter* class、function 章節，以及 **PEP 362**。

path entry (路徑項目)

在 *import path* (引入路徑) 中的一個位置，而 *path based finder* (基於路徑的尋檢器) 會參考該位置來尋找要 import 的模組。

path entry finder (路徑項目尋檢器)

被 *sys.path_hooks* 中的一個可呼叫物件 (callable) (意即一個 *path entry hook*) 所回傳的一種 *finder*，它知道如何以一個 *path entry* 定位模組。

關於路徑項目尋檢器實作的 method，請參 *importlib.abc.PathEntryFinder*。

path entry hook (路徑項目)

在 *sys.path_hooks* 列表中的一個可呼叫物件 (callable)，若它知道如何在一個特定的 *path entry* 中尋找模組，則會回傳一個 *path entry finder* (路徑項目尋檢器)。

path based finder (基於路徑的尋檢器)

預設的元路徑尋檢器 (*meta path finder*) 之一，它會在一個 *import path* 中搜尋模組。

path-like object (類路徑物件)

一個表示檔案系統路徑的物件。類路徑物件可以是一個表示路徑的 *str* 或 *bytes* 物件，或是一個實作 *os.PathLike* 協定的物件。透過呼叫 *os.fspath()* 函式，一個支援 *os.PathLike* 協定的物件可以被轉為 *str* 或 *bytes* 檔案系統路徑；而 *os.fsdecode()* 及 *os.fsencode()* 則分別可用於確保 *str* 及 *bytes* 的結果。由 **PEP 519** 引入。

PEP

Python Enhancement Proposal (Python 增提案)。PEP 是一份設計明文件，它能 Python 社群提供資訊，或是描述 Python 的一個新功能或該功能的程序和環境。PEP 應該要提供簡潔的技術規範以及被提案功能的運作原理。

PEP 的存在目的，是要成重大新功能的提案、社群中關於某個問題的意見收集，以及已納入 Python 的設計策的記，這些過程的主要機制。PEP 的作者要負責在社群建立共識記反對意見。

請參 **PEP 1**。

portion (部分)

在單一中的一組檔案 (也可能儲存在一個 zip 檔中)，這些檔案能對一個命名空間套件 (namespace package) 有所貢獻，如同 **PEP 420** 中的定義。

positional argument (位置引數)

請參 *argument* (引數)。

provisional API (暫行 API)

暫行 API 是指，從標準函式庫的向後相容性 (backwards compatibility) 保證中，故意被排除的 API。雖然此類介面，只要它們被標示暫行的，理論上不會有重大的變更，但如果核心開發人員認為有必要，也可能會出現向後不相容的變更 (甚至包括移除該介面)。這種變更不會無端地生——只有 API 被納入之前未察覺的嚴重基本缺陷被揭露時，它們才會發生。

即使對於暫行 API，向後不相容的變更也會被視「最後的解方案」——對於任何被發現的問題，仍然會盡可能找出一個向後相容的解方案。

這個過程使得標準函式庫能隨著時間不斷進化，而避免耗費過長的時間去鎖定有問題的設計錯誤。請參 **PEP 411** 了解更多細節。

provisional package (暫行套件)

請參 *provisional API* (暫行 API)。

Python 3000

Python 3.x 系列版本的稱 (很久以前創造的，當時第 3 版的發布是在遠的未來。) 也可以縮寫為 [Py3k]。

Pythonic (Python 風格的)

一個想法或一段程式碼，它應用了 Python 語言最常見的慣用語，而不是使用其他語言常見的概念來實作程式碼。例如，Python 中常見的一種習慣用法，是使用一個 *for* 陳述式，對一個可代物

件的所有元素進行遍歷。許多其他語言有這種類型的架構，所以不熟悉 Python 的人有時會使用一個數值計數器來代替：

```
for i in range(len(food)):
    print(food[i])
```

相較之下，以下方法更簡潔、更具有 Python 風格：

```
for piece in food:
    print(piece)
```

qualified name (限定名稱)

一個「點分隔名稱」，它顯示從一個模組的全域作用域到該模組中定義的 class、函式或 method 的「路徑」，如 [PEP 3155](#) 中的定義。對於頂層的函式和 class 而言，限定名稱與其物件名稱相同：

```
>>> class C:
...     class D:
...         def meth(self):
...             pass
...
>>> C.__qualname__
'C'
>>> C.D.__qualname__
'C.D'
>>> C.D.meth.__qualname__
'C.D.meth'
```

當用於引用模組時，完全限定名稱 (*fully qualified name*) 是表示該模組的完整點分隔路徑，包括任何的父套件，例如 `email.mime.text`：

```
>>> import email.mime.text
>>> email.mime.text.__name__
'email.mime.text'
```

reference count (參照計數)

The number of references to an object. When the reference count of an object drops to zero, it is deallocated. Some objects are *immortal* and have reference counts that are never modified, and therefore the objects are never deallocated. Reference counting is generally not visible to Python code, but it is a key element of the CPython implementation. Programmers can call the `sys.getrefcount()` function to return the reference count for a particular object.

regular package (正規套件)

一個傳統的 *package* (套件)，例如一個包含 `__init__.py` 檔案的目錄。

另請參閱 [namespace package](#) (命名空間套件)。

REPL

An acronym for the “read–eval–print loop”, another name for the *interactive* interpreter shell.

__slots__

在 class 內部的一個宣告，它藉由預先宣告實例屬性的空間，以及消除實例 dictionary (字典)，來節省記憶體。雖然該技術很普遍，但它有點難以正確地使用，最好保留給那種在一個記憶體關鍵 (memory-critical) 的應用程式中存在大量實例的罕見情況。

sequence (序列)

一個 *iterable* (可迭代物件)，它透過 `__getitem__()` special method (特殊方法)，使用整數索引來支援高效率的元素存取，它定義了一個 `__len__()` method 來回傳該序列的長度。一些建置序列型包括 *list*、*str*、*tuple* 和 *bytes*。請注意，雖然 *dict* 也支援 `__getitem__()` 和 `__len__()`，但它被視為對映 (mapping) 而不是序列，因其查找方式是使用任意的 *immutable* 鍵，而不是整數。

抽象基底類 (abstract base class) `collections.abc.Sequence` 定義了一個更加豐富的介面，不僅止於 `__getitem__()` 和 `__len__()`，還增加了 `count()`、`index()`、`__contains__()` 和 `__reversed__()`。實作此擴充介面的型別，可以使用 `register()` 被明確地註冊。更多關於序列方法的文件，請見常見序列操作。

set comprehension (集合綜合運算)

一種緊密的方法，用來處理一個可代物件中的全部或部分元素，將處理結果以一個 `set` 回傳。`results = {c for c in 'abracadabra' if c not in 'abc'}` 會生一個字串 `set: {'r', 'd'}`。請參 `comprehensions`。

single dispatch (單一調度)

generic function (泛型函式) 調度的一種形式，在此，實作的選擇是基於單一引數的型。

slice (切片)

一個物件，它通常包含一段 *sequence* (序列) 的某一部分。建立一段切片的方法是使用下標符號 (subscript notation) `[]`，若要給出多個數字，則在數字之間使用冒號，例如 `variable_name[1:3:5]`。在括號 (下標) 符號的部，會使用 *slice* 物件。

soft deprecated

A soft deprecation can be used when using an API which should no longer be used to write new code, but it remains safe to continue using it in existing code. The API remains documented and tested, but will not be developed further (no enhancement).

The main difference between a "soft" and a (regular) "hard" deprecation is that the soft deprecation does not imply scheduling the removal of the deprecated API.

Another difference is that a soft deprecation does not issue a warning.

See [PEP 387: Soft Deprecation](#).

special method (特殊方法)

一種會被 Python 自動呼叫的 `method`，用於對某種型執行某種運算，例如加法。這種 `method` 的名稱會在開頭和結尾有兩個下底。Special method 在 `specialnames` 中有詳細明。

statement (陳述式)

陳述式是一個套組 (suite，一個程式碼「區塊」) 中的一部分。陳述式可以是一個 *expression* (運算式)，或是含有關鍵字 (例如 `if`、`while` 或 `for`) 的多種結構之一。

static type checker (態型檢查器)

會讀取 Python 程式碼分析的外部工具，能找出錯誤，像是使用了不正確的型。另請參 *型提示* (*type hints*) 以及 *typing* 模組。

strong reference (參照)

在 Python 的 C API 中，參照是對物件的參照，該物件持有該參照的程式碼所擁有。建立參照時透過呼叫 `Py_INCREF()` 來獲得參照、除參照時透過 `Py_DECREF()` 釋放參照。

`Py_NewRef()` 函式可用於建立一個對物件的參照。通常，在退出參照的作用域之前，必須在該參照上呼叫 `Py_DECREF()` 函式，以避免漏一個參照。

另請參 *borrowed reference* (借用參照)。

text encoding (文字編碼)

Python 中的字串是一個 Unicode 碼點 (code point) 的序列 (範圍在 `U+0000` -- `U+10FFFF` 之間)。若要儲存或傳送一個字串，它必須被序列化一個位元組序列。

將一個字串序列化位元組序列，稱「編碼」，而從位元組序列重新建立該字串則稱「解碼 (decoding)」。

有多種不同的文字序列化編解碼器 (*codecs*)，它們被統稱「文字編碼」。

text file (文字檔案)

一個能讀取和寫入 *str* 物件的一個 *file object* (檔案物件)。通常，文字檔案實際上是存取位元組導向的資料流 (byte-oriented datastream) 會自動處理 *text encoding* (文字編碼)。文字檔案的例子有：以文字模式 ('`r`' 或 '`w`') 開的檔案、`sys.stdin`、`sys.stdout` 以及 `io.StringIO` 的實例。

另請參 *binary file* (二進位檔案)，它是一個能讀取和寫入類位元組串物件 (*bytes-like object*) 的檔案物件。

triple-quoted string (三引號字串)

由三個雙引號 (") 或單引號 (') 的作邊界的一個字串。雖然它們有提供於單引號字串的任何額外功能，但基於許多原因，它們仍是很有用的。它們讓你可以字串中包含未跳 (unescaped)

的單引號和雙引號，而且它們不需使用連續字元 (continuation character) 就可以跨越多行，這使得它們在編寫明字串時特別有用。

type (型別)

一個 Python 物件的型別定義了它是什麼類型的物件；每個物件都有一個型別。一個物件的型別可以用它的 `__class__` 屬性來存取，或以 `type(obj)` 來檢索。

type alias (型別別名)

一個型別的同義詞，透過將型別指定給一個識別符 (identifier) 來建立。

型別別名對於簡化型別提示 (type hint) 很有用。例如：

```
def remove_gray_shades(
    colors: list[tuple[int, int, int]]) -> list[tuple[int, int, int]]:
    pass
```

可以寫成這樣，更具有可讀性：

```
Color = tuple[int, int, int]

def remove_gray_shades(colors: list[Color]) -> list[Color]:
    pass
```

請參閱 `typing` 和 **PEP 484**，有此功能的描述。

type hint (型別提示)

一種 *annotation* (解釋)，它指定一個變數、一個 class 屬性或一個函式的參數或回傳值的預期型別。

型別提示是選擇性的，而不是被 Python 限制的，但它們對靜態型別檢查器 (static type checkers) 很有用，能協助 IDE 完成程式碼的補全 (completion) 和重構 (refactoring)。

全域變數、class 屬性和函式（不含區域變數）的型別提示，都可以使用 `typing.get_type_hints()` 來存取。

請參閱 `typing` 和 **PEP 484**，有此功能的描述。

universal newlines (通用行字元)

一種解譯文字流 (text stream) 的方式，會將以下所有的情況識別為一行的結束：Unix 行尾慣例 '\n'、Windows 慣例 '\r\n' 和舊的 Macintosh 慣例 '\r'。請參閱 **PEP 278** 和 **PEP 3116**，以及用於 `bytes.splitlines()` 的附加用途。

variable annotation (變數解釋)

一個變數或 class 屬性的 *annotation* (解釋)。

解釋變數或 class 屬性時，賦值是選擇性的：

```
class C:
    field: 'annotation'
```

變數解釋通常用於型別提示 (type hint)：例如，這個變數預期會取得 `int` (整數) 值：

```
count: int = 0
```

變數解釋的語法在 `annassign` 章節有詳細的解釋。

請參閱 `function annotation` (函式解釋)、**PEP 484** 和 **PEP 526**，皆有此功能的描述。關於解釋的最佳實踐方法，另請參閱 `annotations-howto`。

virtual environment (虛擬環境)

一個協作隔離 (cooperatively isolated) 的執行環境，能讓 Python 的使用者和應用程式得以安裝和升級 Python 發行套件，而不會對同一個系統上運行的其他 Python 應用程式的行為產生干擾。

另請參閱 `venv`。

virtual machine (虛擬機器)

一部完全由軟體所定義的電腦 (computer)。Python 的虛擬機器會執行由 *bytecode* (位元組碼) 編譯器所發出的位元組碼。

Zen of Python (Python 之禪)

Python 設計原則與哲學的列表，其內容有助於理解和使用此語言。此列表可以透過在互動式提示字元後輸入「`import this`」來找到它。

關於這些📄明文件

這些📄明文件是透過 [Sphinx](#)（一個專📄 Python 📄明文件所撰寫的文件處理器）將使用 [reStructuredText](#) 撰寫的原始檔轉📄而成。

如同 Python 自身，透過自願者的努力下📄出文件與封裝後自動化執行工具。若想要回報臭蟲，請見 [reporting-bugs](#) 頁面，📄含相關資訊。我們永遠歡迎新的自願者加入！

致謝：

- Fred L. Drake, Jr.，原始 Python 文件工具集的創造者以及一大部份📄容的作者；
- 創造 [reStructuredText](#) 和 [Docutils](#) 工具組的 [Docutils](#) 專案；
- Fredrik Lundh 先生，[Sphinx](#) 從他的 [Alternative Python Reference](#) 計劃中獲得許多的好主意。

B.1 Python 文件的貢獻者們

許多人都曾📄 Python 這門語言、Python 標準函式庫和 Python 📄明文件貢獻過。Python 所發📄的原始碼中含有部份貢獻者的清單，請見 [Misc/ACKS](#)。

正因📄 Python 社群的撰寫與貢獻才有這份這📄棒的📄明文件 -- 感謝所有貢獻過的人們！

沿革與授權

C.1 軟體沿革

Python 是由荷蘭數學和計算機科學研究學會（CWI，見 <https://www.cwi.nl/>）的 Guido van Rossum 於 1990 年代早期所創造，目的是作一種稱作 ABC 語言的後繼者。儘管 Python 包含了許多來自其他人的貢獻，Guido 仍是其主要作者。

1995 年，Guido 在維吉尼亞州雷斯頓的國家創新研究公司（CNRI，見 <https://www.cnri.reston.va.us/>）繼續他在 Python 的工作，在那發行了該軟體的多個版本。

2000 年五月，Guido 和 Python 核心開發團隊轉移到 BeOpen.com 成立了 BeOpen PythonLabs 團隊。同年十月，PythonLabs 團隊轉移到 Digital Creations（現 Zope Corporation；見 <https://www.zope.org/>）。2001 年，Python 軟體基金會（PSF，見 <https://www.python.org/psf/>）成立，這是一個專擁有 Python 相關的智慧財產權而創立的非營利組織。Zope Corporation 是 PSF 的一個贊助會員。

所有的 Python 版本都是開源的（有關開源的定義，參見 <https://opensource.org/>）。歷史上，大多數但非全部的 Python 版本，也是 GPL 相容的；以下表格總結各個版本的差異。

發行版本	源自	年份	擁有者	GPL 相容性？
0.9.0 至 1.2	不適用	1991-1995	CWI	是
1.3 至 1.5.2	1.2	1995-1999	CNRI	是
1.6	1.5.2	2000	CNRI	否
2.0	1.6	2000	BeOpen.com	否
1.6.1	1.6	2001	CNRI	否
2.1	2.0+1.6.1	2001	PSF	否
2.0.1	2.0+1.6.1	2001	PSF	是
2.1.1	2.1+2.0.1	2001	PSF	是
2.1.2	2.1.1	2002	PSF	是
2.1.3	2.1.2	2002	PSF	是
2.2 以上	2.1.1	2001 至今	PSF	是

備註

GPL 相容並不表示我們是在 GPL 下發行 Python。不像 GPL，所有的 Python 授權都可以讓你發行修改後的版本，但不一定要使你的變更成開源。GPL 相容的授權使得 Python 可以結合其他在 GPL 下發

的軟體一起使用；但其它的授權則不行。

感謝許多的外部志工，在 Guido 指導下的付出，使得這些版本的發成可能。

C.2 關於存取或以其他方式使用 Python 的合約條款

Python 軟體和明文件的授權是基於 *PSF* 授權合約。

從 Python 3.8.6 開始，明文件中的範例、程式庫和其他程式碼，是被雙重授權 (dual licensed) 於 PSF 授權合約以及 *Zero-Clause BSD* 授權。

有些被納入 Python 中的軟體是基於不同的授權。這些授權將會與其授權之程式碼一起被列出。關於這些授權的不完整清單，請參被收軟體的授權與致謝。

C.2.1 用於 PYTHON 3.13.0rc2 的 PSF 授權合約

1. This LICENSE AGREEMENT is between the Python Software Foundation
 ("PSF"), and
 the Individual or Organization ("Licensee") accessing and otherwise
 using Python
 3.13.0rc2 software in source or binary form and its associated
 documentation.
2. Subject to the terms and conditions of this License Agreement, PSF
 hereby
 grants Licensee a nonexclusive, royalty-free, world-wide license to
 reproduce,
 analyze, test, perform and/or display publicly, prepare derivative
 works,
 distribute, and otherwise use Python 3.13.0rc2 alone or in any
 derivative
 version, provided, however, that PSF's License Agreement and PSF's
 notice of
 copyright, i.e., "Copyright © 2001-2024 Python Software Foundation; All
 Rights
 Reserved" are retained in Python 3.13.0rc2 alone or in any derivative
 version
 prepared by Licensee.
3. In the event Licensee prepares a derivative work that is based on or
 incorporates Python 3.13.0rc2 or any part thereof, and wants to make the
 derivative work available to others as provided herein, then Licensee
 hereby
 agrees to include in any such work a brief summary of the changes made
 to Python
 3.13.0rc2.
4. PSF is making Python 3.13.0rc2 available to Licensee on an "AS IS"
 basis.
 PSF MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY
 OF
 EXAMPLE, BUT NOT LIMITATION, PSF MAKES NO AND DISCLAIMS ANY
 REPRESENTATION OR
 WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR
 THAT THE

USE OF PYTHON 3.13.0rc2 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.

5. PSF SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 3.13.0rc2

FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 3.13.0rc2, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.

7. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between PSF and Licensee. This License Agreement does not grant permission to use PSF trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.

8. By copying, installing or otherwise using Python 3.13.0rc2, Licensee agrees to be bound by the terms and conditions of this License Agreement.

C.2.2 用於 PYTHON 2.0 的 BEOPEN.COM 授權合約

BEOPEN PYTHON 開源授權合約第 1 版

1. This LICENSE AGREEMENT is between BeOpen.com ("BeOpen"), having an office at 160 Saratoga Avenue, Santa Clara, CA 95051, and the Individual or Organization ("Licensee") accessing and otherwise using this software in source or binary form and its associated documentation ("the Software").
2. Subject to the terms and conditions of this BeOpen Python License Agreement, BeOpen hereby grants Licensee a non-exclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use the Software alone or in any derivative version, provided, however, that the BeOpen Python License is retained in the Software, alone or in any derivative version prepared by Licensee.
3. BeOpen is making the Software available to Licensee on an "AS IS" basis. BEOPEN MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, BEOPEN MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF THE SOFTWARE WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
4. BEOPEN SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF THE SOFTWARE FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF USING, MODIFYING OR DISTRIBUTING THE SOFTWARE, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.
5. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
6. This License Agreement shall be governed by and interpreted in all respects

(繼續下一頁)

(繼續上一頁)

by the law of the State of California, excluding conflict of law provisions. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between BeOpen and Licensee. This License Agreement does not grant permission to use BeOpen trademarks or trade names in a trademark sense to endorse or promote products or services of Licensee, or any third party. As an exception, the "BeOpen Python" logos available at <http://www.pythonlabs.com/logos.html> may be used according to the permissions granted on that web page.

7. By copying, installing or otherwise using the software, Licensee agrees to be bound by the terms and conditions of this License Agreement.

C.2.3 用於 PYTHON 1.6.1 的 CNRI 授權合約

1. This LICENSE AGREEMENT is between the Corporation for National Research Initiatives, having an office at 1895 Preston White Drive, Reston, VA 20191 ("CNRI"), and the Individual or Organization ("Licensee") accessing and otherwise using Python 1.6.1 software in source or binary form and its associated documentation.
2. Subject to the terms and conditions of this License Agreement, CNRI hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python 1.6.1 alone or in any derivative version, provided, however, that CNRI's License Agreement and CNRI's notice of copyright, i.e., "Copyright © 1995-2001 Corporation for National Research Initiatives; All Rights Reserved" are retained in Python 1.6.1 alone or in any derivative version prepared by Licensee. Alternately, in lieu of CNRI's License Agreement, Licensee may substitute the following text (omitting the quotes): "Python 1.6.1 is made available subject to the terms and conditions in CNRI's License Agreement. This Agreement together with Python 1.6.1 may be located on the internet using the following unique, persistent identifier (known as a handle): 1895.22/1013. This Agreement may also be obtained from a proxy server on the internet using the following URL: <http://hdl.handle.net/1895.22/1013>."
3. In the event Licensee prepares a derivative work that is based on or incorporates Python 1.6.1 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python 1.6.1.
4. CNRI is making Python 1.6.1 available to Licensee on an "AS IS" basis. CNRI MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, CNRI MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON 1.6.1 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
5. CNRI SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 1.6.1 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 1.6.1, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.
6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
7. This License Agreement shall be governed by the federal intellectual property law of the United States, including without limitation the federal copyright law, and, to the extent such U.S. federal law does not apply, by the law of the Commonwealth of Virginia, excluding Virginia's conflict of law provisions. Notwithstanding the foregoing, with regard to derivative works based on Python

(繼續下一頁)

(繼續上一頁)

1.6.1 that incorporate non-separable material that was previously distributed under the GNU General Public License (GPL), the law of the Commonwealth of Virginia shall govern this License Agreement only as to issues arising under or with respect to Paragraphs 4, 5, and 7 of this License Agreement. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between CNRI and Licensee. This License Agreement does not grant permission to use CNRI trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.

8. By clicking on the "ACCEPT" button where indicated, or by copying, installing or otherwise using Python 1.6.1, Licensee agrees to be bound by the terms and conditions of this License Agreement.

C.2.4 用於 PYTHON 0.9.0 至 1.2 的 CWI 授權合約

Copyright © 1991 – 1995, Stichting Mathematisch Centrum Amsterdam, The Netherlands. All rights reserved.

Permission to use, copy, modify, and distribute this software and its documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Stichting Mathematisch Centrum or CWI not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

STICHTING MATHEMATISCH CENTRUM DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS, IN NO EVENT SHALL STICHTING MATHEMATISCH CENTRUM BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

C.2.5 用於 PYTHON 3.13.0rc2 明文程式碼的 ZERO-CLAUSE BSD 授權

Permission to use, copy, modify, and/or distribute this software for any purpose with or without fee is hereby granted.

THE SOFTWARE IS PROVIDED "AS IS" AND THE AUTHOR DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS. IN NO EVENT SHALL THE AUTHOR BE LIABLE FOR ANY SPECIAL, DIRECT, INDIRECT, OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

C.3 被收 軟體的授權與致謝

本節是一個不完整但持續增加的授權與致謝清單，對象是在 Python 發 版本中所收 的第三方軟體。

C.3.1 Mersenne Twister

`random` 模組底下的 `_random` C 擴充程式包含了以 <http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/MT2002/emt19937ar.html> 的下載 容 基礎的程式碼。以下是原始程式碼的完整聲明：

```
A C-program for MT19937, with initialization improved 2002/1/26.
Coded by Takuji Nishimura and Makoto Matsumoto.

Before using, initialize the state by using init_genrand(seed)
or init_by_array(init_key, key_length).

Copyright (C) 1997 - 2002, Makoto Matsumoto and Takuji Nishimura,
All rights reserved.

Redistribution and use in source and binary forms, with or without
modification, are permitted provided that the following conditions
are met:

1. Redistributions of source code must retain the above copyright
   notice, this list of conditions and the following disclaimer.

2. Redistributions in binary form must reproduce the above copyright
   notice, this list of conditions and the following disclaimer in the
   documentation and/or other materials provided with the distribution.

3. The names of its contributors may not be used to endorse or promote
   products derived from this software without specific prior written
   permission.

THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS
"AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT
LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR
A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR
CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL,
EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO,
PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR
PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF
LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING
NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS
SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

Any feedback is very welcome.
http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html
email: m-mat @ math.sci.hiroshima-u.ac.jp (remove space)
```

C.3.2 Sockets

`socket` 模組使用 `getaddrinfo()` 和 `getnameinfo()` 函式，它們在 WIDE 專案 (<https://www.wide.ad.jp/>) 中，於不同的原始檔案中被編碼：

```
Copyright (C) 1995, 1996, 1997, and 1998 WIDE Project.
All rights reserved.
```

```
Redistribution and use in source and binary forms, with or without
modification, are permitted provided that the following conditions
are met:
```

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
3. Neither the name of the project nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission.

```
THIS SOFTWARE IS PROVIDED BY THE PROJECT AND CONTRIBUTORS ``AS IS'' AND
ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE
IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE
ARE DISCLAIMED.  IN NO EVENT SHALL THE PROJECT OR CONTRIBUTORS BE LIABLE
FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL
DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS
OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION)
HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT
LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY
OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF
SUCH DAMAGE.
```

C.3.3 非同步 socket 服務

`test.support.asyncchat` 和 `test.support.asyncore` 模組包含以下聲明：

```
Copyright 1996 by Sam Rushing
```

```
    All Rights Reserved
```

```
Permission to use, copy, modify, and distribute this software and
its documentation for any purpose and without fee is hereby
granted, provided that the above copyright notice appear in all
copies and that both that copyright notice and this permission
notice appear in supporting documentation, and that the name of Sam
Rushing not be used in advertising or publicity pertaining to
distribution of the software without specific, written prior
permission.
```

```
SAM RUSHING DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE,
INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS, IN
NO EVENT SHALL SAM RUSHING BE LIABLE FOR ANY SPECIAL, INDIRECT OR
CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS
OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT,
NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN
CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.
```

C.3.4 Cookie 管理

`http.cookies` 模組包含以下聲明：

```
Copyright 2000 by Timothy O'Malley <timo@alum.mit.edu>
```

```
    All Rights Reserved
```

```
Permission to use, copy, modify, and distribute this software
and its documentation for any purpose and without fee is hereby
granted, provided that the above copyright notice appear in all
copies and that both that copyright notice and this permission
notice appear in supporting documentation, and that the name of
Timothy O'Malley not be used in advertising or publicity
pertaining to distribution of the software without specific, written
prior permission.
```

```
Timothy O'Malley DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS
SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY
AND FITNESS, IN NO EVENT SHALL Timothy O'Malley BE LIABLE FOR
ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES
WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS,
WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS
ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR
PERFORMANCE OF THIS SOFTWARE.
```

C.3.5 執行追 F

`trace` 模組包含以下聲明：

```
portions copyright 2001, Autonomous Zones Industries, Inc., all rights...
err... reserved and offered to the public under the terms of the
Python 2.2 license.
```

```
Author: Zooko O'Whielacronx

and that both that copyright notice and this permission notice appear in
supporting documentation, and that the name of neither Automatrix,
Bioreason or Mojam Media be used in advertising or publicity pertaining to
distribution of the software without specific, written prior permission.
```

C.3.6 UUencode 與 UUdecode 函式

The uu codec contains the following notice:

```
Copyright 1994 by Lance Ellinghouse
Cathedral City, California Republic, United States of America.
    All Rights Reserved
Permission to use, copy, modify, and distribute this software and its
documentation for any purpose and without fee is hereby granted,
provided that the above copyright notice appear in all copies and that
both that copyright notice and this permission notice appear in
supporting documentation, and that the name of Lance Ellinghouse
not be used in advertising or publicity pertaining to distribution
of the software without specific, written prior permission.
LANCE ELLINGHOUSE DISCLAIMS ALL WARRANTIES WITH REGARD TO
THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND
FITNESS, IN NO EVENT SHALL LANCE ELLINGHOUSE CENTRUM BE LIABLE
FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES
WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN
ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT
OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

Modified by Jack Jansen, CWI, July 1995:
- Use binascii module to do the actual line-by-line conversion
  between ascii and binary. This results in a 1000-fold speedup. The C
  version is still 5 times faster, though.
- Arguments more compliant with Python standard
```

C.3.7 XML 遠端程序呼叫

`xmlrpc.client` 模組包含以下聲明：

```
The XML-RPC client interface is

```

C.3.12 OpenSSL

The modules *hashlib*, *posix* and *ssl* use the OpenSSL library for added performance if made available by the operating system. Additionally, the Windows and macOS installers for Python may include a copy of the OpenSSL libraries, so we include a copy of the OpenSSL license here. For the OpenSSL 3.0 release, and later releases derived from that, the Apache License v2 applies:

```

                                Apache License
                                Version 2.0, January 2004
                                https://www.apache.org/licenses/

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions.

"License" shall mean the terms and conditions for use, reproduction,
and distribution as defined by Sections 1 through 9 of this document.

"Licensors" shall mean the copyright owner or entity authorized by
the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all
other entities that control, are controlled by, or are under common
control with that entity. For the purposes of this definition,
"control" means (i) the power, direct or indirect, to cause the
direction or management of such entity, whether by contract or
otherwise, or (ii) ownership of fifty percent (50%) or more of the
outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity
exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications,
including but not limited to software source code, documentation
source, and configuration files.

"Object" form shall mean any form resulting from mechanical
transformation or translation of a Source form, including but
not limited to compiled object code, generated documentation,
and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or
Object form, made available under the License, as indicated by a
copyright notice that is included in or attached to the work
(an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object
form, that is based on (or derived from) the Work and for which the
editorial revisions, annotations, elaborations, or other modifications
represent, as a whole, an original work of authorship. For the purposes
of this License, Derivative Works shall not include works that remain
separable from, or merely link (or bind by name) to the interfaces of,
the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including
the original version of the Work and any modifications or additions
to that Work or Derivative Works thereof, that is intentionally
submitted to Licensors for inclusion in the Work by the copyright owner
or by an individual or Legal Entity authorized to submit on behalf of
the copyright owner. For the purposes of this definition, "submitted"
means any form of electronic, verbal, or written communication sent
to the Licensors or its representatives, including but not limited to

```

(繼續下一頁)

(繼續上一頁)

communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.
3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.
4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:
 - (a) You must give any other recipients of the Work or Derivative Works a copy of this License; and
 - (b) You must cause any modified files to carry prominent notices stating that You changed the files; and
 - (c) You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and
 - (d) If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and

(繼續下一頁)

(繼續上一頁)

do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.
6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.
7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.
8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.
9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

C.3.13 expat

除非在建置 `pyexpat` 擴充時設定 `--with-system-expat`，否則該擴充會用一個含 `expat` 原始碼的副本來建置：

```
Copyright (c) 1998, 1999, 2000 Thai Open Source Software Center Ltd
and Clark Cooper

Permission is hereby granted, free of charge, to any person obtaining
a copy of this software and associated documentation files (the
"Software"), to deal in the Software without restriction, including
without limitation the rights to use, copy, modify, merge, publish,
distribute, sublicense, and/or sell copies of the Software, and to
permit persons to whom the Software is furnished to do so, subject to
the following conditions:

The above copyright notice and this permission notice shall be included
in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND,
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF
MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT.
IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY
CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT,
TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE
SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.
```

C.3.14 libffi

除非在建置 `_ctypes` 模組底下 `_ctypes` 擴充程式時設定 `--with-system-libffi`，否則該擴充會用一個含 `libffi` 原始碼的副本來建置：

```
Copyright (c) 1996-2008 Red Hat, Inc and others.

Permission is hereby granted, free of charge, to any person obtaining
a copy of this software and associated documentation files (the
``Software''), to deal in the Software without restriction, including
without limitation the rights to use, copy, modify, merge, publish,
distribute, sublicense, and/or sell copies of the Software, and to
permit persons to whom the Software is furnished to do so, subject to
the following conditions:

The above copyright notice and this permission notice shall be included
in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED ``AS IS'', WITHOUT WARRANTY OF ANY KIND,
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF
MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND

- `sched_setparam()` (於 `os` 模組中), 710
`sched_setscheduler()` (於 `os` 模組中), 710
`SCHED_SPORADIC` (於 `os` 模組中), 709
`sched_yield()` (於 `os` 模組中), 710
`scheduler` (`sched` 中的類), 986
`SCM_CREDS2` (於 `socket` 模組中), 1108
`scope_id` (`ipaddress.IPv6Address` 的屬性), 1476
`Screen` (`turtle` 中的類), 1540
`screensize()` (於 `turtle` 模組中), 1533
`script_from_examples()` (於 `doctest` 模組中), 1687
`scroll()` (`curses.window` 的方法), 832
`ScrolledCanvas` (`turtle` 中的類), 1540
`ScrolledText` (`tkinter.scrolledtext` 中的類), 1577
`scrollok()` (`curses.window` 的方法), 832
`script()` (於 `hashlib` 模組中), 635
`seal()` (於 `unittest.mock` 模組中), 1758
`search()` (`imaplib.IMAP4` 的方法), 1417
`search()` (`re.Pattern` 的方法), 143
`search()` (於 `re` 模組中), 139
`search` (搜尋)
 `path` (路徑), `module` (模組), 480, 1881, 1978
`second` (`datetime.datetime` 的屬性), 217
`second` (`datetime.time` 的屬性), 225
`seconds` (`datetime.timedelta` 的屬性), 207
`secrets`
 `module`, 644
`SECTCRE` (`configparser.ConfigParser` 的屬性), 617
`sections()` (`configparser.ConfigParser` 的方法), 620
`secure` (`http.cookiejar.Cookie` 的屬性), 1456
`secure` (`http.cookies.Morsel` 的屬性), 1447
`Secure Sockets Layer` (安全 socket 層), 1128
`security considerations` (安全性注意事項), 2174
`security_level` (`ssl.SSLContext` 的屬性), 1151
`security` (安全)
 `http.server`, 1446
`see()` (`tkinter.ttk.Treeview` 的方法), 1591
`seed()` (`random.Random` 的方法), 377
`seed()` (於 `random` 模組中), 374
`seed_bits` (`sys.hash_info` 的屬性), 1878
`seek()` (`io.IOBase` 的方法), 718
`seek()` (`io.TextIOBase` 的方法), 724
`seek()` (`io.TextIOWrapper` 的方法), 725
`seek()` (`mmap.mmap` 的方法), 1186
`seek()` (`sqlite3.Blob` 的方法), 541
`SEEK_CUR` (於 `os` 模組中), 660
`SEEK_DATA` (於 `os` 模組中), 661
`SEEK_END` (於 `os` 模組中), 660
`SEEK_HOLE` (於 `os` 模組中), 661
`SEEK_SET` (於 `os` 模組中), 660
`seekable()` (`bz2.BZ2File` 的方法), 561
`seekable()` (`io.IOBase` 的方法), 718
`seekable()` (`mmap.mmap` 的方法), 1186
`select`
 `module`, 1163
`select()` (`imaplib.IMAP4` 的方法), 1418
`select()` (`selectors.BaseSelector` 的方法), 1171
`select()` (`tkinter.ttk.Notebook` 的方法), 1585
`select()` (於 `select` 模組中), 1164
`selected_alpn_protocol()` (`ssl.SSLSocket` 的方法), 1143
`selected_npn_protocol()` (`ssl.SSLSocket` 的方法), 1143
`selection()` (`tkinter.ttk.Treeview` 的方法), 1592
`selection_add()` (`tkinter.ttk.Treeview` 的方法), 1592
`selection_remove()` (`tkinter.ttk.Treeview` 的方法), 1592
`selection_set()` (`tkinter.ttk.Treeview` 的方法), 1592
`selection_toggle()` (`tkinter.ttk.Treeview` 的方法), 1592
`selector` (`urllib.request.Request` 的屬性), 1369
`SelectorEventLoop` (`asyncio` 中的類), 1062
`SelectorKey` (`selectors` 中的類), 1171
`selectors`
 `module`, 1170
`SelectSelector` (`selectors` 中的類), 1172
`Self` (於 `typing` 模組中), 1624
`Semaphore` (`asyncio` 中的類), 1032
`Semaphore` (`multiprocessing` 中的類), 927
`Semaphore` (`threading` 中的類), 905
`Semaphore()` (`multiprocessing.managers.SyncManager` 的方法), 933
`semaphores, binary` (號, 二進位), 995
`SEMI` (於 `token` 模組中), 2071
`SEND` (`opcode`), 2105
`send()` (`http.client.HTTPConnection` 的方法), 1401
`send()` (`imaplib.IMAP4` 的方法), 1418
`send()` (`logging.handlers.DatagramHandler` 的方法), 811
`send()` (`logging.handlers.SocketHandler` 的方法), 810
`send()` (`multiprocessing.connection.Connection` 的方法), 924
`send()` (`socket.socket` 的方法), 1121
`send_bytes()` (`multiprocessing.connection.Connection` 的方法), 925
`send_error()` (`http.server.BaseHTTPRequestHandler` 的方法), 1442
`send_fds()` (於 `socket` 模組中), 1116
`send_header()` (`http.server.BaseHTTPRequestHandler` 的方法), 1442
`send_message()` (`smtplib.SMTP` 的方法), 1425
`send_response()` (`http.server.BaseHTTPRequestHandler` 的方法), 1442
`send_response_only()` (`http.server.BaseHTTPRequestHandler` 的方法), 1442
`send_signal()` (`asyncio.subprocess.Process` 的方法), 1037
`send_signal()` (`asyncio.SubprocessTransport` 的方法), 1073
`send_signal()` (`subprocess.Popen` 的方法), 976
`sendall()` (`socket.socket` 的方法), 1121

- `sendcmd()` (*ftplib.FTP* 的方法), 1406
- `sendfile()` (*asyncio.loop* 的方法), 1052
- `sendfile()` (*socket.socket* 的方法), 1122
- `sendfile()` (於 *os* 模組中), 666
- `sendfile()` (*wsgiref.handlers.BaseHandler* 的方法), 1361
- `SendfileNotAvailableError`, 1042
- `sendmail()` (*smtpplib.SMTP* 的方法), 1425
- `sendmsg()` (*socket.socket* 的方法), 1122
- `sendmsg_afalg()` (*socket.socket* 的方法), 1122
- `sendto()` (*asyncio.DatagramTransport* 的方法), 1073
- `sendto()` (*socket.socket* 的方法), 1121
- `sentinel` (*multiprocessing.Process* 的屬性), 918
- `sentinel` (於 *unittest.mock* 模組中), 1751
- `sep` (於 *os* 模組中), 711
- `SEPTEMBER` (於 *calendar* 模組中), 249
- `Sequence` (*collections.abc* 中的類), 272
- `Sequence` (*typing* 中的類), 1659
- `SequenceMatcher` (*difflib* 中的類), 157
- `sequence` (序列), 2189
 - `iteration` (代), 45
 - `object` (物件), 46
 - `type` (型), *immutable* (不可變), 48
 - `type` (型), *mutable* (可變), 48
 - `type` (型), *operations on* (操作於), 46, 48
- `serialize()` (*sqlite3.Connection* 的方法), 535
- `serializing` (序列化)
 - `objects` (物件), 493
- `serve_forever()` (*asyncio.Server* 的方法), 1061
- `serve_forever()` (*socketserver.BaseServer* 的方法), 1434
- `Server` (*asyncio* 中的類), 1061
- `server` (*http.server.BaseHTTPRequestHandler* 的屬性), 1440
- `server` (*socketserver.BaseRequestHandler* 的屬性), 1436
- `server_activate()` (*socketserver.BaseServer* 的方法), 1435
- `server_address` (*socketserver.BaseServer* 的屬性), 1434
- `server_bind()` (*socketserver.BaseServer* 的方法), 1435
- `server_close()` (*socketserver.BaseServer* 的方法), 1434
- `server_hostname` (*ssl.SSLSocket* 的屬性), 1144
- `server_side` (*ssl.SSLSocket* 的屬性), 1144
- `server_software` (*wsgiref.handlers.BaseHandler* 的屬性), 1360
- `server_version` (*http.server.BaseHTTPRequestHandler* 的屬性), 1441
- `server_version` (*http.server.SimpleHTTPRequestHandler* 的屬性), 1443
- `ServerProxy` (*xmlrpc.client* 中的類), 1458
- `server` (伺服器)
 - www*, 1439
- `service_actions()` (*socketserver.BaseServer* 的方法), 1434
- `session` (*ssl.SSLSocket* 的屬性), 1144
- `session_reused` (*ssl.SSLSocket* 的屬性), 1144
- `session_stats()` (*ssl.SSLContext* 的方法), 1150
- `Set` (*ast* 中的類), 2038
- `Set` (*collections.abc* 中的類), 273
- `Set` (*typing* 中的類), 1657
- `set` (建類), 85
- `Set Breakpoint`, 1601
- `set comprehension` (集合綜合運算), 2190
- `set()` (*asyncio.Event* 的方法), 1030
- `set()` (*configparser.ConfigParser* 的方法), 622
- `set()` (*configparser.RawConfigParser* 的方法), 623
- `set()` (*contextvars.ContextVar* 的方法), 992
- `set()` (*http.cookies.Morsel* 的方法), 1448
- `set()` (*test.support.os_helper.EnvironmentVarGuard* 的方法), 1794

- XMLGenerator (`xml.sax.saxutils` 中的類_F), 1336
- XMLID() (於 `xml.etree.ElementTree` 模組中), 1302
- XMLNS_NAMESPACE (於 `xml.dom` 模組中), 1313
- XMLParser (`xml.etree.ElementTree` 中的類_F), 1309
- xml.parsers.expat
module, 1341
- xml.parsers.expat.errors
module, 1348
- xml.parsers.expat.model
module, 1347
- XMLParserType (於 `xml.parsers.expat` 模組中), 1341
- XMLPullParser (`xml.etree.ElementTree` 中的類_F), 1311
- XMLReader (`xml.sax.xmlreader` 中的類_F), 1337
- xmlrpc.client
module, 1458
- xmlrpc.server
module, 1466
- xml.sax
module, 1329
- xml.sax.handler
module, 1330
- xml.sax.saxutils
module, 1336
- xml.sax.xmlreader
module, 1337
- xor() (於 `operator` 模組中), 423
- xview() (`tkinter.ttk.Treeview` 的方法), 1592
- ## Y
- ycor() (於 `turtle` 模組中), 1521
- year
calendar 命令列選項, 251
- year (`datetime.date` 的屬性), 210
- year (`datetime.datetime` 的屬性), 217
- Year 2038 (2038 年問題), 727
- yeardatescalendar() (`calendar.Calendar` 的方法), 246
- yeardays2calendar() (`calendar.Calendar` 的方法), 246
- yeardayscalendar() (`calendar.Calendar` 的方法), 246
- YES (於 `tkinter.messagebox` 模組中), 1576
- YESEXPR (於 `locale` 模組中), 1502
- YESNO (於 `tkinter.messagebox` 模組中), 1577
- YESNOCANCEL (於 `tkinter.messagebox` 模組中), 1577
- Yield (`ast` 中的類_F), 2060
- YIELD_VALUE (`opcode`), 2096
- YieldFrom (`ast` 中的類_F), 2060
- yiq_to_rgb() (於 `coloursys` 模組中), 1490
- yview() (`tkinter.ttk.Treeview` 的方法), 1592
- ## Z
- z
於字串格式化, 123
- z85decode() (於 `base64` 模組中), 1281
- z85encode() (於 `base64` 模組中), 1281
- Zen of Python (Python 之_F), 2192
- ZeroDivisionError, 112
- zfill() (`bytearray` 的方法), 76
- zfill() (`bytes` 的方法), 76
- zfill() (`str` 的方法), 60
- zip()
built-in function, 31
- ZIP_BZIP2 (於 `zipfile` 模組中), 571
- ZIP_DEFLATED (於 `zipfile` 模組中), 571
- zip_longest() (於 `itertools` 模組中), 406
- ZIP_LZMA (於 `zipfile` 模組中), 572
- ZIP_STORED (於 `zipfile` 模組中), 571
- zipapp
module, 1858
- zipapp 命令列選項
-c, 1859
--compress, 1859
-h, 1859
--help, 1859
--info, 1859
-m, 1859
--main, 1859
-o, 1859
--output, 1859
-p, 1859
--python, 1859
- zipfile
module, 571
- ZipFile (`zipfile` 中的類_F), 572
- zipfile 命令列選項
-c, 581
--create, 581

- e, 581
 - extract, 581
 - l, 581
 - list, 581
 - metadata-encoding, 581
 - t, 581
 - test, 581
- zipimport
 - module, 1987
- zipimporter (*zipimport* 中的類), 1988
- ZipImportError, 1988
- ZipInfo (*zipfile* 中的類), 571
- zlib
 - module, 553
- ZLIB_RUNTIME_VERSION (於 *zlib* 模組中), 556
- ZLIB_VERSION (於 *zlib* 模組中), 556
- zoneinfo
 - module, 240
- ZoneInfo (*zoneinfo* 中的類), 242
- ZoneInfoNotFoundError, 245
- zscore() (*statistics.NormalDist* 的方法), 394
